Remark 3.14. The structured distance to singularity in (3.19) is unchanged if Δ is replaced with $W'\Delta W$, where $W = \operatorname{diag}(W_1, I_{n-m})$ and $W_1 \in \mathcal{C}^{m\times m}$ is any unitary matrix. So (3.20) is the upper triangular Schur form of the structured constraint set

$$\{\Delta_{11} \in \mathcal{C}^{m\times m} : \rho(\Delta_{11}) \le \phi_1, \|\Delta_{11}\| \le \phi_2\}.$$

We opted for (3.20) for convenience.

Remark 3.15. Note that, unlike the block diagonal uncertainty set associated with the structured singular value, the perturbation set $\boldsymbol{\Delta}^m_{\phi_1,\phi_2}$ is not a vector space. However, if $\gamma > 0$, then $\boldsymbol{\Delta}^m_{\gamma\phi_1,\gamma\phi_2} = \gamma\boldsymbol{\Delta}^m_{\phi_1,\phi_2}$. In the next section, we use this observation to relate the results of this section to the structured singular value.

It follows from Lemmas 3.7 and 3.11 that the evaluation of the distance to singularity requires the solution of the maximization problem in (3.18). Theorem 3.19 below proves that all maximizers for $\max_{\Delta_{11}\in\boldsymbol{\Delta}^m_{\phi_1,\phi_2}} \|I + \zeta(I-\Delta_{11})^{-1}\|$ are independent of $\zeta\ \forall\ \zeta > 0$, are all minimizers for (3.17), and are given by

$$\boldsymbol{\Delta}^m_{\phi_1,\phi_2,\mathrm{all}} = \{T'\Delta^m_{\phi_1,\phi_2}T : T \in \mathcal{C}^{m\times m}, T'T = I, T \text{ is diagonal}\}, \tag{3.22}$$

where $\Delta^m_{\phi_1,\phi_2} \in \boldsymbol{\Delta}^m_{\phi_1,\phi_2}$ is the upper triangular Toeplitz matrix defined by

$$\Delta^m_{\phi_1,\phi_2,ij} = \left\{ \begin{array}{cc} 0, & j < i \\ \phi_1, & j = i \\ (-\frac{\phi_1}{\phi_2})^{j-i-1}\frac{\phi_2^2-\phi_1^2}{\phi_2}, & j > i \end{array} \right\}, \tag{3.23}$$

e.g. for $m = 5$,

$$\Delta^m_{\phi_1,\phi_2} = \begin{bmatrix} \phi_1 & \frac{\phi_2^2-\phi_1^2}{\phi_2} & -\frac{\phi_1}{\phi_2}\frac{\phi_2^2-\phi_1^2}{\phi_2} & (\frac{\phi_1}{\phi_2})^2\frac{\phi_2^2-\phi_1^2}{\phi_2} & -(\frac{\phi_1}{\phi_2})^3\frac{\phi_2^2-\phi_1^2}{\phi_2} \\ 0 & \phi_1 & \frac{\phi_2^2-\phi_1^2}{\phi_2} & -\frac{\phi_1}{\phi_2}\frac{\phi_2^2-\phi_1^2}{\phi_2} & (\frac{\phi_1}{\phi_2})^2\frac{\phi_2^2-\phi_1^2}{\phi_2} \\ 0 & 0 & \phi_1 & \frac{\phi_2^2-\phi_1^2}{\phi_2} & -\frac{\phi_1}{\phi_2}\frac{\phi_2^2-\phi_1^2}{\phi_2} \\ 0 & 0 & 0 & \phi_1 & \frac{\phi_2^2-\phi_1^2}{\phi_2} \\ 0 & 0 & 0 & 0 & \phi_1 \end{bmatrix}.$$

We first derive some properties of $\Delta^m_{\phi_1,\phi_2}$. The constraints in (3.20) can be written as

$$|\lambda_i(\Delta_{11})| \le \phi_1, \quad \sigma_i(\Delta_{11}) \le \phi_2 \ \forall i.$$

All the eigenvalues of $\Delta^m_{\phi_1,\phi_2}$ are equal to ϕ_1 so that the spectral radius constraint in $\mathbf{\Delta}^m_{\phi_1,\phi_2}$ is maximally achieved by $\Delta^m_{\phi_1,\phi_2}$. The next result gives the singular values of $\Delta^m_{\phi_1,\phi_2}$ and gives an idea of how the singular value constraints are also maximally achieved.

LEMMA 3.16. *For $m>1$, partition $\Delta^m_{\phi_1,\phi_2}$ as*

$$\Delta^m_{\phi_1,\phi_2} = \begin{bmatrix} \Delta^{m-1}_{\phi_1,\phi_2} & x_m \\ 0 & \phi_1 \end{bmatrix}.$$

Then

$$x_m x_m' = \frac{\phi_2^2-\phi_1^2}{\phi_2^2}[\phi_2^2 I_{m-1} - (\Delta^{m-1}_{\phi_1,\phi_2})(\Delta^{m-1}_{\phi_1,\phi_2})']. \tag{3.24}$$

Hence,

$$\lambda_i(\Delta^m_{\phi_1,\phi_2})=\phi_1 \ \forall i; \quad \sigma_i(\Delta^m_{\phi_1,\phi_2})=\phi_2, i\le m-1; \quad \sigma_m(\Delta^m_{\phi_1,\phi_2})=\phi_1\left(\frac{\phi_1}{\phi_2}\right)^{m-1}. \tag{3.25}$$

Finally, all $\Delta_{11} \in \mathbf{\Delta}^m_{\phi_1,\phi_2}$ such that (3.25) *is satisfied are given by $\mathbf{\Delta}^m_{\phi_1,\phi_2,\mathrm{all}}$ in* (3.22).

Proof. Note first that

$$x_{m+1} = \begin{bmatrix} -\frac{\phi_1}{\phi_2}x_m \\ \frac{\phi_2^2-\phi_1^2}{\phi_2} \end{bmatrix}.$$

The result is clearly true for $m=2$. Assume the result for m and let $\alpha = \frac{\phi_2^2-\phi_1^2}{\phi_2^2}$. Then,

$$\alpha[\phi_2^2 I - (\Delta^m_{\phi_1,\phi_2})(\Delta^m_{\phi_1,\phi_2})'] = \alpha \begin{bmatrix} \phi_2^2 I_{m-1} - (\Delta^{m-1}_{\phi_1,\phi_2})(\Delta^{m-1}_{\phi_1,\phi_2})' - x_m x_m' & -x_m\phi_1 \\ -\phi_1 x_m' & \phi_2^2-\phi_1^2 \end{bmatrix}$$
$$= \begin{bmatrix} \frac{\phi_1^2}{\phi_2^2}x_m x_m' & -\frac{\phi_1}{\phi_2}\frac{\phi_2^2-\phi_1^2}{\phi_2}x_m \\ -\frac{\phi_1}{\phi_2}\frac{\phi_2^2-\phi_1^2}{\phi_2}x_m' & (\frac{\phi_2^2-\phi_1^2}{\phi_2})^2 \end{bmatrix} = x_{m+1}x_{m+1}'.$$

This proves the first result and establishes that $[\phi_2^2 I - (\Delta^m_{\phi_1,\phi_2})(\Delta^m_{\phi_1,\phi_2})']$ is a nonnegative rank 1 matrix. It follows that $m-1$ singular values of $\Delta^m_{\phi_1,\phi_2}$ are equal to ϕ_2. Since $\Delta^m_{\phi_1,\phi_2}$ has m eigenvalues equal to ϕ_1, it follows that the smallest singular value is $\phi_1(\frac{\phi_1}{\phi_2})^{m-1}$, which proves (3.25). To prove the last part, let

$$\Delta_m = \begin{bmatrix} \Delta_{m-1} & x_m \\ 0 & \phi_1 \end{bmatrix} \in \mathbf{\Delta}^m_{\phi_1,\phi_2}$$

satisfy (3.25). Then $\phi_2^2 I - \Delta_m\Delta_m' \ge 0$ and has rank 1. Thus

$$\phi_2^2 I - \Delta_m\Delta_m' = \begin{bmatrix} \phi_2^2 I_{m-1} - \Delta_{m-1}\Delta_{m-1}' - x_m x_m' & -\phi_1 x_m \\ -\phi_1 x_m' & \phi_2^2-\phi_1^2 \end{bmatrix} = \begin{bmatrix} x_1 \\ x_2 \end{bmatrix}\begin{bmatrix} x_1' & \bar{x}_2 \end{bmatrix},$$

for some $\begin{bmatrix} x_1 \\ x_2 \end{bmatrix} \in \mathcal{C}^{m\times 1}$. Solving for x_1 and x_2 gives

$$x_m x_m' = \frac{\phi_2^2-\phi_1^2}{\phi_2^2}(\phi_2^2 I_{m-1} - \Delta_{m-1}\Delta_{m-1}'), \tag{3.26}$$

so that (3.25) is satisfied for Δ_{m-1} with m replaced by $m-1$. Repeating the procedure with Δ_m replaced by Δ_{m-1} shows that (3.26) is satisfied. Since $\Delta^m_{\phi_1,\phi_2}$ satisfies (3.24), it follows that the only nonuniqueness is in the Cholesky factorizations in (3.26). It is a simple exercise to verify that this is covered by (3.22). ∎

Before we state our main results, we need the following two technical lemmas.

LEMMA 3.17. *Suppose that* $L = L_1 - L_2$ *with* $L_1 = L_1' > 0$, $L_2 = L_2' \geq 0$, $\operatorname{rank}(L_2) = 1$, *and* $L = L' \geq 0$. *Let* $Y = \beta L_2 - L_3$ *with* $\beta > 0$, $L_3 = L_3' \geq 0$, $\operatorname{rank}(L_3) = 1$, *and* $Y = Y' \geq 0$. *Then for any* $\epsilon > 0$,

$$\underline{\lambda}(L + \epsilon Y) = \underline{\lambda}(L) = 0 \Rightarrow Y = 0.$$

Proof. First write L_2 and L_3 in the forms $L_2 = l_2 l_2'$ and $L_3 = l_3 l_3'$, where l_2 and l_3 are column vectors, and decompose l_3 in directors parallel and orthogonal to l_2, i.e.,

$$l_3 = \frac{l_2' l_3}{\|l_2\|^2} l_2 + p, \quad p := l_3 - \frac{l_2' l_3}{\|l_2\|^2} l_2.$$

Clearly $l_2' p = 0$. Thus, $Y = \beta l_2 l_2' - l_3 l_3' \geq 0 \Rightarrow \beta p' l_2 l_2' p = 0 \geq p' l_3 l_3' p \Rightarrow l_3' p = 0$. Hence,

$$l_3' \left(l_3 - \frac{l_2' l_3}{\|l_2\|^2} l_2 \right) = 0 \quad \Rightarrow |l_2' l_3| = \|l_2\| \|l_3\|,$$

and hence $l_3 = \lambda l_2$ for some $\lambda \in \mathcal{C}$. Using again $Y \geq 0$ shows that $|\lambda| \leq \sqrt{\beta}$, and so

$$Y = \beta \left(1 - \frac{|\lambda|^2}{\beta} \right) L_2 := \alpha\beta L_2,$$

for some $0 \leq \alpha \leq 1$. Suppose that $\alpha > 0$, so that $Y \neq 0$. Pick a nonzero vector y such that $y'(L + \epsilon Y)y = 0$. Then

$$y'(L + \epsilon Y)y = 0 \Rightarrow y' L y = 0, y' Y y = 0 \Rightarrow y' L_2 y = 0 \Rightarrow y' L_1 y = 0,$$

contradicting the positive definiteness of L_1. ∎

LEMMA 3.18. *Let*

$$\Delta = \begin{bmatrix} \delta_{11} & \delta_{12} \\ 0 & \delta_{22} \end{bmatrix} \in \mathcal{C}^{2\times 2}.$$

There exists unitary W *such that*

$$W' \Delta W = \begin{bmatrix} \delta_{22} & \delta_{12} \\ 0 & \delta_{11} \end{bmatrix}.$$

Proof. If $\delta_{11} = \delta_{22}$, take $W = I_2$ and if $\delta_{12} = 0$, take W to be a permutation matrix. Otherwise take

$$W = \frac{1}{\sqrt{|\delta_{22} - \delta_{11}|^2 + |\delta_{12}|^2}} \begin{bmatrix} |\delta_{12}| & -(\bar{\delta}_{22} - \bar{\delta}_{11})|\delta_{12}|/\bar{\delta}_{12} \\ (\delta_{22} - \delta_{11})|\delta_{12}|/\delta_{12} & |\delta_{12}| \end{bmatrix}. \qquad ∎$$

The following is our main result for this section.

THEOREM 3.19. *Let $0 \le \phi_1 \le \phi_2 \le 1$, with $\phi_1 < 1$. Consider the optimization*

$$\max \{\|I + \zeta(I - \Delta_{11})^{-1}\| : \Delta_{11} \in \mathbf{\Delta}^m_{\phi_1,\phi_2}\}. \tag{3.27}$$

Then $\Delta^m_{\phi_1,\phi_2}$ is a maximizer for all $\zeta \ge 0$, where $\mathbf{\Delta}^m_{\phi_1,\phi_2}$ is defined in (3.20) *and $\Delta^m_{\phi_1,\phi_2}$ in* (3.23). *Furthermore, for all $\zeta > 0$, the set of all maximizers is given by $\mathbf{\Delta}^m_{\phi_1,\phi_2,\mathrm{all}}$ defined in* (3.22). *Finally, $\mathbf{\Delta}^m_{\phi_1,\phi_2,\mathrm{all}}$ is the set of all minimizers for* (3.17).

Proof. Let $\Delta^m_{11} \in \mathbf{\Delta}^m_{\phi_1,\phi_2}$ be partitioned as

$$\Delta^m_{11} = \begin{bmatrix} \Delta^{m-1}_{11} & x \\ 0 & \delta \end{bmatrix},$$

and define $X = I - \Delta^{m-1}_{11}$ and $F = I + \zeta X^{-1}$. Using a Schur complement argument,

$$\begin{aligned}
\|\Delta^m_{11}\| \le \phi_2 &\Leftrightarrow \phi_2^2 I - \Delta^m_{11}(\Delta^m_{11})' \ge 0 \\
&\Leftrightarrow \begin{bmatrix} \phi_2^2 I - \Delta^{m-1}_{11}(\Delta^{m-1}_{11})' - xx' & -\bar{\delta}x \\ -\delta x' & \phi_2^2 - |\delta|^2 \end{bmatrix} \ge 0 \\
&\Leftrightarrow \phi_2^2 I - \Delta^{m-1}_{11}(\Delta^{m-1}_{11})' - xx' - \frac{|\delta|^2}{\phi_2^2 - |\delta|^2} xx' \ge 0 \\
&\Leftrightarrow xx' \le \frac{\phi_2^2 - |\delta|^2}{\phi_2^2}(\phi_2^2 I - \Delta^{m-1}_{11}(\Delta^{m-1}_{11})') \\
&\Leftrightarrow X^{-1}xx'X^{-\prime} \le \frac{\phi_2^2 - |\delta|^2}{\phi_2^2}[X^{-1} + X^{-\prime} - I - (1 - \phi_2^2)X^{-1}X^{-\prime}] \\
&\Leftrightarrow X^{-1}xx'X^{-\prime} = \frac{\phi_2^2 - |\delta|^2}{\phi_2^2}[X^{-1} + X^{-\prime} - I - (1 - \phi_2^2)X^{-1}X^{-\prime}] - Y,
\end{aligned}$$

for some Y such that

$$0 \le Y = Y' \le \frac{\phi_2^2 - |\delta|^2}{\phi_2^2}[X^{-1} + X^{-\prime} - I - (1 - \phi_2^2)X^{-1}X^{-\prime}]. \tag{3.28}$$

Now,

$$\begin{aligned}
\gamma &= \|I + \zeta(I - \Delta^m_{11})^{-1}\| \\
&\Leftrightarrow \underline{\lambda}\left(\begin{bmatrix} \gamma^2 I - FF' - \frac{\zeta^2}{|1-\delta|^2}X^{-1}xx'X^{-\prime} & -\frac{\zeta}{1-\delta}(1 + \frac{\zeta}{1-\delta})X^{-1}x \\ -\frac{\zeta}{1-\delta}(1 + \frac{\zeta}{1-\delta})x'X^{-\prime} & \gamma^2 - |1 + \frac{\zeta}{1-\delta}|^2 \end{bmatrix}\right) = 0 \\
&\Leftrightarrow \underline{\lambda}\left[\gamma^2 I - FF' - \frac{\zeta^2\gamma^2}{|1-\delta|^2(\gamma^2 - |1 + \frac{\zeta}{1-\delta}|^2)}X^{-1}xx'X^{-\prime}\right] = 0 \\
&\Leftrightarrow \underline{\lambda}\left[L(\gamma^2) + \frac{\zeta^2\gamma^2}{|1-\delta|^2}Y\right] = 0,
\end{aligned}$$

where we have set

$$L(\gamma^2) = \left(\gamma^2 - |1 + \frac{\zeta}{1-\delta}|^2\right)(\gamma^2 I - FF') - \frac{\zeta^2\gamma^2}{|1-\delta|^2}\frac{\phi_2^2 - |\delta|^2}{\phi_2^2}[X^{-1} + X^{-\prime} - I - (1 - \phi_2^2)X^{-1}X^{-\prime}],$$

and where we have assumed that $\gamma > \max\{|1 + \frac{\zeta}{1-\delta}|^2, \|(I + \zeta X^{-1})\|\}$ since the right-hand side is clearly not the maximum γ. Thus (3.27) can be written as

$$\max\left\{\gamma : \underline{\lambda}\left[L(\gamma^2) + \frac{\zeta^2\gamma^2}{|1-\delta|^2}Y\right] = 0, |\delta| \le \phi_1, \Delta^{m-1}_{11} \in \mathbf{\Delta}^{m-1}_{\phi_1,\phi_2}, Y \text{ satisfies (3.28)}\right\}. \tag{3.29}$$

Next, we maximize (3.29) with respect to Y; that is, for given $\Delta_{11}^{m-1} \in \mathbf{\Delta}_{\phi_1,\phi_2}^{m-1}$ and $\delta \in \mathcal{C}$ such that $|\delta| \le \phi_1$, we solve

$$\max\left\{\gamma : \underline{\lambda}\left[L(\gamma^2) + \frac{\zeta^2\gamma^2}{|1-\delta|^2}Y\right] = 0, \quad Y \text{ satisfies (3.28)}\right\}. \tag{3.30}$$

Since $Y = Y' \ge 0$, $L(0) > 0$, and $L(\gamma^2) \sim \gamma^4 I > 0$ as $\gamma^2 \to \infty$, it follows that γ is maximized by $Y = 0$. Note that

$$\begin{aligned} Y = 0 &\Leftrightarrow xx' = \frac{\phi_2^2 - |\delta|^2}{\phi_2^2}(\phi_2^2 I - \Delta_{11}^{m-1}(\Delta_{11}^{m-1})') \\ &\Rightarrow \operatorname{rank}(\phi_2^2 I - \Delta_{11}^{m}(\Delta_{11}^{m})') = 1 \\ &\Leftrightarrow \sigma_i(\Delta_{11}^{m}) = \phi_2; i \le m-1 \end{aligned}$$

and is therefore feasible since Δ_{ϕ_1,ϕ_2}^m satisfies this property. That $Y = 0$ is the only maximizer for (3.30) follows from Lemma 3.17 with

$$\begin{aligned} &L_1 = (\gamma_o^2 - |1 + \tfrac{\zeta}{1-\delta}|^2)(\gamma_o^2 I - FF'), && \beta = \tfrac{|1-\delta|^2}{\zeta^2\gamma_o^2}, && \epsilon = \tfrac{\zeta^2\gamma_o^2}{|1-\delta|^2}, \\ &L_2 = \tfrac{\zeta^2\gamma_o^2}{|1-\delta|^2}\tfrac{\phi_2^2 - |\delta|^2}{\phi_2^2}[X^{-1} + X^{-\prime} - I - (1-\phi_2^2)X^{-1}X^{-\prime}], && L_3 = X^{-1}xx'X^{-\prime}, \end{aligned}$$

where γ_o is the maximum in (3.30). It follows that (3.29) can be written as

$$\max\left\{\gamma : \underline{\lambda}[L(\gamma^2)] = 0, |\delta| \le \phi_1, xx' = \frac{\phi_2^2 - |\delta|^2}{\phi_2^2}(\phi_2^2 I - \Delta_{11}^{m-1}(\Delta_{11}^{m-1})'), \Delta_{11}^{m-1} \in \mathbf{\Delta}_{\phi_1,\phi_2}^{m-1}\right\}.$$

Next, we maximize γ with respect to δ. Now,

$$\begin{aligned} \underline{\lambda}[L(\gamma^2)] = 0 &\Leftrightarrow \underline{\lambda}\left[\gamma^2 I - FF' - \frac{\zeta^2\gamma^2(\phi_2^2 - |\delta|^2)/\phi_2^2}{|1-\delta|^2(\gamma^2 - |1 + \frac{\zeta}{1-\delta}|^2)}BB'\right] = 0 \\ &\Leftrightarrow \gamma^2 - \left|1 + \frac{\zeta}{1-\delta}\right|^2 - \frac{\zeta^2\gamma^2(\phi_2^2 - |\delta|^2)}{\phi_2^2|1-\delta|^2}B'(\gamma^2 I - FF')^{-1}B = 0, \end{aligned}$$

where $BB' := X^{-1} + X^{-\prime} - I - (1-\phi_2^2)X^{-1}X^{-\prime}$. Setting $\delta = r\phi_1 e^{j\theta}$, with $0 \le r \le 1$ and $-\pi \le \theta \le \pi$, a simple calculation gives

$$\frac{\partial\gamma^2}{\partial\theta} = \frac{2r\phi_1(1 + \zeta - \phi_2^2\gamma^2)\sin\theta}{\phi_2^2(1 - 2r\phi_1\cos\theta + r^2\phi_1^2) + \zeta^2(\phi_2^2 - r^2\phi_1^2)B'(\gamma^2 I - FF')^{-1}FF'(\gamma^2 I - FF')^{-1}B},$$

which vanishes when δ is real. Setting δ real,

$$\frac{\partial\gamma^2}{\partial\delta} = \frac{2\zeta}{1-\delta}\,\frac{1 + \zeta - \delta + \gamma^2\zeta(\phi_2^2 - \delta)B'(\gamma^2 I - FF')^{-1}B}{\phi_2^2(1-\delta)^2 + \zeta^2(\phi_2^2 - \delta^2)B'(\gamma^2 I - FF')^{-1}FF'(\gamma^2 I - FF')^{-1}B},$$

which is positive for all δ, so γ is maximized by $\delta = \phi_1$. It follows from Lemma 3.18 that all diagonal entries of a maximizing Δ_{11}^m are equal to ϕ_1 since, if not, we can use a sequence of unitary similarity transformations that preserve the upper triangular structure of Δ_{11}^m to bring this diagonal entry to the (m, m) entry, contradicting the maximality of Δ_{11}^m. It follows from the last part of Lemma 3.16 that Δ_{ϕ_1,ϕ_2}^m is a maximizer and all maximizers are given by $\mathbf{\Delta}_{\phi_1,\phi_2,\text{all}}^m$. Note that the maximizers for

(3.27) are independent of ζ. Finally, Lemma 3.11 shows that all minimizers for (3.17) are a subset of all maximizers for (3.27). However, it is clear that the cost function in (3.17) is the same for all $\Delta_{11}^m \in \mathbf{\Delta}^m_{\phi_1,\phi_2,\text{all}}$. This proves the last part. ∎

The solution of Problem 3.13 is now summarized in the following result.

COROLLARY 3.20. *Let all variables be as in Problem* 3.13. *Then*

$$\begin{aligned}\gamma^2_{\mathbf{\Delta}^m_{\phi_1,\phi_2}} &:= \min_{\substack{\det(A-\Delta)=0\\ E_1{}'\Delta E_1 \in \mathbf{\Delta}^m_{\phi_1,\phi_2}}} \|\Delta\|^2 = \min_{\substack{\|(\gamma^2 I-\Delta_{11})(I-\Delta_{11})^{-1}\|=a_{m+1}\\ \gamma>1\\ \Delta_{11}\in\mathbf{\Delta}^m_{\phi_1,\phi_2}}} \gamma^2\\ &= \min_{\substack{\|(\gamma^2 I-\Delta^m_{\phi_1,\phi_2})(I-\Delta^m_{\phi_1,\phi_2})^{-1}\|=a_{m+1}\\ \gamma>1}} \gamma^2 = 1 + \min_{\substack{\|I+\zeta(I-\Delta_{11})^{-1}\|=a_{m+1}\\ \zeta>0\\ \Delta_{11}\in\mathbf{\Delta}^m_{\phi_1,\phi_2}}} \zeta\\ &= 1 + \min_{\substack{\|I+\zeta(I-\Delta^m_{\phi_1,\phi_2})^{-1}\|=a_{m+1}\\ \zeta>0}} \zeta = 1+\zeta_{\mathbf{\Delta}^m_{\phi_1,\phi_2}},\end{aligned}$$

where

$$\zeta^{-1}_{\mathbf{\Delta}^m_{\phi_1,\phi_2}} = \bar{\lambda}\left(\begin{bmatrix} \frac{(I-\Delta^m_{\phi_1,\phi_2})^{-1}+(I-\Delta^m_{\phi_1,\phi_2}{}')^{-1}}{a^2_{m+1}-1} & -\frac{(I-\Delta^m_{\phi_1,\phi_2})^{-1}}{\sqrt{a^2_{m+1}-1}}\\ -\frac{(I-\Delta^m_{\phi_1,\phi_2}{}')^{-1}}{\sqrt{a^2_{m+1}-1}} & 0\end{bmatrix}\right).$$

Remark 3.21. To characterize the set of all optimal structured perturbations in (3.21) we proceed as follows. Theorem 3.19 gives $\mathbf{\Delta}^m_{\phi_1,\phi_2,\text{all}}$ as the set of minimizers for (3.17). Remark 3.14 shows that we can absorb the unitary diagonal T in (3.22) in a unitary W_1. This gives all leading $m\times m$ blocks of (3.21) (it can be shown that if $\phi_1=\phi_2$, then this gives only a class of solutions). For the other blocks, we appeal to Remark 3.10 with Δ_{11} replaced by $\Delta^m_{\phi_1,\phi_2}$. We spare the readers the full details.

The following result gives an interpretation of $\Delta^m_{\phi_1,\phi_2}$. Since the solution of Theorem 3.19 is independent of ζ, letting $\zeta\to\infty$ suggests the following.

THEOREM 3.22. *Let* $0\le\phi_1\le\phi_2\le 1$ *be given. Consider the minimization*

$$\min\{\underline{\sigma}(I-\Delta_{11}) : \Delta_{11}\in\mathbf{\Delta}^m_{\phi_1,\phi_2}\} = \left(\max\{\|(I-\Delta_{11})^{-1}\| : \Delta\in\mathbf{\Delta}^m_{\phi_1,\phi_2}\}\right)^{-1}.$$

Then $\Delta_{11}=\Delta^m_{\phi_1,\phi_2}$ *is a minimizer and the set of all minimizers is given by* $\mathbf{\Delta}^m_{\phi_1,\phi_2,\text{all}}$.

Proof. The proof is almost identical to that of Theorem 3.19 and is omitted. ∎

Remark 3.23. Thus an interpretation of $\Delta^m_{\phi_1,\phi_2}$ is that it is the "most nearly rank reducing matrix" within $\mathbf{\Delta}^m_{\phi_1,\phi_2}$ to the identity matrix. This generalizes the unstructured as well as the structured case for $m=1$.

4. Upper bound on the structured singular value. In this section we use our previous results to derive an upper bound on the structured singular value.

THEOREM 4.1. *Let* $M\in\mathcal{C}^{n\times n}$ *be as defined in section* 2 *and let* $\mathbf{\Delta}\subseteq\mathcal{C}^{n\times n}$ *denote a block diagonal structured uncertainty set. Let* $\bar{\phi}_1$ *and* $\bar{\phi}_2$ *be upper bounds on the maximizations in* (2.5) *and* (2.6), *respectively, and assume that* $0\le\bar{\phi}_1\le\bar{\phi}_2\le 1$. *Then a lower bound on the structured stability radius* $r_{\mathbf{\Delta}}(M)$, *defined as in* (2.2), *is given by*

$$\begin{aligned}\underline{r}_{\mathbf{\Delta}}(M) &:= \min\{\|\Delta\| : \det(I-\Delta\Sigma)=0, \rho(E_1{}'\Delta E_1)\le\bar{\phi}_1\|\Delta\|, \|E_1{}'\Delta E_1\|\le\bar{\phi}_2\}\\ &= \min\{\gamma : \|(\gamma I-\Delta^m_{\bar{\phi}_1,\bar{\phi}_2})(\gamma^{-1}I-\Delta^m_{\bar{\phi}_1,\bar{\phi}_2})^{-1}\| = \sigma^{-1}_{m+1}, \gamma\ge 1\}\ge 1 \qquad (4.1)\end{aligned}$$

and is decreasing in σ_{m+1}, *where* $\Delta^m_{\bar{\phi}_1,\bar{\phi}_2}$ *is defined in* (3.23). *Furthermore,*

$$\bar{\phi}_1 < 1 \Rightarrow r_{\mathbf{\Delta}}(M) > 1 \quad \textit{and} \quad \underline{r}_{\mathbf{\Delta}}(M) > 1.$$

Finally, $r_{\mathbf{\Delta}}(M) = \underline{r}_{\mathbf{\Delta}}(M)$ *if and only if there exists* $\Delta \in \mathbf{\Delta}$ *such that*

$$V_1'\Delta U_1 = [\underline{r}_{\mathbf{\Delta}}(M)]^{-1} W' \Delta^m_{\bar{\phi}_1,\bar{\phi}_2} W,$$

for some unitary W.

Proof. The first part follows from (2.9), Remark 3.15, and Corollary 3.20. First note that

$$\begin{aligned}
\gamma_{\mathbf{\Delta}^m_{\bar{\phi}_1,\bar{\phi}_2}} &= \min\{\|\Delta\| : \det(A-\Delta) = 0, \rho(E_1{}'\Delta E_1) \le \bar{\phi}_1, \|E_1'\Delta E_1\| \le \bar{\phi}_2\} \\
&= \min\{\gamma : \|(\gamma^2 I - \Delta^m_{\bar{\phi}_1,\bar{\phi}_2})(I - \Delta^m_{\bar{\phi}_1,\bar{\phi}_2})^{-1}\| = a_{m+1}, \gamma > 1\} \\
&= \min\{\gamma : \|(\gamma I - \gamma^{-1}\Delta^m_{\bar{\phi}_1,\bar{\phi}_2})(\gamma^{-1} I - \gamma^{-1}\Delta^m_{\bar{\phi}_1,\bar{\phi}_2})^{-1}\| = a_{m+1}, \gamma > 1\} \\
&= \min\{\gamma : \|(\gamma I - \Delta_{\gamma^{-1}\bar{\phi}_1,\gamma^{-1}\bar{\phi}_2})(\gamma^{-1} I - \Delta_{\gamma^{-1}\bar{\phi}_1,\gamma^{-1}\bar{\phi}_2})^{-1}\| = a_{m+1}, \gamma > 1\}. \qquad (4.2)
\end{aligned}$$

To turn the "absolute" bounds $\rho(E_1'\Delta E_1) \le \bar{\phi}_1$ and $\|E_1'\Delta E_1\| \le \bar{\phi}_2$ into the "relative" bounds $\rho(E_1'\Delta E_1) \le \bar{\phi}_1\|\Delta\|$ and $\|E_1'\Delta E_1\| \le \bar{\phi}_2\|\Delta\|$, we simply write $\rho(E_1'\Delta E_1) \le \frac{\bar{\phi}_1}{\gamma}\gamma$ and $\|E_1'\Delta E_1\| \le \frac{\bar{\phi}_2}{\gamma}\gamma$; i.e., we re-define $\gamma^{-1}\bar{\phi}_1 \to \bar{\phi}_1$ and $\gamma^{-1}\bar{\phi}_2 \to \bar{\phi}_2$ in (4.2), which gives immediately the required expression for $\underline{r}_{\mathbf{\Delta}}(M)$. The fact that $\underline{r}_{\mathbf{\Delta}}(M)$ is (strictly) decreasing in σ_{m+1} follows from Lemma 3.11 since $a_{m+1} = \sigma_{m+1}^{-1}$.The fact that $r_{\mathbf{\Delta}}(M) > 1$ if $\bar{\phi}_1 < 1$ follows from Corollary 3.20. Finally, consider the two minimization problems in (2.9). The set of all minimizers in the right-hand side of (2.9) is given by all $\Delta \in \mathcal{C}^{n\times n}$ such that $\det(A-\Delta) = 0$, $\rho(E_1'\Delta E_1) \le \bar{\phi}_1 \underline{r}_{\mathbf{\Delta}}(M)$, and $\|E_1'\Delta E_1\| \le \bar{\phi}_2 \underline{r}_{\mathbf{\Delta}}(M)$, or equivalently,

$$E_1'\Delta E_1 = W \Delta^m_{\bar{\phi}_1 \underline{r}_{\mathbf{\Delta}}^{-1}(M), \bar{\phi}_2 \underline{r}_{\mathbf{\Delta}}^{-1}(M)} W' = \underline{r}_{\mathbf{\Delta}}^{-1}(M) W \Delta^m_{\bar{\phi}_1,\bar{\phi}_2} W',$$

where W is an arbitrary unitary matrix (see Remarks 3.14, 3.15, and 3.21). Now equality is possible in (2.9) if and only if there exists a minimizer of the left-hand side of (2.9), which is also a minimizer of the right-hand side of (2.9), i.e., if and only if there exists a $\Delta \in \mathbf{\Delta}$ such that $V_1'\Delta U_1 = [\underline{r}_{\mathbf{\Delta}}(M)]^{-1} W' \Delta^m_{\bar{\phi}_1,\bar{\phi}_2} W$. ∎

Remark 4.2. The evaluation of $\underline{r}_{\mathbf{\Delta}}(M)$ in (4.1) is a simple eigenvalue problem of dimension $4m \times 4m$, as the following development shows. Let $a = \sigma_{m+1}^{-1}$ and $\Psi = \Delta^m_{\bar{\phi}_1,\bar{\phi}_2}$. Then

$$\begin{aligned}
a &= \|(\gamma I - \Psi)(\gamma^{-1} I - \Psi)^{-1}\| \\
&\Rightarrow \det\{a^2 I - (\gamma^{-1} I - \Psi')^{-1}(\gamma I - \Psi')(\gamma I - \Psi)(\gamma^{-1} I - \Psi)^{-1}\} = 0 \\
&\Rightarrow \det\{\gamma^4 I - \gamma^3(\Psi + \Psi') - \gamma^2(a^2-1)\Psi'\Psi + \gamma a^2(\Psi + \Psi') - a^2 I\} = 0 \\
&\Rightarrow \det\left(\gamma I - \begin{bmatrix} 0 & I & 0 & 0 \\ 0 & 0 & I & 0 \\ 0 & 0 & 0 & I \\ a^2 I & -a^2(\Psi+\Psi') & (a^2-1)\Psi'\Psi & \Psi + \Psi' \end{bmatrix}\right) = 0. \qquad (4.3)
\end{aligned}$$

It follows that γ is the smallest real eigenvalue larger than 1 of the $4m \times 4m$ block matrix in (4.3).

Remark 4.3. The work shows that if we can get an upper bound on $\mu_{\mathbf{\Delta}}(M_0)$, where M_0 is defined in (2.7) and is a reduced rank matrix (with the rank equal to the multiplicity of the largest singular value of M), then we can easily obtain a bound on M. This suggests that μ is "hard" for unitary M.

Remark 4.4. The theorem is a generalization of the result in [14] which solved the case $m = 1$. That result was limited since, at the end of the D-iteration, the largest singular value has multiplicity larger than one (otherwise it is equal to $\mu_{\mathbf{\Delta}}(M)$) [21].

In the final part of this section we outline the main steps of an algorithm which may be used to breach the D-iteration upper bound of M, provided a reduced rank μ problem can be solved.

ALGORITHM 4.5. *Given $M \in \mathcal{C}^{n\times n}$ and a complex block diagonal uncertainty structure $\mathbf{\Delta}$, the following algorithm obtains an upper bound of $\mu_{\mathbf{\Delta}}(M)$, $\bar{\mu}_{\mathbf{\Delta}}(M)$:*

1. *(Optional.) Solve the LMI optimization* (2.3) *to obtain the D-iteration upper bound of M. Normalize M by absorbing the D-iteration scalings obtained from the optimization.*
2. *If step* 1 *has been carried out and the multiplicity of the largest singular value of M is one, then $\mu_{\mathbf{\Delta}}(M) = \bar{\mu}_{\mathbf{\Delta}}(M) = \|M\|$ and the algorithm terminates.*
3. *Normalize $\|M\| = 1$ by dividing by its norm. Carry out the singular value decomposition of M given in* (2.1) *and let m be the multiplicity of the largest singular value of M (which is* 1*).*
4. *If step* 1 *(optional) has been carried out, set $\bar{\phi}_2 = 1$; else solve the LMI optimization* (2.3) *and set $\bar{\phi}_2 = \sqrt{\gamma}$.*
5. *From the singular value decomposition in step* 3*, define the (reduced rank) matrix M_0 as in Remark* 2.2*. Calculate the tightest possible upper bound of $\mu_{\mathbf{\Delta}}(M_0)$ and set it equal to $\bar{\phi}_1$.*
6. *If $\bar{\phi}_1 = 1$, set $\bar{\mu}_{\mathbf{\Delta}}(M) = \|M\|$ (after reversing the scaling in step* 3 *and/or* 1*) and exit. No tighter bound can be obtained.*
7. *Set $\Psi = \Delta^m_{\bar{\phi}_1,\bar{\phi}_2}$ defined in* (3.23) *and $a = \sigma^{-1}_{m+1}$, where σ_{m+1} is the $(m+1)$st largest singular value of M.*
8. *Solve the $4m \times 4m$ eigenvalue problem given in* (4.3) *and set $\underline{r}_{\mathbf{\Delta}}(M)$ as the smallest real eigenvalue larger than one. Then $\bar{\mu}_{\mathbf{\Delta}}(M) = \underline{r}^{-1}_{\mathbf{\Delta}}(M)$ (after reversing the scaling in step* 3 *and/or* 1*).*

5. Example. Consider a modified example from [21] with uncertainty structure $m_c = 0$ and $m_C = 4$. Let a matrix $M \in \mathcal{C}^{4\times 4}$ after D-iteration have the form

$$M = \begin{bmatrix} U_1 & U_2 \end{bmatrix} \begin{bmatrix} I_2 & 0 \\ 0 & \Sigma_2 \end{bmatrix} \begin{bmatrix} V_1' \\ V_2' \end{bmatrix}, \quad U_1 = \begin{bmatrix} a & 0 \\ b & b \\ c & jc \\ d & f \end{bmatrix}, \quad V_1 = \begin{bmatrix} 0 & a \\ b & -b \\ c & -jc \\ e^{j\psi_1} f & e^{j\psi_2} d \end{bmatrix},$$

where $a = \sqrt{2/k}$, $b = c = 1/\sqrt{k}$, $d = -\sqrt{\beta/k}$, $f = (1+j)\sqrt{1/k\beta}$, $\psi_1 = -\pi/2$, and $\psi_2 = \pi$, with $k = 3 + \sqrt{3}$ and $\beta = \sqrt{3} - 1$. Also $\|\Sigma_2\| = \sigma_2$. Here, U_2 and V_2 are any unitary completions of U_1 and V_1, respectively. Let $M_0 = U_1 V_1'$. Then $\sigma_1(M_0) = 1$.

It is shown in [21] that $\mu_{\mathbf{\Delta}}(M_0) < 0.895 = \bar{\phi}_1$. (In fact, a rather involved calculation shows that

$$\mu_{\mathbf{\Delta}}(M_0) = \sqrt{\frac{1 + 2\sqrt{16 - 9\sqrt{3}}}{3}} = 0.872359\ldots,$$

although we use the value given in [21]). Figure 5.1 shows how the upper bound on $\mu_{\mathbf{\Delta}}(M) = \frac{1}{\underline{r}_{\mathbf{\Delta}}(M)}$ (calculated by finding the smallest root larger than 1 of the quartic in (4.3)) varies with σ_2. Note that the D-iteration upper bound is equal to 1 $\forall$ σ_2 such that $0 \le \sigma_2 \le 1$.

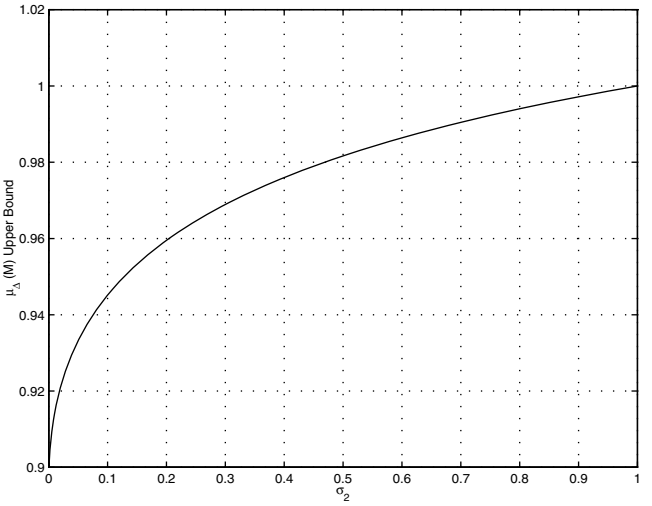

FIG. 5.1. *The upper bound on μ as a function of σ_2 for $0 \leq \sigma_2 < 1$, where $\sigma_1 = 1$ and $\bar{\phi}_1 = 0.895$ for matrix M.*

6. Summary. In this section we summarize our results. All variables are as defined in Theorem 4.1. Our main results are as follows:

- We have shown that $\mu_{\mathbf{\Delta}}(M) = 1$ if and only if $\mu_{\mathbf{\Delta}}(M_0) = 1$. It follows that determining whether there exists a gap between μ and its upper bound is equivalent to solving a μ problem of rank equal to the multiplicity of the largest singular value of M.
- We have shown that if we can obtain an upper bound on $\mu_{\mathbf{\Delta}}(M_0)$ less than 1, then we can give an upper bound on $\mu_{\mathbf{\Delta}}(M)$ which is smaller than 1.

Other secondary results are as follows:

- We used a semidefinite relaxation of the nonconvex optimization in (2.6) to derive an upper bound which admits no gap (Lemma 2.3).
- We generalized the distance to singularity results of [16] to the matrix case (Corollary 3.20).
- We solved a distance problem (Theorem 3.22).

7. Conclusions. The approach in [16] for tackling structured uncertainty was proposed around the time μ was proposed and seems to have been neglected. We have established a connection between these two approaches and we hope interest in the first approach will revive.

Hitherto, the interest in low rank μ problems has been limited to some properties concerning the gap between μ and its upper D-iteration bound, and to other theoretical considerations [20, 24, 25, 26]. We have shown that the solution of a reduced rank μ problem, which has limited direct relevance to realistic structured uncertainty descriptions, will induce an upper bound on the more relevant full rank problem. It is not clear at present whether the reduced rank μ problems constructed here have any special structure that makes them hard to compute. We hope that our work will spur more research on the reduced rank problem to help answer this question.

The approach followed here shares many characteristics with our previous work on the QIP problem [18] and potentially can be extended to a wide class of optimization problems utilizing convex relaxation techniques.

Appendix. Proof of Lemma 2.3. Let all variables be as defined in section 2. In order to fix notation, assume that

$$\mathbf{\Delta} = \{\Delta \in \mathcal{C}^{n\times n} \ : \ \Delta = \mathrm{diag}(\delta_1 I_{r_1}, \ldots, \delta_s I_{r_s}, \Delta_1, \ldots, \Delta_F), \delta_i \in \mathcal{C}, \Delta_j \in \mathcal{C}^{m_j \times m_j}\},$$

where $i \in \underline{S}$, $j \in \underline{F}$, and $n = \sum_{i=1}^{n} r_i + \sum_{i=1}^{F} m_i$. It follows that

$$\mathcal{D} = \{D = \mathrm{diag}(D_1, \ldots, D_s, d_1 I_{m_1}, \ldots, d_F I_{m_F}),\ D_i = D_i' \geq 0,\ d_j \geq 0\},$$

where $i \in \underline{S}$ and $j \in \underline{F}$. Define also the sets $\mathcal{Q} = \{\Delta \in \mathcal{B}\mathbf{\Delta} \ : \ \Delta\Delta' = I_n\}$, $\mathcal{D}_+ = \{D \in \mathcal{D} : D > 0\}$, and $\mathcal{Z} = \{D - \hat{D} : D, \hat{D} \in \mathcal{D}\}$. Clearly $\mathcal{Z}$ is a linear vector space consisting of all Hermitian matrices in $\mathcal{C}^{n\times n}$ with block diagonal structure inherited from $\mathcal{D}$, and thus $\mathcal{D} \subseteq \mathcal{Z}$. Let $M \in \mathcal{C}^{n\times n}$ have a singular value decomposition given by (2.1), in which $U_1, V_1 \in \mathcal{C}^{n\times r}$ are the parts of the left and right singular matrices of M, respectively, corresponding to the largest singular value, which is 1. Let U_1 and V_1 be partitioned conformally to the block diagonal structure of $\mathbf{\Delta}$, i.e.,

$$U_1 = \begin{bmatrix} A_1' & \cdots & A_S' & E_1' & \cdots & E_F' \end{bmatrix}', \quad V_1 = \begin{bmatrix} B_1' & \cdots & B_S' & H_1' & \cdots & H_F' \end{bmatrix}',$$

in which $A_i \in \mathcal{C}^{r_i \times r}$, $B_i \in \mathcal{C}^{r_i \times r}$, $E_j \in \mathcal{C}^{m_j \times r}$, and $H_j \in \mathcal{C}^{m_j \times r}$, for $i \in \underline{S}$ and $j \in \underline{F}$. Note that the notation used here is almost identical to that used in [21] (but see Lemma A.5).

LEMMA A.1. *Let $p, q \in \mathcal{C}^n$. Then*

1. *there exists $\Delta \in \mathcal{C}^{n\times n}$, $\|\Delta\| \leq 1$ such that $\Delta p = q$ if and only if $p'p \geq q'q$.*
2. *there exists $\delta \in \mathcal{C}$, $|\delta| \leq 1$ such that $\delta p = q$ if and only if $pp' \geq qq'$.*
3. *the following statements are equivalent:* (i) *There exists $\delta \in \mathcal{C}$, $|\delta| = 1$ such that $\delta p = q$.* (ii) *$pp' = qq'$.* (iii) *$q'Hq = p'Hp$ for every Hermitian $H \in \mathcal{C}^{n\times n}$.*
4. *there exists $Q \in \mathcal{C}^{n\times n}$, $QQ' = I_n$ such that $Qp = q$ if and only if $p'p = q'q$.*

Proof. The proof is a slight extension of parallel results in [9] and [20] (see also [22]) and is reproduced for completeness. Assume $p \neq 0$; otherwise the result is trivial.

1. If $\Delta p = q$ with $\|\Delta\| \leq 1$, then $\|p\| \geq \|q\|$ or $p'p - q'q \geq 0$. Conversely if $\|p\| \geq \|q\|$, choose the contractive rank-one matrix $\Delta = qp'/\|p\|^2$. Then $\Delta p = q$.
2. If $\delta p = q$ and $|\delta| \leq 1$, then $pp' - qq' = (1 - |\delta|^2)pp' \geq 0$. Conversely, let $pp' - qq' \geq 0$. For every x such that $p'x = 0$, we have

   $$x'(pp' - qq')x \geq 0 \Rightarrow x'qq'x = 0 \Rightarrow q'x = 0 \Rightarrow \mathcal{N}(p') \subseteq \mathcal{N}(q') \Rightarrow \mathcal{R}(q) \subseteq \mathcal{R}(p).$$

   Thus, there exists $\delta \in \mathcal{C}$ such that $q = \delta p$. Now, $0 \leq pp' - qq' = (1 - |\delta|^2)pp'$ implies that $|\delta| \leq 1$.
3. (i) $\Rightarrow$ (ii): This is immediate, since $qq' = \delta\bar{\delta}pp' = |\delta|^2 pp' = pp'$. (ii) $\Rightarrow$ (i): Using an argument similar to the one used in part 2, we conclude that $\mathcal{R}(p) = \mathcal{R}(q)$, i.e., $q = \delta p$ for some $\delta \in \mathcal{C}$, $\delta \neq 0$. Now, $qq' = |\delta|^2 pp'$ so that $|\delta| = 1$. (i) $\Rightarrow$ (iii): By direct calculation, $q'Hq = |\delta|^2 p'Hp = p'Hp$ for every $H = H'$. (iii) $\Rightarrow$ (i): Setting $H = I_n$ shows that $\|p\| = \|q\|$. Setting $H = pp'$ gives $|q'p| = \|p\|\|q\|$ and thus $q = \delta p$ for some scalar δ such that $|\delta| = 1$.
4. Similar to items 1–3 above. ∎

The next lemma characterizes the following two sets:

$$\Psi(x) = \{z \in \mathcal{C}^n : z = \Delta U_1 x, \Delta \in \mathcal{B}\mathbf{\Delta}\}$$

and

$$\Psi_o(x) = \{z \in \mathcal{C}^n : z = \Delta U_1 x, \Delta \in \mathcal{Q}\},$$

in which x is a fixed vector in $\mathcal{C}^n$.

LEMMA A.2. *Let $z \in \mathcal{C}^n$, partitioned conformally with $\mathbf{\Delta}$, i.e.,*

$$z' = \left[\begin{array}{cccccc} z_1' & \dots & z_S' & z_{S+1}' & \dots & z_{S+F}' \end{array} \right],$$

where $z_i \in \mathcal{C}^{r_i}$ for $i \in \underline{S}$ and $z_{S+i} \in \mathcal{C}^{m_i}$ for $i \in \underline{F}$. Then, for $x \in \mathcal{C}^n$,

$$\Psi(x) = \{z \in \mathcal{C}^n \ : \ z_i z_i' \le A_i x x' A_i', i \in \underline{S} \ ; \ \|z_{S+i}\| \le \|E_i x\|, i \in \underline{F}\} \tag{A.1}$$

and

$$\Psi_o(x) = \{z \in \mathcal{C}^n \ : \ z_i z_i' = A_i x x' A_i', i \in \underline{S} \ ; \ \|z_{S+i}\| = \|E_i x\|, \ i \in \underline{F}\}. \tag{A.2}$$

Further,

$$z_i' H_i z_i = x' A_i' H_i A_i x \ \text{ for every } \ z \in \Psi_o(x), \ i \in \underline{S} \text{ and } H_i = H_i' \in \mathcal{C}^{r_i \times r_i}. \tag{A.3}$$

Finally,

$$z \in \Psi_o(x) \text{ if and only if } z' Z z - x' U_1' Z U_1 x = 0 \text{ for every } Z \in \mathcal{Z}. \tag{A.4}$$

Proof. The characterization of the sets $\Psi(x)$ and $\Psi_o(x)$ follows immediately from Lemma A.1. The identity (A.3) is also a direct consequence of Lemma A.1(3). Finally, in order to show (A.4), take $Z = \text{diag}(Q_1, \dots, Q_S, q_{S+1} I_{m_1}, \dots, q_{S+F} I_{m_F})$ with $Q_i = Q_i' \in \mathcal{C}^{r_i \times r_i}$ and $q_{S+i} \in \mathcal{R}$. Then

$$z' Z z - x' U_1' Z U_1 x = \sum_{i=1}^{S} (z_i' Q_i z_i - x' A_i' Q_i A_i x) + \sum_{i=1}^{F} q_{S+i} (\|z_{S+i}\|^2 - \|E_i x\|^2) = 0, \tag{A.5}$$

using (A.2) and (A.3). Conversely, suppose that (A.5) holds for every $Z \in \mathcal{Z}$ and for each $i \in \underline{S}$ choose $Q_j = O_{m_j}$ $(j \ne i)$ and $q_{S+j} = 0 \ \forall \ j \in \underline{F}$. Then, $z' Q_i z_i = x' A_i' Q_i A_i x$ for every $Q_i = Q_i'$, which from Lemma A.1 implies that $z_i z_i' = A_i x x' A_i'$ for each $i \in \underline{S}$. Similarly, setting $Q_i = O_{m_i} \ \forall \ i \in \underline{S}$, $q_{S+j} = 0 \ \forall \ j \in \underline{F} \backslash \{i\}$, and $q_{S+i} = 1$ gives $\|z_{S+i}\| = \|E_i x\|$ and thus $z \in \Psi_o(x)$. □

Before proving Lemma 2.3 the following result is also needed.

LEMMA A.3. *Let $Z = Z'$ and define*

$$P_\alpha = \left[\begin{array}{cc} 0 & 0 \\ 0 & \Lambda \end{array} \right] - \alpha \left[\begin{array}{c} X' \\ \tilde{X}' \end{array} \right] Z \left[\begin{array}{cc} X & \tilde{X} \end{array} \right],$$

where $\Lambda = \Lambda' > 0$ and $X_o := [X \ \tilde{X}]$ is unitary. Then there exists $\alpha > 0$ such that $P_\alpha \ge 0$ if and only if $X' Z X \le 0$.

Proof. (a) If $P_\alpha \ge 0$ for some $\alpha > 0$, then the $(1,1)$ block of P_α is certainly semidefinite, i.e., $X' Z X \le 0$. (b) Assume that $X' Z X \le 0$. We will show that $X_o P_\alpha X_o' \ge 0$ for all sufficiently small $\alpha > 0$. First note that

$$X_o P_\alpha X_o' = \left[\begin{array}{cc} X & \tilde{X} \end{array} \right] \left[\begin{array}{cc} 0 & 0 \\ 0 & \Lambda \end{array} \right] \left[\begin{array}{c} X' \\ \tilde{X}' \end{array} \right] - \alpha Z = \tilde{X} \Lambda \tilde{X}' - \alpha Z.$$

Every vector $\xi \in \mathcal{C}^n$ can be written (uniquely) as $\xi = X\theta_1 + \tilde{X}\theta_2$. Now,

$$\begin{aligned} \xi' X_o P_\alpha X_o' \xi &= \xi' (\tilde{X} \Lambda \tilde{X}' - \alpha Z) \xi = (\theta_1' X' + \theta_2' \tilde{X}')(\tilde{X} \Lambda \tilde{X}' - \alpha Z)(X\theta_1 + \tilde{X}\theta_2) \\ &= \theta_2' \Lambda \theta_2 - \alpha (\theta_1' X' Z X \theta_1 + 2\text{Re}(\theta_1' X' Z \tilde{X} \theta_2) + \theta_2' \tilde{X}' Z \tilde{X} \theta_2). \end{aligned}$$

If $\theta_2 \neq 0$, this is positive for all sufficiently small α. If $\theta_2 = 0$ ($\Rightarrow \theta_1 \neq 0$ for $\xi \neq 0$), we get $X_o P_\alpha X_o' = -\alpha\theta_1' X'ZX\theta_1 \geq 0$ for every $\alpha \geq 0$. In either case, there exists $\alpha > 0$ (sufficiently small) such that $X_o P_\alpha X_o' \geq 0$, which implies that $P_\alpha \geq 0$. ∎

We can now prove the first part of Lemma 2.3.

LEMMA A.4. *With all variables as defined above,*

$$\max_{\Delta \in \mathcal{B}\mathbf{\Delta}} \|V_1'\Delta U_1\|^2 = \min_{\substack{D \in \mathcal{D} \\ D - V_1 V_1{}' \geq 0 \\ \gamma I - U_1{}' D U_1 \geq 0}} \gamma. \tag{A.6}$$

Proof. We call the maximization on the left of (A.6) the primal problem and the minimization on the right the dual problem. The primal problem can be written as

$$\max_{\substack{\Delta \in \mathcal{B}\mathbf{\Delta} \\ x'x \leq 1}} x'U_1'\Delta' V_1 V_1{}' \Delta U_1 x = \max_{\substack{x'x \leq 1 \\ z \in \Psi(x)}} z' V_1 V_1{}' z, \tag{A.7}$$

where $\Psi(x)$ is defined in (A.1). Consider the following identity:

$$\begin{aligned} z' V_1 V_1{}' z = &-\gamma(1 - x'x) - (x'U_1' D U_1 x - z' D z) - z'(D - V_1 V_1{}')z \\ &- x'(\gamma I - U_1' D U_1)x + \gamma. \end{aligned} \tag{A.8}$$

For all x, z satisfying the constraints of the primal problem in (A.7) (i.e., $x'x \leq 1$, $z \in \Psi(x)$), all D satisfying the constraints of the dual problem in (2.8) (i.e., $D \in \mathcal{D}$, $D - V_1 V_1{}' \geq 0$, and $\gamma I - U_1{}' D U_1 \geq 0$), and all $\gamma > 0$, we have that the four terms on the right of (A.8) are nonpositive, i.e.,

1. $1 - x'x \geq 0$ (primal),
2. $x'U_1' D U_1 x - z' D z \geq 0$ (primal),
3. $z'(D - V_1 V_1') z \geq 0$ (dual),
4. $x'(\gamma I - U_1' D U_1)x \geq 0$ (dual).

The nonnegativity of the second term follows from the following argument. Write

$$x'U_1' D U_1 x - z' D z = \sum_{i=1}^{S} (x' A_i' D_i A_i x - z_i' D_i z_i) + \sum_{i=1}^{F} d_i (\|E_i x\|^2 - \|z_{S+i}\|^2),$$

where $D_i = D_i' \geq 0 \ \forall\ i \in \underline{S}$ and $d_i \geq 0 \ \forall\ i \in \underline{F}$. Now, from Lemma A.2, $z \in \Psi(x)$ implies that $\|z_{S+i}\| \leq \|E_i x\| \ \forall\ i \in \underline{F}$. Further, since $z \in \Psi(x)$ we have

$$\begin{aligned} &A_i x x' A_i' - z_i z_i' \geq 0 \quad \forall\ i \in \underline{S} \\ &\quad \Rightarrow D_i^{1/2} (A_i x x' A_i' - z_i z_i') D_i^{1/2} \geq 0 \quad \forall\ D_i^{1/2} = (D_i^{1/2})' \geq 0,\ i \in \underline{S} \\ &\quad \Rightarrow D_i^{1/2} A_i x x' A_i' D_i^{1/2} \geq D_i^{1/2} z_i z_i' D_i^{1/2} \quad \forall\ D_i^{1/2} = (D_i^{1/2})' \geq 0,\ i \in \underline{S}. \end{aligned}$$

Lemma A.1(2) implies that there exist $\lambda_i \in \mathcal{C}$, $|\lambda_i| \leq 1$ such that $\lambda_i D_i^{1/2} A_i x = D_i^{1/2} z_i$, $i \in \underline{S}$, and thus $\|D_i^{1/2} A_i x\|^2 - \|D_i^{1/2} z_i\|^2 \geq 0$, so that the second term is nonnegative.

Thus, the first four terms in the global identity are all nonpositive, and hence

$$\max_{\substack{x'x \leq 1 \\ z \in \Psi(x)}} z' V_1 V_1{}' z \leq \min_{\substack{D \in \mathcal{D} \\ \gamma I - U_1{}' D U_1 \geq 0 \\ D - V_1 V_1{}' \geq 0}} \gamma.$$

It follows that the dual problem solution is an upper bound on the primal's. Next we show that they are equal.

Let γ and D be feasible for the dual problem. Then

1. $\underline{\lambda}(D - V_1V_1') = 0$, and
2. $\underline{\lambda}(\gamma I - U_1'DU_1) = 0$.

Equality in (2) is obvious: If $\gamma I - U_1'DU_1$ was not singular at optimality, then there would exist $\hat{\gamma} < \gamma$ such that $\hat{\gamma} I - U_1'DU_1 \geq 0$, contradicting the optimality of γ. To show (1), suppose for contradiction that $D - V_1V_1' > 0$. Then $(D - \mu I) - V_1V_1' \geq 0$ for some $\mu > 0$ (sufficiently small). Now $\gamma I - U_1'DU_1 \geq 0$ and so $(\gamma - \mu)I - U_1'(D - \mu I)U_1 \geq 0$, contradicting again the optimality of γ, since $\mu > 0$ can be chosen small enough so that $D - \mu I \in \mathcal{D}$. (Note that in this case the assumption $D - V_1V_1' > 0$ implies that $D > 0$.) Thus both (1) and (2) hold.

Thus $\dim \mathcal{N}(\gamma I - U_1'DU_1) \geq 1$ and $\dim \mathcal{N}(D - V_1V_1') \geq 1$, where $\mathcal{N}(\cdot)$ denotes the null space, are necessary for γ, D to be optimal for the dual problem. Let

$$D - V_1V_1' = \begin{bmatrix} X & \tilde{X} \end{bmatrix} \begin{bmatrix} 0 & 0 \\ 0 & \Lambda_1 \end{bmatrix} \begin{bmatrix} X' \\ \tilde{X}' \end{bmatrix}, \tag{A.9}$$

where $X \in \mathcal{C}^{n \times m_1}$, $[X \;\; \tilde{X}]$ unitary, and $\Lambda_1 = \Lambda_1' > 0$ and let

$$\gamma I - U_1'DU_1 = \begin{bmatrix} Y & \tilde{Y} \end{bmatrix} \begin{bmatrix} 0 & 0 \\ 0 & \Lambda_2 \end{bmatrix} \begin{bmatrix} Y' \\ \tilde{Y}' \end{bmatrix}, \tag{A.10}$$

where $Y \in \mathcal{C}^{n \times m_2}$, $[Y \;\; \tilde{Y}]$ unitary, and $\Lambda_2 = \Lambda_2' > 0$. We prove that γ, D are optimal if and only if there does not exist $Z \in \mathcal{Z}$ such that $X'ZX \leq 0$ and $Y'U_1'ZU_1Y > 0$.

Suppose $X'ZX \leq 0$ and $Y'U_1'ZU_1Y > 0$ for some $Z \in \mathcal{Z}$. Define $D_\alpha = D - \alpha Z$ for $\alpha \geq 0$. Then it is easy to show that

$$\begin{bmatrix} X' \\ \tilde{X}' \end{bmatrix} (D_\alpha - V_1V_1') \begin{bmatrix} X & \tilde{X} \end{bmatrix} = \begin{bmatrix} -\alpha X'ZX & -\alpha X'Z\tilde{X} \\ -\alpha \tilde{X}'ZX & \Lambda_1 - \alpha \tilde{X}'Z\tilde{X} \end{bmatrix}$$

and

$$\begin{bmatrix} Y' \\ \tilde{Y}' \end{bmatrix} (\gamma I - U_1'D_\alpha U_1) \begin{bmatrix} Y & \tilde{Y} \end{bmatrix} = \begin{bmatrix} \alpha Y'U_1'ZU_1Y & \alpha Y'U_1'ZU_1\tilde{Y} \\ \alpha \tilde{Y}'U_1'ZU_1Y & \Lambda_2 + \alpha \tilde{Y}'U_1'ZU_1\tilde{Y} \end{bmatrix}.$$

It is now straightforward using Lemma A.3 and a Schur-type argument to show that there exists $\alpha > 0$ such that $D_\alpha - V_1V_1' \geq 0$ and $\gamma I - U_1'D_\alpha U_1 > 0$, and so there exists $\gamma_\alpha < \gamma$ such that $\gamma_\alpha I - U_1'D_\alpha U_1 \geq 0$, proving that γ, D are not optimal.

Conversely, suppose that γ and D are not optimal so that there exists $\gamma_o < \gamma$ and $D_o \in \mathcal{D}$ such that $D_o - V_1V_1' \geq 0$ and $\gamma_o I - U_1'D_oU_1 \geq 0$. Define $Z = D - D_o$ so that $Z \in \mathcal{Z}$. Now

$$0 = X'(D - V_1V_1')X = X'(D_o - V_1V_1' + Z)X = X'(D_o - V_1V_1')X + X'ZX,$$

and so $X'ZX \leq 0$. Also

$$\begin{aligned} 0 &= Y'(\gamma I - U_1'DU_1)Y = Y'(\gamma_o I - U_1'D_oU_1 + (\gamma - \gamma_o)I - U_1'ZU_1)Y \\ &= Y(\gamma_o I - U_1'D_oU_1)Y + (\gamma - \gamma_o)I - Y'U_1'ZU_1Y, \end{aligned}$$

and so $Y'U_1'ZU_1Y > 0$. This proves that γ, D are optimal for the dual problem if and only if there does not exist $Z \in \mathcal{Z}$ such that $X'ZX \leq 0$ and $Y'U_1'ZU_1Y > 0$.

Finally, we need to prove the absence of gap between the primal and dual problems. Let γ and D be optimal for the dual and suppose that (A.9) and (A.10) are satisfied. It follows from the identity (A.8) that there is no gap if there exist $z \in \mathcal{C}^n$ and $x \in \mathcal{C}^m$ such that

1. $x'x = 1$ (so that x is feasible and the first term on the right of (A.8) is zero);
2. $z \in \Psi_o(x)$ (so that z is feasible and the second term is zero; see Lemma A.2);
3. $z \in \mathcal{N}(D - V_1V_1')$, or equivalently, $z = X\tilde{z}$ for some $\tilde{z} \in \mathcal{C}^{m_1}$ (so that the third term is zero);
4. $x \in \mathcal{N}(\gamma I - U_1'DU_1)$, or equivalently, $x = Y\tilde{x}$ for some $\tilde{x} \in \mathcal{C}^{m_2}$ (so that the fourth term is zero).

It follows that there is no gap if there exist $\tilde{z} \in \mathcal{C}^{m_1}$ and $\tilde{x} \in \mathcal{C}^{m_2}$ such that $\tilde{x}'\tilde{x} = \tilde{z}'\tilde{z} = 1$ and $X\tilde{z} \in \Psi_o(Y\tilde{x})$, i.e., if there exist $\tilde{x}$ and $\tilde{z}$ such that $\|\tilde{x}\| = \|\tilde{z}\| = 1$ and

$$\tilde{z}'X'ZX\tilde{z} - \tilde{x}'Y'U_1'ZU_1Y\tilde{x} = 0,$$

for every $Z \in \mathcal{Z}$. We thus need to prove that such $\tilde{z}$ and $\tilde{x}$ exist if γ, D are optimal, that is, if there does not exist $Z \in \mathcal{Z}$ such that $X'ZX \le 0$ and $Y'U_1'ZU_1Y > 0$.

Assume for contradiction that $\exists Z \in \mathcal{Z}$ such that $\tilde{z}'X'ZX\tilde{z} - \tilde{x}'Y'U_1'ZU_1Y\tilde{x} \neq 0 \ \forall\ \tilde{z} \in \mathcal{C}^{m_1}$ and $\tilde{x} \in \mathcal{C}^{m_2}$ with $\|\tilde{z}\| = \|\tilde{x}\| = 1$. We need to show that this contradicts optimality of (γ, D) or, equivalently, that it implies the existence of $Z \in \mathcal{Z}$ such that $X'ZX \le 0$ and $Y'U_1ZU_1Y > 0$. Next note that since $Z \in \mathcal{Z} \Leftrightarrow -Z \in \mathcal{Z}$, the assumed condition is equivalent to the existence of $Z \in \mathcal{Z}$ such that $\tilde{z}'X'ZX\tilde{z} < \tilde{x}'Y'U_1'ZU_1Y\tilde{x}$ for every $\tilde{z} \in \mathcal{C}^{m_1}$ and $\tilde{x} \in \mathcal{C}^{m_2}$ with $\|\tilde{z}\| = \|\tilde{x}\|$. This implies, in particular, that

$$\overline{\lambda}(X'ZX) = \max_{\|\tilde{z}\|=1} \tilde{z}'X'ZX\tilde{z} < \min_{\|\tilde{x}\|=1} \tilde{x}'Y'U_1'ZU_1Y\tilde{x} = \underline{\lambda}(Y'U_1'ZU_1Y).$$

Next, set $\delta = \frac{1}{2}[\overline{\lambda}(X'ZX) + \underline{\lambda}(Y'U_1'ZU_1Y)]$. Then,

$$\tilde{z}'X'(Z - \delta I)X\tilde{z} < \tilde{x}'Y'U_1'(Z - \delta I)U_1Y\tilde{x}$$

$\forall\ \tilde{z} \in \mathcal{C}^{m_1}$ and $\tilde{x} \in \mathcal{C}^{m_2}$ with $\|\tilde{z}\| = \|\tilde{x}\|$. Now,

$$\max_{\|\tilde{z}\|=1} \tilde{z}'X'(Z - \delta I)X\tilde{z} = \overline{\lambda}(X'ZX) - \delta = \frac{1}{2}\left[\ \overline{\lambda}(X'ZX) - \underline{\lambda}(Y'Y_1'ZU_1Y)\right] < 0,$$

so that $X'(Z - \delta I)X < 0$. Similarly,

$$\min_{\|\tilde{x}\|=1} \tilde{x}'Y'U_1'(Z - \delta I)U_1Y\tilde{x} = \frac{1}{2}\left[\underline{\lambda}(Y'Y_1'ZU_1Y) - \overline{\lambda}(X'ZX)\right] > 0,$$

which implies that $Y'U_1'(Z - \delta I)U_1Y > 0$ and establishes the required contradiction since $Z - \delta I \in \mathcal{Z}$. ∎

In the remaining part of the appendix we prove the second part of Lemma 2.3. This requires two preliminary results as follows.

LEMMA A.5. *With all variables as defined above,* $\inf\{\|D^{1/2}MD^{-1/2}\| : D \in \mathcal{D}_+\} = \|M\|$ *if and only if* $\underline{\lambda}(U_1'ZU_1 - V_1'ZV_1) \le 0$ *for every* $Z \in \mathcal{Z}$.

Proof. See [21]. Note that our definition of $\mathcal{Z}$ is slightly different from the definition in [21], but this does not affect the result. ∎

LEMMA A.6. *With all variables as defined above,* $\inf\{\|D^{1/2}MD^{-1/2}\| : D \in \mathcal{D}_+\} = \|M\|$ *if and only if* $\inf\{\|D^{1/2}M_0D^{-1/2}\| : D \in \mathcal{D}_+\} = \|M\|$.

Proof. The proof is immediate from Lemma A.5 since M and M_0 share the same left and right singular vector matrices corresponding to $\|M\| = 1$ (U_1 and V_1, respectively). ∎

The second part of Lemma 2.3 can now be established as follows.

LEMMA A.7. *If the optimum in* (2.3) *is* 1*, the optimum in* (2.6) *is* 1.

Proof. First note that for every $D \in \mathcal{D}_+$,

$$M'DM - \gamma^2 D \geq 0 \Leftrightarrow D^{-1/2}M'DMD^{-1/2} - \gamma^2 I \leq 0 \Leftrightarrow \|D^{1/2}MD^{-1/2}\| \leq \gamma,$$

and hence via a continuity argument [11] the optimum in (2.3) is 1 if and only if $\inf\{\|D^{1/2}MD^{-1/2}\| : D \in \mathcal{D}_+\} = 1$. Thus, from Lemma A.6 we also have that $\inf\{\|D^{1/2}M_0D^{-1/2}\| : D \in \mathcal{D}_+\} = 1$, and hence the optimization problem $\min\{\gamma : D \in \mathcal{D}, \gamma^2 D - M_0'DM_0 \geq 0\}$ has optimum solutions $\gamma = 1$ and $D = I$. Now suppose for contradiction that $\max\{\|V_1'\Delta U_1\| : \Delta \in \mathcal{B}\mathbf{\Delta}\} < 1$, or, in view of Lemma A.4 that $\min\{\gamma : D \in \mathcal{D}, D - V_1V_1' \geq 0, \gamma I - U_1'DU_1 \geq 0\} < 1$. Write the minimum γ as $\gamma = 1-\epsilon$ for some $\epsilon > 0$ and the corresponding optimum $D = I - Z$ for some $Z \in \mathcal{Z}$. Then

$$(1-\epsilon)I - U_1'(I-Z)U_1 \geq 0 \Leftrightarrow U_1'ZU_1 \geq \epsilon I > 0.$$

Also,

$$(I-Z) - V_1V_1' \geq 0 \Rightarrow V_1'[(I-Z) - V_1V_1']V_1 \geq 0 \Rightarrow V_1'ZV_1 \leq 0.$$

Thus $U_1'ZU_1 - V_1'ZV_1 > 0$ for some $Z \in \mathcal{Z}$, which contradicts Lemma A.5. ∎

Lemma 2.3 now follows from Lemmas A.4 and A.7.

ON A CLASS OF STOCHASTIC OPTIMAL CONTROL PROBLEMS RELATED TO BSDES WITH QUADRATIC GROWTH*

MARCO FUHRMAN†, YING HU‡, AND GIANMARIO TESSITORE§

Abstract. In this paper, we study a class of stochastic optimal control problems, where the drift term of the equation has a linear growth on the control variable, the cost functional has a quadratic growth, and the control process takes values in a closed set (not necessarily compact). This problem is related to some backward stochastic differential equations (BSDEs) with quadratic growth and unbounded terminal value. We prove that the optimal feedback control exists, and the optimal cost is given by the initial value of the solution of the related BSDE.

Key words. stochastic optimal control, backward stochastic differential equations, quadratically growing driver, unbounded final condition

AMS subject classifications. 93E20, 60H10

DOI. 10.1137/050633548

1. Introduction.

In this paper, we consider a controlled equation of the form

$$\begin{cases} dX_t = b(t, X_t)\, dt + \sigma(t, X_t)\, [dW_t + r(t, X_t, u_t)\, dt], & t \in [0, T], \\ X_0 = x. \end{cases} \tag{1.1}$$

In the equation, W is an $\mathbb{R}^d$-valued Wiener process, defined on a complete probability space $(\Omega, \mathcal{F}, \mathbb{P})$ with respect to a filtration $(\mathcal{F}_t)_{t\geq 0}$ satisfying the usual conditions; the unknown process X takes values in $\mathbb{R}^n$; x is a given element of $\mathbb{R}^n$; and u is the control process, which is assumed to be an $(\mathcal{F}_t)$-adapted process taking values in a given nonempty closed set $K \subset \mathbb{R}^m$. The control problem consists of minimizing a cost functional of the form

$$J = \mathbb{E} \int_0^T g(t, X_t, u_t)\, dt + \mathbb{E}\, \phi(X_T). \tag{1.2}$$

We suppose that r has a linear growth in u, g has quadratic growth in x and u, and ϕ has quadratic growth in x.

The main novelty of the present paper, in comparison with the existing literature, is that on the one hand we assume that neither K nor r is bounded; on the other hand we consider a degenerate control problem (since nothing is assumed on the image of σ). Moreover, we also allow ϕ to have quadratic growth.

Nonlinear backward stochastic differential equations (BSDEs) were first introduced by Pardoux and Peng [11]. A major application of BSDEs is in stochastic control; see, e.g., [4] and [12]. We also refer the reader to [9], [5], and [7]. From several points of view, the class of control problems addressed in these papers, and in the references therein, is more general than the one considered here, but assumptions implying "bounded control image" (i.e., boundedness of K or r in our notation) are a common feature of all the above papers. The special "unbounded" case corresponding to the assumptions $K = \mathbb{R}^m$ and $g = \frac{1}{2}|u|^2 + q(t,x)$ is treated in [6] by an ad hoc exponential transform. We notice that in [6] ϕ is allowed to take the value $+\infty$. Finally, the same special case (in which the Hamiltonian is exactly the square of the norm of the gradient) was treated in [8] by analytic techniques under nondegeneracy assumptions and in an infinite-dimensional framework.

The difficulty here is that the Hamiltonian corresponding to the control problem has quadratic growth in the gradient and consequently the associated BSDE has quadratic growth in the Z variable. Well-posedness for this class of BSDEs has been proved in [10] in the case of bounded terminal value. Since we allow for unbounded terminal cost, to treat such equations we have to apply the techniques recently introduced in [2]. We notice that for such BSDEs no general uniqueness results are known: we replace uniqueness with the selection of a maximal solution. Moreover, the usual application of the Girsanov technique is not allowed (since the Novikov condition is not guaranteed), and we have to develop specific arguments both to prove the fundamental relation (see section 4) and to obtain the existence of a (weak) solution to the closed loop equation (see section 5). Our main result is to prove that the optimal feedback control exists and the optimal cost is given by the value Y_0 of the maximal solution (Y, Z) of the BSDE with the quadratic growth and unbounded terminal value mentioned above. Moreover, we show that we can construct an optimal feedback in terms of the process Z. Finally, we prove that if we fix a particular optimal feedback law, then the solution of the corresponding closed loop equation is unique; see Proposition 5.4.

An alternative approach to the control problem may consist of applying the stochastic maximum principle; see, e.g., [12] for a detailed exposition. However, this would require further differentiability conditions on the coefficients of the controlled equation and would not immediately imply existence of an optimal control, since the maximum principle is usually stated as a necessary condition for optimality.

The paper is organized as follows. In the next section, we describe the control problem; in section 3, we study the related BSDE; and in section 4, we establish the fundamental relation between the optimal control problem and BSDE. The last section is devoted to the proof of the existence of optimal feedback control.

2. The control problem. We consider the optimal control problem given by a state equation of the form

$$\begin{cases} dX_t = b(t, X_t)\, dt + \sigma(t, X_t)\, [dW_t + r(t, X_t, u_t)\, dt], & t \in [0, T], \\ X_0 = x, \end{cases} \tag{2.1}$$

and given by a cost functional of the form

$$J = \mathbb{E} \int_0^T g(t, X_t, u_t)\, dt + \mathbb{E}\, \phi(X_T). \tag{2.2}$$

We work under the following assumptions.

HYPOTHESIS 2.1.

1. *The process W is a Wiener process in $\mathbb{R}^d$, defined on a complete probability space $(\Omega, \mathcal{F}, \mathbb{P})$ with respect to a filtration $(\mathcal{F}_t)$ satisfying the usual conditions.*
2. *The set K is a nonempty closed subset of $\mathbb{R}^m$.*
3. *The functions $b : [0,T] \times \mathbb{R}^n \to \mathbb{R}^n$, $\sigma : [0,T] \times \mathbb{R}^n \to \mathbb{R}^{n\times d}$, $r : [0,T] \times \mathbb{R}^n \times K \to \mathbb{R}^d$, $g : [0,T] \times \mathbb{R}^n \times K \to \mathbb{R}$, $\phi : \mathbb{R}^n \to \mathbb{R}$ are Borel measurable.*
4. *For all $t \in [0,T]$, $x \in \mathbb{R}^n$, $r(t,x,\cdot)$ and $g(t,x,\cdot)$ are continuous functions from K to $\mathbb{R}^d$ and from K to $\mathbb{R}$, respectively.*
5. *There exists a constant $C > 0$ such that for every $t \in [0,T]$, $x, x' \in \mathbb{R}^n$, $u \in K$ it holds that*

$$|b(t,x) - b(t,x')| \le C|x - x'|, \qquad |b(t,x)| \le C(1 + |x|), \tag{2.3}$$

$$|\sigma(t,x) - \sigma(t,x')| \le C|x - x'|, \tag{2.4}$$

$$|\sigma(t,x)| \le C, \tag{2.5}$$

$$|r(t,x,u) - r(t,x',u)| \le C(1 + |u|)|x - x'|, \tag{2.6}$$

$$|r(t,x,u)| \le C(1 + |u|), \tag{2.7}$$

$$0 \le g(t,x,u) \le C(1 + |x|^2 + |u|^2), \tag{2.8}$$

$$0 \le \phi(x) \le C(1 + |x|^2). \tag{2.9}$$

6. *There exist $R > 0$ and $c > 0$ such that for every $t \in [0,T]$, $x \in \mathbb{R}^n$, and every $u \in K$ satisfying $|u| \ge R$,*

$$g(t,x,u) \ge c|u|^2. \tag{2.10}$$

We will say that an $(\mathcal{F}_t)$-adapted stochastic process $\{u_t,\ t \in [0,T]\}$ with values in K is an admissible control if it satisfies

$$\mathbb{E}\int_0^T |u_t|^2 dt < \infty. \tag{2.11}$$

This square summability requirement is justified by (2.10): a control process which is not square summable would have infinite cost.

Remark 2.2. Some classes of linear quadratic control problems fall within the scope of our result. Consider the controlled system

$$\begin{cases} dX_t = A(t)X_t\, dt + b(t)\, dt + \Sigma(t)\,[dW_t + B(t)u_t\, dt], & t \in [0,T], \\ X_0 = x \end{cases} \tag{2.12}$$

and the cost functional

$$J = \frac{1}{2}\mathbb{E}\int_0^T [\langle Q(t)X_t, X_t\rangle + \langle R(t)u_t, u_t\rangle]\, dt + \frac{1}{2}\mathbb{E}\,\langle SX_T, X_T\rangle,$$

and assume that A, b, Σ, B, Q, R are bounded Borel measurable functions with values in $\mathbb{R}^{n\times n}$, $\mathbb{R}^n$, $\mathbb{R}^{n\times d}$, $\mathbb{R}^{d\times m}$, $\mathbb{R}^{n\times n}$, $\mathbb{R}^{m\times m}$, respectively, and that $S \in \mathbb{R}^{n\times n}$; also suppose that $Q(t) \geq 0$, $S \geq 0$, $R(t) \geq cI$ for some $c > 0$ and all t, in the sense of the usual matrix order. Then Hypothesis 2.1 is verified. We are not assuming $K = \mathbb{R}^m$ in general. If $K = \mathbb{R}^m$, then the usual linear quadratic theory applies and gives more general results in the sense that state- and control-dependent noise can be considered, as well as a more general drift coefficient, in (2.12).

Next we show that for every admissible control, the solution to (2.1) exists.

PROPOSITION 2.3. *Let u be an admissible control. Then there exists a unique, continuous, $(\mathcal{F}_t)$-adapted process X satisfying $\mathbb{E}\sup_{t\in[0,T]}|X_t|^2 < \infty$, and $\mathbb{P}$-a.s.,*

$$X_t = x + \int_0^t b(s, X_s)\, ds + \int_0^t \sigma(s, X_s)\, dW_s + \int_0^t \sigma(s, X_s)\, r(s, X_s, u_s)\, ds, \quad t \in [0, T].$$

Proof. The proof of Proposition 2.3 relies on an approximation procedure that will be used again in what follows. We introduce the sequence of stopping times

$$\tau_n = \inf\left\{t \in [0, T] \ : \ \int_0^t |u_s|^2 ds > n\right\},$$

with the convention that $\tau_n = T$ if the indicated set is empty. By (2.11), for $\mathbb{P}$-almost every $\omega \in \Omega$, there exists an integer $N(\omega)$ depending on ω such that

$$n \geq N(\omega) \qquad \Longrightarrow \qquad \tau_n(\omega) = T. \tag{2.13}$$

Let us fix $u^0 \in K$, and for every n, let us define

$$u_t^n = u_t\ 1_{t\leq\tau_n} + u^0\ 1_{t>\tau_n}$$

and consider the equation

$$\begin{cases} dX_t^n = b(t, X_t^n)\, dt + \sigma(t, X_t^n)\, [dW_t + r(t, X_t^n, u_t^n)\, dt], & t \in [0, T], \\ X_0^n = x. \end{cases} \tag{2.14}$$

We claim that (2.14) has a unique solution X^n in the class of $(\mathcal{F}_t)$-adapted processes X satisfying $\sup_{t\in[0,T]}\mathbb{E}\,|X_t|^2 < \infty$.

To prove the claim we use a classical argument: We first write (2.14) in the form

$$dX_t = b(t, X_t)\, dt + \widetilde{b}(t, X_t)\, dt + \sigma(t, X_t)\, dW_t,$$

where $\widetilde{b}(t, x) = \sigma(t, x, u_t^n) r(t, x, u_t^n)$ is a stochastic coefficient which satisfies, by (2.3)–(2.7),

$$|\widetilde{b}(t, x) - \widetilde{b}(t, x')| = |\sigma(t, x, u_t^n) r(t, x, u_t^n) - \sigma(t, x', u_t^n) r(t, x', u_t^n)| \leq C(1 + |u_t^n|)|x - x'|,$$

$$|\widetilde{b}(t, x)| = |\sigma(t, x, u_t^n) r(t, x, u_t^n)| \leq C(1 + |u_t^n|), \qquad t \in [0, T], \quad x, x' \in \mathbb{R}^n.$$

We define $K_t(\omega) = C(1 + |u_t^n(\omega)|)$, and we note that

$$\int_0^T |K_t|^2 dt \leq C\left(1 + \int_0^T |u_t^n|^2 dt\right) \leq C(1 + n + |u_0|^2) =: \widetilde{C}, \qquad \mathbb{P}\text{-a.s.},$$

by the definition of τ_n. Next we introduce the norm $\|X\|^2 := \sup_{t\in[0,T]} e^{-2\lambda t}\mathbb{E}\,|X_t|^2$ and prove that the mapping Γ defined by

$$\Gamma(X)_t = \int_0^t b(s,X_s)\,ds + \int_0^t \widetilde{b}(s,X_s)\,ds + \int_0^t \sigma(s,X_s)\,dW_s, \qquad t\in[0,T],$$

is a contraction with respect to this norm for sufficiently large $\lambda > 0$. For a pair of processes X, X', we have

$$\begin{aligned}
\mathbb{E}\left|\int_0^t [\widetilde{b}(s,X_s) - \widetilde{b}(s,X'_s)]\,ds\right|^2 &\le \mathbb{E}\left(\int_0^t K_s|X_s - X'_s|\,ds\right)^2 \\
&\le \mathbb{E}\left(\int_0^t |K_s|^2 ds \int_0^t |X_s - X'_s|^2\,ds\right) \\
&\le \widetilde{C}\mathbb{E}\int_0^t |X_s - X'_s|^2\,ds \\
&\le \widetilde{C}\|X - X'\|^2 \int_0^t e^{2\lambda s}\,ds,
\end{aligned}$$

and it follows that

$$\begin{aligned}
\sup_{t\in[0,T]} e^{-2\lambda t}\mathbb{E}\left|\int_0^t [\widetilde{b}(s,X_s) - \widetilde{b}(s,X'_s)]\,ds\right|^2 &\le \widetilde{C}\|X - X'\|^2 \int_0^t e^{-2\lambda(t-s)}\,ds \\
&\le \frac{\widetilde{C}}{2\lambda}\|X - X'\|^2.
\end{aligned}$$

The other verifications needed to prove the contraction property are standard. The claim is proved.

It is clear that the solution X^n of (2.14) is also continuous. Moreover, we have

$$X_t^n = X_t^{n+1} \qquad \text{for} \qquad t \le \tau_n;$$

therefore there exists a process X such that

$$X_t = X_t^n \qquad \text{for} \qquad t \le \tau_n,$$

and X is clearly the required solution. The property $\mathbb{E}\sup_{t\in[0,T]}|X_t|^2 < \infty$ is an immediate consequence of the following lemma, which concludes the proof. □

LEMMA 2.4. *Under the previous assumptions, the family of random variables*

$$\sup_{t\in[0,T]} |X_t^n|^2, \qquad n = 1,2,\dots,$$

is uniformly integrable.

Proof. We set $M_t^n = \int_0^t \sigma(s,X_s^n)\,dW_s$. By (2.14), we have

$$X_t^n = x + \int_0^t b(s,X_s^n)\,ds + \int_0^t \sigma(s,X_s^n)r(s,X_s^n,u_s^n)\,ds + M_t^n.$$

First, we claim that the family $\{\sup_{t\in[0,T]}|M_t^n|^2;\, n = 1,2,\dots\}$ is uniformly integrable; indeed it is uniformly bounded in $L^p(\Omega,\mathcal{F},\mathbb{P})$ for every $p\in[1,\infty)$, since by the Burkholder–Davis–Gundy inequalities and the boundedness of σ (see (2.5)),

$$\mathbb{E}\sup_{t\in[0,T]}|M_t^n|^{2p} \le C\mathbb{E}\left(\int_0^T |\sigma(s,X_s^n)|^2\,ds\right)^p \le C$$

for some constant independent of n. Next we note that, by (2.7),

$$\left|\int_0^t \sigma(s,X_s^n)r(s,X_s^n,u_s^n)\,ds\right|^2 \le C\int_0^t (1+|u_s^n|)^2\,ds \le C\left(1+\int_0^T |u_s|^2\,ds\right).$$

Then, setting $l_t^n = \sup_{r\in[0,t]}|X_r^n|^2$, we obtain by (2.3),

$$\begin{aligned} l_t^n &\le C\left(1+\int_0^T |u_s|^2\,ds + \sup_{t\in[0,T]}|M_t^n|^2\right) + C\int_0^t |X_s^n|^2\,ds \\ &\le C\left(1+\int_0^T |u_s|^2\,ds + \sup_{t\in[0,T]}|M_t^n|^2\right) + C\int_0^t l_s^n\,ds. \end{aligned}$$

From the Gronwall lemma we deduce

$$l_t^n \le C\left(1+\int_0^T |u_s|^2\,ds + \sup_{t\in[0,T]}|M_t^n|^2\right),$$

and the required uniform integrability follows. □

The stochastic control problem associated with (2.1)–(2.2) consists of minimizing the cost functional $J(x,u)$ among all the admissible controls.

3. The forward-backward system. We consider again the functions b,σ,g,ϕ satisfying the assumptions in Hypothesis 2.1. We define the Hamiltonian function

$$\psi(t,x,z) = \inf_{u\in K}[g(t,x,u)+z\cdot r(t,x,u)], \qquad t\in[0,T],\quad x\in\mathbb{R}^n,\quad z\in\mathbb{R}^d, \tag{3.1}$$

where $\cdot$ denotes the usual scalar product in $\mathbb{R}^d$. We collect some immediate properties of the function ψ.

LEMMA 3.1. *The map ψ is a Borel measurable function from $[0,T]\times\mathbb{R}^n\times\mathbb{R}^d$ to $\mathbb{R}$. There exists a constant $C>0$ such that*

$$-C(1+|z|^2) \le \psi(t,x,z) \le g(t,x,u)+C|z|(1+|u|) \qquad \forall u\in K. \tag{3.2}$$

Moreover, the infimum in (3.1) *is attained in a ball of radius $C(1+|x|+|z|)$, that is,*

$$\psi(t,x,z) = \min_{u\in K,|u|\le C(1+|x|+|z|)}[g(t,x,u)+z\cdot r(t,x,u)], \tag{3.3}$$

$$t\in[0,T],\quad x\in\mathbb{R}^n,\quad z\in\mathbb{R}^d,$$

and

$$\psi(t,x,z) < g(t,x,u)+z\cdot r(t,x,u) \quad \textit{if} \quad |u|>C(1+|x|+|z|). \tag{3.4}$$

Finally, for every $t\in[0,T]$ and $x\in\mathbb{R}^n$, $z\to\psi(t,x,z)$ is continuous on $\mathbb{R}^d$.

Proof. The measurability of ψ is straightforward since, by the continuity of r and g with respect to u, we have $\psi(t,x,z)=\inf_{u\in\widehat{K}}[g(t,x,u)+z\cdot r(t,x,u)]$, $t\in[0,T]$, $x\in\mathbb{R}^n$, $z\in\mathbb{R}^d$, where $\widehat{K}$ is any countable dense subset of K.

Coming now to the proof of (3.2), we notice that, since g is nonnegative and satisfies (2.10), we have $g(t,x,u) \geq c(|u|^2 - R^2)$ (c and R are the same as in (2.10)). By (2.7) and (2.8), we have

$$g(t,x,u) + z \cdot r(t,x,u) \geq c(|u|^2 - R^2) - C|z|(1+|u|), \tag{3.5}$$

and it follows that

$$\begin{aligned}\psi(t,x,z) \geq \inf_{u\in\mathbb{R}^m}[g(t,x,u) + z\cdot r(t,x,u)] &\geq \inf_{u\in\mathbb{R}^m}[c(|u|^2 - R^2) - C|z|(1+|u|)] \\ &= -C_1|z|^2 - C_2,\end{aligned}$$

by direct computation, for suitable constants C_1 and C_2. This proves the left-hand side of (3.2). The right-hand side of (3.2) is immediate, since by (2.7),

$$\psi(t,x,z) \leq g(t,x,u) + z\cdot r(t,x,u) \leq g(t,x,u) + |z|C(1+|u|).$$

We come now to the second assertion. By (3.5) we get

$$g(t,x,u) + z\cdot r(t,x,u) \geq c|u|\left(|u| - \frac{C}{c}|z|\right) - cR^2 - C|z|. \tag{3.6}$$

On the other hand, if we fix an arbitrary $u^0 \in K$, then

$$g(t,x,u^0) + z\cdot r(t,x,u^0) \leq C(1+|x|^2+|u^0|^2) + C|z|(1+|u^0|) \leq C_3(1+|x|^2+|z|). \tag{3.7}$$

Hence, there exists a constant $C > 0$ such that, if $|u| > C(1+|x|+|z|)$, then

$$g(t,x,u) + z\cdot r(t,x,u) > g(t,x,u^0) + z\cdot r(t,x,u^0),$$

and (3.3) follows from the continuity of g and r with respect to u.

Finally, the continuity of $\psi(t,x,\cdot)$ can be easily proved, taking into account (3.3). □

Next we take an arbitrarily complete probability space $(\Omega, \mathcal{F}, \mathbb{P}^\circ)$ and a Wiener process W° in $\mathbb{R}^d$ with respect to $\mathbb{P}^\circ$. We denote by $(\mathcal{F}_t^\circ)$ the associated Brownian filtration, i.e., the filtration generated by W° and augmented by the $\mathbb{P}^\circ$-null sets of $\mathcal{F}$; $(\mathcal{F}_t^\circ)$ satisfies the usual conditions.

We introduce the forward equation

$$\begin{cases} dX_t = b(t,X_t)\,dt + \sigma(t,X_t)\,dW_t^\circ, & t\in[0,T], \\ X_0 = x, \end{cases} \tag{3.8}$$

whose solution is a continuous $(\mathcal{F}_t^\circ)$-adapted process, which exists and is unique by classical results. Next we consider the associated backward equation

$$\begin{cases} dY_t = -\psi(t,X_t,Z_t)\,dt + Z_t\,dW_t^\circ, & t\in[0,T], \\ Y_T = \phi(X_T). \end{cases} \tag{3.9}$$

The solution of (3.9) exists in the sense specified by the following proposition.

PROPOSITION 3.2. *Assume that b, σ, g, ϕ satisfy Hypothesis* 2.1. *Then there exist Borel measurable functions*

$$v : [0,T]\times\mathbb{R}^n \to \mathbb{R}, \quad \zeta : [0,T]\times\mathbb{R}^n \to \mathbb{R}^d$$

with the following property: For an arbitrarily chosen complete probability space $(\Omega, \mathcal{F}, \mathbb{P}^\circ)$ *and Wiener process* W° *in* $\mathbb{R}^d$*, denoting by* X *the solution of* (3.8)*, the processes* Y, Z *defined by*

$$Y_t = v(t, X_t), \quad Z_t = \zeta(t, X_t)$$

satisfy

$$\mathbb{E}^\circ \sup_{t\in[0,T]} |Y_t|^2 < \infty, \quad \mathbb{E}^\circ \int_0^T |Z_t|^2 \, dt < \infty;$$

moreover, Y *is continuous and nonnegative, and* $\mathbb{P}^\circ$*-a.s.,*

$$Y_t + \int_t^T Z_s \, dW_s^\circ = \phi(X_T) + \int_t^T \psi(s, X_s, Z_s) \, ds, \quad t \in [0, T].$$

Finally, this solution is the maximal solution among all the solutions (Y', Z') *of* (3.9) *satisfying*

$$\mathbb{E}^\circ \left[\sup_{t\in[0,T]} |Y'_t|^2 \right] < +\infty.$$

Proof. From Lemma 3.1, there exists a constant $C > 0$ such that

$$-C(1 + |z|^2) \le \psi(t, x, z) \le g(t, x, u^0) + C(1 + |u^0|)|z|.$$

Let us first note that

$$\mathbb{E}^\circ \sup_{t\in[0,T]} |X_t|^p < \infty \ \forall p \ge 2.$$

Next, we adopt the same strategy as that in [2] to construct a maximal solution to (3.9); i.e., for each $n \ge C$, we define the globally Lipschitz continuous function,

$$\psi_n(t, x, z) = \sup\{\psi(t, x, q) - n|q - z| : q \in \mathbb{Q}^d\},$$

which is decreasing and converges to ψ; then by (Y^n, Z^n) we denote the unique solution to the BSDE with Lipschitz coefficient ψ_n,

$$\begin{cases} dY_t^n = -\psi_n(t, X_t, Z_t^n) \, dt + Z_t^n \, dW_t^\circ, & t \in [0, T], \\ Y_T^n = \phi(X_T), \end{cases} \tag{3.10}$$

and by (Y^S, Z^S) the unique solution to the BSDE,

$$\begin{cases} dY_t^S = -[g(t, X_t, u^0) + C(1 + |u^0|)|Z_t^S|] \, dt + Z_t^S \, dW_t^\circ, & t \in [0, T], \\ Y_T^S = \phi(X_T), \end{cases} \tag{3.11}$$

where C is the same as in (3.2). We notice that, since $\psi_n(t, x, 0) \ge \psi(t, x, 0) \ge 0$, then by an application of the comparison theorem (see [4]),

$$0 \le Y_t^n \le Y_t^S.$$

Then let us introduce the following stopping time: For $k \ge 1$,

$$\tau_k = \inf\{t \in [0, T] : \max(|X_t|, Y_t^S) > k\},$$

with the convention that $\tau_k = T$ if the indicated set is empty.

Then $(Y_k^n, Z_k^n) := (Y_{t\wedge\tau_k}^n, Z_t^n 1_{t\le\tau_k})$ satisfies the following BSDE:

$$Y_k^n(t) = \xi_k^n + \int_t^T 1_{s\le\tau_k}\psi_n(s, X_s, Z_k^n(s))ds - \int_t^T Z_k^n(s)dW_s^\circ,$$

where of course $\xi_k^n = Y_k^n(T) = Y_{\tau_k}^n$.

For fixed k, Y_k^n is decreasing in n and remains bounded by k. It follows from Lemma 3 in [2] (which is a slight generalization of Proposition 2.4 in [10]) that there exists a process (Y_k, Z_k) such that Y_k is a continuous process, $E\int_0^T |Z_k(s)|^2 ds < +\infty$,

$$\lim_n \sup_{t\in[0,T]} |Y_k^n(t) - Y_k(t)| = 0, \quad \lim_n E\int_0^T |Z_k^n(t) - Z_k(t)|^2 dt = 0,$$

and (Y_k, Z_k) solves the BSDE

$$Y_k(t) = \xi_k + \int_t^T 1_{s\le\tau_k}\psi(s, X_s, Z_k(s))ds - \int_t^T Z_k(s)dW_s^\circ, \tag{3.12}$$

where $\xi_k = \inf_n Y_{\tau_k}^n$.

On the other hand, $\tau_k \le \tau_{k+1}$, and, from the definition of (Y_k^n, Z_k^n), we have

$$Y_{k+1}^n(t\wedge\tau_k) = Y_k^n(t), \quad Z_{k+1}^n(t)1_{t\le\tau_k} = Z_k^n(t).$$

Sending n to infinity, we get

$$Y_{k+1}(t\wedge\tau_k) = Y_k(t), \quad Z_{k+1}(t)1_{t\le\tau_k} = Z_k(t).$$

Now we define Y and Z on $[0,T]$ by setting

$$Y_t = Y_k(t), \quad Z_t = Z_k(t) \quad \text{if} \quad t\in[0,\tau_k].$$

For $\mathbb{P}^\circ$-a.s. ω, there exists an integer $K(\omega)$ such that for $k \ge K(\omega)$, $\tau_k(\omega) = T$. Thus Y is a continuous process, $Y_T = \phi(X_T)$, and $\int_0^T |Z_t|^2 ds < \infty$, $\mathbb{P}^\circ$-a.s.

From (3.12), (Y, Z) satisfies

$$Y_{t\wedge\tau_k} = Y_{\tau_k} + \int_{t\wedge\tau_k}^{\tau_k} \psi(s, X_s, Z(s))ds - \int_{t\wedge\tau_k}^{\tau_k} Z(s)dW_s^\circ. \tag{3.13}$$

By sending k to infinity, we deduce that (Y, Z) is a solution of (3.9) and

$$\lim_n \sup_{t\in[0,T]} |Y_t^n - Y_t| = 0, \quad \lim_n \int_0^T |Z_t^n - Z_t|^2 dt = 0, \qquad \mathbb{P}^\circ\text{-a.s.}$$

Thus $|Z^n - Z|$ converges to zero in measure $d\mathbb{P}^\circ \otimes dt$, and passing, if needed, to a subsequence (that by abuse of language we still denote Z^n), we can assume that $|Z^n - Z| \to 0$, $d\mathbb{P}^\circ \otimes dt$ almost everywhere.

Now, as ψ_n is globally Lipschitz continuous, from [4] (see also [6]) there exist Borel measurable functions

$$v^n : [0,T]\times\mathbb{R}^n \to \mathbb{R}, \quad \zeta^n : [0,T]\times\mathbb{R}^n \to \mathbb{R}^d$$

such that

$$Y_t^n = v^n(t, X_t), \quad Z_t^n = \zeta^n(t, X_t).$$

It suffices to define

$$v(t,x) = \liminf_{n\to\infty} v^n(t,x), \text{ and } \zeta(t,x) = \liminf_{n\to\infty} \zeta^n(t,x)$$

(where the second lim inf is intended coordinatewise) to get

$$Y_t = v(t, X_t), \quad Z_t = \zeta(t, X_t),$$

which implies that (v, ζ) is the Borel function we look for.

Finally, $0 \le Y_t \le Y_t^S$ implies that

$$\mathbb{E} \sup_{t\in[0,T]} |Y_t|^2 < \infty,$$

and from the equation

$$|Y_t|^2 + \int_t^{\tau_k} |Z_s|^2 ds = 2\int_t^{\tau_k} Y_s \psi(s, X_s, Z_s) ds - 2\int_t^{\tau_k} Y_s Z_s dW_s^\circ,$$

taking into consideration that

$$Y_s\psi(s,X_s,Z_s) \le Y_s(g(s,X_s,u^0) + C(1+|u^0|)|Z_s|) \le Y_s^S(g(s,X_s,u^0) + C(1+|u^0|)|Z_s|),$$

we deduce, by standard arguments, that

$$\mathbb{E}^\circ \int_0^T |Z_t|^2 dt < \infty.$$

Moreover, this solution is the maximal solution among all the solutions (Y', Z') satisfying

$$\mathbb{E}^\circ \left[\sup_{t\in[0,T]} |Y_t'|^2 \right] < +\infty,$$

and it suffices to apply Proposition 5 of [2] to deduce that $Y^n \ge Y'$ and then $Y \ge Y'$. □

4. The fundamental relation. In this section we revert to the notation introduced in the first section and still assume that Hypothesis 2.1 holds.

