LEMMA 1. *Given a set $\Sigma_i \subseteq \Sigma$, a language $K \subseteq \Sigma^*$ with the natural projection operation $P_i : \Sigma^* \to \Sigma_i^*$ and corresponding inverse projection $P_i^{-1} : \Sigma_i^* \to \Sigma^*$,*

1. $P_i(\overline{K}) = \overline{P_i(K)}$.
2. $P_i^{-1}(\overline{K}) = \overline{P_i^{-1}(K)}$.

LEMMA 2. *Given a language $K \subseteq \Sigma^*$, a set of projection operations $\{P_1, \ldots, P_n\}$, and translation mappings $\{\Psi_{11}, \ldots, \Psi_{1n}\}$,*

$$\forall i \in \{1, \ldots, n\} \, (K = \Psi_{1i}(K)) \Rightarrow (\Psi_{1i}(P_1(K)) = P_i(K)) \, .$$

The next result relates the $\Psi_{ij}(\cdot)$ operator with the prefix-closure of languages.

LEMMA 3. *Given a language K and the $\Psi_{ij}(\cdot)$ operator introduced above,*

$$\Psi_{ij}(\overline{K}) = \overline{\Psi_{ij}(K)}.$$

Proof. Suppose $s \in \overline{\Psi_{ij}(K)}$. Then there exists a string t such that $st \in \Psi_{ij}(K)$.

$$\begin{aligned} &\Rightarrow \Psi_{ij}(st) \in K \\ &\Rightarrow \Psi_{ij}(s)\Psi_{ij}(t) \in K \\ &\Rightarrow \Psi_{ij}(s) \in \overline{K} \\ &\Rightarrow s \in \Psi_{ij}(\overline{K}). \end{aligned}$$

The reverse direction of this proof follows from performing the steps above in the opposite order. □

Lemma 3 can be used to show the following theorem about the symmetry of prefix-closed languages.

THEOREM 2. *Let K be symmetric with respect to $\{\Psi_{11}, \ldots, \Psi_{1n}\}$. Then, $\overline{K}$ is symmetric with respect to $\{\Psi_{11}, \ldots, \Psi_{1n}\}$.*

Proof. Because K is symmetric with respect to $\{\Psi_{11}, \ldots, \Psi_{1n}\}$, then for all $i, j \in \{1, \ldots, n\}$, $\Psi_{ij}(K) = K$. Hence, by Lemma 3, for all $i, j \in \{1, \ldots, n\}$, $\Psi_{ij}(\overline{K}) = \overline{K}$ and therefore $\overline{K}$ is symmetric with respect to $\{\Psi_{11}, \ldots, \Psi_{1n}\}$. □

Even though a language K may be symmetric with respect to $\{\Psi_{11}, \ldots, \Psi_{1n}\}$ and separable with respect to the sets of projections $\{P_1, \ldots, P_n\}$, it is possible that the sets of languages $\{P_1^{-1}(P_1(K)), \ldots, P_n^{-1}(P_n(K))\}$ are conflicting. Consider the following example.

Example 3. Consider the automaton G that is the trimmed version of $G_1 \| G_2$ from Example 1 with the states renamed for convenience. This automaton can be seen in Figure 3.

Note that $\mathcal{L}_m(G) = ((\alpha_1\alpha_2 + \alpha_2\alpha_1)\,\gamma + (\beta_1\beta_2 + \beta_2\beta_1)\,\lambda)^*$. By inspection, this language is symmetric with respect to $\{\Psi_{11}, \ldots, \Psi_{1n}\}$ and separable with respect to $\{P_1, \ldots, P_n\}$.

Now consider the G_1 and G_2 automata seen in Figure 1. Note that $P_1(\mathcal{L}(G)) = \mathcal{L}(G_1)$ and $P_2(\mathcal{L}(G)) = \mathcal{L}(G_2)$. As seen in Figure 2, the parallel composition of

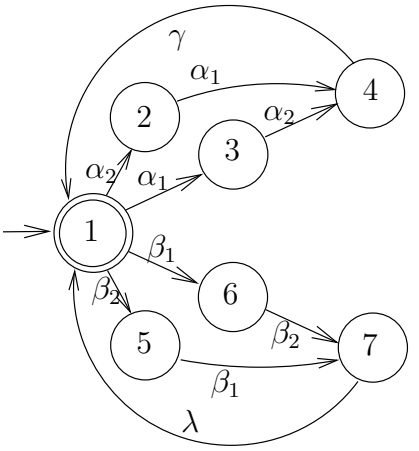

FIG. 3. *The automaton* $G = Trim(G_1 \| G_2)$.

G_1 and G_2 is blocking. Therefore $\{P_1^{-1}(P_1(\mathcal{L}_m(G_1))), \ldots, P_n^{-1}(P_n(\mathcal{L}_m(G_2)))\}$ are conflicting.

Finally, note that even though a language K may be symmetric with respect to $\{\Psi_{11}, \ldots, \Psi_{1n}\}$ and $\{P_1^{-1}(P_1(K)), \ldots, P_n^{-1}(P_n(K))\}$ are nonconflicting, it is possible that K is not separable with respect to $\{P_1, \ldots, P_n\}$. Consider the language $K = \{\epsilon, \alpha_1, \alpha_2\}$. K is symmetric with respect to the mapping induced by the event sets $\{\alpha_1\}$ and $\{\alpha_2\}$. Because

$$P_1^{-1}(P_1(K)) = \{\alpha_2^*, \alpha_2^*\alpha_1\alpha_2^*\} = \overline{P_1^{-1}(P_1(K))}$$

and

$$P_2^{-1}(P_2(K)) = \{\alpha_1^*, \alpha_1^*\alpha_2\alpha_1^*\} = \overline{P_2^{-1}(P_2(K))},$$

it holds that

$$P_1^{-1}(P_1(K)) \cap P_2^{-1}(P_2(K)) = \overline{P_1^{-1}(P_1(K))} \cap \overline{P_2^{-1}(P_2(K))} = \{\epsilon, \alpha_1, \alpha_2, \alpha_1\alpha_2, \alpha_2\alpha_1\}.$$

Consequently, $\overline{P_1^{-1}(P_1(K)) \cap P_2^{-1}(P_2(K))} = \overline{P_1^{-1}(P_1(K))} \cap \overline{P_2^{-1}(P_2(K))}$, and thus $P_1^{-1}(P_1(K))$ and $P_2^{-1}(P_2(K))$ are nonconflicting. However, $K = \{\epsilon, \alpha_1, \alpha_2\}$ is not separable with respect to $\{\{\alpha_1\}, \{\alpha_2\}\}$ because $\{\alpha_1\alpha_2, \alpha_2\alpha_1\} \subset P_1^{-1}(P_1(K)) \cap P_2^{-1}(P_2(K))$, but neither $\alpha_1\alpha_2$ nor $\alpha_2\alpha_1$ is in K.

4. Quotient automata for verification. Given a set of automata $\{G_1, \ldots, G_n\}$ such that the size of their respective state spaces is bounded by k, the composed automaton $G_1 \| \cdots \| G_n$ has k^n reachable states in the worst case. Therefore, as n grows, the size of the state space of $G_1 \| \cdots \| G_n$ can become unbearably large. This would consequently cause many verification and control procedures that require an enumeration over all of the reachable states of $G_1 \| \cdots \| G_n$, such as those discussed in [26, 28], to take an unbearable amount of time if n is large.

However, for many types of symmetric systems a quotient automaton construction can be used to greatly decrease computation time when testing if some important properties hold at various system states [4, 27]. The underlying idea behind a

quotient automaton construction is that the system states, X^n for $G_1 \| \cdots \| G_n$, are partitioned into equivalence classes $\{X_1, \ldots, X_z\} \subseteq 2^{(X^n)}$ and each state equivalence class X_j is assigned a unique representative state x'_j from a set of representative states $\{x'_1, \ldots, x'_z\}$. The set of representative states $\{x'_1, \ldots, x'_z\}$ forms the state space of the quotient automaton and the transition structure is defined such that if there is a transition between two states $x_i \in X_i$ and $x_j \in X_j$, then there is a transition between the corresponding representative states x'_i and x'_j in the quotient automaton. Depending on how the states of $G_1 \| \cdots \| G_n$ are partitioned into $\{X_1, \ldots, X_z\}$ and how the labeling of transitions in the quotient automaton are assigned, it could be necessary and sufficient for various system properties to hold in the original system if the properties hold in the quotient automaton.

In general, defining the most efficient state partition for a quotient automaton to verify important system properties such as state reachability is computationally difficult and at least as difficult as the graph isomorphism problem [10]. However, for special systems, such as the similar module systems discussed in this paper, there has been research (such as in [7, 27]) into using predefined efficient state partitionings for the construction of quotient automata constructions that are used to test important system properties in the composed system $G_1 \| \cdots \| G_n$. This predefinition of the quotient structure avoids the difficult computations associated with finding the most efficient state partitioning, but still allows for efficient state partitionings that are generally useful in practice.

This section presents a predefined state partitioning of the system states in the composed similar module system $G_1 \| \cdots \| G_n$ for the construction of a nondeterministic quotient automaton $\tilde{G}$. This partitioning uses sets of states with the same component states as the state equivalence classes used in the quotient automaton construction. The $\tilde{G}$ automaton constructed in this manner can be used to test state reachability properties in the composed similar module system $G_1 \| \cdots \| G_n$ from which it was constructed. A simple tutorial example is shown that demonstrates how the states of the composed similar module system can be partitioned into sets of "equivalent" states.

Example 4. Reconsider the system first introduced in Example 1 with a third component G_3 similar to G_1 and G_2 in Figure 1. The automaton $G_1 \| G_2 \| G_3$ can be seen in Figure 4.

State $(1, 1, 2)$ in $G_1 \| G_2 \| G_3$ is equivalent to $(2, 1, 1)$, $(1, 2, 2)$, $(2, 1, 2)$, etc., with respect to the sets of module states these composed states contain. By inspection, these states are also equivalent with respect to some important system properties such as deadlock, blocking, and reachability. However, not all of these states are reachable from the initial state in the same number of transitions.

The intuition behind Example 4 is that state orderings and duplicated component states do not matter when testing several important global properties. A quotient automaton $\tilde{G}$ for testing these properties in similar module systems is now formally introduced.

4.1. The construction of $\tilde{G}$. Define $G^{\|} = (X^{\|}, x_0^{\|}, \Sigma, \delta^{\|}, X_m^{\|}) = G_1 \| \cdots \| G_n$. A state $x^{\|} \in X^{\|}$ from the composed automaton is an n-tuple of states in X. Let $\tilde{x}$ represent the set of module states that compose the n-tuple $x^{\|}$. For example, the set $\{1, 2, 6\}$ is the set of module states that compose the states $(1, 2, 6, 2)$ and $(1, 6, 6, 2)$ in $X^{\|}$. The function $Comp : X^{\|} \to 2^X$ is defined such that $Comp(x^{\|}) = \tilde{x}$ and the function $Comp^{-1}(\tilde{x})$ returns the set of states that have exactly the states in $\tilde{x}$ in their n-tuple. As an example of the operation of the $Comp(\cdot)$ and $Comp^{-1}(\cdot)$ functions

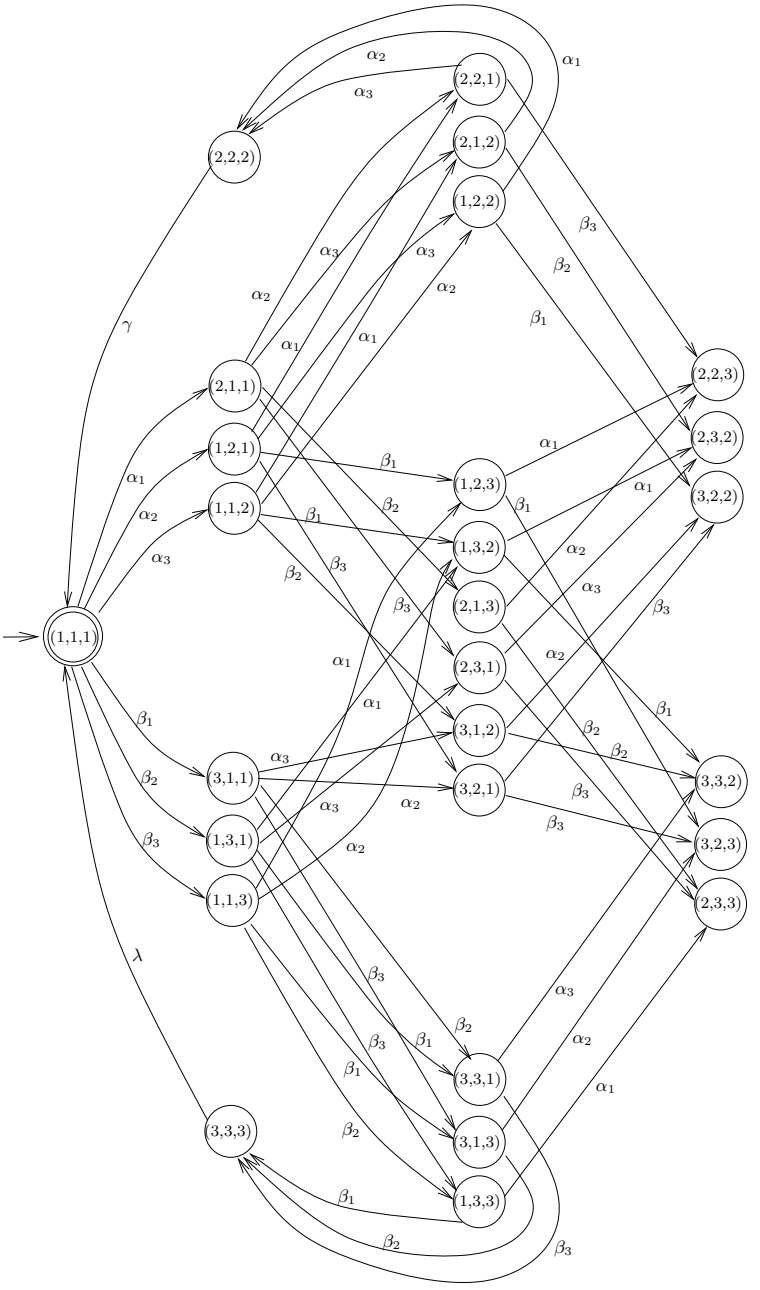

FIG. 4. *The automaton* $G_1 \| G_2 \| G_3$.

for the system in Example 4, $Comp((2,1,2)) = \{1,2\}$, $Comp((2,1,3)) = \{1,2,3\}$, $Comp^{-1}(\{1,2\}) = \{(1,2,2),(2,1,2),(2,2,1),(1,1,2),(1,2,1),(2,1,1)\}$. Note that [6, 7, 27] use state component permutation operators to define the state equivalence classes. It is discussed below that the state equivalence classes defined using the $Comp(\cdot)$ operator are generally much more efficient than those using permutation operators.

The set of state equivalence classes defined by the $Comp(\cdot)$ function is used as the state space of $\tilde{G}$. Let $\tilde{G} = (\tilde{X}, \{x_0\}, \Sigma_1, \tilde{\delta}, \tilde{X}_m)$ where $\tilde{X} = 2^X$, the power set of the component automaton G_i states, and let $\tilde{X}_m$, the set of marked states, be the states of $\tilde{G}$ such that all component states in the set are marked, i.e., $\tilde{X}_m = 2^{X_m}$. The possibly nondeterministic transition operator $\tilde{\delta}(\cdot,\cdot)$ is defined such that if there exists two states $x^{\|} \in Comp^{-1}(\tilde{x})$ and $y^{\|} \in Comp^{-1}(\tilde{y})$ and an event $\sigma_i \in \Sigma_i$ such that $\delta^{\|}(x^{\|}, \sigma_i) = y^{\|}$, then there is a corresponding transition in $\tilde{G}$ from $\tilde{x}$ to $\tilde{y}$ labeled as $\Psi_{i1}(\sigma_i)$. A formal construction algorithm for $\tilde{G}$ is now given.

ALGORITHM 1 (quotient construction algorithm).

Input:
$\{G_1, \ldots, G_n\}$ such that for all $i \in \{1, \ldots, n\}$,
$G_i = \left(X^i, x_0^i, \Sigma_i, \delta_i, X_m^i\right)$.

Output:
$\tilde{G} = (\tilde{X}, \tilde{x}_0, \Sigma, \tilde{\delta}, \tilde{X}_m)$.
(Note that $\tilde{\delta} \subseteq (\tilde{X} \times \Sigma \times \tilde{X})$).

Assumptions:
$\{G_1, \ldots, G_n\}$ is a similar module system with respect to $\{\Psi_{11}, \ldots, \Psi_{1n}\}$.
S is a stack with the normal *push* and *pop* operations.

Initialize:
$\tilde{X} := \{\{x_0\}\}$;
$\tilde{x}_0 := \{x_0\}$;
$\tilde{\delta} := \emptyset$;
$S := [\tilde{x}_0]$;
If $\tilde{x}_0 \subseteq X_m$
Then $\tilde{X}_m := \tilde{x}_0$
Else $\tilde{X}_m := \emptyset$;

Repeat:
{
$\tilde{x}_s := pop(S)$
Do the following for all $\sigma \in \Sigma$:
{
If $(\sigma \in \Sigma_g) \wedge$ (for all $x \in \tilde{x}, \delta_1(x, \sigma)!$)
Then
{
$\tilde{x}_c := \{\delta_1(x, \sigma) | x \in \tilde{x}\}$;
$\tilde{\delta} := \tilde{\delta} \cup (\tilde{x}_s, \sigma, \tilde{x}_c)$;
If $\tilde{x}_c \notin \tilde{X}$
Then
{
$\tilde{X} := \tilde{X} \cup \tilde{x}_c$;
$push(S, \tilde{x}_c)$;
If $\tilde{x}_c \subseteq X_m$
Then $\tilde{X}_m := \tilde{X}_m \cup \{\tilde{x}_c\}$
}
}
}
If $(\sigma \in \Sigma_{p1}) \wedge (|\tilde{x}| < n) \wedge (\delta_1(x, \sigma)!) \wedge (x \in \tilde{x})$
Then
{

```
                    x̃_c := x̃ ∪ {δ_1(x, σ)};
                    δ̃ := δ̃ ∪ (x̃_s, σ, x̃_c);
                    If x̃_c ∉ X̃
                        Then
                            {
                            X̃ := X̃ ∪ x̃_c;
                            push(S, x̃_c);
                           If x̃_c ⊆ X_m
                                Then X̃_m := X̃_m ∪ {x̃_c}
                            }
                }
            }
        }
        If (σ ∈ Σ_p1) ∧ (|x̃| > 1) ∧ (δ_1(x, σ)!) ∧ (x ∈ x̃)
            Then
                {
                x̃_c := [x̃ \ {x}] ∪ {δ_1(x, σ)};
                δ̃ := δ̃ ∪ (x̃_s, σ, x̃_c);
                If x̃_c ∉ X̃
                    Then
                        {
                        X̃ := X̃ ∪ x̃_c;
                        push(S, x̃_c);
                       If x̃_c ⊆ X_m
                            Then X̃_m := X̃_m ∪ {x̃_c}
                        }
                }
            }
        }
    }
Until S is empty;
Return G̃ = (X̃, x̃_0, Σ, δ̃, X̃_m).
```

Note that even if $G^{\|}$ is a deterministic automaton, the corresponding $\tilde{G}$ automaton may be nondeterministic. That is, at a state $\tilde{x} \in \tilde{X}$ there may be several outgoing transitions, each labeled by an event σ. In this case the state transition function $\tilde{\delta}$ is defined such that $\tilde{\delta} : \tilde{X} \times \Sigma_1 \to 2^{\tilde{X}}$, where for a state $\tilde{x} \in \tilde{X}$ and an event $\sigma \in \Sigma_1$, $\tilde{\delta}(\tilde{x}, \sigma) \subseteq \tilde{X}$ represents the set of states in $\tilde{G}$ that lead from $\tilde{x}$ by transitions labeled by σ. Therefore, the state transition function $\tilde{\delta}$ is defined such that

(2)
$$\tilde{\delta}(\tilde{x}, \sigma) = \begin{cases} \{\delta_1(x, \sigma) | x \in \tilde{x}\} & \text{if } (\sigma \in \Sigma_g) \wedge (\forall x \in \tilde{x}, \delta_1(x, \sigma)!) \\ \tilde{x} \cup \{\delta_1(x, \sigma)\} & \text{if } (\sigma \in \Sigma_{p1}) \wedge (|\tilde{x}| < n) \wedge (\delta_1(x, \sigma)!) \wedge (x \in \tilde{x}) \\ [\tilde{x} \setminus \{x\}] \cup \{\delta_1(x, \sigma)\} & \text{if } (\sigma \in \Sigma_{p1}) \wedge (|\tilde{x}| > 1) \wedge (\delta_1(x, \sigma)!) \wedge (x \in \tilde{x}) \end{cases}.$$

The state transition definition is also extended in the usual manner to allow for strings of transitions labeled by strings of events in Σ_1^* instead of single transitions labeled by a single event.

The intuition behind the definition of $\tilde{\delta}(\cdot, \cdot)$ is now shown in three parts for the three cases in which this transition operator is defined.

The first case of the $\tilde{\delta}(\cdot, \cdot)$ definition corresponds to the occurrence of a global

event $\sigma \in \Sigma_g$ such that all elements of $\tilde{x}$ are updated simultaneously on the occurrence of σ. All elements of $\tilde{x}$ need to be updated on the occurrence of σ because all states in $Comp^{-1}(\tilde{x})$ from $G^{\|}$ are updated on the occurrence of σ according to the transition rules of $\delta^{\|}(\cdot,\cdot)$. Therefore, $\delta_1(x,\sigma)$ is defined for all $x \in \tilde{x}$. This implies that $Comp\left(\delta^{\|}(x^{\|},\sigma)\right) \in \tilde{\delta}(\tilde{x},\sigma)$, and in this case $\{\delta_1(x,\sigma)|x \in \tilde{x}\} \in \tilde{\delta}(\tilde{x},\sigma)$ if $\sigma \in \Sigma_g$ and $\delta_1(x,\sigma)$ is defined for all $x \in \tilde{x}$.

The second case of the definition corresponds to the situation in which there exists some composed state $x^{\|} \in Comp^{-1}(\tilde{x})$ such that there exists $i,j \in \{1,\ldots,n\}$ such that $i \neq j$ and $x^{\|^i} = x^{\|^j}$. In other words, $|\tilde{x}| < n$ as required for this case in the definition of $\tilde{\delta}(\cdot,\cdot)$. Therefore, at $x^{\|}$, if an event $\sigma_{pi} \in \Sigma_{pi}$ were to occur such that $\delta_i(x^{\|^i},\sigma_{pi})!$, then the resulting state $\delta^{\|}(x^{\|},\sigma_{pi})$ would exist and

$$Comp(\delta(x^{\|},\sigma_{pi})) = Comp(x^{\|}) \cup \left\{\delta_i(x^{\|^i},\sigma_{pi})\right\}$$

as a replicated state in $x^{\|}$ would update on the occurrence of σ_{pi}. Therefore,

$$Comp(x^{\|}) \cup \left\{\delta_i(x^{\|^i},\sigma_{pi})\right\} \in \tilde{\delta}(x^{\|},\Psi_{i1}(\sigma_{pi})),$$

and for this case there is some $x \in \tilde{x}$, $\sigma \in \Sigma_{p1}$ such that $\tilde{x} \cup \{\delta_1(x,\sigma)\} \in \tilde{\delta}(\tilde{x},\sigma)$ as specified in the definition of $\tilde{\delta(\cdot,\cdot)}$.

The third case of the definition corresponds to the situation in which there exists some state $x^{\|} \in Comp^{-1}(\tilde{x})$ such that there exists $i \in \{1,\ldots,n\}$ and for any $j \in (\{1,\ldots,n\} \setminus \{i\})$, $x^{\|^i} \neq x^{\|^j}$. Thus, $|\tilde{x}| > 1$, as required for this case of the definition of $\tilde{\delta}(\cdot,\cdot)$. Therefore, at $x^{\|}$, if an event $\sigma_{pi} \in \Sigma_{pi}$ were to occur such that $\delta_i(x^{\|^i},\sigma_{pi})!$, then the resulting state $\delta(x^{\|},\sigma_{pi})$ would be in

$$\left(\left[Comp(x^{\|}) \setminus \left\{x^{\|^i}\right\}\right] \cup \left\{\delta_i(x^{\|^i},\sigma_{pi})\right\}\right) \in \tilde{\delta}(Comp(\tilde{x}),\Psi_{i1}(\sigma_{pi})),$$

and for this case there is some $x \in \tilde{x}$ and $\sigma_{pi} \in \Sigma_{pi}$ such that

$$[\tilde{x} \setminus x] \cup \{\delta_1(x,\sigma)\} \in \tilde{\delta}(\tilde{x},\sigma)$$

as specified in the definition of $\tilde{\delta(\cdot,\cdot)}$. For this case a module state that is not replicated in $x^{\|}$ is updated on the occurrence of a private event.

Also, notation is sometimes used in which for two states $\tilde{x},\tilde{y} \in \tilde{X}$ and an event $\sigma \in \Sigma_1$, $\tilde{x}\overset{\sigma}{\mapsto}_{\tilde{G}}\tilde{y}$ denotes that there is a transition in $\tilde{G}$ labeled by σ from $\tilde{x}$ to $\tilde{y}$. Similarly, for two states $x^{\|},y^{\|} \in X^{\|}$ and an event $\sigma \in \Sigma$, $x^{\|}\overset{\sigma}{\mapsto}_{G^{\|}}y^{\|}$ denotes that there is a transition in $G^{\|}$ labeled by σ from $x^{\|}$ to $y^{\|}$.

The similar module system introduced in Example 4 is now used to demonstrate the construction of a simple reduced state space composed automaton $\tilde{G}$.

Example 5. Consider the similar module system comprised of the automata G_1,G_2,G_3 discussed in Example 4 above. The set of state equivalence classes in the composed automaton $G_1\|G_2\|G_3$ with respect to the $Comp(\cdot)$ operation is

$$\{\{1\},\{2\},\{3\},\{1,2\},\{1,3\},\{2,3\},\{1,2,3\}\}.$$

The quotient automaton $\tilde{G}$ constructed from G_1,G_2,G_3 can be seen in Figure 5.

The three different cases for transitions in the definition of $\tilde{\delta}(\cdot,\cdot)$ are all exhibited in this example of $\tilde{G}$.

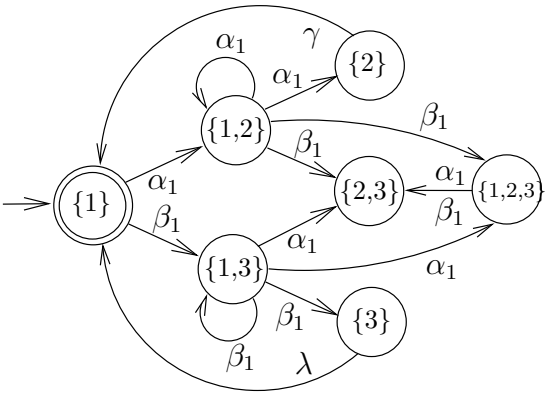

FIG. 5. *The automaton $\tilde{G}$ constructed from G_1, G_2, G_3.*

Consider the $\{2\} \overset{\gamma}{\mapsto}_{\tilde{G}} \{1\}$ transition in $\tilde{G}$. This transition is in the first case of the $\tilde{\delta}(\cdot,\cdot)$ definition and in the original $G_1 \| G_2 \| G_3$ automaton; it corresponds to the $(2,2,2) \overset{\gamma}{\mapsto}_{G_1\|G_2\|G_3} (1,1,1)$ transition. That is, a global event γ occurs and all states of $(2,2,2)$ are updated simultaneously.

Now consider the $\{1,2\} \overset{\alpha_1}{\mapsto}_{\tilde{G}} \{1,2\}$ transition in $\tilde{G}$. This transition corresponds to several transitions in the $G_1 \| G_2 \| G_3$ automaton, including the transition $(1,1,2) \overset{\alpha_2}{\mapsto}_{G_1\|G_2\|G_3} (1,2,2)$. For this transition, module state 1 is replicated and the second module state of $(1,1,2)$ is updated on the occurrence of α_2, but the first module state remains 1. The $\{1,2\} \overset{\alpha_1}{\mapsto}_{\tilde{G}} \{1,2\}$ transition is in the second case for transitions in the definition of $\tilde{\delta}(\cdot,\cdot)$.

The $\{1,2\} \overset{\alpha_1}{\mapsto}_{\tilde{G}} \{2\}$ transition corresponds to the third case in the definition of $\tilde{\delta}(\cdot,\cdot)$. In the original $G_1 \| G_2 \| G_3$ automaton, this transition corresponds to the $(2,2,1) \overset{\alpha_3}{\mapsto}_{G_1\|G_2\|G_3} (2,2,2)$ transition, among others. In this case there is only one module in state 1, and on the occurrence of α_3 this module updates to state 2 and the other modules remain unaltered.

Also notice that $\tilde{G}$ contains a transition $\{1\} \overset{\alpha_1}{\mapsto}_{\tilde{G}} \{1,2\}$. This corresponds to the second case of transitions in the definition of $\tilde{\delta}(\cdot,\cdot)$. It is true that $\{2,2,1\} \in Comp^{-1}(\{1,2\})$, but in $G_1 \| G_2 \| G_3$ there is no event σ such that there is a transition $(1,1,1) \overset{\sigma}{\mapsto}_{G_1\|G_2\|G_3} (2,2,1)$. Therefore, state reachability in $\tilde{G}$ does not exactly imply state reachability in $G_1 \| G_2 \| G_3$ for the same number of transitions. However, there is a string $\alpha_1\alpha_2$ such that $(1,1,1) \overset{\alpha_1\alpha_2}{\mapsto}_{G_1\|G_2\|G_3} (2,2,1)$. It is shown below that state reachability in $\tilde{G}$ is shown to imply a form of reachability in $G_1 \| \cdots \| G_n$ and vice versa.

4.2. Verifying system properties using $\tilde{G}$. Fundamental reachability results related to the $\tilde{G}$ and $G^{\|}$ constructions for similar module systems are now shown.

LEMMA 4. *Suppose a similar module system $\{G_1, \ldots, G_n\}$ is given that is used to construct $G^{\|}$ and $\tilde{G}$. For two states of $G^{\|}$, $x_1^{\|}, x_2^{\|} \in X^{\|}$ such that $Comp(x_1^{\|}) = \tilde{x}_1$ and $Comp(x_2^{\|}) = \tilde{x}_2$ and a string of transitions labeled by $t^{\|} \in \Sigma^*$ such that $x_1^{\|} \overset{t^{\|}}{\mapsto}_{G^{\|}} = x_2^{\|}$, there exists a string of transitions labeled by $\tilde{t} \in \Sigma_1^*$ such that, according to the transition rules of $\tilde{G}$, $\tilde{x}_1 \overset{\tilde{t}}{\mapsto}_{\tilde{G}} \tilde{x}_2$.*

Proof. This lemma is shown using a proof by generalized induction on the length of $t^{\|}$. For the base of induction, suppose $|t^{\|}| = 1$. The base of induction is shown in three cases according to the three cases in the definition of $\tilde{\delta}(\cdot,\cdot)$.

For the first case, suppose that $t^{\|} = \sigma_g \in \Sigma_g$. It is assumed that $\delta^{\|}(x_1^{\|}, \sigma_g) = x_2^{\|}$, and thus for all $i \in \{1,\ldots,n\}$, $\delta_i({x_1^{\|}}^i, \sigma_g) = {x_2^{\|}}^i$. Consequently, for all $x \in \tilde{x}_1$,

$$\exists i \in \{1,\ldots,n\} \text{ such that } \delta_1(x, \sigma_g) = {x_2^{\|}}^i \in \tilde{x}_2,$$

and for all $x \in \tilde{x}_2$,

$$\exists i \in \{1,\ldots,n\} \text{ such that } {x_1^{\|}}^i \in \tilde{x}_1 \text{ and } \delta_1({x_1^{\|}}^i, \sigma_g) = x.$$

Therefore, by the first case of the definition of $\tilde{\delta}(\cdot,\cdot)$, $\tilde{x}_1 \overset{\sigma_g}{\mapsto}_{\tilde{G}} \tilde{x}_2$.

For the second case of the base of induction, suppose that $t^{\|} = \sigma_{pi} \in \Sigma_{pi}$ and $\exists j \in \{1,\ldots,n\}$ such that $j \neq i$ and $x_i^{\|} = x_j^{\|}$. Therefore, when module G_i is in state ${x_1^{\|}}^i$, the module can update on the occurrence of σ_{pi} to state ${x_2^{\|}}^i$, and all other modules in $G^{\|}$ do not update; i.e., for all $k \neq i$, ${x_1^{\|}}^k = {x_2^{\|}}^k$. $\delta^{\|}(x_1^{\|}, \sigma_{pi}) = x_2^{\|}$, and thus $\delta_i({x_1^{\|}}^i, \sigma_{pi}) = {x_2^{\|}}^i$ and for $k \in \{1,\ldots,n\}$, $i \neq k$ ${x_1^{\|}}^k = {x_2^{\|}}^k$. Therefore, by the second case of the definition of $\tilde{\delta}(\cdot,\cdot)$, $\tilde{x}_1 \overset{\sigma_{pi}}{\mapsto}_{G^{\|}} \tilde{x}_2$.

For the third case of the base of induction, suppose that $t^{\|} = \sigma_{pi} \in \Sigma_{pi}$ and for all $j \in \{1,\ldots,n\}$ such that $j \neq i$ and $x_i^{\|} \neq x_j^{\|}$. Therefore, when module G_i is in state ${x_1^{\|}}^i$, the module can update on the occurrence of σ_{pi} to state ${x_2^{\|}}^i$, and all other modules in $G^{\|}$ do not update; i.e., for all $k \neq i$, ${x_1^{\|}}^k = {x_2^{\|}}^k$. $\delta^{\|}(x_1^{\|}, \sigma_{pi}) = x_2^{\|}$, and thus $\delta_i({x_1^{\|}}^i, \sigma_{pi}) = {x_2^{\|}}^i$ and for $k \in \{1,\ldots,n\}$, $i \neq k$ ${x_1^{\|}}^k = {x_2^{\|}}^k$. Therefore, by the second case of the definition of $\tilde{\delta}(\cdot,\cdot)$, $\tilde{x}_1 \overset{\sigma_{pi}}{\mapsto}_{G^{\|}} \tilde{x}_2$. This completes the base of induction.

For the induction hypothesis, suppose that there is a string of transitions labeled by $t^{\|} \in \Sigma^n$ such that $x_1^{\|} \overset{t^{\|}}{\mapsto}_{G^{\|}} x_2^{\|}$, $Comp(x_1^{\|}) = \tilde{x}_1$, and $Comp(x_2^{\|}) = \tilde{x}_2$. Then there exists a string of transitions labeled by $\tilde{t} \in \Sigma_1^*$ such that $\tilde{x}_1 \overset{\tilde{t}}{\mapsto}_{\tilde{G}} \tilde{x}_2$.

For the induction step, suppose there is a string of transitions labeled by $t^{\|} \in \Sigma^n$ and a transition labeled by $\sigma^{\|} \in \Sigma$ such that $x_1^{\|} \overset{t^{\|}\sigma^{\|}}{\mapsto}_{G^{\|}} x_3^{\|}$, $Comp(x_1^{\|}) = \tilde{x}_1$, and $Comp(x_3^{\|}) = \tilde{x}_3$. Because $x_1^{\|} \overset{t^{\|}\sigma^{\|}}{\mapsto}_{G^{\|}} x_3^{\|}$, there must be a state $x_2^{\|}$ such that $x_1^{\|} \overset{t^{\|}}{\mapsto}_{G^{\|}} x_2^{\|}$ and $x_2^{\|} \overset{\sigma^{\|}}{\mapsto}_{G^{\|}} x_3^{\|}$, where $Comp(x_2^{\|}) = \tilde{x_2}$. Because of the induction hypothesis, there is a string of transitions labeled by $\tilde{t} \in \Sigma_1^*$ such that $\tilde{x}_1 \overset{\tilde{t}}{\mapsto}_{\tilde{G}} \tilde{x}_2$. By the same argument as used in the proof of the base of induction above, there is a transition labeled by $\tilde{\sigma} \in \Sigma_1$ such that $\tilde{x}_2 \overset{\tilde{\sigma}}{\mapsto}_{\tilde{G}} \tilde{x}_3$. Therefore, there is a string of transitions labeled by $\tilde{t}\tilde{\sigma} \in \Sigma_1^*$ such that $\tilde{x}_1 \overset{\tilde{t}\tilde{\sigma}}{\mapsto}_{\tilde{G}} \tilde{x}_3$. ∎

LEMMA 5. *Suppose a similar module system $\{G_1,\ldots,G_n\}$ is given that is used to construct $G^{\|}$ and $\tilde{G}$ with two states of the quotient automaton $\tilde{x}_1, \tilde{x}_2 \in 2^X$, a state $x_1^{\|} \in X^{\|}$ such that $Comp(x_1^{\|}) = \tilde{x}_1$, and a string of transitions labeled by $\tilde{t} \in \Sigma_1^*$ such that $\tilde{x}_1 \overset{\tilde{t}}{\mapsto}_{\tilde{G}} \tilde{x}_2$. Then there exists a state $x_2^{\|} \in X^{\|}$ and a string of transitions labeled by $t^{\|} \in \Sigma^*$ such that $Comp(x_2^{\|}) = \tilde{x}_2$ and $x_1^{\|} \overset{t^{\|}}{\mapsto}_{G^{\|}} x_2^{\|}$.*

Proof. The $\tilde{G}$ automaton can be thought of as a partial simulation of the behavior of the corresponding $G^{\|}$ automaton. For $\tilde{x}_1 \overset{\tilde{t}}{\mapsto}_{\tilde{G}} \tilde{x}_2$, suppose that $\tilde{t}' < \tilde{t}$ and $\tilde{x}_1 \overset{\tilde{t}'}{\mapsto}_{\tilde{G}} \tilde{x}$.

If $\sigma_g \in \Sigma_g$ and $\tilde{t}'\sigma_g < \tilde{t}$, then for $x^{\|} \in Comp^{-1}(\tilde{x})$, the transition at $\tilde{x}$ labeled by σ_g corresponds to a transition in $G^{\|}$, where all component states of $x^{\|}$ update simultaneously. If $\sigma_p \in \Sigma_{p1}$ and $\tilde{t}'\sigma_p < \tilde{t}$, then for $x^{\|} \in Comp^{-1}(\tilde{x})$, the transition at $\tilde{x}$ labeled by σ_p corresponds in $G^{\|}$ to exactly one component state ${x^{\|}}^i$ of $x^{\|}$ for some $i \in \{1, \ldots, n\}$ that updates on the occurrence of an event $\sigma_{pi} = \Psi_{1i}(\sigma_p)$.

Therefore, if $\tilde{x}_1 \overset{\tilde{t}}{\mapsto}_{\tilde{G}} \tilde{x}_2$, then for every component state $x_1 \in \tilde{x}_1$, there must be a string of transitions labeled by events in Σ_1^* that leads to a component state $x_2 \in \tilde{x}_2$ according to the transition rules of G_1, and for every component state $x_2 \in \tilde{x}_2$, there must be a string of transitions labeled by events in Σ_1^* from a component state in $x_1 \in \tilde{x}_1$ to the component state x_2 according to the transition rules of G_1. All of these strings are able to occur synchronously with respect to the occurrence of global events and are copies of the string $\tilde{t}$ with some events from Σ_{p1} removed.

With this reasoning the string of events $\tilde{t} \in \Sigma_1^*$ such that $\tilde{x}_1 \overset{\tilde{t}}{\mapsto}_{\tilde{G}} \tilde{x}_2$ can be split into a set of strings $T = \{t_{x_1^1 x_2^1}, \ldots, t_{x_1^m x_2^m}\} \subseteq \Sigma_1^*$ such that

- for all $i \in \{1, \ldots, m\}$, $t_{x_1^i x_2^i}$ is a copy of $\tilde{t}$ with some Σ_{p1} events removed.
- $P_g(t_{x_1^1 x_2^1}) = \cdots = P_g(t_{x_1^m x_2^m})$.
- for every component state $x_1^i \in \tilde{x}_1$, there is at least one component state $x_2^i \in \tilde{x}_2$ and a string of events $t_{x_1^i x_2^i} \in T$ such that $\delta^1(x_1^i, t_{x_1^i x_2^i}) = x_2^i$.
- for every component state $x_2^j \in \tilde{x}_2$, there is at least one component state $x_1^j \in \tilde{x}_1$ and a string of events $t_{x_1^j x_2^j} \in T$ such that $\delta^1(x_1^i, t_{x_1^i x_2^i}) = x_2^i$.
- $m = \max\{|\tilde{x}_1|, |\tilde{x}_2|\} \leq n$.

Consider the ordered list of n strings,

$$L_t = [t_{x_1^1 x_2^1}, \ldots, t_{x_1^m x_2^m}, t_{x_1^m x_2^m}, \ldots, t_{x_1^m x_2^m}].$$

Corresponding to L_t, there are two ordered lists of pairs of states in X,

$$L_x^1 = [x_1^1, \ldots, x_1^m, x_1^m, \ldots, x_1^m],$$
$$L_x^2 = [x_2^1, \ldots, x_2^m, x_2^m, \ldots, x_2^m]$$

such that if

$$x_{1\Psi}^{\|} = (x_1^1, \ldots, x_1^m, x_1^m, \ldots, x_1^m),$$
$$x_{2\Psi}^{\|} = (x_2^1, \ldots, x_2^m, x_2^m, \ldots, x_2^m),$$

then

$$Comp(x_{1\Psi}^{\|}) = \tilde{x}_1,$$
$$Comp(x_{2\Psi}^{\|}) = \tilde{x}_2.$$

Moreover, according to the transition rules of G_1, $\delta^1(x_{k,1}, t_k) = x_{k,2}$ where $L_t(k) = t_k$ is the kth string in L_t and $L_x^1(k) = x_{k,1}$ and $L_x^2(k) = x_{k,2}$ are the kth states in L_x^1 and L_x^2, respectively. Suppose that $x_{1\Psi}^{\|} = x_1^{\|}$. It is discussed below how this assumption can be made without loss of generality.

The list of strings L_t are now converted using the $\Psi_{1i}(\cdot)$ operator to the list

$$L_t^{\Psi} = [\Psi_{11}(t_{x_1 x_2}^1), \ldots, \Psi_{1m}(t_{x_1 x_2}^m), \Psi_{1(m+1)}(t_{x_1 x_2}^m), \ldots, \Psi_{1n}(t_{x_1 x_2}^m)].$$

Because all of the strings in this converted list can still be synchronized on the occurrence of events in Σ_g, the intersection

$$\begin{aligned}\big(&P_1^{-1}(\Psi_{11}(t^1_{x_1x_2}))\cap\cdots\cap P_m^{-1}(\Psi_{1m}(t^m_{x_1x_2}))\\&\cap P_{m+1}^{-1}(\Psi_{1(m+1)}(t^m_{x_1x_2}))\cap\cdots\cap P_n^{-1}(\Psi_{1n}(t^m_{x_1x_2}))\big)\end{aligned}$$

is nonempty. Let $t^{\|}_{\Psi}$ be some string in this intersection. From the construction above for L^1_x and L^2_x, if $x^{\|}_{1\Psi}$ is the n-tuple corresponding to the list of states in L^1_x, and $x^{\|}_{2\Psi}$ is the n-tuple corresponding to the list of states in L^2_x, then $\delta^{\|}(x^{\|}_{1\Psi}, t^{\|}_{\Psi}) = x^{\|}_{2\Psi}$. Let $x^{\|}_2$ be a copy of $x^{\|}_{2\Psi}$. Therefore, there exists a state $x^{\|}_2 \in X^{\|}$ and a string of transitions labeled by $t^{\|} \in \Sigma^*$ such that $Comp(x^{\|}_2) = \tilde{x}_2$ and $x^{\|}_1 \overset{t^{\|}}{\mapsto}_{G^{\|}} x^{\|}_2$.

Notice that the lists L_t, L^1_x, and L^2_x could be constructed in an alternative manner by replicating the appropriate elements of these lists in the proper locations to force $x^{\|}_{1\Psi}$ to be a copy of any arbitrary $x^{\|}_1$. □

An example is now given to aid in the visualization of the constructions used in the proof of Lemma 5.

Example 6. It is now shown how to construct lists L_t, L^1_x, L^2_x and the states $x^{\|}_{1\Psi}$, $x^{\|}_{1\Psi}$ in Lemma 5 from given $\tilde{x}_1$, $\tilde{x}_2$, $x^{\|}_1$, and $\tilde{t}$ using the $\tilde{G}$ automaton in Example 4. Suppose $\tilde{x}_1 = \{1,2\}$, $\tilde{x}_2 = \{2,3\}$, $\tilde{t} = \alpha_1\gamma\beta_1\beta_1\alpha_1$, and $x^{\|}_1 = (1,1,2)$.

From $x^{\|}_1 = (1,1,2)$, L^1_x is set to be $[1,1,2]$. Let $L_t = [\alpha_1\gamma\alpha_1, \alpha_1\gamma\beta_1, \gamma\beta_1]$ and let $L^2_x = [2,3,3]$. Therefore, $x^{\|}_{1\Psi} = (1,1,2)$ and $x^{\|}_{1\Psi} = (2,3,3)$. The proper L_t and L^2_x can be found mechanically by a search over all possible candidate strings, which is guaranteed to be finite.

Note that

$$\begin{aligned}\delta_1(1,\alpha_1\gamma\alpha_1) &= 2,\\ \delta_1(1,\alpha_1\gamma\beta_1) &= 3,\\ \delta_1(2,\gamma\beta_1) &= 3.\end{aligned}$$

Also note that $L^{\Psi}_t = [\alpha_1\gamma\alpha_1, \alpha_2\gamma\beta_2, \gamma\beta_3]$ and that it is possible for the string $t^{\|}$ corresponding to $\tilde{t}$ to be $\alpha_1\alpha_2\gamma\alpha_1\beta_2\beta_3$. Therefore, $\delta^{\|}((1,1,2), \alpha_1\alpha_2\gamma\alpha_1\beta_2\beta_3) = (2,3,3)$.

The dual of Lemma 5 is now shown, where $x^{\|}_2$ is specified instead of $x^{\|}_1$.

LEMMA 6. *Suppose a similar module system $\{G_1,\ldots,G_n\}$ is given that is used to construct $G^{\|}$ and $\tilde{G}$ with two states of the quotient automaton $\tilde{x}_1, \tilde{x}_2 \in 2^X$, a state $x^{\|}_2 \in X^{\|}$ such that $Comp(x^{\|}_2) = \tilde{x}_2$, and a string of transitions labeled by $\tilde{t} \in \Sigma^*$ such that $\tilde{x}_1 \overset{\tilde{t}}{\mapsto}_{\tilde{G}} \tilde{x}_2$. Then there exists a state $x^{\|}_1 \in X^{\|}$ and string of transitions labeled by $t^{\|} \in \Sigma^*_1$ such that $Comp(x^{\|}_1) = \tilde{x}_1$ and $x^{\|}_1 \overset{t^{\|}}{\mapsto}_{G^{\|}} x^{\|}_2$.*

Proof. This proof follows from the same construction as in Lemma 5 except that the lists L_t, L^1_x, and L^2_x could be constructed to correspond to any state $x^{\|}_2$ such that $x^{\|}_2 \in Comp^{-1}(\tilde{x}_2)$ and $x^{\|}_2$ is the n-tuple corresponding to the list of states in L^2_x. □

THEOREM 3. *Suppose a similar module system $\{G_1,\ldots,G_n\}$ is given that is used to construct $G^{\|}$ and $\tilde{G}$. A state $x^{\|} \in X^{\|}$ deadlocks according to the transition rules of $G^{\|}$ if and only if the state $Comp(x^{\|}) = \tilde{x}$ deadlocks according to the transition rules of $\tilde{G}$.*

Proof. The proof of this theorem is demonstrated in two parts. First, it is shown

that if $x^{\|} \in X^{\|}$ deadlocks according to the transition rules of $G^{\|}$, then the state $Comp(x^{\|}) = \tilde{x}$ deadlocks according to the transition rules of $\tilde{G}$.

If $x^{\|} \in X^{\|}$ deadlocks according to the transition rules of $G^{\|}$, then there is no global event $\sigma_g \in \Sigma_g$ that could synchronize a state transition in all component states of $x^{\|}$. Due to the first case of the state transition function $\tilde{\delta}(\cdot,\cdot)$, there is therefore no global event $\sigma_g \in \Sigma_g$ that could synchronize a state transition in all component states of $\tilde{x}$. Also, there are no private events $\sigma_{pi} \in \Sigma_{pi}$ that could occur at any of the component states of $x^{\|}$. There can therefore be no events $\sigma_{p1} \in \Sigma_{p1}$ that could occur at any of the states of $\tilde{x}$ according to the transition rules of G_1. Consequently, there are no transitions driven by an event $\sigma_{p1} \in \Sigma_{p1}$ that could occur at the state $\tilde{x}$ according to the second and third cases of the transition rules of $\tilde{G}$. Therefore, the state $Comp(x^{\|}) = \tilde{x}$ deadlocks according to the transition rules of $\tilde{G}$.

Now it is shown that if $x^{\|} \in X^{\|}$ does not deadlock according to the transition rules of $G^{\|}$, then the state $Comp(x^{\|}) = \tilde{x}$ does not deadlock according to the transition rules of $\tilde{G}$. If $x^{\|} \in X^{\|}$ does not deadlock according to the transition rules of $G^{\|}$, then there is a state $y^{\|} \in X^{\|}$ and an event $\sigma \in \Sigma$ for a transition in $G^{\|}$ such that $x^{\|} \overset{\sigma}{\mapsto}_{G^{\|}} = y^{\|}$. Therefore, by Lemma 4, there exists a string of transitions labeled by $\tilde{t} \in \Sigma_1^*$ such that according to the transition rules of $\tilde{G}$, $Comp(x^{\|}) \overset{\tilde{t}}{\mapsto}_{\tilde{G}} Comp(y^{\|})$. Therefore, the state $Comp(x^{\|}) = \tilde{x}$ does not deadlock according to the transition rules of $\tilde{G}$. □

THEOREM 4. *Suppose a similar module system $\{G_1, \ldots, G_n\}$ is given that is used to construct $G^{\|}$ and $\tilde{G}$. A state $x^{\|} \in X^{\|}$ is reachable according to the transition rules of $G^{\|}$ if and only if the state $Comp(x^{\|}) = \tilde{x}$ is reachable according to the transition rules of $\tilde{G}$.*

Proof. This theorem is demonstrated in two parts. For the first part of this proof, suppose that a state $x^{\|} \in X^{\|}$ is reachable according to the transition rules of $G^{\|}$. Therefore, there is a string of transitions labeled by $t^{\|}$ such that $x_0^{\|} \overset{t^{\|}}{\mapsto}_{G^{\|}} x^{\|}$. Because of Lemma 4, there is a string of transitions labeled by $\tilde{t}$ such that $\tilde{x}_0 \overset{\tilde{t}}{\mapsto}_{\tilde{G}} \tilde{x}$, where $Comp(x^{\|}) = \tilde{x}$.

For the second part of this proof, suppose that a state $\tilde{x} \in \tilde{X}$ is reachable according to the transition rules of $\tilde{G}$. Therefore, there is a string of transitions labeled by $\tilde{t}$ such that $\tilde{x}_0 \overset{\tilde{t}}{\mapsto}_{\tilde{G}} \tilde{x}$. Using Lemma 6 there is a string of transitions labeled by $t^{\|}$ such that for some $x_0^{\|'} \in Comp^{-1}(\tilde{x}_0)$, $x_0^{\|'} \overset{t^{\|}}{\mapsto}_{G^{\|}} x^{\|}$. Because $Comp^{-1}(\tilde{x}_0) = \{x_0^{\|}\}$, there is a string of transitions labeled by $t^{\|}$ such that $x_0^{\|} \overset{t^{\|}}{\mapsto}_{G^{\|}} x^{\|}$, where $Comp(x^{\|}) = \tilde{x}$. □

THEOREM 5. *Suppose a similar module system $\{G_1, \ldots, G_n\}$ is given that is used to construct $G^{\|}$ and $\tilde{G}$. A state $x^{\|} \in X^{\|}$ is blocking according to the transition rules of $G^{\|}$ if and only if the state $Comp(x^{\|}) = \tilde{x}$ is blocking according to the transition rules of $\tilde{G}$.*

Proof. Suppose that the state $x^{\|} \in X^{\|}$ is nonblocking according to the transition rules of $G^{\|}$. Therefore, there is a state $x_m^{\|} \in X_m^{\|}$ and a string of transitions labeled by $t^{\|}$ such that $x^{\|} \overset{t^{\|}}{\mapsto}_{G^{\|}} x_m^{\|}$. Because of Lemma 4, there is a string of transitions labeled by $\tilde{t}$ such that $\tilde{x} \overset{\tilde{t}}{\mapsto}_{\tilde{G}} \tilde{x}_m$, where $Comp(x_m^{\|}) = \tilde{x}_m$. Because $Comp(x_m^{\|}) = \tilde{x}_m$, $\tilde{x}_m$ must be marked.

Suppose that the state $\tilde{x} \in \tilde{X}$ is nonblocking according to the transition rules of $\tilde{G}$. Therefore, there is a state $\tilde{x}_m \in \tilde{X}_m$ and a string of transitions labeled by $\tilde{t}$ such that $\tilde{x} \overset{\tilde{t}}{\mapsto}_{\tilde{G}} \tilde{x}_m$. By Lemma 5 there is a string of transitions labeled by $t^{\|}$ and a state

$x_2^{\|}$ such that $x^{\|} \overset{t^{\|}}{\mapsto}_{G^{\|}} x_2^{\|}$ and $Comp(x_2^{\|}) = \tilde{x}_m$. Because $Comp(x_2^{\|}) = \tilde{x}_m$, and $\tilde{x}_m$ is marked, then $x_2^{\|}$ must also be marked. Therefore, $x^{\|}$ is nonblocking. □

4.3. The size of the state space of $\tilde{G}$. It should be apparent that the $\tilde{G}$ constructed from the similar module system $\{G_1, \ldots, G_n\}$ has a smaller state space than the $G^{\|}$ automaton constructed from the same set of modules. The worst-case size of the $\tilde{G}$ automaton state space is now quantified. Suppose that $k = |X|$, the size of the state space of the individual modules. Consider the following example that shows how the $\tilde{G}$ construction can have a bounded number of states even if the number of modules is unbounded.

Example 7. Consider the similar module system G_1, G_2 as in Example 1 and the corresponding $\tilde{G}_2$ constructed from these automata, which can be seen in Figure 6. The automata G_1, G_2 use $X = \{1, 2, 3\}$ as their state space and $\tilde{G}_2$ uses $\{\{1\}, \{2\}, \{3\}, \{1, 2\}, \{1, 3\}, \{2, 3\}\}$ as its state space.

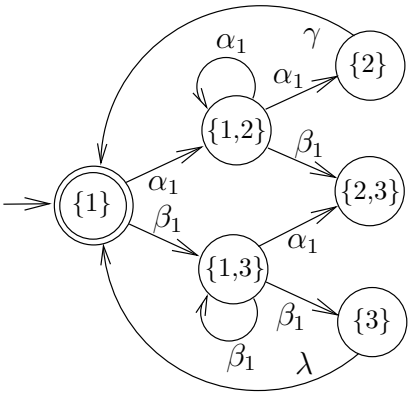

FIG. 6. *The automaton $\tilde{G}_2$ constructed from G_1, G_2.*

Now consider the set of similar modules, except with three components G_1, G_2, G_3 and a corresponding $\tilde{G}$ automaton, as discussed in Example 5. The automaton $\tilde{G}$ can be seen in Figure 5. The automata G_1, G_2, G_3 use $X = \{1, 2, 3\}$ as their state space and $\tilde{G}$ for this set of modules uses $2^X = \{\{1\}, \{2\}, \{3\}, \{1, 2\}, \{1, 3\}, \{2, 3\}, \{1, 2, 3\}\}$ as its state space. Note that the largest cardinality subset of X is $\{1, 2, 3\}$.

Again consider the same set of similar modules, except with four components G_1, G_2, G_3, G_4 and the corresponding quotient automaton $\tilde{G}_4$, which can be seen in Figure 7. The automata G_1, G_2, G_3, G_4 use $X = \{1, 2, 3\}$ as their state space and $\tilde{G}_4$ uses

$$2^X = \{\{1\}, \{2\}, \{3\}, \{1, 2\}, \{1, 3\}, \{2, 3\}, \{1, 2, 3\}\}$$

as its state space. The only difference between the $\tilde{G}_4$ automaton and the $\tilde{G}$ automaton for the three module system seen in Figure 5 is that there are added self-loop transitions at state $\{1, 2, 3\}$ labeled by α_1 and β_1 events.

Now consider the same set of n similar modules $\{G_1, \ldots, G_n\}$ with $n \geq 4$. The automaton $\tilde{G}_n$ constructed from this set of modules still uses

$$2^X = \{\{1\}, \{2\}, \{3\}, \{1, 2\}, \{1, 3\}, \{2, 3\}, \{1, 2, 3\}\}$$

as its state space and is structurally equivalent to the $\tilde{G}_4$ automaton. That is, all defined transitions in $\tilde{G}_n$ are also defined in $\tilde{G}_n$. Therefore, the $\tilde{G}_n$ construction is

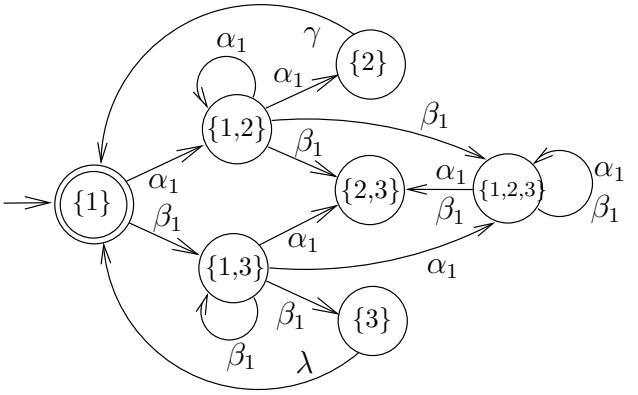

FIG. 7. *The automaton $\tilde{G}_4$ constructed from G_1, G_2, G_3, G_4.*

equivalent to the $\tilde{G}_4$ construction no matter how many modules are used as long as $n \geq 4$. Furthermore, the size of the state space of $\tilde{G}_n$ does not change for $n \geq 3$. This is due to the fact that $|X| = 3$, and for $n \geq 3$, $\tilde{X} = 2^X$.

Given an n-module system, each state of $\tilde{G}$ can have at most n component states, and in each state of $\tilde{G}$ no component states are repeated. Therefore, the maximum number of component states in $\tilde{G}$ is $\max(n, k)$. Consequently, the worst-case size of $\tilde{X}$ needs to be analyzed in two cases, $n \geq k$ and $n < k$.

Case 1: $n < k$. Each of the states of $\tilde{G}$ has at most n component states. There are possibly $\binom{k}{i}$ states with i component states. Therefore, if the sum of the possible number of state sets for each number of components is taken from i to n, then the number of possible state sets for $\tilde{G}$ for $n < k$ is

$$\sum_{i=1}^{n} \binom{k}{i}. \tag{3}$$

Note that for $n < k$, the number of possible state sets for $\tilde{G}$ is bounded by $2^k - 1$.

Case 2: $n \geq k$. For this case, any state set in the power set 2^X is a possible state of $\tilde{G}$, except for the empty set $\emptyset$. Therefore, the size of the state space of $\tilde{G}$ is at most

$$|2^X \setminus \{\emptyset\}| = 2^k - 1. \tag{4}$$

This means that if $n \geq k$, then the size of $\tilde{G}$ is independent of the number of modules, and testing state reachability, blocking, and deadlock-freeness can be done without regard to the number of components.

Therefore, if $\tilde{X}_{\tilde{G}}$ is the set of reachable states in $\tilde{G}$, then

$$|\tilde{X}_{\tilde{G}}| \leq \left\{ \begin{array}{ll} \sum_{i=1}^{n} \binom{k}{i} & \text{if } n < k \\ 2^k - 1 & \text{if } n \geq k \end{array} \right\}. \tag{5}$$

Furthermore, no matter how many modules comprise a similar module system, $|\tilde{X}_{\tilde{G}}| \leq 2^k - 1$. This is much less than the worst-case number of reachable states in $G^{\|}$, k^n. Therefore, the verification of such important system properties as state reachability and blocking can be performed with a large reduction in the number of composed states that need to be searched. Furthermore, using the $\tilde{G}$ construction,

the difficulty of verifying these properties is independent of the number of modules if the number of modules is sufficiently large. This construction shows more of the computational advantages gained when investigating modular systems with symmetry between components. Other quotient automaton constructions shown in [6, 7, 27], which use permutation operators to define the state equivalence classes, have a worst-case size of $\left(\frac{(k+n-1)!}{(k-1)!n!}\right)$ for testing state reachability properties, and the size of this automaton grows as the number of modules grows. Note that with some mathematical manipulation it can be shown that

$$\left\{\begin{array}{ll} \sum_{i=1}^{n}\binom{k}{i} & \text{if } n < k \\ 2^k - 1 & \text{if } n \geq k \end{array}\right\} \leq \left(\frac{(k+n-1)!}{(k-1)!n!}\right). \tag{6}$$

Therefore, $|\tilde{X}_{\tilde{G}}| \leq \left(\frac{(k+n-1)!}{(k-1)!n!}\right)$.

5. Verification for local specifications. Now topics related to the verification of similar module systems with respect to local specifications are discussed. First, the class of behavior language specifications used is defined.

DEFINITION 5. *A set of languages $\{K_1, \ldots, K_n\}$ is called a set of similar languages if for all $i \in \{1, \ldots, n\}$, $K_i \subseteq \Sigma_i^*$ and $\Psi_{1i}(K_1) = K_i$.*

Suppose it needs to be checked if for all i that $P_i\left(\mathcal{L}_m(G_1 \| \cdots \| G_n)\right) = K_i$. This property can be checked solely by verifying that $\mathcal{L}_m(G_i) = K_i$ for similar module systems. The following corollary is a direct extension of Theorem 1.

COROLLARY 1. *Given a local language specification K_i and a similar module system $\{G_1, \ldots, G_n\}$, $P_i\left(\mathcal{L}_m(G_1 \| \cdots \| G_n)\right) = K_i$ if and only if $\mathcal{L}_m(G_i) = K_i$. Likewise, $P_i\left(\mathcal{L}(G_1 \| \cdots \| G_n)\right) = \overline{K_i}$ if and only if $\mathcal{L}(G_i) = \overline{K_i}$.*

The problems of verifying whether $\mathcal{L}_m(G_i) = K_i$ and $\mathcal{L}(G_i) = \overline{K_i}$ are both known to be computationally simple if K_i is specified by a deterministic automaton and G_i is likewise deterministic. This greatly simplifies previously known verification methods based on more general modular systems because local behavior in a composed similar module system can be tested by investigating a single module.

6. Decomposition properties. This section presents one of the main results of this paper: a polynomial time decomposition method for composed similar module systems that runs in polynomial time. Sufficient conditions are first shown such that if a language K is separable, then $\overline{K}$ is also separable.

LEMMA 7. *Given a language K and a set of projections $\{P_1, \ldots, P_n\}$, if K is separable with respect to $\{P_1, \ldots, P_n\}$ and the set of languages*

$$\{P_1^{-1}(P_1(K)), \ldots, P_n^{-1}(P_n(K))\}$$

is nonconflicting, then $\overline{K}$ is separable with respect to $\{P_1, \ldots, P_n\}$.

Proof. Using Lemma 1, it is known that

$$\forall i \in \{1, \ldots, n\}, P_i^{-1}(P_i(\overline{K})) = \overline{P_i^{-1}(P_i(K))}.$$

Consequently,

$$\cap_{i=1}^{n} \overline{P_i^{-1}(P_i(K))} = \cap_{i=1}^{n} P_i^{-1}(P_i(\overline{K})).$$

Due to the assumption that the languages $\{P_1^{-1}(P_1(K)), \ldots, P_n^{-1}(P_n(K))\}$ are nonconflicting,

$$\overline{\cap_{i=1}^{n} P_i^{-1}(P_i(K))} = \cap_{i=1}^{n} P_i^{-1}(P_i(\overline{K})).$$

Therefore, due to the separability of K,

$$K = \cap_{i=1}^{n} P_i^{-1}(P_i(K))$$

and

$$\overline{K} = \cap_{i=1}^{n} P_i^{-1}(P_i(\overline{K})). \qquad \square$$

It is now demonstrated how symmetric and separable languages can be modeled using the similar module system framework.

THEOREM 6. *Suppose that a set of global events Σ_g is given with private events $\{\Sigma_{p1}, \ldots, \Sigma_{pn}\}$ that can be mapped to one another using $\Psi_{ij}(\cdot)$ operations. If an automaton $H = (X, x_0, \Sigma, \delta, X_m)$ is given that is trim and the language marked by the automaton $\mathcal{L}_m(H)$ is symmetric with respect to $\{\Psi_{11}, \ldots, \Psi_{1n}\}$ and separable with respect to $\{P_1, \ldots, P_n\}$, then there exists a similar module system $\{H_1, \ldots, H_n\}$ such that*

$$\mathcal{L}_m(H_1 \| \cdots \| H_n) = \mathcal{L}_m(H)$$

and

$$\forall i \in \{1, \ldots, n\},\ P_i(\mathcal{L}_m(H)) = \mathcal{L}_m(H_i).$$

Proof. Using standard methods, given Σ_i and H, an automaton H_i can be constructed such that $\mathcal{L}_m(H_i) = P_i(\mathcal{L}_m(H))$ for all i such that $i \in \{1, \ldots, n\}$. Because $\mathcal{L}_m(H)$ is symmetric with respect to $\{\Psi_{11}, \ldots, \Psi_{1n}\}$,

$\forall i, j \in \{1, \ldots, n\}\ \Psi_{ij}(\mathcal{L}_m(H)) = \mathcal{L}_m(H)$,

$\Rightarrow \Psi_{ij}(P_i(\mathcal{L}_m(H))) = P_j(\mathcal{L}_m(H))$.

$\Rightarrow \Psi_{ij}(\mathcal{L}_m(H_i)) = \mathcal{L}_m(H_j)$.

Therefore, the automata $\{H_1, \ldots, H_n\}$ can be constructed such that they are copies of one another with respect to a renaming of their private events.

Because $\mathcal{L}_m(H)$ is separable with respect to $\{P_1, \ldots, P_n\}$,

$P_1^{-1}(P_1(\mathcal{L}_m(H))) \cap \cdots \cap P_n^{-1}(P_n(\mathcal{L}_m(H))) = \mathcal{L}_m(H)$

$\Rightarrow P_1^{-1}(\mathcal{L}_m(H_1)) \cap \cdots \cap P_n^{-1}(\mathcal{L}_m(H_n)) = \mathcal{L}_m(H)$

$\Rightarrow \mathcal{L}_m(H_1 \| \cdots \| H_n) = \mathcal{L}_m(H)$ due to properties of the parallel composition operation.

$\Rightarrow \forall i \in \{1, \ldots, n\} P_i(\mathcal{L}_m(H_1 \| \cdots \| H_n)) = P_i(\mathcal{L}_m(H))$

$\Rightarrow \forall i \in \{1, \ldots, n\} \mathcal{L}_m(H_i) = P_i(\mathcal{L}_m(H))$.

This last step is by the result of Theorem 1 shown above. $\square$

In the proof of Theorem 6 any method can be used to construct the similar module system $\{H_1, \ldots, H_n\}$ from H such that $\mathcal{L}_m(H_1 \| \cdots \| H_n) = \mathcal{L}_m(H)$. Note that there might not even be a unique set of automata $\{H_1, \ldots, H_n\}$ such that $\mathcal{L}_m(H_1 \| \cdots \| H_n) = \mathcal{L}_m(H)$. However, the standard method of computing a set of automata $\{H_1, \ldots, H_n\}$ such that $\mathcal{L}_m(H_1 \| \cdots \| H_n) = \mathcal{L}_m(H)$ consists of converting all transitions labeled by events in $\Sigma \setminus \Sigma_1$ in H to nondeterministic ϵ-transitions. Then, this nondeterministic automaton is converted into a deterministic automaton H_1. Unfortunately, the determinization algorithm takes time and space exponential in the size of H in the worst case. The other automata $\{H_2, \ldots, H_n\}$ are copies of H_1 with respect to $\Psi_{1i}(\cdot)$ event translations.

There has been little discussion in the discrete-event systems literature on ways of more efficiently performing modular decompositions besides ad hoc methods developed on a case-by-case basis. Developing formal methods for performing this operation

is very important for many real-world problems in which a large complicated system model would need to be converted into simpler, modular model blocks. This section presents a computationally efficient algorithm for performing this decomposition on similar module systems. As an example of a situation in which such a decomposition algorithm would be useful, it can be at times difficult to model the behavior of a biological cell without observing its interactions with other biological cells. Notice that at the proper level of abstraction, a biological cellular network can be thought of as a similar module system. Therefore, if a discrete-event system model of a biological cellular network is developed from observations of the behaviors of the cellular network, then the decomposition algorithm would provide an efficient method to develop a model for a cell that comprises the cellular network.

Before the decomposition method is presented, an intuitive introduction to the algorithm's operation is now given. Let $\{H_1, \ldots, H_n\}$ be the desired modules that compose the given symmetric and separable H, i.e., $\mathcal{L}_m(H) = \mathcal{L}_m(H_1 \| \cdots \| H_n)$. Suppose distributed simulations of the composed behavior of $\{H_1, \ldots, H_n\}$ are run such that the only way for private events to occur would be in strings such as $\sigma_{p1}\Psi_{12}(\sigma_{p1}) \cdots \Psi_{1n}(\sigma_{pn}) = \sigma_{p1}\sigma_{p2} \cdots \sigma_{pn}$ with no interleavings of other events. On the occurrence of these $\sigma_{p1}\sigma_{p2} \cdots \sigma_{pn}$ strings the local states $\{H_1, \ldots, H_n\}$ are forced to update with identical state transitions. Because $\mathcal{L}_m(H) = \mathcal{L}_m(H_1 \| \ldots \| H_n)$, this lockstep simulation of private behaviors in the global system model can be used to calculate the local system behaviors. Given H, this automaton can be trimmed in a special manner by allowing only global events and strings of private events $\sigma_{p1}\sigma_{p2} \cdots \sigma_{pn}$, as outlined above, to occur. The behavior of this specially trimmed automaton matches the behavior of the lockstep simulation of the $\{H_1, \ldots, H_n\}$ automata. Then, if the event σ_{p1} is substituted for every occurrence of a string $\sigma_{p1}\sigma_{p2} \cdots \sigma_{pn}$, the behavior of the resulting automaton will match the behavior of the H_1 module.

In the following algorithm, a slightly modified set notation for the state transition function is used; i.e., if $\delta(x, s) = y$ for state transition function $\delta(\cdot, \cdot)$, states x, y, and string s, then the notation that $(x, s, y) \in \delta$ is used. For simplicity it is assumed that the inputted automaton H is deterministic and trim.

ALGORITHM 2 (decomposition construction algorithm).

Input:
$H = \left(X^H, x_0^H, \Sigma, \delta^H, X_m^H\right)$
$\Sigma_1, \ldots, \Sigma_n$
(Note that $\delta^H \subseteq (X^H \times \Sigma \times X^H)$).

Output:
$\{H_1, \ldots, H_n\}$ such that for all $i \in \{1, \ldots, n\}$,
$H_i = \left(X^i, x_0^i, \Sigma_i, \delta_i, X_m^i\right)$.
(Note that $\delta_i \subseteq (X^i \times \Sigma_i \times X^i)$).

Assumptions:
H is trim.
S is a stack with the normal *push* and *pop* operations.

Initialize:
$X := \{x_0^H\}$;
$x_0 := x_0^H$;
$\delta^1 := \emptyset$;
$S := [x_0]$;

Repeat:
{
$x_s = pop(S)$

Do the following for all $x_b \in X^H$:
{
Do the following for all $\sigma_g \in \Sigma_g$ with $(x_s, \sigma_g, x_b) \in \delta^H$:
{
$\delta^1 := \delta^1 \cup \{(x_s, \sigma_g, x_b)\}$;
If $x_b \notin X$
Then
{
$X := X \cup \{x_b\}$;
$push(S, x_b)$;
}
}
Do the following for all $\sigma_{p1} \in \Sigma_{p1}, \ldots, \sigma_{pn} \in \Sigma_{pn}$
such that $\sigma_{pi} = \Psi_{1i}(\sigma_{p1})$, $(x_s, \sigma_{p1}\sigma_{p2}\cdots\sigma_{pn}, x_b) \in \delta^H$:
{
$\delta^1 := \delta^1 \cup \{(x_s, \sigma_{p1}, x_b)\}$;
If $x_b \notin X$
Then
{
$X := X \cup \{x_b\}$;
$push(S, x_b)$;
}
}
}
}
Until S is empty;
$X_m = X_m^H \cap X$;
Construct $\{H_2, \ldots, H_n\}$ from H_1 using $\Psi_{1i}(\cdot)$ operations;
Return $\{H_1, \ldots, H_n\}$.

For Algorithm 2 it may be known that there exists a set of automaton $\{H_1', \ldots, H_n'\}$ such that $\mathcal{L}_m(H) = \mathcal{L}_m(H_1' \| \cdots \| H_n')$. However, the automata $\{H_1', \ldots, H_n'\}$ might not be known explicitly, and thus Algorithm 2 gives a polynomial time method to compute a similar module system $\{H_1, \ldots, H_n\}$ such that $\mathcal{L}_m(H) = \mathcal{L}_m(H_1 \| \cdots \| H_n)$ and for all $i \in \{1, \ldots, n\}$, $P_i(\mathcal{L}_m(H)) = \mathcal{L}_m(H_i)$. The correctness of the decomposition algorithm is demonstrated in the following theorem.

THEOREM 7. *Suppose there is a trim automaton H and there exists a set of similar module automata $\{H_1', \ldots, H_n'\}$ such that $\mathcal{L}_m(H) = \mathcal{L}_m(H_1' \| \cdots \| H_n')$. Then, if Algorithm 2 is run with H as input, a similar module system $\{H_1, \ldots, H_n\}$ is returned such that*

$$\mathcal{L}_m(H) = \mathcal{L}_m(H_1 \| \cdots \| H_n)$$

and

$$\forall i \in \{1, \ldots, n\},\ P_i(\mathcal{L}_m(H)) = \mathcal{L}_m(H_i).$$

Proof. From H, a specially trimmed version of H called H^{lock} can be constructed by trimming all private event transitions in H except those that correspond to occurrences of chains of private events

$$\sigma_{p1}\Psi_{12}(\sigma_{p1})\cdots\Psi_{1n}(\sigma_{p1})$$

for $\sigma_{p1} \in \Sigma_{p1}$, and no other events are allowed to be interleaved in these strings.

Therefore,

$$\mathcal{L}_m(H^{lock}) = \mathcal{L}_m(H) \cap (\{\sigma_{p1}\Psi_{12}(\sigma_{p1}) \cdots \Psi_{1n}(\sigma_{p1}) | \sigma_{p1} \in \Sigma_{p1}\} \cup \Sigma_g)^* .$$

Now consider the composition of the $\{H'_1, \ldots, H'_n\}$ automata, where global events are allowed to occur freely and private events are restricted to occur only in strings $\sigma_{p1}\Psi_{12}(\sigma_{p1}) \cdots \Psi_{1n}(\sigma_{p1})$ for $\sigma_{p1} \in \Sigma_{p1}$ with no other events interleaved, as above. This automaton marks the same language as H^{lock} shown above because $\mathcal{L}_m(H) = \mathcal{L}_m(H'_1 \| \cdots \| H'_n)$. Furthermore, due the construction of H^{lock}, it should be apparent that

$$P_i\left(\mathcal{L}_m(H^{lock})\right) = \mathcal{L}_m(H'_i)$$

because the marking behavior of H_i can be reclaimed from H^{lock} by replacing the $\sigma_{p1}\Psi_{12}(\sigma_{p1}) \cdots \Psi_{1n}(\sigma_{p1})$ transitions with a single σ_{p1} transition. Therefore,

$$P_i\left[\mathcal{L}_m(H) \cap (\{\sigma_{p1}\Psi_{12}(\sigma_{p1}) \cdots \Psi_{1n}(\sigma_{p1}) | \sigma_{p1} \in \Sigma_{p1}\} \cup \Sigma_g)^*\right] = \mathcal{L}_m(H'_i).$$

Algorithm 2 constructs H_1 by restricting the behavior of private events in H to strings such as $\sigma_{p1}\Psi_{12}(\sigma_{p1}) \cdots \Psi_{1n}(\sigma_{p1})$ and then converts these transition strings into σ_{p1} events. Therefore,

$$\mathcal{L}_m(H_1) = P_i\left[\mathcal{L}_m(H) \cap (\{\sigma_{p1}\Psi_{12}(\sigma_{p1}) \cdots \Psi_{1n}(\sigma_{p1}) | \sigma_{p1} \in \Sigma_{p1}\} \cup \Sigma_g)^*\right].$$

Consequently, $\mathcal{L}_m(H'_1) = \mathcal{L}_m(H_1)$. For all $i \in \{1, \ldots, n\}$, the automata H'_i and H_i are copies of the H'_1 and H_1 automata with respect to a renaming of transition labels by the $\Psi_{1i}(\cdot)$ functions. This implies that

$$\bigcap_{i \in \{1,\ldots,n\}} \mathcal{L}_m(H'_i) = \bigcap_{i \in \{1,\ldots,n\}} \mathcal{L}_m(H_i).$$

Therefore,

$$\mathcal{L}_m(H'_1 \| \cdots \| H'_n) = \mathcal{L}_m(H_1 \| \cdots \| H_n).$$

Hence, $\mathcal{L}_m(H) = \mathcal{L}_m(H_1 \| \cdots \| H_n)$.

By construction, $\{H_1, \ldots, H_n\}$ is a similar module system, and by Theorem 1, it is known that $P_i\left(\mathcal{L}_m(H_1 \| \cdots \| H_n)\right) = \mathcal{L}_m(H_i)$. Therefore, by substitution,

$$\forall i \in \{1, \ldots, n\},\ P_i(\mathcal{L}_m(H)) = \mathcal{L}_m(H_i). \qquad \square$$

Note that due to Theorems 7 and 1 and the facts that $\mathcal{L}_m(H) = \mathcal{L}_m(H'_1 \| \cdots \| H'_n)$, $\mathcal{L}_m(H) = \mathcal{L}_m(H_1 \| \cdots \| H_n)$, it is known that $\mathcal{L}_m(H'_1) = \mathcal{L}_m(H_1)$. Hence Algorithm 2 gives a method for computing automata $\{H_1, \ldots, H_n\}$, which mark the same languages as the similar module systems $\{H'_1, \ldots, H'_n\}$, which comprise the composed system H when $\{H'_1, \ldots, H'_n\}$ are known to exist. Corollary 2 also follows immediately from Theorems 7 and 6.

COROLLARY 2. *Suppose there is a trim automaton H such that $\mathcal{L}_m(H)$ is symmetric with respect to $\{\Psi_{11}, \ldots, \Psi_{1n}\}$ and separable with respect to the set of projections*

$\{P_1, \ldots, P_n\}$. *Then, if Algorithm* 2 *is run with* H *as input, a similar module system* $\{H_1, \ldots, H_n\}$ *is returned such that*

$$\mathcal{L}_m(H) = \mathcal{L}_m(H_1 \| \cdots \| H_n)$$

and

$$\forall i \in \{1, \ldots, n\},\ P_i(\mathcal{L}_m(H)) = \mathcal{L}_m(H_i).$$

The main *Repeat–Until* loop in Algorithm 2 iterates $|X|$ times, which is the size of the state space of H_1. The size of the state space of H_1 is always at least as small as $|X^H|$, the size of the state space of H, and generally much more so. Inside the main iterative loop, there are two types of tests for transition existence: one for individual global events and one for chains of private events. The tests for transition existence are generally efficient and negligible depending on the encoding of H, especially if each state contains a list of its outgoing transitions. In this case, only the existence of $|\Sigma_g|$ global event transitions and $|\Sigma_{p1}|$ private event string transitions at each state need to be tested. If there is a $\sigma_{p1} \in \Sigma_{p1}$ transition at the current state, it needs to be tested if there is a chain of transitions $\sigma_{p1}\sigma_{p2}\cdots\sigma_{pn}$ from the current state. Therefore, for every private event transition detected, at most $n-1$ other transitions need to be tested. Therefore, Algorithm 2 is in $O\left(|X| * (|\Sigma_g| + n * |\Sigma_{p1}|)\right)$.

An example of a run of Algorithm 2 is now given using a trimmed version of the automaton $G_1 \| G_2$ from Example 1.

Example 8. Consider the automaton G that is the trimmed version of $G_1 \| G_2$ from Example 1 with the states renamed for convenience. This automaton can be seen in Figure 3. Recall that $\mathcal{L}_m(G) = \left((\alpha_1\alpha_2 + \alpha_2\alpha_1)\,\gamma + (\beta_1\beta_2 + \beta_2\beta_1)\,\lambda\right)^*$.

Algorithm 2 is now run with G as input for $\Sigma_1 = \{\alpha_1, \beta_1, \gamma, \lambda\}$ and $\Sigma_2 = \{\alpha_2, \beta_2, \gamma, \lambda\}$ as follows:

To initialize: $X := \{1\}$, $x_0 := 1$, $\delta^1 := \emptyset$, $S := [1]$.

The first state is popped off of S. $x_s := 1$.

There are no Σ_g transitions from state 1, but there are two private event chains, $\alpha_1\alpha_2$ and $\beta_1\beta_2$ starting from state 1 and, respectively, leading to states 4 and 7. Therefore, states $4, 7$ are added to X; $(1, \alpha_1, 4)$ and $(1, \beta_1, 7)$ are added to δ^1; and 4, 7 are pushed onto S.

Now, $X = \{1, 4, 7\}$ $\delta^1 = \{(1, \alpha_1, 4), (1, \beta_1, 7)\}$, $S = [4, 7]$.

Next, 4 is popped off of S and $x_s := 4$. There is a Σ_g transition from 4 $(4, \gamma, 1)$, but no private event chains. Therefore, $(4, \gamma, 1)$ is added to δ^1 and no other changes are made.

Next, 7 is popped off of S and $x_s := 7$. There is a Σ_g transition from 7 $(7, \lambda, 1)$, but no private event chains. Therefore, $(7, \lambda, 1)$ is added to δ^1 and no other changes are made. The stack S is empty, so the *Repeat–Until* loop has been completed.

The marked state list is now assigned $X_m = \{1\}$ and this completes the construction of G_1. G_1 is then copied as G_2 by replacing α_1 with α_2 and β_1 with β_2.

This results in the automata seen in Figure 8.

It is now shown that the $\{H_1, \ldots, H_n\}$ automata returned by Algorithm 2 are guaranteed to be trim.

THEOREM 8. *Suppose a trim automaton* H *is given such that* $\mathcal{L}_m(H)$ *is symmetric with respect to* $\{\Psi_{11}, \ldots, \Psi_{1n}\}$ *and separable with respect to the set of projections* $\{P_1, \ldots, P_n\}$. *Let* $\{H_1, \ldots, H_n\}$ *be the automata constructed from* H *using Algorithm* 2. *Then, the automata* $\{H_1, \ldots, H_n\}$ *are all trim.*

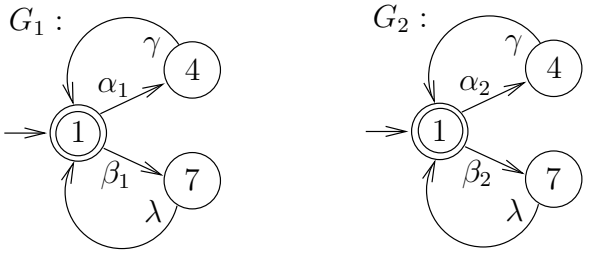

FIG. 8. *The automata G_1 and G_2 decomposed from G in Figure 3.*

Proof. It suffices to show that H_1 is trim.

It is known that all states X in H_1 are reachable from the initial state, and thus to show that H_1 is trim, it must be demonstrated that for every unmarked state in H_1, there must be a string to a marked state.

Suppose $x \in X \setminus X_m$. Because H is trim, there must be two strings $s, t \in \Sigma$ such that s is in

$$\left(\{\sigma_{p1}\Psi_{12}(\sigma_{p1}) \cdots \Psi_{1n}(\sigma_{p1}) | \sigma_{p1} \in \Sigma_{p1}\} \cup \Sigma_g\right)^*,$$

where $\delta^H(x_0^H, s) = x$, and $\delta^H(x, t) \in X_m^H$. Define s_1, t_1 such that $s_1 = P_1(s)$ and $t_1 = P_1(t)$. Because of the construction in Algorithm 2, it must be true that $\delta^1(x_0, s_1) = x$. Furthermore, because $\delta^H(x, t) \in X_m^H$ and t_1 is the string of events that is relevant to H_1 when t occurs, then it must be true that $\delta^1(x, t_1) \in X_m$ because $\mathcal{L}_m(H_1 \| \cdots \| H_n) = \mathcal{L}_m(H)$. □

7. Control operations. Now that verification methods for similar module systems have been discussed, properties related to the control of these systems are explored. The control framework for these systems is first introduced. It is a version of the standard decentralized supervisory control framework specialized for similar module systems.

Given a supervisor S_1 and a system G_1, the composed system of S_1 supervising G_1 is denoted as the supervised system S_1/G_1. Furthermore, because the parallel supervisors are assumed to be realized as finite-state automata, S_1/G_1 is equivalent to $S_1 \| G_1$. Supervisor S_1 is said to be nonblocking for system G_1 if S_1/G_1 is nonblocking, i.e., if $\overline{\mathcal{L}_m(S_1/G_1)} = \mathcal{L}(S_1/G_1)$.

Controller S_i can observe a subset of system events $\Sigma_{oi} \subseteq \Sigma_i$. Furthermore, on the occurrence of observable events, controller S_i may be given sufficient actuation to selectively disable the locally controllable events $\Sigma_{ci} \subseteq \Sigma_i$. Controllers should not be able to disable uncontrollable events, and control actions should not update on the occurrence of unobservable events. Furthermore, let $\Sigma_{uci} = \Sigma_i \setminus \Sigma_{ci}$. Let $P_{oi} : \Sigma^* \to \Sigma_{oi}^*$ be the natural projection that erases events in $\Sigma \setminus \Sigma_{oi}$ and represents the projection operation for the local observations of controller S_i.

For the control systems model, it is assumed that the controller automata $\{S_2, \ldots, S_n\}$ are copies of the generic control module S_1 with the local controller's events replaced according to the $\Psi_{1i}(\cdot)$ mapping. The set of controllers $\{S_1, \ldots, S_n\}$ defined in this way is called a set of *similar controllers*.

DEFINITION 6. *A set of controllers $\{S_1, \ldots, S_n\}$ is called a set of* similar controllers *if all controllers are exact copies of one another with respect to $\Psi_{ij}(\cdot)$ operations. In particular, $\Sigma_{ci} = \Psi_{1i}(\Sigma_{c1})$, $\Sigma_{oi} = \Psi_{1i}(\Sigma_{o1})$, and if controller S_1 disables events $\gamma_1 \subseteq \Sigma_{c1}$ after observing a string s_1, then controller S_i disables $\Psi_{1i}(\gamma_1) \subseteq \Psi_{1i}(\Sigma_{c1})$ after observing string $\Psi_{1i}(s_1)$.*

Note that due to Definition 6, if a global event $\sigma \in \Sigma_g$ is controllable (observable) by S_i, then it is controllable (observable) by all other controllers.

The controllers $\{S_1, \ldots, S_n\}$ are nonblocking for $\{G_1, \ldots, G_n\}$ if

$$\overline{\mathcal{L}_m((S_1/G_1)\| \cdots \|(S_n/G_n))} = \mathcal{L}((S_1/G_1)\| \cdots \|(S_n/G_n)).$$

8. Control for local specifications. There are potentially great reductions in computational effort for many similar module system control problems with local specifications. For a similar module system $\{G_1, \ldots, G_n\}$ and a set of similar language specifications $\{K_1, \ldots, K_n\}$, suppose it is desirable to know if there exists a set of similar controllers $\{S_1, \ldots, S_n\}$ such that

$$\forall i \in \{1, \ldots, n\}, \quad \begin{pmatrix} P_i\left[\mathcal{L}_m((S_1/G_1)\| \cdots \|(S_n/G_n))\right] = K_i \\ \wedge\, P_i\left[\mathcal{L}((S_1/G_1)\| \cdots \|(S_n/G_n))\right] = \overline{K_i} \end{pmatrix}.$$

This problem can be solved by looking only at the local behavior of G_1 and the locally observable and controllable event sets, Σ_{o1} and Σ_{c1}, respectively.

THEOREM 9. *For a similar module system $\{G_1, \ldots, G_n\}$ with local event sets $\{\Sigma_1, \ldots, \Sigma_n\}$, observable event sets $\{\Sigma_{o1}, \ldots, \Sigma_{on}\}$, controllable event sets $\{\Sigma_{c1}, \ldots, \Sigma_{cn}\}$, and local behavior specifications $\{K_1, \ldots, K_n\}$ such that for all $i, j \in \{1, \ldots, n\}$, $K_i \neq \emptyset$ and $K_i \subseteq \mathcal{L}_m(G_i)$, $K_j = \Psi_{ij}(K_i)$, there exists a set of similar controllers $\{S_1, \ldots, S_n\}$ such that for all $i \in \{1, \ldots, n\}$,*

$$P_i\left[\mathcal{L}_m((S_1/G_1)\| \cdots \|(S_n/G_n))\right] = K_i$$

and

$$P_i\left[\mathcal{L}((S_1/G_1)\| \cdots \|(S_n/G_n))\right] = \overline{K_i}$$

if and only if

1. *K_1 is controllable with respect to $\mathcal{L}(G_1)$ and Σ_{uc1}.*
2. *K_1 is observable with respect to $\mathcal{L}(G_1)$, P_{o1}, and Σ_{c1}.*
3. *K_1 is $\mathcal{L}_m(G_1)$-closed.*

Proof. It was shown in Corollary 1 that

$$P_i\left[\mathcal{L}_m((S_1/G_1)\| \cdots \|(S_n/G_n))\right] = K_i$$

and

$$P_i\left[\mathcal{L}((S_1/G_1)\| \cdots \|(S_n/G_n))\right] = \overline{K_i}$$

if and only if $\mathcal{L}_m(S_i/G_i) = K_i$ and $\mathcal{L}(S_i/G_i) = \overline{K_i}$. Due to the similar behavior of the systems, controllers, and specifications, $\mathcal{L}_m(S_i/G_i) = K_i$ and $\mathcal{L}(S_i/G_i) = \overline{K_i}$ if and only if $\mathcal{L}_m(S_1/G_1) = K_1$ and $\mathcal{L}(S_1/G_1) = \overline{K_1}$. The result then follows using the controllability and observability theorem of supervisory control theory [18]. ∎

Theorem 9 shows that controller existence for local behavior specifications can be decided by testing controller existence locally and apart from the interaction of other modules. The controllability and observability theorem is known to be constructive, and therefore there are known methods for synthesizing the local controllers $\{S_1, \ldots, S_n\}$ such that local nonblocking specifications are satisfied when they interact, and the conditions of Theorem 9 are satisfied. These results also generalize to cases when marking properties are not a concern.

Despite these very positive results, a caveat is in order with respect to the nature of language semantics. All local modules in a similar module system may be nonblocking and deadlock free, but blocking and deadlock may both still occur globally. Consider the following example.

Example 9. Consider the automaton $G_1 \| G_2$ introduced in Example 1. The composed automaton $G_1 \| G_2$ is blocking and contains two deadlock states, $(2,3)$ and $(3,2)$. These states are reached when an α event is followed immediately by a β event or when a β event is followed immediately by an α event. Neither G_1 nor G_2 can observe the interleaving of α and β events due to the restriction that the local systems cannot observe events that are private to other modules. However, when the language generated by the system $G_1 \| G_2$ is projected to either the Σ_1 or Σ_2 event sets, the behavior is equivalent to G_1 or G_2, respectively, and these automata are individually nonblocking and deadlock free.

Example 9 shows one of the major limitations of using local language specifications for similar module systems and motivates why attention should not be restricted solely to local behavior. Suppose a set of trim similar specification automata $\{H_1, \ldots, H_n\}$ is given such that for all $i \in \{1, \ldots, n\}$ $\mathcal{L}_m(H_i) = K_i$. One way to ensure that the global composed system is nonblocking after the local controllers are designed would be to verify that $\{K_1, \ldots, K_n\}$ are nonconflicting by testing if $H^{\|}$ is nonblocking. This can be verified fairly efficiently by testing if the $\tilde{H}$ construction is nonblocking, as seen in Theorem 5. For concurrent systems, blocking and deadlock properties are inherently global in nature and cannot generally be investigated on a local level. Another approach to ensuring that the global controlled system is nonblocking would be to use global control specifications instead of local specifications. This situation is explored in the following section.

9. Control for global specifications. Instead of considering a set of local similar specifications $\{K_1, \ldots, K_n\}$, suppose a global language specification K is given and that it needs to be decided if there exist nonblocking similar controllers $\{S_1, \ldots, S_n\}$ for a similar module system $\{G_1, \ldots, G_n\}$ such that $\mathcal{L}_m((S_1/G_1)\| \cdots \|(S_n/G_n)) = K$. Due to the similarity of the controllers and system modules, one would think that K would need to exhibit a degree of symmetry with respect to the occurrence of private events. This is exactly the case in Theorem 10 below.

THEOREM 10. *For a similar module system $\{G_1, \ldots, G_n\}$ with respective local projection operations $\{P_1, \ldots, P_n\}$, observation projections $\{P_{o1}, \ldots, P_{on}\}$, controllable event sets $\{\Sigma_{c1}, \ldots, \Sigma_{cn}\}$, and global behavior specification K such that $K \neq \emptyset$ and $K \subseteq \mathcal{L}_m(G_1 \| \cdots \| G_n)$, a set of nonblocking similar controllers $\{S_1, \ldots, S_n\}$ exists such that $\mathcal{L}_m((S_1/G_1)\| \cdots \|(S_n/G_n)) = K$ if and only if*

1. *$P_1(K)$ is controllable with respect to $\mathcal{L}(G_1)$ and Σ_{uc1}.*
2. *$P_1(K)$ is observable with respect to $\mathcal{L}(G_1)$, P_{o1}, and Σ_{c1}.*
3. *$P_1(K)$ is $\mathcal{L}_m(G_1)$-closed.*
4. *K is symmetric with respect to $\{\Psi_{11}, \ldots, \Psi_{1n}\}$.*
5. *K is separable with respect to $\{P_1, \ldots, P_n\}$.*
6. *$\{P_1^{-1}(P_1(K)), \ldots, P_n^{-1}(P_n(K))\}$ are nonconflicting.*

Proof. This theorem is shown in two parts. Assume there exists a set of controllers $\{S_1, \ldots, S_n\}$ such that

$$K = \mathcal{L}_m((S_1/G_1)\| \cdots \|(S_i/G_i)\| \cdots \|(S_n/G_n)), \tag{7}$$

$$\overline{K} = \mathcal{L}((S_1/G_1)\| \cdots \|(S_i/G_i)\| \cdots \|(S_n/G_n)). \tag{8}$$

By the definition of $\Psi_{1i}(\cdot)$,

$$\begin{aligned}&\Psi_{1i}(\mathcal{L}_m((S_1/G_1)\| \cdots \|(S_i/G_i)\| \cdots \|(S_n/G_n)))\\ &\quad = \mathcal{L}_m((S_i/G_i)\| \cdots \|(S_1/G_1)\| \cdots \|(S_n/G_n)).\end{aligned}$$

The parallel composition operation is commutative, and thus

$$\mathcal{L}_m((S_1/G_1)\| \cdots \|(S_i/G_i)\| \cdots \|(S_n/G_n)) = \mathcal{L}_m((S_i/G_i)\| \cdots \|(S_1/G_1)\| \cdots \|(S_n/G_n)).$$

$\Rightarrow K = \Psi_{1i}(K)$. This proves the fourth part of the implication.

By (7) and (8) there exists a set of controllers $\{S_1, \ldots, S_n\}$ such that
$K = \mathcal{L}_m((S_1/G_1)\| \cdots \|(S_i/G_i)\| \cdots \|(S_n/G_n))$,
$\overline{K} = \mathcal{L}((S_1/G_1)\| \cdots \|(S_i/G_i)\| \cdots \|(S_n/G_n))$
$\Rightarrow$
there exists a set of controllers $\{S_1, \ldots, S_n\}$ such that for all $i \in \{1, \ldots, n\}$,
$P_i(K) = P_i(\mathcal{L}_m((S_1/G_1)\| \cdots \|(S_n/G_n)))$,
$P_i(\overline{K}) = P_i(\mathcal{L}((S_1/G_1)\| \cdots \|(S_n/G_n)))$
$\Rightarrow$ using Corollary 1:
there exists a set of controllers $\{S_1, \ldots, S_n\}$ such that for all $i \in \{1, \ldots, n\}$,
$P_i(K) = \mathcal{L}_m(S_i/G_i)$,
$P_i(\overline{K}) = \mathcal{L}(S_i/G_i)$
$\Rightarrow$ from the controllability and observability theorem of supervisory control theory,

1. $P_i(K)$ is controllable with respect to $\mathcal{L}(G_i)$ and Σ_{uci}.
2. $P_i(K)$ is observable with respect to $\mathcal{L}(G_i)$, P_{oi}, and Σ_{ci}.
3. $P_i(K)$ is $\mathcal{L}_m(G_i)$-closed.

This proves the first three parts of the implication.

It is known that
$K = P_1^{-1}(\mathcal{L}_m(S_1/G_1)) \cap \cdots \cap P_n^{-1}(\mathcal{L}_m(S_n/G_n))$,
$\overline{K} = P_1^{-1}(\mathcal{L}(S_1/G_1)) \cap \cdots \cap P_n^{-1}(\mathcal{L}(S_n/G_n))$
$\Rightarrow$ using Corollary 1:
$K = P_1^{-1}(P_1(K)) \cap \cdots \cap P_n^{-1}(P_n(K))$,
$\overline{K} = P_1^{-1}(\overline{P_1(K)}) \cap \cdots \cap P_n^{-1}(\overline{P_n(K)})$
$\Rightarrow$ using Lemma 1:
$K = P_1^{-1}(P_1(K)) \cap \cdots \cap P_n^{-1}(P_n(K))$,
$\overline{K} = \overline{P_1^{-1}(P_1(K)) \cap \cdots \cap P_n^{-1}(P_n(K))}$.

This proves the fifth and sixth parts of the implication. This completes the first part of the proof.

It is now shown that the controllers exist if the six conditions hold.

Because of the first three conditions, it is known that there exists a controller S_1 such that $P_1(K) = \mathcal{L}_m(S_1/G_1)$ and $\overline{P_1(K)} = \mathcal{L}(S_1/G_1)$.

Because of the separability condition, $K = P_1^{-1}(P_1(K)) \cap \cdots \cap P_n^{-1}(P_n(K))$.

Because of the symmetry condition and Lemma 2, it is known that there exists controllers $S_1, \ldots, S_n$ such that for all $i \in \{1, \ldots, n\}$, $(P_i(K) = \mathcal{L}_m(S_i/G_i))$.

Therefore by substitution,
$K = P_1^{-1}(\mathcal{L}_m(S_1/G_1)) \cap \cdots \cap P_n^{-1}(\mathcal{L}_m(S_n/G_n))$.
This implies that
$K = \mathcal{L}_m((S_1/G_1)\| \cdots \|(S_n/G_n))$.
Because of condition 6 and Lemma 1,
$\overline{P_1^{-1}(P_1(K)) \cap \cdots \cap P_n^{-1}(P_n(K))} = P_1^{-1}(\overline{P_1(K)}) \cap \cdots \cap P_n^{-1}(\overline{P_n(K)})$.
$\Rightarrow$ Because of conditions 5 and 6, $\overline{K}$ is separable, and
$\overline{K} = P_1^{-1}(\overline{P_1(K)}) \cap \cdots \cap P_n^{-1}(\overline{P_n(K)})$.

Because of $\overline{P_1(K)} = \mathcal{L}(S_1/G_1)$, the symmetry condition, and Lemma 2, it is known that there exists controllers $S_1, \ldots, S_n$ such that for all $i \in \{1, \ldots, n\}$,

$(\overline{P_i(K)} = \mathcal{L}(S_i/G_i))$.

Therefore, for the set of similar controllers $\{S_1, \ldots, S_n\}$,

$\overline{K} = P_1^{-1}(\mathcal{L}(S_1/G_1)) \cap \cdots \cap P_n^{-1}(\mathcal{L}(S_n/G_n))$

$\Rightarrow$

$\overline{K} = \mathcal{L}(S_1/G_1 \| \cdots \| S_n/G_n)$.

Overall it has been shown that there exists a set of similar controllers $\{S_1, \ldots, S_n\}$ such that

$K = \mathcal{L}_m((S_1/G_1) \| \cdots \| (S_n/G_n))$,

$\overline{K} = \mathcal{L}((S_1/G_1) \| \cdots \| (S_n/G_n))$. □

The six necessary and sufficient conditions for controller existence in Theorem 10 can be divided into two types. The first three conditions (local controllability, observability, and $\mathcal{L}_m$-closure) are essentially existence conditions for local controllers to achieve local projections of global behavior. These conditions are inherent to many supervisory control problems and have been well known from the early papers in supervisory control theory such as [18, 24]. However, the combination of the last three conditions (symmetry, separability, and nonconflictingness) is unique to this problem setting.

The separability condition ensures that when the specification K is decomposed into sets of desired local behaviors, if automata that mark the desired local behavior are composed, then the behavior of the composed automaton is equal to K. That is, the composition of the automata that mark the $\{P_1(K), \ldots, P_n(K)\}$ (i.e., $\{S_1/G_1, \ldots, S_n/G_n\}$) is equal to K. The nonconflicting condition ensures that if the local automata $(\{S_1/G_1, \ldots, S_n/G_n\})$ are all nonblocking, then the composed automaton $(S_1/G_1 \| \cdots \| S_n/G_n)$ is nonblocking.

The symmetry condition ensures that if K is decomposed with respect to $\{P_1, \ldots, P_n\}$, then the set of modules that mark $\{P_1(K), \ldots, P_n(K)\}$ is a similar module system. This condition in retrospect should be expected when one considers Theorem 6. If the behavior of all controllers operating on the modules is similar with respect to a renaming of local events, then the specification would necessarily be symmetric if it can be achieved.

Taken together, if conditions 1 through 3 are satisfied, then conditions 4 through 6 imply that the global specification K needs to be expressible as a set of similar nonconflicting local specifications $\{P_1(K), \ldots, P_n(K)\}$ if there exists a set of similar controllers $\{S_1, \ldots, S_n\}$ that can be coupled with the similar module system $\{G_1, \ldots, G_n\}$ to achieve the specification K.

Suppose a trim automaton H is given such that $\mathcal{L}_m(H) = K$, where K satisfies the conditions of Theorem 10. Using the decomposition algorithm, Algorithm 2, a set of trim automata $\{H_1, \ldots, H_n\}$ can be constructed from H such that for all $i \in \{1, \ldots, n\}$, $\mathcal{L}_m(H_i) = K_i$ and $P_1^{-1}(K_1) \cap \cdots \cap P_n^{-1}(K_n) = K$ from Theorems 7 and 8. The local similar controllers $\{S_1, \ldots, S_n\}$ can then be synthesized using known centralized control methods.

Note that conditions 1 through 6 together imply that the language K is controllable with respect to $\mathcal{L}(G_1 \| \cdots \| G_n)$, co-observable with respect to $\mathcal{L}(G_1 \| \cdots \| G_n)$, and $\mathcal{L}_m(G_1 \| \cdots \| G_n)$-closed, but the reverse implication does not hold because of the assumptions on the controllers being used. If the controllers were allowed to be asymmetric, a larger class of specifications could be achieved, but this would require an extra amount of coordination in the control synthesis. The considered framework is designed so that once one control module is designed, the implementation of more controllers is merely a matter of copying that first controller.

10. Discussion. A model for a similar module system was given that can be used to model a wide variety of real-world processes. In addition, a method has been shown that can be used to test global blocking and deadlock-freeness without enumerating all possible combinations of system states, and it has been shown that verification of local behavior can be performed in an off-line manner without module interaction. Necessary and sufficient conditions for the existence of local controllers have also been introduced for the similar module system model.

A method has also been shown for decomposing an automaton representing global system behavior into automata representing the local, modular subsystems; this method runs in polynomial time with respect to the size of the local specification automaton. This result is important because the standard methods for performing decompositions currently known in the supervisory control literature take exponential time with respect to the size of the global model in the worst case.

It would be interesting to develop ad hoc methods for controlling similar module systems when the necessary and sufficient conditions for controller existence do not hold. It might be desired to synthesize controllers that achieve behavior that is "maximal" in some sense when the behavioral specifications cannot be matched exactly; that is, to find a set of similar controllers $\{S'_1, \ldots, S'_n\}$ for a similar module system $\{G_1, \ldots, G_n\}$ such that for any other set of similar controllers $\{S_1, \ldots, S_n\}$, $\mathcal{L}(S_1/G_1 \| \cdots \| S_n/G_n) \subseteq \mathcal{L}(S'_1/G_1 \| \cdots \| S'_n/G_n)$.

The case when the control modules are similar has been investigated solely in this paper, but it might be the case in many real-world problems that the control systems may be asymmetric. For instance, one controller may be a "leader" that has more leeway in enforcing global control actions to avoid situations in which blocking and deadlock may occur. It would also be interesting to investigate more general system models. For instance, it is possible that using a method other than parallel composition to model module interaction might lead to other results. Furthermore, it would be interesting to investigate more general system models, where the modules might have some sort of similarity besides being isomorphic with respect to a renaming of private events.

Acknowledgments. The authors would like to thank the associate editor and the reviewers for their useful comments.

MAXIMUM PRINCIPLE FOR SINGULAR STOCHASTIC CONTROL PROBLEMS*

F. DUFOUR† AND B. MILLER‡

Abstract. In this paper, an optimal singular stochastic control problem is considered. For this model, a general stochastic maximum principle is obtained by using a time transformation. This is the first version of the stochastic maximum principle that covers nonlinear cases.

Key words. nonlinear stochastic systems, optimal control, singular control, maximum principle, time change

1. Introduction. In this paper a maximum principle is proved for stochastic singular controls. On a filtered probability space $\big(\Omega, \mathcal{F}, P, \{\mathcal{F}_t\}\big)$ the set of admissible controls is defined as the class of right continuous with left-hand limits (*corlol*) processes $\big\{(u_t, v_t)\big\}$, $\{\mathcal{F}_t\}$-progressively measurable satisfying the following conditions: $\{v_t\}$ is increasing, $v_T \le M$ P-a.s., and $u_t \in K$, $|u_t| \le 1$, where K is a subset of $\mathbb{R}^r$, and $T > 0$ is the finite horizon. Assuming that on the probability space $\big(\Omega, \mathcal{F}, P\big)$ there exists a standard Brownian motion $\{W_t\}$, the state process is defined by the following stochastic differential equation for any admissible control $\big\{(u_t, v_t)\big\}$:

$$x(t) \doteq \zeta + \int_0^t A(s, x(s))ds + \int_{[0,t]} B(s)u(s)dv(s) + \int_0^t D(s, x(s))dW(s), \tag{1.1}$$

and the cost is given by

$$J[C] \doteq E_P\left[G\left(\int_0^T |u(s)|dv(s), x(T)\right)\right], \tag{1.2}$$

where the functions A, B, D, and G are deterministic.

In recent years, singular stochastic control problems have received considerable attention. The connection between singular control problem and optimal stopping problem has been studied by many authors including Alvarez [1, 2], Boetius [5, 6], Boetius and Kohlmann [7], Chow, Menaldi, and Robin [10], Dufour and Miller [14], El Karoui and Karatzas [16, 17], Karatzas [28, 29], and Karatzas and Shreve [31, 32, 33].

Results on the dynamic programming principle can be found in Boetius [6], Haussmann and Suo [25], Fleming and Soner [22], and Zhu [43]. Sufficient conditions for the existence of optimal singular control for general nonlinear models have been obtained in Dufour and Miller [14] and Haussmann and Suo [24]. Explicit problems have been solved, for example, in [11] and [30]. The authors do not pretend to present here an exhaustive panorama of the literature relative to singular control problems. However, the interested reader may consult Boetius [6] for a survey on stochastic singular control problems including theoretical results and applications.

There is a very extensive literature on the maximum principle for stochastic classical control (see, for example, [3], [4], [9], [20], [21], [26], [36], [38], [41], [42], and the references therein; this list of references is not exhaustive).

In this paper we have chosen to define the control strategy as a pair of processes $\{u(t), v(t)\}$, where $|u(t)| \leq 1$, and $v(t)$ is increasing and right continuous. An equivalent description of the singular stochastic control problem would have been to choose a process $\{\zeta(t)\}$ of bounded variation which acts on the dynamic state through the term $\int_{[0,t]} B(s)d\zeta(s)$. The connection between these two definitions of the control process $\{u(t), v(t)\}$ and $\{\zeta(t)\}$ ($\zeta(t) = \int_{[0,t]} u(s)dv(s)$) has been discussed by many authors (see, for example, [11], [22, page 318], [35], and [43]).

To the best knowledge of the authors the stochastic maximum principle for singular controls was only considered by Cadenillas and Haussmann [8]. In their paper Cadenillas and Haussmann used a different approach and different hypotheses that are presented now in order to bring to the fore the main differences between their results and ours. In [8], the control process is described by a process $\{\zeta(t)\}$ (see the above discussion) of bounded variation, and they do not impose any L^p bounds on the control while we assume that the class of admissible controls $\{v(t)\}$ is such that $v(T) \leq M$ for a constant M. However, in [8] the state process must satisfy a linear stochastic differential equation (the functions A and D are assumed to be linear with respect to the state variable $\{x(t)\}$), and the cost function is convex. In our work, we suppose that the state process is defined by a general nonlinear stochastic differential equation, and we do not impose a convexity hypothesis on the cost function (see assumptions A(1)–A(3) in the next section). In many aspects the results obtained in [8] and here are different and complementary.

In general terms, the approach we used to obtain the maximum principle for singular control problems can be divided into three steps. The first step is to convert the original singular control problem into a classical control problem by using a special time transformation. In order to be concise, the description of this method is briefly presented, and only the important properties, which we need here, are given. Although this technique of time change is similar to the one already described in [14], it must be pointed out that the approach used here presents some technical differences that are explained in section 3. The second step is to derive the maximum principle for the auxiliary control problem (see Theorem 4.5). Important properties of the adjoint variables (see Theorem 4.4 and in particular (4.13)) that will be used to obtain the singular maximum principle are derived. The last step consists of recovering from the auxiliary maximum principle the original state and control variables by using a time change, thus giving a maximum principle for the singular control problem (see Theorem 5.9). The form of the maximum principle we obtained turns out to be different from the one derived in [8] since the adjoint variables have a singular part (see Definition 5.1 and in particular the second term of the right-hand side of (5.1)) and since the optimal singular control maximizes an Hamiltonian a.s. with respect to

the Doleans-Dade measure generated by the optimal control $\{v(t)\}$ (see the detailed discussion before Theorem 5.9).

REMARK 1.1. *It must be pointed out that our time change technique cannot be used to solve singular control problems in the context of infinite horizon.*

The finite fuel constraint $(v(T) \leq M)$ *is a crucial assumption in order to derive the maximum principle by using our method of time transformation. Indeed, in* [14]*, it has been shown that our approach of time change enables us to convert a nonlinear singular control problem into an auxiliary control problem where the control variables are of the classical type and where the controller must choose a stopping time. However, since it is very difficult to derive a general maximum principle combining classical control and optimal stopping, we need to impose the finite fuel constraint* $(v(T) \leq M)$ *to convert the singular control problem into the classical control problem where the horizon is fixed. In* [8]*, Cadenillas and Haussmann do not have to impose a finite fuel constraint, but they used different hypotheses (see the discussion above for a comparison between their approach and ours).*

Nevertheless, we have shown in [14] *that our method of time transformation can be applied to study the existence of optimal singular control in a general context where the finite fuel constraint is not a necessary assumption.*

Singular control problems have been studied under various hypotheses (for example, the finite horizon case can be found in [7, 16, 28, 29, 31]*; the infinite horizon case in* [7, 11, 28, 33]*; with a finite fuel constraint in* [16, 28, 33]*).*

The paper is organized as follows. In section 2, we formulate the singular control problem. The time change and the auxiliary control problem is briefly described in section 3. Section 4 deals with the auxiliary maximum principle and its properties. In section 5, the main results are obtained and in particular the stochastic maximum principle for singular controls (see Theorem 5.9). A simple example is presented in section 6 to illustrate the set of necessary conditions that must be satisfied by an optimal solution. In the last section, we make some comments about possible generalizations of our work.

NOTATION.

The Lebesgue measure on $\mathbb{R}$ is denoted by λ.

$\mathbb{N}_N$ is the set of the first N integers, that is, $\mathbb{N}_N = \{1, \ldots, i, \ldots, N\}$.

$\mathbb{N}^* \doteq \{k \in \mathbb{N} : k > 0\}$ and $\mathbb{R}_+ \doteq \{x \in \mathbb{R} : x \geq 0\}$.

If V is a vector, V_i denotes the ith component of V.

If M is a matrix, M_i denotes a vector given by the ith column of the matrix M, and M_{ij} is the element corresponding to the ith row and the jth column.

$(^\top)$ denotes the transpose operation.

For $x \in \mathbb{R}^k$, $|x|$ denotes its Euclidean norm and for a matrix $A \in \mathbb{R}^{k \times d}$ the norm of A is defined by $|A| = \sqrt{\mathrm{tr}\big[AA^\top\big]}$.

For $K \subset \mathbb{R}^k$, $B_1(K) \doteq \{x \in K : |x| \leq 1\}$, and $S_1(K) \doteq \{x \in K : |x| = 1\}$.

$\mathcal{S}_n$ denotes the set of all $(n \times n)$ real symmetric matrices.

$0_n \in \mathbb{R}^n$ is the zero vector.

The indicator function of a set A is defined as $I_A(x)$.

The function δ defined on $\mathbb{N} \times \mathbb{N}$ is such that $\delta_{ij} = 1$ if $i = j$ and $\delta_{ij} = 0$ otherwise.

For $x \in \mathbb{R}$, x^+ is defined by $x^+ = \frac{1}{x}$ if $x \neq 0$ and $x^+ = 0$ if $x = 0$.

If V is a metric space, then $\mathcal{B}(V)$ denotes its associated borel σ-field.

A filtered probability space $\big(\Omega, \mathcal{F}, P, \{\mathcal{F}_t\}\big)$ is said to satisfy the usual hypotheses if the probability space $\big(\Omega, \mathcal{F}, P\big)$ is complete and if the filtration $\{\mathcal{F}_t\}$ is right continuous and if every $\mathcal{F}_t$ contains all P-null sets of $\mathcal{F}$.

Let $(\Omega, \mathcal{F}, P, \{\mathcal{F}_t\})$ be a filtered probability space and $\{\theta_t\}$ be a $[0,1]$-valued, $\{\mathcal{F}_t\}$-progressively measurable process. Suppose that V denotes any of the spaces $\mathbb{R}^k$, $\mathbb{R}^{k\times d}$, or $\mathcal{S}_k$.
Then $L^2\big(\Omega, \mathcal{F}, P, \{\mathcal{F}_t\}; [0,T]; V\big)$ (respectively, $L^2_\theta(\Omega, \mathcal{F}, P, \{\mathcal{F}_t\}; [0,T]; V)$) denotes the set of V-valued processes $\{x(t)\big\}$ which are $\{\mathcal{F}_t\}$-progressively measurable and satisfy $E_P[\int_0^T |x(s)|^2 ds] < +\infty$ (respectively, $E_P[\int_0^T |x(s)|^2[1-\theta(s)]ds] < +\infty$).
If $\mathbb{F}$ denotes the filtered probability space $\big(\Omega, \mathcal{F}, P, \{\mathcal{F}_t\}\big)$, then $L^2\big(\mathbb{F}; [0,T]; V\big)$ (respectively, $L^2_\theta(\mathbb{F}; [0,T]; V)$) is used to write in a more compact form $L^2\big(\Omega, \mathcal{F}, P, \{\mathcal{F}_t\}; [0,T]; V\big)$ (respectively, $L^2_\theta(\Omega, \mathcal{F}, P, \{\mathcal{F}_t\}; [0,T]; V)$).
Moreover, $L^2\big(\Omega, \mathcal{F}, P; V\big)$ denotes the set of V-valued random variables X defined on the probability space $\big(\Omega, \mathcal{F}, P\big)$ such that $E_P\big[|X|^2\big] < +\infty$.
Let $\big(\Omega, \mathcal{F}, P, \{\mathcal{F}_t\}\big)$ be a filtered probability space; if $\{A(t)\}$ is a *corlol*, adapted process of finite variation on each interval $[0,t]$, then dA denotes the measure associated with the distribution function $\{A(t)\}$. For $\{H(t)\}$, a progressively measurable process, the integral process $\int_0^t H(s)dA(s)$ is denoted by $H \cdot A_t$. If $\{A(t)\}$ is an increasing *corlol*, adapted process, the measure defined on $(\mathbb{R}_+ \times \Omega, \mathcal{B}(\mathbb{R}_+) \otimes \mathcal{F})$ by $E_P[\int_0^{+\infty} I_C(s)dA(s)]$ for $C \in \mathcal{B}(\mathbb{R}_+) \otimes \mathcal{F}$ is denoted by $\mathcal{M}_A$.
Let $\big(\Omega, \mathcal{F}, P, \{\mathcal{F}_t\}\big)$ be a filtered probability space satisfying the usual hypotheses and supporting a standard m-dimensional Brownian motion $\{W_t\}$. Then $\{\mathcal{F}_t^W\}$ denotes the augmentation of the natural filtration generated by $\{W_t\}$.

In order to define the state processes, let us introduce the following data:

- T and M are fixed real numbers.
- K is a subset of $\mathbb{R}^r$.
- ζ is a fixed vector in $\mathbb{R}^n$.
- $A : \mathbb{R} \times \mathbb{R}^n \to \mathbb{R}^n$.
- $B : \mathbb{R} \to \mathbb{R}^{n\times r}$.
- $D : \mathbb{R} \times \mathbb{R}^n \to \mathbb{R}^{n\times m}$.
- $G : \mathbb{R} \times \mathbb{R}^n \to \mathbb{R}$.
- $N : \mathbb{R} \to \mathbb{R}^2$ such that $N(t) = \left(\begin{smallmatrix} t-T \\ t^2 - T^2 \end{smallmatrix}\right)$.

Let us introduce the following notation:

$\mathcal{A} : \mathbb{R} \times \mathbb{R}^n \times B_1(K) \times [0,1] \longrightarrow \mathbb{R}^{n+2}$ is defined by

$$\mathcal{A}(t,x,u,z) \doteq \begin{pmatrix} 1-z \\ A(t,x)(1-z) + zB(t)u \\ z|u| \end{pmatrix}$$

and

$\mathcal{D} : \mathbb{R} \times \mathbb{R}^n \times [0,1] \longrightarrow \mathbb{R}^{n+2}$ is defined by

$$\mathcal{D}(t,x,z) \doteq \begin{pmatrix} 0 \\ D(t,x)\sqrt{1-z} \\ 0 \end{pmatrix}$$

$(\forall (t,x,u,z,p,q,P) \in \mathbb{R} \times \mathbb{R}^n \times B_1(K) \times [0,1] \times \mathbb{R}^{2+n} \times \mathbb{R}^{(2+n)\times m} \times \mathbb{R}^{n\times n})$,

$$\mathcal{H}(t,x,u,z,p,q) \doteq \mathcal{A}(t,x,u,z)^\top p + \operatorname{tr}\big[\mathcal{D}(t,x,z)^\top q\big] \tag{1.3}$$

$(\forall (t,x,u,z,p^1,p^2,p^3,q,P,\psi) \in \mathbb{R}\times\mathbb{R}^n\times B_1(K)\times[0,1]\times\mathbb{R}\times\mathbb{R}^n\times\mathbb{R}\times\mathbb{R}^{n\times m}\times\mathbb{R}^{n\times n}\times\mathbb{R}^3)$,

$$J(t,x,p^2,q) \doteq A(t,x)^\top p^2 + \operatorname{tr}\big[D(t,x)^\top q\big], \tag{1.4}$$

$$\begin{aligned} H(t,x,u,z,p^1,p^2,p^3,q,P,\psi) \doteq{}& (\psi_2 p^1 - \psi_1 - 2T\psi_3)(1-z) \\ &+ \psi_2\big[(1-z)A(t,x) + zB(t)u\big]^\top p^2 \\ &+ \psi_2 z|u|p^3 + \psi_2\sqrt{1-z}\operatorname{tr}\big[D(t,x)^\top q\big] \\ &+ \frac{\psi_2}{2}\operatorname{tr}[D(t,x)^\top P D(t,x)](1-z). \end{aligned} \tag{1.5}$$

The following assumptions will be used in the paper:

(A1) The maps A, B, D, and G are C^2.

(A2) The first and second derivatives of A, B, D and the second derivative of G are bounded. The maps $A(t,x)$, $B(t,x)$, $D(t,x)$ are bounded by $C(1+|t|+|x|)$. The first derivative of $G(w,x)$ is bounded by $C(1+|w|+|x|)$.

(A3) $(\forall x\in\mathbb{R}^n)$, $(\forall (w_1,w_2)\in\mathbb{R}\times\mathbb{R})$ if $w_1\le w_2$, then $G(w_1,x)\le G(w_2,x)$.

In the rest of the paper, the derivative of the function B will be denoted by B_t, and the partial derivatives of the function A (respectively, G, $\mathcal{H}$, and J) with respect to the first variable will be denoted by A_t (respectively, $\mathcal{H}_t$ and J_t) and with respect to the second variable will be denoted by A_x (respectively, $\mathcal{H}_x$ and J_x). For $j\in\mathbb{N}_m$, D_{jt} (respectively, D_{jx}) denotes the partial derivative of the function D_j with respect to the first variable (respectively, the second variable). The partial derivative of G with respect to the first variable will be denoted by G_w and with respect to the second variable will be denoted by G_x. The second partial derivatives of the function G (respectively, $\mathcal{H}$ and J) with respect to the second variable will be denoted by G_{xx} (respectively, $\mathcal{H}_{xx}$ and J_{xx}).

2. Problem statement. In this section, we formulate the original singular stochastic control problem presented in the introduction using the formulation described in [18] and in [23].

DEFINITION 2.1. *A singular control is defined by the following term:*

$$C \doteq (\Omega,\mathcal{F},P,\{\mathcal{F}_t\},\{u(t),v(t)\},\{W(t)\},\{x(t)\}),$$

where

(i) $(\Omega,\mathcal{F},P)$ *is a complete probability space with a right continuous complete filtration* $\{\mathcal{F}_t\}$*;*

(ii) $\{W(t)\}$ *is a standard* m*-dimensional* $\{\mathcal{F}_t\}$*-Brownian motion;*

(iii) $\{u(t),v(t)\}$ *is a* $B_1(K)\times\mathbb{R}_+$*-valued,* corlol, $\{\mathcal{F}_t\}$*-progressively measurable process such that* $\{v(t)\}$ *is increasing and satisfies*

$$v(T)\le M; \tag{2.1}$$

(iv) $\{x(t)\}$ *is an* $\mathbb{R}^n$*-valued,* corlol, $\{\mathcal{F}_t\}$*-progressively measurable process such that* $(\forall t\in[0,T])$

$$\begin{aligned} x(t) \doteq{}& \zeta + \int_0^t A(s,x(s))ds + \int_{[0,t]} B(s)u(s)dv(s) \\ &+ \int_0^t D(s,x(s))dW(s), \end{aligned} \tag{2.2}$$

and $x(0-)=\zeta$.

We write $\mathfrak{C}$ *for the set of controls satisfying the previous conditions.*

The cost is given by

$$J[C] \doteq E_P\left[G\left(\int_0^T |u(s)|dv(s), x(T)\right)\right]. \tag{2.3}$$

The set $\mathfrak{C}^a$ *of admissible controls is defined by*

$$\mathfrak{C}^a \doteq \{C \in \mathfrak{C} : J[C] < \infty\}. \tag{2.4}$$

The singular control problem is defined by the minimization of $J[C]$ on $\mathfrak{C}^a$. Assuming the existence of an optimal singular control $\widetilde{C}$, the aim of the paper is to derive necessary conditions for $\widetilde{C}$ to be optimal in terms of variational inequalities (see the maximum principle presented in Theorem 5.9).

3. The auxiliary control problem. In this section, it is shown that the original singular control problem can be converted into a classical control problem by using a time transformation (see Propositions 3.4, 3.5, and 3.7). We used the technique previously described in [14]. These results are presented here with minimal details in order to be concise. The interested reader may consult [14] to have a complete description of this approach. However, it must be pointed out that the model under consideration in [14] and the one presented here are different. Indeed, in order to derive a stochastic maximum principle one needs to have real-valued state constraints (see (3.26) and the definition of N), whereas the constraints used in [14] to derive sufficient conditions for the existence of an optimal control can take infinite value. Moreover, an important difference is that one needs to have a special measurability property for the auxiliary control problem (see the last part of Proposition 3.7) to ensure the existence of the adjoint variables defined by backward stochastic differential equations (see Corollary 4.2).

Assume the existence of an optimal singular control denoted by

$$\widetilde{C} \doteq \left(\widehat{\Omega}, \widehat{\mathcal{F}}, \widehat{P}, \{\widehat{\mathcal{F}}_t\}, \{\widetilde{u}(t), \widetilde{v}(t)\}, \{\widehat{W}(t)\}, \{\widetilde{x}(t)\}\right)$$

such that $\{\widetilde{u}(t), \widetilde{v}(t)\}$ is $\{\widehat{\mathcal{F}}_t^{\widehat{W}}\}$-progressively measurable.

REMARK 3.1. *The existence problem for singular stochastic control has already been studied under general hypotheses in many papers (see, for example,* [14] *and* [24] *and the references therein). As just stated, it is assumed that the optimal control* $\widetilde{C}$ *satisfies an assumption related to the measurability of the singular control* $\{\widetilde{u}(t), \widetilde{v}(t)\}$ *with respect to the filtration generated by the noise* $\{\widehat{\mathcal{F}}_t^{\widehat{W}}\}$. *It must be pointed out that this hypothesis is classical (see, for example, assumption* $(S0)$ *on page* 114 *in* [41] *or the definition of the underlying filtration on page* 967 *in* [38]*).*

With the next proposition, we show how it is possible to construct an optimal singular control $\widehat{C}$ satisfying $\widehat{v}(T) = M$ from the optimal singular control $\widetilde{C}$.

PROPOSITION 3.2. *The control* $\widehat{C}$ *defined by*

$$\widehat{C} \doteq \left(\widehat{\Omega}, \widehat{\mathcal{F}}, \widehat{P}, \{\widehat{\mathcal{F}}_t\}, \{\widehat{u}(t), \widehat{v}(t)\}, \{\widehat{W}(t)\}, \{\widehat{x}(t)\}\right), \tag{3.1}$$

where

$$\widehat{v}(t) = \widetilde{v}(t) I_{[\![0,T[\![} + (M - \widetilde{v}(T) + \widetilde{v}(t)) I_{[\![T,+\infty[\![}, \tag{3.2}$$

$$\widehat{u}(t) = \widetilde{u}(t)\left[\frac{\widetilde{v}(T) - \widetilde{v}(T-)}{M - \widetilde{v}(T-)} I_{[T,+\infty[\times\{\widetilde{v}(T)<M\}} + I_{[T,+\infty[\times\{\widetilde{v}(T)=M\}}\right]$$

$$+ \widetilde{u}(t) I_{[\![0,T[\![}, \tag{3.3}$$

is optimal. Moreover, $\widehat{v}(T) = M$*, and* $\{\widehat{u}(t), \widehat{v}(t)\}$ *is a* $\{\widehat{\mathcal{F}}_t^{\widehat{W}}\}$*-progressively measurable process.*

Proof. From the definition of $\{\widehat{u}(t)\}$ and $\{\widehat{v}(t)\}$, we have that $\widehat{v}(T) = M$, and

$$(\forall t \in [0, T[), \quad \widehat{u}(t) = \widetilde{u}(t), \quad \widehat{v}(t) = \widetilde{v}(t), \quad \text{and} \quad \widehat{u}(T)\Delta\widehat{v}(T) = \widetilde{u}(T)\Delta\widetilde{v}(T); \tag{3.4}$$

consequently, we obtain that $\widehat{x}(T) = \widetilde{x}(T)$, and $\int_{[0,T]} |\widehat{u}(t)| d\widehat{v}(t) = \int_{[0,T]} |\widetilde{u}(t)| d\widetilde{v}(t)$, showing that $J[\widehat{C}] = J[\widetilde{C}]$. Clearly, $\{\widehat{u}(t), \widehat{v}(t)\}$ is a $B_1(K) \times \mathbb{R}_+$-valued, *corlol*, $\{\widehat{\mathcal{F}}_t^{\widehat{W}}\}$-progressively measurable process implying that $\widehat{C}$ is optimal. □

REMARK 3.3. *Now we will work with the optimal control* $\widehat{C}$ *for technical reasons. However, by using Propositions* 3.2 *and* 5.8*, a general stochastic maximum principle will be derived in terms of the optimal control* $\widetilde{C}$ *giving the full generality to our result (see Theorem* 5.9*).*

PROPOSITION 3.4. *Denote the process* $\{t + \widehat{v}(t)\}$ *by* $\{\widehat{\Gamma}(t)\}$*. Let* $\{\eta^*(t)\}$ *be the right inverse of* $\{\widehat{\Gamma}(t)\}$*. Then* $\{\eta^*(t)\}$ *is a continuous time change such that the probability space* $(\widehat{\Omega}, \widehat{\mathcal{F}}, \widehat{P}, \{\widehat{\mathcal{F}}^{\widehat{W}}_{\eta^*(t)}\})$ *satisfies the usual hypotheses. Moreover, there exists a* $[0,1]$*-valued,* $\{\widehat{\mathcal{F}}_t^{\widehat{W}}\}$*-progressively measurable process* $\{\widehat{z}(t)\}$ *such that*

$$\widehat{v}(t) = \int_{[0,t]} \widehat{z}(s) d\widehat{\Gamma}(s). \tag{3.5}$$

Define the $B_1(K) \times [0,1]$*-valued,* $\{\widehat{\mathcal{F}}^{\widehat{W}}_{\eta^*(t)}\}$*-progressively measurable process* $\{(\alpha^*(t), \theta^*(t))\}$ *by*

$$\alpha^*(t) = \widehat{u}(\eta^*(t)) \quad \textit{and} \quad \theta^*(t) = \widehat{z}(\eta^*(t)). \tag{3.6}$$

Then

$$\eta^*(t) = \int_0^t (1 - \theta^*(s)) ds, \tag{3.7}$$

$$J[\widehat{C}] = E_{\widehat{P}}\Big[G\big(\mu^*(T+M), \xi^*(T+M)\big)\Big], \tag{3.8}$$

$$E_{\widehat{P}}\Big[N\big(\eta^*(T+M)\big)\Big] = 0_2, \tag{3.9}$$

where the processes $\{\xi^*(t)\}$ *and* $\{\mu^*(t)\}$ *are solutions of the following equations:*

$$\begin{aligned} \xi^*(t) \doteq \zeta &+ \int_0^t A(\eta^*(s), \xi^*(s))(1 - \theta^*(s)) ds + \int_0^t \theta^*(s) B(\eta^*(s)) \alpha^*(s) ds \\ &+ \int_0^t D(\eta^*(s), \xi^*(s)) \sqrt{(1 - \theta^*(s))(1 - \theta^*(s))^+} d\widehat{W}(\eta^*(s)), \end{aligned} \tag{3.10}$$

$$\mu^*(t) \doteq \int_0^t |\alpha^*(s)| \theta^*(s) ds. \tag{3.11}$$

Moreover,

$$\widehat{x}(t) = \xi^*(\widehat{\Gamma}(t)) \quad \textit{and} \quad \mu^*(T+M) = \int_{[0,T]} |\widehat{u}(s)| d\widehat{v}(s) \tag{3.12}$$

and

$$\widehat{v}(t) = \int_0^{\widehat{\Gamma}_t} \theta^*(s) ds \quad \textit{and} \quad \int_{[0,t]} |\widehat{u}(s)| d\widehat{v}(s) = \int_0^{\widehat{\Gamma}(t)} |\alpha^*(s)| \theta^*(s) ds. \tag{3.13}$$

Proof. Following Proposition 3.1, Proposition 3.2, and Theorem 4.2 in [14], the result can be obtained. □

Let $(\widetilde{\Omega}, \widetilde{\mathcal{F}}, \widetilde{P}, \{\widetilde{\mathcal{F}}_t\})$ be a filtered probability space satisfying the usual hypotheses and supporting a standard m-dimensional Brownian motion $\{\widetilde{V}_t\}$. Define by $(\Omega, \mathcal{G}, Q, \{\mathcal{G}_t\})$ the usual augmentation of the filtered probability space $\{\widehat{\Omega} \times \widetilde{\Omega}, \widehat{\mathcal{F}} \otimes \widetilde{\mathcal{F}}, \widehat{P} \otimes \widetilde{P}, \widehat{\mathcal{F}}^{\widehat{W}}_{\eta^*(t)} \otimes \widetilde{\mathcal{F}}_t\}$.

A random variable $\widehat{X}$ defined on $(\widehat{\Omega}, \widehat{\mathcal{F}}, \widehat{P})$ may be viewed as defined on $(\Omega, \mathcal{G}, Q)$ by setting $\overline{X}(\widehat{\omega}, \widetilde{\omega}) = \widehat{x}(\widehat{\omega})$ for $(\widehat{\omega}, \widetilde{\omega}) \in \widehat{\Omega} \times \widetilde{\Omega}$ and similarly for a random variable defined on $(\widetilde{\Omega}, \widetilde{\mathcal{F}}, \widetilde{P})$. Consequently, let us introduce on $(\Omega, \mathcal{G}, Q, \{\mathcal{G}_t\})$ the following processes:

$$\begin{cases} \overline{\alpha}(t, \widehat{\omega}, \widetilde{\omega}) \doteq \alpha^*(t, \widehat{\omega}), \quad \overline{\theta}(t, \widehat{\omega}, \widetilde{\omega}) \doteq \theta^*(t, \widehat{\omega}), \quad \overline{\eta}(t, \widehat{\omega}, \widetilde{\omega}) \doteq \eta^*(t, \widehat{\omega}), \\ \overline{\xi}(t, \widehat{\omega}, \widetilde{\omega}) \doteq \xi^*(t, \widehat{\omega}), \quad \overline{\mu}(t, \widehat{\omega}, \widetilde{\omega}) \doteq \mu^*(t, \widehat{\omega}), \quad \overline{W}(t, \widehat{\omega}, \widetilde{\omega}) \doteq \widehat{W}(t, \widehat{\omega}), \\ \qquad\qquad \widetilde{W}(t, \widehat{\omega}, \widetilde{\omega}) \doteq \widetilde{V}(t, \widetilde{\omega}). \end{cases} \tag{3.14}$$

Proposition 3.5. *On $(\Omega, \mathcal{G}, Q, \{\mathcal{G}_t\})$, the process $\{\overline{V}(t)\}$ defined by*

$$\overline{V}(t) \doteq \int_0^t \sqrt{(1 - \overline{\theta}(s))^+}\, d\overline{W}(\overline{\eta}(s)) + \int_0^t \sqrt{1 - (1 - \overline{\theta}(s))(1 - \overline{\theta}(s))^+}\, d\widetilde{W}(s) \tag{3.15}$$

is a standard m-dimensional $\{\mathcal{G}_t\}$-Brownian motion. The process $\{\overline{\xi}(t), \overline{\eta}(t), \overline{\mu}(t)\}$ is the unique solution of the following equations:

$$\begin{aligned} \overline{\xi}(t) &= \zeta + \int_0^t A(\overline{\eta}(s), \overline{\xi}(s))[1 - \overline{\theta}(s)]ds + \int_0^t B(\overline{\eta}(s))\overline{\alpha}(s)\overline{\theta}(s)ds \\ &\quad + \int_0^t D(\overline{\eta}(s), \overline{\xi}(s))\sqrt{1 - \overline{\theta}(s)}\, d\overline{V}(s), \end{aligned} \tag{3.16}$$

$$\overline{\eta}(t) = \int_0^t [1 - \overline{\theta}(s)]ds, \tag{3.17}$$

$$\overline{\mu}(t) = \int_0^t |\overline{\alpha}(s)|\overline{\theta}(s)ds. \tag{3.18}$$

Moreover,

$$J[\overline{C}] = E_Q\Big[G\big(\overline{\mu}(T + M), \overline{\xi}(T + M)\big)\Big], \tag{3.19}$$

$$E_Q\Big[N\big(\overline{\eta}(T + M)\big)\Big] = 0_2. \tag{3.20}$$

Proof. From Theorem 2.75 in [27], it follows that $\{\overline{V}(t)\}$ is a standard m-dimensional $\{\mathcal{G}_t\}$-Brownian motion. Using Theorem 6 in [39, page 194], we obtain that the solution $\{\xi(t), \eta(t), \mu(t))\}$ of (3.16)–(3.18) exists and is unique. From the definition of $\{\overline{V}(t)\}$, it is easy to show that $\{\xi(t)\}$ is the unique solution of the following equation:

$$\begin{aligned} \xi(t) &\doteq \zeta + \int_0^t A(\overline{\eta}(s), \xi(s))(1 - \overline{\theta}(s))ds + \int_0^t B(\overline{\eta}(s))\overline{\alpha}(s)\overline{\theta}(s)ds \\ &\quad + \int_0^t D(\overline{\eta}(s), \xi(s))\sqrt{(1 - \overline{\theta}(s))(1 - \overline{\theta}(s))^+}\, d\overline{W}(\overline{\eta}(s)). \end{aligned} \tag{3.21}$$

However, combining the fact that the process $\{\xi^*(t)\}$ is the solution of (3.10) and Proposition 10.46 in [27], it follows that $\{\overline{\xi}(t)\}$ satisfies (3.16). Therefore, $\{\overline{\xi}(t)\}$ is the unique solution of (3.16). Moreover, it is clear from their definitions that the processes $\{\mu(t)\}$ and $\{\overline{\mu}(t)\}$ (respectively, $\{\eta(t)\}$ and $\{\overline{\eta}(t)\}$) are indistinguishable.

Finally, (3.19) and (3.20) follow easily from (3.8) and (3.9) and the definition of the probability Q. □

On the probability space $(\Omega, \mathcal{G}, Q)$, define the filtration $\mathcal{J}_t \doteq \widehat{\mathcal{F}}^{\widehat{W}}_{\eta^*(t)} \otimes \{\emptyset, \widetilde{\Omega}\}$.

The set of auxiliary control $\mathcal{E}$ is the set of $\{\mathcal{J}_t\}$-progressively measurable processes defined on $(\Omega, \mathcal{G}, Q, \{\mathcal{G}_t\})$ and taking their value in $B_1(K) \times [0,1]$. For any $\{(\alpha(t), \theta(t))\}$ in $\mathcal{E}$, the auxiliary state process $(\eta(t), \xi(t), \mu(t))$ is defined on $(\Omega, \mathcal{G}, Q, \{\mathcal{G}_t\})$ by

$$\eta(t) \doteq \int_0^t (1-\theta(s))ds, \tag{3.22}$$

$$\begin{aligned}\xi(t) \doteq \zeta &+ \int_0^t A(\eta(s), \xi(s))(1-\theta(s))ds + \int_0^t B(\eta(s))\alpha(s)\theta(s)ds \\ &+ \int_0^t D(\eta(s), \xi(s))\sqrt{(1-\theta(s))}d\overline{V}(s),\end{aligned} \tag{3.23}$$

$$\mu(t) \doteq \int_0^t |\alpha(s)|\theta(s)ds. \tag{3.24}$$

Note that for any $\{(\alpha(t), \theta(t))\}$ in $\mathcal{E}$, the previous system admits a unique solution. Moreover, we have $E_Q[G(\mu(T+M), \xi(T+M))] < \infty$.

The associated cost functional is defined by

$$\mathcal{M}[\alpha, \theta] \doteq E_Q\Big[G\big(\mu(T+M), \xi(T+M)\big)\Big]. \tag{3.25}$$

Definition 3.6. *The set of admissible auxiliary control $\mathcal{E}_{ad}$ is defined by the set of processes $\{(\alpha(t), \theta(t))\} \in \mathcal{E}$ such that the corresponding auxiliary state process $\{(\eta(t), \xi(t), \mu(t))\}$ satisfies the following constraint:*

$$E_Q\Big[N\big(\eta(T+M)\big)\Big] = 0_2. \tag{3.26}$$

The auxiliary control problem is to minimize the cost (3.25) over $\mathcal{E}_{ad}$.

Proposition 3.7. *The auxiliary control process $\{(\overline{\alpha}(t), \overline{\theta}(t))\}$ defined by* (3.14) *is optimal. Moreover, $\{(\overline{\alpha}(t), \overline{\theta}(t))\}$ and the corresponding optimal auxiliary state $\{(\overline{\eta}(t), \overline{\xi}(t), \overline{\mu}(t))\}$ are $\{\mathcal{J}_t\}$-progressively measurable processes.*

Proof. Using Proposition 3.5, and following the same arguments as in the proof of Theorem 4.6 in [14], the result can be obtained. □

Lemma 3.8. *Denote by $\{\tau_n\}_{n\in\mathbb{N}^*}$ the sequence of $\{\widehat{\mathcal{F}}^{\widehat{W}}_t\}$-stopping times which exhausts the jumps of $\{\widehat{v}(t)\}$. Then $\{\widehat{\Gamma}(\tau_n)\}_{n\in\mathbb{N}^*}$ and $\{\widehat{\Gamma}(\tau_n-)\}_{n\in\mathbb{N}^*}$ are sequences of $\{\widehat{\mathcal{F}}^{\widehat{W}}_{\eta^*(t)}\}$-stopping times.*

Proof. Since $\{\widehat{\Gamma}(t)\}$ is a $\{\widehat{\mathcal{F}}^{\widehat{W}}_{\eta^*(t)}\}$-progressively measurable process, then there exists a sequence of $\{\widehat{\mathcal{F}}^{\widehat{W}}_t\}$-stopping times, $\{\tau_n\}_{n\in\mathbb{N}^*}$, exhausting the jumps of $\{\widehat{\Gamma}(t)\}$. Since $\{\eta^*(t)\}$ is a time change on $\big(\widehat{\Omega}, \widehat{\mathcal{F}}, \widehat{P}, \{\widehat{\mathcal{F}}^{\widehat{W}}_t\}\big)$ and using item a) of Lemma 10.5 in [27], it follows that $\{\widehat{\Gamma}(\tau_n)\}_{n\in\mathbb{N}^*}$ is a sequence of $\{\widehat{\mathcal{F}}_{\eta^*(t)}\}$-stopping times. Moreover, using the fact that $\{\widehat{\Gamma}(\tau_n-) > t\} = \{\eta^*(t) < \tau_n\}$, it follows that $\{\widehat{\Gamma}(\tau_n-)\}_{n\in\mathbb{N}^*}$ is a sequence of $\{\widehat{\mathcal{F}}^{\widehat{W}}_{\eta^*(t)}\}$-stopping times. □

For the rest of the paper, we shall use the following notation for the different filtered probability space under consideration:

$$\widehat{\mathbb{F}}_{\eta^*}^{\widehat{W}} \doteq \left(\widehat{\Omega}, \widehat{\mathcal{F}}, \widehat{P}, \{\widehat{\mathcal{F}}_{\eta^*(t)}^{\widehat{W}}\}\right), \quad \mathbb{G} \doteq \left(\Omega, \mathcal{G}, Q, \{\mathcal{G}_t\}\right), \quad \mathbb{J} \doteq \left(\Omega, \mathcal{G}, Q, \{\mathcal{J}_t\}\right).$$

4. The maximum principle for the auxiliary control problem. In this section, a maximum principle is obtained for the auxiliary singular control problem. Some important properties are derived to render possible the time change in order to obtain the maximum principle for the original singular control problem presented in the next section (see Theorem 5.9). In Proposition 4.1 and Corollary 4.2 the existence of a general backward stochastic differential equations is established. In particular, this result states there exists an $\{\mathcal{J}_t\}$-adapted solution, labeled $(Y(t), X(t))$, to (4.4), although the backward equation is driven by a Wiener process, labeled $\{\overline{V}(t)\}$, such that $\mathcal{G}_t^{\overline{V}} \not\subset \mathcal{J}_t$ and $\mathcal{J}_t \not\subset \mathcal{G}_t^{\overline{V}}$. However, more importantly, a special expression is obtained for $X(t)$ (see (4.5)) that will be crucial in what follows. Using these results, Theorem 4.4 states the existence of the adjoint variables for the auxiliary control variables with an important property shown in (4.13). The stochastic maximum principle for the auxiliary control problem is then obtained in terms of these adjoint variables (see Theorem 4.5).

PROPOSITION 4.1. *On the filtered probability space $\widehat{\mathbb{F}}_{\eta^*}^{\widehat{W}}$, let us assume that the function $f : \widehat{\Omega} \times [0, T+M] \times \mathbb{R}^k \times \mathbb{R}^{k\times m} \to \mathbb{R}^k$ is $\mathcal{M} \otimes \mathcal{B}(\mathbb{R}^k) \otimes \mathcal{B}(\mathbb{R}^{k\times m})$-measurable, where $\mathcal{M}$ denotes the progressive σ-field, and satisfies the following:*

(i) $f(., 0, 0) \in L^2(\widehat{\mathbb{F}}_{\eta^*}^{\widehat{W}}; [0, T+M]; \mathbb{R}^k)$.

(ii) *There exists a constant $L > 0$ such that* $(\forall (y, \overline{y}, z, \overline{z}) \in \mathbb{R}^k \times \mathbb{R}^k \times \mathbb{R}^{k\times m} \times \mathbb{R}^{k\times m})$

$$|f(t, y, z) - f(t, \overline{y}, \overline{z})| \leq L\,[|y - \overline{y}| + |z - \overline{z}|] \qquad \lambda \otimes \widehat{P}\text{-a.s.}$$

Then for any given $Y^* \in L^2(\widehat{\Omega}, \widehat{\mathcal{F}}_{\eta^*(T+M)}^{\widehat{W}}, \widehat{P}; \mathbb{R}^k)$, the backward stochastic differential equation

$$\begin{aligned} Y^*(t) = Y^* &- \int_t^{T+M} f(s, Y^*(s), [1 - \theta^*(s)]Z^*(s))ds \\ &- \int_t^{T+M} Z^*(s)d\widehat{W}(\eta^*(s)) \end{aligned} \tag{4.1}$$

admits a unique solution in the following class of processes:

$$\left(\{Y^*(t)\}, \{Z^*(t)\}\right) \in L^2\left(\widehat{\mathbb{F}}_{\eta^*}^{\widehat{W}}; [0, T+M]; \mathbb{R}^k\right) \times L^2_{\theta^*}\left(\widehat{\mathbb{F}}_{\eta^*}^{\widehat{W}}; [0, T+M]; \mathbb{R}^k\right)$$

with $\{Y^*(t)\}$ continuous.

Proof. Clearly, the function f satisfies hypotheses (5.8) and (5.9) in [15, page 29], where the underlying filtered probability space is given by $\widehat{\mathbb{F}}_{\eta^*}^{\widehat{W}}$. Now, using Theorem 6.1 in [15], it follows that there exists a unique tiple $\left(\{Y^*(t)\}, \{Z^*(t)\}, \{N^*(t)\}\right)$ such that $(\forall t \in [0, T+M])$

$$\begin{aligned} Y^*(t) = Y^* &- \int_t^{T+M} f(s, Y^*(s), [1 - \theta^*(s)]Z^*(s))ds - \int_t^{T+M} Z^*(s)d\widehat{W}(\eta^*(s)) \\ &- \int_t^{T+M} dN^*(s), \end{aligned} \tag{4.2}$$

where

$$\{Y^*(t)\} \in L^2\Big(\widehat{\mathbb{F}}^{\widehat{W}}_{\eta^*}; [0, T+M]; \mathbb{R}^k\Big),$$
$$\{Z^*(t)\} \in L^2_{\theta^*}\Big(\widehat{\mathbb{F}}^{\widehat{W}}_{\eta^*}; [0, T+M]; \mathbb{R}^{k\times m}\Big),$$

and $\{N^*(t)\}$ is a *corlol*, $\mathbb{R}^k$-valued, $\{\widehat{\mathcal{F}}^{\widehat{W}}_{\eta^*(t)}\}$-martingale satisfying

$$(\forall (i,j) \in \mathbb{N}_k \times \mathbb{N}_k), \quad (\forall t \in [0, T+M]), \quad [\widehat{W}_i(\eta^*(.)), N^*_j]_t = 0 \tag{4.3}$$

with $E_{\widehat{P}}[\mathrm{tr}[[N^*, N^*]_{T+M} - [N^*, N^*]_0]] < +\infty$.

Combining the optional stopping theorem, the martingale representation theorem (see Theorem 4.15 in [34, p. 182]), and Proposition (1.5) in [40, p. 181], we obtain that there exists a process $\{\Phi(t)\} \in L^2_{\theta^*}(\widehat{\mathbb{F}}^{\widehat{W}}_{\eta^*}; [0, T+M]; \mathbb{R}^{k\times m})$ such that

$$N^*(t) = E_{\widehat{P}}\left[N^*(T)\right] + \int_0^t \Phi(s) d\widehat{W}(\eta^*(s)).$$

Combining the previous equation, (3.7), and (4.3), we obtain that $\forall (i,j) \in \mathbb{N}_k \times \mathbb{N}_k$, $\forall t \in [0, T+M]$, $\int_0^t \Phi_{ij}(s)(1-\theta^*(s))ds = 0$. Consequently $(\forall t \in [0, T+M])$, $\int_t^{T+M} dN^*(s) = 0$, and the result follows. □

Note that this result is not an immediate consequence of general results for backward stochastic differential equations (see, for example, [15]) since we need in particular to show that the last term in (4.2) cancels.

The next result demonstrates the existence, for a general backward stochastic differential equation driven by the Wiener process $\{\overline{V}(t)\}$ and defined on the probability space $(\Omega, \mathcal{G}, Q, \{\mathcal{G}_t\})$, of an $\{\mathcal{J}_t\}$-adapted solution satisfying (4.5). This result will be used to show the existence of the adjoint variables defined on the same probability space.

COROLLARY 4.2. *On the filtered probability space $\mathbb{G}$, let us assume that the function $g : \Omega \times [0, T+M] \times \mathbb{R}^k \times \mathbb{R}^{k\times m} \to \mathbb{R}^k$ is $\mathcal{N} \otimes \mathcal{B}(\mathbb{R}^k) \otimes \mathcal{B}(\mathbb{R}^{k\times m})$-measurable, where $\mathcal{N}$ denotes the progressive σ-field when the probability space $(\Omega, \mathcal{G}, Q)$ is equipped with the filtration $\{\mathcal{J}_t\}$ and satisfies the following:*

(i) *$g(., 0, 0) \in L^2(\mathbb{J}; [0, T+M]; \mathbb{R}^k)$.*

(ii) *There exists a constant $L > 0$ such that $(\forall (y, \overline{y}, z, \overline{z}) \in \mathbb{R}^k \times \mathbb{R}^k \times \mathbb{R}^{k\times m} \times \mathbb{R}^{k\times m})$*

$$|g(t, y, z) - g(t, \overline{y}, \overline{z})| \le L\left[|y - \overline{y}| + |z - \overline{z}|\right] \qquad \lambda \otimes Q\text{-a.s.}$$

Then for any given $Y \in L^2(\Omega, \mathcal{J}_{T+M}, Q; \mathbb{R}^k)$ the backward stochastic differential equation

$$Y(t) = Y - \int_t^{T+M} g\left(s, Y(s), \sqrt{1-\overline{\theta}(s)}X(s)\right) ds - \int_t^{T+M} X(s) d\overline{V}_s \tag{4.4}$$

admits a unique solution in the following class of processes:

$$\{Y(t), X(t)\} \in L^2\Big(\mathbb{G}; [0, T+M]; \mathbb{R}^k \times \mathbb{R}^{k\times m}\Big)$$

with $\{Y(t)\}$ continuous.

Moreover, $\{Y(t), X(t)\} \in L^2(\mathbb{J}; [0, T+M]; \mathbb{R}^k \times \mathbb{R}^{k\times m})$*, and the process* $\{X(t)\}$ *can be written in the following form:*

$$X(t) = \sqrt{1-\overline{\theta}(t)}Z(t), \tag{4.5}$$

where $\{Z(t)\} \in L^2_{\overline{\theta}}(\mathbb{J}; [0, T+M]; \mathbb{R}^{k\times m})$.

Proof. For (y, z) fixed in $\mathbb{R}^k \times \mathbb{R}^{k\times m}$, the process $\{g(t, x, y)\}$ is $\{\mathcal{J}_t\}$-progressively measurable. Since $\mathcal{J}_t = \widehat{\mathcal{F}}^{\widehat{W}}_{\eta^*(t)} \otimes \{\emptyset, \widetilde{\Omega}\}$

$$(\forall \widehat{\omega} \in \widehat{\Omega}), \quad (\forall (\widetilde{\omega}_1, \widetilde{\omega}_2) \in \widetilde{\Omega} \times \widetilde{\Omega}), \quad g(\widehat{\omega}, \widetilde{\omega}_1, t, x, y) = g(\widehat{\omega}, \widetilde{\omega}_2, t, x, y).$$

For $\widetilde{\omega}_1$ fixed in $\widetilde{\Omega}$, let us define the function $f : \widehat{\Omega} \times [0, T+M] \times \mathbb{R}^k \times \mathbb{R}^{k\times m} \to \mathbb{R}^k$ such that $f(\widehat{\omega}, t, x, y) = g(\widehat{\omega}, \widetilde{\omega}_1, t, x, y)$. Then f is $\mathcal{M} \otimes \mathcal{B}(\mathbb{R}^k) \otimes \mathcal{B}(\mathbb{R}^{k\times m})$-measurable since $\mathcal{N}$ is isomorphic to $\mathcal{M} \otimes \{\emptyset, \widetilde{\Omega}\}$, where $\mathcal{M}$ has been defined in Proposition 4.1. Clearly, f so defined satisfies items (i) and (ii) of Proposition 4.1. In the same manner, define Y^* by $Y^*(\widehat{\omega}) \doteq Y(\widehat{\omega}, \widetilde{\omega}_1)$, and so $Y^* \in L^2(\widehat{\Omega}, \widehat{\mathcal{F}}^{\widehat{W}}_{\eta^*(T+M)}, \widehat{P}; \mathbb{R}^k)$.

Therefore, from Proposition 4.1 we can claim that there exists a unique solution to the following equation:

$$\begin{aligned} Y^*(t) = Y^* &- \int_t^{T+M} f(s, Y^*(s), [1-\theta^*(s)]Z^*(s))ds \\ &- \int_t^{T+M} Z^*(s)d\widehat{W}(\eta^*(s)). \end{aligned} \tag{4.6}$$

It is easy to show that

$$\int_t^{T+M} Z^*(s)d\widehat{W}(\eta^*(s)) = \int_t^{T+M} Z^*(s)\sqrt{(1-\theta^*(s))(1-\theta^*(s))^+}d\widehat{W}(\eta^*(s)). \tag{4.7}$$

Now define $Y(\widehat{\omega}, \widetilde{\omega}, t) \doteq Y^*(\widehat{\omega}, t)$, $Z(\widehat{\omega}, \widetilde{\omega}, t) \doteq Z^*(\widehat{\omega}, t)$. Following the same arguments as in the proof of Proposition 3.5 and combining (4.6) and (4.7), we obtain

$$Y(t) = Y - \int_t^{T+M} g(s, Y(s), [1-\overline{\theta}(s)]Z(s))ds - \int_t^{T+M} \sqrt{1-\overline{\theta}(s)}Z(s)d\overline{V}_s. \tag{4.8}$$

Consequently, we have that $(\{Y(t)\}, \{X(t)\})$ is the solution of (4.4), where

$$X(t) \doteq Z(t)\sqrt{1-\overline{\theta}(t)}.$$

Clearly,

$$\{Y(t), X(t)\} \in L^2\Big(\mathbb{J}; [0, T+M]; \mathbb{R}^k \times \mathbb{R}^{k\times m}\Big).$$

Then we have shown the existence of a solution with the desired property (see (4.5)). The uniqueness follows exactly as in [37]. □

We will need the following result in the proof of the next theorem.

LEMMA 4.3. $\forall (t, x, u, z) \in \mathbb{R} \times \mathbb{R}^n \times B_1(K) \times [0, 1]$, $(p^1, p^2, p^3) \in \mathbb{R} \times \mathbb{R}^n \times \mathbb{R}$, *and* $(q^1, q^2, q^3) \in \mathbb{R}^{1\times m} \times \mathbb{R}^{n\times m} \times \mathbb{R}^{1\times m}$,

$$\mathcal{H}_t(t, x, u, z, p, q) = \big[A_t(t, x)(1-z) + zB_t(t)u\big]^\top p^2 + \sum_{j=1}^m D_{jt}(t, x)^\top q_j^2\sqrt{1-z},$$

$$\mathcal{H}_x(t, x, u, z, p, q) = \big[A_x(t, x)(1-z)\big]^\top p^2 + \sum_{j=1}^m D_{jx}(t, x)^\top q_j^2\sqrt{1-z},$$

where

$$p = \begin{pmatrix} p^1 \\ p^2 \\ p^3 \end{pmatrix}$$

and

$$q = \begin{pmatrix} q^1 \\ q^2 \\ q^3 \end{pmatrix}.$$

Proof. One may easily show that these two equalities follow directly from the definition of $\mathcal{H}$ (see (1.3)). □

With the previous results, we may now obtain in the following theorem a crucial property given by (4.13) of the solution of the backward stochastic differential equations (4.9)–(4.12) which renders possible a time change.

THEOREM 4.4. *On the filtered probability space $\mathbb{G}$, the system of backward stochastic differential equations*

$$d\overline{p}(t) = -\begin{pmatrix} \mathcal{H}_t(\overline{\eta}(t), \overline{\xi}(t), \overline{\alpha}(t), \overline{\theta}(t), \overline{p}(t), \overline{q}(t)) \\ \mathcal{H}_x(\overline{\eta}(t), \overline{\xi}(t), \overline{\alpha}(t), \overline{\theta}(t), \overline{p}(t), \overline{q}(t)) \\ 0 \end{pmatrix} dt + \overline{q}(t) d\overline{V}(t), \tag{4.9}$$

with

$$\overline{p}(T+M) = -\begin{pmatrix} 0 \\ G_x\big(\overline{\mu}(T+M), \overline{\xi}(T+M)\big) \\ G_w\big(\overline{\mu}(T+M), \overline{\xi}(T+M)\big) \end{pmatrix} \tag{4.10}$$

and

$$\begin{aligned} d\overline{P}(t) = {} & -A_x(\overline{\eta}(t), \overline{\xi}(t))^\top \overline{P}(t)(1-\overline{\theta}(t))dt - \overline{P}(t)A_x(\overline{\eta}(t), \overline{\xi}(t))(1-\overline{\theta}(t))dt \\ & - \sum_{j=1}^{m} \left[D_{jx}(\overline{\eta}(t), \overline{\xi}(t))\right]^\top \overline{P}(t) D_{jx}(\overline{\eta}(t), \overline{\xi}(t))(1-\overline{\theta}(t))dt \\ & - \sum_{j=1}^{m} \Big(\left[D_{jx}(\overline{\eta}(t), \overline{\xi}(t))\right]^\top \overline{Q}^j(t) + \overline{Q}^j(t) D_{jx}(\overline{\eta}(t), \overline{\xi}(t)) \Big) \sqrt{1-\overline{\theta}(t)}\, dt \\ & - \mathcal{H}_{xx}(\overline{\eta}(t), \overline{\xi}(t), \overline{\alpha}(t), \overline{\theta}(t), \overline{p}(t), \overline{q}(t))dt + \sum_{j=1}^{m} \overline{Q}^j(t) d\overline{V}_j(t), \end{aligned} \tag{4.11}$$

with

$$\overline{P}(T+M) = -G_{xx}\big(\overline{\mu}(T+M), \overline{\xi}(T+M)\big), \tag{4.12}$$

admits a unique solution in the following class of processes:

$$\Big\{ \overline{p}(t), \overline{q}(t), \overline{P}(t), \big(\overline{Q}^j(t)\big)_{j\in\mathbb{N}_m} \Big\} \in L^2\Big(\mathbb{G}; [0, T+M]; \mathbb{R}^{2+n} \times \mathbb{R}^{(2+n)\times m} \times \mathcal{S}^n \times \Big[\mathcal{S}^n\Big]^m \Big)$$

with $\{\overline{p}(t), \overline{P}(t)\}$ continuous.

Moreover,

$$\begin{cases} \overline{p}(t,\widehat{\omega},\widetilde{\omega}) = p^*(t,\widehat{\omega}), & \overline{q}(t,\widehat{\omega},\widetilde{\omega}) = \sqrt{1-\theta^*(t,\widehat{\omega})}q^*(t,\widehat{\omega}), \\ \overline{P}(t,\widehat{\omega},\widetilde{\omega}) = P^*(t,\widehat{\omega}), & \overline{Q}^j(t,\widehat{\omega},\widetilde{\omega}) = \sqrt{1-\theta^*(t,\widehat{\omega})}Q^{*j}(t,\widehat{\omega}) \end{cases} \tag{4.13}$$

$\forall(\widehat{\omega},\widetilde{\omega}) \in \widehat{\Omega}\times\widetilde{\Omega}$ *and* $\forall j \in \mathbb{N}_m$*, where* $\{p^*(t), P^*(t), q^*(t), \big(Q^{*j}(t)\big)_{j\in\mathbb{N}_m}\}$ *is the unique solution in the following class of processes:*

$$\{p^*(t), P^*(t)\} \in L^2\Big(\widehat{\mathbb{F}}^{\widehat{W}}_{\eta^*}; [0, T+M]; \mathbb{R}^{2+n}\times\mathcal{S}^n\Big),$$

$$\{q^*(t), \big(Q^{*j}(t)\big)_{j\in\mathbb{N}_m}\} \in L^2_{\theta^*}\Big(\widehat{\mathbb{F}}^{\widehat{W}}_{\eta^*}; [0, T+M]; \mathbb{R}^{(2+n)\times m}\times\Big[\mathcal{S}^n\Big]^m\Big)$$

with $\{p^*(t), P^*(t)\}$ *continuous of the system of backward stochastic differential equations defined on the filtered probability space* $\widehat{\mathbb{F}}^{\widehat{W}}_{\eta^*}$*:*

$$\begin{aligned} dp^*(t) = &-\begin{pmatrix} \mathcal{H}_t(\eta^*(t),\xi^*(t),\alpha^*(t),\theta^*(t),p^*(t),\sqrt{1-\theta^*(t)}q^*(t)) \\ \mathcal{H}_x(\eta^*(t),\xi^*(t),\alpha^*(t),\theta^*(t),p^*(t),\sqrt{1-\theta^*(t)}q^*(t)) \\ 0 \end{pmatrix} dt \\ &+ q^*(t)d\widehat{W}(\eta^*(t)) \end{aligned} \tag{4.14}$$

with

$$p^*(T+M) = -\begin{pmatrix} 0 \\ G_x\big(\mu^*(T+M),\xi^*(T+M)\big) \\ G_w\big(\mu^*(T+M),\xi^*(T+M)\big) \end{pmatrix} \tag{4.15}$$

and

$$\begin{aligned} dP^*(t) = &-A_x(\eta^*(t),\xi^*(t))^\top P^*(t)(1-\theta^*(t))dt - P^*(t)A_x(\eta^*(t),\xi^*(t))(1-\theta^*(t))dt \\ &- \sum_{j=1}^m \left[D_{jx}(\eta^*(t),\xi^*(t))\right]^\top P^*(t)D_{jx}(\eta^*(t),\xi^*(t))(1-\theta^*(t))dt \\ &- \sum_{j=1}^m \left(\left[D_{jx}(\eta^*(t),\xi^*(t))\right]^\top Q^{*j}(t) + Q^{*j}(t)D_{jx}(\eta^*(t),\xi^*(t))\right)(1-\theta^*(t))dt \\ &- \mathcal{H}_{xx}(\eta^*(t),\xi^*(t),\alpha^*(t),\theta^*(t),p^*(t),\sqrt{1-\theta^*(t)}q^*(t))dt \\ &+ \sum_{j=1}^m Q^{*j}(t)d\widehat{W}(\eta^*(t)) \end{aligned} \tag{4.16}$$

with

$$P^*(T+M) = -G_{xx}\big(\mu^*(T+M),\xi^*(T+M)\big). \tag{4.17}$$

Proof. Using Lemma 4.3, (4.9) can be written in the form

$$\overline{p}(t) = -\overline{p}(T+M) - \int_t^{T+M} g(s,\overline{p}(s),\sqrt{1-\overline{\theta}(s)}\overline{q}(s))ds - \int_t^{T+M}\overline{q}(s)d\overline{V}_s,$$

where the $\mathbb{R}^{n+2}$-valued function g is defined by

$$\begin{aligned} &g(t,p,q) \\ &= -\begin{pmatrix} \left[A_t(\overline{\eta}(t),\overline{\xi}(t))(1-\overline{\theta}(t)) + \overline{\theta}(t)B_t(\overline{\eta}(t))\overline{\alpha}(t)\right]^\top p^2 + \sum_{j=1}^m D_{jt}(\overline{\eta}(t),\overline{\xi}(t))^\top q_j^2 \\ \left[A_x(\overline{\eta}(t),\overline{\xi}(t))(1-\overline{\theta}(t))\right]^\top p^2 + \sum_{j=1}^m D_{jx}(\overline{\eta}(t),\overline{\xi}(t))^\top q_j^2 \\ 0 \end{pmatrix}, \end{aligned}$$

for

$$p = \begin{pmatrix} p^1 \\ p^2 \\ p^3 \end{pmatrix}$$

with $p^1 \in \mathbb{R}$, $p^2 \in \mathbb{R}^n$, and $p^3 \in \mathbb{R}$ and for

$$q = \begin{pmatrix} q^1 \\ q^2 \\ q^3 \end{pmatrix},$$

where $q^1 \in \mathbb{R}^{1\times n}$, $q^2 \in \mathbb{R}^{n\times n}$, and $q^3 \in \mathbb{R}^{1\times n}$. Moreover, from (4.10), it follows that $\widehat{p}(T+M) \in L^2(\Omega, \mathcal{J}_{T+M}, Q; \mathbb{R}^k)$. Now, using the hypotheses (A1)–(A2) on the data A, B, and D, it is easy to show that (4.9) satisfies the hypotheses of Corollary 4.2. Therefore, the existence and the uniqueness results for (4.9) are a straightforward consequence of Corollary 4.2. Using similar arguments, the existence and the uniqueness results can be obtained for (4.11). By using Proposition 4.1, it can be shown that (4.14)–(4.17) admit a unique solution. The last part of the theorem (see (4.13)) follows easily from Corollary 4.2 and its proof. □

Now we give the maximum principle for the auxiliary control problem.

THEOREM 4.5. *There exist* $\psi \in S_1(\mathbb{R}^3)$ *such that* $(\forall(\alpha,\theta) \in B_1(K) \times [0,1])$

$$\begin{aligned} &H(\eta^*(t), \xi^*(t), \alpha, \theta, p^{*1}(t), p^{*2}(t), p^{*3}(t), r^*(t), P^*(t), \psi) \\ &\qquad \le H(\eta^*(t), \xi^*(t), \alpha^*(t), \theta^*(t), p^{*1}(t), p^{*2}(t), p^{*3}(t), r^*(t), P^*(t), \psi) \end{aligned} \tag{4.18}$$

$\lambda \otimes \widehat{P}$*-a.s. on* $[0, T+M] \times \widehat{\Omega}$*, where* $\{p^{*1}(t)\}$ *(respectively,* $\{p^{*2}(t)\}$*,* $\{p^{*3}(t)\}$*) is an* $\mathbb{R}$ *(respectively,* $\mathbb{R}^n$*,* $\mathbb{R}$*)-valued process, and* $\{q^{*1}(t)\}$ *(respectively,* $\{q^{*2}(t)\}$*,* $\{q^{*3}(t)\}$*) is an* $\mathbb{R}^{1\times m}$ *(respectively,* $\mathbb{R}^{n\times m}$*,* $\mathbb{R}^{1\times m}$*)-valued process with*

$$\left(\left\{ \begin{pmatrix} p^{*1}(t) \\ p^{*2}(t) \\ p^{*3}(t) \end{pmatrix} \right\}, \left\{ \begin{pmatrix} q^{*1}(t) \\ q^{*2}(t) \\ q^{*3}(t) \end{pmatrix} \right\}, \{P^*(t)\}, \left(\{Q^{*j}\}\right)_{j\in\mathbb{N}_m} \right)$$

solutions of (4.14)–(4.17) *and*

$$r^*(t) \doteq \left[q^{*2}(t) - P^*(t) D(\eta^*(t), \xi^*(t)) \right] \sqrt{1 - \theta^*(t)}. \tag{4.19}$$

Proof. From assumptions (A1)–(A2) the hypothesis (3) of Theorem 5 in [38] is satisfied. However, one hypothesis of Theorem 5 in [38] is not satisfied here in the sense that we do not require the control processes $\{\overline{\alpha}(t)\}$, $\{\overline{\theta}(t)\}$ to be $\{\mathcal{F}_t^{\overline{V}}\}$-adapted. As pointed out in [41] (see page 114 and the top of page 116), this hypothesis may appear crucial in order to ensure the existence of the adjoint variables. However, although we required the processes to be $\{\mathcal{J}_t\}$-adapted, the proof of Theorem 5 in [38] remains unchanged since we have shown in Corollary 4.2 the existence and the uniqueness of the adjoint variables with the desired property.

Due to the particular block structure of the matrix $\mathcal{D}$ and from Theorem 5 in [38], it follows that there exist $\psi \in S_1(\mathbb{R}^3)$ such that $(\forall(\alpha,\theta) \in B_1(K) \times [0,1])$ the

variational inequality can be written in the following form:

$$
\begin{aligned}
&(1-\theta)\overline{p}^{1\psi}(t) + (1-\theta)A(\overline{\eta}(t),\overline{\xi}(t))^{\top}\overline{p}^{2\psi}(t) + \theta\big[B(\overline{\eta}(t))\alpha\big]^{\top}\overline{p}^{2\psi}(t) + \theta|u|\overline{p}^{3\psi}(t)\\
&\qquad + \sqrt{1-\theta}\,\mathrm{tr}\big[D(\overline{\eta}(t),\overline{\xi}(t))^{\top}\overline{r}^{\psi}(t)\big] + (1-\theta)\,\mathrm{tr}\big[D(\overline{\eta}(t),\overline{\xi}(t))^{\top}\overline{P}^{\psi}(t)D(\overline{\eta}(t),\overline{\xi}(t))\big]\\
&\leq (1-\overline{\theta}(t))\overline{p}^{1\psi}(t) + (1-\overline{\theta}(t))A(\overline{\eta}(t),\overline{\xi}(t))^{\top}\overline{p}^{2\psi}(t) + \overline{\theta}(t)\big[B(\overline{\eta}(t))\overline{\alpha}(t)\big]^{\top}\overline{p}^{2\psi}(t)\\
&\qquad + \overline{\theta}(t)|\overline{\alpha}(t)|\overline{p}^{3\psi}(t) + \sqrt{1-\overline{\theta}(t)}\,\mathrm{tr}\big[D(\overline{\eta}(t),\overline{\xi}(t))^{\top}\overline{r}^{\psi}(t)\big]\\
&\qquad + (1-\overline{\theta}(t))\,\mathrm{tr}\big[D(\overline{\eta}(t),\overline{\xi}(t))^{\top}\overline{P}^{\psi}(t)D(\overline{\eta}(t),\overline{\xi}(t))\big]
\end{aligned}
\tag{4.20}
$$

$\lambda\otimes P$-a.s. on $[0,T+M]\times\Omega$ with

$$
\overline{r}^{\psi}(t) = \overline{q}^{2\psi}(t) - \overline{P}^{\psi}(t)D(\overline{\eta}(t),\overline{\xi}(t))\sqrt{1-\overline{\theta}(t)},
\tag{4.21}
$$

and where $\{\overline{p}^{1\psi}(t)\}$ (respectively, $\{\overline{p}^{2\psi}(t)\}$, $\{\overline{p}^{3\psi}(t)\}$) is an $\mathbb{R}$ (respectively, $\mathbb{R}^n$, $\mathbb{R}$)-valued process, and $\{\overline{q}^{1\psi}(t)\}$ (respectively, $\{\overline{q}^{2\psi}(t)\}$, $\{\overline{p}^{3\psi}(t)\}$) is an $\mathbb{R}^{1\times m}$ (respectively, $\mathbb{R}^{n\times m}$, $\mathbb{R}^{1\times m}$)-valued process such that

$$
\left(\left\{\begin{pmatrix}\overline{p}^{1\psi}(t)\\ \overline{p}^{2\psi}(t)\\ \overline{p}^{3\psi}(t)\end{pmatrix}\right\},\left\{\begin{pmatrix}\overline{q}^{1\psi}(t)\\ \overline{q}^{2\psi}(t)\\ \overline{q}^{3\psi}(t)\end{pmatrix}\right\}\right)
$$

are the first-order adjoint variables solution of the following backward stochastic differential equation (see equation (21) in [38]):

$$
d\overline{p}^{\psi}(t) = -\begin{pmatrix}\mathcal{H}_t(\overline{\eta}(t),\overline{\xi}(t),\overline{\alpha}(t),\overline{\theta}(t),\overline{p}^{\psi}(t),\overline{q}^{\psi}(t))\\ \mathcal{H}_x(\overline{\eta}(t),\overline{\xi}(t),\overline{\alpha}(t),\overline{\theta}(t),\overline{p}^{\psi}(t),\overline{q}^{\psi}(t))\\ 0\end{pmatrix}dt + \overline{q}^{\psi}(t)d\overline{V}(t)
\tag{4.22}
$$

with

$$
\overline{p}^{\psi}(T+M) = -\begin{pmatrix}\psi_1 N_{1t}\big(\overline{\eta}(T+M)\big) + \psi_3 N_{2t}\big(\overline{\eta}(T+M)\big)\\ \psi_2 G_x\big(\overline{\mu}(T+M),\overline{\xi}(T+M)\big)\\ \psi_2 G_w\big(\overline{\mu}(T+M),\overline{\xi}(T+M)\big)\end{pmatrix}
\tag{4.23}
$$

and where the second-order adjoint variable is the solution of the following equation (see equation (22) in [38]):

$$
\begin{aligned}
d\overline{P}^{\psi}(t) = &-A_x(\overline{\eta}(t),\overline{\xi}(t))^{\top}\overline{P}^{\psi}(t)(1-\overline{\theta}(t))dt - \overline{P}^{\psi}(t)A_x(\overline{\eta}(t),\overline{\xi}(t))(1-\overline{\theta}(t))dt\\
&-\sum_{j=1}^{m}\big[D_{jx}(\overline{\eta}(t),\overline{\xi}(t))\big]^{\top}\overline{P}^{\psi}(t)D_{jx}(\overline{\eta}(t),\overline{\xi}(t))(1-\overline{\theta}(t))dt\\
&-\sum_{j=1}^{m}\Big(\big[D_{jx}(\overline{\eta}(t),\overline{\xi}(t))\big]^{\top}\overline{Q}^{\psi,j}(t) + \overline{Q}^{\psi,j}(t)D_{jx}(\overline{\eta}(t),\overline{\xi}(t))\Big)\sqrt{1-\overline{\theta}(t)}dt\\
&-\mathcal{H}_{xx}(\overline{\eta}(t),\overline{\xi}(t),\overline{\alpha}(t),\overline{\theta}(t),\overline{p}^{\psi}(t),\overline{q}^{\psi}(t))dt + \sum_{j=1}^{m}\overline{Q}^{\psi,j}(t)d\overline{V}_j(t)
\end{aligned}
\tag{4.24}
$$

with

$$
\overline{P}^{\psi}(T+M) = -\psi_2\, G_{xx}\big(\overline{\mu}(T+M),\overline{\xi}(T+M)\big).
\tag{4.25}
$$

From Theorem 3.1 in [37], the solutions of (4.22)–(4.25) exist and are unique. Since $E_P\big[N(\overline{\eta}(T+M))\big] = 0_2$, we have $N_{1t}(\overline{\eta}(T+M)) = 1$, and $N_{2t}(\overline{\eta}(T+M)) = 2T$ (see the definition of N). Therefore, the terminal condition (4.23) is given by

$$\overline{p}^{\psi}(T+M) = - \begin{pmatrix} \psi_1 + 2T\psi_3 \\ \psi_2 G_x\big(\overline{\mu}(T+M), \overline{\xi}(T+M)\big) \\ \psi_2 G_w\big(\overline{\mu}(T+M), \overline{\xi}(T+M)\big) \end{pmatrix}. \tag{4.26}$$

Simple calculations show that

$$\left(\left\{ \psi_2 \overline{p}(t) + \begin{pmatrix} -\psi_1 - 2T\psi_3 \\ 0 \\ 0 \end{pmatrix} \right\}, \{\psi_2 \overline{q}(t)\} \right)$$

is the solution of (4.22) with the terminal condition (4.26). By uniqueness, we obtain that

$$\overline{p}^{\psi}(t) = \psi_2 \overline{p}(t) + \begin{pmatrix} -\psi_1 - 2T\psi_3 \\ 0 \\ 0 \end{pmatrix}, \qquad \overline{q}^{\psi}(t) = \psi_2 \overline{q}(t). \tag{4.27}$$

Moreover, combining (4.27) and the definition of $\mathcal{H}$ (see (1.3)), it is easy to obtain that

$$\mathcal{H}_{xx}(\overline{\eta}(t), \overline{\xi}(t), \overline{\alpha}(t), \overline{\theta}(t), \overline{p}^{\psi}(t), \overline{q}^{\psi}(t)) = \psi_2 \mathcal{H}_{xx}(\overline{\eta}(t), \overline{\xi}(t), \overline{\alpha}(t), \overline{\theta}(t), \overline{p}(t), \overline{q}(t)).$$

Consequently, $(\{\psi_2 \overline{P}(t)\}, (\{\psi_2 \overline{Q}^j(t)\})_{j \in \mathbb{N}_m})$ is the solution of (4.24) with the terminal condition (4.25). By uniqueness, we obtain that

$$\overline{P}^{\psi}(t) = \psi_2 \overline{P}(t), \qquad \overline{Q}^{\psi,j}(t) = \psi_2 \overline{Q}^j(t). \tag{4.28}$$

Now using Theorem 4.4 (see (4.13)) and (4.27), (4.28), it follows that

$$\overline{p}^{\psi}(t, \widehat{\omega}, \widetilde{\omega}) = \psi_2 p^*(t, \widehat{\omega}) + \begin{pmatrix} -\psi_1 - 2T\psi_3 \\ 0 \\ 0 \end{pmatrix}, \qquad \overline{P}^{\psi}(t, \widehat{\omega}, \widetilde{\omega}) = \psi_2 P^*(t, \widehat{\omega}), \tag{4.29}$$

$$\overline{q}^{\psi}(t, \widehat{\omega}, \widetilde{\omega}) = \psi_2 \sqrt{1 - \theta^*(t, \widehat{\omega})} q^*(t, \widehat{\omega}), \qquad \overline{Q}^{\psi,j}(t, \widehat{\omega}, \widetilde{\omega}) = \psi_2 \sqrt{1 - \theta^*(t, \widehat{\omega})} Q^{*j}(t, \widehat{\omega}), \tag{4.30}$$

and from (4.21) it implies that

$$\begin{aligned} \overline{r}^{\psi}(t, \widehat{\omega}, \widetilde{\omega}) &= \psi_2 \sqrt{1 - \theta^*(t, \widehat{\omega})} \Big[q^*(t, \widehat{\omega}) - P^*(t, \widehat{\omega}) D(\eta^*(t, \widehat{\omega}), \xi^*(t, \widehat{\omega})) \Big] \\ &= \psi_2 r^*(t, \widehat{\omega}), \end{aligned} \tag{4.31}$$

where we have used the definitions of $\{\overline{\eta}(t)\}$, $\{\overline{\xi}(t)\}$ (see (3.14)).

Now using the definitions of the processes $\{\overline{\alpha}(t)\}$ and $\{\overline{\theta}(t)\}$, the definition of H (see (1.5)), and (4.30), (4.31), it follows that the variational inequality (4.20) can be written on the filtered probability space $\widehat{\mathbb{F}}^{\widehat{W}}_{\eta^*}$ as $(\forall (\alpha, \theta) \in B_1(K) \times [0,1])$

$$\begin{aligned} &H(\eta^*(t), \xi^*(t), \alpha, \theta, p^{*1}(t), p^{*2}(t), p^{*3}(t), r^*(t), P^*(t), \psi) \\ &\qquad \le H(\eta^*(t), \xi^*(t), \alpha^*(t), \theta^*(t), p^{*1}(t), p^{*2}(t), p^{*3}(t), r^*(t), P^*(t), \psi) \end{aligned}$$

$\lambda \otimes \widehat{P}$-a.s. on $[0, T+M] \times \widehat{\Omega}$, showing the result. □

5. The singular maximum principle and adjoint variables. In this section we first characterize the adjoint variables for the original control problem. Using the important property given by (4.13), it is possible to obtain the adjoint variables for the original control problem as shown in Theorem 5.2 by using a time change. The interesting feature of these adjoint variables is that the first component is the solution of a singular backward equation (see (5.1)). Then some technical results (Lemma 5.3, Proposition 5.4, Corollary 5.5, Lemma 5.7) are derived. Proposition 5.8 is particularly important to describe the connection between the optimal controls $\widetilde{C}$ and $\widehat{C}$. Finally, the stochastic maximum principle for the original singular control problem in the general case is obtained and presented in Theorem 5.9.

In the following definition, we introduce the backward stochastic differential equations that will be satisfied by the adjoint variables for the original control problem. Note the special form of the second term of the right-hand side of (5.1) that gives a singular part for these adjoint variables.

DEFINITION 5.1. *Let $C \in \mathfrak{C}^a$ be a singular control*

$$C \doteq (\Omega, \mathcal{F}, P, \{\mathcal{F}_t\}, \{u(t), v(t)\}, \{W(t)\}, \{x(t)\})$$

such that $\{u(t), v(t)\}$ is $\{\mathcal{F}_t^W\}$-progressively measurable. If the system of backward stochastic differential equations

$$\begin{aligned} p^1(t) &= \int_t^T A_t(s, x(s))^\top p^2(s) ds + \int_{]t,T]} p^2(s)^\top B_t(t) u(s) dv(s) \\ &\quad + \int_t^T \sum_{j=1}^m D_{jt}(t, x(t))^\top q_j^2(s) dt - \int_t^T q^1(s) dW(s), \end{aligned} \tag{5.1}$$

$$\begin{aligned} p^2(t) &= -G_x\left(\int_0^T |u(s)| dv(s), x(T)\right) + \int_t^T A_x(s, x(s))^\top p^2(s) ds \\ &\quad + \int_t^T \sum_{j=1}^m D_{jx}(s, x(s))^\top q_j^2(s) dt - \int_t^T q^2(s) dW(s), \end{aligned} \tag{5.2}$$

$$p^3(t) = -G_w\left(\int_0^T |u(s)| dv(s), x(T)\right) - \int_t^T q^3(s) dW(s), \tag{5.3}$$

and

$$\begin{aligned} P(t) &= -G_{xx}\left(\int_0^T |u(s)| dv(s), x(T)\right) + \int_t^T \Big[A_x(s, x(s))^\top P(s) - P(s) A_x(s, x(s))\Big] ds \\ &\quad + \sum_{j=1}^m \int_t^T D_{jx}(s, x(s))^\top P(s) D_{jx}(s, x(s)) ds + \int_t^T J_{xx}(s, x(s), p^2(s), q^2(s)) ds \\ &\quad + \sum_{j=1}^m \int_t^T \big[D_{jx}(s, x(s))^\top Q^j(s) + Q^j(s) D_{jx}(s, x(s))\big] ds - \int_t^T \sum_{j=1}^m Q^j(s) dW(s), \end{aligned}$$

admits a solution in the class of processes

$$\Big\{p^1(t), p^2(t), p^3(t)\Big\} \in L^2\Big(\mathbb{F}^W; [0,T]; \mathbb{R} \times \mathbb{R}^n \times \mathbb{R}\Big),$$

$$\Big\{q^1(t), q^2(t), q^3(t)\Big\} \in L^2\Big(\mathbb{F}^W; [0,T]; \mathbb{R}^{1\times m} \times \mathbb{R}^{n\times m} \times \mathbb{R}^{1\times m}\Big),$$

$$\Big(\{P(t)\}, \big(\{Q^j(t)\}\big)_{j\in\mathbb{N}_m}\Big) \in L^2\Big(\mathbb{F}^W; [0,T]; \mathcal{S}^n\Big) \times \Big[L^2\Big(\mathbb{F}^W; [0,T]; \mathcal{S}^n\Big)\Big]^m,$$

with $\{p^1(t), p^2(t), p^3(t), P(t)\}$ corlol, *and where* $\mathbb{F}^W \doteq (\Omega, \mathcal{F}, P, \{\mathcal{F}_t^W\})$, *then* $((\{p^i(t)\}, \{q^i(t)\})_{i\in\mathbb{N}_3}, \{P(t)\}, (\{Q^j(t)\})_{j\in\mathbb{N}_m})$ *are called the adjoint variables associated with the control* C. *The solution is said to be unique if the solution of the previous system is unique in this class of processes.*

By using a time transformation, we show that we can obtain the adjoint variables for the original optimal control from $(\{p^*(t)\}, \{q^*(t)\}, \{P^*(t)\}, (\{Q^{*j}(t)\})_{j\in\mathbb{N}_m})$.

THEOREM 5.2. *Define the following processes:*

$$\hat{p}(t) \doteq p^*(\widehat{\Gamma}(t)), \quad \hat{q}(t) \doteq q^*(\widehat{\Gamma}(t)), \quad \widehat{P}(t) \doteq P^*(\widehat{\Gamma}(t)), \quad \widehat{Q}^j(t) \doteq Q^{*j}(\widehat{\Gamma}(t)), \tag{5.4}$$

for $j \in \mathbb{N}_m$, *where* $(\{p^*(t)\}, \{q^*(t)\}, \{P^*(t)\}, (\{Q^{*j}\})_{j\in\mathbb{N}_m})$ *are solutions of* (4.14)–(4.17). *Write* $\hat{p}(t)$ *in the form*

$$\hat{p}(t) = \begin{pmatrix} \hat{p}^1(t) \\ \hat{p}^2(t) \\ \hat{p}^3(t) \end{pmatrix},$$

where $\hat{p}^1(t) \in \mathbb{R}$, $\hat{p}^2(t) \in \mathbb{R}^n$, *and* $\hat{p}^3(t) \in \mathbb{R}$ *and similarly*

$$\hat{q}(t) = \begin{pmatrix} \hat{q}^1(t) \\ \hat{q}^2(t) \\ \hat{q}^3(t) \end{pmatrix},$$

where $\hat{q}^1(t) \in \mathbb{R}^{1\times n}$, $\hat{q}^2(t) \in \mathbb{R}^{n\times n}$, *and* $\hat{q}^3(t) \in \mathbb{R}^{1\times n}$.

Then $((\{\hat{p}^i(t)\}, \{\hat{q}^i(t)\})_{i\in\mathbb{N}_3}, \{\widehat{P}(t)\}, (\{\widehat{Q}^j(t)\})_{j\in\mathbb{N}_m})$ *are the unique adjoint variables associated with the control* $\widehat{C}$.

Proof. Combining Lemma 4.3 and (4.14), (3.7), we obtain

$$\begin{aligned} p^{*2}(t) = &- G_x\big(\mu^*(T+M), \xi^*(T+M)\big) + \int_t^{T+M} A_x(\eta^*(s), \xi^*(s))^\top p^{*2}(s) d\eta^*(s) \\ &+ \int_t^{T+M} \sum_{j=1}^m D_{jx}(\eta^*(s), \xi^*(s))^\top q_j^{*2}(s) d\eta^*(s) - \int_t^{T+M} q^{*2}(s) d\widehat{W}(\eta^*(s)). \end{aligned} \tag{5.5}$$

However, from (3.12), it follows that

$$G_x\big(\mu^*(T+M), \xi^*(T+M)\big) = G_x\bigg(\int_{[0,T]} |\widehat{u}(s)| d\widehat{v}(s), \widehat{x}(T)\bigg).$$

Now, using the fact that $\widehat{\Gamma}(T) = T + M$, (5.5) becomes

$$\begin{aligned} p^{*2}(t) = &-G_x\big(\mu^*(T+M), \xi^*(T+M)\big) + \int_t^{\widehat{\Gamma}(T)} A_x(\eta^*(s), \xi^*(s))^\top p^{*2}(s) d\eta^*(s) \\ &+ \int_t^{\widehat{\Gamma}(T)} \sum_{j=1}^m D_{jx}(\eta^*(s), \xi^*(s))^\top q_j^{*2}(s) d\eta^*(s) - \int_t^{\widehat{\Gamma}(T)} q^{*2}(s) d\widehat{W}(\eta^*(s)). \end{aligned}$$

Consequently, the value of the process $\{p^{*2}(t)\}$ at time $\widehat{\Gamma}(t)$ is given by $\{p^{*2}(\widehat{\Gamma}(t))\}$ and satisfies

$$\begin{aligned} p^{*2}(\widehat{\Gamma}(t)) = &- G_x\bigg(\int_{[0,T]} |\widehat{u}(s)| d\widehat{v}(s), \widehat{x}(T)\bigg) + \int_{\widehat{\Gamma}(t)}^{\widehat{\Gamma}(T)} A_x(\eta^*(s), \xi^*(s))^\top p^{*2}(s) d\eta^*(s) \\ &+ \int_{\widehat{\Gamma}(t)}^{\widehat{\Gamma}(T)} \sum_{j=1}^m D_{jx}(\eta^*(s), \xi^*(s))^\top q_j^{*2}(s) d\eta^*(s) - \int_{\widehat{\Gamma}(t)}^{\widehat{\Gamma}(T)} q^{*2}(s) d\widehat{W}(\eta^*(s)). \end{aligned} \tag{5.6}$$

Clearly, $\{\widehat{\Gamma}(t)\}$ is a time change on the filtered probability space $\widehat{\mathbb{F}}^{\widehat{W}}_{\eta^*}$. According to Definition (1.3) in [40, p. 180], $\{\eta^*(t)\}$ is clearly a $\{\widehat{\Gamma}(t)\}$-continuous process since $\{\eta^*(t)\}$ is the right inverse of $\{\widehat{\Gamma}(t)\}$. Recalling $\eta^*(\widehat{\Gamma}(s)) = s$, $\xi^*(\widehat{\Gamma}(s)) = \widehat{x}(s)$ and applying Proposition (1.4) in [40, p. 180] to the second and the third terms of the right-hand side of (5.6), it follows that

$$\begin{aligned} p^{*2}(\widehat{\Gamma}(t)) = &-G_x\left(\int_{[0,T]} |\widehat{u}(s)|d\widehat{v}(s), \widehat{x}(T)\right) + \int_t^T A_x(s,\widehat{x}(s))^\top p^{*2}(\widehat{\Gamma}(s))ds \\ &+ \int_t^T \sum_{j=1}^m D_{jx}(s,\widehat{x}(s))^\top q_j^{*2}(\widehat{\Gamma}(s))ds - \int_{\widehat{\Gamma}(t)}^{\widehat{\Gamma}(T)} q^{*2}(s)d\widehat{W}(\eta^*(s)). \end{aligned}$$

Finally, applying Proposition (1.5) in [40, p. 181] to the last term of the right-hand side of the previous equation gives

$$\begin{aligned} p^{*2}(\widehat{\Gamma}(t)) = &-G_x\left(\int_{[0,T]} |\widehat{u}(s)|d\widehat{v}(s), \widehat{x}(T)\right) + \int_t^T A_x(s,\widehat{x}(s))^\top p^{*2}(\widehat{\Gamma}(s))ds \\ &+ \int_t^T \sum_{j=1}^m D_{jx}(s,\widehat{x}(s))^\top q_j^{*2}(\widehat{\Gamma}(s))ds - \int_t^T q^{*2}(\widehat{\Gamma}(s))d\widehat{W}(s). \end{aligned} \tag{5.7}$$

Using similar arguments, it is easy to obtain that

(5.8)

$$p^{*3}(\widehat{\Gamma}(t)) = -G_w\left(\int_{[0,T]} |\widehat{u}(s)|d\widehat{v}(s), \widehat{x}(T)\right) - \int_t^T q^3(\widehat{\Gamma}(s))d\widehat{W}(s),$$

$$\begin{aligned} P^*(\widehat{\Gamma}(t)) = &-G_{xx}\left(\int_{[0,T]} |\widehat{u}(s)|d\widehat{v}(s), \widehat{x}(T)\right) + \int_t^T J_{xx}(s,\widehat{x}(s), p^{*2}(\widehat{\Gamma}(s)), q^{*2}(\widehat{\Gamma}(s)))ds \\ &+ \int_t^T \Big[A_x(s,\widehat{x}(s))^\top P^*(\widehat{\Gamma}(s)) - P^*(\widehat{\Gamma}(s))A_x(s,\widehat{x}(s))\Big]ds \\ &+ \sum_{j=1}^m \int_t^T D_{jx}(s,\widehat{x}(s))^\top P^*(\widehat{\Gamma}(s))D_{jx}(s,\widehat{x}(s))ds \\ &+ \sum_{j=1}^m \int_t^T \big[D_{jx}(s,\widehat{x}(s))^\top Q^{*j}(\widehat{\Gamma}(s)) + Q^{*j}(\widehat{\Gamma}(s))D_{jx}(s,\widehat{x}(s))\big]ds \\ &- \int_t^T \sum_{j=1}^m Q^{*j}(\widehat{\Gamma}(s))d\widehat{W}(s). \end{aligned} \tag{5.9}$$

Now for $\{p^{*1}(\widehat{\Gamma}(t))\}$, we have from Lemma 4.3 and (4.14)

$$\begin{aligned} p^{*1}(\widehat{\Gamma}(t)) = &\int_{\widehat{\Gamma}(t)}^{T+M} A_t(\eta^*(s),\xi^*(s))^\top p^{*2}(s)d\eta^*(s) - \int_{\widehat{\Gamma}(t)}^{T+M} q^{*1}(s)d\widehat{W}(\eta^*(s)) \\ &+ \int_{\widehat{\Gamma}(t)}^{T+M} \sum_{j=1}^m D_{jt}(\eta^*(s),\xi^*(s))^\top q_j^{*2}(s)d\eta^*(s) \\ &+ \int_{\widehat{\Gamma}(t)}^{T+M} p^{*2}(s)^\top B_t(\eta^*(s))\alpha^*(s)\theta^*(s)ds. \end{aligned} \tag{5.10}$$

Except for the last term, the same reasoning establishes

$$p^{*1}(\widehat{\Gamma}(t)) = \int_t^T A_t(s,\widehat{x}(s))^\top p^{*2}(\widehat{\Gamma}(s))ds + \int_t^T \sum_{j=1}^m D_{jt}(s,\widehat{x}(s))^\top q_j^{*2}(\widehat{\Gamma}(s))ds$$
$$- \int_t^T q^{*1}(\widehat{\Gamma}(s))d\widehat{W}(s) + \int_{\widehat{\Gamma}(t)}^{\widehat{\Gamma}(T)} p^{*2}(s)^\top B_t(\eta^*(s))\alpha^*(s)\theta^*(s)ds. \tag{5.11}$$

Note from (5.5) that $(\forall t \in [\widehat{\Gamma}(\tau_i-),\widehat{\Gamma}(\tau_i)])\ p^{*2}(t)$ is constant $\widehat{P}$-a.s. on the set $\{\tau_i \le T\}$, and so $(\forall t \in [0,T+M])\ p^{*2}(t) = p^{*2}(\widehat{\Gamma}(\eta^*(t)))$. Consequently, combining the previous equality and (3.6), the last term of (5.11) becomes

$$\int_{\widehat{\Gamma}(t)}^{\widehat{\Gamma}(T)} p^{*2}(s)^\top B_t(\eta^*(s))\alpha^*(s)\theta^*(s)ds = \int_{\widehat{\Gamma}(t)}^{\widehat{\Gamma}(T)} p^{*2}(\widehat{\Gamma}(\eta^*(s)))^\top B_t(\eta^*(s))\widehat{u}(\eta^*(s))d\widetilde{v}(s),$$

where $\widetilde{v}(t) = \int_0^t \theta^*(s)ds$.

Now using item (55.2) in Theorem 55 in [13, p. 132], it follows that

$$\int_{\widehat{\Gamma}(t)}^{\widehat{\Gamma}(T)} p^{*2}(s)^\top B_t(\eta^*(s))\alpha^*(s)\theta^*(s)ds = \int_{]t,T]} p^{*2}(\widehat{\Gamma}(s))^\top B_t(s)\widehat{u}(s)d\widetilde{v}(\widehat{\Gamma}(s)). \tag{5.12}$$

However, $\widehat{v}(t) = \int_0^{\widehat{\Gamma}_t} \theta^*(s)ds = \widetilde{v}(\widehat{\Gamma}(t))$ (see (3.13)). Consequently, combining (5.12) and (5.11) gives

$$p^{*1}(\widehat{\Gamma}(t)) = \int_t^T A_t(s,\widehat{x}(s))^\top p^{*2}(\widehat{\Gamma}(s))ds + \int_t^T \sum_{j=1}^m D_{jt}(s,\widehat{x}(s))^\top q_j^{*2}(\widehat{\Gamma}(s))ds$$
$$- \int_t^T q^{*1}(\widehat{\Gamma}(s))d\widehat{W}(s) + \int_{]t,T]} p^{*2}(\widehat{\Gamma}(s))^\top B_t(s)\widehat{u}(s)d\widehat{v}(s). \tag{5.13}$$

In conclusion, from (5.7), (5.8), (5.9), and (5.13), we obtain that

$$\Big(\big(\{p^{*i}(\widehat{\Gamma}(t))\},\{q^{*i}(\widehat{\Gamma}(t))\}\big)_{i\in\mathbb{N}_3},\{P(\widehat{\Gamma}(t))\},\big(\{Q^{*j}(\widehat{\Gamma}(t))\}\big)_{j\in\mathbb{N}_m}\Big),$$

the adjoint variables associated with the control $\widehat{C}$. By linearity, the uniqueness is easily obtained for $(\{\widehat{P}(t)\},(\{\widehat{Q}^j(t)\})_{j\in\mathbb{N}_m})$, and $(\{\widehat{p}^2(t)\},\{\widehat{q}^2(t)\})$ implying the uniqueness for $(\{\widehat{p}^1(t)\},\{\widehat{q}^1(t)\})$, and $(\{\widehat{p}^3(t)\},\{\widehat{q}^3(t)\})$, which shows the result. □

We present now some technical results that we will need to obtain the maximum principle.

LEMMA 5.3. *For $\psi \in \mathbb{R}^3$, and $(\alpha,\theta) \in B_1(K)\times[0,1]$, write*

$$L(t,\alpha,\theta) = H(\eta^*(t),\xi^*(t),\alpha,\theta,p^{*1}(t),p^{*2}(t),p^{*3}(t),r^*(t),P^*(t),\psi)$$
$$- H(\eta^*(t),\xi^*(t),\alpha^*(t),\theta^*(t),p^{*1}(t),p^{*2}(t),p^{*3}(t),r^*(t),P^*(t),\psi). \tag{5.14}$$

Then, $\forall t \in [\widehat{\Gamma}(\tau_i-), \widehat{\Gamma}(\tau_i)]$,

$$
\begin{aligned}
L(t,\alpha,\theta) &= \psi_2\big[B(\tau_i)(\theta\alpha - \widehat{u}(\tau_i))\big]^\top \hat{p}^2(\tau_i) + \psi_2(\theta|\alpha| - |\widehat{u}(\tau_i)|)\hat{p}^3(\tau_i) \\
&\quad + (1-\theta)\Bigg\{-\psi_1 - 2T\psi_3 + \psi_2\Big[\hat{p}^1(\tau_i-) - [B(\tau_i)\widehat{u}(\tau_i)]^\top (t - \widehat{\Gamma}(\tau_i-))\hat{p}^2(\tau_i) \\
&\quad + A\Big(\tau_i, \widehat{x}(\tau_i-) + B(\tau_i)\widehat{u}(\tau_i)(t-\widehat{\Gamma}(\tau_i-))\Big)^\top \hat{p}^2(\tau_i) \\
&\quad + \frac{1}{2}\operatorname{tr}\Big[D\Big(\tau_i, \widehat{x}(\tau_i-) + B(\tau_i)\widehat{u}(\tau_i)(t-\widehat{\Gamma}(\tau_i-))\Big)^\top \widehat{P}(\tau_i) \\
&\quad \times D\Big(\tau_i, \widehat{x}(\tau_i-) + B(\tau_i)\widehat{u}(\tau_i)(t-\widehat{\Gamma}(\tau_i-))\Big)\Big]\Big]\Bigg\}
\end{aligned}
$$

$\widehat{P}$*-a.s. on* $\{\tau_i \le T\}$.

Proof. Clearly, we have $\widehat{\Gamma}(\tau_i-) < \widehat{\Gamma}(\tau_i)$ $\widehat{P}$-a.s. on $\{\tau_i \le T\}$. Since $\{\eta^*(t)\}$ is the right inverse of $\{\widehat{\Gamma}(t)\}$, it gives that

$$
(\forall t \in [\widehat{\Gamma}(\tau_i-), \widehat{\Gamma}(\tau_i)]), \quad \eta^*(t) = \tau_i \quad \widehat{P}\text{-a.s. on } \{\tau_i \le T\}, \tag{5.15}
$$

and so with (3.6) $(\forall t \in [\widehat{\Gamma}(\tau_i-), \widehat{\Gamma}(\tau_i)])$,

$$
\theta^*(t) = \widehat{z}(\tau_i) \quad \text{and} \quad \alpha^*(t) = \widehat{u}(\tau_i) \quad \widehat{P}\text{-a.s. on } \{\tau_i \le T\}. \tag{5.16}
$$

Therefore, using (3.7)

$$
(\forall t \in [\widehat{\Gamma}(\tau_i-), \widehat{\Gamma}(\tau_i)]), \quad \theta^*(t) = 1 \quad \widehat{P}\text{-a.s. on } \{\tau_i \le T\}, \tag{5.17}
$$

and by (4.19)

$$
(\forall t \in [\widehat{\Gamma}(\tau_i-), \widehat{\Gamma}(\tau_i)]), \quad r^*(t) = 0 \quad \widehat{P}\text{-a.s. on } \{\tau_i \le T\}. \tag{5.18}
$$

Combining Lemma 3.8 and (5.15) we have $(\forall t \in [\widehat{\Gamma}(\tau_i-), \widehat{\Gamma}(\tau_i)])$

$$
\int_{\widehat{\Gamma}(\tau_i-)}^{t} q(s)dW(\eta^*(s)) = 0 \quad \widehat{P}\text{-a.s. on } \{\tau_i \le T\}. \tag{5.19}
$$

Write $p^*(t)$ in the form

$$
p^*(t) = \begin{pmatrix} p^{*1}(t) \\ p^{*2}(t) \\ p^{*3}(t) \end{pmatrix},
$$

where $p^{*1}(t) \in \mathbb{R}$, $p^{*2}(t) \in \mathbb{R}^n$, and $p^{*3}(t) \in \mathbb{R}$.

For $\theta = 1$, simple calculations give that $\forall(\eta,\xi,\alpha,p,q) \in \mathbb{R}\times\mathbb{R}^n \times B_1(K) \times \mathbb{R}^{2+n} \times \mathbb{R}^{(2+n)\times m}$

$$
\mathcal{H}_x(\eta,\xi,\alpha,\theta,p,q) = 0 \quad \text{and} \quad \mathcal{H}_t(\eta,\xi,\alpha,\theta,p,q) = \Big(0|\big[B_t(\eta)\alpha\big]^\top|0\Big)p.
$$

It follows from (4.14), (5.15)–(5.17), and (5.19) that $\widehat{P}$-a.s. surely on $\{\tau_i \le T\}$, $\forall t$ in $[\widehat{\Gamma}(\tau_i-), \widehat{\Gamma}(\tau_i)]$,

$$
p^*(t) = \begin{pmatrix} p^{*1}(\widehat{\Gamma}(\tau_i-)) - \displaystyle\int_{\widehat{\Gamma}(\tau_i-)}^{t} \big[B_t(\tau_i)\widehat{u}(\tau_i)\big]^\top p^{*2}(s)ds \\ p^{*2}(\widehat{\Gamma}(\tau_i)) \\ p^{*3}(\widehat{\Gamma}(\tau_i)) \end{pmatrix}
$$

and so

$$p^*(t) = \begin{pmatrix} \hat{p}^1(\tau_i-) - \left[B_t(\tau_i)\widehat{u}(\tau_i)\right]^\top \hat{p}^2(\tau_i)(t-\widehat{\Gamma}(\tau_i-)) \\ \hat{p}^2(\tau_i) \\ \hat{p}^3(\tau_i) \end{pmatrix}, \tag{5.20}$$

by using the definition of $\hat{p}(t)$.

Using similar arguments, we obtain that $\widehat{P}$-a.s. on $\{\tau_i \leq T\}$

$$(\forall t \in [\widehat{\Gamma}(\tau_i-), \widehat{\Gamma}(\tau_i)]), \quad P^*(t) = P^*(\widehat{\Gamma}(\tau_i)) = \widehat{P}(\tau_i) \tag{5.21}$$

and from (3.10) and (3.12)

$$\begin{aligned} (\forall t \in [\widehat{\Gamma}(\tau_i-), \widehat{\Gamma}(\tau_i)]), \quad \xi^*(t) &= \xi^*(\widehat{\Gamma}(\tau_i-)) + \int_{\widehat{\Gamma}(\tau_i-)}^t \theta^*(s)B(\eta^*(s))\alpha^*(s)ds \\ &= \widehat{x}(\tau_i-) + B(\tau_i)\widehat{u}(\tau_i)\big(t-\widehat{\Gamma}(\tau_i-)\big). \end{aligned} \tag{5.22}$$

Therefore, combining (1.3), (1.5), (5.15), and (5.18), we obtain that $\forall t$ in $[\widehat{\Gamma}(\tau_i-), \widehat{\Gamma}(\tau_i)])$,

$$\begin{aligned} H(\eta^*(t), \xi^*(t), \alpha, \theta, p^{*1}(t), p^{*2}(t), p^{*3}(t), r^*(t), P^*(t), \psi) &= (1-\theta)\Bigg\{-\psi_1 - 2T\psi_3 \\ &+ \psi_2\Big[p^{*1}(t) + A\big(\tau_i, \xi^*(t)\big)^\top p^{*2}(t) + \frac{1}{2}\operatorname{tr}\Big[D\big(\tau_i, \xi^*(t)\big)^\top P^*(t) D\big(\tau_i, \xi^*(t)\big)\Big]\Big]\Bigg\} \\ &+ \psi_2\theta\big[B(\tau_i)\alpha\big]^\top p^{*2}(t) + \psi_2\theta|\alpha|p^{*3}(t) \end{aligned}$$

$\widehat{P}$-a.s. on $\{\tau_i \leq T\}$. Finally, the result follows using the previous equation and (5.14), (5.20), (5.21), and (5.22). □

PROPOSITION 5.4. *Let $\psi \in S_1(\mathbb{R}^3)$ such that the variational inequality* (4.18) *is satisfied. Then, for $(\alpha, \theta) \in B_1(K) \times [0,1]$*

$$(\forall t \in [\widehat{\Gamma}(\tau_i-), \widehat{\Gamma}(\tau_i)]), \quad L(t, \alpha, \theta) \leq 0 \quad \widehat{P}\text{-a.s. on } \{\tau_i \leq T\}. \tag{5.23}$$

Proof. From Lemma 5.3, it follows that $L(t, \alpha, \theta)$ is continuous on $[\widehat{\Gamma}(\tau_i-), \widehat{\Gamma}(\tau_i)]$ $\widehat{P}$-a.s. on $\{\tau_i \leq T\}$. However, using Fubini's theorem and Theorem 4.5, we obtain that

$$\int_{\widehat{\Gamma}(\tau_i-)}^{\widehat{\Gamma}(\tau_i)} I_{\{(t,\widehat{\omega}) \in [0,T+M] \times \widehat{\Omega} : L(t,\alpha,\theta) > 0\}}(s, \widehat{\omega})ds = 0$$

$\widehat{P}$-a.s. on $\{\tau_i \leq T\}$, giving the result. □

COROLLARY 5.5. *Let $\psi \in S_1(\mathbb{R}^3)$ such that the variational inequality* (4.18) *is satisfied. Then, for $(\alpha, \theta) \in B_1(K) \times [0,1]$,*

$$L(\widehat{\Gamma}(t), \alpha, \theta) \leq 0 \quad \mathcal{M}_{\widehat{\Gamma}}\text{-a.s. on } [0,T] \times \widehat{\Omega}. \tag{5.24}$$

Proof. Write

$$\begin{aligned} N(\alpha, \theta) &\doteq \{(t, \widehat{\omega}) \in [0, T+M] \times \widehat{\Omega} : L(t, \alpha, \theta) > 0\}, \\ \widetilde{N}(\alpha, \theta) &\doteq \{(t, \widehat{\omega}) \in [0,T] \times \widehat{\Omega} : (\widehat{\Gamma}(t), \omega) \in N(\alpha, \theta)\}. \end{aligned}$$

Then

$$\begin{aligned}\mathcal{M}_{\widehat{\Gamma}}(\widetilde{N}(\alpha,\theta)) &= E_{\widehat{P}}\left[\int_{[0,T]} I_{\widetilde{N}(\alpha,\theta)}(s,\widehat{\omega})d\widehat{\Gamma}(s)\right]\\ &= E_{\widehat{P}}\left[\int_0^{\widehat{\Gamma}(T)} I_{\widetilde{N}(\alpha,\theta)}(\eta^*(s),\widehat{\omega})ds\right]\\ &= \lambda\otimes\widehat{P}(N^*(\alpha,\theta)),\end{aligned} \tag{5.25}$$

where $N^*(\alpha,\theta)=\{(t,\widehat{\omega})\in[0,T+M]\times\widehat{\Omega}:(\widehat{\Gamma}(\eta^*(t)),\omega)\in N(\alpha,\theta)\}$.

Now, if $(t,\widehat{\omega})\in[\overset{\infty}{\underset{i=1}{\cup}}[\![\widehat{\Gamma}(\tau_i-),\widehat{\Gamma}(\tau_i)]\!]]^c$, then $\widehat{\Gamma}(\eta^*(t))=t$. Consequently,

$$N^*(\alpha,\theta)\cap\left[\overset{\infty}{\underset{i=1}{\cup}}[\![\widehat{\Gamma}(\tau_i-),\widehat{\Gamma}(\tau_i)]\!]\right]^c\subset N(\alpha,\theta)\cap\left[\overset{\infty}{\underset{i=1}{\cup}}[\![\widehat{\Gamma}(\tau_i-),\widehat{\Gamma}(\tau_i)]\!]\right]^c.$$

However, from Theorem 4.5, $\lambda\otimes\widehat{P}(N(\alpha,\theta))=0$. Therefore,

$$\lambda\otimes\widehat{P}(N^*(\alpha,\theta))=\lambda\otimes\widehat{P}\Big(N^*(\alpha,\theta)\cap\overset{\infty}{\underset{i=1}{\cup}}[\![\widehat{\Gamma}(\tau_i-),\widehat{\Gamma}(\tau_i)]\!]\Big). \tag{5.26}$$

Furthermore, writing π for the projection of $[0,T+M]\times\widehat{\Omega}$ to $\widehat{\Omega}$, we have

$$\pi\Big(N^*(\alpha,\theta)\cap[\![\widehat{\Gamma}(\tau_i-),\widehat{\Gamma}(\tau_i)]\!]\Big)\subset\{\tau_i\le T\}\cap\{\widehat{\omega}\in\widehat{\Omega}:L(\widehat{\Gamma}(\tau_i),\alpha,\theta)>0\}.$$

From Proposition 5.4, it follows that $\widehat{P}(\{\tau_i\le T\}\cap\{\widehat{\omega}\in\widehat{\Omega}:L(\widehat{\Gamma}(\tau_i),\alpha,\theta)>0\})=0$, and so $\lambda\otimes\widehat{P}(N^*(\alpha,\theta)\cap\cup_{i=1}^{\infty}[\![\widehat{\Gamma}(\tau_i-),\widehat{\Gamma}(\tau_i)]\!])=0$. Using (5.26), we have $\lambda\otimes\widehat{P}(N^*(\alpha,\theta))=0$, and from (5.25), it follows that $\mathcal{M}_{\widehat{\Gamma}}(\widetilde{N}(\alpha,\theta))=0$, giving the result. □

LEMMA 5.6. *Let $(\Omega,\mathcal{F},P)$ be a complete probability space with a right continuous complete filtration $\{\mathcal{F}_t\}$ and let $\{v(t)\}$ be an $\mathbb{R}_+$-valued,* corlol, *$\{\mathcal{F}_t\}$-progressively measurable increasing process. Define*

$$v'(t)=\begin{cases}\overline{\lim}_{\substack{\epsilon\to0\\ \epsilon>0}}\dfrac{v(t+\epsilon)-v(t-\epsilon)}{2\epsilon} & \text{if the limit exists in } \mathbb{R},\\ 0 & \text{otherwise.}\end{cases}$$

Then $\{v'(t)\}$ is an $\mathbb{R}_+$-valued, $\{\mathcal{F}_t\}$-progressively measurable process.

Proof. Clearly, the $\mathbb{R}_+$-valued process $\{v'(t)\}$ exists. By using the result 14 in [12, page 141], $\{v'(t)\}$ is an $\{\mathcal{F}_t\}$-progressively measurable process. □

LEMMA 5.7. *Let $(\Omega,\mathcal{F},P)$ be a complete probability space with a right continuous complete filtration $\{\mathcal{F}_t\}$ and let $\{v(t)\}$ be an $\mathbb{R}_+$-valued,* corlol, *$\{\mathcal{F}_t\}$-progressively measurable increasing process such that $v(T)\le M$. Write $\Gamma(t)=t+v(t)$ and let $\{z(t)\}$ be an $\{\mathcal{F}_t\}$-progressively measurable process such that $v(t)=\int_{[0,t]}z(s)d\Gamma(s)$. Then $z(t)=1$ $\mathcal{M}_{v^s}$-a.s. on $[0,T]\times\Omega$, and $z(t)=\frac{v'(t)}{1+v'(t)}$ $\mathcal{M}_{v^{ac}}$-a.s. on $[0,T]\times\Omega$.*

Proof. Clearly, we have $(\forall A\in\mathcal{B}([0,T+M]))$ $dv^{ac}(A)=\int_A z(s)d\Gamma^{ac}(s)$, and so $\int_A v'(s)ds=\int_A z(s)\Gamma'(s)ds$. Now using the definition of $\{\Gamma(t)\}$ the last part of the result follows. Denote by F a set such that $\lambda\otimes P(F)=0$ and $(\forall A\in\mathcal{B}([0,T])\otimes\mathcal{F}_T)$ $\mathcal{M}_{\Gamma^s}(A)=\mathcal{M}_{\Gamma}(A\cap F)$. Note that $\mathcal{M}_{v^s}=\mathcal{M}_{\Gamma^s}$. Consequently, $\forall A\in F$,

$$E_P\left[\int_{[0,T]}I_A z(s)d\Gamma(s)\right]=E_P\left[\int_{[0,T]}I_A d\Gamma(s)\right],$$

and so $z(t)=1$ $\mathcal{M}_{v^s}$-a.s. on $[0,T]\times\Omega$, showing the last result. □

The next proposition presents some relations between the optimal singular control $\widetilde{C}$ and $\widehat{C}$. This result is important, as it gives the full generality to our maximum principle.

PROPOSITION 5.8. *Assume the existence of an optimal singular control denoted by*

$$\widetilde{C} \doteq \left(\widehat{\Omega}, \widehat{\mathcal{F}}, \widehat{P}, \{\widehat{\mathcal{F}}_t\}, \{\widetilde{u}(t), \widetilde{v}(t)\}, \{\widehat{W}(t)\}, \{\widetilde{x}(t)\}\right)$$

such that $\{\widetilde{u}(t), \widetilde{v}(t)\}$ *is* $\{\widehat{\mathcal{F}}_t^{\widehat{W}}\}$*-progressively measurable.*

Then the optimal control

$$\widehat{C} \doteq \left(\widehat{\Omega}, \widehat{\mathcal{F}}, \widehat{P}, \{\widehat{\mathcal{F}}_t\}, \{\widehat{u}(t), \widehat{v}(t)\}, \{\widehat{W}(t)\}, \{\widetilde{x}(t)\}\right)$$

defined by (3.2) *and* (3.3) *is such that on the filtered probability space* $(\widehat{\Omega}, \widehat{\mathcal{F}}, \widehat{P}, \{\widehat{\mathcal{F}}_t\})$ *the processes* $\{\widetilde{x}(t)\}$ *and* $\{\widehat{x}(t)\}$ *are indistinguishable, and*

$$\mathcal{M}_{\widetilde{v}^s} \ll \mathcal{M}_{\widehat{v}^s}, \quad \mathcal{M}_{\widetilde{v}^{ac}} = \mathcal{M}_{\widehat{v}^{ac}}, \tag{5.27}$$

$$\widetilde{u}(t) = \widehat{u}(t), \quad \textit{and} \quad \widetilde{v}(t) = \widehat{v}(t) \quad \mathcal{M}_{\widetilde{v}^{ac}}\textit{-a.s. on } [0,T] \times \widehat{\Omega}. \tag{5.28}$$

The adjoint variables $((\{\widetilde{p}^i(t)\}, \{\widetilde{q}^i(t)\})_{i\in\mathbb{N}_3}, \{\widetilde{P}(t)\}, (\{\widetilde{Q}^j(t)\})_{j\in\mathbb{N}_m})$ *associated with* $\widetilde{C}$ *exist and are unique. Moreover, for* $i \in \mathbb{N}_3$, $j \in \mathbb{N}_m$,

$$\widetilde{p}^i(t) = \hat{p}^i(t), \quad \widetilde{q}^i(t) = \hat{q}^i(t), \quad \widetilde{P}(t) = \widehat{P}(t), \quad \textit{and} \quad \widetilde{Q}^j(t) = \widehat{Q}^j(t), \tag{5.29}$$

where $((\{\hat{p}^i(t)\}, \{\hat{q}^i(t)\})_{i\in\mathbb{N}_3}, \{\widehat{P}(t)\}, (\{\widehat{Q}^j(t)\})_{j\in\mathbb{N}_m})$ *are the adjoint variables associated with* $\widehat{C}$.

Proof. From the definition of $\{\widehat{u}(t)\}$ and $\{\widehat{v}(t)\}$ (see (3.2) and (3.3)), we obtain (5.28) and the fact that $\{\widehat{x}(t)\}$ and $\{\widetilde{x}(t)\}$ are indistinguishable. Moreover ($\forall t \in [0,T]$), $\widehat{v}(t) \geq \widetilde{v}(t)$ and $\widehat{v}^{ac}(t) = \widetilde{v}^{ac}(t)$, giving (5.27). Theorem 5.2 shows the existence of the adjoint variables $((\hat{p}^i(t), \hat{q}^i(t))_{i\in\mathbb{N}_3}, \widehat{P}(t), (\widehat{Q}^j(t))_{j\in\mathbb{N}_m})$ associated with $\widehat{C}$. Now (3.4) gives the existence of the adjoint variables $((\widetilde{p}^i(t), \widetilde{q}^i(t))_{i\in\mathbb{N}_3}, \widetilde{P}(t), (\widetilde{Q}^j(t))_{j\in\mathbb{N}_m})$ associated with $\widetilde{C}$ satisfying (5.29). As in the proof of Theorem 5.2, the uniqueness follows from Theorem 3.1 in [37], showing the result. □

We can now establish a necessary condition for any control $\widetilde{C} \in \mathfrak{C}^a$ to be optimal. In fact similarly to the maximum principle for nonsingular control problem (see, for example, [38, 41] and the references therein), we show that if a control $\widetilde{C} = (\widehat{\Omega}, \widehat{\mathcal{F}}, \widehat{P}, \{\widehat{\mathcal{F}}_t\}, \{\widetilde{u}(t), \widetilde{v}(t)\}, \{\widehat{W}(t)\}, \{\widetilde{x}(t)\})$ is optimal, it maximizes a certain Hamiltonian a.s. with respect to the measure of Doleans-Dade generated by the optimal control $\{\widetilde{v}(t)\}$. This last property, which represents an important difference from the classical (nonsingular) control problem where the optimal control maximizes the Hamiltonian a.s. surely with respect to the product measure of the Lebesgue measure and the underlying probability, is already present in the expression of the maximum principle derived by Cadenillas and Haussmann [8] (see the last term of the inequality (66) on page 227 in [8]). Here we present a maximum principle given in terms of three variational inequalities but not in the integral from as in the work by Cadenillas and Haussmann [8]. The first two variational inequalities result from a time change of the variational inequality of the auxiliary control problem. The first one is given with respect to the measure of Doleans-Dade generated by the absolutely continuous

part of $\{\widetilde{v}(t)\}$ (see (5.30)). Note that it does not depend directly on $\{\widetilde{v}(t)\}$ but on the derivative $\frac{d\widetilde{v}}{dt}(t)$. The second one (see (5.32)) is given with respect to the measure of Doleans-Dade generated by the singular part of $\{\widetilde{v}_t\}$. The last inequality can be interpreted as a necessary condition for the size of the jumps of $\{\widetilde{v}_t\}$ (see (5.33)). It is different from the first two ones because it is not obtained from a time change of the variational inequality of the auxiliary control problem (see the proof of the next theorem).

THEOREM 5.9. *Assume the existence of an optimal singular control denoted by*

$$\widetilde{C} \doteq \Big(\widehat{\Omega}, \widehat{\mathcal{F}}, \widehat{P}, \{\widehat{\mathcal{F}}_t\}, \{\widetilde{u}(t), \widetilde{v}(t)\}, \{\widehat{W}(t)\}, \{\widetilde{x}(t)\}\Big)$$

such that $\{\widetilde{u}(t), \widetilde{v}(t)\}$ *is* $\{\widehat{\mathcal{F}}_t^{\widehat{W}}\}$*-progressively measurable. Denote by* $\{\widetilde{\tau}_i\}_{i\in\mathbb{N}^*}$ *the sequence of* $\{\widehat{\mathcal{F}}_t^{\widehat{W}}\}$*-stopping times which exhausts the jumps of* $\{\widetilde{v}(t)\}$*. Then there exist* $\psi \in S_1(\mathbb{R}^3)$ *such that* $\forall (u,z) \in B_1(K)\times[0,1]$

$$\begin{aligned}
&[\widetilde{z}(t)-z]\Big\{-\psi_1 - 2T\psi_3 + \psi_2\Big[\widetilde{p}^1(t) + \frac{1}{2}\operatorname{tr}\big[D(t,\widetilde{x}(t))^\top \widetilde{P}(t) D(t,\widetilde{x}(t))\big] \\
&\qquad + A(t,\widetilde{x}(t))^\top \widetilde{p}^2(t)\Big]\Big\} \\
&\qquad + \psi_2\Big[\big[B(t)[zu-\widetilde{z}(t)\widetilde{u}(t)]\big]^\top \widetilde{p}^2(t) + [z|u| - \widetilde{z}(t)|\widetilde{u}(t)|]\widetilde{p}^3(t) \\
&\qquad + \operatorname{tr}\big[D(t,\widetilde{x}(t))^\top \widetilde{r}(t)\big]\Big(\sqrt{1-z} - \sqrt{1-\widetilde{z}(t)}\Big)\Big] \le 0
\end{aligned} \tag{5.30}$$

$\mathcal{M}_{\widetilde{v}^{ac}}$*-a.s. on* $[0,T]\times\widehat{\Omega}$*, where*

$$\widetilde{r}(t) \doteq \Big[\widetilde{q}^2(t) - \widetilde{P}(t)D(t,\widetilde{x}(t))\Big]\sqrt{1-\widetilde{z}(t)}, \qquad \widetilde{z}(t) \doteq \frac{\widetilde{v}'(t)}{1+\widetilde{v}'(t)}, \tag{5.31}$$

and

$$\begin{aligned}
&\psi_2\Big[[zu-\widetilde{u}(t)]^\top B(t)^\top \widetilde{p}^2(t) + [z|u| - |\widetilde{u}(t)|]\widetilde{p}^3(t)\Big] + (1-z)\Big\{-\psi_1 - 2T\psi_3 \\
&\quad + \psi_2\Big[\widetilde{p}^1(t) + \frac{1}{2}\operatorname{tr}\Big[D(t,\widetilde{x}(t))^\top \widetilde{P}(t) D(t,\widetilde{x}(t))\Big] + A(t,\widetilde{x}(t))^\top \widetilde{p}^2(t)\Big]\Big\} \le 0
\end{aligned} \tag{5.32}$$

$\mathcal{M}_{\widetilde{v}^s}$*-a.s. on* $[0,T]\times\widehat{\Omega}$*, and* $\forall i\in\mathbb{N}$ *and* $\gamma\in[0,1]$

$$\begin{aligned}
&\psi_2\Big[\big[B(\widetilde{\tau}_i)(zu-\widetilde{u}(\widetilde{\tau}_i))\big]^\top \widetilde{p}^2(\widetilde{\tau}_i) + (z|u| - |\widetilde{u}(\widetilde{\tau}_i)|)\widetilde{p}^3(\widetilde{\tau}_i)\Big] + (1-z)\Big\{-\psi_1 - 2T\psi_3 \\
&\qquad + \psi_2\Big[\widetilde{p}^1(\widetilde{\tau}_i-) - \gamma\Big[B_t(\widetilde{\tau}_i)\widetilde{u}(\widetilde{\tau}_i)\Delta\widetilde{v}(\widetilde{\tau}_i)\Big]^\top \widetilde{p}^2(\widetilde{\tau}_i) \\
&\qquad + A\Big(\widetilde{\tau}_i, \widetilde{x}(\widetilde{\tau}_i-) + \gamma B(\widetilde{\tau}_i)\widetilde{u}(\widetilde{\tau}_i)\Delta\widetilde{v}(\widetilde{\tau}_i)\Big)^\top \widetilde{p}^2(\widetilde{\tau}_i) \\
&\qquad + \frac{1}{2}\operatorname{tr}\Big[D\Big(\widetilde{\tau}_i, \widetilde{x}(\widetilde{\tau}_i-) + \gamma B(\widetilde{\tau}_i)\widetilde{u}(\widetilde{\tau}_i)\Delta\widetilde{v}(\widetilde{\tau}_i)\Big)^\top \widetilde{P}(\widetilde{\tau}_i) \\
&\qquad \times D\Big(\widetilde{\tau}_i, \widetilde{x}(\widetilde{\tau}_i-) + \gamma B(\widetilde{\tau}_i)\widetilde{u}(\widetilde{\tau}_i)\Delta\widetilde{v}(\widetilde{\tau}_i)\Big)\Big]\Big]\Big\} \le 0
\end{aligned} \tag{5.33}$$

$\widehat{P}$-a.s. on $\{\widetilde{\tau}_i \leq T\}$, where $((\{\widetilde{p}^i(t)\}, \{\widetilde{q}^i(t)\})_{i\in\mathbb{N}_3}, \{\widetilde{P}(t)\}, (\{\widetilde{Q}^j(t)\})_{j\in\mathbb{N}_m})$ are the adjoint variables associated with $\widetilde{C}$.

Proof. From Proposition 3.2, it follows that the control $\widehat{C}$ defined by (3.1), (3.2), and (3.3) is such that $\widehat{v}(T) = M$. Therefore, we can apply the results of this section to $\widehat{C}$ and in particular Corollary 5.5. The stochastic maximum principle can now be expressed in the following form: there exist $\psi \in S_1(\mathbb{R}^3)$ such that $\forall (u,z) \in B_1(K) \times [0,1]$

$$
\begin{aligned}
&H(\eta^*(\widehat{\Gamma}(t)), \xi^*(\widehat{\Gamma}(t)), \alpha, \theta, p^{*1}(\widehat{\Gamma}(t)), p^{*2}(\widehat{\Gamma}(t)), p^{*3}(\widehat{\Gamma}(t)), r^*(\widehat{\Gamma}(t)), P^*(\widehat{\Gamma}(t)), \psi)\\
&-H(\eta^*(\widehat{\Gamma}(t)), \xi^*(\widehat{\Gamma}(t)), \alpha^*(\widehat{\Gamma}(t)), \theta^*(\widehat{\Gamma}(t)), p^{*1}(\widehat{\Gamma}(t)), p^{*2}(\widehat{\Gamma}(t)), p^{*3}(\widehat{\Gamma}(t)), r^*(\widehat{\Gamma}(t)),\\
&P^*(\widehat{\Gamma}(t)), \psi) \leq 0 \qquad (5.34)
\end{aligned}
$$

$\mathcal{M}_{\widehat{\Gamma}}$-a.s. on $[0,T] \times \widehat{\Omega}$. Since $\{\eta^*(t)\}$ is the right inverse of $\{\widehat{\Gamma}(t)\}$ which is strictly increasing, we have that $\eta^*(\widehat{\Gamma}(t)) = t$. Moreover, combining (3.6), (3.12), (4.19), and the definition of $\{\hat{p}(t)\}$, $\{\hat{q}(t)\}$, $\{\widehat{P}(t)\}$ (see (5.4)), we obtain that $r^*(\widehat{\Gamma}(t)) = \hat{q}^2(t) - \widehat{P}(t)D(t,\widehat{x}(t))\sqrt{1-\widehat{z}(t)}$. Defining $\hat{r}(t) = r^*(\widehat{\Gamma}(t))$ it follows that $(\forall (u,z) \in B_1(K) \times [0,1])$

$$
\begin{aligned}
&H(t, \widehat{x}(t), u, z, \hat{p}^1(t), \hat{p}^2(t), \hat{p}^3(t), \hat{r}(t), \widehat{P}(t), \psi)\\
&\qquad - H(t, \widehat{x}(t), \widehat{u}(t), \widehat{z}(t), \hat{p}^1(t), \hat{p}^2(t), \hat{p}^3(t), \hat{r}(t), \widehat{P}(t), \psi) \leq 0
\end{aligned}
$$

$\mathcal{M}_{\widehat{\Gamma}}$-a.s. on $[0,T] \times \widehat{\Omega}$.

From the definition of $\{\widehat{\Gamma}(t)\}$, we obtain that $\mathcal{M}_{\widehat{v}} \ll \mathcal{M}_{\widehat{\Gamma}}$, and so by Proposition 5.8 it follows that $(\forall (u,z) \in B_1(K) \times [0,1])$

$$
\begin{aligned}
&H(t, \widetilde{x}(t), u, z, \widetilde{p}^1(t), \widetilde{p}^2(t), \widetilde{p}^3(t), \hat{r}(t), \widetilde{P}(t), \psi)\\
&\qquad - H(t, \widetilde{x}(t), \widetilde{u}(t), \widetilde{z}(t), \widetilde{p}^1(t), \widetilde{p}^2(t), \widetilde{p}^3(t), \hat{r}(t), \widetilde{P}(t), \psi) \leq 0 \qquad (5.35)
\end{aligned}
$$

$\mathcal{M}_{\widehat{v}}$-a.s. on $[0,T] \times \widehat{\Omega}$.

From (3.4), it follows that $\widetilde{v}'(t) = \widetilde{v}'(t)$ $\mathcal{M}_{\widetilde{v}^{ac}}$-a.s. on $[0,T] \times \widehat{\Omega}$. Combining Lemma 5.7 and (5.27) and (5.28), we have that $\widehat{z}(t) = \frac{\widetilde{v}'(t)}{1+\widetilde{v}'(t)}$ $\mathcal{M}_{\widetilde{v}^{ac}}$-a.s. on $[0,T] \times \widehat{\Omega}$, and according to the definition of $\widetilde{r}(t)$ (see (5.31)), it implies that $\hat{r}(t) = \widetilde{r}(t)$ $\mathcal{M}_{\widetilde{v}^{ac}}$-a.s. on $[0,T] \times \widehat{\Omega}$. Therefore, we obtain

$$
\begin{aligned}
&H(t, \widetilde{x}(t), u, z, \widetilde{p}^1(t), \widetilde{p}^2(t), \widetilde{p}^3(t), \widetilde{r}(t), \widetilde{P}(t), \psi)\\
&\qquad - H(t, \widetilde{x}(t), \widetilde{u}(t), \widetilde{z}(t), \widetilde{p}^1(t), \widetilde{p}^2(t), \widetilde{p}^3(t), \widetilde{r}(t), \widetilde{P}(t), \psi) \leq 0
\end{aligned}
$$

$\mathcal{M}_{\widetilde{v}^{ac}}$-a.s. on $[0,T] \times \widehat{\Omega}$. With the definition of H (see (1.5)), simple calculations give the first inequality (5.30).

From Lemma 5.7, we have that $\widehat{z}(t) = 1$ and $\hat{r}(t) = 0$ $\mathcal{M}_{\widehat{v}^s}$-a.s. on $[0,T] \times \widehat{\Omega}$. Consequently, using (5.27), (5.35) reduces to $(\forall (u,z) \in B_1(K) \times [0,1])$

$$
\begin{aligned}
&\psi_2\Big[[zu - \widehat{u}(t)]^\top B(t)^\top \widetilde{p}^2(t) + [z|u| - |\widehat{u}(t)|]\widetilde{p}^3(t)\Big] + (1-z)\Big\{-\psi_1 - 2T\psi_3\\
&+ \psi_2\left[\widetilde{p}^1(t) + \frac{1}{2}\operatorname{tr}\big[D(t,\widetilde{x}(t))^\top \widetilde{P}(t) D(t,\widetilde{x}(t))\big] + A(t,\widetilde{x}(t))^\top \widetilde{p}^2(t)\right]\Big\} \leq 0 \qquad (5.36)
\end{aligned}
$$

$\mathcal{M}_{\widetilde{v}^s}$-a.s. on $[0,T]\times\widehat{\Omega}$. Since the left-hand side of the previous inequality is continuous in (z,u), there exists a set $\mathcal{V}\in\mathcal{B}([0,T])\otimes\widehat{\mathcal{F}}_T^{\widehat{W}}$ such that $\mathcal{M}_{\widetilde{v}^s}(\mathcal{V})=0$, and $\forall(t,\widehat{\omega})\in[0,T]\times\widehat{\Omega}-\mathcal{V}$,

$$\psi_2\Big[[zu-\widehat{u}(t)]^\top B(t)^\top\widetilde{p}^2(t)+[z|u|-|\widehat{u}(t)|]\widetilde{p}^3(t)\Big]+(1-z)\Big\{-\psi_1-2T\psi_3$$

$$+\psi_2\left[\widetilde{p}^1(t)+\frac{1}{2}\operatorname{tr}\Big[D(t,\widetilde{x}(t))^\top\widetilde{P}(t)D(t,\widetilde{x}(t))\Big]+A(t,\widetilde{x}(t))^\top\widetilde{p}^2(t)\right]\Big\}\le 0 \tag{5.37}$$

$\forall(u,z)\in B_1(K)\times[0,1]$.

From the definition of $\widehat{u}(t)$ (see (3.3)), we can write $\widehat{u}(t)=\widetilde{u}(t)\widetilde{c}(t)$, where $\widetilde{c}(t)=I_{[\![0,T[\![}+[\frac{\widetilde{v}(T)-\widetilde{v}(T-)}{M-\widetilde{v}(T-)}I_{[T,+\infty[\times\{\widetilde{v}(T)<M\}}+I_{[T,+\infty[\times\{\widetilde{v}(T)=M\}}]$.

Note that $0\le\widetilde{c}(t)\le 1$.

Consequently, from (5.37) we obtain

$$\psi_2\Big[[zu-\widetilde{c}(t)\widetilde{u}(t)]^\top B(t)^\top\widetilde{p}^2(t)+[z|u|-\widetilde{c}(t)|\widetilde{u}(t)|]\widetilde{p}^3(t)\Big]+(1-z)\Big\{-\psi_1-2T\psi_3$$

$$+\psi_2\left[\widetilde{p}^1(t)+\frac{1}{2}\operatorname{tr}\big[D(t,\widetilde{x}(t))^\top\widetilde{P}(t)D(t,\widetilde{x}(t))\big]+A(t,\widetilde{x}(t))^\top\widetilde{p}^2(t)\right]\Big\}\le 0 \tag{5.38}$$

$\forall(u,z)\in B_1(K)\times[0,1]$. Taking $z=1$ and $u=0$ in the previous inequality, it follows that

$$-\psi_2\widetilde{c}(t)\Big[\widetilde{u}(t)^\top B(t,\widetilde{x}(t))^\top\widetilde{p}^2(t)+|\widetilde{u}(t)|\widetilde{p}^3(t)\Big]\le 0.$$

However, for $(t,\widehat{\omega})\in[0,T]\times\widehat{\Omega}-[T,T]\times\{\Delta\widetilde{v}(T)=0\}$, $\widetilde{c}(t)>0$, and so $\widetilde{c}(t)>0$ $\mathcal{M}_{\widetilde{v}^s}$-a.s. on $[0,T]\times\widehat{\Omega}$ since $\mathcal{M}_{\widetilde{v}^s}([T,T]\times\{\Delta\widetilde{v}(T)=0\})=0$.

Consequently,

$$-\psi_2\Big[\widetilde{u}(t)^\top B(t,\widetilde{x}(t))^\top\widetilde{p}^2(t)+|\widetilde{u}(t)|\widetilde{p}^3(t)\Big]$$

$$\le-\psi_2\widetilde{c}(t)\Big[\widetilde{u}(t)^\top B(t,\widetilde{x}(t))^\top\widetilde{p}^2(t)+|\widetilde{u}(t)|\widetilde{p}^3(t)\Big]. \tag{5.39}$$

Combining (5.38) and (5.39), we obtain the inequality (5.32).

From the definition of $\{\widehat{v}(t)\}$ (see (3.2)), we have that $\{\Delta\widehat{v}(T)\neq 0\}=\{\Delta\widetilde{v}(T)\neq 0\}\cup[\{\Delta\widetilde{v}(T)=0\}\cap\{\widetilde{v}(T)<M\}]$. Clearly, $\{\Delta\widetilde{v}(T)=0\}\cap\{\widetilde{v}(T)<M\}\in\widehat{\mathcal{F}}_T^{\widehat{W}}$, and so from Lemma 5.11 in [19], $T_{\{\Delta\widetilde{v}(T)=0\}\cap\{\widetilde{v}(T)<M\}}$ is an $\{\widehat{\mathcal{F}}_t^{\widehat{W}}\}$-stopping time. Moreover, $[\![\widetilde{\tau}_i]\!]\cap[\![T_{\{\Delta\widetilde{v}(T)=0\}\cap\{\widetilde{v}(T)<M\}}]\!]=\emptyset$.

The sequence $\{\{\widetilde{\tau}_i\}_{i\in\mathbb{N}^*},T_{\{\Delta\widetilde{v}(T)=0\}\cap\{\widetilde{v}(T)<M\}}\}$ of $\{\widehat{\mathcal{F}}_t^{\widehat{W}}\}$-stopping times exhausts the jumps of $\{\widehat{v}(t)\}$. Denote by $\{\tau_i\}_{i\in\mathbb{N}^*}$ the sequence $\{\{\widetilde{\tau}_i\}_{i\in\mathbb{N}^*},T_{\{\Delta\widetilde{v}(T)=0\}\cap\{\widetilde{v}(T)<M\}}\}$. We can apply Proposition 5.4 to the optimal control $\widehat{C}$. Taking $t=\widehat{\Gamma}(\tau_i-)+\gamma\Delta\widehat{\Gamma}(\tau_i)$

for $\gamma \in [0,1]$, we have for $(u,z) \in B_1(K) \times [0,1]$

$$\psi_2\Big[\big[B(\tau_i)(zu-\widehat{u}(\tau_i))\big]^\top \hat{p}^2(\tau_i) + (z|u| - |\widehat{u}(\tau_i)|)\hat{p}^3(\tau_i)\Big] + (1-z)\Big\{-\psi_1 - 2T\psi_3$$
$$+ \psi_2\Big[\hat{p}^1(\tau_i-) - \gamma\,[B_t(\tau_i)\widehat{u}(\tau_i)]^\top \Delta\widehat{\Gamma}(\tau_i)\hat{p}^2(\tau_i)$$
$$+ A\Big(\tau_i, \widehat{x}(\tau_i-) + \gamma B(\tau_i)\widehat{u}(\tau_i)\Delta\widehat{\Gamma}(\tau_i)\Big)^\top \hat{p}^2(\tau_i)$$
$$+ \frac{1}{2}\operatorname{tr}\Big[D\Big(\tau_i, \widehat{x}(\tau_i-) + \gamma B(\tau_i)\widehat{u}(\tau_i)\Delta\widehat{\Gamma}(\tau_i)\Big)^\top \widehat{P}(\tau_i)$$
$$\times D\Big(\tau_i, \widehat{x}(\tau_i-) + \gamma B(\tau_i)\widehat{u}(\tau_i)\Delta\widehat{\Gamma}(\tau_i)\Big)\Big]\Big\} \le 0$$

$\widehat{P}$-a.s. on $\{\tau_i \le T\}$. However, from the definition of $\widehat{\Gamma}(t)$ and using (3.2) and (3.3) we have $\widehat{u}(\tau_i)\Delta\widehat{\Gamma}(\tau_i) = \widehat{u}(\tau_i)\Delta\widehat{v}(\tau_i) = \widetilde{u}(\tau_i)\Delta\widetilde{v}(\tau_i)$. Finally, the definition of τ_i and Proposition 5.8 give the last inequality (5.33). □

6. Example. In this section, it is shown how the set of necessary conditions given by the inequalities (5.30), (5.32), and (5.33) can be derived and used for a simple worked-out example. Let us consider the following scalar system:

$$dx(t) = Ax(t) + u(t)dv(t) + dW(t), \tag{6.1}$$

with $A > 0$ and $x(0-) = 1$. The aim is to minimize the cost given by $J[C] = E[x(T)]$, subject to $v(T) \le M$ with $M > 0$. It is easy to show that the control defined by

$$\widetilde{v}(t) = \begin{cases} 0 \text{ for } t < 0, \\ M \text{ for } t \ge 0 \end{cases} \quad \text{and} \quad \widetilde{u}(t) = \begin{cases} -1 \text{ for } t = 0, \\ 0 \text{ for } t > 0 \end{cases} \tag{6.2}$$

is an optimal control.

Consequently, we have

$$\widetilde{p}^1(t) = \widetilde{q}^1(t) = 0, \quad \widetilde{p}^3(t) = \widetilde{q}^3(t) = 0, \quad \widetilde{P}(t) = \widetilde{Q}(t) = 0, \tag{6.3}$$

and

$$d\widetilde{p}^2(t) = -A\widetilde{p}^2(t)dt, \text{ with } \widetilde{p}^2(T) = -1, \text{ and } \widetilde{q}^2(t) = 0. \tag{6.4}$$

Therefore, it follows that $\widetilde{p}^2(t) = -e^{A(T-t)}$. Clearly, we have $\mathcal{M}_{\widetilde{v}^{ac}} = 0$. Since $\mathcal{M}_{\widetilde{v}^s}(.) = I_0(.)$, it is easy to show that (5.32) and (5.33) reduce to

$$\psi_2\Big(zu - \widetilde{u}(0)\Big)\widetilde{p}^2(0) + \Big(1-z\Big)\Big[-\psi_1 - 2T\psi_3$$
$$+ \psi_2 A\Big\{\widetilde{x}(0-) + \gamma\widetilde{u}(0)\Delta\widetilde{v}(0)\Big\}\widetilde{p}^2(0)\Big] \le 0 \tag{6.5}$$

for $u \in [-1,1]$, $z \in [0,1]$, and $\gamma \in [0,1]$.

Consequently, applying Theorem 5.9 to this example, it follows that there exist $\psi \in S_1(\mathbb{R}^3)$ such that $\forall u \in [-1,1]$, $z \in [0,1]$, and $\gamma \in [0,1]$, the previous inequality is satisfied. The variational inequality (6.5) becomes

$$-\psi_2\Big(zu+1\Big)e^{AT} + \Big(1-z\Big)\Big[-\psi_1 - 2T\psi_3 - \psi_2 A\Big\{1-\gamma M\Big\}e^{AT}\Big] \le 0.$$

When $M \leq 1$, a straightforward calculation shows that for any $\psi_2 \in [0,1]$, there exist $\psi_1 \in [-1,1]$ and $\psi_3 \in [-1,1]$ satisfying $\psi_1 + 2T\psi_3 = \sqrt{1-\psi_2^2}$ such that the variational inequality is satisfied $\forall u \in [-1,1]$, $z \in [0,1]$, and $\gamma \in [0,1]$.

When $M > 1$, by choosing ψ_2 such that $0 < \psi_2 \leq 1$, and $A\{M-1\}e^{AT} \leq \frac{\sqrt{1-\psi_2^2}}{\psi_2}$, and again $\psi_1 + 2T\psi_3 = \sqrt{1-\psi_2^2}$, it follows that the variational inequality is satisfied $\forall u \in [-1,1]$, $z \in [0,1]$, and $\gamma \in [0,1]$.

7. Conclusion. Our work can be generalized in several directions: a running cost can be added to the definition of $J[C]$ (with no convexity hypothesis) and a classical control process can be added in the dynamic of the state (for example in A, D and into the running cost if it exists) as in [8]. Soft constraints with the same form of the cost G may also be added to the model (see [23, page 855] for constraints of these types in classical control problems).

OPTIMAL CONTROL OF A SEMILINEAR PDE WITH NONLOCAL RADIATION INTERFACE CONDITIONS*

C. MEYER†, P. PHILIP‡, AND F. TRÖLTZSCH†

Abstract. We consider a control constrained optimal control problem governed by a semilinear elliptic equation with nonlocal interface conditions. These conditions occur during the modeling of diffuse-gray conductive-radiative heat transfer. The problem arises when attempting to optimize the temperature gradient within crystal growth by the physical vapor transport (PVT) method. Based on a minimum principle for the semilinear equation as well as L^∞-estimates for the weak solution, we establish the existence of an optimal solution as well as necessary optimality conditions. The theoretical results are illustrated by numerical computations.

Key words. optimal control, semilinear elliptic equations, nonlocal interface conditions, boundedness of solutions

1. Introduction.

In this paper, we investigate an optimal control problem related to the sublimation growth of silicon carbide (SiC) single crystals by the physical vapor transport (PVT) method. The semiconductor material SiC is used in numerous industrial applications, e.g., the production of optoelectronic devices such as blue and green light emitting diodes (LEDs) and lasers. For the PVT method, polycrystalline SiC powder is placed in a low-pressure inert gas atmosphere at the bottom of a cavity inside a graphite crucible. The crucible is heated to a temperature between 2000 and 3000 K by induction. Due to the high temperature and the low pressure, the SiC powder sublimates and crystallizes at a single-crystalline SiC seed located at the cooled top of the cavity, such that the single crystal grows into the reaction chamber. See [9, 10] for more details.

Here, we neglect the electromagnetic induction problem and focus on the conductive-radiative heat transfer in the growth apparatus. Therefore, we consider a simplified setup of the growth apparatus, shown in Figure 1.1, where Ω_s denotes the domain of the solid graphite crucible, whereas Ω_g is the domain of gas phase inside. A very important determining factor for the crystal's quality and growth rate is the temperature distribution in the gas phase and, especially, the temperature gradient close to the surface of the growing crystal [16]. Since we do not consider the electromagnetic induction, we will optimize the temperature gradient in the gas phase Ω_g by directly controlling the heat source u in Ω_s.

The temperature y inside the growth apparatus is the solution of the conductive-radiative heat transfer problem in the growth apparatus. Accounting for radiative contributions is essential, owing to the high temperatures. Thus, the problem

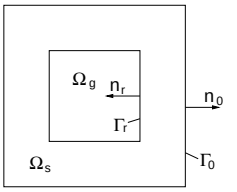

FIG. 1.1. *Two-dimensional section through an exemplary domain for nonlocal radiative heat transfer.*

is described by the stationary heat equation with radiation interface and boundary conditions on Γ_{r} and Γ_0, respectively. We take Ω_{s} to be entirely opaque, whereas Ω_{g} represents a transparent medium which does not interact with radiation. Furthermore, the radiative surfaces $\Gamma_0 := \partial\Omega$ and $\Gamma_{\mathrm{r}} := \overline{\Omega}_{\mathrm{s}} \cap \overline{\Omega}_{\mathrm{g}}$ are presumed to be diffuse-gray; i.e., the emissivity ε is independent of both the direction and the wavelength of the radiation. In particular, the local radiative heat exchange on Γ_0 can be modeled by the Boltzmann radiation condition with an external temperature y_0. Due to the heat exchange between points on Γ_{r}, we obtain an additional radiative heat flux on Γ_{r}, denoted by q_{r}.

In addition to the stationary semilinear heat equation with radiation interface and boundary conditions, we consider box constraints for the control function u. Thus, the optimal control problem, considered here, reads as follows:

$$
\text{(P)} \quad \begin{cases} \text{Minimize} \quad J(y,u) := \dfrac{1}{2}\displaystyle\int_{\Omega_{\mathrm{g}}} |\nabla y - z|^2\,dx + \dfrac{\nu}{2}\int_{\Omega_{\mathrm{s}}} u^2\,dx \\ \text{subject to} \qquad -\mathrm{div}(\kappa_{\mathrm{s}}\nabla y) = u \quad \text{in } \Omega_{\mathrm{s}}, \\ \qquad\qquad -\mathrm{div}(\kappa_{\mathrm{g}}\nabla y) = 0 \quad \text{in } \Omega_{\mathrm{g}}, \\ \qquad\qquad \kappa_{\mathrm{g}}\left(\dfrac{\partial y}{\partial n_r}\right)_{\mathrm{g}} - \kappa_{\mathrm{s}}\left(\dfrac{\partial y}{\partial n_r}\right)_{\mathrm{s}} = q_{\mathrm{r}} \quad \text{on } \Gamma_{\mathrm{r}}, \\ \qquad\qquad \kappa_{\mathrm{s}}\dfrac{\partial y}{\partial n_0} + \varepsilon\sigma\,|y|^3 y = \varepsilon\sigma\, y_0^4 \text{on } \Gamma_0, \\ \qquad \text{and} \quad u_a \le u(x) \le u_b \quad \text{a.e. in } \Omega_{\mathrm{s}}, \end{cases}
$$

where n_0 is the outward unit normal on Γ_0, and n_{r} is the unit normal on Γ_{r} facing outward with respect to Ω_{s} (cf. Figure 1.1). Furthermore, z denotes the desired temperature gradient and $\nu > 0$ is a Tikhonov regularization parameter. In the state equation, σ represents the Boltzmann radiation constant, and κ_{s}, κ_{g} denote the thermal conductivities in Ω_{s}, Ω_{g}, respectively.

In contrast to the boundary condition on Γ_0, the radiative heat transfer on Γ_{r} is nonlocal. The corresponding mathematical model used here is described in detail, e.g., in [15, 18]. It provides the additional radiative heat flux q_{r} on Γ_{r} given by

$$
q_{\mathrm{r}} = (I-K)(I-(1-\varepsilon)K)^{-1}\varepsilon\,\sigma|y|^3 y := G\,\sigma|y|^3 y, \tag{1.1}
$$

where K is an integral operator representing the irradiation on Γ_{r}. The nonlocal operators K and G will be specified in section 3.1. The nonlocal radiation on Γ_{r} represents the main characteristic of our problem, since the nonlinearity in the state equation in (P) is in general not monotone due to nonpositivity of G (see section 3 and [18]).

The state equation in (P) is of semilinear elliptic type. Therefore, the optimal control problem can be viewed as a semilinear elliptic optimal control problem. The list of publications in this field is already quite extensive. We mention only Casas [6], Alibert and Raymond [2], Casas, Tröltzsch, and Unger [7], and Bonnans [5]. This list might be extended considerably by including associated papers on different aspects of numerical analysis.

Our paper differs from all these contributions by the interface conditions containing the nonmonotone and nonlocal operator G. Therefore, our boundary value problem is of nonmonotone type so that special techniques must be applied.

The paper is organized as follows. After stating the mathematical setting in section 2, we provide auxiliary results on the nonlocal operator G as well as a general boundedness result for a class of nonlinear equations; see section 3. In section 4, we prove a weak maximum principle for the semilinear state equation and an L^∞-estimate for its solutions, followed by the existence of an optimal solution in section 5. Section 6 is devoted to the existence and boundedness of a solution to the linearized equation. In section 7, we establish first order necessary optimality conditions based on the differentiability of the solution operator associated with the semilinear equation. The corresponding adjoint state is introduced at the end of section 7. Finally, section 8 presents some numerical results.

2. The mathematical setting. Throughout this paper, we assume the following conditions (A1)–(A3) on the domain Ω and on the quantities and functions occurring in (P):

(A1) We assume that $\Omega \subset \mathbb{R}^N$, $N = 2, 3$, is a bounded simply connected domain with Lipschitz boundary Γ_0. The boundary of the simply connected subdomain $\overline{\Omega}_{\rm g} \subset \Omega$, denoted by $\Gamma_{\rm r}$, is assumed to be a closed Lipschitz surface that is piecewise $C^{1,\delta}$. Notice that the distance from $\Gamma_{\rm r}$ to Γ_0 is positive. Then, $\Omega_{\rm s}$ is defined by $\Omega_{\rm s} = \Omega \backslash \overline{\Omega}_{\rm g}$ (cf. Figure 1.1).

(A2) The Boltzmann radiation constant is assumed to be positive, i.e., $\sigma \in \mathbb{R}^+$. For the thermal conductivity, we assume $\kappa \in L^\infty(\Omega)$ with

$$\kappa(x) = \begin{cases} \kappa_{\rm s}(x) \text{ in } \Omega_{\rm s}, \\ \kappa_{\rm g}(x) \text{ in } \Omega_{\rm g}, \end{cases}$$

and $\kappa(x) \geq \kappa_{\min} > 0$ a.e. on Ω. Furthermore, the emissivity $\varepsilon \in L^\infty(\Gamma_0 \cup \Gamma_{\rm r})$ is bounded by $1 \geq \varepsilon \geq \varepsilon_{\min} > 0$ a.e. on $\Gamma_0 \cup \Gamma_{\rm r}$.

(A3) The desired temperature gradient z is given in $L^2(\Omega_{\rm g})^N$ and ν is a positive constant. For the box constraints, we assume $u_a, u_b \in L^\infty(\Omega_{\rm s})$ and $0 \leq u_a(x) \leq u_b(x)$ a.e. in $\Omega_{\rm s}$.

Notation. For a given p with $1 \leq p \leq \infty$, an operator $B : L^p(\Gamma_{\rm r}) \to L^p(\Gamma_{\rm r})$ is said to be positive if $v \in L^p(\Gamma_{\rm r})$ and $v \geq 0$ a.e. on $\Gamma_{\rm r}$ imply $B\,v \geq 0$ a.e. on $\Gamma_{\rm r}$. Furthermore, $\mathbf{1}$ denotes the function $e(x) \equiv 1$ a.e., and I is the identity operator in the respective function spaces. We introduce the set of admissible controls by $U_{\rm ad} := \{u \in L^\infty(\Omega_{\rm s}) \,|\, u_a(x) \leq u(x) \leq u_b(x) \text{ a.e. in } \Omega_{\rm s}\}$. The measure of a certain set $A \subset \mathbb{R}^n$, $n \geq 1$, is denoted by $|A|$, and $\tau_{\rm r}$ denotes the trace operator on $\Gamma_{\rm r}$, whereas τ_0 is the trace on Γ_0. Throughout this paper, c is a generic constant.

Let W be a Banach space with its dual space W^*. Then, for $f \in W$ and $g \in W^*$, $\langle f\,,\, g\rangle$ denotes the associated pairing.

3. Auxiliary results. In section 3.1, we present some properties of the nonlocal radiation operator G. Since G is in general not positive, the nonlinearity in the

semilinear state equation is nonmonotone. However, G still has sufficiently benign properties such that the nonlinear parts in the state equation are pseudomonotone (see [12]). These properties of G are also used to prove the boundedness of the solution in section 4 below.

In Lemma 3.8 of section 3.2, we will prove the boundedness of the solution y for a general class of nonlinear equations that applies to both the semilinear case and its linearized version.

3.1. The nonlocal radiation operator. The operators K and G arising from the nonlocal radiation on Γ_r were investigated in detail by Laitinen and Tiihonen [12] and Tiihonen [18, 19]. We recall some of their results for convenience.

DEFINITION 3.1. *The integral operator K, representing the irradiation on Γ_r, is given by*

$$(K\,y)(x) = \int_{\Gamma_r} \omega(x,z)\,y(z)\,ds_z \tag{3.1}$$

with a symmetric kernel ω which is, in the two-dimensional case, defined by

$$\omega(x,z) = \Xi(x,z)\,\frac{[n_r(z)\cdot(x-z)][n_r(x)\cdot(z-x)]}{2|z-x|^3}, \tag{3.2a}$$

and, in the three-dimensional case, defined by

$$\omega(x,z) = \Xi(x,z)\,\frac{[n_r(z)\cdot(x-z)][n_r(x)\cdot(z-x)]}{\pi|z-x|^4}, \tag{3.2b}$$

where x, z denote two points on Γ_r, and $n_r(x)$ is the unit normal at x facing outward with respect to Ω_s (see Figure 1.1). Here, Ξ represents the visibility factor, which is given by

$$\Xi(x,z) = \begin{cases} 0 & \text{if } \overline{xz}\cap\Omega_s \neq \emptyset, \\ 1 & \text{if } \overline{xz}\cap\Omega_s = \emptyset. \end{cases}$$

Remark 3.2. Notice that, in case of convex domains, such as in Figure 1.1, we have $\Xi(x,z)\equiv 1$ for all $x,z\in\Gamma_r$.

In [19], it is proven that $\omega(x,z)$ can have a singularity at x of type $|x-z|^{-(1-\delta)}$ in the two-dimensional case and $|x-z|^{-2(1-\delta)}$ in the three-dimensional case, which is, in both cases, integrable. This is the key point to the following lemma also derived in [19].

LEMMA 3.3.

(i) *K maps $L^p(\Gamma_r)$ to $L^p(\Gamma_r)$ for all $1\le p\le\infty$.*
(ii) *If Γ_r is a closed Lipschitz surface that is piecewise $C^{1,\delta}$, then $K\,\mathbf{1}=\mathbf{1}$ holds a.e. on Γ_r.*
(iii) *The operator $I-(1-\varepsilon)K : L^p(\Gamma_r)\to L^p(\Gamma_r)$ is continuously invertible.*

With the help of Lemma 3.3, Laitinen and Tiihonen proved the following properties of $G=(I-K)(I-(1-\varepsilon)K)^{-1}\varepsilon$ (cf. [18, Lemma 6] and [12, Lemma 8]).

LEMMA 3.4.

(i) *G is a bounded linear operator from $L^p(\Gamma_r)$ to itself for all $1\le p\le\infty$.*
(ii) *G can be written as $G=I-H$ with a positive operator H.*
(iii) *For all $y\in L^5(\Gamma_r)$, $\int_{\Gamma_r} G(\sigma|y|^3y)y\,ds\ge 0$ holds true.*

Here, we show another property of G that we will use subsequently.

LEMMA 3.5. *For every function $v(x) \equiv k = const.$ a.e. on Γ_r, we have $G\,v = 0$ and $G^*\,v = 0$.*

Proof. Since K has a symmetric kernel, K is formally self-adjoint, i.e., $\langle v\,,\,K\,w\rangle = \langle K\,v\,,\,w\rangle$ for all $v \in L^p(\Gamma_r)$ and $w \in L^q(\Gamma_r)$, $1/p + 1/q = 1$. Thus, together with Lemma 3.3(ii), we obtain $K^*\,\mathbf{1} = \mathbf{1}$ a.e. on Γ_r. Therefore, with the definition of G, we find

$$G^*v = \varepsilon(I - K^*(1-\varepsilon))^{-1}(I - K^*)v = \varepsilon(I - K^*(1-\varepsilon))^{-1}(k-k) = 0.$$

Furthermore, for an arbitrary constant k, Lemma 3.3(ii) implies

$$(I - (1-\varepsilon)K)k = k - (1-\varepsilon)k = \varepsilon\,k.$$

Thus, by Lemma 3.3(iii), $k = (I - (1-\varepsilon)K)^{-1}\varepsilon\,v$ holds for every function v with $v(x) \equiv k$ a.e. on Γ_r. Hence, we obtain

$$G\,v = (I-K)(I-(1-\varepsilon)K)^{-1}\varepsilon\,v = (I-K)k = 0. \qquad \square$$

3.2. Boundedness for a nonlinear equation. In sections 4 and 6, we show the existence of solutions of the semilinear state equation and its linearization in suitable functions spaces. Moreover, we have to show the boundedness of the solutions of both equations. To unify the proofs, we first prove an auxiliary result for a nonlinear equation of the form

$$\langle F(y)\,,\,v\rangle = \langle f\,,\,v\rangle \qquad \forall\, v \in W, \tag{3.3}$$

where $F : W \to W^*$ is a certain mapping, and y is a given solution in a space $W \subseteq H^1(\Omega)$. It will be shown that, under suitable assumptions, a solution y belongs to the function space

$$V^\infty := H^1(\Omega) \cap L^\infty(\Omega), \tag{3.4}$$

equipped with the norm

$$\|v\|_{V^\infty} = \|v\|_{H^1(\Omega)} + \|v\|_{L^\infty(\Omega)}.$$

Remark 3.6. If $y \in V^\infty$, then $\tau_r\,y \in L^\infty(\Gamma_r)$, and $\tau_0\,y \in L^\infty(\Gamma_0)$.

This is an immediate consequence of Lemma 3.7 below, which follows from Proposition 5.2, part (ii) in [8].

LEMMA 3.7. *For a bounded Lipschitz domain $\Omega \subset \mathbb{R}^n$, $n \in \mathbb{N}$, the trace operator $\tau : H^1(\Omega) \to H^{1/2}(\partial\Omega)$ is positive, i.e., $\tau v \geq 0$ a.e. on $\partial\Omega$ for $v \geq 0$ a.e. on Ω.*

To show the boundedness of a solution to the nonlinear equation (3.3), we use the following hypotheses.

(H1) (*regularity of the inhomogeneity*). The right-hand side of (3.3) can be expressed as

$$\langle f\,,\,v\rangle = \int_\Omega f_\Omega\,v\,dx + \int_{\Gamma_r} f_r\,v\,ds + \int_{\Gamma_0} f_0\,v\,ds,$$

where f_Ω, f_r, and f_0 satisfy $f_\Omega \in L^{p_1}(\Omega)$, $f_r \in L^{p_2}(\Gamma_r)$, and $f_0 \in L^{p_2}(\Gamma_0)$, with $p_1 = 6/(5-s)$, $p_2 = 4/(3-s)$, and $1 < s < 3$.

(H2) (*coercivity*). There is a constant $k_0 \geq 0$ such that, for a given solution $y \in W$ of (3.3) and for each $k > k_0$, the functions

$$\varphi_k(x) := \begin{cases} y(x) - k, & y(x) \geq k, \\ 0, & |y(x)| < k, \\ y(x) + k, & y(x) \leq -k \end{cases} \tag{3.5}$$

are elements of W, and there is a constant $c > 0$ such that the nonlinearity in (3.3) satisfies, for each $k > k_0$,

$$\langle F(y)\,,\, \varphi_k \rangle \geq c\,\|\varphi_k\|^2_{H^1(\Omega)}.$$

LEMMA 3.8. *Suppose that $\Omega \subset \mathbb{R}^3$ satisfies* (A1)*, that $y \in W$ is a solution to* (3.3)*, and that* (H1) *and* (H2) *are fulfilled. Then $y \in V^\infty$, and there exists a constant c_0 depending only on Ω, and not on y, f_Ω, f_r, f_0, such that*

$$\|y\|_{L^\infty(\Omega)} + \|y\|_{L^\infty(\Gamma_\mathrm{r}\cup\Gamma_0)} \leq c_0(k_0 + \|f_\Omega\|_{L^{p_1}(\Omega)} + \|f_\mathrm{r}\|_{L^{p_2}(\Gamma_\mathrm{r})} + \|f_0\|_{L^{p_2}(\Gamma_0)}) \tag{3.6}$$

holds true.

Proof. The proof is based on a technique introduced by Kinderlehrer and Stampacchia [8] and Stampacchia [17] in the linear case. For given $k > k_0$, we define $A_\Omega(k) := \{x \in \Omega \mid |y(x)| \geq k\}$ and introduce $A_\mathrm{r}(k)$ and $A_0(k)$ analogously. Our aim is to show that there is a $k > 0$ with $|A_\Omega(k)| = |A_\mathrm{r}(k)| = |A_0(k)| = 0$. We start with (H2), which yields

$$\begin{aligned}
&\langle F(y)\,,\, \varphi_k \rangle \geq c\,\|\varphi_k\|^2_{H^1(\Omega)} \geq c\,(\|\varphi_k\|^2_{L^6(\Omega)} + \|\varphi_k\|^2_{L^4(\Gamma_\mathrm{r})} + \|\varphi_k\|^2_{L^4(\Gamma_0)}) \\
&\geq c\biggl(\biggl(\int_{A_\Omega(k)} (|y| - k)^6 dx\biggr)^{1/3} + \biggl(\int_{A_\mathrm{r}(k)} (|y| - k)^4 ds\biggr)^{1/2} + \biggl(\int_{A_0(k)} (|y| - k)^4 ds\biggr)^{1/2}\biggr),
\end{aligned}$$

since φ_k equals 0 on $\Omega \setminus A_\Omega(k)$, on $\Gamma_\mathrm{r} \setminus A_\mathrm{r}(k)$, and on $\Gamma_0 \setminus A_0(k)$. If $h > k > k_0 \geq 0$, then $A(h) \subseteq A(k)$, where A stands generally for A_Ω, A_r, and A_0, and we have for an arbitrary $m \in \mathbb{N}$,

$$\biggl(\int_{A(k)} (|y| - k)^m dx\biggr)^{2/m} \geq \biggl(\int_{A(h)} (h - k)^m dx\biggr)^{2/m} = (h - k)^2 |A(h)|^{2/m}.$$

Defining

$$\psi(h) := |A_\Omega(h)|^{1/3} + |A_0(h)|^{1/2} + |A_\mathrm{r}(h)|^{1/2}, \tag{3.7}$$

one obtains

$$\|\varphi_k\|^2_{H^1(\Omega)} \geq c\,(h - k)^2 \psi(h). \tag{3.8}$$

Now, we investigate the right-hand side in (3.3). Hypothesis (H1), Hölder's inequality, and embedding theorems imply

$$\begin{aligned}
\langle f\,,\, \varphi_k \rangle &\leq \|f_\Omega\|_{L^{6/5}(A_\Omega(k))} \|\varphi_k\|_{L^6(\Omega)} + \|f_\mathrm{r}\|_{L^{4/3}(A_\mathrm{r}(k))} \|\varphi_k\|_{L^4(\Gamma_\mathrm{r})} \\
&\quad + \|f_0\|_{L^{4/3}(A_0(k))} \|\varphi_k\|_{L^4(\Gamma_0)} \\
&\leq c\,\bigl(\|f_\Omega\|_{L^{6/5}(A_\Omega(k))} + \|f_\mathrm{r}\|_{L^{4/3}(A_\mathrm{r}(k))} + \|f_0\|_{L^{4/3}(A_0(k))}\bigr) \|\varphi_k\|_{H^1(\Omega)}.
\end{aligned}$$

Applying (H2), (3.3), and Young's inequality, we obtain

$$\|\varphi_k\|^2_{H^1(\Omega)} \le c\left(\|f_\Omega\|^2_{L^{6/5}(A_\Omega(k))} + \|f_{\mathrm{r}}\|^2_{L^{4/3}(A_{\mathrm{r}}(k))} + \|f_0\|^2_{L^{4/3}(A_0(k))}\right). \tag{3.9}$$

Using again Hölder's inequality, the first norm on the right-hand side of (3.9) can be estimated by

$$\begin{aligned}\left(\int_{A_\Omega(k)} f_\Omega^{6/5} dx\right)^{5/3} &\le \left(\|f_\Omega^{6/5}\|_{L^{5/(5-s)}(A_\Omega(k))}|A_\Omega(k)|^{s/5}\right)^{5/3}\\ &\le \|f_\Omega\|^2_{L^{p_1}(\Omega)}|A_\Omega(k)|^{s/3}\end{aligned} \tag{3.10}$$

with $p_1 = 6/(5-s)$ and $1 < s < 3$ as defined above. Similarly, we derive

$$\left(\int_{A_{\mathrm{r}}(k)} f_{\mathrm{r}}^{4/3} dx\right)^{3/2} \le \|f_{\mathrm{r}}\|^2_{L^{p_2}(\Gamma_{\mathrm{r}})}|A_{\mathrm{r}}(k)|^{s/2} \tag{3.11}$$

with $p_2 = 4/(3-s)$ (and analogously on A_0).

Due to the Taylor expansion, we have for three arbitrary real nonnegative numbers a, b, and c that $(a^s + b^s + c^s) \le (a+b+c)^s$ for all $s > 1$. Choosing $a = |A_\Omega(k)|^{1/3}$, $b = |A_{\mathrm{r}}(k)|^{1/2}$, and $c = |A_0(k)|^{1/2}$, combining (3.10), (3.11), and (3.9) yields

$$\|\varphi_k\|^2_{H^1(\Omega)} \le c\,\varrho_f\,\psi(k)^s$$

with $\varrho_f = \|f_\Omega\|^2_{L^{p_1}(\Omega)} + \|f_{\mathrm{r}}\|^2_{L^{p_2}(\Gamma_{\mathrm{r}})} + \|f_0\|^2_{L^{p_2}(\Gamma_0)}$, and ψ as defined in (3.7). Together with (3.8), it follows that

$$\psi(h) \le \frac{c\,\varrho_f}{(h-k)^2}\psi(k)^s \quad \text{for } h > k > k_0 \ge 0. \tag{3.12}$$

Stampacchia proved in [17] that each nonnegative and nonincreasing function $\psi = \psi(t)$ satisfying (3.12) with some $s > 1$ has a zero at some $t = d$, $d > 0$, where

$$d = k_0 + 2^{s/(s-1)}(c|\psi(k_0)|^{s-1})^{1/2}\sqrt{\varrho_f},$$

and, in our case, $|\psi(k_0)| = \psi(k_0)$ can be estimated by

$$\psi(k_0) \le \psi(0) = |\Omega|^{1/3} + |\Gamma_0|^{1/2} + |\Gamma_{\mathrm{r}}|^{1/2}$$

(see also Kinderlehrer and Stampacchia [8, Lemma B.1]). Due to the definition of ψ in (3.7), this implies $|y(x)| \le d$ a.e. on Ω and on $\Gamma_{\mathrm{r}} \cup \Gamma_0$. Thus, with the definition of ϱ_f, we obtain

$$\begin{aligned}\|y\|_{L^\infty(\Omega)} + \|y\|_{L^\infty(\Gamma_{\mathrm{r}}\cup\Gamma_0)} &\le 2\,d\\ &\le 2\left(k_0 + 2^{s/(s-1)}(c|\psi(0)|^{s-1})^{1/2}\sqrt{\varrho_f}\right)\\ &\le c\left(k_0 + \sqrt{\|f_\Omega\|^2_{L^{p_1}(\Omega)} + \|f_{\mathrm{r}}\|^2_{L^{p_2}(\Gamma_{\mathrm{r}})} + \|f_0\|^2_{L^{p_2}(\Gamma_0)}}\right)\\ &\le c_0\left(k_0 + \|f_\Omega\|_{L^{p_1}(\Omega)} + \|f_{\mathrm{r}}\|_{L^{p_2}(\Gamma_{\mathrm{r}})} + \|f_0\|_{L^{p_2}(\Gamma_0)}\right)\end{aligned}$$

by the equivalence of the Euclidian norm and the L^1-norm in $\mathbb{R}^3$. ∎

Remark 3.9. Due to the positivity of the trace operator (cf. Lemma 3.7) in Lemma 3.8, it would have sufficed to prove the boundedness of y on Ω. However, this would not have simplified the proof, as we still needed the direct estimates of the inhomogeneities on Γ_0 and Γ_{r} as carried out above.

4. The semilinear equation. Before we apply Lemma 3.8 to the semilinear equation in (P), we will introduce the variational form of the state equation and recall a theorem of Laitinen and Tiihonen [12] that covers its solvability.

Based on Lemma 3.4, we are now able to derive the weak formulation of the state equation in (P). To fix G, we specify p in Lemma 3.4(i) by $p = 5/4$ and obtain $G : L^{5/4}(\Gamma_r) \to L^{5/4}(\Gamma_r)$. Then, formal integration by parts over Γ_0 and Γ_r yields

$$\begin{aligned} &\int_\Omega \kappa \nabla y \cdot \nabla v \, dx + \int_{\Gamma_r} G(\sigma|y|^3 y) v \, ds + \int_{\Gamma_0} \varepsilon\sigma \, |y|^3 y \, v \, ds \\ &\quad = \int_{\Omega_s} u \, v \, dx + \int_{\Gamma_0} \varepsilon\sigma \, y_0^4 v \, ds \qquad \forall\, v \in V \end{aligned} \tag{4.1}$$

with $V = \{v \in H^1(\Omega) \mid \tau_r v \in L^5(\Gamma_r)\,,\ \tau_0 v \in L^5(\Gamma_0)\}$. Clearly, due to $G : L^{5/4}(\Gamma_r) \to L^{5/4}(\Gamma_r)$, we have $G(\sigma|y|^3 y)v \in L^1(\Gamma_r)$ for all $y, v \in V$. The state space V is equipped with the norm

$$\|v\|_V = \|v\|_{H^1(\Omega)} + \|v\|_{L^5(\Gamma_r)} + \|v\|_{L^5(\Gamma_0)}.$$

A function $y \in V$ is said to be a weak solution of the state equation in (P) if (4.1) is fulfilled for every $v \in V$.

THEOREM 4.1 (see [12, Theorem 2]). *For every $u \in H^1(\Omega_s)^*$ and $y_0 \in L^5(\Gamma_0)$, the semilinear equation* (4.1) *admits a unique solution in V.*

The proof is mainly based on Brezis' theorem [20, Theorem 27.A] for pseudomonotone operators. Laitinen and Tiihonen showed in [12] that the semilinear differential operator defined by the left-hand side in (4.1) fulfills all assumptions of Brezis' theorem; i.e., it is pseudomonotone, bounded, and coercive on V. Thus, (4.1) admits at least one solution in V. The uniqueness then follows from a comparison principle [12, Theorem 4].

Next, we show the boundedness of solutions to (4.1). This result has been obtained by Laitinen and Tiihonen (see [12, Theorem 5]) in a slightly different setting by another method. Here, we need it for the nonlinear equation (4.1) as well as for its linearized version (see section 6). In both cases, Lemma 3.8 can be applied.

THEOREM 4.2. *Assume that $u \in L^2(\Omega_s)$ and $y_0 \in L^{16}(\Gamma_0)$. Then, there exists a constant c_0 depending only on Ω such that*

$$\|y\|_{L^\infty(\Omega)} + \|y\|_{L^\infty(\Gamma_r \cup \Gamma_0)} \le c_0 (1 + \|u\|_{L^2(\Omega_s)} + \|y_0\|^4_{L^{16}(\Gamma_0)}) \tag{4.2}$$

is valid.

Proof. To apply Lemma 3.8, we have to verify (H1) and (H2). Here, we choose the state space $V \subset H^1(\Omega)$ for the space W. Since $y_0 \in L^{16}(\Gamma_0)$ by assumption, we have $y_0^4 \in L^4(\Gamma_0)$, and thus together with the assumed regularity of u, (H1) is satisfied with $f_0 = y_0^4$ and $s = 2$. To verify (H2), we show

$$\int_\Omega \kappa \nabla y \cdot \nabla \varphi_k \, dx + \int_{\Gamma_r} G(\sigma|y|^3 y)\varphi_k \, ds + \int_{\Gamma_0} \varepsilon\sigma \, |y|^3 y \, \varphi_k \, ds \ge c \, \|\varphi_k\|^2_{H^1(\Omega)} \tag{4.3}$$

for each $k \ge 1$, which we will use in the estimate of the Γ_0-term. At first, we show the positivity of the radiation term on Γ_r. To this aim, we split $\varphi_k = \varphi_k^+ + \varphi_k^-$ with

$$\varphi_k^+(x) := \begin{cases} y(x) - k, & y(x) \ge k, \\ 0, & y(x) < k, \end{cases} \qquad \varphi_k^-(x) := \begin{cases} y(x) + k, & y(x) \le -k, \\ 0, & y(x) > -k. \end{cases}$$

It follows that

$$\int_{\Gamma_r} G(\sigma|y|^3 y)\varphi_k \, ds = \int_{\Gamma_r} G(\sigma|y|^3 y)\varphi_k^+ \, ds + \int_{\Gamma_r} G(\sigma|y|^3 y)\varphi_k^- \, ds. \tag{4.4}$$

Due to the linearity of G, the first integral on the right-hand side can be expressed by

$$\int_{\Gamma_r} G(\sigma|y|^3 y)\varphi_k^+ \, ds = \int_{\Gamma_r} G(\sigma\Phi)\varphi_k^+ \, ds + \int_{\Gamma_r} G(\sigma\Psi)\varphi_k^+ \, ds, \tag{4.5}$$

where

$$\Phi(x) := \begin{cases} y(x)^4, & y(x) \geq k, \\ k^4, & y(x) < k, \end{cases} \qquad \Psi(x) := \begin{cases} 0, & y(x) \geq k, \\ |y(x)|^3 y(x) - k^4, & y(x) < k. \end{cases}$$

This partition is necessary since G is nonlocal. Notice that $\Phi + \Psi = |y|^3 y$ and $\Psi(x) \leq 0$ on Γ_r. For the first addend in (4.5), we have, with $y_k(x) := \max\{y(x), k\}$,

$$\int_{\Gamma_r} G(\sigma\Phi)\varphi_k^+ \, ds = \int_{\Gamma_r} G(\sigma\, y_k^4)(y_k - k) \, ds = \int_{\Gamma_r} G(\sigma\, y_k^4) y_k \, ds - \int_{\Gamma_r} \sigma\, y_k^4 G^* k \, ds \geq 0$$

because of Lemma 3.4(iii) and Lemma 3.5. Due to $G = I - H$ and the positivity of H (see Lemma 3.4(ii)), the second integral in (4.5) results in

$$\int_{\Gamma_r} G(\sigma\Psi)\varphi_k^+ \, ds = \sigma \int_{\Gamma_r} \Psi\varphi_k^+ \, ds + \sigma \int_{\Gamma_r} H(-\Psi)\varphi_k^+ \, ds \geq 0,$$

since $\Psi(x) \neq 0$ implies $\varphi_k^+(x) = 0$ and $-\Psi, \varphi_k^+ \geq 0$ holds on Γ_r.

Similarly, we prove the positivity of the second integral on the right-hand side of (4.4) with $y_k(x) := \min\{y(x), -k\}$, defining

$$\Phi(x) := \begin{cases} |y(x)|^3 y(x), & y(x) \leq -k, \\ -k^4, & y(x) > -k, \end{cases} \qquad \Psi(x) := \begin{cases} 0, & y(x) \leq -k, \\ |y(x)|^3 y(x) + k^4, & y(x) > -k. \end{cases}$$

In this way, we have shown that $\int_{\Gamma_r} G(\sigma|y|^3 y)\varphi_k \, ds \geq 0$. It remains to analyze the other integrals in (4.3). The first integral is estimated by

$$\int_\Omega \kappa \nabla y \cdot \nabla \varphi_k \, dx \geq \kappa_{\min} \|\nabla \varphi_k\|^2_{L^2(\Omega)},$$

since $\nabla\varphi_k(x) = 0$ if $\nabla y(x) \neq \nabla\varphi_k(x)$. On Γ_0, using $k \geq k_0 := 1$, we obtain

$$\int_{\Gamma_0} \varepsilon\sigma\, |y|^3 y\, \varphi_k \, ds \geq \varepsilon_{\min}\sigma\, k^3 \|\varphi_k\|^2_{L^2(A_0(k))} \geq \varepsilon_{\min}\sigma\, \|\varphi_k\|^2_{L^2(\Gamma_0)},$$

as $y\,\varphi_k = (\operatorname{sign}\varphi_k)(|\varphi_k| + k)\varphi_k \geq \varphi_k^2$ is valid on $A_0(k) = \{x \in \Omega \mid \varphi_k(x) \neq 0\}$.

Due to the positivity of $\int_{\Gamma_r} G(\sigma|y|^3 y)\varphi_k \, ds$, we finally have

$$\begin{aligned}\int_\Omega \kappa \nabla y \cdot \nabla \varphi_k \, dx + \int_{\Gamma_r} G(\sigma|y|^3 y)\varphi_k \, ds + \int_{\Gamma_0} \varepsilon\sigma \, |y|^3 y \, \varphi_k \, ds \\ \geq c \, (\|\nabla \varphi_k\|^2_{L^2(\Omega)} + \|\varphi_k\|^2_{L^2(\Gamma_0)}) \geq c \, \|\varphi_k\|^2_{H^1(\Omega)}.\end{aligned}$$

Therefore, we can apply Lemma 3.8, and estimate (3.6) gives, with $s = 2$, $k_0 = 1$, $f_\Omega = u$, and $f_0 = y_0^4$,

$$\begin{aligned}\|y\|_{L^\infty(\Omega)} + \|y\|_{L^\infty(\Gamma_r \cup \Gamma_0)} &\leq c_0 \left(1 + \|u\|_{L^2(\Omega_s)} + \|y_0^4\|_{L^4(\Gamma_0)}\right) \\ &\leq c_0 \big(1 + \|u\|_{L^2(\Omega_s)} + \|y_0\|^4_{L^{16}(\Gamma_0)}\big). \qquad \square\end{aligned}$$

For the discussion of an associated linearized equation (see section 6), we need another property of the semilinear solution, namely, the following maximum principle.

THEOREM 4.3. *Suppose that $u(x) \geq 0$ a.e. in Ω_s and $y_0(x) \geq \vartheta > 0$ a.e. on Γ_0. If y is the solution of (4.1), then $y(x) \geq \vartheta$ holds a.e. on Ω and a.e. on $\Gamma_r \cup \Gamma_0$.*

Proof. This time, we use the following test function in (4.1):

$$\rho_\vartheta(x) := \begin{cases} y(x) - \vartheta, & y(x) \leq \vartheta, \\ 0, & y(x) > \vartheta. \end{cases}$$

Furthermore, we define $\Omega^- = \{x \in \Omega \mid y(x) \leq \vartheta\}$ and introduce analogous definitions for Ω_s^-, Γ_0^-, and Γ_r^-. Thus, we have $\rho_\vartheta|_{\Omega \setminus \Omega^-} = 0$, and (4.1) reads

$$\begin{aligned}\int_{\Omega^-} \kappa \nabla y \cdot \nabla \rho_\vartheta \, dx + \int_{\Gamma_r} G(\sigma|y|^3 y)\rho_\vartheta \, ds \\ + \int_{\Gamma_0^-} \varepsilon\sigma(|y|^3 y - y_0^4) \, \rho_\vartheta \, ds = \int_{\Omega_s^-} u \, \rho_\vartheta \, dx.\end{aligned} \tag{4.6}$$

Next, as in the proof of Theorem 4.2, the positivity of the integral over Γ_r can be shown by decomposition:

$$\int_{\Gamma_r} G(\sigma|y|^3 y)\rho_\vartheta \, ds = \int_{\Gamma_r} G(\sigma\Phi)\rho_\vartheta \, ds + \int_{\Gamma_r} G(\sigma\Psi)\rho_\vartheta \, ds$$

with

$$\Phi(x) = \begin{cases} |y(x)|^3 y(x), & y(x) \leq \vartheta, \\ \vartheta^4, & y(x) > \vartheta, \end{cases} \qquad \Psi(x) = \begin{cases} 0, & y(x) \leq \vartheta, \\ |y(x)|^3 y(x) - \vartheta^4, & y(x) > \vartheta. \end{cases}$$

Therefore, (4.6) results in

$$\int_{\Gamma_0^-} \varepsilon\sigma \, (y_0^4 - |y|^3 y) \, \rho_\vartheta \, ds \geq \int_{\Omega^-} \kappa \nabla y \cdot \nabla \rho_\vartheta \, dx - \int_{\Omega_s^-} u \, \rho_\vartheta \, dx \geq 0, \tag{4.7}$$

since $\nabla\rho_\vartheta = \nabla y$ on Ω^-, $\rho_\vartheta \le 0$ by definition, and $u \ge 0$ by assumption. On Γ_0^-, we also have $y - \vartheta \le 0$, implying $y_0^4 - |y|^3 y \ge 0$. Thus, we obtain

$$0 \le \int_{\Gamma_0^-} \varepsilon\sigma\,(y_0^4 - |y|^3 y)\,\rho_\vartheta\,ds = \int_{\Gamma_0^-} \varepsilon\sigma\,(y_0^4 - |y|^3 y)(y-\vartheta)\,ds \le 0,$$

and, consequently, $|\Gamma_0^-| = 0$ or $y = y_0$ or $y = \vartheta$ a.e. on Γ_0, which, in each case, yields the assertion on Γ_0. Therefore, we have $\rho_\vartheta \in H_0^1(\Omega)$.

Now, from (4.7), it follows that

$$\kappa_{\min}\|\nabla\rho_\vartheta\|_{L^2(\Omega)} \le \int_{\Gamma_0^-} \varepsilon\sigma\,(y_0^4 - |y|^3 y)\,\rho_\vartheta\,ds + \int_{\Omega_s^-} u\,\rho_\vartheta\,dx \le 0,$$

since $\nabla\rho_\vartheta = 0$ in $\Omega\backslash\Omega^-$. Hence $\|\nabla\rho_\vartheta\|_{L^2(\Omega)} = \|\rho_\vartheta\|_{H_0^1(\Omega)} = 0$ (notice that we have already shown $\rho_\vartheta = 0$ a.e. on Γ_0). Thus, $\rho_\vartheta = 0$ a.e. in Ω. Hence, we have shown $y \ge \vartheta$ a.e. on both Ω and Γ_0, and Lemma 3.7 then ensures $y \ge \vartheta$ a.e. on Γ_r. ∎

Notice that, within our scope of heat transport modeling, the assumption $y_0(x) \ge \vartheta > 0$ a.e. on Γ_0 constitutes no restriction: Since y_0 represents an external temperature, it is naturally positive.

5. Existence of an optimal solution. With the results of section 4 at hand, the proof of existence of an optimal solution for the optimal control problem (P) is rather standard. We start with the following lemma.

LEMMA 5.1. *Let $u \in L^{6/5}(\Omega_s)$, $y_0 \in L^{16/3}(\Gamma_0)$ be given and assume that the hypotheses of Theorem* 4.3 *are fulfilled. Then a constant c_1 exists depending only on Ω with*

$$\|y\|_{H^1(\Omega)} \le c_1\left(\|u\|_{L^{6/5}(\Omega_s)} + \|y_0\|^4_{L^{16/3}(\Gamma_0)}\right).$$

Proof. Thanks to Theorem 4.1, a unique solution y of (4.1) exists. Using it as a test function in (4.1) yields

$$\int_\Omega \kappa|\nabla y|^2\,dx + \int_{\Gamma_r} G(\sigma|y|^3 y)y\,ds + \int_{\Gamma_0} \varepsilon\sigma\,|y|^3 y^2\,ds = \int_{\Omega_s} u\,y\,dx + \int_{\Gamma_0} \varepsilon\sigma\,y_0^4 y\,ds.$$

Due to Lemma 3.4(iii) and the maximum principle in Theorem 4.3, we have

$$\begin{aligned}&\int_\Omega \kappa|\nabla y|^2\,dx + \int_{\Gamma_r} G(\sigma|y|^3 y)y\,ds + \int_{\Gamma_0} \varepsilon\sigma\,|y|^3 y^2\,ds\\ &\ge \kappa_{\min}\,\|\nabla y\|^2_{L^2(\Omega)} + \varepsilon_{\min}\,\sigma\,\vartheta^3\|y\|^2_{L^2(\Gamma_0)} \ge c\,\|y\|^2_{H^1(\Omega)}.\end{aligned}$$

Therefore, by trace and embedding theorems,

$$\begin{aligned}\|y\|^2_{H^1(\Omega)} &\le c\left(\int_{\Omega_s} u\,y\,dx + \int_{\Gamma_0} \varepsilon\sigma\,y_0^4 y\,ds\right)\\ &\le c\,\left(\|u\|_{L^{6/5}(\Omega_s)}\|y\|_{L^6(\Omega_s)} + \|y_0^4\|_{L^{4/3}(\Gamma_0)}\|y\|_{L^4(\Gamma_0)}\right)\\ &\le c_1\left(\|u\|_{L^{6/5}(\Omega_s)} + \|y_0\|^4_{L^{16/3}(\Gamma_0)}\right)\|y\|_{H^1(\Omega)},\end{aligned}$$

which establishes the case. ∎

THEOREM 5.2. *Assume that* $u_a \geq 0$, $y_0 \in L^{16}(\Gamma_0)$, *and* $y_0 \geq \vartheta > 0$. *Then there exists a solution* $(\bar{u}, \bar{y}) \in L^\infty(\Omega_s) \times V^\infty$ *to* (P).

Proof. As mentioned above, the proof follows standard arguments. We start with a sequence $\{(u_n, y_n)\}_{n=1}^\infty$ converging to the infimum $\bar{J} \geq 0$ of the objective functional in (P), i.e., $J(u_n, y_n) \to \bar{J}$, $n \to \infty$. We will now show the convergence of a subsequence of $\{(u_n, y_n)\}_{n=1}^\infty$ to an optimal solution $(\bar{u}, \bar{y})$.

The box constraints ensure that u is bounded in $L^2(\Omega_s)$. Thus, we can select a weakly converging subsequence w.l.o.g. and again denoted by u_n, $u_n \rightharpoonup \bar{u}$, $n \to \infty$. Since U_{ad} is a closed and convex subset of $L^2(\Omega_s)$, we have $\bar{u} \in U_{ad}$.

In addition to the boundedness, the u_n are also nonnegative because of $u_a \geq 0$. Together with the assumptions on y_0, this yields the boundedness of $\|y_n\|_{H^1(\Omega)}$ thanks to Lemma 5.1. Hence, we can select a weakly converging subsequence and w.l.o.g. y_n itself, i.e., $y_n \rightharpoonup \bar{y}$, $n \to \infty$, in $H^1(\Omega)$. The trace theorem and the compact embedding of $H^{1/2}(\Gamma_r \cup \Gamma_0)$ in $L^2(\Gamma_r \cup \Gamma_0)$ then give

$$\tau y_n \to \tau \bar{y}, \ n \to \infty \quad \text{in } L^2(\Gamma_r \cup \Gamma_0).$$

Now, the convergence of the nonlinearities can be derived on Γ_r and Γ_0. Since u_n, $n \in \mathbb{N}$, is uniformly bounded in $L^2(\Omega_s)$, and $y_0 \in L^{16}(\Gamma_0)$ by assumption, Theorem 4.2 ensures that a constant d exists with $|y(x)| \leq d$ a.e. in Ω and a.e. in $\Gamma_r \cup \Gamma_0$. One can easily verify that the Nemytskii operator $\Phi(y) := |y|^3 y$ satisfies

$$\|\Phi(y_n) - \Phi(y_m)\|_{L^2(\Gamma_r \cup \Gamma_0)} \leq L(d) \|y_n - y_m\|_{L^2(\Gamma_r \cup \Gamma_0)} \tag{5.1}$$

for all $y_n, y_m \in \{y \in L^\infty(\Gamma_0 \cup \Gamma_r) \,|\, |y(x)| \leq d \text{ a.e. on } \Gamma_0 \cup \Gamma_r\}$. Since this set is closed in $L^2(\Gamma_r \cup \Gamma_0)$, $|\bar{y}(x)| \leq d$ also holds true, and the convergence in $L^2(\Gamma_r \cup \Gamma_0)$ together with (5.1) yields

$$|\tau y_n|^3 \tau y_n \to |\tau \bar{y}|^3 \tau \bar{y} \quad \text{in } L^2(\Gamma_r \cup \Gamma_0). \tag{5.2}$$

Consider now the variational equation (4.1) when passing to the limit. For (u_n, y_n), it reads

$$\begin{aligned} &\int_\Omega \kappa \nabla y_n \cdot \nabla v \, dx + \int_{\Gamma_r} G(\sigma |y_n|^3 y_n) v \, ds + \int_{\Gamma_0} \varepsilon\sigma \, |y_n|^3 y_n \, v \, ds \\ &\quad = \int_{\Omega_s} u_n \, v \, dx + \int_{\Gamma_0} \varepsilon\sigma \, y_0^4 v \, ds. \end{aligned}$$

Due to $y_n \rightharpoonup \bar{y}$ in $H^1(\Omega)$, the first integral on the left-hand side converges to $\int_\Omega \kappa \nabla \bar{y} \cdot \nabla v \, dx$. The boundary integrals on the left-hand side converge because of (5.2) and the continuity of G. Finally, the inhomogeneity converges, owing to $u_n \rightharpoonup \bar{u}$ in $L^2(\Omega_s)$. Therefore, the limit $(\bar{u}, \bar{y})$ satisfies the weak formulation (4.1). The optimality of $(\bar{y}, \bar{u})$ follows in a standard way by the lower semicontinuity of J. ∎

6. The linearized equation. In this section, we investigate the linearization of the state equation (4.1) at a fixed reference pair $(\bar{y}, \bar{u}) \in V^\infty \times L^2(\Omega_s)$.[1] The linearized equation arises from the differentiation of the solution operator associated with the semilinear state equation $S : L^2(\Omega_s) \to V^\infty$ mapping u to y. This derivative

[1]Here and in the following, we will denote a fixed solution of the semilinear equation as well as an optimal solution by $(\bar{u}, \bar{y})$.

of S at $(\bar y, \bar u)$ appears in the variational inequality (see section 7). More precisely, we consider the linearized equation with a more general inhomogeneity in the form

$$
\begin{aligned}
-\mathrm{div}(\kappa\,\nabla y) &= f_\Omega \quad \text{in } \Omega,\\
\kappa_{\mathrm{s}}\left(\frac{\partial y}{\partial n_{\mathrm{r}}}\right)_{\mathrm{s}} - \kappa_{\mathrm{g}}\left(\frac{\partial y}{\partial n_{\mathrm{r}}}\right)_{\mathrm{g}} + 4\,G(\sigma|\bar y|^3 y) &= f_{\mathrm{r}} \quad \text{on } \Gamma_{\mathrm{r}},\\
\kappa_{\mathrm{s}}\frac{\partial y}{\partial n_0} + 4\,\varepsilon\sigma|\bar y|^3 y &= f_0 \quad \text{on } \Gamma_0
\end{aligned}
\tag{6.1}
$$

with $\bar y = S\,\bar u \in V^\infty$ and arbitrary functions $(f_\Omega, f_{\mathrm{r}}, f_0)$ in $L^2(\Omega)\times L^2(\Gamma_{\mathrm{r}})\times L^2(\Gamma_0)$. In the next section, we will show that, under a natural assumption, S is indeed Fréchet differentiable and its derivative $y = S'(\bar u)u$ corresponds to the solution of (6.1) with $f_\Omega = u$, $f_{\mathrm{r}} = 0$, and $f_0 = 0$. However, we first focus on (6.1), and, in the present section, prove the existence of a unique solution in V^∞. The existence theory is based on the theory of Fredholm operators and has to account for eigenvalues. This is due to the fact that the Lax–Milgram lemma cannot be directly applied because of the lack of coercivity caused by the radiation operator G in the linearized case. The boundedness of the solution is again shown by Lemma 3.8.

The variational equation of (6.1) reads

$$
\begin{aligned}
&\int_\Omega \kappa\nabla y\cdot\nabla v\,dx + \int_{\Gamma_0} 4\,\varepsilon\sigma\,|\bar y|^3 y\,v\,ds\\
&\qquad = \int_\Omega f_\Omega\,v\,dx + \int_{\Gamma_{\mathrm{r}}} (f_{\mathrm{r}} - 4\,G(\sigma|\bar y|^3 y))\,v\,ds + \int_{\Gamma_0} f_0\,v\;ds \quad \forall\, v\in H^1(\Omega).
\end{aligned}
\tag{6.2}
$$

Assume for awhile that y is given on the right-hand side. In view of $\bar y\in V^\infty$ and $\bar y\ge \vartheta > 0$ (Theorem 4.3), the bilinear form defined by the left-hand side of (6.2) is bounded and coercive in $H^1(\Omega)$. Therefore, the Lax–Milgram lemma yields continuous linear operators $B_\Omega : L^2(\Omega)\to H^1(\Omega)$, $B_{\mathrm{r}} : L^2(\Gamma_{\mathrm{r}})\to H^1(\Omega)$, and $B_0 : L^2(\Gamma_0)\to H^1(\Omega)$ such that, with $\tilde y := \tau_{\mathrm{r}}\,y$,

$$
y = B_\Omega\,f_\Omega + B_{\mathrm{r}}\,(f_{\mathrm{r}} - 4\,G(\sigma|\tau_{\mathrm{r}}\bar y|^3\tilde y)) + B_0\,f_0.
\tag{6.3}
$$

We are now in a position to formulate the existence theorem for (6.1).

THEOREM 6.1. *Assume $\bar y\in V^\infty$, $\bar y\ge\vartheta>0$, and that $\lambda = 1$ is not an eigenvalue of $B(\bar y)(\,\cdot\,) := -\tau_{\mathrm{r}}\,B_{\mathrm{r}}(4\,G(\sigma|\tau_{\mathrm{r}}\bar y|^3\,\cdot\,))$ with $B(\bar y) : L^2(\Gamma_{\mathrm{r}})\to L^2(\Gamma_{\mathrm{r}})$. Then, to every $(f_\Omega, f_{\mathrm{r}}, f_0)\in L^2(\Omega)\times L^2(\Gamma_{\mathrm{r}})\times L^2(\Gamma_0)$, there exists a unique solution y of (6.1) in $H^1(\Omega)$.*

Proof. In the following, we will suppress the dependency of B on $\bar y$, since $\bar y$ is fixed. Thus, we simply write B instead of $B(\bar y)$. Applying the trace operator τ_{r} to both sides, (6.3) results in

$$
(I-B)\tilde y = \tilde y + \tau_{\mathrm{r}}B_{\mathrm{r}}(4\,G(\sigma|\tau_{\mathrm{r}}\bar y|^3\tilde y)) = \tau_{\mathrm{r}}\,(B_\Omega\,f_\Omega + B_{\mathrm{r}}\,f_{\mathrm{r}} + B_0\,f_0).
\tag{6.4}
$$

Since $B_{\mathrm{r}} : L^2(\Gamma_{\mathrm{r}})\to H^1(\Omega)$, and $\bar y\in V^\infty$ by assumption, and, thus, $\tau_{\mathrm{r}}\bar y\in L^\infty(\Gamma_{\mathrm{r}})$, it follows that B maps $L^2(\Gamma_{\mathrm{r}})$ in $H^{1/2}(\Gamma_{\mathrm{r}})$. Due to compact embedding, B is compact from $L^2(\Gamma_{\mathrm{r}})$ to $L^2(\Gamma_{\mathrm{r}})$. Therefore, $\lambda = 1$ is either one of the countably many eigenvalues of B, or $(I-B)$ is continuously invertible. Thus, we obtain a unique solution $\tilde y\in L^2(\Gamma_{\mathrm{r}})$ of (6.4), provided that $\lambda = 1$ is not an eigenvalue of B.

Furthermore, for every $\tilde{y} \in L^2(\Gamma_\mathrm{r})$, we have $G(\sigma|\tau_\mathrm{r}\bar{y}|^3\tilde{y}) \in L^2(\Gamma_\mathrm{r})$ by means of $\bar{y} \in V^\infty$, and, hence, (6.3) admits a unique solution in $H^1(\Omega)$. ∎

As indicated above, we will employ Theorem 6.1 to prove the Fréchet differentiability of S at the reference solution $(\bar{u}, \bar{y})$, which, in turn, is used to establish first order necessary optimality conditions (see section 7 below). It is well known that regularity assumptions on the solution $\bar{y}$, like those present in Theorem 6.1, are typical for the Fréchet differentiability of solution operators associated with semilinear PDEs. In particular, the assumption that $\lambda = 1$ is not an eigenvalue of $B(\bar{y})$ can be interpreted as such a regularity assumption on the solution $\bar{y}$.

THEOREM 6.2. *Suppose that the assumptions of Theorem* 6.1 *hold true. Then, for all $f_\Omega \in L^2(\Omega)$, $f_\mathrm{r} \in L^4(\Gamma_\mathrm{r})$, and $f_0 \in L^4(\Gamma_\mathrm{r})$, there exists a constant c_2 depending only on Ω such that*

$$\|y\|_{L^\infty(\Omega)} + \|y\|_{L^\infty(\Gamma_\mathrm{r}\cup\Gamma_0)} \le c_2 \left(\|f_\Omega\|_{L^2(\Omega)} + \|f_\mathrm{r}\|_{L^4(\Gamma_\mathrm{r})} + \|f_0\|_{L^4(\Gamma_0)}\right) \tag{6.5}$$

holds true.

Proof. We again use Lemma 3.8 to prove the boundedness, this time with $W = H^1(\Omega)$. We apply it to (6.2) for F defined by

$$\langle F(y)\,,\, v\rangle = \int_\Omega \kappa \nabla y \cdot \nabla v \, dx + \int_{\Gamma_0} 4\,\varepsilon\sigma\,|\bar{y}|^3 y\, v \, ds.$$

Hypothesis (H2) clearly holds with $k_0 = 0$, owing to the coercivity of the bilinear form.

Now, (H1), i.e., the regularity of the right-hand side, is the critical point, since the inhomogeneity on Γ_r in (6.2) depends on the solution y. As before, we choose $s = 2$ in (H1), and thus, the required regularities coincide with the assumptions on f_Ω, f_r, and f_0.

The part of the inhomogeneity depending on y and $\bar{y}$ is given by $-4\,G(\sigma|\bar{y}|^3 y)$. It belongs to $L^4(\Gamma_\mathrm{r})$, since $y \in H^1(\Omega)$, and therefore $\tau_\mathrm{r} y \in L^4(\Gamma_\mathrm{r})$ in addition to $\bar{y} \in V^\infty$. Consequently, (H1) also is satisfied, and Lemma 3.8 can be applied.

It remains to verify a bound that is independent of y. With $k_0 = 0$, estimate (3.6) gives

$$\begin{aligned} &\|y\|_{L^\infty(\Omega)} + \|y\|_{L^\infty(\Gamma_\mathrm{r}\cup\Gamma_0)} \\ &\qquad \le c_0 \left(\|f_\Omega\|_{L^2(\Omega)} + \|f_\mathrm{r}\|_{L^4(\Gamma_\mathrm{r})} + \|4\,G(\sigma|\bar{y}|^3 y)\|_{L^4(\Gamma_\mathrm{r})} + \|f_0\|_{L^4(\Gamma_0)}\right). \end{aligned} \tag{6.6}$$

We estimate the term with y by

$$\|G(\sigma|\bar{y}|^3 y)\|_{L^4(\Gamma_\mathrm{r})} \le c\|G\|_{\mathcal{L}(L^4(\Gamma_\mathrm{r}))}\, \|\bar{y}\|^3_{L^\infty(\Gamma_\mathrm{r})}\, \|y\|_{H^1(\Omega)}. \tag{6.7}$$

With (6.3) and the continuity of B_Ω, B_r, and B_0, we obtain by the boundedness of $\bar{y}$,

$$\begin{aligned} \|y\|_{H^1(\Omega)} \le\ & \|B_\Omega\, f_\Omega + B_\mathrm{r}\, f_\mathrm{r} + B_0\, f_0\|_{H^1(\Omega)} \\ &+ c\,\|B_\mathrm{r}\|_{\mathcal{L}(L^2(\Gamma_\mathrm{r}),H^1(\Omega))}\|G\|_{\mathcal{L}(L^2(\Gamma_\mathrm{r}))}\|\bar{y}\|^3_{L^\infty(\Gamma_\mathrm{r})}\|y\|_{L^2(\Gamma_\mathrm{r})} \\ &\le c\,(\|f_\Omega\|_{L^2(\Omega)} + \|f_\mathrm{r}\|_{L^4(\Gamma_\mathrm{r})} + \|f_0\|_{L^4(\Gamma_0)} + \|y\|_{L^2(\Gamma_\mathrm{r})}). \end{aligned} \tag{6.8}$$

Due to (6.4), $\|\tilde{y}\|_{L^2(\Gamma_\mathrm{r})}$ is bounded by

$$\begin{aligned} \|\tilde{y}\|_{L^2(\Gamma_\mathrm{r})} &\le \|(I-B)^{-1}\|_{\mathcal{L}(L^2(\Gamma_\mathrm{r}))} \cdot \|B_\Omega\, f_\Omega + B_\mathrm{r}\, f_\mathrm{r} + B_0\, f_0\|_{L^2(\Gamma_\mathrm{r})} \\ &\le c(\|f_\Omega\|_{L^2(\Omega)} + \|f_\mathrm{r}\|_{L^4(\Gamma_\mathrm{r})} + \|f_0\|_{L^4(\Gamma_0)}), \end{aligned} \tag{6.9}$$

where Fredholm theory grants $\|(I-B)^{-1}\|_{\mathcal{L}(L^2(\Gamma_r))} < \infty$. Combining (6.7)–(6.9) yields

$$\|G(\sigma|\bar{y}|^3 y)\|_{L^4(\Gamma_r)} \le \tilde{c}\,(\|f_\Omega\|_{L^2(\Omega)} + \|f_r\|_{L^4(\Gamma_r)} + \|f_0\|_{L^4(\Gamma_0)}) \tag{6.10}$$

with a constant $\tilde{c}$ depending only on Ω. Inserting (6.10) in (6.6) finally gives

$$\begin{aligned}\|y\|_{L^\infty(\Omega)} + \|y\|_{L^\infty(\Gamma_r\cup\Gamma_0)} &\le c_0(1+\tilde{c})\left(\|f_\Omega\|_{L^2(\Omega)} + \|f_r\|_{L^4(\Gamma_r)} + \|f_0\|_{L^4(\Gamma_0)}\right)\\ &\le c_2\left(\|f_\Omega\|_{L^2(\Omega)} + \|f_r\|_{L^4(\Gamma_r)} + \|f_0\|_{L^4(\Gamma_0)}\right). \qquad \square\end{aligned}$$

7. First order necessary optimality conditions. With the results of sections 4 and 6, we are now able to show the Fréchet differentiability of the semilinear PDE solution operator $S : u \mapsto y$ from $L^2(\Omega_s)$ to V^∞; see section 7.1. Defining $J(y,u) = J(S\,u,u) =: j(u)$, a standard argument then yields the variational inequality for the optimal pair $(\bar{u},\bar{y})$:

$$j'(\bar{u})(u-\bar{u}) = (\nabla\bar{y} - z, \nabla y)_{L^2(\Omega_g)} + \nu(\bar{u},(u-\bar{u}))_{L^2(\Omega_s)} \ge 0 \quad \forall\, u \in U_{\rm ad}, \tag{7.1}$$

with $\bar{y} = S\,\bar{u}$ and $y = S'(\bar{u})(u-\bar{u})$. The latter relation means that y satisfies the PDE

$$\begin{aligned} -\mathrm{div}(\kappa_s\,\nabla y) &= u-\bar{u} && \text{in } \Omega_s,\\ -\mathrm{div}(\kappa_g\,\nabla y) &= 0 && \text{in } \Omega_g,\\ \kappa_s\left(\frac{\partial y}{\partial n_r}\right)_s - \kappa_g\left(\frac{\partial y}{\partial n_r}\right)_g + 4\,G(\sigma|\bar{y}|^3 y) &= 0 && \text{on } \Gamma_r,\\ \kappa_s\frac{\partial y}{\partial n_0} + 4\,\varepsilon\sigma|\bar{y}|^3 y &= 0 && \text{on } \Gamma_0. \end{aligned} \tag{7.2}$$

Note that (7.2) constitutes a special case of (6.1).

In section 7.2, we transform the variational inequality (7.1) into the standard projection formula depending on the adjoint state p.

7.1. Differentiability of the control-to-state operator. We show the differentiability of S by the implicit function theorem. To that end, let us introduce an auxiliary operator T such that S is implicitly defined by $T(u,S(u)) = 0$. Preparing the definition of T, we consider the following equation that is equivalent to the weak formulation of the semilinear PDE (4.1):

$$\begin{aligned}&\int_\Omega \kappa\nabla y\cdot\nabla v\,dx + \int_{\Gamma_0}\lambda\,y\,v\,ds\\ &\qquad = -\int_{\Gamma_r} G(\sigma|y|^3 y)v\,ds + \int_{\Gamma_0}(\lambda\,y + \varepsilon\sigma\,y_0^4 - \varepsilon\sigma\,|y|^3 y)\,v\,ds + \int_{\Omega_s} u\,v\,dx\end{aligned} \tag{7.3}$$

with a fixed $\lambda > 0$. Due to the positivity of λ, the left-hand side in (7.3) represents a bounded, coercive bilinear form in $H^1(\Omega)$. Thus, for every right-hand side in $H^1(\Omega)^*$, we have a unique solution in $H^1(\Omega)$. Furthermore, similar to the proof of Theorem 6.2, it follows that this solution is bounded if the right-hand side is sufficiently regular, i.e., in $L^2(\Omega)\times L^4(\Gamma_r)\times L^4(\Gamma_0)$. Thus, continuous operators $\tilde{B}_{\Omega_s} : L^2(\Omega_s) \to V^\infty$, $\tilde{B}_0 : L^4(\Gamma_0) \to V^\infty$, and $\tilde{B}_r : L^4(\Gamma_r) \to V^\infty$ exist with

$$y = \tilde{B}_{\Omega_s}\,u - \tilde{B}_r\,(G(\sigma|y|^3 y)) + \tilde{B}_0\,(\lambda\,y + \varepsilon\sigma\,y_0^4 - \varepsilon\sigma\,|y|^3 y),$$

and our auxiliary operator is given by

$$T(u,y) := y - \tilde{B}_{\Omega_s}\, u + \tilde{B}_r\,(G(\sigma|y|^3 y)) - \tilde{B}_0\,(\lambda\, y + \varepsilon\sigma\, y_0^4 - \varepsilon\sigma\,|y|^3 y) \tag{7.4}$$

with $T : L^2(\Omega_s) \times V^\infty \to V^\infty$.

THEOREM 7.1. *Assume that $u_a \geq 0$, $y_0 \in L^{16}(\Gamma_0)$, $y_0 \geq \vartheta > 0$, and $\lambda = 1$ is not an eigenvalue of B, where $B = B(\bar{y})$ is as defined in Theorem* 6.1. *Then, $S : L^2(\Omega_s) \to V^\infty$ is Fréchet differentiable at $(\bar{u}, \bar{y})$, and $y := S'(\bar{u})(u - \bar{u})$ is given by the solution of the linearized equation* (7.2).

Proof. According to the definition of T in (7.4) and because of Theorems 4.1 and 4.2, $y = S(u)$ if and only if $T(u,y) = T(u, S\,u) = 0$, since this equation corresponds to the semilinear equation (4.1). To prove the differentiability of S, it thus suffices to verify the hypotheses of the implicit function theorem for T. This is continuous Fréchet differentiability of T and continuous invertibility of $\frac{\partial T}{\partial y}(\bar{u}, \bar{y})$.

The Nemytskii operator $\Phi(y) = |y|^3 y$ is continuously Fréchet differentiable from $L^\infty(\Gamma_r \cup \Gamma_0)$ to $L^\infty(\Gamma_r \cup \Gamma_0)$; see [11]. The other operators in the definition of T are all continuous and linear operators, and, thus, trivially continuously Fréchet differentiable on their particular spaces, i.e., G from $L^\infty(\Gamma_r)$ to $L^\infty(\Gamma_r)$, $\tilde{B}_{\Omega_s}$ from $L^2(\Omega_s)$ to V^∞, $\tilde{B}_r$ from $L^\infty(\Gamma_r)$ to V^∞, and $\tilde{B}_0$ from $L^\infty(\Gamma_r)$ to V^∞. By the chain rule, T is continuously Fréchet differentiable from $L^2(\Omega_s) \times V^\infty$ to V^∞, and, in particular, continuous.

It remains to show the invertibility of $\frac{\partial T}{\partial y}(\bar{u}, \bar{y})$. For a given $f \in V^\infty$, we have to prove the existence of a unique $y \in V^\infty$ satisfying $\frac{\partial T}{\partial y}(\bar{u}, \bar{y})y = f$, i.e., in view of (7.4),

$$y + 4\tilde{B}_r\,(G(\sigma|\bar{y}|^3 y)) = f + \tilde{B}_0\,(\lambda\, y - 4\varepsilon\sigma\,|\bar{y}|^3 y).$$

With the substitution $y = f - w \in V^\infty$, this is equivalent to the weak formulation

$$\begin{aligned}\int_\Omega \kappa \nabla w \cdot \nabla v\, dx + \int_{\Gamma_r} 4\, G(\sigma|\bar{y}|^3 w) v\, ds + \int_{\Gamma_0} 4\,\varepsilon\sigma\,|\bar{y}|^3 w\, v\, ds \\ = \int_{\Gamma_r} 4\, G(\sigma|\bar{y}|^3 f) v\, ds - \int_{\Gamma_0} (\lambda - 4\,\varepsilon\sigma\,|\bar{y}|^3) f\, v\, ds \quad \forall\, v \in H^1(\Omega),\end{aligned}$$

whose bilinear form coincides with the form of (6.2). Here, the inhomogeneity is given by $f_\Omega = 0$, $f_0 := (\varepsilon\sigma\,|\bar{y}|^3 - \lambda) f \in L^\infty(\Gamma_0)$, and $f_r := 4\, G(\sigma|\bar{y}|^3 f) \in L^\infty(\Gamma_r)$. Thus, it fulfills the hypotheses of Theorems 6.1 and 6.2. We therefore have $w \in V^\infty$, and, hence, to every $f \in V^\infty$, there exists a unique solution $y \in V^\infty$ that yields the desired bijectivity of $\frac{\partial T}{\partial y}(\bar{u}, \bar{y})$.