PROPOSITION 4.1. *Let v, ζ denote the functions in the statement of Proposition 3.2. Then for every admissible control u and for the corresponding trajectory X starting at x, we have*

$$J(u) = v(0,x) + \mathbb{E}\int_0^T [-\psi(t, X_t, \zeta(t,X_t)) + \zeta(t,X_t)\cdot r(t,X_t,u_t) + g(t,X_t,u_t)]\, dt.$$

Proof. We introduce stopping times τ_n and control processes u^n as in the proof of Proposition 2.3, and we denote by X^n the solution to (2.14). Let us define

$$W_t^n = W_t + \int_0^t r(s, X_s^n, u_s^n)\, ds.$$

From the definition of τ_n and from (2.7), it follows that

(4.1)
$$\int_0^T |r(s,X_s^n,u_s^n)|^2\, ds \le C\int_0^T (1+|u_s^n|)^2\, ds \le C\int_0^{\tau_n} (1+|u_s|)^2\, ds + C \le C + Cn.$$

Therefore defining

$$\rho_n = \exp\left(\int_0^T -r(s, X_s^n, u_s^n)\, dW_s - \frac{1}{2}\int_0^T |r(s, X_s^n, u_s^n)|^2\, ds\right),$$

the Novikov condition implies that $\mathbb{E}\rho_n = 1$. Setting $d\mathbb{P}^n = \rho_n d\mathbb{P}$, by the Girsanov theorem W^n is a Wiener process under $\mathbb{P}^n$. Let us denote by $(\mathcal{F}_t^n)$ its natural augmented filtration. Since

$$\begin{cases} dX_t^n = b(t, X_t^n)\, dt + \sigma(t, X_t^n)\, dW_t^n, & t \in [0, T], \\ X_0^n = x \end{cases}$$

has a strong solution by classical results, the process X^n is also $(\mathcal{F}_t^n)$ adapted. Let us define

$$Y_t^n = v(t, X_t^n), \quad Z_t^n = \zeta(t, X_t^n).$$

Then by Proposition 3.2, we have

$$\begin{cases} dY_t^n = Z_t^n\, dW_t^n - \psi(t, X_t^n, Z_t^n)\, dt, & t \in [0, T], \\ Y_T^n = \phi(X_T^n) \end{cases} \tag{4.2}$$

and $\mathbb{E}^n \int_0^T |Z_t^n|^2\, dt < \infty$, where $\mathbb{E}^n$ denotes expectation with respect to $\mathbb{P}^n$. It follows that

$$Y_{\tau_n}^n = \phi(X_T^n) + \int_{\tau_n}^T \psi(t, X_t^n, Z_t^n)\, dt - \int_{\tau_n}^T Z_t^n\, dW_t - \int_{\tau_n}^T Z_t^n \cdot r(t, X_t^n, u_t^n)\, dt. \tag{4.3}$$

We note that for every $p \in [1, \infty)$ we have

$$\rho_n^{-p} = \exp\left(p\int_0^T r(s, X_s^n, u_s^n)\, dW_s^n - \frac{p^2}{2}\int_0^T |r(s, X_s^n, u_s^n)|^2\, ds\right)$$
$$\cdot \exp\left(\frac{p^2 - p}{2}\int_0^T |r(s, X_s^n, u_s^n)|^2\, ds\right).$$

By (4.1) the second exponential is bounded by a constant depending on n and p, while the first one has $\mathbb{P}^n$-expectation, equal to 1. So we conclude that $\mathbb{E}_n \rho_n^{-p} < \infty$. It follows that

$$\mathbb{E}\left(\int_0^T |Z_t^n|^2 dt\right)^{1/2} = \mathbb{E}^n\left(\rho_n^{-2}\int_0^T |Z_t^n|^2 dt\right)^{1/2} \le \left(\mathbb{E}^n \rho_n^{-2}\right)^{1/2}\left(\mathbb{E}^n \int_0^T |Z_t^n|^2 dt\right)^{1/2} < \infty.$$

We conclude that the stochastic integral in (4.3) has zero expectation, and we obtain

$$\mathbb{E}Y_{\tau_n}^n = \mathbb{E}\phi(X_T^n) + \mathbb{E}\int_{\tau_n}^T [\psi(t, X_t^n, Z_t^n) - Z_t^n \cdot r(t, X_t^n, u_t^n)]\, dt.$$

Since by definition, $\psi(t, x, z) - z \cdot r(t, x, u) - g(t, x, u) \le 0$, we have

$$\mathbb{E}Y_{\tau_n}^n \le \mathbb{E}\phi(X_T^n) + \mathbb{E}\int_{\tau_n}^T g(t, X_t^n, u_t^n)\, dt. \tag{4.4}$$

Now we let $n \to \infty$. By the definition of u^n and (2.8),

$$\mathbb{E}\int_{\tau_n}^{T} g(t, X_t^n, u_t^n)\, dt = \mathbb{E}\int_0^T 1_{t>\tau_n} g(t, X_t^n, u^0)\, dt$$
$$\leq C\mathbb{E}\int_0^T 1_{t>\tau_n}(1 + |X_t^n|^2 + |u^0|^2)dt \leq C\mathbb{E}\left[(T-\tau_n)\left(1 + \sup_{t\in[0,T]} |X_t^n|^2\right)\right],$$

and the right-hand side tends to 0 by Lemma 2.4 and (2.13). Next we note that, again by (2.13), for $n \geq N(\omega)$ we have $\tau_n(\omega) = T$ and

$$\phi(X_T^n) = \phi(X_{\tau_n}^n) = \phi(X_{\tau_n}) = \phi(X_T).$$

Moreover, by (2.9),

$$|\phi(X_T^n)| \leq C(1 + |X_T^n|^2) \leq C\left(1 + \sup_{t\in[0,T]} |X_t^n|^2\right),$$

and by Lemma 2.4 the right-hand side is uniformly integrable. We deduce that $\mathbb{E}\phi(X_T^n) \to \mathbb{E}\phi(X_T)$, and from (4.4) we conclude that $\limsup_{n\to\infty} \mathbb{E}Y_{\tau_n}^n \leq \mathbb{E}\phi(X_T)$. On the other hand, for $n \geq N(\omega)$ we have $\tau_n(\omega) = T$ and

$$Y_{\tau_n}^n = Y_T^n = \phi(X_T^n) = \phi(X_T).$$

Since Y^n is positive, by the Fatou lemma, $\mathbb{E}\phi(X_T) \leq \liminf_{n\to\infty} \mathbb{E}Y_{\tau_n}^n$. We have thus proved that

$$\lim_{n\to\infty} \mathbb{E}Y_{\tau_n}^n = \mathbb{E}\phi(X_T). \tag{4.5}$$

Now we return to (4.2) and write

$$Y_{\tau_n}^n = Y_0^n + \int_0^{\tau_n} -\psi(t, X_t^n, Z_t^n)\, dt + \int_0^{\tau_n} Z_t^n\, dW_t + \int_0^{\tau_n} Z_t^n \cdot r(t, X_t^n, u_t^n)\, dt.$$

Arguing as before, we conclude that the stochastic integral has zero $\mathbb{P}$-expectation. Moreover, we have $Y_0^n = v(0,x)$, and, for $t \leq \tau_n$, also have $u_t^n = u_t$, $X_t^n = X_t$, and $Z_t^n = \zeta(t, X_t)$. Thus we obtain

$$\mathbb{E}Y_{\tau_n}^n = v(0,x) + \mathbb{E}\int_0^{\tau_n} [-\psi(t, X_t, \zeta(t, X_t)) + \zeta(t, X_t) \cdot r(t, X_t, u_t)]\, dt$$

and

$$\mathbb{E}\int_0^{\tau_n} g(t, X_t, u_t)\, dt + \mathbb{E}Y_{\tau_n}^n$$
$$= v(0,x) + \mathbb{E}\int_0^{\tau_n} [-\psi(t, X_t, \zeta(t, X_t)) + \zeta(t, X_t) \cdot r(t, X_t, u_t) + g(t, X_t, u_t)]\, dt.$$

Noting that $-\psi(t,x,z) + z \cdot r(t,x,u) + g(t,x,u) \geq 0$ and recalling that $g(t,x,u) \geq 0$, by (4.5) and the monotone convergence theorem, we obtain for $n \to \infty$,

$$\mathbb{E}\int_0^T g(t, X_t, u_t)\, dt + \mathbb{E}\phi(X_T) = v(0,x)$$
$$+ \mathbb{E}\int_0^T [-\psi(t, X_t, \zeta(t, X_t)) + \zeta(t, X_t) \cdot r(t, X_t, u_t) + g(t, X_t, u_t)]\, dt,$$

which gives the required conclusion. □

COROLLARY 4.2. *For every admissible control u and any initial datum x, we have $J(u) \geq v(0,x)$, and the equality holds if and only if the following feedback law holds $\mathbb{P}$-a.s. for almost every $t \in [0,T]$:*

$$\psi(t, X_t, \zeta(t, X_t)) = \zeta(t, X_t) \cdot r(t, X_t, u_t) + g(t, X_t, u_t),$$

where X is the trajectory starting at x and corresponding to control u.

5. Existence of optimal controls: The closed loop equation. Let us consider again the functions b, σ, g, ϕ satisfying the assumptions in Hypothesis 2.1. We recall the definition of the Hamiltonian function:

$$\psi(t,x,z) = \inf_{u \in K} [g(t,x,u) + z \cdot r(t,x,u)], \qquad t \in [0,T], x \in \mathbb{R}^n, \quad z \in \mathbb{R}^d. \tag{5.1}$$

LEMMA 5.1. *There exists a Borel measurable function $\gamma : [0,T] \times \mathbb{R}^n \times \mathbb{R}^d \to K$ such that*

(5.2)
$$\psi(t,x,z) = g(t,x,\gamma(t,x,z)) + z \cdot r(t,x,\gamma(t,x,z)), \qquad t \in [0,T], \quad x \in \mathbb{R}^n, \quad z \in \mathbb{R}^d.$$

Moreover, there exists a constant $C > 0$ such that

$$|\gamma(t,x,z)| \leq C(1 + |x| + |z|). \tag{5.3}$$

Proof. Consider the function $F(t,x,z,u) = g(t,x,u) + z \cdot r(t,x,u)$, $t \in [0,T]$, $x \in \mathbb{R}^n$, $z \in \mathbb{R}^d$. Clearly F is a Carathéodory map (that is, $F(t,x,z,\cdot)$ is continuous for all $t \in [0,T]$, $x \in \mathbb{R}^n$, and $z \in \mathbb{R}^d$, and $F(\cdot,\cdot,\cdot,u)$ is Borel measurable for all $u \in K$; see [1, p. 311]). By (3.3) we have

$$\psi(t,x,z) \in \{F(t,x,z,u) : u \in K\} \quad \forall t \in [0,T], \quad x \in \mathbb{R}^n, \quad z \in \mathbb{R}^d.$$

Thus by the Filippov theorem (see, e.g., [1, Thm. 8.2.10, p. 316]) there exists a Borel measurable map $\gamma : [0,T] \times \mathbb{R}^n \times \mathbb{R}^d \to K$ such that $F(t,x,z,\gamma(t,x,z)) = \psi(t,x,z)$; see [3] as well. The fact that $|\gamma(t,x,z)| \leq C(1+|x|+|z|)$ is an immediate consequence of (3.4). □

Next we address the problem of finding a weak solution to the so-called closed loop equation. We define

$$\underline{u}(t,x) = \gamma(t,x,\zeta(t,x)), \qquad t \in [0,T], \quad x \in \mathbb{R}^n,$$

where ζ is defined in Proposition 3.2. The closed loop equation is

$$\begin{cases} dX_t = b(t,X_t)\,dt + \sigma(t,X_t)\,[dW_t + r(t,X_t,\underline{u}(t,X_t))\,dt], \qquad t \in [0,T], \\ X_0 = x. \end{cases} \tag{5.4}$$

By a weak solution we mean a complete probability space $(\Omega, \mathcal{F}, \mathbb{P})$ with a filtration $(\mathcal{F}_t)$ satisfying the usual conditions, a Wiener process W in $\mathbb{R}^d$ with respect to $\mathbb{P}$ and $(\mathcal{F}_t)$, and a continuous $(\mathcal{F}_t)$-adapted process X with values in $\mathbb{R}^n$ satisfying, $\mathbb{P}$-a.s.,

$$\int_0^T |\underline{u}(t,X_t)|^2\,dt < \infty, \tag{5.5}$$

and such that (5.4) holds. We note that by (2.7) it also follows that

$$\int_0^T |r(t,X_t,\underline{u}(t,X_t))|\,dt < \infty, \quad \mathbb{P}\text{-a.s.},$$

so that (5.4) makes sense.

PROPOSITION 5.2. *Assume that b, σ, g, ϕ satisfy Hypothesis 2.1. Then there exists a weak solution of the closed loop equation, satisfying in addition*

$$\mathbb{E}\int_0^T |\underline{u}(t, X_t)|^2 \, dt < \infty. \tag{5.6}$$

Proof. Let us take an arbitrary complete probability space $(\Omega, \mathcal{F}, \mathbb{P}^\circ)$ and a Wiener process W° in $\mathbb{R}^d$ with respect to $\mathbb{P}^\circ$. Let $(\mathcal{F}_t^\circ)$ be the associated Brownian filtration. We define the process X as the solution of the equation

$$\begin{cases} dX_t = b(t, X_t)\, dt + \sigma(t, X_t)\, dW_t^\circ, & t \in [0, T], \\ X_0 = x. \end{cases} \tag{5.7}$$

The solution is a continuous $(\mathcal{F}_t^\circ)$-adapted process, which exists and is unique by classical results. Moreover, it satisfies $\mathbb{E}^\circ \sup_{t\in[0,T]} |X_t|^p < \infty$ for every $p \in [1, \infty)$.

By Proposition 3.2, setting

$$Y_t = v(t, X_t), \quad Z_t = \zeta(t, X_t),$$

the following backward equation holds:

$$\begin{cases} dY_t = -\psi(t, X_t, Z_t)\, dt + Z_t\, dW_t^\circ, & t \in [0, T], \\ Y_T = \phi(X_T), \end{cases}$$

and we have

$$\mathbb{E}^\circ \int_0^T |Z_t|^2 \, dt < \infty. \tag{5.8}$$

By (2.7) we have $|r(t, X_t, \underline{u}(t, X_t))| \le C(1 + |\underline{u}(t, X_t)|)$, and by (5.3),

$$|\underline{u}(t, X_t)| = |\gamma(t, X_t, \zeta(t, X_t))| \le C(1 + |X_t| + |\zeta(t, X_t)|) = C(1 + |X_t| + |Z_t|). \tag{5.9}$$

Now let us define stopping times

$$\tau_n = \inf\left\{ t \in [0, T] \ : \ \int_0^t |\underline{u}(s, X_s)|^2 ds > n \right\},$$

with the convention that $\tau_n = T$ if the indicated set is empty. By (5.8) and (5.9), for $\mathbb{P}^\circ$-a.s. $\omega \in \Omega$, there exists an integer $N(\omega)$ depending on ω such that $\tau_n(\omega) = T$ for $n \ge N(\omega)$. Let us fix $u^0 \in K$, and for every n let us define

$$u_t^n = \underline{u}(t, X_t)\, 1_{t\le\tau_n} + u^0\, 1_{t>\tau_n},$$

$$M_t^n = \exp\left(\int_0^t r(s, X_s, u_s^n)\, dW_s^\circ - \frac{1}{2}\int_0^t |r(s, X_s, u_s^n)|^2 \, ds \right),$$

$$M_t = \exp\left(\int_0^t r(s, X_s, \underline{u}(s, X_s))\, dW_s^\circ - \frac{1}{2}\int_0^t |r(s, X_s, \underline{u}(s, X_s))|^2 \, ds \right),$$

$$W_t^n = W_t^\circ - \int_0^t r(s, X_s, u_s^n)\, ds,$$

$$W_t = W_t^\circ - \int_0^t r(s, X_s, \underline{u}(s, X_s))\, ds.$$

By the previous estimates, M^n, M, W^n, and W are well defined; moreover,

$$\int_0^T |r(s, X_s, u_s^n) - r(s, X_s, \underline{u}(s, X_s))|^2 \, ds \to 0, \qquad \mathbb{P}^\circ\text{-a.s.},$$

and consequently $M_T^n \to M_T$ in probability and $\sup_{t\in[0,T]} |W_t^n - W_t| \to 0$, $\mathbb{P}^\circ$-a.s. We will conclude the proof by showing that there exists a probability $\mathbb{P}$ such that W is a Wiener process with respect to $\mathbb{P}$ and $(\mathcal{F}_t^\circ)$.

The definition of τ_n and the Novikov condition implies that $\mathbb{E}^\circ M_T^n = 1$. Setting $d\mathbb{P}^n = M_T^n d\mathbb{P}^\circ$, by the Girsanov theorem W^n is a Wiener process with respect to $\mathbb{P}^n$ and $(\mathcal{F}_t^\circ)$. Writing the backward equation with respect to W^n, we obtain

$$Y_{\tau_n} = Y_0 + \int_0^{\tau_n} -\psi(t, X_t, Z_t) \, dt + \int_0^{\tau_n} Z_t \, dW_t^n + \int_0^{\tau_n} Z_t \cdot r(t, X_t, u_t^n) \, dt.$$

Arguing as in the proof of Proposition 4.1, we conclude that the stochastic integral has zero expectation with respect to $\mathbb{P}^n$. Taking into account that $u_t^n = \underline{u}(t, X_t)$ for $t \le \tau_n$, we obtain

$$\begin{aligned}
&\mathbb{E}^n Y_{\tau_n} + \mathbb{E}^n \int_0^{\tau_n} g(t, X_t, \underline{u}(t, X_t)) \, dt \\
&\quad = Y_0 + \mathbb{E}^n \int_0^{\tau_n} [-\psi(t, X_t, Z_t) + Z_t \cdot r(t, X_t, \underline{u}(t, X_t)) + g(t, X_t, \underline{u}(t, X_t))] \, dt \\
&\quad = Y_0,
\end{aligned}$$

with the last equality coming from the definition of $\underline{u}$. Recalling that Y is nonnegative, it follows that

$$\mathbb{E}^n \int_0^{\tau_n} g(t, X_t, \underline{u}(t, X_t)) \, dt \le C$$

for some constant C independent of n. By (2.10) we also deduce

$$\mathbb{E}^n \int_0^{\tau_n} |\underline{u}(t, X_t)|^2 \, dt \le C. \tag{5.10}$$

Next we prove that the family $\{M_T^n, \ n = 1, 2, \dots\}$ is uniformly integrable by showing that $\mathbb{E}^\circ[M_T^n \, 1_{\{M_T^n > c\}}] \to 0$ as $c \to \infty$, uniformly with respect to n. We have

$$\mathbb{E}^\circ[M_T^n \, 1_{\{M_T^n > c\}}] = \mathbb{E}^\circ[M_T^n \, 1_{\{M_T^n > c, \tau_n = T\}}] + \mathbb{E}^\circ[M_T^n \, 1_{\{M_T^n > c, \tau_n < T\}}]. \tag{5.11}$$

The first term in the right-hand side tends to 0 uniformly with respect to n, since

$$\mathbb{E}^\circ[M_T^n \, 1_{\{M_T^n > c, \tau_n = T\}}] = \mathbb{E}^\circ[M_T \, 1_{\{M_T > c, \tau_n = T\}}] \le \mathbb{E}^\circ[M_T \, 1_{\{M_T > c\}}] \to 0,$$

due to the fact that the equality $\mathbb{E}^\circ M_T^n = 1$ and the Fatou lemma imply that $\mathbb{E}^\circ M_T \le 1$. The second term in the right-hand side of (5.11) can be estimated as follows:

$$\begin{aligned}
\mathbb{E}^\circ[M_T^n \, 1_{\{M_T^n > c, \tau_n < T\}}] &\le \mathbb{E}^\circ[M_T^n \, 1_{\tau_n < T\}}] = \mathbb{P}^n(\tau_n < T) \\
&\le \mathbb{P}^n \left(\int_0^{\tau_n} |\underline{u}(t, X_t)|^2 dt > n \right) \le \frac{1}{n} \mathbb{E}^n \int_0^{\tau_n} |\underline{u}(t, X_t))|^2 dt \le \frac{C}{n},
\end{aligned}$$

with the last inequality coming from (5.10). The required uniform integrability follows immediately. Recalling that $M_T^n \to M_T$ in probability, we conclude that $\mathbb{E}^\circ |M_T^n - M_T| \to 0$, and in particular $\mathbb{E}^\circ M_T = 1$, and M is a $\mathbb{P}^\circ$-martingale. Thus we can define

a probability $\mathbb{P}$ by setting $d\mathbb{P} = M_T d\mathbb{P}^\circ$, and by the Girsanov theorem we conclude that W is a Wiener process with respect to $\mathbb{P}$ and $(\mathcal{F}_t^\circ)$.

It remains to prove (5.6). We define stopping times

$$\sigma_n = \inf\left\{t \in [0,T] : \int_0^t |Z_s|^2 ds > n\right\},$$

with the convention that $\sigma_n = T$ if the indicated set is empty. Writing the backward equation with respect to W, we obtain

$$Y_{\sigma_n} = Y_0 + \int_0^{\sigma_n} -\psi(t, X_t, Z_t)\, dt + \int_0^{\sigma_n} Z_t\, dW_t + \int_0^{\sigma_n} Z_t \cdot r(t, X_t, \underline{u}(t, X_t))\, dt,$$

from which we deduce that

$$\begin{aligned}
&\mathbb{E}Y_{\sigma_n} + \mathbb{E}\int_0^{\sigma_n} g(t, X_t, \underline{u}(t, X_t))\, dt \\
&\quad = Y_0 + \mathbb{E}\int_0^{\sigma_n} [-\psi(t, X_t, Z_t) + Z_t \cdot r(t, X_t, \underline{u}(t, X_t)) + g(t, X_t, \underline{u}(t, X_t))]\, dt \\
&\quad = Y_0,
\end{aligned}$$

with the last equality coming from the definition of $\underline{u}$. Recalling that Y is nonnegative, it follows that

$$\mathbb{E}\int_0^{\sigma_n} g(t, X_t, \underline{u}(t, X_t))\, dt \le C$$

for some constant C independent of n. By (2.10) and by sending n to infinity, we finally prove (5.6). □

Corollary 5.3. *By Corollary* 4.2 *it immediately follows that if X is the solution to* (5.4) *and we set $u_s^\sharp = \underline{u}(s, X_s)$, then $J(x, u^\sharp) = v(0, x)$, and consequently X is an optimal state, $u_s^\sharp$ is an optimal control, and $\underline{u}$ is an optimal feedback.*

Next we prove uniqueness in law for the closed loop equation. We remark that condition (5.5) is part of our definition of a weak solution.

Proposition 5.4. *Assume that b, σ, g, ϕ satisfy Hypothesis* 2.1. *Fix $\gamma : [0,T] \times \mathbb{R}^n \times \mathbb{R}^d \to K$ satisfying* (5.2) (*and consequently* (5.3)) *and let $\underline{u}(t,x) = \gamma(t, x, \zeta(t,x))$. Then the weak solution of the closed loop equation* (5.4) *is unique in law.*

Proof. Let $(\Omega, \mathcal{F}, \mathbb{P})$, $(\mathcal{F}_t)$, W, X be a weak solution of (5.4).

Let us define

$$M_T = \exp\left(-\int_0^T r(s, X_s, \underline{u}(s, X_s))\, dW_s - \frac{1}{2}\int_0^T |r(s, X_s, \underline{u}(s, X_s))|^2\, ds\right),$$

$$W_t^\circ = W_t + \int_0^t r(s, X_s, \underline{u}(s, X_s))\, ds.$$

By (2.7) and (5.5), M_T and W° are well defined. We claim that $\mathbb{E}M_T = 1$. Assuming the claim for a moment, and setting $d\mathbb{P}^\circ = M_T d\mathbb{P}$, by the Girsanov theorem W° is a Wiener process under $\mathbb{P}^\circ$, X solves

$$\begin{cases} dX_t = b(t, X_t)\, dt + \sigma(t, X_t)\, dW_t^\circ, & t \in [0,T], \\ X_0 = x, \end{cases}$$

and

$$M_T = \exp\left(- \int_0^T r(s, X_s, \underline{u}(s, X_s))\, dW_s^\circ + \frac{1}{2} \int_0^T |r(s, X_s, \underline{u}(s, X_s))|^2\, ds \right).$$

By the Lipschitz and linear growth conditions on b and σ (see (2.3), (2.4), (2.5)) the law of (X, W°) under $\mathbb{P}^\circ$ is uniquely determined by b, σ, x. Taking into account the last displayed formula, we conclude that the law of (X, W°, M_T) under $\mathbb{P}^\circ$ is also uniquely determined, and consequently so is the law of X under $\mathbb{P}$.

To conclude the proof it remains to show that $\mathbb{E}M_T = 1$. We define stopping times

$$\tau_n = \inf \left\{ t \in [0, T] \ : \ \int_0^t |\underline{u}(s, X_s)|^2 ds > n \right\},$$

with the convention that $\tau_n = T$ if the indicated set is empty. By (5.5), for $\mathbb{P}$-almost every $\omega \in \Omega$, there exists an integer $N(\omega)$ depending on ω such that $\tau_n(\omega) = T$ for $n \geq N(\omega)$. Let us fix $u^0 \in K$, and for every n, let us define

$$u_t^n = \underline{u}(t, X_t)\, 1_{t \leq \tau_n} + u^0\, 1_{t > \tau_n},$$

$$M_T^n = \exp\left(- \int_0^T r(s, X_s, u_s^n)\, dW_s - \frac{1}{2} \int_0^T |r(s, X_s, u_s^n)|^2\, ds \right).$$

By (2.7) and the definition of τ_n, the Novikov condition shows that $\mathbb{E}M_T^n = 1$. Moreover, we have

$$\int_0^T |r(s, X_s, u_s^n) - r(s, X_s, \underline{u}(s, X_s))|^2\, ds \to 0, \qquad \mathbb{P}\text{-a.s.},$$

and consequently $M_T^n \to M_T$ in probability. In order to conclude the proof it is therefore enough to show that the family $\{M_T^n,\, n = 1, 2, \dots\}$ is uniformly integrable.

To prepare for this, let us set $d\mathbb{P}^n = M_T^n d\mathbb{P}$ and note that, by the Girsanov theorem, the process

$$W_t^n = W_t + \int_0^t r(s, X_s, u_s^n)\, ds$$

is a Wiener process under $\mathbb{P}^n$. Since X solves

$$\begin{cases} dX_t = b(t, X_t)\, dt + \sigma(t, X_t)\, dW_t^n, & t \in [0, T], \\ X_0 = x, \end{cases}$$

it follows that X is adapted to the Brownian filtration $(\mathcal{F}_t^n)$ associated to W^n, and its law under $\mathbb{P}^n$ is uniquely determined by b, σ, x. In particular, the quantities

$$C' := \mathbb{E}^n \int_0^T |X_t|^2\, dt, \qquad C'' := \mathbb{E}^n \int_0^T |\zeta(t, X_t)|^2\, dt$$

do not depend on n (here $\mathbb{E}^n$ denotes, of course, the expectation with respect to $\mathbb{P}^n$). C' is clearly finite. By Proposition 3.2, setting $Z_t = \zeta(t, X_t)$, we have

$$\mathbb{E}^n \int_0^T |\zeta(t, X_t)|^2\, dt = \mathbb{E}^n \int_0^T |Z_t|^2\, dt < \infty,$$

and it follows that C'' is also finite.

Now let us prove the uniform integrability of the family $\{M_T^n,\ n = 1, 2, \dots\}$ by showing that $\mathbb{E}[M_T^n\ 1_{\{M_T^n > c\}}] \to$ as $c \to \infty$, uniformly with respect to n. We have

$$\mathbb{E}[M_T^n\ 1_{\{M_T^n > c\}}] = \mathbb{E}[M_T^n\ 1_{\{M_T^n > c, \tau_n = T\}}] + \mathbb{E}[M_T^n\ 1_{\{M_T^n > c, \tau_n < T\}}]. \tag{5.12}$$

The first term in the right-hand side tends to 0 uniformly with respect to n, since

$$\mathbb{E}[M_T^n\ 1_{\{M_T^n > c, \tau_n = T\}}] = \mathbb{E}[M_T\ 1_{\{M_T > c, \tau_n = T\}}] \le \mathbb{E}[M_T\ 1_{\{M_T > c\}}] \to 0,$$

due to the fact that the equality $\mathbb{E}M_T^n = 1$ and the Fatou lemma imply that $\mathbb{E}M_T \le 1$. The second term in the right-hand side of (5.12) can be estimated as follows:

$$\mathbb{E}[M_T^n\ 1_{\{M_T^n > c, \tau_n < T\}}] \le \mathbb{E}[M_T^n\ 1_{\tau_n < T}] = \mathbb{P}^n(\tau_n < T)$$
$$\le \mathbb{P}^n\left(\int_0^{\tau_n} |\underline{u}(t, X_t)|^2 dt > n\right) \le \frac{1}{n}\mathbb{E}^n \int_0^{\tau_n} |\underline{u}(t, X_t)|^2 dt \le \frac{1}{n}\mathbb{E}^n \int_0^T |\underline{u}(t, X_t)|^2 dt.$$

By (5.3) we have

$$|\underline{u}(t, X_t)|^2 = |\gamma(t, X_t, \zeta(t, X_t))|^2 \le C(1 + |X_t|^2 + |\zeta(t, X_t)|^2)$$

for some constant C, and it follows that

$$\mathbb{E}[M_T^n\ 1_{\{M_T^n > c, \tau_n < T\}}] \le \frac{C}{n}\mathbb{E}^n \int_0^T (1 + |X_t|^2 + |\zeta(t, X_t)|^2)\ dt = \frac{C}{n}(T + C' + C''),$$

with C' and C'' defined as above. The required uniform integrability follows immediately, and this concludes the proof. □

ALMOST GLOBAL STOCHASTIC STABILITY*

RAMON VAN HANDEL†

Abstract. We develop a method to prove almost global stability of stochastic differential equations in the sense that almost every initial point (with respect to the Lebesgue measure) is asymptotically attracted to the origin with unit probability. The method can be viewed as a dual to Lyapunov's second method for stochastic differential equations and extends the deterministic result of [A. Rantzer, *Syst. Control Lett.*, 42 (2001), pp. 161–168]. The result can also be used in certain cases to find stabilizing controllers for stochastic nonlinear systems using convex optimization. The main technical tool is the theory of stochastic flows of diffeomorphisms.

Key words. stochastic stability, stochastic flows, nonlinear stochastic control

1. Introduction.

Lyapunov's second method or the method of Lyapunov functions, though developed in the late 19th century, remains one of the most important tools in the study of deterministic differential equations. The power of the method lies in the fact that an important qualitative property of a differential equation, the stability of an equilibrium point, can be proved without solving the equation explicitly. The theory was generalized to stochastic differential equations in the 1960s with fundamental contributions by Has'minskiĭ [10] and Kushner [15].

Lyapunov's method also underlies many important applications in the area of nonlinear control [11]. Finding optimal controls for nonlinear systems is generally an intractable problem, but often a solution can be found which stabilizes the system. Unlike in deterministic control theory, where nonlinear control is now a major field, there are very few results on stochastic nonlinear control. It is only recently that stochastic versions of the classical stabilization results of Jurdjevic-Quinn, Artstein, and Sontag were developed by Florchinger [7, 8, 9] and backstepping designs for stochastic strict-feedback systems were developed by Deng and Krstić [5] and Deng Krstić, and Williams [6].

In this paper we will not consider stochastic stability in the sense of Has'minskiĭ; rather, we ask the following question: for a given Itô stochastic differential equation on $\mathbb{R}^n$, can we prove that for almost every initial state (with respect to the Lebesgue measure on $\mathbb{R}^n$) the solution of the equation converges to the origin almost surely as $t \to \infty$, i.e., is the origin *almost* globally stable? This notion of stability is clearly weaker than global stability in the sense of Has'minskiĭ, but is of potential interest in many cases in which global stability may not be attained.

Our main result is a Lyapunov-type theorem that can be used to prove almost global stability of stochastic differential equations, extending the deterministic result of Rantzer [23]. The theorem has several remarkable properties. It can be viewed as a "dual" to Lyapunov's second method in the following sense: whereas the Lyapunov

condition reads $\mathscr{L}V < 0$, where $\mathscr{L}$ is the characteristic operator of the stochastic differential equation and V is the Lyapunov function, the condition that guarantees almost global stability reads $\mathscr{L}^*D < 0$, where $\mathscr{L}^*$ is the formal adjoint of $\mathscr{L}$ (also known as the Fokker–Planck operator). Hence the relation between the two theorems recalls the duality between densities and expectations which is prevalent throughout the theory of stochastic processes.

A further interesting property is the following convexity property. Suppose we are given an Itô equation of the form

$$x_t = x + \int_s^t (X_0(x_\tau) + u(x_\tau)Y(x_\tau))\,d\tau + \sum_{k=1}^m \int_s^t X_k(x_\tau)\,dW_\tau^k,$$

where $X_k(0) = 0$ for $k = 0, \ldots, m$ and $u(x)$ is a state feedback control. The goal is to design $u(x)$ such that the origin is almost globally stable. It is easily verified that the set of pairs of functions $(D(x), u(x)D(x))$ which satisfy $\mathscr{L}^*D < 0$ is convex. Note that the classical Lyapunov condition $\mathscr{L}V < 0$ is not convex.

The above convexity property was used in the deterministic case by Prajna, Parrilo, and Rantzer [22] to formulate the search for almost globally stabilizing controllers as a convex optimization problem, provided that X_k, Y, D, and u are rational functions. The method applies equally to the stochastic case and thus provides a tool for computer-aided design of stochastic nonlinear controllers.

It must be emphasized that almost global stability is a global property of the flow which places very few restrictions on the local behavior near the origin. In particular, local stability is not implied.[1] A very fruitful approach to studying the local dynamical behavior of stochastic differential equations (and more general random dynamical systems) is developed by Arnold [2]. First, the flow associated to the stochastic differential equation is linearized; then Oseledec's multiplicative ergodic theorem is used to provide a suitable "time-averaged" notion of the eigenvalues of the linearized flow. To prove almost global stability we do not linearize the flow, though the proofs still rely on the flow of diffeomorphisms generated by the stochastic equation. We refer to [1] for an introduction to the dynamical approach to stochastic analysis.

This paper is organized as follows. In section 2 we fix the notation that will be used in the remainder of the paper. In section 3 we reproduce the deterministic result of Rantzer [23] with a significantly different proof that generalizes to the stochastic case. In section 4 we review the theory of stochastic flows of diffeomorphisms generated by stochastic differential equations. Section 5 is devoted to the statement and proof of our main result for the case of globally Lipschitz continuous coefficients. In section 6 the main result is extended to cases in which the global Lipschitz condition does not necessarily hold. A few examples are given in section 7. Finally, in section 8 we discuss the application to control synthesis using convex optimization.

2. Notation. Throughout this article we will consider (stochastic) differential equations in $\mathbb{R}^n$. The Lebesgue measure on $\mathbb{R}^n$ will be denoted by μ. $\mathbb{R}_+$ denotes the nonnegative real numbers and $\mathbb{Z}_+$ the nonnegative integers.

We remind the reader of the following definitions: For $0 < \alpha \leq 1$, a function $f : X \to Y$ from a normed space $(X, \|\cdot\|)$ to a normed space $(Y, \|\cdot\|_Y)$ is called

[1] The term "stability" seems a bit of a misnomer; despite that almost all points converge to the origin, a trajectory that starts close to the origin could move very far from the origin before converging to it. We have used the term that has been used in the deterministic literature, e.g., [18].

globally Hölder continuous of order α if there exists a positive constant C such that

$$\|f(x) - f(y)\|_Y \le C\|x - y\|^\alpha \qquad \forall x, y \in X. \tag{2.1}$$

f is locally Hölder continuous of order α if it satisfies the condition (2.1) on every bounded subset of X. f is called globally (locally) Lipschitz continuous if it is globally (locally) Hölder continuous of order 1. f is called a $C^{k,\alpha}$ function if it is k times continuously differentiable and the kth derivatives are locally Hölder continuous of order α for some $k \in \mathbb{Z}_+$ and $0 < \alpha \le 1$.

3. The deterministic case. In this section we give a new proof of Rantzer's theorem [23], which is a deterministic counterpart of our main result. Our proof demonstrates the main features of the proof of the stochastic result in the simpler deterministic case.

The following lemma is similar to Lemma A.1 in [23], and we omit the proof.

LEMMA 3.1. *Let $f \in C^1(\mathbb{R}^n, \mathbb{R}^n)$ be globally Lipschitz continuous, let $S \subset \mathbb{R}^n$ be an invariant set of $\dot{x}(t) = f(x(t))$, and let $Z \subset S$ be μ-measurable. Let $D \in C^1(S, \mathbb{R})$ be integrable on Z. Then*

$$\int_{\phi_t^{-1}(Z)} D(x)\,dx = \int_Z D(x)\,dx - \int_0^t \int_{\phi_\tau^{-1}(Z)} [\nabla \cdot (fD)](x)\,dx\,d\tau, \tag{3.1}$$

where $\phi_t : \mathbb{R}^n \to \mathbb{R}^n$ is the flow of f.

THEOREM 3.2. *Let $f \in C^1(\mathbb{R}^n, \mathbb{R}^n)$ be globally Lipschitz continuous and let $f(0) = 0$. Suppose there exists $D \in C^1(\mathbb{R}^n \backslash \{0\}, \mathbb{R}_+)$ such that D is integrable on $\{x \in \mathbb{R}^n : |x| > 1\}$ and $[\nabla \cdot (fD)](x) > 0$ for μ-almost all x. Then for μ-almost all initial states $x(0)$ the solution of $\dot{x}(t) = f(x(t))$ tends to the origin as $t \to \infty$.*

Proof. Let $S = \mathbb{R}^n \backslash \{0\}$, $\varepsilon > 0$ and $Z = \{x \in \mathbb{R}^n : |x| > \varepsilon\}$. Note that $\phi_t(x)$ is a diffeomorphism for every $t \in \mathbb{R}$; hence $\phi_t(x)$ is one-to-one, and as $\phi_t(0) = 0$, $t \in \mathbb{R}$, is a solution of $\dot{x}(t) = f(x(t))$ there can be no $x \in S$ such that $\phi_t(x) = 0$ for some $t \in \mathbb{R}$. We have thus verified the invariance of S under the flow $\phi_t(x)$. We now invoke Lemma 3.1. As $D(x)$ is nonnegative, expression (3.1) is also nonnegative. Furthermore, (3.1) is finite because D is integrable on Z, and is nonincreasing due to $[\nabla \cdot (fD)](x) \ge 0$. By monotone convergence the limit as $t \to \infty$ exists and is finite. Hence

$$\int_0^\infty \mathbb{D}(\phi_\tau^{-1}(Z))\,d\tau < \infty, \qquad \mathbb{D}(A) = \int_A [\nabla \cdot (fD)](x)\,dx.$$

Note that the assumption $[\nabla \cdot (fD)](x) \ge 0$ implies that $\mathbb{D}$ is a measure on S. The measure space $(S, \mathbb{D})$ is σ-finite as $\mathbb{D}(\{x \in S : \frac{1}{k} < |x| < k\}) < \infty$ for all $k > 1$ and $\bigcup_{n=2}^\infty \{x \in S : \frac{1}{k} < |x| < k\} = S$.

We now fix some $m \in \mathbb{N}$ and divide the halfline into bins $S_k^m = [(k-1)2^{-m}, k2^{-m}]$, $k \in \mathbb{N}$. From each bin we choose a time $t_k^m \in S_k^m$ such that

$$\mathbb{D}(\phi_{t_k^m}^{-1}(Z)) \le \inf_{t \in S_k^m} \mathbb{D}(\phi_t^{-1}(Z)) + 2^{-k}.$$

For fixed m, we denote this discrete grid by $T_m = \{t_k^m : k \in \mathbb{N}\}$. We now have

$$2^{-m} \sum_{k=1}^\infty \mathbb{D}(\phi_{t_k^m}^{-1}(Z)) \le 2^{-m} + \int_0^\infty \mathbb{D}(\phi_\tau^{-1}(Z))\,d\tau < \infty.$$

As $\mathbb{D}$ is σ-finite we can now apply the Borel–Cantelli lemma, which gives

$$\mathbb{D}\left(\limsup_{k\to\infty}\phi_{t_k^m}^{-1}(Z)\right)=\mu\left(\limsup_{k\to\infty}\phi_{t_k^m}^{-1}(Z)\right)=0,$$

where the first equality follows as $[\nabla\cdot(fD)](x)>0$ μ-a.e. implies $\mu\ll\mathbb{D}$. Consequently

$$\mu\left(\bigcup_{m=1}^{\infty}\limsup_{t\in T_m}\phi_t^{-1}(Z)\right)\le\sum_{m=1}^{\infty}\mu\left(\limsup_{t\in T_m}\phi_t^{-1}(Z)\right)=0.$$

We have thus shown that the set of initial states x for which there are, for some m, infinitely many times $t\in T_m$ such that $\phi_t(x)\in Z$ has Lebesgue measure zero.

We now claim that if $\limsup_{t\to\infty}|\phi_t(x)|>\varepsilon$, then we can choose m so that there are infinitely many times t in T_m such that $\phi_t(x)\in Z$. The statement is trivial if also $\liminf_{t\to\infty}|\phi_t(x)|>\varepsilon$; let us thus assume that $\liminf_{t\to\infty}|\phi_t(x)|\le\varepsilon$. We will need the following result. Due to the global Lipschitz condition and $f(0)=0$, we have

$$|\phi_t(x)|\le|\phi_s(x)|+\int_s^t|f(\phi_\sigma(x))|\,d\sigma\le|\phi_s(x)|+C\int_s^t|\phi_\sigma(x)|\,d\sigma \tag{3.2}$$

for some constant $C>0$. Thus Gronwall's lemma gives $|\phi_t(x)|\le|\phi_s(x)|\,e^{C(t-s)}$. Now note that $\liminf_{t\to\infty}|\phi_t(x)|\le\varepsilon<\limsup_{t\to\infty}|\phi_t(x)|$ implies that there exist $\varepsilon''>\varepsilon'>\varepsilon$ such that (i) there are infinitely many upcrossings of the curve $|\phi_t(x)|$ through ε', and (ii) $|\phi_t(x)|$ crosses ε'' infinitely often. Denote by t'' a time such that $|\phi_{t''}(x)|=\varepsilon''$ and by t' the latest time previous to t'' that $|\phi_{t'}(x)|=\varepsilon'$. Then clearly $t''-t'\ge\frac{1}{C}\log\frac{\varepsilon''}{\varepsilon'}$. As this happens infinitely often, we conclude that $\phi_t(x)$ infinitely often spends a time in excess of $\frac{1}{C}\log\frac{\varepsilon''}{\varepsilon'}$ in Z. But then clearly m can be chosen large enough so that every such interval includes at least one of the $t_k^m\in T_m$.

We have now shown that for μ-almost all $x\in\mathbb{R}^n$ we have $\limsup_{t\to\infty}|\phi_t(x)|\le\varepsilon$, i.e., for μ-almost all $x\in\mathbb{R}^n$ $\exists t_e>0$ such that $|\phi_t(x)|\le\varepsilon$ for $t\ge t_e$. But as this holds for any $\varepsilon>0$ the trajectories must converge to the origin. □

4. Stochastic flows. The purpose of this section is to review, without proofs, some results of the theory of stochastic flows of diffeomorphisms generated by stochastic differential equations. A detailed exposition on the subject can be found in [13, 14], and shorter treatments are in [1, 2, 3, 12].

Throughout this article $(\Omega,\mathcal{F},\mathbb{P})$ denotes the canonical Wiener space of the m-dimensional Brownian motion W_t with two-sided time $\mathbb{R}$. We also introduce the two-parameter filtration $\mathcal{F}_s^t=\sigma\{W_u^k-W_v^k:s\le v\le u\le t,\ 1\le k\le m\}$. The extension to two-sided time is important in that it allows us to treat the Wiener process as a dynamical system [1, 2, 3].

THEOREM 4.1. *There exists a one-parameter group $\{\theta_t:t\in\mathbb{R}\}$ of measure-preserving transformations of $(\Omega,\mathcal{F},\mathbb{P})$ such that $W_t(\theta_s\omega)=W_{t+s}(\omega)-W_s(\omega)$ for all $\omega\in\Omega$ and $s,t\in\mathbb{R}$.*

We will consider Itô stochastic differential equations of the form

$$x_t=x+\int_s^t X_0(x_\tau)\,d\tau+\sum_{k=1}^m\int_s^t X_k(x_\tau)\,dW_\tau^k \tag{4.1}$$

with the following assumptions:

1. $x\in\mathbb{R}^n$.

2. $X_k : \mathbb{R}^n \to \mathbb{R}^n$, $k = 0, \dots, m$, are globally Lipschitz continuous.

The global Lipschitz condition guarantees many nice properties of the solutions; we will assume it for the time being, and later relax this requirement somewhat in section 6.

Denote by $\xi_{s,t}(x, \omega)$ (or simply $\xi_{s,t}(x)$) the solution of (4.1) at time $t \geq s$ given the initial condition $x_s = x$. It is well known that in the case of globally Lipschitz continuous coefficients there exists a unique, nonexploding solution $\xi_{s,t}(x)$ which is an $\mathcal{F}_s^t$-semimartingale and is in L^p for any $p \geq 1$ (see, e.g., [13]).

THEOREM 4.2 (see [13, 2]). *Suppose X_k, $k = 0, \dots, m$, are globally Lipschitz continuous and let $s < t$. Then we have the following properties:*

1. *$\xi_{s,s}(x, \omega) = x$ for all s and ω.*
2. *For any u we have $\xi_{s,t}(\cdot, \theta_u \omega) = \xi_{s+u,t+u}(\cdot, \omega)$.*
3. *For almost all ω we have $\xi_{s,t}(\cdot, \omega) = \xi_{r,t}(\xi_{s,r}(\cdot, \omega), \omega)$ for all $s < r < t$.*
4. *$\xi_{s,t}(x)$ is $\mathbb{P}$-a.s. continuous in (s, t, x).*
5. *For almost all ω the map $\xi_{s,t}(\cdot, \omega) : \mathbb{R}^n \to \mathbb{R}^n$ is a homeomorphism for all $s < t$.*

The following result establishes that, under additional smoothness conditions, $\xi_{s,t}(x)$ is in fact a *stochastic flow of diffeomorphisms*.

THEOREM 4.3 (see [13]). *Suppose X_k, $k = 0, \dots, m$, are globally Lipschitz continuous and that they are $C^{p,\alpha}$ functions for some $p \geq 1$ and $0 < \alpha < 1$. Then for almost all ω the map $\xi_{s,t}(\cdot, \omega) : \mathbb{R}^n \to \mathbb{R}^n$ is a C^p diffeomorphism for any $s \leq t$, and*

$$\frac{\partial \xi_{s,t}(x)^i}{\partial x^j} = \delta_j^i + \sum_{\beta=1}^{n} \int_s^t \frac{\partial X_0^i}{\partial x^\beta}(\xi_{s,\tau}(x)) \frac{\partial \xi_{s,\tau}(x)^\beta}{\partial x^j} \, d\tau + \sum_{k=1}^{m} \sum_{\beta=1}^{n} \int_s^t \frac{\partial X_k^i}{\partial x^\beta}(\xi_{s,\tau}(x)) \frac{\partial \xi_{s,\tau}(x)^\beta}{\partial x^j} \, dW_\tau^k. \tag{4.2}$$

It will be convenient for our purposes to work with the inverse flow $\xi_{s,t}^{-1}(x)$, considered as a backward stochastic process in the time variable s (with t fixed). This will not give rise to ordinary Itô integrals as s behaves like a time-reversed variable, and hence the adaptedness of the process runs backward in time. The Itô backward integral is defined as [13]

$$\int_s^t f_\sigma \overleftarrow{dW}_\sigma \equiv \lim \text{ in prob } \sum_{k=0}^{n-1} f_{t_{k+1}} (W_{t_{k+1}} - W_{t_k}),$$

where f_s is a backward predictable process with $\int_s^t |f_u|^2 \, du < \infty$ almost surely, and the formal construction of the integral from simple functions proceeds along the usual lines. The backward integral has similar properties to the forward integral; in particular, it is a backward $\mathcal{F}_s^t$-local martingale (for fixed t) and satisfies an Itô formula (see, e.g., [4, p. 124]), which is proved in the same way as its forward counterpart: given $\xi_s = \xi_t + \int_s^t a_\sigma \, d\sigma + \sum_k \int_s^t (b_\sigma)_k \overleftarrow{dW}_\sigma^k$ with backward predictable processes a_s, $(b_s)_k$ such that $\int_s^t a_\sigma \, d\sigma < \infty$ almost surely, $\int_s^t |(b_\sigma)_k|^2 \, d\sigma < \infty$ almost surely, then for any C^2 function $F : \mathbb{R}^n \to \mathbb{R}$

$$F(\xi_s) = F(\xi_t) + \frac{1}{2} \sum_{k=1}^{m} \sum_{i,j=1}^{n} \int_s^t (b_\sigma)_k^i (b_\sigma)_k^j \frac{\partial^2 F}{\partial x^i \partial x^j}(\xi_\sigma) \, d\sigma + \sum_{i=1}^{n} \int_s^t a_\sigma^i \frac{\partial F}{\partial x^i}(\xi_\sigma) \, d\sigma + \sum_{k=1}^{m} \sum_{i=1}^{n} \int_s^t (b_\sigma)_k^i \frac{\partial F}{\partial x^i}(\xi_\sigma) \overleftarrow{dW}_\sigma^k. \tag{4.3}$$

We can now formulate the following result.

THEOREM 4.4 (see [13]). *Suppose X_k, $k = 0, \ldots, m$, are globally Lipschitz continuous and that they are $C^{p,\alpha}$ functions for some $p \geq 2$ and $0 < \alpha < 1$. Then*

$$\xi_{s,t}^{-1}(x) = x - \int_s^t \tilde{X}_0(\xi_{\sigma,t}^{-1}(x))\, d\sigma - \sum_{k=1}^m \int_s^t X_k(\xi_{\sigma,t}^{-1}(x))\, \overleftarrow{dW}_\sigma,$$

where we have defined

$$\tilde{X}_0(x) = X_0(x) - \sum_{k=1}^m \sum_{\beta=1}^n X_k^\beta(x) \frac{\partial}{\partial x^\beta} X_k(x).$$

This expression can be manipulated much in the same way as its forward counterpart. In particular, under the conditions of Theorem 4.4 and using (4.3), we obtain for any C^2 function $F : \mathbb{R}^n \to \mathbb{R}$ the backward Itô formula

$$\begin{aligned} F(\xi_{s,t}^{-1}(x)) = F(x) &+ \frac{1}{2} \sum_{k,i,j} \int_s^t X_k^i(\xi_{\sigma,t}^{-1}(x)) X_k^j(\xi_{\sigma,t}^{-1}(x)) \frac{\partial^2 F}{\partial x^i \partial x^j}(\xi_{\sigma,t}^{-1}(x))\, d\sigma \\ &- \sum_i \int_s^t \tilde{X}_0^i(\xi_{\sigma,t}^{-1}(x)) \frac{\partial F}{\partial x^i}(\xi_{\sigma,t}^{-1}(x))\, d\sigma - \sum_{k,i} \int_s^t X_k^i(\xi_{\sigma,t}^{-1}(x)) \frac{\partial F}{\partial x^i}(\xi_{\sigma,t}^{-1}(x))\, \overleftarrow{dW}_\sigma^k. \end{aligned} \tag{4.4}$$

Similarly we can differentiate the inverse flow, giving

$$\begin{aligned} \frac{\partial \xi_{s,t}^{-1}(x)^i}{\partial x^j} = \delta_j^i &- \sum_{\beta=1}^n \int_s^t \frac{\partial \tilde{X}_0^i}{\partial x^\beta}(\xi_{\sigma,t}^{-1}(x)) \frac{\partial \xi_{\sigma,t}^{-1}(x)^\beta}{\partial x^j}\, d\sigma \\ &- \sum_{k=1}^m \sum_{\beta=1}^n \int_s^t \frac{\partial X_k^i}{\partial x^\beta}(\xi_{\sigma,t}^{-1}(x)) \frac{\partial \xi_{\sigma,t}^{-1}(x)^\beta}{\partial x^j}\, \overleftarrow{dW}_\sigma^k. \end{aligned} \tag{4.5}$$

This expression is obtained, in the same way as its forward counterpart (4.2), by letting $y \to 0$ in the backward expression corresponding to [13, p. 219, eqn. (4)].

5. The main result. We consider an Itô equation of the form (4.1). We write

$$\mathscr{L}^* f(x) = \frac{1}{2} \sum_{k=1}^m \sum_{i,j=1}^n \frac{\partial^2}{\partial x^i \partial x^j}(X_k^i(x) X_k^j(x) f(x)) - \sum_{i=1}^n \frac{\partial}{\partial x^i}(X_0^i(x) f(x)).$$

The following is our main result.

THEOREM 5.1. *Let X_k, $k = 0, \ldots, m$, be globally Lipschitz continuous and $C^{2,\alpha}$ functions for some $\alpha > 0$, and let $X_k(0) = 0$. Suppose there exists $D \in C^2(\mathbb{R}^n \backslash \{0\}, \mathbb{R}_+)$ such that D is integrable on $\{x \in \mathbb{R}^n : |x| > 1\}$ and $\mathscr{L}^* D(x) < 0$ for μ-almost all x. Then for every initial time s and μ-a.e. initial state x the flow $\xi_{s,t}(x)$ tends to the origin as $t \to \infty$ $\mathbb{P}$-a.s.*

Before we prove the theorem, let us prove a stochastic version of Lemma 3.1.

LEMMA 5.2. *Suppose X_k, $k = 0, \ldots, m$, are globally Lipschitz continuous and $C^{2,\alpha}$ functions for some $\alpha > 0$. Let $S_\ell \subset S_{\ell+1} \subset \mathbb{R}^n$ be an increasing sequence of open sets such that $\tau_\ell = \sup\{s < t : \xi_{s,t}^{-1}(x) \notin S_\ell\} \to -\infty$ as $\ell \to \infty$ $\mathbb{P}$-a.s. for every $x \in S = \bigcup_\ell S_\ell$. Suppose there is a $D \in C^2(S, \mathbb{R}_+)$ that is integrable on a*

measurable set $Z \subset S$, that obeys $\mathscr{L}^* D \le 0$ on S, and such that for each ℓ there is a $D_\ell \in C^2(\mathbb{R}^n, \mathbb{R}_+)$ that coincides with D on S_ℓ. Then

$$0 \le \int_Z D(x)\,dx + \int_s^t \mathbb{E} \int_{\xi_{\sigma,t}^{-1}(Z)} \mathscr{L}^* D(x)\,dx\,d\sigma$$

for all $s \le t$, and in particular the limit as $s \to -\infty$ of this expression is well defined.

Proof. Denote by $\mathbf{J}_{s,t}(x)$ the matrix with elements $\mathbf{J}_{s,t}(x)^i_j = \partial \xi^{-1}_{s,t}(x)^i / \partial x^j$, i.e.,

$$\mathbf{J}_{s,t}(x)^i_j = \delta^i_j - \sum_\alpha \int_s^t \frac{\partial \tilde{X}^i_0}{\partial x^\alpha}(\xi^{-1}_{\sigma,t}(x))\mathbf{J}_{\sigma,t}(x)^\alpha_j\,d\sigma - \sum_{k,\alpha} \int_s^t \frac{\partial X^i_k}{\partial x^\alpha}(\xi^{-1}_{\sigma,t}(x))\mathbf{J}_{\sigma,t}(x)^\alpha_j \circ\!\!\leftarrow dW^k_\sigma$$

by (4.5). Denote by $|\mathbf{J}_{s,t}(x)|$ its determinant, i.e.,

$$|\mathbf{J}_{s,t}(x)| = \sum_{j_1 \cdots j_n = 1}^n \varepsilon_{j_1,\ldots,j_n} \mathbf{J}_{s,t}(x)^1_{j_1} \mathbf{J}_{s,t}(x)^2_{j_2} \cdots \mathbf{J}_{s,t}(x)^n_{j_n},$$

where $\varepsilon_{j_1,\ldots,j_n}$ is the antisymmetric tensor. Using Itô's rule and straightforward calculations we obtain

$$\begin{aligned}|\,\mathbf{J}_{s,t}(x)| = 1 &- \sum_i \int_s^t \frac{\partial \tilde{X}^i_0}{\partial x^i}(\xi^{-1}_{\sigma,t}(x))|\mathbf{J}_{\sigma,t}(x)|\,d\sigma - \sum_{k,i} \int_s^t \frac{\partial X^i_k}{\partial x^i}(\xi^{-1}_{\sigma,t}(x))|\mathbf{J}_{\sigma,t}(x)| \circ\!\!\leftarrow dW^k_\sigma \\ &+ \frac{1}{2}\sum_{k,i,j} \int_s^t \left[\frac{\partial X^i_k}{\partial x^i}(\xi^{-1}_{\sigma,t}(x))\frac{\partial X^j_k}{\partial x^j}(\xi^{-1}_{\sigma,t}(x)) - \frac{\partial X^i_k}{\partial x^j}(\xi^{-1}_{\sigma,t}(x))\frac{\partial X^j_k}{\partial x^i}(\xi^{-1}_{\sigma,t}(x))\right] |\mathbf{J}_{\sigma,t}(x)|\,d\sigma.\end{aligned}$$

Note that as $\xi^{-1}_{s,t}(\cdot)$ is a diffeomorphism almost surely, its Jacobian $\mathbf{J}_{s,t}(\cdot)$ must almost surely be an invertible matrix; but as $|\mathbf{J}_{s,t}(x)|$ has almost surely continuous sample paths and $|\mathbf{J}_{t,t}(x)| = 1$, this implies that almost surely $|\mathbf{J}_{s,t}(x)| > 0$ for all $s < t$. Using (4.4) with $F = D_\ell$ and Itô's rule we obtain

$$\begin{aligned}0 \le D_\ell(\xi^{-1}_{s,t}(x))|\mathbf{J}_{s,t}(x)| = D_\ell(x) &+ \int_s^t (\mathscr{L}^* D_\ell)(\xi^{-1}_{\sigma,t}(x))|\mathbf{J}_{\sigma,t}(x)|\,d\sigma \\ &- \sum_{k=1}^m \sum_{i=1}^n \int_s^t \frac{\partial X^i_k D_\ell}{\partial x^i}(\xi^{-1}_{\sigma,t}(x))|\mathbf{J}_{\sigma,t}(x)| \circ\!\!\leftarrow dW^k_\sigma.\end{aligned}$$

Now note that as D_ℓ coincides with D on S_ℓ, we can identify $(\mathscr{L}^* D_\ell)(\xi^{-1}_{s\vee\tau_\ell,t}(x)) = (\mathscr{L}^* D)(\xi^{-1}_{s\vee\tau_\ell,t}(x))$ for every ℓ. Moreover, as the last term in the expression above is a backward local martingale, there exists a sequence of stopping times $\tau'_p \searrow -\infty$ such that the stochastic integral stopped at τ'_p is a martingale. Replacing s by $s \vee \tau_\ell \vee \tau'_p$ in the expression above and taking the expectation gives

$$0 \le D(x) + \mathbb{E} \int_{s\vee\tau_\ell\vee\tau'_p}^t (\mathscr{L}^* D)(\xi^{-1}_{\sigma,t}(x))|\mathbf{J}_{\sigma,t}(x)|\,d\sigma.$$

We can now let $\ell, p \to \infty$ by monotone convergence. Integrating both sides gives

$$0 \le \int_Z D(x)\,dx + \int_s^t \mathbb{E} \int_Z (\mathscr{L}^* D)(\xi^{-1}_{\sigma,t}(x))|\mathbf{J}_{\sigma,t}(x)|\,dx\,d\sigma,$$

where we have used Tonelli's theorem to change the order of integration. The result follows after a change of coordinates. □

The proof of Theorem 5.1 is similar to the proof of Theorem 3.2. The stochastic version of the argument following (3.2), however, is a little more subtle, as we do not have a pathwise upper bound on the rate of growth of sample paths. On the other hand, we can establish such a bound *in probability* which, together with the strong Markov property, is sufficient for our purposes; a similar argument was used in [16] to the same effect. For this purpose we give the following lemma, various versions of which appear in the literature (the result below is adapted from [6]).

LEMMA 5.3. *Let X_k, $k = 0, \ldots, m$, be locally Lipschitz continuous and let $\lambda > 0$. Then*

$$\mathbb{P}\left[\sup_{0\le\delta\le\Delta} |\xi_{s,s+\delta}(x) - x| \ge \lambda\right] \le K_1\Delta + K_2\Delta^2,$$

where $K_1, K_2 < \infty$ are constants that depend only on λ and $|x|$.

Proof. Let $\mathbf{W}_t$ be the m-vector with elements W_t^k and let $\mathbf{X}(\cdot)$ be the $n\times m$-matrix with entries $X_k^i(\cdot)$, $k = 1, \ldots, m$. For $r > 0$, define $B_r(x') = \{x \in \mathbb{R}^n : |x - x'| < r\}$, $B_r = B_r(0)$, and

$$\rho_0(r) = \sup_{|y|<r} |X_0(y)|, \qquad \rho_1(r) = \sup_{|y|<r} \|\mathbf{X}(y)\| = \sup_{|y|<r} \mathrm{tr}[\mathbf{X}(y)^T\mathbf{X}(y)]^{1/2}.$$

Let τ_r be the first exit time of $\xi_{s,t}(x)$ from B_r. In [6, p. 1240] it was established that

$$\mathbb{E}\left[\sup_{0\le\delta\le\Delta} |\xi_{s,(s+\delta)\wedge\tau_r}(x) - x|^2\right] \le 2\rho_0(r)^2\Delta^2 + 8\rho_1(r)^2\Delta.$$

Hence we have by Markov's inequality

$$\mathbb{P}\left[\sup_{0\le\delta\le\Delta} |\xi_{s,(s+\delta)\wedge\tau_r}(x) - x| \ge \lambda\right] \le \lambda^{-2}(2\rho_0(r)^2\Delta^2 + 8\rho_1(r)^2\Delta).$$

Now note that $B_\lambda(x)$ is strictly included in $B_{|x|+2\lambda}$, so that the first exit time from $B_\lambda(x)$ is no later than $\tau_{|x|+2\lambda}$. But then the events

$$\left\{\omega : \sup_{0\le\delta\le\Delta} |\xi_{s,(s+\delta)\wedge\tau_{|x|+2\lambda}}(x) - x| \ge \lambda\right\}, \quad \left\{\omega : \sup_{0\le\delta\le\Delta} |\xi_{s,s+\delta}(x) - x| \ge \lambda\right\}$$

are equivalent; after all, the events are equivalent on $\tau_{|x|+2\lambda} > s + \Delta$ by construction, whereas if $\tau_{|x|+2\lambda} \le s + \Delta$, both events must be true as $|\xi_{s,\tau_{|x|+2\lambda}}(x) - x| \ge \lambda$. Hence

$$\mathbb{P}\left[\sup_{0\le\delta\le\Delta} |\xi_{s,s+\delta}(x) - x| \ge \lambda\right] \le \lambda^{-2}(2\rho_0(|x| + 2\lambda)^2\Delta^2 + 8\rho_1(|x| + 2\lambda)^2\Delta),$$

where we have set $r = |x| + 2\lambda$. This completes the proof. □

We now turn to the proof of the main theorem.

Proof of Theorem 5.1. Let $\varepsilon > 0$ and $Z = \{x \in \mathbb{R}^n : |x| > \varepsilon\}$. We begin by applying Lemma 5.2. To this end, define $S_\ell = \{x \in \mathbb{R}^n : |x| > \ell^{-1}\}$, so $S = \bigcup_\ell S_\ell = \mathbb{R}^n\backslash\{0\}$. Clearly D is integrable on Z and there exists a $C^2(\mathbb{R}^n, \mathbb{R}_+)$-approximation D_ℓ of D for each ℓ. It remains to check that $\tau_\ell \to -\infty$. Suppose that this is not the case; then given $x \in S$ there must be a positive probability that $\xi_{s,t}^{-1}(x) = 0$ for some

$-\infty < s < t$. But $\xi_{s,t}^{-1}(0) = 0$ for all s and almost surely $\xi_{s,t}^{-1}(x)$ is one-to-one for all $s < t$, so this cannot happen. Hence all the conditions of Lemma 5.2 are satisfied, and we have

$$0 \le \int_Z D(x)\,dx + \int_s^t \mathbb{E} \int_{\xi_{\sigma,t}^{-1}(Z)} \mathscr{L}^* D(x)\,dx\,d\sigma. \tag{5.1}$$

Now note that (5.1) is nonincreasing with decreasing s due to $\mathscr{L}^* D \le 0$ and is finite because D is integrable on Z. By monotone convergence the limit as $s \to -\infty$ exists and is finite. Hence

$$\int_{-\infty}^t \mathbb{D}(\xi_{\sigma,t}^{-1}(Z))\,d\sigma < \infty, \qquad \mathbb{D}(A) = -\int_A \mathscr{L}^* D(x)\,(\mathbb{P}(d\omega) \times \mu(dx)),$$

where we have used Tonelli's theorem to convert the iterated integral to a single integral with respect to the product measure, and we slightly abuse our notation by writing $\mathbb{D}(\xi_{\sigma,t}^{-1}(Z)) = \mathbb{D}(\{(\omega, x) \in \Omega \times S : \xi_{\sigma,t}(x, \omega) \in Z\})$. Note that $\mathscr{L}^* D \le 0$ implies that $\mathbb{D}$ is a measure on $\Omega \times S$, and $\mathbb{D}$ is σ-finite as $\mathbb{D}(\Omega \times \{x \in S : \frac{1}{k} < |x| < k\}) < \infty$ for all $k > 1$ and $\bigcup_{n=2}^{\infty}(\Omega \times \{x \in S : \frac{1}{k} < |x| < k\}) = \Omega \times S$.

We now fix some $m \in \mathbb{N}$ and divide the halfline into bins $S_k^m = [(k-1)2^{-m}, k2^{-m}]$, $k \in \mathbb{N}$. From each bin we choose a time $t_k^m \in S_k^m$ such that

$$\mathbb{D}(\xi_{t-t_k^m,t}^{-1}(Z)) \le \inf_{s \in S_k^m} \mathbb{D}(\xi_{t-s,t}^{-1}(Z)) + 2^{-k}.$$

For fixed m, we denote this discrete grid by $T_m = \{t_k^m : k \in \mathbb{N}\}$. We now have

$$2^{-m} \sum_{k=1}^{\infty} \mathbb{D}(\xi_{t-t_k^m,t}^{-1}(Z)) \le 2^{-m} + \int_{-\infty}^t \mathbb{D}(\xi_{\sigma,t}^{-1}(Z))\,d\sigma < \infty.$$

Using the fact that the transformation θ_t of Theorem 4.1 is $\mathbb{P}$-preserving to shift the times t_k^m to the forward variable, we obtain

$$\sum_{k=1}^{\infty} \mathbb{D}(\xi_{s,s+t_k^m}^{-1}(Z)) = \sum_{k=1}^{\infty} \mathbb{D}(\xi_{t-t_k^m,t}^{-1}(Z)) < \infty.$$

As $\mathbb{D}$ is σ-finite we can now apply the Borel–Cantelli lemma, which gives

$$\mathbb{D}\left(\limsup_{k\to\infty} \xi_{s,s+t_k^m}^{-1}(Z)\right) = (\mathbb{P} \times \mu)\left(\limsup_{k\to\infty} \xi_{s,s+t_k^m}^{-1}(Z)\right) = 0,$$

where the first equality follows as $\mathscr{L}^* D(x) < 0$ μ-a.e. implies $\mathbb{P} \times \mu \ll \mathbb{D}$. Consequently

$$(\mathbb{P} \times \mu)\left(\bigcup_{m=1}^{\infty} \limsup_{t\in T_m} \xi_{s,s+t}^{-1}(Z)\right) \le \sum_{m=1}^{\infty} (\mathbb{P} \times \mu)\left(\limsup_{t\in T_m} \xi_{s,s+t}^{-1}(Z)\right) = 0.$$

We have thus shown that for all initial states x, except in a set $N \subset \mathbb{R}^n$ of Lebesgue measure zero, there is $\mathbb{P}$-a.s. for any m only a finite number of times t in the discrete grid T_m such that $\xi_{s,s+t}(x) \in Z$.

Let us fix an $x \notin N$. We now claim that the fact that $\mathbb{P}$-a.s. for any m there is only a finite number of times $t \in T_m$ such that $\xi_{s,s+t}(x) \in Z$ implies that $\mathbb{P}$-a.s. $\limsup_{t\to\infty} |\xi_{s,t}(x)| \le \varepsilon$. To see this, suppose $\mathbb{P}[\limsup_{t\to\infty} |\xi_{s,t}(x)| > \varepsilon] = \delta > 0$.

By monotone convergence $\mathbb{E}[\chi_{\limsup|\xi_{s,t}(x)|>\varepsilon'}] \nearrow \delta$ as $\varepsilon' \searrow \varepsilon$; hence there exists an $\varepsilon' > \varepsilon$ such that $\mathbb{P}[\limsup_{t\to\infty}|\xi_{s,t}(x)| > \varepsilon'] > 0$. We have already shown, however, that almost surely $|\xi_{s,t}(x)| \le \varepsilon$ for infinitely many times $t_n \nearrow \infty$. Hence

$$\mathbb{P}\left[\limsup_{t\to\infty}|\xi_{s,t}(x)| > \varepsilon'\right] > 0 \quad\Longrightarrow\quad \mathbb{P}[|\xi_{s,t}(x)| \text{ crosses } \varepsilon \text{ and } \varepsilon' \text{ infinitely often}] > 0.$$

Once we disprove the latter statement, the claim is proved by contradiction.

To this end, introduce the following sequence of predictable stopping times. Let $\sigma_0 = \inf\{t > s : |\xi_{s,t}(x)| \le \varepsilon\}$, $\tau_0 = \inf\{t > \sigma_0 : |\xi_{s,t}(x)| \ge \varepsilon'\}$, and for any $n > 0$ we set $\sigma_n = \inf\{t > \tau_{n-1} : |\xi_{s,t}(x)| \le \varepsilon\}$, $\tau_n = \inf\{t > \sigma_n : |\xi_{s,t}(x)| \ge \varepsilon'\}$. Define

$$\Omega_n(\Delta) = \{\omega \in \Omega : \tau_n < \infty,\ |\xi_{s,\tau_n+\delta}(x)| > \varepsilon\ \forall\, 0 \le \delta \le \Delta\}.$$

For any $\Delta > 0$, the set of $\omega \in \Omega$ such that $\omega \in \Omega_n(\Delta)$ for infinitely many n must be of $\mathbb{P}$-measure zero; after all, we can choose m sufficiently large so that every time interval of length Δ contains at least one point in T_m, and for points $t \in T_m$ we have $|\xi_{s,t}(x)| > \varepsilon$ only finitely often $\mathbb{P}$-a.s. Thus $\sum_n \chi_{\Omega_n(\Delta)} < \infty$ $\mathbb{P}$-a.s. To proceed, we use the following argument (see [17, pp. 398–399]). Introduce the discrete filtration $\mathcal{B}_k = \mathcal{F}_s^{\tau_{k+1}}$ and define $Z_k = X_k - Y_k$ with

$$X_k = \sum_{n=1}^{k} \chi_{\Omega_n(\Delta)}, \qquad Y_k = \sum_{n=1}^{k} \mathbb{E}[\chi_{\Omega_n(\Delta)}|\mathcal{B}_{n-1}].$$

As $\Omega_k(\Delta) \in \mathcal{B}_n$ for all $k \le n$, Z_k is a $\mathcal{B}_k$-martingale. Now define for $a > 0$ the stopping time $\kappa(a) = \inf\{n : Z_n > a\}$. As $|Z_k - Z_{k-1}| \le 1$ almost surely, the stopped process $Z'_k = Z_{k\wedge\kappa(a)}$ is a martingale that is bounded from above, and by the martingale convergence theorem Z'_k converges almost surely as $k \to \infty$ to a finite random variable Z'_∞. But as Z'_k and Z_k coincide on $\{\omega : \sup_n Z_n < a\}$ and $a > 0$ was chosen arbitrarily, we conclude that $Z_k \to Z_\infty < \infty$ on $\{\omega : \sup_n Z_n < \infty\}$ (modulo a null set). Note, however, that X_n and Y_n are both positive increasing processes and we have already established that $\sup_n X_n < \infty$ $\mathbb{P}$-a.s., so $\sup_n Z_n < \infty$ $\mathbb{P}$-a.s. But this implies that Z_k, and hence also Y_k, converges to a finite value $\mathbb{P}$-a.s. Thus we have established

$$\sum_{n=1}^{\infty} \mathbb{E}[\chi_{\Omega_n(\Delta)}|\mathcal{F}_s^{\tau_n}] < \infty \quad \mathbb{P}\text{-a.s.} \quad \text{for any } \Delta > 0.$$

Note that by the continuity of the sample paths, $|\xi_{s,\tau_n}(x)| = \varepsilon'$ on $\tau_n < \infty$. By Lemma 5.3, we can choose $\overline{\Delta} > 0$ sufficiently small such that

$$P(y) = \mathbb{P}\left[\sup_{0\le\delta\le\overline{\Delta}} |\xi_{s,s+\delta}(y) - y| < \frac{\varepsilon' - \varepsilon}{2}\right] \ge \frac{1}{2}$$

for all $|y| = \varepsilon'$. Using the strong Markov property, we can write

$$\infty > \sum_{n=1}^{\infty} \mathbb{E}[\chi_{\Omega_n(\overline{\Delta})}|\mathcal{F}_s^{\tau_n}] \ge \sum_{n=1}^{\infty} P(\xi_{s,\tau_n}(x))\,\chi_{\tau_n<\infty} \ge \frac{1}{2}\sum_{n=1}^{\infty} \chi_{\tau_n<\infty} \quad \mathbb{P}\text{-a.s.}$$

But this implies that $\tau_n < \infty$ finitely often $\mathbb{P}$-a.s., contradicting the assertion that $\mathbb{P}[|\xi_{s,t}(x)| \text{ crosses } \varepsilon \text{ and } \varepsilon' \text{ infinitely often}] > 0$. This is the desired result.

We have now shown that for μ-almost all $x \in \mathbb{R}^n$, $\mathbb{P}$-a.s. $\limsup_{t\to\infty} |\xi_{s,t}(x)| \le \varepsilon$, i.e., for μ-almost all $x \in \mathbb{R}^n$ $\mathbb{P}$-a.s., $\exists t_e > s$ such that $|\xi_{s,t}(x)| \le \varepsilon$ for $t \ge t_e$. But as this holds for any $\varepsilon > 0$ the flow must converge to the origin. □

The proof of Theorem 5.1 is readily extended to prove other assertions, such as the following instability theorem.

THEOREM 5.4. *Let X_k, $k = 0, \dots, m$, be globally Lipschitz continuous and $C^{2,\alpha}$ functions for some $\alpha > 0$. Suppose there exists a $D \in C^2(\mathbb{R}^n, \mathbb{R}_+)$ such that $\mathscr{L}^* D(x) < 0$ for μ-almost all x. Then for every initial time s and μ-a.e. initial state x the flow escapes to infinity, i.e., $|\xi_{s,t}(x)| \to \infty$ as $t \to \infty$ $\mathbb{P}$-a.s.*

Proof. Let $\varepsilon > 0$ and $Z' = \{x \in \mathbb{R}^n : |x| < \varepsilon\}$. Again we begin by applying Lemma 5.2. We can simply choose $S_\ell = S = \mathbb{R}^n$ for all ℓ; by nonexplosion $\tau_\ell = -\infty$ and the remaining conditions are evident. Hence

$$0 \le \int_{Z'} D(x)\, dx + \int_s^t \mathbb{E} \int_{\xi_{\sigma,t}^{-1}(Z')} \mathscr{L}^* D(x)\, dx\, d\sigma.$$

Proceeding in exactly the same way as in the proof of Theorem 5.1 we can now show that for μ-almost all $x \in \mathbb{R}^n$, $\mathbb{P}$-a.s. $\liminf_{t\to\infty} |\xi_{s,t}(x)| \ge \varepsilon$, i.e., for μ-almost all $x \in \mathbb{R}^n$ $\mathbb{P}$-a.s., $\exists t_e > s$ such that $|\xi_{s,t}(x)| \ge \varepsilon$ for $t \ge t_e$. But as this holds for any $\varepsilon > 0$ the flow must escape to infinity. □

Remark. At first sight the statements of Theorems 5.1 and 5.4 may seem contradictory, but this is not the case. The essential difference between the theorems is the region in $\mathbb{R}^n$ on which D is integrable. Roughly speaking, the idea behind the proofs of Theorems 5.1 and 5.4 is to show that if $\mathscr{L}^* D < 0$ μ-a.e., then the solution of the Itô equation can spend only a finite amount of time in any region on which D is integrable. Hence in Theorem 5.1 the solution will be attracted to the origin, whereas in Theorem 5.4 the solution is attracted to infinity.

If we try to satisfy the conditions of Theorems 5.1 and 5.4 simultaneously, we will run into problems. Suppose we have a nonnegative $D \in C^2(\mathbb{R}^n)$, as in Theorem 5.4, which is integrable as in Theorem 5.1. Then D is a normalizable density function, i.e., we could normalize D and interpret it as the density of the Itô equation at some point in time. But then $\mathscr{L}^* D < 0$ would imply that the associated Fokker–Planck equation does not preserve normalization of the density. Evidently Theorem 5.4 can only be satisfied if D is not integrable, whereas Theorem 5.1 requires D to have a singularity at the origin. See section 7 for examples.

6. Further results. In this section we extend the main result to cases in which the global Lipschitz condition is not necessarily satisfied. We first show that the result of Theorem 5.1 still holds if we can convert the coefficients of (4.1) to be globally Lipschitz continuous through a suitably chosen time transformation. In particular, this allows us to treat the case that X_k, $k = 0, \dots, m$, and their first derivatives are polynomially bounded, provided that some additional integrability conditions on D are satisfied. We also extend the main result to the case in which the flow is restricted to an invariant subset of $\mathbb{R}^n$ with compact closure.

THEOREM 6.1. *Let $X_k : \mathbb{R}^n \to \mathbb{R}^n$, $k = 0, \dots, m$, be measurable and let $X_k(0) = 0$. Suppose there is a strictly positive measurable map $c : \mathbb{R}^n \to (0, \infty)$ such that $c(x)$ and $c(x)^{-1}$ are locally bounded, and such that $c(x)X_0(x)$ and $\sqrt{c(x)}\, X_k(x)$, $k = 1, \dots, m$, are globally Lipschitz continuous and $C^{2,\alpha}$ functions for some $\alpha > 0$. Suppose there exists $D : \mathbb{R}^n \backslash \{0\} \to \mathbb{R}_+$ such that $D(x)/c(x)$ is C^2 and is integrable on $\{x \in \mathbb{R}^n : |x| > 1\}$, and $\mathscr{L}^* D(x) < 0$ for μ-almost all x. Then for every initial*

time s and μ-a.e. initial state x the solution x_t of (4.1) tends to the origin as $t \to \infty$ $\mathbb{P}$-a.s.

Proof. Consider the Itô equation

$$y_t = y_s + \int_s^t c(y_\tau) X_0(y_\tau)\, d\tau + \sum_{k=1}^m \int_s^t \sqrt{c(y_\tau)}\, X_k(y_\tau)\, dW_\tau^k. \tag{6.1}$$

We will write $Y_0(y) = c(y)X_0(y)$, $Y_k(y) = \sqrt{c(y)}\, X_k(y)$ $(k = 1, \ldots, m)$, and $\tilde{D}(y) = D(y)/c(y)$. Note that by construction $\tilde{\mathscr{L}}^* \tilde{D}(y) = \mathscr{L}^* D(y)$, where $\tilde{\mathscr{L}}^*$ is the adjoint generator of (6.1). By our assumptions we can apply Theorem 5.1 to the Itô equation (6.1). Thus for all $y_s \in \mathbb{R}^n$, except in a set N with $\mu(N) = 0$, $y_t \to 0$ as $t \to \infty$ $\mathbb{P}$-a.s.

Now choose any $y_s \notin N$ and define

$$\beta_t = \int_s^t c(y_\tau)\, d\tau, \qquad\qquad \alpha_t = \inf\{s : \beta_s > t\}.$$

Note that α_τ is an $\mathcal{F}_s^t$-stopping time for each τ. We claim that $\beta_t \to \infty$ as $t \to \infty$ almost surely; indeed y_t almost surely spends an infinite amount of time in an arbitrarily small neighborhood of the origin, and as $c(x)^{-1}$ is locally bounded $c(x) \geq \delta > 0$ in any such neighborhood. Moreover, $\beta_t < \infty$ almost surely for any t as $c(x)$ is locally bounded, and hence $\alpha_t \to \infty$ as $t \to \infty$ almost surely. From [24, section V.26, p. 175], it follows that the time rescaled solution y_{α_t} is equivalent in law to the solution x_t of (4.1). But as almost all paths of the process y_t go to zero asymptotically and as $\alpha_t \to \infty$ almost surely, the result follows. □

Corollary 6.2. *Suppose that all the conditions of Theorem 5.1 are satisfied except the global Lipschitz condition. Suppose that additionally X_k, $k = 1, \ldots, m$, satisfy $|X_k(x)| \leq C_k(1 + |x|^{p+1})$, $|\partial X_k(x)/\partial x^i| \leq C_k'(1 + |x|^p)$, and $|X_0(x)| \leq C_0(1 + |x|^{2p+1})$, $|\partial X_0(x)/\partial x^i| \leq C_0'(1+|x|^{2p})$ for some $p \geq 1$ and positive constants $C_k, C_k' < \infty$. If $(1+|x|^{2p})D(x)$ is integrable on $\{x \in \mathbb{R}^n : |x| > 1\}$, then Theorem 5.1 still holds.*

Proof. Let $c(x) = (1 + |x|^{2p})^{-1}$, and note that $c(x)$ is smooth, strictly positive and that $c(x)$ and $c(x)^{-1}$ are locally bounded. Let $Y_0(x) = c(x)X_0(x)$ and $Y_k(x) = \sqrt{c(x)}\, X_k(x)$, $k = 1, \ldots, m$; as $\sqrt{c(x)}$ is smooth and X_k, $k = 0, \ldots, m$, are $C^{2,\alpha}$, the coefficients Y_k are also $C^{2,\alpha}$. To show that Y_k are globally Lipschitz continuous it suffices to show that their first derivatives are bounded. Let us write $y_{k,i}(x) = |\partial Y_k/\partial x^i|(x)$. First consider the case $k = 0$. Then

$$y_{0,i}(x) \leq \frac{|\partial X_0(x)/\partial x^i|}{1 + |x|^{2p}} + \frac{2p|x|^{2p-2}|x^i|}{(1 + |x|^{2p})^2}\, |X_0(x)| \leq C_0' + C_0 \frac{2p|x|^{2p-2}|x^i|}{(1 + |x|^{2p})^2}(1 + |x|^{2p+1}),$$

which is bounded. Similarly, for $k \geq 1$

$$y_{k,i}(x) \leq C_k' \frac{1 + |x|^p}{\sqrt{1 + |x|^{2p}}} + C_k \frac{p|x|^{2p-2}|x^i|}{(1 + |x|^{2p})^{3/2}}(1 + |x|^{p+1})$$

is bounded. Finally, $D(x)/c(x) = (1 + |x|^{2p})D(x)$ is C^2, as $D(x)$ is C^2 and $c(x)^{-1}$ is smooth on $\mathbb{R}^n \backslash \{0\}$. Hence, provided $D(x)/c(x)$ is integrable on $\{x \in \mathbb{R}^n : |x| > 1\}$, we can apply Theorem 6.1. □

We now turn our attention to stochastic differential equations which evolve on an invariant set. The following notion of invariance is sufficient for our purposes.

Definition 6.3. *A set K is called backward invariant with respect to the flow $\xi_{s,t}$ if $\xi_{s,t}^{-1}(K) \subset K$ almost surely for all $s < t$.*

We can now formulate the following result.

THEOREM 6.4. *Suppose the Itô equation* (4.1) *evolves on a backward invariant open set K with compact closure $\overline{K}$. Let X_k, $k = 0, \ldots, m$, be $C^{2,\alpha}$ for some $\alpha > 0$ and let $X_k(0) = 0 \in \overline{K}$. Suppose there exists $D \in C^2(\overline{K}\backslash\{0\}, \mathbb{R}_+)$ such that $\mathscr{L}^* D(x) < 0$ for μ-almost all $x \in K$. Then for every initial time s and μ-a.e. initial state $x \in K$ the flow $\xi_{s,t}(x)$ tends to the origin as $t \to \infty$ $\mathbb{P}$-a.s.*

Proof. We will assume without loss of generality that X_k, $k = 0, \ldots, m$, are globally Lipschitz continuous. Indeed, we can smoothly modify X_k outside K to have compact support without changing the properties of the flow in K, and as X_k are already locally Lipschitz continuous their modifications will be globally Lipschitz continuous.

Let $\varepsilon > 0$ and $Z = \{x \in K : |x| > \varepsilon\}$. D is integrable on Z, as D is bounded on Z and Z has compact closure. Let S_ℓ be an increasing sequence of open sets whose closure is strictly contained in $S = K\backslash\{0\}$, such that $\bigcup_\ell S_\ell = S$. Then there exists a $C^2(\mathbb{R}^n, \mathbb{R}_+)$-approximation D_ℓ of D for each ℓ, obtained by smoothly modifying D outside S_ℓ so that its support is contained in $\overline{K}$. That $\tau_\ell \to -\infty$ follows from backward invariance and from the one-to-one property of the flow. Hence all the conditions of Lemma 5.2 are satisfied, and we have

$$0 \leq \int_Z D(x)\, dx + \int_s^t \mathbb{E} \int_{\xi_{\sigma,t}^{-1}(Z)} \mathscr{L}^* D(x)\, dx\, d\sigma.$$

The remainder of the proof proceeds along the same lines as Theorem 5.1. ∎

7. Examples.

Example 1. Consider the Itô equation

$$\begin{aligned} dx_t &= (x_t^2 - 2x_t - z_t^2)\, dt + x_t\, dW_t, \\ dz_t &= 2z_t(x_t - 1)\, dt + z_t\, dW_t. \end{aligned} \tag{7.1}$$

Note that the line $z = 0$ is invariant under the flow of (7.1), where the solution $(x_t, 0)$ for an initial state $(x_0, 0)$ is given by

$$dx_t = (x_t^2 - 2x_t)\, dt + x_t\, dW_t.$$

This equation has an explicit solution (see also [2] for a detailed analysis of the dynamical behavior of this system):

$$x_t = \frac{x_0 e^{-2t} e^{W_t - \frac{1}{2}t}}{1 - x_0 \int_0^t e^{-2s} e^{W_s - \frac{1}{2}s} ds}.$$

Clearly $x_t(\omega)$, $\omega \in \Omega$, explodes in finite time if

$$x_0 > \left(\int_0^\infty e^{-2s} e^{W_s - \frac{1}{2}s} ds \right)^{-1} < \infty.$$

Hence the system (7.1) is certainly not globally stable.

Nonetheless, almost all points $(x_0, z_0) \in \mathbb{R}^2$ are attracted to the origin. To show this, apply Corollary 6.2 with

$$D(x, z) = \frac{1}{(x^2 + z^2)^2}, \qquad \mathscr{L}^* D(x, z) = -\frac{3}{(x^2 + z^2)^2} < 0.$$

Hence for almost every $(x_0, z_0) \in \mathbb{R}^2$, almost surely $(x_t, z_t) \to (0,0)$ as $t \to \infty$.

Example 2. Consider the Itô equation

$$\begin{aligned} dx_t &= 12\,(2z_t - 1)x_t z_t\,dt - \tfrac{1}{2}x_t\,dt + (1-2z_t)x_t\,dW_t, \\ dy_t &= -\tfrac{1}{2}y_t\,dt + (1-2z_t)y_t\,dW_t, \\ dz_t &= -12 z_t x_t^2\,dt + 2(1-z_t)z_t\,dW_t. \end{aligned} \tag{7.2}$$

Let $R_t = 2z_t - 2z_t^2 - x_t^2 - y_t^2$. By Itô's rule we have

$$dR_t = -4\,(1-z_t)z_t R_t\,dt + 2\,(1-2z_t)R_t\,dW_t.$$

Evidently the ellipse $\{(x,y,z) \in \mathbb{R}^3 : 2z - 2z^2 - x^2 - y^2 = 0\}$ is invariant under (7.2). Local uniqueness of the solution implies that the interior of the ellipse is also invariant. Hence $K = \{(x,y,z) \in \mathbb{R}^3 : 2z - 2z^2 - x^2 - y^2 > 0\}$ is a (backward) invariant set for the system (7.2). Consider

$$D(x,y,z) = \frac{1}{z^2}, \qquad \mathscr{L}^* D(x,y,z) = -\frac{12x^2}{z^2} < 0 \quad \mu\text{-a.e.}$$

Hence by Theorem 6.4 for almost every $(x_0, y_0, z_0) \in K$, almost surely $(x_t, y_t, z_t) \to (0,0,0)$ as $t \to \infty$. Note that $(0,0,0)$ is certainly not globally stable: it is easily verified that any point with $x_0 = 0$ and $z_0 \neq 0$ is not attracted to $(0,0,0)$ almost surely, as in this case z_t has a constant nonzero mean.

Example 3. We consider again the system (7.2), but now we are interested in the behavior of points in the invariant set $K' = \{(x,y,z) \in \mathbb{R}^3 : 2z - 2z^2 - x^2 = 0,\ y = 0\}$. As K' is not an open set, we cannot apply Theorem 6.4 to study this case.

Define the transformation $(x,z) \mapsto p = x/z$. Note that p is the stereographic projection of $(x,y,z) \in K'$ which maps $(0,0,0) \mapsto \infty$. As the fixed point $(0,0,0)$ cannot be reached in finite time, we expect that the stereographic projection gives a well-defined dynamical system on $\mathbb{R}$. Using Itô's rule and $2z - 2z^2 - x^2 = 0$ we obtain the Itô equation

$$dp_t = \left(\frac{3}{2} + \frac{20}{2+p^2}\right) p_t\,dt - p_t\,dW_t.$$

Note that this expression satisfies a global Lipschitz condition. Now consider

$$D(p) = \sqrt{2+p^2}, \qquad \mathscr{L}^* D(p) = -\frac{42}{(2+p^2)^{3/2}} < 0.$$

Hence by Theorem 5.4 for almost every $p_0 \in \mathbb{R}$, almost surely $p_t \to \infty$ as $t \to \infty$. This implies that the point $(x,y,z) = (0,0,0)$ is almost globally stable in K'.

8. Application to control synthesis. Consider an Itô equation of the form

$$x_t = x + \int_s^t (X_0(x_\tau) + u_\tau \tilde{X}_0(x_\tau))\,d\tau + \sum_{k=1}^m \int_s^t X_k(x_\tau)\,dW_\tau^k, \tag{8.1}$$

where $\tilde{X}_0$ and X_k, $k = 0, \ldots, m$, are $C^{2,\alpha}$ for some $\alpha > 0$, $X_k(0) = 0$ and u_t is a scalar control input. We consider instantaneous state feedback of the form $u_t = u(x_t)$ where $u(x)$ is $C^{2,\beta}$ for some $\beta > 0$ and $u(0) = 0$. Then by Theorem 5.1 or 6.4 or by

Corollary 6.2, $x_t \to 0$ as $t \to \infty$ almost surely for almost every x_0 if there exists a $D(x)$, with additional properties required by the appropriate theorem, such that

$$\begin{aligned}\mathscr{L}^* D(x) = \frac{1}{2}\sum_{k=1}^{m}\sum_{i,j=1}^{n}\frac{\partial^2}{\partial x^i \partial x^j}(X_k^i(x)X_k^j(x)D(x)) \\ -\sum_{i=1}^{n}\frac{\partial}{\partial x^i}(X_0^i(x)D(x)+\tilde{X}_0^i(x)u(x)D(x)) < 0 \qquad \mu\text{-a.e.}\end{aligned} \tag{8.2}$$

Note that this expression is affine in $D(x)$ and $u(x)D(x)$ and that the set of functions $(D(x), u(x)D(x))$ which satisfy (8.2) is convex. This fact has been used in the deterministic case by Prajna, Parrilo, and Rantzer [22] to search for "almost stabilizing" controllers for systems with polynomial vector fields using convex optimization. As the stochastic case enjoys the same convexity properties as the deterministic Theorem 3.2, this approach can also be applied to find stabilizing controllers for stochastic nonlinear systems. Note that that convex optimization cannot be used to search for globally stabilizing controllers using LaSalle's theorem [22] as LaSalle's convergence criterion [16, 6] is *not* convex.

The purpose of this section is to briefly outline the method of [22] for the synthesis of stabilizing controllers using convex optimization. We will also discuss a simple example.

Suppose that $\tilde{X}_0$ and X_k, $k = 0, \ldots, m$, are polynomial functions (the case of rational functions can be treated in a similar way). Consider $D(x)$ and $u(x)$ parametrized in the following way:

$$D(x) = \frac{a(x)}{b(x)^\gamma}, \qquad u(x) = \frac{c(x)}{a(x)}. \tag{8.3}$$

Here $b(x)$ is a nonnegative polynomial which vanishes only at the origin, $a(x)$ is a polynomial that is nonnegative in a neighborhood of the origin and is such that $u(x)$ is $C^{2,\beta}$, $c(x)$ is a polynomial that vanishes at the origin, and $\gamma > 0$ is a constant. The orders of the polynomials and γ can be chosen in such a way that $D(x)$ satisfies the integrability and growth requirements of Corollary 6.2. For fixed $b(x)$ and γ consider the expression

$$-b(x)^{\gamma+2}\mathscr{L}^* D(x) > 0 \qquad \mu\text{-a.e.} \tag{8.4}$$

with $D(x)$ and $u(x)$ given by (8.3) and $\mathscr{L}^*$ given by (8.2). Then (8.4) is a polynomial inequality that is linear in the polynomial coefficients of $a(x)$ and $c(x)$. Our goal is to formulate the search for these coefficients as a convex optimization problem.

Verifying whether (8.4) is satisfied comes down to testing nonnegativity of a polynomial (a nonnegative polynomial can only vanish on a finite set of points, and hence is positive μ-a.e.). This problem is known to be NP-hard in general; however, a powerful convex relaxation was suggested by Parrilo [20]. Instead of testing (8.4) directly we may ask whether the polynomial can be written as a *sum of squares*, i.e., whether $-b(x)^{\gamma+2}\mathscr{L}^* D(x) = \sum_i p_i(x)^2$ for a set of polynomials $p_i(x)$. The power of this relaxation comes from the fact that every sum of squares polynomial up to a specified order can be represented by a positive semidefinite matrix; hence the search for a sum of squares representation can be performed using semidefinite programming. As (8.4) is convex in $a(x)$ and $c(x)$ the following is a convex optimization problem:

Find polynomials $a(x)$, $c(x)$ such that $-b(x)^{\gamma+2}\mathscr{L}^* D(x)$ is a sum of squares.

This type of problem, known as a sum of squares program, can be solved in a highly efficient manner using the software SOSTOOLS [21]. We refer to [20, 21, 22] for further details on the computational technique.

Remark. Note that $a(0)$ and $c(0)$ depend only on the value of the constant coefficient of the polynomials $a(x)$ and $c(x)$. Thus $c(0) = 0$ can easily be enforced by fixing the constant coefficient of $c(x)$. To make sure $a(x)$ is nonnegative near the origin and $u(x)$ does not blow up, we can, for example, require $a(x)$ to be of the form $\lambda + p(x)$ with $\lambda > 0$ and $p(x)$ to be a sum of squares that vanishes at the origin.

Note that if the Itô equation (8.1) evolves on an invariant open set K with compact closure, then the sum of squares relaxation is overly restrictive. A related relaxation that guarantees only polynomial nonnegativity on K for the case that K is a semialgebraic set is considered in, e.g., [19].

Example. The following example is similar to an example in [22]. Consider the Itô equation

$$\begin{aligned} dx_t &= (2x_t^3 + x_t^2 y_t - 6x_t y_t^2 + 5y_t^3)\,dt + (x_t^2 + y_t^2)\,dW_t, \\ dy_t &= u_t\,dt - (x_t^2 + y_t^2)\,dW_t. \end{aligned}$$

We choose $b(x, y) = x^2 + y^2$ and $\gamma = 2.5$. Using SOSTOOLS we find a solution with controller of order 3 and a constant $a(x)$. Note that these choices satisfy the integrability requirements of Corollary 6.2. We obtain a stabilizing controller

$$u(x) = -2.7\,x^3 + 4.6\,x^2 y - 6.7\,xy^2 - 3.4\,y^3,$$

where

$$\begin{aligned} -(x^2 + y^2)^{4.5}\mathscr{L}^*(x^2 + y^2)^{-2.5} &= 0.35\,y^6 - 0.0015\,xy^5 \\ &\quad + 0.6\,x^2 y^4 + 0.0026\,x^3 y^3 + 0.33\,x^4 y^2 + 0.004\,x^5 y + 0.13\,x^6 \end{aligned}$$

is a sum of squares polynomial.

Remark. A drawback of this method is that $b(x)$ and γ must be fixed at the outset. We have found that the method is very sensitive to the choice of $b(x)$ and γ even in the deterministic case; often an unfortunate choice will cause the search to be infeasible. Moreover it is not clear, even if there exists for polynomial $\tilde{X}_0$, X_k a rational u which almost globally stabilizes the system, that a rational D can always be found that satisfies $\mathscr{L}^* D < 0$. Nonetheless the method can be successful in cases where other methods fail, and as such could be a useful addition to the stochastic nonlinear control engineer's toolbox.

Acknowledgments. This work was performed in Hideo Mabuchi's group, and the author gratefully acknowledges his support. The author would like to thank Anders Rantzer, Luc Bouten, Stephen Prajna, Paige Randall, and especially Houman Owhadi for insightful discussions and comments. The author is particularly thankful to an anonymous referee for pointing out a gap in the proofs and for his careful reading of the manuscript, which has significantly improved the presentation.

FORWARD STABILIZED SPLINE INTERPOLATION*

DAVID L. RUSSELL†

Abstract. Forward interpolation, as discussed here, refers to the problem of interpolating data points revealed, one at a time, in a sequential manner. As such, forward spline interpolation is an inherently unstable process. In this paper we study forward interpolation using a class of "generalized splines": piecewise polynomials of odd degree $2m-1$, continuous to order $m-1$, where $m \geq 2$ is an integer. We show that the problem can be interpreted as a state estimation problem for a discrete linear system and show how successful, stable procedures can be obtained by applying optimal state estimation techniques of "LQG" type long familiar in the theory of such systems. A number of examples are presented.

Key words. spline interpolation, linear recursion equation, linear difference equation, linear discrete control, linear discrete state estimation, discrete system stabilization

1. Forward splines in a systems context.

A *standard spline function* of degree n is a piecewise nth degree polynomial $w(t)$ satisfying the differential equation

$$\frac{d^n w}{dt^n} = f(t),$$

with $f(t)$ piecewise constant. The discontinuities of $f(t)$ occur at an increasing sequence of "knots" $\{t_k \,|\, k = 0, 1, 2, 3, \ldots\}$, with $f(t) \equiv f_{k-1}$, $t \in [t_{k-1}, t_k)$. Setting $h_k = t_k - t_{k-1}$ and defining W_k to be the n-dimensional vector whose jth component is $w^{(j)}(t_k)$, $j = 0, 1, 2, \ldots, n-1$, integration shows that W_k satisfies

$$W_k = \mathbf{E}(h_k)\, W_{k-1} + \mathbf{B}(h_k)\, f_{k-1}, \quad k = 1, 2, 3, \ldots, \tag{1.1}$$

where, for any real h,

$$\mathbf{E}(h) = \begin{pmatrix} 1 & h & \frac{h^2}{2} & \cdots & \frac{h^{n-2}}{(n-2)!} & \frac{h^{n-1}}{(n-1)!} \\ 0 & 1 & h & \cdots & \frac{h^{n-3}}{(n-3)!} & \frac{h^{n-2}}{(n-2)!} \\ 0 & 0 & 1 & \cdots & \frac{h^{n-4}}{(n-4)!} & \frac{h^{n-3}}{(n-3)!} \\ \vdots & \vdots & \vdots & & \vdots & \vdots \\ 0 & 0 & 0 & \cdots & 0 & 1 \end{pmatrix}, \quad \mathbf{B}(h) = \begin{pmatrix} \frac{h^n}{n!} \\ \frac{h^{n-1}}{(n-1)!} \\ \frac{h^{n-2}}{(n-2)!} \\ \vdots \\ h \end{pmatrix}. \tag{1.2}$$

In the standard spline interpolation problem, data values z_k, $k = 0, 1, 2, \ldots, K$, are given in advance, and one wishes to find a spline function $w(t)$ of specified degree, such that $w(t_k) = z_k$ for these values of k. The subject possesses a vast and familiar literature; cf. [3], [11], [6], which we do not add to here. Rather, we are concerned with what we will call *forward spline interpolation*, the name being suggested by comparison with Newton's forward interpolation formula. The data point z_0 is given

*Received by the editors December 29, 2004; accepted for publication (in revised form) April 5, 2006; published electronically October 3, 2006.

initially, and thereafter the z_k, $k = 1, 2, 3, \ldots$, are supplied *one at a time* in the obvious order. The values z_ℓ, $\ell > k$, are unknown, except possibly for some statistical information, at time t_{k-1}. At that point we assume a spline function $w(t)$ has been constructed on $[t_0, t_{k-1})$ interpolating $z_0, z_1, \ldots, z_{k-1}$; z_k then being revealed, it is desired to extend $w(t)$ to the larger interval $[t_0, t_k)$, not changing its definition on $[t_0, t_{k-1})$, with $w(t_k) = z_k$, the overall, repeated process being stable. It turns out this stability does not obtain automatically; it needs to be designed into the process using system theoretic tools.

Splines were studied as discrete linear systems by deBoor and Schoenberg [4] early in the history of the subject but in a "two point boundary value" setting not applicable to the forward interpolation problem. More recently some connections between linear control theory and spline approximation/interpolation have been made in papers by Agwu and Martin [1], Zhang, Tomlinson, and Martin [12], Jackson and Crouch [5], and by Renardy and the present author in [10]. These all deal with spline interpolation in its standard setting and, except for the last cited, in the ordinary differential equation context. The present article studies the forward interpolation problem in the context of *discrete* linear control systems and is developed in terms of *system stabilization* and *state estimation* for such systems.

A picturesque illustration can be given in terms of a ship following a series of lighted buoys through a foggy channel. Visibility is such that, just as each buoy is reached, the next becomes visible. As each buoy is reached a course is plotted out for the next buoy, using a spline function $w(t)$, which can be followed with appropriate motion of the rudder over the time interval $[t_{k-1}, t_k)$. At $t = t_{k-1}$ the position and heading of the ship, assumed to vary continuously with t, correspond to $w_{k-1,0} \equiv w(t_{k-1})$ and $w_{k-1,1} \equiv w'(t_{k-1})$. If $w(t)$ is a piecewise quadratic polynomial, the second derivative $w''(t) \equiv f_{k-1}$ is constant over $[t_{k-1}, t_k)$, corresponding to a constant rudder setting. Assuming we already have $w(t_{k-1}) = z_{k-1}$ and the value $w'(t_{k-1})$, these together with the new requirement $w(t_k) = z_k$ determine a quadratic on $[t_{k-1}, t_k)$. Assuming the intervals $[t_{k-1}, t_k)$ to have constant length h we have

$$w_{k,0} = z_{k-1} + w_{k-1,1}\, h + f_{k-1}\, \frac{h^2}{2}, \qquad w_{k,1} = w_{k-1,1} + f_{k-1}\, h.$$

Taking $w_{k,0} = z_k$, solving for f_{k-1} in the first equation, and substituting the result into the second equation we have

$$w_{k,1} = w_{k-1,1} + \frac{2}{h}\,(z_k - z_{k-1} - w_{k-1,1}h) = -w_{k-1,1} + 2\,\frac{z_k - z_{k-1}}{h}. \tag{1.3}$$

The scalar linear recursion system (1.3) is not asymptotically stable; its single eigenvalue is $\lambda = -1$, and it is not difficult to see that this approach does not yield very satisfactory results. In Figure 1, corresponding to

$$h = 1/3, \quad t_0 = 0, \quad z_k = \begin{cases} 0, & k = 0, \\ t_{k-1}, & k = 1, 2, 3, \\ 1, & k \geq 4, \end{cases} \tag{1.4}$$

the interpolation data z_k are indicated by small circles and the spline interpolant $w(t)$ by a solid curve.

The extension of this "naive" forward spline interpolation process to higher degree standard splines can be described as follows. Taking the first equation of (1.1) for

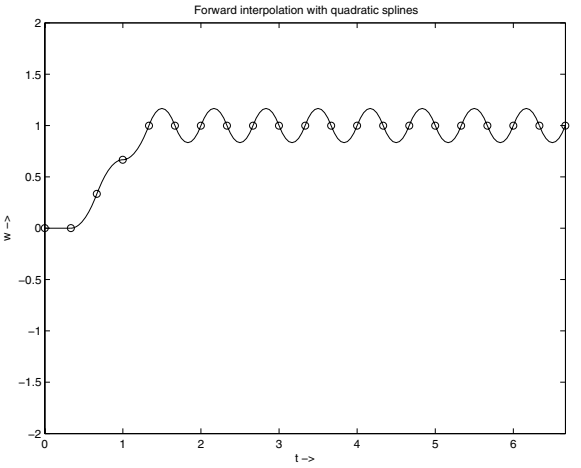

FIG. 1. *Forward interpolation with quadratic splines.*

general $n \geq 2$ we have

$$w_{k,0} = w_{k-1,0} + \sum_{j=1}^{n-1} w_{k-1,j} \frac{h^j}{j!} + f_{k-1} \frac{h^n}{n!}.$$

Setting $w_{k,0} = z_k$, $w_{k-1,0} = z_{k-1}$ and solving for f_{k-1} we have

$$f_{k-1} = \frac{n!}{h^n} \left[(z_k - z_{k-1}) - \mathbf{H}(h) \hat{W}_{k-1} \right], \tag{1.5}$$

where $\mathbf{H}(h) = \left(h \quad \frac{h^2}{2} \quad \cdots \quad \frac{h^{n-1}}{(n-1)!} \right)$ and $\hat{W}$ is a vector of dimension $n-1$ consisting of the $n-1$ highest indexed components of W in (1.1).

THEOREM 1.1. *The naive forward spline procedure just described fails to be asymptotically stable for every $n \geq 2$ and is strongly unstable for $n \geq 3$.*

Proof. Let $\hat{\mathbf{E}}$ denote the $(n-1) \times (n-1)$ matrix obtained by deleting the first column and first row of $\mathbf{E}(h)$ in (1.2), and let $\hat{\mathbf{B}}(h)$ be the $(n-1) \times 1$ matrix $\big((n-1)$-dimensional column vector$\big)$ consisting of the $n-1$ highest indexed components of $\mathbf{B}(h)$ there. Substituting (1.5) into the last $n-1$ equations of (1.1) we obtain the $(n-1)$-dimensional system

$$\hat{W}_k = \left(\hat{\mathbf{E}}(h) - \frac{n!}{h^n} \hat{\mathbf{B}}(h) \mathbf{H}(h) \right) \hat{W}_{k-1} - \frac{n!}{h^n} \hat{\mathbf{B}}(h) \left(z_k - z_{k-1} \right), \quad k = 1, 2, 3, \ldots. \tag{1.6}$$

The matrix $\hat{\mathbf{A}}(h) = \big(\hat{\mathbf{E}}(h) - \frac{n!}{h^n} \hat{\mathbf{B}}(h) \mathbf{H}(h) \big)$ has been studied in the literature; the reader is referred to [4] for the earlier background and to the more recent [10] for a direct, self-contained treatment. From these sources it is known that $\hat{\mathbf{A}}(h)$ has distinct negative (real) eigenvalues occurring in pairs λ, λ^{-1}, except for the single eigenvalue -1 when n is even. (For example, when $n = 3$ the 2×2 matrix $\hat{\mathbf{A}}(h)$ has eigenvalues $-2 \pm \sqrt{3}$.) Clearly we do not have asymptotic stability in these cases. For $n \geq 3$ there must be a real eigenvalue $\lambda < -1$, and we have instability in the strong sense. The proof is complete. ∎

Thus, if we are to pursue our objective further, we must identify a forward spline process which is either inherently stable or which can be stabilized by some means. We will see that stabilization can be accomplished with the use of a class of *generalized splines* (see, e.g., [11, sect. 8.3]); specifically we use piecewise polynomials of odd degree $n = 2m-1$, $m \geq 2$, with $w^{(j)}(t)$, $j = 0, 1, 2, \ldots, m-1$, continuous across the knots. The problem is interpreted in the context of a discrete linear control system similar to (1.1) to which we apply "LQG" stabilization techniques standard for such systems.

We conclude our introductory section with a discussion of the most elementary version of stabilized forward spline interpolation for the case $m = 2, n = 2m-1 = 3$. The generalized splines used here are piecewise polynomials $w(t)$ of degree 3, with $w(t)$ and $w'(t)$ continuous across the equally spaced ($h_k \equiv h > 0$) knots t_k, where they have respective values $w_{k,0}$, $w_{k,1}$. The second and third derivatives have, in general, discontinuities at the t_k; the limits from the right there are denoted by f_k, g_k, respectively. The equations replacing (1.1) then take the form

$$\begin{pmatrix} w_{k,0} \\ w_{k,1} \end{pmatrix} = \begin{pmatrix} 1 & h \\ 0 & 1 \end{pmatrix} \begin{pmatrix} w_{k-1,0} \\ w_{k-1,1} \end{pmatrix} + \begin{pmatrix} h^2/2 & h^3/6 \\ h & h^2/2 \end{pmatrix} \begin{pmatrix} f_{k-1} \\ g_{k-1} \end{pmatrix}, \quad k = 1, 2, 3, \ldots. \tag{1.7}$$

We suppose that a data sequence z_j, $j = 0, 1, 2, \ldots$, is made available one term at a time. At time t_{k-1} a generalized spline $w(t)$, piecewise a polynomial of degree 3 with $w(t)$ and $w'(t)$ continuous, has been constructed on $[t_0, t_{k-1})$, interpolating the data z_j, $j = 0, 1, 2, \ldots, k-1$. We wish to develop a stable process whereby $w(t)$ may be extended to $[t_{k-1}, t_k)$, interpolating the new value z_k and maintaining continuity of $w(t)$ and $w'(t)$ at $t = t_{k-1}$.

For real α to be determined, we set

$$g_k = \frac{\alpha f_k}{h}, \quad k = 0, 1, 2, \ldots. \tag{1.8}$$

The first equation of (1.7) then becomes

$$w_{k,0} = w_{k-1,0} + h\, w_{k-1,1} + h^2 \left(\frac{1}{2} + \frac{\alpha}{6}\right) f_{k-1}, \quad k = 1, 2, 3, \ldots. \tag{1.9}$$

It should be noted that (1.8) relates $w''(t_{k-1})$ and $w'''(t_{k-1})$ but does not imply a fixed ratio between $w''(t)$ and $w'''(t)$ over the interval $[t_{k-1}, t_k)$; indeed, we have $w''(t) = f_k + \frac{\alpha f_k}{h}(t - t_{k-1}) = f_k + w'''(t_{k-1})(t - t_{k-1})$ on that interval. Since $w_{k-1,0} = z_{k-1}$ and we are to have $w_{k,0} = z_k$, solving (1.9) for f_{k-1} yields

$$f_{k-1} = \frac{1}{h^2\,(1/2 + \alpha/6)} \left(z_k - z_{k-1} - h\, w_{k-1,1}\right). \tag{1.10}$$

The second equation of (1.7) then takes the "closed loop" form

$$w_{k,1} = \kappa\, w_{k-1,1} + c \left(\frac{z_k - z_{k-1}}{h}\right) \tag{1.11}$$

with

$$c = \frac{1 + \alpha/2}{1/2 + \alpha/6} = \frac{6 + 3\,\alpha}{3 + \alpha}, \qquad \kappa = 1 - c; \text{ reciprocally, } \alpha = -\frac{3\kappa + 3}{\kappa + 2}.$$

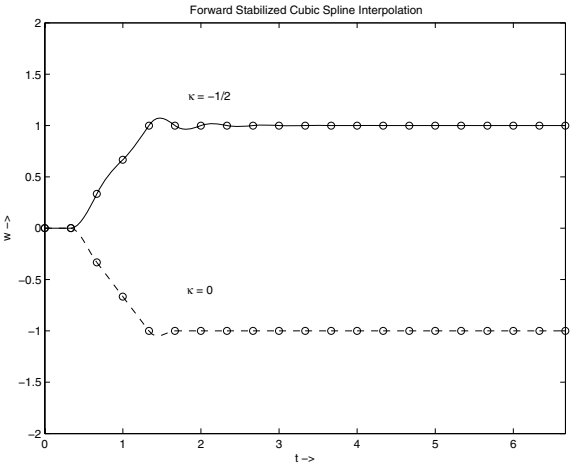

FIG. 2. *Forward stabilized cubic spline interpolation.*

The quadratic spline case corresponds to $\alpha = 0$, $\kappa = -1$, for which the system (1.11) fails to be asymptotically stable. We exclude the case $\alpha = -3$, for which (1.10) is invalid; we cannot achieve $\kappa = -2$; it does not correspond to any valid choice of α.

In discrete linear systems theory a closed loop system wherein all eigenvalues are reduced to zero is called a "deadbeat" system. For most applications deadbeat systems are avoided, but we will see that they play a central role for stabilized forward splines. Here the deadbeat case is $\kappa = 0$, corresponding to $\alpha = -3/2$, $c = 1$, giving $w_{k,1} = \frac{z_k - z_{k-1}}{h}$; $w'(t_k)$ is set equal to the difference quotient $\frac{z_k - z_{k-1}}{h}$. Other cases of interest are $\kappa = 1/2$ and $\kappa = -1/2$, for which (1.11) is exponentially asymptotically stable, corresponding to $\alpha = -9/5$ and $\alpha = -1$, respectively. In all of these cases $w(t)$ is given on $[t_{k-1}, t_k)$, "synthesizing" f_{k-1} via (1.10), by

$$w(t) = w_{k-1,0} + w_{k-1,1}(t - t_{k-1}) + f_{k-1}\left(\frac{(t - t_{k-1})^2}{2} + \alpha\frac{(t - t_{k-1})^3}{6h}\right).$$

We take the case $\kappa = -1/2$, $\alpha = -1$ and apply the method to the data (1.4). The result is shown in the upper part of Figure 2. We display in the lower part of the figure results for the deadbeat case $\kappa = 0$, using the negatives of the z_k in (1.4).

2. Stabilized forward splines of odd degree; error analysis. Let $m \geq 2$ be an integer, let $h_k \equiv h > 0$ constant, and let the "knots" t_k and data z_k be defined as in the preceding sections. Our purpose is to construct a generalized spline function $w(t)$, piecewise of degree $2m-1$ with $w^{(j)}(t)$, $j = 0, 1, 2, \ldots, m-1$, continuous across the knots, sequentially interpolating the data as described earlier. We again define $w_{k,j} = w^{(j)}(t_k)$, $j = 0, 1, 2, \ldots, m-1$. For $j = 0$ we have

$$w_{k,0} = w_{k-1,0} + \sum_{j=1}^{m-1} w_{k-1,j}\frac{h^k}{k!} + f_{k-1}\frac{h^m}{m!} + \sum_{j=1}^{m-1} g_{k-1,j}\frac{h^{j+m}}{(j+m)!}, \tag{2.1}$$

with the "controls" f_{k-1} and $g_{k-1,j}$, $j = 1, 2, \ldots, m-1$, representing the values of $w^{(m)}(t_{k-1}+)$, $w^{(j+m)}(t_k+)$, $j = 1, 2, \ldots, m-1$, respectively. Assuming $w(t)$ already

interpolates the data $z_0, z_1, \ldots, z_{k-1}$ at the knots $t_0, t_1, \ldots, t_{k-1}$, we set

$$g_{k-1,j} \;=\; \frac{a_j\, f_{k-1}}{h^j}, \quad j \;=\; 1, 2, \ldots, m-1, \tag{2.2}$$

for coefficients a_j independent of k but yet to be determined. We substitute (2.2) into (2.1), reminding ourselves that $w_{k-1,0} \;=\; z_{k-1}$ and that we are to have $w_{k,0} \;=\; z_k$. Solving for f_{k-1}, with $a_0 \;=\; 1$,

$$f_{k-1} \;=\; \frac{z_k - z_{k-1} - \sum_{\ell=1}^{m-1} w_{k-1,\ell}\, h^\ell/\ell!}{h^m \left(\sum_{\ell=0}^{m-1} a_\ell/(\ell+m)!\right)}. \tag{2.3}$$

The equations for the derivatives $w^{(j)}(t_\ell) \;=\; w_{\ell,j}$, $j \;=\; 1, 2, \ldots, m-1$, are

$$w_{k,j} = w_{k-1,j} + \sum_{\ell=j+1}^{m-1} w_{k-1,\ell} \frac{h^{\ell-j}}{(\ell-j)!} + f_{k-1} \frac{h^{m-j}}{(m-j)!} + \sum_{\ell=1}^{m-1} g_{k-1,\ell} \frac{h^{\ell+m-j}}{(\ell+m-j)!}. \tag{2.4}$$

Substituting (2.3) into (2.4) we obtain the closed loop equations, for $j \;=\; 1, 2, \ldots, m-1$,

$$w_{k,j} \;=\; w_{k-1,j} \;+\; \sum_{\ell=j+1}^{m-1} w_{k-1,\ell}\, \frac{h^{\ell-j}}{(\ell-j)!} \;+\; \frac{c_j}{h^j} \left(z_k - z_{k-1} \;-\; \sum_{\ell=1}^{m-1} w_{k-1,\ell}\, \frac{h^\ell}{\ell!} \right), \tag{2.5}$$

where

$$c_j \;=\; \frac{\sum_{\ell=0}^{m-1} a_\ell/(\ell+m-j)!}{\sum_{\ell=0}^{m-1} a_\ell/(\ell+m)!}, \quad j \;=\; 1, 2, \ldots, m-1. \tag{2.6}$$

The equations (2.5) combine to form the closed loop system

$$\tilde{W}_k \;=\; \left(\tilde{\mathbf{E}}(h) \;-\; \mathbf{C}(h)\mathbf{H}(h) \right) \tilde{W}_{k-1} \;+\; \mathbf{C}(h)\, (z_k - z_{k-1})\,, \tag{2.7}$$

where $\tilde{\mathbf{E}}(h)$ is the $(m-1)$-dimensional counterpart of $\mathbf{E}(h)$ shown in (1.2), $\tilde{W}$ is the $(m-1)$-dimensional vector consisting of components 1 through $m-1$ of the vector W there, $\mathbf{C}(h)$ is the $(m-1)$-dimensional vector with components c_j/h^j, $j \;=\; 1, 2, \ldots, m-1$, appearing in (2.5), and

$$\mathbf{H}(h) \;=\; \left(h \quad \tfrac{h^2}{2} \quad \cdots \quad \tfrac{h^{m-1}}{(m-1)!} \right). \tag{2.8}$$

From this point on, for notational convenience, we will revert to the use of $\mathbf{E}(h)$ and W, abandoning the $\tilde{}$ modifier. Writing $\zeta_{k-1} \;=\; z_k \;-\; z_{k-1}$ we have

$$W_k = \mathbf{A}(h)\, W_{k-1} + \mathbf{C}(h)\zeta_{k-1}, \quad k \;=\; 1, 2, 3, \ldots; \;\; \mathbf{A}(h) = \mathbf{E}(h) - \mathbf{C}(h)\mathbf{H}(h). \tag{2.9}$$

The row vector $\mathbf{H}(h)$ is fixed as soon as the step length h is chosen. The "feedforward" matrix $\mathbf{C}(h)$ with components c_j/h^j, as shown in (2.5), depends on the choice of the a_j in (2.2), as made clear by (2.6). The a_j, and hence $\mathbf{C}(h)$, are to be chosen so that the system (2.9) is stable and exhibits "desirable" performance characteristics. The stability requirement corresponds to our being able to choose $\mathbf{C}(h)$ so that $\mathbf{A}(h)$ is a discrete stability matrix; i.e., all of its eigenvalues have modulus less than 1. To be

sure we can do this we need to know that the pair $\big(\mathbf{H}(h), \mathbf{E}(h)\big)$ is *observable* ([2], p. 222).

THEOREM 2.1. *The pair* $\big(\mathbf{H}(h), \mathbf{E}(h)\big)$ *is observable.*

Proof. Let P_k, $k = 0, 1, 2, \ldots$, be a vector solution of the homogeneous system $P_k = \mathbf{E}(h)\, P_{k-1}$. Then there is a polynomial $p(t)$ of degree $\leq m-2$ such that $p^{(j)}(t_k) = P_{k,j+1}$, $j = 1, 2, \ldots, m-2$, $k = 0, 1, 2, \ldots$. Let $p^{(-1)}(t)$ be the antiderivative of $p(t)$ such that $p(t_0) = 0$. For $k = 1, 2, 3, \ldots$ we have $p^{(-1)}(t_k) = p^{(-1)}(t_{k-1}) + \mathbf{H}(h)P_{k-1} = \mathbf{H}(h)\mathbf{E}(h)^{k-1}\, P_0$. If the theorem were false, there would be a nonzero vector P_0 such that $\mathbf{H}(h)\mathbf{E}(h)^{k-1}\, P_0 = 0$ for all $k \geq 1$. But then $p^{(-1)}(t_k) = p^{(-1)}(t_0) = 0$, $k = 1, 2, 3, \ldots$, which implies $p^{(-1)}(t) \equiv 0$, and then $P_k \equiv 0$, $k = 0, 1, 2, \ldots$, which is a contradiction. The theorem follows.

With Theorem 2.1 in hand we can conclude, from standard theorems in the control and estimation theory of discrete linear systems (cf. [2], [8], [9]) that $\mathbf{C}(h)$, and hence the c_j appearing in (2.5) can be chosen so that $\mathbf{A}(h) = \mathbf{E}(h) - \mathbf{C}(h)\mathbf{H}(h)$ is a discrete stability matrix; in fact the coefficients c_j can be chosen to achieve any desired eigenvalues for that matrix, including the "deadbeat observer" choice for which all of the eigenvalues of that matrix are zero, and thus $\mathbf{A}(h)$ is nilpotent. □

To begin the error analysis we suppose the data values z_k, $k = 0, 1, 2, \ldots$, are obtained by a sampling process $z_k = z(t_k)$ from an $(m-1)$ times continuously differentiable function $z(t)$. In the context of this paper we would not know a formula for $z(t)$, but we might assume some information about its properties would be available. The accuracy of the generated spline $w(t)$ as an approximation to $z(t)$ for t between the knots t_k depends on how accurately the derivatives of $z(t)$ are matched at the knots by the derivatives of $w(t)$ and on the remainder term $r(t, t_{k-1})$ in the Newton formula

$$z(t) = z(t_{k-1}) + \sum_{\ell=1}^{m-1} \frac{z^{(\ell)}(t_{k-1})}{\ell!}(t - t_{k-1})^{\ell} + r(t, t_{k-1}). \tag{2.10}$$

Repeated differentiation of (2.10) yields, for $j = 1, 2, \ldots, m-1$, the formulae

$$z^{(j)}(t) = z^{(j)}(t_{k-1}) + \sum_{\ell=1}^{m-1-\ell} \frac{z^{(j+\ell)}(t_{k-1})}{\ell!}(t - t_{k-1})^{\ell} + r_j(t, t_{k-1}), \tag{2.11}$$

where $r_j(t, t_{k-1}) = \frac{\partial^j r}{\partial t^j}(t, t_{k-1})$. Taking Z_k, $R_k(h)$ to be the vectors in E^{m-1} with components $Z_{k,j} = z^{(j)}(t_k)$, $R_{k,j}(h) = r_j(h, t_k)$, we obtain the *discrete observed linear system* consisting of the vector counterpart of (2.11),

$$Z_k = \mathbf{E}(h)Z_{k-1} + R_{k-1}(h), \quad k = 1, 2, 3, \ldots, \tag{2.12}$$

and the *linear observation relationship*, or "output,"

$$\zeta_{k-1} = z_k - z_{k-1} = \mathbf{H}(h)Z_{k-1} + r_{k-1}(h) \tag{2.13}$$

which generates the data differences $\zeta_{k-1} = z_k - z_{k-1}$. In (2.12) and (2.13), $\mathbf{E}(h)$ and $\mathbf{H}(h)$ are the $(m-1)\times(m-1)$ matrices discussed following (2.8) and $r_k(h) = r(h, t_k)$. In this context (2.9) can be viewed in a new light; it is a *state estimator system* for the "plant" (2.12) via the output (2.13).

To make use of this insight we introduce the *error vectors*

$$X_k = W_k - Z_k, \quad k = 0, 1, 2, \ldots, \tag{2.14}$$

and see immediately, substracting (2.12) from (2.9), that

$$X_k = \Big(\mathbf{E}(h) - \mathbf{C}(h)\mathbf{H}(h)\Big)X_{k-1} + \mathbf{C}(h)r_{k-1}(h) - R_{k-1}(h)$$

$$\equiv \mathbf{A}(h)X_{k-1} + Q_{k-1}(h), \quad k = 1, 2, 3, \ldots, \tag{2.15}$$

with $\mathbf{A}(h)$ as in (2.9). This *error system* allows us to assess the asymptotic relationship between the spline approximation $w(t)$ and the data source function $z(t)$.

The eigenvalues, but not the eigenvectors, of $\mathbf{A}(h)$ are independent of $h \neq 0$. This follows immediately from

$$\mathbf{J}(h)\mathbf{A}(h)\mathbf{J}(h)^{-1} = \mathbf{A}(1) \equiv \mathbf{A}, \qquad \mathbf{J}(h) = \operatorname{diag}(1 \quad h \quad \cdots \quad h^{m-2}).$$

If we further suppose $z(t)$ to be m times continuously differentiable, we can write

$$r_k(h) = \tilde{r}_k(h)\, h^m, \quad R_{k,\,j}(h) = \tilde{R}_{k,\,j}(h)\, h^{m-j}, \quad j = 1, 2, \ldots, m-1,$$

where $\tilde{r}_k(h), \tilde{R}_{k,\,j}(h)$ are uniformly bounded for t_k in a fixed, compact interval. Then (2.15) transforms into

$$\tilde{X}_k = \mathbf{A}\tilde{X}_{k-1} + \tilde{Q}_{k-1}(h)h^{m-1}, \qquad \tilde{X}_k = \mathbf{J}(h)\, X_k, \tag{2.16}$$

where the $\tilde{Q}_k(h)$ are similarly uniformly bounded. Then we have the following theorem.

THEOREM 2.2. *Let $z(t)$ be m times continuously differentiable for t in a compact interval $\mathcal{I}$, and let all knots t_k under consideration lie in $\mathcal{I}$. Let $\mathbf{C}(1)$ be chosen so that all eigenvalues λ of $\mathbf{A} = \mathbf{E}(1) - \mathbf{C}(1)\mathbf{H}(1)$ satisfy $|\lambda| < 1$. Let $z_k = z(t_k)$, $k = 0, 1, 2, \ldots$, and let $W_0 = 0$. Then there exist constants γ_0, γ_1, μ, $0 \leq \gamma_0 < 1$, $\gamma_1 \geq 0$, $\mu \geq 0$, independent of k and $h \neq 0$, such that*

$$\left\|\tilde{X}_k\right\| \leq \mu\, \gamma_0^k \left\|\tilde{X}_0\right\| + \gamma_1\, h^{m-1}, \quad k = 1, 2, 3, \ldots. \tag{2.17}$$

Proof. From (2.16) we have, for $k = 1, 2, 3, \ldots$,

$$\tilde{X}_k = \mathbf{A}^k \tilde{X}_0 + h^{m-1} \sum_{\ell=0}^{k-1} \mathbf{A}^{k-1-\ell} \tilde{Q}_{k-1}(h) \equiv \tilde{X}_{0,k} + \tilde{X}_{1,k}. \tag{2.18}$$

Assuming $\mathbf{C}(1)$ is chosen as indicated, we take γ_0 to be the largest modulus of any eigenvalue of $\mathbf{A}$. Then there is a positive number μ such that $\left\|\mathbf{A}^\ell\right\| \leq \mu\, \gamma_0^\ell$ for all nonnegative integers ℓ. Thus

$$\left\|\tilde{X}_k\right\| \leq \mu\, \gamma_0^k \left\|\tilde{X}_0\right\| + \mu\, h^{m-1} \sum_{\ell=0}^{k-1} \gamma_0^{k-1-\ell} \left\|\tilde{Q}_{k-1}(h)\right\|.$$

Under our assumptions there is an upper bound $\tilde{Q}$ for the norms $||\tilde{Q}_{k-1}(h)||$, independent of k and h. Then

$$\left\|\tilde{X}_k\right\| \leq \mu\, \gamma_0^k \left\|\tilde{X}_0\right\| + \frac{\mu\, h^{m-1}\tilde{Q}}{1-\gamma_0} = \mu\, \gamma_0^k \left\|\tilde{X}_0\right\| + \gamma_1 h^{m-1}, \tag{2.19}$$

and the proof is complete. □

From (2.16) and (2.18) we have

$$X_k = \mathbf{J}(h)^{-1}\tilde{X}_{0,k} + \mathbf{J}(h)^{-1}\tilde{X}_{1,k} \equiv X_{0,k} + X_{1,k}.$$

These are the *transient* and *steady state* components of the error vector X_k. For the components $X_{1,k,j}$ of the steady state error we clearly have

$$|X_{1,k,j}| \le \gamma_1 h^{m-1}h^{1-j} = \gamma_1 h^{m-j}, \quad j = 1, 2, \ldots, m-1.$$

For the components $X_{0,k,j}$ of the transient error $X_{0,k}$, on the other hand, we have

$$|X_{0,k,j}| \le h^{1-j}\mu\gamma_0^k \left\|\mathbf{J}(h)X_0\right\|.$$

To pursue a different matter, let us suppose $\mathbf{C}(1)$ is chosen so that $\mathbf{A}$ has only zero eigenvalues and hence is nilpotent. Then (2.9) serves as a deadbeat state estimator for (2.12). If the data z_k correspond to values $z(t_k)$, with $z(t)$ an arbitrary polynomial of degree $\le m-1$, then the terms R_{k-1}, r_{k-1} in (2.12) and (2.15) are all zero and the latter becomes

$$X_k = \mathbf{A}(h)X_{k-1}, \quad k = 1, 2, 3, \ldots,$$

implying that $X_k = 0$, $k \ge m-1$. Then using $\mathbf{A}(h)^{m-1} = \mathbf{O}$ together with (2.9) we have

$$Z_{m-1} = W_{m-1} = \sum_{k=1}^{m-1} \mathbf{A}(h)^{m-1-k}\mathbf{C}(h)\left(z_k - z_{k-1}\right), \tag{2.20}$$

showing the components of W_{m-1}, i.e., the derivatives $w^{(j)}(t_{m-1})$, $j = 1, 2, \ldots, m-1$, of $w(t)$ at $t = t_{m-1}$, to be linear combinations of z_k, $k = 0, 1, 2, \ldots, m-1$. Since that is true for all polynomials $z(t)$ of degree $\le m-1$, and since $W_{m-1} = Z_{m-1}$, we conclude that the component equations of (2.20) must agree with the backward finite difference expressions for the derivatives $z^{(j)}(t_{m-1})$ in terms of z_k, $k = 0, 1, 2, \ldots, m-1$ (see, e.g., [6]). The simplest case, for stabilized forward cubic spline interpolation, has already been studied in section 1, where we saw that the deadbeat case corresponds to setting $w'(t_k) = \frac{z_k - z_{k-1}}{h}$, $k \ge 1$. Significantly, in his text [3] de Boor suggests the possible use of such expressions as alternate boundary conditions for spline interpolation (as compared, for example, with the "natural" boundary conditions described there).

3. Stochastic optimality. In the previous sections we have established stabilizability of the forward interpolation system via choice of the feedforward vector $\mathbf{C}(h)$, equivalently $\mathbf{C}(1)$, and we have obtained some general error bounds. The next question naturally arising concerns which choice of $\mathbf{C}(h)$ is "best." This clearly depends on the criteria used and on our notion of how the data values z_k are generated, in other words on the formulation of a *model process* upon whose operation the z_k are assumed to constitute an *observation*. We have started on this in the preceding section, interpreting our process as a plant/state estimator system. Now we need to go further and introduce some statistical concepts into that system. The following development is based on several sources, including [2], [8], and [9].

The first step is to replace (2.12) by

$$Z_k = \mathbf{E}(h)\, Z_{k-1} + N_{k-1}, \tag{3.1}$$

wherein the vectors N_k are now assumed to constitute discrete white noise; i.e., N_k and N_j are uncorrelated for $k \neq j$, with zero mean and constant covariance matrix $\mathbf{N} \equiv \mathcal{E}\,(N_k\, N_k^*)\,,\ \mathcal{E}$ denoting the expected value. These noise terms will be referred to as the *process noise*. Then we replace (2.13) by

$$\zeta_{k-1} \,=\, z(t_k) - z(t_{k-1}) \,=\, \mathbf{H}(h)\, Z_{k-1} \,+\, n_{k-1}, \tag{3.2}$$

where $\mathbf{H}(h)$ is given in (2.8) and the sequence $\{n_{k-1}\}$ is assumed to be scalar white noise with zero mean and covariance $\mathbf{n}$; this is the *observation noise*.

In most applications the remainders R_k, r_k of the preceding section are not white noise, but it will often be advantageous to treat them as if they were. This parallels situations in systems theory wherein unmodelled states, nonlinearities, disturbances, etc., are often lumped together and treated as white noise in design procedures. Our model process might be described as a *stochastically interrupted polynomial* of degree $m-1$. On each interval $[t_{k-1}, t_k)$, $q_k(t) \,\equiv\, z(t_{k-1}) \,+\, \mathbf{H}(t - t_{k-1})Z(t_{k-1})$ is a polynomial of degree $\leq m-1$. If the N_k and n_k were identically zero, we would have $q_k(t) \equiv q(t)$, where $q(t)$ is a fixed polynomial of degree $\leq m-1$ for all t. If there is an integer μ, $1 \leq \mu \leq m-1$, such that $N_{k,j} \equiv 0$ when $j \leq \mu$, we say that $q(t)$ has *smoothness level* μ, since derivatives of order $\leq \mu$ are continuous across the knots.

From (2.9), (3.1), and (3.2) we have the combined plant/state estimator system

$$W_k \,=\, \mathbf{E}(h)\, W_{k-1} \,+\, \mathbf{C}(h)\Big(\zeta_k \,-\, \mathbf{H}(h)W_{k-1}\Big),$$

$$\zeta_k \,=\, \mathbf{H}(h)\, Z_{k-1} \,+\, n_{k-1}, \qquad Z_k \,=\, \mathbf{E}(h)\, Z_{k-1} \,+\, N_{k-1}, \tag{3.3}$$

in which the model system (3.1) plays the role of the plant and the spline generator system (2.9) plays the role of state estimator. Defining the *state estimation error* X_k as in (2.14) and subtracting the last equation of (3.3) from the first we have

$$X_k \,=\, \Big(\mathbf{E}(h) \,-\, \mathbf{C}(h)\mathbf{H}(h)\Big)X_{k-1} \,+\, \mathbf{C}(h)n_{k-1} - N_{k-1}. \tag{3.4}$$

Normally $W_0 \,=\, 0$ because we have no information on derivatives at $t \,=\, t_0$. This gives $X_0 \,=\, -\,Z_0$. Let $\mathbf{X}_k$ be the covariance matrix of X_k. Then (see, e.g., [2])

$$\mathbf{X}_k \,=\, \mathbf{A}(h)\mathbf{X}_{k-1}\mathbf{A}(h)^* \,+\, \mathbf{N} \,+\, \mathbf{n}\,\mathbf{C}(h)\mathbf{C}(h)^*, \quad k \,=\, 1, 2, \ldots, \quad \mathbf{X}_0 \,=\, \mathbf{Z}_0, \tag{3.5}$$

wherein $\mathbf{A}(h)$ is the "closed loop matrix," $\mathbf{A}(h) \,=\, \mathbf{E}(h) \,-\, \mathbf{C}(h)\mathbf{H}(h)$, and $\mathbf{Z}_0$ is the covariance matrix for the (generally unknown) initial "plant state" Z_0. If the feedforward vector $\mathbf{C}(h)$ is chosen so that $\mathbf{A}(h)$ is a discrete stability matrix, then

$$\lim_{k \,\to\, \infty} \mathbf{X}_k \,\equiv\, \mathbf{X} \tag{3.6}$$

exists and represents the ultimate, "steady state" covariance of the error vectors X_k.

The goal of optimal state estimation in this context is to find $\hat{\mathbf{C}}(h)$ such that $\mathbf{A}(h)$ is a discrete stability matrix and the corresponding limiting error covariance $\hat{\mathbf{X}}$ is minimal; i.e., $\hat{\mathbf{X}} \,\leq\, \mathbf{X}$ for $\mathbf{X}$ associated with any other stabilizing feedforward matrix $\mathbf{C}(h)$. This problem has a long history, and the solution is well known; cf., e.g., [2], [7]. The optimal $\hat{\mathbf{C}}(h)$ is given by

$$\hat{\mathbf{C}}(h) \,=\, -\,\mathbf{E}(h)\hat{\mathbf{X}}\mathbf{H}(h)^*\Big(\mathbf{H}(h)\hat{\mathbf{X}}\mathbf{H}(h)^* + \mathbf{n}\Big)^{-1}.$$

The matrix $\hat{\mathbf{X}}$ is given by (3.6) with $\hat{\mathbf{X}}_k$ replacing $\mathbf{X}_k$ and $\hat{\mathbf{C}}(h)$ replacing $\mathbf{C}(h)$ in (3.5). The circularity of this description is escaped by algebraic manipulations which eliminate $\hat{\mathbf{C}}(h)$ from the corresponding version of (3.5); the $\hat{\mathbf{X}}_k$ satisfy the quadratic matrix recursion equation

$$\hat{\mathbf{X}}_k \;=\; \mathbf{E}(h)\hat{\mathbf{X}}_{k-1}\mathbf{E}(h)^* \;+\; \mathbf{N}$$

$$-\,\mathbf{E}(h)\hat{\mathbf{X}}_{k-1}\mathbf{H}(h)^*\Big(\mathbf{H}(h)\hat{\mathbf{X}}_{k-1}\mathbf{H}(h)^* + \mathbf{n}\Big)^{-1}\mathbf{H}(h)\hat{\mathbf{X}}_{k-1}\mathbf{E}(h)^*. \tag{3.7}$$

As is well known and documented in the indicated references,

$$\lim_{k\,\to\,\infty}\,\hat{\mathbf{X}}_k \;\equiv\; \hat{\mathbf{X}}, \tag{3.8}$$

which, in turn, satisfies the steady state quadratic matrix equation

$$\hat{\mathbf{X}} \;-\; \mathbf{E}(h)\hat{\mathbf{X}}\mathbf{E}(h)^* \;-\; \mathbf{N}$$

$$+\,\mathbf{E}(h)\hat{\mathbf{X}}\mathbf{H}(h)^*\Big(\mathbf{H}(h)\hat{\mathbf{X}}\mathbf{H}(h)^* + \mathbf{n}\Big)^{-1}\mathbf{H}(h)\hat{\mathbf{X}}\mathbf{E}(h)^* \;=\; 0. \tag{3.9}$$

The recursion formula (3.7) can be used with $\hat{\mathbf{X}}_0 \;=\; \mathbf{N}$ to produce a sequence $\hat{\mathbf{X}}_k$ which converges quadratically as $k \;\to\; \infty$ to the unique positive symmetric solution $\hat{\mathbf{X}}$ of (3.9). This is frequently used as a numerical procedure to compute the latter matrix; care has to be taken to keep the computed $\hat{\mathbf{X}}_k$ symmetric at each step.

4. An example: $m \;=\; 3,\ n \;=\; 5$. After the case $n \;=\; 3$ discussed in section 1 the next relevant case is $n \;=\; 5,\ m \;=\; 3$. For $k \;=\; 1, 2, 3, \ldots$ we have

$$\begin{pmatrix} w_{k,0} \\ w_{k,1} \\ w_{k,2} \end{pmatrix} \;=\; \begin{pmatrix} 1 & h & \frac{h^2}{2} \\ 0 & 1 & h \\ 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} w_{k-1,0} \\ w_{k-1,1} \\ w_{k-1,2} \end{pmatrix} + \begin{pmatrix} \frac{h^3}{6} & \frac{h^4}{24} & \frac{h^5}{120} \\ \frac{h^2}{2} & \frac{h^3}{6} & \frac{h^4}{24} \\ h & \frac{h^2}{2} & \frac{h^3}{6} \end{pmatrix} \begin{pmatrix} f_{k-1} \\ g_{k-1,1} \\ g_{k-1,2} \end{pmatrix}. \tag{4.1}$$

The specialization of (2.2) here is

$$g_{k-1,1} \;=\; \frac{a_1 f_{k-1}}{h},\quad g_{k-1,2} \;=\; \frac{a_2 f_{k-1}}{h^2},\quad k \;=\; 1, 2, 3, \ldots. \tag{4.2}$$

We substitute (4.2) into (4.1), recall that $w_{k,0} \;=\; z_k$, the given data, and use the resulting first equation to obtain the feedback relation

$$f_k \;=\; \frac{z_k - z_{k-1} - w_{k-1,1}h - w_{k-1,2}h^2/2}{h^3\,(1/6 + a_1/24 + a_2/120)}. \tag{4.3}$$

Then we substitute (4.3) into the second and third equations of (4.1) to obtain

$$\begin{pmatrix} w_{k,1} \\ w_{k,2} \end{pmatrix} \;=\; \begin{pmatrix} 1 - c_1 & (1 - c_1/2)\,h \\ -c_2/h & 1 - c_2/2 \end{pmatrix} \begin{pmatrix} w_{k-1,1} \\ w_{k-1,2} \end{pmatrix} + \begin{pmatrix} c_1/h \\ c_2/h^2 \end{pmatrix} (z_k - z_{k-1}), \tag{4.4}$$

where

$$c_1 \;=\; \frac{1/2 + a_1/6 + a_2/24}{1/6 + a_1/24 + a_2/120}, \qquad c_2 \;=\; \frac{1 + a_1/2 + a_2/6}{1/6 + a_1/24 + a_2/120}. \tag{4.5}$$

The equations (4.5) can be solved for a_1 and a_2 to give

$$a_1 = -8\left(\frac{7\,c_1 - c_2 - 15}{8\,c_1 - c_2 - 20}\right), \qquad a_2 = 20\left(\frac{6\,c_1 - c_2 - 12}{8\,c_1 - c_2 - 20}\right), \tag{4.6}$$

provided c_1 and c_2 are such that $8\,c_1 - c_2 - 20 \neq 0$.

PROPOSITION 4.1. *The restriction* $8\,c_1 - c_2 - 20 \neq 0$ *excludes no pairs* c_1, c_2 *for which the matrix*

$$\tilde{\mathbf{A}}(h) = \begin{pmatrix} 1 - c_1 & (1 - c_1/2)\,h \\ -c_2/h & 1 - c_2/2 \end{pmatrix} \tag{4.7}$$

in (4.4) *is a discrete stability matrix.*

Remark. We saw in section 1 that a similar result applies for the cubic case $m = 2$, $n = 3$. Whether this remains valid for general m, $n = 2m - 1$, remains open.

Proof. The matrix (4.7) has characteristic polynomial with roots

$$\lambda = \frac{1}{2}\left(2 - \left(c_1 + \frac{c_2}{2}\right) \pm \sqrt{\left(c_1 + \frac{c_2}{2}\right)^2 - 4c_2}\right). \tag{4.8}$$

Solving $8c_1 - c_2 - 20 = 0$ for c_2 and substituting into (4.8) we obtain

$$\lambda = \frac{1}{2}\left(12 - 5c_1 \pm \sqrt{25\,c_1^2 - 132\,c_1 + 180}\right).$$

The discriminant of the quadratic under the square root sign is $(132)^2 - 18000 = -576$ so that quadratic is positive for every choice of c_1. For any choice of c_1 the absolute value of the difference between the two roots is $\sqrt{25\,c_1^2 - 132\,c_1 + 180}$, which has a minimum value $12/5 = 2.4$. Since this minimum exceeds 2, no choice of c_1, hence no choice of c_1, c_2, satisfying $8c_1 - c_2 - 20 = 0$ yields both roots with modulus less than 1. We conclude that the exceptional cases described by $8c_1 - c_2 - 20 = 0$ do not limit the choice of stabilizing pairs c_1, c_2; the proof is complete. ∎

Once the closed loop system (4.4) has been obtained the next step is to obtain c_1, c_2 stabilizing the corresponding homogeneous system. Confirming Theorem 2.1, the pair consisting of $\mathbf{H} = (\,1 \quad 1/2\,)$ and $\mathbf{E} = \left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right)$ is readily seen to be *observable*, i.e., $\operatorname{rank}\left(\begin{smallmatrix} \mathbf{H} \\ \mathbf{HE} \end{smallmatrix}\right) = 2$, so the system is stabilizable [2]; by proper choice of c_1 and c_2 the eigenvalues of $\tilde{\mathbf{A}}$ can be placed at will. From the form (4.8) of the roots, deadbeat stabilization is achieved with $c_1 = 3/2$, $c_2 = 1$, which in turn, from (4.6), corresponds to $a_1 = -44/9 = -4.8889$, $a_2 = 80/9 = 8.8889$. Here system (4.4) becomes

$$\begin{pmatrix} w_{k,1} \\ w_{k,2} \end{pmatrix} = \begin{pmatrix} -1/2 & h/4 \\ -1/h & 1/2 \end{pmatrix} \begin{pmatrix} w_{k-1,1} \\ w_{k-1,2} \end{pmatrix} + \begin{pmatrix} 3/2h \\ 1/h^2 \end{pmatrix} (z_k - z_{k-1})\,. \tag{4.9}$$

Substituting (4.9), with k replaced by $k - 1$, back into (4.9) one obtains

$$\begin{pmatrix} w_{k,1} \\ w_{k,2} \end{pmatrix} = \begin{pmatrix} \frac{3}{2h}\,(z_k - z_{k-1}) - \frac{1}{2h}\,(z_{k-1} - z_{k-2}) \\ \frac{1}{h^2}\,(z_k - 2\,z_{k-1} + z_{k-2}) \end{pmatrix}.$$

Thus, with the indicated values of c_1 and c_2, after two steps the procedure sets the derivative, $w_{k,1}$, and the second derivative, $w_{k,2}$, equal to backward divided differences known [6] to be exact expressions for $w'(t_k)$ and $w''(t_k)$ when $w(t)$ is of degree 2.

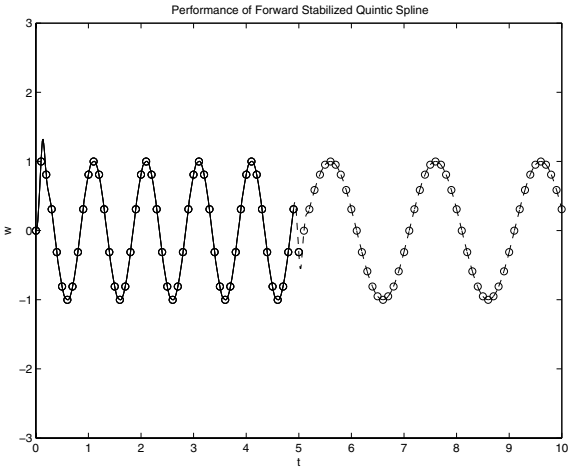

FIG. 3. *Performance of forward stabilized quintic spline.*

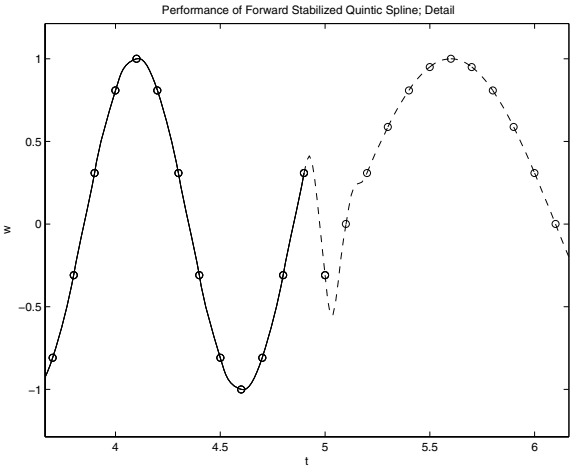

FIG. 4. *Performance of forward stabilized quintic spline; detail.*

Figures 3 and 4 show results when the deadbeat forward quintic spline procedure is carried out with data taken from a function $z(t)$ which combines two different trigonometric functions. The overall interval has length 10 and $h = .2$. Initially $z_0 = z(0) = 0$; thereafter, while $t < 5$, we have $z(t) = \cos(2\pi t)$; a discontinuity occurs at $t = 5$; we have $z(t) = \sin(\pi(t - 5.1))$ for $t \geq 5$. Figure 4 shows the situation near $t = 5$ in greater detail. The discontinuity is treated by the procedure in a controlled manner over the interval $[t_{24}, t_{27}] = [4.8, 5.2]$, and convergence to splines closely approximating $\sin(\pi(t - 5.1))$ occurs rapidly (in two steps, essentially) thereafter.

In the present quintic case a straightforward computation with (3.9) shows that the deadbeat case, wherein the eigenvalues of the closed loop matrix $\tilde{\mathbf{A}}$ are both equal to zero, corresponds to $\mathbf{N} = \operatorname{diag}(1 \quad 4)$, $\mathbf{n} = 0$; i.e., zero observation noise is assumed. This result was obtained by a trial and error process after initially guessing

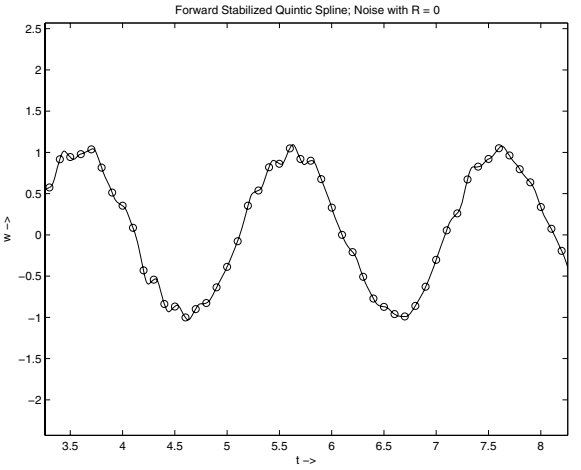

FIG. 5. *Forward stabilized quintic spline; noise with R=0.*

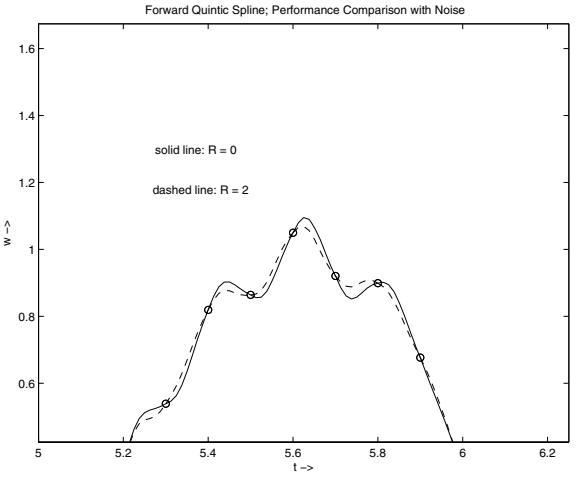

FIG. 6. *Forward quintic spline; performance comparison with noise.*

that the deadbeat estimator would correspond to the zero observation noise situation. A similarly unsystematic treatment of the seventh degree case $m = 4$ (not detailed here) shows the deadbeat state estimator to be achieved in that case with $\mathbf{n} = 0$ with process noise covariance matrix $\mathbf{N} = \text{diag}\,(1 \quad 6 \quad 18)$. Whether for general m the deadbeat estimator always corresponds to diagonal $\mathbf{N}$ with integer diagonal weights combined with $\mathbf{n} = 0$, and what the general form of those diagonal weights might be, are questions for which we have no answer at the present time.

In Figure 5 we show results for this case with data obtained from a sinusoidal function with knot values perturbed by random noise in the range $[-.25, .25]$ supplied by MATLAB. In Figure 6 we look more closely at the central "peak" of Figure 5. The solid curve corresponds to the deadbeat case $\mathbf{n} = 0$ of Figure 6, while the dashed curve corresponds to the same $\mathbf{N}$ but with $\mathbf{n} = 2$, which amounts to assuming observation noise present with that covariance. We observe that the assumption that

noise is present in the observation appears to lead to interpolation with less overshoot between the knots.

OPTIMAL DISTURBANCE ATTENUATION FOR DISCRETE-TIME SWITCHED AND MARKOVIAN JUMP LINEAR SYSTEMS*

JI-WOONG LEE† AND GEIR E. DULLERUD‡

Abstract. An exact condition for uniform stabilization and disturbance attenuation for switched linear systems is given in the discrete-time domain via the union of an increasing family of linear matrix inequality conditions. Associated with each Markovian jump linear system is a switched linear system, so we obtain a necessary and sufficient condition for almost sure uniform stabilization and disturbance attenuation for Markovian jump linear systems as well. The results lead to semidefinite programming–based controller synthesis techniques, from which optimal finite-path-dependent linear dynamic output feedback controllers arise naturally. In particular, under the notion of path-by-path optimal disturbance attenuation, finite-path-dependent controllers can outperform the usual mode-dependent ones.

Key words. discrete linear inclusions, dynamic output feedback, H^∞ control, linear matrix inequalities, linear time-varying systems, semidefinite programming

1. Introduction.

The switched linear system is defined as a family of linear time-varying systems whose parameters vary within a single finite set, and it serves as an abstraction of hybrid systems, where continuous system dynamics and discrete events coexist and depend on each other in complex ways [31]. On the other hand, the Markovian jump linear system is a linear system whose parameters jump according to the state transitions of a finite-state Markov chain, and it typically arises in the context of networked control systems, where the feedback loop is subject to random delays [32]. The parameters of these systems are indexed, where the indices are called the modes of the systems. This paper focuses on the discrete-time domain and considers the problems of uniform disturbance attenuation for switched linear systems and almost sure uniform disturbance attenuation for Markovian jump linear systems, where the uniformity refers to the stability and ℓ^2-gain of the sequences of modes, called switching sequences, that are admissible. We develop semidefinite programming formulations [41] for the solutions to these problems, and their generalizations, without any assumption on the parameters or admissible switching sequences.

The most fundamental problem of discrete-time switched linear systems is determining the asymptotic stability of the discrete linear inclusion (i.e., the family of linear time-varying systems over all infinite sequences of parameters in a given finite set) [12, 21]. This problem basically involves checking the stability of all possible (uncountably many) infinite matrix products due to the fact that the finiteness conjecture (i.e., the conjecture that it suffices to check the stability of periodic products) is generally false [8]. The problem is hence considered undecidable [7]; more precisely,

it is considered semidecidable (i.e., there exists an algorithm that is guaranteed to correctly determine, after a finite amount of computation, the stability of switched linear systems that are indeed stable) [6]. Recently, the authors gave a restatement of the result of [6] and introduced an increasing family of linear matrix inequality conditions whose union characterizes the uniform stability and stabilizability of discrete-time switched linear systems [30]. This result generalizes the multiple Lyapunov function approaches that have provided the most useful tools for stability analysis [9].

This paper complements the previous work on uniform stabilization described above and extends it to disturbance attenuation. The problem of disturbance attenuation reduces to that of $\mathcal{H}^\infty$ control of linear time-invariant systems [16, 26] if the given set of system parameters is a singleton. On the other hand, if the family of admissible switching sequences is a singleton, the problem reduces to that of ℓ^2-induced norm minimization for linear time-varying systems [36, 4], where the set of possible parameter values is finite. Therefore, our work draws on the results in the $\mathcal{H}^\infty$ control and ℓ^2-gain minimization literature. In particular, from the linear operator inequality approach for analyzing linear time-varying systems [17], we deduce that the Riccati difference inequality associated with any stable and contractive linear time-varying system admits a uniformly stabilizing solution that has a finite memory of past parameters. This finite-memory property leads to our analysis results. On the other hand, our controller synthesis results are based on a straightforward extension of the linear matrix inequality approach originally developed for linear time-invariant systems [33, 20].

We relax the standard restriction to mode-dependent controllers (i.e., controllers that perfectly observe the present mode of the system but do not recall past modes) and consider finite-path-dependent controllers (i.e., controllers that not only perfectly observe the present mode but also have a finite memory of past modes). This relaxation, along with the aforementioned finite-memory property, enables us to derive a complete characterization of the existence of finite-path-dependent linear dynamic output feedback controllers that stabilize the switched linear system and achieve a uniform disturbance attenuation level. This characterization is given in terms of the "union" of an increasing family of systems of linear matrix inequality conditions. Although our result inherits the semidecidable nature of the underlying problem, this limitation is not likely to pose difficulties in practice, as examples show that it usually suffices to check the feasibility of the first few systems of linear matrix inequalities from an increasing family. Moreover, the result is amenable to the standard linear matrix inequality–based controller synthesis technique, from which admissible finite-path-dependent controller syntheses arise naturally.

The notion of finite-path-dependent controllers not only serves as a relaxation to achieve an exact condition for disturbance attenuation but also is required for optimality under the notion of path-by-path disturbance attenuation. Roughly speaking, the path-by-path performance is defined as a finite family of disturbance attenuation levels over all admissible switching paths of a given length. This notion of performance is a natural extension of that of uniform disturbance attenuation and can be used to improve upon the performance of a controller synthesis that achieves a given uniform disturbance attenuation level. As long as the path-by-path optimality is concerned, examples show that finite-path-dependent controllers can outperform mode-dependent controllers.

The result described above carries over to the almost sure uniform disturbance attenuation for Markovian jump linear systems because the uniformity requirement for stability and performance enables one to consider each Markovian jump linear

system as a switched linear system, where the underlying Markov chain of the former defines the switching path constraint of the latter. An immediate consequence is that, as long as almost sure uniform disturbance attenuation is concerned, the performance of Markovian jump linear systems is intrinsically robust against variations that preserve the directed graph of the underlying Markov chain (i.e., against sparsity pattern–preserving variations from the given transition probability matrix and initial distribution). On the other hand, under the notion of path-by-path disturbance attenuation, one can reduce the conservatism associated with this robustness property while still maintaining almost sure uniform stability; two Markov chains with the same directed graph can result in widely different path-by-path performances, depending on the actual values of initial and transition probabilities.

A key contribution of this paper to the control of switched linear systems and Markovian jump linear systems is that exact "control-oriented" conditions for (almost sure) stabilization and disturbance attenuation are provided. These conditions are control oriented in the sense that they lead to semidefinite programming–based techniques, which render optimal controllers very efficiently. There has been little work done on the control of disturbance attenuation performances of switched linear systems, other than that some partial analysis results in the continuous-time domain exist [44, 23]. On the other hand, the usual approach in the literature to disturbance attenuation for Markovian jump linear systems has been based on the notion of stochastic stability in both continuous time [28, 34, 13] and discrete time [11, 19, 10, 37]. These results, however, though either partly satisfactory or exact, are not well-suited for efficient optimal controller synthesis. For instance, in the case of independent and identically distributed switching, an exact linear matrix inequality–based synthesis condition for discrete-time jump systems has been obtained in [38]; for general Markov switching, this condition is only sufficient. Moreover, even though stochastically stable Markovian jump linear systems are almost surely stable [29], the usual approach does not guarantee almost sure disturbance attenuation.

The paper is organized as follows. Section 2 analyzes the performance of general linear time-varying systems. Then, based on this analysis, main results on uniform disturbance attenuation for switched linear systems and Markovian jump linear systems are derived in sections 3 and 4, respectively. Section 5 introduces the notion of path-by-path disturbance attenuation and provides some examples including optimal disturbance attenuation for a planar robot, called the Pendubot, subject to random delays in the feedback loop. Finally, concluding remarks are given in section 6.

Notation. If $\mathbf{X} \in \mathbb{R}^{m\times n}$, the range (or image) of $\mathbf{X}$ is denoted by $\operatorname{Im}\mathbf{X}$, the null space (or kernel) of $\mathbf{X}$ by $\operatorname{Ker}\mathbf{X}$, and the rank of $\mathbf{X}$ by $\operatorname{rank}\mathbf{X}$; denoted by $\mathbf{N}(\mathbf{X})$ is any particular full-rank matrix such that $\operatorname{Im}\mathbf{N}(\mathbf{X}) = \operatorname{Ker}\mathbf{X}$. The indicator matrix $\mathbf{1}(\mathbf{X}) = (\mu_{ij}) \in \{0,1\}^{m\times n}$ of an $\mathbf{X} = (x_{ij}) \in \mathbb{R}^{m\times n}$ is such that $\mu_{ij} = 1$ if $x_{ij} \neq 0$ and $\mu_{ij} = 0$ if $x_{ij} = 0$. The matrices whose entries are all 0 (resp., all 1) are denoted by $\mathbf{0}$ (resp., $\mathbf{1}$) whenever m and n are understood. If $\mathbf{X}$, $\mathbf{Y} \in \mathbb{R}^{n\times n}$ are symmetric and $\mathbf{X} - \mathbf{Y}$ is positive definite (resp., nonnegative definite), we write $\mathbf{X} > \mathbf{Y}$ (resp., $\mathbf{X} \geq \mathbf{Y}$). The identity matrix is denoted by $\mathbf{I}$ with n understood.

For $x \in \mathbb{R}^n$, denoted by $\|x\|$ is the Euclidean vector norm $\|x\| = \sqrt{x^{\mathrm{T}}x}$ of x. If $\mathbf{X} \in \mathbb{R}^{m\times n}$, the Euclidean vector norm induces the spectral norm $\|\mathbf{X}\|$ of $\mathbf{X}$ given by $\|\mathbf{X}\| = \sup\{\sqrt{\lambda}\colon \lambda \text{ is an eigenvalue of } \mathbf{X}^{\mathrm{T}}\mathbf{X}\}$. Given a symmetric positive definite matrix $\mathbf{X} \in \mathbb{R}^{n\times n}$, $\|\cdot\|_{\mathbf{X}}$ is the Hilbert norm of $x \in \mathbb{R}^n$ defined by $\|x\|_{\mathbf{X}} = \sqrt{x^{\mathrm{T}}\mathbf{X}x}$. If $\boldsymbol{x} = (x(0), x(1), \dots)$ is a sequence in $\mathbb{R}^n$, then we write $\boldsymbol{x} \in \ell^2(\mathbb{R}^n)$ whenever the ℓ^2 norm of $\boldsymbol{x}$, defined by $\|\boldsymbol{x}\| = \sqrt{\sum_{s=0}^{\infty}\|x(s)\|^2}$, is finite.

2. Analysis of linear time-varying systems. In this section, we analyze the disturbance attenuation performance of the discrete-time linear time-varying system and the asymptotic property of the associated Riccati difference equation. We choose a notation that is compatible with the latter sections of this paper. Let a subset $\boldsymbol{\mathcal{G}}$ of $\mathbb{R}^{n\times n}\times\mathbb{R}^{n\times m}\times\mathbb{R}^{l\times n}\times\mathbb{R}^{l\times m}$ and a sequence $\boldsymbol{\theta}=(\theta(0),\theta(1),\dots)$ in $\{0,1,\dots\}$ be as follows:

$$\boldsymbol{\mathcal{G}}=\{(\mathbf{A}_0,\mathbf{B}_0,\mathbf{C}_0,\mathbf{D}_0),(\mathbf{A}_1,\mathbf{B}_1,\mathbf{C}_1,\mathbf{D}_1),\dots\},\quad \boldsymbol{\theta}=(0,1,\dots). \tag{2.1}$$

With (2.1), we have $(\mathbf{A}_{\theta(t)},\mathbf{B}_{\theta(t)},\mathbf{C}_{\theta(t)},\mathbf{D}_{\theta(t)})=(\mathbf{A}_t,\mathbf{B}_t,\mathbf{C}_t,\mathbf{D}_t)$, and the pair $(\boldsymbol{\mathcal{G}},\boldsymbol{\theta})$ is identified with the discrete-time linear time-varying system

$$\begin{aligned} x(t+1)&=\mathbf{A}_t x(t)+\mathbf{B}_t w(t),\\ z(t)&=\mathbf{C}_t x(t)+\mathbf{D}_t w(t), \end{aligned} \tag{2.2}$$

where $\boldsymbol{\mathcal{G}}$ defines an indexed family of parameter quadruples, and the sequence $\boldsymbol{\theta}$ chooses one quadruple among $\boldsymbol{\mathcal{G}}$ for each $t\ge 0$. Given the initial state $x(0)$ and disturbance sequence $\boldsymbol{w}=(w(0),w(1),\dots)$, (2.2) determines the state sequence $\boldsymbol{x}=(x(0),x(1),\dots)$ and output sequence $\boldsymbol{z}=(z(0),z(1),\dots)$. If $\mathbf{B}_i$, $\mathbf{C}_i$, $\mathbf{D}_i$ are all zero matrices, we write $(\boldsymbol{\mathcal{A}},\boldsymbol{\theta})$ for $(\boldsymbol{\mathcal{G}},\boldsymbol{\theta})$, where

$$\boldsymbol{\mathcal{A}}=\{\mathbf{A}_0,\mathbf{A}_1,\dots\}. \tag{2.3}$$

DEFINITION 2.1. *The system $(\boldsymbol{\mathcal{G}},\boldsymbol{\theta})$, and hence $(\boldsymbol{\mathcal{A}},\boldsymbol{\theta})$, is said to be* uniformly (exponentially) stable *if there exist $c\ge 1$ and $\lambda\in(0,1)$ such that, whenever $\boldsymbol{w}=0$,*

$$\|x(t)\|\le c\,\lambda^{t-t_0}\,\|x(t_0)\| \tag{2.4}$$

for $t\ge t_0\ge 0$ and for $x(t_0)\in\mathbb{R}^n$.

DEFINITION 2.2. *The system $(\boldsymbol{\mathcal{G}},\boldsymbol{\theta})$ is said to be* uniformly (strictly) contractive *if there exists a $\gamma\in(0,1)$ such that, whenever $x(t_0)=0$,*

$$\sum\nolimits_{s=t_0}^{t}\|z(s)\|^2\le\gamma^2\sum\nolimits_{s=t_0}^{t}\|w(s)\|^2 \tag{2.5}$$

for $t\ge t_0\ge 0$ and for $\boldsymbol{w}\in\ell^2(\mathbb{R}^m)$.

Remark 1. It is clear that the uniform contractiveness is equivalent to the condition that the ℓ^2-induced gain from $\boldsymbol{w}$ to $\boldsymbol{z}$ be less than one; that is, for some $\gamma\in(0,1)$, $\|\boldsymbol{z}\|\le\gamma\|\boldsymbol{w}\|$ whenever $x(0)=0$ and $\boldsymbol{w}\in\ell^2(\mathbb{R}^m)$. The infimum of all $\gamma>0$ that satisfy (2.5) is called the ℓ^2-induced norm of the system $(\boldsymbol{\mathcal{G}},\boldsymbol{\theta})$.

LEMMA 2.3. *Let $\boldsymbol{\mathcal{G}}$ and $\boldsymbol{\theta}$ be as in* (2.1)*; let $\boldsymbol{\mathcal{G}}$ be bounded. The following are equivalent:*

(a) *The system $(\boldsymbol{\mathcal{G}},\boldsymbol{\theta})$ is uniformly exponentially stable and uniformly strictly contractive.*

(b) *There exist α_1, $\beta_1>0$, and $\mathbf{X}_t\in\mathbb{R}^{n\times n}$, $t=0,1,\dots$, such that, for all t,*

$$\alpha_1\mathbf{I}\le\mathbf{X}_t\le\beta_1\mathbf{I}; \tag{2.6a}$$

$$\begin{bmatrix}\mathbf{A}_t&\mathbf{B}_t\\ \mathbf{C}_t&\mathbf{D}_t\end{bmatrix}^{\mathrm{T}}\begin{bmatrix}\mathbf{X}_{t+1}&\mathbf{0}\\ \mathbf{0}&\mathbf{I}\end{bmatrix}\begin{bmatrix}\mathbf{A}_t&\mathbf{B}_t\\ \mathbf{C}_t&\mathbf{D}_t\end{bmatrix}-\begin{bmatrix}\mathbf{X}_t&\mathbf{0}\\ \mathbf{0}&\mathbf{I}\end{bmatrix}\le-\alpha_1\mathbf{I}. \tag{2.6b}$$

(c) *There exist α_2, $\beta_2>0$, and $\mathbf{Y}_t\in\mathbb{R}^{n\times n}$, $t=0,1,\dots$, such that, for all t,*

$$\alpha_2\mathbf{I}\le\mathbf{Y}_t\le\beta_2\mathbf{I}; \tag{2.7a}$$

$$\begin{bmatrix}\mathbf{A}_t&\mathbf{B}_t\\ \mathbf{C}_t&\mathbf{D}_t\end{bmatrix}\begin{bmatrix}\mathbf{Y}_t&\mathbf{0}\\ \mathbf{0}&\mathbf{I}\end{bmatrix}\begin{bmatrix}\mathbf{A}_t&\mathbf{B}_t\\ \mathbf{C}_t&\mathbf{D}_t\end{bmatrix}^{\mathrm{T}}-\begin{bmatrix}\mathbf{Y}_{t+1}&\mathbf{0}\\ \mathbf{0}&\mathbf{I}\end{bmatrix}\le-\alpha_2\mathbf{I}. \tag{2.7b}$$

Moreover, if either (b) *or* (c) *holds, one may take*

$$\mathbf{X}_t = \mathbf{Y}_t^{-1} \tag{2.8}$$

for all t.

Proof. The equivalence of (a) and (b) is shown in [17, Thm. 11] via an operator theoretic approach. A simple Schur complement argument, together with the matrix inversion formula, shows that (b) and (c) are equivalent via relation (2.8). ∎

PROPOSITION 2.4. *Let* $\boldsymbol{\mathcal{A}}$ *be as in* (2.3) *and bounded; let* $\boldsymbol{\theta}$ *be as in* (2.1). *Then the system* $(\boldsymbol{\mathcal{A}}, \boldsymbol{\theta})$ *is uniformly exponentially stable if and only if there exist* α_1, $\beta_1 > 0$ *and* $\mathbf{X}_t \in \mathbb{R}^{n\times n}$ *(resp.,* α_2, $\beta_2 > 0$ *and* $\mathbf{Y}_t \in \mathbb{R}^{n\times n}$*),* $t = 0, 1, \dots$, *such that*

$$\alpha_1\mathbf{I} \le \mathbf{X}_t \le \beta_1\mathbf{I}; \quad \mathbf{A}_t^{\mathrm{T}}\mathbf{X}_{t+1}\mathbf{A}_t - \mathbf{X}_t \le -\alpha_1\mathbf{I}$$
$$\textit{(resp., } \alpha_2\mathbf{I} \le \mathbf{Y}_t \le \beta_2\mathbf{I}; \quad \mathbf{A}_t\mathbf{Y}_t\mathbf{A}_t^{\mathrm{T}} - \mathbf{Y}_{t+1} \le -\alpha_2\mathbf{I} \textit{)}$$

for all $t \ge 0$.

Proof. Set the matrices $\mathbf{B}_t$, $\mathbf{C}_t$, $\mathbf{D}_t$, $t \ge 0$, to zero in Lemma 2.3. ∎

Lemma 2.3 is a time-varying version of the classical Kalman–Yacubovitch–Popov (KYP) lemma (see, e.g., [35, 18]). Inequality (2.6b) is called the (extended) KYP inequality, and (2.7b) is its dual form. The solutions of these inequalities are obtained by solving the associated Riccati difference equations. Let $\mathbb{S}$ be the set of all symmetric matrices in $\mathbb{R}^{n\times n}$. For $i = 0, 1, \dots$, let $\mathbb{X}_i$ be the set of symmetric matrices $\mathbf{X} \in \mathbb{R}^{n\times n}$ such that

$$\mathcal{W}_i(\mathbf{X}) = \mathbf{I} - \mathbf{D}_i^{\mathrm{T}}\mathbf{D}_i - \mathbf{B}_i^{\mathrm{T}}\mathbf{X}\mathbf{B}_i$$

is invertible. Define $\mathcal{S}_i \colon \mathbb{X}_i \to \mathbb{S}$, $i = 0, 1, \dots$, by

$$\mathcal{S}_i(\mathbf{X}) = \mathbf{A}_i^{\mathrm{T}}\mathbf{X}\mathbf{A}_i + \mathbf{C}_i^{\mathrm{T}}\mathbf{C}_i + (\mathbf{A}_i^{\mathrm{T}}\mathbf{X}\mathbf{B}_i + \mathbf{C}_i^{\mathrm{T}}\mathbf{D}_i)\mathcal{W}_i(\mathbf{X})^{-1}(\mathbf{B}_i^{\mathrm{T}}\mathbf{X}\mathbf{A}_i + \mathbf{D}_i^{\mathrm{T}}\mathbf{C}_i)$$

for $\mathbf{X} \in \mathbb{X}_i$. Similarly, for $i = 0, 1, \dots$, let $\mathbb{Y}_i$ be the set of symmetric matrices $\mathbf{Y} \in \mathbb{R}^{n\times n}$ such that

$$\mathcal{V}_i(\mathbf{Y}) = \mathbf{I} - \mathbf{D}_i\mathbf{D}_i^{\mathrm{T}} - \mathbf{C}_i\mathbf{Y}\mathbf{C}_i^{\mathrm{T}}$$

is invertible, and define $\mathcal{R}_i \colon \mathbb{Y}_i \to \mathbb{S}$, $i = 0, 1, \dots$, by

$$\mathcal{R}_i(\mathbf{Y}) = \mathbf{A}_i\mathbf{Y}\mathbf{A}_i^{\mathrm{T}} + \mathbf{B}_i\mathbf{B}_i^{\mathrm{T}} + (\mathbf{A}_i\mathbf{Y}\mathbf{C}_i^{\mathrm{T}} + \mathbf{B}_i\mathbf{D}_i^{\mathrm{T}})\mathcal{V}_i(\mathbf{Y})^{-1}(\mathbf{C}_i\mathbf{Y}\mathbf{A}_i^{\mathrm{T}} + \mathbf{D}_i\mathbf{B}_i^{\mathrm{T}})$$

for $\mathbf{Y} \in \mathbb{Y}_i$.

LEMMA 2.5. *Let* $\boldsymbol{\mathcal{G}}$ *and* $\boldsymbol{\theta}$ *be as in* (2.1)*; let* $\boldsymbol{\mathcal{G}}$ *be bounded. The following are equivalent:*

(a) *The system* $(\boldsymbol{\mathcal{G}}, \boldsymbol{\theta})$ *is uniformly exponentially stable and uniformly strictly contractive.*

(b) *There exist* ε_1, δ_1, $\eta_1 > 0$ *such that for all* $T = 0, 1, \dots$, *and* $\varepsilon \in [0, \varepsilon_1]$, *the equation*

$$\mathbf{X}_t^{(\varepsilon,T)} = \mathcal{S}_t\big(\mathbf{X}_{t+1}^{(\varepsilon,T)}\big) + \varepsilon\mathbf{I}, \tag{2.9a}$$

with the terminal condition $\mathbf{X}_{T+1}^{(\varepsilon,T)} = \varepsilon\mathbf{I}$, *satisfies for* $t = 0, \dots, T$ *that*

$$\mathcal{W}_t\big(\mathbf{X}_{t+1}^{(\varepsilon,T)}\big) \ge \eta_1\mathbf{I}; \quad \varepsilon\mathbf{I} \le \mathbf{X}_t^{(\varepsilon,T)} \le \mathbf{X}_t^{(\varepsilon,T+1)} \le \delta_1\mathbf{I}. \tag{2.9b}$$

(c) *There exist* ε_2, δ_2, $\eta_2 > 0$ *such that for all* $t_0 = 0, 1, \dots,$ *and* $\varepsilon \in [0, \varepsilon_2]$, *the equation*

$$\mathbf{Y}_{t+1}^{(\varepsilon,t_0)} = \mathcal{R}_t\big(\mathbf{Y}_t^{(\varepsilon,t_0)}\big) + \varepsilon\mathbf{I}, \tag{2.10a}$$

with the initial condition $\mathbf{Y}_{t_0}^{(\varepsilon,t_0)} = \varepsilon\mathbf{I}$, *satisfies for* $t = t_0, t_0+1, \dots$ *that*

$$\mathcal{V}_t\big(\mathbf{Y}_t^{(\varepsilon,t_0)}\big) \geq \eta_2\mathbf{I}; \quad \varepsilon\mathbf{I} \leq \mathbf{Y}_{t+1}^{(\varepsilon,t_0+1)} \leq \mathbf{Y}_{t+1}^{(\varepsilon,t_0)} \leq \delta_2\mathbf{I}. \tag{2.10b}$$

Moreover, if (b) *holds, then one may take* $\mathbf{X}_t = \lim_{T\to\infty} \mathbf{X}_t^{(\varepsilon,T)}$ *in* (2.6)*; if* (c) *holds, then one may take* $\mathbf{Y}_t = \mathbf{Y}_t^{(\varepsilon,0)}$ *in* (2.7).

Equation (2.9a) is the (generalized) Riccati difference equation associated with the KYP inequality, and (2.10a) is its dual form. The latter evolves forward in time and so provides an explicit recursive expression for computing the solution to the KYP inequalities (2.6)–(2.7). Similar, but less explicit, results from operator theoretic points of view exist [22, 27]. The proof of Lemma 2.5 is based on the following standard lemma. For $\mathbf{Y} \in \mathbb{Y}_i$, let

$$\mathcal{A}_i(\mathbf{Y}) = \mathbf{A}_i + (\mathbf{A}_i\mathbf{Y}\mathbf{C}_i^{\mathrm{T}} + \mathbf{B}_i\mathbf{D}_i^{\mathrm{T}})\mathcal{V}_i(\mathbf{Y})^{-1}\mathbf{C}_i. \tag{2.11}$$

LEMMA 2.6. *Let* $\mathbf{Y}^{(1)}$, $\mathbf{Y}^{(2)} \in \mathbb{Y}_i$*; let* $\boldsymbol{\Delta}^{(12)} = \mathbf{Y}^{(1)} - \mathbf{Y}^{(2)}$. *Then*

$$\begin{aligned}\mathcal{R}_i\big(\mathbf{Y}^{(1)}\big) - \mathcal{R}_i\big(\mathbf{Y}^{(2)}\big) &= \mathcal{A}_i\big(\mathbf{Y}^{(2)}\big)\boldsymbol{\Delta}^{(12)}\mathcal{A}_i\big(\mathbf{Y}^{(2)}\big)^{\mathrm{T}} \\ &\quad + \mathcal{A}_i\big(\mathbf{Y}^{(2)}\big)\boldsymbol{\Delta}^{(12)}\mathbf{C}_i^{\mathrm{T}}\mathcal{V}_i\big(\mathbf{Y}^{(1)}\big)^{-1}\mathbf{C}_i\boldsymbol{\Delta}^{(12)}\mathcal{A}_i\big(\mathbf{Y}^{(2)}\big)^{\mathrm{T}} \qquad (2.12a)\\ &= \mathcal{A}_i\big(\mathbf{Y}^{(1)}\big)\boldsymbol{\Delta}^{(12)}\mathcal{A}_i\big(\mathbf{Y}^{(2)}\big)^{\mathrm{T}}. \qquad (2.12b)\end{aligned}$$

Proof. It follows from [22, Lem. 11, p. 77] that, for $\mathbf{Y} \in \mathbb{Y}_i$, we may write

$$\mathcal{R}_i(\mathbf{Y}) = \overline{\mathbf{A}}_i\mathbf{Y}\overline{\mathbf{A}}_i^{\mathrm{T}} + \overline{\mathbf{Q}}_i + \overline{\mathbf{A}}_i\mathbf{Y}\mathbf{C}_i^{\mathrm{T}}\mathcal{V}_i(\mathbf{Y})^{-1}\mathbf{C}_i\mathbf{Y}\overline{\mathbf{A}}_i^{\mathrm{T}} \tag{2.13}$$

with

$$\begin{aligned}\overline{\mathbf{A}}_i &= \mathbf{A}_i + \mathbf{B}_i\mathbf{D}_i^{\mathrm{T}}(\mathbf{I} - \mathbf{D}_i\mathbf{D}_i^{\mathrm{T}})^{-1}\mathbf{C}_i,\\ \overline{\mathbf{Q}}_i &= \mathbf{B}_i\mathbf{B}_i^{\mathrm{T}} + \mathbf{B}_i\mathbf{D}_i^{\mathrm{T}}(\mathbf{I} - \mathbf{D}_i\mathbf{D}_i^{\mathrm{T}})^{-1}\mathbf{D}_i\mathbf{B}_i^{\mathrm{T}}.\end{aligned}$$

Then [15, Lem. 3.1] leads to (2.12a). Since

$$\mathcal{V}_i\big(\mathbf{Y}^{(1)}\big)^{-1} - \mathcal{V}_i\big(\mathbf{Y}^{(2)}\big)^{-1} - \mathcal{V}_i\big(\mathbf{Y}^{(2)}\big)^{-1}\mathbf{C}_i\boldsymbol{\Delta}^{(12)}\mathbf{C}_i^{\mathrm{T}}\mathcal{V}_i\big(\mathbf{Y}^{(1)}\big)^{-1} = \mathbf{0},$$

it is easily seen that

$$\begin{aligned}\mathcal{A}_i\big(\mathbf{Y}^{(2)}\big) &= \mathcal{A}_i\big(\mathbf{Y}^{(1)}\big)\big(\mathbf{I} - \boldsymbol{\Delta}^{(12)}\mathbf{C}_i^{\mathrm{T}}\mathcal{V}_i\big(\mathbf{Y}^{(2)}\big)^{-1}\mathbf{C}_i\big),\\ \big(\mathbf{I} - \boldsymbol{\Delta}^{(12)}\mathbf{C}_i^{\mathrm{T}}\mathcal{V}_i\big(\mathbf{Y}^{(2)}\big)^{-1}\mathbf{C}_i\big)\big(\mathbf{I} + \boldsymbol{\Delta}^{(12)}\mathbf{C}_i^{\mathrm{T}}\mathcal{V}_i\big(\mathbf{Y}^{(1)}\big)^{-1}\mathbf{C}_i\big) &= \mathbf{I}.\end{aligned}$$

These equalities and (2.12a) yield (2.12b). ∎

Lemma 2.6 is useful in proving asymptotic properties of the Riccati difference equation. In particular, an immediate consequence of (2.12a) is that $\mathcal{R}_i\big(\mathbf{Y}^{(1)}\big) \geq \mathcal{R}_i\big(\mathbf{Y}^{(2)}\big)$ whenever $\mathbf{Y}^{(1)}$, $\mathbf{Y}^{(2)} \in \mathbb{Y}_i$, and $\mathbf{Y}^{(1)} \geq \mathbf{Y}^{(2)}$.

Proof of Lemma 2.5. To first show that (c) is equivalent to (a), suppose that (c) holds. Let $\varepsilon = \varepsilon_2$. Since $\boldsymbol{\mathcal{G}}$ is bounded, (2.10) implies that

$$\begin{aligned}\mathbf{A}_t\mathbf{Y}_t^{(\varepsilon,t_0)}\mathbf{A}_t^{\mathrm{T}} + \mathbf{B}_t\mathbf{B}_t^{\mathrm{T}} - \mathbf{Y}_{t+1}^{(\varepsilon,t_0)} + \alpha\mathbf{I} \\ + \big(\mathbf{A}_t\mathbf{Y}_t^{(\varepsilon,t_0)}\mathbf{C}_t^{\mathrm{T}} + \mathbf{B}_t\mathbf{D}_t^{\mathrm{T}}\big)\mathcal{V}_t\big(\mathbf{Y}_t^{(\varepsilon,t_0)} - \alpha\mathbf{I}\big)^{-1}\big(\mathbf{C}_t\mathbf{Y}_t^{(\varepsilon,t_0)}\mathbf{A}_t^{\mathrm{T}} + \mathbf{D}_t\mathbf{B}_t^{\mathrm{T}}\big) \le \mathbf{0}\end{aligned}$$

for some small $\alpha > 0$. Then the Schur complement formula yields

$$\begin{bmatrix}\mathbf{A}_t & \mathbf{B}_t\\ \mathbf{C}_t & \mathbf{D}_t\end{bmatrix}\begin{bmatrix}\mathbf{Y}_t^{(\varepsilon,t_0)} & \mathbf{0}\\ \mathbf{0} & \mathbf{I}\end{bmatrix}\begin{bmatrix}\mathbf{A}_t & \mathbf{B}_t\\ \mathbf{C}_t & \mathbf{D}_t\end{bmatrix}^{\mathrm{T}} - \begin{bmatrix}\mathbf{Y}_{t+1}^{(\varepsilon,t_0)} & \mathbf{0}\\ \mathbf{0} & \mathbf{I}\end{bmatrix} \le -\alpha\mathbf{I}.$$

Putting $\alpha_2 = \min\{\alpha,\varepsilon\}$, $\beta_2 = \delta_2$, and $\mathbf{Y}_t = \mathbf{Y}_t^{(\varepsilon,0)}$, we obtain condition (c) of Lemma 2.3, which in turn leads to the uniform stability and contractiveness of $(\boldsymbol{\mathcal{G}},\boldsymbol{\theta})$.

Conversely, suppose that $(\boldsymbol{\mathcal{G}},\boldsymbol{\theta})$ is uniformly stable and contractive so that condition (c) of Lemma 2.3 holds. Taking the Schur complement of $\mathbf{C}_t\mathbf{Y}_t\mathbf{C}_t^{\mathrm{T}} + \mathbf{D}_t\mathbf{D}_t^{\mathrm{T}} - \mathbf{I}$ from (2.7b), we obtain

$$\mathcal{V}_t(\mathbf{Y}_t) \ge \alpha_2\mathbf{I}; \quad \mathcal{R}_t(\mathbf{Y}_t) + \alpha_2\mathbf{I} \le \mathbf{Y}_{t+1}$$

for all t. Choose an arbitrary $\varepsilon \in [0,\alpha_2]$. For all $t_0 \ge 0$ and all $t \ge t_0$, define $\mathbf{Y}_{t_0}^{(\varepsilon,t_0)} = \varepsilon\mathbf{I}$ and $\mathbf{Y}_{t+1}^{(\varepsilon,t_0)} = \mathcal{R}_t\big(\mathbf{Y}_t^{(\varepsilon,t_0)}\big) + \varepsilon\mathbf{I}$. Since $\mathbf{Y}_t \ge \alpha_2\mathbf{I}$ for all t, we have $\mathbf{Y}_{t_0} \ge \mathbf{Y}_{t_0}^{(\varepsilon,t_0)}$; by induction, together with (2.12a), we obtain

$$\mathcal{V}_t\big(\mathbf{Y}_t^{(\varepsilon,t_0)}\big) \ge \alpha_2\mathbf{I}; \quad \varepsilon\mathbf{I} \le \mathbf{Y}_t^{(\varepsilon,t_0)} \le \mathbf{Y}_t \le \beta_2\mathbf{I}$$

for $t \ge t_0 \ge 0$. Moreover, $\mathbf{Y}_t^{(\varepsilon,t_0)} \ge \varepsilon\mathbf{I}$ for all t, and so we have $\mathbf{Y}_{t_0+1}^{(\varepsilon,t_0+1)} \le \mathbf{Y}_{t_0+1}^{(\varepsilon,t_0)}$ from (2.12a); by induction, we obtain that

$$\mathbf{Y}_{t+1}^{(\varepsilon,t_0+1)} \le \mathcal{R}_t\big(\mathbf{Y}_t^{(\varepsilon,t_0)}\big) + \varepsilon\mathbf{I} = \mathbf{Y}_{t+1}^{(\varepsilon,t_0)}$$

for $t \ge t_0 \ge 0$. Putting $\varepsilon_2 = \alpha_2$, $\delta_2 = \beta_2$, and $\eta_2 = \alpha_2$, we obtain condition (c). This concludes the proof of the equivalence of (a) and (c). The proof that (a) and (b) are equivalent is analogous, and so is omitted. ∎

THEOREM 2.7. *Let $\boldsymbol{\mathcal{G}}$ and $\boldsymbol{\theta}$ be as in* (2.1)*; let $\boldsymbol{\mathcal{G}}$ be bounded. Suppose that the system $(\boldsymbol{\mathcal{G}},\boldsymbol{\theta})$ is uniformly exponentially stable and uniformly strictly contractive so that condition* (c) *of Lemma* 2.5 *holds. For $\varepsilon \in (0,\varepsilon_2)$ and $t_0 \ge 0$, let $\mathbf{Y}_i^{(\varepsilon,t_0)}$ and $\mathcal{A}_i(\cdot)$, $i = t_0, t_0+1, \dots$, be as in* (2.10a) *and* (2.11)*, respectively, where $\mathbf{Y}_{t_0}^{(\varepsilon,t_0)} = \varepsilon\mathbf{I}$. Then the following hold:*

(a) *For each $\varepsilon \in (0,\varepsilon_2)$ and $t_0 \ge 0$, define*

$$\boldsymbol{\mathcal{A}}^{(\varepsilon,t_0)} = \big\{\mathcal{A}_i\big(\mathbf{Y}_i^{(\varepsilon,t_0)}\big)\colon i = t_0, t_0+1, \dots\big\}, \quad \boldsymbol{\theta}^{(t_0)} = (t_0, t_0+1, \dots).$$

Then each system $\big(\boldsymbol{\mathcal{A}}^{(\varepsilon,t_0)},\boldsymbol{\theta}^{(t_0)}\big)$ is uniformly exponentially stable. Moreover, for each $\varepsilon \in (0,\varepsilon_2)$, there exist $c_\varepsilon \ge 1$ and $\lambda_\varepsilon \in (0,1)$ such that

$$\big\|\mathcal{A}_{t-1}\big(\mathbf{Y}_{t-1}^{(\varepsilon,t_0)}\big)\cdots\mathcal{A}_{t_0}\big(\mathbf{Y}_{t_0}^{(\varepsilon,t_0)}\big)\big\| \le c_\varepsilon\,\lambda_\varepsilon^{t-t_0} \tag{2.14}$$

for $t > t_0 \ge 0$.

(b) *For each $\varepsilon \in (0, \varepsilon_2)$, there exist a nonnegative integer M and α_2, $\beta_2 > 0$ such that* (2.7) *is satisfied with*

$$\mathbf{Y}_t = \begin{cases} \mathbf{Y}_t^{(\varepsilon,0)} & \text{for } t < M; \\ \mathbf{Y}_t^{(\varepsilon,t-M)} & \text{for } t \geq M \end{cases} \tag{2.15}$$

for $t \geq 0$.

Proof. Fix ε, $\varepsilon' \in (0, \varepsilon_2)$ such that $\varepsilon < \varepsilon'$. For $t \geq t_0 \geq 0$, let $\mathbf{Y}_t^{(t_0)} = \mathbf{Y}_t^{(\varepsilon',t_0)} - \mathbf{Y}_t^{(\varepsilon,t_0)}$. Then (2.12a) yields that

$$\mathbf{Y}_{t+1}^{(t_0)} \geq \mathcal{A}_t\big(\mathbf{Y}_t^{(\varepsilon,t_0)}\big)\mathbf{Y}_t^{(t_0)}\mathcal{A}_t\big(\mathbf{Y}_t^{(\varepsilon,t_0)}\big)^{\mathrm{T}} + (\varepsilon' - \varepsilon)\mathbf{I}$$

for all $t \geq t_0$. Since $\varepsilon' - \varepsilon > 0$ and $(\varepsilon' - \varepsilon)\mathbf{I} \leq \mathbf{Y}_t^{(t_0)} \leq (\delta_2 - \epsilon)\mathbf{I}$ for $t \geq t_0 \geq 0$, we have that, with $\mathbf{X}_t^{(t_0)} = \big(\mathbf{Y}_t^{(t_0)}\big)^{-1}$, there exist α_1, $\beta_1 > 0$ such that

$$\alpha_1\mathbf{I} \leq \mathbf{X}_t^{(t_0)} \leq \beta_1\mathbf{I}; \quad \mathcal{A}_t\big(\mathbf{Y}_t^{(\varepsilon,t_0)}\big)^{\mathrm{T}}\mathbf{X}_{t+1}^{(t_0)}\mathcal{A}_t\big(\mathbf{Y}_t^{(\varepsilon,t_0)}\big) - \mathbf{X}_t^{(t_0)} \leq -\alpha_1\mathbf{I}$$

for all t. The uniform stability of the systems $\big(\boldsymbol{\mathcal{A}}^{(\varepsilon,t_0)}, \boldsymbol{\theta}^{(t_0)}\big)$ follows from Proposition 2.4. Due to [30, Lem. 4], inequality (2.14) holds for $t > t_0 \geq 0$ with $c_\varepsilon = \sqrt{\beta_1/\alpha_1}$ and $\lambda_\varepsilon = \sqrt{1 - \alpha_1/\beta_1}$. Thus assertion (a) holds true.

To prove (b), pick a nonnegative integer M such that $c_\varepsilon^2\lambda_\varepsilon^{2M} < \varepsilon/(\delta_2 - \varepsilon)$. Then, using (2.12b), we deduce that there exists an $\varepsilon'' \in (0, \varepsilon)$ such that

$$\begin{aligned} &\mathcal{R}_t\big(\mathbf{Y}_t^{(\varepsilon,t-M)}\big) - \mathcal{R}_t\big(\mathbf{Y}_t^{(\varepsilon,t-M+1)}\big) \\ &\qquad = \mathcal{A}_t\big(\mathbf{Y}_t^{(\varepsilon,t-M)}\big)\cdots\mathcal{A}_{t-M+1}\big(\mathbf{Y}_{t-M+1}^{(\varepsilon,t-M)}\big)\big(\mathcal{R}_{t-M+1}(\varepsilon\mathbf{I}) - \varepsilon\mathbf{I}\big) \\ &\qquad\quad \times \mathcal{A}_{t-M+1}\big(\mathbf{Y}_{t-M+1}^{(\varepsilon,t-M+1)}\big)^{\mathrm{T}}\cdots\mathcal{A}_t\big(\mathbf{Y}_t^{(\varepsilon,t-M+1)}\big)^{\mathrm{T}} \\ &\qquad \leq (\delta_2 - \varepsilon)c_\varepsilon^2\lambda_\varepsilon^{2M}\mathbf{I} \\ &\qquad \leq \varepsilon''\mathbf{I} \end{aligned}$$

for $t \geq M$; or equivalently,

$$\mathcal{R}_t\big(\mathbf{Y}_t^{(\varepsilon,t-M)}\big) - \mathbf{Y}_{t+1}^{(\varepsilon,t-M+1)} \leq -(\varepsilon - \varepsilon'')\mathbf{I}$$

for $t \geq M$. On the other hand,

$$\mathcal{R}_t\big(\mathbf{Y}_t^{(\varepsilon,0)}\big) - \mathbf{Y}_{t+1}^{(\varepsilon,0)} = -\varepsilon\mathbf{I} \leq -(\varepsilon - \varepsilon'')\mathbf{I}.$$

Therefore, $\mathbf{Y}_t$ defined by (2.15) satisfies

$$\mathcal{R}_t(\mathbf{Y}_t) - \mathbf{Y}_{t+1} \leq -(\varepsilon - \varepsilon'')\mathbf{I}$$

for all $t \geq 0$. Using the Schur complement formula, we have that there exists an $\alpha > 0$ such that

$$\begin{bmatrix} \mathbf{A}_t & \mathbf{B}_t \\ \mathbf{C}_t & \mathbf{D}_t \end{bmatrix}\begin{bmatrix} \mathbf{Y}_t & \mathbf{0} \\ \mathbf{0} & \mathbf{I} \end{bmatrix}\begin{bmatrix} \mathbf{A}_t & \mathbf{B}_t \\ \mathbf{C}_t & \mathbf{D}_t \end{bmatrix}^{\mathrm{T}} - \begin{bmatrix} \mathbf{Y}_{t+1} & \mathbf{0} \\ \mathbf{0} & \mathbf{I} \end{bmatrix} \leq -\alpha\mathbf{I}$$

holds for $t \geq 0$. Putting $\alpha_2 = \min\{\alpha, \epsilon\}$ and $\beta_2 = \delta_2$, we see that $\mathbf{Y}_t$ satisfies (2.7) for all $t \geq 0$, and hence assertion (b) holds. ∎

Remark 2. Using (2.13), we may write

$$\mathbf{Y}_{t+1}^{(\varepsilon,t_0)} = \overline{\mathbf{A}}_t \mathbf{Y}_t^{(\varepsilon,t_0)} \overline{\mathbf{A}}_t^{\mathrm{T}} + (\overline{\mathbf{Q}}_t + \varepsilon \mathbf{I}) + \overline{\mathbf{A}}_t \mathbf{Y}_t^{(\varepsilon,t_0)} \mathbf{C}_t^{\mathrm{T}} \mathcal{V}_t\big(\mathbf{Y}_t^{(\varepsilon,t_0)}\big)^{-1} \mathbf{C}_t \mathbf{Y}_t^{(\varepsilon,t_0)} \overline{\mathbf{A}}_t^{\mathrm{T}}$$

for $\varepsilon \in (0, \varepsilon_2)$ and $t \geq t_0 \geq 0$. Let

$$\boldsymbol{\mathcal{G}}' = \{(\overline{\mathbf{A}}_0, \overline{\mathbf{Q}}_0 + \varepsilon \mathbf{I}, \mathbf{C}_0, \mathbf{0}), (\overline{\mathbf{A}}_1, \overline{\mathbf{Q}}_1 + \varepsilon \mathbf{I}, \mathbf{C}_1, \mathbf{0}), \dots\}.$$

If $(\boldsymbol{\mathcal{G}}, \boldsymbol{\theta})$ is uniformly stable, it is easy to verify that $(\boldsymbol{\mathcal{G}}', \boldsymbol{\theta})$ is uniformly detectable and uniformly stabilizable. Then, by [1, 14], the system $\big(\boldsymbol{\mathcal{A}}^{(\varepsilon,t_0)}, \boldsymbol{\theta}^{(t_0)}\big)$ is uniformly stable for each $t_0 \geq 0$; it follows from (2.12b) that, for each $t_0 \geq 0$, $\mathbf{Y}_t^{(\varepsilon,t_0)}$ converges to the unique "moving equilibrium" (i.e., the maximal solution) of the Riccati difference equation (2.10a) as $t - t_0 \to \infty$ [14]. However, part (a) of Theorem 2.7 says that this convergence is uniform in (t, t_0), as the uniform stability of $\big(\boldsymbol{\mathcal{A}}^{(\varepsilon,t_0)}, \boldsymbol{\theta}^{(t_0)}\big)$ is again uniform in t_0.

It is known that, if a given linear time-varying system is uniformly stable, the corresponding Lyapunov inequality admits a solution that has a finite memory of past parameters (see, e.g., [30]). Part (b) of Theorem 2.7 is an extension of this and says that the KYP inequality (or equivalently, the Riccati inequality) associated with a uniformly stable and contractive linear time-varying system has a solution that has a finite memory of past parameters.

3. Control of switched linear systems. The switched linear system is a family of linear time-varying systems whose parameters vary within a single finite set. Fix a positive integer N and define

$$\boldsymbol{\mathcal{G}} = \{(\mathbf{A}_1, \mathbf{B}_1, \mathbf{C}_1, \mathbf{D}_1), \dots, (\mathbf{A}_N, \mathbf{B}_N, \mathbf{C}_N, \mathbf{D}_N)\}, \tag{3.1}$$

where $\mathbf{A}_i \in \mathbb{R}^{n \times n}$, $\mathbf{B}_i \in \mathbb{R}^{n \times m}$, $\mathbf{C}_i \in \mathbb{R}^{l \times n}$, $\mathbf{D}_i \in \mathbb{R}^{l \times m}$ for $i = 1, \dots, N$. Let $\boldsymbol{\Omega}$ be the set of all infinite sequences in $\{1, \dots, N\}$; each member of $\boldsymbol{\Omega}$ is called a *switching sequence*. If $\boldsymbol{\Theta}$ is a nonempty subset of $\boldsymbol{\Omega}$, then the pair $(\boldsymbol{\mathcal{G}}, \boldsymbol{\Theta})$ defines the *switched linear system*, where $\boldsymbol{\Theta}$ is the set of *admissible* switching sequences: for initial states $x(0)$, disturbance sequences $\boldsymbol{w}$, switching sequences $\boldsymbol{\theta} \in \boldsymbol{\Theta}$, and $t \geq 0$, the system $(\boldsymbol{\mathcal{G}}, \boldsymbol{\Theta})$ has the state-space representation

$$\begin{aligned} x(t+1) &= \mathbf{A}_{\theta(t)} x(t) + \mathbf{B}_{\theta(t)} w(t), \\ z(t) &= \mathbf{C}_{\theta(t)} x(t) + \mathbf{D}_{\theta(t)} w(t). \end{aligned} \tag{3.2}$$

If $\theta(t) = i$, then the system is said to be in *mode* i at time t, and its parameters at time t are given by the quadruple $(\mathbf{A}_i, \mathbf{B}_i, \mathbf{C}_i, \mathbf{D}_i)$. When the set $\boldsymbol{\Theta}$ is equal to the entire set $\boldsymbol{\Omega}$, the pair $(\boldsymbol{\mathcal{G}}, \boldsymbol{\Omega})$ defines the *discrete linear inclusion*, which is the switched linear system without a switching path constraint; on the other hand, if $\boldsymbol{\Theta} = \{\boldsymbol{\theta}\}$ is a singleton, then the pair $(\boldsymbol{\mathcal{G}}, \boldsymbol{\Theta})$ is nothing but the linear time-varying system $(\boldsymbol{\mathcal{G}}, \boldsymbol{\theta})$. We require that the stability and contractiveness of the system $(\boldsymbol{\mathcal{G}}, \boldsymbol{\Theta})$ be uniform over all switching sequences in $\boldsymbol{\Theta}$.

DEFINITION 3.1. *The system* $(\boldsymbol{\mathcal{G}}, \boldsymbol{\Theta})$ *is said to be* uniformly (exponentially) stable *if there exist* $c \geq 1$ *and* $\lambda \in (0, 1)$ *such that, whenever* $\boldsymbol{w} = 0$, *inequality* (2.4) *holds for* $t \geq t_0 \geq 0$, *for* $x(t_0) \in \mathbb{R}^n$, *and for* $\theta \in \boldsymbol{\Theta}$.

DEFINITION 3.2. *The system* $(\boldsymbol{\mathcal{G}}, \boldsymbol{\Theta})$ *is said to be* uniformly (strictly) contractive *if there exists a* $\gamma \in (0, 1)$ *such that, whenever* $x(t_0) = 0$, *inequality* (2.5) *holds for* $t \geq t_0 \geq 0$, *for* $\boldsymbol{w} \in \ell^2(\mathbb{R}^m)$, *and for* $\theta \in \boldsymbol{\Theta}$.

For the sake of convenience, we introduce a dummy mode 0 and think of each $\boldsymbol{\theta} \in \boldsymbol{\Theta}$ as a two-sided sequence $(\dots, \theta(-1), \theta(0), \theta(1), \dots)$ by putting $\theta(t) = 0$ for $t < 0$. Fix a nonnegative integer L. Any finite sequence in $\{0, \dots, N\}$ will be called a *(finite) switching path*; in particular, elements of the set $\{0, \dots, N\}^{L+1}$ are switching paths of length L and are called *L-paths*. For $\boldsymbol{\theta} \in \boldsymbol{\Theta}$ and $t \geq 0$, let

$$\theta_L(t) = (\theta(t-L), \dots, \theta(t)).$$

An L-path $(i_0, \dots, i_L)$ is said to *occur in* $\boldsymbol{\Theta}$ if $\theta_L(t) = (i_0, \dots, i_L)$ for some $\boldsymbol{\theta} \in \boldsymbol{\Theta}$ and some $t \geq 0$. Each $\boldsymbol{\theta} \in \boldsymbol{\Theta}$ generates an *L-path switching sequence* $\boldsymbol{\theta}_L$ defined by

$$\boldsymbol{\theta}_L = (\theta_L(0), \theta_L(1), \dots).$$

Denote the set of L-paths occurring in $\boldsymbol{\Theta}$ by $\boldsymbol{\mathcal{L}}_L(\boldsymbol{\Theta})$ so that

$$\boldsymbol{\mathcal{L}}_L(\boldsymbol{\Theta}) = \{\theta_L(t) \colon \boldsymbol{\theta} \in \boldsymbol{\Theta},\ t \geq 0\}.$$

If $(i_0, \dots, i_L) \in \boldsymbol{\mathcal{L}}_L(\boldsymbol{\Theta})$, then write

$$(i_0, \dots, i_L)_- = (i_0, \dots, i_{L-1}), \quad (i_0, \dots, i_L)_+ = (i_1, \dots, i_L)$$

for $L > 0$, and write $(i_0, \dots, i_L)_- = (i_0, \dots, i_L)_+ = 0$ for $L = 0$. *If $L > 0$, define $\boldsymbol{\mathcal{M}}_L(\boldsymbol{\Theta})$ to be the smallest subset of $\boldsymbol{\mathcal{L}}_L(\boldsymbol{\Theta})$ such that the following hold: $\theta_L(t) \in \boldsymbol{\mathcal{M}}_L(\boldsymbol{\Theta})$ for all $t \geq L$ and for all $\boldsymbol{\theta} \in \boldsymbol{\Theta}$, and, for each $j \in \boldsymbol{\mathcal{L}}_0(\boldsymbol{\Theta})$, there exists a switching path $\big(i_0^j, \dots, i_{L-1}^j\big) \in \{0, \dots, N\}^L$ such that*

$$\begin{aligned}(3.3)\quad &\big(i_0^{\theta(0)}, \dots, i_{L-1}^{\theta(0)}, \theta(0)\big),\ \big(i_1^{\theta(0)}, \dots, i_{L-1}^{\theta(0)}, \theta(0), \theta(1)\big),\\ &\qquad\qquad \dots,\ \big(i_{L-1}^{\theta(0)}, \theta(0), \dots, \theta(L-1)\big) \in \boldsymbol{\mathcal{M}}_L(\boldsymbol{\Theta})\end{aligned}$$

for all $\boldsymbol{\theta} \in \boldsymbol{\Theta}$. If $L = 0$, then let $\boldsymbol{\mathcal{M}}_0(\boldsymbol{\Theta}) = \boldsymbol{\mathcal{L}}_0(\boldsymbol{\Theta})$. The sets $\boldsymbol{\mathcal{M}}_L(\boldsymbol{\Theta})$, $L = 0, 1, \dots$, are unique and so are well defined. Let

$$\boldsymbol{\mathcal{M}}_L^-(\boldsymbol{\Theta}) = \{\boldsymbol{i}_- \colon \boldsymbol{i} \in \boldsymbol{\mathcal{M}}_L(\boldsymbol{\Theta})\}, \quad \boldsymbol{\mathcal{L}}_L^-(\boldsymbol{\Theta}) = \{\boldsymbol{i}_- \colon \boldsymbol{i} \in \boldsymbol{\mathcal{L}}_L(\boldsymbol{\Theta})\}.$$

In general, we have

$$\begin{gathered}\boldsymbol{\mathcal{L}}_L(\boldsymbol{\Theta}) \cap \{1, \dots, N\}^{L+1} \subset \boldsymbol{\mathcal{M}}_L(\boldsymbol{\Theta}) \subset \boldsymbol{\mathcal{L}}_L(\boldsymbol{\Theta}) \subsetneq \{0, \dots, N\}^{L+1},\\ \boldsymbol{\mathcal{M}}_L(\boldsymbol{\Theta}) \subset \boldsymbol{\mathcal{M}}_{L+1}^-(\boldsymbol{\Theta}) \subset \boldsymbol{\mathcal{L}}_{L+1}^-(\boldsymbol{\Theta}).\end{gathered}$$

Example 1. Let $\boldsymbol{\Theta}$ consist of three periodic sequences $(1, 1, \dots)$, $(1, 2, 1, 2, \dots)$, and $(2, 2, \dots)$. To simplify notation, write $i_0 \cdots i_L$ for $(i_0, \dots, i_L)$. Then we have

$$\begin{gathered}\boldsymbol{\mathcal{L}}_0(\boldsymbol{\Theta}) = \boldsymbol{\mathcal{M}}_0(\boldsymbol{\Theta}) = \{1, 2\}, \quad \boldsymbol{\mathcal{L}}_1(\boldsymbol{\Theta}) = \{01, 02, 11, 12, 21, 22\},\\ \boldsymbol{\mathcal{L}}_2(\boldsymbol{\Theta}) = \{001, 002, 011, 012, 022, 111, 121, 212, 222\},\end{gathered}$$

and so on. For $L = 1$, we can replace the one-path $(0, 1)$ in $\boldsymbol{\mathcal{L}}_1(\boldsymbol{\Theta})$ with $(1, 1)$ or $(2, 1)$; similarly, the one-path $(0, 2)$ can be replaced with either $(1, 2)$ or $(2, 2)$. Hence, we have

$$\boldsymbol{\mathcal{M}}_1(\boldsymbol{\Theta}) = \{11, 12, 21, 22\}.$$

However, for $L = 2$, if we choose any $(i_0, i_1) \neq (0, 0)$, then we have that at least one of the two-paths $(i_0, i_1, 1)$, $(i_1, 1, 1)$, $(i_1, 1, 2)$ does not belong to $\boldsymbol{\mathcal{L}}_2(\boldsymbol{\Theta})$ and so $(0, 0, 1)$

cannot be replaced with any of $(0,1,1)$, $(1,1,1)$, $(1,2,1) \in \boldsymbol{\mathcal{L}}_2(\boldsymbol{\Theta})$; on the other hand, both the two-paths $(0,0,2)$ and $(0,2,2)$ can be replaced with $(2,2,2) \in \boldsymbol{\mathcal{L}}_2(\boldsymbol{\Theta})$. Hence,

$$\boldsymbol{\mathcal{M}}_2(\boldsymbol{\Theta}) = \{001, 011, 012, 111, 121, 212, 222\}.$$

This $\boldsymbol{\Theta}$ will be used later in Examples 4 and 7.

Example 2. For each positive integer k, let $\boldsymbol{\Theta}^{(k)}$ consist of a single sequence

$$\boldsymbol{\theta}^{(k)} = (\underbrace{1,\dots,1}_{k},\underbrace{2,\dots,2}_{k},\underbrace{1,\dots,1}_{k},\underbrace{2,\dots,2}_{k},\dots),$$

where k 1's and k 2's alternate in $\boldsymbol{\theta}^{(k)}$. Then

$$\boldsymbol{\mathcal{L}}_0\big(\boldsymbol{\Theta}^{(k)}\big) = \boldsymbol{\mathcal{M}}_0\big(\boldsymbol{\Theta}^{(k)}\big) = \{1,2\} \quad \text{for all } k;$$

$$\boldsymbol{\mathcal{L}}_1\big(\boldsymbol{\Theta}^{(k)}\big) = \begin{cases} \{01,12,21\}, & k=1; \\ \{01,11,12,21,22\}, & k \ge 2; \end{cases} \quad \boldsymbol{\mathcal{M}}_1\big(\boldsymbol{\Theta}^{(k)}\big) = \begin{cases} \{12,21\}, & k=1; \\ \{11,12,21,22\}, & k \ge 2; \end{cases}$$

$$\boldsymbol{\mathcal{L}}_2\big(\boldsymbol{\Theta}^{(k)}\big) = \begin{cases} \{001,012,121,212\}, & k=1; \\ \{001,011,112,122,211,221\}, & k=2; \\ \{001,011,111,112,122,211,221,222\}, & k \ge 3; \end{cases}$$

$$\boldsymbol{\mathcal{M}}_2\big(\boldsymbol{\Theta}^{(k)}\big) = \begin{cases} \{121,212\}, & k=1; \\ \{112,122,211,221\}, & k=2; \\ \{111,112,122,211,221,222\} & k \ge 3, \end{cases}$$

and so on. These sets will be used in Example 3. The two-path switching sequence generated by $\boldsymbol{\theta}^{(2)}$, for instance, is

$$\boldsymbol{\theta}_2^{(2)} = (001, 011, 112, 122, 221, 211, 112, 122, 221, 211, \dots).$$

THEOREM 3.3. *Let $\boldsymbol{\mathcal{G}}$ be as in* (3.1)*; let $\boldsymbol{\Theta} \subset \boldsymbol{\Omega}$ be nonempty. The system $(\boldsymbol{\mathcal{G}}, \boldsymbol{\Theta})$ is uniformly exponentially stable and uniformly strictly contractive if and only if there exist a nonnegative integer M and an indexed family $\{\mathbf{X}_{\boldsymbol{j}} : \boldsymbol{j} \in \boldsymbol{\mathcal{M}}_M^-(\boldsymbol{\Theta})\}$ of symmetric positive definite matrices $\mathbf{X}_{\boldsymbol{j}} \in \mathbb{R}^{n\times n}$ such that*

$$\begin{bmatrix} \mathbf{A}_{i_M} & \mathbf{B}_{i_M} \\ \mathbf{C}_{i_M} & \mathbf{D}_{i_M} \end{bmatrix}^{\mathrm{T}} \begin{bmatrix} \mathbf{X}_{\boldsymbol{i}_+} & \mathbf{0} \\ \mathbf{0} & \mathbf{I} \end{bmatrix} \begin{bmatrix} \mathbf{A}_{i_M} & \mathbf{B}_{i_M} \\ \mathbf{C}_{i_M} & \mathbf{D}_{i_M} \end{bmatrix} - \begin{bmatrix} \mathbf{X}_{\boldsymbol{i}_-} & \mathbf{0} \\ \mathbf{0} & \mathbf{I} \end{bmatrix} < \mathbf{0} \tag{3.4}$$

for all M-paths $\boldsymbol{i} = (i_0, \dots, i_M) \in \boldsymbol{\mathcal{M}}_M(\boldsymbol{\Theta})$.