Now, since all hypotheses are satisfied, we can apply the implicit function theorem to (7.4) and obtain, as a derivative of S,

$$y := S'(\bar{u})(u - \bar{u}) = -\left(\frac{\partial T}{\partial y}(\bar{u}, \bar{y})\right)^{-1} \frac{\partial T}{\partial u}(\bar{u}, \bar{y})(u - \bar{u}). \tag{7.5}$$

Finally, a straightforward computation shows that y satisfies (7.5) if and only if y is the solution of the linearized equation (7.2). ∎

7.2. The adjoint equation. A standard technique formally gives the following adjoint equation associated with (P):

$$
\begin{aligned}
\operatorname{div}(\kappa_{\mathrm{g}}\,\nabla p) &= \Delta\bar{y} - \operatorname{div} z \quad \text{in } \Omega_{\mathrm{g}},\\
\operatorname{div}(\kappa_{\mathrm{s}}\,\nabla p) &= 0 \qquad\qquad\quad \text{in } \Omega_{\mathrm{s}},\\
\kappa_{\mathrm{s}}\left(\frac{\partial p}{\partial n_{\mathrm{r}}}\right)_{\mathrm{s}} - \kappa_{\mathrm{g}}\left(\frac{\partial p}{\partial n_{\mathrm{r}}}\right)_{\mathrm{g}} + 4\sigma\,|\bar{y}|^3 G^* p &= \frac{\partial y}{\partial n_{\mathrm{r}}} - z\cdot n_{\mathrm{r}} \quad \text{on } \Gamma_{\mathrm{r}},\\
\kappa_s\,\frac{\partial p}{\partial n_0} + 4\varepsilon\sigma\,|\bar{y}|^3 p &= 0 \qquad\qquad\quad \text{on } \Gamma_0.
\end{aligned}
\tag{7.6}
$$

Formal integration by parts, also on the right-hand side, yields the corresponding weak formulation of (7.6):

$$
\begin{aligned}
&\int_\Omega \kappa\nabla p\cdot\nabla v\,dx \;+\; 4\int_{\Gamma_{\mathrm{r}}} \sigma\,|\bar{y}|^3\,G^*(p)\,v\,ds + 4\int_{\Gamma_0}\varepsilon\sigma\,|\bar{y}|^3\,p\,v\,ds\\
&\quad = \int_{\Omega_{\mathrm{g}}} (\nabla\bar{y} - z)\cdot\nabla v\,dx =: \langle w, v\rangle \quad \forall\, v\in H^1(\Omega)
\end{aligned}
\tag{7.7}
$$

with $w\in H^1(\Omega)^*$, since $\bar{y}\in V^\infty$ and $z\in L^2(\Omega_{\mathrm{g}})$ by (A3).

To show the existence of a unique solution to (7.7), we use a technique similar to that for the linearized equation (6.1) based on the Fredholm alternative (see section 6). To that end, we transform (7.7) into

$$
\int_\Omega \kappa\nabla p\cdot\nabla v\,dx + 4\int_{\Gamma_0}\varepsilon\sigma\,|\bar{y}|^3\,p\,v\,ds = \langle w, v\rangle - 4\int_{\Gamma_{\mathrm{r}}}\sigma\,|\bar{y}|^3\,G^*(p)\,v\,ds.
$$

Due to the positivity of $\bar{y}$, the bilinear form defined by the left-hand side is bounded and coercive in $H^1(\Omega)$. Thus, we again obtain linear continuous operators $B_\Omega : H^1(\Omega)^*\to H^1(\Omega)$ and $B_{\mathrm{r}} : L^2(\Gamma_r)\to H^1(\Omega)$ such that

$$
p = B_\Omega\, w + B_{\mathrm{r}}\,(-4\,\sigma|\bar{y}|^3\,G^*(\tau_{\mathrm{r}}p))
$$

(similar to (6.3)). Now we can argue as in the proof of Theorem 6.1 to obtain the following result.

THEOREM 7.2. *Assume $\bar{y}\in V^\infty$, $\bar{y}\ge\vartheta>0$, and that $\lambda=1$ is not an eigenvalue of $B(\bar{y})(\,\cdot\,) := -\tau_{\mathrm{r}}\,B_{\mathrm{r}}(4\,\sigma|\bar{y}|^3\,G^*(\,\cdot\,))$ with $B(\bar{y}) : L^2(\Gamma_{\mathrm{r}})\to L^2(\Gamma_{\mathrm{r}})$. Then, to every $w\in H^1(\Omega)^*$, there exists a unique solution p of (7.7) in $H^1(\Omega)$.*

Now, if we choose $v=p$ as a test function in the weak formulation of the linearized equation (7.2), we obtain

$$
\int_\Omega \kappa\nabla y\cdot\nabla p\,dx \;+\; 4\int_{\Gamma_{\mathrm{r}}} G(\sigma\,|\bar{y}|^3 y)p\,ds + 4\int_{\Gamma_0}\varepsilon\sigma\,|\bar{y}|^3\,y\,p\,ds = \int_{\Omega_{\mathrm{s}}}(u-\bar{u})p\,dx.
$$

On the other hand, we insert $v=y$ into the weak formulation of the adjoint equation:

$$
\int_\Omega \kappa\nabla p\cdot\nabla y\,dx \;+\; 4\int_{\Gamma_{\mathrm{r}}} \sigma\,|\bar{y}|^3\,y\,G^*(p)\,ds + 4\int_{\Gamma_0}\varepsilon\sigma\,|\bar{y}|^3\,p\,y\,ds = \int_{\Omega_{\mathrm{g}}}(\nabla\bar{y}-z)\cdot\nabla y\,dx.
$$

Substracting one equation from the other yields $(\nabla\bar{y} - z, \nabla y)_{L^2(\Omega_g)} = (u - \bar{u}, p)_{L^2(\Omega_s)}$ for the first expression in the variational inequality (7.1) . Thus, (7.1) can be transformed into

$$j'(\bar{u})(u - \bar{u}) = \int_{\Omega_s} (u - \bar{u})(p + \nu\bar{u})\, dx \geq 0 \quad \forall\, u \in U_{\mathrm{ad}},$$

and, finally, a standard pointwise discussion leads to the projection formula

$$\bar{u}(x) = \mathcal{P}_{[u_a, u_b]} \left\{ -\frac{1}{\nu}\, p(x) \right\} \quad \text{a.e. on } \Omega_s, \tag{7.8}$$

where $\mathcal{P}_{[u_a,u_b]}$ denotes the pointwise projection operator on $[u_a, u_b]$ (cf. Lions [13]).

8. Numerical tests. In this section, we report on some two-dimensional numerical tests. For the computational domain, we chose the square presented in Figure 1.1, which is naturally academic. In contrast to this, the material parameters were close to approximating the realistic distributions given in [15]. Two different temperature levels were investigated in our calculations. At the lower level, the temperature in the gas phase is in the range of the external temperature $y_0 \equiv 293.0$ K, whereas, at the higher level, it constitutes approximately 2000 K and, thus, is sufficiently high for the PVT method mentioned in section 1. In the low-temperature example, the thermal conductivity[2] in the gas phase is fixed at $\kappa_g \equiv 0.0175$ and, having in mind a graphite crucible, at $\kappa_s \equiv 37.0$ in the solid. At the higher temperatures, we obtain $\kappa_g \equiv 0.08$ and $\kappa_s \equiv 24.0$. The emissivity is set to $\varepsilon \equiv 0.65$ at the lower temperature level and $\varepsilon \equiv 0.8$ in the high-temperature case. In all cases, the Boltzmann radiation constant[3] is given by $\sigma = 5.6696 \cdot 10^{-8}$.

To solve the optimal control problems numerically, we used a sequential quadratic programming (SQP) method (see, for instance, [1]). The linearized subproblems were solved with a primal-dual active set algorithm (cf. [3] or [4]). The overall method is described in detail in [14]. Using a projected gradient method with the Armijo step size rule, suitable initial values were generated. The linearized PDEs were approximated by linear finite elements. Since the kernel ω exhibits a singularity as mentioned in section 4, the numerical treatment of K and G, respectively, needs some care, especially in the corners of Ω_g. However, thanks to the simple shape of Γ_r in our case, it is possible to integrate ω exactly, thereby circumventing these problems (see [14] for details). For our numerical investigations, we used a triangle mesh consisting of 98340 points and 196358 elements. Due to the nonlocal radiation boundary condition, it is refined four times on the inner boundary Γ_r. Furthermore, since the corners of Γ_r are nonconvex with respect to the outer domain Ω_s (see Figure 1.1), the mesh is additionally refined eight times in each of these corners up to a local mesh size of approximately $1 \cdot 10^{-5}$.

We present three numerical examples. The first example, at the lower temperature level, represents an exact solution of (P) that is defined in the following. For the Tikhonov parameter, we choose $\nu = 0.01$. The desired temperature gradient[4] is given by $z \equiv (0, 0)^T$, and we take $u_a \equiv 0.0$ and $u_b \equiv 1000$ for the control constraints.[5] Then, it is clear that the global optimal solution to (P) is given by

$$\bar{u} \equiv 0, \qquad p \equiv 0, \qquad \bar{y} = y_0 \equiv 293.0\,\mathrm{K}.$$

In view of Lemma 3.5, it is easy to verify that, with this optimal solution, the state equation (4.1), the adjoint equation (7.7), and the projection formula (7.8) are satisfied. Moreover, we have $J(\bar{y},\bar{u}) = 0$, and thus the solution represents a global optimum. To demonstrate the convergence behavior of the SQP method, the values of the numerically evaluated objective functional are shown in Table 8.1. Here, the rows above the double line refer to the projected gradient method for the initial value search (rows 1–4). The values that correspond to the SQP method are presented in rows 5–7. Note that the initial value was given by $u_h \equiv 500.0$ with an objective functional of 3.750087e+03. As one can see, the SQP method produces a speed-up of the convergence towards the global optimum $J(\bar{y},\bar{u}) = 0$. In what follows, we denote by the subscript h the approximated solution computed by the SQP method. Table 8.2 shows the difference between the discrete solution and the given exact solution. Due to $\bar{u} = \bar{p} = 0$, absolute errors were used. The relative error of the state is $\|y_h - \bar{y}\|_{L^2(\Omega)}/\|\bar{y}\|_{L^2(\Omega)} = 4.407631\text{e}{-09}$.

In contrast to the first example, no exact solution is known in the two following examples. To deal with higher temperatures in the gas phase, we now set $u_a = 125000$ and $u_b = 725000$. To compensate for the comparatively large values of the control, we choose a small Tikhonov regularization parameter $\nu = 5 \cdot 10^{-10}$. The desired temperature gradient is given by $z = (0,-20)^T$. Figures 8.1–8.4 show the optimal solution for this setting. The optimal control shown in Figure 8.1 is defined only in the solid parts Ω_s, and, therefore, its graph shows a hole in the inner square, where the gas phase is located.

As Figure 8.4 illustrates, there are significant differences between the optimal temperature distribution in the gas phase and the desired temperature gradient. With a value of approximately 17 K, the temperature difference between the lower and upper edges of Γ_r is smaller than the desired 20 K. Furthermore, at the upper edge, the temperature is not constant in the x_1-direction. A possible explanation for this result is the strong cooling effect due to the relatively low external temperature. Because of the comparatively large difference of approximately 1700 K between the temperature in the gas phase and the external temperature outside the crucible, one obtains quite steep gradients in the solid part Ω_s, as one can see in Figure 8.3. Therefore, it is not possible to generate the desired flat temperature distribution. In Figure 8.1, we

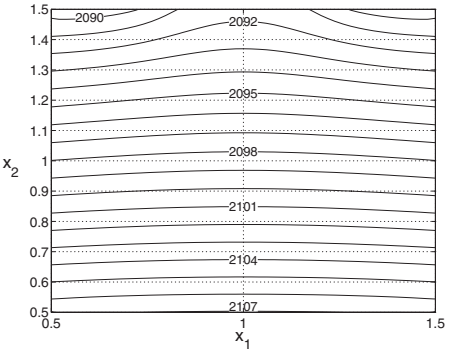

FIG. 8.4. *Isotherms in the gas phase Ω_g in the second example.*

observe noticeable peaks of u_h in the corners of Ω_g. Since the mesh is refined in these corners several times, as mentioned above, this does not seem to show a numerical effect.

Table 8.3 illustrates the development of the objective functional during the iteration. The initial value was given by $u_h \equiv 312500$. The corresponding initial value of the objective functional is 4.921569e+02. As one can see, the algorithm needed more iterations of the projected gradient method than in the first example to find a suitable initial value, i.e., to reach the area of convergence of the SQP method. Again, a strong decrease of the objective functional is observed after the first SQP iteration. To validate the numerical solution, we introduce the following indicators for the relative errors in the optimality system of (P) consisting of the state equation (4.1), the adjoint equation (7.7), and the projection formula (7.8). The error in the state equation is measured by

$$e_y = \frac{\|\hat{y} - y_h\|_{L^2(\Omega)}}{\|y_h\|_{L^2(\Omega)}} \quad \text{with } \hat{y} = S_h(u_h),$$

where S_h is the numerical solution operator of the semilinear equation (4.1). To be more precise, (4.1) is solved numerically by Newton's method on the continuous level such that only the linear PDEs in each Newton step are discretized using finite

elements (see [14] for details). Next, we introduce the solution operator associated with the discrete version of the adjoint equation (7.7) denoted by $S_h'(u_h)^*\,\hat{w}$ with $\langle \hat{w}\,,\, v\rangle = \int_{\Omega_g}(\nabla\hat{y} - z)\cdot\nabla v\,dx$. Then, to verify the discrete adjoint equation, we compute

$$e_p = \frac{\|\hat{p} - p_h\|_{L^2(\Omega)}}{\|p_h\|_{L^2(\Omega)}} \quad \text{with } \hat{p} = S_h'(u_h)^*\hat{w}.$$

Finally, as an indicator for the error in the projection formula (7.8), the SQP solution u_h is compared with the projection of $\hat{p}$, i.e.,

$$e_u = \frac{\|\hat{u} - u_h\|_{L^2(\Omega_s)}}{\|u_h\|_{L^2(\Omega_s)}} \quad \text{with } \hat{u} = \mathcal{P}_{ad}\left\{-\frac{1}{\nu}\hat{p}\right\}.$$

The results are shown in Table 8.4.

In the third example, we set $u_a = 200000$, $u_b = 300000$, and $z = (0, -100)^T$. As in the second example, ν is fixed at $5\cdot 10^{-10}$.

Since the x_2-direction of z is comparatively steep, one cannot expect the desired temperature gradient to be reached with these bounds on the control. Thus, although the optimal control is almost bang-bang (cf. Figure 8.5), the optimal temperature distribution differs considerably from the desired one, as Figure 8.7 and, in particular, Figure 8.8 demonstrate. Figure 8.6 shows the adjoint state in this example. The convergence behavior in this case is illustrated by Table 8.5. We choose $u_h = 230000$ as the initial value. The corresponding value of the objective functional amounts to 5.314663e+03. In this case, there is no noteworthy decrease of the objective functional after starting the SQP method. An explanation for this observation is that the bang-bang structure of the control is already reached after the first projected gradient step. Table 8.6 shows the errors in the optimality system, introduced above, for this example.

OPTIMAL CONTROL OF HYBRID SYSTEMS AND A SYSTEM OF QUASI-VARIATIONAL INEQUALITIES*

HUAN ZHANG† AND MATTHEW R. JAMES‡

Abstract. Optimal control of a class of hybrid dynamical systems is studied using the method of dynamic programming. It is proved that the value function is a discontinuous viscosity solution of the corresponding Hamilton–Jacobi–Bellman (HJB) equation which appears as a system of quasi-variational inequalities (SQVI) coupled by a nonlocal operator with a variable boundary condition. The comparison theorems are established for the sub- and super-solutions of the SQVI.

Key words. hybrid dynamical systems, optimal control, dynamic programming, system of quasi-variational inequalities, viscosity solutions, comparison theorem

1. Introduction.

In recent years, there has been increasing attention given to the study of hybrid dynamical systems. This has been stimulated by increasingly complex applications that involve a combination of discrete and continuous dynamics. The name "hybrid" reflects the mixed nature of the dynamics. The continuous dynamics generally represents the underlying time-driven, continuous-variable physical processes which are usually modeled by a family of differential (or difference) equations, while the high level event-driven discrete dynamics represents some kind of decision making logic regarding the continuous dynamics. The discrete dynamics is usually modeled as timed automata or petri nets. The continuous dynamics and the discrete dynamics interact at some "event" times when the continuous state hits some prescribed sets in the continuous state space. Examples of these systems are found in many areas including production systems (see Cassandras, Pepyne, and Wardi [13]), traffic systems (see Varaiya [25] and Lygeros, Godbole, and Sastry [20]), and air traffic management systems (see Tomlin, Pappas, and Sastry [24]).

Different models have been proposed to model hybrid systems at different levels of generality; among them we mention Branicky, Borkar, and Mitter [11]; Heemels, Schutter, and Bemporad [18]; and Lygeros, Tomlin, and Sastry [21]. In this paper we follow the model of Bensoussan and Menaldi [9], which is actually a simplified version—but with no loss of generality—of the unified model developed in [11]. In both [9] and [11], it is shown that these models are quite general models and include most of the hybrid models in the literature as their special cases.

Optimal control problems of general hybrid systems have been studied by using the maximum principle (see Shaikh and Caines [22] and Sussmann [23]) and dynamic programming (see Branicky, Borkar, and Mitter [11], Bensoussan and Menaldi [9],

and, more recently, Dharmatti and Ramaswamy [16]). In [11], the Hamilton–Jacobi–Bellman (HJB) equations corresponding to the optimal control problem were derived, but no further analysis on the equations has been done. In a more recent work by Ball, Chudoung, and Day [1], the continuous value function corresponding to robust ($\mathcal{H}^\infty$-type) control is proved to satisfy the dynamic programming equations in the continuous viscosity sense; however, their system dynamics model is more special, and they did not provide a uniqueness proof on the solutions of these equations, which, in fact, is crucial to the synthesis of optimal controllers in the approach of dynamic programming. There is a rather complete treatment of the optimal control problem using the dynamic programming approach in [9]. The authors proved that the continuous value function is the unique viscosity solution of the corresponding system of quasi-variational inequalities (SQVI) in some special cases. In [16], the authors proved the uniqueness problem under more general conditions using a different approach. But as our example shows, discontinuous value functions arise frequently for general hybrid optimal control problems. Thus it is desirable to have a theory of optimal hybrid control in the framework of discontinuous value functions. In this paper, we study the optimal control problem for a general class of hybrid systems in the context of discontinuous value functions. In the case of a continuous value function, our results reduce to those of [9] and [16].

The main problem in applying the dynamic programming approach to solve the optimal control problem is how to interpret and, more importantly, characterize the value function as the unique solution of the corresponding HJB equation. In our problem, the HJB equation is

$$\begin{cases} \max\{\mathbf{v}(x,q) - (\mathcal{M}\mathbf{v})(x,q), \lambda\mathbf{v}(x,q) + \mathcal{H}(x,q,\nabla_x\mathbf{v}(x,q))\} = 0 & \text{in } F^c, \\ \mathbf{v}(x,q) = (\mathcal{M}\mathbf{v})(x,q) & \text{on } \partial F^c, \end{cases} \tag{1}$$

where $q \in Q = \{q_1, q_2, \dots, q_p\}$, F^c is the complement of a closed set F, and $\mathcal{M}$ is a nonlocal operator defined by

$$(\mathcal{M}v)(x,q) = \min_{w\in W}\{\kappa(x,q,w) + v(g(x,q,w))\}. \tag{2}$$

Thus it is an SQVI coupled by a nonlocal operator $\mathcal{M}$ with a variable boundary condition. Several issues regarding the SQVI make the characterization process difficult. The first difficulty is the fact that the value function is in general discontinuous due to the structure of the hybrid dynamics and the possible discontinuities of the jumping costs; hence we can interpret it as a solution of the SQVI only in some weak sense (here we employ the notion of discontinuous viscosity solutions introduced by Ishii [19]). It is known that under this notion of weak solution, uniqueness cannot be guaranteed in general (see Barles and Perthame [4], [5] and Blanc [10]); rather, only the maximum sub-solution and minimum super-solution can be characterized. The second difficulty is that the SQVI is coupled by a nonlocal operator which makes it hard to apply the approach of Capuzzo Dolcetta and Evans in [12] when we come to characterize the solution even in the special case of a continuous value function, since the traditional techniques in viscosity solution framework are local in nature. Extra difficulties arise in the boundary behavior of this SQVI, which we see is a variable boundary condition rather than a prescribed function.

In this paper, we generalize the approach of Barles [3] and Bensoussan and Menaldi [9] to the discontinuous case to resolve the difficulties. The essential point of the approach is to introduce two concave operators, whose unique fixed points turn

out to be the maximum sub-solution and minimum super-solution, respectively, and it actually can be shown that they are solutions. Using the two operators, we further show that the two extreme solutions admit the same low semi-continuous envelope, which is the minimum solution. By this we establish the so-called uniqueness in a weak sense; i.e., all solutions have the same lower semi-continuous envelope or the equation has a unique lower semi-continuous solution. Note that our approach in establishing the comparison theorems is essentially different from those of Barles and Perthame [4], [5] and Blanc [10].

There are some similarities between our results and those of the optimal impulse control problem (see Barles [3]), the optimal switching problem (see Capuzzo Dolcetta and Evans [12]), the optimal stopping problem (see Barles and Perthame [4]), and optimal exit problems (see Barles and Perthame [5] and Blanc [10]). Actually, since the structure of the hybrid dynamics involves multiple exits and multiple impulses, the optimal control problem of hybrid dynamical systems can be regarded as the generalization and integration of the above control problems, and under appropriate conditions, the results and approaches fit these special cases.

We begin section 2 by specifying the hybrid model we use and the optimal control problem to be solved. In section 3 we present the dynamic programming principle for the problem. Then in section 4 we prove that the value function is a discontinuous viscosity solution of the associated SQVI. The comparison theorems are given in section 5. Some special cases, including the continuous case, are discussed in section 6. As another application of the approach, we briefly treat the hybrid optimal stopping problem in section 7.

Notation. Given $X \subset \mathbf{R}^n$, a finite set Q, and a set $S \subset (X \times Q)$, denote $S^c = \{(x,q)|(x,q) \in ((X \times Q)\backslash S)\}$ and $S_q = \{x|(x,q) \in S\}$. $\overline{S_q}$ is the closure of S_q in X, ∂S_q is the boundary of S_q and $\partial S = \{(x,q)|x \in \partial S_q\}$, and $\widetilde{S}_q$ is the interior of S_q and $\widetilde{S} = \{(x,q)|x \in \widetilde{S}_q\}$. Given a bounded function $\mathbf{v} : S \to R$, denote by $\mathbf{v}^*$ ($\mathbf{v}_*$) its upper (lower) envelope defined as $\mathbf{v}^*(x,q) = \limsup_{y \in S_q, y \to x} \mathbf{v}(y,q)$,($\mathbf{v}_*(x,q) = \liminf_{y \in S_q, y \to x} \mathbf{v}(y,q)$). $\mathbf{v}$ is called upper semi-continuous (lower semi-continuous) in S if $\mathbf{v}^* = \mathbf{v}$ ($\mathbf{v}_* = \mathbf{v}$) in S. Denote by $USC(S)$ ($LSC(S)$) the set of upper semi-continuous (lower semi-continuous) functions in S, and for a function $\mathbf{v} : X \times Q \to R$, denote by $\mathbf{v}|_S$ the restriction of $\mathbf{v}$ on S.

2. Problem formulation. In this section, we first propose a model of general hybrid dynamical systems and then describe in some detail its trajectory properties and conditions to guarantee that it is well behaved. After this we formulate the infinite horizon discounted optimal control problem.

2.1. Controlled hybrid dynamical systems. Hybrid systems are loosely defined as dynamical systems involving the interaction of continuous state and discrete state dynamics. More precisely, we have the following definition.

DEFINITION 2.1. *A controlled hybrid dynamical system* $\mathbf{H}$ *is a collection*

$$\mathbf{H} = \{X, Q, U, W, f, g, F, O\}, \tag{3}$$

where the items are defined as follows:

- *Hybrid state space $X \times Q$: $X \subset \mathbf{R}^n$ is the continuous state space, and Q is the discrete state space which is a finite set with discrete topology.*
- *Hybrid input space $U \times W$: $U \subset \mathbf{R}^m$ is the continuous input space which is a compact subset of $\mathbf{R}^m$, and W is the discrete input space which is a finite set with discrete topology.*

- *Continuous dynamics f:* $f : X \times Q \times U \to R^n$ *is a family of vector fields describing a family of continuous dynamics.*
- *Discrete dynamics g:* $g : X \times Q \times W \to X \times Q$ *is the discrete transition map.*
- *Forced and optional discrete transition sets* F, O*:* $F, O \subset (X \times Q)$ *are closed subsets of the state space which designate the domain of the discrete dynamics. Let* $D = F \cup O$ *be the discrete transition set.*

To ensure that the dynamics is well behaved, we impose the following conditions on the hybrid systems.

Assumption 2.2. The continuous dynamics f satisfies the following:

1. There exists $C_f > 0$ such that

$$\begin{cases} |f(x,q,u)| \le C_f \quad \forall (x,q,u) \in (X \times Q \times U), \\ |f(x,q,u) - f(y,q,u)| \le C_f |x-y| \quad \forall x, y \in X, \quad \forall q \in Q, \quad \forall u \in U. \end{cases} \tag{4}$$

2. ∂X is smooth and

$$f(x,q,u) \cdot n(x) \ge 0 \quad \forall x \in (\partial X \backslash \partial F_q), \quad \forall q \in Q, \quad \forall u \in U,$$

where $n(x)$ is the unit inner normal to X.

3. ∂F_q is smooth for all $q \in Q$ and

$$f(x,q,u) \cdot n(x) > \alpha > 0 \quad \forall x \in \partial F_q, \quad \forall q \in Q, \quad \forall u \in U,$$

where $n(x)$ is the unit inner normal to F_q.

Assumption 2.3. The discrete dynamics g satisfies

$$\begin{cases} |g(x,q,w)| \le C_g \quad \forall (x,q,w) \in (X \times Q \times W), \\ g(\cdot,q,w) \text{ is continuous in } X \quad \forall q \in Q, \quad \forall w \in W. \end{cases} \tag{5}$$

Remark 2.4. Item 1 in Assumption 2.2 guarantees the existence of the solutions of the continuous dynamics for any initial condition. Item 2 simplifies the behavior of the continuous dynamics on the boundaries of the continuous state space, implying that the state will never exit the state space X by continuous evolution. When X is closed and convex, we can achieve this by projecting outward pointing vector fields to the boundary as suggested in [15].

Remark 2.5. The transversality condition 3 in Assumption 2.2 eliminates the pathological behavior of the continuous dynamics on the boundary of forced jump set F; see [11] for discussion and relaxation. Since the forced discrete transition set F_q acts as an exit set in the hybrid dynamics, this assumption simplifies the exit behavior through the boundary of F_q. Some of our subsequent results and proofs would be more complicated without this assumption. We don't assume a transversality condition for the optional discrete transition set O which is made in [16]. A transversality condition on O implies that when the state enters O, it can escape O only by doing a discrete transition. This is a condition inappropriate for O in a sense that discrete transitions in O are "optional." However, as our example shows, discontinuous value functions can arise without this assumption.

Now, let us see how a controlled hybrid dynamical system works. The execution of the controlled hybrid dynamical system operates as follows:

1. At any time, one of the continuous dynamics $f(\cdot, q, \cdot)$ must be active, while the discrete dynamics can be activated only in some isolated times. When the discrete dynamics is active, it has higher priority than the continuous dynamics.

2. When the state is inside F, the discrete dynamics must be activated, and it must not be activated when the state is outside D.
3. When the state is inside O, the discrete dynamics may be but does not have to be activated.

Under the rules, in order to distinguish the two different types (forced and optional) of discrete transitions, we impose the following assumption.

Assumption 2.6. F and O are strictly separated; i.e.,

$$d(F_q, O_q) > 0 \quad \forall q \in Q.$$

The continuous dynamics changes the continuous state continuously under a continuous input signal and does not change the discrete state. The activation of the discrete dynamics causes a discrete transition which changes the hybrid state to a new state instantaneously. A discrete transition can be a "JUMP" which means only a change in the continuous state variable or a "SWITCH" which means only discrete state changes, or a combination of "JUMP" and "SWITCH." Since we assume here that it takes no time to have a discrete transition, we need to eliminate the pathological executions of multiple discrete transitions at one single time and an infinite number of discrete transitions in any finite period of time that are called "Zeno executions." According to Bensoussan and Menaldi [9], the following assumption is sufficient to eliminate both due to the forced jumps.

Assumption 2.7. g satisfies

$$\inf_{w\in W,(x,q),(x'q')\in F}\{|x' - g|_X(x,q,w)| + |q' - g|_Q(x,q,w)|\} \geq c > 0,$$

where $g|_X : X \times Q \times W \to X$, $g|_Q : X \times Q \times W \to Q$ are the projections of g to X and Q, respectively; i.e., $(g|_X(x,q,w), g|_Q(x,q,w)) = g(x,q,w)$ for all $x \in X$, for all $q \in Q$, for all $w \in W$.

Following the rules, the trajectories of the continuous state are piecewise continuous where discontinuities appear (if the discrete transition is not a SWITCH) at the times of discrete transitions. At every discrete transition time τ_i, let $x(\tau_i^-)$ be the prejump state and let $x(\tau_i^+)$ be the postjump state. The discrete state trajectories are piecewise constant and have discontinuities in the discrete transition time (if it is not a JUMP).

We can see that a control signal of a hybrid system consists of two parts: continuous input and discrete input. A continuous input is a measurable function $u : \mathbf{R}^+ \to U$, which takes effect through the continuous dynamics. Let $\mathcal{U}$ denote the set of all continuous control input. The discrete control takes the form $\{(\tau_i, w_i)\}_1^N$, where

$$0 = \tau_0 \leq \tau_1 \leq \cdots \tau_i \leq \tau_{i+1} \cdots$$

is the sequence of times selected to activate the discrete dynamics to cause discrete transitions. At time τ_i the destination of the discrete transition is parameterized by the discrete input value $w_i \in W$. The total number of activations N can be finite or infinite.

Let us call $\beta = (u(\cdot), \{(\tau_i, w_i)\}_1^N)$ a hybrid control. Obviously, in order to follow the rules of the hybrid dynamical system, not all hybrid controls are acceptable. The two kinds of controls (continuous and discrete) are not independent of each other. Given initial states $(x,q) \in (X \times Q)$ and a continuous control $u(\cdot) \in \mathcal{U}$, we have to activate the discrete dynamics if the state enters F, and we must not activate the

discrete dynamics when the state is outside D. So we have to select those acceptable hybrid controls which we call admissible.

Given any $(x,q) \in (X \times Q)$ and $u(\cdot) \in \mathcal{U}$, define hitting times of F and D to be

$$T^F(x,q,u(\cdot)) = \inf\{t \geq 0 | (x(t),q) \in F\}, \quad T^D(x,q,u(\cdot)) = \inf\{t \geq 0 | (x(t),q) \in D\}, \tag{6}$$

where $x(\cdot)$ is the solution of

$$\dot{x}(t) = f(x(t),q,u(t))$$

with initial state x.

DEFINITION 2.8. *Given initial state $(x,q) \in (X \times Q)$, a hybrid control $\beta = (u(\cdot), \{(\tau_i, w_i)\}_1^N)$ is called an admissible hybrid control with respect to (x,q) if*

1.

$$0 = \tau_0 \leq \tau_1 \leq \cdots \tau_i \leq \tau_{i+1} \cdots, \quad \tau_i \to \infty \text{ if } i \to \infty;$$

2.

$$T^D(x(\tau_i^+), q_i, u(\cdot)) \leq \tau_{i+1} - \tau_i \leq T^F(x(\tau_i^+), q_i, u(\cdot)) \quad \forall i \geq 0.$$

Let $\beta(x,q)$ denote an admissible hybrid control with respect to (x,q) and let $\mathcal{B}(x,q)$ denote the set of all admissible hybrid controls with respect to (x,q).

Any trajectory that starts from an initial hybrid state driven by an admissible hybrid control with respect to the initial state is called an admissible hybrid trajectory. Based on the assumptions on the dynamics and the rules, we know that there exists one and only one admissible hybrid trajectory for any initial hybrid state under any admissible hybrid control input. We now construct a typical hybrid trajectory inductively. Given any initial state $(x,q) \in (X \times Q)$ and $\beta(x,q) \in \mathcal{B}(x,q)$, a hybrid state trajectory is produced as follows:

1. $(x(\tau_0^+), q(\tau_0^+)) = (x,q)$;
2. for $i = 1,2,\ldots,$
   if $\tau_i > \tau_{i-1}$, then for $t \in [\tau_{i-1}, \tau_i)$,
   (a) $\begin{cases} q(t) = q(\tau_{i-1}^+) = q_{i-1} \\ \dot{x}(t) = f(x(t), q(t), u(t)) \end{cases}$ with initial condition $(x(\tau_{i-1}^+), q(\tau_{i-1}^+))$;
   (b) $\begin{cases} q(\tau_i^-) = q(\tau_{i-1}) = q_{i-1} \\ x(\tau_i^-) = \lim_{t \to \tau_i^-} x(t) \end{cases}$;
   if $\tau_i = \tau_{i-1}$, then $(x(\tau_i^-), q(\tau_i^-)) = (x(\tau_{i-1}^+), q(\tau_{i-1}^+))$;
3. $(x(\tau_i^+), q(\tau_i^+)) = g(x(\tau_i^-), q(\tau_i^-), w_i)$.

Notice that if we use $Q = \{1,2,\ldots,p\}$ to represent discrete state space Q, the hybrid dynamics can be written in compact form as

$$\begin{cases} \dot{x}(t) = f(x(t), n(t), u(t)) + \sum_i^N (g|_X(x(\tau_i^-), q(\tau_i^-), w_i) - x(\tau_i^-))\delta(t - \tau_i), \\ \dot{n}(t) = \sum_i^N (g|_Q(x(\tau_i^-), q(\tau_i^-), w_i) - n(\tau_i^-))\delta(t - \tau_i), \end{cases} \tag{7}$$

where δ is the Dirac measure.

2.2. Optimal control problem. Now we associate with every admissible hybrid trajectory a cost which, not surprisingly, is also hybrid, i.e., consists of continuous costs and discrete costs. The continuous costs penalize the continuous running of the hybrid dynamical system and take the form $\ell : X \times Q \times U \to \mathbf{R}^+$. The discrete part is with the form of $\rho : X \times Q \times W \to \mathbf{R}^+$, which represents how much you need to pay for a discrete transition.

We assume the costs satisfy the following assumptions.

Assumption 2.9. The running cost ℓ satisfies

$$\begin{cases} \ell(x,q,u) \le C_\ell \quad \forall (x,q,u) \in (X \times Q \times W), \\ |\ell(x,q,u) - \ell(y,q,u)| \le C_\ell |x-y| \quad \forall x,y \in X, \quad \forall q \in Q, \quad \forall u \in U. \end{cases} \tag{8}$$

Assumption 2.10.

$$\begin{cases} 0 < C_\rho < \rho(x,q,w) < C'_\rho \quad \forall (x,q,w) \in (X \times Q \times W), \\ (\rho^*)_* = \rho_*. \end{cases} \tag{9}$$

Given any initial hybrid state $(x,q) \in (X \times Q)$ and any admissible hybrid control input $\beta(x,q) \in \mathcal{B}(x,q)$, an admissible hybrid trajectory is produced. Then define the (discounted) total cost for the trajectory as

$$\mathbf{J}_{(x,q)}(\beta) = \sum_{i=1}^{N} \left(\int_{\tau_{i-1}}^{\tau_i} \ell(x(s), q_{i-1}, u(s)) e^{-\lambda s} ds + \rho(x(\tau_i^-), q_{i-1}, w_i) e^{-\lambda \tau_i} \right), \tag{10}$$

where $\lambda > 0$ is the discount factor.

The *optimal control of hybrid dynamical systems* is to find an admissible hybrid control input $(\beta^*(x,q))$ for every hybrid state $(x,q) \in (X \times Q)$, such that

$$\mathbf{J}_{(x,q)}(\beta^*) \le \mathbf{J}_{(x,q)}(\beta)$$

for any $\beta(x,q) \in \mathcal{B}(x,q)$.

We will use the approach of dynamic programming to study this problem. In dynamic programming, the key concept is the so-called value function defined for this problem as

$$\mathbf{V}(x,q) = \inf_{\beta(x,q) \in \mathcal{B}(x,q)} \{\mathbf{J}_{(x,q)}(\beta)\} \tag{11}$$

for every initial hybrid state $(x,q) \in (X \times Q)$. In the remainder of the paper we characterize it (if possible) as the unique solution (in some weak sense) of a partial differential equation called an HJB equation.

The following result shows that the value function is nonnegative and bounded.

PROPOSITION 2.11. *The value function is nonnegative and bounded; i.e., there exists $C_v > 0$ such that*

$$0 \le \mathbf{V}(x,q) \le C_v \quad \forall (x,q) \in (X \times Q).$$

Proof. It is obvious that the value function should be nonnegative since all the costs are nonnegative. To prove the boundedness, fix any initial state $(x,q) \in (\mathbf{R}^n \times Q)$. Choose a special admissible hybrid control $\hat{\beta}(x,q) \in \mathcal{B}(x,q)$, such that every discrete transition time $\tau_i, i \ge 1$ is a forced discrete transition time, i.e., $(x(\tau_i^-), q(\tau_i^-)) \in F$ for all $i \ge 1$. Then based on Assumption 2.7, and Theorem

2.1 of Bensoussan and Menaldi [9], we know that there exists an $h > 0$ independent of β such that

$$\tau_{i+1} - \tau_i \geq h$$

for all $i \geq 1$. Hence

$$\begin{aligned}\mathbf{V}(x,q) &\leq \mathbf{J}_{(x,q)}(\hat{\beta}) \\ &\leq \int_0^\infty C_\ell e^{-\lambda s} ds + \sum_{i=1}^{N} C'_\rho e^{-\lambda i h} \\ &= C_\ell \frac{1}{\lambda} + C'_\rho \frac{e^{-\lambda h}(1 - e^{-\lambda N h})}{1 - e^{-\lambda h}} \\ &\leq C_\ell \frac{1}{\lambda} + C'_\rho \frac{e^{-\lambda h}}{1 - e^{-\lambda h}}. \qquad \square\end{aligned}$$

Due to the complex structure of general hybrid dynamical systems, in the general case, the value function could be discontinuous. For general hybrid dynamical systems without the transversality condition in item 3 of Assumption 2.2, three factors contribute to the discontinuities of the value functions. The first is the existence of the forced jump set F_q. F_q acts as the role of exit set for the continuous dynamics. From Barles and Perthame [5] and Blanc [10], we know that the value function is discontinuous for the optimal exit problem unless some compatibility like that of the transversality condition is imposed. The second factor is the restriction of the optional discrete transitions on the domain O, which actually can be turned into the equivalent case of a discontinuous discrete transitional cost without the constraint of O. The last factor is that we allow a discontinuous discrete transition cost ρ. The first factor was eliminated due to the tranversality condition; hence the discontinuity of the value functions are the results of O and ρ. Next we give a simple example to make it clear that the existence of O does lead to a discontinuous value function.

Example 2.12. Consider a hybrid system with $X = \mathbf{R}$, $Q = \{0, 1\}$, $U = [1, 2]$, $W = \{w\}$, $F = \varnothing$, $O_0 = O_1 = [1, 2]$, and continuous dynamics

$$f(x,q,u) = \begin{cases} u & \text{when } q = 0, \\ -u & \text{when } q = 1 \end{cases}$$

and discrete dynamics

$$g(x,q,w) = \begin{cases} (x,1) & \text{when } q = 0, \\ (x,0) & \text{when } q = 1. \end{cases}$$

The costs are as follows:

$$\ell(x,q,u) = \begin{cases} \frac{1}{u} & \text{when } q = 0, \\ \frac{1}{6} & \text{when } q = 1 \end{cases}$$

and discrete transition cost

$$\rho(x,q,w) = \frac{1}{6}.$$

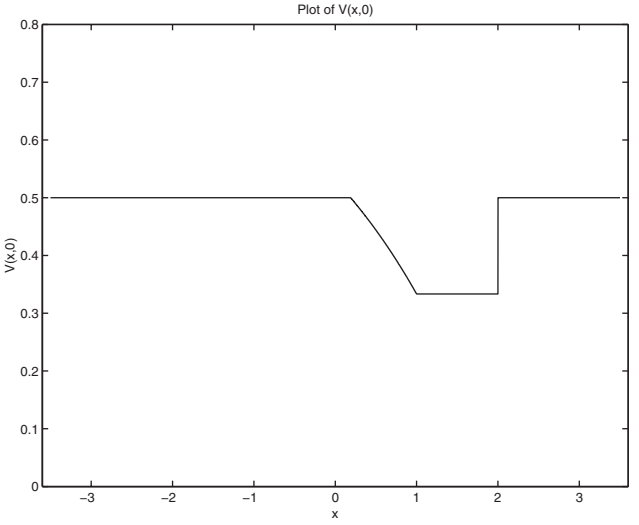

FIG. 1. *Value function* $\mathbf{V}(x,0)$.

Let the discount factor $\lambda = 1$. Then all the data satisfies the assumptions, the value functions can be computed by hand as

$$\mathbf{V}(x,0) = \begin{cases} \frac{1}{2} & \text{when} \quad x > 2, \\ \frac{1}{3} & \text{when} \quad 1 \le x \le 2, \\ \frac{5}{6} - \frac{1}{2}e^{\frac{x-1}{2}} & \text{when} \quad 1 + 2\ln\frac{2}{3} \le x < 1, \\ \frac{1}{2} & \text{when} \quad -1 < x < 1 + 2\ln\frac{2}{3}, \end{cases}$$

and

$$\mathbf{V}(x,1) = \frac{1}{6}, \quad x \in \mathbf{R}.$$

From Figure 1, we can easily see that $\mathbf{V}(x,0)$ is discontinuous at $x = 2$. In this simple example, since $F = \varnothing$ and the discrete transition cost ρ is continuous, the discontinuity of the value function is the result of the existence of O without a transversality condition.

In this paper, we study the optimal control of a hybrid dynamical system without assuming a continuous value function. Hence the analysis of this paper can be regarded as the discontinuous generalization of [9]. In the case of a continuous value function, all of our arguments reduce to the case of paper [9].

3. Dynamic programming principle. Now we turn to study the value function by the approach of dynamic programming. In this section, we develop the so-called dynamic programming principle (DPP) satisfied by the value function, which leads to a system of first order partial differential equations in section 4.

First, let us introduce a function

$$\kappa(x,q,w) = \begin{cases} \rho(x,q,w), & (x,q) \in D, \\ C_\kappa & \text{otherwise}, \end{cases} \tag{12}$$

where $C_\kappa > C_\ell \frac{1}{\lambda} + C'_\rho \frac{e^{-\lambda h}}{1-e^{-\lambda h}}$ is a constant, and a set

$$\mathcal{V} = \{\mathbf{v} : X \times Q \to \mathbf{R} | \mathbf{v} \text{ bounded}\}.$$

Define nonlocal operators $\mathcal{M} : \mathcal{V} \to \mathcal{V}$:

$$(\mathcal{M}\mathbf{v})(x,q) = \min_{w\in W}\{\kappa(x,q,w) + \mathbf{v}(g(x,q,w))\}; \tag{13}$$

$\mathcal{M}^+ : \mathcal{V} \to \mathcal{V}$:

$$(\mathcal{M}^+\mathbf{v})(x,q) = \min_{w\in W}\{\kappa^*(x,q,w) + \mathbf{v}^*(g(x,q,w))\}; \tag{14}$$

$\mathcal{M}^- : \mathcal{V} \to \mathcal{V}$:

$$(\mathcal{M}^-\mathbf{v})(x,q) = \min_{w\in W}\{\kappa_*(x,q,w) + \mathbf{v}_*(g(x,q,w))\}. \tag{15}$$

We give properties of the operators $\mathcal{M}$, $\mathcal{M}^+$, and $\mathcal{M}^-$ in the following lemma.

LEMMA 3.1. *For any function $\mathbf{v} \in \mathcal{V}$, we have*

1. *$\mathcal{M}^+\mathbf{v}^* \in USC(X \times Q)$ and $\mathcal{M}^+\mathbf{v}^* \geq (\mathcal{M}\mathbf{v})^*$;*
2. *$\mathcal{M}^-\mathbf{v}_* \in LSC(X \times Q)$ and $\mathcal{M}^-\mathbf{v}_* \leq (\mathcal{M}\mathbf{v})_*$.*

Proof. Item 1. Fix any $q \in Q$. For any $x \in X$, let w^* be $(\mathcal{M}^+\mathbf{v}^*)(x,q) = \kappa^*(x,q,w^*) + \mathbf{v}^*(g(x,q,w^*))$. For any sequence $x_n \to x$, since $g(\cdot,q,w^*)$ is continuous, we know that $g(x_n,q,w^*) \to g(x,q,w^*)$. Then

$$\begin{aligned}(\mathcal{M}^+\mathbf{v}^*)(x,q) &= \kappa^*(x,q,w^*) + \mathbf{v}^*(g(x,q,w^*))\\ &\geq \limsup_{n\to\infty}\kappa^*(x_n,q,w^*) + \limsup_{n\to\infty}\mathbf{v}^*(g(x_n,q,w^*))\\ &\geq \limsup_{n\to\infty}(\kappa^*(x_n,q,w^*) + \mathbf{v}^*(g(x_n,q,w^*)))\\ &\geq \limsup_{n\to\infty}(\mathcal{M}^+\mathbf{v}^*)(x_n,q),\end{aligned}$$

which proves the upper semicontinuity of $\mathcal{M}^+\mathbf{v}^*$. Since $\mathcal{M}\mathbf{v} \leq \mathcal{M}^+\mathbf{v}^*$,

$$(\mathcal{M}\mathbf{v})^* \leq (\mathcal{M}^+\mathbf{v}^*)^* = \mathcal{M}^+\mathbf{v}^*.$$

Item 2. Fix any $q \in Q$. For any $x \in X$ and any sequence $x_n \to x$, let $w_n^* \in W$ be a sequence such that $(\mathcal{M}^-\mathbf{v}_*)(x_n,q) = \kappa_*(x_n,q,w_n^*) + \mathbf{v}_*(g(x_n,q,w_n^*))$. Since W is a finite set, we can select a constant subsequence, i.e., $w_n^* = w_*$. Similarly, we have $g(x_n,q,w_*) \to g(x,q,w_*)$. Then

$$\begin{aligned}(\mathcal{M}^-\mathbf{v}_*)(x,q) &\leq \kappa_*(x,q,w_*) + \mathbf{v}_*(g(x,q,w_*))\\ &\leq \liminf_{n\to\infty}\kappa_*(x_n,q,w_*) + \liminf_{n\to\infty}\mathbf{v}_*(g(x_n,q,w_*))\\ &\leq \liminf_{n\to\infty}(\kappa_*(x_n,q,w_*) + \mathbf{v}_*(g(x_n,q,w_*)))\\ &= \liminf_{n\to\infty}(\mathcal{M}^-\mathbf{v}_*)(x_n,q),\end{aligned}$$

which proves the lower semicontinuity of $\mathcal{M}^-\mathbf{v}_*$. Since $\mathcal{M}v \geq \mathcal{M}^-\mathbf{v}_*$, then

$$(\mathcal{M}\mathbf{v})_* \geq (\mathcal{M}^-\mathbf{v}_*)_* = \mathcal{M}^-\mathbf{v}_*. \qquad \square$$

The next three theorems consist of the DPP for the value function.

THEOREM 3.2. *The value function* $\mathbf{V}$ *satisfies*

$$\mathbf{V}(x,q) = (\mathcal{M}\mathbf{V})(x,q) \quad \forall (x,q) \in F. \tag{16}$$

Proof. "$\leq$": Fix any $(x,q) \in F$ and $w \in W$, and denote $(x',q') = g(x,q,w)$. For any admissible hybrid control with respect to (x',q'), $\bar{\beta}(g(x,q,w)) = (\bar{u}(\cdot), \{\bar{\tau}_i, \bar{w}_i\}_1^N)$, construct a new hybrid control $\beta = (u(\cdot), \{\tau_i, w_i\}_1^{N+1})$ by

$$\begin{cases} u(t) = \bar{u}(t), \\ \tau_1 = 0, w_1 = w, \tau_i = \bar{\tau}_{i-1}, w_i = \bar{w}_{i-1}, \quad i \geq 2. \end{cases}$$

It is not difficult to see that β is admissible with respect to (x,q); i.e., $\beta(x,q) \in \mathcal{B}(x,q)$. Then

$$\begin{aligned} \mathbf{V}(x,q) &\leq \mathbf{J}_{(x,q)}(\beta) \\ &= \kappa(x,q,w) + \mathbf{J}_{(g(x,q,w))}(\bar{\beta}), \end{aligned}$$

and since $\bar{\beta}(g(x,q,w)) \in \mathcal{B}(g(x,q,w))$ is arbitrary,

$$\begin{aligned} \mathbf{V}(x,q) &\leq \kappa(x,q,w) + \inf_{\bar{\beta}(g(x,q,w)) \in \mathcal{B}(g(x,q,w))} \{\mathbf{J}_{(g(x,q,w))}(\bar{\beta})\} \\ &= \kappa(x,q,w) + \mathbf{V}(g(x,q,w)). \end{aligned}$$

Since we are choosing w arbitrarily, we have

$$\begin{aligned} \mathbf{V}(x,q) &\leq \min_{w \in W} \{\kappa(x,q,w) + \mathbf{V}(g(x,q,w))\} \\ &= (\mathcal{M}\mathbf{V})(x,q). \end{aligned}$$

"$\geq$": For any $(x,q) \in F$ and $\epsilon > 0$, there exists an admissible hybrid control to (x,q), say $\beta(x,q) = (u(\cdot), \{\tau_i, w_i\}_1^N)$, such that

$$\mathbf{V}(x,q) + \epsilon > \mathbf{J}_{(x,q)}(\beta).$$

According to the definition of the admissibility of the hybrid control, $\tau_1 = 0$, and thus

$$\begin{aligned} \mathbf{J}_{(x,q)}(\beta) &= \kappa(x,q,w) + \mathbf{J}_{(g(x,q,w))}(\bar{\beta}) \\ &\geq \kappa(x,q,w) + \mathbf{V}(g(x,q,w)) \\ &\geq (\mathcal{M}\mathbf{V})(x,q), \end{aligned}$$

where $\bar{\beta}(g(x,q,w)) = (\bar{u}(\cdot), \{\bar{\tau}_i, \bar{w}_i\}_1^{N-1})$ is defined as

$$\begin{cases} \bar{u}(t) = u(t), \\ \bar{\tau}_i = \tau_{i+1}, \ \bar{w}_i = w_{i+1}, \quad i \geq 1. \end{cases}$$

Hence

$$\mathbf{V}(x,q) \geq (\mathcal{M}\mathbf{V})(x,q). \qquad \square$$

THEOREM 3.3. *The value function* $\mathbf{V}$ *satisfies the following:*

1. *For any* $(x,q) \in F^c$,

$$\mathbf{V}(x,q) \leq (\mathcal{M}\mathbf{V})(x,q). \tag{17}$$

2. *For any* $u(\cdot) \in \mathcal{U}$ *and any* $0 \le T < T^F(x,q,u(\cdot))$,

$$\mathbf{V}(x,q) \le \int_0^T \ell(x(s),q,u(s))e^{-\lambda s}ds + \mathbf{V}(x(T),q)e^{-\lambda T}, \tag{18}$$

where $x(t) = \int_0^t f(x(t),q,u(t))dt - x$.

Proof. Proof of (17): If $(x,q) \in D^c$, then (17) is trivially true since

$$\mathbf{V}(x,q) \le C_\ell \frac{1}{\lambda} + C'_\rho \frac{e^{-\lambda h}}{1-e^{-\lambda h}} \le C_\kappa = \kappa(x,q,w) \le (\mathcal{M}\mathbf{V})(x,q).$$

If $(x,q) \in O$, then (17) can be proved in exactly the same way as the "$\le$" part of Theorem 3.2.

Proof of (18): Fix any $u(\cdot) \in \mathcal{U}$; then we can get $(x(T),q)$ by $x(T) = \int_0^T f(x(t), q, u(t))dt - x$. Since F is a closed subset, we know that $T^F(x,q,u(\cdot)) > 0$ for $(x,q) \in F^c$ and for any $0 \le T < T^F(x,q,u(\cdot))$, $(x(T),q) \in F^c$. Given any admissible control $\bar\beta(x(T),q) = (\bar u(\cdot), \{\bar\tau_i, \bar w_i\}_1^N)$, construct a new control $\tilde\beta = (\tilde u(\cdot), \{\tilde\tau_i, \tilde w_i\}_1^N)$ by

$$\begin{cases} \tilde u(t) = \begin{cases} u(t), & 0 \le t \le T, \\ \bar u(t-T), & t > T, \end{cases} \\ \tilde\tau_i = \bar\tau_i + T, \ \tilde w_i = \bar w_i, \quad i \ge 1. \end{cases}$$

Then we know that $\tilde\beta \in \mathcal{B}(x,q)$, i.e., the new control is admissible to (x,q), and hence

$$\begin{aligned} \mathbf{V}(x,q) &\le \mathbf{J}_{(x,q)}(\tilde\beta) \\ &= \int_0^T \ell(x(s),q,u(s))e^{-\lambda s}ds + \mathbf{J}_{(x(T),q)}(\bar\beta)e^{-\lambda T}, \end{aligned}$$

and

$$\begin{aligned} \mathbf{V}(x,q) &\le \int_0^T \ell(x(s),q,u(s))e^{-\lambda s}ds + \inf_{\bar\beta(x(T),q)\in\mathcal{B}(x(T),q)} \{\mathbf{J}_{(x(T),q)}(\bar\beta)\}e^{-\lambda T} \\ &= \int_0^T \ell(x(s),q,u(s))e^{-\lambda s}ds + \mathbf{V}(x(T),q)e^{-\lambda T}. \qquad \square \end{aligned}$$

Next, we establish the super-optimality principle for the lower envelope of the value function in the framework of relaxed control theory. Let $\mathbf{P}(U)$ be the space of probability measures on the continuous input space U. A relaxed continuous control is a map $\mu : [0,\infty) \to \mathbf{P}(U)$. Denote $\widehat{\mathcal{U}} = \{\mu_{(\cdot)}\}$. If we change the continuous dynamics to

$$\hat f(x,q,\mu) = \int_U f(x,q,u)d\mu \tag{19}$$

and the continuous running cost to

$$\hat\ell(x,q,\mu) = \int_U \ell(x,q,u)d\mu \tag{20}$$

and keep other data unchanged, then we get the optimal control problem in the context of a relaxed control framework. Let us denote by $\hat\beta(x,q) = (\mu_{(\cdot)}, \{\tau_i, w_i\}_1^N)$ a relaxed admissible hybrid control with respect to (x,q). The admissibility of a relaxed hybrid

control is defined in the same way as that of admissible hybrid controls except that the trajectory is replaced by the corresponding relaxed one. Let $\widehat{\mathcal{B}}(x,q) = \{\hat{\beta}(x,q)\}$.

Now we give the super-optimality principle for the value function.

THEOREM 3.4. *If for some $(x,q) \in F^c$, $\mathbf{V}_*(x,q) < (\mathcal{M}^-\mathbf{V}_*)(x,q)$, then there exists $t(x,q) > 0$ such that for all $0 \le T < t(x,q)$, we have*

$$\mathbf{V}_*(x,q) \ge \inf_{\mu_{(\cdot)} \in \widehat{\mathcal{U}}} \left\{ \int_0^T \int_U \ell(\hat{x}(s),q,u) e^{-\lambda s} d\mu_s ds + \mathbf{V}_*(\hat{x}(T),q) e^{-\lambda T} \right\}, \tag{21}$$

where $\mu_{(\cdot)}$ is the relaxed control and $\hat{x}(\cdot)$ is the solution of $\dot{\hat{x}}(t) = \int_U f(\hat{x}(t),q,u) d\mu_t$ with initial state x.

Proof. For any $(x,q) \in F^c$, choose $x_n \to x$ such that $\mathbf{V}(x_n,q) \to \mathbf{V}_*(x,q)$. Since F is closed, $x_n \in F_q^c$ for n large enough; thus we can assume that $x_n \in F_q^c$ is true for all n. For every n, let $\beta^n(x_n,q) \in \mathcal{B}(x_n,q)$ such that

$$\mathbf{V}(x_n,q) + 1/n \ge \mathbf{J}_{(x_n,q)}(\beta^n).$$

We now show that there must exist $t(x,q) > 0$ such that for n large enough, $(\tau^n)_1 > t(x,q)$. If $(x,q) \in D^c$, it is trivially true since the first discrete transition can happen only after the state enters D, and we notice that D is closed. So we need only show it is true for the case of $(x,q) \in O$. Assume for the sake of contradiction that there exists a subsequence (still denoted as $(\tau^n)_1$) such that $(\tau^n)_1 \to 0$. Since W is a finite set, we can assume there exists $w_1 \in W$ such that $(w^n)_1 = w_1$ for $n \ge 1$. Denote by $x^n(\cdot)$ the continuous state trajectory with initial condition (x_n,q) and control β^n. We know that

$$x^n((\tau^n)_1^-) \to x \quad \text{and} \quad g(x^n((\tau^n)_1^-),q,w_1) \to g(x,q,w_1)$$

by the continuity of the discrete transition dynamics. Hence

$$\begin{aligned}
\mathbf{V}_*(x,q) &= \lim_{n\to\infty} (\mathbf{V}(x_n,q) + 1/n) \\
&\ge \liminf_{n\to\infty} \Bigg(\int_0^{(\tau^n)_1} \ell(x^n(s),q,u^n(s)) e^{-\lambda s} ds + \kappa(x^n((\tau^n)_1^-),q,w_1) e^{-\lambda(\tau^n)_1} \\
&\qquad + \mathbf{V}(g(x^n((\tau^n)_1^-),q,w_1) e^{-\lambda(\tau^n)_1}) \Bigg) \\
&\ge \kappa_*(x,q,w_1) + \mathbf{V}_*(g(x,q,w_1)) \\
&\ge (\mathcal{M}^-\mathbf{V}_*)(x,q),
\end{aligned}$$

which contradicts the assumption. We have shown that for $0 \le T < t(x,q)$ and n large enough

$$\begin{aligned}
\mathbf{V}(x_n,q) + 1/n &\ge \mathbf{J}(x_n,q,\beta_n) \\
&\ge \int_0^T \ell(x^n(s),q,u^n(s)) e^{-\lambda s} ds + \mathbf{V}(x^n(T),q) e^{-\lambda T} \\
&\ge \int_0^T \ell(x^n(s),q,u^n(s)) e^{-\lambda s} ds + \mathbf{V}_*(x^n(T),q) e^{-\lambda T}.
\end{aligned}$$

If we regard the control sequence $u^n(\cdot)$ on $[0,T]$ as the relaxed controls, then there is a relaxed control $\mu_{(\cdot)}$ such that $u^n(\cdot) \to \mu_{(\cdot)}$ weakly. Noticing the fact that $x_n \to x$,

we know $x^n(s) \to \hat{x}(s)$ uniformly on $[0,T]$ and

$$\int_0^T \ell(x^n(s),q,u^n(s))e^{-\lambda s}ds \to \int_0^T \int_U \ell(\hat{x}(s),q,u)d\mu_s e^{-\lambda s}ds.$$

Hence it holds that

$$\begin{aligned}\mathbf{V}_*(x,q) &\geq \int_0^T \int_U \ell(\hat{x}(s),q,u)e^{-\lambda s}d\mu_s ds + \mathbf{V}_*(\hat{x}(T),q)e^{-\lambda T} \\ &\geq \inf_{\mu_{(\cdot)}\in\widehat{\mathcal{U}}}\left(\int_0^T \int_U \ell(\hat{x}(s),q,u)e^{-\lambda s}d\mu_s ds + \mathbf{V}_*(\hat{x}(T),q)e^{-\lambda T}\right). \qquad \square\end{aligned}$$

4. SQVI and discontinuous viscosity solution. In this section, we prove the value function to be a discontinuous viscosity solution of the HJB equations based on the DPP proved in the previous section. In our problem these equations appear as the following SQVI due to the existence of the discrete phenomena; furthermore, the existence of forced discrete transition set F gives the SQVI a variable boundary condition which is different from the usual boundary condition.

Consider a system of first order partial differential equations

$$\max\{\mathbf{v}(x,q) - (\mathcal{M}\mathbf{v})(x,q), \lambda\mathbf{v}(x,q) + \mathcal{H}(x,q,\nabla_x\mathbf{v}(x,q))\} = 0 \quad \text{in } F^c \tag{22}$$

with boundary condition

$$\mathbf{v}(x,q) = (\mathcal{M}\mathbf{v})(x,q) \quad \text{on } \partial F^c, \tag{23}$$

where the Hamiltonian $\mathcal{H} : X \times Q \times \mathbf{R}^n \to \mathbf{R}$ is defined as

$$\mathcal{H}(x,q,p) = \sup_{u\in U}\{-\langle f(x,q,u),p\rangle - \ell(x,q,u)\}. \tag{24}$$

The idea is to extract the information about the value function from the SQVI (22) and boundary condition (23). In the best possible case, (22) and (23) determine the value function completely in the region $(X \times Q)\backslash F$. Then from (16), we can compute the value function in area F, thus determining the whole value function.

Notice that the above SQVI constitutes a collection of $|Q| = p$ partial differential equations coupled together by the nonlocal operator $\mathcal{M}$. So the solutions are in the form of a vector

$$\mathbf{v} = (\mathbf{v}((\cdot),q_1),\mathbf{v}((\cdot),q_2),\dots,\mathbf{v}((\cdot),q_p))$$

or a function $\mathbf{v} : (X \times Q) \to \mathbf{R}$. A similar form of SQVI also appears in the optimal switching problem (see Capuzzo Dolcetta and Evans [12]), but the difference is that in their case, the SQVI is coupled by a local operator. It is also interesting to see that our boundary condition is not a prescribed function but is determined by the values of the solution inside F^c.

It is known that in general the value function can satisfy the HJB equations only in a weak sense such as in the sense of viscosity solutions rather than in the classic sense. In our problem, since the value function is not necessarily even continuous, we need to use the following notion of a discontinuous viscosity solution originally introduced by Ishii [19].

DEFINITION 4.1. *A bounded function* $\mathbf{v} : (\overline{F^c}) \to \mathbf{R}$ *such that* $\mathbf{v} \in USC(\overline{F^c})$ $(\mathbf{v} \in LSC(\overline{F^c}))$ *is a viscosity sub-solution (super-solution) of SQVI* (22) *with boundary*

condition (23) *in the viscosity sense if, for any* $\phi : \overline{F^c} \to \mathbf{R}$ *such that* $\phi \in C^1(\overline{F^c})$ *and for any* x_0 (x_1)*, the local maximum (local minimum) of* $\mathbf{v}(\cdot, q) - \phi(\cdot, q)$ *satisfies*

(25)
$$\begin{cases} \max\{\mathbf{v}(x_0,q) - (\mathcal{M}^+\mathbf{v})(x_0,q), \lambda\mathbf{v}(x_0,q) + \mathcal{H}(x_0,q,\nabla_x\phi(x_0,q))\} \le 0 & \text{if } x_0 \in F_q^c, \\ \mathbf{v}(x_0,q) \le (\mathcal{M}^+\mathbf{v})(x_0,q) & \text{if } x_0 \in \partial F_q^c, \end{cases}$$

respectively,

$$\max\{\mathbf{v}(x_1,q) - (\mathcal{M}^-\mathbf{v})(x_1,q), \lambda\mathbf{v}(x_1,q) + \mathcal{H}(x_1,q,\nabla_x\phi(x_1,q))\} \ge 0 \quad \forall\ x_1. \tag{26}$$

A bounded function $\mathbf{v} : \overline{F^c} \to \mathbf{R}$ *is a (discontinuous) viscosity solution of* (22) *with boundary condition* (23) *if* $\mathbf{v}^*$ ($\mathbf{v}_*$) *is a sub-solution (super-solution) of* (22) *with boundary condition* (23) *in the viscosity sense.*

Remark 4.2. Following the usual definition of discontinuous viscosity solution with boundary condition satisfied in the viscosity sense (see, for example, [5]), the inequality of our sub-solution property should be

$$\begin{cases} \max\{\mathbf{v}(x_0,q) - (\mathcal{M}^+\mathbf{v})(x_0,q), \lambda\mathbf{v}(x_0,q) + \mathcal{H}(x_0,q,\nabla_x\phi(x_0,q))\} \le 0 & \text{if } x_0 \in F_q^c, \\ \min\left\{ \begin{matrix} \mathbf{v}(x_0,q) - (\mathcal{M}^+\mathbf{v})(x_0,q), \\ \max\{\mathbf{v}(x_0,q) - (\mathcal{M}^+\mathbf{v})(x_0,q), \lambda\mathbf{v}(x_0,q) + \mathcal{H}(x_0,q,\nabla_x\phi(x_0,q))\}\} \le 0 \end{matrix} \right\} & \text{if } x_0 \in \partial F_q^c, \end{cases}$$

which is equivalent to (25). Similarly, for our super-solution property inequality, it should be

$$\begin{cases} \max\{\mathbf{v}(x_1,q) - (\mathcal{M}^-\mathbf{v})(x_1,q), \lambda\mathbf{v}(x_1,q) + \mathcal{H}(x_1,q,\nabla_x\phi(x_1,q))\} \ge 0 & \text{if } x_1 \in F_q^c, \\ \max\left\{ \begin{matrix} \mathbf{v}(x_1,q) - (\mathcal{M}^-\mathbf{v})(x_1,q), \\ \max\{\mathbf{v}(x_1,q) - (\mathcal{M}^-\mathbf{v})(x_1,q), \lambda\mathbf{v}(x_1,q) + \mathcal{H}(x_1,q,\nabla_x\phi(x_1,q))\}\} \ge 0 \end{matrix} \right\} & \text{if } x_1 \in \partial F_q^c, \end{cases}$$

which is the same as (26).

Now we come to the main result of this section.

THEOREM 4.3. *The value function* $\mathbf{V}|_{\overline{F^c}}$ *is a discontinuous viscosity solution of the SQVI* (22) *with boundary condition* (23) *in the sense of Definition* 4.1.

Proof of the sub-solution property. We need to show that for any ϕ and x_0 in Definition 4.1 such that $\mathbf{V}^*(\cdot, q) - \phi(\cdot, q)$ has a local maximum at $x_0 \in \overline{F^c}$, (25) holds for $\mathbf{V}^*(x_0, q)$. From (16), (17), and Lemma 3.1 we know that

$$\mathbf{V}^* \le (\mathcal{M}\mathbf{V})^* \le \mathcal{M}^+\mathbf{V}^* \quad \text{in } \overline{F^c};$$

then we need only show that

$$\lambda\mathbf{V}^*(x_0,q) + \mathcal{H}(x_0,q,\nabla_x\phi(x_0,q)) \le 0 \quad \text{in } F^c.$$

Fix any $u \in U$, and let $u(t) = u,\ t \ge 0$. Since F_q^c is open, there is a $\gamma > 0$ such that

$$r(x_0,q,u) = \inf_{x \in B(x_0,\gamma)} T^F(x,q,u(\cdot)) > 0.$$

Then, thanks to (18), for any $0 \le T < r(x_0, q, u)$, we have

$$\mathbf{V}(x,q) \le \int_0^T \ell(x(s),q,u)e^{-\lambda s}ds + \mathbf{V}(x(T),q)e^{-\lambda T}$$

for any $x \in B(x_0, \gamma)$, which implies

$$\mathbf{V}^*(x_0, q) \le \int_0^T \ell(x_0(s), q, u) e^{-\lambda s} ds + \mathbf{V}^*(x_0(T), q) e^{-\lambda T},$$

where $x_0(\cdot)$ is the continuous state trajectory with initial condition (x_0, q). On the other hand, for T small enough, we have

$$\mathbf{V}^*(x_0(T), q) \le \phi(x_0(T), q) + (\mathbf{V}^*(x_0, q) - \phi(x_0, q)),$$

and thus we obtain

$$\mathbf{V}^*(x_0, q)(1 - e^{-\lambda T})/T \le 1/T \Big(\int_0^T \ell(x_0(s), q, u) e^{-\lambda s} ds + (\phi(x_0(T), q) - \phi(x_0, q)) e^{-\lambda T} \Big).$$

Let $T \to 0$. We get

$$\lambda \mathbf{V}^*(x_0, q) - \nabla_x \phi(x_0, q) f(x_0, q, u) - \ell(x_0, q, u) \le 0.$$

Now we maximize over u and obtain

$$\lambda \mathbf{V}^*(x_0, q) + \sup_{u \in U} \{ -\nabla_x \phi(x_0, q) f(x_0, q, u) - \ell(x_0, q, u) \} \le 0.$$

This proves that $\mathbf{V}^*$ is a sub-solution.

To prove that $\mathbf{V}_*$ is also a super-solution, we need a known result in relaxed control theory; see, for example, section 2.2 of Chapter III in [2]. In our problem, let

$$\widehat{\mathcal{H}}(x, q, p) = \sup_{\mu \in \mathbf{P}(U)} \{ -\langle \hat{f}(x, q, \mu), p \rangle - \hat{\ell}(x, q, \mu) \}. \tag{27}$$

Then we have the following lemma.

LEMMA 4.4. *For any* $(x, q) \in (X \times Q)$ *and* $p \in \mathbf{R}^n$,

$$\mathcal{H}(x, q, p) = \widehat{\mathcal{H}}(x, q, p). \tag{28}$$

Proof. Choose relaxed controls $\mu = \delta_u$; then

$$\widehat{\mathcal{H}}(x, q, p) \ge \sup_{u \in U} \{ -\langle \hat{f}(x, q, \delta_u), p \rangle - \hat{\ell}(x, q, \delta_u) \} = \mathcal{H}(x, q, p).$$

On the other hand,

$$\begin{aligned} -\langle \hat{f}(x, q, \mu), p \rangle - \hat{\ell}(x, q, \mu) &= \int_U (-\langle f(x, q, u), p \rangle - \ell(x, q, u)) d\mu \\ &\le \int_U \sup_{u \in U} \{ -\langle f(x, q, u), p \rangle - \ell(x, q, u) \} d\mu \\ &= \mathcal{H}(x, q, p). \end{aligned}$$

Then $\widehat{\mathcal{H}}(x, q, p) \le \mathcal{H}(x, q, p)$. ∎

Now we can prove the super-solution property for $\mathbf{V}_*$.

Proof of the super-solution property. What we need to show is that for any ϕ in Definition 4.1 and any local minimum of $\mathbf{V}_*(\cdot,q)-\phi(\cdot,q)$ at $x_1\in\overline{F_q^c}$, (26) holds for $\mathbf{V}_*$. It is known in viscosity solution theory (see, for example, Remark 1.2 on p. 26 of [2]) that we can assume without loss of generality that $\mathbf{V}_*(x_1,q)=\phi(x_1,q)$; hence there exists $\gamma_1>0$ such that

$$\mathbf{V}_*(x,q)-\phi(x,q)\geq 0 \quad \forall x\in B(x_1,\gamma_1). \tag{29}$$

If

$$\mathbf{V}_*(x_1,q)=(\mathcal{M}^-\mathbf{V}_*)(x_1,q),$$

there is nothing to prove; then we assume that

$$\mathbf{V}_*(x_1,q)<(\mathcal{M}^-\mathbf{V}_*)(x_1,q)$$

and show that

$$\lambda\mathbf{V}_*(x_1,q)+\mathcal{H}(x_1,q,\nabla_x\phi(x_1,q))\geq 0.$$

Case 1. $(x_1,q)\in F^c$. We assume for the sake of contradiction that there exists $\delta>0$ such that

$$\lambda\mathbf{V}_*(x_1,q)+\mathcal{H}(x_1,q,\nabla_x\phi(x_1,q))<-2\delta.$$

From the assumption $\mathbf{V}_*(x_1,q)=\phi(x_1,q)$ and Lemma 4.4, we get

$$\lambda\phi(x_1,q)+\widehat{\mathcal{H}}(x_1,q,\nabla_x\phi(x_1,q))<-2\delta,$$

which means

$$\lambda\phi(x_1,q)-\langle\hat{f}(x_1,q,\mu),\nabla_x\phi(x_1,q)\rangle-\hat{\ell}(x_1,q,\mu)<-2\delta \quad \forall\mu\in\mathbf{P}(U).$$

Hence we know there exists $\gamma_2>0$ such that

$$\lambda\phi(x,q)-\langle\hat{f}(x,q,\mu),\nabla_x\phi(x,q)\rangle-\hat{\ell}(x,q,\mu)<-\delta,\ \ \forall x\in B(x_1,\gamma_2),\ \ \mu\in\mathbf{P}(U). \tag{30}$$

Based on the standard estimation of ordinary differential equations, we know there exists $t_0>0$ such that

$$\hat{x}(t)\in B(x_1,\gamma_1\wedge\gamma_2) \quad \forall 0\leq t<t_0,$$

where $\hat{x}(\cdot)$ is the solution of $\hat{x}(t)=\hat{f}((\hat{x})(t),q,\mu_t),\hat{x}(0)=x_1$ for any relaxed control $\mu\in\widehat{\mathcal{U}}$.

On the other hand, from Theorem 3.4, let $\hat{\mu}\in\widehat{\mathcal{U}}$ be such that for sufficiently small $T>0$

$$\mathbf{V}_*(x_1,q)\geq\int_0^T\hat{\ell}(\hat{x}(t),q,\hat{\mu}_t)e^{-\lambda t}dt+\mathbf{V}_*(\hat{x}(T),q)e^{-\lambda T}-\frac{\delta}{2\lambda}(1-e^{-\lambda T}). \tag{31}$$

For this relaxed control $\hat{\mu}$ and its relaxed state trajectory $\hat{x}(\cdot)$, from (30)

$$\lambda\phi(\hat{x}(t),q)-\langle\hat{f}(\hat{x}(t),q,\hat{\mu}_t),\nabla_x\phi(\hat{x}(t),q)\rangle-\hat{\ell}(\hat{x}(t),q,\hat{\mu}_t)<-\delta \quad \text{a.e. } 0\leq t<T.$$

Then we have

$$\lambda e^{-\lambda t}\phi(\hat{x}(t),q) - e^{-\lambda t}\langle \hat{f}(\hat{x}(t),q,\hat{\mu}_t), \nabla_x \phi(\hat{x}(t),q)\rangle \\ - e^{-\lambda t}\hat{\ell}(\hat{x}(t),q,\hat{\mu}_t) < -e^{-\lambda t}\delta \quad \text{a.e. } 0 \le t < T.$$

Integrating from 0 to T, we get

$$\phi(x_1,q) < \int_0^T \hat{\ell}(\hat{x}(t),q,\hat{\mu}_t)e^{-\lambda t}dt + \phi(\hat{x}(T),q)e^{-\lambda T} - \frac{\delta}{\lambda}(1-e^{-\lambda T}).$$

Subtracting (31) and noting the fact $\mathbf{V}_*(x_1,q) = \phi(x_1,q)$ and (29), we get a contradiction:

$$0 < (\phi(\hat{x}(T),q) - \mathbf{V}_*(\hat{x}(T),q))e^{-\lambda T} - \frac{\delta}{2\lambda}(1-e^{-\lambda T}) \\ \le -\frac{\delta}{2\lambda}(1-e^{-\lambda T}).$$

Case 2. $x_1 \in \partial F_q^c$. Letting $x^n \to x_1$, $x^n \in \overline{F_q^c}$, and $\mathbf{V}(x^n,q) \to \mathbf{V}_*(x_1,q)$, we show that there exists a subsequence (still denoted $\{x^n\}$) such that $x^n \in F_q^c$. Otherwise, there exists $\hat{N}$ such that for $n > \hat{N}$, $x^n \in \partial F_q^c$. Since F_q is closed, we know that $x^n \in F_q$. Then from Theorem 3.2, we know that $\mathbf{V}(x^n,q) = (\mathcal{M}\mathbf{V})(x^n,q)$; this implies

$$\begin{aligned}\mathbf{V}_*(x_1,q) &= \lim_{n\to\infty} \mathbf{V}(x^n,q) \\ &\ge \liminf_{n\to\infty} (\mathcal{M}\mathbf{V})(x^n,q) \\ &\ge (\mathcal{M}\mathbf{V})_*(x_1,q) \\ &\ge (\mathcal{M}^-\mathbf{V}_*)(x_1,q),\end{aligned}$$

which contradicts our assumption. So we assume $x^n \in F_q^c$ for all n. Let $\beta^n(x^n,q) \in \mathcal{B}(x^n,q)$ such that

$$\mathbf{V}(x^n,q) + 1/n \ge \mathbf{J}_{(x^n,q)}(\beta^n).$$

Then we can proceed as in the proof of Theorem 3.4 to show that there exists a $t(x,q) > 0$ such that $t(x_1,q) < (\tau^n)_1$ for large n, and by using the weak convergence argument, we can show for any $0 \le t < t(x_1,q)$ that

$$\mathbf{V}_*(x_1,q) \ge \inf_{\mu_{(\cdot)} \in \widehat{\mathcal{U}}} \left\{ \int_0^t \int_U \ell(\hat{x}(s),q,u)e^{-\lambda s} d\mu_s ds + \mathbf{V}_*(\hat{x}(t),q)e^{-\lambda t} \right\}.$$

This is the super-optimality principle for the point (x_1,q). Then proceeding as in the proof of Case 1, we conclude that

$$\lambda \mathbf{V}_*(x_1,q) + \mathcal{H}_q(x_1, \nabla_x \phi(x_1,q)) \ge 0,$$

which finally shows that $\mathbf{V}_*$ is a super-solution. □

5. Comparison theorems. In general, we cannot guarantee that $\mathbf{V}$ is the unique viscosity solution of SQVI (22) with boundary condition (23) in the sense of Definition 4.1. As in the case of an optimal stopping problem with discontinuous stopping cost [4] and an optimal exit control problem [5], [10], we can define several slightly different optimal control problems which have different values but all satisfy SQVI (22) with boundary condition (23) in the sense of Definition 4.1. The reason is that since only the upper and lower envelopes are involved in the definition of discontinuous viscosity solutions, there is no way to completely recover a discontinuous function from the information provided by its envelopes. However, among all of these solutions we can identify the maximum and minimum solutions.

The main task of this section is to construct and prove the existence of these two extreme solutions in Theorems 5.3 and 5.6, and to show that the minimum solution actually is the unique lower semi-continuous solution by showing that all solutions have the same lower semi-continuous envelope. We accomplish all of this by using a different approach from that of Barles and Perthame [5] and Blanc [10]. The approach used here is a generalization of the idea developed by Bensoussan and Lions [8] and Barles [3] that they use to prove the uniqueness results for continuous solutions.

5.1. Characterization of the maximum solution. Let $\mathcal{V}^+ = \{\mathbf{v} : X \times Q \to \mathbf{R} | \mathbf{v} \geq 0 \text{ and } \mathbf{v} \in USC(X \times Q)\}$. Define a nonlinear operator $\mathcal{T}^+ : \mathcal{V}^+ \to \mathcal{V}^+$:

$$(\mathcal{T}^+\mathbf{v})(x,q) = \inf_{u(\cdot)\in\mathcal{U}, 0\leq\theta\leq T^F(x,q,u(\cdot))} \left\{ \int_0^\theta \ell(x(s),q,u(s))e^{-\lambda s}ds + (\mathcal{M}^+\mathbf{v})(x(\theta),q)e^{-\lambda\theta} \right\}, \tag{32}$$

where $x(t)$ is the solution of

$$\dot{x}(t) = f(x(t),q,u(t))$$

with initial state $x(0) = x$.

The next result summarizes the properties of the operator $\mathcal{T}^+$, which is similar to the operator $\mathcal{T}$ in [3], and the proofs are deferred to Appendix A.2.

LEMMA 5.1. *The operator $\mathcal{T}^+$ satisfies the following:*

1. $\mathcal{T}^+\mathbf{v}_1 \geq \mathcal{T}^+\mathbf{v}_2$ *for* $\mathbf{v}_1, \mathbf{v}_2 \in \mathcal{V}^+$ *such that* $\mathbf{v}_1 \geq \mathbf{v}_2$.
2. $\mathcal{T}^+(\alpha\mathbf{v}_1 + (1-\alpha)\mathbf{v}_2) \geq \alpha\mathcal{T}^+\mathbf{v}_1 + (1-\alpha)\mathcal{T}^+\mathbf{v}_2$ *for all* $\alpha \in [0,1]$ *and* $\mathbf{v}_1, \mathbf{v}_2 \in \mathcal{V}^+$.
3. $\mathbf{v}_1, \mathbf{v}_2 \in \mathcal{V}^+$ *and* $\mathbf{v}_1 - \mathbf{v}_2 \leq \gamma\mathbf{v}_1$ *for some* $\gamma \in [0,1]$. *Then there exits a constant* $0 < C_T < 1$ *independent of* γ *such that*

$$\mathcal{T}^+\mathbf{v}_1 - \mathcal{T}^+\mathbf{v}_2 \leq \gamma(1-\alpha)\mathcal{T}^+\mathbf{v}_1$$

   for all $\alpha \in [0, C_T]$.
4. *If* $\mathbf{v}_1, \mathbf{v}_2 \in \mathcal{V}^+$ *such that* $\mathbf{v}_1 = \mathcal{T}^+\mathbf{v}_1$ *and* $\mathbf{v}_2 = \mathcal{T}^+\mathbf{v}_2$, *then* $\mathbf{v}_1 = \mathbf{v}_2$.

Property 4 in Lemma 5.1 says that the operator $\mathcal{T}^+$ has only one fixed point in the set $\mathcal{V}^+$. Next we show that this fixed point is actually the value function of an optimal control problem with modified costs for the same hybrid system dynamics. In Theorem 5.3, we prove that this fixed point is the maximum solution of SQVI (22) with boundary condition (23).

For the same hybrid system (3), given any hybrid initial state $(x,q) \in (X \times Q)$ and any admissible hybrid control $\beta(x,q) \in \mathcal{B}(x,q)$, define a new cost to be

$$\mathbf{J}^+_{(x,q)}(\beta) = \sum_{i=1}^{N} \left(\int_{\tau_{i-1}}^{\tau_i} \ell(x(s), q_{i-1}, u(s)) e^{-\lambda s} ds + \kappa^*(x(\tau_i^-), q_{i-1}, w_i) e^{-\lambda \tau_i} \right) \tag{33}$$

and the new value function to be

$$\mathbf{V}^+(x,q) = \inf_{\beta(x,q) \in \mathcal{B}(x,q)} \{\mathbf{J}^+_{(x,q)}(\beta)\} \tag{34}$$

for all (x,q).

PROPOSITION 5.2. *$\mathbf{V}^+$ satisfies $\mathbf{V}^+ = \mathcal{T}^+\mathbf{V}^+$.*

Proof. By an argument similar to that in the proof of (16) in Theorem 3.2, we can show for any hybrid state $(x,q) \in (X \times Q)$ that

$$\mathbf{V}^+(x,q) \le (\mathcal{M}^+\mathbf{V}^+)(x,q).$$

Following the proof of (18) in Theorem 3.3, for any $u(\cdot) \in \mathcal{U}$ and $0 \le \theta \le T^F(x,q,u(\cdot))$, we can obtain

$$\begin{aligned} \mathbf{V}^+(x,q) &\le \int_0^\theta \ell(x(s), q, u(s)) e^{-\lambda s} ds + \mathbf{V}^+(x(\theta), q) e^{-\lambda \theta} \\ &\le \int_0^\theta \ell(x(s), q, u(s)) e^{-\lambda s} ds + (\mathcal{M}^+\mathbf{V}^+)(x(\theta), q) e^{-\lambda \theta}, \end{aligned}$$

where $x(t)$ is the solution of

$$\dot{x}(t) = f(x(t), q, u(t))$$

with initial state $x(0) = x$. Then we have

$$\begin{aligned} \mathbf{V}^+(x,q) &\le \inf_{u(\cdot) \in \mathcal{U}, 0 \le \theta \le T^F(x,q,u(\cdot))} \left\{ \int_0^\theta \ell(x(s), q, u(s)) e^{-\lambda s} ds + (\mathcal{M}^+\mathbf{V}^+)(x(\theta), q) e^{-\lambda \theta} \right\} \\ &= (\mathcal{T}^+\mathbf{V}^+)(x,q). \end{aligned}$$

To prove the reverse inequality, for any $\epsilon > 0$, there exists control $\beta^\epsilon(x,q) \in \mathcal{B}(x,q)$ such that

$$\begin{aligned} \mathbf{V}^+(x,q) + \epsilon &\ge \mathbf{J}^+_{(x,q)}(\beta^\epsilon) \\ &\ge \int_0^{\tau_1^\epsilon} \ell(x^\epsilon(s), q, u^\epsilon(s)) e^{-\lambda s} ds + (\kappa^*(x^\epsilon((\tau_1^\epsilon)^-), q, w_1^\epsilon) \\ &\qquad + \mathbf{V}^+(g(x^\epsilon((\tau_1^\epsilon)^-), q, w_1^\epsilon))) e^{-\lambda \tau_1^\epsilon} \\ &\ge \int_0^{\tau_1^\epsilon} \ell(x^\epsilon(s), q, u^\epsilon(s)) e^{-\lambda s} ds + (\mathcal{M}^+\mathbf{V}^+)(x^\epsilon(x^\epsilon((\tau_1^\epsilon)^-), q)) e^{-\lambda(\tau_1^\epsilon)}. \end{aligned}$$

Since for any $(x,q) \in (X \times Q)$ and any $\beta(x,q) = (u(\cdot), \{(\tau_i, w_i)\}_1^N)$

$$0 \le \tau_1 \le T^F(x,q,u(\cdot)),$$

it holds that

$$\begin{aligned}\mathbf{V}^+(x,q)+\epsilon &\geq \inf_{u(\cdot)\in\mathcal{U},0\leq\theta\leq T^F(x,q,u(\cdot))}\Big\{\int_0^\theta \ell(x(s),q,u(s))e^{-\lambda s}ds \\ &\qquad + (\mathcal{M}^+\mathbf{V}^+)(x(\theta),q)e^{-\lambda\theta}\Big\} \\ &= (\mathcal{T}^+\mathbf{V}^+)(x,q),\end{aligned}$$

where $x(T^F(x,q,u(\cdot))) = \int_0^{T^F(x,q,u(\cdot))} f(x(t,q,u(t)))dt - x$. □

Now we come to the main result of the section, showing that the restriction of $\mathbf{V}^+$ on set $\overline{F^c}$ is the maximum solution.

THEOREM 5.3. *$\mathbf{V}^+|_{\overline{F^c}}$ is the maximum sub-solution and solution of SQVI* (22) *with boundary condition* (23) *in the sense of Definition* 4.1.

Proof. Take any bounded nonnegative sub-solution $\mathbf{v} : \overline{F^c} \to \mathbf{R}$; this determines $(\mathcal{M}^+\mathbf{v})(x,q)$ for all $(x,q) \in \widetilde{F}$ according to the definition of $\mathcal{M}^+$. Define function $V : X \times Q \to \mathbf{R}$ by

$$V(x,q) = \begin{cases}\mathbf{v}(x,q) & \text{if } (x,q)\in\overline{F^c},\\ 0 & \text{if } (x,q)\in\widetilde{F}.\end{cases}$$

It is easy to see that $V \in \mathcal{V}^+$, that V is bounded, i.e., there exists $\widehat{C}$ such that $0 \leq V \leq \widehat{C}$, and that V satisfies the following:

1.

(35) $V|_{\overline{F^c}}$ is a bounded sub-solution of SQVI (22) with boundary condition (23);

2.

$$V(x,q) \leq (\mathcal{M}^+V)(x,q) \quad \forall\ (x,q)\in\widetilde{F}. \tag{36}$$

For any fixed $q \in Q$, according to the definition of operator $\mathcal{T}^+$ (32)

$$\begin{aligned}(\mathcal{T}^+V)(x,q) = \inf_{u(\cdot)\in\mathcal{U},0\leq\theta\leq T^F(x,q,u(\cdot))}\Big\{&\int_0^\theta \ell(x(s),q,u(s))e^{-\lambda s}ds \\ &+ (\mathcal{M}^+V)(x(\theta),q)e^{-\lambda\theta}\Big\};\end{aligned}$$

thus $(\mathcal{T}^+V)|_{\overline{F^c}}(\cdot,q)$ is the value function of the optimal stopping control in restricted area F_q^c of the continuous system

$$\dot{x} = f(x,q,u)$$

with discontinuous stopping cost $(\mathcal{M}^+V)(\cdot,q)$, and since $(\mathcal{M}^+V)(\cdot,q)$ is upper semi-continuous, we know (see Appendix A.1 for a discussion of the problem of an optimal stopping control problem in a restricted area) that $(\mathcal{T}^+V)|_{\overline{F^c}}(\cdot,q)$ is the maximum sub-solution of the QVI

$$\max\{\mathbf{u}(x,q) - (\mathcal{M}^+V)(x,q), \lambda\mathbf{u}(x,q) - \mathcal{H}(x,q,\nabla_x\mathbf{u}(x,q))\} = 0 \quad \text{in } F_q^c \tag{37}$$

with boundary condition

$$\mathbf{u}(x,q) = (\mathcal{M}^+V)(x,q) \quad \text{in } \partial F_q^c. \tag{38}$$

While by assumption $V|_{\overline{F^c}}(\cdot, q)$ is a sub-solution of (37) and boundary condition (38),

$$V(x,q) \le (\mathcal{T}^+ V)(x,q) \quad \forall x \in \overline{F_q^c}.$$

Since it is true for any $q \in Q$, then

$$V \le (\mathcal{T}^+ V) \quad \text{in } \overline{F^c}. \tag{39}$$

When $(x,q) \in \widetilde{F}$, according to the definition of $\mathcal{T}^+$ (32),

$$(\mathcal{T}^+ V)(x,q) = (\mathcal{M}^+ V)(x,q);$$

hence combining this with (36) and (39) we get

$$V \le (\mathcal{T}^+ V) \text{ in } X \times Q.$$

On the other hand, from the definition of operator $\mathcal{T}^+$ (32), it can be shown in a manner similar to that of the proof of Theorem 3.3 that

$$(\mathcal{T}^+ V)(x,q) \le (\mathcal{M}^+ V)(x,q) \le (\mathcal{M}^+(\mathcal{T}^+ V))(x,q) \quad \forall (x,q) \in (X \times Q) \tag{40}$$

and

$$(\mathcal{T}^+ V)(x,q) \le \int_0^T \ell(x(s), q, u(s)) e^{-\lambda s} ds + (\mathcal{T}^+ V)(x(T), q) e^{-\lambda T} \tag{41}$$

for any $(x,q) \in F^c$, $u(\cdot) \in \mathcal{U}$, and $0 \le T < T^F(x,q,u(\cdot))$. Inequalities (40) and (41) are the sub-optimality principles for $\mathcal{T}^+ V$. Then by the same procedure as in the proof of Theorem 4.3, we can show that $(\mathcal{T}^+ V)_{\overline{F^c}}$ is also a sub-solution of SQVI (22) with boundary condition (23). Hence we know that $\mathcal{T}^+ V$ also satisfies conditions (35) and (36); replacing V with $\mathcal{T}^+ V$ in the above analysis, we have

$$\mathcal{T}^+ V \le \mathcal{T}^+(\mathcal{T}^+ V).$$

The above analysis suggests that if we start from any function $V \in \mathcal{V}^+$ satisfying conditions (35) and (36), we get a sequence of nondecreasing functions

$$\{V, \mathcal{T}^+ V, (\mathcal{T}^+)^2 V, \dots, (\mathcal{T}^+)^n V, \dots\}, \tag{42}$$

and every function in this sequence satisfies conditions (35) and (36).

Next we show that this sequence converges uniformly to a function in $\mathcal{V}^+$.

Since for any $(x,q) \in (X \times Q)$

$$\begin{aligned}(\mathcal{T}^+ V)(x,q) &\le (\mathcal{M}^+ V)(x,q) \\ &= \min_{w \in W} \{\kappa^*(x,q,w) + V(g(x,q,w))\} \\ &\le \widehat{C}' + \widehat{C},\end{aligned}$$

where $\widehat{C}'$ is the upper bound for κ^*, from the relation

$$(\mathcal{T}^+)^n V = \mathcal{T}^+((\mathcal{T}^+)^{n-1} V) \le \mathcal{M}((\mathcal{T}^+)^{n-1} V),$$

we can obtain the following bound for $(\mathcal{T}^+)^n V$ inductively:

$$(\mathcal{T}^+)^n V \le n\widehat{C}' + \widehat{C}$$

for any $n \geq 1$. Since $V \geq 0$, we have

$$\mathcal{T}^+ V - V \leq \mathcal{T}^+ V.$$

Using item 3 in Lemma 5.1, we know there exists $0 < \alpha < 1$ such that

$$(\mathcal{T}^+)^2 V - \mathcal{T}^+ V \leq (1-\alpha)((\mathcal{T}^+)^2 V).$$

Then it is easy to show inductively by using item 3 in Lemma 5.1 that for any $n \geq 2$

$$\begin{aligned}(\mathcal{T}^+)^n V - (\mathcal{T}^+)^{n-1} V &\leq (1-\alpha)^{n-1}((\mathcal{T}^+)^n V) \\ &\leq (1-\alpha)^{n-1}(n\widehat{C}' + \widehat{C}).\end{aligned}$$

Since $\sum_1^\infty (1-\alpha)^{n-1}(n\widehat{C}' + \widehat{C}) < \infty$, we know that for any $q \in Q$, the sequence

$$\{V(\cdot,q), (\mathcal{T}^+ V)(\cdot,q), ((\mathcal{T}^+)^2 V)(\cdot,q), \dots, ((\mathcal{T}^+)^n V)(\cdot,q), \dots\}$$

is uniformly convergent. Let $\widehat{\mathbf{V}}(\cdot,q) = \lim_{n\to\infty}((\mathcal{T}^+)^n V)(\cdot,q)$.

Finally, we show that $\widehat{\mathbf{V}} = \mathbf{V}^+$.

First for any n,

$$(\mathcal{T}^+)^n V \leq \mathcal{M}^+((\mathcal{T}^+)^{n-1} V) \leq \mathcal{M}^+ \widehat{\mathbf{V}};$$

then

$$\widehat{\mathbf{V}} \leq \mathcal{M}^+ \widehat{\mathbf{V}} \text{ in } X \times Q. \tag{43}$$

Furthermore, we can follow the same argument as in the proof of (18) to prove that for any $(x,q) \in F^c$, $u(\cdot) \in \mathcal{U}$, and $0 \leq T < T^F(x,q,u(\cdot))$,

$$((\mathcal{T}^+)^n V)(x,q) \leq \int_0^T \ell(x(s),q,u(s)) e^{-\lambda s} ds + ((\mathcal{T}^+)^n V)(x(T),q) e^{-\lambda T},$$

which implies

$$\widehat{\mathbf{V}}(x,q) \leq \int_0^T \ell(x(s),q,u(s)) e^{-\lambda s} ds + \widehat{\mathbf{V}}(x(T),q) e^{-\lambda T}. \tag{44}$$

Equations (43) and (44) are the sub-optimality principles for $\widehat{\mathbf{V}}$, which means that $\widehat{\mathbf{V}}|_{\overline{F^c}}$ is also a sub-solution of SQVI (22) with boundary condition (23). Hence $\widehat{\mathbf{V}}$ also satisfies conditions (35) and (36); thus

$$\widehat{\mathbf{V}} \leq \mathcal{T}^+ \widehat{\mathbf{V}}.$$

On the other hand, let

$$\sigma_n = \sup_{x,q}(\widehat{\mathbf{V}} - (\mathcal{T}^+)^n V)(x,q);$$

then $\sigma_n \geq 0$ and $\lim_n \sigma_n = 0$ by the uniform convergence of sequence (42). For any n,

$$\begin{aligned}\widehat{\mathbf{V}} &\geq (\mathcal{T}^+)^{n+1} V \\ &= \mathcal{T}^+((\mathcal{T}^+)^n V) \\ &\geq \mathcal{T}^+(\widehat{\mathbf{V}} - \sigma_n) \\ &\geq \mathcal{T}^+ \widehat{\mathbf{V}} - \sigma_n.\end{aligned}$$

Hence

$$\widehat{\mathbf{V}} \geq \mathcal{T}^+ \widehat{\mathbf{V}}.$$

Then we conclude that

$$\widehat{\mathbf{V}} = \mathcal{T}^+ \widehat{\mathbf{V}}.$$

We have already shown that $\mathbf{V}^+ = \mathcal{T}^+ \mathbf{V}^+$. Thanks to item 4 in Lemma 5.1, we know that

$$\mathbf{V}^+ = \widehat{\mathbf{V}} \geq V.$$

By restricting $\mathbf{V}^+$ and V to $\overline{F^c}$, we get

$$\mathbf{V}^+|_{\overline{F^c}} \geq V|_{\overline{F^c}} = \mathbf{v}.$$

What is left to be shown is that $(\mathbf{V}^+)_*|_{\overline{F^c}}$ is also a super-solution of SQVI (22) with boundary condition (23). By the same argument as in Theorem 3.4, we can prove the super-optimality principle for $(V^+)_*$ by using the fact that

$$(\kappa^*)_* = \kappa_*.$$

Thus following the second part of the proof of Theorem 4.3, we can show that it is a super-solution of SQVI (22) with boundary condition (23).

The proof is complete. □

5.2. Characterization of the minimum solution. In this section, we use the same approach to identify the minimum super-solution for the SQVI (22) with boundary condition (23). It is no surprise that the minimum super-solution is also a solution (hence, minimum solution). By the same argument, the minimum super-solution is the value function of the optimal control problem in a relaxed control framework for the same hybrid systems but with the costs replaced by their lower envelopes. Also, it is the unique fixed point of the nonlinear operator $\mathcal{T}^- : \mathcal{V}^- \to \mathcal{V}^-$ defined as

$$(\mathcal{T}^- v)(x,q) = \inf_{\mu_{(\cdot)} \in \widehat{\mathcal{U}}, 0 \leq \theta \leq \widehat{T}^F(x,q,\mu_{(\cdot)})} \left\{ \int_0^\theta \int_U \ell(\hat{x}(s),q,u) e^{-\lambda s} d\mu_s ds + (\mathcal{M}^- v)(\hat{x}(\theta),q) e^{-\lambda\theta} \right\}, \tag{45}$$

where $\hat{x}(t)$ is the solution of

$$\dot{\hat{x}}(t) = \int_U f(\hat{x}(t),q,u) d\mu_t$$

with initial state $\hat{x}(0) = x$ and $\mathcal{V}^-$ the set of all bounded and nonnegative lower semi-continuous functions; i.e., $\mathcal{V}^- = \{\mathbf{v} : X \times Q \to \mathbf{R} | \mathbf{v} \geq 0 \text{ and } \mathbf{v} \in LSC(X \times Q)\}$.

As in Lemma 5.1, we can prove properties of $\mathcal{T}^-$ similar to those of $\mathcal{T}^+$.

LEMMA 5.4. *The operator $\mathcal{T}^-$ satisfies the following:*

1. $\mathcal{T}^- \mathbf{v}_1 \geq \mathcal{T}^- \mathbf{v}_2$ *for* $\mathbf{v}_1, \mathbf{v}_2 \in \mathcal{V}^-$ *such that* $\mathbf{v}_1 \geq \mathbf{v}_2$.
2. $\mathcal{T}^-(\alpha \mathbf{v}_1 + (1-\alpha)\mathbf{v}_2) \geq \alpha \mathcal{T}^- \mathbf{v}_1 + (1-\alpha)\mathcal{T}^- \mathbf{v}_2$ *for all* $\alpha \in [0,1]$ *and* $\mathbf{v}_1, \mathbf{v}_2 \in \mathcal{V}^-$.

3. $\mathbf{v}_1, \mathbf{v}_2 \in \mathcal{V}^-$ *and* $\mathbf{v}_1 - \mathbf{v}_2 \leq \gamma \mathbf{v}_1$ *for some* $\gamma \in [0,1]$. *Then there exists constant* $0 < C_T < 1$ *independent of* γ *such that*

$$\mathcal{T}^- \mathbf{v}_1 - \mathcal{T}^- \mathbf{v}_2 \leq \gamma(1-\alpha)\mathcal{T}^- \mathbf{v}_1$$

for all $\alpha \in [0, C_T]$.

4. *If* $\mathbf{v}_1, \mathbf{v}_2 \in \mathcal{V}^-$ *such that* $\mathbf{v}_1 = \mathcal{T}^- \mathbf{v}_1$ *and* $\mathbf{v}_2 = \mathcal{T}^- \mathbf{v}_2$, *then* $\mathbf{v}_1 = \mathbf{v}_2$.

Now, let us define the optimal control problem for the same hybrid systems whose value function is the minimum super-solution we want. For the same hybrid system (3), given any hybrid initial state $(x,q) \in (X \times Q)$ and any relaxed admissible hybrid control $\hat{\beta}(x,q) \in \widehat{\mathcal{B}}(x,q)$, define a new cost to be

$$\mathbf{J}^-_{(x,q)}(\hat{\beta}) = \sum_{i=1}^{N} \Big(\int_{\tau_{i-1}}^{\tau_i} \int_U \ell(\hat{x}(s), q_{i-1}, u) e^{-\lambda s} d\mu_s ds + \kappa_*(\hat{x}(\tau_i^-), q_{i-1}, w_i) e^{-\lambda \tau_i} \Big) \tag{46}$$

and the value function to be

$$\mathbf{V}^-(x,q) = \inf_{\hat{\beta}(x,q) \in \widehat{\mathcal{B}}(x,q)} \{ \mathbf{J}^-_{(x,q)}(\hat{\beta}) \}. \tag{47}$$

By an argument similar to that used in the proof of Proposition 5.2, we have the following proposition.

PROPOSITION 5.5. $\mathbf{V}^-$ *satisfies* $\mathbf{V}^- = \mathcal{T}^- \mathbf{V}^-$.

Now we show that $\mathbf{V}^-|_{\overline{F^c}}$ is the minimum solution of SQVI (22) with boundary condition (23).

THEOREM 5.6. $\mathbf{V}^-|_{\overline{F^c}}$ *is the minimum super-solution and solution of SQVI* (22) *with boundary condition* (23) *in the sense of definition* 4.1.

Proof. Take any bounded and nonnegative super-solution $\mathbf{v} : \overline{F^c} \to \mathbf{R}$. According to the definition of $\mathcal{M}^-$, we can compute $(\mathcal{M}^- \mathbf{v})(x,q)$ for all $(x,q) \in \widetilde{F}$. Define function $V : X \times Q \to \mathbf{R}$ by

$$V(x,q) = \begin{cases} \mathbf{v}(x,q) & \text{if } (x,q) \in \overline{F^c}, \\ \widetilde{C} & \text{if } (x,q) \in \widetilde{F}, \end{cases}$$

where $\widetilde{C}$ is large enough. It is easy to see that $V \in \mathcal{V}^-$ and that V satisfies

1.

$$V|_{\overline{F^c}} \text{ is a super-solution of (22) with boundary condition (23);} \tag{48}$$

2.

$$V(x,q) \geq (\mathcal{M}^- V)(x,q) \quad \forall (x,q) \in \widetilde{F}. \tag{49}$$

Then for any $q \in Q$, from the definition of $\mathcal{T}^-$,

$$(\mathcal{T}^- V)(x,q) = \inf_{\mu_{(\cdot)} \in \widehat{\mathcal{U}}, 0 \leq \theta \leq \widehat{T}^F(x,q,\mu_{(\cdot)})} \Big\{ \int_0^\theta \int_U \ell(\hat{x}(s), q, u) e^{-\lambda s} d\mu_s ds + (\mathcal{M}^- V)(\hat{x}(\theta), q) e^{-\lambda \theta} \Big\}.$$

We know that $\mathcal{T}^- V$ can be regarded as the value function of the optimal stopping control problem in restricted area F_q^c of the nonhybrid system

$$\dot{x} = f(x,q,u)$$

with discontinuous stopping costs $(\mathcal{M}^- V)(\cdot, q)$. Since $(\mathcal{M}^- V)(\cdot, q)$ is lower semi-continuous (see appendix), $(\mathcal{T}^- V)(\cdot, q)|_{\overline{F^c}}$ is the minimum super-solution of QVI (37) with boundary condition (38). By assumption, $V(\cdot, q)|_{\overline{F^c}}$ is a super-solution of it, and thus

$$V(x, q) \geq (\mathcal{T}^- V)(x, q) \quad \forall x \in \overline{F_q^c}.$$

When $(x, q) \in \widetilde{F}$, by (49) and the definition of $\mathcal{T}^-$, we know that

$$V(x, q) \geq (\mathcal{M}^- V)(x, q) = \mathcal{T}^- V(x, q);$$

hence

$$V \geq (\mathcal{T}^- V) \text{ in } X \times Q.$$

On the other hand, by an argument similar to that of Theorem 3.4, we can prove the following super-optimality principle for $\mathcal{T}^- V$ in F^c: for any $(x, q) \in F^c$ where

$$(\mathcal{T}^- V)(x, q) < (\mathcal{M}^-(\mathcal{T}^- V))(x, q),$$

there exists $\tilde{t}(x, q) > 0$ such that

$$(\mathcal{T}^- V)(x, q) \geq \inf_{\mu(\cdot) \in \widehat{\mathcal{U}}} \left\{ \int_0^t \int_U \ell(\hat{x}(s), q, u) e^{-\lambda s} ds + (\mathcal{T}^- V)(\hat{x}(t), q) e^{-\lambda t} \right\}$$

for all $0 \leq t < \tilde{t}(x, q)$. Then by the same procedure as in the proof in Theorem 4.3, $(\mathcal{T}^- V)|_{\overline{F^c}}$ is also a super-solution of (22) with boundary condition (23). Since we know that

$$\mathcal{T}^- V = \mathcal{M}^- V \geq \mathcal{M}^-(\mathcal{T}^- V) \quad \text{in } \tilde{F},$$

it holds that $\mathcal{T}^- V$ also satisfies conditions (48) and (49), and thus

$$\mathcal{T}^- V \geq \mathcal{T}^-(\mathcal{T}^- V) = (\mathcal{T}^-)^2 V.$$

The above argument shows that if we start from any bounded function $V \in \mathcal{V}^-$ satisfying conditions (48) and (49), we can get a sequence of nonincreasing functions

$$\{V, \mathcal{T}^- V, (\mathcal{T}^-)^2 V, \dots, (\mathcal{T}^-)^n V, \dots\}$$

all of which satisfy conditions (48) and (49). By a similar argument, we can show that for any fixed $q \in Q$, the sequence

$$\{V(\cdot, q), (\mathcal{T}^- V)(\cdot, q), ((\mathcal{T}^-)^2 V)(\cdot, q), \dots, ((\mathcal{T}^-)^n V)(\cdot, q), \dots\}$$

uniformly converges. Let $\widetilde{\mathbf{V}}(\cdot, q) = \lim_{n \to \infty}((\mathcal{T}^-)^n V)(\cdot, q)$.

We now show that $\widetilde{\mathbf{V}} = \mathbf{V}^-$.

Since for any n,

$$\widetilde{\mathbf{V}} \leq (\mathcal{T}^-)^n V = \mathcal{T}^-((\mathcal{T}^-)^{n-1} V) \leq \mathcal{M}^-((\mathcal{T}^-)^{n-1} V),$$

we get

$$\widetilde{\mathbf{V}} \leq \mathcal{M}^- \widetilde{\mathbf{V}}.$$

Assume for some $(x,q) \in F^c$ that

$$\widetilde{\mathbf{V}}(x,q) < (\mathcal{M}^-\widetilde{\mathbf{V}})(x,q).$$

For any n, let $(\mu_n(\cdot), \theta_n)$ be

$$\begin{aligned}((\mathcal{T}^-)^n V)(x,q) + \frac{1}{n} > \int_0^{\theta_n} \int_U \ell(\hat{x}_n(s),q,u) e^{-\lambda s} d\mu_n(s) ds \\ + (\mathcal{M}^-((\mathcal{T}^-)^{n-1}V))(\hat{x}_n(\theta_n),q) e^{-\lambda\theta_n};\end{aligned}$$

then there exists $\hat{t}(x,q) > 0$ such that $\theta_n \geq \hat{t}(x,q)$ for n large enough. Otherwise, assume there exists a convergent subsequence (still denoted as θ_n); then we easily get a contradiction:

$$\widetilde{\mathbf{V}}(x,q) \geq (\mathcal{M}^-\widetilde{\mathbf{V}})(x,q).$$

Hence for every $0 \leq t < \hat{t}(x,q)$, we have

$$((\mathcal{T}^-)^n V)(x,q) + \frac{1}{n} \geq \int_0^t \int_U \ell(\hat{x}_n(s),q,u) e^{-\lambda s} d\mu_n(s) ds + ((\mathcal{T}^-)^n V)(\hat{x}_n(t),q) e^{-\lambda t}$$

for all large n. By the argument of weak convergence, we know that there exits $\mu_{(\cdot)}$ such that $\mu_n(\cdot)$ converges to $\mu_{(\cdot)}$ weakly, and

$$\begin{aligned}\widetilde{\mathbf{V}}(x,q) &\geq \int_0^t \int_U \ell(\hat{x}(s),q,u) e^{-\lambda s} d\mu_s ds + \widetilde{\mathbf{V}}(\hat{x}(t),q) e^{-\lambda t} \\ &\geq \inf_{\mu_{(\cdot)} \in \widehat{\mathcal{U}}} \left\{ \int_0^t \int_U \ell(\hat{x}(s),q,u) e^{-\lambda s} d\mu_s ds + \widetilde{\mathbf{V}}(\hat{x}(t),q) e^{-\lambda t} \right\}.\end{aligned}$$

This is the super-solution property for $\widetilde{V}$; hence we know $\widetilde{\mathbf{V}}|_{\overline{F^c}}$ is also a super-solution of (22) with boundary condition (23). When $(x,q) \in \widetilde{F}$, $(\mathcal{T}^-)^n V$ satisfies

$$((\mathcal{T}^-)^n V)(x,q) \geq (\mathcal{M}^-((\mathcal{T}^-)^n V))(x,q)$$

for every n; then

$$\widetilde{\mathbf{V}}(x,q) \geq (\mathcal{M}^-\widetilde{\mathbf{V}})(x,q) \quad \forall (x,q) \in \widetilde{F}.$$

We have just shown that conditions (48) and (49) are satisfied by the function $\widetilde{\mathbf{V}}$; hence

$$\widetilde{\mathbf{V}} \geq \mathcal{T}^-\widetilde{\mathbf{V}}.$$

On the other hand, let

$$\sigma_n = \sup_{x,q}((\mathcal{T}^-)^n V - \widetilde{\mathbf{V}})(x,q);$$

then $\sigma_n \geq 0$ and $\lim_n \sigma_n = 0$ by the uniform convergence, and hence for any n,

$$\begin{aligned}\widetilde{\mathbf{V}} &\leq (\mathcal{T}^-)^{n+1} V \\ &= \mathcal{T}^-((\mathcal{T}^-)^n V) \\ &\leq \mathcal{T}^-(\widetilde{\mathbf{V}} + \sigma_n) \\ &= \mathcal{T}^-\widetilde{\mathbf{V}} + \sigma_n.\end{aligned}$$

Hence

$$\widetilde{\mathbf{V}} \le \mathcal{T}^- \widetilde{\mathbf{V}},$$

and then

$$\widetilde{\mathbf{V}} = \mathcal{T}^- \widetilde{\mathbf{V}}.$$

Thanks to property 5.4 in Lemma 5.4 and Proposition 5.5, we know that

$$\mathbf{V}^- = \widetilde{\mathbf{V}} \le V.$$

When restricting $\mathbf{V}^-$ and V on $\overline{F^c}$, we have

$$\mathbf{V}^-|_{\overline{F^c}} \le V|_{\overline{F^c}} = \mathbf{v},$$

which shows that $\mathbf{V}^-|_{\overline{F^c}}$ is the minimum super-solution.

From the definition of $\mathbf{V}^-$ (47), it is easy to check that for any $(x, q) \in (X \times Q)$

$$\mathbf{V}^-(x,q) \le (\mathcal{M}^- \mathbf{V}^-)(x,q) \le (\mathcal{M}\mathbf{V}^-)(x,q),$$

and for any $\mu_{(\cdot)} \in \widehat{\mathcal{U}}$ and $0 \le T \le \widehat{T}^F(x,q,\mu_{(\cdot)})$

$$\mathbf{V}^-(x,q) \le \int_0^T \int_U \ell(\hat{x}(s),q,u) e^{-\lambda s} d\mu_s ds + \mathbf{V}^-(\hat{x}(T),q) e^{-\lambda T}.$$

These inequalities are the sub-optimality principles for $\mathbf{V}^-$, and consequently, it can be shown that $(\mathbf{V}^-)^*|_{\overline{F^c}}$ is a sub-solution of (22) with boundary condition (23) by routine.

The proof is complete. □

5.3. Weak sense uniqueness. We have specified two extreme solutions for the SQVI (22) with boundary condition (23); next we show that they share the same lower envelope. This property also holds for the extreme solutions for the equations arising from the optimal stopping problem [4] and the optimal exit problem [5], [10]; however, their approach in proving this point is not readily applicable for our case since multiple (possibly an infinite number of) exits are involved, and it can be seen that we need a few more conditions to guarantee this property.

THEOREM 5.7. *If* $\mathcal{M}^- v_* = (\mathcal{M}^+ v)_*$ *for all* $v \in \mathcal{V}^+$, *then* $\mathbf{V}^- = \mathbf{V}^+_*$.

Proof. By definition of $\mathcal{T}^-$,

$$\begin{aligned}(\mathcal{T}^- \mathbf{V}^+_*)(x,q) &= \inf_{\mu_{(\cdot)} \in \widehat{\mathcal{U}}, 0 \le \theta \le \widehat{T}^F(x,q,\mu_{(\cdot)})} \left\{ \int_0^\theta \int_U \ell(\hat{x}(s),q,u) e^{-\lambda s} d\mu_s ds \right. \\ &\qquad \left. + (\mathcal{M}^- \mathbf{V}^+_*)(\hat{x}(\theta),q) e^{-\lambda\theta} \right\} \\ &= \inf_{\mu_{(\cdot)} \in \widehat{\mathcal{U}}, 0 \le \theta \le \widehat{T}^F(x,q,\mu_{(\cdot)})} \left\{ \int_0^\theta \int_U \ell(\hat{x}(s),q,u) e^{-\lambda s} d\mu_s ds \right. \\ &\qquad \left. + (\mathcal{M}^+ \mathbf{V}^+)_*(\hat{x}(\theta),q) e^{-\lambda\theta} \right\}.\end{aligned}$$

By Proposition A.4 in Appendix A.1 concerning optimal stopping in a restricted area, we know that

$$\begin{aligned}(\mathcal{T}^-\mathbf{V}_*^+)(x,q) &= (\mathcal{T}^+\mathbf{V}^+)_*(x,q)\\ &= \mathbf{V}_*^+(x,q);\end{aligned}$$

hence $\mathbf{V}_*^+$ is the fixed point of $\mathcal{T}^-$, but we know that $\mathbf{V}^-$ is the unique fixed point of $\mathcal{T}^-$, so we conclude that $\mathbf{V}^- = \mathbf{V}_*^+$. □

Let V be any solution of (22); then $\mathbf{V}^- \le V \le \mathbf{V}^+$. Hence $\mathbf{V}^- \le V_* \le \mathbf{V}_*^+ = \mathbf{V}^-$, and we get $V_* = \mathbf{V}^-$. Thus all the solutions have the same lower envelope which is the minimum solution. If we define SQVI (22) as having a unique solution in the weak sense if all its solutions share the same lower envelope, then we have just proved that the uniqueness in the weak sense holds for SQVI (22) with boundary condition (23) under the condition of Theorem 5.7. Another implication of Theorem 5.7 is that SQVI (22) with boundary condition (23) has a unique lower semi-continuous solution $\mathbf{V}^-$.

6. Special cases and optimal hybrid controllers. We have shown that extreme solutions $\mathbf{V}^-$ and $\mathbf{V}^+$ of the dynamic programming equations are the value functions of slightly different hybrid optimal control problems. The original value function we are really interested in resides somewhere between $\mathbf{V}^-$ and $\mathbf{V}^+$. Thus $\mathbf{V}^-$ and $\mathbf{V}^+$ can be regarded as the lower and upper bound of the value function we want to compute. Although these boundary functions themselves are the value functions of optimal hybrid control problems, from the proofs of Theorems 5.3 and 5.6 we know that they are actually the limit functions of corresponding monotone sequences,

$$\{V, \mathcal{T}^+V, (\mathcal{T}^+)^2V, \dots, (\mathcal{T}^+)^nV, \dots\}$$

and

$$\{V, \mathcal{T}^-V, (\mathcal{T}^-)^2V, \dots, (\mathcal{T}^-)^nV, \dots\}.$$

Every element in these two sequences can be computed according to

$$\begin{aligned}((\mathcal{T}^+)^nV)(x,q) = \inf_{u(\cdot)\in\mathcal{U}, 0\le\theta\le T^F(x,q,u(\cdot))} \Big\{ &\int_0^\theta \ell(x(s),q,u(s))e^{-\lambda s}ds\\ &+ (\mathcal{M}^+((\mathcal{T}^+)^{n-1}V))(x(\theta),q)e^{-\lambda\theta}\Big\}\end{aligned}$$

and

$$\begin{aligned}((\mathcal{T}^-)^nV)(x,q) = \inf_{\mu_{(\cdot)}\in\widehat{\mathcal{U}}, 0\le\theta\le\widehat{T}^F(x,q,\mu_{(\cdot)})} \Big\{ &\int_0^\theta\int_U \ell(\hat{x}(s),q,u)e^{-\lambda s}d\mu_s ds\\ &+ (\mathcal{M}^-((\mathcal{T}^+)^{n-1}V))(\hat{x}(\theta),q)e^{-\lambda\theta}\Big\},\end{aligned}$$

which essentially are optimization problems over nonhybrid controls. So in this sense, computing $\mathbf{V}^-$ and $\mathbf{V}^+$ is easier than computing $\mathbf{V}$.

But it is still desirable to identify some special cases in which the value function itself can be determined completely from the SQVI, i.e., from $\mathbf{V}^-$ and $\mathbf{V}^+$.

6.1. Lower semi-continuous value function. We first discuss the case of a lower semi-continuous value function. We show under some conditions that the value function is the minimum solution.

THEOREM 6.1. *If the value function* $\mathbf{V}$ *satisfies* $\mathcal{M}^-\mathbf{V}_* = (\mathcal{M}\mathbf{V})_*$, *then* $\mathbf{V}_* = \mathbf{V}^-$; *in particular, if furthermore* $\mathbf{V}$ *is lower semi-continuous, then* $\mathbf{V} = \mathbf{V}^-$.

Proof. First, as in the proof of Proposition 5.2, we can show that

$$\mathbf{V}(x,q) = \inf_{u(\cdot)\in\mathcal{U},0\le\theta\le T^F(x,q,u(\cdot))} \left\{ \int_0^\theta \ell(x(s),q,u(s))e^{-\lambda s}ds + (\mathcal{M}\mathbf{V})(x(\theta),q)e^{-\lambda\theta} \right\}.$$

Actually, this can be regarded as another version of DPP for $\mathbf{V}$. Next, for any (x,q)

$$\begin{aligned}(\mathcal{T}^-\mathbf{V}_*)(x,q) &= \inf_{\mu_{(\cdot)}\in\widehat{\mathcal{U}},0\le\theta\le\widehat{T}^F(x,q,\mu_{(\cdot)})} \left\{ \int_0^\theta \int_U \ell(\hat{x}(s),q,u)e^{-\lambda s}d\mu_s ds \right.\\ &\qquad \left. + (\mathcal{M}^-\mathbf{V}_*)(\hat{x}(\theta),q)e^{-\lambda\theta} \right\}\\ &= \inf_{\mu_{(\cdot)}\in\widehat{\mathcal{U}},0\le\theta\le\widehat{T}^F(x,q,\mu_{(\cdot)})} \left\{ \int_0^\theta \int_U \ell(\hat{x}(s),q,u)e^{-\lambda s}d\mu_s ds \right.\\ &\qquad \left. + (\mathcal{M}\mathbf{V})_*(\hat{x}(\theta),q)e^{-\lambda\theta} \right\}.\end{aligned}$$

Also, by Proposition A.4, we know that

$$(\mathcal{T}^-\mathbf{V}_*)(x,q) = \mathbf{V}_*(x,q);$$

hence $\mathbf{V}_*$ is the fixed point of $\mathcal{T}^-$, but we know $\mathbf{V}^-$ is the unique fixed point of $\mathcal{T}^-$, and so we conclude that $\mathbf{V}_* = \mathbf{V}^-$. □

6.2. Continuous value function. If we let $O = F^c$ and the jumping cost ρ be bounded and uniformly continuous, then according to the definition of $\mathbf{V}^-$ and $\mathbf{V}^+$, we know that $\mathbf{V}^+ = \mathbf{V}^- = \mathbf{V}$; i.e., the maximum sub-solution coincides with the minimum super-solution, which implies that $\mathbf{V}$ is continuous and is the unique viscosity solution of SQVI (22) with boundary condition (23). In this case, the operators become $\mathcal{T}^+ = \mathcal{T}^- = \mathcal{T}$, where $\mathcal{T}$ is defined as

$$(\mathcal{T}v)(x,q) = \inf_{u(\cdot)\in\mathcal{U},0\le\theta\le T^F(x,q,u(\cdot))} \left\{ \int_0^\theta \ell(x(s),q,u(s))e^{-\lambda s}ds + (\mathcal{M}v)(x(\theta),q)e^{-\lambda\theta} \right\}.$$

The value function $\mathbf{V}$ is the unique fixed point of $\mathcal{T}$. Then the analysis and the results developed in the previous sections reduce to the case of [9].

Based on the above discussion, we conclude that the following theorem holds.

THEOREM 6.2. *In the special case of* $O = F^c$ *and* $\rho \in C(X\times Q)$, *the value function* $\mathbf{V} \in C(X\times Q)$ *is the unique viscosity solution of SQVI* (22) *with boundary condition* (23).

6.3. Smooth value functions and optimal controller. While in general value functions and viscosity solutions are not smooth, it is helpful to consider the smooth case, since light is shed on the nature of the optimal solution. So let us assume that the value function is smooth and therefore the concept of viscosity solution reduces to the notion of a classical smooth solution. Then consequently the value

function is the unique classic solution of SQVI (22). In this special case, we consider the nature of the optimal controller.

Define the optimal jumping set to be

$$\mathcal{S} = \{(x,q) \in (\mathbf{R}^n \times Q) | \mathbf{V}(x,q) = (\mathcal{M}\mathbf{V})(x,q)\}. \tag{50}$$

It is obvious that $F \subset S$. When the state enters $\mathcal{S}$, the optimal control is to have a discrete transition with an optimal discrete input $w^*(x,q)$ defined by

$$w^*(x,q) = \arg\min\{\rho(x,q,w) + \mathbf{V}(g(x,q,w))\} \quad \forall (x,q) \in S.$$

Outside $\mathcal{S}$, from SQVI (22) it must hold that

$$\lambda \mathbf{V}(x,q) + \mathcal{H}(x,q,\nabla_x \mathbf{V}(x,q)) = 0;$$

from this, we get the optimal continuous controller $u^*(x,q)$ through

$$u^*(x,q) = \arg\max\{-\langle f(x,q,u), \nabla_x \mathbf{V}(x,q)\rangle - \ell(x,q,u)\}.$$

Finally, $(\mathcal{S}, w^*, u^*)$ are the optimal hybrid controllers.

We now give the algorithm to compute the optimal state trajectory initiated at (x,q) under the optimal controllers.

Step 1. **Initialization**, $i = 0$, $j = 0$, $\tau_0^* = 0$, $(x^*((\tau^*)_0^+), q_0^*) = (x,q)$.

Step 2. For $i = 0, 1, 2, \dots$,

if $(x^*((\tau^*)_i^+), q_i^*) \in \mathcal{S}$, then "**JUMP**" and set $\tau_{i+1}^* = \tau_i^*$,

$$(x^*((\tau^*)_{i+1}^+), q_{i+1}^*) = g(x^*((\tau^*)_i^+), q_i^*, w^*(x^*((\tau^*)_i^+), q_i^*)).$$

Otherwise, first do "**CONTINUOUS EVOLUTION**"

$$\begin{cases} x^*(t) = \int_0^t f(x^*(t), q^*(t), u^*(x^*(t), q^*(t)))dt - x^*((\tau^*)_i^+), \\ q^*(t) = q_i^* \end{cases}$$

until $\tau_{i+1} = \tau_i + T^{\mathcal{S}}(x^*((\tau_i^*)^+), q_i^*, u^*(\cdot))$ and set $x^*((\tau^*)_{i+1}^-) = \lim_{t \to \tau_{i+1}^*} x^*(t)$; then "**JUMP**"

$$(x^*((\tau^*)_{i+1}^+), q_{i+1}^*) = g(x^*((\tau^*)_{i+1}^-), q_i^*, w^*(x^*((\tau^*)_{i+1}^-), q_i^*)).$$

7. Optimal stopping problem. In this section, we discuss briefly the optimal stopping control problem for hybrid systems. The aim of this section is to show that the approach developed above can be used to solve the optimal stopping problem. For simplicity, we assume that in the hybrid system (3) $F = \varnothing$.

Let us first define our hybrid stopping problem. Given any initial hybrid state $(x,q) \in X \times Q$, admissible hybrid control $\beta(x,q) \in \mathcal{B}(x,q)$, and a fixed time $\theta \geq 0$, denote the number of discrete transitions that happen before time θ to be

$$N_{(x,q)}^{\beta}(\theta) = \max\{i \geq 1 | \tau_i < \theta\}$$

and the number of discrete transitions that happen at time θ to be

$$M_{(x,q)}^{\beta}(\theta) = |\{i \geq 1 | \tau_i = \theta\}|.$$

$M^{\beta}_{(x,q)}(\theta) = 0$ implies that no jumps happen at time θ and that it is a time of continuous evolution.

To stop an admissible hybrid trajectory, we need to decide the stopping time $\theta \geq 0$ and the number of jumps $0 \leq k(\theta) \leq M^{\beta}_{(x,q)}(\theta)$ at time θ, so we call $(\theta, k(\theta))$ a hybrid stopping time and $(\beta(x,q), \theta, k(\theta))$ an admissible hybrid stopping control with respect to (x,q). Define

$$\theta^{+}_{k(\theta)} = \begin{cases} \theta \mathbf{I}\{M^{\beta}_{(x,q)}(\theta) = 0\} + \tau^{-}_{N^{\beta}_{(x,q)}(\theta)+1} \mathbf{I}\{M^{\beta}_{(x,q)}(\theta) > 0\}, & k(\theta) = 0, \\ \tau^{+}_{N^{\beta}_{(x,q)}(\theta)+k(\theta)}, & 1 \leq k(\theta) \leq M^{\beta}_{(x,q)}(\theta). \end{cases}$$

By the definition, we know that $(x(\theta^{+}_{k(\theta)}), q(\theta^{+}_{k(\theta)}))$ is the state where the trajectory is stopped by $(\theta, k(\theta))$.

We consider the problem of stopping the trajectory in some optimal way. Given any initial state $(x,q) \in (\mathbf{R}^n \times Q)$ and admissible hybrid stopping control $(\beta(x,q), \theta, k(\theta))$, define the total stopping cost,

$$\begin{aligned} \mathbf{J}_{(x,q)}(\beta, \theta, k(\theta)) = & \sum_{i=1}^{N^{\beta}_{(x,q)}(\theta)} \left(\int_{\tau_{i-1}}^{\tau_i} \ell(x(s), q_{i-1}, u(s)) e^{-\lambda s} ds + \rho(x(\tau_i^-), q_{i-1}, w_i) e^{-\lambda \tau_i} \right) \\ & + \int_{\tau_{N^{\beta}_{(x,q)}(\theta)}}^{\theta} \ell(x(s), q_{N^{\beta}_{(x,q)}(\theta)}, u(s)) e^{-\lambda s} ds \\ & + \sum_{j=1}^{k(\theta)} \rho\left(x(\tau^{-}_{(N^{\beta}_{(x,q)}(\theta)+j)}), q_{(N^{\beta}_{(x,q)}(\theta)+j-1)}, w_{(N^{\beta}_{(x,q)}(\theta)+j)} \right) e^{-\lambda \theta} \\ & + \psi\left(x(\theta^{+}_{k(\theta)}), q_{(N^{\beta}_{(x,q)}(\theta)+k(\theta))} \right) e^{-\lambda \theta}, \end{aligned} \tag{51}$$

and the value function,

$$\mathbf{V}(x,q) = \inf_{\beta(x,q) \in \mathcal{B}(x,q), \theta \geq 0, 0 \leq k(\theta) \leq N^{\beta}_{(x,q)}(\theta)} \{\mathbf{J}_{(x,q)}(\beta, \theta, k(\theta))\}, \tag{52}$$

where $\psi : \mathbf{R}^n \times Q \to \mathbf{R}^+$ is the stopping cost subject to the following assumption.

Assumption 7.1. There exists $0 < C^1_{\psi} < C^2_{\psi}$ such that

$$0 < C^1_{\psi} \leq \psi(x,q) \leq C^2_{\psi} \quad \forall (x,q) \in \mathbf{R}^n \times Q \tag{53}$$

and

$$(\psi^*)_* = \psi_*. \tag{54}$$

The *optimal stopping control of the hybrid system* is to find an admissible stopping control $(\beta^*(x,q), \theta^*, k^*(\theta^*))$ for every hybrid state (x,q), such that

$$\mathbf{J}_{(x,q)}(\beta^*, \theta^*, k^*(\theta^*)) \leq \mathbf{J}_{(x,q)}(\beta, \theta, k(\theta))$$

for any $\beta(x,q) \in \mathcal{B}(x,q)$, $\theta \geq 0, 0 \leq k(\theta) \leq M^{\beta}_{(x,q)}(\theta)$.

By a technique similar to that of Theorem 4.3, following the DPP for the value function, we can show that the value function is the discontinuous viscosity solution of the following SQVI:

$$\max\{\mathbf{v}(x,q)-\psi(x,q),\mathbf{v}(x,q)-(\mathcal{M}\mathbf{v})(x,q),\lambda\mathbf{v}(x,q)+\mathcal{H}(x,q,\nabla_x\mathbf{v}(x,q))\}=0, \tag{55}$$

where the operator $\mathcal{M}$ and the Hamiltonian $\mathcal{H}$ are defined the same as in (13) and (24).

Similarly, the proofs of comparison theorems for the sub- and super-solutions of the above SQVI rely on the nonlinear operator $\mathcal{T}^+:\mathcal{V}^+\to\mathcal{V}^+$ defined as

$$(\mathcal{T}^+v)(x,q)=\inf_{u(\cdot)\in\mathcal{U},\theta\geq 0}\left\{\int_0^\theta \ell(x(s),q,u(s))e^{-\lambda s}ds+(\mathcal{L}^+v)(x(\theta),q)e^{-\lambda\theta}\right\}, \tag{56}$$

where $x(t)$ is the solution of

$$\dot{x}(t)=f(x(t),q,u(t))$$

with initial state $x(0)=x$ and where $\mathcal{L}^+:\mathcal{V}^+\to\mathcal{V}^+$ is defined as

$$\mathcal{L}^+v=\min\{\psi^*,\mathcal{M}^+v\}. \tag{57}$$

We can show as in Theorem 5.3 that the function defined below is the unique fixed point of $\mathcal{T}^+$ defined above and the maximum sub-solution and solution of SQVI (55).

For the same hybrid system (3), given any initial state $(x,q)\in(\mathbf{R}^n\times Q)$, define a function

$$\mathbf{V}^+(x,q)=\inf_{\beta(x,q)\in\mathcal{B}(x,q),\theta\geq 0,0\leq k(\theta)\leq N^\beta_{(x,q)}(\theta)}\{\mathbf{J}^+_{(x,q)}(\beta,\theta,k(\theta))\}, \tag{58}$$

where

$$\begin{aligned}\mathbf{J}^+_{(x,q)}(\beta,\theta,k(\theta))=&\sum_{i=1}^{N^\beta_{(x,q)}(\theta)}\left(\int_{\tau_{i-1}}^{\tau_i}\ell(x(s),q_{i-1},u(s))e^{-\lambda s}ds+\kappa^*(x(\tau_i^-),q_{i-1},w_i)e^{-\lambda\tau_i}\right)\\&+\int_{\tau_{N^\beta_{(x,q)}(\theta)}}^{\theta}\ell(x(s),q_{N^\beta_{(x,q)}(\theta)},u(s))e^{-\lambda s}ds\\&+\sum_{j=1}^{k(\theta)}\kappa^*\left(x(\tau^-_{(N^\beta_{(x,q)}(\theta)+j)}),q_{(N^\beta_{(x,q)}(\theta)+j-1)},w_{(N^\beta_{(x,q)}(\theta)+j)}\right)e^{-\lambda\theta}\\&+\psi^*\left(x(\theta^+_{k(\theta)}),q_{(N^\beta_{(x,q)}(\theta)+k(\theta))}\right)e^{-\lambda\theta},\end{aligned} \tag{59}$$

where $(\beta,\theta,k(\theta))$ is any hybrid stopping control.

Proceeding as in Theorem 5.6, the minimum super-solution of SQVI (55) is

$$\mathbf{V}^-(x,q)=\inf_{\hat{\beta}(x,q)\in\widehat{\mathcal{B}}(x,q),\theta\geq 0,0\leq k(\theta)\leq M^{\hat{\beta}}_{(x,q)}(\theta)}\{\mathbf{J}^-_{(x,q)}(\hat{\beta},\theta,k(\theta))\}, \tag{60}$$

where

(61)

$$\begin{aligned}\mathbf{J}^-_{(x,q)}(\hat{\beta},\theta,k(\theta)) = &\sum_{i=1}^{N^{\hat{\beta}}_{(x,q)}(\theta)} \int_{\tau_{i-1}}^{\tau_i}\int_U (\ell(\hat{x}(s),q_{i-1},u)e^{-\lambda s}d\mu_s + \kappa_*(x(\tau_i^-),q_{i-1},w_i)e^{-\lambda\tau_i})\\ &+ \int_{\tau_{N^{\hat{\beta}}_{(x,q)}(\theta)}}^{\theta}\int_U \ell\Big(\hat{x}(s),q_{N^{\hat{\beta}}_{(x,q)}(\theta)},u\Big)e^{-\lambda s}d\mu_s\\ &+ \sum_{j=1}^{k(\theta)}\kappa_*\Big(\hat{x}\Big(\tau^-_{(N^{\hat{\beta}}_{(x,q)}(\theta)+j)}\Big),q_{(N^{\hat{\beta}}_{(x,q)}(\theta)+j-1)},w_{(N^{\hat{\beta}}_{(x,q)}(\theta)+j)}\Big)e^{-\lambda\theta}\\ &+ \psi_*\Big(\hat{x}(\theta^+_{k(\theta)}),q_{(N^{\hat{\beta}}_{(x,q)}(\theta)+k(\theta))}\Big)e^{-\lambda\theta},\end{aligned}$$

which is the unique fixed point of the following nonlinear operator $\mathcal{T}^- : \mathcal{V}^- \to \mathcal{V}^-$:

$$(\mathcal{T}^-v)(x,q) = \inf_{\mu_{(\cdot)}\in\widehat{\mathcal{U}},\theta\ge 0}\left\{\int_0^\theta\int_U \ell(\hat{x}(s),q,u)e^{-\lambda s}d\mu_s ds + (\mathcal{L}^-v)(\hat{x}(\theta),q)e^{-\lambda\theta}\right\}, \tag{62}$$

where $\hat{x}(t)$ is the solution of

$$\dot{\hat{x}}(t) = \int_U f(\hat{x}(t),q,u)d\mu_t$$

with initial state $\hat{x}(0) = x$ and where $\mathcal{L}^- : \mathcal{V}^- \to \mathcal{V}^-$ is defined as

$$\mathcal{L}^-v = \min\{\psi_*, \mathcal{M}^-v\}. \tag{63}$$

Appendix A.

A.1. On the restricted optimal stopping problem. In this appendix, we establish the results concerning the restricted optimal stopping problem (ROSP). Consider a continuous system

$$\dot{x}(t) = f(x(t),u(t)),\ x(0)\in\Omega, \tag{64}$$

where $\Omega \subset \mathbf{R}^n$ is a bounded open set with smooth boundary $\partial\Omega$. The continuous vector fields $f : \overline{\Omega}\times U \to \mathbf{R}^n$ satisfy

$$\begin{cases}|f(x,u)| \le C & \forall x\in\overline{\Omega},\quad \forall u\in U,\\ |f(x,u)-f(y,u)| \le C|x-y| & \forall x,y\in\overline{\Omega},\quad \forall u\in U.\end{cases}$$

Given initial state $x\in\overline{\Omega}$ and control $(u(\cdot),\theta)$, the associated cost functional is defined as

$$\begin{aligned}J(x,u(\cdot),\theta) = &\int_0^{\theta\wedge T(x,u(\cdot))} \ell(x(t),u(t))e^{-\lambda t}dt + \varphi_1(x(\theta))e^{-\lambda\theta}\mathbf{I}\{\theta < T(x,u(\cdot))\}\\ &+ \varphi_2(x(T(x,u(\cdot))))e^{-\lambda T(x,u(\cdot))}\mathbf{I}\{\theta\ge T(x,u(\cdot))\},\end{aligned} \tag{65}$$

where $T(x,u(\cdot)) = \inf\{t\ge 0 | x(t)\in\Omega^c\}$ is the first exit time from Ω, $\ell : \overline{\Omega}\times U\to\mathbf{R}$ is the continuous running cost satisfying

$$\begin{cases}|\ell(x,u)| \le C & \forall x\in\overline{\Omega},\quad \forall u\in U,\\ |\ell(x,u)-\ell(y,u)| \le C|x-y| & \forall x,y\in\overline{\Omega},\quad \forall u\in U,\end{cases}$$

and $\varphi_1 : \Omega \to \mathbf{R}$ and $\varphi_2 : \partial\Omega \to \mathbf{R}$ are the bounded stopping cost and exit cost, respectively, both of which can be discontinuous.

The value function is defined as

$$V(x) = \inf_{u(\cdot)\in\mathcal{U},\theta\geq 0} J(x, u(\cdot), \theta), x \in \overline{\Omega}. \tag{66}$$

From the definition of the cost function (65), we know we can either stop the trajectory with a stopping cost before it exits Ω or exit Ω with an exit cost. The ROSP is to find a way to do it optimally. If we let

$$\psi(x) = \begin{cases} \varphi_1(x), & x \in \Omega, \\ \varphi_2(x), & x \in \partial\Omega, \end{cases}$$

then the value function can be expressed in a more compact form by

$$V(x) = \inf_{u(\cdot)\in\mathcal{U},0\leq\theta\leq T(x,u(\cdot))} \left(\int_0^\theta \ell(x(t), u(t))e^{-\lambda t}dt + \psi(x(\theta))e^{-\lambda\theta} \right). \tag{67}$$

From now on, we take (67) as the definition of the value function.

Since our main purpose is to prove the results needed in the proof of Theorems 5.3 and 5.6, we will not discuss the most general case. Instead, we assume the following transversality condition:

$$f(x, u) \cdot n(x) > \beta > 0 \quad \forall x \in \partial\Omega, \ \forall u \in U, \tag{68}$$

where $n(x)$ is the unit outer normal to Ω at x. Since the ROSP essentially is a combination of the optimal stopping problem (see Barles and Perthame [4]) and optimal exit problem (see Blanc [10]), the transversality condition eliminates the complexities due to the exit problem in the boundary, and hence the results of ROSP are very similar to those of the optimal stopping problem without constraint.

The goal of this section of the appendix is to explore the relation between the value function (67) and the HJB equation

$$\begin{cases} \max\{v(x) - \psi(x), \lambda v(x) + \mathcal{H}(x, \nabla v(x))\} = 0 & \text{in } \Omega, \\ v(x) = \psi(x) & \text{in } \partial\Omega. \end{cases} \tag{69}$$

We especially want to show that it has two extreme solutions under assumption (68) defined by

$$V^+(x) = \inf_{u(\cdot)\in\mathcal{U},0\leq\theta\leq T(x,u(\cdot))} \left(\int_0^\theta \ell(x(t), u(t))e^{-\lambda t}dt + \varphi^*(x(\theta))e^{-\lambda\theta} \right) \tag{70}$$

and minimum super-solution and solution

$$V^-(x) = \inf_{\mu_{(\cdot)}\in\mathcal{U},0\leq\theta\leq T(x,\mu_{(\cdot)})} \left(\int_0^\theta \int_U \ell(\hat{x}(t), u)e^{-\lambda t}d\mu_t dt + \varphi_*(\hat{x}(\theta))e^{-\lambda\theta} \right), \tag{71}$$

where $\hat{x}(\cdot)$ is the relaxed trajectory of $\dot{\hat{x}}(t) = \int_U f(\hat{x}(t), u)d\mu_t$ with relaxed control input $\mu_{(\cdot)}$.

We begin with simple cases.

THEOREM A.1. *Under the transversality condition* (68)*, the value function* (67) *is uniformly continuous in* $\overline{\Omega}$ *if* ψ *is uniformly continuous in* $\overline{\Omega}$*, and it is the unique viscosity solution of HJB equation* (69)*.*

Proof. Introduce $\widetilde{U} = U \cup \{w\}$, dynamics

$$\tilde{f}(x,\tilde{u}) = \begin{cases} f(x,u), & \tilde{u} = u \in U, \\ 0, & \tilde{u} = w, \end{cases}$$

and cost

$$\tilde{\ell}(x,\tilde{u}) = \begin{cases} \ell(x,u), & \tilde{u} = u \in U, \\ \psi(x), & \tilde{u} = w; \end{cases}$$

then ROSP is transformed into an optimal exit problem for new dynamics under new cost, i.e.,

$$V(x) = \inf_{\tilde{u}(\cdot)\in\widetilde{\mathcal{U}}} \left(\int_0^{T(x,\tilde{u}(\cdot))} \tilde{\ell}(\tilde{x}(t),\tilde{u}(t)) e^{-\lambda t} dt + \psi(\tilde{x}(T(x,\tilde{u}(\cdot)))) e^{-\lambda T(x,\tilde{u}(\cdot))} \right).$$

By the known result of the optimal exit problem (see Barles and Perthame [5]), we know that under the tranversality condition, the value function is uniformly continuous (the maximum solution and minimum solution coincide) and is the unique viscosity solution of the HJB equation

$$\begin{cases} \lambda v(x) + \widetilde{\mathcal{H}}(x, \nabla v(x)) = 0 & \text{in } \Omega, \\ v(x) = \psi(x) & \text{in } \partial\Omega, \end{cases}$$

where $\widetilde{\mathcal{H}}(x,p) = \sup_{\tilde{u}\in\widetilde{U}}(-\tilde{f}(x,\tilde{u})\cdot p - \tilde{\ell}(x,\tilde{u}))$. It is easy to check that this equation is equivalent to HJB equation (69). The proof is complete. □

Next, we consider a discontinuous stopping cost. Based on the above theorem, we can proceed as Barles and Perthame [5] to obtain a stability result.

LEMMA A.2. *Let ψ_n be a nonincreasing (resp., nondecreasing) sequence of bounded uniformly continuous functions such that*

$$\inf_n \psi_n = \psi^* \quad \Big(\sup_n \psi_n = \psi_* \Big);$$

then $V^+ = \inf_n V_n$ ($V^- = \sup_n V_n$), where V_n is defined as in (67) *with ψ_n replacing ψ.*

The proof of the lemma is similar to the proof of Theorem II.3 of Barles and Perthame [4] and is omitted here. Then basing our work on Lemma A.2 and following the proof of Theorems II.4 and II.5 in [4], we come to the main theorem.

THEOREM A.3. *Under the transversality conditions* (68), *V^+ (V^-) is the maximum sub-solution and solution (minimum super-solution and solution) of HJB equation* (37).

As for the uniqueness in a weak sense, following the similar proof of Proposition I.4 of [4], we have the following proposition.

PROPOSITION A.4. *Under condition* (68), *we have*

$$V_*^+ = V_* = V^-.$$

A.2. Proof of Lemma 5.1. Item 1. Since for any $(x,q) \in (X \times Q)$,

$$\begin{aligned}(\mathcal{M}^+\mathbf{v}_1)(x,q) &= \min_{w\in W}\{\kappa^*(x,q,w) + \mathbf{v}_1(g(x,q,w))\}\\ &= \kappa^*(x,q,\hat{w}) + \mathbf{v}_1(g(x,q,\hat{w}))\\ &\geq \kappa^*(x,q,\hat{w}) + \mathbf{v}_2(g(x,q,\hat{w}))\\ &\geq \min_{w\in W}\{\kappa^*(x,q,w) + \mathbf{v}_2(g(x,q,w))\}\\ &= (\mathcal{M}^+\mathbf{v}_2)(x,q),\end{aligned}$$

it holds that

$$\begin{aligned}(\mathcal{T}^+\mathbf{v}_1)(x,q) &= \inf_{u(\cdot)\in\mathcal{U},0\leq\theta\leq T^F(x,q,u(\cdot))}\Big\{\int_0^\theta \ell(x(s),q,u(s))e^{-\lambda s}ds\\ &\qquad + (\mathcal{M}^+\mathbf{v}_1)(x(\theta),q)e^{-\lambda\theta}\Big\}\\ &\geq \inf_{u(\cdot)\in\mathcal{U},0\leq\theta\leq T^F(x,q,u(\cdot))}\Big\{\int_0^\theta \ell(x(s),q,u(s))e^{-\lambda s}ds\\ &\qquad + (\mathcal{M}^+\mathbf{v}_2)(x(\theta),q)e^{-\lambda\theta}\Big\}\\ &= (\mathcal{T}^+\mathbf{v}_2)(x,q).\end{aligned}$$

Item 2. Since for any $(x,q) \in (X \times Q)$,

$$\begin{aligned}(\mathcal{M}^+(\alpha\mathbf{v}_1 + (1-\alpha)\mathbf{v}_2))(x,q) &= \min_{w\in W}\{\kappa^*(x,q,w) + (\alpha\mathbf{v}_1 + (1-\alpha)\mathbf{v}_2)(g(x,q,w))\}\\ &= (\alpha + (1-\alpha))\kappa^*(x,q,\hat{w}) + (\alpha\mathbf{v}_1 + (1-\alpha)\mathbf{v}_2)(g(x,q,\hat{w}))\\ &\geq \alpha\Big\{\min_{w\in W}\{\kappa^*(x,q,w) + \mathbf{v}_1(g(x,q,w))\Big\}\\ &\quad + (1-\alpha)\Big\{\min_{w\in W}\{\kappa^*(x,q,w) + \mathbf{v}_2(g(x,q,w))\Big\}\\ &= \alpha(\mathcal{M}^+\mathbf{v}_1)(x,q) + (1-\alpha)(\mathcal{M}^+\mathbf{v}_2)(x,q),\end{aligned}$$

it holds that

$$\begin{aligned}&(\mathcal{T}^+(\alpha\mathbf{v}_1 + (1-\alpha)\mathbf{v}_2))(x,q)\\ &= \inf_{u(\cdot)\in\mathcal{U},0\leq\theta\leq T^F(x,q,u(\cdot))}\Big\{\int_0^\theta \ell(x(s),q,u(s))e^{-\lambda s}ds\\ &\qquad + (\mathcal{M}^+(\alpha\mathbf{v}_1 + (1-\alpha)\mathbf{v}_2))(x(\theta),q)e^{-\lambda\theta}\Big\}\\ &\geq \inf_{u(\cdot)\in\mathcal{U},0\leq\theta\leq T^F(x,q,u(\cdot))}\Big\{\int_0^\theta \ell(x(s),q,u(s))e^{-\lambda s}ds\\ &\qquad + (\alpha\mathcal{M}^+\mathbf{v}_1 + (1-\alpha)\mathcal{M}^+\mathbf{v}_2)(x(\theta),q)e^{-\lambda\theta}\Big\}\\ &\geq \alpha\inf_{u(\cdot)\in\mathcal{U},0\leq\theta\leq T^F(x,q,u(\cdot))}\Big\{\int_0^\theta \ell(x(s),q,u(s))e^{-\lambda s}ds\\ &\qquad + (\mathcal{M}^+\mathbf{v}_1)(x(\theta),q)e^{-\lambda\theta}\Big\}\end{aligned}$$

$$+(1-\alpha)\inf_{u(\cdot)\in\mathcal{U},0\le\theta\le T^F(x,q,u(\cdot))}\left\{\int_0^\theta \ell(x(s),q,u(s))e^{-\lambda s}ds + (\mathcal{M}^+\mathbf{v}_2)(x(\theta),q)e^{-\lambda\theta}\right\}$$
$$=\alpha(\mathcal{T}^+\mathbf{v}_1)(x,q)+(1-\alpha)(\mathcal{T}^+\mathbf{v}_2)(x,q).$$

Item 3. By Item 1, we know that

$$\mathcal{T}^+((1-\gamma)\mathbf{v}_1)\le\mathcal{T}^+\mathbf{v}_2.$$

Then using Item 2 with $\alpha=1-\gamma$, we have

$$\mathcal{T}^+((1-\gamma)\mathbf{v}_1+\gamma 0)\ge(1-\gamma)\mathcal{T}^+\mathbf{v}_1+\gamma\mathcal{T}^+0$$

and then

$$\mathcal{T}^+\mathbf{v}_2\ge(1-\gamma)\mathcal{T}^+\mathbf{v}_1+\gamma\mathcal{T}^+0.$$

Let

$$\bar{\mathbf{v}}_1(x,q)=\inf_{u(\cdot)\in\mathcal{U}}\left\{\int_0^{T^F(x,q,u(\cdot))}\ell(x(s),q,u(s))e^{-\lambda s}ds + (\mathcal{M}^+\mathbf{v}_1)(x(T^F(x,q,u(\cdot))),q)e^{-\lambda T^F(x,q,u(\cdot))}\right\}.$$

This function is obviously bounded, so there exists C_1 such that $\bar{v}_1\le C_1$ and

$$(\mathcal{M}^+0)(x,q)=\min_{w\in W}\{\kappa^*(x,q,w)\}\ge C_\rho.$$

Let $\alpha\le C_T<(\frac{C_\rho}{C_1}\wedge 1)$; then

$$\begin{aligned}(\mathcal{T}^+0)(x,q)&=\inf_{u(\cdot)\in\mathcal{U},0\le\theta\le T^F(x,q,u(\cdot))}\left\{\int_0^\theta\ell(x(s),q,u(s))e^{-\lambda s}ds+(\mathcal{M}^+0)(x(\theta),q)e^{-\lambda\theta}\right\}\\&\ge\inf_{u(\cdot)\in\mathcal{U},0\le\theta\le T^F(x,q,u(\cdot))}\left\{\int_0^\theta\ell(x(s),q,u(s))e^{-\lambda s}ds+C_\rho e^{-\lambda\theta}\right\}\\&\ge\inf_{u(\cdot)\in\mathcal{U},0\le\theta\le T^F(x,q,u(\cdot))}\left\{\int_0^\theta\alpha\ell(x(s),q,u(s))e^{-\lambda s}ds+\alpha\bar{\mathbf{v}}_1(x(\theta),q)e^{-\lambda\theta}\right\}\\&=\alpha\bar{\mathbf{v}}_1(x,q)\end{aligned}$$

and

$$\begin{aligned}(\mathcal{T}^+\mathbf{v}_1)(x,q)&=\inf_{u(\cdot)\in\mathcal{U},0\le\theta\le T^F(x,q,u(\cdot))}\left\{\int_0^\theta\ell(x(s),q,u(s))e^{-\lambda s}ds+(\mathcal{M}^+\mathbf{v}_1)(x(\theta),q)e^{-\lambda\theta}\right\}\\&\le\inf_{u(\cdot)\in\mathcal{U}}\left\{\int_0^{T^F(x,q,u(\cdot))}\ell(x(s),q,u(s))e^{-\lambda s}ds+(\mathcal{M}^+\mathbf{v}_1)(x(T^F(x,q,u(\cdot))),q)e^{-\lambda T^F(x,q,u(\cdot))}\right\}\\&=\bar{\mathbf{v}}_1(x,q).\end{aligned}$$

Hence

$$\mathcal{T}^+ 0 \geq \alpha \mathcal{T}^+ \mathbf{v}_1;$$

then

$$\mathcal{T}^+ \mathbf{v}_2 \geq (1-\gamma)\mathcal{T}^+ \mathbf{v}_1 + \gamma\alpha \mathcal{T}^+ \mathbf{v}_1.$$

We have

$$\mathcal{T}^+ \mathbf{v}_1 - \mathcal{T}^+ \mathbf{v}_2 \leq \gamma(1-\alpha)\mathcal{T}^+ \mathbf{v}_1.$$

Item 4. Since

$$\mathbf{v}_1 - \mathbf{v}_2 \leq \mathbf{v}_1,$$

using Item 3, with $\gamma = 1$, we know there exists $0 < \alpha < 1$ such that

$$\mathcal{T}^+ \mathbf{v}_1 - \mathcal{T}^+ \mathbf{v}_2 \leq (1-\alpha)\mathcal{T}^+ \mathbf{v}_1,$$

and since $\mathbf{v}_1, \mathbf{v}_2$ are fixed points,

$$\mathbf{v}_1 - \mathbf{v}_2 \leq (1-\alpha)\mathbf{v}_1.$$

Using Item 3 again, with $\gamma = 1-\alpha$, we have

$$\mathcal{T}^+ \mathbf{v}_1 - \mathcal{T}^+ \mathbf{v}_2 \leq (1-\alpha)^2 \mathcal{T}^+ \mathbf{v}_1,$$

which means

$$\mathbf{v}_1 - \mathbf{v}_2 \leq (1-\alpha)^2 \mathbf{v}_1.$$

Continuing this procedure, we have

$$\mathbf{v}_1 \leq \mathbf{v}_2.$$

By the same argument we can show that

$$\mathbf{v}_2 \leq \mathbf{v}_1.$$

Then

$$\mathbf{v}_1 = \mathbf{v}_2.$$

THE CONTROL TRANSMUTATION METHOD AND THE COST OF FAST CONTROLS*

LUC MILLER†

Abstract. In this paper, the null-controllability in any positive time T of the first-order equation (1) $\dot{x}(t) = e^{i\theta}Ax(t) + Bu(t)$ ($|\theta| < \pi/2$ fixed) is deduced from the null-controllability in some positive time L of the second-order equation (2) $\ddot{z}(t) = Az(t) + Bv(t)$. The differential equations (1) and (2) are set in a Banach space, B is an admissible unbounded control operator, and A is a generator of cosine operator function. The control transmutation method makes explicit the input function u of (1) in terms of the input function v of (2): $u(t) = \int_{\mathbb{R}} k(t,s)v(s)\,ds$, where the compactly supported kernel k depends only on T and L. This method proves roughly that the norm of a u steering the system (1) from an initial state $x(0) = x_0$ to the final state $x(T) = 0$ grows at most like $\|x_0\| \exp(\alpha_* L^2/T)$ as the control time T tends to zero. (The rate α_* is characterized independently by a one-dimensional controllability problem.) In applications to the cost of fast controls for the heat equation, L is roughly the length of the longest ray of geometric optics which does not intersect the control region.

Key words. controllability, fast controls, control cost, transmutation, cosine operator function, heat equation, linear Ginzburg–Landau equation

1. Introduction.

This paper concerns the relationship between the null-controllability of the following first- and second-order controllable systems:

$$\dot{x}(t) = e^{i\theta}Ax(t) + Bu(t), \qquad t \in \mathbb{R}_+, \quad x(0) = x_0, \tag{1.1}$$

$$\ddot{z}(t) = Az(t) + Bv(t), \qquad t \in \mathbb{R}, \quad z(0) = z_0,\ \dot{z}(0) = 0, \tag{1.2}$$

where x and z are the systems trajectories in the Banach space X, x_0 and z_0 are initial states, u and v are input functions with values in the Banach space U, A is an unbounded generator, B is an unbounded control operator, θ is a given angle in $]-\pi/2, \pi/2[$, each dot denotes a derivative with respect to the time t, and $\mathbb{R}_+ = [0, \infty)$. (The detailed setting is given in section 2.)

Equation (1.1) with $u = 0$ describes an irreversible system (always smoothing), and we think of it as a parabolic distributed system with infinite propagation speed. Equation (1.2) with $v = 0$ describes a reversible system (e.g., conservative), and we think of it as a hyperbolic distributed system with finite propagation speed.

For example, if A is the negative Laplacian on a Euclidean region and the input function is a locally distributed boundary value set by B, then (1.2) is a boundary controlled scalar wave equation, and (1.1) with $\theta = 0$ is a boundary controlled heat equation (section 6 elaborates on this example). Thus, this paper applies to the controllability of the diffusion equation that models the propagation of heat in a medium at rest when the temperature does not vary too much. This diffusion equation is also a

simplified model for various physical phenomena in neutronics, viscous fluids mechanics, and electromagnetism when A is a more general coercive symmetric second-order elliptic operator (cf. section I.B.1.1 in [11]). If $\theta \neq 0$, then (1.1) interpolates between the heat equation and the Schrödinger equation. Thus, this paper applies to the controllability of the linear part of the complex Ginzburg–Landau equation, which describes a vast variety of physical phenomena from nonlinear waves to second-order phase transitions, from superconductivity, superfluidity, and Bose–Einstein condensation to liquid crystals and strings in field theory (cf. [2]). In particular, the one-dimensional linearized Ginzburg–Landau model considered in [1] enters this setting. If $\pi/2 - \theta$ is a small positive constant, then (1.1) is a viscous perturbation of the Schrödinger equation, which appears naturally in the building of stable numerical schemes (cf. [19]). Although conservative physical systems (e.g., the linear system of elasticity, or Maxwell's equations; cf. section I.B.1.2 in [11]) provide examples of (1.2) for which some controllability results are known, we have not yet found one for which the corresponding first-order system (1.1) is relevant to physics or engineering (besides the scalar wave equation considered in section 6).

This paper presents the *control transmutation method* (cf. [18] for a survey on transmutations in other contexts), which can be seen as a shortcut to Russell's famous harmonic analysis method in [26]. It consists of explicitly constructing controls u in any time T for the heat-like equation (1.1) in terms of controls v in time L for the corresponding wave-like equation (1.2), i.e., $u(t) = \int_{\mathbb{R}} k(t,s)v(s)\,ds$, where the compactly supported kernel k depends on T and L.[1] It proves that the exact controllability of (1.2) in some time L implies the null-controllability of (1.1) in any time with a relevant upper bound on the cost of controls for (1.1) as T tends to 0, in short, *the cost of fast controls* (as in the title of this paper and of [30]). Thanks to the geodesic condition of Bardos, Lebeau, and Rauch (cf. [6]) for the controllability of the wave equation, the application of this method to the boundary controllability of the heat equation (cf. section 6) yields new geometric bounds on the cost of fast controls, extending the results of [22] on internal controllability.[2] This method applies as soon as the wave equation is controllable, no matter how singular the coefficients in A are (e.g., discontinuous coefficients in transmission problems in [12], coefficients of bounded variation in [16]) but it does not seem to adapt to time-dependent coefficients. The companion paper [21] concerns the quite different case $|\theta| = \pi/2$ (in particular, there is no smoothing effect) and applies to the Schrödinger equation, which is the control problem to which a transmutation method was first applied by Phung in [25].

The relationship between first- and second-order controllable systems has been investigated in previous papers, always with $\theta = 0$ and the additional initial data $\dot{z}(0) = z_1$ in X (i.e., considering trajectories of (1.2) in the state space $X \times X$). In [13], it was proved that the approximate controllability of (1.2) with $\dot{z}(0) = z_1$ in some time implies the approximate controllability of (1.1) for any time (the control transmutation method yields an alternative proof) and proves the converse under some assumptions on the spectrum of A. The converse is investigated further in [32]

[1] Although L denotes a time here, it also denotes a length in the construction of k and in the main application to the wave and heat equations; the notation is meant as a reminder of this key fact of the method.

[2] The controllability of the heat equation holds even if the geometry prevents the controllability of the wave equation, but in that case no explicit geometric bound on the cost of fast controls is known. For interior controllability, a bound of the form $\exp(C_\beta/T^\beta)$ for any $\beta > 1$ is proved in [24], but the positive constant C_β is not explicit. A better bound of the form $\exp(C_1/T)$ is proved in [15], at least in the Euclidean case (cf. Remark 6.4), but the positive constant C_1 is not explicit either.

(in Hilbert spaces) and [31]. In a restricted setting, the null-controllability of (1.1) was deduced from the exact controllability of (1.2) with $\dot{z}(0) = z_1$ in [26] and [27] by the indirect method of biorthogonal bases[3] (recently used in [16]).

The study of the cost of fast controls was initiated by Seidman in [28] with a result on the heat equation obtained by Russell's method. Seidman also obtained results on the Schrödinger equation by working directly on the corresponding window problem for series of complex exponentials (see [23] for improvements and references). With collaborators, he later treated the case of finite-dimensional linear systems (cf. [30]) and generalized the window problem to a larger class of complex exponentials (cf. [29]). Fernández-Cara and Zuazua obtained results on the cost of fast interior controls for the heat equation discussed in Remark 6.4 (see [15]). Since their approach is based on global Carleman estimates (cf. [17]) it should extend to boundary controllability and to a very large class of equations with variable coefficients possibly depending on time as well. The control transmutation method generalizes upper bounds on the cost of fast controls from the one-dimensional setting (which reduces to a window problem) to the general setting, which we specify in the next section. Some open problems are stated in Remarks 3.3 and 6.4.

2. The setting. We assume that A is the generator of a strongly continuous cosine operator function Cos; i.e., the second-order Cauchy problem for $\ddot{z}(t) = A(t)z$ is well-posed and Cos is its propagator. (For a textbook presentation of cosine operator functions, we refer to Chapter 2 of [14] or section 3.14 of [3].) The associated sine operator function is $\mathrm{Sin}(t) = \int_0^t \mathrm{Cos}(s)ds$ (with the usual Bochner integral). Cos and Sin are strongly continuous functions on $\mathbb{R}$ of bounded operators on X. Moreover, A generates a holomorphic semigroup T of angle $\pi/2$ (cf. Theorem 3.14.17 of [3]). In particular, $S(t) = T(e^{i\theta}t)$ defines a strongly continuous semigroup $(S(t))_{t\in\mathbb{R}_+}$ of bounded operators on X. In this setting, for any source term $f \in L^1_{\mathrm{loc}}(\mathbb{R}, X)$, for any initial data x_0, z_0, and z_1 in X, the inhomogeneous first- and second-order Cauchy problems

$$\dot{x}(t) = e^{i\theta}Ax(t) + f(t), \qquad t \in \mathbb{R}_+, \quad x(0) = z_0, \tag{2.1}$$

$$\ddot{z}(t) = Az(t) + f(t), \qquad t \in \mathbb{R}, \quad z(0) = z_0,\ \dot{z}(0) = z_1, \tag{2.2}$$

have unique mild solutions $x \in C^0(\mathbb{R}_+, X)$ and $z \in C^0(\mathbb{R}, X)$ defined by

$$x(t) = S(t)x_0 + \int_0^t S(t-s)f(s)dt, \quad z(t) = \mathrm{Cos}(t)z_0 + \mathrm{Sin}(t)z_1 + \int_0^t \mathrm{Sin}(t-s)f(s)dt.$$

Remark 2.1. When A is a negative self-adjoint unbounded operator on a Hilbert space T, Cos and Sin are simply defined by the functional calculus as $T(t) = \exp(tA)$, $\mathrm{Cos}(t) = \cos(t\sqrt{-A})$, and $\mathrm{Sin}(t) = (\sqrt{-A})^{-1}\sin(t\sqrt{-A})$.

Following [33], we now make natural assumptions on B for any initial data in the state space X to define a unique continuous trajectory of each system (1.1) and (1.2). Let X_{-1} be the completion of X with respect to the norm $\|x\|_{-1} = \|(A-\beta)^{-1}x\|$ for some $\beta \in \mathbb{C}$ outside the spectrum of A. X_{-1} is also the dual of the space X_1 defined as

[3]The systematic approach to controllability based on biorthogonal bases (cf. [4]) does not apply in our general setting where A may not have eigenfunctions (e.g., on some unbounded domains). When it does apply, it builds on some knowledge about the eigenvalues and the analysis of some exponential series, whereas the control transmutation method per se does not (cf. Remark 3.3). A more detailed comparison can be found in [22], in the specific case which lead the author to this new method.

the domain $D(A)$ with the norm $\|x\|_1 = \|(A-\beta)x\|$. We assume that $B \in \mathcal{L}(U, X_{-1})$ is *an admissible unbounded control operator* in the following sense:

(2.3)
$$\forall t > 0, \forall u \in L^2([0,t];U),\ \int_0^t S(s)Bu(s)ds \in X \quad \text{and} \quad \int_0^t \mathrm{Sin}(s)Bu(s)ds \in X.$$

In this setting, for any x_0 and z_0 in X, for any u and v in $L^2_{\mathrm{loc}}(\mathbb{R}_+;U)$, the unique solutions x and z in $C^0(\mathbb{R};X)$ of (1.1) and (1.2), respectively, are defined by

(2.4)
$$x(t) = S(t)x_0 + \int_0^t S(t-s)Bu(s)dt, \quad z(t) = \mathrm{Cos}(t)z_0 + \int_0^t \mathrm{Sin}(t-s)Bv(s)ds.$$

The natural notions of controllability cost for the linear systems (1.1) and (1.2) are as follows.

DEFINITION 2.2. *The system* (1.1) *is* null-controllable in time T *if for all* x_0 *in* X *there is a* u *in* $L^2(\mathbb{R}_+;U)$ *such that* $u(t) = 0$ *for* $t > T$ *and* $x(T) = 0$. *The* controllability cost *for* (1.1) *in time* T *is the smallest positive constant* $\kappa_{1,T}$ *such that, for all* ϕ_0, *there is such a* u *satisfying* $\int_0^T \|u(t)\|^2 dt \leqslant \kappa_{1,T}\|x_0\|^2$.

The system (1.2) *is* null-controllable in time T *if for all* z_0 *in* X *there is a* v *in* $L^2(\mathbb{R}_+;U)$ *such that* $v(t) = 0$ *for* $t > T$ *and* $z(T) = \dot{z}(T) = 0$. *The* controllability cost *for* (1.2) *in time* T *is the smallest positive constant* $\kappa_{2,T}$ *such that, for all* z_0, *there is such a* v *satisfying* $\int_0^T \|v(t)\|^2 dt \leqslant \kappa_{2,T}\|z_0\|^2$.

Remark 2.3. Equivalently, for all x_T in $S(T)X$, there is a u in $L^2(0,T;U)$ such that $x(0) = 0$ and $x(T) = x_T$, and, for all z_0, z_1, z_2, and z_3 in X, there is a v in $L^2(0,T;U)$ such that $(z(0), \dot{z}(0)) = (z_0, z_1)$ and $(z(T), \dot{z}(T)) = (z_2, z_3)$. This is the usual notion of exact controllability for (1.2) (cf. Lemma 2.4).

Although the notion of null-controllability for (1.2) in Definition 2.2 seems weaker than usual, the following lemma proves that it is equivalent to the usual notion.

LEMMA 2.4. *If* (1.2) *is null-controllable in time* T *in the sense of Definition* 2.2 *then, for all* z_0 *and* z_1 *in* X, *there is an input* v *in* $L^2(\mathbb{R}_+;U)$ *such that* $v(t) = 0$ *for* $t > T$ *and the solution of* $\ddot{z}(t) = Az(t) + Bv(t)$ $(t \in \mathbb{R})$ *with initial condition* $(z(0), \dot{z}(0)) = (z_0, z_1)$ *satisfies the final condition* $(z(T), \dot{z}(T)) = (0,0)$.

Proof. Assume that the system (1.2) satisfies Definition 2.2, and let z_0 and z_1 be in X. We shall build an input w in $L^2(0,T;U)$ such that the solution y of $\ddot{y}(t) = Ay(t) + Bw(t)$ with $(y(0), \dot{y}(0)) = (0, z_1)$ satisfies $(y(T), \dot{y}(T)) = (y_0, 0)$ for some $y_0 \in X$. Let v_1 be the input v in Definition 2.2, and let v_2 be the input v in Definition 2.2, with z_0 replaced by y_0. Due to the linearity of the system, the input $v_1(t) - v_2(T-t) + w(t)$ steers the system from (z_0, z_1) to $(0,0)$, as required to complete the proof of the lemma. The rest of the proof builds w and y.

Applying Definition 2.2 with z_0 replaced by z_1 yields an input v and the solution

$$z(s) = \mathrm{Cos}(s)z_1 + \int_0^s \mathrm{Sin}(r)Bv(s-r)dr, \quad z(T) = \dot{z}(T) = 0.$$

We define w and y by $w(t) = \int_0^t v(s)ds$ and $y(t) = \int_0^t z(s)ds$, for $t \in [0,T]$. The final

condition $\dot{y}(T) = z(T) = 0$ is immediately satisfied. Since $\mathrm{Sin}(t) = \int_0^t \mathrm{Cos}(s)ds$,

$$y(t) - \mathrm{Sin}(t)z_1 = \int_0^t \int_0^s \mathrm{Sin}(r)Bv(s-r)dr\,ds = \int_0^t \int_r^t \mathrm{Sin}(r)Bv(s-r)ds\,dr$$
$$= \int_0^t \mathrm{Sin}(r)B \int_r^t v(s-r)ds\,dr = \int_0^t \mathrm{Sin}(r)Bw(t-r)\,dr.$$

The exchange of integrals in the second step is justified since $(s,r) \mapsto \mathrm{Sin}(r)Bv(s-r)$ is continuous with values in X_{-1}. (Cos and Sin extend by density to strongly continuous functions on $\mathbb{R}$ of bounded operators on X_{-1} since they commute with $A - \beta$.) This integral formula means that y is the mild solution of $\ddot{y}(t) = Ay(t) + Bw(t)$ with initial condition $(y(0), \dot{y}(0)) = (0, z_1)$. □

3. The results and the method. Our estimate of the cost of fast controls for (1.1) builds, through the control transmutation method, on the same estimate for a simple system of type (1.1), i.e., on a segment $[0, L]$ with Dirichlet ($N = 0$) or Neumann ($N = 1$) condition at the left end controlled at the right end through a Dirichlet condition,

$$\partial_t \phi = e^{i\theta}\partial_s^2 \phi \text{ on }]0,T[\times]0,L[\,, \quad \partial_s^N \phi_{\restriction s=0} = 0, \quad \phi_{\restriction s=L} = u, \quad \phi_{\restriction t=0} = \phi_0. \tag{3.1}$$

With the notation of section 2, $x = \phi$, $A = \partial_s^2$ on $X = L^2(0,L)$ with $D(A) = \{f \in H^2(0,L) \mid \partial_s^N f(0) = f(L) = 0\}$, $\|\cdot\|_1$ with $\beta = 0$ is the homogeneous Sobolev $\dot{H}^2(0,L)$ norm, and B on $U = \mathbb{C}$ is the dual of $C \in \mathcal{L}(X_1; U)$ defined by $Cf = \partial_s f(L)$.

It is well known that the controllability of this system reduces by spectral analysis to classical results on nonharmonic Fourier series. The following upper bound for the cost of fast controls, proved in section 4, is an application of a refined result of Seidman, Avdonin, and Ivanov in [29].

THEOREM 3.1. *There are positive constants α and γ such that, for all $N \in \{0,1\}$, $L > 0$, $T \in \left]0, \inf(\pi, L)^2\right]$, the controllability cost $\kappa_{L,T}$ of the system* (3.1) *satisfies* $\kappa_{L,T} \leqslant \gamma \exp(\alpha L^2/T)$.

This theorem leads to the following definition of the optimal fast control cost rate for (3.1).

DEFINITION 3.2. *The rate α_* is the smallest positive constant such that for all $\alpha > \alpha_*$ there exists $\gamma > 0$ satisfying the property stated in Theorem* 3.1.

Remark 3.3. Computing α_* is an interesting open problem, and its solution does not have to rely on the analysis of a series of complex exponentials. The best estimate so far is $\alpha_* \in [1/2, 4(36/37)^2]$ for $\theta = 0$ (cf. [22]).

Our main result is a generalization of Theorem 3.1 to the first-order system (1.1) under some condition on the second-order system (1.2), as follows.

THEOREM 3.4. *If the system* (1.2) *is null-controllable for times greater than L_*, then the system* (1.1) *is null-controllable in any time T. Moreover, the controllability cost $\kappa_{1,T}$ of* (1.1) *satisfies the following upper bound (with α_* defined above):*

$$\limsup_{T \to 0} T \ln \kappa_{1,T} \leqslant \alpha_* L_*^2. \tag{3.2}$$

Remark 3.5. The upper bound (3.2) means that the norm of an input function u steering the system (1.1) from an initial state x_0 to zero grows at most like $\gamma \|x_0\| \exp(\alpha L^2/(2T))$ as the control time T tends to zero (for any α_* and some $\gamma > 0$). The falsity of the converse of the first statement in Theorem 3.4 is well known, e.g., in the more specific setting of section 6.

Remark 3.6. As observed in [9], (3.2) yields a logarithmic modulus of continuity for the minimal time function $T_{\min} : X \to [0, +\infty)$ of (1.1); i.e., $T_{\min}(x_0)$, defined as the infimum of the times $T > 0$ for which there is a u in $L^2(\mathbb{R}; Y)$ such that $\int_0^T \|u(t)\|^2 dt \leqslant 1$, $u(t) = 0$ for $t \notin [0, T]$, and $x(T) = 0$, satisfies the following continuity property: $\alpha > \alpha_*$ there is a $c > 0$ such that, for all x_0 and x_0' in X with $\|x_0 - x_0'\|$ small enough, $|T_{\min}(x_0) - T_{\min}(x_0')| \leqslant \alpha L_*^2 / \ln(c/\|x_0 - x_0'\|)$.

It is well known that the semigroup T can be expressed as an integral over the cosine operator function Cos (cf. the second proof of Theorem 3.14.17 in [3]):

$$\forall x \in X, \forall t \in \mathbb{C} \text{ such that } |\arg t| < \pi/2, \quad T(t)x = \int k(t, s) \operatorname{Cos}(s) x ds, \tag{3.3}$$

where $k(0, s) = \delta(s)$ and $k(t, s) = \exp(-s^2/(4t))/\sqrt{\pi t}$ for $\operatorname{Re} t > 0$. This equation has been referred to as the abstract Poisson or Weierstrass formula. Starting with the observation that k is the fundamental solution of the heat equation on the line, i.e., k is the solution of $\partial_t k = \partial_s^2 k$ with the Dirac measure at the origin as initial condition, the *transmutation control method* consists of replacing the kernel k in (3.3) by some *fundamental controlled solution* on the segment $[-L, L]$, controlled at both ends (cf. (5.8)). The one-dimensional Theorem 3.1 is used to construct this fundamental controlled solution in section 4, and the transmutation is performed in section 5.

4. The fundamental controlled solution. This section begins with an outline of the standard application of [29] to the proof of Theorem 3.1. Following closely section 5 of [22], the rest of the section outlines the construction of a "fundamental controlled solution" k in the following sense, where $\mathcal{D}'(\mathcal{O})$ denotes the space of distributions on the open set $\mathcal{O}$ endowed with the weak topology, $\mathcal{M}(\mathcal{O})$ denotes the subspace of Radon measures on $\mathcal{O}$, and δ denotes the Dirac measure at the origin.

Definition 4.1. *The distribution $k \in C^0([0, T]; \mathcal{M}(]-L, L[))$ is a fundamental controlled solution for* (4.1) *at cost* (γ, α) *if*

$$\partial_t k = e^{-i\theta} \partial_s^2 k \quad \text{in } \mathcal{D}'(]0, T[\times]-L, L[), \tag{4.1}$$

$$k_{\restriction t=0} = \delta \quad \text{and} \quad k_{\restriction t=T} = 0, \tag{4.2}$$

$$\|k\|^2_{L^2(]0,T[\times]-L,L[)} \leqslant \gamma e^{\alpha L^2/T}. \tag{4.3}$$

The operator A defined at the beginning of section 3 is negative self-adjoint on the Hilbert space $L^2(0, L)$. It has a sequence $\{\mu_n\}_{n\in\mathbb{N}^*}$ of negative decreasing eigenvalues and an orthonormal Hilbert basis $\{e_n\}_{n\in\mathbb{N}^*}$ in $L^2(0, L)$ of corresponding eigenfunctions. Explicitly, $\sqrt{-\mu_n} = (n + \nu)\pi/L$ with $\nu = 0$ for $N = 0$ (Dirichlet) and $\nu = 1/2$ for $N = 1$ (Neumann). First note that Theorem 3.1 can be reduced to the case $L = \pi$ by the rescaling $(t, s) \mapsto (\sigma^2 t, \sigma s)$ with $\sigma = L/\pi$. In terms of the coordinates $c = (c_n)_{n\in\mathbb{N}^*}$ of $A^{N/2} f_0$ in the Hilbert basis $(e_n)_{n\in\mathbb{N}^*}$, where f_0 is the initial state of the dual observability problem, Theorem 3.1 with $L = \pi$ reduces by duality to the following window problem: there exist $\alpha > 0$ and $\gamma > 0$ such that, for all $T \in \left]0, \pi^2\right]$,

$$\forall c \in l^2(\mathbb{N}^*), \quad \sum_{n\in\mathbb{N}^*} |c_n|^2 \leqslant \gamma e^{\alpha\pi^2/T} \int_0^T |F(t)|^2 dt, \quad \text{where } F(t) = \sum_{n=1}^{\infty} c_n e^{\exp(i\theta)\mu_n t}.$$

Since this results from Theorem 1 of [29] with $\lambda_n \sim i e^{i\theta} n^2$, as in section 5:2 of [29], the proof of Theorem 3.1 is complete.

Now we consider a system governed by the same equation as (3.1) but on the twofold segment $[-L, L]$ controlled at both ends:

$$\partial_t \phi - e^{-i\theta}\partial_s^2 \phi = 0 \quad \text{in }]0,T[\times]-L,L[, \quad \phi_{\restriction s=\pm L} = u_\pm, \quad \phi_{\restriction t=0} = \phi_0, \tag{4.4}$$

with initial state $\phi_0 \in L^2(0,L)$ and input functions u_- and u_+ in $L^2(0,T)$. As in Proposition 5.1 of [22], applying Theorem 3.1 with $N = 0$ to the odd part of ϕ_0 and with $N = 1$ to the even part of ϕ_0 proves that the controllability cost of (4.4) is not greater than the controllability cost of (3.1) and therefore satisfies the same estimate stated in Theorem 3.1. As in Proposition 5.2 of [22], we may now successively combine the smoothing effect of (4.4) with no input (i.e., $u_+ = u_- = 0$) and this controllability cost estimate (plugged into the integral formula expressing ϕ in terms of ϕ_0 and $u_\pm = \phi_{\restriction s=\pm L}$) to obtain the following result.

PROPOSITION 4.2. *For all $\alpha > \alpha_*$ there exists $\gamma > 0$ such that for all $L > 0$ and $T \in]0, \inf(\pi/2, L)^2]$ there is a fundamental controlled solution for* (4.4) *at cost* (γ, α) *(cf. Definition* 4.1*).*

5. The transmutation of second-order controls into first-order controls. In this section we prove Theorem 3.4.

Let $x_0 \in X$ be an initial state for (1.1), and let $L > L_*$. Let $z \in C^0(\mathbb{R}_+; X)$ and $v \in L^2(\mathbb{R}_+; U)$ be the solution and input function obtained by applying the exact controllability of (1.2) in time L to the initial state $z_0 = x_0$.

We define $\underline{z} \in C^0(\mathbb{R}; X)$ and $\underline{v} \in L^2(\mathbb{R}; U)$ as the extensions of ζ and v by reflection with respect to $s = 0$; i.e., $\underline{z}(s) = \zeta(s) = \underline{z}(-s)$ and $\underline{v}(s) = v(s) = \underline{v}(-s)$ for $s \geqslant 0$. They inherit the following from (2.4):

$$\underline{z}(t) = \mathrm{Cos}(t)x_0 + \int_0^t \mathrm{Sin}(t-s)B\underline{v}(s)ds. \tag{5.1}$$

Definition 2.2 of $\kappa_{2,L}$ implies the following cost estimate for $\underline{v}$:

$$\int \|\underline{v}(s)\|^2 ds = 2\int_0^L \|v(s)\|^2 ds \leqslant 2\kappa_{2,L}\|x_0\|^2. \tag{5.2}$$

Since $D(A)$ is dense in X, there is a sequence $(x_n)_{n\in N^*}$ in $D(A)$ converging to x_0 in X. Since X_1 is dense in X_{-1}, there is a sequence $(f_n)_{n\in\mathbb{N}^*}$ in $C^1(\mathbb{R}; X_1)$ converging to $B\underline{v}$ in $L^2(\mathbb{R}; X_{-1})$. For each $n \in \mathbb{N}^*$, let $\underline{z}_n$ be defined in $C^2(\mathbb{R}; X)$ by

$$\underline{z}_n(t) = \mathrm{Cos}(t)x_n + \int_0^t \mathrm{Sin}(t-s)f_n(s)ds,$$

which converges to $\underline{z}(t)$ in X for all t due to (5.1). Since $\underline{z}_n$ is a genuine solution of $\ddot{\underline{z}}(t) = A\underline{z}_n(t) + f_n(t)$ (cf. Lemma 4.1 of [14]), we have for all φ in $D(A')$

$$s \mapsto \langle \underline{z}_n(s), \varphi\rangle \in H^2(\mathbb{R}) \quad \text{and} \quad \frac{d^2}{ds^2}\langle \underline{z}_n(s), \varphi\rangle = \langle \underline{z}_n(s), A'\varphi\rangle + \langle f_n(s), \varphi\rangle.$$

Hence, $\langle \underline{z}_n(t), \varphi\rangle = \langle x_n, \varphi\rangle + \int_0^t (t-s)\langle \underline{z}_n(s), A'\varphi\rangle + \int_0^t (t-s)\langle f_n(s), \varphi\rangle$. Passing to the limit yields $\langle \underline{z}(t), \varphi\rangle = \langle x_0, \varphi\rangle + \int_0^t (t-s)\langle \underline{z}(s), A'\varphi\rangle + \int_0^t (t-s)\langle B\underline{v}(s), \varphi\rangle$. Therefore

$$s \mapsto \langle \underline{z}(s), \varphi\rangle \in H^2(\mathbb{R}) \quad \text{and} \quad \frac{d^2}{ds^2}\langle \underline{z}(s), \varphi\rangle = \langle \underline{z}(s), A\varphi\rangle + \langle B\underline{v}(s), \varphi\rangle, \tag{5.3}$$

$$\langle \underline{z}(s), \varphi\rangle = 0 \quad \text{and} \quad \frac{d}{ds}\langle \underline{z}(s), \varphi\rangle = 0 \quad \text{for } |s| = L. \tag{5.4}$$

Let $\alpha > \alpha_*$ and $T \in]0, \inf(1, L^2)[$. Let $\gamma > 0$ and $k \in C^0([0,T]; \mathcal{M}(]-L, L[))$ be the corresponding constant and fundamental controlled solution given by Proposition 4.2. We define $\underline{k} \in C^0(\mathbb{R}_+; \mathcal{M}(\mathbb{R}))$ as the extension of k by zero; i.e., $\underline{k}(t,s) = \bar{k}(t,s)$ on $[0,T]\times]-L, L[$ and $\underline{k}$ is zero everywhere else. It inherits from k the following properties:

$$\partial_t \underline{k} = e^{i\theta} \partial_s^2 \underline{k} \quad \text{in } \mathcal{D}'(]0,T[\times]-L,L[), \tag{5.5}$$

$$\underline{k}_{]t=0} = \delta \quad \text{and} \quad \underline{k}_{]t=T} = 0, \tag{5.6}$$

$$\|\underline{k}\|^2_{L^2(\mathbb{R}_+\times\mathbb{R})} \leqslant \gamma e^{\alpha L^2/T}. \tag{5.7}$$

The main idea of the proof is to use $\underline{k}$ as a kernel to transmute $\underline{z}$ and $\underline{v}$ into a solution x and a control u for (1.1). The transmutation formulas

$$x(t) = \int \underline{k}(t,s)\underline{z}(s)\,ds \quad \text{and} \quad \forall t > 0,\ u(t) = \int \underline{k}(t,s)\underline{v}(s)\,ds \tag{5.8}$$

define $x \in C^0(\mathbb{R}_+; X)$ and $u \in L^2(\mathbb{R}_+; U)$ since $\underline{k} \in C^0(\mathbb{R}_+; \mathcal{M}(\mathbb{R})) \cap L^2(\mathbb{R}_+; L^2(\mathbb{R}))$, $\underline{z} \in C^0(\mathbb{R}; X)$, and $\underline{v} \in L^2(\mathbb{R}; U)$. The property (5.6) of $\underline{k}$ implies $x(0) = x_0$ and $x(T) = 0$. Equations (5.3), (5.4), and (5.5) imply, by integrating by parts,

$$\forall \varphi \in D(\mathcal{A}'), \quad t \mapsto \langle x(t), \varphi\rangle \in H^1(\mathbb{R}_+) \quad \text{and} \quad \frac{d}{dt}\langle x(t), \varphi\rangle = \langle x(t), A'\varphi\rangle + \langle Bu(t), \varphi\rangle.$$

This characterizes x as the unique solution of (1.1) in the weak sense (cf. [5]), which implies that x and u satisfy (2.4). Since $\int \|u(t)\|^2 dt \leqslant \iint |\underline{k}(t,s)|^2 ds\, dt \int \|\underline{v}(s)\|^2 ds$, (5.7) and (5.2) imply the following cost estimate, which completes the proof of Theorem 3.4:

$$\int_0^T \|u(t)\|^2 dt \leqslant 2\kappa_{2,L}\gamma e^{\alpha L^2/T}\|x_0\|^2.$$

6. Geometric bounds on the cost of fast boundary controls for the heat equation. When the second-order equation (1.2) has a finite propagation speed and is controllable, the control transmutation method yields geometric upper bounds on the cost of fast controls for the first-order equation (1.1). From this point of view, this method is an adaptation of the kernel estimates method of Cheeger, Gromov, and Taylor in [10]. This was illustrated in [22] and [23] on the internal controllability of heat and Schrödinger equations on Riemannian manifolds, which have the wave equation as corresponding second-order equation. Some similar lower bounds are proved in these papers (without assuming the controllability of the wave equation) which imply that the upper bounds are optimal with respect to time-dependence. In this section, we illustrate the control transmutation method on the analogous boundary control problems for the heat equation.

Let (M, g) be a smooth connected compact n-dimensional Riemannian manifold with metric g and smooth boundary ∂M. When $\partial M \neq \emptyset$, M denotes the interior and $\overline{M} = M \cup \partial M$. Let Δ denote the (negative) Laplacian on (M, g) and ∂_ν denote the exterior Neumann vector field on ∂M. The characteristic function of a set S is denoted by χ_S.

Let $X = L^2(M)$. Let A be defined by $Af = \Delta f$ on $D(A) = H^2(M) \cap H_0^1(M)$. Let C be defined from $D(A)$ to $U = L^2(\partial M)$ by $Cf = \partial_\nu f_{]\Gamma}$, where Γ is an open subset of ∂M, and let B be the dual of C. With this setting, (1.1) with $\theta = 0$ and

(1.2) are the heat and wave equations controlled by the Dirichlet boundary condition on Γ. In particular, (1.2) becomes

$$\begin{aligned} &\partial_t^2 z - \Delta z = 0 \ \text{ on } \ \mathbb{R}_t \times M, \quad z = \chi_\Gamma v \ \text{ on } \ \mathbb{R}_t \times \partial M, \\ &z(0) = z_0 \in L^2(M), \quad \dot z(0) = 0, \quad v \in L^2_{\mathrm{loc}}(\mathbb{R}; L^2(\partial M)), \end{aligned} \tag{6.1}$$

It is well known that B is an admissible observation operator (cf. Corollary 3.9 in [6]). To ensure existence of a null-control for the wave equation we use the geometrical optics condition of Bardos, Lebeau, and Rauch (specifically Example 1 after Corollary 4.10 in [6]):

(6.2) There is a positive constant L_Γ such that every generalized geodesic of length greater than L_Γ passes through Γ at a nondiffractive point.

Generalized geodesics are the rays of geometrical optics (we refer to [20] for a presentation of this condition with a discussion of its significance). We make the additional assumption that they can be uniquely continued at the boundary ∂M. As in [6], to ensure this, we may assume either that ∂M has no contacts of infinite order with its tangents (e.g., $\partial M = \emptyset$), or that g and ∂M are real analytic. For instance, we recall that (6.2) holds when Γ contains a closed hemisphere of a Euclidean ball M of diameter $L_\Gamma/2$, or when $\Gamma = \partial M$ and M is a strictly convex bounded Euclidean set which does not contain any segment of length L_Γ.

THEOREM 6.1 (after [6]). *If* (6.2) *holds, then the wave equation* (6.1) *is null-controllable in any time greater than* L_Γ.

Thanks to this theorem, Theorem 3.4 implies the following claim.

THEOREM 6.2. *If* (6.2) *holds, then the equation*

$$\begin{aligned} &\partial_t y - e^{i\theta}\Delta y = 0 \ \text{ on } \ \mathbb{R}_t \times M, \quad y = \chi_\Gamma u \ \text{ on } \ \mathbb{R}_t \times \partial M, \\ &y(0) = y_0 \in H^{-1}(M), \quad u \in L^2_{loc}(\mathbb{R}; L^2(\partial M)), \end{aligned}$$

is null-controllable in any time T. *Moreover, the controllability cost* $\kappa_{1,T}$ *(cf. Definition* 2.2*) satisfies (with* α_* *as in Definition* 3.2*)* $\limsup_{T\to 0} T \ln \kappa_{1,T} \leqslant \alpha_* L_\Gamma^2$.

Remark 6.3. Note that Theorem 3.2 in [6] almost proves the converse of Theorem 6.1, thus showing that (6.2) is a sharp condition. Moreover [7, 8] prove that the full equivalence does hold when χ_Γ is replaced by a smooth function with the same zero level set $\partial\Omega \setminus \Gamma$. (This slight difference of model should not be perceptible in applications.) Hence the control transmutation method does not allow us to improve L_Γ in Theorem 6.2.

Remark 6.4. For more results and references on the cost of fast controls for the heat equation, we refer to [15, 22]. It is a known fact that the heat equation is null-controllable for any nonempty control region Γ, and hence the converse to the first statement of this theorem is not true. When M is a bounded Euclidean set and Δ has constant coefficients, [15] proves that the lim sup in the second statement is finite for any interior control region, but does not give an explicit bound. Motivated by the nonlinear heat equation, it considers the heat equation with a time-dependent potential and describes how the cost depends on the norm of this potential, whereas the control transmutation method seems to apply only to time-independent potentials (on which the lim sup above does not depend). As explained in section 2.4 of [22], in the general case without condition (6.2), one could try to adapt Carleman inequalities with phases ϕ to obtain a bound in terms of the following distance function d :

$d(x,y) = \sup\{\phi(y) - \phi(x)\}$, for all x and y in M, where the supremum is taken over all Lipschitz functions $\phi : M \to \mathbb{R}$ with $|\nabla\phi| \leqslant 1$ almost everywhere. (d also has a geometric characterization in terms of path of least action.)

ZERO-SUM ERGODIC STOCHASTIC GAMES WITH FELLER TRANSITION PROBABILITIES*

ANNA JAŚKIEWICZ† AND ANDRZEJ S. NOWAK‡

Abstract. We consider zero-sum stochastic games with Borel state spaces satisfying a generalized geometric ergodicity condition. The main objective of this paper is to establish a minimax theorem for a class of ergodic stochastic games with the Feller transition probability function. All previous results on ergodic stochastic games are based on a strong continuity of the transition probabilities in the actions of the players.

Key words. discrete-time zero-sum stochastic games, Borel state space, average optimal strategies, optimality equation

1. Introduction. This paper deals with zero-sum Borel state space stochastic games under the average payoff criterion. We make certain stochastic stability assumptions on the transition structure of the game which imply the so-called V-uniform geometric ergodicity of the Markov chains governed by the stationary strategies of the players. Such conditions are inspired by the works of Kartashov [17] and Meyn and Tweedie [23, 24] and by some recent results concerning Markov control processes; see [9, 10] and the references cited therein. Other related papers on stochastic games are [11, 14, 15, 20, 21, 29, 30, 38]. A common feature of the aforementioned works is the assumption that the transition probabilities are strongly continuous in the actions of the players. Such a restriction is often not satisfied in applications. Weakly continuous transition probabilities are, in some situations (e.g., dynamic programming problems or stochastic games), much more natural; see [8] for a relevant example.

The aim of this paper is to establish a new minimax theorem for a class of ergodic zero-sum stochastic games with the Borel state space and Feller transition (i.e., weakly continuous) probability function. To the best of our knowledge no results of this type are known in the existing literature. Nevertheless, one can refer to [16, 34] for a related result in the context of dynamic programming (one person games). Furthermore, we also study the so-called optimality or Shapley equation for the games under consideration. We show that stationary strategies obtained from this equation are strong average optimal. The proof makes use of the vanishing discount factor approach. In order to overcome some difficulties (compared with earlier papers) we need to use Michael's theorem on continuous selections [25] and a version of Serfozo's extension of Fatou's lemma for varying probability measures.

A general approach to Borel state space stochastic games was developed by Maitra and Sudderth [22]. They have considered a very large class of payoffs (including the average payoff case) and proved the existence of the game value for general universally

measurable strategies. Let us note, however, that optimal strategies need not exist in the games considered in [22]. Their assumption on the transition probability function is different from weak continuity. In fact, it is assumed to be strongly continuous, but only in the actions of one player. Therefore, our theorem on the existence of the game value does not follow from Maitra and Sudderth's work [22]. The ergodicity assumptions which are made in our paper are crucial and may be regarded as quite restrictive. However, they allow us to prove the existence of optimal (or even strong optimal) strategies for a very large class of stochastic games. It is worth mentioning that many optimization models and dynamic games in engineering and economics are ergodic [5, 6, 13, 19, 23]. From a mathematical point of view, it is straightforward to construct weakly continuous ergodic transition laws.

The paper is organized as follows. In section 2 we describe the model and basic assumptions. Section 3 contains some auxiliary material concerning generalized limits of sequences of functions and Fatou's lemma. In section 4 we state our main results with the proofs.

2. The model and assumptions. Before we present our model and state the results, we recall some terminology and describe some auxiliary lemmas on continuous selections.

Let Y be a Borel space, i.e., a nonempty Borel subset of a complete separable metric space. By $\mathcal{B}(Y)$, we denote the σ-algebra of all Borel subsets of Y. Let $P(Y)$ be the space of all probability measures on $\mathcal{B}(Y)$, endowed with the weak topology (see [3] or [32]). This topology, for any Borel space Y, can be characterized in terms of convergent sequences (Proposition 7.21 in [3]). Namely, a sequence $\{p_n\}$ converges to some $p \in P(Y)$ in the weak topology if and only if

$$\int_Y u(y)p_n(dy) \to \int_Y u(y)p(dy)$$

for every $u \in C(Y)$. Here $C(Y)$ denotes the space of all bounded continuous functions on Y, endowed with the supremum metric.

For the reader's convenience, we recall some basic results which we shall be using later on. If Y is compact, then $P(Y)$ is compact as well (see Proposition 7.22 in [3]). If Y is Borel, then $P(Y)$ is Borel too (see Corollary 7.25.1 in [3]).

Let X and Y be Borel spaces. By a Borel measurable transition probability from X to Y we mean a function $\phi : \mathcal{B}(Y) \times X \mapsto [0,1]$ such that, for each $B \in \mathcal{B}(Y)$, $\phi(B|\cdot)$ is a Borel measurable function on X, and $\phi(\cdot|x) \in P(Y)$ for each $x \in X$. It is well known that every Borel measurable mapping $g : X \mapsto P(Y)$ induces a transition probability by setting $\phi(\cdot|x) := g(x)(\cdot)$ (see Proposition 7.25 in [3]). If g is continuous (with respect to the weak topology on $P(Y)$), then the corresponding transition probability is called *weakly continuous* or *Feller*.

Let $M : X \mapsto \mathcal{B}(Y)$ be a set-valued mapping. For any $D \subset Y$, define

$$M^{-1}(D) := \{x \in X : M(x) \cap D \neq \emptyset\}.$$

If $M^{-1}(D)$ is a closed (resp., an open) subset in X for each closed (resp., open) subset D of Y, then M is said to be upper (resp., lower) semicontinuous. A mapping $M : X \mapsto \mathcal{B}(Y)$ is called continuous if it is both lower and upper semicontinuous. For a further discussion of semicontinuous set-valued mappings consult [18, 33].

Let $\Phi : X \mapsto \mathcal{B}(P(Y))$ be the set-valued mapping defined by $\Phi(x) := P(M(x))$, $x \in X$.

LEMMA 2.1 (Theorem 3 in [12]). *If M is nonempty compact valued and continuous, then Φ is also continuous and compact valued.*

The next lemma concerns continuous selections for lower semicontinuous set-valued mappings and is essentially due to Michael [25].

LEMMA 2.2. *Assume that M is nonempty compact valued and continuous. Let $x_0 \in X$ and $\nu_0 \in \Phi(x_0)$. Then Φ admits a continuous selection whose graph contains the point (x_0, ν_0), that is, there exists a continuous mapping $\phi : X \mapsto P(Y)$ such that $\phi(x) \in \Phi(x)$ for each $x \in X$ and $\phi(x_0) = \nu_0$.*

Note that $\Psi(x) := \Phi(x)$ for $x \neq x_0$ and $\Psi(x_0) := \{\nu_0\}$ is lower semicontinuous and compact convex valued. The proof of Lemma 2.2 relies on showing that Ψ has a continuous selection and follows along the same lines as that of Theorem 1.5^* in [33], which in turn is a modification of Michael's proof (see [25] or Theorem 8.1.8 in [18]) given for lower semicontinuous set-valued mappings with closed convex values in a Banach space.

A *zero-sum stochastic game* is described by the following objects:

(i) S is the *set of states* for the game and is assumed to be a Borel space.

(ii) A and B are the *action spaces* for players 1 and 2, respectively, and are also assumed to be Borel spaces.

(iii) $A(s) \subset A$ and $B(s) \subset B$ are nonempty compact *sets of actions available* to players 1 and 2, respectively, in state $s \in S$. It is assumed that the set-valued mappings $s \mapsto A(s)$ and $s \mapsto B(s)$ are continuous. Let

$$K = \{(s, a, b) : s \in S,\ a \in A(s),\ \text{and } b \in B(s)\}$$

and

$$\bar{K} = \{(s, \nu, \rho) : s \in S,\ \nu \in P(A(s)),\ \text{and } \rho \in P(B(s))\}.$$

It is obvious that K is a closed subset of $S \times A \times B$. By Lemma 2.1, $\bar{K}$ is a closed subset of the Borel space $S \times P(A) \times P(B)$.

(iv) q is a Borel measurable transition probability from K to S, called the *law of motion among states*. If s is a state at some stage of the game and the players select actions $a \in A(s)$ and $b \in B(s)$, then $q(\cdot|s, a, b)$ is the probability distribution of the next state of the game.

(v) $r : K \mapsto R$ is a Borel measurable *(daily) reward function* for player 1 (*cost function* for player 2).

A *strategy* for player 1 is a sequence $\pi = \{\pi_n\}$, where π_n $(n \geq 0)$ is a transition probability such that $\pi_n(\cdot|h_n) \in P(A)$ for any given history $h_n = (s_0, a_0, b_0, \dots, s_n)$ of the game and $\pi_n(A(s_n)|h_n) = 1$. (Clearly, $h_0 = s_0$.) A strategy for player 2 is defined in a similar way. By Π $[\Gamma]$ we denote the *class of all strategies for player* 1 (resp., *player* 2). Let F be the set of all Borel measurable transition probabilities f from S to $P(A)$ such that $f(s) \in P(A(s))$ for each $s \in S$. A *Markov strategy* π for player 1 is of the form $\pi = \{f_0, f_1, \dots\}$, where $f_n \in F$, $n \geq 0$. A *stationary strategy* π for player 1 is of the form $\pi = \{f, f, \dots\}$, where $f \in F$. Thus, every stationary strategy $\pi = \{f, f, \dots\}$ for player 1 can be identified with the mapping $f \in F$. Similarly, we define the set G of all stationary strategies for player 2.

Let $H = K \times K \times K \times \cdots$ be the space of all infinite histories of the game endowed with the Borel σ-algebra. For any $\pi \in \Pi$ and $\gamma \in \Gamma$, every initial state $s_0 = s \in S$ a probability measure $P_s^{\pi\gamma}$ and a stochastic process $\{s_m, a_m, b_m\}$ are defined on H in a canonical way, where the random variables s_m, a_m, and b_m describe the state and the action chosen by players 1 and 2, respectively, at the mth stage of the game.

A formal construction of the stochastic process and $P_s^{\pi\gamma}$ is based on the Ionescu–Tulcea theorem (see Proposition V.1.1 in [26], [4], or Chapter 7 in [3]). Thus, for each initial state $s_0 = s \in S$, any strategies $\pi \in \Pi$, $\gamma \in \Gamma$, and any finite horizon n, the total *expected n-stage reward* to player 1 is

$$J_n(s,\pi,\gamma) = E_s^{\pi\gamma}\left[\sum_{m=0}^{n-1} r(s_m, a_m, b_m)\right],$$

where $E_s^{\pi\gamma}$ means the expectation operator with respect to the probability measure $P_s^{\pi\gamma}$ with $s = s_0$. (The assumptions imposed on r and q below guarantee that all expectations considered in what follows are well defined.) If β is a fixed real number in $(0,1)$, called the *discount factor*, then the *expected discounted reward* to player 1 is

$$J_\beta(s,\pi,\gamma) = E_s^{\pi\gamma}\left[\sum_{m=0}^{\infty} \beta^m r(s_m, a_m, b_m)\right].$$

The *expected average reward per unit time* to player 1 is defined as

$$J(s,\pi,\gamma) = \liminf_{n\to\infty} \frac{J_n(s,\pi,\gamma)}{n}.$$

For any initial state $s \in S$, define

$$L(s) := \sup_{\pi\in\Pi} \inf_{\gamma\in\Gamma} J(s,\pi,\gamma) \quad \text{and} \quad U(s) := \inf_{\gamma\in\Gamma} \sup_{\pi\in\Pi} J(s,\pi,\gamma). \tag{1}$$

Then L (U) is called the *lower (upper) value*, respectively, in the average payoff stochastic game. It is always true that $L(s) \le U(s)$ for $s \in S$. If $L(s) = U(s)$ for all $s \in S$, then this common function is called the *value* of the stochastic game and is denoted by ξ.

Suppose that the average reward stochastic game has a value ξ. A strategy $\pi^* \in \Pi$ is called *optimal for player* 1 in the average payoff stochastic game iff

$$\inf_{\gamma\in\Gamma} J(s,\pi^*,\gamma) = \xi(s)$$

for all $s \in S$, and a strategy $\gamma^* \in \Gamma$ is called *optimal for player* 2 in the average payoff stochastic game iff

$$\sup_{\pi\in\Pi} J(s,\pi,\gamma^*) = \xi(s)$$

for all $s \in S$. Of course, the value and optimal strategies are defined similarly for the β-discounted and n-stage stochastic games.

We impose the following continuity assumptions.

C1: $r : K \mapsto R$ is continuous.

C2: $q : K \mapsto P(S)$ is weakly continuous.

C3: There exists a continuous function $V : S \mapsto [1,\infty)$ such that $|r(s,a,b)| \le V(s)$ for every $(s,a,b) \in K$.

C4: The function

$$(s,a,b) \mapsto \int_S V(y) q(dy|s,a,b)$$

is continuous on K.

The following assumption has been recently made in the theory of Markov control processes and stochastic games [9, 10, 16, 38]. Some special cases were considered in [11, 14, 15, 30].

C5: (1) There exist a Borel function $\delta : K \mapsto [0,1]$ and a probability measure φ on S such that

$$q(B|s,a,b) \geq \delta(s,a,b)\varphi(B)$$

for any Borel set $B \subset S$ and $s \in S$.

(2) $\int_S \inf_{a\in A(s)} \inf_{b\in B(s)} \delta(s,a,b)\varphi(ds) > 0$.

(3) $\varphi(V) := \int_S V(s)\varphi(ds) < \infty$.

(4) For some $\lambda \in (0,1)$ and every $(s,a,b) \in K$, it holds that

$$\int_S V(y)q(dy|s,a,b) \leq \lambda V(s) + \delta(s,a,b)\varphi(V).$$

By Proposition 7.50 in [3] the function $s \mapsto \inf_{a\in A(s)} \inf_{b\in B(s)} \delta(s,a,b)$ is universally measurable. Therefore, the integral in C5(2) is well defined.

Let $C_V(S)$ denote the subset of all continuous functions on S for which the so-called V-norm

$$\|u\|_V := \sup_{s\in S} \frac{|u(s)|}{V(s)}$$

is finite. The space of Borel measurable functions u on S for which $\|u\|_V < \infty$ is denoted by $L_V^\infty(S)$. Let μ be a finite signed measure on $\mathcal{B}(S)$. The V-norm of μ is defined by

$$\|\mu\|_V := \sup_{\|u\|_V\leq 1} \left| \int_S u(s)\mu(ds) \right| = \int_S V(s)|\mu|(ds),$$

where $|\mu| = \mu^+ + \mu^-$ denotes the total variation of μ, and μ^+, μ^- stand for the positive and negative parts of μ, respectively. From C5(3)–(4), it follows that the integral $\int_S |u(y)|q(dy|s,a,b)$ is finite for all $(s,a,b) \in K$ and each $u \in L_V^\infty(S)$.

Let $s \in S$, $\nu \in P(A(s))$, and $\rho \in P(B(s))$. We define

$$r(s,\nu,\rho) = \int_{A(s)} \int_{B(s)} r(s,a,b)\rho(db)\nu(da),$$

and for any Borel set $D \subset S$, we put

$$q(D|s,\nu,\rho) = \int_{A(s)} \int_{B(s)} q(D|s,a,b)\rho(db)\nu(da).$$

Thus, for any $f \in F$ and $g \in G$, $r(s,f(s),g(s))$ and $q(D|s,f(s),g(s))$ ($s \in S$, $D \in \mathcal{B}(S)$) have clear meanings.

An important consequence of C5 is that for any $f \in F$ and $g \in G$, the state process $\{s_n\}$ is a positive recurrent aperiodic Markov chain with the unique invariant probability measure (also called stationary distribution) denoted by π_{fg}. In addition, $\{s_n\}$ is V-uniformly ergodic; that is, there exist $\theta > 0$ and $\alpha \in (0,1)$ such that

$$\left| \int_S u(y)q^n(dy|s,f(s),g(s)) - \int_S u(y)\pi_{fg}(dy) \right| \leq V(s)\|u\|_V\theta\alpha^n \tag{2}$$

for every $s \in S$, $n \geq 1$ and each $u \in L_V^\infty(S)$. Here $q^n(\cdot|s, f(s), g(s))$ denotes the n-step transition probability induced by q, $f \in F$, and $g \in G$. Clearly, for integers $n \geq 2$ and $D \in \mathcal{B}(S)$, we have

$$q^n(D|s, f(s), g(s)) := \int_S q^{(n-1)}(D|s', f(s'), g(s'))q(ds'|s, f(s), g(s))$$

and $q^1(D|s', f(s'), g(s')) := q(D|s', f(s'), g(s'))$. It is obvious that (2) means that

$$\|q^n(\cdot|s, f(s), g(s)) - \pi_{fg}(\cdot)\|_V \leq V(s)\theta\alpha^n. \tag{3}$$

For a detailed discussion of C5 and its consequences consult Proposition 10.2.5 in [10], Theorem 3.6 in [17], and Proposition 4.4 in [38]. If V is bounded, (3) implies the convergence of the n-step transition probabilities to the invariant measure in the usual total variation norm. See section 16.1 in [23] and Theorem 2.3 in [24] for a further discussion of this issue. It is worth mentioning that the aperiodicity of the Markov chains involved is connected with assumption C5(1). Clearly, allowing for unbounded functions V enables us to consider a much larger class of chains induced by the stationary strategies of the players. On the other hand, one can also consider unbounded payoff functions. A special case of C5, where $\delta(s, a, b) = 1_C(s)$ and $C \subset S$ is a nonempty Borel set, is extensively studied in [23, 24]. The set C is called a "small set" and C5(4) is called the "drift inequality." In interesting examples C is a relatively compact set in S. If C5 is satisfied with such a special function δ, one can observe a "drift" towards the set C no matter which strategies of the players are used. The expected time for reaching the set C from a state $s \in S$ is bounded by $V(s)$ up to a multiplicative constant (see Theorem 14.2.2 in [23]). This property clearly shows that models with unbounded function V are more interesting for practical applications even in the case where the payoff functions are bounded.

From (2), we conclude that

$$J(f, g) := J(s, f, g) = \int_S r(s, f(s), g(s))\pi_{fg}(ds) \tag{4}$$

for every $f \in F$ and $g \in G$; that is, the expected average payoff is independent of the initial state.

Let $u \in L_V^\infty(S)$. Define

$$u'(s, a, b) = r(s, a, b) + \beta \int_S u(y)q(dy|s, a, b)$$

and

$$\bar{u}(s, \nu, \rho) = \int_{A(s)} \int_{B(s)} u'(s, a, b)\rho(db)\nu(da),$$

where $(s, a, b) \in K$ and $(s, \nu, \rho) \in \bar{K}$. We shall need the following auxiliary result.

LEMMA 2.3. *Let* C1–C4 *hold. If u is lower (resp., upper) semicontinuous, then u' (resp., $\bar{u}$) is lower (resp., upper) semicontinuous on K (resp., $\bar{K}$).*

Proof. This proof is standard (see Lemma 3.3(a) in [9] or Lemmas 5.4 and 5.5 in [28]). □

To simplify our notation, we shall use the following (lower) value operators. For each function $u \in L_V^\infty(S)$ and $\beta \in (0, 1]$, we put

$$(T_\beta u)(s) = \sup_{\nu \in P(A(s))} \inf_{\rho \in P(B(s))} \left[r(s, \nu, \rho) + \beta \int_S u(y)q(dy|s, \nu, \rho) \right], \tag{5}$$

where $s \in S$, and we set $Tu = T_\beta u$ when $\beta = 1$. We close this section with some auxiliary results on minimax selections which are closely related to Theorem 5.1 in [28]. We note that r is continuous on K and q is Feller. Moreover, by Lemma 2.1 the set-valued mappings $s \mapsto P(A(s))$ and $s \mapsto P(B(s))$ are continuous. If u is upper semicontinuous, then by Lemma 2.3 and Berge's theorems (see pp. 115–116 in [2]) $T_\beta u$ is upper semicontinuous, and by a minimax selection theorem [27], there exists some $f \in F$ such that

$$\begin{aligned}(T_\beta u)(s) &= \max_{\nu \in P(A(s))} \inf_{\rho \in P(B(s))} \left[r(s,\nu,\rho) + \beta \int_S u(y) q(dy|s,\nu,\rho) \right] \\ &= \inf_{\rho \in P(B(s))} \left[r(s,f(s),\rho) + \beta \int_S u(y) q(dy|s,f(s),\rho) \right] \qquad (6)\end{aligned}$$

for each $s \in S$. Similarly, if u is lower semicontinuous, then by Lemma 2.3 and Berge's theorems, $T_\beta u$ is lower semicontinuous, and by Fan's minimax theorem [7] and a measurable selection theorem [27], there exists some $g \in G$ such that

$$\begin{aligned}(T_\beta u)(s) &= \min_{\rho \in P(B(s))} \sup_{\nu \in P(A(s))} \left[r(s,\nu,\rho) + \beta \int_S u(y) q(dy|s,\nu,\rho) \right] \\ &= \sup_{\nu \in P(A(s))} \left[r(s,\nu,g(s)) + \beta \int_S u(y) q(dy|s,\nu,g(s)) \right] \qquad (7)\end{aligned}$$

for each $s \in S$.

Let $u \in C_V(S)$. Then, by Fan's minimax theorem [7], (6), and (7), $T_\beta u \in C_V(S)$. Moreover, there exist $f \in F$ and $g \in G$ such that

$$\begin{aligned}(T_\beta u)(s) &= \max_{\nu \in P(A(s))} \min_{\rho \in P(B(s))} \left[r(s,\nu,\rho) + \beta \int_S u(y) q(dy|s,\nu,\rho) \right] \\ &= \min_{\rho \in P(B(s))} \max_{\nu \in P(A(s))} \left[r(s,\nu,\rho) + \beta \int_S u(y) q(dy|s,\nu,\rho) \right] \\ &= r(s,f(s),g(s)) + \beta \int_S u(y) q(dy|s,f(s),g(s)) \\ &= \max_{\nu \in P(A(s))} \left[r(s,\nu,g(s)) + \beta \int_S u(y) q(dy|s,\nu,g(s)) \right] \qquad (8) \\ &= \min_{\rho \in P(B(s))} \left[r(s,f(s),\rho) + \beta \int_S u(y) q(dy|s,f(s),\rho) \right] \qquad (9)\end{aligned}$$

for each $s \in S$.

3. Fatou's lemma for varying probability measures. Let $\{w_n\}$ be a sequence of functions in $L_V^\infty(S)$. As in [35], we consider the following "generalized liminf (limsup)":

$$w_*(s) := \inf \left\{ \liminf_{n\to\infty} w_n(s_n) : s_n \to s \right\} \qquad (10)$$

and

$$w^*(s) := \sup \left\{ \limsup_{n\to\infty} w_n(s_n) : s_n \to s \right\}. \qquad (11)$$

LEMMA 3.1. *The function w_* (resp., w^*) is lower (resp., upper) semicontinuous.*

Proof. Let ρ be the metric on S defining the topology. For any $s \in S$ and $r > 0$, put $B(s,r) := \{y : \rho(s,y) \le r\}$. Note that $w_*(s)$ can be written in the following form:

$$w_*(s) = \sup_n \inf_{k \ge n} \left(\inf_{y \in B(s,1/n)} w_k(y) \right).$$

Fix $s \in S$ and assume that $w_*(s) > d$ for some real number d. To prove that $w_*(s)$ is lower semicontinuous at s, we need to show that there exists $\delta > 0$ such that $w_*(y) > d$ for every $y \in B(s,\delta)$. Since

$$\inf_{k \ge n} \left(\inf_{y \in B(s,1/n)} w_k(y) \right) \uparrow w_*(s),$$

there exists an N such that

$$\inf_{k \ge l} \left(\inf_{y \in B(s,1/l)} w_k(y) \right) > d \quad \forall l > N.$$

Let $m > 2l > l > N$ and $\delta := \frac{1}{2l}$. Then we get

$$\begin{aligned} w_*(y) &= \sup_n \inf_{k \ge n} \left(\inf_{z \in B(y,1/n)} w_k(z) \right) \ge \inf_{k \ge m} \left(\inf_{z \in B(y,1/m)} w_k(z) \right) \\ &\ge \inf_{k \ge m} \left(\inf_{z \in B(s,1/l)} w_k(z) \right) \ge \inf_{k \ge l} \left(\inf_{z \in B(s,1/l)} w_k(z) \right) > d. \end{aligned}$$

The proof of the upper semicontinuity of the function $w^*(s)$ at s is similar to the above one with starting point

$$w^*(s) = \inf_n \sup_{k \ge n} \left(\sup_{y \in B(s,1/n)} w_k(y) \right). \qquad \square$$

LEMMA 3.2. *Let $\{\mu_n\} \subset P(S)$ be converging weakly to some $\mu_0 \in P(S)$. If $\{v_n\}$ is a sequence of nonnegative Borel measurable functions on S and v_* is defined as in* (10), *then*

$$\int_S v_*(s)\mu_0(ds) \le \liminf_{n \to \infty} \int_S v_n(s)\mu_n(ds), \tag{12}$$

and if the functions $\{v_n\}$ are nonpositive, then

$$\int_S v^*(s)\mu_0(ds) \ge \limsup_{n \to \infty} \int_S v_n(s)\mu_n(ds) \tag{13}$$

with v^* defined as in (11).

Proof. Inequality (12) was established by Serfozo [35] for the vague convergence of (possibly unboundeded) measures and under an additional assumption that S is a locally compact space. One can note, however, that when the weak convergence of μ_n to μ_0 in $P(S)$ is considered, then $K = S$ can be assumed at the beginning of the proof of Lemma 3.2 in [35] and the result follows. Obviously, (13) can be easily concluded from (12) by taking into account the sequence $\{-v_n\}$. $\square$

LEMMA 3.3. *Assume that* $\{\mu_n\}$ *converges weakly to some* $\mu_0 \in P(S)$ *and* $\{w_n\}$ *is a sequence of functions in* $C_V(S)$ *such that* $\|w_n\|_V \le b$ *for all* n *and some constant* $b > 0$. *If* V *is a continuous function and* $\int_S V(s)\mu_m(ds) < \infty$ *for every* $m \ge 0$ *and*

$$\int_S V(s)\mu_m(ds) \to \int_S V(s)\mu_0(ds) \tag{14}$$

as $m \to \infty$, *then*

$$\int_S w_*(s)\mu_0(ds) \le \liminf_{n\to\infty} \int_S w_n(s)\mu_n(ds) \tag{15}$$

and

$$\int_S w^*(s)\mu_0(ds) \ge \limsup_{n\to\infty} \int_S w_n(s)\mu_n(ds). \tag{16}$$

Proof. Define $v_n(s) := w_n(s) + bV(s)$ and note that $v_n \ge 0$. For any $s \in S$ and arbitrary sequence $s_n \to s$ as $n \to \infty$, we have

$$\liminf_{n\to\infty} v_n(s_n) = bV(s) + \liminf_{n\to\infty} w_n(s_n).$$

Hence $v_*(s) = bV(s) + w_*(s)$, $s \in S$, and consequently

$$\int_S v_*(s)\mu_0(ds) = b\int_S V(s)\mu_0(ds) + \int_S w_*(s)\mu_0(ds).$$

Applying (12) to the sequence $\{v_n\}$ and (14), we easily get

$$\liminf_{n\to\infty} \int_S w_n(s)\mu_n(ds) + b\int_S V(s)\mu_0(ds) = \liminf_{n\to\infty} \int_S v_n(s)\mu_n(ds)$$

$$\ge \int_S v_*(s)\mu_0(ds) = \int_S w_*(s)\mu_0(ds) + b\int_S V(s)\mu_0(ds)$$

which immediately gives (15).

Similarly, (16) can be concluded from (13) by taking $v_n(s) := w_n(s) - bV(s) \le 0$. □

4. Main results. Now we are ready to present our main results. First of all, we state some theorems for the finite horizon and discounted stochastic games. Similar results are given for stochastic games with Feller transition probabilities in [4] and Theorem 4.1 in [28], but with some differences in other assumptions.

THEOREM 4.1. *Assume* (i)–(v), C1–C4, *and* C5(4). *Then, the finite horizon discounted stochastic game has a value and both players have optimal Markov strategies. Moreover, if* ξ_k *is the value function for the* k*-stage game, then* $\xi_k \in C_V(S)$ *and*

$$\xi_{n+1}(s) = (T_\beta \xi_n)(s) \quad \textit{for each} \quad s \in S,\ n \ge 1.$$

Proof. The proof proceeds by induction and makes use of standard dynamic programming arguments, Lemma 2.3, and measurable selections results described in section 2. Optimal Markov strategies $\pi^* = \{f_0, f_1, \dots\}$ and $\gamma^* = \{g_0, g_1, \dots\}$ are

constructed such that for $k \geq 0$, $(f_k(s), g_k(s))$ is a pair of optimal (mixed) strategies in the zero-sum game with the payoff function

$$r(s,a,b) + \beta \int_S \xi_k(y) q(dy|s,a,b),$$

where $a \in A(s)$, $b \in B(s)$, and $\xi_0(y) := 0$ for all $y \in S$. □

THEOREM 4.2. *Assume* (i)–(v), C1–C4, *and* C5(4). *Then the discounted stochastic game has a value* ξ_β *and both players have optimal stationary strategies* $f_\beta \in F$ *and* $g_\beta \in G$. *Moreover,* $\xi_\beta \in C_V(S)$ *and*

$$\begin{aligned} \xi_\beta(s) &= (T_\beta \xi_\beta)(s) = r(s, f_\beta(s), g_\beta(s)) + \beta \int_S \xi_\beta(y) q(dy|s, f_\beta(s), g_\beta(s)) \\ &= \max_{\nu \in P(A(s))} \left[r(s, \nu, g_\beta(s)) + \beta \int_S \xi_\beta(y) q(dy|s, \nu, g_\beta(s)) \right] \\ &= \min_{\rho \in P(B(s))} \left[r(s, f_\beta(s), \rho) + \beta \int_S \xi_\beta(y) q(dy|s, f_\beta(s), \rho) \right] \end{aligned} \tag{17}$$

for every $s \in S$.

Proof. First, we show that T_β has a fixed point for each $\beta \in (0,1)$. By Theorem 4.1, for each $n \geq 0$, we have

$$\begin{aligned} \xi_n(s) &= \min_{\gamma \in \Gamma} \max_{\pi \in \Pi} E_s^{\pi\gamma} \left(\sum_{m=0}^{n-1} \beta^m r(s_m, a_m, b_m) \right) \\ &= \max_{\pi \in \Pi} \min_{\gamma \in \Gamma} E_s^{\pi\gamma} \left(\sum_{m=0}^{n-1} \beta^m r(s_m, a_m, b_m) \right) \end{aligned}$$

and

$$\xi_n(s) = (T_\beta^n \xi_0)(s)$$

for every $s \in S$, $n \geq 1$. From assumption C5, one can easily prove by induction that

$$E_s^{\pi\gamma}(V(s_n)) \leq \lambda^n V(s) + \varphi(V) \sum_{k=0}^{n-1} \lambda^k \leq V(s) + \frac{\varphi(V)}{1-\lambda}. \tag{18}$$

Assume that $n > k$. Note that

$$\begin{aligned} |\xi_n(s) - \xi_k(s)| &\leq \sup_{\pi \in \Pi} \sup_{\gamma \in \Gamma} \left| E_s^{\pi\gamma} \left(\sum_{m=0}^{n-1} \beta^m r(s_m, a_m, b_m) \right) \right. \\ &\qquad \left. - E_s^{\pi\gamma} \left(\sum_{m=0}^{k-1} \beta^m r(s_m, a_m, b_m) \right) \right| \\ &\leq \sup_{\pi \in \Pi} \sup_{\gamma \in \Gamma} E_s^{\pi\gamma} \left(\sum_{m=k}^{n-1} \beta^m \left| r(s_m, a_m, b_m) \right| \right) \\ &\leq \sup_{\pi \in \Pi} \sup_{\gamma \in \Gamma} E_s^{\pi\gamma} \left(\sum_{m=k}^{n-1} \beta^m V(s_m) \right). \end{aligned}$$

Hence from (18), it follows that

$$|\xi_n(s) - \xi_k(s)| \le \sum_{m=k}^{n-1} \beta^k V(s)d \le \frac{\beta^m}{(1-\beta)} V(s)d$$

for some constant $d > 0$. This implies that $\{\xi_n\}$ is a Cauchy sequence in $C_V(S)$. Put

$$\xi_\beta(s) = \lim_{n\to\infty} \xi_n(s), \quad s \in S.$$

Note that $\xi_\beta \in C_V(S)$ and

$$\|\xi_n - \xi_\beta\|_V = \sup_{s\in S} \frac{|\xi_n(s) - \xi_\beta(s)|}{V(s)} \longrightarrow 0 \quad \text{when} \quad n \to \infty. \tag{19}$$

For $n \ge 2$, it holds that

$$\xi_n(s) = (T_\beta^n \xi_0)(s) = (T_\beta \xi_{n-1})(s).$$

It is also true that $T_\beta \xi_{n-1} \to T_\beta \xi_\beta$ when $n \to \infty$. For this, note that

$$\begin{aligned} |(T_\beta \xi_n)(s) - (T_\beta \xi_\beta)(s)| &\le \max_{a\in A(s)} \max_{b\in B(s)} \int_S \frac{|\xi_n(y) - \xi_\beta(y)|}{V(y)} V(y) q(dy|s,a,b) \\ &\le \|\xi_n - \xi_\beta\|_V \max_{a\in A(s)} \max_{b\in B(s)} \int_S V(y) q(dy|s,a,b). \end{aligned}$$

Now from C5(4) and (19), we conclude that $T_\beta \xi_n \to T_\beta \xi_\beta$ as $n \to \infty$. Hence ξ_β is a fixed point of T_β. The existence of f_β and g_β satisfying (17) follows from a measurable selection theorem (compare with (8) and (9)). □

Remark 4.1. The contraction condition made in [4] is different from our assumptions. Similar assumptions are made in [9], where some minimax control processes are studied. The proof of Theorem 4.2 is quite standard, but from a formal point of view the result is new.

THEOREM 4.3. *Assume* (i)–(v) *and* C1–C5. *Then the average payoff stochastic game has a value* ξ*, which is independent of the initial state, and both players have optimal stationary strategies. Moreover,* $\xi = \lim_{\beta\to 1}(1-\beta)\xi_\beta(s^*)$ *for any state* $s^* \in S$.

Proof. By Theorem 4.2 the value ξ_β of the β-discounted game and stationary strategies $f_\beta \in F$, $g_\beta \in G$ exists for every $\beta \in (0,1)$. Fix a state $s^* \in S$ and consider a sequence $\{\beta_n\}$ of discount factors converging to one. Define

$$w_n(s) = \xi_{\beta_n}(s) - \xi_{\beta_n}(s^*), \quad \xi_n = (1-\beta_n)\xi_{\beta_n}(s^*).$$

Then, from (17), it follows that

$$\begin{aligned} \xi_n + w_n(s) &= \min_{\rho\in P(B(s))} \max_{\nu\in P(A(s))} \left[r(s,\nu,\rho) + \beta_n \int_S w_n(t) q(dt|s,\nu,\rho) \right] \\ &= \max_{\nu\in P(A(s))} \left[r(s,\nu,g_{\beta_n}(s)) + \beta_n \int_S w_n(t) q(dt|s,\nu,g_{\beta_n}(s)) \right] \quad s \in S. \end{aligned} \tag{20}$$

By Lemma 7 in [30] (also see the argument given on page 135 in [10]), the sequence $\{\xi_n\}$ is bounded and there is no loss of generality when assuming that ξ_n converges to some real number ξ^* as $n \to \infty$. Moreover, by Lemma 8 in [30] (also see Lemma 10.4.2

in [10]), it follows that $\|w_n\|_V \le b$ for some constant b. Now, we fix a state $s_0 \in S$ and consider an arbitrary sequence of states $\{s_n\}$ such that $s_n \to s_0$ as $n \to \infty$. Then from (20), putting $g_n := g_{\beta_n}$, we obtain

$$\xi_n + w_n(s_n) = \max_{\nu \in P(A(s_n))} \left[r(s_n, \nu, g_n(s_n)) + \beta_n \int_S w_n(y) q(dy|s_n, \nu, g_n(s_n)) \right]. \tag{21}$$

Let $\{n_k\}$ be a subsequence of positive integers for which

$$\liminf_{n\to\infty} w_n(s_n) = \lim_{k\to\infty} w_{n_k}(s_{n_k}).$$

Obviously, $\lim_{k\to\infty} \xi_{n_k} = \xi^*$ and

$$\xi^* + \liminf_{n\to\infty} w_n(s_n) = \liminf_{n\to\infty} [\xi_n + w_n(s_n)] = \lim_{k\to\infty} [\xi_{n_k} + w_{n_k}(s_{n_k})].$$

Consequently, from (21), we obtain

$$\begin{aligned} &\xi^* + \liminf_{n\to\infty} w_n(s_n) \\ &\quad = \lim_{k\to\infty} \max_{\nu \in P(A(s_{n_k}))} \left[r(s_{n_k}, \nu, g_{n_k}(s_{n_k})) + \beta_{n_k} \int_S w_{n_k}(y) q(dy|s_{n_k}, \nu, g_{n_k}(s_{n_k})) \right]. \end{aligned}$$

Let F_C be the set of all continuous stationary strategies for player 1. By Lemmas 2.1 and 2.2, F_C is nonempty. Choose any $f \in F_C$. Then, we have

$$\begin{aligned} &\xi^* + \liminf_{n\to\infty} w_n(s_n) \\ &\quad \ge \liminf_{k\to\infty} \left[r(s_{n_k}, f(s_{n_k}), g_{n_k}(s_{n_k})) + \beta_{n_k} \int_S w_{n_k}(y) q(dy|s_{n_k}, f(s_{n_k}), g_{n_k}(s_{n_k})) \right]. \end{aligned} \tag{22}$$

Note that $Z := \{s_0\} \cup \{s_n\}$ is compact in S. We know that the set-valued mapping $s \mapsto P(B(s))$ is continuous and compact valued. These facts together with Berge's theorems (see [2] or Theorem 7.4.2 in [18]) imply that $\bigcup_{z\in Z} P(B(z))$ is compact in $P(B)$. Therefore, $\{g_{n_k}(s_{n_k})\}$ has a subsequence converging to some $\rho_0 \in P(B)$. Without loss of generality, let $g_{n_k}(s_{n_k}) \to \rho_0$, as $k \to \infty$. By the continuity of $s \mapsto P(B(s))$, $\rho_0 \in P(B(s_0))$. On the other hand, $f(s_{n_k}) \to f(s_0) \in P(A(s_0))$, because $f \in F_C$. Clearly, $q(\cdot|s_{n_k}, f(s_{n_k}), g_{n_k}(s_{n_k})) \to q(\cdot|s_0, f(s_0), \rho_0)$ weakly as $k \to \infty$. By (22) and Lemma 3.3, we infer that

$$\begin{aligned} &\xi^* + \liminf_{n\to\infty} w_n(s_n) \\ &\quad \ge \liminf_{k\to\infty} r(s_{n_k}, f(s_{n_k}), g_{n_k}(s_{n_k})) + \liminf_{k\to\infty} \int_S w_{n_k}(y) q(dy|s_{n_k}, f(s_{n_k}), g_{n_k}(s_{n_k})) \\ &\quad \ge r(s_0, f(s_0), \rho_0) + \liminf_{k\to\infty} \int_S w_{n_k}(y) q(dy|s_{n_k}, f(s_{n_k}), g_{n_k}(s_{n_k})) \\ &\quad \ge r(s_0, f(s_0), \rho_0) + \int_S \bar{w}_*(y) q(dy|s_0, f(s_0), \rho_0), \end{aligned} \tag{23}$$

where $\bar{w}_*$ is the generalized liminf of the sequence $\bar{w}_k = w_{n_k}$. Let $w_*(s_0)$ be the generalized liminf of $\{w_n\}$ defined in (10). Then $w_* \le \bar{w}_*$, and applying this fact to (23) we get

$$\xi^* + \liminf_{n\to\infty} w_n(s_n) \ge r(s_0, f(s_0), \rho_0) + \int_S w_*(y) q(dy|s_0, f(s_0), \rho_0).$$

Furthermore, by the fact that a continuous selector $f \in F_C$ can be chosen in such a way that an arbitrary value from $P(A(s))$ is assigned to the point s_0 (see Lemma 2.2), we infer that

$$\xi^* + \liminf_{n\to\infty} w_n(s_n) \geq \sup_{f\in F_C} \left[r(s_0, f(s_0), \rho_0) + \int_S w_*(y) q(dy|s_0, f(s_0), \rho_0) \right]$$
$$= \sup_{\nu\in P(A(s_0))} \left[r(s_0, \nu, \rho) + \int_S w_*(y) q(dy|s_0, \nu, \rho) \right].$$

Since w_* is lower semicontinuous (see Lemma 3.1), we can write

$$\xi^* + \liminf_{n\to\infty} w_n(s_n) \geq \min_{\rho\in P(B(s_0))} \sup_{\nu\in P(A(s_0))} \left[r(s_0, \nu, \rho) + \int_S w_*(y) q(dy|s_0, \nu, \rho) \right].$$

By the definition of w_* (see (10)), we have

$$\xi^* + w_*(s_0) \geq \min_{\rho\in P(B(s_0))} \sup_{\nu\in P(A(s_0))} \left[r(s_0, \nu, \rho) + \int_S w_*(y) q(dy|s_0, \nu, \rho) \right]. \tag{24}$$

Since s_0 was chosen arbitrarily, then (24) holds with s_0 replaced by any $s \in S$.

We already know that the function w_* is lower semicontinuous. By (24) and a minimax measurable selection theorem (see (7)), there exists some $g^* \in G$ such that

$$\xi^* + w_*(s) \geq r(s, \nu, g^*(s)) + \int_S w_*(y) q(dy|s, \nu, g^*(s)) \tag{25}$$

for every $s \in S$ and $\nu \in P(A(s))$. Iterating (25), one can show in a standard manner (see [10, 30]) that

$$\xi^* \geq \sup_{\pi\in\Pi} J(s, \pi, g^*) \geq U(s) \tag{26}$$

for each $s \in S$ (U is defined in (1)).

Now, let $f_{\beta_n} = f_n$ be a stationary optimal strategy to player 1 in the β_n-discounted stochastic game. We need to prove that $\xi^* \leq L(s)$. From (20) and Fan's minimax theorem [7] (see also (9)), it can be easily seen that

$$\xi_n + w_n(s_n) = \min_{\rho\in P(B(s_n))} \left[r(s_n, f_n(s_n), \rho) + \beta_n \int_S w_n(y) q(dy|s_n, f_n(s_n), \rho) \right].$$

Assume that $s_n \to s_0$ and consider the generalized limsup $w^*(s_0)$ (see (11)). Proceeding along similar lines, we take again a subsequence $\{n_k\}$ of positive integers such that

$$\limsup_{n\to\infty} w_n(s_n) = \lim_{k\to\infty} w_{n_k}(s_{n_k}).$$

Then using Lemma 3.3 and (6), we obtain some $f^* \in F$ such that

$$\xi^* + w^*(s) \leq r(s, f^*(s), \rho) + \int_S w^*(y) q(dy|s, f^*(s), \rho) \tag{27}$$

for every $s \in S$ and $\rho \in P(B(s))$. Again standard dynamic programming arguments, based on (27), show that

$$\xi^* \leq \inf_{\gamma\in\Gamma} J(s, f^*, \gamma) \leq L(s) \tag{28}$$

for each $s \in S$ (L is defined in (1)). By (26) and (28), we have

$$\xi^* = \sup_{\pi\in\Pi} J(s,\pi,g^*) = \inf_{\gamma\in\Gamma} J(s,f^*,\gamma) = J(s,f^*,g^*) = J(f^*,g^*); \tag{29}$$

that is, the game has a value $\xi(s) = \xi^*$, and f^*, g^* are stationary optimal strategies for players 1 and 2, respectively. □

Remark 4.2. Theorem 4.3 is a *first* result on ergodic stochastic games with Feller transition probabilities satisfying fairly general assumptions. All related papers [14, 15, 20, 21, 29, 30, 38] are based on the strong continuity assumption on q that the mapping $(s,a,b) \mapsto q(D|s,a,b)$ is continuous in (a,b) for every Borel subset D of S. The payoffs and transitions in the mentioned papers need not be continuous with respect to the state variable. The situation studied in this paper is somewhat more delicate. Note that to overcome some technical difficulties we have to use Michael's theorem on continuous selections [25], which plays no part in the proofs given in the aforementioned papers. Feller transition probabilities are, in some applications, more natural than strongly continuous ones.

Remark 4.3. A general class of Borel stochastic games with "limsup payoffs" was studied by Maitra and Sudderth [22]. The average payoffs belong to this class. They proved the existence of the value in history-dependent strategies in a very general setup. The payoff functions in [22] are bounded. What is more important for us is their assumption on q that $b \mapsto q(D|s,a,b)$ is continuous for any Borel set $D \subset S$ and (s,a). Clearly, the weak continuity of the transition law is something different and Theorem 4.3 is not a corollary to their work.

Our last result concerns the optimality equation (sometimes called the Shapley equation [38]) for the average payoff stochastic games. It is well known that under our assumption C5 the Markov chain induced by any stationary strategies of the players is ϕ-irreducible. The ϕ-irreducibility with a probability (or σ-finite) *irreducibility measure* ϕ means that if $\phi(B) > 0$ for some set $B \in \mathcal{B}(S)$, then the chance that a Markov chain (starting at any $s \in S$) ever enters B is positive. By Remark 2.1 on page 15 in [31], one can take $\phi = \varphi$ in our setup, but the family of irreducibility measures is infinite, even for the Markov chain induced by a fixed pair of stationary strategies of the players. In particular, note that any nontrivial restriction of an irreducibility measure is still an irreducibility measure and such a restriction can give zero weight to any selected part of the state space. To avoid such a situation it is desirable to introduce the definition of the *maximal irreducibility measure* for the Markov chain under consideration. It is usually denoted by ψ and dominates all possible irreducibility measures of the chain and has some other natural properties. For a formal definition of ψ consult pages 88–89 in [23]. The maximal irreducibility measure describes the range of the chain more completely than any other irreducibility measure which one could construct initially. By Proposition 10.1.2 in [23], ψ (which may depend on $f \in F$, $g \in G$) and π_{fg} are equivalent. Below we make a stronger irreducibility assumption.

IA: The Markov chains induced by any stationary strategies of the players have a common maximal irreducibility measure denoted by ψ.

Usually it is assumed that ψ is σ-finite, but there is no restriction if we consider ψ to be a probability measure [23]. An important consequence of assumption IA is that all the invariant probability measures π_{fg} ($f \in F$, $g \in G$) are equivalent (see Proposition 10.1.2 in [23]). Clearly, IA is a generalization of the irreducible case for countable state space games, where it is assumed that any two states are communicating under any stationary pair of strategies. The maximal irreducibility measure in such a special case is the geometric distribution or counting measure.

THEOREM 4.4. *Let* (i)–(v), C1–C4, *and* IA *hold. Then there exist a constant* ξ^*, *a function* $h \in L_V^\infty(S)$, *and strategies* $f^* \in F$ *and* $g^* \in G$ *such that*

$$\begin{aligned}(30)\quad \xi^* + h(s) &= r(s, f^*(s), g^*(s)) + \int_S h(y) q(dy|s, f^*(s), g^*(s)) \\ &= \max_{\nu \in P(A(s))} \left[r(s, \nu, g^*(s)) + \int_S h(y) q(dy|s, \nu, g^*(s)) \right] \\ &= \min_{\rho \in P(B(s))} \left[r(s, f^*(s), \rho) + \int_S h(y) q(dy|s, f^*(s), \rho) \right] \quad \psi - a.e.\end{aligned}$$

Proof. By Theorem 4.3, there exists a pair (f^*, g^*) of stationary optimal strategies and the value $\xi(s) = \xi^* = J(f^*, g^*)$. Put $h(s) := w_*(s)$, $s \in S$. By (24) and (25), and Fan's minimax theorem for each $s \in S$, we have

$$\begin{aligned}\xi^* + h(s) &\geq \sup_{\nu \in P(A(s))} \left[r(s, \nu, g^*(s)) + \int_S h(y) q(dy|s, \nu, g^*(s)) \right] \\ &= \min_{\rho \in P(B(s))} \sup_{\nu \in P(A(s))} \left[r(s, \nu, \rho) + \int_S h(y) q(dy|s, \nu, \rho) \right] \\ &= \sup_{\nu \in P(A(s))} \min_{\rho \in P(B(s))} \left[r(s, \nu, \rho) + \int_S h(y) q(dy|s, \nu, \rho) \right] \\ &\geq \min_{\rho \in P(B(s))} \left[r(s, f^*(s), \rho) + \int_S h(y) q(dy|s, f^*(s), \rho) \right].\end{aligned}$$

Applying a measurable selection theorem [27], we conclude that there exists some $g_0 \in G$ such that

$$(31)\qquad \xi^* + h(s) \geq R(s, f^*, g_0) := r(s, f^*(s), g_0(s)) + \int_S h(y) q(dy|s, f^*(s), g_0(s))$$

for each $s \in S$. Define

$$D := \{s \in S : \quad \xi^* + h(s) > R(s, f^*, g_0)\}.$$

Assume that $\psi(D) > 0$. Since $\psi \ll \pi_{f^* g_0}$ (see Proposition 10.1.2 in [23]), we have $\pi_{f^* g_0}(D) > 0$. Integrating both sides of (31) with respect to the invariant probability measure $\pi_{f^* g_0}$ and using (4), we get

$$J(f^*, g^*) = \xi^* > \int_S r(y, f^*(y), g_0(y)) \pi_{f^* g_0}(dy) = J(f^*, g_0).$$

This contradicts the fact that f^* is an optimal strategy for player 1. Therefore $\psi(D) = 0$, and (30) follows with $\xi^* = J(f^*, g^*)$ and $h = w_*$. □

Remark 4.4. The optimality equation has relevance to studying strong average optimality in games [10]. The question as to whether (30) holds for every $s \in S$ remains open. It has an affirmative answer when q is strongly continuous in actions (a, b) of the players, i.e., if we assume that the mapping $(a, b) \mapsto q(D|s, a, b)$ is continuous on $A(s) \times B(s)$ for every $s \in S$ and any Borel set $D \subset S$. Let us make this assumption. A simple modification of Lemma 2.1 in [28] shows that there exists a sequence of Borel measurable mappings $\{\phi_n\}$ from S to $A \times B$ such that $A(s) \times B(s) = \mathrm{cl}\{\phi_n(s)\}$, $s \in S$. Define the transition probability Q from S to S by

$$Q(\cdot|s) := \sum_{n=1}^{\infty} \frac{1}{2^n} q(\cdot|s, \phi_n(s)).$$

It is easy to see that Q corresponds to a stationary (correlated) strategy of the players $\phi(s) := \sum_{n=1}^{\infty} \frac{1}{2^n} \delta_{\phi_n(s)}$, $s \in S$, where $\delta_{\phi_n(s)}$ is the probability measure concentrated at the point $\phi_n(s)$. Assuming IA and C5, and using Proposition 4.2.3 in [23], we infer that there exists a Borel absorbing set $S_1 \subset S \setminus D$ (D is defined in the proof of Theorem 4.4) for Q, that is, $Q(S_1|s) = 1$ for every $s \in S_1$. This implies that $q(S_1|s, \phi_n(s)) = 1$ for each $n \geq 1$ and $s \in S_1$. In other words, S_1 is absorbing for every $q(\cdot|s, \phi_n(s))$, $n \geq 1$. Since $\{\phi_n(s)\}$ is dense in $A(s) \times B(s)$ and q is strongly continuous in actions, we obtain $q(S_1|s, a, b) = 1$ for each $a \in A(s)$, $b \in B(s)$, and $s \in S_1$. Consequently, $q(S_1|s, f(s), g(s)) = 1$ for $s \in S_1$ and $f \in F$, $g \in G$. The existence of such an absorbing set is a crucial factor used in the proofs of Theorem in [15] and Theorem 2 in [14], where a sequence of functions converging to the solution of the Shapley equation (for every $s \in S$) is defined. In other words, the results given in [14, 15] for games with strongly continuous transition probabilities are valid under assumption IA. The same procedure leading to a solution of the Shapley equation for every $s \in S$ can be used in the framework of this paper whenever q is strongly continuous in actions.

Remark 4.5. In a recent paper [38], Vega-Amaya proposes an approach based on a contraction mapping, but the value ξ^* must be known in advance. His proof applies to a strongly continuous transition probability q and can be modified to cover the weakly continuous case as well if we additionally assume that the function δ in C5 is *continuous* on K. This assumption excludes a very important case, in which $\delta(s, a, b) = 1_C(s)$, $(s, a, b) \in K$, and C is a Borel (or even a closed or an open) set. If δ is not a continuous function, then the mapping, given by Vega-Amaya, maps continuous functions into Borel (or even universally measurable) ones. Therefore the Banach fixed point theorem cannot be applied.

Remark 4.6. The Markov chains induced by stationary strategies of the players are, under our assumptions, aperiodic. As noted by Tijms [37], the results obtained for aperiodic models can also be applied to periodic ones by a suitable transformation. The unichain assumption which we make in this paper is difficult to relax in general state space models, especially when we wish to have optimal strategies for both players. When the state space is countable some weakening of the assumptions is possible; see [1] and its references.

Acknowledgments. The authors wish to thank four anonymous referees for useful comments.

FEEDBACK BOUNDARY STABILIZATION OF THE TWO-DIMENSIONAL NAVIER–STOKES EQUATIONS*

JEAN-PIERRE RAYMOND†

Abstract. We study the exponential stabilization of the linearized Navier–Stokes equations around an unstable stationary solution, by means of a feedback boundary control, in dimension 2 or 3. The feedback law is determined by solving a linear-quadratic control problem. We do not assume that the normal component of the control is equal to zero. In the nonzero case the state equation, satisfied by the velocity field $\mathbf{y}$, is decoupled into an evolution equation, satisfied by $P\mathbf{y}$, where P is the so-called Helmholtz projection operator, and a quasi-stationary elliptic equation, satisfied by $(I-P)\mathbf{y}$. Using this decomposition, we show that the feedback law can be expressed as a function only of $P\mathbf{y}$. In the two-dimensional case we show that the linear feedback law provides a local exponential stabilization of the Navier–Stokes equations.

Key words. Dirichlet control, feedback control, stabilization, Navier–Stokes equations, Oseen equations, Riccati equation

1. Setting of the problem.

Let Ω be a bounded and connected domain in $\mathbb{R}^2$ or $\mathbb{R}^3$ with a regular boundary Γ, $\nu > 0$, and consider a pair $(\mathbf{w}, \chi)$—a velocity field and a pressure—solution to the stationary Navier–Stokes equations in Ω:

$$-\nu\Delta\mathbf{w} + (\mathbf{w}\cdot\nabla)\mathbf{w} + \nabla\chi = \mathbf{f} \quad \text{and} \quad \operatorname{div}\mathbf{w} = 0 \quad \text{in } \Omega, \qquad \mathbf{w} = \mathbf{u}_s^\infty \quad \text{on } \Gamma. \tag{1.1}$$

We assume that $\mathbf{w}$ is regular and is an unstable solution of the instationary Navier–Stokes equations.

The purpose of this paper is to determine a Dirichlet boundary control $\mathbf{u}$, in feedback form, localized in a part of the boundary Γ, so that the corresponding controlled system

$$\begin{aligned} &\frac{\partial\mathbf{y}}{\partial t} - \nu\Delta\mathbf{y} + (\mathbf{y}\cdot\nabla)\mathbf{w} + (\mathbf{w}\cdot\nabla)\mathbf{y} + (\mathbf{y}\cdot\nabla)\mathbf{y} + \nabla p = 0, \quad \operatorname{div}\mathbf{y} = 0 \quad \text{in } Q_\infty, \\ &\mathbf{y} = M\mathbf{u} \quad \text{on } \Sigma_\infty, \quad \mathbf{y}(0) = \mathbf{y}_0 \quad \text{in } \Omega, \end{aligned} \tag{1.2}$$

is stable for initial values $\mathbf{y}_0$ small enough in an appropriate space $\mathbf{X}(\Omega)$. In this setting, $Q_\infty = \Omega\times(0,\infty)$, $\Sigma_\infty = \Gamma\times(0,\infty)$, $\mathbf{X}(\Omega)$ is a subspace of $\mathbf{V}_n^0(\Omega) = \{\mathbf{y}\in \mathbf{L}^2(\Omega) \mid \operatorname{div}\mathbf{y} = 0 \text{ in } \Omega,\ \mathbf{y}\cdot\mathbf{n} = 0 \text{ on } \Gamma\}$, and the operator M is a restriction operator precisely defined in section 2. If we set $(\mathbf{z}, q) = (\mathbf{w}+\mathbf{y}, \chi+p)$ and if $\mathbf{u} = 0$, we see that $(\mathbf{z}, q)$ is the solution to the Navier–Stokes equations

$$\begin{aligned} &\frac{\partial\mathbf{z}}{\partial t} - \nu\Delta\mathbf{z} + (\mathbf{z}\cdot\nabla)\mathbf{z} + \nabla q = \mathbf{f}, \quad \operatorname{div}\mathbf{z} = 0 \quad \text{in } Q_\infty, \\ &\mathbf{z} = \mathbf{u}_s^\infty \ \text{ on } \Sigma_\infty, \quad \mathbf{z}(0) = \mathbf{w}+\mathbf{y}_0 \quad \text{in } \Omega. \end{aligned}$$

Thus $\mathbf{y}_0$ is a perturbation of the stationary solution $\mathbf{w}$.

To study the local feedback stabilization of system (1.2), we first study the feedback stabilization of the corresponding linearized system

$$\begin{aligned} &\frac{\partial \mathbf{y}}{\partial t} - \nu\Delta\mathbf{y} + (\mathbf{w}\cdot\nabla)\mathbf{y} + (\mathbf{y}\cdot\nabla)\mathbf{w} + \nabla p = 0 \quad \text{in } Q_\infty, \\ &\text{div } \mathbf{y} = 0 \quad \text{in } Q_\infty, \quad \mathbf{y} = M\mathbf{u} \quad \text{on } \Sigma_\infty, \quad \mathbf{y}(0) = \mathbf{y}_0 \quad \text{in } \Omega. \end{aligned} \tag{1.3}$$

To stabilize this system we can look for a control $\mathbf{u}$ belonging either to $L^2(0,\infty;\mathbf{V}^0(\Gamma))$ or to $L^2(0,\infty;\mathbf{V}_n^0(\Gamma))$, where

$$\begin{aligned} \mathbf{V}^0(\Gamma) &= \Big\{\mathbf{y}\in\mathbf{L}^2(\Gamma) \mid \langle \mathbf{y}\cdot\mathbf{n}, 1\rangle_{H^{-1/2}(\Gamma),H^{1/2}(\Gamma)} = 0\Big\} \quad \text{and} \\ \mathbf{V}_n^0(\Gamma) &= \Big\{\mathbf{y}\in\mathbf{L}^2(\Gamma) \mid \mathbf{y}\cdot\mathbf{n} = 0 \text{ on } \Gamma\Big\}. \end{aligned}$$

A linear feedback law stabilizing (1.3) in $\mathbf{X}(\Omega) \subset \mathbf{V}_n^0(\Omega)$, with a control $\mathbf{u} \in L^2(0,\infty;\mathbf{V}^0(\Gamma))$, is determined by a bounded operator $K \in \mathcal{L}(\mathbf{X}(\Omega),\mathbf{V}^0(\Gamma))$ such that the solution of the closed loop system

$$\begin{aligned} &\frac{\partial \mathbf{y}}{\partial t} - \nu\Delta\mathbf{y} + (\mathbf{w}\cdot\nabla)\mathbf{y} + (\mathbf{y}\cdot\nabla)\mathbf{w} + \nabla p = 0 \quad \text{in } \Omega\times(0,T), \\ &\text{div } \mathbf{y} = 0 \quad \text{in } \Omega\times(0,T), \quad \mathbf{y} = MK\mathbf{y} \quad \text{on } \Gamma\times(0,T), \quad \mathbf{y}(0) = \mathbf{y}_0 \quad \text{in } \Omega, \end{aligned}$$

obeys

$$|\mathbf{y}(t)|_{\mathbf{X}(\Omega)} \le C|\mathbf{y}_0|_{\mathbf{X}(\Omega)} \quad \text{for all } t\in(0,\infty). \tag{1.4}$$

The feedback control law is given by

$$\mathbf{u}(t) = K\mathbf{y}(t) \quad \text{for all } t\in(0,\infty). \tag{1.5}$$

In place of (1.4) we can look for an exponential decay

$$|\mathbf{y}(t)|_{\mathbf{X}(\Omega)} \le Ce^{-\sigma t}|\mathbf{y}_0|_{\mathbf{X}(\Omega)} \quad \text{for all } t\in(0,\infty), \quad \text{with } \sigma>0. \tag{1.6}$$

Let us underline that a feedback law of the form (1.5) is a pointwise (in time) feedback law. A feedback law may be of a different form, for example of the form

$$\mathbf{u} = L_0\mathbf{y}_0, \qquad L_0 \in \mathcal{L}(\mathbf{X}(\Omega), L^2(0,\infty;\mathbf{V}^0(\Gamma))).$$

In engineering applications, pointwise feedback laws are needed because they are more robust with respect to perturbations in the models. This paper is focused on the characterization of pointwise feedback laws for the Oseen and the Navier–Stokes equations.

Several important questions must be addressed when we look for a pointwise feedback law able to stabilize system (1.3) or (1.2):

(Q_1) Does there exist a control $\mathbf{u}\in L^2(0,\infty;\mathbf{V}^0(\Gamma))$ such that the solution of (1.3) obeys (1.6) or (1.4)? In other words, is the system (1.3) stabilizable?

(Q_2) Assume that K is a pointwise feedback law able to stabilize system (1.3) in $\mathbf{X}(\Omega)$. Does K also stabilize the nonlinear system (1.2) for $|\mathbf{y}_0|_{\mathbf{X}(\Omega)}$ small enough?

(Q_3) Assume that we have proved the existence of a feedback law stabilizing system (1.3). Can we find an equation characterizing K which can be numerically solved by classical methods?

We stop the list here, but lot of other questions are very important in applications, such as the robustness of feedback laws and the numerical accuracy of approximations.

In this paper, we do not address the stabilizability of system (1.3), and we shall use the existing results in the literature. This paper is mainly devoted to (Q_2) and (Q_3). But first we mention some results addressing (Q_1).

When $\mathbf{w} \in \mathbf{L}^\infty(\Omega)$ and $\mathbf{X}(\Omega) = \mathbf{V}_n^0(\Omega) \cap \mathbf{L}^4(\Omega)$, the existence of a boundary control $\mathbf{u} \in L^2(0,\infty;\mathbf{V}^0(\Gamma))$ such that the solution of system (1.3) obeys (1.6) may be deduced, by using an extension method, from exact controllability results with internal controls stated in [8].

In the three-dimensional case, and when $\mathbf{X}(\Omega) = \{\mathbf{y} \in \mathbf{H}^1(\Omega) \mid \text{ div } \mathbf{y} = 0 \text{ in } \Omega\}$, the existence of a feedback control law exponentially stabilizing (1.2) or (1.3) is proved in [12]. However, the feedback operator constructed in [12] is of the form L_0. (It is not a pointwise feedback operator, and it requires the knowledge of the eigenfunctions and the eigenvalues of the Oseen operator of (1.3).)

In the three-dimensional cases, when Ω is simply connected, Barbu, Lasiecka, and Triggiani [4] have proved the stabilizability of system (1.3) in $\mathbf{X}(\Omega) = \{\mathbf{y} \in \mathbf{H}^{1/2+\varepsilon}(\Omega) \mid \text{div } \mathbf{y} = 0 \text{ in } \Omega,\ \mathbf{y}\cdot\mathbf{n} = 0 \text{ on } \Gamma\}$ with controls $\mathbf{u} \in L^2(0,\infty;\mathbf{V}_n^0(\Gamma))$ acting everywhere on the boundary Γ. Some additional results in the two-dimensional case are also stated in [4] (see also section 7.1).

Let us now focus on (Q_2) and (Q_3). One way to address these questions is to use optimal control theory, where the pointwise feedback law is obtained by solving an infinite time horizon control problem of the form

$$(\mathcal{Q}) \qquad \inf\Big\{ J(\mathbf{y},\mathbf{u}) \ \mid \ (\mathbf{y},\mathbf{u}) \text{ satisfies (1.3)},\ \mathbf{u} \in L^2(0,T;\mathbf{U}) \Big\}.$$

More precisely, one has to prove that the value function of problem ($\mathcal{Q}$) obeys

$$\inf(\mathcal{Q}) = \Big(\Pi \mathbf{y}_0, \mathbf{y}_0\Big)_{\mathbf{V}_n^0(\Omega)},$$

where $\Pi \in \mathcal{L}(\mathbf{V}_n^0(\Omega))$, $\Pi = \Pi^* \geq 0$. Next the feedback law is defined thanks to the operator Π. In this framework, question (Q_3) can be reformulated as follows: Does the operator Π satisfy an algebraic Riccati equation in the domain of the Oseen operator?

The answer depends on the choice of J and $\mathbf{U}$ and is not necessarily obvious in the case of a boundary control problem.

According to the stabilizability results mentioned above, we have two possible choices for $\mathbf{U}$:

$$\mathbf{U} = \mathbf{V}_n^0(\Gamma) \quad \text{or} \quad \mathbf{U} = \mathbf{V}^0(\Gamma).$$

Both choices are interesting for applications [9, 10, 11, 13]. Even if $\mathbf{U} = \mathbf{V}^0(\Gamma)$ leads to a slightly complicated analysis, this case is interesting, since the normal velocity is used as a control in many applications [14, 15, 16, 20, 25]. These papers are devoted to the suppression of vortex shedding past a cylinder. That corresponds to the case where $\Omega = \Omega_e \setminus \overline{\Omega_i}$, Ω_i is a bounded domain in $\mathbb{R}^2$ with a regular boundary Γ_i, and Ω_e is another bounded domain in $\mathbb{R}^2$ with a regular boundary Γ_e such that $\overline{\Omega_i} \subset \Omega_e$ (Ω_i is a disk in the case of a circular cylinder). Given a stationary velocity $\mathbf{u}_s^\infty$, we can take $(\mathbf{w},\chi)$ as the solution to the stationary Navier–Stokes equation (1.1) with $\mathbf{f} = 0$. In that case the control has to be localized in a part of the boundary Γ_i, and Γ_e must be far enough from the cylinder so that the solution to the stationary or instationary

Navier–Stokes equations gives a good approximation of the corresponding equation in the exterior domain $\mathbb{R}^2 \setminus \overline{\Omega_i}$. Some heuristic feedback laws have been successfully tested in numerical experiments [25, 20], but in general these feedback laws, which are designed for a very specific value of $\mathbf{u}_s^\infty$, are not robust with respect to perturbations of $\mathbf{u}_s^\infty$, in contrast to feedback laws obtained by solving Riccati equations.

This paper is written in the case when $\mathbf{U} = \mathbf{V}^0(\Gamma)$, and the adaptation to the case when $\mathbf{U} = \mathbf{V}_n^0(\Gamma)$ is given in section 7.1. We would like to underline that the choice of J is critical. Indeed once $\mathbf{X}(\Omega)$, $\mathbf{U}$, and J are chosen, K is generally uniquely determined. Thus we have to choose J so that the corresponding feedback law also stabilizes system (1.2). The functional J is usually of the form

$$J(\mathbf{y}, \mathbf{u}) = \frac{1}{2} \int_0^\infty |C\mathbf{y}(t)|^2_{\mathbf{V}^0(\Omega)}\, dt + \frac{1}{2} \int_0^\infty |\mathbf{u}(t)|^2_{\mathbf{U}}\, dt,$$

where the observation operator C may be a bounded or an unbounded operator in $\mathbf{V}^0(\Omega) = \{\mathbf{y} \in \mathbf{L}^2(\Omega) \mid \operatorname{div} \mathbf{y} = 0\}$ when $\mathbf{U} = \mathbf{V}^0(\Gamma)$ (or in $\mathbf{V}_n^0(\Omega)$ when $\mathbf{U} = \mathbf{V}_n^0(\Gamma)$). If $D(C)$ denotes the domain of C in $\mathbf{V}^0(\Omega)$ (or in $\mathbf{V}_n^0(\Omega)$ when $\mathbf{U} = \mathbf{V}_n^0(\Gamma)$), the solution $\mathbf{y}$ of (1.3) is searched in $L^2(0, \infty; D(C))$. In [4, 2], C is chosen so that $|C\mathbf{y}|_{\mathbf{V}^0(\Omega)}$ is a norm in $\mathbf{V}_n^0(\Omega)$ equivalent to the usual norm of the space $\mathbf{H}^{3/2+\varepsilon}(\Omega)$, for some $\varepsilon > 0$. The idea in [4, 2] is to choose the operator C so that the norm $|C\mathbf{y}|_{\mathbf{V}^0(\Omega)}$ is strong enough to dominate the nonlinearity of the Navier–Stokes equations. In that way a Lyapunov function for the nonlinear closed loop system can be defined thanks to Π. The price to pay is that the operator Π, corresponding to this problem, does not satisfy a Riccati equation in the domain of the Oseen operator. An algebraic Riccati equation is stated only in $D((A_\Pi)^2)$ [4, section 4.5], where A_Π is the infinitesimal generator of the associated closed loop system. Thus the domain in which the Riccati equation is stated depends on the unknown Π of the equation. This is a serious drawback.

Here we follow a different approach. We choose J as follows:

$$J(\mathbf{y}, \mathbf{u}) = \frac{1}{2} \int_0^T \int_\Omega |\mathbf{y}|^2\, dxdt + \frac{1}{2} \int_0^T \int_\Gamma |\mathbf{u}|^2\, dxdt. \tag{1.7}$$

One difficulty comes from the fact that, choosing $\mathbf{U} = \mathbf{V}^0(\Gamma)$, the system (1.3) cannot be written in the form of a classical evolution equation. We have shown in [26] that (1.3) can be rewritten in the form

$$\begin{aligned} &P\mathbf{y}' = AP\mathbf{y} + BM\mathbf{u}, \qquad \mathbf{y}(0) = \mathbf{y}_0, \\ &(I - P)\mathbf{y} = (I - P)D_A\gamma_n M\mathbf{u}, \end{aligned} \tag{1.8}$$

where A is the corresponding Oseen operator, B is a boundary control operator, P is the so-called Helmholtz or Leray projector, and D_A the Dirichlet operator associated with A. For the precise definitions and properties of these operators we refer to section 2. Writing system (1.3) in the form (1.8), we show that the control problem $(\mathcal{Q})$ can be rewritten in the form of another control problem in which the state variable is $P\mathbf{y}$ and not $\mathbf{y}$. This transformation is essential in our approach. It leads to a Riccati equation which is the natural one for the new control problem, but which is not the expected one if we consider only problem $(\mathcal{Q})$. Moreover, the Riccati equation is satisfied in the domain of A.

Now the challenge is to prove that the linear feedback law determined in this way also stabilizes the nonlinear equation (1.2). This is not obvious, because the norm

of $\mathbf{y}$ involved in J is too weak to dominate the nonlinearity of the Navier–Stokes equations. Thus we cannot follow the Lyapunov function approach as in [2] and [4]; we develop a completely different approach. We study the regularizing properties of the operator Π. Thanks to these results—which, to the best of our knowledge, are new even in the case of other parabolic equations like the heat equation—we are able to establish a local feedback stabilization result for the Navier–Stokes equation for initial data $\mathbf{y}_0$ small enough in the space $\mathbf{V}_n^{1/2-\varepsilon}(\Omega) = \mathbf{V}_n^0(\Omega) \cap \mathbf{H}^{1/2-\varepsilon}(\Omega)$, for all $0 < \varepsilon < 1/4$. We show that the solution to the closed loop nonlinear system obeys an exponential decay in the corresponding space $\mathbf{V}^{1/2-\varepsilon}(\Omega) = \mathbf{V}^0(\Omega) \cap \mathbf{H}^{1/2-\varepsilon}(\Omega)$.

Finally, we note that in the three-dimensional case, the stabilization of the nonlinear problem cannot be treated with the same tools and requires a more delicate analysis [27, 28].

The paper is organized as follows. The Oseen operator and some associated boundary control operators are studied in section 2. Optimality conditions for the finite horizon control problem of the Oseen equations are established in section 3. We study the corresponding infinite time horizon control problem in section 4. We show that the optimal solution of this problem is characterized by an optimality system. This kind of characterization, which is known in the case of bounded control operators [1, 3] is to the best of our knowledge new in the case of unbounded operators. Thanks to this optimality system, we are able to study the regularity properties of the feedback operator. In order to study the nonlinear problem, we first study in section 5 a nonhomogeneous linear-quadratic control problem. The nonhomogeneous term will play the role of the nonlinearity in the next section. The local stabilization of the Navier–Stokes equations is studied in section 6. Some additional results are stated in section 7. We have collected some regularity results needed throughout the paper in an appendix.

2. Functional framework.

2.1. Notation and assumptions. Let us introduce the following spaces: $H^s(\Omega;\mathbb{R}^N) = \mathbf{H}^s(\Omega)$, $L^2(\Omega;\mathbb{R}^N) = \mathbf{L}^2(\Omega)$; the same notation conventions will be used for trace spaces and for the spaces $H_0^s(\Omega;\mathbb{R}^N)$. We also introduce different spaces of free divergence functions and some corresponding trace spaces:

$$\mathbf{V}^s(\Omega) = \left\{\mathbf{y} \in \mathbf{H}^s(\Omega) \mid \text{ div } \mathbf{y} = 0 \text{ in } \Omega, \ \langle \mathbf{y}\cdot\mathbf{n}, 1\rangle_{H^{-1/2}(\Gamma),H^{1/2}(\Gamma)} = 0\right\} \quad \text{for } s \geq 0,$$

$$\mathbf{V}_n^s(\Omega) = \left\{\mathbf{y} \in \mathbf{H}^s(\Omega) \mid \text{ div } \mathbf{y} = 0 \text{ in } \Omega, \ \mathbf{y}\cdot\mathbf{n} = 0 \text{ on } \Gamma\right\} \quad \text{for } s \geq 0,$$

$$\mathbf{V}_0^s(\Omega) = \left\{\mathbf{y} \in \mathbf{H}^s(\Omega) \mid \text{ div } \mathbf{y} = 0 \text{ in } \Omega, \ \mathbf{y} = 0 \text{ on } \Gamma\right\} \quad \text{for } s > 1/2,$$

$$\mathbf{V}^s(\Gamma) = \left\{\mathbf{y} \in \mathbf{H}^s(\Gamma) \mid \langle \mathbf{y}\cdot\mathbf{n}, 1\rangle_{H^{-1/2}(\Gamma),H^{1/2}(\Gamma)} = 0\right\} \quad \text{for } s \geq -1/2\,.$$

In the above setting, $\mathbf{n}$ denotes the unit normal to Γ outward Ω. We shall use the notation $Q_T = \Omega \times (0,T)$, $\Sigma_T = \Gamma \times (0,T)$, $Q_{\bar{t},T} = \Omega \times (\bar{t},T)$, and $\Sigma_{\bar{t},T} = \Gamma \times (\bar{t},T)$ for $\bar{t} > 0$, and $0 < T \leq \infty$. For spaces of time dependent functions we set

$$\mathbf{V}^{s,\sigma}(Q_T) = H^\sigma(0,T;\mathbf{V}^0(\Omega)) \cap L^2(0,T;\mathbf{V}^s(\Omega))$$

and

$$\mathbf{V}^{s,\sigma}(\Sigma_T) = H^\sigma(0,T;\mathbf{V}^0(\Gamma)) \cap L^2(0,T;\mathbf{V}^s(\Gamma)).$$

We assume that Ω is of class C^4 and $\mathbf{w} \in \mathbf{V}^3(\Omega)$.

In order to find a control $\mathbf{u}$, supported in an open subset Γ_c of Γ, we introduce a weight function $m \in C^2(\Gamma)$ with values in $[0,1]$, with support in Γ_c, equal to 1 in Γ_0, where Γ_0 is an open subset in Γ_c. Associated with this function m we introduce the operator $M \in \mathcal{L}(\mathbf{V}^0(\Gamma))$ defined by

$$M\mathbf{u}(x) = m(x)\mathbf{u}(x) - \frac{m}{\int_\Gamma m}\left(\int_\Gamma m\mathbf{u}\cdot\mathbf{n}\right)\mathbf{n}(x),$$

where $|\Gamma|$ is the $(N-1)$-dimensional Lebesgue measure of Γ. In this way, we can replace the condition $\mathrm{supp}(\mathbf{u}) \subset \Gamma_c$ by considering a boundary condition of the form

$$\mathbf{z} - \mathbf{w} = M\mathbf{u} \quad \text{on} \quad \Sigma_\infty.$$

The main interest of this operator M is that if $\mathbf{u} \in L^2(0,\infty;H^s(\Gamma_c;\mathbb{R}^N)) \cap H^{s/2}(0,\infty;L^2(\Gamma_c;\mathbb{R}^N))$ for some $0 < s \le 2$, and if $\tilde{\mathbf{u}}$ denotes the extension of $\mathbf{u}$ by zero to $\Sigma_\infty \backslash \big(\Gamma_c \times (0,\infty)\big)$, then $M\tilde{\mathbf{u}}$ belongs to $L^2(0,\infty;H^s(\Gamma;\mathbb{R}^N)) \cap H^{s/2}(0,\infty;L^2(\Gamma;\mathbb{R}^N))$, which is not true for $\tilde{\mathbf{u}}$.

For all $\psi \in H^{1/2+\varepsilon'}(\Omega)$, with $\varepsilon' > 0$, we denote by $c(\psi)$ and $c(m\psi)$ the constants defined by

$$c(\psi) = \frac{1}{|\Gamma|}\int_\Gamma \psi \quad \text{and} \quad c(m\psi) = \frac{1}{|\Gamma|}\int_\Gamma m\psi. \tag{2.1}$$

2.2. Properties of some operators. In the following we consider the linearized Navier–Stokes equation

$$\begin{aligned} &\frac{\partial \mathbf{y}}{\partial t} - \nu\Delta\mathbf{y} + (\mathbf{w}\cdot\nabla)\mathbf{y} + (\mathbf{y}\cdot\nabla)\mathbf{w} + \nabla p = 0 \quad \text{in } Q_T, \\ &\operatorname{div}\mathbf{y} = 0 \quad \text{in } Q_T, \quad \mathbf{y} = M\mathbf{u} \quad \text{on } \Sigma_T, \quad \mathbf{y}(0) = \mathbf{y}_0 \quad \text{in } \Omega, \end{aligned} \tag{2.2}$$

and the adjoint equation

$$\begin{aligned} &-\frac{\partial \mathbf{\Phi}}{\partial t} - \nu\Delta\mathbf{\Phi} - (\mathbf{w}\cdot\nabla)\mathbf{\Phi} + (\nabla\mathbf{w})^T\mathbf{\Phi} + \nabla\psi = \mathbf{y} \quad \text{in } Q_T, \\ &\operatorname{div}\mathbf{\Phi} = 0 \quad \text{in } Q_T, \quad \mathbf{\Phi} = 0 \quad \text{on } \Sigma_T, \quad \mathbf{\Phi}(T) = 0 \quad \text{in } \Omega, \end{aligned} \tag{2.3}$$

where T is finite or infinite. To study these equations, we introduce the Stokes and the Oseen operators associated with (2.2) and (2.3). Let P be the orthogonal projector in $\mathbf{L}^2(\Omega)$ onto $\mathbf{V}_n^0(\Omega)$, and denote by $(A_0, D(A_0))$, $(A, D(A))$, and $(A^*, D(A^*))$ the unbounded operators in $\mathbf{V}_n^0(\Omega)$ defined by

$$\begin{aligned} &D(A_0) = \mathbf{H}^2(\Omega) \cap \mathbf{V}_0^1(\Omega), \quad A_0\mathbf{y} = P\Delta\mathbf{y} \quad \text{for all } \mathbf{y} \in D(A_0), \\ &D(A) = \mathbf{H}^2(\Omega) \cap \mathbf{V}_0^1(\Omega), \quad A\mathbf{y} = \nu P\Delta\mathbf{y} - P((\mathbf{w}\cdot\nabla)\mathbf{y}) - P((\mathbf{y}\cdot\nabla)\mathbf{w}), \\ &D(A^*) = \mathbf{H}^2(\Omega) \cap \mathbf{V}_0^1(\Omega), \quad A^*\mathbf{y} = \nu P\Delta\mathbf{y} + P((\mathbf{w}\cdot\nabla)\mathbf{y}) - P((\nabla\mathbf{w})^T\mathbf{y}). \end{aligned}$$

Throughout the following we denote by $\lambda_0 > 0$ an element in the resolvent set of A satisfying

$$\begin{aligned} &\big((\lambda_0 I - A)\mathbf{y}, \mathbf{y}\big)_{\mathbf{V}_n^0(\Omega)} \ge \omega_0 |\mathbf{y}|^2_{\mathbf{V}_0^1(\Omega)} \quad \text{for all } \mathbf{y} \in D(A) \\ &\text{and} \\ &\big((\lambda_0 I - A^*)\mathbf{y}, \mathbf{y}\big)_{\mathbf{V}_n^0(\Omega)} \ge \omega_0 |\mathbf{y}|^2_{\mathbf{V}_0^1(\Omega)} \quad \text{for all } \mathbf{y} \in D(A^*) \end{aligned} \tag{2.4}$$

for some $0 < \omega_0 < 1$.

THEOREM 2.1. *The unbounded operator $(A-\lambda_0 I)$ (respectively, $(A^*-\lambda_0 I)$) with domain $D(A-\lambda_0 I)=D(A)$ (respectively, $D(A^*-\lambda_0 I)$) is the infinitesimal generator of a bounded analytic semigroup on $\mathbf{V}_n^0(\Omega)$. Moreover, for all $0\le\alpha\le 1$, we have*

$$D((\lambda_0 I-A)^\alpha)=D((\lambda_0 I-A^*)^\alpha)=D((\lambda_0 I-\nu A_0)^\alpha)=D((-A_0)^\alpha)\,.$$

Proof. Under condition (2.4) the analyticity of the semigroup generated by $(A-\lambda_0 I)$ is well known (see [6, Chapter 1, Theorem 2.1.2]). The characterization of the domains of fractional powers of $(\lambda_0 I-A)$ and $(\lambda_0 I-A^*)$ may be deduced from [24]. □

Observe that the semigroups $(e^{t(A-\lambda_0 I)})_{t\ge 0}$ and $(e^{t(A^*-\lambda_0 I)})_{t\ge 0}$ are exponentially stable on $\mathbf{V}_n^0(\Omega)$ and that

$$\|e^{t(A-\lambda_0 I)}\|_{\mathcal{L}(\mathbf{V}_n^0(\Omega))}\le e^{-\omega t}\quad\text{and}\quad\|e^{t(A^*-\lambda_0 I)}\|_{\mathcal{L}(\mathbf{V}_n^0(\Omega))}\le e^{-\omega t}$$

for all $\omega<\omega_0$ (see [6, Chapter 1, Theorem 2.12]).

LEMMA 2.2. *If $\mathbf{\Phi}$ belongs to $\mathbf{V}^{3/2+\varepsilon}(\Omega)\cap\mathbf{V}_0^1(\Omega)$ for some $\varepsilon>0$, then $\frac{\partial\mathbf{\Phi}}{\partial\mathbf{n}}\cdot\mathbf{n}=0$ on Γ.*

Proof. This result is proved in [4, Lemma 3.3.1] for functions $\mathbf{\Phi}$ belonging to $\mathbf{V}_0^1(\Omega)\cap(C^1(\overline{\Omega}))^N$. Since $\mathbf{V}_0^1(\Omega)\cap(C^2(\overline{\Omega}))^N$ is dense in $\mathbf{V}^{3/2+\varepsilon}(\Omega)\cap\mathbf{V}_0^1(\Omega)$, the result is still true for functions in $\mathbf{V}^{3/2+\varepsilon}(\Omega)\cap\mathbf{V}_0^1(\Omega)$ when $\varepsilon>0$. □

Let us introduce D_A and D_p, two Dirichlet operators associated with A, defined as follows. For $\mathbf{u}\in\mathbf{V}^0(\Gamma)$, set $D_A\mathbf{u}=\mathbf{y}$ and $D_p\mathbf{u}=q$, where $(\mathbf{y},q)$ is the unique solution in $\mathbf{V}^{1/2}(\Omega)\times(H^{1/2}(\Omega)/\mathbb{R})'$ to the equation

$$\begin{aligned}&\lambda_0\mathbf{y}-\nu\Delta\mathbf{y}+(\mathbf{w}\cdot\nabla)\mathbf{y}+(\mathbf{y}\cdot\nabla)\mathbf{w}+\nabla q=0\quad\text{in }\Omega,\\&\operatorname{div}\mathbf{y}=0\quad\text{in }\Omega,\quad\mathbf{y}=\mathbf{u}\quad\text{on }\Gamma.\end{aligned}$$

LEMMA 2.3. (i) *The operator D_A is a bounded operator from $\mathbf{V}^0(\Gamma)$ into $\mathbf{V}^0(\Omega)$; moreover, it satisfies*

$$\|D_A\mathbf{u}\|_{\mathbf{V}^{s+1/2}(\Omega)}\le C(s)\|\mathbf{u}\|_{\mathbf{V}^s(\Omega)}\qquad\textit{for all } 0\le s\le 2\,.$$

(ii) *The operator $D_A^*\in\mathcal{L}(\mathbf{V}^0(\Omega),\mathbf{V}^0(\Gamma))$, the adjoint operator of $D_A\in\mathcal{L}(\mathbf{V}^0(\Gamma),\mathbf{V}^0(\Omega))$, is defined by*

$$D_A^*\mathbf{g}=-\nu\frac{\partial\mathbf{z}}{\partial\mathbf{n}}+\pi\mathbf{n}-c(\pi)\mathbf{n},\tag{2.5}$$

where $(\mathbf{z},\pi)$ is the solution of

$$\lambda_0\mathbf{z}-\nu\Delta\mathbf{z}-(\mathbf{w}\cdot\nabla)\mathbf{z}+(\nabla\mathbf{w})^T\mathbf{z}+\nabla\pi=\mathbf{g}\ \textit{ and }\ \operatorname{div}\mathbf{z}=0\ \textit{ in }\Omega,\ \ \mathbf{z}=0\ \textit{ on }\Gamma\tag{2.6}$$

and $c(\pi)$ is defined by (2.1).

Proof. Part (i) is well known when $\mathbf{w}=0$ (see, e.g., [31]). Its adaptation in the case when $\mathbf{w}\in\mathbf{V}^3(\Omega)$ is given in [26, Corollary 7.1]. Part (ii) is stated in [26, Lemma 7.4]. □

Let us define the operators $\gamma_\tau\in\mathcal{L}(\mathbf{V}^0(\Gamma))$ and $\gamma_n\in\mathcal{L}(\mathbf{V}^0(\Gamma))$ by

$$\gamma_\tau\mathbf{u}=\mathbf{u}-\big(\mathbf{u}\cdot\mathbf{n}\big)\mathbf{n}\quad\text{and}\quad\gamma_n\mathbf{u}=\big(\mathbf{u}\cdot\mathbf{n}\big)\mathbf{n}=\mathbf{u}-\gamma_\tau\mathbf{u}\qquad\text{for all }\mathbf{u}\in\mathbf{V}^0(\Gamma)\,.$$

Let us also denote by P_Γ the projector in $\mathbf{L}^2(\Gamma)$ onto $\mathbf{V}^0(\Gamma)$ defined by $P_\Gamma \mathbf{u} = \mathbf{u} - \frac{m}{\int_\Gamma m}\big(\int_\Gamma \mathbf{u}\cdot\mathbf{n}\big)\mathbf{n}$. Observe that $M = P_\Gamma m$, where m denotes the multiplication operator by the function m. Introducing the spaces

$$\mathbf{V}^0_\tau(\Gamma) = \Big\{\mathbf{u} \in \mathbf{V}^0(\Gamma) \mid \gamma_\tau \mathbf{u} = 0\Big\} \qquad \text{and} \qquad \mathbf{V}^0_n(\Gamma) = \Big\{\mathbf{u} \in \mathbf{V}^0(\Gamma) \mid \gamma_n \mathbf{u} = 0\Big\},$$

we have $\mathbf{V}^0(\Gamma) = \mathbf{V}^0_\tau(\Gamma) \oplus \mathbf{V}^0_n(\Gamma)$.

LEMMA 2.4. *The operator M obeys the following properties:*

$$M = M^*, \qquad M\gamma_\tau = \gamma_\tau M = m\gamma_\tau, \quad \textit{and} \quad M\gamma_n = \gamma_n M\,.$$

The operators γ_τ and γ_n satisfy

$$\gamma_\tau = \gamma_\tau^*, \qquad \gamma_n = \gamma_n^*, \quad \textit{and} \quad (I-P)D_A = (I-P)D_A\gamma_n.$$

Proof. From the definition of M it follows that

$$\Big(M\mathbf{u}, \mathbf{v}\Big)_{\mathbf{V}^0(\Gamma)} = \int_\Gamma m\mathbf{u}\cdot\mathbf{v} = \int_\Gamma \mathbf{u}\cdot P_\Gamma m\mathbf{v} = \Big(\mathbf{u}, M\mathbf{v}\Big)_{\mathbf{V}^0(\Gamma)},$$

for all $\mathbf{u} \in \mathbf{V}^0(\Gamma)$ and all $\mathbf{v} \in \mathbf{V}^0(\Gamma)$. Thus $M = M^*$. Observe that $P_\Gamma\gamma_\tau = \gamma_\tau = \gamma_\tau P_\Gamma$ and $m\gamma_\tau = \gamma_\tau m$. Thus we have

$$M\gamma_\tau = P_\Gamma m\gamma_\tau = m\gamma_\tau = \gamma_\tau m = \gamma_\tau M.$$

Thus the second identity is established. Since $\gamma_\tau + \gamma_n = I$, where I is the identity operator in $\mathbf{V}^0(\Gamma)$, we have $M(\gamma_\tau + \gamma_n) = (\gamma_\tau + \gamma_n)M$, and the identity $M\gamma_n = \gamma_n M$ follows from the equality $M\gamma_\tau = \gamma_\tau M$. The first two identities satisfied by γ_τ and γ_n are obvious. Moreover, if $\gamma_n\mathbf{u} = 0$, then $D_A\mathbf{u} \in \mathbf{V}^0_n(\Omega)$ and $(I-P)D_A\mathbf{u} = 0$. This proves the last identity. ∎

In the next lemma we study the properties of an operator R_A, which plays a crucial role in optimality conditions of control problems that we consider.

LEMMA 2.5. *The operator*

$$R_A = MD_A^*(I-P)D_AM + I$$

is an isomorphism from $\mathbf{V}^0(\Gamma)$ into itself. Moreover, for all $0 \le s \le 3/2$, its restriction to $\mathbf{V}^s(\Gamma)$ is an isomorphism from $\mathbf{V}^s(\Gamma)$ into itself. In addition, R_A satisfies

$$R_A\gamma_n = \gamma_n R_A\gamma_n \quad \textit{and} \quad R_A\gamma_\tau = \gamma_\tau R_A\gamma_\tau = \gamma_\tau.$$

The restriction of R_A to $\mathbf{V}^0_\tau(\Gamma)$ is an isomorphism from $\mathbf{V}^0_\tau(\Gamma)$ into itself, and we have

$$R_A^{-1}\mathbf{u} = (\gamma_n R_A\gamma_n)^{-1}\mathbf{u} = \gamma_n R_A^{-1}\gamma_n\mathbf{u} = \gamma_n R_A^{-1}\mathbf{u} \quad \textit{for all } \mathbf{u} \in \mathbf{V}^0_\tau(\Gamma)\,.$$

Proof. Let s belong to $[0, 3/2]$. The operator D_A is continuous from $\mathbf{V}^s(\Gamma)$ into $\mathbf{V}^{s+1/2}(\Omega)$, $(I-P)$ is bounded from $\mathbf{V}^{s+1/2}(\Omega)$ into itself, and D_A^* is bounded from $\mathbf{V}^{s+1/2}(\Omega)$ into $\mathbf{V}^{s+1}(\Gamma)$. Thus $MD_A^*(I-P)D_AM$ is bounded from $\mathbf{V}^s(\Gamma)$ into $\mathbf{V}^{s+1}(\Gamma)$, and compact in $\mathbf{V}^s(\Gamma)$. Let us show that the kernel of R_A is reduced to 0. If $\mathbf{u} \in \mathbf{V}^0(\Gamma)$ obeys $R_A\mathbf{u} = 0$, then we have

$$\begin{aligned} 0 &= \Big(R_A\mathbf{u}, \mathbf{u}\Big)_{\mathbf{V}^0(\Gamma)} = \Big((I-P)D_AM\mathbf{u}, (I-P)D_AM\mathbf{u}\Big)_{\mathbf{V}^0(\Omega)} + \Big(\mathbf{u}, \mathbf{u}\Big)_{\mathbf{V}^0(\Gamma)} \\ &\ge \Big(\mathbf{u}, \mathbf{u}\Big)_{\mathbf{V}^0(\Gamma)}. \end{aligned}$$

Thus $\mathbf{u} = 0$, which shows that R_A is injective. From the Fredholm alternative it follows that R_A is an isomorphism from $\mathbf{V}^s(\Gamma)$ into itself.

With the identities stated in Lemma 2.4, we can write

$$\Big(R_A\gamma_n\mathbf{u},\mathbf{v}\Big)_{\mathbf{V}^0(\Gamma)} = \Big((I-P)D_AM\gamma_n\mathbf{u},(I-P)D_A\gamma_nM\mathbf{v}\Big)_{\mathbf{V}^0(\Omega)} + \Big(\gamma_n\mathbf{u},\gamma_n\mathbf{v}\Big)_{\mathbf{V}^0(\Gamma)}$$
$$= \Big((I-P)D_AM\gamma_n\mathbf{u},(I-P)D_AM\gamma_n\mathbf{v}\Big)_{\mathbf{V}^0(\Omega)} + \Big(\gamma_n\mathbf{u},\gamma_n\mathbf{v}\Big)_{\mathbf{V}^0(\Gamma)} = \Big(R_A\gamma_n\mathbf{u},\gamma_n\mathbf{v}\Big)_{\mathbf{V}^0(\Gamma)}$$

for all $\mathbf{u}\in\mathbf{V}^0(\Gamma)$ and all $\mathbf{v}\in\mathbf{V}^0(\Gamma)$. Thus $R_A\gamma_n = \gamma_nR_A\gamma_n$.

Similarly, we have

$$\Big(R_A\gamma_\tau\mathbf{u},\mathbf{v}\Big)_{\mathbf{V}^0(\Gamma)} = \Big(\gamma_\tau\mathbf{u},\mathbf{v}\Big)_{\mathbf{V}^0(\Gamma)}$$

for all $\mathbf{u}\in\mathbf{V}^0(\Gamma)$ and all $\mathbf{v}\in\mathbf{V}^0(\Gamma)$, because $(I-P)D_AM\gamma_\tau\mathbf{u} = 0$. Thus $R_A\gamma_\tau = \gamma_\tau$, from which we deduce $\gamma_\tau R_A\gamma_\tau = \gamma_\tau$.

From the above identities it follows that

$$R_A\mathbf{u} = R_A\gamma_n\mathbf{u} = \gamma_nR_A\gamma_n\mathbf{u}\in\mathbf{V}^0_\tau(\Gamma) \qquad \text{for all } \mathbf{u}\in\mathbf{V}^0_\tau(\Gamma).$$

Thus the restriction of R_A to $\mathbf{V}^0_\tau(\Gamma)$ is an isomorphism from $\mathbf{V}^0_\tau(\Gamma)$ into itself. Also observe that the restriction of $\gamma_nR_A\gamma_n$ to $\mathbf{V}^0_\tau(\Gamma)$ enjoys the same property. The last identities in the lemma follow from these properties. □

We introduce the operators

$$B_n = (\lambda_0I - A)PD_A\gamma_n, \qquad B_\tau = (\lambda_0I-A)D_A\gamma_\tau\,, \qquad B = B_n + B_\tau.$$

Let us set

$$B_{n,\alpha} = (\lambda_0I-A)^{\alpha-1}B_n = (\lambda_0I-A)^\alpha PD_A\gamma_n,$$
$$B_{\tau,\alpha} = (\lambda_0I-A)^{\alpha-1}B_\tau = (\lambda_0I-A)^\alpha D_A\gamma_\tau,$$

and $B_\alpha = B_{n,\alpha} + B_{\tau,\alpha}$.

THEOREM 2.6. *For all $\alpha\in\,]0,\frac14[$, $B_{n,\alpha}$, and $B_{\tau,\alpha}$ belong to $\mathcal{L}(\mathbf{V}^0(\Gamma),\mathbf{V}^0_n(\Omega))$.*

Proof. Let us prove the result for $B_{n,\alpha}$; the other one can be shown in a similar way. Let $\mathbf{u}\in\mathbf{V}^0(\Gamma)$, and set $\mathbf{y} = D_A\gamma_n(\mathbf{u})$. Then $P\mathbf{y} = PD_A\gamma_n(\mathbf{u})$ belongs to $\mathbf{V}^{1/2}_n(\Omega)$. We have

(2.7)

$$\Big\langle(\lambda_0I-A)P\mathbf{y},\mathbf{z}\Big\rangle_{(D(A^*))',D(A^*)}$$
$$= \Big\langle(\lambda_0I-A)^\alpha P\mathbf{y},(\lambda_0I-A^*)^{1-\alpha}\mathbf{z}\Big\rangle_{(D((-A^*)^{1-\alpha}))',D((-A^*)^{1-\alpha})}$$
$$= \int_\Omega \mathbf{y}P(\lambda_0\mathbf{z} - \nu\Delta\mathbf{z} - (\mathbf{w}\cdot\nabla)\mathbf{z} + (\nabla\mathbf{w})^T\mathbf{z}) \quad \text{for all } \mathbf{z}\in D(A^*) = \mathbf{V}^2(\Omega)\cap\mathbf{V}^1_0(\Omega).$$

Every $\mathbf{z}\in D(A^*)$ is the solution to the equation

$$\lambda_0\mathbf{z} - \nu\Delta\mathbf{z} - (\mathbf{w}\cdot\nabla)\mathbf{z} + (\nabla\mathbf{w})^T\mathbf{z} + \nabla q = \mathbf{f}, \quad \text{div }\mathbf{z} = 0 \quad \text{in }\Omega, \quad \mathbf{z} = 0 \quad \text{on }\Gamma,$$

where $\mathbf{f} = P(\lambda_0\mathbf{z} - \nu\Delta\mathbf{z} - (\mathbf{w}\cdot\nabla)\mathbf{z} + (\nabla\mathbf{w})^T\mathbf{z})$. It is well known that $\nu\frac{\partial\mathbf{z}}{\partial\mathbf{n}} - q\,\mathbf{n}$ satisfies the estimate

$$\Big|\nu\frac{\partial\mathbf{z}}{\partial\mathbf{n}} - q\,\mathbf{n}\Big|_{\mathbf{V}^0(\Gamma)} \le C|\mathbf{f}|_{D((-A^*)^{-\alpha})} \le C|\mathbf{z}|_{D((-A^*)^{1-\alpha})},$$

provided that $0 < \alpha < 1/4$. Thus we have

$$\left|\int_\Omega \mathbf{y}\mathbf{f}\right| = \left|\int_\Omega \mathbf{y}P\Big(\lambda_0\mathbf{z} - \nu\Delta\mathbf{z} - (\mathbf{w}\cdot\nabla)\mathbf{z} + (\nabla\mathbf{w})^T\mathbf{z}\Big)\right|$$
$$= \left|\int_\Omega \mathbf{y}\Big(\lambda_0\mathbf{z} - \nu\Delta\mathbf{z} - (\mathbf{w}\cdot\nabla)\mathbf{z} + (\nabla\mathbf{w})^T\mathbf{z} + \nabla q\Big)\right| = \left|\int_\Gamma \left(-\nu\frac{\partial\mathbf{z}}{\partial\mathbf{n}} + q\,\mathbf{n}\right)\cdot\gamma_n(\mathbf{u})\right|$$
$$\le |\mathbf{u}|_{\mathbf{V}^0(\Gamma)}\left|\nu\frac{\partial\mathbf{z}}{\partial\mathbf{n}} - q\,\mathbf{n}\right|_{\mathbf{V}^0(\Gamma)} \le C|\mathbf{u}|_{\mathbf{V}^0(\Gamma)}|\mathbf{z}|_{D((-A^*)^{1-\alpha})}.$$

Combining this inequality with (2.7), we obtain

$$|(\lambda_0 I - A)^\alpha P\mathbf{y}|_{\mathbf{V}_n^0(\Omega)}$$
$$\le \sup_{|\mathbf{z}|_{D((-A^*)^{1-\alpha})}=1}\left|\int_\Omega \mathbf{y}P\Big(\lambda_0\mathbf{z} - \nu\Delta\mathbf{z} - (\mathbf{w}\cdot\nabla)\mathbf{z} + (\nabla\mathbf{w})^T\mathbf{z}\Big)\right|$$
$$\le C|\mathbf{u}|_{\mathbf{V}^0(\Gamma)}.$$

Thus the proof is complete. □

PROPOSITION 2.7. *For all $\mathbf{\Phi} \in D(A^*)$, $B^*\mathbf{\Phi}$ belongs to $\mathbf{V}^{1/2}(\Gamma)$, and we have*

$$B^*\mathbf{\Phi} = D_A^*(\lambda_0 I - A^*)\mathbf{\Phi}, \quad B_\tau^*\mathbf{\Phi} = \gamma_\tau D_A^*(\lambda_0 I - A^*)\mathbf{\Phi}, \quad B_n^*\mathbf{\Phi} = \gamma_n D_A^*(\lambda_0 I - A^*)\mathbf{\Phi},$$

and

$$B^*\mathbf{\Phi} = -\nu\frac{\partial\mathbf{\Phi}}{\partial\mathbf{n}} + \psi\mathbf{n} - c(\psi)\mathbf{n}, \qquad B_\tau^*\mathbf{\Phi} = \gamma_\tau B^*\mathbf{\Phi} = -\nu\frac{\partial\mathbf{\Phi}}{\partial\mathbf{n}},$$
$$\textit{and} \quad B_n^*\mathbf{\Phi} = \gamma_n B^*\mathbf{\Phi} = \psi\mathbf{n} - c(\psi)\mathbf{n},$$

with

$$\nabla\psi = (I - P)\Big[\nu\Delta\mathbf{\Phi} + (\mathbf{w}\cdot\nabla)\mathbf{\Phi} - (\nabla\mathbf{w})^T\mathbf{\Phi}\Big],$$

and $c(\psi)$ is defined by (2.1). *In particular, if $\mathbf{\Phi} \in \mathbf{V}^s(\Omega) \cap \mathbf{V}_0^1(\Omega)$ with $s \ge 2$, then the following estimate holds:*

$$|B^*\mathbf{\Phi}|_{\mathbf{V}^{s-3/2}(\Gamma)} \le C|\mathbf{\Phi}|_{\mathbf{V}^s(\Omega)\cap\mathbf{V}_0^1(\Omega)}.$$

Proof. The first result is a direct consequence of the definition of B and of the fact that B is a bounded operator from $\mathbf{V}^0(\Gamma)$ into $(D(A^*))'$. The identities for $B_\tau^*\mathbf{\Phi}$ and $B_n^*\mathbf{\Phi}$ follow from Lemma 2.4. From the definitions of B^* and D_A^* it follows that

$$B^*\mathbf{\Phi} = -\nu\frac{\partial\hat{\mathbf{\Phi}}}{\partial\mathbf{n}} + \hat{\psi}\mathbf{n} - c(\hat{\psi})\mathbf{n},$$

where $(\hat{\mathbf{\Phi}}, \hat{\psi})$ is defined by

$$\lambda_0\hat{\mathbf{\Phi}} - \nu\Delta\hat{\mathbf{\Phi}} - (\mathbf{w}\cdot\nabla)\hat{\mathbf{\Phi}} + (\nabla\mathbf{w})^T\hat{\mathbf{\Phi}} + \nabla\hat{\psi} = P(\lambda_0 I - A^*)\mathbf{\Phi} = (\lambda_0 I - A^*)\mathbf{\Phi} \quad \text{in } \Omega,$$
$$\text{div } \hat{\mathbf{\Phi}} = 0 \quad \text{in } \Omega, \quad \hat{\mathbf{\Phi}} = 0 \quad \text{on } \Gamma,$$

and $c(\hat{\psi})$ is defined by (2.1). From the first equation we deduce $(\lambda_0 I - A^*)\mathbf{\Phi} = (\lambda_0 I - A^*)\hat{\mathbf{\Phi}}$. Thus $\mathbf{\Phi} = \hat{\mathbf{\Phi}}$. Next we can see that $\hat{\psi}$ is the unique element in $H^1(\Omega)/\mathbb{R}$ defined by

$$\begin{aligned}\nabla\hat{\psi} &= (I-P)\Big[-\lambda_0\hat{\mathbf{\Phi}} + \nu\Delta\hat{\mathbf{\Phi}} + (\mathbf{w}\cdot\nabla)\hat{\mathbf{\Phi}} - (\nabla\mathbf{w})^T\hat{\mathbf{\Phi}}\Big]\\ &= (I-P)\Big[\nu\Delta\mathbf{\Phi} + (\mathbf{w}\cdot\nabla)\mathbf{\Phi} - (\nabla\mathbf{w})^T\mathbf{\Phi}\Big].\end{aligned}$$

The estimate of $B^*\mathbf{\Phi}$ follows directly from its definition. The proof is complete. ∎

3. A finite time horizon control problem. To deal with the stabilization problem formulated in section 1, we first study the following optimal control problem:

$$(\mathcal{Q}^T_{s,\zeta}) \qquad \inf\Big\{J_T(s,\mathbf{y},\mathbf{u}) \;\Big|\; (\mathbf{y},\mathbf{u}) \text{ satisfies (3.1)},\ \mathbf{u}\in\mathbf{V}^{0,0}(\Sigma_{s,T})\Big\},$$

where

$$J_T(s,\mathbf{y},\mathbf{u}) = \frac{1}{2}\int_s^T\int_\Omega |\mathbf{y}|^2\,dxdt + \frac{1}{2}\int_s^T |\mathbf{u}(t)|^2_{\mathbf{V}^0(\Gamma)}\,dt$$

and

$$\begin{aligned}&\frac{\partial\mathbf{y}}{\partial t} - \nu\Delta\mathbf{y} + (\mathbf{w}\cdot\nabla)\mathbf{y} + (\mathbf{y}\cdot\nabla)\mathbf{w} + \nabla p = 0 \quad \text{in } Q_{s,T},\\ &\text{div } \mathbf{y} = 0 \quad \text{in } Q_{s,T}, \quad \mathbf{y} = M\mathbf{u} \quad \text{on } \Sigma_{s,T}, \quad \mathbf{y}(s) = \zeta \quad \text{in } \Omega.\end{aligned} \tag{3.1}$$

The main objective of this section is to establish optimality conditions for $(\mathcal{Q}^T_{s,\zeta})$ and to show that the optimal solution $(\bar{\mathbf{y}},\bar{\mathbf{u}})$ obeys a pointwise feedback formulation defined thanks to the solution to a differential Riccati equation. To look for the solution $\mathbf{u}$ to problem $(\mathcal{Q}^T_{s,\zeta})$ in feedback form, we rewrite (3.1) in the form

$$\begin{aligned}&P\mathbf{y}' = AP\mathbf{y} + BM\mathbf{u} \quad \text{in } (s,T), \qquad \mathbf{y}(s) = \zeta,\\ &(I-P)\mathbf{y} = (I-P)D_A\gamma_n M\mathbf{u} \quad \text{in } (s,T).\end{aligned}$$

As we see that the situation is more complicated than in the case when we have a single equation of the form $\mathbf{y}' = A\mathbf{y} + B\mathbf{u}$ and when the feedback law is of the form $\bar{\mathbf{u}}(t) = -B^*\Pi(t)\bar{\mathbf{y}}(t)$ (Π being the solution of some differential Riccati equation). To overcome the difficulty arising from the presence of the second equation $(I-P)\mathbf{y} = (I-P)D_A\gamma_n M\mathbf{u}$, which is not an evolution equation, we also transform the functional J_T in the following way:

$$\begin{aligned}J_T(s,\mathbf{y},\mathbf{u}) &= \frac{1}{2}\int_s^T\int_\Omega |\mathbf{y}|^2 + \frac{1}{2}\int_s^T\int_\Gamma |\mathbf{u}|^2\\ &= \frac{1}{2}\int_s^T\int_\Omega |P\mathbf{y}|^2 + \frac{1}{2}\int_s^T\int_\Omega |(I-P)\mathbf{y}|^2 + \frac{1}{2}\int_s^T\int_\Gamma |\mathbf{u}|^2\end{aligned}$$

and

$$\begin{aligned}&\frac{1}{2}\int_s^T\int_\Omega |(I-P)\mathbf{y}|^2 + \frac{1}{2}\int_s^T\int_\Gamma |\mathbf{u}|^2\\ &= \frac{1}{2}\int_s^T\int_\Omega |(I-P)D_A M\gamma_n\mathbf{u}|^2 + \frac{1}{2}\int_s^T\int_\Gamma (|\gamma_\tau\mathbf{u}|^2 + |\gamma_n\mathbf{u}|^2)\\ &= \frac{1}{2}\int_s^T\int_\Gamma \Big(|(MD_A^*(I-P)D_AM)^{1/2}\gamma_n\mathbf{u}|^2 + |\gamma_n\mathbf{u}|^2 + |\gamma_\tau\mathbf{u}|^2\Big).\end{aligned}$$

Thus, if $\mathbf{y}$ is the solution of (3.1), we have

$$J_T(s,\mathbf{y},\mathbf{u}) = I_T(s,\mathbf{y},\mathbf{u}) = \frac{1}{2}\int_s^T\int_\Omega |P\mathbf{y}|^2 + \frac{1}{2}\int_s^T\int_\Gamma |R_A^{1/2}\gamma_n\mathbf{u}|^2 + \frac{1}{2}\int_s^T\int_\Gamma |\gamma_\tau\mathbf{u}|^2,$$

where R_A is the operator introduced in Lemma 2.5.

The control problem $(\mathcal{Q}^T_{s,\zeta})$ is equivalent to

$$(\mathcal{P}^T_{s,\zeta}) \qquad \inf\Big\{ I_T(s,\mathbf{y},\mathbf{u}) \;\mid\; (\mathbf{y},\mathbf{u}) \text{ satisfies (3.2)},\ \mathbf{u}\in \mathbf{V}^{0,0}(\Sigma_{s,T})\Big\},$$

where

$$P\mathbf{y}' = AP\mathbf{y} + BM\mathbf{u} \quad \text{in } (s,T), \qquad \mathbf{y}(s) = \zeta. \tag{3.2}$$

Even if problems $(\mathcal{Q}^T_{s,\zeta})$ and $(\mathcal{P}^T_{s,\zeta})$ are equivalent, we are going to see that the optimality conditions for $(\mathcal{P}^T_{s,\zeta})$ allow us to prove regularity results for the optimal solution $(\bar{\mathbf{y}},\bar{\mathbf{u}})$, which we cannot obtain with the optimality system of problem $(\mathcal{Q}^T_{s,\zeta})$.

THEOREM 3.1. *For all $s\in[0,T]$ and all $\zeta\in\mathbf{V}^0_n(\Omega)$, problem $(\mathcal{P}^T_{s,\zeta})$ admits a unique solution $(\mathbf{y}^s_\zeta,\mathbf{u}^s_\zeta)$ and*

$$\mathbf{u}^s_\zeta = -MB^*_\tau\mathbf{\Phi}^s_\zeta - R_A^{-1}MB^*_n\mathbf{\Phi}^s_\zeta \quad \textit{in } (s,T), \tag{3.3}$$

where $\mathbf{\Phi}^s_\zeta$ is solution to the equation

$$-\mathbf{\Phi}' = A^*\mathbf{\Phi} + P\mathbf{y}^s_\zeta \quad \textit{in } (s,T), \qquad \mathbf{\Phi}(T) = 0\,. \tag{3.4}$$

Conversely the system

$$\begin{aligned} &P\mathbf{y}' = AP\mathbf{y} - B_\tau M^2 B^*_\tau\mathbf{\Phi} - B_n M R_A^{-1} M B^*_n\mathbf{\Phi} \quad \textit{in } (s,T), \qquad P\mathbf{y}(s) = \zeta\,,\\ &-\mathbf{\Phi}' = A^*\mathbf{\Phi} + P\mathbf{y} \quad \textit{in } (s,T), \qquad \mathbf{\Phi}(T) = 0\,, \end{aligned} \tag{3.5}$$

admits a unique solution $(P\mathbf{y}^s_\zeta,\mathbf{\Phi}^s_\zeta)$ in $L^2(s,T;\mathbf{V}^0_n(\Omega))\times(\mathbf{V}^{2,1}(Q_{s,T})\cap L^2(s,T;\mathbf{V}^1_0(\Omega))$, and $(P\mathbf{y}^s_\zeta - (I-P)D_AMR_A^{-1}MB^*_n\mathbf{\Phi}^s_\zeta, -MB^*_\tau\mathbf{\Phi}^s_\zeta - R_A^{-1}MB^*_n\mathbf{\Phi}^s_\zeta)$ is the optimal solution to $(\mathcal{P}^T_{s,\zeta})$.

Remark 3.2. Due to Lemma 2.5, we have

$$MB^*_\tau\mathbf{\Phi}^s_\zeta + R_A^{-1}MB^*_n\mathbf{\Phi}^s_\zeta = R_A^{-1}MB^*\mathbf{\Phi}^s_\zeta,$$

but we prefer to write it using the decomposition of B^* in the form $B^*_\tau + B^*_n$ to give the respective expressions of the tangential and the normal components.

Proof. Step 1. The existence of a unique solution $(\mathbf{y}^s_\zeta,\mathbf{u}^s_\zeta)$ to problem $(\mathcal{P}^T_{s,\zeta})$ is obvious. Let $\mathbf{u}$ be in $L^2(s,T;\mathbf{V}^0(\Gamma))$ and $\mathbf{v}\in L^2(s,T;\mathbf{V}^0(\Gamma))$. Denote by $(\mathbf{y}_\mathbf{u},p_\mathbf{u})$ the solution to (3.2) corresponding to $\mathbf{u}$, and set

$$I_T(s,\mathbf{y}_\mathbf{u},\mathbf{u}) = \mathbf{I}_T(\mathbf{u}).$$

We have

$$\mathbf{I}'_T(\mathbf{u})\mathbf{v} = \int_s^T\int_\Omega P\mathbf{y}_\mathbf{u}\cdot P\mathbf{z} + \int_s^T\int_\Gamma R_A\gamma_n\mathbf{u}\cdot\gamma_n\mathbf{v} + \int_s^T\int_\Gamma \gamma_\tau\mathbf{u}\cdot\gamma_\tau\mathbf{v},$$

where $\mathbf{z}$ is the solution to

$$P\mathbf{z}' = AP\mathbf{z} + BM\mathbf{v} \quad \text{in } (s,T), \qquad P\mathbf{z}(s) = 0, \qquad (I-P)\mathbf{z} = (I-P)D_A M\mathbf{v}\,.$$

Let $\mathbf{\Phi}$ be the solution to the equation

$$-\mathbf{\Phi}' = A^*\mathbf{\Phi} + P\mathbf{y}_\mathbf{u}, \qquad \mathbf{\Phi}(T) = 0\,.$$

Due to Lemma 8.6, $\mathbf{\Phi}$ belongs to $\mathbf{V}^{2,1}(Q_{s,T})$. Thus $B^*\mathbf{\Phi}$ belongs to $L^2(s,T;\mathbf{V}^0(\Gamma))$. The functions $\mathbf{z}$ and $\mathbf{\Phi}$ obey the following identity:

$$\int_s^T \int_\Omega P\mathbf{y}_\mathbf{u} \cdot P\mathbf{z} = \int_s^T \Big\langle BM\mathbf{v}(\tau), \mathbf{\Phi}(\tau)\Big\rangle_{(D(A^*))',D(A^*)} d\tau = \int_s^T \int_\Gamma \mathbf{v} \cdot MB^*\mathbf{\Phi}\,.$$

Thus

$$\mathbf{I}_T'(\mathbf{u})\mathbf{v} = \int_s^T \int_\Gamma \mathbf{v} \cdot MB^*\mathbf{\Phi} + \int_s^T \int_\Gamma R_A\gamma_n\mathbf{u} \cdot \gamma_n\mathbf{v} + \int_s^T \int_\Gamma \gamma_\tau\mathbf{u} \cdot \gamma_\tau\mathbf{v}. \tag{3.6}$$

If $(\mathbf{y}_\zeta^s, \mathbf{u}_\zeta^s)$ is the solution to problem $(\mathcal{P}_{s,\zeta}^T)$, we have $\mathbf{I}_T'(\mathbf{u}_\zeta^s) = 0$, which gives

$$\gamma_n\mathbf{u}_\zeta^s = -\gamma_n R_A^{-1} MB^*\mathbf{\Phi}_\zeta^s = -R_A^{-1} MB_n^*\mathbf{\Phi}_\zeta^s \quad \text{and} \quad \gamma_\tau\mathbf{u}_\zeta^s = -\gamma_\tau MB^*\mathbf{\Phi}_\zeta^s = -MB_\tau^*\mathbf{\Phi}_\zeta^s\,.$$

Step 2. From Step 1 of the proof it follows that $(\mathbf{y}_\zeta^s, \mathbf{\Phi}_\zeta^s)$ is a solution of system (3.5). ($\mathbf{\Phi}_\zeta^s$ is the solution to (3.4).) If $(\bar{\mathbf{y}}, \bar{\mathbf{\Phi}})$ is a solution of system (3.5), and if we set $\bar{\mathbf{u}} = -MB_\tau^*\bar{\mathbf{\Phi}} - R_A^{-1}MB_n^*\bar{\mathbf{\Phi}}$, with (3.6) we can verify that $\mathbf{I}_T'(\bar{\mathbf{u}}) = 0$, which implies that $\bar{\mathbf{u}} = \mathbf{u}_\zeta^s$. Thus $\bar{\mathbf{y}} = \mathbf{y}_\zeta^s$ and $\bar{\mathbf{\Phi}} = \mathbf{\Phi}_\zeta^s$. The proof is complete. □

There is another way to characterize the optimal solution of $(\mathcal{P}_{s,\zeta}^T)$; it consists of writing the optimality conditions for $(\mathcal{Q}_{s,\zeta}^T)$. More precisely, we can state the following theorem.

THEOREM 3.3. *For all $s \in [0,T]$ and all $\zeta \in \mathbf{V}_n^0(\Omega)$, the unique solution $(\mathbf{y}_\zeta^s, \mathbf{u}_\zeta^s)$ of problem $(Q_{s,\zeta}^T)$ is characterized by*

$$\mathbf{u}_\zeta^s = m\left(\nu\frac{\partial\mathbf{\Phi}_\zeta^s}{\partial\mathbf{n}} - \psi_\zeta^s\mathbf{n}\right) + c(m\psi_\zeta^s)\mathbf{n}\,, \tag{3.7}$$

where $(\mathbf{\Phi}_\zeta^s, \psi_\zeta^s)$ is the solution to

$$\begin{aligned} &-\frac{\partial\mathbf{\Phi}}{\partial t} - \nu\Delta\mathbf{\Phi} - (\mathbf{w}\cdot\nabla)\mathbf{\Phi} + (\nabla\mathbf{w})^T\mathbf{\Phi} + \nabla\psi = \mathbf{y}_\zeta^s \quad \textit{in } Q_{s,T},\\ &\operatorname{div}\mathbf{\Phi} = 0 \quad \textit{in } Q_{s,T}, \quad \mathbf{\Phi} = 0 \quad \textit{on } \Sigma_{s,T}, \quad \mathbf{\Phi}(T) = 0 \quad \textit{in } \Omega\,, \end{aligned} \tag{3.8}$$

and $c(m\psi_\zeta^s)$ is the constant defined by (2.1) *corresponding to $m\psi_\zeta^s$.*

Remark 3.4. It is clear that the solution $\mathbf{\Phi}_\zeta^s$ of (3.8) is equal to the solution of (3.4). This is the reason why they are denoted in the same way.