Proof. To show sufficiency, fix an M and suppose (3.4) holds for $\boldsymbol{i} = (i_0, \dots, i_M) \in \boldsymbol{\mathcal{M}}_M(\boldsymbol{\Theta})$. Assume $M > 0$ without loss of generality. By the definition of $\boldsymbol{\mathcal{M}}_M(\boldsymbol{\Theta})$, one can choose $\big(i_0^j, \dots, i_{M-1}^j\big) \in \{0,\dots,N\}^M$, $j \in \{\theta(0) : \boldsymbol{\theta} \in \boldsymbol{\Theta}\}$, such that (3.3), with L replaced by M, holds for all $\boldsymbol{\theta} \in \boldsymbol{\Theta}$. Put

$$\mathbf{X}_t = \begin{cases} \mathbf{X}_{\left(i_0^{\theta(0)},\dots,i_{M-1}^{\theta(0)}\right)} & \text{for } t = 0; \\ \mathbf{X}_{\left(i_t^{\theta(0)},\dots,i_{M-1}^{\theta(0)},\theta(0),\dots,\theta(t-1)\right)} & \text{for } 0 < t < M; \\ \mathbf{X}_{(\theta(t-M),\dots,\theta(t-1))} & \text{for } t \ge M. \end{cases}$$

Then, since $\boldsymbol{\mathcal{M}}_M(\boldsymbol{\Theta})$ is finite, one can choose α, $\beta > 0$ independently of $\boldsymbol{\theta} \in \boldsymbol{\Theta}$ such that, in particular,

$$\alpha\mathbf{I} \le \mathbf{X}_t \le \beta\mathbf{I}; \quad \mathbf{A}_{\theta(t)}^{\mathrm{T}} \mathbf{X}_{t+1} \mathbf{A}_{\theta(t)} - \mathbf{X}_t < -\alpha\mathbf{I}$$

for $t \geq 0$; hence it follows from Proposition 2.4 and the first half of the proof of Theorem 2.7 that the system $(\boldsymbol{\mathcal{G}}, \boldsymbol{\Theta})$ is uniformly stable. On the other hand, the finiteness of $\boldsymbol{\mathcal{M}}_M(\boldsymbol{\Theta})$ implies that there exists an $\eta \in (0,1)$, which is independent of $\boldsymbol{\theta}$, such that

$$\begin{bmatrix} x(t) \\ w(t) \end{bmatrix}^{\mathrm{T}} \left(\begin{bmatrix} \mathbf{A}_{\theta(t)} & \mathbf{B}_{\theta(t)} \\ \mathbf{C}_{\theta(t)} & \mathbf{D}_{\theta(t)} \end{bmatrix}^{\mathrm{T}} \begin{bmatrix} \mathbf{X}_{t+1} & \mathbf{0} \\ \mathbf{0} & \mathbf{I} \end{bmatrix} \begin{bmatrix} \mathbf{A}_{\theta(t)} & \mathbf{B}_{\theta(t)} \\ \mathbf{C}_{\theta(t)} & \mathbf{D}_{\theta(t)} \end{bmatrix} - \begin{bmatrix} \mathbf{X}_t & \mathbf{0} \\ \mathbf{0} & \mathbf{I} \end{bmatrix} + \eta \begin{bmatrix} \mathbf{0} & \mathbf{0} \\ \mathbf{0} & \mathbf{I} \end{bmatrix} \right) \begin{bmatrix} x(t) \\ w(t) \end{bmatrix} \leq 0$$

for all $x(t) \in \mathbb{R}^n$ and $w(t) \in \mathbb{R}^m$ so that

$$\|z(t)\|^2 + \|x(t+1)\|^2_{\mathbf{X}_{t+1}} - \|x(t)\|^2_{\mathbf{X}_t} \leq (1-\eta)\|w(t)\|^2$$

for $t \geq 0$. If $t \geq t_0 \geq 0$ and $x(t_0) = 0$, then this inequality, as well as the fact that $\mathbf{X}_{\boldsymbol{i}} > \mathbf{0}$ for all $\boldsymbol{i} \in \boldsymbol{\mathcal{M}}^-_M(\boldsymbol{\Theta})$, leads to

$$\sum\nolimits_{s=t_0}^{t} \|z(s)\|^2 \leq (1-\eta) \sum\nolimits_{s=t_0}^{t} \|w(s)\|^2.$$

Putting $\gamma = \sqrt{1-\eta}$ yields (2.5) for $t \geq t_0 \geq 0$. Since γ is independent of $\boldsymbol{\theta}$, this inequality holds for all $\boldsymbol{\theta} \in \boldsymbol{\Theta}$, too. Hence the system $(\boldsymbol{\mathcal{G}}, \boldsymbol{\Theta})$ is uniformly contractive as well as uniformly stable. This proves sufficiency.

To show necessity, suppose that $(\boldsymbol{\mathcal{G}}, \boldsymbol{\Theta})$ is uniformly stable and contractive. Consider the augmented disturbance signal $\tilde{w}(t) = [w(t)^{\mathrm{T}}\ v(t)^{\mathrm{T}}]^{\mathrm{T}}$ with $v(t) \in \mathbb{R}^n$, $t \geq 0$, and the perturbed system $\big(\boldsymbol{\mathcal{G}}^{(\varepsilon)}, \boldsymbol{\Theta}\big)$, where

$$\boldsymbol{\mathcal{G}}^{(\varepsilon)} = \big\{\big(\mathbf{A}_1, \mathbf{B}_1^{(\varepsilon)}, \mathbf{C}_1, \mathbf{D}_1^{(\varepsilon)}\big), \ldots, \big(\mathbf{A}_N, \mathbf{B}_N^{(\varepsilon)}, \mathbf{C}_N, \mathbf{D}_N^{(\varepsilon)}\big)\big\},$$
$$\mathbf{B}_i^{(\varepsilon)} = [\mathbf{B}_i\ \sqrt{\varepsilon}\mathbf{I}] \in \mathbb{R}^{n \times (m+n)}, \quad \mathbf{D}_i^{(\varepsilon)} = [\mathbf{D}_i\ \mathbf{0}] \in \mathbb{R}^{l \times (m+n)}.$$

Then there exists a sufficiently small $\varepsilon_2 > 0$, dependent on γ in (2.5) but independent of $\boldsymbol{\Theta}$, such that $(\boldsymbol{\mathcal{G}}^{(\varepsilon)}, \boldsymbol{\Theta})$ is uniformly stable and contractive for all $\varepsilon \in (0, \varepsilon_2)$. If we fix an $\varepsilon \in (0, \varepsilon_2)$, then by Lemma 2.5, there exist δ_2, $\eta_2 > 0$ such that the (dual) Riccati equation $\mathbf{Y}_{t+1}^{(\varepsilon,t_0)} = \mathcal{R}_{\theta(t)}\big(\mathbf{Y}_t^{(\varepsilon,t_0)}\big) + \varepsilon\mathbf{I}$, with the initial condition $\mathbf{Y}_{t_0}^{(\varepsilon,t_0)} = \varepsilon\mathbf{I}$, satisfies

$$\mathcal{V}_{\theta(t)}\big(\mathbf{Y}_t^{(\varepsilon,t_0)}\big) \geq \eta_2\mathbf{I}; \quad \varepsilon\mathbf{I} \leq \mathbf{Y}_{t+1}^{(\varepsilon,t_0)} \leq \delta_2\mathbf{I}$$

for $t \geq t_0 \geq 0$ and for $\boldsymbol{\theta} \in \boldsymbol{\Theta}$. Part (b) of Theorem 2.7 and its proof then imply that there exists a nonnegative integer M, which depends only on ε, δ_2, η_2, and $\boldsymbol{\mathcal{G}}$, such that for some α_2, $\beta_2 > 0$, $\mathbf{Y}_t$ given by (2.15), with $\mathbf{A}_t = \mathbf{A}_{\theta(t)}$, $\mathbf{B}_t = \mathbf{B}_{\theta(t)}$, $\mathbf{C}_t = \mathbf{C}_{\theta(t)}$, and $\mathbf{D}_t = \mathbf{D}_{\theta(t)}$, satisfies (2.7) for $\boldsymbol{\theta} \in \boldsymbol{\Theta}$ and $t \geq 0$. Then Lemmas 2.3 and 2.5 imply that the symmetric positive definite matrices $\mathbf{X}_t$, $t \geq 0$, satisfying (2.6) can be taken to be of the form

$$\mathbf{X}_t = f(\theta(t-M), \ldots, \theta(t-1))$$

for some function $f\colon \{0, \ldots, N\}^M \to \mathbb{S}$, where $\theta(s) = 0$ for $s < 0$. Putting

$$\mathbf{X}_{(\theta(t-M),\ldots,\theta(t-1))} = f(\theta(t-M), \ldots, \theta(t-1))$$

leads to (3.4) for $\boldsymbol{i} = (i_0, \dots, i_M) \in \boldsymbol{\mathcal{L}}_M(\boldsymbol{\Theta})$. Since $\boldsymbol{\mathcal{M}}_M(\boldsymbol{\Theta}) \subset \boldsymbol{\mathcal{L}}_M(\boldsymbol{\Theta})$, and since the path length M is independent of $\boldsymbol{\theta}$, we obtain the desired result. ∎

Remark 3. In Theorem 3.3 the number of linear matrix inequalities (3.4) to solve simultaneously, given M, is equal to the cardinality of $\boldsymbol{\mathcal{M}}_M(\boldsymbol{\Theta})$ and bounded above by $\sum_{k=1}^{M+1} N^k$; the number of matrix variables to solve for is equal to the cardinality of $\boldsymbol{\mathcal{M}}_M^-(\boldsymbol{\Theta})$. In particular, if either $\boldsymbol{\Theta} = \boldsymbol{\Omega}$ or $\boldsymbol{\theta} \in \boldsymbol{\Theta}$ for some $\boldsymbol{\theta}$ which is recurrent with respect to $\{1, \dots, N\}$, so that every finite switching path in $\{1, \dots, N\}$ occurs infinitely many times in $\boldsymbol{\theta}$, then the cardinality of $\boldsymbol{\mathcal{M}}_M(\boldsymbol{\Theta})$ is precisely N^{M+1}.

Remark 4. If $N = 1$, then we have $\boldsymbol{\Theta} = \{(1, 1, \dots)\}$, and the set $\boldsymbol{\mathcal{M}}_M(\boldsymbol{\Theta})$ is a singleton for each M, and so Theorem 3.3 reduces to the classical KYP lemma.

If inequalities (3.4), with $\mathbf{X}_{\boldsymbol{j}} > \mathbf{0}$ for $\boldsymbol{j} \in \boldsymbol{\mathcal{M}}_M^-(\boldsymbol{\theta})$, are feasible for some M, then it is also feasible when M is replaced with any integer greater than M. Hence Theorem 3.3 characterizes the performance of switched linear systems via the countably infinite union of an increasing family of systems of linear matrix inequalities. For uniform stability and contractiveness, not only is each member of this family sufficient, but also the union of the family is necessary.

The condition in Theorem 3.3 simplifies if we focus on the uniform stability only. For nonnegative integers L and $\boldsymbol{\Theta} \subset \boldsymbol{\Omega}$, let $\boldsymbol{\mathcal{N}}_L(\boldsymbol{\Theta})$ be the largest subset of $\boldsymbol{\mathcal{M}}_L(\boldsymbol{\Theta})$ satisfying the following: For each $(i_0, \dots, i_L) \in \boldsymbol{\mathcal{N}}_L(\boldsymbol{\Theta})$, there exist an integer $M > L$ and a switching path $(i_0, \dots, i_M)$ such that $(i_{M-L}, \dots, i_M) = (i_0, \dots, i_L)$ and $(i_t, \dots, i_{t+L}) \in \boldsymbol{\mathcal{N}}_L(\boldsymbol{\Theta})$ for $0 \le t \le M - L$. Then we have

$$\boldsymbol{\mathcal{N}}_L(\boldsymbol{\Theta}) \subset \boldsymbol{\mathcal{M}}_L(\boldsymbol{\Theta}) \cap \{1, \dots, N\}^{M+1}.$$

For example, if

$$\boldsymbol{\Theta} = \{(1, 2, 2, 2, 2, \dots), (1, 1, 2, 2, 2, \dots), (1, 1, 1, 2, 2, \dots), \dots\},$$

then $\boldsymbol{\mathcal{N}}_0(\boldsymbol{\Theta}) = \{1, 2\}$, $\boldsymbol{\mathcal{N}}_1(\boldsymbol{\Theta}) = \{11, 22\}$, $\boldsymbol{\mathcal{N}}_2(\boldsymbol{\Theta}) = \{111, 222\}$, and so on.

COROLLARY 3.4. *Let $\boldsymbol{\mathcal{G}}$ be as in* (3.1)*; let $\boldsymbol{\Theta} \subset \boldsymbol{\Omega}$ be nonempty. The system $(\boldsymbol{\mathcal{G}}, \boldsymbol{\Theta})$ is uniformly exponentially stable if and only if there exist a nonnegative integer M and matrices $\mathbf{X}_{\boldsymbol{j}} > \mathbf{0}$ such that*

$$\mathbf{A}_{i_M}^{\mathrm{T}} \mathbf{X}_{\boldsymbol{i}_+} \mathbf{A}_{i_M} - \mathbf{X}_{\boldsymbol{i}_-} < \mathbf{0} \tag{3.5}$$

for all $\boldsymbol{i} = (i_0, \dots, i_M) \in \boldsymbol{\mathcal{N}}_M(\boldsymbol{\Theta})$.

Proof. Set the matrices $\mathbf{B}_i$, $\mathbf{C}_i$, $\mathbf{D}_i$, $i = 1, \dots, N$, to zero in (3.4) to obtain (3.5). Since $\boldsymbol{\mathcal{N}}_M(\boldsymbol{\Theta}) \subset \boldsymbol{\mathcal{M}}_M(\boldsymbol{\Theta})$, it suffices to show sufficiency. If (3.5) holds for all $\boldsymbol{i} = (i_0, \dots, i_M) \in \boldsymbol{\mathcal{N}}_M(\boldsymbol{\Theta})$, perform the following algorithm:

0. Set $\widetilde{\boldsymbol{\mathcal{M}}}_M(\boldsymbol{\Theta}) = \boldsymbol{\mathcal{N}}_M(\boldsymbol{\Theta})$.
1. If $\widetilde{\boldsymbol{\mathcal{M}}}_M(\boldsymbol{\Theta}) = \boldsymbol{\mathcal{M}}_M(\boldsymbol{\Theta})$, then stop; otherwise, choose an $\boldsymbol{i} = (i_0, \dots, i_M) \in \boldsymbol{\mathcal{M}}_M(\boldsymbol{\Theta}) \setminus \widetilde{\boldsymbol{\mathcal{M}}}_M(\boldsymbol{\Theta})$ such that $(i_1, \dots, i_M, i_{M+1}) \in \widetilde{\boldsymbol{\mathcal{M}}}_M(\boldsymbol{\Theta})$ for some $i_{M+1} \in \{1, \dots, N\}$. (By definition of $\boldsymbol{\mathcal{M}}_M(\boldsymbol{\Theta})$, such an M-path $\boldsymbol{i}$ exists.)
2. If $\boldsymbol{i}_- \notin \{\hat{\boldsymbol{\imath}}_- : \hat{\boldsymbol{\imath}} \in \widetilde{\boldsymbol{\mathcal{M}}}_M(\boldsymbol{\Theta})\}$, then choose an $\alpha > 0$ such that $\mathbf{A}_{i_M}^{\mathrm{T}} \mathbf{X}_{\boldsymbol{i}_+} \mathbf{A}_{i_M} - \alpha \mathbf{I} < \mathbf{0}$, put $\mathbf{X}_{\boldsymbol{i}_-} = \alpha \mathbf{I}$, and go to step 4.
3. Choose an $\alpha > 0$ such that $\mathbf{A}_{i_M}^{\mathrm{T}} \mathbf{X}_{\boldsymbol{i}_+} \mathbf{A}_{i_M} - \alpha \mathbf{X}_{\boldsymbol{i}_-} < \mathbf{0}$, and substitute $\mathbf{X}_{\boldsymbol{i}_-}$ with $\alpha \mathbf{X}_{\boldsymbol{i}_-}$. (By definition of $\boldsymbol{\mathcal{N}}_M(\boldsymbol{\Theta})$, $\boldsymbol{i}_-$ is not equal to $\boldsymbol{i}_+$.) Whenever there exists an integer $L > 0$ and a switching path $(i_{-L}, \dots, i_{-1})$ such that $(i_{t-L}, \dots, i_{t+M-L})_- \in \{\hat{\boldsymbol{\imath}}_- : \hat{\boldsymbol{\imath}} \in \widetilde{\boldsymbol{\mathcal{M}}}_M(\boldsymbol{\Theta})\}$ for all $0 \le t \le L$, then substitute $\mathbf{X}_{(i_{-L}, \dots, i_{M-L})_-}$ with $\alpha \mathbf{X}_{(i_{-L}, \dots, i_{M-L})_-}$, too. (Again, by definition of $\boldsymbol{\mathcal{N}}_M(\boldsymbol{\Theta})$, such a path $(i_{-L}, \dots, i_{M-L})_-$ cannot be equal to $\boldsymbol{i}_+$.)

4. Substitute $\widetilde{\boldsymbol{\mathcal{M}}}_M(\boldsymbol{\Theta})$ with $\widetilde{\boldsymbol{\mathcal{M}}}_M(\boldsymbol{\Theta}) \cup \{\boldsymbol{i}\}$ and go to step 1.

Since the cardinality of $\boldsymbol{\mathcal{M}}_M(\boldsymbol{\Theta})$ is finite, we will have reconstructed an entire family $\{\mathbf{X}_{\boldsymbol{j}} : \boldsymbol{j} \in \boldsymbol{\mathcal{M}}_M^-(\boldsymbol{\Theta})\}$ of matrices $\mathbf{X}_{\boldsymbol{j}} > \mathbf{0}$ at the termination of this algorithm so that (3.5) holds for all $\boldsymbol{i} = (i_0, \ldots, i_M) \in \boldsymbol{\mathcal{M}}_M(\boldsymbol{\Theta})$. □

Remark 5. If $\boldsymbol{\Theta}$ is defined via a strongly connected directed graph, then Corollary 3.4 reverts to the stability analysis result in [30].

Now, consider the set

$$\boldsymbol{\mathcal{T}} = \{(\mathbf{A}_i, \mathbf{B}_{1,i}, \mathbf{B}_{2,i}, \mathbf{C}_{1,i}, \mathbf{C}_{2,i}, \mathbf{D}_{11,i}, \mathbf{D}_{12,i}, \mathbf{D}_{21,i}) : i = 1, \ldots, N\} \tag{3.6}$$

with $\mathbf{A}_i \in \mathbb{R}^{n\times n}$, $\mathbf{B}_{1,i} \in \mathbb{R}^{n\times m_1}$, $\mathbf{B}_{2,i} \in \mathbb{R}^{n\times m_2}$, $\mathbf{C}_{1,i} \in \mathbb{R}^{l_1\times n}$, $\mathbf{C}_{2,i} \in \mathbb{R}^{l_2\times n}$, $\mathbf{D}_{11,i} \in \mathbb{R}^{l_1\times m_1}$, $\mathbf{D}_{12,i} \in \mathbb{R}^{l_1\times m_2}$, $\mathbf{D}_{21,i} \in \mathbb{R}^{l_2\times m_1}$ for $i = 1, \ldots, N$. If $\boldsymbol{\Theta} \subset \boldsymbol{\Omega}$ and is nonempty, then the pair $(\boldsymbol{\mathcal{T}}, \boldsymbol{\Theta})$ defines the *controlled switched linear system* represented by

$$\begin{aligned} x(t+1) &= \mathbf{A}_{\theta(t)}x(t) + \mathbf{B}_{1,\theta(t)}w(t) + \mathbf{B}_{2,\theta(t)}u(t), \\ z(t) &= \mathbf{C}_{1,\theta(t)}x(t) + \mathbf{D}_{11,\theta(t)}w(t) + \mathbf{D}_{12,\theta(t)}u(t), \\ y(t) &= \mathbf{C}_{2,\theta(t)}x(t) + \mathbf{D}_{21,\theta(t)}w(t). \end{aligned} \tag{3.7}$$

Given the initial state $x(0)$, disturbance sequence $\boldsymbol{w} = (w(t))$, control sequence $\boldsymbol{u} = (u(t))$, and switching sequence $\boldsymbol{\theta} \in \boldsymbol{\Theta}$, this system of equations defines the evolution of the state $x(t)$, controlled output $z(t)$, and measured output $y(t)$ for $t \geq 0$. Based on the analysis result given by Theorem 3.3, we will be deriving a necessary and sufficient condition for controller synthesis.

We make the standard assumption that *the mode $\theta(t)$ is perfectly observed at each time instant t*; however, relaxing the standard restriction to mode-dependent controllers (i.e., controllers that do not recall past modes), we consider all controllers that have a finite memory of past modes as well as a perfect observation of the current mode. Fix a nonnegative integer L. Let

$$\boldsymbol{\Theta}_L = \{\boldsymbol{\theta}_L : \boldsymbol{\theta} \in \boldsymbol{\Theta}\}$$

be the set of L-path switching sequences generated by $\boldsymbol{\Theta}$; let

$$\boldsymbol{\mathcal{K}} = \{(\mathbf{A}_{K,\boldsymbol{i}}, \mathbf{B}_{K,\boldsymbol{i}}, \mathbf{C}_{K,\boldsymbol{i}}, \mathbf{D}_{K,\boldsymbol{i}}) : \boldsymbol{i} \in \boldsymbol{\mathcal{L}}_L(\boldsymbol{\Theta})\} \tag{3.8}$$

with $\mathbf{A}_{K,\boldsymbol{i}} \in \mathbb{R}^{n_K\times n_K}$, $\mathbf{B}_{K,\boldsymbol{i}} \in \mathbb{R}^{n_K\times l_2}$, $\mathbf{C}_{K,\boldsymbol{i}} \in \mathbb{R}^{m_2\times n_K}$, $\mathbf{D}_{K,\boldsymbol{i}} \in \mathbb{R}^{m_2\times l_2}$ for $\boldsymbol{i} \in \boldsymbol{\mathcal{L}}_L(\boldsymbol{\Theta})$. Then the pair $(\boldsymbol{\mathcal{K}}, \boldsymbol{\Theta}_L)$ defines the *L-path-dependent (linear output feedback) controller (of order n_K)*, which determines the control sequence $\boldsymbol{u}$ according to

$$\begin{aligned} x_K(t+1) &= \mathbf{A}_{K,\theta_L(t)}x_K(t) + \mathbf{B}_{K,\theta_L(t)}y(t), \\ u(t) &= \mathbf{C}_{K,\theta_L(t)}x_K(t) + \mathbf{D}_{K,\theta_L(t)}y(t) \end{aligned} \tag{3.9}$$

given the initial controller state $x_K(0)$ and L-path switching sequence $\boldsymbol{\theta}_L \in \boldsymbol{\Theta}_L$. Controllers that are L-path-dependent for some nonnegative integer L shall be said to be *finite-path-dependent*; zero-path-dependent controllers are called *mode-dependent*. The dependence of these controllers on the past measurements $y(0), \ldots, y(t)$ at each time instant t is encoded in the partition

$$\mathbf{K}_{\boldsymbol{i}} = \begin{bmatrix} \mathbf{A}_{K,\boldsymbol{i}} & \mathbf{B}_{K,\boldsymbol{i}} \\ \mathbf{C}_{K,\boldsymbol{i}} & \mathbf{D}_{K,\boldsymbol{i}} \end{bmatrix} \in \mathbb{R}^{(n_K+m_2)\times(n_K+l_2)}, \quad \boldsymbol{i} \in \boldsymbol{\mathcal{L}}_L(\boldsymbol{\Theta}).$$

Given a finite-path-dependent controller $(\boldsymbol{\mathcal{K}}, \boldsymbol{\Theta}_L)$, where L is the path length, let

$$\begin{aligned}\widetilde{\mathbf{A}}_{\boldsymbol{i}} &= \widehat{\mathbf{A}}_{i_L} + \widehat{\mathbf{B}}_{2,i_L}\mathbf{K}_{\boldsymbol{i}}\widehat{\mathbf{C}}_{2,i_L}, \quad \widetilde{\mathbf{B}}_{\boldsymbol{i}} = \widehat{\mathbf{B}}_{1,i_L} + \widehat{\mathbf{B}}_{2,i_L}\mathbf{K}_{\boldsymbol{i}}\widehat{\mathbf{D}}_{21,i_L},\\ \widetilde{\mathbf{C}}_{\boldsymbol{i}} &= \widehat{\mathbf{C}}_{1,i_L} + \widehat{\mathbf{D}}_{12,i_L}\mathbf{K}_{\boldsymbol{i}}\widehat{\mathbf{C}}_{2,i_L}, \widetilde{\mathbf{D}}_{\boldsymbol{i}} = \mathbf{D}_{11,i_L} + \widehat{\mathbf{D}}_{12,i_L}\mathbf{K}_{\boldsymbol{i}}\widehat{\mathbf{D}}_{21,i_L}\end{aligned} \tag{3.10}$$

for $\boldsymbol{i} = (i_0, \dots, i_L) \in \boldsymbol{\mathcal{L}}_L(\boldsymbol{\Theta})$, with

$$\widehat{\mathbf{A}}_i = \begin{bmatrix}\mathbf{A}_i & \mathbf{0}\\ \mathbf{0} & \mathbf{0}\end{bmatrix} \in \mathbb{R}^{(n+n_K)\times(n+n_K)},$$

$$\widehat{\mathbf{B}}_{1,i} = \begin{bmatrix}\mathbf{B}_{1,i}\\ \mathbf{0}\end{bmatrix} \in \mathbb{R}^{(n+n_K)\times m_1}, \qquad \widehat{\mathbf{B}}_{2,i} = \begin{bmatrix}\mathbf{0} & \mathbf{B}_{2,i}\\ \mathbf{I} & \mathbf{0}\end{bmatrix} \in \mathbb{R}^{(n+n_K)\times(n_K+m_2)},$$

$$\widehat{\mathbf{C}}_{1,i} = \begin{bmatrix}\mathbf{C}_{1,i} & \mathbf{0}\end{bmatrix} \in \mathbb{R}^{l_1\times(n+n_K)}, \quad \widehat{\mathbf{C}}_{2,i} = \begin{bmatrix}\mathbf{0} & \mathbf{I}\\ \mathbf{C}_{2,i} & \mathbf{0}\end{bmatrix} \in \mathbb{R}^{(n_K+l_2)\times(n+n_K)},$$

$$\widehat{\mathbf{D}}_{12,i} = \begin{bmatrix}\mathbf{0} & \mathbf{D}_{12,i}\end{bmatrix} \in \mathbb{R}^{l_1\times(n_K+m_2)}, \widehat{\mathbf{D}}_{21,i} = \begin{bmatrix}\mathbf{0}\\ \mathbf{D}_{21,i}\end{bmatrix} \in \mathbb{R}^{(n_K+l_2)\times m_1}$$

for $i \in \{1, \dots, N\}$. Let

$$\boldsymbol{\mathcal{T}}_{\boldsymbol{\mathcal{K}}} = \big\{\big(\widetilde{\mathbf{A}}_{\boldsymbol{i}}, \widetilde{\mathbf{B}}_{\boldsymbol{i}}, \widetilde{\mathbf{C}}_{\boldsymbol{i}}, \widetilde{\mathbf{D}}_{\boldsymbol{i}}\big) : \boldsymbol{i} \in \boldsymbol{\mathcal{L}}_L(\boldsymbol{\Theta})\big\}.$$

If we define the closed-loop state by

$$\tilde{x}(t) = \begin{bmatrix} x(t)^{\mathrm{T}} & x_K(t)^{\mathrm{T}}\end{bmatrix}^{\mathrm{T}} \in \mathbb{R}^{n+n_K},$$

then the *closed-loop system* $(\boldsymbol{\mathcal{T}}_{\boldsymbol{\mathcal{K}}}, \boldsymbol{\Theta}_L)$ has the representation

$$\begin{aligned}\tilde{x}(t+1) &= \widetilde{\mathbf{A}}_{\theta_L(t)}\tilde{x}(t) + \widetilde{\mathbf{B}}_{\theta_L(t)}w(t),\\ z(t) &= \widetilde{\mathbf{C}}_{\theta_L(t)}\tilde{x}(t) + \widetilde{\mathbf{D}}_{\theta_L(t)}w(t)\end{aligned} \tag{3.11}$$

for each L-path switching sequence $\boldsymbol{\theta}_L \in \boldsymbol{\Theta}_L$.

Let N_L be the cardinality of $\boldsymbol{\mathcal{L}}_L(\boldsymbol{\Theta})$. If we label the elements of $\boldsymbol{\mathcal{L}}_L(\boldsymbol{\Theta})$ from 1 to N_L, then each L-path switching sequence $\boldsymbol{\theta}_L = (\theta_L(0), \theta_L(1), \dots) \in \boldsymbol{\Theta}_L$ can be considered a *closed-loop switching sequence* in $\{1, \dots, N_L\}$; letting $\theta_L(t) = 0$ for $t < 0$, the *closed-loop switching path* $(\theta_L(t-M), \dots, \theta_L(t))$ can be identified with the switching path $(\theta(t-L-M), \dots, \theta(t))$ for each triple (t, L, M) of nonnegative integers. This leads to the following identities for all integers $L > 0$ and $M \geq 0$:

$$\boldsymbol{\mathcal{M}}_M(\boldsymbol{\Theta}_L) = \boldsymbol{\mathcal{L}}_M(\boldsymbol{\Theta}_L) = \boldsymbol{\mathcal{L}}_{M+L}(\boldsymbol{\Theta}). \tag{3.12}$$

Hence, even if $L > 0$, the closed-loop system $(\boldsymbol{\mathcal{T}}_{\boldsymbol{\mathcal{K}}}, \boldsymbol{\Theta}_L)$ is a switched linear system, where the *closed-loop modes* are the L-paths in $\boldsymbol{\mathcal{L}}_L(\boldsymbol{\Theta})$, and the *closed-loop M-paths* are the $(M+L)$-paths in $\boldsymbol{\mathcal{L}}_{M+L}(\boldsymbol{\Theta})$ for each nonnegative integer M.

LEMMA 3.5. *Let $\boldsymbol{\mathcal{T}}$ be as in* (3.6)*; let $\boldsymbol{\Theta} \subset \boldsymbol{\Omega}$ be nonempty. Suppose that $\boldsymbol{\mathcal{K}}$ is finite-path-dependent as in* (3.8) *with some nonnegative integer L. Then the closed-loop system $(\boldsymbol{\mathcal{T}}_{\boldsymbol{\mathcal{K}}}, \boldsymbol{\Theta}_L)$ is uniformly exponentially stable and uniformly strictly contractive if and only if there exist an integer $M \geq L$ and an indexed family $\{\mathbf{X}_{\boldsymbol{j}} : \boldsymbol{j} \in \boldsymbol{\mathcal{L}}_M^-(\boldsymbol{\Theta})\}$ of symmetric positive definite matrices $\mathbf{X}_{\boldsymbol{j}} \in \mathbb{R}^{(n+n_K)\times(n+n_K)}$ such that*

$$\mathbf{H}_{(i_0,\dots,i_M)} + \mathbf{G}_{i_M}^{\mathrm{T}}\mathbf{K}_{(i_{M-L},\dots,i_M)}^{\mathrm{T}}\mathbf{F}_{i_M} + \mathbf{F}_{i_M}^{\mathrm{T}}\mathbf{K}_{(i_{M-L},\dots,i_M)}\mathbf{G}_{i_M} < \mathbf{0} \tag{3.13}$$

for all M-paths $(i_0,\dots,i_M)\in\boldsymbol{\mathcal{L}}_M(\boldsymbol{\Theta})$, where

$$\mathbf{H}_{\boldsymbol{i}}=\begin{bmatrix}-\mathbf{X}_{\boldsymbol{i}_+}^{-1} & \widehat{\mathbf{A}}_{i_M} & \widehat{\mathbf{B}}_{1,i_M} & \mathbf{0}\\ \widehat{\mathbf{A}}_{i_M}^{\mathrm{T}} & -\mathbf{X}_{\boldsymbol{i}_-} & \mathbf{0} & \widehat{\mathbf{C}}_{1,i_M}^{\mathrm{T}}\\ \widehat{\mathbf{B}}_{1,i_M}^{\mathrm{T}} & \mathbf{0} & -\mathbf{I} & \mathbf{D}_{11,i_M}^{\mathrm{T}}\\ \mathbf{0} & \widehat{\mathbf{C}}_{1,i_M} & \mathbf{D}_{11,i_M} & -\mathbf{I}\end{bmatrix}\in\mathbb{R}^{(2n+2n_K+m_1+l_1)\times(2n+2n_K+m_1+l_1)}$$

for $\boldsymbol{i}=(i_0,\dots,i_M)\in\boldsymbol{\mathcal{L}}_M(\boldsymbol{\Theta})$ and where

$$\begin{bmatrix}\mathbf{F}_i\\ \mathbf{G}_i\end{bmatrix}=\begin{bmatrix}\widehat{\mathbf{B}}_{2,i}^{\mathrm{T}} & \mathbf{0} & \mathbf{0} & \widehat{\mathbf{D}}_{12,i}^{\mathrm{T}}\\ \mathbf{0} & \widehat{\mathbf{C}}_{2,i} & \widehat{\mathbf{D}}_{21,i} & \mathbf{0}\end{bmatrix}\in\mathbb{R}^{(2n_K+m_2+l_2)\times(2n+2n_K+m_1+l_1)}$$

for $i\in\{1,\dots,N\}$.

Proof. Let us first assume that $L>0$. It follows from Theorem 3.3 and (3.12) that $(\boldsymbol{\mathcal{T}}_{\boldsymbol{\mathcal{K}}},\boldsymbol{\Theta}_L)$ is uniformly stable and contractive if and only if there exists a nonnegative integer M satisfying the following: either $M=0$ and there is a single $\mathbf{X}_0>\mathbf{0}$ such that

$$\begin{bmatrix}\widetilde{\mathbf{A}}_{\boldsymbol{i}} & \widetilde{\mathbf{B}}_{\boldsymbol{i}}\\ \widetilde{\mathbf{C}}_{\boldsymbol{i}} & \widetilde{\mathbf{D}}_{\boldsymbol{i}}\end{bmatrix}^{\mathrm{T}}\begin{bmatrix}\mathbf{X}_0 & \mathbf{0}\\ \mathbf{0} & \mathbf{I}\end{bmatrix}\begin{bmatrix}\widetilde{\mathbf{A}}_{\boldsymbol{i}} & \widetilde{\mathbf{B}}_{\boldsymbol{i}}\\ \widetilde{\mathbf{C}}_{\boldsymbol{i}} & \widetilde{\mathbf{D}}_{\boldsymbol{i}}\end{bmatrix}-\begin{bmatrix}\mathbf{X}_0 & \mathbf{0}\\ \mathbf{0} & \mathbf{I}\end{bmatrix}<\mathbf{0}\tag{3.14a}$$

for $\boldsymbol{i}=(i_0,\dots,i_L)\in\boldsymbol{\mathcal{L}}_L(\boldsymbol{\Theta})$, or $M>0$ and there are $\mathbf{X}_{(j_1,\dots,j_{M+L})}>\mathbf{0}$ such that

$$\begin{aligned}&\begin{bmatrix}\widetilde{\mathbf{A}}_{(i_M,\dots,i_{M+L})} & \widetilde{\mathbf{B}}_{(i_M,\dots,i_{M+L})}\\ \widetilde{\mathbf{C}}_{(i_M,\dots,i_{M+L})} & \widetilde{\mathbf{D}}_{(i_M,\dots,i_{M+L})}\end{bmatrix}^{\mathrm{T}}\begin{bmatrix}\mathbf{X}_{\boldsymbol{i}_+} & \mathbf{0}\\ \mathbf{0} & \mathbf{I}\end{bmatrix}\\ &\qquad\times\begin{bmatrix}\widetilde{\mathbf{A}}_{(i_M,\dots,i_{M+L})} & \widetilde{\mathbf{B}}_{(i_M,\dots,i_{M+L})}\\ \widetilde{\mathbf{C}}_{(i_M,\dots,i_{M+L})} & \widetilde{\mathbf{D}}_{(i_M,\dots,i_{M+L})}\end{bmatrix}-\begin{bmatrix}\mathbf{X}_{\boldsymbol{i}_-} & \mathbf{0}\\ \mathbf{0} & \mathbf{I}\end{bmatrix}<\mathbf{0}\end{aligned}\tag{3.14b}$$

for $\boldsymbol{i}=(i_0,\dots,i_{M+L})\in\boldsymbol{\mathcal{L}}_{M+L}(\boldsymbol{\Theta})$. If $M=0$, then we may put $\mathbf{X}_{(j_1,\dots,j_L)}=\mathbf{X}_0$ for all L-paths $(j_1,\dots,j_L)$ and write (3.14a) as

$$\begin{bmatrix}\widetilde{\mathbf{A}}_{\boldsymbol{i}} & \widetilde{\mathbf{B}}_{\boldsymbol{i}}\\ \widetilde{\mathbf{C}}_{\boldsymbol{i}} & \widetilde{\mathbf{D}}_{\boldsymbol{i}}\end{bmatrix}^{\mathrm{T}}\begin{bmatrix}\mathbf{X}_{\boldsymbol{i}_+} & \mathbf{0}\\ \mathbf{0} & \mathbf{I}\end{bmatrix}\begin{bmatrix}\widetilde{\mathbf{A}}_{\boldsymbol{i}} & \widetilde{\mathbf{B}}_{\boldsymbol{i}}\\ \widetilde{\mathbf{C}}_{\boldsymbol{i}} & \widetilde{\mathbf{D}}_{\boldsymbol{i}}\end{bmatrix}-\begin{bmatrix}\mathbf{X}_{\boldsymbol{i}_-} & \mathbf{0}\\ \mathbf{0} & \mathbf{I}\end{bmatrix}<\mathbf{0};\tag{3.14c}$$

if (3.14c) holds for $\boldsymbol{i}\in\boldsymbol{\mathcal{L}}_L(\boldsymbol{\Theta})$, with some $\mathbf{X}_{(j_1,\dots,j_L)}>\mathbf{0}$, then Lemma 2.3 and the finiteness of $\boldsymbol{\mathcal{L}}_L(\boldsymbol{\Theta})$ imply that $(\boldsymbol{\mathcal{T}}_{\boldsymbol{\mathcal{K}}},\boldsymbol{\Theta}_L)$ is uniformly stable and contractive. Now, as in [20, p. 431], rewrite (3.14b) and (3.14c) (the former for $M>0$ and the latter for $M=0$) as inequalities of the form (3.13) using the decompositions (3.10) along with the Schur complement formula and an appropriate congruence transformation. Replacing M with $M-L$ then yields the desired result.

If $L=0$, then $\boldsymbol{\mathcal{M}}_M(\boldsymbol{\Theta}_L)=\boldsymbol{\mathcal{M}}_M(\boldsymbol{\Theta})$, which is not equal to $\boldsymbol{\mathcal{L}}_{M+L}(\boldsymbol{\Theta})=\boldsymbol{\mathcal{L}}_M(\boldsymbol{\Theta})$ in general. However, the proof of Theorem 3.3 shows that the existence of $\mathbf{X}_{\boldsymbol{j}}>\mathbf{0}$, $\boldsymbol{j}\in\boldsymbol{\mathcal{M}}_M^-(\boldsymbol{\Theta})$, such that (3.4) holds for all $\boldsymbol{i}=(i_0,\dots,i_M)\in\boldsymbol{\mathcal{M}}_M(\boldsymbol{\Theta})$, suffices for the existence of $\mathbf{X}_{\boldsymbol{j}}>\mathbf{0}$, $\boldsymbol{j}\in\boldsymbol{\mathcal{L}}_M^-(\boldsymbol{\Theta})$, such that (3.4) holds for all $\boldsymbol{i}=(i_0,\dots,i_M)\in\boldsymbol{\mathcal{L}}_M(\boldsymbol{\Theta})$. Therefore, the proof of the result for $L=0$ is identical to the case of $L>0$. ∎

Note that Lemma 3.5 is stated in terms of the closed-loop $(M-L)$-paths in $\boldsymbol{\mathcal{L}}_M(\boldsymbol{\Theta})$, $M\geq L$, rather than the closed-loop M-paths in $\boldsymbol{\mathcal{M}}_M(\boldsymbol{\Theta}_L)$, because the former are easier to deal with. Inequality (3.13) is amenable to the standard linear matrix

inequality embedding technique, originally developed for linear time-invariant systems [33, 20]. Finite-path-dependent controllers arise naturally from this technique.

DEFINITION 3.6. *The controller* $(\boldsymbol{\mathcal{K}}, \boldsymbol{\Theta}_L)$ *is said to be an* admissible (L-path-dependent) synthesis (of order n_K) *for the system* $(\boldsymbol{\mathcal{T}}, \boldsymbol{\Theta})$ *if the closed-loop system* $(\boldsymbol{\mathcal{T}}_{\boldsymbol{\mathcal{K}}}, \boldsymbol{\Theta}_L)$ *is uniformly exponentially stable and uniformly strictly contractive.*

THEOREM 3.7. *Let* $\boldsymbol{\mathcal{T}}$ *be as in* (3.6)*; let* $\boldsymbol{\Theta} \subset \boldsymbol{\Omega}$ *be nonempty. Suppose that* $n_K \geq n$*. There exists an admissible finite-path-dependent synthesis of order* n_K *for the system* $(\boldsymbol{\mathcal{T}}, \boldsymbol{\Theta})$ *if and only if there exist a nonnegative integer* M *and an indexed family* $\{(\mathbf{R}_{\boldsymbol{j}}, \mathbf{S}_{\boldsymbol{j}}) \colon \boldsymbol{j} \in \boldsymbol{\mathcal{M}}_M^-(\boldsymbol{\Theta})\}$ *of pairs of symmetric positive definite matrices* $\mathbf{R}_{\boldsymbol{j}}$, $\mathbf{S}_{\boldsymbol{j}} \in \mathbb{R}^{n \times n}$ *such that*

(3.15a)
$$\mathbf{N}_{F,i_M}^{\mathrm{T}} \left(\begin{bmatrix} \mathbf{A}_{i_M} & \mathbf{B}_{1,i_M} \\ \mathbf{C}_{1,i_M} & \mathbf{D}_{11,i_M} \end{bmatrix} \begin{bmatrix} \mathbf{R}_{\boldsymbol{i}_-} & \mathbf{0} \\ \mathbf{0} & \mathbf{I} \end{bmatrix} \begin{bmatrix} \mathbf{A}_{i_M} & \mathbf{B}_{1,i_M} \\ \mathbf{C}_{1,i_M} & \mathbf{D}_{11,i_M} \end{bmatrix}^{\mathrm{T}} - \begin{bmatrix} \mathbf{R}_{\boldsymbol{i}_+} & \mathbf{0} \\ \mathbf{0} & \mathbf{I} \end{bmatrix} \right) \mathbf{N}_{F,i_M} < \mathbf{0},$$

(3.15b)
$$\mathbf{N}_{G,i_M}^{\mathrm{T}} \left(\begin{bmatrix} \mathbf{A}_{i_M} & \mathbf{B}_{1,i_M} \\ \mathbf{C}_{1,i_M} & \mathbf{D}_{11,i_M} \end{bmatrix}^{\mathrm{T}} \begin{bmatrix} \mathbf{S}_{\boldsymbol{i}_+} & \mathbf{0} \\ \mathbf{0} & \mathbf{I} \end{bmatrix} \begin{bmatrix} \mathbf{A}_{i_M} & \mathbf{B}_{1,i_M} \\ \mathbf{C}_{1,i_M} & \mathbf{D}_{11,i_M} \end{bmatrix} - \begin{bmatrix} \mathbf{S}_{\boldsymbol{i}_-} & \mathbf{0} \\ \mathbf{0} & \mathbf{I} \end{bmatrix} \right) \mathbf{N}_{G,i_M} < \mathbf{0},$$

(3.15c)
$$\begin{bmatrix} \mathbf{R}_{\boldsymbol{i}_-} & \mathbf{I} \\ \mathbf{I} & \mathbf{S}_{\boldsymbol{i}_-} \end{bmatrix} \geq \mathbf{0}$$

for all M*-paths* $\boldsymbol{i} = (i_0, \ldots, i_M) \in \boldsymbol{\mathcal{M}}_M(\boldsymbol{\Theta})$*, where*

$$\mathbf{N}_{F,i} = \mathbf{N}\big(\begin{bmatrix} \mathbf{B}_{2,i}^{\mathrm{T}} & \mathbf{D}_{12,i}^{\mathrm{T}} \end{bmatrix} \big), \quad \mathbf{N}_{G,i} = \mathbf{N}\big(\begin{bmatrix} \mathbf{C}_{2,i} & \mathbf{D}_{21,i} \end{bmatrix} \big)$$

for $i \in \{1, \ldots, N\}$*. Moreover, if* (3.15) *holds for all* $\boldsymbol{i} = (i_0, \ldots, i_M) \in \boldsymbol{\mathcal{M}}_M(\boldsymbol{\Theta})$*, then there exist a nonnegative integer* $L \leq M$ *and matrices* $\mathbf{K}_{(j_0,\ldots,j_L)} \in \mathbb{R}^{(n_K+m_2)\times(n_K+l_2)}$ *such that* (3.13) *holds for all* $(i_0, \ldots, i_M) \in \boldsymbol{\mathcal{M}}_M(\boldsymbol{\Theta})$ *with*

(3.16)
$$\mathbf{X}_{\boldsymbol{j}} = \begin{bmatrix} \mathbf{S}_{\boldsymbol{j}} & \mathbf{U}_{\boldsymbol{j}} \mathbf{V}_{\boldsymbol{j}}^{\frac{1}{2}} \\ \mathbf{V}_{\boldsymbol{j}}^{\frac{1}{2}} \mathbf{U}_{\boldsymbol{j}}^{\mathrm{T}} & \mathbf{V}_{\boldsymbol{j}} \end{bmatrix} = \begin{bmatrix} \mathbf{R}_{\boldsymbol{j}} & -\mathbf{R}_{\boldsymbol{j}} \mathbf{U}_{\boldsymbol{j}} \mathbf{V}_{\boldsymbol{j}}^{-\frac{1}{2}} \\ -\mathbf{V}_{\boldsymbol{j}}^{-\frac{1}{2}} \mathbf{U}_{\boldsymbol{j}}^{\mathrm{T}} \mathbf{R}_{\boldsymbol{j}} & \mathbf{V}_{\boldsymbol{j}}^{-\frac{1}{2}} (\mathbf{I} + \mathbf{U}_{\boldsymbol{j}}^{\mathrm{T}} \mathbf{R}_{\boldsymbol{j}} \mathbf{U}_{\boldsymbol{j}}) \mathbf{V}_{\boldsymbol{j}}^{-\frac{1}{2}} \end{bmatrix}^{-1} > \mathbf{0}$$

for $\boldsymbol{j} \in \boldsymbol{\mathcal{M}}_M^-(\boldsymbol{\Theta})$*, where* $\mathbf{U}_{\boldsymbol{j}} \in \mathbb{R}^{n \times n_K}$, $\mathbf{V}_{\boldsymbol{j}} \in \mathbb{R}^{n_K \times n_K}$ *are any matrices such that* $\mathbf{U}_{\boldsymbol{j}} \mathbf{U}_{\boldsymbol{j}}^{\mathrm{T}} = \mathbf{S}_{\boldsymbol{j}} - \mathbf{R}_{\boldsymbol{j}}^{-1}$ *and* $\mathbf{V}_{\boldsymbol{j}} > \mathbf{0}$*; in particular, one may take* $L = M$*.*

Proof. It follows from [20, Lem. 3.1] that, with $L = M$, inequality (3.13) in $\mathbf{K}_{(i_{M-L},\ldots,i_M)} = \mathbf{K}_{(i_0,\ldots,i_M)}$ is feasible if and only if

$$\mathbf{N}(\mathbf{F}_{i_M})^{\mathrm{T}} \mathbf{H}_{(i_0,\ldots,i_M)} \mathbf{N}(\mathbf{F}_{i_M}) < \mathbf{0}; \quad \mathbf{N}(\mathbf{G}_{i_M})^{\mathrm{T}} \mathbf{H}_{(i_0,\ldots,i_M)} \mathbf{N}(\mathbf{G}_{i_M}) < \mathbf{0}.$$

These inequalities are equivalent to (3.15) due to the Schur complement arguments in [20, sect. 5] together with the matrix inverse completion result in [33, Lem. 6.2]. The proof of the latter shows that $\mathbf{X}_{\boldsymbol{j}}$, $\boldsymbol{j} \in \boldsymbol{\mathcal{M}}_M^-(\boldsymbol{\Theta})$, can be reconstructed from $\mathbf{R}_{\boldsymbol{j}}$ and $\mathbf{S}_{\boldsymbol{j}}$ through (3.16). Now, since $\boldsymbol{\mathcal{M}}_M(\boldsymbol{\Theta}) \subset \boldsymbol{\mathcal{L}}_M(\boldsymbol{\Theta})$, the existence of matrices $\mathbf{K}_{(i_0,\ldots,i_M)}$, such that (3.13) holds for $(i_0, \ldots, i_M) \in \boldsymbol{\mathcal{L}}_M(\boldsymbol{\Theta})$, implies the feasibility of (3.15) for $(i_0, \ldots, i_M) \in \boldsymbol{\mathcal{M}}_M(\boldsymbol{\Theta})$.

To show the converse, suppose that there are a nonnegative integer M and matrices $\mathbf{R}_{\boldsymbol{j}}$, $\mathbf{S}_{\boldsymbol{j}} > \mathbf{0}$, $\boldsymbol{j} \in \boldsymbol{\mathcal{M}}_M^-(\boldsymbol{\Theta})$, such that (3.15) holds for $\boldsymbol{i} = (i_0, \ldots, i_M) \in \boldsymbol{\mathcal{M}}_M(\boldsymbol{\Theta})$. Assume $M > 0$ without loss of generality. Reconstruct $\mathbf{X}_{\boldsymbol{j}} > \mathbf{0}$, $\boldsymbol{j} \in \boldsymbol{\mathcal{M}}_M^-(\boldsymbol{\Theta})$, through

(3.16). Then there exist matrices $\mathbf{K}_{(i_0,\ldots,i_M)}$, $(i_0,\ldots,i_M) \in \boldsymbol{\mathcal{M}}_M(\boldsymbol{\Theta})$, such that (3.13), with $L = M$, holds for $(i_0,\ldots,i_M) \in \boldsymbol{\mathcal{M}}_M(\boldsymbol{\Theta})$. By the definition of $\boldsymbol{\mathcal{M}}_M(\boldsymbol{\Theta})$, for each $j \in \boldsymbol{\mathcal{L}}_0(\boldsymbol{\Theta})$, one can choose a switching path $\left(i_0^j,\ldots,i_{M-1}^j\right) \in \{0,\ldots,N\}^M$ such that (3.3), with $L = M$, holds for all $\boldsymbol{\theta} \in \boldsymbol{\Theta}$. If we put

$$\mathbf{X}_{\theta_M(t)} = \begin{cases} \mathbf{X}_{\left(i_0^{\theta(0)},\ldots,i_{M-1}^{\theta(0)}\right)}, & t = 0; \\ \mathbf{X}_{\left(i_t^{\theta(0)},\ldots,i_{M-1}^{\theta(0)},\theta(0),\ldots,\theta(t)\right)}, & 0 < t < M; \end{cases}$$

$$\mathbf{K}_{\theta_M(t)} = \begin{cases} \mathbf{K}_{\left(i_0^{\theta(0)},\ldots,i_{M-1}^{\theta(0)}\right)}, & t = 0; \\ \mathbf{K}_{\left(i_t^{\theta(0)},\ldots,i_{M-1}^{\theta(0)},\theta(0),\ldots,\theta(t)\right)}, & 0 < t < M, \end{cases}$$

for all $\boldsymbol{\theta}_M \in \boldsymbol{\Theta}_M$ and $t \geq 0$ such that $\theta_M(t) \notin \boldsymbol{\mathcal{M}}_M(\boldsymbol{\Theta})$, then we recover (3.13) for all $(i_0,\ldots,i_M) \in \boldsymbol{\mathcal{L}}_M(\boldsymbol{\Theta})$. The result then follows from Lemma 3.5. ∎

Remark 6. Given a nonnegative integer M, the number of systems of linear matrix inequalities (3.15) to solve simultaneously is equal to the cardinality of $\boldsymbol{\mathcal{M}}_M(\boldsymbol{\Theta})$, and the feasibility of inequalities (3.15) is sufficient for the existence of an admissible L-path-dependent synthesis for some $L \leq M$. However, given a nonnegative integer L, the feasibility of (3.15) for some $M \leq L$ is sufficient but not necessary for the existence of an admissible L-path-dependent synthesis. In fact, even if the existence of an admissible L-path-dependent controller guarantees that inequalities (3.15) are feasible for some finite M, there is no upper bound on such an M. See Example 3.

Remark 7. In the case of reduced order controllers with $n_K < n$, the matrices $\mathbf{R}_{\boldsymbol{j}}$, $\mathbf{S}_{\boldsymbol{j}}$, $\boldsymbol{j} \in \boldsymbol{\mathcal{M}}_M^-(\boldsymbol{\Theta})$, must satisfy

$$\operatorname{rank} \begin{bmatrix} \mathbf{R}_{\boldsymbol{i}_-} & \mathbf{I} \\ \mathbf{I} & \mathbf{S}_{\boldsymbol{i}_-} \end{bmatrix} \leq n + n_K,$$

in addition to (3.15), for all $\boldsymbol{i} = (i_0,\ldots,i_M) \in \boldsymbol{\mathcal{M}}_M(\boldsymbol{\Theta})$.

COROLLARY 3.8. *Let $\boldsymbol{\mathcal{T}}$ be as in* (3.6)*; let $\boldsymbol{\Theta} \subset \boldsymbol{\Omega}$ be nonempty. Suppose that $n_K \geq n$. There exists a finite-path-dependent linear output feedback controller of order n_K that uniformly stabilizes the system $(\boldsymbol{\mathcal{T}}, \boldsymbol{\Theta})$ if and only if there exist a nonnegative integer M and matrices $\mathbf{R}_{\boldsymbol{j}}$, $\mathbf{S}_{\boldsymbol{j}} > \mathbf{0}$ such that*

$$\mathbf{N}(\mathbf{B}_{i_M}^{\mathrm{T}})^{\mathrm{T}}(\mathbf{A}_{i_M}\mathbf{R}_{\boldsymbol{i}_-}\mathbf{A}_{i_M}^{\mathrm{T}} - \mathbf{R}_{\boldsymbol{i}_+})\mathbf{N}(\mathbf{B}_{i_M}^{\mathrm{T}}) < \mathbf{0}, \tag{3.17a}$$

$$\mathbf{N}(\mathbf{C}_{i_M})^{\mathrm{T}}(\mathbf{A}_{i_M}^{\mathrm{T}}\mathbf{S}_{\boldsymbol{i}_+}\mathbf{A}_{i_M} - \mathbf{S}_{\boldsymbol{i}_-})\mathbf{N}(\mathbf{C}_{i_M}) < \mathbf{0}, \tag{3.17b}$$

$$\begin{bmatrix} \mathbf{R}_{\boldsymbol{i}_-} & \mathbf{I} \\ \mathbf{I} & \mathbf{S}_{\boldsymbol{i}_-} \end{bmatrix} \geq \mathbf{0} \tag{3.17c}$$

for all $\boldsymbol{i} = (i_0,\ldots,i_M) \in \boldsymbol{\mathcal{N}}_M(\boldsymbol{\Theta})$.

Proof. In (3.15), set the matrices $\mathbf{B}_{1,i}$, $\mathbf{C}_{1,i}$, $\mathbf{D}_{11,i}$, $\mathbf{D}_{12,i}$, and $\mathbf{D}_{21,i}$ to zero for all $i = 1, \ldots, N$, and obtain (3.17). The rest of the proof proceeds similarly to that of Corollary 3.4. ∎

Remark 8. Corollary 3.8 reverts to the stabilization result in [30] if a strongly connected directed graph defines $\boldsymbol{\Theta}$.

Suppose that a set of matrices $\mathbf{K}_{\boldsymbol{i}}$, $\boldsymbol{i} \in \boldsymbol{\mathcal{M}}_L(\boldsymbol{\Theta})$, is obtained by solving (3.13) via Theorem 3.7 for some nonnegative integer $L \leq M$. If $L = 0$, then it follows from $\boldsymbol{\mathcal{M}}_0(\boldsymbol{\Theta}) = \boldsymbol{\mathcal{L}}_0(\boldsymbol{\Theta})$ that we have all the matrices $\mathbf{K}_i$, $i \in \boldsymbol{\mathcal{L}}_0(\boldsymbol{\Theta})$, that define an admissible zero-path-dependent controller synthesis. If $L > 0$, on the other hand,

then choose switching paths $\big(i_0^j,\dots,i_{L-1}^j\big)\in\{0,\dots,N\}^L$, $j\in\boldsymbol{\mathcal{L}}_0(\boldsymbol{\Theta})$, such that (3.3) holds for all $\boldsymbol{\theta}\in\boldsymbol{\Theta}$, and put

$$\mathbf{K}_{\theta_L(t)}=\mathbf{K}_{\left(i_t^{\theta(0)},\dots,i_{L-1}^{\theta(0)},\theta(0),\dots,\theta(t)\right)}$$

whenever $\boldsymbol{\theta}_L\in\boldsymbol{\Theta}_L$, $t<L$, and $\theta_L(t)\notin\boldsymbol{\mathcal{M}}_L(\boldsymbol{\Theta})$; then we recover all matrices $\mathbf{K}_{\boldsymbol{i}}$, $\boldsymbol{i}\in\boldsymbol{\mathcal{L}}_L(\boldsymbol{\Theta})$, that define an admissible L-path-dependent controller synthesis.

Example 3. Let $\boldsymbol{\theta}^{(k)}$ be as in Example 2 for positive integers k. Let

$$\boldsymbol{\mathcal{T}}=\{(1,-1,1,-1,1,1,-1,-1),(1,0,0,0,0,0,0,0)\}$$

and $\boldsymbol{\Theta}^{(k)}=\big\{\boldsymbol{\theta}^{(k)}\big\}$ so that the controlled system $\big(\boldsymbol{\mathcal{T}},\boldsymbol{\Theta}^{(k)}\big)$ has the representation

$$\begin{aligned}x(t+1)&=x(t)-w(t)+u(t),\\ z(t)&=-x(t)+w(t)-u(t),\\ y(t)&=x(t)-w(t)\end{aligned}$$

in mode 1 (i.e., when $\theta^{(k)}(t)=1$), and

$$x(t+1)=x(t),\quad z(t)=0,\quad y(t)=0$$

in mode 2 (i.e., when $\theta^{(k)}(t)=2$). Let M be a nonnegative integer. If $M<k$, then, because mode 2 is not stabilizable and because $\boldsymbol{\mathcal{M}}_M\big(\boldsymbol{\Theta}^{(k)}\big)$ contains the switching path $(2,\dots,2)$ that consists of mode 2 only, inequality (3.15) cannot be satisfied for all $\boldsymbol{i}=(i_0,\dots,i_M)\in\boldsymbol{\mathcal{M}}_M\big(\boldsymbol{\Theta}^{(k)}\big)$. On the other hand, the cardinality of $\boldsymbol{\mathcal{M}}_M\big(\boldsymbol{\Theta}^{(k)}\big)$ is equal to that of $\boldsymbol{\mathcal{M}}_k\big(\boldsymbol{\Theta}^{(k)}\big)$ for all $M>k$. Hence, to design an admissible synthesis for $\big(\boldsymbol{\mathcal{T}},\boldsymbol{\Theta}^{(k)}\big)$, it suffices to consider the single path length $M=k$ in (3.15). It is readily verified that there indeed is an admissible finite-path-dependent controller for $\big(\boldsymbol{\mathcal{T}},\boldsymbol{\Theta}^{(k)}\big)$ for each k. This shows that there does not exist a general upper bound on the path length M in Theorem 3.7.

In this particular example, it is easy to find solutions $\mathbf{R}_{\boldsymbol{j}},\mathbf{S}_{\boldsymbol{j}}>\mathbf{0}$, $\boldsymbol{j}\in\boldsymbol{\mathcal{M}}_M^-\big(\boldsymbol{\Theta}^{(k)}\big)$, to (3.15) with $M=k$, such that $L=0$ (which leads to mode-dependent controllers) suffices for (3.13) to be feasible. This indicates that the existence of an admissible L-path controller synthesis does not necessarily lead to the feasibility of (3.15) with $M=L$.

DEFINITION 3.9. *Let $\gamma>0$. The system $(\boldsymbol{\mathcal{G}},\boldsymbol{\Theta})$ is said to* satisfy uniform disturbance attenuation level γ *if there exists a $\tilde{\gamma}\in(0,\gamma)$ such that, whenever $x(t_0)=0$,*

$$\sum\nolimits_{s=t_0}^{t}\|z(s)\|^2\le\tilde{\gamma}^2\sum\nolimits_{s=t_0}^{t}\|w(s)\|^2$$

for $t\ge t_0\ge0$, for $\boldsymbol{w}\in\ell^2(\mathbb{R}^m)$, and for $\boldsymbol{\theta}\in\boldsymbol{\Theta}$.

DEFINITION 3.10. *Let $\gamma>0$. The controller $(\boldsymbol{\mathcal{K}},\boldsymbol{\Theta}_L)$ is said to be a* γ-admissible (L-path-dependent) synthesis (of order n_K), *or to* achieve uniform disturbance attenuation level γ, *for the system $(\boldsymbol{\mathcal{T}},\boldsymbol{\Theta})$ if the closed-loop system $(\boldsymbol{\mathcal{T}}_{\boldsymbol{\mathcal{K}}},\boldsymbol{\Theta}_L)$ is uniformly exponentially stable and satisfies uniform disturbance attenuation level γ.*

Given a $\gamma>0$, let

$$\boldsymbol{\mathcal{G}}^{(\gamma)}=\big\{(\mathbf{A}_i,\gamma^{-1/2}\mathbf{B}_i,\gamma^{-1/2}\mathbf{C}_i,\gamma^{-1}\mathbf{D}_i)\colon i=1,\dots,N\big\}.$$

Then $(\boldsymbol{\mathcal{G}},\boldsymbol{\Theta})$ satisfies uniform disturbance attenuation level γ if and only if $\big(\boldsymbol{\mathcal{G}}^{(\gamma)},\boldsymbol{\Theta}\big)$ is uniformly strictly contractive. Using this fact and Theorem 3.7, and applying the Schur complement formula to (3.15a) and (3.15b), we obtain the following.

COROLLARY 3.11. *Let $\boldsymbol{\mathcal{T}}$ be as in* (3.6)*, and let $\boldsymbol{\Theta} \subset \boldsymbol{\Omega}$ be nonempty. Let $\gamma > 0$. Suppose that $n_K \geq n$. There exists a γ-admissible finite-path-dependent synthesis of order n_K for the system $(\boldsymbol{\mathcal{T}}, \boldsymbol{\Theta})$ if and only if there exist a nonnegative integer M and an indexed family $\{(\mathbf{R}_{\boldsymbol{j}}, \mathbf{S}_{\boldsymbol{j}}) \colon \boldsymbol{j} \in \boldsymbol{\mathcal{M}}_M^-(\boldsymbol{\Theta})\}$ of pairs of symmetric positive definite matrices $\mathbf{R}_{\boldsymbol{j}}$, $\mathbf{S}_{\boldsymbol{j}} \in \mathbb{R}^{n\times n}$ such that*

$$\begin{bmatrix} \mathbf{N}_{F,i_M} & \mathbf{0} \\ \mathbf{0} & \mathbf{I} \end{bmatrix}^{\mathrm{T}} \begin{bmatrix} \mathbf{A}_{i_M}\mathbf{R}_{\boldsymbol{i}_-}\mathbf{A}_{i_M}^{\mathrm{T}} - \mathbf{R}_{\boldsymbol{i}_+} & \mathbf{A}_{i_M}\mathbf{R}_{\boldsymbol{i}_-}\mathbf{C}_{1,i_M}^{\mathrm{T}} & \mathbf{B}_{1,i_M} \\ \mathbf{C}_{1,i_M}\mathbf{R}_{\boldsymbol{i}_-}\mathbf{A}_{i_M}^{\mathrm{T}} & \mathbf{C}_{1,i_M}\mathbf{R}_{\boldsymbol{i}_-}\mathbf{C}_{1,i_M}^{\mathrm{T}} - \gamma\mathbf{I} & \mathbf{D}_{11,i_M} \\ \mathbf{B}_{1,i_M}^{\mathrm{T}} & \mathbf{D}_{11,i_M}^{\mathrm{T}} & -\gamma\mathbf{I} \end{bmatrix} \times \begin{bmatrix} \mathbf{N}_{F,i_M} & \mathbf{0} \\ \mathbf{0} & \mathbf{I} \end{bmatrix} < \mathbf{0}, \tag{3.18a}$$

$$\begin{bmatrix} \mathbf{N}_{G,i_M} & \mathbf{0} \\ \mathbf{0} & \mathbf{I} \end{bmatrix}^{\mathrm{T}} \begin{bmatrix} \mathbf{A}_{i_M}^{\mathrm{T}}\mathbf{S}_{\boldsymbol{i}_+}\mathbf{A}_{i_M} - \mathbf{S}_{\boldsymbol{i}_-} & \mathbf{A}_{i_M}^{\mathrm{T}}\mathbf{S}_{\boldsymbol{i}_+}\mathbf{B}_{1,i_M} & \mathbf{C}_{1,i_M}^{\mathrm{T}} \\ \mathbf{B}_{1,i_M}^{\mathrm{T}}\mathbf{S}_{\boldsymbol{i}_+}\mathbf{A}_{i_M} & \mathbf{B}_{1,i_M}^{\mathrm{T}}\mathbf{S}_{\boldsymbol{i}_+}\mathbf{B}_{1,i_M} - \gamma\mathbf{I} & \mathbf{D}_{11,i_M}^{\mathrm{T}} \\ \mathbf{C}_{1,i_M} & \mathbf{D}_{11,i_M} & -\gamma\mathbf{I} \end{bmatrix} \times \begin{bmatrix} \mathbf{N}_{G,i_M} & \mathbf{0} \\ \mathbf{0} & \mathbf{I} \end{bmatrix} < \mathbf{0}, \tag{3.18b}$$

$$\begin{bmatrix} \mathbf{R}_{\boldsymbol{i}_-} & \mathbf{I} \\ \mathbf{I} & \mathbf{S}_{\boldsymbol{i}_-} \end{bmatrix} \geq \mathbf{0} \tag{3.18c}$$

for all $\boldsymbol{i} = (i_0, \ldots, i_M) \in \boldsymbol{\mathcal{M}}_M(\boldsymbol{\Theta})$. Moreover, if (3.18) *holds for all $\boldsymbol{i} = (i_0, \ldots, i_M) \in \boldsymbol{\mathcal{M}}_M(\boldsymbol{\Theta})$, then there exist a nonnegative integer $L \leq M$ and matrices $\mathbf{K}_{(i_{M-L},\ldots,i_M)} \in \mathbb{R}^{(n_K+m_2)\times(n_K+l_2)}$ such that* (3.13) *holds for $(i_0, \ldots, i_M) \in \boldsymbol{\mathcal{M}}_M(\boldsymbol{\Theta})$ with*

$$\mathbf{H}_{(i_0,\ldots,i_M)} = \begin{bmatrix} -\mathbf{X}_{(i_0,\ldots,i_M)_+}^{-1} & \widehat{\mathbf{A}}_{i_M} & \widehat{\mathbf{B}}_{1,i_M} & \mathbf{0} \\ \widehat{\mathbf{A}}_{i_M}^{\mathrm{T}} & -\mathbf{X}_{(i_0,\ldots,i_M)_-} & \mathbf{0} & \widehat{\mathbf{C}}_{1,i_M}^{\mathrm{T}} \\ \widehat{\mathbf{B}}_{1,i_M}^{\mathrm{T}} & \mathbf{0} & -\gamma\mathbf{I} & \mathbf{D}_{11,i_M}^{\mathrm{T}} \\ \mathbf{0} & \widehat{\mathbf{C}}_{1,i_M} & \mathbf{D}_{11,i_M} & -\gamma\mathbf{I} \end{bmatrix}, \tag{3.19}$$

where the matrices $\mathbf{X}_{\boldsymbol{j}}$ are reconstructed via (3.16) *for $\boldsymbol{j} \in \boldsymbol{\mathcal{M}}_M^-(\boldsymbol{\Theta})$; in particular, one may take $L = M$.*

Example 4. Let

$$\boldsymbol{\mathcal{T}} = \{(0.3, 0, 0, 1, 1, 0, 1, 0), (3, 0.5, 1, 1, 1, 0, 1, 0)\};$$

let $\boldsymbol{\Theta}$ be as in Example 1. Then the controlled system $(\boldsymbol{\mathcal{T}}, \boldsymbol{\Theta})$ has the representation

$$x(t+1) = 0.3x(t), \quad z(t) = x(t) + u(t), \quad y(t) = x(t)$$

in mode 1, and

$$x(t+1) = 3x(t) + 0.5w(t) + u(t), \quad z(t) = x(t) + u(t), \quad y(t) = x(t)$$

in mode 2. With $M = 0$, the system of linear matrix inequalities (3.18) is feasible for any $\gamma > 1$; it is easy to see that, if $\gamma = 1$, then inequalities (3.18) are not feasible for any $M \geq 0$. Solving the semidefinite program of minimizing γ subject to (3.18), and applying Corollary 3.11, we obtain a mode-dependent controller $(\boldsymbol{\mathcal{K}}, \boldsymbol{\Theta}_0)$ with

$$\mathbf{K}_1 = \begin{bmatrix} 0 & 0 \\ 0 & -1 \end{bmatrix}, \quad \mathbf{K}_2 = \begin{bmatrix} 0 & 0 \\ 0 & -3 \end{bmatrix}.$$

The resulting controller $(\boldsymbol{\mathcal{K}}, \boldsymbol{\Theta}_0)$ has the representation

$$u(t) = \begin{cases} -y(t) & \text{if } \theta(t) = 1, \\ -3y(t) & \text{if } \theta(t) = 2. \end{cases}$$

This controller is *optimal* in the sense that it achieves any uniform disturbance attenuation level greater than one, and that no finite-path-dependent linear dynamic output feedback controller achieves the uniform disturbance attenuation level equal to one. (The optimal controller is static in this case because $\mathbf{C}_{2,1} = \mathbf{C}_{2,2} = 1$ and $\mathbf{D}_{21,1} = \mathbf{D}_{21,2} = 0$ lead to perfect observation of the state.) The controller, however, is not optimal under the notion of path-by-path disturbance attenuation—see Example 7.

4. Control of Markovian jump linear systems. In Markovian jump linear systems, the switching sequence is modeled as a finite-state homogeneous Markov chain. Let $\boldsymbol{\mathcal{G}}$ be as in (3.1). Let $p = (p_i) \in \mathbb{R}^{1\times N}$ be a row vector whose entries are nonnegative and sum to one; let $\mathbf{P} = (p_{ij}) \in \mathbb{R}^{N\times N}$ be a (row) stochastic matrix so that each row of $\mathbf{P}$ has nonnegative entries that sum to one. Then the discrete-time *Markovian jump linear system*, defined by the triple $(\boldsymbol{\mathcal{G}}, \mathbf{P}, p)$, has the representation (3.2). Here, the switching sequence $\boldsymbol{\theta}$ is a realization of the Markov chain defined by the pair $(\mathbf{P}, p)$, where $\mathbf{P}$ is the transition probability matrix and p the initial distribution. The state $\theta(t)$ of the chain $(\mathbf{P}, p)$ at time t defines the mode of $(\boldsymbol{\mathcal{G}}, \mathbf{P}, p)$ at time t; the distribution of the mode at time t is given by $p\mathbf{P}^t$. As in the previous section, let $\boldsymbol{\Omega}$ be the space of all infinite sequences in $\{1, \dots, N\}$. Let P be the unique consistent probability measure [39] on $\boldsymbol{\Omega}$ such that

$$P\{\, \theta(t+1) = j \mid \theta(t) = i \,\} = p_{ij}, \quad P\{\, \theta(0) = i \,\} = p_i$$

for all i, j, and t.

DEFINITION 4.1. *The system* $(\boldsymbol{\mathcal{G}}, \mathbf{P}, p)$ *is said to be* almost surely uniformly (exponentially) stable *if there exists a set* $\boldsymbol{\Theta} \subset \boldsymbol{\Omega}$ *with* $P(\boldsymbol{\Theta}) = 1$ *such that the system* $(\boldsymbol{\mathcal{G}}, \boldsymbol{\Theta})$ *is uniformly exponentially stable.*

DEFINITION 4.2. *The system* $(\boldsymbol{\mathcal{G}}, \mathbf{P}, p)$ *is said to be* almost surely uniformly (strictly) contractive *if there exists a set* $\boldsymbol{\Theta} \subset \boldsymbol{\Omega}$ *with* $P(\boldsymbol{\Theta}) = 1$ *such that the system* $(\boldsymbol{\mathcal{G}}, \boldsymbol{\Theta})$ *is uniformly strictly contractive.*

A switching sequence $\boldsymbol{\theta}$ in $\{1, \dots, N\}$ is said to be *admissible* with respect to $(\mathbf{P}, p)$ if $p_{\theta(0)} > 0$ and $p_{\theta(t)\theta(t+1)} > 0$ for $t \geq 0$. If we define

$$\boldsymbol{\Theta}(\mathbf{P}, p) = \{\boldsymbol{\theta} \in \boldsymbol{\Omega} \colon \boldsymbol{\theta} \text{ is admissible with respect to } (\mathbf{P}, p)\}$$

and let

$$\boldsymbol{\mathcal{M}}_L(\mathbf{P}, p) = \boldsymbol{\mathcal{M}}_L(\boldsymbol{\Theta}(\mathbf{P}, p)), \quad \boldsymbol{\mathcal{M}}_L^-(\mathbf{P}, p) = \boldsymbol{\mathcal{M}}_L^-(\boldsymbol{\Theta}(\mathbf{P}, p))$$

for nonnegative integers L, then we have $P(\Theta(\mathbf{P}, p)) = 1$; on the other hand, whenever $(i_0, \dots, i_L) \in \boldsymbol{\mathcal{M}}_L(\mathbf{P}, p)$, we have that $P\{\boldsymbol{\theta} \in \boldsymbol{\Omega} \colon (i_0, \dots, i_L) \in \boldsymbol{\mathcal{L}}_L(\{\boldsymbol{\theta}\})\} > 0$ so that $\boldsymbol{\mathcal{M}}_L(\mathbf{P}, p) \subset \boldsymbol{\mathcal{M}}_L(\boldsymbol{\Theta})$ whenever $\boldsymbol{\Theta} \subset \boldsymbol{\Omega}$ and $P(\boldsymbol{\Theta}) = 1$.

Example 5. Let $N = 3$, and let $(\mathbf{P}, p)$ be a Markov chain with

$$\mathbf{1}(\mathbf{P}) = \begin{bmatrix} 1 & 1 & 1 \\ 0 & 0 & 1 \\ 0 & 0 & 1 \end{bmatrix}.$$

If $\mathbf{1}(p) = [1\ 0\ 0]$, then

$$\boldsymbol{\mathcal{L}}_0(\mathbf{P},p) = \boldsymbol{\mathcal{M}}_0(\mathbf{P},p) = \{1,2,3\};$$
$$\boldsymbol{\mathcal{L}}_1(\mathbf{P},p) = \{01,11,12,13,23,33\}, \quad \boldsymbol{\mathcal{M}}_1(\mathbf{P},p) = \{11,12,13,23,33\},$$

and so on. However, if $\mathbf{1}(p) = [0\ 1\ 1]$, then

$$\boldsymbol{\mathcal{L}}_0(\mathbf{P},p) = \boldsymbol{\mathcal{M}}_0(\mathbf{P},p) = \{2,3\};$$
$$\boldsymbol{\mathcal{L}}_1(\mathbf{P},p) = \{02,03,23,33\}, \quad \boldsymbol{\mathcal{M}}_1(\mathbf{P},p) = \{02,23,33\},$$

and so on.

THEOREM 4.3. *Let $\boldsymbol{\mathcal{G}}$ be as in* (3.1)*; let* $(\mathbf{P},p)$ *be a Markov chain. The system* $(\boldsymbol{\mathcal{G}},\mathbf{P},p)$ *is almost surely uniformly exponentially stable and almost surely uniformly strictly contractive if and only if there exist a nonnegative integer M and an indexed family* $\{\mathbf{X}_{\boldsymbol{j}} : \boldsymbol{j} \in \boldsymbol{\mathcal{M}}_M^-(\mathbf{P},p)\}$ *of symmetric positive definite matrices* $\mathbf{X}_{\boldsymbol{j}} \in \mathbb{R}^{n\times n}$ *such that* (3.4) *holds for all M-paths* $\boldsymbol{i} = (i_0,\dots,i_M) \in \boldsymbol{\mathcal{M}}_M(\mathbf{P},p)$.

Proof. The result is immediate from Theorem 3.3: sufficiency follows from $P(\Theta(\mathbf{P},p)) = 1$, and necessity from the fact that $\boldsymbol{\Theta} \subset \boldsymbol{\Omega}$ and $P(\boldsymbol{\Theta}) = 1$ implies $\boldsymbol{\mathcal{M}}_L(\mathbf{P},p) \subset \boldsymbol{\mathcal{M}}_L(\boldsymbol{\Theta})$. □

Remark 9. Define

$$n_i(0) = 1, \quad n_i(L+1) = \sum\nolimits_{\{j\,:\,p_{ij}>0\}} n_j(L)$$

for $i \in \{1,\dots,N\}$ and for $L = 0, 1, \dots$. Given a Markov chain $(\mathbf{P},p)$, let

$$S(p) = \{j : p_j > 0\}, \quad T(\mathbf{P},p) = \big\{j : p_i p_{ij}^{(k)} > 0 \text{ for some } (i,k)\big\},$$

where $\mathbf{P}^k = \big(p_{ij}^{(k)}\big)$ is the k-step transition probability matrix [24]. Then, in Theorem 4.3, the number of linear matrix inequalities (3.4) to solve simultaneously, with a fixed M, is equal to the cardinality of $\boldsymbol{\mathcal{M}}_M(\mathbf{P},p)$, which is precisely given by

$$\sum\nolimits_{j\in S(p)\setminus T(\mathbf{P},p)} \sum\nolimits_{k=0}^{M-1} n_j(k) + \sum\nolimits_{j\in S(p)\cup T(\mathbf{P},p)} n_j(M).$$

In particular, if $\mathbf{P}$ is irreducible (i.e., if the directed graph of $\mathbf{P}$ is strongly connected—see, e.g., [25]), then the cardinality of $\boldsymbol{\mathcal{M}}_M(\mathbf{P},p)$ is equal to $\sum_{j=1}^N n_j(M)$.

Remark 10. Theorem 4.3 implies that the Markovian jump linear system $(\boldsymbol{\mathcal{G}},\mathbf{P},p)$ is almost surely uniformly stable and contractive if and only if the switched linear system $(\boldsymbol{\mathcal{G}},\boldsymbol{\Theta}(\mathbf{P},p))$ is uniformly stable and contractive. Therefore, Markovian jump linear systems can be treated as if they are switched linear systems. Moreover, since the set $\boldsymbol{\Theta}(\mathbf{P},p)$ depends only on the sparsity patterns of $\mathbf{P}$ and p, the almost sure uniform stability and contractiveness of $(\boldsymbol{\mathcal{G}},\mathbf{P},p)$ is robust against sparsity pattern–preserving deviations from $\mathbf{P}$ and p.

Remark 11. When only the almost sure uniform stability is considered, it is immediate from Corollary 3.4 that it suffices to consider the "irreducible parts" of the Markov chain $(\mathbf{P},p)$; see [30].

Let $\boldsymbol{\mathcal{T}}$ be as in (3.6), and let $(\mathbf{P},p)$ be a Markov chain. Then the triple $(\boldsymbol{\mathcal{T}},\mathbf{P},p)$ defines the *controlled Markovian jump linear system* described by (3.7), where $\boldsymbol{\theta}$ is a realization of $(\mathbf{P},p)$. As in the previous section, we make the standard assumption that *the state $\theta(t)$ of the chain* $(\mathbf{P},p)$ *is perfectly observed at each time instant t*; we consider all finite-path-dependent controllers.

Fix a nonnegative integer L. Let

$$\boldsymbol{\mathcal{K}} = \{(\mathbf{A}_{K,\boldsymbol{i}}, \mathbf{B}_{K,\boldsymbol{i}}, \mathbf{C}_{K,\boldsymbol{i}}, \mathbf{D}_{K,\boldsymbol{i}}) \colon \boldsymbol{i} \in \boldsymbol{\mathcal{L}}_L(\boldsymbol{\Theta}(\mathbf{P}, p))\}.$$

Then the pair $(\boldsymbol{\mathcal{K}}, \boldsymbol{\Theta}(\mathbf{P}, p)_L)$ defines an L-path-dependent controller, whose representation is given by (3.9). Label the L-paths in $\boldsymbol{\mathcal{L}}_L(\boldsymbol{\Theta}(\mathbf{P}, p))$ in dictionary order from 1 to N_L, where N_L is the cardinality of $\boldsymbol{\mathcal{L}}_L(\boldsymbol{\Theta}(\mathbf{P}, p))$. Define $\mathbf{P}^{(L)} = (q_{ij}) \in \mathbb{R}^{N_L \times N_L}$ as follows: Whenever $(i_0, \ldots, i_L)$ and $(j_0, \ldots, j_L)$ are L-paths labeled i and j, respectively, set $q_{ij} = p_{i_L j_L}$ if $(i_0, \ldots, i_L)_+ = (j_0, \ldots, j_L)_-$; otherwise, set $q_{ij} = 0$. Also, define a row vector $p^{(L)} = (q_i) \in \mathbb{R}^{N_L}$ as follows: Whenever $(i_0, \ldots, i_L)$ is an L-path labeled i, set $q_i = p_{i_L}$ if $(i_0, \ldots, i_L)_- = (0, \ldots, 0)$; otherwise, set $q_i = 0$. Then the pair $(\mathbf{P}^{(L)}, p^{(L)})$ defines the *L-path Markov chain* generated by $(\mathbf{P}, p)$. Consequently, the closed-loop system, given by the triple $(\boldsymbol{\mathcal{T}}_{\boldsymbol{\mathcal{K}}}, \mathbf{P}^{(L)}, p^{(L)})$ with

$$\boldsymbol{\mathcal{T}}_{\boldsymbol{\mathcal{K}}} = \left\{ \left(\widetilde{\mathbf{A}}_{\boldsymbol{i}}, \widetilde{\mathbf{B}}_{\boldsymbol{i}}, \widetilde{\mathbf{C}}_{\boldsymbol{i}}, \widetilde{\mathbf{D}}_{\boldsymbol{i}} \right) \colon \boldsymbol{i} \in \boldsymbol{\mathcal{L}}_L(\boldsymbol{\Theta}(\mathbf{P}, p)) \right\},$$

is a Markovian jump linear system whose representation is of the form (3.11) for each realization $\boldsymbol{\theta}_L$ of $(\mathbf{P}^{(L)}, p^{(L)})$.

DEFINITION 4.4. *Let $\gamma > 0$. The system $(\boldsymbol{\mathcal{G}}, \mathbf{P}, p)$ is said to* satisfy almost sure uniform disturbance attenuation level γ *if there exists a set $\boldsymbol{\Theta} \subset \boldsymbol{\Omega}$ with $P(\boldsymbol{\Theta}) = 1$ such that the system $(\boldsymbol{\mathcal{G}}, \boldsymbol{\Theta})$ satisfies uniform disturbance attenuation level γ.*

DEFINITION 4.5. *Let $\gamma > 0$. The controller $(\boldsymbol{\mathcal{K}}, \boldsymbol{\Theta}(\mathbf{P}, p)_L)$ is said to be a* γ-admissible (L-path-dependent) synthesis (of order n_K), *or to* achieve almost sure uniform disturbance attenuation level γ, *for the system $(\boldsymbol{\mathcal{T}}, \mathbf{P}, p)$ if the closed-loop system $(\boldsymbol{\mathcal{T}}_{\boldsymbol{\mathcal{K}}}, \mathbf{P}^{(L)}, p^{(L)})$ satisfies almost sure uniform disturbance attenuation level γ.*

THEOREM 4.6. *Let $\boldsymbol{\mathcal{T}}$ be as in* (3.6)*; let $(\mathbf{P}, p)$ be a Markov chain. Let $\gamma > 0$. Suppose that $n_K \geq n$. There exists a γ-admissible finite-path-dependent synthesis of order n_K for the system $(\boldsymbol{\mathcal{T}}, \mathbf{P}, p)$ if and only if there exist a nonnegative integer M and an indexed family $\{(\mathbf{R}_{\boldsymbol{j}}, \mathbf{S}_{\boldsymbol{j}}) \colon \boldsymbol{j} \in \boldsymbol{\mathcal{M}}_M^-(\mathbf{P}, p)\}$ of pairs of symmetric positive definite matrices $\mathbf{R}_{\boldsymbol{j}}$, $\mathbf{S}_{\boldsymbol{j}} \in \mathbb{R}^{n \times n}$ such that* (3.18) *holds for all M-paths $\boldsymbol{i} = (i_0, \ldots, i_M) \in \boldsymbol{\mathcal{M}}_M(\mathbf{P}, p)$. Moreover, if* (3.18) *holds for all $\boldsymbol{i} = (i_0, \ldots, i_M) \in \boldsymbol{\mathcal{M}}_M(\mathbf{P}, p)$, then there exist a nonnegative integer $L \leq M$ and matrices $\mathbf{K}_{(i_{M-L}, \ldots, i_M)} \in \mathbb{R}^{(n_K + m_2) \times (n_K + l_2)}$ such that* (3.13)*, with* (3.19)*, holds for $(i_0, \ldots, i_M) \in \boldsymbol{\mathcal{M}}_M(\mathbf{P}, p)$, where the matrices $\mathbf{X}_{\boldsymbol{j}}$ are given by* (3.16) *for $\boldsymbol{j} \in \boldsymbol{\mathcal{M}}_M^-(\mathbf{P}, p)$; in particular, one may take $L = M$.*

Proof. The result immediately follows from Corollary 3.11. ∎

Remark 12. The existence of finite-path-dependent controller syntheses achieving an almost sure uniform disturbance attenuation level for the Markovian jump linear system $(\boldsymbol{\mathcal{T}}, \mathbf{P}, p)$ is robust against sparsity pattern–preserving deviations from $\mathbf{P}$ and p. The conservatism associated with this robustness property can be reduced via path-by-path disturbance attenuation—see the examples in the next section.

Example 6. Let the Markov chain $(\mathbf{P}, p)$ have

$$\mathbf{1}(\mathbf{P}) = \begin{bmatrix} 0 & 1 & 1 \\ 0 & 0 & 1 \\ 1 & 0 & 0 \end{bmatrix}, \quad \mathbf{1}(p) = \begin{bmatrix} 1 & 1 & 1 \end{bmatrix}. \tag{4.1}$$

Then we have

$$\boldsymbol{\mathcal{M}}_0(\mathbf{P}, p) = \{1, 2, 3\}, \quad \boldsymbol{\mathcal{M}}_1(\mathbf{P}, p) = \{12, 13, 23, 31\},$$
$$\boldsymbol{\mathcal{M}}_2(\mathbf{P}, p) = \{123, 131, 231, 312, 313\},$$

and so on. Let

$$\boldsymbol{\mathcal{T}} = \{(0.5,0,0,0,0,0,0,0),(3,0,0,0,0,0,0,0),(2,1,1,1,1,1,1,1)\}$$

so that the controlled Markovian jump linear system $(\boldsymbol{\mathcal{T}}, \mathbf{P}, p)$ has the representation

$$\begin{aligned} x(t+1) &= 0.5x(t), \quad z(t) = 0, \quad y(t) = 0; \\ x(t+1) &= 3x(t), \quad z(t) = 0, \quad y(t) = 0; \end{aligned}$$

or

$$\begin{aligned} x(t+1) &= 2x(t) + w(t) + u(t), \\ z(t) &= x(t) + w(t) + u(t), \\ y(t) &= x(t) + w(t), \end{aligned}$$

depending on whether the mode at time t is 1, 2, or 3, respectively. With $M = 0$, the system of linear matrix inequalities (3.18), over $i_0 \in \boldsymbol{\mathcal{M}}_0(\mathbf{P}, p)$, is not feasible for any $\gamma > 0$. However, with $M = 1$, the semidefinite program of minimizing γ subject to (3.18) over $(i_0, i_1) \in \boldsymbol{\mathcal{M}}_1(\mathbf{P}, p)$ leads to $\gamma = 0.834$; the same is true for all $M > 1$. Setting $L = M = 1$ in (3.13) with (3.19), we obtain

$$\mathbf{K}_{(1,2)} = \mathbf{K}_{(3,1)} = \begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix}, \quad \mathbf{K}_{(1,3)} = \begin{bmatrix} 0 & 0 \\ 0 & -1 \end{bmatrix}, \quad \mathbf{K}_{(2,3)} = \begin{bmatrix} 0 & 0.0000 \\ 0 & -1.5555 \end{bmatrix}. \tag{4.2}$$

The resulting one-path-dependent controller is optimal (up to the third digit below the decimal point) in the sense that no finite-path-dependent linear dynamic output feedback controller achieves the disturbance attenuation level 0.833. This controller is applied as follows: For $t = 0$, use $\mathbf{K}_{(3,1)}$ if $\theta(0) = 1$, use $\mathbf{K}_{(1,2)}$ if $\theta(0) = 2$, and use either $\mathbf{K}_{(1,3)}$ or $\mathbf{K}_{(2,3)}$ if $\theta(0) = 3$; for $t > 0$, use $\mathbf{K}_{(\theta(t-1),\theta(t))}$.

It turns out that setting $L = 0$ and $M = 1$ in (3.13) with (3.19) also works and results in a mode-dependent optimal controller with

$$\mathbf{K}_1 = \mathbf{K}_2 = \begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix}, \quad \mathbf{K}_3 = \begin{bmatrix} 0 & 0.0000 \\ 0 & -1.5555 \end{bmatrix}. \tag{4.3}$$

This mode-dependent controller, however, is not optimal under a path-by-path disturbance attenuation criterion—see Example 8.

5. Path-by-path disturbance attenuation. In this section, we formulate a refined disturbance attenuation problem for switched linear systems. The result holds for Markovian jump linear systems as well. We introduce the notion of path-by-path disturbance attenuation that improves upon the uniform disturbance attenuation performance presented in previous sections. It turns out that, under the notion of path-by-path disturbance attenuation, finite-path-dependent controllers can outperform mode-dependent ones—see Examples 7 and 8. We shall use the same notation as in section 3.

DEFINITION 5.1. *If there exist a nonnegative integer M, a positive integer n_K, an indexed family $\Gamma = \{\gamma_{\boldsymbol{i}} : \boldsymbol{i} \in \boldsymbol{\mathcal{M}}_M(\boldsymbol{\Theta})\}$ of positive numbers $\gamma_{\boldsymbol{i}}$, and an indexed family $\{(\mathbf{R}_{\boldsymbol{j}}, \mathbf{S}_{\boldsymbol{j}}) : \boldsymbol{j} \in \boldsymbol{\mathcal{M}}_M^-(\boldsymbol{\Theta})\}$ of pairs of symmetric positive definite matrices $\mathbf{R}_{\boldsymbol{j}}$, $\mathbf{S}_{\boldsymbol{j}} \in \mathbb{R}^{n \times n}$ such that*

$$\text{(5.1a)}\quad \begin{bmatrix}\mathbf{N}_{F,i_M} & \mathbf{0}\\ \mathbf{0} & \mathbf{I}\end{bmatrix}^{\mathrm{T}} \begin{bmatrix}\mathbf{A}_{i_M}\mathbf{R}_{\boldsymbol{i}_-}\mathbf{A}_{i_M}^{\mathrm{T}} - \mathbf{R}_{\boldsymbol{i}_+} & \mathbf{A}_{i_M}\mathbf{R}_{\boldsymbol{i}_-}\mathbf{C}_{1,i_M}^{\mathrm{T}} & \mathbf{B}_{1,i_M}\\ \mathbf{C}_{1,i_M}\mathbf{R}_{\boldsymbol{i}_-}\mathbf{A}_{i_M}^{\mathrm{T}} & \mathbf{C}_{1,i_M}\mathbf{R}_{\boldsymbol{i}_-}\mathbf{C}_{1,i_M}^{\mathrm{T}} - \gamma_{\boldsymbol{i}}\mathbf{I} & \mathbf{D}_{11,i_M}\\ \mathbf{B}_{1,i_M}^{\mathrm{T}} & \mathbf{D}_{11,i_M}^{\mathrm{T}} & -\gamma_{\boldsymbol{i}}\mathbf{I}\end{bmatrix} \times \begin{bmatrix}\mathbf{N}_{F,i_M} & \mathbf{0}\\ \mathbf{0} & \mathbf{I}\end{bmatrix} < \mathbf{0},$$

$$\text{(5.1b)}\quad \begin{bmatrix}\mathbf{N}_{G,i_M} & \mathbf{0}\\ \mathbf{0} & \mathbf{I}\end{bmatrix}^{\mathrm{T}} \begin{bmatrix}\mathbf{A}_{i_M}^{\mathrm{T}}\mathbf{S}_{\boldsymbol{i}_+}\mathbf{A}_{i_M} - \mathbf{S}_{\boldsymbol{i}_-} & \mathbf{A}_{i_M}^{\mathrm{T}}\mathbf{S}_{\boldsymbol{i}_+}\mathbf{B}_{1,i_M} & \mathbf{C}_{1,i_M}^{\mathrm{T}}\\ \mathbf{B}_{1,i_M}^{\mathrm{T}}\mathbf{S}_{\boldsymbol{i}_+}\mathbf{A}_{i_M} & \mathbf{B}_{1,i_M}^{\mathrm{T}}\mathbf{S}_{\boldsymbol{i}_+}\mathbf{B}_{1,i_M} - \gamma_{\boldsymbol{i}}\mathbf{I} & \mathbf{D}_{11,i_M}^{\mathrm{T}}\\ \mathbf{C}_{1,i_M} & \mathbf{D}_{11,i_M} & -\gamma_{\boldsymbol{i}}\mathbf{I}\end{bmatrix} \times \begin{bmatrix}\mathbf{N}_{G,i_M} & \mathbf{0}\\ \mathbf{0} & \mathbf{I}\end{bmatrix} < \mathbf{0},$$

$$\text{(5.1c)}\quad \begin{bmatrix}\mathbf{R}_{\boldsymbol{i}_-} & \mathbf{I}\\ \mathbf{I} & \mathbf{S}_{\boldsymbol{i}_-}\end{bmatrix} \geq \mathbf{0} \quad \left(\textit{and, if } n_K < n, \quad \operatorname{rank}\begin{bmatrix}\mathbf{R}_{\boldsymbol{i}_-} & \mathbf{I}\\ \mathbf{I} & \mathbf{S}_{\boldsymbol{i}_-}\end{bmatrix} \leq n + n_K\right)$$

for all M-paths $\boldsymbol{i} = (i_0, \ldots, i_M) \in \boldsymbol{\mathcal{M}}_M(\boldsymbol{\Theta})$, then an L-path-dependent controller $(\boldsymbol{\mathcal{K}}, \boldsymbol{\Theta}_L)$ (of order n_K) is said to achieve path-by-path disturbance attenuation level Γ *for the system $(\boldsymbol{\mathcal{T}}, \boldsymbol{\Theta})$ whenever it is constructed in the following manner: Choose a nonnegative integer $L \leq M$, symmetric positive definite matrices $\mathbf{X}_{(i_0,\ldots,i_M)_-} \in \mathbb{R}^{(n+n_K)\times(n+n_K)}$, and matrices $\mathbf{K}_{(i_{M-L},\ldots,i_M)} \in \mathbb{R}^{(n_K+m_2)\times(n_K+l_2)}$ such that* (3.13) *holds for all M-paths $(i_0, \ldots, i_M) \in \boldsymbol{\mathcal{M}}_M(\boldsymbol{\Theta})$ with*

$$\text{(5.2)}\quad \mathbf{H}_{(i_0,\ldots,i_M)} = \begin{bmatrix}-\mathbf{X}^{-1}_{(i_0,\ldots,i_M)_+} & \widehat{\mathbf{A}}_{i_M} & \widehat{\mathbf{B}}_{1,i_M} & \mathbf{0}\\ \widehat{\mathbf{A}}_{i_M}^{\mathrm{T}} & -\mathbf{X}_{(i_0,\ldots,i_M)_-} & \mathbf{0} & \widehat{\mathbf{C}}_{1,i_M}^{\mathrm{T}}\\ \widehat{\mathbf{B}}_{1,i_M}^{\mathrm{T}} & \mathbf{0} & -\gamma_{(i_0,\ldots,i_M)}\mathbf{I} & \mathbf{D}_{11,i_M}^{\mathrm{T}}\\ \mathbf{0} & \widehat{\mathbf{C}}_{1,i_M} & \mathbf{D}_{11,i_M} & -\gamma_{(i_0,\ldots,i_M)}\mathbf{I}\end{bmatrix}.$$

The only difference between the synthesis conditions for the uniform disturbance attenuation and path-by-path disturbance attenuation is that, while a single variable γ is used in (3.18) and (3.19) for the former, multiple variables $\gamma_{(i_0,\ldots,i_M)}$ are used in (5.1) and (5.2) for the latter. Suppose that there exists a finite-path-dependent controller synthesis of order $n_K = n$ for $(\boldsymbol{\mathcal{T}}, \boldsymbol{\Theta})$ that achieves a uniform disturbance attenuation level $\gamma_0 > 0$, and that the system of inequalities (3.18) is feasible with $M = M_0$. Then one can improve the closed-loop performance further by obtaining a *path-by-path optimal* controller synthesis through semidefinite programming as follows.

ALGORITHM 5.2.

Step 0. *Set $n_K = n$. Choose $\gamma \geq \gamma_0$, $M \geq M_0$, and $\lambda_{\boldsymbol{i}} > 0$, $\boldsymbol{i} \in \boldsymbol{\mathcal{M}}_M(\boldsymbol{\Theta})$.*

Step 1. *Minimize $\sum_{\boldsymbol{i}\in\boldsymbol{\mathcal{M}}_M(\boldsymbol{\Theta})} \lambda_{\boldsymbol{i}}\gamma_{\boldsymbol{i}}$ subject to* (5.1)*, with the additional constraint $\gamma_{\boldsymbol{i}} \leq \gamma$, for $\boldsymbol{i} = (i_0, \ldots, i_M) \in \boldsymbol{\mathcal{M}}_M(\boldsymbol{\Theta})$.*

Step 2. *Reconstruct $\mathbf{X}_{\boldsymbol{j}}$ from $(\mathbf{R}_{\boldsymbol{j}}, \mathbf{S}_{\boldsymbol{j}})$ via* (3.16) *for all $\boldsymbol{j} \in \boldsymbol{\mathcal{M}}_M^-(\boldsymbol{\Theta})$.*

Step 3. *Solve* (3.13) *with* (5.2) *for all $(i_0, \ldots, i_M) \in \boldsymbol{\mathcal{M}}_M(\boldsymbol{\Theta})$, and obtain a nonnegative integer $L \leq M$ and matrices $\mathbf{K}_{(i_{M-L},\ldots,i_M)}$.*

The path-by-path optimal controller $(\mathbf{K}, \boldsymbol{\Theta}_L)$ resulting from Algorithm 5.2 shall be said to be *M-path Pareto optimal* because of the following property: If $(\mathbf{K}, \boldsymbol{\Theta}_L)$ achieves path-by-path disturbance attenuation level $\{\gamma_{\boldsymbol{i}} \colon \boldsymbol{i} \in \boldsymbol{\mathcal{M}}_M(\boldsymbol{\Theta})\}$, then no M-path-dependent controller can achieve a disturbance attenuation level $\{\tilde{\gamma}_{\boldsymbol{i}} \colon \boldsymbol{i} \in \boldsymbol{\mathcal{M}}_M(\boldsymbol{\Theta})\}$ such that $\tilde{\gamma}_{\boldsymbol{i}} \leq \gamma_{\boldsymbol{i}}$ for all $\boldsymbol{i} \in \boldsymbol{\mathcal{M}}_M(\boldsymbol{\Theta})$ and such that $\tilde{\gamma}_{\boldsymbol{i}} < \gamma_{\boldsymbol{i}}$ for some

$\boldsymbol{i} \in \boldsymbol{\mathcal{M}}_M(\boldsymbol{\Theta})$. In general, different sets of weights $\lambda_{\boldsymbol{i}}$, $\boldsymbol{i} \in \boldsymbol{\mathcal{M}}_M(\boldsymbol{\Theta})$, result in different interpretations of optimality—see Examples 7 and 8—and hence different Pareto optimal path-by-path disturbance attenuation levels—see Example 9.

Example 7. Let us revisit the controlled switched linear system $(\boldsymbol{\mathcal{T}}, \boldsymbol{\Theta})$ considered in Example 4. In this example, we set $\gamma = 10^3$ and $\lambda_{\boldsymbol{i}} = 1$, $\boldsymbol{i} \in \boldsymbol{\mathcal{M}}_M(\boldsymbol{\Theta})$, for Algorithm 5.2. Running Algorithm 5.2 with $M = 0$, it turns out that the mode-dependent controller obtained in Example 4 achieves any path-by-path disturbance attenuation level $\{\gamma_i\}$ satisfying $\gamma_1 > 0$ and $\gamma_2 > 1$. In particular, this mode-dependent controller is γ_1-admissible for $(\boldsymbol{\mathcal{T}}, (1, 1, \dots))$ and γ_2-admissible for $(\boldsymbol{\mathcal{T}}, \{(1, 2, 1, 2, \dots), (2, 2, \dots)\})$ whenever $\gamma_1 > 0$ and $\gamma_2 > 1$. Running Algorithm 5.2 with $M = 1$ leads to $\gamma_{(1,1)} = \gamma_{(2,1)} = 0$ and $\gamma_{(1,2)} = 0.795$, but $\gamma_{(2,2)} = 1.16$, which is greater than one.

However, running Algorithm 5.2 with $M = 2$ leads to a one-path-dependent controller $(L = 1)$ with

$$\mathbf{K}_{(0,1)} = \mathbf{K}_{(1,1)} = \mathbf{K}_{(2,1)} = \begin{bmatrix} 0 & 0 \\ 0 & -1 \end{bmatrix}, \quad \mathbf{K}_{(1,2)} = \begin{bmatrix} 0 & 0 \\ 0 & -1 \end{bmatrix}, \quad \mathbf{K}_{(2,2)} = \begin{bmatrix} 0 & 0 \\ 0 & -3 \end{bmatrix}.$$

This controller is two-path Pareto optimal and achieves any path-by-path disturbance attenuation level $\{\gamma_{\boldsymbol{i}} : \boldsymbol{i} \in \boldsymbol{\mathcal{M}}_2(\boldsymbol{\Theta})\}$ such that $\gamma_{\boldsymbol{i}} > 1$ for $\boldsymbol{i} = (2, 2, 2)$, and $\gamma_{\boldsymbol{i}} > 0$ otherwise. In particular, this one-path-dependent controller is γ_1-admissible for $(\boldsymbol{\mathcal{T}}, \{(1, 1, \dots), (1, 2, 1, 2, \dots)\})$ and γ_2-admissible for $(\boldsymbol{\mathcal{T}}, (2, 2, \dots))$ whenever $\gamma_1 > 0$ and $\gamma_2 > 1$. Clearly, this is an improvement over the path-by-path performance of the mode-dependent controller obtained in Example 4 with $M = 0$. In fact, it is not difficult to see that, in this example, no mode-dependent controller can achieve a path-by-path disturbance attenuation level $\{\gamma_{\boldsymbol{i}} : \boldsymbol{i} \in \boldsymbol{\mathcal{M}}_2(\boldsymbol{\Theta})\}$ such that, say, $\gamma_{\boldsymbol{i}} = 0.01$ for $\boldsymbol{i} \neq (2, 2, 2)$.

Example 8. This example revisits the controlled Markovian jump linear system $(\boldsymbol{\mathcal{T}}, \mathbf{P}, p)$ considered in Example 6. Since $\mathbf{1}(\mathbf{P}^5) = \mathbf{1}$, the Markov chain $(\mathbf{P}, p)$ is irreducible and aperiodic [25]. Let $\pi = [\pi_1 \ \pi_2 \ \pi_3]$ be the unique steady-state distribution of the chain. For each nonnegative integer M, let

$$\lambda_{(i_0,\dots,i_M)} = \pi_{i_0} p_{i_0 i_1} \cdots p_{i_{M-1} i_M}, \quad (i_0, \dots, i_M) \in \boldsymbol{\mathcal{M}}_M(\mathbf{P}, p). \tag{5.3}$$

Then Algorithm 5.2 minimizes the "average steady-state disturbance attenuation level over M-paths," where each M-path $(i_0, \dots, i_M)$ is interpreted as the mode i_M preceded by the path $(i_0, \dots, i_{M-1})$. With $\gamma = \infty$ and $M = 1$, we obtain the one-path-dependent controller $(L = 1)$ given by (4.2). This controller achieves the path-by-path disturbance attenuation level $\{\gamma_{\boldsymbol{i}} : \boldsymbol{i} \in \boldsymbol{\mathcal{M}}_1(\mathbf{P}, p)\}$ where, e.g., $\gamma_{(1,2)} = \gamma_{(1,3)} = \gamma_{(3,1)} = 0.001$ and $\gamma_{(2,3)} = 0.834$; the weighted sum of these disturbance attenuation levels $\gamma_{\boldsymbol{i}}$ is $0.001 + 0.833\pi_2$. On the other hand, the mode-dependent controller given by (4.3) achieves the path-by-path disturbance attenuation level $\{\tilde{\gamma}_{\boldsymbol{i}} : \boldsymbol{i} \in \boldsymbol{\mathcal{M}}_1(\mathbf{P}, p)\}$ where, e.g., $\tilde{\gamma}_{(1,2)} = \tilde{\gamma}_{(3,1)} = 0.001$ and $\tilde{\gamma}_{(1,3)} = \tilde{\gamma}_{(2,3)} = 0.834$. Clearly, the one-path-dependent controller performs better than the mode-dependent controller in terms of average steady-state performance. In fact, it is not difficult to see that, for some chain $(\mathbf{P}, p)$ with (4.1), there does not exist a mode-dependent controller that achieves the average steady-state performance level $0.001 + 0.833\pi_2$.

Example 9. We are to balance the Pendubot [40], a two-link planar robot with revolute joints and actuation at the shoulder, subject to random but bounded delays in the feedback loop from the relative angular position sensor to the actuator. We

use the following linearized model (of order 4) borrowed from [43]:

$$\begin{aligned} x(t+1) &= \mathbf{A}x(t) + \mathbf{B}_1 w(t) + \mathbf{B}_2 u(t), \\ z(t) &= \mathbf{C}_1 x(t) + \mathbf{D}_{11} w(t) + \mathbf{D}_{12} u(t), \\ y(t) &= \mathbf{C}_2 x(t) + \mathbf{D}_{21} w(t); \end{aligned}$$

$$\mathbf{A} = \begin{bmatrix} 0.9992 & 0.0050 & 0.0003 & 0.0000 \\ -0.3369 & 0.9992 & 0.1242 & 0.0003 \\ 0.0008 & 0.0000 & 1.0007 & 0.0050 \\ 0.3263 & 0.0008 & 0.2786 & 1.0007 \end{bmatrix}, \quad \mathbf{B}_1 = \begin{bmatrix} -0.0001 \\ -0.0232 \\ 0.0012 \\ 0.4742 \end{bmatrix}, \quad \mathbf{B}_2 = \begin{bmatrix} 0.0006 \\ 0.2243 \\ -0.0001 \\ -0.0232 \end{bmatrix},$$

$$\mathbf{C}_1 = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix}, \quad \mathbf{D}_{11} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}, \quad \mathbf{D}_{12} = \begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix}, \quad \mathbf{C}_2 = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \end{bmatrix}, \quad \mathbf{D}_{21} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}.$$

The random delays in the feedback loop are modeled as a Markov chain such that the amount of delay at time t is given by $\theta(t) - 1$ if $\theta(t)$ is the state of the chain at time t. If the maximum possible amount of delay is $N - 1$, then the augmented state

$$\hat{x}(t) = \begin{bmatrix} x(t)^{\mathrm{T}} & y(t-1)^{\mathrm{T}} & \cdots & y(t-N+1)^{\mathrm{T}} \end{bmatrix}^{\mathrm{T}}$$

and delayed measurement $\hat{y}(t)$ yield the Markovian jump linear system (of order 14)

$$\begin{aligned} \hat{x}(t+1) &= \mathbf{A}_{\theta(t)} \hat{x}(t) + \mathbf{B}_{1,\theta(t)} w(t) + \mathbf{B}_{2,\theta(t)} u(t), \\ z(t) &= \mathbf{C}_{1,\theta(t)} \hat{x}(t) + \mathbf{D}_{11,\theta(t)} w(t) + \mathbf{D}_{12,\theta(t)} u(t), \\ \hat{y}(t) &= \mathbf{C}_{2,\theta(t)} \hat{x}(t) + \mathbf{D}_{21,\theta(t)} w(t), \end{aligned}$$

where

$$\mathbf{A}_i = \begin{bmatrix} \mathbf{A} & \mathbf{0} & \cdots & \mathbf{0} & \mathbf{0} \\ \mathbf{C}_2 & \mathbf{0} & \cdots & \mathbf{0} & \mathbf{0} \\ \mathbf{0} & \mathbf{I} & \cdots & \mathbf{0} & \mathbf{0} \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ \mathbf{0} & \mathbf{0} & \cdots & \mathbf{I} & \mathbf{0} \end{bmatrix}, \quad \mathbf{B}_{1,i} = \begin{bmatrix} \mathbf{B}_1 \\ \mathbf{D}_{21} \\ \mathbf{0} \\ \vdots \\ \mathbf{0} \end{bmatrix}, \quad \mathbf{B}_{2,i} = \begin{bmatrix} \mathbf{B}_2 \\ \mathbf{0} \\ \mathbf{0} \\ \vdots \\ \mathbf{0} \end{bmatrix},$$

$$\mathbf{C}_{1,i} = \begin{bmatrix} \mathbf{C}_1 & \mathbf{0} & \mathbf{0} & \cdots & \mathbf{0} \end{bmatrix}, \quad \mathbf{D}_{11,i} = \mathbf{D}_{11}, \quad \mathbf{D}_{12,i} = \mathbf{D}_{12}$$

for $i = 1, \ldots, N$, and

$$\begin{bmatrix} \mathbf{C}_{2,1} \\ \mathbf{C}_{2,2} \\ \vdots \\ \mathbf{C}_{2,N} \end{bmatrix} = \begin{bmatrix} \mathbf{C}_2 & \mathbf{0} & \cdots & \mathbf{0} \\ \mathbf{0} & \mathbf{I} & \cdots & \mathbf{0} \\ \vdots & \vdots & \ddots & \vdots \\ \mathbf{0} & \mathbf{0} & \cdots & \mathbf{I} \end{bmatrix}, \quad \begin{bmatrix} \mathbf{D}_{21,1} \\ \mathbf{D}_{21,2} \\ \vdots \\ \mathbf{D}_{21,N} \end{bmatrix} = \begin{bmatrix} \mathbf{D}_{21} \\ \mathbf{0} \\ \vdots \\ \mathbf{0} \end{bmatrix}.$$

The measurements are time-stamped, so the controller perfectly observes $\theta(t)$ at each time t. Let $N = 6$. Let the transition probability matrix $\mathbf{P}$ of the Markov chain be

$$\mathbf{P} = \begin{bmatrix} 0.3 & 0.7 & 0 & 0 & 0 & 0 \\ 0.2 & 0.2 & 0.6 & 0 & 0 & 0 \\ 0.2 & 0.2 & 0.2 & 0.4 & 0 & 0 \\ 0.2 & 0.2 & 0.2 & 0.2 & 0.2 & 0 \\ 0.1 & 0.1 & 0.1 & 0.1 & 0.3 & 0.3 \\ 0.1 & 0.1 & 0.1 & 0.1 & 0.3 & 0.3 \end{bmatrix},$$

where the fact that the controller can always use the most recent measurement is accounted for [42]; the initial distribution p is assumed to be equal to the unique steady-state distribution

$$\pi = \begin{bmatrix} 0.2142 & 0.2999 & 0.2699 & 0.1440 & 0.0504 & 0.0216 \end{bmatrix}.$$

The semidefinite program minimizing the uniform disturbance attenuation level γ subject to (3.18) over $\boldsymbol{i} = (i_0, \ldots, i_M) \in \boldsymbol{\mathcal{M}}_M(\mathbf{P}, p)$ yields approximately $\gamma = 11.1$ for $M = 0$ and $\gamma = 10.6$ for $M \geq 1$. Now running Algorithm 5.2 with $\gamma = 100$, $M = 1$, and $\lambda_{\boldsymbol{i}}$ as in (5.3) yields $\gamma_{\boldsymbol{i}}$, $\boldsymbol{i} \in \boldsymbol{\mathcal{M}}_1(\mathbf{P}, p)$, such that $\sum_{\boldsymbol{i} \in \boldsymbol{\mathcal{M}}_1(\mathbf{P},p)} \lambda_{\boldsymbol{i}} \gamma_{\boldsymbol{i}} = 9.96$, where, if $\boldsymbol{\Lambda} = (\lambda_{(i,j)})$ and $\boldsymbol{\Gamma} = (\gamma_{(i,j)})$, then

$$\boldsymbol{\Lambda} = \begin{bmatrix} 0.0643 & 0.1499 & 0 & 0 & 0 & 0 \\ 0.0600 & 0.0600 & 0.1799 & 0 & 0 & 0 \\ 0.0540 & 0.0540 & 0.0540 & 0.1080 & 0 & 0 \\ 0.0228 & 0.0228 & 0.0228 & 0.0228 & 0.0228 & 0 \\ 0.0050 & 0.0050 & 0.0050 & 0.0050 & 0.0151 & 0.0151 \\ 0.0022 & 0.0022 & 0.0022 & 0.0022 & 0.0065 & 0.0065 \end{bmatrix},$$

$$\boldsymbol{\Gamma} = \begin{bmatrix} 9.52 & 9.56 & 0 & 0 & 0 & 0 \\ 9.48 & 9.52 & 9.39 & 0 & 0 & 0 \\ 9.61 & 9.65 & 9.53 & 9.24 & 0 & 0 \\ 10.1 & 9.99 & 9.87 & 9.57 & 10.1 & 0 \\ 17.7 & 17.7 & 17.6 & 17.1 & 10.4 & 10.9 \\ 27.9 & 28.0 & 27.7 & 27.2 & 18.9 & 11.5 \end{bmatrix}.$$

On the other hand, running Algorithm 5.2 with $\gamma = 100$, $M = 1$, and $\lambda_{\boldsymbol{i}} = 1$, $\boldsymbol{i} \in \boldsymbol{\mathcal{M}}_1(\mathbf{P}, p)$, yields the disturbance attenuation levels $\tilde{\gamma}_{\boldsymbol{i}}$, $\boldsymbol{i} \in \boldsymbol{\mathcal{M}}_1(\mathbf{P}, p)$, such that $\frac{1}{N_1} \sum_{\boldsymbol{i} \in \boldsymbol{\mathcal{M}}_1(\mathbf{P},p)} \tilde{\gamma}_{\boldsymbol{i}} = 10.3$, where N_1 is the cardinality of $\boldsymbol{\mathcal{M}}_1(\mathbf{P}, p)$ and equals 26. If $\widetilde{\boldsymbol{\Gamma}} = (\tilde{\gamma}_{(i,j)})$, then

$$\widetilde{\boldsymbol{\Gamma}} = \begin{bmatrix} 13.3 & 16.9 & 0 & 0 & 0 & 0 \\ 9.90 & 12.9 & 17.7 & 0 & 0 & 0 \\ 7.05 & 8.86 & 12.4 & 16.9 & 0 & 0 \\ 5.74 & 6.75 & 8.84 & 12.0 & 16.0 & 0 \\ 5.11 & 5.80 & 7.05 & 9.09 & 11.9 & 13.5 \\ 5.32 & 5.68 & 6.75 & 8.61 & 11.2 & 12.1 \end{bmatrix}.$$

The two sets of disturbance attenuation levels given by $\boldsymbol{\Gamma}$ and $\widetilde{\boldsymbol{\Gamma}}$ are very different from each other, yet they are both one-path Pareto optimal. □

6. Conclusion. This paper dealt with switched linear systems and Markovian jump linear systems in the discrete-time domain and developed complete conditions for (almost sure) uniform disturbance attenuation and (almost sure) path-by-path disturbance attenuation. These conditions naturally give rise to finite-path-dependent controllers and admit semidefinite programming algorithms for optimal dynamic output feedback controller synthesis. Limitations of these algorithms include that, in the worst case, the computational complexity grows exponentially in the number M of past modes that the optimal controller recalls, and that nonexistence of an admissible controller synthesis is not guaranteed to be correctly determined after a finite amount of computation. These limitations are due to the problem's nature and considered

unavoidable; nevertheless, they will not pose difficulties in most cases because M is usually very small.

There is at least one conceptually important question unanswered in this paper. This question is whether mode-dependent controllers perform as well as finite-path-dependent controllers as long as uniform disturbance attenuation is concerned; a more specific question is whether, given a Markovian jump linear system, there exists a stabilizing mode-dependent controller whenever a finite-path-dependent controller can stabilize the system. Under the notion of path-by-path disturbance attenuation, however, we showed that finite-path-dependent controllers can outperform mode-dependent ones.

The optimal disturbance attenuation example in Example 9 showed that our results provide a new contribution to the study of networked control systems. The proposed controller synthesis techniques are expected to be applicable to other time-delay systems. Related to switched and Markovian jump linear systems are linear parameter-varying systems, where the common design approaches for gain scheduling [5, 2, 3] are similar to those for mode-dependent controllers. A possible future research direction is to investigate if the approach of finite-path-dependent controller synthesis applies to the control of linear parameter-varying systems.

AN APPROXIMATION ALGORITHM FOR THE DISCRETE TEAM DECISION PROBLEM*

RANDY COGILL† AND SANJAY LALL‡

Abstract. In this paper we study a discrete version of the classical team decision problem. It has been shown previously that the general discrete team decision problem is NP-hard. Here we present an efficient approximation algorithm for this problem. For the maximization version of this problem with nonnegative rewards, this algorithm computes decision rules which are guaranteed to be within a fixed bound of optimal.

Key words. team theory, decentralized control, approximation algorithms

1. Introduction.

The problem of decentralized control arises when several decision makers, each with limited information, must make simultaneous cooperative decisions. The fact that multiple decisions are made on the basis of incomplete and differing observations of the overall system state is what sets decentralized control problems apart from conventional control problems. Such problems arise naturally in applications involving sensing and communication networks. An example is detection by multiple sensors in a sensor network [7]. The job of the sensors is to take measurements of the environment and transmit a minimal amount of information to a fusion center which estimates the state of the environment based on the information received from the sensors. Each sensor is faced with a decentralized decision making problem: based on its limited measurement of the environment, it must decide what information it should send to maximize the probability that the fusion center makes a correct estimate.

Marschak was probably the first to study the problem of decentralized decision making. In his work [5], he introduced *team theory* as a framework for studying decision making problems in organizations. The class of problems considered by team theory, called team decision problems, are analogous in some ways to static games. In these problems, the state of the system is chosen randomly according to some specified probability, and each decision maker partially observes the state. Based on their observations, each decision maker chooses an action. The goal is to choose decision rules which maximize the expected value of a reward which is jointly a function of the system state and all actions.

The later work of Radner [6] presented optimality conditions for a class of team decision problems with reward functions which are concave and differentiable in the decision variables. The main result of that work is that, subject to some technical conditions, *person-by-person optimal* policies are globally optimal for such problems.

A set of decision rules is person-by-person optimal if no improvement can be obtained by changing the decision rule for one decision maker while leaving the decision rules for others fixed. A person-by-person optimal policy can be computed by sequentially optimizing the decision rule for each decision maker while leaving the remaining decision rules fixed.

The problems we are interested in have state and action sets which are finite, so the results regarding global optimality of person-by-person optimal policies do not apply. In fact, the problems that we consider may have many person-by-person optimal policies, and there may exist a person-by-person optimal policy which is quite poor compared to the globally optimal policy. Although problems with finite state and action spaces were presented in the original work by Marschak [5], no positive results regarding computation of optimal policies for these problems followed. Tsitsiklis showed in [8] that the general team decision problem with finite state and action spaces is NP-hard, explaining the lack of positive results for this problem. Another recent paper which considers the discrete team decision problem is [9]. In that paper, the authors consider problems with finite state and action spaces and reward functions which are *multimodular* in the decision variables. Multimodularity of functions on discrete spaces is analogous to concavity of functions on continuous spaces. The authors attempt to use multimodularity to extend the results of Radner to discrete problems. They show that necessary and sufficient optimality conditions are not assured by multimodularity, but this property still can be exploited when searching for optimal policies.

Since it is highly unlikely that an algorithm exists which can efficiently compute optimal solutions to the general team decision problem, this leads us to ask if an efficient algorithm exists which can compute acceptable suboptimal solutions. Many problems, although NP-hard, admit efficient *approximation algorithms* which produce solutions guaranteed to be within a fixed bound of optimal [1]. In this paper we present an approximation algorithm for the team decision problem. Specifically, the contributions of this paper are the following:

- For the general team problem with two decision makers, we present an algorithm that runs in $\mathcal{O}(|Y_1||Y_2||U_1||U_2|)$ time. When the objective is to maximize a nonnegative reward function, this algorithm computes a decentralized policy guaranteed to be within a factor of $1/\min\{|U_1|, |U_2|\}$ of optimal. Here, $|Y_1|, |Y_2|$ are the number of states and $|U_1|, |U_2|$ are the number of actions associated with decision makers 1 and 2. Even the special case with $\min\{|U_1|, |U_2|\} = 2$ is still NP-hard, and in this case we obtain a $1/2$ approximation factor.
- We consider the class of team decision problems with two decision makers and multimodular reward functions, as in [9]. We show that this special case is still NP-hard, although the presence of multimodularity leads to a significantly tighter approximation ratio of $1/2 - 1/(2\max\{|U_1|, |U_2|\})$ for our algorithm.

An outline of this paper is as follows. In section 2, we introduce the general discrete team decision problem and provide a proof that this problem is NP-hard. In section 3, we present an approximation algorithm for the general team decision problem and prove an approximation ratio for this algorithm. In section 4, we consider a special class of team decision problems with multimodular cost functions. In this section, we show that this class of problems is still NP-hard, but the approximation ratio for our algorithm is significantly tighter on these problems.

2. Problem formulation and complexity. In this section we will present the TEAM DECISION PROBLEM (TDP), the problem which is the subject of this paper. Before presenting the formal definition, we will briefly describe this problem in words. The problem is essentially a feedback control problem, where the goal is to choose actions in response to observations with the goal of maximizing some reward. The system is in a state described by the variables (y_1, y_2). After observing the system state, we would like to choose a pair of actions (u_1, u_2) to make the reward $c(y_1, y_2, u_1, u_2)$ as large as possible. However, the actions must be chosen in a decentralized manner. That is, action u_1 is chosen based only on an observation of y_1 and action u_2 is chosen based only on an observation of y_2. Our goal is to choose decision rules $\gamma_1 : Y_1 \to U_1$ and $\gamma_2 : Y_2 \to U_2$ to maximize some measure of total reward. A formal definition of the problem is the following.

TEAM DECISION PROBLEM. *Given finite sets Y_1, Y_2, U_1, U_2 and a nonnegative reward function $c : Y_1 \times Y_2 \times U_1 \times U_2 \to \mathbb{Q}_+$, find decision rules $\gamma_i : Y_i \to U_i$, $i = 1, 2$ which maximize the reward*

$$J(\gamma_1, \gamma_2) = \sum_{y_1, y_2} c(y_1, y_2, \gamma_1(y_1), \gamma_2(y_2)).$$

A few words are in order regarding the formulation given above. First of all, this formulation only considers the case in which two decision makers are choosing actions. In general, we have problems where n decision makers are independently choosing actions $u_1, \ldots, u_n$. It turns out, as we will see shortly, that this problem is computationally intractable even in the two decision maker case. This is the simplest special case which exhibits the inherent computational complexity of this problem, and this case is the focus of this paper. It is worth noting that the approach taken in this paper can be extended to problems with more than two decision makers, although the resulting approximation guarantees degrade exponentially as the number of decision makers increases.

In [8], this problem is posed as maximization of the *expected* reward with respect to some probability mass function $p(y_1, y_2)$. While this formulation may relate more naturally to the applications where this problem is of interest, the formulation in terms of expected reward and the formulation in terms of total reward are essentially equivalent. That is, given any instance of the problem of maximizing expected reward, we can easily modify the reward function to obtain an equivalent instance of maximizing total reward. Conversely, any instance of the problem of maximizing total reward is equivalent to an instance of maximizing expected reward where $p(y_1, y_2)$ is uniform. Therefore, we consider the problem of maximizing total reward simply to reduce the amount of required notation.

Also, it is interesting to note that the corresponding centralized problem is trivial. By the centralized problem, we mean the problem of choosing a policy $\gamma : Y_1 \times Y_2 \to U_1 \times U_2$, to maximize the total reward. This problem is solved by simply choosing the (u_1, u_2) which maximizes $c(y_1, y_2, u_1, u_2)$ for each (y_1, y_2). Although the centralized problem is easy, it was shown in [8] that TDP is NP-hard, even when $|U_1| = |U_2| = 2$.

Here we will present a simple new proof of NP-hardness to keep our treatment self contained. We will do this by also showing that the special case of TDP with $|U_1| = |U_2| = 2$, which we refer to as TDP-2, is NP-hard. Our proof of NP-hardness of TDP-2 involves reducing the problem MAXIMUM CUT [1] to TDP-2. The problem MAXIMUM CUT is the following. As input, we are given an undirected graph $G = (V, E)$. The goal is to partition the set of vertices V into two sets S and $\overline{S}$ so that

the number of edges crossing from vertices in S to vertices in $\overline{S}$ is maximized. Given that MAXIMUM CUT is NP-hard, we have the following theorem.

THEOREM 2.1. *The problem* TDP-2 *is NP-hard.*

Proof. Consider an arbitrary instance of MAXIMUM CUT specified by an undirected graph $G = (V, E)$. We construct a corresponding instance of TDP-2 as follows. Let $Y_1 = Y_2 = V$. Define c_1 as

$$c_1(y_1, y_2, u_1, u_2) = \begin{cases} |V|^2 & \text{if } y_1 = y_2 \text{ and } u_1 = u_2, \\ 0 & \text{otherwise.} \end{cases}$$

Define c_2 as

$$c_2(y_1, y_2, u_1, u_2) = \begin{cases} 1 & \text{if } (y_1, y_2) \in E \text{ and } u_1 \neq u_2, \\ 0 & \text{otherwise.} \end{cases}$$

The goal is to show that the instance of MAXIMUM CUT is solved by finding an optimal policy for the instance of TDP-2 with reward

$$c(y_1, y_2, u_1, u_2) = c_1(y_1, y_2, u_1, u_2) + c_2(y_1, y_2, u_1, u_2).$$

The optimal reward satisfies $|V|^3 < J(\gamma_1^*, \gamma_2^*)$. The lower bound is achieved by choosing any policy satisfying $\gamma_1 = \gamma_2$. Such policies maximize the component of the reward associated with c_1. As long as G contains one edge, we can always achieve reward strictly greater than $|V|^3$. Moreover, if $\gamma_1(i) \neq \gamma_2(i)$ for some i, then $J(\gamma_1, \gamma_2) \leq |V|^3$. This is because, in this case, the component of the reward associated with c_1 is at most $(|V| - 1)|V|^2$ and the component of the reward associated with c_2 is at most $|V|^2$. Hence $\gamma_1^* = \gamma_2^*$.

Given any decision rules γ_1 and γ_2 satisfying $\gamma_1 = \gamma_2$, we obtain a cut for the instance of MAXIMUM CUT by letting

$$v_i \in \begin{cases} S & \text{if } \gamma_1(v_i) = 1, \\ \overline{S} & \text{if } \gamma_1(v_i) = 0 \end{cases}$$

for all $v_i \in V$. The capacity of this cut is exactly $\frac{1}{2}J(\gamma_1, \gamma_2) - \frac{1}{2}|V|^3$. Hence, any algorithm which computes optimal policies for arbitrary instances of TDP-2 in polynomial time can be easily modified to compute optimal cuts for arbitrary instances of MAXIMUM CUT in polynomial time. □

3. An approximation algorithm. Given that TDP is NP-hard, it is highly unlikely that an efficient algorithm for computing optimal policies exists. However, for many NP-hard problems there exist efficient *approximation algorithms* which produce suboptimal solutions which achieve a reward guaranteed to be within some constant factor of optimal. In this section we will give an approximation algorithm for TDP which produces a suboptimal policy in $\mathcal{O}(|Y_1||Y_2||U_1||U_2|)$ operations.

Before presenting our approximation algorithm, we would like to first consider algorithms that produce *person-by-person* optimal policies [6]. A person-by-person optimal policy is a pair of decision rules γ_1, γ_2 for which no improvement can be obtained by modifying γ_1 while leaving γ_2 fixed or by modifying γ_2 while leaving γ_1 fixed. A person-by-person optimal solution can be considered analogous in some ways to a Nash equilibrium. Person-by-person optimal solutions can be computed by choosing initial decision rule γ_1 and γ_2 and alternately maximizing over one decision

TABLE 3.1

For this reward function there is a person-by-person optimal policy with reward $J(\gamma_1, \gamma_2) = 8$. The optimal policy has reward $J(\gamma_1^*, \gamma_2^*) = 400$.

	$y_1 = 0$ $u_1 = 0$	$y_1 = 0$ $u_1 = 1$	$y_1 = 1$ $u_1 = 0$	$y_1 = 1$ $u_1 = 1$
$y_2 = 0$ $u_2 = 0$	2	1	1	2
$y_2 = 0$ $u_2 = 1$	1	100	100	1
$y_2 = 1$ $u_2 = 0$	1	100	100	1
$y_2 = 1$ $u_2 = 1$	2	1	1	2

rule while leaving the other decision rule fixed until no more improvement is obtained. For discrete problems, this process will terminate in a finite number of iterations.

For problems with rewards which are continuous, differentiable, and concave in the variables u_1 and u_2, it was shown that person-by-person optimality implies global optimality [6]. This is probably the best-known result for team decision problems. It is natural, then, to believe that person-by-person optimal policies may be acceptable solutions to discrete team decision problems. The purpose for considering person-by-person optimal solutions here is to show that, in fact, person-by-person optimal solutions may achieve a reward which is arbitrarily far from the globally optimal reward in discrete problems.

Consider the problem instance with the reward function given in Table 3.1. For this instance, consider the policy $\gamma_1(0) = 0$, $\gamma_1(1) = 1$, $\gamma_2(0) = 0$, $\gamma_2(1) = 1$. This policy is person-by-person optimal and achieves a reward of $J(\gamma_1, \gamma_2) = 8$. However, the optimal policy achieves a reward of $J(\gamma_1^*, \gamma_2^*) = 400$. Here, a person-by-person optimal policy is suboptimal by a factor of 50. Of course, we can modify the example to make the reward achieved by the person-by-person optimal as far from the optimal reward as we like. Therefore, algorithms which start with an arbitrary policy and seek person-by-person optimal solutions cannot produce polices which are within a guaranteed bound of optimal.

We will now present our approximation algorithm for TDP. Roughly speaking, this algorithm first constructs a "marginalized" reward function

$$c_1(y_1, u_1) = \sum_{u_2, y_2} c(y_1, y_2, u_1, u_2),$$

then computes a decision rule $\gamma_1 : Y_1 \to U_1$ which is optimal for this marginalized reward. Then, given γ_1, we compute the decision rule $\gamma_2 : Y_2 \to U_2$ which is optimal with respect to γ_1. Unlike an arbitrary person-by-person optimal policy, this policy is guaranteed to be within a constant factor of optimal, where the factor depends on $|U_1|$ and $|U_2|$. To obtain the tightest suboptimality guarantee, we may first compute γ_2 and then γ_1.

ALGORITHM 3.1. *Assume, without loss of generality, that $|U_1| \geq |U_2|$.*

1. *Let $\gamma_1(y_1) \in argmax_{u_1}\{\sum_{u_2}\sum_{y_2} c(y_1, y_2, u_1, u_2)\}$ for all $y_1 \in Y_1$.*
2. *Let $\gamma_2(y_2) \in argmax_{u_2}\{\sum_{y_1} c(y_1, y_2, \gamma_1(y_1), u_2)\}$ for all $y_2 \in Y_2$.*

If $|U_2| > |U_1|$, then we just compute γ_2 first, followed by γ_1. The approximation guarantee for the previous algorithm is given in the following theorem.

THEOREM 3.2. *For* TDP*, Algorithm* 3.1 *produces a policy* γ_1, γ_2 *with value satisfying*

$$J(\gamma_1, \gamma_2) \geq \frac{1}{\min\{|U_1|, |U_2|\}} J(\gamma_1^*, \gamma_2^*).$$

Proof. Without any loss of generality, here we will assume that $|U_1| \geq |U_2|$. Since $\gamma_1(y_1) \in \operatorname{argmax}_{u_1} \sum_{u_2} \sum_{y_2} c(y_1, y_2, u_1, u_2)$, we have

$$\begin{aligned}\sum_{y_2} \sum_{u_2} c(y_1, y_2, \gamma_1(y_1), u_2) &\geq \sum_{y_2} \sum_{u_2} c(y_1, y_2, \gamma_1^*(y_1), u_2) \\ &\geq \sum_{y_2} c(y_1, y_2, \gamma_1^*(y_1), \gamma_2^*(y_2))\end{aligned}$$

for each $y_1 \in Y_1$. Also, $\gamma_2(y_2) \in \operatorname{argmax}_{u_2} \sum_{y_1} c(y_1, y_2, \gamma_1(y_1), u_2)$, so

$$\sum_{y_1} c(y_1, y_2, \gamma_1(y_1), \gamma_2(y_2)) \geq \frac{1}{|U_2|} \sum_{u_2} \left(\sum_{y_1} c(y_1, y_2, \gamma_1(y_1), u_2) \right)$$

for each $y_2 \in Y_2$. Therefore, the reward achieved by policy γ_1, γ_2 satisfies

$$\begin{aligned}\sum_{y_1} \sum_{y_2} c(y_1, y_2, \gamma_1(y_1), \gamma_2(y_2)) &\geq \sum_{y_2} \left(\frac{1}{|U_2|} \sum_{u_2} \sum_{y_1} c(y_1, y_2, \gamma_1(y_1), u_2) \right) \\ &= \frac{1}{|U_2|} \sum_{y_1} \left(\sum_{y_2} \sum_{u_2} c(y_1, y_2, \gamma_1(y_1), u_2) \right) \\ &\geq \frac{1}{|U_2|} \sum_{y_1} \sum_{y_2} c(y_1, y_2, \gamma_1^*(y_1), \gamma_2^*(y_2)). \qquad \square\end{aligned}$$

Although the approximation guarantee degrades as the number of available decisions increases, we must keep in mind that even TDP-2 is NP-hard, and in this case we obtain an approximation factor of 1/2.

It is worth noting that Algorithm 3.1, and consequently the proof of Theorem 3.2, has an alternate interpretation in terms of *randomized* decision rules. In this interpretation, γ_2 is initially set to be the randomized decision rule which selects actions randomly according to a uniform distribution, regardless of the value of y_2. We then choose γ_1 to be the decision rule which is optimal with respect to this randomized γ_2. Finally, the randomized γ_2 is replaced with the decision rule which is optimal with respect to the chosen γ_1. While this interpretation of Algorithm 3.1 is slightly more complex conceptually, this interpretation can be used to simplify the proof of Theorem 3.2.

We can show that the bound is tight for this algorithm, and it is achieved on a simple example with $|U_1| = |U_2| = |Y_1| = |Y_2| = 2$. Consider the reward function given in Table 3.2. Here, ϵ is some arbitrarily small constant which is simply introduced to avoid any ambiguity associated with adding a tie-breaking mechanism into the algorithm. The policy produced by the algorithm, $\gamma_1(0) = 0$, $\gamma_1(1) = 0$, $\gamma_2(0) = 1$, $\gamma_2(1) = 1$, achieves $J(\gamma_1, \gamma_2) = 2 + 2\epsilon$. This is true regardless of which variables we

TABLE 3.2
The bound in Theorem 3.2 *is tight for this reward function.*

	$y_1 = 0$ $u_1 = 0$	$y_1 = 0$ $u_1 = 1$	$y_1 = 1$ $u_1 = 0$	$y_1 = 1$ $u_1 = 1$
$y_2 = 0$ $u_2 = 0$	1	0	0	1
$y_2 = 0$ $u_2 = 1$	0	1	$1 + \epsilon$	0
$y_2 = 1$ $u_2 = 0$	0	1	1	0
$y_2 = 1$ $u_2 = 1$	$1 + \epsilon$	0	0	1

choose to marginalize over first. However, the optimal policy $\gamma_1(0) = 0$, $\gamma_1(1) = 1$, $\gamma_2(0) = 0$, $\gamma_2(1) = 1$ achieves $J(\gamma_1^*, \gamma_2^*) = 4 + \epsilon$. Since ϵ can be chosen arbitrarily small, the ratio between the reward achieved by the computed policy and optimal policy can be made arbitrarily close to 1/2. Similar examples can be constructed for larger values of $|U_1|$ and $|U_2|$.

It is worth noting that the policy constructed by Algorithm 3.1 in the previous example is person-by-person optimal. This means that the bound in Theorem 3.2 is still tight even for person-by-person optimal policies obtained by iterating over decision rules using the decision rules produced by Algorithm 3.1 as a starting point.

4. Approximation ratio for multimodular rewards. In this section we consider a class of team decision problems with specially structured rewards and show that our algorithm achieves a tighter approximation ratio on these problems. The problems that we consider here can be thought of as the discrete counterpart of the problems considered by Radner [6]. In particular, Radner considered problems with rewards which are continuous, differentiable, and concave in the decision variables. It was shown that globally optimal policies can be easily computed for these problems. Here we consider rewards which are *multimodular* in discrete decision variables. Multimodularity is an extension of the notion of convexity to functions of discrete variables. Discrete team decision problems with multimodular rewards were studied previously in [9]. The authors attempt to use multimodularity to extend the results of Radner to discrete problems. They show that necessary and sufficient optimality conditions are not assured by multimodularity, but this property still can be exploited when searching for optimal policies. Here we show the class of problems with multimodular rewards is still NP-hard. However, the presence of multimodularity improves the approximation ratio to $1/2 - 1/(2\max\{|U_1|, |U_2|\})$ for the algorithm presented in the previous section. Combining this with the bound proven in the last section, this gives a bound of 1/3 in the worst case which only *improves* as the sizes of U_1 and U_2 increase.

The concept of multimodularity was introduced by Hajek in [2]. In that paper, multimodularity is defined in terms of local properties of a function and the definition we give below is proven later to be a property equivalent to multimodularity. However, here we do not use most of the theory developed for multimodular functions. We use the definition below because it most clearly relates to convexity.

DEFINITION 4.1. *A function $f : \mathbb{Z}^n \to \mathbb{R}$ is said to be* multimodular *iff there exists a concave function $g : \mathbb{R}^n \to \mathbb{R}$ such that $f(x) = g(x)$ for all $x \in \mathbb{Z}^n$.*

It is worth noting that in the existing literature, multimodular functions are typically defined as discrete functions which coincide with *convex* functions. Since

we do not know of a corresponding term for discrete functions which coincide with concave functions, we simply refer to these as multimodular as well. Also, throughout this section we consider functions which are defined on some subset $S \subset \mathbb{Z}^n$. When we say that such a function is multimodular, we mean that there is some concave function which coincides with f everywhere on S.

We can now describe the class of reward functions that we consider in this section. Specifically, we consider rewards $c : Y_1 \times Y_2 \times U_1 \times U_2$ such that for each $y_1 \in Y_1$ and $y_2 \in Y_2$, $c(y_1, y_2, u_1, u_2)$ is multimodular in u_1 and u_2. To make this statement precise, we have $U_1 = \{1, \ldots, |U_1|\}$ and $U_2 = \{1, \ldots, |U_2|\}$. We refer to this class of problems as TDP-M. We can make the following claim regarding the complexity of TDP-M.

THEOREM 4.2. *The problem* TDP-M *is NP-hard.*

Proof. The show this, we just need to show that every instance of TDP-2 is an instance of TDP-M. This is done by showing any function $f : \{0,1\} \times \{0,1\} \to \mathbb{R}$ is multimodular.

For some function $f : \{0,1\} \times \{0,1\} \to \mathbb{R}$, suppose that $f(0,0) + f(1,1) \leq f(0,1) + f(1,0)$. We can define the following piecewise affine continuation on $[0,1] \times [0,1]$:

$$g(x_1, x_2) = \begin{cases} (1-x_1-x_2)f(0,0) + x_1 f(1,0) + x_2 f(0,1) & \text{for } x_1 + x_2 \leq 1, \\ (1-x_2)f(1,0) + (1-x_1)f(0,1) + (x_1+x_2-1)f(1,1) & \text{for } x_1 + x_2 > 1. \end{cases}$$

Verifying that this function is concave on $[0,1] \times [0,1]$ is somewhat tedious, but straightforward. If $f(0,0) + f(1,1) > f(0,1) + f(1,0)$, then we define g as

$$g(x_1, x_2) = \begin{cases} (1-x_2)f(0,0) + (x_2-x_1)f(0,1) + x_1 f(1,1) & \text{for } x_1 \leq x_2, \\ (1-x_1)f(0,0) + (x_1-x_2)f(1,0) + x_2 f(1,1) & \text{for } x_1 > x_2, \end{cases}$$

which is concave on $[0,1] \times [0,1]$. □

Now that we have established that TDP-M is NP-hard, our goal is to show that our algorithm has a tighter approximation ratio for these problems. To ensure the tightest approximation ratio for this class of problems, we make one very minor change to the algorithm.

ALGORITHM 4.3. *Assume, without loss of generality, that* $|U_2| \geq |U_1|$.

1. *Let* $\gamma_1(y_1) \in \operatorname{argmax}_{u_1} \{\sum_{u_2} \sum_{y_2} c(y_1, y_2, u_1, u_2)\}$ *for all* $y_1 \in Y_1$.
2. *Let* $\gamma_2(y_2) \in \operatorname{argmax}_{u_2} \{\sum_{y_1} c(y_1, y_2, \gamma_1(y_1), u_2)\}$ *for all* $y_2 \in Y_2$.

The only difference between this algorithm and Algorithm 3.1 is the order in which the decision rules are computed. As we saw previously, the approximation ratio depends on the number of decisions available to the decision rule which is computed second. For the approximation ratio proven in Theorem 3.2, the quality of the approximation degrades with the number of decisions. For the approximation ratio proven in this section, the quality of the approximation *improves* with the number of decisions.

Before proving approximation ratio for TDP-M, we first need to establish several properties of multimodular functions of a single variable.

LEMMA 4.4. *A function* $f : \mathbb{Z} \to \mathbb{R}$ *is multimodular iff*

$$f(x_2) \geq \frac{x_3 - x_2}{x_3 - x_1} f(x_1) + \frac{x_2 - x_1}{x_3 - x_1} f(x_3)$$

for any $x_1 \leq x_2 \leq x_3$.

Proof. If the inequality is violated for some x_1, x_2, and x_3, then clearly it is violated for any $g : \mathbb{R} \to \mathbb{R}$ which coincides with f. Conversely, if the inequality holds for all $x_1 \le x_2 \le x_3$, then it's easy to verify that the piecewise affine continuation of f,

$$g(x) = (\lceil x \rceil - x) f(\lfloor x \rfloor) + (x - \lfloor x \rfloor) f(\lceil x \rceil),$$

is concave. Here, $\lfloor x \rfloor$ denotes the largest integer less than or equal to x and $\lceil x \rceil$ denotes the smallest integer strictly greater than x. □

When proving Theorem 3.2 in the previous section, we used the fact that the sum of a set of nonnegative numbers is an upper bound on the maximum of these numbers. The key to obtaining a tighter approximation ratio for multimodular rewards is to use the fact that the gap between these two quantities can be quite large when the set of numbers corresponds to the values taken by a multimodular function. This is stated precisely in the following theorem.

THEOREM 4.5. *Suppose $f : \{1, \dots, N\} \to \mathbb{R}_+$ is multimodular. Then*

$$\sum_{i=1}^{N} f(i) \ge \frac{N-1}{2} f(j)$$

for all $j \in \{1, \dots, N\}$.

Proof. Let k be such that $f(k) \ge f(j)$ for all $j \in \{1, \dots, N\}$. We just need to show that $\sum_{i=1}^{N} f(i) \ge \frac{N-1}{2} f(k)$. Since $f(1) \ge 0$ and $f(N) \ge 0$, Lemma 4.4 gives

$$f(i) \ge \frac{i-1}{k-1} f(k) \quad \text{for all } 1 \le i \le k,$$
$$f(i) \ge \frac{N-i}{N-k} f(k) \quad \text{for all } k \le i \le N.$$

If $k = 1$ or $k = N$, we just have one of these inequalities for all $1 \le i \le N$. Using these inequalities,

$$\begin{aligned}\sum_{i=1}^{N} f(i) &\ge \sum_{i=1}^{k} \frac{i-1}{k-1} f(k) + \sum_{k+1}^{N} \frac{N-i}{N-k} f(k) \\ &= \frac{1}{k-1} \left(\frac{1}{2} k(k-1) \right) f(k) + \frac{1}{N-k} \left(\frac{1}{2} (N-k)(N-k-1) \right) f(k) \\ &= \frac{N-1}{2} f(k). \qquad \square\end{aligned}$$

We can now prove the main result of this section.

THEOREM 4.6. *For* TDP-M*, Algorithm* 4.3 *produces a policy γ_1, γ_2 with value satisfying*

$$J(\gamma_1, \gamma_2) \ge \left(\frac{1}{2} - \frac{1}{2 \max\{|U_1|, |U_2|\}} \right) J(\gamma_1^*, \gamma_2^*).$$

Proof. Without any loss of generality, here we will assume that $|U_2| \ge |U_1|$. In the proof of Theorem 3.2, we use the fact that

$$\sum_{u_2} c(y_1, y_2, \gamma_1^*(y_1), u_2) \ge c(y_1, y_2, \gamma_1^*(y_1), \gamma_2^*(y_2)). \tag{4.1}$$

For any fixed y_1 and y_2, $c(y_1, y_2, \gamma_1^*(y_1), u_2)$ is multimodular in u_2. Therefore, we can use Theorem 4.5 to strengthen inequality (4.1) to

$$\sum_{u_2} c(y_1, y_2, \gamma_1^*(y_1), u_2) \geq \frac{|U_2| - 1}{2} c(y_1, y_2, \gamma_1^*(y_1), \gamma_2^*(y_2)).$$

This gives us the bound

$$\begin{aligned}
\sum_{y_1}\sum_{y_2} c(y_1, y_2, \gamma_1(y_1), \gamma_2(y_2)) &\geq \sum_{y_2}\left(\frac{1}{|U_2|}\sum_{u_2}\sum_{y_1} c(y_1, y_2, \gamma_1(y_1), u_2)\right) \\
&\geq \frac{1}{|U_2|}\sum_{y_1}\sum_{y_2}\left(\sum_{u_2} c(y_1, y_2, \gamma_1^*(y_1), u_2)\right) \\
&\geq \left(\frac{1}{2} - \frac{1}{2|U_2|}\right)\sum_{y_1}\sum_{y_2} c(y_1, y_2, \gamma_1^*(y_1), \gamma_2^*(y_2)). \qquad \square
\end{aligned}$$

Note that this bound is not tight for the case where $|U_1| = 2$ or $|U_2| = 2$. This is simply because the bound proven in Theorem 4.4 is trivial and never tight when $N = 2$. Of course in this the case, the bound proven in Theorem 3.2 still holds and is tight. With this in mind, the bound in Theorem 4.6 says that the approximation ratio for any instance of TDP-M is at least 1/3, and approaches 1/2 as the sizes of U_1 and U_2 increase.

5. Conclusions. In this paper we presented an approximation algorithm for the discrete team decision problem [8, 9]. We focused on problems involving two decision makers. For the general discrete team decision problem, the approximation ratio for our algorithm depends on the number of actions available to each decision maker. For the case when at least one decision maker chooses between two actions, which is still NP-hard, we have an approximation ratio of 1/2. We then considered a special case of the discrete team decision problem which can be thought of as the discrete counterpart of the problems considered by Radner [6]. We show that this special class of problems is still NP-hard, but the approximation ratio for our algorithm is significantly tighter on these problems.

ELLIPSOIDAL TECHNIQUES FOR REACHABILITY UNDER STATE CONSTRAINTS*

A. B. KURZHANSKI† AND P. VARAIYA†

Abstract. The paper presents a scheme to calculate approximations of reach sets and tubes for linear control systems with time-varying coefficients, bounds on the controls, and *constraints on the state*. The scheme provides tight external approximations by ellipsoid-valued tubes. The tubes touch the reach tubes from the outside at *each point* of their boundary so that the surface of the reach tube is totally covered by curves that belong to the approximating tubes. The result is an exact parametric representation of reach tubes through families of external ellipsoidal tubes. The parameters that characterize the approximating ellipsoids are solutions of ordinary differential equations with coefficients given partly in explicit analytical form and partly through the solution of a recursive optimization problem. The scheme combines the calculation of external approximations of infinite sums and intersections of ellipsoids, and suggests an approach to calculate reach sets of hybrid systems.

Key words. reachability, reach sets, control problems, HJB equations, duality theory

DOI. 10.1137/S0363012903437605

1. Introduction.

Recent activities in automation of real-time processes have renewed interest in the calculation of reach sets $\mathcal{X}(\tau, t_0, x^0)$ of linear controlled systems of the form

$$\dot{x} = A(t)x + B(t)u, \quad \tau \geq t_0. \tag{1}$$

Typically, there are additional constraints. The most difficult calculations are for state constraints, and for hybrid or switched systems in which the state and dynamics are reset [23, 24, 21, 7]. State constraints are considered in this paper. Hybrid systems are treated in a separate paper [17].

Among methods for reach set calculation are those based on ellipsoidal techniques. Most of the early publications in this area, e.g., [1, 2], determined a *single* (such as minimum volume) ellipsoid that externally approximates the reach set at a *single* point in time.

In a series of papers [12, 13, 15, 16] the authors developed a parametrized family of ellipsoidal approximations, both external and internal, which are

- *tight*—no other ellipsoid in the family can be "squeezed" between the reach set and the approximating ellipsoid;
- *exact*—the intersection of the external ellipsoids and the union of the internal ellipsoids equals the reach set; and
- *recursive*—a single differential equation provides parameters that specify ellipsoids which approximate the reach set for *all* times.

†Electronics Research Laboratory, University of California at Berkeley, Berkeley, CA 94720-1770 (kurzhans@eecs.berkeley.edu, varaiya@eecs.berkeley.edu).

The approach in these papers is first to convert the problem of calculating the reach set into an equivalent *optimization* problem; then to show that the corresponding value function satisfies a forward Hamilton–Jacobi–Bellman (HJB) equation; and finally to use convex analysis to approximate the level sets of the value function. The same approach is followed here.

The situation in which (1) contains a disturbance term

$$\dot{x} = A(t)x + B(t)u + C(t)v, \quad \tau \geq t_0,$$

and reachability must be guaranteed independent of the disturbance v, requires consideration of *feedback* control. That situation is treated in [14].

This paper deals with reach tubes for control systems (1), with bounds $u(t) \in \mathcal{P}(t)$ on the control, and state constraints $x(t) \in \mathcal{Y}(t)$. As in the case without state constraints [16], the approximating tubes are generated by ellipsoid-valued maps that satisfy a semigroup property and thus form a generalized dynamical system. The ellipsoidal maps are chosen in a certain class, which can be characterized through ordinary differential equations. But, unlike in [16], these differential equations now contain parameters that are the online solutions of a recursive dual optimization problem. The optimizers of the dual problem are the Lagrange multipliers of the state constraints, and may contain generalized Dirac delta functions [27, 28]. However, simpler equations are obtained if we drop the requirement of tightness (resp., exactness).

Section 2 defines the reachability problem for general nonlinear systems. It formulates the associated optimization problem and shows that its value function satisfies an HJB equation. Section 3 uses convex analysis to characterize the reach sets for linear systems with state constraints in terms of the maximum principle. The state constraints introduce a Lagrange multiplier in the adjoint equation. Section 4 derives a different version of the maximum principle [22] that permits a recursive calculation of the reach sets. Section 5 develops the scheme for ellipsoidal approximations. Section 6 exhibits additional properties of the multipliers. Section 7 works out the example of a double integrator. A brief conclusion is presented in section 8. Additional properties of the multipliers necessary for the proofs are borrowed from previous publications and summarized in the appendix.

2. The reachability problem with state constraints. The controlled system is described by the differential equation,

$$\dot{x} = f(t, x, u), \quad t_0 \leq t \leq \tau, \tag{2}$$

in which the state $x \in \mathbb{R}^n$ and the control $u \in \mathbb{R}^m$ are restricted by

$$u(t) \in \mathcal{P}(t), \qquad x(t) \in \mathcal{Y}(t), \tag{3}$$

for all $t \geq t_0$. Here $\mathcal{P}(t), \mathcal{Y}(t)$ are compact set-valued functions in $\mathbb{R}^m, \mathbb{R}^n$, respectively, continuous in the Hausdorff metric. The initial state is restricted by $x(t_0) \in \mathcal{X}^0$, a compact subset of $\mathbb{R}^n$. The function $f(t, x, u)$ is assumed to ensure uniqueness and uniform extension of solutions to any finite interval of time for any $x(t_0) = x^0$, $u(t) \in \mathcal{P}(t)$, $t \geq t_0$.

Definition 2.1. *Given set-valued* positions $\{t_0, \mathcal{X}^0\}$, $\mathcal{X}^0 \cap \mathcal{Y}(t_0) \neq \emptyset$, *the* reach set *(or "attainability domain")* $\mathcal{X}(\tau, t_0, \mathcal{X}^0)$ at time $\tau > t_0$ *is the set*

$$\mathcal{X}[\tau] = \mathcal{X}(\tau, t_0, \mathcal{X}^0)$$

of all states $x[\tau] = x(\tau, t_0, x^0)$, $x^0 = x(t_0) \in \mathcal{X}(t_0) = \mathcal{X}^0$, *that can be reached at time* τ *by system* (2), *from some* $x^0 \in \mathcal{X}^0$, *using all possible controls* u *that ensure constraints* (3). *The set-valued function* $\tau \mapsto \mathcal{X}[\tau] = \mathcal{X}(\tau, t_0, \mathcal{X}^0)$ *is the* reach tube *from* $\{t_0, \mathcal{X}^0\}$.

The basic problem is simply stated.

Problem 2.1. Calculate the reach sets $\mathcal{X}(\tau, t_0, \mathcal{X}^0), \tau \geq t_0$.

A fairly general approach is to relate reach sets to an optimization problem [15]. This could be done by calculating certain *value functions* that may be selected in several ways. Consider first the value function

$$V(\tau, x) = \min_u \left\{ d^2(x(t_0), \mathcal{X}^0) + \int_{t_0}^{\tau} d^2(x(t), \mathcal{Y}(t))dt \right\}, \tag{4}$$

under the restriction $x(\tau) = x$. Here the minimum is over all measurable functions $u(t) \in \mathcal{P}(t)$, $x(t), t \geq t_0$, is the corresponding trajectory, and

$$d^2(x, \mathcal{X}) = \min\{(x - z, x - z) | z \in \mathcal{X}\}$$

is the square of the distance function $d(x, \mathcal{X})$.

LEMMA 2.1. *The following relation is true:*

$$\mathcal{X}(\tau, t_0, \mathcal{X}^0) = \{x : V(\tau, x) \leq 0\}.$$

This follows from the definition of the reach set $\mathcal{X}(\tau, t_0, \mathcal{X}^0)$, which is thus a *level set* of $V(\tau, x)$.

To state the important semigroup property of the value function, we extend definition (4) to more general boundary conditions, namely,

$$V(\tau, x \mid t_0, V(t_0, \cdot)) = \min_u \left\{ V(t_0, \cdot) + \int_{t_0}^{\tau} d^2(x(t), \mathcal{Y}(t))dt \mid u(\cdot) \in \mathcal{P}(\cdot) \right\},$$

under the restriction $x(\tau) = x$. The function $V(t_0, \cdot)$ is any boundary condition. In (4) the boundary condition is $V(t_0, x) = d^2(x, \mathcal{X}^0)$.

THEOREM 2.1. *The value function* $V(\tau, x)$ *satisfies* the principle of optimality, *which has the semigroup form*

$$V(\tau, x \mid t_0, V(t_0, \cdot)) = V(\tau, x \mid t, V(t, \cdot \mid t_0, V(t_0, \cdot))), \quad t_0 \leq t \leq \tau. \tag{5}$$

These properties are established through conventional arguments [5] that also yield similar properties for reach sets. The solution of the reachability problem can be cast in the form of a solution of the "forward" HJB equation that follows from (5). To develop this approach we further assume that the functions $V(t, x)$ and $\varphi(t, x)$ are *differentiable*.

A standard procedure [5] yields

$$V_t(t, x) + \max\{(V_x(t, x), f(t, x, u)) - d^2(x, \mathcal{Y}(t)) \mid u(t) \in \mathcal{P}(t)\} = 0, \quad t_0 \leq t \leq \tau, \tag{6}$$

with boundary condition $V(t_0, x) = d^2(x, \mathcal{X}^0)$. Here V_t, V_x stand for the partial derivatives of $V(t, x)$. Note that the term $d^2(x, \mathcal{Y}(t)) \neq 0$ only outside the state constraint $\mathcal{Y}(t)$.

An alternative scheme relies on the value function

$$V(\tau, x) = \min_u \{\varphi_0(t_0, x(t_0))\}. \tag{7}$$

The minimum in (7) is over all $u(t) \in \mathcal{P}(t),\ t \in [t_0, \tau]$, under restrictions $x(\tau) = x$ and $\varphi(t, x) \le 1,\ t \in [t_0, \tau]$. We will use this formulation for the case when

$$\varphi_0(t_0, x) = (x - x^0, (X^0)^{-1}(x - x^0))^{1/2},\ X^0 = X^{0\prime} > 0,$$

$$\varphi(t, x) = (x - y(t), (Y(t))^{-1}(x - y(t)))^{1/2},\ Y(t) = Y'(t) > 0,$$

so that the initial condition and the state constraints are ellipsoidal:

$$x(t_0) \in \mathcal{E}(x^0, X^0) = \{x : \varphi_0(t_0, x) \le 1\},$$

$$x(t) \in \mathcal{E}(y(t), Y(t)) = \{x : \varphi(t, x(t)) \le 1,\ \ t \in [t_0, \tau]\}.$$

Once $x(\tau; t_0, x(t_0)) = x(\tau) = x$ is fixed, one may figure out whether $x \in \mathcal{X}(\tau, t_0, \mathcal{X}^0)$ by looking at the value $V(\tau, x)$. Then the respective vector $x(t_0) \in \mathcal{E}(x^0, X^0)$ iff there exists a control $u(t),\ t \in [t_0, \tau]$, that ensures $V(\tau, x) \le 1$, so that $x(\tau) \in \mathcal{X}(\tau, t_0, \mathcal{X}^0)$ iff $V(\tau, x) \le 1$.

Therefore the reach set at time τ is

$$\mathcal{X}(\tau, t_0, \mathcal{X}^0) = \{x \mid V(\tau, x) \le 1\},$$

which is thus a level set of $V(\tau, x)$, and the previously stated *semigroup property* of the value function (the principle of optimality) holds again.

The solution of the reachability problem can again be cast in the form of a solution of the forward HJB equation—now somewhat different from (6). Again assume the functions $V(t, x)$ and $\varphi(t, x)$ are *differentiable*.

Denote

$$\mathcal{H}(t, x, V, u) = V_t(t, x) + (V_x(t, x), f(t, x, u)). \tag{8}$$

LEMMA 2.2. *The formal HJB equation is*

$$\max_{u \in \mathcal{P}(t)} \mathcal{H}(t, x, V, u) = 0 \ \textit{if}\ \varphi(t, x) < 1, \tag{9}$$

and

$$\max_{u \in \mathcal{P}_s(t)} \mathcal{H}(t, x, V, u) = 0 \ \textit{if}\ \varphi(t, x) = 1, \tag{10}$$

with

$$\mathcal{P}_s(t) = \mathcal{P}(t) \cap \{u \mid \mathcal{H}(t, x, \varphi, u) \le 0\}, \tag{11}$$

and with the boundary condition

$$V(t_0, x) = \varphi_0(t_0, x). \tag{12}$$

We sketch a proof of Lemma 2.2.

Together with $\varphi(t, x) < 1$, the principle of optimality (5), with $t_0 = \tau - \sigma$, gives

$$0 = \min_u \{V(\tau - \sigma, x(\tau - \sigma)) - V(\tau, x) \mid u \in \mathcal{P}(t),\ t \in [\tau - \sigma, \tau]\} \tag{13}$$

or

$$\max_{u \in \mathcal{P}(t)} \{\mathcal{H}(t, x, V, u)\} = \mathcal{H}(t, x, V, u^0) = 0. \tag{14}$$

With $\varphi(t,x)=1$ we apply the same principle but only through those controls that do not allow the trajectory to move outside the state constraint. These are

$$\mathcal{P}_s=\{u\in\mathcal{P}(t)\cap\{u\mid\mathcal{H}(t,x,\varphi,u)\le 0\}\}.$$

Let $u^0(t,x)$ be the optimal control for the trajectory $x^0(t)$ that starts at $x(\tau)=x$ and minimizes $\varphi_0(t_0,x(t_0))$ under constraints $\varphi(t,x(t))\le 1,\ t\in[t_0,\tau]$.

Note that with $\varphi(t,x(t))=1$ we have two cases: either $\mathcal{H}(t,x(t),\varphi,u^0)=0$, which means the related optimal trajectory runs along the state constraint boundary, or

$$d\varphi(t,x(t))/dt|_{u=u^0}=\mathcal{H}(t,x(t),\varphi,u^0)<0,$$

so the optimal trajectory departs from the boundary, and for $\sigma>0$ we have $\varphi(t+\sigma,x(t+\sigma))<1$. Relations $\mathcal{H}(t,x(t),\varphi,u^0)\equiv 0$ and (14) allow one to find the control u^0 along the state constraint boundary.

If all the operations in (6), (9), (10) result in smooth functions, then these equations may have a classical solution [5]. Otherwise (9), (10) form a symbolic generalized HJB equation, which has to be described in terms of subdifferentials, Dini derivatives, or their equivalents.

However, the typical situation is that V *is not differentiable*. The treatment of (6), (9), (10) then involves the notion of a generalized "viscosity" solution for these equations or their equivalents [5, 30]. One approach is to use the method of characteristics as developed for this type of equation [3, 4, 30]. But it is a fairly complicated procedure, especially in the nonsmooth case for which the method requires additional refinement. Another approach is to look for the solution through level set methods [29].

However, for the specific "linear-convex" problems of this paper the function $V(t,x)$ is indeed differentiable. Moreover, in this case an effective ellipsoidal technique may be applied, which allows one to bypass calculation of solutions to the HJB equation.

3. Linear-convex systems. Consider the linear system

$$\dot{x}=A(t)x+B(t)u,\quad t_0\le t\le t_1, \tag{15}$$

in which $A(t),B(t)$ are continuous, and the system is completely controllable (see [18]). The control set $\mathcal{P}(t)$ is a nondegenerate ellipsoid, $\mathcal{P}(t)=\mathcal{E}(p(t),P(t))$, and

$$\mathcal{E}(p(t),P(t))=\{u\mid(u-p(t),P(t)(u-p(t)))\le 1\}, \tag{16}$$

with $p(t)\in\mathbb{R}^p$ (the center of the ellipsoid) and the symmetric positive definite matrix function $P(t)\in\mathbb{R}^{p\times p}$ (the shape matrix of the ellipsoid) continuous in t. The *support function* of the ellipsoid is

$$\rho(l\mid\mathcal{E}(p(t),P(t)))=\max\{(l,u)\mid u\in\mathcal{E}(p(t),P(t))\}=(l,p(t))+(l,P(t)l)^{1/2}.$$

The *state constraint* is

$$x(t)\in\mathcal{Y}(t),\quad t\in[t_0,t_1], \tag{17}$$

in which $\mathcal{Y}(t)$ is an ellipsoidal-valued function $\mathcal{Y}(t)=\mathcal{E}(y(t),Y(t))$, $Y(t)=Y'(t)>0, Y\in\mathbb{R}^{n\times n}$, and with $y(t),Y(t)$ absolutely continuous. Lastly, $\mathcal{X}^0=\mathcal{E}(x^0,X^0)$ is also an ellipsoid.

In [12] and [15] it is also assumed that the constraints on the controls and initial values are ellipsoidal, which makes the explanations more transparent. However, these methods are applicable to box-valued constraints as well [15, 8].

LEMMA 3.1. *For the linear system* (15), *with convex-valued restrictions* (3), *the reach set* $\mathcal{X}(\tau, t_0, \mathcal{X}^0)$ *at time* τ *is convex and compact.*

Problem 3.1 for calculating the reach set is now formulated as follows.

Problem 3.1. Calculate the support functions $\rho(l \mid \mathcal{X}(\tau, t_0, \mathcal{X}^0)),\ l \in \mathbb{R}^n$.

This is equivalent to solving the following optimal control problem with state constraints:

$$\rho(l \mid \mathcal{X}(\tau, t_0, \mathcal{X}^0)) = \max(l, x(\tau))$$

$$\text{subject to } x(t_0) \in \mathcal{X}^0,\ u(t) \in \mathcal{P}(t),\ x(t) \in \mathcal{Y}(t),\ t_0 \le t \le \tau.$$

For each vector l the solution to the optimal control problem is attained at the terminal point $x^{(0)}(\tau)$ of an *optimal trajectory* $x^{(0)}(t),\ t \in [t_0, \tau]$, which starts from a point $x^{(0)}(t_0) \in \mathcal{X}^0$ determined throughout the solution process.

We will solve Problem 3.1 by calculating the value function (7), namely,

$$V(\tau, x) = \min_u \{ d(x(t_0), \mathcal{E}(x^0, X^0)) \mid x(\tau, x) = x,$$
$$u(t) \in \mathcal{P}(t),\ x(t) \in \mathcal{E}(y(t), Y(t)),\ t \in [t_0, \tau] \},$$

for system (15), using the techniques of convex analysis [11, 9].

To handle the state constraints $\mathcal{X}[\tau]$, one usually imposes the following *constraint qualification.*

Assumption 3.1. There exist a control $u(t) \in \mathcal{P}(t),\ t \in [t_0, \tau]$, $x^0 \in \mathcal{X}^0$, and $\varepsilon > 0$, such that the trajectory $x[t] = x(t, t_0, x^0) = x(t, t_0, x^0 \mid u(\cdot))$ satisfies

$$x(t, t_0, x^0) + \epsilon \mathcal{B}_n(0) \subset \mathcal{Y}(t),\ t \in [t_0, \tau].$$

Here $\mathcal{B}_n(0) = \{z : (z, z) \le 1,\ \ z \in \mathbb{R}^n\}$. Under Assumption 3.1 this gives

$$V(\tau, x) = (l, x) - \mathbf{\Psi}(\tau, t_0, l),$$

where

$$\mathbf{\Psi}(\tau, t_0, l) = \min\{\Psi(\tau, t_0, l, \Lambda(\cdot)) \mid \Lambda(\cdot)\}, \tag{18}$$

$$\Psi(\tau, t_0, l, \Lambda(\cdot)) = s(t_0, \tau, l \mid \Lambda(\cdot))x^0 + (s(t_0, \tau, l \mid \Lambda(\cdot))X^0 s'(t_0, \tau, l \mid \Lambda(\cdot)))^{1/2}$$
$$+ \int_{t_0}^{\tau} \Big(s(t, \tau, l \mid \Lambda(\cdot))B(t)p(t) + (s(t, \tau, l \mid \Lambda(\cdot))B(t)P(t)B'(t)s'(t, \tau, l \mid \Lambda(\cdot)))^{1/2} \Big) dt$$
$$+ \int_{t_0}^{\tau} d\Lambda(t) y(t) + (d\Lambda(t) Y(t) d\Lambda(t))^{1/2}.$$

Here, $s(t, \tau, l \mid \Lambda(\cdot)),\ t \le \tau$, is the *row-vector* solution to the adjoint equation

$$ds = -sA(t)dt + d\Lambda(t),\ \ s(\tau) = l, \tag{19}$$

and $\Lambda(\cdot) \in \mathbf{V}_n[t_0, \tau]$ is the space of n-dimensional functions of bounded variation on $[t_0, \tau]$. We also used the notation

$$\int_{t_0}^{\tau} (d\Lambda(\cdot) Y(t) d\Lambda(\cdot))^{1/2} = \max \left(\int_{t_0}^{\tau} d\Lambda(t) h(t) \mid h(t) \in \mathcal{E}(0, Y(t)), t \in [t_0, \tau] \right).$$

This is the maximum of a Stieltjes integral over continuous functions $h(t) \in \mathcal{E}(0, Y(t))$. The minimum Ψ over $\Lambda(\cdot)$ is reached because of Assumption 3.1.

A direct consequence of formula (18) is the solution to Problem 3.1.

THEOREM 3.1. *Under Assumption* 3.1, *the support function* $\rho(l \mid \mathcal{X}[\tau])$ *is given by*

$$\rho(l \mid \mathcal{X}[\tau]) = \mathbf{\Psi}(\tau, t_0, l) = \min\{\Psi(\tau, t_0, l, \Lambda(\cdot)) \mid \Lambda(\cdot) \in \mathbf{V}_n[t_0, \tau]\}. \tag{20}$$

Let $\Lambda^{(0)}(\cdot) = \arg\min\{\Psi(\tau, t_0, l, \Lambda(\cdot)) \mid \Lambda(\cdot) \in \mathbf{V}_n[t_0, \tau]\}$ be the minimizer of (20) and let $s^{(0)}[t] = s(t, \tau, l \mid \Lambda^{(0)}(\cdot))$ be the solution to (19) with $\Lambda(\cdot) = \Lambda^{(0)}(\cdot)$.

The application of formula (18) indicates a new approach to the next proposition. Alternate derivations of this approach can be found in [11] and [9, pp. 116–121].

THEOREM 3.2 (the "standard" maximum principle under state constraints). *For Problem* 3.1 *under Assumption* 3.1, *the optimal control* $u^{(0)}(t)$, *initial condition* $x^{(0)}$, *and trajectory* $x^{(0)}[t] = x(t, t_0, x^{(0)} | u^{(0)}(\cdot))$ *must satisfy the "maximum principle"*

$$s^{(0)}[t]B(t)u^{(0)}(t) = \max\{s^{(0)}[t]B(t)u \mid u \in \mathcal{E}(p(t), P(t))\}, \tag{21}$$

and the "maximum conditions"

$$\int_{t_0}^{\tau} (d\Lambda^{(0)}(t)y(t) + (d\Lambda^{(0)}(t)Y(t)d\Lambda^{(0)\prime}(t))^{1/2}) = \int_{t_0}^{\tau} d\Lambda^{(0)}(t)x^{(0)}[t] \tag{22}$$

$$= \max\left\{\int_{t_0}^{\tau} (d\Lambda^{(0)}(t)z(t)) \mid z(t) \in \mathcal{E}(y(t), Y(t))\right\},$$

$$s^{(0)}[t_0]x^{(0)}[t_0] = s^{(0)}[t_0]x^0 + (s^{(0)}[t_0], X^0 s^{(0)}[t_0])^{1/2} = \max\{s^{(0)}[t_0]x \mid x \in \mathcal{E}(x^0, X^0)\}. \tag{23}$$

Here we note that the minimum over $\Lambda(\cdot) \in \mathbf{V}_n[t_0, \tau]$ in (20) may be replaced with the minimum over the pair $\{M(t), \lambda(t)\}$, with $d\Lambda(t) = l'M(t)d\lambda(t)$, in which the $n \times n$ matrix $M(t)$ is continuous, and $\lambda(\cdot) \in \mathbf{V}_1[t_0, \tau]$ is a scalar function of bounded variation. Moreover, $M(t)$ may be chosen within a compact set $\mathcal{C}_0$ of continuous functions. This new form of the multiplier $d\Lambda(t)$ is a result of combining the earlier schemes of [6, 10]. We summarize this result as follows.

LEMMA 3.2. *The multiplier* $\Lambda^{(0)}(t)$ *allows the representation*

$$d\Lambda^{(0)}(t) = l'M^{(0)}(t)d\lambda^{(0)}(t), \tag{24}$$

with $M^{(0)}(\cdot) \in \mathcal{C}_0,\ \lambda^{(0)}(\cdot) \in \mathbf{V}_1[t_0, \tau]$.

Denote by $S_M(t, \tau) = S(t, \tau \mid M(\cdot), \lambda(\cdot))$ the solution of the matrix equation

$$dS = -SA(t)dt + M(t)d\lambda(t),\ \ S(\tau) = I. \tag{25}$$

This is a symbolic expression for the linear differential equation whose solution for fixed τ is

$$S_M(t, \tau) = \exp\left(\int_t^{\tau} A(s)ds\right) - \int_t^{\tau} \left(\exp\int_t^{s} A(\xi)d\xi\right)M(s)d\lambda(s),$$

in which the second integral is a Stieltjes integral.

As in the scheme of [10], the single-valued functional $\Psi(\tau, t_0, l, \Lambda(\cdot))$ may be substituted with the set-valued integral

$$R(\tau, t_0, M(\cdot), \lambda(\cdot), \mathcal{X}^0) = S(t_0, \tau \mid M(\cdot), \lambda(\cdot))\mathcal{E}(x^0, X^0)$$
$$+ \int_{t_0}^{\tau} S(t, \tau \mid M(\cdot), \lambda(\cdot))B(t)\mathcal{E}(p(t), P(t))dt + \int_{t_0}^{\tau} d\lambda(t)M(t)\mathcal{E}(y(t), Y(t))dt, \tag{26}$$

which yields the next result whose analytical form differs from that in [10].

LEMMA 3.3. *The following equalities hold:*

$$\mathcal{X}[\tau] = \cap\{R(\tau, t_0, M(\cdot), \lambda(\cdot), \mathcal{X}^0) \mid M(\cdot), \lambda(\cdot)\}$$
$$= \cap\{R(\tau, t_0, M(\cdot), \lambda(\cdot), \mathcal{X}^0) \mid M(\cdot), \lambda \equiv t\},$$

for $M(\cdot) \in \mathcal{C}_0, \lambda \in \mathbf{V}_1[t_0, \tau]$.

Note that $l'M(t)d\lambda(t) = d\Lambda(\cdot)$ is the Lagrange multiplier responsible for the state constraint, with $M(t)$ continuous in t, and $\lambda(t)$, with bounded variation, responsible for the jumps of the multiplier $\Lambda(\cdot)$. Such properties of the multipliers are due to the linearity of the system and the type of the constraints on u, x, taken in this paper (see [9, 6]). In general, the multipliers responsible for the state constraints may be represented through a measure of general type and therefore may contain singular components. This is not the case, however, in the problems of this paper *due to the next assumption which is now required.*

Assumption 3.2. The multipliers $\Lambda^{(0)}(t), \lambda^{(0)}(t)$ do not have singular components.

LEMMA 3.4. *Assumption* 3.2 *holds if the support function* $\rho(q \mid \mathcal{Y}(t))$ *is absolutely continuous in* t*, uniformly in* $q, (q, q) \leq 1$*, and for each* l *the optimal trajectory for Problem* 3.1 *visits the boundary* $\partial\mathcal{Y}(t)$ *for a finite number of intervals.*

Note that Lemma 3.3 gives the reach set at time τ as an intersection of sets $R(\tau, t_0, M(\cdot), \lambda(\cdot), \mathcal{X}^0)$ parametrized by functions $M(\cdot) \in \mathcal{C}_0$. Theorem 3.1 or Lemma 3.3 may be used to calculate the reach set $\mathcal{X}[\tau]$ *for any fixed time* τ.

However, on many occasions our objective is to recursively calculate the whole tube $\mathcal{X}[\tau], \tau \geq t_0$. This means that while solving Problem 2.1 for increasing values of τ, we want a procedure that does not require one to solve the whole problem "afresh" for each new value of τ, but allows the use of the solutions for previous values.

There is a difficulty here, namely, given $M(\cdot), \lambda(\cdot)$, one may observe that in general, $R(\tau, t_0, M(\cdot), \lambda(\cdot), \mathcal{X}^0) \neq R(\tau, t, M(\cdot), \lambda(\cdot), R(t, t_0, M(\cdot), \lambda(\cdot), \mathcal{X}^0))$, which means R given by (26) does not satisfy the semigroup property. Therefore Theorem 3.2 and Lemmas 3.2 and 3.3 have to be modified to meet the recursion requirements. Such a move would yield a modified version of the maximum principle under state constraints for linear systems that eliminates the last difficulty.

4. The modified maximum principle. To achieve the desired results, in the following sections we shall use some properties related to the structure of the optimal controls and the state constraints. These properties and additional assumptions are summarized in the appendix and are typical of the problems under discussion. They are borrowed from previous investigations.

Starting with Assumptions 3.1 and 3.2 and presuming the conditions of Lemma 3.4 are true, let us first restrict Λ in (24) to satisfy the relation $d\Lambda(t) = l'M(t)d\lambda(t)$, in which $\lambda(t)$ is *absolutely continuous.* According to Property A.1 of the appendix this means $d\Lambda(t) = l'M(t)\eta(t)dt$, and $\eta(t) = d\lambda(t)/dt \equiv 0$ for $t \in T_Y = \{t \mid x_l^{(0)}(t) \in int\mathcal{Y}(t)\}$, when $x_l^{(0)}(t)$ is the optimal trajectory for Problem 3.1, for the given l.

Denoting $L(t) = S^{-1\prime}(t,\tau \mid M(\cdot),\eta(\cdot))M(t)\eta(t)$, we may replace

$$dS/dt = -SA(t) + M(t)\eta(t), \quad S(t_0,t_0 \mid M(\cdot),l(\cdot)) = I, \tag{27}$$

whose solution is $S(t,\tau \mid M(\cdot),l(\cdot))$, with

$$dS_L/dt = -S_L(A(t) - L(t)), \quad S_L(\tau,\tau) = I,$$

whose solution is $S_L(t,\tau)$. Then $S(t,\tau \mid M(\cdot),l(\cdot)) \equiv S_L(t,\tau),\ t \in [t_0,\tau]$.

In this case, $R(\tau,t_0,M(\cdot),\eta(\cdot),\mathcal{X}^0)$ transforms into

$$\mathcal{R}(\tau,t_0,L(\cdot)) = S_L(t_0,\tau)\mathcal{E}(x^0,X^0) + \int_{t_0}^{\tau} S_L(t,\tau)(\mathcal{E}(B(t)p(t),B(t)P(t)B'(t))$$

$$+L(t)\mathcal{E}(y(t),Y(t)))dt = \mathcal{X}(\tau,t_0,L(\cdot),\mathcal{X}^0) = \mathcal{X}_L[\tau],$$

and $\mathcal{X}_L[\tau]$ turns out to be the solution to the differential inclusion

$$\dot{x}(t) \in (A(t) - L(t))x + L(t)\mathcal{E}(y(t),Y(t)) + \mathcal{E}(B(t)p(t),B(t)P(t)B'(t)), \tag{28}$$

$$t \geq t_0, \quad x^0 \in \mathcal{E}(x^0,X^0). \tag{29}$$

Here also the compact set $\mathcal{C}_0$ of functions $M(t)$ transforms into a compact set $\mathcal{C}_{00}$ of functions $L(t)$.

We thus arrive at the following important property, which is similar to those proved in [10].

LEMMA 4.1. *The reach set $\mathcal{X}[\tau]$ is the intersection*

$$\mathcal{X}[\tau] = \cap\{\mathcal{X}_L(\tau,t_0,\mathcal{E}(x^0,X^0)) \mid L(\cdot)\} \tag{30}$$

of the "cuts" or "sections" $\mathcal{X}_L(\tau,t_0,\mathcal{E}(x^0,X^0))$ of the reach tubes (solution tubes) $\mathcal{X}_L(\cdot) = \{\mathcal{X}_L[t] : t \geq t_0\}$ of the differential inclusion (28), (29). *The intersection is over all $L(\cdot) \in \mathcal{C}_{00}$, a compact set of continuous matrix functions $L(t), t \in [t_0,\tau]$.*

A further calculation using convex analysis yields the next formula.

THEOREM 4.1. *The support function*

$$\rho(l \mid \mathcal{X}(\tau,t_0,\mathcal{E}(x^0,X^0))) = \inf\{\rho(l \mid \mathcal{X}_L(\tau,t_0,\mathcal{E}(x^0,X^0))) \mid L(\cdot)\}, \tag{31}$$

with

$$\rho(l \mid \mathcal{X}_L(\tau,t_0,\mathcal{E}(x^{(0)},X^0))) = (l,x_L^\star[t]) + (l,G_L(\tau,t_0)X^0G_L'(\tau,t_0)l)^{1/2} \tag{32}$$

$$+\int_{t_0}^{\tau}(l,G_L(\tau,s)B(s)P(s)B'(s)G_L'(\tau,s)l)^{1/2}ds$$

$$+\int_{t_0}^{\tau}(l,G_L(\tau,s)L(s)Y(s)L'(s)G_L'(\tau,s)l)^{1/2}ds.$$

Here

$$x_L^\star[t] = G_L(t,t_0)x^0 + \int_{t_0}^{t} G_L(t,s)B(s)p(s)ds,$$

and $G_L(\tau,s) = S_L(s,\tau)$ is the transition matrix for the homogeneous system

$$\dot{x} = (A(t) - L(t))x\,; \;\; G_L(t,t) = I, \;\; L(\cdot) \in \mathcal{C}_{00}.$$

The significance of the last result is that in this specific problem the support function of the intersection (30) is equal to the *pointwise infimum* (31) of the support functions rather than to their *infimal convolution* as given by general theory [25].

It is not unimportant to specify when the infimum in (31) is attained; that is, it is actually a minimum. Indeed, it may happen that for a given l, the minimum over $L(\cdot)$ is in the class $\mathcal{C}_{00}$ (this, for example, is the case when $\lambda(t)$ turns out to be absolutely continuous, as in the above). But to ensure the minimum is always reached, we have to broaden the class of functions $L(\cdot)$.

To illustrate how to continue the procedure we will assume the following.

Assumption 4.1. For each $l \in \mathbb{R}^n$, the optimal trajectory $x_l^0(t)$ of Problem 3.1 visits the boundary $\partial\mathcal{Y}(t)$ only during one time interval $[t_1,t_2]$, $t_0 \le t_1$, $t_2 \le \tau$.
(The case of finite or countable collection of such intervals is treated in a similar way.)

Then, instead of the product $M(t)l(t)$, in (27) we must deal with multipliers of the form $\mathcal{M}(t) = M(t)l(t) + M_1\delta(t-t_1) + M_2\delta(t-t_2)$, where M_1, M_2 are $n \times n$ matrices.

By introducing a new multiplier $\mathcal{L}(t) = L(t) + L_1\delta(t-t_1) + L_2\delta(t-t_2)$ under transformation $\mathcal{L}(t) = S^{-1}(t,\tau \mid \mathcal{M}(\cdot))\mathcal{M}(t)$, we shall match the formulas for $R(\tau,t_0,\mathcal{M}(\cdot))$ and its transformed version $\mathcal{R}(\tau,t_0,\mathcal{L}(\cdot))$.

Applying the schemes of [6, 10] to the specific case of this paper, it is possible to rewrite the preceding assertions.

LEMMA 4.2. *The support function*

(33)
$$\rho(l \mid \mathcal{X}[\tau]) = \rho(l \mid \mathcal{X}(\tau,t_0,\mathcal{E}(x^0,X^0))) = \min\{\rho(l \mid \mathcal{X}_{\mathcal{L}}(\tau,t_0,\mathcal{E}(x^0,X^0)) \mid \mathcal{L}(\cdot)\},$$

with

$$\rho(l \mid \mathcal{X}_{\mathcal{L}}(\tau,t_0,\mathcal{E}(x^0,X^0)) = \Phi(l,\mathcal{L}(\cdot),\tau,t_0), \tag{34}$$

and

$$\begin{aligned}\Phi(l,\mathcal{L}(\cdot),\tau,t_0) &= (l,x_*[t]) + (l,\mathcal{G}(\tau,t_0)X^0\mathcal{G}'(\tau,t_0)l)^{1/2} \\ &+ \int_{t_0}^{\tau} (l,\mathcal{G}(\tau,s)B(s)P(s)B'(s)\mathcal{G}'(\tau,s)l)^{1/2}ds \\ &+ \int_{t_0}^{\tau} (l,\mathcal{G}(\tau,s)L(s)Y(s)L'(s)\mathcal{G}'(\tau,s)l)^{1/2}ds \\ &+ \int_{t_0}^{\tau} (l,\mathcal{G}(\tau,s)L_1Y(s)L_1'\mathcal{G}'(\tau,s)l)^{1/2}d\chi(s,t_1) \\ &+ \int_{t_0}^{\tau} (l,\mathcal{G}(\tau,s)L_2Y(s)L_2'\mathcal{G}'(\tau,s)l)^{1/2}d\chi(s,t_2).\end{aligned} \tag{35}$$

Here $\mathcal{G}(\tau, s)$ is the transition matrix for the homogeneous system

$$dx = (A(t) - L(t))xdt - L_1 x d\chi(s, t_1) - L_2 x d\chi(s, t_2),$$

namely,

$$\mathcal{G}(\tau, s) = \exp\left(\int_s^\tau (A(\xi) - L(\xi))dt - \int_s^\tau (L_1 d\chi(s, t_1) + L_2 d\chi(s, t_2))\right),$$

so that

$$x(t) = \mathcal{G}(\tau, t_0)x^0,$$

and $\chi(s, t')$ is the step function,

$$\chi(s, t') \equiv 0, s < t';\ \chi(s, t') \equiv 1, s \geq t',\ d\chi(s, t')/ds = \delta(s - t').$$

The vector $x_*[t]$ in (35) may be described by

$$\begin{aligned} dx_*[t] &= ((A(t) - L(t))x_*[t] + B(t)p(t) + L(t)y(t))dt, \\ -L_1(x_*[t] - y(t))d\chi(s, t_1) &- L_2(x_*[t] - y(t))d\chi(s, t_2), x_*[t_0] = x^0. \end{aligned} \tag{36}$$

Remark 4.1. Note that in the exponent $\mathcal{G}(t, s)$ we have the difference of a Riemann integral and a Riemann–Stieltjes integral. On the other hand, the last two integrals in (35) should be interpreted as Lebesgue–Stieltjes integrals [20, 26]. This does not cause additional difficulty since the multipliers L_1, L_2 are among the optimizers in (33).

A result similar to (30) is all the more true for the sets $\mathcal{X}_{\mathcal{L}}(\tau, t_0, \mathcal{E}(x^0, X^0))$.

COROLLARY 4.1. *The following intersection holds:*

$$\mathcal{X}[\tau] = \mathcal{X}(\tau, t_0, \mathcal{E}(x^0, X^0)) = \cap\{\mathcal{X}_{\mathcal{L}}(\tau, t_0, \mathcal{E}(x^0, X^0)) \mid \mathcal{L}(\cdot)\}.$$

The difference between Lemmas 4.1 and 4.2 is that in the former it is not guaranteed that the boundary $\partial\mathcal{X}[\tau]$ is touched at each point by one of the intersecting sets $\mathcal{X}_L(\tau, t_0, \mathcal{E}(x^0, X^0))$, whereas in the latter the boundary $\partial\mathcal{X}[\tau]$ is indeed touched at each point by one of the sets $\mathcal{X}_{\mathcal{L}}(\tau, t_0, \mathcal{E}(x^0, X^0))$. This is because the minimum in (33) is attained.

Under Assumptions 3.1, 3.2, 4.1, and Assumption A.1 of the appendix, the reasoning above leads to the next result.

LEMMA 4.3. *The reach set $\mathcal{X}[t] = \mathcal{X}(t, t_0, \mathcal{E}(x^0, X^0))$ is a convex compact set in $\mathbb{R}^n$ which evolves continuously in t.*

The boundary of the reach set $\mathcal{X}[t]$ has an important characterization. Consider a point x^* on the boundary $\partial\mathcal{X}[\tau]$ of the reach set $\mathcal{X}[\tau] = \mathcal{X}(\tau, t_0, \mathcal{E}(x^0, X^0))$.[1]

Then there exists a *support vector* z^* such that

$$(z^*, x^*) = \rho(z^* \mid \mathcal{X}[\tau]).$$

Let $\mathcal{L}^0(\cdot)$ be the minimizer for the problem (see (33))

$$\rho(z^* \mid \mathcal{X}[\tau]) = \min\{\Phi(z^*, \mathcal{L}(\cdot), \tau, t_0) \mid \mathcal{L}(\cdot)\} = \Phi(z^*, \mathcal{L}^0(\cdot), \tau, t_0). \tag{37}$$

[1]The boundary $\partial\mathcal{X}[\tau]$ of $\mathcal{X}[\tau]$ may be defined as the set $\partial\mathcal{X}[\tau] = \mathcal{X}[\tau] \setminus \text{int}\mathcal{X}[\tau]$. Under the controllability assumption, $\mathcal{X}[\tau]$ has a nonempty interior, $\text{int}\mathcal{X}[\tau] \neq \emptyset$, $\tau > t_0$.

Then the control $u = u^*(t)$, the initial state $x(t_0) = x^{*0} \in \mathcal{E}(x^0, X^0)$, and the corresponding trajectory $x^*(t)$, along which system (15) is transferred from state $x^*(t_0) = x^{*0}$ to $x(\tau) = x^*$, are specified by the following "modified maximum principle."

THEOREM 4.2 (the modified maximum principle under state constraints). *For Problem* 3.1, *suppose state* x^* *is such that*

$$(z^*, x^*) = \rho(z^* \mid \mathcal{X}[\tau]).$$

Then the control $u^*(t)$, *which steers the system* (15) *from* $x^*(t_0) = x^{*0}$ *to* $x^*(\tau) = x^*$ *under constraints* $u(t) \in \mathcal{E}(p(t), P(t))$, $x(t) \in \mathcal{E}(y(t), Y(t))$ *while ensuring*

$$(z^*, x^*) = \max\{(z^*, x) \mid x \in \mathcal{X}[\tau]\},$$

satisfies the following pointwise "maximum principle" for the control ($s \in [t_0, \tau]$)*:*

$$(38)\quad (z^{*\prime}\mathcal{G}^0(\tau, s)B(s), u^*(s)) = \max_u\{(z^{*\prime}\mathcal{G}^0(\tau, s)B(s), u) \mid u \in \mathcal{E}(p(s), P(s))\}$$

$$= (z^*, \mathcal{G}^0(\tau, s)B(s)p(s)) + (z^*, \mathcal{G}^0(\tau, s)B(s)P(s)B'(s)\mathcal{G}^0(\tau, s)z^*)^{1/2},\ s \in [t_0, \tau],$$

and the "maximum conditions" for the system trajectory (pointwise),

$$(39)\quad (z^{*'}\mathcal{G}^0(\tau, s)\mathcal{L}^0(s), x^*(s)) = \max_p\{(z^{*'}\mathcal{G}^0(\tau, s)\mathcal{L}^0(s), p) \mid p \in \mathcal{E}(y(s), Y(s))\}$$

$$= (z^{*'}\mathcal{G}^0(\tau, s)\mathcal{L}^0(s)y(s)) + (z^*, \mathcal{G}^0(\tau, s)\mathcal{L}^0(s)Y(s)\mathcal{L}^{0\prime}(s)\mathcal{G}^0(\tau, s)z^*)^{1/2},$$

and the initial state,

$$(40)\qquad (z^*, \mathcal{G}^0(\tau, t_0)x^{*0}) = \max\{(z^*, x) \mid x \in \mathcal{G}^0(\tau, t_0)\} = \rho(z^* \mid \mathcal{E}(x^0, X^0))$$

$$= (z^*, \mathcal{G}^0(\tau, t_0)x^0) + (z^*, \mathcal{G}^0(\tau, t_0)X^0\mathcal{G}^{0\prime}(\tau, t_0)z^*)^{1/2}.$$

Here $\mathcal{G}^0(\tau, s)$ *stands for the matrix function* $\mathcal{G}(\tau, s)$ *taken for* $\mathcal{L}^0(s)$*—the minimizer of problem* (37).

The function $h(\tau, s)) = l_*{}'\mathcal{G}^0(\tau, s)B(s)$ is taken right-continuous.[2]

Remark 4.2. Suppose we want to solve Problem 3.1, seeking $\rho(l^*(t) \mid \mathcal{X}[t])$ along a curve $l^*(t), t > t_0$. Then, taking $l^*(t) = l'_*(\mathcal{G}^0)^{-1}(t, s)$, one may observe that the *integrands* in functional $\Phi(l^*(t), \mathcal{L}^0(\cdot), t, t_0)$ of (33)–(35) will be independent of t. This property ensures the existence of a *recursive* computational procedure, as indicated in the next section (see also [15]). The modified maximum principle of this section thus allows a solution in *recursive form.* This is not the case for the standard maximum principle.

We now pass to the construction of ellipsoidal approximations for the reach sets.

[2]In the general case, under Assumption 3.2, the optimal trajectory may visit the smooth boundary of the state constraint for a countable set of closed intervals, and the function $L^0_*(\cdot)$ allows not more than a countable set of discontinuities of the first order.

5. External ellipsoids. Despite the linearity of the system, the direct calculation of reach sets is rather difficult. Among effective methods for such calculations are those that rely on ellipsoidal techniques [12, 15]. Indeed, although the initial set $\mathcal{E}(x^0, X^0)$ and the control set $\mathcal{E}(q(t), Q(t))$ are ellipsoids, the reach set $\mathcal{X}[t] = \mathcal{X}(t, t_0, \mathcal{E}(x^0, X^0))$ will of course *not* generally be an ellipsoid.

As shown in [12, 15], in the absence of state constraints the reach set $\mathcal{X}[t]$ may be approximated both externally and internally by ellipsoids $\mathcal{E}_-$ and $\mathcal{E}_+$, with $\mathcal{E}_- \subseteq \mathcal{X}[t] \subseteq \mathcal{E}_+$. Here we deal only with external approximations, but taken under state constraints.

An approximation $\mathcal{E}(x_+, X_+)$ is said to be *tight* if there exists a vector $z \in \mathbb{R}^n$ such that $\rho(z \mid \mathcal{E}(x_+, X_+)) = \rho(z \mid \mathcal{X}[t])$ (the ellipsoid $\mathcal{E}(x_+, X_+)$ *touches* $\mathcal{X}[t]$ along direction z). We shall look for external approximations that are tight, on one hand, and are also recursively computable, on the other.

In order to apply ellipsoidal techniques to state-constrained problems, recall Lemma 4.1 and Corollary 4.1, which indicate how the reach set $\mathcal{X}[t] = \mathcal{X}(t, t_0, \mathcal{X}^0)$ may be presented as an intersection of reach sets $\mathcal{X}_L$ or $\mathcal{X}_\mathcal{L}$ for the system (28) or (36) *without state constraints*. We first study how to approximate sets $\mathcal{X}_L$ by ellipsoids.

To demonstrate the nature of the procedures suggested in this paper we shall introduce the ellipsoidal technique in two stages. First, transform the system coordinates in (15) from x to z according to the formula $z(t) = S(t, t_0)x(t)$, with

$$dS(t, t_0)/dt = -S(t, t_0)A(t), \quad S(t_0, t_0) = I.$$

Then system (15) and state constraint $x(t) \in \mathcal{Y}(t)$ transform into

(41)
$$\dot{z} = S(t, t_0)B(t)u = B_N(t)u, \quad z(t) \in S(t, t_0)\mathcal{E}(y(t), Y(t)), \; z(t_0) \in S(t, t_0)\mathcal{E}(x^0, X^0),$$

while the constraint on control $u \in \mathcal{P}(t) = \mathcal{E}(p(t), P(t))$ remains the same.

Returning to the *old notation*, we will deal with system

(42)
$$\dot{x} = B(t)u, \; x(t_0) \in \mathcal{E}(x^0, X^0), \; y(t) \in \mathcal{Y}(t).$$

Thus, without loss of generality, in the forthcoming formulas we assume $A(t) \equiv 0$.

Problem 5.1. Given a vector function $l^*(t)$, continuously differentiable in t, find external ellipsoids $\mathcal{E}_{L+}[t] = \mathcal{E}(x_L^*(t), X_L^*(t)) \supset \mathcal{X}_L[t]$ such that *for all* $t \geq t_0$, the equalities

$$\rho(l^*(t) \mid \mathcal{X}_L[t]) = \rho(l^*(t) \mid \mathcal{E}_{L+}[t]) = (l^*(t), x_L^*(t))$$

hold, so that the supporting hyperplane for $\mathcal{X}_L[t]$ generated by $l^*(t)$, namely, the plane $(x - x_L^*(t), l^*(t)) = 0$ which touches $\mathcal{X}_L[t]$ at point $x^*(t)$, is also a supporting hyperplane for $\mathcal{E}_{L+}[t]$ and touches it at the same point.

Remark 5.1. Under Assumption 4.1 for the optimal trajectories $x^{(0)}(\cdot)$ of Problem 3.1 the boundary $\partial\mathcal{X}[\tau]$ of the reach set $\mathcal{X}[\tau]$ consists of three types of points, namely (I) those that are reached by $x^{(0)}(\tau)$ *without having visited the boundary of the state constraint*, then (II) those that are reached by $x^{(0)}(\tau)$ *after having visited the boundary of the state constraint*, and (III) those that lie *on the boundary of the state constraint*. Since case (I) has been investigated in detail in [15] and case (III) is trivial, our present investigation actually deals only with case (II).

Apart from Assumptions 3.1 and 3.2, let us assume in this section that the functions $L(\cdot)$ in what follows do not have any delta function components. (The case when such components are present is treated in the next section.)

The solution to Problem 5.1 is given within the following statement.

THEOREM 5.1. *With $l^*(t)$ given, the solution to Problem* 5.1 *is an ellipsoid $\mathcal{E}^*_{L+}[t] = \mathcal{E}_L(x^*_L(t), X^*_L[t])$, in which*

$$X^*_L[t] = \left(\int_{t_0}^{t} (p_u(t,s) + p_Y(t,s))ds + p_0(t,s)\right) \tag{43}$$

$$\times\left(\int_{t_0}^{t} (p_u(t,s))^{-1} G_L(t,s)B(s)P(s)B'(s)G'_L(t,s)ds\right.$$

$$\left. + \int_{t_0}^{t} (p_Y(t,s))^{-1} G_L(t,s)L_t(s)Y(s){L_t}'(s)G'_L(t,s)ds + p_0^{-1}(t)G_L(t,t_0)X^0G'_L(t,t_0)\right),$$

and

$$p_u(t,s) = (l^*(t), G_L(t,s)P(s)G'_L(t,s)l^*(t))^{1/2}, \tag{44}$$

$$p_Y(t,s) = (l^*(t), G_L(t,s)L_t(s)Y(s)L_tG'_L(t,s)l^*(t))^{1/2},$$

$$p_0(t) = (l(t_0), G_L(t,t_0)X^0G'_L(t,t_0)l(t_0))^{1/2},$$

with $x^*_L(t) = x^\star_L[t]$.

This result follows from [12, 15]. Since the calculations have to be made for all t, the parametrizing functions $p_u(t,s), p_Y(t,s), s \in [t_0,t], p_0(t)$ must also formally depend on t.

In other words, relations (43), (44) need to be calculated "afresh" for each t. It may be more convenient for computational purposes to have them in recursive form. As indicated in [15], in the absence of state constraints this could be done by selecting function $l^*(t)$ in an appropriate way. For the case of state constraints we follow Remark 4.2, arriving at the next assumption.

Assumption 5.1. The function $l^*(t)$ is of the form $l^{*'}(t) = l'_*G_L(t_0,t)$, with $l_* \in \mathbb{R}^n$ given.

Under Assumption 5.1 the function $l^*(t)$ is the solution to the differential equation

$$\dot{l}^* = L'(t)l^*,\ l^*(t_0) = l_*. \tag{45}$$

The tight external ellipsoids to $\mathcal{X}_L(t)$, which are

$$\mathcal{E}(x^*_L(t), X^*_L(t)) \supseteq \mathcal{X}_L(t) \supseteq \mathcal{X}[t],$$

may be described applying the formulas of [15, p. 189] to system (28). Each of these ellipsoids will be an external estimate for $\mathcal{X}[t]$.

But to describe the collection of tight ellipsoids for $\mathcal{X}[t]$ we have to ensure the following property:

$$\rho(l|\mathcal{X}[t]) = \min\{(l, x^*_L(t)) + (l, X^*_{L+}(t)l)^{1/2} \mid L(\cdot) \in \mathcal{C}_{00}\}. \tag{46}$$

Under our assumptions *the minimum over $L(\cdot)$* in (33) *is attained for any $l = l^*(t) = G'_L(t_0,t)l^* \in \mathbb{R}^n$*, the minimizers being denoted as $L^t_*(\cdot) \in \mathcal{C}_{00}$.[3]

[3]The same minimum value is also attained here in classes of functions broader than $\mathcal{C}_{00}$.

But prior to moving ahead we have to investigate the following. Suppose element $L_*^t(s)$ is the minimizer of functional

$$\Phi(G'_L(t_0,t)l_*, L(\cdot), t, t_0) = \mathbf{\Phi}(l_*, L(\cdot), t, t_0).$$

The question is, If we minimize function $\Phi(l_*, L(\cdot), t+\sigma, t_0), \sigma > 0$, over a larger interval $[t_0, t+\sigma]$ than before, will the minimizer $L_*^{t+\sigma}(s)$, for the latter problem, taken within $s \in [t_0, t]$, be the same as the minimizer $L_*^t(s), s \in [t_0, t]$ for $\mathbf{\Phi}(l_*, L(\cdot), t, t_0)$?

The answer to this question is given by the next lemma.

LEMMA 5.1. *Taking $l = l^*(t)$ according to Assumption* 5.1, *suppose $L_*^t(s), s \in [t_0, t]$ and $L_*^{t+\sigma}(s), s \in [t_0, t+\sigma], \sigma > 0$, are the minimizers of functionals $\mathbf{\Phi}(l, L(\cdot), t, t_0)$ and $\mathbf{\Phi}(l, L(\cdot), t+\sigma, t_0)$, respectively. Then*

$$L_*^t(s) \equiv L_*^{t+\sigma}(s), \quad s \in [t_0, t].$$

The proof is achieved by contradiction. Note that under Assumption 5.1 and due to Property A.1 of the appendix we may always take $L(t) \equiv 0$ when $t < \tau_1,\ t > \tau_2$, where τ_1, τ_2 are the points of arrival and departure at the state constraint.

Following Assumption 5.1, we proceed further by selecting $L(\cdot)$ to be the minimizer of functional $\Phi(l_*, L(\cdot), t, t_0)$, namely, we now take $L(s) = L_*^t(s) = L_*(s),\ s \in [t_0, t]$, which depends on l_*, s, but, as indicated in Lemma 5.1, does not depend on t.

Let $G_*(t,s)$ denote the transition matrix for the homogeneous system (45) when $L(t) \equiv L_*(t)$.

Then $p_u(t,s), p_Y(t,s), p_0(t)$ of (44) transform into

$$p_u(t,s) = (l_*, G_*(t_0,s)B(s)P(s)B'(s)G'_*(t_0,s)l_*)^{1/2} = p_u(s), \tag{47}$$

$$p_Y(t,s) = (l_*, G_*(t_0,s)L_*(s)Y(s)L_*{}'(s)G'_*(t_0,s)l_*)^{1/2} = p_Y(s),$$

$$p_0(t) = (l_*, X^0 l_*)^{1/2} = p_0;$$

matrix $X_L^*[t]$ transforms into

$$X_+^*[t] = \left(\int_{t_0}^t (p_u(s) + p_Y(s))ds + p_0\right) \tag{48}$$

$$\times\left(\int_{t_0}^t (p_u(s))^{-1} G_*(t_0,s)B(s)P(s)B'(s)G'_*(t_0,s)ds\right.$$

$$\left.+ \int_{t_0}^t (p_Y(s))^{-1} G_*(t_0,s)L_*(s)Y(s)L_*{}'(s)G'_*(t_0,s)ds + p_0^{-1}X^0\right);$$

and the function $\Phi(l^*(t), L_{*t}(\cdot), t, t_0)$ transforms into

$$\Phi(l_*, L_{*t}(\cdot), t, t_0) \tag{49}$$

$$= (l_*, x^*(t)) + (l_*, X^0 l_*)^{1/2} + \int_{t_0}^t (l_*, G_*(t_0,s)B(s)P(s)B'(s)G'_*(t_0,s)l_*)^{1/2}ds$$

$$+ \int_{t_0}^t (l_*, G_*(t_0,s)L_*(s)Y(s)L'_*(s)G'_*(t_0,s)l_*)^{1/2}ds,$$

with $x_L^*(t)$ transformed into

$$x_+^*[t] = x^0 + \int_{t_0}^t G_*(t_0,s)(B(s)p(s) + L_*(s)y(s))ds.$$

We may now differentiate $X_+^*[t], x_+^*[t]$. According to the appendix, the necessary condition (68) for a jump in $L_*(t)$ is not fulfilled, and therefore $L_*(t) \equiv \mathcal{L}^0(t)$.

Denoting

$$\pi_u(t) = p_u(t)\left(\int_{t_0}^t (p_u(s) + p_Y(s))ds + p_0\right)^{-1},$$

$$\pi_Y(t) = p_Y(t)\left(\int_{t_0}^t (p_u(s) + p_Y(s))ds + p_0\right)^{-1}, \tag{50}$$

and differentiating $X_+^*[t], x^*[t]$, we arrive at

$$\dot{X}_+^*[t] = (\pi_u(t) + \pi_Y(t))X_+^*[t] + (\pi_u(t))^{-1}G_*(t_0,t)B(t)P(t)B'(t)G_*{}'(t_0,t) \tag{51}$$
$$+(\pi_Y(t))^{-1}G_*(t_0,t)L_*(t)Y(t)L_*'(t)G_*{}'(t_0,t),$$

$$\dot{x}_+^*[t] = G_*(t_0,t)B(t)p(t) + L_*(t)y(t), \tag{52}$$

$$X_+^*[t_0] = X^0, \;\; x^*[t_0] = x^0. \tag{53}$$

Returning to the function $l^*(t) = G_L'(t_0,t)l_*$ with $G_L'(t,s) = G_*(t,s)$, we have $X_+[t] = G_*(t,t_0)X_+^*[t]G_*(t,t_0)$ and

$$\dot{X}_+[t] = (A(t) - L_*(t))X_+[t] + X_+[t](A(t) - L_*(t))' + G_*(t,t_0)\dot{X}_+^*[t]G_*(t,t_0), \tag{54}$$

so that

$$\dot{X}_+[t] = -L_*(t)X_+[t] - X_+[t]L_*(t) \tag{55}$$
$$+(\pi_u(t) + \pi_Y(t))X_+[t] + (\pi_u(t))^{-1}B(t)P(t)B'(t) + (\pi_Y(t))^{-1}L_*(t)Y(t)L_*{}'(t)$$

and

$$\dot{x}_+ = -L_*(t)x_+ + B(t)p(t) + L_*(t)y(t).$$

Finally, returning to the case $A(t) \neq 0$, we have

$$\mathbf{X}_+[t] = S(t,t_0)X_+[t]S'(t,t_0), \; \mathbf{x}(t) = S(t,t_0)x_+(t),$$

$$\dot{\mathbf{X}}_+[t] = (A(t) - L_*(t))\mathbf{X}_+[t] + \mathbf{X}_+[t](A(t) - L_*(t)) \tag{56}$$
$$+ (\pi_u(t) + \pi_Y(t))\mathbf{X}_+[t] + (\pi_u(t))^{-1}B(t)P(t)B'(t)$$
$$+ (\pi_Y(t))^{-1}L_*(t)Y(t)L_*{}'(t), \; \mathbf{X}_+[t_0] = X^0,$$

and

$$\dot{\mathbf{x}} = (A(t) - L_*(t))\mathbf{x} + B(t)p(t) + L_*(t)y(t), \; \mathbf{x}(t_0) = x^0. \tag{57}$$

Rewriting $\pi_u(t)$, $\pi_Y(t)$ following schemes of [15, p. 189] for these items (see also Property A.4 of the appendix), we have

$$\pi_u(t) = (l^*(t), B(t)P(t)B'(t)l^*(t))^{1/2}/(l^*(t), X_+^*(t)l^*(t))^{1/2}, \tag{58}$$

$$\pi_Y(t) = (l^*(t), L_*(t)Y(t)L_*'(t)l^*(t))^{1/2}/(l^*(t), X_+^*(t)l^*(t))^{1/2}.$$

Summarizing the results we come to the following.

THEOREM 5.2. *With shape matrix $Y(t)$ of the state constraint being nondegenerate and if, under Assumptions* 3.1, 4.1, *and A.*1, *the multipliers $L_*(t)$ responsible for the state constraint have no jumps ($d\Lambda(t) = \lambda(t)dt$), then the external ellipsoids $\mathcal{E}(\mathbf{x}[t], \mathbf{X}[t]) \supseteq \mathcal{X}[t]$ have the form* (56), (57) *with $\mathbf{X}[t_0] = X^0$, $\mathbf{x}[t_0] = x^0$.*

Moreover, with $l^*(t) = G_*{}'(t_0, t)l_*$, $l_* \in \mathbb{R}^n$, the ellipsoids $\mathcal{E}(\mathbf{x}[t], \mathbf{X}[t])$ touch the set $\mathcal{X}[t]$ along the curve $x^*(t)$ which satisfies the condition

$$(l^*(t), x^*(t)) = \rho(l^*(t) \mid \mathcal{X}[t]),\ t \le \tau_1,\ t \ge \tau_2,$$

so that

$$(l^*(t), x^*(t)) = \rho(l^*(t) \mid \mathcal{X}[t]) = \rho(l^*(t) \mid \mathcal{E}(\mathbf{x}[t], \mathbf{X}[t])). \tag{59}$$

On the state constraint boundary, with $t \in [\tau_1, \tau_2]$, the trajectory which satisfies the first equality of (59) may be uniquely determined by the maximum condition (39).

The overall procedure of calculation for Problem 3.1 starting from a point in the interior of the state constraint is as follows.

(i) Consider an array of initial vectors l_* located on the unit ball $\mathcal{B}(0)$ in $\mathbb{R}^n$. Then for each l_* proceed as follows (possibly, in parallel).

(ii) For each l_* construct the array of external ellipsoids $\mathcal{E}_+[\tau]_{l_*}$ for Problem 3.1 of system (15) *without state constraints* following the explicit formulas of [15].

(iii) Construct the array of ellipsoids $\mathcal{E}(\mathbf{x}[t], \mathbf{X}[t])$, namely,

(iii-a) for a given l_* find related $l^*(t) = l_*G_*(t, t_0)$ and, further on, the related curve $x^{(0)}(t)$ for the reachability problem without state constraints. Note that on the interval $[t_0, \tau_1)$, where $L_*(t) \equiv 0$, we have

$$x^{(0)}(t) = x^*(t) + X_+(t)l^*(t)(l^*(t), X_+(t)l^*(t))^{1/2},$$

where the explicit relations for elements $x^*(t), X_+(t)$ of this formula are indicated in Property A.4 of the appendix. Follow curve $x^{(0)}(t)$ until the state constraint boundary is reached at time, say, τ_1;

(iii-b) for $l^*(\tau_1)$ solve the optimization problem (33) over $L(\cdot)$. Use Lemma A.1 of the appendix for additional information on optimizer $L_*(\cdot)$, taking τ_2 as a parameter which varies within interval $[\tau_1, \tau]$;

(iii-c) given optimizer $L_*(\cdot)$, which depends on the selected l_*, solve equations (56), (57), determining the related external ellipsoid $\mathcal{E}_{l_*}(\mathbf{x}[t], \mathbf{X}[t])$.

(iv) In view of Remark 5.1, the intersection

$$\cap\{\mathcal{E}_+[\tau]_{l_*} | l_* \in \mathcal{B}(0)\} \cap \{\mathcal{E}_{l_*}(\mathbf{x}[t], \mathbf{X}[t]) \mid l_* \in \mathcal{B}(0)\} \cap \mathcal{E}(y(\tau), Y(\tau)) = \mathcal{X}_a[\tau] \supseteq \mathcal{X}[\tau]$$

is an external approximation of $\mathcal{X}[\tau]$. Loosely speaking, the greater is the number of vectors l_* used as starting points of the calculations, the more accurate will be the approximation $\mathcal{X}_a$.