Proof. Let $\mathbf{u}$ be in $L^2(s,T;\mathbf{V}^0(\Gamma))$ and $\mathbf{v} \in L^2(s,T;\mathbf{V}^0(\Gamma))$. Denote by $\mathbf{y}_\mathbf{u}$ the solution to (3.1), and set

$$J_T(s, \mathbf{y}_\mathbf{u}, \mathbf{u}) = \mathbf{J}_T(\mathbf{u}).$$

We have

$$\mathbf{J}_T'(\mathbf{u})\mathbf{v} = \int_s^T \int_\Omega \mathbf{y}_\mathbf{u} \cdot \mathbf{z} + \int_s^T \int_\Gamma \mathbf{u} \cdot \mathbf{v},$$

where $(\mathbf{z}, q)$ is the solution to

$$\frac{\partial \mathbf{z}}{\partial t} - \nu\Delta\mathbf{z} + (\mathbf{w}\cdot\nabla)\mathbf{z} + (\mathbf{z}\cdot\nabla)\mathbf{w} + \nabla q = 0 \quad \text{in } Q_{s,T},$$
$$\text{div } \mathbf{z} = 0 \quad \text{in } Q_{s,T}, \quad \mathbf{y} = M\mathbf{v} \quad \text{on } \Sigma_{s,T}, \quad \mathbf{z}(s) = 0 \quad \text{in } \Omega.$$

Let $(\mathbf{\Phi}, \psi)$ be the solution to the equation

$$-\frac{\partial \mathbf{\Phi}}{\partial t} - \nu\Delta\mathbf{\Phi} - (\mathbf{w}\cdot\nabla)\mathbf{\Phi} + (\nabla\mathbf{w})^T\mathbf{\Phi} + \nabla\psi = \mathbf{y_u} \quad \text{in } Q_{s,T},$$
$$\text{div } \mathbf{\Phi} = 0 \quad \text{in } Q_{s,T}, \quad \mathbf{\Phi} = 0 \quad \text{on } \Sigma_{s,T}, \quad \mathbf{\Phi}(T) = 0 \quad \text{in } \Omega\,.$$

We can verify that

$$\int_s^T \int_\Omega \mathbf{y_u}\cdot\mathbf{z} = \int_s^T \int_\Gamma \left(-\nu\frac{\partial \mathbf{\Phi}}{\partial \mathbf{n}} + \psi\mathbf{n}\right)\cdot M\mathbf{v} = \int_s^T \int_\Gamma m\left(-\nu\frac{\partial \mathbf{\Phi}}{\partial \mathbf{n}} + \psi\mathbf{n}\right)\cdot\mathbf{v}.$$

Thus $\mathbf{u}_\zeta^s$ is characterized by

$$\int_s^T \int_\Gamma \left(-m\nu\frac{\partial \mathbf{\Phi}_\zeta^s}{\partial \mathbf{n}} + m\psi_\zeta^s\mathbf{n} + \mathbf{u}_\zeta^s\right)\cdot\mathbf{v} = 0$$

for all $\mathbf{v} \in \mathbf{V}^0(\Gamma)$; that is,

$$\gamma_\tau\mathbf{u}_\zeta^s = m\nu\frac{\partial \mathbf{\Phi}_\zeta^s}{\partial \mathbf{n}} \quad \text{and} \quad \gamma_n\mathbf{u}_\zeta^s = -m\psi_\zeta^s\mathbf{n} + c(m\psi_\zeta^s)\mathbf{n}.$$

The proof is complete. □

Since $(\mathcal{P}_{s,\zeta}^T)$ and $(\mathcal{Q}_{s,\zeta}^T)$ admit the same solution, we have

$$-MB_\tau^*\mathbf{\Phi}_\zeta^s - R_A^{-1}MB_n^*\mathbf{\Phi}_\zeta^s = m\left(\nu\frac{\partial \mathbf{\Phi}_\zeta^s}{\partial \mathbf{n}} - \psi_\zeta^s\mathbf{n}\right) + c(m\psi_\zeta^s)\mathbf{n}\,.$$

The characterization given in (3.7) seems to be easier to use than the one in (3.3). However, we are going to see that we are able to characterize the regularity of the solution $(\mathbf{y}_\zeta^s, \mathbf{u}_\zeta^s)$ in an optimal way by using (3.3), which is not the case with (3.7). To understand the relationship between (3.3) and (3.7), let us rewrite the second equation in (3.5) in the form

$$-\frac{\partial \mathbf{\Phi}_\zeta^s}{\partial t} - \nu\Delta\mathbf{\Phi}_\zeta^s - (\mathbf{w}\cdot\nabla)\mathbf{\Phi}_\zeta^s + (\nabla\mathbf{w})^T\mathbf{\Phi}_\zeta^s + \nabla\tilde{\psi}_\zeta^s = P\mathbf{y}_\zeta^s \quad \text{in } Q_{s,T},$$
$$\text{div } \mathbf{\Phi}_\zeta^s = 0 \quad \text{in } Q_{s,T}, \quad \mathbf{\Phi}_\zeta^s = 0 \quad \text{on } \Sigma_{s,T}, \quad \mathbf{\Phi}(T) = 0 \quad \text{in } \Omega. \tag{3.9}$$

Observe that $\nabla\tilde{\psi}_\zeta^s = \nabla\psi_\zeta^s - (I-P)\mathbf{y}_\zeta^s$, where ψ_ζ^s is the pressure appearing in (3.8).

LEMMA 3.5. *If $(\mathbf{\Phi}_\zeta^s, \tilde{\psi}_\zeta^s)$ is the solution to* (3.9)*, then*

$$B^*\mathbf{\Phi}_\zeta^s(t) = -\nu\frac{\partial \mathbf{\Phi}_\zeta^s}{\partial \mathbf{n}}(t) + \tilde{\psi}_\zeta^s(t)\mathbf{n} - c(\tilde{\psi}_\zeta^s(t))\mathbf{n} \quad \textit{for almost all } t \in (s,T),$$

and the optimal control $\mathbf{u}_\zeta^s$ is defined by

$$\mathbf{u}_\zeta^s = m\nu\frac{\partial \mathbf{\Phi}_\zeta^s}{\partial \mathbf{n}} - R_A^{-1}M\tilde{\psi}_\zeta^s\mathbf{n}. \tag{3.10}$$

Proof. From Proposition 2.7 it follows that

$$B^*\mathbf{\Phi}^s_\zeta(t) = -\nu\frac{\partial \mathbf{\Phi}^s_\zeta}{\partial \mathbf{n}}(t) + \hat\psi^s_\zeta(t)\mathbf{n} - c(\hat\psi^s_\zeta(t))\mathbf{n}\,,$$

where $\nabla\hat\psi^s_\zeta$ is defined by

$$\nabla\hat\psi^s_\zeta = (I-P)\Big[\nu\Delta\mathbf{\Phi}^s_\zeta + (\mathbf{w}\cdot\nabla)\mathbf{\Phi}^s_\zeta - (\nabla\mathbf{w})^T\mathbf{\Phi}^s_\zeta\Big]\,.$$

Thus $\nabla\hat\psi^s_\zeta = \nabla\tilde\psi^s_\zeta$ because $(I-P)\big(\frac{\partial\mathbf{\Phi}^s_\zeta}{\partial t}\big) = 0$. Therefore $\mathbf{u}^s_\zeta$ is defined by

$$\mathbf{u}^s_\zeta = -MB^*_\tau\mathbf{\Phi}^s_\zeta - R_A^{-1}MB^*_n\mathbf{\Phi}^s_\zeta = \Big(-M\gamma_\tau - R_A^{-1}M\gamma_n\Big)\left(\nu\frac{\partial\mathbf{\Phi}^s_\zeta}{\partial\mathbf{n}} - \tilde\psi^s_\zeta\mathbf{n}\right),$$

and due to Lemma 2.5, the proof is complete. □

In the following theorem we improve the regularity result of the optimal solution.

THEOREM 3.6. *The solution* $(\mathbf{y}^s_\zeta, \mathbf{\Phi}^s_\zeta)$ *to system* (3.5) *belongs to* $\mathbf{V}^{1,1/2}(Q_{s,T}) \times L^2(s,T;\mathbf{V}^3(\Omega)\cap\mathbf{V}^1_0(\Omega)) \cap H^{3/2}(s,T;\mathbf{V}^0_n(\Omega))$. *In particular,* $\mathbf{\Phi}^s_\zeta$ *belongs to* $C([s,T];\mathbf{V}^2(\Omega)\cap\mathbf{V}^1_0(\Omega))$.

Proof. Since $B^*\mathbf{\Phi}^s_\zeta \in L^2(s,T;\mathbf{V}^0(\Gamma))$, due to Lemmas 8.1 and 8.3, $\mathbf{y}^s_\zeta$ belongs to $\mathbf{V}^{1/2-\varepsilon,1/4-\varepsilon}(Q_{s,T})$ for all $\varepsilon>0$. From Lemmas 8.6 and 8.8 it follows that

$$\frac{\partial\mathbf{\Phi}^s_\zeta}{\partial\mathbf{n}} \in \mathbf{V}^{1-\varepsilon,1/2-\varepsilon/2}(\Sigma_{s,T}) \qquad \text{and} \qquad \nabla\tilde\psi^s_\zeta \in \mathbf{H}^{1/2-\varepsilon,1/4-\varepsilon/2}(Q_{s,T})$$

for all $\varepsilon>0$, where $\tilde\psi^s_\zeta$ is the pressure appearing in (3.9). From this regularity result and from Lemma 3.5, we deduce that $B^*\mathbf{\Phi}^s_\zeta \in \mathbf{V}^{1/2-\varepsilon,1/4-\varepsilon/2}(\Sigma_{s,T})$ and $\mathbf{u}^s_\zeta \in \mathbf{V}^{1/2-\varepsilon,1/4-\varepsilon/2}(\Sigma_{s,T})$ for all $\varepsilon>0$, where $\mathbf{u}^s_\zeta = -MB^*_\tau\mathbf{\Phi}^s_\zeta - R_A^{-1}MB^*_n\mathbf{\Phi}^s_\zeta$ is the solution of problems $(Q^T_{s,\zeta})$ and $(P^T_{s,\zeta})$. Still applying Lemma 8.3, we obtain $\mathbf{y}^s_\zeta \in \mathbf{V}^{1-\varepsilon,1/2-\varepsilon}(Q_{s,T})$ for all $\varepsilon>0$, and repeating the above analysis for $B^*\mathbf{\Phi}^s_\zeta$, we can show that $\mathbf{u}^s_\zeta \in \mathbf{V}^{1-\varepsilon,1/2-\varepsilon/2}(\Sigma_{s,T})$ for all $\varepsilon>0$. Still with Lemmas 8.1 and 8.3, we prove that $\mathbf{y}^s_\zeta$ belongs to $\mathbf{V}^{1,1/2}(Q_{s,T})$. Due to Lemma 8.6, $\mathbf{\Phi}^s_\zeta$ belongs to $\mathbf{V}^{3,3/2}(Q_{s,T})$. In particular, $\mathbf{\Phi}^s_\zeta$ belongs to $C([s,T];\mathbf{V}^2(\Omega)\cap\mathbf{V}^1_0(\Omega))$. The proof is now complete. □

Remark 3.7. Observe that the regularity result stated in Theorem 3.6 has been obtained by using the expression of $\mathbf{u}^s_\zeta$ given in (3.10). In (3.10), only the pressure $\tilde\psi^s_\zeta$ appears, and $\tilde\psi^s_\zeta$ depends only on $\mathbf{\Phi}^s_\zeta$. Thus by improving the regularity of $\mathbf{\Phi}^s_\zeta$ we are able to improve the regularity of $\tilde\psi^s_\zeta$, and this is what is done in Lemma 8.8. If we use the expression of $\mathbf{u}^s_\zeta$ given in (3.7), the pressure ψ^s_ζ obeys $\nabla\psi^s_\zeta = \nabla\tilde\psi^s_\zeta + (I-P)\mathbf{y}^s_\zeta$. Since the regularity with respect to the time variable of $(I-P)\mathbf{y}^s_\zeta$ cannot be improved, we are not able to improve the regularity of $\mathbf{u}^s_\zeta$ by using (3.7).

COROLLARY 3.8. *For all* $s\in[0,T]$ *and all* $\zeta\in\mathbf{V}^0_n(\Omega)$, *the unique solution* $(\mathbf{y}^s_\zeta,\mathbf{u}^s_\zeta)$ *to problem* $(\mathcal{P}^T_{s,\zeta})$ *and the corresponding solution* $(\mathbf{y}^s_\zeta,\mathbf{\Phi}^s_\zeta)$ *to system* (3.5) *obey*

$$I_T(s,\mathbf{y}^s_\zeta,\mathbf{u}^s_\zeta) = \frac{1}{2}\int_\Omega \mathbf{\Phi}^s_\zeta(s)\cdot\zeta\,.$$

Proof. By multiplying by $\mathbf{\Phi}_\zeta^s$ the equation (3.1) satisfied by $(\mathbf{y}_\zeta^s, \mathbf{u}_\zeta^s)$, integrating in space and time, making integration by parts, and using (3.9) satisfied by $\mathbf{\Phi}_\zeta^s$, we can prove that

$$\int_\Omega \mathbf{\Phi}_\zeta^s(s)\cdot\zeta = \int_s^T\int_\Omega |P\mathbf{y}_\zeta^s|^2 + \int_s^T\int_\Gamma \left(\nu\frac{\partial \mathbf{\Phi}_\zeta^s}{\partial \mathbf{n}} - \tilde{\psi}_\zeta^s\mathbf{n} + c(\tilde{\psi}_\zeta^s)\mathbf{n}\right)\cdot M\mathbf{u}_\zeta^s.$$

Next using (3.10), we can show that

$$\int_s^T\int_\Gamma \left(\nu\frac{\partial \mathbf{\Phi}_\zeta^s}{\partial \mathbf{n}} - \tilde{\psi}_\zeta^s\mathbf{n} + c(\tilde{\psi}_\zeta^s)\mathbf{n}\right)\cdot M\mathbf{u}_\zeta^s = \int_s^T\int_\Gamma |R_A^{1/2}\gamma_n\mathbf{u}_\zeta^s|^2 + \int_s^T\int_\Gamma |\gamma_\tau\mathbf{u}_\zeta^s|^2,$$

and the proof is complete. ∎

Let $\Pi(s)$ be the operator defined by

$$\Pi(s)\ :\ \zeta \longmapsto \mathbf{\Phi}_\zeta^s(s)\,, \tag{3.11}$$

where $(P\mathbf{y}_\zeta^s, \mathbf{\Phi}_\zeta^s)$ is the unique solution to system (3.5). From Theorem 3.6 it follows that $\Pi(s) \in \mathcal{L}(\mathbf{V}_n^0(\Omega), \mathbf{V}^2(\Omega)\cap\mathbf{V}_0^1(\Omega))$. Using Theorem 3.6, we can prove that the family of operators $(\Pi(s))_{s\in[0,T]}$ defined by (3.11) belongs to $C_s([0,T];\mathcal{L}(\mathbf{V}_n^0(\Omega)))$ (the space of functions Π from $[0,T]$ into $\mathcal{L}(\mathbf{V}_n^0(\Omega))$ such that, for all $\mathbf{y}\in\mathbf{V}_n^0(\Omega)$, $\Pi(\cdot)\mathbf{y}$ is continuous from $[0,T]$ into $\mathbf{V}_n^0(\Omega)$). Next, using the optimality system (3.5), we can show that Π is the unique solution in $C_s([0,T];\mathcal{L}(\mathbf{V}_n^0(\Omega)))$ to the Riccati equation

$$\begin{gathered}
\Pi^*(t) = \Pi(t) \quad\text{and}\quad \Pi(t)\ge 0;\\
\text{for all } \mathbf{y}\in\mathbf{V}_n^0(\Omega),\ t\in[0,T],\\
\Pi(t)\mathbf{y}\in\mathbf{V}^2(\Omega)\cap\mathbf{V}_0^1(\Omega) \quad\text{and}\quad |\Pi(t)\mathbf{y}|_{\mathbf{V}^2(\Omega)} \le C|\mathbf{y}|_{\mathbf{V}_n^0(\Omega)};\\
-\Pi'(t) = A^*\Pi(t) + \Pi(t)A - \Pi(t)B_\tau M^2 B_\tau^*\Pi(t) - \Pi(t)B_n M R_A^{-1} M B_n^*\Pi(t) + I,\\
\Pi(T) = 0.
\end{gathered} \tag{3.12}$$

From the definition of Π, from Theorem 3.1 and Corollary 3.8, we deduce the following theorem. We also refer to [23, Theorem 1.2.2.1], where the existence of a unique solution to (3.12) is established.

THEOREM 3.9. *The solution* $(\mathbf{y},\mathbf{u})$ *to problem* $(\mathcal{P}_{0,\mathbf{y}_0}^T)$ *belongs to* $C([0,T];\mathbf{V}^0(\Omega))\times C([0,T];\mathbf{V}^0(\Gamma))$*; it obeys the feedback formula*

$$\mathbf{u}(t) = -\Big(MB_\tau^* + R_A^{-1}MB_n^*\Big)\Pi(t)P\mathbf{y}(t),$$

and the optimal cost is given by

$$J(\mathbf{y},\mathbf{u}) = \frac{1}{2}\Big(\Pi(0)\mathbf{y}_0,\mathbf{y}_0\Big)_{\mathbf{V}_n^0(\Omega)}.$$

If we set $\widehat{\Pi}(t) = \Pi(T-t)$, then $\widehat{\Pi}$ is the unique solution in $C_s([0,T];\mathcal{L}(\mathbf{V}_n^0(\Omega)))$ to the Riccati equation

$$\begin{gathered}
\widehat{\Pi}^*(t) = \widehat{\Pi}(t) \quad\text{and}\quad \widehat{\Pi}(t)\ge 0;\\
\text{for all } \mathbf{y}\in\mathbf{V}_n^0(\Omega),\ t\in[0,T],\\
\widehat{\Pi}(t)\mathbf{y}\in\mathbf{V}^2(\Omega)\cap\mathbf{V}_0^1(\Omega) \quad\text{and}\quad |\widehat{\Pi}(t)\mathbf{y}|_{\mathbf{V}^2(\Omega)} \le C|\mathbf{y}|_{\mathbf{V}_n^0(\Omega)};\\
\widehat{\Pi}'(t) = A^*\widehat{\Pi}(t) + \widehat{\Pi}(t)A - \widehat{\Pi}(t)B_\tau M^2 B_\tau^*\widehat{\Pi}(t) - \widehat{\Pi}(t)B_n M R_A^{-1} M B_n^*\widehat{\Pi}(t) + I,\\
\widehat{\Pi}(0) = 0.
\end{gathered} \tag{3.13}$$

From the definition of $\widehat{\Pi}$ it follows that $\Pi(0) = \widehat{\Pi}(T)$.

4. An infinite time horizon problem. In this section we want to study problem $(\mathcal{P}^{\infty}_{0,\mathbf{y}_0})$, and we want to study the regularity of its solution according to the regularity of $\mathbf{y}_0$. For notational simplicity, problem $(\mathcal{P}^{\infty}_{0,\mathbf{y}_0})$ will now be denoted by $(\mathcal{P}_{0,\mathbf{y}_0})$, and the state variable by $\mathbf{y}$ and not $P\mathbf{y}$ as in the previous section. With this notation the problem we consider is

$$(\mathcal{P}_{0,\mathbf{y}_0}) \qquad \inf\Big\{ I(\mathbf{y},\mathbf{u}) \ \mid \ (\mathbf{y},\mathbf{u}) \text{ satisfies (4.1)}, \ \mathbf{u} \in \mathbf{V}^{0,0}(\Sigma_\infty)\Big\},$$

where

$$I(\mathbf{y},\mathbf{u}) = \frac{1}{2}\int_0^\infty \int_\Omega |\mathbf{y}|^2 \, dxdt + \frac{1}{2}\int_0^\infty \Big(|\gamma_\tau \mathbf{u}(t)|^2_{\mathbf{V}^0(\Gamma)} + |R_A^{1/2}\gamma_n \mathbf{u}(t)|^2_{\mathbf{V}^0(\Gamma)}\Big)\, dt$$

and

$$\mathbf{y}' = A\mathbf{y} + BM\mathbf{u} \quad \text{in } (0,\infty), \qquad \mathbf{y}(0) = \mathbf{y}_0. \tag{4.1}$$

Accordingly, for $0 \le s < k < \infty$, problem $(\mathcal{P}^k_{s,\zeta})$ will now be defined by

$$(\mathcal{P}^k_{s,\zeta}) \qquad \inf\Big\{ I_k(s,\mathbf{y},\mathbf{u}) \ \mid \ (\mathbf{y},\mathbf{u}) \text{ satisfies (4.2)}, \ \mathbf{u} \in \mathbf{V}^{0,0}(\Sigma_{s,k})\Big\},$$

where

$$I_k(s,\mathbf{y},\mathbf{u}) = \frac{1}{2}\int_s^k \int_\Omega |\mathbf{y}|^2 \, dxdt + \frac{1}{2}\int_s^k \Big(|\gamma_\tau \mathbf{u}(t)|^2_{\mathbf{V}^0(\Gamma)} + |R_A^{1/2}\gamma_n \mathbf{u}(t)|^2_{\mathbf{V}^0(\Gamma)}\Big)\, dt$$

and

$$\mathbf{y}' = A\mathbf{y} + BM\mathbf{u} \quad \text{in } (s,k), \qquad \mathbf{y}(s) = \zeta. \tag{4.2}$$

THEOREM 4.1. *For all $\mathbf{y}_0 \in \mathbf{V}^0_n(\Omega)$, problem $(\mathcal{P}_{0,\mathbf{y}_0})$ admits a unique solution $(\mathbf{y}_{\mathbf{y}_0}, \mathbf{u}_{\mathbf{y}_0})$. There exists $\Pi \in \mathcal{L}(\mathbf{V}^0_n(\Omega))$, obeying $\Pi = \Pi^*$, such that the optimal cost is given by*

$$I(\mathbf{y}_{\mathbf{y}_0}, \mathbf{u}_{\mathbf{y}_0}) = \frac{1}{2}\Big(\Pi \mathbf{y}_0, \mathbf{y}_0\Big)_{\mathbf{V}^0_n(\Omega)}.$$

Proof. From the null controllability results stated in [8], we can deduce that there exist controls $\mathbf{u} \in L^2(0,\infty;\mathbf{V}^0(\Gamma))$ such that $I(\mathbf{y}_\mathbf{u},\mathbf{u}) < \infty$, where $\mathbf{y}_\mathbf{u}$ is the solution of (4.1) corresponding to $\mathbf{u}$. The null controllability results in [8] are stated for a distributed control. Using an extension of the domain, this result also provides a null controllability result for a control localized on the boundary. The existence of a unique solution $(\mathbf{y}_{\mathbf{y}_0}, \mathbf{u}_{\mathbf{y}_0})$ to $(\mathcal{P}_{0,\mathbf{y}_0})$ follows from classical arguments.

From the dynamic programming principle, it follows that the mapping

$$T \longmapsto \Big(\widehat{\Pi}(T)\mathbf{y}_0, \mathbf{y}_0\Big)_{\mathbf{V}^0_n(\Omega)}$$

is nondecreasing, and we have

$$\frac{1}{2}\Big(\widehat{\Pi}(T)\mathbf{y}_0, \mathbf{y}_0\Big)_{\mathbf{V}^0_n(\Omega)} \le I(\mathbf{y}_{\mathbf{y}_0}, \mathbf{u}_{\mathbf{y}_0}) < \infty\,.$$

As in [7] or in [23], we can show that there exists an operator $\Pi \in \mathcal{L}(\mathbf{V}_n^0(\Omega))$ satisfying $\Pi = \Pi^* \geq 0$ and

$$\Pi \mathbf{y}_0 = \lim_{T\to\infty} \widehat{\Pi}(T)\mathbf{y}_0 \qquad \text{for all } \mathbf{y}_0 \in \mathbf{V}_n^0(\Omega).$$

Let us show that $I(\mathbf{y}_{\mathbf{y}_0}, \mathbf{u}_{\mathbf{y}_0}) = \frac{1}{2}\big(\Pi \mathbf{y}_0, \mathbf{y}_0\big)_{\mathbf{V}_n^0(\Omega)}$. Problem $(\mathcal{P}^k_{0,\mathbf{y}_0})$ admits a unique solution $(\mathbf{y}_k, \mathbf{u}_k)$ characterized by

$$\begin{aligned} &\mathbf{y}_k' = A\mathbf{y}_k + BM\mathbf{u}_k \quad \text{in } (0,k), \qquad \mathbf{y}_k(0) = \mathbf{y}_0, \\ &-\mathbf{\Phi}_k' = A^*\mathbf{\Phi}_k + \mathbf{y}_k \quad \text{in } (0,k), \qquad \mathbf{\Phi}_k(k) = 0, \\ &\gamma_\tau \mathbf{u}_k = -MB_\tau^* \mathbf{\Phi}_k, \qquad \gamma_n \mathbf{u}_k = -R_A^{-1} MB_n^* \mathbf{\Phi}_k. \end{aligned} \tag{4.3}$$

Convergence of $\mathbf{y}_k$ *and* $\mathbf{u}_k$. Denote by $\tilde{\mathbf{u}}_k$ the extension by zero of $\mathbf{u}_k$ to (k,∞), and by $\tilde{\mathbf{y}}_k$ the extension by zero of $\mathbf{y}_k$ to (k,∞). Since we have

$$\begin{aligned} &\int_0^k \int_\Omega |\mathbf{y}_k|^2 \, dxdt + \int_0^k \Big(|\gamma_\tau \mathbf{u}_k(t)|^2_{\mathbf{V}^0(\Gamma)} + |R_A^{1/2}\gamma_n \mathbf{u}_k(t)|^2_{\mathbf{V}^0(\Gamma)} \Big)\, dt \\ &\leq \int_0^\infty \int_\Omega |\mathbf{y}_{\mathbf{y}_0}|^2 \, dxdt + \int_0^\infty \Big(|\gamma_\tau \mathbf{u}_{\mathbf{y}_0}(t)|^2_{\mathbf{V}^0(\Gamma)} + |R_A^{1/2}\gamma_n \mathbf{u}_{\mathbf{y}_0}(t)|^2_{\mathbf{V}^0(\Gamma)} \Big)\, dt\,, \end{aligned}$$

the sequences $(\tilde{\mathbf{y}}_k)_k$ and $(\tilde{\mathbf{u}}_k)_k$ are respectively bounded in $L^2(0,\infty;\mathbf{V}_n^0(\Omega))$ and $L^2(0,\infty;\mathbf{V}^0(\Gamma))$. Thus there exist $\mathbf{y}_\infty \in L^2(0,\infty;\mathbf{V}_n^0(\Omega))$ and $\mathbf{u}_\infty \in L^2(0,\infty;\mathbf{V}^0(\Gamma))$ such that

$$\begin{aligned} &\tilde{\mathbf{u}}_k \rightharpoonup \mathbf{u}_\infty \quad \text{weakly in } L^2(0,\infty;\mathbf{V}^0(\Gamma)), \\ &\tilde{\mathbf{y}}_k \rightharpoonup \mathbf{y}_\infty \quad \text{weakly in } L^2(0,\infty;\mathbf{V}_n^0(\Omega)). \end{aligned}$$

By passing to the limit in the above inequality, we obtain

$$\begin{aligned} &\int_0^\infty \int_\Omega |\mathbf{y}_\infty|^2 \, dxdt + \int_0^\infty \Big(|\gamma_\tau \mathbf{u}_\infty(t)|^2_{\mathbf{V}^0(\Gamma)} + |R_A^{1/2}\gamma_n \mathbf{u}_\infty(t)|^2_{\mathbf{V}^0(\Gamma)} \Big)\, dt \\ &\leq \int_0^\infty \int_\Omega |\mathbf{y}_{\mathbf{y}_0}|^2 \, dxdt + \int_0^\infty \Big(|\gamma_\tau \mathbf{u}_{\mathbf{y}_0}(t)|^2_{\mathbf{V}^0(\Gamma)} + |R_A^{1/2}\gamma_n \mathbf{u}_{\mathbf{y}_0}(t)|^2_{\mathbf{V}^0(\Gamma)} \Big)\, dt\,. \end{aligned}$$

And by passing to the limit in the equation satisfied by $(\mathbf{y}_k, \mathbf{u}_k)$, we have

$$\mathbf{y}_\infty' = A\mathbf{y}_\infty + BM\mathbf{u}_\infty \quad \text{in } (0,\infty), \qquad \mathbf{y}_\infty(0) = \mathbf{y}_0.$$

Thus the pair $(\mathbf{y}_\infty, \mathbf{u}_\infty)$ is admissible, and we have

$$(\mathbf{y}_\infty, \mathbf{u}_\infty) = (\mathbf{y}_{\mathbf{y}_0}, \mathbf{u}_{\mathbf{y}_0}),$$

because $I(\mathbf{y}_\infty, \mathbf{u}_\infty) \leq I(\mathbf{y}_{\mathbf{y}_0}, \mathbf{u}_{\mathbf{y}_0})$. Therefore we can claim that

$$\tilde{\mathbf{u}}_k \to \mathbf{y}_{\mathbf{y}_0} \quad \text{in } L^2(0,\infty;\mathbf{V}^0(\Gamma)) \quad \text{and} \quad \tilde{\mathbf{y}}_k \to \mathbf{u}_{\mathbf{y}_0} \quad \text{in } L^2(0,\infty;\mathbf{V}_n^0(\Omega)).$$

Since

$$I_k(0, \mathbf{y}_k, \mathbf{u}_k) = \frac{1}{2}\Big(\widehat{\Pi}(k)\mathbf{y}_0, \mathbf{y}_0\Big)_{\mathbf{V}_n^0(\Omega)},$$

by passing to the limit when k tends to infinity, we obtain

$$I(\mathbf{y}_{\mathbf{y}_0}, \mathbf{u}_{\mathbf{y}_0}) = \frac{1}{2}\Big(\Pi \mathbf{y}_0, \mathbf{y}_0\Big)_{\mathbf{V}_n^0(\Omega)}. \qquad \square$$

We denote by $\varphi(\mathbf{y}_0)$ the value function of problem $(\mathcal{P}_{0,\mathbf{y}_0})$, that is,

$$\varphi(\mathbf{y}_0) = I(\mathbf{y}_{\mathbf{y}_0}, \mathbf{u}_{\mathbf{y}_0}).$$

LEMMA 4.2. *For every $\mathbf{y}_0 \in \mathbf{V}_n^0(\Omega)$, the system*

$$\begin{aligned} &\mathbf{y}' = A\mathbf{y} - B_\tau M^2 B_\tau^* \mathbf{\Phi} - B_n M R_A^{-1} M B_n^* \mathbf{\Phi} \quad \text{in } (0,\infty), \qquad \mathbf{y}(0) = \mathbf{y}_0, \\ &-\mathbf{\Phi}' = A^* \mathbf{\Phi} + \mathbf{y} \quad \text{in } (0,\infty), \qquad \mathbf{\Phi}(\infty) = 0, \\ &\mathbf{\Phi}(t) = \Pi \mathbf{y}(t) \quad \text{for all } t \in (0,\infty), \end{aligned} \tag{4.4}$$

admits a unique solution in $L^2(0,\infty;\mathbf{V}_n^0(\Omega)) \times \mathbf{V}^{2,1}(Q_\infty)$. This solution belongs to $C_b(\mathbb{R}^+;\mathbf{V}_n^0(\Omega)) \cap \mathbf{V}^{1,1/2}(Q_\infty) \times \mathbf{V}^{3,3/2}(Q_\infty)$, and it satisfies

$$\|\mathbf{y}\|_{C_b(\mathbb{R}^+;\mathbf{V}_n^0(\Omega))} + \|\mathbf{y}\|_{\mathbf{V}^{1,1/2}(Q_\infty)} + \|\mathbf{\Phi}\|_{\mathbf{V}^{3,3/2}(Q_\infty)} \le C|\mathbf{y}_0|_{\mathbf{V}_n^0(\Omega)}.$$

The pair $(\mathbf{y}, -MB_\tau^*\mathbf{\Phi} - R_A^{-1}MB_n^*\mathbf{\Phi})$ is the solution of $(\mathcal{P}_{0,\mathbf{y}_0})$.

Proof. For notational simplicity the solution to $(\mathcal{P}_{0,\mathbf{y}_0})$ will now be denoted by $(\hat{\mathbf{y}}, \hat{\mathbf{u}})$. We denote by $\varphi_k(0,\mathbf{y}_0)$ the value function of problem $(\mathcal{P}^k_{0,\mathbf{y}_0})$ and by $\varphi_k(\bar{t},\zeta)$ the value function of problem $(\mathcal{P}^k_{\bar{t},\zeta})$.

Let $(\mathbf{y}_k^{\bar{t}}, \mathbf{u}_k^{\bar{t}})$ be the solution of $(\mathcal{P}^k_{\bar{t},\mathbf{y}_k(\bar{t})})$, and let $(\mathbf{y}_k, \mathbf{u}_k)$ be the solution of $(\mathcal{P}^k_{0,\mathbf{y}_0})$ characterized by (4.3). Denote by $\mathbf{\Phi}_k^{\bar{t}}$ the adjoint state corresponding to $(\mathbf{y}_k^{\bar{t}}, \mathbf{u}_k^{\bar{t}})$, and by $\mathbf{\Phi}_k$ the adjoint state corresponding to $(\mathbf{y}_k, \mathbf{u}_k)$. From the dynamic programming principle it follows that $(\mathbf{y}_k^{\bar{t}}, \mathbf{u}_k^{\bar{t}}, \mathbf{\Phi}_k^{\bar{t}})(t) = (\mathbf{y}_k, \mathbf{u}_k, \mathbf{\Phi}_k)(t)$ for all $t \in (\bar{t}, k)$. Therefore we have $\mathbf{\Phi}_k^{\bar{t}}(\bar{t}) = \mathbf{\Phi}_k(\bar{t}) \in \partial_y \varphi_k(\bar{t}, \mathbf{y}_k(\bar{t}))$; that is, $\mathbf{\Phi}_k(\bar{t}) = \widehat{\Pi}(k-\bar{t})\mathbf{y}_k(\bar{t})$. Thus

$$|\mathbf{\Phi}_k(\bar{t})|_{\mathbf{V}_n^0(\Omega)} \le \|\widehat{\Pi}(k-\bar{t})\| |\mathbf{y}_k(\bar{t})|_{\mathbf{V}_n^0(\Omega)} \le C|\mathbf{y}_k(\bar{t})|_{\mathbf{V}_n^0(\Omega)}$$

and

$$\|\tilde{\mathbf{\Phi}}_k\|_{L^2(0,\infty;\mathbf{V}_n^0(\Omega))} \le C\|\tilde{\mathbf{y}}_k\|_{L^2(0,\infty;\mathbf{V}_n^0(\Omega))},$$

where $\tilde{\mathbf{\Phi}}_k$ (respectively, $\tilde{\mathbf{y}}_k$) is the extension by zero of $\mathbf{\Phi}_k$ (respectively, $\mathbf{y}_k$) to (k,∞). In the proof of Theorem 4.1 we have shown that $(\tilde{\mathbf{y}}_k)_k$ is bounded in $L^2(0,\infty;\mathbf{V}_n^0(\Omega))$ and that it converges to $\hat{\mathbf{y}}$ in $L^2(0,\infty;\mathbf{V}_n^0(\Omega))$. Therefore $(\tilde{\mathbf{\Phi}}_k)_k$ is also bounded in $L^2(0,\infty;\mathbf{V}_n^0(\Omega))$. Observe that $\tilde{\mathbf{\Phi}}_k$ is also the solution of the equation

$$-\tilde{\mathbf{\Phi}}_k' = (A^* - \lambda_0 I)\tilde{\mathbf{\Phi}}_k + \tilde{\mathbf{y}}_k + \lambda_0 \tilde{\mathbf{\Phi}}_k, \qquad \tilde{\mathbf{\Phi}}_k(\infty) = 0.$$

Thus

$$\tilde{\mathbf{\Phi}}_k(t) = \int_t^\infty e^{(A^* - \lambda_0 I)(\tau - t)}(\tilde{\mathbf{y}}_k(\tau) + \lambda_0 \tilde{\mathbf{\Phi}}_k(\tau))\, d\tau \qquad \text{for all } t \ge 0.$$

From Young's inequality for convolutions it follows that $(\tilde{\mathbf{\Phi}}_k)_k$ is also bounded in $L^\infty(0,\infty;\mathbf{V}_n^0(\Omega))$. There then exists $\hat{\mathbf{\Phi}} \in L^\infty(0,\infty;\mathbf{V}_n^0(\Omega)) \cap L^2(0,\infty;\mathbf{V}_n^0(\Omega))$ such that, after extraction of a subsequence, we have

$$\tilde{\mathbf{\Phi}}_k \rightharpoonup \hat{\mathbf{\Phi}} \quad \text{weakly in } L^2(0,\infty;\mathbf{V}_n^0(\Omega)) \quad \text{and} \quad \text{weak-star in } L^\infty(0,\infty;\mathbf{V}_n^0(\Omega)),$$

and $\hat{\mathbf{\Phi}}$ obeys the equation

$$\hat{\mathbf{\Phi}}(t) = \int_t^\infty e^{(A^*-\lambda_0 I)(\tau-t)}(\hat{\mathbf{y}}(\tau) + \lambda_0\hat{\mathbf{\Phi}}(\tau))\,d\tau \qquad \text{for all } t \geq 0.$$

Step 1. *Regularity of* $\hat{\mathbf{\Phi}}$. We have

$$-\hat{\mathbf{\Phi}}' = (A^* - \lambda_0 I)\hat{\mathbf{\Phi}} + \lambda_0\hat{\mathbf{\Phi}} + \hat{\mathbf{y}} \quad \text{in } (0,\infty), \qquad \hat{\mathbf{\Phi}}(\infty) = 0\,.$$

Since $\hat{\mathbf{\Phi}}$ belongs to $L^2(0,\infty;\mathbf{V}_n^0(\Omega))$, we deduce that $\hat{\mathbf{\Phi}}$ belongs to $L^2(0,\infty;\mathbf{V}_0^1(\Omega)) \cap \mathbf{V}^{2,1}(Q_\infty)$ (see Lemma 8.5). Moreover, due to Lemma 8.9, the sequence $(\tilde{\mathbf{u}}_k)_k = (-MB_\tau^*\tilde{\mathbf{\Phi}}_k - R_A^{-1}MB_n^*\tilde{\mathbf{\Phi}}_k)_k$ converges weakly in $L^2(0,\infty;\mathbf{V}^0(\Gamma))$ to $-MB_\tau^*\hat{\mathbf{\Phi}} - R_A^{-1}MB_n^*\hat{\mathbf{\Phi}}$. Thus $\hat{\mathbf{u}} = -MB_\tau^*\hat{\mathbf{\Phi}} - R_A^{-1}MB_n^*\hat{\mathbf{\Phi}}$, and $(\hat{\mathbf{y}},\hat{\mathbf{\Phi}})$ obeys the first two equations in (4.4).

Step 2. Let us show that if $(\mathbf{y},\mathbf{\Phi}) \in L^2(0,\infty;\mathbf{V}_n^0(\Omega)) \times \mathbf{V}^{2,1}(Q_\infty)$ is a solution to system (4.4), then $\mathbf{y}$ belongs $C_b([0,\infty);\mathbf{V}_n^0(\Omega) \cap \mathbf{V}^{1,1/2}(Q_\infty)$, $\mathbf{\Phi} \in \mathbf{V}^{3,3/2}(Q_\infty)$, and

$$\begin{aligned} &\|\mathbf{y}\|_{C_b([0,\infty);\mathbf{V}_n^0(\Omega))} + \|\mathbf{y}\|_{\mathbf{V}^{1,1/2}(Q_\infty)} + \|\mathbf{\Phi}\|_{\mathbf{V}^{3,3/2}(Q_\infty)} \\ &\leq C(|\mathbf{y}_0|_{\mathbf{V}_n^0(\Omega)} + \|\mathbf{y}\|_{L^2(0,\infty;\mathbf{V}_n^0(\Omega))} + \|\mathbf{\Phi}\|_{L^2(0,\infty;\mathbf{V}_n^0(\Omega))})\,. \end{aligned} \tag{4.5}$$

To establish this result we rewrite system (4.4) as follows:

$$\begin{aligned} &\mathbf{y}' = (A - \lambda_0 I)\mathbf{y} - B_\tau M^2 B_\tau^*\mathbf{\Phi} - B_n M R_A^{-1} M B_n^*\mathbf{\Phi} + \lambda_0\mathbf{y} \quad \text{in } (0,\infty), \qquad \mathbf{y}(0) = \mathbf{y}_0, \\ &-\mathbf{\Phi}' = (A^* - \lambda_0 I)\mathbf{\Phi} + \mathbf{y} + \lambda_0\mathbf{\Phi} \quad \text{in } (0,\infty), \qquad \mathbf{\Phi}(\infty) = 0. \end{aligned} \tag{4.6}$$

Due to Lemma 8.9 we know that $B^*\mathbf{\Phi} \in L^2(0,\infty;\mathbf{V}^0(\Gamma))$. Applying Lemmas 8.1 and 8.3, we obtain

$$\|\mathbf{y}\|_{\mathbf{V}^{1/2-\varepsilon',1/4-\varepsilon'/2}(Q_\infty)} \leq C(|\mathbf{y}_0|_{\mathbf{V}_n^0(\Omega)} + \|\mathbf{y}\|_{L^2(0,\infty;\mathbf{V}_n^0(\Omega))} + \|\mathbf{\Phi}\|_{L^2(0,\infty;\mathbf{V}_n^0(\Omega))}) \quad \text{for all } \varepsilon' > 0.$$

Still from Lemma 8.9, we deduce that $B^*\mathbf{\Phi} \in \mathbf{V}^{1/2-\varepsilon',1/4-\varepsilon'/2}(\Sigma_\infty)$ for all $\varepsilon' > 0$. Applying successively Lemmas 8.1, 8.3, and 8.9, we can prove that $\mathbf{y}$ belongs to $\mathbf{V}^{1-\varepsilon',1/2-\varepsilon'/2}(Q_\infty)$ and $B^*\mathbf{\Phi}$ belongs to $\mathbf{V}^{1-\varepsilon',1/2-\varepsilon'/2}(\Sigma_\infty)$ for all $\varepsilon' > 0$. Another iteration gives $\mathbf{y} \in \mathbf{V}^{1,1/2}(Q_\infty) \cap C_b([0,\infty);\mathbf{V}_n^0(\Omega))$ (because $\mathbf{y}_0 \in \mathbf{V}_n^0(\Omega)$). From Lemma 8.5 we deduce that $\mathbf{\Phi} \in \mathbf{V}^{3,3/2}(Q_\infty)$, and the estimate (4.5) holds true.

Step 3. *We show that the pair* $(\hat{\mathbf{y}},\hat{\mathbf{\Phi}})$ *obeys the third equation in* (4.4). With Lemma 8.5 we can show that

$$\tilde{\mathbf{\Phi}}_k(t) \rightharpoonup \hat{\mathbf{\Phi}}(t) \quad \text{weakly in } \mathbf{V}_n^0(\Omega) \qquad \text{for all } t \geq 0.$$

Since

$$\mathbf{\Phi}_k(t) \in \partial_{\mathbf{y}}\varphi_k(t,\mathbf{y}_k(t)), \qquad \mathbf{\Phi}_k(t) \rightharpoonup \hat{\mathbf{\Phi}}(t) \quad \text{weakly in } \mathbf{V}_n^0(\Omega),$$

and

$$\varphi_k(t,\mathbf{y}_k(t)) \to \varphi(\hat{\mathbf{y}}(t)) \quad \text{as } k \to \infty,$$

we deduce that

$$\hat{\mathbf{\Phi}}(t) \in \partial\varphi(\hat{\mathbf{y}}(t)), \quad \text{i.e.,} \quad \hat{\mathbf{\Phi}}(t) = \Pi\hat{\mathbf{y}}(t).$$

Thus we have shown that $(\hat{\mathbf{y}},\hat{\mathbf{\Phi}})$ obeys the third equation in (4.4).

Step 4. *Uniqueness.* If a solution $(\mathbf{y}, \mathbf{\Phi}) \in L^2(0,\infty;\mathbf{V}_n^0(\Omega)) \times \mathbf{V}^{2,1}(Q_\infty)$ is a solution to system (4.4), due to Step 2 it obeys (4.5), and we can show that

$$\int_0^k |\mathbf{y}(t)|^2_{\mathbf{V}_n^0(\Omega)}dt + \int_0^k |MB_\tau^*\mathbf{\Phi}(t)|^2_{\mathbf{V}^0(\Gamma)}dt + \int_0^k |R_A^{-1}MB_n^*\mathbf{\Phi}(t)|^2_{\mathbf{V}^0(\Gamma)}dt$$
$$= \int_\Omega \mathbf{y}_0\mathbf{\Phi}(0) - \int_\Omega \mathbf{y}(k)\mathbf{\Phi}(k).$$

Passing to the limit when k tends to infinity, we obtain

$$\int_0^\infty |\mathbf{y}(t)|^2_{\mathbf{V}_n^0(\Omega)}dt + \int_0^\infty |MB_\tau^*\mathbf{\Phi}(t)|^2_{\mathbf{V}^0(\Gamma)}dt + \int_0^\infty |R_A^{-1}MB_n^*\mathbf{\Phi}(t)|^2_{\mathbf{V}^0(\Gamma)}dt = \int_\Omega \mathbf{y}_0\mathbf{\Phi}(0).$$

Thus if $\mathbf{y}_0 = 0$, we have $\mathbf{y} = 0$. From the relation $\mathbf{\Phi} = \Pi\mathbf{y}$ we deduce that $\mathbf{\Phi} = 0$, and the uniqueness is established.

Step 5. *Final estimate.* From the previous steps it follows that $(\hat{\mathbf{y}}, \hat{\mathbf{\Phi}})$ is the unique solution to system (4.4). Since $\|\hat{\mathbf{y}}\|_{L^2(0,\infty;\mathbf{V}_n^0(\Omega))} \le C|\mathbf{y}_0|_{\mathbf{V}_n^0(\Omega)}$, we have

$$\|\hat{\mathbf{\Phi}}\|_{L^2(0,\infty;\mathbf{V}_n^0(\Omega))} \le C|\mathbf{y}_0|_{\mathbf{V}_n^0(\Omega)},$$

and the estimate of the lemma follows from (4.5). ∎

COROLLARY 4.3. *If* $\mathbf{y}_0 \in \mathbf{V}_n^{1/2-\varepsilon}(\Omega)$ *for some* $0 < \varepsilon \le 1/2$, *then the solution* $(\mathbf{y}, \mathbf{\Phi})$ *of system* (4.4) *belongs to* $\mathbf{V}^{3/2-\varepsilon,3/4-\varepsilon/2}(Q_\infty) \times \mathbf{V}^{7/2-\varepsilon,7/4-\varepsilon/2}(Q_\infty)$, *and we have*

$$\|\mathbf{y}\|_{\mathbf{V}^{3/2-\varepsilon,3/4-\varepsilon/2}(Q_\infty)} + \|\mathbf{\Phi}\|_{\mathbf{V}^{7/2-\varepsilon,7/4-\varepsilon/2}(Q_\infty)} + \|B^*\mathbf{\Phi}\|_{\mathbf{V}^{3/2-\varepsilon,3/4-\varepsilon/2}(Q_\infty)}$$
$$\le C|\mathbf{y}_0|_{\mathbf{V}_n^{1/2-\varepsilon}(\Omega)}.$$

Proof. With Lemmas 4.2 and 8.9, we first prove that $\mathbf{u} \in \mathbf{V}^{1,1/2}(\Sigma_\infty)$. Applying Lemmas 8.1 and 8.3, it follows that $\mathbf{y}$ belongs to $\mathbf{V}^{3/2-\varepsilon,3/4-\varepsilon/2}(Q_\infty)$. The estimate for $\mathbf{\Phi}$ follows from Lemma 8.5, and we deduce that $B^*\mathbf{\Phi} \in \mathbf{V}^{3/2-\varepsilon,3/4-\varepsilon/2}(Q_\infty)$ with Lemma 8.9. ∎

Remark 4.4. Due to Lemma 4.2, if $\mathbf{y}_0 \in \mathbf{V}_n^0(\Omega)$, then $\mathbf{\Phi}$ belongs to $C([0,T];\mathbf{V}^2(\Omega) \cap \mathbf{V}_0^1(\Omega))$. In particular, $\mathbf{\Phi}(0)$ belongs to $\mathbf{V}^2(\Omega) \cap \mathbf{V}_0^1(\Omega)$. From Corollary 4.3 we deduce that if $\mathbf{y}_0 \in \mathbf{V}_n^{1/2-\varepsilon}(\Omega)$, then $\mathbf{\Phi} \in C([0,T];\mathbf{V}^{5/2-\varepsilon}(\Omega) \cap \mathbf{V}_0^1(\Omega))$ and $\mathbf{\Phi}(0)$ belongs to $\mathbf{V}^{5/2-\varepsilon}(\Omega) \cap \mathbf{V}_0^1(\Omega)$. This means that Π belongs to $\mathcal{L}(\mathbf{V}_n^0(\Omega), \mathbf{V}^2(\Omega) \cap \mathbf{V}_0^1(\Omega))$, and Π also belongs to $\mathcal{L}(\mathbf{V}_n^{1/2-\varepsilon}(\Omega), \mathbf{V}^{5/2-\varepsilon}(\Omega) \cap \mathbf{V}_0^1(\Omega))$.

Since B^* is continuous from $\mathbf{V}^2(\Omega) \cap \mathbf{V}_0^1(\Omega)$ into $\mathbf{V}^{1/2}(\Gamma)$ (see Proposition 2.7), the operator $B^*\Pi$ belongs to $\mathcal{L}(\mathbf{V}_n^0(\Omega), \mathbf{V}^{1/2}(\Gamma))$, and $B^*\Pi$ also belongs to $\mathcal{L}(\mathbf{V}_n^{1/2-\varepsilon}(\Omega), \mathbf{V}^{1-\varepsilon}(\Gamma))$ for all $\varepsilon > 0$.

From Lemma 4.2 it follows that, for all $\mathbf{y}_0 \in \mathbf{V}_n^0(\Omega)$, the evolution equation

$$\mathbf{y}' = A\mathbf{y} - B_\tau M^2 B_\tau^*\Pi\mathbf{y} - B_n M R_A^{-1} M B_n^*\Pi\mathbf{y} \quad \text{in } (0,\infty), \qquad \mathbf{y}(0) = \mathbf{y}_0, \tag{4.7}$$

admits at least one weak solution belonging to $L^2(0,\infty;\mathbf{V}_n^0(\Omega)) \cap C_b(\mathbb{R};\mathbf{V}_n^0(\Omega))$. It is easy to show that this solution is unique. Due to Lemma 4.2, it is equal to $\mathbf{y}_{\mathbf{y}_0}$, where $(\mathbf{y}_{\mathbf{y}_0}, \mathbf{u}_{\mathbf{y}_0})$ is the solution of $(\mathcal{P}_{0,\mathbf{y}_0})$. Still from Lemma 4.2, we deduce that the family of operators $(S(t))_{t\ge0}$ defined by

$$S(t) \ : \ \mathbf{y}_0 \longmapsto \mathbf{y}_{\mathbf{y}_0}(t)$$

is a strongly continuous exponentially stable semigroup on $\mathbf{V}_n^0(\Omega)$. Let $(A_\Pi, D(A_\Pi))$ be its infinitesimal generator, and let us denote by $(e^{tA_\Pi})_{t\geq 0}$ the semigroup $(S(t))_{t\geq 0}$. Since the semigroup $(e^{tA_\Pi})_{t\geq 0}$ is exponentially stable on $\mathbf{V}_n^0(\Omega)$, we can define $D(A_\Pi)$ by

$$D(A_\Pi) = \left\{ \mathbf{y} \in \mathbf{V}_n^0(\Omega) \mid \mathbf{y} = -\int_0^\infty e^{\tau A_\Pi}\mathbf{f}\, d\tau \text{ for some } \mathbf{f} \in \mathbf{V}_n^0(\Omega) \right\},$$

and $A_\Pi \mathbf{y} = \mathbf{f}$ if $\mathbf{y} = -\int_0^\infty e^{\tau A_\Pi}\mathbf{f}\, d\tau \in D(A_\Pi)$.

We want to find a more explicit characterization of $D(A_\Pi)$ and A_Π. From Remark 4.4, it follows that the operator $A - BMR_A^{-1}MB^*\Pi$ may be considered as a bounded operator from $\mathbf{V}_n^0(\Omega)$ into $(D(A_0))'$, the dual of $D(A_0)$ with respect to the pivot space $\mathbf{V}_n^0(\Omega)$. We want to prove that

$$D(A_\Pi) = \left\{ \mathbf{y} \in \mathbf{V}_n^0(\Omega) \mid A - BMR_A^{-1}MB^*\Pi \in \mathbf{V}_n^0(\Omega) \right\}. \tag{4.8}$$

For that we are going to use the characterization of $(A_\Pi^*, D(A_\Pi^*))$, the adjoint of $(A_\Pi, D(A_\Pi))$. Let us define the unbounded operator $(A_\Pi^\sharp, D(A_\Pi^\sharp))$ in $\mathbf{V}_n^0(\Omega)$ by

$$D(A_\Pi^\sharp) = D(A_0) \quad \text{and} \quad A_\Pi^\sharp \mathbf{\Phi} = A^*\mathbf{\Phi} - (B^*\Pi)^* MR_A^{-1}MB^*\mathbf{\Phi} \quad \text{for all } \mathbf{\Phi} \in D(A_\Pi^\sharp),$$

where $(B^*\Pi)^* \in \mathcal{L}(\mathbf{V}^{-1/2}(\Gamma), \mathbf{V}_n^0(\Omega))$ is the adjoint of $B^*\Pi \in \mathcal{L}(\mathbf{V}_n^0(\Omega), \mathbf{V}^{1/2}(\Gamma))$. We know that $(A^* - \lambda_0 I, D(A^*))$ is the infinitesimal generator of a bounded analytic semigroup on $\mathbf{V}_n^0(\Omega)$. Let $(L, D(L))$ be the unbounded operator in $\mathbf{V}_n^0(\Omega)$ defined by $D(L) = \mathbf{V}^{3/2+\varepsilon}(\Omega) \cap \mathbf{V}_0^1(\Omega)$ with $0 < \varepsilon < 1/2$, and $L\mathbf{\Phi} = (B^*\Pi)^* MR_A^{-1}MB^*\mathbf{\Phi}$. We can easily verify that L is $(A^* - \lambda_0 I)$-bounded with relative bound zero. From [21, Corollary 2.5, p. 500] it follows that $(A_\Pi^\sharp - \lambda_0 I, D(A_0))$ is the infinitesimal generator of a quasi-bounded analytic semigroup on $\mathbf{V}_n^0(\Omega)$. Thus $(A_\Pi^\sharp, D(A_0))$ is also the infinitesimal generator of an analytic semigroup on $\mathbf{V}_n^0(\Omega)$. Consider the equations

$$\mathbf{\Phi}' = A_\Pi^\sharp \mathbf{\Phi}, \qquad \mathbf{\Phi}(0) = \mathbf{\Phi}_0, \tag{4.9}$$

and

$$-\hat{\mathbf{\Phi}}' = A_\Pi^\sharp \hat{\mathbf{\Phi}}, \qquad \hat{\mathbf{\Phi}}(T) = \mathbf{\Phi}_0. \tag{4.10}$$

We clearly have $\mathbf{\Phi}(T-t) = \hat{\mathbf{\Phi}}(t)$ for all $t \in [0,T]$. If $\mathbf{\Phi}_0 \in D(A_0)$, then the solution $\mathbf{\Phi}$ to (4.9) belongs to $C([0,T]; D(A_0)) \cap C^1([0,T]; D(A_0))$. With (4.7) and (4.10), we can show that

$$\left(\mathbf{y}_0, e^{TA_\Pi^\sharp}\mathbf{\Phi}_0\right)_{\mathbf{V}_n^0(\Omega)} = \left(e^{TA_\Pi}\mathbf{y}_0, \mathbf{\Phi}_0\right)_{\mathbf{V}_n^0(\Omega)} = \left(\mathbf{y}_0, e^{TA_\Pi^*}\mathbf{\Phi}_0\right)_{\mathbf{V}_n^0(\Omega)}$$

for all $\mathbf{y}_0 \in \mathbf{V}_n^0(\Omega)$, $\mathbf{\Phi}_0 \in \mathbf{V}_n^0(\Omega)$, and $T > 0$. Thus the two semigroups $\left(e^{TA_\Pi^\sharp}\right)_{t\geq 0}$ and $\left(e^{TA_\Pi^*}\right)_{t\geq 0}$ on $\mathbf{V}_n^0(\Omega)$ are identical, and we have $(A_\Pi^\sharp, D(A_0)) = (A_\Pi^*, D(A_\Pi^*))$. For all $\mathbf{g} \in \mathbf{V}_n^0(\Omega)$, the equation $A_\Pi^*\mathbf{\Phi} = \mathbf{g}$ admits $-\int_0^\infty e^{\tau A_\Pi^*}\mathbf{g}\, d\tau$ as unique solution in $D(A_\Pi^*)$. Thus, for all $\mathbf{g} \in \mathbf{V}_n^0(\Omega)$, the solution $-\int_0^\infty e^{\tau A_\Pi^*}\mathbf{g}\, d\tau$ to the equation $A_\Pi^*\mathbf{\Phi} = A_\Pi^\sharp\mathbf{\Phi} = \mathbf{g}$ belongs to $D(A_0)$.

Let us come back to the characterization of $D(A_\Pi)$. Let $\mathbf{y}$ be in $D(A_\Pi)$, and set $A_\Pi\mathbf{y} = \mathbf{f}$. Setting $\mathbf{z}(t) = -\int_0^t e^{\tau A_\Pi}\mathbf{f}\, d\tau = -\int_0^t e^{(t-s)A_\Pi}\mathbf{f}\, ds$, using the definition of

weak solution for $\mathbf{z}$, by passing to the limit when t tends to infinity, we can show that $\mathbf{y}$ satisfies the equation

$$A\mathbf{y} - BMR_A^{-1}MB^*\Pi\mathbf{y} = \mathbf{f}, \tag{4.11}$$

where $\mathbf{f} = A_\Pi\mathbf{y}$. Thus

$$D(A_\Pi) \subset \Big\{\mathbf{y} \in \mathbf{V}_n^0(\Omega) \mid A - BMR_A^{-1}MB^*\Pi \in \mathbf{V}_n^0(\Omega)\Big\}.$$

In (4.11), $A\mathbf{y} - BMR_A^{-1}MB^*\Pi\mathbf{y}$ is considered as an element in $(D(A_0))'$. This means that $\mathbf{y}$ is a solution to (4.11) if and only if

$$\int_\Omega \mathbf{y}A^*\mathbf{\Phi} - \int_\Gamma MR_A^{-1}MB^*\Pi\,\mathbf{y}\,B^*\mathbf{\Phi} = \int_\Omega \mathbf{y}A_\Pi^*\mathbf{\Phi} = \int_\Omega \mathbf{f}\,\mathbf{\Phi} \quad \text{for all } \mathbf{\Phi} \in D(A_0). \tag{4.12}$$

To prove (4.8), it is now sufficient to show that the solution to (4.11) or (4.12) is unique. Assume that $\mathbf{y} \in \mathbf{V}_n^0(\Omega)$ obeys (4.12) with $\mathbf{f} = 0$. If we take the solution $\mathbf{\Phi}$ of $A_\Pi^*\mathbf{\Phi} = \mathbf{y}$ in (4.12), we obtain $\int_\Omega |\mathbf{y}|^2 = 0$. Thus $\mathbf{y} = 0$, and the equality (4.8) is established.

THEOREM 4.5. *The unbounded operator $(A_\Pi, D(A_\Pi))$ defined by*

$$D(A_\Pi) = \Big\{\mathbf{y} \in \mathbf{V}_n^0(\Omega) \mid A - BMR_A^{-1}MB^*\Pi \in \mathbf{V}_n^0(\Omega)\Big\},$$
$$A_\Pi\mathbf{y} = A\mathbf{y} - BMR_A^{-1}MB^*\Pi\mathbf{y} \quad \textit{for all } \mathbf{y} \in D(A_\Pi),$$

is the infinitesimal generator of an analytic exponentially stable semigroup on $\mathbf{V}_n^0(\Omega)$.

The operator Π is the unique weak solution to the algebraic Riccati equation

$$\Pi^* = \Pi \in \mathcal{L}(\mathbf{V}_n^0(\Omega)) \quad \textit{and} \quad \Pi \geq 0,$$
$$\textit{for all } \mathbf{y} \in \mathbf{V}_n^0(\Omega), \qquad \Pi\mathbf{y} \in \mathbf{V}^2(\Omega) \cap \mathbf{V}_0^1(\Omega) \quad \textit{and} \quad |\Pi\mathbf{y}|_{\mathbf{V}^2(\Omega)} \leq C|\mathbf{y}|_{\mathbf{V}_n^0(\Omega)},$$
$$A^*\Pi + \Pi A - \Pi B_\tau M^2 B_\tau^*\Pi - \Pi B_n MR_A^{-1}MB_n^*\Pi + I = 0.$$

Moreover, $\Pi \in \mathcal{L}(\mathbf{V}_n^{1/2-\varepsilon}(\Omega); \mathbf{V}^{5/2-\varepsilon}(\Omega) \cap \mathbf{V}_0^1(\Omega))$.

Proof. The first part of the theorem is already proved. We have already shown that $\Pi^* = \Pi \geq 0$ and that $\Pi \in \mathcal{L}(\mathbf{V}_n^0(\Omega), \mathbf{V}^2(\Omega) \cap \mathbf{V}_0^1(\Omega))$. Since $\Pi \in \mathcal{L}(\mathbf{V}_n^0(\Omega), \mathbf{V}^2(\Omega) \cap \mathbf{V}_0^1(\Omega))$, it is relatively easy to prove that Π is the unique solution to the algebraic Riccati equation stated in the theorem. The uniqueness is shown in [23, Theorem 2.2.1] under a weaker condition than $\Pi \in \mathcal{L}(\mathbf{V}_n^0(\Omega), \mathbf{V}^2(\Omega) \cap \mathbf{V}_0^1(\Omega))$. □

5. Problems with a nonhomogeneous source term. For all $\bar{t} \geq 0$ and all $\mathbf{y}_0 \in \mathbf{V}_n^0(\Omega)$ we consider the problem

$$(\mathcal{P}_{\bar{t},\mathbf{y}_0,\mathbf{f}}) \qquad \inf\Big\{I(\bar{t},\mathbf{y},\mathbf{u}) \;\mid\; (\mathbf{y},\mathbf{u}) \text{ satisfies (5.1)},\ \mathbf{u} \in \mathbf{V}^{0,0}(\Sigma_{\bar{t},\infty})\Big\},$$

where

$$I(\bar{t},\mathbf{y},\mathbf{u}) = \frac{1}{2}\int_{\bar{t}}^\infty \int_\Omega |\mathbf{y}|^2\,dxdt + \frac{1}{2}\int_{\bar{t}}^\infty \Big(|\gamma_\tau\mathbf{u}(t)|^2_{\mathbf{V}^0(\Gamma)} + |R_A^{1/2}\gamma_n\mathbf{u}(t)|^2_{\mathbf{V}^0(\Gamma)}\Big)\,dt$$

and

$$\mathbf{y}' = A\mathbf{y} + BM\mathbf{u} + \mathbf{f} \quad \text{in } (\bar{t},\infty), \qquad \mathbf{y}(\bar{t}) = \mathbf{y}_0. \tag{5.1}$$

The function $\mathbf{f}$ belongs to $L^{2/(1+2\varepsilon)}(0,\infty;\mathbf{V}_n^0(\Omega))\cap L^2(0,\infty;(\mathbf{V}^{2\varepsilon}(\Omega))')$, with $0<\varepsilon<1/2$. In this section we want to study the regularity of solutions to the control problem $(\mathcal{P}_{0,\mathbf{y}_0,\mathbf{f}})$ according to the regularity of $\mathbf{y}_0$. This result will be used in the next section to study the local stabilization of the two-dimensional Navier–Stokes equations.

THEOREM 5.1. *For all $\bar t\ge 0$, $\mathbf{y}_0\in\mathbf{V}_n^0(\Omega)$, and $\mathbf{f}\in L^{2/(1+2\varepsilon)}(0,\infty;\mathbf{V}_n^0(\Omega))$, problem $(\mathcal{P}_{\bar t,\mathbf{y}_0,\mathbf{f}})$ admits a unique solution $(\mathbf{y}_{\bar t,\mathbf{y}_0,\mathbf{f}},\mathbf{u}_{\bar t,\mathbf{y}_0,\mathbf{f}})$, and the optimal cost $\varphi(\bar t,\mathbf{y}_0,\mathbf{f})=J(\bar t,\mathbf{y}_{\bar t,\mathbf{y}_0,\mathbf{f}},\mathbf{u}_{\bar t,\mathbf{y}_0,\mathbf{f}})$ obeys*

$$\varphi(\bar t,\mathbf{y}_0,\mathbf{f})\le C\Big(|\mathbf{y}_0|^2_{\mathbf{V}_n^0(\Omega)}+\|\mathbf{f}\|^2_{L^{2/(1+2\varepsilon)}(\bar t,\infty;\mathbf{V}_n^0(\Omega))}\Big),\tag{5.2}$$

where the constant C is independent of $\bar t$.

Proof. The semigroup generated by A_Π on $\mathbf{V}_n^0(\Omega)$ is analytic and exponentially stable. Thus the solution to the equation

$$\mathbf{z}'=A_\Pi\mathbf{z}+\mathbf{f},\qquad \mathbf{z}(\bar t)=\mathbf{y}_0,$$

is defined by

$$\mathbf{z}(t)=e^{(t-\bar t)A_\Pi}\mathbf{y}_0+\int_{\bar t}^t e^{(t-\tau)A_\Pi}\mathbf{f}(\tau)\,d\tau,$$

and it obeys

$$|\mathbf{z}(t)|_{\mathbf{V}_n^0(\Omega)}\le Ce^{-\omega(t-\bar t)}|\mathbf{y}_0|_{\mathbf{V}_n^0(\Omega)}+C\int_{\bar t}^t e^{-\omega(t-\tau)}|\mathbf{f}(\tau)|_{\mathbf{V}_n^0(\Omega)}\,d\tau,$$

for some $C>0$ and some $\omega>0$. It follows that

$$\|\mathbf{z}\|_{L^2(\bar t,\infty;\mathbf{V}_n^0(\Omega))}\le C\big(|\mathbf{y}_0|_{\mathbf{V}_n^0(\Omega)}+\|\mathbf{f}\|_{L^{2/(1+2\varepsilon)}(\bar t,\infty;\mathbf{V}_n^0(\Omega))}\big),$$

where the constant C is independent of $\bar t$. Since $MB_\tau^*\Pi$ and $R_A^{-1}MB_n^*\Pi$ are bounded operators from $\mathbf{V}_n^0(\Omega)$ into $\mathbf{V}^0(\Gamma)$ (see Remark 4.4 and Lemma 2.5), we also have

$$\begin{aligned}&\|MB_\tau^*\Pi\mathbf{z}\|_{L^2(\bar t,\infty;\mathbf{V}^0(\Gamma))}+\|R_A^{-1}MB_n^*\Pi\mathbf{z}\|_{L^2(\bar t,\infty;\mathbf{V}^0(\Gamma))}\\&\quad\le C\big(|\mathbf{y}_0|_{\mathbf{V}_n^0(\Omega)}+\|\mathbf{f}\|_{L^{2/(1+2\varepsilon)}(\bar t,\infty;\mathbf{V}_n^0(\Omega))}\big).\end{aligned}$$

The pair $(\mathbf{z},-MB_\tau^*\Pi\mathbf{z}-R_A^{-1}MB_n^*\Pi\mathbf{z})$ is admissible for $(\mathcal{P}_{\bar t,\mathbf{y}_0,\mathbf{f}})$, and we have

$$I(\bar t,\mathbf{z},-MB_\tau^*\Pi\mathbf{z}-R_A^{-1}MB_n^*\Pi\mathbf{z})\le C\big(|\mathbf{y}_0|^2_{\mathbf{V}_n^0(\Omega)}+\|\mathbf{f}\|^2_{L^{2/(1+2\varepsilon)}(\bar t,\infty;\mathbf{V}_n^0(\Omega))}\big).$$

Therefore by classical arguments we can prove that $(\mathcal{P}_{\bar t,\mathbf{y}_0,\mathbf{f}})$ admits a unique solution $(\mathbf{y}_{\bar t,\mathbf{y}_0,\mathbf{f}},\mathbf{u}_{\bar t,\mathbf{y}_0,\mathbf{f}})$ and that the optimal cost $\varphi(\bar t,\mathbf{y}_0,\mathbf{f})=J(\bar t,\mathbf{y}_{\bar t,\mathbf{y}_0,\mathbf{f}},\mathbf{u}_{\bar t,\mathbf{y}_0,\mathbf{f}})$ obeys (5.2). ∎

LEMMA 5.2. *For all $\mathbf{u}\in L^2(0,\infty;\mathbf{V}^0(\Gamma))$, $\mathbf{y}\in L^2(0,\infty;\mathbf{V}_n^0(\Omega))$, the equation*

$$-\mathbf{\Phi}'=A_\Pi^*\mathbf{\Phi}-(MB_\tau^*\Pi)^*\gamma_\tau\mathbf{u}-(R_A^{-1}MB_n^*\Pi)^*\gamma_n\mathbf{u}+\mathbf{y}\quad\text{in }(0,\infty),\qquad\mathbf{\Phi}(\infty)=0,\tag{5.3}$$

admits a unique solution in $L^2(0,\infty;\mathbf{V}_n^0(\Omega))$ and

$$\|\mathbf{\Phi}\|_{L^2(0,\infty;\mathbf{V}_n^0(\Omega))}+\|\mathbf{\Phi}\|_{L^\infty(0,\infty;\mathbf{V}_n^0(\Omega))}\le C(\|\mathbf{y}\|_{L^2(0,\infty;\mathbf{V}_n^0(\Omega))}+\|\mathbf{u}\|_{L^2(0,\infty;\mathbf{V}^0(\Gamma))}).$$

Proof. We already know that $(MB_\tau^*\Pi)^* \in \mathcal{L}(\mathbf{V}^0(\Gamma), \mathbf{V}_n^0(\Omega))$ and $(R_A^{-1}MB_n^*\Pi)^* \in \mathcal{L}(\mathbf{V}^0(\Gamma), \mathbf{V}_n^0(\Omega))$. Thus from the exponential stability of the semigroup $(e^{tA_\Pi^*})_{t\geq 0}$ we find

$$|\mathbf{\Phi}(t)|_{\mathbf{V}_n^0(\Omega)} \leq C\int_t^\infty e^{-\omega(\tau-t)}(|\mathbf{y}(\tau)|_{\mathbf{V}_n^0(\Omega)} + |\mathbf{u}(\tau)|_{\mathbf{V}^0(\Gamma)})d\tau.$$

The estimates of the lemma follow from Young's inequality for convolutions. The uniqueness of the solution is obvious. ∎

LEMMA 5.3. *Let* $\mathbf{f}$ *be in* $L^{2/(1+2\varepsilon)}(0,\infty;\mathbf{V}_n^0(\Omega))$, $\mathbf{y}_0$ *be in* $\mathbf{V}_n^0(\Omega)$, *denote by* $(\hat{\mathbf{y}},\hat{\mathbf{u}})$ *the solution to problem* $(\mathcal{P}_{0,\mathbf{y}_0,\mathbf{f}})$, *and let* $\hat{\mathbf{\Phi}}$ *be the solution to* (5.3) *corresponding to* $(\hat{\mathbf{y}},\hat{\mathbf{u}})$. *Then* $(\hat{\mathbf{y}},\hat{\mathbf{\Phi}})$ *is also a solution in* $L^2(0,\infty;\mathbf{V}_n^0(\Omega)) \times L^2(0,\infty;\mathbf{V}_n^0(\Omega))$ *to the system*

$$\begin{aligned} &\mathbf{y}' = A\mathbf{y} - B_\tau M^2 B_\tau^*\mathbf{\Phi} - B_n M R_A^{-1} M B_n^*\mathbf{\Phi} + \mathbf{f} \quad \textit{in } (0,\infty), \qquad \mathbf{y}(0) = \mathbf{y}_0,\\ &-\mathbf{\Phi}' = A^*\mathbf{\Phi} + \mathbf{y} \quad \textit{in } (0,\infty), \qquad \mathbf{\Phi}(\infty) = 0. \end{aligned} \tag{5.4}$$

The following estimate holds:

$$\|\hat{\mathbf{y}}\|_{L^2(0,\infty;\mathbf{V}_n^0(\Omega))} + \|\hat{\mathbf{\Phi}}\|_{\mathbf{V}^{2,1}(Q_\infty)} \leq C\big(|\mathbf{y}_0|_{\mathbf{V}_n^0(\Omega)} + \|\mathbf{f}\|_{L^{2/(1+2\varepsilon)}(0,\infty;\mathbf{V}_n^0(\Omega))}\big).$$

Proof. Step 1. Due to estimate (5.2), we have

$$\|\hat{\mathbf{y}}\|_{L^2(0,\infty;\mathbf{V}_n^0(\Omega))} + \|\hat{\mathbf{u}}\|_{L^2(0,\infty;\mathbf{V}^0(\Gamma))} \leq C\Big(|\mathbf{y}_0|_{\mathbf{V}_n^0(\Omega)} + \|\mathbf{f}\|_{L^{2/(1+2\varepsilon)}(0,\infty;\mathbf{V}_n^0(\Omega))}\Big).$$

Consider the problem

$$(\mathcal{P}_{0,\mathbf{y}_0,\mathbf{f}}^k) \qquad \inf\Big\{I_k(0,\mathbf{y},\mathbf{u}) \;\mid\; (\mathbf{y},\mathbf{u}) \text{ satisfies (5.5)},\ \mathbf{u}\in\mathbf{V}^{0,0}(\Sigma_{0,k})\Big\},$$

where

$$I_k(0,\mathbf{y},\mathbf{u}) = \frac{1}{2}\int_0^k\int_\Omega |\mathbf{y}|^2\,dxdt + \frac{1}{2}\int_0^k \Big(|\gamma_\tau\mathbf{u}(t)|^2_{\mathbf{V}^0(\Gamma)} + |R_A^{1/2}\gamma_n\mathbf{u}(t)|^2_{\mathbf{V}^0(\Gamma)}\Big)\,dt$$

and

$$\mathbf{y}' = A\mathbf{y} + BM\mathbf{u} + \mathbf{f} \quad \text{in } (0,k), \qquad \mathbf{y}(0) = \mathbf{y}_0. \tag{5.5}$$

Problem $(\mathcal{P}_{0,\mathbf{y}_0,\mathbf{f}}^k)$ admits a unique solution $(\mathbf{y}_k,\mathbf{u}_k)$ characterized by

$$\begin{aligned} &\mathbf{y}_k' = A\mathbf{y}_k + BM\mathbf{u}_k + \mathbf{f} \quad \text{in } (0,k), \qquad \mathbf{y}_k(0) = \mathbf{y}_0,\\ &-\mathbf{\Phi}_k' = A^*\mathbf{\Phi}_k + \mathbf{y}_k \quad \text{in } (0,k), \qquad \mathbf{\Phi}_k(k) = 0,\\ &\gamma_\tau\mathbf{u}_k = -MB_\tau^*\mathbf{\Phi}_k, \qquad \gamma_n\mathbf{u}_k = -R_A^{-1}MB_n^*\mathbf{\Phi}_k. \end{aligned} \tag{5.6}$$

Since we have

$$\begin{aligned} &\int_0^k\int_\Omega |\mathbf{y}_k|^2\,dxdt + \int_0^k \Big(|\gamma_\tau\mathbf{u}_k(t)|^2_{\mathbf{V}^0(\Gamma)} + |R_A^{1/2}\gamma_n\mathbf{u}_k(t)|^2_{\mathbf{V}^0(\Gamma)}\Big)\,dt\\ &\leq \int_0^\infty\int_\Omega |\hat{\mathbf{y}}|^2\,dxdt + \int_0^\infty \Big(|\gamma_\tau\hat{\mathbf{u}}(t)|^2_{\mathbf{V}^0(\Gamma)} + |R_A^{1/2}\gamma_n\hat{\mathbf{u}}(t)|^2_{\mathbf{V}^0(\Gamma)}\Big)\,dt, \end{aligned}$$

as in the proof of Theorem 4.1, we can show that

$$\tilde{\mathbf{u}}_k \to \hat{\mathbf{u}} \quad \text{in } L^2(0,\infty;\mathbf{V}^0(\Gamma)) \quad \text{and} \quad \tilde{\mathbf{y}}_k \to \hat{\mathbf{y}} \quad \text{in } L^2(0,\infty;\mathbf{V}^0(\Omega)), \tag{5.7}$$

where $\tilde{\mathbf{u}}_k$ and $\tilde{\mathbf{y}}_k$ denote the extensions by zero of $\mathbf{u}_k$ and $\mathbf{y}_k$ to (k,∞).

Step 2. *Passage to the limit for* $\mathbf{\Phi}_k$. Let $\tilde{\mathbf{\Phi}}_k$ be the extension by zero of $\mathbf{\Phi}_k$ to (k,∞). We have

$$-\tilde{\mathbf{\Phi}}_k' = A^*\tilde{\mathbf{\Phi}}_k + \tilde{\mathbf{y}}_k \quad \text{in } (0,\infty), \qquad \tilde{\mathbf{\Phi}}_k(\infty) = 0\,.$$

We already know that $(MB_\tau^*\Pi)^* \in \mathcal{L}(\mathbf{V}^0(\Gamma),\mathbf{V}_n^0(\Omega))$ and $(R_A^{-1}MB_n^*\Pi)^* \in \mathcal{L}(\mathbf{V}^0(\Gamma),\mathbf{V}_n^0(\Omega))$. We can rewrite the above equation in the form

$$-\tilde{\mathbf{\Phi}}_k' = A_\Pi^*\tilde{\mathbf{\Phi}}_k - (MB_\tau^*\Pi)^*\gamma_\tau\tilde{\mathbf{u}}_k - (R_A^{-1}MB_n^*\Pi)^*\gamma_n\tilde{\mathbf{u}}_k + \tilde{\mathbf{y}}_k \quad \text{in } (0,\infty), \qquad \tilde{\mathbf{\Phi}}_k(\infty) = 0. \tag{5.8}$$

Due to (5.7) and to Lemma 5.2, we can claim that

$$\|\tilde{\mathbf{\Phi}}_k - \hat{\mathbf{\Phi}}\|_{L^\infty(0,\infty;\mathbf{V}_n^0(\Omega))} + \|\tilde{\mathbf{\Phi}}_k - \hat{\mathbf{\Phi}}\|_{L^2(0,\infty;\mathbf{V}_n^0(\Omega))} \longrightarrow 0 \quad \text{when } k \longrightarrow \infty,$$

where $\hat{\mathbf{\Phi}}$ is the solution of (5.3) corresponding to $(\hat{\mathbf{y}},\hat{\mathbf{u}})$. Notice that

$$\begin{aligned} &\|\hat{\mathbf{\Phi}}\|_{L^2(0,\infty;\mathbf{V}_n^0(\Omega))} \le C\big(\|\hat{\mathbf{u}}\|_{L^2(0,\infty;\mathbf{V}^0(\Gamma))} + \|\hat{\mathbf{y}}\|_{L^2(0,\infty;\mathbf{V}_n^0(\Omega))}\big) \\ &\le C\big(|\mathbf{y}_0|_{\mathbf{V}_n^0(\Omega)} + \|\mathbf{f}\|_{L^{2/(1+2\varepsilon)}(0,\infty;\mathbf{V}_n^0(\Omega))}\big). \end{aligned} \tag{5.9}$$

By passing to the limit in the equation

$$\tilde{\mathbf{\Phi}}_k(t) = \int_t^\infty e^{(A^*-\lambda_0 I)(\tau-t)}(\tilde{\mathbf{y}}_k(\tau) + \lambda_0\tilde{\mathbf{\Phi}}_k(\tau))\,d\tau,$$

with Lemmas 8.6 and 8.9, we can show that $(\tilde{\mathbf{\Phi}}_k)_k$ converges to $\hat{\mathbf{\Phi}}$ in $\mathbf{V}^{2,1}(Q_\infty)$, $(B^*\tilde{\mathbf{\Phi}}_k)_k$ converges to $B^*\hat{\mathbf{\Phi}}$ in $L^2(0,\infty;\mathbf{V}^0(\Gamma))$, and $\hat{\mathbf{\Phi}}$ satisfies

$$\hat{\mathbf{\Phi}}(t) = \int_t^\infty e^{(A^*-\lambda_0 I)(\tau-t)}(\hat{\mathbf{y}}(\tau) + \lambda_0\hat{\mathbf{\Phi}}(\tau))\,d\tau.$$

Thus $\hat{\mathbf{\Phi}}$ satisfies the second equation in (5.4) corresponding to $\hat{\mathbf{y}}$. Since $(\tilde{\mathbf{u}}_k)_k = (-MB_\tau^*\tilde{\mathbf{\Phi}}_k - R_A^{-1}MB_n^*\tilde{\mathbf{\Phi}}_k)_k$ converges to $\hat{\mathbf{u}}$, we have $\hat{\mathbf{u}} = -MB_\tau^*\hat{\mathbf{\Phi}} - R_A^{-1}MB_n^*\hat{\mathbf{\Phi}}$, and $(\hat{\mathbf{y}},\hat{\mathbf{\Phi}})$ obeys the system (5.4). The estimate for $\hat{\mathbf{\Phi}}$ follows from Lemma 8.5 and from (5.9). □

THEOREM 5.4. *Assume that* $\mathbf{f} \in L^{2/(1+2\varepsilon)}(0,\infty;\mathbf{V}_n^0(\Omega)) \cap L^2(0,\infty;(\mathbf{V}^{2\varepsilon}(\Omega))')$. *If* $\mathbf{y}_0 \in \mathbf{V}_n^0(\Omega)$, *then the solution* $(\mathbf{y},\mathbf{\Phi})$ *of system* (5.4) *belongs to* $\mathbf{V}^{1,1/2}(Q)\times\mathbf{V}^{3,3/2}(Q)$ *and we have*

$$\begin{aligned} &\|\mathbf{y}\|_{C_b([0,\infty);\mathbf{V}_n^0(\Omega))} + \|\mathbf{y}\|_{\mathbf{V}^{1,1/2}(Q_\infty)} + \|\mathbf{\Phi}\|_{\mathbf{V}^{3,3/2}(Q_\infty)} \\ &\le C(|\mathbf{y}_0|_{\mathbf{V}_n^0(\Omega)} + \|\mathbf{f}\|_{L^{2/(1+2\varepsilon)}(0,\infty;\mathbf{V}_n^0(\Omega))} + \|\mathbf{f}\|_{L^2(0,\infty;(\mathbf{V}^{2\varepsilon}(\Omega))')})\,. \end{aligned}$$

If $\mathbf{y}_0 \in \mathbf{V}_n^{1/2-\varepsilon}(\Omega)$ *for some* $0<\varepsilon<1/2$, *then the solution* $(\mathbf{y},\mathbf{\Phi})$ *of system* (5.4) *belongs to* $\mathbf{V}^{3/2-\varepsilon,3/4-\varepsilon/2}(Q)\times\mathbf{V}^{7/2-\varepsilon,7/4-\varepsilon/2}(Q)$, *and we have*

$$\begin{aligned} &\|\mathbf{y}\|_{\mathbf{V}^{3/2-\varepsilon,3/4-\varepsilon/2}(Q)} + \|\mathbf{\Phi}\|_{\mathbf{V}^{7/2-\varepsilon,7/4-\varepsilon/2}(Q)} \\ &\le C(|\mathbf{y}_0|_{\mathbf{V}_n^{1/2-\varepsilon}(\Omega)} + \|\mathbf{f}\|_{L^{2/(1+2\varepsilon)}(0,\infty;\mathbf{V}_n^0(\Omega))} + \|\mathbf{f}\|_{L^2(0,\infty;(\mathbf{V}^{2\varepsilon}(\Omega))')}) \end{aligned}$$

and

$$\|B^*\mathbf{\Phi}\|_{\mathbf{V}^{3/2-\varepsilon,3/4-\varepsilon/2}(Q)} \le C(|\mathbf{y}_0|_{\mathbf{V}_n^{1/2-\varepsilon}(\Omega)}+\|\mathbf{f}\|_{L^{2/(1+2\varepsilon)}(0,\infty;\mathbf{V}_n^0(\Omega))}+\|\mathbf{f}\|_{L^2(0,\infty;(\mathbf{V}^{2\varepsilon}(\Omega))')}).$$

Proof. Assume that $\mathbf{y}_0 \in \mathbf{V}_n^0(\Omega)$. Applying Lemmas 8.1, 8.2, and 8.3, we first obtain that $\mathbf{y}$ belongs to $\mathbf{V}^{1/2-\varepsilon',1/4-\varepsilon'/2}(Q_\infty)$ for all $\varepsilon' > 0$. From Lemma 8.9, we deduce that $B^*\mathbf{\Phi} \in \mathbf{V}^{1/2-\varepsilon',1/4-\varepsilon'/2}(\Sigma_\infty)$ for all $\varepsilon' > 0$. As in the proof of Lemma 4.2, we can use a bootstrap argument to show that $\mathbf{y} \in \mathbf{V}^{1,1/2}(Q_\infty) \cap C_b([0,\infty);\mathbf{V}_n^0(\Omega))$ and $\mathbf{\Phi} \in \mathbf{V}^{3,3/2}(Q_\infty)$, with the corresponding estimates for $\mathbf{y}$ and $\mathbf{\Phi}$. The same procedure can be used to prove the other estimates in the case when $\mathbf{y}_0 \in \mathbf{V}_n^{1/2-\varepsilon}(\Omega)$. ∎

6. Stabilization of the two-dimensional Navier–Stokes equations. Throughout this section, we assume that $N = 2$.

6.1. First stabilization result. Consider the Navier–Stokes equations with the linear feedback law determined in section 4:

$$\begin{aligned} &P\mathbf{y}' = A_\Pi P\mathbf{y} + PF(\mathbf{y}) \quad \text{in } (0,\infty), \qquad P\mathbf{y}(0) = \mathbf{y}_0, \\ &(I-P)\mathbf{y} = -(I-P)D_A M R_A^{-1} M B_n^* \Pi P\mathbf{y} \quad \text{in } (0,\infty), \end{aligned} \tag{6.1}$$

where $F(\mathbf{y}) = -(\mathbf{y}\cdot\nabla)\mathbf{y}$.

THEOREM 6.1. *For all $0 < \varepsilon < 1/4$, there exist $\mu_0 > 0$ and a nondecreasing function η from $\mathbb{R}^+$ into itself such that if $\mu \in (0,\mu_0)$ and $|\mathbf{y}_0|_{\mathbf{V}_n^{1/2-\varepsilon}(\Omega)} \le \eta(\mu)$, then* (6.1) *admits a unique solution in the set*

$$D_\mu = \Big\{\mathbf{y} \in \mathbf{V}^{3/2-\varepsilon,3/4-\varepsilon/2}(Q_\infty) \mid \|\mathbf{y}\|_{\mathbf{V}^{3/2-\varepsilon,3/4-\varepsilon/2}(Q_\infty)} \le \mu\Big\}.$$

Moreover, $(I-P)\mathbf{y}$ belongs to $H^{3/4-\varepsilon/2}(0,\infty;\mathbf{V}^{1/2}(\Omega)) \cap L^2(0,\infty;\mathbf{V}^{3/2-\varepsilon}(\Omega))$.

LEMMA 6.2. *For all $\mathbf{y}_0 \in \mathbf{V}_n^{1/2-\varepsilon}(\Omega)$ and all $\mathbf{f} \in L^{2/(1+2\varepsilon)}(0,\infty;\mathbf{V}_n^0(\Omega)) \cap L^2(0,\infty;(\mathbf{V}^{2\varepsilon}(\Omega))')$ the solution to the equation*

$$\mathbf{y}' = A_\Pi \mathbf{y} + \mathbf{f}, \qquad \mathbf{y}(0) = \mathbf{y}_0, \tag{6.2}$$

obeys

$$\|\mathbf{y}\|_{\mathbf{V}^{3/2-\varepsilon,3/4-\varepsilon/2}(Q_\infty)} \le C_1\big(|\mathbf{y}_0|_{\mathbf{V}_n^{1/2-\varepsilon}(\Omega)}+\|\mathbf{f}\|_{L^{2/(1+2\varepsilon)}(0,\infty;\mathbf{V}_n^0(\Omega))}+\|\mathbf{f}\|_{L^2(0,\infty;(\mathbf{V}^{2\varepsilon}(\Omega))')}\big).$$

Proof. Since the semigroup $(e^{tA_\Pi})_{t\ge 0}$ is exponentially stable on $\mathbf{V}_n^0(\Omega)$, equation (6.2) admits a unique solution $\mathbf{y}$ belonging to $C_b([0,\infty);\mathbf{V}_n^0(\Omega)) \cap L^2(0,\infty;\mathbf{V}_n^0(\Omega))$ which satisfies

$$\|\mathbf{y}\|_{L^\infty(0,\infty;\mathbf{V}_n^0(\Omega))} + \|\mathbf{y}\|_{L^2(0,\infty;\mathbf{V}_n^0(\Omega))} \le C\big(|\mathbf{y}_0|_{\mathbf{V}_n^{1/2-\varepsilon}(\Omega)} + \|\mathbf{f}\|_{L^{2/(1+2\varepsilon)}(0,\infty;\mathbf{V}_n^0(\Omega))}\big).$$

We denote by $(\hat{\mathbf{y}},\hat{\mathbf{\Phi}})$ the solution to system (5.4). We set

$$\mathbf{r}(t) = \hat{\mathbf{\Phi}}(t) - \Pi\mathbf{y}(t).$$

We denote by $\tilde{\mathbf{y}}$ the solution to the equation

$$\tilde{\mathbf{y}}' = A\tilde{\mathbf{y}} + B_\tau M^2 B_\tau^*\mathbf{r} + B_n M R_A^{-1} M B_n^*\mathbf{r}, \qquad \tilde{\mathbf{y}}(0) = 0.$$

From the definition of $\mathbf{r}$ it follows that

$$\begin{aligned}&-B_\tau M^2 B_\tau^* \hat{\mathbf{\Phi}} - B_n M R_A^{-1} M B_n^* \hat{\mathbf{\Phi}}\\ &= -B_\tau M^2 B_\tau^* \Pi \mathbf{y} - B_n M R_A^{-1} M B_n^* \Pi \mathbf{y} - B_\tau M^2 B_\tau^* \mathbf{r} - B_n M R_A^{-1} M B_n^* \mathbf{r}\,.\end{aligned}$$

Thanks to this identity, we can rewrite (6.2) in the form

$$\mathbf{y}' = A\mathbf{y} - B_\tau M^2 B_\tau^* \hat{\mathbf{\Phi}} - B_n M R_A^{-1} M B_n^* \hat{\mathbf{\Phi}} + B_\tau M^2 B_\tau^* \mathbf{r} + B_n M R_A^{-1} M B_n^* \mathbf{r} + \mathbf{f}, \quad \mathbf{y}(0) = \mathbf{y}_0\,.$$

Thus $\mathbf{y} = \hat{\mathbf{y}} + \tilde{\mathbf{y}}$. Due to Theorem 5.4, we notice that

$$\begin{aligned}&\|B^* \hat{\mathbf{\Phi}}\|_{\mathbf{V}^{3/2-\varepsilon,3/4-\varepsilon/2}(\Sigma_\infty)}\\ &\quad \le C\big(|\mathbf{y}_0|_{\mathbf{V}_n^{1/2-\varepsilon}(\Omega)} + \|\mathbf{f}\|_{L^{2/(1+2\varepsilon)}(0,\infty;\mathbf{V}_n^0(\Omega))} + \|\mathbf{f}\|_{L^2(0,\infty;(\mathbf{V}^{2\varepsilon}(\Omega))')}\big).\end{aligned}$$

Moreover, $\mathbf{y}$ belongs to $L^2(0,\infty;\mathbf{V}_n^0(\Omega))$ and $B^*\Pi \in \mathcal{L}(\mathbf{V}_n^0(\Omega), \mathbf{V}^{1/2}(\Gamma))$ (see Remark 4.4). Thus $B^*\mathbf{r} = B^*\hat{\mathbf{\Phi}} - B^*\Pi\mathbf{y}$ belongs to $\mathbf{V}^{0,0}(\Sigma_\infty)$ and

$$\|B^*\mathbf{r}\|_{\mathbf{V}^{0,0}(\Sigma_\infty)} \le C\big(|\mathbf{y}_0|_{\mathbf{V}_n^{1/2-\varepsilon}(\Omega)} + \|\mathbf{f}\|_{L^{2/(1+2\varepsilon)}(0,\infty;\mathbf{V}_n^0(\Omega))} + \|\mathbf{f}\|_{L^2(0,\infty;(\mathbf{V}^{2\varepsilon}(\Omega))')}\big).$$

From Lemma 8.3 it follows that

$$\|\tilde{\mathbf{y}}\|_{\mathbf{V}^{1/2-\varepsilon',1/4-\varepsilon'}(Q_\infty)} \le C\|B^*\mathbf{r}\|_{\mathbf{V}^{0,0}(\Sigma_\infty)} \qquad \text{for all } \varepsilon' > 0.$$

Thus $\mathbf{y} = \hat{\mathbf{y}} + \tilde{\mathbf{y}}$ belongs to $\mathbf{V}^{1/2-\varepsilon',1/4-\varepsilon'/2}(Q_\infty)$ for all $\varepsilon' > 0$. Therefore $B^*\mathbf{r}$ belongs to $\mathbf{V}^{1/2-\varepsilon',1/4-\varepsilon'/2}(\Sigma_\infty)$ because $B^*\Pi \in \mathcal{L}(\mathbf{V}_n^{1/2-\varepsilon'}(\Omega), \mathbf{V}^{1-\varepsilon'}(\Gamma))$ for all $\varepsilon' > 0$ (see Remark 4.4), and we have

$$\begin{aligned}&\|B^*\mathbf{r}\|_{\mathbf{V}^{1/2-\varepsilon',1/4-\varepsilon'/2}(\Sigma_\infty)}\\ &\quad \le C\big(|\mathbf{y}_0|_{\mathbf{V}_n^{1/2-\varepsilon}(\Omega)} + \|\mathbf{f}\|_{L^{2/(1+2\varepsilon)}(0,\infty;\mathbf{V}_n^0(\Omega))} + \|\mathbf{f}\|_{L^2(0,\infty;(\mathbf{V}^{2\varepsilon}(\Omega))')}\big) \text{ for all } \varepsilon' > 0.\end{aligned}$$

With another iteration we can prove an estimate of $B^*\mathbf{r}$ in $\mathbf{V}^{1-\varepsilon',1/2-\varepsilon'/2}(\Sigma_\infty)$. Still with Lemma 8.3 we obtain

$$\|\tilde{\mathbf{y}}\|_{\mathbf{V}^{3/2-\varepsilon'',3/4-\varepsilon''}(Q_\infty)} \le C\|B^*\mathbf{r}\|_{\mathbf{V}^{1-\varepsilon',1/2-\varepsilon'/2}(\Sigma)}$$

for all $\varepsilon'' > \varepsilon' > 0$. With Theorem 5.4, we have

$$\|\hat{\mathbf{y}}\|_{\mathbf{V}^{3/2-\varepsilon,3/4-\varepsilon/2}(Q_\infty)} \le C\big(|\mathbf{y}_0|_{\mathbf{V}_n^{1/2-\varepsilon}(\Omega)} + \|\mathbf{f}\|_{L^{2/(1+2\varepsilon)}(0,\infty;\mathbf{V}_n^0(\Omega))} + \|\mathbf{f}\|_{L^2(0,\infty;(\mathbf{V}^{2\varepsilon}(\Omega))')}\big),$$

and the proof is complete. □

LEMMA 6.3. *If* $\mathbf{z}$ *belongs to* $\mathbf{V}^{3/2-\varepsilon,3/4-\varepsilon/2}(Q_\infty)$*, then*

$$\begin{aligned}&\|\mathbf{z}\|_{L^{1/\varepsilon}(0,\infty;\mathbf{V}^{1/2+\varepsilon}(\Omega))}\\ &\quad \le C\|\mathbf{z}\|^{(1-2\varepsilon)}_{L^\infty(0,\infty;\mathbf{V}^{1/2-\varepsilon}(\Omega))}\|\mathbf{z}\|^{2\varepsilon}_{L^2(0,\infty;\mathbf{V}^{3/2-\varepsilon}(\Omega))} \le C\|\mathbf{z}\|_{\mathbf{V}^{3/2-\varepsilon,3/4-\varepsilon/2}(Q_\infty)}.\end{aligned}$$

Proof. We first observe that

$$|\mathbf{z}(t)|_{\mathbf{V}^{1/2+\varepsilon}(\Omega)} \le C|\mathbf{z}(t)|^{(1-2\varepsilon)}_{\mathbf{V}^{1/2-\varepsilon}(\Omega)}|\mathbf{z}(t)|^{2\varepsilon}_{\mathbf{V}^{3/2-\varepsilon}(\Omega)}.$$

Therefore we have

$$\int_0^\infty |\mathbf{z}(t)|^{1/\varepsilon}_{\mathbf{V}^{1/2+\varepsilon}(\Omega)} dt \le C\|\mathbf{z}\|^{(1-2\varepsilon)/\varepsilon}_{L^\infty(0,\infty;\mathbf{V}^{1/2-\varepsilon}(\Omega))} \int_0^\infty |\mathbf{z}(t)|^2_{\mathbf{V}^{3/2-\varepsilon}(\Omega)} dt.$$

The proof is complete. □

LEMMA 6.4. *Let ε be in $(0,1/4)$. If $\mathbf{z}$ belongs to $\mathbf{V}^{3/2-\varepsilon,3/4-\varepsilon/2}(Q_\infty)$, then*

$$\|(\mathbf{z}\cdot\nabla)\mathbf{z}\|_{L^{2/(1+2\varepsilon)}(0,\infty;\mathbf{L}^2(\Omega))}+\|P\mathrm{div}(\mathbf{z}\otimes\mathbf{z})\|_{L^2(0,\infty;(\mathbf{V}^{2\varepsilon}(\Omega))')}\le C_2\|\mathbf{z}\|^2_{\mathbf{V}^{3/2-\varepsilon,3/4-\varepsilon/2}(Q_\infty)}.$$

Proof. We have

$$\|(\mathbf{z}\cdot\nabla)\mathbf{z}\|_{\mathbf{L}^2(\Omega)}\le\|\mathbf{z}\|_{\mathbf{L}^{4/(1-2\varepsilon)}(\Omega)}\|\nabla\mathbf{z}\|_{\mathbf{L}^{4/(1+2\varepsilon)}(\Omega)}\le C\|\mathbf{z}\|_{\mathbf{V}^{1/2+\varepsilon}(\Omega)}\|\mathbf{z}\|_{\mathbf{V}^{3/2-\varepsilon}(\Omega)}.$$

Therefore with Lemma 6.3, it follows that

$$\|(\mathbf{z}\cdot\nabla)\mathbf{z}\|_{L^{2/(1+2\varepsilon)}(0,\infty;\mathbf{L}^2(\Omega))}\le C\|\mathbf{z}\|_{L^{1/\varepsilon}(0,\infty;\mathbf{V}^{1/2+\varepsilon}(\Omega))}\|\mathbf{z}\|_{L^2(0,\infty;\mathbf{V}^{3/2-\varepsilon}(\Omega))}$$

$$\le C\|\mathbf{z}\|^2_{\mathbf{V}^{3/2-\varepsilon,3/4-\varepsilon/2}(Q_\infty)}.$$

From [19, Theorem B.3] we deduce that

$$\|\mathbf{z}\otimes\mathbf{z}\|_{\mathbf{H}^{1-2\varepsilon,1/2-\varepsilon}(Q_\infty)}\le C\|\mathbf{z}\|^2_{\mathbf{V}^{3/2-\varepsilon,3/4-\varepsilon/2}(Q_\infty)}.$$

The divergence operator is continuous from $\mathbf{L}^2(\Omega)$ into $\mathbf{H}^{-1}(\Omega)$, and from $\mathbf{H}^1(\Omega)$ to $\mathbf{L}^2(\Omega)$. Thus it is also continuous from $\mathbf{H}^{1-2\varepsilon}(\Omega)$ into $(\mathbf{H}^{2\varepsilon}(\Omega))'$. The projector P is continuous from $\mathbf{L}^2(\Omega)$ into $\mathbf{V}^0_n(\Omega)$, and from $\mathbf{H}^{-1}(\Omega)$ into $\mathbf{V}^{-1}(\Omega)$ (see, e.g., [32]). Thus it is also continuous from $(\mathbf{H}^{2\varepsilon}(\Omega))'$ into $(\mathbf{V}^{2\varepsilon}_n(\Omega))'$. Therefore we have

$$\|P\mathrm{div}(\mathbf{z}\otimes\mathbf{z})\|_{L^2(0,\infty;(\mathbf{V}^{2\varepsilon}_n(\Omega))')}\le C\|\mathbf{z}\otimes\mathbf{z}\|_{L^2(0,\infty;\mathbf{H}^{1-2\varepsilon}(\Omega))}\le C\|\mathbf{z}\|^2_{\mathbf{V}^{3/2-\varepsilon,3/4-\varepsilon/2}(Q_\infty)}.$$

Observe that the condition $0<\varepsilon<1/4$ is needed to have $(\mathbf{H}^{2\varepsilon}(\Omega))'\hookrightarrow\mathbf{H}^{-1}(\Omega)$. ∎

LEMMA 6.5. *Let ε be in $(0,1/4)$. The mapping PF is locally Lipshitz continuous from $\mathbf{V}^{3/2-\varepsilon,3/4-\varepsilon/2}(Q_\infty)$ into $L^{2/(1+2\varepsilon)}(0,\infty;\mathbf{V}^0_n(\Omega))\cap L^2(0,\infty;(\mathbf{V}^{2\varepsilon}(\Omega))')$. More precisely we have*

$$\|PF(\mathbf{z}_1)-PF(\mathbf{z}_2)\|_{L^{2/(1+2\varepsilon)}(0,\infty;\mathbf{V}^0_n(\Omega))}+\|PF(\mathbf{z}_1)-PF(\mathbf{z}_2)\|_{L^2(0,\infty;(\mathbf{V}^{2\varepsilon}(\Omega))')}$$
$$\le C_2\big(\|\mathbf{z}_1\|_{\mathbf{V}^{3/2-\varepsilon,3/4-\varepsilon/2}(Q_\infty)}+\|\mathbf{z}_2\|_{\mathbf{V}^{3/2-\varepsilon,3/4-\varepsilon/2}(Q_\infty)}\big)\|\mathbf{z}_1-\mathbf{z}_2\|_{\mathbf{V}^{3/2-\varepsilon,3/4-\varepsilon/2}(Q_\infty)}.$$

Proof. From Lemma 6.4 it follows that PF is a mapping from $\mathbf{V}^{3/2-\varepsilon,3/4-\varepsilon/2}(Q_\infty)$ into $L^{2/(1+2\varepsilon)}(0,\infty;\mathbf{V}^0_n(\Omega))\cap L^2(0,\infty;(\mathbf{V}^{2\varepsilon}(\Omega))')$. By calculations similar to those in Lemma 6.4, we obtain

$$\|PF(\mathbf{z}_1)-PF(\mathbf{z}_2)\|_{L^{2/(1+2\varepsilon)}(0,\infty;\mathbf{V}^0_n(\Omega))}+\|PF(\mathbf{z}_1)-PF(\mathbf{z}_2)\|_{L^2(0,\infty;(\mathbf{V}^{2\varepsilon}(\Omega))')}$$
$$\le\|P((\mathbf{z}_1\cdot\nabla)(\mathbf{z}_1-\mathbf{z}_2))\|_{L^{2/(1+2\varepsilon)}(0,\infty;\mathbf{V}^0_n(\Omega))}+\|P(((\mathbf{z}_1-\mathbf{z}_2)\cdot\nabla)\mathbf{z}_2)\|_{L^{2/(1+2\varepsilon)}(0,\infty;\mathbf{V}^0_n(\Omega))}$$
$$+\|P\mathrm{div}(\mathbf{z}_1\otimes(\mathbf{z}_1-\mathbf{z}_2))\|_{L^2(0,\infty;(\mathbf{V}^{2\varepsilon}_n(\Omega))')}+\|P\mathrm{div}((\mathbf{z}_1-\mathbf{z}_2)\otimes\mathbf{z}_2)\|_{L^2(0,\infty;(\mathbf{V}^{2\varepsilon}_n(\Omega))')}$$
$$\le C_2\big(\|\mathbf{z}_1\|_{\mathbf{V}^{3/2-\varepsilon,3/4-\varepsilon/2}(Q_\infty)}+\|\mathbf{z}_2\|_{\mathbf{V}^{3/2-\varepsilon,3/4-\varepsilon/2}(Q_\infty)}\big)\|\mathbf{z}_1-\mathbf{z}_2\|_{\mathbf{V}^{3/2-\varepsilon,3/4-\varepsilon/2}(Q_\infty)}.$$

The proof is complete. ∎

LEMMA 6.6. *If $P\mathbf{y}$ belongs to $\mathbf{V}^{3/2-\varepsilon,3/4-\varepsilon/2}(Q_\infty)$ for some $0<\varepsilon<1/2$, then*

$$\|(I-P)D_AMR_A^{-1}MB_n^*\Pi P\mathbf{y}\|_{\mathbf{V}^{3/2-\varepsilon,3/4-\varepsilon/2}(Q_\infty)}\le C_3\|P\mathbf{y}\|_{\mathbf{V}^{3/2-\varepsilon,3/4-\varepsilon/2}(Q_\infty)}.$$

Proof. The operator $B^*\Pi$ belongs to $\mathcal{L}(\mathbf{V}^{1/2-\varepsilon}_n(\Omega),\mathbf{V}^{1-\varepsilon}(\Gamma))$ (see Remark 4.4). Thus $MR_A^{-1}MB_n^*\Pi$ belongs to $\mathcal{L}(\mathbf{V}^{1/2-\varepsilon}_n(\Omega),\mathbf{V}^{1-\varepsilon}(\Gamma))$, and $D_AMR_A^{-1}MB_n^*\Pi$ belongs

to $\mathcal{L}(\mathbf{V}_n^{1/2-\varepsilon}(\Omega), \mathbf{V}^{3/2-\varepsilon}(\Omega))$. The lemma follows from the continuity properties of the operator $(I-P)$. ∎

Proof of Theorem 6.1. We set $\mu_0 = \frac{1}{4C_1C_2(1+C_3)}$ and $\eta(\mu) = \frac{3\mu}{4C_1(1+C_3)}$. For $\mathbf{z} \in \mathbf{V}^{3/2-\varepsilon,3/4-\varepsilon/2}(\Omega)$, we denote by $\mathbf{y_z}$ the solution to the equation

$$\begin{aligned} &P\mathbf{y}' = A_\Pi P\mathbf{y} + PF(\mathbf{z}), \qquad \mathbf{y}(0) = \mathbf{y}_0, \\ &(I-P)\mathbf{y} = -(I-P)D_A M R_A^{-1} M B_n^* \,\Pi P\mathbf{y}\,. \end{aligned} \tag{6.3}$$

We are going to prove that the mapping $\mathbf{M} : \mathbf{z} \mapsto \mathbf{y_z}$ is a contraction in D_μ.

Step 1. From Lemmas 6.2, 6.4, and 6.6 it follows that

$$\begin{aligned} &\|\mathbf{y_z}\|_{\mathbf{V}^{3/2-\varepsilon,3/4-\varepsilon/2}(Q_\infty)} \le \|P\mathbf{y_z}\|_{\mathbf{V}^{3/2-\varepsilon,3/4-\varepsilon/2}(Q_\infty)} + \|(I-P)\mathbf{y_z}\|_{\mathbf{V}^{3/2-\varepsilon,3/4-\varepsilon/2}(Q_\infty)} \\ &\le C_1(1+C_3)\big(|\mathbf{y}_0|_{\mathbf{V}^{1/2-\varepsilon}(\Omega)} + \|PF(\mathbf{z})\|_{L^{2/(1+2\varepsilon)}(0,\infty;\mathbf{V}_n^0(\Omega))} + \|PF(\mathbf{z})\|_{L^2(0,\infty;(\mathbf{V}^{2\varepsilon}(\Omega))')}\big) \\ &\le C_1(1+C_3)\left(\frac{3\mu}{4C_1(1+C_3)} + C_2\|\mathbf{z}\|^2_{\mathbf{V}^{3/2-\varepsilon,3/4-\varepsilon/2}(Q_\infty)}\right) \le \frac{3\mu}{4} + C_1(1+C_3)C_2\mu^2 \le \mu \end{aligned}$$

if $\mu < \mu_0$. Thus $\mathbf{M}$ is a mapping from D_μ into itself.

Step 2. From Lemmas 6.2 and 6.5 it follows that

$$\begin{aligned} &\|P\mathbf{y}_{\mathbf{z}_1} - P\mathbf{y}_{\mathbf{z}_2}\|_{\mathbf{V}^{3/2-\varepsilon,3/4-\varepsilon/2}(Q_\infty)} \\ &\le C_1\big(\|PF(\mathbf{z}_1) - PF(\mathbf{z}_2)\|_{L^{2/(1+2\varepsilon)}(0,\infty;\mathbf{V}_n^0(\Omega))} + \|PF(\mathbf{z}_1) - PF(\mathbf{z}_2)\|_{L^2(0,\infty;(\mathbf{V}^{2\varepsilon}(\Omega))')}\big) \\ &\le C_2C_1\big(\|\mathbf{z}_1\|_{\mathbf{V}^{3/2-\varepsilon,3/4-\varepsilon/2}(Q_\infty)} + \|\mathbf{z}_2\|_{\mathbf{V}^{3/2-\varepsilon,3/4-\varepsilon/2}(Q_\infty)}\big)\|\mathbf{z}_1 - \mathbf{z}_2\|_{\mathbf{V}^{3/2-\varepsilon,3/4-\varepsilon/2}(Q_\infty)} \\ &\le 2C_2C_1\mu\|\mathbf{z}_1 - \mathbf{z}_2\|_{\mathbf{V}^{3/2-\varepsilon,3/4-\varepsilon/2}(Q_\infty)}. \end{aligned}$$

Thus with Lemma 6.6 and the previous estimate we obtain

$$\|\mathbf{y}_{\mathbf{z}_1} - \mathbf{y}_{\mathbf{z}_2}\|_{\mathbf{V}^{3/2-\varepsilon,3/4-\varepsilon/2}(Q_\infty)} \le 2C_2C_1\mu(1+C_3)\|\mathbf{z}_1 - \mathbf{z}_2\|_{\mathbf{V}^{3/2-\varepsilon,3/4-\varepsilon/2}(Q_\infty)}.$$

Thus if $\mu < \mu_0$, the mapping $\mathbf{M}$ is a contraction in D_μ, and the system (6.1) admits a unique solution in D_μ. ∎

6.2. Second stabilization result. To obtain a feedback law providing an exponential stabilization of the Navier–Stokes equation, we are going to use the linear feedback law determined thanks to an auxiliary problem. For that, we set

$$\hat{\mathbf{y}} = e^{\omega t}\mathbf{y}, \qquad \hat{\mathbf{u}} = e^{\omega t}\mathbf{u}.$$

If

$$\begin{aligned} &P\mathbf{y}' = AP\mathbf{y} + PF(\mathbf{y}) + BM\mathbf{u}, \qquad P\mathbf{y}(0) = \mathbf{y}_0, \\ &(I-P)\mathbf{y} = (I-P)D_A\gamma_n M\mathbf{u}, \end{aligned}$$

then $\hat{\mathbf{y}}$ is the solution to the system

$$\begin{aligned} &P\hat{\mathbf{y}}' = AP\hat{\mathbf{y}} + \omega P\hat{\mathbf{y}} + e^{-\omega t}PF(\hat{\mathbf{y}}) + BM\hat{\mathbf{u}}, \qquad P\hat{\mathbf{y}}(0) = \mathbf{y}_0, \\ &(I-P)\hat{\mathbf{y}} = (I-P)D_A\gamma_n M\hat{\mathbf{u}}. \end{aligned}$$

Set $A_\omega = A + \omega I$, and let $\Pi_\omega \in \mathcal{L}(\mathbf{V}_n^0(\Omega))$ be the solution to the algebraic Riccati equation

$$\begin{aligned} &\Pi_\omega = \Pi_\omega^* \ge 0, \\ &\Pi_\omega A_\omega + A_\omega^*\Pi_\omega - \Pi_\omega B_\tau M^2 B_\tau^*\Pi_\omega - \Pi_\omega B_n M\, R_A^{-1}\, MB_n^*\Pi_\omega + I = 0. \end{aligned} \tag{6.4}$$

The existence of a unique solution in $\mathcal{L}(\mathbf{V}_n^0(\Omega);\mathbf{V}^2(\Omega)\cap\mathbf{V}_0^1(\Omega))$ to this equation may be proved as in section 4. As in section 4, it can be shown that

$$I(\mathbf{z}_{\mathbf{y}_0},\mathbf{v}_{\mathbf{y}_0})=\frac{1}{2}\Big(\Pi_\omega\mathbf{y}_0,\mathbf{y}_0\Big)_{\mathbf{V}_n^0(\Omega)},$$

where $(\mathbf{z}_{\mathbf{y}_0},\mathbf{v}_{\mathbf{y}_0})$ is the solution of the control problem

$$(\mathcal{P}_{0,\mathbf{y}_0})\qquad \inf\Big\{I(\mathbf{z},\mathbf{v})\ \mid\ (\mathbf{z},\mathbf{v})\text{ satisfies (6.5)},\ \mathbf{v}\in\mathbf{V}^{0,0}(\Sigma_\infty)\Big\},$$

where I is the functional of section 4, and

$$\mathbf{z}'=A_\omega\mathbf{z}+BM\mathbf{v}\quad\text{in }(0,\infty),\qquad \mathbf{z}(0)=\mathbf{y}_0. \tag{6.5}$$

Consider the Navier–Stokes equations with the linear feedback law

$$\begin{aligned}&P\hat{\mathbf{y}}'=A_{\omega,\Pi_\omega}P\hat{\mathbf{y}}+e^{-\omega t}PF(\hat{\mathbf{y}}),\qquad P\hat{\mathbf{y}}(0)=\mathbf{y}_0,\\&(I-P)\hat{\mathbf{y}}=-(I-P)D_AMR_A^{-1}MB_n^*\,\Pi_\omega P\hat{\mathbf{y}},\end{aligned} \tag{6.6}$$

where

$$D(A_{\omega,\Pi_\omega})=D(A_{\Pi_\omega})\quad\text{and}\quad A_{\omega,\Pi_\omega}\mathbf{y}=A_{\Pi_\omega}\mathbf{y}+\omega\mathbf{y}\quad\text{for all }\mathbf{y}\in D(A_{\Pi_\omega}).$$

As previously, if $\hat{\mathbf{y}}$ is a solution to (6.6), then $\mathbf{y}=e^{-\omega t}\hat{\mathbf{y}}$ is the solution of

$$\begin{aligned}&P\mathbf{y}'=AP\mathbf{y}-B_\tau M^2B_\tau^*\Pi_\omega P\mathbf{y}-B_n\,MR_A^{-1}M\,B_n^*\Pi_\omega P\mathbf{y}+PF(\mathbf{y}),\qquad P\mathbf{y}(0)=\mathbf{y}_0,\\&(I-P)\mathbf{y}=-(I-P)D_AR_A^{-1}MB_n^*\Pi_\omega P\mathbf{y}.\end{aligned} \tag{6.7}$$

THEOREM 6.7. *For all $0<\varepsilon<1/4$, there exist $\mu_0>0$ and a nondecreasing function η_0 from $\mathbb{R}^+$ into itself such that if $\mu\in(0,\mu_0)$ and $\|\mathbf{y}_0\|_{\mathbf{V}_n^{1/2-\varepsilon}(\Omega)}\le\eta_0(\mu)$, then (6.7) admits a unique solution in the set*

$$D_\mu=\Big\{\mathbf{y}\in\mathbf{V}^{3/2-\varepsilon,3/4-\varepsilon/2}(Q_\infty)\mid\|e^{\omega(\cdot)}\mathbf{y}\|_{\mathbf{V}^{3/2-\varepsilon,3/4-\varepsilon/2}(Q_\infty)}\le\mu\Big\}.$$

Moreover, $\mathbf{y}$, which belongs to $C_b([0,\infty);\mathbf{V}^{1/2-\varepsilon}(\Omega))$, satisfies

$$|\mathbf{y}(t)|_{\mathbf{V}^{1/2-\varepsilon}(\Omega)}\le C(\mathbf{w},\mu,\omega)\ e^{-\omega t}.$$

Proof. Substituting $F(\mathbf{y})$ by $e^{-\omega t}F(\hat{\mathbf{y}})$ in the proof of Theorem 6.1, we can show that there exists $\mu_0>0$ and a nondecreasing function η_0 from $\mathbb{R}^+$ into itself such that if $\mu\in(0,\mu_0)$ and $\|\mathbf{y}_0\|_{\mathbf{V}_n^{1/2-\varepsilon}(\Omega)}\le\eta_0(\mu)$ for some $0<\varepsilon<1/4$, the equation (6.6) admits a unique solution $\hat{\mathbf{y}}$ in $\widehat{D}_\mu=\big\{\mathbf{y}\in\mathbf{V}^{3/2-\varepsilon,3/4-\varepsilon/2}(Q_\infty)\mid\|\mathbf{y}\|_{\mathbf{V}^{3/2-\varepsilon,3/4-\varepsilon/2}(Q_\infty)}\le\mu\big\}$, and $|\hat{\mathbf{y}}(t)|_{\mathbf{V}^{1/2-\varepsilon}(\Omega)}\le C(\mathbf{w},\mu,\omega)$. Thus $\mathbf{y}=e^{-\omega t}\hat{\mathbf{y}}$ is the solution of (6.7), belongs to D_μ, and satisfies

$$|\mathbf{y}(t)|_{\mathbf{V}^{1/2-\varepsilon}(\Omega)}\le C(\mathbf{w},\mu,\omega)\ e^{-\omega t}.$$

The proof is complete. ∎

7. Additional results.

7.1. Control by a tangential velocity. Assume that Ω and $\mathbf{w}$ are such that (1.3) is stabilizable in $\mathbf{V}_n^{1/2-\varepsilon}(\Omega)$ with controls $\mathbf{u} \in L^2(0,\infty;\mathbf{V}_n^0(\Gamma))$ satisfying $\mathrm{supp}(\mathbf{u}) \subset \Gamma_0 \times (0,\infty)$, where Γ_0 is an open set in Γ in which the function m is equal to 1 (see the assumptions on the function m at the beginning of section 2). Such a stabilizability result is stated in [4, Theorem B.1.1]. With such a result, as in section 6.2 (and section 4), we can show that the algebraic Riccati equation

$$\Pi_\omega \in \mathcal{L}(\mathbf{V}_n^0(\Omega)), \quad \Pi_\omega = \Pi_\omega^* \geq 0, \quad \Pi_\omega A_\omega + A_\omega^* \Pi_\omega - \Pi_\omega B_\tau M^2 B_\tau^* \Pi_\omega + I = 0, \tag{7.1}$$

admits a unique solution satisfying $\Pi_\omega \in \mathcal{L}(\mathbf{V}_n^0(\Omega); \mathbf{V}^2(\Omega) \cap \mathbf{V}_0^1(\Omega))$, which enjoys the same regularizing properties as in Theorem 4.5. Since we deal with controls belonging to $\mathbf{V}_n^0(\Gamma)$, the operator R_A is now the identity. As in Theorem 6.7, we can prove that, for all $0 < \varepsilon < 1/4$, there exist $\mu_0 > 0$ and a nondecreasing function η_0 from $\mathbb{R}^+$ into itself such that if $\mu \in (0,\mu_0)$ and $\|\mathbf{y}_0\|_{\mathbf{V}_n^{1/2-\varepsilon}(\Omega)} \leq \eta_0(\mu)$, the equation

$$\mathbf{y}' = A\mathbf{y} - B_\tau M^2 B_\tau^* \Pi_\omega \mathbf{y} + PF(\mathbf{y}), \qquad \mathbf{y}(0) = \mathbf{y}_0,$$

admits a unique solution in the set

$$D_\mu = \Big\{ \mathbf{y} \in \mathbf{V}^{3/2-\varepsilon,3/4-\varepsilon/2}(Q_\infty) \cap L^2(0,\infty;\mathbf{V}_n^0(\Omega)) \mid \|e^{\omega\,(\cdot)}\mathbf{y}\|_{\mathbf{V}^{3/2-\varepsilon,3/4-\varepsilon/2}(Q_\infty)} \leq \mu \Big\}.$$

Moreover, $\mathbf{y}$, which belongs to $C_b([0,\infty);\mathbf{V}_n^{1/2-\varepsilon}(\Omega))$, satisfies

$$|\mathbf{y}(t)|_{\mathbf{V}_n^{1/2-\varepsilon}(\Omega)} \leq C(\mathbf{w},\mu,\omega)\; e^{-\omega t}.$$

Notice that the local feedback stabilization of the two-dimensional Navier–Stokes equations is not studied in [4] (only the stabilization of the linearized Navier–Stokes equations is studied in two dimensions in [4, Appendix B]). If we transpose the results obtained in [4] in the three-dimensional case to the two-dimensional case, the results are completely different from the ones we obtain. Indeed we here prove a local stabilization result for the Navier–Stokes equations thanks to the solution of a classical Riccati equation (equation (7.1)), while the Riccati equation obtained in [4, section 4] is defined only in the domain of the square of the feedback operator, which is unknown.

7.2. Dependence of solutions with respect to ν for the stabilization of the Stokes equation. The dependence of solutions to our control problems with respect to ν is very complicated because the stationary solution $\mathbf{w}$ involved in the Oseen operator also depends on ν in a complicated way. There is one particular situation for which we can clarify this dependence; it is the one corresponding to $\mathbf{w} = 0$. Assume that the semigroup generated by $(\nu P\Delta + \omega I,\ \mathbf{V}^2(\Omega) \cap \mathbf{V}_0^1(\Omega))$ on $\mathbf{V}_n^0(\Omega)$ is unstable for a given $\omega > 0$. What has been done in section 6.2 is still valid if $\mathbf{w} \equiv 0$. Let Π_ω be the solution to (6.4) corresponding to $A = \nu A_0$ and $A_\omega = \nu A_0 + \omega I$. Consider the solution $\hat{\mathbf{y}}$ to the closed loop system

$$\begin{aligned} &P\hat{\mathbf{y}}' = AP\hat{\mathbf{y}} + \omega P\hat{\mathbf{y}} - B\,MR_A^{-1}M\,B^*\Pi_\omega P\hat{\mathbf{y}}, \qquad P\hat{\mathbf{y}}(0) = \mathbf{y}_0, \\ &(I-P)\hat{\mathbf{y}} = -(I-P)D_A R_A^{-1} M B_n^* \Pi_\omega P\hat{\mathbf{y}}. \end{aligned}$$

From the previous sections we know that

$$I(\hat{\mathbf{y}}, -MR_A^{-1}M\,B^*\Pi_\omega P\hat{\mathbf{y}}) = \frac{1}{2}\Big(\Pi_\omega \mathbf{y}_0, \mathbf{y}_0\Big)_{\mathbf{V}_n^0(\Omega)}$$

and

$$|\hat{\mathbf{y}}(t)|_{\mathbf{V}^{1/2-\varepsilon}(\Omega)} \le C(\varepsilon,\omega)e^{-\sigma t}|\mathbf{y}_0|_{\mathbf{V}^{1/2-\varepsilon}(\Omega)}$$

for all $0 < \varepsilon \le 1/2$, where $C(\varepsilon,\omega) > 0$ depends on ε and ω, and σ is positive but not precisely known. Setting $\mathbf{y} = e^{-\omega t}\hat{\mathbf{y}}$, we can check that $\mathbf{y}$ is the solution to the closed loop system

$$\begin{aligned} &P\mathbf{y}' = AP\mathbf{y} - B\,MR_A^{-1}M\,B^*\Pi_\omega P\mathbf{y}, \qquad P\mathbf{y}(0) = \mathbf{y}_0, \\ &(I-P)\mathbf{y} = -(I-P)D_AR_A^{-1}MB_n^*\Pi_\omega P\mathbf{y}, \end{aligned} \tag{7.2}$$

and $\mathbf{y}$ obeys the decay rate

$$|\mathbf{y}(t)|_{\mathbf{V}^{1/2-\varepsilon}(\Omega)} \le C(\varepsilon)e^{-(\omega+\sigma)t}|\mathbf{y}_0|_{\mathbf{V}^{1/2-\varepsilon}(\Omega)} \le C(\varepsilon)e^{-\omega t}|\mathbf{y}_0|_{\mathbf{V}^{1/2-\varepsilon}(\Omega)}.$$

Thus we have solved the boundary feedback stabilization problem of the Stokes equations with a prescribed exponential decay rate ω. Now we would like to clarify the dependence of the solution $\mathbf{y}$ of (7.2) with respect to ν.

We have to clarify the dependence of Π_ω with respect to ν. For that we first have to clarify the dependence of R_A, B, and B^* with respect to ν. We can choose $\lambda_0 = 0$ in the definition of D_A. We denote by $D_{A_0}\mathbf{u}$ the solution $\mathbf{y}$ to the equation

$$-\Delta\mathbf{y} + \nabla q = 0 \quad \text{and} \quad \text{div } \mathbf{y} = 0 \quad \text{in } \Omega, \qquad \mathbf{y} = \mathbf{u} \quad \text{on } \Gamma,$$

and we have $D_A = \frac{1}{\nu}D_{A_0}$ because $\lambda_0 = 0$. Thus $D_A^* = \frac{1}{\nu}D_{A_0}^*$, and $R_A = MD_A^*(I-P)D_AM + I = \frac{1}{\nu^2}MD_{A_0}^*(I-P)D_{A_0}M + I$. Since $B = (-A)PD_A = (-A_0)PD_{A_0}$, we observe that B and B^* do not depend on ν.

Let ν_1 and ν_2 be two viscosity coefficients such that $\nu_1 > \nu_2$. Assume that the semigroup generated by $(\nu_1 P\Delta + \omega I,\ \mathbf{V}^2(\Omega) \cap \mathbf{V}_0^1(\Omega))$ on $\mathbf{V}_n^0(\Omega)$ is unstable for a given $\omega > 0$.

For $i = 1, 2$, let $\Pi_{\nu_i,\omega}$ be the solution to (6.4) corresponding to $A_\omega = A_{\nu_i,\omega} = \nu_i A_0 + \omega I$.

With this notation we can observe that $\Pi_{\nu_1,\omega}$ is also the solution to the equation

$$\Pi_{\nu_1,\omega}A_{\nu_2,\omega} + A_{\nu_2,\omega}^*\Pi_{\nu_1,\omega}$$
$$-\frac{\nu_2}{\nu_1}\Pi_{\nu_1,\omega}BM\left(\frac{1}{\nu_1^2}MD_{A_0}^*(I-P)D_{A_0}M + I\right)^{-1}MB^*\Pi_{\nu_1,\omega} + \frac{\nu_2}{\nu_1}I + \omega I\left(\frac{\nu_2}{\nu_1} - 1\right) = 0.$$

Since $\nu_1 > \nu_2$, we can verify that

$$\begin{aligned} &\frac{\nu_2}{\nu_1}BM\left(\frac{1}{\nu_1^2}MD_{A_0}^*(I-P)D_{A_0}M + I\right)^{-1}MB^* \\ &= BM\left(\frac{1}{\nu_1\nu_2}MD_{A_0}^*(I-P)D_{A_0}M + I\right)^{-1}MB^* \\ &\ge BM\left(\frac{1}{\nu_2^2}MD_{A_0}^*(I-P)D_{A_0}M + I\right)^{-1}MB^* \end{aligned}$$

(where the inequality $\le$ is the inequality between quadratic forms), and

$$\frac{\nu_2}{\nu_1}I + \omega I\left(\frac{\nu_2}{\nu_1} - 1\right) \le I.$$

Thus, as in [7], we can claim that

$$\Pi_{\nu_1,\omega} \le \Pi_{\nu_2,\omega}.$$

If $\mathbf{y}_{\nu_i}$ is the solution to the closed loop system (7.2) for $A = \nu_i A_0$, we have

$$I(e^{-\omega t}\mathbf{y}_{\nu_1}, -e^{-\omega t} M R^{-1}_{\nu_1 A_0} M\, B^* \Pi_{\nu_1,\omega} P \mathbf{y}_{\nu_1}) = \tfrac{1}{2}\Big(\Pi_{\nu_1,\omega}\mathbf{y}_0, \mathbf{y}_0\Big)$$
$$\le I(e^{-\omega t}\mathbf{y}_{\nu_2}, -e^{-\omega t} M R^{-1}_{\nu_2 A_0} M\, B^* \Pi_{\nu_2,\omega} P \mathbf{y}_{\nu_2}) = \tfrac{1}{2}\Big(\Pi_{\nu_2,\omega}\mathbf{y}_0, \mathbf{y}_0\Big),$$

which provides a comparison between the L^2 of the solution to the stabilization problems according to the value of ν.

8. Appendix. In this section we prove some regularity results for the state and the adjoint equations.

LEMMA 8.1. *If* $\mathbf{y}_0 \in \mathbf{V}_n^{1/2-\varepsilon}(\Omega)$ *with* $0 < \varepsilon \le 1/2$, *the weak solution to the equation*

$$\mathbf{y}' = (A - \lambda_0)\mathbf{y} \quad \text{in } (0,\infty), \qquad \mathbf{y}(0) = \mathbf{y}_0,$$

obeys

$$\|\mathbf{y}\|_{C_b([0,\infty);\mathbf{V}_n^{1/2-\varepsilon}(\Omega))} + \|\mathbf{y}\|_{\mathbf{V}^{3/2-\varepsilon,3/4-\varepsilon/2}(Q_\infty)} \le C|\mathbf{y}_0|_{\mathbf{V}_n^{1/2-\varepsilon}(\Omega)}.$$

Proof. The exponential stability of the semigroup $(e^{t(A-\lambda_0 I)})_{t\ge 0}$ gives a bound for $\mathbf{y}$ in $L^2(0,\infty;\mathbf{V}_n^{1/2-\varepsilon}(\Omega))$. Using the estimate in $L^2(0,\infty;\mathbf{V}_n^{1/2-\varepsilon}(\Omega))$, the other estimates may be obtained by using the proofs in [5] and interpolation results. ∎

LEMMA 8.2. *If* $\mathbf{f} \in L^{2/(1+2\varepsilon)}(0,\infty;\mathbf{V}_n^0(\Omega))$, *the solution* $\mathbf{y}$ *to the equation*

$$\mathbf{y}' = (A - \lambda_0 I)\mathbf{y} + \mathbf{f} \quad \text{in } (0,\infty), \qquad \mathbf{y}(0) = 0,$$

obeys

$$\|\mathbf{y}\|_{L^2(0,\infty;\mathbf{V}^{2-2\varepsilon}(\Omega))} \le C\|\mathbf{f}\|_{L^{2/(1+2\varepsilon)}(0,\infty;\mathbf{V}_n^0(\Omega))}.$$

If $0 < \varepsilon < 1/4$ *and* $\mathbf{f} \in L^2(0,\infty;(\mathbf{V}_n^{2\varepsilon}(\Omega))')$, *then*

$$\|\mathbf{y}\|_{\mathbf{V}^{2-2\varepsilon,1-\varepsilon}(Q_\infty)} \le C\|\mathbf{f}\|_{L^2(0,\infty;(\mathbf{V}_n^{2\varepsilon}(\Omega))')}.$$

Proof. From the identity

$$(-A + \lambda_0 I)^{1-\varepsilon}\mathbf{y}(t) = \int_0^t (-A + \lambda_0 I)^{1-\varepsilon} e^{(t-\tau)(A-\lambda_0 I)}\mathbf{f}(\tau)\, d\tau,$$

it follows that

$$\|\mathbf{y}(t)\|_{\mathbf{V}^{2-2\varepsilon}(\Omega)} \le C\int_0^t e^{-\omega(t-\tau)}(t-\tau)^{-1+\varepsilon}|\mathbf{f}(\tau)|_{\mathbf{V}_n^0(\Omega)}\, d\tau.$$

Thus, with the generalized Young inequality for convolutions (see [30, p. 32]), we have

$$\|\mathbf{y}\|_{L^r(0,\infty;\mathbf{V}^{2-2\varepsilon}(\Omega))} \le C\|\mathbf{f}\|_{L^{2/(1+2\varepsilon)}(0,\infty;\mathbf{V}_n^0(\Omega))} \tag{8.1}$$

for all $2/(1+2\varepsilon) \le r \le 2$.

(ii) Now we assume that $\mathbf{f}$ belongs to $L^2(0,\infty;(\mathbf{V}_n^{2\varepsilon}(\Omega))')$. To prove the estimate in that case we proceed by interpolation. We know that

$$\|\mathbf{y}\|_{\mathbf{V}^{2,1}(Q_\infty)} \le C\|\mathbf{f}\|_{L^2(0,\infty;\mathbf{V}_n^0(\Omega))} \qquad \text{and} \qquad \|\mathbf{y}\|_{\mathbf{V}^{1,1/2}(Q_\infty)} \le C\|\mathbf{f}\|_{L^2(0,\infty;\mathbf{V}^{-1}(\Omega))}.$$

Since we have

$$[L^2(0,\infty;\mathbf{V}_n^0(\Omega)), L^2(0,\infty;\mathbf{V}^{-1}(\Omega))]_{2\varepsilon} = ([L^2(0,\infty;\mathbf{V}_n^0(\Omega)), L^2(0,\infty;\mathbf{V}_0^1(\Omega))]_{2\varepsilon})' = L^2(0,\infty;(\mathbf{V}_n^{2\varepsilon}(\Omega))'),$$

we obtain the desired result by interpolation. (Notice that $[\mathbf{V}_n^0(\Omega),\mathbf{V}_0^1(\Omega)]_{2\varepsilon} = \mathbf{V}_n^{2\varepsilon}(\Omega)$ because $0<\varepsilon<1/4$.) □

LEMMA 8.3. *If* $\mathbf{u}$ *belongs to* $\mathbf{V}^{s,s/2}(\Sigma_\infty)$ *with* $0 \le s < 1$, *then the weak solution to the equation*

$$\mathbf{y}' = (A-\lambda_0)\mathbf{y} + BM\mathbf{u} \quad \text{in } (0,\infty), \qquad \mathbf{y}(0) = 0,$$

obeys

$$\|\mathbf{y}\|_{\mathbf{V}^{1/2+s-\varepsilon,1/4+s/2-\varepsilon/2}(Q_\infty)} \le C\|\mathbf{u}\|_{\mathbf{V}^{s,s/2}(\Sigma_\infty)} \quad \text{for all } \varepsilon > 0.$$

If $\mathbf{u}$ *belongs to* $\mathbf{V}^{s,s/2}(\Sigma_\infty)$ *with* $1 < s \le 2$, *and if* $\mathbf{u}(0) = 0$, *then*

$$\|\mathbf{y}\|_{\mathbf{V}^{1/2+s-\varepsilon,1/4+s/2-\varepsilon/2}(Q_\infty)} \le C\|\mathbf{u}\|_{\mathbf{V}^{s,s/2}(\Sigma_\infty)} \quad \text{for all } \varepsilon > 0.$$

Proof. Similar estimates are proved in [26, Theorem 2.3] for a finite time interval. It is sufficient to rewrite the proof and to use the exponential stability of the semigroup $(e^{t(A-\lambda_0 I)})_{t\ge 0}$ to obtain the desired results. □

LEMMA 8.4. *For all* $\mathbf{y} \in \mathbf{V}_n^2(\Omega)$, *the solution* $\mathbf{\Phi} \in \mathbf{V}^2(\Omega) \cap \mathbf{V}_0^1(\Omega)$ *to the stationary equation* $\lambda_0\mathbf{\Phi} - A^*\mathbf{\Phi} = \mathbf{y}$ *obeys*

$$|\mathbf{\Phi}|_{\mathbf{V}^4(\Omega)} \le C|\mathbf{y}|_{\mathbf{V}_n^2(\Omega)}.$$

Proof. We rewrite the equation in the form

$$\lambda_0\mathbf{\Phi} - \nu P\Delta\mathbf{\Phi} = \mathbf{y} - P((\mathbf{w}\cdot\nabla)\mathbf{\Phi}) + P((\nabla\mathbf{w})^T\mathbf{\Phi}).$$

Since $\mathbf{w} \in \mathbf{V}^3(\Omega)$ and $\mathbf{\Phi} \in \mathbf{V}^2(\Omega)$, then $P((\mathbf{w}\cdot\nabla)\mathbf{\Phi})$ and $P((\nabla\mathbf{w})^T\mathbf{\Phi})$ belong to $\mathbf{V}^1(\Omega)$, which gives an estimate of $\mathbf{\Phi}$ in $\mathbf{V}^3(\Omega)$. Knowing that $\mathbf{\Phi} \in \mathbf{V}^3(\Omega)$, $P((\mathbf{w}\cdot\nabla)\mathbf{\Phi})$, and $P((\nabla\mathbf{w})^T\mathbf{\Phi})$ belong to $\mathbf{V}^2(\Omega)$, the proof is complete. □

LEMMA 8.5. *If the function* $\mathbf{y}$ *belongs to* $\mathbf{V}^{s,s/2}(Q_\infty) \cap L^2(0,\infty;\mathbf{V}_n^0(\Omega))$ *with* $0 \le s \le 2$, *then the solution* $\mathbf{\Phi}$ *to the equation*

$$-\mathbf{\Phi}' = (A^*-\lambda_0 I)\mathbf{\Phi} + \mathbf{y} \quad \text{in } (0,\infty), \qquad \mathbf{\Phi}(\infty) = 0, \tag{8.2}$$

satisfies

$$\|\mathbf{\Phi}\|_{\mathbf{V}^{s+2,s/2+1}(Q_\infty)} \le C\|\mathbf{y}\|_{\mathbf{V}^{s,s/2}(Q_\infty)}. \tag{8.3}$$

Proof. Step 1. Let us first prove estimate (8.3) for $s = 0$. Assume that $\mathbf{y} \in L^2(0,\infty;\mathbf{V}_n^0(\Omega))$. The existence of a unique solution $\mathbf{\Phi}$ to (8.2) in $L^2(0,\infty;\mathbf{V}_n^0(\Omega))$ follows from the exponential stability of the semigroup $(e^{t(A^*-\lambda_0 I)})_{t\ge 0}$ on $\mathbf{V}_n^0(\Omega)$. Moreover, we have

$$\|\mathbf{\Phi}\|_{L^2(0,\infty;\mathbf{V}_n^0(\Omega))} \le C\|\mathbf{y}\|_{L^2(0,\infty;\mathbf{V}_n^0(\Omega))}. \tag{8.4}$$

It is sufficient to prove estimate (8.3) for $s = 0$ and $\mathbf{y} \in C_c(0,\infty;\mathbf{V}_n^0(\Omega))$. In that case, it can be deduced from (8.4) with the method of proof in [5, Theorem 1.1].

Step 2. Now let us assume that $\mathbf{y}$ belongs to $\mathbf{V}^{2,1}(Q_\infty)$, and let us prove estimate (8.3) for $s = 2$. We have

$$(-A^* + \lambda_0 I)\mathbf{\Phi}(t) = \int_t^\infty (-A^* + \lambda_0 I)e^{(\tau-t)(A^*-\lambda_0 I)}\mathbf{y}(\tau)\,d\tau.$$

Integrating by parts, we obtain

$$(-A^* + \lambda_0 I)\mathbf{\Phi}(t) = \mathbf{y}(t) + \int_t^\infty e^{(\tau-t)(A^*-\lambda_0 I)}\mathbf{y}'(\tau)\,d\tau.$$

Since $\mathbf{y}'$ belongs to $L^2(0,\infty;\mathbf{V}_n^0(\Omega))$, with estimate (8.3) for $s = 0$ we have

$$\left\| \int_t^\infty e^{(\tau-t)(A^*-\lambda_0 I)}\mathbf{y}'(\tau)\,d\tau \right\|_{\mathbf{V}^{2,1}(Q_\infty)} \le C\|\mathbf{y}'\|_{L^2(0,\infty;\mathbf{V}_n^0(\Omega))}.$$

Thus

$$\begin{aligned}\|(-A^* + \lambda_0 I)\mathbf{\Phi}\|_{L^2(0,\infty;\mathbf{V}^2(\Omega))} &\le C(\|\mathbf{y}\|_{L^2(0,\infty;\mathbf{V}^2(\Omega))} + \|\mathbf{y}'\|_{L^2(0,\infty;\mathbf{V}_n^0(\Omega))})\\ &\le C\|\mathbf{y}\|_{\mathbf{V}^{2,1}(Q_\infty)}.\end{aligned}$$

From regularity results for the stationary Oseen equation (Lemma 8.4), it follows that

$$\|\mathbf{\Phi}\|_{L^2(0,\infty;\mathbf{V}^4(\Omega))} \le C\|(-A^* + \lambda_0 I)\mathbf{\Phi}\|_{L^2(0,\infty;\mathbf{V}^2(\Omega))}.$$

Thus

$$\|\mathbf{\Phi}\|_{L^2(0,\infty;\mathbf{V}^4(\Omega))} \le C\|\mathbf{y}\|_{\mathbf{V}^{2,1}(Q_\infty)}.$$

From (8.2) we deduce

$$\begin{aligned}\|\mathbf{\Phi}'\|_{L^2(0,\infty;\mathbf{V}^2(\Omega))} &\le C(\|(-A^* + \lambda_0 I)\mathbf{\Phi}\|_{L^2(0,\infty;\mathbf{V}^2(\Omega))} + \|\mathbf{y}\|_{L^2(0,\infty;\mathbf{V}^2(\Omega))})\\ &\le C\|\mathbf{y}\|_{\mathbf{V}^{2,1}(Q_\infty)}.\end{aligned}$$

The estimate (8.3) is obtained by interpolation between the estimates obtained for $s = 0$ and $s = 2$. □

LEMMA 8.6. *For all* $\mathbf{y} \in L^2(0,T;\mathbf{V}_n^0(\Omega))$, *the solution to the equation*

$$-\mathbf{\Phi}' = A^*\mathbf{\Phi} + \mathbf{y} \quad \text{in } (0,T), \qquad \mathbf{\Phi}(T) = 0, \tag{8.5}$$

satisfies

$$\|\mathbf{\Phi}\|_{\mathbf{V}^{2,1}(Q_T)} \le C\|\mathbf{y}\|_{L^2(0,T;\mathbf{V}_n^0(\Omega))}. \tag{8.6}$$

If the function $\mathbf{y}$ *belongs to* $\mathbf{V}^{s,s/2}(Q_T)$ *with* $0 \le s < 3/2$, *then the function* $\mathbf{\Phi}$ *belongs to* $\mathbf{V}^{s+2,s/2+1}(Q_T)$, *and the following estimate holds:*

$$\|\mathbf{\Phi}\|_{\mathbf{V}^{s+2,s/2+1}(Q_T)} \le C\|\mathbf{y}\|_{\mathbf{V}^{s,s/2}(Q_T)}. \tag{8.7}$$

Proof. The estimate (8.6) follows from [5, Theorem 1.1]. If $\mathbf{y}$ belongs to $\mathbf{V}^{2,1}(Q_T)$ and if $\mathbf{y}(T) \in \mathbf{V}_0^1(\Omega)$, we have

$$\|\mathbf{\Phi}'\|_{L^2(0,T;\mathbf{V}^2(\Omega))} + \|\mathbf{\Phi}\|_{L^2(0,T;\mathbf{V}^4(\Omega))} \le C\|\mathbf{y}\|_{\mathbf{V}^{2,1}(Q_T)};$$

see, e.g., [29]. The estimate for $0 \le s < 3/2$ is obtained by interpolation between the estimates obtained for $s = 0$ and $s = 2$. For $s < 3/2$ the regularity condition $y(T) \in \mathbf{V}_0^1(\Omega)$ is not needed. ∎

LEMMA 8.7. *Let $\mathbf{\Phi}$ be the solution to* (8.2)*, and let ψ be the pressure associated with $\mathbf{\Phi}$, that is, the function satisfying*

$$
\begin{aligned}
&-\frac{\partial \mathbf{\Phi}}{\partial t} - \nu \Delta \mathbf{\Phi} - (\mathbf{w}\cdot\nabla)\mathbf{\Phi} + (\nabla \mathbf{\Phi})^T \mathbf{w} + \lambda_0 \mathbf{\Phi} + \nabla \psi = \mathbf{y} \quad \text{in } Q_\infty,\\
&\operatorname{div} \mathbf{\Phi} = 0 \quad \text{in } Q_\infty, \quad \mathbf{\Phi} = 0 \quad \text{on } \Sigma_\infty, \quad \mathbf{\Phi}(\infty) = 0 \quad \text{in } \Omega.
\end{aligned} \tag{8.8}
$$

If, in (8.2)*, $\mathbf{y}$ belongs to $L^2(0,\infty;\mathbf{V}_n^0(\Omega))$, then the function ψ belongs to $L^2(0,\infty;H^1(\Omega))$. If, in addition, $\mathbf{y}$ belongs to $\mathbf{V}^{s,s/2}(Q_\infty)$ with $0 \le s \le 2$, then the function ψ belongs to $L^2(0,\infty;H^{s+1}(\Omega)) \cap H^{s/2}(0,\infty;H^1(\Omega))$.*

Proof. Assume that $\mathbf{y}$ belongs to $L^2(0,\infty;\mathbf{V}_n^s(\Omega)) \cap H^{s/2}(0,\infty;\mathbf{V}_n^0(\Omega))$ with $0 \le s \le 2$. From Lemma 8.5 it follows that

$$
\left(\mathbf{y} + \frac{\partial \mathbf{\Phi}}{\partial t} + \nu \Delta \mathbf{\Phi} + (\mathbf{w}\cdot\nabla)\mathbf{\Phi} - (\nabla \mathbf{\Phi})^T \mathbf{w} \right) \in \mathbf{H}^{s,s/2}(Q_\infty).
$$

Thus $\nabla\psi$ belongs to $\mathbf{H}^{s,s/2}(Q_\infty)$, and the proof is complete. ∎

LEMMA 8.8. *If, in* (8.5)*, $\mathbf{y}$ belongs to $\mathbf{V}^{s,s/2}(Q_T) \cap L^2(0,T;\mathbf{V}_n^s(\Omega))$ with $0 \le s < 3/2$, then the function ψ, the pressure associated with $\mathbf{\Phi}$, belongs to $L^2(0,T;H^{s+1}(\Omega)) \cap H^{s/2}(0,T;H^1(\Omega))$.*

Proof. The proof is similar to the previous one. ∎

LEMMA 8.9. *Let $\mathbf{\Phi} \in \mathbf{V}^{2,1}(Q_\infty)$ be the solution to* (8.2)*, and set*

$$
\mathbf{u} = -(M\gamma_\tau + R_A^{-1} M\gamma_n) B^* \mathbf{\Phi}\,.
$$

If, in (8.2)*, the function $\mathbf{y}$ belongs to $L^2(0,\infty;\mathbf{V}_n^s(\Omega)) \cap H^{s/2}(0,\infty;\mathbf{V}_n^0(\Omega))$ with $0 \le s \le 2$, then*

$$
\begin{aligned}
&\|B^*\mathbf{\Phi}\|_{L^2(0,\infty;\mathbf{V}^{s+1/2}(\Gamma)) \cap H^{s/2}(0,\infty;\mathbf{V}^{1/2}(\Gamma))} + \|\mathbf{u}\|_{L^2(0,\infty;\mathbf{V}^{s+1/2}(\Gamma)) \cap H^{s/2}(0,\infty;\mathbf{V}^{1/2}(\Gamma))}\\
&\le C \|\mathbf{y}\|_{\mathbf{V}^{s,s/2}(Q_\infty)}.
\end{aligned} \tag{8.9}
$$

Proof. As in Lemma 3.5, we can show that

$$
\mathbf{u} = -(M\gamma_\tau + R_A^{-1} M\gamma_n) \left(\nu \frac{\partial \mathbf{\Phi}}{\partial \mathbf{n}} - \psi\, \mathbf{n} + c(\psi)\mathbf{n} \right),
$$

where ψ is the pressure associated with $\mathbf{\Phi}$ and $c(\psi)$ is the constant defined in (2.1).

Since $\mathbf{y}$ belongs to $L^2(0,\infty;\mathbf{V}_n^s(\Omega)) \cap H^{s/2}(0,\infty;\mathbf{V}_n^0(\Omega))$, from Lemma 8.5 we deduce that $\mathbf{\Phi}$ belongs to $\mathbf{V}^{s+2,s/2+1}(Q_\infty)$, and from Lemma 8.7 it follows that ψ belongs to $L^2(0,\infty;H^{s+1}(\Omega)) \cap H^{s/2}(0,\infty;H^1(\Omega))$. Thus $\mathbf{u}$ belongs to $L^2(0,\infty;H^{s+1/2}(\Gamma)) \cap H^{s/2}(0,\infty;H^{1/2}(\Gamma))$. ∎

Acknowledgments. The author thanks the referees for their valuable questions and suggestions, which have contributed to improving the first version of the paper. After this paper was submitted, I. Lasiecka informed the author of her joint work with V. Barbu and R. Triggiani [4]. The author thanks I. Lasiecka for providing him a copy of this joint paper and for discussions in Oberwolfach.

A NEW APPROACH TO ADAPTIVE NONLINEAR REGULATION*

F. DELLI PRISCOLI†, L. MARCONI‡, AND A. ISIDORI§

Abstract. This paper shows how the theory of adaptive observers can be effectively used in the design of internal models for nonlinear output regulation. The main result obtained in this way is a new method for the synthesis of adaptive internal models, which substantially enhances the existing theory of adaptive output regulation by allowing nonlinear internal models and more general classes of controlled plants.

Key words. adaptive observers, internal model, regulation, tracking, nonlinear control

1. Introduction.

The problem of controlling the output of a system so as to achieve asymptotic tracking of prescribed trajectories and/or asymptotic rejection of disturbances is a central problem in control theory. There are essentially three different possible approaches to the problem: tracking by dynamic inversion, adaptive tracking, and tracking via internal models.

Tracking by dynamic inversion consists of computing a precise initial state and a precise control input (or equivalently a reference trajectory of the state) such that, if the system is accordingly initialized and driven, its output exactly reproduces the reference signal. The computation of such a control input, though, requires "perfect knowledge" of the entire trajectory to be tracked as well as "perfect knowledge" of the model of the controlled plant. Thus, this type of approach is not suited to the presence of large uncertainties on plant parameters or on the reference signal.

Adaptive tracking can successfully handle parameter uncertainties, but it still presupposes the knowledge of the entire trajectory to be tracked (to be used in the design of the adaptation algorithm), and therefore this approach is not suited to the problem of tracking unknown trajectories.

Internal model–based tracking, on the other hand, is able to handle simultaneously uncertainties in plant parameters as well as in the trajectory to be tracked. It has been proven that, if the trajectory to be tracked belongs to the set of all trajectories generated by some fixed dynamical system, a controller which incorporates an internal model of such a system is able to secure asymptotic decay to zero of the tracking error for every possible trajectory in this set and does it robustly with respect to parameter uncertainties. This is in sharp contrast with the two approaches mentioned above, where, in lieu of the assumption that a signal is within a class of signals generated by an exogenous system, one instead needs to assume complete knowledge of the past, present, and future time history of the trajectory to be tracked. It is for this

reason that the internal model–based approach seems to be best suited to problems of tracking unknown reference trajectories or rejecting unknown disturbances.

A generalized problem of tracking and asymptotic disturbance rejection is usually cast as follows. A nonlinear system is given, modeled by equations of the form

$$\begin{aligned} \dot{x} &= f(x, u, v), \\ y &= k(x, v), \\ e &= h(x, v), \end{aligned}$$

with state x, control input u, measured output y, and regulated output e. In this system, v is an exogenous input, which represents actual *disturbances* as well as *commands* to be followed, and it is assumed that, as a function of time, $v(t)$ can be seen as generated by a separate autonomous dynamical system, called the *exosystem*. Generally speaking, the problem of tracking and asymptotic disturbance rejection (sometimes also referred to as the generalized *servomechanism problem* or the *output regulation problem*) is to design a controller so as to obtain a closed-loop system in which

- all trajectories are bounded, and
- the regulated output $e(t)$ asymptotically decays to 0 as $t \to \infty$.

The peculiar aspect of this design problem is the characterization of the class of all possible exogenous inputs (disturbances as well as commands) as the set of all possible solutions of a fixed (finite-dimensional) differential equation. This can be seen as an intermediate choice between two extremes: the (pessimistic) case in which the design is required to obtain certain goals in the presence of the *worst possible* exogenous input, or the (optimistic) case in which the controller is assumed *to have access* to the exogenous input v. In this design problem, the controller does not have access to the exogenous input in real time, but the latter is restricted to range over a "finite-dimensional" set of functions (such as the set of solutions of a fixed differential equation). The vector v may include constant uncertain parameters, which have a trivial dynamics, and hence can be viewed as solutions of a (trivial) differential equation. In other words, in this setting, *any source of uncertainty* (about an actual disturbance affecting the system, an actual trajectory to be tracked, any unknown constant parameter in the plant, or any unknown constant parameter in the exosystem itself) is treated as *uncertainty in the initial condition* of a fixed autonomous finite-dimensional dynamical system, which is then seen as a source of all possible constant, as well time-varying, uncertainties.

For linear multivariable systems this problem was addressed in very elegant geometric terms by Davison, Francis, Wonham [7, 9, 8], and others. A nonlinear enhancement of this theory, which uses a combination of geometry and nonlinear dynamical systems theory, was presented in [16, 12, 11, 5] in the context of solving the problem near an equilibrium, in the presence of exogenous signals which were produced by a Poisson stable system. In particular, Huang showed how, by appropriately designing the internal model, the controlled output could be steered toward zero in spite of plant parameter uncertainties, thus extending to the nonlinear setting one of the most remarkable features of internal model–based design for linear systems. Under suitable hypotheses, the (local) design methods presented in these works have been extended [18, 15, 24] to the case of arbitrarily large (but compact) sets of initial data. A substantial limitation of classical internal model–based control (for linear as well as nonlinear systems) is the sensitivity to parameter uncertainties in the exosystem. This limitation, though, was later removed, under convenient hypotheses, in the paper [25], where the possibility of using techniques of adaptive control to cope with

unknown parameters in the exosystem was successfully demonstrated. The adaptive design methodology of [25] was soon recognized as a useful way to cope with parameter uncertainties in the exosystem. It was, for instance, used in [29] for the solution of a global decentralized regulation problem for a class of nonlinear systems.

In the recent paper [2], the problem in question has been posed in more general terms, not tied, as all previous contributions were, to the existence of a privileged equilibrium point about which the (local as well semiglobal) analysis was conducted. The more general foundations laid in this way make it possible to overcome certain restrictions of the earlier theory, notably the assumption that the controlled plant has an asymptotically stable zero dynamics, which is replaced by the substantially weaker hypothesis that the latter (the zero dynamics) possess a compact attractor. Another major enhancement of this newer approach is a systematic method for the design of nonlinear internal models (see [3]). The presence of parametric uncertainties in the exosystem, however, is not explicitly addressed in [3, 2].

The purpose of the present paper is to show how the problem of handling *parametric uncertainties in the exosystem* can be successfully addressed by means of a new approach which relies, on one hand, on the general nonequilibrium theory developed in [2] and, on the other hand, on the theory of adaptive observers for nonlinear systems pioneered in [1] and [21]. The result obtained in this way is a totally new method for the synthesis of adaptive internal models and substantially extends the adaptive regulation theory presented in [25] by allowing nonlinear internal models and more general classes of controlled plants.

2. Output regulation and limit sets. The purpose of output regulation is to obtain a closed-loop system in which all trajectories with initial conditions in a fixed (but otherwise arbitrary) compact set are bounded and the regulated output converges to zero as time tends to infinity. As shown in [2], intimately associated with this problem is the notion of a *limit set* of a given bounded set of initial conditions. For the reader's convenience, the notion in question is summarized as follows.

Consider an *autonomous* ordinary differential equation

$$\dot{x} = f(x) \tag{1}$$

in which $x \in \mathbb{R}^n$, $t \in \mathbb{R}$, with $f(x)$ a locally Lipschitz function. Let

$$\phi : \quad (t, x) \mapsto \phi(t, x)$$

define the flow of (1). Suppose the flow is forward complete. The *ω-limit set* of a subset $B \subset \mathbb{R}^n$, written $\omega(B)$, is the totality of all points $x \in \mathbb{R}^n$ for which there exists a sequence of pairs (x_k, t_k), with $x_k \in B$ and $t_k \to \infty$ as $k \to \infty$, such that

$$\lim_{k \to \infty} \phi(t_k, x_k) = x \,.$$

In case $B = \{x_0\}$, the set thus defined, $\omega(x_0)$, is precisely the ω-limit set, as defined by Birkhoff, of the point x_0. Note that, in general,

$$\bigcup_{x_0 \in B} \omega(x_0) \subset \omega(B) \,,$$

but the equality may not hold.

It is well known that if $\phi(t, x_0)$ is bounded in positive time, then the set $\omega(x_0)$ is nonempty, compact, invariant, and

$$\lim_{t \to \infty} \operatorname{dist}(\phi(t, x_0), \omega(x_0)) = 0 \,.$$

If B is not just the singleton $\{x_0\}$, the following more general property holds. Recall that a set A is said to *uniformly attract* a set B under the flow of (1) if for every $\varepsilon > 0$ there exists a time $\bar{t}$ such that

$$\operatorname{dist}(\phi(t,x),A) \leq \varepsilon \qquad \text{for all } t \geq \bar{t} \text{ and for all } x \in B.$$

Then the following holds (see [10, page 8]).

LEMMA 1. *If B is a nonempty bounded set for which there is a compact set J which uniformly attracts B (and thus, in particular, if B is any nonempty bounded set whose positive orbit has a bounded closure), then $\omega(B)$ is nonempty, compact, invariant, and uniformly attracts B. Moreover, if $\omega(B) \in \operatorname{int}(B)$, then $\omega(B)$ is stable in the sense of Lyapunov.*

3. Class of systems and main assumptions. In this paper we discuss the design of output regulators for nonlinear systems modeled by equations of the form

$$\begin{aligned} \dot{z} &= f_0(\varrho,w,z) + f_1(\varrho,w,z,e_1)e_1, \\ \dot{e}_1 &= e_2 \\ &\vdots \\ \dot{e}_{r-1} &= e_r, \\ \dot{e}_r &= q(\varrho,w,z,e_1,\dots,e_r) + u, \\ e &= e_1, \\ y &= \operatorname{col}(e_1,\dots,e_r), \end{aligned} \tag{2}$$

with state $(z,e_1,\dots,e_r) \in \mathbb{R}^n \times \mathbb{R}^r$, control input $u \in \mathbb{R}$, regulated output $e \in \mathbb{R}$, measured output $y \in \mathbb{R}^r$, and in which the exogenous (disturbance) input $w \in \mathbb{R}^s$ is generated by an exosystem

$$\dot{w} = s(\varrho,w)\,. \tag{3}$$

In this model, $\varrho \in \mathbb{R}^p$ is a vector of *constant* uncertain parameters, ranging over a fixed compact set P. The vector ϱ is the aggregate of a finite set of uncertain parameters affecting the controlled plant and another, possibly different, set of uncertain parameters affecting the exosystem. These parameters may be regarded as "trivial components" of an "augmented" exogenous input, but for the sake of clarity, and also consistency with some of the earlier literature, their role will be kept separate. Occasionally, throughout the paper, the "augmented" exosystem

$$\begin{aligned} \dot{\varrho} &= 0, \\ \dot{w} &= s(\varrho,w) \end{aligned} \tag{4}$$

will be rewritten in more compact form as

$$\dot{\mathbf{w}} = \mathbf{s}(\mathbf{w}), \tag{5}$$

where $\mathbf{w} = \operatorname{col}(\varrho,w)$.

The functions $f_0(\cdot), f_1(\cdot), q(\cdot), s(\cdot)$ in (2) and (4) are assumed to be at least continuously differentiable. The initial conditions of (2) range over a set $Z \times E$, in which Z is a fixed *compact* subset of $\mathbb{R}^n$ and $E = \{(e_1,\dots,e_r) \in \mathbb{R}^r : |e_i| \leq c\}$, with c a fixed number. The initial conditions of the exosystem (5) range over a *compact* subset $\mathbf{W}$ of $\mathbb{R}^p \times \mathbb{R}^s$. In this framework the problem of output regulation is to design an output feedback regulator of the form

$$\begin{aligned} \dot{\zeta} &= \varphi(\zeta,y), \\ u &= \gamma(\zeta,y) \end{aligned}$$

such that *for all initial conditions* $\mathbf{w}(0) \in \mathbf{W}$ *and* $(z(0), e_1(0), \dots, e_r(0)) \in Z \times E$ *the trajectories of the closed-loop system are bounded and* $\lim_{t\to\infty} e(t) = 0$.

Augmenting (2) with (4) yields a system which, viewing u as input and e as output, has relative degree r. The associated "augmented" zero dynamics, which is forced by the control

$$u = -q(\varrho, w, z, 0, \dots, 0)\,, \tag{6}$$

is given by

$$\begin{aligned} \dot{\varrho} &= 0, \\ \dot{w} &= s(\varrho, w), \\ \dot{z} &= f_0(\varrho, w, z)\,. \end{aligned} \tag{7}$$

The ability to design feedback controllers which solve the problem of output regulation very much depends, among other things, on certain properties of the autonomous system (7), viewed as a system with state (ϱ, w, z) and "output" provided by (6). For notational convenience, throughout the paper, we will sometime rewrite (7) and (6) in more compact form as

$$\dot{\mathbf{z}} = \mathbf{f}_0(\mathbf{z}) \tag{8}$$

and

$$u = \mathbf{q}_0(\mathbf{z}),$$

having set $\mathbf{z} = \mathrm{col}(\varrho, w, z)$. Accordingly, we set $\mathbf{Z} = \mathbf{W} \times Z$.

In what follows, we retain three of the basic assumptions that were introduced in [2] and express certain properties of the augmented zero dynamics (7). The assumptions in question are the following:

Assumption (i): The set $\mathbf{W}$ is a compact differential submanifold (with boundary) of $\mathbb{R}^p \times \mathbb{R}^s$, and $\mathbf{W}$ is invariant for (5).

Assumption (ii): There exists a compact subset $\mathcal{Z}$ of $\mathbf{W} \times \mathbb{R}^n$ which contains the positive orbit of the set $\mathbf{Z}$ under the flow of (8), and $\omega(\mathbf{Z})$ is a differential submanifold (with boundary) of $\mathbf{W} \times \mathbb{R}^n$. Moreover, there exists a number $d_1 > 0$ such that

$$\mathbf{z} \in \mathbf{W} \times \mathbb{R}^n\,, \quad \mathrm{dist}(\mathbf{z}, \omega(\mathbf{Z})) \le d_1 \Rightarrow \mathbf{z} \in \mathbf{Z}.$$

We remark on the above hypotheses that, since the positive orbit of the set $\mathbf{Z}$ under the flow of (8) is bounded, the set $\omega(\mathbf{Z})$, namely the ω-limit set of $\mathbf{Z}$ under the flow of (8), is a nonempty, compact, and invariant subset of $\mathbf{W} \times \mathbb{R}^n$ which uniformly attracts all trajectories of (8) with initial conditions in $\mathbf{Z}$. It can also be shown (as in [2]) that for every $\mathbf{w} \in \mathbf{W}$ there is $z \in \mathbb{R}^n$ such that $(\mathbf{w}, z) \in \omega(\mathbf{Z})$. In what follows, for convenience, the set $\omega(\mathbf{Z})$ will be simply denoted as $\mathcal{A}_0$.

The last condition in Assumption (ii) implies that for every $\varepsilon > 0$ there is $\delta > 0$ such that

$$\mathbf{z}_0 \in \mathbf{W} \times \mathbb{R}^n\,, \quad \mathrm{dist}(\mathbf{z}_0, \mathcal{A}_0) \le \delta \Rightarrow \mathrm{dist}(\mathbf{z}(t, \mathbf{z}_0),\, \mathcal{A}_0) \le \varepsilon \qquad \text{for all } t \ge 0,$$

in which $\mathbf{z}(t, \mathbf{z}_0)$ denotes the solution of (8) passing through $\mathbf{z}_0$ at time $t = 0$.

In the next hypothesis, which will be used in the last part of the paper, we strengthen this property as follows.

Assumption (iii): There exist $M \geq 1$, $a > 0$, and $d_2 \leq d_1$ such that

$$\mathbf{z}_0 \in \mathbf{W} \times \mathbb{R}^n, \quad \operatorname{dist}(\mathbf{z}_0, \mathcal{A}_0) \leq d_2 \Rightarrow \operatorname{dist}(\mathbf{z}(t, \mathbf{z}_0), \mathcal{A}_0) \leq M e^{-at} \operatorname{dist}(\mathbf{z}_0, \mathcal{A}_0).$$

The results presented in [2], like essentially most previous results on output regulation, relied upon the hypothesis that the set of all "feed-forward inputs capable of securing perfect tracking" (that is, the set of inputs of the form $u(t) = \mathbf{q}_0(\mathbf{z}(t))$, with $\mathbf{z}(t)$ a trajectory of the restriction of (8) to $\mathcal{A}_0$) could be seen as a subset of the set of outputs of a suitable linear system. The system in question was used to construct a (linear, as a matter of fact) internal model. This assumption was weakened in the paper [6], where it was assumed that the controls in question can be put in the form $u(t) = \beta(\xi(t))$, with $\beta : \mathbb{R}^d \to \mathbb{R}$ a smooth function and $\xi(t)$ obeying a linear differential equation. A further extension was proposed in [3], where a general method for the construction of fully nonlinear internal models was presented, but the method in question did not allow for the presence of uncertain parameters in the exosystem. In this paper we introduce a different kind of hypothesis, leading to a somewhat more restricted class of internal models, but which—in return—allows for uncertain parameters in the exosystem.

Assumption (iv): There exist positive integers d and q, a C^d map

$$\begin{aligned} \tau \quad : \quad & \mathcal{Z} \to \mathbb{R}^d, \\ & \mathbf{z} \mapsto \tau(\mathbf{z}), \end{aligned}$$

a C^0 map

$$\begin{aligned} \theta \quad : \quad & P \to \mathbb{R}^q, \\ & \varrho \mapsto \theta(\varrho), \end{aligned}$$

an observable pair $(A, C) \in \mathbb{R}^{d \times d} \times \mathbb{R}^{1 \times d}$, a C^1 map $\phi : \mathbb{R} \to \mathbb{R}^d$, and a C^d map $\Omega : \mathbb{R} \to \mathbb{R}^{d \times q}$ such that the following identities (which we call *immersion property*)

$$\frac{\partial \tau}{\partial \mathbf{z}} \mathbf{f}_0(\mathbf{z}) = A\,\tau(\mathbf{z}) + \phi(C\tau(\mathbf{z})) + \Omega(C\tau(\mathbf{z}))\,\theta(\varrho), \tag{9}$$

$$\mathbf{q}_0(\mathbf{z}) = C\,\tau(\mathbf{z}) \tag{10}$$

hold for all $\mathbf{z} \in \mathcal{A}_0$, $\varrho \in P$.

Remark. Note that Assumption (iv) can be rephrased to say that for each initial condition $\mathbf{z}(0) \in \mathcal{A}_0$ of (8), there is a pair $\xi(0), \theta$ such that the control input $u(t) = \mathbf{q}_0(\mathbf{z}(\mathbf{t}))$ (which is the unique input capable of keeping $e(t)$ identically at zero) can be seen as the output of a system of the form

$$\begin{aligned} \dot{\xi} &= A\xi + \phi(u) + \Omega(u)\theta, \\ \dot{\theta} &= 0, \\ u &= C\xi. \end{aligned} \tag{11}$$

Remark. If the vector ϱ of constant uncertain parameters enters linearly in the vector field $\mathbf{f}_0(\mathbf{z})$ and the map $\mathbf{q}_0(\mathbf{z})$ is not affected by ϱ, necessary and sufficient conditions for the existence of a ϱ-independent *diffeomorphism* $\tau(\cdot)$, which satisfies (9)–(10) with $\theta(\varrho) = \varrho$, can be found in [21]. It must be stressed, though, that Assumption (iv) can be fulfilled under much weaker conditions because (a) the immersion map τ is

not necessarily required to be a diffeomorphism (as the dimension d of the final state space is not restricted to be equal to the dimension $p+s+n$ of the original state space); (b) the mapping $\tau(\cdot)$ can be ϱ-dependent; and (c) "overparametrization" is allowed in the definition of the map $\theta(\cdot)$, which in this way is not necessarily the identity map.

Without loss of generality (see [20, page 208]), we will assume throughout that the matrices A and C in (11) have the form

$$A = \begin{pmatrix} 0 & 1 & 0 & \cdots & 0 \\ 0 & 0 & 1 & \cdots & 0 \\ \cdot & \cdot & \cdot & \cdots & \cdot \\ 0 & 0 & 0 & \cdots & 1 \\ 0 & 0 & 0 & \cdots & 0 \end{pmatrix}, \qquad C = \begin{pmatrix} 1 & 0 & 0 & \cdots & 0 \end{pmatrix}.$$

Furthermore, since the maps $\Omega(\cdot)$ and $\phi(\cdot)$ are continuously differentiable and relations (9)–(10) are supposed to hold over the compact set $\mathcal{A}_0$, it can be assumed without loss of generality that functions $\phi(\cdot)$ and $\Omega(\cdot)$ have compact support. This being the case, the functions in question can be assumed *globally Lipschitz*; i.e., there exist L_ϕ and L_Ω such that

$$|\phi(s_1)-\phi(s_2)| \le L_\phi |s_1-s_2|, \qquad |\Omega(s_1)-\Omega(s_2)| \le L_\Omega |s_1-s_2|$$

for all s_1, s_2.

The immersion property specified in Assumption (iv) enables us to use, for the design of controllers, the theory of adaptive observers pioneered in [1] and developed in [21]. As shown in that theory, convergence of certain estimates occurs under the assumption that certain signals are "persistently exciting." In the present context, a similar role is played (as we will see later in the proof of Lemma 6) by an assumption which can be expressed as follows. For each $\mathbf{z}_0 \in \mathcal{A}_0$, consider the map

$$\begin{aligned} \varphi_{\mathbf{z}_0} \quad : \quad & \mathbb{R} \to \mathbb{R}^{1\times q}, \\ & t \mapsto \sum_{i=1}^{d} C A^{i-1} \Omega^{(d-i)}(C\tau(\mathbf{z}(t,\mathbf{z}_0))) \end{aligned}$$

in which $\Omega^{(k)}(C\tau(\mathbf{z}(t,\mathbf{z}_0)))$ denotes the kth derivative of $\Omega(C\tau(\mathbf{z}(t,\mathbf{z}_0)))$ with respect to the argument t.

Assumption (v): For each $\mathbf{z}_0 \in \mathcal{A}_0$, the q entries of $\varphi_{\mathbf{z}_0}(\cdot)$ are linearly independent functions, namely

$$\varphi_{\mathbf{z}_0}(t)\theta = 0 \qquad \text{for all } t \in \mathbb{R} \Rightarrow \theta = 0.$$

Remark. While the hypothesis in question plays, in the present context, a role equivalent to the role of the assumption of *persistence of excitation* in classical adaptive control (i.e., it implies convergence of certain parameter estimates to their true values) it must be stressed that Assumption (v) here is different, at least for two reasons. First, this assumption does not require (as the assumption of persistency of excitation does) that certain signals have "finite energy" over any finite time interval of the form $[t, t+\delta]$, but simply that certain signals are just linearly independent over the entire time axis. Second, this assumption is only a property of the solutions of $\dot{\mathbf{z}} = \mathbf{f}_0(\mathbf{z})$ with initial conditions in $\mathcal{A}_0$.

In the remaining part of this section we show that *there is no loss of generality* in addressing the simpler case in which the relative degree of (2) is $r = 1$. As a matter of fact, consider the change of variable

$$e_r \;\mapsto\; \tilde{e} := e_r + g^{r-1}a_0e_1 + g^{r-2}a_1e_2 + \cdots + ga_{r-2}e_{r-1},$$

where g is a *positive* design parameter and a_i, $i = 0, \ldots, r-2$, are such that all roots of the polynomial $\lambda^{r-1} + a_{r-2}\lambda^{r-1} + \cdots + a_1\lambda + a_0 = 0$ have negative real part. This changes system (2) into a system of the form

$$\begin{aligned} \dot{\tilde{z}} &= \tilde{f}_0(\varrho, w, \tilde{z}) + \tilde{f}_1(\varrho, w, \tilde{z}, \tilde{e})\tilde{e}, \\ \dot{\tilde{e}} &= \tilde{q}(\varrho, w, \tilde{z}, \tilde{e}, g) + u \end{aligned} \tag{12}$$

in which

$$\tilde{z} = \operatorname{col}(z, e_1, \ldots, e_{r-1}),$$

$$\tilde{f}_0(\varrho, w, \tilde{z}) = \begin{pmatrix} f_0(\varrho, w, z) + f_1(\varrho, w, z, e_1)e_1 \\ e_2 \\ \cdots \\ e_{r-1} \\ -g^{r-1}a_0e_1 - g^{r-2}a_1e_2 - \cdots - ga_{r-2}e_{r-1} \end{pmatrix}, \qquad \tilde{f}_1(\varrho, w, \tilde{z}, \tilde{e}) = \begin{pmatrix} 0 \\ 0 \\ \cdots \\ 0 \\ 1 \end{pmatrix},$$

and

$$\begin{aligned} \tilde{q}(\varrho, w, \tilde{z}, \tilde{e}, g) = {} & q(\varrho, w, z, e_1, \ldots, e_r) - g^{r-1}a_0e_2 - \cdots - g^2a_{r-3}e_{r-1} \\ & - ga_{r-2}[\tilde{e} - g^{r-1}a_0e_1 - g^{r-2}a_1e_2 - \cdots - ga_{r-2}e_{r-1}]. \end{aligned} \tag{13}$$

Let the initial conditions of (12) range over a set of the form $Z \times Z_e \times \tilde{E}$, in which $Z_e = \{(e_1, \ldots, e_{r-1} : |e_i| \le c\}$ and $\tilde{E} = \{\tilde{e} : |\tilde{e}| \le \tilde{c}\}$ with

$$\tilde{c} \ge (1 + g^{r-1}a_0 + g^{r-2}a_1 + \cdots + ga_{r-2})c$$

(note the dependence on the choice of the a_i's and of g).

Let system (12) be augmented with (4) and consider a regulation problem with *regulated* output $\tilde{e}$ and *measured* output $\tilde{y} = \tilde{e}$. The system, viewed as a system with input u and output $\tilde{e}$, has relative degree 1 and its zero dynamics, forced by the control

$$u = -\tilde{q}(\varrho, w, \tilde{z}, 0, g), \tag{14}$$

is given by

$$\begin{aligned} \dot{\varrho} &= 0, \\ \dot{w} &= s(\varrho, w), \\ \dot{\tilde{z}} &= \tilde{f}_0(\varrho, w, \tilde{z})\,. \end{aligned} \tag{15}$$

Consistent with the notation used for (7) and (6), the autonomous system (15) and the map (14) can be rewritten in more succinct form as

$$\dot{\tilde{\mathbf{z}}} = \tilde{\mathbf{f}}_0(\tilde{\mathbf{z}}) \tag{16}$$

and

$$u = \tilde{\mathbf{q}}_0(\tilde{\mathbf{z}})\,.$$

Suppose that a controller of the form

$$\begin{aligned} \dot{\zeta} &= \varphi(\zeta, \tilde{y}), \\ u &= \gamma(\zeta, \tilde{y}) \end{aligned} \tag{17}$$

has been found which solves the problem of output regulation thus defined. Then, we immediately realize that the controller

$$\begin{aligned} \dot{\zeta} &= \varphi(\zeta, e_r + g^{\,r-1}\, a_0\, e_1 + g^{\,r-2}\, a_1\, e_2 + \cdots + g\, a_{r-2}\, e_{r-1}), \\ u &= \gamma(\zeta, e_r + g^{\,r-1}\, a_0\, e_1 + g^{\,r-2}\, a_1\, e_2 + \cdots + g\, a_{r-2}\, e_{r-1}) \end{aligned} \tag{18}$$

solves the problem of output regulation for the original plant (2). To this end, note first of all that (18) is an admissible controller for (2) because it is driven only by the components $e_1, \ldots, e_r$ of the measured output y of (2). Trivially, the composition of (2) with (18) differs from the composition of (12) with (17) only by a linear change of coordinates, and for any initial state of (2) in $Z \times E$, the corresponding initial state of (12) is in $Z \times Z_e \times \tilde{E}$. Thus, all trajectories of (2), controlled by (18), with initial conditions in $Z \times E$, are bounded. The trajectories in question are such that $\lim_{t\to\infty} \tilde{e}(t) = 0$. But since

$$\begin{aligned} \dot{e}_1 &= e_2 \\ &\vdots \\ \dot{e}_{r-1} &= -(g^{r-1}a_0e_1 + g^{r-2}a_1e_2 + \cdots + ga_{r-2}e_{r-1}) + \tilde{e} \end{aligned}$$

and the a_i's are coefficients of a Hurwitz polynomial, it is readily concluded that also $\lim_{t\to\infty} e_1(t) = 0$. Therefore (18) solves the problem of output regulation for system (2).

In light of these considerations, what is left to show in order to prove the desired claim (namely, the fact that there is no loss of generality in addressing the problem for systems having relative degree 1) is that the zero dynamics (15) and the associated map (14) inherit, from (7) and (6), the appropriate properties which make the solution of the problem of output regulation possible. Specifically, we will prove that if (7) and (6) satisfy Assumptions (i)–(iv) above, then (15) and (14) satisfy an *identical* set of assumptions, *provided that* the parameter g is chosen sufficiently large. This is formalized in the next lemma.

LEMMA 2. *Suppose that Assumptions* (i)–(v) *hold for* (7) *and* (6). *Set* $\tilde{\mathbf{Z}} = \mathbf{W} \times Z \times Z_e$. *Then there exists* $g^\star > 0$ *such that for all fixed* $g \geq g^\star$ *the following hold:*

(ii)′ *There exists a compact subset* $\tilde{\mathcal{Z}}$ *of* $\mathbf{W} \times \mathbb{R}^n \times \mathbb{R}^{r-1}$ *which contains the positive orbit of the set* $\tilde{\mathbf{Z}}$ *under the flow of* (16), *and* $\tilde{\mathcal{A}}_0 := \omega(\tilde{\mathbf{Z}})$ *is a differential submanifold (with boundary) of* $\mathbf{W} \times \mathbb{R}^n \times \mathbb{R}^{r-1}$. *Moreover, there exists a number* $\tilde{d}_1 > 0$ *such that*

$$\tilde{\mathbf{z}} \in \mathbf{W} \times \mathbb{R}^n \times \mathbb{R}^{r-1}\,, \quad \operatorname{dist}(\tilde{\mathbf{z}}, \tilde{\mathcal{A}}_0) \leq \tilde{d}_1 \Rightarrow \tilde{\mathbf{z}} \in \tilde{\mathbf{Z}}.$$

(iii)′ *There exist* $\tilde{M} \geq 1$, $\tilde{a} > 0$, *and* $\tilde{d}_2 \leq \tilde{d}_1$ *such that*

$$\tilde{\mathbf{z}}_0 \in \mathbf{W} \times \mathbb{R}^n \times \mathbb{R}^{r-1}, \operatorname{dist}(\tilde{\mathbf{z}}_0, \tilde{\mathcal{A}}_0) \leq \tilde{d}_2 \Rightarrow \operatorname{dist}(\tilde{\mathbf{z}}(t, \tilde{\mathbf{z}}_0), \tilde{\mathcal{A}}_0) \leq \tilde{M} e^{-\tilde{a}t} \operatorname{dist}(\tilde{\mathbf{z}}_0, \tilde{\mathcal{A}}_0)$$

in which $\tilde{\mathbf{z}}(t, \tilde{\mathbf{z}}_0)$ *denotes the solution of* (16) *passing through* $\tilde{\mathbf{z}}_0$ *at time* $t = 0$.

(iv)′ *There exists a* C^d *map*

$$\begin{aligned} \tilde{\tau} : \tilde{\mathcal{Z}} &\to \mathbb{R}^d, \\ \tilde{\mathbf{z}} &\mapsto \tilde{\tau}(\tilde{\mathbf{z}}) \end{aligned}$$

such that the immersion property

$$\frac{\partial \tilde{\tau}}{\partial \tilde{\mathbf{z}}} \tilde{\mathbf{f}}_0(\tilde{\mathbf{z}}) = A\tilde{\tau}(\tilde{\mathbf{z}}) + \phi(C\tilde{\tau}(\tilde{\mathbf{z}})) + \Omega(C\tilde{\tau}(\tilde{\mathbf{z}}))\,\theta(\varrho),$$

$$\tilde{\mathbf{q}}_0(\tilde{\mathbf{z}}) = C\tilde{\tau}(\tilde{\mathbf{z}})$$

holds for all $\tilde{\mathbf{z}} \in \tilde{\mathcal{A}}_0$ *and* $\varrho \in P$.

(v)′ *For each* $\tilde{\mathbf{z}}_0 \in \tilde{\mathcal{A}}_0$ *the* q *entries of the map*

$$\begin{aligned} \tilde{\varphi}_{\tilde{\mathbf{z}}_0} : \mathbb{R} &\to \mathbb{R}^{1\times q}, \\ t &\mapsto \sum_{i=1}^{d} CA^{i-1}\Omega^{(d-i)}(C\tilde{\tau}(\tilde{\mathbf{z}}(t, \tilde{\mathbf{z}}_0))) \end{aligned}$$

are linearly independent functions.

Proof. Consider the change of variable

$$x = \begin{pmatrix} x_1 \\ x_2 \\ \vdots \\ x_{r-1} \end{pmatrix} := D_g^{-1} \begin{pmatrix} e_1 \\ e_2 \\ \vdots \\ e_{r-1} \end{pmatrix} \qquad \text{with} \qquad D_g = \begin{pmatrix} 1 & 0 & \dots & 0 \\ 0 & g & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & g^{r-2} \end{pmatrix},$$

which transforms system (15) into

$$\begin{aligned} \dot{z} &= f_0(\varrho, w, z) + f_1(\varrho, w, z, x_1)x_1, \\ \dot{x} &= gAx, \end{aligned} \tag{19}$$

where A is a Hurwitz matrix. Note that if $g > 1$, which we can assume without loss of generality, then $(e_1(0), \dots, e_r(0)) \in E$ implies $x(0) \in Z_e$. System (19) augmented with (4) can be regarded as a particular case of system (64) of the appendix, to which Lemma 7 applies. In particular by property (b) of the latter, there is a number $g^\star > 0$ such that for all $g \geq g^\star$ the positive orbit of $\mathbf{Z} \times Z_e$ under the flow of (4)–(19) is bounded. As a consequence, the ω-limit set $\tilde{\mathcal{A}}_0$ of $\mathbf{Z} \times Z_e$ is a nonempty, compact, invariant set which uniformly attracts $\mathbf{Z} \times Z_e$. We prove now that $\tilde{\mathcal{A}}_0 = \mathcal{A}_0 \times \{0\}$. To this end, note first of all that $\mathcal{A}_0 \times \{0\}$ by construction is contained in $\tilde{\mathcal{A}}_0$. Moreover, x is necessarily 0 at any point of $\mathcal{A}_0$. In fact suppose, by contradiction, that there is a point $(\mathbf{z}, x)$ of $\tilde{\mathcal{A}}_0$ with $x \neq 0$. As $g > 0$ and A is Hurwitz, it follows that the trajectory $x(t)$ of (4)–(19) originating from $(\mathbf{z}, x)$ is unbounded in backward time, which contradicts the fact that $\tilde{\mathcal{A}}_0$ is a compact invariant (in particular in backward time) set. Finally, since $\mathcal{A}_0$ is the ω-limit set of $\mathbf{Z}$ under the flow of (7), we can conclude that necessarily $\tilde{\mathcal{A}}_0 = \mathcal{A}_0 \times \{0\}$. This in particular proves claim (ii)′. Claim (iii)′, namely exponential attractivity of $\tilde{\mathcal{A}}_0$, is an easy consequence of property (a) of Lemma 7 and of the fact that the lower subsystem of (19) is exponentially stable. To prove claim (iv)′, note that (6), (13), (14) imply $\tilde{\mathbf{q}}_0(\tilde{\mathbf{z}})|_{\mathcal{Z}\times\{0\}} = \mathbf{q}_0(\mathbf{z})$. From this,

claims (iv)′ and (v)′ immediately follow from Assumptions (iv) and (v), taking as $\tilde{\tau}(\tilde{\mathbf{z}})$ any differentiable function such that $\tilde{\tau}(\tilde{\mathbf{z}})|_{\mathcal{A}_0\times\{0\}} = \tau(\mathbf{z})|_{\mathcal{A}_0}$. This completes the proof. □

Motivated by the previous considerations and result, in what follows we focus our attention on the case in which $r = 1$, i.e., on the special case in which system (2) is a system of the form

$$\begin{aligned} \dot{z} &= f_0(\varrho, w, z) + f_1(\varrho, w, z, e_1)e_1, \\ \dot{e}_1 &= q(\varrho, w, z, e_1) + u, \\ e &= e_1, \\ y &= e_1, \end{aligned} \tag{20}$$

and we assume that Assumptions (i)–(iv) hold.

4. The adaptive internal model.

4.1. The structure of the regulator. Inspired by various important results on the design of adaptive observers design (see [1, 17, 20, 22]), we propose in what follows to consider a regulator modeled by equations of the form

$$\begin{aligned} u &= \xi_1 + v, \\ \dot{\xi} &= A\xi + \phi(\xi_1) + \Omega(\xi_1)\hat{\theta} + H(X, \xi_1)v - M(X)\mathrm{dzv}_\ell(\hat{\theta}), \\ \dot{\hat{\theta}} &= \beta(X, \xi_1)v - \mathrm{dzv}_\ell(\hat{\theta}), \\ \dot{X} &= FX + G\Omega(\xi_1) \end{aligned} \tag{21}$$

in which ξ_1 denotes the first component of ξ, the matrix X is a $(d-1)\times q$ matrix, and $M(X)$ is a $d \times q$ matrix defined as

$$M(X) = \begin{pmatrix} 0 \\ X \end{pmatrix},$$

while the vectors $H(X, \xi_1), \beta(X, \xi_1)$ and the matrices F, G have the form described below. The function $\mathrm{dzv}_\ell(\cdot)$, whose role is to introduce the so-called switching σ modification in the adaptation law (see [17, Theorem 8.5.2]), is defined as[1]

$$\mathrm{dzv}_\ell(\mathrm{col}(s_1, \ldots, s_q)) = \mathrm{col}(\mathrm{dz}_\ell(s_1), \ldots, \mathrm{dz}_\ell(s_q))$$

in which $\mathrm{dz}_\ell(\cdot)$ is any continuously differentiable function satisfying

$$\mathrm{dz}_\ell(x) = \begin{cases} 0 & \text{if } |x| \le \ell, \\ x & \text{if } |x| \ge \ell + 1, \end{cases} \tag{22}$$

and the amplitude ℓ of the *dead-zone* is chosen so that

$$\ell > \max_{\varrho\in P} |\theta(\varrho)|\,.$$

[1]It must be stressed that the presence of the dead-zone function in (21) is not, strictly speaking, essential, as the same theoretical results presented in the section could be established also by dropping the terms $M(X)\mathrm{dzv}_\ell(\hat{\theta})$ and $\mathrm{dzv}_\ell(\hat{\theta})$ in the second and third lines of (21). Its presence, though, is appropriate if robustness with respect to bounded additive disturbances is sought. Moreover, it sensibly simplifies the proof of Lemma 4.

This controller can be viewed as a "copy" of (11), corrected by an "innovation term" and augmented with an "adaptation law" for $\hat{\theta}$ and with a "filter" which generates the "auxiliary state" X. The additional input v, which is a "stabilizing control," will eventually be taken as $v = -ky$.

Following the theory of adaptive observers of [1] and [21] (see also [22]), the functions $H(X, \xi_1), \beta(X, \xi_1)$ and the matrices F, G of (21) are chosen as follows. Define new variables

$$\begin{aligned} \tilde{\theta} &= \hat{\theta} - \theta(\varrho), \\ \eta &= \xi - M(X)\tilde{\theta} \end{aligned} \tag{23}$$

(note that $\eta_1 = \xi_1$) and observe that, in the new variables, the second equation of (21) reads as follows (for convenience, we omit the arguments (X, ξ_1) in H and β and the argument X in M):

$$\begin{aligned} \dot{\eta} &= A(\eta + M\tilde{\theta}) + \phi(\xi_1) + \Omega(\xi_1)(\theta(\varrho) + \tilde{\theta}) + Hv - \dot{M}\tilde{\theta} - M\beta v \\ &= A\eta + [AM + \Omega(\xi_1) - \dot{M}]\tilde{\theta} + [H - M\beta]v + \phi(\xi_1) + \Omega(\xi_1)\theta(\varrho)\,. \end{aligned} \tag{24}$$

The third equation, instead, becomes trivially

$$\dot{\tilde{\theta}} = \beta v - \mathrm{dzv}_{\ell}\,(\tilde{\theta} + \theta(\varrho))\,.$$

The choices of $H(X, \xi_1), \beta(X, \xi_1)$ and of F, G are meant to simplify the terms

$$[AM + \Omega(\xi_1) - \dot{M}]\tilde{\theta} + [H - M\beta]v$$

in expression (24). First of all, note that choosing

$$H = M\beta + K,$$

with K a constant vector (whose expression will be determined later), causes the second term to become equal to Kv. As for the first term, the idea is to impose that

$$[AM + \Omega(\xi_1) - \dot{M}]\tilde{\theta} = b\beta^{\mathrm{T}}\tilde{\theta},$$

in which b is a $d \times 1$ fixed vector. The identity in question holds if M satisfies

$$\dot{M} = (A - bCA)M + (I - bC)\Omega(\xi_1)$$

and β is taken as

$$\beta^{\mathrm{T}} = CAM + C\Omega(\xi_1)\,.$$

In this way, the second equation of (21) takes the simplified form

$$\dot{\eta} = A\eta + b\beta^{\mathrm{T}}\tilde{\theta} + Kv + \phi(\eta_1) + \Omega(\eta_1)\theta(\varrho), \tag{25}$$

to which we will return later. To show that the required differential equation for M can be enforced, pick a column vector $b = \mathrm{col}(1, b_2, \ldots, b_d)$. Then, bearing in mind the definition of M, it is easily realized that the required differential equation holds if the matrices F and G in the differential equation for X have the form (see [21])

$$F = \begin{pmatrix} -b_2 & 1 & \cdots & 0 & 0 \\ \cdot & \cdot & \cdots & \cdot & \cdot \\ -b_{d-1} & 0 & \cdots & 0 & 1 \\ -b_d & 0 & \cdots & 0 & 0 \end{pmatrix}, \qquad G = \begin{pmatrix} -b_2 & 1 & \cdots & 0 & 0 & 0 \\ \cdot & \cdot & \cdots & \cdot & \cdot & \cdot \\ -b_{d-1} & 0 & \cdots & 0 & 1 & 0 \\ -b_d & 0 & \cdots & 0 & 0 & 1 \end{pmatrix}. \tag{26}$$

In summary, the quantities $H(X,\xi_1), \beta(X,\xi_1), F, G$ which appear in the controller (21) are determined as follows: F and G are the matrices in (26), $\beta(X,\xi_1)$ is chosen as

$$\beta(X,\xi_1) = \left[CA\begin{pmatrix}0\\X\end{pmatrix} + C\Omega(\xi_1)\right]^{\mathrm{T}}, \tag{27}$$

and $H(X,\xi_1)$ is chosen as

$$H(X,\xi_1) = \begin{pmatrix}0\\X\end{pmatrix}\left[CA\begin{pmatrix}0\\X\end{pmatrix} + C\Omega(\xi_1)\right]^{\mathrm{T}} + K\,. \tag{28}$$

The vector b, whose entries determine the choice of F and G and the parameter K, which appears in the expression of $H(X,\xi_1)$, will be chosen later.

The controller thus defined determines a closed-loop system which, in the coordinates indicated above, can be written as (recall that $e_1 = e$)

$$\begin{aligned}
\dot{\varrho} &= 0,\\
\dot{w} &= s(\varrho, w),\\
\dot{z} &= f_0(\varrho, w, z) + f_1(\varrho, w, z, e)e,\\
\dot{e} &= q(\varrho, w, z, e) + \eta_1 + v,\\
\dot{\eta} &= A\eta + b\beta^{\mathrm{T}}\tilde{\theta} + Kv + \phi(\eta_1) + \Omega(\eta_1)\theta(\varrho),\\
\dot{\tilde{\theta}} &= \beta v - \mathrm{dzv}_\ell\,(\tilde{\theta} + \theta(\varrho)),\\
\dot{X} &= FX + G\Omega(\eta_1),
\end{aligned} \tag{29}$$

where β is a function of X and η_1. This system, viewed as a system with input v and output e, has relative degree 1, and its zero dynamics is that of

$$\begin{aligned}
\dot{\varrho} &= 0,\\
\dot{w} &= s(\varrho, w),\\
\dot{z} &= f_0(\varrho, w, z),\\
\dot{\eta} &= A\eta - K[q(\varrho, w, z, 0) + \eta_1] + b\beta^{\mathrm{T}}\tilde{\theta} + \phi(\eta_1) + \Omega(\eta_1)\theta(\varrho),\\
\dot{\tilde{\theta}} &= -\beta[q(\varrho, w, z, 0) + \eta_1] - \mathrm{dzv}_\ell\,(\tilde{\theta} + \theta(\varrho)),\\
\dot{X} &= FX + G\Omega(\eta_1).
\end{aligned} \tag{30}$$

Intuition suggests that if the latter have convenient asymptotic properties, and in particular possess a locally exponentially stable compact attractor, an additional control of the form $v = -ke$ (with large $k > 0$) should be able to solve the problem of output regulation. This intuition relies upon the extension of a consolidated design paradigm for semiglobal stabilization of equilibrium points of minimum-phase nonlinear systems, namely the fact that a high-gain feedback $v = -ke$ is sufficient to guarantee asymptotic stability (with an arbitrarily large domain of attraction) for a system of the form

$$\dot{x} = f(x) + g(x)e, \qquad \dot{e} = h(x) + v$$

if $x = 0$ is exponentially stable for $\dot{x} = f(x)$ and $h(0) = 0$ (see, e.g., [14]). This intuition will be rendered rigorous in section 5 (see also the appendix). For the time being we are interested in studying the asymptotic properties of (30). This, indeed, is the main objective of the next three subsections.

4.2. Trajectories of (30) are bounded. In studying the asymptotic properties of this system, it is convenient to take advantage of the "immersion" assumption, Assumption (iii), introduced above. Specifically, suppose that the initial conditions for ϱ, w, z are taken in the set $\mathbf{Z}$, a subset of a set $\mathcal{Z}$ which by hypothesis is positively invariant for the subsystem formed by the first three equations of (30). Thus, for any such initial conditions and for any $t \geq 0$, the function $\tau(\varrho, w(t), z(t))$ is well defined, and it is legitimate to consider the change of variables

$$\chi = \eta - \tau(\varrho, w, z)\,.$$

This transforms system (30) into a system of the form (use here (9) and (10), which hold on $\mathcal{A}_0 \subset \mathcal{Z}$)

$$\begin{aligned}
\dot{\varrho} &= 0,\\
\dot{w} &= s(\varrho, w),\\
\dot{z} &= f_0(\varrho, w, z),\\
\dot{\chi} &= (A - KC)\chi + b\beta^{\mathrm{T}}\tilde{\theta} + \Delta(\chi_1, \tau_1, \theta) + \varsigma_1(\varrho, w, z),\\
\dot{\tilde{\theta}} &= -\beta\chi_1 - \mathrm{dzv}_\ell\,(\tilde{\theta} + \theta(\varrho)) + \beta\varsigma_2(\varrho, w, z),\\
\dot{X} &= FX + G\Omega(\chi_1 + \tau_1)\,,
\end{aligned} \tag{31}$$

with $\chi_1 = C\chi$ and $\tau_1 = C\tau$, in which

$$\Delta(\chi_1, \tau_1, \theta) = \phi(\chi_1 + \tau_1) - \phi(\tau_1) + [\Omega(\chi_1 + \tau_1) - \Omega(\tau_1)]\theta(\varrho)$$

is a term which vanishes at $\chi_1 = 0$ and

$$\begin{aligned}
\varsigma_1(\varrho, w, z) &= -K(q(\varrho, w, z, 0) + \tau_1(\varrho, w, z)) + A\tau(\varrho, w, z) + \phi(\tau_1(\varrho, w, z))\\
&\quad + \Omega(\tau_1(\varrho, w, z))\theta(\varrho) - \frac{\partial\tau}{\partial z} f_0(\varrho, w, z) - \frac{\partial\tau}{\partial w} s(\varrho, w),\\
\varsigma_2(\varrho, w, z) &= \tau_1(\varrho, w, z) + q(\varrho, w, z, 0)
\end{aligned} \tag{32}$$

are terms vanishing on $\mathcal{A}_0$. In particular note that, since $\phi(y)$ and $\Omega(y)$ can be taken to be globally Lipschitz and θ ranges over a compact set, there exists a number L such that

$$|\Delta(\chi_1, \tau_1, \theta)| \leq L_\phi\,|\chi_1| + L_\Omega|\chi_1|\,|\theta| \leq L|\chi_1|$$

for all $\chi_1 \in \mathbb{R}$, all $\mathbf{z} \in \mathcal{Z}$, and all $\theta \in P$.

The idea is now to choose the b_i's and K so that system (31) has certain desirable asymptotic properties. To this end, let b_i be such that the polynomial

$$p(\lambda) = \lambda^{d-1} + b_2\lambda^{d-2} + \cdots + b_{d-1}\lambda + b_d \tag{33}$$

has $d - 1$ roots with negative real part. As a consequence the matrix F in the last equation of (31) is Hurwitz. This, in view of the assumptions on the first three equations, suggests that the asymptotic properties of (31) are entirely determined by those of the fourth and fifth equations.

As indicated in [21, Theorem 2.1], the appropriate choice for K in (25) is

$$K = Ab + \lambda b, \tag{34}$$

in which $\lambda > 0$. To see why this is the case, note first of all that, using a little algebra, it is not difficult to prove the following.

LEMMA 3. *Choose K as in* (34) *and set*

$$T = \begin{pmatrix} 1 & 0 \\ \hat{b} & I \end{pmatrix}, \qquad \hat{b} = -\begin{pmatrix} b_2 \\ \cdot \\ b_{d-1} \\ b_d \end{pmatrix}.$$

Then

$$T(A - KC)T^{-1} = \begin{pmatrix} -\lambda & \hat{c} \\ 0 & F \end{pmatrix}, \quad Tb = \begin{pmatrix} 1 \\ 0 \end{pmatrix}, \quad CT^{-1} = C\,,$$

in which $\hat{c} = (\,1 \quad 0 \quad \cdots \quad 0\,)$ and F is the matrix defined in (26).

From this fact, standard arguments can be invoked to claim boundedness of the trajectories of (31). In fact, the following result holds.

LEMMA 4. *Suppose Assumptions* (i), (ii), (iv) *hold. There is a number λ^* such that, if $\lambda \geq \lambda^*$, all trajectories of* (31) *are bounded.*

Proof. First of all, recall that, by Assumption (ii), $(\varrho, w(t), z(t)) \in \mathcal{Z}$ for all $t \geq 0$, where $\mathcal{Z}$ is a compact set. Thus, looking at expression $\varsigma_1(\varrho, w, z)$ of (32), it is seen that there exists a number $\bar{\varsigma}_1$ (depending on the design parameter λ because the latter appears in K) such that

$$|\varsigma_1(\varrho, w(t), z(t))| \leq \bar{\varsigma}_1 \qquad \text{for all } t \geq 0\,. \tag{35}$$

Observe also that, so long as trajectories of (31) exist on some interval $[0, T]$, $|X(t)|$ is bounded by a number which depends only on $|X(0)|$ (because $|\Omega(\cdot)|$, having compact support, is bounded by some fixed number). As a consequence, $|\beta|$ also is bounded, again by a number which depends only on $|X(0)|$. Thus, system (31) cannot have finite escape times. Moreover, looking at the expression of $\varsigma_2(\varrho, w, z)$ in (32), it is possible to conclude the existence of a number $\bar{\varsigma}_2$ such that

$$|\beta\varsigma_2(\varrho, w(t), z(t))| \leq \bar{\varsigma}_2 \qquad \text{for all } t \geq 0\,. \tag{36}$$

With this in mind, to prove the lemma it remains to show that also χ and $\tilde{\theta}$ are bounded. To this end, let χ be partitioned as $\chi = \mathrm{col}(\chi_1, \chi_2)$, in which χ_2 is a $(d-1) \times 1$ vector, and change χ_2 into

$$\zeta = \hat{b}\chi_1 + \chi_2\,.$$

In this way, the fourth and fifth equations of system (31) are changed into

$$\begin{aligned} \dot{\chi}_1 &= -\lambda\chi_1 + \hat{c}\zeta + \beta^{\mathrm{T}}\tilde{\theta} + C\Delta(\chi_1, \tau_1, \theta) + C\varsigma_1(\varrho, w, z), \\ \dot{\zeta} &= F\zeta + (\,\hat{b} \quad I\,)\,\Delta(\chi_1, \tau_1, \theta) + (\,\hat{b} \quad I\,)\,C\varsigma_1(\varrho, w, z), \\ \dot{\tilde{\theta}} &= -\beta\chi_1 - \mathrm{dzv}_\ell(\tilde{\theta} + \theta(\varrho)) + \beta\varsigma_2(\varrho, w, z,)\,. \end{aligned} \tag{37}$$

With this in mind, choose for (37) the Lyapunov function

$$V(\chi_1, \zeta, \tilde{\theta}) = \chi_1^2 + \zeta^{\mathrm{T}}P\zeta + \tilde{\theta}^{\mathrm{T}}\tilde{\theta}\,, \tag{38}$$

in which P is the positive definite solution of $PF + F^{\mathrm{T}}P = -I$. This yields

$$\begin{aligned}\dot V =& -2\lambda\chi_1^2 + 2\chi_1\hat c\zeta + 2\chi_1\beta^{\mathrm{T}}\tilde\theta + 2\chi_1 C\Delta(\chi_1,\tau_1,\theta) + 2\chi_1 C\varsigma_1(\varrho,w,z)\\ &-|\zeta|^2 + 2\zeta^{\mathrm{T}}P\begin{pmatrix}\hat b & I\end{pmatrix}\Delta(\chi_1,\tau_1,\theta) + 2\zeta^{\mathrm{T}}P\begin{pmatrix}\hat b & I\end{pmatrix}C\varsigma_1(\varrho,w,z)\\ &-2\tilde\theta^{\mathrm{T}}\beta\chi_1 - 2\tilde\theta^{\mathrm{T}}\mathrm{dzv}_\ell(\tilde\theta+\theta(\varrho)) + 2\tilde\theta^{\mathrm{T}}\beta\varsigma_2(\varrho,w,z)\\ \le& -2\lambda\chi_1^2 - |\zeta|^2 - 2\tilde\theta^{\mathrm{T}}\mathrm{dzv}_\ell(\tilde\theta+\theta(\varrho)) + L_1|\chi_1|^2 + L_2|\chi_1|\,|\zeta|\\ &+L_3|\chi_1||\varsigma_1(\varrho,w,z)| + L_4|\zeta||\varsigma_1(\varrho,w,z)| + 2|\tilde\theta||\beta\varsigma_2(\varrho,w,z)|,\end{aligned} \tag{39}$$

in which L_i, $i = 1,\dots,4$, are suitable positive constants. By completing the squares and using (35)–(36), we obtain

$$\dot V \le -\left(2\lambda - L_1 + \frac{1}{2}L_2^2\right)\chi_1^2 - \frac{1}{2}|\zeta|^2 - 2\tilde\theta^{\mathrm{T}}\mathrm{dzv}_\ell(\tilde\theta+\theta(\varrho)) + L_3|\chi_1|\bar\varsigma_1 + L_4|\zeta|\bar\varsigma_1 + 2|\tilde\theta|\bar\varsigma_2. \tag{40}$$

Bearing in mind the definition (22) and the choice of ℓ, observe that

$$\tilde\theta^{\mathrm{T}}\mathrm{dzv}_\ell(\tilde\theta+\theta(\varrho)) \ge 0 \qquad \text{for all } \tilde\theta\in\mathbb{R}^q \quad \text{and} \quad \varrho\in P\,. \tag{41}$$

It is also easy to check that for any $\delta > \sqrt{q}(2\ell+1)$ there is a positive number c_1 such that

$$|\tilde\theta| \ge \delta \Rightarrow 2\tilde\theta^{\mathrm{T}}\mathrm{dzv}_\ell(\tilde\theta+\theta(\varrho)) \ge c_1|\tilde\theta|^2 \qquad \text{for all } \tilde\theta\in\mathbb{R}^q \quad \text{and} \quad \varrho\in P\,. \tag{42}$$

Now pick a value of λ large enough so that $\bar\lambda := 2\lambda - L_1 - L_2^2/2 > 0$ and note that inequality (40), by adding and subtracting the term $c_1|\tilde\theta|^2$ in the right-hand side of (40) and using property (42), yields

$$\dot V \le -c_2|(\chi_1,\zeta,\tilde\theta)|^2 + c_3|(\chi_1,\zeta,\tilde\theta)| + c_1\delta^2,$$

in which $c_2 = \min\{\bar\lambda, \frac{1}{2}, c_1\}$ and $c_3 = 3\max\{L_3\bar\varsigma_1, L_4\bar\varsigma_1, 2\bar\varsigma_2\}$. From this, boundedness of $\chi(t)$ and $\tilde\theta(t)$ follows by standard arguments. ∎

We can therefore draw the following conclusion about system (30). Let the initial conditions $\eta(0), \tilde\theta(0), X(0)$ be taken in fixed compact sets $\mathbf{H}$, Θ, $\mathbf{X}$.[2] Then, the positive orbit of the set

$$\mathbf{B} = \mathbf{Z}\times\mathbf{H}\times\Theta\times\mathbf{X}$$

under the flow of (30) is bounded. As a consequence $\omega(\mathbf{B})$, the ω-limit set of $\mathbf{B}$ under the flow of (30), is a nonempty, compact, and invariant set, which uniformly attracts all trajectories of (30) with initial conditions in $\mathbf{B}$.

4.3. The limit set of (30). We proceed now to investigate the structure of the set $\omega(\mathbf{B})$. To this end, we look at the equivalent system (31); we note that the first three equations are independent of the last three and we rewrite them in compact form as in (8) (and consistently we rewrite the terms $\varsigma_i(\varrho,w,z)$, $i = 1,2$, as $\varsigma_i(\mathbf{z})$ and

[2] Recall that $\tilde\theta(t) = \hat\theta(t) - \theta(\varrho)$ and $\eta(t) = \xi(t) - \beta(X(t),\xi_1(t))\tilde\theta(t)$. Thus, to establish boundedness of trajectories when $\xi(0)$, $\hat\theta(0)$, and $X(0)$ are taken in fixed compact sets, it suffices to consider the case in which $\tilde\theta(0)$, $\eta(0)$, and $X(0)$ are taken in fixed compact sets.

$\tau(z, w, \varrho)$ as $\tau(\mathbf{z})$). In particular, because of the special triangular structure of (31), we note that if $(\mathbf{z}, \chi, \tilde{\theta}, X)$ is a point of $\omega(\mathbf{B})$, necessarily $\mathbf{z}$ is a point in the ω-limit set of $\mathbf{Z}$ under the flow of (8); that is, $\mathbf{z}$ is a point of $\mathcal{A}_0$. This implies that on $\omega(\mathbf{B})$ we have $\varsigma_1(\mathbf{z}) = \varsigma_2(\mathbf{z}) = 0$, and thus system (31) simplifies to

$$\begin{aligned} \dot{\mathbf{z}} &= \mathbf{f}_0(\mathbf{z}), \\ \dot{\chi} &= (A - KC)\chi + b\beta^{\mathrm{T}}\tilde{\theta} + \Delta(\chi_1, \tau_1, \theta), \\ \dot{\tilde{\theta}} &= -\beta\chi_1 - \mathrm{dzv}_\ell(\tilde{\theta} + \theta(\varrho)), \\ \dot{X} &= FX + G\Omega(\chi_1 + \tau_1(\mathbf{z})). \end{aligned} \tag{43}$$

In the following we will be able to prove that on points of $\omega(\mathbf{B})$, necessarily $\chi = 0$, $\tilde{\theta} = 0$, and the value of X is entirely determined by the properties of the system

$$\begin{aligned} \dot{\mathbf{z}} &= \mathbf{f}_0(\mathbf{z}), \\ \dot{X} &= FX + G\Omega(\tau_1(\mathbf{z})), \end{aligned} \tag{44}$$

in which $\tau_1(\mathbf{z})$ is the obvious abbreviated notation for $\tau_1(z, w, \varrho)$. To this end, we describe first an interesting feature of the latter system.

LEMMA 5. *The graph of the C^1 map*

$$\begin{aligned} \sigma : \mathcal{A}_0 &\to \mathbb{R}^{(d-1)\times q}, \\ \mathbf{z} &\mapsto \int_{-\infty}^{0} e^{-Fs} G\Omega(\tau_1(\mathbf{z}(s, \mathbf{z})))ds \end{aligned}$$

is invariant for (44). *Moreover, if Assumption* (v) *holds, then for any $\mathbf{z}_0 \in \mathcal{A}_0$, the identity*

$$\theta^{\mathrm{T}}\beta(\sigma(\mathbf{z}(t, \mathbf{z}_0)), \tau_1(\mathbf{z}(t, \mathbf{z}_0))) = 0 \qquad \textit{for all } t \in \mathbb{R} \tag{45}$$

implies $\theta = 0$.

Proof. Let $\mathbf{z}(t, \mathbf{z}_0)$ denote the solution of (8) passing through $\mathbf{z}_0$ at time $t = 0$ and note that, if $\mathbf{z}_0 \in \mathcal{A}_0$, then $\mathbf{z}(t, \mathbf{z}_0) \in \mathcal{A}_0$ for all t (thus, in particular, since $\mathcal{A}_0$ is compact, $|\mathbf{z}(t, \mathbf{z}_0)|$ is bounded by a number which depends only on $\mathcal{A}_0$). Then, since F is a Hurwitz matrix, the map $\sigma(\cdot)$ is well defined. A simple calculation shows that

$$\sigma(\mathbf{z}(t, \mathbf{z}_0)) = e^{Ft}\sigma(\mathbf{z}_0) + \int_0^t e^{F(t-s)} G\Omega(\tau_1(\mathbf{z}(s, \mathbf{z}_0)))ds\,.$$

This shows that

$$\mathrm{graph}(\sigma) = \{(\mathbf{z}, X) : \mathbf{z} \in \mathcal{A}_0, X = \sigma(\mathbf{z})\}$$

is invariant for (44).

To prove the second property in the lemma, let $\bar{C}$ be a $(d-1)$-dimensional row vector in which all entries are 0, except the first one, which is equal to 1. Bearing in

mind the definitions of $\beta(\cdot,\cdot)$ and $\sigma(\cdot)$, it is seen that

$$\begin{aligned}\beta^{\mathrm{T}}(\sigma(\mathbf{z}(t,\mathbf{z}_0)),\tau_1(\mathbf{z}(t,\mathbf{z}_0))) &= \bar{C}\int_{-\infty}^{0} e^{-Fs}G\Omega(\tau_1(\mathbf{z}(s,\mathbf{z}(t,\mathbf{z}_0))))ds + C\Omega(\tau_1(\mathbf{z}(t,\mathbf{z}_0)))\\ &= \bar{C}\int_{-\infty}^{0} e^{-Fs}G\Omega(\tau_1(\mathbf{z}(s+t,\mathbf{z}_0)))ds + C\Omega(\tau_1(\mathbf{z}(t,\mathbf{z}_0)))\\ &= \bar{C}\int_{-\infty}^{t} e^{F(t-s')}G\Omega(\tau_1(\mathbf{z}(s',\mathbf{z}_0)))ds' + C\Omega(\tau_1(\mathbf{z}(t,\mathbf{z}_0))).\end{aligned}$$

If (45) holds for some $\theta\in\mathbb{R}^q$, then

$$\bar{C}\int_{-\infty}^{t} e^{F(t-s)}G\Omega(\tau_1(\mathbf{z}(s,\mathbf{z}_0)))\theta ds + C\Omega(\tau_1(\mathbf{z}(t,\mathbf{z}_0)))\theta = 0 \qquad \text{for all } t\in\mathbb{R}. \tag{46}$$

Now let

$$x(t) := \int_{-\infty}^{t} e^{F(t-s)}G\Omega(\tau_1(\mathbf{z}(s,\mathbf{z}_0)))\theta ds$$

and note that this satisfies

$$\dot{x}(t) = Fx(t) + G\Omega(\tau_1(\mathbf{z}(t,\mathbf{z}_0)))\theta\,. \tag{47}$$

Bearing in mind the definitions of F and G, letting x_i denote the i-component of x and $\Omega_i(\cdot)$ the ith row of $\Omega(\cdot)$, this yields

$$\dot{x}_i(t) = b_{i+1}(x_1(t) + \Omega_1(\tau_1(\mathbf{z}(t,\mathbf{z}_0)))\theta) + x_{i+1}(t) + \Omega_{i+1}(\tau_1(\mathbf{z}(t,\mathbf{z}_0)))\theta, \qquad i=1,\dots,d-1, \tag{48}$$

(with the understanding that $x_d = 0$). Now note that, by definition of $\bar{C}$ and C, condition (46) implies

$$x_1(t) + \Omega_1(\tau_1(\mathbf{z}(t,\mathbf{z}_0)))\theta = 0 \qquad \text{for all } t\in\mathbb{R}$$

from which, using (48) recursively, it is easy to conclude that

$$\sum_{i=1}^{d}\Omega_i^{(d-i)}(\tau_1(\mathbf{z}(t,\mathbf{z}_0)))\theta = 0 \qquad \text{for all } t\in\mathbb{R}.$$

Observing that $\Omega_i(\cdot) = CA^{i-1}\Omega(\cdot)$, and bearing in mind the definition of map $\varphi_{\mathbf{z}_0}(\cdot)$, this proves the claim. □

Remark. Consider the restriction of (44) to $\mathcal{A}_0\times\mathbb{R}^{(d-1)\times q}$. Since the graph of $\sigma(\cdot)$ is invariant for (44), changing X into $\tilde{X} = X - \sigma(\mathbf{z})$ yields

$$\begin{aligned}\dot{\mathbf{z}} &= \mathbf{f}_0(\mathbf{z}),\\ \dot{\tilde{X}} &= F\tilde{X}.\end{aligned}$$

We see from this that the solution $X(t)$ of (44) passing through X_0 at time $t=0$ can be expressed as

$$X(t) = e^{Ft}[X_0 - \sigma(\mathbf{z}_0)] + \sigma(\mathbf{z}(t,\mathbf{z}_0)). \tag{49}$$

Using this result, it is easy to show that $\omega(\mathbf{B})$ assumes a very simple structure. As a matter of fact, the following result holds.

LEMMA 6. *Suppose that, in addition to Assumptions* (i), (ii), (iv), *also Assumption* (v) *holds. Then the values of* χ *and* $\tilde{\theta}$ *on any point of* $\omega(\mathbf{B})$ *are necessarily zero.*

Proof. By contradiction, suppose a point $\mathbf{p} = (\mathbf{z}, \chi_0, \tilde{\theta}_0, X)$ with either $\chi_0 \neq 0$ or $\tilde{\theta}_0 \neq 0$ is in $\omega(\mathbf{B})$. Since $\omega(\mathbf{B})$ is compact and invariant, in particular in backward time, the backward trajectory of (43) starting at this point is bounded. Along this trajectory, the function

$$V(t) := V(\chi_1(t), \zeta(t), \tilde{\theta}(t))$$

in (38) satisfies $V(t) \leq C$ for all $t \leq 0$ for some $C > 0$. Moreover, since $e(\mathbf{z}) = 0$ on $\omega(\mathbf{B})$, the same computations indicated in the proof of Lemma 4 show that

$$\dot{V}(t) \leq -\left(2\lambda - L_1 - \frac{1}{2}L_2^2\right)|\chi_1(t)|^2 - \frac{1}{2}|\zeta(t)|^2 - 2\tilde{\theta}(t)\mathrm{dzv}_\ell(\tilde{\theta}(t) + \theta(\varrho)),$$

in which L_1 and L_2 are the same constants introduced in the proof of Lemma 4. From this, using property (41), it turns out that if $\lambda \geq \lambda^\star$ (where $\lambda^\star$ is the same as in Lemma 4) then $V(t)$ is nonincreasing along trajectories. As a consequence, since $V(t)$ is bounded, there must exist a finite number V_α such that

$$\lim_{t \to -\infty} V(t) = V_\alpha \,.$$

The trajectory in question is attracted, in backward time, by its own α-limit set $\alpha(\mathbf{p})$, which, as it is well known, is nonempty, compact, and invariant. Moreover, by definition, the function $V(\chi_1, \zeta, \tilde{\theta})$ has the same value V_α at any point of $\alpha(\mathbf{p})$.

Now, as in the classical proof of LaSalle's invariance principle, pick an initial condition $\hat{\mathbf{p}}$ in the set $\alpha(\mathbf{p})$ and consider the corresponding trajectory of (43), which remains in $\alpha(\mathbf{p})$ for all times. Along such a trajectory, $V(t)$ is constantly equal to V_α, and hence

$$\chi_1(t) = 0, \qquad \zeta(t) = 0, \qquad \mathrm{dzv}_\ell(\tilde{\theta}(t) + \theta(\varrho)) = 0 \qquad \text{for all } t \in \mathbb{R}.$$

Entering these constraints in (43), and observing that the vector b is nonzero, it is seen that necessarily

$$\begin{aligned} &\tilde{\theta}^{\mathrm{T}}\beta(X, \tau_1(\mathbf{z})) = 0, \\ &\dot{\tilde{\theta}} = 0, \\ &\dot{X} = FX + G\Omega(\tau_1(\mathbf{z})). \end{aligned}$$

The second condition shows that $\tilde{\theta}(t)$ is a constant, say $\tilde{\theta}^*$, along such a trajectory. The third condition says that $X(t)$ is a solution of

$$\dot{X} = FX + G\Omega(\tau_1(\mathbf{z})).$$

Now, since F is Hurwitz, it is seen from (49) that $X(t)$ is bounded for $t \leq 0$ only if $X(0) = \sigma(\mathbf{z}(0))$, where $\sigma(\cdot)$ is the map introduced in Lemma 5, in which case $X(t) = \sigma(\mathbf{z}(t))$. Since $X(t)$ has to be bounded because $\alpha(\mathbf{p})$ is compact, it follows

that $X(t)$ is necessarily equal to $\sigma(\mathbf{z}(t))$. This being the case, bearing in mind the expression of β and the definition of the map $\varphi(\cdot)$, the first condition shows that necessarily

$$(\tilde{\theta}^*)^{\mathrm{T}}\beta(\sigma(\mathbf{z}(t,\mathbf{z}_0)),\tau_1(\mathbf{z}(t,\mathbf{z}_0))) = 0 \qquad \text{for all } t \in \mathbb{R}.$$

From this, in view of Assumption (v) and the result in Lemma 5, it follows that $\tilde{\theta}^* = 0$. It is seen in this way that $(\chi_1, \zeta, \tilde{\theta}) = (0,0,0)$ at any point of $\alpha(\mathbf{p})$, and this proves that $V_\alpha = 0$. But this is a contradiction because $V(t)$ is nonincreasing along trajectories and $V(0)$ is strictly positive if either $\chi_0 \neq 0$ or $\tilde{\theta}_0 \neq 0$. □

To complete the analysis, it remains to determine the values of X on points of $\omega(\mathbf{B})$. Knowing that $\chi_1 = 0$ on any such points, it follows from the previous analysis, and in particular from Lemma 5, that $X = \sigma(\mathbf{z})$. Altogether, bearing in mind how systems (30) and (43) are related, the following conclusion holds.

PROPOSITION 1. *Under Assumptions* (i), (ii), (iv), *and* (v) *the set* $\omega(\mathbf{B})$ *is the graph of a continuous map defined on* $\mathcal{A}_0$. *Any point of* $\omega(\mathbf{B})$ *is a point* $(\mathbf{z}, \eta, \tilde{\theta}, X)$ *in which* $\mathbf{z} \in \mathcal{A}_0$ *and*

$$\eta = \tau(\mathbf{z}), \qquad \tilde{\theta} = 0, \qquad X = \sigma(\mathbf{z})\,.$$

4.4. Exponential attractivity of the limit set of (30). Finally, we prove that the set $\omega(\mathbf{B})$ is locally exponentially attractive for the trajectories of the zero dynamics (30) of system (29) if the set $\mathcal{A}_0$ is locally exponentially attractive for the trajectories of (8). This fact is formalized in the next proposition.

PROPOSITION 2. *Suppose that, in addition to Assumptions* (i), (ii), (iv), *and* (v), *also Assumption* (iii) *holds. Then* $\omega(\mathbf{B})$ *is locally exponentially attractive for* (30).

Proof. Consider again the equivalent system (31); let the compact notation $\dot{\mathbf{z}} = \mathbf{f}_0(\mathbf{z})$ be used for the first three equations and let the variables (χ_1, ζ), introduced in the proof of Lemma 4, replace χ. Let $\bar{\sigma} : \mathcal{Z} \to \mathbb{R}^{(d-1)\times q}$ be any continuously differentiable map which on $\mathcal{A}_0$ agrees with the map σ introduced in Lemma 5, and change X into $\tilde{X} = X - \sigma(\mathbf{z})$. In this way, the last equation of (31) is transformed into an equation of the form

$$\dot{\tilde{X}} = F\tilde{X} + R(\chi_1, \mathbf{z}) + Q(\mathbf{z}) \tag{50}$$

in which

$$Q(\mathbf{z}) = F\bar{\sigma}(\mathbf{z}) + G\Omega(\tau_1(\mathbf{z})) - \frac{\partial \bar{\sigma}}{\partial \mathbf{z}}\mathbf{f}_0(\mathbf{z})$$

is a (matrix-valued) function vanishing on $\mathcal{A}_0$, while

$$R(\chi_1, \mathbf{z}) = G[\Omega(\chi_1 + \tau_1(\mathbf{z})) - \Omega(\tau_1(\mathbf{z}))]$$

is vanishing for $\chi_1 = 0$ for all $\mathbf{z} \in \mathcal{Z}$. Setting $\mathbf{x} = \mathrm{col}(\chi_1, \zeta, \tilde{\theta})$ and denoting by $\tilde{X}_1$ the first row of $\tilde{X}$, system (31) can be conveniently rewritten as the interconnection of system (50) with the system

$$\begin{aligned} \dot{\mathbf{z}} &= \mathbf{f}_0(\mathbf{z}), \\ \dot{\mathbf{x}} &= \mathbf{A}(\mathbf{z})\mathbf{x} + \mathbf{h}(\mathbf{z}, \mathbf{x}) + G(\mathbf{z}, \mathbf{x}, \tilde{X})\nu(\mathbf{z}) + h(\mathbf{x}, \tilde{X}), \end{aligned} \tag{51}$$

in which

$$\mathbf{A}(\mathbf{z}) = \begin{pmatrix} -\lambda + r_1(\mathbf{z}) & \hat{c} & B^{\mathrm{T}}(\mathbf{z},0,0) \\ r_2(\mathbf{z}) & F & 0 \\ -B(\mathbf{z},0,0) & 0 & 0 \end{pmatrix},$$

$$G(\mathbf{z},\mathbf{x},\tilde{X}) = \begin{pmatrix} C & 0 & 0 \\ 0 & (\,\hat{b}\; I\,) & 0 \\ 0 & 0 & B(\mathbf{z},\mathbf{x},\tilde{X}) \end{pmatrix},$$

$$\nu(\mathbf{z}) = \begin{pmatrix} \varsigma_1(\mathbf{z}) \\ \varsigma_1(\mathbf{z}) \\ \varsigma_2(\mathbf{z}) \end{pmatrix}, \qquad h(\mathbf{x},\tilde{X}) = \begin{pmatrix} \tilde{X}_1\tilde{\theta} \\ 0 \\ -\tilde{X}_1^{\mathrm{T}}\chi_1 \end{pmatrix},$$

with

$$\begin{aligned} B(\mathbf{z},\mathbf{x},\tilde{X}) &= \beta(\tilde{X} + \sigma(\mathbf{z}), \chi_1 + \tau_1(\mathbf{z})), \\ r_1(\mathbf{z}) &= C\,[\partial\Delta/\partial\chi_1]_{\chi_1=0}\,, \\ r_2(\mathbf{z}) &= \begin{pmatrix} \hat{b} & I \end{pmatrix}[\partial\Delta/\partial\chi_1]_{\chi_1=0}\,, \end{aligned}$$

and where the vector $\mathbf{h}(\mathbf{z},\mathbf{x})$ is such that

$$\lim_{|\mathbf{x}|\to 0} \frac{|\mathbf{h}(\mathbf{z},\mathbf{x})|}{|\mathbf{x}|} = 0$$

uniformly in $\mathbf{z}$ (as the latter ranges over a compact set). Note that $\nu(\mathbf{z})$ is a vector of functions vanishing for $\mathbf{z} \in \mathcal{A}_0$ and that $h(\mathbf{x},\tilde{X})$ is a vector collecting higher order terms.

With this in mind, consider now the auxiliary system

$$\begin{aligned} \dot{\mathbf{z}} &= \mathbf{f}_0(\mathbf{z}), \\ \dot{\mathbf{y}} &= \mathbf{A}(\mathbf{z})\mathbf{y} \end{aligned} \tag{52}$$

with initial conditions $(\mathbf{z}(0),\mathbf{y}(0))$ in the compact set $\mathbf{Z}\times\mathbf{Y}$, where $\mathbf{Y} = \{\mathbf{y} : |\mathbf{y}| \le c\}$, with $c > 1$. Arguments identical to those used in the proof of Lemmas 4 and 6 make it possible to claim the existence of a $\lambda^\star > 0$ such that for all $\lambda > \lambda^\star$ the trajectories $(\mathbf{z}(t),\mathbf{y}(t))$ are bounded in positive time and that

$$\omega(\mathbf{Z}\times\mathbf{Y}) = \mathcal{A}_0 \times \{0\}\,.$$

We show now that $\mathcal{A}_0 \times \{0\}$ is locally exponentially attractive for (52). To this end, let $\mathbf{z}(t,\mathbf{z}_0)$ and $\mathbf{y}(t,\mathbf{y}_0)$ denote the solution pair of (52) passing through $\mathbf{z}_0$ and, respectively, $\mathbf{y}_0$ at time $t = 0$. Recall (see section 2) that $\mathcal{A}_0 \times \{0\}$ attracts the set $\mathbf{Z}\times\mathbf{Y}$ *uniformly*. Therefore, since $|\mathbf{y}| \le \mathrm{dist}((\mathbf{z},\mathbf{y}), \mathcal{A}_0 \times \{0\})$, for any $\varepsilon > 0$ there exists $T_\varepsilon > 0$ such that

$$|\mathbf{y}(t,\mathbf{y}_0)| \le \varepsilon \qquad \text{for all } \; t \ge T_\varepsilon \quad \text{and all} \quad (\mathbf{z}_0,\mathbf{y}_0) \in \mathbf{Z}\times\mathbf{Y}. \tag{53}$$

With this in mind, let δ be such that $\mathrm{dist}(\mathbf{z}_0,\mathcal{A}_0) \le \delta$ implies $\mathbf{z}(t,\mathbf{z}_0) \in \mathbf{Z}$ for all $t \ge 0$, which is always possible, since $\mathcal{A}_0$ is stable in the sense of Lyapunov for the upper equation of (52). Pick any $\mathbf{z}_0$ within a δ-distance from $\mathcal{A}_0$ and regard the bottom equation of (52) as a *time-varying linear* system

$$\dot{\mathbf{y}} = \mathbf{A}(\mathbf{z}(t,\mathbf{z}_0))\mathbf{y}\,. \tag{54}$$

Pick a pair $t \geq t_0 \geq 0$ and let $\Phi(t, t_0, \mathbf{z}_0)$ denote the associated state transition matrix (which, of course, depends on the choice of $\mathbf{z}_0$). By construction, the ith column $\phi_i(t, t_0, \mathbf{z}_0)$ of $\Phi(t, t_0, \mathbf{z}_0)$ is the solution of (54) which satisfies $\phi_i(t_0, t_0, \mathbf{z}_0) = \mathbf{v}_i$, where $\mathbf{v}_i$ is a vector in which all entries are zero, except the ith one, which is equal to 1. Consider now again (52) with initial conditions $\mathbf{z}(0) = \mathbf{z}(t_0, \mathbf{z}_0)$ and $\mathbf{y}(0) = \mathbf{v}_i$ (note that $(\mathbf{z}(t_0, \mathbf{z}_0), \mathbf{v}_i) \in \mathbf{Z} \times \mathbf{Y}$). Since (52) is time invariant, we observe that $\mathbf{y}(t, \mathbf{v}_i) = \phi_i(t + t_0, t_0, \mathbf{z}_0)$ for all $t \geq 0$. Thus, by appealing to (53), it is deduced that, for any ε, there exists T_ε such that

$$|\phi_i(t + t_0, t_0, \mathbf{z}_0)| \leq \varepsilon \quad \text{for all} \quad t \geq T_\varepsilon$$

and all $\mathbf{z}_0$, so long as $\operatorname{dist}(\mathbf{z}_0, \mathcal{A}_0) \leq \delta$. This, in turn, by standard results (see, e.g., [23, page 92]) implies the existence of positive numbers M and a (independent of $\mathbf{z}_0$) such that

$$|\Phi(t, t_0, \mathbf{z}_0)| \leq M e^{-a(t-t_0)} \qquad \text{for all} \quad t \geq t_0 \geq 0 \tag{55}$$

and all $\mathbf{z}_0$, so long as $\operatorname{dist}(\mathbf{z}_0, \mathcal{A}_0) \leq \delta$.

By a classical converse Lyapunov theorem (see Theorem 3.12 in [19]), we deduce from (55) the existence of a continuously differentiable and symmetric function $\bar{P}(t)$, a continuous and symmetric function $Q(t)$, and constants c_1, c_2, and c_3 such that

$$\frac{d\bar{P}(t)}{dt} + \bar{P}(t)\mathbf{A}(\mathbf{z}(t, \mathbf{z}_0)) + \mathbf{A}^{\mathrm{T}}(\mathbf{z}(t, \mathbf{z}_0))\bar{P}(t) = -Q(t) \tag{56}$$

with

$$0 < c_1 I \leq \bar{P}(t) \leq c_2 I \qquad \text{and} \qquad Q(t) \geq c_3 I > 0 \tag{57}$$

for all $t \geq 0$.

Bearing in mind this result, we return now to the overall system (50), (51) which can be more conveniently seen as a *time-varying nonlinear* system

$$\begin{aligned} \dot{\tilde{X}} &= F\tilde{X} + R(\mathbf{x}, \mathbf{z}(t, \mathbf{z}_0)) + Q(\mathbf{z}(t, \mathbf{z}_0)), \\ \dot{\mathbf{x}} &= \mathbf{A}(\mathbf{z}(t, \mathbf{z}_0))\mathbf{x} + \mathbf{h}(\mathbf{z}(t, \mathbf{z}_0), \mathbf{x}) + G(\mathbf{z}(t, \mathbf{z}_0), \mathbf{x}, \tilde{X})\nu(\mathbf{z}(t, \mathbf{z}_0)) + h(\mathbf{x}, \tilde{X}) \end{aligned} \tag{58}$$

in which, with a mild abuse of notation, we denote $R(\mathbf{x}, \mathbf{z}(t, \mathbf{z}_0)) = R(\chi_1, \mathbf{z}(t, \mathbf{z}_0))$.

In particular note that, as far as the higher order terms $\mathbf{h}(\mathbf{z}(t, \mathbf{z}_0), \mathbf{x})$ and $h(\mathbf{x}, \tilde{X})$ are concerned, for any $\epsilon > 0$ there is $\delta_\epsilon > 0$ such that

$$|(\mathbf{x}, \tilde{X})| \leq \delta_\epsilon \Rightarrow |\mathbf{h}(\mathbf{z}(t, \mathbf{z}_0), \mathbf{x})| \leq \epsilon|\mathbf{x}|\,, \quad |h(\mathbf{x}, \tilde{X})| \leq \epsilon|(\mathbf{x}, \tilde{X})|$$

for all $t \geq 0$ and all $\mathbf{z}_0 \in \mathbf{Z}$. Moreover, note that by Assumption (iii) and from the definitions of $\nu(\cdot)$ and $Q(\cdot)$ (and in particular from the fact that these functions are differentiable and vanishing on $\mathcal{A}_0$) it follows that there are positive constants M_z, a_z, and d such that

$$|\nu(\mathbf{z}(t, \mathbf{z}_0))| \leq M_z e^{-a_z t} \operatorname{dist}(\mathbf{z}_0, \mathcal{A}_0)\,, \quad |Q(\mathbf{z}(t, \mathbf{z}_0))| \leq M_z e^{-a_z t} \operatorname{dist}(\mathbf{z}_0, \mathcal{A}_0)$$

for all $t \geq 0$ and all $\mathbf{z}_0$ satisfying $\operatorname{dist}(\mathbf{z}_0, \mathcal{A}_0) \leq d$. Observe also that, since it is known that trajectories of (31) are bounded, there is a number $\bar{G}$ such that $|\mathbf{G}(\mathbf{z}(t, \mathbf{z}_0), \mathbf{x}(t), \tilde{X}(t))| \leq \bar{G}$ for all $t \geq 0$.

Using these facts, simple Lyapunov arguments can be adopted to show that system (58) is locally exponentially stable if it is the *cascade* system

$$\begin{aligned}\dot{\tilde{X}} &= F\tilde{X} + R(\mathbf{x}, \mathbf{z}(t, \mathbf{z}_0)),\\ \dot{\mathbf{x}} &= \mathbf{A}(\mathbf{z}(t, \mathbf{z}_0))\mathbf{x}\,.\end{aligned}$$

But local exponential stability of the previous system immediately follows by standard cascade arguments using the fact that F is Hurwitz, by the existence of $\bar{P}$ satisfying (56)–(57), and by definition of $R(\mathbf{x}, \mathbf{z})$. This concludes the proof of the proposition. □

5. Adaptive output regulation. We return now to the closed-loop system obtained from the interconnection of (20), (4), and (21). As mentioned before, this system, viewed as a system with input v and output $e = e_1$, has relative degree 1. To put it in "normal form" we use, instead of (23), the change of variables

$$\begin{aligned}\tilde{\theta} &= \hat{\theta} - \theta(\rho) - \int_0^e \beta(X, \xi_1 - CKe + CKs)ds,\\ \eta &= \xi - M(X)[\hat{\theta} - \theta(\rho)] - Ke,\end{aligned} \tag{59}$$

which is meant to cancel the residual input v from the η and $\tilde{\theta}$ dynamics (see [13, Proposition 9.1.1]). This, after some simple algebra and some obvious rearrangement of terms, yields a system of the form

$$\begin{aligned}
&\dot{\varrho} = 0,\\
&\dot{w} = s(\varrho, w),\\
&\dot{z} = f_0(\varrho, w, z) + f_1(\varrho, w, z, e)e,\\
&\dot{\eta} = A\eta + b\beta^{\mathrm{T}}\tilde{\theta} - K[q(\varrho, w, z, 0) + \eta_1] + \phi(\eta_1) + \Omega(\eta_1)\theta + \delta_1(\varrho, w, z, e, X, \eta_1)e,\\
&\dot{\tilde{\theta}} = -\beta[q(\varrho, w, z, 0) + \eta_1] + \delta_2(\varrho, w, z, e, X, \eta_1)\, e - \mathrm{dzv}_\ell(\tilde{\theta} + \theta(\varrho)),\\
&\dot{X} = FX + G\Omega(\eta_1) + \delta_3(\eta_1, e)e,\\
&\dot{e} = [q(\varrho, w, z, 0) + \eta_1] + \vartheta(\varrho, w, z, e)e + v,
\end{aligned} \tag{60}$$

in which $\delta_1(\cdot)$, $\delta_2(\cdot)$, $\delta_3(\cdot)$, and $\vartheta(\cdot)$ are continuously differentiable functions of their arguments.

A more succinct form can be obtained by setting $\mathbf{w}$ as in section 3 and setting

$$\mathbf{x} = \mathrm{col}(\eta, \tilde{\theta}, X_1, \ldots X_q),$$

(where X_i denotes the ith column of X) in which case the system in question can be rewritten in the form[3]

$$\begin{aligned}\dot{\mathbf{w}} &= \mathbf{s}(\mathbf{w}),\\ \dot{z} &= f_0(\mathbf{w}, z) + f_1(\mathbf{w}, z, e)e,\\ \dot{\mathbf{x}} &= \mathbf{g}_0(\mathbf{w}, z, \mathbf{x}) + \mathbf{g}_1(\mathbf{w}, z, \mathbf{x}, e)e,\\ \dot{e} &= \mathbf{h}(\mathbf{w}, z, \mathbf{x}) + \mathbf{k}(\mathbf{w}, z, \mathbf{x}, e)e + v.\end{aligned} \tag{61}$$

[3]By a minor abuse of notation we have replaced $f_0(\varrho, w, z)$ and $f_1(\varrho, w, z, e)$ with $f_0(\mathbf{w}, z)$ and, respectively, $f_1(\mathbf{w}, z, e)$.

In this notation, the set of equations

$$\begin{aligned} \dot{\mathbf{w}} &= \mathbf{s}(\mathbf{w}), \\ \dot{z} &= f_0(\mathbf{w}, z), \\ \dot{\mathbf{x}} &= \mathbf{g}_0(\mathbf{w}, z, \mathbf{x}) \end{aligned} \tag{62}$$

is a succinct version for the set of equations (30), whose asymptotic properties have been analyzed in the previous section. More precisely, under the hypotheses introduced earlier, the positive orbit of $\mathbf{Z} \times \Xi \times \Theta \times \mathbf{X}$ under the flow (62) is bounded and all trajectories uniformly converge to the compact invariant set $\omega(\mathbf{B})$ described in Proposition 1. Moreover, the function $\mathbf{h}(\mathbf{w}, z, \mathbf{x})$, which is a succinct version of the quantity $-[q(\varrho, w, z, 0) + \eta_1]$ in (60), vanishes on the set $\omega(\mathbf{B})$. With this in mind we are now in position to formulate our final result, which states that the controller (21) completed with

$$v = -ke \tag{63}$$

solves the problem of output regulation if k is chosen sufficiently large.

PROPOSITION 3. *Consider system* (20) *with exosystem* (4). *Let* $\mathbf{W}, Z, E$ *be fixed compact sets of initial conditions, for which Assumptions* (i)–(iv) *indicated in section* 3 *are supposed to hold. Suppose, in addition, that Assumption* (v) *introduced in section* 4.3 *holds. Consider the controller* (21) *completed with* (63) *and initial conditions in a fixed compact set* $\mathbf{K}$. *Then, there exists a number* $k^* > 0$ *such that if* $k \geq k^*$, *the positive orbit of* $\mathbf{W} \times Z \times E \times \mathbf{K}$ *in the closed loop system is bounded and* $e(t) \to 0$ *as* $t \to \infty$.

Proof. The result directly follows from Proposition 4 of the appendix. In particular it is easy to check that system (61)–(63) can be viewed as a system of the form (64), with the role of x in (64) being played here by the one-dimensional variable e. The properties established for (62) and the fact that $\mathbf{h}(\mathbf{w},z,\mathbf{x})$ vanishes on $\omega(\mathbf{B})$ show that all the assumptions of Proposition 4 are satisfied. Thus, the desired result follows by taking a large value of k. □

Remark. The previous proposition indicates that the proposed controller (21) completed with (63) solves the problem of output regulation for the relative degree 1 system (20). Bearing in mind the discussion at the end of section 3, though, it follows that a controller of the form (21), completed with

$$v = -k(e_r + g^{r-1}a_0e_1 + g^{r-2}a_1e_2 + \cdots + ga_{r-2}e_{r-1}),$$

is able to solve the problem of output regulation for the original plant (2) if g is large enough. In this respect, it is worth stressing that the assumptions under which the proposed controller solves the problem need only be checked on the original system (2) and not necessarily on the transformed, relative degree 1, system (12).

Appendix. A small-gain property. Consider a system of the form

$$\begin{aligned} \dot{\varrho} &= 0, \\ \dot{w} &= s(\varrho, w), \\ \dot{z} &= f_0(\varrho, w, z) + \ell(\varrho, w, z, x), \\ \dot{x} &= q_0(\varrho, w, z) + r(\varrho, w, z, x) + gAx, \end{aligned} \tag{64}$$

in which $(\varrho, w, z, x) \in \mathbb{R}^p \times \mathbb{R}^s \times \mathbb{R}^n \times \mathbb{R}^m$. Let the functions $f_0(\cdot), q_0(\cdot), g(\cdot), \ell(\cdot), s(\cdot)$ be continuously differentiable and, moreover, let $\ell(\varrho, w, z, 0) = 0$ and $r(\varrho, w, z, 0) = 0$

for all $(\varrho, w, z) \in \mathbb{R}^p \times \mathbb{R}^s \times \mathbb{R}^n$. A is a given Hurwitz matrix and g is a positive number. As in section 3, let $\mathcal{P} \subset \mathbb{R}^p$, $W \subset \mathbb{R}^s$, $Z \subset \mathbb{R}^n$ denote compact sets of initial conditions for ϱ, w, z, set $\mathbf{z} = \mathrm{col}(\varrho, w, z)$, and $\mathbf{Z} = \mathcal{P} \times W \times Z$. Suppose that the autonomous system

$$\begin{aligned} \dot{\varrho} &= 0, \\ \dot{w} &= s(\varrho, w), \\ \dot{z} &= f_0(\varrho, w, z), \end{aligned} \tag{65}$$

with initial conditions in the compact set $\mathbf{Z}$, satisfies Assumptions (i), (ii), (iii) of section 3 and, consistent with the abbreviated notation used throughout the paper, set $\mathcal{A}_0 = \omega(\mathbf{Z})$. The following lemma describes some relevant properties of (64), proven in [4] (see also [26, 27, 28]), which are instrumental in proving the desired results.

LEMMA 7. *Consider system* (64) *under the assumptions specified above, with initial conditions in* $\mathbf{Z} \times X$, *with* $X \subset \mathbb{R}^m$ *a compact set. Then the following hold:*

(a) *There exist positive numbers* d, M, a, *and* γ *such that if*

$$\mathrm{dist}(\mathbf{z}(0), \mathcal{A}_0) \le d \qquad \textit{and} \qquad |x(t)| \le d \quad \textit{for all } t \ge 0,$$

then

$$\mathrm{dist}(\mathbf{z}(t), \mathcal{A}_0) \le M e^{-at} \mathrm{dist}(\mathbf{z}(0), \mathcal{A}_0) + \gamma \max_{\tau \in [0,t]} |x(\tau)| \qquad \textit{for all } t \ge 0.$$

(b) *For all* $\epsilon > 0$ *there exist* $g^\star > 0$ *and* $T > 0$ *such that for all* $g \ge g^\star$ *the positive orbit of* $\mathbf{Z} \times X$ *under the flow of* (64) *is bounded and*

$$\mathrm{dist}(\mathbf{z}(t), \mathcal{A}_0) \le \epsilon, \qquad |x(t)| \le \epsilon \qquad \textit{for all } t \ge T.$$

The previous lemma provides the tools needed to study the asymptotic behavior of system (64) under the additional hypothesis that the function $q_0(\varrho, w, z)$ vanishes on $\mathcal{A}_0$ (or, equivalently, that $\mathcal{A}_0 \times \{0\}$ is invariant for (64)). This is specified in the next proposition.

PROPOSITION 4. *Consider system* (64) *under the assumptions specified above and assume, in addition, that* $q_0(\varrho, w, z) = 0$ *for all* $(\varrho, w, z) \in \mathcal{A}_0$. *Then for any compact set* X *there exists* $g_1^\star > 0$ *such that, for all* $g \ge g_1^\star$, *the positive orbit of* $\mathbf{Z} \times X$ *under the flow of* (64) *is bounded and* $\lim_{t \to \infty} x(t) = 0$.

Proof. The proof is an easy consequence of the results of Lemma 7 and of the small-gain theorem. As a matter of fact, we can pick $\epsilon \le d$ and set

$$\mathcal{S}_\epsilon = \{(\mathbf{z}, x) \in \mathbb{R}^{p+s+n} \times \mathbb{R}^m \ : \ \mathrm{dist}(\mathbf{z}, \mathcal{A}_0) \le \epsilon, \quad |x| \le \epsilon\}.$$

From property (b), it is seen that if $g \ge g^\star$, any initial condition in $\mathbf{Z} \times X$ produces a trajectory of (64) which is bounded in forward time and satisfies $(\mathbf{z}(t), x(t)) \in \mathcal{S}_\epsilon$ for all $t \ge T$. From property (a), it is seen that

$$\mathrm{dist}(\mathbf{z}(t-T), \mathcal{A}_0) \le M e^{-a(t-T)} \mathrm{dist}(\mathbf{z}(T), \mathcal{A}_0) + \gamma \max_{\tau \in [T, t-T]} |x(\tau)|$$

for all $t \ge T$. Note that the differentiable function $r(\varrho, w, z, x)$, which vanishes for $x = 0$, can be estimated as

$$|r(\varrho, w, z, x)| \le \alpha |x|$$

for all $(\mathbf{z}, x) \in \mathcal{S}_\varepsilon$, while the differentiable function $q_0(\varrho, w, z)$, which vanishes on $\mathcal{A}_0$, can be estimated as

$$|q_0(\varrho, w, z)| \leq \beta \operatorname{dist}(\mathbf{z}, \mathcal{A}_0)$$

for all $\mathbf{z} \in \mathcal{S}_\varepsilon$. Now, let $P > 0$ denote the solution of $PA + A^{\mathrm{T}}P = -I$, and let $\underline{\lambda}$ and $\bar{\lambda}$, respectively, denote the smallest and largest eigenvalue of P. Standard arguments can be used to show that, for all $t \geq T$,

$$|x(t)| \leq \sqrt{\frac{\bar{\lambda}}{\underline{\lambda}}}\, e^{-\frac{\lambda_g}{4\bar{\lambda}}(t-T)}|x(T)| + \frac{4\beta}{\lambda_g}|P| \max_{\tau \in [T, t-T]} \operatorname{dist}(\mathbf{z}, \mathcal{A}_0),$$

where $\lambda_g = g - 2|P|\alpha$. Hence the result follows by classical small-gain arguments if $g_1^\star \geq g^\star$ is picked so that the small-gain condition

$$\lambda_{g_1^\star} > 4\beta|P|\gamma$$

is fulfilled. This completes the proof of Proposition 4. □

INTERCONNECTED SYSTEMS WITH UNCERTAIN COUPLINGS: EXPLICIT FORMULAE FOR μ-VALUES, SPECTRAL VALUE SETS, AND STABILITY RADII*

MICHAEL KAROW†, DIEDERICH HINRICHSEN‡, AND ANTHONY J. PRITCHARD§

Abstract. In this paper we study the variation of the spectrum of block-diagonal systems under perturbations of compatible block structure with fixed zero blocks at arbitrarily prescribed locations ("Gershgorin-type perturbations"). We derive explicit and computable formulae for the associated μ-values. The results are then applied to characterize spectral value sets and stability radii for such perturbed systems. By specializing our results to the scalar diagonal case, the classical eigenvalue inclusion theorems of Gershgorin, Brauer, and Brualdi are obtained as corollaries. Moreover it follows that the inclusion regions of Brauer and Brualdi are optimal for the corresponding perturbation structures.

Key words. linear systems, perturbations, spectral value sets, stability radii, μ-values

DOI. 10.1137/050626508

1. Introduction. More than 20 years ago, various researchers recognized the importance of block-diagonal perturbations for describing structured uncertainties of interconnected systems where the overall model uncertainty is a consequence of those in its components; see [7] and [23]. Structured singular values (μ-values) were introduced in [7] as a means of analyzing the effect of block-diagonal perturbations. In recent years this concept has proved to be an effective tool in the robustness analysis of systems with structured uncertainties and in the synthesis of robust control systems; see, e.g., [1], [8], [19], [24].

Generalizing the definition in [7], the μ-value of a matrix $M \in \mathbb{C}^{q\times l}$ with respect to a given perturbation set $\mathbf{\Delta} \subset \mathbb{C}^{l\times q}$ and a given norm $\|\cdot\|$ on $\mathbb{C}^{l\times q}$ is the inverse of the smallest $\|\Delta\|$, $\Delta \in \mathbf{\Delta}$, such that 1 is an element of the spectrum of the matrix product ΔM; see [15]. The μ-value is denoted by $\mu_{\mathbf{\Delta}}(M)$. Explicit characterizations of $\mu_{\mathbf{\Delta}}(M)$, $M \in \mathbb{C}^{q\times l}$, have been obtained in the full block case where $\mathbf{\Delta} = \mathbb{C}^{l\times q}$ or $\mathbf{\Delta} = \mathbb{R}^{l\times q}$. For most other perturbation structures, e.g., block-diagonal, computable formulae are not available and so robust analysis/synthesis is usually based on upper bounds for the μ-value; see [18], [19]. In this paper we study the converse of the usual case in that we consider μ-problems where the *nominal matrix* M is block-diagonal and the *perturbations* $\Delta \in \mathbf{\Delta}$ are constrained only by the condition that they have zero blocks at certain fixed locations, e.g., on the diagonal ("Gershgorin type perturbations"). In contrast to the usual case we will be able to derive a number of computable exact formulae for the corresponding μ-values.

These formulae will then be applied to obtain computable characterizations of

spectral value sets and *stability radii* of block-diagonal systems under Gershgorin-type perturbations. Our objective is not only to prove new results but also to illustrate, on the methodological side, that the techniques of μ-*analysis* in combination with the concepts of *spectral values sets* and *stability radii* provide powerful tools for the spectral analysis of interconnected systems with uncertain couplings.

Pseudospectra (spectral value sets for unstructured complex perturbations) have been applied in various areas of the mathematical sciences, for instance, in numerical analysis [27] and the stability analysis of fluid flows [22], [27]. However, they have not found many applications in systems and control theory. For some papers in this field, see [12], [14], [15]. The *spectral value set* of a matrix A under perturbations $A \rightsquigarrow A_\Delta$, $\Delta \in \mathbf{\Delta}$, consists of all eigenvalues of the perturbed matrices A_Δ with $\Delta \in \mathbf{\Delta}$ constrained by $\|\Delta\| < \delta$. Here δ reflects the level of uncertainty of the nominal matrix measured in terms of some norm $\|\cdot\|$. By visualizing spectral value sets as the perturbation level changes, one obtains insight into the mobility of the eigenvalues under the perturbations in question. This is particularly useful for the stability analysis of uncertain linear systems.

A linear system is said to be stable with respect to a given stability region $\mathbb{C}_g$ in the complex plane if all the eigenvalues of the system matrix lie in $\mathbb{C}_g$. The nominal matrix A is regarded as an approximation to a system matrix whose exact value is unknown. If $\sigma(A) \subset \mathbb{C}_g$ and a bound for the level of uncertainty is known, then the exact system matrix will also be stable provided that the associated spectral value set is contained in $\mathbb{C}_g$.

An alternative but related approach is through the concept of a *stability radius* [13], [15]. This is defined to be the smallest perturbation level for which at least one of the perturbed matrices A_Δ with $\Delta \in \mathbf{\Delta}$, $\|\Delta\| \leq \delta$ becomes unstable. It is therefore a robustness measure of the $\mathbb{C}_g$-stability of the nominal matrix A. We will see that spectral value sets and stability radii can be expressed in terms of μ-values (section 2).

In this paper we consider perturbations of the form $A \rightsquigarrow A_\Delta = A + B\Delta C$, where A, B, C are given block-diagonal matrices and $\Delta \in \mathbf{\Delta}$. The perturbed matrices A_Δ can be viewed as the system matrices of composite systems obtained by the interconnection of subsystems via couplings determined by the Δ's; see section 3. The overall transfer matrix of the block-diagonal system is the direct sum of the transfer matrices of its subsystems and thus the formulae we obtain for μ-values of block-diagonal matrices can be applied to this transfer matrix to yield computable formulae for the corresponding spectral value sets and stability radii.

In the decentralized control of large scale systems it is common to adopt a *decomposition principle* where the overall system is regarded as the interconnection of decoupled subsystems. For such systems a notion of *connective stability* has been introduced where the decoupled subsystems are assumed to be stable and the system is said to be connectively stable if the overall system is stable for all interconnections in a set E which reflects the size and structure of the interconnections; see [25]. We will see that the results we develop for the stability radii of systems of the form A_Δ can be used to obtain precise statements for the connective stability of large scale systems.

The organization of the paper is as follows. In section 2 we give definitions of spectral value sets and stability radii and establish their connection to μ-values. In section 3 we introduce the perturbation structures to be considered and interpret them in the context of interconnected systems. Sections 4 and 5 contain the main results of this paper. Here we provide formulae for the computation of μ-values

with respect to Gershgorin-type perturbations and apply them to obtain computable characterizations of spectral value sets and stability radii. Two different types of norms will be considered on the perturbation spaces. In section 6 we specialize our results to the full class of all off-diagonal perturbations. Finally in section 7 we relate our results to the classical eigenvalue inclusion theorems of Gershgorin, Brauer and Brualdi; see [16].

2. The framework. In this section we introduce some basic concepts and fix the notation. The symbols $\mathbb{N}, \mathbb{R}, \mathbb{R}_+, \mathbb{C}$ denote the sets of positive integers, real numbers, nonnegative real numbers, and complex numbers, respectively. For $a \in \mathbb{C}$ the closed disk of radius $r > 0$ in $\mathbb{C}$ is $\mathcal{D}(a,r) = \{s \in \mathbb{C}; |s-a| \le r\}$. By $\mathbb{K}^{n\times m}$ we denote the set of $n \times m$ matrices with entries in $\mathbb{K}$, $\mathbb{K} = \mathbb{R}$ or $\mathbb{C}$. Furthermore, $\mathbb{K}^n = \mathbb{K}^{n\times 1}$ is the set of column vectors of length n. The transpose of $A \in \mathbb{K}^{n\times m}$ is denoted by $A^\top$. If A is square, then $\sigma(A)$, $\rho(A) = \mathbb{C} \setminus \sigma(A)$, and $\varrho(A)$ denote its spectrum, its resolvent set, and its spectral radius, respectively, $\varrho(A) = \max\{|s|;\, s \in \sigma(A)\}$. We let $L_{n,l,q}$ be the set of triples of matrices (A,B,C) with $A \in \mathbb{C}^{n\times n}, B \in \mathbb{C}^{n\times l}, C \in \mathbb{C}^{q\times n},\ n,l,q \in \mathbb{N}$.

By $\partial\mathcal{S}$ we denote the boundary of the set $\mathcal{S} \subseteq \mathbb{C}$. We use the conventions

$$0^{-1} = \infty, \quad \infty^{-1} = 0, \quad \inf \emptyset = \infty, \tag{1}$$

where $\emptyset$ stands for the empty set. Throughout the paper we will consider the following perturbation structures; see [15].

DEFINITION 2.1. *Let $l,q \in \mathbb{N}$. By $\mathcal{P}_{l,q}$ we denote the set of pairs $(\mathbf{\Delta}, \|\cdot\|)$, where*

- *$\mathbf{\Delta} \neq \{0\}$ is a nonempty closed subset of $\mathbb{C}^{l\times q}$ which is star-shaped with respect to 0; i.e., $\Delta \in \mathbf{\Delta}$ implies $t\Delta \in \mathbf{\Delta}$ for every $t \in [0,1]$;*
- *$\|\cdot\|$ is a norm on the real vector space $\operatorname{span}_{\mathbb{R}} \mathbf{\Delta} \subseteq \mathbb{C}^{l\times q}$.*

By $\mathcal{P}^{\mathbb{C}}_{l,q}$ we denote the set of pairs $(\mathbf{\Delta}, \|\cdot\|)$, where

- *$\mathbf{\Delta} \neq \{0\}$ is a nonempty closed subset of $\mathbb{C}^{l\times q}$ which satisfies $\mathbb{C}\mathbf{\Delta} = \mathbf{\Delta}$; i.e., $\Delta \in \mathbf{\Delta}$ implies that $s\Delta \in \mathbf{\Delta}$ for every $s \in \mathbb{C}$;*
- *$\|\cdot\|$ is a norm on the complex vector space $\operatorname{span}_{\mathbb{C}} \mathbf{\Delta} \subseteq \mathbb{C}^{l\times q}$.*

The pairs $(\mathbf{\Delta}, \|\cdot\|) \in \mathcal{P}_{l,q}$ are called perturbation structures*, and the pairs $(\mathbf{\Delta}, \|\cdot\|) \in \mathcal{P}^{\mathbb{C}}_{l,q}$ are called* complex perturbation structures*.*

By definition we have $\mathcal{P}^{\mathbb{C}}_{l,q} \subset \mathcal{P}_{l,q}$. Given any triple $(A,B,C) \in L_{n,l,q}$ and a perturbation structure $(\mathbf{\Delta}, \|\cdot\|)$, we consider perturbations of A of the form

$$A \rightsquigarrow A_\Delta = A + B\Delta C, \quad \Delta \in \mathbf{\Delta}. \tag{2}$$

DEFINITION 2.2. *Let $(\mathbf{\Delta}, \|\cdot\|) \in \mathcal{P}_{l,q}$ be a perturbation structure. The spectral value set of the triple $(A,B,C) \in L_{n,l,q}$ with respect to $(\mathbf{\Delta}, \|\cdot\|) \in \mathcal{P}_{l,q}$ and perturbation level $\delta > 0$ is the following subset of the complex plane:*

$$\begin{aligned} \sigma_{\mathbf{\Delta}}(A,B,C;\delta) &:= \bigcup_{\Delta\in\mathbf{\Delta},\ \|\Delta\|<\delta} \sigma(A + B\Delta C) \\ &= \{s \in \mathbb{C};\ \exists\, \Delta \in \mathbf{\Delta} : \|\Delta\| < \delta,\ \textit{and } \det(sI_n - (A + B\Delta C)) = 0\}. \end{aligned} \tag{3}$$

Thus the spectral value set $\sigma_{\mathbf{\Delta}}(A,B,C;\delta)$ is the union of all the spectra of the perturbed matrices A_Δ where $\Delta \in \mathbf{\Delta}$, $\|\Delta\| < \delta$. The assumption that the perturbation class $\mathbf{\Delta}$ is star-shaped with respect to 0 guarantees that each connected component of $\sigma_{\mathbf{\Delta}}(A,B,C;\delta)$ contains an eigenvalue of A.

A concept closely related to the notion of *spectral value set* is that of *stability radius*. It presupposes that a stability region $\mathbb{C}_g \subset \mathbb{C}$ is given and measures the robustness of $\mathbb{C}_g$-stability of a matrix A with respect to perturbations of the form (2).

DEFINITION 2.3. *Let $\mathbb{C}_g$ be a nonempty open subset of $\mathbb{C}$. A matrix $A \in \mathbb{C}^{n\times n}$ is said to be $\mathbb{C}_g$-stable if $\sigma(A) \subset \mathbb{C}_g$. The $\mathbb{C}_g$-stability radius of $(A, B, C) \in L_{n,l,q}$ with respect to $(\mathbf{\Delta}, \|\cdot\|) \in \mathcal{P}_{l,q}$ is defined as follows:*

$$r_{\mathbf{\Delta}}(A, B, C; \mathbb{C}_g) := \inf\{\|\Delta\| \,;\, \Delta \in \mathbf{\Delta}, A + B\Delta C \text{ is not } \mathbb{C}_g\text{-stable}\}$$

$$= \inf\{\|\Delta\| \,;\, \Delta \in \mathbf{\Delta},\ \sigma(A + B\Delta C) \not\subset \mathbb{C}_g\}. \tag{4}$$

If A is not $\mathbb{C}_g$-stable, then $r_{\mathbf{\Delta}}(A, B, C; \mathbb{C}_g) = 0$. It is easily seen that a minimum in (4) always exists if $r_{\mathbf{\Delta}}(A, B, C; \mathbb{C}_g)$ is finite. Obviously,

$$r_{\mathbf{\Delta}}(A, B, C; \mathbb{C}_g) = \inf\{\delta > 0 \,;\, \sigma_{\mathbf{\Delta}}(A, B, C; \delta) \not\subseteq \mathbb{C}_g\}.$$

Next, we give the definition of μ-values.

DEFINITION 2.4. *For $(\mathbf{\Delta}, \|\cdot\|) \in \mathcal{P}_{l,q}$ the corresponding μ-value of $M \in \mathbb{C}^{q\times l}$ is given by*

$$\mu_{\mathbf{\Delta}}(M) := [\,\inf\{\|\Delta\| \,;\, \Delta \in \mathbf{\Delta},\ 1 \in \sigma(\Delta M)\,\}\,]^{-1}. \tag{5}$$

Note that the set $\mathbf{\Delta}_M = \{\Delta \in \mathbf{\Delta};\ 1 \in \sigma(\Delta M)\}$ is closed and does not contain the zero matrix. Thus a minimum in (5) is attained and is nonzero unless $\mathbf{\Delta}_M = \emptyset$. Hence, with the conventions (1), $\mu_{\mathbf{\Delta}}(M)$ is always well defined and $\mu_{\mathbf{\Delta}}(M) = 0$ if and only if $\mathbf{\Delta}_M = \emptyset$.

The following theorem specifies the relationship between spectral value sets, stability radii, and μ-values.

THEOREM 2.5. *Let $(\mathbf{\Delta}, \|\cdot\|) \in \mathcal{P}_{l,q}$, $(A, B, C) \in L_{n,l,q}$, and $G(s) = C(sI_n - A)^{-1}B$. Then*

$$\mu_{\mathbf{\Delta}}(G(s)) = [\inf\{\|\Delta\| \mid \Delta \in \mathbf{\Delta},\ s \in \sigma(A + B\Delta C)\,\}]^{-1}, \quad s \in \rho(A); \tag{6}$$

$$\sigma_{\mathbf{\Delta}}(A, B, C; \delta) = \sigma(A) \cup \{s \in \rho(A);\ \mu_{\mathbf{\Delta}}(G(s)) > \delta^{-1}\}, \quad \delta > 0; \tag{7}$$

$$r_{\mathbf{\Delta}}(A, B, C; \mathbb{C}_g) = \left(\sup_{s\in\partial\mathbb{C}_g} \mu_{\mathbf{\Delta}}(G(s))\right)^{-1} \quad \text{if } A \text{ is } \mathbb{C}_g\text{-stable.} \tag{8}$$

Proof. (6) follows from the definition of $\mu_{\mathbf{\Delta}}(\cdot)$ and the equivalence

$$s \in \sigma(A + B\Delta C) \ \Leftrightarrow\ 1 \in \sigma(\Delta G(s)), \tag{9}$$

which holds for all $s \in \rho(A)$ and all $\Delta \in \mathbb{C}^{l\times q}$; see [13, Proposition 2.3]. Then the characterizations (7), (8) are immediate consequences of (6). ∎

Theorem 2.5 is the basis for our further development. It shows that spectral value sets and stability radii can be calculated by evaluating the function $s \mapsto \mu_{\mathbf{\Delta}}(G(s))$. For completeness we mention some facts related to the characterization (7). The proofs can be found in [15], [17].

Remark 2.6. Let $(\mathbf{\Delta}, \|\cdot\|) \in \mathcal{P}_{l,q}^{\mathbb{C}}$. Then, for any $\delta > 0$,

(i) the sets $\sigma_{\mathbf{\Delta}}(A,B,C;\delta) \setminus \sigma(A) = \{\, s \in \rho(A) \,;\, \mu_{\mathbf{\Delta}}(G(s)) > \delta^{-1} \,\}$ are open;

(ii) the closure of $\sigma_{\mathbf{\Delta}}(A,B,C;\delta)$ is given by

$$\operatorname{cl}\left(\sigma_{\mathbf{\Delta}}(A,B,C;\delta)\right) = \bigcup_{\substack{\Delta \in \mathbf{\Delta} \\ \|\Delta\| \le \delta}} \sigma(A + B\Delta C) = \sigma(A) \cup \{s \in \rho(A) \,;\, \mu_{\mathbf{\Delta}}(G(s)) \ge \delta^{-1}\}; \tag{10}$$

(iii) the boundary of $\sigma_{\mathbf{\Delta}}(A,B,C;\delta)$ satisfies

$$\partial\sigma_{\mathbf{\Delta}}(A,B,C;\delta) \setminus \sigma(A) = \{\, s \in \rho(A) \,;\, \mu_{\mathbf{\Delta}}(G(s)) = \delta^{-1} \}.$$

Note that these statements do not hold for all perturbation structures $(\mathbf{\Delta}, \|\cdot\|) \in \mathcal{P}_{l,q}$.

Next, we give a useful characterization of $\mu_{\mathbf{\Delta}}(\cdot)$ via the spectral radius. It generalizes a result of [19].

LEMMA 2.7. *Let $M \in \mathbb{C}^{q\times l}$ and $(\mathbf{\Delta}, \|\cdot\|) \in \mathcal{P}_{l,q}^{\mathbb{C}}$. Then*

$$\mu_{\mathbf{\Delta}}(M) = \max\{\, \varrho(\Delta M) \,;\, \Delta \in \mathbf{\Delta}, \|\Delta\| = 1 \,\}. \tag{11}$$

Suppose that the maximum in (11) *is nonzero and is attained at $\Delta \in \mathbf{\Delta}$, $\|\Delta\| = 1$. Let $\Delta_1 = s^{-1}\Delta$, where $s \in \sigma(\Delta M)$ and $|s| = \varrho(\Delta M) \neq 0$. Then $\Delta_1 \in \mathbf{\Delta}$, $1 \in \sigma(\Delta_1 M)$, and $\|\Delta_1\| = \mu_{\mathbf{\Delta}}(M)^{-1}$.*

Proof. Let ϱ_0 denote the maximum on the right-hand side of (11). For any nonzero $\Delta \in \mathbf{\Delta}$ we have $\varrho(\Delta M) = \|\Delta\|\, \varrho(\frac{\Delta}{\|\Delta\|} M) \le \|\Delta\|\, \varrho_0$. Hence, the condition $1 \in \sigma(\Delta M)$ implies that $1 \le \|\Delta\|\, \varrho_0$. This yields $\mu_{\mathbf{\Delta}}(M) \le \varrho_0$. Equality holds if $\varrho_0 = 0$. Suppose $\varrho_0 \neq 0$. Then the matrix Δ_1 satisfies $\|\Delta_1\| = \varrho_0^{-1}$ and $\|\Delta_1\| \ge \mu_{\mathbf{\Delta}}(M)^{-1}$. Thus $\varrho_0 = \mu_{\mathbf{\Delta}}(M)$. ∎

We now determine $\mu_{\mathbf{\Delta}}(M)$ for the case that $\mathbf{\Delta} = \mathbb{C}^{l\times q}$ and the underlying norm is an operator norm. Let $\|\cdot\|_\alpha, \|\cdot\|_\beta$ be norms on $\mathbb{C}^q$ and $\mathbb{C}^l$, respectively. Then the induced operator norms on $\mathbb{C}^{l\times q}$ (resp., $\mathbb{C}^{q\times l}$) are defined by

$$\|\Delta\|_{\alpha,\beta} = \max_{y \in \mathbb{C}^q \setminus \{0\}} \frac{\|\Delta y\|_\beta}{\|y\|_\alpha},\ \Delta \in \mathbb{C}^{l\times q}, \quad \text{and} \quad \|M\|_{\beta,\alpha} = \max_{u \in \mathbb{C}^l \setminus \{0\}} \frac{\|Mu\|_\alpha}{\|u\|_\beta},\ M \in \mathbb{C}^{q\times l}.$$

Recall that, for every $\Delta \in \mathbb{C}^{l\times q}$, there exist $y \in \mathbb{C}^q$, $u \in \mathbb{C}^l$, with $\|y\|_\alpha = \|u\|_\beta^D = 1$ and

$$\|\Delta\|_{\alpha,\beta} = u^\top \Delta y.$$

Here $\|\cdot\|_\beta^D$ denotes the dual of the norm $\|\cdot\|_\beta$,

$$\|u\|_\beta^D = \max_{z \in \mathbb{C}^l \setminus \{0\}} \frac{|u^\top z|}{\|z\|_\beta}, \quad u \in \mathbb{C}^l.$$

PROPOSITION 2.8. *Let $\|\cdot\|_\alpha, \|\cdot\|_\beta$ be norms on $\mathbb{C}^q$ and $\mathbb{C}^l$, respectively. Let $\|\cdot\| = \|\cdot\|_{\alpha,\beta}$ be the induced operator norm and $\mathbf{\Delta} := \mathbb{C}^{l\times q}$. Then the following hold:*

(a) *For any $M \in \mathbb{C}^{q\times l}$, $\mu_{\mathbf{\Delta}}(M) = \|M\|_{\beta,\alpha}$.*

(b) *Suppose $M \neq 0$. Let $u \in \mathbb{C}^l$, $y \in \mathbb{C}^q$ be such that $\|u\|_\beta = \|y\|_\alpha^D = 1$ and $y^\top M u = \|M\|_{\beta,\alpha}$. Then the matrix $\Delta_0 := \|M\|_{\beta,\alpha}^{-1} u y^\top$ satisfies $1 \in \sigma(\Delta_0 M)$ and $\|\Delta_0\| = \mu_{\mathbf{\Delta}}(M)^{-1}$.*

Proof. If $1 \in \sigma(\Delta M)$, then there is $u \neq 0$ with $u = \Delta M u$. Hence,

$$0 \neq \|u\|_\beta = \|\Delta M u\|_\beta \leq \|\Delta\|_{\alpha,\beta}\, \|M\|_{\beta,\alpha}\, \|u\|_\beta.$$

Thus $1 \leq \|\Delta\|_{\alpha,\beta}\, \|M\|_{\beta,\alpha}$. This implies $\mu_{\mathbf{\Delta}}(M) \leq \|M\|_{\beta,\alpha}$. Equality holds if $M = 0$. Let $M \neq 0$. Then the matrix Δ_0 satisfies $\|\Delta_0\|_{\alpha,\beta} = \|M\|^{-1}_{\beta,\alpha}$. Furthermore, $\Delta_0 M u = u$. Thus $1 \in \sigma(\Delta_0 M)$. It follows that $\mu_{\mathbf{\Delta}}(M) \geq \|\Delta_0\|^{-1}_{\alpha,\beta} = \|M\|_{\beta,\alpha}$. So $\mu_{\mathbf{\Delta}}(M) = \|M\|_{\beta,\alpha} = \|\Delta_0\|^{-1}_{\alpha,\beta}$. ∎

Remark 2.9. Throughout the rest of this paper we consider only complex perturbation structures. There are some results available for real perturbation structures. For example, if $M \in \mathbb{C}^{q\times l}$ and $\mathbf{\Delta} = \mathbb{R}^{l\times q}$, there are formulae for $\mu_{\mathbf{\Delta}}(M)$ (and hence for spectral value sets and stability radii) if $\mathbb{R}^l$ and $\mathbb{R}^q$ are normed with Euclidean norms; see [15], [17], and [21]. In [15] formulae are proved for stability radii of a real diagonal matrix with respect to real off-diagonal perturbations; see Corollary 6.6 for the complex case. Also in [20] a formula is given for the stability radius of real symmetric systems with respect to real symmetric (or diagonal) dynamic perturbations.

Remark 2.10. $\sigma_{\mathbf{\Delta}}(A, B, C; \delta)$, $r_{\mathbf{\Delta}}(A, B, C; \mathbb{C}_g)$, and $\mu_{\mathbf{\Delta}}(G(s))$ depend strongly upon the perturbation norm $\|\cdot\|$ on $\mathbf{\Delta}$. Also the problem of evaluating numerically the formulae in Theorem 2.5 depends strongly on this norm. In a given application one should therefore carefully choose the norm on the perturbation space in such a way that it reflects the parametric uncertainty of the application and is also suitable from a computational viewpoint. In order to provide greater flexibility we have stated the results in the following sections for different classes of norms from which one can choose the most appropriate norm in a given case. In general, the (approximate) computation of $\sigma_{\mathbf{\Delta}}(A, B, C; \delta)$, $r_{\mathbf{\Delta}}(A, B, C; \mathbb{C}_g)$, $\mu_{\mathbf{\Delta}}(G(s))$ is a difficult problem, but under specific conditions efficient algorithms and estimation procedures are available; see, e.g., [5], [1], [18], [9], [26], [11].

3. Composite systems. Let us introduce some additional notation. In the following, q, l are finite sequences $q = (q_1, \ldots, q_m)$, $l = (l_1, \ldots, l_m)$. We write $\underline{m} := \{1, 2, \ldots, m\}$ and denote by $\mathbb{C}^{q\times l} := \{[M_{jk}];\, M_{jk} \in \mathbb{C}^{q_j \times l_k} \text{ for } (j,k) \in \underline{m} \times \underline{m}\}$ the set of $m \times m$ block matrices

$$[M_{jk}] = [M_{jk}]_{j\in\underline{m},k\in\underline{m}} = \begin{bmatrix} M_{11} & \cdots & M_{1m} \\ \vdots & & \vdots \\ M_{m1} & \cdots & M_{mm} \end{bmatrix}. \tag{12}$$

The block-diagonal matrix with blocks $M_j \in \mathbb{C}^{q_j\times l_j}$, $j \in \underline{m}$ is denoted by

$$M = \oplus_{j=1}^m M_j := \operatorname{diag}(M_1, \ldots, M_m) = \begin{bmatrix} M_1 & & & 0 \\ & M_2 & & \\ & & \ddots & \\ 0 & & & M_m \end{bmatrix} \in \mathbb{C}^{q\times l}.$$

For any index set $\mathcal{I} \subseteq \underline{m} \times \underline{m}$ we denote by $\mathbf{\Delta}_{\mathcal{I},q,l}$ the set of block matrices Δ of the form

$$\Delta = [\Delta_{jk}] := \begin{bmatrix} \Delta_{11} & \cdots & \Delta_{1m} \\ \vdots & & \vdots \\ \Delta_{m1} & \cdots & \Delta_{mm} \end{bmatrix}, \quad \Delta_{jk} \in \mathbb{C}^{l_j\times q_k} \text{ and } \Delta_{jk} = 0 \text{ if } (j,k) \notin \mathcal{I}. \tag{13}$$

Given $(A_j, B_j, C_j) \in L_{n_j,l_j,q_j}$, $j \in \underline{m}$, the object of this paper is to study the variation of the spectrum of the block-diagonal matrix $A = \oplus_{j=1}^m A_j$ under perturbations of the form

$$A \rightsquigarrow A_\Delta := A + B\Delta C, \quad \Delta \in \mathbf{\Delta}_{\mathcal{I},q,l}, \tag{14}$$

where B, C are the block-diagonal matrices $B = \oplus_{j=1}^m B_j$, $C = \oplus_{j=1}^m C_j$.

The matrices A_Δ have the following system theoretic interpretation. Consider the system

$$\Sigma : \qquad \dot{x}(t) = Ax(t) + Bu(t), \qquad y(t) = Cx(t) \tag{15}$$

which is the direct sum of the m subsystems

$$\Sigma_j : \qquad \dot{x}_j(t) = A_j x_j(t) + B_j u_j(t), \qquad y_j(t) = C_j x_j(t), \qquad j \in \underline{m}. \tag{16}$$

The transfer matrix of Σ is the direct sum of the transfer matrices of these subsystems:

$$G(s) = C(sI - A)^{-1}B = \oplus_{j=1}^m G_j(s), \qquad G_j(s) := C_j(sI_{n_j} - A_j)^{-1}B_j, \ \ j \in \underline{m}. \tag{17}$$

Introducing the couplings

$$u_j(t) = \sum_{k \in \underline{m},\, (j,k) \in \mathcal{I}} \Delta_{jk}\, y_k(t), \quad j \in \underline{m}, \tag{18}$$

one obtains the composite system

$$\Sigma_\Delta : \qquad \begin{bmatrix} \dot{x}_1 \\ \vdots \\ \dot{x}_m \end{bmatrix} = (A + B\Delta C) \begin{bmatrix} x_1 \\ \vdots \\ x_m \end{bmatrix} = A_\Delta \begin{bmatrix} x_1 \\ \vdots \\ x_m \end{bmatrix}. \tag{19}$$

Thus the perturbed system Σ_Δ with system matrix A_Δ can be viewed as the composite system obtained by interconnecting the subsystems Σ_j via the couplings (18) defined by the perturbation blocks Δ_{jk}. The unperturbed ("nominal") system $\Sigma_0 : \ \dot{x} = Ax$ obtained by setting $\Delta = 0$ is simply the direct sum of the subsystems $\dot{x}_j = A_j x_j$.

The pairs $(j,k) \in \mathcal{I}$ can be regarded as the oriented edges of a directed graph $\Gamma(\underline{m}, \mathcal{I})$ whose vertices are the numbers $1, \ldots, m$. This is illustrated in Example 3.1 for the case where $m = 3$. Observe that in the directed graph the endpoint of the edge (j,k) is the first component, j.[1] This orientation reflects the interconnection structure (18).

Example 3.1. Consider the index set $\mathcal{I} = \{(1,2), (1,3), (2,1), (3,2), (3,3)\}$. Then the matrices $\Delta \in \mathbf{\Delta}_{\mathcal{I},q,l}$ take the form

$$\Delta = \begin{bmatrix} 0 & \Delta_{12} & \Delta_{13} \\ \Delta_{21} & 0 & 0 \\ 0 & \Delta_{32} & \Delta_{33} \end{bmatrix}.$$

The directed graph $\Gamma(\underline{3}, \mathcal{I})$ and the block diagram of the closed loop system (19) are shown in Figure 1.

[1] Note that this is the reverse of standard notation in graph theory. We have used our notation to be in harmony with the system theoretic interpretation.

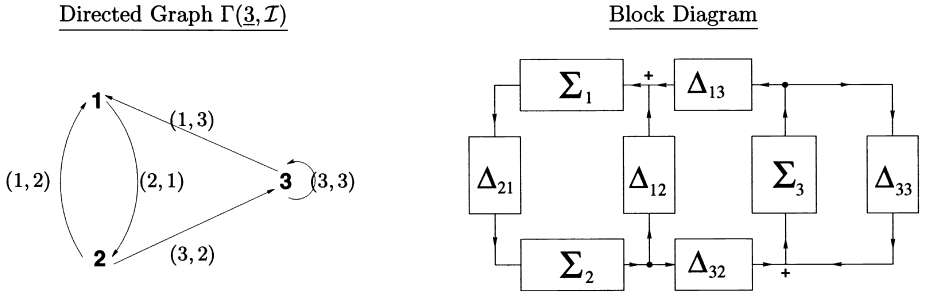

FIG. 1. *Composite system.*

Applying Theorem 2.5, the spectral value sets and stability radii of the system (A, B, C) under perturbations of the form (14) are given by

$$\sigma_{\mathbf{\Delta}_{\mathcal{I},q,l}}(A,B,C;\delta) = \sigma(A) \cup \{s \in \rho(A)\,;\, \mu_{\mathbf{\Delta}_{\mathcal{I},q,l}}(G(s)) > \delta^{-1}\} \tag{20}$$

and

$$r_{\mathbf{\Delta}_{\mathcal{I},q,l}}(A,B,C;\mathbb{C}_g) = \left(\sup_{s\in\partial\mathbb{C}_g} \mu_{\mathbf{\Delta}_{\mathcal{I},q,l}}(G(s))\right)^{-1}. \tag{21}$$

In order to determine the spectral value sets and stability radii via (20), (21) we need to study the μ-values of block-diagonal matrices $M = \oplus_{j=1}^{m} M_j$ with respect to perturbations $\Delta \in \mathbf{\Delta}_{\mathcal{I},q,l}$. Note that this is just the inverse situation of traditional μ-analysis where block-diagonal perturbations of arbitrary matrices are considered; see [7]. Applying Proposition 2.7, we obtain

$$\mu_{\mathbf{\Delta}_{\mathcal{I},q,l}}(M) = \max_{\substack{\Delta\in\mathbf{\Delta}_{\mathcal{I},q,l}\\ \|\Delta\|=1}} \varrho(\Delta M), \quad M \in \mathbb{C}^{q\times l}. \tag{22}$$

The size of the perturbations $\Delta \in \mathbf{\Delta}_{\mathcal{I},q,l}$ will be measured by two types of norms: a weighted maximum of the nonzero block norms $\|\Delta_{jk}\|$, $(j,k) \in \mathcal{I}$, and mixed operator norms of the overall matrix Δ. In the next two sections we derive formulae for $\mu_{\mathbf{\Delta}_{\mathcal{I},q,l}}(M)$ with respect to these types of norms.

Remark 3.2. A composite system Σ of the form (15) which is the direct sum of subsystems Σ_i of the form (16) is said to be *connectively stable* with respect to a given set of interconnections E (possibly time-varying and/or nonlinear) if $\sigma(A_j) \subset \mathbb{C}_-$, $j \in \underline{m}$, and the origin of the interconnected system obtained from the block-diagonal system Σ by the feedback $u(t) = e(t, y(t))$ is globally asymptotically stable for all $e \in E$; see [25]. In the literature many different methods have been put forward for obtaining sufficient criteria of connective stability based on knowledge of the subsystems Σ_i and their interconnection structure. Input-output and passivity methods have been used, but the most popular seem to be Liapunov methods; see [25]. The advantage of these methods is that time-varying and nonlinear interconnections can be considered. However, the robustness results obtained in this way are in general quite conservative. This is in contrast with the full block case (where $\mathbf{\Delta}_{\mathcal{I},q,l} = \mathbb{C}^{l\times q}$; i.e., $\mathcal{I} = \underline{m} \times \underline{m}$). In this case a quadratic Liapunov function of optimal robustness can be constructed which secures asymptotic stability for all time-varying nonlinearities with gain strictly smaller than $r_{\mathbb{C}^{l\times q}}(A, B, C; \mathbb{C}_-)$; see [13] and [15, section 5.6].

It remains an open problem to determine those perturbation structures $\mathbf{\Delta}_{\mathcal{I},q,l}$ for which it is possible to construct a joint quadratic Liapunov function for all perturbed systems Σ_Δ, $\Delta \in \mathbf{\Delta}_{\mathcal{I},q,l}$, $\|\Delta\| < r_{\mathbf{\Delta}_{\mathcal{I},q,l}}(A,B,C;\mathbb{C}_-)$. Such a Liapunov function would secure the connective stability for all time-varying nonlinearities with gain strictly smaller than $r_{\mathbf{\Delta}_{\mathcal{I},q,l}}(A,B,C;\mathbb{C}_-)$.

4. Weighted maximum norms. We consider the same basic framework as that in section 3. Let $\|\cdot\|_{\alpha_j}$ be a norm on $\mathbb{C}^{q_j}$ and $\|\cdot\|_{\beta_k}$ be a norm on $\mathbb{C}^{l_k}$. We assume that we are given a nonnegative weight matrix $R = [r_{jk}] \in \mathbb{R}_+^{m\times m}$ and introduce the index set

$$\mathcal{I} = \mathcal{I}_R := \{(j,k) \in \underline{m} \times \underline{m}\,;\, r_{jk} > 0\}. \tag{23}$$

With these data we associate a normed perturbation space $(\mathbf{\Delta}_{\mathcal{I},q,l}, \|\cdot\|)$, where (see (13))

$$\mathbf{\Delta}_{\mathcal{I},q,l} = \{[\Delta_{jk}]\,;\, \Delta_{jk} \in \mathbb{C}^{l_j\times q_k} \text{ for } j,k \in \underline{m} \text{ and } \Delta_{jk} = 0 \text{ if } (j,k) \notin \mathcal{I}\} \tag{24}$$

and $\|\cdot\|$ is the weighted maximum norm

$$\|\Delta\| := \max_{(j,k)\in\mathcal{I}} r_{jk}^{-1} \|\Delta_{jk}\|_{\alpha_k,\beta_j}, \quad \Delta \in \mathbf{\Delta}_{\mathcal{I},q,l}. \tag{25}$$

Note that the following equivalence holds for $\Delta \in \mathbb{C}^{l\times q}$:

$$(\Delta \in \mathbf{\Delta}_{\mathcal{I},q,l} \text{ and } \|\Delta\| \le 1) \quad \Leftrightarrow \quad \|\Delta_{jk}\|_{\alpha_k,\beta_j} \le r_{jk} \text{ for all } (j,k) \in \underline{m} \times \underline{m}. \tag{26}$$

In this section we determine the μ-value of block-diagonal matrices with respect to the perturbation structure $(\mathbf{\Delta}_{\mathcal{I},q,l}, \|\cdot\|)$ and apply it to obtain formulae for spectral value sets and stability radii. We will make use of the following well-known results from the theory of nonnegative matrices; see [2], [10], [16].

- (ϱ1) If $A \in \mathbb{R}^{n\times n}$ is nonnegative, the spectral radius $\varrho(A)$ is an eigenvalue of A and there exists a nonnegative eigenvector corresponding to $\varrho(A)$.
- (ϱ2) Let $A_1, A_2 \in \mathbb{R}^{n\times n}$. If $0 \le A_1 \le A_2$, then $\varrho(A_1) \le \varrho(A_2)$.
- (ϱ3) If $\alpha v \le Av$ and $v \ge 0$, $v \ne 0$, then $\alpha \le \varrho(A)$. If $Av \le \beta v$ and $v_i > 0$ for $i \in \underline{n}$, then $\varrho(A) \le \beta$.

The next lemma is a consequence of (ϱ3).

LEMMA 4.1. *Let $Y_{jk} \in \mathbb{C}^{l_j\times l_k}$, $j,k \in \underline{m}$, and $\|\cdot\|_{\beta_j}$ be a norm on $\mathbb{C}^{l_j}$. Then*

$$\varrho\left(\begin{bmatrix} Y_{11} & \dots & Y_{1m} \\ \vdots & & \vdots \\ Y_{m1} & \dots & Y_{mm} \end{bmatrix}\right) \le \varrho\left(\begin{bmatrix} \|Y_{11}\|_{\beta_1,\beta_1} & \dots & \|Y_{1m}\|_{\beta_m,\beta_1} \\ \vdots & & \vdots \\ \|Y_{m1}\|_{\beta_1,\beta_m} & \dots & \|Y_{mm}\|_{\beta_m,\beta_m} \end{bmatrix}\right). \tag{27}$$

Proof. Let $\lambda \in \mathbb{C}$ be an eigenvalue of the block matrix $[Y_{jk}]$, i.e.,

$$\begin{bmatrix} Y_{11} & \dots & Y_{1m} \\ \vdots & & \vdots \\ Y_{m1} & \dots & Y_{mm} \end{bmatrix} \begin{bmatrix} x_1 \\ \vdots \\ x_m \end{bmatrix} = \lambda \begin{bmatrix} x_1 \\ \vdots \\ x_m \end{bmatrix}, \qquad x_j \in \mathbb{C}^{l_j}, \quad j \in \underline{m},$$

and $x_j \ne 0$ for at least one j. Then $\lambda x_j = \sum_{k=1}^m Y_{jk}x_k$ for all $j \in \underline{m}$. This implies

$$|\lambda|\,\|x_j\|_{\beta_j} \le \sum_{k=1}^m \|Y_{jk}\|_{\beta_k,\beta_j}\,\|x_k\|_{\beta_k}, \qquad j \in \underline{m}.$$

Setting $A = (\|Y_{jk}\|_{\beta_k,\beta_j})_{j,k\in\underline{m}}$ and $v = (v_j)_{j\in\underline{m}}$, where $v_j = \|x_j\|_{\beta_j}$, we have

$$|\lambda|\, v_j \le (Av)_j, \qquad j \in \underline{m}.$$

Hence $|\lambda| \le \varrho(A)$ by (ϱ3), and this implies (27). □

We associate with any given block matrix $M = [M_{jk}] \in \mathbb{C}^{q\times l}$ of the form (12) the following nonnegative $m \times m$ matrix of block norms:

$$\tilde{M} = \begin{bmatrix} \|M_{11}\|_{\beta_1,\alpha_1} & \dots & \|M_{1m}\|_{\beta_m,\alpha_1} \\ \vdots & & \vdots \\ \|M_{m1}\|_{\beta_1,\alpha_m} & \dots & \|M_{mm}\|_{\beta_m,\alpha_m} \end{bmatrix}. \tag{28}$$

We now prove the main result of this section.

THEOREM 4.2. *Suppose $R = [r_{jk}] \in \mathbb{R}^{m\times m}$ is a nonnegative matrix and $\mathcal{I} = \mathcal{I}_R$ is given by* (23). *If $M = [M_{jk}] \in \mathbb{C}^{q\times l}$ and $\tilde{M} = (\|M_{jk}\|_{\beta_k,\alpha_j})_{j,k\in\underline{m}}$ is the associated matrix of block norms, then, with respect to the norm* (25),

$$\mu_{\mathbf{\Delta}_{\mathcal{I},q,l}}(M) \le \varrho(R\,\tilde{M}). \tag{29}$$

Equality holds in (29) *if $M = \oplus_{j=1}^m M_j$, $M_j \in \mathbb{C}^{q_j\times l_j}$, $j \in \underline{m}$, is block-diagonal, viz.*

$$\mu_{\mathbf{\Delta}_{\mathcal{I},q,l}}(M) = \varrho(R\,\mathrm{diag}(\|M_1\|_{\beta_1,\alpha_1},\dots,\|M_m\|_{\beta_m,\alpha_m})). \tag{30}$$

Proof. We have already seen that by Lemma 2.7,

$$\mu_{\mathbf{\Delta}_{\mathcal{I},q,l}}(M) = \max_{\substack{\Delta\in\mathbf{\Delta}_{\mathcal{I},q,l}\\ \|\Delta\|=1}} \varrho(\Delta\, M)\,. \tag{31}$$

Moreover, if $(\Delta M)_{jk}$ is the (j,k)-entry of the $m \times m$ block matrix $\Delta M \in \mathbb{C}^{l\times l}$, then

$$\|(\Delta M)_{jk}\|_{\beta_k,\beta_j} = \left\|\sum_{i=1}^m \Delta_{ji}M_{ik}\right\|_{\beta_k,\beta_j} \le \sum_{i=1}^m \|\Delta_{ji}\|_{\alpha_i,\beta_j}\,\|M_{ik}\|_{\beta_k,\alpha_i} = (\tilde{\Delta}\tilde{M})_{jk},\ j,k\in\underline{m}, \tag{32}$$

where $\tilde{\Delta} := [\|\Delta_{jk}\|_{\alpha_k,\beta_j}]_{j,k\in\underline{m}}$. Now let $\Delta = [\Delta_{jk}] \in \mathbf{\Delta}_{\mathcal{I},q,l}$ with $\|\Delta\| \le 1$. Then $\tilde{\Delta} \le R$ by (26) and

$$\begin{aligned} \varrho(\Delta M) &\le \varrho([\,\|\,(\Delta M)_{jk}\,\|_{\beta_k,\beta_j}\,]) && \text{(by Lemma 4.1)}\\ &\le \varrho(\tilde{\Delta}\tilde{M}) && \text{(by (32) and property (ϱ2))}\\ &\le \varrho(R\tilde{M}) && \text{(by (26) and property (ϱ2)).} \end{aligned}$$

Thus,

$$\mu_{\mathbf{\Delta}_{\mathcal{I},q,l}}(M) = \max_{\substack{\Delta\in\mathbf{\Delta}_{\mathcal{I},q,l}\\ \|\Delta\|=1}} \varrho(\Delta\, M) \le \varrho(R\tilde{M}).$$

It remains to show that the latter inequality is actually an equality if $M = \oplus_{j=1}^m M_j$ is block-diagonal. For $k\in\underline{m}$ let $y_k \in \mathbb{C}^{q_k}$ and $u_k \in \mathbb{C}^{l_k}$ be such that $\|u_k\|_{\beta_k} = \|y_k\|_{\alpha_k}^D = 1$ and $y_k^\top M_k u_k = \|M_k\|_{\beta_k,\alpha_k}$. Let $\Delta^0 = [\Delta^0_{jk}]$, where $\Delta^0_{jk} = r_{jk}u_j y_k^\top$. Then $\Delta^0 \in \mathbf{\Delta}_{\mathcal{I},q,l}$ and $\|\Delta^0\| = 1$. Since $R\tilde{M} = R\,\mathrm{diag}(\|M_1\|_{\beta_1,\alpha_1},\dots,\|M_m\|_{\beta_m,\alpha_m}) \in$

$\mathbb{R}^{m\times m}$ is nonnegative, there is a nonnegative vector $\xi = [\xi_1, \dots, \xi_m]^\top \in \mathbb{R}^m$ such that $R\tilde{M}\xi = \varrho(R\tilde{M})\xi$. Define $w = [\xi_1 u_1^\top, \dots, \xi_m u_m^\top]^\top$. Then a straightforward computation yields $\Delta^0(\oplus_{k=1}^m M_k)\, w = \varrho(R\tilde{M})w$. Thus $\mu_{\mathbf{\Delta}_{\mathcal{I},q,l}}(M) \geq \varrho(\Delta^0(\oplus_{k=1}^m M_k)) \geq \varrho(R\tilde{M})$, and the proof is complete. ∎

For the case where all the α_j and β_k are 2-norms, a characterization of $\mu_{\mathbf{\Delta}_{\mathcal{I},q,l}}(M)$ is given in Part I of [6] which shows that the μ-value can be obtained as the solution of a smooth constrained optimization problem. Associated computational aspects are discussed in Part II of [6].

We will now apply the above theorem to determine the spectral value sets and stability radii of block-diagonal matrices A with respect to perturbations of the form (14). Let $\mathcal{B}_R(\delta)$ denote the open ball with radius $\delta > 0$ about the origin in the perturbation space $\mathbf{\Delta}_{\mathcal{I},q,l}$ provided with the norm (25),

$$\mathcal{B}_R(\delta) = \{\Delta \in \mathbf{\Delta}_{\mathcal{I},q,l}; \|\Delta\| < \delta\}. \tag{33}$$

It follows from (26) that $\mathcal{B}_R(\delta)$ is the set of block matrices $\Delta = [\Delta_{jk}]$ satisfying

$$\|\Delta_{jk}\|_{\alpha_k,\beta_j} < \delta\, r_{jk}, \quad (j,k) \in \mathcal{I} = \mathcal{I}_R, \quad \|\Delta_{jk}\|_{\alpha_k,\beta_j} = 0 \quad \text{otherwise.}$$

COROLLARY 4.3. *Suppose $R = [r_{jk}] \in \mathbb{R}^{m\times m}$ is a nonnegative matrix and $\mathcal{I} = \mathcal{I}_R$ is given by* (23). *Let $(A_j, B_j, C_j) \in L_{n_j,l_j,q_j}$, $j \in \underline{m}$, and consider perturbations* (14) *of the block-diagonal matrix A. If $\mathbf{\Delta}_{\mathcal{I},q,l}$ is provided with the norm* (25) *and $G_j(s)$ is defined by* (17), *then the following hold:*

(a) *The spectral value set $\sigma_{\mathbf{\Delta}_{\mathcal{I},q,l}}(A, B, C; \delta)$ is given by*

$$\bigcup_{\Delta\in\mathcal{B}_R(\delta)} \sigma(A_\Delta) = \sigma(A) \cup \left\{ s \in \rho(A)\,;\, \varrho(R\,\mathrm{diag}(\|G_1(s)\|_{\beta_1,\alpha_1}, \dots, \|G_m(s)\|_{\beta_m,\alpha_m})) > \delta^{-1} \right\}.$$

(b) *Let $\mathbb{C}_g$ be an open subset of $\mathbb{C}$ and suppose $A_1, \dots, A_m$ are $\mathbb{C}_g$-stable (i.e., $\sigma(A) \subset \mathbb{C}_g$). Then the stability radius is given by*

$$r_{\mathbf{\Delta}_{\mathcal{I},q,l}}(A, B, C; \mathbb{C}_g) = \left(\sup_{s\in\partial\mathbb{C}_g} \varrho(R\,\mathrm{diag}(\|G_1(s)\|_{\beta_1,\alpha_1}, \dots, \|G_m(s)\|_{\beta_m,\alpha_m})) \right)^{-1}. \tag{34}$$

Proof. Applying Theorem 4.2, (a) follows directly from (20) and (b) follows from (21). ∎

We conclude this section by specializing the previous results to the scalar *diagonal* case where $A = \mathrm{diag}(a_1, \dots, a_n)$ is perturbed to $A_\Delta = A + \Delta$ with

$$\Delta \in \mathbf{\Delta}_{\mathcal{I}} := \{\Delta \in \mathbb{C}^{n\times n}\,;\, \Delta_{jk} = 0 \text{ if } r_{jk} = 0\}. \tag{35}$$

Here $R = (r_{jk})_{j,k\in\underline{n}}$ is a given nonnegative $n \times n$ matrix, and the perturbation space $\mathbf{\Delta}_{\mathcal{I}}$ is provided with the norm

$$\|\Delta\| = \max_{(j,k)\in\mathcal{I}} r_{jk}^{-1}|\Delta_{jk}|, \quad \Delta \in \mathbf{\Delta}_{\mathcal{I}}, \quad \text{where } \mathcal{I} := \mathcal{I}_R = \{(j,k) \in \underline{n} \times \underline{n}\,;\, r_{jk} > 0\}. \tag{36}$$

This can be subsumed into the above framework by setting $m = n$, $l_j = q_j = 1$ for $j \in \underline{m}$; $(A_j, B_j, C_j) = (a_j, 1, 1)$, $j \in \underline{m}$; and $\|\Delta_{jk}\|_{\alpha_k,\beta_j} = |\Delta_{jk}|$, $j, k \in \underline{m}$. Note that for this special case $G_j(s) = (s - a_j)^{-1}$, $j \in \underline{m}$.

COROLLARY 4.4. *Suppose $R = [r_{jk}] \in \mathbb{R}^{n\times n}$ is a nonnegative matrix with associated index set $\mathcal{I} = \mathcal{I}_R$ defined by* (36) *and normed perturbation space $(\mathbf{\Delta}_{\mathcal{I}}, \|\cdot\|)$ defined by* (35) *and* (36). *Let $a_1, \dots, a_n \in \mathbb{C}$, $\sigma_0 = \{a_1, \dots, a_n\}$, and set $A_\Delta = \mathrm{diag}(a_1, \dots, a_n) + \Delta$ for arbitrary $\Delta \in \mathbb{C}^{n\times n}$. Then the following hold:*

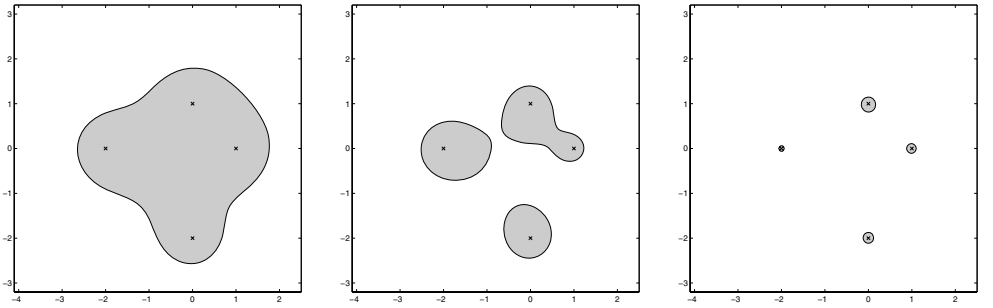

FIG. 2. *The sets S_j defined in* (40).

(a) $$\bigcup_{\Delta\in\mathbb{C}^{n\times n},\,|\Delta|\le R} \sigma(A_\Delta) = \sigma_0 \cup \{s\in\mathbb{C}\setminus\sigma_0\,;\ \varrho(R\,\mathrm{diag}(|s-a_1|^{-1},\dots,|s-a_n|^{-1}))\ge 1\ \}.$$

(b) *If $\mathbb{C}_g$ is an open subset of $\mathbb{C}$, $\sigma_0\subset\mathbb{C}_g$, then*

(37)
$$r_{\mathbf{\Delta}_{\mathcal{I}_R}}(\mathrm{diag}(a_1,\dots,a_n),I_n,I_n;\mathbb{C}_g) = \left(\sup_{s\in\partial\mathbb{C}_g}\varrho\left(R\,\mathrm{diag}(|s-a_1|^{-1},\dots,|s-a_n|^{-1})\right)\right)^{-1}.$$

(c) *In particular, if $\mathbb{C}_g=\mathbb{C}_-:=\{s\in\mathbb{C}\,;\,\Re s<0\}$ and $a_1,\dots,a_n<0$, then*

(38)
$$r_{\mathbf{\Delta}_{\mathcal{I}_R}}(\mathrm{diag}(a_1,\dots,a_n),I_n,I_n;\mathbb{C}_-) = \left(\varrho(R\,\mathrm{diag}(|a_1|^{-1},\dots,|a_n|^{-1}))\right)^{-1}.$$

Proof. (a) follows directly from Corollary 4.3(a) since $\|\Delta\|\le 1$ if and only if $\Delta\in\mathcal{B}_R(\delta)$ for all $\delta>1$. Equation (37) is a special case of (34) since $G_j(s)=(s-a_j)^{-1}$. To verify (38) note that by assumption, $a_1,\dots,a_n\in\mathbb{R}$ and so the functions $\omega\mapsto|i\,\omega-a_k|^{-1}$ attain their maxima on $\mathbb{R}$ at $\omega=0$. Hence, the monotonicity property ($\varrho 2$) of the spectral radius yields

$$\sup_{s\in i\mathbb{R}}\varrho\left(R\,\mathrm{diag}(|s-a_1|^{-1},\dots,|s-a_n|^{-1})\right) = \varrho\left(R\,\mathrm{diag}(|a_1|^{-1},\dots,|a_n|^{-1})\right).$$

Thus, (38) is a consequence of (37). ∎

Example 4.5. Suppose $A=\mathrm{diag}(1,i,-2,-2i)$ and

$$R_1=\frac{1}{4}\begin{bmatrix}0&6&2&2\\2&0&2&2\\2&2&0&8\\1&1&2&0\end{bmatrix},\quad R_2=\frac{1}{4}\begin{bmatrix}0&6&0&0\\0&0&2&2\\2&2&0&8\\1&1&2&0\end{bmatrix},\quad R_3=\frac{1}{4}\begin{bmatrix}0&6&0&0\\0&0&2&2\\0&0&0&8\\1&1&0&0\end{bmatrix}. \tag{39}$$

Figure 2 shows the sets

$$S_j := \bigcup_{\Delta\in\mathbb{C}^{4\times4},\,|\Delta|\le R_j}\sigma(A+\Delta),\qquad j=1,2,3. \tag{40}$$

Note that R_1 (resp., R_2) is obtained from R_3 by replacing all (resp., some) off-diagonal zeros of R_3 with $1/2$. Since $R_1\ge R_2\ge R_3$, the sets S_j decrease as j varies from 1 to 3. The pictures have been obtained via Corollary 4.4(a).

5. Mixed operator norms. We consider the same basic framework as that in the previous two sections. Let $\|\cdot\|_{\mathbb{C}^m}$ be an absolute norm on $\mathbb{C}^m$ which is invariant with respect to a permutation of the coordinates (for instance, a p-norm, $1 \le p \le \infty$), and let $\mathcal{N}(\cdot)$ be the induced operator norm on $\mathbb{C}^{m\times m}$. For $j,k \in \underline{m}$ let $\|\cdot\|_{\alpha_j}$ be a norm on $\mathbb{C}^{q_j}$ and let $\|\cdot\|_{\beta_k}$ be a norm on $\mathbb{C}^{l_k}$. Given any index set $\mathcal{I} \subseteq \underline{m}\times\underline{m}$, we define a norm on the perturbation space $\mathbf{\Delta}_{\mathcal{I},q,l}$ (24) by the formula

$$\|\Delta\| := \mathcal{N}\left(\begin{bmatrix} \|\Delta_{11}\|_{\alpha_1,\beta_1} & \cdots & \|\Delta_{1m}\|_{\alpha_m,\beta_1} \\ \vdots & & \vdots \\ \|\Delta_{m1}\|_{\alpha_1,\beta_m} & \cdots & \|\Delta_{mm}\|_{\alpha_m,\beta_m} \end{bmatrix}\right), \quad \Delta = [\Delta_{jk}] \in \mathbf{\Delta}_{\mathcal{I},q,l}. \tag{41}$$

In this section we derive a formula for the μ-value of *block-diagonal* matrices M with respect to the perturbation space $\mathbf{\Delta}_{\mathcal{I},q,l}$ provided with the norm (41). As a preparation we consider the general case of an arbitrary block matrix $M \in \mathbb{C}^{q\times l}$ of the form (12) and determine an upper bound for $\mu^{\|\cdot\|}_{\mathbf{\Delta}_{\mathcal{I},q,l}}(M)$ [2] in terms of the associated nonnegative $m \times m$ matrix $\tilde{M}$; see (28).

PROPOSITION 5.1. *Let $M_{jk} \in \mathbb{C}^{q_j\times l_k}$, $j,k \in \underline{m}$, $M = [M_{jk}]$, and $\mathcal{I} \subseteq \underline{m}\times\underline{m}$. Then with respect to the norm* (41),

$$\mu^{\|\cdot\|}_{\mathbf{\Delta}_{\mathcal{I},q,l}}(M) \le \mu^{\mathcal{N}}_{\mathbf{\Delta}_{\mathcal{I}}}(\tilde{M}), \tag{42}$$

where $\tilde{M}$ is defined by (28) *and*

$$\mathbf{\Delta}_{\mathcal{I}} := \{[\delta_{ij}] \in \mathbb{C}^{m\times m}; \delta_{ij} = 0 \text{ for } (i,j) \notin \mathcal{I}\}. \tag{43}$$

Proof. To prove (42) it suffices by Lemma 2.7 to show that for each $\Delta \in \mathbf{\Delta}_{\mathcal{I},q,l}$ with $\|\Delta\| = 1$ there exists $\tilde{\Delta} \in \mathbf{\Delta}_{\mathcal{I}}$ such that $\mathcal{N}(\tilde{\Delta}) = 1$ and $\varrho(\Delta M) \le \varrho(\tilde{\Delta}\tilde{M})$. Given any $\Delta \in \mathbf{\Delta}_{\mathcal{I},q,l}$ with $\|\Delta\| = 1$, let $\tilde{\Delta} \in \mathbb{R}^{m\times m}$ be the matrix in the parentheses on the right-hand side of (41). Then $\tilde{\Delta} \in \mathbf{\Delta}_{\mathcal{I}}$ and $\mathcal{N}(\tilde{\Delta}) = \|\Delta\| = 1$ by (41). Let $u = (u^j)_{j\in\underline{m}} \in \oplus_{j=1}^m \mathbb{C}^{l_j}$, $u \ne 0$, and $\lambda \in \mathbb{C}$ be such that $\Delta M u = \lambda u$ and $|\lambda| = \varrho(\Delta M)$. We set $\tilde{u} = (\|u^j\|_{\beta_j})_{j\in\underline{m}}$. If $\Delta M u = ((\Delta M u)^j)_{j\in\underline{m}} \in \oplus_{j=1}^m \mathbb{C}^{l_j}$ is partitioned as u, then, for every $j \in \underline{m}$,

$$\begin{aligned} \|(\Delta M u)^j\|_{\beta_j} &= \left\| \sum_{k=1}^m \sum_{i=1}^m \Delta_{ji} M_{ik} u^k \right\|_{\beta_j} \le \sum_{k=1}^m \sum_{i=1}^m \|\Delta_{ji}\|_{\alpha_i,\beta_j} \|M_{ik}\|_{\beta_k,\alpha_i} \|u^k\|_{\beta_k} \\ &= (\tilde{\Delta}\tilde{M}\tilde{u})^j. \end{aligned}$$

It follows that we have the componentwise inequality

$$\tilde{\Delta}\tilde{M}\tilde{u} \ge \left(\|(\Delta M u)^j\|_{\beta_j}\right)_{j\in\underline{m}} = |\lambda|\tilde{u}$$

and so $\varrho(\tilde{\Delta}\tilde{M}) \ge |\lambda| = \varrho(\Delta M)$ by (ϱ3). This concludes the proof. ∎

We will now prove that equality holds in (42) if $M = [M_{jk}]$ is block-diagonal, i.e., $M_{jk} = 0$ for $j,k \in \underline{m}$, $j \ne k$. In the proof we will make use of some elementary notions from graph theory [16], [2] which are summarized in the following remark.

[2] Since in this section we will consider μ-values with respect to more than one norm, we use the notation $\mu^{\|\cdot\|}_{\mathbf{\Delta}_{\mathcal{I},q,l}}$ where there may be a risk of confusion.

Remark 5.2. A finite sequence $\gamma = (j_1, \dots, j_\ell)$ of integers is said to be a path from j_1 to j_ℓ in the directed graph $\Gamma(\underline{m}, \mathcal{I})$ if $(j_i, j_{i+1}) \in \mathcal{I}$ for all $i \in \underline{\ell - 1}$. Two nodes j, k of $\Gamma(\underline{m}, \mathcal{I})$ are said to be strongly connected if there exists a path from j to k and a path from k to j in $\Gamma(\underline{m}, \mathcal{I})$. A subset $J \subset \underline{m}$ is said to be strongly connected if any two distinct nodes in J are strongly connected in $\Gamma(\underline{m}, \mathcal{I})$. The maximal strongly connected subsets of $\underline{m}$ are called the strongly connected components of the directed graph $\Gamma(\underline{m}, \mathcal{I})$. They form a partition of $\underline{m}$. A finite sequence $\gamma = (j_1, \dots, j_\ell)$ of mutually distinct integers is said to be a cycle of length $|\gamma| := \ell \geq 1$ of the directed graph $\Gamma(\underline{m}, \mathcal{I})$ if $(j_i, j_{i+1}) \in \mathcal{I}$ for all $i \in \underline{\ell - 1}$ and $(j_\ell, j_1) \in \mathcal{I}$. We will write $j \in \gamma$ if $j = j_i$ for some $i \in \underline{\ell}$. By $\mathcal{Z}(\mathcal{I})$ we denote the set of all cycles in $\Gamma(\underline{m}, \mathcal{I})$. A cycle $\gamma \in \mathcal{Z}(\mathcal{I})$ is said to be nontrivial if $|\gamma| \geq 2$. If for a given $j_0 \in \underline{m}$ there does not exist a nontrivial cycle $\gamma \in \mathcal{Z}(\mathcal{I})$ such that $j_0 \in \gamma$, then $\{j_0\}$ is a strongly connected component of $\Gamma(\underline{m}, \mathcal{I})$.

For any $A = [a_{jk}] \in \mathbb{C}^{m \times m}$ we set $\mathcal{I}_A := \{(j,k) \in \underline{m} \times \underline{m}\,;\, a_{jk} \neq 0\}$. Let $\gamma = (j_1, \dots, j_\ell) \in \mathcal{Z}(\underline{m} \times \underline{m})$. Then the cycle product of A over γ is defined as

$$\textstyle\prod_\gamma A := \prod_{i=1}^{\ell} a_{j_i j_{i+1}}, \qquad \text{where } j_{\ell+1} := j_1.$$

Note that if $\gamma = (j)$ is a cycle of length 1, then $\prod_\gamma A = a_{jj}$.

If $A = [a_{jk}], B = [b_{jk}] \in \mathbb{C}^{m \times m}$ we denote by $A \circ B$ the Hadamard product of A and B, $A \circ B = [a_{jk} b_{jk}] \in \mathbb{C}^{m \times m}$. For nonnegative matrices the Hadamard product satisfies the following inequality which is a corollary of Theorem 5.7.21 in [16].

LEMMA 5.3. *Let $A, B \in \mathbb{R}_+^{m \times m}$. If $\mathcal{Z}(\mathcal{I}_A) = \emptyset$, then $\varrho(B \circ A) = 0$. Otherwise we have*

$$\varrho(B \circ A) \leq \varrho(B) \max_{\gamma \in \mathcal{Z}(\mathcal{I}_A)} \left(\textstyle\prod_\gamma A \right)^{\frac{1}{|\gamma|}}.$$

Given $(m_1, \dots, m_\ell) \in \mathbb{N}^\ell$, $\ell \geq 1$, and matrices $C_j \in \mathbb{C}^{m_j \times m_{j+1}}$, $j \in \underline{\ell}$, where $m_{\ell+1} := m_1$, the associated block cyclic matrix is defined by

$$Z(C_1, \dots, C_\ell) := \begin{bmatrix} 0 & C_1 & 0 & \cdots & 0 \\ 0 & \ddots & C_2 & \ddots & \vdots \\ \vdots & & \ddots & \ddots & 0 \\ 0 & \cdots & \cdots & 0 & C_{\ell-1} \\ C_\ell & 0 & \cdots & \cdots & 0 \end{bmatrix} \in \mathbb{C}^{(\sum_{j=1}^{\ell} m_j) \times (\sum_{j=1}^{\ell} m_j)}.$$

The next result which follows from the Frobenius theorem (see [10, Chapter XIII, section 2]) determines the spectral radius of nonnegative cyclic matrices with scalar blocks.

LEMMA 5.4. *Let $c_1, \dots, c_\ell \geq 0$, $\ell \in \mathbb{N}$. Then the spectrum of the cyclic matrix $Z(c_1, \dots, c_\ell)$ is given by*

$$\sigma\left(Z(c_1, \dots, c_\ell)\right) = \{ e^{2\pi i \frac{k-1}{\ell}} \varrho \,;\, k \in \underline{\ell} \}, \tag{44}$$

where $\varrho = \varrho(Z(c_1, \dots, c_\ell)) = (c_1 c_2 \cdots c_\ell)^{1/\ell}$.

The following theorem is the main result of this section.

THEOREM 5.5. *Suppose $M_j \in \mathbb{C}^{q_j \times l_j}$ for $j \in \underline{m}$, $M = \oplus_{j=1}^m M_j$, and $\mathcal{I} \subseteq \underline{m} \times \underline{m}$ are given and let $\mathcal{I}_0 := \{(j,k) \in \mathcal{I}\,;\, M_j \neq 0 \text{ and } M_k \neq 0\}$. If $(\mathbf{\Delta}_{\mathcal{I},q,l}, \|\cdot\|)$ is the perturbation structure defined by (24), (41) and $\mathbf{\Delta}_{\mathcal{I}}$ defined by (43) is provided with the norm $\mathcal{N}$, then*

$$\mu^{\|\cdot\|}_{\mathbf{\Delta}_{\mathcal{I},q,l}}(M) = \mu^{\mathcal{N}}_{\mathbf{\Delta}_{\mathcal{I}}}(\tilde{M}) = \begin{cases} \max\limits_{\gamma \in \mathcal{Z}(\mathcal{I}_0)} \big(\prod_{j\in\gamma} \|M_j\|_{\beta_j,\alpha_j} \big)^{\frac{1}{|\gamma|}} & \text{if } \mathcal{Z}(\mathcal{I}_0) \neq \emptyset, \\ 0 & \text{if } \mathcal{Z}(\mathcal{I}_0) = \emptyset, \end{cases} \tag{45}$$

where $\tilde{M} = \operatorname{diag}(\|M_1\|_{\beta_1,\alpha_1}, \ldots, \|M_m\|_{\beta_m,\alpha_m})$.