Remark 5.2. If it is not necessary to find the tight external approximations for the exact reach set $\mathcal{X}[\tau]$, but a conservative estimate of $\mathcal{X}[\tau]$ using *only one* ellipsoid would suffice, then there is no need to solve the optimization problem (33) in L, since the ellipsoids $\mathcal{E}(\mathbf{x}[t], \mathbf{X}[t])$, defined by (56), (57), happen to be external estimates of $\mathcal{X}[\tau]$ *for all* $L(\cdot)$. One may single out one of these through some appropriate criterion.

An obviously conservative estimate may also be obtained by intersecting the reach set without state constraints with the ellipsoid that defines the state constraint. The objective of this paper, however, is to indicate the calculation of the *exact reach set under state constraints*, especially when the state constraint produces a reach set different from the one without state constraints.

We now pass to the more general case, in which the multipliers may have delta function components.

6. Generalized multipliers. In this section, Assumptions 3.1 and A.1 and the conditions of Lemma 3.4 are taken to be true together with Assumption 3.2. This allows us to consider ellipsoidal approximations without the additional requirement of Property A.2 in the appendix.

Now functional $\Phi(l, \mathcal{L}(\cdot), \tau, t_0)$ has the form (35), and its minimizer for a given $l = l^*(\tau)$ is of the form

$$\mathcal{L}^0(t) = L^0_*(t) + L^0_1\delta(t-\tau_1) - L^0_2\delta(t-\tau_2)$$

for all $l^*(\tau)$ with $L^0_*(t)$ absolutely continuous and $L^0_*(t) \equiv 0$ whenever $x^*(t) \in \mathrm{int}\mathcal{Y}(t)$. Then the respective transition matrix is $\mathcal{G}(t,s) = \mathcal{G}^0_*(t,s)$ and $l^*(t) = \mathcal{G}^{0\prime}_*(t,s)l^*$.

Here $\mathcal{L}^0(\cdot)$ may be interpreted as the generalized derivative of a generalized Lagrange multiplier $\mathbf{\Lambda^0}(\cdot)$ similar to $\Lambda^0(\cdot)$ of section 3. $\mathbf{\Lambda^0}(\cdot)$ is piecewise absolutely right-continuous, with possible jumps at points τ_1, τ_2 and possible jumps at t_0 and/or τ (when it happens that $t_0 = \tau_1$ and/or $\tau = \tau_2$). $\mathbf{\Lambda^0}(t) \equiv \mathrm{const}$, whenever $x^*(t) \in \mathrm{int}\mathcal{Y}(t)$.

Following the reasoning of the previous section, we may derive equations for the approximating external ellipsoids similar to (56), (57). The necessary prerequisites for such a move are similar to Lemma 5.1 and Theorems 5.1 and 5.2.

Thus, we come to equations for the tight external ellipsoids:

(60)
$$dx^* = ((A(t) - L^0_*(t))x^* + (B(t)p(t) + L^0_*(t)y(t))dt - \sum_{i=1}^{2} L^0_i(x^* - y(t))d\chi_i(t,\tau_i),$$

(61)
$$dX_+[t] = ((A(t) - L^0_*(t))X_+[t] + X_+[t](A'(t) - L^{0\prime}_*(t))dt$$
$$+ \left(\pi_u(t) + \pi_Y(t) + \sum_{i=1}^{k}\pi_i\right)X_+[t]dt + (\pi_u(t))^{-1}B(t)P(t)B'(t)dt$$
$$+(\pi_Y(t))^{-1}L^0_*(t)Y(t)L^{0\prime}_*(t)dt + \sum_{i=1}^{2}\pi_i^{-1}L^0_iY(t)L^{0\prime}_i d\chi(t,\tau_i),$$
$$X_+[t_0] = X^0, \quad x^*(t_0) = x^0.$$

The $\pi_i > 0$ are additional parametrizing coefficients similar to $\pi_Y(t)$.

The last equation may be interpreted as before (see Remark 4.1).

THEOREM 6.1. *Under Assumptions* 3.2, *A*.1, 5.1, *and those of Lemma* 3.4 *with* $l^*(t) = {G_*'}^0(t_0,t)l_*,\ l_* \in \mathbb{R}^n$, *the external ellipsoids* $\mathcal{E}(x^*(t), X_+^*[t]) \supseteq \mathcal{X}[t]$ *have the form* (52), (55) *with* $X_+^*[t_0] = X^0,\ \ x^*(t_0) = x^0$. *One may select the parametrizing coefficients* $\pi_u, \pi_{Y(t)}, p_i$ *so that the ellipsoids* $\mathcal{E}(x^*(t), X_+^*[t])$ *touch set* $\mathcal{X}[t]$ *along the curve* $x^*(t)$, *which satisfies condition* (59).

If the optimal trajectories visit the boundary of the state constraint $m > 1$ times, then the reasoning is the same as in the above, and the sums in (60), (61) will have $2m$ terms.

Remark 6.1. The results of this paper remain true if the state constraint is applied to a system output $z(t) = Tx(t),\ z \in \mathbb{R}^k,\ k < n$, rather than to the whole state vector x. The state constraint $\mathcal{Y}$ is then given by an elliptical cylinder in $\mathbb{R}^n$. The proofs may be achieved either by directly following the scheme of this paper or by substituting the elliptical cylinder with an ellipsoid having $n-k$ axes of size r followed by the limit transition $r \to \infty$.

7. Example. The system is the double integrator:

$$\dot{x}_1 = x_2,\ \ \dot{x}_2 = u,\ \ x(0) = 0, \tag{62}$$

under constraints

$$|u| \le \mu, \quad |x_2| \le \nu. \tag{63}$$

We wish to find the reach set $\mathcal{X}[\tau]$ at time $\tau > 0$.

The state constraint may be treated either directly or as a limit as $\epsilon \to 0$ of the ellipsoid $\varepsilon^2 x_1^2 + x_2^2 \le \nu^2$.

The treatment of this example in [9, p. 119] indicated the following:

1. The boundary of the reach set $\mathcal{X}[\tau]$ at each time τ consists of three types of points as follows:
   (a) points reached without visiting the boundary of the state constraint;
   (b) points reached after visiting the boundary of the state constraint for some time;
   (c) points on the boundary of the state constraint.
2. Each optimal trajectory $x^{(0)}(t)$, for given $l \in \mathbb{R}^2$, visits the state constraint not more than once.
3. The necessary conditions for a jump of the multiplier responsible for the state constraint are not fulfilled, so there are no jumps.
4. Assumption A.1 of the appendix is fulfilled.

Case (1a) is treated according to [15, p. 202], while case (1c) is trivial. Therefore we concentrate on case (1b).

The exact parametric equations for case (1b) may be derived, following [9, pp. 119–121], by minimizing over η the functional

$$\rho(l|\mathcal{X}[\tau]) = \min\left\{\mu\int_0^\tau |s_2(t)|d\xi + \nu\int_0^\tau |\eta(t)|d\xi - (l,x) \mid \eta(\cdot)\right\}, \tag{64}$$

where $s_2(t) = -l_1\xi + l_2 - \int_0^t \eta(\xi)d\xi$ is the solution to the adjoint equation

$$\dot{s_1} = 0,\ \dot{s_2} = -s_1 + \eta(t), s_1(\tau) = l_1, s_2(\tau) = l_2.$$

This gives parametric equations for the boundary $\partial\mathcal{X}[\tau]$:

$$x_1 = -\mu(t_1 - \sigma)^2 + c, \;\; x_2 = \mu\sigma + d, \; \tau_1 \leq \sigma \leq \tau.$$

Here $\tau_1 = \nu/\mu < \tau$ is the first instance when the trajectory reaches the boundary of the state constraint, while σ is a parameter that indicates the instance of τ_2 when the trajectory leaves this boundary. Also $c = \nu(\tau - t_0) - \nu^2/2\mu; d = \nu - \mu\tau$. Here we have used Assumption A.1 of the appendix, which implies that optimizer $\eta^0(t)$ satisfies relations

$$\eta^0(t) \equiv -l_1, \; t \in [\tau_1, \tau_2], \;\; \eta^0(t) \equiv 0, \; t \notin [\tau_1, \tau_2],$$

and $s_1(t) \equiv -l_1$.

A typical trajectory for case (b) is when it reaches the boundary of the state constraint at time τ_1 and then runs along the boundary and leaves it at time τ_2. Later it runs toward the boundary $\partial\mathcal{X}[\tau]$ while staying in the interior of the constraint.

For the interval $[t_0, \tau]$, the adjoint system given above, when written in matrix form (27), is

$$\dot{S} = -SA(t) + M(t)\eta(t). \tag{65}$$

To solve the problem through a numerical procedure involving external ellipsoids, using recursive formula and following section 6, transform the adjoint equation (65) of the above into the modified form

$$\dot{S}_L = -S_L(A(t) - L(t)), S(\tau) = I.$$

Taking $l_* = l_*(0)$, we will have $l_*' M(t)\eta^0(t) = (0,1)\eta^0(t)$ when $t \in [\tau_1, \tau_2]$. This yields $M(t) = M_0(t)$ depending on η^0. Direct calculation then allows one to find for each l_* the relation for the optimizer $L_*(t)$ of (31). This is

$$L_*(t) = S_{M_0}(t)^{-1} M_0(t), \; t \in [\tau_1, \tau_2],$$

with $L_*(t) \equiv 0$ when $t < \tau_1, t > \tau_2$. Here $S_M(t)$ is the solution to (65) with initial condition $S_M(\tau) = I$ and $M(t) \equiv 0, \; t, \tau_1, t > \tau_2$.

Recalling the ellipsoidal equations, we have

$$\dot{X} = (A(t) - L(t))X + X(A(t) - L(t))' \tag{66}$$

$$+(\pi_u(t) + \pi_Y(t))X + \pi_u^{-1}(t)BP(t)B' + \pi_Y^{-1}(t)L(t)Y(t)L(t).$$

Here one should take $L(t) = L_*(t)$ and π_u, π_Y according to (58).

The algorithm for this example involves the following steps:

1. For the given starting direction l_* find time $\tau_1 = \nu/\mu$ of the first exit (i.e., encounter with the boundary of the state constraint).
2. Solve extremal problem (64), determining $l_1 = -\eta^0 = \text{const}$ and l_2, for each $\tau_2 = \sigma \in [\tau_1, \tau]$.
3. Construct the ellipsoidal approximations for the system without constraint $t \leq \tau_1$, taking $L(t) \equiv 0$. Denote these as $\mathcal{E}(0, X_l^+(\tau))$.
4. For each $\tau_2 = \sigma \in [\tau_1, \tau]$ construct the ellipsoidal approximation following (66).

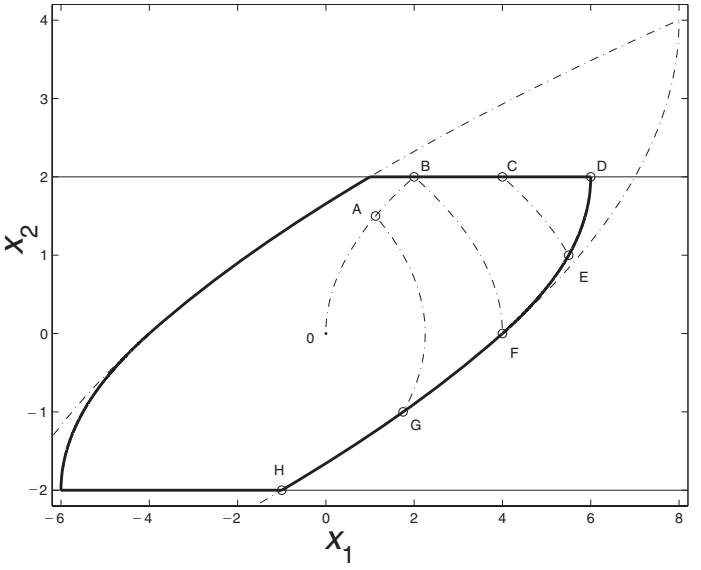

FIG. 1. *Reach set: structure of the boundary.*

The part of the boundary related to case (b) is described by the boundary of the intersection $\cap\{\mathcal{E}(0, X(\tau)) \mid L(\cdot)\}$, where $L(\cdot)$ actually is reduced to the parameter $\sigma = \tau_2$. Denote this as $\mathcal{E}(0, X^+_\sigma(\tau))$.

The total reach set is the intersection of the approximations for each group (a), (b), and (c), namely,

$$\mathcal{X}[\tau] = \mathcal{X}(\tau, 0, 0) = \bigcap_l \mathcal{E}(0, X^+_l(\tau)) \bigcap_\sigma \mathcal{E}(0, X^+_\sigma(\tau)) \bigcap \mathcal{E}(0, Y).$$

Figure 1 shows the structure of the reach set boundary, given here by a thick line. The system trajectory OAG reaches its end point G without visiting the boundary of the state constraint. Point G is attained at time τ. It lies on the reach set boundary of type (a) (see section 7). Trajectory OBF visits the boundary of the state constraint at only one point $\tau_1 = \tau_2 < \tau$. Its end point F is a point of both types (a) and (b). Trajectory OBCE lies on the boundary of the state constraint during the interval $[\tau_1, \tau_2)$ with $\tau_1 < \tau_2 < \tau$, and its end point E lies on the reach set boundary of type (b). Finally, trajectory OBD reaches the boundary of the state constraint at time $\tau_2 < \tau$ and lies on it until the final time τ, so that point D is of both types (b) and (c). Thus, the part of the reach set boundary along points BDEFGH consists of segments BD (of type (c)), DF (of type (b)), and FGH (of type (a)).

Figure 2 shows the structure of the generalized Lagrange multiplier $\eta(t)$ for the case of trajectory $x_2(t)$ of type OBCE shown in the top of the figure. Here $\eta \equiv 0$ on intervals $[0, \tau_1)$ and $[\tau_2, \tau]$ and $\eta \equiv \text{const}$ on $[\tau_1, \tau_2)$. Note that the related trajectory $x_2(t)$ runs along the boundary of the state constraint during the interval $[\tau_1, \tau_2)$, where $\eta(t) \neq 0$. Points τ_1, τ_2 potentially could have δ-functions (indicated by question marks) as components of η. But the necessary conditions for the existence of such components are not fulfilled in this example.

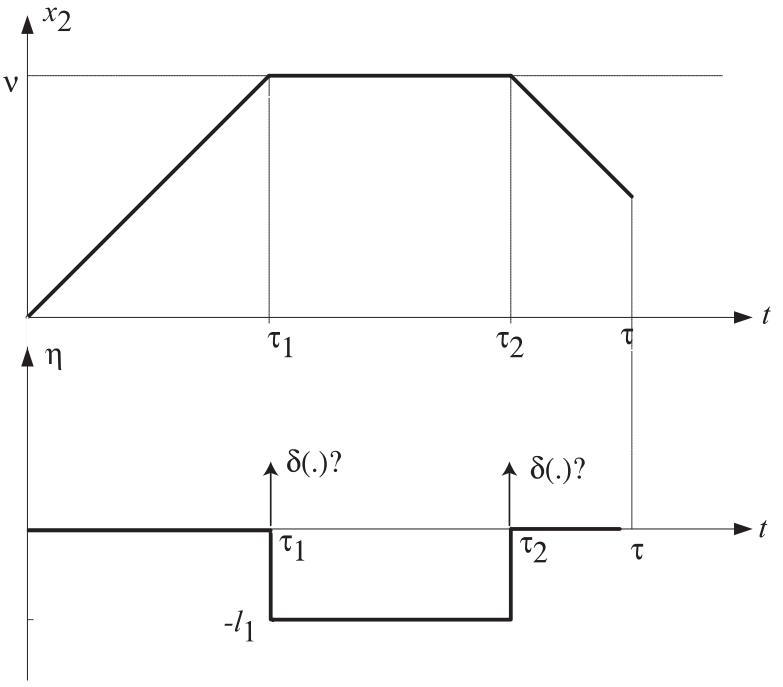

FIG. 2. *Structure of multiplier* η.

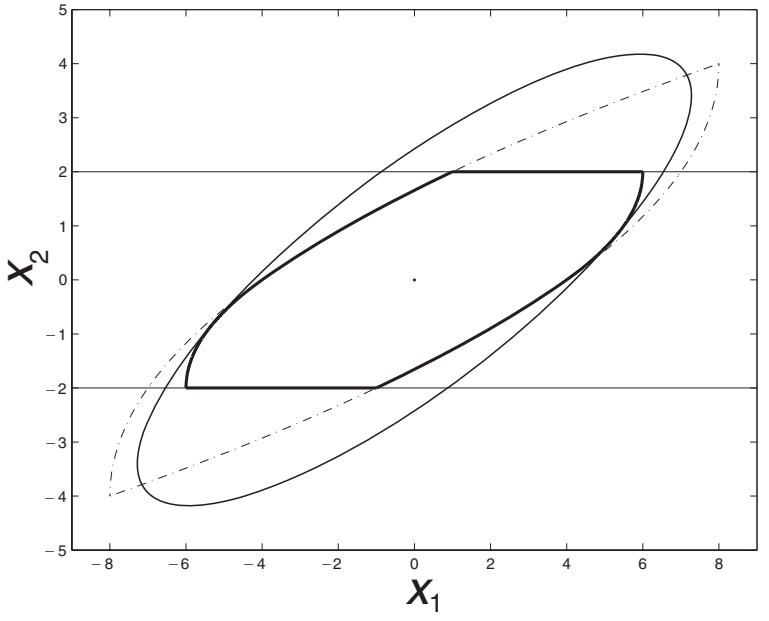

FIG. 3. *External ellipsoid at boundary point of type* (b).

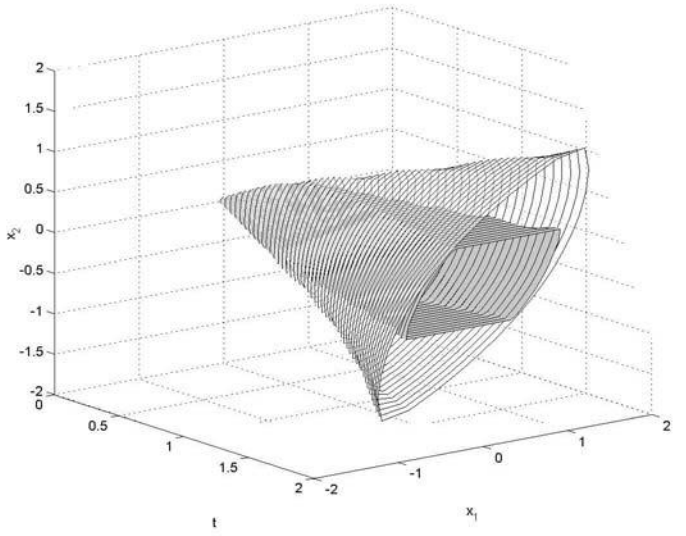

FIG. 4. *Reach tubes with and without state constraints.*

Figure 3 shows an external ellipsoid (thin line) for the boundary of the reach set under state constraints (thick line), indicating its difference from the reach set without state constraints (dash-dotted line). Figure 4 illustrates the final reach tube with and without state constraints for this example.

8. Conclusion. In this paper we presented an ellipsoidal technique to calculate reach sets for linear systems with constraints on the control and state. The suggested scheme introduces parametrized families of tight ellipsoidal-valued tubes that approximate the exact reach tube from above, touching the tube along specially selected "good" curves [31] that cover the entire exact tube. This leads to recursive relations that compared to other approaches, simplify calculations. The proofs rely on a special "recursive" version of the maximum principle under state constraints.

Appendix. In this appendix we present some additional facts useful for proving the main assertions of this paper.

One difficulty in solving the control problem under state constraints (Problem 3.1) is to determine the set of times $\{t \,:\, x(t) \in \partial\mathcal{Y}(t)\}$. This is a union of closed intervals during which the optimal trajectory is on the boundary of the state constraint.

Here are some helpful facts. For Problem 3.1 under Assumptions 3.1 and 3.2, the Properties A.1–A.3 given below are modifications of those shown in [9, section 6, pp. 94–120], and [11, 6].

Property A.1. For any $l \in \mathbb{R}^n$, the minimizer of (20) is $\Lambda^{(0)}(t) = \text{const}$ and in (24) the corresponding minimizer is $\lambda^{(0)}(t) = \text{const}$ during time intervals for which $x(t) \in \text{int}\mathcal{Y}(t)$, the interior of $\mathcal{Y}(t)$.

Since $l'M^{(0)}(t)d\lambda^{(0)}(t) = d\Lambda^{(0)}(t)$, we may track whether the trajectory is on the boundary of $\mathcal{Y}(t)$ by the multiplier $\lambda^{(0)}(t)$. Thus, we need not be interested in values of $M^{(0)}(t)$ when the trajectory is not on the boundary $\partial\mathcal{Y}(t)$.

Property A.2. Suppose $l \in \mathbb{R}^n$ is given and $x^{(0)}(t)$ is the solution of Problem 3.1. For the function $\Lambda^{(0)}(t)$ to have a jump at t^*, under the smoothness conditions on the state constraint of Lemma 3.4, t^* must be a time of arrival or departure from the boundary of the tube $\mathcal{E}(y(t), Y(t)),\ t_0 \le t \le \tau$, and the trajectory $x^{(0)}(t)$ must be *tangent* to the tube $\mathcal{E}(y(t), Y(t))$ at t^* [9, p. 106]. Thus, $x^{(0)}(t)$ is differentiable at t^* and

$$(\chi, \dot{x}^{(0)}(t^* - 0)) = (\chi, \dot{x}^{(0)}(t^* + 0)) = 0. \tag{67}$$

Here χ is the support vector to the state constraint $\mathcal{Y}(t^*)$ at $x^{(0)}(t^*)$. In general, if the jump is $\Lambda(t^* + 0) - \Lambda(t^* - 0) = \chi$, then the necessary condition for such a jump is

$$(\chi, \dot{x}^{(0)}(t^* + 0) - \dot{x}^{(0)}(t^* - 0)) \ge 0. \tag{68}$$

For example, if $x^{(0)}(t^* - \sigma), \sigma > 0$, lies inside the interior of the constraint set and $x(t^* + \sigma)$ lies on the boundary, then

$$(\chi, \dot{x}^{(0)}(t^* + 0) - \dot{x}^{(0)}(t^* - 0)) \le 0,$$

and (68) will be fulfilled only if this inner product equals zero.

We also need the following assumption.

Assumption A.1. For Problem 3.1, with given l, there exists no control $u^*(s)$ that satisfies the maximum principle

$$l' S(s, \tau \mid M^{(0)}(\cdot), \lambda^{(0)}(\cdot)) B(s) u^*(s)$$

$$= \max\{l' S(s, \tau \mid M^{(0)}(\cdot), \lambda^{(0)}(\cdot)) B(s) u \mid u \in \mathcal{E}(p(s), P(s))\}$$

for $\{s \mid l' S(s, \tau \mid M^{(0)}(\cdot), \lambda^{(0)}(\cdot)) B(s) \ne 0\}$ and at the same time ensures for these values of s that the corresponding trajectory $x^*(s) \in \partial\mathcal{Y}(s)$.

Property A.3. Assumption A.1 holds.

This means that if the control $u^{(0)}(s)$ is determined by the maximum principle, with $h^{(0)}(\tau, s) = l' S(s, \tau \mid M^{(0)}(\cdot), \lambda^{(0)}(\cdot)) B(s) \ne 0$, and therefore attains its extremal values under given hard bounds, then this control cannot also keep the corresponding trajectory $x^{(0)}(s)$ along the boundary $\partial\mathcal{Y}(s)$. In other words, in this case *the maximum principle is degenerate along the state constraint*, i.e., $h^{(0)}(\tau, s) \equiv 0$ and does not help to find the control when the trajectory lies on the boundary $\partial\mathcal{Y}(s)$.

This assumption excludes the case when the solution of Problem 3.1 *without state constraints* also happens to solve the same problem with state constraints.

LEMMA A.1. *Under Assumption A.1 applied to Problem* 3.1, *the function*

$$h^{(0)}(\tau, s) = l' S(s, \tau \mid M^{(0)}(\cdot), \lambda^{(0)})(\cdot) B(s) \equiv 0$$

whenever $x^{(0)}(s) \in \partial\mathcal{Y}(s)$.

Property A.4. The equations for tight external ellipsoids *without state constraints* are explained in detail in [15, pp. 188–190, 198, 199]. Here is the basic result.

The equality

$$\rho(l^*(t) \mid \mathcal{X}[\tau]) = (l^*(t), x^{(0)}(t)) + (l^*(t), X_+(t) l^*(t))^{1/2}$$

is true for all $t \ge t_0$. Here

$$x^{(0)}(t) = x^*(t) + X_+^*(t) l^*(t) (l^*(t), X_+^*(t) l^*(t))^{1/2},$$

with

$$\dot{x}^* = A(t)x^* + B(t)p(t),\ x^*(t_0) = x^0,$$

$$\dot{X}_+^* = A(t)X_+ + X_+A'(t) + \pi(t)X_+ + \pi^{-1}(t)P(t),\ X_+(t_0) = X^0,$$

$$l^*(t) = -A(t)'l^*(t),\ l^*(t_0) = l_*,$$

and

$$\pi(t) = (l^*(t), B(t)P(t)B'(t)l^*(t))^{1/2}/(l^*(t), X_+(t)l^*(t))^{1/2}. \tag{69}$$

This indicates that by solving the given explicit equations we may find the support function $\rho(l^*(t)|\mathcal{X}[\tau])$ *for all* $l_* \in \mathcal{B}(0)$, the unit ball in $\mathbb{R}^n$, so that the related vectors $l^*(t) = l_*'S(t_0, t)$ would cover all the directions in $\mathbb{R}^n$ and, after being normalized, the set of all the vectors $l^*(t)/(l^*(t), l^*(t))^{1/2}$ would also coincide with $\mathcal{B}(0)$.

Acknowledgments. The authors thank M. N. Kirilin for the computer illustrations.

GLOBAL CARLEMAN INEQUALITIES FOR PARABOLIC SYSTEMS AND APPLICATIONS TO CONTROLLABILITY*

ENRIQUE FERNÁNDEZ-CARA† AND SERGIO GUERRERO†

Abstract. This paper has been conceived as an overview on the controllability properties of some relevant (linear and nonlinear) parabolic systems. Specifically, we deal with the null controllability and the exact controllability to the trajectories. We try to explain the role played by the observability inequalities in this context and the need of global Carleman estimates. We also recall the main ideas used to overcome the difficulties motivated by nonlinearities. First, we considered the classical heat equation with Dirichlet conditions and distributed controls. Then we analyze recent extensions to other linear and semilinear parabolic systems and/or boundary controls. Finally, we review the controllability properties for the Stokes and Navier–Stokes equations that are known to date. In this context, we have paid special attention to obtaining the necessary Carleman estimates. Some open questions are mentioned throughout the paper. We hope that this unified presentation will be useful for those researchers interested in the field.

Key words. Carleman inequalities, parabolic equations, unique continuation, observability, null controllability

Introduction. The goal of this paper is to provide a panorama of an important subfield of control theory: the null controllability analysis of parabolic equations and systems.

The main contributions to this area are due to O. Yu. Imanuvilov, who popularized the use of global Carleman estimates in the context of null controllability. Many arguments from [36], [30], [39], and [37] will be reproduced here. Another relevant contributor has been E. Zuazua, who was able to deduce global controllability results for some nonlinear systems for the first time in [56].

The controllability of partial differential equations has been the object of intensive research during the last few decades. In 1978, Russell [53] made a survey of the most relevant results that were available in the literature at that time. In that paper, the author described a number of different tools that were developed to address controllability problems, often inspired and related to other subjects concerning partial differential equations: multipliers, moment problems, nonharmonic Fourier series, etc. More recently, J.-L. Lions introduced the so-called *Hilbert uniqueness method* (for instance, see [44], [45], [46]). That was the starting point of a fruitful period on the subject.

It would be impossible to present here all the relevant results that have been proved in this area. We will thus reduce our scope drastically, considering only null controllability problems for parabolic equations and systems.

In order to get an idea, let us consider the simplest case of the linear heat equation

with Dirichlet boundary conditions and distributed controls:

$$\begin{cases} y_t - \Delta y = v1_{\mathcal{O}} & \text{in} \quad Q = \Omega \times (0,T), \\ y = 0 & \text{on} \quad \Sigma = \partial\Omega \times (0,T), \\ y(0) = y^0 & \text{in} \quad \Omega. \end{cases} \tag{0.1}$$

Here, $\Omega \subset \mathbf{R}^N$ is a bounded domain of class C^2, $\mathcal{O} \subset \Omega$ is a nonempty open subset, $1_{\mathcal{O}}$ is the characteristic function of $\mathcal{O}$, and T is a given positive time. We assume that the initial state y^0 is given in $L^2(\Omega)$ and try to find a control $v \in L^2(\mathcal{O} \times (0,T))$ such that the associated state $y = y(x,t)$ possesses a desired behavior at time $t = T$.

Roughly speaking, systems of parabolic type like (0.1) are characterized by *non-reversibility*, the *dissipativity* of the solutions (i.e., the fact that *energy* is lost along the trajectories), and the *regularizing effect*.

In accordance with this last property, it is not possible to lead the solutions of (0.1) exactly to *every* final state in a Sobolev space like $L^2(\Omega)$ or $H^m(\Omega)$, unless the control is exerted *brutally*, i.e., unless we are in the trivial and uninteresting situation $\mathcal{O} = \Omega$.

On the contrary, it may be interesting to investigate whether it is possible to drive the solutions to (0.1) (acting on a small set $\mathcal{O} \subset\subset \Omega$) exactly to a state on a trajectory. For instance, it is completely meaningful to search for controls v such that the associated states y satisfy

$$y(T) = 0 \quad \text{in} \quad \Omega. \tag{0.2}$$

If such controls exist, we say that (0.1) is *null controllable* at time T.

Observe that the null controllability of a parabolic system is a very useful property from the viewpoint of applications. Indeed, it permits us to reach in a finite amount of time a state that is "natural" for the system. All the work has to be done for $t \in [0,T]$. Afterwards, no additional effort is needed to get a satisfactory situation.

It is also easy to see that, for a linear system of the kind above, null controllability is equivalent to *exact controllability to the trajectories*, i.e., to the following property: for any $y^0 \in L^2(\Omega)$ and any function $\overline{y}$ satisfying

$$\begin{cases} \overline{y}_t - \Delta \overline{y} = 0 & \text{in} \quad Q, \\ \overline{y} = 0 & \text{on} \quad \Sigma \end{cases}$$

and

$$\overline{y} \in C^0([0,T]; L^2(\Omega)),$$

there exist controls v such that

$$y(T) = \overline{y}(T) \quad \text{in} \quad \Omega.$$

It will be explained below that the null controllability of a linear parabolic system is, roughly speaking, equivalent to the *observability* of the associated adjoint states.

More precisely, for each $\varphi^0 \in L^2(\Omega)$, let us consider the so-called *adjoint system*

$$\begin{cases} -\varphi_t - \Delta \varphi = 0 & \text{in} \quad Q, \\ \varphi = 0 & \text{on} \quad \Sigma, \\ \varphi(T) = \varphi^0 & \text{in} \quad \Omega. \end{cases} \tag{0.3}$$

Then (0.1) is null controllable with controls in $L^2(\mathcal{O}\times(0,T))$ if and only if there exists $C>0$ such that

$$\|\varphi(0)\|^2_{L^2(\Omega)} \le C \iint_{\mathcal{O}\times(0,T)} |\varphi|^2\,dx\,dt \qquad \forall \varphi^0 \in L^2(\Omega). \tag{0.4}$$

At present, the most powerful tools to prove inequalities like (0.4) for general parabolic systems are *global Carleman estimates*. They have the form

$$\iint_{\Omega\times(0,T)} \rho^2\,|\varphi|^2\,dx\,dt \le C \iint_{\mathcal{O}\times(0,T)} \rho^2\,|\varphi|^2\,dx\,dt, \tag{0.5}$$

where $\rho=\rho(x,t)$ is continuous and strictly positive for $t\in(0,T)$. The previous considerations motivate the need for establishing such estimates.

It is also natural to ask if null controllability and/or exact controllability to the trajectories hold in the framework of semilinear or even genuinely nonlinear parabolic systems. For instance, we can be interested in controls and states satisfying

$$\begin{cases} y_t - \Delta y + f(y) = v1_{\mathcal{O}} & \text{in} \quad Q,\\ y=0 & \text{on} \quad \Sigma,\\ y(0)=y^0 & \text{in} \quad \Omega \end{cases} \tag{0.6}$$

and (0.2), where the function $f:\mathbf{R}\mapsto\mathbf{R}$ is given and, for instance, we assume that $f\in C^1(\mathbf{R})$ and $f(0)=0$.

For systems of this kind, a classical approach relies on the use of *fixed point arguments*. The idea is to find a fixed point of the mapping $z\mapsto y$, where y is, together with some v, a solution to the linearized system

$$\begin{cases} y_t - \Delta y + \dfrac{f(z)}{z}\,y = v1_{\mathcal{O}} & \text{in} \quad Q,\\ y=0 & \text{on} \quad \Sigma,\\ y(0)=y^0 & \text{in} \quad \Omega \end{cases} \tag{0.7}$$

satisfying (0.2). The existence of v is again equivalent to an observability inequality which is implied by appropriate Carleman estimates similar to (0.5).

The fixed point approach can be applied whenever, among other things, the way the constants arising in Carleman estimates depend on the coefficients of the linearized systems is known in detail. Therefore, a careful analysis of (0.5) is needed.

The theoretical results we present below can be applied in many contexts. For instance, they can serve as tools for

- controlling the temperature of a medium eventually influenced by transport and/or chemical effects;
- controlling the velocity field of a real fluid (like those modeled by the Navier–Stokes equations), etc.

In the following sections, we will explain how these ideas can be applied to several parabolic equations and systems. A similar (but different) overview on this topic is [6], where the author is also concerned with the stabilization of parabolic systems.

An important aspect of the controllability of time-dependent systems that will not be treated in this paper is the analysis and obtainment of numerical approximations. Of course, the most interesting question concerning the null controllability of (0.1) and (0.6) is *how to construct* a control with the desirable properties.

Several ideas that reproduce the theoretical arguments at a finite-dimensional level were given, for instance, in [34]. Unfortunately, the proposed algorithms seem to be still too expensive. We simply point out here that the controllability analysis we recall in section 2, based on the solution of a linear fourth order problem, could provide some promising ideas.

There are many other important subjects related to the controllability of parabolic equations that will not be visited here. Let us mention some of them:

- The analysis of the existence of *insensitizing controls* in the sense of [47] or, more generally, the null controllability of cascade systems. This has been the objective of considerable work in recent years (see, for instance, [12], [9], and [26]).
- The controllability of parabolic systems with memory. This includes interesting families of linear viscoelastic fluids. Some partial results in this field are given in [7] and [14].
- The control of coupled systems of parabolic-hyperbolic type, like a combination of heat and wave equations, the system of thermoelasticity, etc. Some of these problems have been treated in [57], [42], and [43].
- The control of fluid-solid interaction systems. This seems to be unexplored at present. For very simple models, some results are given in [13].
- The control of nondeterministic systems. Some advances were made in the context of linear problems. See, for instance, [8]. In this field, the main open question turns out to be the obtainment of controllability results for nonlinear systems, due to the lack of compactness.

The plan of this paper is the following. In section 1, we consider the classical heat equation and some variants. Essentially, we deal there with heat equations with *strong* solutions. We recall the proof of a basic Carleman estimate and present some applications to semilinear systems.

Section 2 is devoted to the null controllability analysis of other more complicated parabolic equations involving *weak* and/or *very weak* solutions. It will be shown that the proof of the related Carleman inequalities is much more involved and needs some extra work. We will also indicate how this can be used to deduce the exact controllability to the trajectories of more general semilinear systems.

Finally, section 3 is concerned with systems of the Stokes kind. Here, the main difficulties are caused by the pressure. We will recall a recent argument leading to an appropriate but not completely satisfactory Carleman inequality. We will also explain how this leads to the null controllability of Stokes-like systems and to the local exact controllability to the trajectories of the Navier–Stokes equations.

1. Null controllability of the linear heat equation and applications.

1.1. Null controllability and observability. Let us consider again the simplest case of the linear heat equation with Dirichlet boundary conditions and distributed control with support in a small set:

$$\begin{cases} y_t - \Delta y = v1_{\mathcal{O}} & \text{in} \quad Q, \\ y = 0 & \text{on} \quad \Sigma, \\ y(0) = y^0 & \text{in} \quad \Omega. \end{cases} \tag{1.1}$$

We assume that $\mathcal{O} \subset\subset \Omega$ is a nonempty (small) open subset and T is a given positive time. In what follows, $n(x)$ will stand for the outward unit normal vector at the point $x \in \partial\Omega$. We assume that the initial state y^0 is given in $L^2(\Omega)$, and we try to

find a control $v \in L^2(\mathcal{O} \times (0,T))$ such that the associated state $y = y(x,t)$ possesses a desired behavior at time $t = T$.

Recall that under these assumptions, system (1.1) has a unique *weak* solution y satisfying

$$y \in L^2(0,T; H_0^1(\Omega)) \cap C^0([0,T]; L^2(\Omega))$$

that depends continuously on y^0 and v.

Our interest is to provide an answer to the following questions.

Question 1: *Null controllability.* For every $y^0 \in L^2(\Omega)$, can a control $v \in L^2(\mathcal{O} \times (0,T))$ be found such that $y(T) = 0$ in Ω?

This question will be answered affirmatively in this section. To this end, we will introduce, for each $\varphi^0 \in L^2(\Omega)$, the adjoint system

$$\begin{cases} -\varphi_t - \Delta\varphi = 0 & \text{in} \quad Q, \\ \varphi = 0 & \text{on} \quad \Sigma, \\ \varphi(T) = \varphi^0 & \text{in} \quad \Omega, \end{cases} \tag{1.2}$$

and we will try to answer the following auxiliary question.

Question 2: *Observability inequality.* Can we find a constant $C > 0$ such that, for each $\varphi^0 \in L^2(\Omega)$, the associated solution of (1.2) satisfies

$$\|\varphi(0)\|^2_{L^2(\Omega)} \leq C \iint_{\mathcal{O}\times(0,T)} |\varphi|^2 \, dx \, dt \,? \tag{1.3}$$

An affirmative answer to Question 2 implies an affirmative answer to Question 1. This is what is proved in the following result.

THEOREM 1.1. *The observability inequality* (1.3) *implies the null controllability of* (1.1).

Proof. We divide the proof into two steps. First, we build a sequence of controls $v_\varepsilon \in L^2(\mathcal{O} \times (0,T))$ with $\varepsilon > 0$ which provide the *approximate controllability* of (1.1) (see (1.7)). Second, we pass to the limit when ε tends to zero and we conclude.

Step 1. Let $y^0 \in L^2(\Omega)$ and $\varepsilon > 0$ be given. Let us introduce the functional J_ε, with

$$J_\varepsilon(\varphi^0) = \frac{1}{2} \iint_{\mathcal{O}\times(0,T)} |\varphi|^2 \, dx \, dt + \varepsilon \|\varphi^0\|_{L^2(\Omega)} + (\varphi(0), y^0)_{L^2(\Omega)} \tag{1.4}$$

for every $\varphi^0 \in L^2(\Omega)$. Here, φ is the solution of (1.2) associated to the initial condition φ^0. Using (1.3), it is not difficult to check that J_ε is strictly convex, continuous, and coercive in $L^2(\Omega)$, so it possesses a unique minimum $\varphi^0_\varepsilon \in L^2(\Omega)$, whose associated solution is denoted by φ_ε. Let us now introduce the control $v_\varepsilon = \varphi_\varepsilon 1_\mathcal{O}$, and let us denote by y_ε the solution of (1.1) associated to v_ε.

Let y_1 be the final state of the solution to (1.1) with vanishing control. Let us remark that the unique interesting case to be studied turns out to be when $\|y_1\|_{L^2(\Omega)} > \varepsilon$, since this is equivalent to $\varphi^0_\varepsilon \neq 0$. See [19] for more details. Under this assumption, we can differentiate the functional J_ε at φ^0_ε and obtain a necessary condition for J_ε to reach a minimum at φ^0_ε, say,

$$\iint_{\mathcal{O}\times(0,T)} \varphi_\varepsilon \, \varphi \, dx \, dt + \varepsilon \left(\frac{\varphi^0_\varepsilon}{\|\varphi^0_\varepsilon\|_{L^2(\Omega)}}, \varphi^0 \right)_{L^2(\Omega)} + (\varphi(0), y^0)_{L^2(\Omega)} = 0 \tag{1.5}$$

for every $\varphi^0 \in L^2(\Omega)$.

Using this and (1.3) for $\varphi^0 = \varphi^0_\varepsilon$, we obtain $\|v_\varepsilon\|_{L^2(\mathcal{O}\times(0,T))} \leq \sqrt{C}\,\|y^0\|_{L^2(\Omega)}$, where C is the observability constant of (1.3).

Since systems (1.1) and (1.2) are in duality, we have

$$\iint_{\mathcal{O}\times(0,T)} \varphi_\varepsilon\,\varphi\,dx\,dt = (y_\varepsilon(T),\varphi^0)_{L^2(\Omega)} - (y^0,\varphi(0))_{L^2(\Omega)}, \tag{1.6}$$

which, combined with (1.5), yields

$$\|y_\varepsilon(T)\|_{L^2(\Omega)} \leq \varepsilon. \tag{1.7}$$

Step 2. Since the sequence $\{v_\varepsilon\}$ is bounded in $L^2(\mathcal{O}\times(0,T))$, it possesses a (weakly) convergent subsequence to certain $v \in L^2(\mathcal{O}\times(0,T))$. Using classical parabolic estimates we deduce that, at least for a subsequence,

$$y_\varepsilon \to y \quad \text{weakly in } L^2(0,T;H^1_0(\Omega)) \cap H^1(0,T;H^{-1}(\Omega)), \tag{1.8}$$

where y is the solution of (1.1) with control v. In particular, this gives weak convergence for $\{y_\varepsilon(t)\}\,(t \in [0,T])$ in $L^2(\Omega)$ so we have $y(T) = 0$.

Remark 1. At this point, some comments must be made:

1. We have proved that (1.3) implies null controllability with a control that satisfies

$$\|v\|_{L^2(\mathcal{O}\times(0,T))} \leq \sqrt{C}\,\|y^0\|_{L^2(\Omega)}, \tag{1.9}$$

where C is the observability constant.

Conversely, if we have null controllability with controls $v \in L^2(\mathcal{O}\times(0,T))$ that satisfy

$$\|v\|_{L^2(\mathcal{O}\times(0,T))} \leq \sqrt{C}\,\|y^0\|_{L^2(\Omega)} \tag{1.10}$$

for some constant $C > 0$, then it can be checked that we have (1.3) with the same constant C.

2. It is possible to present a similar argument in a general frame. Let us consider three Hilbert spaces U, H, E and two linear continuous operators $L \in \mathcal{L}(U;E)$ and $M \in \mathcal{L}(H;E)$. Then we have

$$\|M^*\varphi^0\|_H \leq C\|L^*\varphi^0\|_{U'} \quad \forall \varphi^0 \in E' \tag{1.11}$$

for some positive constant C if and only if $R(M) \subset R(L)$ and, moreover,

$$\forall y^0 \in H,\ \exists v \in U \text{ such that } Lv = My^0,\ \|v\|_U \leq C\|y^0\|_H. \tag{1.12}$$

Properties of this kind have been established and analyzed for the first time in the framework of control theory in [52]. They have been successfully used in many different contexts in recent years.

3. Because of linearity, the null controllability of (1.1) is equivalent to the exact controllability to (uncontrolled) trajectories. In other words, (1.1) is null controllable if and only if, for every $\overline{y}^0 \in L^2(\Omega)$, we can find a control $v \in L^2(\mathcal{O}\times(0,T))$ such that $y(T) = \overline{y}(T)$ in Ω, where y is the solution of (1.1) associated to v, and $\overline{y}$ satisfies

$$\begin{cases} \overline{y}_t - \Delta\overline{y} = 0 & \text{in } Q, \\ \overline{y} = 0 & \text{on } \Sigma, \\ \overline{y}(0) = \overline{y}^0 & \text{in } \Omega. \end{cases} \tag{1.13}$$

4. In general, for any $y^1 \in L^2(\Omega)$, it is not reasonable to look for a control $v \in L^2(\mathcal{O} \times (0,T))$ such that $y(T) = y^1$ in Ω (recall that $\mathcal{O} \subset\subset \Omega$). Indeed, due to the regularizing effect, every solution to (1.1) is space-analytic in $\Omega \setminus \overline{\mathcal{O}}$ at time T, which is not necessarily the case for y^1. Thus, the *exact controllability problem* is out of order for the heat equation.

In what follows, for the reasons stated above, we will focus on the proof of (1.3). This will rely on other (previous) inequalities for the solutions to (1.2), known as *global Carleman inequalities*. Let us mention that a general global Carleman inequality adopts the form

$$\iint_{\Omega\times(0,T)} \rho^2 \,|\varphi|^2 \,dx\,dt \le C \iint_{\mathcal{O}\times(0,T)} \rho^2 \,|\varphi|^2 \,dx\,dt, \tag{1.14}$$

where $\rho = \rho(x,t)$ is a continuous and strictly positive weight function. For a function ρ satisfying $\rho > 0$ in $\overline{\Omega} \times (0,T)$, we will be able to deduce (1.14) and then estimates like

$$\iint_{\Omega\times(T/4,3T/4)} |\varphi|^2 \,dx\,dt \le C \iint_{\mathcal{O}\times(0,T)} |\varphi|^2 \,dx\,dt. \tag{1.15}$$

This, together with the dissipation properties of the solutions of (1.2), will lead to (1.3). More details are given below.

Remark 2. To our knowledge, the first (boundary) controllability results for the heat equation were obtained by Egorov in the early sixties; see [17]. Later, an important general principle was established by Russell in [52]: if T_0 is sufficiently large and the wave system

$$\begin{cases} y_{tt} - \Delta y = v1_{\mathcal{O}} & \text{in} \quad \Omega \times (0,T_0), \\ y = 0 & \text{on} \quad \partial\Omega \times (0,T_0), \\ y(0) = y^0, \quad y_t(0) = y^1 & \text{in} \quad \Omega \end{cases} \tag{1.16}$$

is *exactly controllable* at time T_0, then (1.1) is null controllable at time T for all $T > 0$.

This principle has been revisited by several authors. In particular, an "abstract" version is given in [4].

Using the *method of moments*, the exact controllability of (1.16) can be established for large T_0 when, for instance, $\overline{\mathcal{O}}$ is a neighborhood of $\partial\Omega$. Thus, one has null controllability for (1.1) in this case.

Remark 3. In the particular case of the classical heat equation (1.1), there is another way to prove (1.3), based on the spectral decomposition of the solutions. This approach was introduced by Lebeau and Robbiano [41] and led to the null controllability of the heat equation with controls supported by general subdomains $\mathcal{O} \subset\subset \Omega$ for the first time.

1.2. A global Carleman inequality for the linear heat equation and its consequences.

LEMMA 1.2. *Let $\omega \subset\subset \Omega$ be a nonempty open subset. Then there exists $\eta^0 \in C^2(\overline{\Omega})$ such that $\eta^0 > 0$ in Ω, $\eta^0 = 0$ on $\partial\Omega$, and $|\nabla\eta^0| > 0$ in $\overline{\Omega \setminus \omega}$.*

A proof of this lemma can be found in [30]. A much easier proof can be developed when Ω is star shaped with respect to a point $x^0 \in \omega$.

Let ω be a nonempty open set satisfying $\omega \subset\subset \mathcal{O}$ and let us set

$$\begin{aligned} \alpha(x,t) &= \frac{e^{2\lambda m\|\eta^0\|_\infty} - e^{\lambda(m\|\eta^0\|_\infty+\eta^0(x))}}{t(T-t)}, \\ \xi(x,t) &= \frac{e^{\lambda(m\|\eta^0\|_\infty+\eta^0(x))}}{t(T-t)} \end{aligned} \tag{1.17}$$

for $(x,t) \in Q$, where η^0 is the function furnished by Lemma 1.2 for this ω and $m > 1$. Weight functions of this kind were first introduced by Imanuvilov. See [30] for a systematic use of them.

Now we arrive at the main result of this section.

LEMMA 1.3. *There exist three constants $\lambda_1 = C(\Omega,\mathcal{O}) \geq 1$, $s_1 = C(\Omega,\mathcal{O})(T+T^2)$, and $C_1(\Omega,\mathcal{O})$ such that, for any $\lambda \geq \lambda_1$ and any $s \geq s_1$, the following inequality holds:*

$$\begin{aligned} & s^{-1}\iint_Q e^{-2s\alpha}\,\xi^{-1}(|q_t|^2+|\Delta q|^2)\,dx\,dt + s\,\lambda^2\iint_Q e^{-2s\alpha}\,\xi\,|\nabla q|^2\,dx\,dt \\ & \quad + s^3\,\lambda^4\iint_Q e^{-2s\alpha}\,\xi^3\,|q|^2\,dx\,dt \leq C_1\Big(\iint_Q e^{-2s\alpha}\,|q_t+\Delta q|^2\,dx\,dt \\ & \quad + s^3\,\lambda^4\iint_{\mathcal{O}\times(0,T)} e^{-2s\alpha}\,\xi^3\,|q|^2\,dx\,dt\Big) \end{aligned} \tag{1.18}$$

for all $q \in C^2(\overline{Q})$ with $q = 0$ on Σ.

In what follows, $C(\Omega,\mathcal{O})$ or simply C will denote a generic constant depending only on Ω and $\mathcal{O}$.

Before giving the proof of Lemma 1.3, we will deduce the observability inequality (1.3) (and, accordingly, the null controllability of (1.1)) from this result. This can be made in three steps.

Step 1. From the density of the smooth functions in the space where the solutions of (1.2) with $\varphi^0 \in L^2(\Omega)$ live, we first observe that the Carleman inequality above is verified by all of them. Thus, fixing $\lambda = \lambda_1$, we get

$$\iint_Q e^{-2s\alpha}\,t^{-3}(T-t)^{-3}\,|\varphi|^2\,dx\,dt \leq C\iint_{\mathcal{O}\times(0,T)} e^{-2s\alpha}\,t^{-3}(T-t)^{-3}\,|\varphi|^2\,dx\,dt \tag{1.19}$$

for all $s \geq s_1$.

Step 2. Using the inequalities

$$e^{-2s_1\alpha}\,t^{-3}(T-t)^{-3} \geq e^{-2C(\Omega,\mathcal{O})(1+1/T)}\frac{1}{T^6} \quad \text{in} \quad \Omega\times(T/4,3T/4) \tag{1.20}$$

and

$$e^{-2s_1\alpha}\,t^{-3}(T-t)^{-3} \leq e^{-C(\Omega,\mathcal{O})(1+1/T)}\frac{1}{T^6} \quad \text{in} \quad \Omega\times(0,T), \tag{1.21}$$

we get

$$\iint_{\Omega\times(T/4,3T/4)} |\varphi|^2\,dx\,dt \leq C(\Omega,\mathcal{O},T)\iint_{\mathcal{O}\times(0,T)} |\varphi|^2\,dx\,dt, \tag{1.22}$$

with a constant $C(\Omega, \mathcal{O}, T)$ of the form $e^{C(\Omega,\mathcal{O})(1+1/T)}$.

Step 3. From the equation verified by φ, we readily obtain

$$\|\varphi(0)\|^2_{L^2(\Omega)} \leq \frac{2}{T}\int_{T/4}^{3T/4} \|\varphi(t)\|^2_{L^2(\Omega)}\, dt. \tag{1.23}$$

This, together with (1.22), gives the observability inequality (1.3).

In view of Theorem 1.1, we have the following.

THEOREM 1.4. *The system* (1.1) *is null controllable with controls* $v \in L^2(\mathcal{O} \times (0,T))$ *that verify*

$$\|v\|_{L^2(\mathcal{O}\times(0,T))} \leq C\|y^0\|_{L^2(\Omega)}, \tag{1.24}$$

where the constant C *is of the form* $e^{C(\Omega,\mathcal{O})(1+1/T)}$.

Let us now give the proof of the Carleman estimate (1.18). The proof we present here is based on the ideas in [30]. We will try to keep an explicit dependence of all the constants with respect to the parameters s and λ and the final time T. This follows the spirit of [27] and will be crucial for the analysis of similar nonlinear problems.

Proof of Lemma 1.3. For simplicity, we will divide the proof into three steps.

Step 1. *Change of variables and plan of what follows.* In this step, we set the differential equation satisfied by a new function ψ, which will be q up to a weight function.

Thus, let us introduce the new functions $\psi = e^{-s\alpha}\, q$ and $g = e^{-s\alpha}\, f$, where we have denoted $f = q_t + \Delta q$. Then we easily obtain that

$$M_1\psi + M_2\psi = g_{s,\lambda}, \tag{1.25}$$

where

$$\begin{aligned} M_1\psi &= -2s\,\lambda^2\,|\nabla\eta^0|^2\,\xi\,\psi - 2s\,\lambda\,\xi\,\nabla\eta^0\cdot\nabla\psi + \psi_t, \\ M_2\psi &= s^2\,\lambda^2\,|\nabla\eta^0|^2\,\xi^2\,\psi + \Delta\psi + s\,\alpha_t\,\psi, \end{aligned} \tag{1.26}$$

and

$$g_{s,\lambda} = g + s\,\lambda\,\Delta\eta^0\,\xi\,\psi - s\,\lambda^2\,|\nabla\eta^0|^2\,\xi\,\psi. \tag{1.27}$$

To simplify the notation, we will denote by $(M_i\psi)_j$ $(1 \leq i \leq 2,\ 1 \leq j \leq 3)$ the jth term in the expression of $M_i\psi$ given in (1.26).

Observe that, at first sight, it seems "natural" to put $(M_1\psi)_1$ on the right-hand side of (1.25). However, we have decided to keep it on the left, because it will serve to produce a positive term on $|\nabla\psi|^2$ (see the scalar product $((M_1\psi)_1, (M_2\psi)_2)_{L^2(Q)}$ below).

With the previous notation, we have from (1.25)

$$\|M_1\psi\|^2_{L^2(Q)} + \|M_2\psi\|^2_{L^2(Q)} + 2\sum_{i,j=1}^{3} ((M_1\psi)_i, (M_2\psi)_j)_{L^2(Q)} = \|g_{s,\lambda}\|^2_{L^2(Q)}. \tag{1.28}$$

In the following steps, we will see that the definition we have made of α makes $2(M_1\psi, M_2\psi)_{L^2(Q)}$ positive up to several terms that can be controlled whenever we make an appropriate choice of the parameters s and λ.

More precisely, in the second step we will make the computations of the double products $2(M_1\psi, M_2\psi)_{L^2(Q)}$. This will give an inequality with two global terms of

$|\psi|^2$ and $|\nabla\psi|^2$ on the left-hand side, while two local terms of $|\psi|^2$ and $|\nabla\psi|^2$ will appear on the right-hand side (see (1.57)). In the third step we will add two terms (involving ψ_t and $\Delta\psi$) to the left of (1.57). This will help us to eliminate the local term containing $\nabla\psi$ that appears on the right-hand side and will provide a Carleman inequality for the function ψ (see (1.63)). Finally, we will turn back to the original function q and deduce the inequality (1.18).

Step 2. *First estimates*. In this step, we will develop the nine terms appearing in $(M_1\psi, M_2\psi)_{L^2(Q)}$. For this, we will integrate by parts several times with respect to the space and time variables, so derivatives of the weight functions will be involved. Actually, we will use the estimates

$$\begin{aligned} &\partial_i\alpha = -\partial_i\xi = -\lambda\,\partial_i\eta^0\,\xi \le C\,\lambda\,\xi, \\ &\alpha_t = -(T-2t)\frac{e^{2\lambda m\|\eta^0\|_\infty} - e^{\lambda(m\|\eta^0\|_\infty+\eta^0)}}{t^2(T-t)^2} \le C\,T\,\xi^2, \end{aligned} \tag{1.29}$$

where C is a positive constant depending only on Ω and $\mathcal{O}$.

The last inequality follows from the fact that

$$e^{2\lambda m\|\eta^0\|_\infty} \le e^{2\lambda(m\|\eta^0\|_\infty+\eta^0)} \quad \text{in } \Omega. \tag{1.30}$$

First, we have

$$((M_1\psi)_1, (M_2\psi)_1)_{L^2(Q)} = -2s^3\,\lambda^4 \iint_Q |\nabla\eta^0|^4\,\xi^3\,|\psi|^2\,dx\,dt = A. \tag{1.31}$$

Then

$$\begin{aligned} ((M_1\psi)_2, (M_2\psi)_1)_{L^2(Q)} &= -2s^3\,\lambda^3 \iint_Q |\nabla\eta^0|^2\,\xi^3\,(\nabla\eta^0\cdot\nabla\psi)\,\psi\,dx\,dt \\ &= 3s^3\,\lambda^4 \iint_Q |\nabla\eta^0|^4\,\xi^3\,|\psi|^2\,dx\,dt \\ &\quad + s^3\,\lambda^3 \iint_Q \Delta\eta^0\,|\nabla\eta^0|^2\,\xi^3\,|\psi|^2\,dx\,dt \\ &\quad + 2s^3\,\lambda^3 \sum_{i,j=1}^N \iint_Q \partial_i\eta^0\,\partial_{ij}\eta^0\,\partial_j\eta^0\,\xi^3\,|\psi|^2\,dx\,dt \\ &= B_1 + B_2 + B_3. \end{aligned} \tag{1.32}$$

We clearly have that $A+B_1$ is a positive term. As a consequence of the properties of η^0 (see Lemma 1.2), we have

$$\begin{aligned} A + B_1 = s^3\,\lambda^4 \iint_Q |\nabla\eta^0|^4\,\xi^3\,|\psi|^2\,dx\,dt \ge C\,s^3\,\lambda^4 \iint_Q \xi^3\,|\psi|^2\,dx\,dt \\ - C\,s^3\,\lambda^4 \iint_{\omega\times(0,T)} \xi^3\,|\psi|^2\,dx\,dt = \widetilde{A} - \widetilde{B} \end{aligned} \tag{1.33}$$

for some $C = C(\Omega, \mathcal{O})$. The first of these last two integrals ($\widetilde{A}$) will stay on the left-hand side, while the second one ($\widetilde{B}$) will go to the right-hand side.

The terms B_2 and B_3 are absorbed by $\widetilde{A}$ by simply taking $\lambda \ge C$, since $\eta^0 \in C^2(\overline{\Omega})$.

We also have

$$\begin{aligned}((M_1\psi)_3,(M_2\psi)_1)_{L^2(Q)} &= s^2\,\lambda^2\iint_Q |\nabla\eta^0|^2\,\xi^2\,\psi_t\,\psi\,dx\,dt\\ &= -s^2\,\lambda^2\iint_Q |\nabla\eta^0|^2\,\xi\,\xi_t\,|\psi|^2\,dx\,dt,\end{aligned}\tag{1.34}$$

which, by virtue of (1.29), is bounded by

$$C\,s^2\,\lambda^2\,T\iint_Q \xi^3\,|\psi|^2\,dx\,dt.\tag{1.35}$$

This term can also be absorbed if we take $\lambda \geq 1$ and $s \geq C(\Omega,\mathcal{O})\,T$.

Consequently, we have

$$\begin{aligned}(M_1\psi,(M_2\psi)_1)_{L^2(Q)} &= ((M_1\psi)_1+(M_1\psi)_2+(M_1\psi)_3,(M_2\psi)_1)_{L^2(Q)}\\ &\geq C\,s^3\,\lambda^4\iint_Q \xi^3\,|\psi|^2\,dx\,dt\\ &\quad - C\,s^3\,\lambda^4\iint_{\omega\times(0,T)} \xi^3\,|\psi|^2\,dx\,dt\end{aligned}\tag{1.36}$$

for any $\lambda \geq C(\Omega,\mathcal{O})$ and $s \geq C(\Omega,\mathcal{O})\,T$.

On the other hand, we have

$$\begin{aligned}((M_1\psi)_1,(M_2\psi)_2)_{L^2(Q)} &= -2s\,\lambda^2\iint_Q |\nabla\eta^0|^2\,\xi\,\Delta\psi\,\psi\,dx\,dt\\ &= 2s\,\lambda^2\iint_Q |\nabla\eta^0|^2\,\xi\,|\nabla\psi|^2\,dx\,dt\\ &\quad + 4s\,\lambda^2\sum_{i,j=1}^N\iint_Q \partial_i\eta^0\,\partial_{ij}\eta^0\,\xi\,\partial_j\psi\,\psi\,dx\,dt\\ &\quad + 2s\,\lambda^3\iint_Q |\nabla\eta^0|^2\,\xi\,(\nabla\eta^0\cdot\nabla\psi)\,\psi\,dx\,dt\\ &= C_1+C_2+C_3.\end{aligned}\tag{1.37}$$

We will keep C_1 on the left-hand side. For C_2 and C_3, we have

$$C_2 \leq C\,s\,\lambda^4\iint_Q \xi\,|\psi|^2\,dx\,dt + C\,s\iint_Q \xi\,|\nabla\psi|^2\,dx\,dt\tag{1.38}$$

and

$$C_3 \leq C\,s^2\,\lambda^4\iint_Q \xi^2\,|\psi|^2\,dx\,dt + C\,\lambda^2\iint_Q |\nabla\psi|^2\,dx\,dt.\tag{1.39}$$

Therefore, taking $s \geq C\,T^2$, we find that

$$\begin{aligned}C_1+C_2+C_3 &\geq 2s\,\lambda^2\iint_Q |\nabla\eta^0|^2\,\xi\,|\nabla\psi|^2\,dx\,dt\\ &\quad - C\,s^2\,\lambda^4\iint_Q \xi^2\,|\psi|^2\,dx\,dt - C\iint_Q (s\,\xi+\lambda^2)\,|\nabla\psi|^2\,dx\,dt.\end{aligned}\tag{1.40}$$

We also have

$$\begin{aligned}((M_1\psi)_2,(M_2\psi)_2)_{L^2(Q)} &= -2s\,\lambda\iint_Q \xi\,(\nabla\eta^0\cdot\nabla\psi)\,\Delta\psi\,dx\,dt\\ &= -2s\,\lambda\iint_\Sigma \frac{\partial\eta^0}{\partial n}\,\xi\,\left|\frac{\partial\psi}{\partial n}\right|^2 d\sigma\,dt\\ &\quad + 2s\,\lambda\sum_{i,j=1}^N\iint_Q \partial_{ij}\eta^0\,\xi\,\partial_i\psi\,\partial_j\psi\,dx\,dt\\ &\quad + 2s\,\lambda^2\iint_Q \xi\,|\nabla\eta^0\cdot\nabla\psi|^2\,dx\,dt\\ &\quad + s\,\lambda\iint_Q \xi\,\nabla\eta^0\cdot\nabla|\nabla\psi|^2\,dx\,dt\\ &= D_1+D_2+D_3+D_4.\end{aligned}\tag{1.41}$$

Let us remark that D_3 is a positive term. Furthermore,

$$D_2\le C\,s\,\lambda\iint_Q \xi\,|\nabla\psi|^2\,dx\,dt.\tag{1.42}$$

After some additional computations we also see that

$$\begin{aligned}D_4 &= s\,\lambda\iint_Q \xi\,\nabla\eta^0\cdot\nabla|\nabla\psi|^2\,dx\,dt = s\,\lambda\iint_\Sigma \xi\,\frac{\partial\eta^0}{\partial n}\,\left|\frac{\partial\psi}{\partial n}\right|^2 d\sigma\,dt\\ &\quad - s\,\lambda^2\iint_Q |\nabla\eta^0|^2\,\xi\,|\nabla\psi|^2\,dx\,dt - s\,\lambda\iint_Q \Delta\eta^0\,\xi\,|\nabla\psi|^2\,dx\,dt\\ &= D_{41}+D_{42}+D_{43}.\end{aligned}\tag{1.43}$$

By virtue of the properties satisfied by η^0, we notice that $D_1+D_{41}\ge 0$ and that D_{43} can be bounded in the same way as D_2.

Consequently,

$$\begin{aligned}D_1+D_2+D_3+D_4 &\ge -s\,\lambda^2\iint_Q |\nabla\eta^0|^2\,\xi\,|\nabla\psi|^2\,dx\,dt\\ &\quad - C\,s\,\lambda\iint_Q \xi\,|\nabla\psi|^2\,dx\,dt.\end{aligned}\tag{1.44}$$

Additionally, we find that

$$((M_1\psi)_3,(M_2\psi)_2)_{L^2(Q)} = \iint_Q \psi_t\,\Delta\psi\,dx\,dt = 0.\tag{1.45}$$

From (1.40)–(1.45), we deduce that

$$\begin{aligned}(M_1\psi,(M_2\psi)_2)_{L^2(Q)} &= ((M_1\psi)_1+(M_1\psi)_2+(M_1\psi)_3,(M_2\psi)_2)_{L^2(Q)}\\ &\ge s\,\lambda^2\iint_Q |\nabla\eta^0|^2\,\xi\,|\nabla\psi|^2\,dx\,dt\\ &\quad - C\,s^2\,\lambda^4\iint_Q \xi^2\,|\psi|^2\,dx\,dt\\ &\quad - C\iint_Q (s\,\lambda\,\xi+\lambda^2)\,|\nabla\psi|^2\,dx\,dt\end{aligned}\tag{1.46}$$

for $\lambda\ge 1$ and $s\ge C\,T^2$.

Hence, we have the following for $\lambda \geq C(\Omega, \mathcal{O})$ and $s \geq C(\Omega, \mathcal{O})\, T^2$:

$$\begin{aligned}(M_1\psi, (M_2\psi)_2)_{L^2(Q)} \geq{}& C\, s\, \lambda^2 \iint_Q \xi\, |\nabla\psi|^2\, dx\, dt \\ &- C\, s^2\, \lambda^4 \iint_Q \xi^2\, |\psi|^2\, dx\, dt \\ &- C\, s\, \lambda^2 \iint_{\omega\times(0,T)} \xi\, |\nabla\psi|^2\, dx\, dt.\end{aligned} \tag{1.47}$$

Let us now consider the scalar product

$$\begin{aligned}((M_1\psi)_1, (M_2\psi)_3)_{L^2(Q)} &= -2s^2\, \lambda^2 \iint_Q |\nabla\eta^0|^2\, \alpha_t\, \xi\, |\psi|^2\, dx\, dt \\ &\leq C\, s^2\, \lambda^2\, T \iint_Q \xi^3\, |\psi|^2\, dx\, dt.\end{aligned} \tag{1.48}$$

Obviously, this is absorbed by $\widetilde{A}$ if we take $\lambda \geq 1$ and $s \geq C\, T$.

Furthermore,

$$\begin{aligned}((M_1\psi)_2, (M_2\psi)_3)_{L^2(Q)} &= -2s^2\, \lambda \iint_Q \alpha_t\, \xi\, (\nabla\eta^0 \cdot \nabla\psi)\, \psi\, dx\, dt \\ &= s^2\, \lambda^2 \iint_Q \alpha_t\, |\nabla\eta^0|^2\, \xi\, |\psi|^2\, dx\, dt \\ &\quad + s^2\, \lambda \iint_Q \nabla\alpha_t \cdot \nabla\eta^0\, \xi\, |\psi|^2\, dx\, dt \\ &\quad + s^2\, \lambda \iint_Q \alpha_t\, \Delta\eta^0\, \xi\, |\psi|^2\, dx\, dt.\end{aligned} \tag{1.49}$$

From (1.29), one can easily check that the previous three terms can be bounded (if $\lambda \geq 1$) by

$$C\, s^2\, \lambda^2\, T \iint_Q \xi^3\, |\psi|^2\, dx\, dt. \tag{1.50}$$

Thus, we have

$$((M_1\psi)_2, (M_2\psi)_3)_{L^2(Q)} \geq -C\, s^2\, \lambda^2\, T \iint_Q \xi^3\, |\psi|^2\, dx\, dt. \tag{1.51}$$

Finally, we have

$$\begin{aligned}((M_1\psi)_3, (M_2\psi)_3)_{L^2(Q)} &= s \iint_Q \alpha_t\, \psi_t\, \psi\, dx\, dt \\ &= -\frac{1}{2} s \iint_Q \alpha_{tt}\, |\psi|^2\, dx\, dt \leq C\, s\, T^2 \iint_Q \xi^3\, |\psi|^2\, dx\, dt,\end{aligned} \tag{1.52}$$

since

$$\alpha_{tt} \leq C\, \xi^2 (1 + T^2\, \xi) \leq C\, T^2\, \xi^3. \tag{1.53}$$

From (1.48)–(1.52), we deduce for $\lambda \geq C(\Omega, \mathcal{O})$ and $s \geq C(\Omega, \mathcal{O})\, T$ that

$$\begin{aligned}(M_1\psi, (M_2\psi)_3)_{L^2(Q)} &= ((M_1\psi)_1 + (M_1\psi)_2 + (M_1\psi)_3, (M_2\psi)_3)_{L^2(Q)} \\ &\geq -C\ s^3\,\lambda^2 \iint_Q \xi^3\,|\psi|^2\,dx\,dt.\end{aligned} \tag{1.54}$$

Taking into account (1.36), (1.47), and (1.54), we obtain

$$\begin{aligned}(M_1\psi, M_2\psi)_{L^2(Q)} &\geq C \iint_Q (s\,\lambda^2\,\xi\,|\nabla\psi|^2 + s^3\,\lambda^4\,\xi^3\,|\psi|^2)\,dx\,dt \\ &\quad - C \iint_{\omega\times(0,T)} (s\,\lambda^2\,\xi\,|\nabla\psi|^2 + s^3\,\lambda^4\,\xi^3\,|\psi|^2)\,dx\,dt\end{aligned} \tag{1.55}$$

for any $\lambda \geq C(\Omega, \mathcal{O})$ and $s \geq C(\Omega, \mathcal{O})(T + T^2)$. Using (1.28), this gives

$$\begin{aligned}&\|M_1\psi\|^2_{L^2(Q)} + \|M_2\psi\|^2_{L^2(Q)} + \iint_Q (s\,\lambda^2\,\xi\,|\nabla\psi|^2 + s^3\,\lambda^4\,\xi^3\,|\psi|^2)\,dx\,dt \\ &\quad \leq C\left(\|g_{s,\lambda}\|^2_{L^2(Q)} + \iint_{\omega\times(0,T)} (s\,\lambda^2\,\xi\,|\nabla\psi|^2 + s^3\,\lambda^4\,\xi^3\,|\psi|^2)\,dx\,dt\right) \\ &\quad \leq C\bigg(\iint_Q e^{-2s\alpha}\,|f|^2\,dx\,dt + s^2\,\lambda^4 \iint_Q \xi^2\,|\psi|^2\,dx\,dt \\ &\qquad + s\lambda^2 \iint_{\omega\times(0,T)} \xi\,|\nabla\psi|^2\,dx\,dt + s^3\,\lambda^4 \iint_{\omega\times(0,T)} \xi^3\,|\psi|^2\,dx\,dt\bigg).\end{aligned} \tag{1.56}$$

Thus, we also have

$$\begin{aligned}&\|M_1\psi\|^2_{L^2(Q)} + \|M_2\psi\|^2_{L^2(Q)} + \iint_Q (s\,\lambda^2\,\xi\,|\nabla\psi|^2 + s^3\,\lambda^4\,\xi^3\,|\psi|^2)\,dx\,dt \\ &\quad \leq C\left(\iint_Q e^{-2s\alpha}\,|f|^2\,dx\,dt + s\,\lambda^2 \iint_{\omega\times(0,T)} \xi\,|\nabla\psi|^2\,dx\,dt\right. \\ &\qquad \left. + s^3\,\lambda^4 \iint_{\omega\times(0,T)} \xi^3\,|\psi|^2\,dx\,dt\right)\end{aligned} \tag{1.57}$$

for $\lambda \geq C(\Omega, \mathcal{O})$ and $s \geq C(\Omega, \mathcal{O})(T + T^2)$.

Step 3. *Indirect estimates and conclusion.* The final step will be to add integrals of $|\Delta\psi|^2$ and $|\psi_t|^2$ to the left-hand side of (1.57). This can be made using the expressions of $M_i\psi$ $(i = 1, 2)$. Indeed, from (1.26) we have

$$\begin{aligned}s^{-1} \iint_Q \xi^{-1}\,|\psi_t|^2\,dx\,dt &\leq C\bigg(s\,\lambda^2 \iint_Q \xi\,|\nabla\psi|^2\,dx\,dt \\ &\quad + s\,\lambda^4 \iint_Q \xi\,|\psi|^2\,dx\,dt + \|M_1\psi\|^2_{L^2(Q)}\bigg)\end{aligned} \tag{1.58}$$

and

$$\begin{aligned}s^{-1} \iint_Q \xi^{-1}\,|\Delta\psi|^2\,dx\,dt &\leq C\bigg(s^3\,\lambda^4 \iint_Q \xi^3\,|\psi|^2\,dx\,dt \\ &\quad + s\,T^2 \iint_Q \xi^3\,|\psi|^2\,dx\,dt + \|M_2\psi\|^2_{L^2(Q)}\bigg)\end{aligned} \tag{1.59}$$

for $s \geq C\,T^2$. Accordingly, we deduce from (1.57) that

$$\begin{aligned}
&\iint_Q (s^{-1}\,\xi^{-1}(|\psi_t|^2 + |\Delta\psi|^2) + s\,\lambda^2\,\xi\,|\nabla\psi|^2 + s^3\,\lambda^4\,\xi^3\,|\psi|^2)\,dx\,dt \\
&\qquad \leq C\left(\iint_Q e^{-2s\alpha}\,|f|^2\,dx\,dt + s\,\lambda^2 \iint_{\omega\times(0,T)} \xi\,|\nabla\psi|^2\,dx\,dt\right. \\
&\qquad\qquad \left. +\ s^3\,\lambda^4 \iint_{\omega\times(0,T)} \xi^3\,|\psi|^2\,dx\,dt\right)
\end{aligned} \tag{1.60}$$

for any $\lambda \geq C(\Omega, \mathcal{O})$ and $s \geq C(\Omega, \mathcal{O})(T + T^2)$.

We are now ready to eliminate the second integral on the right-hand side. To this end, let us introduce a function $\theta = \theta(x)$, with

$$\theta \in C_c^2(\mathcal{O}), \quad \theta \equiv 1 \quad \text{in} \quad \omega, \quad 0 \leq \theta \leq 1, \tag{1.61}$$

and let us make some computations. We have

$$\begin{aligned}
s\,\lambda^2 \iint_{\omega\times(0,T)} \xi\,|\nabla\psi|^2\,dx\,dt &\leq\ s\,\lambda^2 \iint_{\mathcal{O}\times(0,T)} \theta\,\xi\,|\nabla\psi|^2\,dx\,dt \\
&= -s\,\lambda^2 \iint_{\mathcal{O}\times(0,T)} \theta\,\xi\,\Delta\psi\,\psi\,dx\,dt \\
&\quad - s\,\lambda^2 \iint_{\mathcal{O}\times(0,T)} \xi\,(\nabla\theta\cdot\nabla\psi)\,\psi\,dx\,dt \\
&\quad - s\,\lambda^3 \iint_{\mathcal{O}\times(0,T)} \theta\,\xi\,(\nabla\eta^0\cdot\nabla\psi)\,\psi\,dx\,dt \\
&\leq\ \varepsilon\,s^{-1} \iint_{\mathcal{O}\times(0,T)} \xi^{-1}\,|\Delta\psi|^2\,dx\,dt \\
&\quad + C\left(s^3\,\lambda^4 \iint_{\mathcal{O}\times(0,T)} \xi^3\,|\psi|^2\,dx\,dt + s\,\lambda^4 \iint_{\mathcal{O}\times(0,T)} \xi\,|\psi|^2\,dx\,dt\right)
\end{aligned} \tag{1.62}$$

for a small enough constant $\varepsilon = \varepsilon(\Omega, \mathcal{O}) > 0$ and where we have used the fact that $\lambda \geq 1$. Hence, we can eliminate the integral of $|\nabla\psi|^2$ on the right-hand side of (1.60), paying the price of having $|\psi|^2$ in $\mathcal{O}\times(0,T)$. From (1.60) and this remark, we deduce that

$$\begin{aligned}
&\iint_Q (s^{-1}\,\xi^{-1}(|\psi_t|^2 + |\Delta\psi|^2) + s\,\lambda^2\,\xi\,|\nabla\psi|^2 + s^3\,\lambda^4\,\xi^3\,|\psi|^2)\,dx\,dt \\
&\qquad \leq C\left(\iint_Q e^{-2s\alpha}\,|f|^2\,dx\,dt + s^3\,\lambda^4 \iint_{\mathcal{O}\times(0,T)} \xi^3\,|\psi|^2\,dx\,dt\right)
\end{aligned} \tag{1.63}$$

for $\lambda \geq C(\Omega, \mathcal{O})$ and $s \geq C(\Omega, \mathcal{O})(T + T^2)$.

We finally turn back to our original function, which was given by $q = e^{s\alpha}\psi$. For

the moment, we have

$$\begin{aligned} & s^{-1}\iint_Q \xi^{-1}\,|\psi_t|^2\,dx\,dt + s^{-1}\iint_Q \xi^{-1}\,|\Delta\psi|^2\,dx\,dt \\ & \quad + s\,\lambda^2\iint_Q \xi\,|\nabla\psi|^2\,dx\,dt + s^3\,\lambda^4\iint_Q e^{-2s\alpha}\,\xi^3\,|q|^2\,dx\,dt \\ & \quad \le C\left(\iint_Q e^{-2s\alpha}\,|f|^2\,dx\,dt + s^3\,\lambda^4\iint_{\mathcal{O}\times(0,T)} e^{-2s\alpha}\,\xi^3\,|q|^2\,dx\,dt\right). \end{aligned} \tag{1.64}$$

Using that

$$\nabla q = e^{s\alpha}(\nabla\psi - s\,\lambda\,\nabla\eta^0\,\xi\,\psi), \tag{1.65}$$

we find

$$\begin{aligned} s\,\lambda^2\iint_Q e^{-2s\alpha}\,\xi\,|\nabla q|^2\,dx\,dt \le C\,s\,\lambda^2\iint_Q \xi\,|\nabla\psi|^2\,dx\,dt \\ + C\,s^3\,\lambda^4\iint_Q e^{-2s\alpha}\,\xi^3\,|q|^2\,dx\,dt. \end{aligned} \tag{1.66}$$

Consequently, we can add the previous integral of $|\nabla q|^2$ to the left-hand side of (1.64):

$$\begin{aligned} & s^{-1}\iint_Q \xi^{-1}\,|\psi_t|^2\,dx\,dt + s^{-1}\iint_Q \xi^{-1}\,|\Delta\psi|^2\,dx\,dt \\ & \quad + s\,\lambda^2\iint_Q \xi\,|\nabla q|^2\,dx\,dt + s^3\,\lambda^4\iint_Q e^{-2s\alpha}\,\xi^3\,|q|^2\,dx\,dt \\ & \quad \le C\left(\iint_Q e^{-2s\alpha}\,|f|^2\,dx\,dt + s^3\,\lambda^4\iint_{\mathcal{O}\times(0,T)} e^{-2s\alpha}\,\xi^3\,|q|^2\,dx\,dt\right). \end{aligned} \tag{1.67}$$

For Δq, we use the identity

$$\Delta\psi = e^{-s\alpha}(\Delta q + s\,\lambda\,\Delta\eta^0\,\xi\,q + s\,\lambda^2\,|\nabla\eta^0|^2\,\xi\,q + 2s\,\lambda\,\xi\,\nabla\eta^0\cdot\nabla q + s^2\,\lambda^2\,|\nabla\eta^0|^2\,\xi^2\,q) \tag{1.68}$$

and obtain

$$\begin{aligned} s^{-1}\iint_Q e^{-2s\alpha}\,\xi^{-1}\,|\Delta q|^2\,dx\,dt \le C\Bigg(s^{-1}\iint_Q \xi^{-1}\,|\Delta\psi|^2\,dx\,dt \\ + s\,\lambda^2\iint_Q e^{-2s\alpha}\,\xi\,|q|^2\,dx\,dt + s\,\lambda^4\iint_Q e^{-2s\alpha}\,\xi\,|q|^2\,dx\,dt \\ + s\,\lambda^2\iint_Q e^{-2s\alpha}\,\xi\,|\nabla q|^2\,dx\,dt + s^3\,\lambda^4\iint_Q e^{-2s\alpha}\,\xi^3\,|q|^2\,dx\,dt\Bigg). \end{aligned} \tag{1.69}$$

Finally, for q_t we get

$$\begin{aligned} s^{-1}\iint_Q e^{-2s\alpha}\,\xi^{-1}\,|q_t|^2\,dx\,dt \le C\Bigg(s^{-1}\iint_Q \xi^{-1}\,|\psi_t|^2\,dx\,dt \\ + s\,T^2\iint_Q e^{-2s\alpha}\,\xi^3\,|q|^2\,dx\,dt\Bigg), \end{aligned} \tag{1.70}$$

where we have used the identity $q_t = e^{s\alpha}(\psi_t + s\,\alpha_t\,\psi)$. Thus, taking $\lambda \geq 1$ and $s \geq C(\Omega, \mathcal{O})(T + T^2)$, we are able to introduce all the terms involving $|\Delta q|^2$ and $|q_t|^2$ on the left-hand side of (1.64). This gives (1.18) and concludes the proof of Lemma 1.3.

Remark 4. It would be very interesting to know whether the powers of s and λ arising in (1.18) are optimal. In other words, would it be possible to deduce an inequality like (1.18) with higher powers of s and λ accompanying the terms on the left-hand side? A positive answer to this would lead to the controllability of nonlinear parabolic systems more general than those considered in subsections 1.3.2 and 2.2.1.

1.3. Applications and generalizations. There are many other similar systems for which null controllability properties can be analyzed as before. Let us mention some of them.

1.3.1. General parabolic linear systems. We will now try to apply the Carleman inequality obtained in the previous subsection to systems where the heat equation has a zero order term and a first order term in the divergence form. More precisely, we would like to prove the null controllability of the system

$$\begin{cases} y_t - \Delta y + \nabla \cdot (y\,B(x,t)) + a(x,t)\,y = v1_{\mathcal{O}} & \text{in} \quad Q, \\ y = 0 & \text{on} \quad \Sigma, \\ y(0) = y^0 & \text{in} \quad \Omega, \end{cases} \tag{1.71}$$

where $y^0 \in L^2(\Omega)$, $a \in L^\infty(Q)$, and $B \in L^\infty(Q)^N$.

In this case, the associated adjoint system is the following:

$$\begin{cases} -\varphi_t - \Delta\varphi - B(x,t)\cdot\nabla\varphi + a(x,t)\varphi = 0 & \text{in} \quad Q, \\ \varphi = 0 & \text{on} \quad \Sigma, \\ \varphi(T) = \varphi^0 & \text{in} \quad \Omega. \end{cases} \tag{1.72}$$

A result similar to Theorem 1.1 holds for systems (1.71) and (1.72). Consequently, what we have to do is prove an observability inequality for the solutions to (1.72).

In this situation, Lemma 1.3 provides a first estimate of the kind (1.18) (with q replaced by φ), with two additional terms on the right-hand side, namely,

$$C\iint_Q e^{-2s\alpha}\,|a\,\varphi|^2\,dx\,dt \quad \text{and} \quad C\iint_Q e^{-2s\alpha}\,|B\cdot\nabla\varphi|^2\,dx\,dt. \tag{1.73}$$

But these can be absorbed by the left-hand side if we take s large enough. Indeed, it suffices to take

$$s \geq C(\Omega,\mathcal{O})\,T^2(\|a\|_\infty^{2/3} + \|B\|_\infty^2) \tag{1.74}$$

to have

$$\begin{aligned} &C\left(\iint_Q e^{-2s\alpha}\,|a\,\varphi|^2\,dx\,dt + \iint_Q e^{-2s\alpha}\,|B\cdot\nabla\varphi|^2\,dx\,dt\right) \\ &\quad \leq \frac{1}{2}s^3\,\lambda^4\iint_Q e^{-2s\alpha}\,\xi^3\,|\varphi|^2\,dx\,dt + \frac{1}{2}s\,\lambda^2\iint_Q e^{-2s\alpha}\,\xi\,|\nabla\varphi|^2\,dx\,dt. \end{aligned} \tag{1.75}$$

Arguing as we did when we proved the observability inequality for the solutions to (1.2), we easily find

$$\iint_{\Omega\times(T/4,3T/4)} |\varphi|^2\,dx\,dt \leq C(\Omega,\mathcal{O},T,a,B)\iint_{\mathcal{O}\times(0,T)} |\varphi|^2\,dx\,dt, \tag{1.76}$$

with a constant

$$C(\Omega,\mathcal{O},T,a,B)=\exp\{C(1+1/T+\|a\|_\infty^{2/3}+\|B\|_\infty^2)\}. \tag{1.77}$$

On the other hand, the dissipativity of φ yields

$$\|\varphi(0)\|^2_{L^2(\Omega)}\le \exp\{C\,T(\|a\|_\infty+\|B\|_\infty^2)\}\,\|\varphi(t)\|^2_{L^2(\Omega)} \tag{1.78}$$

for all $t\in(T/4,3T/4)$. Combining (1.76) and (1.78), we see that

$$\|\varphi(0)\|^2_{L^2(\Omega)}\le e^{C(1+1/T+\|a\|_\infty^{2/3}+T\,\|a\|_\infty+(1+T)\|B\|_\infty^2)}\iint_{\mathcal{O}\times(0,T)}|\varphi|^2\,dx\,dt \tag{1.79}$$

for all the solutions of (1.72) associated to final data $\varphi^0\in L^2(\Omega)$. As mentioned above (see Theorem 1.1), this implies the null controllability of (1.71).

THEOREM 1.5. *System* (1.71) *is null controllable, with controls* v *satisfying*

$$\|v\|_{L^2(\mathcal{O}\times(0,T))}\le C(\Omega,\mathcal{O},T,a,B)\|y^0\|_{L^2(\Omega)}, \tag{1.80}$$

where

$$C(\Omega,\mathcal{O},T,a,B)=e^{C(\Omega,\mathcal{O})(1+1/T+\|a\|_\infty^{2/3}+T\|a\|_\infty+(1+T)\|B\|_\infty^2)}. \tag{1.81}$$

Remark 5. In a recent paper, Seidman [54] looked at the qualitative asymptotic behavior of the constants found in estimates of the kind (1.80) with respect to relevant parameters. In particular, the blow-up of $C(\Omega,\mathcal{O},T,a,B)$ as $T\to 0$ has been analyzed in some particular cases.

The next step will be to establish the null controllability for a general linear heat equation system with first order terms and coefficients in $L^\infty(Q)$, i.e., an equation of the form

$$y_t-\Delta y+B(x,t)\cdot\nabla y+a(x,t)\,y=v1_{\mathcal{O}}, \tag{1.82}$$

with $a\in L^\infty(Q)$ and $B\in L^\infty(Q)^N$. A different Carleman inequality is now required since, in the corresponding adjoint equation, there is the term $-\nabla\cdot(\varphi\,B(x,t))$, which belongs to $L^2(0,T;H^{-1}(\Omega))$. This will be treated in section 2 using arguments from [39].

1.3.2. Extension to some semilinear systems. We will now consider possible extensions of the null controllability results above to nonlinear problems of the form

$$\begin{cases} y_t-\Delta y+f(y)=v1_{\mathcal{O}} & \text{in} \quad Q,\\ y=0 & \text{on} \quad \Sigma,\\ y(0)=y^0 & \text{in} \quad \Omega, \end{cases} \tag{1.83}$$

where

$$f\in C^1(\mathbf{R})\ \text{(for instance)},\quad f(0)=0,\quad \text{and}\quad |f(s)|\le C(1+|s|). \tag{1.84}$$

The classical strategy used in [36] and [30] relies on the introduction of a mapping

$$z\in L^2(Q)\mapsto y_z\in L^2(Q), \tag{1.85}$$

where y_z is, together with v_z, a solution of

$$\begin{cases} (y_z)_t - \Delta y_z + g(z)y_z = v_z 1_{\mathcal{O}} & \text{in} \quad Q, \\ y_z = 0 & \text{on} \quad \Sigma, \\ y_z(0) = y^0 & \text{in} \quad \Omega \end{cases} \tag{1.86}$$

such that

$$y_z(T) = 0 \tag{1.87}$$

and (1.80) holds for v_z with $a = g(z)$ and $B \equiv 0$. Here, g is given by

$$g(s) = \begin{cases} \dfrac{f(s)}{s} & \text{if} \quad s \neq 0, \\ f'(0) & \text{if} \quad s = 0. \end{cases} \tag{1.88}$$

Using the previous results and arguing as in [36], it can be seen that this mapping can be correctly defined. It can also be proved that it is continuous and compact. Furthermore, in view of (1.84), the estimate (1.80) written for v_z, and the classical estimates for y_z, it maps the whole space $L^2(Q)$ into a ball. Hence, from Schauder's theorem, we deduce that this mapping possesses a fixed point and, consequently, the following holds.

THEOREM 1.6. *Under conditions* (1.84) *on* f, *system* (1.83) *is null controllable, with controls* v *satisfying*

$$\|v\|_{L^2(\mathcal{O}\times(0,T))} \leq \exp\{C(\Omega,\mathcal{O})(1 + 1/T + \|g\|_\infty^{2/3} + T\|g\|_\infty)\}\|y^0\|_{L^2(\Omega)}, \tag{1.89}$$

where g *is given by* (1.88).

This fixed point approach for the solution of controllability problems for nonlinear systems was introduced in [56] in the context of the controllability of the wave equation. Later, it was successfully applied to the semilinear heat equation in [36], [19], [30], [20], and [28].

The next case corresponds to a superlinear f, i.e., to a function not satisfying the last condition in (1.84). In this context, it is much more complicated to estimate the norms of v_z and y_z, since g is not necessarily uniformly bounded. However, something can still be made in some particular cases. More precisely, the following result is proved in [28].

THEOREM 1.7. *Assume that*

$$\begin{cases} f \in C^1(\mathbf{R}) \quad (\textit{for instance}), \quad f(0) = 0, \quad \textit{and} \\ \dfrac{|f(s)|}{s\,\log^{3/2}(1+|s|)} \longrightarrow 0 \quad \textit{as } |s| \to +\infty. \end{cases} \tag{1.90}$$

Then (1.83) *is null controllable with controls* $v \in L^\infty(\mathcal{O} \times (0,T))$.

Remark 6. It is also proved in [28] that, in general, when

$$|f(s)| \sim |s|\log^\beta(1+|s|) \tag{1.91}$$

for some $\beta > 2$, (1.83) is not null controllable. However, it is unknown whether or not the system (1.83) is null controllable when this is satisfied with $\frac{3}{2} < \beta \leq 2$.

1.3.3. Another boundary conditions. Let us consider the following system, where the heat equation is completed with linear Robin (or Fourier) boundary conditions:

$$\begin{cases} y_t - \Delta y = v1_{\mathcal{O}} & \text{in} \quad Q, \\ \dfrac{\partial y}{\partial n} + a(x,t)\, y = 0 & \text{on} \quad \Sigma, \\ y(0) = y^0 & \text{in} \quad \Omega, \end{cases} \tag{1.92}$$

where $a \in L^\infty(\Sigma)$ and $y^0 \in L^2(\Omega)$. Recall that under these assumptions there exists a unique solution y to (1.92), with

$$y \in L^2(0,T; H^1(\Omega)) \cap C^0([0,T]; L^2(\Omega)).$$

Arguing as above, it is readily seen that the null controllability of (1.92) is implied by the observability of the adjoint system

$$\begin{cases} -\varphi_t - \Delta \varphi = 0 & \text{in} \quad Q, \\ \dfrac{\partial \varphi}{\partial n} + a(x,t)\, \varphi = 0 & \text{on} \quad \Sigma, \\ \varphi(T) = \varphi^0 & \text{in} \quad \Omega. \end{cases} \tag{1.93}$$

An observability inequality for the solutions to (1.93) is proved in [30], under the additional assumption $a_t \in L^\infty(\Sigma)$. As a consequence, one also has the null controllability of (1.92) whenever a fulfills this hypothesis. For some partial results concerning a nonlinear version of (1.92), see [15].

An improvement of these results has been obtained in the more recent work [21]. See section 2 for further details.

1.3.4. Another controllability problems. Another interesting problem is the null controllability of the heat equation with boundary controls, which means the null controllability of the system

$$\begin{cases} y_t - \Delta y = 0 & \text{in} \quad Q, \\ y = v1_\gamma & \text{on} \quad \Sigma, \\ y(0) = y^0 & \text{in} \quad \Omega, \end{cases} \tag{1.94}$$

when γ is a (small) part of $\partial\Omega$. In this case, the adjoint system is again (1.2) but the required observability inequality is somewhat different. More precisely, we need the estimate

$$\|\varphi(0)\|^2_{L^2(\Omega)} \le C \iint_{\gamma\times(0,T)} \left|\frac{\partial \varphi}{\partial n}\right|^2 d\sigma\, dt \tag{1.95}$$

for all solutions to (1.2).

This can be obtained as a consequence of the following Carleman estimates, similar to (1.18) (see [30]):

$$\begin{aligned} &\iint_Q e^{-2s\widetilde{\alpha}} \big((s\,\widetilde{\xi})^{-1}(|q_t|^2 + |\Delta q|^2) + s\,\lambda^2\,\widetilde{\xi}\,|\nabla q|^2 + s^3\,\lambda^4\,\widetilde{\xi}^3\,|q|^2\big)\, dx\, dt \\ &\quad \le C\left(\iint_Q e^{-2s\widetilde{\alpha}}\,|q_t + \Delta q|^2\, dx\, dt + s\iint_{\gamma\times(0,T)} e^{-2s\widetilde{\alpha}}\,\widetilde{\xi}\left|\frac{\partial q}{\partial n}\right|^2 d\sigma\, dt\right). \end{aligned}$$

Here, $\widetilde{\alpha} = \widetilde{\alpha}(x,t)$ and $\widetilde{\xi} = \widetilde{\xi}(x,t)$ are appropriate weight functions, similar to α and ξ, respectively.

Using (1.95) and arguments like those in the proof of Theorem 1.1, one can easily deduce the null controllability of (1.94).

1.3.5. Other more general partial differential equations. The previous null controllability results can also be extended to more general equations with sufficiently regular coefficients. For instance, for the system

$$\begin{cases} y_t - \partial_i(a_{ij}(x,t)\,\partial_j y) = v1_{\mathcal{O}} & \text{in} \quad Q, \\ y = 0 & \text{on} \quad \Sigma, \\ y(0) = y^0 & \text{in} \quad \Omega, \end{cases} \tag{1.96}$$

where the coefficients $a_{ij} \in C^2(\overline{Q})$ are uniformly elliptic, it is proved in [30] that null controllability is achieved. This result has recently been improved in [51]; see subsection 2.2.3 below.

2. Null controllability of other more general parabolic problems.

2.1. The case of the linear heat equation with general zero and first order terms. In this subsection, we are going to prove the null controllability, with distributed controls, of the linear heat equation with zero and first order terms and coefficients in $L^\infty(Q)$, i.e.,

$$\begin{cases} y_t - \Delta y + B(x,t)\cdot\nabla y + a(x,t)\,y = v1_{\mathcal{O}} & \text{in} \quad Q, \\ y = 0 & \text{on} \quad \Sigma, \\ y(0) = y^0 & \text{in} \quad \Omega, \end{cases} \tag{2.1}$$

with $y^0 \in L^2(\Omega)$, $a \in L^\infty(Q)$, and $B \in L^\infty(Q)^N$. To achieve this, we will first prove an observability inequality for the associated adjoint system

$$\begin{cases} -\varphi_t - \Delta\varphi - \nabla\cdot(\varphi\,B(x,t)) + a(x,t)\,\varphi = 0 & \text{in} \quad Q, \\ \varphi = 0 & \text{on} \quad \Sigma, \\ \varphi(T) = \varphi^0 & \text{in} \quad \Omega. \end{cases} \tag{2.2}$$

More precisely, we will prove that

$$\|\varphi(0)\|^2_{L^2(\Omega)} \le C \iint_{\mathcal{O}\times(0,T)} |\varphi|^2\,dx\,dt \tag{2.3}$$

for all $\varphi^0 \in L^2(\Omega)$ for some $C = C(\Omega, \mathcal{O}, T, a, B)$. To this end we will use the following lemma, which provides a suitable Carleman inequality (see [39]).

LEMMA 2.1. *There exist $\lambda_2 = C(\Omega,\mathcal{O})$, $s_2 = C(\Omega,\mathcal{O})(T+T^2)$, and $C_2 = C_2(\Omega,\mathcal{O}) > 0$ such that, for any $\lambda \ge \lambda_2$ and any $s \ge s_2$, one has*

$$\begin{aligned} &s\,\lambda^2 \iint_Q e^{-2s\alpha}\,\xi\,|\nabla q|^2\,dx\,dt + s^3\,\lambda^4 \iint_Q e^{-2s\alpha}\,\xi^3\,|q|^2\,dx\,dt \\ &\quad\le C_2\Bigg(s^3\,\lambda^4 \iint_{\mathcal{O}\times(0,T)} e^{-2s\alpha}\,\xi^3\,|q|^2\,dx\,dt \\ &\qquad + \iint_Q e^{-2s\alpha}\,|F_0|^2\,dx\,dt + s^2\,\lambda^2 \iint_Q e^{-2s\alpha}\,\xi^2\,|F|^2\,dx\,dt\Bigg) \end{aligned} \tag{2.4}$$

for all functions $q \in C^1(\overline{Q})$ *with* $q = 0$ *on* Σ *and* $q_t + \Delta q = F_0 + \nabla \cdot F$, *where* $F_0 \in L^2(Q)$, $F \in L^2(Q)^N$. *Here,* α *and* ξ *are the functions defined just before Lemma* 1.3.

For the moment, let us assume that Lemma 2.1 is true and let us deduce an observability inequality of the kind (2.3) for the solutions to (2.2). Fixing $\lambda = \lambda_2$ and applying Lemma 2.1 to φ, we have

$$\begin{aligned} &s^3 \iint_Q e^{-2s\alpha}\, \xi^3\, |\varphi|^2\, dx\, dt + s \iint_Q e^{-2s\alpha}\, \xi\, |\nabla \varphi|^2\, dx\, dt \\ &\quad \le C \left(s^3 \iint_{\mathcal{O}\times(0,T)} e^{-2s\alpha}\, \xi^3\, |\varphi|^2\, dx\, dt + \|a\|_\infty^2 \iint_Q e^{-2s\alpha}\, |\varphi|^2\, dx\, dt \right. \\ &\qquad \left. + s^2\, \|B\|_\infty^2 \iint_Q e^{-2s\alpha}\, \xi^2 |\varphi|^2\, dx\, dt \right) \end{aligned} \tag{2.5}$$

for any $s \ge s_2$. Consequently, we also have

$$\iint_Q e^{-2s\alpha}\, t^{-3}(T-t)^{-3}\, |\varphi|^2\, dx\, dt \le C \iint_{\mathcal{O}\times(0,T)} e^{-2s\alpha}\, t^{-3}(T-t)^{-3}\, |\varphi|^2\, dx\, dt \tag{2.6}$$

for all $s \ge C\,(T + T^2 + T^2\,(\|a\|_\infty^{2/3} + \|B\|_\infty^2))$, whence it is easy to deduce that

$$\iint_{\Omega\times(T/4,3T/4)} |\varphi|^2\, dx\, dt \le e^{C(1+1/T+\|a\|_\infty^{2/3}+\|B\|_\infty^2)} \iint_{\mathcal{O}\times(0,T)} |\varphi|^2\, dx\, dt. \tag{2.7}$$

On the other hand, we also have (1.78) for the solutions to (2.2). This, together with (2.7), leads to the desired observability inequality (2.3). Thus, we have the following.

THEOREM 2.2. *System* (2.1) *is null controllable with controls* v *satisfying* (1.80) *and* (1.81).

Following [39], let us now give the proof of the Carleman inequality (2.4).

Proof of Lemma 2.1. Let $q = q(x,t)$ satisfy the hypothesis stated above and set $q^0 = q|_{t=T}$. Then q can be viewed as a solution by transposition of the backwards system

$$\begin{cases} q_t + \Delta q = F_0 + \nabla \cdot F & \text{in} \quad Q, \\ q = 0 & \text{on} \quad \Sigma, \\ q(T) = q^0 & \text{in} \quad \Omega. \end{cases} \tag{2.8}$$

In other words, for each $G \in L^2(0,T; H^{-1}(\Omega))$ we must have

$$\int_0^T \langle G(t), q(t)\rangle\, dt = -\int_0^T \langle F_0(t) + \nabla \cdot F(t), z(t)\rangle\, dt + (q^0, z(T))_{L^2(\Omega)}, \tag{2.9}$$

where z is the solution of the linear problem

$$\begin{cases} z_t - \Delta z = G & \text{in} \quad Q, \\ z = 0 & \text{on} \quad \Sigma, \\ z(0) = 0 & \text{in} \quad \Omega. \end{cases} \tag{2.10}$$

Here, $\langle \cdot, \cdot \rangle$ denotes the usual duality product between $H^{-1}(\Omega)$ and $H_0^1(\Omega)$.

Let s and λ be as in Lemma 1.3 and let us introduce the following fourth order problem, which will be justified below:

$$\begin{cases} \mathcal{L}(e^{-2s\alpha}\mathcal{L}^*p) + s^3\,\lambda^4\,e^{-2s\alpha}\,\xi^3\,q = -s^3\,\lambda^4\,e^{-2s\alpha}\,\xi^3\,p1_{\mathcal{O}} & \text{in} \quad Q, \\ p = 0, \quad e^{-2s\alpha}\mathcal{L}^*p = 0 & \text{on} \quad \Sigma, \\ (e^{-2s\alpha}\mathcal{L}^*p)(0) = (e^{-2s\alpha}\mathcal{L}^*p)(T) = 0 & \text{in} \quad \Omega. \end{cases} \tag{2.11}$$

Here, we have used the notation $\mathcal{L}q \equiv q_t - \Delta q, \quad \mathcal{L}^*q \equiv -q_t - \Delta q$. The partial differential problem (2.11) possesses exactly one (weak) solution p with

$$\iint_Q e^{-2s\alpha}(\xi^{-1}(|p_t|^2 + |\Delta p|^2) + \xi\,|\nabla p|^2 + \xi^3\,|p|^2)\,dx\,dt < +\infty. \tag{2.12}$$

Indeed, let P_0 be the linear space

$$P_0 = \{z \in C^2(\overline{Q}) : z = 0 \text{ on } \Sigma\} \tag{2.13}$$

and let us set

$$\begin{cases} \kappa(p,p') = \displaystyle\iint_Q e^{-2s\alpha}\,\mathcal{L}^*p\,\mathcal{L}^*p'\,dx\,dt \\ \qquad\qquad + s^3\,\lambda^4 \displaystyle\iint_{\mathcal{O}\times(0,T)} e^{-2s\alpha}\,\xi^3\,p\,p'\,dx\,dt \quad \forall p, p' \in P_0 \end{cases} \tag{2.14}$$

and

$$l(p) = -s^3\,\lambda^4 \iint_Q e^{-2s\alpha}\,\xi^3\,q\,p\,dx\,dt \quad \forall p \in P_0. \tag{2.15}$$

Then $\kappa(\cdot\,,\cdot)$ is a positive and symmetric bilinear form in P_0.

Let P be the completion of P_0 for the norm $\|p\|_P = (\kappa(p,p))^{1/2}$. Then P is a Hilbert space for the scalar product $\kappa(\cdot\,,\cdot)$ and, in view of the Carleman inequality (1.18), we have that the functions in P satisfy (2.12). It is also clear from (1.18) that l is a continuous linear form on P:

$$|l(p)| \le C\left(s^3\,\lambda^4 \iint_Q e^{-2s\alpha}\,\xi^3\,|q|^2\,dx\,dt\right)^{1/2} \|p\|_P \quad \forall p \in P. \tag{2.16}$$

Consequently, from the Lax–Milgram lemma, the following variational equation possesses exactly one solution $p \in P$:

$$\kappa(p,p') = l(p') \quad \forall p' \in P. \tag{2.17}$$

It is not difficult to see that the unique solution to (2.17) also solves the fourth order problem (2.11) in the distributional sense.

Of course, the space P and the function $p \in P$ depend on the choice we have made of s and λ.

Now, let us set

$$\widehat{z} = -e^{-2s\alpha}\,\mathcal{L}^*p, \quad \widehat{u} = s^3\,\lambda^4\,e^{-2s\alpha}\,\xi^3\,p1_{\mathcal{O}}. \tag{2.18}$$

It is readily seen from (2.11) that $\widehat{z}$ is, together with $\widehat{u}$, a solution to the null controllability problem

$$\begin{cases} \widehat{z}_t - \Delta \widehat{z} = s^3\,\lambda^4\, e^{-2s\alpha}\,\xi^3\, q + \widehat{u} 1_{\mathcal{O}} & \text{in} \quad Q, \\ \widehat{z} = 0 & \text{on} \quad \Sigma, \\ \widehat{z}(0) = \widehat{z}(T) = 0 & \text{in} \quad \Omega. \end{cases} \tag{2.19}$$

For the moment, we will assume that there exist positive $\widetilde{s} = \widetilde{s}(\Omega, \mathcal{O})$ and $\widetilde{\lambda} = \widetilde{\lambda}(\Omega, \mathcal{O})$, such that

$$\begin{aligned} & s^{-3}\lambda^{-4} \iint_{\mathcal{O}\times(0,T)} e^{2s\alpha}\,\xi^{-3} |\hat{u}|^2\,dx\,dt + \iint_Q e^{2s\alpha}\,|\hat{z}|^2\,dx\,dt \\ & \quad + s^{-2}\lambda^{-2} \iint_Q e^{2s\alpha}\,\xi^{-2} |\nabla \hat{z}|^2\,dx\,dt \le C\,s^3\,\lambda^4 \iint_Q e^{-2s\alpha}\,\xi^3\,|q|^2\,dx\,dt \end{aligned} \tag{2.20}$$

for all $s \ge \widetilde{s}(T + T^2)$ and $\lambda \ge \widetilde{\lambda}$.