Proof. Let c denote the right-hand-side of (45). We first show that

$$\mu^{\|\cdot\|}_{\mathbf{\Delta}_{\mathcal{I},q,l}}(M) \leq \mu^{\mathcal{N}}_{\mathbf{\Delta}_{\mathcal{I}}}(\tilde{M}) = \max_{\substack{\tilde{\Delta} \in \mathbf{\Delta}_{\mathcal{I}} \\ \mathcal{N}(\tilde{\Delta})=1}} \varrho\left(\tilde{\Delta}\,\tilde{M}\right) \leq c. \tag{46}$$

The first inequality in (46) follows directly from Proposition 5.1. To prove the second inequality in (46) let $E = [e_{jk}] \in \mathbb{R}^{m\times m}$, where $e_{jk} = 1$ if $(j,k) \in \mathcal{I}$ and $e_{jk} = 0$ otherwise. Set

$$A := E\tilde{M} = E \operatorname{diag}(\|M_1\|_{\beta_1,\alpha_1} \ldots \|M_m\|_{\beta_m,\alpha_m}) = [\, e_{jk}\|M_k\|_{\beta_k,\alpha_k}\,] \in \mathbb{R}^{m\times m}_+.$$

Then $\mathcal{I}_A \subseteq \mathcal{I}$, $\mathcal{Z}(\mathcal{I}_A) = \mathcal{Z}(\mathcal{I}_0)$, and we have $\prod_\gamma A = \prod_{j\in\gamma} \|M_j\|_{\beta_j,\alpha_j}$ for every cycle $\gamma \in \mathcal{Z}(\mathcal{I})$. Thus

$$c = \begin{cases} \max\limits_{\gamma \in \mathcal{Z}(\mathcal{I}_A)} \big(\prod_\gamma A\big)^{\frac{1}{|\gamma|}} & \text{if } \mathcal{Z}(\mathcal{I}_A) \neq \emptyset, \\ 0 & \text{otherwise.} \end{cases} \tag{47}$$

Let $\tilde{\Delta} = [\tilde{\Delta}_{jk}] \in \mathbf{\Delta}_{\mathcal{I}}$ with $\mathcal{N}(\tilde{\Delta}) = 1$. Then $\tilde{\Delta}\tilde{M} = [\tilde{\Delta}_{jk}\, e_{jk}\, \|M_k\|_{\beta_k,\alpha_k}] = \tilde{\Delta} \circ (E\tilde{M}) = \tilde{\Delta} \circ A$, and so by Lemma 5.3 and (47)

$$\varrho(\tilde{\Delta}\tilde{M}) = \varrho(\tilde{\Delta} \circ A) \leq \varrho(\tilde{\Delta})\, c \leq \mathcal{N}(\tilde{\Delta}) c = c.$$

This proves (46). If $c = 0$, then equality holds in (46) and hence (45). By Lemma 2.7 it remains to construct, for each cycle $\gamma \in \mathcal{Z}(\mathcal{I}_0)$, a matrix $\Delta^\gamma \in \mathbf{\Delta}_{\mathcal{I},q,l}$ such that $\|\Delta^\gamma\| = 1$ and

$$\varrho\left(\Delta^\gamma \left(\oplus_{j=1}^m M_j\right)\right) \geq \left(\prod_{j\in\gamma} \|M_j\|_{\beta_j,\alpha_j}\right)^{\frac{1}{|\gamma|}}. \tag{48}$$

The construction of Δ^γ is as follows. Suppose that $\gamma = (j_1, \ldots, j_\ell)$. For $j \in \underline{m}$ let $u_j \in \mathbb{C}^{\ell_j}$ and $y_j \in \mathbb{C}^{q_j}$ be such that $\|u_j\|_{\beta_j} = \|y_j\|^D_{\alpha_j} = 1$ and $y_j^\top M_j u_j = \|M_j\|_{\beta_j,\alpha_j}$. Let $\Delta^\gamma := [\Delta^\gamma_{jk}]$, where

$$\Delta^\gamma_{jk} := \begin{cases} u_{j_i} y_{j_{i+1}}^\top & \text{if } (j,k) = (j_i, j_{i+1}),\ i \in \underline{\ell-1}, \\ u_{j_\ell} y_{j_1}^\top & \text{if } (j,k) = (j_\ell, j_1), \\ 0 \in \mathbb{C}^{l_j \times q_k} & \text{otherwise.} \end{cases} \qquad j,k \in \underline{m}.$$

For instance, if m=4, then

$$\Delta^{(1,3,4)} = \begin{bmatrix} 0 & 0 & u_1 y_3^\top & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & u_3 y_4^\top \\ u_4 y_1^\top & 0 & 0 & 0 \end{bmatrix}, \qquad \Delta^{(3,4,2,1)} = \begin{bmatrix} 0 & 0 & u_1 y_3^\top & 0 \\ u_2 y_1^\top & 0 & 0 & 0 \\ 0 & 0 & 0 & u_3 y_4^\top \\ 0 & u_4 y_2^\top & 0 & 0 \end{bmatrix}.$$

We claim that Δ^γ has the required properties. Obviously, $\Delta^\gamma \in \mathbf{\Delta}_{\mathcal{I},q,l}$. To see that $\|\Delta^\gamma\| = 1$, note that Δ^γ contains $\ell \geq 1$ nonzero blocks and in each block row and each block column of Δ^γ there is at most one nonzero block. All nonzero blocks have norm 1. Since the norm $\|\cdot\|_{\mathbb{C}^m}$ is absolute and invariant with respect to a permutation of the coordinates, it follows that

$$\|\Delta^\gamma\| = \mathcal{N}(\,[\,\|\Delta^\gamma_{jk}\|_{\alpha_j,\beta_k}\,]\,) = 1.$$

Let us show (48). Observe that the principal block submatrix of $\Delta^\gamma M$ corresponding to the block rows and columns with numbers $j_1, \dots, j_\ell$ is permutation similar to the block cyclic matrix

$$Z(u_{j_1} y_{j_2}^\top M_{j_2}, u_{j_2} y_{j_3}^\top M_{j_3}, \dots, u_{j_\ell} y_{j_1}^\top M_{j_1}) = Z(u_{j_1} y_{j_2}^\top, u_{j_2} y_{j_3}^\top, \dots, u_{j_\ell} y_{j_1}^\top)\left(\oplus_{i=1}^\ell M_{j_i}\right).$$

By Lemma 5.4 the product $\varrho := \left(\prod_{j\in\gamma} \|M_j\|_{\beta_j,\alpha_j}\right)^{\frac{1}{|\gamma|}}$ is the spectral radius of the matrix

$$Z = Z(\|M_{j_1}\|_{\beta_{j_1},\alpha_{j_1}}, \dots, \|M_{j_\ell}\|_{\beta_{j_\ell},\alpha_{j_\ell}}).$$

Let $\xi = [\xi_{j_1}, \dots, \xi_{j_\ell}]^\top \in \mathbb{R}^\ell_+$ be an eigenvector of Z corresponding to ϱ; see (ϱ1). Then the following relations hold:

$$\|M_{j_i}\|_{\beta_{j_i},\alpha_{j_i}} \xi_{j_{i+1}} = \left(\prod_{j\in\gamma} \|M_j\|_{\beta_j,\alpha_j}\right)^{\frac{1}{|\gamma|}} \xi_{j_i}, \qquad i \in \underline{\ell},\ j_{\ell+1} := j_1. \tag{49}$$

Now set $w := [w_1^\top, \dots, w_m^\top]^\top$, where

$$w_j = \begin{cases} \xi_{j_{i+1}} u_{j_i} & \text{if } j = j_i,\ i \in \underline{\ell},\ j_{\ell+1} := j_1, \\ 0 \in \mathbb{C}^{\ell_j} & \text{otherwise,} \end{cases} \qquad j \in \underline{m},$$

and let $\widehat{w} := [w_{j_1}^\top, w_{j_2}^\top, \dots, w_{j_\ell}^\top]^\top$. Then using (49), we have

$$\begin{aligned} &Z(u_{j_1} y_{j_2}^\top, u_{j_2} y_{j_3}^\top, \dots, u_{j_\ell} y_{j_1}^\top)\left(\oplus_{i=1}^\ell M_{j_i}\right)\widehat{w} \\ &\quad = \begin{bmatrix} 0 & u_{j_1} y_{j_2}^\top M_{j_2} & 0 & \dots & 0 \\ 0 & 0 & u_{j_2} y_{j_3}^\top M_{j_3} & & \vdots \\ \vdots & \vdots & \ddots & \ddots & \vdots \\ 0 & 0 & & \ddots & u_{j_{\ell-1}} y_{j_\ell}^\top M_{j_\ell} \\ u_{j_\ell} y_{j_1}^\top M_{j_1} & 0 & \dots & \dots & 0 \end{bmatrix} \begin{bmatrix} \xi_{j_2} u_{j_1} \\ \xi_{j_3} u_{j_2} \\ \vdots \\ \xi_{j_\ell} u_{j_{\ell-1}} \\ \xi_{j_1} u_{j_\ell} \end{bmatrix} \\ &\quad = \begin{bmatrix} \|M_{j_2}\|_{\beta_{j_2},\alpha_{j_2}} \xi_{j_3} u_{j_1} \\ \|M_{j_3}\|_{\beta_{j_3},\alpha_{j_3}} \xi_{j_4} u_{j_2} \\ \vdots \\ \vdots \\ \|M_{j_\ell}\|_{\beta_{j_\ell},\alpha_{j_\ell}} \xi_{j_1} u_{j_{\ell-1}} \\ \|M_{j_1}\|_{\beta_{j_1},\alpha_{j_1}} \xi_{j_2} u_{j_\ell} \end{bmatrix} = \left(\prod_{j\in\gamma} \|M_j\|_{\beta_j,\alpha_j}\right)^{\frac{1}{|\gamma|}} \begin{bmatrix} \xi_{j_2} u_{j_1} \\ \xi_{j_3} u_{j_2} \\ \vdots \\ \vdots \\ \xi_{j_\ell} u_{j_{\ell-1}} \\ \xi_{j_1} u_{j_\ell} \end{bmatrix} \\ &\quad = \left(\prod_{j\in\gamma} \|M_j\|_{\beta_j,\alpha_j}\right)^{\frac{1}{|\gamma|}} \widehat{w}. \end{aligned}$$

This implies that $\Delta^\gamma \left(\oplus_{j=1}^m M_j\right) w = \left(\prod_{j\in\gamma} \|M_j\|_{\beta_j,\alpha_j}\right)^{\frac{1}{|\gamma|}} w$. Thus (48) holds, and the proof is complete. ∎

As a corollary we obtain the following characterization of spectral value sets and stability radii for the perturbation space $(\mathbf{\Delta}_{\mathcal{I},q,l}, \|\cdot\|)$.

COROLLARY 5.6. *Suppose* $(A_j, B_j, C_j) \in L_{n_j,l_j,q_j}$ *for* $j \in \underline{m}$, $\delta > 0$, $\mathcal{I} \subset \underline{m} \times \underline{m}$ *and* $\mathbf{\Delta} = \mathbf{\Delta}_{\mathcal{I},q,l}$ *is provided with the norm* (41). *Let* $A = \oplus_{j=1}^m A_j$, $B = \oplus_{j=1}^m B_j$, $C = \oplus_{j=1}^m C_j$, *and*

$$G_j(s) := C_j(sI_{n_j} - A_j)^{-1}B_j,\ j \in \underline{m}, \quad \mathcal{I}_0 := \{(j,k) \in \mathcal{I};\ B_j \neq 0, C_k \neq 0\}.$$

Then the following hold:

(a) *If* $\mathcal{Z}(\mathcal{I}_0) \neq \emptyset$, *the spectral value set of* A *with respect to perturbations of the form* (14) *is given by*

(50)
$$\bigcup_{\Delta\in\mathbf{\Delta}_{\mathcal{I},q,l},\,\|\Delta\|<\delta} \sigma(A_\Delta) = \sigma(A) \cup \left\{ s \in \rho(A);\ \max_{\gamma\in\mathcal{Z}(\mathcal{I}_0)} \prod_{j\in\gamma} \|G_j(s)\|_{\beta_j,\alpha_j} > \delta^{-|\gamma|} \right\}.$$

If $\mathcal{Z}(\mathcal{I}_0) = \emptyset$, *then all the eigenvalues of* A *are fixed under perturbations of the form* (14); *i.e.,*

$$\bigcup_{\Delta\in\mathbf{\Delta}_{\mathcal{I},q,l}} \sigma(A_\Delta) = \sigma(A).$$

(b) *If* $j_0 \in \underline{m}$, *and there does not exist any cycle* $\gamma \in \mathcal{Z}(\mathcal{I}_0)$ *such that* $j_0 \in \gamma$, *then*

$$\sigma(A_{j_0}) \subseteq \sigma(A_\Delta), \quad \Delta \in \mathbf{\Delta}_{\mathcal{I},q,l}.$$

(c) *Let* $\mathbb{C}_g$ *be an open subset of* $\mathbb{C}$ *and suppose* $A_1, \ldots, A_m$ *are* $\mathbb{C}_g$*-stable. Then the stability radius* $r_{\mathbf{\Delta}_{\mathcal{I},q,l}}(A, B, C; \mathbb{C}_g)$ *is given by*

$$r_{\mathbf{\Delta}_{\mathcal{I},q,l}}(A, B, C; \mathbb{C}_g)$$
(51)
$$= \begin{cases} \left[\sup_{s\in\partial\mathbb{C}_g} \max_{\gamma\in\mathcal{Z}(\mathcal{I}_0)} \left(\prod_{j\in\gamma} \|G_j(s)\|_{\beta_j,\alpha_j} \right)^{\frac{1}{|\gamma|}} \right]^{-1} & \text{if } \mathcal{Z}(\mathcal{I}_0) \neq \emptyset, \\ \infty & \text{if } \mathcal{Z}(\mathcal{I}_0) = \emptyset. \end{cases}$$

Proof. (a) Since $G(s) = \oplus_{j=1}^m G_j(s)$ is the transfer function of (A, B, C), (a) is a direct consequence of Theorems 2.5 and 5.5.

(b) Suppose $\Delta \in \mathbf{\Delta}_{\mathcal{I},q,l}$. Since $A_\Delta = [A_{jk} + B_j\Delta_{jk}C_k]$ and $B_j\Delta_{jk}C_k = 0$ if $(j,k) \notin \mathcal{I}$, $B_j = 0$, or $C_k = 0$, we have $\mathcal{I}_{B\Delta C} \subseteq \mathcal{I}_0$ and $\mathcal{I}_{A_\Delta} \subseteq \mathcal{I}_A \cup \mathcal{I}_0 \subseteq \{(k,k);\ k \in \underline{m}\} \cup \mathcal{I}_0$. Now assume that there does not exist any cycle $\gamma \in \mathcal{Z}(\mathcal{I}_0)$ such that $j_0 \in \gamma$. Then $(j_0, j_0) \notin \mathcal{I}_0$; hence $B_{j_0}\Delta_{j_0j_0}C_{j_0} = 0$, and $\{j_0\}$ is a strongly connected component of the directed graph $\Gamma(\underline{m}, \mathcal{I}_{A_\Delta})$. This implies that A_Δ is permutation similar to a matrix $\tilde{A}$ of block upper triangular form:

$$A_\Delta \sim \tilde{A} = \begin{bmatrix} \tilde{A}_{11} & \cdot & \cdots & \tilde{A}_{1r} \\ & \tilde{A}_{22} & \cdots & \tilde{A}_{2r} \\ & & \ddots & \vdots \\ & & & \tilde{A}_{rr} \end{bmatrix},$$

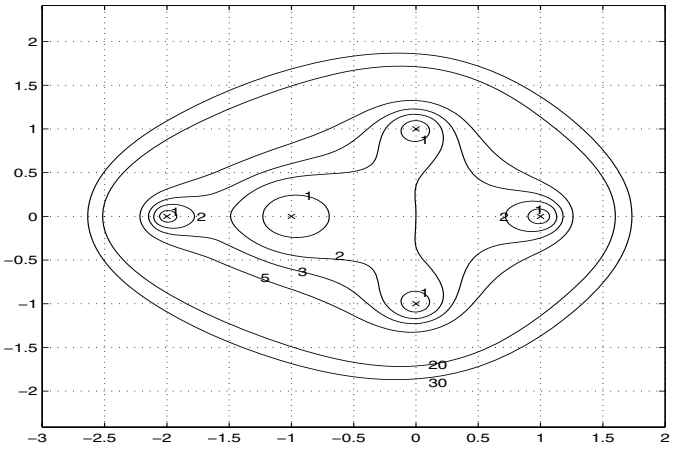

FIG. 3. *The boundaries of the Brualdi sets* $\mathcal{B}(-2,-1,1,-i,i;\delta)$, $\delta = 1,2,3,5,20,30$.

where the diagonal blocks correspond to the connected components of the graph $\Gamma(\underline{m},\mathcal{I}_{A_\Delta})$; see [2, section 2.3]. Hence $A_{j_0} = A_{j_0} + B_{j_0}\Delta_{j_0 j_0}C_{j_0} = \tilde{A}_{kk}$ for some $k \in \underline{r}$ and this shows that $\sigma(A_{j_0}) \subset \sigma(A_\Delta)$.

(c) If $\mathcal{Z}(\mathcal{I}_0) = \emptyset$, then the last statement of (a) implies $r_{\mathbf{\Delta}_{\mathcal{I},q,l}}(A,B,C;\mathbb{C}_g) = \infty$. Now suppose $\mathcal{Z}(\mathcal{I}_0) \neq \emptyset$. By the continuity of the spectrum, $r_{\mathbf{\Delta}_{\mathcal{I},q,l}}(A,B,C;\mathbb{C}_g)$ is the largest value of δ such that $\sigma(A_\Delta) \cap \partial\mathbb{C}_g = \emptyset$ for all $\Delta \in \mathbf{\Delta}_{\mathcal{I},q,l}$ of norm $\|\Delta\| < \delta$. By (a) this condition is equivalent to

$$\max_{\gamma\in\mathcal{Z}(\mathcal{I}_0)} \prod_{j\in\gamma} \|G_j(s)\|_{\beta_j,\alpha_j} \leq \delta^{-|\gamma|}, \quad s \in \partial\mathbb{C}_g,$$

or, equivalently,

$$\sup_{s\in\partial\mathbb{C}_g} \max_{\gamma\in\mathcal{Z}(\mathcal{I}_0)} \left(\prod_{j\in\gamma} \|G_j(s)\|_{\beta_j,\alpha_j}\right)^{\frac{1}{|\gamma|}} \leq \delta^{-1}.$$

This concludes the proof of (51). ∎

We will now specialize the previous result to the case where the blocks are reduced to scalars, i.e., $l_i = q_i = 1$ for $i \in \underline{m}$. In this case a more concrete version of the formula (50) is obtained in which the spectral value sets are expressed as a finite union of sets of the following form:

(52)
$$\mathcal{B}(z_1,\ldots,z_\ell;\delta) := \left\{s\in\mathbb{C}\,;\, \prod_{j\in\underline{\ell}}|s-z_j| \leq \delta\right\}, \qquad \ell\in\mathbb{N},\ z_1,\ldots,z_\ell\in\mathbb{C}, \quad \delta\geq 0.$$

These sets are called *Brualdi sets* in honor of Brualdi who introduced them in [4]. They will be further discussed in what follows. Note that $\mathcal{B}(z_1,\ldots,z_\ell;0) = \{z_1,\ldots,z_\ell\}$ and $\mathcal{B}(z;\delta) = \mathcal{D}(z;\delta)$ is the closed disk of radius δ about z. For an illustration, see Figure 3.

COROLLARY 5.7. *Suppose* $a_j, b_j, c_j \in \mathbb{C}$, $j \in \underline{n}$, $A = \operatorname{diag}(a_1,\ldots,a_n)$, $B = \operatorname{diag}(b_1,\ldots,b_n)$, $C = \operatorname{diag}(c_1,\ldots,c_n)$, $\mathcal{I} \subseteq \underline{n}\times\underline{n}$, *and* $\|\cdot\|_{\mathbb{C}^n}$ *is an arbitrary norm on*

$\mathbb{C}^n$ *with induced operator norm* $\mathcal{N}(\cdot)$ *on* $\mathbb{C}^{n\times n}$. *Let*

$$\begin{aligned}
&\mathbf{\Delta}_{\mathcal{I}} := \{\,[\Delta_{jk}]\in\mathbb{C}^{n\times n}\,;\,\Delta_{jk}\in\mathbb{C} \text{ and } \Delta_{jk}=0 \text{ if } (j,k)\notin\mathcal{I}\},\\
&\|\Delta\| := \mathcal{N}(|\Delta|) = \mathcal{N}\left(\begin{bmatrix} |\Delta_{11}| & \dots & |\Delta_{1n}| \\ \vdots & & \vdots \\ |\Delta_{n1}| & \dots & |\Delta_{nn}| \end{bmatrix}\right), \quad \Delta\in\mathbf{\Delta}_{\mathcal{I}}\,, \qquad (53)\\
&A_\Delta := A + B\Delta C,\\
&\mathcal{I}_0 := \{(j,k)\in\mathcal{I}\,;\,b_jc_k\neq 0\}.
\end{aligned}$$

Then the following statements hold.

(a) *For all* $\delta>0$,

$$\bigcup_{\substack{\Delta\in\mathbf{\Delta}_{\mathcal{I}}\\ \|\Delta\|\le\delta}} \sigma(A_\Delta) = \{a_1,\dots,a_n\} \cup \bigcup_{(j_1,\dots,j_\ell)\in\mathcal{Z}(\mathcal{I}_0)} \mathcal{B}\left(a_{j_1},\dots,a_{j_\ell}\,;\,\delta^\ell\textstyle\prod_{i=1}^{\ell}|b_{j_i}c_{j_i}|\right). \tag{54}$$

(b) *Let* $j_0\in\underline{n}$ *and suppose there does not exist any cycle* $\gamma\in\mathcal{Z}(\mathcal{I}_0)$ *such that* $j_0\in\gamma$. *Then* $a_{j_0}\in\sigma(A_\Delta)$ *for all* $\Delta\in\mathbf{\Delta}_{\mathcal{I}}$.

(c) *If* $\mathbb{C}_g$ *is an open subset of* $\mathbb{C}$, $a_1,\dots,a_n\in\mathbb{C}_g$, *then*

$$\begin{aligned}
&r_{\mathbf{\Delta}_{\mathcal{I}}}(A,B,C;\mathbb{C}_g)\\
&\quad= \begin{cases} \inf\limits_{s\in\partial\mathbb{C}_g}\min\limits_{\gamma\in\mathcal{Z}(\mathcal{I}_0)} \left(\prod_{j\in\gamma}|s-a_j|/|b_jc_j|\right)^{\frac{1}{|\gamma|}} & \text{if } \mathcal{Z}(\mathcal{I}_0)\neq\emptyset,\\ \infty & \text{if } \mathcal{Z}(\mathcal{I}_0)=\emptyset. \end{cases}
\end{aligned} \tag{55}$$

Proof. (a) If $\mathcal{Z}(\mathcal{I}_0)=\emptyset$, then Corollary 5.6 (a) implies

$$\bigcup_{\Delta\in\mathbf{\Delta}_{\mathcal{I}},\,\|\Delta\|\le\delta}\sigma(A_\Delta) = \{a_1,\dots,a_n\}\,.$$

Now suppose that $\mathcal{Z}(\mathcal{I}_0)\neq\emptyset$ and let $\delta>0$. Since

$$G(s) = \operatorname{diag}(g_1(s),\dots,g_n(s)), \quad g_j(s) = c_j(s-a_j)^{-1}b_j,\ j\in\underline{n},$$

is the transfer function of the system (A,B,C), we have by (10) and Theorem 5.5 the following equivalences for $s\in\mathbb{C}\setminus\{a_1,\dots,a_n\}$:

$$\begin{aligned}
s\in&\bigcup_{\Delta\in\mathbf{\Delta}_{\mathcal{I}},\,\|\Delta\|\le\delta}\sigma(A_\Delta)\\
&\Leftrightarrow \mu^{\|\cdot\|}_{\mathbf{\Delta}_{\mathcal{I}}}(\operatorname{diag}(c_1(s-a_1)^{-1}b_1,\dots,c_n(s-a_n)^{-1}b_n))\ge\delta^{-1}\\
&\Leftrightarrow \max_{\gamma\in\mathcal{Z}(\mathcal{I}_0)}\left(\textstyle\prod_{j\in\gamma}|c_j(s-a_j)^{-1}b_j|\right)^{\frac{1}{|\gamma|}}\ge\delta^{-1}\\
&\Leftrightarrow \exists\,\gamma\in\mathcal{Z}(\mathcal{I}_0):\ \left(\textstyle\prod_{j\in\gamma}|c_j(s-a_j)^{-1}b_j|\right)^{\frac{1}{|\gamma|}}\ge\delta^{-1}\\
&\Leftrightarrow \exists\,\gamma\in\mathcal{Z}(\mathcal{I}_0):\ \textstyle\prod_{j\in\gamma}|s-a_j|\le\delta^{|\gamma|}\prod_{j\in\gamma}|b_jc_j|.
\end{aligned}$$

Hence (54) holds.

(b) is a special case of Corollary 5.6(b).

(c) Since $|g_j(s)|^{-1}=|s-a_j|/|b_jc_j|$ if $b_jc_j\neq 0$, formula (55) is a special case of (51). ∎

Remark 5.8. (i) Corollaries 5.6 and 5.7 show that the spectral value sets and stability radii of block-diagonal and diagonal matrices with respect to the normed perturbation structure $(\mathbf{\Delta}_{\mathcal{I},q,l}, \|\cdot\|)$ (see (41)) are independent of the norm $\mathcal{N}$.

(ii) For the special case that $\mathbb{C}_g = \mathbb{C}_-$ and $a_1, \dots, a_n < 0$ it follows from (55) that

$$\begin{aligned} r_{\mathbf{\Delta}_{\mathcal{I}}}(A, B, C; \mathbb{C}_-) &= \min_{\gamma \in \mathcal{Z}(\mathcal{I}_0)} \left(\prod_{j \in \gamma} |a_j| / |b_j c_j| \right)^{\frac{1}{|\gamma|}} \\ &= \min_{\gamma \in \mathcal{Z}(\mathcal{I}_0)} \left(\prod_{j \in \gamma} r_{\mathbb{C}}(a_j, b_j, c_j; \mathbb{C}_-) \right)^{\frac{1}{|\gamma|}}. \end{aligned}$$

By Corollary 5.7 Brualdi sets play a fundamental role in determining the spectral value sets of diagonal matrices with respect to perturbations $\Delta \in \mathbf{\Delta}_{\mathcal{I}}$. We conclude this section with some remarks concerning these sets. Each Brualdi set (52) can be represented as the intersection of a family of sets which are unions of ℓ closed disks of centers z_i, $i \in \underline{\ell}$. More precisely, we have the following proposition.

PROPOSITION 5.9. *Let $z_1, \dots, z_\ell \in \mathbb{C}$ and $\delta > 0$. Then*

$$\mathcal{B}(z_1, \dots, z_\ell; \delta) = \bigcap_{\substack{r_1, \dots, r_\ell > 0, \\ \prod_{j \in \underline{\ell}} r_j = 1}} \left(\bigcup_{j \in \underline{\ell}} \mathcal{D}(z_j; \delta^{\frac{1}{\ell}} r_j) \right). \tag{56}$$

Proof. Let D denote the set on the right-hand side of (56). Suppose that $s \notin D$. Then there are $r_1, \dots, r_\ell > 0$ such that $\prod_{j \in \underline{\ell}} r_j = 1$ and $|s - z_j| > \delta^{\frac{1}{\ell}} r_j$ for all $j \in \underline{\ell}$. Multiplying the latter inequalities we obtain that $\prod_{j \in \underline{\ell}} |s - z_j| > \delta$. Thus $s \notin \mathcal{B}(z_1, \dots, z_\ell; \delta)$. Hence $\mathcal{B}(z_1, \dots, z_\ell; \delta) \subseteq D$. Now suppose that $s \notin \mathcal{B}(z_1, \dots, z_\ell; \delta)$; then $\delta_1 := \prod_{j \in \underline{\ell}} |s - z_j| > \delta$. If we define $r_j > 0$ by $|s - z_j| = \delta_1^{\frac{1}{\ell}} r_j$, $j \in \underline{\ell}$, then $s \notin \bigcup_{j \in \underline{\ell}} \mathcal{D}(z_j; \delta^{\frac{1}{\ell}} r_j)$ and $\prod_{j \in \underline{\ell}} r_j = 1$. So $s \notin D$. ∎

From the relation (56) one can derive an upper bound for the connected components of Brualdi sets.

PROPOSITION 5.10. *Let $z_1, \dots, z_\ell \in \mathbb{C}$ and $\delta > 0$. Then the following hold:*

(a) *Each connected component of $\mathcal{B}(z_1, \dots, z_\ell; \delta)$ contains at least one of the points z_j, $j \in \underline{\ell}$.*

(b) *Let $\epsilon > 0$ and suppose that for a given $j \in \underline{\ell}$*

$$\min_{k \in \underline{\ell}, k \neq j} |z_j - z_k| > \delta^{\frac{1}{\ell}} \left(\epsilon + \epsilon^{-\frac{1}{\ell - 1}} \right). \tag{57}$$

Then the connected component K_j of $\mathcal{B}(z_1, \dots, z_\ell; \delta)$ with $z_j \in K_j$ is contained in $\mathcal{D}(z_j; \epsilon \delta^{\frac{1}{\ell}})$.

Proof. (a) Set $f(s) := \prod_{j \in \underline{\ell}} (s - z_j)$. Let K be a connected component of $\mathcal{B}(z_1, \dots, z_\ell; \delta)$. Then K is compact. Hence there exists $s_0 \in K$ such that $|f(s_0)| = \min_{s \in K} |f(s)|$. Let U be an open neighborhood of s_0 such that $U \cap \mathcal{B}(z_1, \dots, z_\ell; \delta) = U \cap K$. By the definition of $\mathcal{B}(z_1, \dots, z_\ell; \delta)$ we have $|f(s)| > \delta$ for all $s \in U \setminus K$. Thus $|f(s_0)| = \min_{s \in U} |f(s)|$ and this implies $f(s_0) = 0$ since f is holomorphic and nonconstant. Thus $s_0 = z_j$ for some $j \in \underline{\ell}$.

(b) For $i \in \underline{\ell}$ set

$$r_i = \begin{cases} \epsilon & \text{if } i = j, \\ \epsilon^{-\frac{1}{\ell - 1}} & \text{otherwise.} \end{cases}$$

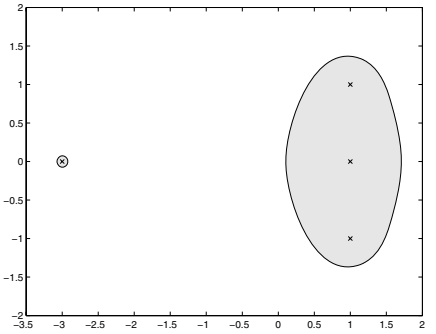

FIG. 4. *The Brualdi set* $\mathcal{B}(-3, 1, 1+\imath, 1-\imath; \delta)$, $\delta = 5$.

Then $\prod_{i\in\underline{\ell}} r_i = 1$ and Proposition 5.9 yields that $\mathcal{B}(z_1, \dots, z_\ell; \delta) \subseteq \bigcup_{i\in\underline{\ell}} \mathcal{D}(z_i; \delta^{\frac{1}{\ell}} r_i)$. The condition (57) implies that $\mathcal{D}(z_j; \delta^{\frac{1}{\ell}} r_j) \cap \mathcal{D}(z_k; \delta^{\frac{1}{\ell}} r_k) = \emptyset$ for all $k \neq j$. Thus $K_j \subseteq \mathcal{D}(z_j; \delta^{\frac{1}{\ell}} r_j)$. ∎

Roughly speaking, the above proposition states that if the distance of $z_j \in \mathbb{C}$ from the numbers $z_k \in \mathbb{C}$, $k \neq j$, is large, then the connected component K_j of $\mathcal{B}(z_1, \dots, z_\ell; \delta)$ is a small set. This is illustrated in Figure 4.

6. Off-diagonal perturbation structures. We consider the same basic framework as that in section 5 but now the index set is off-diagonal:

$$\mathcal{I}_{\text{off}} := \{(j,k) \in \underline{m} \times \underline{m};\ j \neq k\}. \tag{58}$$

The corresponding perturbation class $\mathbf{\Delta}_{\mathcal{I}_{\text{off}},q,l}$ is the set of all $m \times m$ block matrices $\Delta = [\Delta_{jk}]$ such that $\Delta_{jk} \in \mathbb{C}^{l_j \times q_k}$ and $\Delta_{jj} = 0$ for all $j, k \in \underline{m}$. In this section we derive formulae for the corresponding μ-function, spectral value sets, and stability radii.

Recall the following inequality for the geometric mean.

LEMMA 6.1. *Let* $c_1 \geq c_2 \geq \cdots \geq c_\ell \geq 0$. *Then, for all* $k \in \underline{\ell}$, $(\prod_{j=1}^{\ell} c_j)^{\frac{1}{\ell}} \leq (\prod_{j=1}^{k} c_j)^{\frac{1}{k}}$.

For $\mathcal{I} = \mathcal{I}_{\text{off}}$ the following proposition is a special case of Theorem 5.5.

PROPOSITION 6.2. *Let* $M_j \in \mathbb{C}^{q_j \times l_j}$, $j \in \underline{m}$, $M = \bigoplus_{j=1}^{m} M_j$. *Then with respect to the norm* (41),

$$\mu_{\mathbf{\Delta}_{\mathcal{I}_{\text{off}},q,\ell}}(M) = \max_{1\leq j<k\leq m} \sqrt{\|M_j\|_{\beta_j,\alpha_j}\ \|M_k\|_{\beta_k,\alpha_k}}.$$

Proof. Each pair $(j,k) \in \underline{m} \times \underline{m}$, $j \neq k$, is a cycle in the graph associated with $\mathcal{I}_{\text{off}}$. Thus

$$\max_{1\leq j<k\leq m} \sqrt{\|M_j\|_{\beta_j,\alpha_j}\ \|M_k\|_{\beta_k,\alpha_k}} \leq \max_{\gamma\in\mathcal{Z}(\mathcal{I}_{\text{off}})} \left(\prod_{j\in\gamma} \|M_j\|_{\beta_j,\alpha_j}\right)^{\frac{1}{|\gamma|}}. \tag{59}$$

Each cycle $\gamma \in \mathcal{Z}(\mathcal{I}_{\text{off}})$ has length $|\gamma| \geq 2$. Let $\gamma = (j_1, \dots, j_\ell)$, and let $j_i, j_r \in \gamma$ be such that $i \neq r$ and $\|M_{j_i}\|_{\beta_{j_i},\alpha_{j_i}} \geq \|M_{j_r}\|_{\beta_{j_r},\alpha_{j_r}} \geq \|M_{j_\nu}\|_{\beta_{j_\nu},\alpha_{j_\nu}}$ for all $\nu \in \underline{\ell} \setminus \{i, r\}$. By Lemma 6.1 we have that $(\prod_{j\in\gamma} \|M_j\|_{\beta_j,\alpha_j})^{\frac{1}{|\gamma|}} \leq \sqrt{\|M_{j_i}\|_{\beta_{j_i},\alpha_{j_i}}\ \|M_{j_r}\|_{\beta_{j_r},\alpha_{j_r}}}$. Thus, equality holds in (59). Now, the proposition follows from Theorem 5.5. ∎

An analogous result holds if the underlying norm on $\mathbf{\Delta}_{\mathcal{I}_{\mathrm{off}},q,l}$ is the operator norm induced by p-norms on $\mathbb{C}^{l_1+\cdots+l_m}$ and $\mathbb{C}^{q_1+\cdots+q_m}$. The corresponding μ-function will be denoted by $\mu^{(p)}_{\mathbf{\Delta}_{\mathcal{I}_{\mathrm{off}},q,l}}(\cdot)$. To prove the result we need the following lemma.

LEMMA 6.3. *Let $m_j, n_j \in \mathbb{N}$, $j = 1, 2$, and suppose $\|\cdot\|_\alpha$ and $\|\cdot\|_\beta$ are absolute norms on $\mathbb{C}^{m_1+m_2}$ and $\mathbb{C}^{n_1+n_2}$, respectively. If $X \in \mathbb{C}^{m_1\times n_2}$, $Y \in \mathbb{C}^{m_2\times n_1}$, and $Z \in \mathbb{C}^{m_2\times n_2}$, then*

$$\left\| \begin{bmatrix} 0 & tX \\ tY & Z \end{bmatrix} \right\|_{\beta,\alpha} \le t \left\| \begin{bmatrix} 0 & X \\ Y & Z \end{bmatrix} \right\|_{\beta,\alpha}, \quad t \ge 1.$$

Proof. The function

$$\zeta \mapsto f(\zeta) := \left\| \begin{bmatrix} 0 & X \\ Y & \zeta Z \end{bmatrix} \right\|_{\beta,\alpha}$$

is convex on $\mathbb{R}$, and since $\|\cdot\|_\alpha$ and $\|\cdot\|_\beta$ are absolute, we have that

$$f(-\zeta) = \left\| \begin{bmatrix} I_{m_1} & 0 \\ 0 & -I_{m_2} \end{bmatrix} \begin{bmatrix} 0 & X \\ Y & \zeta Z \end{bmatrix} \begin{bmatrix} -I_{n_1} & 0 \\ 0 & I_{n_2} \end{bmatrix} \right\|_{\beta,\alpha} = f(\zeta)$$

for all $\zeta \in \mathbb{R}$. From this it follows that f is a nondecreasing function on $[0, \infty)$. Thus for all $t \ge 1$,

$$\left\| \begin{bmatrix} 0 & tX \\ tY & Z \end{bmatrix} \right\|_{\beta,\alpha} = tf\left(\frac{1}{t}\right) \le tf(1) = t \left\| \begin{bmatrix} 0 & X \\ Y & Z \end{bmatrix} \right\|_{\beta,\alpha}. \qquad \square$$

In the following theorem $\|\cdot\|_p$ denotes the operator norm induced by p-norms on the corresponding vector spaces.

THEOREM 6.4. *Suppose $p \in [1, \infty]$, $M_j \in \mathbb{C}^{q_j\times l_j}$ for $j \in \underline{m}$ and $M = \bigoplus_{j=1}^m M_j$. Then*

$$\mu^{(p)}_{\mathbf{\Delta}_{\mathcal{I}_{\mathrm{off}},q,l}}\left(\bigoplus_{j=1}^m M_j\right) = \max_{1\le j<k\le m} \sqrt{\|M_j\|_p \, \|M_k\|_p}\,.$$

Proof. Without loss of generality we may assume that $\|M_1\|_p \ge \|M_2\|_p \ge \|M_j\|_p$ for $j \ge 3$. Let $\Delta \in \mathbf{\Delta}_{\mathcal{I}_{\mathrm{off}},q,l}$. Then $\Delta = \begin{bmatrix} 0 & X \\ Y & Z \end{bmatrix}$ for some $X \in \mathbb{C}^{l_1\times Q'}, Y \in \mathbb{C}^{L'\times q_1}$, $Z \in \mathbb{C}^{L'\times Q'}$, where $Q' = \sum_{j=2}^m q_j$, $L' = \sum_{j=2}^m l_j$. Suppose first that $M_2 = 0$. Then all eigenvalues of $\Delta M = \begin{bmatrix} 0 & 0 \\ YM_1 & 0 \end{bmatrix}$ are zero for all $\Delta \in \mathbf{\Delta}_{\mathcal{I}_{\mathrm{off}},q,l}$. Consequently, $\mu^{(p)}_{\mathbf{\Delta}_{\mathcal{I}_{\mathrm{off}},q,l}}(M) = 0 = \sqrt{\|M_1\|_p \|M_2\|_p}$. Suppose now that $M_2 \ne 0$ and let

$$F_t := \mathrm{diag}(tI_{q_1}, I_{Q'}), \qquad G_t := \mathrm{diag}(tI_{l_1}, I_{L'}), \qquad t := \sqrt{\frac{\|M_1\|_p}{\|M_2\|_p}} \ge 1.$$

Then $\|t^{-2}M_1\|_p = \|M_2\|_p$ and therefore

$$\|F_t^{-1} M G_t^{-1}\|_p = \|\operatorname{diag}\left(t^{-2}M_1, M_2, M_3, \ldots, M_m\right)\|_p = \|M_2\|_p.$$

By Lemma 6.3 $\|G_t \Delta F_t\|_p \le t\,\|\Delta\|_p$ for all $\Delta \in \mathbf{\Delta}_{\mathcal{I}_{\mathrm{off}},q,l}$. Suppose that $\|\Delta\|_p = 1$. Then we have

$$\begin{aligned} \varrho(\Delta M) &\le \|G_t \Delta M G_t^{-1}\|_p = \|(G_t \Delta F_t)(F_t^{-1} M G_t^{-1})\|_p \\ &\le \|G_t \Delta F_t\|_p \, \|F_t^{-1} M G_t^{-1}\|_p = \|G_t \Delta F_t\|_p \, \|M_2\|_p \\ &\le \|\Delta\|_p \, t \, \|M_2\|_p = \sqrt{\|M_1\|_p \|M_2\|_p}\,. \end{aligned}$$

Therefore $\mu^{(p)}_{\mathbf{\Delta}_{\mathcal{I}_{\mathrm{off}},q,l}}(M) \le \sqrt{\|M_1\|_p \|M_2\|_p}$. To see that equality holds, let $u_j \in \mathbb{C}^{l_j}$, $y_j \in \mathbb{C}^{q_j}$, $j = 1, 2$, be such that $\|u_j\|_p = \|y_j\|_p^D = 1$ and $y_j^\top M_j u_j = \|M_j\|_p$, $j = 1, 2$. Define

$$\Delta_0 := \operatorname{diag}\left(\begin{bmatrix} 0 & u_1 y_2^\top \\ u_2 y_1^\top & 0 \end{bmatrix}, 0\right) \in \mathbf{\Delta}_{\mathcal{I}_{\mathrm{off}},q,l}\,, \qquad u := \begin{bmatrix} \sqrt{\|M_2\|_p}\, u_1 \\ \sqrt{\|M_1\|_p}\, u_2 \\ 0 \end{bmatrix} \in \mathbb{C}^{l_1+\cdots+l_m}.$$

Then $\|\Delta_0\|_p = 1$, and an easy calculation yields $\Delta_0 M u = \sqrt{\|M_1\|_p \, \|M_2\|_p}\, u$. Thus $\mu^{(p)}_{\mathbf{\Delta}_{\mathcal{I}_{\mathrm{off}},q,l}}(M) \ge \varrho(\Delta_0 M) \ge \sqrt{\|M_1\|_p \, \|M_2\|_p}$, and this concludes the proof. ∎

We have not been able to extend Theorem 6.4 to arbitrary index sets $\mathcal{I} \subseteq \underline{m} \times \underline{m}$ and so we formulate a conjecture in this respect as an open question.

Open question: Does the identity

$$\mu^{(p)}_{\mathbf{\Delta}_{\mathcal{I},q,l}}\left(\bigoplus_{j=1}^m M_j\right) = \max_{\gamma \in \mathcal{Z}(\mathcal{I})} \left(\prod_{j\in\gamma} \|M_j\|_p\right)^{\frac{1}{|\gamma|}}$$

hold for arbitrary index sets $\mathcal{I} \subseteq \underline{m} \times \underline{m}$?

As corollaries of Proposition 6.2 and Theorem 6.4 we obtain the following formulae for spectral value sets and stability radii. The first corollary deals with the general block-diagonal case, and the second deals with the (scalar) diagonal case.

COROLLARY 6.5. *Suppose* $(A_j, B_j, C_j) \in L_{n_j,l_j,q_j}$, $j \in \underline{m}$, $A = \oplus_{j=1}^m A_j$, $B = \oplus_{j=1}^m B_j$, $C = \oplus_{j=1}^m C_j$, $\delta > 0$, *and* $\mathbf{\Delta}_{\mathcal{I}_{\mathrm{off}},q,l}$ *is provided with the norm* (41) *or with the operator norm induced by some p-norm,* $1 \le p \le \infty$.

Let $G_j(s) = C_j(sI_{n_j} - A_j)^{-1}B_j$, $j \in \underline{m}$, *and define* $\|G_i(s)\| = \|G_i(s)\|_{\beta_i,\alpha_i}$ *or* $\|G_i(s)\| = \|G_i(s)\|_p$, $i \in \underline{m}$, *respectively. Then the following hold:*

(a) *The spectral value set of A with respect to perturbations of the form*

$$A \rightsquigarrow A_\Delta = A + B\Delta C, \quad \Delta \in \mathbf{\Delta}_{\mathcal{I}_{\mathrm{off}},q,l},\ \|\Delta\| < \delta, \tag{60}$$

is given by

$$\begin{aligned} &\bigcup_{\substack{\Delta \in \mathbf{\Delta}_{\mathcal{I}_{\mathrm{off}},q,l} \\ \|\Delta\| < \delta}} \sigma(A_\Delta) \\ &\quad = \sigma(A) \cup \left\{ s \in \rho(A);\ \max_{1\le j<k\le m} \sqrt{\|G_j(s)\|\|G_k(s)\|} > \delta^{-1} \right\}. \end{aligned} \tag{61}$$

(b) *Let* $\mathbb{C}_g$ *be an open subset of* $\mathbb{C}$ *and suppose* $A_1, \ldots, A_m$ *are* $\mathbb{C}_g$*-stable. Then the stability radius is given by*

$$\begin{aligned} r_{\mathbf{\Delta}_{\mathcal{I}_{\mathrm{off}},q,l}}(A, B, C; \mathbb{C}_g) &= \left[\sup_{s\in\partial\mathbb{C}_g} \max_{1\le j<k\le m} \sqrt{\|G_j(s)\|\|G_k(s)\|} \right]^{-1} \\ &\ge \min_{1\le j<k\le m} \sqrt{r_{\mathbb{C}}(A_j, B_j, C_j; \mathbb{C}_g)\, r_{\mathbb{C}}(A_k, B_k, C_k; \mathbb{C}_g)}. \end{aligned} \tag{62}$$

Proof. Making use of Theorem 2.5 and Proposition 6.2 (resp., Theorem 6.4), the corollary can be proved in a way similar to that of Corollary 5.6(a),(c). ∎

COROLLARY 6.6. *Suppose* $a_j, b_j, c_j \in \mathbb{C}$, $j \in \underline{n}$, $A = \operatorname{diag}(a_1, \dots, a_n)$, $B = \operatorname{diag}(b_1, \dots, b_n)$, $C = \operatorname{diag}(c_1, \dots, c_n)$, *and* $\mathcal{N}(\cdot)$ *is an arbitrary operator norm on* $\mathbb{C}^{n\times n}$. *Let*

$$\mathbf{\Delta}_{\mathcal{I}_{\text{off}}} := \left\{[\Delta_{jk}] \in \mathbb{C}^{n\times n}\,;\, \Delta_{11} = \cdots = \Delta_{nn} = 0\right\}$$

be provided with the norm $\|\cdot\| = \|\cdot\|_p$, $1 \le p \le \infty$, *or*

$$\|\Delta\| := \mathcal{N}(|\Delta|) = \mathcal{N}\left(\begin{bmatrix} |\Delta_{11}| & \dots & |\Delta_{1n}| \\ \vdots & & \vdots \\ |\Delta_{n1}| & \dots & |\Delta_{nn}| \end{bmatrix}\right), \quad \Delta \in \mathbf{\Delta}_{\mathcal{I}_{\text{off}}}, \tag{63}$$

$$A_\Delta := A + B\Delta C.$$

If $A = \operatorname{diag}(a_1, \dots, a_n)$, $B = \operatorname{diag}(b_1, \dots, b_n)$, $C = \operatorname{diag}(c_1, \dots, c_n)$, *then the following statements hold:*

(a) *For all* $\delta > 0$,

$$\bigcup_{\Delta\in\mathbf{\Delta}_{\mathcal{I}_{\text{off}}},\, \|\Delta\|\le\delta} \sigma(A_\Delta) = \Big\{s \in \mathbb{C}; \min_{1\le j<k\le n} |s - a_j||s - a_k| \le \delta^2 |b_j c_j b_k c_k|\Big\}. \tag{64}$$

(b) *If* $\mathbb{C}_g$ *is an open subset of* $\mathbb{C}$ *and* $a_1, \dots, a_n \in \mathbb{C}_g$, *then*

$$r_{\mathbf{\Delta}_{\mathcal{I}_{\text{off}}}}(A, B, C; \mathbb{C}_g) = \inf_{s\in\partial\mathbb{C}_g} \min_{1\le j<k\le n} \left(\frac{|s - a_j|}{|b_j c_j|}\frac{|s - a_k|}{|b_k c_k|}\right)^{1/2}. \tag{65}$$

Proof. Making use of Theorem 2.5 and Proposition 6.2 (resp., Theorem 6.4) the corollary can be proved in a way similar to that of Corollary 5.7. □

If $\mathbb{C}_g = \mathbb{C}_-$ and $a_1, \dots, a_n < 0$, then $|\imath\omega - a_j| \ge |a_j|$ for all $\omega \in \mathbb{R}$, $j \in \underline{n}$, so that (65) implies

$$r_{\mathbf{\Delta}_{\mathcal{I}_{\text{off}}}}(A, B, C; \mathbb{C}_-) = \min_{1\le j<k\le n} \left(\frac{|a_j a_k|}{|b_j c_j b_k c_k|}\right)^{1/2}.$$

7. Application: Inclusion theorems. An arbitrary matrix $A = [a_{jk}] \in \mathbb{C}^{n\times n}$ can be represented as a perturbation of the diagonal matrix $D_A = \operatorname{diag}(a_{11}, \dots, a_{nn})$ by an off-diagonal perturbation matrix Δ_A:

$$A = D_A + \Delta_A, \quad \text{where } \Delta_A = A - D_A \in \mathbf{\Delta}_{\mathcal{I}_{\text{off}}} := \left\{[\Delta_{jk}] \in \mathbb{C}^{n\times n}\,;\, \Delta_{11} = \cdots = \Delta_{nn} = 0\right\}.$$

Hence, setting

$$\mathcal{I} := \mathcal{I}_A \cap \mathcal{I}_{\text{off}} = \{(j, k) \in \underline{n} \times \underline{n}\,;\, j \ne k \text{ and } a_{jk} \ne 0\}, \tag{66}$$

we have by Remark 2.6(ii) that

$$\sigma(A) \subseteq \bigcup_{\Delta\in\mathbf{\Delta}_{\mathcal{I}},\, \|\Delta\|\le\|\Delta_A\|} \sigma(D_A + \Delta) = \overline{\sigma_{\mathbf{\Delta}_{\mathcal{I}}}(D_A, I_n, I_n; \|\Delta_A\|)}. \tag{67}$$

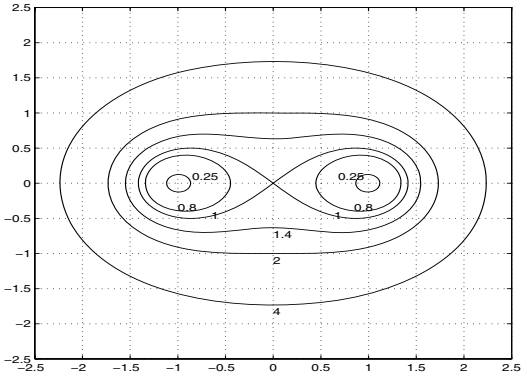

FIG. 5. *The ovals of Cassini* $\mathcal{C}(1,-1;\rho)$, $\rho = 0.25, 0.8, 1, 1.4, 2, 4$.

Applying the previous results about spectral value sets of diagonal matrices, one obtains different estimates for the location of the spectrum of A (depending on whether one chooses the perturbation norm to be (36) or (63)). In this section we recall the classical eigenvalue inclusion theorems of Gershgorin, Brauer, and Brualdi and show how they can be obtained as corollaries of the results in the previous sections.

Gershgorin's theorem states that for all $A = [a_{jk}] \in \mathbb{C}^{n\times n}$

$$\sigma(A) \subset \mathcal{G}_A := \bigcup_{j\in\underline{n}} \mathcal{D}(a_{jj}; R_j(A)), \quad \text{where } R_j(A) := \sum_{k\in\underline{n},k\neq j} |a_{jk}|. \tag{68}$$

Gershgorin's theorem was improved by Brauer [3]. He used inclusion regions for the eigenvalues of the following type:

$$\mathcal{C}(z_1, z_2; \rho) := \{ s\in\mathbb{C} \,;\, |s - z_1|\,|s - z_2| \leq \rho \}, \qquad z_1, z_2 \in \mathbb{C},\ \rho \geq 0.$$

The sets $\mathcal{C}(z_1, z_2; \rho)$ and their boundaries are called the *ovals of Cassini*. For an illustration, see Figure 5. Brauer's theorem states that

$$\sigma(A) \subseteq \mathcal{C}_A := \bigcup_{1\leq j<k\leq n} \mathcal{C}(a_{jj}, a_{kk}; R_j(A)R_k(A)), \quad A = [a_{jk}] \in \mathbb{C}^{n\times n}. \tag{69}$$

A further refinement has been obtained by Brualdi [4] who gave more precise information about the location of the eigenvalues by taking into account the zero structure of A. For this he introduced sets of the form (52) which now carry his name. With every matrix $A = [a_{jk}] \in \mathbb{C}^{n\times n}$ we associate the following union of Brualdi sets:

$$\mathcal{B}_A := \bigcup_{(j_1,\ldots,j_\ell)\in\mathcal{Z}(\mathcal{I})} \mathcal{B}\left(a_{j_1j_1}, \ldots, a_{j_\ell j_\ell}; \textstyle\prod_{i=1}^{\ell} R_{j_i}(A)\right), \tag{70}$$

where R_j are as in (68) and $\mathcal{I} := \mathcal{I}_A \cap \mathcal{I}_{\text{off}}$; see (66). Brualdi's theorem states that

$$\sigma(A) \subseteq \mathcal{B}_A \tag{71}$$

provided that each index $j \in \underline{n}$ is contained in some cycle $\gamma \in \mathcal{Z}(\mathcal{I})$. From Corollary 5.7 we obtain the following slight extension of this result.

COROLLARY 7.1. *Let* $A \in \mathbb{C}^{n\times n}$ *and set*

$$\begin{aligned}\sigma_0(A) &:= \{a_{jj}\,;\, j\in\underline{n} \text{ and } \forall \gamma\in\mathcal{Z}(\mathcal{I}) : j\notin\gamma\}\\ &= \{a_{jj}\,;\, j\in\underline{n} \text{ and } (j\in\gamma\in\mathcal{Z}(\mathcal{I}_A)\Rightarrow \gamma=(j))\}.\end{aligned}$$

Then $\sigma_0(A)\subseteq\sigma(A)$ *and* $\sigma(A)\setminus\sigma_0(A)\subseteq\mathcal{B}_A$. *In particular, if* $\sigma_0(A)=\emptyset$, *then* $\sigma(A)\subseteq\mathcal{B}_A$.

Proof. If $A\in\mathbb{C}^{n\times n}$ is a diagonal matrix, then there is nothing to prove. Assume that A is nondiagonal and has off-diagonal row sums $R_j(A)$, $j\in\underline{n}$. Set $\tilde{\Delta}=[\tilde{\Delta}_{jk}]\in\mathbb{C}^{n\times n}$, where

$$\tilde{\Delta}_{jk} := \begin{cases} R_j(A)^{-1}a_{jk} & \text{if } j\neq k \text{ and } R_j(A)\neq 0,\\ 0 & \text{otherwise.}\end{cases}$$

Then $A = A_{\tilde{\Delta}} := \operatorname{diag}(a_{11},\dots,a_{nn}) + \operatorname{diag}(R_1(A),\dots,R_n(A))\,\tilde{\Delta}$, and $\|\tilde{\Delta}\|_1 = 1$. Note that $\|\Delta\|_1 = \|\,|\Delta|\,\|_1$ is a norm of the form (63). Furthermore, we have that $\tilde{\Delta}\in\mathbf{\Delta}_{\mathcal{I}}$, where $\mathcal{I}=\mathcal{I}_A\cap\mathcal{I}_{\text{off}}$. Thus

$$\begin{aligned}\sigma(A)\subseteq &\bigcup_{\Delta\in\mathbf{\Delta}_{\mathcal{I}},\,\|\Delta\|_1\le 1}\sigma(A_\Delta),\\ &\text{where } A_\Delta := \operatorname{diag}(a_{11},\dots,a_{nn}) + \operatorname{diag}(R_1(A),\dots,R_n(A))\,\Delta.\end{aligned}$$

Hence, applying Corollary 5.7 with the norm $\mathcal{N}(\cdot)=\|\cdot\|_1$, $\delta=1$, $b_i=R_i(A)$, and $c_i=1$, $i\in\underline{n}$, we obtain the result: $\sigma_0(A)\subseteq\sigma(A)$ follows from (b) and $\sigma(A)\backslash\sigma_0(A)\subseteq\mathcal{B}_A$ follows from (a). ∎

An equivalent extension of Brualdi's result can be found in [29, Theorem 2.5] (note that the definition of $\mathcal{B}_A$ in [29] is different from ours).

We conclude this paper with a brief discussion of the relationship between the above results of Gershgorin, Brauer, and Brualdi. First note that $\mathcal{B}(z_1;\rho)=\mathcal{D}(z_1;\rho)$ and $\mathcal{B}(z_1,z_2;\rho)=\mathcal{C}(z_1,z_2;\rho)$. The following proposition yields a useful tool for establishing inclusion relations between these sets.

PROPOSITION 7.2. *Let* $z_1,\dots,z_\ell\in\mathbb{C}$ *and* $\rho_1,\dots,\rho_\ell\ge 0$. *Then*

$$\mathcal{B}\left(z_1,\dots,z_\ell;\textstyle\prod_{j\in\underline{\ell}}\rho_j\right)\subseteq\bigcup_{k\in\underline{\ell}}\mathcal{B}\left(z_1,\dots,\widehat{z}_k,\dots,z_\ell;\textstyle\prod_{j\in\underline{\ell},\,j\neq k}\rho_j\right),$$

where $\mathcal{B}\left(z_1,\dots,\widehat{z}_k,\dots,z_\ell;\prod_{j\in\underline{\ell},\,j\neq k}\rho_j\right)=\left\{\, s\in\mathbb{C}\,;\ \prod_{j\in\underline{\ell},\,j\neq k}|s-z_j|\le\prod_{j\in\underline{\ell},j\neq k}\rho_j\,\right\}$.

Proof. Suppose that $s\notin\bigcup_{k\in\underline{\ell}}\mathcal{B}\,(z_1,\dots,\widehat{z}_k,\dots,z_\ell;\prod_{j\in\underline{\ell},\,j\neq k}\,\rho_j)$. Then we have, for all $k\in\underline{\ell}$, $\prod_{j\in\underline{\ell},\,j\neq k}|s-z_j|>\prod_{j\in\underline{\ell},\,j\neq k}\rho_j$. By multiplying these ℓ inequalities we obtain $(\prod_{j\in\underline{\ell}}|s-z_j|\,)^{\ell-1}>(\prod_{j\in\underline{\ell}}\rho_j\,)^{\ell-1}$. Thus $s\notin\mathcal{B}(z_1,\dots,z_\ell;\prod_{j\in\underline{\ell}}\rho_j)$. ∎

By induction we obtain from Proposition 7.2 the following corollary.

COROLLARY 7.3. *Let* $z_1,\dots,z_\ell\in\mathbb{C}$ *and* $\rho_1,\dots,\rho_\ell\ge 0$. *Then*

$$\mathcal{B}\left(z_1,\dots,z_\ell;\textstyle\prod_{j\in\underline{\ell}}\rho_j\right)\subseteq\bigcup_{1\le j<k\le\ell}\mathcal{C}(z_j,z_k;\rho_j\rho_k)\subseteq\bigcup_{j\in\underline{\ell}}\mathcal{D}(z_j;\rho_j).$$

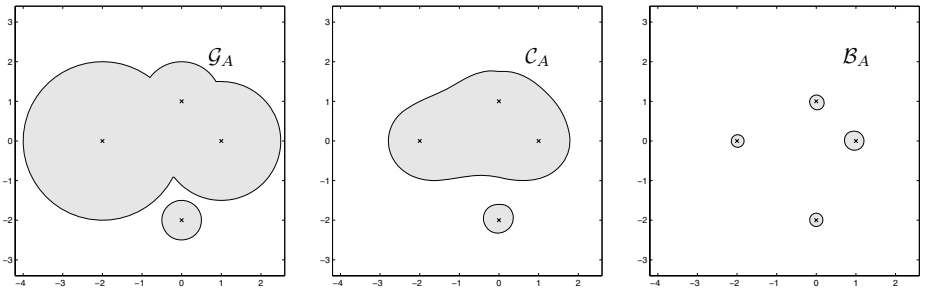

FIG. 6. *Comparison of the regions* $\mathcal{G}_A$, $\mathcal{C}_A$, *and* $\mathcal{B}_A$.

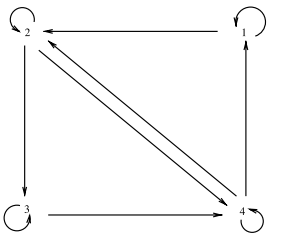
Corollary 7.3 implies that for all $A \in \mathbb{C}^{n\times n}$, $n \geq 2$,

$$\mathcal{B}_A \subseteq \mathcal{C}_A \subseteq \mathcal{G}_A. \tag{72}$$

Thus the theorems of Brauer and Gershgorin are consequences of Corollary 7.1. The first inclusion in (72) has been shown by Varga [28], the second by Brauer [3]. Note that each of the three sets, $\mathcal{B}_A, \mathcal{C}_A, \mathcal{G}_A$, is closed (as a finite union of closed sets).

Example 7.4. Consider the following matrix and the corresponding incidence graph:

$$A = \begin{bmatrix} 1 & 1.5 & 0 & 0 \\ 0 & \imath & 0.5 & -0.5\imath \\ 0 & 0 & -2 & 2 \\ 0.25 & 0.25\imath & 0 & -2\imath \end{bmatrix}$$



The matrix A can be represented as a sum of the diagonal matrix $A_0 = \mathrm{diag}(1, \imath, -2, -2\imath)$ and the off-diagonal perturbation $R_3 \in \mathcal{I}_{\mathrm{off}}$ defined in Example 4.5. Figure 6 illustrates the eigenvalue inclusion regions for A due to Gershgorin, Brauer, and Brualdi.

The crosses mark the diagonal elements of A. Comparing the right-hand figures in Figures 2 and 6, we see that the inclusion provided by Corollary 4.4(a) is somewhat tighter than the estimate provided by Brualdi's theorem; see (71).

The above example should not convey the impression that Brualdi sets are always considerably smaller then the corresponding Brauer sets. In fact, one can easily see that they are equal if all off-diagonal entries of A are nonzero, i.e., $\mathcal{I}_A \supset \mathcal{I}_{\mathrm{off}}$. For more details on this, see [29, section 2.3].

Although the theorems of Gershgorin, Brauer, and Brualdi follow directly from our main results, we emphasize that the problems underlying the inclusion theorems and those underlying our results are quite different. The inclusion theorems consider the matrix $A = D_A + \Delta_A$ as *given* and establish *upper bounds* for $\sigma(A)$ viewing A as the result of a (known) off-diagonal perturbation of D_A. On the contrary, Corollaries 5.7 and 4.4 provide precise formulae for the union of the spectra of *all* the matrices $A_\Delta = D_A + \Delta$ where Δ is an arbitrary complex matrix of norm $\leq \delta$ with the zero

structure determined by $\mathcal{I}$ (resp., an arbitrary complex matrix satisfying $|\Delta| \le R$). In these corollaries the diagonal matrix D_A, the index set $\mathcal{I}$, and the uncertainty level $\delta > 0$ (resp., the diagonal matrix D_A and the nonnegative matrix R) are the only data. It follows from Corollary 6.6 that

(73)
$$\sigma(A) \subseteq \bigcup_{\substack{\Delta \in \mathbf{\Delta}_{\mathcal{I}_{\text{off}}} \\ \|\Delta\|_1 \le 1}} \sigma(D_A + B\Delta) = \left\{ s \in \mathbb{C}; \min_{1 \le j < k \le m} |s - a_{jj}||s - a_{kk}| \le R_j(A) R_k(A) \right\} = \mathcal{C}_A,$$

where $B = \operatorname{diag}(R_1(A), \dots, R_n(A))$; see (69). Under the assumptions of Brualdi's theorem we have

(74)
$$\sigma(A) \subseteq \bigcup_{\substack{\Delta \in \mathbf{\Delta}_{\mathcal{I}} \\ \|\Delta\|_1 \le 1}} \sigma(D_A + B\Delta) = \bigcup_{(j_1, \dots, j_\ell) \in \mathcal{Z}(\mathcal{I})} \mathcal{B}\left(a_{j_1}, \dots, a_{j_\ell}; \textstyle\prod_{i=1}^{\ell} R_i(A) \right) = \mathcal{B}_A,$$

where $\mathcal{I} := \mathcal{I}_A \cap \mathcal{I}_{\text{off}}$; see the proof of Corollary 7.1, (54), and (70). Hence the upper bounds in the inclusion theorems of Brauer and Brualdi, respectively, are *tight* estimates which cannot be improved if we presuppose as the only a priori knowledge the diagonal of A and the off-diagonal row sums $R_j(A)$ (resp., the diagonal of A, the zero pattern of A, and the off-diagonal row sums $R_j(A)$). To make this more precise we note that

$$\{D_A + B\Delta;\ \Delta \in \mathbf{\Delta}_{\mathcal{I}_{\text{off}}} \text{ and } \|\Delta\|_1 \le 1\}$$

is the set of all matrices $\tilde{A} \in \mathbb{C}^{n \times n}$ with the same diagonal as A and with off-diagonal row sums $R_j(\tilde{A}) \le R_j(A)$. By (73) the Brauer set $\mathcal{C}_A$ is exactly the union of the spectra of all these matrices. Similarly,

$$\{D_A + B\Delta;\ \Delta \in \mathbf{\Delta}_{\mathcal{I}} \text{ and } \|\Delta\|_1 \le 1\}$$

is the set of all matrices $\tilde{A} \in \mathbb{C}^{n \times n}$ with the same diagonal as A, with row sums $R_j(\tilde{A}) \le R_j(A)$, and with $\mathcal{I}_{\tilde{A}} \subset \mathcal{I}_A$. Under the assumptions of Brualdi's theorem it follows from (74) that the Brualdi set $\mathcal{B}_A$ is exactly the union of the spectra of all these matrices. A more detailed discussion on the sharpness of the Brualdi inclusion theorem can be found in [29, section 2.4].

Remark 7.5. In the same way as in the proof of Corollary 5.7 one could derive from Corollaries 5.6 and 6.5 inclusion theorems for the eigenvalues of a block matrix. Such results are obtained in [29] by a different approach from ours.

PRACTICAL OUTPUT-FEEDBACK RISK-SENSITIVE CONTROL FOR STOCHASTIC NONLINEAR SYSTEMS WITH STABLE ZERO-DYNAMICS*

YUN-GANG LIU† AND JI-FENG ZHANG‡

Abstract. This paper addresses the design problem of practical (or satisfaction) output-feedback controls for stochastic strict-feedback nonlinear systems in observer canonical form with stable zero-dynamics under long-term average tracking risk-sensitive cost criteria. The cost function adopted here is of the quadratic-integral type usually encountered in practice, rather than the quartic-integral one used to avoid difficulty in control design and performance analysis of the closed-loop system. A sequence of coordinate diffeomorphisms is introduced to separate the zero-dynamics from the entire system, so that the transformed system has an appropriate form suitable for integrator backstepping design. For any given risk-sensitivity parameter and desired cost value, by using the integrator backstepping methodology, an output-feedback control is constructively designed such that (a) the closed-loop system is bounded in probability and (b) the long-term average risk-sensitive cost is upper bounded by the desired value. In addition, this paper does not require the uniform boundedness of the gain functions of the system noise. Furthermore, an example is given to show the effectiveness of the theory.

Key words. nonlinear system, stochastic system, integrator backstepping methodology, risk-sensitive control, output-feedback control, zero dynamics

1. Introduction.

Research on global stabilization control design for nonlinear systems has been accelerated over the last two decades. After the celebrated characterization of the feedback linearizable systems (see [13]), a breakthrough was achieved with the introduction of the integrator backstepping design methodology (see [20]), which provides a general constructive tool for designing global stabilization controls for nonlinear systems in or feedback equivalent to strict-feedback form. Since the early 1990s, a series of research results on strict-feedback systems have been obtained by using this methodology together with other design tools, such as nonlinear damping, tuning functions, and MT filters (see, e.g., [8], [15], [18], [19], [22], [23], [32], [34], and [38]).

The research on risk-sensitive control can be traced back to the early 1970s, when Jacobson introduced the linear exponential quadratic Gaussian (LEQG) problem (see [14]). Then, Whittle put a risk-sensitivity parameter into the cost, and solved the linear discrete-time problem (see [39]). Bensoussan and van Schuppen considered the continuous-time case in their paper [4]. But the significance of the risk-sensitive control was not fully realized until the 1990s. It has been known that risk-sensitive control is more general than H_∞ control and H_2 control, and closely related to differential game problems (see, e.g., [9], [10], [17], [31], [37], and [40]). For example, when

the noise vanishes, the large deviation limit of the risk-sensitive control is nothing but a deterministic differential game problem. These connections have initialized and accelerated the research on stochastic risk-sensitive controls over the last decade.

The design of controls for strict-feedback stochastic nonlinear systems has received intense investigation recently (see, e.g., [1], [5], [6], [7], [11], [26], [27], [28], [29], [33], and [35]), where [7], [11], and [33] considered full state-feedback control design, and [1], [5], [6], [26], [27], [28], [29], and [35] considered output-feedback control design. Under the assumption (A), "the disturbance vector field vanishes at the origin," [5], [7], and [11] studied the problem of designing a control to asymptotically stabilize the closed-loop systems in the large. Meanwhile, [1], [6], [26], [27], [28], [29], [33], and [35] considered the control design to achieve the boundedness in probability of the closed-loop system without using assumption (A). Specifically, [7] considered the disturbance attenuation problem; [35] considered the stabilization problem of systems with stable zero-dynamics; [33], [26], [1], and [29] considered the design of satisfaction control under a quadratic, a quartic regulation, and a quadratic tracking risk-sensitive cost criterion, respectively. [1] used the assumption (B), "the gain functions of stochastic noise are uniformly bounded," while [26], [29], and [33] did not; [27] and [28] considered the reduced-order observer-based stabilization control design of the single-input multioutput stochastic nonlinear systems.

This paper studies the problem of output-feedback control design for a class of stochastic nonlinear systems in observer canonical form with stable zero-dynamics under a quadratic tracking risk-sensitive cost criterion. In general, the design of output-feedback control is more difficult and challenging than that of full state-feedback control. Since the early 1990s, a general framework for studying output-feedback control problems has been developed. The key thought is to first introduce the so-called *information state*, which is a generalization of observer or filter, and then, by a measure transformation, to change the output-feedback control design problem into a full state-feedback problem of an augmented system (see, e.g., [2], [3], [12], [16], and [17]). However, generally speaking, the equality (or inequality) of the information state satisfied is infinite-dimensional, to which an explicit finite-dimensional solution exists only for linear or special nonlinear systems (see [2]). The method of this paper is different from the information state one and can be used to deal with more general inherently nonlinear systems. The objective of this paper is very practical: to search for a *satisfaction* control rather than an optimal one. This makes it possible to avoid the measure transformation. In order to get the explicit formula of the control, strict-feedback nonlinear systems are considered. The main results of this paper indicate that for any given risk-sensitivity parameter and desired tracking risk-sensitive cost value, a dynamic output-feedback control can always be constructively designed so that the closed-loop system is bounded in probability and the long-time average risk-sensitive cost is upper bounded by the desired value. While [1] considered assumption (B) to be essential, the current paper does not use this assumption. In addition, the value range of the characteristic parameter of the value function used for backstepping design is enlarged from $\frac{2}{3}$ (see [26]) to set $(\frac{1}{2}, 1)$. This provides control designers with a freedom in choosing the value function.

The remainder of the paper is organized as follows. Section 2 provides some notation. Section 3 describes the system model and formulates the control objective to be studied. Section 4 describes the constructive design procedure of the control by employing an integrator backstepping approach, and presents several important lemmas for the closed-loop performance analysis. Section 5 addresses the main results

of this paper. Section 6 gives a simulation example to illustrate our theoretical findings. Section 7 gives some concluding remarks. The paper ends with two appendices. Appendix A introduces the definitions of stability notions *asymptotically stable in the large* and *bounded in probability*, and gives a key theorem of sufficient conditions for the solvability of the control problem. Appendix B provides some technical lemmas that play an important role in the control design and performance analysis.

2. Notation. Throughout this paper, $\mathbb{N}$ denotes the set of all natural numbers; $\mathbb{R}$ denotes the set of all real numbers, and $\mathbb{R}^n$ denotes the real n-dimensional space, $n \in \mathbb{N}$; $\mathcal{C}^i$ denotes the set of all functions with continuous partial derivative up to ith order, $i \in \mathbb{N}$, and $\mathcal{C}^\infty$ denotes the set of all smooth functions; for a given vector or matrix W, we use $W^\top$ to denote its transpose; $\mathrm{Tr}(W)$ denotes its trace when W is square, i.e., the sum of all elements on the main diagonal line; we use $|W|$ to denote the absolute value for scalar numbers, and $\|W\|$ to denote the Euclidean norm for vectors and the corresponding induced norm for matrices; we also introduce the Frobenius norm of W defined by $\|W\|_F = \sqrt{\mathrm{Tr}(W^\top W)}$ with properties: $\|W\| \leq \|W\|_F$ and $\|WV\|_F \leq \|W\|\|V\|_F$ for any matrix V with appropriate dimension; for any $x \in \mathbb{R}^n$, x_i denotes its ith element, $x_{[i]}$ denotes the column vector consisting of the first i elements of x in the original order, i.e., $x_{[i]} = [x_1, \ldots, x_i]^\top$; for any given ith continuously differentiable function $y_d(t)$, $y_d^{(i)}(t)$ denotes the ith derivative with respect to the time variable t, the first and second derivatives are denoted by $\dot{y}_d$ and $\ddot{y}_d$, respectively, and $y_d^{[i]}$ denotes the $(i+1)$-dimensional column vector consisting of y_d, $\dot{y}_d, \ldots, y_d^{(i)}$, i.e., $y_d^{[i]} = [y_d, \dot{y}_d, \ddot{y}_d, \ldots, y_d^{(i)}]^\top$. Obviously, $x_{[1]} = x_1$, $x_{[n]} = x$, $y_d^{[0]} = y_d$. $0_{i\times j}$ denotes the $(i \times j)$-dimensional matrix with all zero elements and will be written as 0 for brevity when there is no confusion caused. We use I_i to denote the $i \times i$ identity matrix. For a set A, I_A denotes the characteristic function of the set. For any given symmetric matrix P, $\lambda_{\max}(P)$ and $\lambda_{\min}(P)$ denote its maximum and minimum eigenvalue, respectively.

In addition, when a function shows up for the first time, we will clearly write out its arguments, and then, for simplicity of expression in later use, we sometimes drop the arguments when no confusion is caused.

For a given stochastic system

$$\mathrm{d}x = f(t,x)\,\mathrm{d}t + h(t,x)\,\mathrm{d}w, \quad x(t_0) = x_0,$$

define a differential operator $\mathcal{L}$:

$$\mathcal{L}V(t,\,x) = \frac{\partial V(t,\,x)}{\partial t} + \frac{\partial V(t,\,x)}{\partial x} f(t,\,x) + \frac{1}{2}\mathrm{Tr}\left(\frac{\partial^2 V(t,\,x)}{\partial x^2} h(t,\,x)\,(h(t,\,x))^\top\right),$$

where x is an n-dimensional state vector, $n \in \mathbb{N}$; $f : [0,\ \infty) \times \mathbb{R}^n \to \mathbb{R}^n$ and $h : [0,\ \infty) \times \mathbb{R}^n \to \mathbb{R}^{n\times s}$, $s \in \mathbb{N}$, are assumed to be continuous in t and locally Lipschitz in x; w is an s-dimensional vector-valued Brownian motion defined on a probability space $(\Omega,\ \mathcal{F},\ \mathcal{P})$; and $V : [0, \infty) \times \mathbb{R}^n \to \mathbb{R}$ is $\mathcal{C}^1$ in t and $\mathcal{C}^2$ in x.

3. Problem formulation.

3.1. System model. We consider the stochastic nonlinear systems in observer canonical form with zero-dynamics of the form (see [35]):

$$
\begin{aligned}
\mathrm{d}x_1 &= x_2\,\mathrm{d}t + f_1(y)\,\mathrm{d}t + h_1(y)\,\mathrm{d}w,\\
&\vdots\\
\mathrm{d}x_{\rho-1} &= x_\rho\,\mathrm{d}t + f_{\rho-1}(y)\,\mathrm{d}t + h_{\rho-1}(y)\,\mathrm{d}w,\\
\mathrm{d}x_\rho &= x_{\rho+1}\,\mathrm{d}t + f_\rho(y)\,\mathrm{d}t + b_m g(y)u\,\mathrm{d}t + h_\rho(y)\,\mathrm{d}w,\\
&\vdots\\
\mathrm{d}x_{n-1} &= x_n\,\mathrm{d}t + f_{n-1}(y)\,\mathrm{d}t + b_1 g(y)u\,\mathrm{d}t + h_{n-1}(y)\,\mathrm{d}w,\\
\mathrm{d}x_n &= f_n(y)\,\mathrm{d}t + b_0 g(y)u\,\mathrm{d}t + h_n(y)\,\mathrm{d}w,\\
y &= x_1,
\end{aligned}
\tag{3.1}
$$

where $x = [x_1, \ldots, x_n]^\top$ is the n-dimensional state vector, $n \in \mathbb{N}$, and its initial value $x(t_0) = x_0$ is fixed but unknown; u is the scalar control input; y is the scalar measurable output; $f_i : \mathbb{R} \to \mathbb{R}$, $i = 1, \ldots, n$, are the system nonlinearities depending only on output y; $h_i : \mathbb{R} \to \mathbb{R}^{1\times s}$, $i = 1, \ldots, n$, are the gain functions of the system noise depending only on y, $s \in \mathbb{N}$; $g : \mathbb{R} \to \mathbb{R}$ is the nonlinear gain function of the control input u depending only on y; $w \in \mathbb{R}^s$ is a vector-valued standard Brownian motion defined on probability space $(\Omega, \mathcal{F}, \mathcal{P})$, with Ω being a sample space, $\mathcal{F}$ being a filtration, and $\mathcal{P}$ being the probability measure, $s \in \mathbb{N}$; $m \in \mathbb{N}$ satisfies $0 \le m < n$; and $\rho = n - m \in \mathbb{N}$ is the relative degree of the system.

The main results of this paper are based on the following assumptions:

A1. The nonlinear functions f_i and h_i $(i = 1, \ldots, n)$ are smooth. That is, $f_i \in \mathcal{C}^\infty$ and $h_i \in \mathcal{C}^\infty$; the nonlinear function g is continuous; and, for any $y \in \mathbb{R}$, $g(y) \neq 0$.

A2. All the roots of the polynomial $b_m s^m + \cdots + b_1 s + b_0$, $b_m \neq 0$, have negative real parts.

A3. Desired system output y_d is deterministic, and it and its derivatives $\dot{y}_d, \ldots, y_d^{(\rho)}$ are known and bounded; i.e., there exist known positive constants $C_{y_d^{(i)}}$, $i = 0, \ldots, \rho$, that bound the reference trajectory y_d and its derivatives.

Assumption A1 is standard for this class of control problems, to ensure that f_i and h_i $(i = 1, \ldots, n)$ are local Lipschitz functions and, together with assumption A3, to ensure the global boundedness of $h_i(y_d)$ $(i = 1, \ldots, n)$. Assumption A2 ensures that the zero-dynamics are stable.

Unlike the problem of feedback stabilization, there is no need to require that the origin $x = \mathbf{0}_{n\times 1}$ be the equilibrium point of the open-loop system. This is because the purpose of the tracking control is to make the system output conform to the time-varying desired system output $y_d(t)$, rather than to steer the system state to the origin $x = \mathbf{0}_{n\times 1}$.

3.2. Control objective. The goal of control design is to make the solution process of the system (3.1) be bounded in probability and the following quadratic tracking risk-sensitive cost criterion achieve a predefined long-term cost value:

$$
J_\theta(y) = \limsup_{T\to\infty} \frac{1}{T}\frac{2}{\theta}\ln\left(E\left(\exp\left(\frac{\theta}{2}\int_0^T (y - y_d)^2\,\mathrm{d}t\right)\right)\right). \tag{3.2}
$$

That is, for any given positive cost value R_l (arbitrarily close to zero), the risk-sensitive cost $J_\theta(y)$ is not greater than R_l, where θ is called the risk-sensitivity parameter and $y - y_d$ is called the output tracking error. When $\theta > 0$, the cost function weights

heavily the large deviation of $y - y_d$ through the exponential operator, which leads to a risk-averse control design problem. The greater the value of θ, the more conservative is the controller. Actually, by the value of θ, the risk-sensitive problem can be classified (see [10] and [31]) as follows: (i) when $\theta > 0$, it is a risk-averse problem; (ii) when $\theta < 0$, it is a risk-seeking problem; (iii) when $\theta \to 0$, the cost function converges to a standard integral cost, and so it is known as a risk-neutral problem.

In this paper, we will study only the case where θ is positive.

For convenience of expression, we give the following definition.

DEFINITION 3.1. *For a given positive risk-sensitivity parameter θ, a controller u is said to achieve a guaranteed risk-sensitive cost R_l ($R_l > 0$) if the following inequality holds for the output of the closed-loop system:*

$$J_\theta(y) \le R_l.$$

In addition to the purposes of cost upper bound, we are also interested in achieving *boundedness in probability* for the closed-loop system. This notion, together with the *asymptotical stability in the large*, was introduced in the classical book [21] and has now been widely used. For the sake of the self-containedness of this paper, we will restate these two notions in Appendix A.

The system (3.1) can be rewritten into the following compact form:

$$\mathrm{d}x = f(x)\,\mathrm{d}t + Bg(x)u\,\mathrm{d}t + h(x)\,\mathrm{d}w, \tag{3.3}$$

where

$$f(x) = \begin{bmatrix} x_2 + f_1(x_1) \\ \vdots \\ x_n + f_{n-1}(x_1) \\ f_n(x_1) \end{bmatrix}, \qquad g(x) = g(x_1),$$

$$B = \begin{bmatrix} \mathbf{0}_{(n-m-1)\times 1} \\ b_m \\ \vdots \\ b_0 \end{bmatrix}, \qquad h(x) = \begin{bmatrix} h_1(x_1) \\ h_2(x_1) \\ \vdots \\ h_n(x_1) \end{bmatrix}.$$

If $\rho = 1$, then $m = n - \rho = n - 1$. For this special case, vector B defined above is simply $[b_{n-1}, \ldots, b_1, b_0]^\top$.

For tracking purposes, the controller to be designed is time-varying in general, and so is the resulting closed-loop system, even though the original system is not. Thus, as in [26] and [33], with the long-term average risk-sensitive cost criterion $J_\theta(y)$, for a given desired cost value $R_l > 0$, a practical risk-sensitive output-feedback tracking control is designed as

$$\begin{cases} \dot{\xi} = \alpha\,(t,\, \xi,\, y)\,, & \alpha \in \mathcal{C}^1, \\ u = \mu\,(t,\, \xi,\, y)\,, & \mu \in \mathcal{C}^1, \end{cases} \tag{3.4}$$

so that there exists a nonnegative value function $V(t, x, \xi)$, which is $\mathcal{C}^1$ in t and $\mathcal{C}^2$ in (x, ξ) and radially unbounded with respect to x and ξ, satisfying the following Hamilton–Jacobi–Bellman (HJB) inequality:

$$\begin{aligned} \frac{\partial V}{\partial t} + \begin{bmatrix} \dfrac{\partial V}{\partial x} & \dfrac{\partial V}{\partial \xi} \end{bmatrix} \begin{bmatrix} f + Bg\mu \\ \alpha \end{bmatrix} + \frac{\theta}{4} \frac{\partial V}{\partial x} hh^\top \left(\frac{\partial V}{\partial x} \right)^\top \\ + \frac{1}{2} \mathrm{Tr} \left(\frac{\partial^2 V}{\partial x^2} hh^\top \right) + (y - y_d)^2 \;\le\; R_l. \end{aligned} \tag{3.5}$$

From (3.5), it is easy to see that the essential difference between the stochastic HJB and deterministic HJB equations is that the former has the Itô term $\frac{1}{2}\mathrm{Tr}(\frac{\partial^2 V}{\partial x^2}hh^\top)$. How to deal with this term is the key to the control design and performance analysis.

4. Output-feedback risk-sensitive control design. We shall design the output-feedback tracking controller in three steps. First, we introduce an observer to rebuild the system states. With the observer dynamics in the loop, we introduce a sequence of coordinate diffeomorphisms transforming the system into a lower triangular structure which is amenable to the application of integrator backstepping methodology. Then, we describe the control design procedure and present several lemmas, which will be used for the performance analysis of the closed-loop systems in the next section.

4.1. Observer design. Since the states of (3.1), except for the state x_1 which can be obtained directly since $y = x_1$, are unknown and need an observer to rebuild,

$$\begin{aligned}
\dot{\widehat{x}}_1 &= \widehat{x}_2 + k_1(y - \widehat{x}_1) + f_1(y),\\
&\vdots\\
\dot{\widehat{x}}_{\rho-1} &= \widehat{x}_\rho + k_{\rho-1}(y - \widehat{x}_1) + f_{\rho-1}(y),\\
\dot{\widehat{x}}_\rho &= \widehat{x}_{\rho+1} + k_\rho(y - \widehat{x}_1) + f_\rho(y) + b_m g(y)u,\\
&\vdots\\
\dot{\widehat{x}}_{n-1} &= \widehat{x}_n + k_{n-1}(y - \widehat{x}_1) + f_{n-1}(y) + b_1 g(y)u,\\
\dot{\widehat{x}}_n &= k_n(y - \widehat{x}_1) + f_n(y) + b_0 g(y)u,
\end{aligned} \tag{4.1}$$

where $k_1, k_2, \ldots, k_n$ are design constants such that all the roots of polynomial $s^n + k_1 s^{n-1} + \cdots + k_n$ have negative real parts. The initial condition for observer (4.1) is set by certain value $\widehat{x}(t_0) = \widehat{x}_0$.

Let $\widehat{x} = [\widehat{x}_1, \widehat{x}_2, \ldots, \widehat{x}_n]^\top$. Both system output y and observer state vector $\widehat{x}$ are available for control design. Denote the state estimation error as $\widetilde{x} = x - \widehat{x}$. Then we have

$$\mathrm{d}\widetilde{x} = \begin{bmatrix} -k_1 & & & \\ \vdots & & I_{n-1} & \\ -k_n & 0 & \cdots & 0 \end{bmatrix} \widetilde{x}\,\mathrm{d}t + h(y)\,\mathrm{d}w \triangleq A\widetilde{x}\,\mathrm{d}t + h(y)\,\mathrm{d}w. \tag{4.2}$$

Thus, with observer dynamics (4.1) in the loop, we have the following entire system:

$$\begin{aligned}
\mathrm{d}\widetilde{x} &= A\widetilde{x}\,\mathrm{d}t + h(y)\,\mathrm{d}w,\\
\mathrm{d}y &= (\widehat{x}_2 + \widetilde{x}_2)\,\mathrm{d}t + f_1(y)\,\mathrm{d}t + h_1(y)\,\mathrm{d}w,\\
\dot{\widehat{x}}_2 &= \widehat{x}_3 + k_2(y - \widehat{x}_1) + f_2(y),\\
&\vdots\\
\dot{\widehat{x}}_{\rho-1} &= \widehat{x}_\rho + k_{\rho-1}(y - \widehat{x}_1) + f_{\rho-1}(y),\\
\dot{\widehat{x}}_\rho &= \widehat{x}_{\rho+1} + k_\rho(y - \widehat{x}_1) + f_\rho(y) + b_m g(y)u,\\
&\vdots\\
\dot{\widehat{x}}_{n-1} &= \widehat{x}_n + k_{n-1}(y - \widehat{x}_1) + f_{n-1}(y) + b_1 g(y)u,\\
\dot{\widehat{x}}_n &= k_n(y - \widehat{x}_1) + f_n(y) + b_0 g(y)u.
\end{aligned} \tag{4.3}$$

System (4.3) has three parts, which are associated with the estimation error $\widetilde{x}$, system output y, and observer states $\widehat{x}_2, \ldots, \widehat{x}_\rho$, respectively. In particular, when $\rho = 1$, then $m = n - \rho = n - 1$. For this case, the second subequation of (4.3) shall be replaced by the following equation:

$$\mathrm{d}y = (\widehat{x}_2 + \widetilde{x}_2)\,\mathrm{d}t + f_1(y)\,\mathrm{d}t + b_{n-1}g(y)u\mathrm{d}t + h_1(y)\,\mathrm{d}w.$$

In the next subsections, with this entire system as starting point, we shall search for the desired controller.

4.2. Coordinate diffeomorphisms. To prepare for the backstepping design in the next subsection, we introduce a series of ρ coordinate diffeomorphisms (see [36]) so as to convert the entire system (4.3) into zero-dynamics canonical form, which is amenable to the application of integrator backstepping methodology.

The idea of such coordinate diffeomorphisms was first introduced in [30] and significantly modified in Chapter 8 of [24]. Our presentation, including the two cases of $\rho = 1$ and $\rho > 1$, is much more direct and easier to implement.

4.2.1. Case of $\boldsymbol{\rho = 1}$. When $\rho = 1$, $m = n-\rho = n-1$. This means that control input appears in every subequation of (3.1) and (4.1). In this case, one coordinate transformation is sufficient to obtain the desired structure.

Let $\varsigma_0 = [y, \widehat{x}_2, \ldots, \widehat{x}_n]^\top$. Then, by (4.3), we have the following dynamics for ς_0:

$$\mathrm{d}\varsigma_0 = D_0\varsigma_0\,\mathrm{d}t + G_0(y, \widetilde{x}_1)\,\mathrm{d}t + [1,\, \mathbf{0}_{1\times(n-1)}]^\top \widetilde{x}_2\,\mathrm{d}t + g(y)B_0u\,\mathrm{d}t + H_0(y)\,\mathrm{d}w, \tag{4.4}$$

where

$$\begin{aligned}
D_0 &= \begin{bmatrix} 0 & & \\ \vdots & & I_{n-1} \\ 0 & 0 & \cdots\ 0 \end{bmatrix},\\
G_0 &= [f_1(y),\, f_2(y) + k_2\widetilde{x}_1, \ldots, f_n(y) + k_n\widetilde{x}_1]^\top,\\
B_0 &= [b_{n-1}, \ldots, b_1, b_0]^\top,\\
H_0 &= [(h_1(y))^\top,\, \mathbf{0}_{s\times(n-1)}]^\top.
\end{aligned}$$

By coordinate transformation we would like to transform the vector B_0 into one with all elements being zero except the first element, b_{n-1}. Let $\varsigma_1 = T_1\varsigma_0$, where T_1 is the same as I_n, except with the first column replaced by $[1, -b_{n-2}/b_{n-1}, \ldots, -b_0/b_{n-1}]^\top$. Then, T_1^{-1} is also the same as I_n, except with the first column replaced by $\left[1, \frac{b_{n-2}}{b_{n-1}}, \ldots, \frac{b_0}{b_{n-1}}\right]^\top$.

Then we have

$$\mathrm{d}\varsigma_1 = D_1\varsigma_1\,\mathrm{d}t + G_1(y, \widetilde{x}_1)\,\mathrm{d}t + [1, L_2^\top]^\top \widetilde{x}_2\,\mathrm{d}t + g(y)B_1u\,\mathrm{d}t + H_1(y)\,\mathrm{d}w,$$

where $D_1 = T_1D_0T_1^{-1}$ is the same as D_0, except with the first and second columns replaced by $[d_{11}, \ldots, d_{1,n}]^\top$ and $[1, -b_{n-2}/b_{n-1}, \ldots, -b_0/b_{n-1}]^\top$, respectively:

$$\begin{aligned}
G_1 &= T_1G_0(y, \widetilde{x}_1) \triangleq \left[\overline{g}_{11}(y) + \overline{d}_{11}\widetilde{x}_1, \ldots, \overline{g}_{1n}(y) + \overline{d}_{1n}\widetilde{x}_1\right]^\top,\\
L_2 &= [-b_{n-2}/b_{n-1}, \ldots, -b_1/b_{n-1},\, -b_0/b_{n-1}]^\top,\\
B_1 &= T_1B_0 = [b_{n-1},\, \mathbf{0}_{1\times m}]^\top,\\
H_1 &= T_1H_0(y) \triangleq \left[(\widehat{h}_1(y))^\top, \ldots, (\widehat{h}_n(y))^\top\right]^\top.
\end{aligned}$$

Denote $\eta = \varsigma_1 = [\eta_1, \dots, \eta_n]^\top$ and $\zeta = [\eta_2, \eta_3, \dots, \eta_n]^\top$. Then, the dynamics of $\widetilde{x}$, ζ, and η_1 can be expressed as follows:

$$
\begin{aligned}
\mathrm{d}\widetilde{x} &= A\widetilde{x}\,\mathrm{d}t + h(y)\,\mathrm{d}w,\\
\mathrm{d}\zeta &= \begin{bmatrix} -\frac{b_{n-2}}{b_{n-1}} & & \\ \vdots & & I_{n-2} \\ -\frac{b_1}{b_{n-1}} & & \\ -\frac{b_0}{b_{n-1}} & 0 \quad \cdots & 0 \end{bmatrix} \zeta\,\mathrm{d}t + \begin{bmatrix} d_{12} \\ d_{13} \\ \vdots \\ d_{\rho n} \end{bmatrix} y\,\mathrm{d}t \\
&\quad + \begin{bmatrix} \overline{g}_{12}(y) + \overline{d}_{12}\widetilde{x}_1 \\ \overline{g}_{13}(y) + \overline{d}_{13}\widetilde{x}_1 \\ \vdots \\ \overline{g}_{1n}(y) + \overline{d}_{1n}\widetilde{x}_1 \end{bmatrix} \mathrm{d}t - \frac{1}{b_{n-1}} \begin{bmatrix} b_{n-2} \\ \vdots \\ b_1 \\ b_0 \end{bmatrix} \widetilde{x}_2 \mathrm{d}t + \begin{bmatrix} \widehat{h}_2(y) \\ \widehat{h}_3(y) \\ \vdots \\ \widehat{h}_n(y) \end{bmatrix} \mathrm{d}w \qquad (4.5)\\
&\triangleq E\zeta\,\mathrm{d}t + L_1\widetilde{x}_1\,\mathrm{d}t + L_2\widetilde{x}_2\,\mathrm{d}t + G(y)\,\mathrm{d}t + \Psi(y)\,\mathrm{d}w,\\
\mathrm{d}\eta_1 &= \left[1,\, \mathbf{0}_{1\times(n-2)}\right]\zeta\,\mathrm{d}t + (\overline{g}_{11}(y) + d_{11}y)\,\mathrm{d}t\\
&\quad + \overline{d}_{11}\widetilde{x}_1\,\mathrm{d}t + \widetilde{x}_2\,\mathrm{d}t + b_{n-1}g(y)u\,\mathrm{d}t + \widehat{h}_1(y)\,\mathrm{d}w,
\end{aligned}
$$

where

$$
\begin{aligned}
y &= \eta_1,\\
L_1 &= [\overline{d}_{12},\, \overline{d}_{13}, \dots, \overline{d}_{1n}]^\top,\\
G &= [\overline{g}_{12}(y) + d_{12}y,\, \overline{g}_{13}(y) + d_{13}y, \dots, \overline{g}_{1n}(y) + d_{1n}y]^\top.
\end{aligned}
$$

This system is equivalent to the entire system (4.3) under the transformation $[\eta_1,\, \zeta^\top]^\top = T_1[y, \widehat{x}_2, \dots, \widehat{x}_n]^\top$. The structure of (4.5) makes the design of an output feedback controller much easier (see the latter design procedure for details).

4.2.2. Case of $\rho > 1$. Let us now give the coordinate transformations for the case of $\rho > 1$. From the ρ transformations below one can see that there exist some essential differences between this case and the case of $\rho = 1$.

Let $\overline{g}_{01}(y) = f_1(y)$, $\overline{d}_{0i} = k_i$, and $\overline{g}_{0i}(y) = f_i(y)$ $(i = 2, \dots, n)$. Then we have the following dynamics for $\varsigma_0 = [y, \widehat{x}_2, \dots, \widehat{x}_n]^\top$:

$$
\mathrm{d}\varsigma_0 = D_0\varsigma_0\,\mathrm{d}t + G_0(y, \widetilde{x}_1)\,\mathrm{d}t + [1,\, \mathbf{0}_{1\times(n-1)}]^\top\widetilde{x}_2\,\mathrm{d}t + g(y)B_0u\,\mathrm{d}t + H_0(y)\,\mathrm{d}w,
$$

where matrix D_0 and function H_0 are the same as those of (4.4), and

$$
\begin{aligned}
G_0 &= [f_1(y),\, f_2(y) + k_2\widetilde{x}_1, \dots, f_n(y) + k_n\widetilde{x}_1]^\top\\
&\triangleq [\overline{g}_{01}(y) + \overline{d}_{01}\widetilde{x}_1,\, \overline{g}_{02}(y) + \overline{d}_{02}\widetilde{x}_1, \dots, \overline{g}_{0n}(y) + \overline{d}_{0n}\widetilde{x}_1]^\top\\
&\triangleq [g_{01}(y, \widetilde{x}_1),\, g_{02}(y, \widetilde{x}_1), \dots, g_{0n}(y, \widetilde{x}_1)]^\top,\\
B_0 &= [\mathbf{0}_{1\times(\rho-1)}, b_m, b_{m-1}, \dots, b_0]^\top.
\end{aligned}
$$

By the first transformation, we would like to transform the matrix B_0 into one with all elements being zero except the ρth element, b_m. Let $\varsigma_1 = T_1\varsigma_0$, where T_1 is the same as I_n, except with the ρth column replaced by $\left[\mathbf{0}_{1\times(\rho-1)}, 1, -\frac{b_{m-1}}{b_m}, \dots, -\frac{b_0}{b_m}\right]^\top$.

Then T_1^{-1} is also the same as I_n, except with the ρth column replaced by $\big[\mathbf{0}_{1\times(\rho-1)}, 1, -\frac{b_{m-1}}{b_m}, \ldots, -\frac{b_0}{b_m}\big]^\top$.

Then we have

$$\mathrm{d}\varsigma_1 = D_1\varsigma_1\,\mathrm{d}t + G_1(y,\widetilde{x}_1)\,\mathrm{d}t + \big[1, \mathbf{0}_{1\times(n-1)}\big]^\top \widetilde{x}_2\,\mathrm{d}t + g(y)B_1u\,\mathrm{d}t + H_1(y)\,\mathrm{d}w,$$

where $D_1 = T_1D_0T_1^{-1}$ is the same as D_0 except with the ρth and $(\rho+1)$st columns replaced by $[\mathbf{0}_{1\times(\rho-2)}, 1, d_{11}, \ldots, d_{1,m+1}]^\top$ and $[\mathbf{0}_{1\times(\rho-1)}, 1, -b_{m-1}/b_m, \ldots, -b_0/b_m]^\top$, respectively,

$$\begin{aligned}
G_1 &= T_1G_0(y,\widetilde{x}_1)\\
&\triangleq [\overline{g}_{11}(y) + \overline{d}_{11}\widetilde{x}_1, \ldots, \overline{g}_{1n}(y) + \overline{d}_{1n}\widetilde{x}_1]^\top\\
&\triangleq [g_{11}(y,\widetilde{x}_1), \ldots, g_{1n}(y,\widetilde{x}_1)]^\top,\\
B_1 &= T_1B_0 = [\mathbf{0}_{1\times(\rho-1)},\, b_m,\, \mathbf{0}_{1\times m}]^\top,\\
H_1 &= T_1H_0(y) = H_0(y).
\end{aligned}$$

By the ith $(i = 2, \ldots, \rho-1)$ transformation, we would like to transform the $(\rho-i+2)$nd column of the matrix D_{i-1} into the $(\rho-i+1)$st unit vector. Let $\varsigma_i = T_i\varsigma_{i-1}$, where T_i is the same as I_n except with the $(\rho-i+1)$st column replaced by $[\mathbf{0}_{1\times(\rho-i)}, 1, -d_{i-1,1}, \ldots, -d_{i-1,m+i-1}]^\top$. Then, T_i^{-1} is also the same as I_n except with the $(\rho-i+1)$st column replaced by $[\mathbf{0}_{1\times(\rho-i)}, 1, d_{i-1,1}, \ldots, d_{i-1,m+i-1}]^\top$.

This leads to

$$\mathrm{d}\varsigma_i = D_i\varsigma_i\,\mathrm{d}t + G_i(y,\widetilde{x}_1)\,\mathrm{d}t + [1, \mathbf{0}_{1\times(n-1)}]^\top\widetilde{x}_2\,\mathrm{d}t + g(y)B_iu\,\mathrm{d}t + H_i(y)\,\mathrm{d}w,$$

where $D_i = T_iD_{i-1}T_i^{-1}$ is the same as D_0 except with the $(\rho-i+1)$st and $(\rho+1)$st columns replaced by $[\mathbf{0}_{1\times(\rho-i-1)}, 1, d_{i1}, \ldots, d_{i,i+m}]^\top$ and $[\mathbf{0}_{1\times(\rho-1)}, 1, -b_{m-1}/b_m, \ldots, -b_0/b_m]^\top$, respectively,

$$\begin{aligned}
G_i &= T_iG_{i-1}(y,\widetilde{x}_1)\\
&\triangleq [\overline{g}_{i1}(y) + \overline{d}_{i1}\widetilde{x}_1, \ldots, \overline{g}_{in}(y) + \overline{d}_{in}\widetilde{x}_1]^\top\\
&\triangleq [g_{i1}(y,\widetilde{x}_1), \ldots, g_{in}(y,\widetilde{x}_1)]^\top,\\
B_i &= T_iB_{i-1} = B_1 = [\mathbf{0}_{1\times(\rho-1)},\, b_m,\, \mathbf{0}_{1\times m}]^\top,\\
H_i &= T_iH_{i-1}(y) = H_0(y).
\end{aligned}$$

Finally, by the last transformation, we would like to transform the second column of the matrix $D_{\rho-1}$ into the first unit vector. Let $\varsigma_\rho = T_\rho\varsigma_{\rho-1}$, where T_ρ is the same as I_n except with the first column replaced by $[1, -d_{\rho-1,1}, \ldots, -d_{\rho-1,n-1}]^\top$. Then, T_ρ^{-1} is also the same as I_n except with the first column replaced by $[1, d_{\rho-1,1}, \ldots, d_{\rho-1,n-1}]^\top$.

This leads to

$$\begin{aligned}
\mathrm{d}\varsigma_\rho = {} & D_\rho\varsigma_\rho\,\mathrm{d}t + G_\rho(y,\widetilde{x}_1)\,\mathrm{d}t + [1, -d_{\rho-1,1}, \ldots, -d_{\rho-1,n-1}]^\top\widetilde{x}_2\,\mathrm{d}t\\
& + g(y)B_\rho u\,\mathrm{d}t + H_\rho(y)\,\mathrm{d}w,
\end{aligned}$$

where $D_\rho = T_\rho D_{\rho-1} T_\rho^{-1}$ is the same as D_0 except with the first and $(\rho+1)$st column replaced by $[d_{\rho 1}, \dots, d_{\rho n}]^\top$ and $[\mathbf{0}_{1\times(\rho-1)}, 1, -b_{m-1}/b_m, \dots, -b_0/b_m]^\top$, respectively,

$$\begin{aligned}
G_\rho &= T_\rho G_{\rho-1}(y, \widetilde{x}_1) \\
&\triangleq \left[\overline{g}_{\rho 1}(y) + \overline{d}_{\rho 1}\widetilde{x}_1, \dots, \overline{g}_{\rho n}(y) + \overline{d}_{\rho n}\widetilde{x}_1\right]^\top \\
&\triangleq \left[g_{\rho 1}(y, \widetilde{x}_1), \dots, g_{\rho n}(y, \widetilde{x}_1)\right]^\top, \\
B_\rho &= T_\rho B_{\rho-1} = B_1, \\
H_\rho &= T_\rho H_{\rho-1} = T_\rho H_0 \triangleq \left[(\widehat{h}_1(y))^\top, \dots, (\widehat{h}_n(y))^\top\right]^\top.
\end{aligned}$$

Denote $\eta = \varsigma_\rho = [\eta_1, \dots, \eta_n]^\top$ and $\zeta = [\eta_{\rho+1}, \dots, \eta_n]^\top$. Then $\eta_1 = y$, and the dynamics of estimation error, the zero-dynamics of ζ, and the lower triangular form for the dynamics of $\eta_1, \dots, \eta_\rho$ can be expressed as follows:

$$\begin{aligned}
\mathrm{d}\widetilde{x} &= A\widetilde{x}\,\mathrm{d}t + h(y)\,\mathrm{d}w, \\
\mathrm{d}\zeta &= \begin{bmatrix} -\frac{b_{m-1}}{b_m} & & \\ \vdots & & I_{m-1} \\ -\frac{b_1}{b_m} & & \\ -\frac{b_0}{b_m} & 0 \quad \cdots \quad 0 & \end{bmatrix} \zeta\,\mathrm{d}t + \begin{bmatrix} d_{\rho,\rho+1} \\ \vdots \\ d_{\rho n} \end{bmatrix} y\,\mathrm{d}t \\
&\quad + \begin{bmatrix} -d_{\rho-1,\rho} \\ \vdots \\ -d_{\rho-1,n-1} \end{bmatrix} \widetilde{x}_2\,\mathrm{d}t + \begin{bmatrix} g_{\rho,\rho+1}(y, \widetilde{x}_1) \\ \vdots \\ g_{\rho n}(y, \widetilde{x}_1) \end{bmatrix} \mathrm{d}t + \begin{bmatrix} \widehat{h}_{\rho+1}(y) \\ \vdots \\ \widehat{h}_n(y) \end{bmatrix} \mathrm{d}w \qquad (4.6) \\
&\triangleq E\zeta\,\mathrm{d}t + L_1\widetilde{x}_1\,\mathrm{d}t + L_2\widetilde{x}_2\,\mathrm{d}t + G(y)\,\mathrm{d}t + \Psi(y)\,\mathrm{d}w, \\
\mathrm{d}\eta_1 &= d_{\rho 1} y\,\mathrm{d}t + (\eta_2 + \widetilde{x}_2)\,\mathrm{d}t + g_{\rho 1}(y, \widetilde{x}_1)\,\mathrm{d}t + \widehat{h}_1(y)\,\mathrm{d}w, \\
\mathrm{d}\eta_2 &= [d_{\rho 2} y + \eta_3 + g_{\rho 2}(y, \widetilde{x}_1) - d_{\rho-1,1}\widetilde{x}_2]\,\mathrm{d}t + \widehat{h}_2(y)\,\mathrm{d}w, \\
&\vdots \\
\mathrm{d}\eta_{\rho-1} &= [d_{\rho,\rho-1} y + \eta_\rho + g_{\rho,\rho-1}(y, \widetilde{x}_1) - d_{\rho-1,\rho-2}\widetilde{x}_2]\,\mathrm{d}t + \widehat{h}_{\rho-1}(y)\,\mathrm{d}w, \\
\mathrm{d}\eta_\rho &= \left[1, \mathbf{0}_{1\times(m-1)}\right]\zeta\,\mathrm{d}t + d_{\rho\rho} y\,\mathrm{d}t + g_{\rho\rho}(y, \widetilde{x}_1)\,\mathrm{d}t \\
&\quad + b_m g(y) u\,\mathrm{d}t - d_{\rho-1,\rho-1}\widetilde{x}_2\,\mathrm{d}t + \widehat{h}_\rho(y)\,\mathrm{d}w,
\end{aligned}$$

where

$$\begin{aligned}
y &= \eta_1, \\
L_1 &= [\overline{d}_{\rho,\rho+1}, \dots, \overline{d}_{\rho n}]^\top, \\
G &= [\overline{g}_{\rho,\rho+1}(y) + d_{\rho,\rho+1} y, \dots, \overline{g}_{\rho,n}(y) + d_{\rho n} y]^\top.
\end{aligned}$$

This system is equivalent to the entire system (4.3) under the transformation $[\eta_1, \dots, \eta_\rho, \zeta^\top]^\top = T_\rho \cdots T_1 [y, \widehat{x}_2, \dots, \widehat{x}_n]^\top$. The structure of (4.6) allows the design of an output feedback controller by using integrator backstepping methodology.

4.3. Control design procedure. We now start to design the desired controller with the estimation error $\widetilde{x}$ and the zero-dynamics ζ (given by (4.5) for the case of

$\rho = 1$ and (4.6) for the case of $\rho > 1$). To do so, let $\chi = [\zeta^\top,\ \widetilde{x}^\top]^\top \in \mathbb{R}^{n+m}$. Then for both $\rho = 1$ and $\rho > 1$ we have

$$\begin{aligned} \mathrm{d}\chi &= \begin{bmatrix} E & L \\ \mathbf{0}_{n\times m} & A \end{bmatrix} \chi\,\mathrm{d}t + \begin{bmatrix} G(y) \\ \mathbf{0}_{n\times 1} \end{bmatrix} \mathrm{d}t + \begin{bmatrix} \Psi(y) \\ h(y) \end{bmatrix} \mathrm{d}w \\ &\triangleq W\chi\,\mathrm{d}t + F(y)\,\mathrm{d}t + \Phi(y)\,\mathrm{d}w, \end{aligned} \tag{4.7}$$

where $L = [L_1,\ L_2,\ \mathbf{0}_{m\times(n-2)}]$, and F and Φ are $\mathcal{C}^\infty$.

For the objective of a tight controller, the dynamics χ would be partitioned as $\chi = [\chi_a^\top,\ \chi_b^\top]^\top$, where $\chi_a = [\zeta^\top,\ \widetilde{x}_1]^\top \in \mathbb{R}^{m+1}$ is available for feedback design, while $\chi_b = [\widetilde{x}_2, \ldots, \widetilde{x}_n]^\top \in \mathbb{R}^{n-1}$ is not. Furthermore, χ_a and χ_b satisfy the following stochastic differential equations, respectively:

$$\begin{aligned} \mathrm{d}\chi_a &= \begin{bmatrix} E & L_1 \\ \mathbf{0}_{1\times m} & -k_1 \end{bmatrix} \chi_a\,\mathrm{d}t + \begin{bmatrix} L_2 & \mathbf{0}_{m\times(n-2)} \\ 1 & \mathbf{0}_{1\times(n-2)} \end{bmatrix} \chi_b\,\mathrm{d}t \\ &\quad + \begin{bmatrix} G(y) \\ 0 \end{bmatrix} \mathrm{d}t + \begin{bmatrix} \Psi(y) \\ h_1(y) \end{bmatrix} \mathrm{d}w \\ &\triangleq W_a\chi_a\,\mathrm{d}t + L_a\chi_b\,\mathrm{d}t + F_a(y)\,\mathrm{d}t + \Phi_a(y)\,\mathrm{d}w, \end{aligned} \tag{4.8a}$$

$$\begin{aligned} \mathrm{d}\chi_b &= \begin{bmatrix} 0 & & \\ \vdots & I_{n-2} & \\ 0 & 0 \cdots & 0 \end{bmatrix} \chi_b\,\mathrm{d}t + \begin{bmatrix} 0 & \cdots & 0 & -k_2 \\ \vdots & \ddots & \vdots & \vdots \\ 0 & \cdots & 0 & -k_n \end{bmatrix} \chi_a\,\mathrm{d}t \\ &\quad + \begin{bmatrix} h_2(y) \\ \vdots \\ h_n(y) \end{bmatrix} \mathrm{d}w \\ &\triangleq W_b\chi_b\,\mathrm{d}t + L_b\chi_a\,\mathrm{d}t + \Phi_b(y)\,\mathrm{d}w, \end{aligned} \tag{4.8b}$$

where F_a, Φ_a, and Φ_b are $\mathcal{C}^\infty$.

Remark 4.1. From subsection 4.2 we know that E, G, L, and Ψ in (4.7)–(4.8) are differently defined with respect to $\rho = 1$ and $\rho > 1$, respectively, and so are W, W_a, W_b, F, F_a, F_b, L_a, L_b, and Φ_a. Thus, for the sake of the unambiguousness, these two cases will be separately handled below.

We are now in a position to develop a recursive construction procedure for the desired risk-sensitive controller.

4.3.1. Initial assignment. First, we present the initial assignment for the entire design procedure.

By assumption A2, we know that matrix E is Hurwitz. This, together with the Hurwitz property of matrix A, implies that W is also Hurwitz. Therefore, there exists a symmetric and positive definite matrix P such that

$$W^\top P + PW = -I_{n+m}. \tag{4.9}$$

We introduce a value function (or *Lyapunov* function) for the χ system:

$$V_0(\chi) = \phi(\xi(\chi)) = \delta(c + \xi(\chi))^\gamma - \delta c^\gamma, \quad \xi = \chi^\top P\chi, \tag{4.10}$$

where $0 < \delta \le 1$, $c > 0$, $\frac{1}{2} < \gamma < 1$. Design constants c and δ will be specified later. Constant γ is pregiven and called the *characteristic parameter* of value function V_0. Clearly, $V_0(\chi)$ is positive definite and radially unbounded, and it vanishes at the origin $\chi = \mathbf{0}_{(n+m)\times 1}$.

Remark 4.2. Risk-sensitive control is much different from stochastic stabilization, and thus the methods developed by [5], [6], and [35] are not suitable for our control objective. Therefore, here we introduce a subquadratic function V_0 characterized by γ (see (4.10)), by which a method suitable for output-feedback risk-sensitive control design is developed.

Let $z_1 = y - y_d$ be the tracking error. Then, by assumptions A1 and A3, there exist a vector-valued smooth function $\overline{F}(y_d, z_1)$ and a matrix-valued smooth function $\overline{\Phi}(y_d, z_1)$ such that

$$F(y) = F(z_1 + y_d) = F(y_d) + z_1\overline{F}(y_d, z_1), \tag{4.11a}$$

$$\Phi(y) = \Phi(z_1 + y_d) = \Phi(y_d) + z_1\overline{\Phi}(y_d, z_1). \tag{4.11b}$$

LEMMA 4.1. *There exist a smooth vector-valued function $\sigma_0(\chi, y)$, a smooth function $N_0(y_d, \chi_a, z_1)$, and smooth $r_0(y_d)$, $C_0(y_d)$ such that*

$$\mathrm{d}V_0 \le \sigma_0\,\mathrm{d}w - \frac{\theta}{4}\sigma_0\sigma_0^\top\,\mathrm{d}t - \frac{r_0\,\|\chi\|^2}{(c+\chi^\top P\chi)^{1-\gamma}}\,\mathrm{d}t + N_0 z_1\,\mathrm{d}t + C_0\,\mathrm{d}t. \tag{4.12}$$

Proof. By (4.7) and the Itô formula we have

$$\begin{aligned}\mathrm{d}V_0 = {}& -\frac{\partial\phi}{\partial\xi}\|\chi\|^2\,\mathrm{d}t + \sigma_0(y,\chi)\,\mathrm{d}w - \frac{\theta}{4}\sigma_0\sigma_0^\top\,\mathrm{d}t + \frac{\theta}{4}\sigma_0\sigma_0^\top\,\mathrm{d}t \\ & + 2\frac{\partial\phi}{\partial\xi}\chi^\top PF(y)\,\mathrm{d}t + \frac{1}{2}\mathrm{Tr}\left(\frac{\partial^2 V_0}{\partial\chi^2}\Phi(y)(\Phi(y))^\top\right)\mathrm{d}t,\end{aligned} \tag{4.13}$$

where $\sigma_0 = \frac{\partial V_0}{\partial\chi}\Phi$ is a row vector-valued function. In the above equality, we have used the technique of subtracting from and adding term $\frac{\theta}{4}\sigma_0\sigma_0^\top\,\mathrm{d}t$ to its right-hand side. Notice that $\frac{\partial V_0}{\partial\chi} = \frac{\partial\phi}{\partial\xi}\cdot\frac{\partial\xi}{\partial\chi}$ and $\frac{\partial\phi}{\partial\xi} = \frac{\delta\gamma}{(c+\xi)^{1-\gamma}}$. Then we have

$$\sigma_0 = \frac{\partial\phi}{\partial\xi}\cdot\frac{\partial\xi}{\partial\chi}\Phi = \frac{2\delta\gamma}{(c+\xi)^{1-\gamma}}\chi^\top P\Phi(y). \tag{4.14}$$

Let $\xi_a = \chi_a^\top(P_1 - P_2P_3^{-1}P_2^\top)\chi_a$, where $P = \begin{bmatrix} P_1 & P_2 \\ P_2^\top & P_3\end{bmatrix}$, $P_1 \in \mathbb{R}^{(m+1)\times(m+1)}$, $P_2 \in \mathbb{R}^{(m+1)\times(n-1)}$, $P_3 \in \mathbb{R}^{(n-1)\times(n-1)}$. Clearly, since P is positive definite, so is $P_1 - P_2P_3^{-1}P_2^\top$. Then ξ_a is available for feedback design and satisfies $0 \le \xi_a \le \xi$. For the first term of the second line on the right-hand side of (4.13), by using (4.11a), we have

$$\begin{aligned}2\frac{\partial\phi}{\partial\xi}\chi^\top PF(y) &= 2\frac{\partial\phi}{\partial\xi}\chi^\top P(F(y_d) + \overline{F}(y_d, z_1)z_1) \\ &= \frac{2\delta\gamma\chi^\top PF(y_d)}{(c+\xi)^{1-\gamma}} + \frac{2\delta\gamma\chi^\top P\overline{F}(y_d, z_1)}{(c+\xi)^{1-\gamma}}z_1 \\ &\le \frac{\delta\gamma\varepsilon_{01}^2\|\chi\|^2}{(c+\xi)^{1-\gamma}} + \frac{\delta\gamma\|PF(y_d)\|^2}{\varepsilon_{01}^2(c+\xi)^{1-\gamma}} + \frac{\delta\gamma\|P\overline{F}(y_d, z_1)\|^2}{\varepsilon_{02}^2(c+\xi)^{1-\gamma}}z_1^2 + \frac{\delta\gamma\varepsilon_{02}^2\|\chi\|^2}{(c+\xi)^{1-\gamma}} \\ &\le \frac{\delta\gamma(\varepsilon_{01}^2+\varepsilon_{02}^2)\|\chi\|^2}{(c+\chi^\top P\chi)^{1-\gamma}} + \frac{\delta\gamma\|PF(y_d)\|^2}{\varepsilon_{01}^2 c^{1-\gamma}} + \frac{\delta\gamma\|P\overline{F}(y_d, z_1)\|^2}{\varepsilon_{02}^2(c+\xi_a)^{1-\gamma}}z_1^2.\end{aligned} \tag{4.15}$$

Here and hereafter, ε_{01}, ε_{02}, ε_{03}, and ε_{04} are positive design constants to be determined later.

For the term $\frac{\theta}{4}\sigma_0\sigma_0^\top\,\mathrm{d}t$ on the right-hand side of (4.13), by (4.11b) we have

$$
\begin{aligned}
\frac{\theta}{4}\sigma_0\sigma_0^\top &= \frac{\theta\delta^2\gamma^2\chi^\top P\Phi(y)(\Phi(y))^\top P\chi}{(c+\chi^\top P\chi)^{2-2\gamma}}\\
&= \frac{\theta\delta^2\gamma^2\chi^\top P\left(\Phi(y_d)+z_1\overline{\Phi}(y_d,\,z_1)\right)\cdot\left(\Phi(y_d)+z_1\overline{\Phi}(y_d,\,z_1)\right)^\top P\chi}{(c+\chi^\top P\chi)^{2-2\gamma}}\\
&= \frac{\theta\delta^2\gamma^2\chi^\top P\Phi(y_d)(\Phi(y_d))^\top P\chi}{(c+\chi^\top P\chi)^{2-2\gamma}}\\
&\quad+\frac{\theta\delta^2\gamma^2\left[\chi_a^\top,\,\chi_b^\top\right]P\left(2\Phi(y_d)+z_1\overline{\Phi}(y_d,\,z_1)\right)(\overline{\Phi}(y_d,\,z_1))^\top P[\chi_a^\top,\,\chi_b^\top]^\top}{(c+\chi^\top P\chi)^{2-2\gamma}}z_1 \qquad (4.16)\\
&= \frac{\theta\delta^2\gamma^2\chi^\top P\Phi(y_d)(\Phi(y_d))^\top P\chi}{(c+\chi^\top P\chi)^{2-2\gamma}}\\
&\quad+\frac{\theta\delta^2\gamma^2\left[\chi_a^\top,\,\mathbf{0}_{1\times(n-1)}\right]P\overline{\Phi}(y_d,\,z_1)(\overline{\Phi}(y_d,\,z_1))^\top P\left[\chi_a^\top,\,\mathbf{0}_{1\times(n-1)}\right]^\top}{(c+\chi^\top P\chi)^{2-2\gamma}}z_1^2\\
&\quad+\frac{\theta\delta^2\gamma^2\chi^\top P\left(2\Phi(y_d)+z_1\overline{\Phi}(y_d,\,z_1)\right)(\overline{\Phi}(y_d,\,z_1))^\top P\left[\mathbf{0}_{1\times(m+1)},\,\chi_b^\top\right]^\top}{(c+\chi^\top P\chi)^{2-2\gamma}}z_1\\
&\quad+\frac{2\theta\delta^2\gamma^2\chi^\top P\Phi(y_d)(\overline{\Phi}(y_d,\,z_1))^\top P\left[\chi_a^\top,\,\mathbf{0}_{1\times(n-1)}\right]^\top}{(c+\chi^\top P\chi)^{2-2\gamma}}z_1\\
&\quad+\frac{\theta\delta^2\gamma^2\left[\chi_a^\top,\,\mathbf{0}_{1\times(n-1)}\right]P\overline{\Phi}(y_d,\,z_1)(\overline{\Phi}(y_d,\,z_1))^\top P[\mathbf{0}_{1\times(m+1)},\,\chi_b^\top]^\top}{(c+\chi^\top P\chi)^{2-2\gamma}}z_1^2\\
&\le \frac{\theta\delta^2\gamma^2\|P\Phi(y_d)\|_F^2}{c^{1-\gamma}}\frac{\|\chi\|^2}{(c+\chi^\top P\chi)^{1-\gamma}}\\
&\quad+\frac{\theta\delta^2\gamma^2\left[\chi_a^\top,\,\mathbf{0}_{1\times(n-1)}\right]P\overline{\Phi}(y_d,\,z_1)(\overline{\Phi}(y_d,\,z_1))^\top P\left[\chi_a^\top,\,\mathbf{0}_{1\times(n-1)}\right]^\top}{(c+\xi_a)^{2-2\gamma}}z_1^2\\
&\quad+\frac{\theta\delta^2\gamma^2\|P\|^2\left\|\left(2\Phi(y_d)+z_1\overline{\Phi}(y_d,\,z_1)\right)(\overline{\Phi}(y_d,\,z_1))^\top\right\|_F^p}{p\varepsilon_{03}^p(c+\xi_a)^{p-\gamma(p+1)}}z_1^p\\
&\quad+\frac{(p-1)\theta\delta^2\gamma^2\|P\|^2\varepsilon_{03}^{\frac{p}{p-1}}}{p\lambda_{\min}^{\frac{1}{p-1}}(P)}\frac{\|\chi\|^2}{(c+\chi^\top P\chi)^{1-\gamma}}\\
&\quad+\frac{\theta\delta^2\gamma^2\|P\|^4}{\varepsilon_{04}^2(c+\xi_a)^{3-3\gamma}}\|\chi_a\|^2\left(\|\Phi(y_d)\|_F^2+\frac{z_1^2}{2}\|\overline{\Phi}(y_d,\,z_1)\|_F^2\right)\|\overline{\Phi}(y_d,\,z_1)\|_F^2z_1^2\\
&\quad+\frac{3\theta\delta^2\gamma^2\varepsilon_{04}^2\|\chi\|^2}{2(c+\chi^\top P\chi)^{1-\gamma}},
\end{aligned}
$$

where p is a positive even integer (that is, it takes values in set $\{2,4,6,8,\ldots\}$) and satisfies the inequality $p\ge\frac{\gamma}{1-\gamma}$ (or $\gamma\le\frac{p}{p+1}$). Let $q=\frac{p}{p-1}$. Then, p and q satisfy $\frac{1}{p}+\frac{1}{q}=1$. In the inequality (4.16), we have used the Young's inequality

$$
x^\top y\le\frac{\varepsilon^pW^p(x,\,y)}{p}\|x\|^p+\frac{1}{q\varepsilon^qW^q(x,\,y)}\|y\|^q\qquad\forall\,x,y\in\mathbb{R}^n,\,\varepsilon>0,\,W(x,\,y)>0,
$$

to get

$$\begin{aligned}
&\frac{\theta\delta^2\gamma^2\chi^\top P\left(2\Phi(y_d)+z_1\overline{\Phi}(y_d,\,z_1)\right)(\overline{\Phi}(y_d,\,z_1))^\top P[\mathbf{0}_{1\times(m+1)},\,\chi_b^\top]^\top}{(c+\chi^\top P\chi)^{2-2\gamma}}z_1\\
&\le\frac{\theta\delta^2\gamma^2\|P\|^2W^p(\chi)\left\|\left(2\Phi(y_d)+z_1\overline{\Phi}(y_d,\,z_1)\right)(\overline{\Phi}(y_d,\,z_1))^\top\right\|^p}{p\varepsilon_{03}^p(c+\xi)^{2p(1-\gamma)}}z_1^p\\
&\quad+\frac{\theta\delta^2\gamma^2\|P\|^2\varepsilon_{03}^q\|\chi\|^{2q}}{qW^q(\chi)}\\
&\le\frac{\theta\delta^2\gamma^2\|P\|^2\left\|\left(2\Phi(y_d)+z_1\overline{\Phi}(y_d,\,z_1)\right)(\overline{\Phi}(y_d,\,z_1))^\top\right\|_F^p}{p\varepsilon_{03}^p(c+\xi_a)^{p-\gamma(p+1)}}z_1^p\\
&\quad+\frac{(p-1)\theta\delta^2\gamma^2\|P\|^2\varepsilon_{03}^{\frac{p}{p-1}}}{p\lambda_{\min}^{\frac{1}{p-1}}(P)}\frac{\|\chi\|^2}{(c+\chi^\top P\chi)^{1-\gamma}},
\end{aligned}$$

with $W(\chi)=(c+\xi)^{1+\frac{\gamma}{p}-\gamma}$, and

$$\begin{aligned}
&\frac{2\theta\delta^2\gamma^2\chi^\top P\Phi(y_d)(\overline{\Phi}(y_d,\,z_1))^\top P\left[\chi_a^\top,\,\mathbf{0}_{1\times(n-1)}\right]^\top}{(c+\chi^\top P\chi)^{2-2\gamma}}z_1\\
&\le\frac{\theta\delta^2\gamma^2\left(\frac{1}{\varepsilon_{04}^2(W(\chi))^2}\left\|P\Phi(y_d)(\overline{\Phi}(y_d,z_1))^\top P[\chi_a^\top,\mathbf{0}_{1\times(n-1)}]^\top\right\|^2z_1^2+\varepsilon_{04}^2(W(\chi))^2\|\chi\|^2\right)}{(c+\chi^\top P\chi)^{2-2\gamma}}\\
&\le\frac{\theta\delta^2\gamma^2\|P\|^4}{\varepsilon_{04}^2(c+\xi_a)^{3-3\gamma}}\|\chi_a\|^2\left\|\Phi(y_d)\right\|_F^2\left\|\overline{\Phi}(y_d,\,z_1)\right\|_F^2z_1^2+\frac{\theta\delta^2\gamma^2\varepsilon_{04}^2\|\chi\|^2}{(c+\chi^\top P\chi)^{1-\gamma}},
\end{aligned}$$

$$\begin{aligned}
&\frac{\theta\delta^2\gamma^2[\chi_a^\top,\,\mathbf{0}_{1\times(n-1)}]P\overline{\Phi}(y_d,\,z_1)(\overline{\Phi}(y_d,\,z_1))^\top P[\mathbf{0}_{1\times(m+1)},\,\chi_b^\top]^\top}{(c+\chi^\top P\chi)^{2-2\gamma}}z_1^2\\
&\le\frac{\theta\delta^2\gamma^2\left(\frac{1}{\varepsilon_{04}^2W^2(\chi)}\left\|[\chi_a^\top,\mathbf{0}_{1\times(n-1)}]P\overline{\Phi}(y_d,z_1)(\overline{\Phi}(y_d,z_1))^\top P\right\|^2z_1^4+\varepsilon_{04}^2W^2(\chi)\|\chi_b\|^2\right)}{2(c+\chi^\top P\chi)^{2-2\gamma}}\\
&\le\frac{\theta\delta^2\gamma^2\|P\|^4}{2\varepsilon_{04}^2(c+\xi_a)^{3-3\gamma}}\|\chi_a\|^2\left\|\overline{\Phi}(y_d,\,z_1)\right\|_F^4z_1^4+\frac{\theta\delta^2\gamma^2\varepsilon_{04}^2\|\chi\|^2}{2(c+\chi^\top P\chi)^{1-\gamma}},
\end{aligned}$$

with $W(\chi)=(c+\xi)^{\frac{1}{2}-\frac{1}{2}\gamma}$.

For the last term on the right-hand side of (4.13), by (4.11b), we have

$$\begin{aligned}
&\frac{1}{2}\mathrm{Tr}\left(\frac{\partial^2V_0}{\partial\chi^2}\Phi\Phi^\top\right)\\
&=\mathrm{Tr}\left(\left(\frac{\delta\gamma P}{(c+\chi^\top P\chi)^{1-\gamma}}-\frac{2\delta\gamma(1-\gamma)P\chi\chi^\top P}{(c+\chi^\top P\chi)^{2-\gamma}}\right)\Phi\Phi^\top\right)\\
&\le\frac{2\delta\gamma}{c^{1-\gamma}}\mathrm{Tr}\left((\Phi(y_d))^\top P\Phi(y_d)\right)+\frac{2\delta\gamma\mathrm{Tr}\left((\overline{\Phi}(y_d,\,z_1))^\top P\overline{\Phi}(y_d,\,z_1)\right)}{(c+\xi_a)^{1-\gamma}}z_1^2.
\end{aligned}\tag{4.17}$$

Substituting (4.15), (4.16), and (4.17) into (4.13), we get (4.12) with

$$r_0 = \delta\gamma(1-\varepsilon_{01}^2-\varepsilon_{02}^2) - \theta\delta^2\gamma^2\left(\frac{3}{2}\varepsilon_{04}^2 + \frac{\|P\Phi(y_d)\|_F^2}{c^{1-\gamma}} + \frac{(p-1)\varepsilon_{03}^{\frac{p}{p-1}}\|P\|^2}{p\lambda_{\min}^{\frac{1}{p-1}}(P)}\right), \tag{4.18}$$

$$\begin{aligned}
N_0 = {} & \frac{\delta\gamma\left\|P\overline{F}(y_d,\, z_1)\right\|^2}{\varepsilon_{02}^2(c+\xi_a)^{1-\gamma}}z_1 \\
& + \frac{\theta\delta^2\gamma^2\left[\chi_a^\top,\, \mathbf{0}_{1\times(n-1)}\right]P\overline{\Phi}(y_d,\, z_1)(\overline{\Phi}(y_d,\, z_1))^\top P\left[\chi_a^\top,\, \mathbf{0}_{1\times(n-1)}\right]^\top}{(c+\xi_a)^{2-2\gamma}}z_1 \\
& + \frac{\theta\delta^2\gamma^2\|P\|^2\left\|\left(2\Phi(y_d)+z_1\overline{\Phi}(y_d,\, z_1)\right)(\overline{\Phi}(y_d,\, z_1))^\top\right\|_F^p}{p\varepsilon_{03}^p(c+\xi_a)^{p-\gamma(p+1)}}z_1^{p-1} \\
& + \frac{\theta\delta^2\gamma^2\|P\|^4}{\varepsilon_{04}^2(c+\xi_a)^{3-3\gamma}}\|\chi_a\|^2\left(\|\Phi(y_d)\|_F^2 + \frac{z_1^2}{2}\|\overline{\Phi}(y_d,\, z_1)\|_F^2\right)\|\overline{\Phi}(y_d,\, z_1)\|_F^2 z_1 \\
& + \frac{2\delta\gamma\mathrm{Tr}\left((\overline{\Phi}(y_d,\, z_1))^\top P\overline{\Phi}(y_d,\, z_1)\right)}{(c+\xi_a)^{1-\gamma}}z_1,
\end{aligned}$$

$$C_0 = \frac{\delta\gamma}{c^{1-\gamma}}\left(\frac{\|PF(y_d)\|^2}{\varepsilon_{01}^2} + 2\mathrm{Tr}\left(P\Phi(y_d)(\Phi(y_d))^\top\right)\right). \tag{4.19}$$

□

The control design procedure will be presented for the two cases of $\rho = 1$ and $\rho > 1$ separately in subsections 4.3.2 and 4.3.3 below.

4.3.2. Control design for the case of $\rho = 1$. Let us now present the control design for the system (3.1) with $\rho = 1$. From (4.5) and (4.7) we obtain the following overall systems:

$$\mathrm{d}\chi = W\chi\,\mathrm{d}t + F(y)\,\mathrm{d}t + \Phi(y)\,\mathrm{d}w, \tag{4.20a}$$

$$\mathrm{d}\eta_1 = b_{n-1}g(y)u\,\mathrm{d}t + d_1\chi_b\,\mathrm{d}t + g_1(y,\, \chi_a)\,\mathrm{d}t + \widehat{h}_1(y)\,\mathrm{d}w, \tag{4.20b}$$

where

$$\begin{aligned}
& y = \eta_1, \\
& d_1 = [1,\ \mathbf{0}_{1\times(n-2)}], \\
& g_1 = \overline{g}_{11}(y) + \overline{d}_{11}[\mathbf{0}_{1\times(n-1)},\ 1]\chi_a + d_{11}y + \left[1,\ \mathbf{0}_{1\times(n-1)}\right]\chi_a.
\end{aligned}$$

It is easy to check that g_1 and $\widehat{h}_1$ are $\mathcal{C}^\infty$.

Let $\alpha_1 = b_{n-1}g(y)u$, $S_1 = d_1$, $F(y_d^{[1]},\, \chi_1,\, \eta_1) = g_1(y,\, \chi_a) - \dot{y}_d$, and $\Psi_1(y) = \widehat{h}_1(y)$. Then, by (4.20), we have the dynamics of tracking error $z_1 = \eta_1 - y_d$:

$$\mathrm{d}z_1 = (\alpha_1 + S_1\chi_b + F_1)\,\mathrm{d}t + \Psi_1\,\mathrm{d}w. \tag{4.21}$$

Let $V_1 = V_0 + \Xi_1(y_d)z_1^2$, where V_0 is defined by (4.10) and Ξ_1 is to be specified later.

Then, by (4.12) and (4.21), we have

(4.22)

$$\begin{aligned}
\mathrm{d}V_1 &= \mathrm{d}V_0 + 2z_1\Xi_1(\alpha_1 + F_1 + S_1\chi_b)\,\mathrm{d}t + \frac{\partial \Xi_1}{\partial t}z_1^2\,\mathrm{d}t + \Xi_1\Psi_1\Psi_1^\top\,\mathrm{d}t + 2\Xi_1\Psi_1 z_1\,\mathrm{d}w \\
&\le \sigma_1(y_d,\,\chi,\,z_1)\,\mathrm{d}w - \frac{\theta}{4}\sigma_1\sigma_1^\top\,\mathrm{d}t - \beta_1\Xi_1 z_1^2\,\mathrm{d}t + \beta_1\Xi_1 z_1^2\,\mathrm{d}t - r_0(y_d)\frac{\|\chi\|^2}{(c+\xi)^{1-\gamma}}\,\mathrm{d}t \\
&\quad + 2z_1\Xi_1(y_d)(\alpha_1 + F_1)\,\mathrm{d}t + \frac{\partial \Xi_1}{\partial t}z_1^2\,\mathrm{d}t + N_0(y_d,\,\chi_a,\,z_1)z_1\,\mathrm{d}t \\
&\quad + \frac{\theta}{4}\sigma_1\sigma_1^\top\,\mathrm{d}t - \frac{\theta}{4}\sigma_0\sigma_0^\top\,\mathrm{d}t + M_1\chi_b z_1\,\mathrm{d}t + \Xi_1\Psi_1\Psi_1^\top\,\mathrm{d}t + C_0(y_d)\,\mathrm{d}t,
\end{aligned}$$

where $M_1 = 2\Xi_1 S_1$, $\sigma_1 = \sigma_0 + 2\Xi_1\Psi_1 z_1$. In the above inequality, we have used the technique of subtracting from and adding to its right-hand side the terms $\frac{\theta}{4}\sigma_1\sigma_1^\top\,\mathrm{d}t$ and $\beta_1\Xi_1 z_1^2\,\mathrm{d}t$. Here and hereafter, $\beta_1,\,\beta_1,\ldots,\beta_\rho$ are positive design constants to be determined.

Since $\sigma_0 = \frac{\partial V_0}{\partial \chi}\Phi(y)$ is unavailable for feedback design, so is the term $\frac{\theta}{4}\sigma_1\sigma_1^\top\,\mathrm{d}t - \frac{\theta}{4}\sigma_0\sigma_0^\top\,\mathrm{d}t$ on the right-hand side of (4.22). Therefore, we give the following estimate:

(4.23)

$$\begin{aligned}
\frac{\theta}{4}(\sigma_1\sigma_1^\top - \sigma_0\sigma_0^\top) &= \theta\Xi_1\sigma_0\Psi_1^\top z_1 + \theta\Xi_1^2\Psi_1\Psi_1^\top z_1^2 \\
&= \theta\Xi_1^2\Psi_1\Psi_1^\top z_1^2 + \theta\varepsilon_{11}^2\left\|\left(\frac{\partial V_0}{\partial \chi}\right)^\top\right\|^2 \\
&\quad + \frac{\theta}{4\varepsilon_{11}^2}\Xi_1^2\Psi_1\Phi^\top\Phi\Psi_1^\top z_1^2 - \theta\varepsilon_{11}^2\left\|\left(\frac{\partial V_0}{\partial \chi}\right)^\top - \frac{\Xi_1}{2\varepsilon_{11}^2}\Phi\Psi_1^\top z_1\right\|^2 \\
&\le -\theta\varepsilon_{11}^2\left\|\left(\frac{\partial V_0}{\partial \chi}\right)^\top - \frac{\Xi_1}{2\varepsilon_{11}^2}\Phi\Psi_1^\top z_1\right\|^2 + \frac{4\theta\delta^2\gamma^2\varepsilon_{11}^2\|P\|^2}{c^{1-\gamma}} \\
&\quad \cdot \frac{\|\chi\|^2}{(c+\chi^\top P\chi)^{1-\gamma}} + \theta\Xi_1^2\left(\Psi_1\Psi_1^\top + \frac{1}{4\varepsilon_{11}^2}\Psi_1\Phi^\top\Phi\Psi_1^\top\right)z_1^2,
\end{aligned}$$

where (and whereafter) ε_{11} and ε_1 are positive design constants to be specified.

Define

$$\Delta_{11}(y_d,\chi,z_1) = \theta\varepsilon_{11}^2\left\|\left(\frac{\partial V_0}{\partial \chi}\right)^\top - \frac{\Xi_1}{2\varepsilon_{11}^2}\Phi\Psi_1^\top z_1\right\|^2, \tag{4.24a}$$

$$\Delta_{12}(y_d,\chi,z_1) = \frac{\varepsilon_1^{\frac{p_1}{p_1-1}}(p_1-1)}{p_1}\|\chi_b\|^{\frac{p_1}{p_1-1}} + \frac{\|M_1^\top\|^{p_1}}{p_1\varepsilon_1^{p_1}}z_1^{p_1} - M_1\chi_b z_1. \tag{4.24b}$$

Clearly, $\Delta_{11} \ge 0$. Thus also, by Young's inequality, it is easy to see that $\Delta_{12} \ge 0$.

If p_1 takes values in set $\{4,\,6,\,8,\,10,\ldots\}$ and satisfies $p_1 \ge \frac{2\gamma}{2\gamma-1}$, then we can give an upper bound for "$M_1\chi_b z_1$":

$$M_1\chi_b z_1 = -\Delta_{12} + \frac{\varepsilon_1^{\frac{p_1}{p_1-1}}(p_1-1)}{p_1}\|\chi_b\|^{\frac{p_1}{p_1-1}} + \frac{\|M_1^\top\|^{p_1}}{p_1\varepsilon_1^{p_1}}z_1^{p_1} \tag{4.25}$$
$$\le -\Delta_{12} + \frac{\varepsilon_1^{\frac{p_1}{p_1-1}}(p_1-1)}{p_1}\lambda_{\max}^{1-\gamma}(P)\left(\mathcal{M}_\gamma(c) + \frac{\|\chi\|^2}{(c+\chi^\top P\chi)^{1-\gamma}}\right)$$
$$+ \frac{\varepsilon_1^{\frac{p_1}{p_1-1}}(p_1-1)}{p_1}\mathcal{K}\left(\frac{p_1}{p_1-1}, 2\gamma\right) + \frac{\|M_1^\top\|^{p_1}}{p_1\varepsilon_1^{p_1}}z_1^{p_1},$$

where $\mathcal{K}(a_1, a_2)$ is defined in Lemma B.3.

Since there exist smooth functions $\overline{\Psi}_1(y_d, z_1)$ and $\overline{\Psi}_{11}(y_d, z_1)$ satisfying

$$\Psi_1 = \overline{\Psi}_1(y_d, z_1) = \overline{\Psi}_1(y_d) + z_1\overline{\Psi}_{11}(y_d, z_1),$$

for the fourth term of the last line on the right-hand side of (4.22) we have

$$\Xi_1\Psi_1\Psi_1^\top = \Xi_1\|(\overline{\Psi}_1(y_d) + z_1\overline{\Psi}_{11}(y_d, z_1))^\top\|^2 \tag{4.26}$$
$$\le 2\Xi_1\|(\overline{\Psi}_1(y_d))^\top\|^2 + 2\Xi_1\|(\overline{\Psi}_{11}(y_d, z_1))^\top\|^2 z_1^2.$$

Choose

$$\Xi_1 = \frac{\kappa_1}{1 + \|(\overline{\Psi}_1(y_d))^\top\|^2}, \tag{4.27}$$

where (and whereafter) $\kappa_1, \kappa_2, \ldots, \kappa_\rho$ are positive design constants to be determined.

Thus, by substituting (4.23), (4.25), (4.26), and (4.27) into (4.22), and via some straightforward calculations, we get

$$\mathrm{d}V_1 \le -z_1^2\,\mathrm{d}t + \sigma_1\,\mathrm{d}w - \frac{\theta}{4}\sigma_1\sigma_1^\top\,\mathrm{d}t - \frac{r_1(y_d)\|\chi\|^2}{(c+\chi^\top P\chi)^{1-\gamma}}\,\mathrm{d}t \tag{4.28}$$
$$- \Xi_1\beta_1 z_1^2\,\mathrm{d}t + 2z_1\Xi_1\left(\alpha_1 - \overline{\alpha}_1(y_d^{[1]}, \chi_a, \eta_1)\right)\mathrm{d}t$$
$$- \Delta_1(y_d, \chi, z_1)\,\mathrm{d}t + 2\Xi_1 z_1 z_2\,\mathrm{d}t + C_1(y_d^{[1]})\,\mathrm{d}t,$$

where

$$r_1 = r_0(y_d) - \frac{4\theta\delta^2\gamma^2\varepsilon_{11}^2\|P\|^2}{c^{1-\gamma}} - \frac{\varepsilon_1^{\frac{p_1}{p_1-1}}(p_1-1)}{p_1}\lambda_{\max}^{1-\gamma}(P), \tag{4.29}$$

$$N_1 = F_1 + \frac{\beta_1 z_1}{2} + \frac{z_1}{2\Xi_1}\frac{\partial\Xi_1}{\partial y_d}\dot{y}_d + \frac{\|M_1^\top\|^{p_1}}{2p_1\Xi_1\varepsilon_1^{p_1}}z_1^{p_1-1} \tag{4.30}$$
$$+ \theta\Xi_1\left(\frac{\Psi_1\Psi_1^\top}{2} + \frac{\Psi_1\Phi^\top\Phi\Psi_1^\top}{8\varepsilon_{11}^2}\right)z_1 + \|(\overline{\Psi}_{11}(y_d, z_1))^\top\|^2 z_1,$$

$$\overline{\alpha}_1 = \left\{-N_1 - \frac{z_1}{2\Xi_1} - \frac{N_0}{2\Xi_1}\right\}\Big|_{z_1=\eta_1-y_d}, \tag{4.31}$$

$$\Delta_1 = \Delta_{11} + \Delta_{12}, \quad \text{with } \Delta_{11} \text{ and } \Delta_{12} \text{ being defined by (4.24)},$$

$$C_1 = C_0(y_d) + \frac{\varepsilon_1^{\frac{p_1}{p_1-1}}(p_1-1)}{p_1}\lambda_{\max}^{1-\gamma}(P)\mathcal{M}_\gamma(c) + 2\Xi_1\|(\overline{\Psi}_1(y_d))^\top\|^2 \tag{4.32}$$
$$+ \frac{\varepsilon_1^{\frac{p_1}{p_1-1}}(p_1-1)}{p_1}\mathcal{K}\left(\frac{p_1}{p_1-1}, 2\gamma\right).$$

It is easy to check that C_1, r_1, and $\overline{\alpha}_1$ are $\mathcal{C}^\infty$.

Thus, we can choose the function $\alpha_1(y_d^{[1]}, \chi_a, \eta_1)$ in the following form:

$$\alpha_1 = \overline{\alpha}_1(y_d^{[1]}, \chi_a, \eta_1). \tag{4.33}$$

From this and the definition of α_1, i.e., $\alpha_1 = b_{n-1}g(y)u$, we immediately obtain the following risk-sensitive controller:

$$u = \frac{\alpha_1}{b_{n-1}g(y)} = \frac{1}{b_{n-1}g(y)}\,\overline{\alpha}_1(y_d^{[1]}, \chi_a, \eta_1). \tag{4.34}$$

Then, by (4.28) and (4.33), we have

$$\begin{aligned} \mathrm{d}V_1 \le {} & -z_1^2\,\mathrm{d}t + \sigma_1\,\mathrm{d}w - \frac{\theta}{4}\sigma_1\sigma_1^\top\,\mathrm{d}t - \frac{r_1(y_d)\|\chi\|^2}{(c+\chi^\top P\chi)^{1-\gamma}}\,\mathrm{d}t \\ & - \Xi_1\beta_1 z_1^2\,\mathrm{d}t - \Delta_1(y_d, \chi, z_1)\,\mathrm{d}t + C_1(y_d^{[1]})\,\mathrm{d}t. \end{aligned} \tag{4.35}$$

4.3.3. Control design for the case of $\rho > 1$. This subsection investigates the control design for the system (3.1) with $\rho > 1$. From the procedure addressed below, we know that the control design for this case is more complicated than that for the case of $\rho = 1$ given in subsection 4.3.2.

First, from (4.6) and (4.7) we obtain the following overall systems amenable for integrator backstepping design:

$$\begin{aligned} \mathrm{d}\chi &= W\chi\,\mathrm{d}t + F(y)\,\mathrm{d}t + \Phi(y)\,\mathrm{d}w, \\ \mathrm{d}\eta_1 &= \eta_2\,\mathrm{d}t + d_1\chi_b\,\mathrm{d}t + g_1(y, \chi_a)\,\mathrm{d}t + \widehat{h}_1(y)\,\mathrm{d}w, \\ \mathrm{d}\eta_2 &= \eta_3\,\mathrm{d}t + d_2\chi_b\,\mathrm{d}t + g_2(y, \chi_a)\,\mathrm{d}t + \widehat{h}_2(y)\,\mathrm{d}w, \\ &\vdots \\ \mathrm{d}\eta_{\rho-1} &= \eta_\rho\,\mathrm{d}t + d_{\rho-1}\chi_b\,\mathrm{d}t + g_{\rho-1}(y, \chi_a)\,\mathrm{d}t + \widehat{h}_{\rho-1}(y)\,\mathrm{d}w, \\ \mathrm{d}\eta_\rho &= b_m g(y)u\,\mathrm{d}t + d_\rho\chi_b\,\mathrm{d}t + g_\rho(y, \chi_a)\,\mathrm{d}t + \widehat{h}_\rho(y)\,\mathrm{d}w, \end{aligned} \tag{4.36}$$

where

$$\begin{aligned} & y = \eta_1, \\ & d_1 = [1, \mathbf{0}_{1\times(n-2)}], \quad d_i = [-d_{\rho-1,i-1}, \mathbf{0}_{1\times(n-2)}],\ i = 2, \dots, \rho, \\ & g_i = g_{\rho i}\,(y, [\mathbf{0}_{1\times m}, 1]\chi_a) + d_{\rho i}y, \quad i = 1, \dots, \rho-1, \\ & g_\rho = g_{\rho\rho}\,(y, [\mathbf{0}_{1\times m}, 1]\chi_a) + d_{\rho\rho}y + [1, \mathbf{0}_{1\times m}]\,\chi_a. \end{aligned}$$

It is easy to check that g_i, $\widehat{h}_i$, $i = 1, \dots, \rho$, are $\mathcal{C}^\infty$.

Below is the backstepping design procedure, which involves ρ steps in all.

Step 1. Define variable $z_2 = \eta_2 - \alpha_1(y_d^{[1]}, \chi_a, \eta_1)$ and value function $V_1 = V_0 + \Xi_1(y_d)z_1^2$ for this step, where α_1 is a smooth function known as a virtual control law and Ξ_1 is a positive and smooth function. Both α_1 and Ξ_1 will be specified in this step.

From (4.36) it follows that

$$\mathrm{d}z_1 = (z_2 + \alpha_1 + F_1(y_d^{[1]}, \chi_a, \eta_1))\,\mathrm{d}t + S_1\chi_b\,\mathrm{d}t + \Psi_1(\eta_1)\,\mathrm{d}w, \tag{4.37}$$

where $F_1 = g_1(y, \chi_a) - \dot{y}_d$, $S_1 = d_1$, $\Psi_1 = \widehat{h}_1(y)$.

Clearly, (4.37) has the same structure as that of (4.21). Then, as in the case of $\rho = 1$, the virtual controller α_1 can be given by (4.33), which is such that

$$\begin{aligned}(4.38)\qquad \mathrm{d}V_1 \le{}& -z_1^2\,\mathrm{d}t + \sigma_1(y_d,\,\chi,\,z_1)\,\mathrm{d}w - \frac{\theta}{4}\sigma_1\sigma_1^{\top}\,\mathrm{d}t - \frac{r_1(y_d)\|\chi\|^2}{(c+\chi^{\top}P\chi)^{1-\gamma}}\,\mathrm{d}t\\ &- \Xi_1\beta_1 z_1^2\,\mathrm{d}t - \Delta_1(y_d,\,\chi,\,z_1)\,\mathrm{d}t + 2\Xi_1 z_1 z_2\,\mathrm{d}t + C_1(y_d^{[1]})\,\mathrm{d}t,\end{aligned}$$

where σ_1, r_1, Ξ_1, Δ_1, C_1 are defined as in the case of $\rho = 1$.

This completes *Step* 1.

Step i ($i = 2, \ldots, \rho-1$). Suppose that from step 1 through to step $i-1$ we have obtained $z_j = \eta_j - \alpha_{j-1}(y_d^{[j-1]}, \chi_a, \eta_{[j-1]})$, $j = 1, \ldots, i$, and value function

$$V_{i-1} = V_0 + \sum_{j=1}^{i-1}\Xi_j(y_d^{[j-1]},\,\chi_a,\,z_{[j-1]})z_j^2$$

satisfying

$$\begin{aligned}(4.39)\qquad \mathrm{d}V_{i-1} \le{}& -z_1^2\,\mathrm{d}t + \sigma_{i-1}(y_d^{[i-2]},\,\chi,\,z_{[i-1]})\,\mathrm{d}w - \frac{\theta}{4}\sigma_{i-1}\sigma_{i-1}^{\top}\,\mathrm{d}t\\ &- r_{i-1}(y_d)\frac{\|\chi\|^2}{(c+\chi^{\top}P\chi)^{1-\gamma}}\,\mathrm{d}t - \Delta_{i-1}(y_d^{[i-2]},\,\chi,\,z_{[i-1]})\,\mathrm{d}t\\ &- \sum_{j=1}^{i-1}\Xi_j\left(\beta_j - 2\sum_{m=j+1}^{i-1}(m-1)\,\kappa_m\right)z_j^2\,\mathrm{d}t\\ &+ 2\Xi_{i-1}z_{i-1}z_i\,\mathrm{d}t + C_{i-1}(y_d^{[i-1]},\,\chi_a,\,z_{[i-1]})\,\mathrm{d}t,\end{aligned}$$

where

$$\begin{aligned}\mathrm{d}z_1 &= (z_2 + \alpha_1 + F_1(y_d^{[1]},\,\chi_a,\,\eta_1))\mathrm{d}t + S_1\chi_b\mathrm{d}t + \Psi_1(\eta_1)\mathrm{d}w,\\ \mathrm{d}z_j &= (z_{j+1} + \alpha_j + F_j(y_d^{[j]},\,\chi_a,\,\eta_{[j]}))\mathrm{d}t + S_j(y_d^{[j-1]},\,\chi_a,\,\eta_{[j-1]})\chi_b\mathrm{d}t\\ &\quad + \Psi_j(y_d^{[j-1]},\,\chi_a,\,\eta_{[j-1]})\mathrm{d}w,\quad j = 2,\,3,\ldots,i-1,\\ \sigma_{i-1} &= \sigma_0 + \sum_{j=1}^{i-1}\left(2\Xi_j z_j\Psi_j + z_j^2\frac{\partial\Xi_j}{\partial\chi_a}\Phi_a + z_j^2\sum_{k=1}^{j-1}\frac{\partial\Xi_j}{\partial z_k}\Psi_k\right),\end{aligned}$$

$$(4.40)\qquad r_{i-1} = r_1(y_d),$$

$$(4.41)\qquad C_{i-1} = C_1(y_d^{[1]}) + \sum_{j=2}^{i-1}2\Xi_j\|(\overline{\Psi}_j(y_d^{[j-1]},\,\chi_a,\,\mathbf{0}_{(j-1)\times 1}))^{\top}\|^2,$$

and $\Delta_{i-1} = \Delta_{i-1,1}(y_d^{[i-2]},\,\chi,\,z_{[i-1]}) + \Delta_{i-1,2}(y_d^{[i-2]},\,\chi_b,\,z_{[i-1]})$. Here $\Delta_{i-1,1}$ and $\Delta_{i-1,2}$ are given as follows:

$$\begin{aligned}\Gamma_j(y_d^{[j-1]},\,\chi_a,\,z_{[j]}) &= \Psi_j + \frac{z_j}{2\Xi_j}\frac{\partial\Xi_j}{\partial\chi_a}\Phi_a + \frac{z_j}{2\Xi_j}\sum_{k=1}^{j-1}\frac{\partial\Xi_j}{\partial z_k}\Psi_k,\quad j = 1,\ldots,i-1,\\ \Delta_{i-1,1} &= \theta\varepsilon_{11}^2\left\|\left(\frac{\partial V_0}{\partial\chi}\right)^{\top} - \frac{1}{2\varepsilon_{11}^2}\sum_{j=1}^{i-1}\Xi_j\Phi\Gamma_j^{\top}z_j\right\|^2,\\ M_k(y_d^{[k-1]},\,\chi_a,\,z_{[k]}) &= 2\Xi_k S_k + z_k\sum_{j=1}^{k-1}\frac{\partial\Xi_k}{\partial z_j}S_j + z_k\frac{\partial\Xi_k}{\partial\chi_a}L_a,\quad 1\le k\le i-1,\end{aligned}$$

$$(4.42)\qquad \Delta_{i-1,2} = \frac{\varepsilon_1^{\frac{p_1}{p_1-1}}(p_1-1)}{p_1}\|\chi_b\|^{\frac{p_1}{p_1-1}} + \frac{\left\|\sum_{k=1}^{i-1}M_k^{\top}z_k\right\|^{p_1}}{p_1\varepsilon_1^{p_1}} - \left(\sum_{k=1}^{i-1}M_k z_k\right)\chi_b.$$

It should be noted that Ξ_i, F_j, S_j, Γ_j, Ψ_j, M_j, $j = 1, \ldots, i-1$, α_j, $\overline{\alpha}_j$, $i = 0, 1, \ldots, i-1$, σ_{i-1}, r_{i-1}, C_{i-1} are $\mathcal{C}^\infty$. By Young's inequality, it is easy to see that $\Delta_{i-1,\,2} \geq 0$.

Let $\varrho_{i-1}(y_d^{[i-2]}, \chi_a, z_{[i-2]},\, z_{i-1}) = \frac{1}{p_1 \varepsilon_1^{p_1}} \| \sum_{k=1}^{i-2} M_k^\top z_k + M_{i-1}^\top z_{i-1} \|^{p_1}$. Then

$$\begin{aligned}\Upsilon_{i-1}(y_d^{[i-2]}, \chi_a, z_{[i-1]}) &\triangleq \frac{1}{p_1 \varepsilon_1^{p_1}} \left(\left\| \sum_{k=1}^{i-2} M_k^\top z_k + M_{i-1}^\top z_{i-1} \right\|^{p_1} - \left\| \sum_{k=1}^{i-2} M_k^\top z_k \right\|^{p_1} \right) \\ &= \varrho_{i-1}(y_d^{[i-2]}, \chi_a, z_{[i-2]}, z_{i-1}) - \varrho_{i-1}(y_d^{[i-2]}, \chi_a, z_{[i-2]}, 0).\end{aligned}$$

Thus, by using the identity (see [25])

$$f(X) - f(0) = \left(\int_0^1 \left. \frac{\partial f(s)}{\partial s} \right|_{s=\beta X} d\beta \right) X,$$

we have

$$\Upsilon_{i-1} = z_{i-1} \overline{\Upsilon}_{i-1}(y_d^{[i-2]}, \chi_a, z_{[i-1]}), \tag{4.43}$$

where

$$\overline{\Upsilon}_{i-1} = \int_0^1 \left. \frac{\partial \varrho_{i-1}(\cdot,\, s)}{\partial s} \right|_{s=\alpha z_{i-1}} d\alpha.$$

Let $z_{i+1} = \eta_{i+1} - \alpha_i(y_d^{[i]}, \chi_a, \eta_{[i]})$, where α_i is a $\mathcal{C}^\infty$ function to be defined later. Then we have

$$\begin{aligned}\mathrm{d}z_i = {} & (z_{i+1} + \alpha_i + F_i(y_d^{[i]},\, \chi_a,\, \eta_{[i]}))\, \mathrm{d}t \\ & + S_i(y_d^{[i-1]},\, \chi_a,\, \eta_{[i-1]})\chi_b\, \mathrm{d}t + \Psi_i(y_d^{[i-1]},\, \chi_a,\, \eta_{[i-1]})\, \mathrm{d}w,\end{aligned} \tag{4.44}$$

where

$$\begin{aligned}F_i = {} & g_i(y,\, \chi_a) - \sum_{j=1}^{i-1} \frac{\partial \alpha_{i-1}}{\partial \eta_j} (\eta_{j+1} + g_j(y,\, \chi_a)) - \frac{\partial \alpha_{i-1}}{\partial \chi_a} (W_a \chi_a + F_a(y)) \\ & - \sum_{j=0}^{i-1} \frac{\partial \alpha_{i-1}}{\partial y_d^{(j)}} y_d^{(j+1)} - \frac{1}{2} \mathrm{Tr} \left(\frac{\partial^2 \alpha_{i-1}}{\partial ([\chi_a^\top,\, \eta_{[i-1]}^\top]^\top)^2} \begin{bmatrix} \Phi_a \\ \widehat{h}_1 \\ \vdots \\ \widehat{h}_{i-1} \end{bmatrix} \begin{bmatrix} \Phi_a \\ \widehat{h}_1 \\ \vdots \\ \widehat{h}_{i-1} \end{bmatrix}^\top \right), \\ S_i = {} & d_i - \sum_{j=1}^{i-1} \frac{\partial \alpha_{i-1}}{\partial \eta_j} d_j - \frac{\partial \alpha_{i-1}}{\partial \chi_a} L_a, \\ \Psi_i = {} & \widehat{h}_i(y) - \sum_{j=1}^{i-1} \frac{\partial \alpha_{i-1}}{\partial \eta_j} \widehat{h}_j(y) - \frac{\partial \alpha_{i-1}}{\partial \chi_a} \Phi_a(y)\end{aligned}$$

all are smooth functions.

Now we introduce the value function for this step as follows:

$$V_i = V_{i-1} + \Xi_i(y_d^{[i-1]},\, \chi_a,\, z_{[i-1]})z_i^2, \tag{4.45}$$

where Ξ_i is a positive smooth weighting function to be determined below in this step. By (4.39) and (4.44), we have

$$\begin{aligned}
\mathrm{d}V_i &= \mathrm{d}V_{i-1} + 2z_i\Xi_i(z_{i+1} + \alpha_i + F_i + S_i\chi_b)\,\mathrm{d}t + z_i^2\sum_{j=0}^{i-1}\frac{\partial\Xi_i}{\partial y_d^{(j)}}y_d^{(j+1)}\,\mathrm{d}t \\
&\quad + z_i^2\left(\frac{\partial\Xi_i}{\partial\chi_a}(W_a\chi_a + F_a + L_a\chi_b) + \sum_{j=1}^{i-1}\frac{\partial\Xi_i}{\partial z_j}(z_{j+1} + \alpha_j + F_j + S_j\chi_b)\right)\mathrm{d}t \\
&\quad + \frac{1}{2}\mathrm{Tr}\left(\frac{\partial^2(\Xi_i z_i^2)}{\partial([\chi_a^\top,\, z_{[i]}^\top]^\top)^2}\begin{bmatrix}\Phi_a\\ \Psi_1\\ \vdots\\ \Psi_i\end{bmatrix}\begin{bmatrix}\Phi_a\\ \Psi_1\\ \vdots\\ \Psi_i\end{bmatrix}^\top\right)\mathrm{d}t \\
&\quad + 2\Xi_i z_i\Psi_i\,\mathrm{d}w + z_i^2\left(\frac{\partial\Xi_i}{\partial\chi_a}\Phi_a + \sum_{j=1}^{i-1}\frac{\partial\Xi_i}{\partial z_j}\Psi_j\right)\mathrm{d}w \\
&\le -z_1^2\,\mathrm{d}t + \sigma_i(y_d^{[i-1]}, \chi, z_{[i]})\,\mathrm{d}w - \frac{\theta}{4}\sigma_i\sigma_i^\top\,\mathrm{d}t + \frac{\theta}{4}(\sigma_i\sigma_i^\top - \sigma_{i-1}\sigma_{i-1}^\top)\,\mathrm{d}t \\
&\quad - \beta_i\Xi_i z_i^2\,\mathrm{d}t + \beta_i\Xi_i z_i^2\,\mathrm{d}t - \frac{r_{i-1}(y_d)\,\|\chi\|^2}{(c + \chi^\top P\chi)^{1-\gamma}}\,\mathrm{d}t \\
&\quad - \sum_{j=1}^{i-1}\Xi_j\left(\beta_j - 2\sum_{m=j+1}^{i-1}(m-1)\,\kappa_m\right)z_j^2\,\mathrm{d}t - \Delta_{i-1}\,\mathrm{d}t \\
&\quad + 2z_i\Xi_i\big(z_{i+1} + \alpha_i + \overline{F}_i(y_d^{[i]}, \chi_a, z_{[i]})\big)\,\mathrm{d}t + z_i M_i(y_d^{[i-1]}, \chi_a, z_{[i]})\chi_b\,\mathrm{d}t \\
&\quad + C_{i-1}\,\mathrm{d}t + \frac{1}{2}\mathrm{Tr}\left(\frac{\partial^2(\Xi_i z_i^2)}{\partial([\chi_a^\top,\, z_{[i]}^\top]^\top)^2}\begin{bmatrix}\Phi_a\\ \Psi_1\\ \vdots\\ \Psi_i\end{bmatrix}\begin{bmatrix}\Phi_a\\ \Psi_1\\ \vdots\\ \Psi_i\end{bmatrix}^\top\right)\mathrm{d}t,
\end{aligned} \tag{4.46}$$

where

$$\begin{aligned}
\sigma_i &= \sigma_{i-1} + 2\Xi_i z_i\Psi_i + z_i^2\frac{\partial\Xi_i}{\partial\chi_a}\Phi_a + z_i^2\sum_{j=1}^{i-1}\frac{\partial\Xi_i}{\partial z_j}\Psi_j, \\
\overline{F}_i &= F_i + \frac{\Xi_{i-1}}{\Xi_i}z_{i-1} + \frac{z_i}{2\Xi_i}\left(\sum_{j=0}^{i-1}\frac{\partial\Xi_i}{\partial y_d^{(j)}}y_d^{(j+1)}\right. \\
&\qquad\qquad \left. + \sum_{j=1}^{i-1}\frac{\partial\Xi_i}{\partial z_j}(z_{j+1} + \alpha_j + F_j) + \frac{\partial\Xi_i}{\partial\chi_a}(W_a\chi_a + F_a)\right), \\
M_i &= 2\Xi_i S_i + z_i\sum_{j=1}^{i-1}\frac{\partial\Xi_i}{\partial z_j}S_j + z_i\frac{\partial\Xi_i}{\partial\chi_a}L_a
\end{aligned}$$

all are smooth functions. Here, we have used the technique of subtracting and adding terms $\frac{\theta}{4}\sigma_i\sigma_i^\top\,\mathrm{d}t$ and $\beta_i\Xi_i z_i^2\,\mathrm{d}t$ to the right-hand side of inequality (4.46).

Let $\overline{\sigma}_{i-1}(y_d^{[i-2]},\chi,z_{[i-1]})=\sigma_{i-1}-\frac{\partial V_0}{\partial\chi}\Phi=\sum_{j=1}^{i-1}(2\Xi_j z_j\Psi_j+z_j^2\frac{\partial\Xi_j}{\partial\chi_a}\Phi_a+z_j^2\sum_{k=1}^{j-1}\frac{\partial\Xi_j}{\partial z_k}\Psi_k)$. Then by noticing that $\overline{\sigma}_{i-1}$ is independent of χ_b, we have

(4.47)

$$
\begin{aligned}
&-\Delta_{i-1,1}+\frac{\theta}{4}(\sigma_i\sigma_i^\top-\sigma_{i-1}\sigma_{i-1}^\top)\\
&\quad=-\theta\varepsilon_{11}^2\left\|\left(\frac{\partial V_0}{\partial\chi}\right)^\top-\frac{1}{2\varepsilon_{11}^2}\sum_{j=1}^{i-1}\Xi_j\Phi\Gamma_j^\top z_j\right\|^2+\theta\Xi_i\sigma_{i-1}\Gamma_i^\top z_i+\theta\Xi_i^2\Gamma_i\Gamma_i^\top z_i^2\\
&\quad=-\theta\varepsilon_{11}^2\left\|\left(\frac{\partial V_0}{\partial\chi}\right)^\top-\frac{1}{2\varepsilon_{11}^2}\sum_{j=1}^{i-1}\Xi_j\Phi\Gamma_j^\top z_j\right\|^2\\
&\qquad+\theta\Xi_i\frac{\partial V_0}{\partial\chi}\Phi\Gamma_i^\top z_i+\theta\Xi_i(\overline{\sigma}_{i-1}+\Xi_i\Gamma_i z_i)\Gamma_i^\top z_i\\
&\quad=-\theta\varepsilon_{11}^2\left\|\left(\frac{\partial V_0}{\partial\chi}\right)^\top-\frac{1}{2\varepsilon_{11}^2}\sum_{j=1}^{i-1}\Xi_j\Phi\Gamma_j^\top z_j\right\|^2\\
&\qquad+\left(\theta\left(\frac{\partial V_0}{\partial\chi}-\frac{1}{2\varepsilon_{11}^2}\sum_{j=1}^{i-1}\Xi_j\Gamma_j\Phi^\top z_j\right)\Xi_i\Phi\Gamma_i^\top z_i-\frac{\theta}{4\varepsilon_{11}^2}\Xi_i^2\Gamma_i\Phi^\top\Phi\Gamma_i^\top z_i^2\right)\\
&\qquad+\frac{\theta}{4\varepsilon_{11}^2}\Xi_i^2\Gamma_i\Phi^\top\Phi\Gamma_i^\top z_i^2+\frac{\theta}{2\varepsilon_{11}^2}\sum_{j=1}^{i-1}\Xi_j\Gamma_j\Phi^\top z_j\Xi_i\Phi\Gamma_i^\top z_i\\
&\qquad+\theta\Xi_i(\overline{\sigma}_{i-1}+\Xi_i\Gamma_i z_i)\Gamma_i^\top z_i\\
&\quad=-\Delta_{i1}+\theta\Xi_i\Bigg(\frac{1}{4\varepsilon_{11}^2}\Xi_i\Gamma_i\Phi^\top\Phi z_i\\
&\qquad\qquad+\frac{1}{2\varepsilon_{11}^2}\sum_{j=1}^{i-1}\Xi_j\Gamma_j\Phi^\top\Phi z_j+\overline{\sigma}_{i-1}+\Xi_i\Gamma_i z_i\Bigg)\Gamma_i^\top z_i,
\end{aligned}
$$

where

$$
\Gamma_i(y_d^{[i-1]},\,\chi_a,\,z_{[i]})=\Psi_i+\frac{z_i}{2\Xi_i}\frac{\partial\Xi_i}{\partial\chi_a}\Phi_a+\frac{z_i}{2\Xi_i}\sum_{j=1}^{i-1}\frac{\partial\Xi_i}{\partial z_j}\Psi_j,
$$

$$
\Delta_{i1}(y_d^{[i-1]},\,\chi,\,z_{[i]})=\theta\varepsilon_{11}^2\left\|\left(\frac{\partial V_0}{\partial\chi}\right)^\top-\frac{1}{2\varepsilon_{11}^2}\sum_{j=1}^{i}\Xi_j\Phi\Gamma_j^\top z_j\right\|^2. \tag{4.48}
$$

Similar to (4.25), by using (4.42) we have

$$
\begin{aligned}
(4.49)\qquad & M_i\chi_b z_i - \Delta_{i-1,2} \\
&= \left(\sum_{k=1}^{i} M_k z_k\right)\chi_b - \frac{\varepsilon_1^{\frac{p_1}{p_1-1}}(p_1-1)}{p_1}\|\chi_b\|^{\frac{p_1}{p_1-1}} - \frac{\left\|\sum_{j=1}^{i-1} M_j^\top z_j\right\|^{p_1}}{p_1\varepsilon_1^{p_1}} z_1^{p_1} \\
&= -\left(\frac{\varepsilon_1^{\frac{p_1}{p_1-1}}(p_1-1)}{p_1}\|\chi_b\|^{\frac{p_1}{p_1-1}} + \frac{\left\|\sum_{j=1}^{i} M_j^\top z_j\right\|^{p_1}}{p_1\varepsilon_1^{p_1}} - \sum_{j=1}^{i} M_j z_j \chi_b\right) \\
&\quad + \frac{1}{p_1\varepsilon_1^{p_1}}\left(\left\|\sum_{j=1}^{i-1} M_j^\top z_j + M_i^\top z_i\right\|^{p_1} - \left\|\sum_{j=1}^{i-1} M_j^\top z_j\right\|^{p_1}\right) \\
&= -\Delta_{i2} + \Upsilon_i,
\end{aligned}
$$

where

$$
\begin{aligned}
(4.50)\qquad \Delta_{i2}(y_d^{[i-1]}, \chi_b, z_{[i]}) &= \frac{(p_1-1)\varepsilon_1^{\frac{p_1}{p_1-1}}}{p_1}\|\chi_b\|^{\frac{p_1}{p_1-1}} + \frac{1}{p_1\varepsilon_1^{p_1}}\left\|\sum_{j=1}^{i} M_j^\top z_j\right\|^{p_1} \\
&\quad - \sum_{j=1}^{i} M_j z_j \chi_b, \\
\Upsilon_i(y_d^{[i-1]}, \chi_a, z_{[i]}) &= \frac{1}{p_1\varepsilon_1^{p_1}}\left(\left\|\sum_{j=1}^{i-1} M_j^\top z_j + M_i^\top z_i\right\|^{p_1} - \left\|\sum_{j=1}^{i-1} M_j^\top z_j\right\|^{p_1}\right).
\end{aligned}
$$

By Young's inequality, it is easy to see that $\Delta_{i2} \geq 0$. And similar to (4.43), there exists a smooth function $\overline{\Upsilon}_i(y_d^{[i-1]}, \chi_a, z_{[i]})$ such that

$$
\Upsilon_i = z_i\overline{\Upsilon}_i(y_d^{[i-1]}, \chi_a, z_{[i]}).
$$

By assumptions A1 and A3, we know that there exist vector-valued smooth functions $\overline{\Psi}_i(y_d^{[i-1]}, \chi_a, \eta_{[i-1]})$ and $\overline{\Psi}_{ij}(y_d^{[i-1]}, \chi_a, z_{[j]})$, $j = 1, \ldots, i-1$, such that

$$
\begin{aligned}
\Psi_i(y_d^{[i-1]}, \chi_a, \eta_{[i-1]}) &= \overline{\Psi}_i(y_d^{[i-1]}, \chi_a, z_{[i-1]}) \\
&= \overline{\Psi}_i(y_d^{[i-1]}, \chi_a, \mathbf{0}_{(i-1)\times 1}) + \sum_{j=1}^{i-1}\overline{\Psi}_{ij}(y_d^{[i-1]}, \chi_a, z_{[j]})z_j.
\end{aligned}
$$

Then, for the last term on the right-hand side of (4.46), we have

(4.51)

$$
\begin{aligned}
&\frac{1}{2}\mathrm{Tr}\left(\frac{\partial^2(\Xi_i z_i^2)}{\partial([\chi_a^\top, z_{[i]}^\top]^\top)^2}\begin{bmatrix}\Phi_a\\ \Psi_1\\ \vdots\\ \Psi_i\end{bmatrix}\begin{bmatrix}\Phi_a\\ \Psi_1\\ \vdots\\ \Psi_i\end{bmatrix}^\top\right) \\
&= \frac{1}{2}\mathrm{Tr}\left(\begin{bmatrix} \dfrac{\partial^2\Xi_i}{\partial([\chi_a^\top, z_{[i-1]}^\top]^\top)^2}z_i^2 & 2\left(\dfrac{\partial\Xi_i}{\partial[\chi_a^\top, z_{[i-1]}^\top]^\top}\right)^\top z_i \\ 2\dfrac{\partial\Xi_i}{\partial[\chi_a^\top, z_{[i-1]}^\top]^\top}z_i & 2\Xi_i \end{bmatrix}\begin{bmatrix}\Phi_a\\ \Psi_1\\ \vdots\\ \Psi_i\end{bmatrix}\begin{bmatrix}\Phi_a\\ \Psi_1\\ \vdots\\ \Psi_i\end{bmatrix}^\top\right)
\end{aligned}
$$

$$
\begin{aligned}
&= \frac{1}{2}\mathrm{Tr}\left(\begin{bmatrix} \dfrac{\partial^2 \Xi_i}{\partial([\chi_a^\top,\, z_{[i-1]}^\top]^\top)^2} z_i & 2\left(\dfrac{\partial \Xi_i}{\partial[\chi_a^\top,\, z_{[i-1]}^\top]^\top}\right)^\top \\ 2\dfrac{\partial \Xi_i}{\partial[\chi_a^\top,\, z_{[i-1]}^\top]^\top} & 0 \end{bmatrix} \begin{bmatrix} \Phi_a \\ \Psi_1 \\ \vdots \\ \Psi_i \end{bmatrix} \begin{bmatrix} \Phi_a \\ \Psi_1 \\ \vdots \\ \Psi_i \end{bmatrix}^\top\right) z_i \\
&\quad + \Xi_i \left(\overline{\Psi}_i(y_d^{[i-1]},\, \chi_a,\, \mathbf{0}_{(i-1)\times 1}) + \sum_{j=1}^{i-1} \overline{\Psi}_{ij}(y_d^{[i-1]},\, \chi_a,\, z_{[j]}) z_j\right) \\
&\qquad \times \left(\overline{\Psi}_i(y_d^{[i-1]},\, \chi_a,\, \mathbf{0}_{(i-1)\times 1}) + \sum_{j=1}^{i-1} \overline{\Psi}_{ij}(y_d^{[i-1]},\, \chi_a,\, z_{[j]}) z_j\right)^\top \\
&\le \frac{1}{2}\mathrm{Tr}\left(\begin{bmatrix} \dfrac{\partial^2 \Xi_i}{\partial([\chi_a^\top,\, z_{[i-1]}^\top]^\top)^2} z_i & 2\left(\dfrac{\partial \Xi_i}{\partial[\chi_a^\top,\, z_{[i-1]}^\top]^\top}\right)^\top \\ 2\dfrac{\partial \Xi_i}{\partial[\chi_a^\top,\, z_{[i-1]}^\top]^\top} & 0 \end{bmatrix} \begin{bmatrix} \Phi_a \\ \Psi_1 \\ \vdots \\ \Psi_i \end{bmatrix} \begin{bmatrix} \Phi_a \\ \Psi_1 \\ \vdots \\ \Psi_i \end{bmatrix}^\top\right) z_i \\
&\quad + 2\Xi_i \left\| (\overline{\Psi}_i(y_d^{[i-1]},\, \chi_a,\, \mathbf{0}_{(i-1)\times 1}))^\top \right\|^2 \\
&\quad + 2(i-1)\Xi_i \sum_{j=1}^{i-1} \Xi_j^{-1} \left\| (\overline{\Psi}_{ij}(y_d^{[i-1]},\, \chi_a,\, z_{[j]}))^\top \right\|^2 \Xi_j z_j^2.
\end{aligned}
$$

Choose

(4.52)
$$
\Xi_i = \frac{\kappa_i}{1 + \left\| (\overline{\Psi}_i(y_d^{[i-1]},\, \chi_a,\, \mathbf{0}_{(i-1)\times 1}))^\top \right\|^2 + \sum_{j=1}^{i-1} \Xi_j^{-1} \left\| (\overline{\Psi}_{ij}(y_d^{[i-1]},\, \chi_a,\, z_{[j]}))^\top \right\|^2}.
$$

Then we have

$$
\begin{aligned}
&2\Xi_i \left\| (\overline{\Psi}_i(y_d^{[i-1]},\, \chi_a,\, \mathbf{0}_{(i-1)\times 1}))^\top \right\|^2 \le 2\kappa_i, \\
&2(i-1)\Xi_i \sum_{j=1}^{i-1} \Xi_j^{-1} \left\| (\overline{\Psi}_{ij}(y_d^{[i-1]},\, \chi_a,\, z_{[j]}))^\top \right\|^2 \Xi_j z_j^2 \le 2(i-1)\kappa_i \sum_{j=1}^{i-1} \Xi_j z_j^2.
\end{aligned}
$$

By substituting (4.47)–(4.52) into (4.46), we get

$$
\begin{aligned}
\mathrm{d}V_i \le\ & -z_1^2\,\mathrm{d}t + \sigma_i\,\mathrm{d}w - \frac{\theta}{4}\sigma_i\sigma_i^\top\,\mathrm{d}t - r_i(y_d)\frac{\|\chi\|^2}{(c+\chi^\top P\chi)^{1-\gamma}}\,\mathrm{d}t \\
& - \sum_{j=1}^{i} \Xi_j \left(\beta_j - 2\sum_{m=j+1}^{i} (m-1)\,\kappa_m\right) z_j^2\,\mathrm{d}t - \Delta_i(y_d^{[i-1]}, \chi, z_{[i]})\,\mathrm{d}t \\
& + 2\Xi_i z_i z_{i+1}\,\mathrm{d}t + 2z_i\Xi_i(\alpha_i - \overline{\alpha}_i(y_d^{[i]},\, \chi_a,\, \eta_{[i]}))\,\mathrm{d}t \\
& + C_i(y_d^{[i]},\, \chi_a,\, z_{[i-1]})\,\mathrm{d}t,
\end{aligned} \tag{4.53}
$$

where

(4.54)

$r_i = r_{i-1}(y_d)$, with r_{i-1} being defined by (4.40),

$\Delta_i = \Delta_{i1} + \Delta_{i2}$, with Δ_{i1} and Δ_{i2} being defined by (4.48) and (4.50), respectively,

$$N_i(y_d^{[i]}, \chi_a, z_{[i]}) = \overline{F}_i + \frac{\overline{\Upsilon}_i}{2\Xi_i} + \frac{\beta_i z_i}{2}$$
$$+ \frac{\theta}{2}\left(\frac{1}{4\varepsilon_{11}^2}\Xi_i\Gamma_i\Phi^\top\Phi z_i + \frac{1}{2\varepsilon_{11}^2}\sum_{j=1}^{i-1}\Xi_j\Gamma_j\Phi^\top\Phi z_j + \overline{\sigma}_{i-1} + \Xi_i\Gamma_i z_i\right)\Gamma_i^\top$$
$$+ \frac{1}{4\Xi_i}\mathrm{Tr}\left(\begin{bmatrix} \dfrac{\partial^2\Xi_i}{\partial([\chi_a^\top,\, z_{[i-1]}^\top]^\top)^2} z_i & 2\left(\dfrac{\partial\Xi_i}{\partial[\chi_a^\top,\, z_{[i-1]}^\top]^\top}\right)^\top \\ 2\dfrac{\partial\Xi_i}{\partial[\chi_a^\top,\, z_{[i-1]}^\top]^\top} & 0 \end{bmatrix} \begin{bmatrix} \Phi_a \\ \Psi_1 \\ \vdots \\ \Psi_i \end{bmatrix} \begin{bmatrix} \Phi_a \\ \Psi_1 \\ \vdots \\ \Psi_i \end{bmatrix}^\top\right),$$

$$\overline{\alpha}_i = \left\{ - N_i(y_d^{[i]}, \chi_a, z_{[i]})\right\}\Big|_{z_j = \eta_j - \alpha_{j-1},\, j=1,\ldots,i},$$

$$C_i = C_{i-1} + 2\Xi_i\left\|(\overline{\Psi}_i(y_d^{[i-1]}, \chi_a, \mathbf{0}_{(i-1)\times 1}))^\top\right\|^2, \quad C_{i-1} \text{ is given by (4.41).} \tag{4.55}$$

Now, we choose virtual controller $\alpha_i(y_d^{[i]}, \chi_a, \eta_{[i]})$ as follows:

$$\alpha_i = \overline{\alpha}_i(y_d^{[i]}, \chi_a, \eta_{[i]}). \tag{4.56}$$

Substituting (4.56) into (4.53), we have

$$\begin{aligned} \mathrm{d}V_i \le {} & -z_1^2\,\mathrm{d}t + \sigma_i\,\mathrm{d}w - \frac{\theta}{4}\sigma_i\sigma_i^\top\,\mathrm{d}t - r_i(y_d)\frac{\|\chi\|^2}{(c+\chi^\top P\chi)^{1-\gamma}}\,\mathrm{d}t - \Delta_i\,\mathrm{d}t \\ & - \sum_{j=1}^{i}\Xi_j\left(\beta_j - 2\sum_{m=j+1}^{i}(m-1)\,\kappa_m\right)z_j^2\,\mathrm{d}t \\ & + 2\Xi_i z_i z_{i+1}\,\mathrm{d}t + C_i(y_d^{[i]}, \chi_a, z_{[i]})\,\mathrm{d}t. \end{aligned} \tag{4.57}$$

This completes *Step i*.

Step ρ. It is easy to see that the results of Step i hold also for $i = \rho$, where $\eta_{\rho+1} = b_m g(y)u$. Define the value function V_ρ as in (4.45) with $i = \rho$ for this step. Then, V_ρ satisfies (4.57) with $i = \rho$. Set $z_{\rho+1} = 0$. Then, we arrive at the controller

$$u(y_d^{[\rho]}, \chi_a, \eta_{[\rho]}) = \frac{1}{b_m g(y)}\alpha_\rho(y_d^{[\rho]}, \chi_a, \eta_{[\rho]}), \tag{4.58}$$

where α_ρ is defined by letting $i = \rho$ in (4.56). Let $V_\rho = V_{\rho-1} + \Xi(y_d^{[\rho-1]}, \chi_a, z_{[\rho-1]})z_\rho^2$. Then we have

$$\begin{aligned} \mathrm{d}V_\rho \le {} & -z_1^2\,\mathrm{d}t + \sigma_\rho(y_d^{[\rho-1]}, \chi_a, z)\,\mathrm{d}w - \frac{\theta}{4}\sigma_\rho\sigma_\rho^\top\,\mathrm{d}t \\ & - r_\rho(y_d)\frac{\|\chi\|^2}{(c+\chi^\top P\chi)^{1-\gamma}}\,\mathrm{d}t - \Delta_\rho(y_d^{[\rho-1]}, \chi, z)\,\mathrm{d}t \\ & - \sum_{j=1}^{\rho}\Xi_j\left(\beta_j - 2\sum_{m=j+1}^{\rho}(m-1)\,\kappa_m\right)z_j^2\,\mathrm{d}t + C_\rho(y_d^{[\rho]}, \chi_a, z_{[\rho]})\,\mathrm{d}t, \end{aligned} \tag{4.59}$$

where Ξ_ρ, σ_ρ, r_ρ, Δ_ρ, and C_ρ are defined in the same way as in Step i ($i = 2, \ldots, \rho-1$), with i being replaced by ρ.

So far, we have completed the entire backstepping design.

4.4. Properties of the design procedure. In this subsection, we give several properties of the design procedure above. To avoid duplication of the expression, here only the case of $\rho > 1$ is considered, since the case of $\rho = 1$ has the same properties.

By Lemmas B.1 and B.2, we have

$$\begin{aligned} r_\rho(y_d)\frac{\|\chi\|^2}{(c+\xi)^{1-\gamma}} &\geq \frac{r_\rho(y_d)}{(\lambda_{\max}(P))^{1-\gamma}}\|\chi\|^{2\gamma} - r_\rho(y_d)\mathcal{M}_\gamma(c) \\ &\geq \frac{r_\rho(y_d)}{\lambda_{\max}(P)}\left((c+\xi)^\gamma - c^\gamma\right) - r_\rho(y_d)\mathcal{M}_\gamma(c) \\ &= \frac{r_\rho(y_d)}{\delta\lambda_{\max}(P)}\phi(\xi) - r_\rho(y_d)\mathcal{M}_\gamma(c), \end{aligned} \tag{4.60}$$

where $r_\rho(y_d) = r_1(y_d)$ is defined by (4.54) and ξ and $\phi(\xi)$ are defined in (4.10).

Define

$$\overline{r}(y_d) = \frac{r_\rho(y_d)}{\delta\lambda_{\max}(P)}, \tag{4.61}$$

$$\overline{\beta}_i = \beta_i - 2\sum_{j=i+1}^{\rho}(j-1)\,\kappa_j, \quad i = 1, \ldots, \rho, \tag{4.62}$$

$$C(y_d^{[\rho]}, \chi_a, z_{[\rho]}) = C_\rho + r_\rho(y_d)\mathcal{M}_\gamma(c). \tag{4.63}$$

Then, by (4.59) (or (4.35) for the case of $\rho = 1$) and (4.60)–(4.63), we have

$$\mathrm{d}V_\rho \leq \sigma_\rho\,\mathrm{d}w - \frac{\theta}{4}\sigma_\rho\sigma_\rho^\top\,\mathrm{d}t - z_1^2\,\mathrm{d}t - \overline{r}\,\phi(\xi)\,\mathrm{d}t - \sum_{i=1}^{\rho}\Xi_i\overline{\beta}_i z_i^2\,\mathrm{d}t - \Delta_\rho\,\mathrm{d}t + C\,\mathrm{d}t. \tag{4.64}$$

The following lemma presents the method specifying the design constants.

LEMMA 4.2. *For any given cost value $R_l > 0$, risk-sensitivity parameter $\theta > 0$, and characteristic parameter $\gamma \in (\frac{1}{2}, 1)$, there always exist positive design constants $\delta, c, \varepsilon_{01}, \varepsilon_{02}, \varepsilon_{03}, \varepsilon_{04}, \varepsilon_1, \varepsilon_{11}, \beta_1, \ldots, \beta_\rho, \kappa_1, \ldots, \kappa_\rho$, such that the following inequalities hold:*

$$r_\rho \geq r > 0, \quad \overline{\beta}_1 > 0, \ldots, \overline{\beta}_\rho > 0, \quad \textit{and} \quad C_\rho \leq R_l, \tag{4.65}$$

where r is constant.

Proof. The proof can be accomplished by properly selecting a set of design constants.

Design constants δ, ε_{01}, and ε_{02} are chosen such that

$$0 < \delta \leq 1, \tag{4.66}$$

$$0 < \varepsilon_{01} < \frac{\sqrt{2}}{4}, \tag{4.67}$$

$$0 < \varepsilon_{02} < \frac{\sqrt{2}}{4}. \tag{4.68}$$

For given $\gamma \in (\frac{1}{2}, 1)$, even numbers $p \in \{2, 4, 6, \ldots\}$ and $p_1 \in \{4, 6, 8, \ldots\}$ are chosen such that

$$\frac{p_1}{2(p_1-1)} \le \gamma \le \frac{p}{p+1}.$$

For example, when $\gamma = \frac{2}{3}$, even numbers $p \ge 2$ and $p_1 \ge 4$ are proper; when $\gamma = \frac{4}{5}$, then even numbers $p \ge 4$ and $p_1 \ge 4$ are proper; when $\gamma = \frac{3}{5}$, then even numbers $p \ge 2$ and $p_1 \ge 6$ are proper.

Then, for given $\gamma \in (\frac{1}{2}, 1)$, risk-sensitivity parameter θ, desired positive risk-sensitive cost value R_l, given output y_d, selected δ, ε_{01}, p, and p_1, and design constants ε_{03}, ε_{04}, c, and ε_1 are chosen such that

$$0 < \varepsilon_{03} < \left(\frac{p \lambda_{\min}^{\frac{1}{p-1}}(P)}{12\theta\delta\gamma(p-1)\|P\|^2} \right)^{\frac{p-1}{p}}, \tag{4.69}$$

$$0 < \varepsilon_{04} < \sqrt{\frac{1}{18\theta\delta\gamma}}, \tag{4.70}$$

(4.71)

$$c \ge \max\left\{1, \left(\max\left\{ \frac{5\delta\gamma \max_{|y_d|\le C_{y_d}} \|PF(y_d)\|^2}{R_l \varepsilon_{01}^2}, 12\theta\delta\gamma \max_{|y_d|\le C_{y_d}} \left(\|P\Phi(y_d)\|_F^2\right), \right.\right.\right.$$
$$\left.\left.\left. \frac{10\delta\gamma \max_{|y_d|\le C_{y_d}} \mathrm{Tr}\left(P\Phi(y_d)\Phi^\top(y_d)\right)}{R_l} \right\}\right)^{\frac{1}{1-\gamma}}\right\},$$

$$0 < \varepsilon_1 < \delta \left(\min\left\{ \frac{p_1 R_l}{5(p_1-1)(1+\mathcal{K}(\frac{p_1}{p_1-1}, 2\gamma))}, \quad \frac{p_1 R_l}{5(p_1-1)\lambda_{\max}^{1-\gamma}(P)\mathcal{M}_\gamma(c)}, \right.\right.$$
$$\left.\left. \frac{\gamma p_1}{8(p_1-1)\lambda_{\max}^{1-\gamma}(P)} \right\}\right)^{\frac{p_1-1}{p_1}}. \tag{4.72}$$

For given γ and selected constants c and δ, constant ε_{11} is chosen such that

$$0 < \varepsilon_{11} < \sqrt{\frac{c^{1-\gamma}}{16\theta\delta\gamma\|P\|^2}}. \tag{4.73}$$

Design constants $\kappa_1, \ldots, \kappa_\rho$ are chosen such that

$$0 < \kappa_i = \min\left\{1, \quad \frac{R_l}{10\rho}\right\}, \quad i = 1, \ldots, \rho. \tag{4.74}$$

For given κ_i's, design constants $\beta_1, \ldots, \beta_\rho$ are chosen such that

$$\beta_i > 2 \sum_{m=i+1}^{\rho} (m-1)\,\kappa_m, \quad i = 1, \ldots, \rho. \tag{4.75}$$

Thus, by (4.54) with $i = \rho$, (4.29), (4.18), (4.67)–(4.73), we have $r_\rho(y_d) > \frac{1}{8}\delta\gamma > 0$; by (4.62) and (4.75) we have $\overline{\beta}_1 > 0, \ldots, \overline{\beta}_\rho > 0$; by (4.59) (or (4.35) for the case of $\rho = 1$), (4.32), (4.19), (4.67), (4.71), (4.72), and (4.75), we have $C_\rho \le R_l$. □

For the value function V_ρ, we have the following lemma.

LEMMA 4.3. *There are positive definite, continuous, and radially unbounded functions* $W_1(\chi, z)$ *and* $W_2(\chi, z)$ *such that*

$$W_1(\chi, z) \le V_\rho(y_d^{[\rho-1]}, \chi, z) \le W_2(\chi, z). \tag{4.76}$$

Proof. Define

$$W_1(\chi, z) = V_0(\chi) + \sum_{i=1}^{\rho} \min_{|y_d|\le C_{y_d},\ldots,|y_d^{(i-1)}|\le C_{y_d^{(i-1)}}} \Xi_i(y_d^{[i-1]}, \chi_a, z_{[i-1]}) z_i^2,$$

$$W_2(\chi, z) = V_0(\chi) + \sum_{i=1}^{\rho} \max_{|y_d|\le C_{y_d},\ldots,|y_d^{(i-1)}|\le C_{y_d^{(i-1)}}} \Xi_i(y_d^{[i-1]}, \chi_a, z_{[i-1]}) z_i^2.$$

Then inequality (4.76) holds.

We now show that $W_1(\chi, z)$ and $W_2(\chi, z)$ are positive definite, continuous, and radially unbounded. Clearly, W_1 and W_2 are continuous. In fact, based on $W_1(\chi, z) \le W_2(\chi, z)$ and $W_2(\mathbf{0}_{(n+m)\times 1}, \mathbf{0}_{\rho\times 1}) = 0$, it suffices to show that so is $W_1(\chi, z)$.

Let us next prove the positive definition and radial unboundedness of W_1 by induction. It is clear that $V_0(\chi)$ is positive definite and radially unbounded by the definition (4.10).

By the definition (4.27) of Ξ_1, assumption A3, and the smoothness of $\|\overline{\Psi}_1\|^2$, we see that $\min_{|y_d|\le C_{y_d}} \Xi_1(y_d)$ is existent and positive. Thus, $V_0(\chi)+\min_{|y_d|\le C_{y_d}} \Xi_1(y_d) z_1^2$ is positive definite and radially unbounded.

Clearly, $\min_{|y_d|\le C_{y_d}, |y_d^{(1)}|\le C_{y_d^{(1)}}} \Xi_2(y_d^{[1]}, \chi_a, z_1)$ is positive and continuous with respect to (χ_a, z_1). Thus, by Lemma B.4 in Appendix B we can get the positive definiteness and radial unboundedness of $V_0(\chi)+\min_{|y_d|\le C_{y_d}} \Xi_1(y_d) z_1^2 + \min_{|y_d|\le C_{y_d}, |y_d^{(1)}|\le C_{y_d^{(1)}}} \Xi_2(y_d^{[1]}, \chi_a, z_1) z_2^2$.

Suppose that $V_0(\chi) + \sum_{j=1}^{i-1} \min_{|y_d|\le C_{y_d},\ldots,|y_d^{(j-1)}|\le C_{y_d^{(j-1)}}} \Xi_j(y_d^{[j-1]}, \chi_a, z_{[j-1]}) z_j^2$ $(i = 3, 4, \ldots, \rho)$ is positive definite and radially unbounded. Then, from the positiveness and continuity of $\min_{|y_d|\le C_{y_d},\ldots,|y_d^{(i-1)}|\le C_{y_d^{(i-1)}}} \Xi_i(y_d^{[i-1]}, \chi_a, z_{[i-1]})$ and Lemma B.4 in Appendix B, we obtain the positive definiteness and radial unboundedness of

$$V_0(\chi) + \sum_{j=1}^{i} \min_{|y_d|\le C_{y_d},\ldots,|y_d^{(j-1)}|\le C_{y_d^{(j-1)}}} \Xi_j(y_d^{[j-1]}, \chi_a, z_{[j-1]}) z_i^2.$$

Thus, by induction, $W_1(\chi, z)$ is positive definite and radially unbounded. ∎

The following two properties are largely straightforward.

PROPERTY 4.1. *If the design constants are chosen such that inequalities* (4.65) *hold, then we have*

$$\begin{aligned} \mathrm{d}V_\rho \le & -(y - y_d)^2\,\mathrm{d}t + \sigma_\rho\,\mathrm{d}w - \frac{\theta}{4}\sigma_\rho\sigma_\rho^\top\,\mathrm{d}t \\ & - l\big(y_d^{[\rho-1]}, \chi, z_{[\rho]}\big)\,\mathrm{d}t + R_l\,\mathrm{d}t + r(y_d)\mathcal{M}_\gamma(c)\mathrm{d}t, \end{aligned} \tag{4.77}$$

where $l = \overline{r}(y_d)\phi(\xi) + \sum_{i=1}^{\rho} \Xi_i \overline{\beta}_i z_i^2 + \Delta_\rho$ *is nonnegative.*

Proof. By (4.59) (or (4.35) for the case of $\rho = 1$) and (4.65) one can easily get (4.77). □

PROPERTY 4.2. *If design constants are chosen such that inequalities* (4.65) *hold, then*

$$\mathcal{L}V_\rho \le -z_1^2 + R_l, \tag{4.78}$$

$$\mathcal{L}V_\rho \le -c_1 V_\rho + c_2, \tag{4.79}$$

where constants c_1 *and* c_2 *satisfy*

$$\begin{cases} c_1 = \min\left\{ \frac{r}{\delta\lambda_{\max}(P)}, \overline{\beta}_1, \overline{\beta}_2, \dots, \overline{\beta}_\rho \right\} > 0, \\ c_2 = R_l + \max_{y_d} r_\rho(y_d)\mathcal{M}_\gamma(c). \end{cases} \tag{4.80}$$

Proof. When design constants are chosen such that inequalities (4.65) hold, then (4.78) comes from (4.77), and (4.79) comes from (4.61)–(4.64), $V_\rho = \phi(\xi) + \sum_{i=1}^{\rho} \Xi_i z_i^2$, and

$$\overline{r}(y_d) \ge c_1, \overline{\beta}_1 \ge c_1, \dots, \overline{\beta}_\rho \ge c_1, \quad \text{and} \quad C \le c_2. \qquad \square$$

5. Main results. In this section, we summarize the main results of this paper as a theorem.

THEOREM 5.1. *Consider the system* (3.1) *and the tracking risk-sensitive cost criterion* (3.2). *Suppose that assumptions* A1–A3 *hold. Then, for any given risk-sensitivity parameter* $\theta > 0$ *and desired cost value* $R_l > 0$, *there exists an output-feedback controller such that the closed-loop system*

1. *has a unique solution on* $[0, \infty)$ *almost surely,*
2. *admits a guaranteed cost value* R_l *for the risk-sensitive cost criterion* (3.2),
3. *is bounded in probability.*

Proof. We prove this theorem only for the case of $\rho > 1$ by construction. The proof for the case $\rho = 1$ is similar and straightforward, and so is omitted here.

For any given risk-sensitivity parameter $\theta > 0$ and desired cost value $R_l > 0$, section 4 provides a constructive design procedure of an output-feedback risk-sensitive controller. From Lemma 4.2, it is easily known that there are design constants such that inequalities (4.65) hold. Then, Lemma 4.3, (4.59), and the first two statements of Theorem A.1 imply statements 1 and 2.

Property 4.2, together with the third statement of Theorem A.1, leads directly to the boundedness in probability of $[\chi^\top, z_{[\rho]}^\top]^\top$. To show statement 3, let us first show the boundedness in probability of $[\eta_1, \dots, \eta_\rho]^\top$.

By $\eta_1 = y = z_1 + y_d$ and assumption A3, it is easy to see that η_1 is bounded in probability. Suppose that $[\eta_1, \dots, \eta_{k-1}]^\top$ is bounded in probability for k ($k = 2, \dots, \rho$). Then by $\eta_k = z_k + \alpha_{k-1}(y_d^{[k-1]}, \chi_a, \eta_{[k-1]})$, the smoothness of α_{k-1}, and assumption A3, we know that η_k, and hence $[\eta_1, \dots, \eta_k]^\top$, is bounded in probability. Therefore, by induction, $[\eta_1, \dots, \eta_\rho]^\top$ is bounded in probability.

Thus, by $[\eta_1, \dots, \eta_\rho, \zeta^\top]^\top = T_\rho, \dots, T_1[y, \widehat{x}_2, \dots, \widehat{x}_n]^\top$ and $\chi = [\zeta^\top, \widetilde{x}^\top]^\top$, it is easy to derive that $\widetilde{x}$ and $[y, \widehat{x}_2, \dots, \widehat{x}_n]^\top$ are bounded in probability. This, together with $y = x_1$, $\widehat{x}_1 = y - \widetilde{x}_1$, and $[x_2, \dots, x_n]^\top = [\widetilde{x}_2 + \widehat{x}_2, \dots, \widetilde{x}_n + \widehat{x}_n]$, leads to the boundedness in probability of $[x^\top, \widehat{x}^\top]^\top$. That is, statement 3 is true. □

Remark 5.1. As for the value range of characteristic parameter γ in value function V_ρ (or V_0 given by (4.10)), the following two points are considered. First, since χ_b is unknown, in order to guarantee stability of the closed-loop system, we use

$-\frac{r_0(y_d)\|\chi\|^2}{(c+\chi^\top P\chi)^{1-\gamma}}\,\mathrm{d}t$ to dominate the term $M_1\chi_b z_1\,\mathrm{d}t$ on the right-hand side of (4.22). This requires that the power 2γ of χ_b (or χ) in the term $\frac{r_0(y_d)\|\chi\|^2}{(c+\chi^\top P\chi)^{1-\gamma}}\,\mathrm{d}t$ on the right-hand side of (4.22) be greater than 1, the power of χ_b of $M_1\chi_b z_1\,\mathrm{d}t$, that is, $\gamma > 1/2$. Second, to deal with the term $\sigma_0\,\mathrm{d}w$ on the right-hand side of (4.13), we use the technique of subtracting and adding $\frac{\theta}{4}\sigma_0\sigma_0^\top\,\mathrm{d}t$ on the right-hand side of (4.13). The negative term $-\frac{\theta}{4}\sigma_0\sigma_0^\top\,\mathrm{d}t$ is used to control the term $\sigma_0\,\mathrm{d}w$, while the positive term $\frac{\theta}{4}\sigma_0\sigma_0^\top\,\mathrm{d}t$ is dominated by term $-\frac{\partial\phi}{\partial\xi}\|\chi\|^2\,\mathrm{d}t$ and the system input. Thus, it is natural to require that the power 2γ of χ in $\frac{\partial\phi}{\partial\xi}\|\chi\|^2$ be greater than $4\gamma-2$, the power of χ in $\sigma_0\sigma_0^\top$; that is, $2\gamma > 4\gamma - 2$, or equivalently, $\gamma < 1$.

6. Example. Consider the second-order system

$$\begin{aligned}\mathrm{d}x_1 &= x_2\mathrm{d}t + u\mathrm{d}t + \frac{1}{2}y^2\mathrm{d}w,\\ \mathrm{d}x_2 &= u\,\mathrm{d}t,\\ y &= x_1.\end{aligned}$$

The purpose is to design u based on only y such that the output y of the closed-loop system tracks the sinusoidal signal:

$$y_d(t) = a\sin(\omega t), \quad a = 2,\ \omega = 2.$$

Clearly, in this case, we have $n = 2$, $m = 1$, $\rho = 1$, and $h(y) = [\frac{1}{2}y^2,\ 0]^\top$.

Design the following state observer:

$$\begin{aligned}\dot{\widehat{x}}_1 &= \widehat{x}_2 + k_1(y - \widehat{x}_1) + u, \quad k_1 = 1,\\ \dot{\widehat{x}}_2 &= k_2(y - \widehat{x}_1) + u, \qquad\quad k_2 = 1.\end{aligned}$$

Then, the estimation error $\widetilde{x} = [x_1 - \widehat{x}_1,\ x_2 - \widehat{x}_2]^\top$ satisfies the following equation:

$$\mathrm{d}\widetilde{x} = \begin{bmatrix} -1 & 1\\ -1 & 0\end{bmatrix}\widetilde{x}\mathrm{d}t + h(y)\mathrm{d}w \triangleq A\widetilde{x}\mathrm{d}t + h(y)\mathrm{d}w.$$

Set $\varsigma_0 = [y,\ \widehat{x}_2]^\top$. Then we have the following dynamical equation for ς_0:

$$\mathrm{d}\varsigma_0 = \begin{bmatrix} 0 & 1\\ 0 & 0\end{bmatrix}\varsigma_0\mathrm{d}t + \begin{bmatrix} 0\\ \widetilde{x}_1\end{bmatrix}\mathrm{d}t + \begin{bmatrix} 1\\ 0\end{bmatrix}\widetilde{x}_2\mathrm{d}t + \begin{bmatrix} 1\\ 1\end{bmatrix}u\,\mathrm{d}t + \begin{bmatrix} \frac{1}{2}y^2\\ 0\end{bmatrix}\mathrm{d}w.$$

Let $\varsigma_1 = T_1\varsigma_0$, $T_1 = \begin{bmatrix} 1 & 0\\ -1 & 1\end{bmatrix}$, $T_1^{-1} = \begin{bmatrix} 1 & 0\\ 1 & 1\end{bmatrix}$. Then we have

$$\mathrm{d}\varsigma_1 = \begin{bmatrix} 1 & 1\\ -1 & -1\end{bmatrix}\varsigma_1\mathrm{d}t + \begin{bmatrix} 0\\ \widetilde{x}_1\end{bmatrix}\mathrm{d}t + \begin{bmatrix} 1\\ -1\end{bmatrix}\widetilde{x}_2\mathrm{d}t + \begin{bmatrix} 1\\ 0\end{bmatrix}u\,\mathrm{d}t + \begin{bmatrix} \frac{1}{2}y^2\\ -\frac{1}{2}y^2\end{bmatrix}\mathrm{d}w.$$

Let $\eta = [\eta_1,\ \eta_2]^\top = \varsigma_1$ and $\zeta = \eta_2$. Then we have $\eta_1 = y$ and the following dynamics used to control design:

$$\begin{aligned}\mathrm{d}\widetilde{x} &= A\widetilde{x}\mathrm{d}t + h(y)\mathrm{d}w,\\ \mathrm{d}\zeta &= (-\zeta - y + \widetilde{x}_1 - \widetilde{x}_2)\mathrm{d}t - \frac{1}{2}y^2\,\mathrm{d}w,\\ \mathrm{d}y &= (\zeta + y + u + \widetilde{x}_2)\mathrm{d}t + \frac{1}{2}y^2\,\mathrm{d}w.\end{aligned}$$

In this case, we have

$$W = \begin{bmatrix} -1 & 1 & -1 \\ 0 & -1 & 1 \\ 0 & -1 & 0 \end{bmatrix}.$$

By solving Lyapunov equation $W^\top P + PW = -I_3$, we get

$$P = \begin{bmatrix} 0.5000 & 0.3333 & -0.1667 \\ 0.3333 & 1.5000 & -0.6667 \\ -0.1667 & -0.6667 & 1.6667 \end{bmatrix}.$$

Clearly, P is symmetric and positive definite. The eigenvalues of P are 0.3978, 0.9476, 2.3213, and thus, $\lambda_{\min}(P) = 0.3978$, $\lambda_{\max}(P) = 2.3213$.

Let $\gamma = \frac{2}{3}$, $p = 2$, $p_1 = 4$, $z_1 = y - y_d$, $\chi_a = [\zeta, \widetilde{x}_1]^\top$, $\xi_a = \chi_a^\top (P_1 - P_2 P^{-1} P_2^\top)\chi_a = 0.4833\zeta^2 + 1.2333\widetilde{x}_1^2 + 0.5332\zeta\widetilde{x}_1$. Then we design the controller $u(y_d^{[1]}, \chi_a, \eta_1) = \alpha_1(y_d^{[1]}, \chi_a, \eta_1)$ as follows:

$$\alpha_1 = \left\{ -N_1 - \frac{z_1}{2\Xi_1} - \frac{N_0}{2\Xi_1} \right\}\Big|_{z_1 = \eta_1 - y_d}$$

with $\Xi_1 = \frac{4\kappa_1}{4 + y_d^4}$ and

$$\begin{aligned} N_0 = {} & \frac{0.2593\delta}{\varepsilon_{02}^2} \cdot \frac{1}{(c + \xi_a)^{\frac{1}{3}}} + \frac{4\theta\delta^2}{9} \cdot \frac{(y + y_d)^2 (0.5834\widetilde{x}_1 - 0.0833\zeta)^2 z_1}{(c + \xi_a)^{\frac{2}{3}}} \\ & + \frac{3.2261\theta\delta^2}{\varepsilon_{04}^2} \cdot \frac{(\zeta^2 + \widetilde{x}_1^2)\left(2y_d^4 + z_1^2 (y + y_d)^2\right)(y + y_d)^2 z_1}{c + \xi_a} \\ & + \frac{0.2993\theta\delta^2}{\varepsilon_{03}^2} \cdot (y + y_d)^2 (y^2 + y_d^2)^2 z_1 + \frac{\delta}{3} \cdot \frac{(y + y_d)^2 z_1}{(c + \xi_a)^{\frac{1}{3}}}, \\ N_1 = {} & \zeta - \dot{y}_d + \frac{\beta_1}{2} z_1 + \frac{z_1}{2\Xi_1} \frac{\partial \Xi_1}{\partial y_d} \dot{y}_d + \frac{2}{\varepsilon_1^4} \Xi_1^3 z_1^3 + \frac{\theta}{8} \Xi_1 \left(1 + \frac{y^4}{8\varepsilon_{11}^2}\right) y^4 z_1 \\ & + \frac{1}{4}(y + y_d)^2 z_1. \end{aligned}$$

Here, the desired cost value R_l is set to 0.5. Accordingly, the design constants in Lemma 4.2 are chosen as $\delta = 0.9$, $\theta = 0.2$, $\varepsilon_{01} = 0.3$, $\varepsilon_{02} = 0.3$, $\varepsilon_{03} = 0.32$, $\varepsilon_{04} = 0.68$, $c = 100$, $\varepsilon_1 = 0.1$, $\varepsilon_{11} = 0.29$, $\kappa_1 = 0.05$, $\beta_1 = 40$; the stochastic disturbance $\frac{\mathrm{d}w}{\mathrm{d}t}$ is chosen to be Gaussian white noise with power 1; and the initial conditions are simply set to $x_1(0) = 0.8$, $x_2(0) = 0$, $\widehat{x}_1(0) = 0$, $\widehat{x}_2(0) = 0$.

The simulation results are shown in Figures 1–4 given below. In particular, Figure 1 is about x_1 (solid line) and its estimation $\widehat{x}_1$ (dashdotted line); Figure 2 is about x_2 (solid line) and its estimation $\widehat{x}_2$ (dashdotted line); Figure 3 is about desired output y_d (solid line), system output y (dashdotted line), and tracking error $y - y_d$ (dashed line); Figure 4 is about control input u; Figure 5 gives a diagram of $\frac{1}{t}\int_0^t (y(s) - y_d(s))^2 \mathrm{d}s$, used to demonstrate the validity of the design. From Figure 3 and Figure 5 we can see that the system output tracks the desired output ideally.

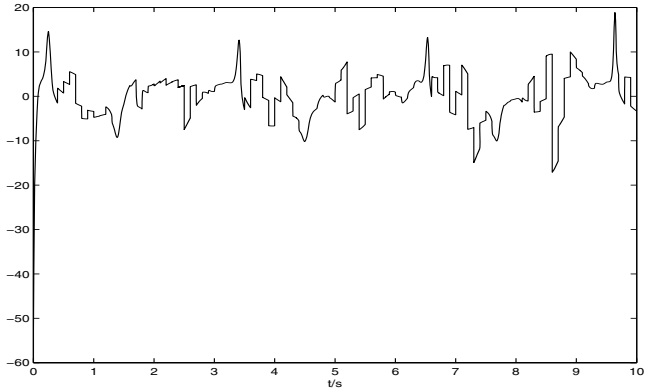

FIG. 4. *Control input* u.

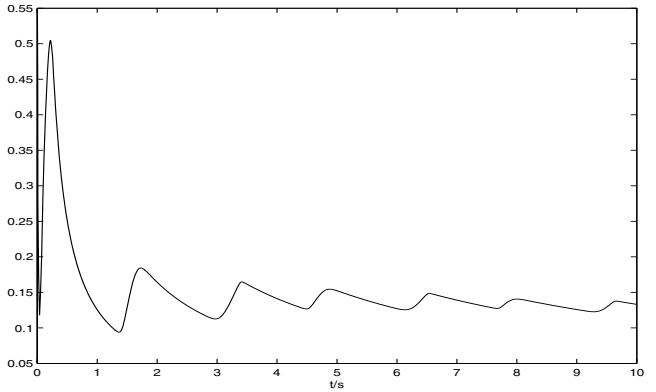

FIG. 5. $\frac{1}{t}\int_0^t (y(s) - y_d(s))^2 \mathrm{d}s$.

7. Concluding remarks. In this paper, the practical output-feedback control design problem of stochastic nonlinear strict-feedback systems in observer canonical form with stable zero-dynamics under a long-term tracking risk-sensitive cost criterion is investigated. A state observer is designed to guarantee an exponentially convergent state estimate when there is no disturbance. By introducing a state-transformation, we transform the system with the state observer in the loop into a lower triangular structure. And then, for any given risk-sensitivity parameter and desired cost value, by using an integrator backstepping method, we present constructively the output-feedback control design algorithm. The cost function adopted here is of quadratic form usually encountered in practice, rather than the quartic one used to avoid difficulty on controller design and performance analysis of the closed-loop systems. It is shown that under our control design (a) the closed-loop system is bounded in probability, and (b) the long-term average risk-sensitive cost of the closed-loop systems is upper bounded by the desired value. Besides, the value range of the characteristic parameters of the value function is investigated. As a special case when system vector nonlinearity and stochastic disturbance vector field vanish at the desired output y_d, it can be expected that there exists a control such that the closed-loop system is asymptotically stable in the large and admits a zero risk-sensitive cost. This question is now under study.

Appendix A. Preliminary results. In this appendix, we give the definitions of *bounded in probability* and *asymptotically stable in the large*, as well as a key theorem to present the sufficient conditions for these two stability notions.

For a general control-free stochastic nonlinear system,

$$\mathrm{d}x = f(t,x)\,\mathrm{d}t + h(t,x)\mathrm{d}w, \quad x(t_0) = x_0, \tag{A.1}$$

where x is an n-dimensional state vector, $n \in \mathbb{N}$; $f: [0,\ \infty) \times \mathbb{R}^n \to \mathbb{R}^n$ and $h: [0,\ \infty) \times \mathbb{R}^n \to \mathbb{R}^{n\times s}$, $s \in \mathbb{N}$, are assumed to be continuous in t and locally Lipschitz in x; w is an s-dimensional vector-valued Brownian motion defined on a probability space $(\Omega,\ \mathcal{F},\ \mathcal{P})$; $t_0 \geq 0$ and $x_0 \in \mathbb{R}^n$. Denote the solution to (A.1) by $x_{t_0,x_0}(t)$.

Definition A.1. *The solution process* $\{x_{t_0,x_0}(t),\ t \geq t_0\}$ *is said to be* bounded in probability *if*

$$\lim_{\varepsilon\to\infty} \sup_{t\in[t_0,\,\infty)} \mathcal{P}\left\{\|x_{t_0,x_0}(t)\| > \varepsilon\right\} = 0.$$

Definition A.2. *Consider the system* (A.1)*, with* $f(t,\mathbf{0}_{n\times 1}) = \mathbf{0}_{n\times 1}$ *and* $h(t,\mathbf{0}_{n\times 1}) = \mathbf{0}_{n\times s}$ $\forall t \geq 0$*. The identically zero solution process is said to be* asymptotically stable in the large *if* $\forall \varepsilon > 0$*,* $t_0 \in [0,\ \infty)$*,*

$$\lim_{\|x_0\|\to 0^+} \mathcal{P}\left\{\sup_{t\geq 0} \|x_{t_0,x_0}(t)\| \geq \varepsilon\right\} = 0$$

and $\forall x_0 \in \mathbb{R}^n$*,* $\forall t_0 \in [0,\ \infty)$*,*

$$\mathcal{P}\left\{\lim_{t\to\infty} x_{t_0,x_0}(t) = \mathbf{0}_{n\times 1}\right\} = 1.$$

The following theorem gives the sufficient conditions for the above two stochastic stability concepts.

Theorem A.1. *Consider stochastic nonlinear system* (A.1) *and the following risk-sensitive cost criterion:*

$$J_\theta = \limsup_{T\to\infty} \frac{1}{T}\,\frac{2}{\theta}\ln\left(E\left(\exp\left(\frac{\theta}{2}\int_0^T q(t,x_{0,x_0}(t))\,\mathrm{d}t\right)\right)\right), \tag{A.2}$$

where $\theta > 0$ *is the risk-sensitive parameter and* $q: [0,\ \infty)\times\mathbb{R}^n \to \mathbb{R}$ *is a nonnegative continuous function. For any* $\theta > 0$ *and any desired cost value* $R_l > 0$*, if there exists a nonnegative value function* $V: [0,\ \infty)\times\mathbb{R}^n \to \mathbb{R}$*, which is* $\mathcal{C}^1$ *in the first argument and* $\mathcal{C}^2$ *in the second argument; a continuous function* $\sigma: [0,\ \infty)\times\mathbb{R}^n \to \mathbb{R}^{1\times s}$*; a nonnegative continuous function* $l: [0,\ \infty)\times\mathbb{R}^n \to \mathbb{R}$*; and a nonnegative, continuous, and radially unbounded function* $W_1: \mathbb{R}^n \to \mathbb{R}$ *such that*

$$W_1(x) \leq V(t,x) \ \ \forall (t,\,x) \in [0,\,\infty)\times\mathbb{R}^n, \tag{A.3}$$

$$\begin{aligned}\mathrm{d}V(t,\,x) = {}& \sigma(t,\,x)\,\mathrm{d}w - \frac{\theta}{4}\sigma(t,\,x)(\sigma(t,\,x))^\top\,\mathrm{d}t - l(t,\,x)\,\mathrm{d}t\\ & - q(t,\,x)\,\mathrm{d}t + R_l\,\mathrm{d}t \qquad \forall (t,\,x) \in [0,\,\infty)\times\mathbb{R}^n,\end{aligned} \tag{A.4}$$

then the following statements hold:

1. *The system* (A.1) *has a unique solution on* $[t_0,\,\infty)$ *almost surely* $\forall t_0 \geq 0$.

2. $J_\theta(x_0) \le R_l \ \forall x_0 \in \mathbb{R}^n$.
3. *If, in addition, there are constants* $c_{l1} \in (0, \infty)$ *and* $c_{l2} \in (0, \infty)$ *such that*

$$\mathcal{L}V(t,x) \le -c_{l1}V(t,\,x) + c_{l2} \quad \forall (t,\,x) \in [0,\,\infty) \times \mathbb{R}^n, \tag{A.5}$$

then the solution of system (A.1) *is bounded in probability.*

4. *If, in addition,* $f(t,\,\mathbf{0}_{n\times 1}) = \mathbf{0}_{n\times 1}$, $h(t,\,\mathbf{0}_{n\times 1}) = \mathbf{0}_{n\times s}\ \forall t \ge 0$, W_1 *is positive definite,* $R_l = 0$, *and there exist a continuous and positive definite function* $W_2 : \mathbb{R}^n \to \mathbb{R}$ *and a positive definite function* $W_3 : \mathbb{R}^n \to \mathbb{R}$ *such that*

$$V(t,\,x) \le W_2(x) \quad \forall (t,\,x) \in [0,\,\infty) \times \mathbb{R}^n, \tag{A.6}$$

$$\frac{\theta}{4}\sigma(t,\,x)(\sigma(t,\,x))^\top + l(t,\,x) + q(t,\,x) \ge W_3(x) \quad \forall (t,\,x) \in [0,\,\infty) \times \mathbb{R}^n, \tag{A.7}$$

then the zero solution of the system (A.1) *is asymptotically stable in the large.*

Proof. Define $\widehat{V} \triangleq V + R_l$. Clearly, $\widehat{V}$ is nonnegative and satisfies

$$\mathcal{L}\widehat{V} = -\frac{\theta}{4}\sigma(t,\,x)(\sigma(t,x))^\top - l(t,\,x) - q(t,\,x) + R_l \le \widehat{V}$$

and

$$\lim_{r\to\infty} \inf_{\|x\|>r} \widehat{V}(t,x) \ge \lim_{r\to\infty} \inf_{\|x\|>r} W_1(x) = \infty \quad \forall t \in [0,\,\infty).$$

Then, by Theorem 4.1 of Chapter III of [21], statement 1 follows.

For statement 2, fix $t_0 = 0$ and $x_0 \in \mathbb{R}^n$. By (A.4), we have

$$\begin{aligned} &V(T,\,x_{0,x_0}(T)) + \int_0^T (q(t,\,x_{0,x_0}(t)) + l(t,\,x_{0,x_0}(t)))\,\mathrm{d}t \\ &\le V(0,\,x_0) + \int_0^T \sigma(t,\,x_{0,x_0}(t))\,\mathrm{d}w \\ &\quad - \frac{\theta}{4}\int_0^T \sigma(t,\,x_{0,x_0}(t))(\sigma(t,x_{0,x_0}(t)))^\top\,\mathrm{d}t + R_l\,T \quad \forall T \ge 0. \end{aligned}$$

This implies that

$$\begin{aligned} &\frac{1}{T}\frac{2}{\theta}\ln\Bigg(E\Bigg(\exp\left(\frac{\theta}{2}\int_0^T q(t,\,x_{0,x_0}(t))\,\mathrm{d}t\right)\Bigg)\Bigg) \\ &\le \frac{1}{T}\frac{2}{\theta}\ln\Bigg(E\Bigg(\exp\left(\frac{\theta}{2}\left(V(T,\,x_{0,x_0}(T)) + \int_0^T \left(q(t,\,x_{0,x_0}(t)) + l(t,\,x_{0,x_0}(t))\right)\mathrm{d}t\right)\right)\Bigg)\Bigg) \\ &\le \frac{V(0,\,x_0)}{T} + \frac{1}{T}\frac{2}{\theta}\ln\Bigg(E\Bigg(\exp\left(\frac{\theta}{2}\left(\int_0^T \sigma(t,\,x_{0,x_0}(t))\,\mathrm{d}w\right.\right. \\ &\qquad\qquad \left.\left. - \frac{\theta}{4}\int_0^T \sigma(t,\,x_{0,x_0}(t))(\sigma(t,\,x_{0,x_0}(t)))^\top\,\mathrm{d}t\right)\right)\Bigg)\Bigg) + R_l. \end{aligned}$$

Let, $\forall T \ge 0$,

$$\zeta(T) \triangleq \exp\left(\int_0^T \frac{\theta}{2}\sigma(t,\,x_{0,x_0}(t))\,\mathrm{d}w - \frac{\theta^2}{8}\int_0^T \sigma(t,\,x_{0,x_0}(t))(\sigma(t,x_{0,x_0}(t)))^\top\,\mathrm{d}t\right).$$

Then $\zeta(T)$ is a supermartingale (see [33]), and $E(\zeta(T)) \le E(\zeta(0)) = 1\ \forall T \ge 0$. Thus, we have

$$J_\theta(x_0) \le \limsup_{T\to\infty}\left(\frac{V(0,\,x_0)}{T} + \frac{1}{T}\frac{2}{\theta}\ln\left(E\left(\zeta(T)\right)\right) + R_l\right) \le R_l.$$

This establishes statement 2.

For statement 3, fix $t_0 \in [0,\,\infty)$ and $x_0 \in \mathbb{R}^n$. Let

$$\alpha(c) = \inf_{\|x\|>c,\, x\in\mathbb{R}^n} W_1(x) \quad \forall c \in [0,\,\infty).$$

Then, by (A.3) and (A.5), we have, for sufficiently large $c \in [0,\,\infty)$ and any $t \ge t_0$,

$$\begin{aligned}
\mathcal{P}(\|x_{t_0,x_0}(t)\| > c) &= \int_\Omega I_{\{\|x_{t_0,x_0}(t)\|>c\}}(\omega)\mathcal{P}(d\omega)\\
&= \int_\Omega \frac{I_{\{\|x_{t_0,x_0}(t)\|>c\}}W_1(x_{t_0,x_0}(t))}{W_1(x_{t_0,x_0}(t))}\mathcal{P}(d\omega)\\
&\le \frac{E(W_1(x_{t_0,x_0}(t)))}{\alpha(c)} \le \frac{E(V(t,\,x_{t_0,x_0}(t)))}{\alpha(c)}\\
&\le \frac{V(t_0,\,x_0) + c_{l2}/c_{l1}}{\alpha(c)}.
\end{aligned}$$

Since the fact that W_1 is radially unbounded implies that $\alpha(c) \to \infty$ as $c \to \infty$, then statement 3 follows.

For statement 4, we note that V is clearly positive definite,

$$0 \le \lim_{x\to\mathbf{0}_{n\times 1}} \sup_{t\ge 0} V(t,\,x) \le \lim_{x\to\mathbf{0}_{n\times 1}} W_2(x) = 0,$$

which implies that V has infinitesimal upper limit, $\mathcal{L}V(t,\,x) = -\frac{\theta}{4}\sigma(t,\,x)(\sigma(t,\,x))^\top - l(t,\,x) - q(t,\,x) \le -W_3(x)\ \forall (t,\,x) \in [0,\,\infty)\times\mathbb{R}^n$, which is negative definite, and

$$\lim_{R\to\infty} \inf_{\|x\|>R,\, x\in\mathbb{R}^n} \inf_{t>0} V(t,\,x) \ge \lim_{R\to\infty} \inf_{\|x\|>R,\, x\in\mathbb{R}^n} W_1(x) = \infty.$$

By Theorem 4.4 in Chapter V of [21], the zero solution of system (A.1) is asymptotically stable in the large. ∎

Appendix B. Technical lemmas.

LEMMA B.1. *Let $n \in \mathbb{N}$, P be an $n \times n$-dimensional symmetric positive definite matrix, $\gamma \in (\frac{1}{2},\,1)$,*

$$\Pi_\gamma(x,c) = \|x\|^{2\gamma}\lambda_{\max}^{\gamma-1}(P) - (c + x^\top Px)^{\gamma-1}\|x\|^2 \qquad \forall x \in \mathbb{R}^n,\ \forall c \in (0,\,\infty),$$

and

$$\mathcal{M}_\gamma(c) = \sup_{x\in\mathbb{R}^n} \Pi_\gamma(x,c) \quad \forall c \in (0,\,\infty).$$

Then $\Pi_\gamma(x,c) \ge 0\ \forall x \in \mathbb{R}^n,\ \forall c \in (0,\,\infty)$; and $\mathcal{M}_\gamma$ is strictly increasing on $(0,\,\infty)$; and

$$\lim_{c\to 0^+} \mathcal{M}_\gamma(c) = 0, \qquad \lim_{c\to+\infty} \mathcal{M}_\gamma(c) = +\infty.$$

Proof. Clearly, for any nonzero vector $x \in \mathbb{R}^n$, we have

$$\Pi(x,\, c) > \Pi(x,\, 0) = 0 \quad \forall c \in (0,\, \infty).$$

From this together with $\Pi(\mathbf{0}_{n\times 1},\, c) = 0\ \forall c \in (0,\, \infty)$, it follows that $\Pi_\gamma(x,c) \geq 0$ $\forall x \in \mathbb{R}^n$, $\forall c \in (0,\, \infty)$.

Let us next prove the properties of $\mathcal{M}_\gamma$. From the definitions of $\lambda_{\max}(P)$ and $\lambda_{\min}(P)$, it follows that for any nonzero vector $x \in \mathbb{R}^n$,

$$\lambda_{\min}(P) \,\leq\, \frac{x^\top P x}{\|x\|^2} \,\leq\, \lambda_{\max}(P).$$

Further, by $\gamma < 1$ we have for any nonzero vector $x \in \mathbb{R}^n$,

$$\begin{aligned}
\Pi_\gamma(x,c) \;&\leq\; \|x\|^{2\gamma}\lambda_{\max}^{\gamma-1}(P) - (c+\lambda_{\max}(P)\|x\|^2)^{\gamma-1}\|x\|^2 \\
&=\; \lambda_{\max}^{\gamma-1}(P)\|x\|^{2\gamma}\left(1-\left(1+\frac{c}{\lambda_{\max}(P)\|x\|^2}\right)^{\gamma-1}\right) \\
&=\; \frac{\lambda_{\max}^{\gamma-1}(P)\|x\|^{2\gamma}}{\left(1+\frac{c}{\lambda_{\max}(P)\|x\|^2}\right)^{\gamma-1}}\left(\left(1+\frac{c}{\lambda_{\max}(P)\|x\|^2}\right)^{1-\gamma}-1\right) \\
&\leq\; \lambda_{\max}^{\gamma-1}(P)\|x\|^{2\gamma}\left(1+\frac{c(1-\gamma)}{\lambda_{\max}(P)\|x\|^2}-1\right) \\
&=\; c(1-\gamma)\lambda_{\max}^{\gamma-2}(P)\|x\|^{2(\gamma-1)} \\
&\longrightarrow 0 \qquad \text{as} \quad \|x\| \to \infty,
\end{aligned}$$

where we have used the following inequality: $(1+a)^r \leq 1+ar\ \forall a \in [0,\, \infty)$, $\forall r \in (0,\, 1)$.

Let

$$\mathcal{X}_0 = \{x \in \mathbb{R}^n : Px = \lambda_{\max}(P)x\}\,.$$

Then it can be shown that for any constant $c > 0$,

$$\mathcal{M}_\gamma(c) \,\geq \sup_{x\in\mathcal{X}_0,\|x\|=1} \Pi_\gamma(x,c) = \lambda_{\max}^{\gamma-1}(P) - (c+\lambda_{\max}(P))^{\gamma-1} \,>\, 0.$$

Therefore, there is a nonzero $x_1 \in \mathbb{R}^n$ at which $\Pi_\gamma(x,c)$ reaches its maximum. Furthermore, we can show that $x_1 \in \mathcal{X}_0$, since otherwise there would be $x_1^\top P x_1 < \lambda_{\max}(P)\|x_1\|^2$. Take $x_0 \in \mathcal{X}_0$ such that $\|x_0\| = \|x_1\|$. Then,

$$\begin{aligned}
\Pi_\gamma(x_0,c) &= \|x_0\|^{2\gamma}\lambda_{\max}^{\gamma-1}(P) - (c+x_0^\top P x_0)^{\gamma-1}\|x_0\|^2 \\
&= \|x_0\|^{2\gamma}\lambda_{\max}^{\gamma-1}(P) - (c+\lambda_{\max}(P)\|x_0\|^2)^{\gamma-1}\|x_0\|^2 \\
&= \|x_1\|^{2\gamma}\lambda_{\max}^{\gamma-1}(P) - (c+\lambda_{\max}(P)\|x_1\|^2)^{\gamma-1}\|x_1\|^2 \\
&> \|x_1\|^{2\gamma}\lambda_{\max}^{\gamma-1}(P) - (c+x_1^\top P x_1)^{\gamma-1}\|x_1\|^2.
\end{aligned}$$

This contradicts the fact that x_1 is the maximum point of $\Pi_\gamma(x,c)$.

Thus, there must be

$$\begin{aligned}
\mathcal{M}_\gamma(c) &= \sup_{x\in\mathbb{R}^n} \Pi_\gamma(x,c) = \sup_{x\in\mathcal{X}_0} \Pi_\gamma(x,c) \\
&= \sup_{x\in\mathcal{X}_0} \left[\|x\|^{2\gamma}\lambda_{\max}^{\gamma-1}(P) - (c+\lambda_{\max}(P)\|x\|^2)^{\gamma-1}\|x\|^2\right].
\end{aligned}$$

In other words, the vector maximization problem has been transformed into a scalar one in α of the following two-variable function $f(\alpha, c)$:

$$f(\alpha, c) = \alpha^{\gamma}\lambda_{\max}^{\gamma-1}(P) - (c + \lambda_{\max}(P)\alpha)^{\gamma-1}\alpha.$$

That is, for any given $c \geq 0$, we have

$$\mathcal{M}_{\gamma}(c) = \sup_{\alpha \geq 0} f(\alpha, c).$$

Noticing that

$$\frac{\partial f(\alpha, c)}{\partial c} = (1-\gamma)(c + \lambda_{\max}(P)\alpha)^{\gamma-2}\alpha \ > \ 0 \quad \forall \alpha > 0, \ \forall c > 0,$$

we know that $f(\alpha, c)$ is a strictly increasing function of c for fixed $\alpha \in (0, \infty)$. It can also be shown that $\mathcal{M}_{\gamma}(c)$ is strictly increasing; i.e., for any $0 < c_1 < c_2$ there is always $0 < \mathcal{M}_{\gamma}(c_1) < \mathcal{M}_{\gamma}(c_2)$ due to the following argument. Let α_{c_1} maximize $f(\alpha, c_1)$, or $\mathcal{M}_{\gamma}(\alpha_{c_1}, c_1) = f(\alpha_{c_1}, c_1) = \sup_{\alpha \geq 0} f(\alpha, c_1)$. Then by the monotonicity of $f(\alpha, \cdot)$, we have

$$\mathcal{M}_{\gamma}(c_1) = f(\alpha_{c_1}, c_1) \ < \ f(\alpha_{c_1}, c_2) \ \leq \ \sup_{\alpha \geq 0} f(\alpha, c_2) = \mathcal{M}_{\gamma}(c_2).$$

Note that, $\forall c \in (0, \infty)$ and $\forall x \in \mathbb{R}^n$ with $x \neq \mathbf{0}_{n\times 1}$,

$$\begin{aligned}
\Pi_{\gamma}(x, c) &\leq \|x\|^{2\gamma}\lambda_{\max}^{\gamma-1}(P) - (c + \lambda_{\max}(P)\|x\|^2)^{\gamma-1}\|x\|^2 \\
&= \frac{\|x\|^{2\gamma}\lambda_{\max}^{\gamma-1}(P)}{(c + \lambda_{\max}(P)\|x\|^2)^{1-\gamma}} \left((c + \lambda_{\max}(P)\|x\|^2)^{1-\gamma} - \lambda_{\max}^{1-\gamma}(P)\|x\|^{2(1-\gamma)} \right) \\
&= \frac{\|x\|^{2\gamma}\lambda_{\max}^{\gamma-1}(P)}{(c + \lambda_{\max}(P)\|x\|^2)^{1-\gamma}} \left(\left(1 + \frac{c}{\lambda_{\max}(P)\|x\|^2} \right)^{1-\gamma} \lambda_{\max}^{1-\gamma}(P)\|x\|^{2(1-\gamma)} \right. \\
&\qquad \left. - \lambda_{\max}^{1-\gamma}(P)\|x\|^{2(1-\gamma)} \right) \\
&= \frac{\|x\|^2}{(c + \lambda_{\max}(P)\|x\|^2)^{1-\gamma}} \left(\left(1 + \frac{c}{\lambda_{\max}(P)\|x\|^2} \right)^{1-\gamma} - 1 \right) \\
&< \frac{\|x\|^2}{(c + \lambda_{\max}(P)\|x\|^2)^{1-\gamma}} \frac{c(1-\gamma)}{\lambda_{\max}(P)\|x\|^2} \\
&= \frac{c(1-\gamma)(\lambda_{\max}(P))^{-1}}{(c + \lambda_{\max}(P)\|x\|^2)^{1-\gamma}}.
\end{aligned}$$

Clearly, we have $\Pi_{\gamma}(\mathbf{0}_{n\times 1}, c) = 0 < \frac{c(1-\gamma)(\lambda_{\max}(P))^{-1}}{(c)^{1-\gamma}}$ $\forall c \in (0, \infty)$. Then,

$$\Pi_{\gamma}(x, c) < \frac{c(1-\gamma)(\lambda_{\max}(P))^{-1}}{(c + \lambda_{\max}(P)\|x\|^2)^{1-\gamma}} \quad \forall c \in (0, \infty), \ \forall x \in \mathbb{R}^n.$$

This implies that, $\forall c \in (0, \infty)$,

$$\mathcal{M}_{\gamma}(c) \ = \ \sup_{x \in \mathbb{R}^n} \Pi_g(x, c) \leq \sup_{x \in \mathbb{R}^n} \frac{c(1-\gamma)(\lambda_{\max}(P))^{-1}}{(c + \lambda_{\max}(P)\|x\|^2)^{1-\gamma}} \ = \ c^{\gamma}(1-\gamma)(\lambda_{\max}(P))^{-1}.$$

Clearly, $\mathcal{M}_{\gamma}(c) > 0$ $\forall c \in (0, \infty)$. Moreover, we have

$$0 \leq \lim_{c \to 0^+} \mathcal{M}_g(c) \leq \lim_{c \to 0^+} c^{\gamma}(1-\gamma)(\lambda_{\max}(P))^{-1} = 0.$$

We now show

$$\lim_{c\to+\infty} \mathcal{M}_\gamma(c) = +\infty, \tag{B.1}$$

since otherwise, by the fact that $\mathcal{M}_\gamma(c)$ is strictly increasing in $[0, \infty)$, $\lim_{c\to+\infty} \mathcal{M}_\gamma(c)$ would be existent and finite. Let $\Upsilon = \lim_{c\to+\infty} \mathcal{M}_\gamma(c)$. Then for $c = \left(1 - \frac{1}{2^{1-\gamma}}\right)^{-\frac{1}{\gamma}} \cdot (2\lambda_{\max}(P)\Upsilon)^{\frac{1}{\gamma}}$, we would have $\mathcal{M}_\gamma(c) \geq f(c\lambda_{\max}^{-1}(P), c) = 2\Upsilon > \Upsilon$. This contradicts $\Upsilon = \lim_{c\to+\infty} \mathcal{M}_\gamma(c)$ and the fact that $\mathcal{M}_\gamma(c)$ is strictly increasing in $[0, \infty)$. Thus, (B.1) is true. □

Remark B.1. Lemma B.1 means that the difference between term $\|x\|^{2\gamma}\lambda_{\max}^{\gamma-1}(P)$ and term $(c + x^\top Px)^{\gamma-1}\ \|x\|^2$ is less than or equal to $\mathcal{M}_\gamma(c)$, which is arbitrarily close to zero as constant c is.

LEMMA B.2. *Let $n \in \mathbb{N}$, $P \in \mathbb{R}^{n\times n}$ be symmetric and positive definite, $c \in [0, \infty)$, and $\gamma \in (\frac{1}{2}, 1)$. Define the function*

$$\Delta_\gamma(x, c) = (c + x^\top Px)^\gamma - c^\gamma - \lambda_{\max}^\gamma(P)\|x\|^{2\gamma}, \quad \forall c \geq 0,\ \forall x \in \mathbb{R}^n.$$

Then we have

$$\Delta_\gamma(x, c) \leq 0 \quad \forall x \in \mathbb{R}^n,\ \forall c \geq 0. \tag{B.2}$$

Proof. Let $z = \|x\|^2$ and $\overline{\Delta}_\gamma(z, c) = (c + \lambda_{\max}(P)z)^\gamma - c^\gamma - \lambda_{\max}^\gamma(P)z^\gamma$. Then, $\overline{\Delta}_\gamma(z, c) \geq \Delta_\gamma(x, c)\,\forall\, c \geq 0$, and for any $z > 0$ and $c \geq 0$,

$$\begin{aligned}\frac{\partial\overline{\Delta}_\gamma(z,\, c)}{\partial z} &= \frac{\gamma\lambda_{\max}(P)}{(c + \lambda_{\max}(P)z)^{1-\gamma}} - \frac{\gamma\lambda_{\max}^\gamma(P)}{z^{1-\gamma}} \\ &\leq \frac{\gamma\lambda_{\max}^\gamma(P)}{(c\lambda_{\max}^{-1}(P) + z)^{1-\gamma}} - \frac{\gamma\lambda_{\max}^\gamma(P)}{z^{1-\gamma}} \leq 0.\end{aligned}$$

This together with $\overline{\Delta}_\gamma(0, c) = \Delta_\gamma(0, c) = 0$ gives (B.2). □

Remark B.2. From Lemmas B.1 and B.2, we know that for any $\chi \in \mathbb{R}^{n+m}$ there exist the following inequalities:

$$\begin{aligned}\|\chi\|^{2\gamma} &\leq \lambda_{\max}^{1-\gamma}(P)\left(\mathcal{M}_\gamma(c) + \frac{\|\chi\|^2}{(c + \chi^\top P\chi)^{1-\gamma}}\right), \\ (c + \chi^\top P\chi)^\gamma - c^\gamma &\leq \lambda_{\max}(P)\left(\mathcal{M}_\gamma(c) + \frac{\|\chi\|^2}{(c + \chi^\top P\chi)^{1-\gamma}}\right).\end{aligned} \tag{B.3}$$

LEMMA B.3. *For any given constants a_1 and a_2 satisfying $1 \leq a_1 \leq a_2$, set $f_{a_1,\, a_2}(x) = x^{a_1} - x^{\alpha_2}\ \forall x \geq 0$, and*

$$\begin{cases}\mathcal{K}(a_1, a_2) = \frac{a_2 - a_1}{a_2}\left(\frac{a_1}{a_2}\right)^{\frac{a_1}{a_2 - a_1}} & \text{if } a_1 < a_2, \\ \mathcal{K}(a_1, a_2) = 0 & \text{if } a_1 = a_2.\end{cases}$$

Then

$$\sup_{x\geq 0} f_{a_1,\, a_2}(x) = \mathcal{K}(a_1, a_2). \tag{B.4}$$

Proof. When $1 \leq a_1 < a_2$, by $\frac{\mathrm{d}}{\mathrm{d}x} f_{a_1,\, a_2}(x) = a_1x^{a_1-1} - a_2x^{\alpha_2-1} = 0$, we see that $f_{a_1,\, a_2}(x)$ achieves its maximum at $x_m = (\frac{a_1}{a_2})^{\frac{1}{a_2-a_1}}$. Substituting x_m into $f_{a_1,\, a_2}(x)$ leads to (B.4).

When $a_2 = a_1 \geq 1$, (B.4) is obvious since, in this case, $f_{a_1,a_2}(x) \equiv 0$ and $\mathcal{K}(a_1, a_2) = 0$. □

LEMMA B.4. *For positive definite and radially unbounded functions $V_1 : \mathbb{R}^m \to \mathbb{R}$ and $V_2 : \mathbb{R} \to \mathbb{R}$, and a positive continuous function $\Xi : \mathbb{R}^m \to \mathbb{R}^+$, $m \in \mathbb{N}$, define $V(X, x) = V_1(X) + \Xi(X)V_2(x)$. Then, for any $[X^\top, x]^\top \neq \mathbf{0}_{(m+1)\times 1}$, $V(X, x) > 0$, and in addition, if $\sqrt{\|X\|^2 + x^2} \to \infty$, $V(X, x) \to \infty$. That is, $V(X, x)$ is positive definite and radially unbounded.*

Proof. We first show the positive definiteness of $V(X, x)$. From $[X^\top, x]^\top \neq 0_{(m+1)\times 1}$ we have either $X \neq 0_{m\times 1}$ or $X = 0_{m\times 1}$ and $x \neq 0$. If $X \neq 0_{m\times 1}$, then we have $V(X, x) \geq V_1(X) > 0$. If $X = 0_{m\times 1}$ and $x \neq 0$, then by the positiveness of Ξ we have $V(0_{m\times 1}, x) \geq \Xi(0_{m\times 1})V_2(x) > 0$. Clearly, $V(\mathbf{0}_{m\times 1}, 0) = 0$. Thus, $V(X, x)$ is positive definite.

Let us next show the radial unboundedness of $V(X, x)$ by contradiction. Suppose there were a sequence of $\{X_k, x_k, k \in \mathbb{N}\}$ satisfying $\lim_{k\to\infty}(\|X_k\| + \|x_k\|) = \infty$ and a constant $C > 0$ such that $V(X_k, x_k) \leq C < \infty \ \forall k \in \mathbb{N}$. Then, there would be $V_1(X_k) \leq C \ \forall k \in \mathbb{N}$ and $\Xi(X_k)V_2(x_k) \leq C \ \forall k \in \mathbb{N}$. Noticing the positive definiteness and radial unboundedness of V_1, one can show that there is a constant $\delta_1(C) > 0$ such that

$$\|X_k\| \leq \delta_1(C) \quad \forall k \in \mathbb{N}. \tag{B.5}$$

Let $M = \min_{\|X\|\leq\delta_1(C)} \Xi(X)$. Then, by the positiveness and continuity of Ξ we have $M > 0$. Thus, $V_2(x_k) \leq \frac{C}{M} \ \forall k \in \mathbb{N}$. This together with the positive definiteness and radial unboundedness of V_2 in turn implies that there exists a constant $\delta_2(C/M) > 0$ such that

$$\|x_k\| \leq \delta_2(C/M) \quad \forall k \in \mathbb{N}. \tag{B.6}$$

From this and (B.5) we have $\|X_k\| + \|x_k\| \leq \delta_1(C) + \delta_2(C/M) < \infty \ \forall k \in \mathbb{N}$, which contradicts $\lim_{k\to\infty}(\|X_k\| + \|x_k\|) = \infty$. Thus, $V(X, x)$ is radially unbounded. □

Acknowledgments. The authors wish to thank Professor Zigang Pan for helpful discussions on this topic. The authors are also indebted to the anonymous referees for their valuable comments.

GLOBAL STABILIZATION OF THE GENERALIZED KORTEWEG–DE VRIES EQUATION POSED ON A FINITE DOMAIN*

LIONEL ROSIER† AND BING-YU ZHANG‡

Abstract. This paper is concerned with the internal stabilization of the generalized Korteweg–de Vries equation on a bounded domain. The global well-posedness and the exponential stability are investigated when the exponent in the nonlinear term ranges over the interval $[1, 4)$. The global exponential stability is obtained whatever the location where the damping is active, confirming positively a conjecture of Perla Menzala, Vasconcellos, and Zuazua [*Quart. Appl. Math.*, 60 (2002), pp. 111–129].

Key words. generalized Korteweg–de Vries equation, unique continuation property, smoothing effect, Carleman estimate

1. Introduction.

In this paper we study the generalized Korteweg–de Vries (GKdV) equation posed on a finite interval $I = (0, L)$ with a localized damping

$$\partial_t u + \partial_x u + a(u)\partial_x u + \partial_x^3 u + b(x)u = 0, \quad 0 \le x \le L, \quad t \ge 0, \tag{1.1}$$

satisfying the homogeneous boundary conditions

$$u(0,t) = 0, \quad u(L,t) = 0, \quad \partial_x u(L,t) = 0, \quad t \ge 0, \tag{1.2}$$

and the initial condition

$$u(x,0) = \phi(x), \qquad 0 \le x \le L. \tag{1.3}$$

Here $b \equiv b(x) \in L^2(I)$ is a given nonnegative function with its support ω being a subset of I, and the function $a \equiv a(\mu)$ is a given smooth function satisfying the growth condition

$$a(0) = 0, \qquad |a^{(j)}(\mu)| \le C(1 + |\mu|^{p-j}) \qquad \forall\ \mu \in \mathbb{R} \tag{1.4}$$

for $j = 0, 1$ if $1 \le p < 2$ and for $j = 0, 1, 2$ if $p \ge 2$.

We are mainly concerned with two issues regarding the initial boundary value problem (IBVP) (1.1)–(1.3). One is the well-posedness of the IBVP (1.1)–(1.3) in the classical Sobolev space $H^s(I)$. That is, we aim to establish existence, uniqueness, and persistence properties of solutions corresponding to the given initial data ϕ, together with continuous dependence of solution upon the initial data ϕ. The other one is the long time behavior of solutions of the IBVP (1.1)–(1.3). More precisely, we will

investigate if the solution of (1.1)–(1.3) tends to zero as $t \to \infty$ and under what rate it decays.

When $a(\mu) = \mu$ and $b \equiv 0$, (1.1) is the celebrated Korteweg–de Vries (KdV) equation

$$\partial_t u + \partial_x u + u\partial_x u + \partial_x^3 u = 0, \tag{1.5}$$

which was derived by Korteweg and de Vries [18] in 1895 as a model for propagation of surface water waves along a channel. The equation has been studied extremely intensively from various aspects of both mathematics and physics since the early 1960s when *soliton* was discovered through the KdV equation and the *inverse scattering transform*, a so-called nonlinear Fourier transform, was invented to solve the initial value problem of the KdV equation (cf. [19, 21]). In particular, the pure initial value problem for the KdV equation posed on the whole line $\mathbb{R}$ or on a periodic domain $\mathbb{S}$ has received a lot of attention in the past three decades for its well-posedness problem in the classical Sobolev space $H^s(\mathbb{R})$ or $H^s(\mathbb{S})$ (see [1, 2, 5, 6, 10, 13, 14, 15, 16] and the references therein). So far, the best known results are that the pure initial value problem of the KdV equation, when posed on the real line $\mathbb{R}$, is well-posed in the space $H^s(\mathbb{R})$ for $s > -\frac{3}{4}$ [16, 10] and is, when posed on the periodic domain $\mathbb{S}$, well-posed in the space $H^s(\mathbb{S})$ for $s \geq -1$ [12].

For the KdV equation posed on a finite interval, the study of its IBVP began with Bubnov [7], who investigated the general two-point boundary value problem

$$\begin{cases} \partial_t u + u\partial_x u + \partial_x^3 u = f(x,t), \qquad u(x,0) = 0, \\ \alpha_1 \partial_x^2 u(0,t) + \alpha_2 \partial_x u(0,t) + \alpha_3 u(0,t) = 0, \\ \beta_1 \partial_x^2 u(1,t) + \beta_2 \partial_x u(1,t) + \beta_3 u(1,t) = 0, \\ \xi_1 \partial_x u(1,t) + \xi_2 u(1,t) = 0 \end{cases} \tag{1.6}$$

posed on the interval $(0,1)$. Here $\alpha_j,\ \beta_j,\ \xi_i \in \mathbb{R},\ j = 1,2,3,\ i = 1,2$, are constants, and assumptions are imposed so that the L^2-norm of the solutions of the linear version of (1.6) (obtained by dropping the nonlinear term $u\partial_x u$) is decreasing. It was shown in [7] that for given $T > 0$ and $f \in H^1([0,T]; L^2(0,1))$, there exists a $T^* > 0$ depending on $\|f\|_{H^1([0,T];L^2(0,1))}$ such that (1.6) admits a unique solution

$$u \in L^2([0,T^*]; H^3(0,1)), \qquad u_t \in L^\infty([0,T^*]; L^2(0,1)) \cap L^2([0,T^*]; H^1(0,1)).$$

In [4], Bona, Sun, and Zhang studied the following nonhomogeneous boundary value problem for the KdV equation posed on the interval $(0,1)$:

$$\begin{cases} \partial_t u + \partial_x u + u\partial_x u + \partial_x^3 u = 0, \qquad u(x,0) = \phi(x), \\ u(0,t) = h_1(t), \quad u(1,t) = h_2(t), \quad \partial_x u(1,t) = h_3(t). \end{cases} \tag{1.7}$$

The IBVP (1.7) was shown in [4] to be well-posed in the space $H^s(0,1)$ for $s \geq 0$ with $h_j \in H^{(s+1)/3}_{loc}(\mathbb{R}^+)$, $j = 1,2$, and $h_3 \in H^{s/3}_{loc}(\mathbb{R}^+)$. Earlier, in the case of $h_j = 0$, $j = 1,2,3$, Zhang [38] showed that the IBVP (1.7) is well-posed in the space $H^{3k+1}(0,1)$ for $k = 0,1,2,\ldots$, and Perla Menzala, Vasconcellos, and Zuazua [24] showed that the IBVP (1.7) is well-posed in the space $L^2(0,1)$. The reader is referred

to [3, 9, 11] for more references on the IVBP for the KdV equation posed either on a finite interval or on the half-line $\mathbb{R}^+$.

The study of long time behavior of solutions of the KdV equation posed on a finite interval was also started by Bubnov [8]. In [17], Komornik, Russell, and Zhang considered the stabilization problem for the KdV equation posed on finite interval $(0,\pi)$ with the periodic boundary conditions

$$\begin{cases} \partial_t u + \partial_x u + u\partial_x u + \partial_x^3 u = f, \qquad u(x,0) = \phi(x), \\ \\ \partial_x^j u(0,t) = \partial_x^j u(\pi,t), \qquad j = 0,1,2, \end{cases} \tag{1.8}$$

where $f \equiv f(x,t)$ is considered as a control input acting on the whole domain $(0,\pi)$. A special feedback control law $f = \mathcal{B}u$ is designed to ensure the conservation of mass, and the resulting closed loop system

$$\begin{cases} \partial_t u + \partial_x u + u\partial_x u + \partial_x^3 u = \mathcal{B}u, \qquad u(x,0) = \phi(x), \\ \\ \partial_x^j u(0,t) = \partial_x^j u(\pi,t), \qquad j = 0,1,2, \end{cases} \tag{1.9}$$

is demonstrated to be exponentially stable; its solution converges exponentially to the average value of its initial datum ϕ over the domain $(0,\pi)$ as $t \to \infty$. The same problem was studied by Russell and Zhang [29, 31], assuming that the control input f acted only on an open subdomain of $(0,\pi)$. The resulting closed loop system is shown to be locally exponentially stable in the sense that the initial data ϕ is required to be small in a certain sense. In [30], Russell and Zhang studied boundary stabilization of the KdV equation posed on a finite interval $(0,\pi)$ with the periodic boundary conditions. The resulting closed loop system appears in the following form:

$$\begin{cases} \partial_t u + \partial_x u + u\partial_x u + \partial_x^3 u = 0, \qquad u(x,0) = \phi(x), \\ \\ u(0,t) = u(\pi,t), \quad \partial_x^2 u(0,t) = \partial_x^2 u(\pi,t), \quad \partial_x u(\pi,t) = \alpha \partial_x u(0,t), \end{cases} \tag{1.10}$$

where $-1 < \alpha < 1$ is a constant. The system was shown by Russell and Zhang [30] to be locally exponentially stable when $\alpha \neq -\frac{1}{2}$. For the exceptional case $\alpha = -\frac{1}{2}$, the system (1.10) was also shown to be locally exponentially stable later by Sun [34] via a different approach. A similar boundary stabilization problem was studied by Zhang [38] for the KdV equation posed on a finite interval $(0,1)$ with the Dirichlet boundary condition. The resulting closed loop system is of the form

$$\begin{cases} \partial_t u + \partial_x u + u\partial_x u + \partial_x^3 u = 0, \qquad u(x,0) = \phi(x), \\ \\ u(0,t) = 0, \quad u(1,t) = 0, \quad \partial_x u(1,t) = \gamma \partial_x u(0,t) \end{cases} \tag{1.11}$$

with $0 \leq |\gamma| < 1$. When $0 < |\gamma| < 1$, the system (1.11) was shown to be locally exponentially stable.

For the KdV equation posed on a finite interval $(0,L)$ with the homogeneous boundary conditions,

$$\begin{cases} \partial_t u + \partial_x u + u\partial_x u + \partial_x^3 u = 0, \quad 0 \leq x \leq L, \quad t \geq 0, \\ \\ u(x,0) = \phi(x), \\ \\ u(0,t) = 0, \quad u(L,t) = 0, \quad \partial_x u(L,t) = 0; \end{cases} \tag{1.12}$$

it is easily seen that any smooth solution u of (1.12) satisfies

$$\frac{d}{dt}\int_0^L |u(x,t)|^2 dx = -|\partial_x u(0,t)|^2.$$

This leads one to guess that any solution u of (1.12) may decay to zero as $t \to \infty$. However, this may not always be the case. In [25], Rosier discovered that if the length L of the domain $(0, L)$ belongs to the set

$$\mathcal{E} = \left\{ \frac{2\pi}{\sqrt{3}}\sqrt{k^2+kl+l^2},\ k \text{ and } l \text{ are positive integers} \right\},$$

then the linear system associated with the IBVP (1.12) possesses a solution with a constant L^2-norm. It is thus reasonable to say that not all solutions of (1.12) decay to 0 as $t \to \infty$.

If the length L of the interval I does not belong to the set $\mathcal{E}$, it has been demonstrated in [24] by Perla Menzala, Vasconcellos, and Zuazua that there exist $\delta > 0$ and $\gamma > 0$ such that if $\phi \in L^2(I)$ with

$$\|\phi\|_{L^2(I)} \le \delta,$$

then

$$\|u(\cdot,t)\| \le C\|\phi\|_{L^2(I)} e^{-\gamma t} \qquad \forall\, t \ge 0,$$

where C depends only on $\|\phi\|_{L^2(I)}$.

In order to handle the case of $L \in \mathcal{E}$ and to have the solutions of (1.12) with large amplitude stabilized, Perla Menzala, Vasconcellos, and Zuazua [24] introduced an extra damping term $b(x)u$ to the equation in (1.12) to get the following system:

$$\begin{cases} \partial_t u + \partial_x u + u\partial_x u + \partial_x^3 u + b(x)u = 0, \quad 0 \le x \le L, \quad t \ge 0, \\ u(x,0) = \phi(x), \\ u(0,t) = 0, \quad u(L,t) = 0, \quad \partial_x u(L,t) = 0. \end{cases} \tag{1.13}$$

Here $b \in L^\infty(I)$ is assumed to be a nonnegative function satisfying $b(x) \ge b_0 > 0$ a.e. in an open, nonempty subset ω of I. Perla Menzala, Vasconcellos, and Zuazua [24] showed the following theorem.

THEOREM 1.1 (Perla Menzala, Vasconcellos, and Zuazua). *For any given $\phi \in L^2(I)$, the IBVP* (1.13) *admits a unique solution $u \in C(\mathbb{R}^+; L^2(I)) \cap L^2_{loc}(\mathbb{R}^+; H^1(I))$. Moreover, if*

$$\omega \text{ contains two sets of the form } (0,\delta) \text{ and } (L-\delta, L) \quad \text{for some } \delta > 0, \tag{1.14}$$

then, for any $L > 0$ and $N > 0$, there exist $C > 0$ and $\mu > 0$ such that for any $\phi \in L^2(I)$ with $\|\phi\|_{L^2(I)} \le N$, the corresponding solution u of (1.13) *satisfies*

$$\|u(\cdot,t)\|_{L^2(I)} \le C\|\phi\|_{L^2(I)} e^{-\mu t} \qquad \forall\, t \ge 0. \tag{1.15}$$

Remarks.

(a) The result of Perla Menzala, Vasconcellos, and Zuazua presented in Theorem 1.1 represents a significant advance in the subject of stabilization of the KdV equation. Indeed, all the previous results except [17], in which the feedback control acts on the whole domain, are local in the sense that only *small amplitude* solutions have been shown to decay exponentially; they are essentially linear stability results. In contrast, the stability result presented in Theorem 1.1 is global; all solutions of (1.13), large or small, decay exponentially in the space $L^2(I)$. It is truly a nonlinear stability result.

(b) Perla Menzala, Vasconcellos, and Zuazua have conjectured in [24] that Theorem 1.1 still holds without the assumption (1.14). Pazoto [22] has proved that this is indeed true. The idea of the proof is as follows: Pazoto shows that the unique continuation property holds, whatever ω is, in proving by multipliers and compactness arguments that any solution vanishing on a subinterval is necessarily smooth.

(c) In Theorem 1.1, the determination of the decay rate ν depends on the size of the initial value ϕ in the space $L^2(I)$. The system (1.12) is locally uniformly exponentially stable in $L^2(I)$.

In this paper, motivated by Perla Menzala, Vasconcellos, and Zuazua's work, we will consider the IBVP of the GKdV equation as described by (1.1)–(1.3) for its well-posedness and long time behavior of its solutions. We will first extend the well-posedness result established in [4] for the IBVP (1.7) for the KdV equation to the IBVP (1.1)–(1.3) for the GKdV equation.

THEOREM 1.2. *Suppose the growth condition* (1.4) *for* $a = a(\mu)$ *is satisfied with*

$$1 \le p < 2.$$

Let $0 \le s \le 3$ *and* $T > 0$ *be given. Then for any given* $\phi \in H^s(I)$ *satisfying the* s*-compatibility conditions*

$$\begin{cases} \phi(0) = \phi(L) = 0 \quad \textit{when } 1/2 < s \le 3/2, \\ \\ \phi(0) = \phi(L) = \phi'(L) = 0 \quad \textit{when } 3/2 < s \le 3, \end{cases} \tag{1.16}$$

the IBVP (1.1)–(1.3) *admits a unique solution*

$$u \in C([0,T]; H^s(I)) \cap L^2(0,T; H^{s+1}(I)).$$

Moreover, the solution u *depends on its initial value continuously in the corresponding spaces.*[1]

Remarks.

(i) We may extend the theorem to include the nonhomogeneous boundary conditions as in [4]. But we choose not to do so here since our main concern is the long time behavior of solutions of (1.1)–(1.3).

(ii) The property that $\phi \in H^s(I)$ implies that the corresponding solution $u \in L^2(0,T; H^{s+1}(I))$ reveals a type of global Kato smoothing effect of the GKdV equation posed on a finite interval. This global Kato smoothing effect together with the property of persistence of regularity presented in Theorem 1.2 yields the following strong smoothing properties for solutions of (1.1)–(1.3):

$$\phi \in L^2(I) \Longrightarrow \ u \in C([\epsilon,T]; H^3(I)) \cap L^2(\epsilon,T; H^4(I)) \quad \text{for any } \epsilon > 0.$$

[1] If a is a real analytic function, then the solution u depends on its initial value analytically in the corresponding spaces (cf. [4, 39]).

In the case of $p \geq 2$, we have the following local well-posedness result.

THEOREM 1.3. *Suppose the growth condition* (1.4) *for* $a = a(\mu)$ *is satisfied with*

$$p \geq 2.$$

Then for any given $\phi \in H^s(I)$ *with* $s = 3$ *or with* 3 *satisfying the* s*-compatibility condition* (1.16) *there exists a* $T^* > 0$ *depending on* $\|\phi\|_{H^s(I)}$ *such that the IBVP* (1.1)–(1.3) *admits a unique solution* $u \in C([0,T^*]; H^s(I)) \cap L^2(0,T^*; H^{s+1}(I))$ *which depends on its initial value continuously.*

In order to get the global well-posedness results in the space $H^1(I)$ or $H^3(I)$, one needs some a priori H^1- or H^3-global estimate. However, those a priori estimates are not available. In fact, the only available a priori estimate for the IBVP (1.1)–(1.3) is an L^2-a priori estimate which is not sufficient to yield a global well-posedness result because we do not know if the IBVP (1.1)–(1.3) is locally well-posed in the space $L^2(I)$. Whether Theorem 1.3 can be extended to a global well-posedness result at least in the case of $2 \leq p < 4$ remains an interesting open question. On the other hand, when $2 \leq p < 4$, the following a priori estimates are known to hold for solutions of (1.1)–(1.3) (cf. Lemma 2.5 in section 2):

$$\|u(\cdot,T)\|^2_{L^2(I)} + \int_0^T (\partial_x u)^2(0,\tau)d\tau + \int_0^T \int_0^L b(x)u^2(x,\tau)dxd\tau = \|\phi\|^2_{L^2(I)}$$

and

$$\int_0^T \int_0^L |\partial_x u|^2 \, dxdt \leq \frac{L+(C+1)T}{2}||\phi||^2_{L^2(I)} + C_p T||\phi||^{\frac{8+2p}{4-p}}_{L^2(I)}.$$

Taking advantage of these estimates, we are able to establish the global existence of solutions of (1.1)–(1.3) in the space $L^2(I)$.

THEOREM 1.4. *Suppose the growth condition* (1.4) *for* $a = a(\mu)$ *is satisfied with*

$$1 \leq p < 4.$$

Then for any given $\phi \in L^2(I)$*, the IBVP* (1.1)–(1.3) *admits a solution*

$$u \in C_w(\mathbb{R}^+; L^2(I)) \cap L^2_{loc}(\mathbb{R}^+; H^1(I)).$$

Note that when $1 \leq p < 2$, a solution given by Theorem 1.4 is identical to the unique solution provided by Theorem 1.2.

With the well-posedness results in hand, we may then investigate the long time behavior of solutions. The following theorem is the main result of this paper.

THEOREM 1.5. *Under the assumptions of Theorem* 1.4*, assume additionally that the support* ω *of the function* b *in* (1.1) *contains a nonempty open subset of* $(0,L)$*. Then there exists a number* $\nu > 0$ *depending only on* L *and a nondecreasing continuous function* $\beta : \mathbb{R}^+ \to \mathbb{R}^+$ *such that for a given* $\phi \in L^2(I)$*, any solution* u *of* (1.1)–(1.3) *provided by Theorem* 1.4 *satisfies*

$$\|u(\cdot,t)\|_{L^2(I)} \leq \beta\big(\|\phi\|_{L^2(I)}\big)e^{-\nu t} \qquad \forall\ t \geq 0. \tag{1.17}$$

Remarks.

(1) Theorem 1.5 confirms positively the conjecture of Perla Menzala, Vasconcellos, and Zuazua [24] for the GKdV equation.

(2) The decay rate ν in Theorem 1.5 depends only on L and does not, in particular, depend on the size of the initial value ϕ in the space $L^2(I)$. The system (1.1)–(1.3) is globally uniformly exponentially stable.

Theorem 1.5 will be proved by the same compactness-uniqueness argument used by Perla Menzala, Vasconcellos, and Zuazua [24]. The key is to establish the following unique continuation property for the solution of the GKdV equation.

Unique continuation property. Let ω be the support of b in the interval I. If $v \in L^\infty(0,T;L^2(I)) \cap L^2(0,T;H^1(I))$ solves

$$\begin{cases} \partial_t v + \partial_x v + a(v)\partial_x v + \partial_x^3 v = 0, \quad 0 \le x \le L, \quad t \ge 0, \\ \\ v(0,t) = 0, \quad v(L,t) = 0, \quad \partial_x v(L,t) = 0 \end{cases}$$

and, in addition, satisfies

$$\partial_x v(0,t) = 0 \qquad \forall\ t \in (0,T)$$

and

$$v(x,t) = 0 \qquad \forall\ (x,t) \in \omega \times (0,T),$$

then v vanishes on $I \times (0,T)$.

When $1 \le p < 2$, the solution v, in fact, belongs to the space $C([\epsilon,T];H^3(I))$ for any $0 < \epsilon < T$ thanks to the strong smoothing property of the GKdV equation (cf. Remark (ii) of Theorem 1.2). Thus v vanishes on the whole domain $I \times (0,T)$ by the standard unique continuation property of the KdV-type equation (cf. [32, 37]). When $2 \le p < 4$, we cannot use the standard unique continuation property because we do not know if $v \in C([\epsilon,T];H^3(I))$. Instead, we will use a new unique continuation property for the GKdV equation as described below.

THEOREM 1.6. *Let $0 < l < L$ and $T > 0$. If $w \in L^\infty(0,T;H^1(0,l))$ solves*

$$\begin{cases} \partial_t w + \partial_x w + a(w)\partial_x w + \partial_x^3 w = 0 & \text{in } (0,l) \times (0,T), \\ w(0,t) = 0 & \text{for a.e. } t \in (0,T), \\ w \equiv 0 & \text{in } (l',l) \times (0,T) \end{cases}$$

with $a \in C^0(\mathbb{R};\mathbb{R})$ and $0 < l' < l$, then $w \equiv 0$ in $(0,l) \times (0,T)$.

The proof of this unique continuation property is mainly based on a key Carleman estimate for the KdV equation established earlier by Rosier [27] (see also Lemma 3.4 in section 3).

When $1 \le p < 2$, for a given $\phi \in L^2(I)$, (1.1)–(1.3) admits a unique solution u which not only decays exponentially in the space $L^2(I)$ but also in the space $H^3(I)$ as described by the following theorem.

THEOREM 1.7. *Under the assumption of Theorem* 1.2, *assume additionally that the support ω of the function b in* (1.1) *contains a nonempty open subset of $(0,L)$. Then there exists a number $\nu > 0$ depending only on L and a continuous function $\alpha : \mathbb{R}^+ \times \mathbb{R}^+ \to \mathbb{R}^+$ such that for any $\varepsilon > 0$ and any $\phi \in L^2(I)$, the corresponding solution u of* (1.1)–(1.3) *satisfies*

$$\|u(\cdot,t)\|_{H^3(I)} \le \alpha\big(\|\phi\|_{L^2(I)}, \epsilon\big) e^{-\nu t} \qquad \forall\ t \ge \epsilon. \tag{1.18}$$

The paper is organized as follows. In section 2, we study the well-posedness problem of the IBVP (1.1)–(1.3) and provide the proofs of Theorems 1.2, 1.3, and 1.4. In section 3, the long time behavior of solutions of (1.1)–(1.3) is investigated.

2. Well-posedness. In this section, attention will be given to the nonlinear IBVP

$$\begin{cases} \partial_t u + \partial_x u + a(u)\partial_x u + \partial_x^3 u + b(x)u = 0, \quad u(x,0) = \phi(x), \quad x \in (0,L), \\ \\ u(0,t) = 0, \quad u(L,t) = 0, \quad \partial_x u(L,t) = 0 \end{cases} \tag{2.1}$$

for its well-posedness in the classical Sobolev space $H^s(I)$.

Considered first is the linear problem

$$\begin{cases} \partial_t u + \partial_x u + \partial_x^3 u = 0, \quad u(x,0) = \phi(x)\,, \quad x \in (0,L), \\ \\ u(0,t) = 0, \quad u(L,t) = 0, \quad \partial_x u(L,t) = 0 \end{cases} \tag{2.2}$$

with homogeneous boundary conditions and no forcing. Let A be the linear operator defined by

$$Af = -f''' - f'$$

with the domain

$$\mathcal{D}(A) = \{f \in H^3(I),\ f(0) = f(L) = f'(L) = 0\}.$$

The IBVP (2.2) can be written as the initial value problem of an abstract evolution equation in the space $L^2(I)$, namely

$$\frac{du}{dt} = Au, \qquad u(0) = \phi, \tag{2.3}$$

where the spatial variable is suppressed. It is easily verified that both A and its adjoint A^* are dissipative, i.e.,

$$\Big\langle Af, f \Big\rangle_{L^2(I)} \le 0, \qquad \Big\langle A^* g, g \Big\rangle_{L^2(I)} \le 0$$

for any $f \in \mathcal{D}(A)$ and $g \in \mathcal{D}(A^*)$, where $A^* g = g''' + g'$ and

$$\mathcal{D}(A^*) = \{f \in H^3(0,L);\ f(0) = f'(0) = f(L) = 0\}.$$

Thus the operator A is the infinitesimal generator of a C_0-semigroup $W(t)$ in the space $L^2(I)$ (see [23]). By semigroup theory (see [23]), in this situation in the overlying space $L^2(I)$, for any $\phi \in L^2(I)$,

$$u(t) = W(t)\phi$$

belongs to the space $C_b(\mathbb{R}^+; L^2(I))$. The function u thus defined is called a *mild solution* of (2.2). Such solutions certainly solve (2.2) in the sense of distributions. If $\phi \in \mathcal{D}(A)$, then $u(t) = W(t)\phi$ belongs to the space $C(\mathbb{R}^+; H^3(I)) \cap C^1(\mathbb{R}^+; L^2(I))$ and $u(t) \in \mathcal{D}(A)$ for all $t \ge 0$. Moreover, the equation is satisfied in the sense of $C(\mathbb{R}^+; L^2(I))$ and, in particular, pointwise a.e. Such solutions are called *strong solutions*.

LEMMA 2.1. *For any $\phi \in L^2(I)$, $u(t) = W(t)\phi$ satisfies*

$$\|u(\cdot,t)\|^2_{L^2(I)} + \int_0^t (\partial_x u)^2(0,\tau)d\tau = \|\phi\|^2_{L^2(I)}, \tag{2.4}$$

$$\int_0^L xu^2(x,t)dx + 3\int_0^t\int_0^L (\partial_x u)^2(x,\tau)dxd\tau \le (L+t)\int_0^L \phi^2(x)dx \tag{2.5}$$

for any $t \ge 0$. Moreover, u has the property

$$\partial_x u \in C_b([0,L]; L_t^2(\mathbb{R}^+)),$$

and there exists a constant C such that

$$\sup_{x\in I} \|\partial_x u(x,\cdot)\|_{L^2(\mathbb{R}^+)} \le C\|\phi\|_{L^2(I)}. \tag{2.6}$$

Proof. See [4]. □

Note that estimate (2.6) for $W(t)$ reveals a sharp Kato smoothing effect of the system described by the IBVP (2.2). Next, attention is turned to the inhomogeneous linear problem

$$\begin{cases} \partial_t u + \partial_x u + \partial_x^3 u = f(x,t), \qquad u(x,0) = 0\,, \\ \\ u(0,t) = 0, \quad u(L,t) = 0, \quad \partial_x u(L,t) = 0\,. \end{cases} \tag{2.7}$$

In terms of the operator A defined above, one may write (2.7) as an initial value problem for an abstract nonhomogeneous evolution equation, namely

$$\frac{du}{dt} = Au + f, \qquad u(0) = 0. \tag{2.8}$$

By standard semigroup theory (see again [23]), for any $f \in L^1_{loc}(\mathbb{R}^+; L^2(I))$,

$$u(t) = \int_0^t W(t-\tau)f(\tau)d\tau \tag{2.9}$$

belongs to the space $C(\mathbb{R}^+; L^2(I))$ and is called a mild solution of (2.8). It is a weak solution of (2.7) in the sense of distributions. In addition, if $f(t) \in \mathcal{D}(A)$ for $t > 0$ and $Af \in L^1_{loc}(\mathbb{R}^+; L^2(I))$, then $u(t)$ given by (2.9) solves (2.8) a.e. on $[0,T)$ and is called a strong solution of (2.8).

LEMMA 2.2. *There exists a constant C such that for any $f \in L^1_{loc}(\mathbb{R}^+; L^2(I))$, the solution u of* (2.7) *satisfies*

$$\|u(\cdot,t)\|_{L^2(I)} + \|\partial_x u(0,\cdot)\|_{L^2(0,t)} \le C\|f\|_{L^1(0,t;L^2(I))} \tag{2.10}$$

and

$$\int_0^L xu^2(x,t)dx + \int_0^t\int_0^L (\partial_x u)^2(x,\tau)dxd\tau \le C(L+t)\|f\|^2_{L^1(0,t;L^2(I))} \tag{2.11}$$

for any $t \ge 0$. Moreover, the solution u has the property

$$\partial_x u \in C_b([0,L]; L_t^2(\mathbb{R}^+)),$$

and there exists a constant C such that

$$\sup_{x\in I} \|\partial_x u(x,\cdot)\|_{L^2(\mathbb{R}^+)} \le C\|f\|_{L^1(0,t;L^2(I))}. \tag{2.12}$$

Proof. See [4]. □

For any $T > 0$ and $0 \le s \le 3$, let X_s be the collection of all functions ϕ in the space $H^s(I)$ satisfying the compatibility conditions (1.16) with its usual topology, and let $Y_{s,T}$ be the collection of

$$v \in C([0,T]; X_s) \cap L^2([0,T]; H^{s+1}(I))$$

with $\partial_x v \in C([0,L]; L^2(0,T))$. A norm $\|\cdot\|_{Y_{s,T}}$ on the space $Y_{s,T}$ is defined by

$$\|v\|_{Y_{s,T}} := \left(\|v\|^2_{C([0,T];H^s(I))} + \|v\|^2_{L^2([0,T];H^{s+1}(I))} + \|\partial_x v\|^2_{C([0,L];L^2(0,T))} \right)^{1/2}$$

for $v \in Y_{s,T}$.

LEMMA 2.3. *Let a be a C^0 function satisfying*

$$|a(\mu)| \le C(1 + |\mu|^p) \quad \text{for any } \mu \in \mathbb{R}$$

with $0 \le p \le 2$. There exists a constant C such that for any $T > 0$ and u, $v \in Y_{0,T}$,

$$\int_0^T \|a(u(\cdot,t))\partial_x v(\cdot,t)\|_{L^2(I)} dt \le CT^{(2-p)/4} \|u\|^p_{Y_{0,T}} \|v\|_{Y_{0,T}} + CT^{1/2} \left(1 + \|u\|^p_{Y_{0,T}}\right) \|v\|_{Y_{0,T}}.$$

Proof. Using the assumption on the function a and the inequality

$$\|u(\cdot,t)\|_{L^\infty(I)} \le C \left(\|u(\cdot,t)\|_{L^2(I)} + \|u(\cdot,t)\|^{\frac{1}{2}}_{L^2(I)} \|\partial_x u(\cdot,t)\|^{\frac{1}{2}}_{L^2(I)} \right),$$

one obtains

$$\|a(u(\cdot,t))\partial_x v(\cdot,t)\|_{L^2(I)} \le C\|u(\cdot,t)\|^p_{L^\infty(I)} \|\partial_x v(\cdot,t)\|_{L^2(I)} + C\|\partial_x v(\cdot,t)\|_{L^2(I)}$$

$$\le C\|u(\cdot,t)\|^{p/2}_{L^2(I)} \|\partial_x u(\cdot,t)\|^{p/2}_{L^2(I)} \|\partial_x v(\cdot,t)\|_{L^2(I)} + C\left(1 + \|u(\cdot,t)\|^p_{L^2(I)}\right) \|\partial_x v(\cdot,t)\|_{L^2(I)}.$$

The first term, when integrated with respect to t, is bounded as follows:

$$\int_0^T \|u(\cdot,t)\|^{p/2}_{L^2(I)} \|\partial_x u(\cdot,t)\|^{p/2}_{L^2(I)} \|\partial_x v(\cdot,t)\|_{L^2(I)} dt$$

$$\le \sup_{0\le t\le T} \|u(\cdot,t)\|^{p/2}_{L^2(I)} \left(\int_0^T \|\partial_x u(\cdot,t)\|^2_{L^2(I)} dt \right)^{p/4} \left(\int_0^T \|\partial_x v(\cdot,t)\|^{4/(4-p)}_{L^2(I)} dt \right)^{(4-p)/4}$$

$$\le T^{(2-p)/4} \|u\|^p_{Y_{0,T}} \|v\|_{Y_{0,T}}$$

if $0 \le p \le 2$. Thus

$$\int_0^T \|a(u(\cdot,t))\partial_x v(\cdot,t)\|_{L^2(I)} dt \le C2^{p/2} T^{(2-p)/4} \|u\|^p_{Y_{0,T}} \|v\|_{Y_{0,T}} + CT^{1/2} \left(1 + \|u\|^p_{Y_{0,T}}\right) \|v\|_{Y_{0,T}}.$$

The proof is complete. □

LEMMA 2.4. *There exists a constant C depending only on L such that for any $T > 0$, $1 \le p \le 2$, $b \in L^2(I)$, and u, v, $w \in Y_{0,T}$,*

$$\int_0^T \|bu\|_{L_x^2(I)} dt \le CT^{1/2} \|b\|_{L^2(I)} \|u\|_{Y_{0,T}}, \tag{2.13}$$

$$\int_0^T \|u\partial_x w\|_{L_x^2(I)} dt \le CT^{1/4} \|u\|_{Y_{0,T}} \|w\|_{Y_{0,T}}, \tag{2.14}$$

$$\int_0^T \|u|w|^{p-1}\partial_x w\|_{L_x^2(I)} dt \le CT^{(2-p)/4} \|u\|_{Y_{0,T}} \|w\|_{Y_{0,T}}^p, \tag{2.15}$$

and

$$\int_0^T \|u|v|^{p-1}\partial_x w\|_{L_x^2(I)} dt \le CT^{(2-p)/4} \|u\|_{Y_{0,T}} \|w\|_{Y_{0,T}} \|v\|_{Y_{0,T}}^{p-1}. \tag{2.16}$$

Proof. The estimate (2.13) follows from the direct calculation

$$\int_0^T \left(\int_0^L |b(x)|^2 |u(x,t)|^2 dx \right)^{\frac{1}{2}} dt \le \int_0^T \sup_{x\in(0,L)} |u(x,t)| \left(\int_0^L |b(x)|^2 dx \right)^{\frac{1}{2}} dt$$
$$\le CT^{\frac{1}{2}} \|b\|_{L^2(I)} \|u\|_{Y_{0,T}}.$$

The other estimates can be proved by a similar argument as that in the proof of Lemma 2.3 and are therefore omitted. The proof is complete. □

Now we turn to the nonlinear problem (2.1). We first present the following global a priori estimates for solutions of the IBVP (2.1).

LEMMA 2.5. *Let a be a C^0 function satisfying*

$$|a(\mu)| \le C(1 + |\mu|^p) \quad \text{for any } \mu \in \mathbb{R}$$

with $0 \le p < 4$. There exists a constant C_p such that for any smooth solution u of (2.1), the following estimates hold:

$$\|u(\cdot,T)\|_{L^2(I)}^2 + \int_0^T (\partial_x u)^2(0,\tau) d\tau + 2\int_0^T \int_0^L b(x) u^2(x,\tau) dx d\tau = \|\phi\|_{L^2(I)}^2 \tag{2.17}$$

and

$$\int_0^T \int_0^L |\partial_x u|^2 \, dx dt \le \frac{L + (C+1)T}{2} ||\phi||_{L^2(I)}^2 + C_p T ||\phi||_{L^2(I)}^{\frac{8+2p}{4-p}} \tag{2.18}$$

for any $T > 0$.

Proof. Multiply both sides of the equation in (2.1) by u and integrate with respect to x over the interval I and about t over the interval $(0,T)$. An integration by parts leads directly to the equality (2.17). To prove the inequality (2.18), let us first introduce the functions

$$A(u) := \int_0^u a(v)\, dv, \qquad \tilde{A}(u) := \int_0^u v a(v)\, dv.$$

Multiplying both sides of the equation in (2.1) by xu and integrating over $(0,L)\times(0,T)$, we obtain after some integrations by parts

$$\frac{1}{2}\left(\int_0^L x|u(x,T)|^2dx-\int_0^L x|\phi(x)|^2dx\right)+\frac{3}{2}\int_0^T\int_0^L|\partial_x u|^2dxdt-\frac{1}{2}\int_0^T\int_0^L|u|^2dxdt$$
$$-\int_0^T\int_0^L\tilde{A}(u)\,dxdt+\int_0^T\int_0^L xb(x)|u|^2dxdt=0.$$

Combining this equality with (2.17), we obtain

$$\frac{3}{2}\int_0^T\int_0^L|\partial_x u|^2dxdt\le\frac{L+T}{2}||\phi||^2_{L^2(I)}+\int_0^T\int_0^L\tilde{A}(u)\,dxdt. \tag{2.19}$$

We infer from the assumption on a that

$$|\tilde{A}(u)|\le C\left(\frac{u^2}{2}+\frac{|u|^{p+2}}{p+2}\right).$$

Hence

$$\begin{aligned}\left|\int_0^T\int_0^L\tilde{A}(u)\,dxdt\right|&\le\frac{C}{2}\int_0^T\int_0^L|u|^2dxdt+\frac{C}{p+2}\int_0^T\int_0^L|u|^{p+2}dxdt\\&\le\frac{CT}{2}||\phi||^2_{L^2(I)}+\frac{C}{p+2}\int_0^T||u||^2_{L^2(I)}\cdot||u||^p_{L^\infty(I)}dt\\&\le\frac{CT}{2}||\phi||^2_{L^2(I)}+\frac{2^{\frac{p}{2}}C}{p+2}\int_0^T||u||^{2+\frac{p}{2}}_{L^2(I)}\cdot||\partial_x u||^{\frac{p}{2}}_{L^2(I)}\,dt\\&\le\frac{CT}{2}||\phi||^2_{L^2(I)}+\frac{2^{\frac{p}{2}}CT^{1-\frac{p}{4}}}{p+2}||\phi||^{2+\frac{p}{2}}_{L^2(I)}\left(\int_0^T||\partial_x u||^2_{L^2(I)}dt\right)^{\frac{p}{4}}\\&\le\frac{CT}{2}||\phi||^2_{L^2(I)}+C_pT||\phi||^{\frac{8+2p}{4-p}}_{L^2(I)}+\frac{1}{2}\int_0^T\int_0^L|\partial_x u|^2dxdt\end{aligned} \tag{2.20}$$

for some positive constant C_p which depends only on C and p. The inequality (2.18) then follows from (2.19) and (2.20). The proof is complete. □

We now present our first well-posedness result for the IBVP (2.1).

PROPOSITION 2.6. *Let a be a C^1 function satisfying*

$$|a(\mu)|\le C(1+|\mu|^p),\quad |a'(\mu)|\le C(1+|\mu|^{p-1})\quad \text{for any } \mu\in\mathbb{R}$$

with $1\le p<2$, and let $T>0$ be given. For any $\phi\in X_0$, the IBVP (2.1) admits a unique solution $u\in Y_{0,T}$, which also satisfies

$$\|u\|_{Y_{0,T}}\le\beta_0(\|\phi\|_{X_0})\|\phi\|_{X_0}, \tag{2.21}$$

where $\beta_0:\mathbb{R}^+\to\mathbb{R}^+$ is a nondecreasing continuous function. Moreover, the corresponding solution map is locally Lipschitz continuous; for any ϕ, $\psi\in X_0$, the corresponding solutions u and v of (2.1) satisfy

$$\|u-v\|_{Y_{0,T}}\le\beta_0(\|\phi\|_{X_0}+\|\psi\|_{X_0})\|\phi-\psi\|_{X_0}. \tag{2.22}$$

Proof. Write the IBVP (2.1) in its integral equation form

$$u(t) = W(t)\phi - \int_0^t W(t-\tau)\Big[(a(u)\partial_x u)(\tau) + (bu)(\tau)\Big]d\tau, \tag{2.23}$$

where the spatial variable is suppressed throughout. For given $\phi \in X_0$, let $r > 0$ and $\theta > 0$ be constants to be determined. Let

$$S_{\theta,r} = \{v \in Y_{0,\theta},\ \|v\|_{Y_{0,\theta}} \le r\}.$$

The set $S_{\theta,r}$ is a closed, convex, and bounded subset of the space $Y_{0,\theta}$ and therefore is a complete metric space in the topology induced from $Y_{0,\theta}$. Define a map Γ on $S_{\theta,r}$ by

$$\Gamma(v) = W(t)\phi - \int_0^t W(t-\tau)\Big[(a(v)\partial_x v)(\tau) + (bv)(\tau)\Big]d\tau$$

for $v \in S_{\theta,r}$. Applying Lemmas 2.2, 2.3, and 2.4, it is adduced that there are constants C_0, C_1, and C_2 for which

$$\begin{aligned}\|\Gamma(v)\|_{Y_{0,\theta}} &\le C_0\|\phi\|_{X_0} + C_1\int_0^\theta \Big[\|a(v)\partial_x v(\cdot,\tau)\|_{L^2(I)} + \|bv(\cdot,\tau)\|_{L^2(I)}\Big]d\tau \\ &\le C_0\|\phi\|_{X_0} + C_1\theta^{(2-p)/4}\|v\|_{Y_{0,\theta}}^{p+1} + C_2\theta^{\frac{1}{2}}(\|b\|_{L^2(I)}+1)\|v\|_{Y_{0,\theta}} \\ &\le C_0\|\phi\|_{X_0} + C_1\theta^{(2-p)/4}r^p\|v\|_{Y_{0,\theta}} + C_2\theta^{\frac{1}{2}}(\|b\|_{L^2(I)}+1)\|v\|_{Y_{0,\theta}}\end{aligned}$$

for any $v \in S_{r,\theta}$. In addition, for any $v,\ w \in S_{r,\theta}$,

$$\begin{aligned}\Gamma(v) - \Gamma(w) &= \int_0^t W(t-\tau)\big[a(v)\partial_x v - a(w)\partial_x w + b(v-w)\big]d\tau \\ &= \int_0^t W(t-\tau)\big[a(v)\partial_x(v-w) + (a(v)-a(w))\partial_x w + b(v-w)\big]d\tau.\end{aligned}$$

Thus

$$\begin{aligned}\|\Gamma(v) - \Gamma(w)\|_{Y_{0,\theta}} &\le C_1\int_0^\theta \big[\|a(v)\partial_x(v-w)\|_{L^2_x(I)} \\ &\qquad + \|(a(v)-a(w))\partial_x w\|_{L^2_x(I)} + \|b(v-w)\|_{L^2_x(I)}\big]\,d\tau \\ &\le C_1\int_0^\theta \big[\|a(v)\partial_x(v-w)\|_{L^2_x(I)} + \|\left(1+|v|^{p-1}+|w|^{p-1}\right)(v-w)\partial_x w\|_{L^2_x(I)} \\ &\qquad + \|b(v-w)\|_{L^2_x(I)}\big]\,d\tau \\ &\le C_1\theta^{\frac{2-p}{4}}\Big(\|v\|_{Y_{0,\theta}}^p + \|w\|_{Y_{0,\theta}}^p + \|v\|_{Y_{0,\theta}}^{p-1}\|w\|_{Y_{0,\theta}}\Big)\|v-w\|_{Y_{0,\theta}} \\ &\qquad + C_1\theta^{1/4}\|w\|_{Y_{0,\theta}}\|v-w\|_{Y_{0,\theta}} + C_2\theta^{\frac{1}{2}}(\|b\|_{L^2(I)}+1)\|v-w\|_{Y_{0,\theta}} \\ &\le 3C_1\theta^{\frac{2-p}{4}}r^p\|v-w\|_{Y_{0,\theta}} + C_1\theta^{1/4}r\|v-w\|_{Y_{0,\theta}} + C_2\theta^{\frac{1}{2}}(\|b\|_{L^2(I)}+1)\|v-w\|_{Y_{0,\theta}}.\end{aligned}$$

Choosing $r > 0$ and $\theta > 0$ so that

$$\begin{cases} r = 2C_0\|\phi\|_{X_0}, \\ \\ 3C_1\theta^{(2-p)/4}r^p + C_1\theta^{1/4}r + C_2\theta^{1/2}(\|b\|_{L^2(I)} + 1) \le \frac{1}{2}, \end{cases} \tag{2.24}$$

then

$$\|\Gamma(v)\|_{Y_{0,\theta}} \le r, \qquad \|\Gamma(v) - \Gamma(w)\|_{Y_{0,\theta}} \le \frac{1}{2}\|v - w\|_{Y_{0,\theta}}$$

for any v, $w \in S_{\theta,r}$. Thus, with such a choice of r and θ, Γ is a contraction mapping of $S_{r,\theta}$. Its fixed point $u = \Gamma(u)$ is the unique solution of the IBVP (2.1) in $S_{\theta,r}$. Note that θ depends only on $\|\phi\|_{X_0}$ and

$$\sup_{0\le t\le\theta} \|u(\cdot,t)\|_{L^2(I)} \le \|\phi\|_{X_0}.$$

By the standard extension argument, one may extend θ to T. The proof is complete. □

Next, we show that the IBVP (2.1) is well-posed in the space X_3.

PROPOSITION 2.7. *Let $b \in H^1(I)$, let a be a C^1 function satisfying*

$$|a(\mu)| \le C(1 + |\mu|^p), \quad |a'(\mu)| \le C(1 + |\mu|^{p-1}) \quad \textit{for any } \mu \in \mathbb{R}$$

with $1 \le p < 2$, and let $T > 0$ be given. For any $\phi \in X_3$, the IBVP (2.1) admits a unique solution $u \in Y_{3,T}$. Moreover, there exists a nondecreasing continuous function $\beta_3 : \mathbb{R}^+ \to \mathbb{R}^+$ such that

$$\|u\|_{Y_{3,T}} \le \beta_3(\|\phi\|_{X_0})\|\phi\|_{X_3}. \tag{2.25}$$

Proof. By Proposition 2.6, (2.1) admits a unique solution $u \in Y_{0,T}$. We just need to show further that $u \in Y_{3,T}$. For this purpose, let $v = u_t$. Then the function v is a solution of

$$\begin{cases} \partial_t v + \partial_x v + \big(a'(u)\partial_x u\big)v + a(u)\partial_x v + \partial_x^3 v + b(x)v = 0, \\ \\ v(x,0) = \phi^*(x), \\ \\ v(0,t) = 0, \quad v(L,t) = 0, \quad \partial_x v(L,t) = 0 \end{cases} \tag{2.26}$$

with

$$\phi^*(x) = -\phi'''(x) - \phi'(x) - a(\phi(x))\phi'(x) - b(x)\phi(x).$$

Observe that $\phi^* \in X_0$ and that there exists a constant $C = C(\|\phi\|_{X_0})$ such that

$$\|\phi^*\|_{X_0} \le C\|\phi\|_{X_3}.$$

We may write (2.26) in its integral form

$$v(t) = W(t)\phi^* - \int_0^t W(t-\tau)\Big(a'(u(\cdot,\tau))\partial_x u(\cdot,\tau)v(\cdot,\tau) + a(u(\cdot,\tau))\partial_x v(\cdot,\tau) + b(\cdot)v(\cdot,\tau)\Big)d\tau.$$

Using Lemma 2.4 and proceeding as in the proof of Proposition 2.6, we see that (2.26) admits a unique solution $v \in Y_{0,T}$. Notice that $u_t = v$, $b \in H^1(I)$, and $u \in$

$Y_{0,T}$. Since $u \in H^1(0,T;H^1(I)) \subset C([0,T];C(\bar{I}))$, we obviously have that $a(u)\partial_x u \in L^2(0,T;L^2(I))$. It then follows from

$$\partial_x^3 u = -\partial_t u - \partial_x u - b(x)u - a(u)\partial_x u = -v - \partial_x u - b(x)u - a(u)\partial_x u \tag{2.27}$$

that $u \in L^2(0,T;H^3(I))$; hence $u \in C([0,T];H^2(I))$. This implies further that $\partial_x u$, bu, and $a(u)\partial_x u$ all belong to the space $C([0,T];L^2(I)) \cap L^2(0,T;H^1(I))$. Using (2.27) again yields that $u \in Y_{3,T}$. The proof is complete. □

According to Propositions 2.6 and 2.7, the IBVP (2.1) defines a continuous nonlinear map K from the space X_j to $Y_{j,T}$ for $j = 0, 3$. Next, we show that K is a continuous map from X_s to $Y_{s,T}$ for $0 \le s \le 3$ by using the following nonlinear interpolation theory (cf. [35, 1]), which implies the well-posedness of the IBVP (2.1) in the space X_s for $0 \le s \le 3$.

Let B_0 and B_1 be two Banach spaces such that $B_1 \subset B_0$ with the inclusion map continuous. Let $f \in B_0$ and, for $t \ge 0$, define

$$K(f,t) = \inf_{g \in B_1} \{\|f-g\|_{B_0} + t\|g\|_{B_1}\}.$$

For $0 < \theta < 1$ and $1 \le p \le +\infty$, define

$$[B_0, B_1]_{\theta,p} = B_{\theta,p} = \left\{ f \in B_0 : \ \|f\|_{\theta,p} = \left(\int_0^{+\infty} K(f,t)^p t^{-\theta p - 1} dt \right)^{1/p} < +\infty \right\}$$

with the usual modification for the case $p = +\infty$. Then $B_{\theta,p}$ is a Banach space with norm $\| \ \|_{\theta,p}$. Given two pairs of indices (θ_1, p_1) and (θ_2, p_2) as above, then $(\theta_1, p_1) \prec (\theta_2, p_2)$ means

$$\begin{cases} \theta_1 < \theta_2 & \text{or} \\ \\ \theta_1 = \theta_2 & \text{and } p_1 > p_2. \end{cases}$$

If $(\theta_1, p_1) \prec (\theta_2, p_2)$, then $B_{\theta_2,p_2} \subset B_{\theta_1,p_1}$ with the inclusion map continuous.

THEOREM 2.8. *Let B_0^j and B_1^j be Banach spaces such that $B_1^j \subset B_0^j$ with continuous inclusion mappings, $j = 1, 2$. Let λ and q lie in the ranges $0 < \lambda < 1$ and $1 \le q \le +\infty$. Suppose A is a mapping such that*

(i) *$A : \ B^1_{\lambda,q} \to B_0^2$ and for $f, \ g \in B^1_{\lambda,q}$,*

$$\|Af - Ag\|_{B_0^2} \le C_0(\|f\|_{B^1_{\lambda,q}} + \|g\|_{B^1_{\lambda,q}})\|f-g\|_{B_0^1}$$

and

(ii) *$A : \ B_1^1 \to B_1^2$ and for $h \in B_1^1$,*

$$\|Ah\|_{B_1^2} \le C_1(\|h\|_{B^1_{\lambda,q}})\|h\|_{B_1^1},$$

where $C_j : \ \mathbb{R}^+ \to \mathbb{R}^+$ are continuous nondecreasing functions, $j = 0, 1$. Then if $(\theta, p) \ge (\lambda, q)$, A maps $B^1_{\theta,p}$ into $B^2_{\theta,p}$ and for $f \in B^1_{\theta,p}$,

$$\|Af\|_{B^2_{\theta,p}} \le C(\|f\|_{B^1_{\lambda,q}})\|f\|_{B^1_{\theta,p}},$$

where for $r > 0$, $C(r) = 4C_0(4r)^{1-\theta}C_1(3r)^{\theta}$.

Remark. This theorem is identical to Theorem 2 of Tartar [35] except that Tartar makes the more restrictive assumption that the nondecreasing functions C_0 and C_1

depend only on the B_0^1 norms of the functions in question. Theorem 2.8 was used by Bona and Scott [1] to prove the global well-posedness of the pure initial value problem for the KdV equation on the whole line in fractional order Sobolev spaces $H^s(\mathbb{R})$.

Here is the promised well-posedness result for the IBVP (2.1) in X_s.

THEOREM 2.9. *Let a be a C^1 function satisfying*

$$|a(\mu)| \le C(1+|\mu|^p), \quad |a'(\mu)| \le C(1+|\mu|^{p-1}) \quad \text{for any } \mu \in \mathbb{R} \tag{2.28}$$

with $1 \le p < 2$, and let $T > 0$ and $0 \le s \le 3$ be given. In addition, assume $b \in L^2(I)$ when $s = 0$ and $b \in H^1(I)$ when $s > 0$. Then, for any $\phi \in X_s$, the IBVP (2.1) admits a unique solution $u \in Y_{s,T}$. Moreover, there exists a nondecreasing continuous function $\beta_s : \mathbb{R}^+ \to \mathbb{R}^+$ such that

$$\|u\|_{Y_{s,T}} \le \beta_s(\|\phi\|_{X_0})\|\phi\|_{X_s}.$$

Proof. Choose

$$B_0^1 = X_0, \quad B_1^1 = X_3, \quad B_0^2 = Y_{0,T}, \quad B_1^2 = Y_{3,T}.$$

Let A be the solution map of the IBVP (2.1): $u = A(\phi)$. For given s with $0 < s < 3$, choose $p = 2$ and $\theta = s/3$. Then

$$B_{\theta,p}^2 = Y_{s,T}, \qquad B_{\theta,p}^1 = X_s.$$

In this case, assumptions (i) and (ii) of Theorem 2.8 are (2.22) and (2.25), respectively, which we have already proved. The proof is then completed by invoking Theorem 2.8. □

By Theorem 2.9, the condition $\phi \in X_s$ implies that the corresponding solution $u \in L^2(0,T;H^{s+1}(I))$. Thus, for any $0 < \epsilon < T$, one can always find a time $t_1 \in (0,\epsilon)$ such that $u(\cdot,t_1) \in H^{s+1}(I)$. The following corollary, which reveals a strong smoothing property of the system (2.1), follows directly from Theorem 2.9.

COROLLARY 2.10. *Under the assumptions of Theorem 2.9, for any $\phi \in L^2(I)$, the corresponding solution u of (2.1) belongs to the space $C([\epsilon,T];H^3(I)) \cap L^2(\epsilon,T;H^4(I))$ for any $\epsilon > 0$.*

In Theorem 2.9, the nonlinear term $a(u)$ of the equation in (2.1) is required to satisfy (2.28) with $1 \le p < 2$. We consider next the case of $p \ge 2$.

Let $\mathcal{B}$ be the linear operator defined by $\mathcal{B}f = b(x)f$. Consider $A_b = A + \mathcal{B}$ as an unbounded operator on $L^2(I)$ with the domain

$$\mathcal{D}(A_b) = \{f \in H^3(I),\ f(0) = f(L) = f'(L) = 0\}.$$

The operator A_b is the infinitesimal generator of a C_0-semigroup $W_b(t)$ in the space $L^2(I)$. For any $\phi \in L^2(I)$,

$$u(t) = W_b(t)\phi$$

belongs to the space $C_b(\mathbb{R}^+;L^2(I))$ and solves

$$\begin{cases} \partial_t u + \partial_x u + \partial_x^3 u + b(x)u = 0, \qquad u(x,0) = \phi(x)\,, \\ \\ u(0,t) = 0, \quad u(L,t) = 0, \quad \partial_x u(L,t) = 0. \end{cases} \tag{2.29}$$

LEMMA 2.11. *Let $T > 0$ and $0 \le s \le 3$ be given. Assume that $b \in L^2(I)$ if $s = 0$ and $b \in H^1(I)$ if $s > 0$. Then there exists a constant C depending only on T and s such that*

$$\|W_b(t)\phi\|_{Y_{s,T}} \le C\|\phi\|_{X_s} \quad \text{for any } \phi \in X_s \tag{2.30}$$

and

$$\left\|\int_0^t W_b(t-\tau)f(\cdot,\tau)d\tau\right\|_{Y_{s,T}} \le C\|f\|_{L^1(0,T;H^s(I))} \quad \text{for any } f \in L^1(0,T;X_s). \tag{2.31}$$

Proof. The estimate (2.30) is established by using a similar (but simpler, because there is no nonlinear term in the equation) argument as that used in the proof of Theorem 2.9. To see that (2.31) is true, note that

$$\begin{aligned}\left\|\int_0^t W_b(t-\tau)f(\cdot,\tau)d\tau\right\|_{C([0,T];H^s(I))} &\le \int_0^T \|W_b(t-\tau)f(\cdot,\tau)\|_{C([\tau,T]_t;H^s(I))}\,d\tau \\ &\le C\int_0^T \|f(\cdot,\tau)\|_{H^s(I)}d\tau\end{aligned}$$

and

$$\begin{aligned}\left\|\int_0^t W_b(t-\tau)f(\cdot,\tau)d\tau\right\|_{L^2(0,T;H^{s+1}(I))} &\le \int_0^T \|W_b(t-\tau)f(\cdot,\tau)\|_{L^2([\tau,T]_t;H^{s+1}(I))}\,d\tau \\ &\le C\int_0^T \|f(\cdot,\tau)\|_{H^s(I)}d\tau.\end{aligned}$$

Moreover, using the same argument as that used in the proof of Proposition 2.17 in [4] yields

$$\sup_{x\in I}\left\|\partial_x\int_0^t W_b(t-\tau)f(\cdot,\tau)d\tau\right\|_{L^2(0,T)} \le C\int_0^T \|f(\cdot,\tau)\|_{H^s(I)}d\tau.$$

Inequality (2.31) then follows by combining the above three estimates. The proof is complete. □

We have the following estimate by direct calculation.

LEMMA 2.12. *Let a be a C^1 function satisfying*

$$|a(\mu)| \le C(1+|\mu|^p), \quad |a'(\mu)| \le C(1+|\mu|^{p-1}) \quad \text{for any } \mu \in \mathbb{R}$$

with $p \ge 1$. There exists a constant C such that

$$\|a(u)\partial_x v\|_{L^1(0,T;H^1(I))} \le CT^{1/2}\left(1+\|u\|_{Y_{1,T}}+\|u\|_{Y_{1,T}}^p\right)\|v\|_{Y_{1,T}} \quad \text{for any } u,\ v \in Y_{1,T}.$$

Using the notation of the semigroup $W_b(t)$, the nonlinear IBVP (2.1) may be written in the following integral form:

$$u(t) = W_b(t)\phi - \int_0^t W_b(t-\tau)a(u(\cdot,\tau))\partial_x u(\cdot,\tau)d\tau.$$

The same arguments as those in the proof of Propositions 2.6 and 2.7 lead to the following (local) well-posedness result for the IBVP (2.1).

THEOREM 2.13. *Let $b \in H^1(I)$, let a be a C^2 function satisfying*

$$|a(\mu)| \le C(1+|\mu|^p), \quad |a'(\mu)| \le C(1+|\mu|^{p-1}), \quad |a''(\mu)| \le C(1+|\mu|^{p-2}) \quad \text{for any } \mu \in \mathbb{R}$$

with $p \ge 2$, and let $j = 1$ or 3 be given. Then for any $\phi \in X_j$ there exists a $T^* > 0$ depending only on $\|\phi\|_{X_1}$ such that the IBVP (2.1) admits a unique solution $u \in Y_{j,T^*}$. Moreover, there exists a nondecreasing continuous function $\alpha_j : \mathbb{R}^+ \to \mathbb{R}^+$ such that

$$\|u\|_{Y_{j,T^*}} \le \alpha_j(\|\phi\|_{X_1})\|\phi\|_{X_j}.$$

Remark. The well-posedness result presented in Theorem 2.13 is local in the sense that the length of the time interval $(0, T^*)$ in which the solution exists depends on the norm of the initial value ϕ in the space X_1. In order to obtain the global well-posedness result, one needs to establish the corresponding global a priori estimate for the IBVP (2.1) in the space X_1, which is not available. In fact, the only available global a priori estimate for the IBVP (2.1) is the L^2-estimate presented in Lemma 2.5. On the other hand, whether the IBVP (2.1) is well-posed in the space $L^2(I)$ in the case of $p \ge 2$ is still an open question.

The next theorem shows that if $\phi \in X_0$, then the IBVP (2.1) admits one solution $u \in C_w(R^+; L^2(I)) \cap L^2_{loc}(R^+; H^1(I))$.

THEOREM 2.14. *Let a be a C^2 function satisfying*

$$|a(\mu)| \le C(1+|\mu|^p), \quad |a'(\mu)| \le C(1+|\mu|^{p-1}), \quad |a''(\mu)| \le C(1+|\mu|^{p-2}) \quad \text{for any } \mu \in \mathbb{R}$$

with $2 \le p < 4$. Then, for any given $\phi \in X_0$, the IBVP (2.1) admits at least one solution $u \in C_w(\mathbb{R}^+; L^2(I)) \cap L^2_{loc}(\mathbb{R}^+; H^1(I))$.

Proof. Let $\{a_n\}$ denote a sequence of functions in $C_0^\infty(\mathbb{R}; \mathbb{R})$ such that

$$|a_n^{(j)}(\mu)| \le C(2 + |\mu|^{p-j}) \qquad \forall n \ge 0,\ \forall \mu \in \mathbb{R},\ j = 0, 1, 2; \tag{2.32}$$

$$a_n(\mu) \to a(\mu) \quad \text{uniformly on each compact set in } R. \tag{2.33}$$

Observe that $|a_n(\mu)| \le C(n)(1 + |\mu|)$ and $|a_n'(\mu)| \le C(n)(1 + |\mu|)$. According to Proposition 2.6, there exists a (unique) solution $u_n \in C(\mathbb{R}^+; L^2(I)) \cap L^2(\mathbb{R}^+; H_0^1(I))$ of the modified boundary initial value problem

$$\begin{cases} \partial_t u_n + \partial_x^3 u_n + \partial_x u_n + a_n(u_n)\partial_x u_n + b u_n = 0, \\ u_n(0,t) = u_n(L,t) = \partial_x u_n(L,t) = 0, \\ u_n(x,0) = \phi(x). \end{cases} \tag{2.34}$$

Let us introduce the functions

$$A_n(u) := \int_0^u a_n(v)\, dv, \qquad \tilde{A}_n(u) := \int_0^u v a_n(v)\, dv.$$

According to Lemma 2.5,

$$||u_n(T)||^2_{L^2(I)} = ||\phi||^2_{L^2(I)} - \int_0^T |\partial_x u_n(0,t)|^2 dt - 2\int_0^T \int_0^L b(x)|u_n|^2 dx dt$$

and

$$\int_0^T \int_0^L |\partial_x u_n|^2\, dx dt \le \frac{L + (C+1)T}{2} ||\phi||^2_{L^2(I)} + C_p T ||\phi||^{\frac{8+2p}{4-p}}_{L^2(0,L)}$$

for any $T \geq 0$ and $n \geq 0$. Thus $\{u_n\}$ is bounded in $L^\infty(\mathbb{R}^+; L^2(I)) \cap L^2_{loc}(\mathbb{R}^+; H^1_0(I))$, and there exist a function $u \in L^\infty(\mathbb{R}^+; L^2(I)) \cap L^2_{loc}(\mathbb{R}^+; H^1(I))$ and a subsequence of $\{u_n\}$, again denoted by $\{u_n\}$, such that

$$u_n \rightharpoonup u \quad \text{in } L^\infty(\mathbb{R}^+; L^2(I)) \text{ weak}*, \tag{2.35}$$

$$u_n \rightharpoonup u \quad \text{in } L^2_{loc}(\mathbb{R}^+; H^1(I)) \text{ weak}. \tag{2.36}$$

To pass to the limit in (2.34) we have to pay some attention to the nonlinear term $a_n(u_n)\partial_x u_n = \partial_x[A_n(u_n)]$. Let us introduce the function $A(u) := \int_0^u a(v)\,dv$. We aim to prove that

$$A_n(u_n) \to A(u) \quad \text{in } \mathcal{D}'(I_x \times (0, +\infty)_t).$$

We first prove the following claim.

Claim 1. Let $T > 0$ and $\alpha \in (1, \frac{6}{p+1}]$. Then $A_n(u_n)$ is bounded in $L^\alpha(I \times (0,T))$.

Proof of Claim 1. It follows from (2.32) that

$$|A_n(u)| \leq C\left(2|u| + \frac{|u|^{p+1}}{p+1}\right) \leq C'(1 + |u|^{p+1})$$

and

$$|A_n(u)|^\alpha \leq C''(1 + |u|^{\alpha(p+1)}),$$

where C' and C'' denote some positive constants which depend only on C, p, and α. Therefore

$$\begin{aligned}\int_0^T \int_0^L |A_n(u_n)|^\alpha dxdt &\leq C''\left(TL + \int_0^T \int_0^L |u_n|^{\alpha(p+1)} dxdt\right)\\ &\leq C''\left(TL + \int_0^T ||u_n||^2_{L^2(I)} \cdot ||u_n||^{\alpha(p+1)-2}_{L^\infty(I)} dt\right)\\ &\leq C''\left(TL + ||\phi||^{1+\frac{\alpha(p+1)}{2}}_{L^2(I)} \int_0^T ||\partial_x u_n||^{\frac{\alpha(p+1)-2}{2}}_{L^2(I)} dt\right).\end{aligned}$$

As $\frac{\alpha(p+1)-2}{2} \leq 2$, the result in Claim 1 follows from Lemma 2.5. □

Next we prove the following claim.

Claim 2. Let T and α be as in Claim 1. Then the sequences $\{a_n(u_n)\partial_x u_n\}$ and $\{\partial_t u_n\}$ are bounded in $L^\alpha(0,T; H^{-2}(I))$.

Proof of Claim 2. Notice first that $L^\alpha(I) \subset H^{-1}(I)$ (as $H^1_0(I) \subset L^\infty(I)$); hence $a_n(u_n)\partial_x u_n = \partial_x[A_n(u_n)]$ is bounded in $L^\alpha(0,T; H^{-2}(I))$. Clearly, $\partial_x^3 u_n$ is bounded in $L^2(0,T; H^{-2}(I))$ and $\partial_x u_n + b u_n$ is bounded in $L^2(0,T; L^2(I))$, so we conclude that $\partial_t u_n = -(\partial_x^3 u_n + \partial_x u_n + a_n(u_n)\partial_x u_n + b u_n)$ is bounded in $L^\alpha(0,T; H^{-2}(I))$. □

As the first embedding in $H^1_0(I) \subset L^2(I) \subset H^{-2}(I)$ is compact, we infer from [33, Cor. 4] that the sequence $\{u_n\}$ is relatively compact in $L^2(0,T; L^2(I))$ for each $T > 0$. Therefore, extracting a subsequence of $\{u_n\}$ again denoted by $\{u_n\}$, we have that

$$u_n \to u \text{ (strongly)} \quad \text{in } L^2_{loc}(\mathbb{R}^+; L^2(I)) \text{ and a.e.} \tag{2.37}$$

Using (2.33) and (2.37), it is easy to see that

$$A_n(u_n(x,t)) \to A(u(x,t)) \quad \text{for a.e. } (x,t) \in (0,L) \times \mathbb{R}^+.$$

On the other hand, picking any $\alpha \in (1, \frac{6}{p+1}]$, we deduce from Claim 1 that there exists a function $g \in L^\alpha_{loc}(\mathbb{R}^+; L^\alpha(I))$ such that (for a subsequence)

$$A_n(u_n) \rightharpoonup g \quad \text{in } L^\alpha((0,L)\times(0,T))$$

for any $T > 0$. The following lemma is an easy consequence of the Egoroff theorem.

LEMMA 2.15. *Let Ω be an open set in R^N, and let $\{f_n\}$ be a sequence of functions in $L^p(\Omega)$ (with $1 < p < \infty$) such that $f_n \rightharpoonup f$ in $L^p(\Omega)$ and $f_n(x) \to g(x)$ a.e. Then $f(x) = g(x)$ a.e.*

We infer from Lemma 2.15 that $g(x,t) = A(u(x,t))$ a.e. Therefore,

$$A_n(u_n) \to A(u) \quad \text{in } \mathcal{D}'((0,L)\times R^+),$$

and taking the spatial derivative, we obtain

$$a_n(u_n)\partial_x u_n \to a(u)\partial_x u \quad \text{in } \mathcal{D}'((0,L)\times R^+). \tag{2.38}$$

Gathering (2.37) and (2.38) together, and taking the limit in (2.34), we conclude that u solves the equation in (2.1) in the sense of distributions.

Since u_n is bounded in $L^\infty(0,T;L^2(I))$ (see (2.17)) and $\partial_t u_n$ is bounded in $L^\alpha(0,T;\, H^{-2}(I))$ (with $\alpha > 1$), we infer from [33, Cor. 4] that for a subsequence, again denoted by $\{u_n\}$,

$$u_n \to u \quad \text{in } C([0,T], H^{-1}(I)) \quad \text{for any } T > 0. \tag{2.39}$$

In particular,

$$u(0) = \lim_{n\to+\infty} u_n(0) = \phi.$$

As $u \in L^\infty(0,T;L^2(I)) \cap C_w([0,T],H^{-1}(I))$, we deduce from [36, Lem. 1.4, p. 263] that $u \in C_w([0,T],L^2(I))$. □

DEFINITION 2.16. *A function $u \in C_w(\mathbb{R}^+;L^2(I)) \cap L^2_{loc}(\mathbb{R}^+;H^1_0(I))$ is said to be a* weak solution *of* (2.1) *if there exist a sequence $\{a_n\}$ of functions in $C^\infty_0(\mathbb{R};\mathbb{R})$ satisfying* (2.32) *and* (2.33) *and a sequence of strong solutions u_n to* (2.34) *such that* (2.35), (2.36), (2.37), *and* (2.39) *hold true.*

3. Exponential stability. In this section we study the long time behavior of weak solutions of (2.1). The goal is to show that any weak solution of (2.1) decays exponentially in the space $L^2(I)$. As a weak solution of (2.1) may fail to be unique, the concept of exponential stability has to be generalized in the following way.

DEFINITION 3.1. *System* (2.1) *is said to be* locally uniformly exponentially stable *in $L^2(I)$ if for any $r > 0$ there exist two constants $C > 0$ and $\nu > 0$ such that for any $\phi \in L^2(I)$ with $||\phi||_{L^2(I)} < r$ and for any weak solution $u = u(x,t)$ of* (2.1), *it holds that*

$$||u(\cdot,t)||^2_{L^2(I)} \le C\,||\phi||^2_{L^2(I)} e^{-\nu t} \qquad \forall t \ge 0. \tag{3.1}$$

If the constant ν in (3.1) *is independent of r, the system* (2.1) *is said to be* globally uniformly exponentially stable *in $L^2(I)$.*

We first show that the system (2.1) is locally uniformly exponentially stable in $L^2(I)$.

PROPOSITION 3.2. *Assume that $a = a(\mu)$ is a C^2 function which satisfies*

$$|a(\mu)| \le C(1+|\mu|^p), \quad |a'(\mu)| \le C(1+|\mu|^{p-1}), \quad |a''(\mu)| \le C(1+|\mu|^{p-2}) \quad \text{for any } \mu \in \mathbb{R}$$

with $1 \le p < 4$ and $b \in L^2(I)$. Then the system (2.1) is locally uniformly exponentially stable in $L^2(I)$.

The following Carleman estimate [27, Prop. 2.3] will play a great role in establishing the unique continuation property of the GKdV equation as described by Lemma 3.4.

LEMMA 3.3. *Let T and l be positive numbers. Then there exist a smooth positive function ψ on $[0,l]$ and two constants $C_0 > 0$, $s_0 > 0$ such that for any*

$$q \in L^2(0,T;H^3(0,l)) \cap H^1(0,T;L^2(0,l)) \tag{3.2}$$

fulfilling

$$q(0,t) = q(l,t) = \partial_x q(l,t) = \partial_x^2 q(l,t) = 0$$

and for any $s \ge s_0$ we have

$$\begin{aligned} &\int_0^T\int_0^l \left\{ \frac{s^5}{t^5(T-t)^5}|q|^2 + \frac{s^3}{t^3(T-t)^3}|\partial_x q|^2 + \frac{s}{t(T-t)}|\partial_x^2 q|^2 \right\} \exp\left(-\frac{2s\psi(x)}{t(T-t)}\right) dxdt \\ &\le C_0 \int_0^T\int_0^l |\partial_t q + \partial_x^3 q + \partial_x q|^2 \exp\left(-\frac{2s\psi(x)}{t(T-t)}\right) dxdt. \end{aligned} \tag{3.3}$$

(Notice that Lemma 3.3 is stated in [27] under the extra assumption that $q \in C^3([0,l]\times[0,T])$, but (3.2) is what is really needed to perform the computations.)

LEMMA 3.4. *Let $l > 0$ and $T > 0$. If $v \in L^\infty(0,T;H^1(0,l))$ solves*

$$\begin{cases} \partial_t v + \partial_x v + a(v)\partial_x v + \partial_x^3 v = 0 & \text{in } (0,l)\times(0,T), \\ v(0,t) = 0 & \text{for a.e. } t \in (0,T), \\ v \equiv 0 & \text{in } (l',l)\times(0,T) \end{cases}$$

with $a \in C^0(\mathbb{R};\mathbb{R})$ and $0 < l' < l$, then $v \equiv 0$ in $(0,l)\times(0,T)$.

Proof. As the function v is not expected to fulfill (3.2), we have to smooth it. For any function $u = u(x,t)$ and any $h > 0$, we set

$$u^{[h]}(x,t) = \frac{1}{h}\int_t^{t+h} u(x,s)\,ds.$$

Recall that if $u \in L^p(0,T;V)$, where $1 \le p \le +\infty$ and V denotes any Banach space, then $u^{[h]} \in W^{1,p}(0,T-h;V)$, $||u^{[h]}||_{L^p(0,T-h;V)} \le ||u||_{L^p(0,T;V)}$, and for $p < \infty$ and $T' < T$

$$u^{[h]} \to u \quad \text{in } L^p(0,T';V) \text{ as } h \to 0.$$

Pick any $T' < T$. Then for any small enough number h, $v^{[h]} \in W^{1,\infty}(0,T';H_0^1(0,l))$, and $v^{[h]}$ solves

$$\partial_t v^{[h]} + \partial_x v^{[h]} + \partial_x^3 v^{[h]} + (a(v)\partial_x v)^{[h]} = 0 \quad \text{in } (0,l)\times(0,T'), \tag{3.4}$$

$$v^{[h]}(0,t) = 0 \quad \text{in } (0,T'), \tag{3.5}$$

$$v^{[h]} \equiv 0 \quad \text{in } (l',l)\times(0,T'). \tag{3.6}$$

As $v \in L^\infty(0,T;H^1(0,l))$, $a(v)\partial_x v \in L^\infty(0,T;L^2(0,l))$; hence it follows from (3.4) that $v^{[h]}_{xxx} \in L^\infty(0,T';L^2(0,l))$ and so $v^{[h]} \in L^\infty(0,T';H^3(0,l))$. It follows then from Lemma 3.3 that for any $s \geq s_0$ we have

$$
\begin{aligned}
(3.7)\quad & \int_0^{T'}\int_0^l \left\{ \frac{s^5}{t^5(T'-t)^5}|v^{[h]}|^2 + \frac{s^3}{t^3(T'-t)^3}|\partial_x v^{[h]}|^2 \right. \\
& \qquad \left. + \frac{s}{t(T'-t)}|\partial_x^2 v^{[h]}|^2 \right\} \exp\left(-\frac{2s\psi(x)}{t(T'-t)}\right) dxdt \\
& \leq C_0 \int_0^{T'}\int_0^l |(a(v)\partial_x v)^{[h]}|^2 \exp\left(-\frac{2s\psi(x)}{t(T'-t)}\right) dxdt \\
& \leq 2C_0 \int_0^{T'}\int_0^l |a(v)\partial_x v^{[h]}|^2 \exp\left(-\frac{2s\psi(x)}{t(T'-t)}\right) dxdt \\
& \quad + 2C_0 \int_0^{T'}\int_0^l |(a(v)\partial_x v)^{[h]} - a(v)\partial_x v^{[h]}|^2 \exp\left(-\frac{2s\psi(x)}{t(T'-t)}\right) dxdt \\
& \equiv I_1 + I_2.
\end{aligned}
$$

We first estimate I_1. Since $a(v) \in L^\infty(0,T;L^\infty(0,l))$, we have

$$
(3.8)\qquad I_1 \leq C \int_0^{T'}\int_0^l |\partial_x v^{[h]}|^2 \exp\left(-\frac{2s\psi(x)}{t(T'-t)}\right) dxdt
$$

for some constant C which does not depend on h. Comparing the powers of s in the right-hand side of (3.8) with those in the left-hand side of (3.7), we deduce that the term I_1 in (3.7) may be dropped by increasing the constants C_0 and s_0 in a convenient way. From now on, we fix s, say, to the value s_0. We claim that $I_2 \to 0$ as $h \to 0$. As $\exp(-\frac{2s_0\psi(x)}{t(T'-t)}) \leq 1$, it is sufficient to prove that

$$
(3.9)\qquad (a(v)\partial_x v)^{[h]} \to a(v)\partial_x v \quad \text{in } L^2(0,T';L^2(0,l)),
$$

$$
(3.10)\qquad a(v)\partial_x v^{[h]} \to a(v)\partial_x v \quad \text{in } L^2(0,T';L^2(0,l)).
$$

Property (3.9) is obvious for $a(v)\partial_x v \in L^2(0,T;L^2(0,l))$, and (3.10) follows from the fact that $a(v) \in L^\infty(0,T;L^\infty(0,l))$ and that $v \in L^2(0,T;H^1(0,l))$. We conclude that as $h \to 0$ the integral term

$$
\begin{aligned}
\int_0^{T'}\int_0^l & \left\{ \frac{s_0^5}{t^5(T'-t)^5}|v^{[h]}|^2 + \frac{s_0^3}{t^3(T'-t)^3}|\partial_x v^{[h]}|^2 \right. \\
& \left. + \frac{s_0}{t(T'-t)}|\partial_x^2 v^{[h]}|^2 \right\} \exp\left(-\frac{2s\psi(x)}{t(T'-t)}\right) dxdt
\end{aligned}
$$

tends to 0. On the other hand, $v^{[h]} \to v$ in $L^2(0,T';L^2(0,l))$. It follows that $v \equiv 0$ in $(0,l)\times(0,T')$. As T' may be taken arbitrarily close to T, we infer that $v \equiv 0$ in $(0,l)\times(0,T)$. This completes the proof of Lemma 3.4. □

The following unique continuation property is a direct consequence of Lemma 3.4.

LEMMA 3.5. *Let $L > 0$ and $T > 0$ be two real numbers, and let $\omega \subset (0,L)$ be a nonempty open set. If $v \in L^\infty(0,T;H^1(I))$ solves*

$$
\begin{cases}
\partial_t v + \partial_x v + a(v)\partial_x v + \partial_x^3 v = 0 & \text{in } (0,L)\times(0,T), \\
v(0,t) = v(L,t) = 0 & \text{for a.e. } t \in (0,T), \\
v \equiv 0 & \text{in } \omega \times (0,T)
\end{cases}
$$

with $a \in C^0(\mathbb{R};\mathbb{R})$, then $v \equiv 0$ in $(0,L)\times(0,T)$.

Proof. Without loss of generality we may assume that $\omega = (l_1, l_2)$ with $0 \leq l_1 < l_2 \leq L$. Pick $l = (l_1 + l_2)/2$. Applying Lemma 3.4 to the function $v(x,t)$ on $(0,l)\times(0,T)$ and then to the function $v(L-x,T-t)$ on $(0,L-l)\times(0,T)$, we conclude that $v \equiv 0$ on $(0,L)\times(0,T)$. □

Now we are in a position to present the proof of Proposition 3.2.

Proof of Proposition 3.2. First, notice that if u is a weak solution of (2.1) emanating from a given initial state $\phi \in L^2(I)$, then by Lemma 2.5 there exists a constant C_p depending only on p such that for any $T > 0$,

$$||u(\cdot,T)||^2_{L^2(I)} = ||\phi||^2_{L^2(I)} - \int_0^T |\partial_x u(0,t)|^2\, dt - 2\int_0^T \int_0^L b|u|^2\, dxdt \tag{3.11}$$

and

$$||\partial_x u||^2_{L^2(0,T;L^2(I))} \leq \frac{L+(C+1)T}{2}||\phi||^2_{L^2(I)} + C_p T||\phi||^{\frac{8+2p}{4-p}}_{L^2(I)}. \tag{3.12}$$

On the other hand, multiplying (2.1) by $(T-t)u$ yields

$$\begin{aligned} T||\phi||^2_{L^2(I)} = &\int_0^T \int_0^L |u(x,t)|^2\, dxdt + \int_0^T (T-t)|\partial_x u(0,t)|^2 dt \\ &+ 2\int_0^T \int_0^L (T-t)b|u(x,t)|^2 dxdt. \end{aligned} \tag{3.13}$$

We now proceed as in the proof of [24, Thm. 3.1]. Let $r > 0$ be given. The proof would be complete if the following claim is true.

Claim 3. For any $T > 0$ and any $r > 0$ there exists a positive constant $C = C(r,T)$ such that for any weak solution u issuing from a state $\phi \in L^2(I)$ with $||\phi||_{L^2(I)} < r$, it holds that

$$||\phi||^2_{L^2(I)} \leq C\left(\int_0^T |\partial_x u(0,t)|^2 dt + 2\int_0^T \int_0^L b(x)|u(x,t)|^2 dxdt\right). \tag{3.14}$$

Indeed, if Claim 3 is proved, then it follows from (3.11) and (3.14) that there exists a constant $\gamma \in (0,1)$ such that

$$||u(\cdot,kT)||^2_{L^2(I)} \leq \gamma^k ||\phi||^2_{L^2(I)} \qquad \forall k \geq 0.$$

Since $||u(\cdot,t)||_{L^2(I)} \leq ||u(\cdot,kT)||_{L^2(I)}$ for $kT \leq t < (k+1)T$, we readily obtain

$$||u(\cdot,t)||^2_{L^2(I)} \leq \frac{1}{\gamma}||\phi||^2_{L^2(I)} e^{\frac{\log\gamma}{T}t}$$

from which the result stated in Proposition 3.2 follows.

To prove Claim 3, because of the identity (3.13), it is sufficient to show that there exists some constant $C_1 > 0$ such that

$$\int_0^T \int_0^L |u|^2 dxdt \leq C_1\left(\int_0^T |\partial_x u(0,t)|^2 dt + 2\int_0^T \int_0^L b(x)|u|^2 dxdt\right), \tag{3.15}$$

provided that $||u(.,0)||_{L^2(I)} < r$. To this end, we argue by contradiction.

Suppose that (3.15) fails to be true. Then there exists a sequence of weak solutions $u_n \in C_w([0,T];L^2(I)) \cap L^2(0,T;H_0^1(I))$ of (2.1) with

$$||u_n(\cdot,0)||_{L^2(I)} < r \tag{3.16}$$

and such that

$$\lim_{n\to+\infty} \frac{||u_n||^2_{L^2(0,T;L^2(I))}}{\int_0^T |\partial_x u_n(0,t)|^2 dt + 2\int_0^T \int_0^L b(x)|u_n|^2 dxdt} = +\infty.$$

Let $\lambda_n := ||u_n||_{L^2(0,T;L^2(I))}$ and $v_n(x,t) := u_n(x,t)/\lambda_n$. Notice that λ_n is bounded from above, according to (3.11) and (3.16). Hence, extracting a subsequence if needed, we may assume that

$$\lambda_n \to \lambda \geq 0.$$

Then v_n fulfills

$$\begin{aligned}
&\partial_t v_n + \partial_x^3 v_n + \partial_x v_n + a(\lambda_n v_n)\partial_x v_n + b v_n = 0,\\
&v_n(0,t) = v_n(L,t) = \partial_x v_n(L,t) = 0,\\
&||v_n||_{L^2(0,T;L^2(I))} = 1,
\end{aligned}$$

and

$$\int_0^T |\partial_x v_n(0,t)|^2 dt + 2\int_0^T \int_0^L b(x)|v_n|^2 dxdt \to 0$$

as $n \to +\infty$. It follows from (3.13) that $||v_n(.,0)||_{L^2(I)} = ||u_n(.,0)/\lambda_n||_{L^2(I)}$ is bounded. Noticing that

$$|a(\lambda_n \mu)| \leq C(1 + |\lambda_n|^p |\mu|^p) \leq C'(1 + |\mu|^p),$$

where C' denotes a positive constant which does not depend on μ and n, we obtain from (3.12) applied to v_n that v_n is bounded in $L^2(0,T;H_0^1(I))$. Proceeding as in the proof of Claim 2, it is easily seen that $a(\lambda_n v_n)\partial_x v_n$ and $\partial_t v_n$ are bounded in $L^\alpha(0,T;H^{-2}(I))$ with $\alpha > 1$. Extracting a subsequence, we may assume that

$$v_n \rightharpoonup v \quad \text{in } L^\infty(0,T;L^2(I)) \text{ weak}*; \tag{3.17}$$

$$v_n \rightharpoonup v \quad \text{in } L^2(0,T;H_0^1(I)) \text{ weak}; \tag{3.18}$$

$$v_n \to v \quad \text{in } L^2(0,T;L^2(I)) \text{ and a.e.}; \tag{3.19}$$

$$v_n \to v \quad \text{in } C([0,T],H^{-1}(I)); \tag{3.20}$$

$$a(\lambda_n v_n)\partial_x v_n \to a(\lambda v)\partial_x v \text{ in } \mathcal{D}'(I\times(0,T)). \tag{3.21}$$

It follows that v solves

$$\partial_t v + \partial_x^3 v + \partial_x v + a(\lambda v)\partial_x v + bv = 0 \quad \text{in } \mathcal{D}'(I\times(0,T)), \tag{3.22}$$

$$v(0,t) = v(L,t) = \partial_x v(L,t) = 0. \tag{3.23}$$

Moreover, $||v||_{L^2(0,T;L^2(I))} = 1$ and $0 = \int_0^T \int_0^L b(x)|v|^2\, dxdt$; hence

$$v \equiv 0 \quad \text{on } \omega \times (0,T).$$

To conclude, the following result is needed.

LEMMA 3.6. *Let $0 < t_1 < t_2 < T$. Then there exists a subinterval $(t_1', t_2') \subset (t_1, t_2)$ such that $v \in L^\infty(t_1', t_2'; H^1(I))$.*

Proof of Lemma 3.6. C will denote here a constant which may vary from line to line. Using (2.39) for each weak solution w_n, we may pick a sequence $\{a_n\}$ in $C_0^\infty(\mathbb{R};\mathbb{R})$ fulfilling (2.32) and such that, if w_n denotes the solution of

$$\begin{cases} \partial_t w_n + \partial_x^3 w_n + \partial_x w_n + a_n(\lambda_n w_n)\partial_x w_n + b w_n = 0, \quad x \in (0,L), \quad t \geq 0, \\ \\ w_n(x,0) = v_n(x,0), \\ \\ w_n(0,t) = w_n(L,t) = \partial_x w_n(L,t) = 0, \end{cases}$$

we have as $n \to \infty$

$$v_n - w_n \to 0 \quad \text{in } C([0,T], H^{-1}(I)). \tag{3.24}$$

As

$$||w_n||_{L^2(0,T;H^1(I))} \leq C,$$

we may pick a sequence $\{\tau_n\}$ in $(t_1, (t_1+t_2)/2)$ such that $\tau_n \to \tau$ and $||w_n(\tau_n)||_{H^1(I)} \leq C$. Using (3.20) and (3.24) we obtain that

$$w_n(\tau_n + \cdot) \to v(\tau + \cdot) \quad \text{in } C([0,\varepsilon], H^{-1}(I))$$

for any $\varepsilon < (t_2 - t_1)/2$. According to Theorem 2.13, for ε sufficiently small,

$$||w_n(\tau_n + \cdot)||_{L^\infty(0,\varepsilon;H^1(I))} \leq C;$$

hence $v \in L^\infty(\tau, \tau+\varepsilon; H^1(I))$. □

Let $t_1 \in (0,T)$, and let $t_2 \in (t_1, T)$. According to Lemma 3.6, $v \in L^\infty(t_1', t_2'; H^1(I))$ for some interval $(t_1', t_2') \subset (t_1, t_2)$. It follows then from Lemma 3.5 that $v \equiv 0$ on $(0,L) \times (t_1', t_2')$. As t_2 is arbitrarily close to t_1, we obtain by continuity of v in $H^{-1}(I)$ that $v(.,t) = 0$. Thus $v \equiv 0$, which contradicts the fact that $||v||_{L^2(0,T;L^2(I))} = 1$. The proof is complete. □

Now we present the main result of this paper, asserting that the system (2.1) is globally uniformly exponentially stable in the space $L^2(I)$.

THEOREM 3.7. *Assume that $a = a(\mu)$ is a C^2 function which satisfies*

$$|a(\mu)| \leq C(1+|\mu|^p), \quad |a'(\mu)| \leq C(1+|\mu|^{p-1}), \quad |a''(\mu)| \leq C(1+|\mu|^{p-2}) \quad \textit{for any } \mu \in \mathbb{R}$$

with $1 \leq p < 4$ and $b \in L^2(I)$. Then the system (2.1) *is globally uniformly exponentially stable in the space $L^2(I)$; i.e., there exist a $\nu^* > 0$ and a continuous nonnegative function $\alpha_0 : \mathbb{R}^+ \to \mathbb{R}^+$ such that for a given $\phi \in L^2(I)$, any weak solution u of* (2.1) *satisfies*

$$\|u(\cdot,t)\|_{L^2(I)} \leq \alpha_0(\|\phi\|_{L^2(I)}) e^{-\nu^* t} \qquad \forall\ t \geq 0.$$

Proof. By Proposition 3.2, there exists a $\nu^* > 0$ such that if

$$\|\phi\|_{L^2(I)} \leq 1,$$

then the corresponding solution u of (2.1) satisfies

$$\|u(\cdot,t)\|_{L^2(I)} \leq C\|\phi\|_{L^2(I)} e^{-\nu^* t} \qquad \forall\ t \geq 0 \tag{3.25}$$

for some constant $C \geq 1$ which depends only on $\|\phi\|_{L^2(I)}$. In addition, for a given $r > 0$, there exist two constants $C_r > 0$ and $\nu_r > 0$ such that if $\|\phi\|_{L^2(I)} \leq r$, then any weak solution u of (2.1) satisfies

$$\|u(\cdot,t)\|_{L^2(I)} \leq C_r||\phi||_{L^2(I)}e^{-\nu_r t} \qquad \forall\ t \geq 0.$$

Consequently, setting $T_r := \nu_r^{-1}\ln(rC_r)$, we have that

$$\begin{aligned}\|u(\cdot,t)\|_{L^2(I)} &\leq C\|u(\cdot,T_r)\|_{L^2(I)}e^{-\nu^*(t-T_r)} \qquad \forall\ t \geq T_r\\ &\leq CC_r||\phi||_{L^2(I)}e^{\nu^* T_r}e^{-\nu^* t} \qquad \forall\ t \geq 0.\end{aligned}$$

The proof is complete. □

For a given function $u = u(x,t)$, a real number $s \geq 0$, and an interval (a,b), define

$$\|v\|^s_{Y_{(a,b)}} := \Big(\|v\|^2_{C([a,b];H^s(I))} + \|v\|^2_{L^2([a,b];H^{s+1}(I))} + \|\partial_x v\|^2_{C([0,L];L^2(a,b))}\Big)^{1/2}.$$

As a direct corollary of Theorem 3.7 and Lemma 2.5, we have the following result.

COROLLARY 3.8. *Under the assumptions of Theorem* 3.7*, there exists a* $\nu^* > 0$ *such that for any* $T > 0$ *and* $\phi \in L^2(I)$*, there exists a nonnegative continuous function* $\alpha_0 :\ \mathbb{R}^+ \times \mathbb{R}^+ \to \mathbb{R}^+$ *such that any weak solution* u *of* (2.1) *satisfies*

$$\|u\|_{Y^0_{(t,t+T)}} \leq \alpha_0(\|\phi\|_{L^2(I)}, T)e^{-\nu^* t}$$

for any $t \geq 0$.

Under the assumptions of Theorem 2.9, if $\phi \in H^s(I)$ with $0 \leq s \leq 3$ satisfies the compatibility conditions (1.16), then the corresponding solution u of (2.1) belongs to the space $C(\mathbb{R}^+; H^s(I))$. Our next theorem shows that the system (2.1) is globally uniformly exponentially stable in the space $H^3(I)$. First, we show that the system (2.1) is globally uniformly exponentially stable in the space $H^3(I)$ if $\phi \in H^3(I)$ as described below.

PROPOSITION 3.9. *Under the assumptions of Theorem* 2.9 *with* $a(0) = 0$ *additionally, there exist a* $\nu^* > 0$ *and a continuous nonnegative function* $\alpha_3 :\ \mathbb{R}^+ \to \mathbb{R}^+$ *such that for any* $\phi \in H^3(I)$ *satisfying the compatibility conditions, the corresponding solution* u *satisfies*

$$\|u(\cdot,t)\|_{H^3(I)} \leq \alpha_3(\|\phi\|_{L^2(I)})\|\phi\|_{H^3(I)}e^{-\nu^* t} \qquad \forall\ t \geq 0.$$

Proof. Let $v = u_t$. Then v solves the following IBVP linearized KdV equation:

$$\begin{cases} \partial_t v + \partial_x v + \partial_x(a(u)v) + bv + \partial_x^3 v = 0, \quad x \in (0,L), \quad t \geq 0,\\ v(x,0) = \phi^*(x),\\ v(0,t) = 0, \quad v(L,t) = 0, \quad v_x(L,t) = 0, \end{cases} \tag{3.26}$$

where

$$\phi^* = -\phi''' - a(\phi)\phi' - \phi' - b\phi.$$

Note that $\phi \in H^3(I)$ implies that $\phi^* \in L^2(I)$ and that there exists a constant $C = C(||\phi||_{L^2(I)})$ such that $\|\phi^*\|_{L^2(I)} \leq C(\|\phi\|_{H^3(I)})$ for any $\phi \in H^3(I)$. The same argument as that in the proof of Proposition 2.6 shows that

$$\|v\|_{Y_{0,T}} \leq \sigma(\|u\|_{Y_{0,T}})\|\phi^*\|_{L^2(I)}, \tag{3.27}$$

where $\sigma : \mathbb{R}^+ \to \mathbb{R}^+$ is a nondecreasing continuous function. By the semigroup property of the system (3.26), we can rewrite (3.27) as

$$\|v\|_{Y_{0,[t,t+T]}} \leq \sigma(\|u\|_{Y_{0,[t,t+T]}})\|v(\cdot,t)\|_{L^2(I)} \tag{3.28}$$

for any $t \geq 0$, where $Y_{0,[t,t+T]}$ is defined as $Y_{0,T} =: Y_{0,[0,T]}$. Using the notation of the semigroup $W_b(t)$, the solution v of (3.26) may be written as

$$v(t) = W_b(t)\phi^* - \int_0^t W_b(t-\tau)(a(u)v)_x(\tau)d\tau.$$

According to Proposition 3.2 (with $a \equiv 0$), $u_1(x,t) = W_b(t)\phi^*(x)$ satisfies

$$\|u_1(\cdot,t)\|_{L^2(I)} \leq Ce^{-\alpha t}\|\phi^*\|_{L^2(I)} \qquad \forall t \geq 0,$$

where C and α are some positive constants independent of ϕ^*. In addition, by Lemma 2.3, $u_2(x,t) = \int_0^t W_b(t-\tau)(\partial_x(a(u)v))(\tau)d\tau$ satisfies

$$\|u_2(\cdot,T)\| \leq C_T\|u\|^p_{Y_{0,T}}\|v\|_{Y_{0,T}}.$$

Thus,

$$\|v(\cdot,T)\|_{L^2(I)} \leq C_1e^{-\alpha T}\|\phi^*\|_{L^2(I)} + C_2\|u\|^p_{Y_{0,T}}\sigma(\|u\|_{Y_{0,T}})\|\phi^*\|_{L^2(I)}.$$

Let $y_n = v(\cdot,nT)$ for $n = 0,1,2,\ldots$, and let w be the solution of the IBVP

$$\begin{cases} \partial_t w + \partial_x w + \partial_x(qw) + bw + \partial_x^3 w = 0, \quad x \in (0,L), \quad 0 \leq t, \\ w(x,0) = y_n, \\ w(0,t) = 0, \quad w(L,t) = 0, \quad w_x(L,t) = 0 \end{cases} \tag{3.29}$$

with $q(x,t) = a(u(x,t+nT))$. Then $y_{n+1}(x) = w(x,T)$ by the semigroup properties of the system (3.26). Consequently, we have the following estimate for y_{n+1}:

$$\|y_{n+1}\|_{L^2(I)} \leq C_1e^{-\alpha T}\|y_n\|_{L^2(I)} + C_2\|u\|^p_{Y_{0,[nT,(n+1)T]}}\sigma(\|u\|_{Y_{0,[nT,(n+1)T]}})\|y_n\|_{L^2(I)}$$

for any $n \geq 0$. Choose T and β such that

$$C_1e^{-\alpha T} = \gamma < 1$$

and

$$\gamma + C_2\beta^p\sigma(\beta) = r < 1.$$

In addition, according to Corollary 3.8, one can choose $N > 0$ such that

$$\|u\|_{Y_{0,[nT,(n+1)T]}} < \beta \qquad \forall\, n \geq N.$$

Consequently, for such chosen T and N,

$$\|y_{n+1}\|_{L^2(I)} \leq r\|y_n\|_{L^2(I)} \qquad \forall\, n \geq N.$$

This inequality implies that there exists a $\nu^* > 0$ such that

$$\|v(\cdot,t)\|_{L^2(I)} = \|\partial_t u(\cdot,t)\|_{L^2(I)} \leq C\alpha_3\left(\|\phi\|_{L^2(I)}\right)\|\phi\|_{H^3(I)}e^{-\nu^* t} \qquad \forall\, t \geq 0. \tag{3.30}$$

Then, using (3.28) and Corollary 3.8 yields that

$$\|v\|_{Y_{0,[t,t+T]}} \le \alpha_4\left(\|\phi\|_{L^2(I)}, T\right)\|\phi\|_{H^3(I)}e^{-\nu^* t} \tag{3.31}$$

for any $t \ge 0$. In particular,

$$\|u_t\|_{L^2(t,t+T;H^1(I))} \le \alpha_4\left(\|\phi\|_{L^2(I)}, T\right)\|\phi\|_{H^3(I)}e^{-\nu^* t}$$

and

$$\|u\|_{L^2(t,t+T;H^1(I))} \le \alpha_0\left(\|\phi\|_{L^2(I)}, T\right)e^{-\nu^* t}$$

for any $t \ge 0$. Consequently,

$$\|a(u(\cdot,t))\partial_x u(\cdot,t)\|_{L^2(I)} + \|\partial_x u(\cdot,t)\|_{L^2(I)} \le \alpha_5\left(\|\phi\|_{L^2(I)}, T\right)\|\phi\|_{H^3(I)}e^{-\nu^* t}$$

for any $t \ge 0$.

The conclusion of Proposition 3.9 follows from the above estimates, since

$$\partial_x^3 u = -\partial_t u - a(u)\partial_x u - \partial_x u - bu.$$

The proof is complete. □

THEOREM 3.10. *Let a be a C^1 function satisfying $a(0) = 0$ and*

$$|a(\mu)| \le C(1+|\mu|^p), \quad |a'(\mu)| \le C(1+|\mu|^{p-1}) \quad \text{for any } \mu \in \mathbb{R}$$

with $1 \le p < 2$. Then there exists a $\nu > 0$ depending only on L such that for any $\phi \in L^2(I)$ and any $\varepsilon > 0$, the corresponding solution u of (2.1) belongs to the space $C(\mathbb{R}^{+*}; H^3(I))$ and satisfies

$$\|u(\cdot,t)\|_{H^3(I)} \le C_\varepsilon e^{-\nu t} \qquad \forall\ t \ge \varepsilon$$

for some constant $C_\varepsilon > 0$.

Proof. It follows directly from Corollary 2.10 and Proposition 3.9. □

Acknowledgments. This work was begun while the second author was visiting the Université Henri Poincaré Nancy 1 in 2003 and completed while the first author was visiting the University of Cincinnati in 2004. The authors thank both institutions for their hospitality, Enrique Zuazua, who brought the paper [22] to their attention, and the anonymous referees for their very useful comments.

COMPLETE STABILITY ANALYSIS OF NEUTRAL-TYPE FIRST ORDER TWO-TIME-DELAY SYSTEMS WITH CROSS-TALKING DELAYS*

RIFAT SIPAHI† AND NEJAT OLGAC†

Abstract. The stability robustness of first order linear time invariant dynamics of *neutral type* with multiple time delays against delay uncertainties is taken into consideration. We depart from a simpler investigation of Hale and Huang [*J. Math. Anal. Appl.*, 178 (1993), pp. 344–362], which studies the same problem for retarded-type systems. On this basis we further introduce two challenging features by including (a) terms that add neutral dynamics and (b) an additional term that introduces cross-talk between the multiple delays. To the best of the authors' knowledge, the stability posture of this class of systems can be treated only by a unique procedure. It is known as cluster treatment of characteristic roots (CTCR), which was recently developed for *retarded*-type dynamics. We first show the applicability of CTCR to the stability analysis of *neutral*-type multiple-delay dynamics. Next, we prove the well-known "small-delay" phenomenon for the dynamics at hand, interestingly, as a natural by-product of the CTCR paradigm. Finally, we present several case studies to display the steps and the strengths of CTCR. This deployment is scalable to treat similar problems with higher order dynamics, which have direct ramifications to some practical control applications.

Key words. neutral time-delayed dynamics, stability, multiple time delays, cluster treatment of characteristic roots (CTCR)

1. Introduction.

We consider a general class of delayed differential equations (DDEs) from the stability robustness perspective, which has not been successfully investigated in the literature. The class is of first order *neutral type*, linear time invariant (LTI) time-delay systems with two cross-talking delays. The dynamics is written in conventional form [6], [7], [8] as

$$\begin{aligned} &\frac{d}{dt}[x(t) - ax(t-\tau_1) - bx(t-\tau_2)] \\ &= cx(t-\tau_1) + dx(t-\tau_2) + fx(t-\tau_1-\tau_2) + gx(t), \end{aligned} \tag{1.1}$$

where a, b, c, d, f, g are all real scalars as well as the dependent variable $x(t)$, $(\tau_1, \tau_2) \in \mathbf{R}^{2+}$. We highlight the $fx(t-\tau_1-\tau_2)$ term as the "delay cross-talk" feature in the problem. The problem is to analyze the stability robustness of this system against time-delay uncertainties in the semi-infinite first quadrant of $(\tau_1, \tau_2) \in \mathbf{R}^{2+}$. The characteristic equation of these dynamics is transcendental,

$$CE = s(1 - ae^{-\tau_1 s} - be^{-\tau_2 s}) - ce^{-\tau_1 s} - de^{-\tau_2 s} - fe^{-(\tau_1+\tau_2)s} - g = 0, \tag{1.2}$$

where arguments of CE, (s, τ_1, τ_2) are suppressed. The stability robustness question of this system reduces to finding (τ_1, τ_2) regions where all the characteristic roots

of (1.2) remain in $\mathbf{C}^-$, the open left half of the complex plane. For a notational selection we represent the right half open plane by $\mathbf{C}^+$ and the imaginary axis by $\mathbf{C}^0$ in the rest of the text. The entire complex plane becomes the union of all three, $\mathbf{C} = \mathbf{C}^- \cup \mathbf{C}^0 \cup \mathbf{C}^+$.

It is clear from (1.2) that the highest power of s is accompanied by exponential terms (a and b nonzero) with time-delay signatures, qualifying it as a *neutral type* [2], [14], [6], [7], [8], [3], [1], [15], [20]. Furthermore, the term multiplying f introduces the cross-talk between the delays. That is, the delays τ_1 and τ_2 appear in summation form. We wish to make a clarifying statement here. Although the dynamics in (1.1) are selected as scalar (for ease of conveyance only), the procedure described in the rest of the paper is scalable to higher-dimensional systems (rather than scalar), for which such cross-talk among the delays appears quite naturally [19], [20]. For instance, if one considers the two-dimensional state-space representation of a retarded system as

$$\dot{\mathbf{y}} = \mathbf{A}\mathbf{y} + \mathbf{B}_1\mathbf{y}(t-\tau_1) + \mathbf{B}_2\mathbf{y}(t-\tau_2), \qquad y \in \mathbf{R}^2,\ \mathbf{A},\ \mathbf{B}_1,\ \mathbf{B}_2 \in \mathbf{R}^{2\times 2}, \tag{1.3}$$

it is trivial to see that the respective characteristic equation typically carries the signature of $e^{-(\tau_1+\tau_2)s}$ (i.e., cross-talking time delays) beyond the individual delay terms $e^{-\tau_1 s}$ and $e^{-\tau_2 s}$. The system is a first order vector equation, which can be decoupled into two second order scalar equations.

To the best of the authors' knowledge, no methodology exists in the literature today to resolve the stability robustness of such dynamics. For simplicity of the treatment (without loss of generality), we select scalar dynamics in this paper. In this regard, (1.2) is an extended version of the retarded-type characteristic equation treated in a cornerstone study [5] in "multiple-delay systems" literature, where a, b, f are all taken to be zero.

There are some practical ramifications of the class of dynamics we consider here. For instance, multiple time-delay feedback control is used to tune a vibration absorber (called the "delayed resonator") to two distinct excitation frequencies, in (3) in [22], with $n = 2$. The cited investigation, however, does not address the stability question of such systems. Furthermore, in (2) in [16] the authors experimentally demonstrate the viability of using acceleration feedback with time delay that renders neutral dynamics for the *delayed resonator* vibration absorber. As such, neutral dynamics with multiple delays becomes a practical phenomenon, of which the stability repercussions need further investigation. And the scalar form of these dynamics, as given in (1.1), is a meaningful starting platform to present the conceptual process we wish to follow.

It is well known that neutral-type DDEs exhibit drastic differences in their characteristic behavior compared to the retarded-type dynamics [14], [6], [7], [8], [15]. This difference may occur when either one or both components of the delay vector $\{\boldsymbol{\tau}\} = (\tau_1, \tau_2)$ transit from 0 to 0^+. We denote this transition as $\boldsymbol{\tau}_{(1,2)} : 0 \to 0^+$ in the rest of the text. During this transition, the root continuity argument may collapse and infinitely many unbounded characteristic roots may appear in $\mathbf{C}^+$. Such a root discontinuity, however, never takes place anywhere else in the $\boldsymbol{\tau} \in \mathbf{R}^{2+}$ domain. Clearly, if it occurs, this behavior precludes stability for any $(\tau_1, \tau_2) \in \mathbf{R}^{2+}$ even if the initial stability posture for $\boldsymbol{\tau} = \mathbf{0}$ is stable. This "small-delay phenomenon," or "strong stability condition," has been extensively studied in the literature [2], [14], [6], [7], [8], [3], [1], [15], and conditions guaranteeing root continuity in the transition of $\boldsymbol{\tau}_{(1,2)} : 0 \to 0^+$ have been investigated with respect to the system properties. It is also known that one should first guarantee the root continuity for $\boldsymbol{\tau}_{(1,2)} : 0 \to 0^+$ before performing the stability analysis on neutral DDEs. It is shown in [2] that to prevent

the small-delay phenomenon from occurring, the difference equation (also known as discrete kernel operator [14], [15]) consisting of the left-hand side of (1.1),

$$L(\tau_1, \tau_2) = 1 - ae^{-\tau_1 s} - be^{-\tau_2 s} = 0, \tag{1.4}$$

has to be *stable* for $\boldsymbol{\tau}_{(1,2)} : 0 \to 0^+$. It is further proven [2] that this requires the parametric condition

$$|a| + |b| < 1. \tag{1.5}$$

This inequality constitutes the *necessary and sufficient condition* for neutral dynamics (1.1) to possess root continuity during the transition of $\boldsymbol{\tau}_{(1,2)} : 0 \to 0^+$, but it is only a *necessary condition* for the system to exhibit stability at a point or in a region within $\boldsymbol{\tau} \in \mathbf{R}^{2+}$, $\boldsymbol{\tau} \neq \mathbf{0}$. This is a very critical nuance, which will be revisited throughout the text.

Dynamics that possess stable discrete kernel operator are called τ-*stabilizable* [14], [15], and we use this terminology in this text as well. Note that τ-stabilizability does not guarantee that for some values of $(\tau_1, \tau_2) \in \mathbf{R}^{2+}$ this system will be stable. But conversely, if the system is not τ-stabilizable (i.e., it is τ-nonstabilizable), no $(\tau_1, \tau_2) \in \mathbf{R}^{2+}$ can impart stability even if nondelayed dynamics, $\boldsymbol{\tau} = \mathbf{0}$, are stable. In other words, τ-stabilizability is a *necessary* but not *sufficient* condition for a stabilizing delay set $(\tau_1, \tau_2) \in \mathbf{R}^{2+}$ to exist, as the name τ-stabilizability implies.

As the main motivation of this study, we state that there is no prior literature which declares the aimed "stability map" of this system in $\{\boldsymbol{\tau}\} \in \mathbf{R}^{2+}$ exhaustively and exactly (i.e., nonconservatively). Exhaustiveness means *all* the stable regions in any given segment of interest in (τ_1, τ_2) space attached to or detached from the origin $(0, 0)$. There is considerable literature treating this very problem, primarily using the Lyapunov stability perspective, which results in very conservative stability bounds in the domain of the time delays; see, for example, [10] and the references therein. Furthering this conservatism, these methods almost exclusively search for a stability region including the origin, $\{\boldsymbol{\tau}\} = \mathbf{0}$ (also called the *delay margin problem*). We distinguished the objective in this paper from the mentioned investigations, as we aim to determine all the stability regions exactly and exhaustively. To resolve this problem, we resort to a very recent conceptual development of the authors: the cluster treatment of characteristic roots (CTCR) [19], [18], [15], [20]. This procedure was originally introduced for retarded systems. In this work we implement the CTCR technique on multiple-delay neutral systems for the first time and obtain the corresponding stability picture.

The CTCR reveals the complete stability robustness against delay uncertainties. We also show that the t-stabilizability condition (i.e., the discrete kernel operator (1.4) to be stable or the parametric inequality (1.5) to hold) is obtained as a by-product of the CTCR. Interestingly, the CTCR approach also offers a very practical way of proving this necessary condition.

One can encounter a small number of investigations in the literature on DDEs with multiple delays. The existing reports consider simpler dynamics than (1.1) where a, b, f are all taken to be zero. These selections reduce the dynamics to a "retarded" class of time-delayed systems (TDS). For example, [5] addresses this question to determine the only stability region attached to the origin (a feature which arises from the simplified dynamics). [12] proposes some interesting lemmas for the location of the characteristic roots when additional conditions are imposed: $f = 0$, $\tau_1 = 1$, $1 < \tau_2 < 2$. The study indicates the overwhelming difficulties which arise for cases

with $\tau_2 > 2$. [11], [21] treat the stability question on second order systems, which are resonant when delays are zero, a different problem from the one treated here. All of these simplifications impose some strong restrictions for the respective methods to be expanded for the problem here. In [19], [15], [20] the treatment entails a novel concept (CTCR) for a very general class of retarded TDS cases overcoming such restrictions. The present text is motivated by the deployment of this new development to a new problem with the inclusion of $a\dot{\mathbf{x}}(t-\tau_1)$ and $b\dot{\mathbf{x}}(t-\tau_2)$ terms (which introduce the neutral behavior) and $f\dot{\mathbf{x}}(t-\tau_1-\tau_2)$ (i.e., delay cross-talk term). These additions complicate the exercise considerably. Furthermore, we will show that this deployment will reveal the τ-stabilizability condition (1.5) as an imbedded by-product.

In the following section we present a review of the enabling paradigm, CTCR. Section 3 discusses the small-delay phenomenon and re-proves the τ-stabilizability condition. In section 4 we display the stability analysis results for some case studies with different selections of a, b, c, d, f, g. Section 5 contains some observations and conclusions based on the new paradigm, CTCR.

2. Review of CTCR. The highlights of the CTCR framework, borrowed from [19], [20], are presented next. We restate that these previous investigations are for *retarded*-type multiple-delay systems. Neutral systems, however, with single delay only are addressed in [18], [14], [15]. We have shown earlier that for single-delay treatments [18], [13], [14], [15] CTCR can be deployed independently from the formation of the dynamics being of retarded or neutral type. The natural pursuit of research brings us to the topic of this paper: neutral-type dynamics with multiple time delays.

We first present some important features and definitions of the general class of systems represented by (1.1):

1. There is a countably infinite number of characteristic roots of (1.2) for a given delay set (τ_1, τ_2). It is impracticable to evaluate their distribution (i.e., their topology for all variations of the delay set $(\tau_1, \tau_2) \in \mathbf{R}^{2+}$) in the quest of assessing the asymptotic stability. It is also known that for the dynamics to switch the stability posture, the characteristic roots should cross the imaginary axis, say at $s = \omega i$. Thus, for a successful stability analysis, one needs to detect exhaustively all the possible imaginary axis crossings. Let us denote the complete set of such crossing frequencies as $\mathbf{\Omega}$, and the corresponding root set as $\mathbf{S}_\Omega$:

$$\mathbf{\Omega} = \{\omega \,|\, CE(s = \omega i, \boldsymbol{\tau}) = 0,\ \boldsymbol{\tau} \in \mathbf{R}^{2+},\ \omega \in \mathbf{R}\}, \tag{2.1a}$$

$$\mathbf{S}_\Omega = \{s = \omega i \,|\, \omega \in \Omega\}. \tag{2.1b}$$

We also assume that this set, $\mathbf{\Omega}$, along with the generating delays, $\boldsymbol{\tau}$, is known completely at this stage.

2. Let us denote the correspondence between the delays (τ_1, τ_2) and ω with the notation $\langle \boldsymbol{\tau}, \omega \rangle$. Notice that, typically, there exist infinitely many characteristic roots ($s = \omega i$, $\omega \in \mathbf{\Omega}$, as $\mathbf{\Omega}$ represents a set of continuum) and the respective $\langle \boldsymbol{\tau}, \omega \rangle$ correspondence. Hence, one needs a treatment of these infinitely many roots simply by grouping them into sets, which show similar characteristics. We call this grouping the *root clustering* operation. To achieve this, however, those identifier characteristics, which we name the *clustering features*, need to be determined.

3. It is known that an imaginary root $s = \omega i$ with $\langle \boldsymbol{\tau}, \omega \rangle$, $\boldsymbol{\tau} = (\tau_1, \tau_2)$, correspondence will be repeated infinitely many times for the mesh points with equidistant grid size:

$$(\tau_{1j}, \tau_{2k}) = \left(\tau_1 + \frac{2\pi}{\omega} j,\ \tau_2 + \frac{2\pi}{\omega} k\right), \qquad j = 0, 1, 2, \ldots,\ k = 0, 1, 2, \ldots. \tag{2.2}$$

Considering the existence of root continuity, we state that *small* perturbations on τ yield *small* perturbations on ω, i.e.,

$$\langle \boldsymbol{\tau} + \boldsymbol{\epsilon}, \omega + \epsilon_c \rangle, \qquad 0 < |\boldsymbol{\epsilon}| \ll 1,\ 0 < |\epsilon_c| \ll 1. \tag{2.3}$$

Clearly, $\boldsymbol{\epsilon} = (\epsilon_1, \epsilon_2)$ and ϵ_c are interdependent through the characteristic equation (1.2). Further elaboration on this point is kept outside the document to better streamline the discussions. One can detect infinitely many curves in the $\boldsymbol{\tau}$ domain, which traverse through these infinitely many mesh points (2.2) earmarked by ω. According to the D-subdivision method [4], these trajectories continuously partition the t domain into encapsulated regions in which the number of unstable roots, NU, remains fixed.

4. The *first clustering feature* follows the above comment: It is proven in [19], [15], [20] for much more general forms of the dynamics than (1.1) that there is a manageably small number of curves in (τ_1, τ_2) space which we call the "kernel curves," $\wp_0(\tau_1, \tau_2)$, where *all* the characteristic root sets can be found, containing at least one pair of imaginary roots. These imaginary roots, when determined for the entire domain of delays $(\tau_1, \tau_2) \in \mathbf{R}^{2+}$, constitute the set $\mathbf{S}_\Omega$ as identified earlier (2.1). In summary, the kernel curves correspond to the complete set, $\mathbf{S}_\Omega$, in the sense of $\langle \boldsymbol{\tau}, \omega \rangle$.

The points on the kernel curves satisfy an important condition:

$$0 < \tau_k < \frac{2\pi}{\omega}, \qquad k = 1, 2. \tag{2.4}$$

This condition implies that the points on the kernel curves exhibit the smallest positive delay value for each delay complying with $\langle \boldsymbol{\tau}, \omega \rangle$. Assume that all such points on the kernel curves, call them generically "kernel points," $\boldsymbol{\tau}_{ker}$, are already known for *all* possible $\omega \in \boldsymbol{\Omega}$. By definition, the kernel curve formation is unique for a given system (1.1). The following notation encapsulates the complete representation of the kernel curve:

$$\wp_0 = \left\{ \boldsymbol{\tau} | \langle \boldsymbol{\tau}, \omega \rangle, \boldsymbol{\tau} \in \mathbf{R}^{2+}, \omega \in \boldsymbol{\Omega}, 0 \le \tau_k \le \frac{2\pi}{\omega}, k = 1, 2 \right\}. \tag{2.5}$$

For an exclusive stability analysis, this kernel curve set must be determined *completely* and *exhaustively*. The crucial feature of the kernel curves is that they represent *all* the possible imaginary roots of (1.2) for the entire $\boldsymbol{\tau} \in \mathbf{R}^{2+}$ domain. If there is a $\langle \boldsymbol{\tau}, \omega \rangle$ occurrence, either $\boldsymbol{\tau}$ is on the kernel curves or it can be reduced to a point on the kernel curves using j and k counters defined by (2.2) and (2.4) (one may even call it the "projection on the kernel"). That is, any and every delay set, $\boldsymbol{\tau}$, which results in a root $s \in \mathbf{S}_\Omega$ has to be represented in this "kernel set." The *first clustering feature*, therefore, appears very naturally; it is $\boldsymbol{\Omega}$, which represents the complete loci of $\boldsymbol{\tau}_{ker} \in \mathbf{R}^{2+}$ for which there exists at least a pair of imaginary characteristic roots of (1.2).

5. Kernel curves, $\wp_0(\tau_1, \tau_2)$, are, in fact, the loci of $\boldsymbol{\tau}$ described in (2.2) with the points represented by $j = k = 0$. Notice that there are ∞^2 (two-dimensional infinite) candidate points defined by (2.2) in the $\boldsymbol{\tau} \in \mathbf{R}^{2+}$ domain resulting in the same imaginary root, $\omega i \in \mathbf{S}_\Omega$. Those curves corresponding to $j > 0$ and $k > 0$ are called the "offspring curves," or "offspring" for short, and denoted by $\wp_{jk}(\tau_1, \tau_2)$,

where j and k identify the jth and kth generation offspring in τ_1 and τ_2, respectively. Consequently, the complete set containing the kernel curves and the offspring becomes $\wp(\tau_1, \tau_2)$:

$$\wp(\tau_1, \tau_2) = \wp_0(\tau_1, \tau_2) \cup \bigcup_{j=1}^{\infty} \bigcup_{k=1}^{\infty} \wp_{jk}(\tau_1, \tau_2). \tag{2.6}$$

6. It is critical to note that all the infinitely many trajectories of $\wp_{jk}(\tau_1, \tau_2)$ are created from the kernel curves, $\wp_0(\tau_1, \tau_2)$, via a nonlinear shifting term $2\pi/\omega$, as per (2.2). In addition to this, any kernel point on the trajectories of $\wp_0(\tau_1, \tau_2)$ defined by $j = k = 0$ imposes its ω signature identically onto its offspring ($j > 0$ and $k > 0$). Thus, $\mathbf{\Omega}$ remains *invariant* from kernel curves to offspring curves.

7. The kernel curves and the offspring constitute the complete (and exhaustive) distribution of (τ_1, τ_2) points where the characteristic equation $CE(s, \tau_1, \tau_2)$ has root sets containing at least one pair of imaginary roots. And outside the set $\wp(\tau_1, \tau_2)$ there is not a single point, which renders imaginary characteristic roots. These are the only locations in the (τ_1, τ_2) domain where the system (1.1) could transit from stable to unstable posture (or vice versa). These contours $\wp(\tau_1, \tau_2)$ must be determined exhaustively. Since $\wp(\tau_1, \tau_2)$ is completely generated from the kernel curves $\wp_0(\tau_1, \tau_2)$, it is sufficient for our purposes to determine these kernel curves exhaustively. We present a procedure for achieving this later in this section.

8. *Root tendency invariance property.* The root tendency along the τ_j, $j = 1, 2$, axis at the crossing of $s = \omega i$ is defined by $RT^{\tau_j}_{s=\omega i} = sgn(\Re(\frac{\partial s}{\partial \tau_j}|_{s=\omega i}))$. The root tendencies at $s \in \mathbf{S}_\Omega$ along τ_1 (or τ_2) across the corresponding points on a kernel curve and its offspring remain unchanged so long as τ_2 (or τ_1) is kept fixed. This is a proven feature for much more general constructs than (1.1) known as the "root tendency invariance" property; see [19, Proposition II], [15], [20]. This very strong property constitutes the *second clustering feature* along the contours defined by (10). Through this feature one can mark stabilizing (or destabilizing) transitions along the curves $\wp(\tau_1, \tau_2)$.

2.1. Steps of the CTCR procedure. Based on the above properties one can establish the complete stability robustness picture of the system by performing the following steps of the CTCR procedure:

1. Determine exhaustively the kernel and offspring curves, $\wp(\tau_1, \tau_2)$.

2. Start from a nondelayed system, $\boldsymbol{\tau} = \mathbf{0}$, evaluating $NU(0)$ via a trivial application of the Routh–Hurwitz method.

3. Following line segments in $\boldsymbol{\tau} \in \mathbf{R}^{2+}$, which are parallel to the individual coordinates τ_1 and τ_2, connect the origin ($\boldsymbol{\tau} = \mathbf{0}$) to a point of interest (τ_{1t}, τ_{2t}), where subscript t is used for target.

4. As this path crosses the kernel and offspring curves, increase NU by $+2$ (or -2) for the $RT = +1$ (-1), according to the D-subdivision method of El'sgol'ts [4].

5. Exhaustively identify the regions in $\boldsymbol{\tau} \in \mathbf{R}^{2+}$ where (τ_{1t}, τ_{2t}) results in $NU = 0$ as "stable" and the others ($NU > 0$) "unstable."

This completes the CTCR procedure and the stability robustness picture of this system.

Remember that the delays $\{\boldsymbol{\tau}\}$'s corresponding to the $s \in \mathbf{S}_\Omega$ set were assumed to be known in the first step of the above procedure. However, a methodology is still needed to create the topology in (2.1) and the corresponding kernel curves in (2.5) exhaustively. We discuss a *holographic mapping* procedure next to achieve this. For a

better understanding we will guide the reader through the details of the above steps in section 4 for the special dynamics at hand.

2.2. Exhaustive and complete determination of the kernel curves. This step is very critical to CTCR for obvious reasons. The complete contour of (τ_1, τ_2) which results in at least one imaginary root $s = \omega i$, $\omega \in \mathbf{R}$, must be determined. For this we use the Rekasius substitution, which was first introduced in [17] and also utilized in [19], [13], [15], [20]. It suggests the following representation for exponential terms:

$$e^{-\tau_j s} = \frac{1 - T_j s}{1 + T_j s}, \qquad T_j \in \mathbf{R},\ j = 1, 2. \tag{2.7}$$

This substitution becomes exact for $s = \omega i$, provided that the relation between T_i and τ_i,

$$\tau_{jk} = \frac{2}{\omega}[\tan^{-1}(\omega T_j) + k\pi], \qquad k = 0, 1, 2, \ldots, \tag{2.8}$$

holds. It represents an asymmetric mapping. A given ω and a T_j value correspond to infinitely many equidistant delays, τ_{jk}, $j = 1, 2$, $k = 0, 1, 2, \ldots$, where $\tau_{j,k+1} - \tau_{jk} = \frac{2\pi}{\omega}$ is the fixed grid size in the τ_j distribution. Notice that this grid size is identical for both τ_1 and τ_2 sets. In the other direction, however, the mapping is one-to-one, that is, each τ_j value maps into a single T_j value.

This asymmetric mapping between $\tau_j \leftrightarrow T_j$ transforms the transcendental CE of (1.2) into a new characteristic equation $CE_T(s, T_1, T_2)$, which is of fractional polynomial type. Multiplying this equation by $(1 + T_1 s)(1 + T_2 s)$, one obtains

$$\overline{CE}(s, T_1, T_2) = \sum_{j=0}^{3} b_j(T_1, T_2) s^j = 0. \tag{2.9}$$

Notice that $b_j(T_1, T_2)$ are some multinomials in two parameters T_1, T_2 except b_0, which is a constant. An interesting relation between the infinite-dimensional equation (1.2) and the third degree equation (2.9) is that they share the *same imaginary root sets completely*. The claim is that

$$\begin{aligned} \boldsymbol{\Omega} &= \boldsymbol{\Omega}[s | CE(s, \tau_1, \tau_2) = 0, (\tau_1, \tau_2) \in \mathbf{R}^{2+}] \cap \mathbf{C}^0 \\ &\equiv \overline{\boldsymbol{\Omega}}[s | \overline{CE}(s, T_1, T_2) = 0, (T_1, T_2) \in \mathbf{R}^2] \cap \mathbf{C}^0, \end{aligned} \tag{2.10}$$

where $\overline{\boldsymbol{\Omega}}$ represents the complete topology of root sets of $\overline{CE}$ in the $(T_1, T_2) \in \mathbf{R}^2$. The left-hand side of identity (2.10) consists of all the imaginary characteristic roots of CE for some $(\tau_1, \tau_2) \in \mathbf{R}^{2+}$, and the right-hand side is the same imaginary root set for $\overline{CE}$ at some $(T_1, T_2) \in \mathbf{R}^2$. Every (T_1, T_2) pair, which results in an imaginary root $s = \omega i$ of $\overline{CE}(s, T_1, T_2)$, represents infinitely many (τ_{1j}, τ_{2k}) pairs as per (2.8). In other words, a unique $\boldsymbol{\tau}_{ker}$ and infinitely many offspring arise. For further mathematical details on this property, the reader is referred to [19], [15], [20].

The most beneficial point in transforming $CE(s, \tau_1, \tau_2)$ to $\overline{CE}(s, T_1, T_2)$ is obvious: The parametric equation (2.9) is much easier to study than (1.2). This is a tremendous reduction in the complexity of determining the imaginary characteristic roots of (1.2), as we will observe later. $\overline{\boldsymbol{\Omega}}$ can be determined completely for the entire space of $(T_1, T_2) \in \mathbf{R}^2$ as $(s = \omega i,\ \omega \in \overline{\boldsymbol{\Omega}})$. As per the claim in (2.10) this set of imaginary roots is identical to $\mathbf{S}_\Omega$. Based on these observations the following structured

TABLE 1
The Routh array for $\overline{CE}(s, T_1, T_2)$, arguments suppressed.

s^3	b_3	b_1
s^2	b_2	b_0
s^1	$\frac{b_2 b_1 - b_3 b_0}{b_2} = R_1$	
s^0	b_0	

steps are most natural. One should first find the projection of the kernel curves in (T_1, T_2) space. We will name it the *core curve* just to discriminate its domain (T_1, T_2) from the kernel curves in (τ_1, τ_2). The correspondence between the two sets of curves is discussed in the following segments. The kernel and offspring curves constitute the complete set of contours in (τ_1, τ_2) where the possible stability transition can occur according to the D-subdivision method of [4].

Let us now show how to determine the core curve of $\overline{CE}(s, T_1, T_2)$, i.e., those (T_1, T_2) that give rise to $s = \omega i$ of $\overline{CE}(s, T_1, T_2)$. The easiest procedure for finding all the imaginary roots of such characteristic polynomials is the classical Routh–Hurwitz method [9]. From the well-known rules of the Routh array of Table 1, the imaginary roots of the cubic equation (2.9) are encountered at any point (T_1, T_2) where

$$R_1(T_1, T_2) = 0 \tag{2.11}$$

is satisfied with an additional condition,

$$b_2(T_1, T_2) b_0 > 0. \tag{2.12}$$

At these points one can determine a crossing frequency $\omega = \sqrt{b_0 / b_2(T_1, T_2)} \in \mathbf{R}$.

The implicit expressions (2.11) and (2.12) represent the core curve completely. The full expansion of the Routh array for the system (1.1) is given in the appendix. Notice the formation of $R_1(T_1, T_2)$, which is a multinomial in T_1 and T_2 of degrees 2 and 2, respectively. Therefore, for a given value of T_2 (T_1), there can be at most 2 (2) real T_1 (T_2). That is, the core curve has at most two separate segments. Since there is one-to-one mapping between the core curves in (T_1, T_2) and the kernel curves in (τ_1, τ_2) as proven in [19], [15], [20], this system can possess at most two separate contours for the kernel curves in (τ_1, τ_2), although these two contours may be split into separate segments according to the positivity condition in (2.4). The next step in CTCR is to numerically map these core curves into kernel curves via (2.8) and further to offspring in (τ_1, τ_2) space via (2.2). This completes the determination process of the entire set of kernel and offspring curves, $\wp(\tau_1, \tau_2)$.

With $\wp(\tau_1, \tau_2)$ at hand the second clustering feature can now be utilized. Namely, some segments of the kernel curves are identified as stabilizing transitions as opposed to destabilizing transitions. Ultimately, the D-subdivision methodology is implemented to declare a unique stability map of the system in (τ_1, τ_2) space. This map, in fact, constitutes an exact (nonconservative) declaration of the stability robustness picture against uncertain delays (τ_1, τ_2). And to the best of our knowledge, this is unique.

3. An interesting result on τ-stabilizability. In this section, we further discuss τ-stabilizability and show that it is, in fact, a natural by-product of the CTCR procedure. Several rigorous and cumbersome proofs of the τ-stabilizability condition (1.5) can be found in the literature [6], [7], [8]. As was stated earlier, if this necessary condition is not satisfied, even an infinitesimally small time delay $\boldsymbol{\tau}_{(1,2)} : 0 \to 0^+$

destabilizes the system, although the nondelayed ($\boldsymbol{\tau} = \mathbf{0}$) system may start asymptotically stable. Infinitely many unbounded unstable roots appear, the root continuity argument collapses in the vicinity, and consequently the D-subdivision method [4], which is really the basis of CTCR, does not apply anymore. The CTCR procedure is, however, still valid except for its final step involving D-subdivision deployment. When applied for small delays, the CTCR procedure indeed gives rise to the τ-stabilizability property. This is the highlight of the discussions in this section.

LEMMA 3.1. *The necessary condition for the system in* (1.1) *to be stable for any* $\boldsymbol{\tau} \in \mathbf{R}^{2+}$ *is the* τ*-stabilizability condition given in* (1.5).

Proof. In order to examine the stability transition of (1.1) as τ varies $\boldsymbol{\tau}_{(1,2)} : 0 \to 0^+$, we first check the stability posture of the nondelayed dynamics, which is written as

$$CE(s, \boldsymbol{\tau} = \mathbf{0}) = s(1 - a - b) - (c + d + f + g) = 0. \tag{3.1}$$

For this system to represent any dynamics, $1 - a - b$ must be nonzero. Furthermore, if $(1 - a - b)(c + d + f + g)$ is negative (positive), the nondelayed system has one stable (unstable) pole. We next investigate the $\boldsymbol{\tau}_{(1,2)} : 0 \to 0^+$ transition. During this transition, we wish to observe no change in the stability posture of the system. The contrary occurrence would mean $\omega \to \infty$ (i.e., the Riemann sphere crossing; see [15]), which invites infinitely many unbounded unstable roots. This instability posture is impossible to recover from within the $\tau_1 > 0$, $\tau_2 > 0$ domain. The reason is simply that even for some $RT = -1$ points in the quadrant, $\tau_1 > 0$, $\tau_2 > 0$, there will only be a pair (or finite number of pairs in some degenerate cases) of roots returning to $\mathbf{C}^-$, since the root continuity is now in effect. We need infinitely many such crossings to take place in order to recover from the destabilizing effect caused by the small delay. Thus, $\tau_j : 0 \to \epsilon_j$, $0 \ll \epsilon_j < 1$, has to exert no Riemann sphere crossings for any stable behavior to exist.

If there is such a crossing for small delays, we can use the Rekasius transformed equation (2.9) along with $\boldsymbol{\tau} \to \mathbf{T}$ correspondence given in (2.8). Notice that for small delays, (2.8) becomes

$$\tan\left(\frac{\tau_j \omega}{2}\right) = T_j \omega, \qquad j = 1, 2, \tag{3.2}$$

which implies that $\tau_j : 0 \to \epsilon_j$ corresponds to $T_j : 0 \to \epsilon_j/2$. In short, the τ_j and T_j variations are of the same order of magnitude. In the two-dimensional delay domain such a transition can be represented selecting a directional slope m, which is defined as

$$m = \tau_2/\tau_1 = T_2/T_1, \qquad m \in [0, \infty). \tag{3.3}$$

The "no crossing" requirement should be independent of m. Using the relation (3.3), equation (2.9) becomes

$$\overline{CE}(s, \mathbf{T}) = \overline{CE}(s, T_1, mT1) = 0. \tag{3.4}$$

Taking the limit for $0 < T_1 \ll 1$ on (3.4), we arrive at the following by dropping higher powers of T_1 and favoring the lowest power only in the coefficients of s:

$$\begin{aligned} &\lim_{0<T_1\ll 1} \overline{CE}(s, T_1, mT_1) = (1 + a + b) m T_1^2 s^3 \\ &+ (1 + a - b + m\{1 - a + b\}) T_1 s^2 + (1 - a - b) s + (-c - d - f - g) = 0. \end{aligned} \tag{3.5}$$

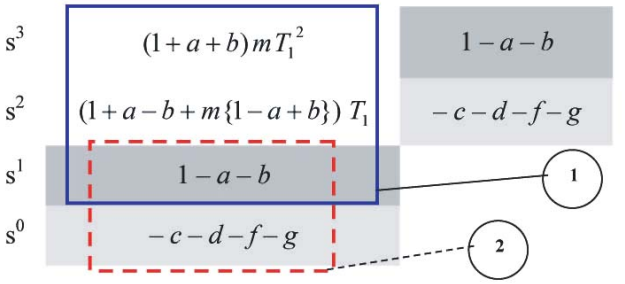

FIG. 1. *The Routh array on* (3.5) *with termwise limit* $T_1 \to \epsilon_1/2$.

We wish to find the conditions on the system parameters a, b, c, d, f, g so that (3.5) does not exhibit an imaginary root. If one forms the respective Routh array and incorporates the small T_1 approximation (i.e., favoring the lowest degree terms) for each term during the formation of this array, Figure 1 is obtained. The first column should exhibit no sign change. It consists of two blocks:

1. The coefficients of the quadratic expression for the discrete kernel operator (1.4) after Rekasius substitution. That is,

$$\begin{aligned}\overline{L}(s, T_1, T_2) &= (1 + T_1 s)(1 + T_2 s) - a(1 - T_1 s) - b(1 - T_2 s) \\ &= (1 + a + b)mT_1^2 s^2 + (1 + a - b + m\{1 - a + b\})T_1 s + (1 - a - b) = 0.\end{aligned} \tag{3.6}$$

2. The block, which is found by the coefficients of s in the nondelayed characteristic equation (3.1). If these two coefficients agree (disagree) in sign, the nondelayed dynamics are stable (unstable), respectively. In turn, it implies that the nondelayed system has no (one) root in $\mathbf{C}^+$.

If we wish to observe no change of stability posture from $T_1 : 0 \to \epsilon_1/2$ transition, independent of m, the terms in block 1 should agree in sign. This proposition yields the conditions

$$c_1 = 1 + a + b > 0, \tag{3.7a}$$

$$c_2 = 1 + a - b + (1 - a + b)m > 0, \tag{3.7b}$$

$$c_1 = 1 - a - b > 0. \tag{3.7c}$$

It is trivial to show that these conditions reduce to a simple form $|a| + |b| < 1$, which is the τ-stabilizability condition (1.5) as shown in the literature [6], [7], [8]. The admissible region in the space of (a, b) is given in Figure 2. If (a, b) satisfy (3.7), it simply guarantees that there will not be a crossing while $\boldsymbol{\tau}_{(1,2)} : 0 \to 0^+$. This property also implies that the system may be stable for some values of $(\tau_1, \tau_2) \in \mathbf{R}^{2+}$. □

Summary observations:

1. Using CTCR, we arrive at the same necessary condition for τ-stabilizability (1.5) as declared in [6], [7], [8] via a simple mathematical manipulation (Figure 1). This shows that τ-stabilizability is a natural by-product of the CTCR procedure.

2. As can be seen from Figure 2, τ-stabilizability is independent of τ_1 and τ_2 and is dictated only by the parametric selection of (a, b) pairs.

4. Example case studies. We present three case studies here for some combinations of parametric possibilities of (1.2). The first case is handled following a step-by-step pursuit of CTCR to assist the reader. The others are offered in their final outcome with some observations.

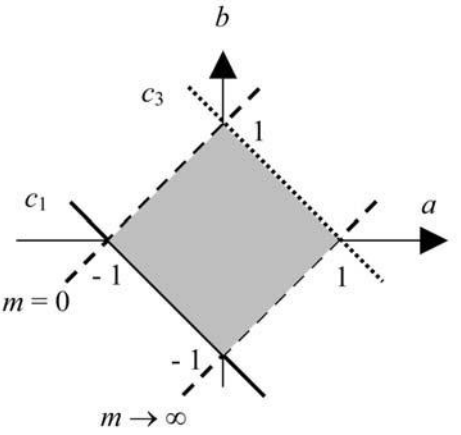

FIG. 2. *Depiction of conditions in* (3.7) *and* τ*-stabilizability region.*

4.1. Case I. Let us take $a = -0.8$, $b = -0.15$, $c = -1.5$, $d = 2$, $f = -5$, $g = 1$ in (1.2). It is clear that these dynamics are τ-stabilizable since the condition in (1.5) is satisfied, i.e., $|a| + |b| < 1$; therefore we proceed to the stability analysis. The characteristic equation is

$$s(1 + 0.8\,e^{-\tau_1 s} + 0.15\,e^{-\tau_2 s}) + 1.5\,e^{-\tau_1 s} - 2\,e^{-\tau_2 s} + 5\,e^{-(\tau_1+\tau_2)s} - 1 = 0, \tag{4.1}$$

which is stable with a pole at $s = -1.7949$ for $\{\boldsymbol{\tau}\} = \mathbf{0}$. After Rekasius substitution, we obtain the corresponding equation to (2.9) as

$$T_1T_2s^3 + (90T_1T_2 + 33T_2 + 7T_1)s^2 + (-50T_2 - 190T_1 + 39)s + 70 = 0. \tag{4.2}$$

The Routh array conditions for the complete core curve and the corresponding imaginary roots, following (2.11), (2.12) and the descriptions in the appendix, are

$$\frac{(-171T_2 - 13.3)T_1^2 + (-31.8T_2 - 45T_2^2 + 2.73)T_1 + 12.87T_2 - 16.5T_2^2}{(90T_2 + 7)T_1 + 33T_2} = 0, \tag{4.3}$$

$$b_2(T_1, T_2)b_0 = (90T_2 + 7)T_1 + 33T_2 > 0. \tag{4.4}$$

Figure 3 displays the viable curves satisfying (4.3) and (4.4) in (T_1, T_2) space. The core curve is those sections of the thick black curve which lie in the background region (shaded). Its determination, however, is exhaustive. Notice that the R_1 expression is quadratic in both T_1 and T_2; see also the appendix, (A.1). Therefore, for one value of T_1 there are at most two real T_2's, and vice versa. That is, at most two separate contours may constitute the core curve. The corresponding kernel curve in (τ_1, τ_2) space is generated numerically using (2.8), as seen in Figure 4 (thick line, shown in red in the electronic version). This figure also contains the complete range of crossing frequencies, $\boldsymbol{\Omega}$. Accordingly the system under consideration can only possess imaginary roots within the range of $1.6 \leq \omega \leq 51.12$ *rad/s* which defines the set $\boldsymbol{\Omega}$. The kernel curves contain all (τ_1, τ_2) points, which create the imaginary root set of the system entirely. That is, these dynamics can have only those imaginary characteristic roots generated by this kernel curve, and *no point in* $\boldsymbol{\tau} \in \mathbf{R}^{2+}$ *space* can render an imaginary root at ω not belonging to $\boldsymbol{\Omega}$. Corresponding offspring curves to the kernel

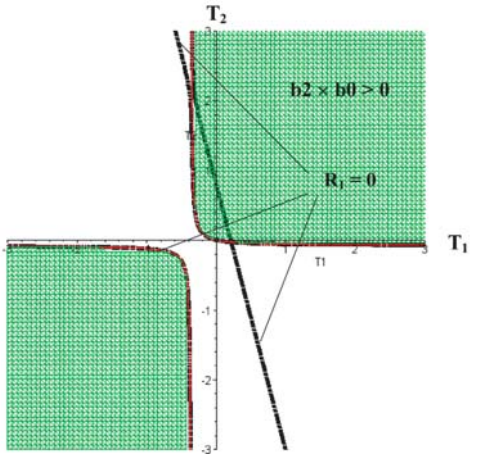

FIG. 3. $\{\mathbf{T}\}$ *domain representation, equality condition* (4.3)*, and the inequality condition in* (4.4).

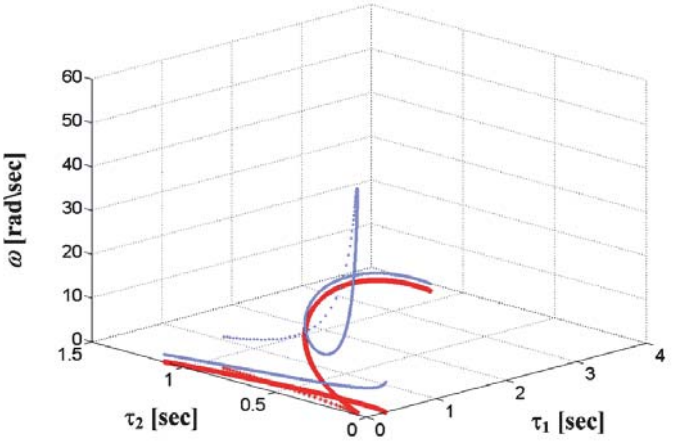

FIG. 4. *The complete kernel formation (thick line, shown in red in the electronic version) of Case* I *and the only possible* ω*'s (thin line, shown in blue in the electronic version).*

are obtained using (2.2) and are displayed in Figure 5 (thin line, shown in blue in the electronic version). They also generate exactly the same set of imaginary roots as the kernel curves, nothing more and nothing less. This concludes the formation of the first clustering feature. All the points (τ_1, τ_2), which render imaginary characteristic roots, are in Figure 5 as kernel and offspring curves.

We now look at the kernel curves and determine the root tendencies. For instance, at points A_1, A_2, and A_3, $RT^{\tau_2} = -1$ (i.e., stabilizing) and it is invariant from kernel curves to all the offspring curves. Using the D-subdivision method of [4] one can determine the number of unstable roots NU in each region in Figure 5. They are sparingly shown in the figure. Obviously wherever $NU = 0$, the stable region appears, which is shaded in the figure. In Figure 5, we also recognize that the dynamics are τ_2-independent stable for $\tau_1 < 0.0595$ s. Just to give an idea of the efficiency of the CTCR procedure, we state the CPU time of creating Figure 5 (on a 3.2 MHz Pentium 4 with 512 MB RAM) to be 25 seconds.

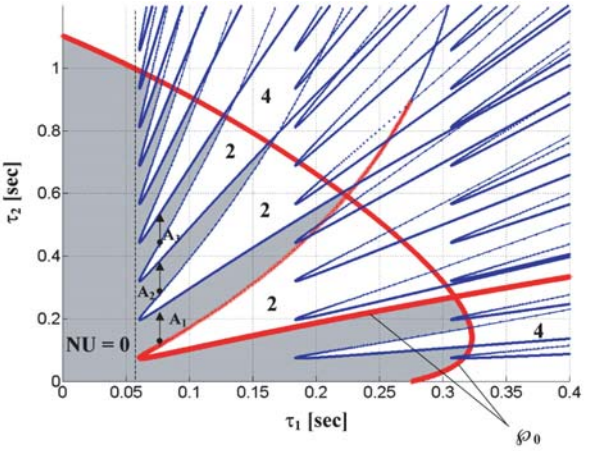

FIG. 5. *Complete stability picture of Case* I.

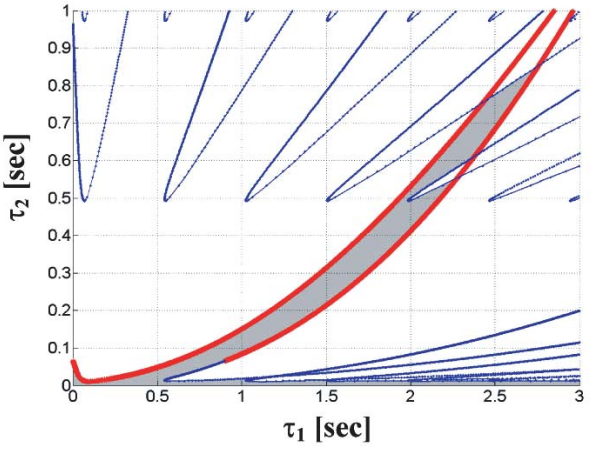

FIG. 6. *Complete stability picture of Case* II.

4.2. Case II. The system with parameters $a = 0.05$, $b = 0.9$, $c = 0.25$, $d = -1$, $f = -1.25$, $g = -1$ is again τ-stabilizable, i.e., $|a| + |b| < 1$. In Figure 6, we suppress the intermediary steps and give the stability picture only. The stable region is shaded ($NU = 0$). We observe that for $\tau_2 < 0.0109$ s the system becomes τ_1-independent stable. Also, we find (following the same logic as in Case I) that the only resonance frequencies of these dynamics are within the range $0.58 \leq \omega \leq 12.97$ rad/s, which is the set $\mathbf{\Omega}$.

4.3. Case III. Take $a = -0.35$, $b = 0.4$, $c = -12$, $d = -18$, $f = 4$, $g = -6$ as the set of parameters. The system is again τ-stabilizable. Without the intermediary steps, we show in Figure 7 the stability picture only. The stable region is shaded ($NU = 0$). We observe that for $\tau_2 < 0.0139$ s the system becomes τ_1-independent stable, and for $\tau_1 < 0.0525$ s the system is τ_2-independent stable. For this case, the only possible resonance frequencies are within the set $\mathbf{\Omega} : \{1.62 \leq \omega \leq 48.06$ $rad/s\}$.

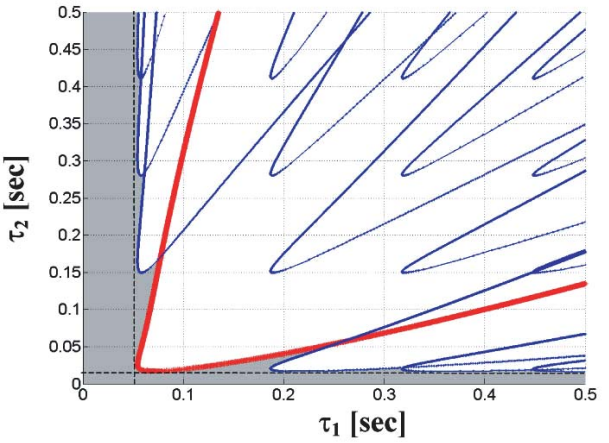

FIG. 7. *Complete stability picture of Case* III.

5. Conclusion. A general class of first order LTI scalar, two-time-delay systems of *neutral type* is studied for their stability posture. The unique features in this work are twofold. First, we have the *additional terms* that convert a cornerstone study on retarded-type dynamics by Hale and Huang [5] into a neutral type. Second, the dynamics are exacerbated by a *cross-talk term in the delays*. Both these added dynamics make the stability analysis considerably more complex. A new framework, the cluster treatment of characteristic roots (CTCR), is deployed to overcome these added complexities. CTCR offers a systematic and numerically very efficient procedure for the creation of complete stability maps of such systems. Moreover, CTCR is also deployed to re-prove the well-known necessary condition of the small delay phenomenon of neutral dynamics. It turns out that the CTCR procedure automatically generates this condition as a by-product. The end results are demonstrated in numerical case studies.

Appendix. Take the most general form of (1.2). Making the substitution of (2.7), creating (2.9), and deploying the Routh array as in Table 1, one obtains the corresponding terms to (2.11) and (2.12) as

$$
\begin{aligned}
R_1(T_1,T_2) = [&(\{2gc - 2fd - c^2 + d^2 - g^2 + f^2\}T_2 + ad - af + ag + bf + g \\
&- bg + bc - bd - ac - c + d - f)T_1^2 + (\{-d^2 - g^2 + c^2 + 2gd - 2fc + f^2\}T_2^2 \\
&+ \{2bd - 2af + 2ac - 2f - 2bf - 2bg + 2g - 2c - 2bc - 2ad - 2ag - 2d\}T_2 \\
&- 1 - b^2 + 2b + a^2)T_1 + (-d + af - ac + g + bc - f + c - bf + ad \\
&+ bg - bd - ag)T_2^2 + (b^2 + 2a - a^2 - 1)T_2]/b_2(T_1,T_2),
\end{aligned}
\tag{A.1}
$$

$$
\begin{aligned}
b_2(T_1,T_2) &= (\{c + d - f - g\}T_2 + 1 + a - b)T_1 + (1 - a + b)T_2, \\
b_0 &= -(c + d + f + g).
\end{aligned}
\tag{A.2}
$$

SECOND-ORDER OPTIMALITY CONDITIONS FOR SCALAR AND VECTOR OPTIMIZATION PROBLEMS IN BANACH SPACES*

HELMUT GFRERER†

Abstract. In this paper we present a very general and unified theory of second-order optimality conditions for general optimization problems subject to abstract constraints in Banach spaces. Our results apply both to the scalar case and the multicriteria case. Our approach rests essentially on the use of a signed distance function for characterizing metric regularity of a certain multifunction associated with the problem. We prove variational results which show that, in a certain sense, our results are the best possible that one can obtain by using second-order analysis. We demonstrate how recently devised optimality conditions can be derived from our general framework, how they can be extended under weakened assumptions from the scalar case to the multiobjective case, and even how some new results also can be obtained.

Key words. second-order optimality conditions, metric regularity, multipliers, abstract constraints, vector optimization

1. Introduction.

In this paper we study second-order optimality conditions, both necessary and sufficient, for the following optimization problem:

$$\text{(P)} \qquad \text{L-minimize } f(x) \quad \text{subject to} \quad g(x) \in K,$$

where $f : X \to U$ and $g : X \to V$ are mappings from the Banach space X into other Banach spaces U and V, $K \subset V$ is a closed convex set, and where $L \subset U$ is a closed convex cone with nonempty interior, $\operatorname{int} L \neq \emptyset$. We define two kinds of local L-minimizers as follows.

DEFINITION 1.1. *An element $\bar{x} \in X$ is called a* local weak minimizer *for* (P) *if $g(\bar{x}) \in K$ and if there exists a neighborhood N of $\bar{x}$ such that for each $x \in N$ with $g(x) \in K$, one has $f(x) - f(\bar{x}) \notin -\operatorname{int} L$. A local weak minimizer $\bar{x}$ is called a* strict local minimizer *for* (P) *if for each $x \in N \setminus \{\bar{x}\}$ with $g(x) \in K$, one has $f(x) - f(\bar{x}) \notin -L$.*

Note that (P) includes the very common problem of constrained scalar minimization, for which $U = \mathbb{R}$ and $L = \mathbb{R}_+$. Local weak minimizers for (P) then amount to usual local minimizers. The case of scalar minimization problems is the one we are most interested in, but by our approach it is also possible to treat vector optimization problems without considerable additional effort in the case of abstract constraints.

A number of well-known optimization problems can be formulated in the form (P) in a natural way. For instance, when $V = \hat{V} \times \mathbb{R}^m$, $K = \{0\} \times \mathbb{R}^m_-$, and $g = (G, g_1, \ldots, g_m)$, the feasible set of (P) is defined by an equality constraint $G(x) = 0$ and finitely many inequality constraints $g_i(x) \leq 0$, and the scalar version of (P) becomes a possibly infinite-dimensional *mathematical programming problem.*

Second-order optimality conditions have been studied in numerous publications; for scalar problems, see [4], [6], [9], [16], [18], [23], [30], [31], and for vector optimization

problems, see [5], [8], [20], [21], [22]. Our approach has been strongly inspired by the results of Levitin, Miljutin, and Osmolovskii [26] and Ioffe [16] for the mathematical programming problem. The aim of this paper is to generalize the results from [16], [26] to the problem (P). We present second-order conditions, sufficient (respectively, necessary) for local strict (respectively, weak) minimizers, which differ only by the replacement of an inequality with a strict inequality. Besides this desirable feature, we prove the following variational principle: If the second-order sufficient conditions are not fulfilled at a strict local minimizer $\bar{x}$, then we can find twice continuously differentiable perturbations $\delta f : X \to U$, $\delta g : X \to V$ having vanishing function values and first- and second-order derivatives at $\bar{x}$, such that $\bar{x}$ is not a local weak minimizer for (P), with f and g replaced by $f+\delta f$ and $g+\delta g$, respectively. A similar result also holds for the necessary conditions, provided the following suitable condition on the constraints is fulfilled: If the second-order necessary conditions hold at a point $\bar{x}$, then $\bar{x}$ is a strict local minimizer for some perturbed problem. Let us mention that the condition on the constraints we use is weaker than the very common constraint qualification of Robinson [32].

These variational principles indicate that among those second-order conditions which can be formulated solely in terms of the two convex sets L and K and function values and derivatives up to second order of f and g at a given point $\bar{x}$, our results are optimal. However, specific structures like linearity or convexity are present in many practical problems, and exploiting these structures could of course lead to better optimality conditions.

Given a point $\bar{x} \in X$, fixed throughout this paper, our results can be expressed in terms of a certain multifunction associated with (P) and $\bar{x}$. Let $h : X \to U \times V$ be defined by

$$h(x) := (f(x) - f(\bar{x}),\ g(x)), \qquad C := (-L) \times K, \qquad Y := U \times V. \tag{1.1}$$

Then the multifunction $\Gamma : X \rightrightarrows Y$, given by

$$\Gamma(x) := h(x) - C, \tag{1.2}$$

forms the basis of our investigations. In what follows we use the norm $\|(u,v)\| := \max\{\|u\|, \|v\|\}$ on the product space $Y = U \times V$.

Our notation is fairly standard. In a normed space Z, $B_Z := \{z \in Z : \|z\| \le 1\}$ denotes the closed unit ball and $S_Z := \{z \in Z : \|z\| = 1\}$ denotes the unit sphere. The topological dual space is denoted by Z^*. By $\langle z^*, z\rangle$ we denote the value $z^*(z)$ of the linear functional $z^* \in Z^*$ at $z \in Z$. For a set $D \subset Z$, we denote by $\sigma_D(\cdot)$ its support function $\sigma_D(z^*) := \sup_{z\in D}\langle z^*, z\rangle$ and by $d(\cdot, D)$ the distance function $d(z,D) := \inf_{y\in D}\|z-y\|$. For a set $D \subset Z$ the tangent cone (contingent or Bouligand cone) to D at $z \in D$ is

$$T_D(z) := \Big\{s \in Z : \exists t_n \to 0_+,\ \exists s_n \to s \text{ such that } z + t_n s_n \in D\Big\},$$

equivalent to $T_D(z) = \big\{s : \liminf_{t\to 0_+} d(z+ts, D)/t = 0\big\}$. If D is a convex set, we have that $T_D(z) = \big\{s : \limsup_{t\to 0_+} d(z+ts, D)/t = 0\big\}$.

If W is another normed space, we denote by $L(Z,W)$ the space of all continuous linear operators from Z into W. If $A \in L(Z,W)$, then $A^* : W^* \to Z^*$ denotes the adjoint operator of A.

2. Basic ideas and preliminaries. The aim of this section is to give some general background on the results we will prove. Let us recall the notion of (local) metric regularity as follows.

DEFINITION 2.1. *Let $\Psi : X \rightrightarrows Y$ be a set-valued map, $\bar{y} \in \Psi(\bar{x})$. The multifunction Ψ is called* metrically regular near $(\bar{x}, \bar{y})$ *if there are neighborhoods $N_{\bar{x}}$, $N_{\bar{y}}$ of $\bar{x}$, $\bar{y}$, respectively, and some $k > 0$ such that $d(x, \Psi^{-1}(y)) \leq k\, d(y, \Psi(x))$ for each $(x, y) \in N_{\bar{x}} \times N_{\bar{y}}$. The lower bound of such k will be called the* constant *of metric regularity of Ψ near $(\bar{x}, \bar{y})$ and denoted by* $\operatorname{Reg} \Psi(\bar{x}, \bar{y})$.

For a survey on the theory of metric regularity and also on the equivalent notions of *pseudo-Lipschitz continuity* and *openness with a linear rate*, we refer to [19] and to the monographs [24], [36]. In the context of optimization, in particular for the theory of necessary optimality conditions, the notion of metric regularity is widely used in connection with constraint qualification conditions. Indeed, the usual constraint qualification conditions of Slater, Mangasarian and Fromowitz, and Robinson are equivalent to metric regularity in an appropriate setting.

However, we will use the notion of metric regularity in another context. It was pointed out by Robinson [34] (see [10] for a similar approach) that there is a very close connection between local weak minimizers and a certain singular behavior of the multifunction Γ at $\bar{x}$.

DEFINITION 2.2. *Let $\Psi : X \rightrightarrows Y$ be a set-valued map, $\bar{y} \in \Psi(\bar{x})$. We call $\bar{y}$ an* extreme value *of Ψ at $\bar{x}$ if for some neighborhood N of $\bar{x}$, $\Psi(N)$ is not a neighborhood of $\bar{y}$.*

The following result is due to Robinson [34].

PROPOSITION 2.3. *If $\bar{x}$ is a local weak minimizer of* (P)*, then* 0 *is an extreme value of Γ at $\bar{x}$.*

Of course, if 0 is an extreme value of Γ at $\bar{x}$, then Γ is not metrically regular near $(\bar{x}, 0)$. This fact was used in [34] to obtain first-order necessary conditions. The notion of extremals is common with first-order optimality conditions (see [28] for a recent survey); however, it seems that Robinson [34] was the first to state that the usual (Fritz John or Kuhn–Tucker) conditions can be interpreted as negations of sufficient conditions for metric regularity of Γ near $(\bar{x}, 0)$. The second-order necessary conditions we present in this paper rely on the following observation.

PROPOSITION 2.4. *Let (x_n) be a sequence converging to $\bar{x}$ such that for each n, the multifunction Γ is metrically regular near $(x_n, 0)$. Then $\bar{x}$ is not a local weak minimizer for* (P).

Proof. We show that 0 is not an extreme value of Γ at $\bar{x}$. Then the assertion follows immediately from Proposition 2.3. Indeed, for any neighborhood N of $\bar{x}$, we can fix some x_n and some $r > 0$ such that $x_n + rB_X \subset N$. Since Γ is metrically regular near $(x_n, 0)$, 0 is not an extreme value of Γ at x_n. Hence, $\Gamma(N) \supset \Gamma(x_n + rB_X)$ is a neighborhood of 0 and we may conclude that 0 is not an extreme value of Γ at $\bar{x}$. ∎

It is clear from the proof of Proposition 2.4 that it would be sufficient to assume that Γ is not open at $(x_n, 0)$. However, we assumed the stronger property of metric regularity because there exist fairly accurate characterizations of metric regularity of Γ. It was shown by Ioffe [19] that metric regularity of Γ near $(\tilde{x}, 0)$ can be characterized by the slope of the functions $\psi_y(x) := d(y, \Gamma(x))$ for y near 0 and x near $\tilde{x}$. A quite similar result was derived by Rockafellar [35]. A link to sufficient conditions is given in terms of the function $\psi_0(x)$ by the following simple observation: The element $\bar{x}$ is a strict local minimizer for (P) if and only if for some neighborhood N of $\bar{x}$ we have

$$\psi_0(x) = d(0, \Gamma(x)) = \max\{d(f(x) - f(\bar{x}), -L),\ d(g(x), K)\} > 0, \quad \bar{x} \neq x \in N.$$

In our special case, $\psi_y(x)$ is simply the distance from y to the closed convex set $\Gamma(x) = h(x) - C$. Hence, instead of the very general theory for characterizing metric regularity by subdifferential calculus given in [19], we can use another approach providing more geometric insight. The core of our investigations will be the notion of a signed distance function, which seems to have been first used in the context of mathematical programming by Hiriart-Urruty [14], [15].

LEMMA 2.5. *Let D be a closed convex subset of a normed space Z and let $\hat{d}_D : Z \to \mathbb{R} \cup \{\pm\infty\}$ be given by*

$$\hat{d}_D(z) := \sup_{z^* \in S_{Z^*}} \{\langle z^*, z\rangle - \sigma_D(z^*)\}.$$

Then, for all $z \in Z$ we have

$$\hat{d}_D(z) = \begin{cases} d(z, D) & \text{if } z \notin D, \\ -\max\{\rho : z + \rho B_Z \subset D\} & \text{if } z \in D. \end{cases}$$

Proof. If $D = \emptyset$ or $D = Z$, then the assertion follows easily from the relations $\sigma_\emptyset(\cdot) \equiv -\infty$, $d(\cdot, \emptyset) \equiv +\infty$, $\sigma_Z(\cdot) \equiv +\infty$, $\sup\{\rho : z + \rho B_Z \subset Z\} = \infty$.

Now assume $\emptyset \neq D \neq Z$. If $z \notin D$, we obtain by the minimum norm duality theorem (see, e.g., [27]) $0 < d(z, D) = \max\{\langle z^*, z\rangle - \sigma_D(z^*) : z^* \in B_{Z^*}\}$. Since $z^* \to \langle z^*, z\rangle - \sigma_D(z^*)$ is positively homogenous and $d(z, D) > 0$, the maximum must be attained at some point $z^* \in S_{Z^*}$. Hence, $\hat{d}_D(z) = d(z, D)$ for all $z \notin D$. Now, let $z \in D$ and set $\bar{\rho} := \sup\{\rho : z + \rho B_Z \subset D\}$. Since D is closed, we have $z + \bar{\rho} B_Z \subset D$. Then, for each $z^* \in S_{Z^*}$ we have $\sigma_D(z^*) \geq \sigma_{z+\bar{\rho}B_Z}(z^*) = \langle z^*, z\rangle + \bar{\rho}$, implying $\hat{d}_D(z) \leq -\bar{\rho}$. On the other hand, for each $\rho > \bar{\rho}$ there exists some $z_\rho \in (z + \rho B_Z) \setminus D$, and thus

$$\begin{aligned} 0 < d(z_\rho, D) = \hat{d}_D(z_\rho) &= \sup_{z^* \in S_{Z^*}} \{\langle z^*, z_\rho\rangle - \sigma_D(z^*)\} \\ &\leq \sup_{z^* \in S_{Z^*}} \{\langle z^*, z\rangle - \sigma_D(z^*)\} + \sup_{z^* \in S_{Z^*}} \langle z^*, z_\rho - z\rangle = \hat{d}_D(z) + \|z_\rho - z\| \leq \hat{d}_D(z) + \rho, \end{aligned}$$

showing $\hat{d}_D(z) > -\rho$ for each $\rho > \bar{\rho}$. Hence, $\hat{d}_D(z) \geq -\bar{\rho}$ also holds. ∎

For $z \in D$, $-\hat{d}_D(z)$ is the radius of the largest ball around z contained in D and acts as a measure for "openness" of D around z. Note that for $z \notin D$ the distance $d(z, D) = \hat{d}_D(z)$ may be interpreted as a measure for "openness" of the complementary set $Z \setminus D$ around z.

In the rest of this section we reformulate some well-known results on metric regularity for a set-valued mapping $\Gamma : X \rightrightarrows Y$ of the form $\Gamma(x) = h(x) - C$ in connection with Lemma 2.5, where X and Y are Banach spaces, $h : X \to Y$ is an arbitrary mapping, and $C \subset Y$ is a closed convex subset of Y.

Assume $h(\bar{x}) \in C$. If h is strictly differentiable at $\bar{x}$, i.e., h is Fréchet differentiable at $\bar{x}$ and the derivative $h'(\bar{x})$ satisfies

$$\lim_{x, x' \to \bar{x}} \frac{\|h(x) - h(x') - h'(\bar{x})(x - x')\|}{\|x - x'\|} = 0,$$

then the following statements are equivalent:

(1) The multifunction Γ is metrically regular near $(\bar{x}, 0)$.

(2) The linearization $\Psi(x) := h(\bar{x}) + h'(\bar{x})(x - \bar{x}) - C$ is metrically regular near $(\bar{x}, 0)$.

(3) There holds $0 \in \operatorname{int}(h(\bar{x}) + h'(\bar{x})X - C)$.

This is basically Cominetti's Corollary 2.2 in [9]. It follows further from [9, Thm. 2.1] that $\operatorname{Reg}\Gamma(\bar{x},0) = \operatorname{Reg}\Psi(\bar{x},0)$. By the generalized open mapping theorem [33, Thm. 1] we can equivalently replace condition (3) with one of the following conditions:

(3′) There is some $\tilde{\kappa} \geq 0$ such that $0 \in \operatorname{int}(h(\bar{x}) + \tilde{\kappa}h'(\bar{x})B_X - C)$.

(3″) For all $\kappa > 0$ one has $0 \in \operatorname{int}(h(\bar{x}) + \kappa h'(\bar{x})B_X - C)$.

Though condition (3) is more convenient to verify in applications, we work with condition (3′) since it also provides some bound on $\operatorname{Reg}\Psi(\bar{x},0)$ (see Lemma 2.9 below).

In what follows we use extensively the function $\hat{d}_C(y,A,\kappa) : Y \times L(X,Y) \times \mathbb{R} \to \mathbb{R}$ given by

$$\hat{d}_C(y,A,\kappa) := \sup_{y^* \in S_{Y^*}} \{\langle y^*, y\rangle - \sigma_C(y^*) - \kappa\|A^*y^*\|\}.$$

The following proposition will be the core of the duality theory used in this paper.

PROPOSITION 2.6. *For each $A \in L(X,Y)$, each $y \in Y$, and each $\kappa \geq 0$ let $D_C(y,A,\kappa)$ be given by $D_C(y,A,\kappa) := y + \kappa AB_X - C$. Then one has*

$$\hat{d}_C(y,A,\kappa) = \begin{cases} d(0, D_C(y,A,\kappa)) & \text{if } 0 \notin \operatorname{cl} D_C(y,A,\kappa), \\ 0 & \text{if } 0 \in \operatorname{bd} D_C(y,A,\kappa), \\ -\sup\ \rho\ :\ \rho B_Y \subset D_C(y,A,\kappa) & \text{if } 0 \in \operatorname{int} D_C(y,A,\kappa). \end{cases}$$

Proof. We apply Lemma 2.5 to the set $D := \operatorname{cl} D_C(y,A,\kappa)$. Since

$$\sigma_D(y^*) = \sigma_{D_C(y,A,\kappa)}(y^*) = \sup_{x \in \kappa B_X, c \in C} \langle y^*, y + Ax - c\rangle = \langle y^*, y\rangle + \kappa\|A^*y^*\| + \sigma_C(-y^*),$$

we obtain

$$\begin{aligned} \hat{d}_D(0) &= \sup_{y^* \in S_{Y^*}} \{\langle y^*, 0\rangle - \sigma_D(y^*)\} = \sup_{y^* \in S_{Y^*}} \{\langle -y^*, y\rangle - \kappa\|A^*y^*\| - \sigma_C(-y^*)\} \\ &= \sup_{y^* \in S_{Y^*}} \{\langle y^*, y\rangle - \kappa\|A^*y^*\| - \sigma_C(y^*)\} = \hat{d}_C(y,A,\kappa). \end{aligned}$$

Next consider the closed convex set $M := \{(x, y+Ax-c) : x \in \kappa B_X,\ c \in C\} \subset X \times Y$. Since X is complete, the projection of M onto X is the bounded set κB_X, and the projection of M onto Y amounts to $D_C(y,A,\kappa)$, we may apply [33, Lem. 1] to obtain $\operatorname{int} D = \operatorname{int} D_C(y,A,\kappa)$. Since we also have $d(0,D) = d(0, D_C(y,A,\kappa))$, the assertion of the theorem follows from Lemma 2.5. ∎

It follows that Γ is metrically regular near $(\bar{x},0)$ if and only if $\hat{d}_C(h(\bar{x}), h'(\bar{x}), \tilde{\kappa}) < 0$ for some $\tilde{\kappa} \geq 0$. Using a slightly different but equivalent formula, this was already observed by Sach [37].

We now state some basic properties of the function $\hat{d}_C(y,A,\kappa)$.

LEMMA 2.7. *Let $A \in L(X,Y)$ be fixed. Then the function $\hat{d}_C(\cdot,A,\cdot)$ is convex on $Y \times \mathbb{R}$. For each fixed y, the function $\hat{d}_C(y,A,\cdot)$ is monotonically decreasing on $\mathbb{R}$, and for each fixed $\kappa \in \mathbb{R}$, the function $\hat{d}_C(\cdot,A,\kappa)$ is Lipschitz on Y with constant 1.*

Proof. Since $\hat{d}_C(\cdot,A,\cdot)$ is the pointwise supremum of a family of affine linear functions, convexity easily follows. The other assertions also follow immediately. ∎

The following two lemmas basically are the results of the equivalence between metric regularity and openness with a linear rate.

LEMMA 2.8. *Let $A \in L(X,Y)$, $y \in Y$, and $\kappa \geq 0$ be such that $\hat{d}_C(y,A,\kappa) < 0$. Then*

$$d(0, A^{-1}(C-y)) \leq \frac{\kappa}{d(y,C) - \hat{d}_C(y,A,\kappa)} d(y,C).$$

Proof. If $y \in C$, then obviously $d(y,C) = d(0,A^{-1}(C-y)) = 0$ holds. Now suppose $y \notin C$. Then $d(y,C) = d(0,y-C) = \hat{d}_C(y,A,0) > 0$ and $\bar{\alpha} := d(y,C)/(d(y,C) - \hat{d}_C(y,A,\kappa)) \in (0,1)$. Convexity of $\hat{d}_C(y,A,\cdot)$ implies that for each $\alpha \in (\bar{\alpha},1]$,

$$\hat{d}_C(y,A,\alpha\kappa) \leq \hat{d}_C(y,A,0) + \alpha(\hat{d}_C(y,A,\kappa) - \hat{d}_C(y,A,0)) < 0,$$

yielding $0 \in \operatorname{int}(y + \alpha\kappa AB_X - C)$ by Proposition 2.6. Hence, for each $\alpha \in (\bar{\alpha},1]$ there exists some $x_\alpha \in \alpha\kappa B_X$ such that $x_\alpha \in A^{-1}(C-y)$. Therefore,

$$d(0,A^{-1}(C-y)) \leq \inf_{\alpha \in (\bar{\alpha},1]} \|x_\alpha\| \leq \inf_{\alpha \in (\bar{\alpha},1]} \alpha\kappa = \bar{\alpha}\kappa = \frac{\kappa}{d(y,C) - \hat{d}_C(y,A,\kappa)} d(y,C). \quad \square$$

LEMMA 2.9. *For given $A \in L(X,Y)$, $\tilde{y} \in C$, and $\tilde{x} \in X$ consider the set-valued map $\Psi(x) := \tilde{y} + A(x-\tilde{x}) - C$. If Ψ is metrically regular near $(\tilde{x},0)$, then*

$$\operatorname{Reg}\Psi(\tilde{x},0) = \lim_{\kappa \to 0_+} \frac{\kappa}{-\hat{d}_C(\tilde{y},A,\kappa)} = \inf\left\{ \frac{\kappa}{-\hat{d}_C(\tilde{y},A,\kappa)} \,:\, \kappa > 0 \right\}.$$

Proof. As already stated above, Ψ is metrically regular near $(\tilde{x},0)$ if and only if $0 \in \operatorname{int}(\tilde{y} + \kappa AB_X - C)$ for all $\kappa > 0$, i.e., $\hat{d}_C(\tilde{y},A,\kappa) < 0$. Convexity of $\hat{d}_C(\tilde{y},A,\cdot)$, together with $\hat{d}_C(\tilde{y},A,0) \leq 0$, implies that the function $\eta(\kappa) := \kappa/(-\hat{d}_C(\tilde{y},A,\kappa))$ is increasing for positive κ. Thus, $\bar{\eta} := \lim_{\kappa \to 0_+} \eta(\kappa)$ exists and $\bar{\eta} = \inf\{\eta(\kappa) \,:\, \kappa > 0\}$. Since Ψ is assumed to be metrically regular near $(\tilde{x},0)$, for each $\epsilon > 0$ there are positive scalars k and ρ with $k < \operatorname{Reg}\Psi(\tilde{x},0) + \epsilon$ and $\operatorname{int}(\rho B_Y) \subset \Psi(\tilde{x} + k\rho B_X)$. Hence, $\hat{d}_C(\tilde{y},A,k\rho) \leq -\rho < 0$ by Proposition 2.6 and $\operatorname{Reg}\Psi(\tilde{x},0) + \epsilon \geq k \geq \eta(k\rho) \geq \bar{\eta}$. On the other hand, for arbitrarily fixed $\tilde{\kappa} > 0$ and $t \in (0,1)$, let $\epsilon := -t\hat{d}_C(\tilde{y},A,\tilde{\kappa})$ and $k := \eta(\tilde{\kappa})/(1-t)$. Next we choose neighborhoods $N_{\tilde{x}}$ of $\tilde{x}$ and N_0 of 0 such that $\|A(x-\tilde{x}) - y\| \leq \epsilon$ for all $x \in N_{\tilde{x}}$ and $y \in N_0$. Then, for any $x \in N_{\tilde{x}}$ and $y \in N_0$ we have $\hat{d}_C(w,A,\tilde{\kappa}) \leq \hat{d}_C(\tilde{y},A,\tilde{\kappa}) + \epsilon = -\kappa/k$, where $w := \tilde{y} - y + A(x-\tilde{x})$. Since $d(y,\Psi(x)) = d(w,C) \geq 0$, by using Lemma 2.8 we obtain

$$d(x,\Psi^{-1}(y)) = d(0,A^{-1}(C-w)) \leq \frac{\kappa d(w,C)}{\kappa/k + d(w,C)} \leq k d(y,\Psi(x)),$$

showing $\operatorname{Reg}\Psi(\tilde{x},0) \leq k = \eta(\tilde{\kappa})/(1-t)$. Since we may choose $t > 0$ and $\tilde{\kappa}$ arbitrarily small, $\operatorname{Reg}\Psi(\tilde{x},0) \leq \bar{\eta}$ follows. $\square$

We now state the main result for deriving the second-order necessary optimality conditions. It concerns the solvability of inclusions of the form $h(x) \in C$ near a given point x^0. This question has been extensively studied in varying degrees of generality by several authors and is ultimately related to the notion of metric regularity and the equivalent notions of pseudo-Lipschitz continuity and openness with a linear rate. We refer here only to [3], [9], [11], [12], [25], [29], [32]. The following proposition is an adaptation of such results by using the signed distance function $\hat{d}_C$ to express the constant of metric regularity.

PROPOSITION 2.10. *Let $\hat{x} \in X$ be given and suppose that there exist a continuous linear mapping $A \in L(X,Y)$, a vector $x^0 \in X$, and scalars $R > 0$, $\hat{\kappa} \geq 0$, and $\gamma > 0$ such that the following conditions are fulfilled:*

$$\|h(x') - h(x) - A(x' - x)\| \leq \gamma \|x' - x\| \ \forall x, x' \in \hat{x} + RB_X, \tag{2.1}$$

$$h(\hat{x}) + A(x^0 - \hat{x}) \in C, \ r := \|x^0 - \hat{x}\| < R/2, \tag{2.2}$$

$$2\gamma(\hat{\kappa} + 3r) + \hat{d}_C(h(\hat{x}), A, \hat{\kappa}) < 0. \tag{2.3}$$

Then there exists some $\tilde{x} \in x^0 + rB_X$ such that $h(\tilde{x}) \in C$ and Γ is metrically regular near $(\tilde{x}, 0)$. Moreover, $\hat{d}_C(h(\tilde{x}), A, \hat{\kappa} + \|\tilde{x} - \hat{x}\|) \leq \hat{d}_C(h(\tilde{x}), A, \hat{\kappa}) + \gamma\|\tilde{x} - \hat{x}\|$.

Proof. Though the statement also follows from [25, Thm. 5.1] (with some different constants appearing in (2.3)), we prefer to give a proof based on the "basic lemma" of [19]. Let $x \in x^0 + rB_X \subset \hat{x} + RB_X$ be arbitrarily fixed. Using (2.1), (2.3), and the inequality $-\|x - \hat{x}\|\|A^*y^*\| \leq -\langle y^*, A(x - \hat{x})\rangle$ we obtain

$$\begin{aligned}
&\hat{d}_C(h(x), A, \hat{\kappa} + \|x - \hat{x}\|) = \sup_{y^* \in S_{Y^*}} \{\langle y^*, h(x)\rangle - \sigma_C(y^*) - (\hat{\kappa} + \|x - \hat{x}\|)\|A^*y^*\|\} \\
&\leq \sup_{y^* \in S_{Y^*}} \{\langle y^*, h(\hat{x})\rangle - \sigma_C(y^*) - \hat{\kappa}\|A^*y^*\| + \langle y^*, h(x) - h(\hat{x})\rangle - \langle y^*, A(x - \hat{x})\rangle\} \\
&\leq \sup_{y^* \in S_{Y^*}} \{\langle y^*, h(\hat{x})\rangle - \sigma_C(y^*) - \hat{\kappa}\|A^*y^*\|\} + \sup_{y^* \in S_{Y^*}} \langle y^*, h(x) - h(\hat{x}) - A(x - \hat{x})\rangle \\
&\leq \hat{d}_C(h(\hat{x}), A, \hat{\kappa}) + \gamma\|x - \hat{x}\| \leq \hat{d}_C(h(\hat{x}), A, \hat{\kappa}) + 2\gamma r < 0.
\end{aligned}$$

Hence, by Lemma 2.8 there exists $\triangle x \in X$ with $h(x) + A\triangle x \in C$ and

$$\|\triangle x\| \leq \frac{\hat{\kappa} + \|x - \hat{x}\|}{-\hat{d}_C(h(\hat{x}), A, \hat{\kappa}) - \gamma\|x - \hat{x}\|} d(h(x), C) \leq \frac{\hat{\kappa} + 2r}{-\hat{d}_C(h(\hat{x}), A, \hat{\kappa}) - 2\gamma r} d(h(x), C).$$

Now choose $\alpha \in (0, 1]$ such that $u := x + \alpha\triangle x \in \hat{x} + RB_X$. Then we have

$$\begin{aligned}
d(h(u), C) &\leq d(h(x) + A\alpha\triangle x, C) + \|h(u) - h(x) - \alpha A\triangle x\| \\
&\leq (1 - \alpha) d(h(x), C) + \gamma\alpha\|\triangle x\| \\
&\leq d(h(x), C) - \alpha\|\triangle x\| \left(\frac{-\hat{d}_C(h(\hat{x}), A, \hat{\kappa}) - 2\gamma r}{\hat{\kappa} + 2r} - \gamma \right) \\
&= d(h(x), C) - K^{-1}\|x - u\|,
\end{aligned}$$

where $K := (\hat{\kappa} + 2r)/(-\hat{d}_C(h(\hat{x}), A, \hat{\kappa}) - \gamma(\hat{\kappa} + 4r))$. Using (2.1) and (2.2) we obtain

$$d(h(x^0), C) \leq d(h(\hat{x}) + A(x^0 - \hat{x}), C) + \|h(x^0) - h(\hat{x}) - A(x^0 - \hat{x})\| \leq \gamma r.$$

Rearranging (2.3) yields $Kd(h(x^0), C) \leq K\gamma r < r$ and by [19, basic lem.] there is some $\tilde{x}$ with $d(h(\tilde{x}), C) = 0$ and $\|\tilde{x} - x^0\| \leq Kd(h(x^0), C) < r$.

In a second step we show that Γ is metrically regular near $(\tilde{x}, 0)$. Since $\hat{d}_C(h(\tilde{x}), A, \hat{\kappa} + \|\tilde{x} - \hat{x}\|) \leq \hat{d}_C(h(\hat{x}), A, \hat{\kappa}) + \gamma\|\tilde{x} - \hat{x}\| < 0$, we obtain from Lemma 2.9 that $\Psi(x) := h(\tilde{x}) + A(x - \tilde{x}) - C$ is metrically regular near $(\tilde{x}, 0)$ and

$$\operatorname{Reg} \Psi(\tilde{x}, 0) \leq \frac{\hat{\kappa} + \|\tilde{x} - \hat{x}\|}{-d_C(h(\hat{x}), A, \hat{\kappa}) - \gamma\|\tilde{x} - \hat{x}\|} \leq \frac{\hat{\kappa} + 2r}{-d_C(h(\hat{x}), A, \hat{\kappa}) - 2\gamma r} < \frac{1}{2\gamma}.$$

Since $\Gamma(x) = \Psi(x) + (h(x) - h(\tilde{x}) - A(x - \tilde{x}))$ and $h(\cdot) - h(\tilde{x}) - A(\cdot - \tilde{x})$ is Lipschitz near $\tilde{x}$ with constant γ, we may conclude from [9, Thm. 2.1] that Γ is metrically regular near $(\tilde{x}, 0)$. ∎

3. The main optimality conditions. In what follows let $\bar{x} \in X$ be fixed, let the function $h : X \to Y$ and the closed convex set $C \subset Y$ be given by (1.1), and let Γ be given by (1.2). The second-order sufficient conditions given in this paper are an equivalent characterization of essential local minimizers of second order given by the following definition of Penot [31].

DEFINITION 3.1. *We say that $\bar{x}$ is an* essential local minimizer of second order *for problem* (P) *if $\bar{x}$ is feasible and there exists some neighborhood N of $\bar{x}$ and some real $\beta > 0$ such that*

$$d(0, \Gamma(x)) \geq \beta \|x - \bar{x}\|^2 \quad \forall x \in N. \tag{3.1}$$

Note that for scalar f, Definition 3.1 is equivalent to Penot's definition [31] of essential local minimizers of second order.

Since $d(0, \Gamma(x)) = d(h(x), C) = \max\{d(f(x) - f(\bar{x}), -L), d(g(x), K)\}$, an essential local minimizer of second order also fulfills

$$d(f(x) - f(\bar{x}), -L) \geq \beta \|x - \bar{x}\|^2 \quad \forall x \in g^{-1}(K) \cap N, \tag{3.2}$$

which clearly implies that $\bar{x}$ is a strict local minimizer. A point $\bar{x} \in g^{-1}(K)$ satisfying (3.2) is called by Jiménez and Novo [20] a *strict local minimizer of second order* for problem (P). Note that for scalar f, (3.2) is nothing else than the so-called *quadratic growth condition.* Equation (3.2) is also sufficient for $\bar{x}$ to be an essential local minimizer, provided the mapping $g(x) - K$ associated with the constraints is metrically regular near $(\bar{x}, 0)$ and f is Lipschitz near $\bar{x}$. To see this, note that by Definition 2.1 there are $k > 0$ and a neighborhood $\hat{N}$ of $\bar{x}$ such that for each $x \in \hat{N}$ there is some $\hat{x} \in g^{-1}(K)$ with $\|\hat{x} - x\| \leq k d(0, g(x) - K) = k d(g(x), K)$. We can also assume that f is Lipschitz on $\hat{N}$ with constant $\lambda > 0$. Now let us fix $\hat{\beta} > 0$ such that $\hat{\beta}(1 + k\lambda) \leq \beta/4$ and choose a positive radius $r \leq 1/(2k\hat{\beta})$ such that $\bar{x} + \frac{3}{2} r B_X \subset \hat{N} \cap N$. If $d(g(x), K) \geq \hat{\beta}\|x - \bar{x}\|^2$, then obviously $d(0, \Gamma(x)) \geq \hat{\beta}\|x - \bar{x}\|^2$ follows. On the other hand, for all $x \in \bar{x} + r B_X$ with $d(g(x), K) \leq \hat{\beta}\|x - \bar{x}\|^2$ we have $\|\hat{x} - x\| \leq k\hat{\beta}\|x - \bar{x}\|^2 \leq \frac{1}{2}\|x - \bar{x}\|$, implying $\hat{x} \in N$ and $\|\hat{x} - \bar{x}\| \geq \frac{1}{2}\|x - \bar{x}\|$. Using (3.2) we obtain

$$\begin{aligned} d(f(x) - f(\bar{x}), -L) &\geq d(f(\hat{x}) - f(\bar{x}), -L) - \lambda\|x - \hat{x}\| \geq \beta\|\hat{x} - \bar{x}\|^2 - \lambda k d(g(x), K) \\ &\geq \left(\frac{\beta}{4} - \lambda k \hat{\beta}\right) \|\hat{x} - \bar{x}\|^2 \geq \hat{\beta}\|x - \bar{x}\|^2. \end{aligned}$$

It follows that $d(0, \Gamma(x)) \geq \hat{\beta}\|x - \bar{x}\|^2$ holds for all $x \in \bar{x} + r B_X$.

Our optimality conditions are valid under the following assumption.

ASSUMPTION 1. *The mapping h is Fréchet differentiable at $\bar{x}$, and for some radius $\bar{r} > 0$ and some scalar $\eta \geq 0$ we have*

$$\|h(x_1) - h(x_2) - h'(\bar{x})(x_1 - x_2)\| \leq \eta \max\{\|x_1 - \bar{x}\|, \|x_2 - \bar{x}\|\}\|x_1 - x_2\|$$

for all $x_1, x_2 \in \bar{x} + \bar{r} B_X$.

For example, Assumption 1 is satisfied if h is continuously differentiable at $\bar{x}$ and h' is Lipschitz near $\bar{x}$ or if h is twice Fréchet differentiable at $\bar{x}$.

THEOREM 3.2. *Suppose that Assumption* 1 *is satisfied at $\bar{x}$. If $\bar{x}$ is a local weak minimizer for* (P)*, then*

$$\liminf_{\substack{x \to \bar{x} \\ \tau \to 0_+}} \frac{\hat{d}_C(h(x), h'(\bar{x}), \tau\|x - \bar{x}\|)}{\|x - \bar{x}\|^2} \geq 0. \tag{3.3}$$

Moreover, a feasible point $\bar{x}$ is an essential local minimizer of second order for (P) *if and only if*

$$\liminf_{\substack{x\to\bar{x}\\ \tau\to 0_+}} \frac{\hat{d}_C(h(x), h'(\bar{x}), \tau\|x-\bar{x}\|)}{\|x-\bar{x}\|^2} > 0. \tag{3.4}$$

Proof. We prove the first assertion by contraposition. Assume that (3.3) does not hold. We will show that $\bar{x}$ is not a local weak minimizer. In fact, if (3.3) fails to hold, there are sequences $x_n \to \bar{x}$, $\tau_n \to 0_+$ and a positive scalar $\beta > 0$ such that $\hat{d}_C(h(x_n), h'(\bar{x}), \tau_n\|x_n-\bar{x}\|) \le -\beta\|x_n-\bar{x}\|^2 < 0$ for all n. By Proposition 2.6, for each n we can find some $s_n \in \kappa_n B_X$ with $h(x_n) + h'(\bar{x})s_n \in C$, where $\kappa_n := \tau_n\|\bar{x}-x_n\|$. Let $\bar{r}$ and η be given by Assumption 1. Then for all n sufficiently large we have $\|x_n-\bar{x}\| + 3\kappa_n < \bar{r}$, $8\eta(\|x_n-\bar{x}\| + 3\kappa_n)\kappa_n - \beta\|x_n-\bar{x}\|^2 < 0$, and we may apply Proposition 2.10 with data $\hat{x} := x_n$, $A := h'(\bar{x})$, $x^0 := x_n + s_n$, $R = 3\kappa_n$, $\hat{\kappa} := \kappa_n$, and $\gamma := \eta(\|x_n-\bar{x}\| + 3\kappa_n)$ to find some $\tilde{x}_n \in X$ with $h(\tilde{x}_n) \in C$ and $\|x_n-\tilde{x}_n\| \le 2\kappa_n$ such that Γ is metrically regular at $\tilde{x}_n$. Since $\tilde{x}_n \to \bar{x}$, it follows from Proposition 2.4 that $\bar{x}$ is not a local weak minimizer and the first assertion is proved. To prove the only if part of the second assertion, we use quite similar arguments. Suppose that (3.4) does not hold. We will show that $\bar{x}$ is not an essential local minimizer of second order. If (3.4) fails to hold, we can find sequences $x_n \to \bar{x}$ and $\tau_n \to 0_+$ such that $\hat{d}_C(h(x_n), h'(\bar{x}), \tau_n\|x_n-\bar{x}\|) \le \|x_n-\bar{x}\|^2/n$ for all n. Using Proposition 2.6, we may also assume that $d(0, h(x_n) + \tau_n\|x_n-\bar{x}\|h'(\bar{x})B_X - C) \le \|x_n-\bar{x}\|^2/n$. Hence, for each n there exist some $s_n \in \tau_n\|x_n-\bar{x}\|B_X$ and some $c_n \in C$ such that $\|h(x_n) + h'(\bar{x})s_n - c_n\| \le (2/n)\|x_n-\bar{x}\|^2$. Using Assumption 1 we obtain

$$\begin{aligned} d(0, \Gamma(x_n+s_n)) &\le \|h(x_n+s_n) - c_n\| \\ &\le \|h(x_n) + h'(\bar{x})s_n - c_n\| + \|h(x_n+s_n) - h(x_n) - h'(\bar{x})s_n\| \\ &\le (2/n)\|x_n-\bar{x}\|^2 + \eta(\|x_n-\bar{x}\| + \|s_n\|)\|s_n\| = o(\|x_n-\bar{x}\|^2). \end{aligned}$$

Since $\|x_n+s_n\| \ge \|x_n-\bar{x}\|(1-\tau_n)$, it follows that $\bar{x}$ is not an essential local minimizer of second order. To complete the proof of the theorem we must show the if part of the second assertion. This follows immediately from the inequality

$$d(0, \Gamma(x)) = d(h(x), C) \ge \hat{d}_C(h(x), h'(\bar{x}), \tau\|x-\bar{x}\|),$$

valid for all $x \in X$ and $\tau > 0$. ∎

In what follows we use the following definition to refer to points satisfying the necessary condition (3.3).

Definition 3.3. *We say that $\bar{x}$ is a* critical point of second order *for* (P) *if $\bar{x}$ is feasible for* (P)*, h is Fréchet differentiable at $\bar{x}$, and condition* (3.3) *is fulfilled.*

Now we derive second-order conditions from Theorem 3.2 by means of a second-order approximation of h. To simplify the presentation, we restrict ourselves to the case that some uniform second-order expansion of h at $\bar{x}$ is possible.

Assumption 2. *h is second-order directionally differentiable at $\bar{x}$ in the sense that h is Fréchet differentiable at $\bar{x}$, the limit*

$$h''(\bar{x}; z) := \lim_{t\to 0_+} \frac{h(\bar{x}+tz) - h(\bar{x}) - th'(\bar{x})z}{t^2/2}$$

exists for all $z \in X$, and convergence is uniform with respect to z in bounded sets.

If Assumption 2 is satisfied, we obviously have $h''(\bar{x};\alpha z) = \alpha^2 h''(\bar{x};z)$ for all $\alpha \geq 0$ and all $z \in X$. Further, a uniform approximation of the form $h(x) = h(\bar{x}) + h'(\bar{x})(x-\bar{x}) + \frac{1}{2}h''(\bar{x};x-\bar{x}) + o(\|x-\bar{x}\|^2)$ holds. Hence, the following corollary follows immediately.

COROLLARY 3.4. *Suppose $\bar{x}$ is feasible for* (P) *and suppose that Assumptions* 1 *and* 2 *are satisfied. Then, $\bar{x}$ is a critical point (respectively, essential local minimizer) of second order for* (P) *if and only if there exists some scalar $\beta \geq 0$ (respectively, $\beta > 0$) such that for each sequence $(z_n, t_n, \tau_n) \subset S_X \times \mathbb{R}_+ \times \mathbb{R}_+$ with $t_n \to 0_+$ and $\tau_n \to 0_+$ one has*

$$\liminf_{n\to\infty} \sup_{y^* \in S_{Y^*}} \left\{ \frac{\langle y^*, h(\bar{x}) + t_n h'(\bar{x}) z_n \rangle - \sigma_C(y^*)}{t_n^2} + \frac{1}{2}\langle y^*, h''(\bar{x};z_n)\rangle - \frac{\tau_n}{t_n}\|h'(\bar{x})^* y^*\| \right\} \geq \beta. \tag{3.5}$$

The following two theorems give further details on the optimality conditions of Theorem 3.2 and Corollary 3.4.

THEOREM 3.5. *Suppose that a feasible point $\bar{x}$ is not an essential local minimizer of second order for* (P). *Then there exists a twice continuously differentiable mapping $\delta h := (\delta f, \delta g)$ satisfying $\delta h(\bar{x}) = 0$, $\delta h'(\bar{x}) = 0$, and $\delta h''(\bar{x}) = 0$, such that $\bar{x}$ is not a local weak minimizer for* (P) *with f and g replaced by $f + \delta f$ and $g + \delta g$, respectively.*

Proof. Since $\bar{x}$ is not an essential local minimizer, there exists a sequence $x_n \to \bar{x}$ satisfying $d_n := \max\{d(f(x_n) - f(\bar{x}), -L),\ d(g(x_n), K)\} = o(\|x_n - \bar{x}\|^2)$. Hence, we can find a sequence $y_n = (u_n, v_n)$ in $(-\operatorname{int} L) \times K$ such that $\|h(x_n) - y_n\| = \max\{\|f(x_n) - f(\bar{x}) - u_n\|, \|g(x_n) - v_n\|\} \leq d_n + \|x_n - \bar{x}\|^3 =: \bar{d}_n$. Taking a subsequence if necessary, we may suppose that

$$\sum_{n=1}^{\infty} \frac{\bar{d}_n}{\|x_n - \bar{x}\|^2} < \infty. \tag{3.6}$$

We shall now construct a subsequence of (x_n), still denoted by (x_n), satisfying

$$\tau_n := \|x_n - \bar{x}\| \leq \frac{d(\bar{x}, A_{n-1})}{4} \leq \frac{\tau_{n-1}}{4} \quad \forall n \geq 2, \tag{3.7}$$

where A_n denotes the convex hull of $x_1, \ldots, x_n$. Let m_n denote the dimension of the linear hull of $x_1 - \bar{x}, \ldots, x_n - \bar{x}$. If the sequence (m_n) is bounded, $x_1 - \bar{x}, x_2 - \bar{x}, \ldots$ are contained in a finite-dimensional subspace $E \subset X$. Hence, we can find a subsequence of (x_n), still denoted by (x_n), and $z \in E$, $\|z\| = 1$ such that $(x_n - \bar{x})/\tau_n \to z$. By passing once more to a subsequence if necessary, we may also assume that $\|(x_n - \bar{x})/\tau_n - z\| \leq 1/2$ for all n and $\tau_n \leq \tau_{n-1}/8$ for all $n \geq 2$. Now, let $n \geq 2$ and $x \in A_{n-1}$ be arbitrarily fixed. Then x can be expressed as a convex combination $\sum_{i=1}^{n-1} \alpha_i x_i$, and we obtain

$$\begin{aligned} \|x - \bar{x}\| &= \left\| \sum_{i=1}^{n-1} \alpha_i (x_i - \bar{x}) \right\| \geq \left\| \sum_{i=1}^{n-1} \alpha_i \tau_i z \right\| - \left\| \sum_{i=1}^{n-1} \alpha_i \tau_i \left(\frac{x_i - \bar{x}}{\tau_i} - z \right) \right\| \\ &\geq \frac{1}{2} \sum_{i=1}^{n-1} \alpha_i \tau_i \geq \frac{\tau_{n-1}}{2}. \end{aligned}$$

Since $x \in A_{n-1}$ was arbitrary, we have $d(\bar{x}, A_{n-1}) \geq \tau_{n-1}/2 \geq 4\tau_n$, and (3.7) follows. On the other hand, if the sequence (m_n) is unbounded, we can find a subsequence of (x_n), still denoted by (x_n), such that $m_n = n$ holds for all n. Then we have $\bar{x} \notin A_n$ for all n. Since A_n is the convex hull of finitely many points, A_n is closed. Therefore, we have $d(\bar{x}, A_n) > 0$ for all n, and by taking again a suitable subsequence, (3.7) holds.

By the minimum norm duality theorem (see, e.g., [27]), we can find for each $n \geq 2$ some $p_n^* \in B_{X^*}$ such that $d(x_n, A_{n-1}) = \langle p_n^*, x_n \rangle - \sigma_{A_{n-1}}(p_n^*)$. Then, for each $n' < n$ we have $x_{n'} \in A_{n-1}$, and hence

$$\langle p_n^*, x_n - x_{n'} \rangle \geq \langle p_n^*, x_n \rangle - \sigma_{A_{n-1}}(p_n^*) = d(x_n, A_{n-1}) \geq d(\bar{x}, A_{n-1}) - \tau_n \geq 3\tau_n.$$

On the other hand, for each n there exists also $q_n^* \in S_{X^*}$ such that $\langle q_n^*, x_n - \bar{x} \rangle = \tau_n$, implying

$$\langle q_n^*, x_n - x_{n'} \rangle = \langle q_n^*, x_n - \bar{x} \rangle + \langle q_n^*, \bar{x} - x_{n'} \rangle \geq \tau_n - \tau_{n'} \geq \frac{3}{4}\tau_n$$

for each $n' > n$. Now, for each n let

$$\delta h_n(x) := \max\left\{1 - 2\frac{\langle p_n^*, x_n - x \rangle^2 + \langle q_n^*, x_n - x \rangle^2}{\tau_n^2}, 0\right\}^3 (y_n - h(x_n)) \quad \forall x \in X,$$

where $p_1^* := 0$. It follows that

$$\delta h_n(x_{n'}) = \begin{cases} y_n - h(x_n) & \text{for } n = n', \\ 0 & \text{for } n \neq n'. \end{cases} \tag{3.8}$$

Further, δh_n is twice continuously differentiable and

$$\begin{aligned} \delta h_n'(x)s &= -12c_n^2(x)B_n(x,s)r_n, \\ \delta h_n''(x)st &= 12c_n(x)r_n\left(8B_n(x,s)B_n(x,t) - c_n(x)\frac{\langle p_n^*, s\rangle\langle p_n^*, t\rangle + \langle q_n^*, s\rangle\langle q_n^*, t\rangle}{\tau_n^2}\right), \end{aligned}$$

where $c_n(x) := \max\{1 - 2(\langle p_n^*, x_n - x\rangle^2 + \langle q_n^*, x_n - x\rangle^2)/\tau_n^2, 0\}$, $r_n := y_n - h(x_n)$, and $B_n(x,s) := (\langle p_n^*, x - x_n\rangle\langle p_n^*, s\rangle + \langle q_n^*, x - x_n\rangle\langle q_n, s\rangle)/\tau_n^2$. Obviously, $0 \leq c_n(x) \leq 1$ holds for all $x \in X$. If $c_n(x) > 0$, we have $|\langle p_n^*, x - x_n\rangle| \leq \tau_n/\sqrt{2}$ and $|\langle q_n^*, x - x_n\rangle| \leq \tau_n/\sqrt{2}$, implying $|B_n(x,s)| \leq \sqrt{2}\|s\|/\tau_n$. Hence, by these facts and (3.6), we obtain

$$\sum_{n=1}^{\infty} \|\delta h_n(x)\| \leq \sum_{n=1}^{\infty} \bar{d}_n < \infty, \quad \sum_{n=1}^{\infty} \|\delta h_n'(x)\| \leq \sum_{n=1}^{\infty} 12\sqrt{2}\frac{\bar{d}_n}{\tau_n} < \infty,$$

$$\sum_{n=1}^{\infty} \|\delta h_n''(x)\| \leq \sum_{n=1}^{\infty} 216\frac{\bar{d}_n}{\tau_n^2} < \infty$$

for all $x \in X$. Since Y is a Banach space, we may conclude that $\delta h := \sum_{n=1}^{\infty} \delta h_n$ is well defined and twice continuously differentiable due to the uniform convergence with respect to x of $\sum_n \delta h_n$, $\sum_n \delta h_n'$, and $\sum_n \delta h_n''$. Because $\langle q_n^*, x_n - \bar{x}\rangle = \tau_n$, we have $c_n(\bar{x}) = 0$ for all n. Therefore, $\delta h(\bar{x}) = 0$, $\delta h'(\bar{x}) = 0$, $\delta h''(\bar{x}) = 0$. Splitting δh into the two components δf and δg, it remains to show that $\bar{x}$ is not a local weak

minimizer for (P), with f and g replaced by $f+\delta f$ and $g+\delta g$. Since $\delta h(\bar{x})=0$, $\bar{x}$ is feasible also for the perturbed problem, and the value of the objective function at $\bar{x}$ remains unchanged. However, since $\delta h(x_n)=y_n-h(x_n)$ for each n by (3.8), we obtain

$$(g+\delta g)(x_n)=g(x_n)+(v_n-g(x_n))=v_n\in K,$$

$$(f+\delta f)(x_n)-(f+\delta f)(\bar{x})=f(x_n)+u_n-(f(x_n)-f(\bar{x}))-f(\bar{x})=u_n\in -\operatorname{int} L.$$

Since $x_n\to\bar{x}$, this completes the proof. □

THEOREM 3.6. *Assume that $\bar{x}$ is a critical point of second order for problem* (P). *Further assume that*

$$\operatorname{int}(h'(\bar{x})B_X-C)\neq\emptyset. \tag{3.9}$$

Then there exist a mapping $\delta h=(\delta f,\delta g)$ with $\delta h(x)=\psi(\|x-\bar{x}\|)y$, where $y\in Y$ and $\psi:\mathbb{R}_+\to\mathbb{R}_+$ is a twice continuously differentiable function satisfying $\psi(0)=\psi'(0)=\psi''(0)=0$, such that $\bar{x}$ is a strict local minimizer for (P) *with f and g replaced by $f+\delta f$ and $g+\delta g$, respectively.*

Proof. Define

$$\eta(r):=-\min\left\{0,\inf_{\bar{x}\neq x\in\bar{x}+rB_X}\frac{\hat{d}_C(h(x),h'(\bar{x}),\|x-\bar{x}\|^{3/2})}{\|x-\bar{x}\|^2}\right\},\quad r>0.$$

Then, η is monotonically increasing and $\lim_{r\to 0_+}\eta(r)=0=:\eta(0)$. We shall now construct a twice continuously differentiable function $\psi:\mathbb{R}_+\to\mathbb{R}_+$ so that $\psi(0)=\psi'(0)=\psi''(0)=0$ and $\psi(r)>r^2\eta(r)$ for all $r\in(0,1)$. At first we define recursively a sequence (φ_n) of positive reals by $\varphi_0:=\eta(1)+1$ and $\varphi_n:=\max\{\varphi_{n-1}/2,\eta(2^{-n})\}$. If $\varphi_n=\varphi_{n-1}/2$, we obviously have $\varphi_n<\varphi_{n-1}$. On the other hand, if $\varphi_n=\eta(2^{-n})$, then by the monotonicity of η we have $\varphi_n\le\eta(2^{-(n-1)})\le\varphi_{n-1}$. Hence, the sequence (φ_n) is decreasing. Moreover, it is easy to see that $\lim_n\varphi_n=0$. Hence, we can construct a continuously increasing function $\varphi:\mathbb{R}_+\to\mathbb{R}_+$ in such a way that $\varphi(0)=0$, φ is linear on every interval $[2^{-(n+1)},2^{-n}]$, $\varphi(2^{-n})=\varphi_n$, and $\varphi(t)=\varphi_0+(t-1)\varphi_0$ for $t>1$. Define $\psi'(r):=256\int_0^r\varphi(\xi)d\xi$ for all $r\ge 0$. Since $\varphi(\xi)$ is positive and increasing for $\xi>0$ and since $\varphi_{n+1}\ge\varphi_n/2$, we get

$$\psi'(2^{-n})>256\int_{2^{-(n+1)}}^{2^{-n}}\varphi(2^{-(n+1)})d\xi=256\cdot 2^{-(n+1)}\varphi_{n+1}\ge 64\cdot 2^{-n}\varphi_n$$

for all n. Now define $\psi(r):=\int_0^r\psi'(\xi)d\xi$ for $r\ge 0$. Let $r\in(0,1)$ be arbitrarily fixed and let n denote the unique number such that $r\in[2^{-(n+1)},2^{-n})$. Using similar arguments as above we obtain

$$\begin{aligned}\psi(r)&>\int_{2^{-(n+2)}}^{2^{-(n+1)}}\psi'(2^{-(n+2)})d\xi=2^{-(n+2)}\psi'(2^{-(n+2)})\\&>64\cdot(2^{-(n+2)})^2\varphi_{n+2}\ge(2^{-n})^2\varphi_n\ge(2^{-n})^2\eta(2^{-n})\ge r^2\eta(r).\end{aligned}$$

Further, it is easy to see that ψ has the claimed differentiability properties.

By virtue of (3.9) we can find some $\tilde{y}\in Y$ so that $0\in\operatorname{int}(\tilde{y}+h(\bar{x})+h'(\bar{x})B_X-C)$. By Proposition 2.6 we have $-2\rho:=\hat{d}_C(\tilde{y}+h(\bar{x}),h'(\bar{x}),1)<0$. Now let $\delta h(x):=$

$\psi(\|x-\bar{x}\|)y$, where $y := -\tilde{y}/\rho$. Now we show that $\bar{x}$ is a strict local minimizer for the perturbed problem. By Lemma 2.7, $\hat{d}_C(\cdot, h'(\bar{x}), \cdot)$ is convex. Thus

$$\begin{aligned}\hat{d}_C((1+\alpha)h(x) - \alpha(\tilde{y}+h(\bar{x})), h'(\bar{x}), (1+\alpha)\|x-\bar{x}\|^{3/2} - \alpha) \\ \geq (1+\alpha)\hat{d}_C(h(x), h'(\bar{x}), \|x-\bar{x}\|^{3/2}) - \alpha\hat{d}_C(\tilde{y}+h(\bar{x}), h'(\bar{x}), 1) \\ \geq -(1+\alpha)\|x-\bar{x}\|^2\eta(\|x-\bar{x}\|) + 2\alpha\rho\end{aligned}$$

for all $\alpha \geq 0$ and all x. By Lipschitz continuity of $\hat{d}_C(\cdot, h'(\bar{x}), \kappa)$ we obtain

$$\begin{aligned}&\hat{d}_C(h(x) - \alpha\tilde{y}, h'(\bar{x}), (1+\alpha)\|x-\bar{x}\|^{3/2} - \alpha) \\ &\geq -\|x-\bar{x}\|^2\eta(\|x-\bar{x}\|) + \alpha[2\rho - \|x-\bar{x}\|^2\eta(\|x-\bar{x}\|) - \|h(x)-h(\bar{x})\|].\end{aligned} \tag{3.10}$$

Finally, we can find some $R \in (0,1)$ such that for all $x \in \bar{x} + RB_X$ we have

$$\|x-\bar{x}\|^2\eta(\|x-\bar{x}\|) + \|h(x)-h(\bar{x})\| < \rho, \ \frac{\psi(\|x-\bar{x}\|)}{\rho} \leq \|x-\bar{x}\|^{3/2}.$$

Hence, for all $x \in \bar{x} + RB_X$, $x \neq \bar{x}$, we have

$$\kappa(x) := \left(1 + \frac{\psi(\|x-\bar{x}\|)}{\rho}\right)\|x-\bar{x}\|^{3/2} - \frac{\psi(\|x-\bar{x}\|)}{\rho} \geq \frac{\psi(\|x-\bar{x}\|)}{\rho}\|x-\bar{x}\|^{3/2} > 0,$$

and by using (3.10) with $\alpha = \psi(\|x-\bar{x}\|)/\rho$,

$$\hat{d}_C((h+\delta h)(x), h'(\bar{x}), \kappa(x)) \geq -\|x-\bar{x}\|^2\eta(\|x-\bar{x}\|) + \psi(\|x-\bar{x}\|) > 0,$$

which together with Proposition 2.6 shows that $d((h+\delta h)(x), C) > 0$. Using $\delta f(\bar{x}) = 0$, we obtain that $\bar{x}$ is a strict local minimizer for the perturbed problem. □

Now, the smoothness of the perturbation function δh given by Theorem 3.6 depends on geometric properties of the underlying space X. However, in any case, δh fulfills Assumptions 1 and 2: It is easy to see that δh is Fréchet differentiable at $\bar{x}$ with $\delta h'(\bar{x}) = 0$ and second-order directionally differentiable with

$$\delta h''(\bar{x}; z) = \lim_{t \to 0_+} \frac{\psi(t\|z\|) - \psi(0) - t\psi'(0)}{t^2/2} y = 0 \quad \forall z \in X, \tag{3.11}$$

and that the convergence in (3.11) is uniform with respect to z in bounded sets. Further, δh fulfills Assumption 1 with arbitrarily small η. In fact, let $\eta > 0$ be arbitrarily fixed. Since ψ is twice continuously differentiable with $\psi''(0) = \psi'(0) = 0$, we can find some $r_\eta > 0$ so that $\|y\||\psi'(r)| \leq \eta r$ for all $r \in [0, r_\eta]$. By the mean-value theorem, for every $x_1, x_2 \in \bar{x} + r_\eta B_X$ we can find some r in the interval $[\|x_1-\bar{x}\|, \|x_2-\bar{x}\|] \subset [0, r_\eta]$ so that $\psi(\|x_1-\bar{x}\|) - \psi(\|x_2-\bar{x}\|) = \psi'(r)(\|x_1-\bar{x}\| - \|x_2-\bar{x}\|)$. Since $\|y\||\psi'(r)| \leq \eta r \leq \eta \max\{\|x_1-\bar{x}\|, \|x_2-\bar{x}\|\}$ and $\delta h'(\bar{x}) = 0$, we obtain

$$\begin{aligned}\|\delta h(x_1) - \delta h(x_2) - \delta h'(\bar{x})(x_1-x_2)\| &= \|\psi'(r)(\|x_1-\bar{x}\| - \|x_2-\bar{x}\|)y\| \\ &\leq |\psi'(r)|\|y\|\|x_1-x_2\| \leq \eta\max\{\|x_1-\bar{x}\|, \|x_2-\bar{x}\|\}\|x_1-x_2\|.\end{aligned}$$

Hence, Assumption 1 is fulfilled for δh.

Moreover, it is easy to see that δh is twice continuously differentiable if X is a Hilbert space. Similarly, if X is Hilbertizable (i.e., there exists a norm $|||\cdot|||$ that is equivalent to the one of X and for which X is a Hilbert space), some straightforward

modifications of the proof of Theorem 3.6 yield that the assertion remains valid with some twice continuously differentiable perturbation function of the form $\delta h(x) = \psi(|\|x - \bar{x}\||)y$.

Now let us discuss condition (3.9). If (3.9) is not fulfilled, as a consequence of Proposition 2.6 we have that the necessary conditions (3.3) and (3.5) with $\beta = 0$ automatically hold, regardless of whether $\bar{x}$ is a local weak minimizer or not. In this case, the necessary conditions only reflect some degeneration of the problem.

DEFINITION 3.7. *Let h be differentiable at $\bar{x}$. Then $\bar{x}$ is called* nondegenerate *if* (3.9) *holds, i.e.,* $\operatorname{int}(h'(\bar{x})B_X - C) \neq \emptyset$.

Note that condition (3.9) is actually a condition on the constraints: since we assume $\operatorname{int} L \neq \emptyset$, (3.9) holds if and only if

$$\operatorname{int}(g'(\bar{x})B_X - K) \neq \emptyset. \tag{3.12}$$

As a consequence of the generalized open mapping theorem [33, Thm. 1], this can also be equivalently written as $\operatorname{int}(g'(\bar{x})X - K) \neq \emptyset$. This shows that condition (3.12) is weaker than Robinson's constraint qualification

$$0 \in \operatorname{int}(g(\bar{x}) + g'(\bar{x})X - K), \tag{3.13}$$

stating the metric regularity of the constraint mapping $g(x) - K$ at $(\bar{x}, 0)$.

If $\operatorname{int} K \neq \emptyset$, then (3.12) is trivially fulfilled. If the constraints can be subdivided into general inequality constraints of the form $\tilde{g}(x) \in \tilde{K}$ with $\operatorname{int} \tilde{K} \neq \emptyset$ and "equality" constraints $G(x) \in Q$, where the interior of the closed convex set Q is possibly empty, $\operatorname{int} Q = \emptyset$, then condition (3.12) holds if and only if the condition on the "equality" constraints

$$\operatorname{int}(G'(\bar{x})B_X - Q) \neq \emptyset \tag{3.14}$$

holds. For instance, in the case of the mathematical programming problem, we have $Q = \{0\}$, and then conditions (3.12) and (3.14), respectively, are equivalent to the well-known Lyusternik condition $G'(\bar{x})X = \hat{V}$. It has been already observed by several authors (see, e.g., [4], [5], [18], [26]) that only some regularity assumptions on the equality constraints are required for the development of second-order necessary conditions. Another special case of interest appears when the "equality" constraints are explicit constraints of the form $x \in Q$, i.e., $G(x) = x$. Then condition (3.14), and hence also condition (3.12), is fulfilled for such structured constraints, and consequently $\bar{x}$ is nondegenerate.

Note that condition (3.9) is essential in Theorem 3.6: For the scalar problem

$$\min_{x \in \mathbb{R}^2} -x_1^2 - x_2^2 \quad \text{subject to} \quad x_1 x_2 = 0,$$

the point $\bar{x} = (0, 0)$ is degenerate (i.e., (3.9) is not fulfilled) and by using the second-order necessary conditions [1, Thm. 3.2] one can see that the conclusion of Theorem 3.6 does not hold. For a survey on second-order conditions in the degenerate case for a special class of problems, we refer to the monograph [2]. Note that our definition of degenerate points corresponds to that of *abnormal points* in [1] and [2].

In this paper we restrict ourselves to necessary optimality conditions for nondegenerate local minimizers only. However, in another paper [13] we present new second-order necessary conditions which are meaningful also in the degenerate case. These conditions rest also upon Propositions 2.4 and 2.10; however, second-order derivatives are used to build first-order approximations of first derivatives, whereas in this paper second-order derivatives are used only to build second-order expansions of our problem functions.

4. First-order necessary conditions revisited. Up to now we have said nothing about first-order necessary conditions. One reason is that some kind of first-order necessary conditions are implicitly contained in the second-order conditions; another reason is that at an essential local minimizer of second order the classical multiplier conditions need not hold, as can be seen from an example that will be presented in the next section.

Throughout this section we assume that h is strictly differentiable at $\bar{x}$. Then, Fritz John–type optimality conditions can be written in the form

$$f'(\bar{x})^*u^* + g'(\bar{x})^*v^* = 0, \quad 0 \neq (u^*, v^*) \in L^* \times N_K(g(\bar{x})) \subset U^* \times V^*, \tag{4.1}$$

where $L^* := \{u^* \in U^* : \langle u^*, u\rangle \geq 0 \text{ for all } u \in L\}$ is the dual cone of the cone L and $N_K(z) := \{v^* \in V^* : \langle v^*, v - z\rangle \leq 0 \text{ for all } v \in K\}$ is the normal cone to K at z. Setting $y^* := (u^*, v^*)$ and using the notation of h and C, condition (4.1) can also be written in a shorter form as

$$h'(\bar{x})^*y^* = 0, \quad y^* \in N_C(h(\bar{x})), \quad y^* \neq 0. \tag{4.2}$$

In what follows we denote the set of multipliers y^* satisfying the Fritz John conditions (4.2) by Λ_{FJ}. It should be noted that in general Λ_{FJ} may be empty. An additional condition has to be imposed to ensure the existence of a nontrivial multiplier y^* at a local weak minimizer for (P). For instance, condition (3.9) can be used, as easily follows from Theorem 3 in [34].

We say that the Kuhn–Tucker conditions hold if the Fritz John conditions (4.1) hold with $u^* \neq 0$. It is well known that at a local weak minimizer the Kuhn–Tucker conditions hold under Robinson's constraint qualification (3.13); see [34, Thm. 4]. We denote by Λ_{KT} the set of multipliers y^* satisfying the Kuhn–Tucker conditions.

We now discuss some aspects of first-order conditions in terms of the material presented in section 2. If $\bar{x}$ is a local weak minimizer of problem (P), then by Proposition 2.3 $h(\cdot) - C$ is not metrically regular near $(\bar{x}, 0)$, or equivalently, since h is assumed to be strictly differentiable at $\bar{x}$,

$$\hat{d}_C(h(\bar{x}), h'(\bar{x}), 1) = \sup_{y^* \in S_{Y^*}} \{\langle y^*, h(\bar{x})\rangle - \sigma_C(y^*) - \|h'(\bar{x})^*y^*\|\} \geq 0.$$

Since $h(\bar{x}) \in C$ we have $\langle y^*, h(\bar{x})\rangle - \sigma_C(y^*) \leq 0$ for all y^*. Hence, $h(\cdot) - C$ is not metrically regular near $(\bar{x}, 0)$ if and only if there exists a sequence $(y_n^*) \subset S_{Y^*}$ with

$$\lim_{n\to\infty} \{\sigma_C(y_n^*) - \langle y_n^*, h(\bar{x})\rangle\} = 0, \quad \lim_{n\to\infty} \|h'(\bar{x})^*y_n^*\| = 0. \tag{4.3}$$

LEMMA 4.1. *If $\bar{x}$ is a critical point of second order for problem* (P)*, then $h(\cdot) - C$ is not metrically regular at $(\bar{x}, 0)$.*

Proof. We argue by contraposition. Assume on the contrary that $h(\cdot) - C$ is metrically regular near $(\bar{x}, 0)$. Then $\bar{x}$ is not a local weak minimizer; i.e., there exist a sequence $(x_n) \to \bar{x}$ such that $x_n \neq \bar{x}$ and $h(x_n) \in C$ for all n. Define $\tau_n := \|x_n - \bar{x}\|$. Then, by the definition of a critical point of second order, we obtain a sequence $(y_n^*) \subset S_{Y^*}$ such that

$$\liminf_{n\to\infty} \left\{ \frac{\langle y_n^*, h(x_n)\rangle - \sigma_C(y_n^*)}{\|x_n - \bar{x}\|^2} - \|h'(\bar{x})^*y_n^*\| \right\} \geq 0.$$

Since $h(x_n) \in C$ we have $\langle y_n^*, h(x_n)\rangle - \sigma_C(y_n^*) \leq 0$, implying $\lim_{n\to\infty} \|h'(\bar{x})^*y_n^*\| = \lim_{n\to\infty} \langle y_n^*, h(x_n)\rangle - \sigma_C(y_n^*) = 0$. By continuity of h at $\bar{x}$, we obtain that the sequence

(y_n^*) satisfies (4.3). Hence, $h(\cdot) - C$ is not metrically regular at $(\bar{x}, 0)$, which is a contradiction. ∎

Now let $(y_n^*) \subset S_{Y^*}$ be an arbitrary sequence satisfying (4.3). By the Alaoglu–Bourbaki theorem, B_{Y^*} is weakly* compact, and hence the sequence (y_n^*) has at least one weak* accumulation point. Let $\bar{y}^* \in B_{Y^*}$ denote an arbitrary weak* accumulation point of (y_n^*). Since both $\sigma_C(\cdot) - \langle \cdot, h(\bar{x})\rangle$ and $\|h'(\bar{x})^* \cdot \|$ are weakly* lower semicontinuous, we have $h'(\bar{x})^*\bar{y}^* = 0$ and $\sigma_C(\bar{y}^*) - \langle \bar{y}^*, h(\bar{x})\rangle = 0$, where the latter can also be written as $\bar{y}^* \in N_C(h(\bar{x}))$. This implies $\bar{y}^* \in \Lambda_{FJ}$, provided $\bar{y}^* \neq 0$. Now assume that $\bar{x}$ is nondegenerate and let $\bar{y} \in h(\bar{x}) + \operatorname{int}(h'(\bar{x})B_X - C)$ and $-\rho := \hat{d}_C(h(\bar{x}) - \bar{y}, h'(\bar{x}), 1) < 0$. Then we have $\langle y_n^*, h(\bar{x}) - \bar{y}\rangle - \sigma_C(y_n^*) - \|h'(\bar{x})^* y_n^*\| \leq -\rho$, implying $\langle \bar{y}^*, \bar{y}\rangle \geq \rho > 0$. Therefore, $0 \neq \bar{y}^*$ and consequently $\bar{y}^* \in \Lambda_{FJ}$. Thus, we have shown the following result, which will be useful in what follows.

PROPOSITION 4.2. *Assume that $\bar{x}$ is nondegenerate and let $(y_n^*) \subset S_{Y^*}$ be a sequence satisfying* (4.3). *Then, for each weak* accumulation point $\bar{y}^*$ of (y_n^*) one has $\bar{y}^* \in \Lambda_{FJ} \cap B_{Y^*}$.*

In the case of scalar minimization the commonly used set of Lagrange multipliers is given by $\{v^* \in V^* : (1, v^*) \in \Lambda_{FJ}\}$. It is well known that the set of Lagrange multipliers is convex and weakly* compact if Robinson's constraint qualification (3.13) is fulfilled (see, e.g., [7, Thm. 3.9]). Now we generalize this result to problem (P), where we also replace the assumption of Robinson's constraint qualification with the weaker condition (3.9).

For arbitrary $y \in Y$ let $\Lambda_{FJ}^y := \{y^* \in \Lambda_{FJ} : \langle y^*, y\rangle = 1\}$. Note that in the case of scalar minimization the set of Lagrange multipliers is related to Λ_{FJ}^y with $y = (1, 0) \in \mathbb{R} \times V$ and that Robinson's constraint qualification holds if and only if $(1, 0) \in \operatorname{int}(h(\bar{x}) + h'(\bar{x})X - C)$. The following theorem appears to be new even in the scalar case.

THEOREM 4.3. *Let $\Lambda_{FJ} \neq \emptyset$ and assume that $\bar{x}$ is nondegenerate. Then for all $y \in \operatorname{int}(h(\bar{x}) + h'(\bar{x})B_X - C)$ the set Λ_{FJ}^y is a nonempty, convex, and weakly* compact subset of Y^* and Λ_{FJ} is generated by Λ_{FJ}^y in the sense that $\Lambda_{FJ} = (0, +\infty)\Lambda_{FJ}^y$.*

Proof. It is clear that Λ_{FJ}^y is convex and weakly* closed for all $y \in Y$, but possibly empty. Now let $y \in \operatorname{int}(h(\bar{x}) + h'(\bar{x})B_X - C)$ be arbitrarily chosen and let $-\rho := \hat{d}_C(h(\bar{x}) - y, h'(\bar{x}), 1) < 0$. Then, for all $y^* \in \Lambda_{FJ}$ we have

$$\left\langle \frac{y^*}{\|y\|^*}, -y \right\rangle = \left\langle \frac{y^*}{\|y\|^*}, h(\bar{x}) - y \right\rangle - \sigma_C\left(\frac{y^*}{\|y\|^*}\right) - \left\| h'(\bar{x})^* \frac{y^*}{\|y\|^*} \right\| \leq -\rho,$$

implying $\langle y^*, y\rangle \geq \rho\|y^*\|$. Hence, Λ_{FJ}^y is also nonempty and Λ_{FJ} is generated by Λ_{FJ}^y. Moreover, for all $y^* \in \Lambda_{FJ}^y \subset \Lambda_{FJ}$ we have $1 = \langle y^*, y\rangle \geq \rho\|y^*\|$ showing that Λ_{FJ}^y is bounded. Hence, together with the Alaoglu–Bourbaki theorem, the weak* compactness follows. ∎

For the sake of completeness we state the following corollary (see [34, Thm. 4]).

COROLLARY 4.4. *Let $\Lambda_{FJ} \neq \emptyset$ and assume that Robinson's constraint qualification $0 \in \operatorname{int}(g(\bar{x}) + g'(\bar{x})X - K)$ is fulfilled. Then one has $\Lambda_{FJ} = \Lambda_{KT}$.*

5. Simplification of the second-order conditions. Needless to say, the second-order optimality conditions given by Corollary 3.4 can be verified in practice only with some great effort. We derive now second-order conditions which are easier to handle. However, we restrict ourselves to those conditions which are equivalent to those of Corollary 3.4, at least under some additional assumptions on the problem. We devote this section also to comparisons with other works.

Throughout this section we assume that Assumptions 1 and 2 are fulfilled. It follows that $h''(\bar{x};\cdot)$ is Lipschitzian on bounded sets. Indeed, let $z_1, z_2 \in X$ be fixed. For any $\epsilon > 0$ there exists some $\delta > 0$ such that for all $t \in (0,\delta)$ one has

$$\left\| \frac{h(\bar{x}+tz_i) - h(\bar{x}) - th'(\bar{x})z_i}{t^2/2} - h''(\bar{x};z_i) \right\| \le \epsilon, \quad i = 1,2.$$

Hence, using Assumption 1, it follows for all $t > 0$ sufficiently small that

$$\begin{aligned} \|h''(\bar{x};z_1) - h''(\bar{x};z_2)\| &\le \left\| \frac{h(\bar{x}+tz_1) - h(\bar{x}+tz_2) - th'(\bar{x})(z_1-z_2)}{t^2/2} \right\| + 2\epsilon \\ &\le 2\eta \max\{\|z_1\|, \|z_2\|\}\|z_1 - z_2\| + 2\epsilon. \end{aligned}$$

Since ϵ was arbitrary, the claimed Lipschitz continuity of $h''(\bar{x};\cdot)$ on bounded sets follows.

LEMMA 5.1. *Let $(z_n, t_n, \tau_n) \subset S_X \times \mathbb{R}_+ \times \mathbb{R}_+$ be a sequence such that $t_n \to 0_+$, $\tau_n \to 0_+$. If there is some $\beta > 0$ such that $d(h(\bar{x}) + t_n h'(\bar{x})z_n, C) \ge \beta t_n$ for all n, then $\liminf_{n\to\infty} t_n^{-2} \hat{d}_C(h(\bar{x}) + t_n h'(\bar{x})z_n + \frac{t_n^2}{2}h''(\bar{x};z_n), h'(\bar{x}), \tau_n t_n) = \infty$.*

Proof. For each n let $y_n^* \in S_{Y^*}$ be with $\langle y_n^*, h(\bar{x}) + t_n h'(\bar{x})z_n\rangle - \sigma_C(y_n^*) = d(h(\bar{x}) + t_n h'(\bar{x})z_n, C)$ according to the minimum norm duality theorem. Then, by the definition of $\hat{d}_C$ we have $t_n^{-2}\hat{d}_C(h(\bar{x}) + t_n h'(\bar{x})z_n + \frac{t_n^2}{2}h''(\bar{x};z_n), h'(\bar{x}), \tau_n t_n) \ge \frac{1}{2}\langle y_n^*, h''(\bar{x};z_n)\rangle + t_n^{-1}(\beta - \tau_n \|h'(\bar{x})^* y_n^*\|) \to \infty$. ∎

Therefore, in order to verify the second-order conditions (3.5) we need only consider sequences (z_n, t_n, τ_n) with $d(h(\bar{x}) + t_n h'(\bar{x})z_n, C) = o(t_n)$, which can also be written as $d(h'(\bar{x})z_n, T_C(h(\bar{x}))) \to 0$.

LEMMA 5.2. *If $\bar{x}$ is not a critical point (respectively, essential local minimizer) of second order, then there are a scalar $\rho > 0$ (respectively, $\rho \ge 0$) and a sequence $(z_n, t_n, \tau_n) \subset S_X \times \mathbb{R}_+ \times \mathbb{R}_+$ with $t_n \to 0_+$, $\tau_n \to 0_+$ such that $d(h(\bar{x}) + t_n h'(\bar{x})z_n + \frac{t_n^2}{2}h''(\bar{x};z_n), C) = o(t_n^2)$ and*

$$\liminf_{n\to\infty} t_n^{-2}\hat{d}_C\left(h(\bar{x}) + t_n h'(\bar{x})z_n + \frac{t_n^2}{2}h''(\bar{x};z_n), h'(\bar{x}), C\right) \le -\rho.$$

Proof. If $\bar{x}$ is not a critical point of second order, consider the sequences $(x_n) \to \bar{x}$, $(\tau_n) \to 0_+$, (κ_n), $(\tilde{x}_n)$ and the scalars $\beta > 0$, η used in the proof of Theorem 3.2. By using the last assertion of Proposition 2.10 we also obtain

$$\begin{aligned} \hat{d}_C(h(\tilde{x}_n), h'(\bar{x}), 3\kappa_n) &\le \hat{d}_C(h(\tilde{x}_n), h'(\bar{x}), \kappa_n + \|\tilde{x}_n - x_n\|) \\ &\le -\beta\|x_n - \bar{x}\|^2 + 2\eta(\|x_n - \bar{x}\| + \kappa_n)\kappa_n \le -\frac{3}{4}\beta\|x_n - \bar{x}\|^2. \end{aligned} \tag{5.1}$$

By Assumption 2 the assertion follows with $\tilde{t}_n := \|\tilde{x}_n - \bar{x}\|$, $\tilde{z}_n := t_n^{-1}(\tilde{x}_n - \bar{x})$, $\tilde{\tau}_n := 3\kappa_n/t_n$, and $\rho = 3\beta/4$.

The assertion about essential local minimizers follows easily from Definition 3.1. ∎

Next we consider the optimality conditions (3.5) for sequences $(z_n, t_n, \tau_n) \subset S_X \times \mathbb{R}_+ \times \mathbb{R}_+$, where (z_n) is convergent to some $z \in S_X$. By Lemma 5.1 we have only to consider the case $z \in \mathcal{C}(\bar{x})$, where the set

$$\mathcal{C}(\bar{x}) := \{z \in X : h'(\bar{x})z \in T_C(h(\bar{x}))\}$$

is called the *critical cone* of problem (P) at $\bar{x}$. We also need a tool to describe the possible curvature of a set. As a consequence of Lemma 5.2, the use of the *second-order compound tangent set* introduced by Penot [30] seems to be an appropriate approach.

DEFINITION 5.3. *Let E, F be normed spaces, let D be a subset of F, let $A \in L(E,F)$ be a continuous linear operator, and let $\bar{f} \in D$. Then for $z \in E$ the* second-order compound tangent set *to D at $(\bar{f}, z)$ (with respect to A) is the set*

$$D''_A(\bar{f}, z) := \{w \in F : \exists z_n \to z,\ t_n \to 0_+ :\ d(\bar{f} + t_n A z_n + t_n^2 w/2, D) = o(t_n^2)\}.$$

THEOREM 5.4. *If $\bar{x}$ is an essential local minimizer (respectively, nondegenerate critical point) of second order for problem* (P)*, then there exists a scalar $\beta > 0$ (respectively, $\beta \geq 0$) such that for each $z \in \mathcal{C}(\bar{x}) \cap S_X$ either we have $C''_{h'(\bar{x})}(h(\bar{x}), z) = \emptyset$ or for each $w \in C''_{h'(\bar{x})}(h(\bar{x}), z)$ there exists a multiplier $y^* \in \Lambda_{FJ} \cap B_{Y^*}$ with*

$$\langle y^*, h''(\bar{x}; z) - w\rangle \geq \beta. \tag{5.2}$$

Proof. Assume that $\bar{x}$ is a critical point (respectively, essential local minimizer) of second order, let $\beta \geq 0$ (respectively, $\beta > 0$) be as in Corollary 3.4, and let $z \in \mathcal{C}(\bar{x}) \cap S_X$ be arbitrarily chosen. In the case of $C''_{h'(\bar{x})}(h(\bar{x}), z) = \emptyset$ there is nothing to prove. Thus, let $w \in C''_{h'(\bar{x})}(h(\bar{x}), z)$. By the definition of $C''_{h'(\bar{x})}(h(\bar{x}), z)$, there is a sequence (z_n, t_n, w_n) with limit $(z, 0_+, w)$ such that $h(\bar{x}) + t_n h'(\bar{x}) z_n + \frac{1}{2} t_n^2 w_n \in C$. Since $z \in S_X$ and $z_n \to z$, we may also assume that $(z_n) \subset S_X$. By Corollary 3.4, taking $\tau_n = \sqrt{t_n}$, there exists a sequence $(y_n^*) \subset S_{Y^*}$, approaching the supremum in (3.5) sufficiently accurately, such that

$$\begin{aligned} \liminf_{n\to\infty} \Bigg\{ & \frac{\langle y_n^*, h(\bar{x}) + t_n h'(\bar{x}) z_n\rangle - \sigma_C(y_n^*)}{t_n^2} \\ & + \frac{1}{2}\langle y_n^*, h''(\bar{x}; z_n)\rangle - \frac{\|h'(\bar{x})^* y_n^*\|}{\sqrt{t_n}} \Bigg\} \geq \beta. \end{aligned} \tag{5.3}$$

Since $h''(\bar{x}, \cdot)$ is continuous, $\langle y_n^*, h''(\bar{x}; z_n)\rangle$ is uniformly bounded. Therefore, we have $\langle y_n^*, h(\bar{x}) + t_n h'(\bar{x}) z_n\rangle - \sigma_C(y_n^*) \geq (\beta - k) t_n^2$ for some constant $k > 0$ and all n sufficiently large, and together with $\langle y_n^*, h(\bar{x})\rangle \leq \sigma_C(y_n^*)$ we obtain $\langle y_n^*, h(\bar{x})\rangle - \sigma_C(y_n^*) \to 0$. We also have $\langle y_n^*, h(\bar{x}) + t_n h'(\bar{x}) z_n + \frac{1}{2} t_n^2 w_n\rangle \leq \sigma_C(y_n^*)$, and by (5.3) we obtain

$$\liminf_{n\to\infty} \left\{ \frac{1}{2}\langle y_n^*, -w_n + h''(\bar{x}; z_n)\rangle - \frac{1}{\sqrt{t_n}} \|h'(\bar{x})^* y_n^*\| \right\} \geq \beta.$$

Hence, $h'(\bar{x})^* y_n^* \to 0$ and $\liminf_{n\to\infty} \langle y_n^*, h''(\bar{x}; z) - w\rangle \geq \beta$. By the Alaoglu–Bourbaki theorem, the sequence (y_n^*) has at least one weak* accumulation point $y^* \in B_{Y^*}$. If $\bar{x}$ is nondegenerate, every accumulation point y^* belongs to Λ_{FJ} by Proposition 4.2 and also fulfills (5.2). Hence, the assertion about nondegenerate critical points is proved. If $\bar{x}$ is an essential local minimizer, it follows that every weak* accumulation point y^* of (y_n^*) satisfies $\langle y^*, h''(\bar{x}; z) - w\rangle \geq \beta > 0$, showing $y^* \neq 0$ and hence $y^* \in \Lambda_{FJ}$. This completes the proof of the theorem. □

Note that the case $C''_{h'(\bar{x})}(h(\bar{x}), z) = \emptyset$ may be treated as a kind of second-order condition where no multipliers are involved.

COROLLARY 5.5. *Let $\bar{x}$ be an essential local minimizer (respectively, nondegenerate critical point) of second order for* (P)*. Then there exists a scalar $\beta > 0$ (respectively, $\beta \geq 0$) such that for every $z \in \mathcal{C}(\bar{x}) \cap S_X$ satisfying $C''_{h'(\bar{x})}(h(\bar{x}), z) \neq \emptyset$ and*

every convex subset W of $C''_{h'(\bar{x})}(h(\bar{x}),z)$ there exists a multiplier $y^* \in \Lambda_{FJ}$ such that $\langle y^*, h''(\bar{x};z)\rangle - \sigma_W(y^*) \geq \beta$.

Proof. Let $\tilde{\Lambda} := (\Lambda_{FJ} \cup \{0\}) \cap B_{Y^*}$ (respectively, $\tilde{\Lambda} := \Lambda^y_{FJ}$ with $y \in \operatorname{int}(h(\bar{x}) + h'(\bar{x})B_X - C)$). Then, by Theorem 5.4 we have $\inf_{w\in W} \sup_{y^*\in\tilde{\Lambda}} \langle y^*, h''(\bar{x};z) - w\rangle \geq \beta$. Since $\tilde{\Lambda}$ is weakly* compact, the assertion follows from the classical minsup theorem of Moreau. ∎

Theorem 5.4 and Corollary 5.5 generalize the necessary optimality conditions [30] to vector optimization problems. Moreover, the assumption on metric regularity of the constraints used in [30] is replaced with condition (3.9). As a consequence, we have to formulate the necessary conditions in terms of Fritz John multipliers $y^* \in \Lambda_{FJ}$ instead of multipliers $y^* \in \Lambda_{KT}$.

THEOREM 5.6. *Let X be finite dimensional. Suppose that for each $z \in \mathcal{C}(\bar{x}) \cap S_X$ satisfying $C''_{h'(\bar{x})}(h(\bar{x}),z) \neq \emptyset$ there is a scalar $\beta_z \geq 0$ such that for each $w \in C''_{h'(\bar{x})}(h(\bar{x}),z)$ there exists a multiplier $y^* \in \Lambda_{FJ}$ with*

$$\langle y^*, h''(\bar{x};z) - w\rangle \geq \beta_z. \tag{5.4}$$

Then $\bar{x}$ is a critical point of second order for (P)*. If $\beta_z > 0$ for all $z \in \mathcal{C}(\bar{x}) \cap S_X$ satisfying $C''_{h'(\bar{x})}(h(\bar{x}),z) \neq \emptyset$, then $\bar{x}$ is even an essential local minimizer of second order.*

Proof. The proof is by contraposition. Suppose that $\bar{x}$ is not an essential local minimizer of second order. Let the scalar $\rho \geq 0$ and the sequence $(z_n, t_n, \tau_n) \subset S_X \times \mathbb{R}_+ \times \mathbb{R}_+$ be chosen so that the conclusion of Lemma 5.2 holds. Since X is finite dimensional we may assume that (z_n) converges to some $z \in S_X$, where we have eventually passed to a subsequence. Since $d(h(\bar{x}) + t_n h'(\bar{x})z_n + \frac{1}{2}t_n^2 h''(\bar{x},z_n), C) = o(t_n^2)$ we have $z \in \mathcal{C}(\bar{x})$ and $h''(\bar{x};z) \in C''_{h'(\bar{x})}(h(\bar{x}),z)$. By taking $w = h''(\bar{x};z)$ we see that (5.4) cannot hold with $\beta_z > 0$, which is a contradiction. Now assume that $\bar{x}$ is not even a critical point of second order. Then $\rho > 0$, and we may also assume that $\hat{d}_C(h(\bar{x}) + t_n h'(\bar{x})z_n + (1/2)t_n^2 h''(\bar{x};z_n), h'(\bar{x}), \tau_n t_n) < -\rho t_n^2/2$ for all n. Then, for each $w \in \frac{\rho}{2}B_Y$ and each n there is some $\xi_{n,w} \in B_X$ with $h(\bar{x}) + t_n h'(\bar{x})(z_n + \tau_n\xi_{n,w}) + \frac{1}{2}t_n^2(h''(\bar{x};z_n) + w) \in C$. Thus, $h''(\bar{x};z) + w \in C''_{h'(\bar{x})}(h(\bar{x}),z)$. Let $\epsilon > 0$ be chosen so small such that $w := -\epsilon h''(\bar{x};z) \in \frac{\rho}{2}B_Y$. By our hypothesis there is some $\bar{y}^* \in \Lambda_{FJ}$ such that $\langle \bar{y}^*, -w\rangle = \epsilon\langle \bar{y}^*, h''(\bar{x};z)\rangle \geq 0$. Since $\bar{y}^* \neq 0$ and Λ_{FJ} is a cone we may assume that $\bar{y}^* \in \Lambda_{FJ} \cap S_{Y^*}$. Since $\langle \bar{y}^*, h(\bar{x})\rangle - \sigma(\bar{y}^*) = \|h'(\bar{x})^*\bar{y}^*\| = 0$ we obtain $\langle \bar{y}^*, h''(\bar{x};z_n)\rangle = 2t_n^{-2}(\langle \bar{y}^*, h(\bar{x}) + t_n h'(\bar{x})z_n + \frac{1}{2}t_n^2 h''(\bar{x};z_n)\rangle - \sigma_C(\bar{y}^*) - \tau_n t_n \|h'(\bar{x})^*\bar{y}^*\|) < -\rho$ for all n. Passing to the limit, we obtain $\langle \bar{y}^*, h''(\bar{x};z)\rangle \leq -\rho < 0$, which clearly contradicts $\epsilon\langle \bar{y}^*, h''(\bar{x};z)\rangle \geq 0$. ∎

Theorem 5.6 generalizes the sufficient conditions of [31, Prop. 5.1] to vector optimization problems. Moreover, we do not assume under any circumstances that the set of Fritz John multipliers Λ_{FJ} is nonempty: Theorem 5.6 states that $\bar{x}$ is an essential local minimizer of second order if $C''_{h'(\bar{x})}(h(\bar{x}),z) = \emptyset$ for every $z \in \mathcal{C}(\bar{x}) \cap S_X$ and X is finite dimensional, even if $\Lambda_{FJ} = \emptyset$. On the other hand, from Theorem 5.4 it follows that at an essential local minimizer of second order, the set Λ_{FJ} of multipliers is not empty if there is some $z \in \mathcal{C}(\bar{x}) \cap S_X$ with $C''_{h'(\bar{x})}(h(\bar{x}),z) \neq \emptyset$.

COROLLARY 5.7. *Let X be finite dimensional and assume that the set of Fritz John multipliers Λ_{FJ} at $\bar{x}$ is empty $\Lambda_{FJ} = \emptyset$. Then the element $\bar{x}$ is an essential local minimizer of second order for problem* (P) *if and only if for all $z \in \mathcal{C}(\bar{x}) \cap S_X$ one has $C''_{h'(\bar{x})}(h(\bar{x}),z) = \emptyset$.*

The following example illustrates the situation of Corollary 5.7.

Example 5.1. Let $X = \mathbb{R}$ and choose a closed convex set $K \subset V$ of an infinite-dimensional space V such that K does not have a supporting functional at some boundary point $\bar{v} \in \operatorname{bd} K$, i.e., $N_K(\bar{v}) = \{0\}$. Let $s \in V$ be a direction such that $\bar{v} + xs \in K$ if $x \geq 0$ and $\bar{v} + xs \notin K$ if $x < 0$. Consider the scalar optimization problem

$$\min_{x \in \mathbb{R}} f(x) := x \quad \text{subject to} \quad g(x) := \bar{v} + xs \in K.$$

Clearly, $\bar{x} = 0$ is a strictly local minimizer; however, the set of multipliers Λ_{FJ} is empty. Indeed, the Fritz John conditions read as

$$u^* + \langle v^*, s \rangle = 0, \quad u^* \geq 0, \quad v^* \in N_K(\bar{v})$$

and can be fulfilled only by the trivial solution $(u^*, v^*) = 0$. Since $N_K(\bar{v}) = \{0\}$, we have $T_K(\bar{v}) = V$. Hence, $-s \in T_K(\bar{v})$ and therefore $\mathcal{C}(0) = \mathbb{R}_-$. We obtain from the definition that $\bar{x} = 0$ is an essential local minimizer of second order if and only if s is so that $\liminf_{x \to 0-} x^{-2} d(g(x), K) > 0$. By Corollary 5.7, this is also equivalent to the condition that the second-order compound tangent set of $C = \mathbb{R}_- \times K$ at $(0, \bar{v})$ in direction -1 is empty. To be more concrete, let $V = L_1([0,1])$ be the Banach space of measurable, absolutely integrable functions on $[0,1]$, $K = \{v \in L_1([0,1]) : v(\xi) \geq 0 \text{ a.e.}\}$, $\bar{v}(\xi) = \xi$, $s(\xi) = 1$. Then $g(x)(\xi) = \xi + x$ and we obtain $d(g(x), K) = \int_0^1 -\min\{\xi + x, 0\} d\xi = \frac{1}{2}x^2$ for $x < 0$. Hence, $\bar{x} = 0$ is an essential local minimizer in this case. Now let us show that $C''_{h'(\bar{x})}(h(\bar{x}), -1) = \emptyset$. To do this we show that the second-order compound tangent set $K''_s(\bar{v}, -1)$ is empty. Assume that there is a sequence $(z_n, t_n, v_n) \in \mathbb{R} \times \mathbb{R}^+ \times L_1([0,1])$ with limit $(-1, 0_+, v)$ such that $\bar{v} + t_n z_n s + \frac{1}{2} t_n^2 v_n \in K$. It follows that $v_n(\xi) \geq -2t_n^{-2}(\xi + t_n z_n)$ for almost all $\xi \in [0, -t_n z_n]$ and therefore $\int_0^{-t_n z_n} v_n(\xi) d\xi \geq z_n^2 \to 1$. On the other hand, we have $\int_0^{-t_n z_n} v(\xi) d\xi \to 0$, and therefore $v_n \not\to v$, which is a contradiction. This shows that the compound tangent set $K''_s(\bar{v}, -1)$ (and hence also $C''_{h'(\bar{x})}(h(\bar{x}), -1)$) is empty.

The computation of second-order compound tangent sets is a rather complex task. In some situations the compound tangent set can be equivalently replaced with another set which is easier to handle. Let us consider the following notion of outer second-order regularity as introduced in [6].

DEFINITION 5.8. *Let D be a subset of the normed space F and let $\bar{f} \in D$, $s \in F$.*

1. *The* outer second-order tangent set *to D at $\bar{f}$ in direction s is the set*

$$T_D^2(\bar{f}, s) := \{r \in F : \exists t_n \to 0_+ \text{ such that } d(\bar{f} + t_n s + t_n^2 r/2, D) = o(t_n^2)\}.$$

2. *Let E be another normed space and let $A \in L(E, F)$ be a continuous linear mapping. We say that a set $\mathcal{A}_{D,A}(\bar{f}, s)$ is an* upper second-order approximation set *for D at the point $\bar{f}$ in direction s with respect to A if for any sequence $(f_n) \subset D$ of the form $f_n = \bar{f} + t_n s + \frac{1}{2} t_n^2 r_n$, where $t_n \to 0_+$ and $r_n = Ae_n + w_n$ with (w_n) being a convergent sequence in F and (e_n) being a sequence in E satisfying $t_n e_n \to 0$, the following condition holds:*

$$\lim_{n \to \infty} d(r_n, \mathcal{A}_{D,A}(\bar{f}, s)) = 0.$$

We say that D is outer second-order regular *at the point $\bar{f}$ in direction s with respect to A if $T_D^2(\bar{f}, s)$ is an upper second-order approximation set at the point $\bar{f}$ in direction s with respect to A.*

Obviously, $T_D^2(\bar f, Az) \subset D_A''(\bar f, z)$ always hold. Hence, Theorem 5.4 remains true if we replace $C''_{h'(\bar x)}(h(\bar x), z)$ with the smaller set $T_C^2(h(\bar x), h'(\bar x)z)$. Further, $D_A''(\bar f, z)$ is always an upper second-order approximation set for D at $\bar f$ in direction Az with respect to A. Indeed, let $f_n = \bar f + t_n Az + \frac{1}{2}t_n^2 r_n \in D$ be a sequence, where $t_n \to 0_+$, $r_n = Ae_n + w_n$ with $w_n \to w \in F$, and $t_n e_n \to 0$. Then, since $f_n = \bar f + t_n A(z + \frac{1}{2}t_n e_n) + \frac{1}{2}t_n^2 w_n$, we obtain $w \in D_A''(\bar f, z)$. Hence, $d(r_n, D_A''(\bar f, z) + \mathrm{Range}(A)) \to 0$. Noting that $D_A''(\bar f, z) + \mathrm{Range}(A) = D_A''(\bar f, z)$, we see that $D_A''(\bar f, z)$ is an upper second-order approximation set.

Using similar arguments we can also show that any upper second-order approximation set $\mathcal{A}_{D,A}(\bar f, Az)$ satisfies $D_A''(\bar f, z) \subset \mathrm{cl}\,(\mathcal{A}_{D,A}(\bar f, Az) + \mathrm{Range}(A))$.

Use of the concepts of outer second-order tangent sets and upper second-order approximation sets has the advantage that the constraints and the objective can be treated separately.

THEOREM 5.9.

1. *Let $\bar x$ be an essential local minimizer (respectively, nondegenerate critical point) of second order for problem* (P). *Then there is a real $\beta > 0$ (respectively, $\beta \ge 0$) such that for every critical direction $z \in \mathcal{C}(\bar x) \cap S_X$ satisfying $T_K^2(g(\bar x), g'(\bar x)z) \ne \emptyset$ and for every $v \in T_K^2(g(\bar x), g'(\bar x)z)$ there exists some multiplier $y^* = (u^*, v^*) \in \Lambda_{FJ} \cap B_{Y^*}$ such that*

$$\langle u^*, f''(\bar x; z)\rangle + \langle v^*, g''(\bar x; z) - v\rangle \ge \beta.$$

2. *Assume that X is finite dimensional. To every $z \in \mathcal{C}(\bar x) \cap S_X$ let there correspond an upper second-order approximation set $\mathcal{A}_K(z) := \mathcal{A}_{K,g'(\bar x)}(g(\bar x), g'(\bar x)z)$ for the set K at the point $g(\bar x)$ in the direction $g'(\bar x)z$ with respect to $g'(\bar x)$. Assume that for each $z \in \mathcal{C}(\bar x) \cap S_X$ there is some $\beta_z \ge 0$ such that for each $v \in \mathcal{A}_K(z)$ there exists some $y^* = (u^*, v^*) \in \Lambda_{FJ} \cap B_{Y^*}$ with*

$$\langle u^*, f''(\bar x; z)\rangle + \langle v^*, g''(\bar x; z) - v\rangle \ge \beta_z. \tag{5.5}$$

Then, $\bar x$ is a critical point of second order. In addition, if $\beta_z > 0$ for every $z \in \mathcal{C}(\bar x) \cap S_X$, then $\bar x$ is even an essential local minimizer of second order.

Proof. Since for every $v \in T_K^2(g(\bar x), g'(\bar x)z)$ we have $(0, v) \in T_C^2(h(\bar x), h'(\bar x)z) \subset C''_{h'(\bar x)}(h(\bar x), z)$, the first part follows immediately from Theorem 5.4. To show the second part, we use Theorem 5.6. Let $z \in \mathcal{C}(\bar x) \cap S_X$, satisfying $C''_{h'(\bar x)}(h(\bar x), z) \ne \emptyset$ and $w \in C''_{h'(\bar x)}(h(\bar x), z)$, be arbitrarily fixed. By the definition of compound tangent sets there is a sequence (z_n, t_n, w_n) with limit $(z, 0_+, w)$ such that $h(\bar x) + t_n h'(\bar x)z_n + \frac{1}{2}t_n^2 w_n \in C$. Setting $w_n = (u_n, v_n)$ we have $g(\bar x) + t_n g'(\bar x)z + \frac{1}{2}t_n^2(2t_n^{-1}g'(\bar x)(z_n - z) + v_n) \in K$. Hence, there is a sequence $(\tilde v_n) \subset \mathcal{A}_K(z)$ with $\nu_n := 2t_n^{-1}g'(\bar x)(z_n - z) + v_n - \tilde v_n \to 0$. Now let $y_n^* := (u_n^*, v_n^*) \in \Lambda_{FJ} \cap B_{Y^*}$ with $\langle u_n^*, f''(\bar x; z)\rangle + \langle v_n^*, g''(\bar x; z) - \tilde v_n\rangle \ge \beta_z$. Since Λ_{FJ} is a cone we may assume $y_n^* \in S_{Y^*}$. Because of $t_n f'(\bar x)z + \frac{1}{2}t_n^2(2t_n^{-1}f'(\bar x)(z_n - z) + u_n) \in -L$, $u_n^* \in L^*$, and because L is a cone, we have $\langle u_n^*, 2t_n^{-1}f'(\bar x)(z_n - z) + u_n\rangle \le -2t_n^{-1}\langle u_n^*, f'(\bar x)z\rangle$. Together with $h'(\bar x)^* y_n^* = 0$ we obtain

$$\begin{aligned}\langle y_n^*, w_n\rangle &= \langle y_n^*, 2t_n^{-1}h'(\bar x)(z_n - z) + w_n\rangle \\ &= \langle u_n^*, 2t_n^{-1}f'(\bar x)(z_n - z) + u_n\rangle + \langle v_n^*, \tilde v_n + \nu_n\rangle \\ &\le -2t_n^{-1}\langle u_n^*, f'(\bar x)z\rangle - \beta_z + \langle u_n^*, f''(\bar x; z)\rangle + \langle v_n^*, g''(\bar x; z)\rangle + \langle v_n^*, \nu_n\rangle.\end{aligned}$$

Rearranging yields $\langle y_n^*, h''(\bar x; z) - w_n\rangle \ge \beta_z + 2t_n^{-1}\langle u_n^*, f'(\bar x)z\rangle - \langle v_n^*, \nu_n\rangle$. Since $z \in \mathcal{C}(\bar x)$ we have $(f'(\bar x)z, g'(\bar x)z) \in T_{-L}(0) \times T_K(g(\bar x))$ and, because of $(u_n^*, v_n^*) \in L^* \times$

$N_K(g(\bar{x}))$ we obtain $\langle u_n^*, f'(\bar{x})z\rangle \le 0$ and $\langle v_n^*, g'(\bar{x})z\rangle \le 0$. Thus, $0 = \langle y_n^*, h'(\bar{x})z\rangle = \langle u_n^*, f'(\bar{x})z\rangle + \langle v_n^*, g'(\bar{x})z\rangle \le 0$ and consequently $\langle u_n^*, f'(\bar{x})z\rangle = \langle v_n^*, g'(\bar{x})z\rangle = 0$. Together with $(w_n, \nu_n) \to (w, 0)$ we obtain $\liminf_{n\to\infty}\langle y_n^*, h''(\bar{x}; z) - w\rangle \ge \beta_z$. By the Alaoglu–Bourbaki theorem the sequence y_n^* has a weak* accumulation point y^*, and by definition of the weak* topology, we also have $\langle y^*, h''(\bar{x}; z) - w\rangle \ge \beta_z$. If $\beta_z > 0$, we obviously have $y^* \ne 0$ and thus $y^* \in \Lambda_{FJ}$. If $\beta_z = 0$, and $\bar{x}$ is nondegenerate, then we have $y^* \in \Lambda_{FJ}$ by Proposition 4.2. Finally, if $\bar{x}$ is degenerate, then $\bar{x}$ is always a critical point of second order for problem (P). Now the assertion follows from Theorem 5.6. □

For ease of presentation we have not included in the sufficient conditions of Theorem 5.9 the case that for some directions $z \in \mathcal{C}(\bar{x}) \cap S_X$ no upper second-order approximation set $\mathcal{A}_K(z) := \mathcal{A}_{K,g'(\bar{x})}(g(\bar{x}), g'(\bar{x})z)$ whatsoever exists. We also dispense with formulating a corollary analogous to Corollary 5.5. Theorem 5.9 improves the results of [6] even for scalar optimization problems. Our necessary conditions for a local minimum require only $\bar{x}$ to be nondegenerate, whereas Robinson's constraint qualification (3.13) is used in [6]. However, second-order necessary conditions are stated in [7, Thm. 3.50] for a special case of nondegenerate minimizers $\bar{x}$ without presuming Robinson's constraint qualification, namely when the constraints can be written in the form $g(x) = (\tilde{g}(x), x)$, $K = \tilde{K} \times Q$, where $\operatorname{int}\tilde{K} \ne \emptyset$, i.e., general inequality constraints together with explicit constraints.

The second-order sufficient conditions in [6] state that if for each $z \in \mathcal{C}(\bar{x}) \cap S_X$ there exists an upper second-order approximation set $\mathcal{A}_K(z) := \mathcal{A}_{K,g'(\bar{x})}(g(\bar{x}), g'(\bar{x})z)$, and if there exists $y^* = (u^*, v^*) \in \Lambda_{FJ}$ such that

$$\langle u^*, f''(\bar{x}; z)\rangle + \langle v^*, g''(\bar{x}; z)\rangle > \sigma_{\mathcal{A}_K(z)}(v^*), \tag{5.6}$$

then $\bar{x}$ is a strict locally optimal solution fulfilling the quadratic growth condition (3.2). Note that (5.6) always implies (5.5), and condition (5.5) is actually weaker for nonconvex approximation sets $\mathcal{A}_K(z)$.

Example 5.2. Let $\mathbb{S}^m$ denote the Hilbert space of symmetric $m \times m$ matrices equipped with the scalar product $\langle x, y\rangle = \operatorname{trace}(xy)$, and denote by $\mathbb{S}^m_+ \subset \mathbb{S}^m$ the cone of positive semidefinite $m \times m$ matrices. Consider for arbitrarily fixed γ the scalar problem

$$\begin{aligned} &\min_{x\in\mathbb{S}^2} f(x) := \frac{1}{2}(x_{11}^2 - x_{12}^2) \\ \text{subject to}\quad &g_1(x) := \frac{1}{2}(\det x + \langle \bar{s}, x\rangle) + \gamma(x_{12} - 1)^2 = 0, \\ &x \in \mathbb{S}^2_+, \end{aligned}$$

at $\bar{x} := \left(\begin{smallmatrix} 1 & 1 \\ 1 & 1 \end{smallmatrix}\right)$, where $\bar{s} := \left(\begin{smallmatrix} 1 & -1 \\ -1 & 1 \end{smallmatrix}\right)$. In terms of problem (P) we have $g(x) = (g_1(x), x)$ and $K = \{0\} \times \mathbb{S}^2_+$. There holds $g_1'(\bar{x}) = \bar{s} \ne 0$, and together with $\operatorname{int}\mathbb{S}^2_+ \ne \emptyset$ it easily follows that $\bar{x}$ is nondegenerate. Now one can show that $N_{\mathbb{S}^2_+}(\bar{x}) = \{t\bar{s} : t \le 0\}$, and hence we have $g'(\bar{x})^* v^* = 0$ with $v^* := (1, -\bar{s}) \in N_K(0, \bar{x})$, and it follows that Robinson's constraint qualification (3.13) is not fulfilled. It also follows that the second-order qualification condition (TR) used in [22], [31], $g'(\bar{x})X - T_{T_K(g(\bar{x}))}(g'(\bar{x})z) = V$, is not fulfilled for any $z \in \mathcal{C}(\bar{x})$. Some straightforward calculations show that $\bar{x}$ is the only feasible point, and hence is a strict minimizer when $\gamma > 0$. When $\gamma = 0$ the feasible set amounts to the ray $t\bar{x}, t \ge 0$, and hence every feasible point is a local nonstrict minimizer. Finally, when $\gamma < 0$, $\bar{x}$ is no longer a local minimizer. Now let us consider

the second-order conditions of Theorem 5.9. It is possible to show (see section 5.3.1 in [7]) that the critical cone evaluates as $\mathcal{C}(\bar{x}) = \{z \in \mathbb{S}^2 : z_{11} \le z_{12},\ \langle \bar{s}, z\rangle = 0\}$ and that $T^2_K((0,\bar{x}),(0,z)) = \{(0,v) : \langle \bar{s}, v\rangle + 2\det z \ge 0\}$ holds for all $z \in \mathcal{C}(\bar{x})$. The set Λ_{FJ} of multipliers is given by all $y^* := (\alpha,\mu,\eta) \in \mathbb{R}_+ \times \mathbb{R} \times \mathbb{S}^2 \neq (0,0,0)$ so that

$$\alpha f'(\bar{x}) + \mu g_1'(\bar{x}) + \eta = \alpha \begin{pmatrix} 1 & -\frac{1}{2} \\ -\frac{1}{2} & 0 \end{pmatrix} + \mu\bar{s} + \eta = 0, \quad \eta \in N_{\mathbb{S}^2_+(\bar{x})} = \{t\bar{s} : t \le 0\}.$$

Thus, $\Lambda_{FJ} = \{(0,\mu,-\mu\bar{s}) : \mu > 0\}$. Now, for arbitrary $z \in \mathcal{C}(\bar{x})$, $v \in T^2_K((0,\bar{x}),(0,z))$, and $y^* = (0,\mu,-\mu\bar{s})$, where $\mu > 0$, the left-hand side of relation (5.5) amounts to

$$\kappa(z,v,\mu) := \mu(2\gamma z_{12}^2 + \det z + \langle \bar{s}, v\rangle).$$

By setting $z := \frac{1}{\sqrt{6}}\left(\begin{smallmatrix} 0 & 1 \\ 1 & 2 \end{smallmatrix}\right) \in \mathcal{C}(\bar{x}) \cap S_X$, $v := \left(\begin{smallmatrix} 1 & 1 \\ 1 & 1 \end{smallmatrix}\right) \in T^2_K((0,\bar{x}),(0,z))$ we obtain $\kappa(z,v,\mu) = \mu\gamma/3$, and from the first part of Theorem 5.9 we conclude that $\bar{x}$ is not a critical point of second order, and therefore also not a local minimizer when $\gamma < 0$. Note that the second-order necessary conditions known from the literature cannot be applied to this problem. In the case of $\gamma = 0$ it follows that the point $\bar{x}$ is not an essential local minimizer of second order.

Now let us turn to sufficient conditions. For $z \in \mathcal{C}(\bar{x})$ we have $z_{11} \le z_{12} \le z_{22}$, $0 \le z_{12} - z_{11} = z_{22} - z_{12} =: \epsilon$, and $0 \le \epsilon^2 = (z_{12} - z_{11})(z_{22} - z_{12}) = -\det z - 2z_{12}^2 + z_{12}(z_{11} + z_{22}) = -\det z$. Thus, $\|z\|^2 = z_{11}^2 + 2z_{12}^2 + z_{22}^2 = 4z_{12}^2 + 2\epsilon^2 = 4z_{12}^2 - 2\det z$, and since $\langle \bar{s}, v\rangle \ge -2\det z$ holds for $v \in T^2_K((0,\bar{x}),(0,z))$ we obtain

$$\kappa(z,v,\mu) \ge \mu(2\gamma z_{12}^2 - \det z) \ge \frac{1}{2}\mu \min\{\gamma, 1\}\|z\|^2$$

for $\gamma \ge 0$. Using [7, Prop. 3.89] and [6, Cor. 4.6] we obtain that $K = \{0\} \times \mathbb{S}^2_+$ is outer second-order regular at $(0,\bar{x})$ in any direction $(0,z)$, $z \in T_{\mathbb{S}^2_+}(\bar{x})$, and with respect to any mapping A. By using the second part of Theorem 5.9 with $\mathcal{A}_K(z) = T^2_K((0,\bar{x}),(0,z))$ we obtain that $\bar{x}$ is an essential local minimizer (respectively, critical point) of second order when $\gamma > 0$ (respectively, $\gamma \ge 0$). Note that for $\gamma = 0$ the point $\bar{x}$ is a nondegenerate critical point but not an essential local minimizer of second order. Hence, from Theorems 3.5 and 3.6 it follows that, on the one hand, there exist twice continuously differentiable perturbations of the objective and the constraints with vanishing function values and first- and second-order derivatives such that $\bar{x}$ is a strict local minimum for the perturbed problem, and on the other hand, there exist perturbations of this kind such that $\bar{x}$ is not a local minimum. Further note that the second-order necessary conditions make sense even though the multiplier associated with the objective is always zero; i.e., the Kuhn–Tucker conditions are not fulfilled.

The necessary conditions of Theorem 5.4 can be considerably simplified if

$$0 \in C''_{h'(\bar{x})}(h(\bar{x}), z) \quad \forall z \in \mathcal{C}(\bar{x}). \tag{5.7}$$

This condition is fulfilled, for instance, when K is a generalized polyhedral set (i.e., K can be represented as the intersection of a closed affine subspace and a finite number of closed half spaces), or more generally, if $0 \in T^2_K(g(\bar{x}), g'(\bar{x})z)$ for all z in a dense subset of $\mathcal{C}(\bar{x})$ (this is the so-called *extended polyhedricity condition* in [7]). It is clear from the definition of compound tangent sets that $C''_{h'(\bar{x})}(h(\bar{x}),z) \subset \mathrm{cl}\,(T_C(h(\bar{x})) + \mathrm{Range}(h'(\bar{x})))$. Hence, for each $w \in C''_{h'(\bar{x})}(h(\bar{x}),z)$ and every $y^* \in \Lambda_{FJ}$

we have $\langle y^*, w\rangle \leq 0$. Therefore, if (5.7) holds, the necessary conditions (5.2) of Theorem 5.4 can be rewritten as

$$\forall z \in \mathcal{C}(\bar{x}) \cap S_X \ \exists y^* \in \Lambda_{FJ} : \ \langle y^*, h''(\bar{x}; z)\rangle \geq \beta.$$

In the case of the mathematical programming problem, with $\beta = 0$, we obtain exactly the common second-order necessary conditions [16].

In order to prove sufficiency we need the following regularity condition on the cone of critical directions.

CONDITION 5.10. *For every sequence* $(z_n) \subset S_X$ *with* $d(h'(\bar{x})z_n, T_C(h(\bar{x}))) \to 0$ *there holds* $d(z_n, \mathcal{C}(\bar{x})) \to 0$.

THEOREM 5.11. *Assume that Condition* 5.10 *holds at* $\bar{x}$ *and assume that there exists some* $\beta \geq 0$ *such that for each* $z \in \mathcal{C}(\bar{x}) \cap S_X$ *we can find some multiplier* $y^* \in \Lambda_{FJ} \cap B_{Y^*}$ *satisfying* $\langle y^*, h''(\bar{x}; z)\rangle \geq \beta$. *Then* $\bar{x}$ *is a critical point of second order. If* $\beta > 0$, *then* $\bar{x}$ *is even an essential local minimizer of second order.*

Proof. The proof is by contraposition. Assume that $\bar{x}$ is not a critical point (respectively, essential local minimizer). Let the scalar $\rho > 0$ (respectively, $\rho \geq 0$) and the sequence $(z_n, t_n, \tau_n) \subset S_X \times \mathbb{R}_+ \times \mathbb{R}_+$ be chosen so that the conclusion of Lemma 5.2 holds. From $d(h(\bar{x}) + t_n h'(\bar{x})z_n + \frac{1}{2}t_n^2 h''(\bar{x}; z_n), C) = o(t_n^2)$ we obtain $d(h'(\bar{x})z_n, T_C(h(\bar{x}))) = O(t_n)$ and by Condition 5.10 we can find another sequence, say (z_n'), with $(z_n') \subset \mathcal{C}(\bar{x}) \cap S_X$ and $z_n - z_n' \to 0$. By the assumptions of the theorem there is some $\beta \geq 0$ (respectively, $\beta > 0$) so that for each n we can find some $(y_n^*) \subset \Lambda_{FJ} \cap B_{Y^*}$ with $\langle y_n^*, h''(\bar{x}; z_n')\rangle \geq \beta$. Without loss of generality we have $y_n^* \in S_{Y^*}$. Since $h''(\bar{x}; \cdot)$ is Lipschitzian on bounded sets we get

$$\begin{aligned} -\rho &\geq \liminf_{n\to\infty} \frac{\hat{d}_C(h(\bar{x}) + t_n h'(\bar{x})z_n + \frac{1}{2}t_n^2 h''(\bar{x}; z_n), h'(\bar{x}), \tau_n t_n)}{t_n^2} \\ &\geq \liminf_{n\to\infty} \frac{1}{2}\langle y_n^*, h''(\bar{x}; z_n)\rangle \geq \frac{1}{2}(\beta + \liminf_{n\to\infty} \langle y_n^*, h''(\bar{x}; z_n) - h''(\bar{x}; z_n')\rangle) = \frac{1}{2}\beta, \end{aligned}$$

which is a contradiction. □

Apart from the case when X is finite dimensional, Condition 5.10 is fulfilled also in other situations. For instance, for the mathematical programming problem, when Range$(h'(\bar{x}))$ is closed, we can apply Hoffman's lemma [17] to verify Condition 5.10, and we obtain the standard second-order sufficient conditions [16] from the above theorem. Hence, the common second-order conditions are equivalent characterizations of critical points and essential local minimizers of second order, respectively.

The following result is new even in the case of scalar minimization and even when Robinson's constraint qualification condition (3.13) is fulfilled.

THEOREM 5.12. *Assume that* $\bar{x}$ *is a nondegenerate critical point (respectively, essential local minimizer) of second order for problem* (P). *Then there is a real* $\beta \geq 0$ *(respectively,* $\beta > 0$) *such that the following holds: For any pair* $(\bar{y}, w) \in Y \times Y$ *such that there is a sequence* $(z_n, t_n) \subset S_X \times \mathbb{R}_+$ *with* $t_n \to 0_+$, $d(h(\bar{x}) + t_n h'(\bar{x})z_n + \frac{1}{2}t_n^2 w, C) = o(t_n^2)$, *and* $h''(\bar{x}; z_n) \to \bar{y}$, *we can find some* $y^* \in \Lambda_{FJ} \cap B_{Y^*}$ *such that* $\langle y^*, \bar{y} - w\rangle \geq \beta$.

Proof. The proof follows along the same lines as the proof of Theorem 5.4 and is therefore omitted. □

Using a proof similar to that of Theorem 5.6 one can show that the second-order conditions of Theorem 5.12 are also sufficient for critical points (respectively, essential local minimizers) if Y is finite dimensional.

Example 5.3 (cf. [7, Ex. 3.25]). Consider the scalar minimization problem

$$\min_{x\in\ell_2} \sum_{i=1}^{\infty} \frac{1}{i} x_i - x_i^2 \quad \text{subject to} \quad x \in K,$$

where $X = \ell_2$ is the Hilbert space of square summable sequences and $K := \{(x_i) : x_i \geq 0 \text{ for all } i\}$. It follows that $Y = \mathbb{R} \times \ell_2$ and $C = \mathbb{R}_- \times K$. Since $g(x) = x$, $\bar{x} = 0$ is nondegenerate and the cone of critical directions and the set of multipliers, respectively, are given by $\mathcal{C}(0) = \{0\}$ and $\Lambda_{FJ} = \{(u^*, v^*) \in \mathbb{R} \times \ell_2 : u^* > 0, v_i^* = u^*/i \; for \; all \; i\}$. Now consider the sequence of directions $z^n = (z_k^n) \in \ell_2$, $n = 1, \ldots$, with $z_k^n = 1$ if $k = n$ and $z_k^n = 0$ if $k \neq n$, and the sequence of scalars $t_n = 2n^{-1}$. Clearly, $h''(\bar{x}; z_n) \to \bar{y} := (-2, 0) \in \mathbb{R} \times \ell_2$. For $w := (-1, 0) \in \mathbb{R} \times \ell_2$ we obtain $d(h(\bar{x}) + t_n h'(\bar{x}) z_n + \frac{1}{2} t_n^2 w, C) = 0$. Hence, we have $\langle y^*, \bar{y} - w \rangle = u^*(-2 - (-1)) = -u^* < 0$ for all $y^* := (u^*, v^*) \in \Lambda_{FJ}$, and from Theorem 5.12 it follows that $\bar{x} = 0$ is not a critical point.

DUAL KALMAN–BUCY FILTERS AND INTERACTIVE ENTROPY PRODUCTION*

NIGEL J. NEWTON†

Abstract. This paper investigates partially observed linear Gaussian systems in continuous time from an information-theoretic viewpoint. It identifies information *supply*, *storage*, and *dissipation* processes that quantify various dependencies between the unobservable and observable components of the state variables of such systems, which we call the *signal* and *observation* processes. The storage is that information in the past of the observation useful for estimating the present and future of the signal. It is so called because it is the information "stored" in the state variable of the Kalman–Bucy filter. The optimal properties of the Kalman–Bucy filter bring about a particular symmetry in its joint dynamics with the signal. This enables a *dual* system, with the same structure as the original, to be derived by time reversal. The information supply and dissipation processes of this dual problem are those of the original, with roles interchanged. The same symmetry enables us to define an entropic measure of the local time-asymmetry of the *interaction* between the signals and filters, which we call the *rate of interactive entropy production*. This is shown to be directly connected with the rates of information supply and dissipation. It is also intimately connected with the entropy production of an abstract statistical mechanical system at or near a stationary nonequilibrium state.

Key words. Bayesian inference, dual filters, entropic derivative, information theory, nonequilibrium statistical mechanics, statistical filtering

1. Introduction.

This article investigates continuous-time, partially observed linear systems from an information-theoretic viewpoint. The systems considered have state variables comprising unobservable and observable components, which we call the *signal* and the *observation*, respectively. The key property of the state variable here is that it is Markov. This allows the future and the past of certain estimation problems to be separated by the present. More specifically, we define information *supply*, *storage*, and *dissipation* processes, which quantify the information contained in the past and present values of the observation on, respectively, the entire path of the signal, the present and future values of the signal, and the past of the signal. In the context of filtering, one is not concerned with the improvement of estimates of past values of the signal as new information supply becomes available, but rather with the optimal estimation of the current signal value from the current supply. For this reason it is not necessary for the filter state variable to hold the entire current information supply, but only that part useful for estimating the present and the future of the signal, i.e., the storage. The storage is so called because it is "stored" in the state variable of the Kalman–Bucy filter.

The signal and filter processes are jointly *and* marginally Markov, and because of this the processes have a particular symmetry that yields a *dual* filtering problem when time reversed. This dual problem has a structure identical to that of the original. Furthermore, its information supply, storage, and dissipation processes are intimately related to those of the original problem; the information *flows* occurring in the dual problems are time-reversed versions of each other.

We build on earlier work appearing in [12], which is centered on a statistical mechanical analogy for stable, time-homogeneous, nondegenerate, Gaussian processes. In this analogy, an abstract statistical mechanical system characterized by the process interacts with a heat bath in such a way that the "universe" comprising the system and the heat bath obeys a law of nondecrease of entropy analogous to the second law of thermodynamics. Under the special conditions of [12] (stability, time-homogeneity, and nondegeneracy) the process has a unique invariant distribution to which other distributions of the process converge. This invariant distribution is the maximum entropy "state" of the abstract universe. In the theory of nonequilibrium statistical mechanics, invariant distributions are called *stationary equilibrium states* or *stationary nonequilibrium states* according to the flow of some quantity (often energy) in the state, an equilibrium state being one for which this flow is zero. (See, for example, [1], [5], or [8].)

This statistical mechanical analogy is applied in [12] to the *joint* process comprising the signal and its Kalman–Bucy filter. It is shown there that, whatever the nature of the invariant distribution of the signal process alone, that of the joint process is a stationary nonequilibrium state. Energy is shown to flow, in the stationary state, around a loop comprising the heat bath and two subsystems termed the "conditional signal" and the "filter." This energy flow is accompanied by an entropy flow, which can be isolated from any flows of entropy occurring *within* either of the subsystems. This is done by what we define as *interactive entropy production*. This quantity can be interpreted, independently of the statistical mechanical analogies in [12], as an entropic measure of the time-asymmetry of the interaction between the signal and filter processes. This interpretation is meaningful without the special conditions of [12]. The definition of interactive entropy production is extended in this paper to the more general case, and its properties are investigated. It is intimately related to the information flows that occur in the original and dual filtering problems.

Information-theoretic aspects of filters have received much attention in the literature. For example, a variety of information-theoretic measures of optimality, such as the mutual information between the observation and the estimation error, are considered in [4], [7], and [16]. In particular, these papers show that many of these measures are optimized by the Kalman–Bucy filter in the linear Gaussian case. More interesting is the fact that they provide a framework for deriving suboptimal filters in the nonlinear case. The measure of interest in this paper is the mutual information between the observation path and the signal value. The results can be extended to nonlinear systems (see [13] and [14]), but then involve the infinite-dimensional nonlinear filter. The results most closely connected with the information flow aspects of this paper are to be found in [3] and [15].

2. Information flow in the Kalman–Bucy filter. This section investigates the information flows that occur between signal and observation processes in a partially observed linear Gaussian system. Up to a point it interprets classical results; what we call here the information *supply* was first evaluated for partially observed diffusions in [3], and a study of the mutual information for the filter and path estimators

was made in [15]. (See also [10].) Results of the type presented in this section, only for the time-homogeneous, nondegenerate case, were developed in [12].

All random quantities are defined on the filtered probability space $(\Omega, \mathcal{F}, (\mathcal{F}_t,\ t \in [-T,T]), \mathbb{P})$. (The use of a *symmetric* time interval simplifies the discussion of the dual filter in section 3.) The signal, X, is an $\mathbb{R}^n$-valued continuous-time process satisfying

$$X_t = \xi + \int_{-T}^{t} A(s)X_s\,ds + V_t \quad \text{for } t \in [-T,T], \tag{2.1}$$

where A is a continuous $\mathbb{R}^{n\times n}$-valued function on $[-T,T]$, ξ is an $\mathcal{F}_{-T}$-measurable $\mathbb{R}^n$-valued Gaussian random variable with mean zero and nonsingular covariance matrix P_i, and

$$V_t = \int_{-T}^{t} \Psi(s)\,d\tilde{V}_s \quad \text{for } t \in [-T,T].$$

Here, Ψ is a Lipschitz continuous $\mathbb{R}^{n\times r}$-valued function on $[-T,T]$, and $(\tilde{V}_t, \mathcal{F}_t)$ is an r-vector Brownian motion, left-shifted in time by T, for some $r \le n$. With this definition, X is a zero-mean Gaussian process with covariance matrix process P satisfying the following equation:

$$P(t) = P_i + \int_{-T}^{t} \left(A(s)P(s) + P(s)A(s)' + \Sigma_V(s)\right)\,ds \quad \text{for } t \in [-T,T],$$

where $\Sigma_V = \Psi\Psi'$.

The observation, Y, is an $\mathbb{R}^n$-valued continuous-time process satisfying

$$Y_t = \xi + \zeta + \int_{-T}^{t} \Sigma_W(s)X_s\,ds + W_t \quad \text{for } t \in [-T,T], \tag{2.2}$$

where ζ is an $\mathcal{F}_{-T}$-measurable Gaussian random variable, independent of ξ, with mean zero and nonsingular covariance matrix M,

$$W_t = \int_{-T}^{t} \Gamma(s)\,d\tilde{W}_s \quad \text{for } t \in [-T,T],$$

Γ is a Lipschitz continuous $\mathbb{R}^{n\times d}$-valued function on $[-T,T]$ for some $d \le n$, $(\tilde{W}_t, \mathcal{F}_t)$ is a d-vector left-shifted Brownian motion, independent of V, and $\Sigma_W = \Gamma\Gamma'$.

Remark 2.1. Y comprises an "initial" observation Y^i $(= \xi + \zeta)$, and a "running" observation $(Y_t - Y^i,\ t \in [-T,T])$. The former can be thought of as summarizing partial observations of an extended version of X that solves an equation of type (2.1) over times prior to $-T$.

Remark 2.2. The running observation is essentially of dimension d since it can be replaced with the d-dimensional process

$$\tilde{Y}^r_t = \int_{-T}^{t} \Gamma(s)'X_s\,ds + \tilde{W}_t \quad \text{for } t \in [-T,T],$$

with no loss in information content regarding the signal.

Remark 2.3. The signal and observation noise processes, V and W, have "built-in" nonstandard quadratic covariations

$$d[V,V']_t = \Sigma_V(t)\,dt \quad \text{and} \quad d[W,W']_t = \Sigma_W(t)\,dt.$$

This avoids any further need for specific square roots of Σ_V and Σ_W and clarifies the discussion of duality in section 3.

Remark 2.4. The more general model, in which ξ and ζ have nonzero means and the linear drift coefficients in (2.1) and (2.2) are replaced with affine functions, can easily be re-expressed in the form above. It is then an equivalent filtering problem to estimate the centered signal from a centered version of the observations.

The Kalman–Bucy filter generates the conditional distribution of X_t given $(Y_s, s \in [-T,t])$, which is Gaussian. The *covariance* form of the filter propagates the mean vector, $\hat{X}$, and covariance matrix, Q, of the conditional distribution. These evolve as follows:

$$\begin{aligned} \hat{X}_{-T} &= P_i(P_i+M)^{-1}Y^i, \\ d\hat{X}_t &= (A(t)-Q(t)\Sigma_W(t))\,\hat{X}_t\,dt + Q(t)\,dY_t, \\ Q(-T) &= \left(P_i^{-1}+M^{-1}\right)^{-1}, \\ \dot{Q}(t) &= A(t)Q(t)+Q(t)A(t)'+\Sigma_V(t)-Q(t)\Sigma_W(t)Q(t). \end{aligned} \tag{2.3}$$

(See, for example, [2].) Since P_i and M are positive definite, the inverse matrices here are well defined, and $P(t)$, $Q(t)$, and $P(t)-Q(t)$ are all positive definite for all t.

Let $\mathcal{F}^Y$ be the filtration generated by Y, and let ν be the associated innovations process:

$$\begin{aligned} \mathcal{F}_t^Y &:= \sigma(Y_s,\ s\in[-T,t]) \\ \nu_t &:= Y_t - \hat{X}_{-T} - \int_{-T}^t \Sigma_W(s)\hat{X}_s\,ds \qquad \text{for } t\in[-T,T]. \end{aligned} \tag{2.4}$$

Then $(\nu_t, \mathcal{F}_t^Y)$ is a continuous n-vector Gaussian martingale with the same quadratic covariation as W, but with a nonzero initial value having the n-variate Gaussian distribution $N(0, M-Q(-T))$. (Here, and in what follows, we denote the n-variate Gaussian distribution with mean vector μ and covariance matrix Σ by $N(\mu,\Sigma)$ and denote its density (when $|\Sigma|\neq 0$) by $n(\mu,\Sigma)$.) Of course the filter can be expressed entirely in terms of the innovations process as follows:

$$\hat{X}_t = P_iM^{-1}\nu_{-T} + \int_{-T}^t A(s)\hat{X}_s\,ds + \int_{-T}^t Q(s)\,d\nu_s. \tag{2.5}$$

(This, together with the representation (2.4) for Y, and the fact that (2.5) has a strong solution, confirms that the filtration generated by ν coincides with $\mathcal{F}^Y$.)

We define information *supply*, *storage*, and *dissipation* processes as follows:

$$\begin{aligned} S(t) &:= I(X\,;\,(Y_s, s\in[-T,t])), \\ C(t) &:= I((X_s, s\in[t,T])\,;\,(Y_s, s\in[-T,t])) \quad \text{for } t\in[-T,T], \\ D(t) &:= S(t)-C(t), \end{aligned} \tag{2.6}$$

where, for random variables Θ and Φ taking values in Borel spaces and having joint and marginal distributions $\mathbb{P}_{\Theta\Phi}$, $\mathbb{P}_\Theta$, and $\mathbb{P}_\Phi$, $I(\Theta\,;\,\Phi)$ is the *mutual information*:

$$I(\Theta\,;\,\Phi) = \begin{cases} \displaystyle\int \log\left(\frac{d\mathbb{P}_{\Theta\Phi}}{d(\mathbb{P}_\Theta\otimes\mathbb{P}_\Phi)}\right) d\mathbb{P}_{\Theta\Phi} & \text{if the integral exists,} \\ +\infty & \text{otherwise.} \end{cases} \tag{2.7}$$

Since X is Markov, and the increments of W are independent of X and of each other, $\hat{X}_t$ is a sufficient statistic for the problem of estimating the future of X (X_s, $s \in [t,T]$), from the past of Y (Y_s, $s \in [-T,t]$), and so

$$\begin{aligned} C(t) &= I((X_s, s \in [t,T])\,;\, \hat{X}_t) \\ &= I(X_t\,;\, \hat{X}_t) \\ &= \tfrac{1}{2}\log|P_i + M| - \tfrac{1}{2}\log|M| + \tfrac{1}{2}\int_{-T}^{t} \operatorname{tr}(\Sigma_W(s)Q(s))\,ds \\ &\quad - \tfrac{1}{2}\int_{-T}^{t} \operatorname{tr}\left(\Sigma_V(s)(Q(s)^{-1} - P(s)^{-1})\right)\,ds. \end{aligned} \tag{2.8}$$

The information supply can be evaluated by means of a simple generalization of Theorem 3 in [3]. This involves a measure transformation on $(\Omega, \mathcal{F}_T)$. Let $\mathbb{P}^M$ be the measure on $\mathcal{F}_T$ whose Radon–Nikodym derivative with respect to $\mathbb{P}$ is L_T, where L is the continuous process defined as follows:

$$\begin{aligned} L_t := \frac{n(0, P_i + M)(Y^i)}{n(\xi, M)(Y^i)} \exp\Bigg(&- \int_{-T}^{t} (X_s - \hat{X}_s)'\,dW_s \\ &- \tfrac{1}{2}\int_{-T}^{t} (X_s - \hat{X}_s)'\Sigma_W(s)(X_s - \hat{X}_s)\,ds\Bigg). \end{aligned} \tag{2.9}$$

Lemma 2.1.

(i) *$\mathbb{P}$ and $\mathbb{P}^M$ are mutually absolutely continuous probability measures.*

(ii) *Under $\mathbb{P}^M$, (ξ, V) and ν are independent, but retain the marginal distributions they have under $\mathbb{P}$.*

(iii) *Under $\mathbb{P}^M$, the processes X and $\hat{X}$ are independent, but retain the marginal distributions they have under $\mathbb{P}$.*

Proof. It is a standard result that

$$\mathbf{E}\left(\exp\left(\tfrac{1}{2}\int_{-T}^{T} (X_t - \hat{X}_t)'\Sigma_W(t)(X_t - \hat{X}_t)\,dt\right) \,\middle|\, \mathcal{F}_{-T}\right) < \infty \quad \text{a.s.}$$

(See, for example, [9].) Thus it follows from the Girsanov theorem that, under $\mathbb{P}$, $(L_t, \mathcal{F}_t)$ is a martingale with

$$\mathbf{E}\,(L_t \,|\, \mathcal{F}_{-T}) = \frac{n(0, P_i + M)(Y^i)}{n(\xi, M)(Y^i)} \quad \text{for all } t \in [-T,T]$$

so that $\mathbf{E}L_T = 1$, and this establishes part (i). Now, for each $t \in [-T,T]$,

$$\begin{bmatrix} V_t \\ \nu_t \end{bmatrix} = \begin{bmatrix} 0 \\ \nu_{-T} \end{bmatrix} + \int_{-T}^{t} \begin{bmatrix} 0 \\ \Sigma_W(s)(X_s - \hat{X}_s) \end{bmatrix} ds + \begin{bmatrix} V_t \\ W_t \end{bmatrix},$$

and so it follows from Girsanov's theorem that, under $\mathbb{P}^M$, $((V_t, \nu_t), \mathcal{F}_t)$ is a $2n$-dimensional Gaussian martingale with quadratic covariation

$$d\left[\begin{bmatrix} V \\ \nu \end{bmatrix}, \begin{bmatrix} V \\ \nu \end{bmatrix}'\right]_t = \begin{bmatrix} \Sigma_V(t) & 0 \\ 0 & \Sigma_W(t) \end{bmatrix} dt. \tag{2.10}$$

The independence of ξ and ν_{-T} under $\mathbb{P}^M$ follows from elementary manipulations of the n-variate Gaussian densities in (2.9), and this establishes part (ii). Part (iii) follows from part (ii) and the innovations representation of $\hat{X}$ in (2.5). □

In what follows, we shall call $\mathbb{P}^M$ the *product-of-marginals* measure.

The information supply can now be evaluated as follows:

$$\begin{aligned} S(t) &= \mathbf{E}\log\left(L_t^{-1}\right) \\ &= \frac{1}{2}\log|P_i + M| - \frac{1}{2}\log|M| + \frac{1}{2}\int_{-T}^{t} \mathrm{tr}(\Sigma_W(s)Q(s))\,ds, \end{aligned} \tag{2.11}$$

and so the dissipation has the form

$$D(t) = \frac{1}{2}\int_{-T}^{t} \mathrm{tr}\left(\Sigma_V(s)(Q(s)^{-1} - P(s)^{-1})\right)\,ds. \tag{2.12}$$

It also easily follows that, for any $s \le t$,

$$\begin{aligned} S(t) - D(s) &= C(s) + \mathbf{E}\log\left(L_t^{-1}L_s\right) \\ &= I((X_r, r \in [s,T])\,;\,(Y_r, r \in [-T,t])), \end{aligned}$$

so that the dissipation, $D(s)$, is the information on X derived from $(Y_r,\ r \in [-T,t])$ that is of no use in estimating the values that X takes from time s onward.

In one respect, the Kalman–Bucy filter can be thought of as being a data *encoder*. At time t, it partially encodes the observation path $(Y_s,\ s \in [-T,t])$ as the statistic $\hat{X}_t$. Clearly this encoding is *lossy* because the observation path cannot be recovered from $\hat{X}_t$. Since both $(Y_s,\ s \in [-T,t])$ and $\hat{X}_t$ take values in uncountably infinite spaces, we cannot define absolute information quantities for them, and so we cannot define a meaningful measure of the *total* information loss arising from the encoding. However, we *can* define a meaningful measure of information loss in the context of a specific estimation problem; this is simply the amount by which the *mutual* information between the estimand and $\hat{X}_t$ is less than that between the estimand and $(Y_s,\ s \in [-T,t])$. For the problem of estimating the whole process X, the encoding of the Kalman–Bucy filter at time t loses information, but for the problem of estimating the future of X, $(X_s,\ s \in [t,T])$, it is lossless. We note that S, C, and D are all *mutual* information quantities and, as such, have absolute meaning.

In a dynamic sense, the Kalman–Bucy filter can be thought of as an *information processor* that receives new observation-derived information at the rate $\dot{S}(t)$, and dissipates historical information at the rate $\dot{D}(t)$. It stores an amount of observation-derived information $C(t)$, which is that part of the supply to date useful for estimating the present and future of X.

3. The dual filter. The duality ideas for discrete-time systems in [6] are extended here to the continuous-time system (2.1), (2.2). These ideas use the concept of *dual bases* for finite-dimensional, linear spaces. When the state and observation processes of a finite-dimensional, discrete-time system, evolving over a finite time interval, are taken as a set of basis vectors, the vectors of a dual basis can be shown to be the state and observation processes of another system, which is naturally termed the *dual system*. In the continuous-time setting of this article, the dual system is derived through time reversal.

It turns out that the dual filters are most conveniently expressed in *information form*. For the Kalman–Bucy filter of section 2, this propagates the vector process Z

$(:= Q^{-1}\hat{X})$ instead of $\hat{X}$. The signal and information filter processes, X and Z, are *coupled* Markov processes evolving *jointly* according to the following equations:

$$\begin{aligned} \begin{bmatrix} X_{-T} \\ Z_{-T} \end{bmatrix} &= \begin{bmatrix} I_n & 0 \\ M^{-1} & M^{-1} \end{bmatrix} \begin{bmatrix} \xi \\ \zeta \end{bmatrix}, \\ d\begin{bmatrix} X_t \\ Z_t \end{bmatrix} &= A_J(t) \begin{bmatrix} X_t \\ Z_t \end{bmatrix} dt + d\begin{bmatrix} V_t \\ W_t \end{bmatrix}, \end{aligned} \tag{3.1}$$

where I_n is the $n \times n$ identity matrix, and

$$A_J(t) := \begin{bmatrix} A(t) & 0 \\ \Sigma_W(t) & -\big(A(t) + \Sigma_V(t)Q(t)^{-1}\big)' \end{bmatrix}. \tag{3.2}$$

Under the product-of-marginals measure, $\mathbb{P}^M$, X, and Z are *independent* Markov processes whose evolutions are conveniently expressed by the "marginal" equations:

$$\begin{aligned} \begin{bmatrix} X_{-T} \\ Z_{-T} \end{bmatrix} &= \begin{bmatrix} I_n & 0 \\ 0 & M^{-1}(P_i + M)M^{-1} \end{bmatrix} \begin{bmatrix} \xi \\ \nu_{-T} \end{bmatrix}, \\ d\begin{bmatrix} X_t \\ Z_t \end{bmatrix} &= A_M(t) \begin{bmatrix} X_t \\ Z_t \end{bmatrix} dt + d\begin{bmatrix} V_t \\ \nu_t \end{bmatrix}, \end{aligned} \tag{3.3}$$

where

$$A_M(t) := \begin{bmatrix} A(t) & 0 \\ 0 & -\big(A(t) + \Sigma_V(t)Q(t)^{-1}\big)' + \Sigma_W(t)Q(t) \end{bmatrix}. \tag{3.4}$$

The dual system is obtained by time-reversing (X, Z). For each $t \in [-T, T]$, let

$$\begin{aligned} X_t^* &:= Z_{-t}, \\ Z_t^* &:= X_{-t}, \\ \mathcal{F}_t^* &:= \sigma(X_s^*, Z_s^*,\ s \in [-T, t]), \\ A^*(t) &:= A(-t)' + Q(-t)^{-1}\Sigma_V(-t) - \Sigma_W(-t)\big(Q(-t)^{-1} - P(-t)^{-1}\big)^{-1}, \\ \Sigma_V^*(t) &:= \Sigma_W(-t), \\ \Sigma_W^*(t) &:= \Sigma_V(-t), \\ Q^*(t) &:= Q(-t)^{-1} - P(-t)^{-1}, \\ V_t^* &:= X_t^* - X_{-T}^* - \int_{-T}^{t} A^*(s)X_s^*\, ds, \\ W_t^* &:= Z_t^* - Z_{-T}^* - \int_{-T}^{t} \big(\Sigma_W^*(s)X_s^* - (A^*(s) + \Sigma_V^*(s)Q^*(s)^{-1})'Z_s^*\big)\, ds, \\ \nu_t^* &:= P(T)^{-1}Z_{-T}^* + \int_{-T}^{t} \Sigma_W^*(s)\,(X_s^* - Q^*(s)Z_s^*)\, ds + W_t^*. \end{aligned} \tag{3.5}$$

Proposition 3.1.

(i) *Under* $\mathbb{P}$, *the process* $((V_t^*, W_t^*),\ \mathcal{F}_t^*,\ t \in [-T, T])$ *is a* $2n$*-dimensional, Gaussian martingale with initial value zero and quadratic covariation*

$$\left[\begin{bmatrix} V^* \\ W^* \end{bmatrix}, \begin{bmatrix} V^* \\ W^* \end{bmatrix}'\right]_t = \int_{-T}^{t} \begin{bmatrix} \Sigma_V^*(s) & 0 \\ 0 & \Sigma_W^*(s) \end{bmatrix} ds. \tag{3.6}$$

(ii) *Under* $\mathbb{P}^M$*, the process* $((V_t^*, \nu_t^*),\ \mathcal{F}_t^*,\ t \in [-T,T])$ *is a* $2n$*-dimensional, Gaussian martingale with initial value* $(0, P(T)^{-1}Z_{-T}^*)$ *(which is independent of* X_{-T}^**) and the quadratic covariation of* (3.6).

(iii) *For each* $t \in [-T,T]$,

$$\begin{aligned}\mathcal{F}_t^* &= \sigma(X_{-T}^*,\, Z_{-T}^*;\, (V_s^*,\, W_s^*),\, s \in [-T,t]) \\ &= \sigma(X_{-T}^*,\, Z_{-T}^*;\, (V_s^*,\, \nu_s^*),\, s \in [-T,t]).\end{aligned} \tag{3.7}$$

Proof. Let $(\Theta(s,t),\ -T \le s \le t \le T)$ be the matrix fundamental solution of (3.1) without the "driving" process; i.e.,

$$\begin{aligned}&\Theta(s,s) = I_{2n} \quad \text{for } -T \le s \le T, \\ &\frac{\partial \Theta(s,t)}{\partial t} = A_J(t)\Theta(s,t) \quad \text{for } -T \le s \le t \le T.\end{aligned} \tag{3.8}$$

Then it follows that for $-T \le s \le t \le T$,

$$\mathbf{E}\begin{bmatrix} Z_s^* \\ X_s^* \end{bmatrix}\begin{bmatrix} Z_t^* \\ X_t^* \end{bmatrix}' = \Theta(-t,-s)P_J(-t),$$

where $P_J(t)$ is the covariance matrix of (X_t, Z_t):

$$P_J(t) := \begin{bmatrix} P(t) & (P(t)-Q(t))Q(t)^{-1} \\ Q(t)^{-1}(P(t)-Q(t)) & Q(t)^{-1}(P(t)-Q(t))Q(t)^{-1} \end{bmatrix}. \tag{3.9}$$

Straightforward calculations now show that, for any $-T \le r \le s \le t \le T$,

$$\mathbf{E}\begin{bmatrix} Z_r^* \\ X_r^* \end{bmatrix}\begin{bmatrix} V_t^* - V_s^* \\ W_t^* - W_s^* \end{bmatrix}' = 0,$$

and that (3.6) holds, and so (V^*, W^*) is a zero-mean, independent-increments, Gaussian process, independent of (X_{-T}^*, Z_{-T}^*) and with the quadratic covariation of (3.6). It is thus a Gaussian martingale with this quadratic covariation with respect to the filtration it generates. It now follows from the definitions of V^* and W^* that

$$(X^*, Z^*) = \Phi^*\left((X_{-T}^*, Z_{-T}^*),\, (V^*, W^*)\right),$$

where Φ^* is the strong solution of (3.10) below. This proves the first equation in (3.7) and proves part (i) of the proposition. The second equation in (3.7) and part (ii) of the proposition can be proved in a similar manner, but starting from the matrix fundamental solution of (3.3). □

It follows from the definitions of V^*, W^*, and ν^* that (X^*, Z^*) satisfies the following two equations:

$$\begin{aligned}&\begin{bmatrix} X_{-T}^* \\ Z_{-T}^* \end{bmatrix} = \begin{bmatrix} I_n & 0 \\ (M^*)^{-1} & (M^*)^{-1} \end{bmatrix}\begin{bmatrix} \xi^* \\ \zeta^* \end{bmatrix}, \\ &d\begin{bmatrix} X_t^* \\ Z_t^* \end{bmatrix} = A_J^*(t)\begin{bmatrix} X_t^* \\ Z_t^* \end{bmatrix}dt + d\begin{bmatrix} V_t^* \\ W_t^* \end{bmatrix},\end{aligned} \tag{3.10}$$

and

$$\begin{aligned}&\begin{bmatrix} X_{-T}^* \\ Z_{-T}^* \end{bmatrix} = \begin{bmatrix} I_n & 0 \\ 0 & (M^*)^{-1}(P_i^* + M^*)(M^*)^{-1} \end{bmatrix}\begin{bmatrix} \xi^* \\ \nu_{-T}^* \end{bmatrix}, \\ &d\begin{bmatrix} X_t^* \\ Z_t^* \end{bmatrix} = A_M^*(t)\begin{bmatrix} X_t^* \\ Z_t^* \end{bmatrix}dt + d\begin{bmatrix} V_t^* \\ \nu_t^* \end{bmatrix},\end{aligned} \tag{3.11}$$

where A_J^* and A_M^* are defined as in (3.2) and (3.4), but with dual quantities, and

$$\begin{aligned} \xi^* &:= X^*_{-T}, \\ \zeta^* &:= M^* Z^*_{-T} - X^*_{-T}, \\ M^* &:= Q(T)^{-1}, \\ P_i^* &:= Q(T)^{-1}(P(T) - Q(T))Q(T)^{-1}. \end{aligned} \tag{3.12}$$

Equations (3.10) and (3.11) are the equivalents of (3.1) and (3.3) for a dual filtering problem: straightforward calculations show that X^* is a zero-mean Gaussian process, that $X^*(t)$ has covariance matrix

$$P^*(t) := Q(-t)^{-1}(P(-t) - Q(-t))Q(-t)^{-1},$$

and that Z^* is its information filter process given the dual observations

$$Y_t^* = \xi^* + \zeta^* + \int_{-T}^t \Sigma_W^*(s) X_s^*\, ds + W_t^* \quad \text{for } t \in [-T, T].$$

These are made up of initial and running components in the same way as was Y. To complete the duality, we note that Q^*, as defined in (3.5), is indeed the conditional covariance matrix for this filter. Thus, in reverse time, the information filter of the original problem, Z, becomes an autonomous signal process, and the signal process of the original problem, X, becomes its Kalman–Bucy filter, in information form, given the dual observations Y^*.

In analogy with the definitions of $S(t)$, $C(t)$, and $D(t)$ of section 2, we can identify the information supply, storage, and dissipation for the dual filter:

$$\begin{aligned} S^*(t) &:= I(X^*\,;\, (Y_s^*, s \in [-T, t])) \\ &= \tfrac{1}{2}\log|P_i^* + M^*| - \tfrac{1}{2}\log|M^*| + + \tfrac{1}{2}\int_{-T}^t \operatorname{tr}(\Sigma_W^*(s)Q^*(s))\, ds \\ &= S^*(-T) + (D(T) - D(-t)), \\ C^*(t) &:= I((X_s^*, s \in [t, T])\,;\, (Y_s^*, s \in [-T, t])) \\ &= C(-t), \\ D^*(t) &:= S^*(t) - C^*(t) \\ &= \tfrac{1}{2}\int_{-T}^t \operatorname{tr}\left(\Sigma_V^*(s)\left(Q^*(s)^{-1} - P^*(s)^{-1}\right)\right) ds \\ &= S(T) - S(-t). \end{aligned} \tag{3.13}$$

This shows that the time-reversed information flows for the original problem can be interpreted as the forward-time information flows for the dual problem, with supply and dissipation swapping roles.

It may seem, at first sight, that $\dot{S}^*(-t)$ should equal $\dot{S}(t)$ since both concern the supply of information between X and Z over the short time interval $[t, t + \delta t]$. That this is not so is because S and S^* are *cumulative* information quantities with derivatives that represent the flow rate of *new* information. What constitutes new information between X and Z depends on the time direction over which information is being accumulated. Over the time interval $[t, t + \delta t]$ an amount $S(t + \delta t) - S(t)$ of new information is supplied in the forward problem. Because this is new, it relates to

a dependency between $X_{t+\delta t}$ and $Z_{t+\delta t}$ that is not present between $(X_s,\ s \in [-T,t])$ and $(Z_s,\ s \in [-T,t])$. For this reason the dual filter dissipates it and

$$D^*(-t) - D^*(-t-\delta t) = S(t+\delta t) - S(t).$$

A central role is played in the information supply rate of the original filter by the "signal-to-noise ratio" matrix $\Sigma_W(t)$. Its dual, $\Sigma_V(t)$, controls the rate of information *dissipation* for the forward filter: the larger it is, the greater is the effect of the signal noise, and this increases the rate at which the signal "forgets its past." We can think of information for the forward filter as being supplied by the observation process, Y, stored temporarily in the filter state, Z_t, and then absorbed by the signal noise process, V. This notion that the signal noise can *erase* past information supply is at the heart of some statistical mechanical analogies developed in [12].

Equation (3.10) provides an "inverse construction" of the pair (X,Z). In (3.1), X is defined in an autonomous fashion, and Z is defined in a way that couples it to X and results in a particular joint distribution, P_{XZ}. In the inverse construction (3.10), this dependency is reversed. Clearly Y can be found from Z (and vice versa) by means of (3.3) and (2.4), and so (3.10) also provides an inverse construction of the pair (X,Y). This construction can be formulated in terms of optimal control, as follows.

The equations for Z^* in (3.11) and (3.10) can be rewritten as

$$dZ_t^* = \bar{A}(t)Z_t^*\,dt + dv_t^* \tag{3.14}$$

and

$$dZ_t^* = \bar{A}(t)Z_t^*\,dt + \Sigma_V(-t)U^*(Z_t^*,t)\,dt + dW_t^*, \tag{3.15}$$

respectively, where

$$\begin{aligned}\bar{A}(t) &:= -\left(A^*(t) + \Sigma_V^*(t)Q^*(t)^{-1}\right)' + \Sigma_W^*(t)Q^*(t)\\ &= -A(-t) - \Sigma_V(-t)P(-t)^{-1}\end{aligned} \tag{3.16}$$

and

$$U^*(z^*,t) = X_t^* - \left(Q(-t)^{-1} - P(-t)^{-1}\right)z^*. \tag{3.17}$$

Equation (3.14) is the autonomous equation for X, (2.1), reversed in time; (3.15) can be thought of as being a *controlled* version of (3.14), in which the control, U^*, is random through its dependence on X^*. Regarding the outcome of Y (and hence X^*) as a fixed parameter, the effect of the control is to change the distribution of the path Z^* into a regular version of its Y-conditional distribution. In fact U^* is the optimal control in an LQG (linear quadratic Gaussian) problem for Z^* with the *apparent information* for estimators of X given Y as cost. (See [11].) The use of a suboptimal control in this time-reversed problem corresponds to the dissipation of information at a rate exceeding $\dot{D}$. This fact is useful in the study of suboptimal filtering. (See [14].) Of course, the same arguments can be applied to the equations for Z in (3.3) and (3.1) to characterize the dissipation of the dual filtering problem in terms of a dual LQG control problem for Z in forward time.

4. Interactive entropy production. This section further investigates the interaction between the signal and filter processes of (3.1). Starting from a concept of

entropy production for the signal, it defines an entropic measure of the local time-asymmetry of this interaction, which we shall call the *rate of interactive entropy production* between the signal and filter processes. This was introduced in the context of a statistical mechanical analogy for the signal and filter under special conditions in [12]. The (pertinent) special conditions are recalled here, as follows:

(S1) Σ_V and Σ_W are not dependent on t;

(S2) Σ_V and Σ_W are positive definite for all $t \in [-T, T]$.

We first consider the signal process alone under these conditions. For each $-T \le t - \epsilon < t + \epsilon \le T$, let $\Pi^X_{t+\epsilon|t}$ and $\Pi^X_{t-\epsilon|t}$ be regular X_t-conditional distributions of the processes $(X_u,\, u \in [t, t+\epsilon])$ and $(Z^*_u,\, u \in [-t, -t+\epsilon])$, respectively. (These are segments of the process X extending forward and backward from time t by an amount ϵ.) It follows from (S1), (S2), and the Girsanov theorem that $\Pi^X_{t+\epsilon|t} \sim \Pi^X_{t-\epsilon|t}$ (a.s.), and that

$$\frac{d\Pi^X_{t+\epsilon|t}}{d\Pi^X_{t-\epsilon|t}}(X) = \exp\biggl(\int_t^{t+\epsilon} X'_s(A(s) - \bar{A}(s-2t))'\Sigma_V^{-1}\, dV_s + \frac{1}{2}\int_t^{t+\epsilon} X'_s(A(s) - \bar{A}(s-2t))'\Sigma_V^{-1}(A(s) - \bar{A}(s-2t))X_s\, ds\biggr),$$

where $\bar{A}$ is as defined in (3.16). The rate of entropy production of X at time $t \in (-T, T)$, when (S1) and (S2) hold, can then be defined as follows:

$$\begin{aligned} R_X(t) &:= \lim_{\epsilon \downarrow 0} \epsilon^{-1} \mathbf{E} h\left(\Pi^X_{t+\epsilon\,|\,t} | \Pi^X_{t-\epsilon|t}\right) \\ &= \tfrac{1}{2}\mathrm{tr}\left((A(t) - \bar{A}(-t))'\Sigma_V^{-1}(A(t) - \bar{A}(-t))P(t)\right), \end{aligned} \tag{4.1}$$

where, for measures α and β on the same measurable space, $h(\alpha\,|\,\beta)$ is the *relative entropy*

$$h(\alpha\,|\,\beta) = \begin{cases} \displaystyle\int \log\left(\frac{d\alpha}{d\beta}\right) d\alpha & \text{if the integral exists,} \\ +\infty & \text{otherwise.} \end{cases} \tag{4.2}$$

This definition of R_X is too strong in the general case since it is then possible for the measures $\Pi^X_{t+\epsilon|t}$ and $\Pi^X_{t-\epsilon|t}$ to be relatively singular. This can occur even if (S2) holds, since a small difference between the quadratic variations of X on either side of time t will result in the relative singularity of $\Pi^X_{t+\epsilon|t}$ and $\Pi^X_{t-\epsilon|t}$. We weaken the definition here by replacing $\Pi^X_{t+\epsilon|t}$ and $\Pi^X_{t-\epsilon|t}$ in (4.1) with their respective $t+\epsilon$ and $t-\epsilon$ marginals. The eventuality that $\Sigma_W(t)$ is singular is handled by a relaxation argument, as follows. For any $\delta \in (0, 1]$, let X^δ be the $\mathbb{R}^n$-valued process defined by the following equation:

$$X^\delta_t = \xi + \int_{-T}^t A(s)X^\delta_s\, ds + V_t + \delta B_t \quad \text{for } t \in [-T, T], \tag{4.3}$$

where $(B_t, \mathcal{F}_t)$ is a left-shifted n-vector Brownian motion independent of V (and W). Let $\mathcal{L}^\delta(t,x)$ and $\bar{\mathcal{L}}^\delta(t,x)$ be the forward and backward generators of the process X^δ:

$$\mathcal{L}^\delta(t,x) := \sum_{i=1}^n (A(t)x)_i \frac{\partial}{\partial x_i} + \frac{1}{2}\sum_{i,j=1}^n \left(\Sigma_V(t) + \delta^2 I_n\right)_{i,j} \frac{\partial^2}{\partial x_i \partial x_j},$$

$$\bar{\mathcal{L}}^\delta(t,x) := \sum_{i=1}^n (\bar{A}^\delta(t)x)_i \frac{\partial}{\partial x_i} + \frac{1}{2}\sum_{i,j=1}^n \left(\Sigma_V(t) + \delta^2 I_n\right)_{i,j} \frac{\partial^2}{\partial x_i \partial x_j},$$

where

$$\bar{A}^{\delta}(t) := -A(-t) - \left(\Sigma_V(-t) + \delta^2 I_n\right) P^{\delta}(-t)^{-1}, \tag{4.4}$$

and P^{δ} is the covariance matrix process of X^{δ}. Let $\mathcal{L}$ $(= \mathcal{L}^0)$ and $\bar{\mathcal{L}}$ $(= \bar{\mathcal{L}}^0)$ be the forward and backward generators of the original signal X. The following lemma provides some justification for the definition that follows, and it establishes some facts about the processes $(X^{\delta},\, \delta \in (0,1])$.

LEMMA 4.1.

$$\lim_{\delta \downarrow 0} \sup_{t \in [-T,T]} |X_t - X_t^{\delta}| = 0 \quad a.s., \tag{4.5}$$

$$\lim_{\delta \downarrow 0} \sup_{t \in [-T,T]} \|P(t) - P^{\delta}(t)\| = 0, \tag{4.6}$$

and, for any $f \in C_b^2(\mathbb{R}^n;\, \mathbb{R})$,

$$\begin{aligned} &\lim_{\delta \downarrow 0} \sup_{t,x} \left|(\mathcal{L}f)(t,x) - \left(\mathcal{L}^{\delta} f\right)(t,x)\right| = 0, \\ &\lim_{\delta \downarrow 0} \sup_{t,x} \left|\left(\bar{\mathcal{L}} f\right)(t,x) - \left(\bar{\mathcal{L}}^{\delta} f\right)(t,x)\right| = 0. \end{aligned} \tag{4.7}$$

Proof. The difference, $X - X^{\delta}$, satisfies a simple linear equation and can be represented by the following convolution integral:

$$X_t - X_t^{\delta} = \delta \int_{-T}^{t} \begin{bmatrix} I_n & 0 \end{bmatrix} \Theta(s,t) \begin{bmatrix} I_n \\ 0 \end{bmatrix} dB_s,$$

where Θ is as defined in (3.8). Equations (4.5) and (4.6) readily follow from this.

It now follows from (4.6) that $\sup_t \|\bar{A}(t) - \bar{A}^{\delta}(t)\|$ converges to zero, and this establishes (4.7). □

DEFINITION 4.2. *For each* $t \in (-T, T)$, *the* rate of entropy production *of the process* X *at time* t *is*

$$\begin{aligned} R_X(t) := \lim_{\delta \downarrow 0} \lim_{\epsilon \downarrow 0} \epsilon^{-1} \mathbf{E} h\left(\pi^{X,\delta}_{t+\epsilon|t} \,|\, \pi^{X,\delta}_{t-\epsilon|t}\right) \quad &\text{if the limit in } \delta \text{ exists}, \\ +\infty \quad &\text{otherwise}, \end{aligned} \tag{4.8}$$

where, for each $\delta \in (0,1]$ *and each* $\epsilon \in (0, \max(T-t,\, T+t)]$, $\pi^{X,\delta}_{t+\epsilon|t}$ *and* $\pi^{X,\delta}_{t-\epsilon|t}$ *are regular* X_t^{δ}*-conditional distributions of* $X^{\delta}_{t+\epsilon}$ *and* $X^{\delta}_{t-\epsilon}$, *respectively.*

The following proposition shows that this definition is consistent with that in (4.1), and evaluates $R_X(t)$.

PROPOSITION 4.3.

(i) *For any* $t \in (-T, T)$,

$$\begin{aligned} R_X(t) = \lim_{\delta \downarrow 0} \frac{1}{2} \mathrm{tr}\left((A(t) - \bar{A}^{\delta}(-t))' \left(\Sigma_V(t) + \delta^2 I_n\right)^{-1} (A(t) - \bar{A}^{\delta}(-t)) P^{\delta}(t) \right) \\ \text{if the limit exists}, \\ +\infty \quad \text{otherwise}. \end{aligned} \tag{4.9}$$

(ii) *For any* $t \in (-T, T)$ *such that* $|\Sigma_V(t)| \neq 0$,

$$R_X(t) = \frac{1}{2} \mathrm{tr}\left((A(t) - \bar{A}(-t))' \Sigma_V(t)^{-1} (A(t) - \bar{A}(-t)) P(t) \right). \tag{4.10}$$

Proof. $\pi^{X,\delta}_{t+\epsilon|t}$ and $\pi^{X,\delta}_{t-\epsilon|t}$ are nondegenerate Gaussian distributions on $\mathbb{R}^n$, with means $m^{+\delta}(\epsilon)$ and $m^{-\delta}(\epsilon)$, and covariance matrices $P^{+\delta}(\epsilon)$ and $P^{-\delta}(\epsilon)$, satisfying

$$\begin{aligned}
m^{+\delta}(\epsilon) &= X^\delta_t + \int_t^{t+\epsilon} A(s)m^{+\delta}(s)\,ds,\\
m^{-\delta}(\epsilon) &= X^\delta_t + \int_t^{t+\epsilon} \bar{A}^\delta(s-2t)m^{-\delta}(s)\,ds,\\
P^{+\delta}(\epsilon) &= \int_t^{t+\epsilon} \left(A(s)P^{+\delta}(s) + P^{+\delta}(s)A(s)' + \Sigma_V(s) + \delta^2 I_n\right)\,ds,\\
P^{-\delta}(\epsilon) &= \int_t^{t+\epsilon} \left(\bar{A}^\delta(s-2t)P^{-\delta}(s) + P^{-\delta}(s)\bar{A}^\delta(s-2t)' + \Sigma_V(2t-s) + \delta^2 I_n\right)\,ds.
\end{aligned}$$

Since Σ_V is Lipschitz continuous, it follows that, for each $\delta \in (0,1]$,

$$\begin{aligned}
P^{+\delta}(\epsilon) &= (\Sigma_V(t) + \delta^2 I_n)\epsilon + O(\epsilon^2),\\
P^{-\delta}(\epsilon) &= (\Sigma_V(t) + \delta^2 I_n)\epsilon + O(\epsilon^2),\\
P^{-\delta}(\epsilon)^{-1}P^{+\delta}(\epsilon) &= I_n + O(\epsilon),
\end{aligned}$$

and

$$\log\left(P^{-\delta}(\epsilon)^{-1}P^{+\delta}(\epsilon)\right) = P^{-\delta}(\epsilon)^{-1}P^{+\delta}(\epsilon) - I_n + O(\epsilon^2).$$

From these expressions it follows that

$$\begin{aligned}
h\left(\pi^{X,\delta}_{t+\epsilon\,|\,t}\,|\,\pi^{X,\delta}_{t-\epsilon|t}\right) &= -\frac{1}{2}\log\left(\left|P^{-\delta}(\epsilon)^{-1}P^{+\delta}(\epsilon)\right|\right) + \frac{1}{2}\mathrm{tr}\left(P^{-\delta}(\epsilon)^{-1}P^{+\delta}(\epsilon) - I_n\right)\\
&\quad + \frac{1}{2}\left(m^{+\delta}(\epsilon) - m^{-\delta}(\epsilon)\right)' P^{-\delta}(\epsilon)^{-1}\left(m^{+\delta}(\epsilon) - m^{-\delta}(\epsilon)\right)\\
&= \frac{1}{2}\left(m^{+\delta}(\epsilon) - m^{-\delta}(\epsilon)\right)' P^{-\delta}(\epsilon)^{-1}\left(m^{+\delta}(\epsilon) - m^{-\delta}(\epsilon)\right) + O(\epsilon^2)\\
&= \frac{1}{2}\left(X^\delta_t\right)'\left(A(t) - \bar{A}^\delta(-t)\right)'\left(\Sigma_V(t) + \delta^2 I_n\right)^{-1}\left(A(t) - \bar{A}^\delta(-t)\right)X^\delta_t\epsilon\\
&\quad + r(X^\delta_t, \delta, \epsilon)\epsilon^2,
\end{aligned}$$

where $r(X^\delta_t, \delta, \epsilon)$ is quadratic in the components of X^δ_t with coefficients that are uniformly bounded in (δ, ϵ). So

$$\begin{aligned}
&\lim_{\epsilon\downarrow 0}\epsilon^{-1}\mathbf{E}h\left(\pi^{X,\delta}_{t+\epsilon|t}\,|\,\pi^{X,\delta}_{t-\epsilon|t}\right)\\
&\qquad = \frac{1}{2}\mathrm{tr}\left(\left(A(t) - \bar{A}^\delta(-t)\right)'\left(\Sigma_V(t) + \delta^2 I_n\right)^{-1}\left(A(t) - \bar{A}^\delta(-t)\right)P^\delta(t)\right),
\end{aligned}$$

which proves part (i). Part (ii) follows from this and (4.6). □

Remark 4.1. $R_X(t)$ measures the *degree of time-asymmetry* of the process X at time t. Imagine a game in which one player secretly samples X at the three times $t-\epsilon$, t, and $t+\epsilon$, tosses a coin, reverses the time sequence of the samples if "heads" occurs, and then shows the other player the sequence, asking whether or not it has been reversed. $R_X(t)$ is a measure of the average degree of ease with which the second player could answer correctly.

Remark 4.2. If $\Sigma_V(t)$ is singular, then it is possible (but not necessary) for $R_X(t)$ to be infinite. Consider, for example, the time-homogeneous case in which

$$A = \begin{bmatrix} -2 & 1 \\ 1 & -2 \end{bmatrix} \quad \text{and} \quad \Sigma_V = \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix}.$$

This has invariant distribution $N(0, P_{SS})$ with covariance matrix

$$P_{SS} = \frac{1}{24} \begin{bmatrix} 7 & 2 \\ 2 & 1 \end{bmatrix}.$$

It can be shown that if X_t has this distribution (for example), then $R_X(t)$ is infinite. Furthermore, the second player in the game described above could determine whether or not the sequence of samples had been reversed with probability one by comparing the signs of $X_{t,1} - 2X_{t,2}$ and $X_{t+\epsilon,2} - X_{t-\epsilon,2}$ for sufficiently small ϵ. Even though this example is hypoelliptic, this is not enough to make $R_X(t)$ finite.

Remark 4.3. The rate of entropy production of the time-reversed process Z^* at time t is the same as that of the forward process X at time $-t$.

Remark 4.4. R_X is *homeomorphism invariant*. If f is a continuous, one-to-one mapping from $\mathbb{R}^n$ to $\mathbb{R}^n$, then it induces new distributions on $\mathbb{R}^n$ corresponding to $\pi^{X,\delta}_{t+\epsilon|t}$ and $\pi^{X,\delta}_{t-\epsilon|t}$. These can be used to define the rate of entropy production of the process $f(X_t)$ at time t. This is, of course, equal to $R_X(t)$.

Remark 4.5. $R_X(t)$ is nonnegative. It is zero if and only if $\bar{A}(-t) = A(t)$, in which case the dynamics of X are locally time symmetric at time t.

We now use the rates of entropy production of the joint process (X, Z), and those of the signal and filter processes, X and Z, to define an information-theoretic measure of the *interaction* between the latter two, which we shall call the *rate of interactive entropy production*. Crucial to the definition is the fact that X and Z are both *marginally* as well as jointly Markov. Like that of (marginal) entropy production, the definition of interactive entropy production relies on a relaxation argument. Let X^δ be as defined in (4.3), and let Y^δ be the following relaxed observation process:

$$Y^\delta_t = \xi + \zeta + \int_{-T}^{t} (\Sigma_W(s) + \delta^2 I_n) X^\delta_s \, ds + W_t + \delta \tilde{B}_t, \tag{4.11}$$

where $(\tilde{B}_t, \mathcal{F}_t)$ is a left-shifted n-vector Brownian motion, independent of V, W, and B. Let (Z^δ, Q^δ) be the information form of the Kalman–Bucy filter for X^δ given Y^δ, and let $\mathbb{P}^{M,\delta}$ be the associated product-of-marginals measure. (See the discussion preceding Lemma 2.1.)

The following lemma provides some justification for the definition that follows, and it establishes some facts about the processes $(Z^\delta, Q^\delta, \delta \in (0, 1])$.

LEMMA 4.4.

$$\lim_{\delta \downarrow 0} \sup_{t \in [-T,T]} |Z_t - Z^\delta_t| = 0 \quad a.s., \tag{4.12}$$

$$\lim_{\delta \downarrow 0} \sup_{t \in [-T,T]} \|Q(t) - Q^\delta(t)\| = 0, \tag{4.13}$$

and, for any $f \in C_b^2(\mathbb{R}^{2n};\mathbb{R})$,

$$\begin{aligned}\lim_{\delta\downarrow 0}\sup_{t,x}\left|\left(\mathcal{L}^J f\right)(t,x)-\left(\mathcal{L}^{J,\delta} f\right)(t,x)\right|&=0,\\ \lim_{\delta\downarrow 0}\sup_{t,x}\left|\left(\bar{\mathcal{L}}^J f\right)(t,x)-\left(\bar{\mathcal{L}}^{J,\delta} f\right)(t,x)\right|&=0,\end{aligned}\tag{4.14}$$

where $\mathcal{L}^{J,\delta}$ *and* $\bar{\mathcal{L}}^{J,\delta}$ *are the forward and backward generators of the joint process* (X^δ, Z^δ), *and* $\mathcal{L}^J$ $(=\mathcal{L}^{J,0})$ *and* $\bar{\mathcal{L}}^J$ $(=\bar{\mathcal{L}}^{J,0})$ *are the forward and backward generators of* (X,Z).

Proof. The difference $Q-Q^\delta$ satisfies the following equation:

$$\begin{aligned}\frac{d}{dt}\left(Q-Q^\delta\right)(t)=A(t)\left(Q-Q^\delta\right)(t)+\left(Q-Q^\delta\right)(t)A(t)'\\ -\left(Q+Q^\delta\right)(t)\Sigma_W(t)\left(Q-Q^\delta\right)(t)+\delta^2 Q^\delta(t)^2.\end{aligned}$$

Since $\sup_{t,\delta}\|Q^\delta(t)\|$ is bounded, there exist finite positive constants K_1 and K_2 such that

$$\frac{d}{dt}\|Q(t)-Q^\delta(t)\|\le K_1\|Q(t)-Q^\delta(t)\|+K_2\delta^2 \quad \text{for all } t\in[-T,T],$$

and so (4.13) follows from the Gronwall lemma. Equation (4.12) now follows from (3.1) and (4.6) by straightforward approximation. The fact that $P^\delta(t)$, $Q^\delta(t)$, and $\bar{A}^\delta(t)$ converge to $P(t)$, $Q(t)$, and $\bar{A}(t)$, respectively, establishes (4.14). ∎

Since the joint process (X^δ, Z^δ) is Markov under both $\mathbb{P}$ and $\mathbb{P}^{M,\delta}$, it has rates of entropy production ($R_J^\delta(t)$ and $R_M^\delta(t)$) under these measures. The difference $R_J^\delta(t)-R_M^\delta(t)$ isolates that part of $R_J^\delta(t)$ associated with the interaction of X^δ and Z^δ. This is the rationale for the following definition.

Definition 4.5. *For each* $t\in(-T,T)$, *the* rate of interactive entropy production *between the signal and filter processes* X *and* Z *at time* t *is*

$$R_I(t):=\lim_{\delta\downarrow 0}\left(\lim_{\epsilon\downarrow 0}\epsilon^{-1}\mathbf{E}h\left(\pi^{J,\delta}_{t+\epsilon|t}\,|\,\pi^{J,\delta}_{t-\epsilon|t}\right)-\lim_{\epsilon\downarrow 0}\epsilon^{-1}\mathbf{E}h\left(\pi^{M,\delta}_{t+\epsilon|t}\,|\,\pi^{M,\delta}_{t-\epsilon|t}\right)\right),\tag{4.15}$$

where $\pi^{J,\delta}_{t+\epsilon|t}$ *is a regular* (X_t^δ, Z_t^δ)*-conditional distribution of* $(X^\delta_{t+\epsilon}, Z^\delta_{t+\epsilon})$ *under* $\mathbb{P}$, $\pi^{J,\delta}_{t-\epsilon|t}$ *is a regular* (X_t^δ, Z_t^δ)*-conditional distribution of* $(X^\delta_{t-\epsilon}, Z^\delta_{t-\epsilon})$ *under* $\mathbb{P}$, *and* $\pi^{M,\delta}_{t+\epsilon|t}$ *and* $\pi^{M,\delta}_{t-\epsilon|t}$ *are corresponding regular conditional distributions under* $\mathbb{P}^{M,\delta}$.

Proposition 4.6. *For any* $t\in(-T,T)$,

$$R_I(t)=\dot{S}(t)+\dot{D}(t),\tag{4.16}$$

where S *and* D *are the information supply and dissipation processes of* (2.6).

Proof. It follows from Proposition 4.3 that

$$\begin{aligned}R_J^\delta(t)&:=\lim_{\epsilon\downarrow 0}\epsilon^{-1}\mathbf{E}h\left(\pi^{J,\delta}_{t+\epsilon|t}\,|\,\pi^{J,\delta}_{t-\epsilon|t}\right)\\ &=\frac{1}{2}\mathrm{tr}\Big((A_J^\delta(t)-UA_J^{\delta*}(-t)U)'(\Sigma_J(t)+\delta^2 I_{2n})^{-1}\\ &\qquad\times(A_J^\delta(t)-UA_J^{\delta*}(-t)U)P_J^\delta(t)\Big)\end{aligned}\tag{4.17}$$

and

$$R_M^\delta(t) := \lim_{\epsilon\downarrow 0} \epsilon^{-1}\mathbf{E}^M h\left(\pi^{M,\delta}_{t+\epsilon|t} \,|\, \pi^{M,\delta}_{t-\epsilon|t}\right)$$

$$= \frac{1}{2}\mathrm{tr}\Big((A_M^\delta(t) - UA_M^{\delta *}(-t)U)'(\Sigma_J(t) + \delta^2 I_{2n})^{-1} \times (A_M^\delta(t) - UA_M^{\delta *}(-t)U)P_M^\delta(t)\Big), \tag{4.18}$$

where A_J^δ, $A_J^{\delta *}$, A_M^δ, $A_M^{\delta *}$, and P_J^δ are the equivalents of A_J, A_J^*, A_M, A_M^*, and P_J for the relaxed problem, U is the $2n \times 2n$ transposition matrix

$$U = \begin{bmatrix} 0 & I_n \\ I_n & 0 \end{bmatrix}, \tag{4.19}$$

Σ_J is the joint quadratic covariation rate matrix of (2.10), and P_M^δ is the product-of-marginals covariance matrix process for the relaxed problem,

$$P_M^\delta = \begin{bmatrix} P^\delta & 0 \\ 0 & (Q^\delta)^{-1}(P^\delta - Q^\delta)(Q^\delta)^{-1} \end{bmatrix}. \tag{4.20}$$

Straightforward calculations now show that

$$R_J^\delta(t) - R_M^\delta(t) = \frac{1}{2}\mathrm{tr}\left((\Sigma_W(t) + \delta^2 I_n)Q^\delta(t)\right) + \frac{1}{2}\mathrm{tr}\left((\Sigma_V(t) + \delta^2 I_n)\left(Q^\delta(t)^{-1} - P^\delta(t)^{-1}\right)\right),$$

which, together with (2.11), (2.12), (4.6), and (4.13), completes the proof. □

Remark 4.6. R_I inherits the properties of R_X discussed in Remarks 4.1, 4.3, 4.4, and 4.5. It measures the time-asymmetry of the *interaction* between the signal and filter processes, and as shown by Proposition 4.6, this is entirely associated with the flow of information. The rate of interactive entropy production of the dual system at time $-t$ is the same as that of the original system at time t.

Remark 4.7. $R_I(t)$ is finite even if $R_J(t)$ and $R_M(t)$ are not. Consider the example system with signal as in Remark 4.2 and with the time-homogeneous observation covariance matrix $\Sigma_W = \Sigma_V$. When in their joint invariant distribution, the signal and filter processes are strongly locally time asymmetric in the sense that $R_X(t) = R_Z(t) = +\infty$. However, their interaction is not, in the sense that $R_I(t)$ is finite. The strong time-asymmetry of the joint process is associated with the *marginal* dynamics of X and Z and not with their interaction.

Remark 4.8. If $|\Sigma_V(t)| \neq 0$ and $|\Sigma_W(t)| \neq 0$, then

$$R_I(t) = R_J(t) - R_M(t) = R_J(t) - R_X(t) - R_Z(t), \tag{4.21}$$

where R_J and R_M are the (finite) rates of entropy production of the joint process (X, Z) under $\mathbb{P}$ and $\mathbb{P}^M$, respectively, and R_Z is the rate of entropy production of the filter process, Z.

5. Connections with statistical mechanics. In [12] a statistical mechanical analogy for the signal is developed that depends on (S1), (S2), and an additional condition, as follows:

(S3) A does not depend on t, and all of its eigenvalues have negative real parts. Under these conditions X has the unique invariant distribution, $N(0, P_{SS})$, where

$$AP_{SS} + P_{SS}A' + \Sigma_V = 0. \tag{5.1}$$

The analogy involves an abstract statistical mechanical system whose *state* is a probability measure on $(\mathbb{R}^n, \mathcal{B}^n)$. In fact the state at time t is the distribution of X_t, $N(0, P(t))$. In state μ, the system has *energy* $\mathcal{E}(\mu)$, *entropy* $\mathcal{S}(\mu)$, and *free energy* $\mathcal{F}(\mu)$, where

$$\begin{aligned} \mathcal{E}(\mu) &:= \int H(x)\mu(dx), \\ \mathcal{S}(\mu) &:= -h(\mu \,|\, \mathrm{Leb}), \\ \mathcal{F}(\mu) &:= \mathcal{E}(\mu) - \mathcal{S}(\mu); \end{aligned} \tag{5.2}$$

h is the relative entropy of (4.2), Leb is the Lebesgue measure, and H is the following *Hamiltonian*:

$$H(x) := \tfrac{1}{2} x' P_{SS}^{-1} x. \tag{5.3}$$

It is shown in [12] that the free energy $\mathcal{F}$ is minimized by the *stationary state*, $N(0, P_{SS})$, and that, for any state process $(\mu_t,\, t \in [-T, T])$ satisfying the Kolmogorov forward (Fokker–Planck) equation associated with X, the free energy is nonincreasing. In particular this is true of the state process $(N(0, P(t)),\, t \in [-T, T])$. The state evolves toward the minimum free energy state, $N(0, P_{SS})$, in such a way that the free energy is nonincreasing. The introduction of a *heat bath*, with which the abstract statistical mechanical system interacts, connects this property with the second law of thermodynamics. (See [12].)

In the statistical mechanics literature, stationary states are referred to as stationary *equilibrium* states, or stationary *nonequilibrium* states, according to the net *flow* of some quantity (often energy) in the state, an equilibrium state being one for which this flow is zero. (See, for example, [1], [5], or [8].) Stationary nonequilibrium states of physical systems are typically associated with strictly increasing entropy. For example, if a cylinder of gas is heated at one end and cooled at the other, a stationary *nonequilibrium* state is eventually set up in the gas, in which heat flows from the hot end to the cool end—heat flowing from a hot object to a cool object causes entropy to increase in the universe. For this reason, nonequilibrium states have associated nonzero rates of entropy production. For the abstract system associated with the signal process, X, the rate of entropy production is defined in Definition 4.2. This is zero (and $N(0, P_{SS})$ is a stationary *equilibrium* state) if and only if X is *self-adjoint* in the sense that $P_{SS}A' = AP_{SS}$. Otherwise $N(0, P_{SS})$ is a stationary *nonequilibrium* state.

The statistical mechanical analogy of [12] is also applied there to the joint process (X, Z), again under the special conditions (S1)–(S3). This describes a "joint" system with Hamiltonian

$$H_J(x, z) := \frac{1}{2} \begin{bmatrix} x' & z' \end{bmatrix} P_{J,SS}^{-1} \begin{bmatrix} x \\ z \end{bmatrix}, \tag{5.4}$$

where $P_{J,SS}$ is the stationary covariance matrix, to which $P_J(t)$ of (3.9) converges. This joint system is shown to exhibit, when in its stationary state $N(0, P_{J,SS})$, an

energy flow around a loop comprising two subsystems and a heat bath. These subsystems are termed the "conditional signal" and the "filter" systems. They are characterized by the processes $X - QZ$ and Z in the same way that the original system is characterized by X, and the joint system by (X, Z). The subsystems are "physically distinct" in the sense that (i) their characterizing processes, $X - QZ$ and Z, are *marginally* Markov; (ii) the energy of the joint system is the sum of the energies of the subsystems; and (iii) the entropy of the joint system is the sum of the entropies of the subsystems. Property (i), in particular, shows that it is possible to identify rates of entropy production for each of the two subsystems as well as for the joint system. These rates correspond to nonequilibrium statistical mechanics occurring *within* the subsystems. By subtracting them from that of the joint system, a rate of entropy production associated purely with the interaction between the subsystems is isolated. Of course, this is the rate of interactive entropy production, defined in section 4. The energy flow in the stationary nonequilibrium state of this analogy is, therefore, directly connected with the information flows of the Kalman–Bucy filter. The reader is referred to [12] for a complete discussion of this analogy.

These statistical mechanical analogies can be extended to the more general setting of this paper in a number of ways. For example, one can regard the time-varying nature of A and Σ_V as being the effect of external *forces* applied to the abstract system associated with X. Suppose that (S2) holds and that

(S3′) for each $t \in [-T, T]$, all eigenvalues of $A(t)$ have negative real parts.

Then we can define a "stationary" covariance matrix, $P_{SS}(t)$, for each t as the solution of the following equation:

$$A(t)P_{SS}(t) + P_{SS}(t)A(t)' + \Sigma_V(t) = 0. \tag{5.5}$$

The time-varying nature of P_{SS} now gives rise to a *time-varying* Hamiltonian

$$H(t, x) := \tfrac{1}{2}x'P_{SS}(t)^{-1}x. \tag{5.6}$$

If the energy, entropy, and free energy functionals of the abstract system remain as defined in (5.2), but with this time-varying Hamiltonian, then the minimum free energy state, $N(0, P_{SS}(t))$, changes with time. If the external force remains constant on some interval $[s, t]$, then the state of the system will evolve toward $N(0, P_{SS}(s))$ on this interval, and will do so in a manner that gives rise to a nonincreasing free energy. On the other hand, if the external force continues to change, then the state will "attempt to track" the moving target, $N(0, P_{SS}(t))$. In this case, the abstract system will rarely, if ever, be in its minimum free energy state.

If the changes in A and Σ_V occur on a time scale that is large in comparison to the magnitude of the eigenvalues of A, then the system state may be close to the minimum free energy state at all times. The changing nature of $\mathcal{E}(N(0, P(t)))$ is then partly due to interaction with the heat bath (short time scale), and partly due to energy transferred to or from the system by the time-varying force (long time scale). This is analogous to a cylinder of gas (with identical or different end temperatures) whose volume is changed slowly by the movement of a piston.

Of course, the abstract system associated with the joint process (X, Z) can also be thought of in this way. Even though, in general, the energy of this system will be time-varying, it is still possible to identify a circular flow of energy around a loop of subsystems. As in the special case of [12], this is directly connected with the flow of information between the signal and filter processes.

The reader interested in further discussion of statistical mechanical analogies is referred to [12] and [14].

6. Conclusions. This paper has developed dual linear filtering problems and has defined and related information flows for them. The information processing carried out by the dual filter has been shown to be a time-reversed version of that carried out by the original. The information flow rates between signal and filter processes are intimately connected with entropy production in nonequilibrium statistical mechanical systems. This interpretation is developed fully elsewhere (see [12] and [14]).

The derivation of dual filters by the techniques of this paper is not restricted to linear models. The same approach can be taken with nonlinear filters. (See [13].) The dual filters thus obtained are finite-dimensional and typically nonlinear. Of course this does not herald the "El Dorado" of finite-dimensional nonlinear filtering because the finite-dimensionality of these particular filters depends on a very special relation existing between the distribution and dynamics of the signal and observation processes.

Acknowledgment. The author would like to thank Professor Sanjoy Mitter of the Laboratory for Information and Decision Systems (LIDS) at MIT for suggesting this subject area as one fruitful for research, for providing encouragement and support during a number of visits made by the author to LIDS, and for the many engaging discussions that took place during those visits.

REGULARITY OF THE EIKONAL EQUATION WITH NEUMANN BOUNDARY CONDITIONS IN THE PLANE: APPLICATION TO FRONTS WITH NONLOCAL TERMS*

PIERRE CARDALIAGUET† AND CLAUDIO MARCHI‡

Abstract. The first part of the paper is devoted to length estimates of the boundary of the reachable set for the plane and state constrained controlled system $x'(t) = c(t, x(t))b(t)$ (where $|b(t)| \leq 1$ a.e.). This study is motivated in the second part by the analysis of dislocation dynamics, which can be modeled as a curve $\Gamma(t)$ moving in an open set $\Omega \subset \mathbb{R}^2$ according to some nonlocal law with Neumann boundary conditions on $\partial\Omega$. The length estimates of the first part play a crucial role in the proof of the existence and uniqueness of a *viscosity* solution for this model.

Key words. dislocation dynamics, eikonal equation, Hamilton–Jacobi equations, Neumann boundary condition, discontinuous viscosity solutions, nonlocal equations

1. Introduction. In this paper, we study the dynamics of a curve $\Gamma(t) \subset \Omega$ which moves according to the following nonlocal law:

$$V_{t,x} = \bar{c}_1(t,x) + I\left(\mathbf{1}_{K(t)}\right)(t,x), \tag{1}$$

where Ω is an open subset of $\mathbb{R}^2$, $V_{t,x}$ is the normal velocity at the point x at time t, $K(t)$ is the set enclosed by the curve $\Gamma(t)$, the map I is defined by

$$I(\rho)(t,x) := \int_\Omega \bar{c}_2(t,x,y)\rho(y)\,dy \qquad \forall \rho \in \mathbb{L}^1(\Omega),$$

and $\bar{c}_2$ solves the *elasticity equation* (see [2, 3]). Moreover, the curve Γ can touch the boundary $\partial\Omega$ only orthogonally. Our investigation originated from the so-called *phase field* model of dislocation, introduced by Rodney, Le Bouar, and Finel [13]: a dislocation is a line of crystal defect, and it moves on its slip plane with a normal velocity proportional to the Peach–Koehler force acting on the line:

$$V_{t,x} = \bar{c}_1(t,x) + \bar{c}_2 \star_x \mathbf{1}_{K(t)}(t,x), \tag{2}$$

where $\bar{c}_1$ is the contribution given by an exterior field, while $\bar{c}_2 \star_x \mathbf{1}_{K(t)}$ (the convolution is done only w.r.t. the space variable $x \in \mathbb{R}^2$) is a force created by the dislocation itself. Equations of this type have been studied only in the whole space: one of the main issues of this note is that we reduced the slip plane to a open subset Ω and addressed the dynamics' modifications given by the presence of $\partial\Omega$.

For dynamics in the whole space, let us recall that if we set

$$\rho(t,x) = \mathbf{1}_{K(t)}(x) \equiv \begin{cases} 1 & \text{if} \quad x \in K(t), \\ 0 & \text{otherwise,} \end{cases} \tag{3}$$

then ρ is a (discontinuous) viscosity solution to the following Cauchy problem for a nonlocal Hamilton–Jacobi equation

$$\begin{cases} \frac{\partial \rho}{\partial t} = (\bar{c}_1 + \bar{c}_2 \star_x \rho)\,|\nabla \rho| & \text{in} \quad (0,+\infty) \times \mathbb{R}^2, \\ \rho(0,x) = \mathbf{1}_{K_0}(x) & \text{on} \quad \mathbb{R}^2, \end{cases}$$

where K_0 is the starting set. For $\bar{c}_2 \geq 0$, the equation fulfills the *inclusion principle*, so the existence and uniqueness of the solution follow from a result by Cardaliaguet [9]; from a physical point of view, however, this case is not interesting because $\bar{c}_2$ needs to have zero mean. For $\bar{c}_2$ changing sign, Alvarez, Hoch, Le Bouar, and Monneau [2, 3] proved the short time existence and uniqueness of the solution, provided that the dislocation starts from a Lipschitz graph. Finally, in a forthcoming paper, Alvarez, Cardaliaguet, and Monneau [1] addressed the existence and uniqueness of the solution in an arbitrary time interval under the assumption that the starting set K_0 fulfills the *interior sphere condition* of radius $r > 0$ (i.e., for every $x \in \partial K_0$, there exists a unitary vector p such that $B(x - rp, r) \subseteq K_0$) and that $\bar{c}_i$ fulfills (beside some regularity assumptions)

$$\bar{c}_1(t,x) \geq \|\bar{c}_2(t,\cdot)\|_{\mathbb{L}^1(\mathbb{R}^2)} \qquad \forall (t,x) \in (0,+\infty) \times \mathbb{R}^2$$

(which assures that the dislocation is noncontracting: $\bar{c}_1 + \bar{c}_2 \star_x \mathbf{1}_K \geq 0$ for every Borel set K). Actually, these results also apply when the space is $\mathbb{R}^N$, even if the only interesting case for the phase field model is $N = 2$.

In our study of (1), the function ρ defined by (3) is a discontinuous solution to the following problem with Neumann boundary conditions in the viscosity sense:

$$\begin{cases} \frac{\partial \rho}{\partial t} = \big(\bar{c}_1 + I(\rho)\big)|\nabla \rho| & \text{in} \quad (0,+\infty) \times \Omega, \\ \rho(0,x) = \mathbf{1}_{K_0}(x) & \text{on} \quad \Omega, \\ \frac{\partial \rho}{\partial \nu} = 0 & \text{on} \quad (0,+\infty) \times \partial\Omega \end{cases} \tag{4}$$

(ν is the outward unity normal to $\partial\Omega$). One of the main issues of this paper is that we establish the existence and uniqueness (in a sense that will be specified in section 4) of the solution to the above initial boundary value problem under some interior sphere condition on the initial set K_0 and a condition on $\bar{c}_1$ and $\bar{c}_2$ ensuring that the dislocation is expanding.

As in [1], we shall use the Banach fixed point theorem for the mapping Φ on $C^0([0,T], \mathbb{L}^1(\Omega))$ that associates to any $\rho^0 \in C^0([0,T], \mathbb{L}^1(\Omega))$ the unique discontinuous solution to

$$\begin{cases} \frac{\partial \rho}{\partial t} = c_{\rho^0}|\nabla \rho| & \text{in} \quad (0,T) \times \Omega, \\ \rho(0,x) = \mathbf{1}_{K_0}(x) & \text{on} \quad \Omega, \\ \frac{\partial \rho}{\partial \nu} = 0 & \text{on} \quad (0,T) \times \partial\Omega \end{cases}$$

with $c_{\rho^0} := \big(\bar{c}_1 + I(\rho^0)\big)$. In order to prove that Φ is a well-defined contraction, we use the *representation formula*: for $0 \leq \rho^0 \leq 1$, the level set $\{\Phi(\rho^0)(t,\cdot) = 1\}$ coincides with the *reachable set* (for the precise definition, see formula (7) below) of the following control problem with reflecting boundary:

$$\begin{cases} y'(s) = c_{\rho^0}(s, y(s))\big[b(s) - \langle b(s); \nu(y(s))\rangle \mathbf{1}_{\partial\Omega}(y(s))\nu(y(s))\big] & \text{a.e. in } [0,t], \\ y(0) \in K_0, \quad y(s) \in \overline{\Omega} \qquad \forall s \in [0,t], \end{cases} \tag{5}$$

where the control $b : [0,t] \to B(0,1)$ is a measurable map and $\nu(y(s))$ is the outward unitary normal to $\partial\Omega$ in $y(s)$; namely, $z \in \{\Phi(\rho^0)(t,\cdot) = 1\}$ if and only if there exists a measurable map $b : [0,t] \to B(0,1)$ and a solution y to (5) with $y(t) = z$.

For proving that Φ is a contraction, we are led to estimate the Lebesgue measure of the reachable set and the Hausdorff measure of its boundary. In the case $\Omega = \mathbb{R}^N$ treated in [1], these estimates were based on the fact that the interior sphere assumption stated on the initial set K_0 propagates: the reachable set of the (unconstrained) control system satisfies the interior sphere condition for all times (see [7]). This gives a bound from above for the curvature of the reachable set at each time t, from which an estimate of the length of its boundary is derived. In our case, when $\Omega \neq \mathbb{R}^2$, the interior sphere condition does *not* propagate: as we show below, the curvature of the reachable set can blow up near the boundary of Ω. The main contribution of this paper is to explain how to overcome this difficulty, at least in dimension 2. In particular we show that the boundary of the reachable set has bounded length, although not necessarily finite curvature. From this we deduce estimates on the Lebesgue measure of the reachable set and the existence and uniqueness for problem (4).

The paper is organized as follows: In the rest of this introduction we give an example in which many features of our problem appear, and we set some notation. Section 2 is devoted to the estimates of the volume and the boundary of the reachable set of problem (5). The existence and uniqueness of the solution to (4) (and, in particular, the dynamics of Γ) are established in section 4 (using some technical estimates stated in section 3). Finally, the appendix is devoted to the proof of an extension of the Pontryagin maximum principle (stated in section 2).

1.1. Toy example. We give here an elementary example showing that the reachable set of a reflected controlled system of the form (5) can have a curvature which blows up at some point.

Consider $c \equiv 1$, $\Omega = \mathbb{R}^2 \backslash B(0,1)$, and $K_0 = B\left((-4,0),1\right)$. In this case the reachable set $\mathcal{R}(t)$ for the reflected control problem (5) can be explicitly computed. For this we note that $\mathcal{R}(t)$ is just the set of points $x \in \overline{\Omega}$ which is at a *geodesic distance* (in Ω) from K_0 not larger than t.

Hence for $t \in [0,2]$, $\mathcal{R}(t) = \bar{B}\big((-4,0),1+t\big)$ (see Figure 1). For $t \in [2,\sqrt{15}]$, $\mathcal{R}(t) = \bar{B}\big((-4,0),1+t\big)\backslash B(0,1)$ (see Figure 2).

After $\bar{t} = \sqrt{15} - 1$, some geodesics need to bend around $\partial\Omega$ for reaching the points in the "cone of shade" due to the presence of $\mathcal{C}\Omega$ (see Figure 3). In this case, all the points in this cone of shade are reached by geodesics passing through either the point $P_1 = (-1/4, -\sqrt{15}/4)$ or the point $P_2 = (-1/4, \sqrt{15}/4)$. These geodesics are made up of a straight line from $(-4,0)$ to P_1 or P_2, an arc on $\partial\Omega$, and again a straight line tangent to $\partial\Omega$. For the sake of simplicity, let us consider the coordinate system centered in $(0,0)$ with the ξ-axis and η-axis given, respectively, by the vector $(-1/4, -\sqrt{15}/4)$ and $(\sqrt{15}/4, -1/4)$ (i.e., in the new system $P_1 = (1,0)$). For $t \in (\bar{t}, 4)$, the coordinates of the point of $\partial\mathcal{R}(t)$ reached by a geodesic passing through P_1 and remaining on $\partial\Omega$ from the time $\bar{t}$ to the time s (for some $s \in [\bar{t}, t]$) are given by

$$\begin{cases} \xi(s) = \cos(s-\bar{t}) - (t-s)\sin(s-\bar{t}), \\ \eta(s) = \sin(s-\bar{t}) + (t-s)\cos(s-\bar{t}). \end{cases}$$

By standard arguments, one can verify that the curvature of $\partial\mathcal{R}(t)$ at that point is $(t-s)^{-2}$; in particular, as $s \to t$, it tends to $+\infty$.

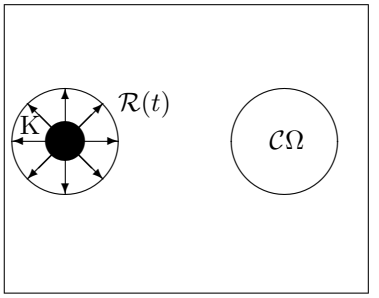

FIG. 1.

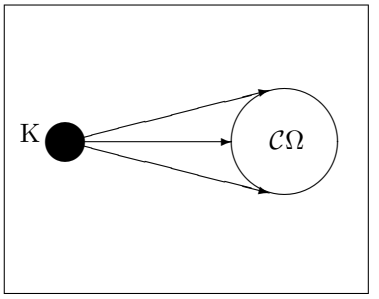

FIG. 2.

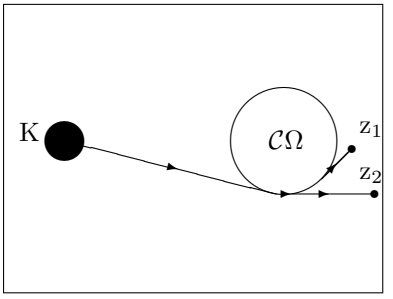

FIG. 3.

Notation. For each $K \subset \mathbb{R}^2$, $\partial_{\mathbb{R}^2} K$ and ∂K stand for its boundary in the natural topology of $\mathbb{R}^2$ and, respectively, in the induced topology of Ω; in other words, we have

$$\partial K := \partial_{\mathbb{R}^2} K \cap \Omega.$$

Moreover, $\mathcal{C}K := \mathbb{R}^2 \backslash K$, and $\mathbf{1}_K$ is the *characteristic* function of K; i.e., $\mathbf{1}_K(x) = 1$ if $x \in K$, and $\mathbf{1}_K(x) = 0$ if $x \in \mathcal{C}K$. For all sets K and H in $\mathbb{R}^2$, $d^{\mathcal{H}}(K, H)$ stands for the Hausdorff distance between the sets K and H:

$$d^{\mathcal{H}}(K, H) := \max\left\{ \max_{s \in K} \operatorname{dist}(s, H),\ \max_{u \in H} \operatorname{dist}(u, K) \right\},$$

where $\operatorname{dist}(s, H) := \min\{|s - u| : u \in H\}$. We denote by $B(p, r)$ the ball centered in $p \in \mathbb{R}^2$ with radius $r > 0$; B is the abridged notation of $B(0, 1)$. For every $x, y \in \Omega$,

$d^\Omega(x,y)$ is their *geodesic distance*; namely,

$$d^\Omega(x,y) := \inf\left\{ l \mid \begin{array}{c} \exists \text{ an AC arc, contained in } \Omega, \text{ with length } l \\ \text{and extremities in } x \text{ and } y \end{array} \right\}.$$

For a function ρ, ρ^* (resp., ρ_*) denotes the upper semicontinuous envelope (resp., the lower semicontinuous envelope) of ρ.

2. Main estimates for the reachable set. In this section we consider the reachable set for the reflected control problem

$$\text{(6)} \quad \begin{cases} y'(t) = c(t,y(t))\big[b(t) - \langle b(t), \nu(y(t))\rangle \mathbf{1}_{\partial\Omega}(y(t))\nu(y(t))\big] & \text{a.e. in } (0,T), \\ y(t) \in \overline{\Omega} \qquad \forall t \geq 0, \\ y(0) = y_0 \in K_0, \end{cases}$$

where $b : (0,T) \to B$ is a time measurable control and $\nu(y(t))$ is the outward unit normal to $\partial\Omega$ at $y(t)$. Let us recall that if Ω has a $\mathcal{C}^2$ boundary and c is sufficiently regular, then, for any measurable control $b : (0,T) \to B$ and any initial position $y_0 \in K_0$, (6) has a unique solution.

The reachable set at time $t > 0$ for this reflected control system is given by

$$\text{(7)} \qquad \mathcal{R}(t) = \{x \in \overline{\Omega} \mid \exists y \text{ solution to (6) on } [0,t] \text{ with } y(t) = x\}.$$

Our aim is to show that the boundary of this set has a finite Hausdorff measure and that its volume depends in a Lipschitz continuous way on the time.

For doing this we will need the following conditions on c, K_0, and Ω:

$$\text{(8)} \quad \begin{cases} \text{(i)} & c \text{ is continuous and derivable w.r.t. the second variable,} \\ \text{(ii)} & 0 < m \leq c(t,x) \leq M \qquad \forall (t,x) \in \mathbb{R}^+ \times \Omega, \\ \text{(iii)} & |c(t,x_1) - c(t,x_2)| \leq L_0|x_1 - x_2| \qquad \forall (t,x_1),(t,x_2) \in \mathbb{R}^+ \times \Omega, \\ \text{(iv)} & |D_x c(t,x_1) - D_x c(t,x_2)| \leq L_1|x_1 - x_2| \qquad \forall (t,x_1),(t,x_2) \in \mathbb{R}^+ \times \Omega \end{cases}$$

for some positive constants m, M, L_0, and L_1.

The initial set $K_0 \subset \Omega$ has to satisfy the following:

$$\text{(9)} \qquad K_0 \text{ is compact and fulfills the interior sphere condition with radius } r;$$

namely, for any $x \in \partial K_0$, there is some $p \in \mathbb{R}^2$, $|p| = 1$, with $B(x - rp, r) \subset K_0$. On Ω we assume that

$$\text{(10)} \qquad \begin{cases} \Omega \text{ is connected, } \partial\Omega \text{ is of class } \mathcal{C}^2, \text{ and } \mathcal{C}\Omega \text{ fulfills the} \\ \qquad \text{interior sphere condition with radius } r_1 > 0. \end{cases}$$

We also require that

$$\text{(11)} \qquad \exists\, k_0 > 0 \quad \text{such that} \quad |x-y| \leq d^\Omega(x,y) \leq k_0|x-y| \qquad \forall x, y \in \Omega$$

(the first inequality being obvious).

We finally introduce the minimal time function τ, which plays a crucial role in our study:

$$\text{(12)} \qquad \tau(x) := \inf\{t : x \in \mathcal{R}(t)\};$$

it is the time needed by the reflected controlled system to reach a point x when starting from K_0.

By standard argument (see [5]), we have the following lemma.

LEMMA 2.1. *The function τ is Lipschitz continuous with a Lipschitz constant less than k_0/m, where m and k_0 are defined in* (8) *and* (11). *Moreover, τ satisfies the Hamilton–Jacobi equation $c(\tau(x),x)|\nabla\tau(x)| = 1$ in the viscosity sense in $\Omega \setminus K_0$.*

We also note that the level sets of τ fulfill

$$\{x : \tau(x) = t\} \supseteq \partial\mathcal{R}(t); \tag{13}$$

in general, the inclusion is strict.

2.1. Extremal solutions and the Pontryagin maximum principle.

DEFINITION 2.2. *An admissible trajectory y is called extremal on $[0,t]$ if $\tau(y(t)) = t$.*

It is well known (for a detailed study of extremal trajectories, see [4, 8, 10, 15] and the references therein) that if y is an extremal trajectory on $[0,t]$, then $\tau(y(s)) = s$ for any $s \in [0,t]$. Throughout this section, $\mathcal{Y}(t)$ denotes the set of extremal trajectories on $[0,t]$:

$$\mathcal{Y}(t) = \{y \text{ extremal trajectory on } [0,t]\}.$$

The following result, proved in the appendix, is an extension of the Pontryagin maximum principle for our reflected control problem. It is inspired by similar results of Frankowska [12] on the regularity of the state and the adjoint for state constraints system. Let us note that the equation on p' is new in this context.

Here we denote by d the signed distance to the boundary of Ω:

$$d(x) = \begin{cases} -d_{\partial\Omega}(x) & \text{if } x \in \Omega, \\ d_\Omega(x) & \text{otherwise.} \end{cases}$$

From assumption (10), the function d is $\mathcal{C}^2$ in a neighborhood of $\partial\Omega$. Finally, for any $s \in \mathbb{R}$, we set $(s)_+ = \max\{s, 0\}$.

LEMMA 2.3. *Let $x(\cdot)$ be an extremal trajectory on the time interval $[0,T]$. Then there is a Lipschitz continuous function $p : [0,T] \to \mathbb{R}^N \setminus \{0\}$ and a measurable map $\lambda : [0,T] \to \mathbb{R}$ such that*

$$\begin{cases} x'(t) = c(t,x(t))\dfrac{p(t)}{|p(t)|} & \forall t \in (0,T), \\ p'(t) = -\left[D_x c(t,x(t)) - \lambda(t) Dd(x(t))\right]|p(t)| & \text{for a.e. } t \in (0,T), \\ \lambda(t) = \Big(-\Big\langle D^2 d(x(t)) c(t,x(t)) \frac{p(t)}{|p(t)|}, \frac{p(t)}{|p(t)|} \Big\rangle \\ \qquad\qquad + \langle Dd(x(t)), D_x c(t,x(t)) \rangle \Big)_+ \mathbf{1}_{\partial\Omega}(x(t)) & \text{for a.e. } t \in (0,T), \\ x(t) \in \overline{\Omega} \qquad \forall t \in (0,T). \end{cases} \tag{14}$$

The map p is called the adjoint of x.

Remark 2.4. Lemma 2.3 states, in particular, that any extremal trajectory is $\mathcal{C}^{1,1}$.

Remark 2.5. Problem (6) can be rewritten as a constraint problem; actually, its extremal trajectories coincide with those of problem

$$\begin{cases} y'(t) = c(t,y(t))b(t) & \text{a.e. in } (0,T), \\ y(t) \in \overline{\Omega} \qquad \forall t \geq 0, & y(0) = y_0 \in K_0, \end{cases}$$

and the function λ is a multiplier. Of course, other types of Neumann boundary conditions give rise to control problems that fail this property.

We now state several consequences of Lemma 2.3.

COROLLARY 2.6. *For any $T > 0$, the set $\mathcal{Y}(T)$ is compact w.r.t. the $\mathcal{C}^1$ norm.*

Proof. From standard arguments the set $\mathcal{Y}(T)$, endowed with the $\mathcal{C}^0$ norm, is compact. Let (y_n) be a converging sequence of $\mathcal{Y}(T)$ for the $\mathcal{C}^0$ norm, and let y be its limit. We claim that y_n converges to y for the $\mathcal{C}^1$ norm.

From Lemma 2.3, for any n, there is some Lipschitz map $p_n : [0,T] \to \mathbb{R}^N \backslash \{0\}$ such that $|p_n(0)| = 1$ and (14) holds. In particular, the (p_n) are Lipschitz continuous with a Lipschitz constant depending only on the regularity of Ω and of c. Hence a subsequence, still denoted (p_n), converges uniformly to some Lipschitz continuous function p such that $|p(0)| = 1$ and p is a solution to

$$\begin{cases} p'(t) = -\left[D_x c(t,x(t)) - \lambda(t) Dd(x(t))\right] |p(t)|, \\ \lambda(t) = \Big(-\left\langle D^2 d(x(t)) c(t,x(t)) \frac{p(t)}{|p(t)|}, \frac{p(t)}{|p(t)|} \right\rangle \\ \qquad\qquad + \langle Dd(x(t)), D_x c(t,x(t)) \rangle \Big)_+ \mathbf{1}_{\partial\Omega}(x(t)) \end{cases}$$

for a.e. $t \in (0,T)$. In particular, we deduce that $p(t) \neq 0$. Therefore, since $y_n'(t) = c(t, y_n(t)) p_n(t)/|p_n(t)|$, (y_n') uniformly converges to $y'(t) = c(t,y(t))p(t)/|p(t)|$.

So we have proved that for any sequence (y_n) of $\mathcal{Y}(T)$, there is a subsequence which converges in the $\mathcal{C}^1$ norm, whence we get the desired result. □

The next statement explains that two extremal trajectories on $[0,T]$ when crossing on $(0,T)$ necessarily have the same velocity.

LEMMA 2.7. *Let y_1 and y_2 be two extremal trajectories on $[0,T]$ for which there is some $t \in (0,T)$ with $y_1(t) = y_2(t) \in \partial\Omega$. Then $y_1'(t) = y_2'(t)$.*

Remark 2.8. Contrary to what happens in the unconstrained case ($\Omega = \mathbb{R}^2$), two different extremal trajectories of our reflected control problem can indeed cross, in particular on the boundary of Ω (as shown in Figure 3).

Proof. Since Ω has a $\mathcal{C}^2$ boundary, $y_1(t) = y_2(t) \in \partial\Omega$, and y_1 and y_2 are $\mathcal{C}^1$ and remain in $\overline{\Omega}$ on $[0,T]$, we deduce that the vectors $y_1'(t)$ and $y_2'(t)$ are necessarily tangent to $\partial\Omega$. Since, moreover, $|y_1'(t)| = c(t, y_1(t)) = |y_2'(t)|$ and we are in the plane, this leads to $y_1'(t) = \pm y_2'(t)$. Suppose for a while that $y_1'(t) = -y_2'(t)$. Then, thanks to Lemma 2.1, we have for any $h > 0$ sufficiently small

$$2h = \tau(y_2(t+h)) - \tau(y_1(t-h)) \leq \frac{k_0}{m} |y_1(t-h) - y_2(t+h)| = \frac{k_0}{m} h\epsilon(h),$$

where $\epsilon(h) \to 0$ as $h \to 0^+$. This is impossible. So $y_1'(t) = y_2'(t)$. □

As a consequence, we have the following technical result which shall be useful in the proof of the main perimeter estimate.

COROLLARY 2.9. *Let $\delta > 0$ and $T > 0$ be fixed. There is some positive σ such that if y_1 and y_2 are two extremal trajectories on some interval $[0, t_1 + \delta]$ and $[0, t_2 + \delta]$, for $t_1, t_2 \in (0,T]$, and if $y_1(t_1) \in \partial\Omega$, $y_2(t_2) \in \partial\Omega$ with $|y_1(t_1) - y_2(t_2)| \leq \sigma$, then*

$$\left| \frac{y_1'(t_1)}{|y_1'(t_1)|} - \frac{y_2'(t_2)}{|y_2'(t_2)|} \right| \leq c_b |y_1(t_1) - y_2(t_2)|,$$

where c_b depends only on the $\mathcal{C}^2$ regularity of $\partial\Omega$.

Proof. Let us first define the constant c_b. Since we are in the plane and Ω has a $\mathcal{C}^2$ boundary, there is a constant c_b (depending on the curvature of $\partial\Omega$ in $K_0 + B_{MT}$)

such that, for any $y_1, y_2 \in \partial\Omega \cap (K_0 + B_{MT})$ and for any v_1, v_2 unit tangent vector to $\partial\Omega$ at y_1 and y_2, we have either

$$|v_1 - v_2| \le c_b|y_1 - y_2| \qquad \text{or} \qquad |v_1 + v_2| \le c_b|y_1 - y_2|.$$

We now argue by contradiction, by assuming that there is a sequence $\sigma_n \to 0^+$ and, for any n, some pair y_1^n and y_2^n of extremal trajectories on some time intervals $[0, t_1^n + \delta]$ and $[0, t_2^n + \delta]$, such that

$$|y_1^n(t_1^n) - y_2^n(t_2^n)| \le \sigma_n \tag{15}$$

and

$$\left| \frac{(y_1^n)'(t_1^n)}{|(y_1^n)'(t_1^n)|} - \frac{(y_2^n)'(t_2^n)}{|(y_2^n)'(t_2^n)|} \right| > c_b|y_1^n(t_1^n) - y_2(t_2^n)|.$$

Let us observe that by conditions (8), we have

$$y_i^n(t) \in K_0 + B_{MT} \qquad \forall n \in \mathbb{N},\, t \in [0,T] \quad (i = 1,\, 2).$$

From the definition of c_b, the previous inequality implies that

$$\left| \frac{(y_1^n)'(t_1^n)}{|(y_1^n)'(t_1^n)|} + \frac{(y_2^n)'(t_2^n)}{|(y_2^n)'(t_2^n)|} \right| \le c_b|y_1^n(t_1^n) - y_2(t_2^n)|, \tag{16}$$

because $(y_1^n)'(t_1^n)/|(y_1^n)'(t_1^n)|$ and $(y_2^n)'(t_2^n)/|(y_2^n)'(t_2^n)|$ are tangent to $\partial\Omega$ at $y_1^n(t_1^n)$ and $y_2^n(t_2^n)$, respectively.

Thanks to Corollary 2.6 we can extract subsequences of (y_1^n), (y_2^n), (t_1^n), and (t_2^n)—still denoted (y_1^n), (y_2^n), (t_1^n), and (t_2^n)—converging to some y_1, y_2, t_1, and t_2, where y_1 and y_2 are extremal, on $[0, t_1 + \delta]$ and $[0, t_2 + \delta]$. From (15), we have $y_1(t_1) = y_2(t_2)$ and therefore $t_1 = t_2$. Then (16) becomes $y_1'(t_1) = -y_2'(t_2)$ with $y'(t_1) \neq 0$ because of Lemma 2.3. This is in contradiction with Lemma 2.7. ∎

2.2. Main estimates. We now state the main results of this section. The first one states, thanks to (13), that the length of the boundary of the reachable set—or, more precisely, its Hausdorff measure $\mathcal{H}^1$ (see [11])—remains bounded. The second one explains that the volume of the reachable set depends in a Lipschitz continuous way on the time.

PROPOSITION 2.10. *For $T > 0$, there exists a constant C such that*

$$\mathcal{H}^1\big(\{\tau = t\}\big) \le C \qquad \forall t \in [0,T].$$

The constant C depends on Ω and on the constants r, m, M, L_0, L_1, and T in assumptions (8)–(11).

As a consequence we have the following corollary.

COROLLARY 2.11. *Under the assumptions of Proposition* 2.10,

$$|\mathcal{R}(t_1)\backslash\mathcal{R}(t_0)| \le MC(t_1 - t_0) \qquad \forall 0 \le t_0 \le t_1 \le T,$$

where C is the constant in Proposition 2.10 *and M is given by* (8).

Remark 2.12. In particular, the map

$$t \to \rho(t) \equiv \mathbf{1}_{\mathcal{R}(t)}$$

is locally Lipschitz continuous in $\mathbb{L}^1(\Omega)$.

The proofs of Proposition 2.10 and Corollary 2.11 are the aim of the rest of the section. For proving Proposition 2.10, we divide the set $\{\tau = t\}$ into two sets: the first one consists of points which can be reached with extremal trajectories remaining in the interior of Ω. The second one is made up of points for which the associated extremal trajectories have to touch $\partial\Omega$. For the first set, the techniques of [1] can be adapted, although they have to be localized. For the second set, the key idea amounts to comparing its length with the length of $\partial\Omega$.

Let us introduce more precise notation: for $t \geq 0$ we set

$$E_t := \{x \in \partial\Omega \mid \exists y \in \mathcal{Y}(t),\ \exists s \in [0,t] \text{ with } y(s) = x\}, \tag{17}$$

$$D_t^{int} := \{x \in \Omega \mid \exists y \in \mathcal{Y}(t) \text{ with } y(t) = x \text{ and } y([0,t]) \cap \partial\Omega = \emptyset\}, \tag{18}$$

$$D_t^{bnd} := \{x \in \Omega \mid \exists y \in \mathcal{Y}(t),\ \exists s \in [0,t) \text{ with } y(t) = x \text{ and } y(s) \in \partial\Omega\}. \tag{19}$$

We note that D_t^{int} is exactly the subset of points of $\{\tau = t\}$ which can be reached with extremal trajectories remaining in the interior of Ω, while D_t^{bnd} is the set of points of $\{\tau = t\}$ reached by extremal trajectories passing by $\partial\Omega$. Furthermore,

$$\{\tau = t\} = D_t^{int} \cup D_t^{bnd}.$$

2.3. Estimates for the set reachable by passing by $\partial\Omega$. In this part we estimate the length of D_t^{bnd}. For this we heavily use the fact that we are dealing with a plane system. We do not know if similar constructions can be done in higher dimensions.

Since we cannot directly estimate the length of D_t^{bnd}, we need to introduce an approximation of this set given, for any $\delta > 0$, by

$$D_t^{bnd}(\delta) = \left\{ x \in \Omega \mid \begin{array}{l} \exists y \in \mathcal{Y}(t),\ \exists s \in [0, t-\delta) \text{ with } y(t) = x, \\ y(s) \in \partial\Omega \text{ and } y((s,t]) \cap \partial\Omega = \emptyset \end{array} \right\}.$$

We note for later use that the set D_t^{bnd} is the increasing limit of the $D_t^{bnd}(\delta)$ as δ decreases to 0^+.

LEMMA 2.13. *Let $T > 0$ be fixed. There are $C_1 > 0$ and, for any $\delta > 0$, a constant $\sigma > 0$ such that if y_1, y_2 belong to $D_t^{bnd}(\delta)$, $y_1(\cdot)$, $y_2(\cdot)$ belong to $\mathcal{Y}(t)$, and $s_1, s_2 \in [0, t-\delta)$ with (for $j = 1, 2$)*

$$y_j(t) = y_j, \quad y_j(s_j) \in \partial\Omega, \quad y_j((s_j,t]) \cap \partial\Omega = \emptyset, \quad \text{and } |y_1(s_1) - y_2(s_2)| \leq \sigma,$$

then

$$|y_1 - y_2| \leq C_1 |y_1(s_1) - y_2(s_2)|.$$

The constant C_1 depends on the various constants of the problem and on T but not on δ.

Proof. From Corollary 2.9, there is some positive σ such that if y_1 and y_2 are two extremal trajectories on some interval $[0, t_1 + \delta]$ and $[0, t_2 + \delta]$ and if $y_1(t_1) \in \partial\Omega$, $y_2(t_2) \in \partial\Omega$ (for some $t_1, t_2 \leq T$) with $|y_1(t_1) - y_2(t_2)| \leq \sigma$, then

$$\left| \frac{y_1'(t_1)}{|y_1'(t_1)|} - \frac{y_2'(t_2)}{|y_2'(t_2)|} \right| \leq c_b |y_1(t_1) - y_2(t_2)|, \tag{20}$$

where c_b depends only on the $\mathcal{C}^2$ regularity of $\partial\Omega$.

Now let y_j, $y_j(\cdot)$ and s_j $(j = 1, 2)$ be as in the statement. Without loss of generality, we assume that $s_1 \leq s_2$. Let p_1 and p_2 be the adjoint of y_1 and y_2 defined in Lemma 2.3. On $[s_j, t]$, the pair (y_j, p_j) is the unique solution of the differential equation

$$\left\{ \begin{array}{ll} y_j'(s) = c(s, y_j(s)) \dfrac{p_j(s)}{|p_j(s)|} & \forall s \in (s_j, t), \\ p_j'(s) = -D_x c(s, y_j(s))\, |p_j(s)| & \text{for a.e. } s \in (s_j, t) \end{array} \right. \tag{21}$$

with initial condition $(y_j(s_j), p_j(s_j))$. Without loss of generality, we can assume that $|p_j(s_j)| = 1$. From these equations, we deduce that

$$\frac{d}{ds}\left(|p_j(s)|\right) = \frac{\langle p_j'(s), p_j(s)\rangle}{|p_j(s)|} = -\langle D_x c(s, y_j(s)), p_j(s)\rangle,$$

whence, for some constant $L > 0$,

$$-L|p_j(s)| \leq \frac{d}{ds}|p_j(s)| \leq L|p_j(s)|$$

and, by integration,

$$e^{-L(s-s_j)} \leq |p_j(s)| \leq e^{L(s-s_j)} \qquad \forall s \in [s_j, t]. \tag{22}$$

In particular, (21) can be written as a Cauchy problem with a Lipschitz right-hand side.

From the Lipschitz continuity of τ given in Lemma 2.1 we have

$$|s_2 - s_1| = \tau(y_2(s_2)) - \tau(y_1(s_1)) \leq \frac{k_0}{m}|y_2(s_2) - y_1(s_1)|. \tag{23}$$

We also note that inequality (20) can be rewritten as

$$|p_1(s_1) - p_2(s_2)| \leq c_b|y_1(s_1) - y_2(s_2)|. \tag{24}$$

Finally, because of (21) and the bounds on c and $D_x c$ (stated in (8)), there is some constant C_0 such that

$$|y_1(s_2) - y_1(s_1)| + |p_1(s_2) - p_1(s_1)| \leq C_0|s_2 - s_1| \leq \frac{C_0 k_0}{m}|y_2(s_2) - y_1(s_1)|. \tag{25}$$

Putting together (23), (24), and (25) and using the Gronwall inequality for (21) then easily gives

$$|y_1(s) - y_2(s)| + |p_1(s) - p_2(s)| \leq C_1|y_1(s_1) - y_2(s_2)|$$

for any $s \in [s_2, t]$ for some constant $C_1 = C_1(T, m, c_b, k_0, M, L_0, L_1)$. Setting $s = t$ gives the desired inequality. □

LEMMA 2.14. *Fix $T > 0$. With the same constant C_1 as in Lemma 2.13, we have*

$$\mathcal{H}^1(D_t^{bnd}) \leq C_1 \mathcal{H}^1(\partial\Omega) \qquad \forall 0 \leq t \leq T.$$

Proof. Let C_1 and, for $\delta > 0$ fixed, σ be as in Lemma 2.13. Let $\varepsilon > 0$ and a family of sets $\{B_i\}_{i\in\mathbb{N}}$ be such that

$$\mathrm{diam} B_i \leq \inf\{\varepsilon, \sigma\}, \quad \bigcup_{i=1}^{+\infty} B_i \supseteq \partial\Omega, \quad \text{and} \quad \mathcal{H}^1(\partial\Omega) \geq \sum_{i=1}^{+\infty} \mathrm{diam} B_i - \varepsilon.$$

We denote by K_i the set of points of $D_t^{bnd}(\delta)$ which can be reached by an extremal trajectory touching $\partial\Omega$ for the last time in B_i; in other words, $x \in K_i$ if and only if there exists an extremal trajectory y with $y(t) = x$ and $y(s_0) \in B_i$ for $s_0 := \max\{s \in [0,t] : y(s) \in \partial\Omega\}$.

Since we have chosen $\mathrm{diam}B_i \leq \sigma$, Lemma 2.13 states that

$$\mathrm{diam}(K_i) \leq C_1 \mathrm{diam}B_i \qquad \forall i \in \mathbb{N}. \tag{26}$$

Moreover, since

$$\bigcup_{i=1}^{+\infty} K_i = D_t^{bnd}(\delta) \qquad \text{and} \qquad \mathrm{diam}(K_i) \leq C_1\epsilon,$$

we have

$$\mathcal{H}^1_{C_1\varepsilon}(D_t^{bnd}(\delta)) \leq \sum_{i=1}^{+\infty} \mathrm{diam}(K_i) \leq C_1 \left(\mathcal{H}^1(\partial\Omega) + \varepsilon\right)$$

(for the precise definition of $\mathcal{H}^1_\delta$, see [11, pp. 60ff.]). As $\varepsilon \to 0$, we get

$$\mathcal{H}^1(D_t^{bnd}(\delta)) \leq C_1 \mathcal{H}^1(\partial\Omega).$$

Recalling that C_1 does not depend on δ, we can let $\delta \to 0^+$ to get the result. □

2.4. Estimates for the set reachable by remaining in the interior of Ω. We now aim at computing the length of D_t^{int}, the part of the boundary consisting of the points which can be reached by remaining in the interior of Ω.

Let us recall that the interior sphere condition does *not* propagate in $\Omega \neq \mathbb{R}^2$ (contrary to what happens in $\mathbb{R}^2$, eventually with a radius depending on time; see [1] and [7]). However, a local version of propagation (established in Lemma 2.15) holds also in Ω. This property and a bound on the measure of ∂K_0 (still due to the interior sphere condition) will be crucial in the proof of our estimate for $\mathcal{H}^1(D_{t_1}^{int})$ (see Lemma 2.16 and Remark 2.17).

The estimates below follow the original ideas of Cannarsa and Frankowska [7] and the computations of [1]. In particular, the two following lemmata are just a localized version of Lemmata 3.1 and 6.1 of [1].

LEMMA 2.15. *Under assumption* (9)*, let $y(\cdot)$ be some extremal trajectory on the time interval $[0,t]$, with adjoint $p(\cdot)$, for which there is some $\eta > 0$ with*

$$B(y(s), \eta) \subset \Omega \qquad \forall s \in [0,t].$$

Then, if we set $\kappa = 3L_0 + L_1$, we have

$$B\left(y(t) - re^{-\kappa t}\frac{p(t)}{|p(t)|}, re^{-\kappa t}\right) \cap B\left(y(t), \eta e^{-L_0 t}\right) \subset \mathcal{R}(t).$$

Proof. We explain only the main differences with the proofs of Lemmata 3.1 and 6.1 of [1]. Without loss of generality, we assume that $|p(0)| = 1$. We define the vector field $f(s,y) = c(s,y)p(s)/|p(s)|$ and set $\bar\kappa = 2L_0 + L_1$. We consider, for any $\theta \in B(0, |p(t)|)$ such that

$$re^{-\bar\kappa t}|p(t) - \theta| \leq \eta e^{-L_0 t}, \tag{27}$$

the solution y_θ of the backward differential equation

$$\begin{cases} y'_\theta(s) = f(s, y_\theta(s)) & \forall s \in [0,t], \\ y_\theta(t) = y(t) - re^{-\bar\kappa t}(p(t) - \theta). \end{cases}$$

Following [1], one can show that $y_\theta(0) \in K_0$. Furthermore, a straightforward application of the Gronwall lemma yields to

$$y_\theta(s) \in B(y(s), \eta e^{-L_0 s}) \subset \Omega \qquad \forall s \in [0,t],$$

because $y_\theta(t) \in B(y(t), \eta e^{-L_0 t})$ thanks to (27). So y_θ is a solution to the control system (6) which remains in Ω on $[0,t]$, and therefore $y_\theta(t) \in \mathcal{R}(t)$. This proves that

$$B\left(y(t) - re^{-\bar\kappa t}p(t), re^{-\bar\kappa t}|p(t)|\right) \cap B\left(y(t), \eta e^{-L_0 t}\right) \subset \mathcal{R}(t).$$

Since $\kappa = \bar\kappa + L_0$ and $|p(s)| \geq e^{-L_0 t}$ (thanks to the differential equation satisfied by p), the proof is complete. □

LEMMA 2.16. *For $0 \leq t_0 \leq t_1 \leq T$, we have*

$$\mathcal{H}^1(D^{int}_{t_1}) \leq e^{C_2(t_1 - t_0)}\mathcal{H}^1(D^{int}_{t_0}),$$

where $C_2 = L_0 + Me^{\kappa T}/r$ with $\kappa = 3L_0 + L_1$.