Let us then prove (2.4). First, we will get an estimate for the second term on the left-hand side of (2.4). In view of (2.9) written for $G = s^3\,\lambda^4\, e^{-2s\alpha}\,\xi^3\, q + \widehat{u} 1_{\mathcal{O}}$, we have

$$s^3\,\lambda^4 \iint_Q e^{-2s\alpha}\,\xi^3\,|q|^2\,dx\,dt = -\iint_{\mathcal{O}\times(0,T)} q\,\widehat{u}\,dx\,dt + \int_0^T \langle F_0(t) + \nabla \cdot F(t), \widehat{z}(t)\rangle\,dt. \tag{2.21}$$

Therefore,

$$\begin{aligned} & s^3\,\lambda^4 \iint_Q e^{-2s\alpha}\,\xi^3\,|q|^2\,dx\,dt \\ & \le \left(\int_0^T \int_{\mathcal{O}} e^{-2s\alpha}\,\xi^3\,|q|^2\,dx\,dt \right)^{1/2} \left(\int_0^T \int_{\mathcal{O}} e^{2s\alpha}\,\xi^{-3}\,|\widehat{u}|^2\,dx\,dt \right)^{1/2} \\ & \quad + \left(\iint_Q e^{-2s\alpha} |F_0|^2\,dx\,dt \right)^{1/2} \left(\iint_Q e^{2s\alpha} |\widehat{z}|^2\,dx\,dt \right)^{1/2} \\ & \quad + \left(\iint_Q e^{-2s\alpha}\,\xi^2 |F|^2\,dx\,dt \right)^{1/2} \left(\iint_Q e^{2s\alpha}\,\xi^{-2} |\nabla \widehat{z}|^2\,dx\,dt \right)^{1/2}. \end{aligned} \tag{2.22}$$

And now, using (2.20), we see that

$$\begin{aligned} & s^3\,\lambda^4 \iint_Q e^{-2s\alpha}\,\xi^3\,|q|^2\,dx\,dt \le C \Bigg(s^3\,\lambda^4 \iint_{\mathcal{O}\times(0,T)} e^{-2s\alpha}\,\xi^3\,|q|^2\,dx\,dt \\ & \quad + \iint_Q e^{-2s\alpha}\,|F_0|^2\,dx\,dt + s^2\,\lambda^2 \iint_Q e^{-2s\alpha}\,\xi^2\,|F|^2\,dx\,dt \Bigg) \end{aligned} \tag{2.23}$$

for $s \ge \widehat{s}(T + T^2)$ and $\lambda \ge \widehat{\lambda}$.

Let us now get an estimate for the first term on the left-hand side of (2.4). To this end, we multiply by $s\,\lambda^2\, e^{-2s\alpha}\,\xi\, q$ the equation satisfied by q and integrate in space

and time. This gives

$$
\begin{aligned}
s\,\lambda^2 \iint_Q e^{-2s\alpha}\,\xi\,|\nabla q|^2\,dx\,dt + s\frac{\lambda^2}{2}\iint_Q \left((e^{-2s\alpha}\,\xi)_t - \Delta(e^{-2s\alpha}\,\xi)\right)|q|^2\,dx\,dt \\
= s\,\lambda^2 \iint_Q e^{-2s\alpha}(\xi\,F_0\,q - \xi\,F\cdot\nabla q)\,dx\,dt \\
- s\,\lambda^2 \iint_Q F\cdot\nabla(e^{-2s\alpha}\,\xi) q\,dx\,dt.
\end{aligned}
\tag{2.24}
$$

Then we use the estimates

$$
\begin{aligned}
&|(e^{-2s\alpha}\,\xi)_t| \le C\,e^{-2s\alpha}\,(s\,T\,\xi^3 + T\,\xi^2) \le C\,s^2\,e^{-2s\alpha}\,\xi^3, \\
&|\Delta(e^{-2s\alpha}\,\xi)| \le C\,s^2\,\lambda^2\,e^{-2s\alpha}\,\xi^3
\end{aligned}
\tag{2.25}
$$

for $s \ge C(T + T^2)$,

$$
\begin{aligned}
s\,\lambda^2 \left|\iint_Q e^{-2s\alpha}\,\xi\,F_0\,q\,dx\,dt\right| &\le C\left(s^3\lambda^4 \iint_Q e^{-2s\alpha}\xi^3|q|^2\,dx\,dt \right. \\
&\qquad \left. + s^{-1}\iint_Q e^{-2s\alpha}\xi^{-1}|F_0|^2\,dx\,dt\right), \\
s\,\lambda^2 \left|\iint_Q e^{-2s\alpha}\,\xi\,F\cdot\nabla q\,dx\,dt\right| &\le C\,s\,\lambda^2 \iint_Q e^{-2s\alpha}\,\xi\,|F|^2\,dx\,dt \\
&\qquad + \frac{1}{2}s\,\lambda^2 \iint_Q e^{-2s\alpha}\,\xi\,|\nabla q|^2\,dx\,dt,
\end{aligned}
\tag{2.26}
$$

and

$$
\begin{aligned}
&s\,\lambda^2 \left|\iint_Q F\cdot\nabla(e^{-2s\alpha}\,\xi) q\,dx\,dt\right| \\
&\le C\left(s\,\lambda^2 \iint_Q e^{-2s\alpha}\,\xi\,|F|^2\,dx\,dt + s^3\,\lambda^4 \iint_Q e^{-2s\alpha}\,\xi^3\,|q|^2\,dx\,dt\right),
\end{aligned}
\tag{2.27}
$$

to obtain from (2.24) the following:

$$
\begin{aligned}
s\,\lambda^2 \iint_Q e^{-2s\alpha}\,\xi\,|\nabla q|^2\,dx\,dt \le C\left(s^3\,\lambda^4 \iint_Q e^{-2s\alpha}\,\xi^3\,|q|^2\,dx\,dt \right. \\
\left. + \iint_Q e^{-2s\alpha}\,|F_0|^2\,dx\,dt + s\,\lambda^2 \iint_Q e^{-2s\alpha}\,\xi\,|F|^2\,dx\,dt\right)
\end{aligned}
\tag{2.28}
$$

for $s \ge C(T + T^2)$. This, together with (2.23), provides (2.4).

Let us finally prove (2.20).

We first multiply the equation in (2.11) by p, so we have

$$
\chi(p,p) = -s^3\,\lambda^4 \iint_Q e^{-2s\alpha}\,\xi^3\,q\,p\,dx\,dt,
\tag{2.29}
$$

which, combined with the Carleman inequality (1.18) proved in Lemma 1.3, provides the desired inequality for the two first terms on the left-hand side of (2.20).

To estimate the first order term, we multiply by $s^{-2}\lambda^{-2}e^{2s\alpha}\,\xi^{-2}\,\widehat{z}$ the equation verified by $\widehat{z}$. Then we integrate by parts with respect to the space variable and get

$$\begin{aligned} &s^{-2}\lambda^{-2}\iint_Q e^{2s\alpha}\,\xi^{-2}\,\widehat{z}\,\widehat{z}_t\,dx\,dt + s^{-2}\lambda^{-2}\iint_Q e^{2s\alpha}\,\xi^{-2}\,|\nabla\widehat{z}|^2\,dx\,dt \\ &\quad - 2s^{-1}\lambda^{-1}\iint_Q e^{2s\alpha}\,\xi^{-1}\nabla\eta^0\cdot\nabla\widehat{z}\,\widehat{z}\,dx\,dt \\ &\quad - 2s^{-2}\lambda^{-1}\iint_Q e^{2s\alpha}\,\xi^{-2}\nabla\eta^0\cdot\nabla\widehat{z}\,\widehat{z}\,dx\,dt \\ &\quad = s\,\lambda^2\iint_Q \xi\,q\,\widehat{z} + s^{-2}\lambda^{-2}\iint_{\mathcal{O}\times(0,T)} e^{2s\alpha}\,\xi^{-2}\,\widehat{u}\,\widehat{z}\,dx\,dt. \end{aligned} \tag{2.30}$$

This time, let us integrate by parts in the first term with respect to the time variable:

$$\begin{aligned} &s^{-2}\lambda^{-2}\iint_Q e^{2s\alpha}\,\xi^{-2}\,\widehat{z}\,\widehat{z}_t\,dx\,dt \\ &\quad = -\frac{1}{2}s^{-2}\lambda^{-2}\iint_Q (e^{2s\alpha}\,\xi^{-2})_t\,|\widehat{z}|^2\,dx\,dt \\ &\quad \le C\,s^{-1}\lambda^{-2}\,T\iint_Q e^{2s\alpha}\,|\widehat{z}|^2\,dx\,dt \le C\iint_Q e^{2s\alpha}\,|\widehat{z}|^2\,dx\,dt \end{aligned} \tag{2.31}$$

for $s \ge C\,T$ and $\lambda \ge 1$.

Finally, we use Young's inequality for the other terms of (2.30) and obtain

$$\begin{aligned} &- 2s^{-1}\lambda^{-1}\iint_Q e^{2s\alpha}\,\xi^{-1}\nabla\eta^0\cdot\nabla\widehat{z}\,\widehat{z}\,dx\,dt \\ &- 2s^{-2}\lambda^{-1}\iint_Q e^{2s\alpha}\,\xi^{-2}\nabla\eta^0\cdot\nabla\widehat{z}\,\widehat{z}\,dx\,dt \\ &\quad \le C\iint_Q e^{2s\alpha}\,|\widehat{z}|^2\,dx\,dt + \frac{1}{2}s^{-2}\lambda^{-2}\iint_Q e^{2s\alpha}\,\xi^{-2}\,|\nabla\widehat{z}|^2\,dx\,dt, \end{aligned} \tag{2.32}$$

$$s\,\lambda^2\iint_Q \xi\,q\,\widehat{z} \le C\left(\iint_Q e^{2s\alpha}\,|\widehat{z}|^2\,dx\,dt + s^3\,\lambda^4\iint_Q e^{-2s\alpha}\,\xi^3\,|q|^2\,dx\,dt\right), \tag{2.33}$$

and

$$\begin{aligned} &s^{-2}\lambda^{-2}\iint_{\mathcal{O}\times(0,T)} e^{2s\alpha}\,\xi^{-2}\,\widehat{u}\,\widehat{z}\,dx\,dt \\ &\quad \le C\left(\iint_Q e^{2s\alpha}\,|\widehat{z}|^2\,dx\,dt + s^{-3}\lambda^{-4}\iint_{\mathcal{O}\times(0,T)} e^{2s\alpha}\,\xi^{-3}\,|\widehat{u}|^2\,dx\,dt\right) \end{aligned} \tag{2.34}$$

for $s \ge C\,T^2$.

As a conclusion, we deduce (2.20) directly from (2.30).

Remark 7. In the same spirit of Remark 4, it would be very interesting to know whether or not the powers of s and λ in (2.4) are optimal.

2.2. Null controllability of other semilinear problems and further comments. With the help of Lemma 2.1, Theorem 2.2, and some variants, we can now prove the null controllability of other nonlinear parabolic systems. This is the goal of this section.

2.2.1. Null controllability of the semilinear heat equation with nonlinearities in the zero and first order terms. In this paragraph, we will deduce the null controllability of the system

$$\begin{cases} y_t - \Delta y + f(y, \nabla y) = v 1_{\mathcal{O}} & \text{in} \quad Q, \\ y = 0 & \text{on} \quad \Sigma, \\ y(0) = y^0 & \text{in} \quad \Omega, \end{cases} \tag{2.35}$$

where we suppose $y^0 \in H_0^1(\Omega) \cap W^{1,\infty}(\Omega)$, $f \in C^1(\mathbf{R} \times \mathbf{R}^N)$, $f(0,0) = 0$, and

$$f(s,p) = g(s,p)s + G(s,p) \cdot p \quad \forall (s,p) \in \mathbf{R} \times \mathbf{R}^N \tag{2.36}$$

for some functions g and G satisfying $|g| \leq C$ and $|G| \leq C$.

To this end, we will combine Theorem 2.2 and a fixed point argument.

Thus, let us consider the map

$$z \in L^2(0,T; H_0^1(\Omega)) \mapsto y_z \in L^2(0,T; H_0^1(\Omega)), \tag{2.37}$$

where (y_z, v_z) is the solution of

$$\begin{cases} (y_z)_t - \Delta y_z + g(z, \nabla z)\, y_z + G(z, \nabla z) \cdot \nabla y_z = v_z 1_{\mathcal{O}} & \text{in} \quad Q, \\ y_z = 0 & \text{on} \quad \Sigma, \\ y_z(0) = y^0, \quad y_z(T) = 0 & \text{in} \quad \Omega, \end{cases} \tag{2.38}$$

constructed as in the previous subsection. We know that

$$\|v_z\|_{L^2(\mathcal{O} \times (0,T))} \leq K \, \|y^0\|_{L^2(\Omega)}, \tag{2.39}$$

with a constant K of the form

$$K = \exp\left\{ C \left(1 + \frac{1}{T} + \|g\|_\infty^{2/3} + T \, \|g\|_\infty + (1+T)\|G\|_\infty^2 \right) \right\}. \tag{2.40}$$

Now, one can check from parabolic regularity and the fact that g and G are uniformly bounded that Kakutani's fixed point theorem is applicable. For convenience, let us state this result.

THEOREM 2.3. *Let Z be a Banach space and let $\Lambda : Z \mapsto Z$ be a set-valued mapping satisfying the following assumptions:*

1. *$\Lambda(z)$ is a nonempty closed convex set of Z for every $z \in Z$.*
2. *There exists a nonempty convex compact set $K \subset Z$ such that $\Lambda(K) \subset K$.*
3. *Λ is upper-hemicontinuous in Z, i.e., for each $\sigma \in Z'$ the single-valued mapping*

$$z \mapsto \sup_{y \in \Lambda(z)} \langle \sigma, y \rangle_{Z',Z} \tag{2.41}$$

is upper-semicontinuous.

Then Λ possesses a fixed point in the set K, i.e., there exists $z \in K$ such that $z \in \Lambda(z)$.

For the proof, see, for instance, [3]. We then have the following result.

THEOREM 2.4. *Under the previous assumptions on y^0 and f,* (2.35) *is null controllable with controls v satisfying*

$$\|v\|_{L^2(\mathcal{O}\times(0,T))} \leq K \|y^0\|_{L^2(\Omega)}, \tag{2.42}$$

where the constant K is given by (2.40).

Now, we pretend to extend this result to the (superlinear) case where we only have $f \in C^1(\mathbf{R}\times\mathbf{R}^N)$ and $f(0,0) = 0$. This time, to apply similar arguments, one must work in the space $L^\infty(0,T;W^{1,\infty}(\Omega))$ instead of $L^2(0,T;H_0^1(\Omega))$. In fact, we have the following result (see [16]).

THEOREM 2.5. *Assume that $f \in C^1(\mathbf{R}\times\mathbf{R}^N)$, $f(0,0) = 0$, and* (2.36) *holds with*

$$\frac{g(s,p)}{\log^{3/2}(1+|s|+|p|)} \to 0 \quad \textit{and} \quad \frac{G(s,p)}{\log^{1/2}(1+|s|+|p|)} \to 0 \tag{2.43}$$

as $|s| \to +\infty$. Then (2.35) *is null controllable with controls in $L^\infty(\mathcal{O}\times(0,T))$.*

Remark 8. As in Theorem 1.7, it is unknown whether system (2.35) is controllable when

$$|g(s,p)| \sim \log^\beta(1+|s|+|p|) \quad \text{and/or} \quad |G(s,p)| \sim \log^\gamma(1+|s|+|p|) \tag{2.44}$$

with $\beta > \frac{3}{2}$, $\gamma > \frac{1}{2}$.

Let us now address other typical controllability problems in this context.

(A) Going back to system (1.83), with no hypothesis on the growth of f, the null controllability can be achieved if f possesses the "good sign," that is to say, if $f(s)\,s \geq 0$ for all $s \in \mathbf{R}$.

In this situation, it can be proved that, for any $\rho > 0$, there exists a time $T = T(\Omega,\mathcal{O},f,\rho) > 0$ such that, for every $y^0 \in L^2(\Omega)$ with $\|y^0\|_{L^2(\Omega)} \leq \rho$, there exists a control $v \in L^2(\mathcal{O}\times(0,T))$ whose associated solution y verifies $y(T) = 0$ (see [2], [5], and [28] for more details).

(B) Using methods similar to those above, the exact controllability to the trajectories can be deduced as well. For instance, the following result is proved in [16].

THEOREM 2.6. *Let us assume that $y^0 \in H_0^1(\Omega)\cap W^{1,\infty}(\Omega)$, $f \in C^1(\mathbf{R}\times\mathbf{R}^N)$,*

$$\frac{1}{\log^{3/2}(1+|s|+|p|)} \left| \int_0^1 \frac{\partial f}{\partial s}(s_0+\lambda s, p_0+\lambda p)\, d\lambda \right| \to 0 \tag{2.45}$$

and

$$\frac{1}{\log^{1/2}(1+|s|+|p|)} \left| \int_0^1 \frac{\partial f}{\partial p_i}(s_0+\lambda s, p_0+\lambda p)\, d\lambda \right| \to 0 \tag{2.46}$$

for $1 \leq i \leq N$ as $|(s,p)| \to +\infty$, uniformly in $(s_0,p_0) \in K$ for every compact set $K \subset \mathbf{R}\times\mathbf{R}^N$. Let $y_*^0 \in H_0^1(\Omega)\cap W^{1,\infty}(\Omega)$ and $v_* \in L^\infty(\mathcal{O}\times(0,T))$ be given and let $y_* \in C([0,T];W^{1,\infty}(\Omega))$ be the corresponding solution to (2.35). *Then there exists $v \in L^\infty(\mathcal{O}\times(0,T))$ such that its associated solution y verifies $y(T) = y_*(T)$.*

2.2.2. Heat equations with Fourier boundary conditions. In this paragraph, we will recall some recent results concerning the null and exact controllability to the trajectories of the following partial differential systems:

$$\begin{cases} y_t - \Delta y + B \cdot \nabla y + a\, y = v 1_{\mathcal{O}} & \text{in} \quad Q, \\ \dfrac{\partial y}{\partial n} + \beta\, y = 0 & \text{on} \quad \Sigma, \\ y(0) = y^0 & \text{in} \quad \Omega \end{cases} \tag{2.47}$$

and

$$\begin{cases} y_t - \Delta y + F(y, \nabla y) = v 1_{\mathcal{O}} & \text{in} \quad Q, \\ \dfrac{\partial y}{\partial n} + f(y) = 0 & \text{on} \quad \Sigma, \\ y(0) = y^0 & \text{in} \quad \Omega, \end{cases} \tag{2.48}$$

where $y^0 \in L^2(\Omega)$,

$$a \in L^\infty(Q), \quad B \in L^\infty(Q)^N, \quad \beta \in L^\infty(\Sigma), \tag{2.49}$$

and (for instance)

$$F \in C^1(\mathbf{R} \times \mathbf{R}^N), \quad f \in C^1(\mathbf{R}). \tag{2.50}$$

Let us first deduce a null controllability result for (2.47). To this end, we will need, as before, an observability estimate for the solutions to the adjoint system associated to (2.47).

Thus, let us consider the backwards system

$$\begin{cases} -\varphi_t - \Delta\varphi - \nabla \cdot (\varphi\, B(x,t)) + a(x,t)\, \varphi = 0 & \text{in} \quad Q, \\ (\nabla\varphi + \varphi\, B(x,t)) \cdot n + \beta(x,t)\, \varphi = 0 & \text{on} \quad \Sigma, \\ \varphi(T) = \varphi^0 & \text{in} \quad \Omega, \end{cases} \tag{2.51}$$

where $\varphi^0 \in L^2(\Omega)$. For the solutions to these problems, one has the following Carleman inequality (see [21]):

$$\iint_Q e^{-2s\zeta}\, \kappa^3\, |\varphi|^2\, dx\, dt \le C \iint_{\mathcal{O}\times(0,T)} e^{-2s\zeta}\, \kappa^3\, |\varphi|^2\, dx\, dt \tag{2.52}$$

for appropriate positive weight functions κ and ζ (similar to those defined in section 1) depending on a parameter λ and a suitable choice of s and λ. The proof of (2.52) can be achieved using duality arguments similar to those presented in the proof of Lemma 2.1.

From (2.52), one can easily deduce an observability inequality for the solutions to (2.51). This yields the next null controllability result.

THEOREM 2.7. *Let* (2.49) *be fulfilled. Then, for all* $y^0 \in L^2(\Omega)$, *there exists a control* $v \in L^\infty(\mathcal{O} \times (0,T))$ *such that the associated solution to* (2.47) *verifies*

$$y(T) = 0 \quad \textit{in} \quad \Omega. \tag{2.53}$$

Finally, the same arguments used in [28], based on the explicit dependence of the constant C in (2.52) with respect to T and the L^∞-norms of the coefficients a, B, and β, lead to an exact controllability result to the trajectories for the nonlinear system (2.48).

THEOREM 2.8. *Let* (2.50) *be fulfilled and let* $\overline{y}$ *be a solution of the nonlinear system* (2.48) *with* $v \equiv 0$ *such that*

$$\overline{y} \in L^2(0,T;H^1(\Omega)) \cap L^\infty(Q), \quad \overline{y}(0) \in L^\infty(\Omega).$$

Moreover, assume that the functions F *and* f *verify*

$$\lim_{|s|\to\infty} \frac{|F(s,p)-F(r,p)|}{|s-r|\log^{3/2}(1+|s-r|)} = 0 \tag{2.54}$$

uniformly in $(r,p) \in \mathbf{R}\times\mathbf{R}^N$,

$$\begin{cases} \forall L>0,\ \exists M>0 \ \text{ such that} \\ |F(s,p)-F(r,p)| \le M|s-r|, \quad |F(s,p)-F(s,q)| \le M|p-q| \\ \forall (s,r,p,q) \in [-L,L]^2 \times \mathbf{R}^N \times \mathbf{R}^N, \end{cases} \tag{2.55}$$

and

$$\lim_{|s|\to\infty} \frac{|f(s)-f(r)|}{|s-r|\log^{1/2}(1+|s-r|)} = 0 \tag{2.56}$$

uniformly in $r \in \mathbf{R}$. *Then there exist controls* $v \in L^\infty(\mathcal{O}\times(0,T))$ *and associated solutions* y *to* (2.48) *such that* $y(T) = \overline{y}(T)$.

For the proof of this result and other related questions, see [22].

2.2.3. Null controllability of some variants of the heat system. Here, we are interested in solving the null controllability problem of more general parabolic systems, where various coefficients appear in the differential equation.

We first consider the case of a general second order differential operator in the heat system—more precisely, the following problem:

$$\begin{cases} y_t - \displaystyle\sum_{i,j=1}^N \partial_i(a_{ij}\,\partial_j y) = v1_{\mathcal{O}} & \text{in} \quad Q, \\ y = 0 & \text{on} \quad \Sigma, \\ y(0) = y^0 & \text{in} \quad \Omega, \end{cases} \tag{2.57}$$

where $y^0 \in L^2(\Omega)$ and the coefficients $a_{ij} = a_{ji} \in W^{1,\infty}(Q)\,(1 \le i,j \le N)$ form a uniformly elliptic matrix. For the solutions to the adjoint system associated to (2.57) (which is in fact the same), we find a global Carleman inequality in the recent paper [51]. Of course, this leads to the null controllability of (2.57).

Analogously as we found in Theorem 2.2, this allows us to deduce a null controllability result for (2.57) in a more general case.

THEOREM 2.9. *Let us assume that, in* (2.57), *the coefficients* a_{ij} *are of the form* $a_{ij} = a_{ij}^0 + \varepsilon\, h_{ij}$ *with* $a_{ij}^0 = a_{ji}^0 \in W^{1,\infty}(Q)$ *uniformly elliptic,* $(T-t)^{-1/2}h_{ij} \in L^\infty(Q)$ *and* ε *small enough, depending on* Ω, $\mathcal{O}$, T, a_{ij}^0, *and* h_{ij}. *Then, for any* $T>0$, *system* (2.57) *is null controllable at time* T.

For the proof of Theorem 2.9, it suffices to combine the previously mentioned result for general $a_{ij} \in W^{1,\infty}(Q)$ with Lemma 2.1 adapted to this situation.

The second case we consider is the following:

$$\begin{cases} y_t - \displaystyle\sum_{i,j=1}^{N} a_{ij}\,\partial_{ij} y = v1_{\mathcal{O}} & \text{in} \quad Q, \\ y = 0 & \text{on} \quad \Sigma, \\ y(0) = y^0 & \text{in} \quad \Omega, \end{cases} \tag{2.58}$$

with $y^0 \in L^2(\Omega)$. To prove the null controllability of (2.58), we can use a recent Carleman inequality which can be found in [23] for heat equations with right-hand sides in $L^2(0,T;H^{-2}(\Omega))$. This is given in the following result.

LEMMA 2.10. *Let us consider the following problem:*

$$\begin{cases} -z_t - \Delta z = \displaystyle\sum_{i,j=1}^{N} \partial_{ij} H_{ij} & \textit{in} \quad Q, \\ z = 0 & \textit{on} \quad \Sigma, \\ z(T) = z^0 & \textit{in} \quad \Omega, \end{cases} \tag{2.59}$$

where $z_0 \in H^{-1}(\Omega)$ and the functions H_{ij} verify $H_{ij} \in L^2(Q)$ with

$$\sum_{j=1}^{N} \partial_j H_{ij} \in L^2(Q) \quad \textit{and} \quad \sum_{j=1}^{N} H_{ij}\, n_j = 0. \tag{2.60}$$

There exist constants $C_3(\Omega,\mathcal{O}) > 0$, $\lambda_3 = C(\Omega,\mathcal{O})$, and $s_3 = C(\Omega,\mathcal{O})(T+T^2)$ such that

$$\begin{aligned} s^3\lambda^4 \iint_Q e^{-2s\alpha}\,\xi^3\,|z|^2\,dx\,dt \le C_3 \Bigg(& s^3\lambda^4 \iint_{\mathcal{O}\times(0,T)} e^{-2s\alpha}\,\xi^3\,|z|^2\,dx\,dt \\ & + s^4\lambda^4 \sum_{i,j=1}^{N} \iint_Q e^{-2s\alpha}\,\xi^4\,|H_{ij}|^2\,dx\,dt \Bigg) \end{aligned} \tag{2.61}$$

for all $\lambda \ge \lambda_3$ and $s \ge s_3$.

Let us introduce the adjoint system to (2.58):

$$\begin{cases} -\varphi_t - \partial_{ij}(a_{ij}\,\varphi) = 0 & \text{in} \quad Q, \\ \varphi = 0 & \text{on} \quad \Sigma, \\ \varphi(T) = \varphi^0 & \text{in} \quad \Omega. \end{cases} \tag{2.62}$$

A simple application of Lemma 2.10 gives the following result.

THEOREM 2.11. *Let T be an arbitrary positive time. Let us suppose that $a_{ij} = \delta_{ij} + \varepsilon\, h_{ij}\,(i,j = 1,\dots,N)$ with $(T-t)^{-1/2} h_{ij} \in L^\infty(Q)$ and $\varepsilon > 0$ small enough, depending on Ω, $\mathcal{O}$, and T. Then* (2.58) *is null controllable at time T.*

Let us finally consider the control problem

$$\begin{cases} b\,y_t - \Delta y = v1_{\mathcal{O}} & \text{in} \quad Q, \\ y = 0 & \text{on} \quad \Sigma, \\ y(0) = y^0 & \text{in} \quad \Omega, \end{cases} \tag{2.63}$$

whose adjoint system is the following:

$$\begin{cases} -(b\,\varphi)_t - \Delta\varphi = 0 & \text{in} \quad Q, \\ \varphi = 0 & \text{on} \quad \Sigma, \\ \varphi(T) = \varphi^0 & \text{in} \quad \Omega. \end{cases} \tag{2.64}$$

In order to analyze the null controllability of (2.63), we need a Carleman inequality for heat equations with right-hand sides in $H^{-1}(0,T;L^2(\Omega))$. Its proof can also be found in [23].

LEMMA 2.12. *Consider the system*

$$\begin{cases} -z_t - \Delta z = G_t\,Q, \\ z = 0\,\Sigma, \\ z(T) = z^0\,\Omega, \end{cases} \tag{2.65}$$

where $z^0 \in H^{-1}(\Omega)$ *and* $G \in L^2(Q)$ *with* $G \in C_w([0,T];H^{-1}(\Omega))$. *Then there exist* $C_4(\Omega,\mathcal{O}) > 0$, $\lambda_4 = C(\Omega,\mathcal{O})$, *and* $s_4 = C(\Omega,\mathcal{O})(T+T^2)$ *such that*

$$\begin{aligned} s^3\lambda^4 \iint_Q e^{-2s\alpha}\,\xi^3\,|z|^2\,dx\,dt \le C_4 \Bigg(& s^3\lambda^4 \iint_{\mathcal{O}\times(0,T)} e^{-2s\alpha}\,\xi^3\,|z|^2\,dx\,dt \\ & + s^4\lambda^4 \iint_Q e^{-2s\alpha}\,\xi^4\,|G|^2\,dx\,dt \Bigg) \end{aligned} \tag{2.66}$$

for all $\lambda \ge \lambda_4$ *and* $s \ge s_4$.

From this Carleman inequality, one can readily deduce the following result.

THEOREM 2.13. *Let* T *be a positive time and let us assume that* $b = 1 + \varepsilon\,h$ *with* $(T-t)^{-1/2}h \in L^\infty(Q)$ *and* $\varepsilon > 0$ *small enough, depending on* Ω, $\mathcal{O}$, *and* T. *Then system* (2.63) *is null controllable at time* T.

Remark 9. The proofs of Lemmas 2.10 and 2.12 are based on the duality arguments presented in Lemma 2.1. Observe in particular that the solutions to systems (2.58) and (2.63) belong only to $L^2(Q)$ and must be defined by transposition.

3. Null controllability of systems of the Stokes kind. In this section, $N = 2$ or $N = 3$. The controllability properties of the Navier–Stokes system have been the subject of intensive research these last years. The question was first considered by Lions in [48], where *approximate controllability* was conjectured. This was followed by several papers, where various partial (positive) answers were furnished. See [18], [10], [11], and [50]. Concerning null controllability and exact controllability to the trajectories, the first local results were given in [29].

For completeness, we will recall briefly one of the main results in [10]. This paper deals with the approximate controllability of the two-dimensional Navier–Stokes equations with *Navier-slip* boundary conditions on the lateral boundary $\partial\Omega \times (0,T)$. Thus, let us assume that the state equation is

$$\begin{cases} y_t + (y\cdot\nabla)y - \Delta y + \nabla p = v1_{\mathcal{O}}, \quad \nabla\cdot y = 0 & \text{in} \quad Q, \\ y\cdot n = 0, \quad \nabla\times y = 0 & \text{on} \quad \Sigma, \\ y(0) = y^0 & \text{in} \quad \Omega \end{cases} \tag{3.1}$$

(where $\Omega \subset \mathbf{R}^2$). The general fact the author makes good use of is the treatment of $(y\cdot\nabla)y$ as the leading term, while $-\Delta y$ is considered as a "disturbance."

Roughly speaking, the following is proved: Let y^0 and y^1 be two prescribed velocity fields. Then the fluid can be driven from y^0 at time $t = 0$ to a velocity field at time $t = T$ which is arbitrarily close to y^1. Here, "arbitrarily close" means that, for instance, the distance of the velocity field to y^1 in $W^{-1,\infty}(\Omega)$ and the distance of the vorticity to $\nabla \times y_1$ in all spaces $L^\infty(K)$ ($K \subset \Omega$ is an arbitrary compact set) can be made arbitrarily small. This is proved for any $T > 0$, for any regular Ω, y^0, and y^1, and for all nonempty open sets $\mathcal{O} \subset \Omega$.

The proof is as follows:

1. For each $\alpha > 0$, it is possible to find v_α and a couple (y_α, p_α) such that y_α is a gradient outside $\mathcal{O} \times (0,T)$,

$$\begin{cases} y_{\alpha,t} + (y_\alpha \cdot \nabla) y_\alpha - \Delta y_\alpha + \nabla p_\alpha = v_\alpha 1_{\mathcal{O}}, \quad \nabla \cdot y_\alpha = 0 & \text{in} \quad Q, \\ y_\alpha \cdot n = 0, \quad \nabla \times y_\alpha = 0 & \text{on} \quad \Sigma, \\ y_\alpha(0) = y_\alpha(T) = 0 & \text{in} \quad \Omega \end{cases} \tag{3.2}$$

and, furthermore, the linearized Euler system at y_α, that is to say,

$$\begin{cases} z_t + (y_\alpha \cdot \nabla) z + (z \cdot \nabla) y_\alpha + \nabla \pi = w 1_{\mathcal{O}}, \quad \nabla \cdot z = 0 & \text{in} \quad Q, \\ z \cdot n = 0, \quad \nabla \times z = 0 & \text{on} \quad \Sigma, \end{cases} \tag{3.3}$$

is α-controllable in the following sense: For any given z_0 and z_d of class C^∞, there exists a control w such that (3.3) possesses at least one solution bounded in $C^3(\overline{Q})$ independently of α and satisfying

$$z(0) = z_0 \ \text{ in } \ \Omega$$

and

$$z(T) = z_d \ \text{ in } \ \{\, x \in \Omega;\ \text{dist}\,(x, \partial\Omega) \geq \alpha \,\}$$

(notice we are saying that, for every α, this property is satisfied *for any* z_0 and z_d).

2. Let us set $v(x,t) = 0$ in (3.1) for $t \in [0, (1-\delta)T]$ (δ will be determined below). This defines y and p without ambiguity in $\Omega \times [0, (1-\delta)T]$ and, in particular, we can speak of $y((1-\delta)T)$. In $[(1-\delta)T, T]$, we do the following:

- First, v_α, y_α, and p_α are rescaled. In view of the α-controllability of (3.3), we introduce a first control function $\widetilde{v}$:

$$\widetilde{v}(x,t) \equiv \frac{1}{\delta} v_\alpha\left(x, \frac{1}{\delta}(t - (1-\delta)T)\right) + w\left(x, \frac{1}{\delta}(t - (1-\delta)T)\right).$$

  The associate state is

$$(\widetilde{y}, \widetilde{p}) \equiv \frac{1}{\delta}(y_\alpha, p_\alpha)\left(x, \frac{1}{\delta}(t - (1-\delta)T)\right) + (z, \pi)\left(x, \frac{1}{\delta}(t - (1-\delta)T)\right).$$

  Here, w and (z, π) are perturbations depending on α (which will be also fixed below), the initial state $y((1-\delta)T)$, and the desired state y_d. In order to drive (3.1) to a final state close to y_d, it is natural (at least formally) to look for a control close to $\widetilde{v}$ for $t \in [(1-\delta)T, T]$.
- We introduce a second control function by modifying $\widetilde{v}$ just as needed. Thus, we solve the following problem:

$$\begin{cases} y_t + (y \cdot \nabla) y - \Delta y + \nabla p = v 1_{\mathcal{O}} + (\nabla \times \overline{y})(y - \widetilde{y})^\perp, \quad \nabla \cdot y = 0 & \text{in} \quad Q, \\ y \cdot n = 0, \quad \nabla \times y = 0 & \text{on} \quad \Sigma, \\ y(0) = y^0 & \text{in} \quad \Omega. \end{cases}$$

Here, we have introduced the function

$$\overline{y}(x,t) = \frac{1}{\delta} y_\alpha \left(x, \frac{1}{\delta}(t-(1-\delta)T) \right), \quad (a_1,a_2)^\perp = (-a_2,a_1).$$

Since $\nabla \times \overline{y}$ vanishes outside $\mathcal{O} \times (0,T)$, it is clear that (y,p) solves (3.1) with

$$v = \widetilde{v} + (\nabla \times \overline{y})(y - \widetilde{y})^\perp.$$

Now, the task is reduced to show that for every $\varepsilon > 0$, there exist positive α and δ such that

$$\|y(T) - y_d\|_{W^{-1,\infty}} \leq \varepsilon. \tag{3.4}$$

This can be achieved in the following way. Let us set $R = y - y^0$, $\omega = \nabla \times R$. Then

$$\partial_t \omega + (R + y^0) \cdot \nabla \omega - \Delta \omega = -(R+z) \cdot \nabla(\nabla \times z) + \Delta(\nabla \times z)$$

in $\Omega \times ((1-\delta)T, T)$. Furthermore, $R(x,(1-\delta)T) \equiv 0$ and z and all its derivatives of order ≤ 3 are uniformly bounded. This leads, at first time, to a pointwise estimate of ω and then to an estimate of $R(\cdot,T)$ in $W^{-1,\infty}(\Omega)$ when α and δ are sufficiently small. Consequently, for any given $\varepsilon > 0$, there exist $\alpha^0 > 0$ and $\eta : (0,\alpha^0) \mapsto \mathbf{R}_+$ such that whenever $0 < \alpha < \alpha^0$ and $0 < \delta < \eta(\alpha)$, one has (3.4) (for further details, see [10]).

This method has several limitations. Thus, the boundary conditions have to be of the Navier-slip type. In practice, this is equivalent to prescribing the values on the boundary of the stream function and the vorticity. At present, it is unknown how the method has to be modified in order to keep its validity in the context of Dirichlet (no-slip) boundary conditions. The case in which Ω is a manifold without boundary is considered in [11].

An extension of this method to Boussinesq systems in spatial dimensions $N = 2$ and $N = 3$ has been given in [31]. For the analysis of the similar three-dimensional situation for the Euler equations, see [33].

In the remainder of this section, we will be concerned with the null controllability of Stokes-like and Navier–Stokes systems completed with Dirichlet boundary conditions. Let us recall the definition of the following spaces, which are usual in the analysis of Stokes systems:

$$\mathcal{V} = \{ z \in C_0^\infty(\Omega)^N : \nabla \cdot z = 0 \text{ in } \Omega \}$$

and

$$H \text{ (resp., } V) = \text{the adherence of } \mathcal{V} \text{ in } L^2(\Omega)^N \text{ (resp., } H_0^1(\Omega)^N).$$

We have

$$H = \{ z \in L^2(\Omega)^N : \nabla \cdot z = 0 \text{ in } \Omega,\ z \cdot n = 0 \text{ on } \partial\Omega \} \tag{3.5}$$

and

$$V = \{ z \in H_0^1(\Omega)^N : \nabla \cdot z = 0 \text{ in } \Omega \}. \tag{3.6}$$

For instance, see [55].

3.1. Null controllability of Stokes systems. We are first interested in proving the null controllability of some systems of the Stokes kind with distributed control. In other words, we would like to be able to find v, y, and p such that

$$\begin{cases} y_t - \Delta y + \nabla \cdot (y \otimes \overline{y}) + \nabla \cdot (\overline{y} \otimes y) + \nabla p = v 1_{\mathcal{O}} & \text{in} \quad Q, \\ \nabla \cdot y = 0 & \text{in} \quad Q, \\ y = 0 & \text{on} \quad \Sigma, \\ y(0) = y^0 & \text{in} \quad \Omega \end{cases} \tag{3.7}$$

and

$$y(T) = 0 \quad \text{in } \Omega \tag{3.8}$$

for any $y^0 \in H$. Here, we will assume that the following regularity properties hold:

$$\overline{y} \in L^\infty(Q)^N, \quad \overline{y}_t \in L^2(0,T; L^\sigma(\Omega))^N, \tag{3.9}$$

with $\sigma > 1$ if $N = 2$ and $\sigma > 6/5$ if $N = 3$.

Let us remark that (3.7) can be viewed as the linearized Navier–Stokes system, so we are actually trying to prove the exact controllability to the trajectories of those equations. In fact, this will serve to deduce the local exact controllability to the trajectories of the Navier–Stokes equations.

A previous result of this kind was proved in [37] under stronger hypotheses on the trajectory $\overline{y}$. In what follows, we will sketch the arguments presented in [24], which are also based on those in [37].

Concerning the null controllability of (3.7), we will first recall a Carleman inequality for the backwards system

$$\begin{cases} -\varphi_t - \Delta \varphi - (D\varphi)\,\overline{y} + \nabla \pi = 0 & \text{in} \quad Q, \\ \nabla \cdot \varphi = 0 & \text{in} \quad Q, \\ \varphi = 0 & \text{on} \quad \Sigma, \\ \varphi(T) = \varphi^0 & \text{in} \quad \Omega, \end{cases} \tag{3.10}$$

where $D\varphi = \nabla \varphi + \nabla \varphi^t$ and, consequently, the ith component of $(D\varphi)\,\overline{y}$ is

$$((D\varphi)\,\overline{y})_i = \sum_{j=1}^{N} (\partial_j \varphi^i + \partial_i \varphi^j)\,\overline{y}_j. \tag{3.11}$$

To this end, let us introduce the following weight functions:

$$\begin{aligned} &\beta(x,t) = \frac{e^{5/4\lambda k \|\eta\|_\infty} - e^{\lambda(k\|\eta\|_\infty + \eta(x))}}{t^4 (T-t)^4}, \quad \gamma(x,t) = \frac{e^{\lambda(k\|\eta\|_\infty + \eta(x))}}{t^4(T-t)^4}, \\ &\widehat{\beta}(t) = \min_{x \in \overline{\Omega}} \beta(x,t), \quad \beta^*(t) = \max_{x \in \overline{\Omega}} \beta(x,t), \\ &\widehat{\gamma}(t) = \max_{x \in \overline{\Omega}} \gamma(x,t), \quad \gamma^*(t) = \min_{x \in \overline{\Omega}} \gamma(x,t). \end{aligned} \tag{3.12}$$

Here, $k > 4$ is a fixed number and η is the function given by Lemma 1.2 associated to $\omega = \mathcal{O}_5 \subset\subset \mathcal{O}$. Then we have the following.

LEMMA 3.1. *Let us assume that* (3.9) *is satisfied. Then for every* $\varphi^0 \in H$ *there exist three positive constants* $\overline{s}$, $\overline{\lambda}$, *and* C *depending only on* Ω *and* $\mathcal{O}$, *such that*

$$\begin{aligned} &s^{-1}\iint_Q e^{-2s\beta}\,\gamma^{-1}\,|\varphi_t|^2\,dx\,dt + s^{-1}\iint_Q e^{-2s\beta}\,\gamma^{-1}\,|\Delta\varphi|^2\,dx\,dt \\ &+ s\lambda^2\iint_Q e^{-2s\beta}\,\gamma\,|\nabla\varphi|^2\,dx\,dt + s^3\lambda^4\iint_Q e^{-2s\beta}\,\gamma^3\,|\varphi|^2\,dx\,dt \\ &\le C\,s^{16}\lambda^{40}(1+T^2)\iint_{\mathcal{O}\times(0,T)} e^{-8s\widehat{\beta}+6s\beta^*}\,\widehat{\gamma}^{16}\,|\varphi|^2\,dx\,dt \end{aligned} \tag{3.13}$$

for all $\lambda \ge \overline{\lambda}(1 + \|\overline{y}\|_\infty + \|\overline{y}_t\|^2_{L^2(L^\sigma)} + e^{\overline{\lambda}T\|\overline{y}\|^2_\infty})$ *and* $s \ge \overline{s}(T^4 + T^8)$.

The proof of Lemma 3.1 is given in the next subsection. Notice that the hypotheses imposed above over $\overline{y}$ are not completely satisfactory. In fact, it is expected (and desirable) that an inequality like (3.13) hold for any $\overline{y} \in L^\infty(Q)^N$, but for the moment this is unknown.

Now, from this Carleman inequality, one can deduce the null controllability of (3.7) in a classical way.

THEOREM 3.2. *Let us assume that* (3.9) *holds. Then for any* $T > 0$, *the linear system* (3.7) *is null controllable with controls* $v \in L^2(\mathcal{O}\times(0,T))^N$ *at time* T.

After some additional work, one can also deduce some local controllability results for the Navier–Stokes equations. Specifically, we mean local exact controllability to the trajectories. Thus, let us introduce the Navier–Stokes system

$$\begin{cases} y_t - \Delta y + \nabla\cdot(y\otimes y) + \nabla p = v1_{\mathcal{O}} & \text{in} \quad Q, \\ \nabla\cdot y = 0 & \text{in} \quad Q, \\ y = 0 & \text{on} \quad \Sigma, \\ y(0) = y^0 & \text{in} \quad \Omega. \end{cases} \tag{3.14}$$

We have the following.

THEOREM 3.3. *Let* $(\overline{y},\overline{p})$ *be a solution to the Navier–Stokes problem*

$$\begin{cases} \overline{y}_t - \Delta\overline{y} + \nabla\cdot(\overline{y}\otimes\overline{y}) + \nabla\overline{p} = 0 & \textit{in} \quad Q, \\ \nabla\cdot\overline{y} = 0 & \textit{in} \quad Q, \\ \overline{y} = 0 & \textit{on} \quad \Sigma, \\ \overline{y}(0) = \overline{y}^0 & \textit{in} \quad \Omega \end{cases} \tag{3.15}$$

verifying (3.9), *and let us introduce the space* E, *with*

$$E = H \quad \textit{if} \quad N = 2 \qquad \textit{and} \qquad E = H\cap L^4(\Omega)^3 \quad \textit{if} \quad N = 3. \tag{3.16}$$

Then there exists $\varepsilon > 0$ *such that for each* $y^0 \in E$ *satisfying* $\|\overline{y}^0 - y^0\|_E \le \varepsilon$, *there exist controls* $v \in L^2(\mathcal{O}\times(0,T))^N$ *and associated states* (y,p) *such that one has* (3.14) *and*

$$y(T) = \overline{y}(T) \quad \textit{in} \quad \Omega. \tag{3.17}$$

This result can be proved by arguing as follows. We deduce in a first step a null controllability result for (3.7) with suitable right-hand side f.

More precisely, let us set $Ly = y_t - \Delta y + \nabla \cdot (\overline{y} \otimes y + y \otimes \overline{y})$ and let us introduce the spaces E_N, with

$$\begin{aligned} E_2 = \{\, (y,v) : {} & e^{2s\widehat{b}-sb^*}\widehat{\gamma}^{-15/4}y,\ e^{4s\widehat{b}-3sb^*}\widehat{\gamma}^{-8}v1_\omega \in L^2(Q)^2, \\ & e^{sb^*/2}(\gamma^*)^{-1/4}y \in L^2(0,T;V) \cap L^\infty(0,T;H), \\ & \exists p : e^{sb^*}(\gamma^*)^{-1/2}(Ly + \nabla p - v1_\omega) \in L^2(0,T;H^{-1}(\Omega)^2)\,\} \end{aligned}$$

and

$$\begin{aligned} E_3 = \{\, (y,v) : {} & e^{2s\widehat{b}-sb^*}\widehat{\gamma}^{-15/4}y,\ e^{4s\widehat{b}-3sb^*}\widehat{\gamma}^{-8}v1_\omega \in L^2(Q)^3, \\ & e^{sb^*/2}(\gamma^*)^{-1/4}y \in L^2(0,T;V) \cap L^\infty(0,T;H), \\ & e^{sb^*/2}(\gamma^*)^{-1/4}y \in L^4(0,T;L^{12}(\Omega)^3), \\ & \exists p : e^{sb^*}(\gamma^*)^{-1/2}(Ly + \nabla p - v1_\omega) \in L^2(0,T;W^{-1,6}(\Omega)^3)\,\}, \end{aligned}$$

where the new weight functions b, b^*, etc., are given by

$$b(x,t) = \frac{e^{5/4\lambda m\|\eta^0\|_\infty} - e^{\lambda(m\|\eta^0\|_\infty + \eta^0(x))}}{\ell(t)^4},$$

$$\widehat{b}(t) = \min_{x\in\overline{\Omega}} b(x,t), \quad b^*(t) = \max_{x\in\overline{\Omega}} b(x,t),$$

$$\gamma(x,t) = \frac{e^{\lambda(m\|\eta^0\|_\infty + \eta^0(x))}}{\ell(t)^4},$$

$$\widehat{\gamma}(t) = \max_{x\in\overline{\Omega}} \gamma(x,t), \quad \gamma^*(t) = \min_{x\in\overline{\Omega}} \gamma(x,t).$$

Here, we have introduced

$$\ell(t) = \begin{cases} T^2/4 & \text{for} \quad 0 < t < T/2, \\ t(T-t) & \text{for} \quad T/2 < t < T. \end{cases}$$

We then have the following.

PROPOSITION 3.4. *Assume that $\overline{y}$ satisfies* (3.9) *and*

- $y^0 \in H$, $e^{sb^*}(\gamma^*)^{-1/2}f \in L^2(0,T;H^{-1}(\Omega)^2)$ *if* $N = 2$;
- $y^0 \in L^4(\Omega)^3 \cap H$, $e^{sb^*}(\gamma^*)^{-1/2}f \in L^2(0,T;W^{-1,6}(\Omega)^3)$ *if* $N = 3$.

Then there exists a control $v \in L^2(\omega \times (0,T))^N$ such that if y is the associated solution to (3.7)*, we have $(y,v) \in E_N$.*

Notice that this is actually a null controllability result for (3.7). Indeed, if $(y,v) \in E_N$, we have in particular that $y(T) = 0$ in Ω.

The rest of the proof of Theorem 3.3 relies on an appropriate *inverse mapping theorem*. More precisely, we use the following result from [1].

PROPOSITION 3.5. *Let X, F be two Banach spaces and let $\mathcal{A} : X \mapsto F$ satisfy $\mathcal{A} \in C^1(X;F)$. Assume that $e_0 \in X$, $\mathcal{A}(e_0) = h_0$, and $\mathcal{A}'(e_0) : X \mapsto F$ is an epimorphism. Then there exists $\delta > 0$ such that for every $h \in F$ satisfying $\|h - h_0\|_F < \delta$, there exists a solution of the equation*

$$\mathcal{A}(e) = h, \quad e \in X.$$

Let us consider the mapping $\mathcal{A} : X \mapsto F$, given by

$$\mathcal{A}(y,v) = (Ly + (y\cdot\nabla)y + \nabla p - v1_\omega, y(\cdot,0)) \quad \forall (y,v) \in X,$$

where $X = E_N$ and

$$F = \begin{cases} L^2(e^{sb^*}(\gamma^*)^{-1/2}; H^{-1}(\Omega)^2) \times H & \text{if } N = 2, \\ L^2(e^{sb^*}(\gamma^*)^{-1/2}; W^{-1,6}(\Omega)^3) \times (L^4(\Omega)^3 \cap H) & \text{if } N = 3. \end{cases}$$

From the definition of E_N, one can easily check that $\mathcal{A}$ is well defined and satisfies $\mathcal{A} \in C^1(X; F)$. Furthermore, the identity

$$\mathrm{Im}(\mathcal{A}'(0,0)) = F$$

is equivalent to the result stated in Proposition 3.4. Therefore, we can apply Proposition 3.5 to $\mathcal{A}$ with $e_0 = (0,0)$ and $h_0 = (0,0)$. This ends the proof of Theorem 3.3.

For more details concerning the local exact controllability of (3.14), see [24]; see also [25].

3.2. Proof of the Carleman inequality. In this subsection, we sketch the proof of Lemma 3.1. This is contained in a more general case covered by the results in [24]. Throughout the proof, C will denote a generic positive constant that may depend on Ω and $\mathcal{O}$ and can change its value from one line to the next.

For easier comprehension, we will divide the proof in several steps.

3.2.1. Carleman estimate for the heat equation and first estimate of the pressure. Let us apply the Carleman inequality (1.18) to each component φ^i with right-hand side

$$-\partial_i \pi + ((D\varphi)\,\overline{y})_i \quad (1 \le i \le N). \tag{3.18}$$

Introducing the notation

$$\begin{aligned} I(s,\lambda;\varphi) = {} & s^{-1} \iint_Q e^{-2sb}\,\gamma^{-1}\,(|\varphi_t|^2 + |\Delta\varphi|^2)\,dx\,dt \\ & + s\lambda^2 \iint_Q e^{-2s\beta}\,\gamma\,|\nabla\varphi|^2\,dx\,dt + s^3\lambda^4 \iint_Q e^{-2s\beta}\,\gamma^3\,|\varphi|^2\,dx\,dt, \end{aligned} \tag{3.19}$$

one has

$$\begin{aligned} I(s,\lambda;\varphi) \le C \Bigg(& s^3\lambda^4 \iint_{\mathcal{O}_5\times(0,T)} e^{-2s\beta}\,\gamma^3\,|\varphi|^2\,dx\,dt \\ & + \iint_Q e^{-2s\beta}\,(|\nabla\pi|^2 + |(D\varphi)\,\overline{y}|^2)\,dx\,dt \Bigg) \end{aligned} \tag{3.20}$$

for $\lambda \ge C$ and $s \ge C(T^7 + T^8)$.

Taking $\lambda \ge C\,\|\overline{y}\|_\infty$ and $s \ge C\,T^8$, one can eliminate the term $|(D\varphi)\,\overline{y}|^2$ on the right-hand side, whence we obtain

$$I(s,\lambda;\varphi) \le C \left(s^3\lambda^4 \iint_{\mathcal{O}_5\times(0,T)} e^{-2s\beta}\,\gamma^3\,|\varphi|^2\,dx\,dt + \iint_Q e^{-2s\beta}\,|\nabla\pi|^2\,dx\,dt \right) \tag{3.21}$$

for $\lambda \ge C(1 + \|\overline{y}\|_\infty)$ and $s \ge C(T^4 + T^8)$.

Let us now present an estimate of the last integral. To this end, we will apply the main result in [38] to the elliptic equation

$$-\Delta\pi(t) = -\nabla \cdot ((D\varphi)\,\overline{y})(t) \quad \text{in} \quad \Omega \tag{3.22}$$

for each $t \in (0,T)$. This provides

(3.23)
$$\int_\Omega e^{2\tau e^{\lambda\eta}} |\nabla\pi(t)|^2\,dx \le C\bigg(\int_{\mathcal{O}_5} e^{2\tau e^{\lambda\eta}} (|\nabla\pi(t)|^2 + \tau^2\lambda^2\, e^{2\lambda\eta}\, |\pi(t)|^2)dx + \tau \int_\Omega e^{2\tau e^{\lambda\eta}}\, e^{\lambda\eta}\, |(D\varphi)\,\overline{y}(t)|^2\,dx + \tau^{1/2}\, e^{2\tau}\, \|\pi(t)\|^2_{H^{1/2}(\partial\Omega)}\bigg)$$

for λ, $\tau \ge C$.

One can readily see that the local term of $|\nabla\pi|^2$ can be eliminated by arguing as in the proof of Lemma 1.3, so we obtain

(3.24)
$$\int_\Omega e^{2\tau e^{\lambda\eta}} |\nabla\pi(t)|^2\,dx \le C\bigg(\tau^2\lambda^2 \int_{\mathcal{O}_4} e^{2\tau e^{\lambda\eta}}\, e^{2\lambda\eta}\, |\pi(t)|^2 dx + \tau \int_\Omega e^{2\tau e^{\lambda\eta}}\, e^{\lambda\eta}\, |(D\varphi)\,\overline{y}(t)|^2\,dx + \tau^{1/2}\, e^{2\tau}\, \|\pi(t)\|^2_{H^{1/2}(\partial\Omega)}\bigg)$$

for an open subset $\mathcal{O}_4$ verifying $\mathcal{O}_5 \subset\subset \mathcal{O}_4 \subset\subset \mathcal{O}$.

Next, we put

$$\tau = \frac{s}{t^4(T-t)^4} e^{\lambda k\|\eta\|_\infty}, \tag{3.25}$$

we multiply (3.24) by

$$exp\left\{-2s\frac{e^{5/4\lambda k\|\eta\|_\infty}}{t^4(T-t)^4}\right\}, \tag{3.26}$$

and we integrate with respect to t in $(0,T)$. This yields

$$\begin{aligned}\iint_Q e^{-2s\beta}\, |\nabla\pi|^2\,dx\,dt \le C\bigg(& s^2\lambda^2 \iint_{\mathcal{O}_4\times(0,T)} e^{-2s\beta}\, \gamma^2\, |\pi|^2\,dx\,dt \\ & + s\iint_Q e^{-2s\beta}\, \gamma\, |(D\varphi)\,\overline{y}|^2\,dx\,dt \\ & + s^{1/2}\int_0^T e^{-2s\beta^*}\, (\gamma^*)^{1/2}\, \|\pi(t)\|^2_{H^{1/2}(\partial\Omega)}\,dt\bigg)\end{aligned} \tag{3.27}$$

for $\lambda \ge C$ and $s \ge C\,T^8$.

Let us now estimate the term containing the trace of π following the ideas of [37]. Thus, let us introduce the functions

$$\varphi^* = s^{1/4}\, e^{-s\beta^*}\, (\gamma^*)^{1/4}\, \varphi \quad \text{and} \quad \pi^* = s^{1/4}\, e^{-s\beta^*}\, (\gamma^*)^{1/4}\, \pi, \tag{3.28}$$

which satisfy

$$\begin{cases} -\varphi^*_t - \Delta\varphi^* + \nabla\pi^* = (D\varphi^*)\,\overline{y} - s^{1/4}\,(e^{-s\beta^*}\,(\gamma^*)^{1/4})_t\,\varphi & \text{in} \quad Q, \\ \nabla\cdot\varphi^* = 0 & \text{in} \quad Q, \\ \varphi^* = 0 & \text{on} \quad \Sigma, \\ \varphi^*(T) = 0 & \text{in} \quad \Omega. \end{cases} \tag{3.29}$$

Using well-known regularity properties of the Stokes system, we find

(3.30)
$$\begin{aligned}\|\pi^*\|^2_{L^2(0,T;H^{1/2}(\partial\Omega))} &\le C\left(\iint_Q (|D\varphi^*\,\overline{y}|^2 + s^{1/2}|(e^{-s\beta^*}\,(\gamma^*)^{1/4})_t|^2\,|\varphi|^2)\,dx\,dt\right)\\ &\le C\left(s^{1/2}\iint_Q e^{-2s\beta^*}\,(\gamma^*)^{1/2}\,|(D\varphi)\,\overline{y}|^2\,dx\,dt\right.\\ &\qquad\left. + s^{5/2}\,T^2\iint_Q e^{-2s\beta^*}\,(\gamma^*)^3\,|\varphi|^2\,dx\,dt\right)\end{aligned}$$

for $s \ge C\,T^8$. This, used in combination with (3.27), leads to the inequality

$$\begin{aligned}\iint_Q e^{-2s\beta}\,|\nabla\pi|^2\,dx\,dt \le C\Bigg(&s^2\lambda^2\iint_{\mathcal{O}_4\times(0,T)} e^{-2s\beta}\,\gamma^2\,|\pi|^2\,dx\,dt\\ &+ s\iint_Q e^{-2s\beta}\,\gamma\,|(D\varphi)\,\overline{y}|^2\,dx\,dt\\ &+ s^{5/2}\,T^2\iint_Q e^{-2s\beta}\,\gamma^3\,|\varphi|^2\,dx\,dt\Bigg),\end{aligned} \tag{3.31}$$

which must hold for $\lambda \ge C$ and $s \ge C\,T^8$.

We finally insert this inequality into (3.21) and absorb the last two terms on the right-hand side:

$$I(s,\lambda;\varphi) \le C\,s^2\lambda^2\iint_{\mathcal{O}_4\times(0,T)} e^{-2s\beta}(s\lambda^2\,\gamma^3\,|\varphi|^2 + \gamma^2\,|\pi|^2)\,dx\,dt \tag{3.32}$$

for $\lambda \ge C(1 + \|\overline{y}\|_\infty)$ and $s \ge C(T^4 + T^8)$.

3.2.2. Local estimate of the pressure. The goal of this paragraph is to estimate the local integral of π appearing in (3.32). This is the most complicated part of the proof. Let us assume that we have chosen π such that

$$\int_{\mathcal{O}_4} \pi(t)\,dx = 0 \quad \forall t \in (0,T). \tag{3.33}$$

Then from the definition of the weight functions and the Poincaré–Wirtinger inequality, we have

$$\begin{aligned}s^2\lambda^2\iint_{\mathcal{O}_4\times(0,T)} e^{-2s\beta}\,\gamma^2\,|\pi|^2\,dx\,dt &\le s^2\lambda^2\iint_{\mathcal{O}_4\times(0,T)} e^{-2s\widehat{\beta}}\,\widehat{\gamma}^2\,|\pi|^2\,dx\,dt\\ &\le C\,s^2\lambda^2\iint_{\mathcal{O}_4\times(0,T)} e^{-2s\widehat{\beta}}\,\widehat{\gamma}^2\,|\nabla\pi|^2\,dx\,dt.\end{aligned} \tag{3.34}$$

Recall that $\widehat{\beta} = \widehat{\beta}(t)$ and $\widehat{\gamma} = \widehat{\gamma}(t)$ are given as follows:

$$\widehat{\beta}(t) = \min_{\overline{\Omega}} \beta(x,t), \quad \widehat{\gamma}(t) = \max_{\overline{\Omega}} \gamma(x,t). \tag{3.35}$$

From the differential equation in (3.10), we deduce that in order to estimate the last integral in (3.34), it suffices to bound locally the Laplacian and the time derivative of the velocity field φ.

A local estimate of $\Delta\varphi$. Let us first introduce two open sets $\mathcal{O}_2$ and $\mathcal{O}_3$, with

$$\mathcal{O}_4 \subset\subset \mathcal{O}_3 \subset\subset \mathcal{O}_2 \subset\subset \mathcal{O}, \tag{3.36}$$

and a function $\rho \in \mathcal{D}(\mathcal{O}_2)$, with $\rho \equiv 1$ in $\mathcal{O}_3$.

Next, we put

$$u(x,t) = \widehat{p}(t)\,\rho(x)\,\Delta\varphi(x,T-t) \quad \forall (x,t) \in \mathbf{R}^N \times (0,T), \tag{3.37}$$

where we have denoted by $\widehat{p}$ the function $\widehat{p}(t) = s\lambda\, e^{-s\widehat{\beta}}\,\widehat{\gamma}$.

From (3.10), we obtain

$$(\Delta\varphi(T-t))_t - \Delta(\Delta\varphi(T-t)) = f \quad \text{in } Q, \tag{3.38}$$

with

$$f(t) = \Delta((D\varphi)\,\overline{y})(T-t) - \nabla(\nabla\cdot((D\varphi)\,\overline{y})(T-t)). \tag{3.39}$$

This provides the following heat problem for the function u:

$$\begin{cases} u_t - \Delta u = F & \text{in} \quad \mathbf{R}^N \times (0,T), \\ u(0) = 0 & \text{in} \quad \mathbf{R}^N, \end{cases} \tag{3.40}$$

with

$$F(t) = \widehat{p}\,\rho\, f + \widehat{p}'\,\rho\,\Delta\varphi(T-t) - 2\widehat{p}\,\nabla\rho\cdot\nabla\Delta\varphi(T-t) - \widehat{p}\,\Delta\rho\,\Delta\varphi(T-t) \tag{3.41}$$

for all $t \in (0,T)$. Then we rewrite F in the form $F = F_1 + F_2$, with

$$\begin{aligned} F_1(t) = {} & \widehat{p}\,\Delta(\rho((D\varphi)\,\overline{y})(T-t)) - \widehat{p}\,\nabla(\nabla\cdot(\rho((D\varphi)\,\overline{y})(T-t))) \\ & + \widehat{p}'\,\Delta(\rho\,\varphi(T-t)) \end{aligned} \tag{3.42}$$

and

$$\begin{aligned} F_2(t) = {} & -2\widehat{p}\,\nabla\rho\cdot\nabla((D\varphi)\overline{y})(T-t) - \widehat{p}\,\Delta\rho\,((D\varphi)\,\overline{y})(T-t) \\ & + \widehat{p}\,\nabla(\nabla\rho\cdot((D\varphi)\,\overline{y})(T-t)) + \widehat{p}\,\nabla\rho\cdot(\nabla\cdot((D\varphi)\,\overline{y})(T-t)) \\ & - 2\widehat{p}'\,\nabla\rho\cdot\nabla\varphi(T-t) - \widehat{p}'\,\Delta\rho\,\varphi(T-t) - 2\widehat{p}\,\nabla\rho\cdot\nabla\Delta\varphi(T-t) \\ & - \widehat{p}\,\Delta\rho\,\Delta\varphi(T-t), \end{aligned} \tag{3.43}$$

and we define u^i $(i = 1,2)$ as the solution to

$$\begin{cases} u^i_t - \Delta u^i = F_i & \text{in} \quad \mathbf{R}^N \times (0,T), \\ u^i(0) = 0 & \text{in} \quad \mathbf{R}^N. \end{cases} \tag{3.44}$$

An estimate of u^1. Let us remark that $F_1 \in L^2(0,T;H^{-2}(\mathbf{R}^N)^N)$, while we would like to estimate the L^2-norm of u^1. Accordingly, we have to define u^1 like a solution by transposition. More precisely, u^1 is the unique function in $L^2(\mathbf{R}^N \times (0,T))^N$ verifying

$$\begin{aligned} \iint_{\mathbf{R}^N\times(0,T)} u^1 \cdot k\,dx\,dt = {} & \iint_{\mathbf{R}^N\times(0,T)} \widehat{p}\,\rho((D\varphi)\,\overline{y}(T-t))\cdot\Delta z\,dx\,dt \\ & - \iint_{\mathbf{R}^N\times(0,T)} \widehat{p}\,\rho((D\varphi)\,\overline{y}(T-t))\cdot\nabla(\nabla\cdot z)\,dx\,dt \\ & + \iint_{\mathbf{R}^N\times(0,T)} \widehat{p}'\,\rho\,\varphi(T-t)\cdot\Delta z\,dx\,dt \end{aligned} \tag{3.45}$$

for any $k \in L^2(\mathbf{R}^N \times (0,T))^N$, where z is the solution of

$$\begin{cases} -z_t - \Delta z = k & \text{in} \quad \mathbf{R}^N \times (0,T), \\ z(T) = 0 & \text{in} \quad \mathbf{R}^N. \end{cases} \tag{3.46}$$

Then we get the following directly from (3.45):

$$\begin{aligned} &\iint_{\mathbf{R}^N \times (0,T)} |u^1|^2 \, dx \, dt \\ &\quad \le C \left(\iint_{\mathbf{R}^N \times (0,T)} |\widehat{p} \, \rho \, (D\varphi) \, \overline{y}|^2 \, dx \, dt + \iint_{\mathbf{R}^N \times (0,T)} |\widehat{p}' \, \rho \, \varphi|^2 \, dx \, dt \right) \\ &\quad \le C \left(\iint_{\mathcal{O}_2 \times (0,T)} |\widehat{p}|^2 \, |(D\varphi) \, \overline{y}|^2 \, dx \, dt + \iint_{\mathcal{O}_2 \times (0,T)} |\widehat{p}'|^2 \, |\varphi|^2 \, dx \, dt \right). \end{aligned} \tag{3.47}$$

An estimate of u^2. This time we must take into account the fact that the function F_2 belongs to the space $L^2(0,T;H^{-1}(\mathbf{R}^N)^N)$. But it is also essential to remember that supp $F_2 \subset \mathcal{O}_2 \setminus \overline{\mathcal{O}}_3$, since derivatives of ρ appear everywhere. This allows us to write, for $x \in \mathcal{O}_4$,

$$u^2(x,t) = \int_0^t \int_{\mathcal{O}_2 \setminus \overline{\mathcal{O}}_3} G(x-y, t-s) \, F_2(y,s) \, dy \, ds, \tag{3.48}$$

where G is the fundamental solution of the heat equation, i.e.,

$$G(x,t) = \frac{1}{(4\pi t)^{N/2}} e^{-\frac{|x|^2}{2t}} \quad \forall (x,t) \in \mathbf{R}^N \times \mathbf{R}_+. \tag{3.49}$$

Now, we integrate by parts with respect to y in (3.48), taking all the space derivatives out of $(D\varphi)\,\overline{y}$ and φ. This gives the following equality:

$$u^2(x,t) = \int_0^t \int_{\mathcal{O}_2 \setminus \overline{\mathcal{O}}_3} \sum_{\alpha \in I, \beta \in J} D_y^\alpha G(x-y, t-s) \, D_y^\beta \rho(y) \, w_{\alpha,\beta}(y,s) \, dy \, ds, \tag{3.50}$$

where

$$w_{\alpha,\beta}(y,s) = (A_{\alpha,\beta} \, \widehat{p}(s) + B_{\alpha,\beta} \, \widehat{p}'(s)) \varphi(y,s) + C_{\alpha,\beta} \, \widehat{p}(s) \, ((D\varphi) \, \overline{y})(y,s) \tag{3.51}$$

for appropriate constants $A_{\alpha,\beta}$, $B_{\alpha,\beta}$, and $C_{\alpha,\beta}$,

$$I \subset \{\gamma \in \mathrm{N}^N : |\gamma| \le 3\} \quad \text{and} \quad J \subset \{\gamma \in \mathrm{N}^N : 1 \le |\gamma| \le 4\}. \tag{3.52}$$

Next, we denote by d the quantity $d = \operatorname{dist}(\partial\mathcal{O}_3, \partial\mathcal{O}_4)$, we fix $\delta \in (0,d)$, and we observe that

$$|D_y^\alpha G(x-y, t-s)| \le C \, \exp\left(-\frac{\delta^2}{2(t-s)} \right) \quad \forall x \in \mathcal{O}_4, \, \forall y \in \mathcal{O}_2 \setminus \overline{\mathcal{O}}_3. \tag{3.53}$$

Therefore, we deduce from (3.50) that

$$|u^2(x,t)| \le C \int_0^t \int_{\mathcal{O}_2 \setminus \overline{\mathcal{O}}_3} e^{-\frac{\delta^2}{2(t-s)}} \, |w(y,s)| \, dy \, ds \quad \forall (x,t) \in \mathcal{O}_4 \times (0,T), \tag{3.54}$$

where

$$w(y,s) = (\widehat{p}(s) + \widehat{p}\,'(s))\varphi(y,s) + \widehat{p}(s)\,((D\varphi)\,\overline{y})(y,s). \tag{3.55}$$

Integrating with respect to x and t in $\mathcal{O}_4 \times (0,T)$, we find that

$$\begin{aligned}\iint_{\mathcal{O}_4\times(0,T)} |u^2|^2\,dx\,dt &\le C\,T\int_0^T\!\!\int_0^t e^{-\delta^2/(t-s)}\,\|w(y,s)\|^2_{L^2(\mathcal{O}_2)}\,ds\,dt \\ &= C\,T\int_0^T (f_1 * f_2)(t)\,dt,\end{aligned} \tag{3.56}$$

where

$$f_1(t) = e^{-\delta^2/t} \quad \text{and} \quad f_2(t) = \|w(t)\|^2_{L^2(\mathcal{O}_2)}. \tag{3.57}$$

Notice that $f_1, f_2 \in L^1(0,T)$. As a consequence of Young's inequality, we have

$$\begin{aligned}\iint_{\mathcal{O}_4\times(0,T)} |u^2|^2\,dx\,dt &\le C\,T\iint_{\mathcal{O}_2\times(0,T)} |w|^2\,dx\,dt \\ &\le C\,T\bigg(\iint_{\mathcal{O}_2\times(0,T)} (|\widehat{p}|^2 + |\widehat{p}\,'|^2)|\varphi|^2\,dx\,dt \\ &\qquad + \iint_{\mathcal{O}_2\times(0,T)} |\widehat{p}|^2\,|(D\varphi)\,\overline{y}|^2\,dx\,dt\bigg).\end{aligned} \tag{3.58}$$

Combining this with (3.47), we obtain the local estimate of $\Delta\varphi$:

$$\begin{aligned}s^2\lambda^2\iint_{\mathcal{O}_4\times(0,T)} e^{-2s\widehat{\beta}}\,\widehat{\gamma}^2\,|\Delta\varphi|^2\,dx\,dt &\le C(1+T)\bigg(\iint_{\mathcal{O}_2\times(0,T)} (|\widehat{p}|^2 + |\widehat{p}\,'|^2)|\varphi|^2\,dx\,dt \\ &\qquad + \iint_{\mathcal{O}_2\times(0,T)} |\widehat{p}|^2\,|(D\varphi)\,\overline{y}|^2\,dx\,dt\bigg).\end{aligned} \tag{3.59}$$

A local estimate of $\boldsymbol{\varphi_t}$. Let us first introduce the weight function p, with

$$p(t) = s^{15/4}\,e^{-2s\widehat{\beta}+s\beta^*}\,\widehat{\gamma}^{15/4}. \tag{3.60}$$

By setting $(\psi,\theta) = (p\,\varphi, p\,\pi)$, we have

$$\begin{cases} -\psi_t - \Delta\psi - (D\psi)\,\overline{y} + \nabla\theta = -p'\,\varphi & \text{in } Q, \\ \nabla\cdot\psi = 0 & \text{in } Q, \\ \psi = 0 & \text{on } \Sigma, \\ \psi(T) = 0 & \text{in } \Omega. \end{cases} \tag{3.61}$$

Recall that the term we have to estimate is

$$\begin{aligned}\iint_{\mathcal{O}_4\times(0,T)} |\widehat{p}|^2\,|\varphi_t|^2\,dx\,dt &= \iint_{\mathcal{O}_4\times(0,T)} p^{-2}\,|\widehat{p}|^2\,|p\,\varphi_t|^2\,dx\,dt \\ &= s^{-11/2}\lambda^2\iint_{\mathcal{O}_4\times(0,T)} e^{-2s\beta^*+2s\widehat{\beta}}\,\widehat{\gamma}^{-11/2}\,|\psi_t - p'\,\varphi|^2\,dx\,dt.\end{aligned} \tag{3.62}$$

Hence, we will try to estimate the (weighted) L^2-norm of the time derivative of ψ. To this end, we integrate by parts with respect to t:

$$\begin{aligned} & s^{-11/2}\lambda^2 \iint_{\mathcal{O}_4\times(0,T)} e^{-2s\beta^*+2s\widehat{\beta}}\,\widehat{\gamma}^{-11/2}\,|\psi_t|^2\,dx\,dt \\ &= \frac{1}{2}s^{-11/2}\lambda^2 \iint_{\mathcal{O}_4\times(0,T)} (e^{-2s\beta^*+2s\widehat{\beta}}\,\widehat{\gamma}^{-11/2})_{tt}\,|\psi|^2\,dx\,dt \\ &\quad -s^{-11/2}\lambda^2 \iint_{\mathcal{O}_4\times(0,T)} e^{-2s\beta^*+2s\widehat{\beta}}\,\widehat{\gamma}^{-11/2}\,\psi_{tt}\,\psi\,dx\,dt. \end{aligned} \tag{3.63}$$

One can easily check that

$$s^{-11/2}\lambda^2(e^{-2s\beta^*+2s\widehat{\beta}}\,\widehat{\gamma}^{-11/2})_{tt} \le C\,s^{-7/2}\lambda^2\,T^2\,e^{-2s\beta^*+2s\widehat{\beta}}\,\widehat{\gamma}^{-3} \tag{3.64}$$

for $s \ge C\,T^8$.

Therefore, we must concentrate on estimating the last term in (3.63). Now, we first denote by p^* the function

$$p^* = s^{-11/2}\lambda^{-4}\,e^{-2s\beta^*+2s\widehat{\beta}}\,\widehat{\gamma}^{-11/2} \tag{3.65}$$

and then use Hölder's inequality:

$$\begin{aligned} \lambda^6 \iint_{\mathcal{O}_4\times(0,T)} p^*\,\psi_{tt}\,\psi\,dx\,dt &\le \lambda^6\,\|p^*\,\psi_{tt}\|_{L^2(0,T;L^q(\mathcal{O}_4))}\,\|\psi\|_{L^2(0,T;L^{q'}(\mathcal{O}_4))} \\ &\le 2\|p^*\,\psi_{tt}\|^2_{L^2(0,T;L^q(\mathcal{O}_4))} \\ &\quad + 2\lambda^{12}\|\psi\|^2_{L^2(0,T;L^{q'}(\mathcal{O}_4))}, \end{aligned} \tag{3.66}$$

where q is chosen lower than σ but greater than 1 in dimension $N = 2$ and greater than $6/5$ in dimension $N = 3$, and q' is the conjugate exponent of q (recall that $\sigma > 1$ if $N = 2$ and $\sigma > 6/5$ if $N = 3$).

Let us first deal with the second term on the right-hand side of (3.66). Let $\rho \in C^2(\mathcal{O}_3)$ be a cut-off function satisfying

$$\text{supp}\ \rho \subset \mathcal{O}_3 \quad \text{and} \quad \rho \equiv 1 \text{ in } \mathcal{O}_4. \tag{3.67}$$

Then

$$\begin{aligned} \|\psi\|^2_{L^2(L^{q'}(\mathcal{O}_4))} &\le \|\Delta(\rho\,\psi)\|^2_{L^2(L^2(\mathcal{O}_3))} \\ &= \|\Delta\rho\,\psi + 2\nabla\rho\cdot\nabla\psi + \rho\,\Delta\psi\|^2_{L^2(L^2(\mathcal{O}_3))}. \end{aligned} \tag{3.68}$$

Following the same steps as in the previous section for obtaining the local estimate of $\Delta\varphi$, after some long computations, one can readily get an estimate of the last term on the right-hand side of (3.68). Consequently, we have

$$\|\psi\|^2_{L^2(0,T;L^{q'}(\mathcal{O}_4))} \le C(1+\|\overline{y}\|^2_\infty)(1+T)\iint_{\mathcal{O}_1\times(0,T)} (|\psi|^2 + |\nabla\psi|^2 + |p'\varphi|^2)\,dx\,dt, \tag{3.69}$$

where $\mathcal{O}_1$ is an open set verifying

$$\mathcal{O}_2 \subset\subset \mathcal{O}_1 \subset\subset \mathcal{O}. \tag{3.70}$$

Finally, we treat the norm of $p^*\psi_{tt}$ in (3.66).

Observing the problem verified by $(p^*\,\psi_t, p^*\,\theta_t)$, one can obtain the next a priori estimate for ψ_{tt}:

$$\begin{aligned}\|p^*\,\psi_{tt}\|_{L^2(L^q)} \le (1+\|\overline{y}\|_\infty)\,e^{C(1+T\|\overline{y}\|_\infty^2)}\,\big(\|p^*\,p''\,\varphi\|_{L^2(L^2)}\\ +\|p^*\,p'\,\varphi_t\|_{L^2(L^2)}+\|(p^*)'\,\psi_t\|_{L^2(L^2)}+\|p^*\,(D\psi)\,\overline{y}_t\|_{L^2(L^q)}\big)\,.\end{aligned}\tag{3.71}$$

Consequently, from (3.62)–(3.66) and (3.69)–(3.71), we have

$$\begin{aligned}&\iint_{\mathcal{O}_4\times(0,T)}|\widehat{p}|^2\,|\varphi_t|^2\,dx\,dt\\ &\quad\le(1+\|\overline{y}\|_\infty^2)\,e^{C(1+T\|\overline{y}\|_\infty^2)}\,\Big(\lambda^{12}(1+T)(\|p\,\varphi\|^2_{L^2(L^2(\mathcal{O}_1))}\\ &\quad+\|p\,\nabla\varphi\|^2_{L^2(L^2(\mathcal{O}_1))}+\|p'\varphi\|^2_{L^2(L^2(\mathcal{O}_1))})+\|p^*\,p''\,\varphi\|^2_{L^2(L^2)}\\ &\quad+\|p^*\,p'\,\varphi_t\|^2_{L^2(L^2)}+\|(p^*)'\,\psi_t\|^2_{L^2(L^2)}+\|p^*\,(D\psi)\,\overline{y}_t\|^2_{L^2(L^q)}\Big)\,.\end{aligned}\tag{3.72}$$

An estimate of $p^*\,(D\psi)\,\overline{y}_t$. Let $\ell\in(1,+\infty)$ be given. In this section, we will prove that for $\overline{y}\in L^\infty(Q)^N$, we have $p^*\,\psi\in L^\infty(0,T;W^{1,\ell}(\Omega))^N$ for all $\ell<\infty$, and we will get an estimate of its norm. Once this is established, we will directly obtain an estimate of $p^*\,(D\psi)\,\overline{y}_t$ in $L^2(L^q)$ (taking ℓ large enough).

Thus, let us look at the system fulfilled by $(p^*\,\psi, p^*\,\theta)$:

$$\begin{cases}-(p^*\,\psi)_t-\Delta(p^*\,\psi)-D(p^*\,\psi)\,\overline{y}+\nabla(p^*\,\theta)=-(p^*)'\,\psi-p^*\,p'\,\varphi & \text{in } Q,\\ \nabla\cdot(p^*\,\psi)=0 & \text{in } Q,\\ p^*\,\psi=0 & \text{on } \Sigma,\\ (p^*\,\psi)(T)=0 & \text{in } \Omega.\end{cases}\tag{3.73}$$

We can first view ψ as a function in

$$L^2(0,T;H^2(\Omega)^N)\cap L^\infty(0,T;V).\tag{3.74}$$

Then, using interpolation inequalities, we have that $D(p^*\,\psi)\,\overline{y}\in L^{k_1}(L^{k_2})$, with $2<k_1<4$ and $3<k_2<6$ (which will be chosen below) verifying

$$\frac{4/3}{k_1}+\frac{2}{k_2}=1.\tag{3.75}$$

Using well-known regularity properties of the Stokes system (see [32]), we obtain from (3.73) that

$$p^*\,\psi\in L^{k_1}(0,T;W^{2,k_2}(\Omega)^N)\tag{3.76}$$

and

$$\|p^*\,\psi\|_{L^{k_1}(W^{2,k_2})}\le C(\|(p^*)'\,\psi+p^*\,p'\,\varphi\|_{L^{k_1}(L^{k_2})}+\|\overline{y}\|_\infty\|\nabla(p^*\,\psi)\|_{L^{k_1}(L^{k_2})}.\tag{3.77}$$

We can now perform a bootstrap argument again based on a priori estimates of the Stokes system but this time with a right-hand side in $L^{k_1}(L^\ell)$ with

$$\frac{2}{k_1}+\frac{6}{\ell}=1.\tag{3.78}$$

This determines the value of k_1 and, consequently, of k_2 as well. This yields $\nabla(p^*\,\theta) \in L^{k_1}(L^\ell)$ and

$$\|\nabla(p^*\,\theta)\|_{L^{k_1}(L^\ell)} \le C(\|(p^*)'\,\psi + p^*\,p'\,\varphi\|_{L^{k_1}(L^l)} + \|\overline{y}\|_\infty\,\|\nabla(p^*\,\psi)\|_{L^{k_1}(L^\ell)}). \tag{3.79}$$

Combining this last inequality and (3.77), we get

$$\begin{aligned}\|\nabla(p^*\,\theta)\|_{L^{k_1}(L^\ell)} \le C(1+\|\overline{y}\|_\infty^2)(&\|(p^*+(p^*)')\,\Delta\psi\|_{L^2(L^2)}\\ &+ \|((p^*+(p^*)')\,\psi)_t\|_{L^2(L^2)} + \|p^*\,p'\,\Delta\varphi\|_{L^2(L^2)}\\ &+ \|(p^*\,p'\,\varphi)_t\|_{L^2(L^2)}).\end{aligned} \tag{3.80}$$

This tells us that we can view (3.73) as a system of N heat equations with right-hand sides in $L^{k_1}(0,T;L^\ell(\Omega))$. Then, using the representation of the solution of heat systems in terms of the semigroup, we deduce that

$$\|p^*\,\psi(t)\|_{W^{1,\ell}(\Omega)} \le \int_0^t (t-s)^{-1/2}\|B(s)\|_{L^\ell(\Omega)}\,ds \quad \forall t \in (0,T), \tag{3.81}$$

where $B(s) = -(p^*)'\,\psi - p^*\,p'\,\varphi + D(p^*\,\psi)\,\overline{y} - \nabla(p^*\,\theta)$. See [40] for more details.

Since $k_1 > 2$, from Young's inequality we see that $\|p^*\,\psi\|_{W^{1,\ell}(\Omega)} \in L^\infty(0,T)$ and

$$\|p^*\,\psi\|_{L^\infty(W^{1,\ell})} \le (1-k_1'/2)^{-1/k_1'}\,T^{-1/2+1/k_1'}\,\|B\|_{L^{k_1}(L^\ell)}. \tag{3.82}$$

Hence, from (3.80), we obtain the estimate

$$\begin{aligned}\|p^*\,\psi\|_{L^\infty(W^{1,\ell})} \le C\,T^{-1/2+1/k_1'}(1+\|\overline{y}\|_\infty^2)(&\|(p^*+(p^*)')\,\Delta\psi\|_{L^2(L^2)}\\ &+ \|((p^*+(p^*)')\,\psi)_t\|_{L^2(L^2)} + \|p^*\,p'\,\Delta\varphi\|_{L^2(L^2)} + \|(p^*\,p'\,\varphi)_t\|_{L^2(L^2)})\end{aligned} \tag{3.83}$$

and, consequently, with a proper choice of ℓ, we have

$$\begin{aligned}\|p^*\,D\psi\,\overline{y}_t\|_{L^2(L^q)} \le \|p^*\,(D\psi)\|_{L^\infty(L^\ell)}\,\|\overline{y}_t\|_{L^2(L^\sigma)} &\le C\,\|\overline{y}_t\|_{L^2(L^\sigma)}\,T^{-1/2+1/k_1'}(1+\|\overline{y}\|_\infty^2)\\ &\Big(\|(p^*+(p^*)')\,\Delta\psi\|_{L^2(L^2)} + \|((p^*+(p^*)')\,\psi)_t\|_{L^2(L^2)}\\ &+ \|p^*\,p'\,\Delta\varphi\|_{L^2(L^2)} + \|(p^*\,p'\,\varphi)_t\|_{L^2(L^2)}\Big).\end{aligned} \tag{3.84}$$

Finally, we put (3.84) together with (3.72) to obtain the desired local estimate of φ_t:

$$\begin{aligned}&\iint_{\mathcal{O}_4\times(0,T)} |\widehat{p}|^2\,|\varphi_t|^2\,dx\,dt\\ &\le (1+\|\overline{y}\|_\infty^6)\,\|\overline{y}_t\|_{L^2(L^\sigma)}^2\,e^{C(1+T\|\overline{y}\|_\infty^2)}\Big(\lambda^{12}(1+T)(\|p\,\varphi\|_{L^2(L^2(\mathcal{O}_1))}^2\\ &\quad + \|p\,\nabla\varphi\|_{L^2(L^2(\mathcal{O}_1))}^2 + \|p'\,\varphi\|_{L^2(L^2(\mathcal{O}_1))}^2) + T^{-1+2/k_1'}(\|p^*\,p''\,\varphi\|_{L^2(L^2)}^2\\ &\quad + \|(p^*)'\,p'\,\varphi\|_{L^2(L^2)}^2 + \|p^*\,p'\,\varphi_t\|_{L^2(L^2)}^2 + \|p^*\,p'\,\Delta\varphi\|_{L^2(L^2)}^2\\ &\quad + \|p^*\,\psi_t\|_{L^2(L^2)}^2 + \|(p^*)'\,\psi_t\|_{L^2(L^2)}^2 + \|(p^*)'\,\psi\|_{L^2(L^2)}^2\\ &\quad + \|(p^*)''\,\psi\|_{L^2(L^2)}^2 + \|p^*\,\Delta\psi\|_{L^2(L^2)}^2 + \|(p^*)'\,\Delta\psi\|_{L^2(L^2)}^2)\Big).\end{aligned} \tag{3.85}$$

3.2.3. Conclusion. In this subsection we will end the proof of Lemma 3.1. We will first see that the global integrals in (3.85) can be absorbed by the terms in $I(s,\lambda;\varphi)$, and then we will combine the local estimates to end the proof.

Notice that the next bounds hold for the weight functions:

$$|p^*p'| + |(p^*)'p| \le C\,T\,s^{-3/4}\lambda^{-4}e^{-s\beta^*}\widehat{\gamma}^{-1/2}, \tag{3.86}$$

$$|(p^*)'p'| + |(p^*)''p| + |p^*p''| \le C\,T^2\,s^{1/4}\lambda^{-4}e^{-s\beta^*}(\gamma^*)^{3/4}. \tag{3.87}$$

Combining this and (3.85), we get

$$\begin{aligned}
&\iint_{\mathcal{O}_4\times(0,T)} |\widehat{p}|^2\,|\varphi_t|^2\,dx\,dt \\
&\le (1+\|\overline{y}\|_\infty^6)\,\|\overline{y}_t\|^2_{L^2(L^\sigma)} e^{C(1+T\,\|\overline{y}\|_\infty^2)}\Bigg(\lambda^{12}(1+T)(\|p\,\varphi\|^2_{L^2(L^2(\mathcal{O}_1))} \\
&\quad + \|p'\,\varphi\|^2_{L^2(L^2(\mathcal{O}_1))} + \|p\,\nabla\varphi\|^2_{L^2(L^2(\mathcal{O}_1))}) \\
&\quad + s^3\lambda^{-8}\iint_Q e^{-2s\beta^*}(\gamma^*)^3|\varphi|^2\,dx\,dt \\
&\quad + s^{-1}\lambda^{-8}\iint_Q e^{-2s\beta^*}\widehat{\gamma}^{-1}(|\varphi_t|^2 + |\Delta\varphi|^2)\,dx\,dt\Bigg)
\end{aligned} \tag{3.88}$$

for $s \ge C(T^4+T^8)$.

Taking now $\lambda \ge C(1+\|\overline{y}\|_\infty + \|\overline{y}_t\|^2_{L^2(L^\sigma)} + e^{C\,T\,\|\overline{y}\|_\infty^2})$, we obtain

$$\begin{aligned}
\iint_{\mathcal{O}_4\times(0,T)} |\widehat{p}|^2\,|\varphi_t|^2\,dx\,dt &\le C\,\lambda^{20}(1+T)(\|p\,\varphi\|^2_{L^2(L^2(\mathcal{O}_1))} \\
&\quad + \|p'\,\varphi\|^2_{L^2(L^2(\mathcal{O}_1))} + \|p\,\nabla\varphi\|^2_{L^2(L^2(\mathcal{O}_1))}) + \varepsilon\,I(s,\lambda;\varphi).
\end{aligned} \tag{3.89}$$

Let us finally combine (3.89), (3.32), (3.34), and (3.59). This yields

$$\begin{aligned}
I(s,\lambda;\varphi) \le C\,\lambda^{20}(1+T)\Big(&\|p\,\varphi\|^2_{L^2(L^2(\mathcal{O}_1))} + \|p'\,\varphi\|^2_{L^2(L^2(\mathcal{O}_1))} \\
&+ \|p\,\nabla\varphi\|^2_{L^2(L^2(\mathcal{O}_1))}\Big)
\end{aligned} \tag{3.90}$$

for $s \ge C(T^4+T^8)$ and $\lambda \ge C(1+\|\overline{y}\|_\infty + \|\overline{y}_t\|^2_{L^2(L^\sigma)} + e^{C\,T\,\|\overline{y}\|_\infty^2})$.

It remains only to absorb the last norm in (3.90). This can be achieved using localization arguments. Indeed, we have

$$\begin{aligned}
\iint_{\mathcal{O}_1\times(0,T)} |p|^2\,|\nabla\varphi|^2\,dx\,dt \le C\Bigg(&s\lambda^{20}(1+T)\iint_{\mathcal{O}\times(0,T)} e^{2s\beta^*}|p|^4\,\widehat{\gamma}\,|\varphi|^2\,dx\,dt \\
&+ \varepsilon\,s^{-1}\lambda^{-20}(1+T)^{-1}\iint_{\mathcal{O}\times(0,T)} e^{-2s\beta^*}\widehat{\gamma}^{-1}|\Delta\varphi|^2\,dx\,dt\Bigg)
\end{aligned} \tag{3.91}$$

for a constant $\varepsilon = \varepsilon(\Omega,\mathcal{O}) > 0$ small enough.

In conclusion, we get from (3.90)

$$I(s,\lambda;\varphi) \le C\, s^{16}\lambda^{40}(1+T^2) \iint_{\mathcal{O}\times(0,T)} e^{-8s\widehat{\alpha}+6s\alpha^*}\, \widehat{\xi}^{16}\, |\varphi|^2\, dx\, dt \tag{3.92}$$

for $s \ge C(T^4+T^8)$ and $\lambda \ge C(1+\|\overline{y}\|_\infty + \|\overline{y}_t\|^2_{L^2(L^\sigma)} + e^{C\,T\,\|\overline{y}\|^2_\infty})$, which is exactly (3.13).

3.3. Some additional comments. In this subsection, we will indicate several recent results. The first two concern the controllability of the three-dimensional Stokes and Navier–Stokes systems with two scalar controls. The third one is related to the null controllability of the Stokes system with slip boundary conditions.

3.3.1. Three-dimensional Stokes and Navier–Stokes systems and two scalar controls. Let us consider system (3.7) with $N = 3$. What we would like to do now is to control acting over a (small) part of Ω just in two directions. More precisely, if we denote the control by $v = (v_1, v_2, v_3)$, we intend to drive the system (3.7) to zero at time $t = T$ with the restriction

$$v_1 = 0 \quad \text{or} \quad v_2 = 0 \quad \text{or} \quad v_3 = 0. \tag{3.93}$$

In the context of approximate controllability, this question was considered (and solved) in [49] for cylindrical domains Ω.

We will have to impose an additional restriction on the control domain $\mathcal{O}$, namely,

$$\exists x^0 \in \partial\Omega,\ \exists \varepsilon > 0 \text{ such that } \overline{\mathcal{O}} \cap \partial\Omega \supset B(x^0;\varepsilon) \cap \partial\Omega. \tag{3.94}$$

The following result holds.

THEOREM 3.6. *Let T be an arbitrary positive time. Let* (3.9) *and* (3.94) *be fulfilled. Then, for every $y^0 \in H$, there exists a two-dimensional L^2 control v such that the solution to* (3.7) *satisfies*

$$y(T) = 0 \quad \text{in} \quad \Omega. \tag{3.95}$$

Let us indicate briefly the idea of the proof. It is not restrictive to assume that

$$B(x^0;\varepsilon) \cap \overline{\Omega} \subset \overline{\mathcal{O}}$$

and, for instance,

$$n_3(x) \ne 0 \quad \forall x \in B(x^0;\varepsilon) \cap \partial\Omega.$$

In view of the general arguments proved in section 1, the key point is to get a Carleman inequality of the form

$$s^{-1} \iint_Q \rho^2 |\varphi|^2\, dx\, dt \le C \iint_{\mathcal{O}\times(0,T)} \rho^2 \left(|\varphi_1|^2 + |\varphi_2|^2\right)\, dx\, dt \tag{3.96}$$

for the solutions to (3.10).

Let us set $\mathcal{O}_0 = B(x^0;\varepsilon) \cap \Omega$. We start from (3.13), which must hold for some $C > 0$. In $\mathcal{O}_0$, we have

$$\varphi_3(x,t) = \int_{l(x,t)} (\partial_1\varphi_1 + \partial_2\varphi_2)(x_1, x_2, \xi_3, t)\, d\xi_3, \tag{3.97}$$

where $l(x,t)$ is an appropriate segment in $\mathcal{O}_0$ that starts from (x,t), is parallel to e_3, and ends at a point on $\partial\Omega$.

Using (3.97) in (3.13), in view of Fubini's formula, Hölder's inequality, and standard localization arguments, together with the particular definition of the set $\mathcal{O}_0$, one can find a Carleman inequality with local terms of $|\varphi_1|^2$ and $|\varphi_2|^2$ on the right-hand side. This and the dissipativity of system (3.10) imply, in a usual way, an observability inequality for the associated solutions with only these two terms on the right-hand side, which yields the result stated in Theorem 3.6.

As a consequence of Theorem 3.6, following again the arguments developed in [37] and [24], one can deduce the local exact controllability to the trajectories of the Navier–Stokes system with two scalar controls:

THEOREM 3.7. *Let $(\overline{y}, \overline{p})$ be a solution of* (3.15) *verifying* (3.9) *and $\overline{y}(0) \in E = H \cap L^4(\Omega)^3$. There exists $\varepsilon > 0$ such that, for each $y^0 \in E$ satisfying*

$$\|y^0 - \overline{y}(0)\|_{L^4} \leq \varepsilon,$$

one can find a two-dimensional L^2 control v and an associated solution (y, p) to (3.14) *for which we have*

$$y(T) = \overline{y}(T) \quad \text{in } \Omega. \tag{3.98}$$

3.3.2. Stokes systems with slip boundary conditions. Let us introduce the following system:

$$\begin{cases} y_t - \Delta y + \nabla p = v 1_{\mathcal{O}} & \text{in} \quad Q, \\ \nabla \cdot y = 0 & \text{in} \quad Q, \\ y \cdot n = 0, \quad ((Dy) \cdot \vec{n})_{tg} + (A(x,t)\, y)_{tg} = 0 & \text{on} \quad \Sigma, \\ y(0) = y^0 & \text{in} \quad \Omega. \end{cases} \tag{3.99}$$

Here, we have used the notation a_{tg} to denote the tangential component of any vector $a \in \mathbf{R}^N$:

$$a_{tg} = a - (a \cdot n)n. \tag{3.100}$$

We will impose the following assumptions on A:

$$\begin{aligned} &A \in H^{(3-\delta)/2}(0, T; H^{1/2}(\partial\Omega)^{N\times N}), \\ &A \in H^{1-\delta}(0, T; H^{-1+N/2+2\delta'}(\partial\Omega)^{N\times N}), \end{aligned} \tag{3.101}$$

where $0 < \delta < 1/2$ arbitrarily close to $1/2$ and $\delta < \delta' < 1/2$. Then we have the next result from [35].

THEOREM 3.8. *Let us assume that A is a uniformly elliptic matrix verifying $A \in L^\infty(\Sigma)^{N\times N}$ and* (3.101). *Then, for each $y^0 \in H$, there exists $v \in L^2(\mathcal{O}\times(0,T))^N$ such that the solution to* (3.99) *satisfies*

$$y(T) = 0 \quad \text{in } \Omega. \tag{3.102}$$

Remark 10. It would be interesting to know if this result still holds, for general uniformly elliptic $A \in L^\infty(\Sigma)^{N\times N}$, without the hypotheses (3.101). However, this seems to be a difficult question.

For similar systems for the Stokes or Navier–Stokes equations involving nonlinear slip boundary conditions, the situation is much more complicated. See [35] for more details.

PHASE-FIELD RELAXATION OF TOPOLOGY OPTIMIZATION WITH LOCAL STRESS CONSTRAINTS*

MARTIN BURGER† AND ROMAN STAINKO‡

Abstract. We introduce a new relaxation scheme for structural topology optimization problems with local stress constraints based on a phase-field method. In the basic formulation we have a PDE-constrained optimization problem, where the finite element and design analysis are solved simultaneously. The starting point of the relaxation is a reformulation of the material problem involving linear and 0-1 constraints only. The 0-1 constraints are then relaxed and approximated by a Cahn–Hilliard-type penalty in the objective functional, which yields convergence of minimizers to 0-1 designs as the penalty parameter decreases to zero. A major advantage of this kind of relaxation opposed to standard approaches is a uniform constraint qualification that is satisfied for any positive value of the penalization parameter. The relaxation scheme yields a large-scale optimization problem with a high number of linear inequality constraints. We discretize the problem by finite elements and solve the arising finite-dimensional programming problems by a primal-dual interior point method. Numerical experiments for problems with local stress constraints based on different criteria indicate the success and robustness of the new approach.

Key words. topology optimization, local stress constraints, phase-field methods, interior-point methods, one-shot methods

1. Introduction.

Topology optimization denotes problems of finding optimal material distributions in given design domains subject to certain criteria and, possibly, satisfying several additional constraints. In the last two decades, advances in homogenization, optimization theory, and numerical analysis as well as new engineering approaches caused topology optimization techniques to become a standard tool of engineering design (cf. [5, 18] for an overview), in particular in structural mechanics. In structural optimization there are two design-constraint combinations of particular importance, namely the maximization of material stiffness at given mass and the minimization of mass while keeping a certain stiffness. The formulation of the first combination as the so-called minimal compliance problem has become standard, and seems to be well understood with respect to its mathematical properties (cf., e.g., [2, 8, 26]), and various successful numerical techniques have been proposed (cf., e.g., [3, 7, 20, 27, 31]). The treatment of the second problem is, by far, less understood, although this problem characterizes one of the oldest mechanical requirements in structural design, e.g., in aeronautics minimization of mass without material failure under loading is an important issue. Until now there seems to have been no approach capable of computing reliable (global) optima with respect to local stress constraints within reasonable computational effort.

The main source of difficulties in this problem is a lack of constraint qualification in the feasible set defined by the local stress constraints, which already appear for simple truss structures (cf. [24, 29]). Moreover, there are several complications for specific methods, e.g., convergence issues of homogenized stress criteria for material interpolation schemes (cf. [5, 17]).

We start by describing the main mathematical setup used in what follows. By $\Omega \subset \mathbb{R}^d$ $(d = 2, 3)$ we denote the design domain, which we assume to be sufficiently regular. The function $\mathbf{u} : \Omega \subset \mathbb{R}^d \to \mathbb{R}^d$ denotes the elastic displacement, the strain

$$\mathbf{e}_{ij} := \frac{1}{2}\left(\frac{\partial \mathbf{u}_i}{\partial x_j} + \frac{\partial \mathbf{u}_j}{\partial x_i}\right)$$

and the stress σ, determined from the strain via a standard linearly elastic relation

$$\sigma_{ij} = \sum_{k,\ell} C_{ijk\ell}\mathbf{e}_{k\ell}$$

with a suitable symmetric positive definite elasticity tensor $(C_{ijk\ell})$; i.e.,

$$\sum_{i,j,k,\ell} C_{ijk\ell}\mathbf{e}_{ij}\mathbf{e}_{k\ell} \geq \eta \sum_{ij} \mathbf{e}_{ij}^2$$

for some $\eta > 0$. Below we shall abbreviate the stress-strain relation as $\sigma = \mathbf{C} : \mathbf{e}$. The scaled density of the material is denoted by $\chi : \Omega \to \{0, 1\}$, which we normalize to $\chi(\mathbf{x}) = 1$ if there is material at the point $\mathbf{x}$ and $\chi(\mathbf{x}) = 0$ otherwise. Then the stress constrained topology optimization problem is given by

$$\begin{aligned}
\int_\Omega \chi \, \mathrm{d}\mathbf{x} \quad &\to \quad \min_{\chi \in \{0,1\} \text{ a.e.}}, \\
\operatorname{div} \sigma = 0 \quad &\text{in } \{\chi = 1\}, \\
\sigma = \mathbf{C} : \mathbf{e} \quad &\text{in } \Omega, \\
\mathbf{u} = \mathbf{0} \quad &\text{on } \Gamma_D \subset \partial\Omega, \\
\sigma \cdot \mathbf{n} = \mathbf{t} \quad &\text{on } \Gamma_N \subset \partial\Omega, \\
\sigma \cdot \mathbf{n} = \mathbf{0} \quad &\text{on } \partial\{\chi = 1\} \cup (\partial\Omega - \Gamma_D - \Gamma_N), \\
\sigma^{\min} \leq \sigma \leq \sigma^{\max} \quad &\text{in } \{\chi = 1\}, \\
\mathbf{u}^{\min} \leq \mathbf{u} \leq \mathbf{u}^{\max} \quad &\text{in } \Omega,
\end{aligned}$$

where $\mathbf{n}$ denotes the outward unit normal and $\mathbf{t}$ is a traction force applied on a part Γ_N of the boundary $\partial\Omega$. In the current geometrical setup, the material is kept fixed on Γ_D, while the remaining part $\partial\Omega - \Gamma_D - \Gamma_N$ does not need to represent material boundaries. Moreover, we have ignored body forces for simplicity, but they could be incorporated by adding a right-hand side to the divergence equation.

The matrices $\sigma^{\min}$ and $\sigma^{\max}$ denote the allowed minimal and maximal value for the local stresses, respectively. We shall call this criterion total stress constraints. Alternatively, the case of von Mises stress constraints is of interest, where the local constraints on σ are replaced by

$$\Phi(\sigma) \leq \Phi^{\max}, \tag{1.1}$$

where the von Mises stress is denoted via the functional $\Phi : \mathbb{R}^{d\times d} \to \mathbb{R}$ given by

$$\Phi(\sigma) = \sqrt{\frac{\sum_{i,j}(\lambda_i - \lambda_j)^2}{2}},$$

where $\lambda_j, j = 1, \dots, d$, are the principal stresses (the eigenvalues of σ). Note that for $d = 2$, the case we are focusing on, we simply have

$$\Phi(\sigma) = |\lambda_1 - \lambda_2| = \sqrt{(\sigma_{11} - \sigma_{22})^2 + 4\sigma_{12}^2}.$$

A frequently used approach to overcome the difficulties with the missing constraint qualification is the so-called epsilon-relaxation approach (cf. [15, 24]), originally used in the optimization of truss structures, which perturbs the stress criterion by some small parameter ϵ. In the topology optimization of continuum structures, the ϵ-relaxation can be combined with standard material interpolation schemes and finite element discretization in order to compute approximations of solutions, an approach carried out by Duysinx and Bendsøe [17]. A drawback of the ϵ-relaxation approach is the fact that the constraint qualification is not uniform for positive ϵ and there could still be cases where the Slater qualifications is violated (see [17] for a discrete setting). Recently, it has been shown for such examples by Stolpe and Svanberg [29] that the trajectories of minimizers of the ϵ-relaxed approach can have a discontinuity for arbitrarily small ϵ, and as a consequence it is difficult (or even impossible) to compute reliable minimizers of topology optimization problems with local stress constraints using this approach.

Due to the well-known ill-posedness of topology optimization problems (see [26]), we add a perimeter penalization to the objective functional; i.e., we minimize

$$J^\gamma(\chi) = \gamma \int_\Omega \chi \, \mathrm{d}\mathbf{x} + |\chi|_{BV} \tag{1.2}$$

for a (large) parameter $\gamma > 0$, where

$$|\chi|_{BV} := \sup_{\substack{\mathbf{g} \in C_0^\infty(\Omega;\mathbb{R}^d) \\ \|\mathbf{g}\|_\infty \le 1}} \int_\Omega \operatorname{div} \mathbf{g} \; \chi \, \mathrm{d}\mathbf{x}.$$

The additional perimeter term equals the length of the curve $\partial\{\chi = 1\}$ for $d = 2$ and the area of the surface $\partial\{\chi = 1\}$ for $d = 3$. The boundedness of the perimeter regularizes the topology optimization problem; in particular it excludes checkerboard effects and mesh-dependent results (cf. [19, 23]).