Remark 2.17. In particular, since K_0 satisfies the interior ball condition, $\mathcal{H}^1(\partial K_0)$ is finite (Lemma 2.2 of [1]), and we have (setting $t_0 = 0$ and $t_1 = t$)

$$\mathcal{H}^1(D^{int}_t) \leq e^{C_2 t}\mathcal{H}^1(\partial K_0) \qquad \forall t \in [0,T].$$

Proof. Without loss of generality, we can assume that $\mathcal{H}^1(D^{int}_{t_0}) < +\infty$. For $\eta > 0$ let us set

$$D^{int}_t(\eta) = \left\{ x \in \Omega \mid \begin{array}{c} \tau(x) = t \text{ and } \exists y \in \mathcal{Y}(t) \text{ with } y(t) = x \\ \text{and } d_{\partial\Omega}(y(s)) \geq \eta \text{ for any } s \in [0,t] \end{array} \right\}.$$

We note that $D^{int}_t(\eta)$ is closed and that

$$D^{int}_t \subset \bigcup_{\eta > 0} D^{int}_t(\eta). \tag{28}$$

Let us fix $\epsilon > 0$ and $\delta > 0$, and let us choose an (at most) countable collection of compact sets (K_i) such that $K_i \subset D^{int}_{t_0}(\eta)$,

$$D^{int}_{t_0}(\eta) = \bigcup_i K_i, \quad \operatorname{diam}(K_i) \leq \min\left\{\eta e^{-(L_0 + C_2)T}, \delta e^{-C_2 T}\right\} \qquad \forall i, \tag{29}$$

and

$$\mathcal{H}^1(D^{int}_{t_0}(\eta)) \geq \sum_i \operatorname{diam}(K_i) - \epsilon.$$

For any $s \in [t_0, t_1]$, let $K'_i(s)$ be the set of points $y \in D^{int}_s(\eta)$ for which there is an extremal trajectory $y(\cdot)$ with $y(s) = y$, $y(t_0) \in K_i$ and $d_{\partial\Omega}(y(t)) \geq \eta$ for any $t \in [0,s]$. We note for later use that

$$D^{int}_s(\eta) \subset \bigcup_i K'_i(s) \qquad \forall s \in [t_0, t_1]. \tag{30}$$

We claim that

$$\operatorname{diam}(K_i'(s)) \le \min\{\eta e^{-L_0 T}, e^{C_2 s}\operatorname{diam}(K_i)\} \qquad \forall s \in [t_0, t_1]. \tag{31}$$

For proving the claim, let

$$\theta = \inf\{s \in [t_0, t_1] \ : \ \operatorname{diam}(K_i'(s)) \ge \eta e^{-L_0 T}\}$$

with convention $\inf \emptyset = t_1$. One readily checks from its definition that $s \to \operatorname{diam}(K_i'(s))$ is right upper semicontinuous and left continuous. Therefore $\theta > t_0$ because

$$\operatorname{diam}(K_i'(t_0)) = \operatorname{diam}(K_i) < \eta e^{-L_0 T}.$$

For $y_1, y_2 \in K_i'(\theta)$, let $y_1(\cdot)$ and $y_2(\cdot)$ be two extremal trajectories on $[0, \theta]$ with $y_j(\theta) = y_j$, $d_{\partial\Omega}(y_j(t)) \ge \eta$ for any $t \in [0, \theta]$ and $y_j(t_0) \in K_i$ for $j = 1, 2$. We denote by $p_j(\cdot)$ the adjoint of $y_j(\cdot)$. Since $y_j(s) \in K_i'(s)$ for $s \in [t_0, \theta)$, and from the definition of θ, we have

$$|y_1(s) - y_2(s)| \le \operatorname{diam}(K_i'(s)) < \eta e^{-L_0 T} \qquad \forall s \in [t_0, \theta).$$

In particular, $y_2(s)$ belongs to $B(y_1(s), \eta e^{-L_0 s})$. Since $d_{\partial\Omega}(y_1(s)) \ge \eta$ for any $s \in [0, t_1]$, and since $y_2(s)$ lies on the boundary of the reachable set, Lemma 2.15 states that $y_2(s)$ does not belong to the interior of the ball centered at $y_1(s) - re^{-\kappa s} p_1(s)/|p_1(s)|$ and of radius $re^{-\kappa s}$. Hence

$$|y_2(s) - y_1(s)|^2 + 2re^{-\kappa s}\langle y_2(s) - y_1(s), p_1(s)/|p_1(s)|\rangle \ \ge \ 0.$$

Reversing the roles of y_1 and y_2 also gives

$$|y_2(s) - y_1(s)|^2 + 2re^{-\kappa s}\langle y_1(s) - y_2(s), p_2(s)/|p_2(s)|\rangle \ \ge \ 0.$$

whence we get

$$\left\langle y_1(s) - y_2(s), \frac{p_1(s)}{|p_1(s)|} - \frac{p_2(s)}{|p_2(s)|} \right\rangle \ \le \ \frac{e^{\kappa T}}{r}|y_1(s) - y_2(s)|^2. \tag{32}$$

Setting $\rho(s) = \frac{1}{2}|y_1(s) - y_2(s)|^2$, we have, for $s \in [t_0, \theta)$,

$$\begin{aligned}
\rho'(s) &= \langle y_1'(s) - y_2'(s), y_1(s) - y_2(s)\rangle \\
&= \left\langle c(s, y_1(s))\tfrac{p_1(s)}{|p_1(s)|} - c(s, y_2(s))\tfrac{p_2(s)}{|p_2(s)|}, y_1(s) - y_2(s) \right\rangle \\
&= \tfrac{1}{2}(c(s, y_1(s)) - c(s, y_2(s)))\left\langle \tfrac{p_2(s)}{|p_2(s)|} + \tfrac{p_1(s)}{|p_1(s)|}, y_1(s) - y_2(s) \right\rangle \\
&\qquad + \tfrac{1}{2}(c(s, y_1(s)) + c(s, y_2(s)))\left\langle \tfrac{p_1(s)}{|p_1(s)|} - \tfrac{p_2(s)}{|p_2(s)|}, y_1(s) - y_2(s) \right\rangle \\
&\le L_0|y_1(s) - y_2(s)|^2 + \tfrac{Me^{\kappa T}}{r}|y_1(s) - y_2(s)|^2
\end{aligned}$$

(in the last inequality, relations (8) and (32) have been used). Therefore, by the definition of C_2, we have $\rho'(s) \le 2C_2\rho(s)$ and deduce that

$$|y_1(s) - y_2(s)| \le |y_1(t_0) - y_2(t_0)|e^{C_2(s-t_0)} \le \operatorname{diam}(K_i)e^{C_2(s-t_0)} \qquad \forall s \in [t_0, \theta],$$

because $y_1(t_0)$ and $y_2(t_0)$ belong to K_i. So we have proved that, for all $s \in [t_0, \theta]$,

$$\operatorname{diam}(K_i'(s)) \leq \operatorname{diam}(K_i) e^{C_2(s-t_0)}.$$

Therefore, because of the definition of θ, we complete the proof of our claim (31) if we show that $\theta = t_1$. To this end, for $s = \theta$, we get

$$\operatorname{diam}(K_i'(\theta)) \leq \operatorname{diam}(K_i) e^{C_2(\theta-t_0)} < \eta e^{-L_0 T}$$

from the choice of $\operatorname{diam}(K_i)$ in (29). In particular, since $s \to \operatorname{diam}(K_i'(s))$ is right upper semicontinuous, we necessarily have $\theta = t_1$, and (31) is proved.

We now complete the proof of the lemma: the family $(K_i'(t_1))$ is a covering of $D_{t_1}^{int}(\eta)$, from (30), with

$$\operatorname{diam}(K_i'(t_1)) \leq \operatorname{diam}(K_i) e^{C_2(t_1-t_0)} \leq \delta$$

from (29). Therefore

$$\mathcal{H}^1_\delta(D_{t_1}^{int}(\eta)) \leq \sum_i \operatorname{diam}(K_i'(t_1)) \leq e^{C_2(t_1-t_0)} (\mathcal{H}^1(D_{t_0}^{int}(\eta)) + \epsilon).$$

Letting $\delta, \epsilon, \eta \to 0^+$ gives the desired result. □

2.5. Proofs of Proposition 2.10 and of Corollary 2.11.

Proof of Proposition 2.10. Taking into account Lemmata 2.14 and 2.16, we obtain

$$\mathcal{H}^1\big(\{\tau = t\}\big) = \mathcal{H}^1\big(D_t^{bnd}\big) + \mathcal{H}^1\big(D_t^{int}\big) \leq C_1 \mathcal{H}^1(\partial\Omega) + e^{C_2 T} \mathcal{H}^1(\partial K_0),$$

where $\mathcal{H}^1(\partial K_0)$ is finite because K_0 is compact and satisfies the interior ball condition (see, for instance, [1]). □

Proof of Corollary 2.11. Let us recall that τ is Lipschitz continuous and satisfies the Hamilton–Jacobi equation $c(\tau(x), x)|\nabla\tau(x)| = 1$ in the viscosity sense and thus a.e. in $\Omega \setminus K_0$. From assumption (8), we therefore have that

$$\frac{1}{M} \leq |\nabla\tau(x)| \leq \frac{k_0}{m} \qquad \text{a.e. in } \ \Omega \setminus K_0. \tag{33}$$

The coarea formula states that

$$\int_{\mathcal{R}(t_1)\setminus\mathcal{R}(t_0)} |\nabla\tau(x)|\, dx = \int_{t_0}^{t_1} \mathcal{H}^1\big(\{\tau = s\}\big)\, ds. \tag{34}$$

By assumption (33) and Proposition 2.10, we deduce, respectively, that

$$\int_{\mathcal{R}(t_1)\setminus\mathcal{R}(t_0)} |\nabla\tau(x)|\, dx \geq \frac{1}{M} |\mathcal{R}(t_1)\setminus\mathcal{R}(t_0)|,$$

$$\int_{t_0}^{t_1} \mathcal{H}^1\big(\{\tau = s\}\big)\, ds \ \leq \ C(t_1 - t_0).$$

Substituting the previous two inequalities into (34) completes the proof. □

3. Estimate for contraction. Let us consider two velocities c_1 and c_2, both satisfying assumptions (8), and the corresponding reflected control problems (for $j = 1, 2$)

$$\text{(35)}\quad \begin{cases} y'(t) = c_j(t, y(t))\big[b(t) - \langle b(t), \nu(y(t))\rangle \mathbf{1}_{\partial\Omega}(y(t))\nu(y(t))\big] & \text{a.e. in } (0,T), \\ y(0) \in K_j, \end{cases}$$

where $b : \mathbb{R}_+ \to B$ denotes the time measurable control. We assume that the sets K_1 and K_2 fulfill the interior sphere condition of radius $r > 0$ and that Ω satisfies (10)–(11). We denote by $\mathcal{R}_j(t)$ the reachable set of (35) at time t.

The main result of this section is some estimate of the volume of the symmetric difference $\mathcal{R}_1(t)\Delta\mathcal{R}_2(t)$.

PROPOSITION 3.1. *Under the above assumptions on c_j, K_j, and Ω, there exists for any $T > 0$ a constant $N = N(\Omega, r, m, M, L_0, L_1, T)$ such that*

$$|\mathcal{R}_1(t)\Delta\mathcal{R}_2(t)| \le N\gamma(t)$$

with

$$\gamma(t) := d^{\mathcal{H}}(K_1, K_2)e^{(L_0+M/r_1)t} + \int_0^t \|c_1(s,\cdot) - c_2(s,\cdot)\|_\infty e^{(L_0+M/r_1)(t-s)}ds,$$

where r_1 is the constant introduced in (10).

The proof is postponed until the end of the section.

Our starting point is the following lemma.

LEMMA 3.2. *Under the previous hypotheses on c_j, K_j, and Ω, we have*

$$\mathcal{R}_2(t) \subseteq \mathcal{R}_1(t) + \gamma(t)B.$$

In particular, we deduce that

$$\mathcal{R}_2(t) \subseteq \mathcal{R}_1(t + k_0\gamma(t)/m),$$

where k_0 is the constant introduced in inequality (11).

Proof. We set $\gamma_0 := d^{\mathcal{H}}(K_1, K_2)$ and, without loss of generality (thanks to Remark 2.5), consider an extremal trajectory z of (35) for $j = 2$ having the form

$$\begin{cases} z'(t) = c_2(t, z(t))b_2(t), \\ z(0) = z_0 \in K_2. \end{cases}$$

We define y as the reflected trajectory with velocity c_1, driven by the control b_2:

$$\begin{cases} y'(t) = c_1(t, y(t))\big[b_2(t) - \langle b_2(t), \nu(y(t))\rangle \mathbf{1}_{\partial\Omega}(y(t))\nu(y(t))\big], \\ y(0) = y_0, \end{cases}$$

where $y_0 \in K_1$ satisfies $|z_0 - y_0| \le \gamma_0$. For the sake of simplicity, we denote

$$b_1(t) := b_2(t) - \langle b_2(t), \nu(y(t))\rangle \mathbf{1}_{\partial\Omega}(y(t))\nu(y(t)).$$

For $g(s) := |z(s) - y(s)|^2/2$, there holds that

$$\begin{aligned} g'(s) &= \langle c_2(s, z(s))b_2(s) - c_1(s, y(s))b_1(s), z(s) - y(s)\rangle \\ &= \langle [c_2(s, z(s)) - c_1(s, z(s))]\, b_2(s), z(s) - y(s)\rangle \\ &\qquad + \langle c_1(s, z(s))b_2(s) - c_1(s, y(s))b_1(s), z(s) - y(s)\rangle \qquad \text{(36)} \\ &\le \|c_1(s,\cdot) - c_2(s,\cdot)\|_\infty |z(s) - y(s)| \\ &\quad + \langle c_1(s, z(s))b_2(s) - c_1(s, y(s))b_1(s), z(s) - y(s)\rangle. \end{aligned}$$

Using assumption (8), we get

$$\begin{aligned}
&\langle c_1(s,z(s))b_2(s) - c_1(s,y(s))b_1(s), z(s)-y(s)\rangle \\
&= \langle [c_1(s,z(s)) - c_1(s,y(s))]\, b_2(s), z(s)-y(s)\rangle \\
&\qquad - c_1(s,y(s))\langle b_1(s)-b_2(s), z(s)-y(s)\rangle \\
&\le L_0|z(s)-y(s)|^2 \\
&\qquad + c_1(s,y(s))\langle b_2(s), \nu(y(s))\rangle\langle \nu(y(s)), z(s)-y(s)\rangle \mathbf{1}_{\partial\Omega}(y(s)).
\end{aligned} \tag{37}$$

Let us recall that $\mathcal{C}\Omega$ fulfills the interior sphere condition with radius r_1. We claim that, for almost every $s \in [0,t]$, there holds that

$$\langle b_2(s), \nu(y(s))\rangle\langle \nu(y(s)), z(s)-y(s)\rangle \mathbf{1}_{\partial\Omega}(y(s)) \le \frac{1}{r_1}|z(s)-y(s)|^2. \tag{38}$$

This inequality is obvious if $y \notin \partial\Omega$. Consider $y \in \partial\Omega$, whence we get

$$|z(s) - y(s) - r_1\nu(y(s))|^2 \ge r_1^2,$$

from which we deduce that

$$\langle \nu(y(s)), z(s)-y(s)\rangle \le \frac{1}{2r_1}|z(s)-y(s)|^2.$$

By the arbitrariness of points $y(s)$ and $z(s)$, we deduce our claim (38).

Substituting relations (37) and (38) into (36), we deduce that

$$g'(s) \le \|c_1(s,\cdot) - c_2(s,\cdot)\|_\infty |z(s)-y(s)| + (L_0 + M/r_1)|z(s)-y(s)|^2;$$

in particular, for $\rho(s) := |z(s)-y(s)|$, the previous inequality gives

$$\rho'(s) \le \|c_1(s,\cdot) - c_2(s,\cdot)\|_\infty + (L_0 + M/r_1)\rho(s).$$

Applying the Gronwall lemma, we get

$$\rho(t) \le \rho(0)e^{(L_0+M/r_1)t} + \int_0^t \|c_1(s,\cdot) - c_2(s,\cdot)\|_\infty e^{(L_0+M/r_1)(t-s)}\, ds.$$

By the arbitrariness of z_0, the first part of the statement is proved.

By assumption (8) and inequality (11), the minimal time for reaching a point $y \in \Omega$ starting from $\bar{y} \in \Omega$ is less than or equal to $k_0|y-\bar{y}|/m$ (this value is the time needed to follow the geodesic between y and $\bar{y}$ at the minimal velocity m). Therefore, the second part of the statement is an immediate consequence of the previous one. □

Proof of Proposition 3.1. We estimate only the measure of $|\mathcal{R}_2(t)\backslash\mathcal{R}_1(t)|$; the other difference can be estimated by similar arguments, so we shall omit it. From Lemma 3.2 and Corollary 2.11 we have

$$|\mathcal{R}_2(t)\backslash\mathcal{R}_1(t)| \le |\mathcal{R}_1(t + k_0\gamma(t)/m)\backslash\mathcal{R}_1(t)| \le MCk_0\gamma(t)/m.$$

Setting $N = MCk_0/m$ completes the proof. □

4. Application to dislocation dynamics in a region. The aim of this section is to investigate the existence and uniqueness of the solution to the following nonlocal problem:

$$\left\{\begin{array}{ll} \frac{\partial \rho}{\partial t} = \big(\bar{c}_1 + I(\rho)\big)|\nabla \rho| & \text{in} \quad (0,+\infty)\times\Omega, \\ \rho(0,x) = \rho_0(x) \equiv \mathbf{1}_{K_0}(x) & \text{on} \quad \Omega, \\ \frac{\partial \rho}{\partial \nu} = 0 & \text{on} \quad (0,+\infty)\times\partial\Omega, \end{array}\right. \tag{39}$$

where ν is the outward unitary normal to $\partial\Omega$ and the map I is defined as follows:

$$I(\rho)(t,x) = \int_\Omega \bar{c}_2(t,x,y)\rho^*(y)\,dy \qquad \forall \rho \in \mathbb{L}^1(\Omega) \tag{40}$$

for any function $\rho : \Omega \to [0,1]$, where ρ^* denotes the upper semicontinuous envelope of ρ.

Besides assumptions (9)–(11) on the sets Ω and K_0, we require throughout this section that the maps $\bar{c}_1 : \mathbb{R}^+ \times \mathbb{R}^2 \to \mathbb{R}$ and $\bar{c}_2 : \mathbb{R}^+ \times \mathbb{R}^2 \times \mathbb{R}^2 \to \mathbb{R}$ satisfy the following:

$$\left\{\begin{array}{ll} \text{(i)} & \bar{c}_1 \text{ and } \bar{c}_2 \text{ are continuous and derivable w.r.t. the second variable,} \\ \text{(ii)} & |\bar{c}_1(t,x)| + \|\bar{c}_2(t,x,\cdot)\|_1 \le M \qquad \forall (t,x) \in \mathbb{R}^+ \times \Omega, \\ \text{(iii)} & |\bar{c}_1(t,x_1) - \bar{c}_1(t,x_2)| + \|\bar{c}_2(t,x_1,\cdot) - \bar{c}_2(t,x_2,\cdot)\|_1 \le L_0|x_1 - x_2| \\ & \qquad \forall (t,x_1),(t,x_2) \in \mathbb{R}^+ \times \Omega, \\ \text{(iv)} & |D_x\bar{c}_1(t,x_1) - D_x\bar{c}_1(t,x_2)| + \|D_x\bar{c}_2(t,x_1,\cdot) - D_x\bar{c}_2(t,x_2,\cdot)\|_1 \\ & \qquad \le L_1|x_1 - x_2|, \qquad \forall (t,x_1),(t,x_2) \in \mathbb{R}^+ \times \Omega, \\ \text{(v)} & |\bar{c}_2(t,x,y)| \le M \qquad \forall (t,x,y) \in \mathbb{R}^+ \times \Omega \times \Omega \end{array}\right. \tag{41}$$

(where $\|\cdot\|_1$ denotes the $\mathbb{L}^1$ norm in Ω) for some positive constants M, L_0, and L_1, and, for some $m > 0$, the following relation holds:

$$\bar{c}_1(t,x) - \|\bar{c}_2(t,x,\cdot)\|_1 \ge m \qquad \forall (t,x) \in [0,+\infty)\times\Omega. \tag{42}$$

This assumption implies that the dislocation is always expanding. We note that under the assumption (41) and (42), the map $c_\rho := \bar{c}_1 + I(\rho)$ satisfies (8) for any map $\rho \in C^0([0,+\infty), \mathbb{L}^1(\Omega,[0,1]))$. Moreover, the constants entering into relations (8) do not depend on the function ρ.

Let us recall that in the framework of discontinuous *viscosity* solutions (see the monographs by Barles [5] and by Bardi and Capuzzo-Dolcetta [4] for an overview) uniqueness of the solution means that two solutions ρ_1 and ρ_2 have the same upper and lower semicontinuous envelopes: $(\rho_1)^* = (\rho_2)^*$ and $(\rho_1)_* = (\rho_2)_*$. Now we can introduce our definition of viscosity solution.

DEFINITION 4.1. *A function ρ is a viscosity solution to problem* (39) *if* $\rho \in C^0([0,+\infty), \mathbb{L}^1(\Omega))$ *and if the unique discontinuous solution u to the initial-boundary value problem*

$$\left\{\begin{array}{ll} \frac{\partial u}{\partial t} = c_\rho(t,x)|\nabla u| & \textit{in} \quad (0,+\infty)\times\Omega, \\ u(0,x) = \rho_0(x) \equiv \mathbf{1}_{K_0}(x) & \textit{on} \quad \Omega, \\ \frac{\partial u}{\partial \nu} = 0 & \textit{on} \quad (0,+\infty)\times\partial\Omega \end{array}\right. \tag{43}$$

with $c_\rho(t,x) := \bar{c}_1(t,x) + I(\rho)(t,x)$ fulfills $u^* = \rho^*$ and $u_* = \rho_*$ in $[0,+\infty)\times\Omega$.

The well-posedness of system (43) is ensured by the following lemma, which also provides a representation formula for this system.

LEMMA 4.2. *Under the above assumptions on* Ω, K_0, $\bar{c}_1$, *and* $\bar{c}_2$, *for any* $\rho \in C^0([0,+\infty), \mathbb{L}^1(\Omega))$ *there exists a unique discontinuous solution* u *to the initial boundary value problem* (43). *Moreover, for* $t > 0$, *we have*

$$u(t,x) \in \{0,1\} \qquad \forall x \in \overline{\Omega} \qquad \text{and} \qquad \{x \mid u^*(t,x) = 1\} = \mathcal{R}(t), \tag{44}$$

where $\mathcal{R}(t)$ *is the reachable set for the control problem* (6) *introduced in section* 2 *with* $c(t,x) = c_\rho(t,x)$.

Proof. In order to show the relation between the level sets of the solution ρ and the reachable set $\mathcal{R}(t)$, let us introduce the following Mayer problem: the value function $\psi(t,x)$ is defined as

$$\psi(t,x) := \max_b \mathbf{1}_{K_0}(y(0)),$$

where y is the solution to the following *backward* reflected control problem:

$$\begin{cases} y'(s) = c(s,y(s))\big[b(s) - \langle b(s), \nu(y(s))\rangle \mathbf{1}_{\partial\Omega}(y(s))\nu(y(s))\big] & \text{a.e. in } [0,t], \\ y(t) = x. \end{cases}$$

Arguing as in [14], one can easily prove that ψ is a solution to (43).

In order to prove the uniqueness of the solution, let us first show that the *fattening* phenomenon (for the precise definition, see [6]) does not occur in $[0,T]$ for every $T \in \mathbb{R}^+$. To this end, we introduce $u_0 \in BUC(\Omega)$, $u_0 \le 1$, such that $\{x \mid u_0(x) \ge 0\} = K_0$ and $\{x \mid u_0(x) > 0\} = \text{Int } K_0$, and we consider the following problem:

$$\begin{cases} \frac{\partial u}{\partial t} = c_\rho(t,x)|\nabla u| & \text{in} \quad (0,+\infty)\times\Omega, \\ u(0,x) = u_0(x) & \text{on} \quad \Omega, \\ \frac{\partial u}{\partial \nu} = 0 & \text{on} \quad (0,+\infty)\times\partial\Omega. \end{cases} \tag{45}$$

It is well known (see [6]) that there exists exactly one solution $u \in UC$ of this problem. For every $s \in \mathbb{R}$, we set $K_s := \{u_0 \ge s\}$ and denote $\mathcal{R}_s(t)$ the reachable set in time t when starting from K_s. The function $\mathbf{1}_{\mathcal{R}_s(t)}(x)$ is a (discontinuous) viscosity solution to problem (45) with u_0 replaced by $\mathbf{1}_{K_s}$. The comparison principle (which applies because u is sufficiently regular; see [6]) entails

$$u(t,x) - s - \epsilon \le \mathbf{1}_{\mathcal{R}_s(t)}(x) \qquad \forall s,\epsilon \in \mathbb{R},\ x \in \mathbb{R}^2,\ t \in \mathbb{R}^+$$

and, in particular,

$$\{(t,x) \mid u(t,x) \ge s + \epsilon\} \subseteq \mathcal{R}_s(t) \qquad \forall s,\epsilon \in \mathbb{R},\ t \in \mathbb{R}^+. \tag{46}$$

On the other hand, let v_ϵ be the UC solution to problem (45) with u_0 replaced by $v_{0\epsilon} \in UC$ such that $\{v_{0\epsilon} \ge 0\} = K_{s-\epsilon}$, $\{v_{0\epsilon} > 0\} = \text{Int } K_{s-\epsilon}$ and $v_{0\epsilon} \ge 1$ on K_s. Therefore, again by the comparison principle, we have $\mathbf{1}_{\mathcal{R}_s} \le v_\epsilon$ and also

$$\mathcal{R}_s(t) \subseteq \{v_\epsilon(t,x) \ge 0\} = \{u(t,x) - s + \epsilon \ge 0\} \tag{47}$$

(the equality is due to the *geometricity* of the partial differential equation; see [6]).

By the stability theorem, passing to the limit as $\epsilon \to 0$ in relations (46)–(47), we obtain

$$\overline{\{(t,x) \mid u(t,x) > s\}} \subseteq \cup_t \mathcal{R}_s(t) \subseteq \{(t,x) \mid u(t,x) \ge s\} \qquad \forall s \in \mathbb{R}.$$

Taking into account assumptions (8) and (11), we have

$$\lim_{\eta\to 0^+} \cup_{t\in[0,T]}\mathcal{R}_{s+\eta}(t) = \cup_{t\in[0,T]}\mathcal{R}_s(t).$$

From the last two relations, we deduce that

$$\overline{\{(t,x)\in[0,T]\times\Omega \mid u(t,x)>s\}} = \{(t,x)\in[0,T]\times\Omega \mid u(t,x)\geq s\} \qquad \forall s\in\mathbb{R},$$

whence, by the arbitrariness of T, fattening does not occur. Finally, the uniqueness of the solution follows by an adaptation of the arguments used by Barles, Soner, and Souganidis [6]. □

Let us state the main result of this section.

THEOREM 4.3. *Under the assumptions* (9)–(11) *on the sets* Ω *and* K_0 *and* (41)–(42) *on* $\bar{c}_1$ *and* $\bar{c}_2$*, the initial boundary value problem* (39) *has a unique discontinuous viscosity solution* $\rho\in C^0\left([0,+\infty),\mathbb{L}^1(\Omega)\right)$.

Proof. Let us fix $T_0>0$ and prove the existence and uniqueness of the solution in a strip $[0,T_0]$. For this it is enough to show that there is some positive τ with the following property: for any $T\in[0,T_0]$, if the existence and uniqueness of solutions hold on $[0,T]$, then they hold on $[0,T+\tau]$.

Let us first define τ. For this let C, r_1, and N be the constants given in Propositions 2.10 and 3.1 for the time T_0+1. We fix $\tau\in(0,1]$ and $0<\alpha<1$ with

$$\tau\leq 1/MC, \qquad e^{(L_0+M/r_1)\tau}\leq 1+\alpha\frac{L_0+M/r_1}{NM}.$$

Next, we define the set

$$\mathcal{E}_T := \left\{\rho\in C^0\left([0,T+\tau],\mathbb{L}^1(\Omega)\right) \mid \begin{array}{l}\rho \text{ unique solution to (39) on } [0,T],\\ 0\leq\rho\leq 1,\ \sup\limits_{t\in[T,T+\tau]}\|\rho(t)\|_1\leq\|\rho(T,\cdot)\|_1+1\end{array}\right\}.$$

Let us introduce the mapping $\Phi:\mathcal{E}_T\to C^0\left([0,T+\tau],\mathbb{L}^1(\Omega)\right)$ defined in the following way: for $\rho^0\in\mathcal{E}_T$, $\Phi(\rho^0)$ is the unique viscosity solution to

$$\left\{\begin{array}{lll}\frac{\partial\rho}{\partial t}=\left(\bar{c}_1+I(\rho^0)\right)|\nabla\rho| & \text{in} & (0,T+\tau)\times\Omega,\\ \rho(0,x)=\rho_0(x)\equiv\mathbf{1}_{K_0}(x) & \text{on} & \Omega,\\ \frac{\partial\rho}{\partial\nu}=0 & \text{on} & (0,T+\tau)\times\partial\Omega.\end{array}\right. \tag{48}$$

The well-posedness of Φ is established in Lemma 4.2. We claim that Φ maps $\mathcal{E}_T$ into itself. Combining the representation formula (44) of Lemma 4.2 with Corollary 2.11, we have, for all $t\in[T,T+\tau]$,

$$\|\rho(t,\cdot)\|_1\leq\|\rho(t,\cdot)-\rho(T,\cdot)\|_1+\|\rho(T,\cdot)\|_1\leq\|\rho(T,\cdot)\|_1+1$$

(in the last inequality, relation $\tau\leq 1/MC$ has been used).

Now we claim that Φ is a contraction. Fix $\rho_1^0,\rho_2^0\in\mathcal{E}_T$ and set

$$c_i := \bar{c}_1+I(\rho_i^0) \qquad \text{and} \qquad \rho_i:=\Phi(\rho_i^0) \qquad (i=1,\,2).$$

We note that since $\rho_1^0=\rho_2^0$ on $[0,T]$, we have $c_1=c_2$ on $[0,T]$. Moreover,

$$\|c_1-c_2\|_\infty = \sup_{t\in[0,T+\tau]}\left\|I(\rho_1^0-\rho_2^0)(t,\cdot)\right\|_\infty \leq M\sup_{t\in[0,T+\tau]}\left\|\rho_1^0(t,\cdot)-\rho_2^0(t,\cdot)\right\|_1.$$

Therefore, using Proposition 3.1 and the fact that $c_1 = c_2$ on $[0,T]$, we have, for $t \in [T, T+\tau]$,

$$\begin{aligned}\|\rho_1(t,\cdot) - \rho_2(t,\cdot)\|_1 &\le N \|c_1 - c_2\|_\infty \int_T^t e^{(L_0+M/r_1)(t-s)} ds \\ &\le NM \frac{e^{(L_0+M/r_1)\tau} - 1}{L_0 + M/r_1} \sup_{t\in[T,T+\tau)} \left\|\rho_1^0(t,\cdot) - \rho_2^0(t,\cdot)\right\|_1 \\ &\le \alpha \sup_{t\in[T,T+\tau)} \left\|\rho_1^0(t,\cdot) - \rho_2^0(t,\cdot)\right\|_1\end{aligned}$$

(in the last inequality, relation $e^{(L_0+M/r_1)\tau} \le 1 + \alpha \frac{L_0+M/r_1}{NM}$ has been used). In particular, we have proved that Φ is a contraction, and by the Banach fixed point theorem, there exists a unique solution in the strip $[0, T+\tau]$. □

Remark 4.4. This result can be immediately extended to the case of functions $\bar{c}_2$ satisfying only (41)(i)–(iv). Actually, in the proof, one just needs the constant

$$\tilde{M} := \max\{\bar{c}_2(t,x,y) |\, t \in [0, T+1],\, x,\, y \in (K_0 + B_{M(T+1)})\},$$

which gives an upper estimate of $\bar{c}_2$ in the reachable set in time $T+1$. In this case, τ needs to be chosen in the following way:

$$\tau \le 1/MC, \qquad e^{(L_0+M/r_1)\tau} \le 1 + \alpha \frac{L_0 + M/r_1}{N\tilde{M}}.$$

5. Appendix: Proof of Lemma 2.3. Without loss of generality, we assume that the function c is defined and fulfills conditions (8) on the whole space $\mathbb{R}^+ \times \mathbb{R}^2$. For $\epsilon > 0$, we introduce the unconstrained controlled problem:

$$x' = c_\epsilon(t,x)b, \qquad |b| \le 1, \qquad \text{where } c_\epsilon(t,x) = \left(c(t,x) - \frac{d_\Omega(x)}{\epsilon}\right)_+,$$

where $(s)_+ = \max(0,s)$. We denote by $\mathcal{R}_\epsilon(t)$ the reachable set at time t starting from K_0 for this control system. Let us point out that it is a subset of $\mathbb{R}^2$ (and not only of $\overline{\Omega}$, as is $\mathcal{R}(t)$). From standard arguments, we have the inclusion $\mathcal{R}(t) \subset \mathcal{R}_\epsilon(t)$ for any $t \ge 0$. We are going to prove that for $\epsilon > 0$ small enough, extremal trajectories for the perturbed problem ending in $\overline{\Omega}$ are actually extremal trajectories for the initial problem.

Let $\epsilon > 0$ small to be chosen later. Also let $x_\epsilon(\cdot)$ be an extremal trajectory of the perturbed problem ending at some $x \in \overline{\Omega}$ at time T. From the definition of c_ϵ, the Pontryagin maximum principle for Lipschitz continuous dynamics (see, for instance, [10]) states that there are $p_\epsilon : [0,T] \to (\mathbb{R}^N \backslash \{0\})$ Lipschitz continuous and $\lambda_\epsilon : [0,T] \to [0,1]$ measurable such that

$$\text{(49)} \quad \begin{cases} x_\epsilon'(t) = c_\epsilon(t, x_\epsilon(t)) \dfrac{p_\epsilon(t)}{|p_\epsilon(t)|} & \forall t \in (0,T), \\ p_\epsilon'(t) = -\left[D_x c(t, x(t)) - \dfrac{\lambda_\epsilon(t)}{\epsilon} Dd(x(t))\right] |p(t)| & \text{for a.e. } t \in (0,T), \\ \lambda_\epsilon(t) = 0 \text{ if } x_\epsilon(t) \in \Omega, & \lambda_\epsilon(t) = 1 \text{ if } x_\epsilon(t) \notin \overline{\Omega}. \end{cases}$$

We claim that $x_\epsilon(t) \in \overline{\Omega}$ for $t \in [0,T]$. Indeed, suppose on the contrary that $x_\epsilon(t) \notin \overline{\Omega}$ for some $t \in [0,T]$. Let (a,b) be the largest interval containing t such that

$x_\epsilon(s) \notin \overline{\Omega}$ for $s \in (a,b)$. We note that $x_\epsilon(a)$ and $x_\epsilon(b)$ belong to $\partial\Omega$ because $x(T) \in \overline{\Omega}$. Moreover, at $s = a$ we have

$$\langle Dd(x_\epsilon(a)), x_\epsilon'(a)\rangle = \left\langle Dd(x_\epsilon(a)), c_\epsilon(a, x_\epsilon(a))\frac{p_\epsilon(a)}{|p_\epsilon(a)|}\right\rangle \ \geq\ 0.$$

In particular, $\langle Dd(x_\epsilon(a)), p_\epsilon(a)\rangle \geq 0$. In the same way, since $\langle Dd(x_\epsilon(b)), x_\epsilon'(b)\rangle \leq 0$, we have $\langle Dd(x_\epsilon(b)), p_\epsilon(b)\rangle \leq 0$. Hence

$$\begin{aligned} 0 &\geq \int_a^b \frac{d}{dt}\langle Dd(x_\epsilon(s)), p_\epsilon(s)\rangle\, ds \\ &\geq \int_a^b \left[c_\epsilon(s, x_\epsilon(s))\left\langle D^2 d(x_\epsilon(s))\frac{p_\epsilon(s)}{|p_\epsilon(s)|}, \frac{p_\epsilon(s)}{|p_\epsilon(s)|}\right\rangle |p_\epsilon(s)| \right. \\ &\qquad \left. - \langle D_x c(s, x_\epsilon(s)), Dd(x_\epsilon(s))\rangle |p_\epsilon(s)| + \tfrac{1}{\epsilon}|p_\epsilon(s)|\right] ds, \end{aligned}$$

where we have used the fact that for $\epsilon > 0$ sufficiently small and $s \in (a,b)$, $x_\epsilon(s)$ is close to $\partial\Omega$, and therefore d is of class $\mathcal{C}^2$ at $x_\epsilon(s)$ with $|Dd(x_\epsilon(s))| = 1$. From our assumptions, c_ϵ, Dc, and $D^2 d$ are bounded by some constant M, and therefore

$$0 \geq \int_a^b \left[-M^2 - M + \frac{1}{\epsilon}\right] |p_\epsilon(s)| ds.$$

This leads to a contradiction for $\epsilon < 1/[M + M^2]$ because $p_\epsilon(s) \neq 0$ for $s \in [0,T]$. So we have proved that for $\epsilon > 0$ sufficiently small and $t \in [0,T]$, $x_\epsilon(t) \in \overline{\Omega}$. In particular, x_ϵ is actually an extremal trajectory of the unperturbed problem on $[0,T]$.

We now fix ϵ as above. We now claim that, conversely, any extremal trajectory $x(\cdot)$ of the unperturbed problem on the time interval $[0,T]$ is an extremal trajectory of the perturbed problem. Indeed, let T_ϵ be the minimal time for which there is a solution of the perturbed problem reaching $x(T)$. Obviously, $T_\epsilon \leq T$. Moreover, there is an extremal trajectory $x_\epsilon(\cdot)$ for the perturbed problem reaching $x(T)$ at time T_ϵ. But we have already proved that this trajectory is actually a trajectory of the unperturbed problem. So $T_\epsilon \geq T$, whence we get an equality: $T_\epsilon = T$. This proves that $x(T) \in \partial_{\mathbb{R}^2}\mathcal{R}_\epsilon(T)$, and thus $x(\cdot)$ is actually an extremal trajectory for the perturbed problem.

Now let x be an extremal trajectory of the unperturbed problem on the time interval $[0,T]$. Since it is also extremal for the perturbed problem on $[0,T]$, we can use again the Pontryagin maximum principle: there are $p : [0,T] \to (\mathbb{R}^N \backslash \{0\})$ Lipschitz continuous and $\lambda_\epsilon : [0,T] \to [0,1]$ measurable such that

$$\begin{cases} x'(t) = c_\epsilon(t, x(t))\dfrac{p(t)}{|p(t)|} & \forall t \in (0,T), \\ p'(t) = -\left[D_x c(t, x(t)) - \dfrac{\lambda_\epsilon(t)}{\epsilon} Dd(x(t))\right] |p(t)| & \text{for a.e. } t \in (0,T), \\ \lambda_\epsilon(t) = 0 \text{ if } x(t) \in \Omega, & \lambda_\epsilon(t) = 1 \text{ if } x(t) \notin \overline{\Omega}. \end{cases}$$

Note that $c_\epsilon(t, x(t)) = c(t, x(t))$ because $x(t) \in \overline{\Omega}$ for any t. Let us now identify λ_ϵ. For this we set

$$E = \{t \in [0,T] \mid x(t) \in \partial\Omega\}.$$

Then, for almost every $t \in E$, we have $\langle Dd(x(t)), x'(t)\rangle = 0$, and thus $\langle Dd(x(t)), p(t)\rangle = 0$ thanks to (49). Therefore, for almost every $t \in E$, we also have

$$\left\langle D^2 d(x(t))c(t,x(t))\frac{p(t)}{|p(t)|}, p(t)\right\rangle + \left\langle Dd(x(t)), -\left(D_x c(t,x(t)) - \frac{\lambda_\epsilon(t)}{\epsilon} Dd(x(t))\right)|p(t)|\right\rangle = 0.$$

Since $|Dd| = 1$ and $\lambda_\epsilon \geq 0$, we get

$$\frac{\lambda_\epsilon(t)}{\epsilon} = \Big[-\left\langle D^2 d(x(t))c(t,x(t))\frac{p(t)}{|p(t)|}, \frac{p(t)}{|p(t)|}\right\rangle + \langle Dd(x(t)), D_x c(t,x(t))\rangle\Big]_+ \mathbf{1}_{\partial\Omega}(x(t)).$$

Setting $\lambda(t) = \lambda_\epsilon(t)/\epsilon$, we get the desired result.

CLASSIFICATION OF ESTIMATION ALGEBRAS WITH STATE DIMENSION 2*

XI WU† AND STEPHEN S.-T. YAU†

Abstract. This paper considers general finite-dimensional estimation algebras associated with nonlinear filtering systems. General considerations and approaches toward the classification of finite-dimensional estimation algebras are proposed. Some structural results are obtained. The properties of Euler operator and the solutions to an underdetermined partial differential equation, which inevitably arise in an estimation algebra, are studied. These tools and techniques are applied to the study of finite-dimensional estimation algebras with state dimension 2 to obtain a complete classification result. It is shown that a finite-dimensional estimation algebra with state dimension 2 can only have dimension less than or equal to 6. Moreover, the Mitter conjecture and the Levine conjecture hold for finite-dimensional estimation algebras with state dimension 2.

Key words. finite-dimensional filter, estimation algebra, nonlinear drift

1. Introduction.

The Lie algebraic method, pioneered by Brockett [3], Brockett and Clark [5], and Mitter [15], provides an important research direction for nonlinear filtering theory. By interpreting the Duncan–Mortensen–Zakai equation or its robust form as a partial differential equation with time varying parameters, one derives an approach to filtering based on Lie algebra as well as the theory of linear differential operators. The search and construction of the finite-dimensional filter are turned into the study of the structure of the estimation algebra. In return, the theory of estimation algebra provides a systematic tool to deal with questions concerning finite-dimensional filters. It has led to a number of new results concerning finite-dimensional filters and to a deeper understanding of the structure of nonlinear filtering in general. It explains convincingly in [6] and [11] why it is easy to find exact recursive filters for linear dynamical systems, while it is very hard to handle the cubic sensor problem. Some new filters have been discovered using the estimation algebra [1], [16], [20], [21], [24]. More importantly, the finite-dimensionality of the estimation algebra guarantees the explicit construction of the finite-dimensional recursive filter, and the filter so constructed is universal in the sense of [7]. However, as an inherited difficulty from the nonlinear filtering, many questions are not satisfyingly answered and still open. Two excellent survey papers [10], [14] provide the detailed material on the Wei–Norman approach, the connections between estimation algebra and nonlinear filtering, the application of the Lie algebra method to a variety of specific nonlinear filtering problems, and the construction of the approximate filters, as well as sufficient reviews of the requisite background and a sufficient number of examples. For more contemporary results, see [23].

At the International Congress of Mathematics in 1983, Brockett [4] proposed classifying all the finite-dimensional estimation algebras. In [26], the concept of estimation algebra of maximal rank was introduced by Yau and Chiou. The complete classification of such a subclass finite-dimensional estimation algebra was done by Yau and his coworkers in a series of papers, and the final results were reported in [25]. In [27], the conditions by which a general estimation algebra has dimension less than or equal to 4 were discussed. In [17], a new class of finite-dimensional estimation algebras were constructed when the state dimension $n \geq 3$. In this paper, the finite-dimensional estimation algebras that can arise when the underlying stochastic systems have state dimension 2 are completely classified. It is shown that an estimation algebra with state dimension 2 can have only 1, 2, 4, 5, or 6 dimensions. The finite-dimensional estimation algebras with state dimension 1 were considered in [5] and [16].

This paper is organized as follow: Section 2 introduces some basic concepts of estimation algebra for a nonlinear filtering system and gives the classification result on the finite-dimensional estimation algebra of maximal rank. In section 3, some tools and techniques are discussed for the classification of general estimation algebras. The complete classification of estimation algebras with state dimension 2 is given in section 4.

2. Basic concepts. In this paper, the filtering system to be considered is based on the following continuous signal-observation model:

$$\begin{cases} dx(t) = f\big(x(t)\big)dt + g\big(x(t)\big)dv(t), & x(0) = x_0, \\ dy(t) = h\big(x(t)\big)dt + dw(t), & y(0) = 0. \end{cases} \tag{2.1}$$

Here x, v, y, and w are, respectively, R^n, R^n, R^m, and R^m valued processes, and v and w have components which are independent, standard Brownian processes. Moreover, $f = (f_1, \ldots, f_n)$ and $h = (h_1, \ldots, h_m)$ are assumed to be C^∞ smooth and g is an orthogonal matrix. $x(t)$ is referred to as the state of the system at time t and $y(t)$ as the observation at time t.

Let $\rho(t, x)$ denote the conditional probability density of the state $x(t)$ given the observation $\{y(s) : 0 \leq s \leq t\}$. $\rho(t, x)$ is governed by the well-known Duncan–Mortensen–Zakai (DMZ) equation, which is a stochastic partial differential equation in terms of an unnormalized version of $\rho(t, x)$, denoted by $\sigma(t, x)$ (see [13], for example). Under the Stratonovich calculus, the DMZ equation for the filtering system (2.1) can be written as

$$\begin{cases} d\sigma(t, x) = L_0\sigma(t, x)dt + \displaystyle\sum_{i=1}^{m} h_i\sigma(t, x)dy_i(t), \\ \sigma(0, x) = \sigma_0, \end{cases} \tag{2.2}$$

where

$$L_0 = \frac{1}{2}\sum_{i=1}^{n} \frac{\partial^2}{\partial x_i^2} - \sum_{i=1}^{n} f_i \frac{\partial}{\partial x_i} - \sum_{i=1}^{n} \frac{\partial f_i}{\partial x_i} - \frac{1}{2}\sum_{i=1}^{m} h_i^2. \tag{2.3}$$

The term σ_0 is the probability density of the initial state x_0.

The Wei–Norman result [19] on constructing explicit solutions to complex partial differential equations suggests a formal approach to constructing a finite-dimensional filter by defining the estimation algebra as a Lie algebra generated by the operators occurring in the DMZ equation.

DEFINITION 2.1. *If X and Y are differential operators, the Lie bracket of X and Y, $[X,Y]$, is defined by $[X,Y]\phi = X(Y\phi) - Y(X\phi)$ for any C^∞-function ϕ.*

DEFINITION 2.2. *The estimation algebra E of a filtering system* (2.1) *is defined as the Lie algebra generated by $\{L_0, h_1, \dots, h_m\}$, i.e., $E = \langle L_0, h_1, \dots, h_m\rangle_{L.A.}$, where L_0 is defined in* (2.3).

The following theorem due to Ocone [16] is the first result to show what kind of functions can appear in a finite-dimensional estimation algebra.

THEOREM 2.3 (see [16]). *Let E be a finite-dimensional estimation algebra. If ϕ is a function in E, then ϕ is a polynomial of degree at most* 2.

In fact, Mitter and Levine have conjectured the following.

MITTER CONJECTURE. *Let E be a finite-dimensional estimation algebra. If ϕ is a function in E, then ϕ is a polynomial of degree at most* 1.

LEVINE CONJECTURE (see [12]). *Let E be a finite-dimensional estimation algebra. The differential operators in E have orders at most* 2.

A fundamental step in the Lie algebraic approach as introduced in [21] is to represent the elliptic operator L_0 in (2.3) in a more compact form by defining

$$D_i = \frac{\partial}{\partial x_i} - f_i, \tag{2.4}$$

$$\eta = \sum_{i=1}^{n} \frac{\partial f_i}{\partial x_i} + \sum_{i=1}^{n} f_i^2 + \sum_{i=1}^{m} h_i^2. \tag{2.5}$$

Then

$$L_0 = \frac{1}{2}\Big(\sum_{i=1}^{n} D_i^2 - \eta\Big). \tag{2.6}$$

DEFINITION 2.4. *The Ω-matrix of a filtering system* (2.1) *is an $n \times n$ matrix $\Omega = (\omega_{ij})$ defined by*

$$\omega_{ij} = \frac{\partial f_j}{\partial x_i} - \frac{\partial f_i}{\partial x_j} \qquad \forall\ 1 \le i, j \le n. \tag{2.7}$$

When $\Omega = O$, i.e., f is a gradient vector field in view of the Poincaré lemma, the filtering system and the corresponding estimation algebra are called exact. In [9] and [18], the finite-dimensional exact estimation algebras are completely classified. In [24], Yau classified the finite-dimensional estimation algebras when the Ω-matrix has constant entries.

THEOREM 2.5 (see [24]). *Let E be an estimation algebra of* (2.1) *whose Ω-matrix has constant entries.*

(1) *If η (in* (2.5)*) is a polynomial of degree at most* 2 *and $h_1, \dots, h_m$ are affine in x, then E is finite-dimensional and has a basis consisting of $E_0 = L_0$, $E_1, \dots, E_p, E_{p+1}, \dots, E_q, 1$ (for some $p < q$). The differential operators $E_1, \dots, E_p$ have the form*

$$\sum_{j=1}^{n} \alpha_{ij} D_j + \beta_j, \qquad 1 \le i \le p,$$

where α_{ij}'s are constants and β_i's are affine in x, and the differential operators $E_{p+1}, \dots, E_q$ are affine in x. Moreover, the quadratic part of $\eta - \sum_{i=1}^{m} h_i^2$ is positive semidefinite.

(2) *Conversely, if E is finite-dimensional, then $h_1, \dots, h_m$ are affine in x, i.e., the observation matrix $H = [\nabla h_1, \dots, \nabla h_m]$ is a constant matrix. Furthermore, if the observation matrix has rank n, then η is a polynomial of degree at most 2 and E is of dimension $2n+2$ with a basis given by $1, x_1, \dots, x_n, D_1, \dots, D_n$, and L_0.*

DEFINITION 2.6. *An estimation algebra E is said to be of maximal rank if, for any $1 \le i \le n$, there exists a constant c_i, such that $x_i + c_i \in E$.*

By direct calculation, if E is of maximal rank, $[L_0, x_i + c_i] = D_i \in E$, and $[D_i, x_i + c_i] = 1 \in E$. Thus, $\langle 1, x_1, \dots, x_n \rangle$ form a vector space of E. Any degree 1 polynomial is an element of E.

THEOREM 2.7 (see [25]). *Let E be an estimation algebra of (2.1). If E is of maximal rank and finite-dimensional, then*

(1) $\frac{\partial f_j}{\partial x_i} - \frac{\partial f_i}{\partial x_j} = c_{ij}$ $\forall 1 \le i, j \le n$, *where c_{ij}'s are constants;*

(2) $h_1, \dots, h_m$ *are affine in x;*

(3) η *is a polynomial of degree 2 and the quadratic part of $\eta - \sum_{i=1}^m h_i^2$ is positive semidefinite.*

Moreover, E is of dimension $2n+2$ with a basis given by $1, x_1, \dots, x_n, D_1, \dots, D_n$, and L_0.

For the convenience of the reader, the following elementary lemma on the calculations of the Lie bracket of the estimation algebra is listed without proof.

LEMMA 2.8 (see [8], [24]). *Let E be an estimation algebra for the filtering system (2.1). $\Omega = (\omega_{ij})$ is defined as in (2.7). $X, Y, Z \in E$ and $g, h \in C^\infty(R^n)$. Then*

(1) $[XY, Z] = X[Y, Z] + [X, Z]Y$;

(2) $[gD_i, h] = g\frac{\partial h}{\partial x_i}$;

(3) $[gD_i, hD_j] = -gh\omega_{ij} + g\frac{\partial h}{\partial x_i}D_j - h\frac{\partial g}{\partial x_j}D_i$;

(4) $[gD_i^2, h] = 2g\frac{\partial h}{\partial x_i}D_i + g\frac{\partial^2 h}{\partial x_i^2}$;

(5) $[D_i^2, hD_j] = 2\frac{\partial h}{\partial x_i}D_iD_j - 2h\omega_{ij}D_i + \frac{\partial^2 h}{\partial x_i^2}D_j - h\frac{\partial \omega_{ij}}{\partial x_i}$;

(6) $[D_i^2, D_j^2] = 4\omega_{ji}D_jD_i + 2\frac{\partial \omega_{ji}}{\partial x_j}D_i + 2\frac{\partial \omega_{ji}}{\partial x_i}D_j + \frac{\partial^2 \omega_{ji}}{\partial x_i \partial x_j} + 2\omega_{ji}^2$;

(7) $[D_k^2, hD_iD_j] = 2\frac{\partial h}{\partial x_k}D_kD_iD_j + 2h\omega_{jk}D_iD_k + 2h\omega_{ik}D_kD_j + \frac{\partial^2 h}{\partial x_k^2}D_iD_j + 2h\frac{\partial \omega_{jk}}{\partial x_i}D_k + h\frac{\partial \omega_{jk}}{\partial x_k}D_i + h\frac{\partial \omega_{ik}}{\partial x_k}D_j + h\frac{\partial^2 \omega_{jk}}{\partial x_i \partial x_k}$;

(8) $[gD_iD_j, hD_k] = g\frac{\partial h}{\partial x_j}D_iD_k + g\frac{\partial h}{\partial x_i}D_jD_k + gh\omega_{kj}D_i + gh\omega_{ki}D_j + g\frac{\partial^2 h}{\partial x_i \partial x_j}D_k + gh\frac{\partial \omega_{kj}}{\partial x_i} - h\frac{\partial g}{\partial x_k}D_iD_j$.

3. Preliminary results.

3.1. Differential operator. Let U be the set of differential operators in the form

$$A = \sum_{(i_1, \dots, i_n) \in I_A} a_{i_1, \dots, i_n} D_1^{i_1} \cdots D_n^{i_n}, \tag{3.1}$$

where nonzero functions $a_{i_1, \dots, i_n} \in C^\infty(R^n)$ and I_A is the finite index set of A. Each element of the index set is an n-tuple $(i_1, \dots, i_n)$ of nonnegative integers. The norm of an index $i = (i_1, \dots, i_n)$ is defined to be $|i| = \sum_{l=1}^n i_l$. The order of A is denoted by $ord\ A = \max_{i=(i_1, \dots, i_n) \in I_A} |i|$. If $A = 0$, $ord\ A$ is defined to be $-\infty$. It is clear that for $A, B \in U$

$$ord\ (AB) = ord\ (BA) = ord\ A + ord\ B, \tag{3.2}$$

$$ord\ (A \pm B) \le \max(ord\ A, ord\ B). \tag{3.3}$$

U is a Lie algebra under the Lie bracket $[\cdot,\cdot]$ defined earlier. Two differential operators A and B in U are equal if they have the identical index sets $I_A = I_B$ and $a_{i_1,\ldots,i_n} = b_{i_1,\ldots,i_n} \forall (i_1,\ldots,i_n) \in I_A$. Let U_k denote the subspace of U consisting of elements with order less than or equal to k. In particular, $U_0 = C^\infty(R^n)$. As usual, *mod* is used to denote the equivalence class, i.e., if V is a subspace of U,

$$A = B, \qquad \text{mod } V \Longleftrightarrow A - B \in V. \tag{3.4}$$

If $A, B \in U$, define

$$Ad_A B = [A, B], \qquad Ad_A^l B = [A, Ad_A^{l-1} B], \quad l \geq 1, \tag{3.5}$$

where Ad_A^0 is the identity operator by standard convention.

Recall that

$$D_i = \frac{\partial}{\partial x_i} - f_i, \qquad 1 \leq i \leq n, \tag{3.6}$$

$$L_0 = \frac{1}{2}\left(\sum_{i=1}^n D_i^2 - \eta\right), \qquad \eta = \sum_{i=1}^n \frac{\partial f_i}{\partial x_i} + \sum_{i=1}^n f_i^2 + \sum_{i=1}^m h_i^2. \tag{3.7}$$

The estimation algebra $E = \langle L_0, h_1, \ldots, h_m \rangle_{L.A.}$. Since $L_0 \in U_2$ and $h_i \in U_0, 1 \leq i \leq m$, $E \subset U$. Every element of E will have representation in the form of (3.1).

The finite-dimensionality of E can be measured in terms of the finite order of the elements in E. If E is finite-dimensional, then the orders of its element will have an upper bound. In particular, if there exists a sequence of elements $A_j \in E$ such that the orders of A_j's are strictly increasing, E is not finite-dimensional.

The following is a very useful lemma in the computation of the orders of the differential operators generated under the Lie bracket.

LEMMA 3.1. *Let $g, h \in C^\infty(R^n)$ and let $i_1, \ldots, i_n, j_1, \ldots, j_n$ be nonnegative integers with $\sum_{l=1}^n i_l = r$, $\sum_{l=1}^n j_l = s$, and $r + s \geq 2$. Let δ_{ij} be the Kronecker symbol, i.e., $\delta_{ij} = 0$ if $i \neq j$ and $\delta_{ij} = 1$ if $i = j$. Then*

$$\begin{aligned}[gD_1^{i_1} \cdots D_n^{i_n}, hD_1^{j_1} \cdots D_n^{j_n}] \\ = \sum_{l=1}^n \left(i_l g \frac{\partial h}{\partial x_l} - j_l h \frac{\partial g}{\partial x_l}\right) D_1^{i_1+j_1-\delta_{1l}} \cdots D_n^{i_n+j_n-\delta_{nl}}, \quad \text{mod } U_{r+s-2}.\end{aligned} \tag{3.8}$$

Proof. If $r + s = 2$, there are two cases:

$$[gD_iD_j, h] = -[h, gD_iD_j] = g\frac{\partial h}{\partial x_j}D_i + g\frac{\partial h}{\partial x_i}D_j + g\frac{\partial^2 h}{\partial x_i \partial x_j}, \tag{3.9}$$

$$[gD_i, hD_j] = -[hD_j, gD_i] = gh\omega_{ij} + g\frac{\partial h}{\partial x_i}D_j - h\frac{\partial g}{\partial x_j}D_i. \tag{3.10}$$

Clearly, (3.8) holds for these two cases. Induction on $r + s$ is used to prove (3.8).

If $r + s > 2$, at least one of r and s is greater than 0. Without loss of generality, assume $r > 0$. (In the case where $r = 0$ and $s > 0$, by using the property $[A, B] = -[B, A]$, the same procedure applies below.) Since $\sum_{l=1}^n i_l = r > 0$, at least one i_l is no less than 1. Assume $i_k \geq 1$. By Lemma 2.8, $gD_1^{i_1} \cdots D_k^{i_k} \cdots D_n^{i_n} = D_k g D_1^{i_1} \cdots D_k^{i_k - 1} \cdots D_n^{i_n}$, mod U_{r-1}. Hence,

$$gD_1^{i_1} \cdots D_k^{i_k} \cdots D_n^{i_n} = D_k g D_1^{i_1} \cdots D_k^{i_k - 1} \cdots D_n^{i_n} + A, \tag{3.11}$$

where $A \in U_{r-1}$. By the assumption of the induction, $[A, hD_1^{j_1} \cdots D_n^{j_n}] \in U_{r+s-2}$, since each term of A has order less than or equal to $r-1$. Therefore,

$$
\begin{aligned}
&[gD_1^{i_1} \cdots D_n^{i_n}, hD_1^{j_1} \cdots D_n^{j_n}] \\
&= [D_k g D_1^{i_1} \cdots D_k^{i_k - 1} \cdots D_n^{i_n}, hD_1^{j_1} \cdots D_n^{j_n}] \\
&= D_k [gD_1^{i_1} \cdots D_k^{i_k - 1} \cdots D_n^{i_n}, hD_1^{j_1} \cdots D_n^{j_n}] \\
&\qquad + [D_k, hD_1^{j_1} \cdots D_n^{j_n}] g D_1^{i_1} \cdots D_k^{i_k - 1} \cdots D_n^{i_n} \\
&= D_k \sum_{l=1}^{n} \left((i_l - \delta_{lk}) g \frac{\partial h}{\partial x_l} - j_l h \frac{\partial g}{\partial x_l} \right) D_1^{i_1 + j_1 - \delta_{1l}} \cdots D_k^{i_k + j_k - 1 - \delta_{kl}} \cdots D_n^{i_n + j_n - \delta_{nl}} \\
&\qquad + \frac{\partial h}{\partial x_k} D_1^{j_1} \cdots D_k^{j_k} \cdots D_n^{j_n} g D_1^{i_1} \cdots D_k^{i_k - 1} \cdots D_n^{i_n} \\
&= \sum_{l=1}^{n} \left((i_l - \delta_{lk}) g \frac{\partial h}{\partial x_l} - j_l h \frac{\partial g}{\partial x_l} \right) D_1^{i_1 + j_1 - \delta_{1l}} \cdots D_k^{i_k + j_k - \delta_{kl}} \cdots D_n^{i_n + j_n - \delta_{nl}} \\
&\qquad + g \frac{\partial h}{\partial x_k} D_1^{i_1 + j_1} \cdots D_k^{i_k + j_k - 1} \cdots D_n^{i_n + j_n} \\
&= \sum_{l=1}^{n} \left(i_l g \frac{\partial h}{\partial x_l} - j_l h \frac{\partial g}{\partial x_l} \right) D_1^{i_1 + j_1 - \delta_{1l}} \cdots D_n^{i_n + j_n - \delta_{nl}}, \quad \mod U_{r+s-2}. \qquad \square
\end{aligned}
$$

In fact, (3.8) is still valid for $r + s = 0$ or 1 if the definition of U_k is extended to when $k < 0$, $U_k = \{0\}$, i.e., U_k has just one element 0 when $k < 0$.

A direct result from Lemma 3.1 is that for $A, B \in U$,

$$
ord\ [A, B] \leq ord\ A + ord\ B - 1. \tag{3.12}
$$

Moreover, if $ord\ [A, B] = ord\ A + ord\ B - 1$, the highest order terms of $[A, B]$ are uniquely determined in (3.8) by those of A and B.

The following is a very important theorem on the polynomial structure of coefficient functions of the differential operators in E which generalizes Wong's [22] result.

THEOREM 3.2. *Let E be a finite-dimensional estimation algebra and let the D_i's be defined as in* (3.6). *If $l \geq 0$ and*

$$
A = \sum_{|(i_1, \ldots, i_n)| = l+1} a_{i_1, \ldots, i_n} D_1^{i_1} \cdots D_n^{i_n}, \quad \mod U_l,
$$

is in E, then $a_{i_1, \ldots, i_n}$'s are polynomials.

Proof. If not all the $a_{i_1, \ldots, i_n}$'s are polynomials, at least one, say, $a_{j_1, \ldots, j_n}$, is transcendental. Then there exists a variable x_k in which $a_{j_1, \ldots, j_n}$ is transcendental, i.e., $\frac{\partial^s a_{j_1, \ldots, j_n}}{\partial x_k^s} \neq 0\ \forall s \geq 0$.

Now, among the indices $(j_1, \ldots, j_n)$ of all $a_{j_1, \ldots, j_n}$ that are transcendental in x_k, there exists one $(j_1, \ldots, j_n)$ having the largest kth index j_k. Without loss of generality, assume $k = 1$ and $a_{j_1, \ldots, j_n}$ is transcendental in x_1 and j_1 is the largest among the first indices whose coefficient functions are transcendental in x_1, i.e., if $a_{i_1, \ldots, i_n}$ is

transcendental in x_1 as well, then $j_1 \geq i_1$. Let

$$A_1 = [L_0, A] = \left[L_0, \sum_{|(i_1,\ldots,i_n)|=l+1} a_{i_1,\ldots,i_n} D_1^{i_1} \cdots D_n^{i_n} \right]$$

$$= \sum_{|(i_1,\ldots,i_n)|=l+1} \sum_{r=1}^{n} \frac{\partial a_{i_1,\ldots,i_n}}{\partial x_r} D_1^{i_1} \cdots D_{r-1}^{i_{r-1}} D_r^{i_r+1} D_{r+1}^{i_{r+1}} \cdots D_n^{i_n}, \mod U_{l+1}.$$

The coefficient function of $D_1^{j_1+1} D_2^{j_2} \cdots D_n^{j_n}$ in A_1 is

$$\frac{\partial a_{j_1,j_2,\ldots,j_n}}{\partial x_1} + \frac{\partial a_{j_1+1,j_2-1,\ldots,j_n}}{\partial x_2} + \cdots + \frac{\partial a_{j_1+1,j_2,\ldots,j_n-1}}{\partial x_n}. \tag{3.13}$$

Since j_1 is the largest first index such that a is transcendental in x_1, except that the first term in (3.13) is transcendental in x_1, the other $(n-1)$ terms are all polynomials in x_1. Hence, the coefficient function (3.13) of $D_1^{j_1+1} D_2^{j_2} \cdots D_n^{j_n}$ is transcendental in x_1.

Similarly, let $|(i_1, \ldots, i_n)| = l+2$, $i_1 \geq j_1+2$, and consider the coefficient functions of $D_1^{i_1} D_2^{i_2} \cdots D_n^{i_n}$ in A_1. Their coefficient functions are the sum of $\frac{\partial a_{p_1,p_2,\ldots,p_n}}{\partial x_q}$, where $|(p_1, \ldots, p_n)| = l+1$ and $p_1 \geq j_1 + 1$. By assumption on the a's, these functions are all polynomials in x_1.

Thus, from A to A_1, the differential orders increase by 1, while the transcendental structure on x_1 remains unchanged. The coefficient function of $D_1^{j_1+1} D_2^{j_2} \cdots D_n^{j_n}$ in A_1 is transcendental in x_1 and $j_1 + 1$ is the largest first indices whose coefficient functions are transcendental in x_1. (Note that there may exist other a's having this property, but they must have different numbers in another index, say the nth index. These terms are linearly independent.)

By keeping this process, $A_2 = [L_0, A_1], A_3 = [L_0, A_2], \ldots$. A_k has order of $l + k + 1 \to \infty$. Contradiction! □

3.2. Linear rank and quadratic rank. Unlike estimation algebras of maximal rank (cf. Definition 2.6), it is not clear whether x_i's are elements of a general estimation algebra E. Moreover, 1 may not be in E either. To simplify the situation, the concept of linear rank is introduced in this section together with quadratic rank to explore the structure of the function elements in E. In what follows, dim E is denoted the dimension of the estimation algebra E. For a polynomial ϕ, $\phi^{(k)}$ denotes its homogeneous degree k part.

THEOREM 3.3. *Let $E = \langle L_0, h_1, \ldots, h_m \rangle_{L.A.}$ and $\bar{E} = \langle 1, L_0, h_1, \ldots, h_m \rangle_{L.A.}$. Then E is finite-dimensional if and only if $\bar{E}$ is finite-dimensional.*

Proof. Since $E \subset \bar{E}$, it suffices to show dim $\bar{E}$ − dim $E \leq 1$ if dim $E < \infty$.

Start from the generators of $\bar{E}$ to construct increasing subsets A_k of $\bar{E}$, as follows:

- $A_0 = \{1, L_0, h_1, \ldots, h_m\}$;
- for $k \geq 1$, $A_k = \{a_1 B_1 + a_2 B_2 + a_3 [B_3, B_4] : a_i \in R, B_j \in A_{k-1}, i = 1, 2, 3, j = 1, 2, 3, 4\}$.

Clearly $A_k \nearrow \bar{E}$ as $k \to \infty$. Now, assume that dim $E < \infty$. Let vector space $E^* = E + 1 := \{aX + b : X \in E, a, b \in R\}$. It is easy to show by induction that

$A_k \subset E^*$ for $k \geq 0$. Thus,

$$\bar{E} = \cup_{k\geq 0} A_k \subset E^*,$$

which means

$$\dim \bar{E} \leq \dim E^* \leq \dim E + 1. \qquad \square$$

Thus, the estimation algebra E of a filtering problem being finite-dimensional is equivalent to the finite-dimensionality of $\langle E, 1\rangle_{L.A.}$. In the discussion of the finite-dimensionality of E, 1 can always be assumed an element of E.

Under the assumption that $1 \in E$, any degree 1 polynomial in $E \Longrightarrow$ its homogeneous degree 1 part is in E.

DEFINITION 3.4. *Let $L(E) \subset E$ be the vector space (Lie subalgebra of E) consisting of all the homogeneous degree* 1 *polynomials in E. Then $\nu(E) := \dim L(E)$ is called the linear rank of the estimation algebra E.*

From this definition, an estimation algebra of maximal rank is in fact an estimation algebra with linear rank n.

Note that an estimation algebra is associated with a filtering system and is coordinate-dependent. The recognition of the structurally equivalent estimation algebras is very important in the classification problem. Since an estimation algebra is essentially a Lie algebra, the definitions of homomorphism and isomorphism of estimation algebras follow from those of Lie algebras. It is shown in [2], [8], and [14] that orthogonal variable transformation and affine transformations extend to estimation algebra isomorphisms.

Let $\nu(E) = r$. Clearly $r \leq n$ and there exist r independent linear functions (the basis of L) $l_1(x), \ldots, l_r(x)$ such that

$$(l_1(x), \ldots, l_r(x))^T = Ax,$$

where A is an $r \times n$ matrix with rank r. From the singular value decomposition theorem, there exist orthogonal matrices $U(r \times r)$, $V(n \times n)$ such that

$$A = U[D \quad 0]V^T,$$

where $D = \operatorname{diag}(d_1, \ldots, d_r)$, with $d_1, \ldots, d_r \neq 0$ the singular values of A. Thus,

$$U^T Ax = U^T AV(V^T x) = [D \quad 0]V^T x.$$

After an orthogonal change of the variable $y = V^T x$, it is easy to see that for $1 \leq i \leq r$, y_i is a linear combination of $l_j(x)$ $(1 \leq j \leq r)$. In view of $\nu(E) = r$, $\{y_i, 1 \leq i \leq r\}$ is the basis of $L(E)$.

Hence, by an orthogonal variable transformation, if necessary, a linear function l is in E if and only if

$$l(x) \in L(E) := span\{x_1, \ldots, x_r\}.$$

DEFINITION 3.5. *For a given function $h \in E$, its quadratic part $h^{(2)} = x^T Ax$ for a symmetric matrix A. The quadratic rank $\lambda(h)$ of h is defined as the rank of A. The quadratic rank $\lambda(E)$ of E is the greatest quadratic rank of $h \in E$, i.e., $\lambda(E) = \max_{h\in E} \lambda(h)$.*

LEMMA 3.6. *Let E be an estimation algebra with linear rank r and $\phi \in E$. Then the quadratic part of ϕ is*

$$\phi^{(2)} = x^T \begin{pmatrix} A_1 & 0 \\ 0 & A_2 \end{pmatrix} x,$$

where A_1 and A_2 are symmetric matrices with dimensions $r \times r$ and $(n-r)\times(n-r)$.

Proof. $\phi^{(2)}$ is a degree 2 homogeneous polynomial; therefore it can be written as $\phi^{(2)} = x^T A x$ for a symmetric matrix $A = (a_{ij})$ of dimension $n \times n$.

Since $\nu(E) = r$, $x_i \in E$ if and only if $1 \le i \le r$. For $1 \le i \le r$, $[L_0, x_i] = D_i \in E$, and

$$[D_i, \phi] = \frac{\partial \phi}{\partial x_i} = 2\sum_{j=1}^{n} a_{ij} x_j \in E, \qquad \text{mod } R.$$

Hence, $a_{ij} = 0$ for $r+1 \le j \le n$, $1 \le i \le r$. By the symmetry of A, the lemma follows. □

Now, consider an estimation algebra E with linear rank r and quadratic rank k. From the definition of the quadratic rank of E, there exists $p_0 \in E$ such that the quadratic rank of p_0 is k. By Lemma 3.6, $p_0^{(2)}(x) = x^T \left(\begin{smallmatrix} A_1 & 0 \\ 0 & A_2 \end{smallmatrix}\right) x$. Let $k_1 = \operatorname{rank}(A_1)$, $k_2 = \operatorname{rank}(A_2)$. Then $k = k_1 + k_2$, $0 \le k_1 \le r$, and $0 \le k_2 \le n-r$. Since A_1 and A_2 are real symmetric, there are orthogonal matrices U_1 and U_2 such that $A_1 = U_1 \left(\begin{smallmatrix} D_1 & 0 \\ 0 & 0 \end{smallmatrix}\right) U_1^T$ and $A_2 = U_2 \left(\begin{smallmatrix} 0 & 0 \\ 0 & D_2 \end{smallmatrix}\right) U_2^T$, where D_1 and D_2 are nonsingular diagonal matrices with dimensions $k_1 \times k_1$ and $k_2 \times k_2$. By taking the orthogonal variable transformation $T = \left(\begin{smallmatrix} U_1 & 0 \\ 0 & U_2 \end{smallmatrix}\right)$, $p_0^{(2)} = \sum_{i=1}^{k_1} d_i x_i^2 + \sum_{i=n-k_2+1}^{n} d_i x_i^2$, where $d_i \ne 0$. Moreover, by an affine variable transformation, if necessary,

$$p_0 = \sum_{i=1}^{k_1} d_i x_i^2 + \sum_{i=n-k_2+1}^{n} d_i x_i^2 + \sum_{i=k_1+1}^{n-k_2} c_i x_i + c_0 \in E \tag{3.14}$$

$$\Longrightarrow [[L_0, p_0], p_0] = \sum_{i=1}^{k_1} 4 d_i^2 x_i^2 + \sum_{i=n-k_2+1}^{n} 4 d_i^2 x_i^2 + \sum_{i=k_1+1}^{n-k_2} c_i^2 \in E$$

$$\Longrightarrow q_0 := \sum_{i=1}^{k_1} d_i^2 x_i^2 + \sum_{i=n-k_2+1}^{n} d_i^2 x_i^2 \in E, \tag{3.15}$$

$$\Longrightarrow q_j := [[L_0, q_{j-1}], q_{j-1}] = \sum_{i=1}^{k_1} 4^j d_i^{2j+2} x_i^2 + \sum_{i=n-k_2+1}^{n} 4^j d_i^{2j+2} x_i^2 \in E, \quad j \ge 1. \tag{3.16}$$

If no d_i^2's are equal, then the coefficient matrix of (3.16) for x_i^2 forms a Vandermonde matrix. By the invertibility of the Vandermonde matrix, x_i^2 can be represented as a linear combination of q_j's, and therefore $x_i^2 \in E$. Hence,

$$\sum_{i=1}^{k_1} x_i^2 + \sum_{i=n-k_2+1}^{n} x_i^2 \in E. \tag{3.17}$$

If some d_i^2's are equal, for example, d_i^2's equal for $l_1 \le i \le l_2$ in (3.14), they can be grouped to be solved as one variable. Instead of individual $x_i^2 \in E$ for $l_1 \le i \le l_2$, $x_{l_1}^2 + \cdots + x_{l_2}^2 \in E$ is obtained as a group under the above Vandermonde argument.

In any case, (3.17) can be constructed as long as the quadratic rank of E is k. An important observation is that both orthogonal variable transformation so used and affine variable transformation do not change the basis of $L(E)$. In summary, we have the following.

THEOREM 3.7. *Let E be a finite-dimensional estimation algebra with linear rank r and quadratic rank k.*

There exists $p_0 = \sum_{i=1}^{k_1} x_i^2 + \sum_{i=n-k_2+1}^{n} x_i^2 \in E$, where $k_1 + k_2 = k$, $k_1 \leq r$, and $k_2 \leq n - r$.

If $\phi \in E$ is a degree 1 polynomial, then ϕ is independent of $x_{r+1}, \ldots, x_n$.

If $\phi \in E$ is a degree 2 polynomial, then $\phi^{(2)}$ is independent of $x_{k_1+1}, \ldots, x_{n-k_2}$.

3.3. Euler operator. As discussed in section 3.1, the finite-dimensionality of an estimation algebra relies on the order of the differential operators as well as the coefficient functions. The conditions on the constructible differential operators with bounded order are shifted to those on the coefficient functions to ensure the finite-dimensionality. Thus, it is important to extract the conditions on some primary characteristics such as ω_{ij}'s from some transformations. The Euler operator (see Definition 3.8) is one of such transformations that occur frequently, especially when a quadratic polynomial is assumed to be an element of the estimation algebra. This section studies the properties of the inverse image of the Euler operators. The results obtained in this section generalize the results discussed in [18] and [27].

DEFINITION 3.8. *Let l be a positive integer such that $l \leq n$. The Euler operator $E_l(\cdot)$ is defined to be a differential operator such that*

$$E_l(\phi) = \sum_{i=1}^{l} x_i \frac{\partial \phi}{\partial x_i}$$

for any $\phi \in C^\infty(R^n)$.

In the case $l = n$, $E(\cdot)$ is used instead of $E_n(\cdot)$.

LEMMA 3.9. *Let $m > 0$ be a positive integer and $\zeta \in C^\infty(R^n)$. If $E_l(\zeta) + m\zeta = 0$, then $\zeta = 0$.*

Proof. Let $\phi = x_1^m \zeta$. Then

$$E_l(\phi) = \sum_{i=1}^{l} x_i \frac{\partial}{\partial x_i}(x_1^m \zeta) = m x_1^m \zeta + x_1^m \sum_{i=1}^{l} x_i \frac{\partial \zeta}{\partial x_i} = x_1^m (m\zeta + E_l(\zeta)) = 0, \tag{3.18}$$

$$\begin{aligned} &\phi(x_1, \ldots, x_l, \ldots, x_n) - \phi(\epsilon x_1, \ldots, \epsilon x_l, x_{l+1}, \ldots, x_n) \\ &= \int_\epsilon^1 \frac{d\phi}{dt}(tx_1, \ldots, tx_l, x_{l+1}, \ldots, x_n) dt \\ &= \int_\epsilon^1 \sum_{i=1}^{l} x_i \frac{\partial \phi}{\partial x_i}(tx_1, \ldots, tx_l, x_{l+1}, \ldots, x_n) dt \end{aligned}$$

$$= \int_\epsilon^1 \frac{1}{t}(E_l(\phi))(tx_1, \ldots, tx_l, x_{l+1}, \ldots, x_n) dt = \int_\epsilon^1 \frac{0}{t} dt = 0. \tag{3.19}$$

Hence, $\phi(x_1, \ldots, x_l, \ldots, x_n) = \epsilon^m x_1^m \zeta(\epsilon x_1, \ldots, \epsilon x_l, x_{l+1}, \ldots, x_n)$. Since $\zeta \in C^\infty(R^n)$, the limit $\lim_{\epsilon \to 0} \zeta(\epsilon x_1, \ldots, \epsilon x_l, x_{l+1}, \ldots, x_n)$ exists. By letting $\epsilon \to 0$, one has that $\phi = 0 \Longrightarrow \zeta = 0$. □

LEMMA 3.10. *Let $\zeta \in C^\infty(R^n)$. If $E_l(\zeta) = 0$, then ζ is a C^∞-function in $x_{l+1}, \ldots, x_n$ variables.*

Proof. For $1 \le j \le l$,

$$\frac{\partial}{\partial x_j} E_l(\zeta) = \frac{\partial \zeta}{\partial x_j} + E_l\left(\frac{\partial \zeta}{\partial x_j}\right) = 0. \tag{3.20}$$

By Lemma 3.9, $\frac{\partial \zeta}{\partial x_j} = 0$. Therefore, ζ is independent of $x_1, \ldots, x_l$. □

LEMMA 3.11. *Let $m > 0$ be a positive integer and $\zeta \in C^\infty(R^n)$. If $E_l(\zeta) - m\zeta = 0$, then ζ is either 0 or a degree m homogeneous polynomial in $x_1, \ldots, x_l$ variables with coefficients in C^∞-functions of $x_{l+1}, \ldots, x_n$ variables.*

Proof. Let $D = (\frac{\partial}{\partial x_1})^{\alpha_1} \cdots (\frac{\partial}{\partial x_l})^{\alpha_l}$ with $\sum_{i=1}^{l} \alpha_i = m$.

By induction,

$$D(E_l(\zeta)) = E_l(D\zeta) + mD\zeta. \tag{3.21}$$

Hence, $E_l(D\zeta) = D(E_l(\zeta) - m\zeta) = 0$. By Lemma 3.10 $D\zeta$ is a C^∞-function in $x_{l+1}, \ldots, x_n$ variables. This means that ζ is a polynomial of degree $s \le m$ in $x_1, \ldots, x_l$ variables with coefficients in C^∞-functions of $x_{l+1}, \ldots, x_n$ variables.

Let $\zeta = \sum_{0 \le |i| \le s} a_{i_1 \cdots i_l}(x_{l+1}, \ldots, x_n) x_1^{i_1} \cdots x_l^{i_l}$. Then

$$\begin{aligned}
E_l(\zeta) - m\zeta &= E_l\left(\sum_{0 \le |i| \le s} a_{i_1 \cdots i_l}(x_{l+1}, \ldots, x_n) x_1^{i_1} \cdots x_l^{i_l}\right) \\
&\quad - m \sum_{0 \le |i| \le s} a_{i_1 \cdots i_l}(x_{l+1}, \ldots, x_n) x_1^{i_1} \cdots x_l^{i_l} \\
&= \sum_{0 \le |i| \le s} |i| a_{i_1 \cdots i_l}(x_{l+1}, \ldots, x_n) x_1^{i_1} \cdots x_l^{i_l} \\
&\quad - m \sum_{0 \le |i| \le s} a_{i_1 \cdots i_l}(x_{l+1}, \ldots, x_n) x_1^{i_1} \cdots x_l^{i_l} \\
&= \sum_{0 \le |i| \le s} (|i| - m) a_{i_1 \cdots i_l}(x_{l+1}, \ldots, x_n) x_1^{i_1} \cdots x_l^{i_l} \\
&= 0. \qquad (3.22)
\end{aligned}$$

Thus, every term $(|i| - m) a_{i_1 \cdots i_l}(x_{l+1}, \ldots, x_n)$ must be 0. If $\zeta \neq 0$, s must be equal to m while $a_{i_1 \cdots i_l}(x_{l+1}, \ldots, x_n) = 0$ for $|i| < m$. □

LEMMA 3.12. *Let m be a constant integer and $\zeta \in C^\infty(R^n)$ such that $E_l(\zeta) + m\zeta$ is a polynomial of degree k (≥ 0) in $x_1, \ldots, x_l$ variables with coefficients in C^∞-functions of $x_{l+1}, \ldots, x_n$ variables. If ζ is a polynomial of degree s in $x_1, \ldots, x_l$ variables with coefficients in C^∞-functions of $x_{l+1}, \ldots, x_n$, then $s \ge k$.*

Proof. Let $\zeta = \sum_{0 \le |i| \le s} a_{i_1 \cdots i_l}(x_{l+1}, \ldots, x_n) x_1^{i_1} \cdots x_l^{i_l}$. By repeating the same process in (3.22),

$$E_l(\zeta) + m\zeta = \sum_{0 \le |i| \le s} (|i| + m) a_{i_1 \cdots i_l}(x_{l+1}, \ldots, x_n) x_1^{i_1} \cdots x_l^{i_l}. \tag{3.23}$$

For $E_l(\zeta) + m\zeta$ to be a polynomial of degree k in $x_1, \ldots, x_l$ variables with coefficients in C^∞-functions of $x_{l+1}, \ldots, x_n$ variables, s must be no less than k. □

THEOREM 3.13. *Let m be a constant integer and $\zeta \in C^\infty(R^n)$ such that $E_l(\zeta) + m\zeta$ is a polynomial of degree k (≥ 0) in $x_1, \ldots, x_l$ variables with coefficients in C^∞-functions of $x_{l+1}, \ldots, x_n$ variables.*

If $m + k + 1 > 0$, ζ is a polynomial of degree k in $x_1, \ldots, x_l$ variables with coefficients in C^∞-functions of $x_{l+1}, \ldots, x_n$.

If $m + k + 1 \leq 0$, ζ is a polynomial of degree k or degree $-m$ ($\geq k + 1 > 0$) in $x_1, \ldots, x_l$ variables with coefficients in C^∞-functions of $x_{l+1}, \ldots, x_n$.

Proof. Let $D = (\frac{\partial}{\partial x_1})^{\alpha_1} \cdots (\frac{\partial}{\partial x_l})^{\alpha_l}$ with $\sum_{i=1}^{l} \alpha_i = k + 1 \geq 1$. Since $E_l(\zeta) + m\zeta$ is a polynomial of degree k in $x_1, \ldots, x_l$ variables with coefficients in C^∞-functions of $x_{l+1}, \ldots, x_n$ variables,

$$D(E_l(\zeta) + m\zeta) = D(E_l(\zeta)) + mD\zeta = 0. \tag{3.24}$$

On the other hand, by (3.21),

$$D(E_l(\zeta)) = E_l(D\zeta) + (k + 1)D\zeta. \tag{3.25}$$

By (3.24) and (3.25),

$$E_l(D\zeta) + (m + k + 1)D\zeta = 0. \tag{3.26}$$

Now, there are three cases:

(i) $m + k + 1 > 0$. By Lemma 3.9, $D\zeta = 0$. This means that ζ is a polynomial of degree $\leq k$ in $x_1, \ldots, x_l$ variables with coefficients in C^∞-functions of $x_{l+1}, \ldots, x_n$ variables. By Lemma 3.12, ζ is a polynomial of degree k in $x_1, \ldots, x_l$ variables with coefficients in C^∞-functions of $x_{l+1}, \ldots, x_n$ variables.

(ii) $m + k + 1 = 0$. By Lemma 3.10, $D\zeta$ is 0 or a nonzero C^∞-function in $x_{l+1}, \ldots, x_n$. Thus, ζ is a polynomial of degree $\leq k + 1$ in $x_1, \ldots, x_l$ variables with coefficients in C^∞-functions of $x_{l+1}, \ldots, x_n$. By Lemma 3.12, ζ is a polynomial of degree k or $k + 1$ ($= -m$) in $x_1, \ldots, x_l$ variables with coefficients in C^∞-functions of $x_{l+1}, \ldots, x_n$ variables.

(iii) $m + k + 1 < 0$ ($m < -k - 1 < 0$). Let $m' = -(m + k + 1) > 0$. Then (3.26) becomes $E_l(D\zeta) - m'D\zeta = 0$. By Lemma 3.11, $D\zeta$ is either 0 or a degree m' homogeneous polynomial in $x_1, \ldots, x_l$ variables with coefficients in C^∞-functions of $x_{l+1}, \ldots, x_n$ variables. If it is the latter case, ζ is a polynomial of degree $(k+1)+m' = -m > 0$ in $x_1, \ldots, x_l$ variables with coefficients in C^∞-functions of $x_{l+1}, \ldots, x_n$. If $D\zeta = 0$, ζ is a polynomial of degree at most k in $x_1, \ldots, x_l$ variables with coefficients in C^∞-functions of $x_{l+1}, \ldots, x_n$ variables. By combining these two situations with Lemma 3.12, ζ is a polynomial of degree k or degree $-m$ in $x_1, \ldots, x_l$ variables with coefficients in C^∞-functions of $x_{l+1}, \ldots, x_n$ variables since $-m > k$. ∎

THEOREM 3.14. *Let m be a constant integer and $\zeta \in C^\infty(R^n)$ such that $E_l(\zeta) + m\zeta = \varphi$, where φ is a C^∞-function in $x_{l+1}, \ldots, x_n$ variables.*

If $m > 0$, then $\zeta = \frac{1}{m}\varphi$.

If $m = 0$, then $\varphi = 0 \Longrightarrow \zeta$ is a C^∞-function in $x_{l+1}, \ldots, x_n$ variables.

If $m \leq -1$, then $\zeta = \xi + \frac{1}{m}\varphi$, where ξ is either 0 or a degree $-m$ homogeneous polynomial in $x_1, \ldots, x_l$ variables with coefficients in C^∞-functions of $x_{l+1}, \ldots, x_n$ variables.

Proof. (i) If $m + 1 > 0$, by Theorem 3.13, ζ is a C^∞-function in $x_{l+1}, \ldots, x_n$ variables $\Longrightarrow E_l(\zeta) = 0 \Longrightarrow m\zeta = \varphi \Longrightarrow \zeta = \frac{1}{m}\varphi$ if $m \neq 0$; $\varphi = 0$ if $m = 0$.

(ii) $m \leq -1$. Let $\xi = \zeta - \frac{1}{m}\varphi$. Then $E_l(\xi) + m\xi = 0$. By Lemma 3.11, ξ is either 0 or a degree $-m$ homogeneous polynomial in $x_1, \ldots, x_l$ variables with coefficients in C^∞-functions of $x_{l+1}, \ldots, x_n$ variables. ∎

THEOREM 3.15. *Let m be a constant integer and $\zeta \in C^\infty(R^n)$ such that $E_l(\zeta) + m\zeta \in P_k(x_1, \ldots, x_n)$, a polynomial of degree $k \geq 0$ in $x_1, \ldots, x_n$ variables.*

If $m > 0$, $\zeta \in P_k(x_1, \ldots, x_n)$.

If $m = 0$, $\zeta \in P_k(x_1, \ldots, x_n) + a(x_{l+1}, \ldots, x_n)$, where $a(x_{l+1}, \ldots, x_n)$ is a C^∞-function in $x_{l+1}, \ldots, x_n$ variables.

Proof. By Theorem 3.13, $\zeta = \sum_{0 \leq |i| \leq k} a_{i_1 \cdots i_l}(x_{l+1}, \ldots, x_n) x_1^{i_1} \cdots x_l^{i_l}$ for $m \geq 0$. By (3.23)

$$E_l(\zeta) + m\zeta = \sum_{0 \leq |i| \leq k} (|i| + m) a_{i_1 \cdots i_l}(x_{l+1}, \ldots, x_n) x_1^{i_1} \cdots x_l^{i_l}. \tag{3.27}$$

If $m > 0$, $|i| + m > 0 \Longrightarrow a_{i_1 \cdots i_l}(x_{l+1}, \ldots, x_n)$ must be a polynomial of degree less than or equal to $k - \sum_{j=1}^{l} i_j$ in $x_{l+1}, \ldots, x_n$ variables since $x_1^{i_1} \cdots x_l^{i_l}$'s are linearly independent.

If $m = 0$, only when $|i| = 0$, i.e., when $i_1 = \cdots = i_l = 0$, $a_{i_1 \cdots i_l}(x_{l+1}, \ldots, x_n)$ may not be a polynomial. □

3.4. Underdetermined partial differential equation. From Theorems 2.5 and 2.7, for the finite-dimensional estimation algebras of maximal rank, $F = \eta - \sum_{i=1}^{m} h_i^2$ must be a polynomial of degree at most 2. Notice that the filtering system (2.1) is completely parameterized by the pair, (f, h). It follows by (2.5) that the underdetermined partial differential equation

$$\sum_{i=1}^{n} \frac{\partial f_i}{\partial x_i} + \sum_{i=1}^{n} f_i^2 = F \tag{3.28}$$

provides a complete characterization of the realization set of such systems. Therefore, it is of primary interest to investigate the solution and solution properties for this class of equations.

In (3.28), $f_1, \ldots, f_n$ and F are C^∞-functions on R^n. F is given and $f_1, \ldots, f_n$ are treated as unknown. Although there is only one equation with n unknowns, (3.28) may not have solutions. The following important result can be found in [24].

THEOREM 3.16 (see [24]). *Let $F(x_1, \ldots, x_n)$ be a C^∞-function on R^n. Suppose that there exists a path $c : R \to R^n$ and $\delta > 0$ such that $\lim_{t \to \infty} \|c(t)\| = \infty$ and $\lim_{t \to \infty} \sup_{B_\delta(c(t))} F = -\infty$, where $B_\delta(c(t)) = \{x \in R^n : \|x - c(t)\| < \delta\}$. Then there are no C^∞-functions $f_1, f_2, \ldots, f_n$ on R^n satisfying* (3.28).

The following results are applications of Theorem 3.16 that will be used in the classification problems.

THEOREM 3.17. *Let $F(x_1, \ldots, x_n)$ be a polynomial on R^n, let $c(t) = (c_1(t), \ldots, c_n(t))$ be a polynomial path (i.e., $c_i(t)$'s are polynomials in t), and let $\epsilon = (\epsilon_1, \ldots, \epsilon_n)$. Then $F(c(t) + \epsilon)$ is a polynomial in t, i.e., $F(c(t) + \epsilon) = \sum_{j=0}^{d} a_j(\epsilon) t^j$, where $a_j(\epsilon)$'s are polynomials of $\epsilon_1, \ldots, \epsilon_n$. If there exists a path $c(t)$ such that the coefficient $a_d(\epsilon)$ of the leading term of $F(c(t) + \epsilon)$ is a negative constant and $d \geq 1$, there are no C^∞-functions $f_1, f_2, \ldots, f_n$ on R^n satisfying the equation*

$$\sum_{i=1}^{n} \frac{\partial f_i}{\partial x_i} + \sum_{i=1}^{n} f_i^2 = F. \tag{3.29}$$

Proof. Suppose $a_d(\epsilon) = a_d$ is a negative constant with $d \geq 1$. It is clear that $\lim_{t\to\infty} \|c(t)\| = \infty$.

For $0 \leq j \leq d-1$, $a_j(\epsilon)$ is a polynomial in $\epsilon_1, \ldots, \epsilon_n$. By continuity, there exists a $\delta > 0$ and a ball $B_\delta(0) = \{\epsilon \in R^n \ : \ \|\epsilon\| < \delta\}$, such that for any $\epsilon \in B_\delta(0)$, the following bounds hold:

$$|a_j(\epsilon) - a_j(0)| \leq 1 \qquad \forall 0 \leq j \leq d-1. \tag{3.30}$$

It follows that for $t > 0$,

$$\sup_{B_\delta(c(t))} F(x_1, \ldots, x_n) = \sup_{\epsilon\in B_\delta(0)} F(c(t)+\epsilon) = \sup_{\epsilon\in B_\delta(0)} a_d t^d + \sum_{j=0}^{d-1} a_j(\epsilon) t^j$$

$$\leq a_d t^d + \sum_{j=0}^{d-1} (1 + a_j(0)) t^j \longrightarrow -\infty \quad \text{as } t \to \infty,$$

since $a_d < 0$ and $d \geq 1$. The assertion follows immediately by Theorem 3.16. □

THEOREM 3.18. *Let $F(x_1, \ldots, x_n)$ be a degree $d \geq 1$ polynomial on R^n. The homogeneous degree d part of F is denoted by $F_d = \sum_{|i|=d} a_i x_1^{i_1} \cdots x_n^{i_n}$, where $i = (i_1, \ldots, i_n)$. If there exist n numbers $b_1, \ldots, b_n$ such that $F_d(b_1, \ldots, b_n) < 0$, there are no C^∞-functions $f_1, f_2, \ldots, f_n$ on R^n satisfying* (3.29).

Proof. By taking the polynomial path $c(t) = (b_1 t, \ldots, b_n t)$ one has that $F(c(t)+\epsilon)$ is a degree d polynomial in t and the coefficient of t^d in $F(c(t)+\epsilon)$ is a negative constant $F_d(b_1, \ldots, b_n) < 0$. The proof is concluded by using Theorem 3.17. □

COROLLARY 3.19. *Let $F(x_1, \ldots, x_n)$ be a polynomial on R^n. If the degree of F is odd, there are no C^∞-functions $f_1, f_2, \ldots, f_n$ on R^n satisfying* (3.29).

COROLLARY 3.20. *Let $F(x_1, \ldots, x_n)$ be a degree $d \geq 1$ polynomial on R^n. If there exist C^∞-functions $f_1, f_2, \ldots, f_n$ on R^n satisfying* (3.29)*, the homogeneous degree d part of F is a nonnegative function.*

In fact, the above theorems can be further generalized to the case when F is a polynomial in $x_1, \ldots, x_r$ variables with C^∞ coefficient functions in $x_{r+1}, \ldots, x_n$. For example, we have the following.

THEOREM 3.21. *Let d and $r \leq n$ be two positive integers and*

$$F(x_1, \ldots, x_n) = \sum_{|i|\leq d} a_i(x_{r+1}, \ldots, x_n) x_1^{i_1} \cdots x_r^{i_r},$$

where $i = (i_1, \ldots, i_r)$, and where a_i's are C^∞-functions in $x_{r+1}, \ldots, x_n$ variables. The homogeneous degree d part in $x_1, \ldots, x_r$ variables of F is denoted by $F_d = \sum_{|i|=d} a_i(x_{r+1}, \ldots, x_n) x_1^{i_1} \cdots x_r^{i_r}$. If there exist n numbers $b_1, \ldots, b_n$ such that $F_d(b_1, \ldots, b_n) < 0$, there are no C^∞-functions $f_1, f_2, \ldots, f_n$ on R^n satisfying (3.29).

Proof. Take the path $c(t) = (b_1 t, \ldots, b_r t, b_{r+1}, \ldots, b_n)$. Clearly $\lim_{t\to\infty} \|c(t)\| \to \infty$ since $F_d(b_1, \ldots, b_n) < 0$.

Let $\epsilon = (\epsilon_1, \ldots, \epsilon_n)$. Then $F(c(t) + \epsilon)$ is a polynomial in t,

$$F(c(t) + \epsilon) = F_d(b_1, \ldots, b_r, b_{r+1} + \epsilon, \ldots, b_n + \epsilon) t^d + \sum_{j=0}^{d-1} c_j(\epsilon) t^j.$$

By continuity, there exist a $\delta > 0$ and a ball $B_\delta(0) = \{\epsilon \in R^n \ : \ \|\epsilon\| < \delta\}$, such that for any $\epsilon \in B_\delta(0)$, the following bounds hold:

$$F_d(b_1,\dots,b_r,b_{r+1}+\epsilon,\dots,b_n+\epsilon) \le \frac{1}{2}F_d(b_1,\dots,b_n) < 0,$$
$$|c_j(\epsilon)-c_j(0)| \le 1 \qquad \forall 0 \le j \le d-1.$$

It follows that for $t > 0$,

$$\begin{aligned}\sup_{B_\delta(c(t))} F(x_1,\dots,x_n) &= \sup_{\epsilon\in B_\delta(0)} F(c(t)+\epsilon)\\ &= \sup_{\epsilon\in B_\delta(0)} F_d(b_1,\dots,b_r,b_{r+1}+\epsilon,\dots,b_n+\epsilon)t^d + \sum_{j=0}^{d-1} c_j(\epsilon)t^j\\ &\le \frac{1}{2}F_d(b_1,\dots,b_n)t^d + \sum_{j=0}^{d-1}(1+c_j(0))t^j \longrightarrow -\infty, \quad \text{as } t\to\infty,\end{aligned}$$

since $F_d(b_1,\dots,b_n) < 0$ and $d \ge 1$. The assertion follows immediately by Theorem 3.16. □

4. Classification of estimation algebras $n = 2$. In this section, the state dimension is assumed to be $n = 2$, i.e., there are two state variables x_1 and x_2. The estimation algebra $E = \langle L_0, h_1, \dots, h_m\rangle_{L.A.}$, where

$$L_0 = \frac{1}{2}(D_1^2 + D_2^2 - \eta), \qquad D_i = \frac{\partial}{\partial x_i} - f_i, \quad i = 1,2, \tag{4.1}$$

$$\eta = \sum_{i=1}^{2}\frac{\partial f_i}{\partial x_i} + \sum_{i=1}^{2} f_i^2 + \sum_{i=1}^{m} h_i^2. \tag{4.2}$$

m is assumed to be a positive integer; otherwise $E = \langle L_0\rangle_{L.A.}$ is a one-dimensional estimation algebra. The Ω-matrix is a 2×2 antisymmetric matrix. Therefore, only $\omega_{12} = -\omega_{21}$ is unknown.

By Theorem 3.3, 1 is assumed to be an element of E in the discussion.

4.1. Linear structure of the Ω-matrix.

THEOREM 4.1. *Suppose* $\dim E < \infty$ *and* $Y = p(x)D_2, \mod U_0 \in E$. *Then* p *is a polynomial in* x_1, x_2 *of degree at most* 1.

Proof. By Theorem 3.2, p is a polynomial in x_1, x_2. Let $l = deg\ p$ and $p^{(l)}$ be the homogeneous degree l part of p. Then

$$p^{(l)} = \sum_{i=0}^{l} a_i x_1^{l-i}x_2^i = \sum_{i=s}^{t} a_i x_1^{l-i}x_2^i,$$

where a_i's are constants, $0 \le s \le t \le l$, $a_s \ne 0$, $a_t \ne 0$, and $a_i = 0$ for $i < s$ or $i > t$. Let $Y_k = Ad_{L_0}^k Y$ for $k \ge 0$. By induction,

$$Y_k = Ad_{L_0}^k Y = \sum_{j=0}^{k}\binom{k}{j}\frac{\partial^k p}{\partial x_1^{k-j}\partial x_2^j}D_1^{k-j}D_2^{j+1}, \quad \mod U_k,$$

where $\binom{k}{j}$'s are binomial numbers. In particular,

$$Y_l = \sum_{j=0}^{l}\binom{l}{j}(l-j)!j!a_j D_1^{l-j}D_2^{j+1} = l!\sum_{j=s}^{t} a_j D_1^{l-j}D_2^{j+1}, \quad \mod U_l,$$

and

$$Y_{l-1} = \sum_{j=0}^{l-1} \binom{l-1}{j} \frac{\partial^{l-1} p}{\partial x_1^{l-j-1} \partial x_2^j} D_1^{l-j-1} D_2^{j+1}$$

$$= \sum_{j=0}^{l-1} (l-1)! \Big((l-j) a_j x_1 + (j+1) a_{j+1} x_2 + c_j \Big) D_1^{l-j-1} D_2^{j+1}, \quad \mod U_{l-1},$$

where c_j's are constants from the $(l-1)$th partial derivatives of the homogeneous degree $l-1$ part of p.

Now, depending on whether or not $s = 0$, and in the case when $s = 0$ whether a_1, a_2 are 0, there are four cases for which similar constructions of sequences with different calculations will show that l must be less than 2 if E is finite-dimensional.

(i) *Case* 1. $s \neq 0$.

$$\begin{aligned}
A_0 := Y_{l-1} &= (d_0 x_2 + (l-1)! c_{s-1}) D_1^{l-s} D_2^s \\
&\quad + \text{terms with lower order in } D_1, \quad \mod U_{l-1}, \\
A_1 := Y_l &= d_1 D_1^{l-s} D_2^{s+1} \ + \text{terms with lower order in } D_1, \quad \mod U_l, \\
A_2 := [A_1, A_0] &= (s+1) d_1 d_0 D_1^{2(l-s)} D_2^{2s} \\
&\quad + \text{terms with lower order in } D_1, \quad \mod U_{2l-1}, \\
&\vdots \\
A_{r+1} := [A_r, A_0] &= d_{r+1} D_1^{(r+1)(l-s)} D_2^{(r+1)s-r+1} \\
&\quad + \text{terms with lower order in } D_1, \quad \mod U_{(r+1)l-r},
\end{aligned}$$

where $d_0 = (l-1)! s a_s \neq 0$, $d_1 = l! a_s \neq 0$, and $d_{r+1} = (rs - r + 2) d_r d_0 \neq 0$ for $r \geq 1$. The orders of A_{r+1}'s are $(r+1)l - r + 1 \to \infty$ unless $l < 2$.

(ii) *Case* 2. $s = 0$ and $a_1 \neq 0$.

$$\begin{aligned}
A_0 := Y_{l-1} &= (l! a_0 x_1 + d_0 x_2 + (l-1)! c_0) D_1^{l-1} D_2 \\
&\quad + \text{terms with lower order in } D_1, \quad \mod U_{l-1}, \\
A_1 := Y_l &= d_1 D_1^l D_2 \ + \text{terms with lower order in } D_1, \quad \mod U_l, \\
A_2 := [A_1, A_0] &= d_1 d_0 D_1^{2l-1} D_2 \\
&\quad + \text{terms with lower order in } D_1, \quad \mod U_{2l-1}, \\
&\vdots \\
A_{r+1} := [A_r, A_0] &= d_{r+1} D_1^{(r+1)l-r} D_2 \\
&\quad + \text{terms with lower order in } D_1, \quad \mod U_{(r+1)l-r},
\end{aligned}$$

where $d_0 = (l-1)! a_1 \neq 0$, $d_1 = l! a_0 \neq 0$, and $d_{r+1} = d_r d_0 \neq 0$ for $r \geq 1$. The orders of A_{r+1}'s are $(r+1)l - r + 1 \to \infty$ unless $l < 2$.

(iii) *Case* 3. $s = 0$ and $a_1 = a_2 = 0$.

$$\begin{aligned}
A_0 &:= Y_{l-1} = (d_0x_1 + (l-1)!c_0)D_1^{l-1}D_2 + (l-1)!c_2D_1^{l-2}D_2^2 \\
&\qquad + \text{degree 1 coeff. terms with lower order in } D_1, \quad \mod U_{l-1}, \\
A_1 &:= Y_l = d_1D_1^lD_2 \\
&\qquad + \text{constant coeff. terms with lower order in } D_1, \quad \mod U_l, \\
A_2 &:= [A_1, A_0] = ld_1d_0D_1^{2l-2}D_2^2 \\
&\qquad + \text{constant coeff. terms with lower order in } D_1, \quad \mod U_{2l-1}, \\
&\vdots \\
A_{r+1} &:= [A_r, A_0] = d_{r+1}D_1^{(r+1)l-2r}D_2^{r+1} \\
&\qquad + \text{constant coeff. terms with lower order in } D_1, \quad \mod U_{(r+1)l-r},
\end{aligned}$$

where $d_0 = l!a_0 \neq 0$, $d_1 = l!a_0 \neq 0$, and $d_{r+1} = (rl - 2r + 2)d_rd_0 \neq 0$ for $r \geq 1$ and $l \geq 2$. The orders of A_{r+1}'s are $(r+1)l - r + 1 \to \infty$ unless $l < 2$.

(iv) *Case* 4. $s = 0$, $a_1 = 0$, but $a_2 \neq 0$.

$$Y_l = d_1D_1^lD_2 + d_3D_1^{l-2}D_2^3 \ + \text{terms with lower order in } D_1, \quad \mod U_l,$$

where $d_1 = l!a_0 \neq 0$ and $d_3 = l!a_2 \neq 0$. If $l \geq 2$, consider $Z = [Y_l, pD_2]$ and $A_0 = Ad_{L_0}^{l-2}Z$:

$$\begin{aligned}
Z = [Y_l, pD_2] &= d_1\frac{\partial p}{\partial x_2}D_1^lD_2 + ld_1\frac{\partial p}{\partial x_1}D_1^{l-1}D_2^2 \\
&\qquad + \text{terms with lower order in } D_1, \quad \mod U_l, \\
A_0 = Ad_{L_0}^{l-2}Z &= d_1\frac{\partial^{l-1}p}{\partial x_1^{l-2}\partial x_2}D_1^{2l-2}D_2 \ + \text{terms with lower order in } D_1, \quad \mod U_{2l-2}.
\end{aligned}$$

Since $p^{(l)} = a_0x_1^l + a_2x_1^{l-2}x_2^2 \ +$ terms with lower degree in x_1, $\frac{\partial^{l-1}p}{\partial x_1^{l-2}\partial x_2} = 2(l-2)!a_2x_2 + c_2$, where c_2 is $(l-2)!$ multiplied by the coefficient of $x_1^{l-2}x_2$ in p. Hence,

$$\begin{aligned}
A_0 &= (e_0x_2 + d_1c_2)D_1^{2l-2}D_2 \ + \text{ terms with lower order in } D_1, \quad \mod U_{2l-2}, \\
A_1 &:= Y_l = d_1D_1^lD_2 + d_3D_1^{l-2}D_2^3 \\
&\qquad + \text{terms with lower order in } D_1, \quad \mod U_l, \\
A_2 &:= [A_1, A_0] = d_1e_0D_1^{3l-2}D_2 \\
&\qquad + \text{terms with lower order in } D_1, \quad \mod U_{3l-2}, \\
&\vdots \\
A_{r+1} &:= [A_r, A_0] = e_{r+1}D_1^{(2r+1)l-2r}D_2 \\
&\qquad + \text{terms with lower order in } D_1, \quad \mod U_{(2r+1)l-2r},
\end{aligned}$$

where $e_0 = 2(l-2)!a_2d_1 \neq 0$, $e_1 = d_1 \neq 0$, and $e_{r+1} = e_re_0 \neq 0$. The orders of A_{r+1}'s are $(2r+1)l - 2r + 1 \to \infty$ unless $l < 2$. □

THEOREM 4.2. *Suppose* $\dim E < \infty$. $x_1 + c \in E \Rightarrow \omega_{12}$ *is a polynomial of degree at most* 1.

Proof. Clearly, $L_0, x_1, D_1 \in E$.

$$H_0 := [L_0, D_1] = \omega_{12} D_2 + \frac{1}{2}\frac{\partial \omega_{12}}{\partial x_2} + \frac{1}{2}\frac{\partial \eta}{\partial x_1} \in E. \tag{4.3}$$

By Theorem 4.1, ω_{12} is a polynomial of degree at most 1. □

THEOREM 4.3. *Suppose* $\dim E < \infty$. $x_1^2 + c \in E \Rightarrow \omega_{21}$ *is a constant.*

Proof.

$$K_0 = \left[L_0, \frac{1}{2}(x_1^2 + c)\right] - \frac{1}{2} = x_1 D_1 \in E,$$

$$K_1 = [L_0, K_0] = D_1^2 - \alpha_2 D_2 + \frac{1}{2}E_1(\eta) - \frac{1}{2}\frac{\partial \alpha_2}{\partial x_2} \in E,$$

$$K_2 = [K_1, K_0] = 2D_1^2 + E_1(\alpha_2)D_2 + \alpha_2^2 - \frac{1}{2}E_1^2(\eta) + \frac{1}{2}E_1\left(\frac{\partial \alpha_2}{\partial x_2}\right) \in E,$$

$$Z_0 = K_2 - 2K_1 = (E_1(\alpha_2) + 2\alpha_2)D_2 + \gamma(x) \in E, \tag{4.4}$$

where $\alpha_2 = x_1\omega_{21}$, $E_1(\cdot) = x_1\frac{\partial}{\partial x_1}$, and $\gamma(x) = \alpha_2^2 - E_1(\eta) - \frac{1}{2}E_1^2(\eta) + \frac{\partial \alpha_2}{\partial x_2} + \frac{1}{2}E_1(\frac{\partial \alpha_2}{\partial x_2})$.

By Theorem 4.1, $E_1(\alpha_2) + 2\alpha_2$ is a polynomial of at most 1, and so is $\alpha_2 = x_1\omega_{21}$ by Theorem 3.15. Since $\omega_{21} \in C^\infty(R^2)$, ω_{21} must be a constant. □

LEMMA 4.4. *Suppose* $K_0 = x_1D_1 + x_2D_2 \in E$ *and* $Y = \sum_{i=0}^k b_i(x)D_1^{k-i}D_2^i$, mod $U_{k-1} \in E$. *Let* $b_i^{(r)}$ *denote the homogeneous degree* r *part of* b_i *for* $0 \le i \le k$. *Then* $\sum_{i=0}^k b_i^{(r)}D_1^{k-i}D_2^i$, mod $U_{k-1} \in E$, *for* $r \ge 0$.

Proof. Let $E(\cdot) = \sum_{i=1}^2 x_i\frac{\partial}{\partial x_i}$.

$$\left[K_0, \sum_{i=0}^k b_i D_1^{k-i}D_2^i\right] = \sum_{i=0}^k (E(b_i) - kb_i)D_1^{k-i}D_2^i, \qquad \text{mod } U_{k-1}. \tag{4.5}$$

Let $l = \max_{0\le i\le k} deg\ b_i$. Use (4.5) to construct a sequence of elements

$$Z_r = \sum_{j=0}^{l-r} c_{rj} \sum_{i=0}^k b_i^{(j)} D_1^{k-i}D_2^i \in E, \qquad \text{mod } U_{k-1}, \tag{4.6}$$

in E as follows:

(1) $Z_0 = Y$, i.e., $c_{0j} = 1, 0 \le j \le l$;

(2) $Z_{r+1} = (l - r - k)Z_r - [K_0, Z_r] \Longrightarrow c_{(r+1)j} = (l - r - j)c_{rj}, 0 \le j \le l - r - 1$.

Note that in (4.6) $c_{rj} \ne 0$ for $r \le l$. Starting from $Z_l = c_{l0}\sum_{i=0}^k b_i^{(0)}D_1^{k-i}D_2^i$, mod U_{k-1}, $Z_{l-1} = c_{(l-1)0}\sum_{i=0}^k b_i^{(0)}D_1^{k-i}D_2^i + c_{(l-1)1}\sum_{i=0}^k b_i^{(1)}D_1^{k-i}D_2^i$, mod $U_{k-1}, \ldots,$ $Z_r, \ldots,$ one can solve $\sum_{i=0}^k b_i^{(r)}D_1^{k-i}D_2^i$ successively. This means

$$\sum_{i=0}^k b_i^{(r)}D_1^{k-i}D_2^i, \quad \text{mod } U_{k-1} \in E. \qquad \square$$

LEMMA 4.5. *Suppose* $\dim E < \infty$. *Let* $Y = \sum_{i=i_0}^{i_k} b_i(x)D_1^{k-i}D_2^i$ mod $U_{k-1} \in E$ *be a differential operator with the highest order* k *in* E *(obviously* $k \ge 2$*), where* $0 \le i_0 \le i_k \le k$. *Then*

$$\frac{\partial b_{i_0}}{\partial x_1} = \frac{\partial b_{i_k}}{\partial x_2} = 0, \qquad \frac{\partial b_i}{\partial x_1} + \frac{\partial b_{i-1}}{\partial x_2} = 0, \quad i_0 + 1 \le i \le i_k. \tag{4.7}$$

Proof.

$$[L_0, Y] = \sum_{i=i_0}^{i_k} \frac{\partial b_i}{\partial x_1} D_1^{k+1-i} D_2^i + \sum_{i=i_0}^{i_k} \frac{\partial b_i}{\partial x_2} D_1^{k-i} D_2^{i+1} \tag{4.8}$$
$$= \frac{\partial b_{i_0}}{\partial x_1} D_1^{k+1} + \sum_{i=i_0+1}^{i_k} \left(\frac{\partial b_i}{\partial x_1} + \frac{\partial b_{i-1}}{\partial x_2} \right) D_1^{k+1-i} D_2^i + \frac{\partial b_{i_k}}{\partial x_2} D_2^{k+1}, \text{ mod } U_k.$$

Since E's elements have the highest differential order k, all the coefficient functions of the order $k+1$ terms in the above equation must be 0. □

LEMMA 4.6. *Suppose* dim $E < \infty$ *and* $Y = p_1 D_1 + p_2 D_2$, mod $U_0 \in E$, *where* $p_1 = \sum_{j=1}^{l} a_j x_1^{l-j} x_2^j$ *and* $p_2 = -\sum_{j=1}^{l} a_j x_1^{l+1-j} x_2^{j-1}$, a_j*'s are constants and* $a_j \neq 0$ *for some* j. *Then* $l \leq 2$.

Proof. Since dim $E < \infty$, there exists an element $P_0 = \sum_{i=i_0}^{i_k} b_i(x) D_1^{k-i} D_2^i$, mod $U_{k-1} \in E$, that has the highest differential order k, where $0 \leq i_0 \leq i_k \leq k$, $b_{i_0} \neq 0$, and $b_{i_k} \neq 0$. By Lemma 4.4, b_i's can be assumed to be homogeneous polynomials. More precisely, P_0 can be assumed to have the following properties:

(C1) $P_0 = \sum_{i=i_0}^{i_k} b_i(x) D_1^{k-i} D_2^i$, mod $U_{k-1} \in E$, $0 \leq i_0 \leq i_k \leq k$, $b_{i_0} \neq 0$, and $b_{i_k} \neq 0$.

(C2) P_0 has the highest differential order in E, i.e., if $A \in E$, then *ord* $A \leq k$.

(C3) $\frac{\partial b_{i_0}}{\partial x_1} = \frac{\partial b_{i_k}}{\partial x_2} = 0$, $\frac{\partial b_i}{\partial x_1} + \frac{\partial b_{i-1}}{\partial x_2} = 0$, $i_0 + 1 \leq i \leq i_k$.

(C4) b_i's are homogeneous degree r polynomials.

Moreover, among the elements in E satisfying (C1) and (C2), P_0 can be chosen such that b_i's have the highest degree:

(C5) Among all elements in E with order k, b_i's have the highest degree.

Assume $l \geq 3$.

Assume either $i_0 > 0$ or $i_k < k$. Without loss of generality, assume $i_0 > 0$.

$$[P_0, Y] = \left[P_0, \sum_{i=1}^{2} p_i D_i \right] = \left[b_{i_0} D_1^{k-i_0} D_2^{i_0} + \cdots \sum_{i=1}^{2} p_i D_i \right]$$
$$= i_0 b_{i_0} \frac{\partial p_1}{\partial x_2} D_1^{k+1-i_0} D_2^{i_0-1}$$
$$+ \text{ terms with lower order in } D_1, \qquad \text{mod } U_{k-1}.$$

Since $\frac{\partial p_1}{\partial x_2} \neq 0$ is a degree $l-1 \geq 2$ polynomial, while b_{i_0} is a polynomial independent of x_1 by (C3), $i_0 b_{i_0} \frac{\partial p_1}{\partial x_2}$ is a polynomial of degree higher than b_{i_0}. This contradicts with (C5). Thus,

(C6) $i_0 = 0$ and $i_k = k$, i.e., $P_0 = \sum_{i=0}^{k} b_i(x) D_1^{k-i} D_2^i$, mod U_{k-1}, where $b_0 \neq 0$ and $b_k \neq 0$.

Again, consider $[P_0, Y]$,

$$[P_0, Y] = \left[P_0, \sum_{i=1}^{2} p_i D_i \right] = \left[b_0 D_1^k + b_1 D_1^{k-1} D_2 + \cdots \sum_{i=1}^{2} p_i D_i \right]$$
$$= \left(k b_0 \frac{\partial p_1}{\partial x_1} - p_2 \frac{\partial b_0}{\partial x_2} + b_1 \frac{\partial p_1}{\partial x_2} \right) D_1^k$$
$$+ \text{ terms with lower order in } D_1, \qquad \text{mod } U_{k-1}. \tag{4.9}$$

By (C3), (C4), and (C6), one can assume that

$$b_0 = x_2^r, \quad \text{where } r \geq 0, \tag{4.10}$$

$$b_1 = -rx_1x_2^{r-1} + cx_2^r, \quad \text{where } c \text{ is an unknown constant.} \tag{4.11}$$

Using (4.10) and (4.11), we obtain the coefficient function of the D_1^k term in $[P_0, \sum_{i=1}^2 p_i D_i]$ given in (4.9):

$$\begin{aligned} &kb_0\frac{\partial p_1}{\partial x_1} - p_2\frac{\partial b_0}{\partial x_2} + b_1\frac{\partial p_1}{\partial x_2} \\ &= (ca_1 - ra_2)x_1^{l-1}x_2^r + \sum_{j=2}^{l-1}(-jra_{j+1} + jca_j + k(l-j+1)a_{j-1})x_1^{l-j}x_2^{r+j-1} \\ &\qquad + (lca_l + ka_{l-1})x_2^{l+r-1}. \end{aligned} \tag{4.12}$$

Equation (4.12) is a degree $l+r-1 > r$ homogeneous polynomial. To meet condition (C5), every term in (4.12) must be 0. That is, $a_1, \ldots, a_l$ must satisfy

$$\begin{aligned} &ca_1 - ra_2 = 0, \qquad lca_l + ka_{l-1} = 0, \\ &-jra_{j+1} + jca_j + k(l-j+1)a_{j-1} = 0 \quad \text{for } 2 \leq j \leq l-1. \end{aligned} \tag{4.13}$$

The above relations can be summarized as a matrix equation:

$$\begin{pmatrix} c & -r & & & & & \\ k(l-1) & 2c & -2r & & & & \\ & k(l-2) & 3c & -3r & & & \\ & & \ddots & \ddots & \ddots & & \\ & & & 2k & (l-1)c & -(l-1)r & \\ & & & & k & lc & \end{pmatrix} \begin{pmatrix} a_1 \\ a_2 \\ a_3 \\ \vdots \\ a_{l-1} \\ a_l \end{pmatrix} = 0. \tag{4.14}$$

Let A denote the $l \times l$ tridiagonal matrix in the above equation. Since all the $A(i, i+1)$ entries are nonpositive while all $A(i, i-1)$ entries are positive, it is easy by induction that $c = 0$ is a necessary condition for the determinant of A to be 0. More specifically, let B_i denote an $i \times i$ matrix having the entries $B_i(s,t) = A(s,t)$ for $1 \leq s, t \leq i$, i.e., B_i is the upper left block of A with size $i \times i$. The determinants of B_i's have the following recursion:

$$|B_1| = c, \qquad |B_2| = 2c^2 + d_1, \tag{4.15}$$

$$|B_{i+1}| = (i+1)c|B_i| + d_i|B_{i-1}|, \tag{4.16}$$

where $d_i = (l-i)ikr > 0$. If l is odd, $|A| = |B_l| = c \cdot q(c^2)$, where q is a nondegenerate polynomial of degree $(l-1)/2$ with nonnegative coefficients. If l is even, $|A| = |B_l| = q(c^2)$, where q is a nondegenerate polynomial of degree $l/2$ with nonnegative coefficients. Thus, to ensure the existence of nontrivial solutions of $a_1, \ldots, a_l$, c must be 0.

Similarly, by assuming $b_k = x_1^r$ and repeating the same computation for the coefficient function of D_2^k term in $[P, \sum_{i=1}^2 p_i D_i]$, one will get

$$\begin{pmatrix} c_1 & -r & & & & & \\ k(l-1) & 2c_1 & -2r & & & & \\ & k(l-2) & 3c_1 & -3r & & & \\ & & \ddots & \ddots & \ddots & & \\ & & & 2k & (l-1)c_1 & -(l-1)r & \\ & & & & k & lc_1 & \end{pmatrix} \begin{pmatrix} a_l \\ a_{l-1} \\ a_{l-2} \\ \vdots \\ a_2 \\ a_1 \end{pmatrix} = 0, \tag{4.17}$$

and c_1 must be 0 as well.

This first observation from (4.14) and (4.17) is that $r \neq 0$. Otherwise, one will have $a_1 = \cdots = a_{l-1} = 0$ from (4.14) and $a_l = \cdots = a_2 = 0$ from (4.17) since $c = c_1 = 0$.

Now, $r \neq 0$ and $c = c_1 = 0$, again by solving (4.14) and (4.17),

$$a_j = \begin{cases} 0, & j = 2, l-1, \\ \frac{k(l-j+2)}{r(j-1)} a_{j-2}, & 3 \leq j \leq l, \end{cases} \qquad a_j = \begin{cases} 0, & j = 2, l-1, \\ \frac{r(l-j+2)}{k(j-1)} a_{j-2}, & 3 \leq j \leq l. \end{cases} \tag{4.18}$$

Hence, l must be an odd number and $k = r$ so that (4.18) holds. Without loss of generality, a_1 can be assumed to be 1. That is,

$$\begin{gathered} l \text{ is an odd number } \geq 3, \quad a_1 = a_l = 1, \quad a_2 = 0, \\ a_j = \frac{l-j+2}{j-1} a_{j-2} \text{ for } 3 \leq j \leq l. \end{gathered} \tag{4.19}$$

(C7) $k = r$. This means the degree of the coefficient function b_i in P_0 must be the same as the order of P_0. That is,

$$P_0 = x_2^k D_1^k - k x_1 x_2^{k-1} D_1^{k-1} D_2 \ + \text{terms with lower order in } D_1, \text{ mod } U_{k-1}. \tag{4.20}$$

Consider any $N = \sum_{j=0}^{t} n_j(x) D_1^{t-j} D_2^j$, mod $U_{t-1} \in E$,

$$\begin{aligned} [P_0, N] &= \left[\sum_{i=0}^{k} b_i(x) D_1^{k-i} D_2^i, \sum_{j=0}^{t} n_j(x) D_1^{t-j} D_2^j \right] \\ &= \left(k b_0 \frac{\partial n_0}{\partial x_1} - t n_0 \frac{\partial b_0}{\partial x_1} + b_1 \frac{\partial n_0}{\partial x_2} - n_1 \frac{\partial b_0}{\partial x_2} \right) D_1^{k+t-1} \\ &\qquad + \text{terms with lower order in } D_1 \\ &= k x_2^{k-1} \left(x_2 \frac{\partial n_0}{\partial x_1} - x_1 \frac{\partial n_0}{\partial x_2} - n_1 \right) D_1^{k+t-1} \\ &\qquad + \text{terms with lower order in } D_1, \text{ mod } U_{k+t-2}. \end{aligned} \tag{4.21}$$

If $t \geq 2$, then

$$n_1 = x_2 \frac{\partial n_0}{\partial x_1} - x_1 \frac{\partial n_0}{\partial x_2}. \tag{4.22}$$

Otherwise, $[P_0, N]$ will have order $k + t - 1 > k$, contradicting (C2).

In particular, by (4.22),

$$\text{if } n_0 = x_2^s \Longrightarrow n_1 = -s x_1 x_2^{s-1} \quad \text{for } s \geq 0. \tag{4.23}$$

Now, suppose that $N = x_2^s D_1^t - s x_1 x_2^{s-1} D_1^{t-1} D_2 +$ terms with lower order in D_1, mod $U_{t-1} \in E$. By using (4.18)

$$\begin{aligned} [N, Y] &= [\ x_2^s D_1^t - s x_1 x_2^{s-1} D_1^{t-1} D_2 + \cdots p_1 D_1 + p_2 D_2\ ] \\ &= \left(t x_2^s \frac{\partial p_1}{\partial x_1} - s x_2^{s-1} p_2 - s x_1 x_2^{s-1} \frac{\partial p_1}{\partial x_2} \right) D_1^t \\ &\qquad + \text{terms with lower order in } D_1 \\ &= (t-s) \sum_{j=1}^{l-2} (l-j) a_j x_1^{l-j-1} x_2^{j+s} D_1^t \\ &\qquad + \text{terms with lower order in } D_1, \text{ mod } U_{t-1}, \end{aligned} \tag{4.24}$$

$$\begin{aligned} Ad_{L_0}^{l-2}[N, Y] &= (t-s)(l-1)! x_2^{s+1} D_1^{t+l-2} \\ &\qquad + \text{terms with lower order in } D_1, \text{ mod } U_{t+l-1}. \end{aligned} \tag{4.25}$$

Equations (4.23), (4.24), and (4.25) show that if $s < t$,

$$x_2^s D_1^t \ + \text{terms with lower order in } D_1, \ \mod U_{t-1} \in E$$

$$\implies x_2^{s+1} D_1^{t+l-2} \ + \text{terms with lower order in } D_1, \ \mod U_{t+l-3} \in E. \tag{4.26}$$

Since $l \geq 3$, $s+1 < t+l-2$, and repeating (4.26) will make E not finite-dimensional. Now, choose $N = 2L_0$. Then the above procedure (4.23)–(4.26) applies. Contradiction! □

THEOREM 4.7. *Suppose* $\dim E < \infty$. $x_1^2 + x_2^2 + c \in E \Rightarrow \omega_{12}$ *is a polynomial of degree at most* 1.

Proof.

$$K_0 = \left[L_0, \frac{1}{2}(x_1^2 + x_2^2 + c)\right] - 1 = x_1 D_1 + x_2 D_2 \in E,$$

$$K_1 = [L_0, K_0] = \sum_{i=1}^{2} D_i^2 - \sum_{i=1}^{2} \alpha_i D_i + \frac{1}{2} E(\eta) - \frac{1}{2} \sum_{i=1}^{2} \frac{\partial \alpha_i}{\partial x_i} \in E,$$

$$K_2 = 2L_0 - K_1 = \sum_{i=1}^{2} \alpha_i D_i + \frac{1}{2} \sum_{i=1}^{2} \frac{\partial \alpha_i}{\partial x_i} - \eta - \frac{1}{2} E(\eta) \in E,$$

where $\alpha_1 = x_2 \omega_{12}$, $\alpha_2 = x_1 \omega_{21}$, $E(\cdot) = \sum_{i=1}^{2} x_i \frac{\partial}{\partial x_i}$. By Theorem 3.2, α_i is a polynomial. Since ω_{12} is smooth, ω_{12} must be a polynomial as well.

Let $\alpha_i^{(r)}$ be the homogeneous degree r part of α_i. By Lemma 4.4,

$$\sum_{i=1}^{2} \alpha_i^{(r)} D_i \in E, \quad \mod U_0.$$

On the other hand,

$$\sum_{i=1}^{2} x_i \alpha_i = \sum_{i,j=1}^{2} x_i x_j \omega_{ij} = 0 \Longrightarrow x_1 \alpha_1^{(r)} + x_2 \alpha_2^{(r)} = 0.$$

By Lemma 4.6, $\alpha_i^{(r)} = 0$ for $r > 2$. Therefore, ω_{12} is a polynomial of degree at most 1. □

THEOREM 4.8. *Suppose* $\dim E < \infty$. h_i*'s are polynomials at most of degree* 1.

Proof. Without loss of generality, h_1 is assumed to be a polynomial of degree 2. By orthogonal and affine transformations, h_1 is either $ax_1^2 + cx_2 + d$ or $ax_1^2 + bx_2^2 + d$, where $a, b \neq 0$.

(i) If $h_1 = ax_1^2 + cx_2 + d$, then $[[L_0, h_1], h_1] = 4a^2 x_1^2 + c^2 \in E$. By Theorem 4.3, ω_{21} is a constant. Hence, E is not finite-dimensional according to Theorem 2.5.

(ii) Assume $h_1 = ax_1^2 + bx_2^2 + d$. $[[L_0, h_1], h_1] = 4a^2 x_1^2 + 4b^2 x_2^2 \in E$. If $a \neq b$, both $x_1^2 + c$ and $x_2^2 + c$ are in E. From the discussion (i), E is not finite-dimensional. Hence, $h_1 = ax_1^2 + ax_2^2 + c$. By Theorem 4.7, ω_{12} is a polynomial of degree at most 1. Moreover, ω_{12} must be a nondegenerate degree 1 polynomial by Theorem 2.5, i.e., $\omega_{12} = c_1 x_1 + c_2 x_2 + c_0$, where $c_1 \neq 0$ or $c_2 \neq 0$.

From $K_0, K_2 \in E$ in Theorem 4.7 and by the construction of (4.6), let $Z_0 = K_2$ and $Z_{r+1} = (1-r)Z_r - [K_0, Z_r]$ for $r = 0, 1$,

$$Z_0 = \sum_{i=1}^{2} \alpha_i D_i + q_0 \in E,$$

$$Z_1 = c_0 x_2 D_1 - c_0 x_1 D_2 + q_0 - E(q_0) - \sum_{i=1}^{2} \alpha_i^2 \in E,$$

$$Z_2 = -c_0 x_2 \alpha_1 + c_0 x_1 \alpha_2 + E\left(\sum_{i=1}^{2} \alpha_i^2\right) - E(q_0 - E(q_0)) \in E,$$

where $q_0 = \frac{1}{2}\sum_{i=1}^{2} \frac{\partial \alpha_i}{\partial x_i} - \eta - \frac{1}{2}E(\eta)$. Since Z_2 must be a polynomial of degree less than or equal to 2, regardless of whether c_0 is 0 or not, $q_0 - E(q_0)$ or $E(q_0 - E(q_0))$ is a degree 4 polynomial by Theorem 3.15. So η is a degree 4 polynomial (by Theorems 3.13 and 3.15). Moreover, the homogeneous degree 4 part of η is

$$\eta^{(4)} = c\left(\sum_{i=1}^{2} \alpha_i^2\right)^{(4)} = c(x_1^2 + x_2^2)(c_1 x_1 + c_2 x_2)^2.$$

Hence, the homogeneous degree 4 part of $\eta - \sum h_i^2$ is

$$c(x_1^2 + x_2^2)(c_1 x_1 + c_2 x_2)^2 - a^2(x_1^2 + x_2^2)^2 - \sum_{i>1}^{m} (h_i^{(2)})^2.$$

By taking $x_1 = -c_2$ and $x_2 = c_1$, the above expression results in a negative number. By Theorem 3.18, there are no smooth solutions in f_i. □

THEOREM 4.9. *Suppose* $\dim E < \infty$. *If* $\phi \in E$, ϕ *is a polynomial of degree at most* 1.

Proof. (i) If E has linear rank 2, E is of maximal rank, and therefore no degree 2 polynomials are in E by Theorem 2.7.

(ii) If E has linear rank 0, then h_i's must be constants. E is finite-dimensional and $E \subset \langle L_0, 1\rangle_{L.A.}$. Any function element in E must be a constant.

(iii) Let E have linear rank 1, i.e., there exists a function $d_i x_1 + e_i \in E \Longrightarrow D_1 \in E$.

From the proof of Theorem 4.8, by orthogonal and affine transformations, a degree 2 polynomial $\phi \in E$ only has the form $ax_1^2 + ax_2^2 + d$, where $a \neq 0$. Again by Theorem 4.8, $\omega_{12} = c_1 x_1 + c_2 x_2 + c_0$, where $c_1 \neq 0$ or $c_2 \neq 0$ (otherwise ω_{12} is a constant).

By (4.3), $[L_0, D_1] = \omega_{12} D_2 + \varphi \in E$. Thus

$$[\omega_{12} D_2 + \varphi, ax_1^2 + ax_2^2 + d] = 2ax_2\omega_{12} = 2ac_1 x_1 x_2 + 2ac_2 x_2^2 + 2ac_0 x_2 \in E.$$

If $c_1 \neq 0$, $[D_1, 2ac_1 x_1 x_2 + 2ac_2 x_2^2 + 2ac_0 x_2] = 2ac_1 x_2$ is dependent on x_2. This contradicts the linear rank of E being 1. If $c_1 = 0$ and $c_2 \neq 0$, from $2ac_2 x_2^2 + 2ac_0 x_2$ and $ax_1^2 + ax_2^2 + d$, are in E, one has that $x_1^2 + c_4 x_2 + c_5 \in E$. From the discussion (i) in the proof of Theorem 4.8, E is not finite-dimensional. □

4.2. Constant structure of the Ω-matrix. In this section, E is assumed to be finite-dimensional and have linear rank 1. As discussed in the proof of Theorem 4.9, the structure of E is very clear when E's linear rank is 0 or 2.

Assume $x_1 \in E$. Then if a function $p \in E$, p is a degree 1 polynomial in x_1 as a result of Theorem 4.9 as well as the linear rank assumption. By Theorem 4.2, $\omega_{12} = c_1x_1 + c_2x_2 + c_0$. It will be shown that ω_{12} must be a constant in this section.

By assumptions, $L_0, x_1, D_1, 1 \in E$. Moreover, the following elements are in E:

$$H_0 = [L_0, D_1] = \omega_{12}D_2 + \frac{1}{2}\frac{\partial \eta}{\partial x_1} + \frac{1}{2}c_2, \tag{4.27}$$

$$H_1 = [D_1, H_0] = c_1D_2 - \omega_{12}^2 + \frac{1}{2}\frac{\partial^2 \eta}{\partial x_1^2}, \tag{4.28}$$

$$H_2 = [D_1, H_1] = -3c_1\omega_{12} + \frac{1}{2}\frac{\partial^3 \eta}{\partial x_1^3}, \tag{4.29}$$

$$\begin{aligned} H_3 &= [H_1, H_0] - c_2H_1 \\ &= 3c_2\omega_{12}^2 + \frac{1}{2}c_1\frac{\partial^2 \eta}{\partial x_1 \partial x_2} - \frac{1}{2}c_2\frac{\partial^2 \eta}{\partial x_1^2} - \frac{1}{2}\omega_{12}\frac{\partial^3 \eta}{\partial x_1^2 \partial x_2}, \end{aligned} \tag{4.30}$$

$$\begin{aligned} X_0 &= [L_0, H_0] \\ &= c_1D_1D_2 + c_2D_2^2 + \left(-\omega_{12}^2 + \frac{1}{2}\frac{\partial^2 \eta}{\partial x_1^2}\right)D_1 + \frac{1}{2}\frac{\partial^2 \eta}{\partial x_1 \partial x_2}D_2 \\ &\quad + \left(-\frac{1}{2}c_1\omega_{12} + \frac{1}{2}\omega_{12}\frac{\partial \eta}{\partial x_2} + \frac{1}{4}\frac{\partial^3 \eta}{\partial x_1^3} + \frac{1}{4}\frac{\partial^3 \eta}{\partial x_1 \partial x_2^2}\right). \end{aligned} \tag{4.31}$$

LEMMA 4.10. *η is a polynomial in x_1 of degree at most 4 with coefficients being functions of x_2. Let $\eta = \sum_{i=0}^4 a_i x_1^i$, where a_i's are functions of x_2. Then*

(i) *a_4 is a constant;*

(ii) *$a_3 = c_1c_2x_2 +$ constant;*

(iii) *$(c_1^2 - 4a_4)c_2 = 0$;*

(iv) *$3c_2^3x_2^2 + 6c_0c_2^2x_2 - c_2a_2 + \frac{1}{2}c_1a_1' - c_0a_2' - c_2a_2'x_2 =$ constant.*

Proof. Since H_2 is a function $\in E$, H_2 is independent of x_2 and a degree 1 polynomial in x_1. Therefore, η is a polynomial in x_1 of degree at most 4 with coefficient functions in x_2. Let $\eta = \sum_{i=0}^4 a_i x_1^i$, where a_i's are functions of x_2.

$H_2 \in E \Longrightarrow a_4$ is a constant, and $a_3 = c_1c_2x_2 +$ constant.

(iii) and (iv) follow from $H_3 \in E$ by substituting $\eta = \sum_{i=0}^4 a_i x_1^i$ into (4.30). ∎

Now, from (4.31), $X_0 \in E$.

$$\begin{aligned} X &= [L_0, X_0] \\ &= \left[L_0, c_1D_1D_2 + c_2D_2^2 + \left(-\omega_{12}^2 + \frac{1}{2}\frac{\partial^2 \eta}{\partial x_1^2}\right)D_1 + \frac{1}{2}\frac{\partial^2 \eta}{\partial x_1 \partial x_2}D_2\right] \\ &= \left(-3c_1\omega_{12} + \frac{1}{2}\frac{\partial^3 \eta}{\partial x_1^3}\right)D_1^2 + \left(-4c_2\omega_{12} + \frac{\partial^3 \eta}{\partial x_1^2 \partial x_2}\right)D_1D_2 \\ &\quad + \left(c_1\omega_{12} + \frac{1}{2}\frac{\partial^3 \eta}{\partial x_1 \partial x_2^2}\right)D_2^2 \\ &= q_0D_1^2 + q_1D_1D_2 + q_2D_2^2 \in E, \quad \text{mod } U_1, \end{aligned} \tag{4.32}$$

where $q_0 = -3c_1\omega_{12} + \frac{1}{2}\frac{\partial^3 \eta}{\partial x_1^3}$, $q_1 = -4c_2\omega_{12} + \frac{\partial^3 \eta}{\partial x_1^2 \partial x_2}$, $q_2 = c_1\omega_{12} + \frac{1}{2}\frac{\partial^3 \eta}{\partial x_1 \partial x_2^2}$. By

Lemma 4.10 (i) and (ii),

$$\frac{\partial q_0}{\partial x_1} = 12a_4 - 3c_1^2, \quad \frac{\partial q_0}{\partial x_2} = 0, \tag{4.33}$$

$$\frac{\partial q_1}{\partial x_1} = 2c_1c_2, \quad \frac{\partial q_1}{\partial x_2} = -4c_2^2 + 2a_2'', \tag{4.34}$$

$$\frac{\partial q_2}{\partial x_1} = c_1^2 + a_2'', \quad \frac{\partial q_2}{\partial x_2} = c_1c_2 + \frac{1}{2}a_1''' + a_2'''x_1. \tag{4.35}$$

LEMMA 4.11. $a_4 = \frac{1}{4}c_1^2$.

Proof. If $a_4 \neq \frac{1}{4}c_1^2$, i.e., $r := \frac{\partial q_0}{\partial x_1} = 12a_4 - 3c_1^2 \neq 0$, then from X in (4.32) and L_0 one can construct a sequence of elements in E whose orders strictly increase as follows:

$$\begin{aligned}
Y_1 &= [L_0, X] = rD_1^3 + \sum_{i=1}^{3} p_{1i}D_1^{3-i}D_2^i, \quad \text{mod } U_2, \\
Y_2 &= [Y_1, X] = [rD_1^3 + p_{11}D_1^2D_2 + \cdots q_0D_1^2 + q_1D_1D_2 + q_2D_2^2] \\
&= \left(3r\frac{\partial q_0}{\partial x_1} + p_{11}\frac{\partial q_0}{\partial x_2}\right)D_1^4 + \sum_{i=1}^{4} p_{2i}D_1^{4-i}D_2^i \\
&= 3r^2D_1^4 + \sum_{i=1}^{4} p_{2i}D_1^{4-i}D_2^i, \quad \text{mod } U_3, \\
&\vdots
\end{aligned}$$

Assume that $Y_k = r_kD_1^{k+2} + \sum_{i=1}^{k+2} p_{ki}D_1^{k+2-i}D_2^i$, mod U_{k+1}, with $r_k \neq 0$:

$$\begin{aligned}
Y_{k+1} &= [Y_k, X] = [r_kD_1^{k+2} + p_{k1}D_1^{k+1}D_2 + \cdots q_0D_1^2 + q_1D_1D_2 + q_2D_2^2] \\
&= \left((k+2)r_k\frac{\partial q_0}{\partial x_1} + p_{k1}\frac{\partial q_0}{\partial x_2}\right)D_1^{k+3} + \sum_{i=1}^{k+3} p_{(k+1)i}D_1^{k+3-i}D_2^i \\
&= r_{k+1}D_1^{k+3} + \sum_{i=1}^{k+3} p_{(k+1)i}D_1^{k+3-i}D_2^i, \quad \text{mod } U_{k+2},
\end{aligned}$$

where $r_{k+1} = (k+2)rr_k \neq 0$. □

THEOREM 4.12. *If $c_1c_2 \neq 0$, E is not finite-dimensional.*

Proof. Assume that $c_1c_2 \neq 0$.

(i) From Lemma 4.11 and (4.32), (4.33), q_0 is a constant.

(ii) Let $r_1 := \frac{\partial q_1}{\partial x_1} = 2c_1c_2$ in (4.34):

$$\begin{aligned}
Z &= [L_0, X] = [L_0, q_0D_1^2 + q_1D_1D_2 + q_2D_2^2] \\
&= r_1D_1^2D_2 \ + \text{terms with lower order in } D_1, \quad \text{mod } U_2.
\end{aligned}$$

Suppose q_1 in (4.32) is a polynomial of degree k in x_2, i.e., $\frac{\partial^k q_1}{\partial x_2^k}$ is a nonzero constant.

If $k \geq 1$,

$$\begin{aligned}
A_1 &= [Z, X] \\
&= [r_1 D_1^2 D_2 \ + \text{terms with lower order in } D_1, q_0 D_1^2 + q_1 D_1 D_2 + q_2 D_2^2] \\
&= r_1 \frac{\partial q_1}{\partial x_2} D_1^3 D_2 + \text{terms with lower order in } D_1, \quad \mod U_3, \\
A_2 &= [Z, A_1] = \Big[r_1 D_1^2 D_2 \ + \text{terms with lower order in } D_1, \\
&\qquad r_1 \frac{\partial q_1}{\partial x_2} D_1^3 D_2 \ + \text{terms with lower order in } D_1 \Big] \\
&= r_1^2 \frac{\partial^2 q_1}{\partial x_2^2} D_1^5 D_2 \ + \text{terms with lower order in } D_1, \quad \mod U_5, \\
&\ \vdots \\
A_k &= [Z, A_{k-1}] = r_1^k \frac{\partial^k q_1}{\partial x_2^k} D_1^{2k+1} D_2 \ + \text{terms with lower order in } D_1, \quad \mod U_{2k+1}.
\end{aligned}$$

Now one can repeat the above process by letting $Z = A_k$ to construct a sequence of elements in E whose orders strictly increase.

Hence, k must be zero, which means $\frac{\partial q_1}{\partial x_2} = 0 \Longrightarrow a_2'' = 2c_2^2$.

(iii) By taking twice the derivative with respect to x_2 in Lemma 4.10 (iv) and substituting $a_2'' = 2c_2^2$, one has $c_1 a_1''' = 0 \Longrightarrow a_1''' = 0$.

Thus, $X = q_0 D_1^2 + q_1 D_1 D_2 + q_2 D_2^2$, mod U_1, is in E, with

$$\frac{\partial q_0}{\partial x_1} = \frac{\partial q_0}{\partial x_2} = 0, \tag{4.36}$$

$$\frac{\partial q_1}{\partial x_1} = 2c_1 c_2 = r_1 \neq 0, \qquad \frac{\partial q_1}{\partial x_2} = 0, \tag{4.37}$$

$$\frac{\partial q_2}{\partial x_1} = c_1^2 + 2c_2^2 = r_2 > 0, \qquad \frac{\partial q_2}{\partial x_2} = c_1 c_2 = \frac{1}{2} r_1, \tag{4.38}$$

$$\begin{aligned}
Y_0 &= [L_0, X] = [L_0, q_0 D_1^2 + q_1 D_1 D_2 + q_2 D_2^2] \\
&= p_{01} D_1^2 D_2 + p_{02} D_1 D_2^2 + p_{03} D_2^3, \quad \mod U_2,
\end{aligned} \tag{4.39}$$

where $p_{01} = r_1, p_{02} = r_2, p_{03} = \frac{1}{2} r_1$. For $l \geq 0$, suppose $Y_l = p_{l1} D_1^2 D_2^{l+1} + p_{l2} D_1 D_2^{l+2} + p_{l3} D_2^{l+3} \in E$, mod U_{l+2}, where p_{l1}, p_{l2}, p_{l3} are constants.

$$\begin{aligned}
Y_{l+1} &= [Y_l, X] = [p_{l1} D_1^2 D_2^{l+1} + p_{l2} D_1 D_2^{l+2} + p_{l3} D_2^{l+3}, q_0 D_1^2 + q_1 D_1 D_2 + q_2 D_2^2] \\
&= 2p_{l1} \frac{\partial q_1}{\partial x_1} D_1^2 D_2^{l+2} + p_{l2} \frac{\partial q_1}{\partial x_1} D_1 D_2^{l+3} + (l+1) p_{l1} \frac{\partial q_2}{\partial x_2} D_1^2 D_2^{l+2} \\
&\quad + 2p_{l1} \frac{\partial q_2}{\partial x_1} D_1 D_2^{l+3} + (l+2) p_{l2} \frac{\partial q_2}{\partial x_2} D_1 D_2^{l+3} + p_{l2} \frac{\partial q_2}{\partial x_1} D_2^{l+4} \\
&\quad + (l+3) p_{l3} \frac{\partial q_2}{\partial x_2} D_2^{l+4}
\end{aligned}$$

$$= \frac{l+5}{2} r_1 p_{l1} D_1^2 D_2^{l+2} + (2r_2 p_{l1} + \frac{l+4}{2} r_1 p_{l2}) D_1 D_2^{l+3}$$
$$+ \left(r_2 p_{l2} + \frac{l+3}{2} r_1 p_{l3} \right) D_2^{l+4}$$
$$= p_{(l+1)1} D_1^2 D_2^{l+2} + p_{(l+1)2} D_1 D_2^{l+3} + p_{(l+1)3} D_2^{l+4}, \quad \text{mod } U_{l+3},$$

where $p_{(l+1)1} = \frac{l+5}{2} r_1 p_{l1}$, $p_{(l+1)2}, p_{(l+1)3}$ are constants. Since $p_{01} = r_1 \neq 0$, $p_{l1} \neq 0$ for any l. Thus, Y_l is a differential operator of degree $l+3$. Contradiction! □

LEMMA 4.13. *If $c_1 = 0, c_2 \neq 0$, we have* (i) $a_4 = 0$*;* (ii) $a_3 = 0$; (iii) $a_2 = \omega_{12}^2 +$ *constant;* (iv) $a_1''' = 0$.

Proof. (i) follows from Lemma 4.11.

By Lemma 4.10 (ii), a_3 is a constant. Since a_3 is the coefficient of an odd order term in η with the highest order in x_1, $a_3 = 0$ by Theorem 3.21.

(iii) follows from (4.28). H_1 is a function in E when $c_1 = 0$.

Now, q_0, q_1 are actually constants in (4.32), while $\frac{\partial q_2}{\partial x_1} = a_2'' = 2c_2^2$ and $\frac{\partial q_2}{\partial x_2} = \frac{1}{2} a_1'''$.

Let a_1'' be a degree k polynomial in x_2, i.e., $\frac{d^{k+2} a_1}{dx_2^{k+2}}$ is a nonzero constant. If $k > 1$,

$$Z_0 = Ad_{L_0}^k X = \frac{1}{2} \frac{d^{k+2} a_1}{dx_2^{k+2}} D_2^{k+2}, \quad \text{mod } U_{k+1},$$
$$Y_0 = [Z_0, X] = (k+2) \left(\frac{1}{2} \right)^2 \frac{d^{k+2} a_1}{dx_2^{k+2}} \frac{d^3 a_1}{dx_2^3} D_2^{k+3}, \quad \text{mod } U_{k+2}.$$

By letting $Z_l = Ad_{L_0}^{k-1} Y_{l-1}$ and $Y_l = [Z_l, X]$ for $l \geq 1$, one can construct a sequence of elements in E with strictly increasing orders.

If $k = 1$, consider $Z_0 = [L_0, X] = \frac{\partial q_2}{\partial x_1} D_1 D_2^2 + \frac{\partial q_2}{\partial x_2} D_2^3$, mod U_2, and $Z_{l+1} = [Z_l, X]$ for $l \geq 0$. Assume

$$Z_l = p_{l0} D_1 D_2^{l+2} + p_{l1} D_2^{l+3}, \qquad \text{mod } U_{l+2},$$

where $p_{00} = \frac{\partial q_2}{\partial x_1} = 2c_2^2$ and $p_{01} = \frac{\partial q_2}{\partial x_2} = \frac{1}{2} \frac{d^3 a_1}{dx_2^3}$. Then

$$Z_{l+1} = [Z_l, X] = [p_{l0} D_1 D_2^{l+2} + p_{l1} D_2^{l+3}, q_0 D_1^2 + q_1 D_1 D_2 + q_2 D_2^2]$$
$$= (l+2) p_{l0} \frac{\partial q_2}{\partial x_2} D_1 D_2^{l+3} + \left(p_{l0} \frac{\partial q_2}{\partial x_1} + (l+3) p_{l1} \frac{\partial q_2}{\partial x_2} \right) D_2^{l+4}, \quad \text{mod } U_{l+3}.$$

Therefore,

$$p_{(l+1)0} = (l+2) p_{l0} \frac{\partial q_2}{\partial x_2} \Longrightarrow p_{l0} = (l+1)! \frac{\partial q_2}{\partial x_1} \left(\frac{\partial q_2}{\partial x_2} \right)^l \neq 0.$$

Z_l's have strictly increasing orders. Contradiction!

Hence k must be zero $\Longrightarrow a_1''' = 0$. □

THEOREM 4.14. *If $c_1 = 0, c_2 \neq 0$, E is not finite-dimensional.*

Proof. In the proof of this theorem, $r_1, r_2, \ldots$ are used to denote constants. The exact values of these r_i's are not important. Some r_i's may be used repeatedly to denote different constants.

By substituting Lemma 4.13 (i)–(iv) into (4.31), we obtain

$$
\begin{aligned}
Z_0 &= X_0 - r_1 D_1 - r_2 x_1 - r_3 \\
&= c_2 D_2^2 + \frac{1}{2}\frac{\partial^2 \eta}{\partial x_1 \partial x_2} D_2 + \frac{1}{2}\omega_{12}\frac{\partial \eta}{\partial x_2}, \qquad (4.40)\\
Z_1 &= [L_0, Z_0] - r_5 D_1 \\
&= \frac{1}{2}\frac{\partial^3 \eta}{\partial x_1 \partial x_2^2} D_2^2 + \left(\frac{3}{2} c_2 \frac{\partial \eta}{\partial x_2} + \frac{1}{2}\omega_{12}\frac{\partial^2 \eta}{\partial x_2^2}\right) D_2, \quad \mod U_0, \\
Z_2 &= [L_0, Z_1] = a_2'' D_1 D_2^2 + \left(\frac{3}{2} c_2 \frac{\partial^2 \eta}{\partial x_1 \partial x_2} - \frac{1}{2}\omega_{12}\frac{\partial^3 \eta}{\partial x_1 \partial x_2^2}\right) D_1 D_2 \\
&\quad + \left(2 c_2 \frac{\partial^2 \eta}{\partial x_2^2} + \frac{1}{2}\omega_{12}\frac{\partial^3 \eta}{\partial x_2^3}\right) D_2^2, \quad \mod U_1, \\
Z_3 &= [L_0, Z_2] = 3 c_2 \frac{\partial^3 \eta}{\partial x_1 \partial x_2^2} D_1 D_2^2 + \left(a_2'' \omega_{12} + \frac{5}{2} c_2 \frac{\partial^3 \eta}{\partial x_2^3} + \frac{1}{2}\omega_{12}\frac{\partial^4 \eta}{\partial x_2^4}\right) D_2^3 \\
&= p_1 D_1 D_2^2 + p_2 D_2^3, \quad \mod U_2, \qquad (4.41)
\end{aligned}
$$

where $p_1 = 3c_2 \frac{\partial^3 \eta}{\partial x_1 \partial x_2^2} = 3c_2(a_1'' + 2a_2'' x_1)$ is degree 1 in x_1 and independent of x_2 with $\frac{\partial p_1}{\partial x_1} = 6c_2 a_2'' = 12 c_2^3 \neq 0$, and $p_2 = a_2'' \omega_{12} + \frac{5}{2} c_2 \frac{\partial^3 \eta}{\partial x_2^3} + \frac{1}{2}\omega_{12}\frac{\partial^4 \eta}{\partial x_2^4}$ is a function of x_2 and independent of x_1. By Theorem 3.2, p_2 must be a polynomial in x_2; otherwise E is not finite-dimensional.

By (4.40), $Y_0 = [Z_0, Z_3] = 2c_2 \frac{\partial p_2}{\partial x_2} D_2^4$, $\mod U_3 \in E$, $Y_1 = [Z_0, Y_0] = (2c_2)^2 \frac{\partial^2 p_2}{\partial x_2^2} D_2^5$, $\mod U_4 \in E$, $\ldots$, $Y_l = Ad_{Z_0}^{l+1} Z_3 = (2c_2)^{l+1} \frac{\partial^{l+1} p_2}{\partial x_2^{l+1}} D_2^{l+4}$, $\mod U_{l+3} \in E$. If $deg\ p_2 = k \geq 1$, one can construct an infinite sequence of elements in E whose orders strictly increase as follows:

$$
\begin{aligned}
W_0 &= Ad_{Z_0}^k Z_3 = (2c_2)^k \frac{\partial^k p_2}{\partial x_2^k} D_2^{k+3} \\
&= d_0 D_2^{e_0}, \quad \mod U_{e_0 - 1}, \quad \text{where } d_0 = (2c_2)^k \frac{\partial^k p_2}{\partial x_2^k} \neq 0, e_0 = k + 3, \\
W_{l+1} &= Ad_{Z_0}^{k-1}[W_l, Z_3] = Ad_{Z_0}^{k-1}[d_l D_2^{e_l}, p_1 D_1 D_2^2 + p_2 D_2^3] \\
&= Ad_{Z_0}^{k-1} e_l d_l \frac{\partial p_2}{\partial x_2} D_2^{e_l + 2} \\
&= e_l d_l (2c_2)^{k-1} \frac{\partial^k p_2}{\partial x_2^k} D_2^{e_l + k + 1} \\
&= d_{l+1} D_2^{e_{l+1}}, \quad \mod U_{e_{l+1} - 1},
\end{aligned}
$$

where $d_{l+1} = e_l d_l (2c_2)^{k-1} \frac{\partial^k p_2}{\partial x_2^k} \neq 0$, and $e_{l+1} = e_l + k + 1 > e_l$. Therefore, p_2 is a constant.

Now, p_1 is a degree 1 polynomial in x_1, and p_2 is a constant in (4.41).

$$V_0 = [L_0, Z_3] = \frac{\partial p_1}{\partial x_1} D_1^2 D_2^2, \quad \text{mod } U_3,$$

$$V_1 = [V_0, Z_3] = 2\left(\frac{\partial p_1}{\partial x_1}\right)^2 D_1^2 D_2^4, \quad \text{mod } U_5,$$

$$V_{l+1} = [V_l, Z_3] = \left[2^l \left(\frac{\partial p_1}{\partial x_1}\right)^{l+1} D_1^2 D_2^{2(l+1)}, p_1 D_1 D_2^2 + p_2 D_2^3\right]$$

$$= 2^{l+1}\left(\frac{\partial p_1}{\partial x_1}\right)^{l+2} D_1^2 D_2^{2(l+2)}, \quad \text{mod } U_{2l+5}.$$

Again, V_l's have increasing orders. Hence, E is not finite-dimensional. □

LEMMA 4.15. *If $c_1 \neq 0, c_2 = 0$, we have* (i) $a_4 = \frac{1}{4}c_1^2$; (ii) a_3 *is a constant;* (iii) $a_2'' = 0$; (iv) $a_1'' = 0$.

Proof. (i) follows from Lemma 4.11.

(ii) follows from Lemma 4.10 (ii).

Substituting $c_2 = 0$ into Lemma 4.10 (iv), $c_1 a_1' - 2c_0 a_2' =$ constant. Hence,

$$a_1'' = 2\frac{c_0}{c_1} a_2''. \tag{4.42}$$

From (4.32)–(4.35), q_0 is a constant, $\frac{\partial q_1}{\partial x_1} = 0$, $\frac{\partial q_1}{\partial x_2} = 2a_2''$. Consider

$$Y_0 = [L_0, [X, x_1]] = [L_0, 2q_0 D_1 + q_1 D_2] = \frac{\partial q_1}{\partial x_2} D_2^2 = 2a_2'' D_2^2, \quad \text{mod } U_1. \tag{4.43}$$

Let a_2'' be a degree k polynomial in x_2, i.e., $\frac{d^{k+2}a_2}{dx_2^{k+2}}$ is a nonzero constant. Then the orders of the elements $Z_0 = Ad_{L_0}^k Y_0$, $Y_l = [Z_{l-1}, Y_0]$, $Z_{l+1} = Ad_{L_0}^{k-1} Y_l$ for $l \geq 1$ will be strictly increasing unless $k = 0$. Hence, a_2'' must be a constant.

By (4.35) and (4.42), $\frac{\partial q_2}{\partial x_2} = 0$. Thus, among q_0, q_1, and q_2 in X in (4.32), q_0 is a constant, $\frac{\partial q_1}{\partial x_1} = \frac{\partial q_2}{\partial x_2} = 0$, $\frac{\partial q_1}{\partial x_2} = 2a_2''$, and $\frac{\partial q_2}{\partial x_1} = c_1^2 + a_2''$ are constants. Consider $Y_l = Ad_{-X}^l Y_0$, where Y_0 is in (4.43).

$$Y_1 = [Y_0, X] = \left[\frac{\partial q_1}{\partial x_2} D_2^2, q_0 D_1^2 + q_1 D_1 D_2 + q_2 D_2^2\right] = 2\left(\frac{\partial q_1}{\partial x_2}\right)^2 D_1 D_2^2, \quad \text{mod } U_2,$$

$$Y_2 = [Y_1, X] = \left[2\left(\frac{\partial q_1}{\partial x_2}\right)^2 D_1 D_2^2, q_0 D_1^2 + q_1 D_1 D_2 + q_2 D_2^2\right]$$

$$= 4\left(\frac{\partial q_1}{\partial x_2}\right)^3 D_1^2 D_2^2 \; + \; \text{terms with lower order in } D_1$$

$$\text{with constant coefficients}, \quad \text{mod } U_3,$$

$$\vdots$$

$$
\begin{aligned}
Y_{l+1} &= [Y_l, X] \\
&= \left[2^l \left(\frac{\partial q_1}{\partial x_2} \right)^{l+1} D_1^l D_2^2 \ + \ \text{terms with lower order in } D_1 \text{ with constant coefficients,} \right. \\
&\qquad\qquad \left. q_0 D_1^2 + q_1 D_1 D_2 + q_2 D_2^2 \right] \\
&= 22^l \left(\frac{\partial q_1}{\partial x_2} \right)^{l+1} \frac{\partial q_1}{\partial x_2} D_1^{l+1} D_2^2 \ + \ \text{terms with lower order in } D_1 \\
&\qquad\qquad \text{with constant coefficients} \\
&= 2^{l+1} \left(\frac{\partial q_1}{\partial x_2} \right)^{l+2} D_1^{l+1} D_2^2 \ + \ \text{terms with lower order in } D_1 \\
&\qquad\qquad \text{with constant coefficients } \mathrm{mod} U_{l+2}.
\end{aligned}
$$

Thus, the order of Y_l goes to infinity unless $\frac{\partial q_1}{\partial x_2} = 0 \Longrightarrow a_2'' = 0 \Longrightarrow a_1'' = 0$ by (4.42). □

LEMMA 4.16. *If $c_1 \neq 0, c_2 = 0$, then η is a degree 4 polynomial in x_1, x_2 with its principal part $\eta^{(4)} = \frac{1}{4} c_1^2 x_1^4$.*

Proof. Again, $r_1, r_2, \ldots$ are used to denote constants. The exact values of these r_i's are not important. Some r_i's may be used repeatedly to denote different constants.

By substituting Lemma 4.15 (i)–(iv) into (4.31),

$$
\begin{aligned}
Z_0 &= X_0 - r_1 x_1 - r_2 \\
&= c_1 D_1 D_2 + \left(-\omega_{12}^2 + \frac{1}{2} \frac{\partial^2 \eta}{\partial x_1^2} \right) D_1 + \frac{1}{2} \frac{\partial^2 \eta}{\partial x_1 \partial x_2} D_2 + \frac{1}{2} \omega_{12} \frac{\partial \eta}{\partial x_2}, \\
Z_1 &= [L_0, Z_0] - r_3 D_1 \\
&= r_4 D_1^2 + c_1 \omega_{12} D_2^2 + 2a_2' D_1 D_2 + c_1 \frac{\partial \eta}{\partial x_2} D_1 \\
&\quad + \left(-\omega_{12}^3 + \frac{1}{2} \omega_{12} \frac{\partial^2 \eta}{\partial x_1^2} + \frac{1}{2} \omega_{12} \frac{\partial^2 \eta}{\partial x_2^2} + \frac{1}{2} c_1 \frac{\partial \eta}{\partial x_1} \right) D_2, \quad \mathrm{mod}\ U_0, \\
Z_2 &= [L_0, Z_1] = c_1^2 D_1 D_2^2 + r_5 D_1^2 + \left(3a_2' \omega_{12} + \frac{1}{2} \omega_{12} \frac{\partial^3 \eta}{\partial x_2^3} + \frac{1}{2} c_1 \frac{\partial^2 \eta}{\partial x_1 \partial x_2} \right) D_2^2 \\
&\quad + \left(2r_4 \omega_{12} - 5c_1 \omega_{12}^2 + \frac{3}{2} c_1 \frac{\partial^2 \eta}{\partial x_2^2} + c_1 \frac{\partial^2 \eta}{\partial x_1^2} + \frac{1}{2} \omega_{12} \frac{\partial^3 \eta}{\partial x_1^3} \right) D_1 D_2, \quad \mathrm{mod}\ U_1, \\
Z_3 &= [L_0, Z_2] = r_6 D_1^2 D_2 + \left(r_7 + 2c_1 \frac{\partial^3 \eta}{\partial x_2^3} \right) D_1 D_2^2 + \left(c_1^2 \omega_{12} + \frac{1}{2} \omega_{12} \frac{\partial^4 \eta}{\partial x_2^4} \right) D_2^3 \\
&= r_6 D_1^2 D_2 + (r_7 + 2c_1 a_0''') D_1 D_2^2 + \left(c_1^2 + \frac{1}{2} a_0'''' \right) \omega_{12} D_2^3, \quad \mathrm{mod}\ U_2, \\
Y_0 &= [Z_3, x_1] = 2r_6 D_1 D_2 + (r_7 + 2c_1 a_0''') D_2^2, \quad \mathrm{mod}\ U_1.
\end{aligned}
$$

From the proof of Lemma 4.13 (iii), $\frac{\partial}{\partial x_2}(r_7 + 2c_1 a_0''') = 0 \rightarrow a_0'''' = 0$. By Lemma 4.15, η is a degree 4 polynomial in x_1, x_2 with principal part $\eta^{(4)} = \frac{1}{4} c_1^2 x_1^4$. □

THEOREM 4.17. *If $c_1 \neq 0, c_2 = 0$, E is not finite-dimensional.*

Proof. From Lemma 4.15, (4.28), and (4.27),

$$H_1 = [D_1, H_0] = c_1 D_2 - \omega_{12}^2 + \frac{1}{2}\frac{\partial^2 \eta}{\partial x_1^2}$$

$$= c_1 D_2 + \frac{1}{2}c_1^2 x_1^2 + (3a_3 - 2c_1 c_0)x_1 + a_2 - c_0^2, \tag{4.44}$$

$$H_0 = [L_0, D_1] = \omega_{12} D_2 + \frac{1}{2}\frac{\partial \eta}{\partial x_1} + \frac{1}{2}c_2$$

$$= (c_1 x_1 + c_0)D_2 + \frac{1}{2}(a_1 + 2a_2 x_1 + 3a_3 x_1^2 + 4a_4 x_1^3)$$

$$= x_1 H_1 + d_0 H_1 + \left(\frac{1}{2}d x_1^2 + d_0 d x_1 + d_2 x_2 + d_3\right), \tag{4.45}$$

where

$$d = 3c_0 c_1 - 3a_3,\ d_0 = \frac{c_0}{c_1},\ d_2 = \frac{1}{2}a_1' - d_0 a_2', \tag{4.46}$$

and d_3 is a constant with unknown value. (Note that all the d's here are constants.)

From (4.44), D_2 can be represented in terms of H_1, x_1, x_2, i.e.,

$$D_2 = \frac{1}{c_1}\left(H_1 - \left(\frac{1}{2}c_1^2 x_1^2 + (3a_3 - 2c_1 c_0)x_1 + a_2 - c_0^2\right)\right). \tag{4.47}$$

Thus, any element in E can be represented in terms of D_1, H_1, x_1, x_2. The following relations hold:

$$[D_1, x_1] = 1, \qquad [D_1, x_2] = 0, \tag{4.48}$$

$$[H_1, x_1] = 0, \qquad [H_1, x_2] = c_1, \tag{4.49}$$

$$[D_1, H_1] = 3a_3 - 3c_1 c_0 = -d. \tag{4.50}$$

Definition. Let A be a differential operator of order k in E. Then A has a unique representation:

$$A = \sum_{i=0}^{k}\sum_{j=0}^{i} h_{ij} D_1^{i-j} H_1^j, \tag{4.51}$$

where h_{ij}'s are polynomials in x_1, x_2. (It is worth mentioning that in the scope of this theorem, η is a polynomial by Lemma 4.16. In general, it is not clear whether h_{ij} is a polynomial or not.) The *degree* of A is defined to be $deg\ A = \max_i \max_j \{deg\ h_{ij} + 2i\}$. In other words, the degree of the differential operator A is the degree of the polynomial (of x_1, x_2, x_3, x_4 variables) obtained by replacing D_1, H_1 by x_3^2, x_4^2 in the form (4.51) of A.

For example, in (4.45), H_0 is a sum of three terms. The first, $x_1 H_1$, is of degree 3; the second, $d_0 H_1$, is of degree 2; the order 0 term $\frac{1}{2}d x_1^2 + d_0 d x_1 + d_2 x_2 + d_3$ is of degree 2. Hence, $deg\ H_0 = 3$. Similarly, $deg\ D_2 = 2$ by (4.47).

Since $D_1 H_1 = H_1 D_1 - d$, $H_1 h = h H_1 + c_1 \frac{\partial h}{\partial x_2}$, and $D_1 h = h D_1 + \frac{\partial h}{\partial x_1}$, it is easy to show by induction that *deg* is commutative. Moreover, for any $X, Y \in E$,

$$deg\ X + Y \leq \max\{deg\ X, deg\ Y\}, \quad deg\ XY = deg\ YX, \quad deg\ XY \leq deg\ X + deg\ Y. \tag{4.52}$$

Let $Y_l = Ad^l_{L_0} D_1$. The following will show that $deg\ Y_l = l+2$ and

$$Y_{2l} = D_1 H_1^l + Z_{2l}, \qquad Y_{2l+1} = x_1 H_1^{l+1} + Z_{2l+1}, \tag{4.53}$$

where Z_k is a differential operator with $deg\ Z_k \le k+1$:

- $l = 0$, $Y_0 = D_1$, $deg\ Y_0 = 2$, $Z_0 = 0$.
- $l = 1$, $Y_1 = [L_0, D_1] = H_0 = x_1 H_1 + Z_1$, where $Z_1 = d_0 H_1 + (\frac{1}{2} dx_1^2 + d_0 dx_1 + d_2 x_2 + d_3)$ by (4.45). $deg\ Y_1 = 3$, $deg\ Z_1 \le 2$.

Suppose $Y_{2l-1} = x_1 H_1^l + Z_{2l-1}$ with $deg\ Z_{2l-1} \le 2l$.

$$\begin{aligned} Y_{2l} &= [L_0, Y_{2l-1}] = [L_0, x_1 H_1^l + Z_{2l-1}] \\ &= [L_0, x_1] H_1^l + x_1 [L_0, H_1^l] + [L_0, Z_{2l-1}] = D_1 H_1^l + Z_{2l}, \end{aligned}$$

where $Z_{2l} = x_1 [L_0, H_1^l] + [L_0, Z_{2l-1}]$. By Lemma 4.18,

$$deg\ Z_{2l} \le \max\{1 + deg\ [L_0, H_1^l], deg\ [L_0, Z_{2l-1}]\} \le 2l+1.$$

$$\begin{aligned} Y_{2l+1} &= [L_0, Y_{2l}] = [L_0, D_1 H_1^l + Z_{2l}] = [L_0, D_1] H_1^l + D_1 [L_0, H_1^l] + [L_0, Z_{2l}] \\ &= (x_1 H_1 + Z_1) H_1^l + D_1 [L_0, H_1^l] + [L_0, Z_{2l}] = x_1 H_1^{l+1} + Z_{2l+1}, \end{aligned}$$

where $Z_{2l+1} = Z_1 H_1^l + D_1 [L_0, H_1^l] + [L_0, Z_{2l}]$ with

$$deg\ Z_{2l+1} \le \max\{deg\ Z_1 H_1^l, 2 + deg\ [L_0, H_1^l], deg\ [L_0, Z_{2l}]\} = 2l+2.$$

Hence, (4.53) holds by induction. $deg\ Y_l = l+2 \to \infty$. E is not finite-dimensional. □

LEMMA 4.18.

(i) *Let* $A_l = [L_0, H_1^l]$, $B_l = [L_0, D_1^l]$. *Then* $deg\ A_l \le 2l$ *and* $deg\ B_l \le 2l+1$.

(ii) *Let* $C = [L_0, h D_1^{i_1} H_1^{i_2}]$. *Then* $deg\ C \le deg\ h + 2(i_1 + i_2) + 1$.

(iii) $deg\ [L_0, A] \le deg\ A + 1$.

Proof. (i) $l = 1$,

$$\begin{aligned} A_1 = [L_0, H_1] &= \left[L_0, c_1 D_2 + \frac{1}{2} c_1^2 x_1^2 + (3a_3 - 2c_1 c_0) x_1 + a_2 - c_0^2 \right] \\ &= -d D_1 + d_1 H_1 + (d_1 d + c_1 d_2) x_1 + d_4, \end{aligned}$$

where d, d_2 are in (4.46), and $d_1 = \frac{a_2'}{c_1}$ and $d_4 = \frac{1}{2} c_1 a_0' - \frac{1}{c_1} a_2 a_2' + d_1 c_0^2$ are constants. (Note: Actually one extra condition has been obtained on a_0 that $a_0'' = 2(\frac{a_2'}{c_1})^2 = 2d_1^2$ since d_4 is in E and independent of x_2.) Thus, $deg\ A_1 = 2$. By (4.45), $deg\ B_1 = deg\ H_0 = 3$.

$$\begin{aligned} A_{l+1} = [L_0, H_1^{l+1}] &= [L_0, H_1^l] H_1 + H_1^l [L_0, H_1] \\ &= A_l H_1 + H_1^l A_1, \\ B_{l+1} = [L_0, D_1^{l+1}] &= [L_0, D_1^l] D_1 + D_1^l [L_0, D_1] \\ &= B_l D_1 + D_1^l B_1. \end{aligned}$$

By induction and (4.52), (i) holds since $deg\ A_{l+1} \le \max\{deg\ A_l + deg\ H_1, deg\ H_1^l + deg\ A_1\} \le 2(l+1)$, $deg\ B_{l+1} \le \max\{deg\ B_l + deg\ D_1, deg\ D_1^l + deg\ B_1\} \le 2(l+1)+1$.

(ii)

$$\begin{aligned} C &= [L_0, h D_1^{i_1} H_1^{i_2}] \\ &= [L_0, h] D_1^{i_1} H_1^{i_2} + h [L_0, D_1^{i_1}] H_1^{i_2} + h D_1^{i_1} [L_0, H_1^{i_2}]. \\ &= \sum_{j=1}^{2} \frac{\partial h}{\partial x_j} D_j D_1^{i_1} H_1^{i_2} + \frac{1}{2} \sum_{j=1}^{2} \frac{\partial^2 h}{\partial x_j^2} D_1^{i_1} H_1^{i_2} + h B_{i_1} H_1^{i_2} + h D_1^{i_1} A_{i_2}. \end{aligned}$$

Since $deg\ D_2 = 2$ by (4.47),

$$\begin{aligned}
&deg\ C\\
&\le \max\left\{deg\ \frac{\partial h}{\partial x_1}D_1^{i_1+1}H_1^{i_2}, deg\ \frac{\partial h}{\partial x_2}D_2D_1^{i_1}H_1^{i_2}, deg\ \frac{\partial^2 h}{\partial x_1^2}D_1^{i_1}H_1^{i_2},\right.\\
&\qquad \left. deg\ \frac{\partial^2 h}{\partial x_2^2}D_1^{i_1}H_1^{i_2}, deg\ hB_{i_1}H_1^{i_2}, deg\ hD_1^{i_1}A_{i_2}\right\}\\
&\le \max\{deg\ h - 1 + 2(i_1+i_2+1), deg\ h - 1 + 2(i_1+i_2+1), deg\ h - 2 + 2i_1 + 2i_2,\\
&\qquad deg\ h - 2 + 2i_1 + 2i_2, deg\ h + 2i_1 + 1 + 2i_2, deg\ h + 2i_1 + 2i_2\}\\
&= deg\ h + 2(i_1+i_2) + 1.
\end{aligned}$$

(iii) Let $A = \sum_{i=0}^{k}\sum_{j=0}^{i} h_{ij}D_1^{i-j}H_1^j$. Then by (ii)

$$\begin{aligned}
deg\ [L_0, A] &= deg\ \left[L_0, \sum_{i=0}^{k}\sum_{j=0}^{i} h_{ij}D_1^{i-j}H_1^j\right]\\
&\le \max_{i,j} deg\ [L_0, h_{ij}D_1^{i-j}H_1^j] \le \max_{i,j} deg\ h_{ij} + 2i + 1\\
&= deg\ A + 1. \qquad \square
\end{aligned}$$

By putting Theorems 4.12, 4.14, and 4.17 together, we obtain the following.

THEOREM 4.19. *If E has linear rank 1 and is finite-dimensional, then the Ω-matrix has constant entries.*

4.3. Classification results. First assume E has linear rank 1. By Theorem 4.9, h_i's must be degree at most 1 polynomials in x_1. By Theorem 4.19, ω_{12} is a constant.

(i) If $\omega_{12} = 0$, $[L_0, D_1] = \frac{1}{2}\frac{\partial \eta}{\partial x_1} \in E$. Thus, η must be a degree 2 polynomial in x_1 plus a C^∞-function in x_2. $E = \{L_0, x_1, D_1, 1\}$. For example, $f_1 = x_1$, $f_2 = \sin x_2$, $h_1 = x_1$, $\eta = 2x_1^2 + 1 + \cos x_2 + \sin^2 x_2$.

(ii) If $\omega_{12} \neq 0$,

$$A_1 := [L_0, D_1] = \omega_{12}D_2 + \frac{1}{2}\frac{\partial \eta}{\partial x_1} \in E, \tag{4.54}$$

$$A_2 := [D_1, A_1] = -\omega_{12}^2 + \frac{1}{2}\frac{\partial^2 \eta}{\partial x_1^2} \in E, \tag{4.55}$$

$$\begin{aligned}
A_3 := [L_0, A_1] = &\left(\frac{1}{2}\frac{\partial^2 \eta}{\partial x_1^2} - \omega_{12}^2\right)D_1 + \frac{1}{2}\frac{\partial^2 \eta}{\partial x_1 \partial x_2}D_2\\
&+\frac{1}{2}\omega_{12}\frac{\partial \eta}{\partial x_2} + \frac{1}{4}\frac{\partial^3 \eta}{\partial x_1^3} + \frac{1}{4}\frac{\partial^3 \eta}{\partial x_1 \partial x_2^2} \in E.
\end{aligned} \tag{4.56}$$

By (4.55), $\eta = d_0x_1^3 + d_1x_1^2 + e_2(x_2)x_1 + e_3(x_2)$. By Theorem 3.21, $d_0 = 0$. By (4.56) and $D_1 \in E$,

$$\frac{1}{2}\frac{\partial^2 \eta}{\partial x_1 \partial x_2}D_2 + \frac{1}{2}\omega_{12}\frac{\partial \eta}{\partial x_2} + \frac{1}{4}\frac{\partial^3 \eta}{\partial x_1 \partial x_2^2} \in E. \tag{4.57}$$

By Theorem 4.1, $\frac{\partial^2 \eta}{\partial x_1 \partial x_2} = e_2'(x_2)$ is a polynomial of degree at most 1. Thus, e_2 is a polynomial of degree at most 2 in x_2. By substituting e_2 and e_3 into η and removing

D_1, x_1, and 1 from (4.54) and (4.57), one has

$$\bar{A}_1 = \omega_{12} D_2 + \frac{1}{2} e_2 \in E, \tag{4.58}$$

$$\bar{A}_3 = \frac{1}{2} e_2' D_2 + \frac{1}{2} \omega_{12} (e_2' x_1 + e_3') \in E. \tag{4.59}$$

If e_2 is a degree 2 polynomial in x_2, then $[\bar{A}_1, \bar{A}_3] - \frac{1}{2} e_2'' \bar{A}_1 = \frac{1}{2}\omega_{12}^2 e_3'' - \frac{1}{4}(e_2 e_2'' + e_2' e_2') + \frac{1}{2}\omega_{12}^2 e_2'' x_1 \in E$. Since the degree 2 term of $e_2 e_2'' + e_2' e_2'$ will never be zero, $e_3(x_2)$ must be a degree 4 polynomial. Now, consider

$$B_1 = [L_0, \bar{A}_3] = \frac{1}{2} e_2'' D_2^2 + \frac{1}{2}\omega_{12}(e_2'' x_1 + e_3'') D_2 + \frac{1}{4} e_2'(e_2' x_1 + e_3') + \frac{1}{4}\omega_{12} e_3'' \in E,$$

$$B_2 = [L_0, B_1] = \frac{1}{2} e_2''[L_0, D_2^2] + \left[L_0, \frac{1}{2}\omega_{12}(e_2'' x_1 + e_3'') D_2\right]$$

$$= \frac{1}{2}\omega_{12} e_3''' D_2^2 - \frac{1}{2}\omega_{12} e_2'' D_2 D_1 \in E, \qquad \mod U_1.$$

From the discussion of the proof of Lemma 4.13 (iii), e_3''' must be a constant. Contradiction! Hence, e_2 must be a degree 1 polynomial.

Consider $\omega_{12}\bar{A}_3 - \frac{1}{2} e_2' \bar{A}_1 = \frac{1}{2}\omega_{12}^2 e_2' x_1 + \frac{1}{2}\omega_{12}^2 e_3' - \frac{1}{4} e_2' e_2 \in E \Longrightarrow \frac{1}{2}\omega_{12}^2 e_3' - \frac{1}{4} e_2' e_2$ is independent of x_2 and e_3 must be a degree 2 polynomial. Hence, η is a degree 2 polynomial in x_1 and x_2. E is of dimension 5 and $E = \{L_0, x_1, D_1, D_2 + c x_2, 1\}$.

For example, $f_1 = 5x_1 - 3x_2$, $f_2 = 4x_2$, $h_1 = x_1$. Then $\omega_{12} = 3$ and $\eta = 26x_1^2 - 30 x_1 x_2 + 25 x_2^2 + 9$. It is easy to show that $E = \{L_0, x_1, D_1, D_2 - 5x_2, 1\}$.

If E has linear rank 0, h_i's must be constants, and $E = \{L_0\}$ or $E = \{L_0, 1\}$.

If E has linear rank 2, E is of maximal rank. The Ω-matrix must have constant entries and $E = \{L_0, x_1, x_2, D_1, D_2, 1\}$ by Theorem 2.7. In summary, we have the following.

THEOREM 4.20. *Let $n = 2$. If E is finite-dimensional, then*

(1) *if h_i's are constants, $E = \{L_0\}$ or $E = \{L_0, 1\}$;*

(2) *otherwise, Ω-matrix has constant entries. h_i's must be affine in x_1 and x_2. E has dimension of either 4, 5, or 6.*

Moreover, from the above discussion, it is easy to see that if E is finite-dimensional, it has only elements with order less than or equal to 2. Thus, the Levine conjecture holds for the finite-dimensional estimation algebras with state dimension 2.

EXACT BOUNDARY CONTROLLABILITY FOR 1-D QUASILINEAR WAVE EQUATIONS*

LI TATSIEN† AND YU LIXIN‡

Abstract. In this paper we present a unified constructive method to establish the local exact boundary controllability for 1-D quasilinear wave equations with boundary conditions of various types.

Key words. exact boundary controllability, 1-D quasilinear wave equation

1. Introduction and main results. There are many publications concerning the exact controllability for linear hyperbolic systems (see Lions [11], Russell [12], and the references therein). In the semilinear case, some results on the exact boundary controllability for semilinear wave equations are obtained by Zuazua [15], [16], [17], Lasiecka and Triggiani [3], Emanuilov [2], etc. However, even in the 1-D case, only a few results are known for quasilinear wave equations.

Consider the following quasilinear wave equation:

$$\frac{\partial^2 u}{\partial t^2} - \frac{\partial}{\partial x}\left(K\left(u, \frac{\partial u}{\partial x}\right)\right) = F\left(u, \frac{\partial u}{\partial x}, \frac{\partial u}{\partial t}\right), \tag{1.1}$$

where $K = K(u, v)$ is a given C^2 function of u and v such that

$$K_v(u, v) > 0, \tag{1.2}$$

and $F = F(u, v, w)$ is a given C^1 function of u, v and w satisfying

$$F(0, 0, 0) = 0. \tag{1.3}$$

Moreover, without loss of generality, we may assume that

$$K(0, 0) = 0. \tag{1.4}$$

On one end $x = 0$ we prescribe any one of the following boundary conditions:

$$u = h(t) \qquad \text{(of Dirichlet type)}, \tag{1.5.1}$$

$$u_x = h(t) \qquad \text{(of Neumann type)}, \tag{1.5.2}$$

$$u_x - \alpha u = h(t) \qquad \text{(of the third type)}, \tag{1.5.3}$$

or

$$u_x - \bar{\alpha} u_t = h(t) \qquad \text{(of the dissipative type)}, \tag{1.5.4}$$

where α and $\bar{\alpha}$ are given positive constants and $h(t)$ is a C^2 function (in case (1.5.1)) or a C^1 function (in cases (1.5.2)–(1.5.4)).

Similarly, on another end, $x = 1$, the boundary condition is

$$u = \bar{h}(t) \qquad \text{(of Dirichlet type)}, \tag{1.6.1}$$

$$u_x = \bar{h}(t) \qquad \text{(of Neumann type)}, \tag{1.6.2}$$

$$u_x + \beta u = \bar{h}(t) \qquad \text{(of the third type)}, \tag{1.6.3}$$

or

$$u_x + \bar{\beta} u_t = \bar{h}(t) \qquad \text{(of the dissipative type)}, \tag{1.6.4}$$

where β and $\bar{\beta}$ are given positive constants and $\bar{h}(t)$ is a C^2 function (in case (1.6.1)) or a C^1 function (in cases (1.6.2)–(1.6.4)).

In the case that K and F in (1.1) are independent of u, if on one end, say, on $x = 0$, the boundary condition is given by (1.5.1), by means of the local exact boundary controllability for quasilinear hyperbolic systems without zero eigenvalues, Li and Rao [6] established the corresponding local exact boundary controllability with the boundary control $\bar{h}(t)$ on another end, $x = 1$; while, if on $x = 0$, the boundary condition is given by (1.5.3), by means of the theory on the local exact boundary controllability for quasilinear hyperbolic systems without zero eigenvalues together with a kind of nonlocal boundary conditions, Li and Xu [8] established the corresponding local exact boundary controllability with the boundary control $\bar{h}(t)$ on another end, $x = 1$. However, the method used in [6] and [8] cannot be applied to the following cases: (1) K and F in (1.1) depend explicitly on u; for instance, (1.1) is a linear or nonlinear Klein–Gordon equation. (2) The boundary condition on $x = 0$ is of Neumann type or of the dissipative type. (3) Boundary controls are simultaneously given on both ends $x = 0$ and $x = 1$.

In this paper, we will present a unified method to get the local exact boundary controllability with boundary controls on one end or on two ends for (1.1) with boundary conditions (1.5) and (1.6) of different types. The main results are the following two theorems.

THEOREM 1.1 (exact boundary controllability with boundary controls acting on two ends). *Let*

$$T > \frac{1}{\sqrt{K_v(0,0)}}. \tag{1.7}$$

For any given initial data (φ, ψ) *and final data* (Φ, Ψ) *with small norms*

$$\|(\varphi,\psi)\|_{C^2[0,1]\times C^1[0,1]} \text{ and } \|(\Phi,\Psi)\|_{C^2[0,1]\times C^1[0,1]},$$

there exist boundary controls $h(t)$ *and* $\bar{h}(t)$ *with small norms* $\|h\|_{C^2[0,T]}$ *and* $\|\bar{h}\|_{C^2[0,T]}$ *(for* (1.5.1) *and* (1.6.1)*) or with small norms* $\|h\|_{C^1[0,T]}$ *and* $\|\bar{h}\|_{C^1[0,T]}$ *(for* (1.5.2)–(1.5.4) *and* (1.6.2)–(1.6.4)*) such that the mixed initial-boundary value problem for* (1.1) *with the initial condition*

$$t = 0: \quad u = \varphi(x), \quad u_t = \psi(x), \quad 0 \le x \le 1, \tag{1.8}$$

one of the boundary conditions (1.5) *on* $x = 0$*, and one of the boundary conditions* (1.6) *on* $x = 1$ *admits a unique* C^2 *solution* $u = u(t, x)$ *with small* C^2 *norm on the domain*

$$R(T) = \{(t, x) |\ \ 0 \le t \le T, \ \ 0 \le x \le 1\}, \tag{1.9}$$

which exactly satisfies the final condition

$$t = T : \ \ u = \Phi(x), \ \ u_t = \Psi(x), \ \ 0 \le x \le 1. \tag{1.10}$$

THEOREM 1.2 (exact boundary controllability with boundary control acting on one end). *Let*

$$T > \frac{2}{\sqrt{K_v(0,0)}}. \tag{1.11}$$

Suppose that

$$\bar{\alpha} \ne \frac{1}{\sqrt{K_v(0,0)}}, \tag{1.12}$$

where $\bar{\alpha}$ *is given in* (1.5.4)*. For any given initial data* (φ, ψ) *and final data* (Φ, Ψ) *with small norms* $\|(\varphi, \psi)\|_{C^2[0,1]\times C^1[0,1]}$ *and* $\|(\Phi, \Psi)\|_{C^2[0,1]\times C^1[0,1]}$ *and for any given function* $h(t)$ *with small norm* $\|h\|_{C^2[0,T]}$ *(in case* (1.5.1)*) or with small norm* $\|h\|_{C^1[0,T]}$ *(in cases* (1.5.2)–(1.5.4)*) such that the conditions of* C^2 *compatibility (for details, see Remark* 1.1 *below) are satisfied at the points* $(0, 0)$ *and* $(T, 0)$*, respectively, there exists a boundary control* $\bar{h}(t)$ *with small norm* $\|\bar{h}\|_{C^2[0,T]}$ *(in case* (1.6.1)*) or with small norm* $\|\bar{h}\|_{C^1[0,T]}$ *(in cases* (1.6.2)–(1.6.4)*) such that the mixed initial-boundary value problem for* (1.1) *with the initial condition* (1.8)*, one of the boundary conditions* (1.5) *on* $x = 0$*, and one of the boundary conditions* (1.6) *on* $x = 1$ *admits a unique* C^2 *solution* $u = u(t, x)$ *with small* C^2 *norm on the domain* $R(T)$ *(see* (1.9)*), which exactly satisfies the final condition* (1.10)*.*

Remark 1.1. Precisely speaking, the conditions of C^2 compatibility at the point $(0, 0)$ are given, respectively, for boundary conditions (1.5.1)–(1.5.4) as follows:

(1.13.1)
$$\begin{cases} h(0) = \varphi(0), \\ h'(0) = \psi(0), \\ h''(0) - K_u(\varphi(0), \varphi'(0))\varphi'(0) - K_v(\varphi(0), \varphi'(0))\varphi''(0) = F(\varphi(0), \varphi'(0), \psi(0)); \end{cases}$$

(1.13.2)
$$\begin{cases} h(0) = \varphi'(0), \\ h'(0) = \psi'(0); \end{cases}$$

(1.13.3)
$$\begin{cases} \varphi'(0) - \alpha\varphi(0) = h(0), \\ \psi'(0) - \alpha\psi(0) = h'(0); \end{cases}$$

or

(1.13.4)
$$\begin{cases} \varphi'(0) - \bar{\alpha}\psi(0) = h(0), \\ \psi'(0) - \bar{\alpha}(K_u(\varphi(0), \varphi'(0))\varphi'(0) + K_v(\varphi(0), \varphi'(0))\varphi''(0) + F(\varphi(0), \varphi'(0), \psi(0))) = h'(0). \end{cases}$$

The conditions of C^2 compatibility at the point $(T, 0)$ are similar.

2. C^2 solution on a preassigned domain for 1-D quasilinear wave equations. Since the hyperbolic wave has a finite speed of propagation, the exact boundary controllability for the quasilinear wave equation requires that the controllability time T must be suitably large so that two maximum determinate domains associated with the initial data and the final data, respectively, are separated. Hence, in order to get the exact boundary controllability, we should first prove the existence and uniqueness of the classical solution on the time interval $0 \le t \le T_0$, where $T_0 > 0$ is a preassigned and possibly quite large number.

In order to get the existence and uniqueness of the C^2 solution on a preassigned domain for 1-D quasilinear wave equations with boundary conditions of various types, the best way is to reduce the equation to a first order quasilinear hyperbolic system, then apply the corresponding theory on the existence and uniqueness of the C^1 solution to this system with general nonlinear boundary conditions on a preassigned domain (see [4], [7], [14]), and finally obtain the desired result in a unified way; alternatively, we may apply a careful extension method based on some well-known results on the local existence and uniqueness of the C^2 solution for quasilinear wave equations with boundary conditions of some prescribed types (for instance, see [13]) to get the desired result in an exhaustive way for all possible cases, respectively.

As a result, we can get the following lemma.

LEMMA 2.1. *Under the assumptions given at the beginning of section* 1*, suppose furthermore that the usual conditions of C^2 compatibility (cf.* (1.13)*) are satisfied at the points* $(0,0)$ *and* $(0,1)$*, respectively. Then, for a given $T_0 > 0$, the forward mixed initial-boundary value problem* (1.1)*,* (1.5)–(1.6)*, and* (1.8) *admit a unique C^2 solution $u = u(t,x)$ with small C^2 norm on the domain*

$$R(T_0) = \{(t,x) |\ \ 0 \le t \le T_0, \quad 0 \le x \le 1\}, \tag{2.1}$$

provided that the norms $\|(\varphi,\psi)\|_{C^2[0,1]\times C^1[0,1]}$ and $\|h\|_{C^2[0,T_0]}, \|\bar{h}\|_{C^2[0,T_0]}$ (for (1.5.1) *and* (1.6.1)*) or $\|h\|_{C^1[0,T_0]}, \|\bar{h}\|_{C^1[0,T_0]}$ (for* (1.5.2)–(1.5.4) *and* (1.6.2)–(1.6.4)*) are small enough (depending on T_0).*

Similar results can be obtained for the backward mixed initial-boundary value problem. We then have the following lemma.

LEMMA 2.2. *Under the assumptions given at the beginning of section* 1*, suppose that* (1.12) *holds and*

$$\bar{\beta} \ne \frac{1}{\sqrt{K_v(0,0)}}. \tag{2.2}$$

For a given $T_0 > 0$, suppose furthermore that the conditions of C^2 compatibility are satisfied at the points $(T_0,0)$ *and* $(T_0,1)$*, respectively. Then the backward mixed initial-boundary value problem* (1.1)*,* (1.5)–(1.6)*, and the final condition*

$$t = T_0: \qquad u = \Phi(x), \quad u_t = \Psi(x), \qquad 0 \le x \le 1, \tag{2.3}$$

admit a unique C^2 solution $u = u(t,x)$ with small C^2 norm on the domain (2.1)*, provided that the norms $\|(\Phi,\Psi)\|_{C^2[0,1]\times C^1[0,1]}$ and $\|h\|_{C^2[0,T_0]}, \|\bar{h}\|_{C^2[0,T_0]}$ (for* (1.5.1) *and* (1.6.1)*) or $\|h\|_{C^1[0,T_0]}, \|\bar{h}\|_{C^1[0,T_0]}$ (for* (1.5.2)–(1.5.4) *and* (1.6.2)–(1.6.4)*) are small enough (depending on T_0).*

3. Proof of Theorem 1.1. As in [5] (also see [7] and [9]), in order to prove Theorem 1.1, it suffices to prove the following lemma.

LEMMA 3.1. *Let $T>0$ be defined by* (1.7). *For any given initial data (φ,ψ) and final data (Φ,Ψ) with small norms $\|(\varphi,\psi)\|_{C^2[0,1]\times C^1[0,1]}$ and $\|(\Phi,\Psi)\|_{C^2[0,1]\times C^1[0,1]}$, the quasilinear wave equation* (1.1) *admits a C^2 solution $u=u(t,x)$ with small C^2 norm on the domain $R(T)=\{(t,x)|\ 0\le t\le T,\ 0\le x\le 1\}$, which satisfies simultaneously the initial condition* (1.8) *and the final condition* (1.10).

Proof. By (1.7), there exists an $\varepsilon_0>0$ so small that

$$T>\max_{|u|+|v|\le\varepsilon_0}\frac{1}{\sqrt{K_v(u,v)}}. \tag{3.1}$$

Let

$$T_1=\frac{1}{2}\max_{|u|+|v|\le\varepsilon_0}\frac{1}{\sqrt{K_v(u,v)}}. \tag{3.2}$$

We divide the proof into several steps.

(i) We first consider the following forward mixed initial-boundary value problem of (1.1) with the initial condition (1.8) and the boundary conditions

$$x=0:\qquad u=f_0(t), \tag{3.3}$$

$$x=1:\qquad u=f_1(t), \tag{3.4}$$

where f_0 and f_1 are any given C^2 functions of t with small $C^2[0,T_1]$ norm such that the conditions of C^2 compatibility are satisfied at the points $(0,0)$ and $(0,1)$, respectively. By Lemma 2.1, on the domain

$$\{(t,x)|\ \ 0\le t\le T_1,\ \ 0\le x\le 1\} \tag{3.5}$$

there exists a unique C^2 solution $u=u^{(1)}(t,x)$ with small C^2 norm and

$$|u^{(1)}(t,x)|+\left|\frac{\partial u^{(1)}}{\partial x}(t,x)\right|\le\varepsilon_0. \tag{3.6}$$

Thus, we can determine the corresponding value of $(u^{(1)}(t,x),\frac{\partial u^{(1)}}{\partial x}(t,x))$ on $x=\frac{1}{2}$ as

$$x=\frac{1}{2}:\qquad (u,u_x)=(a(t),\bar a(t)),\quad 0\le t\le T_1, \tag{3.7}$$

the $C^2[0,T_1]$ norm of $a(t)$ and the $C^1[0,T_1]$ norm of $\bar a(t)$ are small.

(ii) Similarly, we consider the following backward mixed initial-boundary value problem of (1.1) with the final condition (1.10) and the boundary conditions

$$x=0:\qquad u=g_0(t), \tag{3.8}$$

$$x=1:\qquad u=g_1(t), \tag{3.9}$$

where g_0 and g_1 are any given C^2 functions of t with small $C^2[T-T_1,T]$ norm such that the conditions of C^2 compatibility are satisfied at the points $(T,0)$ and $(T,1)$, respectively. By Lemma 2.2, on the domain

$$\{(t,x)|\ T-T_1\le t\le T,\ \ 0\le x\le 1\} \tag{3.10}$$

there exists a unique C^2 solution $u = u^{(2)}(t,x)$ with small C^2 norm and

$$|u^{(2)}(t,x)| + \left|\frac{\partial u^{(2)}}{\partial x}(t,x)\right| \le \varepsilon_0. \tag{3.11}$$

Thus, we can determine the corresponding value of $(u^{(2)}(t,x), \frac{\partial u^{(2)}}{\partial x}(t,x))$ on $x = \frac{1}{2}$ as

$$x = \frac{1}{2}: \qquad (u, u_x) = (b(t), \bar{b}(t)), \quad T - T_1 \le t \le T, \tag{3.12}$$

where the $C^2[T-T_1, T]$ norm of $b(t)$ and the $C^1[T-T_1, T]$ norm of $\bar{b}(t)$ are small.

(iii) We can find $c(t) \in C^2[0,T]$ with small C^2 norm and $\bar{c}(t) \in C^1[0,T]$ with small C^1 norm such that

$$(c(t), \bar{c}(t)) = \begin{cases} (a(t), \bar{a}(t)), & 0 \le t \le T_1, \\ (b(t), \bar{b}(t)), & T - T_1 \le t \le T. \end{cases} \tag{3.13}$$

Noting (1.2), we now change the status of t and x, and on the domain

$$R_l(T) = \left\{ (t,x) |\ 0 \le t \le T, \quad 0 \le x \le \frac{1}{2} \right\} \tag{3.14}$$

we consider the following leftward mixed initial-boundary value problem of (1.1) with the initial condition

$$x = \frac{1}{2}: \qquad u = c(t), \quad u_x = \bar{c}(t), \quad 0 \le t \le T, \tag{3.15}$$

and the boundary conditions

$$t = 0: \qquad u = \varphi(x), \qquad 0 \le x \le \frac{1}{2}, \tag{3.16}$$

$$t = T: \qquad u = \Phi(x), \qquad 0 \le x \le \frac{1}{2}, \tag{3.17}$$

where $\varphi(x)$ and $\Phi(x)$ are given by (1.8) and (1.10), respectively.

Obviously, the corresponding conditions of C^2 compatibility are satisfied at the points $(0, \frac{1}{2})$ and $(T, \frac{1}{2})$, respectively. Hence, by Lemma 2.2, there exists a unique C^2 solution $u = u_l(t,x)$ with small C^2 norm on the domain $R_l(T)$ and

$$|u_l(t,x)| + \left|\frac{\partial u_l}{\partial x}(t,x)\right| \le \varepsilon_0 \qquad \text{on } R_l(T), \tag{3.18}$$

provided that the C^2 norms of $\varphi(x)$, $\Phi(x)$, $f_0(t)$, $f_1(t)$, $g_0(t)$, and $g_1(t)$ are small enough.

(iv) Similarly, the rightward mixed initial-boundary value problem of (1.1) with the initial condition (3.15) and the boundary conditions

$$t = 0: \qquad u = \varphi(x), \qquad \frac{1}{2} \le x \le 1, \tag{3.19}$$

$$t = T: \qquad u = \Phi(x), \qquad \frac{1}{2} \le x \le 1, \tag{3.20}$$

admits a unique C^2 solution $u = u_r(t,x)$ with small C^2 norm on the domain

$$R_r(T) = \left\{(t,x)|\ \ 0 \le t \le T,\ \ \frac{1}{2} \le x \le 1\right\} \tag{3.21}$$

and

$$|u_r(t,x)| + \left|\frac{\partial u_r}{\partial x}(t,x)\right| \le \varepsilon_0 \qquad \text{on } R_r(T). \tag{3.22}$$

(v) Let

$$u(t,x) = \begin{cases} u_l(t,x), & (t,x) \in R_l(T), \\ u_r(t,x), & (t,x) \in R_r(T). \end{cases} \tag{3.23}$$

We prove

$$t = 0: \qquad u_t = \psi(x), \qquad 0 \le x \le 1, \tag{3.24}$$

$$t = T: \qquad u_t = \Psi(x), \qquad 0 \le x \le 1. \tag{3.25}$$

In fact, the C^2 solutions $u = u_l(t,x)$ (resp., $u = u_r(t,x)$) and $u = u^{(1)}(t,x)$ satisfy simultaneously (1.1), the initial condition

$$x = \frac{1}{2}: \qquad u = a(t),\ \ u_x = \bar{a}(t), \qquad 0 \le t \le T_1, \tag{3.26}$$

and the boundary condition (3.16) (resp., (3.19)). By uniqueness (cf. [10]) and the choice of T_1 given in (3.2), the mixed initial-boundary value problem (1.1), (3.26), and (3.16) (resp., (3.19)) has a unique C^2 solution on the domain

$$\left\{(t,x)|\ 0 \le t \le 2T_1 x,\ \ 0 \le x \le \frac{1}{2}\right\} \tag{3.27}$$

$$\left(\text{resp., } \left\{(t,x)|\ 0 \le t \le 2T_1(1-x),\ \ \frac{1}{2} \le x \le 1\right\}\right).$$

(In fact, this domain is included in the corresponding maximum determinate domain.) Then

$$u(t,x) \equiv u^{(1)}(t,x) \tag{3.28}$$

on these domains and, in particular, on the interval $0 \le x \le 1$ on the x-axis. Hence, noting (1.8), we immediately get (3.24). In a similar manner we obtain (3.25).

Thus, $u = u(t,x)$ satisfies all the requirements of Lemma 3.1.

4. Proof of Theorem 1.2. As in [6] (also see [9]), in order to get Theorem 1.2 it suffices to prove the following lemma.

LEMMA 4.1. *Let $T > 0$ be defined by* (1.11). *Under the assumptions of Theorem* 1.2, *the quasilinear wave equation* (1.1) *with the boundary condition* (1.5) *on $x = 0$ admits a C^2 solution $u = u(t,x)$ with small C^2 norm on the domain $R(T) = \{(t,x)|\ 0 \le t \le T,\ 0 \le x \le 1\}$, which satisfies the initial condition* (1.8) *and the final condition* (1.10).

Proof. Noting (1.11), there exists an $\varepsilon_0 > 0$ so small that

$$T > 2 \max_{|v|+|v|\le\varepsilon_0} \frac{1}{\sqrt{K_v(u,v)}}. \tag{4.1}$$

Let

$$T_1 = \max_{|u|+|v|\le\varepsilon_0} \frac{1}{\sqrt{K_v(u,v)}}. \tag{4.2}$$

(i) We first consider the following forward mixed initial-boundary value problem of (1.1) with the initial condition (1.8) and the boundary conditions (1.5) and (3.4) (in which $f_1 \in C^2[0,T_1]$ with small C^2 norm and the conditions of C^2 compatibility at the point $(0,1)$ are assumed to be satisfied). By the assumptions of Theorem 1.2, the conditions of C^2 compatibility are also satisfied at the points $(0,0)$. Then, by Lemma 2.1, on the domain (3.5) there exists a unique C^2 solution $u = u^{(1)}(t,x)$ with small C^2 norm, and (3.6) holds. Thus, we can determine the corresponding value of $(u^{(1)}(t,x), \frac{\partial u^{(1)}}{\partial x}(t,x))$ on $x = 0$ as

$$x = 0: \qquad (u, u_x) = (a(t), \bar{a}(t)), \quad 0 \le t \le T_1, \tag{4.3}$$

and the $C^2[0,T_1]$ norm of $a(t)$ and the $C^1[0,T_1]$ norm of $\bar{a}(t)$ are small.

(ii) Similarly, we consider the following backward mixed initial-boundary value problem of (1.1) with the final condition (1.10) and the boundary conditions (1.5) and (3.9) (in which $g_1 \in C^2[T-T_1,T]$ with small C^2 norm and the conditions of C^2 compatibility at the point $(T,1)$ are assumed to be satisfied). By the assumptions of Theorem 1.2, the conditions of C^2 compatibility are also satisfied at the point $(T,0)$. Then, by Lemma 2.2, on the domain (3.10) there exists a unique C^2 solution $u = u^{(2)}(t,x)$ with small C^2 norm, and (3.11) holds. Thus, we can determine the corresponding value of $(u^{(2)}(t,x), \frac{\partial u^{(2)}}{\partial x}(t,x))$ on $x = 0$ as

$$x = 0: \qquad (u, u_x) = (b(t), \bar{b}(t)), \quad T - T_1 \le t \le T, \tag{4.4}$$

and the $C^2[T-T_1,T]$ norm of $b(t)$ and the $C^1[T-T_1,T]$ norm of $\bar{b}(t)$ are small.

(iii) Noting that both $(u, u_t, u_x) = (a(t), a'(t), \bar{a}(t))$ and $(b(t), b'(t), \bar{b}(t))$ satisfy the boundary condition (1.5), we can find $c(t) \in C^2[0,T]$ with small C^2 norm and $\bar{c}(t) \in C^1[0,T]$ with small C^1 norm such that (3.13) holds and $(u, u_t, u_x) = (c(t), c'(t), \bar{c}(t))$ satisfies the boundary condition (1.5) on the whole interval $[0,T]$.

We now change the status of t and x and consider the following rightward mixed initial-boundary value problem of (1.1) with the initial condition

$$x = 0: \qquad u = c(t), \quad u_x = \bar{c}(t), \quad 0 \le t \le T, \tag{4.5}$$

and the boundary conditions

$$t = 0: \qquad u = \varphi(x), \quad 0 \le x \le 1, \tag{4.6}$$

$$t = T: \qquad u = \Phi(x), \quad 0 \le x \le 1, \tag{4.7}$$

where $\varphi(x)$ and $\Phi(x)$ are given in (1.8) and (1.10), respectively.

Obviously, the conditions of C^2 compatibility at the points $(0,0)$ and $(T,0)$ are satisfied. Then, by Lemma 2.1, there exists a unique C^2 solution $u = u(t,x)$ with small C^2 norm on the domain $R(T) = \{(t,x)|\ 0 \le t \le T,\ 0 \le x \le 1\}$ and

$$|u(t,x)| + \left|\frac{\partial u}{\partial x}(t,x)\right| \le \varepsilon_0 \qquad \text{on } R(T). \tag{4.8}$$

The C^2 solutions $u = u(t,x)$ and $u = u^{(1)}(t,x)$ satisfy simultaneously (1.1), the initial condition

$$x = 0: \qquad u = a(t), \quad u_x = \bar{a}(t), \quad 0 \le t \le T_1, \tag{4.9}$$

and the boundary condition (4.6). Noting the choice of T_1 given by (4.2), by the uniqueness (cf. [10]), the mixed initial-boundary value problem (1.1), (4.9), and (4.6) has a unique C^2 solution on the domain

$$\{(t,x)|\ 0 \le t \le T_1(1-x), \quad 0 \le x \le 1\}. \tag{4.10}$$

Then

$$u(t,x) \equiv u^{(1)}(t,x) \tag{4.11}$$

on this domain and, in particular, on the interval $0 \le x \le 1$ on the x-axis. Hence, noting (1.8), we get (3.24). Similarly, we obtain (3.25).

Thus, $u = u(t,x)$ satisfies all the requirements of Lemma 4.1.

5. Remarks.

Remark 5.1. The exact controllability time given in Theorem 1.1 or Theorem 1.2 is optimal.

Remark 5.2. If the boundary conditions (1.5.2)–(1.5.4) on $x = 0$ are replaced, respectively, by

$$x = 0: \qquad K(u, u_x) = h(t), \tag{5.1}$$

$$x = 0: \qquad K(u, u_x) - \alpha u = h(t), \tag{5.2}$$

and

$$x = 0: \qquad K(u, u_x) - \bar{\alpha} u_t = h(t), \tag{5.3}$$

and the boundary conditions (1.6.2)–(1.6.4) on $x = 1$ are replaced, respectively, by

$$x = 1: \qquad K(u, u_x) = \bar{h}(t), \tag{5.4}$$

$$x = 1: \qquad K(u, u_x) + \beta u = \bar{h}(t), \tag{5.5}$$

and

$$x = 1: \qquad K(u, u_x) + \bar{\beta} u_t = \bar{h}(t), \tag{5.6}$$

the conclusions of Theorems 1.1 and 1.2 are still valid provided that the conditions of C^2 compatibility (1.13.2)–(1.13.4), etc., at the points $(0,0)$ and $(T,0)$ are changed correspondingly and (1.12) is replaced by

$$\bar{\alpha} \ne \sqrt{K_v(0,0)}. \tag{5.7}$$

Remark 5.3. For more general boundary conditions such as

$$x = 0: \qquad R(t, u, u_x, u_t) = 0, \tag{5.8}$$

similar results can be obtained under suitable conditions.

Remark 5.4. The method presented in this paper works also for some kinds of second order quasilinear hyperbolic systems and higher order quasilinear hyperbolic equations.

Acknowledgment. The authors would like to express their sincere thanks to the referees for their valuable comments and suggestions.

LINEAR SYSTEMS SUBJECT TO INPUT SATURATION AND TIME DELAY: FINITE-GAIN L^p-STABILIZATION*

KARIM YAKOUBI† AND YACINE CHITOUR†

Abstract. This paper deals with finite-gain stabilization of linear systems by static feedbacks which are bounded and time-delayed. For neutrally stable continuous-time linear systems, we provide a saturated linear feedback law ensuring finite-gain stability with respect to every L^p-norm, $p \in [1, \infty]$, with an arbitrary small bound on the control and large (constant) delay. Moreover, we provide upper bounds for the corresponding L^p-gains which are delay-independent.

Key words. input saturation, time-delay systems, Lyapunov functions, finite-gain stability

1. Introduction.

In this paper, we address the finite-gain L^p-stabilization issue for continuous-time delay linear systems subject to input saturation, i.e., of the type

$$(S) : \dot{x}(t) = Ax(t) - rB\sigma\left(u(t-h)\right), \tag{1}$$

with state $x \in R^n$, input value $u \in R^m$, and where $r \in (0, 1]$ depends only on (S), the constant delay $h \geq 0$ appears in the input, and $\sigma : R^m \to R^m$ is of "saturation" type (definitions are given in section (2)). The present paper is a continuation of [12], where the global asymptotic stabilization issue for systems (S) was successfully addressed. It also has to be noted that the present paper is technically independent of [12].

We use $(S)_h^r$, $r \in (0, 1]$, $h \geq 0$, to denote the control system (S) with input bound r and input time delay h. We omit the index r if it is equal to one; similarly for the index h if it is equal to zero.

In the zero-delay case, the above problem has been widely investigated in the last ten years; see, for example, [4], [6], [1], and references therein, for both continuous-time and discrete-time linear systems. It was shown in [4] ([1], [3], respectively, for the discrete case) that, for neutrally stable open-loop systems, linear feedback laws can be used to achieve finite-gain stability, with respect to every L^p-norm (l_p-norm, respectively). For the continuous case, it is proved in [6] that finite-gain L^p-stability is possible if and only if (S) satisfies

$$(\mathbf{C}) : \begin{cases} \text{(i) all eigenvalues of } A \text{ are in the closed left-half plane,} \\ \\ \text{(ii) the pair } (A, B) \text{ is stabilizable.} \end{cases}$$

An $n \times n$ matrix A is said to be neutrally stable if all solutions of $\dot{x} = Ax$ in the continuous case ($x(t+1) = Ax(t)$ in the discrete case, respectively) are bounded; equivalently, A has no eigenvalues with positive real part and each Jordan block corresponding to a purely imaginary eigenvalue has size one (all the eigenvalues of A

are inside or on the unit circle, with those on the unit circle having all Jordan blocks of size one, respectively).

In this paper, we focus on the continuous case in the presence of time delay in the input. It is trivial to see that condition (C) is also necessary in the nonzero-delay case and it seems natural to expect condition (C) to also be sufficient.

Our objective here consists of showing that the results of [4] carry over to continuous linear time-delay systems. More specifically, we show that, for neutrally stable continuous linear time-delay systems subject to input saturation, finite-gain L^p-stabilization can be achieved by the use of linear feedbacks for every $p \in [1, \infty]$. The issue of L^p-stabilization for delay systems was already addressed in the literature by a systematic use of linear matrix inequalities (LMIs)(cf. [2], [10]). While many of the arguments of the present paper are conceptually similar to those of [4], there are technical aspects that are different and not obvious. Indeed, as in [4], the proof to get finite-gain L^p-stability relies on passivity techniques. We determine a suitable "storage" function V_p and establish for it a "dissipation inequality" of the form $\frac{dV_p(x_u(t))}{dt} \leq -\|x_u(t)\|^p + \lambda_p \|u(t)\|^p$ for some constant $\lambda_p > 0$ possibly depending on the input bound r and the delay h. For more discussion on passivity, see [11], for instance. Recall that the "storage function" in [4], V_p^0, is nonsmooth. In the present situation, the "storage function" V_p will be the sum of a term similar to V_p^0 and a Lyapunov–Krasovskii functional, in order to take care of the delay. However, unlike in [4], the saturation in (1) needs to be multiplied by a small factor r dependent on the delay h in order to ensure finite-gain L^p-stability.

Moreover, by carefully choosing the factor r and the linear feedback inside the saturation, we are able to provide upper bounds for the L^p-gains of $(S)_h^r$ which are *independent* of $h > 0$. We refer to that property as the *unrestricted finite-gain L^p-stability*. The argument corresponding to that uniformity result is specific to the nonzero-delay case and constitutes the most technical part of the paper. Moreover, that argument requires new technical ingredients with respect to those of [4]. We first start with the single-input case, where it amounts to estimating the behavior of the solution P_r of a parameterized Lyapunov equation (L_r), $r \in (0, 1]$, as the parameter r tends to zero. The multi-input case requires additional work. We first rewrite the original system as an appropriate cascade of single-input subsystems, all of them except one being perturbed by an external disturbance, appearing outside the saturation (see Theorem 2). We then proceed inductively on the number of distinct algebraic multiplicities of the eigenvalues of A.

Generally speaking, our treatment of the aforementioned issues on time-delay systems follows a common pattern. We always try to reformulate them as problems for perturbed *delay-free* systems and handle the perturbation with Lyapunov techniques. That strategy works well because the input saturation makes the perturbation uniformly bounded with respect to the delay.

Organization of the paper. In section 2, we provide the main notation used in the paper and state the theorem relative to the unrestricted finite-gain L^p-stabilization. Section 3 is devoted to the proofs of the main theorems. We start with that of the single-input case. Then, before starting the proof of the multi-input case, we illustrate the cascade argument through the detailed analysis of an eight-dimensional example and then proceed with the general case. Finally, we gather in the appendices the proofs of the two main technical results. The first one describes the asymptotic behavior of the solution of a Lyapunov equation (single-input case) and the second one is devoted to the cascade argument necessary to address the multi-input case.

2. Notation and statements of the main results. For $x \in R^n, \|x\|$ and x^T denote, respectively, the Euclidean norm of x and the transpose of x. Similarly, for any $n \times m$ matrix K, K^T and $\|K\|$ denote, respectively, the transpose of K and the induced 2-norm of K. Moreover, $\lambda_{\min}(K)$ and $\lambda_{\max}(K)$ denote the minimal and the maximal singular eigenvalues of the matrix K. For a square matrix K, we use $\mathrm{Tr}(K)$ to denote the trace of K. If $f(.)$ and $g(.)$ are two real-valued functions, we mean by $f(r) \asymp_0 g(r)$ that there are positive constants ξ_1 and ξ_2 such that for r small enough,

$$\xi_1 g(r) \leq f(r) \leq \xi_2 g(r).$$

For $h > 0$, let $x_t(\theta) := x(t+\theta)$, $-h \leq \theta \leq 0$. Initial conditions for time-delay systems are elements of $C_h := C([-h, 0], R^n)$, the Banach space of continuous R^n-valued functions defined on $[-h, 0]$, equipped with the supremum norm, $\|x_t\|_h = \sup_{-h\leq\theta\leq 0} \|x(t+\theta)\|$.

We next introduce the class of saturation functions to be considered and state the main results on finite-gain stability.

2.1. Saturation functions. We next formally define what we mean by a saturation.

DEFINITION 1. *We call $\sigma : R \longrightarrow R$ a saturation function (S-function) if there exist two real numbers $0 < a \leq K_\sigma$ such that for all $t, t' \in R$,*

(i) $|\sigma(t) - \sigma(t')| \leq K_\sigma \inf(1, |t - t'|)$,

(ii) $|\sigma(t) - at| \leq K_\sigma t\sigma(t)$.

It is assumed here that the function is normalized at the origin, i.e., $a = \sigma'(0) = 1$. A constant K_σ defined as above is called an S-bound for σ. Note that (i) is equivalent to the fact that σ is bounded and globally Lipschitz, while (ii) is equivalent to

$$t\sigma(t) > 0 \text{ for } t \neq 0, \quad \liminf_{|t|\to\infty} |\sigma(t)| > 0, \quad \limsup_{t\to 0} \frac{\sigma(t) - t}{t^2} < \infty.$$

If m is a positive integer, we say that σ is an R^m-valued S-function if $\sigma = (\sigma_1, \ldots, \sigma_m)^T$, where each component σ_i is an S-function and, for $s = (s_1, \ldots, s_m)^T \in R^m$,

$$\sigma(s) := \Big(\sigma_1(s_1), \sigma_2(s_2), \ldots, \sigma_m(s_m)\Big)^T.$$

2.2. L^p-stability. For $p \in [1, \infty]$ and $0 \leq h$ (and $T \geq h$, respectively), we use L^p to denote $L^p(-h, \infty)$ and we let $\|y\|_{L^p}$ ($\|y\|_{L^p}([-h, T])$, respectively) denote the L^p-norm

$$\|y\|_{L^p} = \left(\int_{-h}^{\infty} \|y(t)\|^p dt\right)^{\frac{1}{p}} \quad \left(\|y\|_{L^p([-h,T])} = \left(\int_{-h}^{T} \|y(t)\|^p dt\right)^{\frac{1}{p}}, \quad \text{respectively}\right)$$

if $p < \infty$ and

$$\|y\|_{L^\infty} = ess \sup_{-h\leq t<\infty} \|y(t)\|, \quad \left(\|y\|_{L^\infty([-h,T])} = ess \sup_{-h\leq t\leq T} \|y(t)\|, \quad \text{respectively}\right).$$

Consider the control system with delay in the input given by

$$(\Sigma)_h : \dot{x} = f\left(x(t), u(t-h)\right), \quad t \geq 0, \tag{2}$$

where the state x and the control u take, respectively, values in R^n and R^m and $f : R^n \times R^m \to R^n$ is locally Lipschitz in (x, u), with $f(0, 0) = 0$. Trajectories of $(\Sigma)_h$ starting at $x_0 \in C_h$ and corresponding to an input $u \in L^p$ are defined for a time interval I of R^+ (depending on x_0 and u) and verify (2) for a.e. $t \in I$. Let $\bar{0}$ be the zero function in C_h.

DEFINITION 2 (L^p-stability). *Given $p \in [1, \infty]$, the continuous-time delay system $(\Sigma)_h$ is said to be L^p-stable if, for every $u \in L^p$, we have $x_u \in L^p$, where x_u denotes the solution of $(\Sigma)_h$ corresponding to u with initial condition $x_0 = \bar{0}$.*

DEFINITION 3 (finite-gain L^p-stability). *Given $p \in [1, \infty]$, the continuous-time delay system $(\Sigma)_h$ is said to be finite-gain L^p-stable if it is L^p-stable, and there exists a positive constant M_p such that, for every $u \in L^p$,*

$$\|x_u\|_{L^p} \leq M_p \|u\|_{L^p}.$$

Furthermore, the infimum over such numbers M_p will be called the L^p-gain of the system.

We now state our main results.

THEOREM 1. *Let A, B be $n \times n, n \times m$ matrices, respectively. Let σ be an R^m-valued S-function. Assume that A is neutrally stable and (A, B) is controllable. Then, for every $h \geq 0$, there exists an $n \times m$ matrix F_h such that the system*

$$(S)_h^r : \dot{x} = Ax - rB\sigma\left(F_h^T x(t-h) + u(t-h)\right) \text{ for } t \geq 0$$

has the unrestricted finite-gain L^p-stability property for every $p \in [1, \infty]$; i.e., for every $h > 0$, there exists $r^*(h) \in (0, 1]$ such that for every $p \in [1, \infty]$, $(S)_h^r$, $r \in (0, r^*(h)]$, is finite-gain L^p-stable.

Remark 1. In the absence of u, the equilibrium point $\bar{0}$ is globally asymptotically stable for the delayed system $\dot{x} = Ax - rB\sigma\left(F_h^T x(t-h)\right)$.

Theorem 1 is a particular case of a stronger result given next.

THEOREM 2. *With the same hypothesis on A, B, and σ, consider the delayed system (still denoted $(S)_h^r$)*

$$(S)_h^r : \dot{x} = Ax - rB\sigma\left(F_h^T x(t-h) + u_1(t-h)\right) + ru_2(t-h) \text{ for } t \geq 0,$$

where F_h is defined as in Theorem 1 *and the input u_2 takes values in R^n. Then, there exist a constant $C_0 > 0$ and, for every $1 \leq p \leq \infty$, a constant $M_p > 0$ such that for every $h > 0$ there is an $r^*(h) \in (0, 1]$ for which the trajectories x_{u_1,u_2} of $(S)_h^r$, $r \in (0, r^*(h)]$, starting at $\bar{0}$ and corresponding to $u_1, u_2 \in L^p$ with $\|u_2\|_{L^\infty} \leq C_0$, verify*

$$\|x_{u_1,u_2}\|_{L^p} \leq M_p(\|u_1\|_{L^p} + \|u_2\|_{L^p}).$$

The proof of Theorem 2 is deferred to section 3.

Remark 2. It will be clear from our argument that we can in fact obtain the stronger input-to-state stable (ISS)-like property (see [7] and references therein)

$$\|x^{\psi}_{u_1,u_2}\|_{L^p} \leq \theta_p(\|\psi\|_h) + M_p(\|u_1\|_{L^p} + \|u_2\|_{L^p}),$$

where $\psi \in C_h$ is the initial condition for the trajectory $x^{\psi}_{u_1,u_2}$ corresponding to u_1, u_2 and θ_p is a $\mathcal{K}$-function (i.e., $\theta_p : R^+ \to R^+$ is continuous and strictly increasing and satisfies $\theta_p(0) = 0$).

3. Proof of Theorem 2. From elementary linear algebra, a neutrally stable matrix A is similar to a matrix

$$\begin{pmatrix} A_1 & 0 \\ 0 & A_2 \end{pmatrix}, \tag{3}$$

where A_1 is a $q \times q$ Hurwitz matrix and A_2 is an $(n-q) \times (n-q)$ skew-symmetric matrix. So, up to a change of coordinates, we may assume that A is already in the form (3). In these coordinates, we write $B = (B_1^T \quad B_2^T)^T$, where B_2 is an $(n-q) \times m$ matrix, and we write vectors as $x = (x_1^T, x_2^T)^T$ and $u_2 = (u_{21}^T, u_{22}^T)^T$.

For $r \in (0,1]$ and $h > 0$, consider the feedback law $(0, F_h^T)$. Then system $(S)_h^r$, with this choice of F_h^T, can be written as

$$\dot{x}_1(t) = A_1 x_1(t) - rB_1\sigma[F_h^T x_2(t-h) + u_1(t-h)] + ru_{21}(t-h),$$

$$\dot{x}_2(t) = A_2 x_2(t) - rB_2\sigma\left(F_h^T x_2(t-h) + u_1(t-h)\right) + ru_{22}(t-h).$$

Since A_1 is Hurwitz, it will be sufficient to show that there exists an $r^*(h) \in (0,1]$, such that the x_2-subsystem is finite-gain L^p-stable for all $r \in (0, r^*(h)]$.

The controllability assumption on (A,B) implies that the pair (A_2, B_2) is also controllable. Therefore, the theorem is a consequence of the following proposition.

PROPOSITION 1. *Let σ, u_1, u_2 be as in Theorem 2. Let (A,B) be a controllable pair with A skew-symmetric. Then, for every $h \geq 0$, there exist an $n \times m$ matrix F_h and $r^*(h) \in (0,1]$ such that, for every $r \in (0, r^*(h)]$, the system*

$$(S)_h^r : \dot{x}(t) = Ax(t) - rB\sigma\left(F_h^T x(t-h) + u_1(t-h)\right) + ru_2(t-h) \text{ for } t \geq 0$$

verifies the conclusion of Theorem 2.

Remark 3. In the single-input case ($m = 1$), F_h can be chosen as $e^{-Ah}B$, which corresponds, up to the delay h, to the linear feedback law suggested by the passivity approach and used in [4]. A simple adaptation of the proof to the multi-input case shows that such a feedback can also be used to get finite-gain L^p-stability but the corresponding L^p-gain is, in general, delay-dependent.

Proof. We start the proof by zooming in on the single-input case. The general proof first starts with algebraic transformations and proceeds by induction on the number of distinct algebraic multiplicities of the eigenvalues of A.

3.1. The single-input case. Let $h > 0$ and consider the feedback law $F_h = e^{-Ah}B = e^{-Ah}b$. Then, $\|F_h\| = \|b\|$. Let y be the solution of

$$\begin{aligned} &\dot{y}(t) = (A - rbb^T)y(t) + ru_2(t-h) \text{ for } t \geq 0, \\ &y_0 = \bar{0} \quad \text{ on } [-h, 0], \end{aligned} \tag{4}$$

with $u_2 \in L^p$ and $\|u_2\|_{L^\infty} \leq C_0$, where C_0 is a positive constant to be determined later. (By an obvious abuse of notation, L^p denotes here $L^p([-h,\infty), R^n)$.) Since A is skew-symmetric, the matrix $A_r := A - rbb^T$ is Hurwitz for every $r > 0$. Then (4) is L^p-stable for any $1 \leq p \leq \infty$ (see [4, Remark 4]). Let γ_p be its L^p-gain, so $\|y\|_{L^p} \leq \gamma_p \|u_2\|_{L^p}$. We need the next lemma, whose proof is given in Appendix A. □

LEMMA 1. *Let A and b be as in Proposition 1. Then, the following properties hold.*

(i) *There exist an* $r^* \in (0,1]$ *and positive constants* C_1, C_1', C_2, *and* C_2' *such that, for all* $t \geq 0$ *and* $r \in (0, r^*]$,

$$C_1' e^{-C_2' r t} \leq ||e^{(A - r b b^T)t}|| \leq C_1 e^{-C_2 r t}. \tag{5}$$

(ii) *For* $r \geq 0$, *let* P_r *be the unique positive-definite solution to the Lyapunov equation*

$$(L_r): \quad P_r(A - rbb^T) + (A - rbb^T)^T P_r = -I_n. \tag{6}$$

Then,

$$\lambda_{\max}(P_r) \asymp_0 \lambda_{\min}(P_r) \asymp_0 \frac{1}{r}. \tag{7}$$

We also need the following lemma.

LEMMA 2. *Let* γ_p *be the* L^p*-gain of* (4). *So,* $\gamma_p \leq \frac{C_1}{C_2}$.

Proof. For $t \geq 0$, set $A_r := A - rbb^T$. Then, $y(t) = r \int_0^t e^{A_r(t-s)} u_2(s-h) ds$. From (5), we have

$$\begin{aligned} \|y(t)\| &\leq r \int_0^t \|e^{A_r(t-s)}\| \|u_2(s-h)\| ds \\ &\leq r C_1 \int_0^t e^{-rC_2(t-s)} \|u_2(s-h)\| ds. \end{aligned} \tag{8}$$

Let G_p be the L^p-gain of the control system with state $\chi \in R$ given by

$$(S_\chi): \dot{\chi}(t) = -rC_2 \chi(t) + rC_1 v(t-h),$$

where $v \in L^p([-h, \infty], R)$. It is clear from (8) that $\gamma_p \leq G_p$. So, for each $1 < p < \infty$, we have

$$|\chi(t)|^{p-2} \chi(t) \dot{\chi}(t) = -rC_2 |\chi(t)|^p + rC_1 |\chi(t)|^{p-2} \chi(t) v(t-h).$$

For every $t \geq 0$, integrating the last equation from zero to ∞ and using Hölder's inequality (with $p' = \frac{p}{p-1}$ and $q' = p$), we have

$$rC_2 \|\chi\|_{L^p}^p \leq rC_1 \|\chi\|_{L^p}^{p-1} \|v\|_{L^p},$$

because $\chi(t) \to 0$ if $t \to \infty$ (see [4, Lemma 4]). Then $\|\chi\|_{L^p} \leq \frac{C_1}{C_2} \|v\|_{L^p}$. For $p = 1$, if we integrate (S_χ) from zero to ∞, we have the result. It remains to study the case $p = \infty$. We have

$$\|y(t)\| \leq rC_1 \|v\|_{L^\infty} \int_0^\infty e^{-rC_2(t-s)} ds \leq \frac{C_1}{C_2} \|v\|_{L^\infty}. \qquad \square$$

Let x be the solution of $(S)_h^r$ (given in Proposition 1) starting at $\bar{0} \in C_h$ and corresponding to u_1, u_2. Set $z := x - y$. Then, z satisfies

$$\dot{z}(t) = Az(t) - rb\Big[\sigma\Big(F_h^T z(t-h) + F_h^T y(t-h) + u_1(t-h)\Big) - b^T y(t)\Big] \text{ for } t \geq 0, \tag{9}$$

$$z_0 = \bar{0}, \quad \text{on } [-h, 0].$$

Let $\tilde{u}(t-h) = F_h^T y(t-h) + u_1(t-h)$ and $\tilde{v}(t) = b^T y(t)$. Choosing the constant $C_0 > 0$ such that $\gamma_\infty \|b\| C_0 \leq \Gamma$, with $\Gamma = \lim_{|\xi|\to\infty} \inf \sigma(\xi) > 0$, we get

$$\|\tilde{v}\|_{L^\infty} \leq \|b\| \|y\|_{L^\infty} \leq \gamma_\infty \|b\| \|u_2\|_{L^\infty} \leq \gamma_\infty \|b\| C_0 \leq \Gamma. \tag{10}$$

Equation (9) can be written as

$$\begin{aligned} &\dot{z}(t) = Az(t) - rb\Big[\sigma\Big(F_h^T z(t-h) + \tilde{u}(t-h)\Big) - \tilde{v}(t)\Big] \text{ for } t \geq 0, \\ &z_0 = \bar{0}, \quad \text{on } [-h, 0]. \end{aligned} \tag{11}$$

From (11), we have

$$z(t) = e^{Ah} z(t-h) - r \int_{t-h}^{t} e^{A(t-\xi)} b\Big[\sigma\Big(F_h^T z(\xi - h) + \tilde{u}(\xi - h)\Big) - \tilde{v}(\xi)\Big] d\xi.$$

Then, $F_h^T z(t-h) + \tilde{u}(t-h) = b^T z(t) + \tilde{d}(t)$, where

$$\tilde{d}(t) = \tilde{u}(t-h) + r \textstyle\int_{t-h}^{t} g(t-\xi) \left[\sigma\left(F_h^T z(\xi - h) + \tilde{u}(\xi - h)\right) - \tilde{v}(\xi)\right] d\xi,$$

$$g(v) = b^T e^{Av} b.$$

According to (11), we obtain

$$\begin{aligned} &\dot{z}(t) = Az(t) - rb\Big[\sigma\Big(b^T z(t) + \tilde{d}(t)\Big) - \tilde{v}(t)\Big] \text{ for } t \geq 0. \\ &z_0 = \bar{0}, \quad \text{on } [-h, 0]. \end{aligned} \tag{12}$$

Let $\tilde{z}(t) = b^T z(t) + \tilde{d}(t)$. As in [4], we consider, for each $1 \leq p < \infty$, the function $V_{0,p} : R^n \longrightarrow R$ given by

$$V_{0,p}(z(t)) = \frac{\|z(t)\|^{p+1}}{p+1}. \tag{13}$$

We next majorize the time derivative of $V_{0,p}$ along the trajectories of (12). We follow the computations leading to (22) of [4] and obtain

$$\begin{aligned} \dot{V}_{0,p}(z(t)) \quad &\leq \quad -r\|z(t)\|^{p-1} \tilde{z}^T(t) \sigma(\tilde{z}(t)) \\ &\quad + r\|z(t)\|^{p-1} \Big((K + \Gamma)\|\tilde{d}(t)\| + M_1 \|\tilde{v}(t)\|\Big), \end{aligned} \tag{14}$$

where, by definition of Γ, there is some $M_1 \geq 1$ so that $\inf_{|\xi| \geq M_1} |\sigma(\xi)| \geq \frac{1}{2}\Gamma$.

Since A_r is Hurwitz, we consider for each $1 < p < \infty$ the differentiable function $V_{1,p} : R^n \to R$ defined by

$$V_{1,p}(z(t)) = (z^T(t) P_r z(t))^{\frac{p}{2}}, \tag{15}$$

where P_r is the solution of (6). We rewrite (12) in the form

$$\begin{aligned} &\dot{z}(t) = A_r z(t) - rb\left[\sigma(\tilde{z}(t)) - \tilde{z}(t) + \tilde{d}(t) - \tilde{v}(t)\right] \text{ for } t \geq 0, \\ &z_0 = \bar{0}, \quad \text{on } [-h, 0]. \end{aligned} \tag{16}$$

The derivative of $V_{1,p}$ along the trajectories of (16) verifies

$$\begin{aligned}
\dot{V}_{1,p} &= p\Big(z^T(t)P_rz(t)\Big)^{\frac{p}{2}-1}z^T(t)P_r\dot{z}(t)\\
&= p\Big(z^T(t)P_rz(t)\Big)^{\frac{p}{2}-1}\Big\{z^T(t)\Big(-I-A_r^TP_r\Big)z(t)-rz^T(t)P_rb\Big[\sigma(\tilde{z}(t))-\tilde{z}(t)\\
&\qquad\qquad +\tilde{d}(t)-\tilde{v}(t)\Big]\Big\}\\
&\leq -p\Big(z^T(t)P_rz(t)\Big)^{\frac{p}{2}-1}\|z(t)\|^2\\
&\quad +p\Big(z^T(t)P_rz(t)\Big)^{\frac{p}{2}-1}rK\|P_rb\|\|z(t)\|\Big\{\tilde{z}^T(t)\sigma(\tilde{z}(t))+\tfrac{1}{K}\Big(\|\tilde{d}(t)\|+\|\tilde{v}(t)\|\Big)\Big\}\\
&\leq \begin{cases}
-\dfrac{p}{\Big(\lambda_{\max}(P_r)\Big)^{1-\frac{p}{2}}}\|z(t)\|^p+\dfrac{rpK\|P_rb\|}{\Big(\lambda_{\min}(P_r)\Big)^{1-\frac{p}{2}}}\|z(t)\|^{p-1}\tilde{z}^T(t)\sigma(\tilde{z}(t))\\
+\dfrac{rp\|P_rb\|}{\Big(\lambda_{\min}(P_r)\Big)^{1-\frac{p}{2}}}\|z(t)\|^{p-1}\Big(\|\tilde{d}(t)\|+\|\tilde{v}(t)\|\Big) \qquad \text{if } 1<p\leq 2,\\
-p\Big(\lambda_{\min}(P_r)\Big)^{\frac{p}{2}-1}\|z(t)\|^p+rpK\|P_rb\|\Big(\lambda_{\max}(P_r)\Big)^{\frac{p}{2}-1}\|z(t)\|^{p-1}\tilde{z}^T(t)\sigma(\tilde{z}(t))\\
+rp\|P_rb\|\Big(\lambda_{\max}(P_r)\Big)^{\frac{p}{2}-1}\|z(t)\|^{p-1}\Big(\|\tilde{d}(t)\|+\|\tilde{v}(t)\|\Big) \quad \text{if } 2\leq p<\infty.
\end{cases}
\end{aligned}$$

For $1\leq p<\infty$, set

$$\lambda_{p,r}:=\begin{cases}
\dfrac{pK\|P_rb\|}{\Big(\lambda_{\min}(P_r)\Big)^{1-\frac{p}{2}}} & \text{if } 1\leq p\leq 2,\\
pK\|P_rb\|\Big(\lambda_{\max}(P_r)\Big)^{\frac{p}{2}-1} & \text{if } 2\leq p<\infty.
\end{cases}$$

Finally, consider, for each $1\leq p<\infty$, the following function:

$$V_{2,p}(z(t)):=\Big(\lambda_{p,r}V_{0,p}+V_{1,p}\Big)(z(t)). \tag{17}$$

Along trajectories of (12), we obtain, for $1<p<\infty$,

$$\dot{V}_{2,p}\leq -\zeta_{p,r}\|z(t)\|^p+\kappa_{p,r}\|z(t)\|^{p-1}\Big(\|\tilde{d}(t)\|+\|\tilde{v}(t)\|\Big), \tag{18}$$

where

$$\begin{cases}
\zeta_{p,r}=\begin{cases}
\dfrac{p}{(\lambda_{\max}(P_r))^{1-\frac{p}{2}}} & \text{if } 1<p\leq 2,\\
p(\lambda_{\min}(P_r))^{\frac{p}{2}-1} & \text{if } 2\leq p<\infty,
\end{cases}\\
\kappa_{p,r}=r\lambda_{p,r}\max\{1+K+\Gamma,1+M_1\}.
\end{cases}$$

There exists $T > h$ such that the differentiable function $V_{1,p}$ verifies $\|DV_{1,p}(z)\| \leq c\lambda_{p,r}\|z\|^{p-1}$ for all $z \in R^n$ and $t \geq T$, where c is some positive constant independent of p. Moreover, $V_{1,p}$ can be chosen so that $\limsup_{p\to 1^+} \lambda_{p,r} = \lambda_{1,r} < \infty$, and the limit $V_{1,1}(z) = \lim_{p\to 1^+} V_{1,p}(z)$ exists for all $z \in R^n$.

By the Lebesgue dominated convergence theorem (applied to a sequence $\{p^j\}_{j=1}^{\infty}$ decreasing to 1) we know that the above inequality is also true for $p = 1$.

Consider the Lyapunov–Krasovskii functional, given by

$$H_\mu(t) = \mu \int_{t-2h}^{t} \left(\int_s^t \|z(l)\|^p dl \right) ds = \mu \int_0^{2h} \left(\int_{t-s}^t \|z(l)\|^p dl \right) ds \tag{19}$$

for $t \geq 2h$, where $\mu > 0$ will be chosen later. Its derivative is equal to

$$\dot{H}_\mu(t) = 2h\mu\|z(t)\|^p - \mu \int_{t-2h}^{t} \|z(s)\|^p ds. \tag{20}$$

Finally, consider the following function:

$$V_p(z(t)) := V_{2,p}(z(t)) + H_\mu(t). \tag{21}$$

Along the trajectories of (12), from (18) and (20), we have

$$\begin{array}{rcl} \dot{V}_p(z(t)) & \leq & -(\zeta_{p,r} - 2h\mu)\|z(t)\|^p + \kappa_{p,r}\|z(t)\|^{p-1}(\|\tilde{d}(t)\| \\ & + & \|\tilde{v}(t)\|) - \mu \int_{t-2h}^{t} \|z(s)\|^p ds. \end{array} \tag{22}$$

From the definition of $\tilde{d}(t)$ and Hölder's inequality, it follows that

$$\begin{array}{rcl} \|\tilde{d}(t)\| + \|\tilde{v}(t)\| & \leq & \|\tilde{u}(t-h)\| + \|\tilde{v}(t)\| + r\max\{1,K\}\|b\|^2 \int_{t-h}^{t} \Big(\|\tilde{u}(\xi - h)\| \\ & + & \|\tilde{v}(\xi)\| \Big) d\xi + rK\|b\|^3 (2h)^{\frac{p-1}{p}} \left(\int_{t-2h}^{t} \|z(s)\|^p ds \right)^{\frac{1}{p}}. \end{array}$$

From (22) and the Hölder inequality (with $p' = \frac{p}{p-1}$ and $q' = p$) we have

$$\begin{array}{rcl} \dot{V}_p(z(t)) & \leq & -(\zeta_{p,r} - 2h\mu)\|z(t)\|^p + \kappa_{p,r}\|z(t)\|^{p-1} \left(\|\tilde{u}(t-h)\| + \|\tilde{v}(t)\|\right) \\ & + & r\max\{1,K\}\|b\|^2\kappa_{p,r}\|z(t)\|^{p-1} \int_{t-h}^{t} \left(\|\tilde{u}(\xi - h)\| + \|\tilde{v}(\xi)\|\right) d\xi \\ & + & rK\|b\|^3\kappa_{p,r}(2h)^{\frac{p-1}{p}} \|z(t)\|^{p-1} \left(\int_{t-2h}^{t} \|z(s)\|^p ds \right)^{\frac{1}{p}} - \mu \int_{t-2h}^{t} \|z(s)\|^p ds \\ & \leq & -\left(\zeta_{p,r} - 2^{\frac{2p-1}{p}} h\mu\right) \|z(t)\|^p + \kappa_{p,r}\|z(t)\|^{p-1} \left(\|\tilde{u}(t-h)\| + \|\tilde{v}(t)\|\right) \\ & + & r\max\{1,K\}\|b\|^2\kappa_{p,r}\|z(t)\|^{p-1} \int_{t-h}^{t} \left(\|\tilde{u}(\xi - h)\| + \|\tilde{v}(\xi)\|\right) d\xi \\ & - & \left(\mu - \frac{1}{p}\mu^{1-p} r^p \kappa_{p,r}^p K^p \|b\|^{3p}\right) \int_{t-2h}^{t} \|z(s)\|^p ds. \end{array}$$

We choose $\mu^*(h)$ and $r^*(h) \in (0,1]$ such that

$$\begin{aligned} \mu^*(h) &= \min\left\{\tfrac{1}{4h}\tfrac{p}{2p-1}\zeta_{p,r}, \tfrac{K\kappa_{p,r}\|b\|^3}{p^{\frac{1}{p}}}\right\}, \\ r^*(h) &= \min\left\{1, \tfrac{p^{\frac{1}{p}+1}}{K(2p-1)\|b\|^3}\tfrac{1}{4h}\tfrac{\zeta_{p,r}}{\kappa_{p,r}}\right\}, \end{aligned} \tag{23}$$

since $\frac{\zeta_{p,r}}{\kappa_{p,r}} \asymp_0 O(1)$. So, for $\mu \le \mu^*(h)$ and $r \le r^*(h)$, we get

$$\begin{aligned} \dot V_p(z(t)) &\le -\tfrac{1}{2}\zeta_{p,r}\|z(t)\|^p + \kappa_{p,r}\|z(t)\|^{p-1}\Big(\|\tilde u(t-h)\| + \|\tilde v(t)\|\Big) \\ &+ r\max\{1,K\}\|b\|^2\kappa_{p,r}\|z(t)\|^{p-1}\int_{t-h}^{t}\Big(\|\tilde u(\xi-h)\| + \|\tilde v(\xi)\|\Big)d\xi \\ &:= -\tfrac{1}{2}\zeta_{p,r}\|z(t)\|^p + \kappa_{p,r}\|z(t)\|^{p-1} \\ &\times\Big[\|\tilde u(t-h)\| + \|\tilde v(t)\| + r\max\{1,K\}\|b\|^2\left(\tilde m(t) + \tilde n(t)\right)\Big], \end{aligned} \tag{24}$$

where $\tilde m(t) = \int_{t-h}^{t}\|\tilde u(\xi-h)\|d\xi$ and $\tilde n(t) = \int_{t-h}^{t}\|\tilde v(\xi)\|d\xi$. A simple computation shows that

$$\|\tilde m\|_{L^p} \le h\|\tilde u\|_{L^p} \text{ and } \|\tilde n\|_{L^p} \le h\|\tilde v\|_{L^p}. \tag{25}$$

For every $t \ge 0$, integrating (24) from 0 to t, we have

$$\begin{aligned} V_p(z(t)) + \tfrac{1}{2}\zeta_{p,r}\int_0^t\|z(s)\|^p ds &\le \kappa_{p,r}\int_0^t\|z(s)\|^{p-1}[\|\tilde u(s-h)\| + \|\tilde v(s)\| \\ &+ r\max\{1,K\}\|b\|^2(\tilde m(s) + \tilde n(s))]ds. \end{aligned}$$

Applying Hölder's inequality to

$$\int_0^t\|z(s)\|^{p-1}\left[\|\tilde u(s-h)\| + \|\tilde v(s)\| + r\max\{1,K\}\|b\|^2\left(\tilde m(s) + \tilde n(s)\right)\right]ds,$$

we conclude that, for all $1 < p < \infty$ and $t \ge 0$,

$$\begin{aligned} V_p(z(t)) + \tfrac{1}{2}\zeta_{p,r}\|z\|^p_{L^p[0,t]} &\le \kappa_{p,r}\|z\|^{p-1}_{L^p[0,t]}[\|\tilde u\|_{L^p} + \|\tilde v\|_{L^p} \\ &+ r\max\{1,K\}\|b\|^2(\|\tilde m\|_{L^p} + \|\tilde n\|_{L^p})]. \end{aligned} \tag{26}$$

Since $V_p \ge 0$, we get that $z \in L^p([0,\infty), R^n)$ and, by using (25),

$$\|z\|_{L^p} \le \frac{2\kappa_{p,r}}{\zeta_{p,r}}\left(1 + rh\max\{1,K\}\|b\|^2\right)\left(\|\tilde u\|_{L^p} + \|\tilde v\|_{L^p}\right). \tag{27}$$

Since $z = x - y, \tilde u = F_h^T y + u_1, \tilde v = b^T y$, we have

$$\|\tilde v\|_{L^p} \le \|b\|\|y\|_{L^p} \le \gamma_p\|b\|\|u_2\|_{L^p},$$

$$\|\tilde u\|_{L^p} \le \|u_1\|_{L^p} + \gamma_p\|b\|\|u_2\|_{L^p},$$

$$\|z\|_{L^p} \ge \|x\|_{L^p} - \|y\|_{L^p} \ge \|x\|_{L^p} - \gamma_p\|u_2\|_{L^p}.$$

Combining this with (27) we have

$$\begin{aligned} \|x\|_{L^p} &\leq 2\tfrac{\kappa_{p,r}}{\zeta_{p,r}}(1+rh\max\{1,K\}\|b\|^2)\|u_1\|_{L^p} \\ &+ \gamma_p\left[1+4\|b\|\tfrac{\kappa_{p,r}}{\zeta_{p,r}}(1+rh\max\{1,K\}\|b\|^2)\right]\|u_2\|_{L^p} \\ &\leq M_p(\|u_1\|_{L^p}+\|u_2\|_{L^p}), \end{aligned} \tag{28}$$

where

$$\begin{aligned} M_p &= \max\Big\{2\tfrac{\kappa_{p,r}}{\zeta_{p,r}}\Big(1+rh\max\{1,K\}\|b\|^2\Big), \\ &\qquad \gamma_p\Big[1+4\|b\|\tfrac{\kappa_{p,r}}{\zeta_{p,r}}(1+rh\max\{1,K\}\|b\|^2)\Big]\Big\}. \end{aligned} \tag{29}$$

It remains to show the independence of the upper bound for M_p with respect to the parameter h. Multiplying both sides of (6) by P_r on the right and taking the trace, one gets

$$\mathrm{Tr}(P_r) = 2r||P_rb||^2.$$

Since $\mathrm{Tr}(P_r) \asymp_0 \lambda_{\max}(P_r)$, by Lemma 1, $||P_rb|| \asymp_0 \frac{1}{r}$. In addition,

$$M_p \asymp_0 \frac{\kappa_{p,r}}{\zeta_{p,r}} = Kr||P_rb|| \left(\frac{\lambda_{\max}(P_r)}{\lambda_{\min}(P_r)}\right)^{|\frac{p}{2}-1|} \asymp_0 O(1). \tag{30}$$

Then, the upper bound for the finite-gain is independent of h for all $p \in [1,\infty)$.

In the case $p=\infty$, finite-gain stabilization was already proved in Lemma 4 of [12] for $n=2$ (just take $f := (\alpha,\beta)^T = 0$ in that lemma). That argument trivially extends to every $n \geq 2$.

Remark 4. In the next subsection, we will proceed with the argument of the multi-input case. Before doing so, we can remark that the feedback $F_h = e^{-hA}B$ L^p-stabilizes the system $(S)_h^r$. However, the L^p-gain depends on the delay. To see that, we simply follow the previous argument. The difference comes up with (7). In this case, there are n eigenvalues of $A_r = A - rbb^T$, $\lambda_1(r),\dots,\lambda_n(r)$, defining continuous functions, which are not analytic in general. These functions, though, can be written as Puiseux series (cf. [5]),

$$\lambda_i(r) = \lambda_i(0) + \sum_{j=1}^{\infty} \alpha_j^{(i)} r^{\frac{j}{p_i}},$$

where $\lambda_i(0)$ is a root of multiplicity ξ of A and p_i is a positive integer eventually larger than one. Therefore, by (30), it is clear that M_p cannot be delay-independent.

3.2. The general case. First, we present an example to clarify the proof of Proposition 1 in the general case, i.e., the multi-input case. The procedure for computing stabilizing feedbacks brings the matrices A and B into a special form.

Example. Consider the following system where eight oscillators are coupled:

$$(S)_h^r : \dot{x}(t) = Ax(t) - rB\sigma(u(t-h)) + rv(t-h), x \in R^{16}, u \in R^3, v \in R^{16}, \tag{31}$$

where $A = \text{ diag } \left(\omega_1 A^{(1)}, \omega_2 A^{(2)}, \omega_3 A^{(2)}, \omega_4 A^{(3)}\right)$, $A^{(i)} = \text{ diag } (A_0)$ repeated i times, $i \in \{1,2,3\}$, $A_0 = \left(\begin{smallmatrix} 0 & 1 \\ -1 & 0 \end{smallmatrix}\right)$ $\omega_i \neq \omega_j$ for $i \neq j$, $\omega_i > 0$ for all $i = 1, \ldots, 4$, and

$$B = \begin{pmatrix} B_1 \\ B_2 \\ B_3 \\ B_4 \end{pmatrix} = \begin{pmatrix} \begin{pmatrix} b^1_{1,3} & b^2_{1,3} & b^3_{1,3} \end{pmatrix} \\ \begin{pmatrix} b^1_{1,2} & b^2_{1,2} & b^3_{1,2} \\ b^1_{2,2} & b^2_{2,2} & b^3_{2,2} \end{pmatrix} \\ \begin{pmatrix} \tilde{b}^1_{1,2} & \tilde{b}^2_{1,2} & \tilde{b}^3_{1,2} \\ \tilde{b}^1_{2,2} & \tilde{b}^2_{2,2} & \tilde{b}^3_{2,2} \end{pmatrix} \\ \begin{pmatrix} b^1_{1,1} & b^2_{1,1} & b^3_{1,1} \\ b^1_{2,1} & b^2_{2,1} & b^3_{2,1} \\ b^1_{3,1} & b^2_{3,1} & b^3_{3,1} \end{pmatrix} \end{pmatrix}.$$

In order to prove the result of finite-gain L^p-stabilization for all $p \in [1, \infty]$ of the system $(S)^r_h$, we rewrite the original system as an appropriate cascade of single-input subsystems. Then, there exists a linear transformation, given below for the general case, that puts (31) in the special form, with $b_0 = (0 \quad 1)^T$:

(32)

$$\begin{cases} (1) \begin{cases} \dot{Y}_{1,1} &= \omega_1 A_0 Y_{1,1} - r b_0 \sigma_1(u_1(t-h)) - r\hat{b}^2_{1,3}\sigma_2(u_2(t-h)) \\ &- r\hat{b}^3_{1,3}\sigma_3(u_3(t-h)) + r v_{1,1}(t-h), \end{cases} \\ (2) \begin{cases} \dot{Y}_{1,2} = \omega_2 A_0 Y_{1,2} - r b_0 \sigma_1(u_1(t-h)) - r\hat{b}^3_{1,2}\sigma_3(u_3(t-h)) + r v_{1,2}(t-h), \\ \dot{Y}_{2,2} = \omega_2 A_0 Y_{2,2} - r b_0 \sigma_2(u_2(t-h)) - r\hat{b}^3_{2,2}\sigma_3(u_3(t-h)) + r v_{2,2}(t-h), \end{cases} \\ (3) \begin{cases} \dot{\tilde{Y}}_{1,2} = \omega_3 A_0 \tilde{Y}_{1,2} - r b_0 \sigma_1(u_1(t-h)) - r\hat{\tilde{b}}^3_{1,2}\sigma_3(u_3(t-h)) + r\tilde{v}_{1,2}(t-h), \\ \dot{\tilde{Y}}_{2,2} = \omega_3 A_0 \tilde{Y}_{2,2} - r b_0 \sigma_2(u_2(t-h)) - r\hat{\tilde{b}}^3_{2,2}\sigma_3(u_3(t-h)) + r\tilde{v}_{2,2}(t-h), \end{cases} \\ (4) \begin{cases} \dot{Y}_{1,3} = \omega_4 A_0 Y_{1,3} - r b_0 \sigma_1(u_1(t-h)) + r v_{1,3}(t-h), \\ \dot{Y}_{2,3} = \omega_4 A_0 Y_{2,3} - r b_0 \sigma_2(u_2(t-h)) + r v_{2,3}(t-h), \\ \dot{Y}_{3,3} = \omega_4 A_0 Y_{3,3} - r b_0 \sigma_3(u_3(t-h)) + r v_{3,3}(t-h). \end{cases} \end{cases}$$

Now, we transform the system $(S)^r_h$ in some appropriate cascade of single-input subsystems $(S_i)^r_h$, $i \geq 1$, where the number of subsystems is equal to the number of distinct algebraic multiplicities corresponding to the eigenvalues of A, and all of them

except one are perturbed by an external disturbance appearing outside the saturation and of sufficiently small amplitudes. These perturbations are characterized by external exogenous signals which are proper perturbations and by other ones coming from the subsystems $(S_j)_h^r$, $j > i$. So, we first rearrange the order of equations defined by $Z_1 = Y_{1,1}, Z_2 = Y_{1,2}, Z_3 = \tilde{Y}_{1,2}, Z_4 = Y_{1,3}, Z_5 = Y_{2,2}, Z_6 = \tilde{Y}_{2,2}, Z_7 = Y_{2,3}$, and $Z_8 = Y_{3,3}$, for which the system (32) transforms into

$$
\left\{
\begin{array}{l}
(S_1)_h^{r_1}\left\{
\begin{array}{rcl}
\dot{Z}_1(t) &=& \omega_1 A_0 Z_1(t) - r_1 b_0 \sigma_1(u_1(t-h)) + r_1 v_1(t-h) \\
&-& r_2 \hat{b}^2_{1,3} \sigma_2(u_2(t-h)) - r_3 \hat{b}^3_{1,3} \sigma_3(u_3(t-h)), \\
\dot{Z}_2(t) &=& \omega_2 A_0 Z_2(t) - r_1 b_0 \sigma_1(u_1(t-h)) + r_1 v_2(t-h) \\
&-& r_3 \hat{b}^3_{1,2} \sigma_3(u_3(t-h)), \\

&-& r_3 \hat{b}^3_{2,2} \sigma_3(u_3(t-h)), \\
\dot{Z}_6(t) &=& \omega_3 A_0 Z_6(t) - r_2 b_0 \sigma_2(u_2(t-h)) + r_2 v_6(t-h) \\
&-& r_3 \hat{\tilde{b}}^3_{2,2} \sigma_3(u_3(t-h)), \\
\dot{Z}_7(t) &=& \omega_4 A_0 Z_7(t) - r_2 b_0 \sigma_2(u_2(t-h)) + r_2 v_7(t-h),
\end{array}
\right. \\
(S_3)_h^{r_3}: \quad \dot{Z}_8(t) = \omega_4 A_0 Z_8(t) - r_3 b_0 \sigma_3(u_3(t-h)) + r_3 v_8(t-h).
\end{array}
\right. \tag{33}
$$

To stabilize this system, we start with the *bidimensional single-input controllable* subsystem

$$
(S_3)_h^{r_3}: \quad \dot{Z}_8(t) = \omega_4 A_0 Z_8(t) - r_3 b_0 \sigma_3(u_3(t-h)) + r_3 v_8(t-h). \tag{34}
$$

According to Proposition 1 in the single-input case, there exist $C_{3,0} > 0$ and, for every $1 \le p \le \infty$, a constant $M_{3,p} > 0$ such that, for every $h > 0$, there is an $\tilde{r}_3(h) \in (0,1]$, for which the system $(S_3)_h^{r_3}$, $r_3 \in (0, \tilde{r}_3(h)]$, with the feedback

$$
u_3(t-h) = b_0^T e^{\omega_4 A_0 h} Z_8(t-h) + v_1^3(t-h), \tag{35}
$$

is finite-gain L^p-stable, i.e., the trajectories $(Z_8)_{\Pi_3}$, $\Pi_3 := (v_1^3, v_8)$, and $r_3 \in (0, \tilde{r}_3(h)]$, starting at $\bar{0}$ and corresponding to $v_1^3, v_8 \in L^p$ with $\|v_8\|_{L^\infty} \le C_{3,0}$, verify

$$
\Big\| (Z_8)_{\Pi_3} \Big\|_{L^p} \le M_{3,p} \Big(\|v_1^3\|_{L^p} + \|v_8\|_{L^p} \Big). \tag{36}
$$

Recall that the upper bound for the L^p-gain $M_{3,p}$ is independent of h because the system $(S_i)_h^{r_i}$, $1 \le i \le 3$, is in cascade and the amplitude $r_3 \le \tilde{r}_3(h)$ has to be chosen smaller than $r_3^*(h)$, the final input bound for the subsystem $(S_3)_h^{r_3}$, i.e., $r_3 \le r_3^*(h)$, which will be determined later. In a second step, we stabilize the subsystem $(S_2)_h^{r_2}$ defined by

$$\begin{aligned} \dot{Z}_{5,6,7}(t) &= A_0^{(3)} Z_{5,6,7}(t) - r_2 b_0^{(3)} \sigma_2(u_2(t-h)) + r_2 v_{5,6,7}(t-h) \\ &- r_3 \tilde{b}_3 \sigma_3(u_3(t-h)), \end{aligned} \tag{37}$$

where $\theta_{5,6,7} := [\theta_5, \theta_6, \theta_7]^T$, $\theta = Z, v$; $b_0^{(3)} := [b_0, b_0, b_0]^T$, $A_0^{(3)} := \operatorname{diag}\,[\omega_2 A_0, \omega_3 A_0, \omega_4 A_0]$, and $\tilde{b}_3 := (\hat{b}_{2,2}^3, \hat{\hat{b}}_{2,2}^3, 0)^T$.

It is clear that $(S_2)_h^{r_2}$ is a *finite dimensional single-input controllable* subsystem with *three distinct eigenvalues*, but perturbed by an external disturbance of sufficiently small amplitude, appearing outside the saturation. According to Proposition 1 (the single-input case), there exist $C_{2,0} > 0$ and, for every $1 \le p \le \infty$, a constant $M_{2,p} > 0$ such that, for every $h > 0$, there is an $\tilde{r}_2(h) \in (0, 1]$ for which the system $(S_2)_h^{r_2}$, $r_2 \in (0, \tilde{r}_2(h)]$, with the perturbed feedback

$$u_2(t-h) = (b_0^{(3)})^T e^{A_0^{(3)} h} Z_{5,6,7}(t-h) + v_1^2(t-h), \tag{38}$$

is finite-gain L^p-stable; i.e., the trajectories $(Z_{5,6,7})_{\Pi_2}$, $\Pi_2 := (v_1^2, v_{5,6,7}, v_1^3, v_8)$, and $r_2 \in (0, \tilde{r}_2(h)]$, starting at $\bar{0}$ and corresponding to $v_1^2, v_{5,6,7}, v_1^3, v_8 \in L^p$ with

$$\|v_{5,6,7}\|_{L^\infty} + \frac{r_3}{r_2} K \|\tilde{b}_3\| \le C_{2,0}, \tag{39}$$

since $\|\sigma_3(.)\|_{L^\infty} \le K$, and where $\|v_{5,6,7}\|_{L^\infty}$ is to be chosen later, verify

$$\left\| (Z_{5,6,7})_{\Pi_2} \right\|_{L^p} \le M_{2,p} \left(\|v_1^2\|_{L^p} + \|v_{5,6,7}\|_{L^p} + \|v_1^3\|_{L^p} + \|v_3\|_{L^p} \right). \tag{40}$$

In addition, the upper bound for the L^p-gain $M_{2,p}$ is independent of the delay $h > 0$. Here, (39) is a necessary condition on r_2, r_3, and $v_{5,6,7}$ to get the final result. The amplitude $r_2 \le r_2^*(h)$, the final input bound of the subsystem $(S_2)_h^{r_2}$, is to be chosen below.

Finally, we need to stabilize the *finite dimensional single-input controllable* system with *four distinct eigenvalues*, $(S_1)_h^{r_1}$. Let $\theta_{1,2,3,4} := [\theta_1, \theta_2, \theta_3, \theta_4]^T$, $\theta = Z, v$; $b_0^{(4)} := [b_0, b_0, b_0, b_0]^T$, $A_0^{(4)} := \operatorname{diag}[\omega_1 A_0, \omega_2 A_0, \omega_3 A_0, \omega_4 A_0]$, $b_2 := [\hat{b}_{1,3}^2, 0, 0, 0]^T$, and $b_3 := [\hat{b}_{1,3}^3, \hat{b}_{1,2}^3, \hat{\hat{b}}_{1,2}^3, 0]^T$. With the previous notation, $(S_1)_h^{r_1}$ becomes

$$\begin{aligned} \dot{Z}_{1,2,3,4}(t) &= A_0^{(4)} Z_{1,2,3,4}(t) - r_1 b_0^{(4)} \sigma_1(u_1(t-h)) + r_1 v_{1,2,3,4}(t-h) \\ &- r_2 b_2 \sigma_2(u_2(t-h)) - r_3 b_3 \sigma_3(u_3(t-h)). \end{aligned} \tag{41}$$

According to Proposition 1 (single-input case), there exist $C_{1,0} > 0$ and, for every $1 \le p \le \infty$, $M_{1,p} > 0$ such that, for every $h > 0$, one has an $\tilde{r}_1(h) \in (0, 1]$ for which the system $(S_1)_h^{r_1}$, $r_1 \in (0, \tilde{r}_1(h)]$, with the feedback

$$u_1(t-h) = (b_0^{(4)})^T e^{A_0^{(4)} h} Z_{1,2,3,4}(t-h) + v_1^1(t-h), \tag{42}$$

is finite-gain L^p-stable; i.e., the trajectories $(Z_{1,2,3,4})_{\Pi_1}$, $\Pi_1 := (v_1^1, v_{1,2,3,4}, v_1^2, v_{5,6,7}, v_1^3, v_8)$, and $r_1 \in (0, r_1^*(h)]$, starting at $\bar{0}$ and corresponding to $v_1^1, v_{1,2,3,4}, v_1^2, v_{5,6,7}, v_1^3, v_8 \in L^p$ with

$$\|v_{1,2,3,4}\|_{L^\infty} + \frac{r_2}{r_1} K\|b_2\| + \frac{r_3}{r_1} K\|b_3\| \leq C_{1,0}, \tag{43}$$

where $\|v_{1,2,3,4}\|_{L^\infty}$ is to be chosen later, verify

$$\begin{aligned} \left\|(Z_{1,2,3,4})_{\Pi_1}\right\|_{L^p} \quad &\leq \quad M_{1,p}\Big(\|v_1^1\|_{L^p} + \|v_{1,2,3,4}\|_{L^p} + \|v_1^2\|_{L^p} \\ &\qquad + \|v_{5,6,7}\|_{L^p} + \|v_1^3\|_{L^p} + \|v_8\|_{L^p}\Big). \end{aligned} \tag{44}$$

Note that the upper bound for the L^p-gain, $M_{1,p}$, is independent of h. In order to satisfy (39) and (43), we first give the following bounds for $\|v_{1,2,3,4}\|_{L^\infty}$ and $\|v_{5,6,7}\|_{L^\infty}$:

$$\|v_{1,2,3,4}\|_{L^\infty} \leq \frac{C_{1,0}}{2} \quad \text{and} \quad \|v_{5,6,7}\|_{L^\infty} \leq \frac{C_{2,0}}{2}. \tag{45}$$

Then, the input bounds r_1, r_2, and r_3 must verify

$$\begin{aligned} &\forall\ 1 \leq i \leq 3, \quad r_i \leq \tilde{r}_i(h), \quad \tfrac{r_3}{r_2} K\|\tilde{b}_3\| \leq \tfrac{C_{2,0}}{2}, \quad \text{and} \\ &\tfrac{r_2}{r_1} K\|b_2\| + \tfrac{r_3}{r_1} K\|b_3\| \leq \tfrac{C_{1,0}}{2}. \end{aligned} \tag{46}$$

It is clear that (46) is verified for $r_i \leq r_i^*(h)$, $1 \leq i \leq 3$, where

$$\begin{aligned} &r_1^*(h) := \tilde{r}_1(h), \quad r_2^*(h) = \min\left\{ \tfrac{C_{1,0}\|\tilde{b}_3\|}{C_{2,0}\|b_3\| + 2K\|b_2\|\|\tilde{b}_3\|} r_1^*(h), \tilde{r}_2(h) \right\}, \\ &r_3^*(h) = \min\left\{ \tfrac{C_{1,0}C_{2,0}}{2K(C_{2,0}\|b_3\| + 2K\|b_2\|\|\tilde{b}_3\|)} r_1^*(h), \tfrac{C_{2,0}}{2K\|\tilde{b}_3\|} \tilde{r}_2(h), \tilde{r}_3(h) \right\}. \end{aligned} \tag{47}$$

Set $r^*(h) := \min_{1 \leq i \leq 3} r_i^*(h)$ and $M_p := M_{1,p} + M_{2,p} + M_{3,p}$. We have shown that there exists a constant $C_0 > 0$ and, for every $1 \leq p \leq \infty$, a constant $M_p > 0$ such that for every $h > 0$ there is an $r^*(h) \in (0, 1]$ for which the system (31), $r \in (0, r^*(h)]$, with the bounded feedback

$$u(t-h) = \begin{pmatrix} (b_0^{(4)})^T e^{A_0^{(4)} h} (Z_{1,2,3,4})_{\Pi_1}(t-h) + v_1^1(t-h) \\ (b_0^{(3)})^T e^{A_0^{(3)} h} (Z_{5,6,7})_{\Pi_2}(t-h) + v_1^2(t-h) \\ b_0^T e^{v_4 A_0 h} (Z_8)_{\Pi_3}(t-h) + v_1^3(t-h) \end{pmatrix}, \tag{48}$$

is finite-gain L^p-stable; i.e., the trajectories $[(Z_{1,2,3,4})_{\Pi_1}, (Z_{5,6,7})_{\Pi_2}, (Z_8)_{\Pi_3}]$, $r \in (0, r^*(h)]$, starting at $\bar{0}$ and corresponding to $[(v_1^1; v_{1,2,3,4}; v_1^2; v_{5,6,7}; v_1^3; v_8), (v_1^2; v_{5,6,7}; v_1^3; v_8), (v_1^3; v_8)] \in L^p$, with

$$\|v_{1,2,3,4}\|_{L^\infty} + \|v_{5,6,7}\|_{L^\infty} + \|v_8\|_{L^\infty} + K\left(\|b_2\| + \|b_3\| + \|\tilde{b}_3\|\right) \leq C_0, \tag{49}$$

verify

$$\begin{aligned} \left\|\left[\left(Z_{1,2,3,4}\right)_{\Pi_1}, \left(Z_{5,6,7}\right)_{\Pi_2}, (Z_8)_{\Pi_3}\right]\right\|_{L^p} \quad &\leq \quad M_p\Big[\|v_1^1\|_{L^p} + \|v_{1,2,3,4}\|_{L^p} \\ &+ \quad \|v_1^2\|_{L^p} + \|v_{5,6,7}\|_{L^p} + \|v_1^3\|_{L^p} + \|v_8\|_{L^p}\Big], \end{aligned} \tag{50}$$

where the upper bound for the corresponding global L^p-gain M_p is delay-independent.

Proof of Proposition 1 *in the general case.* We deal with the general m-input case $m \geq 2$ and prove Proposition 1 by induction on the number of distinct algebraic multiplicities of the eigenvalues of A.

Let l be the number of conjugate pairs of nonzero purely imaginary eigenvalues of A (counting multiplicity) and $\mu^{(0)}$ be the multiplicity of 0 as an eigenvalue of A. Suppose that the l conjugate pairs of nonzero purely imaginary eigenvalues of A are in the form $\{(-i\omega^{(j)}, i\omega^{(j)})_{1\leq j\leq l}, i^2 = -1\}, \omega^{(j)} > 0$, and of algebraic multiplicity $\mu^{(j)}$ for all $1 \leq j \leq l$. Then, $2\sum_{j=1}^{l} \mu^{(j)} + \mu^{(0)} = n$. More precisely, for each $0 \leq j \leq l$, we consider a relabeling of the $\mu^{(j)}$'s, defined by μ_j, corresponding to the eigenvalue ω_j such that $\mu_l \geq \mu_{l-1} \geq \cdots \geq \mu_\kappa \geq \cdots \geq \mu_1 \geq \mu_0 \geq 1$, where μ_κ is the multiplicity corresponding to 0, i.e., there exists $0 \leq \kappa \leq l$ such that $\mu_\kappa = \mu^{(0)}$.

First, we find nonsingular transformation matrices O and T such that the pair (A, B) is transformed into the block diagonal control canonical form

$$OAO^T = \begin{pmatrix} A_{0,\mu_0} & & & & \\ & \ddots & & & \\ & & A_{0,\mu_\kappa} & & (0) \\ & & & \ddots & \\ & (0) & & & A_{0,\mu_l} \end{pmatrix}, \tag{51}$$

where, for every $0 \leq j \leq l$, $j \neq \kappa$, A_{0,μ_j} is a $2\mu_j \times 2\mu_j$ matrix and is in the form

$$A_{0,\mu_j} = \begin{pmatrix} \omega_j A_0 & 0 & \dots & 0 \\ 0 & \omega_j A_0 & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & \omega_j A_0 \end{pmatrix}, \quad \text{with } A_0 = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix},$$

and A_{0,μ_κ} is a $\mu_\kappa \times \mu_\kappa$ zero matrix; and

$$OBT = \Big(B_0, \dots, B_\kappa, \dots, B_{l-1}, B_l\Big)^T, \tag{52}$$

where

$$B_j = \begin{bmatrix} \begin{pmatrix} \begin{pmatrix} b_0 & & \\ (0) & \ddots & (0) \\ & & b_0 \end{pmatrix} & (*)_j \end{pmatrix} & (**)_j \end{bmatrix}, \quad \text{with } b_0 = (0 \quad 1)^T,$$

$0 \leq j \leq l, j \neq \kappa$, and

$$B_\kappa = \begin{bmatrix} \begin{pmatrix} \begin{pmatrix} 1 & & \\ (0) & \ddots & (0) \\ & & 1 \end{pmatrix} & (*)_\kappa \end{pmatrix} & (**)_\kappa \end{bmatrix}.$$

Here $(*)'_j s$, $(**)'_j s, 0 \leq j \leq l$, $j \neq \kappa$, represent, respectively, submatrices of size $2\mu_j \times (\mu_l - \mu_j)$ and $2\mu_j \times (m - \mu_l)$; $(*)_\kappa$ and $(**)_\kappa$ are submatrices of dimensions $\mu_\kappa \times (\mu_l - \mu_\kappa)$ and $\mu_\kappa \times (m - \mu_l)$.

We note that the existence of the above canonical form is shown in Appendix B.

There exists a linear transformation of the system $(S)_h^r$, given in Lemma 4, which simplifies the analysis of the problem. Our method consists of rewriting the original system $(S)_h^r$ as an appropriate l cascade of single-input subsystems of dimension $2\mu_j, 0 \leq j \leq l$, $j \neq \kappa$, and one subsystem of dimension μ_κ, since A has l conjugate pairs of nonzero purely imaginary eigenvalues of the forms $(\pm i\omega_j)_{1\leq j\leq l}$ and 0 is an eigenvalue of A with multiplicity μ_κ. The system $(S)_h^r$ becomes

(53)
$$\begin{aligned}
\dot{Y}_{\theta,\mu_s}(t) &= \omega_s A_0 Y_{\theta,\mu_s}(t) - rb_0\sigma_\theta(u_\theta(t-h)) + rv_{\theta,\mu_s}(t-h) \\
&\qquad -r\textstyle\sum_{j=\mu_s+1}^{m} \hat{b}^j_{\theta,s}\sigma_j(u_j(t-h)), 1 \leq \theta \leq \mu_s, 0 \leq s \leq l, s \neq \kappa, \\
\dot{y}_{\theta,\mu_\kappa}(t) &= -r\sigma_\theta(u_\theta(t-h)) + rv_{\theta,\mu_\kappa}(t-h) \\
&\qquad -r\textstyle\sum_{j=\mu_\kappa+1}^{m} \hat{a}^j_\theta\sigma_j(u_j), 1 \leq \theta \leq \mu_\kappa,
\end{aligned}$$

where $\hat{b}^j_{\theta,s} \in R^2$ and $\hat{a}^j_\theta \in R$ are arbitrarily vectors and real numbers. Without loss of generality, in our proof of the general case, we will suppose that A and B are already in these forms. Consider then

$$\begin{aligned}
(S)_h^r : \dot{Y}(t) &= AY(t) - rB\sigma\left(u(t-h)\right) + rv(t-h) \\
&:= AY(t) - rB\sigma\left(F_h^T Y(t-h) + v^1(t-h)\right) + rv^2(t-h),
\end{aligned}$$

and assume without loss of generality that $(S)_h^r$ is of the form (53). Next, we deal with the general m-input case and prove Proposition 1 by induction on $\bar{\delta} := 1 + \#\{\delta_k > 0, 1 \leq k \leq l\}$, where $\delta_k = \mu_k - \mu_{k-1}$ for all $1 \leq k \leq l$ and $\#$ is the cardinal of distinct algebraic multiplicities of the eigenvalues of the skew-symmetric matrix A.

Let μ^j, $0 \leq j \leq \psi \leq l$, denote the distinct algebraic multiplicities corresponding to the eigenvalues ω^j such that $\mu^0 < \cdots < \mu^\psi$, and let χ^j be the number of equal algebraic multiplicities in each inequality. Then, $\sum_{j=0}^{k} \chi^j = l+1$ and ω^j is composite by χ^j eigenvalues $(\omega_1^j, \ldots, \omega_{\chi^j}^j)$ for all $0 \leq j \leq \psi$. We can show that, for every $0 \leq j \leq \psi$, μ^j corresponds to the jth strict inequality.

Induction hypothesis. For every $1 \leq p \leq \infty$, there exist $M_p, C_0 > 0$ such that, for every $h > 0$, one has an $n \times m$ matrix F_h and $r^*(h) \in (0, 1]$, for which the trajectories Y_{v^1,v^2} of $(S)_h^r$, $r \in (0, r^*(h)]$, starting at $\bar{0}$ and corresponding to $v^1, v^2 \in L^p$ with $\|v^2\|_{L^\infty} \leq C_0$, verify $\|Y_{v^1,v^2}\|_{L^p} \leq M_p\left(\|v^1\|_{L^p} + \|v^2\|_{L^p}\right)$.

Notation. First, we introduce some notation. Let $\mu^j := \mu_1^j = \cdots = \mu_{\chi^j}^j$; for any vector $b_0, b_{0,1}^{(j+1)} := [b_0, \ldots, b_0, 1, b_0, \ldots, b_0]^T$, $b_0^{(j)} := [b_0, \ldots, b_0]^T$, b_0 repeated j times; $A_{0,0}^{(\chi^j+\cdots+\chi^\psi)}$ denotes diag $(\omega_1^j A_0, \ldots, \omega_{\chi^j}^j A_0; \ldots; \omega_1^\psi A_0, \ldots, \omega_{\chi^\psi}^\psi A_0)$ if $\omega_\kappa := 0 \in \{\omega_1^j, \ldots, \omega_{\chi^j}^j; \ldots; \omega_1^\psi, \ldots, \omega_{\chi^\psi}^\psi\}$; $A_0^{(\chi^j+\cdots+\chi^\psi)}$ denotes diag $(\omega_1^j A_0, \ldots, \omega_{\chi^j}^j A_0; \ldots; \omega_1^\psi A_0, \ldots, \omega_{\chi^\psi}^\psi A_0)$ if not, and for every $\theta \leq \mu^j$, $Y^\theta_{\mu^j,\ldots,\mu^\psi} := [Y_{\theta,\mu^j}, \ldots, Y_{\theta,\mu^\psi}]^T$, where $Y^\theta_{\mu^j,\ldots,\mu^j} = Y^\theta_{\mu^j} = (Y_{\theta,\mu_1^j}, \ldots, Y_{\theta,\mu_{\chi^j}^j})^T$ for all $0 \leq j \leq \psi$.

Step 1. Verify that the induction hypothesis is satisfied for $\bar{\delta} = 1$, i.e., $\psi = 0$. Then, $\mu_0 = \mu_1 = \cdots = \mu_l := \rho \geq 1$ and $(*)_j = 0$ for all $0 \leq j \leq l$. In this step, we transform the system $(S)_h^r$ into ρ single-input subsystems made by distinct eigenvalues and by equations which have a common number θ, $1 \leq \theta \leq \rho$, in each subsystem (j),

$0 \le j \le l$; i.e., $(S)_h^r$ is the reunion of ρ-subsystems: $(S)_h^r = \bigcup_{\theta=1}^{\rho}(S_\theta)_h^{r_\theta}$ with

$$(54)\qquad \begin{aligned}(S_\theta)_h^{r_\theta}:\ \dot{Y}_\rho^\theta(t) &= A_{0,0}^{(l+1)}Y_\rho^\theta(t) - r_\theta b_{0,1}^{(l+1)}\sigma_\theta(u_\theta(t-h)) + r_\theta v_\rho^\theta(t-h)\\ &\quad - r_\theta \textstyle\sum_{j=\rho+1}^{m}\hat{b}^j_{\theta,0,\dots,\kappa,\dots,l}\sigma_j(u_j(t-h)),\end{aligned}$$

where $\hat{b}_{\theta,0,\dots,\kappa,\dots,l} := (\hat{b}_{\theta,0},\dots,\hat{b}_{\theta,\kappa},\dots,\hat{b}_{\theta,l})^T$ and $\hat{b}_{\theta,\kappa} := \hat{a}_\theta$. So, $(S_\theta)_h^{r_\theta}$ is *a finite dimensional single-input controllable system* with *distinct eigenvalues* for all $1 \le \theta \le \rho$.

Put $u_j = 0$, $j \ge \rho+1$, and take into account the result previously proved for the single-input case. Then, for every $1 \le \theta \le \rho$, there exist a constant $C_{\theta,0}$ and, for every $1 \le p \le \infty$, a constant $M_{\theta,p} > 0$ such that, for every $h > 0$, there is an $r_\theta^*(h) \in (0,1]$ for which the trajectories $(Y_\rho^\theta)_{v_1^\theta,v_\rho^\theta}$ of $(S_\theta)_h^{r_\theta}$, $r_\theta \in (0, r_\theta^*(h)$, starting at $\bar{0}$ and corresponding to $v_1^\theta, v_\rho^\theta \in L^p$ with $\|v_\rho^\theta\|_{L^\infty} \le C_{\theta,0}$, are finite-gain L^p-stable, with the feedback

$$(55)\qquad u_\theta(t-h) = (b_{0,1}^{(l+1)})^T e^{A_{0,0}^{(l+1)}h}Y_\rho^\theta(t-h) + v_1^\theta(t-h).$$

Moreover,

$$(56)\qquad \left\|(Y_\rho^\theta)_{v_1^\theta,v_\rho^\theta}\right\|_{L^p} \le M_{\theta,p}\left(\|v_1^\theta\|_{L^p} + \|v_\rho^\theta\|_{L^p}\right),\quad \theta = 1,\dots,\rho.$$

Recall that for every $1 \le \theta \le \rho$, the upper bound for the L^p-gain $M_{\theta,p}$ is delay-independent.

Step 2. Assume now that the induction hypothesis is satisfied at the step $\bar{\delta} = k$, i.e., $\psi = k-1$ for all $1 \le k \le l$. Take the $k+1$ distinct algebraic multiplicity μ^k, corresponding to the eigenvalues $\omega^k := (\omega_1^k,\dots,\omega_{\chi^k}^k)$ such that $\mu^0 < \cdots < \mu^k$ and χ^k is the number of equal algebraic multiplicities in the last inequality. Then, ω^k is made of χ^k eigenvalues. Note that the original system $(S)_h^r$ is a cascade of single-input subsystems, denoted $(0),\dots,(k)$, each of them corresponding to the algebraic multiplicity μ^j, $0 \le j \le k$. We can show that each subsystem (j), $j = 0$ to k is made of χ^j subsystems $(\nu)_j$, $\nu = 1$ to χ^j. So, our method consists of transforming the system $(S)_h^r$ in a cascade of single-input $(k+1)$-subsystems; i.e., $(S)_h^r = \cup_{\alpha=0}^{k}(S_{k-\alpha+1})_h^{r^{k-\alpha+1}}$, where each $(S_{k-\alpha+1})_h^{r^{k-\alpha+1}}$ has $\chi^{k-\alpha}+\cdots+\chi^k$ distinct imaginary eigenvalues and is of dimension $(2(\chi^{k-\alpha}+\cdots+\chi^k)-1)(\mu^{k-\alpha}-\mu^{k-\alpha-1})$ if 0 is an eigenvalue or $2(\chi^{k-\alpha}+\cdots+\chi^k)(\mu^{k-\alpha}-\mu^{k-\alpha-1})$ if not for all $1 \le \alpha \le k+1$ with $\mu^{-1} := 0$.

Remark 5. We can see that each subsystem $(S_{k-\alpha+1})_h^{r^{k-\alpha+1}}$, $0 \le \alpha \le k$, is made of equations having the same order number θ, $\mu^{k-\alpha-1}+1 \le \theta \le \mu^{k-\alpha}$, in the subsystems $(k),(k-1),\dots,(k-\alpha)$, where it has distinct imaginary eigenvalues, but perturbed by an external disturbance appearing outside the saturation, except the subsystem $(S_{k+1})_h^{r^{k+1}}$.

For $0 \le \alpha \le k$, each subsystem $(S_{k-\alpha+1})_h^{r^{k-\alpha+1}}$ takes the form

$$(S_{k-\alpha+1})_h^{r^{k-\alpha+1}} \begin{cases} \dot{Y}_{\theta,\mu^{k-\alpha}}(t) = A_{0,0}^{(\chi^{k-\alpha})} Y_{\theta,\mu^{k-\alpha}}(t) - r_\theta^{k-\alpha+1} b_{0,1}^{(\chi^{k-\alpha})} \sigma_\theta(\bar{u}_\theta) \\ \qquad + r_\theta^{k-\alpha+1} \bar{v}_{\theta,\mu^{k-\alpha}} - \sum_{j=\mu^{k-\alpha}+1}^{m} r_j^{k-\alpha+1} \hat{b}_{\theta,\xi^{k-\alpha}}^{j} \sigma_j(\bar{u}_j), \\ \vdots \\ \dot{Y}_{\theta,\mu^{k-1}}(t) = A_0^{(\chi^{k-1})} Y_{\theta,\mu^{k-1}}(t) - r_\theta^{k-\alpha+1} b_0^{(\chi^{k-1})} \sigma_\theta(\bar{u}_\theta) \\ \qquad + r_\theta^{k-\alpha+1} \bar{v}_{\theta,\mu^{k-1}} - \sum_{j=\mu^{k-1}+1}^{m} r_j^{k-\alpha+1} \hat{b}_{\theta,\xi^{k-1}}^{j} \sigma_j(\bar{u}_j), \\ \dot{Y}_{\theta,\mu^{k}}(t) = A_0^{(\chi^{k})} Y_{\theta,\mu^{k}}(t) - r_\theta^{k-\alpha+1} b_0^{(\chi^{k})} \sigma_\theta(\bar{u}_\theta) \\ \qquad + r_\theta^{k-\alpha+1} \bar{v}_{\theta,\mu^{k}} - \sum_{j=\mu^{k}+1}^{m} r_j^{k-\alpha+1} \hat{b}_{\theta,\xi^{k}}^{j} \sigma_j(\bar{u}_j) \end{cases}$$

if $\mu_\kappa \neq \{\mu^{k-\alpha}, \dots, \mu^k\}$ and takes the form

$$(S_{k-\alpha+1})_h^{r^{k-\alpha+1}} \begin{cases} \dot{Y}_{\theta,\mu^{k-\alpha}}(t) = A_{0,0}^{(\chi^{k-\alpha})} Y_{\theta,\mu^{k-\alpha}}(t) - r_\theta^{k-\alpha+1} b_{0,1}^{(\chi^{k-\alpha})} \sigma_\theta(\bar{u}_\theta) \\ \qquad + r_\theta^{k-\alpha+1} \bar{v}_{\theta,\mu^{k-\alpha},0} - \sum_{j=\mu^{k-\alpha}+1}^{m} r_j^{k-\alpha+1} \hat{b}_{\theta,\xi^{k-\alpha},0}^{j} \sigma_j(\bar{u}_j), \\ \vdots \\ \dot{Y}_{\theta,\mu^{j_0}}(t) = A_{0,0}^{(\chi^{j_0})} Y_{\theta,\mu^{j_0}}(t) - r_\theta^{k-\alpha+1} b_{0,1}^{(\chi^{j_0})} \sigma_\theta(\bar{u}_\theta) \\ \qquad + r_\theta^{k-\alpha+1} \bar{v}_{\theta,\mu^{j_0}} - \sum_{j=\mu^{j_0}+1}^{m} r_j^{k-\alpha+1} \hat{b}_{\theta,\xi^{j_0},0}^{j} \sigma_j(\bar{u}_j), \\ \dot{Y}_{\theta,\mu^{j_0-1}}(t) = A_0^{(\chi^{j_0-1})} Y_{\theta,\mu^{j_0-1}}(t) - r_\theta^{k-\alpha+1} b_0^{(\chi^{j_0-1})} \sigma_\theta(\bar{u}_\theta) \\ \qquad + r_\theta^{k-\alpha+1} \bar{v}_{\theta,\mu^{j_0-1}} - \sum_{j=\mu^{j_0-1}+1}^{m} r_j^{k-\alpha+1} \hat{b}_{\theta,\xi^{j_0-1}}^{j} \sigma_j(\bar{u}_j), \\ \vdots \\ \dot{Y}_{\theta,\mu^{k-1}}(t) = A_0^{(\chi^{k-1})} Y_{\theta,\mu^{k-1}}(t) - r_\theta^{k-\alpha+1} b_0^{(\chi^{k-1})} \sigma_\theta(\bar{u}_\theta) \\ \qquad + r_\theta^{k-\alpha+1} \bar{v}_{\theta,\mu^{k-1}} - \sum_{j=\mu^{k-1}+1}^{m} r_j^{k-\alpha+1} \hat{b}_{\theta,\xi^{k-1}}^{j} \sigma_j(\bar{u}_j), \\ \dot{Y}_{\theta,\mu^{k}}(t) = A_0^{(\chi^{k})} Y_{\theta,\mu^{k}}(t) - r_\theta^{k-\alpha+1} b_0^{(\chi^{k})} \sigma_\theta(\bar{u}_\theta) \\ \qquad + r_\theta^{k-\alpha+1} \bar{v}_{\theta,\mu^{k}} - \sum_{j=\mu^{k}+1}^{m} r_j^{k-\alpha+1} \hat{b}_{\theta,\xi^{k}}^{j} \sigma_j(\bar{u}_j) \end{cases}$$

if not, for all $\mu^{k-\alpha-1} + 1 \leq \theta \leq \mu^{k-\alpha}$, where $\bar{\pi} = \pi(t-h)$, $\hat{b}_{\theta,\xi^s}^{j} = (\hat{b}_{\theta,1}^{j}, \dots, \hat{b}_{\theta,\chi^s}^{j})^T$, $k-\alpha \leq s \leq k$, and $\hat{b}_{\theta,\xi^s,0}^{j} = (\hat{b}_{\theta,1}^{j}, \dots, \hat{a}_\theta^j, \dots, \hat{b}_{\theta,\chi^s}^{j})^T$, $k-\alpha \leq s \leq j_0$, and $\mu_\kappa = \mu^{j_0}$.

With the notation, each subsystem $(S_{k-\alpha+1})_h^{r^{k-\alpha+1}}$, $0 \le \alpha \le k$, is given by

(57)
$$\dot{Y}^{\theta}_{\mu^{k-\alpha},\dots,\mu^k}(t)=\begin{cases} A_{0,0}^{(\chi^{k-\alpha}+\cdots+\chi^k)}Y^{\theta}_{\mu^{k-\alpha},\dots,\mu^k}(t)-r_\theta^{k-\alpha+1}b_{0,1}^{(\chi^{k-\alpha}+\cdots+\chi^k)}\sigma_\theta\Big(u_\theta(t-h)\Big) \\ \qquad + r_\theta^{k-\alpha+1}v^{\theta}_{\mu^{k-\alpha},\dots,\mu^k,0}(t-h)+V_{k-\alpha+2}(t-h) \\ \qquad\qquad \text{if } \mu_\kappa \in \{\mu^{k-\alpha},\dots,\mu^k\}, \\ A_{0}^{(\chi^{k-\alpha}+\cdots+\chi^k)}Y^{\theta}_{\mu^{k-\alpha},\dots,\mu^k}(t)-r_\theta^{k-\alpha+1}b_{0}^{(\chi^{k-\alpha}+\cdots+\chi^k)}\sigma_\theta\Big(u_\theta(t-h)\Big) \\ \qquad + r_\theta^{k-\alpha+1}v^{\theta}_{\mu^{k-\alpha},\dots,\mu^k}(t-h)+V_{k-\alpha+2}(t-h) \end{cases}$$

for every $\mu^{k-\alpha-1}+1 \le \theta \le \mu^{k-\alpha}$, where

$$\begin{aligned} V_{k-\alpha+2}(.) &:= -\Big(\textstyle\sum_{j=\mu^{k-\alpha}+1}^{m} r_j^{k-\alpha+2}\hat{b}^j_{\theta,\xi^{k-\alpha}}\sigma_j\Big(u_j(.)\Big) \quad \dots \\ &\qquad\qquad \textstyle\sum_{j=\mu^k+1}^{m} r_j^{k+1}\hat{b}^j_{\theta,\xi^k}\sigma_j\Big(u_j(.)\Big)\Big)^T \\ &:= -r^{k-\alpha+2}_{\mu^{k-\alpha}+1}b_{\mu^{k-\alpha}+1}\sigma_{\mu^{k-\alpha}+1}\Big(u_{\mu^{k-\alpha}+1}(.)\Big)-\cdots-r^{k-\alpha+2}_{\mu^{k-\alpha+1}}b_{\mu^{k-\alpha+1}} \\ &\times \quad \sigma_{\mu^{k-\alpha+1}}\Big(u_{\mu^{k-\alpha+1}}(.)\Big)-\cdots-r^{k+1}_{\mu^{k-1}+1}b_{\mu^{k-1}+1}\sigma_{\mu^{k-1}+1}\Big(u_{\mu^{k-1}+1}(.)\Big) \\ &- \quad r^{k+1}_{\mu^k}b_{\mu^k}\sigma_{\mu^k}\Big(u_{\mu^k}(.)\Big)-\cdots-r^m_m b_m\sigma_m\Big(u_m(.)\Big), \end{aligned}$$

with $\mu^m = m$. First, for $j \ge \mu^k+1$, put $u_j = 0$, then $V_{k+2} = 0$. $(S_{k-\alpha+1})_h^{r^{k-\alpha+1}}$ is a *finite dimensional single-input controllable* system with *distinct eigenvalues* but perturbed by the vector $V_{k-\alpha+2}$ for all $0 \le \alpha \le k$. The problem is that the perturbation may cause instability. In this case, our method of finite-gain stabilizability proceeds step by step, meaning that, first, we begin to finite-gain L^p-stabilize the subsystem $(S_{k+1})_h^{r^{k-\alpha+1}}$ corresponding to $\alpha = 0$, $\mu^{k-1}+1 \le \theta \le \mu^k$, $V_{k+2} = 0$, and made of χ^k distinct eigenvalues $(\omega_1^k,\dots,\omega_{\chi^k}^k)$ of dimension $(2\chi^k-1)(\mu^k-\mu^{k-1})$ if $0 \in \{\omega_1^k,\dots,\omega_{\chi^k}^k\}$ or $2\chi^k(\mu^k-\mu^{k-1})$ if not. As in the first step, we transform the subsystem $(S_{k+1})_h^{r^{k+1}}$ into the union of $\mu^k-\mu^{k-1}$ single-input subsystems made of distinct eigenvalues and equations which have the same order number θ, $\mu^{k-1}+1 \le \theta \le \mu^k$ in each subsystem (ν), $1 \le \nu \le \chi^k$, where the subsystem (ν) corresponds to the eigenvalue ω_ν^k; i.e., $(S_{k+1})_h^{r^{k+1}} = \cup_{\theta=\mu^{k-1}+1}^{\mu^k}(S^\theta_{k+1})_h^{r^{k+1}_\theta}$ with

$$(S^\theta_{k+1})_h^{r^{k+1}_\theta} : \dot{Y}^\theta_{\mu^k}(t) = \begin{cases} A_{0,0}^{(\chi^k)}Y^\theta_{\mu^k}(t) - r_\theta^{k+1}b_{0,1}^{(\chi^k)}\sigma_\theta(u_\theta(t-h)) + r_\theta^{k+1}v^\theta_{\mu^k,0}(t-h) \\ \qquad\qquad \text{if } \mu^k = \mu_\kappa, \\ A_{0}^{(\chi^k)}Y^\theta_{\mu^k}(t) - r_\theta^{k+1}b_{0}^{(\chi^k)}\sigma_\theta(u_\theta(t-h)) + r_\theta^{k+1}v^\theta_{\mu^k}(t-h) \\ \qquad\qquad \text{if not.} \end{cases}$$

$(S^\theta_{k+1})^{r^{k+1}_\theta}_h$ is a *finite dimensional single-input controllable* system with *distinct eigenvalues* for every $\mu^{k-1}+1 \leq \theta \leq \mu^k$. According to the result previously proved for the single-input case ((Step 1), respectively), this subsystem can be finite-gain L^p-stabilized, for all $1 \leq p \leq \infty$ and $\mu^{k-1}+1 \leq \theta \leq \mu^k$, with the feedback

$$u_\theta(t-h) = \begin{cases} (b_0^{(\chi^k)})^T e^{A_0^{(\chi^k)}h} Y^\theta_{\mu^k}(t-h) + v^\theta_1(t-h) \text{ if } \mu^k \neq \mu_\kappa, \\ \\ (b_{0,1}^{(\chi^k)})^T e^{A_{0,0}^{(\chi^k)}h} Y^\theta_{\mu^k}(t-h) + v^\theta_{1,0}(t-h) \text{ if not;} \end{cases} \tag{58}$$

i.e., for every $\mu^{k-1}+1 \leq \theta \leq \mu^k$, there exists a constant $C^{k+1}_{\theta,0} > 0$ and, for every $1 \leq p \leq \infty$, a constant $M^{k+1}_{\theta,p} > 0$ such that, for every $h > 0$, there is an $(\tilde{r}_\theta)^{k+1}(h) \in (0,1]$ for which the trajectories $(Y^\theta_{\mu^k})_{v^\theta_1, v^\theta_{\mu^k}}$ ($(Y^\theta_{\mu^k})_{v^\theta_{1,0}, v^\theta_{\mu^k,0}}$, respectively) of $(S_{k+1})^{r^{k+1}_\theta}_h$, $r^{k+1}_\theta \in (0, (\tilde{r}_\theta)^{k+1}(h)]$, starting at $\bar{0}$ and corresponding to $v^\theta_1, v^\theta_{\mu^k}$ ($v^\theta_{1,0}, v^\theta_{\mu^k,0}$, respectively) $\in L^p$ with $\|v^\theta_{\mu^k}\|_{L^\infty}$ ($\|v^\theta_{\mu^k,0}\|_{L^\infty}$, respectively) $\leq C^{k+1}_{\theta,0}$, verify

$$\begin{aligned} \left\| (Y^\theta_{\mu^k})_{v^\theta_1, v^\theta_{\mu^k}} \right\|_{L^p} &\leq M^{k+1}_{\theta,p} \left(\|v^\theta_1\|_{L^p} + \|v^\theta_{\mu^k}\|_{L^p} \right) \text{ if } \mu_\kappa \neq \mu^k, \\ \left\| (Y^\theta_{\mu^k})_{v^\theta_{1,0}, v^\theta_{\mu^k,0}} \right\|_{L^p} &\leq M^{k+1}_{\theta,p} \left(\|v^\theta_{1,0}\|_{L^p} + \|v^\theta_{\mu^k,0}\|_{L^p} \right) \text{ if } \mu_\kappa = \mu^k. \end{aligned} \tag{59}$$

Recall that, for every $\mu^{k-1}+1 \leq \theta \leq \mu^k$, the upper bound for the corresponding L^p-gain, $M^{k+1}_{\theta,p}$, of the subsystem $(S^\theta_{k+1})^{r^{k+1}_\theta}_h$, $r^{k+1}_\theta \in (0, (\tilde{r}_\theta)^{k+1}(h)]$, is independent of the delay $h > 0$. Note that the amplitude $r^{k+1}_\theta \leq (r^*_\theta)^{k+1}$, the final input bound of the subsystem $(S^\theta_{k+1})^{r^{k+1}_\theta}_h$, which will be determined later. Now, since $2\chi^k(\mu^k - \mu^{k-1})$ is the dimension of the subsystem $(S_{k+1})^{r^{k+1}}_h$ ($(2\chi^k-1)(\mu^k-\mu^{k-1})$, respectively, if $\mu_\kappa = \mu^k$) and $2\chi^k\mu^k$ is the dimension of the subsystem (k), ($(2\chi^k-1)\mu^k$, respectively, if $\mu_\kappa = \mu^k$), then after stabilizing $(S_{k+1})^{r^{k+1}}_h$, it is obvious that $2\chi^k\mu^{k-1}$ or $\left((2\chi^k-1)\mu^{k-1}\right)$ is the dimension of the rest of the subsystem (k), which is made of the subsystems $(j)_k$, $1 \leq j \leq \chi^k$, corresponding to the algebraic multiplicities $\mu^k := \mu^k_1 = \cdots = \mu^k_{\chi^k}$ and the eigenvalues $\omega^k_1, \ldots, \omega^k_{\chi^k}$. Then, the algebraic multiplicity of the eigenvalues of the rest of the system (k) is μ^{k-1} which is the algebraic multiplicity of the subsystem $(k-1)$ corresponding to the eigenvalues $\omega^{k-1}_1, \ldots, \omega^{k-1}_{\chi^{k-1}}$. Therefore, the remaining part of the system $(S)^r_h$, denoted $(\hat{S})^{\hat{r}}_h$, is characterized by $\bar{\delta} = k$ but it is perturbed by the vector of sufficiently small amplitude

$$\hat{V}(.) := -r^{k+1}_{\mu^{k-1}+1} b_{\mu^{k-1}+1} \sigma_{\mu^{k-1}+1}(u_{\mu^{k-1}+1}(.)) - \cdots - r^{k+1}_{\mu^k} b_{\mu^k} \sigma_{\mu^k}(u_{\mu^k}(.)).$$

Set

$$\begin{aligned} \dot{\hat{Y}}(t) &= \hat{A}\hat{Y}(t) - \hat{r}\hat{B}\hat{\sigma}\left(\hat{u}(t-h)\right) + \hat{r}\hat{v}^2(t-h) + \hat{V}(t-h) \\ &:= \hat{A}\hat{Y}(t) - \hat{r}\hat{B}\hat{\sigma}\left(\hat{F}^T_h \hat{Y}(t-h) + \hat{v}^1(t-h)\right) + \hat{r}\hat{v}^2(t-h) + V_{k+1}(t-h) \end{aligned}$$

as the subsystem $(\hat{S})^{\hat{r}}_h$ which is characterized by $\bar{\delta} = k$. By the inductive hypothesis, this subsystem can be finite-gain L^p-stabilized for all $1 \leq p \leq \infty$. So, there exists a constant $\hat{C}_0 > 0$ and, for every $1 \leq p \leq \infty$, a constant $\hat{M}_p > 0$ such

that, for every $h > 0$, there is an $(\hat{r})^*(h) \in (0,1]$ for which the trajectories $(\hat{Y})_{\hat{\Pi}}$, $\hat{\Pi} := ((\hat{v}^1, \hat{v}^2), (v_1^\theta, v_{\mu^k}^\theta)_{\mu^{k-1}+1 \le \theta \le \mu^k})$ if $\mu_\kappa \neq \mu^k$, or $((\hat{v}^1, \hat{v}^2), (v_{1,0}^\theta, v_{\mu^k,0}^\theta)_{\mu^{k-1}+1 \le \theta \le \mu^k})$ if $\mu_\kappa = \mu^k$, of $(\hat{S})_h^{\hat{r}}$, $\hat{r} \in (0, (\hat{r})^*(h)]$, starting at $\bar{0}$ and corresponding to $\hat{v}^1, \hat{v}^2, v_1^{\mu^{k-1}+1}, v_{\mu^k}^{\mu^{k-1}+1}, \ldots, v_1^{\mu^k}, v_{\mu^k}^{\mu^k}$ $(\hat{v}^1, \hat{v}^2, v_{1,0}^{\mu^{k-1}+1}, v_{\mu^k,0}^{\mu^{k-1}+1}, \ldots, v_{1,0}^{\mu^k}, v_{\mu^k,0}^{\mu^k}$ if $\mu_\kappa = \mu^k) \in L^p$ with

$$\|\hat{v}^2\|_{L^\infty} + K \sup_{\mu^{k-1}+1 \le \theta \le \mu^k} \|b_\theta\| \sum_{\theta=\mu^{k-1}+1}^{\mu^k} \frac{r_\theta^{k+1}}{\hat{r}} \le \hat{C}_0, \tag{60}$$

since $\|\sigma_\theta(.)\|_{L^\infty} \le K$, $\theta = \mu^{k-1}+1$ to μ^k, $\|\hat{v}^2\|_{L^\infty}$ is to be chosen later and

$$\hat{u}(t-h) = \hat{B}^T e^{\hat{A}h} \hat{Y}(t-h) + \hat{v}^1(t-h), \tag{61}$$

verify

(62)
$$\|\hat{Y}_{\hat{\Pi}}\|_{L^p} \le \hat{M}_p \begin{cases} \left[\|\hat{v}^1\|_{L^p} + \|\hat{v}^2\|_{L^p} + \sum_{\theta=\mu^{k-1}}^{\mu^k} \left(\|v_1^\theta\|_{L^p} + \|v_{\mu^k}^\theta\|_{L^p}\right)\right] & \text{if } \mu_\kappa \neq \mu^k, \\ \left[\|\hat{v}^1\|_{L^p} + \|\hat{v}^2\|_{L^p} + \sum_{\theta=\mu^{k-1}}^{\mu^k} \left(\|v_{1,0}^\theta\|_{L^p} + \|v_{\mu^k,0}^\theta\|_{L^p}\right)\right] & \text{if } \mu_\kappa = \mu^k. \end{cases}$$

In addition, the upper bound for the L^p-gain $\hat{M}_p$ of the system $(\hat{S})_h^{\hat{r}}$, $\hat{r} \le (\hat{r})^*(h)$, is independent of $h > 0$.

In order to satisfy (60), we first give the following bound for $\|\hat{v}^2\|_{L^\infty}$:

$$\|\hat{v}^2\|_{L^\infty} \le \frac{\hat{C}_0}{2}. \tag{63}$$

Then, the input bounds $\hat{r}$ and r_θ^{k+1}, $\mu^{k-1}+1 \le \theta \le \mu^k$, must verify

(64)
$$\begin{aligned} &\hat{r} \le (\hat{r})^*(h) \quad \forall\ \mu^{k-1}+1 \le \theta \le \mu^k, r_\theta^{k+1} \le (\tilde{r}_\theta)^{k+1}(h) \text{ and} \\ &K \sup_{\mu^{k-1}+1 \le \theta \le \mu^k} \|b_\theta\| \sum_{\theta=\mu^{k-1}+1}^{\mu^k} \frac{r_\theta^{k+1}}{\hat{r}} \le \frac{\hat{C}_0}{2}. \end{aligned}$$

It is clear that (64) is verified for $\hat{r} \le (\hat{r})^*(h)$ and $r_\theta^{k+1} \le (r_\theta^*)^{k+1}(h)$ for all $\mu^{k-1}+1 \le \theta \le \mu^k$, where

$$(r_\theta^*)^{k+1}(h) = \min\left\{ \frac{\hat{C}_0}{2K\mu^k \sup_{\mu^{k-1}+1 \le \theta \le \mu^k} \|b_\theta\|} (\hat{r})^*(h), (\tilde{r}_\theta)^{k+1} \right\}. \tag{65}$$

Set $r^*(h) := \min\left\{(\hat{r})^*(h), \min_{\mu^{k-1}+1 \le \theta \le \mu^k} (r_\theta^*)^{k+1}(h)\right\}$ and $M_p = \sum_{\theta=\mu^{k-1}+1}^{\mu^k} M_{\theta,p}^{k+1} + \hat{M}_p$. We have shown that there exist a constant $C_0 > 0$, and for every $1 \le p \le \infty$, a constant $M_p > 0$ such that for every $h > 0$ there is an $r^*(h) \in (0,1]$ for which the global system $(S)_h^r$, $r \in (0, r^*(h)]$, with the feedback given by (58) and (61), is finite-gain L^p-stabile; i.e., the trajectories $[((Y_{\mu^k}^\theta)_{v_1^\theta, v_{\mu^k}^\theta})_{\mu^{k-1}+1 \le \theta \le \mu^k}, (\hat{Y})_{\hat{\Pi}}]$ $([((Y_{\mu^k}^\theta)_{v_{1,0}^\theta, v_{\mu^k,0}^\theta})_{\mu^{k-1}+1 \le \theta \le \mu^k}, (\hat{Y})_{\hat{\Pi}}]$, respectively), $r \in (0, r^*(h)]$, starting at $\bar{0}$ and corresponding to $[v_1^{\mu^{k-1}+1}, v_{\mu^k}^{\mu^{k-1}+1}, \ldots, v_1^{\mu^k}, v_{\mu^k}^{\mu^k}, \hat{v}^1, \hat{v}^2]$, $([v_{1,0}^{\mu^{k-1}+1}, v_{\mu^k,0}^{\mu^{k-1}+1}, \ldots, v_{1,0}^{\mu^k}, v_{\mu^k,0}^{\mu^k},$

$\hat{v}^1, \hat{v}^2]$, respectively) $\in L^p$, with

$$\begin{array}{l} \|\hat{v}^2\|_{L^\infty} + \sum_{\theta=\mu^{k-1}+1}^{\mu^k} \left(\|v^\theta_{\mu^k}\|_{L^\infty} + \|b_\theta\| \right) \leq C_0 \text{ if } \mu^k \neq \mu_\kappa, \\ \|\hat{v}^2\|_{L^\infty} + \sum_{\theta=\mu^{k-1}+1}^{\mu^k} \left(\|v^\theta_{\mu^k,0}\|_{L^\infty} + \|b_\theta\| \right) \leq C_0 \text{ if } \mu^k = \mu_\kappa, \end{array} \tag{66}$$

verify

$$\left\{ \begin{array}{l} \left\| \left((Y^\theta_{\mu^k})_{v^\theta_1, v^\theta_{\mu^k}} \right)_{\mu^{k-1}+1 \leq \theta \leq \mu^k}, (\hat{Y})_{\hat{\Pi}} \right\|_{L^p} \leq M_p \Big\{ \sum_{\theta=\mu^{k-1}+1}^{\mu^k} \left(\|v^\theta_1\|_{L^p} + \|v^\theta_{\mu^k}\|_{L^p} \right) \\ \qquad\qquad + \|\hat{v}^1\|_{L^p} + \|\hat{v}^2\|_{L^p} \Big\} \text{ if } \mu_\kappa \neq \mu^k, \\ \left\| \left((Y^\theta_{\mu^k})_{v^\theta_{1,0}, v^\theta_{\mu^k,0}} \right)_{\mu^{k-1}+1 \leq \theta \leq \mu^k}, (\hat{Y})_{\hat{\Pi}} \right\|_{L^p} \leq M_p \Big\{ \sum_{\theta=\mu^{k-1}+1}^{\mu^k} \left(\|v^\theta_{1,0}\|_{L^p} + \|v^\theta_{\mu^k,0}\|_{L^p} \right) \\ \qquad\qquad + \|\hat{v}^1\|_{L^p} + \|\hat{v}^2\|_{L^p} \Big\} \text{ if } \mu_\kappa = \mu^k, \end{array} \right. \tag{67}$$

where the upper bound for the corresponding global L^p-gain, M_p, is delay-independent.

The proof of Proposition 1 is complete. □

3.3. Construction of the feedback. In this paragraph we provide an explicit expression of the L^p-stabilizing feedback for the system $(S)^r_h$, namely, the solution to the problem.

PROPOSITION 2. *The bounded state feedback*

$$u(.) = \left(\begin{array}{l} (b^{(l+1)}_{0,1})^T e^{A^{(l+1)}_{0,0} h} Y^\theta_{\mu^0,\ldots,\mu^k}(.) + v^0_{1,\theta}(.), \quad 1 \leq \theta \leq \mu^0, \\ (b^{(\chi^1+\cdots+\chi^k)}_{0,1})^T e^{A^{(\chi^1+\cdots+\chi^k)}_{0,0} h} Y^\theta_{\mu^1,\ldots,\mu^k}(.) + v^1_{1,\theta}(.), \quad \mu^0+1 \leq \theta \leq \mu^1, \\ \vdots \\ (b^{(\chi^{j_0}+\cdots+\chi^k)}_{0,1})^T e^{A^{(\chi^{j_0}+\cdots+\chi^k)}_{0,0} h} Y^\theta_{\mu^{j_0},\ldots,\mu^k}(.) + v^{j_0}_{1,\theta}(.), \ \mu^{j_0-1}+1 \leq \theta \leq \mu^{j_0}, \\ (b^{(\chi^{j_0-1}+\cdots+\chi^k)}_{0})^T e^{A^{(\chi^{j_0-1}+\cdots+\chi^k)}_{0} h} Y^\theta_{\mu^{j_0-1},\ldots,\mu^k}(.) + v^{j_0-1}_{1,\theta}(.), \\ \qquad\qquad \mu^{j_0-2}+1 \leq \theta \leq \mu^{j_0-1}, \\ \vdots \\ (b^{(\chi^{k-1}+\chi^k)}_{0})^T e^{A^{(\chi^{k-1}+\chi^k)}_{0} h} Y^\theta_{\mu^{k-1},\mu^k}(.) + v^{k-1}_{1,\theta}(.), \quad \mu^{k-2}+1 \leq \theta \leq \mu^{k-1}, \\ (b^{(\chi^k)}_{0})^T e^{A^{(\chi^k)}_{0} h} Y^\theta_{\mu^k}(.) + v^k_{1,\theta}(.), \quad \mu^{k-1}+1 \leq \theta \leq \mu^k, \end{array} \right) \tag{68}$$

finite-gain L^p-stabilizes the system $(S)^r_h : \dot{x}(t) = Ax(t) - rB\sigma(u(t-h)) + rv(t-h)$, where $v = (v^{\theta^0}_{\mu^0,\ldots,\mu^k}, \ldots, v^{\theta^k}_{\mu^k}) \in L^p$, $\mu^{j-1}+1 \leq \theta^j \leq \mu^j$ for all $0 \leq j \leq k$; i.e., the

trajectories $((Y^{\theta^0}_{\mu^0,\dots,\mu^k})_{\Pi_1},\dots,(Y^{\theta^k}_{\mu^k})_{\Pi_{k+1}})$, $\Pi_\nu := (v^{\nu-1}_{1,\theta},\, v^{\theta}_{\mu^{\nu-1},\dots,\mu^k},\Pi^T_{\nu+1})^T$, $1\le\nu\le k+1$, $r\in(0,\,r^*(h)]$, *starting at* $\bar 0$ *and corresponding to* $v^0_{1,\theta},v^{\theta}_{\mu^0,\dots,\mu^k},\dots,v^k_{1,\theta},v^{\theta}_{\mu^k}\in L^p$, *verify, for all* $j=0,\dots,k$,

$$\left\|\left((Y^{\theta^0}_{\mu^0,\dots,\mu^k})_{\Pi_1},\dots,(Y^{\theta^k}_{\mu^k})_{\Pi_{k+1}}\right)\right\|_{L^p}\le M_p\sum_{\theta^j=\mu^{j-1}+1}^{\mu^j}\left(\|v^0_{1,\theta^j}\|_{L^p}+\|v^{\theta^j}_{\mu^0,\dots,\mu^k}\|_{L^p}\right),$$

where the upper bound for the corresponding global L^p*-gain* M_p *is delay-independent.*

Appendix A. Proof of Lemma 1. Since the pair (A,b) is controllable and b is a column vector, it is clear that A has n distinct eigenvalues. So, from [5, Theorem XII.1], there exists an $r_1^*\in(0,1)$ such that $A_r=A-rbb^T$ has n different analytic eigenvalues $(\lambda_j(r))_{1\le j\le n}$ for every $r\in(0,r_1^*]$, with $i\omega_j=\lambda_{2j-1}(0)$, $-i\omega_j=\lambda_{2j}(0)$, $1\le j\le[n]$, and $\lambda_n(0)=0$ if n is odd. Note that one can choose the ω_j's to be all positive, except the last one if n is odd. Moreover, A verifies (51), with two-dimensional diagonal blocks equal to ω_jA_0 if $\omega_j>0$ and equal to zero otherwise. Set $D_0:=OAO^T$.

We first show that there exist n positive constants C_j, $1\le j\le n$, and $0<r_2^*\le r_1^*$, such that, for every $r\in(0,r_2^*]$ and $1\le j\le\left[\frac{n}{2}\right]$, we have

$$\lambda_{2j-1}(r)=-(C_j+\varepsilon^1_j(r))r+i(\omega_j+\varepsilon^2_j(r)) \tag{69}$$

and

$$\lambda_{2j}(r)=-(C_j+\varepsilon^1_j(r))r-i(\omega_j+\varepsilon^2_j(r)) \tag{70}$$

(with the obvious extension for $\lambda_n(r)$ in the case n odd), where the functions $\varepsilon^l_j(r)$, $1\le j\le n$, and $l=1,2$, are real-valued and tend to zero as r tends to zero.

We next finish the proof of Lemma 1 assuming that (69) and (70) hold. First, it is clear that, when n is odd, $\omega_n=0$, and in that case, $\varepsilon^2_n\equiv0$. In addition, we deduce, by a simple continuity argument, that the analytic matrix function $A_r:=A-rbb^T$ has distinct eigenvalues for $r\in[0,r_1^*)$ and is thus diagonalizable over C. Therefore, one has $Q(r)A(r)Q(r)^{-1}=D(r)$, where

$Q(0)=O$ and $r\mapsto Q(r)$ is real-valued and continuous; therefore, $Q(r)=O+q(r)$ with $q(r)$ tending to zero as r tends to zero;

$D(0)=D_0$, $r\mapsto D(r)$ is real-valued, continuous, and block diagonal with two-dimensional diagonal blocks equal to $\mathrm{Re}(\lambda_j(r))I_2+Im(\lambda_j(r))A_0$ if $\lambda_j(0)=i\omega_j\neq0$ and equal to the real number $\lambda_j(r)$ if $\lambda_j(0)=0$.

It follows that $Q(r)e^{A(r)t}Q(r)^{-1}=e^{D(r)t}$, and an easy computation yields (5).

One clearly has that $Q(r)(Q(r)^T)^{-1}=I_n+\tilde q(r)$, with $\tilde q(r)$ tending to zero as r tends to zero. For $t\ge0$ and $r\in[0,r_1^*)$, one has

$$Q(r)e^{A(r)t}e^{A(r)^Tt}(Q(r)^T)^{-1}=e^{D(r)t}Q(r)(Q(r)^T)^{-1}e^{D(r)^Tt}=e^{D(r)t}e^{D(r)^Tt}+R(r,t),$$

where $R(r,t)=e^{D(r)t}\tilde q(r)e^{D(r)^Tt}$. In addition, $D(r)$ commutes with $D(r)^T$ and, then, $e^{D(r)t}e^{D(r)^Tt}$ is equal to $e^{(D(r)+D(r)^T)t}$, which is block diagonal with two-dimensional diagonal blocks equal to $e^{2\mathrm{Re}(\lambda_j(r)t}I_2$ if $\lambda_j(0)=i\omega_j\neq0$ and the real number $e^{2\lambda_j(r)t}$ if $\lambda_j(0)=0$. Taking now into account (69) and integrating over R^+, one gets that

$$Q(r)P_r(Q(r)^T)^{-1}=P^1(r)+P^2(r),$$

so that

$P^1(r) = \int_0^\infty e^{D(r)t} e^{D(r)^T t} dt$ where $P^1(r)$ is a diagonal matrix where every diagonal element is bigger than $\frac{C_1}{r}$ for some $C_1 > 0$;
$P^2(r) = \int_0^\infty R(r,t)dt$ with $\|P^2(r)\| \leq \frac{\bar{q}(r)}{r}$, $\bar{q}(r)$ tending to zero as r tends to zero. It is therefore clear that, for r small enough, (7) follows readily.

We now prove (69). Since A is skew-symmetric, there exists an $r_2^* \in (0,1]$ such that for all $r \in (0, r_2^*]$,

$$e^{(A-rbb^T)t} = \sum_{j=1}^{N} M_j(r,t) e^{\lambda_j(r)t}, \tag{71}$$

with $N = [\frac{n+1}{2}]$. As for all $r \in (0, r_3^* = \min\{r_1^*, r_2^*\}]$, $\mathrm{Re}(\lambda_j(r)) < 0$ for $j = 1, \ldots, N$ and $M_j(r,t), j = 1, \ldots, N$, are uniformly bounded (since $A - rbb^T$ is Hurwitz and A is skew-symmetric). It turns out that we have the desired result for every $r \in (0, r_3^*]$, provided that

$$-C_2' \leq \frac{\mathrm{Re}(\lambda_j(r))}{r} \leq -C_2 < 0, \qquad j = 1, \ldots, N,$$

uniformly for some positive constants C_2', $C_2 > 0$ independent of r. Indeed this is true if

$$\mathrm{Re}\left(\frac{\partial \lambda_j(r)}{\partial r}\right)_{|r=0} = \frac{\partial \mathrm{Re}(\lambda_j(r))}{\partial r}_{|r=0} \neq 0, \qquad j = 1, \ldots, N.$$

We have

$$\mathcal{X}_{A-rbb^T}(s) = \det\,(A - rbb^T - sI) = \mathcal{X}_A(s) + r\mathcal{X}_{\bar{A}}(s), \tag{72}$$

with

$$\mathcal{X}_{\bar{A}}(s) = \mathcal{X}_{A-bb^T}(s) - \mathcal{X}_A(s).$$

Set $\lambda_j(0) := iw_j$, $i^2 = -1$, $w_j \geq 0$, $1 \leq j \leq N$, as simple roots of A; then $\mathcal{X}_A'(iw_j) \neq 0, 1 \leq j \leq N$.

For $1 \leq j \leq N$, the relation $\mathcal{X}_{A-rbb^T}(\lambda_j(r)) = 0$ leads to $\mathcal{X}_A(\lambda_j(r)) + r\mathcal{X}_{\bar{A}}(\lambda_j(r)) = 0$, and then

$$\frac{\mathcal{X}_A(\lambda_j(r)) - \mathcal{X}_A(\lambda_j(0))}{r} = -\mathcal{X}_{\bar{A}}(\lambda_j(r)). \tag{73}$$

On the other hand,

$$\mathcal{X}_A(\lambda_j(r)) = \mathcal{X}_A(\lambda_j(0)) + r\mathcal{X}_A'(\lambda_j(0))\lambda_j'(0) + o(r),$$

where $o(r) \to 0$ as $r \to 0$. From (73), it follows that

$$\mathcal{X}_A'(\lambda_j(0))\lambda_j'(0) + o(1) = -\mathcal{X}_{\bar{A}}(\lambda_j(r)),$$

where $o(1) \to 0$ as $r \to 0$. Now, if r converges to zero, we get

$$\lambda_j'(0) = -\frac{\mathcal{X}_{\bar{A}}(i\omega_j)}{\mathcal{X}_A'(i\omega_j)} = -\frac{\mathcal{X}_{A-bb^T}(i\omega_j)}{\mathcal{X}_A'(i\omega_j)} \quad \text{for every } j = 1, \ldots, N.$$

This completes the proof of (69) since $A - bb^T$ is Hurwitz. ∎

Appendix B. Canonical form. Since A is skew-symmetric, there exists an orthogonal $n \times n$ matrix O such that

$$OAO^T = \begin{pmatrix} A_{0,\mu_0} & & & & \\ & \ddots & & & \\ & & A_{0,\mu_\kappa} & & (0) \\ & & & \ddots & \\ & (0) & & & A_{0,\mu_l} \end{pmatrix}, \tag{74}$$

where, for every $0 \le j \le l$, $j \ne \kappa$, A_{0,μ_j} is a $2\mu_j \times 2\mu_j$ matrix in the form

$$A_{0,\mu_j} = \begin{pmatrix} \omega_j A_0 & 0 & \dots & 0 \\ 0 & \omega_j A_0 & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & \omega_j A_0 \end{pmatrix}, \quad \text{with } A_0 = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix},$$

and A_{0,μ_κ} is a $\mu_\kappa \times \mu_\kappa$ zero matrix.

So, up to an orthonormal change of basis, we can assume that $A = \text{diag}\,(A_{0,\mu_j})$, $1 \le j \le l$. Consider now $OX = (X_0, \dots, X_\kappa, \dots, X_l)^T$ and $OB = (B_0, \dots, B_\kappa, \dots, B_l)^T$, where $X_j \in R^{2\mu_j}, X_\kappa \in R^{\mu_\kappa}$, the size of B_j is $2\mu_j \times m$, and the size of B_κ is $\mu_\kappa \times m$ for all $0 \le j \le l$, $j \ne \kappa$. Then, for all $0 \le j \le l$, the system $(S)_h^r$ becomes

$$\dot{X}_j = A_{0,\mu_j} X_j - rB_j \sigma\Big(F_{j,h}^T X_j(t-h) + u_{1,j}(t-h)\Big) + ru_{2,j}(t-h), \tag{75}$$

where $F_{j,h} \in R^{2\mu_j \times m}, F_{\kappa,h} \in R^{\mu_\kappa \times m}, u_{1,j} \in R^m, u_{1,\kappa} \in R^m, u_{2,j} \in R^{2\mu_j}$, and $u_{2,\kappa} \in R^{\mu_\kappa}$ for all $0 \le j \le l$, $j \ne \kappa$, are to be chosen later. Then, it is easy to see that

$$(A, B) \text{ is controllable iff } (A_{0,\mu_j}, B_j) \text{ is for } 0 \le j \le l, j \ne \kappa, \text{ and rank } B_\kappa = \mu_\kappa.$$

Indeed, for all $0 \le j \le l$, $j \ne \kappa$, let $R(A_{0,\mu_j}, B_j)$ be the controllability matrix of the pair (A_{0,μ_j}, B_j). We have $R(A_{0,\mu_j}, B_j) = [B_j, A_{0,\mu_j} B_j]$ since $A_{0,\mu_j}^2 = -\omega_j^2 I_{2\mu_j}$. Then, (A_{0,μ_j}, B_j) is controllable if and only if $\text{rank} R(A_{0,\mu_j}, B_j) = \text{rank}[B_j, A_{0,\mu_j} B_j] = 2\mu_j$.

Let $B = (B_0, \dots, B_\kappa, \dots, B_l)^T = (b_1, \dots, b_m) \in R^{n \times m}$, with for each $1 \le \theta \le m, b_\theta = (b_0^\theta, \dots, b_\kappa^\theta, \dots, b_l^\theta)^T \in R^n$, and $b_j^\theta = (b_{1,j}^\theta, b_{2,j}^\theta, \dots, b_{\mu_j,j}^\theta)^T \in R^{2\mu_j}, 0 \le j \le l$, $j \ne \kappa$, and $b_\kappa^\theta = (a_1^\theta, \dots, a_{\mu_\kappa}^\theta)^T \in R^{\mu_\kappa}$. In the next lemma, we consider a linear transformation which is crucial for the analysis of $(S)_h^r$.

LEMMA 3. *For each $\mu_{k-1} + 1 \le \theta \le \mu_k$, $0 \le k \le l$ fixed, with $\mu_{-1} = 0$, there exists $\alpha^\theta := (\alpha_\theta^\theta, \alpha_{\theta+1}^\theta, \dots, \alpha_m^\theta) \in R^{m-\theta+1}$ such that*

$$\tilde{b}_j^\theta := \sum_{s=\theta}^{m} \alpha_s^\theta b_j^s \ne 0 \quad \forall k \le j \le l. \tag{76}$$

Remark 6. This change of coordinates transforms the matrix B into $\tilde{B} = (\tilde{B}_0, \dots, \tilde{B}_\kappa, \dots, \tilde{B}_l)^T = (\tilde{b}_1, \tilde{b}_2, \dots, \tilde{b}_{\mu_l}, b_{\mu_l+1}, \dots, b_m)$ with, for any $1 \le \theta \le \mu_l$, $\tilde{b}_\theta = (\tilde{b}_0^\theta, \dots, \tilde{b}_\kappa^\theta, \dots, \tilde{b}_l^\theta)^T$and for each $0 \le j \le l, j \ne \kappa, \tilde{b}_j^\theta = (\tilde{b}_{1,j}^\theta, \tilde{b}_{2,j}^\theta, \dots, \tilde{b}_{\mu_j,j}^\theta)^T \ne 0$ and $\tilde{b}_\kappa^\theta = (\tilde{a}_1^\theta, \dots, \tilde{a}_{\mu_\kappa}^\theta)^T \ne 0$.

Proof. There exists $T \in GL(R^m)$ such that $BT = \tilde{B}$ with

$$T = \begin{pmatrix} \alpha_1^1 & 0 & \dots & 0 \\ \alpha_2^1 & \alpha_2^2 & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ \alpha_m^1 & \alpha_m^2 & \dots & \alpha_m^m \end{pmatrix}.$$

The proof is by induction in the number of distinct algebraic multiplicity $\mu_j, 0 \leq j \leq l$, of the eigenvalues of A, i.e., in $\bar{\delta} := 1 + \#\{\delta_k > 0, 1 \leq k \leq l\}$, where $\delta_k := \mu_k - \mu_{k-1}$ for all $1 \leq k \leq l$, since we have the controllability property if and only if (A_{0,μ_j}, B_j), $0 \leq j \leq l$, $j \neq \kappa$, are controllable and $\mathrm{rank}B_\kappa = \mu_\kappa$. First, let $\mu^0 < \mu^1 < \dots < \mu^\psi$, $0 \leq \psi \leq l$, denote the distinct algebraic multiplicities of the eigenvalues of A. Moreover, $\bar{\delta} = 1 + \psi$.

Step 1. Verify that the desired result holds for $\bar{\delta} = 1$; nevertheless $\psi = 0$. Here, when 1 is substituted for $\bar{\delta}$, this gives $\mu_0 = \dots = \mu_\kappa = \dots = \mu_l := \rho$. Specifically, the conclusion of Lemma 3 becomes the following: For each $1 \leq \theta \leq \rho$ fixed, there exists $\alpha^\theta := (\alpha_\theta^\theta, \alpha_{\theta+1}^\theta, \dots, \alpha_m^\theta) \in R^{m-\theta+1}$ such that $\tilde{b}_j^\theta := \sum_{s=\theta}^m \alpha_s^\theta b_j^s \neq 0$ for all $0 \leq j \leq l$. So, $\tilde{B} := (\tilde{b}_1, \dots, \tilde{b}_\rho, b_{\rho+1}, \dots, b_m) = ((\tilde{b}_0^1, \tilde{b}_1^1, \dots, \tilde{b}_l^1)^T, \dots, (\tilde{b}_0^\rho, \tilde{b}_1^\rho, \dots, \tilde{b}_l^\rho)^T, b_{\rho+1}, \dots, b_m)$ and we will prove the lemma by contradiction. The opposite thesis is as follows: For all $\alpha^\theta = (\alpha_\theta^\theta, \dots, \alpha_m^\theta) = R^{m-\theta+1}$, $1 \leq \theta \leq \rho$ fixed, there exists $j(\alpha^\theta) \in [0, l]$ such that $(\tilde{b}_{j(\alpha^\theta)}^\theta)^{(\alpha^\theta)} := \sum_{s=\theta}^m \alpha_s^\theta b_{j(\alpha^\theta)}^s = 0$.

Let, for all $i \leq j \leq m$, $S_{\theta,j} := \{\alpha^\theta \in R^m, 1 \leq \theta \leq \rho / \quad j(\alpha^\theta) = j\}$; then $R^{m-\theta+1} = \bigcup_{j=0}^m S_{\theta,j}$. So, there exists j_0 such that the interior of S_{θ,j_0} is not empty. So, there exist $\bar{r} > 0$ and $\bar{\alpha^\theta}$ such that $B(\bar{\alpha^\theta}, \bar{r})$, the ball of radius $\bar{r}$ centered at $\bar{\alpha^\theta}$, is included in S_{θ,j_0} for all $1 \leq \theta \leq \rho$. Therefore, for all $\alpha^\theta \in B(\bar{\alpha^\theta}, \bar{r})$, $(\tilde{b}_{j_0}^\theta)^{(\alpha^\theta)} = \sum_{s=\theta}^m \alpha_s^\theta b_{j_0}^s = 0, 1 \leq \theta \leq \rho$.

Writing for all $1 \leq \theta \leq \rho$, $\alpha_s^\theta = \bar{\alpha_s^\theta} + (\alpha_s^\theta - \bar{\alpha_s^\theta})$. It follows that $(\tilde{b}_{j_0}^\theta)^{(\alpha^\theta)} = (\tilde{b}_{j_0}^\theta)^{(\bar{\alpha^\theta})} + (\tilde{b}_{j_0}^\theta)^{(\alpha^\theta - \bar{\alpha^\theta})} = (\tilde{b}_{j_0}^\theta)^{(\alpha^\theta - \bar{\alpha^\theta})} = 0$ for all $1 \leq \theta \leq \rho$. Then, for all $\alpha^\theta \in B(0, \bar{r})$, $(\tilde{b}_{j_0}^\theta)^{(\alpha^\theta)} = 0$, $1 \leq \theta \leq \rho$. So, for all $\alpha^\theta \in R^{m-\theta+1}$, $1 \leq \theta \leq \rho$, $(\tilde{b}_{j_0}^\theta)^{(\alpha^\theta)} := \sum_{s=\theta}^m \alpha_s^\theta b_{j_0}^s = 0$. Then, for all $0 \leq s \leq m$, $b_{j_0}^s = 0$. Moreover, $B_{j_0} = (b_{j_0}^1, \dots, b_{j_0}^{\theta-1}, 0, \dots, 0)$. Then, $\mathrm{rank}B_{j_0} \leq \theta - 1 \leq \rho - 1$. It is impossible since $(A_{0,\mu_{j_0}}, B_{j_0})$ is controllable. So, $\mathrm{rank}B_{j_0} = \mu_{j_0} \geq \rho$. This completes step 1.

Step 2. Assume that the desired result holds for $\bar{\delta} = k$; nevertheless $\psi = k - 1$. Then we have k distinct algebraic multiplicities. Let $\mu^0 < \mu^1 < \dots < \mu^{k-1}$ denote the distinct algebraic multiplicities. Therefore, for every $\mu^{\nu-1} + 1 \leq \theta \leq \mu^\nu$, $0 \leq \nu \leq k-1$ with $\mu^{-1} = 0$, there exists $\alpha^\theta := (\alpha_\theta^\theta, \dots, \alpha_m^\theta) \in R^{m-\theta+1}$ such that $\tilde{b}_j^\theta \neq 0$ for all $\nu \leq j \leq l$. Now, we use the assumption from step 2 to show that the results hold for $\bar{\delta} = k + 1$; nevertheless $\sigma = k$. Then $\mu^0 < \mu^1 < \dots < \mu^k$. That is, we want to show that for every $\mu^{k-1} + 1 \leq \theta \leq \mu^k$, there exists $\alpha^\theta := (\alpha_\theta^\theta, \dots, \alpha_m^\theta) \in R^{m-\theta+1}$ such that $\tilde{b}_j^\theta \neq 0$ for all $k \leq j \leq l$.

According to the controllability property of the pair (A_{0,μ^k}, B_ϖ), B_ϖ is the vector corresponding to the algebraic multiplicity μ^k, which implies that $\mathrm{rank}B_\varpi = \mu^k$; it follows that there exists μ^k free columns or lines. Nevertheless, from the assumption of step 2 we have just $\mu^k - \mu^{k-1}$ independent columns. By applying Lemma 3 for all $\mu^{k-1} + 1 \leq \theta \leq \mu^k$ and discarding the vectors $(\tilde{b}_0^{\mu^{j-1}+1}, \dots, \tilde{b}_0^{\mu^j}; \tilde{b}_1^{\mu^{j-1}+1}, \dots, \tilde{b}_1^{\mu^j}; \dots; \tilde{b}_{j-1}^{\mu^{j-1}+1}, \dots, \tilde{b}_{j-1}^{\mu^j})$ for all $1 \leq j \leq k$, one can prove that for every $\mu^{k-1} + 1 \leq \theta \leq \mu^k$, $\tilde{b}_j^\theta \neq 0$ for all $k \leq j \leq l$. ∎

In order to facilitate the analysis of the finite-gain L^p-stability by bounded feedback of continuous-time delay linear skew-symmetric systems, we provide a linear transformation of the system $(S)_h^r$ which simplifies the analysis of the problem. Our method consists of rewriting the original system $(S)_h^r$ as an appropriate l cascade of single-input subsystems of dimension $2\mu_j, 0 \leq j \leq l$, $j \neq \kappa$, and one subsystem of dimension μ_κ, since A has l conjugate pairs of nonzero purely imaginary eigenvalues of the forms $(\pm i\omega_j)_{1\leq j\leq l}$ and 0 is an eigenvalue of A with multiplicity μ_κ. So, we consider the system $(S)_h^r$ with state space R^n, input space R^m, and delay h. More precisely, we consider the system described by the equations

$$
(S)_h^r := \left\{
\begin{array}{l}
(0)\left\{
\begin{array}{rcl}
\dot{X}_{1,\mu_0} &=& \omega_0 A_0 X_{1,\mu_0} - r\tilde{b}_{1,1}^1\sigma_1(u_1) - \cdots - r\tilde{b}_{1,1}^{\mu_0}\sigma_{\mu_0}(u_{\mu_0}) \\
&& + rv_{1,\mu_0} - r\sum_{i=\mu_0+1}^m \tilde{b}_{1,1}^i\sigma_i(u_i), \\
\vdots & & \\
\dot{X}_{\mu_0,\mu_0} &=& \omega_0 A_0 X_{\mu_0,\mu_0} - r\tilde{b}_{\mu_0,1}^1\sigma_1(u_1) - \cdots - r\tilde{b}_{\mu_0,1}^{\mu_0}\sigma_{\mu_0}(u_{\mu_0}) \\
&& + rv_{\mu_0,\mu_0} - \sum_{i=\mu_0+1}^m \tilde{b}_{\mu_0,1}^i\sigma_i(u_i),
\end{array}\right. \\
(1)\left\{
\begin{array}{rcl}
\dot{X}_{1,\mu_1} &=& \omega_1 A_0 X_{1,\mu_1} - r\tilde{b}_{1,1}^1\sigma_1(u_1) - \cdots - r\tilde{b}_{1,1}^{\mu_1}\sigma_{\mu_1}(u_{\mu_1}) \\
&& + rv_{1,\mu_1} - r\sum_{i=\mu_1+1}^m \tilde{b}_{1,1}^i\sigma_i(u_i), \\
\vdots & & \\
\dot{X}_{\mu_1,\mu_1} &=& \omega_1 A_0 X_{\mu_1,\mu_1} - r\tilde{b}_{\mu_1,1}^1\sigma_1(u_1) - \cdots - r\tilde{b}_{\mu_1,1}^{\mu_1}\sigma_{\mu_1}(u_{\mu_1}) \\
&& + rv_{\mu_1,\mu_1} - \sum_{i=\mu_1+1}^m \tilde{b}_{\mu_1,1}^i\sigma_i(u_i),
\end{array}\right. \\
\vdots \\
(\kappa)\left\{
\begin{array}{rcl}
\dot{x}_{1,\mu_\kappa} &=& - r\tilde{a}_1^1\sigma_1(u_1) - r\tilde{a}_1^2\sigma_2(u_2) - \cdots - r\tilde{a}_1^{\mu_\kappa}\sigma_{\mu_\kappa}(u_{\mu_\kappa}) \\
&& + rv_{1,\mu_\kappa} - r\sum_{i=\mu_\kappa+1}^m \tilde{a}_1^i\sigma_i(u_i), \\
\vdots & & \\
\dot{x}_{\mu_\kappa,\mu_\kappa} &=& - r\tilde{a}_{\mu_\kappa}^1\sigma_1(u_1) - r\tilde{a}_{\mu_\kappa}^2\sigma_2(u_2) - \cdots - r\tilde{a}_{\mu_\kappa}^{\mu_\kappa}\sigma_{\mu_\kappa}(u_{\mu_\kappa}) \\
&& + rv_{\mu_\kappa,\mu_\kappa} - r\sum_{i=\mu_\kappa+1}^m \tilde{a}_{\mu_\kappa}^i\sigma_i(u_i),
\end{array}\right. \\
\vdots \\
(l)\left\{
\begin{array}{rcl}
\dot{X}_{1,\mu_l} &=& \omega_l A_0 X_{1,\mu_l} - r\tilde{b}_{1,l}^1\sigma_1(u_1) - \cdots - r\tilde{b}_{1,l}^{\mu_l}\sigma_{\mu_l}(u_{\mu_l}) \\
&& + rv_{1,\mu_l} - r\sum_{i=\mu_l+1}^m \tilde{b}_{1,l}^i\sigma_i(u_i), \\
\vdots & & \\
\dot{X}_{\mu_l,\mu_l} &=& \omega_l A_0 X_{\mu_l,\mu_l} - r\tilde{b}_{\mu_l,l}^1\sigma_1(u_1) - \cdots - r\tilde{b}_{\mu_l,l}^{\mu_l}\sigma_{\mu_l}(u_{\mu_l}) \\
&& + rv_{\mu_l,\mu_l} - r\sum_{i=\mu_l+1}^m \tilde{b}_{\mu_l,l}^i\sigma_i(u_i),
\end{array}\right.
\end{array}
\right.
$$

where $X_{\theta,\mu_s}, b_{\theta,s}^j, \in R^2$, $1 \leq s \leq \mu$, $1 \leq \theta, j \leq \mu_s$, $x_{\theta,\mu_\kappa}, a_\theta^j \in R$, $1 \leq \theta, j \leq \mu_\kappa$, and

there exists $1 \leq s \leq l$, $s \neq \kappa$, such that $\omega_0 = \omega_s$ since $\omega_\kappa = 0$.

After manipulation of lines and columns for the matrix B, we can suppose that $\tilde{b}^\theta_{\theta,j} \neq 0$ for all $1 \leq \theta \leq \mu_j$, $0 \leq j \leq l$, $j \neq \kappa$ and $\tilde{a}^\theta_\theta \neq 0$ for all $1 \leq \theta \leq \mu_\kappa$, since from Lemma 3, $\tilde{b}^\theta_j = (\tilde{b}^\theta_{1,j}, \ldots, \tilde{b}^\theta_{\mu_j,j})^T$ and $\tilde{b}^\theta_\kappa = (\tilde{a}^\theta_1, \ldots, \tilde{a}^\theta_{\mu_\kappa})^T \neq 0$ are for all $1 \leq \theta \leq \mu_j$ and $0 \leq j \leq l$.

LEMMA 4. *Let $\tilde{b}^\theta_{\theta,s} = \tilde{\xi}^\theta_{\theta,s} V^\theta_{\theta,s} b_0$, $1 \leq \theta \leq \mu_s$, $0 \leq s \leq l$, $s \neq \kappa$, with $V^\theta_{\theta,s} \in SO(2)$ the set of orthogonal matrices and $b_0 = (0 \quad 1)^T$. Then, for each $1 \leq \theta, j \leq \mu_s$, $0 \leq s \leq l$, $s \neq \kappa$, the new variables*

$$
\begin{aligned}
&Y_{\theta,\mu_s}(t) = (V^\theta_{\theta,s})^{-1} U^\theta_{j,s} \tfrac{X_{\theta,\mu_s}(t)}{\tilde{\xi}^\theta_{\theta,s}},\\
&Y_{j,\mu_s}(t) = (V^\theta_{\theta,s})^{-1} \tfrac{X_{j,\mu_s}(t)}{\tilde{\xi}^\theta_{j,s}} - (V^\theta_{\theta,s})^{-1} U^\theta_{j,s} \tfrac{X_{\theta,\mu_s}(t)}{\tilde{\xi}^\theta_{\theta,s}}, \theta \neq j,\\
&y_{\theta,\mu_\kappa}(t) = \tfrac{x_{\theta,\mu_\kappa}(t)}{\tilde{a}^\theta_\theta}, 1 \leq \theta \leq \mu_\kappa,\\
&y_{j,\mu_\kappa}(t) = \tfrac{x_{j,\mu_\kappa}(t)}{\tilde{a}^\theta_j} - \tfrac{x_{\theta,\mu_\kappa}(t)}{\tilde{a}^\theta_\theta}, \quad 1 \leq \theta, j \leq \mu_\kappa, \theta \neq j,
\end{aligned}
\tag{77}
$$

where $U^\theta_{j,s} \in SO(2)$, with $U^\theta_{\theta,s} = Id_2$, transform $(S)^r_h$ into the new system

$$
\begin{aligned}
\dot{Y}_{\theta,\mu_s}(t) &= \omega_s A_0 Y_{\theta,\mu_s}(t) - r b_0 \sigma_\theta(u_\theta(t-h)) + r v_{\theta,\mu_s}(t-h)\\
&\quad - r \textstyle\sum_{j=\mu_s+1}^m \hat{b}^j_{\theta,s} \sigma_j(u_j(t-h)), 1 \leq \theta \leq \mu_s, 0 \leq s \leq l, s \neq \kappa,\\
\dot{y}_{\theta,\mu_\kappa}(t) &= -r\sigma_\theta(u_\theta(t-h)) + r v_{\theta,\mu_\kappa}(t-h) - r \textstyle\sum_{j=\mu_\kappa+1}^m \hat{a}^j_\theta \sigma_j(u_j), 1 \leq \theta \leq \mu_\kappa,
\end{aligned}
\tag{78}
$$

where $\hat{b}^j_{\theta,s} \in R^2$ and $\hat{a}^j_\theta \in R$ are arbitrarily vectors and real numbers.

Proof. For each $0 \leq s \leq l$, $(S)^r_h$ becomes

$$
\left\{
\begin{array}{l}
(S_{\neq 0})^r_h \left\{
\begin{array}{rcl}
\dot{X}_{1,\mu_s} &=& \omega_s A_0 X_{1,\mu_s} - r\tilde{b}^1_{1,s}\sigma_1(u_1) - \cdots - r\tilde{b}^{\mu_s}_{1,s}\sigma_{\mu_s}(u_{\mu_s}) + r v_{1,\mu_s}\\
&& - r\sum_{\theta=\mu_s+1}^m \tilde{b}^\theta_{1,s}\sigma_\theta(u_\theta),\\
\dot{X}_{2,\mu_s} &=& \omega_s A_0 X_{2,\mu_s} - r\tilde{b}^1_{2,s}\sigma_1(u_1) - \cdots - r\tilde{b}^{\mu_s}_{2,s}\sigma_{\mu_s}(u_{\mu_s}) + r v_{2,\mu_s}\\
&& - r\sum_{\theta=\mu_s+1}^m \tilde{b}^\theta_{2,s}\sigma_\theta(u_\theta),\\
&\vdots&\\
\dot{X}_{\mu_s,\mu_s} &=& \omega_s A_0 X_{\mu_s,\mu_s} - r\tilde{b}_{\mu_s,s}{}^1\sigma_1(u_1) - \cdots - r\tilde{b}_{\mu_s,s}{}^{\mu_s}\sigma_{\mu_s}(u_{\mu_s}) + r v_{\mu_s,\mu_s}\\
&& - r\sum_{\theta=\mu_s+1}^m \tilde{b}^\theta_{\mu_s,s}\sigma_\theta(u_\theta),
\end{array}
\right.\\
(S_0)^r_h \left\{
\begin{array}{rcl}
\dot{x}_{1,\mu_\kappa} &=& - r\tilde{a}^1_1\sigma_1(u_1) - r\tilde{a}^2_1\sigma_2(u_2) - \cdots - r\tilde{a}^{\mu_\kappa}_1\sigma_{\mu_\kappa}(u_{\mu_\kappa}) + r v_{1,\mu_\kappa}\\
&& - r\sum_{\theta=\mu_\kappa+1}^m \tilde{a}^\theta_1\sigma_\theta(u_\theta),\\
&\vdots&\\
\dot{x}_{\mu_\kappa,\mu_\kappa} &=& - r\tilde{a}^1_{\mu_\kappa}\sigma_1(u_1) - r\tilde{a}^2_{\mu_\kappa}\sigma_2(u_2) - \cdots - r\tilde{a}^{\mu_\kappa}_{\mu_\kappa}\sigma_{\mu_\kappa}(u_{\mu_\kappa}) + r v_{\mu_\kappa,\mu_\kappa}\\
&& - r\sum_{\theta=\mu_\kappa+1}^m \tilde{a}^\theta_{\mu_\kappa}\sigma_\theta(u_\theta).
\end{array}
\right.
\end{array}
\right.
\tag{79}
$$

We have, for each $1 \leq \theta \leq \mu_s, 0 \leq s \leq l$, $s \neq \kappa$, $\tilde{b}^{\theta}_{\theta,s} \neq 0$, and one can suppose that $\|\tilde{b}^{\theta}_{\theta,s}\| = \|\tilde{b}^{\theta}_{j,s}\|, 1 \leq j \leq \mu_s$ (multiplying the equation (θ) of each subsystem (s) by $\tilde{\lambda}^{\theta}_{j,s} := \frac{\|\tilde{b}^{\theta}_{j,s}\|}{\|\tilde{b}^{\theta}_{\theta,s}\|}$). However, there exists $U^{\theta}_{j,s} \in SO(2)$ such that $U^{\theta}_{j,s}\tilde{b}^{\theta}_{\theta,s} = \tilde{b}^{\theta}_{j,s}$.

We can suppose that $\tilde{b}^{\theta}_{j,s} = 0, 1 \leq \theta, j \leq \mu_s, \theta \neq j$. Indeed, simply multiply successively, for each $0 \leq s \leq l$, $s \neq \kappa$, each equation $(\theta), 1 \leq \theta \leq \mu_s$, by $U^{\theta}_{j,s}$, $1 \leq j \leq \mu_s$, and take the linear change of coordinates given by

$$
\begin{aligned}
&Z_{\theta,\mu_s} = U^{\theta}_{j,s} X_{\theta,\mu_s}, \quad 1 \leq \theta, j \leq \mu_s, \quad 0 \leq s \leq l, \quad s \neq \kappa,\\
&Z_{j,\mu_s} = X_{j,\mu_s} - U^{\theta}_{j,s} X_{\theta,\mu_s}, \quad \theta \neq j.
\end{aligned} \tag{80}
$$

But, we have $\tilde{b}^{\theta}_{\theta,s} = \tilde{\xi}^{\theta}_{\theta,s} V^{\theta}_{\theta,s} b_0$ for all $0 \leq s \leq l$, $s \neq \kappa$. Then, for every $1 \leq \theta \leq \mu_s$, $0 \leq s \leq l$, and $s \neq \kappa$, the linear transformation given by $Y_{\theta,\mu_s} = (V^{\theta}_{\theta,s})^{-1} \frac{Z_{\theta,\mu_s}}{\xi^{\theta}_{\theta,s}}$ transforms (81) into the first block of (78). For the subsystem $(S_0)^r_h$ corresponding to $\omega_\kappa = 0$ as an eigenvalue of A with multiplicity μ_κ,

$$
\left\{
\begin{array}{rcl}
\dot{x}_{1,\mu_\kappa} &=& -r\tilde{a}^1_1\sigma_1(u_1) - r\tilde{a}^2_1\sigma_2(u_2) - \cdots - r\tilde{a}^{\mu_\kappa}_1\sigma_{\mu_\kappa}(u_{\mu_\kappa}) + rv_{1,\mu_\kappa}\\
&& - r\sum_{\theta=\mu_\kappa+1}^{m} \tilde{a}^{\theta}_1\sigma_\theta(u_\theta),\\
\vdots &&\\
\dot{x}_{\mu_\kappa,\mu_\kappa} &=& -r\tilde{a}^1_{\mu_\kappa}\sigma_1(u_1) - r\tilde{a}^2_{\mu_\kappa}\sigma_2(u_2) - \cdots - r\tilde{a}^{\mu_\kappa}_{\mu_\kappa}\sigma_{\mu_\kappa}(u_{\mu_\kappa}) + rv_{\mu_\kappa,\mu_\kappa}\\
&& - r\sum_{\theta=\mu_\kappa+1}^{m} \tilde{a}^{\theta}_{\mu_\kappa}\sigma_\theta(u_\theta),
\end{array}
\right.
$$

taking successively the linear transformation $z_{s,\mu_\kappa} = \frac{x_{s,\mu_\kappa}}{\tilde{a}^{\theta}_{s}}$ for all $1 \leq s \leq \mu_\kappa$ and $1 \leq \theta \leq \mu_\kappa$ and using the second part of the transformation given by (77), we have the second equation in (78). So, $(S_0)^r_h$ is transformed in

$$
\begin{aligned}
&\dot{Z}_{1,\mu_s} = \omega_s A_0 Z_{1,\mu_s} - r\tilde{b}^1_{1,s}\sigma_1(u_1) + rv_{1,\mu_s} - r\sum_{\theta=\mu_s+1}^{m} \tilde{b}^{\theta}_{1,s}\sigma_\theta(u_\theta),\\
&\dot{Z}_{2,\mu_s} = \omega_s A_0 Z_{2,\mu_s} - r\tilde{b}^2_{2,s}\sigma_2(u_2) + rv_{2,\mu_s} - r\sum_{\theta=\mu_s+1}^{m} \tilde{b}^{\theta}_{2,s}\sigma_\theta(u_\theta),\\
&\quad\vdots\\
&\dot{Z}_{\mu_s,\mu_s} = \omega_s A_0 Z_{\mu_s,\mu_s} - r\tilde{b}^{\mu_s}_{\mu_s,s}\sigma_{\mu_s}(u_{\mu_s}) + rv_{\mu-s,\mu_s} - r\sum_{\theta=\mu_s+1}^{m} \tilde{b}^{\theta}_{\mu_s,s}\sigma_\theta(u_\theta). \qquad \square
\end{aligned} \tag{81}
$$

Then, with this linear change of coordinates the matrix B can be transformed into

$$B = \begin{bmatrix} B_0 \\ B_1 \\ \vdots \\ B_\kappa \\ \vdots \\ B_{l-1} \\ B_l \end{bmatrix} = \begin{bmatrix} \begin{pmatrix} \begin{pmatrix} b_0 & & \\ (0) & \ddots & (0) \\ & & b_0 \end{pmatrix} & (*)_0 \end{pmatrix} & (**)_0 \\ \begin{pmatrix} \begin{pmatrix} b_0 & & & \\ & \ddots & (0) & \\ & (0) & \ddots & \\ & & & b_0 \end{pmatrix} & (*)_1 \end{pmatrix} & (**)_1 \\ \vdots & \vdots \\ \begin{pmatrix} \begin{pmatrix} 1 & & & & \\ & \ddots & & & \\ & & \ddots & (0) & \\ & (0) & & \ddots & \\ & & & & 1 \end{pmatrix} & (*)_\kappa \end{pmatrix} & (**)_\kappa \\ \vdots & \vdots \\ \begin{pmatrix} \begin{pmatrix} b_0 & & & & \\ & \ddots & & & \\ & & \ddots & (0) & \\ & (0) & & \ddots & \\ & & & & b_0 \end{pmatrix} & (*)_{l-1} \end{pmatrix} & (**)_{l-1} \\ \begin{pmatrix} b_0 & & & & & \\ & \ddots & & & & \\ & & \ddots & (0) & & \\ & (0) & & \ddots & & \\ & & & & \ddots & \\ & & & & & b_0 \end{pmatrix} & (**)_l \end{bmatrix},$$

where $0 \leq \kappa \leq l$. Here $(*)'_j s$, $(**)'_j s, 0 \leq j \leq l$, $j \neq \kappa$, represent, respectively, submatrices of size $2\mu_j \times (\mu_l - \mu_j)$ and $2\mu_j \times (m - \mu_l)$; $(*)_\kappa$ and $(**)_\kappa$ are submatrices of dimensions $\mu_\kappa \times (\mu_l - \mu_\kappa)$ and $\mu_\kappa \times (m - \mu_l)$.

NONOCCURRENCE OF THE LAVRENTIEV PHENOMENON FOR MANY OPTIMAL CONTROL PROBLEMS*

ALEXANDER J. ZASLAVSKI†

Abstract. In this paper we study nonoccurrence of the Lavrentiev phenomenon for a large class of nonconvex optimal control problems identified with the corresponding complete metric space of integrands $\mathcal{M}$, which satisfy a growth condition common in the literature and are Lipschitzian on bounded sets. We establish that for most elements of $\mathcal{M}$ (in the sense of Baire category) the infimum on the full admissible class of trajectory-control pairs is equal to the infimum on a subclass of trajectory-control pairs whose controls are bounded by a certain constant.

Key words. Banach space, integrand, Lavrentiev phenomenon, optimal control problem

DOI. 10.1137/050640370

1. Introduction, assumptions, and main results. In this paper we study nonoccurrence of the Lavrentiev phenomenon for a large class of nonconvex optimal control problems with a state variable and a control variable belonging to Banach spaces. We say that the Lavrentiev phenomenon occurs for an optimal control problem if its infimum on the full admissible class of trajectory-control pairs is less than its infimum on a subclass of trajectory-control pairs with bounded controls.

The Lavrentiev phenomenon in the calculus of variations was discovered in 1926 by M. Lavrentiev in [13]. There it was shown that it is possible for the variational integral of a two-point Lagrange problem, which is sequentially weakly lower semicontinuous on the admissible class of absolutely continuous functions, to possess an infimum on the dense subclass of C^1 admissible functions that is strictly greater than its minimum value on the admissible class. Since this seminal work, the Lavrentiev phenomenon has been of great interest in the calculus of variations [1], [2], [6], [7], [9], [10], [11], [12], [14] [15], [16], [18], [19], [20]. The original example of Lavrentiev was simplified by Mania in [15]. In [6], [7] Ball and Mizel demonstrated that the Lavrentiev phenomenon can occur with fully regular integrands. Sarychev [18] constructed a broad class of integrands that exhibit the Lavrentiev phenomenon. Nonoccurrence of the Lavrentiev phenomenon was studied in [1], [2], [10], [11], [12], [14], [19], [20], [22], [24]. Clarke and Vinter [10] showed that the Lavrentiev phenomenon cannot occur when a variational integrand $f(t, x, u)$ is independent of t. Sychev and Mizel [20] considered a class of integrands $f(t, x, u)$, which are convex with respect to the last variable. For this class of integrands they established that the Lavrentiev phenomenon does not occur. Sarychev and Torres [19] studied a class of optimal control problems with control-affine dynamics and with continuously differentiable integrands $f(t, x, u)$. For this class of problems they established Lipschitzian regularity of minimizers, which implies nonoccurrence of the Lavrentiev phenomenon. Ferriero [12] showed that the Lavrentiev phenomenon cannot occur for a class of higher-order variational problems with integrands which are convex with respect to the last variable.

In [24] we studied nonoccurrence of the Lavrentiev phenomenon for a large class of nonconvex nonautonomous constrained variational problems with integrands which belong to a complete metric space of functions. We established that for most integrands in the sense of the Baire category the Lavrentiev phenomenon does not occur [24]. In the present paper we consider a large class of optimal control problems identified with the corresponding complete metric space of integrands $\mathcal{M}_B$, which satisfy a growth condition common in the literature and satisfy a Lipschitz condition on bounded sets. We establish that for most elements of $\mathcal{M}_B$ (in the sense of the Baire category) the infimum on the full admissible class of trajectory-control pairs is equal to the infimum on a subclass of trajectory-control pairs whose controls are bounded by a certain constant.

In this paper we use the following definitions and notation. For each $t \in R^1$, set $\exp(t) = e^t$. For each function $h : Z \to R^1 \cup \{\infty\}$, where Z is nonempty, and each nonempty subset $Y \subset Z$, set

$$\inf(h) = \inf\{h(z) : \ z \in Z\}, \ \inf(h; Y) = \inf\{h(z) : \ z \in Y\}.$$

Denote by $\mathrm{mes}(\Omega)$ the Lebesgue measure of a Lebesgue measurable set $\Omega \subset R^1$. If $(Z, ||\cdot||)$ is a normed space, then for each $z \in Z$ and each $r > 0$, set

$$B_Z(z, r) = \{y \in Z : \ ||y - z|| \le r\}, \ B_Z(r) = B_Z(0, r).$$

We say that a property of elements of a complete metric space Z is generic (typical) in Z if the set of all elements of Z which possess this property contains an everywhere dense G_δ subset of Z. In this case we also say that the property holds for a generic (typical) element of Z or that a generic (typical) element of Z possesses the property [5], [17], [23].

Assume that $(E, ||\cdot||)$, $(F, ||\cdot||)$ are Banach spaces.

Let $-\infty < \tau_1 < \tau_2 < \infty$. Denote by $W^{1,1}(\tau_1, \tau_2; E)$ the set of all functions $x : [\tau_1, \tau_2] \to E$ for which there exists a Bochner integrable function $u : [\tau_1, \tau_2] \to E$ such that

$$x(t) = x(\tau_1) + \int_{\tau_1}^{t} u(s)ds, \ t \in (\tau_1, \tau_2]$$

(see, e.g., Brezis [8]). It is known that if $x \in W^{1,1}(\tau_1, \tau_2; E)$, then the equation above defines a unique Bochner integrable function u, which is called the derivative of x and is denoted by x'.

We also use the notation $W^{1,1}(\Omega; E) = W^{1,1}(\tau_1, \tau_2; E)$, where $\Omega = [\tau_1, \tau_2]$.

Let $0 \le T_1 < T_2 < \infty$ and let $U : [T_1, T_2] \to 2^F \setminus \{\emptyset\}$ be a set-valued mapping.

Denote by X the set of all pairs of functions (x, u), where $x \in W^{1,1}(T_1, T_2; E)$ and $u : [T_1, T_2] \to F$ is a strongly measurable function which satisfies

$$u(t) \in U(t), \ t \in [T_1, T_2] \text{ almost everywhere (a.e.).} \tag{1.1}$$

To be more precise, we have to define elements of X as classes of pairs equivalent in the sense that (x_1, u_1) and (x_2, u_2) are equivalent if and only if $x_2(t) = x_1(t)$ for all $t \in [T_1, T_2]$ and $u_1(t) = u_2(t)$ for almost every $t \in [T_1, T_2]$.

Denote by $\mathcal{D}(E)$ the collection of all nonempty bounded subsets of E.

Let $G : [T_1, T_2] \times E \times F \to E$ be a continuous mapping, $\phi : [0, \infty) \to [0, \infty)$ be an increasing function, and c_0 be a positive number such that

$$\lim_{t \to \infty} \phi(t)/t = \infty, \tag{1.2}$$

$$||G(t, y_1, v) - G(t, y_2, v)|| \le c_0 ||y_1 - y_2|| \phi(||v||) \tag{1.3}$$

for each $t \in [T_1, T_2]$, each $y_1, y_2 \in E$, and each $v \in F$ and that

$$||G(t, y, v_1) - G(t, y, v_2)|| \le c_0||v_1 - v_2||\phi(||y||) \tag{1.4}$$

for each $t \in [T_1, T_2]$, each $y \in E$, and each $v_1, v_2 \in F$.

It is clear that the mapping G is bounded in the norm topology on any bounded subset of $[T_1, T_2] \times E \times F$.

We assume that there exist a Bochner integrable function $u_*(t)$, $t \in [T_1, T_2]$, and $N_* > 0$ such that

$$u_*(t) \in U(t),\ t \in [T_1, T_2] \text{ a.e. and } ||u_*(t)|| \le N_*,\ t \in [T_1, T_2] \text{ a.e..} \tag{1.5}$$

For each $D \in \mathcal{D}(E)$ denote by $X(G, D)$ the set of all pairs $(x, u) \in X$ such that

$$x(T_1) \in D \text{ and } x'(t) = G(t, x(t), u(t)),\ t \in [T_1, T_2] \text{ a.e..} \tag{1.6}$$

For each $D \in \mathcal{D}(E)$ denote by $X_L(G, D)$ the set of all $(x, u) \in X(G, D)$ such that $||u(t)|| \le M_u$ for $t \in [T_1, T_2]$ a.e., where M_u is a positive constant depending on u.

In this paper we study the nonoccurrence of the Lavrentiev phenomenon for the optimal control problem

$$\int_{T_1}^{T_2} f(t, x(t), u(t))dt \to \min,\ (x, u) \in X(G, D), \tag{P}$$

where $D \in \mathcal{D}(E)$ and f belongs to one of the two complete metric spaces of integrands $\mathcal{M}_A$ and $\mathcal{M}_B$, which will be described below.

Comparing our work with the results of [12], [19], note that in our paper E and F are general Banach spaces, that we do not impose any convexity assumption and any differentiability assumption on integrands f, that the control u is constrained and the right-hand side of differential equations is determined by mappings $G : [T_1, T_2] \times E \times F \to E$ belonging to a large general class of continuous mappings, while in [12], [19] the following assumptions are imposed:

- The spaces E and F are finite-dimensional;
- in [19] integrands are continuously differentiable and in [12] integrands are convex with respect to the last variable;
- the control u is unconstrained;
- $G(t, x, u) = g_1(t, x) + g_2(t, x)u$ in [19] and $G(t, x, u) = u$ in [12].

Now we define the spaces of integrands $\mathcal{M}_A$ and $\mathcal{M}_B$ considered in our paper.

Let $\lambda_0(t)$, $\lambda_1(t)$, $t \in [T_1, T_2]$ be integrable scalar nonnegative functions and let c_1, c_2 be positive constants.

Denote by $\mathcal{M}_A$ the set of all functions $f : [T_1, T_2] \times E \times F \to R^1$ which satisfy the following assumptions:

(A1) f is measurable with respect to the σ-algebra generated by products of Lebesgue measurable subsets of $[T_2, T_2]$ and Borel subsets of $E \times F$.

(A2) For each $M > 0$ there is $M_0 > 0$ such that for almost every $t \in [T_1, T_2]$ the inequality $|f(t, x, u)| \le M_0$ holds for each $x \in B_E(M)$ and each $u \in B_F(M)$.

(A3) For each $\epsilon, M > 0$ there exists $\delta > 0$ such that for almost every $t \in [T_1, T_2]$ the inequality $|f(t, x_1, u) - f(t, x_2, u)| \le \epsilon$ holds for each $u \in B_F(M)$ and each $x_1, x_2 \in B_E(M)$ satisfying $||x_1 - x_2|| \le \delta$.

(A4)

$$f(t, y, v) \ge c_1||G(t, y, v)|| - \lambda_0(t) \text{ for all } (t, y, v) \in [T_1, T_2] \times E \times F, \tag{1.7}$$

$$f(t, y, v) \ge c_2\phi(||v||) - \lambda_1(t) \text{ for all } (t, y, v) \in [T_1, T_2] \times E \times F. \tag{1.8}$$

We equip the set $\mathcal{M}_A$ with the uniformity determined by the base

$$\mathcal{E}_{As}(N,\epsilon)=\{(f,g)\in\mathcal{M}_A\times\mathcal{M}_A:\ |g(t,x,u)-f(t,x,u)|\le\epsilon \tag{1.9}$$
$$\text{for all } (t,x,u)\in[T_1,T_2]\times B_E(N)\times B_F(N)\}$$
$$\cap\{(f,g)\in\mathcal{M}_A\times\mathcal{M}_A:\ |(f-g)(t,x_1,u_1)-(f-g)(t,x_2,u_2)|\le\epsilon(||x_1-x_2||+||u_1-u_2||)$$
$$\text{for each } t\in[T_1,T_2],\ \text{each } x_1,x_2\in B_E(N),\ \text{and each } u_1,u_2\in B_F(N)\},$$

where $N,\epsilon>0$. Clearly the space $\mathcal{M}_A$ with this uniformity is metrizable and complete. We equip the space $\mathcal{M}_A$ with the topology induced by this uniformity. This topology will be called the strong topology of $\mathcal{M}_A$.

We also equip the set $\mathcal{M}_A$ with the uniformity determined by the base

$$\mathcal{E}_{Aw}(N,\epsilon)=\{(f,g)\in\mathcal{M}_A\times\mathcal{M}_A:\ \text{for almost every } t\in[T_1,T_2] \tag{1.10}$$
$$\text{the inequality } |g(t,x,u)-f(t,x,u)|\le\epsilon \text{ holds}$$
$$\text{for each } x\in B_E(N) \text{ and each } u\in B_F(N)\},$$

where $N,\epsilon>0$. We equip the space $\mathcal{M}_A$ with the topology induced by this uniformity. This topology will be called the weak topology of $\mathcal{M}_A$.

Denote by $\mathcal{M}_A^l$ (respectively, $\mathcal{M}_A^c$) the set of all lower semicontinuous (respectively, continuous) functions f in $\mathcal{M}_A$. Clearly $\mathcal{M}_A^l$, $\mathcal{M}_A^c$ are closed subsets of $\mathcal{M}_A$ with the strong topology.

We equip the topological subspaces $\mathcal{M}_A^l,\mathcal{M}_A^c\subset\mathcal{M}_A$ with the relative weak and strong topologies.

It follows from (A1) that for each $f\in\mathcal{M}_A$, each continuous function $x:[T_1,T_2]\to E$, and each strongly measurable function $u:[T_1,T_2]\to F$, the function $f(t,x(t),u(t))$, $t\in[T_1,T_2]$ is Lebesgue measurable.

For each $f\in\mathcal{M}_A$ and each $(x,u)\in X$ define

$$I^f(x,u)=\int_{T_1}^{T_2}f(t,x(t),u(t))dt. \tag{1.11}$$

For each $f\in\mathcal{M}_A$ and each $D\in\mathcal{D}(E)$ we study the optimal control problem

$$I^f(x,u)\to\min,\ (x,u)\in X(G,D). \tag{1.12}$$

DEFINITION 1.1. *Let $f\in\mathcal{M}_A$ and $D\in\mathcal{D}(E)$. We say that the Lavrentiev phenomenon does not occur for the pair (f,D) if for each $\epsilon>0$ there exist $(x,u)\in X(G,D)$ and $K>0$ such that $||u(t)||\le K$ for almost every $t\in[T_1,T_2]$ and $I^f(x,u)\le\inf(I^f;X(G,D))+\epsilon$.*

DEFINITION 1.2. *Let $f\in\mathcal{M}_A$. We say that the Lavrentiev phenomenon does not occur for the integrand f if it does not occur for (f,D) for all $D\in\mathcal{D}(E)$.*

We will establish (see Theorem 1.7) that the Lavrentiev phenomenon does not occur for a generic integrand $f\in\mathcal{M}_A$.

Let c_3 be a nonnegative constant. Denote by $\mathcal{M}_B$ the set of all functions $f:[T_1,T_2]\times E\times F\to R^1$, which satisfy the following assumptions:

(B1) f is measurable with respect to the σ-algebra generated by products of Lebesgue measurable subsets of $[T_2,T_2]$ and Borel subsets of $E\times F$.

(B2) For each $M>0$ there is $M_0>0$ such that for almost every $t\in[T_1,T_2]$ the inequality $|f(t,x,u)|\le M_0$ holds for each $x\in B_E(M)$ and each $u\in B_F(M)$.

(B3) For each $M > 0$ there exists $L > 0$ such that for almost every $t \in [T_1, T_2]$ the inequality $|f(t, x_1, u) - f(t, x_2, u)| \le L||x_1 - x_2||$ holds for each $x_1, x_2 \in B_E(M)$ and each $u \in B_F(M)$.

(B4) Inequality (1.7) holds for all $(t, y, v) \in [T_1, T_2] \times E \times F$ and

$$f(t, y, v) \ge c_2\phi(||v||) - c_3 \text{ for all } (t, y, v) \in [T_1, T_2] \times E \times F. \tag{1.13}$$

We equip the set $\mathcal{M}_B$ with the uniformity determined by the base

$$\begin{aligned}\mathcal{E}_{Bs}(N, \epsilon) = \{(f, g) \in \mathcal{M}_B \times \mathcal{M}_B :\ & |g(t, x, u) - f(t, x, u)| \le \epsilon \\ & \text{for all } (t, x, u) \in [T_1, T_2] \times B_E(N) \times B_F(N)\} \\ \cap\{(f, g) \in \mathcal{M}_B \times \mathcal{M}_B :\ & |(f-g)(t, x_1, u_1) - (f-g)(t, x_2, u_2)| \le \epsilon(||x_1 - x_2|| + ||u_1 - u_2||) \\ & \text{for each } t \in [T_1, T_2],\ \text{each } x_1, x_2 \in B_E(N),\ \text{and each } u_1, u_2 \in B_F(N)\},\end{aligned} \tag{1.14}$$

where $N, \epsilon > 0$. Clearly the space $\mathcal{M}_B$ with this uniformity is metrizable and complete. We equip the space $\mathcal{M}_B$ with the topology induced by this uniformity. This topology will be called the strong topology of $\mathcal{M}_B$.

We also equip the set $\mathcal{M}_B$ with the uniformity determined by the base

$$\begin{aligned}\mathcal{E}_{Bw}(N, \epsilon) = \{(f, g) \in \mathcal{M}_B \times \mathcal{M}_B :\ & \text{for almost every } t \in [T_1, T_2] \\ & \text{the inequality } |g(t, x, u) - f(t, x, u)| \le \epsilon \text{ holds} \\ & \text{for each } x \in B_E(N) \text{ and each } u \in B_F(N)\} \\ \cap\{(f, g) \in \mathcal{M}_B \times \mathcal{M}_B :\ & \text{for almost every } t \in [T_1, T_2] \text{ the inequality} \\ & |(f-g)(t, x_1, u) - (f-g)(t, x_2, u)| \le \epsilon||x_1 - x_2|| \\ & \text{holds for each } x_1, x_2 \in B_E(N) \text{ and each } u \in B_F(N)\},\end{aligned} \tag{1.15}$$

where $N, \epsilon > 0$.

We equip the space $\mathcal{M}_B$ with the topology induced by this uniformity. This topology will be called the weak topology of $\mathcal{M}_B$. Denote by $\mathcal{M}_B^a$ the set of all functions $f \in \mathcal{M}_B$ such that for almost every $t \in [T_1, T_2]$ the function $f(t, \cdot, \cdot) : E \times F \to R^1$ is lower semicontinuous. Denote by $\mathcal{M}_B^l$ (respectively, $\mathcal{M}_B^c$) the set of all lower semicontinuous (respectively, continuous) functions $f \in \mathcal{M}_B$. Clearly $\mathcal{M}_B^a$, $\mathcal{M}_B^l$, and $\mathcal{M}_B^c$ are closed subsets of $\mathcal{M}_B$ with the strong topology.

We equip the topological subspaces $\mathcal{M}_B^a, \mathcal{M}_B^l, \mathcal{M}_B^c \subset \mathcal{M}_B$ with the relative weak and strong topologies.

Remark 1.1. If $\lambda_1(t) = c_3$, $t \in [T_1, T_2]$, then $\mathcal{M}_B \subset \mathcal{M}_A$.

For each $M > 0$ denote by $\mathcal{D}_M(E)$ the collection of all nonempty subsets $D \subset E$ such that $D \subset B_E(M)$.

DEFINITION 1.3. *Let $f \in \mathcal{M}_B$ and M be a positive number. We say that the integrand f possesses the (M)-strong Lipschitz regularity property, abbreviated as (M)-(SLR) property, if there exists $K > 0$ such that for each $g \in \mathcal{M}_B$ satisfying $(f, g) \in \mathcal{E}_{Bw}(K, M)$, each $D \in \mathcal{D}_M(E)$, and each $(x, u) \in X(G, D)$ satisfying mes$(\{t \in [T_1, T_2] :\ ||u(t)|| > K\}) > 0$ there exists $(y, v) \in X(G, D)$ such that $I^g(y, v) < I^g(x, u)$ and $||v(t)|| \le K$ for almost every $t \in [T_1, T_2]$.*

DEFINITION 1.4. *Let $f \in \mathcal{M}_B$. We say that the integrand f possesses the strong Lipschitz regularity property, abbreviated as (SLR) property, if for any positive number M the integrand f possesses the (M)-(SLR) property.*

It is clear that if an integrand $f \in \mathcal{M}_B$ possesses the (SLR) property, $D \in \mathcal{D}(E)$, and $(x, u) \in X(G, D)$ is a minimizer of problem (P), then there is a positive number

$K > 0$ such that $||u(t)|| \le K$ for almost every $t \in [T_1, T_2]$. It is also clear that if an integrand $f \in \mathcal{M}_B$ possesses the (SLR) property and $D \in \mathcal{D}(E)$, then there exist $K > 0$ and a minimizing sequence of trajectory-control pairs $\{(x_n, u_n)\}_{n=1}^{\infty}$ for problem (P) such that $||u_n(t)|| \le K$ for each natural number n and almost every $t \in [T_1, T_2]$. We will establish (see Theorem 1.6) that the (SLR) property is generic in the space $\mathcal{M}_B$.

Note that assumptions (A1)–(A4) and (B1)–(B4) are not very restrictive. They are common in the literature, and the spaces $\mathcal{M}_A$ and $\mathcal{M}_B$ contain many integrands. Therefore it is natural to ask a question if the Lavrentiev phenomenon does not occur for many integrands in $\mathcal{M}_A$ and if the (SLR) property holds for many integrands in $\mathcal{M}_B$. Our first goal is to find conditions on an integrand $f \in \mathcal{M}_B$ (respectively, $f \in \mathcal{M}_A$) which imply the (SLR) property or the (M)-(SLR) property (respectively, nonoccurrence of the Lavrentiev phenomenon). This goal is achieved by Theorems 1.1–1.4. Our second goal is to show nonoccurrence of the Lavrentiev phenomenon for most integrands in $\mathcal{M}_A$ and that most integrands in $\mathcal{M}_B$ possess the (SLR) property. This is achieved by Theorems 1.5–1.7. In order to meet these goals we introduce the following subspaces of integrands.

Let $M > 0$. Denote by $\mathcal{L}_{A,M}$ the set of all functions $f \in \mathcal{M}_A$ which satisfy the following assumption:

(A5) There exist $M_0, M_1, M_2 > 0$, and an integrable scalar nonnegative function $\psi(t)$, $t \in [T_1, T_2]$ which depend only on f and M such that

(i) for each $D \in \mathcal{D}_M(E)$ and each $(x, u) \in X(G, D)$ which satisfies $||u(t)|| \le M + N_*$ for almost every $t \in [T_1, T_2]$ the inequality $||x(t)|| \le M_0$ holds for all $t \in [T_1, T_2]$;

(ii) for almost every $t \in [T_1, T_2]$ the inequality $f(t, x, u) \le M_1$ holds for each $x \in B_E(M + M_0 + N_*)$ and each $u \in B_F(M + M_0 + N_*)$;

(iii) for each $g \in \mathcal{M}_A$, each $D \in \mathcal{D}_M(E)$, and each $(x, u) \in X(G, D)$ satisfying $I^g(x, u) \le (M + M_1)(T_2 - T_1) + 1$ the inequality $||x(t)|| \le M_2$ holds for all $t \in [T_1, T_2]$;

(iv) for each $\epsilon > 0$ there exist $\Gamma, \delta > 0$ such that for almost every $t \in [T_1, T_2]$ the inequality

$$|f(t, x_1, u) - f(t, x_2, u)| \le \epsilon(f(t, x_1, u) + \psi(t))$$

is valid for each $x_1, x_2 \in B_E(M_2 + 1)$ satisfying $||x_1 - x_2|| \le \delta$ and each $u \in F$ satisfying $||u|| \ge \Gamma$.

Remark 1.2. The existence of M_0 in (A5)(i) follows from Lemma 2.5. The existence of M_1 in (A5)(ii) follows from (A2), and the existence of M_2 in (A5)(iii) follows from Lemma 2.7.

Let $M > 0$. Denote by $\mathcal{L}_{B,M}$ the set of all functions $f \in \mathcal{M}_B$ which satisfy the following assumption:

(B5) There exist positive numbers M_0, M_1, M_2, L, δ and an integrable scalar nonnegative function $\psi(t)$, $t \in [T_1, T_2]$, which depend only on f and M such that

(i) for each $D \in \mathcal{D}_M(E)$ and each $(x, u) \in X(G, D)$ which satisfies $||u(t)|| \le M + N_*$ for almost every $t \in [T_1, T_2]$ the inequality $||x(t)|| \le M_0$ holds for all $t \in [T_1, T_2]$;

(ii) for almost every $t \in [T_1, T_2]$ the inequality $f(t, x, u) \le M_1$ holds for each $x \in B_E(M + M_0 + N_*)$ and each $u \in B_F(M + M_0 + N_*)$;

(iii) for each $g \in \mathcal{M}_B$, each $D \in \mathcal{D}_M(E)$, and each $(x, u) \in X(G, D)$ satisfying $I^g(x, u) \le (M + M_1)(T_2 - T_1) + 1$ the inequality $||x(t)|| \le M_2$ holds for all $t \in [T_1, T_2]$;

(iv) for almost every $t \in [T_1, T_2]$ the inequality

$$|f(t, x_1, u) - f(t, x_2, u)| \le L||x_1 - x_2||(f(t, x_1, u) + \psi(t))$$

holds for each $x_1, x_2 \in B_E(M_2 + 1)$ satisfying $||x_1 - x_2|| \le \delta$ and each $u \in F$.

Remark 1.3. The existence of M_0 in (B5)(i) follows from Lemma 2.5. The existence of M_1 in (B5)(ii) follows from (B2) and the existence of M_2 in (B5)(iii) follows from Lemma 2.7.

The following theorem is our first main result. It is also an important ingredient in the proofs of our other main results.

THEOREM 1.1. *Let M be a positive number. Then each integrand $f \in \mathcal{L}_{B,M}$ possesses the (M)-(SLR) property.*

The next theorem follows from Theorem 1.1 and auxiliary results which are proved in section 2.

THEOREM 1.2. *Let $f \in \mathcal{M}_B$ satisfy the following assumption:*

(B6) *For each $q > 0$ there exist positive numbers L, δ and an integrable scalar nonnegative function $\psi(t)$, $t \in [T_1, T_2]$, such that for almost every $t \in [T_1, T_2]$ the inequality*

$$|f(t, x_1, u) - f(t, x_2, u)| \le L||x_1 - x_2||(f(t, x_1, u) + \psi(t))$$

holds for each $x_1, x_2 \in B_E(q)$ satisfying $||x_1 - x_2|| \le \delta$ and for each $u \in F$.

Then f possesses the strong Lipschitz regularity property.

Theorems 1.1 and 1.2 will be proved in section 3.

The next theorem implies that if $M > 0$ and if an integrand f belongs to $\mathcal{L}_{A,M}$, then the Lavrentiev phenomenon does not occur for the pair (f, D), where $D \in \mathcal{D}_M(E)$.

THEOREM 1.3. *Let M, ϵ be positive numbers and let $f \in \mathcal{L}_{A,M}$. Then there exists a neighborhood $\mathcal{U}$ of f in $\mathcal{M}_A$ with the weak topology and $K > 0$ such that for each $g \in \mathcal{U}$ and each $D \in \mathcal{D}_M(E)$ there is $(x, u) \in X(G, D)$ such that $||u(t)|| \le K$ for almost every $t \in [T_1, T_2]$ and $I^g(x, u) \le \inf(I^g; X(G, D)) + \epsilon$.*

The next theorem follows from Theorem 1.3 and auxiliary results which are proved in section 2.

THEOREM 1.4. *Let $f \in \mathcal{M}_A$ satisfy the following assumption:*

(A6) *There exists an integrable scalar nonnegative function $\psi(t)$, $t \in [T_1, T_2]$, such that for each $q, \epsilon > 0$ there are $\Gamma, \delta > 0$ such that for almost every $t \in [T_1, T_2]$ the inequality*

$$|f(t, x_1, u) - f(t, x_2, u)| \le \epsilon(f(t, x_1, u) + \psi(t))$$

is valid for each $x_1, x_2 \in B_E(q)$ satisfying $||x_1 - x_2|| \le \delta$ and each $u \in F$ satisfying $||u|| \ge \Gamma$.

Then for each $M, \epsilon > 0$ there exists a neighborhood $\mathcal{U}$ of f in $\mathcal{M}_A$ with the weak topology and $K > 0$ such that for each $g \in \mathcal{U}$ and each $D \in \mathcal{D}_M(E)$ there is $(x, u) \in X(G, D)$ such that $||u(t)|| \le K$ for almost every $t \in [T_1, T_2]$ and $I^g(x, u) \le \inf(I^g; X(G, D)) + \epsilon$.

Theorem 1.4 implies that if an integrand $f \in \mathcal{M}_A$ satisfies assumption (A6), then the Lavrentiev phenomenon does not occur for f. Theorems 1.3 and 1.4 will be proved in section 4.

The following generic results (Theorems 1.5–1.7) will be obtained by using Theorems 1.1 and 1.3 and an auxiliary density result which will be obtained in section 5. They will be proved in section 6.

THEOREM 1.5. *Let M be a positive number. Then there exists an open (in the weak topology) everywhere dense (in the strong topology) subset $\mathcal{F} \subset \mathcal{M}_B$ such that each $f \in \mathcal{F}$ possesses the (M)-(SLR) property.*

Moreover, $\mathcal{F} \cap \mathcal{M}_B^a$ (respectively, $\mathcal{F} \cap \mathcal{M}_B^l$, $\mathcal{F} \cap \mathcal{M}_B^c$) contains an open (in the weak topology) everywhere dense (in the strong topology) subset of $\mathcal{M}_B^a$ (respectively, $\mathcal{M}_B^l$, $\mathcal{M}_B^c$).

THEOREM 1.6. *There exists a subset $\mathcal{F}_B \subset \mathcal{M}_B$ which is a countable intersection of open (in the weak topology) everywhere dense (in the strong topology) subsets of $\mathcal{M}_B$ such that each $f \in \mathcal{F}_B$ possesses the (SLR) property.*

Moreover, $\mathcal{F}_B \cap \mathcal{M}_B^a$ (respectively, $\mathcal{F}_B \cap \mathcal{M}_B^l$, $\mathcal{F} \cap \mathcal{M}_B^c$) contains a countable intersection of open (in the weak topology) everywhere dense (in the strong topology) subsets of $\mathcal{M}_B^a$ (respectively, $\mathcal{M}_B^l$, $\mathcal{M}_B^c$).

THEOREM 1.7. *There exists a subset $\mathcal{F}_A \subset \mathcal{M}_A$ which is a countable intersection of open (in the weak topology) everywhere dense (in the strong topology) subsets of $\mathcal{M}_A$ such that for each $f \in \mathcal{F}_A$ the Lavrentiev phenomenon does not occur.*

Moreover, $\mathcal{F}_A \cap \mathcal{M}_A^l$ (respectively, $\mathcal{F}_A \cap \mathcal{M}_A^c$) contains a countable intersection of open (in the weak topology) everywhere dense (in the strong topology) subsets of $\mathcal{M}_A^l$ (respectively, $\mathcal{M}_A^c$).

Section 7 contains examples of integrands for which the Lavrentiev phenomenon does not occur and examples of integrands possessing the (SLR) property. These examples include an optimal control problem which is not covered by the results of [12], [19], [24].

Sarychev [18, Theorem 2.1] constructed a large class of integrands which exhibit the Lavrentiev phenomenon. This class includes the famous example of Ball and Mizel [7]. By Theorem 1.4 the Lavrentiev phenomenon does not occur for any integrand $f \in \mathcal{M}_A$ which satisfies assumption (A6). In section 8 we consider the class of integrands studied in [18] and show that these integrands do not satisfy assumption (A6).

Theorem 1.6 establishes that the (SLR) property holds for most integrands in $\mathcal{M}_B$, and Theorem 1.7 establishes nonoccurrence of the Lavrentiev phenomenon for most integrands in $\mathcal{M}_A$ (in the sense of the Baire category) with respect to suitable topologies defined on the spaces of integrands. Such an approach is often used in many situations when a certain property is studied for the whole space rather than for a single element of the space. See, for example, [5], [17], [23] and the references mentioned there. Clearly in this approach a choice of topologies is of great importance. As in [16], [23], [24], in the present paper the topologies are defined on the spaces of integrands, which is quite natural. Note that in the variational analysis and in the optimization theory there are other well-known topologies of variational character, like epiconvergence or bounded Hausdorff convergence [3], [4]. In our case the convergence with respect to these topologies means convergence in the space of functionals $\{I^f : f \in \mathcal{M}\}$ (see (1.11)) on the set $X(G, D)$, where $\mathcal{M}$ is either $\mathcal{M}_A$ or $\mathcal{M}_B$ and D is a nonempty bounded subset of E. Two functionals I^f and I^g with $f, g \in \mathcal{M}$ are close in these topologies if their epigraphs are close in some sense. These topologies are very important and used for many optimization problems [3], [4]. It is not known whether results comparable with those of our paper hold by using such topologies.

In this paper the space of integrands $\mathcal{M}_B$ ($\mathcal{M}_A$, respectively) is equipped with the two topologies where one is weaker than the other. They are called the weak and the strong topologies, respectively. Note that if a set is G_δ and everywhere dense with respect to one of these two topologies, then this fact does imply that the set is G_δ and everywhere dense with respect to the other topology. We show that the (SLR) property (nonoccurrence of the Lavrentiev phenomenon, respectively) holds for all integrands which belong to a set that is a countable intersection of open (in the

weak topology) everywhere dense (in the strong topology) sets. This implies that our properties are generic with respect to any topology which is weaker than the strong topology and is stronger than the weak topology.

The results which will be established in this paper are more complicated than their prototypes in [24], where we study variational problems. Theorem 1.2, one of our main results, establishes that an integrand $f \in \mathcal{M}_B$ which satisfies (B6) possesses the (SLR) property. In order to prove this result, as well as its prototype in [24], we consider a trajectory-control pair $(x, u) \in X(G, D)$ such that $||u(t)||$ is very large on a subset of $[T_1, T_2]$ with a positive Lebesgue measure and construct another admissible trajectory-control pair (y, v), which is an approximation of (x, u). The approximation is constructed as follows: We put $v(t) = u(t)$ for those t where $||u(t)||$ is not too large and use a bounded alternative for $v(t)$ when $||u(t)||$ is large. The trajectory y is obtained as a solution of the differential equation

$$y'(t) = G(t, y(t), v(t)),\ t \in [T_1, T_2], \tag{1.16}$$
$$y(T_1) = x(T_1).$$

Then we need to estimate carefully $||y(t) - x(t)||$ and $f(t, x(t), u(t)) - f(t, y(t), v(t))$ for $t \in [T_1, T_2]$. In [24] and here the control v is constructed explicitly. Since in [24] $G(t, y, v) = v$, (1.16) is very simple and its solution is a function $y(t) = x(T_1) + \int_{T_1}^{t} v(s)ds$, $t \in [T_1, T_2]$. In [24] the explicit form of the trajectory y plays a crucial role in estimations. In the present paper the right-hand side of (1.16) is very general, and this makes the problem more difficult and less understood. The solution of (1.16) cannot be obtained explicitly and even its existence is not obvious. In section 2 we will develop a technique which allows us to obtain the existence of a solution y of (1.16) and to estimate $||x(t) - y(t)||$ for $t \in [T_1, T_2]$. These estimations will be used in order to compare integrals $I^f(x, u)$ and $I^f(y, v)$. In [24], in order to show that the (SLR) is generic in a space of integrands, we consider its subset, which contains all integrands satisfying assumption (B6) (which implies the (SLR) property) and show that this subset is everywhere dense. In this paper we cannot show that the set of all integrands in $\mathcal{M}_B$ satisfying assumption (B6) is an everywhere dense subset of the space $\mathcal{M}_B$ with the strong topology. It happens because the space $\mathcal{M}_B$ is more complicated than its analogue in [24]. In order to overcome this difficulty we introduce the (M)-(SLR) property, which is a weakened version of the (SLR) property, introduce the spaces $\mathcal{L}_{B,M}$, where $M > 0$, and show that any $f \in \mathcal{L}_{B,M}$ possesses the (M)-(SLR) property. Then we manage to show that all the spaces $\mathcal{L}_{B,M}$ are everywhere dense in $\mathcal{M}_B$ with the strong topology. This allows us to obtain our generic result for the space $\mathcal{M}_B$. Analogously we can compare the results for the space $\mathcal{M}_A$ and for its prototype in [24].

2. Auxiliary results.

LEMMA 2.1 (see [21, Lemma 5.1]). *Assume that $t_0 \in [T_1, T_2]$, $y_0 \in E$, and $u : [T_1, T_2] \to F$ is a strongly measurable function satisfying*

$$\int_{T_1}^{T_2} \phi(||u(t)||)dt < \infty,\ \int_{T_1}^{T_2} ||G(t, 0, u(t))||dt < \infty. \tag{2.1}$$

For each $\delta > 0$, set $I_\delta = [t_0 - \delta, t_0 + \delta] \cap [T_1, T_2]$. Then the following assertions hold:

1. *There are $\delta > 0$ and $y \in W^{1,1}(I_\delta; E)$ such that*

$$y(t_0) = y_0,\ y'(t) = G(t, y(t), u(t)),\ t \in I_\delta \text{ a.e.}. \tag{2.2}$$

2. *If* $\delta_1, \delta_2 > 0$ *and if for* $i = 1, 2$, $y_i \in W^{1,1}(I_{\delta_i}; E)$ *satisfies* (2.2) *with* $y = y_i$, $\delta = \delta_i$, *then there is* $\delta_3 \in (0, \min\{\delta_1, \delta_2\})$ *such that* $y_1(t) = y_2(t)$ *for all* $t \in I_{\delta_3}$.

LEMMA 2.2 (see [21, Lemma 5.2]). *Assume that* $u : [T_1, T_2] \to F$ *is a strongly measurable function satisfying* (2.1), $T_1 < S \leq T_2$, $y_1, y_2 \in W^{1,1}(T_1, S; E)$ *satisfy* $y_1(T_1) = y_2(T_1)$, *and that for* $i = 1, 2$,

$$y_i'(t) = G(t, y_i(t), u(t)),\ t \in [T_1, T_2]\ a.e..$$

Then $y_1(t) = y_2(t)$ *for all* $t \in [T_1, S]$.

LEMMA 2.3. *Assume that* $y_0 \in E$, M_0 *is a positive number, and that* $u : [T_1, T_2] \to F$ *is a strongly measurable function such that*

$$||u(t)|| \leq M_0,\ t \in [T_1, T_2]\ a.e.. \tag{2.3}$$

Then there exists $y \in W^{1,1}(T_1, T_2; E)$ *such that*

$$y(T_1) = y_0,\ y'(t) = G(t, y(t), u(t)),\ t \in [T_1, T_2]\ a.e.. \tag{2.4}$$

Proof. Since the function ϕ is increasing and G is bounded on bounded subsets of $[T_1, T_2] \times E \times F$, it follows from (2.3) that (2.1) holds.

Denote by Ω the set of all $S \in (T_1, T_2]$ such that there exists $y \in W^{1,1}(T_1, S; E)$, which satisfies

$$y(T_1) = y_0,\ y'(t) = G(t, y(t), u(t)),\ t \in [T_1, S] \text{ a.e..}$$

In view of (2.1) and Lemma 2.1, $\Omega \neq \emptyset$. Set

$$S_0 = \sup\{\tau :\ \tau \in \Omega\}. \tag{2.5}$$

By (2.1), Lemma 2.2, the definition of Ω, and (2.5) there is a function $y : [T_1, S_0) \to E$ such that for each $\tau \in (T_1, S_0)$ we have $y \in W^{1,1}(T_1, \tau; E)$,

$$y(T_1) = y_0,\ \text{and } y'(t) = G(t, y(t), u(t)),\ t \in [T_1, S_0) \text{ a.e..} \tag{2.6}$$

We show that there exists $\lim_{t \to S_0^-} y(t)$ in the norm topology of E. Let $T_1 \leq \tau < S_0$. It follows from (2.6), (1.3), (2.3), (2.1), and the monotonicity of ϕ that

$$\begin{aligned}
||y(\tau)|| &\leq ||y_0|| + \int_{T_1}^{\tau} ||G(t, y(t), u(t))||dt \leq ||y_0|| + \int_{T_1}^{\tau} ||G(t, 0, u(t))||dt \\
&+ \int_{T_1}^{\tau} ||G(t, y(t), u(t)) - G(t, 0, u(t))||dt \leq ||y_0|| + \int_{T_1}^{\tau} ||G(t, 0, u(t))||dt \\
&+ \int_{T_1}^{\tau} c_0||y(t)||\phi(||u(t)||)dt \leq ||y_0|| + \int_{T_1}^{\tau} ||G(t, 0, u(t))||dt \\
&+ \int_{T_1}^{\tau} c_0||y(t)||\phi(M_0)dt \leq ||y_0|| + \int_{T_1}^{T_2} ||G(t, 0, u(t))||dt + c_0\phi(M_0) \int_{T_1}^{\tau} ||y(t)||dt.
\end{aligned}$$

In view of this inequality and Gronwall's inequality for any $\tau \in [T_1, S_0)$,

$$||y(\tau)|| \leq \left[||y_0|| + \int_{T_1}^{T_2} ||G(t, 0, u(t))||dt\right] \exp(c_0\phi(M_0)(T_2 - T_1)). \tag{2.7}$$

Let $T_1 \le t_1 < t_2 < S_0$. By (2.6), (1.3), (2.3), and the monotonicity of ϕ,

$$||y(t_2) - y(t_1)|| \le \int_{t_1}^{t_2} ||G(t, y(t), u(t))||dt$$
$$\le \int_{t_1}^{t_2} ||G(t, 0, u(t))||dt + \int_{t_1}^{t_2} ||G(t, y(t), u(t)) - G(t, 0, u(t))||dt$$
$$\le \int_{t_1}^{t_2} ||G(t, 0, u(t))||dt + \int_{t_1}^{t_2} c_0\phi(||u(t)||)||y(t)||dt$$
$$\le \int_{t_1}^{t_2} ||G(t, 0, u(t))||dt + c_0\phi(M_0)\int_{t_1}^{t_2} ||y(t)||dt.$$

It follows from this relation, (2.1), and (2.7) that

$$||y(t_2) - y(t_1)|| \to 0 \text{ as } t_1, t_2 \to S_0^-.$$

Therefore there exists $\lim_{t\to S_0^-} y(t)$ in the norm topology which is denoted by $y(S_0)$.

It follows from (1.3), (2.7), the monotonicity of ϕ, (2.1), and (2.7) that

$$\int_{T_1}^{S_0} ||G(t, y(t), u(t))||dt \le \int_{T_1}^{S_0} ||G(t, 0, u(t))||dt + \int_{T_1}^{S_0} c_0||y(t)||\phi(||u(t)||)dt$$
$$\le \int_{T_1}^{S_0} ||G(t, 0, u(t))||dt + c_0\phi(M_0)\int_{T_1}^{S_0} ||y(t)||dt < \infty.$$

Together with (2.6) and the equality $y(S_0) = \lim_{\tau\to S_0^-} y(\tau)$ this inequality implies that

$$y \in W^{1,1}(T_1, S_0; E). \tag{2.8}$$

In order to complete the proof of the lemma it is sufficient to show that $S_0 = T_2$.

Let us assume that $S_0 < T_2$. Then by (2.1) and Lemma 2.1 there exist $\epsilon \in (0, T_2 - S_0)$ and $z \in W^{1,1}(S_0, S_0 + \epsilon; E)$ such that

$$z(S_0) = y(S_0),\ z'(t) = G(t, z(t), u(t)),\ t \in [S_0, S_0 + \epsilon] \text{ a.e..}$$

Combined with (2.8) and (2.6), these relations imply that $S_0 + \epsilon \in \Omega$, a contradiction. The contradiction we have reached proves that $S_0 = T_2$. Lemma 2.3 is proved. □

LEMMA 2.4. *Let $u : [T_1, T_2] \to F$ be a strongly measurable function, $x \in W^{1,1}(T_1, T_2; E)$ satisfy*

$$x'(t) = G(t, x(t), u(t)),\ t \in [T_1, T_2] \text{ a.e.,} \tag{2.9}$$

and let

$$\int_{T_1}^{T_2} ||u(t)||dt < \infty,\ M_0 > N_*,\ \Omega = \{t \in [T_1, T_2] :\ ||u(t)|| > M_0\}. \tag{2.10}$$

Assume that

$$v(t) = u(t),\ t \in [T_1, T_2] \setminus \Omega,\ v(t) = u_*(t),\ t \in \Omega \tag{2.11}$$

and that $y \in W^{1,1}(T_1, T_2; E)$ *satisfies*

$$y(T_1) = x(T_1),\ y'(t) = G(t, y(t), v(t)),\ t \in [T_1, T_2]\ a.e.. \tag{2.12}$$

Then for each $\tau \in [T_1, T_2]$,

$$||y(\tau) - x(\tau)|| \leq 2c_0\phi(\sup\{||x(s)|| :\ s \in [T_1, T_2]\}) \int_\Omega ||u(t)||dt\ exp\left(c_0 \int_{T_1}^{T_2} \phi(||v(t)||)dt\right).$$

Proof. Set

$$M_1 = \sup\{||x(t)|| :\ t \in [T_1, T_2]\}, \tag{2.13}$$

$$d = \int_\Omega ||u(t)||dt. \tag{2.14}$$

Let $\tau \in (T_1, T_2]$. It follows from (2.9), (2.12), (1.3), (2.11), (2.10), (1.4), the monotonicity of ϕ, (1.5), (2.13), and (2.14) that

$$||y(\tau) - x(\tau)|| = || \int_{T_1}^{\tau} G(t, y(t), v(t))dt - \int_{T_1}^{\tau} G(t, x(t), u(t))||$$

$$\leq \int_{T_1}^{\tau} ||G(t, y(t), v(t)) - G(t, x(t), v(t))||dt + \int_{T_1}^{\tau} ||G(t, x(t), v(t)) - G(t, x(t), u(t))||dt$$

$$\leq c_0 \int_{T_1}^{\tau} ||y(t) - x(t)||\phi(||v(t)||)dt + c_0 \int_{T_1}^{\tau} ||u(t) - v(t)||\phi(||x(t)||)dt$$

$$\leq c_0 \int_{T_1}^{\tau} ||y(t) - x(t)||\phi(||v(t)||)dt + c_0\phi(M_1) \int_{[T_1,\tau]\cap\Omega} ||u(t) - v(t)||dt$$

$$\leq c_0 \int_{T_1}^{\tau} ||y(t) - x(t)||\phi(||v(t)||)dt + c_0\phi(M_1) \left[\int_\Omega ||u(t)||dt + N_* \mathrm{mes}(\Omega)\right]$$

$$\leq c_0 \int_{T_1}^{\tau} ||y(t) - x(t)||\phi(||v(t)||)dt + c_0\phi(M_1)2d.$$

By this inequality and Gronwall's inequality, for each $\tau \in [T_1, T_2]$ we get

$$||y(\tau) - x(\tau)|| \leq 2c_0 d\phi(M_1)\exp\left(c_0 \int_{T_1}^{T_2} \phi(||v(t)||)dt\right).$$

This completes the proof of Lemma 2.4. □

LEMMA 2.5. *Let* $M > 0$. *Then there is* $M_0 > 0$ *such that for each* $D \in \mathcal{D}_M(E)$ *and each* $(x, u) \in X(G, D)$ *which satisfies* $||u(t)|| \leq M$ *for almost every* $t \in [T_1, T_2]$ *the inequality* $||x(t)|| \leq M_0$ *holds for all* $t \in [T_1, T_2]$.

Proof. Since G is bounded on any bounded subset of $[T_1, T_2] \times E \times F$ there is $M_1 > 0$ such that

$$||G(t, 0, z)|| \leq M_1 \text{ for each } t \in [T_1, T_2] \text{ and each } z \in B_F(M). \tag{2.15}$$

Set

$$M_0 = [M + M_1(T_2 - T_1)]\exp(c_0\phi(M)(T_2 - T_1)). \tag{2.16}$$

Assume that

$$D \in \mathcal{D}_M(E),\ (x,u) \in X(G,D),\ ||u(t)|| \le M \text{ for } t \in [T_1,T_2] \text{ a.e..} \tag{2.17}$$

By (2.17), (1.6), (2.15), (1.3), and the monotonicity of ϕ for any $t \in [T_1,T_2]$,

$$||x(t)|| \le ||x(T_1)|| + \int_{T_1}^t ||G(s,x(s),u(s))||ds$$

$$\le M + \int_{T_1}^t ||G(s,0,u(s))||ds + \int_{T_1}^t ||G(s,x(s),u(s)) - G(s,0,u(s))||ds$$

$$\le M + M_1(T_2 - T_1) + \int_{T_1}^t c_0||x(s)||\phi(||u(s)||)ds$$

$$\le M + M_1(T_2 - T_1) + c_0\phi(M)\int_{T_1}^t ||x(s)||ds.$$

It follows from this inequality, (2.16), and Gronwall's inequality that for each $t \in [T_1,T_2]$,

$$||x(t)|| \le [M + M_1(T_2 - T_1)]\exp(c_0\phi(M)(T_2 - T_1)) = M_0.$$

Lemma 2.5 is proved. □

Lemmas 2.3 and 2.5, (1.5), and (A2) imply the following auxiliary result.

LEMMA 2.6. *Let $M > 0$ and $f \in \mathcal{M}_A$. Then there is $M_1 > 0$ such that for each $D \in \mathcal{D}_M(E)$,*

$$\inf(I^f; X(D,G)) \le M_1.$$

LEMMA 2.7. *Let $M_0, M_1 > 0$. Then there exists $M_2 > 0$ such that for each $g \in \mathcal{M}_A$, each $D \in \mathcal{D}_{M_0}(E)$, and each $(x,u) \in X(G,D)$ satisfying $I^g(x,u) \le M_1$, the inequality $||x(t)|| \le M_2$ holds for all $t \in [T_1,T_2]$.*

Proof. Set

$$M_2 = M_0 + c_1^{-1}M_1 + c_1^{-1}\int_{T_1}^{T_2} \lambda_0(s)ds. \tag{2.18}$$

Assume that

$$g \in \mathcal{M}_A,\ D \in \mathcal{D}_{M_0}(E),\ (x,u) \in X(G,D),\ I^g(x,u) \le M_1. \tag{2.19}$$

Let $t \in [T_1,T_2]$. It follows from (2.19), (1.6), (1.7), and (2.18) that

$$||x(t)|| \le ||x(T_1)|| + \int_{T_1}^t ||G(s,x(s),u(s))||ds \le M_0 + \int_{T_1}^{T_2} c_1^{-1}[g(s,x(s),u(s)) + \lambda_0(s)]ds$$

$$\le M_0 + c_1^{-1}M_1 + c_1^{-1}\int_{T_1}^{T_2} \lambda_0(s)ds = M_2.$$

Lemma 2.7 is proved. □

3. Proofs of Theorems 1.1 and 1.2. In this section we establish the following result.

THEOREM 3.1. *Let M be a positive number and let $f \in \mathcal{L}_{B,M}$. Then there exists $K > N_*$, $\Delta_1 > 0$ such that for each $g \in \mathcal{M}_B$ satisfying $(f,g) \in \mathcal{E}_{Bw}(K,M)$, each $D \in \mathcal{D}_M(E)$, and each $(x,u) \in X(G,D)$ which satisfies $I^g(x,u) \le \inf(I^g; X(G,D)) + 1$, the following assertion holds: If the set $\Omega := \{t \in [T_1,T_2] : \ ||u(t)|| > K\})$ has a positive Lebesgue measure, then there exists $(y,v) \in X(G,D)$ such that*

$$I^g(y,v) < I^g(x,u) - M\int_\Omega ||u(t)||dt, \ ||x(t)-y(t)|| \le \Delta_1 \int_\Omega ||u(t)||dt, \ t \in [T_1,T_2],$$

$$v(t) = u(t), \ t \in [T_1,T_2] \setminus \Omega, \ v(t) = u_*(t), \ t \in \Omega.$$

It is clear that Theorem 3.1 implies Theorem 1.1.

Proof of Theorem 3.1. Since $f \in \mathcal{L}_{B,M}$, assumption (B5) holds for f. Let $L > 1$, positive numbers M_0, M_1, M_2, δ, and an integrable scalar nonnegative function $\psi(t)$, $t \in [T_1,T_2]$, be as guaranteed by (B5). In view of (B2) there is $M_3 > 0$ such that for almost every $t \in [T_1,T_2]$ the following inequality holds:

(3.1)
$$f(t,h,\xi) \le M_3 \text{ for each } h \in B_E(M_2+N_*+1) \text{ and each } \xi \in B_F(M_2+N_*+1).$$

Set

$$\kappa = 2c_0\phi(M_2)\exp(c_0c_2^{-1}c_3(T_2-T_1) + c_0c_2^{-1}((M+M_1)(T_2-T_1)+1)), \tag{3.2}$$

$$\Delta_1 = (\kappa+1)\left[1 + L + M + L(3M+M_1+c_3)(T_2-T_1) + L\int_{T_1}^{T_2}\psi(t)dt\right] \tag{3.3}$$

and choose $\gamma \in (0,1)$ such that

$$\gamma c_2^{-1}((M+M_1)(T_2-T_1)+1+c_3(T_2-T_1))\kappa < 8^{-1}\min\{1,\delta\}, \tag{3.4}$$

$$(4\gamma)^{-1}c_2 \ge 8\Delta_1.$$

By (1.2) there exists a positive number K such that

$$K > 16(M+M_0+M_1+M_2+M_3+N_*+1+c_3), \tag{3.5}$$

$$\phi(t)t^{-1} \ge \max\{\gamma^{-1}, c_2^{-1}\} \text{ for all } t \ge K. \tag{3.6}$$

Assume that

$$g \in \mathcal{M}_B, \ (f,g) \in \mathcal{E}_{Bw}(K,M), \ D \in \mathcal{D}_M(E), \tag{3.7}$$

$$(x,u) \in X(G,D), \ I^g(x,u) \le \inf(I^g; X(G,D)) + 1, \tag{3.8}$$

$$\text{mes}(\{t \in [T_1,T_2] : \ ||u(t)|| > K\}) > 0. \tag{3.9}$$

Set

$$\Omega = \{t \in [T_1,T_2] : \ ||u(t)|| > K\}, \ d = \int_\Omega ||u(t)||dt. \tag{3.10}$$

Relations (3.9), (3.10), and (3.5) imply that

$$d > 0. \tag{3.11}$$

We will show that $||x(t)|| \le M_2$ for all $t \in [T_1, T_2]$ and $I^g(x,u) \le (M+M_1)(T_2-T_1)+1$. By Lemma 2.3 and (1.5) there exists $x_* \in W^{1,1}(T_1, T_2; E)$ such that

$$(x_*, u_*) \in X(G, D). \tag{3.12}$$

In view of this inclusion, (3.7), (1.5), the choice of M_0, and (B5)(i),

$$||x_*(t)|| \le M_0 \text{ for all } t \in [T_1, T_2]. \tag{3.13}$$

It follows from the choice of M_1, (B2)(ii), (3.13), and (1.5) that for almost every $t \in [T_1, T_2]$,

$$f(t, x_*(t), u_*(t)) \le M_1. \tag{3.14}$$

By (3.14), (3.13), (1.5), (3.5), (3.7), and (1.15) for almost every $t \in [T_1, T_2]$,

$$g(t, x_*(t), u_*(t)) \le f(t, x_*(t), u_*(t)) + M \le M + M_1.$$

Together with (3.8) and (3.12) this inequality implies that

$$I^g(x,u) \le I^g(x_*, u_*) + 1 \le (M + M_1)(T_2 - T_1) + 1. \tag{3.15}$$

It follows from this inequality, the choice of M_2, (B5)(iii), (3.7), and (3.8) that

$$||x(t)|| \le M_2 \text{ for all } t \in [T_1, T_2]. \tag{3.16}$$

By (3.10), (3.6), (1.13), and (3.15),

$$d = \int_\Omega ||u(t)||dt \le \int_\Omega \gamma\phi(||u(t)||)dt \le \gamma \int_{T_1}^{T_2} \phi(||u(t)||)dt$$

$$\le \gamma \int_{T_1}^{T_2} c_2^{-1}[g(t, x(t), u(t)) + c_3]dt = \gamma c_2^{-1}(I^g(x,u) + c_3(T_2 - T_1))$$

$$\le \gamma c_2^{-1}((M + M_1)(T_2 - T_1) + 1 + c_3(T_2 - T_1)). \tag{3.17}$$

Equation (3.10) implies that

$$\text{mes}(\Omega) \le K^{-1} d. \tag{3.18}$$

Set

$$v(t) = u(t),\ t \in [T_1, T_2] \setminus \Omega,\ v(t) = u_*(t),\ t \in \Omega. \tag{3.19}$$

It is clear that $v : [T_1, T_2] \to F$ is a strongly measurable function. Relations (3.19), (1.5), (3.10), and (3.5) imply that

$$||v(t)|| \le K,\ t \in [T_1, T_2] \text{ a.e.}. \tag{3.20}$$

In view of (3.20), Lemma 2.3, and (3.8) there exists $y \in W^{1,1}(T_1, T_2; E)$ such that

$$y(T_1) = x(T_1),\ (y, v) \in X(G, D). \tag{3.21}$$

It follows from Lemma 2.4 (with $M_0 = K$), (3.8), (3.5), (3.17), (3.10), (3.21), (3.19), and (3.16) that for each $t \in [T_1, T_2]$

$$||y(t) - x(t)|| \le \exp\left(c_0 \int_{T_1}^{T_2} \phi(||v(t)||)dt\right) 2c_0 \left(\int_\Omega ||u(t)||dt\right) \phi(M_2). \tag{3.22}$$

By (3.19), (1.5), (3.10), (3.5), the monotonicity of ϕ, (1.13), and (3.15),

$$\int_{T_1}^{T_2} \phi(||v(t)||)dt \le \int_{T_1}^{T_2} \phi(||u(t)||)dt \le c_2^{-1} \int_{T_1}^{T_2} [g(t, x(t), u(t)) + c_3]dt$$
$$\le c_2^{-1} c_3 (T_2 - T_1) + c_2^{-1}[(M + M_1)(T_2 - T_1) + 1].$$

Combined with (3.22), (3.10), and (3.2) this inequality implies that

$$||y(t) - x(t)|| \le d\kappa, \ t \in [T_1, T_2]. \tag{3.23}$$

It follows from (3.23), (3.17), and (3.4) that for all $t \in [T_1, T_2]$,

(3.24)
$$||y(t) - x(t)|| \le d\kappa \le \gamma c_2^{-1}((M + M_1)(T_2 - T_1) + 1 + c_3(T_2 - T_1))\kappa < 8^{-1} \min\{1, \delta\}.$$

Relations (3.24) and (3.16) imply that

$$||y(t)|| \le M_2 + 8^{-1}, \ t \in [T_1, T_2]. \tag{3.25}$$

We will estimate $I^g(x, u) - I^g(y, v)$. It is clear that

$$I^g(x, u) - I^g(y, v) = \int_\Omega g(t, x(t), u(t))dt - \int_\Omega g(t, y(t), v(t))dt \tag{3.26}$$
$$+ \int_{[T_1,T_2]\setminus\Omega} g(t, x(t), u(t))dt - \int_{[T_1,T_2]\setminus\Omega} g(t, y(t), v(t))dt.$$

It follows from (3.25), (3.19), (1.5), and the choice of M_3 (see (3.1)) that for almost every $t \in \Omega$, $f(t, y(t), v(t)) \le M_3$. Together with (3.7), (1.15), (3.25), (3.19), (1.5), and (3.5) this inequality implies that for almost every $t \in \Omega$,

$$g(t, y(t), v(t)) \le M + f(t, y(t), v(t)) \le M + M_3. \tag{3.27}$$

In view of (1.13), the monotonicity of ϕ, (3.10), (3.6), and (3.5) for every $t \in \Omega$,

$$g(t, x(t), u(t)) \ge c_2\phi(||u(t)||) - c_3 \ge c_2\phi(K) - c_3 \ge K - c_3 \ge K/2. \tag{3.28}$$

Relations (3.28), (3.27), and (3.5) imply that for almost every $t \in \Omega$,

$$g(t, x(t), u(t)) - g(t, y(t), v(t)) \ge g(t, x(t), u(t)) - (M + M_3)$$

$$\ge g(t, x(t), u(t)) - K/16 \ge (7/8)g(t, x(t), u(t)).$$

Therefore

$$\int_\Omega g(t, x(t), u(t))dt - \int_\Omega g(t, y(t), v(t))dt \ge (7/8) \int_\Omega g(t, x(t), u(t))dt. \tag{3.29}$$

By (3.19), (3.25), (3.16), (3.24), the choice of L, δ, and (B5)(iv), for almost every $t \in [T_1, T_2] \setminus \Omega$,

$$|f(t, x(t), u(t)) - f(t, y(t), v(t))| = |f(t, x(t), u(t)) - f(t, y(t), u(t))| \tag{3.30}$$

$$\leq L||x(t) - y(t)||(f(t, x(t), u(t)) + \psi(t)).$$

It follows from (3.7), (1.15), (3.5), (3.19), (3.10), (3.30), (3.25), (3.16), and (3.23) that for almost every $t \in [T_1, T_2] \setminus \Omega$,

$$|g(t, x(t), u(t)) - g(t, y(t), v(t))| = |g(t, x(t), u(t)) - g(t, y(t), u(t))|$$

$$\leq |f(t, x(t), u(t)) - f(t, y(t), u(t))| + |(g - f)(t, x(t), u(t)) - (g - f)(t, y(t), u(t))|$$

$$\leq L||x(t) - y(t)||(f(t, x(t), u(t)) + \psi(t)) + M||x(t) - y(t)||$$

$$\leq L||x(t) - y(t)||(g(t, x(t), u(t)) + M + \psi(t)) + M||x(t) - y(t)||$$

$$\leq d\kappa[L(g(t, x(t), u(t)) + M + \psi(t)) + M].$$

By this relation, (1.13), (3.15), and (3.3),

$$\left| \int_{[T_1,T_2]\setminus\Omega} g(t, x(t), u(t))dt - \int_{[T_1,T_2]\setminus\Omega} g(t, y(t), v(t))dt \right| \tag{3.31}$$

$$\leq d\kappa \int_{[T_1,T_2]\setminus\Omega} [L(g(t, x(t), u(t)) + M + \psi(t)) + M]dt$$

$$\leq d\kappa \int_{T_1}^{T_2} [L(g(t, x(t), u(t)) + c_3 + M + \psi(t)) + M]dt$$

$$\leq d\kappa \left[LI^g(x, u) + L(c_3 + M)(T_2 - T_1) + L \int_{T_1}^{T_2} \psi(t)dt + M(T_2 - T_1) \right]$$

$$\leq d\kappa \Bigg[L(M + M_1)(T_2 - T_1) + L(c_3 + M)(T_2 - T_1)$$

$$+ L \int_{T_1}^{T_2} \psi(t)dt + M(T_2 - T_1) + L \Bigg] \leq d\Delta_1.$$

It follows from (1.13), (3.10), (3.6), and (3.5) that for all $t \in \Omega$,

$$g(t, x(t), u(t)) \geq c_2\phi(||u(t)||) - c_3$$

$$\geq c_2\gamma^{-1}||u(t)|| - c_3 \geq c_2\gamma^{-1}||u(t)|| - ||u(t)|| = ||u(t)||(c_2\gamma^{-1} - 1) \geq c_2\gamma^{-1}2^{-1}||u(t)||.$$

Combined with (3.29), (3.10), and (3.4), this inequality implies that

$$\int_\Omega g(t, x(t), u(t))dt - \int_\Omega g(t, y(t), v(t))dt \geq (7/8)c_2\gamma^{-1}2^{-1} \int_\Omega ||u(t)||dt$$

$$\geq (2\gamma)^{-1}(7/8)c_2 d \geq 8\Delta_1 d.$$

Together with (3.31), (3.26), and (3.3) this inequality implies that $I^g(x, u) - I^g(y, v) \geq 7d\Delta_1 > Md$. This completes the proof of Theorem 3.1. □

Proof of Theorem 1.2. Lemma 2.5, (B2), and Lemma 2.7 imply that $f \in \mathcal{L}_{B,M}$ for each $M > 0$. Theorem 1.2 now follows from Theorem 1.1. □

4. Proofs of Theorems 1.3 and 1.4.

Proof of Theorem 1.3. Since $f \in \mathcal{L}_{A,M}$ assumption (A5) holds. Let positive numbers M_0, M_1, M_2 and an integrable scalar nonnegative function $\psi(t)$, $t \in [T_1, T_2]$, be as guaranteed by (A5). Choose a positive number ϵ_0 such that

$$\epsilon_0 < 16^{-1} \min\{\epsilon, 1, M\}(T_2 - T_1 + 1)^{-1}, \tag{4.1}$$

$$\epsilon_0 \left[(M + M_1)(T_2 - T_1) + 3(T_2 - T_1) + \int_{T_1}^{T_2} \lambda_1(t)dt + \int_{T_1}^{T_2} \psi(t)dt \right] < \epsilon/8.$$

Set

$$\kappa = c_2^{-1} \left[(M + M_1)(T_2 - T_1) + 1 + \int_{T_1}^{T_2} \lambda_1(t)dt \right]. \tag{4.2}$$

In view of (A2) there is $M_3 > 0$ such that for almost every $t \in [T_1, T_2]$,

(4.3)
$f(t, h, \xi) \le M_3$ for each $h \in B_E(M_2 + N_* + 1)$ and each $\xi \in B_F(M_2 + N_* + 1)$.

Since the function λ_1 is integrable there exists

$$\epsilon_1 \in (0, \epsilon_0) \tag{4.4}$$

such that

(4.5)
$\int_e \lambda_1(t)dt \le \epsilon/8$ for each Lebesgue measurable set $e \subset [T_1, T_2]$ satisfying $\mathrm{mes}(e) \le \epsilon_1$.

By the choice of M_0, M_1, M_2, ψ, and (A5)(iv) there exist $\Gamma > 0$, $\bar{\delta} \in (0, 1/4)$ such that for almost every $t \in [T_1, T_2]$ the inequality,

$$|f(t, x_1, u) - f(t, x_2, u)| \le \epsilon_0(f(t, x_1, u) + \psi(t)) \tag{4.6}$$

holds for each $x_1, x_2 \in B_E(M_2+1)$ satisfying $||x_1 - x_2|| \le \bar{\delta}$ and each $u \in F$ satisfying $||u|| \ge \Gamma$.

By (A3) there is

$$\delta \in (0, \bar{\delta}) \tag{4.7}$$

such that for almost every $t \in [T_1, T_2]$,

$$|f(t, x_1, u) - f(t, x_2, u)| \le \epsilon_0 \tag{4.8}$$

for each $u \in B_F(\Gamma+M_2+1)$ and each $x_1, x_2 \in B_E(\Gamma+M_2+1)$ satisfying $||x_1-x_2|| \le \delta$.

Choose a number $\gamma \in (0, 1)$ such that

$$\gamma(c_2 + 1)[\exp(c_0\kappa)2c_0\phi(M_2)c_2^{-1}\kappa] < \delta,\ \gamma(c_2 + 1)c_2^{-1}(\kappa + 1) < \epsilon_1. \tag{4.9}$$

By (1.2) we choose a positive number K such that

$$K > 16(M + M_0 + M_1 + M_2 + \Gamma + N_* + 1), \tag{4.10}$$

$$\phi(t)/t \geq \gamma^{-1} \text{ for all } t \geq K \text{ and } \phi(K) > (M_3+1)c_2^{-1}. \tag{4.11}$$

Set

$$\mathcal{U} = \{g \in \mathcal{M}_A : \ (f,g) \in \mathcal{E}_{Aw}(K,\epsilon_0)\}. \tag{4.12}$$

Assume that

$$g \in \mathcal{U}, \ D \in \mathcal{D}_M(E). \tag{4.13}$$

In order to prove the theorem, it is sufficient to show that there exists

$$(y,v) \in X(G,D) \tag{4.14}$$

such that

$$||v(t)|| \leq K, \ t \in [T_1,T_2] \text{ a.e. and } I^g(y,v) \leq \inf(I^g; X(G,D)) + \epsilon. \tag{4.15}$$

There exists a trajectory-control pair (x,u) such that

$$(x,u) \in X(G,D), \ I^g(x,u) \leq \inf(I^g; X(G,D)) + 4^{-1}\min\{\epsilon,1\}. \tag{4.16}$$

We may assume without loss of generality that

$$\text{mes}(\{t \in [T_1,T_2] : \ ||u(t)|| > K\}) > 0. \tag{4.17}$$

Set

$$\Omega_0 = \{t \in [T_1,T_2] : \ ||u(t)|| > K\}, \ \Omega_1 = \{t \in [T_1,T_2] : \ ||u(t)|| \leq \Gamma\},$$
$$\Omega_2 = [T_1,T_2] \setminus (\Omega_0 \cup \Omega_1), \ d = \int_{\Omega_0} ||u(t)||dt. \tag{4.18}$$

By Lemma 2.3 and (1.5) there exists $x_* \in W^{1,1}(T_1,T_2;E)$ such that (3.12) holds. In view of (3.12), (4.13), (1.5), the choice of M_0, and (A5)(i), relation (3.13) holds. It follows from the choice of M_1, (A2)(ii), (3.13), and (1.5) that for almost every $t \in [T_1,T_2]$, relation (3.14) holds.

By (3.14), (3.13), (1.5), (4.10), (4.12), (4.13), (4.1), and (1.10) for almost every $t \in [T_1,T_2]$,

$$g(t,x_*(t),u_*(t)) \leq f(t,x_*(t),u_*(t)) + \epsilon_0 \leq M_1 + M.$$

Together with (4.16) and (3.12) this inequality implies that

$$I^g(x,u) \leq I^g(x_*,u_*) + 1 \leq (M+M_1)(T_2-T_1) + 1. \tag{4.19}$$

It follows from (4.19), (A5)(iii), (4.13), (4.24), and the choice of M_2 that

$$||x(t)|| \leq M_2 \text{ for all } t \in [T_1,T_2]. \tag{4.20}$$

By (4.18), (4.11), (1.8), (4.19), and (4.2),

$$\begin{aligned} d = \int_{\Omega_0} ||u(t)||dt &\leq \int_{\Omega_0} \gamma\phi(||u(t)||)dt \leq \gamma \int_{T_1}^{T_2} \phi(||u(t)||)dt \\ &\leq \gamma \int_{T_1}^{T_2} c_2^{-1}[g(t,x(t),u(t)) + \lambda_1(t)]dt \\ &\leq \gamma c_2^{-1}\left[(M+M_1)(T_2-T_1) + 1 + \int_{T_1}^{T_2} \lambda_1(t)dt\right] \leq \gamma\kappa. \end{aligned} \tag{4.21}$$

Relation (4.18) implies that

$$\text{mes}(\Omega_0) \le K^{-1} \int_{\Omega_0} ||u(t)||dt \le d/K. \tag{4.22}$$

Set

$$v(t) = u(t),\ t \in [T_1, T_2] \setminus \Omega_0,\ v(t) = u_*(t),\ t \in \Omega_0. \tag{4.23}$$

Clearly $v : [T_1, T_2] \to F$ is a strongly measurable function. Relations (4.23), (4.18), (1.5), and (4.10) imply that

$$||v(t)|| \le K,\ t \in [T_1, T_2] \text{ a.e..} \tag{4.24}$$

In view of (4.24), Lemma 2.3, (4.13), and (4.16) there exists $y \in W^{1,1}(T_1, T_2; E)$ such that

$$y(T_1) = x(T_1),\ (y, v) \in X(G, D). \tag{4.25}$$

It follows from Lemma 2.4 (with $M_0 = K$), (4.16), (4.10), (4.18), (4.23), (4.25), (4.21), (4.20), and the monotonicity of ϕ that for each $t \in [T_1, T_2]$,

$$||y(t) - x(t)|| \le \exp\left(c_0 \int_{T_1}^{T_2} \phi(||v(t)||)dt\right) 2c_0 \left(\int_{\Omega_0} ||u(t)||dt\right) \phi(M_2). \tag{4.26}$$

By (4.23), (4.18), (4.10), (1.5), the monotonicity of ϕ, and (1.8),

$$\int_{T_1}^{T_2} \phi(||v(t)||)dt \le \int_{T_1}^{T_2} \phi(||u(t)||)dt \le c_2^{-1} \int_{T_1}^{T_2} [g(t, x(t), u(t)) + \lambda_1(t)]dt$$

$$\le c_2^{-1} \left[(M + M_1)(T_2 - T_1) + 1 + \int_{T_1}^{T_2} \lambda_1(t)dt\right].$$

Combined with (4.2), (4.26), (4.18), (4.21), and (4.9) this inequality implies that for each $t \in [T_1, T_2]$,

$$||y(t) - x(t)|| \le \exp(c_0\kappa)2c_0 d\phi(M_2) \le \exp(c_0\kappa)2c_0\phi(M_2)\kappa\gamma < \delta. \tag{4.27}$$

Together with the inequality $\delta < 1/4$ and (4.20) this inequality implies that

$$||y(t)|| \le M_2 + 1/4 \text{ for all } t \in [T_1.T_2]. \tag{4.28}$$

We will estimate $I^g(x, u) - I^g(y, v)$. It follows from (4.23), (1.5), (4.28), and (4.3) that for almost every $t \in \Omega_0$, $f(t, y(t), v(t)) \le M_3$. Together with (4.28), (4.23), (1.5), (4.13), (4.12), (4.1), (4.10), and (1.10) this inequality implies that for almost every $t \in \Omega_0$,

$$g(t, y(t), v(t)) \le f(t, y(t), v(t)) + \epsilon_0 < f(t, y(t), v(t)) + 1 \le M_3 + 1. \tag{4.29}$$

In view of (4.18), (1.8), and the monotonicity of ϕ for every $t \in \Omega_0$,

$$g(t, x(t), u(t)) \ge c_2\phi(||u(t)||) - \lambda_1(t) \ge c_2\phi(K) - \lambda_1(t).$$

By this inequality, (4.29), and (4.10),

$$\int_{\Omega_0} g(t,x(t),u(t))dt - \int_{\Omega_0} g(t,y(t),v(t))dt$$

$$\geq c_2\phi(K)\mathrm{mes}(\Omega_0) - \int_{\Omega_0} \lambda_1(t)dt - (M_3+1)\mathrm{mes}(\Omega_0) \geq -\int_{\Omega_0} \lambda_1(t)dt. \tag{4.30}$$

Relations (4.21), (4.22), (4.10), and (4.9) imply that $\mathrm{mes}(\Omega_0) \leq d \leq \gamma\kappa < \epsilon_1$. Together with (4.5) this inequality implies that $\int_{\Omega_0} \lambda_1(t)dt \leq \epsilon/8$. Combined with (4.30) this inequality implies that

$$\int_{\Omega_0} g(t,x(t),u(t))dt - \int_{\Omega_0} g(t,y(t),v(t))dt \geq -\epsilon/8. \tag{4.31}$$

By (4.28), (4.20), (4.18), (4.10), (4.23), (4.13), (4.12), and (1.10) for almost every $t \in [T_1,T_2] \setminus \Omega_0$,

$$|f(t,y(t),v(t)) - g(t,y(t),v(t))| \leq \epsilon_0,\ |f(t,x(t),u(t)) - g(t,x(t),u(t))| \leq \epsilon_0. \tag{4.32}$$

It follows from (4.18), (4.10), (4.23), (4.28), (4.20), the choice of δ (see (4.7)), and (4.27) that for almost every $t \in \Omega_1$,

$$|f(t,x(t),u(t)) - f(t,y(t),v(t))| = |f(t,x(t),u(t)) - f(t,y(t),u(t))| \leq \epsilon_0.$$

Combined with (4.32) this relation implies that for almost every $t \in \Omega_1$,

$$|g(t,x(t),u(t)) - g(t,y(t),v(t))| \leq |f(t,x(t),u(t)) - f(t,y(t),v(t))| + 2\epsilon_0 \leq 3\epsilon_0.$$

Together with (4.1) this relation implies that

$$\left|\int_{\Omega_1} g(t,x(t),u(t))dt - \int_{\Omega_1} g(t,y(t),v(t))dt\right| \leq 3\epsilon_0(T_2-T_1) < \epsilon/8. \tag{4.33}$$

By (4.18), (4.23), (4.28), (4.20), the choice of $\Gamma, \bar{\delta}$ (see (4.6)), (4.8), (4.7), and (4.27) for almost every $t \in \Omega_2$,

$$|f(t,x(t),u(t)) - f(t,y(t),v(t))| = |f(t,x(t),u(t)) - f(t,y(t),u(t))|$$
$$\leq \epsilon_0(f(t,x(t),u(t)) + \psi(t)).$$

Combined with (4.32) this relation implies that for almost every $t \in \Omega_2$,

$$|g(t,x(t),u(t)) - g(t,y(t),v(t))| \leq |f(t,x(t),u(t)) - f(t,y(t),v(t))| + 2\epsilon_0$$
$$\leq \epsilon_0(f(t,x(t),u(t)) + \psi(t)) + 2\epsilon_0 \leq \epsilon_0(g(t,x(t),u(t)) + \psi(t) + 3).$$

It follows from this relation, (1.8), (4.19), and (4.1) that

$$\left|\int_{\Omega_2} g(t,x(t),u(t))dt - \int_{\Omega_2} g(t,y(t),v(t))dt\right| \leq \epsilon_0 \int_{\Omega_2} (g(t,x(t),u(t)) + \psi(t) + 3)dt$$

$$\leq \epsilon_0 \int_{T_1}^{T_2} (g(t,x(t),u(t)) + \lambda_1(t) + \psi(t) + 3)dt$$

$$\leq \epsilon_0 \left[(M+M_1)(T_2-T_1) + 1 + 3(T_2-T_1) + \int_{T_1}^{T_2} \lambda_1(t)dt + \int_{T_1}^{T_2} \psi(t)dt\right] < \epsilon/8.$$

By this inequality, (4.33), (4.31), and (4.18), $I^g(x,u) - I^g(y,v) \geq -3\epsilon/8$. Together with (4.16) this relation implies that $I^g(y,v) \leq \inf(I^g; X(G,D)) + 3\epsilon/4$. This completes the proof of Theorem 1.3. □

Proof of Theorem 1.4. Lemma 2.5, (A2), and Lemma 2.7 imply that $f \in \mathcal{L}_{A,M}$ for each $M > 0$. Theorem 1.4 now follows from Theorem 1.3. □

5. A density result. In this section we prove the following result.

PROPOSITION 5.1. *Let $f \in \mathcal{M}_A$ and let ϵ, N, M be positive numbers. Then there exists $g \in \mathcal{L}_{A,M}$ such that*

- $(f,g) \in \mathcal{E}_{As}(N,\epsilon)$;
- *if $f \in \mathcal{M}_A^l$ (respectively, $f \in \mathcal{M}_A^c$), then $g \in \mathcal{M}^l \cap \mathcal{L}_{A,M}$ (respectively, $g \in \mathcal{L}_{A,M} \cap \mathcal{M}_A^c$);*
- *if $\lambda_1(t) = c_3$ for all $t \in [T_1,T_2]$ and if $f \in \mathcal{M}_B$ (respectively, $f \in \mathcal{M}_B^a$, $f \in \mathcal{M}_B^l$, $f \in \mathcal{M}_B^c$), then $g \in \mathcal{L}_{B,M}$ (respectively, $g \in \mathcal{L}_{B,M} \cap \mathcal{M}_B^a$, $g \in \mathcal{L}_{B,M} \cap \mathcal{M}_B^l$, $g \in \mathcal{L}_{B,M} \cap \mathcal{M}_B^c$) and there are constants $M_0 > 0, M_1 > 2, M_2 > 0, L > 0$ such that* (B5)(i) *and* (B5)(iii) *hold for g and that for almost every $t \in [T_1,T_2]$,*

$$g(t,x,u) \leq M_1 - 2 \text{ for each } x \in B_E(M + M_0 + N_*) \text{ and each } u \in B_F(M + M_0 + N_*),$$

$$|g(t,x_1,u) - g(t,x_2,u)| \leq L||x_1 - x_2|| \text{ for each } x_1, x_2 \in B_E(M_2 + 1) \text{ and each } u \in F.$$

In the proof of Proposition 5.1 we use the following auxiliary result which is proved in a straightforward manner.

LEMMA 5.1. *Let $f_1, f_2 : [T_1,T_2] \times E \times F \to R^1$ be scalar functions. Then the following assertions hold:*

1. *If* (A1)–(A3) *hold for f_1, f_2, then* (A1)–(A3) *hold for $f_1 + f_2$, $f_1 f_2$.*
2. *If* (B1)–(B3) *hold for f_1, f_2, then* (B1)–(B3) *hold for $f_1 + f_2$, $f_1 f_2$.*

Proof of Proposition 5.1. Consider a function $\tilde{\phi} : [0,\infty) \to [0,\infty)$ such that for each integer $i \geq 0$,

(5.1)
$$\tilde{\phi}(i) = \phi(i+1),\ \tilde{\phi}(\alpha i + (1-\alpha)(i+1)) = \alpha\tilde{\phi}(i) + (1-\alpha)\tilde{\phi}(i+1) \text{ for all } \alpha \in [0,1].$$

Clearly the function $\tilde{\phi} : [0,\infty) \to [0,\infty)$ is increasing and Lipschitzian on all bounded subsets of $[0,\infty)$,

$$\tilde{\phi}(t) \geq \phi(t) \text{ for all } t \geq 0 \text{ and } \lim_{t\to\infty} \tilde{\phi}(t)/t = \infty. \tag{5.2}$$

By Lemma 2.5 there exists $M_0 > 0$ such that the following property holds:

(P1) For each $D \in \mathcal{D}_M(E)$ and each $(x,u) \in X(G,D)$ which satisfies $||u(t)|| \leq M + N_*$ for almost every $t \in [T_1,T_2]$ the inequality $||x(t)|| \leq M_0$ holds for all $t \in [T_1,T_2]$.

By (A2) there exists $M_1 > 2$ such that for almost every $t \in [T_1,T_2]$ the following inequality holds:

(5.3)
$$f(t,x,u) \leq M_1 - 2 \text{ for each } x \in B_E(M + M_0 + N_*) \text{ and each } u \in B_F(M + M_0 + N_*).$$

By Lemma 2.7 there is $M_2 > 0$ such that the following property holds:

(P2) For each $g \in \mathcal{M}_A$, each $D \in \mathcal{D}_M(E)$, and each $(x,u) \in X(G,D)$ satisfying $I^g(x,u) \leq (M + M_1)(T_2 - T_1) + 1$ the inequality $||x(t)|| \leq M_2$ holds for all $t \in [T_1,T_2]$.

Choose natural numbers

$$N_1 > 4 + N + M + M_0 + N_*,\ N_2 > 4 + M_2 + N + M_0 + N_* + M. \tag{5.4}$$

For $i = 1, 2$ define

$$\begin{aligned} &\psi_i(t) = 1,\ t \in [0, N_i + 1], \\ &\psi_i(t) = 0,\ t \in [N_i + 2, \infty), \\ &\psi_i(t) = N_i + 2 - t,\ t \in (N_i + 1, N_i + 2). \end{aligned} \tag{5.5}$$

Set

$$d_0 = \sup\{||G(t, 0, 0)|| :\ t \in [T_1, T_2]\}. \tag{5.6}$$

It follows from (1.3), (1.4), and (5.6) that for each $(t, y, v) \in [T_1, T_2] \times B_E(N_1 + N_2) \times F$,

$$||G(t, y, v)|| \le ||G(t, 0, v)|| + c_0||y||\phi(||v||) \le ||G(t, 0, 0)|| + c_0||v||\phi(0)$$

$$+ c_0(N_1 + N_2)\phi(||v||) \le d_0 + c_0||v||\phi(0) + c_0(N_1 + N_2)\phi(||v||). \tag{5.7}$$

For each $(t, x, u) \in [T_1, T_2] \times E \times F$ define

$$\begin{aligned} h(t, x, u) = \psi_1(||u||)f(t, x, u) + (1 - \psi_1(||u||))[c_2\tilde{\phi}(||u||) \\ + c_1 d_0 + c_1 c_0||u||\phi(0) + c_1 c_0(N_1 + N_2)\tilde{\phi}(||u||)], \end{aligned} \tag{5.8}$$

$$g(t, x, u) = \psi_2(||x||)h(t, x, u) + (1 - \psi_2(||x||))f(t, x, u). \tag{5.9}$$

Clearly (A1) and (A2) hold for h, g.

It is not difficult to see that (B1), (B2), and (B3) hold for each of the following functions:

$$(t, x, u) \to \psi_1(||u||),\ (t, x, u) \to \psi_2(||x||),$$

$$(t, x, u) \to \tilde{\phi}(||u||),\ (t, x, u) \to ||u||,\ (t, x, u) \in [T_1, T_2] \times E \times F.$$

Together with Lemma 5.1 and the definition of g, h (see (5.8), (5.9)) this implies that (A3) holds for g, h, and if (B3) holds for f, then (B3) holds for g, h. Thus we have shown that g satisfies (A1)–(A3), and if $\lambda_1(t) = c_3$ for all $t \in [T_1, T_2]$ and if $f \in \mathcal{M}_B$, then g satisfies (B3). We will show that (A4) holds for g.

Let $(t, x, u) \in [T_1, T_2] \times E \times F$. There are two cases:

$$||x|| \ge N_2 + 2, \tag{5.10}$$

$$||x|| < N_2 + 2. \tag{5.11}$$

Assume that (5.10) is true. Then by (5.10), (5.9), (5.6), and (A4), which holds for f,

$$g(t, x, u) = f(t, x, u) \ge \max\{c_1||G(t, x, u)|| - \lambda_0(t),\ c_2\phi(||u||) - \lambda_1(t)\}. \tag{5.12}$$

Assume that (5.11) is true. It follows from (5.7), (5.11), (5.4), and (5.2) that

$$\max\{c_1||G(t, x, u)||, c_2\phi(||u||)\} \le [d_0 + c_0||u||\phi(0) + c_0(N_1 + N_2)\phi(||u||)]c_1 + c_0\phi(||u||)$$

$$\leq c_1[d_0 + c_0||u||\phi(0) + c_0(N_1 + N_2)\tilde{\phi}(||u||)] + c_2\tilde{\phi}(||u||).$$

Since (A4) holds for f it follows from this inequality, (5.8), and (5.5) that

$$h(t,x,u) \geq \max\{c_1||G(t,x,u)|| - \lambda_0(t),\ c_2\phi(||u||) - \lambda_1(t)\}.$$

Since (A4) holds for f it follows from this inequality, (5.5), and (5.9) that

$$g(t,x,u) \geq \max\{c_1||G(t,x,u)|| - \lambda_0(t),\ c_2\phi(||u||) - \lambda_1(t)\}.$$

Therefore this inequality holds in both cases, (A4) holds for g, and $g \in \mathcal{M}_A$.

It is clear that if $\lambda_1(t) = c_3$ for all $t \in [T_1, T_2]$ and if $f \in \mathcal{M}_B$, then (B4) holds for g and $g \in \mathcal{M}_B$. Thus we have shown that

(5.13) $g \in \mathcal{M}_A$ and if $\lambda_1(t) = c_3$ for all $t \in [T_1, T_2]$ and if $f \in \mathcal{M}_B$, then $g \in \mathcal{M}_B$.

Evidently

(5.14) if $f \in \mathcal{M}_A^l$ (respectively, $\mathcal{M}_A^c$), then $g \in \mathcal{M}_A^l$ (respectively, $\mathcal{M}_A^c$), if $\lambda_1(t) = c_3$ for all $t \in [T_1, T_2]$ and if $f \in \mathcal{M}_B^a$(respectively, $\mathcal{M}_B^l, \mathcal{M}_B^c$), then $g \in \mathcal{M}_B^a$ (respectively $\mathcal{M}_B^l, \mathcal{M}_B^c$).

We will show that (A5) holds for g. Note that we have already defined the constants $M_0 > 0, M_1 > 2, M_2 > 0$. By (5.9), (5.8), (5.5), and (5.4) for each $t \in [T_1, T_2]$, each $x \in B_E(M + M_0 + N_*)$, and each $u \in B_F(N + M_0 + N_*)$,

$$f(t,x,u) = g(t,x,u). \tag{5.15}$$

Properties (P1) and (P2) and (5.3) imply (A5)(i), (A5)(ii), and (A5)(iii) for g.

Let us show that (A5)(iv) holds.

Assume that

$$x_1, x_2 \in B_E(M_2 + 1),\ u \in F,\ ||u|| \geq N_1 + 2. \tag{5.16}$$

It follows from (5.9), (5.4), (5.16), and (5.5) that for $i = 1, 2$ and all $t \in [T_1, T_2]$,

$$g(t,x_i,u) = h(t,x_i,u) = c_2\tilde{\phi}(||u||) + c_1d_0 + c_1c_0||u||\phi(0) + c_1c_0(N_1 + N_2)\tilde{\phi}(||u||),$$

and $g(t,x_1,u) = g(t,x_2,u)$. Therefore (A5)(iv) holds for g, (A5) holds for g, and $g \in \mathcal{L}_{A,M}$.

Together with (5.14) this implies that

(5.17) $g \in \mathcal{L}_{A,M}$, and if $f \in \mathcal{M}_A^l$ (respectively, $\mathcal{M}_A^c$), then $g \in \mathcal{L}_{A,M} \cap \mathcal{M}_A^l$ (respectively, $\mathcal{L}_{A,M} \cap \mathcal{M}_A^c$).

It follows from (5.8), (5.9), (5.4), and (5.5) that for each $(t,x,u) \in [T_1, T_2] \times B_E(N) \times B_F(N)$,

$$g(t,x,u) = h(t,x,u) = f(t,x,u)$$

and

$$(f,g) \in \mathcal{E}_{As}(N,\epsilon).$$

Now assume that $\lambda_1(t) = c_3$ for all $t \in [T_1, T_2]$ and that $f \in \mathcal{M}_B$. We have already shown that $g \in \mathcal{M}_B$ (see (5.13)). We will show that (B5) holds for g. Note that we have already defined the constants $M_0 > 0, M_1 > 2, M_2 > 0$. Relation (5.15), properties (P1) and (P2), and (5.3) imply (B5)(i), (B5)(ii), and (B5)(iii) for g.

Let us show that (B5)(iv) holds. Since (B3) holds for g there exist $L > 0$ and a Lebesgue measurable set $\Omega \subset [T_1, T_2]$ such that $\mathrm{mes}(\Omega) = T_2 - T_1$ and

$$|g(t, x_1, u) - g(t, x_2, u)| \le L||x_1 - x_2|| \tag{5.18}$$

for each $t \in \Omega$, each $x_1, x_2 \in B_E(M_2 + N_1 + 2)$, and each $u \in B_F(M_2 + N_1 + 2)$.

Assume that

$$x_1, x_2 \in B_E(M_2 + 1),\ u \in F. \tag{5.19}$$

There are two cases:

$$||u|| \ge N_1 + 2, \tag{5.20}$$

$$||u|| < N_1 + 2. \tag{5.21}$$

By (5.9), (5.19), and (5.4) for all $t \in [T_1, T_2]$,

$$g(t, x_i, u) = h(t, x_i, u),\ i = 1, 2. \tag{5.22}$$

Assume that (5.20) holds. Then by (5.20), (5.5), and (5.8) for all $t \in [T_1, T_2]$ we have $h(t, x_1, u) = h(t, x_2, u)$. Together with (5.22) this implies that for all $t \in [T_1, T_2]$ we have $g(t, x_1, u) = g(t, x_2, u)$. Assume that (5.21) holds. Then in view of (5.19), (5.21), and the choice of L, inequality (5.18) is true for all $t \in \Omega$. Clearly, (5.18) holds in both cases for all $t \in \Omega$. Thus we have shown that (5.18) holds for each $u \in F$, each $x_1, x_2 \in B_E(M_2 + 1)$, and each $t \in \Omega$. Therefore (B5)(iv) holds for g and $g \in \mathcal{L}_{B,M}$. This completes the proof of Proposition 5.1. □

It is easy to see that Proposition 5.1 implies the following result.

PROPOSITION 5.2. *Let $M > 0$. Then the set $\mathcal{L}_{A,M}$ (respectively, $\mathcal{L}_{A,M} \cap \mathcal{M}_A^l$, $\mathcal{L}_{A,M} \cap \mathcal{M}_A^c$) is an everywhere dense subset of $\mathcal{M}_A$ (respectively, $\mathcal{M}_a^l$, $\mathcal{M}_A^c$) with the strong topology, and the set $\mathcal{L}_{B,M}$ (respectively, $\mathcal{L}_{B,M} \cap \mathcal{M}_B^a$, $\mathcal{L}_{B,M} \cap \mathcal{M}_B^l$, $\mathcal{L}_{B,M} \cap \mathcal{M}_B^c$) is an everywhere dense subset of $\mathcal{M}_B$ (respectively, $\mathcal{M}_B^a$, $\mathcal{M}_a^l$, $\mathcal{M}_A^c$) with the strong topology.*

6. Proofs of Theorems 1.5–1.7.

Proof of Theorem 1.5. Set $M_0 = 8M$. By Proposition 5.2, $\mathcal{L}_{B,M_0}$ (respectively, $\mathcal{L}_{B,M_0} \cap \mathcal{M}_B^a$, $\mathcal{L}_{B,M_0} \cap \mathcal{M}_B^l$, $\mathcal{L}_{B,M_0} \cap \mathcal{M}_B^c$) is an everywhere dense subset of $\mathcal{M}_B$ (respectively, $\mathcal{M}_B^a$, $\mathcal{M}_B^l$, $\mathcal{M}_B^c$) with the strong topology.

Let $f \in \mathcal{L}_{B,M_0}$. By Theorem 1.1 there is $K(f) > 0$ such that the following property holds:

(P3) For each $g \in \mathcal{M}_B$ satisfying $(f, g) \in \mathcal{E}_{Bw}(K(f), 8M)$, each $D \in \mathcal{D}_{8M}(E)$, and each $(x, u) \in X(G, D)$ satisfying $\mathrm{mes}(\{t \in [T_1, T_2] :\ ||u(t)|| > K(f)\}) > 0$, there exists $(y, v) \in X(G, D)$ such that $I^g(y, v) < I^g(x, u)$ and $||v(t)|| \le K(f)$ for almost every $t \in [T_1, T_2]$.

Denote by $\mathcal{U}(f)$ an open neighborhood of f in $\mathcal{M}_B$ with the weak topology such that

$$\{g \in \mathcal{M}_B :\ (f, g) \in \mathcal{E}_{Bw}(K(f), M)\} \subset \mathcal{U}(f) \subset \{g \in \mathcal{M}_B :\ (f, g) \in \mathcal{E}_{Bw}(K(f), 2M)\}. \tag{6.1}$$

Define $\mathcal{F} = \cup\{\mathcal{U}(f) : \ f \in \mathcal{L}_{B,M_0}\}$. Clearly, $\mathcal{F}$ is an open (in the weak topology) everywhere dense (in the strong topology) subset of $\mathcal{M}_B$, and $\mathcal{F} \subset \mathcal{M}_B^a$ (respectively, $\mathcal{F} \cap \mathcal{M}_B^l$, $\mathcal{F} \cap \mathcal{M}_B^c$) contains an open (in the weak topology) everywhere dense (in the strong topology) subset of $\mathcal{M}_B^a$ (respectively, $\mathcal{M}_B^l$, $\mathcal{M}_B^c$).

Let $g \in \mathcal{F}$. By the definition of $\mathcal{F}$ there is $f \in \mathcal{L}_{B,M_0}$ such that $g \in \mathcal{U}(f)$. Assume that

$$h \in \mathcal{M}_B, \ (g,h) \in \mathcal{E}_{Bw}(K(f), M), \ D \in \mathcal{D}_M(E), \ \ (x,u) \in X(G,D), \tag{6.2}$$

$$\mathrm{mes}(\{t \in [T_1,T_2] : \ ||u(t)|| > K(f)\}) > 0. \tag{6.3}$$

By (6.1), (6.2), and the inclusion $g \in \mathcal{U}(f)$ we have $(h,f) \in \mathcal{E}_{Bw}(K(f), 3M)$. It follows from this inclusion, property (P3), (6.2), and (6.3) that there is $(y,v) \in X(G,D)$ such that $I^h(y,v) < I^h(x,u)$ and $||v(t)|| \le K(f)$ for almost every $t \in [T_1,T_2]$. Theorem 1.5 is proved. □

Theorem 1.6 easily follows from Theorem 1.5.

Proof of Theorem 1.7. Let n be a natural number. By Proposition 5.2, $\mathcal{L}_{A,n}$ (respectively, $\mathcal{L}_{A,n} \cap \mathcal{M}_A^l$, $\mathcal{L}_{A,n} \cap \mathcal{M}_A^c$) is an everywhere dense subset of $\mathcal{M}_A$ (respectively, $\mathcal{M}_A^l$, $\mathcal{M}_A^c$) with the strong topology. By Theorem 1.3 for each $f \in \mathcal{L}_{A,n}$ there exist $K(f,n) > 0$ and an open neighborhood $\mathcal{U}(f,n)$ of f in $\mathcal{M}_A$ with the weak topology such that the following property holds:

(P4) For each $g \in \mathcal{U}(f,n)$ and each $D \in \mathcal{D}_n(E)$ there is $(x,u) \in X(G,D)$ such that $||u(t)|| \le K(f,n)$ for almost every $t \in [T_1,T_2]$ and $I^g(x,u) \le \inf(I^g; X(G,D)) + 1/n$.

Define $\mathcal{F}_A = \cap_{n=1}^{\infty} \cup \{\mathcal{U}(f,n) : \ f \in \mathcal{L}_{A,n}\}$. Clearly $\mathcal{F}_A$ is a countable intersection of open (in the weak topology) everywhere dense (in the strong topology) subsets of $\mathcal{M}_A$, and $\mathcal{F}_A \cap \mathcal{M}_A^l$ (respectively, $\mathcal{F}_A \cap \mathcal{M}_A^c$) contains a countable intersection of open (in the weak topology) everywhere dense (in the strong topology) subsets of $\mathcal{M}_A^l$ (respectively, $\mathcal{M}_A^c$). Let

$$g \in \mathcal{F}_A, \ D \in \mathcal{D}(E), \ \epsilon > 0. \tag{6.4}$$

Choose a natural number m such that

$$D \in \mathcal{D}_m(E), \ \epsilon > 1/m. \tag{6.5}$$

By (6.4) and the definition of $\mathcal{F}_A$ there is $f_m \in \mathcal{L}_{A,m}$ such that $g \in \mathcal{U}(f_m, m)$. It follows from this inclusion, the property (P4), and (6.5) that there is $(x,u) \in X(G,D)$ such that

$$||u(t)|| \le K(f_m,m) \text{ for almost every } t \in [T_1,T_2], \ I^g(x,u) \le \inf(I^g : X(G,D)) + 1/m.$$

In view of these inequalities and (6.5) $\inf(I^g; X_L(G,D)) \le I^g(x,u) \le \inf(I^g; X(G,D)) + \epsilon$. Since ϵ is an arbitrary positive number we conclude that $\inf(I^g; X_L(G,D)) = \inf(I^g; X(G,D))$. This completes the proof of Theorem 1.7. □

7. Examples. We assume that $\phi : [0,\infty) \to [0,\infty)$ is an increasing function satisfying (1.2), $c_0, \tilde{c}_1, \tilde{c}_2$ are positive constants, and $G_1 : [T_1,T_2] \times E \to E$, $G_2 : [T_1,T_2] \times F \to E$ are continuous mappings such that

$$||G_1(t,y_1) - G_1(t,y_2)|| \le c_0||y_1 - y_2||\phi(0) \text{ for each } y_1, y_2 \in E \text{ and each } t \in [T_1,T_2],$$

$$||G_2(t,v_1) - G_2(t,v_2)|| \le c_0||v_1 - v_2||\phi(0) \text{ for each } v_1, v_2 \in F \text{ and each } t \in [T_1,T_2],$$

$$G(t,y,v) = G_1(t,y) + G_2(t,v),\ (t,y,v) \in [T_1,T_2] \times E \times F.$$

It is easy to see that (1.3) holds for each $t \in [T_1,T_2]$, each $y_1, y_2 \in E$, and each $v \in F$, and that (1.4) holds for each $t \in [T_1,T_2]$, each $y \in E$, and each $v_1, v_2 \in F$.

Example 1. Assume that $h : [T_1,T_2] \times E \to R^1$ and $g : [T_1,T_2] \times F \to R^1$ are nonnegative continuous functions which are bounded on bounded sets such that for each $M, \epsilon > 0$ there exists $\delta > 0$ such that $|h(t,x_1) - h(t,x_2)| \le \epsilon$ for each $t \in [T_1,T_2]$ and each $x_1, x_2 \in B_E(M)$ satisfying $||x_1 - x_2|| \le \delta$; that

$$h(t,x) \ge \tilde{c}_1||x||\phi(0) \text{ for each } (t,x) \in [T_1,T_2] \times E, \tag{7.1}$$

$$g(t,u) \ge \tilde{c}_1||u||\phi(0) \text{ for each } (t,u) \in [T_1,T_2] \times F;$$

and that

$$g(t,v) \ge \tilde{c}_2\phi(||v||) \text{ for each } (t,v) \in [T_1,T_2] \times E. \tag{7.2}$$

It is not difficult to see that the function $f(t,x,u) = h(t,x) + g(t,u)$, $(t,x,u) \in [T_1,T_2] \times E \times F$ satisfies (A1)–(A3), (A6), and (A4) with $c_2 = \tilde{c}_2$, $\lambda_1(t) = 0$ for all $t \in [T_1,T_2]$, $c_1 = \tilde{c}_1 c_0^{-1}$, $\lambda_0(t) = c_4$ for all $t \in [T_1,T_2]$, where c_4 is a sufficiently large positive constant.

Example 2. Assume that h and g are as in Example 1 and that the following condition holds:

• For each $M > 0$ there exists $L > 0$ such that

$$|h(t,x_1) - h(t,x_2)| \le L||x_1 - x_2|| \text{ for each } t \in [T_1,T_2] \text{ and each } x_1, x_2 \in B_E(M).$$

It is not difficult to see that the function $f(t,x,u) = h(t,x) + g(t,u)$, $(t,x,u) \in [T_1,T_2] \times E \times F$ satisfies (B1), (B2), (B3), (B6), and (B4) with $c_2 = \tilde{c}_2$, $c_3 = 0$, $c_1 = \tilde{c}_1 c_0^{-1}$, and $\lambda_0(t) = c_4$ for all $t \in [T_1,T_2]$, where c_4 is a sufficiently large positive number.

Example 3. Assume that h and g are as in Example 1 and that

$$\inf\{h(t,x) :\ t \in [T_1,T_2],\ x \in E\} > 0,\ \inf\{g(t,x) :\ t \in [T_1,T_2],\ v \in F\} > 0.$$

It is not difficult to see that the function $f(t,x,u) = h(t,x)g(t,u)$, $(t,x,u) \in [T_1,T_2] \times E \times F$ satisfies (A1), (A2), (A3), (A6), and (A4) with $\lambda_1(t) = 0$ for all $t \in [T_1,T_2]$, a sufficiently small positive constant c_2, and $\lambda_0(t) = c_4$ for all $t \in [T_1,T_2]$, where c_4 is a sufficiently large positive number.

Example 4. Assume that h, g are as in Example 3 and that the following condition holds:

• For each $M > 0$ there exists $L > 0$ such that

$$|h(t,x_1) - h(t,x_2)| \le L||x_1 - x_2|| \text{ for each } t \in [T_1,T_2] \text{ and each } x_1, x_2 \in B_E(M).$$

It is not difficult to see that the function $f(t,x,u) = h(t,x)g(t,u)$, $(t,x,u) \in [T_1,T_2] \times E \times F$ satisfies (B1), (B2), (B3), (B6), and (B4) with $c_3 = 0$, sufficiently small positive constants c_1, c_2, and a sufficiently large positive number c_4.

Example 5. Let us consider the following optimal control problem with $E = F = R^1$, $T_1 = 0$, $T_2 = 1$, and

$$\phi(t) = t^2 + 1 \text{ for all } t \in [0,\infty),\ c_0 = 100.$$

Set

$$G(t,y,v) = (3t+4y+1)|2t+v+2| + (t+v+4)|2t+5y+1|,\ (t,y,v) \in [0,1]\times R^1\times R^1.$$

Clearly the function $G : [0,1]\times R^1\times R^1 \to R^1$ is continuous. It is not difficult to verify that (1.2) holds, (1.3) holds for each $t \in [0,1]$ and each $y_2, y_2, v \in R^1$, and (1.4) holds for each $t \in [0,1]$ and each $y, v_1, v_2 \in R^1$.

For $t \in [0,1]$ set

$$U(t) = [-t^2 - 4t - 4, t^2 + 4t + 4].$$

Clearly (1.5) holds with $N_* = 1$ and $u_*(t) = 0$ for all $t \in [0,1]$.

For each $(t,x,u) \in [0,1]\times R^1\times R^1$ set

$$f(t,x,u) = (\ln(1+t)+1)(x^2+|x|+1)(e^u+2+t) + (u^2+|u|+2t+1)(e^{|x|}+t+1).$$

It is not difficult to see that the integrand f satisfies (B1), (B2), (B3), (B4), and (B6) with sufficiently small positive numbers c_1, c_2 and sufficiently large positive number c_3. Thus the assumptions of Theorem 1.2 hold and it can be applied to the optimal control problem

$$\int_0^1 (\ln(1+t)+1)((x(t))^2+|x(t)|+1)(e^{u(t)}+2+t)$$
$$+((u(t))^2+|u(t)|+2t+1)(e^{|x(t)|}+t+1)dt \to \min,$$

$$x'(t) = (3t+4x(t)+1)|2t+u(t)+2| + (t+u(t)+4)|2t+5x(t)+1|,\ t\in[0,1] \text{ a.e.},$$

$$x(0) = 1,\ u(t) \in [-t^2-4t-4, t^2+4t+4],\ t \in [0,1] \text{ a.e.}.$$

It is clear that this example is not covered by the results of [12], [18], [24].

8. Sarychev integrands. Let γ, σ, k, l, m, r be positive numbers which satisfy

$$l > k > 1,\ m \ge (1+kr)(1-k/l)^{-1}, \tag{8.1}$$

and let C^1-smooth functions $\eta : R^1 \to R^1$, $\Psi_0 : R^1 \to R^1$ and the C^2-smooth function $\psi_0 : R^2 \to R^1$ satisfy the following conditions:

$$\Psi_0(0) = 0,\ \Psi_0(z) \ge \gamma|z|^r \text{ for all } z \in R^1,\ \eta(v) \ge \sigma|v|^m \text{ for all } v \in R^1, \tag{8.2}$$

$$\psi_0(1,1) = 1,\ \psi_0(t,0) > 0 \text{ for all } t \in [0,1], \tag{8.3}$$

$$|\psi_0(t,x)| \le \Theta(x) \text{ for all } (t,x) \in [0,1]\times[0,\infty),$$

where

$$\lim_{x\to\infty} \Theta(x)x^{-1} = 0$$

and

$$(x\partial\psi_0/\partial x - l\psi_0) < 0 \text{ in } [0,1]\times[0,\infty). \tag{8.4}$$

Assume that $L(t,x,v)$ is a C^1-smooth integrand that admits the bounds

$$a \le L(t,x,v) \le b(t,x)(1+|v|^p),\ 0 \le p < l/(l-k), \tag{8.5}$$

with $a \in R^1$ and $b(t,x)$ being positive and bounded on bounded subsets of $[0,1] \times [0,\infty)$.

Sarychev [18, Theorem 2.1] established the existence of a positive number ϵ_0 such that for any $\epsilon \in [0,\epsilon_0]$, the variational problem

$$\int_0^1 \epsilon L(t,x(t),x'(t)) + \Psi_0((x(t))^l - t^k\psi_0(t,x(t)))\eta(x'(t))dt \to \min,$$

$$x(0) = 0,\ x(1) = 1$$

exhibits the Lavrentiev phenomenon.

In this section we prove the following result.

PROPOSITION 8.1. *For any $s \in R^1$, the function*

$$f(t,x,u) := sL(t,x,u) + \Psi_0(x^l - t^k\psi_0(t,x))\eta(u),\ (t,x,u) \in [0,1] \times R^1 \times R^1 \tag{8.6}$$

does not satisfy assumption (A6).

Proof. Let $s \in R^1$. Set

$$F(t,x) = x^l - t^k\psi_0(t,x),\ (t,x) \in R^1 \times R^1. \tag{8.7}$$

It is clear that $F \in C^2(R^2)$ and $F(1,1) = 0$. By (8.3) and (8.4),

$$(\partial F/\partial x)(1,1) = l - (\partial\psi_0/\partial x)(1,1) > 0.$$

By the implicit function theorem [5] there exist $\gamma_1 > 0$, $\gamma_2 > 0$, and a continuous differentiable function $\xi : (1-\gamma_2, 1+\gamma_2) \to R^1$ such that

$$\xi(1) = 1,$$

$$\text{if } t \in (1-\gamma_2, 1+\gamma_2),\ \text{then } |\xi(t) - 1| < \gamma_1 \text{ and } F(t,\xi(t)) = 0, \tag{8.8}$$

$$\text{for each } (t,x) \in (1-\gamma_2, 1+\gamma_2) \times (1-\gamma_1, 1+\gamma_1) \text{ the equality} \tag{8.9}$$

$$F(t,x) = 0 \text{ holds if and only if } x = \xi(t).$$

Assume that the integrand f satisfies assumption (A6) and let an integrable scalar nonnegative function $\psi(t)$, $t \in [0,1]$, be as guaranteed by (A6). In view of (A6) there exist $\Gamma, \delta > 0$ such that for almost every $t \in [0,1]$ the following property holds:

$$|f(t,x_1,u) - f(t,x_2,u)| \le f(t,x_2,u) + \psi(t) \tag{P5}$$

for all $x_1, x_2 \in [-2-\gamma_1, 2+\gamma_1]$ satisfying $|x_1 - x_2| \le \delta$ and each $u \in R^1$ satisfying $|u| \ge \Gamma$.

It follows from the definitions of Γ and δ that there exists

$$t_0 \in (1-\gamma_2/2, 1+\gamma_2/2) \cap (0,1) \tag{8.10}$$

such that $\psi(t_0)$ is finite and property (P5) holds with $t = t_0$.

Clearly $\xi(t_0)$ is well defined and

$$|\xi(t_0) - 1| < \gamma_1,\ F(t_0,\xi(t_0)) = 0. \tag{8.11}$$

Since property (P5) holds with $t = t_0$, it follows from (8.11) that

$$|f(t_0,x,u) - f(t_0,\xi(t_0),u)| \le f(t_0,\xi(t_0),u) + \psi(t_0) \tag{8.12}$$

for each

$$x \in [-2-\gamma_1, 2+\gamma_1] \cap [\xi(t_0)-\delta, \xi(t_0)+\delta] \text{ and each } u \in R^1 \setminus (-\Gamma, \Gamma). \tag{8.13}$$

Choose a number x_0 such that

$$x_0 \in (1-\gamma_1, 1+\gamma_1) \cap (\xi(t_0)-\delta, \xi(t_0)+\delta) \setminus \{\xi(t_0)\}. \tag{8.14}$$

It follows from (8.12), (8.13), and (8.14) that

$$|f(t_0, x_0, u) - f(t_0, \xi(t_0), u)| \le f(t_0, \xi(t_0), u) + \psi(t_0) \text{ for each } u \in R^1 \setminus (-\Gamma, \Gamma). \tag{8.15}$$

Let

$$u \in R^1 \setminus (-\Gamma, \Gamma). \tag{8.16}$$

By (8.10), (8.7), the choice of the function ξ, and (8.8),

$$(\xi(t_0))^l - t_0^k \psi_0(t_0, \xi(t_0)) = 0. \tag{8.17}$$

Together with (8.6) and (8.2) this implies that

$$f(t_0, \xi(t_0), u) = sL(t_0, \xi(t_0), u). \tag{8.18}$$

By (8.7), (8.10), (8.14), and (8.9),

$$|x_0^l - t_0^k \psi_0(t_0, x_0)| = |F(t_0, x_0)| > 0.$$

Together with (8.2) this inequality implies that

$$\Lambda := \Psi_0(x_0^l - t_0^k \psi_0(t_0, x_0)) > 0. \tag{8.19}$$

In view of (8.15), (8.18), (8.19), (8.6), and (8.5) for each $u \in R^1 \setminus (-\Gamma, \Gamma)$,

$$sL(t_0, \xi(t_0), u) + \psi(t_0) \ge f(t_0, x_0, u) - f(t_0, \xi(t_0), u)$$

$$= sL(t_0, x_0, u) + \Lambda\eta(u) - sL(t_0, \xi(t_0), u)$$

and

$$\Lambda\eta(u) \le \psi(t_0) + 2sL(t_0, \xi(t_0), u) - as \text{ for each } u \in R^1 \setminus (-\Gamma, \Gamma). \tag{8.20}$$

It follows from (8.2), (8.19), (8.20), and (8.5) that for each $u \in R^1 \setminus (-\Gamma, \Gamma)$,

$$|u|^m \le \sigma^{-1}\eta(u) \le \sigma^{-1}\Lambda^{-1}[\psi(t_0) + 2sL(t_0, \xi(t_0), u) - as]$$

$$\le \sigma^{-1}\Lambda^{-1}[\psi(t_0) + 2|s|a| + 2|s|b(t_0, \xi(t_0))(1+|u|^p) - as].$$

Since the inequality above holds for all $u \in R^1 \setminus (-\Gamma, \Gamma)$, we conclude that $m \le p$.

On the other hand, it follows from (8.1) and (8.5) that $m \ge (1+kr)l(l-k)^{-1} > p$. The contradiction we have reached proved that the integrand f does not satisfy (A6). Proposition 8.1 is proved. □

ON UNIFORM SOLVABILITY OF PARAMETER-DEPENDENT LYAPUNOV INEQUALITIES AND APPLICATIONS TO VARIOUS PROBLEMS*

P. KRISHNAMURTHY† AND F. KHORRAMI†

Abstract. We consider the problem of finding a common quadratic Lyapunov function to demonstrate the stability of a not necessarily bounded family of matrices which incorporate design freedoms. Generically, this can be viewed as the problem of picking a family of controller (or observer) gains so that the family of closed-loop system matrices admits a common quadratic Lyapunov function. We provide several necessary and sufficient conditions for various structures of matrix families. Specifically, we consider matrix families which can be obtained through similarity transformations from a lower Hessenberg structure. Families of matrices containing a subset of diagonal matrices, which is invariant under the design freedoms, are also considered since they occur in many applications. The conditions for uniform solvability of the Lyapunov inequalities are explicitly given and involve inequalities regarding relative magnitudes of terms in the matrices. Various motivating applications of the obtained results to observer and controller designs for time-varying, switched, and nonlinear systems are highlighted.

Key words. coupled Lyapunov inequalities, state-dependent Lyapunov inequalities, nonlinear systems, switched systems

1. Introduction and problem statement.

We consider the following problem: Given families of matrices $\mathcal{A}(\theta) \in \mathcal{R}^{n\times n}$ and $\mathcal{C}(\theta) \in \mathcal{R}^{1\times n}$ indexed by θ ranging over some (not necessarily bounded) set Θ, is it possible to find a family of vectors $\mathcal{G}(\theta) \in \mathcal{R}^{n\times 1}$, a constant symmetric positive definite matrix $P \in \mathcal{R}^{n\times n}$, and a positive constant ν such that for all $\theta \in \Theta$, the Lyapunov inequality

$$P[\mathcal{A}(\theta) + \mathcal{G}(\theta)\mathcal{C}(\theta)] + [\mathcal{A}(\theta) + \mathcal{G}(\theta)\mathcal{C}(\theta)]^T P \leq -\nu I \tag{1.1}$$

is satisfied with I being the identity matrix of appropriate dimensions? If the answer is yes, provide an explicit construction.

Families of Lyapunov inequalities of the form (1.1) arise in many applications, some of which are outlined in section 5. In the literature, either the solvability of these inequalities is taken as an assumption and a numerical solution sought in specific cases, or the system class is restricted so that one of the approaches below can be applied. However, since the available approaches are predominantly analysis rather than design tools, this restriction could be quite conservative.

The problem statement above poses essentially a design problem since it entails the choosing of $\mathcal{G}(\theta)$ such that the family of matrices $\mathcal{A}(\theta)+\mathcal{G}(\theta)\mathcal{C}(\theta)$ admits a common quadratic Lyapunov function. In applications, this function is usually an observer or a controller gain vector. The associated analysis problem requires finding a matrix $P > 0$ and a positive constant ν to satisfy, for all $\theta \in \Theta$, the Lyapunov inequality

$P\mathcal{A}(\theta)+\mathcal{A}^T(\theta)P \leq -\nu I$. This analysis problem has been investigated extensively, and several results are available in the literature. These results are typically formulated as conditions on the eigenstructure of the matrices $\mathcal{A}(\theta)$, on the stability of associated matrix pencils, or on various geometric properties [17, 15, 13, 21]. Results involving algebraic conditions such as pairwise commutativity of the matrices $\mathcal{A}(\theta)$ are also available [16]. However, these results do not extend readily to the design problem above. Another class of results in the literature, which is inspired by the robust control problem, considers the set $\mathcal{A}(\theta)$ to have a *central* element with the radius of the set being bounded in some manner (for instance, by a bound on the singular values of the perturbation matrix, i.e., the difference between $\mathcal{A}(\theta)$ and the central element of the matrix set) so that the solution of the Lyapunov inequality with the central element also works for all the matrices in the set [18, 24, 23, 4, 2, 22]. This approach can be extended to the design problem to find $\mathcal{G}$ and a matrix $P > 0$ to satisfy (1.1). However, by the very nature of the approach, strong conditions such as compactness (with respect to the usual topology in $\mathcal{R}^{n\times n}$) are required on the matrix family $\mathcal{A}(\theta)$. For instance [23, 14, 20], under the assumptions that the elements of $\mathcal{A}(\theta)$ take values within a compact set, that each $\mathcal{A}(\theta)$ is in lower Hessenberg form with a uniform lower bound on the magnitudes of upper diagonal elements and with the sign of each upper diagonal element being independent of θ, and that $\mathcal{C}(\theta) = [1, 0, \ldots, 0]$, a constant vector $\mathcal{G}$ can be found such that the Lyapunov inequality (1.1) is satisfied for all $\theta \in \Theta$. A condition for the existence of a common similarity transformation to simultaneously transform all the elements of a matrix family $\mathcal{A}(\theta)$ into lower Hessenberg form can be formulated [13, 1] in terms of the solvability of the Lie algebra generated by the matrices in the family. However, these results rely crucially on compactness of the matrix family $\mathcal{A}(\theta)$. In contrast, the results in this paper do not require the matrix family $\mathcal{A}(\theta)$ to be compact.

The results given in this paper are therefore of particular interest in applications wherein the family $\mathcal{A}(\theta)$ is noncompact and wherein design freedoms $\mathcal{G}(\theta)$ are available and allowed to depend on the variable θ. This is the case, for instance, in time-varying systems (where $\theta = t$, the time), switched systems (where θ is a switching state), and nonlinear systems (where θ could be the state or some subset of the state). The obtained results provide extensions in each of these specific areas. We consider particularly the case wherein the matrix family $\mathcal{A}(\theta)$ contains matrices that are in lower Hessenberg form (or that are related to the lower Hessenberg form via a similarity transformation). For greater applicability, the matrix family is also allowed to contain a subset (obtained from diagonal matrices via a similarity transformation) which cannot be influenced by the design freedoms. The obtained results are new even in the case where the matrix family $\mathcal{A}(\theta)$ is compact since, unlike [23, 14, 20, 1], the results in this paper address both a family of the lower Hessenberg form *and* a family of diagonal matrices. Matrices of the lower Hessenberg form (or its transpose) appear in numerous applications, including control of nonlinear lower triangular (strict-feedback) and upper triangular (feedforward) systems. The results addressing the case wherein the matrix family $\mathcal{A}(\theta)$ contains a subset of diagonal matrices which are not influenced by design freedoms have applications in dynamic high-gain scaling–based control [9, 8, 10] and λ-tracking [3]. The applications of the obtained results are further elaborated on in section 5. The general framework of our results and some basic definitions and results are provided in section 2. Theorems giving sufficient conditions for uniform solvability of the Lyapunov inequalities are provided in section 3. The conditions are formulated as inequalities involving relative magnitudes of terms in the matrices. Necessity theorems are presented in section 4

and conditions under which the imposed assumptions are necessary and sufficient are identified.

2. Definitions and a basic theorem. We address the design problem formulated in the introduction for particular structures of $\mathcal{A}(\theta)$ and $\mathcal{C}(\theta)$. Specifically, we consider a partition of $\Theta = \Theta_1 \cup \Theta_2$ with $\mathcal{A}(\theta) = A(\theta)$, $\mathcal{G}(\theta) = G(\theta)$, $\mathcal{C}(\theta) = C(\theta)$ if $\theta \in \Theta_1$ and $\mathcal{A}(\theta) = -D(\theta)$, $\mathcal{G}(\theta) = 0$, $\mathcal{C}(\theta) = 0$ if $\theta \in \Theta_2$. This partition of Θ corresponds to some elements of the matrix family $\mathcal{A}(\theta)$ that cannot be modified by the design functions. The motivation for considering this problem is seen in the applications to scaling-based design and λ-tracking discussed in section 5. Equivalently, we consider the following problem: Given families of matrices $A(\theta) \in \mathcal{R}^{n\times n}$, $D(\theta) \in \mathcal{R}^{n\times n}$, and $C(\theta) \in \mathcal{R}^{1\times n}$, find $G(\theta) \in \mathcal{R}^{n\times 1}$, a constant symmetric positive definite matrix $P \in \mathcal{R}^{n\times n}$, and positive constants ν_1 and ν_2 such that for all $\theta \in \Theta$,

$$P[A(\theta) + G(\theta)C(\theta)] + [A(\theta) + G(\theta)C(\theta)]^T P \le -\nu_1 I, \tag{2.1}$$

$$PD(\theta) + D^T(\theta)P \ge \nu_2 I. \tag{2.2}$$

Definition 1. *A triple (A, C, D) which satisfies* (2.1) *and* (2.2) *with some choice of G, a symmetric positive definite matrix P, and positive constants ν_1 and ν_2 is said to have property $\mathcal{M}$ with the $\mathcal{M}$-associated* 4*-tuple (G, P, ν_1, ν_2).*

The problem posed above is in the "observer design" context, and the dual "controller design" problem can be formulated as follows: Given families of matrices $A(\theta) \in \mathcal{R}^{n\times n}$, $D(\theta) \in \mathcal{R}^{n\times n}$, and $B(\theta) \in \mathcal{R}^{n\times 1}$, find $H(\theta) \in \mathcal{R}^{1\times n}$, a constant symmetric positive definite matrix $P \in \mathcal{R}^{n\times n}$, and positive constants ν_1 and ν_2 such that for all $\theta \in \Theta$,

$$P[A(\theta) + B(\theta)H(\theta)] + [A(\theta) + B(\theta)H(\theta)]^T P \le -\nu_1 I, \tag{2.3}$$

$$PD(\theta) + D^T(\theta)P \ge \nu_2 I. \tag{2.4}$$

Definition 2. *A triple (A, B, D) which satisfies* (2.3) *and* (2.4) *with some choice of H, a symmetric positive definite matrix P, and positive constants ν_1 and ν_2 is said to have property $\mathcal{M}_d$ with the $\mathcal{M}_d$-associated* 4*-tuple (H, P, ν_1, ν_2).*

Theorem 1. *Let $Q \in \mathcal{R}^{n\times n}$ be a nonsingular matrix with $\lambda_{max}(QQ^T) = \overline{Q}$. If the triple (A, C, D) has property $\mathcal{M}$ with $\mathcal{M}$-associated* 4*-tuple (G, P, ν_1, ν_2), then*

(a) *the triple $(QAQ^{-1}, CQ^{-1}, QDQ^{-1})$ has property $\mathcal{M}$ with $\mathcal{M}$-associated* 4*-tuple $(QG, Q^{-T}PQ^{-1}, \frac{\nu_1}{\overline{Q}}, \frac{\nu_2}{\overline{Q}})$;*

(b) *the triple (A^T, C^T, D^T) has property $\mathcal{M}_d$ with $\mathcal{M}_d$-associated* 4*-tuple $(G^T, P^{-1}, \nu_1\lambda_{min}(P^{-2}), \nu_2\lambda_{min}(P^{-2}))$.*

If the triple (A, B, D) has property $\mathcal{M}_d$ with $\mathcal{M}_d$-associated 4*-tuple (H, P, ν_1, ν_2), then*

(c) *the triple (QAQ^{-1}, QB, QDQ^{-1}) has property $\mathcal{M}_d$ with $\mathcal{M}_d$-associated* 4*-tuple $(HQ^{-1}, Q^{-T}PQ^{-1}, \frac{\nu_1}{\overline{Q}}, \frac{\nu_2}{\overline{Q}})$;*

(d) *the triple (A^T, B^T, D^T) has property $\mathcal{M}$ with $\mathcal{M}$-associated* 4*-tuple $(H^T, P^{-1}, \nu_1\lambda_{min}(P^{-2}), \nu_2\lambda_{min}(P^{-2}))$.*

Proof of Theorem 1. The proof follows by standard matrix algebra. ∎

In sections 3 and 4, we consider particular structures of matrix families. By Theorem 1, the obtained results are applicable if the required structures are attained under any of the transformations considered in Theorem 1. Theorem 1 also allows theorems stated in the observer design context to be mapped to the dual controller design context and vice versa. In the rest of this paper, we primarily address the

observer design problem, i.e., solution of (2.1) and (2.2). Dual sufficiency results are summarized in Corollary 1. The duals of the necessity theorems can be obtained along the same lines as in the proof of Corollary 1.

3. Sufficiency theorems. In Theorem 2, conditions guaranteeing solvability of the coupled Lyapunov inequalities (2.1) and (2.2) are provided. Theorem 3 is a robust version of Theorem 2 wherein a perturbation term is introduced in the Lyapunov inequality (2.1). The duals of Theorems 2 and 3 in the controller context, i.e., coupled Lyapunov inequalities (2.3) and (2.4), are given in Corollary 1.

THEOREM 2. *Let $\phi_{(i,j)} : \Theta \mapsto \mathcal{R}$ and $D_i : \Theta \mapsto \mathcal{R}$, $i = 1, \ldots, n$, $j = 1, \ldots, i+1$. Let $A : \Theta \mapsto \mathcal{R}^{n\times n}$ be a matrix in the lower Hessenberg form,*

$$A(\theta) = \begin{bmatrix} \phi_{(1,1)}(\theta) & \phi_{(1,2)}(\theta) & 0 & 0 & \cdots & 0 \\ \phi_{(2,1)}(\theta) & \phi_{(2,2)}(\theta) & \phi_{(2,3)}(\theta) & 0 & \cdots & 0 \\ \phi_{(3,1)}(\theta) & \phi_{(3,2)}(\theta) & \phi_{(3,3)}(\theta) & \phi_{(3,4)}(\theta) & & 0 \\ & & & & \ddots & \\ \phi_{(n-1,1)}(\theta) & & \cdots & & \phi_{(n-1,n-1)}(\theta) & \phi_{(n-1,n)}(\theta) \\ \phi_{(n,1)}(\theta) & & \cdots & & \phi_{(n,n-1)}(\theta) & \phi_{(n,n)}(\theta) \end{bmatrix}, \tag{3.1}$$

and let $C(\theta) = C = [1, 0, \ldots, 0]$ and $D(\theta) = \operatorname{diag}(D_1(\theta), \ldots, D_n(\theta))$. If the sign of each $\phi_{(i,i+1)}(\theta)$ is independent of the argument θ, and if positive constants σ, ρ_{iA}, $i = 2, \ldots, n-1$, $\epsilon_{(i,j)}$, $j = 2, \ldots, i$, $i = 2, \ldots, n$, $\underline{\rho}_{iD}$, $i = 1, \ldots, n-1$, $\overline{\rho}_{iD}$, $i = 1, \ldots, n-1$, and $\underline{\rho}^o_{iD}$, $i = 1, \ldots, n$, exist such that for all $\theta \in \Theta$,

$$\begin{cases} |\phi_{(i,i+1)}(\theta)| \geq \sigma > 0, \quad 1 \leq i \leq n-1, \\ |\phi_{(i,i+1)}(\theta)| \leq \rho_{iA}|\phi_{(i-1,i)}(\theta)|, \quad 2 \leq i \leq n-1, \\ |\phi_{(i,j)}(\theta)| \leq \epsilon_{(i,j)}\sqrt{|\phi_{(i,i+1)}(\theta)||\phi_{(j-1,j)}(\theta)|}, \quad 2 \leq i \leq n-1,\ 2 \leq j \leq i, \\ |\phi_{(n,j)}(\theta)| \leq \epsilon_{(n,j)}\sqrt{|\phi_{(n-1,n)}(\theta)||\phi_{(j-1,j)}(\theta)|}, \quad 2 \leq j \leq n, \end{cases} \tag{3.2}$$

$$\begin{cases} D_i(\theta) \geq \underline{\rho}^o_{iD}, \quad i = 1, \ldots, n, \\ \underline{\rho}_{iD} D_i(\theta) \leq D_{i+1}(\theta) \leq \overline{\rho}_{iD} D_i(\theta), \quad i = 1, \ldots, n-1, \end{cases} \tag{3.3}$$

then the triple (A, C, D) has property $\mathcal{M}$.

Remark 1. Conditions (3.2) are a weaker version of the *cascading upper diagonal dominance* (CUDD) conditions introduced in [12, 7] which require the last two inequalities in (3.2) to be strengthened to

$$|\phi_{(i,j)}(\theta)| \leq \epsilon_{(i,j)}|\phi_{(i,i+1)}(\theta)|, \qquad 2 \leq i \leq n-1,\ 2 \leq j \leq i, \tag{3.4}$$

$$|\phi_{(n,j)}(\theta)| \leq \epsilon_{(n,j)}|\phi_{(n-1,n)}(\theta)|, \qquad 2 \leq j \leq n. \tag{3.5}$$

A matrix A of structure (3.1) and satisfying inequalities (3.2) is called a *weakly cascading upper diagonal dominant* (w-CUDD) matrix. The positive constants ρ_{iA}, $i = 2, \ldots, n-1$, and $\epsilon_{(i,j)}$, $i = 2, \ldots, n$, $j = 2, \ldots, i$, are referred to as the w-CUDD constants of A.

Remark 2. An interesting special case is that in which the elements of $A(\theta)$ and $D(\theta)$ vary within a compact set (or, more strongly, in which Θ is compact and the elements of $A(\theta)$ and $D(\theta)$ are continuous functions of θ). In this case, only the first equations in (3.2) and (3.3) need to be verified since the rest of the conditions in (3.2) and (3.3) are trivially satisfied. Hence, in the special case in which $\{\phi_{(i,j)}(\theta)|\theta \in \Theta\}$, $i = 1, \ldots, n$, $j = 1, \ldots, i+1$, and $\{D_i(\theta)|\theta \in \Theta\}$, $i = 1, \ldots, n$, are compact sets,

Theorem 2 states that a $G(\theta)$, a symmetric positive definite matrix P, and positive constants ν_1 and ν_2 can be found to satisfy the Lyapunov inequalities (2.1) and (2.2) if A, C, and D are of the form shown in Theorem 2 with the sign of each $\phi_{(i,i+1)}(\theta)$ being independent of θ and if positive constants σ and $\underline{\rho}^o_{iD}$, $i = 1, \ldots, n$, exist such that $|\phi_{(i,i+1)}(\theta)| \geq \sigma > 0$, $1 \leq i \leq n-1$, and $D_i(\theta) \geq \underline{\rho}^o_{iD}$, $i = 1, \ldots, n$. These conditions on $A(\theta)$ match those obtained in prior results [23, 14, 20] on uniform solvability of the family of matrix Lyapunov inequalities (2.1) with $A(\theta)$ being in lower Hessenberg form and belonging to a compact set. Note that, even in this special case, Theorem 2 is new since it addresses simultaneous solvability of both (2.1) *and* (2.2).

Theorem 2 is proved through a sequence of lemmas below. In Lemma 1, a family of matrices P that satisfy (2.2) is identified. In Lemma 2, the existence of a matrix in this family that also satisfies (2.1) is shown if the w-CUDD constants of A are small enough. Lemma 3 shows that a diagonal transformation can scale the w-CUDD constants. The proof of Theorem 2 is concluded by observing that D, being diagonal, is invariant under a diagonal transformation.

LEMMA 1. *Let*[1] $P = \hat{P}^T \hat{P}$, $\hat{P} = I - \text{lowerdiag}(k_2, \ldots, k_n)$, *with* $k_2, \ldots, k_n$ *being constants, and let* D *be as defined in Theorem* 2. *Assume that* (3.3) *is satisfied with positive constants* $\underline{\rho}_{iD}$, $\overline{\rho}_{iD}$, *and* $\underline{\rho}^o_{iD}$. *Then, a positive constant* κ *exists such that if* $k_2, \ldots, k_n$ *are smaller in magnitude than* κ, *then* (2.2) *holds with some positive constant* ν_2.

Proof of Lemma 1. See section A.1 in the appendix.

LEMMA 2. *Let* A *and* C *be as defined in Theorem* 2. *Given any constant* $\kappa > 0$, *a constant* $\overline{\rho}_A > 0$ *whose choice depends only on* κ *and* n *exists such that the following property is true: If* (3.2) *holds with some* $\sigma > 0$ *and with the w-CUDD constants* ρ_{iA} *and* $\epsilon_{(i,j)}$ *being smaller than* $\overline{\rho}_A$, *then constants* $k_2, \ldots, k_n$ *smaller in magnitude than* κ *and* $G(\theta) = [g_1(\theta), \ldots, g_n(\theta)]^T$ *exist such that* (2.1) *is satisfied for some positive* ν_1 *with* P *defined as in Lemma* 1.

Proof of Lemma 2. See section A.2 in the appendix.

LEMMA 3. *Let* A *be as defined in* (3.1) *and let* (3.2) *be satisfied with some positive constants* σ, ρ_{iA}, *and* $\epsilon_{(i,j)}$. *Given any positive constant* $\overline{\rho}_A$, *a constant diagonal matrix* T *exists such that the matrix* $\tilde{A} = TAT^{-1}$ *is a w-CUDD matrix with w-CUDD constants smaller than* $\overline{\rho}_A$.

Proof of Lemma 3. See section A.3 in the appendix.

Proof of Theorem 2. Given $A(\theta)$ and $D(\theta)$, obtain κ, $\overline{\rho}_A$, and T as in Lemmas 1, 2, and 3, respectively. Defining $\tilde{A} = TAT^{-1}$, $(\tilde{A}, C, D)$ has property $\mathcal{M}$ with $\mathcal{M}$-associated 4-tuple $(\tilde{G}, \tilde{P}, \tilde{\nu}_1, \tilde{\nu}_2)$ constructed as in the proofs of Lemmas 1 and 2. Using statement (a) in Theorem 1 and noting that $T^{-1}DT = D$, the triple (A, CT, D) has property $\mathcal{M}$ with $\mathcal{M}$-associated 4-tuple $(T^{-1}\tilde{G}, T\tilde{P}T, \tilde{\nu}_1\lambda_{min}(T^2), \tilde{\nu}_2\lambda_{min}(T^2))$. Observing that $CT = T_1 C$, where T_1 is the $(1,1)$th element of T, the triple (A, C, D) has property $\mathcal{M}$ with $\mathcal{M}$-associated 4-tuple $(T_1 T^{-1}\tilde{G}, T\tilde{P}T, \tilde{\nu}_1\lambda_{min}(T^2), \tilde{\nu}_2\lambda_{min}(T^2))$. ∎

THEOREM 3. *Let* A, C, *and* D *be as defined in Theorem* 2. *Let* $\Phi : \Theta \times \mathcal{R}^n \mapsto \mathcal{R}^n$ *be a function such that*[2] $|\Phi(\theta, \omega)|_e \leq_e \Gamma(\theta)|\omega|_e$ *for all* $\theta \in \Theta$ *and* $\omega \in \mathcal{R}^n$, *with* $\Gamma(\theta)$ *being a lower triangular* $n \times n$ *matrix function with nonnegative entries. If* A *and*

[1] lowerdiag$(k_2, \ldots, k_n)$ denotes the $n \times n$ matrix with lower diagonal elements $k_2, \ldots, k_n$ and zeros elsewhere.

[2] $|\beta|_e$ with β being a matrix denotes a matrix of the same dimension as β obtained by replacing each element of β with its absolute value. The relation $\leq_e$ between two vectors denotes an elementwise inequality.

$A+\Gamma$ are w-CUDD, then $G(\theta)$, a matrix $P>0$, and positive constants ν_1 and ν_2 exist such that for all $\theta\in\Theta$ and $\omega\in\mathcal{R}^n$,

$$\omega^T\{P[A(\theta)+G(\theta)C]+[A(\theta)+G(\theta)C]^TP\}\omega+2\omega^TP\Phi(\theta,\omega)\le-\nu_1|\omega|^2, \tag{3.6}$$

$$PD(\theta)+D(\theta)P\ge\nu_2 I. \tag{3.7}$$

Proof of Theorem 3. We have the inequality $\omega^TP\Phi\le|\omega^TP|_e|\Phi|_e\le|\omega^TP|_e\Gamma|\omega|_e=\omega^TPQ_1\Gamma Q_2\omega$, where Q_1 and Q_2 are appropriate diagonal matrices with 1 or -1 as each diagonal entry. Let $\mathcal{Q}:\{1,2,\dots,2^n\}\mapsto\mathcal{R}^{n\times n}$ be an enumeration of the 2^n diagonal matrices of dimension $n\times n$ with each diagonal entry 1 or -1. Consider $\theta'=(\theta,q_1,q_2)\in\Theta\times\{1,\dots,2^n\}\times\{1,\dots,2^n\}$. If $\tilde{A}(\theta')=A(\theta)+\mathcal{Q}(q_1)\Gamma(\theta)\mathcal{Q}(q_2)$ is w-CUDD, then using Theorem 2, the conclusion of Theorem 3 follows. Note that G can be taken to be a function of θ and not θ' since $|Q_1\Gamma Q_2|_e=|\Gamma|_e$, and the choice of G in (A.10) depends only on the upper diagonal elements of $\tilde{A}$ (which are equal to the upper diagonal elements of A) and upper bounds on absolute values of the other elements. Noting that $\mathcal{Q}(q_1)$ and $\mathcal{Q}(q_2)$ vary over all the 2^n diagonal matrices with each diagonal entry 1 or -1, it is seen that the necessary and sufficient condition for $\tilde{A}$ to be w-CUDD (i.e., that $\phi_{(i,j)}+\Gamma_{(i,j)}$ and $\phi_{(i,j)}-\Gamma_{(i,j)}$ should both satisfy the w-CUDD bounds) is that A and $A+\Gamma$ are w-CUDD. □

Corollary 1 (corollary to Theorems 2 and 3). *Let $A(\theta)$ be as given in* (3.1). *Let $D(\theta)=\mathrm{diag}(D_1(\theta),\dots,D_n(\theta))$ and $B(\theta)=B=[0,\dots,0,1]^T$. If positive constants σ, ρ_{iA}, $i=2,\dots,n-1$, $\epsilon_{(i,j)}$, $i=1,\dots,n-1$, $j=1,\dots,i$, $\underline{\rho}_{iD}$, $i=1,\dots,n-1$, $\overline{\rho}_{iD}$, $i=1,\dots,n-1$, and $\underline{\rho}^o_{iD}$, $i=1,\dots,n$, exist such that*[3] *for all $\theta\in\Theta$,*

$$\begin{cases}
|\phi_{(i,i+1)}(\theta)| \ge \sigma>0, & 1\le i\le n-1,\\
|\phi_{(i,i+1)}(\theta)| \ge \rho_{iA}|\phi_{(i-1,i)}(\theta)|, & 2\le i\le n-1,\\
|\phi_{(i,j)}(\theta)| \le \epsilon_{(i,j)}\sqrt{|\phi_{(i,i+1)}(\theta)||\phi_{(j-1,j)}(\theta)|}, & 2\le i\le n-1,\ 2\le j\le i,\\
|\phi_{(i,1)}(\theta)| \le \epsilon_{(i,1)}\sqrt{|\phi_{(i,i+1)}(\theta)||\phi_{(1,2)}(\theta)|}, & 1\le i\le n-1,
\end{cases} \tag{3.8}$$

and (3.3) *are satisfied, then the triple (A,B,D) has property $\mathcal{M}_d$. Furthermore, let $\Phi(\theta,\omega)$ be as defined in Theorem* 3. *If A and $A+\Gamma$ are dual w-CUDD, then $H(\theta)$, a matrix $P>0$, and positive constants ν_1 and ν_2 exist such that for all $\theta\in\Theta$ and $\omega\in\mathcal{R}^n$,*

$$\omega^T\{P[A(\theta)+BH(\theta)]+[A(\theta)+BH(\theta)]^TP\}\omega+2\omega^TP\Phi(\theta,\omega)\le-\nu_1|\omega|^2, \tag{3.9}$$

$$PD(\theta)+D(\theta)P\ge\nu_2 I. \tag{3.10}$$

Proof of Corollary 1. Define the matrices $\tilde{A}=QA^TQ$ and $\tilde{D}=QDQ$ with Q being the $n\times n$ matrix with 1's on the antidiagonal, i.e., $Q_{(i,n-i+1)}=1$, $i=1,\dots,n$, with zeros elsewhere. Premultiplication and postmultiplication of a matrix by Q reverses the order of the rows and columns, respectively. $\tilde{A}$ is of form (3.1) with (i,j)th element $\tilde{A}_{(i,j)}=A_{(n-j+1,n-i+1)}$, and is w-CUDD since, using (3.8),

$$\frac{|\tilde{A}_{(i,i+1)}|}{|\tilde{A}_{(i-1,i)}|}=\frac{|\phi_{(n-i,n-i+1)}|}{|\phi_{(n-i+1,n-i+2)}|}\le\frac{1}{\rho_{n-i+1,A}},\qquad i=2,\dots,n-1, \tag{3.11}$$

[3]Conditions (3.8) are dual to the w-CUDD conditions (3.2). Hence, a matrix of form (3.1) satisfying conditions (3.8) is referred to as a *dual w-CUDD* matrix with ρ_{iA} and $\epsilon_{(i,j)}$ called the dual w-CUDD constants.

$$\frac{|\tilde{A}_{(i,j)}|}{\sqrt{|\tilde{A}_{(i,i+1)}||\tilde{A}_{(j-1,j)}|}} = \frac{|\phi_{(n-j+1,n-i+1)}|}{\sqrt{|\phi_{(n-i,n-i+1)}||\phi_{(n-j+1,n-j+2)}|}}$$

$$\leq \epsilon_{(n-j+1,n-i+1)}, \qquad i = 2,\dots,n-1,\ j = 2,\dots,i, \tag{3.12}$$

$$\frac{|\tilde{A}_{(n,j)}|}{\sqrt{|\tilde{A}_{(n-1,n)}||\tilde{A}_{(j-1,j)}|}} = \frac{|\phi_{(n-j+1,1)}|}{\sqrt{|\phi_{(1,2)}||\phi_{(n-j+1,n-j+2)}|}}$$

$$\leq \epsilon_{(n-j+1,1)}, \qquad 2 \leq j \leq n. \tag{3.13}$$

$\tilde{D}$ is a diagonal matrix with (i,i)th element D_{n-i+1}. Using Theorem 2, the triple $(\tilde{A}, C, \tilde{D})$, where $C = [1, 0, \dots, 0]$, has property $\mathcal{M}$ with an $\mathcal{M}$-associated 4-tuple $(G, \tilde{P}, \tilde{\nu}_1, \tilde{\nu}_2)$. Using statements (b) and (c) of Theorem 1, and noting that $Q^{-1} = Q$ and $QC^T = B$, the triple (A, B, D) has property $\mathcal{M}_d$ with $\mathcal{M}_d$-associated 4-tuple $(G^TQ, Q\tilde{P}^{-1}Q, \tilde{\nu}_1\lambda_{min}(\tilde{P}^{-2}), \tilde{\nu}_2\lambda_{min}(\tilde{P}^{-2}))$. The second assertion in Corollary 1, i.e., solvability of (3.9) and (3.10), can be proved similarly using duality and the arguments in the proof of Theorem 3. □

4. Necessity theorems. In this section, the conservativeness of the assumptions required in Theorem 2 is evaluated by formulating necessary conditions for solvability of the coupled Lyapunov inequalities (2.1) and (2.2). In Theorem 4, negative definite submatrices of $P(A+GC)+(A+GC)^TP$ which are invariant under the design freedoms G are identified. This fundamental result in Theorem 4 is applied in Theorem 5 to prove that a necessary condition for solvability of (2.1) is that if the elements of A off the upper diagonal are smaller than the upper diagonal elements in a sense similar to the last two inequalities in (3.2), then the upper diagonal elements must satisfy the first two inequalities of (3.2). Lemma 4 further shows that the invariance of the signs of $\phi_{(i,i+1)}(\theta)$ is also necessary if the elements of A off the upper diagonal are zero. Theorem 6 shows that the assumed conditions on D are necessary for solvability of (2.2). Corollary 2 combines these results to show that the imposed assumptions are necessary and sufficient if A has nonzero entries only on the upper diagonal.

THEOREM 4. *Let $C = [1, 0, \dots, 0]$. If a matrix A of form (3.1) satisfies (2.1) with some $G(\theta)$, a constant matrix $P > 0$ and a constant $\nu_1 > 0$, then the following is true for every $i \in \{1, \dots, n\}$: Let A_i be the matrix obtained by deleting from A the first i rows and the first i columns. Let $C_i = [1, 0, \dots, 0]^T$ be a $1 \times (n-i)$ vector. Then, a constant vector $K_i = [k_{1_i}, \dots, k_{n-i_i}]^T$, a constant $(n-i) \times (n-i)$ matrix $P_i > 0$, and a positive constant $\tilde{\nu}_i$ exist such that for all $\theta \in \Theta$,*

$$P_i[A_i(\theta) + K_iC_i\phi_{(i,i+1)}(\theta)] + [A_i(\theta) + K_iC_i\phi_{(i,i+1)}(\theta)]^TP_i \leq -\tilde{\nu}_iI. \tag{4.1}$$

Proof of Theorem 4. Assume that (2.1) is satisfied with some G, P, and ν_1. Consider partitions

$$A + GC = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_i \end{bmatrix}, \quad P = \begin{bmatrix} P_{11} & P_{21}^T \\ P_{21} & P_i \end{bmatrix}. \tag{4.2}$$

Note that $A + GC$ differs from A only in the first column. The $(2,2)$ block of $P(A+GC)+(A+GC)^TP$ is $P_iA_i + A_i^TP_i + P_{21}A_{12} + A_{12}^TP_{21}^T$. The $i \times (n-i)$ matrix A_{12} has all elements zero except the $(i,1)$ element, which is equal to $\phi_{(i,i+1)}$. Hence, $P_i^{-1}P_{21}A_{12} = K_iC_i\phi_{(i,i+1)}$ with K_i being a constant $(n-i)\times 1$ vector. Noting that $P_iA_i + A_i^TP_i + P_{21}A_{12} + A_{12}^TP_{21}^T = P_i[A_i + K_iC_i\phi_{(i,i+1)}] + [A_i + K_iC_i\phi_{(i,i+1)}]^TP_i$

and that the $(2,2)$ block being on the principal diagonal must be negative definite for (2.1) to hold, the theorem follows. □

THEOREM 5. *Let A be of form (3.1) and $C = [1, 0, \ldots, 0]$. Let positive constants $\epsilon_{(i,j)}$, $i = 2, \ldots, n$, $j = 2, \ldots, i$, and $\bar{\epsilon}_{(i,j)}$, $i = 3, \ldots, n$, $j = 3, \ldots, i$, exist such that for all $\theta \in \Theta$,*

$$\begin{cases} |\phi_{(i,j)}(\theta)| \leq \epsilon_{(i,j)} \sqrt{|\phi_{(i,i+1)}(\theta)||\phi_{(j-1,j)}(\theta)|}, & 2 \leq i \leq n-1,\ 2 \leq j \leq i, \\ |\phi_{(n,j)}(\theta)| \leq \epsilon_{(n,j)} \sqrt{|\phi_{(n-1,n)}(\theta)||\phi_{(j-1,j)}(\theta)|}, & 2 \leq j \leq n, \\ |\phi_{(i,j)}(\theta)| \leq \bar{\epsilon}_{(i,j)} \sqrt{|\phi_{(i,i+1)}(\theta)||\phi_{(j-2,j-1)}(\theta)|}, & 3 \leq i \leq n-1,\ 3 \leq j \leq i, \\ |\phi_{(n,j)}(\theta)| \leq \bar{\epsilon}_{(n,j)} \sqrt{|\phi_{(n-1,n)}(\theta)||\phi_{(j-2,j-1)}(\theta)|}, & 3 \leq j \leq n. \end{cases} \tag{4.3}$$

If (2.1) is satisfied with some $G(\theta)$, a constant positive definite matrix P, and a positive constant ν_1, then positive constants σ and ρ_{iA}, $i = 2, \ldots, n-1$, exist such that

$$\begin{aligned} &|\phi_{(i,i+1)}(\theta)| \geq \sigma > 0, \quad 1 \leq i \leq n-1, \\ &|\phi_{(i,i+1)}(\theta)| \leq \rho_{iA} |\phi_{(i-1,i)}(\theta)|, \quad 2 \leq i \leq n-1. \end{aligned} \tag{4.4}$$

Proof of Theorem 5. Applying Theorem 4 with $i = n-1$, the existence of positive constants P_{n-1} and $\tilde{\nu}_{n-1}$ and a constant $k_{1_{n-1}}$ are inferred such that $2P_{n-1}[\phi_{(n,n)} + k_{1_{n-1}}\phi_{(n-1,n)}] \leq -\tilde{\nu}_{n-1}$. Noting that, by assumption, $|\phi_{(n,n)}| \leq \epsilon_{(n,n)}|\phi_{(n-1,n)}|$, it is seen that a positive constant σ_n exists such that $|\phi_{(n-1,n)}| \geq \sigma_n$. Applying Theorem 4 with $i = n-2$, a 2×2 matrix $P_{n-2} > 0$, a 2×1 vector K_{n-2}, and a positive constant $\tilde{\nu}_{n-2}$ are obtained such that $P_{n-2}[A_{n-2} + K_{n-2}C_{n-2}\phi_{(n-2,n-1)}] + [A_{n-2} + K_{n-2}C_{n-2}\phi_{(n-2,n-1)}]^T P_{n-2} \leq -\tilde{\nu}_{n-2} I$. Denote the (j,k)th element of P_i by $P_{(j,k)_i}$ and the jth element of vector K_i by k_{j_i}. Since the determinant of $P_{n-2}[A_{n-2} + K_{n-2}C_{n-2}\phi_{(n-2,n-1)}] + [A_{n-2} + K_{n-2}C_{n-2}\phi_{(n-2,n-1)}]^T P_{n-2}$ must be positive, we have

$$\begin{aligned} 0 < &-\Big[P_{(1,2)_{n-2}}\phi_{(n-1,n-1)} + P_{(2,2)_{n-2}}\phi_{(n,n-1)} \\ &\quad + \Big(P_{(1,2)_{n-2}}k_{1_{n-2}} + P_{(2,2)_{n-2}}k_{2_{n-2}}\Big)\phi_{(n-2,n-1)} \\ &\quad + P_{(1,1)_{n-2}}\phi_{(n-1,n)} + P_{(1,2)_{n-2}}\phi_{(n,n)}\Big]^2 \\ &+ 4\Big[P_{(1,1)_{n-2}}\phi_{(n-1,n-1)} + P_{(1,2)_{n-2}}\phi_{(n,n-1)} \\ &\quad + (P_{(1,1)_{n-2}}k_{1_{n-2}} + P_{(1,2)_{n-2}}k_{2_{n-2}})\phi_{(n-2,n-1)}\Big] \\ &\times \Big[P_{(1,2)_{n-2}}\phi_{(n-1,n)} + P_{(2,2)_{n-2}}\phi_{(n,n)}\Big]. \end{aligned} \tag{4.5}$$

Using (4.3) and (4.5), positive constants a_1, a_2, and a_3 exist such that

$$\begin{aligned} P^2_{(1,1)_{n-2}}\phi^2_{(n-1,n)} < &|\phi_{(n-1,n)}|\Big[a_1\sqrt{|\phi_{(n-1,n)}||\phi_{(n-2,n-1)}|} + a_2|\phi_{(n-2,n-1)}|\Big] \\ &+ a_3\phi^2_{(n-2,n-1)}. \end{aligned} \tag{4.6}$$

Since $|\phi_{(n-1,n)}(\theta)| > \sigma_n > 0$, $\phi_{(n-2,n-1)}(\theta)$ cannot be zero for any $\theta \in \Theta$. Dividing both sides of (4.6) by $\phi^2_{(n-2,n-1)}$, it is inferred that $\sup_{\theta\in\Theta} \frac{|\phi_{(n-1,n)}(\theta)|}{|\phi_{(n-2,n-1)}(\theta)|} < \infty$. Hence, a positive constant σ_{n-1} exists such that $|\phi_{(n-2,n-1)}(\theta)| \geq \sigma_{n-1}$ for all $\theta \in \Theta$.

We now proceed by induction. Assume that $\sup_{\theta\in\Theta}\frac{|\phi_{(j,j+1)}(\theta)|}{|\phi_{(j-1,j)}(\theta)|}<\infty$ and $\sigma_{j+1}\stackrel{\triangle}{=}\inf_{\theta\in\Theta}|\phi_{(j,j+1)}|>0$, $j=i+2,\dots,n-1$. Using Theorem 4, a matrix $P_i>0$, a vector K_i, and a positive constant $\tilde{\nu}_i$ are obtained to satisfy (4.1). Noting that the leading 2×2 minor of the left-hand side of (4.1) must have positive determinant,

$$\begin{aligned}0<{}&4\sum_{j=1}^{n-i}P_{(1,j)_i}(\phi_{(i+j,i+1)}+k_{j_i}\phi_{(i,i+1)})\sum_{j=1}^{n-i}P_{(2,j)_i}\phi_{(i+j,i+2)}\\&-\left[\sum_{j=1}^{n-i}P_{(1,j)_i}\phi_{(i+j,i+2)}+\sum_{j=1}^{n-i}P_{(2,j)_i}(\phi_{(i+j,i+1)}+k_{j_i}\phi_{(i,i+1)})\right]^2.\end{aligned}\tag{4.7}$$

Using (4.3) and (4.7), positive constants a_{1j},a_{2j},a_{3j}, $i+1\le j\le n-1$, a_4, and a_5 exist such that

$$\begin{aligned}P^2_{(1,1)_i}\phi^2_{(i+1,i+2)}<{}&\left[a_4|\phi_{(i,i+1)}|+\sum_{j=i+1}^{n-1}a_{1j}\sqrt{|\phi_{(j,j+1)}||\phi_{(i,i+1)}|}\right]\\&\times\left[\sum_{j=i+1}^{n-1}a_{2j}\sqrt{|\phi_{(j,j+1)}||\phi_{(i+1,i+2)}|}\right]\\&+\left[a_5|\phi_{(i,i+1)}|+\sum_{j=i+1}^{n-1}a_{3j}\sqrt{|\phi_{(j,j+1)}||\phi_{(i,i+1)}|}\right]^2.\end{aligned}\tag{4.8}$$

By the induction hypothesis, $\frac{|\phi_{(j,j+1)}(\theta)|}{|\phi_{(j-1,j)}(\theta)|}$, $j=i+2,\dots,n-1$, are bounded. Using (4.8), $\frac{|\phi_{(i+1,i+2)}(\theta)|}{|\phi_{(i,i+1)}(\theta)|}$ is bounded and $\sigma_{i+1}\stackrel{\triangle}{=}\inf_{\theta\in\Theta}|\phi_{(i,i+1)}(\theta)|>0$. The proof is complete by induction. □

LEMMA 4. *Let A be of form* (3.1) *and $C=[1,0,\dots,0]$. For each $i\in\{2,\dots,n\}$, let $\inf_{\theta\in\Theta}\sum_{j=i}^{n}|\phi_{(j,i)}(\theta)|=0$. Let* (2.1) *be satisfied with some $G(\theta)$, a constant matrix $P>0$, and a constant $\nu_1>0$. Then, the elements of P on the upper and lower diagonals, i.e., $P_{(i,i+1)}$, $i=1,\dots,n-1$, are nonzero. Furthermore, if $\phi_{(i,j)}\equiv 0$, $i=2,\dots,n$, $j=2,\dots,i$, then each $\phi_{(i,i+1)}(\theta)$, $i=1,\dots,n-1$, assumes the same sign for all arguments.*

Proof of Lemma 4. If (2.1) holds, the diagonal entries of $A_P\stackrel{\triangle}{=}P[A+GC]+[A+GC]^TP$ must be bounded above by a negative constant. The ith diagonal entry, $i\ge 2$, is given by $2\sum_{j=i-1}^{n}P_{(i,j)}\phi_{(j,i)}$. By assumption, $\inf_{\theta\in\Theta}\sum_{j=i}^{n}|\phi_{(j,i)}(\theta)|=0$. Therefore, the ith diagonal entry of A_P can be bounded above by a negative constant only if $P_{(i,i-1)}=P_{(i-1,i)}\neq 0$. If the entries of A off the upper diagonal are zero, then the ith diagonal entry of A_P is $2P_{(i,i-1)}\phi_{(i-1,i)}$ implying that $\phi_{(i-1,i)}(\theta)$ must assume the same sign for all arguments. □

THEOREM 6. *Let $D(\theta)=\operatorname{diag}(D_1(\theta),\dots,D_n(\theta))$. If a matrix $P>0$ exists such that* (2.2) *is satisfied with $\nu_2>0$, then $\inf_{\theta\in\Theta}D_i(\theta)>0$. Furthermore, if the entries of P on the upper and lower diagonals, i.e., $P_{(i,i+1)}$, $i=1,\dots,n-1$, are nonzero, then positive constants $\underline{\rho}_{iD}$ and $\overline{\rho}_{iD}$, $i=1,\dots,n-1$, exist such that $\underline{\rho}_{iD}D_i(\theta)\le D_{i+1}(\theta)\le\overline{\rho}_{iD}D_i(\theta)$, $i=1,\dots,n-1$.*

Proof of Theorem 6. The ith diagonal element of $PD+DP$ given by $2P_{(i,i)}D_i$ must be bounded below by a positive constant to satisfy (2.2). Hence, D_i must be bounded below by a positive constant. Furthermore, to satisfy (2.2), the 2×2 matrices

on the principal diagonal of $PD + DP$ must have positive determinant, i.e.,

$$4P_{(i,i)}P_{(i+1,i+1)}D_iD_{i+1} > P^2_{(i,i+1)}(D_i + D_{i+1})^2, \qquad i = 1, \ldots, n-1, \tag{4.9}$$

implying that $\frac{D_{i+1}(\theta)}{D_i(\theta)}$ and $\frac{D_i(\theta)}{D_{i+1}(\theta)}$ are upper and lower bounded by positive constants. ∎

COROLLARY 2. *Let $A(\theta)$ be a matrix of the form* (3.1) *with $\phi_{(i,j)} = 0$, $i = 2, \ldots, n$, $j = 2, \ldots, i$, i.e., A contains nonzero terms only on the upper diagonal and the first column. Let $C = [1, 0, \ldots, 0]$ and $D(\theta) = \mathrm{diag}(D_1(\theta), \ldots, D_n(\theta))$. A matrix $P > 0$, positive constants ν_1 and ν_2, and a $G(\theta)$ exist to satisfy* (2.1) *and* (2.2) *if and only if A is w-CUDD, each upper diagonal entry of A assumes the same sign for all arguments, and the elements of $D(\theta)$ satisfy* (3.3) *with $\underline{\rho}^o_{iD}$, $i = 1, \ldots, n$, $\underline{\rho}_{iD}$, and $\overline{\rho}_{iD}$, $i = 1, \ldots, n-1$, being positive constants. Furthermore, a matrix $P > 0$, a positive constant ν_1, and a $G(\theta)$ exist to satisfy* (2.1) *if and only if A is w-CUDD and each upper diagonal entry of A assumes the same sign for all arguments.*

Proof of Corollary 2. The proof is evident from Lemma 4 and Theorems 2, 5, and 6. ∎

5. Applications to controller and observer designs for nonlinear, time-varying, and switched systems. The problem stated in the introduction arises in several applications for nonlinear systems, time-varying systems, and switched systems, a few of which are outlined below.

1. *State-feedback*: Consider a system

$$\dot{x} = A_{l(t)}(x,t)x + B_{l(t)}(x,t)u + \Phi_{l(t)}(x,z,t) \tag{5.1}$$

with state $x \in \mathcal{R}^n$, input $u \in \mathcal{R}$, and disturbance $z \in \mathcal{R}^{n_z}$. $A_1(x,t), \ldots, A_N(x,t)$ are $n \times n$ matrices. $B_1(x,t), \ldots, B_N(x,t)$ and $\Phi_1(x,z,t), \ldots, \Phi_N(x,z,t)$ are $n \times 1$ vectors. $l(t)$ is a positive integer function of time taking values in the set $\{1, 2, \ldots, N\}$. Thus, (5.1) is a nonlinear time-varying switched system. If a matrix $P > 0$, a positive constant ν, and functions $K_i(x,t) \in \mathcal{R}^{1\times n}$, $i = 1, \ldots, N$, can be found to satisfy

$$\begin{aligned} x^T \Big\{ & P\Big[A_i(x,t) + B_i(x,t)K_i(x,t)\Big] \\ & + \Big[A_i(x,t) + B_i(x,t)K_i(x,t)\Big]^T P \Big\} x \\ & + 2x^T P \Phi_i(x,z,t) \le -\nu|x|^2 \\ & \qquad \forall x \in \mathcal{R}^n, z \in \mathcal{R}^{n_z}, i \in \{1, \ldots, N\}, \end{aligned} \tag{5.2}$$

then the state-feedback control law $u = K_{l(t)}(x,t)x$ makes the origin $x = 0$ a globally asymptotically stable equilibrium of system (5.1). The inequality (5.2) is of the form (3.9).

2. *Observer design* (*dual to state-feedback*): Given a system

$$\dot{x} = A_{l(t)}(y,t)x + B_{l(t)}(y,t)u; \quad y = C_{l(t)}(t)x, \tag{5.3}$$

with y being the output, a full-order state observer is given by

$$\dot{\hat{x}} = A_{l(t)}(y,t)\hat{x} + B_{l(t)}(y,t)u + G_{l(t)}(y,t)[C_{l(t)}(t)\hat{x} - y] \tag{5.4}$$

if a matrix $P > 0$, a positive constant ν, and functions $G_i \in \mathcal{R}^{n\times 1}$, $i = 1, \ldots, N$, can be found such that [12]

$$P\Big[A_i(y,t) + G_i(y,t)C_i(t)\Big] + \Big[A_i(y,t) + G_i(y,t)C_i(t)\Big]^T P \le -\nu I, \qquad i = 1, \ldots, N. \tag{5.5}$$

3. *Output-feedback*: A dynamic output-feedback controller can be constructed by combining the state-feedback and observer designs above as long as (5.2) and (5.5) can be satisfied (not necessarily with the same P).
4. *Dynamic high-gain scaling–based state-feedback/observer design/output-feedback*: Dynamic high-gain scaling [11, 5, 19, 6, 9, 8] provides a method for triangular systems to attenuate part of the system dynamics so that the system is approximated by a chain of nonlinear integrators; i.e., the system matrix is approximated by $A(x)$ with A having the form shown in (3.1) with only the upper diagonal entries being nonzero. The coupled inequalities (2.1) and (2.2) appear in observer design and their dual, (2.3) and (2.4), appear in controller design based on this technique. The approach is applicable to systems in both lower triangular (strict-feedback) [11, 5, 19, 8] and upper triangular (feedforward) [6, 9] forms and also some classes of nontriangular systems [10]. The approach is illustrated below for state-feedback controller design for a particular simple class of lower triangular systems.
Consider a system of the form

$$\dot{x}_i = \phi_{(i,i+1)}(x)x_{i+1} + \phi_i(x_0, \ldots, x_i, t), \qquad i = 0, \ldots, n, \tag{5.6}$$

where $x = [x_0, \ldots, x_n]^T$ is the system state and $x_{n+1} = u$ is the input. The functions $\phi_{(i,i+1)}$ are assumed to be continuous and lower bounded in magnitude by a positive constant σ, and the functions ϕ_i are assumed to be bounded as $|\phi_i(x_0, \ldots, x_i, t)| \le |\phi_{(0,1)}(x)|\gamma(x_0)\sum_{j=0}^{i}|x_j|$ with γ being a positive function. It is also assumed that $\phi_{(0,1)}(x) \le \overline{\phi}_{(0,1)}(x_0)|\phi_{(1,2)}(x)|$ for all $x \in \mathcal{R}^n$ with $\overline{\phi}_{(0,1)}$ being a positive function.
Define the scaling $\xi_1 = [x_1 + \zeta(x_0)]/r$, $\xi_i = x_i/r^i$, $i = 2, \ldots, n+1$, with $\zeta(x_0) = x_0\zeta_1(x_0)$ being a design function and r a dynamic scaling parameter. The dynamics of $\xi = [\xi_1, \ldots, \xi_n]^T$ can be written in matrix form as

$$\dot{\xi} = r\Big[A(x) + |\phi_{(1,2)}(x)|BK(x)\Big]\xi - \frac{\dot{r}}{r}D\xi + \Phi + H\xi_1 + \Xi \tag{5.7}$$

by picking the control input to be

$$u = \frac{r^{n+1}}{\phi_{(n,n+1)}}|\phi_{(1,2)}(x)|K(x)\xi, \tag{5.8}$$

where $K(x) \in \mathcal{R}^{1\times n}$, $A(x)$ is of the form in (3.1) with nonzero entries only on the upper diagonal, $B = [0, \ldots, 0, 1]^T$, $D = \mathrm{diag}(1, 2, \ldots, n)$, and

$$\Phi = \Big[\frac{\phi_1}{r}, \ldots, \frac{\phi_n}{r^n}\Big]^T, \tag{5.9}$$

$$H = \Big[\zeta'(x_0)\phi_{(0,1)}(x), 0, \ldots, 0\Big]^T, \tag{5.10}$$

$$\Xi = \frac{1}{r}\Big[(\phi_0 - \zeta(x_0)\phi_{(0,1)}(x))\zeta'(x_0), 0, \ldots, 0\Big]^T. \tag{5.11}$$

The dynamics of r are chosen to be the scalar Riccati equation

$$\dot{r} = |\phi_{(1,2)}(x)|r[-a_1(r-1) + a_2\gamma_1(x_0)] \tag{5.12}$$

with a_1 and a_2 being positive constants and γ_1 being a positive function. It will be shown below that the system is globally asymptotically stabilized with some choice of functions ζ_1 and γ_1 if the coupled Lyapunov inequalities

$$P[\hat{A}(x) + BK(x)] + [\hat{A}(x) + BK(x)]^T P \leq -\nu_1 I, \tag{5.13}$$

$$P[D - I/2] + [D - I/2]P \geq \nu_2 I, \tag{5.14}$$

where $\hat{A}(x) = A(x)/|\phi_{(1,2)}(x)|$, are satisfied with some $K(x)$, a matrix $P > 0$, and positive constants ν_1 and ν_2. The coupled Lyapunov inequalities (5.13) and (5.14) are of the forms (2.3) and (2.4), respectively. Since $\hat{A}$ has nonzero terms (which, by assumption, are continuous and lower bounded in magnitude by a positive constant) only on the upper diagonal, the dual of Corollary 2 gives the necessary and sufficient conditions for solvability of the coupled Lyapunov inequalities (5.13) and (5.14) to be that $|\phi_{(i,i+1)}(x)| \geq \rho_{iA}|\phi_{(i-1,i)}(x)|$, $i = 2, \ldots, n-1$, for all $x \in \mathcal{R}^{n+1}$ with ρ_{iA}, $i = 2, \ldots, n-1$, being positive constants.

The closed-loop stability can be analyzed using the Lyapunov function $V = \frac{1}{2}x_0^2 + r\xi^T P\xi$, which satisfies

$$\begin{aligned}\dot{V} = {} & x_0[\phi_{(0,1)}(x)x_1 + \phi_0] + 2r\xi^T P\Phi + 2r\xi^T PH\xi_1 + 2r\xi^T P\Xi \\ & + r^2|\phi_{(1,2)}(x)|\xi^T\Big[P[\hat{A}(x) + BK(x)] + [\hat{A}(x) + BK(x)]^T P\Big]\xi \\ & - \dot{r}\xi^T\Big[P[D - I/2] + [D - I/2]P\Big]\xi.\end{aligned} \tag{5.15}$$

Using the coupled Lyapunov inequalities (5.13) and (5.14) and the dynamics of r given in (5.12), (5.15) reduces to

$$\begin{aligned}\dot{V} = {} & x_0[\phi_{(0,1)}(x)x_1 + \phi_0] + 2r\xi^T P\Phi + 2r\xi^T PH\xi_1 + 2r\xi^T P\Xi \\ & - r^2|\phi_{(1,2)}(x)|\nu_1|\xi|^2 + a_1 r^2|\phi_{(1,2)}(x)|\overline{\nu}_2|\xi|^2 \\ & - r[a_1 + a_2\gamma_1(x_0)]|\phi_{(1,2)}(x)|\nu_2|\xi|^2,\end{aligned} \tag{5.16}$$

where $\overline{\nu}_2$ is a positive constant large enough to satisfy

$$P[D - I/2] + [D - I/2]P \leq \overline{\nu}_2 I. \tag{5.17}$$

With some algebraic manipulation involving mainly routine quadratic overbounding, it can be shown that if a_2 is chosen to be any positive constant and if a_1, ζ_1, and γ_1 are chosen to satisfy[4]

$$-\frac{3\nu_1}{4} + a_1\overline{\nu}_2 = -a^* < 0, \tag{5.18}$$

$$\zeta_1(x_0) = \frac{1}{\sigma}\operatorname{sign}(\phi_{(0,1)}(0))\left[\frac{\sigma\overline{\phi}_{(0,1)}(x_0)}{\nu_1} + \sigma\gamma(x_0) + 2\sigma + \zeta^*(x_0)\right], \tag{5.19}$$

[4]Since $\phi_{(0,1)}$ is continuous and bounded below in magnitude by a positive constant, it assumes the same sign for all arguments.

$$\gamma_1(x_0) \geq \frac{1}{a_2\nu_2}\Bigg[2\lambda_{max}(P)\overline{\phi}_{(0,1)}(x_0)\gamma(x_0)(n+1) + 2\lambda_{max}(P)|\zeta'(x_0)|\overline{\phi}_{(0,1)}(x_0) + \lambda^2_{max}(P)\overline{\phi}_{(0,1)}(x_0)\Big\{[\gamma(x_0)+|\zeta_1(x_0)|]^2[\zeta'(x_0)]^2 + 2(n+1)\gamma^2(x_0)[1+\zeta_1^2(x_0)]\Big\}\Bigg], \tag{5.20}$$

where ζ^* is a positive function bounded below in magnitude by a positive constant, then (5.16) simplifies to

$$\dot{V} \leq -\zeta^* x_0^2 - r^2 a^* \sigma |\xi|^2. \tag{5.21}$$

It can be inferred from (5.21) that $(r, x) = (1 + \frac{a_2}{a_1}\gamma_1(0), 0, \ldots, 0)$ is a globally asymptotically stable equilibrium of the closed-loop system formed by (5.6), (5.8), and (5.12). The key ingredient in attaining (5.21) is the use of the coupled Lyapunov inequalities (5.13) and (5.14) to obtain (5.16) from (5.15). This approach, which is based on dynamic high-gain scaling, can be applied to both state-feedback and output-feedback control of a variety of nonlinear systems, including strict-feedback systems, feedforward systems, and some classes of nontriangular systems, and can be extended to include adaptation to unknown parameters and robustness to uncertain system terms and appended input-to-state stable (ISS) dynamics [11, 5, 19, 6, 9, 8, 10].

5. *λ-tracking*: Inequalities (2.1) and (2.2), and their duals (2.3) and (2.4), also appear in the literature [3] on the λ-tracking problem for nonlinear systems, where the solvability of the coupled Lyapunov inequalities has been assumed so far. The control objective is to regulate the tracking error to a λ-neighborhood of zero.

6. Conclusion. We considered the problem of finding a uniform solution to a family of parameter-dependent Lyapunov inequalities with the matrices incorporating design freedoms. Generically, this problem can be viewed as picking a family of controller (or observer) gains so that the family of closed-loop system matrices admits a common Lyapunov function. Several sufficient and necessary conditions for specific structures of the matrix families were considered. The solvability conditions involve inequalities regarding relative magnitudes of terms in the matrices. The Lyapunov inequalities arising in the controller and observer contexts were seen to have a dual relation. The duals of some of our theorems were explicitly provided, and the duals of the other theorems can be similarly obtained. Several motivating applications were presented to highlight the importance of the considered structures of the matrix families. The obtained results provide extensions in controller and observer designs for time-varying, switched, and nonlinear systems.

Appendix. Proofs of Lemmas 1–3.

A.1. Proof of Lemma 1. The diagonal matrix D can be decomposed as $D = D_1(\theta)\hat{D}(\theta)$, where $\hat{D}(\theta) = \mathrm{diag}(\hat{D}_1(\theta), \hat{D}_2(\theta), \ldots, \hat{D}_n(\theta))$ with $\hat{D}_i(\theta) = \frac{D_i(\theta)}{D_1(\theta)}$. The inequality $P\hat{D} + \hat{D}P \geq \tilde{\nu}_2 I$ holds with some positive $\tilde{\nu}_2$ if $|k_i| < \kappa$ with small enough κ. This is seen by continuity since this inequality holds when $k_2 = \cdots = k_n = 0$. Note that the functions $\hat{D}_i(\theta)$ are bounded below and above by the positive constants

$\prod_{j=1}^{i-1} \underline{\rho}_{jD}$ and $\prod_{j=1}^{i-1} \overline{\rho}_{jD}$, respectively. An estimate (possibly conservative) for κ can be written, using the diagonal dominance condition, as

$$\kappa = \inf_{\theta \in \Theta} \min \left\{ \frac{2\hat{D}_i(\theta)}{\hat{D}_{i+1}(\theta) + 2\hat{D}_i(\theta) + \hat{D}_{i-1}(\theta)};\ 1 \le i \le n \right\} \tag{A.1}$$

with $\hat{D}_0 = -\hat{D}_1$ and $\hat{D}_{n+1} = -\hat{D}_n$. The inequality $PD + DP \ge \nu_2 I$ with $\nu_2 = \underline{\rho}^o_{1D} \tilde{\nu}_2$ follows if $|k_i| < \kappa$, $i = 2, \ldots, n$. □

A.2. Proof of Lemma 2. Consider the dynamical system $\dot{\omega} = A_c\omega$, where $\omega = [\omega_1, \ldots, \omega_n]^T \in \mathcal{R}^n$ and $A_c = A + GC$. Define the change of coordinates $\Omega = \hat{P}\omega$. We will prove below that, along the trajectories of the dynamical system $\dot{\omega} = A_c\omega$, the Lyapunov inequality $\frac{d}{dt}(\Omega^T\Omega) \le -\alpha\Omega^T\Omega$ is satisfied with α being a positive constant. Since $\Omega^T\Omega = \omega^T P\omega$ by construction, this will imply that (2.1) is satisfied with $\nu_1 = \alpha\lambda_{min}(P)$.

The inverse transformation relating ω to Ω is given by[5]

$$\omega_i = \sum_{l=1}^{i} \Omega_l \prod_{m=l+1}^{i} k_m = \sum_{l=1}^{i} p_k(l+1, i)\Omega_l, \tag{A.2}$$

where $p_k(n_1, n_2) \triangleq \prod_{m=n_1}^{n_2} k_m$. Note that $p_k(n_1, n_2) = 1$ if $n_1 > n_2$. For convenience, we introduce the dummy variables $\omega_{n+1} = \Omega_{n+1} = k_{n+1} = 0$ and $\phi_{(n+1,j)} = 0$, $1 \le j \le n+1$. Differentiating $\Omega_i = \omega_i - k_i\omega_{i-1}$, $2 \le i \le n$, we obtain

$$\begin{aligned}
\dot{\Omega}_i = {} & \Big(g_i - k_i g_{i-1} + \tilde{g}_i\Big)\Omega_1 + \phi_{(i,i+1)}\Omega_{i+1} \\
& + \Big(\phi_{(i,i)} - k_i\phi_{(i-1,i)} + k_{i+1}\phi_{(i,i+1)}\Big)\Omega_i \\
& + \Big(\phi_{(i,i)} - k_i\phi_{(i-1,i)} + k_{i+1}\phi_{(i,i+1)}\Big)\sum_{l=2}^{i-1} p_k(l+1, i)\Omega_l \\
& + \sum_{j=2}^{i-1}\left\{(\phi_{(i,j)} - k_i\phi_{(i-1,j)})\sum_{l=2}^{j} p_k(l+1, j)\Omega_l\right\},
\end{aligned} \tag{A.3}$$

$$\begin{aligned}
\tilde{g}_i = {} & \phi_{(i,1)} - k_i\phi_{(i-1,1)} + \Big(\phi_{(i,i)} - k_i\phi_{(i-1,i)} + k_{i+1}\phi_{(i,i+1)}\Big)p_k(2, i) \\
& + \sum_{j=2}^{i-1}(\phi_{(i,j)} - k_i\phi_{(i-1,j)})p_k(2, j).
\end{aligned} \tag{A.4}$$

Note that $|k_i|$, $i = 2, \ldots, n$, are required to be chosen smaller than κ if ρ_{iA} and $\epsilon_{(i,j)}$ are smaller than $\overline{\rho}_A$. The final construction of k_i and $\overline{\rho}_A$ will ensure these inequality conditions. We derive a bound below for $\sum_{i=2}^{n} \Omega_i\dot{\Omega}_i$ assuming these inequalities. Furthermore, since the positive constant $\overline{\rho}_A$ is free to be arbitrarily chosen, we assume $\overline{\rho}_A < 1$.

Using the w-CUDD conditions given in (3.2), for $2 \le i \le n$,

[5]We follow the convention that $\sum_{i=n_1}^{n_2} f_i = 0$ and $\prod_{i=n_1}^{n_2} f_i = 1$ if $n_1 > n_2$.

$$
\begin{aligned}
\Omega_i\dot{\Omega}_i \le{}& \frac{\kappa}{4}|\phi_{(i,i+1)}|\Omega_{i+1}^2 + \frac{1}{\kappa}|\phi_{(i,i+1)}|\Omega_i^2 \\
&+ \Big[-k_i\phi_{(i-1,i)} + \kappa\overline{\rho}_A|\phi_{(i-1,i)}| + \overline{\rho}_A|\phi_{(i-1,i)}|\Big]\Omega_i^2 \\
&+ \sum_{l=2}^{i-1}\frac{(i-2)(\phi_{(i,i)} - k_i\phi_{(i-1,i)} + k_{i+1}\phi_{(i,i+1)})^2}{\kappa|\phi_{(i-1,i)}|}[p_k(l+1,i)]^2\Omega_l^2 \\
&+ \frac{\kappa}{4}|\phi_{(i-1,i)}|\Omega_i^2 + \sum_{j=2}^{i-1}\sum_{l=2}^{j}\frac{(j-1)(i-2)(\phi_{(i,j)} - k_i\phi_{(i-1,j)})^2}{\kappa|\phi_{(i-1,i)}|}[p_k(l+1,j)]^2\Omega_l^2 \\
&+ \frac{\kappa}{4}|\phi_{(i-1,i)}|\Omega_i^2 + \frac{2}{\kappa}\frac{(g_i - k_ig_{i-1} + \tilde{g}_i)^2}{|\phi_{(i-1,i)}|}\Omega_1^2 + \frac{\kappa}{8}|\phi_{(i-1,i)}|\Omega_i^2 \\
={}& \frac{\kappa}{4}|\phi_{(i,i+1)}|\Omega_{i+1}^2 - k_i\phi_{(i-1,i)}\Omega_i^2 + \Big[\kappa\overline{\rho}_A + \overline{\rho}_A + \frac{\overline{\rho}_A}{\kappa} + \frac{5\kappa}{8}\Big]|\phi_{(i-1,i)}|\Omega_i^2 \\
&+ \sum_{l=2}^{i-1} q_{(i,l)}|\phi_{(l-1,l)}|\Omega_l^2 + \frac{2}{\kappa}\frac{(g_i - k_ig_{i-1} + \tilde{g}_i)^2}{|\phi_{(i-1,i)}|}\Omega_1^2, \qquad \text{(A.5)}
\end{aligned}
$$

where, for $i = 2, \dots, n$ and $l = 2, \dots, i-1$,

$$
\begin{aligned}
q(i,l) = \frac{1}{|\phi_{(l-1,l)}|}\Bigg[&\frac{(i-2)(\phi_{(i,i)} - k_i\phi_{(i-1,i)} + k_{i+1}\phi_{(i,i+1)})^2}{\kappa|\phi_{(i-1,i)}|}[p_k(l+1,i)]^2 \\
&+ \sum_{j=l}^{i-1}\frac{(j-1)(i-2)(\phi_{(i,j)} - k_i\phi_{(i-1,j)})^2}{\kappa|\phi_{(i-1,i)}|}[p_k(l+1,j)]^2\Bigg] \\
\le \frac{(n-2)}{\kappa}\Bigg[&(\epsilon_{(i,i)}\rho_{iA} + \rho_{iA}|k_{i+1}| + |k_i|)^2[p_k(l+1,i)]^2\prod_{r=l}^{i-1}\rho_{rA} \\
&+ (n-1)\sum_{j=l}^{i-1}(\epsilon_{(i,j)}\rho_{iA} + \epsilon_{(i-1,j)}|k_i|)^2[p_k(l+1,j)]^2\prod_{r=l}^{j-1}\rho_{rA}\Bigg] \\
\le \frac{(n-2)\overline{\rho}_A}{\kappa}&\Bigg[(1+2\kappa)^2\kappa^{2(i-l)} + (n-1)(1+\kappa)^2\frac{\kappa^{2(i-l)}-1}{\kappa^2-1}\Bigg]. \qquad \text{(A.6)}
\end{aligned}
$$

Choose any positive constant $\kappa^* < \frac{\kappa}{8}$ and choose $\overline{\rho}_A$ to be a positive constant satisfying

$$
\overline{\rho}_A \le \frac{\frac{\kappa}{8} - \kappa^*}{\kappa + 1 + \frac{1}{\kappa} + \frac{(n-2)}{\kappa}\sum_{l=i+1}^{n}\Big[(1+2\kappa)^2\kappa^{2(l-i)} + (n-1)(1+\kappa)^2\frac{\kappa^{2(l-i)}-1}{\kappa^2-1}\Big]}. \qquad \text{(A.7)}
$$

Note that $\overline{\rho}_A < 1$, implying that the inequalities in (A.5) and (A.6) are valid. Inequality (A.5) reduces to

$$
\begin{aligned}
\sum_{i=2}^{n}\Omega_i\dot{\Omega}_i \le{}& -\sum_{i=2}^{n}k_i\phi_{(i-1,i)}\Omega_i^2 + \sum_{i=2}^{n}(\kappa - \kappa^*)|\phi_{(i-1,i)}|\Omega_i^2 \\
&+ \frac{2}{\kappa}\sum_{i=2}^{n}\frac{(g_i - k_ig_{i-1} + \tilde{g}_i)^2}{|\phi_{(i-1,i)}|}\Omega_1^2. \qquad \text{(A.8)}
\end{aligned}
$$

The constants k_i, $i = 2, \dots, n$, are chosen as[6] $k_i = (\kappa - \kappa^*/4)\,\mathrm{sign}(\phi_{(i-1,i)}(0))$. Since

[6]Note that $\phi_{(i-1,i)}$ takes the same sign for all arguments by assumption.

$\Omega_1 = \omega_1$,

$$\dot{\Omega}_1 = (g_1 + \tilde{g}_1)\Omega_1 + \phi_{(1,2)}\Omega_2$$

$$\implies \Omega_1\dot{\Omega}_1 \leq \Big(g_1 + \tilde{g}_1 + \frac{1}{\kappa^*}|\phi_{(1,2)}|\Big)\Omega_1^2 + \frac{\kappa^*}{4}|\phi_{(1,2)}|\Omega_2^2, \tag{A.9}$$

where $\tilde{g}_1 = \phi_{(1,1)} + k_2\phi_{(1,2)}$. Defining G such that[7]

$$G = [g_1, \ldots, g_n]^T = -\hat{P}^{-1}\left[\frac{2}{\kappa}\sum_{i=2}^{n}\frac{\overline{g}_i^2}{|\phi_{(i-1,i)}|} + \overline{g}_1, 0, \ldots, 0\right]^T, \tag{A.10}$$

$$\overline{g}_1 \geq |\phi_{(1,1)}| + |k_2||\phi_{(1,2)}| + \frac{1}{\kappa^*}|\phi_{(1,2)}| + \frac{\kappa^*}{2}|\phi_{(1,2)}|, \tag{A.11}$$

$$\begin{aligned}\overline{g}_i \geq\ & |\phi_{(i,1)}| + |k_i||\phi_{(i-1,1)}| \\ & + \Big(|\phi_{(i,i)}| + |k_i||\phi_{(i-1,i)}| + |k_{i+1}||\phi_{(i,i+1)}|\Big)|p_k(2,i)| \\ & + \sum_{j=2}^{i-1}(|\phi_{(i,j)}| + |k_i||\phi_{(i-1,j)}|)|p_k(2,j)|, \qquad i = 2, \ldots, n,\end{aligned} \tag{A.12}$$

we finally obtain

$$\begin{aligned}\frac{d}{dt}\left(\frac{1}{2}\sum_{i=1}^{n}\Omega_i^2\right) &= \sum_{i=1}^{n}\Omega_i\dot{\Omega}_i \\ &\leq -\frac{\kappa^*}{2}\sum_{i=2}^{n}|\phi_{(i-1,i)}|\Omega_i^2 - \frac{\kappa^*}{2}|\phi_{(1,2)}|\Omega_1^2 \\ &\leq -\kappa^*\sigma\left(\frac{1}{2}\sum_{i=1}^{n}\Omega_i^2\right).\end{aligned} \tag{A.13}$$

Noting that $\sum_{i=1}^{n}\Omega_i^2 = \omega^T P\omega$, (2.1) is satisfied with $\nu_1 = \kappa^*\sigma\lambda_{min}(P)$. ∎

A.3. Proof of Lemma 3. If the w-CUDD constants of A are smaller than $\overline{\rho}_A$, T can be chosen to be the identity matrix. Otherwise, let

$$\rho_0 = \frac{\max\Big\{\max\{\rho_{iA}|i = 2, \ldots, n-1\}, \max\{\epsilon_{i,j}|i = 2, \ldots, n, j = 2, \ldots, i\}\Big\}}{\overline{\rho}_A}, \tag{A.14}$$

$$T = \mathrm{diag}(T_1, \ldots, T_n), \quad T_i = \rho_0^{n_i}, \quad n_i = (n-i)(n-i+1)/2, \quad i = 1, \ldots, n. \tag{A.15}$$

Note that ρ_0 as defined in (A.14) is greater than 1. The (i,j)th element of $\tilde{A}$ is $\tilde{A}_{(i,j)} = (T_i/T_j)\phi_{(i,j)}$, $i = 1, \ldots, n$, $j = 1, \ldots, i+1$, with zeros everywhere else. Using (A.14),

$$\begin{aligned}\frac{|\tilde{A}_{(i,i+1)}|}{|\tilde{A}_{(i-1,i)}|} = \frac{T_i^2}{T_{i-1}T_{i+1}}\frac{|\phi_{(i,i+1)}|}{|\phi_{(i-1,i)}|} &= \frac{1}{\rho_0}\frac{|\phi_{(i,i+1)}|}{|\phi_{(i-1,i)}|} \\ &\leq \frac{\rho_{iA}}{\rho_0} \leq \overline{\rho}_A,\end{aligned} \tag{A.16}$$

[7]This definition of $\overline{g}_i$ implies that the choice of G depends only on the upper diagonal entries and upper bounds on other elements of A.

$$\begin{aligned}\frac{|\tilde{A}_{(i,j)}|}{\sqrt{|\tilde{A}_{(i,i+1)}||\tilde{A}_{(j-1,j)}|}} &= \sqrt{\frac{T_iT_{i+1}}{T_{j-1}T_j}}\frac{|\phi_{(i,j)}|}{\sqrt{|\phi_{(i,i+1)}||\phi_{(j-1,j)}|}}\\ &= \rho_0^{\frac{(j-i-1)(2n-i-j+1)}{2}}\frac{|\phi_{(i,j)}|}{\sqrt{|\phi_{(i,i+1)}||\phi_{(j-1,j)}|}}\\ &\le \frac{\epsilon_{(i,j)}}{\rho_0} \le \overline{\rho}_A, \qquad i=2,\dots,n-1,\ j=2,\dots,i, \end{aligned} \tag{A.17}$$

$$\begin{aligned}\frac{|\tilde{A}_{(n,j)}|}{\sqrt{|\tilde{A}_{(n-1,n)}||\tilde{A}_{(j-1,j)}|}} &= \sqrt{\frac{T_n^3}{T_{j-1}T_jT_{n-1}}}\frac{|\phi_{(n,j)}|}{\sqrt{|\phi_{(n-1,n)}||\phi_{(j-1,j)}|}}\\ &= \frac{1}{\rho_0^{\frac{1+(n-j+1)^2}{2}}}\frac{|\phi_{(n,j)}|}{\sqrt{|\phi_{(n-1,n)}||\phi_{(j-1,j)}|}}\\ &\le \frac{\epsilon_{(n,j)}}{\rho_0} \le \overline{\rho}_A, \qquad j=2,\dots,n. \end{aligned} \tag{A.18}$$

Hence, $\tilde{A}$ is a w-CUDD matrix with w-CUDD constants smaller than $\overline{\rho}_A$. ∎

DOMAIN DEPENDENCE OF SOLUTIONS TO COMPRESSIBLE NAVIER–STOKES EQUATIONS*

P. I. PLOTNIKOV† AND J. SOKOLOWSKI‡

Abstract. The minimization of the drag functional for the stationary, isentropic, compressible Navier–Stokes equations (NSE) in three spatial dimensions is considered. In order to establish the existence of an optimal shape, the general result on compactness of families of generalized solutions to the NSE is established within in the framework of the modern theory of nonlinear PDEs [P. L. Lions, *Mathematical Topics in Fluid Dynamics. Vol.* 2. *Compressible Models*, Oxford University Press, Clarendon Press, New York, 1998], [E. Feireisl, *Dynamics of Viscous Compressible Fluids*, Oxford University Press, Oxford, UK, 2004]. The family of generalized solutions to the NSE is constructed over a family of admissible domains $\mathcal{U}_{ad}$. Any admissible domain $\Omega = B \setminus S$ contains an obstacle S, e.g., a wing profile. Compactness properties of the family of admissible domains in the form of the condition $(\mathcal{H}_\Omega)$ is imposed. Roughly speaking, the condition $(\mathcal{H}_\Omega)$ is satisfied, provided that for any sequence of admissible domains $\{\Omega_n\} \subset \mathcal{U}_{ad}$ there is a subsequence convergent both in Hausdorff metrics and in the sense of Kuratowski and Mosco. The analysis is performed for the adiabatic constant $\gamma > 1$ in the pressure law $p(\rho) = \rho^\gamma$ and it is based on the technique used in [P. I. Plotnikov and J. Sokolowski, *Comm. Math. Phys.,* 258 (2005), pp. 567–608] in the case of discretized NSE. The result is a generalization to the stationary equations with $\gamma > 1$ of the results obtained in [E. Feireisl, A. H. Novotný, and H. Petzeltová, *Math. Methods Appl. Sci.,* 25 (2002), pp. 1045–1073], [E. Feireisl, *Appl. Math. Optim.,* 47 (2003), pp. 59–78] for evolution equations within the range $\gamma > 3/2$ for the adiabatic ratio.

Key words. Navier–Stokes equations, compressible fluids, shape optimization

DOI. 10.1137/050635304

1. Introduction.

1.1. Shape optimization. In the present paper, a class of shape optimization problems for stationary isothermal compressible Navier–Stokes equations (NSE) is considered. Usually the mathematical analysis of such problems includes the following:

- Proof of the existence of optimal shapes for a sufficiently large class of admissible domains.
- Derivation of necessary optimality conditions, which characterize an optimal domain and can be used for the numerical solution of the shape optimization problem.
- The convergence proof for the numerical method, which can be used to evaluate an optimal shape.

To the best of our knowledge, only the first point is studied in the literature for the compressible NSE and drag minimization. We refer the reader to [10] for the existence results for shape optimization problems in the case of evolution equations for the adiabatic constant $\gamma > 3/2$; see also [9] for related results. In the present paper the case of $\gamma > 1$ is considered in three spatial dimensions. The technique used

is introduced in [12], [24], and [25]. The optimality conditions for drag minimization are derived in [27].

We restrict ourselves to the first issue on the above list of problems to be solved, which is already quite difficult, since there are no existence results for the PDE model itself in the range of parameters we are going to consider, i.e., for the adiabatic constant $\gamma > 1$ in the law $p(\rho) = \rho^\gamma$, which gives the pressure p of the fluid in the function of its density ρ in the isothermal regime. We also point out that the existence of generalized solutions for such equations with nonhomogeneous boundary conditions for a full range of parameters is an open problem; for some results in this direction we refer to [15], [16], [17] for two spatial dimensions and for special geometry of the flow region.

We show that, under appropriate assumptions, the convergence of the sequence of admissible domains implies the convergence of the associated sequence of shape functionals. To make our analysis representative we consider the drag functional, which is the standard choice in view of possible applications in the shape optimization of a wing.

A related shape optimization problem is considered in [10] for evolution equations, and with the adiabatic constant $\gamma > 3/2$. We consider the case of $\gamma > 1$ using the same technique as in [12], [25]. The novelty of our results, in comparison with paper [25], is the PDE model; i.e., we consider here the stationary problem and use a far-reaching approach to the problem based on the new kinetic formulation to the mass balance equation. In [25] the discretized problem introduced in [18] is considered; such a problem depends on the parameter $\alpha > 0$ of the time discretization of evolution equations [18], and the limit case of $\alpha = 0$ is the stationary problem.

The outline of the paper is the following. In section 1.2 an example of a shape optimization problem is presented and the existence result of optimal shapes is given. In section 1.3 the stationary NSE are introduced, and generalized solutions are defined. In section 1.4 the main result of the paper on compactness of generalized solutions and solvability of the drag minimization problem is presented. In section 2 local a priori estimates for generalized solutions are derived. In section 3 weak limits of sequences of generalized solutions are characterized. In section 4 the so-called effective viscous flux is defined and some properties of the viscous flux are obtained. In section 5 the oscillation defect measure is introduced for sequences of densities and its boundedness is proved for generalized solutions. In section 6 the kinetic formulation for the mass balance equation is derived in the form of a transport equation for the distribution function, which characterizes the Young measure associated with weakly convergent sequences of densities. In section 7 the renormalization of the kinetic formulation for the mass balance equation is performed, which shows the strong convergence of sequences of densities. Finally, in section 8 the proof of the main result of the paper is completed.

Since all of our presented results for the adiabatic ratio $\gamma > 1$ seem to be new, we provide the complete proofs for the convenience of the reader. To our knowledge such proofs are not known in the literature. The proof technique was introduced by Lions and by Feireisl, Novotný, and Petzeltová and it is adapted to the specific problem along the lines of [12], [24], and [25].

1.2. Example of the existence of an optimal shape. We use the notation introduced below. Let $(\mathbf{u}, \rho)$ be a generalized solution to the boundary value problem (1.3) posed in the geometrical domain $\Omega = B \setminus S$, where $B \subset \mathbb{R}^3$ is a fixed hold-all domain and S is an obstacle. The family of admissible domains $\Omega \in \mathcal{U}_{\rm ad}$ includes

domains with obstacles of the volume bounded from below, i.e., $\mathrm{meas}(S) \geq \mathrm{Vol}$ for all admissible domains $\Omega = B \setminus S$. Let us consider the problem of drag minimization, in which the shape functional $J(\Omega)$ takes the form

$$J(\Omega) := \mathbf{J}(\rho, \mathbf{u}, \Omega),$$

where the functional $\mathbf{J}(\rho, \mathbf{u}, \Omega)$ is defined in (1.5), over such a family of admissible domains, and let us assume that the set of generalized solutions to (1.3) over admissible domains $\Omega \in \mathcal{U}_{\mathrm{ad}}$ is nonempty. If the family $\mathcal{U}_{\mathrm{ad}}$ is compact with respect to the convergence defined by the condition $(\mathcal{H}_\Omega)$, then there is an optimal domain $\Omega^* = B \setminus S^*$ such that

$$J(\Omega^*) \leq J(\Omega)$$

for all $\Omega \in \mathcal{U}_{\mathrm{ad}}$. We prove the existence result without any regularity assumptions on the boundaries of obstacles. In fact, we prove a compactness result for the family of solutions to the NSE so that the existence of optimal shapes is a simple corollary of the theorem on the compactness of the set of generalized solutions.

1.3. The problem formulation. Suppose that compressible Newtonian fluid occupies the bounded region $\Omega \subset \mathbb{R}^3$. We will assume that $\Omega = B \setminus S$, where B is an open sufficiently large hold all with a sectionally smooth boundary containing a compact obstacle S. We could take, e.g., for B a ball of radius R, $B = \{x | |x| \leq R\}$. We do not impose restrictions on the topology of the flow region. The cases of S with a finite number of connected components or $S = \emptyset$ are taken into consideration. The fluid density $\rho : \Omega \mapsto \mathbb{R}^+$ and the velocity field $\mathbf{u} : \Omega \mapsto \mathbb{R}^3$ are governed by the NSE

$$-\nu\Delta\mathbf{u} - \xi\nabla\mathrm{div}\,\mathbf{u} + \rho\mathbf{u}\nabla\mathbf{u} + \nabla p(\rho) = \rho\mathbf{f}, \quad \mathrm{div}\ (\rho\mathbf{u}) = 0, \tag{1.1}$$

where ν, ξ are positive viscous coefficients and $\mathbf{f} : \Omega \mapsto \mathbb{R}^3$ is a given continuous vector field. We suppose that the flow is barotropic and $p(\rho) = \rho^\gamma$ with the adiabatic constant $\gamma > 1$. If the viscous stress tensor is defined by the equality

$$\Pi = \nu(\nabla\mathbf{u} + \nabla\mathbf{u}^\top) + (\xi - \nu)\mathrm{div}\,\mathbf{u}\,\mathbf{I}, \tag{1.2}$$

then the governing equations can be written in the equivalent divergence form

$$\mathrm{div}\,(\rho\mathbf{u} \otimes \mathbf{u}) + \nabla p(\rho) - \rho\mathbf{f} = \mathrm{div}\,\Pi, \quad \mathrm{div}\,(\rho\mathbf{u}) = 0 \ \text{ in } \ \Omega. \tag{1.3a}$$

In view of possible applications, e.g., to the shape optimization problem of a wing, it is assumed that the velocity field satisfies the nonhomogeneous boundary condition

$$\mathbf{u} = 0 \ \text{ on } \ \partial S, \quad \mathbf{u} = \mathbf{U}^\infty \ \text{ on } \ \partial B, \tag{1.3b}$$

and the density distribution is prescribed on the entrance set

$$\rho = \rho^\infty \ \text{ on } \ \Sigma^+ = \{x \in \partial B : \ \mathbf{U}^\infty \cdot \mathbf{n}(x) < 0\}. \tag{1.3c}$$

Here $\mathbf{n}$ is the outward unit normal vector to $\partial\Omega$. It is assumed that $\mathbf{U}^\infty \in \mathbb{R}^3$ is a given vector and ρ^∞ is a given nonnegative constant.

Boundary condition (1.3b) can be written in the form of the equality $\mathbf{u} = \mathbf{u}^\infty$ on $\partial\Omega$, where $\mathbf{u}^\infty(x)$ is a smooth function defined for any $x \in \mathbb{R}^3$, which vanishes in the vicinity of S and coincides with $\mathbf{U}^\infty$ in an open neighborhood of ∂B. The physical

quantities which characterize the flow include the total energy $\mathbf{E}$, the volume rate of energy dissipation $\mathbf{D}$, and the drag $\mathbf{J}$, and are defined by

$$\mathbf{E} = \int_\Omega \left(\frac{1}{2}\rho|\mathbf{u}|^2 + \frac{\rho^\gamma}{\gamma - 1} \right) dx, \quad \mathbf{D} = \int_\Omega (\nu|\nabla \mathbf{u}|^2 + \xi|\operatorname{div} \mathbf{u}|^2)\, dx, \tag{1.4}$$

$$\mathbf{J} = -\mathbf{U}^\infty \cdot \int_{\partial S} (\Pi - p(\rho)\mathbf{I}) \cdot \mathbf{n}\, dS.$$

The drag $\mathbf{J}$ accounts for the reaction of the surrounding fluid on the obstacle S. For our purposes, the formula for the drag can be written in the equivalent form

$$\mathbf{J}(\rho, \mathbf{u}, \Omega) = \int_\Omega (\Pi - \rho \mathbf{u} \otimes \mathbf{u} - p(\rho)\mathbf{I}) : \nabla \mathbf{u}^\infty dx + \int_\Omega (\mathbf{U}^\infty - \mathbf{u}^\infty) \cdot \mathbf{f} \rho dx. \tag{1.5}$$

We will consider the solutions to problems (1.3) for which the density is nonnegative and the total energies are bounded from above by some positive constant C_Ω. In what follows we will denote by c various constants depending only on $\mathbf{E}$, data $\|\mathbf{f}\|_{C(B)}$, ρ^∞, $\|\mathbf{u}^\infty\|_{C^1(B)}$, material constants γ, ν , ξ, and the domain B.

In this paper the standard notation is used for the function spaces. The space $H^{1,r}(\Omega)$ is the Sobolev space of functions integrable along with the first order generalized derivatives in $L_r(\Omega)$ equipped with its natural norm. For $r = 2$ we use the notation $H^{1,2}(\Omega)$ rather than $H^1(\Omega)$; the notation $H_0^{1,r}(\Omega)$ stands for the closure of $C_0^\infty(\Omega)$ in the norm of $H^{1,r}(\Omega)$.

DEFINITION 1.1. *For given $\mathbf{U}^\infty \in \mathbb{R}^3$ and $\mathbf{f} \in C(\Omega)^3$, a generalized solution to problem* (1.3) *is the pair $(\rho, \mathbf{u})$, where $\rho \in L^\gamma(\Omega)$ is a nonnegative function in Ω and $\mathbf{u} - \mathbf{u}^\infty \in H_0^{1,2}(\Omega)$, which satisfies the following conditions:*

(a) *The scalar function $\rho|\mathbf{u}|^2$ is integrable in Ω, i.e., the total energy $\mathbf{E}$ of the flow is finite. The mass density and the velocity field satisfy the energy inequality*

$$\nu\|\nabla(\mathbf{u} - \mathbf{u}^\infty)\|^2_{L^2(\Omega)} + \xi\|\operatorname{div}(\mathbf{u} - \mathbf{u}^\infty)\|^2_{L^2(\Omega)} + \int_\Omega \rho \mathbf{u} \otimes \mathbf{u} : \nabla \mathbf{u}^\infty\, dx$$

$$+ \int_\Omega p(\rho) \operatorname{div} \mathbf{u}^\infty\, dx - \int_\Omega \rho \mathbf{f} \cdot (\mathbf{u} - \mathbf{u}^\infty)\, dx + \frac{1}{\gamma - 1} \int_{\Gamma^+} (\rho^\infty)^\gamma (\mathbf{U}^\infty \cdot \mathbf{n})\, d\Gamma \le 0. \tag{1.6}$$

(b) *For all vector fields $\varphi \in C_0^1(\Omega)^3$,*

$$\int_\Omega \Big(\rho \mathbf{u} \otimes \mathbf{u} + p(\rho) \Big) : \nabla \varphi\, dx + \int_\Omega \rho \mathbf{f} \cdot \varphi\, dx = \int_\Omega \Pi : \nabla \varphi\, dx. \tag{1.7a}$$

(c) *The integral identity*

$$\int_\Omega \Big(G(\rho)\mathbf{u} \cdot \nabla \psi + \big(G(\rho) - G'(\rho)\rho\big)\psi \operatorname{div} \mathbf{u} \Big)\, dx - \int_{\Sigma^+} \psi G(\rho^\infty) \mathbf{U}^\infty \cdot \mathbf{n} d\Sigma = 0 \tag{1.7b}$$

holds for all functions $\psi \in C^1(\Omega)$ vanishing on $\Sigma^- = \partial B \setminus \Sigma^+$, and all functions $G \in C^1_{loc}[0, \infty)$ with the properties

$$\limsup_{r \to \infty} |G(r)|/r < \infty, \quad [0, \infty) \ni r \mapsto G(r) - G'(r)r \in \mathbb{R}$$

continuous and bounded.

Condition (c) of the above definition means that we consider the renormalized weak solutions of the stationary problem; see [11] for a discussion. Such a definition simplifies further analysis without any loss of generality.

Remark 1.1. Denote by $\Sigma^- = \partial B \setminus \Sigma^+$ the *exit* part of the boundary ∂B. It follows from the definition of generalized solutions that the extensions of the density and of the velocity vector field onto $\mathbb{R}^3$, given by the equalities

$$\begin{aligned} \rho(x) = 0 \ \text{ in } \ S, \qquad \rho(x) = \rho^\infty \ \text{ in } \ \mathbb{R}^3 \setminus (B \cup \Sigma^-), \\ \mathbf{u} = 0 \ \text{ in } \ S, \qquad \mathbf{u} = \mathbf{U}^\infty \ \text{ in } \ \mathbb{R}^3 \setminus B \end{aligned} \tag{1.8}$$

satisfy the integral identity

$$\int_{\mathbb{R}^3} \Big(G(\rho)\mathbf{u} \cdot \nabla\psi + \big(G(\rho) - G'(\rho)\rho\big)\psi \operatorname{div} \mathbf{u} \Big)\, dx = 0 \tag{1.9}$$

for any functions $\psi \in C_0^1(\mathbb{R}^3)$ vanishing near Σ^-.

1.4. Preliminaries and main results. The cost functional for shape optimization problems is the drag $\mathbf{J}(\rho, \mathbf{u}, \Omega)$ defined by formula (1.5). In applications, the drag is usually minimized within the class of admissible shapes. To the best of our knowledge there are no results on the shape optimization problem in the framework of generalized solutions to stationary problems for the adiabatic constant $\gamma > 1$; the case of evolution equations for the adiabatic constant $\gamma > 3/2$ is considered in [10].

The drag depends on the solution $(\rho, \mathbf{u})$ to problem (1.3); however, such a solution, if it does exist, is not in general unique. We point out that the existence of solutions for the adiabatic constant $\gamma \geq 1$ in three spatial dimensions is in general an open and difficult problem [19]. The case of discretized problems is considered in [25] for $\gamma \geq 1$; however, no dependence of solutions on geometrical domains is considered in [25]. On the other hand, the case of drag minimization in two spatial dimensions is studied in [24]. Furthermore, the drag depends on an admissible shape of the obstacle S. The dependence of the drag on the admissible shapes is twofold: first, it depends directly on Ω since the integrals in (1.5) are defined over Ω, and second, it depends on the generalized solutions to the NSE defined in Ω. The restrictions on the shapes of admissible obstacles S are defined in such a way that the set of admissible shapes and the set of the associated generalized solutions are compact. The precise conditions for admissible shapes are established below in the form of condition $(\mathcal{H}_\Omega)$. In the present paper we do not derive the necessary optimality conditions for the problem of drag minimization; we prove only the compactness of the set of solutions over the set of admissible shapes, which leads to the existence of an optimal shape, provided the set of generalized solutions is nonempty. The optimality conditions for the drag minimization problem will be given in forthcoming paper [27].

We are now in a position to formulate the main result of the paper.

Suppose that a sequence of flow domains $\Omega_n = B \setminus S_n$ satisfies the following three conditions, which we refer to collectively as condition $(\mathcal{H}_\Omega)$.

Condition $(\mathcal{H}_\Omega)$.

(a) There is a compact $K_S \Subset B$ such that $\cup_n S_n \subset K_S$.

(b) If a compact set $K \Subset \Omega$, then $K \Subset \Omega_n$ for all large n.

(c) If $w_n \to w$ weakly in $H^{1,2}(B)$ and $w_n \in H_0^{1,2}(\Omega_n)$, then $w \in H_0^{1,2}(\Omega)$.

In this case we will write

$$\Omega_n \overset{\mathcal{H}}{\to} \Omega.$$

It is easily seen that the convergence of the sequence Ω_n both in the Hausdorff metrics and in the sense of Kuratowski and Mosco implies all three conditions listed in $(\mathcal{H}_\Omega)$.

We deal with the complicated system of nonlinear PDEs. Therefore, we need stronger conditions on the convergence of geometrical domains, compared to the classical Kuratowski–Mosco convergence [14], which is adapted to the linear elliptic case. In particular, our conditions are more restrictive when compared to the Kuratowski–Mosco convergence of domains Ω_n.

The first main result of the paper is the following compactness theorem.

THEOREM 1.2. *Assume that there are a sequence (Ω_n) of domains which converges $\Omega_n \overset{\mathcal{H}}{\to} \Omega$ and a sequence of generalized solutions $\{\rho_n, \mathbf{u}_n\}$ to the compressible NSE*

$$\operatorname{div}(\rho_n \mathbf{u}_n \otimes \mathbf{u}_n) + \nabla p(\rho_n) - \rho \mathbf{f} = \operatorname{div} \Pi, \quad \operatorname{div}(\rho_n \mathbf{u}_n) = 0 \ \text{ in } \ \Omega_n, \tag{1.10a}$$

satisfying the boundary conditions

$$\mathbf{u}_n = 0 \ \text{ on } \ \partial S_n, \quad \mathbf{u}_n = \mathbf{U}^\infty \ \text{ on } \ \partial B, \quad \rho_n = \rho^\infty \ \text{ on } \ \Sigma^+. \tag{1.10b}$$

Suppose also that the total energies of the sequence $(\rho_n, \mathbf{u}_n)$ of generalized solutions to problem (1.10) *are uniformly bounded by a constant c_Ω,*

$$\mathbf{E}_n = \int_{\Omega_n} \left(\frac{1}{2} \rho |\mathbf{u}_n|^2 + \frac{1}{\gamma - 1} \rho_n^\gamma \right) dx \le c_\Omega. \tag{1.11}$$

Then there is a subsequence of the sequence $\{\rho_n, \mathbf{u}_n\}$, still denoted by $\{\rho_n, \mathbf{u}_n\}$, such that for any $r < \gamma$,

$$\rho_n \to \rho \ \text{ in } \ L^r(B), \quad p(\rho_n) \to p(\rho) \ \text{ in } \ L^1_{loc}(\Omega), \quad \mathbf{u}_n \to \mathbf{u} \ \text{ weakly in } \ H^{1,2}(B).$$

The pair of functions $(\rho, \mathbf{u})$ serves as a generalized solution to problem (1.3) *for the limit domain Ω; furthermore, the shape functionals converge for $n \to \infty$,*

$$\mathbf{J}(\rho_n, \mathbf{u}_n, \Omega_n) \to \mathbf{J}(\rho, \mathbf{u}, \Omega). \tag{1.12}$$

1.5. Shape optimization. We provide an existence result for the drag minimization. We also list, for the convenience of the reader, the related recent results on the compactness of the solutions to compressible NSE.

In order to compare our results with the recent results given in the literature on the subject, we note that for fixed S and $\gamma > 5/4$, compactness results were obtained in [12]. In the general case, the compactness of solutions to boundary value problems for NSE with $\gamma > 3/2$ was proved in [10] under the assumption that ∂S_n satisfy the "uniform thickness" condition.

Theorem 1.2 leads to the following result on the solvability of the shape optimization problem, which is the second main result of the paper. In order to formulate the result we introduce some notation. Choose an arbitrary continuous function $h : \mathbb{R}^3 \mapsto \mathbb{R}^+$ which is positive with a possible exception of a null capacity set. Choose also a positive constant V and a compact $K \Subset B$ with meas $K \ge V$. Denote by $\mathfrak{O}(h, K, V)$ the family of all compact obstacles $S \subset K$ with meas $K \ge V$ satisfying the following conditions.

Condition S. For each $x \in S$, there are $a^\pm(x) \in \mathbb{R}^3$ so that S contains the plane triangle $x + \Delta(x)$ with $\Delta(x) = \{ sa^- + ta^+ : s, t \ge 0, \, s + t \le 1 \}$ and

$$\min \{ |a^\pm(x)|, \ |a^+(x) \times a^-(x)| \} \ge h(x). \tag{1.13}$$

In particular, the angle $\vartheta(x) = \arcsin\big(|a^+(x) \times a^-(x)||a^-(x)|^{-1}|a^+(x)|^{-1}\big)$ satisfies the inequalities $0 < \vartheta(x) < \pi$ quasi everywhere (q.e.) in S. This condition is fulfilled, for example, if an obstacle admits a finite partition, such that every component of the partition is starlike with respect to two distinct points.

For positive C and compact $S \Subset B$, denote by $\mathcal{E}(C,S)$ the family of generalized solutions to problem (1.3) in domain $\Omega = B \setminus S$ with the total energies bounded from above by a constant, $\mathbf{E} \le C$. The following theorem gives sufficient conditions for the solvability of the drag minimization problem in the class $\mathfrak{O}(h,K,V)$.

THEOREM 1.3. *Suppose that there exist a compact $S \in \mathfrak{O}(h,K,V)$ and a generalized solution $\{\rho,\mathbf{u}\} \in \mathcal{E}(C,S)$ such that $\mathbf{J}(\rho,\mathbf{u},B\setminus S) < \infty$. Then there are $S^* \in \mathfrak{O}(h,K,V)$ and $\{\rho^*,\mathbf{u}^*\} \in \mathcal{E}(C,S^*)$ such that*

$$\mathbf{J}(\rho^*,\mathbf{u}^*,B\setminus S^*) = \inf_{S\in\mathfrak{O}(h,K,V)} \inf_{\{\rho,\mathbf{u}\}\in\mathcal{E}(C,S)} \mathbf{J}(\rho,\mathbf{u},B\setminus S). \tag{1.14}$$

Proof. Choose a minimizing sequences S_n, $(\rho_n,\mathbf{u}_n)$ so that

$$\mathbf{J}(\rho_n,\mathbf{u}_n,B\setminus S_n) \to \inf_{S\in\mathfrak{O}(h,K,V)} \inf_{\{\rho,\mathbf{u}\}\in\mathcal{E}(C,S)} \mathbf{J}(\rho,\mathbf{u},B\setminus S) \ \text{ as } \ n\to\infty.$$

Without any loss of generality, we can assume that the sequence S_n converges in the Hausdorff metric to some compact set $S^* \in \mathfrak{O}(h,K,V)$. By Theorem 1.2, it suffices to prove that

$$\Omega_n = B\setminus S_n \xrightarrow{\ \mathcal{H}\ } B\setminus S^* = \Omega^*.$$

Note that conditions (a) and (b) in $(\mathcal{H}_\Omega)$ follow from the definition of the class $\mathfrak{O}(h,K,V)$ and from the convergence of the sequence S_n in the Hausdorff metric. In order to prove (c) in $(\mathcal{H}_\Omega)$, let us consider an arbitrary sequence $w_n \in H^{1,2}_0(B)$ such that $w_n \to w$ weakly in $H^{1,2}(B)$ and $w_n \in H^{1,2}_0(\Omega_n)$. Without any loss of generality, we can assume that w_n vanishes on $\mathbb{R}^3\setminus\Omega_n$ and w is quasi continuous in $\mathbb{R}^3$. It is necessary to prove that $w \in H^{1,2}_0(\Omega)$. By the Hedberg approximation theorem (see [13]), it is sufficient to show that $w = 0$ q.e. on S^*.

To this end, we choose an arbitrary $x^* \in S^*$ with $h(x^*) > 0$ and note that $x^* = \lim_{n\to\infty} x_n \in S_n$. After passing to a subsequence we can assume that the sequence $a^\pm(x_n)$ converges to vectors $a^\pm(x^*)$ satisfying (1.13). Denote by $\mathcal{O}_n : \mathbb{R}^3 \to \mathbb{R}^3$ the orthogonal linear mapping, which maps $span\{a^\pm(x_n)\}$ onto the coordinate plane $\Pi = \{x\cdot\mathbf{e}_3 = 0\}$, and set

$$W_n(y) = w_n(x_n + \mathcal{O}_n^{-1}y), \quad b^\pm = \mathcal{O}a^\pm(x_n).$$

Since $\mathcal{O}_n \to \mathcal{O}^*$, the functions W_n converge weakly in $H^{1,2}(\mathbb{R}^3)$ and strongly in $L^2(\Pi)$ to $W(y) = w(x^* + \mathcal{O}^{*-1}y)$. Noting that W_n vanishes on the triangle $\mathcal{O}_n\Delta(x_n) \subset \Pi$ we can conclude from this that $W = 0$ on $\mathcal{O}^*\Delta(x^*)$, and hence $w = 0$ on $x^* + \Delta(x^*)$. Since the capacity of the plane disk of radius r is equal to $2r/\pi^2$, the inequality $\operatorname{cap}\,\Delta(x^*)\cap B(x^*,r) \ge r\vartheta(x^*)/\pi^3$ holds true for all $r < h(x^*)$, and hence

$$\liminf_{r\to 0} \frac{\operatorname{cap}\,\Delta(x^*)\cap B(0,r)}{\operatorname{cap}\,B(0,r)} \ge c(x^*) > 0.$$

From this and the above quasi-continuity property of w we can deduce $w(x^*) = 0$. Therefore, $w = 0$ q.e. in S and the proof of the theorem is completed. ∎

Remark 1.2. The minimal value of the drag in the right-hand side of (1.14) depends on V and a choice of a compact K and energy bound C. It increases in V and decreases in C and K.

Remark 1.3. A typical obstacle satisfying the conditions of Theorem 1.3 is a union of starlike bodies endowed with a system of plane wings. The case of curvilinear wings also can be included if we replace $\Delta(x)$ with $g(\Delta(x))$, where $g : \mathbb{R}^3 \to \mathbb{R}^3$ is an arbitrary bi-Lipschitz mapping with $g(0) = 0$.

To the best of our knowledge, there are no global results on the solvability of spatial stationary problems for compressible NSE with nonhomogeneous boundary conditions even for large γ. In this connection we note that there is a significant difference between the question on existence of solutions to boundary value problem (1.3) and the question on solvability of shape optimization problem (1.14). Thus, due to Remark 1.2, the conditions of Theorem 1.3 will be satisfied if there exists *at least one* obstacle S for which problem (1.3) has a finite energy solution. Such a solution can be constructed in the case when both B and S have a spherical symmetry or in the case when ∂S is a smooth surface sufficiently close to ∂B. This condition is also satisfied for sufficiently small data, since in such a case the existence of local solutions is proved at least for the homogeneous boundary conditions. We refer also to [15], [16], [17], [21] for the local existence results in two spatial dimensions with nonhomogeneous boundary conditions.

The remaining part of the paper is devoted to the proof of Theorem 1.2. We begin with the derivation of certain local a priori estimates for the generalized solutions to problem (1.3).

2. A priori estimates. In this section we prove the following theorem on local integrability of generalized solutions; cf. [12], [25], [26].

THEOREM 2.1. *Let $(\rho, \mathbf{u})$ be a generalized solution to problem* (1.3)*, and let Ω' be a subdomain of Ω with dist $(\Omega', \partial\Omega) > d > 0$. Then for $\kappa = 2(\gamma - 1)/(\gamma + 2) > 0$,*

$$\|\rho\mathbf{u}^2\|_{L^{1+\kappa}(\Omega')} \le cd^{-1}, \quad \|\rho\|_{L^{\gamma(1+\kappa)}(\Omega')} \le cN(\Omega'), \tag{2.1}$$

where the constant N depends only on Ω'.

The proof of Theorem 2.1 is divided into a sequence of lemmas. The first lemma gives the estimate of the rate of energy dissipation in terms of the total energy of the fluid.

LEMMA 2.2. *Under the assumptions of Theorem* 2.1*, the velocity vector field is bounded,*

$$\|\mathbf{u}\|_{H^{1,2}(\Omega)} \le c, \tag{2.2}$$

where the constant c depends only on the data of the boundary value problem.

Proof. The proof follows from condition (a) in the definition of generalized solutions to problem (1.3) and from the obvious inequalities

$$\|\mathbf{u}\|_{H^{1,2}(\Omega)} \le c\|\nabla(\mathbf{u} - \mathbf{u}^\infty)\|_{L^2(\Omega)} + \|\mathbf{u}^\infty\|_{C^1(\Omega)},$$

$$\int_\Omega \rho|\mathbf{f} \cdot (\mathbf{u} - \mathbf{u}^\infty)|\, dx \le c(\gamma, B)\|\mathbf{f}\|_{C(\Omega)}(\mathbf{E} + 1)(\|\mathbf{u}^\infty\|_{C^1(\Omega)} + 1). \qquad \square$$

Choose a domain Ω_0 with a smooth boundary so that

$$\Omega' \Subset \Omega_0 \Subset \Omega, \quad \text{dist } (\partial\Omega, \Omega_0) \ge d/3, \quad \text{dist } (\partial\Omega_0, \Omega')) \ge d/3\,.$$

The second lemma shows that the Newtonian potential of the pressure is uniformly bounded on Ω_0.

LEMMA 2.3. *Under the assumptions of Theorem* 2.1,

$$\operatorname*{ess\,sup}_{x\in\Omega_0}\int_\Omega \frac{\rho^\gamma(y)}{|x-y|}dy \le cd^{-1}\,. \tag{2.3}$$

Proof. Introduce the symmetric, nonnegative, matrix-valued function

$$\mathcal{E}=(\mathcal{E}_{i,j})_{3\times 3},\quad \mathcal{E}_{i,j}=\rho u_iu_j+p(\rho)\delta_{i,j},\quad \operatorname{Tr}\mathcal{E}=\rho|\mathbf{u}|^2+3p(\rho),$$

and rewrite integral identity (1.7a) in the form

$$\int_\Omega(\mathcal{E}-\Pi):\nabla\varphi=\int_\Omega\rho\mathbf{f}\cdot\varphi\,dy\quad\text{ for all }\ \varphi\in H_0^{1,2}(\Omega)^3\,. \tag{2.4}$$

Fix an arbitrary $x\in\Omega_0$ and set

$$\mathcal{M}_0(s)=\int_{B(x,s)}\mathbf{n}\otimes\mathbf{n}:\mathcal{E}(y)\,dy,\quad \mathcal{M}_1(s)=\int_{B(x,s)}\operatorname{Tr}\mathcal{E}(y)\,dy,$$
$$\text{where }\ \mathbf{n}=|y-x|^{-1}(y-x)\,.$$

Next choose positive $r<R\le d/3$, $\delta\in[0,R-r)$, $s\in[r,R-\delta)$, and a sequence of continuous functions $h_\delta(t)$ with $h_\delta(t)=1$ for $t\le s$, $h_\delta(s)=0$ for $t\ge s+\delta$, and $h_k'(t)=-1/\delta$ for $t\in(s,s+\delta)$. Substituting the vector function $\varphi(y)=h_\delta(|y-x|)(y-x)$ into (2.4) and taking into account that the functions $\mathcal{M}_j(s), j=0,1$, are absolutely continuous on the interval $[r,R]$, followed by the limit passage $\delta\to 0$, leads to

$$\mathcal{M}_1(s)-s\mathcal{M}_0'(s)=\int_{B(x,s)}\operatorname{Tr}\Pi\,dy-s\int_{\partial B(x,s)}\mathbf{n}\otimes\mathbf{n}:\Pi\,dS-\int_{B(x,s)}\rho(y-x)\cdot\mathbf{f}(y)dy$$

for almost everywhere (a.e.) $s\in(0,R]$. Multiplying both sides of this equality by s^{-2} and integrating the result over the interval $(r,R]$, we find that

$$\int_{(r,R]}\left(\frac{\mathcal{M}_1(s)}{s^2}-\frac{\mathcal{M}_0'(s)}{s}\right)ds=\frac{1}{r}\int_{B(x,r)}\operatorname{Tr}\Pi\,dy$$
$$-\frac{1}{R}\int_{B(x,R)}\operatorname{Tr}\Pi\,dy+\mathfrak{S}\Pi(x,r,R)-\int_{B(y,R)}k_{r,R}(y-x)\mathbf{f}(y)\rho(y)\,dy \tag{2.5}$$

with

$$k_{r,R}(x)=\min\{r^{-1},|x|^{-1}\}-R^{-1},$$
$$\mathfrak{S}\Pi(x,r,R)=\int_{r<|y|<R}\frac{1}{|x-y|}(\mathbf{I}-\mathbf{n}\otimes\mathbf{n}):\Pi(y)\,dy.$$

It is easily seen that

$$\int_{(r,R]}\Big(s^{-2}\mathcal{M}_1(s)-s^{-1}\mathcal{M}_0'(s)\Big)\,ds$$
$$=\int_{(r,R]}\Big(s^{-2}\mathcal{M}_1(s)-s^{-1}\mathcal{M}_1'(s)\Big)\,ds+\int_{(r,R]}s^{-1}d(\mathcal{M}_1(s)-\mathcal{M}_0(s)). \tag{2.6}$$

Integration by parts in the integrals on the right-hand side of (2.6) gives

(2.7)
$$\int_{(r,R]}\Big(s^{-2}\mathcal{M}_1(s)-s^{-1}\mathcal{M}'_1(s)\Big)\,ds=\frac{1}{r}\int_{B(y,r)}\operatorname{Tr}\mathcal{E}(y)\,dy-\frac{1}{R}\int_{B(y,R)}\operatorname{Tr}\mathcal{E}(y)\,dy,$$
$$\int_{(r,R]}s^{-1}d(\mathcal{M}_1(s)-\mathcal{M}_0(s))=\int_{r\le|x-y|\le R}\frac{1}{|x-y|}(\operatorname{Tr}\mathcal{E}(y)-\mathbf{n}\otimes\mathbf{n}:\mathcal{E}(y))\,dy.$$

Combining (2.5)–(2.7), we obtain

$$\frac{\mathcal{M}_1(x,r)}{r}+\int_{r\le|x-y|\le R}\frac{1}{|x-y|}(\operatorname{Tr}\mathcal{E}(y)-\mathbf{n}\otimes\mathbf{n}:\mathcal{E}(y))\,dy=\frac{\mathcal{M}_1(x,R)}{R}$$

(2.8)
$$-\frac{1}{R}\int_{B(x,R)}\operatorname{Tr}\,\Pi dy+\frac{1}{r}\int_{B(x,r)}\operatorname{Tr}\,\Pi dy+\mathfrak{S}\Pi(x,r,R)-\int_{B(y,R)}k_{r,R}(y-x)f(y)\rho(y)dy.$$

It follows from Lemma 2.2 that

$$\frac{1}{R}\int_{B(x,R)}|\operatorname{Tr}\,\Pi|\,dy+\frac{1}{r}\int_{B(x,r)}|\operatorname{Tr}\,\Pi|\,dy+|\mathfrak{S}\Pi(x,r,R)|\le c\int_{B(x,R)}\frac{|\Pi|}{|x-y|}\,dy$$
$$\le\Big(\int_\Omega\frac{dy}{|x-y|^2}\Big)^{1/2}\Big(\int_\Omega|\Pi|^2\,dy\Big)^{1/2}\le c\|\nabla\mathbf{u}\|_{L^2(\Omega)}\le c\,.$$

Passage to the limit $r\to 0$ in (2.8), in view of $\operatorname{Tr}\mathcal{E}(y)-\mathbf{n}\otimes\mathbf{n}:\mathcal{E}(y))\ge p(\rho)$, results in the inequality

$$\int_{B(x,R)}\frac{p\,dy}{|x-y|}\le\frac{c}{R}\int_{B(x,R)}(\rho|\mathbf{u}|^2+p)\,dy+c\|\nabla\mathbf{u}\|_{L^2(\Omega)}+c\|\mathbf{f}\|_{C(\Omega)}\le\frac{c}{R}\,,\tag{2.9}$$

which holds a.e. in Ω_0. It is sufficient to note that for $R=d/3$,

$$\int_\Omega\frac{p(\rho)}{|x-y|}\,dy\le\int_{B(x,d/3)}\frac{p(\rho)}{|x-y|}\,dy+d^{-1}\int_{\Omega\setminus B(x,d/3)}p(\rho)\,dy\le\int_{B(x,R)}\frac{p(\rho)}{|x-y|}\,dy+cd^{-1},$$

which along with (2.9) implies (2.3). The proof of Lemma 2.3 is completed. □

LEMMA 2.4. *Under the assumptions of Theorem* 2.1,

$$\int_{\Omega_0}\rho^\gamma|\mathbf{u}-\mathbf{u}^\infty|^2dx\le cd^{-1}.\tag{2.10}$$

Proof. Let us consider the sequence of functions $\mu_N:\mathbb{R}^3\mapsto\mathbb{R}^+$, $N\ge 2$, defined by

$$\mu_N(x)=\min\{\rho(x)^\gamma,N\}\ \text{ for }\ x\in\Omega_0,\qquad\mu_N(x)=0\ \text{ otherwise.}$$

Since spt μ_N, spt $(\mathbf{u}-\mathbf{u}^\infty)\subset$ cl B, the Adams embedding theorem (see [1], [2]) implies the inequality

$$\int_{\Omega_0}\mu_N|\mathbf{u}-\mathbf{u}^\infty|^2dx\le c\|\mathbf{u}-\mathbf{u}^\infty\|^2_{H^{1,2}(\Omega)}\|(-\Delta^{-1/2})\mu_N\|_{L^2(\mathbb{R}^3)},\tag{2.11}$$

in which the constant c depends only on B. Noting that $(-\Delta^{-1/2})\mu_N = c|x|^{-2} * \mu_N$, we obtain

$$\|(-\Delta^{-1/2})\mu_N\|^2_{L^2(\mathbb{R}^3)} = c\int_{\mathbb{R}^3}\left(\int_{\mathbb{R}^3}\frac{\mu_N(y)}{|x-y|^2}\,dy\right)^2 dx$$
$$= \int_{\mathbb{R}^3}\int_{\mathbb{R}^3}\int_{\mathbb{R}^3}\frac{\mu_N(y)\mu_N(z)}{|x-y|^2|x-z|^2}\,dxdydz.$$

Since

$$\int_{\mathbb{R}^3}\frac{dx}{|x-y|^2|x-z|^2} = c|y-z|^{-1},$$

we conclude from this that

$$\|(-\Delta^{-1/2})\mu_N\|^2_{L^2(\mathbb{R}^3)} = c\int_{\Omega_0}\mu_N(y)\left(\int_{\Omega_0}\frac{\mu_N(z)}{|y-z|}\,dz\right)dy$$
$$\le c\int_{\Omega}\rho^\gamma(y)dy\ \operatorname*{ess\,sup}_{x\in\Omega_0}\int_{\Omega_0}\frac{\mu_N(y)}{|y-x|}\,dy \le c\operatorname*{ess\,sup}_{x\in\Omega_0}\int_{\Omega}\frac{\rho^\gamma(y)}{|y-x|}\,dy.$$

Passage to the limit $N\to\infty$ in (2.11) results in the inequality

$$\int_{\Omega_0}\rho^\gamma|\mathbf{u}-\mathbf{u}^\infty|^2dx \le c\|\mathbf{u}-\mathbf{u}^\infty\|^2_{H_0^{1,2}(B)}\left\{\operatorname*{ess\,sup}_{x\in\Omega_0}\int_{\Omega}\frac{\rho^\gamma(y)}{|y-x|}\,dy\right\}^{1/2}.$$

Combining this result with (2.3), we obtain (2.10). The proof of Lemma 2.4 is completed. □

Proof. We are now in position to complete the proof of Theorem 2.1. Since $\mathbf{u}-\mathbf{u}^\infty \in H_0^{1,2}(B)$, Lemmas 2.4 and 2.2 imply

$$\int_{\Omega_0}\rho^\gamma|\mathbf{u}|^2\,dx \le 2\|\mathbf{u}^\infty\|^2_{C(B)}\mathbf{E} + 2\int_{\Omega_0}\rho^\gamma|\mathbf{u}-\mathbf{u}^\infty|^2dx \le cd^{-1}. \tag{2.12}$$

Applying the Hölder inequality, we obtain

$$\int_{\Omega_0}(\rho|\mathbf{u}|^2)^{1+\kappa}\,dx = \int_{\Omega_0}(\rho|\mathbf{u}|^{2/\gamma})^{1+\kappa}(|\mathbf{u}|^{2(\gamma-1)/\gamma})^{1+\kappa}\,dx$$
$$\le \left(\int_{\Omega_0}\rho^\gamma|\mathbf{u}|^2\,dx\right)^{(1+\kappa)/\gamma}\left(\int_{\Omega_0}|\mathbf{u}|^6\,dx\right)^{(\gamma-1-\kappa)/\gamma}$$

with $\kappa = 2(\gamma-1)/(\gamma+2) > 0$. From this, (2.12), and the boundedness of the embedding $H^{1,2}(B)\hookrightarrow L^6(B)$, we derive the inequality

$$\int_{\Omega_0}(\rho|\mathbf{u}|^2)^{1+\kappa}\,dx \le c\|\mathbf{u}\|^{6(\gamma-1-\kappa)/\gamma}_{H^{1,2}(\Omega)}d^{-(1+\kappa)/\gamma} \le cd^{-(1+\kappa)/\gamma}, \tag{2.13}$$

which along with Lemma 2.2 implies the first estimate from (2.1). In order to prove the second, we choose a function $\eta\in C_0^\infty(\mathbb{R}^3)$ such that

$$0\le\eta\le 1,\quad \eta(x)=1\ \text{ in }\ \Omega',\ \ \operatorname{spt}\eta\Subset\Omega_0,\quad |\nabla\eta|\le cd^{-1}.$$

From the moment equation, it follows that

$$\nabla(\eta p(\rho)) = \operatorname{div}\Big[\eta(\Pi - \rho\mathbf{u}\otimes\mathbf{u})\Big] + \Phi \in \mathcal{D}'(\Omega), \tag{2.14}$$

where $\Phi = \nabla\eta : (\rho\mathbf{u}\otimes\mathbf{u} - \Pi) + \eta\rho\mathbf{f}$. It is easily to see that $\|\Phi\|_{L^1(\Omega)} \le cd^{-1}$. Now choose $s = (1+\kappa)/\kappa > 3$. Recall (see [11]) that for a given function $q \in C_0^\infty(\Omega)$ with

$$[q] := \text{ meas } (\Omega_0)^{-1}\int_{\Omega_0} q\,dx = 0,$$

there exists the vector field $\varphi \in C^\infty(\Omega_0)^3$ such that

$$\operatorname{div}\varphi = q \ \text{ in } \ \Omega_0, \quad \varphi = 0 \ \text{ at } \ \partial\Omega_0, \quad \|\varphi\|_{H^{1,s}(\Omega_0)} \le N(\Omega_0)\|q\|_{L^s(\Omega_0)}. \tag{2.15}$$

Thus, we get

$$\int_{\Omega_0} q\eta p(\rho)\,dx = \int_{\Omega_0}\eta(\rho\mathbf{u}\otimes\mathbf{u} - \Pi) : \nabla\varphi\,dx + \int_{\Omega_0}\eta\varphi\Phi\,dx.$$

Since the embedding $H_0^{1,s}(\Omega_0) \hookrightarrow C(\Omega_0)$ is bounded, we have $|\varphi| \le c\|\varphi\|_{H^{1,s}(\Omega_0)} \le N(\Omega_0)\|q\|_{L^s(\Omega_0)}$, which yields

$$\begin{aligned}\left|\int_{\Omega_0} q\eta p(\rho)\,dx\right| &\le N(\Omega_0)(\|\rho|\mathbf{u}|^2\|_{L^{1+\kappa}(\Omega_0)} + \|\Pi\|_{L^{1+\kappa}(\Omega_0)})\|\varphi\|_{H^{1,s}(\Omega_0)}\\ &\quad + \|\Phi\|_{L^1(\Omega)}\|\varphi\|_{C(\Omega)} \le cN(\Omega_0)d^{-1}\|q\|_{L^s(\Omega_0)}.\end{aligned}$$

It follows from this that

$$\|\eta p(\rho) - [\eta p(\rho)]\|_{L^{s/(s-1)}(\Omega_0)} \le cN(\Omega_0).$$

Note that $s/(s-1) = 1+\kappa$, $\eta = 1$ on Ω', and $[\eta p(\rho)] \le c$. Hence $\|p\|_{L^{1+\kappa}(\Omega')} \le cN(\Omega')d^{-1}$, and the proof of Theorem 2.1 is completed. □

3. Weak convergence. Since the notion of weak limits plays a crucial role in our analysis, we begin with a short description of some basic facts concerning weak convergence and weak compactness. We refer the reader to, e.g., [5] for proofs of basic results.

Let A be an arbitrary bounded, measurable subset of $\mathbb{R}^3$ and $1 < r \le \infty$. Then for every bounded sequence $\{g_n\}_{n\ge1} \subset L^r(A)$, there exist a subsequence, still denoted by $\{g_n\}$, and a function $g \in L^r(A)$ such that for $n \to \infty$,

$$\int_A g_n(x)h(x)dx \to \int_A g(x)h(x)dx \ \text{ for all } \ h \in L^{r/(r-1)}(A).$$

We say the sequence converges $g_n \to g$ weakly in $L^r(A)$ for $r < \infty$ and converges star-weakly in $L^\infty(A)$ in the limit case of $r = \infty$. In the very special case of $r = 1$, it is known that the sequence of g_n contains a weakly convergent subsequence in $L^1(A)$ if and only if there is a continuous function $\Phi : \mathbb{R} \to \mathbb{R}^+$ such that

$$\lim_{s\to\infty}\Phi(s)/s = \infty \ \text{ and } \ \sup_{n\ge1}\|\Phi(g_n)\|_{L^1(A)} < \infty.$$

If the sequence of g_n is only bounded in $L^1(A)$ and A is open, then after passing to a subsequence we can assume that g_n converges star-weakly to a bounded Radon measure measure μ_g, i.e.,

$$\lim_{n\to\infty}\int_A g_n(x)h(x)dx=\int_A h(x)d\mu_g(x)\quad\text{for all compactly supported}\quad h\in C(A).$$

In what follows, the linear space of compactly supported functions on a set A is denoted by $C_0(A)$, and its dual is denoted by $C_0(A)^*$.

Ball's version [3] (see also [20], [23]) of the fundamental Tartar theorem on Young measures gives a simple and effective representation of weak limits in the form of integrals over families of probability measures. The following lemma is a consequence of Ball's theorem.

LEMMA 3.1. *Suppose that a sequence $\{g_n\}_{n\ge1}$ is bounded in $L^r(A)$, $1<r\le\infty$, where A is an open, bounded subset of $\mathbb{R}^3$. Then we have the following characterizations of weak limits.*

(i) *There exists a subsequence, still denoted by $\{g_n\}_{n\ge1}$, and a family of probability measures $\sigma_x\in C_0(\mathbb{R})^*$, $x\in A$, with a measurable distribution function $\Gamma(x,\lambda):=\sigma_x(-\infty,\lambda]$ so that the function $\lambda\mapsto\Gamma(x,\lambda)$ is monotone and continuous from the right and admits the limits $1,0$ for $\lambda\to\pm\infty$. Furthermore, for any continuous function $G:A\times\mathbb{R}\mapsto\mathbb{R}$ such that*

$$\lim_{|\lambda|\to\infty}\|G(\cdot,\lambda)\|_{C(A)}/|\lambda|^r=0\ \ \textit{for}\ \ r<\infty\ \ \textit{and}\ \sup_{|\lambda|}\|G(\cdot,\lambda)\|_{C(A)}<\infty\ \ \textit{for}\ \ r=\infty,$$

the sequence of $G(\cdot,g_n)$ converges weakly in $L^1(A)$ to a function

$$\overline{G}(x)=\int_{\mathbb{R}}G(x,\lambda)d_\lambda\Gamma(x,\lambda).\tag{3.1}$$

Moreover, the function

$$A\ni x\to\int_{\mathbb{R}}|\lambda|^r\,d_\lambda\Gamma(x,\lambda)\in\mathbb{R}$$

belongs to $L^1(A)$.

(ii) *If $G(x,\cdot)$ is convex and the sequence g_n converges weakly (star-weakly for $r=\infty$) to $g\in L^r(A)$, then $\overline{G}(x)\le G(x,g(x))$. If the functions g_n satisfy the inequalities $g_n\le M$ (resp., $g_n\ge m$), then $\Gamma(x,\lambda)=1$ for $\lambda\ge M$ (resp., $\Gamma(x,\lambda)=0$ for $\lambda<m$).*

(iii) *If $\Gamma(1-\Gamma)=0$ a.e. in A, then the sequence g_n converges to g in measure, and hence in $L^s(A)$, for positive $s<r$. Moreover, in this case $\Gamma(x,\lambda)=0$ for $\lambda<g(x)$ and $\Gamma(x,\lambda)=1$ for $\lambda\ge g(x)$*

Let us consider the sequence of generalized solutions $\{(\rho_n,\mathbf{u}_n)\}_{n\ge1}$ to problem (1.3) satisfying all assumptions of Theorem 1.2. Assume that the functions $(\rho_n,\mathbf{u}_n)$ are extended onto $\mathbb{R}^3$ by formulae (1.8), and fix an arbitrary bounded smooth domain D with $B\Subset D$. For such extended functions, by inequalities (1.11) and formulae (1.8), it follows that the sequence $(\rho_n,\mathbf{u}_n)$ contains a subsequence, still denoted by $(\rho_n,\mathbf{u}_n)$, such that

$$\begin{gathered}\rho_n\to\rho\ \text{weakly in}\ L^\gamma(D),\quad \mathbf{u}_n\to\mathbf{u}\ \text{weakly in}\ H^{1,2}(D),\\ \rho_n\to\rho\ \text{weakly in}\ L^{(1+\kappa)\gamma}(\Omega')\ \text{for all}\ \Omega'\Subset\Omega.\end{gathered}\tag{3.2}$$

The behavior of the functions $p(\rho_n)$ is more complicated. Since they are uniformly bounded in $L^1(D)$, we can assume, after passing to a subsequence if necessary, that $p(\rho_n)$ converge weakly to some finite Borel measure μ_p on D. On the other hand, the sequence $\{p(\rho_n)\}$ is bounded in $L^{1+\kappa}(K)$ for any compact $K \Subset \Omega$. Using the diagonal process, we obtain the existence of a subsequence which converges weakly on each compact $K \Subset \Omega$ to some function $\overline{p} \in L^{1+\kappa}_{loc}(\Omega)$. Since

$$\|\overline{p}\|_{L^1(K)} \le \liminf_{n\to\infty} \|p(\rho_n)\|_{L^1(K)} \le c$$

the function $\overline{p}$ is integrable over Ω. Next, we note that the functions $p(\rho_n) = (\rho^\infty)^\gamma$ are bounded and independent of n on $D\setminus B$. Hence the extended function $\overline{p}(x), x \in D$, defined as

$$\overline{p}(x) = \overline{p}(x) \ \text{ in } \ \Omega, \quad \overline{p}(x) = (\rho^\infty)^\gamma \ \text{ in } \ D \setminus B,$$

belongs to the class $L^1(D \setminus S) \cap L^{1+\kappa}_{loc}(\Omega) \cap L^\infty(D \setminus B)$, which implies the equality

$$\int_D h(x) d\mu_p = \int_{D\setminus S} h(x)\overline{p}(x)dx + \int_{\partial B} h(x) d\mu_p + \int_S h(x) d\mu_p \quad \text{for all} \quad h \in C_0(\mathbb{R}^3),$$

where the compact *obstacle* takes the form $S = B \setminus \Omega$. Applying Lemma 3.2 to the sequence of $g_n := \rho_n$ and to the sets $A = D, \Omega'$ leads to the following result on the representation of weak limits of a sequence of generalized solutions to problem (1.3).

LEMMA 3.2. *There exists a subsequence of the sequence* $\{\rho_n, \mathbf{u}_n\}$, *still denoted by* $\{\rho_n, \mathbf{u}_n\}$, *and a distribution function* $\Gamma : D \times \mathbb{R} \mapsto [0,1]$ *such that*

(i) $\Gamma(x,\lambda)$ *meets all requirements of Lemma* 3.1 *and satisfies the equalities*

$$\Gamma(x,\lambda) = 0 \ \ \textit{for} \ \ \lambda < 0 \ \ \textit{a.e. in} \ \ D,$$
$$\Gamma(x,\lambda) = 0 \ \ \textit{for} \ \ \lambda < \rho^\infty, \quad \Gamma(x,\lambda) = 1 \ \ \textit{for} \ \ \lambda \ge \rho^\infty \ \ \textit{a.e. in} \ \ D \setminus B\,.$$

(ii) *for any continuous function* $G : D\times\mathbb{R}$ *such that* $\lim_{\rho\to\infty} \rho^{-\gamma}\|G(\cdot,\rho)\|_{C(D)} = 0$, *the sequence* $G(\cdot,\rho_n)$ *converges weakly in* $L^1(D)$ *to the function*

$$\overline{G}(x) = \int_{[0,\infty)} G(x,\lambda)\, d_\lambda\Gamma(x,\lambda) \ \ \textit{a.e. in} \ \ D. \tag{3.3}$$

In particular, the weak limit of ρ_n *takes the form*

$$\rho(x) = \int_{[0,\infty)} \lambda\, d_\lambda\Gamma(x,\lambda) \equiv \int_{[0,\infty)} (1-\Gamma(x,\lambda))\, d\lambda \ \ \textit{a.e. in} \ \ D. \tag{3.4}$$

(iii) *the function* $\overline{p}$ *admits the representation*

$$\overline{p}(x) = \int_{[0,\infty)} \lambda^\gamma\, d_\lambda\Gamma(x,\lambda) \equiv \gamma \int_{[0,\infty)} \lambda^{\gamma-1}(1-\Gamma(x,\lambda))\, d\lambda \ \ \textit{a.e. in} \ \ D\setminus S\,. \tag{3.5}$$

Since the embedding $H^{1,2}_0(D) \hookrightarrow L^r(D)$ is compact for $r < 6$, we can expect that $\rho_n\mathbf{u}_n$ converge weakly to $\rho\mathbf{u}$. The corresponding result is given by the following lemma.

LEMMA 3.3. *For* $\iota = (\gamma-1)/(\gamma+1) > 0$ *and for any* $\Omega' \Subset \Omega$,

$$\rho_n\mathbf{u}_n \to \rho\mathbf{u} \ \textit{converges weakly in} \ L^{1+\iota}(D)^3,$$
$$\rho_n\mathbf{u}_n \otimes \mathbf{u}_n \to \rho\mathbf{u}\otimes\mathbf{u} \ \textit{weakly in} \ L^{1+\kappa}(\Omega')^9.$$

Proof. Since ρ_n and $\mathbf{u}_n$ are bounded and independent of n in the exterior of B, it suffices to show that $\rho_n\mathbf{u}_n \to \rho\mathbf{u}$ converges weakly in $L^{1+\iota}(B)$. We have

$$\begin{aligned}|\rho_n\mathbf{u}_n|^{1+\iota} &= (\rho_n)^{\frac{1+\iota}{2}}(\rho_n|\mathbf{u}_n|)^{\frac{1+\iota}{2}}\\ &\le \left(\rho_n^{(1+\iota)/2}\right)^{1+\gamma} + \left((\rho_n|\mathbf{u}_n|^2)^{(1+\iota)/2}\right)^{(1+\gamma)/\gamma} = \rho_n^\gamma + \rho_n|\mathbf{u}_n|^2,\end{aligned}$$

which implies the estimate

$$\int_B |\rho_n\mathbf{u}_n|^{1+\iota}\,dx \le \int_B (\rho^\gamma + \rho_n|\mathbf{u}_n|^2)dx \le c\mathbf{E}_n \le c.$$

Hence, it suffices to prove that $\rho_n\mathbf{u}_n$ converges to $\rho\mathbf{u}$ in $\mathcal{D}'$, i.e., in the sense of distributions. For any positive N, set $\rho_n^N = \min\{\rho_n, N\}$. Next note that the functions ρ_n^N converge star-weakly in $L^\infty(B)$ to some function $\overline{\rho^N}$. It is easily seen that the sequence of nonnegative functions $\rho - \overline{\rho^N}$ decreases for $N \to \infty$. Moreover, since

$$\int_B |\rho_n - \rho_n^N|\,dx \le \left(\int_B \rho_n^\gamma\,dx\right)^{1/\gamma} \text{meas}\,\{x : \rho(x)^\gamma \ge N^\gamma\}^{(\gamma-1)/\gamma} \le cN^{-(\gamma-1)}, \tag{3.6}$$

we can pass to the limit for $N \to \infty$,

$$\int_B (\rho - \overline{\rho^N})dx = \lim_{n\to\infty}\int_B (\rho_n - \rho_n^N)\,dx \to 0. \tag{3.7}$$

Since $\mathbf{u}_n$ converge strongly in $L^r(B)$, for $r < 6$, the sequence $\rho_n^N\mathbf{u}_n$ converges to $\overline{\rho^N}\mathbf{u}$ in $\mathcal{D}'(B)$. It follows from this that for any $h \in C_0^\infty(B)^3$,

$$\begin{aligned}&\limsup_{n\to\infty}\left|\int_B (\rho_n\mathbf{u}_n - \rho\mathbf{u})h\,dx\right|\\ &\le \limsup_{n\to\infty}\left|\int_B (\rho_n^N - \rho_n)\mathbf{u}_n h\,dx\right| + \left|\int_B (\overline{\rho^N} - \rho)\mathbf{u}h\,dx\right|.\end{aligned} \tag{3.8}$$

By the Cauchy–Schwarz inequality we have

$$\begin{aligned}&\left|\int_B (\rho_n^N - \rho_n)\mathbf{u}_n h\,dx\right|\\ &\le \|h\|_{C(B)}N^{(\gamma-1)/2}\int_B |\rho_n^N - \rho_n|\,dx + \|h\|_{C(B)}N^{-(\gamma-1)/2}\int_B \rho_n|\mathbf{u}_n|^2\,dx.\end{aligned} \tag{3.9}$$

Combining (3.6), (3.8), and (3.9) leads to the inequality

$$\limsup_{n\to\infty}\left|\int_B (\rho_n\mathbf{u}_n - \rho\mathbf{u})h\,dx\right| \le c\|h\|_{C(B)}N^{-(\gamma-1)/2} + \|h\|_{C(B)}\int_B (\rho - \overline{\rho^N})|\mathbf{u}|\,dx. \tag{3.10}$$

It follows from (3.7) that the sequence of nonnegative integrable functions $(\rho - \overline{\rho^N})|\mathbf{u}|$ decreases and converges to 0 a.e. in B for $N \to \infty$. From this, and by the Fatou theorem, we conclude that the right-hand side of (3.10) tends to 0 as $N \to \infty$, which yields the weak convergence of the sequence $\rho_n\mathbf{u}_n$.

It remains to prove the weak convergence of the sequence $\rho_n \mathbf{u}_n \otimes \mathbf{u}_n$. We begin with the observation that since this sequence is bounded in $L^{1+\kappa}(\Omega')$, it suffices to show that it converges in $\mathcal{D}'(\Omega')$. Arguing as before, we obtain

$$\limsup_{n\to\infty} \left| \int_B (\rho_n \mathbf{u}_n \otimes \mathbf{u}_n - \rho \mathbf{u} \otimes \mathbf{u}) : h \, dx \right| \tag{3.11}$$
$$\leq \limsup_{n\to\infty} \left| \int_B (\rho_n^N - \rho_n) \mathbf{u}_n \otimes \mathbf{u}_n : h \, dx \right| + \int_B (\rho - \overline{\rho^N}) |\mathbf{u}|^2 |h| \, dx$$

for all $h \in C_0^\infty(\Omega')^9$. Using the Young inequality and taking into account that $\rho_n \geq \rho_n^N$, we obtain

$$|(\rho_n - \rho_n^N)\mathbf{u}_n \otimes \mathbf{u}_n| \leq N^{(\gamma-1)/2}(\rho_n - \rho_n^N) + N^{-\kappa(\gamma-1)/2} \rho_n |\mathbf{u}_n|^{2(1+\kappa)}$$
$$\leq N^{(\gamma-1)/2}(\rho_n - \rho_n^N) + N^{-\kappa(\gamma-1)/2} \Big(|\mathbf{u}_n|^6 + (\rho_n |\mathbf{u}_n|^2)^{(1+\kappa)} \Big).$$

Since, by Lemma 2.2, $\|\mathbf{u}_n\|_{L^6(\Omega')} \leq c \|\mathbf{u}_n\|_{H^{1,2}(B)} \leq c$, we conclude from this and inequality (3.6) that

$$\limsup_{n\to\infty} \left| \int_B (\rho_n^N - \rho_n) \mathbf{u}_n \otimes \mathbf{u}_n : h \, dx \right|$$
$$\leq c \|h\|_{C(B)} (N^{-(\gamma-1)/2} + N^{-\kappa(\gamma-1)/2}) \to 0 \quad \text{for} \quad N \to \infty.$$

It is sufficient to observe that, by (3.7) and the Fatou theorem, the last term in the right-hand side of (3.11) tends to 0 for $n \to \infty$. The proof of Lemma 3.3 is completed. □

4. The effective viscous flux. Following [18], we introduce the quantity $V(\rho, \mathbf{u}) = p(\rho) - (\xi + \nu)\operatorname{div} \mathbf{u}$, which is called the effective viscous flux. As was shown in [18], [6], [7], [8], the effective viscous flux enjoys many remarkable properties. The most important is the multiplicative relation $\overline{\varphi(\rho)V} = \overline{\varphi(\rho)}\ \overline{V}$ for weak limits, which was proved in [18] for all $\gamma > 3/2$. The simple proof of this result, based on the new version of the compensated compactness principle, was given in papers [6], [8]. In our case, by Theorem 2.1, the critical estimate $\|\rho_n |\mathbf{u}_n|^2\|_{L^{(1+\kappa)}(\Omega')} \leq c(\Omega')$ holds for every $\Omega' \Subset \Omega$, which leads to the following local version of the compensated compactness result from [8]; see also [11], [22].

LEMMA 4.1. *Let there be given function $\Phi \in C^\infty(\Omega)$ so that $\Phi(x, \lambda)$ vanishes near $\partial\Omega$ and $\partial_\lambda \Phi(x, \lambda) = 0$ for sufficiently large λ. Then*

$$\int_\Omega \overline{\Phi V(\rho, \mathbf{u})} dx = \int_\Omega \overline{\Phi}\ \overline{V} dx, \quad \textit{where} \quad \overline{V} = \overline{p} - (2 + \nu)\operatorname{div} \mathbf{u}. \tag{4.1}$$

Proof. It suffice to prove the lemma for Φ in the form $\Phi = h(x)\varphi(\lambda)$ with $h \in C_0^\infty(\Omega)$, and $\varphi \in C^\infty(\mathbb{R})$ so that $\varphi'(\lambda) = 0$ for all large λ. Denote by $\mathbf{1}_\Omega$ the extension operator, for functions defined in Ω, such that $\mathbf{1}_\Omega u = u$ in Ω and $\mathbf{1}_\Omega u = 0$ in $\Omega^c = \mathbb{R}^3 \backslash \Omega$. The adjoint operator $\mathbf{1}_\Omega^*$ assigns to every function its restriction to Ω. Introduce the linear operators

$$A_i = \mathbf{1}_\Omega^* \Delta^{-1} \partial_{x_i} \mathbf{1}_\Omega, \quad R_{ij} = \mathbf{1}_\Omega^* \partial_{x_i} \Delta^{-1} \partial_{x_j} \mathbf{1}_\Omega, \quad 1 \leq i, \quad j \leq 3.$$

From the classical potential theory, it follows that they admit the following integral representations (the integrals for R_{ij}, R_{ii} are determined in the sense of Cauchy's

principal value):

$$A_i u(x) = \frac{1}{4\pi}\int_\Omega \frac{x_i - y_i}{|x-y|^3} u(y)\,dy,$$

$$R_{ij}u(x) = -\frac{3}{4\pi}\int_\Omega \frac{(x_i-y_i)(x_j-y_j)}{|x-y|^5}u(y)\,dy \quad \text{for} \quad i \neq j,$$

$$R_{ii}u(x) = \frac{1}{4\pi}\int_\Omega \frac{|x-y|^2 - 3|x_i-y_i|^2}{|x-y|^5}u(y)\,dy + \frac{1}{3}u(x).$$

We denote by A the vectorial operator with the entries A_i and by R the matrix operator with the entries $R_{ij}, i,j = 1,2,3$. Recall that the operators $R_{ij} : L^r(\Omega) \mapsto L^r(\Omega)$, $A_i : L^r(\Omega) \mapsto H^{1,r}(\Omega)$ are bounded for every $r > 1$. Since $\Omega_n \overset{\mathcal{H}}{\to} \Omega$, there is n_0 such that spt $h \Subset \Omega_n$ for all $n \geq n_0$.

Multiplying the moment balance equation for $(\rho_n, \mathbf{u}_n)$, $n \geq n_0$, by h we arrive at

$$\begin{aligned}\operatorname{div}\Big\{h\rho_n\mathbf{u}_n\otimes\mathbf{u}_n - \Pi(h\mathbf{u}_n) + hp(\rho_n)\mathbf{I} + \nu\mathbf{u}_n\otimes\nabla h + \nu\nabla h\otimes\mathbf{u}_n + (\xi-\nu)\nabla h\cdot\mathbf{u}_n\mathbf{I}\Big\}\\ -\Big\{\rho_n\mathbf{u}_n\otimes\mathbf{u}_n - \Pi(\mathbf{u}_n) + p(\rho_n)\mathbf{I}\Big\}\nabla h = h\rho_n\mathbf{f} \ \text{ in } \ \mathcal{D}'(\Omega).\end{aligned}$$

Next, apply to both sides of this identity the operator A to obtain

$$\begin{aligned}R : \{h\rho_n\mathbf{u}_n\otimes\mathbf{u}_n - \Pi(h\mathbf{u}_n) + hp(\rho_n)\mathbf{I} + 2\nu\mathbf{u}_n\otimes\nabla h + (\xi-\nu)\nabla h\cdot\mathbf{u}_n\mathbf{I}\}\\ = A\cdot(h\rho_n\mathbf{f}) + A\cdot\Big\{\Big(\rho_n\mathbf{u}_n\otimes\mathbf{u}_n - \Pi(\mathbf{u}_n) + p(\rho_n)\mathbf{I}\Big)\nabla h\Big\} \ \text{ in } \ L^1(\Omega).\end{aligned} \tag{4.2}$$

Since h is compactly supported in Ω, we have

$$\begin{aligned}R : \{-\Pi(h\mathbf{u}_n) + hp(\rho_n)\mathbf{I}\} = hV(\rho_n,\mathbf{u}_n) + (\xi+\nu)\nabla h\cdot\mathbf{u}_n,\\ R : ((\nabla h\cdot\mathbf{u}_n)\mathbf{I}) = \nabla h\cdot\mathbf{u}_n.\end{aligned} \tag{4.3}$$

Multiplying both sides of (4.2) by $\varphi_n = \varphi(\rho_n)$, integrating the result over Ω, and using in addition relations (4.3), we obtain

$$\int_\Omega h\varphi_n V(\rho_n,\mathbf{u}_n)dx + \int_\Omega \varphi_n\big(\mathcal{P}_n + R : (h\rho_n\mathbf{u}_n\otimes\mathbf{u}_n)\big)dx = 0, \tag{4.4}$$

$$\mathcal{P}_n = 2\xi\nabla h\cdot\mathbf{u}_n + 2\nu R : (\mathbf{u}_n\otimes\nabla h) - A\cdot\big\{(\rho_n\mathbf{u}_n\otimes\mathbf{u}_n - \Pi(\mathbf{u}_n) + p_n\mathbf{I})\nabla h + \rho_n h\mathbf{f}\big\}.$$

On the other hand, multiplying both sides of the renormalized mass balance equation for $(\rho_n, \mathbf{u}_n)$ by h and setting $G = \varphi$, we get

$$\operatorname{div}(h\varphi_n\mathbf{u}_n) + h\Big(\varphi_n'(\rho_n)\rho_n - \varphi_n\Big)\operatorname{div}\mathbf{u}_n - \varphi_n\nabla h\cdot\mathbf{u}_n = 0. \tag{4.5}$$

Introduce the vector field

$$\mathbf{v}_n^{(m)} = \rho_n^{(m)}\mathbf{u}_n, \quad \text{where} \quad \rho_n^{(m)} = \min\{m,\rho_n\}, \ m \geq 1.$$

Applying the operator $\mathbf{v}_n^{(m)}\cdot A$ to both sides of (4.5) and integrating the result over Ω, we arrive at the equality

$$\int_\Omega \big\{\mathbf{v}_n^{(m)}\mathfrak{P}_n + \mathbf{v}_n^{(m)}R(h\varphi_n\mathbf{u}_n)\big\}dx = 0, \tag{4.6}$$

where we denote

$$\mathfrak{P}_n = A \cdot \Big\{ h(\varphi'(\rho_n)\rho_n - \varphi_n)\mathrm{div}\,\mathbf{u}_n - \varphi_n \nabla h \cdot \mathbf{u}_n \Big\}.$$

Combining (4.4), (4.6), and the equality

$$\int_\Omega \Big(\mathbf{v}_n^{(m)} R(h\varphi_n \mathbf{u}_n) - \varphi_n R : (h\rho_n \mathbf{u}_n \otimes \mathbf{u}_n) \Big) dx$$

$$= \int_\Omega \Big(\mathbf{v}_{n,i}^{(m)} R_{ij}(h\varphi_n \mathbf{u}_{n,j}) - \varphi_n R_{ij}(h\mathbf{v}_{ni}^{(m)} \mathbf{u}_{n,j}) \Big) dx + \int_\Omega \varphi_n R : \{(\rho_n^{(m)} - \rho_n) h\mathbf{u}_n \otimes \mathbf{u}_n\} dx$$

$$= \int_\Omega h u_{n,j} \Big(\varphi_n R_{ij} \mathbf{v}_{ni}^{(m)} - \mathbf{v}_{n,i}^{(m)} R_{ij} \varphi_n \Big) dx + \int_\Omega \varphi_n R : \{(\rho_n^{(m)} - \rho_n) h\mathbf{u}_n \otimes \mathbf{u}_n\} dx,$$

we obtain the equality

$$\int_\Omega h\varphi_n V(\rho_n, \mathbf{u}_n) dx = \int_\Omega \Big(\mathbf{v}_n^{(m)} (\mathfrak{P}_n - \varphi_n \mathcal{P}_n + \mathfrak{R}_n \Big) dx + \varpi_n^{(m)}, \tag{4.7}$$

in which components of the vector $\mathfrak{R}_n$ and the scalar $\varpi_n^{(m)}$ are defined by

$$\mathfrak{R}_{n,i} = h\mathbf{u}_{n,j} \Big(\varphi_n R_{ij} \mathbf{v}_{n,i}^{(m)} - \mathbf{v}_{n,i}^{(m)} R_{ij} \varphi_n \Big), \tag{4.8}$$

$$\varpi_n^{(m)} = \int_\Omega \varphi_n R : \{(\rho_n^{(m)} - \rho_n) h\mathbf{u}_n \otimes \mathbf{u}_n\} dx, \tag{4.9}$$

respectively. Recall that $\rho_n \mathbf{u}_n \otimes \mathbf{u}_n \nabla h \to \rho \mathbf{u} \otimes \mathbf{u} \nabla h$ and $p_n \nabla h \to \overline{p} \nabla h$ weakly in $L^{1+\kappa}(\Omega)$ for $n \to \infty$. Hence, there are limits for $n \to \infty$,

$$\mathcal{P}_n \to \overline{\mathcal{P}} \ \text{ in } \ L^r(\Omega) \ \text{ for some } \ r > 1, \tag{4.10}$$

where

$$\overline{\mathcal{P}} = 2\xi \nabla h \mathbf{u} + 2\nu R : (\mathbf{u} \otimes \nabla h) - A \cdot \{ \big(\rho \mathbf{u} \otimes \mathbf{u} - \Pi(\mathbf{u}) + \overline{p} \mathbf{I} \big) \nabla h + h\rho \mathbf{f} \},$$

furthermore,

$$\mathfrak{P}_n \to \overline{\mathfrak{P}} \equiv A \cdot \{ h\overline{(\varphi'\rho - \varphi)\mathrm{div}\,\mathbf{u}} - \overline{\varphi} \nabla h \cdot \mathbf{u} \} \ \text{ in } \ L^2(\Omega)\ . \tag{4.11}$$

Since the sequences φ_n and $\mathbf{v}_n^{(m)}$ are bounded in $L^\infty(\Omega)$ and $L^6(\Omega)$, respectively, it follows from the compensated compactness Lemma from [8] that

$$\varphi_n R_{ij} \mathbf{v}_{n,i}^{(m)} - \mathbf{v}_{n,i}^{(m)} R_{ij} \varphi_n \to \overline{\varphi} R_{ij} \overline{\mathbf{v}^{(m)}}_i - \overline{\mathbf{v}^{(m)}}_i R_{ij} \overline{\varphi} \ \text{ weakly in } \ L^2(\Omega).$$

Therefore, $\mathfrak{R}_n$ converges weakly in $L^{3/2}(\Omega)$ to $\overline{\mathfrak{R}} = \{ \mathbf{u}_j (\overline{\varphi} R_{ij} \overline{\mathbf{v}^{(m)}}_i - \overline{\mathbf{v}^{(m)}}_i R_{ij} \overline{\varphi}) \}$. Passing to the limit in (4.7) and using (4.10)–(4.11), we obtain

$$\int_\Omega h\overline{\varphi V} dx = \int_\Omega (\overline{\mathbf{v}} \overline{\mathfrak{P}} - \overline{\varphi}\overline{\mathcal{P}} + \overline{\mathfrak{R}}) dx + \overline{\varpi^{(m)}} \tag{4.12}$$

with $|\overline{\varpi^{(m)}}| \le \limsup |\varpi_n^{(m)}|$. On the other hand, passage to the limit in equalities (4.2) and (4.5) gives

$$\mathrm{div} \Big\{ h\rho \mathbf{u} \otimes \mathbf{u} - \Pi(h\mathbf{u}) + h\overline{p} I + \nu \mathbf{u} \otimes \nabla h + \nu \nabla h \otimes \mathbf{u} + (\xi - \nu) \nabla h \cdot \mathbf{u} \Big\}$$

$$- \big(\rho \mathbf{u} \otimes \mathbf{u} - \Pi(\mathbf{u}) + \overline{p} I \big) \nabla h = h\rho \mathbf{f}, \tag{4.13}$$

$$\mathrm{div}\,(h\overline{\varphi}\mathbf{u}) + h\overline{(\varphi'\rho - \varphi)\mathrm{div}\,\mathbf{u}} - \overline{\varphi} \nabla h \cdot \mathbf{u} = 0. \tag{4.14}$$

Applying the operators $\overline{\varphi}A$ and $\overline{\mathbf{v}}\cdot A$, respectively, to both sides of the moment and the renormalized mass balance equations and arguing as before, we obtain

$$\int_\Omega h\overline{\varphi}\overline{V}dx = \int_\Omega \big(\overline{\mathbf{v}^{(m)}}\overline{\mathfrak{P}} - \overline{\varphi}\overline{\mathcal{P}} + \overline{\mathfrak{R}}\big)dx + \varpi^{(m)}, \tag{4.15}$$
$$\text{where } \ \varpi^{(m)} = \int_\Omega \overline{\varphi}R : [h(\overline{\mathbf{v}} - \rho\mathbf{u})\otimes\mathbf{u}]dx.$$

Combining (4.12) and (4.15), we finally obtain

$$\int_\Omega h\overline{\varphi}\overline{V}dx - \int_\Omega h\overline{\varphi V}dx = \varpi^{(m)} - \overline{\varpi^{(m)}}. \tag{4.16}$$

By Lemma 3.3 the sequence $h\rho_n\mathbf{u}_n\otimes\mathbf{u}_n$ converges weakly in $L^{1+\kappa}(\Omega)$ to $h\rho\mathbf{u}\otimes\mathbf{u}$; obviously $\rho_n^{(m)}\mathbf{u}_n = \mathbf{v}_n^{(m)}$ converges weakly in $L^6(\Omega)$ to $\overline{\mathbf{v}^{(m)}}$. From this we conclude that

$$\begin{aligned}|\varpi^{(m)}| &\le \|R : [h(\overline{\mathbf{v}^{(m)}} - \rho\mathbf{u})\otimes\mathbf{u}]\|_{L^1(\Omega)} \le c\|h(\overline{\mathbf{v}^{(m)}} - \rho\mathbf{u})\otimes\mathbf{u}\|_{L^{1+\kappa/2}(\Omega)}\\ &\le c\limsup_{n\to\infty}\|h(\mathbf{v}_n - \rho_n\mathbf{u}_n)\otimes\mathbf{u}_n\|_{L^{1+\kappa/2}(\text{spt } h)}.\end{aligned}$$

Similar arguments can be used to obtain the same bound for $\limsup_{n\to\infty}|\varpi_n^{(m)}|$. Since the sequence $\rho_n\mathbf{u}_n\otimes\mathbf{u}_n$ is bounded in $L^{1+\kappa}_{loc}(\Omega)$ and the sequence ρ_n is bounded in $L^1(\Omega)$, we have

$$\begin{aligned}\|h(\mathbf{v}_n^{(m)} - \rho_n\mathbf{u}_n)\otimes\mathbf{u}_n\|_{L^{1+\kappa/2}(\text{spt } h)} &\le c(h)\|(\rho_n^{(m)} - \rho_n)\mathbf{u}_n\otimes\mathbf{u}_n\|_{L^{1+\kappa/2}(\text{spt } h)}\\ &\le c\Big(\int_{\{\rho_n>m\}\cap\text{spt } h}(\rho_n|\mathbf{u}_n|^2)^{1+\kappa/2}dx\Big)^{2/(2+\kappa)}\\ &\le c\|\rho_n|\mathbf{u}_n|^2\|_{L^{1+\kappa}(\text{spt } h)}\ \text{mes}\ \{\rho_n > m\}^\beta \le cm^{-\beta},\end{aligned}$$

where $\beta = \kappa(1+\kappa)^{-1}(2+\kappa)^{-1} > 0$. Hence $|\varpi^{(m)}| + |\overline{\varpi^{(m)}}| \to 0$ for $m\to\infty$. It remains to note that the left-hand side of (4.16) does not depend on n, and the proof of Lemma 4.1 is completed. □

COROLLARY 4.2. *Assume that the function $\lambda\mapsto\varphi(\lambda)$ belongs to the class $C^\infty(\mathbb{R})$ and vanishes for sufficiently large λ. Let $\overline{\varphi p}\in L^\infty(D)$ be an L^∞-star-weak limit of the sequence $\{\varphi(\rho_n)p(\rho_n)\}$, $\overline{\varphi\text{div}\,\mathbf{u}}\in L^2(D)$ be L^2- weak limit of the sequence $\{\varphi(\rho_n)\text{div}\,\mathbf{u}_n\}$. Then*

$$\frac{1}{\xi+\nu}\overline{\varphi p} - \overline{\varphi\text{div}\,\mathbf{u}} = \frac{1}{\xi+\nu}\overline{\varphi p} - \overline{\varphi}\text{div}\,\mathbf{u} \quad \textit{in} \quad D\setminus S, \tag{4.17}$$

where $\overline{\varphi}$ and $\overline{p}$ are given by Lemma 3.2.

Proof. Recall that $D\setminus S = (D\setminus B)\cup\Omega$. Since the characteristic function of any compact subset of Ω is a pointwise limit of a sequence of smooth functions compactly supported in Ω, relation (4.17) holds true on each compact subset of Ω. It remains to note that both sides of (4.17) belong to $L^1(D\setminus S)$ and vanish outside of B. □

5. The oscillation defect measure. The notion of the oscillation defect measure was introduced in [6] to justify the existence theory for isentropic flows with *small* values of the adiabatic constant γ. Following [6], [11] the r-oscillation defect measure associated with the sequence $\{\rho_n\}_{n\le1}$ is defined as

$$\mathbf{osc}_r[\rho_n\to\rho\,](K) := \sup_{k\ge1}\limsup_{n\to\infty}\|T_k(\rho_n) - T_k(\rho)\|^r_{L^r(K)},$$

where $T_k(z) = kT(z/k)$, with $T(z)$ a smooth concave function, is equal to z for $z \le 1$ and is a constant for $z \ge 3$. The smoothness properties of T_k are not important and we can take the simplest form $T_k(z) = \min\{z, k\}$. Note that the total energy estimates provide the boundedness of the γ-oscillation defect measure on the whole domain D. The unexpected result was obtained by Feireisl [6] and Feireisl, Novotný, and Petzeltová [8], who showed that the $(1+\gamma)$-oscillation defect measure associated with the sequence $\{\rho_n\}$ is uniformly bounded on all compact subsets of Ω.

Note that in the shape optimization problem we cannot replace the compact subsets $K \Subset \Omega$ with the domain Ω itself, since the oscillation defect measure is not any *regular* set additive function on the family of compact subsets of Ω, i.e., it is not any measure in the sense of measure theory. To bypass this difficulty we observe that the finiteness of the oscillation defect measure on compacts gives some additional information on the properties of the distribution function Γ. Our task is to first extract this information and then to use it in the proof of Theorem 1.2. In order to formulate the appropriate auxiliary result, we define the function $\mathcal{T}_\vartheta(x)$ by the equality

$$\mathcal{T}_\vartheta(x) = \overline{\min\{\rho, \vartheta\}}(x) - \min\{\rho(x), \vartheta(x)\} \quad \text{for each} \quad \vartheta \in C(\Omega)\,.$$

LEMMA 5.1. *Under the assumptions of Theorem* 1.2 *and Lemma* 3.2*, there is a constant c independent of ϑ and K such that the inequalities*

$$\|\mathcal{T}_\vartheta\|^{1+\gamma}_{L^{1+\gamma}(K)} \le \lim_{n\to\infty} \int_\Omega |\min\{\rho_n(x), \vartheta(x)\} - \min\{\rho(x), \vartheta(x)\}|^{1+\gamma} dx \le c \tag{5.1}$$

hold for all $\vartheta \in C(\Omega)$ and $K \Subset \Omega$. We point out that the limit in (5.1) *does exist by the choice of the sequence ρ_n.*

Proof. The proof imitates the proof of Lemma 4.3 from [8]. It can be easily seen that

$$\|\mathcal{T}_\vartheta\|^{1+\gamma}_{L^{1+\gamma}(K)} \le \limsup_{n\to\infty} \int_K |\min\{\rho_n(x), \vartheta(x)\} - \min\{\rho(x), \vartheta(x)\}|^{1+\gamma}\, dx. \tag{5.2}$$

Hence it suffices to show that the right-hand side of this inequality admits a bound independent of ϑ. From the properties of $\min\{\cdot,\cdot\}$, it follows that

$$|\min\{s', \vartheta\} - \min\{s'', \vartheta\}|^{1+\gamma} \le (\min\{s', \vartheta\} - \min\{s'', \vartheta\})(s'^\gamma - s''^\gamma) \quad \text{for all} \quad s', s'' \in \mathbb{R}^+;$$

furthermore, for the weak limits we have the inequalities $\overline{\rho^\gamma} \ge \rho^\gamma$ and $\overline{\min\{\rho, \vartheta\}} \le \min\{\rho, \vartheta\}$, and therefore, for any compactly supported, nonnegative function $h \in C(\Omega)$, we get

$$\begin{aligned}
&\lim_{n\to\infty} \int_\Omega h |\min\{\rho_n, \vartheta\} - \min\{\rho, \vartheta\}|^{1+\gamma}\, dx \\
&\le \lim_{n\to\infty} \int_\Omega h(\min\{\rho_n, \vartheta\} - \min\{\rho, \vartheta\})(\rho_n^\gamma - \rho^\gamma)\, dx \\
&\le \lim_{n\to\infty} \int_\Omega h(\min\{\rho_n, \vartheta\} - \min\{\rho, \vartheta\})(\rho_n^\gamma - \rho^\gamma)\, dx \\
&\quad + \int_\Omega (\overline{\rho^\gamma} - \rho^\gamma)(\min\{\rho, \vartheta\} - \overline{\min\{\rho, \vartheta\}})\, dx \\
&= \lim_{n\to\infty} \int_\Omega h(\rho_n^\gamma \min\{\rho_n, \vartheta\} - \overline{\rho^\gamma}\,\overline{\min\{\rho, \vartheta\}})\, dx \\
&= \lim_{n\to\infty} \int_\Omega h(p(\rho_n) \min\{\rho_n, \vartheta\} - \overline{p}\,\overline{\min\{\rho, \vartheta\}})\, dx.
\end{aligned} \tag{5.3}$$

By Lemma 4.1 with $\Phi(\rho,x)=h(x)\min\{\rho,\vartheta(x)\}$, the right-hand side of (5.3), divided by $(\xi+\nu)$, is equal to

$$
\begin{aligned}
(5.4)\qquad &\lim_{n\to\infty}\int_\Omega h(\min\{\rho_n,\vartheta\}\operatorname{div}\mathbf{u}_n-\overline{\min\{\rho,\vartheta\}}\operatorname{div}\mathbf{u})\,dx\\
&=\lim_{n\to\infty}\int_\Omega h(\min\{\rho_n,\vartheta\}-\min\{\rho,\vartheta\})\operatorname{div}\mathbf{u}_n dx\\
&\quad-\lim_{n\to\infty}\int_\Omega h(\min\{\rho_n,\vartheta\}-\min\{\rho,\vartheta\})\operatorname{div}\mathbf{u}\,dx\\
&\le\delta\limsup_{n\to\infty}\int_\Omega h|\min\{\rho_n,\vartheta\}-\min\{\rho,\vartheta\}|^{1+\gamma}\,dx\\
&\quad+\delta^{-\gamma}\lim_{n\to\infty}\int_\Omega h(|\operatorname{div}\mathbf{u}_n|+|\operatorname{div}\mathbf{u}|)^{(1+\gamma)/\gamma}\\
&\le\delta\lim_{n\to\infty}\int_\Omega h|\min\{\rho_n,\vartheta\}-\min\{\rho,\vartheta\}|^{1+\gamma}\,dx+c\delta^{-\gamma}\|h\|_{C(\Omega)}.
\end{aligned}
$$

Combining (5.4) and (5.3), choosing $h=1$ on K, and choosing $\delta>0$ with δ sufficiently small, we obtain (5.1). □

We reformulate this result in terms of the distribution function Γ. Recall that the functions $\min\{\rho_n,\lambda\}$ are uniformly bounded in $\mathbb{R}^3$ and that $\min\{\rho_n,\lambda\}\operatorname{div}\mathbf{u}_n$ converges weakly in $L^2(D)$ for all nonnegative λ. Introduce the functions

$$
\begin{aligned}
(5.5)\qquad \mathcal{V}_\lambda&=\overline{\Big(\min\{\rho,\lambda\}\operatorname{div}\mathbf{u}\Big)}-\overline{\min\{\rho,\lambda\}}\operatorname{div}\mathbf{u}\in L^2(D),\\
\mathfrak{H}(x)&=\int_{[0,\infty)}\Gamma(x,s)(1-\Gamma(x,s))\,ds,\qquad \mathfrak{H}\in L^\gamma(D).
\end{aligned}
$$

Lemma 5.2. *There is a constant c independent of λ such that*

$$
(5.6)\qquad \|\mathfrak{H}\|_{L^{1+\gamma}(D\setminus S)}+\sup_\lambda\|\mathcal{V}_\lambda\|_{L^1(D\setminus S)}\le c.
$$

Proof. Recall that $D\setminus S=(D\setminus B)\cup\Omega$ and that $H=\mathcal{V}_\lambda=0$ on $D\setminus B$. Hence it is sufficient to prove that for all compacts $K\Subset\Omega$, we have

$$
(5.7)\qquad \|\mathfrak{H}\|_{L^{1+\gamma}(K)}+\sup_\lambda\|\mathcal{V}_\lambda\|_{L^1(K)}\le c,
$$

with the constant c independent of K. We begin with the observation that by Lemma 3.2,

$$
(5.8)\qquad \mathcal{T}_\vartheta(x)=\int_{[0,\infty)}\min\{\lambda,\vartheta(x)\}\,d_\lambda\Gamma(x,\lambda)-\min\left\{\int_{[0,\infty)}\lambda\,d_\lambda\Gamma(x,\lambda),\vartheta(x)\right\}
$$

for all functions $\vartheta\in C(D)$. From this and the identity $\rho(x)=\int_{[0,\infty)}(1-\Gamma(x,\lambda))\,d\lambda$, we conclude that

$$
(5.9)\qquad \mathcal{T}_\vartheta(x)=\int_0^{\vartheta(x)}\Gamma(x,s)\,ds\ \text{ for }\vartheta(x)\ge\rho(x)\ \text{ and }\ \mathcal{T}_\vartheta(x)=\int_{\vartheta(x)}^\infty(1-\Gamma(x,s))\,ds\ \text{ otherwise.}
$$

Next, choose a sequence of continuous nonnegative functions $\{\vartheta_k\}_{k\geq 1}$ which converge for $k \to \infty$ to the density $\vartheta_k \to \rho$ a.e. in $D \setminus S$. By Lemma 5.1 the norms in $L^{1+\gamma}(K)$ of functions $\mathcal{T}_{\vartheta_k}$ are uniformly bounded by a constant independent of k and K. Moreover, $\mathcal{T}_{\vartheta_k}$ converges a.e. in K to the function

$$\mathcal{T}_\rho(x) = \int_0^{\rho(x)} \Gamma(x,s)\,ds = \int_{\rho(x)}^{\infty} (1-\Gamma(x,s))\,ds,$$

which yields the estimates $\|\mathcal{T}_\rho\|_{L^{1+\gamma}(K)} \leq c$ with the constant c independent of K. It remains to note that estimate (5.7) for $\mathfrak{H}$ obviously follows from the inequality $\mathfrak{H} \leq 2\mathcal{T}_\rho$.

To estimate $\mathcal{V}_\lambda$ note that

$$\mathcal{V}_\lambda = \text{w-}\lim_{n\to\infty}\Big((\min\{\rho_n,\lambda\} - \min\{\rho,\lambda\})\operatorname{div}\mathbf{u}_n\Big) - \Big(\text{w-}\lim_{n\to\infty}\min\{\rho_n,\lambda\} - \min\{\rho,\lambda\}\Big)\operatorname{div}\mathbf{u},$$

where w-lim is denotes the weak limit in $L^1(D\setminus S)$. From this and the boundedness of norms $\|\operatorname{div}\mathbf{u}_n\|_{L^2(D)}$, we obtain

$$\begin{aligned}\|\mathcal{V}_\lambda\|_{L^1(K)} \leq \limsup_{n\to\infty}&(\|\operatorname{div}\mathbf{u}_n\|_{L^2(K)} + \|\operatorname{div}\mathbf{u}\|_{L^2(K)})\\ &\times \|\min\{\rho_n(x),\lambda\} - \min\{\rho(x),\lambda\}\|_{L^2(K)},\end{aligned}$$

which along with (5.1) implies (5.7). The proof of Lemma 5.2 is completed. □

6. Kinetic formulation of the mass balance equation. In this section we show that the distribution function $\Gamma(x,\lambda)$ of the Young measure, associated with a given sequence of solutions to problem (1.3), satisfies some integrodifferential transport equation, which is called the kinetic equation. This result is given by the following lemma. Fix an arbitrary function $\zeta(x,\lambda)$ satisfying the conditions

$$\zeta \in C_0^\infty(D\times\mathbb{R}), \qquad \operatorname{spt}\zeta \Subset D\setminus(\Sigma^-\cup S). \tag{6.1}$$

We use the notation ∂_λ for the partial derivatives with respect to the variable λ, e.g., $\partial_\lambda\zeta := \frac{\partial\zeta}{\partial\lambda}$. The absolutely continuous measure is denoted by $d_\lambda\zeta := \partial_\lambda\zeta d\lambda$.

Recall that the compact obstacle is of the form $S = B\setminus\Omega$ and that $\Sigma^- \subset \partial B$ is the *exit* set.

LEMMA 6.1. *Suppose that all assumptions of Theorem* 1.2 *are satisfied and* Γ *is a distribution function of the Young measure associated with a given sequence* $\{\rho_n\}$ *of solutions to problem* (1.3). *Then*

$$\int_{(D\setminus S)\times\mathbb{R}} \Gamma(x,\lambda)\nabla_{x,\lambda}\zeta\cdot\mathbf{w}\,d\lambda\,dx + \int_{(D\setminus S)\times\mathbb{R}} \lambda\mathcal{M}(x,\lambda)\,d_\lambda\zeta dx = 0. \tag{6.2}$$

Here $\mathbf{w}$ *is the solenoidal vector field of the form* $\mathbf{w}(x,\lambda) = (\mathbf{u}(x), -\lambda\operatorname{div}\mathbf{u})$, *and the function* $\mathcal{M}$ *is defined by the equalities*

$$\mathcal{M}(x,\lambda) = -\frac{1}{\xi+\nu}\int_{(-\infty,\lambda)}(s^\gamma - \overline{\rho})\,d_s\Gamma(x,s) = \frac{1}{\xi+\nu}\int_{[\lambda,\infty)}(s^\gamma-\overline{\rho})\,d_s\Gamma(x,s), \tag{6.3}$$

in which the weak limit for the pressure $\overline{\rho}(x) = \int_{\mathbb{R}}\lambda^\gamma d_\lambda\Gamma(x,\lambda)$ *is defined as in Lemma* 3.2. *Integral identity* (6.2) *is equivalent, in the sense of distributions, to the kinetic equation*

$$\begin{aligned}&\frac{\partial}{\partial\lambda}\big[\lambda\operatorname{div}\mathbf{u}(x)\Gamma(x,\lambda)\big] - \operatorname{div}\big(\Gamma(x,\lambda)\mathbf{u}(x)\big) - \frac{\partial}{\partial\lambda}[\lambda\mathcal{M}(x,\lambda)] = 0\\ &\quad \text{in}\ \ \mathcal{D}'\big((D\setminus(S\cup\Sigma^-))\times\mathbb{R}\big).\end{aligned} \tag{6.4}$$

Remark 6.1. Since the kinetic equation is understood in the sense of distributions, the equation remains valid if we replace the intervals of integration $(-\infty,\lambda)$ and $[\lambda,\infty)$ in formulae (6.3) with $(-\infty,\lambda]$ and (λ,∞) respectively; however, this creates some discomfort. To avoid such ambiguity, we observe that (6.2) also holds true if we replace the function $\mathcal{M}$ with its invariant form

$$\mathfrak{M}(x,\lambda) := \frac{1}{2}\Big(\lim_{s\to\lambda+0}\mathcal{M}(x,s)+\lim_{s\to\lambda-0}\mathcal{M}(x,s)\Big). \tag{6.5}$$

Proof. Choose an arbitrary $\varphi\in C_0^\infty(\mathbb{R})$, and note that for all $h\in C^\infty(D)$ with $\operatorname{spt} h \Subset D\setminus\big(\Sigma^-\cup S\big)$,

$$\int_{D\setminus S}\Big\{h\big(\varphi(\rho_n)-\varphi'(\rho_n)\rho_n\big)\operatorname{div}\mathbf{u}_n+\varphi(\rho_n)\nabla h\cdot\mathbf{u}_n\Big\}dx=0.$$

Taking the limit $n\to\infty$, we obtain

$$\int_{D\setminus S}\Big\{h\overline{\big(\varphi-\varphi'\rho\big)\operatorname{div}\mathbf{u}}+\overline{\varphi}\nabla h\cdot\mathbf{u}\Big\}dx=0,$$

which along with (4.17) gives the integral identity for weak limits,

$$\int_{D\setminus S}\Big[h\overline{\big(\varphi-\varphi'\rho\big)}\operatorname{div}\mathbf{u}+\overline{\varphi}\nabla h\cdot\mathbf{u}+\frac{1}{\xi+\nu}\big(\overline{(\varphi-\varphi'\rho)p}-\overline{(\varphi-\varphi'\rho)}\,\overline{p}\big)\Big]dx=0. \tag{6.6}$$

Next choose an arbitrary smooth function $\eta(\lambda)$ which vanishes near $+\infty$ and set $\varphi(\lambda)=\int_\lambda^\infty\eta(s)ds$. Identity (3.3) from Lemma 3.2 combined with the formula of integration by parts for Stieltjes integrals yields the representations

$$\Big(\overline{\varphi-\varphi'\rho}\Big)(x)=\int_{[0,\infty)}\eta(\lambda)\Gamma(x,\lambda)\,d\lambda+\int_{[0,\infty)}\lambda\eta(\lambda)d_\lambda\Gamma(x,\lambda)=\int_{[0,\infty)}\eta\,d_\lambda(\lambda\Gamma)\,,$$

which are substituted into (6.6) and lead to the integral identity

$$\begin{aligned}\int_{(D\setminus S)\times\mathbb{R}}&\Big\{h\operatorname{div}\mathbf{u}\,d_\lambda\big(\lambda\Gamma(x,\lambda)\big)+\Gamma\nabla h\mathbf{u}d\lambda\Big\}\eta\,dx\\&+\frac{1}{\xi+\nu}\int_{D\setminus S}h\Big\{\overline{(\varphi-\varphi'\rho)p}-\overline{(\varphi-\varphi'\rho)}\,\overline{p}\Big\}\,dx=0.\end{aligned} \tag{6.7}$$

Recall that Γ vanishes for $\lambda<0$, the function $G(x,\lambda)=(\varphi(\lambda)-\varphi'(\lambda)\lambda)h(x)$ satisfies all conditions of Lemma 3.2, and h is compactly supported in $D\setminus S$. It follows from this and Lemma 3.2 that

$$\int_{D\setminus S}h\Big(\overline{(\varphi-\varphi'\rho)p}-\overline{(\varphi-\varphi'\rho)}\,\overline{p}\Big)dx=\int_{(D\setminus S)\times\mathbb{R}}h\eta\lambda(\lambda^\gamma-\overline{p})d_\lambda\Gamma(x,\lambda)dx$$

$$+\int_{(D\setminus S)\times\mathbb{R}}h\Big\{\int_\lambda^\infty\eta(s)ds\Big\}(\lambda^\gamma-\overline{p})d_\lambda\Gamma(x,\lambda)dx=-(\xi+\nu)\int_{(D\setminus S)\times\mathbb{R}}h\eta\;d_\lambda\big(\lambda\mathcal{M}(x,\lambda)\big)dx.$$

By substitution of this identity into (6.7), since the linear hull of the set of functions in the form $h\eta$ is dense in $C_0^\infty((D\setminus S)\times\mathbb{R})$, we obtain (6.2), which completes the proof of Lemma 6.1. □

The next lemma describes the basic properties of the function $\mathcal{M}(x,\lambda)$, which are important for further analysis.

LEMMA 6.2. *For a.e.* $x \in D \setminus S$,

(i) $\mathcal{M}(x,\cdot)$ *is nonnegative and vanishes on* $\mathbb{R}^-$. *Moreover, if the Borel function* $\mathfrak{M}(x,.)$ *given by* (6.5) *vanishes* σ_x*-a.e. on the interval* (ω,∞) *with* $\omega = \overline{p}(x)^{1/\gamma}$, *then* $\sigma_x = d_\lambda\Gamma(x,\cdot)$ *is a Dirac measure and*

$$\Gamma(x,\lambda) = 0 \quad \textit{for} \quad \lambda < \overline{p}(x)^{1/\gamma}, \quad \Gamma(x,\lambda) = 1 \quad \textit{for} \quad \lambda \geq \overline{p}(x)^{1/\gamma}.$$

(ii) *for all* $g \in C_0^\infty(0,\infty)$,

$$\int_{\mathbb{R}_\lambda} g(\lambda)\mathcal{M}(x,\lambda)d\lambda = -\int_{[0,\infty)} g'(\lambda)\mathcal{V}_\lambda(x)d\lambda, \tag{6.8}$$

where $\mathcal{V}_\lambda$ *is defined by* (5.5).

Proof. Let θ be a standard mollifying kernel in $\mathbb{R}$,

$$\theta \in \mathcal{D}_+(\mathbb{R}), \quad \int_{\mathbb{R}} \theta(t)\,dt = 1, \quad \text{spt } \theta \Subset \{|t| \leq 1\},$$

with the corresponding mollifier

$$(\mathbf{S}_k\Gamma)(x,\lambda) := k\int_{\mathbb{R}} \theta(k(\lambda - t))\Gamma(x,t)dt.$$

We will write simply Γ_k instead of $\mathbf{S}_k\Gamma$. The mollified distribution function $\Gamma_k(x,\cdot)$ belongs to the class $C^\infty(\mathbb{R})$ and generates the absolutely continuous Stieltjes measure σ_{kx} of the form $d\sigma_{kx} = \partial_\lambda\Gamma_k d\lambda$. It is easily seen that for $k \to \infty$ the sequence of measures σ_{kx} converges star-weakly to the measure $\sigma_x = d_\lambda\Gamma$ in the space of Radon's measures on $\mathbb{R}$. In particular, for all λ with $\sigma_x\{\lambda\} := \lim_{s\to\lambda+0}\Gamma(x,s) - \lim_{s\to\lambda-0}\Gamma(x,s) = 0$, we can pass to the limit to obtain

$$\int_{[0,\lambda)} (t^\gamma - \overline{p})\partial_t\Gamma_k(x,t)\,dt \to \int_{[0,\lambda)} (t^\gamma - \overline{p})\,d_t\Gamma(x,t) \quad \text{for} \quad k \to \infty. \tag{6.9}$$

In other words, relation (6.9) holds true for all λ, except possibly for some countable set. Since $\partial_\lambda\Gamma_k \geq 0$, the function on the left-hand side of (6.9) increases on $(-\infty,\omega)$ and decreases on (ω,∞). From this and (6.9) we conclude that $\mathcal{M}(x,\cdot)$ does not decrease for $\lambda < \omega$ and does not increase for $\lambda > \omega$, which along with the obvious relations $\lim_{\lambda\to\pm\infty}\mathcal{M}(x,\lambda) = 0$ yields the nonnegativity of $\mathcal{M}$.

To prove the second part of (i), note that $\mathfrak{M}(x,\lambda) = \lim_{k\to\infty}\mathbf{S}_k\mathcal{M}(x,\lambda)$ belongs to the first Baire class and hence is measurable in σ_x. It follows from the monotonicity of $\mathfrak{M}(x,\cdot)$ on the interval (ω,∞) that if $\mathfrak{M}(x,\alpha) = 0$ for some $\alpha > \omega$, then $\mathfrak{M}(x,\lambda) = 0$ and $\Gamma(x,\lambda) = 1$ on (α,∞). Assume that $\mathfrak{M}(x,\cdot)$ vanishes σ_x-a.e. on (ω,∞), and consider the set

$$\mathcal{O} = \Big\{\alpha > \omega : \quad \sigma_x(\omega,\alpha) \equiv \lim_{s\to\alpha-0}\Gamma(x,s) - \lim_{s\to\omega+0}\Gamma(x,s) = 0\Big\}.$$

Let us prove that $\mathcal{O} = (\omega,\infty)$. If the set $\mathcal{O}$ is empty, then there is a sequence of points $\lambda_k \searrow \omega$ with $\mathfrak{M}(x,\lambda_k) = 0$, which yields $\Gamma(x,\cdot) = 1$ on (ω,∞), and thus $\mathcal{O} = (\omega,\infty)$. Hence $\mathcal{O} \neq \emptyset$. If $m = \sup\mathcal{O} < \infty$, then there is a sequence $\lambda_k \searrow m$ with $\mathfrak{M}(x,\lambda_k) = 0$, which yields $\Gamma(x,\cdot) = 1$ on (m,∞). By construction, $\Gamma(x,\lambda) = c =$ constant on (ω,m). In other words, restriction of σ_x to (ω,∞) is the monoatomic measure $(1-c)\delta(\cdot - m)$. Hence $\mathfrak{M}(x,m) = 2^{-1}(1-c)(m^\gamma - \omega^\gamma) = 0$, which yields

$c = 1$. From this we can conclude that $\Gamma(x,\cdot) = 1$ on (ω,∞), and σ_x is a probability measure concentrated on $[0,\omega]$. Recalling that $\omega^\gamma = \overline{p}(x)$, we obtain

$$(\xi+\nu)\mathcal{M}(x,0) = \int_{[0,\omega]} (\lambda^\gamma - \omega^\gamma)\, d_\lambda\Gamma(x,\lambda) \geq 0.$$

Hence $d_\lambda\Gamma(x,\lambda)$ is the Dirac measure concentrated at ω, which implies (i).

The proof of (ii) is straightforward. It is easily seen that

$$\begin{aligned}
-(\xi+\nu)\int_{\mathbb{R}} g(\lambda)\mathcal{M}(x,\lambda)\,d\lambda &= \int_{[0,\infty)} \left(\int_{[\lambda,\infty)} g'(s)\,ds\right)\left(\int_{[\lambda,\infty)} (t^\gamma - \overline{p}) d_t\Gamma(x,t)\right) d\lambda \\
&= \int_{[0,\infty)} g'(s)\left(\int_{[0,s)} d\lambda \int_{[\lambda,\infty)} (t^\gamma - \overline{p})\, d_t\Gamma(x,t)\right) ds \\
&= \int_{[0,\infty)} g'(s)\left(\int_{[0,\infty)} \min\{t,s\}(t^\gamma - \overline{p})\, d_t\Gamma(x,t)\right) ds \\
&= \int_{[0,\infty)} g'(s)(\overline{\min\{\rho,s\}p} - \overline{\min\{\rho,s\}}\overline{p})\, ds.
\end{aligned}$$

On the other hand, Lemma 4.1 yields $\overline{\min\{\rho,\lambda\}p} - \overline{\min\{\rho,\lambda\}}\overline{p} = (\xi+\nu)\mathcal{V}_\lambda(x)$. The proof of Lemma 6.2 is completed. □

7. Renormalization of the kinetic equation. The notion of a renormalized solution, introduced in the pioneering paper [4], plays an important role in the theory of compressible NSE developed by Lions and by E. Feireisl and coworkers. Moreover, the kinetic equation itself is a result of the renormalization procedure. Formally we can renormalize (6.4) by multiplying both sides by a function $\Psi'(\Gamma)$, which leads to the transport equation for the function $\Psi(\Gamma)$, but whether this construction is justified a delicate question. The corresponding result is given by the following lemma. Set $\Psi(\Gamma) = \Gamma(1-\Gamma)$.

LEMMA 7.1. *For all functions $h \in C_0^\infty(D\setminus S)$ with spt $h \Subset D\setminus(S\cup\Sigma^-)$ and for all functions $\eta \in C^\infty(\mathbb{R})$ vanishing near $+\infty$, we have the integral identity*

$$\int_{(D\setminus S)\times\mathbb{R}} \mathcal{F}(x,\lambda)dx\,d\lambda = 2\int_{(D\setminus S)} \left(\int_{[0,\infty)} \eta(\lambda)\lambda\mathfrak{M}(x,\lambda)d_\lambda\Gamma(x,\lambda)\right)h(x)\,dx, \tag{7.1}$$

where

$$\mathcal{F} \equiv \eta(\lambda)\Psi(\Gamma)\mathbf{u}(x)\nabla h(x) - \lambda h(x)\Psi(\Gamma)\eta'(\lambda)\operatorname{div}\mathbf{u}(x) + \lambda h(x)\Psi'(\Gamma)\mathcal{M}(x,\lambda)\eta'(\lambda).$$

In other words, the function $\Psi(\Gamma)$ satisfies the transport equation

$$\operatorname{div}_{\lambda,x}\big(\Psi(\Gamma)\mathbf{w}\big) + \frac{\partial}{\partial\lambda}\big(\lambda\Psi'(\Gamma)\mathcal{M}\big) + 2\lambda\mathfrak{M}\frac{\partial\Gamma}{\partial\lambda} = 0 \quad \textit{in} \quad \mathcal{D}'\Big(\big(D\setminus(\Sigma^-\cup S)\big)\times\mathbb{R}\Big).$$

Proof. Note that by assertion (i) of Lemma 3.2, the function Γ is well defined on each domain in $\mathbb{R}^4$, and hence on the whole space $\mathbb{R}^4$. The same conclusion can be drawn for the vector field $\mathbf{u} \in H^{1,2}_{loc}(\mathbb{R}^3)$. Let Θ be the regularizing kernel in $\mathbb{R}^3$, i.e.,

$$\Theta \in \mathcal{D}_+(\mathbb{R}^3), \quad \int_{\mathbb{R}^3} \Theta(x)dx = 1, \quad \text{spt } \Theta \Subset \{|x| \leq 1\},$$

and define the mollifier for scalar or vector functions,

$$\mathbf{T}_m u(x,\lambda) = m^3 \int_\Omega \Theta(m(x-y))u(y,\lambda)\,dy.$$

We will simply write $\Gamma_{k,m}$ and Γ_k instead of $\mathbf{S}_k\mathbf{T}_m\Gamma$ and $\mathbf{S}_k\Gamma$. Obviously, Γ_k are smooth functions of the variable λ and $|\partial^\alpha\Gamma_k(x,\lambda)| \le k^\alpha$. Recall that for any $f \in L^2(D')$ with $D \Subset D'$ and dist $(D', \partial D) > m^{-1}$,

$$\|\mathbf{T}_m f\|_{L^2(D)} \le \|f\|_{L^2(D')}, \quad \mathbf{T}_m f \to f \ \text{ in } \ L^2(D). \tag{7.2}$$

Substituting the test function

$$\zeta(x,\lambda) = m^3\Theta(m(x_0-x))\theta(k(\lambda_0-\lambda)), \quad \text{dist } (x_0,\partial D) > m^{-1}, \quad \lambda_0 \in \mathbb{R},$$

into (6.2), we arrive at the equality

$$\partial_\lambda[\lambda\Gamma_{k,m}\mathrm{div}\,\mathbf{u}] - \mathrm{div}\,(\Gamma_{k,m}\mathbf{u}) - \partial_\lambda\mathbf{S}_k(\lambda\mathbf{T}_m\mathcal{M}) \tag{7.3}$$

$$+\mathfrak{r}_1 + \mathfrak{r}_2 + \mathfrak{r}_3 = 0, \tag{7.4}$$

which holds true in any subdomain of $D \setminus (S \cup \Sigma^-) \times \mathbb{R}$ for sufficiently large m. Here the remainders are given by

$$\mathfrak{r}_1 = \partial_\lambda\{\mathbf{T}_m(\lambda\Gamma_k\mathrm{div}\,\mathbf{u}) - \lambda\mathrm{div}\,\mathbf{u}\mathbf{T}_m\Gamma_k\}, \quad \mathfrak{r}_2 = \mathbf{T}_m\Big[\mathrm{div}\,\mathbf{u}\partial_\lambda\big(\mathbf{S}_k(\lambda\Gamma) - \lambda\mathbf{S}_k\Gamma\big)\Big],$$
$$\mathfrak{r}_3 = \mathrm{div}\,\big[(\mathbf{T}_m\Gamma_k)\mathbf{u} - \mathbf{T}_m(\Gamma_k\mathbf{u})\big].$$

Recall that $\Gamma_{k,m}$ are smooth functions of the variables x and λ. Multiplying both sides of (7.3) by $h\eta\Psi'(\Gamma_{k,n})$ and integrating the result over $D \setminus S$, we arrive at the equality

$$\int_{(D\setminus S)\times\mathbb{R}} \Big\{\eta(\lambda)\Psi(\Gamma_{k,m})\mathbf{u}(x)\nabla h(x) - \lambda h(x)\Psi(\Gamma_{k,m})\eta'(\lambda)\mathrm{div}\,\mathbf{u}(x)\Big\}dx\,d\lambda \tag{7.5}$$

$$+ J^{k,m} + \sum_{l=1}^{3} I_l^{k,m} = 0,$$

where

$$J^{k,m} = -\int_{(D\setminus S)\times\mathbb{R}} F^{k,m}\partial_\lambda\mathbf{S}_k(\lambda\mathbf{T}_m\mathcal{M}),$$

$$I_i^{k,m} = \int_{(D\setminus S)\times\mathbb{R}} F^{k,m}\mathfrak{r}_i \ \text{ with } \ F^{k,m} = h\eta\Psi'(\Gamma_{k,m})\,.$$

Our first task is to find the limits for $m \to \infty$ of the sequences $\{J^{k,m}\}$, $\{I_l^{k,m}\}$. It follows from inequality (7.2) that for $i = 1, 2$,

$$\|\mathfrak{r}_i\|_{L^2((D\setminus S)\times\mathcal{I})} \le k^c(\mathcal{I}) < \infty \ \text{ for all compact } \ \mathcal{I} \subset \mathbb{R}.$$

On the other hand, since η vanishes near ∞ and $\Gamma_{k,m}$ vanishes for $\lambda < 0$, the functions $F^{k,m}$ are uniformly compactly supported, and their absolute values are uniformly bounded. Hence for $i = 1, 2$,

$$\|F^{k,m}\mathfrak{r}_i\|_{L^2((\mathbf{D}\setminus S)\times\mathbb{R})} \le c < \infty \text{ for all } m \ge 1. \tag{7.6}$$

Noting that $\partial_\lambda\big[\lambda\Gamma_k(\cdot,\lambda)\big] \in L^\infty(D)$, taking into account the form of limits in (7.2), we obtain for fixed λ and k, and for $m \to \infty$,

$$\Gamma_{k,m} \to \Gamma_k, \quad \mathbf{T}_m\Big[\partial_\lambda(\lambda\Gamma_k)\mathrm{div}\,\mathbf{u}\Big] - \mathrm{div}\,\mathbf{u}\mathbf{T}_m\Big[\partial_\lambda(\lambda\Gamma_k)\Big] \to 0,$$
$$\mathbf{T}_m\Big[\mathrm{div}\,\mathbf{u}\partial_\lambda\big(\mathbf{S}_k(\lambda\Gamma) - \lambda\mathbf{S}_k\Gamma\big)\Big] \to \Big[\mathrm{div}\,\mathbf{u}\partial_\lambda\big(\mathbf{S}_k(\lambda\Gamma) - \lambda\mathbf{S}_k\Gamma\big)\Big],$$

a.e. in $D \setminus S$, which along with (7.6) yield for $m \to \infty$,

$$F^{k,m}\mathfrak{r}_1 \to 0, \quad F^{k,m}\mathfrak{r}_2 \to F^k\partial_\lambda\Big[\mathrm{div}\,\mathbf{u}\big(\mathbf{S}_k(\lambda\Gamma) - \lambda\mathbf{S}_k\Gamma\big)\Big] \ \text{ in } \ L^1((D\setminus S)\times\mathbb{R}). \tag{7.7}$$

The next evaluations are based on the following result from [4]: Let $\mathbf{u} \in H^{1,2}(D)$ and $g \in L^\infty\big(D \times (a,b)\big)$ with $b - a < \infty$. Then for all $D' \Subset D$,

$$\mathrm{div}\,\big[(\mathbf{T}_m g)\mathbf{u} - \mathbf{T}_m(g\mathbf{u})\big] \to 0 \ \text{ in } \ L^1(D'\times(a,b)).$$

Setting $g(x,\lambda) = \Gamma_k(x,\lambda)$ since $F^{k,m}$ are uniformly bounded and compactly supported in $(D\setminus S)\times\mathbb{R}$, we can conclude that for $m \to \infty$ the functions $F^{k,m}\mathfrak{r}_3$ tend to zero strongly in $L^1\big((D\setminus S)\times\mathbb{R}\big)$. Combining this result with (7.7), we obtain

$$\lim_{m\to\infty} I_1^{m,k} = \lim_{m\to\infty} I_3^{m,k} = 0,$$
$$\lim_{m\to\infty} I_2^{m,k} = I_2^k := \int_{(D\setminus S)\times\mathbb{R}} F^k\Big[\mathrm{div}\,\mathbf{u}\partial_\lambda\big(\mathbf{S}_k(\lambda\Gamma) - \lambda\mathbf{S}_k\Gamma\big)\Big]\,dx\,d\lambda.$$

Similar arguments show that

$$\lim_{m\to\infty} J^{m,k} = J^k := -\int_{(D\setminus S)\times\mathbb{R}} F^k\partial_\lambda\mathbf{S}_k(\lambda\mathcal{M})\,dx\,d\lambda \ \text{ with } \ F^k = h(x)\eta(\lambda)\Psi'(\Gamma_k). \tag{7.8}$$

Taking the limits, first for $m \to \infty$ and then for $k \to \infty$ in (7.5), we arrive at

$$\int_{(D\setminus S)\times\mathbb{R}} \Big\{\eta(\lambda)\Psi(\Gamma)\mathbf{u}(x)\nabla h(x) - \lambda h(x)\Psi(\Gamma)\eta'(\lambda)\mathrm{div}\,\mathbf{u}(x)\Big\}dx\,d\lambda + \lim_{k\to\infty} J^k + \lim_{k\to\infty} I_2^k = 0. \tag{7.9}$$

Let us show that the last term in the left-hand side equals 0. It is easily seen that

$$\partial_\lambda[(\lambda\Gamma)_k - \lambda\Gamma_k](x,\lambda) = k\int_{\mathbb{R}} \tilde\theta(k(\lambda-t))\Gamma(x,t)\,dt, \quad \tilde\theta(t) = t\theta'(t) + \theta(t).$$

Since $\tilde\theta$ is compactly supported and $\int_{\mathbb{R}} \tilde\theta(s)ds = 0$, the sequence of functions $\partial_\lambda[(\lambda\Gamma)_k - \lambda\Gamma_{k,}](x,\lambda)$ is bounded and converges to 0 a.e. in $(D\setminus S)\times\mathbb{R}$. Recalling that the functions F^k are uniformly supported, i.e., the supports spt F^k are included in the given compact subset of $(D\setminus S)\times\mathbb{R}$, and uniformly bounded in $(D\setminus S)\times\mathbb{R}$, we can conclude that $\lim_{k\to\infty} I_2^k = 0$. Next, integration by parts in the formula for J^k leads to

$$J^k = \int_{(D\setminus S)\times\mathbb{R}} h\eta'\Psi'(\Gamma_k)\mathbf{S}_k(\lambda\mathcal{M})dx\,d\lambda - 2W^k \tag{7.10}$$

with

$$W^k = \int_{(D\setminus S)\times\mathbb{R}} h\eta \mathbf{S}_k(\lambda\mathcal{M})\partial_\lambda\Gamma_k \, dx\, d\lambda. \tag{7.11}$$

Integration by part in the Stieltjes integral results in

$$\partial_\lambda\Gamma_k(x,\lambda) = k\partial_\lambda \int_{\mathbb{R}} \theta(k(\lambda - t)\Gamma(x,t)dt = k\int_{\mathbb{R}} \theta(k(\lambda - t)d_t\Gamma(x,t);$$

therefore,

$$\begin{aligned} W^k &= \int_{(D\setminus S)\times\mathbb{R}} h\mathbf{S}_k\Big[\eta\mathbf{S}_k(\lambda\mathcal{M})\Big]\, d_\lambda\Gamma(x,\lambda)\, dx \\ &\equiv \int_{D\setminus S} h(x)\left(\int_{\mathbb{R}} \eta\mathbf{S}_k^2(\lambda\mathcal{M})\, d_\lambda\Gamma(x,\lambda)\right) dx \\ &\quad + \int_{D\setminus S} h(x)\left(\int_{\mathbb{R}} [\mathbf{R}_k\mathbf{S}_k(\lambda\mathcal{M})](x,\lambda)\, d_\lambda\Gamma(x,\lambda)\right) dx \end{aligned} \tag{7.12}$$

with the linear operator $\mathbf{R}_k$ defined, for any $g \in L^\infty\big((D\setminus S)\times\mathbb{R}\big)$, by

$$\mathbf{R}_k g = \int_{\mathbb{R}} r_k(\lambda,t)g(x,t)dt, \quad \text{where} \quad r_k(\lambda,t) = k(\eta(t) - \eta(\lambda))\theta(k(\lambda - t)).$$

Since the function $\eta(\lambda)$ is smooth and vanishes for $\lambda > N = \sup\ \mathrm{spt}\ \eta$, the kernel $r_k(\lambda,t)$ vanishes for $\lambda > N+1$ and satisfies the inequality $\int_{\mathbb{R}} |r_k(\lambda,t)|\, dt \le ck^{-1}$. Thus, we get

$$|\mathbf{R}_k g| \le ck^{-1} \ \operatorname*{ess\,sup}_x \Big\{ \sup_{s\le N+1} |g(x,s)| \Big\},$$

which along with

$$|\mathbf{S}_k(\lambda\mathcal{M})|(x,\lambda) \le \sup_{s\le\lambda+1} s\mathcal{M}(x,s) \le (\lambda+1)\sup_{\mathbb{R}} \mathcal{M}(x,s) \le 2(\lambda+1)\overline{p}(x)$$

implies $|\mathbf{R}_k\mathbf{S}_k(\lambda\mathcal{M})| \le c(\eta)k^{-1}\overline{p}(x)$. Thus,

$$\left| \int_{\mathbb{R}} [\mathbf{R}_k\mathbf{S}_k(\lambda\mathcal{M})](x,\lambda)\, d_\lambda\Gamma(x,\lambda) \right| \le c(\eta)k^{-1}\overline{p}(x).$$

From this and the Lebesgue dominant convergence theorem we conclude that the last term in the right-hand side of (7.12) vanishes for $k \to \infty$. Recall that $\mathbf{S}_k^2$ is the standard mollifying operator with the kernel $\theta * \theta$. Hence for a.e. $x \in D\setminus S$ and for all $\lambda \in \mathbb{R}$, we have $\lim_{k\to\infty}[\mathbf{S}_k^2(\lambda\mathcal{M})](x,\lambda) = \lambda\mathfrak{M}(x,\lambda)$. From this and the Lebesgue dominant convergence theorem related to the measure $d_\lambda\Gamma(x,\cdot)$, we obtain that for a.e. $x \in D\setminus S$,

$$\lim_{k\to\infty} \int_{\mathbb{R}} \eta[\mathbf{S}_k^2(\lambda\mathcal{M})](x,\lambda)\, d_\lambda\Gamma(x,\lambda) = \int_{\mathbb{R}} \eta\lambda\mathfrak{M}\, d_\lambda\Gamma(x,\lambda).$$

Since the integrands in the right-hand side of (7.12) are uniformly bounded, we have

$$\lim_{k\to\infty} W^k = W := \int_{D\setminus S} h(x)\left(\int_{\mathbb{R}} \eta\lambda\mathfrak{M}\, d_\lambda\Gamma(x,\lambda)\right) dx.$$

On the other hand, for $k \to \infty$ the sequences Γ_k and $\mathbf{S}_k\mathcal{M}$ converge a.e. in $(D\setminus S)\times\mathbb{R}$ to Γ and $\mathcal{M}$, respectively; thus, by the limit passage $k \to \infty$ in (7.10), we obtain

$$\lim_{k\to\infty} J^k = \int_{(D\setminus S)\times\mathbb{R}} h\eta'\Psi'(\Gamma)\lambda\mathcal{M}\,dx\,d\lambda - 2W.$$

Substituting this equality into (7.9) and recalling that $\lim_{k\to\infty} I_2^k = 0$, we obtain (7.1). The proof of Lemma 7.1 is completed. □

8. The proof of Theorem 1.2. The theorem will be proved if we show that any sequence of generalized solutions to problem (1.3) satisfying the hypotheses of Theorem 1.2 and Lemmas 3.2 and 3.3 converges a.e. on $D \setminus S$. In light of Lemmas 3.2 and 3.3, it suffices to verify the equality $\Psi(\Gamma) = 0$ in $(D \setminus S) \times \mathbb{R}$.

We begin with proving that renormalized integral identity (7.1) after substituting $h = 1$ turns into the integral inequality

$$\begin{aligned}\int_{(D\setminus S)\times\mathbb{R}} \Big\{\lambda\Psi'(\Gamma)\mathcal{M}\eta' - \lambda\Psi(\Gamma)\eta'\operatorname{div}\mathbf{u}\Big\}dx\,d\lambda \\ \geq 2\int_{(D\setminus S)} \left(\int_{[0,\infty)} \eta(\lambda)\lambda\mathfrak{M}(x,\lambda)d_\lambda\Gamma(x,\lambda)\right)dx,\end{aligned} \tag{8.1}$$

which holds true for all nonnegative functions $\eta \in C^\infty(\mathbb{R})$ vanishing near $+\infty$. The proof is based on the following approximation result, which is shown by an application of the Hedberg approximation theorem [13].

LEMMA 8.1. *For each $k > 1$, there exist a function $\zeta_k \in C^\infty(D)$ and a constant c independent of k such that ζ_k vanishes in a vicinity of S and*

$$0 \leq \zeta_k \leq 1, \quad \text{meas } A_k + \int_D |\nabla\zeta_k\mathbf{u}|\,dx \leq 1/k, \tag{8.2}$$

where $A_k = \{x \in D \setminus S : \zeta_k(x) \leq 1 - 1/k\} \subset D \setminus S$.

Proof. Introduce the function $f(x) = |\mathbf{u}(x)| + \text{dist }(x, S)$. Since $\mathbf{u} - \mathbf{u}^\infty$ belongs to $H_0^{1,2}(D)$ and $\mathbf{u}^\infty$ vanishes near S, it follows from the general theory of Sobolev spaces (see [28]) that f has a quasi-continuous representative which vanishes everywhere on S. By the Hedberg approximation theorem (see [13]), for each $N > 0$ there is $\omega_N \in C_0^\infty(D)$ so that $\omega_N = 1$ in some vicinity of S, $0 \leq \omega_N \leq 1$, and $\|(1-\omega_N)f\|_{H^{1,2}(D)} \leq N^{-1}$. On the other hand, by the absolute continuity property of the integral, there exists a positive continuous function $\mu(s)$ such that, whenever meas $A \leq \delta$, then

$$\int_A (f^2 + |\nabla f|^2)dx \leq \mu(\delta) \qquad \text{and} \quad \mu(\delta) \searrow 0 \quad \text{for} \quad \delta \searrow 0.$$

For any $\delta > 0$, set $S_\delta = \{x : \text{ dist } (x, S) < \delta\}$. Since $\cap S_\delta = S$, the measure of the set $S_\delta \setminus S$ tends to 0 as $\delta \to 0$, which yields

$$\int_{S_\delta} (f^2 + |\nabla f|^2)dx = \int_{S_\delta\setminus S} (f^2 + |\nabla f|^2)dx \leq \mu\big(\text{meas }(S_\delta \setminus S)\big) := r(\delta) \searrow 0 \quad \text{as} \quad \delta \searrow 0.$$

Obviously, for $B_k = \{x \in D \setminus S : 1 - \omega_N(x) > 1/k\}$, we have

$$\frac{\delta^2}{k^2}\int_{B_k\setminus S_\delta} dx \leq \int_D |f|^2(1-\omega_N)^2\,dx \leq N^{-2},$$

which implies

$$\text{meas } \{B_k \setminus S_\delta\} \le k^2(\delta N)^{-2}, \quad \text{meas } B_k \le k^2(\delta N)^{-2} + \text{meas } (S \setminus S_\delta). \tag{8.3}$$

Next, note that

$$\begin{aligned}\int_D (1-\omega_N)^2 |\nabla f|^2\, dx &\le \frac{1}{k^2}\int_{D\setminus B_k} |\nabla f|^2 dx + \int_{B_k\setminus S_\delta} |\nabla f|^2\, dx + \int_{S_\delta} |\nabla f|^2\, dx \\ &\le ck^{-2} + \mu(k^2(\delta N)^{-2}) + r(\delta),\end{aligned}$$

which along with the identity $f\nabla\omega_N = (1-\omega_N)\nabla f - \nabla\big((1-\omega_N)f\big)$ yields the estimate

$$\begin{aligned}\int_D |\nabla\omega_N| f\, dx &\le \|\nabla\big((1-\omega_N)f\big)\|_{L^1(D)} + \int_D (1-\omega_N)|\nabla f|\, dx \\ &\le c\|(1-\omega_N)f\|_{H^{1,2}(D)} + c\left\{\int_D (1-\omega_N)^2|\nabla f|^2\, dx\right\}^{1/2} \\ &\le N^{-1} + ck^{-1} + c\mu^{1/2}\big(k^2(\delta N)^{-2}\big) + cr^{1/2}(\delta).\end{aligned}$$

Fix $\delta > 0$ sufficiently small such that $r^{1/2}(\delta) + \text{meas } (S \setminus S_\delta) \le k^{-1}$; next, choose N sufficiently large such that $\mu^{1/2}(k^2(\delta N)^{-2}) + k^2(\delta N)^{-2} < k^{-1}$. In view of (8.3) and taking into account that $|\mathbf{u}| \le f$, we arrive at

$$\int_D |\nabla\omega_N||\mathbf{u}|\, dx + \text{meas } B_k \le ck^{-1}.$$

Hence $\zeta_k = 1 - \omega_N$ with $A_k = B_k$ satisfies (8.2). The proof of Lemma 8.1 is completed. □

Following [10] let us consider the sequence of functions $\chi_k(x) = \chi(k \text{ dist } (x, \Sigma^- \cup \partial D))$ with an arbitrary, smooth, monotone function χ such that $\chi(z) = 0$ for $z \le 1/2$ and $\chi(z) = 1$ for $z \ge 1$. Since $\Psi(\Gamma)(\cdot,\lambda)$ vanishes outside of B, we have for all sufficiently large k,

$$\nabla\chi_k(\mathbf{u} - \mathbf{u}^\infty) \to 0 \ \text{ in } \ L^1(D\setminus S), \quad \Psi(\Gamma)(\cdot,\lambda)\nabla\chi_k\mathbf{u}^\infty \le 0 \text{ in } D. \tag{8.4}$$

Set $h_k = \zeta_k\chi_k$ and note that

$$\nabla h_k\mathbf{u} \le |\nabla\zeta_k\mathbf{u}| + |\nabla\chi_k(\mathbf{u} - \mathbf{u}^\infty)| + \zeta_k\nabla\chi_k\mathbf{u}^\infty.$$

Recalling the inequality $\eta \ge 0$ and relations (8.2), (8.4), we obtain

$$\limsup_{k\to\infty} \int_{(D\setminus S)\times\mathbb{R}} \Psi(\Gamma)\eta\nabla h_k\mathbf{u}\, dx\, d\lambda \le 0. \tag{8.5}$$

Moreover, the functions h_k converge to 1 in measure on $D \setminus S$. The functions h_k are Lipschitz continuous in $\mathbb{R}^3$ and vanish in the vicinity of $\Sigma^- \cup S$; therefore, they can be used as test functions in (7.1). Substitution of h_k into (7.1), followed by the limit passage $k \to \infty$ in the resulting integral identity, leads to desired inequality (8.1).

Next, we claim that the right-hand side of (8.1) equals zero. To this end, choose an arbitrary nonnegative function $\upsilon \in C^\infty(\mathbb{R})$ with spt $\upsilon \subset (-1,1)$ and $\int_{\mathbb{R}} \upsilon(\lambda)d\lambda = 1$. For fixed $t > 2$, set $\eta(\lambda) = \int_\lambda^\infty \upsilon(s-t)\, ds$. Since $\eta'(\lambda) = 0$ for $|\lambda - t| \ge 1$, and $\eta(\lambda) = 1$ for $\lambda \le t - 1$, we can use (8.1) to obtain

(8.6)
$$2\int_{(D\setminus S)}\Big(\int_{[0,t-1)}\lambda\mathfrak{M}d_\lambda\Gamma\Big)dx\le-(t+1)\int_{(D\setminus S)\times\mathbb{R}}\Big\{\mathcal{M}+\Psi(\Gamma)|\operatorname{div}\mathbf{u}(x)|\Big\}\eta'\,dx\,d\lambda.$$

Using identity (6.8) and the relation

$$\begin{aligned}&-\int_{(D\setminus S)\times\mathbb{R}}\Psi(\Gamma)\ \eta'(\lambda)\ |\operatorname{div}\mathbf{u}|\,dx\,d\lambda\\&\quad\equiv\int_{[0,\infty)}\eta''\Big\{\int_{D\setminus S}\Big[\int_{\Omega\times[0,\lambda)}\Psi(\Gamma(x,s))\,ds\Big]|\operatorname{div}\mathbf{u}|\,dx\Big\}d\lambda\end{aligned}$$

we can rewrite inequality (8.6) in the form

$$2\int_{(D\setminus S)}\Big(\int_{[0,t-1)}\lambda\mathfrak{M}d_\lambda\Gamma\Big)dx\le(1+t)\int_{[1,\infty)}\eta''(\lambda)\wp(\lambda)d\lambda\ ,\tag{8.7}$$

where the function $\wp:[0,\infty)\mapsto\mathbb{R}$ is given by

$$\wp(\lambda)=\int_{(D\setminus S)\times[0,\lambda)}\Psi(\Gamma(x,s))|\operatorname{div}\mathbf{u}(x)|\,dx\,ds+\int_\Omega\mathcal{V}_\lambda(x)dx.$$

Since

$$\int_{[0,\lambda)}\Psi(\Gamma(x,s))\,ds\le\int_{[0,\infty)}\Psi(\Gamma(x,s))\,ds=\mathfrak{H}(x),$$

Lemma 5.2 implies the boundedness of $\wp$ on $\mathbb{R}^+$,

$$|\wp(\lambda)|\le c\|\mathbf{u}\|_{H^{1,2}(D\setminus S)}\,\|\mathfrak{H}\|_{L^2(D\setminus S)}+\|\mathcal{V}_\lambda\|_{L^1(D\setminus S)}\le c.$$

Taking into account that $\eta''(\lambda)=\partial_t\upsilon(\lambda-t)$, inequality (8.7) can be rewritten in the form

$$2\int_{(D\setminus S)}\Big(\int_{[0,t-1)}\lambda\mathfrak{M}d\Gamma(x,\lambda)\Big)dx\le(1+t)\frac{d}{dt}(\upsilon*\wp)(t).\tag{8.8}$$

Since the smooth function $(\upsilon*\wp)(t)$ is uniformly bounded on $\mathbb{R}^+$, there is a sequence $t_k\to\infty$ such that $\lim_{k\to\infty}(t_k+1)\frac{d}{dt}(\upsilon*\wp)(t_k)\le0$. Substitution of $t=t_k$ into (8.8) followed by the limit passage $k\to\infty$ in (8.8) leads to

$$\int_{[0,t-1)}\lambda\mathfrak{M}d\Gamma(x,\lambda)=0\quad\text{for a.e. }\ x\in D\setminus S.$$

In other words, $\mathcal{M}(x,\cdot)$ vanishes σ_x-a.e. on $(0,\infty)$, which along with Lemma 6.2 implies the equality $\Gamma(1-\Gamma)=0$ a.e. in $(D\setminus S)\times\mathbb{R}$. Hence ρ_n converges a.e. in $D\setminus S$. Estimates (1.11) imply the strong convergence of the sequence ρ_n in $L^r(D\setminus S)$ for all $r<\gamma$. Since $(\rho_n,\mathbf{u}_n)$ satisfy all assumptions of Theorem 2.1, we can make use of estimate (2.1) from this theorem, which yields the strong convergence ρ_n in $L^r_{loc}(\Omega)$ for $r<\gamma(1+\kappa)$. In particular, the sequence $p(\rho_n)$ converges to $\overline{p}=p(\rho)$ in $L^1_{loc}(\Omega)$. After substituting $(\rho_n,\mathbf{u}_n)$ into integral identities (1.7a) and (1.7b), followed by the limit passage $n\to\infty$, by Lemma 3.3 we can conclude that the pair $(\rho,\mathbf{u})$ is a generalized solution to problem (1.3). Finally, since $\nabla\mathbf{u}^\infty$ is compactly supported in Ω, the limit passage in (1.12) for the sequence of drag functionals follows by Lemma 3.3 and by the strong convergence of the sequence $p(\rho_n)$ in $L^1_{loc}(\Omega)$.

FEASIBLE AND NONINTERIOR PATH-FOLLOWING IN CONSTRAINED MINIMIZATION WITH LOW MULTIPLIER REGULARITY*

M. HINTERMÜLLER† AND K. KUNISCH†

Abstract. Primal-dual path-following methods for constrained minimization problems in function space with low multiplier regularity are introduced and analyzed. Regularity properties of the path are proved. The path structure allows us to define approximating models, which are used for controlling the path parameter in an iterative process for computing a solution of the original problem. The Moreau–Yosida regularized subproblems of the new path-following technique are solved efficiently by semismooth Newton methods. The overall algorithmic concept is provided, and numerical tests (including a comparison with primal-dual path-following interior point methods) for state constrained optimal control problems show the efficiency of the new concept.

Key words. active set strategy, Moreau–Yosida regularization, path-following methods, primal-dual methods, semismooth Newton methods

1. Introduction.

The efficient numerical solution of inequality constrained minimization problems in function space with low Lagrange multiplier regularity is still a significant challenge. Prototype problems include optimal control problems with pointwise state constraints, boundary control problems in which the control has to satisfy pointwise constraints on the boundary, and classes of control problems with "solutions très faibles" (that is, "very weak solutions" in the sense of Lions). The common feature is low regularity of the Lagrange multipliers associated with the pointwise constraints. This has an immediate effect when characterizing optimality of solutions. Indeed, in the presence of inequality constraints, first order optimality conditions typically involve a so-called *complementarity system* (see, e.g., [10]), which in turn is influenced by the regularity of the Lagrange multiplier associated with the inequality constraint. To be specific, let us assume that $x_1 \in X_1$ has to satisfy the pointwise (almost everywhere) constraint

$$x_1 \le \psi, \tag{1.1}$$

where X_1 denotes a Hilbert space continuously embedded into $L^2(\omega)$ and $\omega \subset \mathbb{R}^m$ is a bounded domain. Further $\psi \in L^2(\omega)$, and $\le$ represents the natural ordering in $L^2(\omega)$. Let $\lambda \in X_1^*$ denote the Lagrange multiplier associated with constraint (1.1), where X_1^* is the topological dual space of X_1. First order optimality characterizations include the complementarity condition

$$x_1 \le \psi, \quad \langle \lambda, x_1 - \xi \rangle_{X_1^*, X_1} \ge 0 \quad \text{for all } \xi \le \psi,\ \xi \in X_1 \tag{1.2}$$

at an optimal solution x_1 with associated Lagrange multiplier λ. Without additional regularity, system (1.2) does not admit a pointwise interpretation, which is frequently crucial for numerical algorithms.

In fact, solution techniques and their (local) convergence behavior often hinge on the multiplier regularity. Classical active set methods, for instance, require a pointwise (almost everywhere) interpretation of λ for the active set estimation. In the case of pointwise constraints, techniques like the projected gradient methods will not work without modification since the sum of the iteration variable and the gradient of the objective, which coincides with the negative multiplier, is needed for the update. Since the iteration variable and the gradient have different regularity properties, this is not feasible in general. An analogous comment applies for projected Newton techniques. Recently it was found that semi smooth Newton methods are highly efficient in solving certain classes of constrained optimization problems in function space [4, 5, 9, 10, 11, 21]. These methods rely on a pointwise almost everywhere interpretation of the complementarity system (1.2) and smoothing properties of the control-to-adjoint-state mapping. In fact, the pointwise interpretation allows us to express (1.2) equivalently as

$$\lambda - \max(0, \lambda + c(x_1 - \psi)) = 0, \tag{1.3}$$

for some arbitrarily fixed $c > 0$, and the smoothing of the control-to-adjoint-state operator typically implies that the mapping

$$\theta : x_1 \mapsto \lambda(x_1) + c(x_1 - \psi)$$

can be considered as $\theta : X_1 \to L^q(\omega)$ with $q > 2$. The norm gap between $L^q(\omega)$ and the space $L^2(\omega)$, in which inequality (1.1) is posed, is crucial in proving generalized differentiability of

$$x_1 \mapsto \max(0, \theta(x_1)),$$

and in arguing well-definedness and locally superlinear convergence of the generalized (semismooth) Newton method for solving the underlying nonsmooth first order optimality system; see [10] for details. Again, the low multiplier regularity may prevent the pointwise interpretation and/or the smoothing of the control-to-adjoint-state mapping.

An approach for solving state constrained optimal control problems that does not rely on the use of multipliers was introduced in [13]. This method operates with the interface (boundary) between the active set $\{x_1 = \psi\}$ and the inactive set $\{x_1 < \psi\}$ as the optimization variable, and the constrained minimization problem is transformed into a shape optimization problem. Since the interface allows for a unique identification of the inactive region, the multiplier itself is not an issue. While this technique is appealing due to its favorable analytical properties, the implementation is rather technical.

Based on recent work [12], in this paper we propose a primal-dual path-following concept for solving the aforementioned constrained minimization problems. It relies on a (generalized) Moreau–Yosida-type regularization of the max-operation involving a scalar parameter. The resulting regular subproblems can be solved efficiently by, e.g., semismooth Newton methods. The relaxation parameter induces a primal-dual path and a path value functional, for which good low-parametric models can be found based on the structure of the relaxation term. These models are subsequently used for driving the path parameter to its limit, i.e., to find a solution of the original (less regular) problem. This procedure has several analytical as well as numerical benefits as follows:

- sufficiently regular subproblems for which standard methods (like semismooth Newton algorithms) converge rapidly in function space setting;

- simple path structure such that one can find good approximating models for the primal-dual path value functional;
- controlled path-parameter updates based on model functions to avoid ill-conditioning;
- wide applicability.

Compared to other path-following concepts, like primal-dual path-following interior point methods (see, e.g., [6, 22, 25, 26] for finite dimensional versions and [20, 23] for function space treatments), the numerical implementation of our technique is rather user-friendly. In fact, in many cases (see, e.g., [1, 25]) competitive primal-dual path-following interior point methods require the addition of slack variables, which increases the problem size, and then appropriate pivot choices for reducing the indefinite system, which has to be solved in every iteration, in order to make the method feasible for large scale optimization. Additionally, within our path-following framework existing subproblem solvers can readily be used. In contrast to our approach, the successful analysis of interior point methods in function space [20, 23, 24] requires sufficient regularity of the multipliers, which prevents an immediate application of these concepts to the problem class considered in this paper. For an alternative regularization concept for state constrained optimal control problems, we refer to [19].

In the case of regular Lagrange multipliers, our earlier work [1, 10] indicates that semismooth Newton and primal-dual active set methods are superior to path-following strategies. This includes a wide class of pointwise control constraints in the optimal control of partial differential equations.

The rest of the paper is organized as follows. In the next section we introduce the problem class under consideration, specify the relaxed path-problems, and analyze properties of the primal-dual path. In section 3 we discuss several constrained optimal control problems which are covered by our model problem. Among these we consider state constrained optimal control problems and Dirichlet boundary control problems. The primal-dual path value function, its differentiability properties, and the definition of approximating models are the contents of section 4. The algorithm is introduced in section 5. A report on test runs, including a comparison of the new method with primal-dual path-following interior point and primal-dual active set techniques, is also given.

2. Problem formulation and properties of the path. Let X_1, X_2, and W be real Hilbert spaces with

$$X_1 \hookrightarrow L^2(\omega) \hookrightarrow X_1^*,$$

where X_1^* denotes the dual of X_1 and ω a bounded domain in $\mathbb{R}^m$. Further set $X = X_1 \times X_2$ and let $x = (x_1, x_2)$ denote a generic element in X.

Let $E \in \mathcal{L}(X, W)$, $f \in W$, and $\psi \in X_1$. Further let $J : X \to \mathbb{R}$ denote a quadratic functional satisfying the following assumption.

ASSUMPTION 2.1. *There exists a constant $\alpha > 0$ such that*

$$\langle J'(x) - J'(y), x - y\rangle_{X^*,X} \geq \alpha |x - y|_X^2 \tag{2.1}$$

whenever $E(x - y) = 0$ for $x, y \in X$.

Here $\langle\cdot,\cdot\rangle_{X^*,X}$, at times denoted by $\langle\cdot,\cdot\rangle$, stands for the duality pairing between X and X^*. We set

$$C := \begin{pmatrix} E \\ (I, 0) \end{pmatrix} : X \to W \times X_1$$

and assume that

$$C \text{ is surjective.} \tag{2.2}$$

The problem under consideration is

$$\begin{aligned} &\text{minimize } J(x) \text{ over } x \in X \\ &\text{subject to } Ex = f, \\ &\qquad x_1 \le \psi, \end{aligned} \tag{P}$$

where $\le$ denotes the ordering in $L^2(\omega)$. By Assumption 2.1 and (2.2) there exists a unique solution $x^* \in X$ to (P). Further by (2.2) there exists [17] a unique Lagrange multiplier pair $(p^*, \lambda^*) \in W^* \times X_1^*$ such that

$$\begin{aligned} &J'(x^*) + E^*p^* + (\lambda^*, 0) = 0 \text{ in } X^*, \\ &\lambda^* \ge 0, \quad x_1^* - \psi \le 0, \quad \langle \lambda^*, x_1^* - \psi \rangle_{X_1^*, X_1} = 0, \end{aligned} \tag{2.3}$$

where $\lambda^* \ge 0$ stands for $\langle \lambda^*, \phi \rangle_{X_1^*, X_1} \ge 0$ for all $\phi \in X_1$ with $\phi \ge 0$. In section 3 we give examples from optimal control with control or state constraints which are covered by our general framework.

We also consider the following problem without inequality constraints:

$$\begin{aligned} &\text{minimize } J(x) \text{ over } x \in X \\ &\text{subject to } Ex = f, \end{aligned} \tag{$\tilde{\text{P}}$}$$

as well as the regularized problems

$$\begin{aligned} &\text{minimize } J(x, \gamma) := J(x) + \frac{1}{2\gamma} \int_\omega |\left(\bar\lambda + \gamma(x_1 - \psi)\right)^+|^2 dw \text{ over } x \in X \\ &\text{subject to } Ex = f, \end{aligned} \tag{P_γ}$$

where $\gamma > 0$ represents a relaxation (or regularization) parameter and $\bar\lambda \in L^2(\omega)$ is an optional shift-parameter. For every $\gamma > 0$ there exists a unique solution $x_\gamma = (x_{1,\gamma}, x_{2,\gamma})$ to (P_γ) satisfying

$$\begin{aligned} &Ex_\gamma = f, \\ &J'(x_\gamma) + E^*p_\gamma + (\lambda_\gamma, 0) = 0 \text{ in } X^*, \\ &\lambda_\gamma = \left(\bar\lambda + \gamma(x_{1,\gamma} - \psi)\right)^+ \text{ in } L^2(\omega). \end{aligned} \tag{2.4}$$

In view of (1.3), the last equation in (2.4) suggests that $\bar\lambda$ acts as a regular approximation of the Lagrange multiplier corresponding to $x_1 \le \psi$. Further, in section 3 we find that in some cases, $\bar\lambda$ can be chosen such that $x_{1,\gamma} \le \psi$ for γ sufficiently large.

We refer to

$$\mathcal{C} = \{(x_\gamma, p_\gamma, \lambda_\gamma) \in X \times W^* \times X_1^* : \gamma \in (0, \infty)\}$$

as the *primal-dual path* associated with (P). For $r > 0$ we further set

$$\mathcal{C}_r = \{(x_\gamma, p_\gamma, \lambda_\gamma) : \gamma \in [r, \infty)\}.$$

PROPOSITION 2.1. *For every $r > 0$, the path $\mathcal{C}_r$ is bounded and, as $\gamma \to \infty$, we have $(x_\gamma, p_\gamma, \lambda_\gamma) \rightharpoonup (x^*, p^*, \lambda^*)$ in $X \times W^* \times X_1^*$. Moreover $x_\gamma \to x^*$ in X.*

Proof. From (2.4) we have

$$\langle J'(x_\gamma) - J'(x^*), x_\gamma - x^*\rangle_{X^*,X} + (\lambda_\gamma, x_{1,\gamma} - x_1^*)_{L^2} = \langle J'(x^*), x^* - x_\gamma\rangle_{X^*,X},$$

and by (2.1),

$$\alpha|x_\gamma - x^*|_X^2 + (\lambda_\gamma, x_{1,\gamma} - x_1^*)_{L^2} \le \langle J'(x^*), x^* - x_\gamma\rangle_{X^*,X}. \tag{2.5}$$

As in [14],

$$(\lambda_\gamma, x_{1,\gamma} - x_1^*)_{L^2} \ge \frac{1}{\gamma}|\lambda_\gamma|_{L^2}^2 - \frac{1}{\gamma}(\lambda_\gamma, \bar\lambda)_{L^2}, \tag{2.6}$$

and hence,

$$\alpha|x_\gamma - x^*|_X^2 + \frac{1}{2\gamma}|\lambda_\gamma|_{L^2}^2 \le |J'(x^*)|_{X^*}|x^* - x_\gamma|_X + \frac{1}{2\gamma}|\bar\lambda|_{L^2}^2. \tag{2.7}$$

In particular we have that $\{x_\gamma\}_{\gamma\ge r}$ is bounded for every $r > 0$. By (2.2),

$$C^*(p_\gamma, \lambda_\gamma) = -J'(x_\gamma),$$

and since C is surjective it follows that $\{(p_\gamma, \lambda_\gamma)\}$ is bounded in $W^* \times X_1^*$. Hence, there exists $(\hat x, \hat p, \hat\lambda)$ such that for a subsequence, $(x_\gamma, p_\gamma, \lambda_\gamma) \rightharpoonup (\hat x, \hat p, \hat\lambda)$. Since $\lambda_\gamma \ge 0$ for all $\gamma > 0$, we find $\langle\hat\lambda, \phi\rangle_{X_1^*,X_1} \ge 0$ for all $\phi \in X_1$ with $\phi \ge 0$. As in [14, section 3], one argues that $\hat x \le \psi$. By (2.3) and (2.4),

$$\langle J'(x_\gamma) - J'(x^*), x_\gamma - x^*\rangle_{X^*,X} + \langle\lambda_\gamma - \lambda^*, x_{1,\gamma} - x_1^*\rangle_{X_1^*,X_1} = 0, \tag{2.8}$$

and from (2.6) we have $(\lambda_\gamma, x_{1,\gamma} - x_1^*) \ge -\frac{1}{2\gamma}|\bar\lambda|_{L^2}^2$. Further, from (2.8) with Assumption 2.1 holding we arrive at

$$0 \le \alpha|x_\gamma - x^*|_X^2 \le \frac{1}{2\gamma}|\bar\lambda|_{L^2}^2 + \langle\lambda^*, x_{1,\gamma} - x^*\rangle_{X_1^*,X_1}.$$

Passing to the limit as $\gamma \to \infty$ yields

$$0 \le \alpha \limsup_{\gamma\to\infty} |x_\gamma - x^*|_X^2 = \langle\lambda^*, \hat x_1 - x_1^*\rangle_{X_1^*,X_1} = \langle\lambda^*, \hat x_1 - \psi\rangle_{X_1^*,X_1} \le 0,$$

and therefore $\lim_{\gamma\to\infty} x_\gamma = x^*$. Taking the limit in (2.4), we find

$$\langle J'(x^*), \phi\rangle_{X^*,X} + \langle E^*\hat p, \phi\rangle_{X^*,X} + \langle\hat\lambda, \phi_1\rangle_{X_1^*,X_1} = 0$$

for all $\phi = (\phi_1, \phi_2) \in X$. This equation also holds with $(\hat p, \hat\lambda)$ replaced by (p^*, λ^*). Since C^* is injective, we have $(\hat p, \hat\lambda) = (p^*, \lambda^*)$. Since the accumulation point of every weakly convergent subsequence of $\{(x_\gamma, p_\gamma, \lambda_\gamma)\}$ is (x^*, p^*, λ^*), the whole sequence converges weakly. ∎

We point out that condition (2.2) is a convenient sufficient condition, which is used for the existence of a Lagrange multiplier and for the a priori estimate just below (2.7). It holds for a reasonably wide class of interesting applications, as will be shown in section 3. In more involved applications, these two consequences of (2.2) must be argued by utilizing the specific properties of the underlying problem.

Next we treat the case $\bar{\lambda} = 0$ and $\gamma \to 0^+$, i.e., convergence towards the problem without inequality constraints.

PROPOSITION 2.2. *If $\bar{\lambda} = 0$, then the path $\mathcal{C}_0$ is bounded in $X \times W^* \times X_1^*$ and $\lim_{\gamma \to 0^+}(x_\gamma, p_\gamma, \lambda_\gamma) = (\tilde{x}, \tilde{p}, 0)$, where $\tilde{x}$ is the solution to $(\tilde{\mathrm{P}})$ with Lagrange multiplier $\tilde{p}$ associated with the constraint $Ex = f$.*

Proof. By (2.4) and (2.7), the family $\{(x_\gamma, p_\gamma, \lambda_\gamma)\}_{\gamma>0}$ is bounded. Moreover $\lim_{\gamma \to 0^+} \lambda_\gamma = 0$ in $L^2(\omega)$ by (2.7). Taking the limit $\gamma \to 0^+$ in (2.4), we find that each accumulation point of $\{(x_\gamma, p_\gamma, \lambda_\gamma)\}_{\gamma>0}$ must satisfy

$$J'(\tilde{x}) + E^*\tilde{p} = 0, \quad E\tilde{x} = f.$$

This implies the claim. ∎

Now we study smoothness properties of the primal-dual path.

PROPOSITION 2.3. *The primal-dual path $\mathcal{C}_r$ is globally Lipschitz continuous for every $r > 0$, and $\gamma \mapsto \lambda_\gamma$ is locally Lipschitz continuous in $L^2(\omega)$. If $\bar{\lambda} = 0$, then $\mathcal{C}_0$ is globally Lipschitz continuous.*

Proof. Let $\gamma, \bar{\gamma} \in [r, \infty)$. Then

(2.9)
$$J'(x_\gamma) - J'(x_{\bar{\gamma}}) + E^*(p_\gamma - p_{\bar{\gamma}}) + \big(\bar{\lambda} + \gamma(x_{1,\gamma} - \psi)\big)^+ - \big(\bar{\lambda} + \bar{\gamma}(x_{1,\bar{\gamma}} - \psi)\big)^+ = 0,$$

and hence with Assumption 2.1 holding,

$$\alpha|x_\gamma - \bar{x}_\gamma|_X^2 + \Big(\big(\bar{\lambda} + \gamma(x_{1,\gamma} - \psi)\big)^+ - \big(\bar{\lambda} + \bar{\gamma}(x_{1,\gamma} - \psi)\big)^+ + \big(\bar{\lambda} + \bar{\gamma}(x_{1,\gamma} - \psi)\big)^+ - \big(\bar{\lambda} + \bar{\gamma}(x_{1,\bar{\gamma}} - \psi)\big)^+, x_{1,\gamma} - x_{1,\bar{\gamma}} \Big)_{L^2} \le 0.$$

Since $x \mapsto (z + x)^+$ is monotone, we have

$$\alpha|x_\gamma - x_{\bar{\gamma}}|_X^2 \le |\gamma - \bar{\gamma}|\,|x_{1,\gamma} - \psi|_{L^2}|x_{1,\gamma} - x_{1,\bar{\gamma}}|_{L^2}.$$

Boundedness of $\{x_{1,\gamma}\}_{\gamma \ge r}$ implies Lipschitz continuity of $\gamma \mapsto x_\gamma$ for $\gamma \ge r$.

From (2.9) we deduce that

$$C^*(p_\gamma - p_{\bar{\gamma}}, \lambda_\gamma - \lambda_{\bar{\gamma}}) = J'(x_{\bar{\gamma}}) - J'(x_\gamma).$$

Therefore surjectivity of C implies that $\gamma \mapsto (p_\gamma, \lambda_\gamma)$ is Lipschitz continuous on $[r, \infty)$. For $\bar{\lambda} = 0$ we have that $\{x_\gamma\}_{\gamma>0}$ is bounded, and global Lipschitz continuity of $\mathcal{C}_0$ follows as before.

Local Lipschitz continuity of $\gamma \mapsto \lambda_\gamma$ in $L^2(\omega)$ results from

$$\begin{aligned} |\lambda_\gamma - \lambda_{\bar{\gamma}}|_{L^2} &= \Big| \big(\bar{\lambda} + \gamma(x_{1,\gamma} - \psi)\big)^+ - \big(\bar{\lambda} + \bar{\gamma}(x_{1,\bar{\gamma}} - \psi)\big)^+ \Big|_{L^2} \\ &\le |(\gamma - \bar{\gamma})x_{1,\gamma}|_{L^2} + |\bar{\gamma}(x_{1,\gamma} - x_{1,\bar{\gamma}})|_{L^2} + |\gamma - \bar{\gamma}||\psi|_{L^2}. \end{aligned}$$ ∎

Henceforth we set for $\gamma > 0$

$$S_\gamma = \{z \in \omega : \bar{\lambda}(z) + \gamma(x_{1,\gamma} - \psi)(z) > 0\}$$

and

$$g(\gamma) = \bar{\lambda} + \gamma(x_{1,\gamma} - \psi).$$

Below we shall assume that X_1 embeds compactly into $L^2(\omega)$. Since $\gamma \mapsto (x_\gamma, p_\gamma)$ is Lipschitz continuous,

$$\left(\frac{1}{\bar\gamma-\gamma}(x_{\bar\gamma}-x_\gamma), \frac{1}{\bar\gamma-\gamma}(p_{\bar\gamma}-p_\gamma)\right)$$

admits a weak accumulation point $(\dot x_\gamma^+, \dot p_\gamma^+)$ in $X \times W^*$ as $\bar\gamma \to \gamma$. Further,

$$\frac{1}{\bar\gamma-\gamma}\left(g(\bar\gamma)-g(\gamma)\right)$$

has $\dot g(\gamma) = x_{1,\gamma} - \psi + \gamma \dot x_{1,\gamma}^+$ as a strong accumulation point in $L^2(\omega)$.

Since J is quadratic, $J''(x_\gamma)$ is independent of x_γ and we henceforth simply use J'' for the bounded linear operator from X to X^*.

PROPOSITION 2.4. *Assume that $X_1 \hookrightarrow L^2(\omega)$ is compact, and set*

$$S_\gamma^+ = S_\gamma \cup \{z : \bar\lambda(z) + \gamma(x_{1,\gamma}-\psi)(z) = 0 \wedge \dot g(\gamma)(z) \geq 0\}.$$

Then $(\dot x_\gamma, \dot p_\gamma)$ satisfies

$$\langle J''(\dot x_\gamma), v\rangle_{X^*,X} + \langle E^*\dot p_\gamma, v\rangle_{X^*,X} + \left((x_{1,\gamma}-\psi+\gamma\dot x_{1,\gamma}^+)\chi_{S_\gamma^+}, v_1\right) = 0$$

for all $v = (v_1, v_2) \in X$.

For the proof we refer to [12]. We now set

$$S_\gamma^0 = \{z \in \omega : \bar\lambda(z) + \gamma(x_{1,\gamma}-\psi)(z) = 0\}.$$

COROLLARY 2.1. *If $\operatorname{meas}(S_\gamma^0) = 0$, then $\gamma \mapsto (x_\gamma, p_\gamma) \in X \times W^*$ is weakly differentiable at γ and $(\dot x_\gamma, \dot p_\gamma)$ satisfies*

$$\langle J''(\dot x_\gamma), v\rangle_{X^*,X} + \langle E^*\dot p_\gamma, v\rangle_{X^*,X} + \left((x_{1,\gamma}-\psi+\gamma\dot x_{1,\gamma})\chi_{S_\gamma}, v_1\right) = 0 \tag{2.10}$$

for all $v = (v_1, v_2) \in X$. Moreover $\gamma \mapsto x_\gamma$ is strongly differentiable at γ.

Proof. Every accumulation point $(\dot x_\gamma, \dot p_\gamma)$ of

$$\left(\frac{1}{\bar\gamma-\gamma}(x_{\bar\gamma}-x_\gamma), \frac{1}{\bar\gamma-\gamma}(p_{\bar\gamma}-p_\gamma)\right)$$

as $\bar\gamma \to \gamma$ satisfies the conclusion of Proposition 2.4. If there are two weak accumulation points, then their difference $(\bar x_\gamma, \bar p_\gamma)$ satisfies $E\bar x_\gamma = 0$ and

$$\langle J''(\bar x_\gamma), v\rangle_{X^*,X} + \langle \bar p_\gamma, Ev\rangle_{X^*,X} + \gamma(\bar x_{1,\gamma}\chi_{S_\gamma}, v_1)_{L^2} = 0 \tag{2.11}$$

for all $v = (v_1, v_2) \in X$. Setting $v = \bar x_\gamma$ in (2.11), we have

$$\langle J''(\bar x_\gamma), \bar x_\gamma\rangle_{X^*,X} + \gamma(\bar x_{1,\gamma}\chi_{S_\gamma}, \bar x_{1,\gamma}) = 0,$$

which implies that $\bar x_\gamma = 0$ by Assumption 2.1. Due to (2.2) and (2.11) we have $\bar p_\gamma = 0$, and weak differentiability follows. From (2.4) and (2.11) we have

$$\left\langle J''(\dot x_\gamma) - \frac{1}{\bar\gamma-\gamma}\left(J'(x_{\bar\gamma}) - J'(x_\gamma)\right), \dot x_\gamma - \frac{1}{\bar\gamma-\gamma}(x_{\bar\gamma}-x_\gamma)\right\rangle_{X^*,X} + \epsilon(\bar\gamma,\gamma) = 0,$$

where

$$\epsilon(\bar\gamma,\gamma)=\Big((x_{1,\gamma}-\psi+\gamma\dot x_{1,\gamma})\chi_{S_\gamma} \\ -\frac{1}{\bar\gamma-\gamma}\left[\big(\bar\lambda+\bar\gamma(x_{1,\bar\gamma}-\psi)\big)^+ \right. \\ \left. -\big(\bar\lambda+\gamma(x_{1,\gamma}-\psi)\big)^+\right],\dot x_{1,\gamma}-\frac{1}{\bar\gamma-\gamma}(x_{1,\bar\gamma}-x_{1,\gamma})\Big)_{L^2}.$$

Since

$$\lim_{\bar\gamma\to\gamma}\epsilon(\bar\gamma,\gamma)=0,$$

strong differentiability of $\gamma\mapsto x_\gamma$ at γ follows from Assumption 2.1. ∎

3. Applications. In this section we discuss several classes of constrained optimal control problems which are special instances of the general problem (P).

3.1. State constraints. The optimal control problem with state constraints,

$$\begin{aligned}&\text{minimize } J(x)=\frac{1}{2}|y-y_d|^2_{L^2(L^2)}+\frac{\beta}{2}|u|^2_{L^2(L^2)} \text{ over } x\in X\\ &\text{subject to } y_t-\Delta y=u \text{ in } (0,T)\times\Omega,\\ &\qquad y(0,\cdot)=0,\quad y=0 \text{ on } (0,T)\times\Gamma,\\ &\qquad y\le\psi \text{ a.e. in } (0,T)\times\Omega,\end{aligned}$$

with $\Gamma=\partial\Omega$ and $x=(y,u)$ is a special case of (P), where

$$\begin{aligned}X_1&=\{y\in L^2(0,T;H^1_0(\Omega)\cap H^2(\Omega)) : y_t\in L^2(0,T;L^2(\Omega))\},\\ X_2&=W=L^2(0,T;L^2(\Omega)),\\ \omega&=(0,T)\times\Omega,\\ E(y,u)&=y_t-\Delta y-u,\end{aligned}$$

$\beta>0$, $T>0$, $y_d\in W$, $\psi\in X_1$, and Ω a bounded domain in $\mathbb{R}^n$, is a special case of (P) with Assumption 2.1 and (2.2) satisfied. The general framework of section 2 provides dual variables $(p^*,\lambda^*)\in W\times X_1^*$. Additional regularity can be obtained by using the optimality conditions; see, e.g., [2, 3].

3.2. Dirichlet control with control constraints. Consider that

$$\begin{aligned}&\text{minimize } J(x)=\frac{1}{2}|y-y_d|^2_{L^2(\Omega)}+\frac{\beta}{2}|u|^2_{H^1(\Gamma)} \text{ over } x\in X\\ &\text{subject to } -\Delta y=f \text{ in } \Omega,\\ &\qquad y=u \text{ on } \Gamma,\\ &\qquad u\le\psi \text{ a.e. in } \Gamma,\end{aligned}\tag{3.1}$$

is a special case of (P) with $x=(u,y)$,

$$\begin{aligned}X&=H^1(\Gamma)\times H^1(\Omega),\quad W=H^{1/2}(\Gamma)\times H^{-1}(\Omega),\\ E(y,u)&=(y-u,-\Delta y-f),\end{aligned}$$

$\beta>0$, $y_d\in H^2(\Omega)$, $\psi\in C^2(\Gamma)$, and Ω a bounded domain in $\mathbb{R}^n$, $n\le 4$, with smooth boundary Γ. Since the variational solution $y=y(u)$ to

$$-\Delta y=f \text{ in } \Omega,\quad y=u \text{ on } \Gamma,$$

satisfies

$$|y(u)|_{H^1} \leq K(|u|_{H^{1/2}} + |f|_{H^{-1}})$$

for some constant K independent of $u \in H^{1/2}(\Gamma)$ and $f \in H^{-1}(\Omega)$, it follows that Assumption 2.1 is satisfied. To verify (2.2) let $(\tilde{u}_1, \tilde{y}, \tilde{u}_2) \in H^{1/2}(\Gamma) \times H^{-1}(\Omega) \times H^1(\Gamma)$. Choose $u = \tilde{u}_2$ and let $y \in H^1(\Omega)$ be the unique variational solution to

$$-\Delta y = \tilde{y} \text{ in } \Omega, \quad y = \tilde{u}_1 + u \text{ on } \Gamma.$$

Then

$$C(y,u) = \begin{pmatrix} y - u \\ -\Delta y \\ u \end{pmatrix} = \begin{pmatrix} \tilde{u}_1 \\ \tilde{y} \\ \tilde{u}_2 \end{pmatrix} \in H^{1/2}(\Gamma) \times H^{-1}(\Omega) \times H^1(\Gamma),$$

and thus C is surjective.

In this case the Lagrange multiplier associated with the inequality constraint $u \leq \psi$ is in $H^{-1}(\Gamma)$ and, hence, the primal-dual active set strategy without regularization cannot be defined.

The regularized problem is given by

$$\begin{aligned} &\text{minimize } \frac{1}{2}|y - y_d|^2_{L^2(\Omega)} + \frac{\beta}{2}|u|^2_{H^1(\Gamma)} + \frac{1}{2\gamma}|\left(\bar{\lambda} + \gamma(u - \psi)\right)^+|^2_{L^2(\Gamma)} \\ &\text{subject to } -\Delta y = f \text{ in } \Omega, \\ &\qquad\qquad y = u \text{ on } \Gamma, \end{aligned} \tag{3.2}$$

with $\bar{\lambda} \in C(\Gamma)$, $\bar{\lambda} \geq 0$. The optimality system for this problem is given by

$$\begin{aligned} &-\Delta y = f \text{ in } \Omega, \quad y = u \text{ on } \Gamma, \\ &-\Delta p = y_d - y \text{ in } \Omega, \quad p = 0 \text{ on } \Gamma, \\ &\beta(-\Delta_\Gamma + I)u + \frac{\partial p}{\partial n} + \left(\bar{\lambda} + \gamma(u - \psi)\right)^+ = 0 \text{ in } H^{-1}(\Gamma), \end{aligned} \tag{3.3}$$

where Δ_Γ denotes the Laplace–Beltrami operator on Γ; see [8]. Let $(y^*, u^*) = (y^*(u^*), u^*)$ denote the solution to (3.1). Then

$$\begin{aligned} &\frac{1}{2}|y_\gamma - y_d|^2_{L^2(\Omega)} + \frac{\beta}{2}|u_\gamma|^2_{H^1(\Gamma)} + \frac{1}{2\gamma}|\left(\bar{\lambda} + \gamma(u_\gamma - \psi)\right)^+|^2_{L^2(\Gamma)} \\ &\qquad \leq \frac{1}{2}|y^* - y_d|^2_{L^2(\Omega)} + \frac{\beta}{2}|u^*|^2_{H^1(\Gamma)} + \frac{1}{2\gamma}|\bar{\lambda}|^2_{L^2(\Gamma)}, \end{aligned}$$

and hence,

$$|u_\gamma|_{H^1} \leq K\left(1 + \frac{1}{\sqrt{\gamma}}|\bar{\lambda}|\right)_{L^2(\Gamma)}. \tag{3.4}$$

Here and below, K denotes a constant independent of $|\bar{\lambda}|_{L^2(\Gamma)}$ and γ. From well-known estimates [16, p. 188] for elliptic equations (3.3) and (3.4), we deduce that

$$\begin{aligned} |y_\gamma|_{H^{3/2}(\Omega)} &\leq K\left(1 + \frac{1}{\sqrt{\gamma}}|\bar{\lambda}|_{L^2(\Gamma)}\right), \\ |p_\gamma|_{H^{7/2}(\Omega)} &\leq K\left(1 + \frac{1}{\sqrt{\gamma}}|\bar{\lambda}|_{L^2(\Gamma)}\right), \\ \left|\frac{\partial p_\gamma}{\partial n}\right|_{H^2(\Gamma)} &\leq K\left(1 + \frac{1}{\sqrt{\gamma}}|\bar{\lambda}|_{L^2(\Gamma)}\right), \end{aligned}$$

and hence,

$$\left|\frac{\partial p_\gamma}{\partial n}\right|_{L^\infty(\Gamma)} \le K\left(1+\frac{1}{\sqrt{\gamma}}|\bar\lambda|_{L^2(\Gamma)}\right), \tag{3.5}$$

if $n \le 4$. From the last equation in (3.3), we deduce that

$$\beta\left\langle(-\Delta_\Gamma + I)\ (u_\gamma-\psi),(u_\gamma-\psi)^+\right\rangle_{X_1^*,X_1} + \left(\frac{\partial p_\gamma}{\partial n}+\bar\lambda+\gamma(u_\gamma-\psi),(u_\gamma-\psi)^+\right)_{L^2(\Gamma)} + \beta\left((-\Delta_\Gamma+I)\psi,(u_\gamma-\psi)^+\right)_{L^2(\Gamma)} = 0,$$

and thus,

$$\beta|(u_\gamma-\psi)^+|^2_{H^1(\Gamma)}+\gamma|(u_\gamma-\psi)^+|^2_{L^2(\Gamma)}+\left(\bar\lambda+\beta(-\Delta_\Gamma+I)\psi+\frac{\partial p_\gamma}{\partial n},(u_\gamma-\psi)^+\right)_{L^2(\Gamma)} \le 0.$$

From (3.5) it follows that

$$\beta|(u_\gamma-\psi)^+|^2_{H^1(\Gamma)}+\gamma|(u_\gamma-\psi)^+|^2_{L^2(\Gamma)} + \left(\bar\lambda+\beta(-\Delta_\Gamma+I)\psi-K\left(1+\frac{|\bar\lambda|}{\sqrt{\gamma}}\right),(u_\gamma-\psi)^+\right)_{L^2(\Gamma)} \le 0.$$

Hence, if $\bar\lambda$ is sufficiently large such that

$$\bar\lambda(x) > \beta(\Delta_\Gamma - I)\psi(x) + 2K \quad \text{for all } x\in\Gamma,$$

then there exists $\bar\gamma$ such that

$$u_\gamma \le \psi \text{ a.e. on } \Gamma \text{ for all } \gamma \ge \bar\gamma,$$

and thus u_γ is feasible for $\gamma \ge \bar\gamma$.

If $|u|^2_{H^1(\Gamma)}$ is replaced with $|u|^2_{H^{1/2}(\Gamma)}$ in (3.1) and accordingly $X = H^{1/2}(\Gamma)\times H^1(\Omega)$, then the Lagrange multiplier associated with $u\le\psi$ is in $H^{-1/2}(\Gamma)$, and again regularization is necessary to employ the primal-dual active set strategy. Following the above arguments, it can be shown that $u_\gamma \le \psi$ if $\bar\lambda \in C^1(\Gamma)$ and if γ is sufficiently large, and that $n \le 3$.

3.3. Dirichlet control with control constraints, revisited. Here we consider two further alternative formulations for Dirichlet boundary control and their treatment by the primal-dual active set strategy. First, we focus on

$$\begin{aligned} &\text{minimize } \frac{1}{2}|y-y_d|^2_{H^1(\Omega)}+\frac{\beta}{2}|u|^2_{L^2(\Gamma)} \text{ over } (y,u)\in H^1(\Omega)\times L^2(\Gamma)\\ &\text{subject to } -\Delta y = f \text{ in } \Omega,\\ &\qquad\qquad y = u \text{ on } \Gamma,\\ &\qquad\qquad u\le\psi \text{ a.e. on } \Gamma, \end{aligned} \tag{3.6}$$

where $y_d\in H^2(\Omega)$, $\beta>0$, $f\in L^2(\Omega)$, and $\psi\in H^2(\Gamma)$. Note that (3.6) admits a unique solution $(y^*,u^*)\in H^1(\Omega)\times H^{1/2}(\Gamma)$. The optimality condition for (3.6) is found to be (the variational form of)

$$\begin{aligned} &-\Delta y = f \text{ in } \Omega, \quad y = u \text{ on } \Gamma,\\ &-\Delta p = y_d - y - \Delta y_d - f \text{ in } \Omega, \quad p = 0 \text{ on } \Gamma,\\ &\left(\beta u+\frac{\partial p}{\partial n}-\frac{\partial y_d}{\partial n},h\right)_{L^2(\Gamma)} \ge 0 \quad \text{for all } h\in\mathcal{C}(u^*), \end{aligned} \tag{3.7}$$

where $(y,p) \in H^1(\Omega) \times H^1(\Omega)$, and

$$\mathcal{C}(u^*) = \{h = u - u^* : u \in L^2(\Gamma),\ u \le \psi\}.$$

Next consider p as a function of $u \in L^2(\Gamma)$ defined via the first four equations in (3.7). Note that the mapping $u \mapsto y(u)$ is continuous from $L^2(\Gamma)$ to $L^2(\Omega)$ (see [16]) and further that $u \mapsto \frac{\partial p(u)}{\partial n}$ is continuous from $L^2(\Gamma)$ to $H^{1/2}(\Gamma)$. Hence, the inequality in (3.7) can be equivalently expressed as

$$\begin{aligned} \beta u + \lambda &= \frac{\partial}{\partial n}(y_d - p), \\ \lambda &= (\lambda + c(u - \psi))^+ \end{aligned}$$

for any $c > 0$. Choosing $c = \beta$, this in turn is equivalent to

$$\beta u + \frac{\partial}{\partial n}(y_d - p) + \left(\frac{\partial}{\partial n}(y_d - p) - \beta\psi\right)^+ = 0. \tag{3.8}$$

As observed above, $u \mapsto \frac{\partial p(u)}{\partial n}$ is continuous from $L^2(\Gamma)$ to $H^{1/2}(\Gamma)$. Hence, for each n there exists $q > 2$ such that $u \mapsto \frac{\partial p(u)}{\partial n}$ is continuous from $L^2(\Gamma)$ to $L^q(\Gamma)$. Now standard techniques [10] can be applied to argue that the primal-dual active set strategy applied to (3.8) is locally superlinearly convergent in $L^2(\Gamma)$.

3.4. Optimal control problem with "solutions très faibles." Finally, we turn to the boundary control problem with solutions in the sense of "solutions très faibles"; e.g. [15, p.76],

$$\begin{aligned} &\text{minimize } \frac{1}{2}\left|\frac{\partial y}{\partial n} - y_d\right|^2_{H^{-1}(\Gamma)} + \frac{\beta}{2}|u|^2_{L^2(\Gamma)} \text{ over } (u,y) \in L^2(\Gamma) \times L^2(\Omega) \\ &\text{subject to } -(y, \Delta v)_{L^2(\Omega)} - (f, v)_{L^2(\Omega)} + \left(u, \frac{\partial v}{\partial n}\right)_{L^2(\Gamma)} = 0 \\ &\qquad\qquad \text{for all } v \in H^2(\Omega) \cap H^1_0(\Omega), \\ &u \le \psi, \end{aligned} \tag{3.9}$$

where $y_d \in H^{-1}(\Gamma)$, $f \in L^2(\Omega)$, $\psi \in L^2(\Gamma)$. We recall that $u \mapsto \frac{\partial y}{\partial n}$ is a continuous mapping from $L^2(\Gamma)$ to $H^{-1}(\Gamma)$; see [15, p. 78]. The adjoint equation for the optimal control problem (3.9) is given by

$$-\Delta p = 0 \text{ in } \Omega, \quad p = (-\Delta_\Gamma)^{-1}\left(y_d - \frac{\partial y}{\partial n}\right) \text{ on } \Gamma, \tag{3.10}$$

and it is known (see [15, p. 77] and [16]) that $p \in H^{3/2}(\Omega)$ and $\frac{\partial p}{\partial n} \in L^2(\Gamma)$. The optimality system for (3.9) consists of the variational equation in (3.9), the adjoint equation (3.10), and the optimality condition

$$\begin{aligned} \beta u + \lambda + \frac{\partial p}{\partial n} &= 0, \\ \lambda &= (\lambda + c(u - \psi))^+ \end{aligned} \tag{3.11}$$

for any $c > 0$. Choosing $c = \beta$ we find, as above, that (3.11) is equivalent to

$$\beta u + \frac{\partial p}{\partial n} + \left(\frac{\partial p}{\partial n} - \beta\psi\right)^+ = 0. \tag{3.12}$$

Note that $u \mapsto \frac{\partial p}{\partial n}$ is a continuous mapping from $L^2(\Gamma)$ into itself, which is not smoothing. Thus, the max-operation in (3.12) is not generalized differentiable in the sense of [10]. The latter property, however, is essential for a superlinear convergence of the primal-dual active set strategy, which we, hence, cannot expect in connection with (3.12).

Turning to the regularized version, we consider, for $\gamma > 0$,

$$\begin{aligned} &\text{minimize } \frac{1}{2}\left|\frac{\partial y}{\partial n} - y_d\right|^2_{H^{-1}(\Gamma)} + \frac{\beta}{2}|u|^2_{L^2(\Gamma)} + \frac{1}{2\gamma}\int_\Gamma \left|\left(\bar\lambda + \gamma(u-\psi)\right)^+\right|^2 \\ &\qquad \text{over } (u,y) \in L^2(\Gamma)\times L^2(\Omega) \\ &\text{subject to } -(y,\Delta v)_{L^2(\Omega)} - (f,v)_{L^2(\Omega)} + \left(u, \frac{\partial v}{\partial n}\right)_{L^2(\Gamma)} = 0 \\ &\qquad \text{for all } v \in H^2(\Omega)\cap H^1_0(\Omega). \end{aligned} \tag{3.13}$$

The optimality system consists of the primal equation, the adjoint equation (3.10), and the optimality condition

$$\beta u + \frac{\partial p}{\partial n} + \left(\bar\lambda + \gamma(u-\psi)\right)^+ = 0.$$

Consequently the solution u_γ to (3.13) is still in only $L^2(\Gamma)$, in general, and the primal-dual active set strategy for (3.13) may not be (superlinearly) convergent.

4. The value functional and its model. Next we introduce the optimal value functional of (P_γ), study its smoothness properties, and approximate it by low-parametric families of model functions. These model functions will be used in section 5, where we develop a path-following algorithm operating with a reliable γ-update strategy.

DEFINITION 4.1. *The functional*

$$\gamma \mapsto V(\gamma) = J(x_\gamma) + \frac{1}{2\gamma}\int_\omega |(\bar\lambda + \gamma(x_{1,\gamma} - \psi))^+|^2 dw$$

defined on $(0,\infty)$ *is called the* primal-dual-path value functional.

The smoothness and monotonicity properties of V provide useful information for tuning γ in an iterative procedure.

PROPOSITION 4.1. *The value functional V is differentiable with*

$$\dot V(\gamma) = -\frac{1}{2\gamma^2}\int_\omega |(\bar\lambda + \gamma(x_{1,\gamma}-\psi))^+|^2 + \frac{1}{\gamma}\int_\omega (\bar\lambda + \gamma(x_{1,\gamma}-\psi))^+(x_{1,\gamma}-\psi).$$

Proof. For $\bar\gamma, \gamma \in (0,\infty)$ we have from (4),

$$\langle J'(x_{\bar\gamma} + x_\gamma), x_{\bar\gamma} - x_\gamma\rangle_{X^*,X} + (\lambda_{\bar\gamma} + \lambda_\gamma, x_{1,\bar\gamma} - x_{1,\gamma})_{L^2} = 0,$$

and therefore

$$\begin{aligned}
V(\bar\gamma) - V(\gamma) &= J(x_{\bar\gamma}) - J(x_\gamma) + \frac{1}{2\bar\gamma}\int_\omega |(\bar\lambda + \bar\gamma(x_{1,\bar\gamma} - \psi))^+|^2 \\
&\quad - \frac{1}{2\gamma}\int_\omega |(\bar\lambda + \gamma(x_{1,\gamma} - \psi))^+|^2 \\
&= \langle J'(x_{\bar\gamma} + x_\gamma), x_{\bar\gamma} - x_\gamma\rangle_{\mathrm{X}^*,\mathrm{X}} + \frac{1}{2\bar\gamma}\int_\omega |(\bar\lambda + \bar\gamma(x_{1,\bar\gamma} - \psi))^+|^2 \\
&\quad - \frac{1}{2\bar\gamma}\int_\omega |(\bar\lambda + \gamma(x_{1,\gamma} - \psi))^+|^2 \\
&= \frac{1}{2\bar\gamma}\int_\omega |(\bar\lambda + \bar\gamma(x_{1,\bar\gamma} - \psi))^+|^2 - \frac{1}{2\gamma}\int_\omega |(\bar\lambda + \gamma(x_{1,\gamma} - \psi))^+|^2 \\
&\quad - \frac{1}{2}\int_\omega ((\bar\lambda + \bar\gamma(x_{1,\bar\gamma} - \psi))^+ + (\bar\lambda + \gamma(x_{1,\gamma} - \psi))^+)(x_{1,\bar\gamma} - x_{1,\gamma}) \\
&= \mathcal{I}_1 + \mathcal{I}_2 + \mathcal{I}_3.
\end{aligned}$$

It can now be argued just as in the proof of Proposition 4.1 of [12] that

$$\lim_{\bar\gamma\to\gamma} \frac{1}{\bar\gamma - \gamma}|\mathcal{I}_2| = \lim_{\bar\gamma\to\gamma} \frac{1}{\bar\gamma - \gamma}|\mathcal{I}_3| = 0$$

and further,

$$\begin{aligned}
\lim_{\bar\gamma\to\gamma} \frac{1}{\bar\gamma - \gamma}\mathcal{I}_1 = &- \frac{1}{2\gamma^2}\int_\omega ((\bar\lambda + \gamma(x_{1,\gamma} - \psi))^+)^2 \\
&+ \frac{1}{\gamma}\int_\omega (\bar\lambda + \gamma(x_{1,\gamma} - \psi))^+(x_{1,\gamma} - \psi),
\end{aligned}$$

as desired. □

It turns out that the monotonicity properties of V may depend on the choice of $\bar\lambda$. For the following discussion we assume that the solution $\tilde x$ to $(\tilde{\mathrm{P}})$ does not satisfy $\tilde x_1 \le \psi$. Let us start by first considering the case $\bar\lambda = 0$. We have

$$\dot V(\gamma) = \frac{1}{2}\int_\omega |(x_{1,\gamma} - \psi)^+|^2 > 0. \tag{4.1}$$

Indeed, if $\dot V(\gamma) = 0$ for some $\gamma > 0$, then $x_{1,\gamma} \le \psi$, i.e., $x_{1,\gamma}$ is feasible. Thus, $\lambda_\gamma = 0$ and, from (2.3) and (2.4), we find that $(x_\gamma, \lambda_\gamma) = (\tilde x, 0)$ is the solution to (2.3) with $\tilde x_1 \le \psi$ which was ruled out by assumption. In case there exist $\bar\lambda$ and $\bar\gamma > 0$ such that

$$x_{1,\gamma} \le \psi \quad \text{for all} \quad \gamma \ge \bar\gamma, \tag{4.2}$$

we have by Proposition 4.1 that $\dot V(\gamma) \le 0$ for $\gamma \ge \bar\gamma$ and, unless the solution $\tilde x$ to $(\tilde{\mathrm{P}})$ satisfies $\tilde x_1 \le \psi$, we obtain $\dot V(\gamma) < 0$ for $\gamma \ge \bar\gamma$. In fact, if $\dot V(\gamma) = 0$, then

$$0 = \dot V(\gamma) \le -\frac{1}{2\gamma^2}\int_\omega |(\bar\lambda + \gamma(x_{1,\gamma} - \psi))^+|^2 \le 0,$$

and hence $\lambda_\gamma = 0$. Therefore $(x_\gamma, \lambda_\gamma) = (\tilde x, 0)$ is the solution of (2.3), which is excluded. Recall that a specific case in which (4.2) holds was given in section 3.2.

Next we study the second order differentiability of V.

PROPOSITION 4.2. *Assume that $X_1 \hookrightarrow L^2(\omega)$ is compact and let $\dot{x}_\gamma$ denote an accumulation point of $\frac{1}{\bar\gamma-\gamma}(x_{1,\bar\gamma} - x_{1,\gamma})$ as $\bar\gamma \to \gamma$. Then for a subsequence γ_n realizing the accumulation point,*

$$\begin{aligned}\lim_{\bar\gamma_n\to\gamma} \frac{1}{\bar\gamma_n - \gamma}(\dot V(\bar\gamma_n) - \dot V(\gamma)) &= \frac{1}{\gamma^3}\int_\omega |(\bar\lambda + \gamma(x_{1,\gamma} - \psi))^+|^2 \\ &- \frac{2}{\gamma^2}\int_\omega (\bar\lambda + \gamma(x_{1,\gamma} - \psi))^+(x_{1,\gamma} - \psi) \\ &+ \frac{1}{\gamma}\int_\omega (x_{1,\gamma} - \psi)(x_{1,\gamma} - \psi + \gamma\dot x_{1,\gamma})\chi_{S_\gamma^+}.\end{aligned} \tag{4.3}$$

If $\operatorname{meas}(S_\gamma^\circ) = 0$, *then $\gamma \to V(\gamma)$ is twice differentiable at γ, and the second derivative is given by the right-hand side in* (4.3) *with $\chi_{S_\gamma^+}$ replaced by χ_{S_γ}.*

Proof. The first claim follows from Proposition 4.1. If meas $(S_\gamma^\circ) = 0$, then accumulation points of $\frac{1}{\bar\gamma-\gamma}(x_{1,\bar\gamma} - x_{1,\gamma})$ as $\bar\gamma \to \gamma$ are unique, and (4.3) with $\chi_{S_\gamma^+}$ replaced by χ_{S_γ}, as well as existence of $\ddot V$ at γ, follow. ∎

We turn to proposing low-parametric model functions m for V which share some of the qualitative properties of V. Notice that, in general, V is not at our disposal quantitatively. However, we shall see that m can be obtained from solves of the regularized problem for different choices of γ. In the next section, these model functions will then be used as a guideline for updating γ; see (5.2). Throughout the following discussion, we assume that the solution $\tilde x$ to $(\tilde P)$ does not satisfy $\tilde x_1 \le \psi$.

4.1. Case $\bar\lambda = 0$. In this case, $\gamma \to V(\gamma)$ is strictly increasing with $V(0)$ equal to the value of the cost in $(\tilde{\mathrm{P}})$ and V^∞ the value of the cost in (P).

PROPOSITION 4.3. *The mapping $\gamma \to \dot V(\gamma)$ is monotonically decreasing.*

Proof. For $\bar\gamma > \gamma > 0$ we have

$$\begin{aligned}J(x_\gamma) + \frac{\gamma}{2}|(x_{1,\gamma} - \psi)^+|^2 &\le J(x_{\bar\gamma}) + \frac{\gamma}{2}|(x_{1,\bar\gamma} - \psi)^+|^2 \\ &\le J(x_{\bar\gamma}) + \frac{\bar\gamma}{2}|(x_{1,\bar\gamma} - \psi)^+|^2 \le J(x_\gamma) + \frac{\bar\gamma}{2}|(x_{1,\gamma} - \psi)^+|^2,\end{aligned}$$

and hence

$$J(x_\gamma) - J(x_{\bar\gamma}) \le \frac{\gamma}{2}(|(x_{1,\bar\gamma} - \psi)^+|^2 - |(x_{1,\gamma} - \psi)^+|^2),$$

and further

$$J(x_{\bar\gamma}) - J(x_\gamma) \le \frac{\bar\gamma}{2}(|(x_{1,\gamma} - \psi)^+|^2 - |(x_{1,\bar\gamma} - \psi)^+|^2),$$

which implies

$$0 \le (\bar\gamma - \gamma)(|(x_{1,\gamma} - \psi)^+|^2 - |(x_{1,\bar\gamma} - \psi)^+|^2) = (\bar\gamma - \gamma)(\dot V(\gamma) - \dot V(\bar\gamma)).$$ ∎

Note that Proposition 4.3 implies that $\ddot V(\gamma) \le 0$ whenever the second derivative of V exists at γ. This can also be derived from (2.9) and (4.3). A class of functions that satisfies the above properties of V is given by

$$m(\gamma) = C_1 - \frac{C_2}{(D+\gamma)^r}, \tag{4.4}$$

with $C_1 \in \mathbb{R},\ C_2 > 0,\ D > 0,\ r > 0$. In fact, $\dot{m} > 0$, $\ddot{m} < 0$ and $m(0)$, $m(\gamma)$ for $\gamma \to \infty$ are well defined. In our use of m for path-following algorithms, (C_1, C_2, D) will be treated differently from r. While r will be chosen as a fixed number, (C_1, C_2, D) will be updated in an iterative procedure. Let us further note that by a simple rescaling, we can always assume that $D = 1$.

Remark 4.1. To give a second motivation for the choice of the model function, we consider the state constrained problem

$$\text{minimize } J(x) = \frac{1}{2}|y - y_d|^2_{L^2(\Omega)} + \frac{\beta}{2}|u|^2_{L^2(\Omega)} \text{ over } x \in X$$

$$\begin{aligned} \text{subject to } \quad -\Delta y &= u \quad && \text{in } \Omega, \\ y &= 0 && \text{on } \partial\Omega, \\ y &\le \psi && \text{a.e. in } \Omega, \end{aligned}$$

where $\beta > 0$, $x = (y, u) \in X = (H^1_0(\Omega) \cap H^2(\Omega)) \times L^2(\Omega)$, $y_d \in L^2(\Omega)$, $\psi \in L^2(\Omega)$, and Ω is a bounded domain in $\mathbb{R}^n$. We utilize the sensitivity equation with respect to γ and assume that meas $\{z : (y - \psi)(z) = 0\} = \emptyset$. Then from Proposition 2.4 with $S_\gamma = \{z : (y - \psi)(z) > 0\}$, we have

$$-\Delta \dot{y} = \frac{1}{2}\dot{p}, \quad -\Delta \dot{p} + (y_\gamma - \psi)^+ + \gamma \dot{y} \chi_{S_\gamma} = -\dot{y},$$

and hence,

$$\alpha \Delta^2 \dot{y} + \dot{y} + \gamma \dot{y} \chi_{S_\gamma} + (y_\gamma - \psi)^+ = 0.$$

Taking the inner product in $L^2(\Omega)$ with $(y_\gamma - \psi)^+$, we have

$$(\alpha \Delta^2 \dot{y} + \dot{y},\ (y_\gamma - \psi)^+) + \gamma(\dot{y}, (y_\gamma - \psi)^+) + |(y_\gamma - \psi)^+|^2_{L^2} = 0.$$

Replacing $(\alpha \Delta^2 \dot{y},\ (y_\gamma - \psi)^+)$ with $(\hat{D}\, \dot{y}, (y_\gamma - \psi)^+)$, where $\hat{D}$ is a positive constant, we arrive at

$$((D + \gamma)\dot{y},\ (y_\gamma - \psi)^+) + |(y_\gamma - \psi)^+|^2_{L^2} = 0, \tag{4.5}$$

where we set $D = \hat{D} + 1$. Recall from Proposition 4.1 and (4.1) that $|(y_\gamma - \psi)^+|^2_{L^2} = 2\dot{V}(\gamma)$ and $|(\dot{y}, y_\gamma - \psi)^+| = \ddot{V}(\gamma)$. Since we replaced $\alpha\Delta^2$ with the constant $\hat{D}$, for the purpose of deriving this model, we replace V with its model m and obtain from (4.5)

$$(D + \gamma)\ddot{m}(\gamma) + 2\dot{m}(\gamma) = 0.$$

The solution to this ordinary differential equation is given by (4.4) with $r = 1$.

4.2. Case $\bar{\boldsymbol{\lambda}} \neq \mathbf{0}$. If (4.2) holds, then $\gamma \to V(\gamma)$ is strictly decreasing for $\gamma \ge \bar{\gamma}$, with $\lim_{\gamma \to \infty} V(\gamma)$ equal to the value of the objective of (P), and $\lim_{\gamma \to 0} V(\gamma) = \infty$.

PROPOSITION 4.4. *Assume that $X_1 \hookrightarrow L^2(\omega)$ is compact, that* meas$(S^\circ_\gamma) = 0$, *and that* (4.2) *holds. Then $\ddot{V}(\gamma) \ge 0$.*

Proof. From (4.3) with $S^+_\gamma = S_\gamma$, we have

$$\ddot{V}(\gamma) = \frac{1}{\gamma^3}\int_{S_\gamma} \bar{\lambda}^2 + \int_{S_\gamma} (x_{1,\gamma} - \psi)\dot{x}_{1,\gamma} \ge \frac{1}{\gamma}\int_{S_\gamma} (x_{1,\gamma} - \psi)^2 + \int_{S_\gamma} (x_{1,\gamma} - \psi)\dot{x}_{1,\gamma}.$$

From Proposition 2.4 and (2.1), we have

$$\gamma|\dot{x}_{1,\gamma}|_{L^2(S_\gamma)} \le |x_{1,\gamma} - \psi|_{L^2(S_\gamma)}.$$

This implies $\ddot{V}(\gamma) \ge 0$. □

A class of model functions, which satisfy the above properties of V, is given by

$$m(\gamma) = C_1 - \frac{C_2}{(D+\gamma)^r} + \frac{B}{\gamma^r}, \tag{4.6}$$

with $C_1 \in \mathbb{R},\ B \ge C_2 > 0,\ D > 0$, and $r \in (0, 1]$. In fact, $m(0) = \infty$, $\lim_{\gamma\to\infty} m(\gamma) = C_1$, $\dot{m}(\gamma) < 0$, and $\ddot{m}(\gamma) > 0$. A rescaling argument similar to the one for $\bar{\lambda} = 0$ allows us to henceforth assume $D = 1$.

5. Numerics. In this section we specify an inexact path-following method for the numerical solution of (P). In the inner loop, it utilizes a locally superlinearly convergent algorithm for solving the regularized path problem (P_γ). The outer loop employs a γ-update strategy based on our model functions (4.4) (respectively, (4.6)). The section ends with a report on test runs for the solution of some state constrained optimal control problems with distributed control and a linear elliptic PDE as the governing equation. We also compare our new algorithm with a primal-dual path-following interior point method [18, 27] adapted to PDE-constrained minimization as in [1] and with the primal-dual active set strategy [1, 2]. Our test problems include cases when the optimal solution lacks strict complementarity, i.e., when the set $\mathcal{S}^* = \{y^* = \psi \ \wedge\ \lambda^* = 0\}$ has positive measure. It is known that lack of strict complementarity may slow the convergence of numerical algorithms. This is due to the difficulty of detecting the correct active (respectively, inactive) set structure in the neighborhood of the solution.

5.1. Inner iteration: An algorithm for solving (P_γ). Here we adopt the primal-dual active set strategy as proposed in [12] for solving problems of the type (P_γ). The method is equivalent to a semismooth Newton algorithm, and, using the techniques in [10], it can be shown to converge locally at a q-superlinear rate.

ALGORITHM PDAS$_\gamma$ (primal-dual active set strategy for γ-regularized problem (P_γ)).

(i) Choose $\bar{\lambda} \ge 0$ and $x^0 \in X$; set $l = 0$.

(ii) Determine the active and inactive sets

$$\mathcal{A}^{l+1} := \{w \in \omega : \bar{\lambda}(w) + \gamma(x_1^l(w) - \psi(w)) > 0\},$$
$$\mathcal{I}^{l+1} := \Omega \setminus \mathcal{A}^{l+1}.$$

(iii) Compute the solution x^{l+1} with associated adjoint state p^{l+1} of

$$\text{minimize } \langle J'(x^l) + \frac{1}{2}\langle J''(x^l)(x - x^l), x - x^l\rangle_{X^*,X} + \frac{1}{2\gamma}|(\bar{\lambda} + \gamma(x_1 - \psi))^+|^2_{L^2(\mathcal{A}^{l+1})} \quad \text{over } x \in X$$
$$\text{subject to } Ex = f \text{ in } W.$$

(iv) Compute

$$\lambda^{l+1} = \begin{cases} 0 & \text{on } \mathcal{I}^{l+1}, \\ \bar{\lambda} + \gamma(x_1^{l+1} - \psi) & \text{on } \mathcal{A}^{l+1}, \end{cases}$$

set $l = l + 1$, and go to (ii).

The first order optimality system of the minimization problem in step (iii) is given by

$$\begin{aligned} &Ex^{l+1} = f \text{ in } W, \\ &J''(x^l)x^{l+1} + E^*p^{l+1} + \big(\gamma(x_1^{l+1} - \psi)\chi_{\mathcal{A}^{l+1}}, 0\big) \\ &\qquad = -J'(x^l) + J''(x^l)x^l - \big(\bar\lambda\chi_{\mathcal{A}^{l+1}}, 0\big) \text{ in } X^*. \end{aligned}$$

Note that this system corresponds to a linearization of (2.4) at x^l. In this context, the max-function

$$x_1 \mapsto \big(\bar\lambda + \gamma(x_1 - \psi)\big)^+$$

is linearized separately on the active and inactive sets determined in step (ii). This is equivalent to employing a generalized (or slant) derivative of the max-function in the spirit of [10, 12] in the process of linearization. Consequently, step (iii) is identical to the solution of the linear system within an iteration of a semismooth Newton method for solving (2.4).

5.2. Outer iteration: Inexact solutions and γ-update. For small γ there is no need for highly accurate solutions of the regularized problem (P_γ), since we expect x_γ to be only a coarse approximation of x^*. Rather we propose a procedure requiring approximate solutions of the path problem lying in some neighborhood of the path only. This is similar to the concept considered in [12] and to path-following for log-barrier-functions. For this purpose we introduce the residuals

$$\begin{aligned} r_x(x) &= \|Ex - f\|_W, \\ r_p(x, p, \lambda) &= \|J'(x) + E^*p + (\lambda, 0)\|_{X^*}, \\ r_\lambda(x_1, \lambda) &= \|\lambda - (\bar\lambda + \gamma(x_1 - \psi))^+\|_{X_1^*} \end{aligned}$$

and define the neighborhood

$$\mathcal{N}(\gamma, r) = \left\{(x, p, \lambda) \in Z : \max\{r_x(x), r_p(x, p, \lambda), r_\lambda(x_1, \lambda)\} \le \frac{\tau}{\gamma^r}\right\}$$

with $Z = X \times X^* \times L^2(\omega)$ for some fixed $\tau > 0$ and $r > 0$. In our implementation, we typically choose r in accordance with our model (4.4) or (4.6). In the subsequent algorithm, for fixed γ, we stop Algorithm PDAS_γ after the first occurrence of $(x^l, p^l, \lambda^l) \in \mathcal{N}(\gamma, r)$ for the first time.

Once an approximate solution of (P_γ) is obtained, we have to update γ. To this end, we introduce the feasibility measure ρ^F and the complementarity measure ρ^C as follows:

$$\begin{aligned} \rho^F(x_1) &:= \int_\omega (x_1 - \psi)^+ dz, \\ \rho^C(x_1) &:= \int_{\mathcal{I}(x_1)} (x_1 - \psi)^+ dz + \int_{\mathcal{A}(x_1)} (x_1 - \psi)^- dz, \end{aligned}$$

where $\mathcal{A}(x_1) = \{z \in \omega : \bar\lambda(z) + \gamma(x_1(z) - \psi(z)) > 0\}$, $\mathcal{I}(x_1) = \omega \setminus \mathcal{A}(x_1)$, and $(\cdot)^- = \min(0, \cdot)$. Whenever $x_1 = x_1^{k+1}$ and $\gamma = \gamma_k$, we write $\mathcal{A}^{k+1}$, $\mathcal{I}^{k+1}$ and ρ_{k+1}^F, ρ_{k+1}^C. For $\max(\rho_{k+1}^F, \rho_{k+1}^C) > 0$, we obtain a candidate γ_{k+1}^+ for γ_{k+1} as

$$\gamma_{k+1}^+ = \max\left(\gamma_k \max\left(\tau_1, \frac{\rho_{k+1}^F}{\rho_{k+1}^C}\right), \frac{1}{\max(\rho_{k+1}^F, \rho_{k+1}^C)^q}\right) \tag{5.1}$$

with $\tau_1 > 1$ and $q \geq 1$; otherwise we set $\gamma_{k+1}^+ = \tau_1 \gamma_k$. We include the quotient $\rho_{k+1}^F / \rho_{k+1}^C$ in order to significantly increase γ whenever $\rho_{k+1}^F \gg \rho_{k+1}^C$, i.e., when the iterates primarily lack feasibility rather than complementarity. The choice $q > 1$ induces certain growth rates for γ. Similar to [12], we also incorporate the following safeguard based on our model (4.4) (respectively, (4.6)): Unless $\gamma_{k+1} < \tau_2 \gamma_k$, with $\tau_2 > 1$, we reduce γ_{k+1}^+ until

$$|t_k(\gamma_{k+1}) - m_k(\gamma_{k+1})| \leq \tau_3 |J(x^{k+1}, \gamma_k) - J(x^k, \gamma_{k-1})|, \tag{5.2}$$

where $0 < \tau_3 < 1$ and $t_k(\gamma) = J(x^{k+1}, \gamma_k) + \frac{\partial J(x^k, \gamma_k)}{\partial \gamma}(\gamma - \gamma_k)$. In other words, the linearization of m_k at γ_{k+1} should not be farther away from m_k than the distance of the previous two objective values of the regularized problem. As soon as (5.2) is satisfied, we set $\gamma_{k+1} = \gamma_{k+1}^+$.

Notice that our safeguard involves the model function in iteration k, which we denote by m_k. To determine the parameters in our model, we use the actual approximate information on the value functional and its derivative as well as the value function at some reference point. In what follows, we argue only for the model (4.6). The case (4.4) is treated similarly. Given γ_k in iteration k, for fixing B_k, $C_{1,k}$, and $C_{2,k}$ in the model $m_k(\gamma)$, we use the conditions

$$m_k(\gamma_k) = J(x^k, \gamma_k), \quad \dot{m}_k(\gamma_k) = \frac{\partial J(x^k, \gamma_k)}{\partial \gamma}(x^k, \gamma_k), \quad m_k(\hat{\gamma}) = J(\hat{x}, \hat{\gamma}),$$

where $\hat{x}$ denotes an approximate solution of (P_γ) at a reference value $\gamma = \hat{\gamma}$.

Now we are able to outline our overall algorithm.

Algorithm IPF (inexact path-following).

(i) Initialized $\gamma_0 > 0$, select $r > 0$, and set $k := 0$.
(ii) Compute $(x^k, p^k, \lambda^k) \in \mathcal{N}(\gamma_k, r)$.
(iii) Update γ_k by (5.1) with safeguard (5.2) to obtain γ_{k+1}.
(iv) Set $k = k + 1$ and go to (ii).

In step (ii) we use PDAS_γ for performing the inner iteration. The convergence of Algorithm IPF follows immediately from the convergence of Algorithm PDAS_γ for every fixed γ and the fact that $\gamma_{k+1} \geq \tau_1 \gamma_k$ with $\tau_1 > 1$ for all k, the property that $\frac{\tau}{\gamma_k^r} \to 0$ for $\gamma_k \to \infty$ in the definition of the neighborhood, and from Proposition 2.1.

5.3. Numerical tests. In this section we report on numerical results for the solution of the following state constrained optimal control problem:

$$\begin{aligned} &\text{Minimize } J(y,u) = \frac{1}{2}|y - y_d|_{L^2}^2 + \frac{\beta}{2}|u|_{L^2}^2 \text{ over } (y,u) \in X \\ &\text{subject to } -\Delta y = u \text{ in } \Omega, \quad y = 0 \text{ on } \Gamma, \\ &\qquad\qquad y \leq \psi \text{ a.e. in } \Omega. \end{aligned}$$

Thus, we have $x = (y, u)$, $X_1 = H_0^1(\Omega)$, $X_2 = L^2(\Omega)$, and $\omega = \Omega = (0,1)^2$.

For the discretization of the Laplace operator in two dimensions we use a standard regular five-point finite difference stencil with mesh size h. Unless specified otherwise, the subsequent test runs of all algorithms are based on a nested iteration technique. For this purpose we define a grid hierarchy with mesh sizes $\{h_i\}_{i=2}^8$ and $h_i = 2^{-i}$. On every grid, we stop Algorithm IPF as soon as

$$\max(r_x(x^k), r_p(x^k, p^k, \lambda^k), r_d(x_1^k, \lambda^k)) \leq 0.1\, h_i^2, \tag{5.3}$$

where $r_d(x_1^k, \lambda^k) = \|\lambda^k - (\lambda^k + x_1^k - \psi)^+\|_{X_1^*}$. For $i = 2$ we initialize the algorithms by choosing $y^0 = \psi_i$, $u_i^0 = -\Delta_i y_i$, and $p_i^0 = \beta u_i^0$. Here and below, subscript i refers to discretized quantities on grid level i. The initial Lagrange multiplier is $\lambda_i^0 = \chi_{\{y_i^0 > \psi_i\}}(\bar\lambda_i + \gamma_0(y_i^0 - \psi_i))$ with $\bar\lambda_i = \max\left(y_{d,i} - (\beta\Delta_i^2 + \mathrm{id}_i)\psi_i, 0\right)$ in the case considered in section 4.2; otherwise $\bar\lambda_i = 0$. For $i > 2$, the interpolation of $(x_{i-1}, p_{i-1}, \lambda_{i-1})$, which is the approximate solution for h_{i-1}, is used as the initial value on the grid with mesh size h_i. The interpolation process is as follows. First, we smooth $(u_{i-1}, p_{i-1}, \lambda_{i-1})$ by applying $(-\Delta_{i-1})^{-1}$, the discrete Laplace operator with homogeneous Dirichlet boundary conditions for h_{i-1}, to the respective components. Then a nine-point-interpolation scheme is applied to obtain $(\tilde u_i, \tilde p_i, \tilde\lambda_i)$; see, e.g., [7]. Finally, we compute

$$u_i^0 = -\left(D_{w_1,i}(D^0_{w_1,i}\tilde u_i) + D_{w_2,i}(D^0_{w_2,i}\tilde u_i)\right),$$

where $D^0_{w_1,i}$ stands for symmetric differences with homogeneous Dirichlet boundary conditions in the w_1-direction, and $D_{w_1,i}$ represents symmetric differences with linear extrapolation on the boundary; similar definitions hold for $D_{w_2,i}$ and $D^0_{w_2,i}$. The adjoint state p_i^0 and the multiplier λ_i^0 are computed analogously.

Whenever a nonzero shift $\bar\lambda$ is used, then we choose

$$\bar\lambda = \max\left(y_d - (\beta\Delta^2 + \mathrm{id})\psi, 0\right).$$

This choice of $\bar\lambda$ is inspired by the reduction of the system consisting of state and adjoint equations, by the optimality condition with respect to u, and by setting $x_1 = \psi$.

Problem 1. The problem data are $y_d = 10(\sin(2\pi x_1) + x_2)$, $\psi \equiv 0.01$, $\beta = 0.1$. In Figure 1 we show the optimal state y_h^* (top left plot) and control u_h^* (far right) and the Lagrange multiplier λ_h^* (bottom) on a 128×128 grid. The behavior of λ_h^* along the boundary between the active and inactive sets at the discrete solution clearly suggests the measure-valuedness of λ^*.

For our model of the primal-dual value functional we use (4.6), i.e., we apply the $\bar\lambda$-shift, with $r = 0.2$. We use $\gamma_0 = 1\mathrm{E}2$ initially. First, we report on the behavior of the algorithms on a fixed grid, i.e., without utilizing the nested iteration concept. In Table 1 we show the iteration numbers for the primal-dual active set method for solving (P) (abbreviated by PDAS), the primal-dual path-following interior point method (PDIP), and our new path-following concept (IPF) for various mesh sizes h. We point out that the stopping rule for each algorithm is given by (5.3). For IPF we also specify the total number of inner iterations, i.e., the total number of iterations of Algorithm PDAS$_\gamma$. In all cases, the algorithms are initialized as in the case of $i = 2$ described above. Further, for Algorithm IPF we use $q = 1.25$ and $\tau_1 = 10$ in (5.1), $\tau_2 = 1.01$ and $\tau_3 = 0.6$ in (5.2), and $\tau = 100$ in $\mathcal{N}(\gamma, r)$. The results in Table 1 indicate that Algorithms IPF and PDIP are superior to PDAS, whereas IPF appears to be more efficient than PDIP. This reflects also our experience from further test runs for additional problems. We also point out that in contrast to PDAS and PDIP our Algorithm IPF admits a function space analysis. As a consequence, the number of (inner) iterations behaves in a rather mesh-independent way. For PDAS a strong dependence of the iteration numbers on the mesh size is observed. The stabilizing iteration numbers for PDIP in the case of mesh refinements suggest that a function space analysis might be possible. However, to the best of our knowledge, no such analysis is yet available for the problem class considered here that includes a regularization parameter tending to zero in the numerical method.

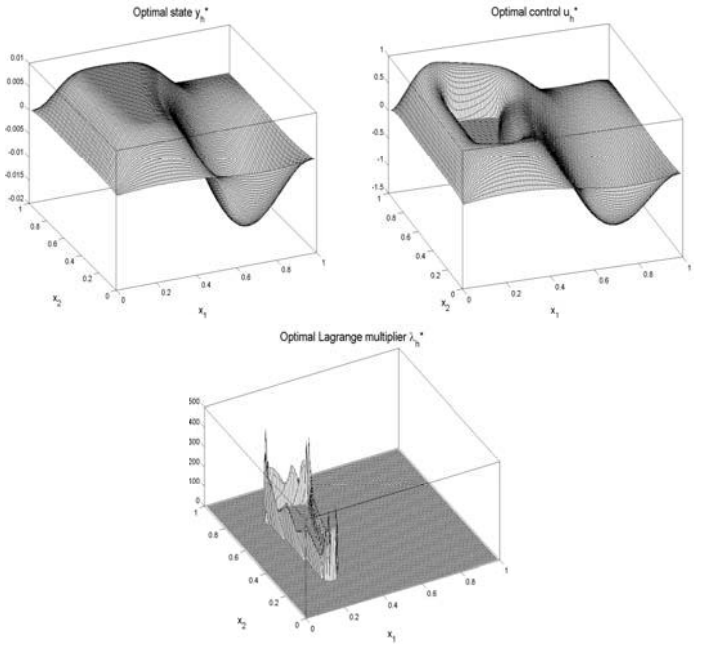

FIG. 1. *Optimal state (top left), optimal control (top right), and optimal multiplier (bottom) for problem* 1 *with* $h = 1/128$.

TABLE 1
Comparison of iteration numbers for different mesh sizes and methods.

Mesh size h	1/16	1/32	1/64	1/128	1/256
PDAS	14	27	54	113	226
PDIP	12	14	15	19	19
IPF	7(11)	9(15)	9(14)	7(13)	8(15)

Next we report on the outcome of our tests when employing the nested iteration concept and when using the interpolation of the approximate coarse grid solution as the initial point on the next finer grid. The results are summarized in Table 2. Note that for IPF we display only the total number of iterations on the respective grid. First observe that all algorithms experience a speed-up when using the nested iteration concept. PDAS especially, although lacking a function space convergence theory, performs remarkably well in this environment when compared to its variant on fixed grids. With respect to iteration numbers, our path concept is slightly faster than PDIP and PDAS. For a comparison of the CPU-times consumed by the respective algorithm, we define CPU-ratio(*algorithm*) = CPU-time(*algorithm*)/CPU-time(IPF). We have

$$\text{CPU-ratio(PDIP)} \approx 2 \quad \text{and} \quad \text{CPU-ratio(PDAS)} \approx 0.8;$$

i.e., PDIP requires twice as much CPU-time as IPF, while PDAS is slightly faster than IPF. This can be explained by the fact that PDAS performs system solves only on the currently inactive set, whereas IPF has to solve a system on the whole domain. However, we point out that the simple structure of the system matrix of IPF, i.e., $(-\Delta)_i + D_i$, with D_i a positive (semi)definite diagonal matrix on the respective grid

TABLE 2
Problem 1. *Comparison of iteration numbers for different mesh sizes and methods based on nested iteration.*

Mesh size h	1/4	1/8	1/16	1/32	1/64	1/128	1/256	total
PDAS	3	4	4	5	6	6	6	34
PDIP	3	2	4	4	5	6	7	31
IPF	4	3	3	4	5	5	5	29

with mesh size h_i, suggests that one can further speed up the solution process of the linear system in every iteration of Algorithm PDAS$_\gamma$. This, however, is beyond the scope of the present work.

Problem 2 *(lack of strict complementarity).* We construct a test problem for which the active set at the solution contains a subset, where strict complementarity does not hold. For this purpose define $\tilde{p}(w_1, w_2) = -w_1(1-w_1)w_2(1-w_2) \in H_0^1(\Omega) \cap C^\infty(\Omega)$ and $\ell(w_1, w_2) = -0.04 + 0.02w_1 - 0.03w_2$. The adjoint state at the solution is given by $p^* = \max(\tilde{p}, \ell)$. Further, we define the active set at the solution as $\mathcal{A}^* = \{\tilde{p} = \ell\}$ and the inactive set as its complement in Ω. We set

$$\tilde{\xi} = \begin{cases} \Delta\tilde{p} \text{ on } \mathcal{I}^*, \\ 0 \text{ on } \mathcal{A}^*, \end{cases}$$

$\xi = \Delta p$, and $\xi_L = \xi - \tilde{\xi}$. Next we decompose the Lagrange multiplier at the solution in a singular part λ_s^* and a regular part λ_r^*. The singular part consists of a line source contribution λ_L^* and an absolutely continuous part λ_a^*:

$$\lambda^* = \lambda_s^* + \lambda_r^* = \lambda_L^* + \lambda_a^* + \lambda_r^*.$$

We define

$$\lambda_L^* = \xi_L, \quad \lambda_a^* = \tilde{\xi}, \quad \lambda_r^*|_{\mathcal{I}^*} = -\tilde{\xi}, \quad \lambda_r^*|_{\mathcal{A}^*} = -100\tilde{p}|_{\mathcal{A}}.$$

Further, $u^* = p^*/\beta$, with $\beta = 0.01$, and $y^* = (-\Delta)^{-1}p^*/\beta$. The bound is given by $\psi|_{\mathcal{A}^*} = y^*|_{\mathcal{A}^*}$ and $\psi|_{\mathcal{I}^*} = (1/(1 + \mathrm{dist}(\mathcal{A}^*)^{0.1}))y^*|_{\mathcal{I}^*}$. Here $\mathrm{dist}(\mathcal{A}^*)$ denotes the distance function to the active set $\mathcal{A}^*$. The desired state is given by $y_d = y^* + \lambda_r^*$.

In Figure 2 we show the optimal state y_h^* (top left) and control u_h^* (top right) and the Lagrange multiplier λ_h^* (bottom) on a 128×128 grid.

Figure 3 provides the bound ψ (top left), the difference $\psi - y^*$ (top right), and the strongly active, weakly active and inactive sets (bottom). For the latter graph note that the weakly active set corresponds to the region where strict complementarity fails to hold (white region). The strongly active set, i.e., the set where $y^* = \psi$ and $\lambda^* > 0$, is displayed in gray. The inactive set is given by the black region.

The parameters in IPF had the values $r = 0.1$, $\tau_1 = 10$, $\tau_2 = 1.01$, $\tau_3 = 0.7$, and $\tau = 100$. We further set $\bar{\lambda} = 0$.

In Table 3 we report the result corresponding to Problem 2. The arrangement of the table is analogous to that of Table 2 for Problem 1. First we note that, compared to the previous problem, the iteration numbers for PDAS increase significantly as the mesh is refined. This is also reflected in the following CPU-time comparison for this example:

$$\text{CPU-ratio(PDIP)} \approx 1.2 \quad \text{and} \quad \text{CPU-ratio(PDAS)} \approx 1.8.$$

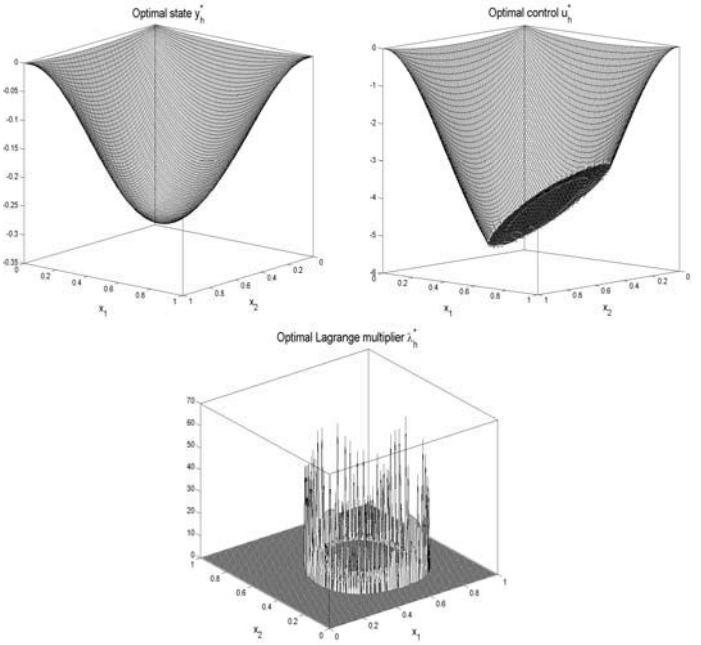

FIG. 2. *Problem* 2. *Optimal state (top left), optimal control (top right), and optimal multiplier (bottom) for* $h = 1/128$.

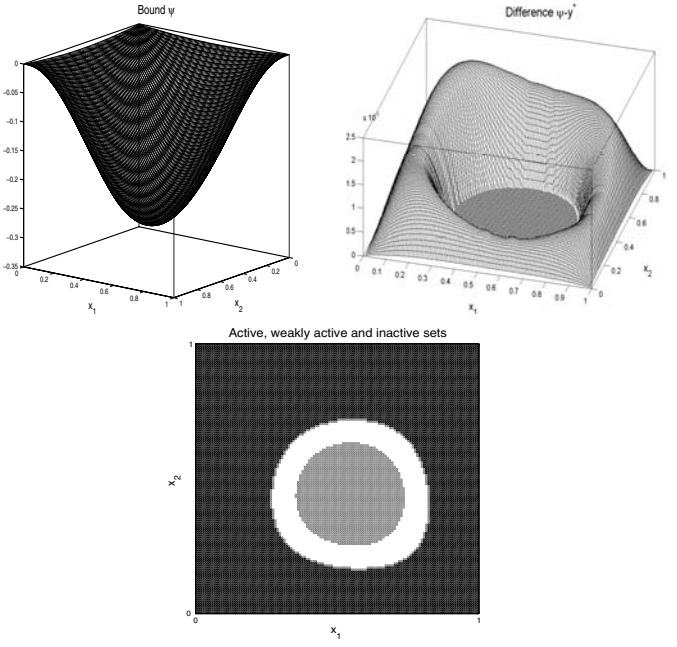

FIG. 3. *Problem* 2. *Bound* ψ *(top left), the difference* $\psi - y^*$ *(top right), and the active and inactive sets (bottom) for* $h = 1/128$.

TABLE 3
Problem 2. *Comparison of iteration numbers for different mesh sizes and methods based on nested iteration.*

Mesh size h	1/4	1/8	1/16	1/32	1/64	1/128	1/256	total
PDAS	2	4	5	9	10	21	40	91
PDIP	3	2	3	3	6	12	11	40
IPF	7	2	4	4	6	8	15	46

Further observe that PDIP needs the lowest total number of iterations, but it requires about 20% more CPU-time than IPF. This can be explained by the fact that interior point approaches typically enlarge the system size by adding slack variables. An a priori system reduction obtained by choosing specific pivots allows us to reduce the large indefinite system occurring in every iteration to a system of the same size as that for IPF. However, in order to compute a solution to the overall system, for PDIP several backward substitutions are required, in contrast to the efforts needed in IPF. Further, we point out that practically relevant versions of primal-dual path-following interior point methods, such as the Mehrotra predictor-corrector algorithm or the Mizuno–Todd–Ye variant (see [1] for an adaptation of these two variants to optimal control of PDEs and for further references), require additional system solves. Depending on the variant, one has either two system solves where the second system has a different right hand side but the same system matrix or two system solves where the second system has a different right hand side *and* a different system matrix as well. The triangular system solves for backward substitution, and the additional system solves mentioned above add significantly to the overall CPU-time. Let us further point out that the reduced systems of PDIP typically have a more involved structure when compared to the systems of IPF; for an account of this fact see, for instance, the systems (4.6) and (4.7) in [1], and the system in Algorithm PDAS$_\gamma$.

A NUMERICAL METHOD FOR A GENERALIZED ALGEBRAIC RICCATI EQUATION*

DELIN CHU†, WEN-WEI LIN‡, AND ROGER C. E. TAN†

Abstract. In this paper we develop a numerical method for computing the semistabilizing solution of a generalized algebraic Riccati equation (GARE). The semistabilizing solution of such a GARE has been used to characterize the solvability of the (J, J')-spectral factorization problem for general rational matrices which have poles and zeros on the extended imaginary axis. The main difficulty for solving such a GARE is that its associated skew-Hamiltonian/Hamiltonian pencil has eigenvalues on the extended imaginary axis; consequently, it is not clear which eigenspace of the associated skew-Hamiltonian/Hamiltonian pencil can characterize the desired semistabilizing solution; i.e., it is not clear which eigenvectors and principal vectors corresponding to the eigenvalues on the extended imaginary axis should be contained in the eigenspace that we wish to compute, and hence the well-known generalized eigenvalue approach for the classical algebraic Riccati equations cannot be directly employed for it. Our proposed method consists of computations of the eigendecomposition of the system pencil corresponding to the eigenvalues on the extended imaginary axis and the stable eigenspace of an augmented matrix pencil; hence, it is a generalization of the generalized eigenvalue approach for the classical algebraic Riccati equations.

Key words. generalized algebraic Riccati equation, semistabilizing solution, eigenvalues, stable eigenspace, extended imaginary axis

1. Introduction.

Throughout this paper, $\mathbf{C}_-$ and $\mathbf{C}_0$ denote the open left half complex plane and the imaginary axis, respectively, and $\mathbf{C}_{0e} = \mathbf{C}_0 \cup \{\infty\}$.

The (J, J')-spectral factorization of rational matrices has many important applications in optimal Hankel-norm model reduction and H_∞ optimization [7, 19], transport theory [20], and stochastic filtering [13]. It is now well known that the algebraic Riccati equations (AREs) play important roles for solving various (J, J')-spectral factorization problems. In [17] the difficulties in numerically solving the classical spectral factorization (a special case of the (J, J')-spectral factorization) of rational matrix $G(s)$ are shown to be related to the existence of poles and zeros of $G(s)$ on $\mathbf{C}_{0e}$ and to the noninvertibility of $G^T(-s)G(s)$. If none of these elements are present, the computation of the classical spectral factorization problem reduces to solving a standard ARE for which numerically reliable algorithms are available [4, 8, 14, 24, 27, 28]. The canonical J-spectral factorization (the (J, J')-spectral factorization with the condition that $G(s)$ has no poles and zeros on $\mathbf{C}_{0e}$) has been solved in [16] in terms of the stabilizing solution of an indefinite ARE. The (J, J')-spectral factorization problem for general rational matrices with poles/zeros on $\mathbf{C}_{0e}$ has also been considered in [2, 3] based on the semistabilizing solution of a generalized

algebraic Riccati equation (GARE) of the form

$$\begin{cases} A_a^T X_a + X_a^T A_a + (C_a^T J C_a - B_a J' B_a^T) - X_a^T B_a (J')^{-1} B_a^T X_a = 0, \\ E_a^T X_a = X_a^T E_a, \end{cases} \tag{1}$$

where

$$E_a = \begin{bmatrix} E & 0 \\ 0 & 0 \end{bmatrix}, \quad A_a = \begin{bmatrix} A & B \\ 0 & I \end{bmatrix}, \quad C_a = \begin{bmatrix} C & D \end{bmatrix}, \quad B_a = \begin{bmatrix} 0 \\ -I \end{bmatrix},$$

$E, A \in \mathbf{R}^{n\times n}$, $B \in \mathbf{R}^{n\times m}$, $C \in \mathbf{R}^{p\times n}$, $D \in \mathbf{R}^{p\times m}$, $J \in \mathbf{R}^{p\times p}$, $J' \in \mathbf{R}^{m\times m}$, E is singular, and J and J' are symmetric and nonsingular. The semistabilizing solution of the GARE (1) is defined as follows.

DEFINITION 1 (see [2, 3]). *A solution $X_a \in \mathbf{R}^{(n+m)\times(n+m)}$ of the GARE (1) is called a semistabilizing solution if*

(i) *the pencil $A_a - B_a(J')^{-1}B_a^T X_a - sE_a$ is regular and its eigenvalues lie in $\mathbf{C}_- \cup \mathbf{C}_{0e}$;*

(ii) *the matrix pair $(C_a, A_a - B_a(J')^{-1}B_a^T X_a - sE_a)$ has neither observable finite poles on $\mathbf{C}_0$ nor observable impulsive poles.*

Recently, a numerical method for computing the semistabilizing solution of the GARE (1) has been proposed in [2, 3] under the following assumptions:

(A1) (E, A, B) is finite dynamic stabilizable and impulse controllable, i.e.,

$$\operatorname{rank}\begin{bmatrix} -sE + A & B \end{bmatrix} = n \quad \forall s \in \mathbf{C}\backslash\mathbf{C}_-$$

and

$$\operatorname{rank}\begin{bmatrix} E & A & B \\ 0 & E & 0 \end{bmatrix} = n + \operatorname{rank}(E);$$

$$\max_{s\in\mathbf{C}} \operatorname{rank}\begin{bmatrix} -sE + A & B \\ C & D \end{bmatrix} = n + m. \tag{A2}$$

A key step in this method is to compute a nonsingular solution of a nonsymmetric ARE of the form

$$A_{a,0}^T X_{a,0} + X_{a,0}^T A_{a,0} + Q_{a,0} + X_{a,0}^T R_{a,0} X_{a,0} = 0. \tag{2}$$

However, the nonsymmetric ARE (2) is much harder to solve than its symmetric version. Up to now, symmetric AREs have been studied extensively, and many numerically reliable methods are available [4, 8, 14, 24, 25, 27, 28]. On the contrary, these existing methods do not work for the nonsymmetric AREs of the form (2). Indeed, there is still a lack of numerically reliable methods for solving the nonsymmetric AREs of the form (2).

Denote

$$G(s) = D + C(sE - A)^{-1}B =: \left[\begin{array}{c|c} -sE + A & B \\ \hline C & D \end{array}\right]. \tag{3}$$

Regarding the assumption (A1), it implies that the descriptor system

$$E\dot{x} = Ax + Bu, \quad y = Cx + Du \tag{4}$$

is controllable at infinity. However, control of descriptor systems is of practical importance for constrained mechanical systems and mechatronics; there, controllability

at infinity can usually not be assumed. But, the uncontrollable part of the system (4) at infinity does not contribute to its transfer matrix $G(s)$. In fact, if the system (4) is not controllable at infinity, according to [11, 26], we can always compute orthogonal matrices P and $\mathcal{P}$ such that

$$\text{(5)}\qquad \begin{cases} \mathcal{P}(sE-A)P = \begin{matrix} \\ \left[\begin{array}{cc} s\mathcal{E}-\mathcal{A} & s\mathcal{E}_{12}-\mathcal{A}_{12} \\ 0 & s\mathcal{E}_{22}-\mathcal{A}_{22} \end{array}\right] \end{matrix} \begin{matrix} \mu & n-\mu \\ \} \mu \\ \} n-\mu \end{matrix}, \\ \mathcal{P}B = \left[\begin{array}{c} \mathcal{B} \\ 0 \end{array}\right] \begin{matrix} \} \mu \\ \} n-\mu \end{matrix}, \quad CP = \begin{matrix} \mu & n-\mu \\ \left[\begin{array}{cc} \mathcal{C} & \mathcal{C}_2 \end{array}\right] \end{matrix}, \end{cases}$$

such that $(\mathcal{E}, \mathcal{A}, \mathcal{B})$ is finite dynamic stabilizable and impulse controllable. Then we will have

$$G(s) = D + \mathcal{C}(s\mathcal{E} - \mathcal{A})^{-1}\mathcal{B}.$$

In addition, the assumption (A2) is necessary for the existence of the (J, J')-spectral factorization of $G(s)$ [2, 3]. Hence, in this paper we shall also assume that *the assumptions* (A1) *and* (A2) *hold*.

Due to the importance of the GARE (1) in solving the (J, J')-spectral factorization problem of general rational matrices, in this paper we study the numerical computation of the semistabilizing solution of the GARE (1) and extend the well-known generalized eigenvalue approach [8, 14, 27] for the classical AREs to the GARE (1). To the best of our knowledge, similar results do not exist in the literature.

The generalized eigenvalue approach [8, 14, 27] for solving the classical AREs is also called the Schur-type method or invariant subspace method and has been studied extensively in the literature (see [8, 14, 27] and the references therein).

Define

$$\text{(6)}\qquad H_a(s) := \left[\begin{array}{cc} A_a - sE_a & -B_a(J')^{-1}B_a^T \\ -C_a^T J C_a + B_a J' B_a^T & -A_a^T - sE_a^T \end{array}\right].$$

$H_a(s)$ is the skew-Hamiltonian/Hamiltonian pencil associated with the GARE (1). The following result is trivial.

COROLLARY 2. (i) *X_a is a solution of the GARE* (1) *if and only if*

$$H_a(s)\left[\begin{array}{c} I \\ X_a \end{array}\right] = \left[\begin{array}{c} I \\ X_a^T \end{array}\right](A_a - B_a(J')^{-1}B_a^T X_a - sE_a).$$

(ii) *The GARE* (1) *has a solution X_a such that the pencil $A_a - B_a(J')^{-1}B_a^T X_a - sE_a$ is regular, and all its eigenvalues are on $\mathbf{C}_- \cup \mathbf{C}_{0e}$ if and only if there exist matrices*

$$\begin{matrix} n+m \\ \left[\begin{array}{c} Y_1 \\ Y_2 \end{array}\right] \end{matrix} \begin{matrix} \\ \} n+m \\ \} n+m \end{matrix} \quad \textit{and} \quad \begin{matrix} n+m \\ \left[\begin{array}{c} Z_1 \\ Z_2 \end{array}\right] \end{matrix} \begin{matrix} \\ \} n+m \\ \} n+m \end{matrix}$$

such that

$$H_a(s)\left[\begin{array}{c} Y_1 \\ Y_2 \end{array}\right] = \left[\begin{array}{c} Z_1 \\ Z_2 \end{array}\right](\Phi - s\Theta), \quad \operatorname{rank}(Y_1) = \operatorname{rank}(Z_1) = n+m, \quad Y_1^T Z_2 = Y_2^T Z_1,$$

where the pencil $\Phi - s\Theta \in \mathbf{R}^{(n+m)\times(n+m)}$ is regular and all its eigenvalues are on $\mathbf{C}_- \cup \mathbf{C}_{0e}$. In this case, such a solution X_a is given by $X_a = Y_2 Y_1^{-1}$.

From Corollary 2, there exists a close connection between the semistabilizing solution of the GARE (1) and the eigenspace of the pencil $H_a(s)$ corresponding to the eigenvalues on $\mathbf{C}_-$ and $\mathbf{C}_{0e}$. However, the eigenstructure of the pencil $H_a(s)$ corresponding to the eigenvalues on $\mathbf{C}_{0e}$ is much more complicated than the structure of its stable eigenspace. This issue is easy to understand as follows: Let τ_1 and τ_2 denote the dimensions of the eigenspaces of the pencil $H_a(s)$ corresponding to the eigenvalues on $\mathbf{C}_-$ and $\mathbf{C}_{0e}$, respectively. Since E is singular, we have

$$\tau_1 < n,\ \tau_1 + \frac{1}{2}\tau_2 = n + m,$$

provided $H_a(s)$ is regular. This implies that there are many different eigenspaces with dimension $n+m$ corresponding to part of the eigenvalues on $\mathbf{C}_-$ and $\mathbf{C}_{0e}$. Hence, it is not possible to check whether one of such eigenspaces characterizes the existence of the semistabilizing solution of the GARE (1) without having some extra insight. Consequently, it is not clear which eigenvectors and principal vectors corresponding to the eigenvalues on $\mathbf{C}_{0e}$ should be contained in the eigenspace that we wish to compute. Therefore, Corollary 2 is not very useful for the numerical computation of the GARE (1), and the generalized eigenvalue approach [8, 14, 27] for solving the classical AREs cannot be directly employed for the GARE (1). In fact it is a challenge to extend the generalized eigenvalue approach for the classical AREs to the GARE (1).

The main contributions of this paper include numerically verifiable necessary and sufficient conditions for the existence of the semistabilizing solution of the GARE (1) and a new numerical method for computing such a semistabilizing solution. The main ingredients of our method include (i) the eigendecomposition of the system pencil corresponding to the eigenvalues on $\mathbf{C}_{0e}$; (ii) the stable eigenspace of an augmented matrix pencil. These two eigendecompositions can be computed by the numerically backward stable algorithms [6, 10, 26]. Hence, we extend the generalized eigenvalue approach for the classical AREs to the GARE (1).

2. Main results. In this section we present necessary and sufficient conditions for the existence of the semistabilizing solution of the GARE (1) and develop a numerically reliable method to compute such a semistabilizing solution. Since the main difficulty for computing the semistabilizing solution of the GARE (1) is that the skew-Hamiltonian/Hamiltonian pencil $H_a(s)$ defined in (6) has eigenvalues on $\mathbf{C}_{0e}$, and also because

$$\operatorname{rank}(H_a(s)) = \operatorname{rank}\left(\begin{bmatrix} A-sE & B & 0 & 0 \\ C & D & 0 & -J^{-1} \\ 0 & 0 & -A^T-sE^T & -C^T \\ 0 & 0 & -B^T & -D^T \end{bmatrix}\right) + m - p \quad \forall s \in \mathbf{C},$$

which implies that the eigenvalues of $H_a(s)$ on $\mathbf{C}_{0e}$ consist of the eigenvalues of the pencils

$$\begin{bmatrix} A-sE & B \\ C & D \end{bmatrix} \quad \text{and} \quad \begin{bmatrix} -A^T-sE^T & -C^T \\ -B^T & -D^T \end{bmatrix}$$

on $\mathbf{C}_{0e}$, considering that the pencils

$$\begin{bmatrix} A-sE & B \\ C & D \end{bmatrix} \quad \text{and} \quad \begin{bmatrix} -A^T-sE^T & -C^T \\ -B^T & -D^T \end{bmatrix}$$

have the same eigenvalues on $\mathbf{C}_{0e}$, we first isolate the eigenvalues of the pencil

$$\begin{bmatrix} A - sE & B \\ C & D \end{bmatrix}$$

on $\mathbf{C}_{0e}$ via the factorizations (7) and (8) in the following theorem.

THEOREM 3. *Let* $n_1 = \operatorname{rank}(E)$.

(i) *There exist orthogonal matrices* $U, V \in \mathbf{R}^{n\times n}$ *and* $\mathcal{V} \in \mathbf{R}^{(n-n_1+m)\times(n-n_1+m)}$ *such that*

$$U \begin{bmatrix} A - sE & B \end{bmatrix} \begin{bmatrix} V & 0 \\ 0 & I \end{bmatrix} \begin{bmatrix} I & 0 \\ 0 & \mathcal{V} \end{bmatrix} = \begin{array}{c} \begin{matrix} n_1 & n-n_1 & m \end{matrix} \\ \begin{bmatrix} A_{11} - sE_{11} & A_{12} & B_1 \\ A_{21} & A_{22} & 0 \end{bmatrix} \begin{matrix} \}n_1 \\ \}n - n_1 \end{matrix} \end{array}, \tag{7}$$

where E_{11} *and* A_{22} *are nonsingular.*

(ii) *Denote*

$$\begin{bmatrix} C & D \end{bmatrix} \begin{bmatrix} V & 0 \\ 0 & I \end{bmatrix} \begin{bmatrix} I & 0 \\ 0 & \mathcal{V} \end{bmatrix} = \begin{array}{c} \begin{matrix} n_1 & n-n_1 & m \end{matrix} \\ \begin{bmatrix} C_1 & C_2 & \mathcal{D} \end{bmatrix}. \end{array}$$

Then the eigendecomposition of the pencil

$$\begin{bmatrix} A_{11} - sE_{11} & A_{12} & B_1 \\ A_{21} & A_{22} & 0 \\ C_1 & C_2 & \mathcal{D} \end{bmatrix}$$

corresponding to the eigenvalues on $\mathbf{C}_{0e}$ *is of the form*

$$S^T \begin{bmatrix} A_{11} - sE_{11} & A_{12} & B_1 \\ A_{21} & A_{22} & 0 \\ C_1 & C_2 & \mathcal{D} \end{bmatrix} Q$$

$$= \begin{array}{c} \begin{matrix} \mu_1 & n_1 - \mu_1 & m & n - n_1 \end{matrix} \\ \begin{bmatrix} \Phi_{11} - s\Theta_{11} & 0 & 0 & 0 \\ \Phi_{21} - s\Theta_{21} & \Phi_{22} - s\Theta_{22} & \Phi_{23} & \Phi_{24} - s\Theta_{24} \\ \Phi_{31} - s\Theta_{31} & \Phi_{32} & \Phi_{33} & \Phi_{34} \\ \Phi_{41} - s\Theta_{41} & 0 & 0 & \Phi_{44} \end{bmatrix} \begin{matrix} \}p + \mu_1 - m \\ \}n_1 - \mu_1 \\ \}m \\ \}n - n_1 \end{matrix} \end{array}, \tag{8}$$

where S *and* Q *are orthogonal matrices with partitioning*

$$Q = \begin{array}{c} \begin{matrix} \mu_1 & n_1 - \mu_1 & m & n - n_1 \end{matrix} \\ \begin{bmatrix} Q_{11} & Q_{12} & Q_{13} & Q_{14} \\ Q_{21} & Q_{22} & Q_{23} & Q_{24} \\ Q_{31} & Q_{32} & Q_{33} & Q_{34} \end{bmatrix} \begin{matrix} \}n_1 \\ \}n - n_1 \\ \}m \end{matrix} \end{array},$$

$$S = \begin{array}{c} \begin{matrix} p + \mu_1 - m & n_1 - \mu_1 & m & n - n_1 \end{matrix} \\ \begin{bmatrix} S_{11} & S_{12} & S_{13} & S_{14} \\ S_{21} & S_{22} & 0 & S_{24} \\ S_{31} & S_{32} & S_{33} & S_{34} \end{bmatrix} \begin{matrix} \}n_1 \\ \}n - n_1 \\ \}p \end{matrix} \end{array}, \tag{9}$$

and

$$\operatorname{rank}(\Theta_{11}) = \mu_1, \quad \operatorname{rank}(\Theta_{22}) = n_1 - \mu_1,$$

$$\operatorname{rank}(\Phi_{44}) = n - n_1, \quad \operatorname{rank}(S_{24}) = n - n_1, \tag{10}$$

$$\operatorname{rank}(\Phi_{11} - s\Theta_{11}) = \mu_1 \quad \forall s \in \mathbf{C}_{0e}, \tag{11}$$

$$\operatorname{rank}\begin{bmatrix} \Phi_{22} - s\Theta_{22} & \Phi_{23} \\ \Phi_{32} & \Phi_{33} \end{bmatrix} = (n_1 - \mu_1) + m \quad \forall s \in \mathbf{C}\backslash\mathbf{C}_0. \tag{12}$$

Proof. The decompositions (7) and (8) are constructed in the appendix. □

Remark 1. It is clear that all eigenvalues of

$$\begin{bmatrix} A - sE & B \\ C & D \end{bmatrix}$$

on $\mathbf{C}_{0e}$ are isolated to

$$\begin{bmatrix} \Phi_{22} - s\Theta_{22} & \Phi_{23} & \Phi_{24} - s\Theta_{24} \\ \Phi_{32} & \Phi_{33} & \Phi_{34} \\ 0 & 0 & \Phi_{44} \end{bmatrix}.$$

Let

$$M_a(s) := \begin{bmatrix} A_{11} - sE_{11} & A_{12} & 0 & 0 & B_1 \\ A_{21} & A_{22} & 0 & 0 & 0 \\ -C_1^T J C_1 & -C_1^T J C_2 & -A_{11}^T - sE_{11}^T & -A_{21}^T & -C_1^T J \mathcal{D} \\ -C_2^T J C_1 & -C_2^T J C_2 & -A_{12}^T & -A_{22}^T & -C_2^T J \mathcal{D} \\ -\mathcal{D}^T J C_1 & -\mathcal{D}^T J C_2 & -B_1^T & 0 & -\mathcal{D}^T J \mathcal{D} \end{bmatrix}. \tag{13}$$

Let ν be the dimension of the stable eigenspace of $M_a(s)$, and the columns of matrix

$$L = \begin{matrix} \\ \\ \\ \\ \\ \end{matrix} \begin{matrix} \overset{\nu}{} \\ \begin{bmatrix} L_1 \\ L_2 \\ L_3 \\ L_4 \\ L_5 \end{bmatrix} \end{matrix} \begin{matrix} \\ \}n_1 \\ \}n - n_1 \\ \}n_1 \\ \}n - n_1 \\ \}m \end{matrix}$$

form a basis for this stable eigenspace; consequently,

$$\begin{cases} \begin{bmatrix} A_{11} & A_{12} & 0 & 0 & B_1 \\ A_{21} & A_{22} & 0 & 0 & 0 \\ -C_1^T J C_1 & -C_1^T J C_2 & -A_{11}^T & -A_{21}^T & -C_1^T J \mathcal{D} \\ -C_2^T J C_1 & -C_2^T J C_2 & -A_{12}^T & -A_{22}^T & -C_2^T J \mathcal{D} \\ -\mathcal{D}^T J C_1 & -\mathcal{D}^T J C_2 & -B_1^T & 0 & -\mathcal{D}^T J \mathcal{D} \end{bmatrix} \begin{bmatrix} L_1 \\ L_2 \\ L_3 \\ L_4 \\ L_5 \end{bmatrix} = \begin{bmatrix} E_{11} & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & E_{11}^T & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} L_1 \\ L_2 \\ L_3 \\ L_4 \\ L_5 \end{bmatrix} \Delta, \\ \Delta \in \mathbf{R}^{\nu \times \nu} \text{ is stable.} \end{cases} \tag{14}$$

It is known that if $n_1 = \nu = n$, then the stabilizing solution of the GARE (1) is determined by L. Analogously, a similar result holds true, as shown in the following theorem.

THEOREM 4. *Assume that the decomposition* (7) *and the eigendecompositions* (8) *and* (14) *have been determined. Then the GARE* (1) *has a semistabilizing solution* X_a *if and only if*

$$S_{33}^T J S_{33} = \mathcal{D}_0^T J' \mathcal{D}_0 \quad \textit{for some nonsingular matrix } \mathcal{D}_0 \in \mathbf{R}^{m\times m}, \tag{15}$$

$$(n_1 - \mu_1) + \nu = n_1 \ (\textit{i.e.,}\ \mu_1 = \nu),\ \begin{bmatrix} L_1 & Q_{12} \end{bmatrix} \textit{ is nonsingular.} \tag{16}$$

Furthermore, a semistabilizing solution X_a *of the GARE* (1) *is given by*

$$X_a = \begin{bmatrix} U^T & 0 \\ 0 & I \end{bmatrix} \hat{X}_a \begin{bmatrix} I & 0 \\ 0 & \mathcal{V}^T \end{bmatrix} \begin{bmatrix} V^T & 0 \\ 0 & I \end{bmatrix} + \begin{bmatrix} 0 & 0 \\ 0 & J' \end{bmatrix}, \tag{17}$$

where $\hat{X}_a$ *is determined by the following linear system of equations:*

$$\begin{bmatrix} I & 0 & 0 \\ 0 & A_{22}^T & 0 \\ 0 & 0 & I_m \end{bmatrix} \hat{X}_a \begin{bmatrix} L_1 & Q_{12} & 0 \\ 0 & 0 & I_{n+m-n_1} \end{bmatrix}$$
$$= \begin{bmatrix} L_3 & 0 & 0 & 0 \\ A_{22}^T L_4 & -C_2^T J C_1 Q_{12} & -C_2^T J C_2/2 & -C_2^T J \mathcal{D} \\ 0 & -J'\mathcal{D}_0 \Phi_{32} & 0 & -J'\mathcal{D}_0 \Phi_{33} Q_{33}^T \end{bmatrix} \begin{bmatrix} I & 0 & 0 & 0 \\ 0 & I & 0 & 0 \\ -L_2 & Q_{22} & I & 0 \\ -L_5 & 0 & 0 & I \end{bmatrix}. \tag{18}$$

Proof. The proof is given in section 3. □

Theorem 4 leads to the following algorithm for computing a semistabilizing solution of the GARE (1).

ALGORITHM 1.

Input: *Matrices* $A, E \in \mathbf{R}^{n\times n}, B, \in \mathbf{R}^{n\times m}, C \in \mathbf{R}^{p\times n}, D \in \mathbf{R}^{p\times m}$, $J \in \mathbf{R}^{p\times p}$, *and* $J' \in \mathbf{R}^{m\times m}$. *Here* J *and* J' *are symmetric.*

Output: *A semistabilizing solution* X_a *of the GARE* (1) *(if possible).*

Step 1: *Compute the decompositions* (7) *and* (8) *using the numerical procedure in the appendix.*

Step 2: *Verify the condition* (15). *If it is not true, print "The GARE* (1) *has no semistabilizing solutions" and then stop. Otherwise, compute the related matrix* $\mathcal{D}_0$.

Step 3: *Compute the eigendecomposition* (14).

Step 4: *Verify the singularity of* $\begin{bmatrix} L_1 & Q_{12} \end{bmatrix}$. *If it is singular, print "The GARE* (1) *has no semistabilizing solutions" and then stop. Otherwise, compute* $\hat{X}_a$ *by solving* (18) [6].

Step 5: *Compute* X_a *by* (17) *and then output it.*

Algorithm 1 is an extension of the generalized eigenvalue approach for the classical AREs, and its main ingredients are the decompositions (7), (8), and (14). All these decompositions are computed by existing numerically backward stable methods [6, 10, 26]. One possible source in Algorithm 1 for loss of accuracy in the numerical solution of the GARE (1) is the condition numbers of $\begin{bmatrix} L_1 & Q_{12} \end{bmatrix}$ and A_{22}. The similar problem is already known for the classical AREs, and there the problem can be resolved by proper scaling [18, 21]. It seems that the results in [18, 21] can be extended to the GARE (1). This is an interesting research topic and is worthy of further investigation.

In the following we present two examples[1] to illustrate Algorithm 1. All computations were performed using MATLAB 7.0 on a Linux system with IEEE standard double precision arithmetic and machine precision $\epsilon \approx 2.22 \times 10^{-16}$.

[1]These two examples were done by Dr. Bai Zhengjian.

Example 1 (see [2, 3]). Let

$$J = \begin{bmatrix} -1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}, \quad J' = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix},$$

and

$$G(s) = \begin{bmatrix} \frac{s}{(s+3)^2} & \frac{1}{s} \\ 0 & \frac{(s-1)(s^2+2)}{s} \\ 0 & 0 \end{bmatrix} = \left[\begin{array}{c|c} A - sE & B \\ \hline C & D \end{array}\right],$$

where

$$A - sE = \begin{bmatrix} -s & 1 & 0 & 0 & 0 & 0 \\ -9 & -s-6 & 0 & 0 & 0 & 0 \\ 0 & 0 & -s & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & -s & 0 \\ 0 & 0 & 0 & 0 & 1 & -s \\ 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix}, \quad B = \begin{bmatrix} 0 & 0 \\ 1 & 0 \\ 0 & 1 \\ 0 & 0 \\ 0 & 0 \\ 0 & 0 \\ 0 & -1 \end{bmatrix},$$

$$C = \begin{bmatrix} 0 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & -2 & 1 & -1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix}, \quad D = \begin{bmatrix} 0 & 0 \\ 0 & 2 \\ 0 & 0 \end{bmatrix}.$$

We compute a semistabilizing solutions X_a of the related GARE (1) by Algorithm 1 and obtain

$$X_a(:, 1:4) = \begin{bmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ -6.4358 \times 10^{-16} & 5.2500 \times 10^{-15} & 8.0000 \times 10^{0} & 0 \\ -3.2313 \times 10^{-16} & 2.6263 \times 10^{-15} & 4.0000 \times 10^{0} & 0 \\ 0 & 0 & 1.2546 \times 10^{-15} & 0 \\ 1.1684 \times 10^{-16} & 7.2990 \times 10^{-15} & 4.0000 \times 10^{0} & 2.0000 \times 10^{0} \\ -1.9971 \times 10^{-15} & 3.4206 \times 10^{-15} & 2.0000 \times 10^{0} & 1.0000 \times 10^{0} \\ -2.7210 \times 10^{-16} & 1.0000 \times 10^{0} & 1.0000 \times 10^{0} & -3.0761 \times 10^{-16} \end{bmatrix},$$

$$X_a(:, 5:8) = \begin{bmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 4.0000 \times 10^{0} & -1.6924 \times 10^{-15} & 0 & 0 \\ 2.0000 \times 10^{0} & -8.4131 \times 10^{-16} & 0 & 0 \\ 6.2731 \times 10^{-16} & 0 & 0 & 0 \\ 2.0000 \times 10^{0} & 2.0000 \times 10^{0} & 0 & 2.0000 \times 10^{0} \\ 1.0000 \times 10^{0} & 2.0000 \times 10^{0} & 1.0000 \times 10^{0} & 0 \\ -1.2835 \times 10^{-15} & 4.5762 \times 10^{-16} & 0 & -1.0000 \times 10^{0} \end{bmatrix}.$$

The accuracy of the GARE (1) can be measured by the following quantities:

$$\|A_a^T X_a + X_a^T A_a + (C_a^T J C_a - B_a J' B_a^T) - X_a^T B_a (J')^{-1} B_a^T X_a\|_2 = 1.4249 \times 10^{-14},$$

$$\frac{\|A_a^T X_a + X_a^T A_a + (C_a^T J C_a - B_a J' B_a^T) - X_a^T B_a (J')^{-1} B_a^T X_a\|_2}{\|A_a^T X_a\|_2 + \|X_a^T A_a\|_2 + \|C_a^T J C_a - B_a J' B_a^T\|_2 + \|X_a^T B_a (J')^{-1} B_a^T X_a\|_2} = 3.7333 \times 10^{-16}$$

and

$$\|E_a^T X_a - X_a^T E_a\|_2 = 8.6151 \times 10^{-15}, \quad \frac{\|E_a^T X_a - X_a^T E_a\|_2}{\|E_a^T X_a\|_2 + \|X_a^T E_a\|_2} = 4.3075 \times 10^{-16}.$$

Example 2. Example 5.5 in [9] is on a descriptor system describing an RLC electrical circuit with an independent loop containing capacitors and voltage sources only and an independent cutset with inductors and current sources only. The GARE (1) corresponding to this system has no semistabilizing solutions. Thus, we modify this system slightly and get

$$E = \begin{bmatrix} -1 & -1 & 0.005 & -0.005 & 0 & 0 & 0 & 0 \\ 0 & 0 & -0.005 & -0.005 & 0 & 0 & 0 & 0 \\ -0.001 & 0 & 0 & -0.25 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & -5 & 0 & 0.1 & 0 & 0 & 0 \\ 0 & 0 & 0.25 & -0.25 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & -0.75 & 0 & 0.1 & -0.2 & -0.2 \end{bmatrix},$$

$$A = \begin{bmatrix} 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 500 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & -1 & 1 \\ 1 & -1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix},$$

$$B = \begin{bmatrix} 0 & 0 \\ 0 & 0 \\ 0 & 0 \\ 0 & 0 \\ -1 & 1 \\ 1 & 0 \\ 0 & 0 \\ 0 & 0 \end{bmatrix}, \quad C = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \end{bmatrix}, \quad D = \begin{bmatrix} 0 & 0 \\ 0 & 0 \\ 0 & 1 \end{bmatrix}.$$

The matrix E is ill-conditioned since

$$\frac{\sigma_{max}(E)}{\sigma_{min}(E)} = 1.7897 \times 10^5,$$

where $\sigma_{max}(E)$ and $\sigma_{min}(E)$ denote the maximal amd mininal nonzero singular values of E. Let

$$J = \begin{bmatrix} -1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 1 \end{bmatrix}, \quad J' = \begin{bmatrix} -1 & 0 \\ 0 & 1 \end{bmatrix}.$$

By performing Algorithm 1, we obtain a semistabilizing solution X_a of the GARE (1)

as follows:

$$X_a(:,1:5) = \begin{bmatrix} 7.5239\times10^{-15} & 7.5239\times10^{-15} & 3.1982\times10^{-14} & 1.9919\times10^{-15} & -6.7917\times10^{-16} \\ 1.1351\times10^{-15} & -4.8032\times10^{-16} & 1.0500\times10^{-2} & -4.9582\times10^{-4} & -2.2298\times10^{-16} \\ 0 & 0 & 4.6515\times10^{-16} & -1.7048\times10^{-16} & 0 \\ 0 & 0 & -1.4111\times10^{-14} & -3.3632\times10^{-16} & 2.9737\times10^{-16} \\ 1.2500\times10^{-1} & -1.2500\times10^{-1} & 2.5000\times10^{-1} & -4.8749\times10^{-1} & -5.2501\times10^{-3} \\ -4.0938\times10^{-15} & -4.1169\times10^{-15} & 5.0000\times10^{-1} & 2.5011\times10^{-2} & -1.0500\times10^{-2} \\ 2.7092\times10^{-15} & 2.6592\times10^{-15} & 4.7499\times10^{-1} & 2.5011\times10^{-2} & -1.0004\times10^{-2} \\ -1.2796\times10^{-15} & -1.2592\times10^{-15} & 1.0572\times10^{-13} & 5.7185\times10^{-15} & -2.2291\times10^{-15} \\ -9.1581\times10^{-1} & -1.0671\times10^{-1} & 4.0455\times10^{-1} & -1.9318\times10^{-1} & -8.4958\times10^{-3} \\ 2.9785\times10^{-1} & -5.1126\times10^{-1} & -4.0455\times10^{-1} & -1.0428\times10^{0} & 8.4958\times10^{-3} \end{bmatrix},$$

$$X_a(:,6:10) = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & -8.0583\times10^{-16} & -2.4175\times10^{-15} \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 9.1926\times10^{-16} & -5.0668\times10^{-16} & -3.4015\times10^{-16} & -1.2500\times10^{-1} & -3.7500\times10^{-1} \\ -4.9531\times10^{-16} & 9.9060\times10^{-16} & 9.9060\times10^{-16} & 0 & 0 \\ -4.6191\times10^{-16} & 9.2380\times10^{-16} & 9.2380\times10^{-16} & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ -3.6153\times10^{-14} & 6.3089\times10^{-15} & 6.3228\times10^{-15} & -1.1067\times10^{0} & -1.0671\times10^{-1} \\ 6.4994\times10^{-14} & 6.1249\times10^{-15} & 6.1804\times10^{-15} & -5.1126\times10^{-1} & 4.8874\times10^{-1} \end{bmatrix}.$$

We have verified that

$$\|A_a^TX_a + X_a^TA_a + (C_a^TJC_a - B_aJ'B_a^T) - X_a^TB_a(J')^{-1}B_a^TX_a\|_2 = 4.0088\times10^{-13},$$

$$\frac{\|A_a^TX_a + X_a^TA_a + (C_a^TJC_a - B_aJ'B_a^T) - X_a^TB_a(J')^{-1}B_a^TX_a\|_2}{\|A_a^TX_a\|_2 + \|X_a^TA_a\|_2 + \|C_a^TJC_a - B_aJ'B_a^T\|_2 + \|X_a^TB_a(J')^{-1}B_a^TX_a\|_2} = 5.0409\times10^{-14},$$

and

$$\|E_a^TX_a - X_a^TE_a\|_2 = 1.1540\times10^{-13}, \quad \frac{\|E_a^TX_a - X_a^TE_a\|_2}{\|E_a^TX_a\|_2 + \|X_a^TE_a\|_2} = 2.4159\times10^{-14}.$$

Before closing this section, the following remark is in order.

Remark 2. (i) The factorization (7) can be related to the feedback regularization. By the assumption (A1), we can compute a feedback matrix F such that the pencil $A+BF-sE$ is regular and of index at most one [12] and then compute two orthogonal matrices $\hat{U}$ and $\hat{V}$ such that

$$\hat{U}(A+BF-sE)\hat{V} = \begin{array}{c} \begin{matrix} n_1 & n-n_1 \end{matrix} \\ \begin{bmatrix} \hat{A}_{11}-s\hat{E}_{11} & \hat{A}_{12} \\ \hat{A}_{21} & \hat{A}_{22} \end{bmatrix} \end{array} \begin{matrix} \}n_1 \\ \}n-n_1 \end{matrix}, \tag{19}$$

where $\hat{E}_{11}$ and $\hat{A}_{22}$ are nonsingular. Let

$$\hat{U}B = \begin{bmatrix} \hat{B}_1 \\ \hat{B}_2 \end{bmatrix} \begin{matrix} \}n_1 \\ \}n-n_1 \end{matrix}, \quad C\hat{V} = \begin{array}{c} \begin{matrix} n_1 & n-n_1 \end{matrix} \\ [\,\hat{C}_1 \quad \hat{C}_2\,] \end{array}. \tag{20}$$

Then

$$\hat{U}\begin{bmatrix} A-sE & B \end{bmatrix}\begin{bmatrix} \hat{V} & 0 \\ F\hat{V} & I \end{bmatrix}\begin{bmatrix} I & 0 & 0 \\ 0 & I & -\hat{A}_{22}^{-1}\hat{B}_2 \\ 0 & 0 & I \end{bmatrix} = \begin{bmatrix} \hat{A}_{11}-s\hat{E}_{11} & \hat{A}_{12} & \hat{B}_1-\hat{A}_{12}\hat{A}_{22}^{-1}\hat{B}_2 \\ \hat{A}_{21} & \hat{A}_{22} & 0 \end{bmatrix}. \tag{21}$$

The decomposition (21) can play the same role as (7). But, if $\hat{A}_{22}$ is ill-conditioned, then the computation of (21) is not numerically reliable. Unfortunately, it is not easy to choose the feedback matrix F such that the resulting matrix $\hat{A}_{22}$ is well-conditioned. Therefore, (21) is not recommended, although it is based on the feedback regularization.

(ii) Let F be such that the pencil $A+BF-sE$ is regular and of index at most one. Define

$$G_F(s) := D + C(sE - A - BF)^{-1}B = \hat{D} + \hat{C}(sI-\hat{A})^{-1}\hat{B}.$$

If $\hat{D}$ is of full column rank, then we can consider the ARE

$$\hat{A}^T\hat{X} + \hat{X}\hat{A} - (\hat{X}\hat{B}^T + \hat{C}^TJ\hat{D})(\hat{D}^TJ\hat{D})^{-1}(\hat{B}^T\hat{X} + \hat{D}^TJ\hat{C}) = 0, \quad \hat{X} = \hat{X}^T. \tag{22}$$

Similar to Lemma 6 in section 3.2, we can show that the GARE (1) has a semistabilizing solution X_a if and only if the ARE (22) has a semistabilizing solution $\hat{X}$, i.e., a solution $\hat{X}$ satisfying that all eigenvalues of $\hat{A} - \hat{B}(\hat{D}^TJ\hat{D})^{-1}(\hat{B}^T\hat{X} + \hat{D}^TJ\hat{C})$ are on $\mathbf{C}_- \cup \mathbf{C}_0$. It seems that we can obtain a semistabilizing solution of the GARE (1) by computing a semistabilizing solution $\hat{X}$ of the ARE (22). However, two problems arise:

- the assumption (A2) cannot guarantee that $\hat{D}$ is of full column rank. If $\hat{D}$ is not of full column rank, then the ARE (22) is not well defined;
- the Hamiltonian matrix $\hat{H}$ associated with the ARE (22) is given by

$$\hat{H} = \begin{bmatrix} \hat{A} - \hat{B}(\hat{D}^TJ\hat{D})^{-1} & -\hat{B}(\hat{D}^TJ\hat{D})^{-1}\hat{B}^T \\ \hat{C}^T(\hat{D}^TJ\hat{D})^{-1}\hat{C} & -(\hat{A} - \hat{B}(\hat{D}^TJ\hat{D})^{-1})^T \end{bmatrix}.$$

  $\hat{H}$ has eigenvalues on $\mathbf{C}_0$, provided $H_a(s)$ has eigenvalues on $\mathbf{C}_0$. In this case, as analyzed in section 1, it is not clear which eigenspace we should compute in order to get a semistabilizing solution of the ARE (22).

Therefore, we cannot get a semistabilizing solution of the GARE (1) by simply applying the feedback regularization approach to the pair $(A-sE, B)$ and then solving the resulting ARE (22).

3. Proof of Theorem 4. Although Theorem 4 may look very simple, its proof is actually not trivial. It is motivated by the following results:

(i) the GARE (1) has a semistabilizing solution if and only if $G(s) = D + C(sE - A)^{-1}B$ has a (J, J')-spectral factorization, provided the pencil $A - sE$ is regular and stable [2, 3];

(ii) the (J, J')-spectral factorization of $G(s)$ is reduced to the canonical (J, J')-spectral factorization if $G(s)$ has no poles and zeros on $\mathbf{C}_{0e}$ [2, 3];

(iii) the canonical (J, J')-spectral factorization problem is solvable if and only a related ARE has a stabilizing solution [16];

(iv) the stabilizing solution of any ARE is characterized uniquely by the stable eigenspace of the associated Hamiltonian matrix [8, 14, 27].

We will prove Theorem 4 in this section outlined as follows:

- in section 3.1 we provide some important properties of eigendecompositions (8) and (14);
- in section 3.2 we reduce the GARE (1) to the GARE (28) which corresponds to the proper rational matrix $\mathcal{G}(s)$ defined in (27);
- in section 3.3, we connect the GARE (28) with the (J, J')-spectral factorization of the proper rational matrix $\mathcal{G}_{\mathcal{K}}(s)$ defined in (35);
- in section 3.4, we reduce the (J, J')-spectral factorization of $\mathcal{G}_{\mathcal{K}}(s)$ to the canonical (J, J')-spectral factorization of the proper rational matrix $\mathcal{G}_{\mathcal{K},\mathcal{Z}}(s)$ defined in (37);
- in section 3.5, by characterizing the stable eigenspace of an associated Hamiltonian matrix we derive numerically verifiable necessary and sufficient conditions for the existence of a canonical (J, J')-spectral factorization of $\mathcal{G}_{\mathcal{K},\mathcal{Z}}(s)$;
- finally, in section 3.6, we prove Theorem 4 by using the results in sections 3.1–3.5.

3.1. Properties of eigendecompositions (8) and (14). In this section we present some basic properties of eigendecompositions (8) and (14). These properties are important in the development of sections 3.4–3.6.

LEMMA 5. (i) *In eigendecomposition* (8), *the orthogonal matrices* Q *and* S *with partitioning* (9) *satisfy*

$$E_{11}Q_{12} = S_{12}\Theta_{22}, \quad \begin{bmatrix} Q_{13} \\ Q_{23} \end{bmatrix} = 0, \quad \begin{bmatrix} Q_{31} & Q_{32} & Q_{34} \end{bmatrix} = 0, \quad \begin{bmatrix} S_{22} \\ S_{32} \end{bmatrix} = 0, \tag{23}$$

$$\operatorname{rank}\begin{bmatrix} Q_{11} & Q_{12} \end{bmatrix} = \operatorname{rank}\begin{bmatrix} S_{11} & S_{12} \end{bmatrix} = n_1, \quad Q_{33}^T Q_{33} = I, \quad \operatorname{rank}(S_{33}) = m. \tag{24}$$

(ii) *In eigendecomposition* (14),

$$L_1^T E_{11}^T L_3 = L_3^T E_{11} L_1, \quad Q_{12}^T E_{11}^T L_3 = 0, \quad L_3^T S_{12} = 0, \tag{25}$$

$$L_3^T S_{13} + (L_1^T C_1^T + L_2^T C_2^T + L_5^T D^T) J S_{33} = 0. \tag{26}$$

Proof. Part (i). From the eigendecomposition (8) it is obvious that

$$E_{11}Q_{12} = S_{12}\Theta_{22}, \quad E_{11}Q_{13} = 0, \quad \begin{bmatrix} S_{22} \\ S_{32} \end{bmatrix}\Theta_{22} = 0, \quad A_{22}Q_{23} = 0,$$

so the nonsingularity of E_{11}, A_{22}, and Θ_{22} gives

$$\begin{bmatrix} Q_{13} \\ Q_{23} \end{bmatrix} = 0, \quad \begin{bmatrix} S_{22} \\ S_{32} \end{bmatrix} = 0.$$

In addition, the orthogonality of Q and the relation

$$\begin{bmatrix} Q_{13} \\ Q_{23} \end{bmatrix} = 0$$

lead to

$$Q_{33}^T Q_{33} = I, \quad \begin{bmatrix} Q_{31} & Q_{32} & Q_{34} \end{bmatrix} = 0.$$

We also have

$$\begin{bmatrix} S_{11}^T \\ S_{12}^T \end{bmatrix} E_{11} \begin{bmatrix} Q_{11} & Q_{12} \end{bmatrix} = \begin{bmatrix} \Theta_{12} & 0 \\ \Theta_{21} & \Theta_{22} \end{bmatrix};$$

consequently,

$$\operatorname{rank}\left(\begin{bmatrix} S_{11}^T \\ S_{12}^T \end{bmatrix} E_{11} \begin{bmatrix} Q_{11} & Q_{12} \end{bmatrix} \right) = \mu_1 + (n_1 - \mu_1) = n_1,$$

and thus this implies that

$$\operatorname{rank} \begin{bmatrix} Q_{11} & Q_{12} \end{bmatrix} = \operatorname{rank} \begin{bmatrix} S_{11} & S_{12} \end{bmatrix} = n_1.$$

Note that S is orthogonal and $\begin{bmatrix} S_{11} & S_{12} \end{bmatrix}$ is of full row rank, as shown above, so

$$\begin{bmatrix} 0 & S_{24} \\ S_{33} & S_{34} \end{bmatrix}$$

is of full column rank, which yields that $\operatorname{rank}(S_{33}) = m$.

Part (ii). We have from the eigendecompositions (8) and (14) and part (i) that

$$\begin{bmatrix} -L_3^T & -L_4^T & L_1^T & L_2^T & L_5^T \end{bmatrix} M_a(s) = (\Delta^T + sI) \begin{bmatrix} L_3^T E_{11} & 0 & -L_1^T E_{11}^T & 0 & 0 \end{bmatrix},$$

$$M_a(s) \begin{bmatrix} Q_{12} & 0 \\ Q_{22} & 0 \\ 0 & 0 \\ 0 & 0 \\ 0 & Q_{33} \end{bmatrix} = \begin{bmatrix} S_{12} & S_{13} \\ 0 & 0 \\ 0 & -C_1^T J S_{33} \\ 0 & -C_2^T J S_{33} \\ 0 & -\mathcal{D}^T J S_{33} \end{bmatrix} \begin{bmatrix} \Phi_{22} - s\Theta_{22} & \Phi_{23} \\ \Phi_{32} & \Phi_{33} \end{bmatrix},$$

which give that

$$\begin{aligned} (\Delta^T + sI)(L_3^T E_{11} L_1 - L_1^T E_{11}^T L_3) &= \begin{bmatrix} -L_3^T & -L_4^T & L_1^T & L_2^T & L_5^T \end{bmatrix} M_a(s) \begin{bmatrix} L_1 \\ L_2 \\ L_3 \\ L_4 \\ L_5 \end{bmatrix} \\ &= (L_1^T E_{11}^T L_3 - L_3^T E_{11} L_1)(\Delta - sI), \end{aligned}$$

$$(\Delta^T + sI) \begin{bmatrix} L_3^T E_{11} Q_{12} & 0 \end{bmatrix} = \begin{bmatrix} -L_3^T & -L_4^T & L_1^T & L_2^T & L_5^T \end{bmatrix} M_a(s) \begin{bmatrix} Q_{12} & 0 \\ Q_{22} & 0 \\ 0 & 0 \\ 0 & 0 \\ 0 & Q_{33} \end{bmatrix}$$

$$= - \begin{bmatrix} L_3^T S_{12} & L_3^T S_{13} + (L_1^T C_1^T + L_2^T C_2^T + L_5^T \mathcal{D}^T) J S_{33} \end{bmatrix} \begin{bmatrix} \Phi_{22} - s\Theta_{22} & \Phi_{23} \\ \Phi_{32} & \Phi_{33} \end{bmatrix}.$$

In the above, $M_a(s)$ is defined by (13). Note that the pencils $\Delta^T + sI$ and $\Delta - sI$ have no common eigenvalues, and the pencils $\Delta^T + sI$ and

$$\begin{bmatrix} \Phi_{22} - s\Theta_{22} & \Phi_{23} \\ \Phi_{32} & \Phi_{33} \end{bmatrix}$$

also have no common eigenvalues; thus,

$$L_3^T E_{11} L_1 - L_1^T E_{11}^T L_3 = 0, \quad L_3^T E_{11} Q_{12} = 0,$$
$$L_3^T S_{12} = 0, \quad L_3^T S_{13} + (L_1^T C_1^T + L_2^T C_2^T + L_5^T \mathcal{D}^T) J S_{33} = 0.$$

Hence, part (ii) is proved. □

3.2. Reduction of the GARE (1) by eliminating the singularity of E. The singularity of the matrix E complicates the eigenstructure of $H_a(s)$ at infinity. To overcome this difficulty, we reduce the GARE (1) to an equivalent one by eliminating the singularity of E in this subsection. This reduction will significantly simplify the computation of the GARE (1).

The orthogonal matrices U, V, and $\mathcal{V}$ transform the pencil

$$\begin{bmatrix} A - sE & B \\ C & D \end{bmatrix}$$

into

$$\begin{bmatrix} A_{11} - sE_{11} & A_{12} & B_1 \\ A_{21} & A_{22} & 0 \\ C_1 & C_2 & \mathcal{D} \end{bmatrix};$$

as a result, the resulting rational matrix

$$\mathcal{G}(s) = \left[\begin{array}{cc|c} A_{11} - sE_{11} & A_{12} & B_1 \\ A_{21} & A_{22} & 0 \\ \hline C_1 & C_2 & \mathcal{D} \end{array}\right] = \left[\begin{array}{c|c} \mathcal{A}_{11} - sE_{11} & B_1 \\ \hline \mathcal{C}_1 & \mathcal{D} \end{array}\right] \tag{27}$$

is proper, although the original rational matrix $G(s)$ defined by (3) is nonproper. Here

$$\mathcal{A}_{11} = A_{11} - A_{12} A_{22}^{-1} A_{21}, \quad \mathcal{C}_1 = C_1 - C_2 A_{22}^{-1} A_{21}.$$

The GARE corresponding to the second realization of $\mathcal{G}(s)$ in (27) is

$$\begin{cases} \mathcal{A}_a^T \mathcal{X}_a + \mathcal{X}_a^T \mathcal{A}_a + (\mathcal{C}_a^T J \mathcal{C}_a - \mathcal{B}_a J' \mathcal{B}_a^T) - \mathcal{X}_a^T \mathcal{B}_a (J')^{-1} \mathcal{B}_a^T \mathcal{X}_a = 0, \\ \mathcal{E}_a^T \mathcal{X}_a = \mathcal{X}_a^T \mathcal{E}_a, \end{cases} \tag{28}$$

where

$$\mathcal{A}_a = \begin{bmatrix} \mathcal{A}_{11} & B_1 \\ 0 & I \end{bmatrix}, \quad \mathcal{E}_a = \begin{bmatrix} E_{11} & 0 \\ 0 & 0 \end{bmatrix}, \quad \mathcal{B}_a = \begin{bmatrix} 0 \\ -I_m \end{bmatrix}, \quad \mathcal{C}_a = \begin{bmatrix} \mathcal{C}_1 & \mathcal{D} \end{bmatrix}.$$

Let

$$\mathcal{H}_a(s) := \begin{bmatrix} \mathcal{A}_a - s\mathcal{E}_a & -\mathcal{B}_a (J')^{-1} \mathcal{B}_a^T \\ -\mathcal{C}_a^T J \mathcal{C}_a + \mathcal{B}_a J' \mathcal{B}_a^T & -\mathcal{A}_a^T - s\mathcal{E}_a^T \end{bmatrix}. \tag{29}$$

The GAREs (1) and (28) are related closely, as shown in the following lemma.

LEMMA 6. *The GARE* (1) *has a semistabilizing solution X_a if and only if the GARE* (28) *has a semistabilizing solution $\mathcal{X}_a$. Furthermore, if $\mathcal{X}_a$ with partitioning*

$$\mathcal{X}_a = \begin{matrix} \\ \end{matrix} \begin{matrix} n_1 & m \end{matrix} \\ \begin{bmatrix} \mathcal{X}_{11} & \mathcal{X}_{12} \\ \mathcal{X}_{21} & \mathcal{X}_{22} \end{bmatrix} \begin{matrix} \}n_1 \\ \}m \end{matrix} \tag{30}$$

is a semistabilizing solution of the GARE (28)*, then a semistabilizing solution* X_a *of the GARE* (1) *is*

$$X_a = \begin{bmatrix} U^T & 0 \\ 0 & I \end{bmatrix} \begin{bmatrix} \mathcal{X}_{11} & 0 & \mathcal{X}_{12} \\ \tilde{X}_{21} & \tilde{X}_{22} & \tilde{X}_{23} \\ \mathcal{X}_{21} & 0 & \mathcal{X}_{22} - J' \end{bmatrix} \begin{bmatrix} I & 0 \\ 0 & \mathcal{V}^T \end{bmatrix} \begin{bmatrix} V^T & 0 \\ 0 & I \end{bmatrix} + \begin{bmatrix} 0 & 0 \\ 0 & J' \end{bmatrix} \tag{31}$$

with

$$\begin{aligned} \tilde{X}_{21} &= -A_{22}^{-T}(C_2^T J C_1 + A_{12}^T \mathcal{X}_{11} - C_2^T J C_2 A_{22}^{-1} A_{21}/2), \\ \tilde{X}_{22} &= -A_{22}^{-T} C_2^T J C_2/2, \ \tilde{X}_{23} = -A_{22}^{-T} C_2^T J \mathcal{D}. \end{aligned} \tag{32}$$

Proof. First, let X_a with partitioning

$$X_a = \begin{matrix} \\ \end{matrix} \begin{matrix} n & m \end{matrix} \\ \begin{bmatrix} X_{11} & X_{12} \\ X_{21} & X_{22} \end{bmatrix} \begin{matrix} \}n \\ \}m \end{matrix}$$

be a semistabilizing solution of the GARE (1). Define

$$\begin{aligned} Y_a &:= \begin{bmatrix} U & 0 \\ 0 & I \end{bmatrix} \left(X_a - \begin{bmatrix} 0 & 0 \\ 0 & J' \end{bmatrix} \right) \begin{bmatrix} V & 0 \\ 0 & I \end{bmatrix} \begin{bmatrix} I & 0 \\ 0 & \mathcal{V} \end{bmatrix} \\ &= \begin{matrix} \\ \end{matrix} \begin{matrix} n_1 & n-n_1 & m \end{matrix} \\ \begin{bmatrix} Y_{11} & Y_{12} & Y_{13} \\ Y_{21} & Y_{22} & Y_{23} \\ Y_{31} & Y_{32} & Y_{33} \end{bmatrix} \begin{matrix} \}n_1 \\ \}n-n_1 \\ \}m \end{matrix} . \end{aligned}$$

Then we have by Corollary 2(i) and through a direct calculation that

$$\begin{aligned} &X_a \text{ is a solution of the GARE (1)} \\ &\Longrightarrow H_a(s) \begin{bmatrix} I \\ X_a \end{bmatrix} = \begin{bmatrix} I \\ X_a^T \end{bmatrix} (A_a - B_a (J')^{-1} B_a^T X_a - s E_a) \\ &\Longrightarrow \begin{bmatrix} A - sE & B & 0 \\ -C^T J C & -C^T J D & -A^T - sE^T \\ -D^T J C & -D^T J D & -B^T \end{bmatrix} \begin{bmatrix} I & 0 \\ 0 & I \\ X_{11} & X_{12} \end{bmatrix} \\ &\quad = \begin{bmatrix} I & 0 \\ X_{11}^T & X_{21}^T \\ X_{12}^T & (X_{22} - J')^T \end{bmatrix} \begin{bmatrix} A - sE & B \\ -(J')^{-1} X_{21} & -(J')^{-1}(X_{22} - J') \end{bmatrix} \\ &\Longrightarrow \begin{bmatrix} A_{11} - sE_{11} & A_{12} & B_1 & 0 & 0 \\ A_{21} & A_{22} & 0 & 0 & 0 \\ -C_1^T J C_1 & -C_1^T J C_2 & -C_1^T J \mathcal{D} & -A_{11}^T - sE_{11}^T & -A_{21}^T \\ -C_2^T J C_1 & -C_2^T J C_2 & -C_2^T J \mathcal{D} & -A_{12}^T & -A_{22}^T \\ -\mathcal{D}^T J C_1 & -\mathcal{D}^T J C_2 & -\mathcal{D}^T J \mathcal{D} & -B_1^T & 0 \end{bmatrix} \begin{bmatrix} I & 0 & 0 \\ 0 & I & 0 \\ 0 & 0 & I \\ Y_{11} & Y_{12} & Y_{13} \\ Y_{21} & Y_{22} & Y_{23} \end{bmatrix} \\ &\quad = \begin{bmatrix} I & 0 & 0 \\ 0 & I & 0 \\ Y_{11}^T & Y_{21}^T & Y_{31}^T \\ Y_{12}^T & Y_{22}^T & Y_{32}^T \\ Y_{13}^T & Y_{23}^T & Y_{33}^T \end{bmatrix} \begin{bmatrix} A_{11} - sE_{11} & A_{12} & B_1 \\ A_{21} & A_{22} & 0 \\ -(J')^{-1} Y_{31} & -(J')^{-1} Y_{32} & -(J')^{-1} Y_{33} \end{bmatrix} \end{aligned}$$

$$\begin{aligned}
&\Longrightarrow Y_{12}=0,\ Y_{13}=0,\ \text{and}\\
&\begin{bmatrix} \mathcal{A}_{11}-sE_{11} & B_1 & 0\\ -\mathcal{C}_1^TJ\mathcal{C}_1 & -\mathcal{C}_1^TJ\mathcal{D} & -\mathcal{A}_{11}^T-sE_{11}^T\\ -\mathcal{D}^TJ\mathcal{C}_1 & -\mathcal{D}^TJ\mathcal{D} & -B_1^T \end{bmatrix}\begin{bmatrix} I & 0\\ 0 & I\\ Y_{11} & 0 \end{bmatrix}\\
&=\begin{bmatrix} I & 0\\ Y_{11}^T & (Y_{31}-Y_{32}A_{22}^{-1}A_{21})^T\\ 0 & Y_{33}^T \end{bmatrix}\begin{bmatrix} \mathcal{A}_{11}-sE_{11} & B_1\\ -(J')^{-1}(Y_{31}-Y_{32}A_{22}^{-1}A_{21}) & -(J')^{-1}Y_{33} \end{bmatrix}\\
&\Longrightarrow \mathcal{H}_a(s)\begin{bmatrix} I\\ \mathcal{X}_a \end{bmatrix}=\begin{bmatrix} I\\ \mathcal{X}_a^T \end{bmatrix}(\mathcal{A}_a-\mathcal{B}_a(J')^{-1}\mathcal{B}_a^T\mathcal{X}_a-s\mathcal{E}_a),
\end{aligned}$$

where

$$\mathcal{X}_a=\begin{bmatrix} Y_{11} & 0\\ Y_{31}-Y_{32}A_{22}^{-1}A_{21} & Y_{33}+J' \end{bmatrix}.$$

Moreover, since the pencil $A_a-B_a(J')B_a^TX_a-sE_a$ is regular and all its eigenvalues lie in $\mathbf{C}_-\cup\mathbf{C}_{0e}$, and $(C_a,A_a-B_a(J')^{-1}B_a^TX_a-sE_a)$ has no observable finite poles on $\mathbf{C}_0$ and no observable impulsive poles, it is trivial to show that $\mathcal{A}_a-\mathcal{B}_a(J')\mathcal{B}_a^T\mathcal{X}_a-s\mathcal{E}_a$ is regular and all its eigenvalues lie in $\mathbf{C}_-\cup\mathbf{C}_{0e}$, and $(\mathcal{C}_a,\mathcal{A}_a-\mathcal{B}_a(J')^{-1}\mathcal{B}_a^T\mathcal{X}_a-s\mathcal{E}_a)$ has no observable finite poles on $\mathbf{C}_0$ and no observable impulsive poles. Hence, $\mathcal{X}_a$ is a semistabilizing solution of the GARE (28).

Conversely, let the GARE (28) have a semistabilizing solution $\mathcal{X}_a$ with partitioning (30). Then we have using Corollary 2(i) that

$$\begin{aligned}
&\mathcal{H}_a(s)\begin{bmatrix} I\\ \mathcal{X}_a \end{bmatrix}=\begin{bmatrix} I\\ \mathcal{X}_a^T \end{bmatrix}(\mathcal{A}_a-\mathcal{B}_a(J')^{-1}\mathcal{B}_a^T\mathcal{X}_a-s\mathcal{E}_a)\\
&\Longrightarrow \mathcal{X}_{12}=0 \text{ and}\\
&\begin{bmatrix} \mathcal{A}_{11}-sE_{11} & B_1 & 0\\ -\mathcal{C}_1^TJ\mathcal{C}_1 & -\mathcal{C}_1^TJ\mathcal{D} & -\mathcal{A}_{11}^T-sE_{11}^T\\ -\mathcal{D}^TJ\mathcal{C}_1 & -\mathcal{D}^TJ\mathcal{D}+J' & -B_1^T \end{bmatrix}\begin{bmatrix} I & 0\\ 0 & I\\ \mathcal{X}_{11} & 0 \end{bmatrix}\\
&=\begin{bmatrix} I & 0\\ \mathcal{X}_{11}^T & \mathcal{X}_{21}^T\\ 0 & (\mathcal{X}_{22}-J')^T \end{bmatrix}\begin{bmatrix} \mathcal{A}_{11}-sE_{11} & B_1\\ -(J')^{-1}\mathcal{X}_{21} & -(J')^{-1}(\mathcal{X}_{22}-J') \end{bmatrix}\\
&\Longrightarrow \begin{bmatrix} A_{11}-sE_{11} & A_{12} & B_1 & 0 & 0\\ A_{21} & A_{22} & 0 & 0 & 0\\ -C_1^TJC_1 & -C_1^TJC_2 & -C_1^TJ\mathcal{D} & -A_{11}^T-sE_{11}^T & -A_{21}^T\\ -C_2^TJC_1 & -C_2^TJC_2 & -C_2^TJ\mathcal{D} & -A_{12}^T & -A_{22}^T\\ -\mathcal{D}^TJC_1 & -\mathcal{D}^TJC_2 & -\mathcal{D}^TJ\mathcal{D} & -B_1^T & 0 \end{bmatrix}\begin{bmatrix} I & 0 & 0\\ 0 & I & 0\\ 0 & 0 & I\\ \mathcal{X}_{11} & 0 & 0\\ \tilde{X}_{21} & \tilde{X}_{22} & \tilde{X}_{23} \end{bmatrix}\\
&=\begin{bmatrix} I & 0 & 0\\ 0 & I & 0\\ \mathcal{X}_{11}^T & \tilde{X}_{21}^T & \mathcal{X}_{21}^T\\ 0 & \tilde{X}_{22}^T & 0\\ 0 & \tilde{X}_{23}^T & (\mathcal{X}_{22}-J')^T \end{bmatrix}\begin{bmatrix} A_{11}-sE_{11} & A_{12} & B_1\\ A_{21} & A_{22} & 0\\ -(J')^{-1}\mathcal{X}_{21} & 0 & -(J')^{-1}(\mathcal{X}_{22}-J') \end{bmatrix},
\end{aligned}$$

where

$$\tilde{X}_{21} = -A_{22}^{-T}(C_2^T J C_1 + A_{12}^T \mathcal{X}_{11} - C_2^T J C_2 A_{22}^{-1} A_{21}/2),$$
$$\tilde{X}_{22} = -A_{22}^{-T} C_2^T J C_2/2,\ \tilde{X}_{23} = -A_{22}^{-T} C_2^T J \mathcal{D}.$$

Hence, a direct verification using the relationship above and taking the fact that $\mathcal{X}_{12} = 0$ into account yields that X_a defined by (31) satisfies

$$H_a(s) \begin{bmatrix} I \\ X_a \end{bmatrix} = \begin{bmatrix} I \\ X_a^T \end{bmatrix} (A_a - B_a (J')^{-1} B_a^T X_a - sE_a).$$

By Corollary 2(i), X_a given by (31) with (32) is a solution of the GARE (1).

In addition, it is easy to see that the pencil $\mathcal{A}_a - \mathcal{B}_a (J')^{-1} \mathcal{B}_a^T \mathcal{X}_a - s\mathcal{E}_a$ is regular and all its eigenvalues lie in $\mathbf{C}_- \cup \mathbf{C}_{0e}$ if and only if the pencil $A_a - B_a (J')^{-1} B_a^T X_a - sE_a$ is regular and all its eigenvalues lie in $\mathbf{C}_- \cup \mathbf{C}_{0e}$, and the matrix pair $(\mathcal{C}_a, \mathcal{A}_a - \mathcal{B}_a (J')^{-1} \mathcal{B}_a^T \mathcal{X}_a - s\mathcal{E}_a)$ has neither observable finite poles on $\mathbf{C}_0$ nor observable impulsive poles if and only if the matrix pair $(C_a, A_a - B_a (J')^{-1} B_a^T X_a - sE_a)$ has neither observable finite poles on $\mathbf{C}_0$ nor observable impulsive poles. Therefore, X_a is a semistabilizing solution of the GARE (1). □

3.3. Connection of the GARE (28) with the (J, J')-spectral factorization of a proper rational matrix. Since Lemma 6 indicates clearly that we need to compute only a semistabilizing solution of the GARE (28) in order to get a semistabilizing solution of the GARE (1), and furthermore, that the GARE (28) is related closely to the (J, J')-spectral factorization problem [2, 3], naturally, we wish to find a connection between the GARE (28) and the (J, J')-spectral factorization of a proper rational matrix. This is the main purpose of this section.

Note that E_{11} is nonsingular and assumption (A1) implies that

$$\operatorname{rank} \begin{bmatrix} \mathcal{A}_{11} - sE_{11} & B_1 \end{bmatrix} = n_1 \quad \forall s \in \mathbf{C} \backslash \mathbf{C}_-;$$

i.e., $(E_{11}^{-1}\mathcal{A}_{11}, E_{11}^{-1}B_1)$ is stabilizable. We have the following lemma.

LEMMA 7 (see [23]). *Under assumption* (A1)*, there exists a* $\mathcal{K} \in \mathbf{R}^{n_1 \times m}$ *such that the pencil* $\mathcal{A}_{11} + B_1\mathcal{K} - sE_{11}$ *is stable.*

In the rest of this section, we shall assume that the matrix $\mathcal{K}$ has been determined such that the pencil $\mathcal{A}_{11} + B_1\mathcal{K} - sE_{11}$ is stable.

Consider the linear time-invariant system

$$E_{11}\dot{x} = \mathcal{A}_{11}x + B_1 u, \quad y = \mathcal{C}_1 x + \mathcal{D}u. \tag{33}$$

Let us introduce the state feedback $u = \mathcal{K}x + v$. Then the resulting closed-loop system is

$$E_{11}\dot{x} = (\mathcal{A}_{11} + B_1\mathcal{K})x + B_1 v, \quad y = (\mathcal{C}_1 + \mathcal{D}\mathcal{K})x + \mathcal{D}v. \tag{34}$$

The transfer matrix of system (34) from the input v to the output y is

$$\mathcal{G}_{\mathcal{K}}(s) := \left[\begin{array}{c|c} \mathcal{A}_{11} + B_1\mathcal{K} - sE_{11} & B_1 \\ \hline \mathcal{C}_1 + \mathcal{D}\mathcal{K} & \mathcal{D} \end{array}\right]. \tag{35}$$

The GARE associated with $\mathcal{G}_{\mathcal{K}}(s)$ is

$$\begin{cases} \mathcal{A}_{a,\mathcal{K}}^T \mathcal{X}_{a,\mathcal{K}} + \mathcal{X}_{a,\mathcal{K}}^T \mathcal{A}_{a,\mathcal{K}} + (\mathcal{C}_{a,\mathcal{K}}^T J \mathcal{C}_{a,\mathcal{K}} - \mathcal{B}_a J' \mathcal{B}_a^T) - \mathcal{X}_{a,\mathcal{K}}^T \mathcal{B}_a (J')^{-1} \mathcal{B}_a^T \mathcal{X}_{a,\mathcal{K}} = 0, \\ \mathcal{E}_a^T \mathcal{X}_{a,\mathcal{K}} = \mathcal{X}_{a,\mathcal{K}}^T \mathcal{E}_a, \end{cases} \tag{36}$$

where

$$\mathcal{A}_{a,\mathcal{K}} = \begin{bmatrix} \mathcal{A}_{11} + B_1\mathcal{K} & B_1 \\ 0 & I \end{bmatrix}, \quad \mathcal{C}_{a,\mathcal{K}} = \begin{bmatrix} \mathcal{C}_1 + \mathcal{D}\mathcal{K} & \mathcal{D} \end{bmatrix}.$$

The following lemma gives the relation between the GAREs (28) and (36).

LEMMA 8. (i) *The GARE* (28) *has a semistabilizing solution* $\mathcal{X}_a$ *if and only if the GARE* (36) *has a semistabilizing solution* $\mathcal{X}_{a,\mathcal{K}}$.

(ii) *The GARE* (36) *has a semistabilizing solution if and only if* $\mathcal{G}_{\mathcal{K}}(s)$ *has a* (J, J')*-spectral factorization; i.e., there exists an invertible rational matrix* $\Xi(s)(s)$ *such that the following conditions hold:*

(1) $\mathcal{G}_{\mathcal{K}}^T(-s)J\mathcal{G}_{\mathcal{K}}(s) = \Xi^T(-s)J'\Xi(s)$;

(2) *all poles and zeros of* $\Xi(s)$ *lie in* $\mathbf{C}_- \cup \mathbf{C}_{oe}$;

(3) $\mathcal{G}_{\mathcal{K}}(s)\Xi^{-1}(s)$ *is proper and has no poles on* $\mathbf{C}_0$.

Proof. Lemma 8(i) and (ii) follow directly from a simple calculation and Theorem 7.4.5 in [3], respectively. □

3.4. Elimination of zeros of $\mathcal{G}_{\mathcal{K}}(s)$ on $\mathbf{C}_{0e}$. According to Lemmas 6 and 8, we need to study the (J, J')-spectral factorization of $\mathcal{G}_{\mathcal{K}}(s)$. Note that $\mathcal{G}_{\mathcal{K}}(s)$ has zeros on $\mathbf{C}_{0e}$; in order to derive the necessary and sufficient conditions for the existence of a (J, J')-spectral factorization of $\mathcal{G}_{\mathcal{K}}(s)$, in the following we reduce the (J, J')-spectral factorization of $\mathcal{G}_{\mathcal{K}}(s)$ to the canonical (J, J')-spectral factorization of a related rational matrix without zeros on $\mathbf{C}_{0e}$.

Let

$$\mathcal{P}_{\mathcal{K}}(s) := \begin{bmatrix} \mathcal{A}_{11} + B_1\mathcal{K} - sE_{11} & B_1 \\ \mathcal{C}_1 + \mathcal{D}\mathcal{K} & \mathcal{D} \end{bmatrix}$$

and

$$\mathcal{M}_{a,\mathcal{K}}(s) := \begin{bmatrix} \mathcal{A}_{11} + B_1\mathcal{K} - sE_{11} & 0 & B_1 \\ -(\mathcal{C}_1 + \mathcal{D}\mathcal{K})^T J(\mathcal{C}_1 + \mathcal{D}\mathcal{K}) & -(\mathcal{A}_{11} + B_1\mathcal{K})^T - sE_{11}^T & -(\mathcal{C}_1 + \mathcal{D}\mathcal{K})^T J\mathcal{D} \\ -\mathcal{D}^T J(\mathcal{C}_1 + \mathcal{D}\mathcal{K}) & -B_1^T & -\mathcal{D}^T J\mathcal{D} \end{bmatrix}.$$

LEMMA 9. *If* $\mathcal{G}_{\mathcal{K}}(s)$ *has a* (J, J')*-spectral factorization, then*

$$\mu_1 = \nu, \quad \text{i.e.,} \quad (n_1 - \mu_1) + \nu = n_1.$$

Proof. We consider two cases.

Case 1: $p = m$. In this case, $\mathcal{P}_{\mathcal{K}}(s)$ is square and regular because of assumption (A1), and we know from the eigendecomposition (8) and Lemma 5 that the number of stable and antistable eigenvalues of $\mathcal{P}_{\mathcal{K}}(s)$ is

$$n_1 + m - [(n_1 - \mu_1) + m] = \mu_1.$$

Since

$$\begin{bmatrix} I & 0 & 0 & 0 \\ 0 & -(\mathcal{C}_1+\mathcal{D}\mathcal{K})^T J & I & 0 \\ 0 & -\mathcal{D}^T J & 0 & I \\ 0 & I & 0 & 0 \end{bmatrix}$$
$$\times \begin{bmatrix} \mathcal{A}_{11}+B_1\mathcal{K}-sE_{11} & B_1 & 0 & 0 \\ \mathcal{C}_1+\mathcal{D}\mathcal{K} & \mathcal{D} & 0 & -J^{-1} \\ 0 & 0 & -(\mathcal{A}_{11}+B_1\mathcal{K})^T-sE_{11}^T & -(\mathcal{C}_1+\mathcal{D}\mathcal{K})^T \\ 0 & 0 & -B_1^T & -\mathcal{D}^T \end{bmatrix}$$
$$\times \begin{bmatrix} I & 0 & 0 & 0 \\ 0 & 0 & I & 0 \\ 0 & I & 0 & 0 \\ J(\mathcal{C}_1+\mathcal{D}\mathcal{K}) & 0 & J\mathcal{D} & I \end{bmatrix} = \begin{bmatrix} \mathcal{M}_{a,\mathcal{K}}(s) & 0 \\ 0 & -J^{-1} \end{bmatrix},$$

it is clear that the stable and antistable eigenvalues of $\mathcal{M}_{a,\mathcal{K}}(s)$ are the stable and antistable eigenvalues of $\mathcal{P}_{\mathcal{K}}(s)$ plus the stable and antistable eigenvalues of $-\mathcal{P}_{\mathcal{K}}(-s)$, so the number of such stable and antistable eigenvalues is $2\mu_1$. On the other hand, we have from the eigendecomposition (14) that the dimension of the stable eigenspace of $\mathcal{M}_{a,\mathcal{K}}(s)$ is ν, and it is a standard result [8, 14] that if λ is an eigenvalue of $\mathcal{M}_{a,\mathcal{K}}(s)$, then $-\bar{\lambda}$ is also an eigenvalue of $\mathcal{M}_{a,\mathcal{K}}(s)$. Therefore, the number of the stable and antistable eigenvalues of $\mathcal{M}_{a,\mathcal{K}}(s)$ is 2ν. Hence,

$$2\mu_1 = 2\nu, \quad \text{i.e.,} \quad \mu_1 = \nu, \quad (n_1-\mu_1)+\nu = n_1.$$

Case 2: $p > m$. Since $\mathcal{G}_{\mathcal{K}}(s)$ has a (J, J')-spectral factorization with a factorization factor $\Xi(s)$ satisfying

$$(G_{\mathcal{K}}(-s)\Xi^{-1}(-s))^T J(G_{\mathcal{K}}(s)\Xi^{-1}(s)) = J',$$

$G_{\mathcal{K}}(s)\Xi^{-1}(s)$ is proper and has no poles on $\mathbf{C}_0$; thus, $G_{\mathcal{K}}(s)\Xi^{-1}(s)$ has no finite zeros on $\mathbf{C}_0$ and nontrivial infinite zeros. Note that from $G_{\mathcal{K}}(s) = (G_{\mathcal{K}}(s)\Xi^{-1}(s))\Xi(s)$ we obtain that the zeros of $G_{\mathcal{K}}(s)$ on $\mathbf{C}_{0e}$ are the same as those of $\Xi(s)$; i.e., the dimension of the eigenspace of $\Xi(s)$ corresponding to the eigenvalues on $\mathbf{C}_{0e}$ is $(n_1-\mu_1)+m$. Therefore, from the above analysis in Case 1, $\Xi^T(-s)J'\Xi(s)$ has $2(n_1+m-\mu_1)$ zeros on $\mathbf{C}_{0e}$. Equivalently, $G_{\mathcal{K}}^T(-s)JG_{\mathcal{K}}(s)$ has $2(n_1+m-\mu_1)$ zeros on $\mathbf{C}_{0e}$. This means that $\mathcal{M}_{a,\mathcal{K}}(s)$ has $2(n_1+m-\mu_1)$ eigenvalues on $\mathbf{C}_{0e}$. The number of stable and antistable eigenvalues of $\mathcal{M}_{a,\mathcal{K}}(s)$ is $2\mu_1$. Hence, similar to Case 1, we must have

$$2\mu_1 = 2\nu, \quad \text{i.e.,} \quad \mu_1 = \nu, \quad (n_1-\mu_1)+\nu = n_1. \qquad \square$$

Since the eigendecomposition (8) and Lemma 5 yield that

$$\mathcal{P}_{\mathcal{K}}(s)\begin{bmatrix} Q_{12} & 0 \\ -\mathcal{K}Q_{12} & Q_{33} \end{bmatrix} = \begin{bmatrix} S_{12} & S_{13} \\ 0 & S_{33} \end{bmatrix}\begin{bmatrix} \Phi_{22}-s\Theta_{22} & \Phi_{23} \\ \Phi_{32} & \Phi_{33} \end{bmatrix},$$

we define

$$\mathcal{W}_{\mathcal{Z}}(s) := \left[\begin{array}{cc|c} \Phi_{22}-s\Theta_{22} & \Phi_{23} & \mathcal{Z} \\ \Phi_{32} & \Phi_{33} & I \\ \hline -\mathcal{K}Q_{12} & Q_{33} & 0 \end{array}\right].$$

LEMMA 10. (i) *For any* $\mathcal{Z} \in \mathbf{R}^{(n_1-\mu_1)\times m}$, $\mathcal{W}_{\mathcal{Z}}(s)$ *is invertible and, furthermore,*

$$\mathcal{G}_{\mathcal{K},\mathcal{Z}}(s) := \mathcal{G}_{\mathcal{K}}(s)\mathcal{W}_{\mathcal{Z}}(s) = \left[\begin{array}{c|c} \mathcal{A}_{11}+B_1\mathcal{K}-sE_{11} & -S_{12}\mathcal{Z}-S_{13} \\ \hline \mathcal{C}_1+\mathcal{D}\mathcal{K} & -S_{33} \end{array}\right]. \tag{37}$$

(ii) *There exists* $\mathcal{Z}$ *such that all finite zeros of* $\mathcal{W}_{\mathcal{Z}}(s)$ *are on* $\mathbf{C}_-$. *For such a* $\mathcal{Z}$, $\mathcal{G}_{\mathcal{K},\mathcal{Z}}(s)$ *is proper and stable and has no finite zeros on* $\mathbf{C}_0$ *and no nontrivial infinite zeros.*

(iii) *For a* $\mathcal{Z}$ *in* (ii), $\mathcal{G}_{\mathcal{K}}(s)$ *has the a* (J,J')*-spectral factorization if and only if* $\mathcal{G}_{\mathcal{K},\mathcal{Z}}(s)$ *has a canonical* (J,J')*-spectral factorization; i.e, there exists an invertible rational matrix* $\Pi(s)$ *such that*

$$\mathcal{G}^T_{\mathcal{K},\mathcal{Z}}(-s)J\mathcal{G}_{\mathcal{K},\mathcal{Z}}(s) = \Pi^T(-s)J'\Pi(s)$$

and all poles and zeros of $\Pi(s)$ *lie in* $\mathbf{C}_-$.

Proof. Note that Q_{33} is nonsingular (see Lemma 5), so $\mathcal{W}_{\mathcal{Z}}(s)$ is always invertible. In addition, (37) follows directly from a simple verification. So, we need to prove only (ii) and (iii) of Lemma 10.

Part (ii). Since S_{33} is of full column rank (see Lemma 5) and E_{11} is nonsingular, $\mathcal{G}_{\mathcal{K},\mathcal{Z}}(s)$ has no nontrivial infinite zeros. Furthermore, from Lemma 5,

$$\left[\begin{array}{c} S_{22} \\ S_{32} \end{array}\right] = 0$$

and $\operatorname{rank}(S_{33}) = m$, so

$$\left[\begin{array}{cc} S_{12} & S_{13} \\ 0 & S_{33} \end{array}\right]$$

is of full column rank; consequently, we have from (9) that

$$\begin{aligned} \operatorname{rank}\left[\begin{array}{cc} \Phi_{22}-s\Theta_{22} & \Phi_{23} \\ \Phi_{32} & \Phi_{33} \\ -\mathcal{K}Q_{12} & Q_{33} \end{array}\right] &= \operatorname{rank}\left(\left[\begin{array}{ccc} S_{12} & S_{13} & 0 \\ 0 & S_{33} & 0 \\ 0 & 0 & I \end{array}\right]\left[\begin{array}{cc} \Phi_{22}-s\Theta_{22} & \Phi_{23} \\ \Phi_{32} & \Phi_{33} \\ -\mathcal{K}Q_{12} & Q_{33} \end{array}\right]\right) \\ &= \operatorname{rank}\left[\begin{array}{cc} (\mathcal{A}_{11}+B_1\mathcal{K}-sE_{11})Q_{12} & 0 \\ (\mathcal{C}_1+\mathcal{D}\mathcal{K})Q_{12} & 0 \\ -\mathcal{K}Q_{12} & Q_{33} \end{array}\right] \quad \forall s \in \mathbf{C}. \end{aligned}$$

Since

$$\left[\begin{array}{cc} Q_{12} & 0 \\ 0 & Q_{33} \end{array}\right]$$

is of full column rank, $\mathcal{A}_{11}+B_1\mathcal{K}-sE_{11}$ is stable, and

$$\left[\begin{array}{cc} \Phi_{22}-s\Theta_{22} & \Phi_{23} \\ \Phi_{32} & \Phi_{33} \end{array}\right]$$

is nonsingular for any $s \in \mathbf{C}\backslash\mathbf{C}_0$, we get that

$$\left[\begin{array}{cc} \Phi_{22}-s\Theta_{22} & \Phi_{23} \\ \Phi_{32} & \Phi_{33} \\ -\mathcal{K}Q_{12} & Q_{33} \end{array}\right]$$

is of full column rank for any $s \in \mathbf{C}$; equivalently,

$$\begin{bmatrix} \Phi_{22} + \Phi_{23} Q_{33}^T \mathcal{K} Q_{12} - s\Theta_{22} \\ \Phi_{32} + \Phi_{33} Q_{33}^T \mathcal{K} Q_{12} \end{bmatrix}$$

is of full column rank for any $s \in \mathbf{C}$ (i.e., is observable). Consequently, there exists a $\mathcal{Z}$ such that the matrix

$$\Theta_{22}^{-1}[\Phi_{22} + \Phi_{23} Q_{33}^T \mathcal{K} Q_{12} - \mathcal{Z}(\Phi_{32} + \Phi_{33} Q_{33}^T \mathcal{K} Q_{12})]$$

is stable. Hence, part (ii) follows.

Part (iii). Assume that $\mathcal{G}_{\mathcal{K},\mathcal{Z}}(s)$ has a canonical (J, J')-spectral factorization:

$$\mathcal{G}_{\mathcal{K},\mathcal{Z}}^T(-s) J \mathcal{G}_{\mathcal{K},\mathcal{Z}}(s) = \Pi^T(-s) J' \Pi(s),$$

where all poles and zeros of $\Pi(s)$ lie in $\mathbf{C}_-$ and $\mathcal{G}_{\mathcal{K},\mathcal{Z}}(s)\Pi^{-1}(s)$ is proper and has no poles on $\mathbf{C}_0$. Let $\Xi(s) = \Pi(s)\mathcal{W}_{\mathcal{Z}}^{-1}(s)$. Then, from (37), we immediately get

$$\mathcal{G}_{\mathcal{K}}^T(-s) J \mathcal{G}_{\mathcal{K}}(s) = \Xi^T(-s) J' \Xi(s).$$

Moreover, $\mathcal{G}_{\mathcal{K}}(s)\Xi^{-1}(s) = \mathcal{G}_{\mathcal{K},\mathcal{Z}}(s)\Pi^{-1}(s)$ is proper and has no poles on $\mathbf{C}_0$. Furthermore, all poles and zeros of $\Pi(s)$ and $\mathcal{W}^{-1}(s)$ lie on $\mathbf{C}_- \cup \mathbf{C}_{0e}$, so all poles and zeros of $\Xi(s)$ also lie on $\mathbf{C}_- \cup \mathbf{C}_{0e}$. Hence $\mathcal{G}_{\mathcal{K}}(s)$ has a (J, J')-spectral factorization.

Conversely, assume that $\mathcal{G}_{\mathcal{K}}(s)$ has a (J, J')-spectral factorization:

$$\mathcal{G}_{\mathcal{K}}^T(-s) J \mathcal{G}_{\mathcal{K}}(s) = \Xi^T(-s) J' \Xi(s),$$

where all poles and zeros of $\Xi(s)$ lie in $\mathbf{C}_- \cup \mathbf{C}_{0e}$ and $\mathcal{G}_{\mathcal{K}}(s)\Xi^{-1}(s)$ is proper and has no poles on $\mathbf{C}_0$. Let $\Pi(s) = \Xi(s)\mathcal{W}_{\mathcal{Z}}(s)$. Then it can be verified that

$$\mathcal{G}_{\mathcal{K},\mathcal{Z}}^T(-s) J \mathcal{G}_{\mathcal{K},\mathcal{Z}}(s) = \Pi^T(-s) J' \Pi(s)$$

and $\mathcal{G}_{\mathcal{K},\mathcal{Z}}(s)\Pi^{-1}(s) = (\mathcal{G}_{\mathcal{K}}(s)\mathcal{W}_{\mathcal{Z}}(s))(\Xi(s)\mathcal{W}_{\mathcal{Z}}(s))^{-1} = \mathcal{G}_{\mathcal{K}}(s)\Xi^{-1}(s)$ is proper and has no poles on $\mathbf{C}_0$.

Since $\mathcal{G}_{\mathcal{K},\mathcal{Z}}(s)$ is stable and has no zeros on $\mathbf{C}_0$ and we have shown that $\mathcal{G}_{\mathcal{K},\mathcal{Z}}(s)\Pi^{-1}(s)$ is proper and has no poles on $\mathbf{C}_0$, $\Pi^{-1}(s)$ cannot have poles and zeros on $\mathbf{C}_0$; i.e., $\Pi(s)$ cannot have poles and zeros on $\mathbf{C}_0$. Therefore, all poles and zeros of $\Pi(s)$ are on $\mathbf{C}_0$ because all poles and zeros of $\Xi(s)$ and $\mathcal{W}_{\mathcal{Z}}(s)$ are on $\mathbf{C}_0 \cup \mathbf{C}_{0e}$. Hence $\mathcal{G}_{\mathcal{K},\mathcal{Z}}(s)$ has a canonical (J, J')-spectral factorization. ∎

3.5. Solvability conditions for the canonical (J, J')-spectral factorization of $\mathcal{G}_{\mathcal{K},\mathcal{Z}}(s)$. Since $\mathcal{G}_{\mathcal{K},\mathcal{Z}}(s)$ is proper and has no poles and zeros (finite zeros and nontrivial infinite zeros) on $\mathbf{C}_{0e}$, hence existing results [16] for the canonical (J, J')-spectral factorizations can be applied to $\mathcal{G}_{\mathcal{K},\mathcal{Z}}(s)$ directly.

LEMMA 11. *Let $\mathcal{Z}$ be such that all finite zeros of $\mathcal{W}_{\mathcal{Z}}(s)$ are on $\mathbf{C}_-$. Then $\mathcal{G}_{\mathcal{K},\mathcal{Z}}(s)$ has a canonical (J, J')-spectral factorization if and only if the conditions* (15) *and* (16) *hold.*

Proof. It is well known [16] that $\mathcal{G}_{\mathcal{K},\mathcal{Z}}(s)$ has a canonical (J, J')-spectral factorization if and only if

$$S_{33}^T J S_{33} = \mathcal{D}_0^T J' \mathcal{D}_0 \quad \text{for some nonsingular } \mathcal{D}_0;$$

i.e., the condition (15) holds, and, furthermore, the ARE

$$\begin{aligned} &E_{11}^{-T}(\mathcal{A}_{11}+B_1\mathcal{K})^TP+P(\mathcal{A}_{11}+B_1\mathcal{K})E_{11}^{-1}+E_{11}^{-T}(\mathcal{C}_1+\mathcal{D}\mathcal{K})^TJ(\mathcal{C}_1+\mathcal{D}\mathcal{K})E_{11}^{-1}\\ &\quad-[P(S_{12}\mathcal{Z}+S_{13})+E_{11}^{-T}(\mathcal{C}_1+\mathcal{D}\mathcal{K})^TJS_{33}](S_{33}^TJS_{33})^{-1}\\ &\quad\times[(S_{12}\mathcal{Z}+S_{13})^TP+S_{33}^TJ(\mathcal{C}_1+\mathcal{D}\mathcal{K})E_{11}^{-1}]=0 \end{aligned} \tag{38}$$

has a stabilizing solution P; i.e., P is a solution of (38) and

$$(\mathcal{A}_{11}+B_1\mathcal{K})E_{11}^{-1}-(S_{12}\mathcal{Z}+S_{13})(S_{33}^TJS_{33})^{-1}[(S_{12}\mathcal{Z}+S_{13})^TP+S_{33}^TJ(\mathcal{C}_1+\mathcal{D}\mathcal{K})\mathcal{E}_{11}^{-1}] \tag{39}$$

is stable.

Define

$$\mathcal{A}_s:=\Phi_{22}+\Phi_{23}Q_{33}^T\mathcal{K}Q_{12}-\mathcal{Z}(\Phi_{32}+\Phi_{33}Q_{33}^T\mathcal{K}Q_{12}),$$
$$\mathcal{B}_s:=(\mathcal{Z}\Phi_{33}-\Phi_{32})Q_{33}^T,\quad \mathcal{C}_s:=\Phi_{32}+\Phi_{33}Q_{33}^T\mathcal{K}Q_{12},\quad \mathcal{D}_s:=-\Phi_{33}Q_{33}^T.$$

Then pencil $A_s-s\Theta_{22}$ is stable, as shown in the proof of Lemma 10. We also have after a simple calculation using the eigendecompositions (8) and (14) and Lemma 5 that

$$\begin{aligned} &\begin{bmatrix} \mathcal{A}_{11}+B_1\mathcal{K}-sE_{11} & 0 & -S_{12}\mathcal{Z}-S_{13}\\ -(\mathcal{C}_1+\mathcal{D}\mathcal{K})^TJ(\mathcal{C}_1+\mathcal{D}\mathcal{K}) & -(\mathcal{A}_{11}+B_1\mathcal{K})^T-sE_{11}^T & (\mathcal{C}_1+\mathcal{D}\mathcal{K})^TJS_{33}\\ S_{33}^TJ(\mathcal{C}_1+\mathcal{D}\mathcal{K}) & \mathcal{Z}^TS_{12}^T+S_{13}^T & -S_{33}^TJS_{33} \end{bmatrix}\\ &\quad\times\begin{bmatrix} L_1 & Q_{12}\\ L_3 & 0\\ \mathcal{D}_s(L_5-\mathcal{K}L_1) & \mathcal{C}_s \end{bmatrix}\\ &\quad=\begin{bmatrix} E_{11}L_1 & S_{12}\\ E_{11}^TL_3 & 0\\ 0 & 0 \end{bmatrix}\begin{bmatrix} \Delta-sI & 0\\ \mathcal{B}_s(L_5-\mathcal{K}L_1) & \mathcal{A}_s-s\Theta_{22} \end{bmatrix}. \end{aligned} \tag{40}$$

Since Lemmas 9 and 10(iii) hold, we have from the well-known relationship between the stabilizing solution of an ARE and its associated Hamiltonian matrix pencil [8, 14, 27] that $\mathcal{G}_{\mathcal{K},\mathcal{Z}}(s)$ has a canonical (J,J')-spectral factorization if and only if the condition (15) holds, $(n_1-\mu_1)+\nu=n_1$, and $\begin{bmatrix} L_1 & Q_{12}\end{bmatrix}$ is nonsingular; i.e., the conditions (15) and (16) hold. □

3.6. Proof of Theorem 4. Now we are ready to prove Theorem 4 based on the results in sections 3.1–3.5.

Proof. Let $\mathcal{K}$ and $\mathcal{Z}$ be such that $\mathcal{A}_{11}+B_1\mathcal{K}-sE_{11}$ is stable and all finite zeros of $\mathcal{W}_{\mathcal{Z}}(s)$ are on $\mathbf{C}_-$, respectively. We have

the GARE (1) has a semistabilizing solution X_a
$\iff$ the GARE (28) has a semistabilizing solution $\mathcal{X}_a$ (by Lemma 6)
$\iff$ $\mathcal{G}_{\mathcal{K}}(s)$ has a (J,J')-spectral factorization (by Lemma 8)
$\iff$ $\mathcal{G}_{\mathcal{K},\mathcal{Z}}(s)$ has a canonical (J,J')-spectral factorization (by Lemma 10)
$\iff$ the conditions (15) and (16) hold (by Lemma 11).

Furthermore, we have using Lemma 5 and the eigendecomposition (8) that

$$\mathcal{D}Q_{33}=S_{33}\Phi_{33},\quad C_1Q_{12}+C_2Q_{22}=S_{33}\Phi_{32},\quad A_{21}Q_{12}+A_{22}Q_{22}=0;$$

thus, under the conditions (15) and (16), we have using Lemma 5 and the eigendecompositions (8) and (14) that

$$\text{rank}\begin{bmatrix} L_1 & Q_{12} & 0 \\ L_5 & 0 & I \end{bmatrix} = \text{rank}\begin{bmatrix} E_{11}L_1 & S_{12} & S_{13} \\ 0 & 0 & \mathcal{D}_0 \end{bmatrix} = n_1 + m, \tag{41}$$

$$\mathcal{H}_a(s)\begin{bmatrix} L_1 & Q_{12} & 0 \\ L_5 & 0 & I \\ L_3 & 0 & 0 \\ J'L_5 & -J'\mathcal{D}_0\Phi_{32} & -J'\mathcal{D}_0\Phi_{33}Q_{33}^T + J' \end{bmatrix}$$

$$= \begin{bmatrix} E_{11}L_1 & S_{12} & S_{13} \\ 0 & 0 & \mathcal{D}_0 \\ E_{11}^T L_3 & 0 & -\mathcal{C}_1^T J S_{33} \\ 0 & 0 & -\mathcal{D}^T J S_{33} + J'\mathcal{D}_0 \end{bmatrix} \begin{bmatrix} \Delta - sI & 0 & 0 \\ 0 & \Phi_{22} - s\Theta_{22} & \Phi_{23}Q_{33}^T \\ 0 & \Phi_{32} & \Phi_{33}Q_{33}^T \end{bmatrix}, \tag{42}$$

and

$$\begin{bmatrix} L_1 & Q_{12} & 0 \\ L_5 & 0 & I \end{bmatrix}^T \begin{bmatrix} E_{11}^T L_3 & 0 & -\mathcal{C}_1^T J S_{33} \\ 0 & 0 & -\mathcal{D}^T J S_{33} + J'\mathcal{D}_0 \end{bmatrix}$$

$$= \begin{bmatrix} L_3 & 0 & 0 \\ J'L_5 & -J'\mathcal{D}_0\Phi_{32} & -J'\mathcal{D}_0\Phi_{33}Q_{33}^T + J' \end{bmatrix}^T \begin{bmatrix} E_{11}L_1 & S_{12} & S_{13} \\ 0 & 0 & \mathcal{D}_0 \end{bmatrix}. \tag{43}$$

So, Corollary 2(i) means that

$$\mathcal{X}_a = \begin{bmatrix} L_3 & 0 & 0 \\ J'L_5 & -J'\mathcal{D}_0\Phi_{32} & -J'\mathcal{D}_0\Phi_{33}Q_{33}^T + J' \end{bmatrix} \begin{bmatrix} L_1 & Q_{12} & 0 \\ L_5 & 0 & I \end{bmatrix}^{-1} \tag{44}$$

is a semistabilizing solution of the GARE (28). Moreover, (42) yields that

$$\mathcal{A}_a - \mathcal{B}_a(J')^{-1}\mathcal{B}_a^T\mathcal{X}_a - s\mathcal{E}_a$$

$$= \begin{bmatrix} E_{11}L_1 & S_{12} & S_{13} \\ 0 & 0 & \mathcal{D}_0 \end{bmatrix}^{-1} \begin{bmatrix} \Delta - sI & 0 & 0 \\ 0 & \Phi_{22} - s\Theta_{22} & \Phi_{23}Q_{33}^T \\ 0 & \Phi_{32} & \Phi_{33}Q_{33}^T \end{bmatrix} \begin{bmatrix} L_1 & Q_{12} & 0 \\ L_5 & 0 & I \end{bmatrix}^{-1}$$

is regular and all its eigenvalues lie in $\mathbf{C}_- \cup \mathbf{C}_{0e}$. In addition, because

$$\begin{bmatrix} \mathcal{C}_1 & \mathcal{D} \end{bmatrix} \begin{bmatrix} L_1 & Q_{12} & 0 \\ L_5 & 0 & I \end{bmatrix} = \begin{bmatrix} \mathcal{C}_1 L_1 + \mathcal{D}L_5 & S_{33}\Phi_{32} & S_{33}\Phi_{33}Q_{33}^T \end{bmatrix},$$

it is easy to know using the fact that Δ is stable and $\begin{bmatrix} \Phi_{32} & \Phi_{33} \end{bmatrix}$ is of full row rank that the pair

$$\left(\begin{bmatrix} \mathcal{C}_1 L_1 + \mathcal{D}L_5 & S_{33}\Phi_{32} & S_{33}\Phi_{33}Q_{33}^T \end{bmatrix}, \begin{bmatrix} \Delta - sI & 0 & 0 \\ 0 & \Phi_{22} - s\Theta_{22} & \Phi_{23}Q_{33}^T \\ 0 & \Phi_{32} & \Phi_{33}Q_{33}^T \end{bmatrix} \right)$$

has neither observable finite poles on $\mathbf{C}_0$ nor observable impulsive poles; equivalently, the pair $(\mathcal{C}_a, \mathcal{A}_a - \mathcal{B}_a(J')^{-1}\mathcal{B}_a^T\mathcal{X}_a - s\mathcal{E}_a)$ has neither observable finite poles on $\mathbf{C}_0$ nor

observable impulsive poles. Therefore, $\mathcal{X}_a$ is a semistabilizing solution of the GARE (28).

Let $\tilde{X}_{21}$, $\tilde{X}_{22}$, and $\tilde{X}_{23}$ be defined in (32). We have

$$\begin{bmatrix} I_{n_1} & 0 & 0 \\ 0 & 0 & I_m \\ 0 & I_{n_2} & 0 \end{bmatrix}\begin{bmatrix} \mathcal{X}_{11} & 0 & \mathcal{X}_{12} \\ \tilde{X}_{21} & \tilde{X}_{22} & \tilde{X}_{23} \\ \mathcal{X}_{21} & 0 & \mathcal{X}_{22}-J' \end{bmatrix}\begin{bmatrix} I_{n_1} & 0 & 0 \\ 0 & 0 & I_{n_2} \\ 0 & I_m & 0 \end{bmatrix}\begin{bmatrix} L_1 & Q_{12} & 0 & 0 \\ L_5 & 0 & I & 0 \\ 0 & 0 & 0 & I \end{bmatrix}$$
$$= \begin{bmatrix} L_3 & 0 & 0 & 0 \\ 0 & -J'\mathcal{D}_0\Phi_{32} & -J'\mathcal{D}_0\Phi_{33}Q_{33}^T & 0 \\ \tilde{X}_{21}L_1+\tilde{X}_{23}L_5 & \tilde{X}_{21}Q_{12} & \tilde{X}_{23} & \tilde{X}_{22} \end{bmatrix},$$

which yields

$$\begin{bmatrix} I & 0 & 0 \\ 0 & A_{22}^T & 0 \\ 0 & 0 & I_m \end{bmatrix}\begin{bmatrix} \mathcal{X}_{11} & 0 & \mathcal{X}_{12} \\ \tilde{X}_{21} & \tilde{X}_{22} & \tilde{X}_{23} \\ \mathcal{X}_{21} & 0 & \mathcal{X}_{22}-J' \end{bmatrix}\begin{bmatrix} L_1 & Q_{12} & 0 \\ 0 & 0 & I \end{bmatrix}$$
$$= \begin{bmatrix} L_3 & 0 & 0 & 0 \\ A_{22}^T\tilde{X}_{21}L_1 & A_{22}^T\tilde{X}_{21}Q_{12} & A_{22}^T\tilde{X}_{22} & A_{22}^T\tilde{X}_{23} \\ J'\mathcal{D}_0\Phi_{33}Q_{33}^TL_5 & -J'\mathcal{D}_0\Phi_{32} & 0 & -J'\mathcal{D}_0\Phi_{33}Q_{33}^T \end{bmatrix}$$
$$= \begin{bmatrix} L_3 & 0 & 0 & 0 \\ A_{22}^T\tilde{X}_{21}L_1 & A_{22}^T\tilde{X}_{21}Q_{12} & -C_2^TJC_2/2 & -C_2^TJ\mathcal{D} \\ J'\mathcal{D}_0\Phi_{33}Q_{33}^TL_5 & -J'\mathcal{D}_0\Phi_{32} & 0 & -J'\mathcal{D}_0\Phi_{33}Q_{33}^T \end{bmatrix}$$
$$= \begin{bmatrix} L_3 & 0 & 0 & 0 \\ A_{22}^T\tilde{X}_{21}L_1-C_2^TJC_2L_2/2-C_2^TJ\mathcal{D}L_5 & A_{22}^T\tilde{X}_{21}Q_{12}+C_2^TJC_2Q_{22}/2 & -C_2^TJC_2/2 & -C_2^TJ\mathcal{D} \\ 0 & -J'\mathcal{D}_0\Phi_{32} & 0 & -J'\mathcal{D}_0\Phi_{33}Q_{33}^T \end{bmatrix}$$
$$\times\begin{bmatrix} I & 0 & 0 & 0 \\ 0 & I & 0 & 0 \\ -L_2 & Q_{22} & I & 0 \\ -L_5 & 0 & 0 & I \end{bmatrix}.$$

Note that the eigendecompositions (8) and (14) and Lemma 5 give that

$$A_{21}Q_{12}+A_{22}Q_{22}=0, \quad A_{21}L_1+A_{22}L_2=0,$$
$$\mathcal{X}_{11}\begin{bmatrix} L_1 & Q_{12} \end{bmatrix}=\begin{bmatrix} L_3 & 0 \end{bmatrix},$$
$$-C_2^TJC_1L_1-C_2^TJC_2L_2-A_{12}^TL_3-C_2^TJ\mathcal{D}L_5=A_{22}^TL_4;$$

so

$$A_{22}^T\tilde{X}_{21}L_1-C_2^TJC_2L_2/2-C_2^TJ\mathcal{D}L_5=A_{22}^TL_4,$$
$$A_{22}^T\tilde{X}_{21}Q_{12}+C_2^TJC_2Q_{22}/2=-C_2^TJC_1Q_{12},$$

and thus

$$\begin{bmatrix} I & 0 & 0 \\ 0 & A_{22}^T & 0 \\ 0 & 0 & I_m \end{bmatrix}\begin{bmatrix} \mathcal{X}_{11} & 0 & \mathcal{X}_{12} \\ \tilde{X}_{21} & \tilde{X}_{22} & \tilde{X}_{23} \\ \mathcal{X}_{21} & 0 & \mathcal{X}_{22}-J' \end{bmatrix}\begin{bmatrix} L_1 & Q_{12} & 0 \\ 0 & 0 & I \end{bmatrix}$$
$$= \begin{bmatrix} L_3 & 0 & 0 & 0 \\ A_{22}^TL_4 & -C_2^TJC_1Q_{12} & -C_2^TJC_2/2 & -C_2^TJ\mathcal{D} \\ 0 & -J'\mathcal{D}_0\Phi_{32} & 0 & -J'\mathcal{D}_0\Phi_{33}Q_{33}^T \end{bmatrix}\begin{bmatrix} I & 0 & 0 & 0 \\ 0 & I & 0 & 0 \\ -L_2 & Q_{22} & I & 0 \\ -L_5 & 0 & 0 & I \end{bmatrix}. \tag{45}$$

Hence, (17) and (18) follow directly from (45) and lemma 6. □

4. Conclusions. In this paper we have derived numerically verifiable necessary and sufficient conditions for the existence of the semistabilizing solution of the GARE (1) and developed Algorithm 1 for computing such a semistabilizing solution. The main ingredients of Algorithm 1 are the computations of eigendecompositions (8) and (14), which are computed by numerically backward stable algorithms in [6, 10, 26]. As a result, Algorithm 1 is a generalization of the well-known generalized eigenvalue approach for the classical AREs to the GARE (1).

There are still some interesting problems related to the GARE (1) that are yet to be solved. Such problems include (i) the conditioning analysis and (ii) the computation of

$$\begin{bmatrix} L_1 \\ L_2 \\ \vdots \\ L_5 \end{bmatrix}$$

in (14) (i.e., the computation of the stable eigenspace of $M_a(s)$) based on the numerically stable and structure-preserving methods in [1, 4]. There are only very few results available for these problems in the existing literature.

Appendix. We construct the decompositions (7) and (8) as follows.

Construction of the decomposition (7).

Step 1. Compute the URV decomposition [6] of E to get orthogonal matrices U and V such that

$$UEV =: \begin{array}{c} \begin{matrix} n_1 & n-n_1 \end{matrix} \\ \begin{bmatrix} E_{11} & 0 \\ 0 & 0 \end{bmatrix} \begin{matrix} \}n_1 \\ \}n-n_1 \end{matrix} \end{array}, \quad \operatorname{rank}(E_{11}) = n_1.$$

Define

$$UAV =: \begin{array}{c} \begin{matrix} n_1 & n-n_1 \end{matrix} \\ \begin{bmatrix} A_{11} & A_{12}^{(1)} \\ A_{21} & A_{22}^{(1)} \end{bmatrix} \begin{matrix} \}n_1 \\ \}n-n_1 \end{matrix} \end{array}, \quad UB =: \begin{array}{c} \\ \begin{bmatrix} B_1^{(1)} \\ B_2^{(1)} \end{bmatrix} \begin{matrix} \}n_1 \\ \}n-n_1 \end{matrix} \end{array}.$$

Since assumption (A1) holds true, we have $\operatorname{rank}\begin{bmatrix} A_{22}^{(1)} & B_2^{(1)} \end{bmatrix} = n - n_1$.

Step 2. Compute the RQ decomposition [6] of $\begin{bmatrix} A_{22}^{(1)} & B_2^{(1)} \end{bmatrix}$ to get orthogonal matrix $\mathcal{V}$ such that

$$\begin{bmatrix} A_{22}^{(1)} & B_2^{(1)} \end{bmatrix} \mathcal{V} =: \begin{array}{c} \begin{matrix} n-n_1 & m \end{matrix} \\ \begin{bmatrix} A_{22} & 0 \end{bmatrix} \end{array}, \quad \operatorname{rank}(A_{22}) = n - n_1.$$

Set

$$\begin{bmatrix} A_{12}^{(1)} & B_1^{(1)} \end{bmatrix} \mathcal{V} =: \begin{array}{c} \begin{matrix} n-n_1 & m \end{matrix} \\ \begin{bmatrix} A_{12} & B_1 \end{bmatrix} \end{array}.$$

Then U, V, and $\mathcal{V}$ lead to the decomposition (7).

Construction of the eigendecomposition of (8).

Step 1. Compute the generalized upper triangular form [26, 10] of the pencil

$$\begin{bmatrix} A_{11} - sE_{11} & A_{12} & B_1 \\ A_{21} & A_{22} & 0 \\ C_1 & C_2 & \mathcal{D} \end{bmatrix}$$

taking assumption (A2) into account to get orthogonal matrices S_1 and Q_1 with partitioning

$$S_1 = \begin{array}{c} \begin{matrix} p+\mu_1-m & n_1-\mu_1 & (n-n_1)+m \end{matrix} \\ \left[\begin{array}{ccc} S_{11} & S_{12} & S_{13}^{(1)} \\ S_{21} & S_{22} & S_{23}^{(1)} \\ S_{31} & S_{32} & S_{33}^{(1)} \end{array}\right] \end{array} \begin{matrix} \}n_1 \\ \}n-n_1 \\ \}p \end{matrix},$$

$$Q_1 = \begin{array}{c} \begin{matrix} \mu_1 & n_1-\mu_1 & (n-n_1)+m \end{matrix} \\ \left[\begin{array}{ccc} Q_{11} & Q_{12} & Q_{13}^{(1)} \\ Q_{21} & Q_{22} & Q_{23}^{(1)} \\ Q_{31} & Q_{32} & Q_{33}^{(1)} \end{array}\right] \end{array} \begin{matrix} \}n_1 \\ \}n-n_1 \\ \}m \end{matrix}$$

such that

$$S_1^T \left[\begin{array}{ccc} A_{11}-sE_{11} & A_{12} & B_1 \\ A_{21} & A_{22} & 0 \\ C_1 & C_2 & \mathcal{D} \end{array}\right] Q_1$$

$$\begin{array}{c} \\ =: \end{array} \begin{array}{c} \begin{matrix} \mu_1 & n_1-\mu_1 & (n-n_1)+m \end{matrix} \\ \left[\begin{array}{ccc} \Phi_{11}-s\Theta_{11} & 0 & 0 \\ \Phi_{21}-s\Theta_{21} & \Phi_{22}^{(1)}-s\Theta_{22}^{(1)} & \Phi_{23}^{(1)} \\ \Phi_{31}^{(1)}-s\Theta_{31}^{(1)} & \Phi_{32}^{(1)} & \Phi_{33}^{(1)} \end{array}\right] \end{array} \begin{matrix} \}p+\mu_1-m \\ \}n_1-\mu_1 \\ \}(n-n_1)+m \end{matrix}, \tag{46}$$

where

$$\operatorname{rank}(\Theta_{11}) = \mu_1, \quad \operatorname{rank}(\Theta_{22}^{(1)}) = n_1-\mu_1,$$

$$\operatorname{rank}(\Phi_{11}-s\Theta_{11}) = \mu_1 \quad \forall s \in \mathbf{C}_{0e}, \tag{47}$$

$$\operatorname{rank}\left[\begin{array}{cc} \Phi_{22}^{(1)}-s\Theta_{22}^{(1)} & \Phi_{23}^{(1)} \\ \Phi_{32}^{(1)} & \Phi_{33}^{(1)} \end{array}\right] = m+n-\mu_1 \quad \forall s \in \mathbf{C}\backslash\mathbf{C}_0. \tag{48}$$

Note that (46) implies that $S_{22}\Theta_{22}^{(1)} = 0$ and $E_{11}Q_{13}^{(1)} = 0$, and so

$$S_{22} = 0, \quad Q_{13}^{(1)} = 0, \quad \left[\begin{array}{c} Q_{23}^{(1)} \\ Q_{33}^{(1)} \end{array}\right]$$

is nonsingular. We also have from (48) that

$$\operatorname{rank}\left[\begin{array}{cc} \Phi_{32}^{(1)} & \Phi_{33}^{(1)} \end{array}\right] = (n-n_1)+m.$$

Consequently, we have using (46) again that

$$n-n_1 = \operatorname{rank}(A_{22}) = \operatorname{rank}\left(\left[\begin{array}{cc} A_{22} & 0 \end{array}\right]\left[\begin{array}{c} Q_{23}^{(1)} \\ Q_{33}^{(1)} \end{array}\right]\right)$$

$$= \operatorname{rank}\left(\left[\begin{array}{cc} S_{22} & S_{23}^{(1)} \end{array}\right]\left[\begin{array}{c} \Phi_{23}^{(1)} \\ \Phi_{33}^{(1)} \end{array}\right]\right) = \operatorname{rank}(S_{23}^{(1)}\Phi_{33}^{(1)}),$$

which yields that $\operatorname{rank}(S_{23}^{(1)}) \geq n - n_1$. But it is clear that $\operatorname{rank}(S_{23}^{(1)}) \leq n - n_1$. Thus, we obtain that

$$\operatorname{rank}(S_{23}^{(1)}) = n - n_1.$$

Step 2. Compute the RQ factorization [6] of $S_{23}^{(1)}$ to get an orthogonal matrix S_2 such that

$$S_{23}^{(1)} S_2 =: \begin{array}{c} \begin{matrix} m & n-n_1 \end{matrix} \\ \left[\begin{array}{cc} 0 & S_{24} \end{array}\right] \end{array}, \quad \operatorname{rank}(S_{24}) = n - n_1.$$

Set

$$S = S_1 \begin{bmatrix} I & 0 \\ 0 & S_2 \end{bmatrix} = \begin{array}{c} \begin{matrix} p+\mu_1-m & n_1-\mu_1 & m & n-n_1 \end{matrix} \\ \left[\begin{array}{cccc} S_{11} & S_{12} & S_{13} & S_{14} \\ S_{21} & S_{22} & 0 & S_{24} \\ S_{31} & S_{32} & S_{33} & S_{34} \end{array}\right] \begin{matrix} \}n_1 \\ \}n-n_1 \\ \}p \end{matrix} \end{array},$$

$$S_2^T \begin{bmatrix} \Phi_{31}^{(1)} - s\Theta_{31}^{(1)} & \Phi_{32}^{(1)} & \Phi_{33}^{(1)} \end{bmatrix} =: \begin{array}{c} \begin{matrix} \mu_1 & n_1-\mu_1 & (n-n_1)+m \end{matrix} \\ \left[\begin{array}{ccc} \Phi_{31} - s\Theta_{31} & \Phi_{32}^{(2)} & \Phi_{33}^{(2)} \\ \Phi_{41} - s\Theta_{41} & \Phi_{42}^{(2)} & \Phi_{43}^{(2)} \end{array}\right] \begin{matrix} \}m \\ \}n-n_1 \end{matrix} \end{array}.$$

Then we have

$$n - n_1 = \operatorname{rank}(S_{23}^{(1)} \Phi_{33}^{(1)}) = \operatorname{rank}(S_{24} \Phi_{43}^{(2)}) = \operatorname{rank}(\Phi_{43}^{(2)}).$$

Step 3. Compute the RQ factorization [6] of $\Phi_{43}^{(2)}$ to get orthogonal matrix Q_2 such that

$$\Phi_{43}^{(2)} Q_2 = \begin{array}{c} \begin{matrix} m & n-n_1 \end{matrix} \\ \left[\begin{array}{cc} 0 & \Phi_{44}^{(3)} \end{array}\right] \end{array}, \quad \operatorname{rank}(\Phi_{44}^{(3)}) = n - n_1.$$

Set

$$\begin{bmatrix} \Phi_{23}^{(1)} \\ \Phi_{33}^{(2)} \end{bmatrix} Q_2 = \begin{array}{c} \begin{matrix} m & n-n_1 \end{matrix} \\ \left[\begin{array}{cc} \Phi_{23} & \Phi_{24}^{(3)} \\ \Phi_{33} & \Phi_{34}^{(3)} \end{array}\right] \begin{matrix} \}n_1-\mu_1 \\ \}m \end{matrix} \end{array}.$$

Step 4. Compute the RQ factorization [6] of $\begin{bmatrix} \Phi_{42}^{(2)} & \Phi_{44}^{(3)} \end{bmatrix}$ to get orthogonal matrix Q_3 with partitioning

$$Q_3 = \begin{array}{c} \begin{matrix} n_1-\mu_1 & n-n_1 \end{matrix} \\ \left[\begin{array}{cc} Q_{11}^{(3)} & Q_{12}^{(3)} \\ Q_{21}^{(3)} & Q_{22}^{(3)} \end{array}\right] \begin{matrix} \}n_1-\mu_1 \\ \}n-n_1 \end{matrix} \end{array}$$

such that

$$\begin{bmatrix} \Phi_{42}^{(2)} & \Phi_{44}^{(3)} \end{bmatrix} Q_3 = \begin{array}{c} \begin{matrix} n_1-\mu_1 & n-n_1 \end{matrix} \\ \left[\begin{array}{cc} 0 & \Phi_{44} \end{array}\right] \end{array}, \quad \operatorname{rank}(\Phi_{44}) = n - n_1.$$

Set

$$Q = Q_1 \begin{bmatrix} I & 0 \\ 0 & Q_2 \end{bmatrix} \begin{bmatrix} I_{\mu_1} & 0 & 0 & 0 \\ 0 & Q_{11}^{(3)} & 0 & Q_{12}^{(3)} \\ 0 & 0 & I & 0 \\ 0 & Q_{21}^{(3)} & 0 & Q_{22}^{(3)} \end{bmatrix} = \begin{matrix} \mu_1 \\ n_1 - \mu_1 \\ m \\ n - n_1 \end{matrix} \begin{matrix} \begin{bmatrix} Q_{11} & Q_{12} & Q_{13} & Q_{14} \\ Q_{21} & Q_{22} & Q_{23} & Q_{24} \\ Q_{31} & Q_{32} & Q_{33} & Q_{34} \end{bmatrix} \end{matrix} \begin{matrix} \}n_1 \\ \}n - n_1 \\ \}m \end{matrix},$$

$$\begin{bmatrix} \Phi_{22}^{(1)} - s\Theta_{22}^{(1)} & \Phi_{24}^{(3)} \\ \Phi_{32}^{(2)} & \Phi_{34}^{(3)} \end{bmatrix} Q_3 = \begin{matrix} n_1 - \mu_1 & n - n_1 \\ \begin{bmatrix} \Phi_{22} - s\Theta_{22} & \Phi_{24} - s\Theta_{24} \\ \Phi_{32} & \Phi_{34} \end{bmatrix} \end{matrix} \begin{matrix} \}n_1 - \mu_1 \\ \}m \end{matrix}.$$

Then a simple calculation gives that Θ_{22} is nonsingular, and (11) and (12) hold. Hence, S and Q give the eigendecomposition (8).

ON THE GAP BETWEEN THE COMPLEX STRUCTURED SINGULAR VALUE AND ITS CONVEX UPPER BOUND*

I. M. JAIMOUKHA†, G. D. HALIKIAS‡, U. MALIK§, AND S. K. GUNGAH§

Abstract. The gap between the complex structured singular value of a complex matrix M and its convex upper bound is considered. New necessary and sufficient conditions for the existence of the gap are derived. It is shown that determining whether there exists such a gap is as difficult as evaluating a structured singular value of a reduced rank matrix (whose rank is equal to the multiplicity of the largest singular value of M). Furthermore, if an upper bound on this reduced rank problem can be obtained, it is shown that this provides an upper bound on the original problem that is lower than the convex relaxation upper bound. An example that illustrates our procedure is given. We also give the solution of several structured-approximation problems of independent interest.

Key words. structured uncertainty, convex relaxation, structured singular value, robust control, μ-analysis, distance to singularity, Toeplitz matrices

1. Notation. $\mathcal{R}$ and $\mathcal{C}$ denote the sets of real and complex numbers, respectively. $\mathcal{C}^{n\times m}$ denotes the space of all $n\times m$ complex matrices. For $A\in\mathcal{C}^{n\times m}$, A' denotes the complex-conjugate transpose and $\sigma_i(A)$ denotes the ith largest singular value. The smallest and largest singular values are denoted by $\underline{\sigma}(A)$ and $\bar{\sigma}(A)$, respectively. The norm of A is defined as $\|A\|=\bar{\sigma}(A)$. For $A\in\mathcal{C}^{n\times n}$, $\lambda(A)$ is the set of all eigenvalues (or spectrum) of A and $\rho(A):=\max\{|\lambda_i|:\lambda_i\in\lambda(A)\}$ is the spectral radius of A. For Hermitian A, $\underline{\lambda}(A)$ denotes the smallest and $\bar{\lambda}(A)$ the largest eigenvalue of A, respectively. The m-dimensional identity matrix is denoted by I_m and the $m\times n$ null matrix is denoted by $0_{m,n}$. The subscripts of the identity and null matrices are dropped if the dimensions can be inferred from the context. All matrices are assumed to be complex unless otherwise stated. If m is a positive integer, then $\underline{m}$ is the set $\{i\in\mathcal{N}:1\le i\le m\}$, where $\mathcal{N}$ denotes the set of positive integers. If A and B are sets, then $A\backslash B=\{x\in A, x\notin B\}$.

A matrix Δ is called γ-unitary if $\Delta\Delta'=\Delta'\Delta=\gamma^2 I$. Let Δ_{11} be a complex matrix and let $\gamma\ge\|\Delta_{11}\|$. An embedding

$$\Delta=\begin{bmatrix}\Delta_{11} & \Delta_{12}\\ \Delta_{21} & \Delta_{22}\end{bmatrix} \tag{1.1}$$

is called a γ-completion of Δ_{11} if $\|\Delta\|=\gamma$. A γ-completion of Δ_{11} is called a γ-unitary completion if it is γ-unitary. If Δ is partitioned as (1.1) and U is a complex matrix such that $I-\Delta_{11}U$ is nonsingular, we define the upper linear fractional map

as $\mathcal{F}_u(\Delta, U) = \Delta_{22} + \Delta_{21}U(I - \Delta_{11}U)^{-1}\Delta_{12}$. If $I - U\Delta_{22}$ is nonsingular, we define the lower linear fractional map as $\mathcal{F}_l(\Delta, U) = \Delta_{11} + \Delta_{12}U(I - \Delta_{22}U)^{-1}\Delta_{21}$.

2. Introduction. The structured singular value (μ) [3, 6, 7, 8, 10, 11, 12, 21, 27, 28] has proved to be an effective analytical and design tool in the area of robust control. As an analysis tool, it is used to establish necessary and sufficient conditions for the robust stability of feedback systems subject to structured uncertainty. Combined with $\mathcal{H}_\infty$ optimal control methods it serves as a synthesis tool for designing feedback systems subject to tight robust-stability and robust-performance specifications.

Unfortunately, deciding whether the structured singular value of a matrix is less than one (say) is an NP-hard problem [4, 5]. This suggests that given any algorithm to compute μ, there will be "worst-case" problems for which the algorithm will fail to find the answer in polynomial time. In practice, upper bounds are often used (giving sufficient robust stability and performance conditions), obtained via the so-called D-iteration procedure, which solves a convex optimization problem. The introduction of this method was initially motivated by the fact that the gap between μ and its convex upper bound is zero for certain simple uncertainty structures (specifically when $2S + F \leq 3$, where S is the number of scalar uncertainty blocks and F the number of full blocks). This class of problems, however, is too small for most practical applications. In general, the gap between μ and its convex upper bound can be arbitrarily large (but grows no faster than linearly in the number of uncertainty blocks) [19].

Despite these conclusions about the computational complexity of the general problem, solving special classes of μ problems can be relatively easy: The solution of the rank-one problem [25, 26] corresponds to the alignment of n complex vectors in two dimensions. Note that despite its simplicity, this class of problems is sufficiently general for carrying out Kharitonov-type analysis of uncertain polynomials. In [24], a low-complexity algorithm was given for solving a special class of rank-2 problems. Considering the Cauchy–Binet expansion of the determinant formula, it seems reasonable to conjecture that the computational complexity of the problem is intimately related to its rank. The main result of this work shows that the gap between μ and its convex upper bound may be breached if we can solve a reduced-rank μ problem. In this case, an upper bound tighter than the D-iteration bound can be obtained using a computationally simple procedure (the solution of an eigenvalue problem).

In our previous work [14] we obtained bounds on $\mu(M)$ by embedding the underlying block-structured uncertainty set within a larger set. This was constructed by imposing the least-conservative bound on the projection of the structured uncertainty in the direction defined by the singular vectors corresponding to the smallest singular value of M. The method has been used successfully for real and mixed-type structured uncertainty, resulting in algorithms with excellent computational performance [15, 17]. In its dynamic version, this technique was also used in [14] to identify the set of all maximally robust controllers which guarantee robust stability for the largest possible class of unstructured additive perturbations containing the uncertainty ball of maximum radius as a subset. (In this case, directionality arises from the Schmidt vectors of a Hankel operator related to the problem; these remain invariant for all maximally robust controllers.) As noted in [14], the approach followed in that work [14] suffered from the fundamental limitation that singular value multiplicity larger than one was not considered. As a result, the bounds on μ obtained by this method cannot outperform the D-iteration bounds (unless the largest singular value of the scaled matrix is simple, in which case the D-iteration bound is equal to μ). In this

paper we rectify this limitation by considering singular values of arbitrary multiplicity. In the following paragraphs we outline the general approach of this work more formally. Let $M \in \mathcal{C}^{n\times n}$ have a singular value decomposition

$$M = U\Sigma V' = \begin{bmatrix} U_1 & U_2 \end{bmatrix} \begin{bmatrix} I_m & 0 \\ 0 & \Sigma_2 \end{bmatrix} \begin{bmatrix} V_1' \\ V_2' \end{bmatrix}, \quad \Sigma_2 = \operatorname{diag}(\sigma_{m+1}, \ldots, \sigma_n), \tag{2.1}$$

with $U_1, V_1 \in \mathcal{C}^{n\times m}$. Assume that $1 > \sigma_{m+1} = \cdots = \sigma_{m+l} > \sigma_{m+l+1} \geq \cdots \geq \sigma_n$ and define $A = \Sigma^{-1} = \operatorname{diag}(A_1, A_2)$, where $A_1 = I_m$ and $A_2 = \operatorname{diag}(a_{m+1}, \ldots, a_n)$, with $1 < a_{m+1} = \cdots = a_{m+l} < a_{m+l+1} \leq \cdots \leq a_n$. Let $\mathbf{\Delta} \subseteq \mathcal{C}^{n\times n}$ denote a block diagonal structured uncertainty set and let $\mathcal{B}\mathbf{\Delta} = \{\Delta \in \mathbf{\Delta} \ : \ \|\Delta\| \leq 1\}$ denote its unit ball. The complex structured singular value of M is defined as $\mu_{\mathbf{\Delta}}(M) = r_{\mathbf{\Delta}}(M)^{-1}$, where

$$r_{\mathbf{\Delta}}(M) := \min_{\Delta\in\mathbf{\Delta}} \{\|\Delta\| : \det(I - \Delta M) = 0\} = \min_{\Delta\in\mathbf{\Delta}} \{\|\Delta\| : \det(A - V'\Delta U) = 0\} \tag{2.2}$$

is the structured stability radius (if $\det(I - \Delta M) \neq 0 \ \forall \Delta \in \mathbf{\Delta}$, define $\mu_{\mathbf{\Delta}}(M) = 0$). Let $\mathcal{D} = \{D \in \mathcal{C}^{n\times n} : D = D' \geq 0 : D\Delta = \Delta D \ \forall \Delta \in \mathbf{\Delta}\} \subseteq \mathcal{C}^{n\times n}$ denote a complementary block diagonal structure to $\mathbf{\Delta}$, and define $\mathcal{D}_+ = \{D \in \mathcal{D} : D > 0\}$. Then

$$\mu_{\mathbf{\Delta}}(M) \leq \inf \{\gamma : D \in \mathcal{D}_+, \ \gamma^2 D - M'DM \geq 0\} := \gamma_o, \tag{2.3}$$

where the infimum in the right-hand side is the so-called D-iteration upper bound. Note that an alternative form of this upper bound is

$$\gamma_o = \inf_{D\in\mathcal{D}_+} \|D^{1/2} M D^{-1/2}\|.$$

This follows readily from the equivalences:

$$\gamma^2 D - M'DM \geq 0 \Leftrightarrow \gamma^2 I - D^{-1/2} M'DMD^{-1/2} \geq 0 \Leftrightarrow \|D^{1/2} M D^{-1/2}\| \leq \gamma,$$

which hold for every $D \in \mathcal{D}_+$. In what follows, we assume that $D = I$ and $\gamma_o = 1$ are the minimizers and we investigate the gap between $\mu_{\mathbf{\Delta}}(M)$ and its upper bound $\|M\| = 1$.

Remark 2.1. We impose the above scaling on M because we intend to investigate in a single framework the case that M is arbitrary and also the case that M is D-optimally scaled. If M is arbitrary, redefining $M \leftarrow \|M\|^{-1} M$ gives M with norm one. Consider next the case arising at the end of the D-iteration: When the infimum in (2.3) is achieved by a $D_o \in \mathcal{D}_+$, the above scaling can be simply performed as $M \leftarrow \gamma_o^{-1} D_o^{1/2} M D_o^{-1/2}$ (we exclude the possibility that $\gamma_o = 0$ as in this case $\mu_\Delta(M) = 0$). Clearly, this is not defined when the infimum is not achieved, i.e., when there exists a sequence of D_i's in $\mathcal{D}_+$ such that $\lim_{i\to\infty} \|D_i^{1/2} M D_i^{-1/2}\| = \gamma_o$, but $\lim_{i\to\infty} D_i = D_o$ is singular. To avoid technical details with infimizing scaling-matrix sequences we restrict our attention throughout the paper to the class of problems for which the infimum in (2.3) is achieved. However, as we now argue, this is made only for simplicity of presentation and does not restrict the generality of our work.

To our knowledge, the question regarding the achievement of the infimum in (2.3) is only partially resolved. In [2], the authors study the limiting behavior of the D-iteration bound, in the equivalent formulation:

$$f_{\min}(M) = \{\|e^D M e^{-D}\| : D \in \mathcal{D}\}, \ \mathcal{D} = \{\mathcal{R}^{n\times n}, D = \operatorname{diag}(D), \operatorname{trace}(D) = 0\}. \tag{2.4}$$

Note that, although only simple diagonal scalings are considered, the results apply to general block diagonal/repeated scalings. The advantage of this formulation arises from the convexity of the function $f(M,D) = \|e^D M e^{-D}\|$. It is shown in [2] that the set of optimal scalings $\{D : D \in \mathcal{D}, \|e^D M e^{-D}\| = f_{\min}(M)\}$ is nonempty and bounded if M is irreducible (for a reducible M the infimum may or may not be attained). If M is reducible, there exists (by definition) a permutation P such that

$$PMP' = \begin{bmatrix} M_{11} & M_{12} \\ 0 & M_{22} \end{bmatrix}$$

with $M_{11} \in \mathcal{C}^{r\times r}$, $r < n$. Since for any permutation matrix, $\|Pe^D P' PMP' Pe^{-D} P'\| = \|e^D M e^{-D}\|$, we can assume that every reducible matrix is of the above form (note that $Pe^D P'$ is diagonal and corresponds to the re-ordering of the diagonal structure). Now, $\mu_{\mathbf{\Delta}}^{-1}(M) = \min\{\|\Delta\| : \Delta \in \mathbf{\Delta}, \det(I - M\Delta) = 0\}$. Since $\det(I - \Delta M) = \det(I - \Delta_1 M_{11}) \det(I - \Delta_2 M_{22})$, where Δ_1 and Δ_2 denote, respectively, the first and second diagonal blocks of Δ, it follows that for every reducible matrix, $\mu_{\mathbf{\Delta}}(M) = \max\{\mu_{\mathbf{\Delta_1}}(M_{11}), \mu_{\mathbf{\Delta_2}}(M_{22})\}$, where $\mathbf{\Delta_1}$ and $\mathbf{\Delta_2}$ denote the two diagonal structures of dimension $r \times r$ and $(n-r) \times (n-r)$ inherited from $\mathbf{\Delta}$. Thus if M is reducible, the results of the paper can be applied separately to M_{11} and M_{22} (assumed irreducible) to obtain upper bounds $\mu_{\mathbf{\Delta_1}}(M_{11}) \le \bar{\mu}_{\mathbf{\Delta_1}}(M_{11})$ and $\mu_{\mathbf{\Delta_2}}(M_{22}) \le \bar{\mu}_{\mathbf{\Delta_2}}(M_{22})$, which are tighter (or at least no worse) than the two individual D-iteration upper bounds. We can then define $\bar{\mu}_{\mathbf{\Delta}}(M) := \max\{\bar{\mu}_{\mathbf{\Delta_1}}(M_{11}), \bar{\mu}_{\mathbf{\Delta_2}}(M_{22})\}$ as a bound on $\mu_{\mathbf{\Delta}}$. Since for any sequence (D^i) in $\mathcal{D}$ we have that

$$\left\| \begin{bmatrix} e^{D_1^i} & 0 \\ 0 & e^{D_2^i} \end{bmatrix} M \begin{bmatrix} e^{-D_1^i} & 0 \\ 0 & e^{-D_2^i} \end{bmatrix} \right\| \ge \max\{\|e^{D_1^i} M_{11} e^{-D_1^i}\|, \|e^{D_1^i} M_{11} e^{-D_1^i}\|\},$$

the bound $\bar{\mu}_{\mathbf{\Delta}}(M)$ can be no worse than the optimal D-iteration bound of M. If M_{11} or M_{22} (or both) are reducible, we can extend the process by partitioning these matrices further to obtain the same conclusion.

In what follows, extensive use is made of the following optimization problems associated with M and their solutions:

$$\max\{\rho(V_1' \Delta U_1) : \Delta \in \mathcal{B}\mathbf{\Delta}\} \tag{2.5}$$

and

$$\max\{\|V_1' \Delta U_1\| : \Delta \in \mathcal{B}\mathbf{\Delta}\}. \tag{2.6}$$

Remark 2.2. Let

$$M_0 = U\Sigma_0 V' := \begin{bmatrix} U_1 & U_2 \end{bmatrix} \begin{bmatrix} I_m & 0 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} V_1' \\ V_2' \end{bmatrix} = U_1 V_1', \tag{2.7}$$

so that M_0 is obtained from the singular value decomposition of M in (2.1) by setting $\Sigma_2 = 0$. Then the optimization in (2.5) becomes

$$\max_{\Delta\in\mathcal{B}\mathbf{\Delta}} \rho(V_1' \Delta U_1) = \max_{\Delta\in\mathcal{B}\mathbf{\Delta}} \rho(\Delta U_1 V_1') = \max_{\Delta\in\mathcal{B}\mathbf{\Delta}} \rho(\Delta M_0) =: \mu_{\mathbf{\Delta}}(M_0)$$

and is therefore a reduced rank μ problem. One of the contributions of this paper is to show that $\mu_{\mathbf{\Delta}}(M) = 1$ if and only if $\mu_{\mathbf{\Delta}}(M_0) = 1$.

The following result uses a semidefinite relaxation of the nonconvex optimization in (2.6) to derive an upper bound, shows that the gap is zero, and proves that the optimum is 1 if M is the (scaled) output of the D-iteration.

LEMMA 2.3. *With all variables as defined above,*

$$\max_{\Delta\in\mathcal{B}\mathbf{\Delta}} \|V_1'\Delta U_1\|^2 = \min\{\gamma : D\in\mathcal{D},\ D - V_1V_1' \geq 0,\ \gamma I - U_1'DU_1 \geq 0\}. \tag{2.8}$$

Furthermore, if the optimum in (2.3) *is* 1*, the optimum in* (2.6) *is* 1.

Proof. See the appendix. □

It is clear that $\|M\| = 1$ is an upper bound on $\mu_{\mathbf{\Delta}}(M)$ and on (2.5) and (2.6). Suppose that $\bar{\phi}_1$ and $\bar{\phi}_2$ are upper bounds on (2.5) and (2.6). The contribution of this paper is to show that if $\bar{\phi}_1$ or $\bar{\phi}_2$ is less than 1, then we can derive an upper bound on $\mu_{\mathbf{\Delta}}(M)$ which is also less than 1. More specifically, since $\rho(E_1'V'\Delta UE_1) \leq \bar{\phi}_1\|\Delta\|$ and $\|E_1'V'\Delta UE_1\| \leq \bar{\phi}_2\|\Delta\|\ \forall\ \Delta\in\mathbf{\Delta}$, where E_1 is the matrix of the first m columns of the $n\times n$ identity matrix, then

$$r_{\mathbf{\Delta}}(M) = \min_{\substack{\det(A-V'\Delta U)=0\\ \Delta\in\mathbf{\Delta}}} \|\Delta\| \geq \min_{\substack{\det(A-\Delta)=0\\ \rho(E_1'\Delta E_1)\leq\bar{\phi}_1\|\Delta\|\\ \|E_1'\Delta E_1\|\leq\bar{\phi}_2\|\Delta\|}} \|\Delta\| =: \underline{r}_{\mathbf{\Delta}}(M). \tag{2.9}$$

It follows that $[\underline{r}_{\mathbf{\Delta}}(M)]^{-1}$, evaluated in section 4, is an upper bound on $\mu_{\mathbf{\Delta}}(M)$.

Remark 2.4. It is implicit in the work in [21] that $\mu_{\mathbf{\Delta}}(M) = 1$ if $\mu_{\mathbf{\Delta}}(M_0) = 1$. It is also clear that the minimum on the right-hand sides of (2.9) is equal to 1 if $\bar{\phi}_1 = \bar{\phi}_2 = 1$. Since (2.6) is an upper bound on (2.5), we can always take $\bar{\phi}_1 \leq \bar{\phi}_2$. So in this work, we require, and therefore assume, that $\bar{\phi}_1 < 1$.

Remark 2.5. Our problem formulation assumes that M is square and nonsingular. This assumption involves no loss of generality and can be easily removed; see [14, Thm. 4.6] for details.

Our general approach in this work closely resembles the method used in [18] for breaching the duality gap between the quadratic integer programming problem and its semidefinite relaxation. Our results in that case involved considerably less technical detail than our present work, although the core idea is similar: The objective in both cases is to apply a convex relaxation to a computationally intractable (NP-hard) problem and, subsequently, to explore the properties of the optimal solution to the dual problem in order to reduce the duality gap. This is achieved in both cases by solving a problem of the same form as the primal, but of reduced complexity. In the following paragraphs we highlight the main results of [18] and its similarities with our present work. We hope that this will make the logic behind the sequence of arguments given in this paper easier to follow.

The quadratic integer programming (QIP) problem involves the maximization of the quadratic form $x'Qx$, in which $Q = Q' \in \mathcal{R}^{n\times n}$ and x is allowed to vary over $\{-1, 1\}^n$. Since this involves 2^{n-1} function evaluations, the computational complexity of the problem grows exponentially in n. Denote the maximum of the primal problem by γ. The convex relaxation upper bound $\bar{\gamma}$ of the problem involves the minimization of the trace of a diagonal matrix D such that $D - Q \geq 0$. It can be shown [18] that (i) the optimal D matrix, D_0 say, is unique; (ii) a simple sufficient condition for the duality gap $\gamma - \bar{\gamma}$ to be zero is that the null-space of $D_0 - Q$ is one-dimensional; (iii) a necessary and sufficient condition for the duality gap to be zero is that $\gamma_m = \frac{1}{n}\max\{x'VV'x\} = 1$, where $x \in \{-1,\ 1\}^n$ and V is an orthonormal matrix whose columns span the m-dimensional null-space of $D_0 - Q$. Let $V = [v_1, v_2, \ldots, v_m]$, where $\{v_i\}$ is an orthonormal basis of $\mathcal{N}(D_0 - Q)$. Introduce a row perturbation matrix

P so that $PV = [V_1' \; V_2']'$, where $V_1 \in \mathcal{R}^{m\times m}$ is nonsingular. Then, (iv) the duality gap is zero if and only if $V_2 V_1^{-1} z = \{-1,\ 1\}^{n-m}$ for some $z \in \{-1,\ 1\}^m$. Note that this gives a test which certifies if the duality gap is zero, requiring only 2^{m-1} evaluations. Finally, let $\underline{\lambda}_+$ be the smallest positive eigenvalue of $D_0 - Q$. Then, (v) $\gamma \leq \bar{\gamma} - n(1-\gamma_m)\underline{\lambda}_+ < \bar{\gamma}$. In other words the duality gap can be breached by evaluating γ_m. Now the maximization defining γ_m has the same form as the primal problem with the crucial difference that now $\text{rank}(VV') = m < n$ (potentially m is much smaller than n). It is shown in [18] that the evaluation of γ_m can be performed in polynomial time (in n) and is of complexity $O(n^{m-1})$. Geometrically the problem corresponds to the evaluation of the extreme points of a zonotope with n generating vectors in $m-1$ dimensions and can be solved by a variety of techniques. In [18] a reverse-enumeration algorithm was used, based on the work of [1], and was found to perform well in practice.

For the problem considered in this work, the primal problem is the evaluation of the structured singular value of an arbitrary matrix ($\mu(M)$), while the dual problem corresponds to its D-iteration upper bound (equation (2.3)). Since the constraint set of the dual problem is convex, the optimal solution can be easily calculated (e.g., via LMI techniques). Redefine M by absorbing the D-iteration matrix scalings and dividing by its norm so that $\|M\| = 1$. Let m be the multiplicity of the largest singular value of M (equal to one) and define U_1 and V_1 via the singular value decomposition of M in (2.1). It is well known [21] that $\mu(M) = 1$ if $m = 1$. In general, to test whether $\mu(M)$ is achieved at the end of the D-iteration we need to verify whether $\mu(M_0) = 1$, which is a reduced rank (m-rank) μ-problem. Breaching the duality gap also requires evaluating $\mu(M_0)$ (or at least obtaining an upper bound $\bar{\phi}_1$ less than 1) and solving an eigenvalue problem (see Theorem 4.1 and Remark 4.2). Note that in this case, since M is redefined at the end of the D-iteration procedure, we must have $\bar{\phi}_2 = 1$.

The similarities of the approach in the two problems are clear. The link is potentially important because it allows us to transfer intuition across different problem domains. We believe that this approach is sufficiently general and can be applied to a more general class of optimization problems when convex relaxations are used.

The structure of the paper is as follows. In section 3 we generalize an approach proposed in [16] to matrices with multiple largest singular value by solving a number of approximation problems involving the structured distance of a matrix to singularity, starting from the simplest case (zero uncertainty matrix subblock) and progressively moving to more general cases (uncertainty subblock is a fixed matrix; uncertainty subblock is free to vary over a compact set). In each case the minimum distance to singularity is obtained in a closed form and involves only straightforward numerical calculations (e.g., the solution of an eigenvalue problem); a complete parameterization of all optimal (minimum-norm) singularizing perturbations is also given in each case. The link to the structured singular value is obtained by specializing these results to a specific structured uncertainty set involving simultaneous spectral radius and norm constraints. This is obtained in Theorem 3.19, which gives the optimal solution in terms of a Toeplitz matrix (and its transformations). The link with μ is formalized in section 4 (Theorem 4.1), where the procedure for breaching the convex bound is outlined. An illustrative example is given in section 5. The results of the work are summarized in section 6. Finally, the main conclusions are drawn in section 7 and the proof of Lemma 2.3 is included in the appendix.

3. Structured distance to singularity. We first consider and generalize a structured uncertainty approach proposed in [16] and establish a connection with the structured singular value. We start by giving the following definition.

DEFINITION 3.1. *Let A be as defined in section 2 and let $E_1 = \begin{bmatrix} I_m & 0_{m\times(n-m)} \end{bmatrix}'$. For any set $\mathbf{\Delta_{11}} \subseteq \mathcal{C}^{m\times m}$ define the structured distance (of A) to singularity*

$$\gamma_{\mathbf{\Delta_{11}}} = \min \{\|\Delta\| : \det(A-\Delta) = 0,\ E_1{}'\Delta E_1 \in \mathbf{\Delta_{11}}\},$$

and the set of all optimal structured rank reducing perturbations

$$\mathcal{D}_{\mathbf{\Delta_{11}}} := \{\Delta \in \mathcal{C}^{n\times n} : \|\Delta\| = \gamma_{\mathbf{\Delta_{11}}}, \det(A-\Delta) = 0, E_1{}'\Delta E_1 \in \mathbf{\Delta_{11}}\}.$$

In this notation the (unstructured) distance to singularity will be denoted as

$$\gamma_{\mathcal{C}^{\mathbf{m}\times\mathbf{m}}} = \min \{\|\Delta\| : \det(A-\Delta)=0,\ E_1{}'\Delta E_1 \in \mathcal{C}^{\mathbf{m}\times\mathbf{m}}\} = \min \{\|\Delta\| : \det(A-\Delta)=0\}.$$

Recall that, unless specified otherwise, all matrices are assumed to be complex. It is thus implicit that $\Delta \in \mathcal{C}^{n\times n}$ in the definition of $\gamma_{\mathbf{\Delta_{11}}}$ above. For the remainder of this section, we evaluate $\gamma_{\mathbf{\Delta_{11}}}$ and $\mathcal{D}_{\mathbf{\Delta_{11}}}$ for several sets $\mathbf{\Delta_{11}}$.

3.1. $\mathbf{\Delta_{11}} = \mathcal{C}$. When $m = 1$, it is clear that the unstructured distance of A from singularity is

$$\gamma_{\mathcal{C}} = \min \{\|\Delta\| : \det(A-\Delta) = 0\} = \underline{\sigma}(A) = 1,$$

and the set of all optimal rank reducing perturbations is given by

$$\mathcal{D}_{\mathcal{C}} = \{\Delta = \operatorname{diag}(1, \Delta_{22}) \in \mathcal{C}^{n\times n}, \Delta_{22} \in \mathcal{C}^{(n-1)\times(n-1)}, \|\Delta_{22}\| \le 1\}.$$

3.2. $\mathbf{\Delta_{11}} = \{\delta \in \mathcal{C} : |\delta| \le \phi\}$, $\mathbf{0 \le \phi < 1}$. In [16] the (1,1) entry of the permissible perturbations was constrained to have modulus $\le \phi$, where $0 \le \phi < 1$ to obtain the following structured distance to singularity.

THEOREM 3.2 (see [16]). *Let $A = \operatorname{diag}(1, a_2, a_3, \ldots, a_n)$ with $1 < a_2 < \cdots < a_n$ be given and define $E_1 = \begin{bmatrix} 1 & 0_{1,n-1} \end{bmatrix}'$ and $\mathbf{\Delta}_\phi = \{\delta \in \mathcal{C} : |\delta| \le \phi\}$ for any $0 \le \phi \le 1$. Then*

$$\gamma_{\mathbf{\Delta}_\phi} := \min \{\|\Delta\| : \det(A-\Delta) = 0,\ E_1{}'\Delta E_1 \in \mathbf{\Delta}_\phi\} = \sqrt{a_2 - \phi(a_2-1)},$$

and for $\phi < 1$, the set of all optimal rank reducing perturbation is given by

$$\mathcal{D}_{\mathbf{\Delta}_\phi} = \left\{ \operatorname{diag}\left(\begin{bmatrix} \phi & \gamma_{\mathbf{\Delta}_\phi} e^{j\theta} \\ \gamma_{\mathbf{\Delta}_\phi} e^{-j\theta} & -\phi \end{bmatrix}, \Delta_{33} \right) : \theta \in \mathcal{R},\ \Delta_{33} \in \mathcal{C}^{(n-2)\times(n-2)}, \|\Delta_{33}\| \le \gamma_{\mathbf{\Delta}_\phi} \right\}.$$

Remark 3.3. Theorem 3.2 was used in [14] to derive an upper bound on μ in the case that m, the multiplicity of the largest singular value of M, is one. In Corollary 3.20 below, we give a generalization of Theorem 3.2 to the case $m \ge 1$. In section 4 this generalization is used to derive an upper bound on μ when $m \ge 1$.

3.3. $\mathbf{\Delta_{11}} = \mathcal{C}^{\mathbf{m}\times\mathbf{m}}$. To motivate the generalization of Theorem 3.2 for $m \ge 1$, we start with the unstructured multidimensional case.

LEMMA 3.4. *Let A and E_1 be as in Definition* 3.1. *Then*

$$\gamma_{\mathcal{C}^{\mathbf{m}\times\mathbf{m}}} = \min \{\|\Delta\| : \det(A-\Delta) = 0\} = 1,$$

and the set of all optimal rank reducing perturbations is given by

$$\mathcal{D}_{\mathcal{C}^{m\times m}} = \left\{ \begin{bmatrix} W & 0 \\ 0 & I_{n-m} \end{bmatrix} \left[\begin{array}{cc|c} 1 & 0 & 0 \\ 0 & \Delta_{22} & \Delta_{23} \\ \hline 0 & \Delta_{32} & \Delta_{33} \end{array}\right] \begin{bmatrix} W' & 0 \\ 0 & I_{n-m} \end{bmatrix} \in \mathcal{C}^{n\times n} : \right.$$

$$\left. WW' = W'W = I_m, \left\| \begin{bmatrix} \Delta_{22} & \Delta_{23} \\ \Delta_{32} & \Delta_{33} \end{bmatrix} \right\| \le 1 \right\}. \tag{3.1}$$

Proof. The proof that $\gamma_{\mathcal{C}^{m\times m}} = 1$ is well known. To prove that all minimizers are given by (3.1) let $\Delta \in \mathcal{C}^{n\times n}$ such that $\|\Delta\| = 1$ and $\det(A-\Delta) = 0$. Let $(A-\Delta)x = 0$ for some $x = \begin{bmatrix} x_1' & x_2' \end{bmatrix}'$ with $x_1 \in \mathcal{C}^m$ and such that $\|x\| = 1$. Then

$$(A-\Delta)x = 0 \Rightarrow x'A^2x = x'\Delta'\Delta x \Rightarrow x'\Delta'\Delta x = 1 \quad \text{and} \quad x_2 = 0 \Rightarrow {E_1}'\Delta E_1 x_1 = x_1$$
$$\Rightarrow 1 = \|{E_1}'\Delta E_1\| \;\&\; 1 \in \lambda({E_1}'\Delta E_1), \tag{3.2}$$

since $\underline{\sigma}(A) = 1$. It is straightforward to verify that all such Δ are captured by (3.1). ∎

3.4. $\boldsymbol{\Delta_{11} = \{0_{m\times m}\}}$. Thus a natural generalization of Theorem 3.2 is to impose constraints on ${E_1}'\Delta E_1$ so that (3.2) is violated. We start with the simplest constraint: ${E_1}'\Delta E_1 = 0$.

LEMMA 3.5. *Let $A = \operatorname{diag}(A_1, A_2) \in \mathcal{R}^{n\times n}$, with $A_1 = \operatorname{diag}(I_{m_1}, A_{22}) \in \mathcal{R}^{m\times m}$ and $A_2 = \operatorname{diag}(a_3 I_{m_3}, A_{44}) \in \mathcal{R}^{(n-m)\times(n-m)}$. Assume that $1 < \underline{\sigma}(A_{22})$, $0 < a_3 < \underline{\sigma}(A_{44})$, and $1 < a_3$. Then the structured distance to singularity is*

$$\gamma_{0_{m\times m}} := \min\{\|\Delta\| : \det(A-\Delta) = 0,\ {E_1}'\Delta E_1 = 0\} = \sqrt{a_3} =: \sqrt{\underline{\sigma}(A_1)\underline{\sigma}(A_2)}. \tag{3.3}$$

Furthermore all optimal rank reducing perturbations are generated by

$$W \left[\begin{array}{ccc||ccc} 0 & 0 & 0 & \sqrt{a_3} & 0 & 0 \\ 0 & 0 & 0 & 0 & \Delta_{13} & \Delta_{14} \\ \hline 0 & 0 & 0 & 0 & \Delta_{23} & \Delta_{24} \\ \hline\hline \sqrt{a_3} & 0 & 0 & 0 & 0 & 0 \\ 0 & \Delta_{31} & \Delta_{32} & 0 & \Delta_{33} & \Delta_{34} \\ \hline 0 & \Delta_{41} & \Delta_{42} & 0 & \Delta_{43} & \Delta_{44} \end{array}\right] W', \tag{3.4}$$

where $W = \operatorname{diag}(W_1, I_{m_2}, W_3, I_{m_4}) \in \mathcal{C}^{n\times n}$ is unitary and

$$\left\| \begin{bmatrix} 0 & 0 & \Delta_{13} & \Delta_{14} \\ 0 & 0 & \Delta_{23} & \Delta_{24} \\ \Delta_{31} & \Delta_{32} & \Delta_{33} & \Delta_{34} \\ \Delta_{41} & \Delta_{42} & \Delta_{43} & \Delta_{44} \end{bmatrix} \right\| \le \sqrt{a_3}. \tag{3.5}$$

Proof. A calculation verifies that all Δ of the form (3.4) have norm $\sqrt{a_3}$ and satisfy $\det(A-\Delta) = 0$. Thus $\sqrt{a_3}$ is an upper bound. Let $\Delta \in \mathcal{C}^{n\times n}$ be such that ${E_1}'\Delta E_1 = 0$ and $\det(A-\Delta) = 0$. Then there exists a nonzero $x = \begin{bmatrix} x_1' & x_2' \end{bmatrix}' \in \mathcal{C}^n$ with $x_1 \in \mathcal{C}^m$ such that $(A-\Delta)x = 0$. It is clear that $x_2 \neq 0$ since A_1 has full rank, and a little reflection will verify that $x_1 \neq 0$, since otherwise $\|\Delta\| \ge a_3 > \sqrt{a_3}$. Let $Z = \operatorname{diag}(z_1, z_2)$, where $z_1 = x_1/\|x_1\|$ and $z_2 = x_2/\|x_2\|$. Then

$$(A-\Delta)x = 0 \Rightarrow (A-\Delta)Z \begin{bmatrix} \|x_1\| \\ \|x_2\| \end{bmatrix} = 0 \Rightarrow \det\left(\begin{bmatrix} z_1'A_1z_1 & 0 \\ 0 & z_2'A_2z_2 \end{bmatrix} - Z'\Delta Z \right) = 0,$$

with the (1,1) entry of $Z'\Delta Z$ equal to zero. It follows from Theorem 3.2 (setting $\phi = 0$) and the fact that $\|Z\| = \|z_1\| = \|z_2\| = 1$ that

$$\|\Delta\| \ge \|Z'\Delta Z\| \ge \sqrt{|z_1'A_1z_1||z_2'A_2z_2|} \ge \sqrt{a_3},$$

with equality if and only if $z_1 = \begin{bmatrix} z_{11}' & 0 \end{bmatrix}'$ and $z_2 = \begin{bmatrix} z_{33}' & 0 \end{bmatrix}'$ with $z_{11} \in \mathcal{C}^{m_1}$ and $z_{33} \in \mathcal{C}^{m_3}$. Thus $\sqrt{a_3}$ is a lower bound and this proves (3.3).

To prove that (3.4) captures all optimal structured perturbations it suffices to show that any Δ which minimizes (3.3) can be written in the form of (3.4). Let

$$\Delta = \begin{bmatrix} O_{m,m} & \Delta_{12} \\ \Delta_{21} & \Delta_{22} \end{bmatrix} \in \mathcal{C}^{n\times n}$$

be any minimizer of (3.3). Also introduce the finer partitions,

$$\Delta_{12} = \begin{bmatrix} \hat{\Delta}_{11} & \hat{\Delta}_{12} \\ \hat{\Delta}_{21} & \hat{\Delta}_{22} \end{bmatrix}, \quad \Delta_{21} = \begin{bmatrix} \bar{\Delta}_{11} & \bar{\Delta}_{12} \\ \bar{\Delta}_{21} & \bar{\Delta}_{22} \end{bmatrix}, \quad \Delta_{22} = \begin{bmatrix} \tilde{\Delta}_{11} & \tilde{\Delta}_{12} \\ \tilde{\Delta}_{21} & \tilde{\Delta}_{22} \end{bmatrix},$$

where $\hat{\Delta}_{11} \in \mathcal{C}^{m_1\times m_3}$, $\bar{\Delta}_{11} \in \mathcal{C}^{m_3\times m_1}$, and $\tilde{\Delta}_{11} \in \mathcal{C}^{m_3\times m_3}$. Since Δ is optimal, a previous argument implies that

$$\det\left(\begin{bmatrix} z_1'A_1z_1 & 0 \\ 0 & z_2'A_2z_2 \end{bmatrix} - \begin{bmatrix} 0 & z_1'\Delta_{12}z_2 \\ z_2'\Delta_{21}z_1 & z_2'\Delta_{22}z_2 \end{bmatrix}\right) = 0, \tag{3.6}$$

and in fact the second matrix in the left-hand side of (3.6) is an optimal rank reducing approximation of the first matrix in the left-hand side of (3.6), with the constraint that the (1,1) entry is zero. Using the parameterization of Theorem 3.2 (with $\phi = 0$), and noting that $z_1'A_1z_1 = \|z_{11}\|^2 = 1$ and $z_2'A_2z_2 = a_3\|z_{33}\|^2 = a_3$, shows that

$$z_1'\Delta_{12}z_2 = z_{11}'\hat{\Delta}_{11}z_{33} = e^{j\theta}\sqrt{a_3}\ , \quad z_2'\Delta_{21}z_1 = z_{33}'\bar{\Delta}_{11}z_{33} = e^{-j\theta}\sqrt{a_3}\ , \tag{3.7}$$

and

$$z_2'\Delta_{22}z_2 = z_{33}'\tilde{\Delta}_{11}z_{33} = 0, \tag{3.8}$$

for some $\theta \in (-\pi, \pi]$. Next define any two unitary completions $U_\perp$ and $V_\perp$ of $e^{j\theta}z_{11}$ and z_{33}, respectively, to construct unitary matrices $W_1 = \begin{bmatrix} e^{j\theta}z_{11} & U_\perp \end{bmatrix}$ and $W_3 = \begin{bmatrix} z_{33} & V_\perp \end{bmatrix}$, and consider the product

$$\begin{bmatrix} W_1' & 0 \\ 0 & I_{m_2} \end{bmatrix} \Delta_{12} \begin{bmatrix} W_3 & 0 \\ 0 & I_{m_4} \end{bmatrix} = \begin{bmatrix} \psi z_{11}'\hat{\Delta}_{11}z_{33} & \psi z_{11}'\hat{\Delta}_{11}V_\perp & \psi z_{11}'\hat{\Delta}_{12} \\ U_\perp'\hat{\Delta}_{11}z_{33} & U_\perp'\hat{\Delta}_{11}V_\perp & U_\perp'\hat{\Delta}_{12} \\ \hat{\Delta}_{21}z_{33} & \hat{\Delta}_{21}V_\perp & \hat{\Delta}_{22} \end{bmatrix},$$

where $\psi = e^{-j\theta}$. Using the first equation in (3.7), the $(1,1)$ block in the right-hand side of the above equation may be written as $\sqrt{a_3}$. Now, since W_1 and W_3 are unitary and $\|\Delta_{12}\| \le \|\Delta\| = \sqrt{a_3}$, we conclude that $z_{11}'\hat{\Delta}_{11}V_\perp = 0$, $z_{11}'\hat{\Delta}_{12} = 0$, $U_\perp'\hat{\Delta}_{11}z_{33} = 0$, and $\hat{\Delta}_{21}z_{33} = 0$. Defining

$$\begin{bmatrix} U_\perp'\hat{\Delta}_{11}V_\perp & U_\perp'\hat{\Delta}_{12} \\ \hat{\Delta}_{21}V_\perp & \hat{\Delta}_{22} \end{bmatrix} = \begin{bmatrix} E_{13} & E_{14} \\ E_{23} & E_{24} \end{bmatrix}$$

thus gives

$$\begin{bmatrix} \hat{\Delta}_{11} & \hat{\Delta}_{12} \\ \hat{\Delta}_{21} & \hat{\Delta}_{22} \end{bmatrix} = \begin{bmatrix} W_1 & 0 \\ 0 & I_{m_2} \end{bmatrix} \begin{bmatrix} \sqrt{a_3} & 0 & 0 \\ 0 & E_{13} & E_{14} \\ 0 & E_{23} & E_{24} \end{bmatrix} \begin{bmatrix} W_3' & 0 \\ 0 & I_{m_4} \end{bmatrix}. \tag{3.9}$$

A similar argument using the second equation in (3.7) and (3.8) shows that

$$\begin{bmatrix} \bar{\Delta}_{11} & \bar{\Delta}_{12} \\ \bar{\Delta}_{21} & \bar{\Delta}_{22} \end{bmatrix} = \begin{bmatrix} W_3 & 0 \\ 0 & I_{m_4} \end{bmatrix} \begin{bmatrix} \sqrt{a_3} & 0 & 0 \\ 0 & E_{31} & E_{31} \\ 0 & E_{41} & E_{42} \end{bmatrix} \begin{bmatrix} W_1' & 0 \\ 0 & I_{m_2} \end{bmatrix} \tag{3.10}$$

and

$$\begin{bmatrix} \tilde{\Delta}_{11} & \tilde{\Delta}_{12} \\ \tilde{\Delta}_{21} & \tilde{\Delta}_{22} \end{bmatrix} = \begin{bmatrix} W_3 & 0 \\ 0 & I_{m_4} \end{bmatrix} \begin{bmatrix} 0 & \tilde{E}_{23} & \tilde{E}_{24} \\ \tilde{E}_{32} & E_{33} & E_{34} \\ \tilde{E}_{42} & E_{43} & E_{44} \end{bmatrix} \begin{bmatrix} W_3' & 0 \\ 0 & I_{m_4} \end{bmatrix}, \tag{3.11}$$

where again the E_{ij}'s and $\tilde{E}_{ij}$'s are well-defined matrices of the appropriate dimensions. Again using $\|\Delta\| = \sqrt{a_3}$ shows that all $\tilde{E}_{ij} = 0$. Writing Δ in full using the form of its partitions defined in (3.9), (3.10), and (3.11) and extracting matrix factors $W = \mathrm{diag}(W_1, I_{m_2}, W_3, I_{m_4})$ and W' from the left and the right respectively, shows that Δ agrees with the form given in (3.4). Finally, the required contractive property in (3.5) follows directly from $\|\Delta\| = \sqrt{a_3}$. ∎

3.5. $\boldsymbol{\Delta_{11} = \{\Delta_{11}\}, \Delta_{11} \in \mathcal{C}^{m\times m}, \|\Delta_{11}\| \le 1, \det(I - \Delta_{11}) \neq 0}$. Next, we impose the constraint ${E_1}'\Delta E_1 = \Delta_{11}$, where Δ_{11} is a given matrix such that (3.2) is violated. First, we need the following results, which can be deduced from [23], concerning properties of linear fractional maps.

LEMMA 3.6. *Let* $H = \begin{bmatrix} H_{11} & H_{12} \\ H_{21} & H_{22} \end{bmatrix}$ *and* U *be complex matrices and assume that* $(I - H_{11}U)^{-1}$, H_{12}^{-1}, *and* H_{21}^{-1} *exist.*

1. *If* H *is nonsingular, then* $\Phi = \mathcal{F}_u(H, U)$ *if and only if* $U = \mathcal{F}_l(H^{-1}, \Phi)$.
2. *If* H *and* U *are nonsingular, then* $[\mathcal{F}_u(H, U)]^{-1} = \mathcal{F}_u(H^{-1}, U^{-1})$.
3. *If* H *is* γ*-unitary for some* $\gamma > 0$, *then* $\|\mathcal{F}_u(H, U)\| = \gamma$ *if and only if* $\|U\| = \gamma^{-1}$ *and* $\|\mathcal{F}_u(H, U)\| < \gamma$ *if and only if* $\|U\| < \gamma^{-1}$.
4. *If* H *is* γ*-unitary for some* $\gamma > 1$, H_{11} *is square,* $I - H_{11}$ *is nonsingular, and* $\|H_{11}\| \le 1$, *then*

$$\|\mathcal{F}_u(H, I)\| = \|(\gamma^2 I - H_{11})(I - H_{11})^{-1}\| = \|(I - H_{11})^{-1}(\gamma^2 I - H_{11})\|.$$

Proof.

1. This follows from a simple calculation.
2. This follows from the definition of the linear fractional map.
3. This is a standard result and follows from the identity

$$\gamma^2 I - \mathcal{F}_u(H, U)'\mathcal{F}_u(H, U) = H_{12}'(I - U'H_{11}')^{-1}(I - \gamma^2 U'U)(I - H_{11}U)^{-1}H_{12}.$$

4. Define $E = (I - H_{11})^{-1}(\gamma^2 I - H_{11})$, $F = \mathcal{F}_u(H, I)$, and $a = \|F\|$. Then

$$\begin{aligned} a = \|F\| &\Leftrightarrow \underline{\lambda}(a^2 I - F'F) = 0 \Leftrightarrow \underline{\lambda}[(a^2 - \gamma^2)I + \gamma^2 I - F'F] = 0 \\ &\Leftrightarrow \underline{\lambda}[(a^2 - \gamma^2)I - (\gamma^2 - 1)H_{12}'(I - H_{11}')^{-1}(I - H_{11})^{-1}H_{12}] = 0 \\ &\Leftrightarrow \underline{\lambda}[(a^2 - \gamma^2)I - (\gamma^2 - 1)(I - H_{11})^{-1}H_{12}H_{12}'(I - H_{11}')^{-1}] = 0 \\ &\Leftrightarrow \underline{\lambda}[(a^2 - \gamma^2)I - (\gamma^2 - 1)(I - H_{11})^{-1}(\gamma^2 I - H_{11}H_{11}')(I - H_{11}')^{-1}] = 0, \end{aligned}$$

where we have used the identity in part 3. On the other hand,

$$\begin{aligned} a^2 I - EE' &= (a^2 - \gamma^2)I + \gamma^2 I - EE' \\ &= (a^2 - \gamma^2)I - (\gamma^2 - 1)(I - H_{11})^{-1}(\gamma^2 I - H_{11}H_{11}')(I - H_{11}')^{-1}, \end{aligned}$$

so that $\underline{\lambda}(a^2 I - EE') = 0$. Thus $a = \|E\|$, which proves the result. ∎

LEMMA 3.7. *Let* A *and* E_1 *be as in Definition* 3.1. *Let* $\Delta_{11} \in \mathcal{C}^{m\times m}$ *be given and assume that* $\|\Delta_{11}\| \le 1$ *and that* $I - \Delta_{11}$ *is nonsingular. Then*

$$\min_{\substack{\det(A-\Delta)=0 \\ {E_1}'\Delta E_1 = \Delta_{11}}} \|\Delta\| = \min_{\substack{\|(\gamma^2 I - \Delta_{11})(I - \Delta_{11})^{-1}\| = a_{m+1} \\ \gamma > 1}} \gamma. \tag{3.12}$$

Proof. We use a lifting procedure to reduce the problem to the case $\Delta_{11}=0$. Since $\|\Delta_{11}\|\le 1$, for any $\gamma>1$ there exist γ-unitary completions of Δ_{11} of the form

$$\Delta_1^\gamma=\begin{bmatrix}\Delta_{11} & \Delta_{13}^\gamma\\ \Delta_{31}^\gamma & \Delta_{33}\end{bmatrix}\in\mathcal{C}^{2m\times 2m},\quad \Delta_0^\gamma=\begin{bmatrix}\Delta_{11} & 0 & \Delta_{13}^\gamma & 0\\ 0 & 0 & 0 & \gamma I_{n-m}\\ \Delta_{31}^\gamma & 0 & \Delta_{33} & 0\\ 0 & \gamma I_{n-m} & 0 & 0\end{bmatrix}\in\mathcal{C}^{2n\times 2n}.$$

It is clear that a_{m+1} is an upper bound to (3.12) (take $\Delta=\operatorname{diag}(\Delta_{11},a_{m+1}I_{n-m})$), so we can assume that $\gamma\le a_{m+1}$. Define

$$X_A^\gamma=\mathcal{F}_u[(\Delta_0^\gamma)^{-1},A]=\operatorname{diag}\left(\mathcal{F}_u[(\Delta_1^\gamma)^{-1},I],\gamma^{-2}A_2\right)=:\operatorname{diag}\left(X_1^\gamma,X_2^\gamma\right).$$

Parts 2 and 3 of Lemma 3.6 prove that $(X_1^\gamma)^{-1}=\mathcal{F}_u(\Delta_1^\gamma,I)$ and $\|(X_1^\gamma)^{-1}\|>\gamma$, respectively, so that $\underline{\sigma}(X_1^\gamma)<\gamma^{-1}$. Also, $\underline{\sigma}(X_2^\gamma)=\gamma^{-2}a_{m+1}>\underline{\sigma}(X_1^\gamma)$ since $\gamma\le a_{m+1}$. For any $\Delta\in\mathcal{C}^{n\times n}$ define

$$\Phi_\Delta^\gamma:=\mathcal{F}_u[(\Delta_0^\gamma)^{-1},\Delta]. \tag{3.13}$$

It is not difficult to show that

$$\|\Delta\|=\gamma\Leftrightarrow\|\Phi_\Delta^\gamma\|=\gamma^{-1},$$
$$E_1{}'\Delta E_1=\Delta_{11}\Leftrightarrow E_1{}'\Phi_\Delta^\gamma E_1=0,$$

and

$$\det(A-\Delta)=0\Leftrightarrow\det(X_A^\gamma-\Phi_\Delta^\gamma)=0,$$

and so

$$\begin{aligned}\min_{\substack{\det(A-\Delta)=0\\ \gamma=\|\Delta\|\\ E_1{}'\Delta E_1=\Delta_{11}}}\gamma&=\min_{\substack{\det(X_A^\gamma-\Phi_\Delta^\gamma)=0\\ \|\Phi_\Delta^\gamma\|=\gamma^{-1}\\ E_1{}'\Phi_\Delta^\gamma E_1=0}}\gamma=\min_{\sqrt{\underline{\sigma}(X_1^\gamma)\underline{\sigma}(X_2^\gamma)}\le\gamma^{-1}}\gamma\\ &=\min_{\|(X_1^\gamma)^{-1}\|\ge a_{m+1}}\gamma,\end{aligned} \tag{3.14}$$

where the last two equalities follow from Lemma 3.5. Now $\|(X_1^\gamma)^{-1}\|$ is continuous in γ, $\|(X_1^1)^{-1}\|=1$ (since Δ_1^1 is unitary), and $\|(X_1^\gamma)^{-1}\|\ge\gamma$. It follows that the inequality constraint in (3.14) is an equality. Part 4 of Lemma 3.6 now establishes that

$$\|(X_1^\gamma)^{-1}\|=\|\mathcal{F}_u(\Delta_1^\gamma,I)\|=\|(\gamma^2I-\Delta_{11})(I-\Delta_{11})^{-1}\|,$$

and this proves (3.12). ∎

Remark 3.8. The optimization on the right-hand side of (3.12) is an eigenvalue problem, as the following argument shows. Setting $\gamma^2=1+\zeta,\zeta>0$, shows that

$$\min_{\substack{\|(\gamma^2I-\Delta_{11})(I-\Delta_{11})^{-1}\|=a_{m+1}\\ \gamma>1}}\gamma=\sqrt{1+\min_{\substack{\|I+\zeta(I-\Delta_{11})^{-1}\|=a_{m+1}\\ \zeta>0}}\zeta}. \tag{3.15}$$

Note that

$$\begin{aligned}a_{m+1}&=\|I+\zeta(I-\Delta_{11})^{-1}\|\\ &\Leftrightarrow\underline{\lambda}\{a_{m+1}^2I-[I+\zeta(I-\Delta_{11})^{-1}][I+\zeta(I-\Delta_{11}')^{-1}]\}=0\\ &\Leftrightarrow\underline{\lambda}\left\{\zeta^{-1}I-\frac{(I-\Delta_{11})^{-1}+(I-\Delta_{11}')^{-1}}{a_{m+1}^2-1}-\zeta\frac{(I-\Delta_{11})^{-1}(I-\Delta_{11}')^{-1}}{a_{m+1}^2-1}\right\}=0\\ &\Leftrightarrow\underline{\lambda}\left(\begin{bmatrix}\zeta^{-1}I-\frac{(I-\Delta_{11})^{-1}+(I-\Delta_{11}')^{-1}}{a_{m+1}^2-1} & -\frac{(I-\Delta_{11})^{-1}}{\sqrt{a_{m+1}^2-1}}\\ -\frac{(I-\Delta_{11}')^{-1}}{\sqrt{a_{m+1}^2-1}} & \zeta^{-1}I\end{bmatrix}\right)=0,\end{aligned}$$

and since $\zeta > 0$, it follows that the minimum ζ in (3.15) is given by ζ_o, where

$$\zeta_o^{-1} = \bar{\lambda}\left(\begin{bmatrix} \frac{(I-\Delta_{11})^{-1}+(I-\Delta_{11}')^{-1}}{a_{m+1}^2-1} & -\frac{(I-\Delta_{11})^{-1}}{\sqrt{a_{m+1}^2-1}} \\ -\frac{(I-\Delta_{11}')^{-1}}{\sqrt{a_{m+1}^2-1}} & 0 \end{bmatrix}\right).$$

Remark 3.9. Lemmas 3.5 and 3.7 generalize the results in [13] by allowing multiplicities of the singular values of A.

Remark 3.10. Let γ_o be the maximum in (3.12) and define $\Phi_\Delta^{\gamma_o}$ as in (3.13). Then it is clear from part 1 of Lemma 3.6 that $\Phi_\Delta^{\gamma_o} = \mathcal{F}_u[(\Delta_0^{\gamma_o})^{-1}, \Delta]$ if and only if $\Delta = \mathcal{F}_l(\Delta_0^{\gamma_o}, \Phi_\Delta^{\gamma_o})$. It follows that all structured rank reducing perturbations for Lemma 3.7 can be obtained via a suitable lower linear fractional map from all structured perturbations for Lemma 3.5. The details, although straightforward, are tedious and are hence omitted.

Lemma 3.7 shows that the structured distance to singularity, when the perturbation Δ is constrained such that ${E_1}'\Delta E_1 = \Delta_{11}$ for a given $\Delta_{11} \in \mathcal{C}^{m\times m}$ such that $\|\Delta_{11}\| \le 1$ and $I - \Delta_{11}$ is nonsingular, reduces to a simple eigenvalue evaluation.

3.6. $\boldsymbol{\Delta_{11} = \{\Delta_{11} \in \mathcal{C}^{m\times m} : \|\Delta_{11}\| \le 1,\ (I-\Delta_{11})^{-1}}$ exists and is bounded}. The following result allows us to evaluate the structured distance to singularity for a general class of constraints on ${E_1}'\Delta E_1$.

LEMMA 3.11. *Let A and E_1 be as in Definition* 3.1 *and let $\boldsymbol{\Delta_{11}}$ be any compact subset of $\mathcal{C}^{m\times m}$ such that $\|\Delta_{11}\| \le 1$ and that $(I-\Delta_{11})^{-1}$ exists and is bounded for all $\Delta_{11} \in \boldsymbol{\Delta_{11}}$. Then*

$$\min\{\|\Delta\| : \det(A-\Delta) = 0,\ {E_1}'\Delta E_1 \in \boldsymbol{\Delta_{11}}\} = \sqrt{1+\zeta_o}\ , \tag{3.16}$$

where

$$\zeta_o = \min\{\zeta : \|I + \zeta(I-\Delta_{11})^{-1}\| = a_{m+1},\ \zeta > 0,\ \Delta_{11} \in \boldsymbol{\Delta_{11}}\}, \tag{3.17}$$

and ζ_o is (strictly) increasing in a_{m+1}. Furthermore if $\Delta_o \in \boldsymbol{\Delta_{11}}$ is a minimizer for (3.17)*, then Δ_o is a maximizer for*

$$\max_{\Delta_{11}\in\boldsymbol{\Delta_{11}}} \|I + \zeta_o(I-\Delta_{11})^{-1}\|. \tag{3.18}$$

Proof. The first part follows from Lemma 3.7 and the compactness of $\boldsymbol{\Delta_{11}}$. For any $\Delta_{11} \in \boldsymbol{\Delta_{11}}$, define $f_{\Delta_{11}}(\zeta) = \|I + \zeta(I-\Delta_{11})^{-1}\|$ for $\zeta \ge 0$. Then $f_{\Delta_{11}}(\zeta)$ is continuous in ζ, $f_{\Delta_{11}}(0) = 1$, and $f_{\Delta_{11}}(\zeta) \to \infty$ as $\zeta \to \infty$. Let Δ_o be a minimizer for (3.17) so that $f_{\Delta_o}(\zeta_o) = a_{m+1}$. Then $f_{\Delta_o}(\zeta) < a_{m+1}\ \forall\ \zeta < \zeta_o$. Suppose that Δ_o is not a maximizer for (3.18) so that $f_{\Delta_1}(\zeta_o) > f_{\Delta_o}(\zeta_o) = a_{m+1}$ for some $\Delta_1 \in \boldsymbol{\Delta_{11}}$. Then by continuity, there exists $0 < \zeta_1 < \zeta_o$ such that $f_{\Delta_1}(\zeta_1) = a_{m+1}$, contradicting the minimality of ζ_o. That ζ_o is increasing in a_{m+1} also follows from continuity. ∎

Remark 3.12. Lemma 3.7 transforms the structured distance to singularity on the left-hand side of (3.16) to the minimization in (3.17), which in turn is transformed using Lemma 3.11 into the minimization in (3.18). Note, however, that this last maximization involves ζ_o, the minimum of (3.17). Furthermore, the lemma shows only that the minimizers of (3.17) are a subset of the maximizers of (3.18). For the class of structured constraints we consider below, we show that the maximizers of (3.18) are (i) independent of ζ_o and (ii) are also minimizers for (3.17).

3.7. $\boldsymbol{\Delta_{11} = \Delta^m_{\phi_1,\phi_2} := \{\Delta_{11} \in \mathcal{C}^{m\times m} : \rho(\Delta_{11}) \le \phi_1, \|\Delta_{11}\| \le \phi_2\},\ 0 \le \phi_1 \le \phi_2 \le 1}$. Finally, we evaluate the structured distance to singularity for a subset of $\boldsymbol{\Delta_{11}}$ defined in subsection 3.6.

PROBLEM 3.13. *Let A and E_1 be as in Definition* 3.1. *Then for any $0 \le \phi_1 \le \phi_2 \le 1$, find the structured distance to singularity*

$$\gamma_{\boldsymbol{\Delta}^m_{\phi_1,\phi_2}} = \min\{\|\Delta\| : \det(A-\Delta) = 0,\ E_1{}'\Delta E_1 \in \boldsymbol{\Delta}^m_{\phi_1,\phi_2}\}, \tag{3.19}$$

where

$$\boldsymbol{\Delta}^m_{\phi_1,\phi_2} = \left\{ \Delta_{11} = \begin{bmatrix} \delta_{11} & \cdots & \delta_{1,m} \\ \vdots & \ddots & \vdots \\ 0 & \cdots & \delta_{mm} \end{bmatrix} \in \mathcal{C}^{m\times m} : |\delta_{ii}| \le \phi_1\ \forall i; \delta_{ij} = 0\ \forall i > j; \|\Delta_{11}\| \le \phi_2 \right\}, \tag{3.20}$$

and the set of all structured rank reducing perturbations

$$\mathcal{D}_{\boldsymbol{\Delta}^m_{\phi_1,\phi_2}} := \left\{ \Delta \in \mathcal{C}^{n\times n} : \|\Delta\| = \gamma_{\boldsymbol{\Delta}^m_{\phi_1,\phi_2}},\ \det(A-\Delta) = 0,\ E_1{}'\Delta E_1 \in \boldsymbol{\Delta}^m_{\phi_1,\phi_2} \right\}. \tag{3.21}$$