In this paper we use a different approach to the relaxation of the local constraints. The starting point of our analysis is a reformulation of the equality constraints describing the elastic equilibrium and the local inequality constraints for stresses and displacements into a system of linear inequality constraints, as recently proposed by Stolpe and Svanberg [30]. This reformulation is approximate at the continuum level but exact for finite element discretizations with suitable parameter choice. The main difficulty is that the arising problem also involves 0-1 constraints in addition to the linear inequalities. The computational effort of methods for the global minimization of these mixed linear programming problems grows fast with the number of degrees of freedom (DOFs) in the discretization, so that the problem could be solved only for very coarse discretizations so far (cf. [28, 30]). Instead of solving mixed linear programming problems, we propose using a phase-field relaxation of the reformulated problem. The phase-field relaxation consists in using an interpolated material density ρ, similar to material interpolation schemes. In addition, a Cahn–Hilliard-type penalization functional (see [14]) of the form

$$P^\epsilon(\rho) = \frac{\epsilon}{2}\int_\Omega |\nabla\rho|^2 \,\mathrm{d}\mathbf{x} + \frac{1}{\epsilon}\int_\Omega W(\rho)\,\mathrm{d}\mathbf{x} \tag{1.3}$$

is used to approximate the perimeter, where $W : \mathbb{R} \to \mathbb{R} \cup \{+\infty\}$ is a scalar function with exactly two minimizers at 0 and 1 satisfying $W(0) = W(1) = 0$. The second term of the penalty functional ensures that the values of the material density ρ converge to 0 or 1 as $\epsilon \to 0$, while the first term controls the perimeter of level sets of ρ. Due to a famous result by Modica and Mortola [22] (cf. also [1, 21]), minimizers of P^ϵ with fixed volume $\int_\Omega \rho \,\mathrm{d}\mathbf{x}$ converge to minimizers χ of the perimeter at fixed volume over functions satisfying $\chi \in \{0, 1\}$ almost everywhere in Ω. This convergence arises in the framework of Γ-convergence (see [10] and the references therein), which ensures, in particular, convergence of minimizers. Together with finite element discretization, we shall use a continuation $\epsilon \to 0$ and solve the arising discretized problems by an interior-point method. Obviously, the phase-field approach is not the only possibility to relax the reformulated constraints; one could, e.g., use a direct relaxation without further approximations, standard material interpolation schemes, or level set methods (cf., e.g., [12]), which are closely related to phase-field methods (see [4]). However, the phase-field relaxation incorporates a variety of advantages with respect to such approaches:

- In contrast to a direct relaxation to a continuous density variable (and also in contrast to material interpolation schemes), the phase-field method still provides geometric information. In particular, one can expect $\{\rho > \eta\}$ (with $\eta \ll \frac{1}{2}$ small) to be a superset of the limit $\{\chi = 1\}$ and $\{\rho < 1 - \eta\}$ to be a subset (for ϵ sufficiently small). Moreover, geometric quantities such as mean curvature can be approximated in terms of derivatives of ρ for small ϵ.
- With the phase-field relaxation one can still use the density linearly in the constraints, which is not true for material interpolation (e.g., in SIMP one has ρ^p, $p > 1$) or for level set methods (where the unknown is a signed distance function to some boundary, and in the relaxation one usually takes an application of a smoothed Heaviside function). The additional nonlinearity does not only complicate the constraints but might also destroy constraint qualifications.
- The parameter ϵ can be used for continuation. For ϵ being large, the functional P^ϵ is strictly convex, so that one can compute global optima for arbitrary initial values. When decreasing ϵ, the minimizer of the previous step can be expected to provide a good initial guess for the next step carried out with a smaller ϵ.

To our knowledge, the phase-field approach in topology optimization was first introduced by Bourdin and Chambolle [9] for a design problem with design-dependent loads, another type of problem where standard material interpolation schemes encounter difficulties. The approach has recently been applied to minimal compliance-type problems by Wang and Zhou [33].

The remainder of this paper is organized as follows: in section 2 we review the constraint reformulation due to [30] and extend the approach to an approximate reformulation of the continuous problem. In section 3 we introduce the phase-field relaxation and analyze its basic properties. The finite element discretization yielding linearly constrained programming problems is discussed in section 4 and the solution of these programming problems by interior-point methods in section 5. Finally, we present numerical results obtained for local as well as for von Mises stress constraints.

2. Reformulation of constraints. In the following we consider a reformulation of constraints on subsets of locally bounded stresses; i.e.,

$$\beta|\sigma_{ij}| \le 1 \qquad \text{in } \Omega, \qquad i,j = 1,\dots,d, \tag{2.1}$$

for some (small) $\beta > 0$ such that $\beta \max_{i,j} \sigma_{ij}^{\max} < 1$ and $\beta \min_{i,j} \sigma_{ij}^{\min} > -1$ (i.e., the original total stress constraints are more restrictive for $\chi = 1$). Condition (2.1) is an additional restriction on the design set, which will be needed for the reformulations below. Since the original stress constraint is stronger than (2.1) in regions with material, the additional constraint just states that the stresses should continue in a reasonable (in particular finite) way in regions without material. The total constraints for the displacement $\mathbf{u}$, the stress σ, and the density χ are given by

$$\begin{aligned}
\operatorname{div} \sigma &= 0 && \text{in } \{\chi = 1\},\\
\sigma &= \mathbf{C} : \mathbf{e}(\mathbf{u}) && \text{in } \Omega,\\
\mathbf{u} &= \mathbf{0} && \text{on } \Gamma_D \subset \partial\Omega,\\
\sigma \cdot \mathbf{n} &= \mathbf{t} && \text{on } \Gamma_N \subset \partial\Omega,\\
\sigma \cdot \mathbf{n} &= \mathbf{0} && \text{on } \partial\{\chi = 1\} \cup (\partial\Omega - \Gamma_D - \Gamma_N),\\
\chi &\in \{0,1\} && \text{a.e. in } \Omega,\\
\Phi^{\min} \le \Phi(\sigma) &\le \Phi^{\max} && \text{in } \{\chi = 1\},\\
\mathbf{u}^{\min} \le \mathbf{u} &\le \mathbf{u}^{\max} && \text{in } \Omega.
\end{aligned} \tag{2.2}$$

We shall reformulate the constraints (2.1), (2.2) as linear inequality constraints for the case of total stress and von Mises stress constraints.

2.1. Reformulation of total stress constraints. We start with the reformulation in the case of total stress constraints, i.e., $\Phi(\sigma) = \sigma$. For this sake we introduce the approximate constraint sets

$$\begin{aligned}
\mathcal{C}^\beta := \{&(\chi,\mathbf{u},\sigma) \in BV(\Omega;[0,1]) \times H^1(\Omega;\mathbb{R}^d) \times L^\infty(\Omega;\mathbb{R}^{d\times d}) \mid\\
&(\chi,\mathbf{u},\sigma) \text{ satisfies (2.1), (2.2)}\}
\end{aligned}$$

and an additional artificial stress variable $\mathbf{s} \in L^\infty(\Omega;\mathbb{R}^{d\times d})$.

Let $(\chi,\mathbf{u},\sigma) \in \mathcal{C}^\beta$, and let $\mathbf{s} = \sigma$ if $\chi = 1$ and $\mathbf{s} = \mathbf{0}$ if $\chi = 0$, i.e., $\mathbf{s} = \chi\sigma$. Then the constraints

$$-(1-\chi)\mathbf{1} \le \beta(\sigma - \mathbf{s}) \le (1-\chi)\mathbf{1} \tag{2.3}$$

with the matrix $\mathbf{1} = (1)_{ij}$ and

$$\sigma^{\min}\chi \le \mathbf{s} \le \sigma^{\max}\chi \tag{2.4}$$

are satisfied. Vice versa, assume that

$$(\chi,\mathbf{u},\sigma,\mathbf{s}) \in BV(\Omega;[0,1]) \times H^1(\Omega;\mathbb{R}^d) \times L^\infty(\Omega;\mathbb{R}^{d\times d}) \times L^\infty(\Omega;\mathbb{R}^{d\times d})$$

fulfills (2.3), (2.4) and $\chi \in \{0,1\}$ almost everywhere. Then, for $\chi = 0$ (2.4) implies $\mathbf{s} = 0$ and (2.3) gives $-1 \le \beta\sigma_{ij} \le 1$. For $\chi = 1$ (2.3) implies $\mathbf{s} = \sigma$ and (2.4) becomes

$$\sigma^{\min}\chi \le \sigma \le \sigma^{\max}\chi.$$

Moreover, since either $\mathbf{s} = \sigma$ or $\mathbf{s} = \mathbf{0}$, we obtain that $\operatorname{div} \mathbf{s} = 0$ almost everywhere in Ω.

Due to the above arguments we conclude that $(\chi, \mathbf{u}, \sigma) \in \mathcal{C}^\beta$ if and only if there exists $\mathbf{s}$ such that

$$
\begin{aligned}
\operatorname{div} \mathbf{s} &= 0 && \text{in } \Omega,\\
\sigma &= \mathbf{C} : \mathbf{e}(\mathbf{u}) && \text{in } \Omega,\\
\mathbf{u} &= \mathbf{0} && \text{on } \Gamma_D \subset \partial\Omega,\\
\mathbf{s}\cdot\mathbf{n} &= \mathbf{t} && \text{on } \Gamma_N \subset \partial\Omega,\\
\mathbf{s}\cdot\mathbf{n} &= \mathbf{0} && \text{on } \partial\Omega - \Gamma_D - \Gamma_N,\\
-(1-\chi)\mathbf{1} \le \beta(\sigma - \mathbf{s}) &\le (1-\chi)\mathbf{1} && \text{in } \Omega,\\
\chi &\in \{0,1\} && \text{a.e. in } \Omega,\\
\sigma^{\min}\chi \le \mathbf{s} &\le \sigma^{\max}\chi && \text{in } \Omega,\\
\mathbf{u}^{\min} \le \mathbf{u} &\le \mathbf{u}^{\max} && \text{in } \Omega.
\end{aligned}
\tag{2.5}
$$

We mention that the conditions $\operatorname{div} \mathbf{s} = 0$, $\mathbf{s}\cdot\mathbf{n} = \mathbf{t}$ on Γ_D, and $\mathbf{s}\cdot\mathbf{n} = \mathbf{0}$ on $\partial\Omega - \Gamma_D - \Gamma_N$ have to be understood in a weak sense, namely, as $\int_\Omega \mathbf{s} : \mathbf{e}(\mathbf{v})\, d\mathbf{x} = \int_{\Gamma_N} \mathbf{v}\cdot\mathbf{t}\, d\mathbf{a}$ for all $\mathbf{v} \in \{\mathbf{v} \in H^1(\Omega;\mathbb{R}^d) \mid \mathbf{v}|_{\Gamma_D} = \mathbf{0}\}$.

Note that (except $\chi \in \{0,1\}$) the constraints (2.5) are linear with respect to the new vector of unknowns $(\chi, \mathbf{u}, \sigma, \mathbf{s})$; in particular all constraints are formulated on Ω and not on the unknown set $\{\chi = 1\}$. We would like to mention that the drawback of the reformulation is an increase in the number of unknowns and a high number of inequality constraints. On the other hand, this higher number of unknowns and constraints seems to be a reasonable price for the linear reformulation of the complicated original constraints.

2.2. Reformulation of von Mises stress constraints. In the following we discuss the reformulation of the inequalities in the case of von Mises stress constraints for dimension $d = 2$ (similar computations are possible for $d = 3$). Since both sides of the constraint (1.1) are positive, we can square them, and since the constraint must hold only for $\chi = 1$, it can be written equivalently as

$$\chi(\sigma_{11} - \sigma_{22})^2 + 4\chi\sigma_{12}^2 \le \chi(\Phi^{\max})^2.$$

A more conservative version of the von Mises criterion (see [30]) is given by

$$\chi|\sigma_{11} - \sigma_{22}| + 2\chi|\sigma_{12}| \le \chi\Phi^{\max}. \tag{2.6}$$

As above we introduce an artificial stress variable $\mathbf{s} = \chi\sigma$, and since $\chi^2 = \chi$, we can reformulate the von Mises constraint as

$$(\mathbf{s}_{11} - \mathbf{s}_{22})^2 + 4(\mathbf{s}_{12})^2 \le \chi(\Phi^{\max})^2.$$

The reformulation of the von Mises stress constraints on the constraint set $\mathcal{C}^\beta$ is given by

$$
\begin{aligned}
\operatorname{div} \mathbf{s} &= 0 && \text{in } \Omega,\\
\sigma &= \mathbf{C} : \mathbf{e}(\mathbf{u}) && \text{in } \Omega,\\
\mathbf{u} &= \mathbf{0} && \text{on } \Gamma_D \subset \partial\Omega,\\
\mathbf{s}\cdot\mathbf{n} &= \mathbf{t} && \text{on } \Gamma_N \subset \partial\Omega,\\
\mathbf{s}\cdot\mathbf{n} &= \mathbf{0} && \text{on } \partial\Omega - \Gamma_D - \Gamma_N,\\
-(1-\chi)\mathbf{1} \le \beta(\sigma - \mathbf{s}) &\le (1-\chi)\mathbf{1} && \text{in } \Omega,\\
(\mathbf{s}_{11} - \mathbf{s}_{22})^2 + 4(\mathbf{s}_{12})^2 &\le \chi(\Phi^{\max})^2 && \text{in } \Omega,\\
\chi &\in \{0,1\} && \text{a.e. in } \Omega,\\
\mathbf{u}^{\min} \le \mathbf{u} &\le \mathbf{u}^{\max} && \text{in } \Omega.
\end{aligned}
\tag{2.7}
$$

Since the von Mises stress is nonnegative, we do not state a lower bound $\Phi^{\min}$ on the stresses in (2.7) (we could choose the redundant constraint $\Phi^{\min} = 0$). Note that in this case, $\chi = 0$ in the von Mises stress constraint does not imply directly $\mathbf{s} = \mathbf{0}$ but only $\mathbf{s}_{11} - \mathbf{s}_{22} = 0$ and $\mathbf{s}_{12} = 0$. However, since $\mathbf{s}$ is divergence-free in addition, we may conclude for those special stresses that $\nabla \mathbf{s}_{11} = \mathbf{0}$. Hence, $\mathbf{s}$ is of the form

$$\mathbf{s} = \chi\sigma + (1-\chi)\begin{pmatrix} C & 0 \\ 0 & C \end{pmatrix}$$

for any constant $C \in \mathbb{R}$. Since such artificial stresses will not change the von Mises stress, and since $\mathbf{s}$ does not have a physical meaning for $\chi = 0$, the additional terms will not play a major role (we are basically free to define $\mathbf{s}$ arbitrarily in $\{\chi = 0\}$). The reformulation (2.7) involves convex quadratic constraints but only with respect to the stress variable $\mathbf{s}$, which still yields constraint qualification after relaxation and discretization.

In this paper we rather use the conservative von Mises stress criterion (2.6), which can actually be reformulated into linear inequalities. Again we use $\mathbf{s} = \chi\sigma$ to obtain

$$|\mathbf{s}_{11} - \mathbf{s}_{22}| + 2|\mathbf{s}_{12}| \le \chi\Phi^{\max}.$$

Moreover, we introduce functions p and q such that $p \ge 0$, $q \ge 0$ and

$$-p \le \mathbf{s}_{11} - \mathbf{s}_{22} \le p, \qquad -q \le \mathbf{s}_{12} \le q.$$

From these constraints we obtain that

$$|\mathbf{s}_{11} - \mathbf{s}_{22}| \le p, \qquad |\mathbf{s}_{12}| \le q.$$

Finally, we impose the constraint

$$p + 2q \le \chi\Phi^{\max}$$

and obtain as a consequence the conservative von Mises stress for $\mathbf{s}$. On the other hand, if the constraint is satisfied by $\mathbf{s}$, the variables

$$\begin{aligned} p &= \max\{-(\mathbf{s}_{11} - \mathbf{s}_{22}), \mathbf{s}_{11} - \mathbf{s}_{22}\}, \\ q &= \max\{-\mathbf{s}_{12}, \mathbf{s}_{12}\} \end{aligned}$$

satisfy the new linear constraints, and thus we conclude equivalence to the original conservative von Mises constraints. The reformulation of the conservative von Mises stress constraints on the constraint set $\mathcal{C}^\beta$ is given by

$$\begin{aligned} \operatorname{div} \mathbf{s} = 0 \quad & \text{in } \Omega, \\ \sigma = \mathbf{C} : \mathbf{e}(\mathbf{u}) \quad & \text{in } \Omega, \\ \mathbf{u} = \mathbf{0} \quad & \text{on } \Gamma_D \subset \partial\Omega, \\ \mathbf{s} \cdot \mathbf{n} = \mathbf{t} \quad & \text{on } \Gamma_N \subset \partial\Omega, \\ \mathbf{s} \cdot \mathbf{n} = \mathbf{0} \quad & \text{on } \partial\Omega - \Gamma_D - \Gamma_N, \\ -(1-\chi)\mathbf{1} \le \beta(\sigma - \mathbf{s}) \le (1-\chi)\mathbf{1} \quad & \text{in } \Omega, \\ p \ge 0, \quad q \ge 0 \quad & \text{in } \Omega, \\ -p \le \mathbf{s}_{11} - \mathbf{s}_{22} \le p \quad & \text{in } \Omega, \\ -q \le \mathbf{s}_{12} \le q \quad & \text{in } \Omega, \\ p + 2q \le \chi\Phi^{\max} \quad & \text{in } \Omega, \\ \chi \in \{0,1\} \quad & \text{a.e. in } \Omega, \\ \mathbf{u}^{\min} \le \mathbf{u} \le \mathbf{u}^{\max} \quad & \text{in } \Omega. \end{aligned}$$

3. Phase-field relaxation. We now turn our attention to the relaxation of the stress constrained topology optimization problem. For this sake we replace the indicator function χ by a density $\rho : \Omega \to [0,1]$ and approximate the perimeter term in the regularized objective functional J^γ (1.2) by the Cahn–Hilliard term P^ϵ (1.3). The resulting relaxation in the case of total stress constraints is given by

$$
\begin{aligned}
M(\rho) = \gamma \int_\Omega \rho \, \mathrm{d}\mathbf{x} + P^\epsilon(\rho) \quad &\to \quad \min, \\
\operatorname{div} \mathbf{s} = 0 \quad &\text{in } \Omega, \\
\sigma = \mathbf{C} : \mathbf{e}(\mathbf{u}) \quad &\text{in } \Omega, \\
\mathbf{u} = \mathbf{0} \quad &\text{on } \Gamma_D, \\
\mathbf{s} \cdot \mathbf{n} = \mathbf{t} \quad &\text{on } \Gamma_N, \\
\mathbf{s} \cdot \mathbf{n} = \mathbf{0} \quad &\text{on } \partial\Omega - \Gamma_D - \Gamma_N, \\
\rho = 1 \quad &\text{on } \Gamma_N, \\
-(1-\rho)\mathbf{1} \le \beta(\sigma - \mathbf{s}) \le (1-\rho)\mathbf{1} \quad &\text{in } \Omega, \\
\sigma^{\min}\rho \le \mathbf{s} \le \sigma^{\max}\rho \quad &\text{in } \Omega, \\
0 \le \rho \le 1 \quad &\text{a.e. in } \Omega, \\
\mathbf{u}^{\min} \le \mathbf{u} \le \mathbf{u}^{\max} \quad &\text{in } \Omega.
\end{aligned}
\tag{3.1}
$$

The function space setting for this relaxation is given by

$$(\rho, \mathbf{u}, \sigma, \mathbf{s}) \in (H^1(\Omega) \cap L^\infty(\Omega)) \times (H^1(\Omega;\mathbb{R}^d) \cap L^\infty(\Omega;\mathbb{R}^d)) \times L^\infty(\Omega;\mathbb{R}^{d\times d})^2.$$

Note that, in addition to the original constraint reformulation (2.5), we have added a Dirichlet boundary condition for ρ on Γ_N, which is well defined in the sense of traces of functions in $H^1(\Omega)$. The reasoning for adding this condition is as follows: in the original constraint we have $\mathbf{s} \cdot \mathbf{n} = \mathbf{t} \neq \mathbf{0}$ on Γ_N. Hence, there exists a small open neighborhood of Γ_N in Ω, where $\chi = 1$ (since otherwise $\chi = 0$ would imply $\mathbf{s} = \mathbf{0}$ and thus $\mathbf{s} \cdot \mathbf{n} = \mathbf{0}$ on Γ_N). In the relaxed formulation, the trace of ρ is positive by analogous arguments but not necessarily equal to one. Thus, the additional constraint will not change the limit of the constraint set, but, on the other hand, it restricts the relaxation and simplifies the analysis of the relaxed problem.

In a similar way we can state a relaxed formulation of the problem with conservative von Mises stress constraints ($d = 2$) as

$$
\begin{aligned}
M(\rho) = \gamma \int_\Omega \rho \, \mathrm{d}\mathbf{x} + P^\epsilon(\rho) \quad &\to \quad \min, \\
\operatorname{div} \mathbf{s} = 0 \quad &\text{in } \Omega, \\
\sigma = \mathbf{C} : \mathbf{e}(\mathbf{u}) \quad &\text{in } \Omega, \\
\mathbf{u} = \mathbf{0} \quad &\text{on } \Gamma_D, \\
\mathbf{s} \cdot \mathbf{n} = \mathbf{t} \quad &\text{on } \Gamma_N, \\
\mathbf{s} \cdot \mathbf{n} = \mathbf{0} \quad &\text{on } \partial\Omega - \Gamma_D - \Gamma_N, \\
\rho = 1 \quad &\text{on } \Gamma_N, \\
-(1-\rho)\mathbf{1} \le \beta(\sigma - \mathbf{s}) \le (1-\rho)\mathbf{1} \quad &\text{in } \Omega, \\
p \ge 0, \quad q \ge 0 \quad &\text{in } \Omega, \\
-p \le \mathbf{s}_{11} - \mathbf{s}_{22} \le p \quad &\text{in } \Omega, \\
-q \le \mathbf{s}_{12} \le q \quad &\text{in } \Omega, \\
p + 2q \le \chi\Phi^{\max} \quad &\text{in } \Omega, \\
0 \le \rho \le 1 \quad &\text{a.e. in } \Omega, \\
\mathbf{u}^{\min} \le \mathbf{u} \le \mathbf{u}^{\max} \quad &\text{in } \Omega,
\end{aligned}
\tag{3.2}
$$

with variables

$$(\rho, \mathbf{u}, \sigma, \mathbf{s}, p, q) \in (H^1(\Omega) \cap L^\infty(\Omega)) \times (H^1(\Omega; \mathbb{R}^d) \times L^\infty(\Omega; \mathbb{R}^d)) \\ \times L^\infty(\Omega; \mathbb{R}^{d\times d})^2 \times L^\infty(\Omega)^2,$$

with the notation $\mathbf{p} = (p_1, p_2)$ and $\mathbf{q} = (q_1, q_2)$. In our discussion below we will focus on total stress constraints, i.e., the relaxed optimization problem (3.1), but analogous reasoning is possible for von Mises stress constraints.

The basis of the relaxation idea is the Γ-convergence of problem (3.1) to (2.5) as ϵ tends to zero (respectively, Γ-convergence of (3.2) to (2.7) for the conservative von Mises constraints). This can be derived from the Γ-convergence of the perimeter term P^ϵ (cf. [21, 22]) to which only a continuous functional is added (compare Proposition 6.2.1 in [16]).

3.1. Structure of the relaxed problem. In the following we further examine the structure of the relaxed problem (3.1). Due to the term $W(\rho)$ in the Cahn–Hilliard penalty, we have to expect the objective functional to be nonconvex, in particular for small ϵ, when minimizers are forced to take values close to 0 or 1. For large ϵ, the first term of the Cahn–Hilliard energy dominates, and thus the optimization problem is convex.

THEOREM 3.1. *Let $W \in C^2([0,1])$. Then there exists $\epsilon_0 > 0$ dependent on Ω only, such that the objective functional $\rho \mapsto M(\rho) = \gamma \int_\Omega \rho \, d\mathbf{x} + P^\epsilon(\rho)$ is convex for all $\epsilon > \epsilon_0$.*

Proof. The objective functional is twice continuously differentiable with derivatives

$$M'(\rho)\psi = \gamma \int_\Omega \psi \, \mathrm{d}\mathbf{x} + \epsilon \int_\Omega \nabla\rho \cdot \nabla\psi \, \mathrm{d}\mathbf{x} + \frac{1}{\epsilon} \int_\Omega W'(\rho)\psi \, \mathrm{d}\mathbf{x}$$

and

$$M''(\rho)(\psi_1, \psi_2) = \epsilon \int_\Omega \nabla\psi_1 \cdot \nabla\psi_2 \, \mathrm{d}\mathbf{x} + \frac{1}{\epsilon} \int_\Omega W''(\rho)\psi_1\psi_2 \, \mathrm{d}\mathbf{x}.$$

Due the constraint $0 \le \rho \le 1$, we obtain $|W''(\rho)| \le W_0$, where $W_0 \in \mathbb{R}$ is the maximum of W'' in the interval $[0,1]$. Moreover, since $\rho = 1$ on Γ_N, admissible variations satisfy $\psi = 0$ on Γ_N, and due to a Friedrich-type inequality, there exists a constant $C_P > 0$ such that

$$\int_\Omega \psi^2 \, \mathrm{d}\mathbf{x} \le C_P \int_\Omega |\nabla\psi|^2 \, \mathrm{d}\mathbf{x}$$

for all admissible variations $\psi \in H^1(\Omega)$ with $\psi = 0$ on Γ_N. Hence,

$$M''(\rho)(\psi, \psi) \ge \left(\epsilon - \frac{W_0 C_P}{\epsilon}\right) \int_\Omega |\nabla\psi|^2 \, \mathrm{d}\mathbf{x}.$$

Consequently, for $\epsilon \ge \epsilon_0 := \sqrt{W_0 C_P}$, M is convex. Since all constraints are linear, the relaxed optimization problem (3.1) is convex. ∎

So far, we have not discussed possible choices for the function W. Commonly used in phase-field simulations of phase-transition problems (e.g., in the Allen–Cahn and Cahn–Hilliard equation; cf., e.g., [4, 13]) is the *double-well potential*

$$W(r) = r^2(1-r)^2, \qquad r \in \mathbb{R}.$$

Recently, the so-called *double-obstacle potential*

$$W(r) = r(1-r), \qquad r \in [0,1], \tag{3.3}$$

has received further attention (see [6]). In the case of evolutions such as the Allen–Cahn equation, the use of the double-obstacle potential is rather a computational complication, since $0 \leq \rho \leq 1$ has to be enforced (in contrast to the evolution with the double-well potential), and the PDE has to be reformulated as a variational inequality. In our case, the choice of the double-obstacle potential (3.3) seems more attractive, since we enforce the bound constraints on ρ anyway (within our system of inequality constraints), and the double-obstacle problem causes a polynomial nonlinearity of lower degree than the double-well potential. Using (3.3) in P^ϵ, we observe that (3.1) and (3.2) are quadratic optimization problems subject to linear constraints.

3.2. Existence of solutions. We now investigate the existence of solutions of the relaxed problem (3.1). For this sake we introduce the Banach spaces of functions with essentially bounded strain

$$BS^\infty(\Omega) := \{\mathbf{u} \in L^\infty(\Omega;\mathbb{R}^d) \mid \mathbf{e}(\mathbf{u}) \in L^\infty(\Omega;\mathbb{R}^{d\times d})\}$$

and square-integrable strain

$$BS^2(\Omega) := \{\mathbf{u} \in L^2(\Omega;\mathbb{R}^d) \mid \mathbf{e}(\mathbf{u}) \in L^2(\Omega;\mathbb{R}^{d\times d})\}$$

with norms

$$\|\mathbf{u}\|_{BS^\infty} := \max\{\|\mathbf{u}\|_\infty, \|\mathbf{e}(\mathbf{u})\|_\infty\}$$

and

$$\|\mathbf{u}\|_{BS^2} := \sqrt{\|\mathbf{u}\|_2^2 + \|\mathbf{e}(\mathbf{u})\|_2^2}.$$

One can verify by standard arguments that $BS^\infty(\Omega)$ is a Banach space (including all elements of the Sobolev space $W^{1,\infty}(\Omega;\mathbb{R}^d)$) and that $BS^2(\Omega)$ is a Hilbert space with scalar product

$$\langle \mathbf{u}, \mathbf{v}\rangle_{BS^2} := \langle \mathbf{u}, \mathbf{v}\rangle_{L^2} + \langle \mathbf{e}(\mathbf{u}), \mathbf{e}(\mathbf{v})\rangle_{L^2}.$$

As usual for weak solutions of PDEs, we understand the equality constraints on $\mathbf{s}$ in a standard weak sense, i.e.,

$$\int_\Omega \mathbf{s} : \nabla\Psi \, \mathrm{d}\mathbf{x} = \int_{\Gamma_N} \mathbf{t}\cdot\Psi \, \mathrm{d}a \qquad \forall\ \Psi \in W^{1,2}(\Omega;\mathbb{R}^d), \Psi|_{\Gamma_D} = 0.$$

Similarly, we interpret the stress-strain relation in an L^2-sense, i.e.,

$$\int_\Omega \left[\sigma : \Psi - \Psi : \mathbf{C} : \mathbf{e}(\mathbf{u})\right] \, \mathrm{d}\mathbf{x} = 0 \qquad \forall\ \Psi \in L^2(\Omega;\mathbb{R}^{d\times d}).$$

We start the analysis with a lower semicontinuity property.

LEMMA 3.1. *Let W be defined by* (3.3). *Then the functional $M : H^1(\Omega) \to \mathbb{R}$ is sequentially weakly lower semicontinuous.*

Proof. Due to the compact embedding $H^1(\Omega) \hookrightarrow L^2(\Omega)$, the linear functional $\rho \mapsto \gamma \int_\Omega \rho \, \mathrm{d}\mathbf{x}$ and the quadratic functional $\rho \mapsto \frac{1}{\epsilon}\int_\Omega W(\rho) \, \mathrm{d}\mathbf{x}$ are weakly continuous.

Together with the sequential weak lower semicontinuity of the square of the norm in Hilbert spaces applied to the third term in M, we obtain the assertion. ∎

Besides lower semicontinuity, a fundamental ingredient for the existence of solutions is compactness in appropriate topologies. In order to obtain some weak compactness, we examine the boundedness of the constraint set.

LEMMA 3.2. *Let $\epsilon > 0$, and let*

$$(\rho, \mathbf{u}, \sigma, \mathbf{s}) \in L^\infty(\Omega) \times BS^\infty(\Omega) \times L^\infty(\Omega; \mathbb{R}^{d\times d})^2$$

satisfy the constraints in (3.1). *Then $(\rho, \mathbf{u}, \sigma, \mathbf{s})$ lies in a bounded set with respect to the corresponding norms.*

Proof. From the bound constraints $0 \le \rho \le 1$ we immediately conclude that ρ lies in the unit ball of $L^\infty(\Omega)$. Consequently, we deduce that

$$\min\left\{\mathbf{0}, \sigma^{\min}\right\} \le \mathbf{s} \le \max\left\{\sigma^{\max}, \mathbf{0}\right\},$$

and hence $\mathbf{s}$ is bounded in the norm of $L^\infty(\Omega; \mathbb{R}^{d\times d})$. Due to

$$\mathbf{s} - \frac{1-\rho}{\beta}\mathbf{1} \le \sigma \le \mathbf{s} + \frac{1-\rho}{\beta}\mathbf{1}$$

we further conclude the boundedness of σ in the norm of $L^\infty(\Omega; \mathbb{R}^{d\times d})$. Finally, the bound constraints on $\mathbf{u}$ imply its boundedness in the norm of $L^\infty(\Omega; \mathbb{R}^d)$, and together with the stress-strain relation and the positive definiteness we may conclude the boundedness of $\mathbf{u}$ in the norm of $BS^\infty(\Omega)$. ∎

With these preliminary results we can provide an existence result for the relaxed topology optimization problem for arbitrary positive ϵ.

THEOREM 3.2. *Let $\epsilon > 0$, $\beta > 0$, and let W be defined by* (3.3). *Moreover, let the admissible set defined by the constraints in* (3.1) *be nonempty. Then there exists a solution*

$$(\rho, \mathbf{u}, \sigma, \mathbf{s}) \in (H^1(\Omega) \cap L^\infty(\Omega)) \times BS^\infty(\Omega) \times L^\infty(\Omega; \mathbb{R}^{d\times d})^2$$

of the constrained optimization problem (3.1).

Proof. For admissible densities $\rho \ge 0$, the objective functional M is bounded below by zero, and hence the infimum m_0 of M on the admissible set is finite. Hence, we can find a minimizing sequence

$$(\rho^n, \mathbf{u}^n, \sigma^n, \mathbf{s}^n) \in (H^1(\Omega) \cap L^\infty(\Omega)) \times BS^\infty(\Omega) \times L^\infty(\Omega; \mathbb{R}^{d\times d})^2$$

such that $M(\rho^n) \to m_0$. Since $M(\rho^n)$ converges, the sequence is bounded in particular, and since

$$\frac{2}{\epsilon} M(\rho^n) \ge \int_\Omega |\nabla \rho^n|^2 \mathrm{d}\mathbf{x},$$

we obtain boundedness of ρ^n in $H^1(\Omega)$. Due to Lemma 3.2 and standard precompactness results for bounded sets in weak or weak-* topologies, we can extract a subsequence (again denoted by the superscript n) such that

$$\begin{aligned}
\rho^n &\to \hat{\rho} \text{ weak in } H^1(\Omega) \text{ and weak-* in } L^\infty(\Omega),\\
\mathbf{u}^n &\to \hat{\mathbf{u}} \text{ weak in } BS^2(\Omega) \text{ and weak-* in } L^\infty(\Omega; \mathbb{R}^d),\\
\sigma^n &\to \hat{\sigma} \text{ weak-* in } L^\infty(\Omega; \mathbb{R}^{d\times d}),\\
\mathbf{s}^n &\to \hat{\mathbf{s}} \text{ weak-* in } L^\infty(\Omega; \mathbb{R}^{d\times d}).
\end{aligned}$$

Due to closedness of simple bounds with respect to weak-* convergence in L^∞, we can conclude that the limit $(\hat\rho, \hat{\mathbf{u}}, \hat\sigma, \hat{\mathbf{s}})$ satisfies all the inequalities in (3.1). Moreover, since for $\Psi \in W^{1,2}(\Omega; \mathbb{R}^d)$ we have in particular $\nabla\Psi \in L^1(\Omega)$, we may conclude that

$$\int_{\Gamma_N} \mathbf{t} \cdot \Psi \, \mathrm{d}a = \int_\Omega \mathbf{s}^n : \nabla\Psi \, \mathrm{d}\mathbf{x} \to \int_\Omega \mathbf{s} : \nabla\Psi \, \mathrm{d}\mathbf{x}$$

due to weak-* convergence in L^∞. Hence, $\hat{\mathbf{s}}$ satisfies the associated equality constraints. From the weak convergence of $\mathbf{u}^n$ in $BS^2(\Omega)$ we conclude that $\hat{\mathbf{u}}$ satisfies the stress-strain relation, and hence $(\hat\rho, \hat{\mathbf{u}}, \hat\sigma, \hat{\mathbf{s}})$ is in the admissible set. With the sequential lower semicontinuity from Lemma 3.1 we finally obtain that, thus, $(\hat\rho, \hat{\mathbf{u}}, \hat\sigma, \hat{\mathbf{s}})$ is a solution of the optimization problem (3.1). ∎

4. Discretization. In the following we consider the discretization of the relaxed problems for $\Omega \subset \mathbb{R}^2$, detailing the analysis again for the case of (3.1). For simplicity (and motivated by the typical choices of design domains), we assume that Ω is of polygonal shape.

Our aim is to construct a finite element approximation on a triangular grid; i.e., we decompose $\Omega = \bigcup_{T\in\mathcal{T}^h} \overline{T}$ for a suitable family $\mathcal{T}^h$ of triangles satisfying standard regularity conditions (see [11]). The parameter $h > 0$ denotes the grid size (equal to the maximal diameter of triangles in $\mathcal{T}^h$). We shall use two different discrete subspaces, namely the H^1-subspace of linear elements (for the density ρ and displacement components $\mathbf{u}_i$)

$$\mathcal{V}^h := \{\varphi \in C(\Omega) \mid \varphi \text{ is affinely linear in } T \;\forall\, T \in \mathcal{T}^h\}$$

and the L^∞-subspace of constant elements (for the stress components σ_{ij} and $\mathbf{s}_{ij}$)

$$\mathcal{W}^h := \{\varphi \in L^\infty(\Omega) \mid \varphi \text{ is constant in } T \;\forall\, T \in \mathcal{T}^h\}.$$

Note that for $\mathbf{u} \in \mathcal{V}^h \times \mathcal{V}^h \subset BS^\infty(\Omega)$, we obtain $\frac{\partial \mathbf{u}_i}{\partial \mathbf{x}_j} \in \mathcal{W}^h$.

The equality constraints are discretized by a standard finite element approach; i.e., we look for $\mathbf{s} \in (\mathcal{W}^h)^{2\times 2}$, $\sigma \in (\mathcal{W}^h)^{2\times 2}$, and $\mathbf{u} \in \mathcal{V}^h \times \mathcal{V}^h$ satisfying

$$\int_\Omega \mathbf{s} : \nabla\Psi \, \mathrm{d}\mathbf{x} = \int_{\Gamma_N} \mathbf{t} \cdot \Psi \, \mathrm{d}a \qquad \forall\, \Psi \in \mathcal{V}^h \times \mathcal{V}^h, \Psi|_{\Gamma_D} = 0$$

and

$$\int_\Omega \left[\sigma : \Psi - \Psi : \mathbf{C} : \mathbf{e}(\mathbf{u})\right] \, \mathrm{d}\mathbf{x} = 0 \qquad \forall\, \Psi \in (\mathcal{W}^h)^{2\times 2}.$$

The bound constraints on the displacement and density $\rho \in \mathcal{V}^h$ can be enforced directly; for piecewise linear functions, the constraints hold if and only if they hold in all nodes of the grid.

Finally, we need to discretize the inequality constraints involving both stress variables and the density. Since the components of σ and $\mathbf{s}$ are in a different subspace than ρ, the discretization is not straightforward. In particular, we cannot pose local constraints in the grid nodes or on edges, since functions in $\mathcal{W}^h$ are discontinuous over the edges. Consequently, the more promising approach is to interpret the inequality constraints as constraints in $\mathcal{W}^h$. For this sake we introduce the discrete projection operator (with respect to the L^2-norm) $\mathcal{P}^h : \mathcal{V}^h \to \mathcal{W}^h$,

$$(\mathcal{P}^h v)|_T := \frac{1}{|T|} \int_T v \, \mathrm{d}\mathbf{x} \qquad \forall\, T \in \mathcal{T}^h, \forall\, v \in \mathcal{V}^h.$$

The discretized formulation of constraints in $\mathcal{W}^h$ can then be formulated as

$$\begin{aligned} -(1-\mathcal{P}^h\rho)\mathbf{1} \le \beta(\sigma - \mathbf{s}) \le (1-\mathcal{P}^h\rho)\mathbf{1} \qquad &\text{in } \Omega, \\ \sigma^{\min}\mathcal{P}^h\rho \le \mathbf{s} \le \sigma^{\max}\mathcal{P}^h\rho \qquad &\text{in } \Omega. \end{aligned}$$

Let the coefficients $\mathbf{R} \in \mathbb{R}^N$, $\mathbf{U} \in \mathbb{R}^{2N}$, $\mathbf{S} \in \mathbb{R}^{3M}$, and $\mathbf{\Sigma} \in \mathbb{R}^{3M}$ contain the coefficients R_j, U_j^i, S_k^{ij}, and Σ_k^{ij} (using the symmetry $S_k^{ij} = S_k^{ji}$ and $\Sigma_k^{ij} = \Sigma_k^{ji}$) of the finite element functions of ρ, $\mathbf{u}$, $\mathbf{s}$, and σ, respectively. The discretized problem can now be written equivalently as a quadratic programming problem with linear constraints for the unknown $(\mathbf{R}, \mathbf{U}, \mathbf{\Sigma}, \mathbf{S}) \in \mathbb{R}^{3N+6M}$:

$$\begin{aligned} \gamma\mathbf{E}^T\mathbf{R} + \frac{\epsilon}{2}\mathbf{R}^T\mathbf{K}\mathbf{R} + \frac{1}{\epsilon}\mathbf{R}^T(\mathbf{E} - \mathbf{M}\mathbf{R}) \quad &\to \quad \min, \\ \left(\mathbf{I} - \mathbf{L}_1^T\mathbf{L}_1\right)\mathbf{B}^T\mathbf{S} &= \mathbf{T}, \\ \mathbf{D}\mathbf{\Sigma} - \mathbf{C}\mathbf{B}\mathbf{U} &= \mathbf{0}, \\ \mathbf{L}_1\mathbf{U} &= \mathbf{0}, \\ \mathbf{L}_2\mathbf{R} &= \mathbf{1}, \\ -\mathbf{Q}(\mathbf{1} - \mathbf{P}\mathbf{R}) \le \beta(\Sigma - \mathbf{S}) &\le \mathbf{Q}(\mathbf{1} - \mathbf{P}\mathbf{R}), \\ \boldsymbol{\sigma}^{\min}\mathbf{Q}\mathbf{P}\mathbf{R} \le \mathbf{S} &\le \boldsymbol{\sigma}^{\max}\mathbf{Q}\mathbf{P}\mathbf{R}, \\ \mathbf{0} \le \mathbf{R} &\le \mathbf{1}, \\ \mathbf{u}^{\min} \le \mathbf{U} &\le \mathbf{u}^{\max}. \end{aligned} \tag{4.1}$$

In the objective functional, $\mathbf{E} \in \mathbb{R}^N$ is a vector representing the coefficients of the constant function 1 with respect to the basis functions ϕ_j. $\mathbf{K} \in \mathbb{R}^{N\times N}$ is a stiffness matrix arising from the finite element discretization of the negative Laplacian in $\mathcal{V}^h$, and $\mathbf{M} \in \mathbb{R}^{N\times N}$ is a mass matrix for the identity in $\mathcal{V}^h$. In the discretized formulation of the constraints, the matrix $\mathbf{B}^T \in \mathbb{R}^{3M\times 2N}$ is the discretization of the divergence operator (restricted to symmetric stress tensors), $\mathbf{C} \in \mathbb{R}^{3M\times 3M}$ represents the stress-strain relation, $\mathbf{D}$ is a (diagonal) mass matrix for the identity in $\mathcal{W}^h$, and $\mathbf{T} \in \mathbb{R}^{2N}$ is a discrete representation of the traction force. The matrices $\mathbf{L}_1 \in \mathbb{R}^{2N_1\times 2N}$ and $\mathbf{L}_2 \in \mathbb{R}^{N_2\times N}$ with entries 0 or 1 realize the boundary conditions, where N_1 is the number of node points on Γ_D and N_2 is the number of node points on Γ_N. $\boldsymbol{\sigma}^{\min}$ and $\boldsymbol{\sigma}^{\max}$ are diagonal matrices, representing the corresponding entries of $\sigma^{\min}$ and $\sigma^{\max}$. Finally, $\mathbf{Q} \in \mathbb{R}^{3M\times M}$ is an extension matrix, and $\mathbf{P} \in \mathbb{R}^{M\times N}$ is the matrix representation of the projection operator $\mathcal{P}^h$.

The above reasoning shows that after discretization we end up with a linearly constrained quadratic programming problem for the variable

$$\mathbf{X} = (\mathbf{R}, \mathbf{U}, \mathbf{\Sigma}, \mathbf{S}) \in \mathbb{R}^{3N+6M}$$

with $2N + 3M + 2N_1 + N_2$ equality, $12M$ inequality constraints, and $6N$ bound constraints. Note that $2N_1$ equalities corresponding to the divergence constraint for nodal points in Γ_D are actually in the form $0 = 0$ and can be eliminated. In addition, we can eliminate the components of $\mathbf{U}$ corresponding to nodal points on Γ_D and the corresponding bound constraints (we have to assume $\mathbf{u}^{\min} \le \mathbf{0} \le \mathbf{u}^{\max}$ in order to obtain feasible points anyway). Moreover, we can eliminate the components of $\mathbf{R}$ corresponding to nodal values on Γ_N and the corresponding bound constraints. Since all values of $\mathbf{\Sigma}$ are determined by the corresponding equality constraints, we remove these constraints and replace $\mathbf{\Sigma}$ by $\mathbf{C}\mathbf{B}\mathbf{U}$ in the inequality constraints. We consequently end up with a smaller programming problem with $3N + 3M - 2N_1 - N_2$ unknowns, $2N - 2N_1$ equality constraints, $12M$ inequality constraints, and $6N - 4N_1 - 2N_2$ bound constraints.

The existence of solutions for the reduced programming problem can be verified in an analogous way to the infinite-dimensional situation under the assumption that there exists a feasible point.

4.1. Constraint qualification. In order to obtain constraint qualification for the linear constraints, it suffices to show that the equality constraints are linearly independent and that there exists a feasible point satisfying all inequalities strictly. Note again that the feasible set does not depend on the relaxation parameter ϵ, and hence the constraint qualification is always uniform with respect to the relaxation.

The linear independence of the equality constraints can be verified by standard reasoning for finite element discretizations, and we therefore turn our attention to the inequality constraints. In order to verify constraint qualification, we shall use a natural assumption, namely, that the stress and displacement obtained from a design domain completely filled with material satisfy the displacement and stress constraints strictly. This assumption is natural, since one expects the maximal stress and displacement to increase for decreasing mass. Thus, if the constraints are active at maximal mass already, it is quite unlikely to find an optimal design with lower mass anyway, or, in other words, the constraints are too severe to compute a different optimum. In mathematical terms, the assumption can be formulated as follows: Let $\mathbf{R}^1 = \mathbf{1}$, and let $\mathbf{U}^1$ and $\mathbf{S}^1 = \mathbf{\Sigma}^1$ be the solutions of the corresponding elasticity problem:

$$(\mathbf{I} - \mathbf{L}_1^T\mathbf{L}_1)\mathbf{B}^T\mathbf{S}^1 = \mathbf{T}, \qquad \mathbf{D}\mathbf{\Sigma}^1 - \mathbf{C}\mathbf{B}\mathbf{U}^1 = \mathbf{0}, \qquad \mathbf{L}_1\mathbf{U}^1 = \mathbf{0},$$

which can be shown to be uniquely defined from standard finite element theory. Then we assume that

$$\boldsymbol{\sigma}^{\min}\mathbf{Q}\mathbf{P}\mathbf{R}^1 < \mathbf{S}^1 < \boldsymbol{\sigma}^{\max}\mathbf{Q}\mathbf{P}\mathbf{R}^1, \qquad \mathbf{u}^{\min} < \mathbf{U}^1 < \mathbf{u}^{\max}, \tag{4.2}$$

where $<$ means strict inequality for each component. Then we obtain the following result.

THEOREM 4.1. *Let* (4.2) *be satisfied, and let* $\beta > 0$ *be sufficiently small. Then the constraint set in* (4.1) *with the elimination of variables and constraints as explained above satisfies the Slater condition.*

Proof. As noticed above, it suffices to find a feasible point satisfying the constraints strictly. For this sake we choose a density $\mathbf{R}^\eta = \eta\mathbf{1}$ with $0 < \eta < 1$. Then $\|\mathbf{R}^1 - \mathbf{R}^\eta\| = N(1-\eta)$; i.e., the distance to $\mathbf{R}^1$ becomes arbitrarily small as $\eta \to 1$. Because of continuity, we can find $0 < \eta < 1$, and a solution $\mathbf{U}^\eta$, $\mathbf{S}^\eta = \eta\Sigma^\eta$ of

$$(\mathbf{I} - \mathbf{L}_1^T\mathbf{L}_1)\mathbf{B}^T\mathbf{S}^\eta = \mathbf{T}, \qquad \mathbf{D}\mathbf{\Sigma}^\eta - \mathbf{C}\mathbf{B}\mathbf{U}^\eta = \mathbf{0}, \qquad \mathbf{L}_1\mathbf{U}^\eta = \mathbf{0},$$

such that

$$\boldsymbol{\sigma}^{\min}\mathbf{Q}\mathbf{P}\mathbf{R}^\eta < \mathbf{S}^\eta < \boldsymbol{\sigma}^{\max}\mathbf{Q}\mathbf{P}\mathbf{R}^\eta, \qquad \mathbf{u}^{\min} < \mathbf{U}^\eta < \mathbf{u}^{\max}$$

holds. Moreover, we have

$$\mathbf{0} < \mathbf{R}^\eta = \eta\mathbf{1} < \mathbf{1}$$

and

$$\begin{aligned} -\mathbf{Q}(1-\eta)\mathbf{1} &= -\mathbf{Q}(\mathbf{1} - \mathbf{P}\mathbf{R}^\eta) < \beta(\mathbf{\Sigma}^\eta - \mathbf{S}^\eta) \\ &= \beta(1-\eta)\mathbf{\Sigma}^\eta < \mathbf{Q}(\mathbf{1} - \mathbf{P}\mathbf{R}^\eta) = \mathbf{Q}(1-\eta)\mathbf{1}, \end{aligned}$$

provided β is sufficiently small. Hence, all (reduced) inequality constraints are satisfied strictly by $(\mathbf{R}^\eta, \mathbf{U}^\eta, \mathbf{S}^\eta, \Sigma^\eta)$, which implies the assertion. ∎

5. Solution of the discretized problem.

5.1. Continuation in ϵ. As motivated in the introduction and in section 3.1 the problem (4.1) will be solved for a decreasing sequence of ϵ. As $\epsilon \to 0$, in analogy to Γ-convergence of the perimeter functional, we expect convergence of the sequence of the minimum solutions to a final solution. Moreover, since the double obstacle term is of leading order in ϵ, such a final solution will have a sharp interface between material ($\{\rho{=}1\}$) and void ($\{\rho{=}0\}$).

To achieve this we will use a continuation method such that we choose a decreasing sequence $\{\epsilon^l\}$ with $\epsilon^l \to 0$ for $l = 0, \ldots, L$, where L describes the total number of continuation levels. The corresponding optimization problems are then solved by an interior-point method, as described in the next section. Between the levels ϵ can be reduced, e.g., like $\epsilon^{l+1} := \delta\epsilon^l$ with $0 < \delta < 1$ or like $\epsilon^{l+1} := (\epsilon^0)^l$ if $0 < \epsilon^0 < 1$. If we decrease ϵ too slowly, we may expect from theory and observations from numerical tests that the final solution is not changed, but we end up with a possibly unnecessary high number of levels L. On the other hand, if ϵ is decreased too quickly, the optimization process might get stuck in some undesired local minimum, since the objective functional $M(\rho)$ is turned from convex to concave too quickly.

5.2. Adaption of the problem to IPOPT. We solve the problem (4.1) with IPOPT, which is a freely available optimization code realizing a primal-dual interior-point method. IPOPT, implemented by A. Wächter and L. T. Biegler, is able to solve problems of the following form:

$$\begin{aligned} &\min_{\mathbf{x}\in\mathbb{R}^n} f(\mathbf{x}) \\ \text{s.t.} \quad & c_{\mathcal{E}}(\mathbf{x}) = \mathbf{0}, \\ & \mathbf{x}^{\min} \le \mathbf{x} \le \mathbf{x}^{\max}. \end{aligned}$$

More information about the implementation of IPOPT can be found in Wächter and Biegler [32]. Tailoring the problem to a black-box optimizer is not the most efficient approach for the numerical solution. However, the aim of this paper is rather to develop and test the general relaxation approach instead of constructing efficient optimization methods.

General nonlinear programming problems with inequality constraints can be written in the above framework using slack variables. So we reformulate (4.1) in the above form by introducing some vector $\mathbf{Z} = (\mathbf{Z}_1, \mathbf{Z}_2, \mathbf{Z}_3, \mathbf{Z}_4) \in \mathbb{R}^{12M}$ of slack variables, leading to

$$\begin{aligned} \gamma\mathbf{E}^T\mathbf{R} + \frac{\epsilon}{2}\mathbf{R}^T\mathbf{K}\mathbf{R} + \frac{1}{\epsilon}\mathbf{R}^T(\mathbf{E} - \mathbf{M}\mathbf{R}) \quad &\to \quad \min_{(\mathbf{R},\mathbf{U},\mathbf{S},\mathbf{Z})\in\mathbb{R}^{3N+15M}}, \\ \left(\mathbf{I} - \mathbf{L}_1^T\mathbf{L}_1\right)\mathbf{B}^T\mathbf{S} - \mathbf{T} &= \mathbf{0}, \\ -\mathbf{Q}(\mathbf{1} - \mathbf{P}\mathbf{R}) - \beta(\mathbf{C}\mathbf{B}\mathbf{U} - \mathbf{S}) + \mathbf{Z}_1 &= \mathbf{0}, \\ \beta(\mathbf{C}\mathbf{B}\mathbf{U} - \mathbf{S}) - \mathbf{Q}(\mathbf{1} - \mathbf{P}\mathbf{R}) + \mathbf{Z}_2 &= \mathbf{0}, \\ \boldsymbol{\sigma}^{\min}\mathbf{Q}\mathbf{P}\mathbf{R} - \mathbf{S} + \mathbf{Z}_3 &= \mathbf{0}, \\ \mathbf{S} - \boldsymbol{\sigma}^{\max}\mathbf{Q}\mathbf{P}\mathbf{R} + \mathbf{Z}_4 &= \mathbf{0}, \\ \mathbf{0} \le \mathbf{R} &\le \mathbf{1}, \\ \mathbf{u}^{\min} \le \mathbf{U} &\le \mathbf{u}^{\max}, \\ \mathbf{0} &\le \mathbf{Z}. \end{aligned} \tag{5.1}$$

Finally we solve a programming problem with $3N + 15M - 2N_1 - N_2$ unknowns, $2N + 12M - 2N_1 - N_2$ equality constraints, and $6N + 12M - 4N_1 - 2N_2$ bound constraints.

A similar discrete programming problem for the problem with the conservative von Mises stress constraints (3.2) can be deduced in an analogous way.

6. Numerical results. For the numerical examples we have chosen two simple examples where the global optimal designs are known on very coarse grids for maximum safety factor problems (see [30]); nevertheless, the topological structure of the final beams for the minimal mass problems are similar. Since we solve perimeter constrained optimization problems, we can expect the results to be independent of the mesh size, which was indeed supported by our numerical tests. For the sake of simplicity Young's modulus and Poisson's ratio of the given material are $E = 1N/m^2$ and $\nu = 0.3$. We used the plain strain model for the computations, and also, for simplicity, all structures have a unit thickness of $1m$ and are loaded with half of the unit load. Reasonable bounds for the displacements $\mathbf{u}$ and the stresses σ are provided by the unique solutions $\overline{\mathbf{u}}$ and $\overline{\sigma}$ of the corresponding elasticity problem when the whole design domain Ω is filled with material $\rho = 1$. Then the displacement bounds are, e.g., set to

$$u_i^{\max} = -u_i^{\min} = 2\max\{|\overline{u}_i(\mathbf{x})| \ : \ \mathbf{x} \in \Omega\}, \qquad i = 1, 2,$$

and the stress bounds to

$$\begin{aligned} \sigma_{11}^{\max} = \sigma_{22}^{\max} &= \max\{|\overline{\sigma}_{11}(\mathbf{x})|, |\overline{\sigma}_{22}(\mathbf{x})| \ : \ \mathbf{x} \in \Omega\}, \\ \sigma_{12}^{\max} = \sigma_{21}^{\max} &= \max\{|\overline{\sigma}_{12}(\mathbf{x})|, |\overline{\sigma}_{21}(\mathbf{x})| \ : \ \mathbf{x} \in \Omega\} \end{aligned}$$

with $\sigma^{\min} = -\sigma^{\max}$. The von Mises stress bound is given by

$$\Phi^{\max} = \max\{\Phi(\sigma(\mathbf{x})) \ : \ \mathbf{x} \in \Omega\}.$$

All numerical examples are performed on a PC using a 2.4 GHz Intel CPU and 2 GB memory. For the mesh generation and the finite element part of the computations the software package NETGEN/NGSolve was used. The optimization part was done using the interior-point code IPOPT. As IPOPT is used as a "black-box," we did not adjust its linear solver and its stopping criterion to our needs. So we stop the optimization process per continuation level if the stopping criterion of IPOPT is fulfilled with a tolerance of 10^{-5} or a maximum number of iterations is reached. For an approximation of the Hessian of the Lagrange functional a BFGS routine is used. In both examples the scaling parameter γ of the mass term in the objective is set to $\gamma = 2$, and we start the ϵ-continuation for $L = 5$ levels with $\epsilon^0 = 1$. Between the levels ϵ is reduced like $\epsilon^{l+1} = 0.25\epsilon^l$.

We want to point out that these numerical examples just show the potential of this solution approach. Since there has been no emphasis on efficiency so far, the computational times are far from being optimal. To decrease ϵ in a more sophisticated way (e.g., in combination with the continuation of μ, the barrier parameter of the interior-point formulation), a proper stopping criterion and a linear solver with optimal complexity for the IPOPT package would decrease the runtimes significantly. So far most of the CPU time is spent in solving linear systems in IPOPT.

6.1. A short beam example. As a first example we treat the problem shown in Figure 6.1. There the load condition, bearings, and geometry are illustrated with a design domain of dimension $2m \times 1m$. Here we consider stress constraints with

TABLE 6.1
Computational data from the short beam example.

Level	Obj. evaluations	Time (h)	Iterations	ϵ
0	629	3.48	150	1
1	1350	6.00	225	0.25
2	1208	7.26	300	0.0625
3	307	3.36	300	0.015625
4	309	3.62	300	0.003906

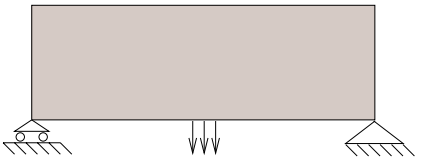

FIG. 6.2. *A long beam example.*

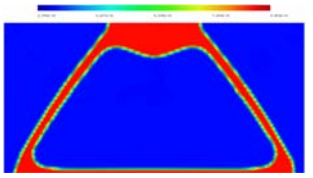

FIG. 6.3. *Optimal material distribution.*

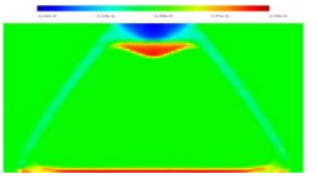

FIG. 6.4. σ_{11} *of the optimal design.*

respect to local stresses. The corresponding bound constraints are

$$\mathbf{u}^{\max} = \begin{pmatrix} 0.525 \\ 0.525 \end{pmatrix} m, \qquad \sigma^{\max} = \begin{pmatrix} \sigma_{11}^{\max} \\ \sigma_{22}^{\max} \\ \sigma_{12}^{\max} \end{pmatrix} = \begin{pmatrix} 0.65 \\ 0.65 \\ 0.262 \end{pmatrix} \frac{N}{m^2}$$

with $\mathbf{u}^{\min} = -\mathbf{u}^{\min}$ and $\sigma^{\min} = -\sigma^{\max}$. A mesh with 14182 elements is used for the optimization process, so we finally end up with 234532 unknowns. In more details we have 7260, 14182, 42546, and 170184 DOFs for the density, displacements, stresses, and slacks, respectively. The total number of equality constraints is 184725 and 191986 for the bound constraints. The overall computational time for the 5 levels is about 23.5 hours, and the volume of the final optimal design is 0.356 m^3 (17.8% of $|\Omega|$). We can see some more detailed information about the short beam computation in Table 6.1. The optimal design and the σ_{11} stress distribution we show in Figures 6.3 and 6.4.

6.2. A long beam example. For the second example we consider the load condition, bearings, and geometry shown in Figure 6.2, where the dimensions of the design domain are $3m \times 1m$. Here we choose to calculate an optimal design with respect to bounded conservative von Mises stress, and again we list the corresponding bound constraints:

$$\mathbf{u}^{\max} = \begin{pmatrix} 0.99 \\ 0.99 \end{pmatrix} m, \qquad \Phi^{\max} = 0.78 \frac{N}{m^2}$$

with $\mathbf{u}^{\min} = -\mathbf{u}^{\min}$. For the discretization and the optimization process we use a mesh with 17291 elements, which results in 355098 unknowns and 8849, 17698,

FIG. 6.7. *ϵ-continuation over 5 levels.*

51873, 51873, and 224784 DOFs for the density, displacements, stresses, conservative von Mises approximation, and slacks, respectively. Here we end up with a total number of 242503 equality constraints and 251352 bound constraints. In Figure 6.5 we see the optimal design of the problem and in Figure 6.6 the corresponding von Mises stress distribution. Moreover, we show in Figure 6.7 a sequence of optimal designs. For solving 5 levels it takes about 26.5 hours, and the volume is reduced to 1.1 m^3 (36.73% of $|\Omega|$). More details about the ϵ-continuation are given in Table 6.2.

TABLE 6.2
Computational data from the long beam example.

Level	Obj. evaluations	Time (h)	Iterations	ϵ
0	769	3.72	150	1
1	1294	6.41	225	0.25
2	1254	9.65	300	0.0625
3	302	5.23	300	0.015625
4	88	1.51	59	0.003906

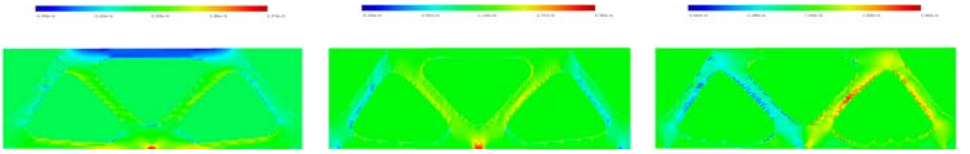

FIG. 6.9. *σ_{11}, σ_{22}, and σ_{12} distribution of the optimal design.*

Finally, in Figures 6.8 and 6.9 we show the displacement and stress distribution of the optimal design. Here we can see that the corresponding displacements and stresses are only nonzero over the parts of the domain occupied with material.

7. Conclusions. A new method for solving structural topology optimization problems with local stress constraints has been presented. The reformulation of the problem and the phase-field relaxation leads to a parameter-dependent family of large-scale optimization problems satisfying uniform constraint qualifications. Using parameter continuation it is possible to compute optima in a robust way with reasonable effort (e.g., compared to mixed linear programming techniques).

So far no particular emphasis has been laid on the efficient solution of the discretized problems for very large number of unknowns (as appearing, e.g., in three-dimensional applications), but there is a lot of potential to speed up the solution techniques, which will be investigated in future research.

Acknowledgments. Useful and stimulating discussions as well as various links to literature are acknowledged to Wolfram Mühlhuber (Audi AG, Ingolstadt), Benjamin Hackl (RICAM, Linz), Karl Kunisch (University Graz and RICAM, Linz), Martin Bendsøe (Danish Technical University, Lyngby), Blaise Bourdin (Louisiana State University, Baton Rouge), and Don Goldfarb (Columbia University, New York). The interior-point code IPOPT (see http://www.coin-or.org/Ipopt/) was used with permission from Andreas Wächter, whom we also thank for kind support. Mesh generation and finite element tools were used from the software package NETGEN/NGSolve developed by Joachim Schöberl at the University of Linz (see http://www.hpfem.jku.at).

STABILITY AND STABILIZATION OF MULTIDIMENSIONAL INPUT/OUTPUT SYSTEMS*

ULRICH OBERST†

Abstract. In this paper we discuss stability and stabilization of continuous and discrete multidimensional input/output (IO) behaviors (of dimension r) which are described by linear systems of complex partial differential (resp., difference) equations with constant coefficients, where the signals are taken from various function spaces, in particular from those of polynomial-exponential functions. Stability is defined with respect to a disjoint decomposition of the r-dimensional complex space into a stable and an unstable region, with the standard stable region in the one-dimensional continuous case being the set of complex numbers with negative real part. A rational function is called stable if it has no poles in the unstable region. An IO behavior is called stable if the characteristic variety of its autonomous part has no points in the unstable region. This is equivalent to the stability of its transfer matrix and an additional condition. The system is called stabilizable if there is a compensator IO system such that the output feedback system is well-posed and stable. We characterize stability and stabilizability and construct all stabilizing compensators of a stabilizable IO system (parametrization). The theorems and proofs are new but essentially inspired and influenced by and related to the stabilization theorems concerning multidimensional IO maps as developed, for instance, by Bose, Guiver, Shankar, Sule, Xu, Lin, Ying, Zerz, and Quadrat and, of course, the seminal papers of Vidyasagar, Youla, and others in the one-dimensional case. In contrast to the existing literature, the theorems and proofs of this paper do not need or employ the so-called fractional representation approach, i.e., various matrix fraction descriptions of the transfer matrix, thus avoiding the often lengthy matrix computations and seeming to be of interest even for one-dimensional systems (at least to the author). An important mathematical tool, new in systems theory, is Gabriel's localization theory which, only in the case of ideal-convex (Shankar, Sule) unstable regions, coincides with the usual one. Algorithmic tests for stability, stabilizability, and ideal-convexity, and the algorithmic construction of stabilizing compensators, are addressed but still encounter many difficulties; see in particular the open problems listed by Xu et al.

Key words. stability, stabilization, multidimensional system, behavior, stable transfer matrix

1. Introduction.

Stabilization theory is a part of control theory and usually involves the following ingredients [7, p. 60].

1. *Stability*: Select the class of admissible systems and define and characterize the stable systems in this class.
2. *Stabilizability*: Determine which admissible systems can be stabilized by output feedback.
3. *Stabilization*: Construct a stabilizing compensator for a given stabilizable system.
4. *Parametrization*: Classify or construct all stabilizing compensators for a given stabilizable system.

In this paper we discuss these problems for continuous and discrete multidimensional input/output (IO) behaviors, which are described by linear systems of complex partial differential equations on $\mathbb{R}^r$ (resp., difference equations on $\mathbb{N}^r$) with constant

coefficients, where the signals are taken from various function spaces—in particular from those of polynomial-exponential functions. Polderman and Willems in [15, sec. 10.8] and Rocha [19] suggest renouncing the IO structure and output feedback in favor of more general behavior interconnections. The first stabilization results for multidimensional systems in this generality are due to Shankar [21], [22].

In contrast to our approach, most multidimensional stabilization papers use a commutative integral domain S of "SISO-stable plants" and describe the admissible systems, often called plants, by a transfer operator or IO map, which is a matrix with coefficients in the quotient field of S; cf., for instance, [26], [6], [23], [25], [31], [32], [7], [8], [16], [17], [18]. This approach to stabilization theory is originally due to Desoer, Kucera, Vidyasagar, Youla, and their coworkers. These systems are called structurally [6] or internally [17] stable if their transfer matrix has entries in S. In their recent paper [29], Wood, Sule, and Rogers treat stability and causality, but not stabilization of continuous multidimensional IO systems.

An IO behavior $\mathcal{B}$ gives rise to its autonomous part $\mathcal{B}^0$, its transfer matrix H, and the largest controllable subbehavior $\mathcal{B}_{\text{cont}}$ which, in turn, has the autonomous part $\mathcal{B}^0_{\text{cont}}$. The entries of the transfer matrix are complex rational functions in r indeterminates s_ρ, i.e., contained in the quotient field $\mathbb{C}(s)$ of the polynomial algebra $A := \mathbb{C}[s] = \mathbb{C}[s_1, \ldots, s_r]$. In general, the transfer matrix does not act on arbitrary inputs as an operator or IO map, and it is an important task to identify those inputs on which it does. Associated with these behaviors is the complex variety $\text{sing}(\mathcal{B})$ of rank singularities and the characteristic varieties $\text{char}(\mathcal{B}^0) \supseteq \text{char}(\mathcal{B}^0_{\text{cont}})$ of the autonomous subbehaviors, the latter coinciding with the variety of poles of H. In the one-dimensional theory, the elements of $\text{char}(\mathcal{B}^0)$ are called the poles, modes, characteristic values, or natural frequencies of the system.

Stability and stabilization of an IO system are defined with respect to a disjoint decomposition $\mathbb{C}^r = \Lambda_1 \uplus \Lambda_2$ of the complex space into a stable region Λ_1 and an unstable region Λ_2, with the standard continuous (resp., discrete) cases being

$$\begin{aligned} &\Lambda_2 = \overline{\mathbb{C}_+}^r,\ \overline{\mathbb{C}_+} := \{z \in \mathbb{C};\ \Re(z) \geq 0\} \text{ or } \Lambda_2 = \overline{\mathbb{C}_+} \times i\mathbb{R}^{r-1}\ ([29]), \\ &\text{resp.,}\ \Lambda_2 = \{z \in \mathbb{C};\ |z| \geq 1\}^r \text{ or } \Lambda_2 = \{z \in \mathbb{C};\ |z| \geq 1\} \times (S^1)^{r-1}. \end{aligned} \tag{1}$$

A rational function is called stable if it has no poles in the unstable region. The ring of all stable rational functions or SISO-stable plants is the quotient ring $A_T \subseteq \mathbb{C}(s)$ with $T := \{t \in A;\ \forall \lambda \in \Lambda_2 : t(\lambda) \neq 0\}$ [25]. The discrete IO maps in the literature are usually assumed to be causal or proper and are considered rational functions in the indeterminates s_ρ^{-1}; then the set Λ_2 from (1) is replaced with the closed unit polydisc [6], [7]. Properness is not assumed in the present paper because it is rather restrictive for partial differential equations, but properness and the ensuing BIBO stability will be discussed in the paper [20].

An IO system $\mathcal{B}$ is called stable if the characteristic variety of its autonomous part is contained in the stable region or, equivalently, if all polynomial-exponential trajectories in $\mathcal{B}^0$ are stable, i.e., involve exponents in the stable region only. In [29] this is called a characteristic variety (CV) condition and used to define stable *autonomous* systems. Stability of $\mathcal{B}$ in this sense is equivalent to the stability of the transfer matrix and an additional condition (see Theorem/Definition 5.1 and Remark 5.2). In particular, a one-dimensional IO system is stable if and only if its autonomous part is asymptotically stable or, equivalently, if its transfer matrix is stable and its singular variety is contained in the stable region. One of the reviewers points out that these two equivalent descriptions of the stability of one-dimensional IO systems should be

called time domain (resp., frequency domain) stability. Multidimensional stable IO systems are externally or IO stable in the sense that the transfer matrix acts as an operator on interesting classes of inputs and generates outputs of the same type as shown in Theorem/Definition 5.3 and Theorem 5.4; the latter applies results on partial differential equations from [4] as do Theorems 6.4 and 7.2 in [29] which, however, hold in special cases only. Theorem 7.6.2 of [15, p. 265], for instance, treats the connection between asymptotic stability and bounded input/bounded output (BIBO) stability of one-dimensional IO systems as done already by Kalman in his fundamental work. The paper [29] contains the interesting idea that stable systems should generate stable outputs from stable inputs *and initial conditions*, with a necessary requirement that the initial value problem be defined and uniquely solvable. For discrete multidimensional systems this is the case for which we give a partial answer and pose Open Problem 5.13, whose study is also worthwhile for continuous systems and certain function spaces.

An IO system $\mathcal{B}$ is called stabilizable if there is an IO system $\mathcal{B}'$ such that the feedback system (in (20), (21)) of $\mathcal{B}$ and $\mathcal{B}'$ is well-posed [26] and stable; then $\mathcal{B}'$ is called a stabilizing compensator. In Theorems 4.4 and 5.8 we characterize stabilizability of $\mathcal{B}$ and construct one stabilizing compensator, whereas Theorems 2.14 and 4.6 describe the parametrization or construction of all stabilizing compensators of a stabilizable IO behavior. The famous prototype of such a parametrization is that of Kucera, Youla, Bongiorno, and Jabr and is detailed by Vidyasagar in [26, Chap. 5]. The theorems on the stabilization of general multidimensional IO systems and their proofs are new but essentially influenced and inspired by and related to the results on the stabilization of IO maps in the references given above.

The proofs employ localization, after the work of Gabriel, as a new mathematical tool in systems theory which is described in Stenström's book [24] and in section 3 of this paper. At no time do the results and proofs need or employ the so-called fractional representation approach (i.e., matrix fraction descriptions of the transfer matrix of various kinds and the, sometimes long [26], [17], [18], ensuing matrix computations); thus they seem simpler and of interest even in the one-dimensional case (at least to the author). The localization technique also avoids the difficulties in [29] with the lack of ideal-convexity [23] of the unstable regions Λ_2. Such a region is called ideal-convex if

$$V(\mathfrak{a}) \cap \Lambda_2 = \emptyset \;\Rightarrow\; \mathfrak{a} \cap T \neq \emptyset \;\forall \text{ ideals } \mathfrak{a} \subset \mathbb{C}[s], \text{ where} \qquad V(\mathfrak{a}) := \{\lambda \in \mathbb{C}^r;\; \forall t \in \mathfrak{a} :\; t(\lambda) = 0\} \tag{2}$$

denotes the algebraic variety of $\mathfrak{a}$. Ideal-convexity is characterized by the coincidence of Gabriel localization with the standard localization functor $M \mapsto M_T$ on A-modules M (see Theorem/Definition 5.6).

Algorithmic problems are addressed in Remark/Open Problem 5.10. The algorithmic test of stability, stabilizability, and ideal-convexity and the algorithmic construction of one or all stabilizing compensators still encounter many difficulties; see in particular the open problems in [7] and [30] which, however, address these difficulties only for the closed unit polydisc of arbitrary dimension as region of instability. Solutions for the closed unit polydisc are known in interesting special cases [6], [7], [8].

Sections 2, 3, and 4 of this paper consider abstract IO systems whose signal spaces are injective cogenerators over a factorial Noetherian integral domain as in [11, Chap. 7] and use, in particular, Matlis' theory of injective modules over Noetherian

rings as in [12]. This generality makes the proofs more transparent and may possibly be used for other types of systems too. As preparation for the stable and stabilizable systems in section 4, section 2 discusses trivial and trivializable systems and the construction of all trivializing compensators. An IO behavior is called trivial if its autonomous part is zero or, equivalently by Theorem/Definition 2.5, if it is controllable and its transfer matrix is polynomial. In section 5 the results of sections 2, 3, and 4 are specialized to multidimensional systems proper as described above.

Due to the large number of papers on stabilization theory, we list only those references which are actually used. But the author is fully conscious of many other important contributions and contributors, such as, for instance, Bisiacco, Fornasini, Marchesini, and Valcher of the Padovian school.

2. Triviality and trivialization by feedback. Let A denote a commutative Noetherian integral domain with its quotient field $K = \mathrm{quot}(A)$, and let $\mathcal{F}$ denote an injective cogenerator which is used as a signal space with its scalar multiplication $\circ$. In this section we consider $\mathcal{F}$-systems or $\mathcal{F}$-behaviors as introduced and studied in [11], in particular [11, Chap. 7, p. 139]. Refer to the first pages of [28] or to [27] for a newer, more elegant introduction to multidimensional behavioral systems theory. It was shown that many cases of interest for systems theory can be developed in this abstract setting. For instance, the continuous case of systems governed by linear systems of partial differential equations with constant coefficients uses the data

$$\begin{gathered} A := \mathbb{C}[s] = \mathbb{C}[s_1, \dots, s_r],\ \mathcal{F} \ni y = y(z),\ s_\rho \circ y = \partial y / \partial z_\rho, \\ z := (z_1, \dots, z_r) \in \mathbb{R}^r,\ \lambda = (\lambda_1, \dots, \lambda_r) \in \mathbb{C}^r,\ \lambda \bullet z := \lambda_1 z_1 + \cdots + \lambda_r z_r, \\ \mathcal{F} := C^\infty(\mathbb{R}^r, \mathbb{C}) \text{ or } \mathcal{F} := \mathcal{D}'(\mathbb{R}^r) \text{ or} \\ \mathcal{F} := C^\infty(\mathbb{R}^r, \mathbb{C})_{\mathrm{lf}} := \{y \in C^\infty(\mathbb{R}^r, \mathbb{C});\ [\mathbb{C}[s] \circ y : \mathbb{C}] < \infty\} \\ = \mathcal{D}'(\mathbb{R}^r)_{\mathrm{lf}} = \oplus_{\lambda \in \mathbb{C}^r} \mathbb{C}[z] \exp(\lambda \bullet z), \end{gathered} \tag{3}$$

whereas multidimensional discrete or r-dimensional systems theory applies the polynomial algebra A as in (3) and the signal space

$$\begin{gathered} \mathcal{F} := \mathbb{C}^{\mathbb{N}^r} = \mathbb{C}[[z]] = \mathbb{C}[[z_1, \dots, z_r]] \ni y = (y_\mu)_{\mu \in \mathbb{N}^r} = \sum_{\mu \in \mathbb{N}^r} y_\mu z^\mu \\ \text{with } (s^\nu \circ y)_\mu := y_{\mu+\nu},\ \mu, \nu \in \mathbb{N}^r. \end{gathered} \tag{4}$$

The corresponding objects over the real field $\mathbb{R}$ instead of the complex field $\mathbb{C}$ are likewise admissible. Recall that an A-module $\mathcal{F}$ is an injective cogenerator if the contravariant *duality functor*,

$$D := \mathrm{Hom}_A(-, \mathcal{F}) : (\mathrm{Mod}_A)^{op} \to \mathrm{Mod}_A,\ M \mapsto \mathrm{Hom}_A(M, \mathcal{F}), \tag{5}$$

preserves and reflects exact sequences, where Mod_A is the category of A-modules. In [11] we used a *large* injective cogenerator $\mathcal{F}$, but this is unnecessary, as was observed in [12]. The column vectors in $\mathcal{F}^l$ are suggestively called *trajectories* also in the abstract module situation.

A matrix $R \in A^{k \times l}$ gives rise to the row submodule

$$U := A^{1 \times k} R = \sum_{i=1}^{k} A R_{i-} \subset F := A^{1 \times l}, \tag{6}$$

the factor module

$$M := A^{1\times l}/U = \sum_{j=1}^{l} A\overline{\delta_j},\ \delta_j := (0,\dots,0,\overset{j}{1},0,\dots,0) \in A^{1\times l},$$

and the behavior

$$\begin{aligned}\mathcal{B} &:= U^{\perp}\\ &:= \{w=(w_j)_{j=1,\dots,l}\in\mathcal{F}^l;\ \forall f=(f_1,\dots,f_l)\in U : f\circ w = f_1\circ w_1+\cdots+f_l\circ w_l = 0\}\\ &= \{w=(w_j)_{j=1,\dots,l}\in\mathcal{F}^l;\ R\circ w = 0\} \underset{\text{ident.}}{=} \operatorname{Hom}_A(M,\mathcal{F}),\ w=(\overline{\delta_j}\mapsto w_j).\end{aligned}$$

Since A is Noetherian, every submodule $U\subset A^{1\times l}$ arises in this fashion. Like $U^{\perp}$ we define, for every submodule $\mathcal{B}$ of $\mathcal{F}^l$, the orthogonal submodule

$$\mathcal{B}^{\perp} := \{f=(f_1,\dots,f_l)\in A^{1\times l};\ \forall w\in\mathcal{B}:\ f\circ w = 0\}\subset A^{1\times l} \tag{7}$$

of all linear equations which are satisfied by all trajectories in $\mathcal{B}$. If $\mathcal{B}:=U^{\perp}$ is a behavior, the relation $\mathcal{B}^{\perp\perp}=U^{\perp\perp\perp}=U^{\perp}=\mathcal{B}$ holds since $(-)^{\perp}$ is a Galois correspondence, whereas the identity $U=\mathcal{B}^{\perp}=U^{\perp\perp}$ is a consequence of the cogenerator property of $\mathcal{F}$ [11, Cor. 2.47].

The matrix R with M and $\mathcal{B}$ as in (6) also gives rise to its *transfer space* (= *signal flow space* in [11, Thm./Def. 2.91])

$$\widetilde{\mathcal{B}} := \{\widetilde{w}\in K^l;\ R\widetilde{w}=0\} \underset{\text{ident.}}{=} \operatorname{Hom}_A(M,K) \underset{\text{ident.}}{=} \operatorname{Hom}_K(K\otimes_A M,K)\subset K^l \tag{8}$$

and, more precisely, to the contravariant exact functor $\operatorname{Hom}_A(-,K)$ on finitely generated A-modules or to the covariant exact functor $\mathcal{B}\mapsto\widetilde{\mathcal{B}}$ on behaviors. Standard linear algebra over the field K can be applied to the K-space $\widetilde{\mathcal{B}}$. In particular, it determines the number

$$\operatorname{rank}(\mathcal{B}) := \operatorname{rank}(M) := [K\otimes_A M : K] = [\widetilde{\mathcal{B}} : K] = l - \operatorname{rank}(R), \tag{9}$$

where $[F:A]$ denotes the dimension of a *free* A-module F.

Let $w=\binom{y}{u}\in\mathcal{F}^{p+m}$, $l=p+m$, be a decomposition of the trajectories w into two components y and u, possibly after a permutation of the components w_j of w, and let $R=(P,-Q)\in A^{k\times(p+m)}$ be the corresponding decomposition of the matrix R such that $\mathcal{B}:=\{w=\binom{y}{u}\in\mathcal{F}^{p+m};\ P\circ y = Q\circ u\}$. The matrix P gives rise to the module $M^0:=A^{1\times p}/A^{1\times k}P$ and the behavior $\mathcal{B}^0:=\{y\in\mathcal{F}^p;\ P\circ y=0\}$.

Result 2.1 (IO structure and transfer matrix; see [11, Thms. 2.69, 2.94]). *The following assertions are equivalent:*

1. $\operatorname{rank}(P)=\operatorname{rank}(R)=p$.
2. *The projection*

$$\operatorname{proj} := (0\,\mathrm{id}_m)\circ : \widetilde{\mathcal{B}} = \left\{\widetilde{w}=\begin{pmatrix}\widetilde{y}\\ \widetilde{u}\end{pmatrix}\in K^{p+m};\ P\widetilde{y}=Q\widetilde{u}\right\}\to K^m,\ \begin{pmatrix}\widetilde{y}\\ \widetilde{u}\end{pmatrix}\mapsto\widetilde{u}, \tag{10}$$

is a K-isomorphism, i.e., for each $\widetilde{u}\in K^m$ the equation $P\widetilde{y}=Q\widetilde{u}$ is uniquely solvable for $\widetilde{y}\in K^p$.

3. *The A-module sequence*

$$\begin{array}{ccccccccc} 0 & \longrightarrow & A^{1\times m} & \overset{\text{inj}:=\circ(0\,\mathrm{id}_m)}{\longrightarrow} & M & \overset{\text{proj}:=\circ\binom{\mathrm{id}_p}{0}}{\longrightarrow} & M^0 & \longrightarrow & 0,\\ & & \eta & \mapsto & \overline{(0,\eta)},\ \overline{(\xi,\eta)} & \mapsto & \overline{\xi} & & \end{array} \tag{11}$$

is exact, and the module M^0 *is a torsion module or* $\operatorname{rank}(M^0) = 0$.

4. *The dual sequence of behaviors*

$$\begin{array}{ccccccccc} 0 & \longrightarrow & \mathcal{B}^0 & \xrightarrow{\binom{\mathrm{id}_p}{0}\circ} & \mathcal{B} & \xrightarrow{\mathrm{proj}:=(0\,\mathrm{id}_m)\circ} & \mathcal{F}^m & \longrightarrow 0, \\ & & y & \mapsto & \binom{y}{0},\ \binom{y}{u} & \mapsto & u & \end{array} \tag{12}$$

is exact, and the behavior $\mathcal{B}^0$ *is autonomous or* $\operatorname{rank}(\mathcal{B}^0) = 0$.

If these equivalent conditions are satisfied, the behavior is called an IO behavior *with the* IO structure $\binom{y}{u}$, *the* input u, *and the* output y. *The rank of* $\mathcal{B}$ *is* m. *There is a unique matrix* $H \in K^{p\times m}$, *the* transfer matrix *of* $\mathcal{B}$, *such that* $PH = Q$. *The inverse of the isomorphism* (10) *has the graph form* $\widetilde{u} \mapsto \binom{H\widetilde{u}}{\widetilde{u}}$, *and for every input* $u \in \mathcal{F}^m$ *there is a trajectory* $\binom{y}{u} \in \mathcal{B}$.

If $\mathcal{B}$ is an IO behavior as in the preceding result, the A-sequence

$$A^{1\times k} \xrightarrow{\circ(P,-Q)} A^{1\times(p+m)} \xrightarrow{\circ\binom{H}{\mathrm{id}_m}} K^{1\times m} \tag{13}$$

is a complex, i.e., $(P,-Q)\binom{H}{id_m} = PH - Q = 0$, and induces an A-epimorphism

$$\begin{gathered} M = A^{1\times(p+m)}/A^{1\times k}(P,-Q) \xrightarrow{\binom{H}{\mathrm{id}_m}} \mathcal{M} := \operatorname{im}\left(\circ\begin{pmatrix} H \\ \mathrm{id}_m \end{pmatrix}\right) = A^{1\times p}H + A^{1\times m}, \\ \overline{(\xi,\eta)} \mapsto \xi H + \eta. \end{gathered} \tag{14}$$

The A-submodule $\mathcal{M}$ of $K^{1\times m}$ is a lattice. Lattices play a decisive part in Quadrat's treatment of stabilization [17, Eq. (38) and Thm. 3], [18] (see also Quadrat's earlier papers quoted there).

Theorem and Definition 2.2 (controllable behaviors and realization). *The module* M *is torsion free if and only if the sequence* (13) *is exact or*

$$\mathcal{B}^\perp = A^{1\times k}(P,-Q) = \{(\xi,\eta) \in A^{1\times(p+m)};\ \xi H + \eta = 0\}. \tag{15}$$

If this is the case, the behavior $\mathcal{B}$ *is called* controllable *and is indeed the* unique controllable *IO behavior with transfer matrix* H *or, in other words, the unique controllable realization of* H, *and moreover,*

$$A^{1\times k}P = \{\xi \in A^{1\times p};\ \xi H \in A^{1\times m}\}. \tag{16}$$

Remark 2.3. As shown by Willems and Rocha for discrete two-dimensional systems and by Pillai and Shankar [14] for continuous multidimensional ones, the term *controllable* is justified by the concatenability of trajectories in controllable systems. A module is torsion free if and only if it can be embedded into a free module and hence, by duality, the system $\mathcal{B}$ is controllable if and only if there is a system epimorphism $\phi : \mathcal{F}^m \to \mathcal{B}$, which Pommaret (resp., Willems) calls a *parametrization* (resp., an *image representation*) of $\mathcal{B}$. The first reviewer suggests calling a controllable system $\mathcal{B}$ torsion free or, more generally, to systematically use the attribute of the system module M also for the system itself. We will stick to the term *controllable* since it is used by most researchers. If d is a common denominator of the entries of H, i.e., if $0 \neq d \in A$ and $dH \in A^{p\times m}$, the multiplication with d is an isomorphism on K, and therefore (15) can also be expressed as

$$A^{1\times k}(P,-Q) = \ker\left(A^{1\times(p+m)} \xrightarrow{\circ\binom{dH}{d\,\mathrm{id}_m}} A^{1\times m}\right).$$

Proof. The theorem is a reformulation of [11, Thm. 7.24]. We give a slightly simpler and more direct proof. If (13) is exact, then (14) is an isomorphism, and hence M is torsion free. If, conversely, M is torsion free, we obtain the *monomorphisms*

(17)
$$\begin{array}{ccccc} M = A^{1\times(p+m)}/A^{1\times k}R & \to & K\otimes_A M = K^{1\times(p+m)}/K^{1\times k}R & \overset{\circ\binom{H}{\mathrm{id}_m}}{\cong} & K^{1\times m}, \\ \overline{(\xi,\eta)} & \mapsto & 1\otimes\overline{(\xi,\eta)} = \overline{(\xi,\eta)} & \mapsto & \xi H+\eta, \end{array}$$

which imply $A^{1\times k}R = \{(\xi,\eta)\in A^{1\times(p+m)};\ \xi H+\eta=0\}$ and the exactness of (13). The first map in (17) is a monomorphism since its kernel is the torsion submodule of M and thus zero. The second isomorphism follows from

$$(P,-Q) = P(\mathrm{id}_p,-H) \text{ and } \mathrm{rank}(P)=p;\ \text{hence } K^{1\times k}(P,-Q) = K^{1\times p}(\mathrm{id}_p,-H),$$

and the exactness of

$$0 \longrightarrow K^{1\times p} \overset{\circ(\mathrm{id}_p,-H)}{\longrightarrow} K^{1\times(p+m)} \overset{\circ\binom{H}{\mathrm{id}_m}}{\longrightarrow} K^{1\times m} \longrightarrow 0$$
$$\text{or } K^{1\times(p+m)}/K^{1\times p}(\mathrm{id}_p,-H) \overset{\circ\binom{H}{\mathrm{id}_m}}{\cong} K^{1\times m}.$$

Concerning equality (16), the identity $PH=Q\in A^{k\times m}$ implies

$$A^{1\times k}P \subseteq \{\xi\in A^{1\times p};\ \xi H\in A^{1\times m}\}.$$

If, conversely, $\eta := -\xi H\in A^{1\times m}$ and thus $\xi H+\eta=0$, the monomorphism (17) implies $(\xi,-\eta)=\zeta(P,-Q)$ for some $\zeta\in A^{1\times k}$ and hence $\xi=\zeta P\in A^{1\times k}P$. ∎

Definition 2.4. *A behavior $\mathcal{B}$ is called* free *(resp.,* projective*) if its module M has this property, and is then controllable. Free behaviors were characterized in* [11, Thm. 7.53] *and were called* strongly *controllable by Rocha in her thesis.*

With these preparations we can now draw the following simple conclusion which, however, is basic for the present paper.

Theorem and Definition 2.5 (trivial IO behaviors). *For an IO behavior $\mathcal{B}$ as in Result* 2.1*, the following conditions are equivalent:*

1. *The autonomous behavior $\mathcal{B}^0$ is zero or $M^0=0$ or $A^{1\times k}P=A^{1\times p}$; i.e., the rows of P generate the full free module $A^{1\times p}$.*
2. *The behavior $\mathcal{B}$ is controllable and $H\in A^{p\times m}$.*

If these equivalent conditions are satisfied, the IO behavior $\mathcal{B}$ is called trivial *and the linear maps*

$$(18)\quad \circ(0\,\mathrm{id}_m) : A^{1\times m}\cong M,\ \eta\mapsto\overline{(0,\eta)},\ \textit{and}\ \ \mathrm{proj} := (0\,\mathrm{id}_m)\circ : \mathcal{B}\cong\mathcal{F}^m,\ \begin{pmatrix} y\\ u\end{pmatrix}\mapsto u,$$

are isomorphisms; in particular M and $\mathcal{B}$ are free. In accordance with the literature, we reserve the term stable *to a more general situation in sections* 4 *and* 5*.*

Proof. $\Rightarrow$: The exact sequences (11) and (12) and $M^0=0$ imply the isomorphisms (18) and hence the freeness and controllability of $\mathcal{B}$. The equality

$$A^{1\times p} = A^{1\times k}P = \{\xi\in A^{1\times p};\ \xi H\in A^{1\times m}\} \text{ implies } A^{1\times p}H\subseteq A^{1\times m};$$

hence $H\in A^{p\times m}$.

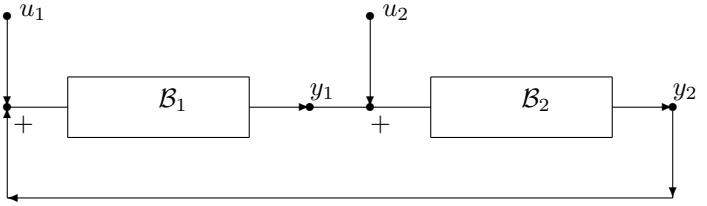

FIG. 2.1.

$\Leftarrow$: The controllability of $\mathcal{B}$ implies equality (16) and then, with $H \in A^{p\times m}$, also $A^{1\times p} = A^{1\times k}P$. ∎

In what follows we consider a feedback system given by the following block diagram [11, Chap. 8] as in Figure 2.1.

The two IO subbehaviors $\mathcal{B}_i$, $i = 1, 2$, of $\mathcal{F}^{p+m}$ are given as

$$\begin{aligned}\mathcal{B}_1 &:= \left\{ \begin{pmatrix} y_1 \\ u_1 \end{pmatrix} \in \mathcal{F}^{p+m};\ P_1 \circ y_1 = Q_1 \circ u_1 \right\},\ P_1H_1 = Q_1,\ P_1 \in A^{k_1\times p},\\ \mathcal{B}_2 &:= \left\{ \begin{pmatrix} u_2 \\ y_2 \end{pmatrix} \in \mathcal{F}^{p+m};\ P_2 \circ y_2 = Q_2 \circ u_2 \right\},\ P_2H_2 = Q_2,\ P_2 \in A^{k_2\times m}.\end{aligned} \tag{19}$$

Let $l := p + m$. The feedback behavior $\mathcal{B} := \text{feedback}(\mathcal{B}_1, \mathcal{B}_2)$ is the behavior

$$\mathcal{B} := \left\{ \begin{pmatrix} y \\ u \end{pmatrix} \in \mathcal{F}^{2l};\ y = \begin{pmatrix} y_1 \\ y_2 \end{pmatrix}, u = \begin{pmatrix} u_2 \\ u_1 \end{pmatrix} \in \mathcal{F}^{p+m} \text{ satisfy (21)} \right\} \tag{20}$$

with

$$P_1 \circ y_1 = Q_1 \circ (u_1 + y_2),\ P_2 \circ y_2 = Q_2 \circ (u_2 + y_1). \tag{21}$$

LEMMA 2.6. *The map*

$$\mathcal{B} = \text{feedback}(\mathcal{B}_1, \mathcal{B}_2) \to \mathcal{B}_1 \times \mathcal{B}_2,\ \begin{pmatrix} y \\ u \end{pmatrix} \mapsto \left(\begin{pmatrix} y_1 \\ u_1 + y_2 \end{pmatrix}, \begin{pmatrix} y_2 \\ u_2 + y_1 \end{pmatrix} \right)$$

is a behavior isomorphism with the inverse map $\left(\binom{y_1}{u_1}, \binom{u_2}{y_2}\right) \mapsto \binom{y}{v}$, *with* $v_1 := u_1 - y_2$ *and* $v_2 := u_2 - y_1$. *In particular,* $\mathcal{B}$ *is controllable (resp., projective) if and only if both* $\mathcal{B}_i$ *have these properties. If* $\mathcal{B}$ *is trivial, then both* $\mathcal{B}_i$ *are projective.*

Proof. It is obvious that the indicated map is indeed the inverse map. Recall that a trivial behavior is free and that projective modules are precisely the direct summands of free ones. ∎

From Result 2.1 we know that the transfer space of $\mathcal{B}_1$ is

$$\widetilde{\mathcal{B}_1} = \left\{ \begin{pmatrix} \widetilde{y_1} \\ \widetilde{u_1} \end{pmatrix} \in K^{p+m};\ \widetilde{y_1} = H_1\widetilde{u_1} \right\}$$

and likewise for $\mathcal{B}_2$. Therefore, the equations of the transfer space of $\mathcal{B}$ according to (8) are

$$\begin{aligned}&\widetilde{y_1} = H_1(\widetilde{u_1} + \widetilde{y_2}),\ \widetilde{y_2} = H_2(\widetilde{u_2} + \widetilde{y_1})\\ \Leftrightarrow\ &(\text{id}_p - H_1H_2)\widetilde{y_1} = H_1\widetilde{u_1} + H_1H_2\widetilde{u_2},\ \widetilde{y_2} = H_2(\widetilde{u_2} + \widetilde{y_1}).\end{aligned} \tag{22}$$

THEOREM 2.7. *The feedback behavior* $\mathcal{B} = \mathrm{feedback}(\mathcal{B}_1, \mathcal{B}_2)$ *is an IO behavior with input* $u = \binom{u_2}{u_1} \in \mathcal{F}^{p+m}$ *if and only if one or, equivalently, all of the matrices*

$$\mathrm{id}_p - H_1 H_2,\ \mathrm{id}_m - H_2 H_1,\ \begin{pmatrix} \mathrm{id}_p & -H_1 \\ -H_2 & \mathrm{id}_m \end{pmatrix}$$

are invertible, i.e., contained in $\mathrm{Gl}_\bullet(K)$. *If this is the case, the autonomous part* $\mathcal{B}^0$ *and the transfer matrix of* $\mathcal{B}$ *are given as*

$$\mathcal{B}^0 = \left\{ y = \begin{pmatrix} y_1 \\ y_2 \end{pmatrix} \in \mathcal{F}^{p+m};\ \begin{pmatrix} P_1 & -Q_1 \\ -Q_2 & P_2 \end{pmatrix} \circ y = 0 \right\} = \mathcal{B}_1 \cap \mathcal{B}_2,$$
$$H := \begin{pmatrix} \mathrm{id}_p & -H_1 \\ -H_2 & \mathrm{id}_m \end{pmatrix}^{-1} \begin{pmatrix} 0 & H_1 \\ H_2 & 0 \end{pmatrix}.$$

Moreover,

$$\mathcal{B}_1^\perp \oplus \mathcal{B}_2^\perp = (\mathcal{B}^0)^\perp.$$

Vidyasagar then calls the feedback system well-posed [26, *p.* 100]. *Rocha calls* $\mathcal{B}^0$ *a regular interconnection of* $\mathcal{B}_1$ *and* $\mathcal{B}_2$ [19, *Def.* 1]. *Direct sum decompositions and regular interconnections of systems have also been treated in* [1] *and* [33] *and in papers on the stabilization of IO maps; see, for instance,* [17], [18].

Proof. It is obvious that (22) are uniquely solvable for $\binom{\widetilde{y_1}}{\widetilde{y_2}} \in K^{p+m}$ for given $\binom{\widetilde{u_2}}{\widetilde{u_1}} \in K^{p+m}$ if and only if $\mathrm{id}_p - H_1 H_2 \in \mathrm{Gl}_p(K)$. The assertion then follows from Result 2.1. The simultaneous invertibility of these matrices is standard and follows trivially by elementary row and column operations. According to Result 2.1, the equations of $\mathcal{B}^0$ follow from (21) of $\mathcal{B}$ by setting the input $u = \binom{u_2}{u_1}$ to zero. The expression for H is implied by the equations

$$\begin{pmatrix} P_1 & -Q_1 \\ -Q_2 & P_2 \end{pmatrix} H = \begin{pmatrix} P_1 & 0 \\ 0 & P_2 \end{pmatrix} \begin{pmatrix} \mathrm{id}_p & -H_1 \\ -H_2 & \mathrm{id}_m \end{pmatrix} H$$
$$= \begin{pmatrix} 0 & Q_1 \\ Q_2 & 0 \end{pmatrix} = \begin{pmatrix} P_1 & 0 \\ 0 & P_2 \end{pmatrix} \begin{pmatrix} 0 & H_1 \\ H_2 & 0 \end{pmatrix}$$

by cancelling the matrix $\binom{P_1 \quad 0}{0 \quad P_2}$ of rank $l = p + m$ on the left.

The sum $(\mathcal{B}^0)^\perp = \mathcal{B}_1^\perp + \mathcal{B}_2^\perp$ follows from $\mathcal{B}^0 = \mathcal{B}_1 \cap \mathcal{B}_2$ by duality. Moreover,

$$\mathrm{rank}((\mathcal{B}^0)^\perp) = p + m = \mathrm{rank}(\mathcal{B}_1^\perp) + \mathrm{rank}(\mathcal{B}_2^\perp) \text{ implies } \mathcal{B}_1^\perp \cap \mathcal{B}_2^\perp = 0;$$
$$\text{hence } (\mathcal{B}^0)^\perp = \mathcal{B}_1^\perp \oplus \mathcal{B}_2^\perp. \qquad \square$$

Remark 2.8. If the feedback behavior of the preceding theorem is well-posed, the matrices

$$G := \begin{pmatrix} 0 & H_1 \\ H_2 & 0 \end{pmatrix} \text{ and } (\mathrm{id} - G)^{-1}(\mathrm{id} - G) = \mathrm{id} \text{ in } K^{(p+m)\times(p+m)} \tag{23}$$

imply

$$H = (\mathrm{id} - G)^{-1} G \text{ and } (\mathrm{id} - G)^{-1} = \mathrm{id} + H,$$

and hence that $(\mathrm{id} - G)^{-1}$ and H share many properties, in particular that H belongs to $A^{(p+m)\times(p+m)}$ if and only if $(\mathrm{id} - G)^{-1}$ does [26, Chap. 5, Lem. 9].

COROLLARY AND DEFINITION 2.9. *If the feedback behavior of the preceding theorem is well-posed, then $\mathcal{B}$ is trivial, i.e., $\mathcal{B}^0 = 0$, if and only if*

$$\mathcal{B}_1^\perp \oplus \mathcal{B}_2^\perp = A^{1\times l} \text{ or, by duality, } \mathcal{B}_1 \oplus \mathcal{B}_2 = \mathcal{F}^{p+m}.$$

If this holds, the modules $U_j = \mathcal{B}_j^\perp$, $j = 1, 2$, are complementary direct summands of $A^{1\times l}$ and the modules $M_j = A^{1\times l}/U_j$ and the behaviors $\mathcal{B}_j$ are projective. We say that the IO behavior $\mathcal{B}_2$ trivializes (instead of stabilizes) $\mathcal{B}_1$.

In the following we assume that the IO behavior $\mathcal{B}_1$ is given and construct all trivializing IO behaviors $\mathcal{B}_2$. The set of all these $\mathcal{B}_2$ is parametrized by an open subset (in the Zariski topology) of a finitely generated polynomial module. This parametrization generalizes the important Youla–Kučera parametrization of the one-dimensional stabilization theory. According to the preceding theorem, we make the necessary assumption that the behavior $\mathcal{B}_1$ is *projective*. We use the exact sequence

$$\begin{gathered} F_1 := A^{1\times k_1} \xrightarrow{d_0 := \circ R_1} F_0 := A^{1\times l} \xrightarrow{\text{can}} M_1 := A^{1\times l}/U_1 \to 0 \\ \text{with } l := p+m,\ R_1 = (P_1, -Q_1),\ U_1 := \text{im}(d_0) = A^{1\times k_1} R_1. \end{gathered} \tag{24}$$

The following remark establishes the well-known one-to-one correspondence between idempotent endomorphisms $e = e^2$ of a module and direct sum decompositions. If

$$e = e^2 \in \text{Hom}_A(F_0, F_0)$$

is an idempotent or a projection, then

$$\begin{gathered} F_0 = \text{im}(e) \oplus \ker(e) \ni x = e(x) + (x - e(x)), \\ x = e(x) \ \Leftrightarrow\ x \in \text{im}(e),\ \ker(e) = \text{im}(\text{id} - e). \end{gathered}$$

Conversely, any direct sum decomposition

$$F_0 = V_1 \oplus V_2 \ni x = x_1 + x_2 =: e(x) + (x - e(x))$$

gives rise to the projection $e = e^2 \in \text{Hom}_A(F_0, F_0)$. The map

$$\begin{gathered} \{e \in \text{Hom}_A(F_0, F_0);\ e = e^2\} \to \{F_0 = V_1 \oplus V_2\}, \\ e \mapsto F_0 = \text{im}(e) \oplus \ker(e) \end{gathered}$$

is bijective. By restricting the preceding bijection to decompositions $F_0 = U_1 \oplus U_2$ with the fixed U_1 from above we obtain the following.

COROLLARY 2.10. *For the data from* (24) *the following map is bijective:*

$$\begin{gathered} \{e \in \text{Hom}_A(F_0, F_0);\ e = e^2,\ \text{im}(e) = U_1\} \to \{F_0 = U_1 \oplus U_2\}, \\ e \mapsto F_0 = U_1 \oplus \ker(e),\ \ker(e) = \text{im}(\text{id}_l - e). \end{gathered}$$

The preceding decompositions can also be described by means of homomorphisms $g \in \text{Hom}_A(F_0, F_1) \cong A^{l\times k_1}$, as was already shown more generally in [9, Lem. 6.2, p. 88]. This is important for constructive purposes in particular.

LEMMA 2.11. *The following conditions are equivalent for a submodule U_1 of F_0 and its factor module $M_1 = F_0/U_1 = \text{cok}(d_0)$:*

1. *The module M_1 is projective.*

2. *U_1 is a direct summand of F_0. Then U_1 is also projective and there is an idempotent $e = e^2 \in \text{Hom}_A(F_0, F_0)$ such that $U_1 = \text{im}(e)$.*

3. *There is a homomorphism* $g \in \mathrm{Hom}_A(F_0, F_1)$ *such that* $d_0 g d_0 = d_0$. *Then* $e := d_0 g$ *is an idempotent with* $U_1 = im(d_0) = \mathrm{im}(e)$.

Proof. The equivalence of 1 and 2 is standard since the projectivity of M_1 is equivalent with the splitting of the exact sequence (24).

$2 \Rightarrow 3$: Let e be an idempotent with image $\mathrm{im}(e) = U_1$. Then the map $e : F_0 \to U_1 = \mathrm{im}(e)$ is surjective. Since U_1 is projective and the map $d_0 : F_1 \to U_1$ is surjective, there is a linear section

$$s : U_1 \to F_1 \text{ such that } \mathrm{id}_{U_1} = d_0 s. \text{ Define } g := se : F_0 \xrightarrow{e} U_1 \xrightarrow{s} F_1. \text{ Then}$$
$$e(x) = d_0 s(e(x)) \in U_1 \text{ for } x \in F_0; \text{ hence } e = d_0 se = d_0 g \text{ and}$$
$$d_0 g d_0 = d_0 s e d_0 = e d_0 = d_0 \text{ since } e(d_0(x)) = d_0(x) \text{ for } d_0(x) \in U_1 = \mathrm{im}(e).$$

$3 \Rightarrow 2$: Assume $d_0 g d_0 = d_0$ and define $e := d_0 g$. Then $e \in \mathrm{Hom}_A(F_0, F_0)$ is an idempotent since $e^2 = (d_0 g d_0) g = d_0 g = e$ and, moreover, $\mathrm{im}(e) = \mathrm{im}(d_0 g) \subseteq \mathrm{im}(d_0) = U_1$. From $d_0 = d_0 g d_0 = e d_0$ we infer $U_1 = \mathrm{im}(d_0) \subseteq \mathrm{im}(e)$ in the same fashion; hence $U_1 = \mathrm{im}(e)$. □

THEOREM 2.12. *Assume that* $M_1 = A^{1\times l}/U_1$ *is projective and that* $g_1 \in \mathrm{Hom}_A(F_0, F_1)$ *and* $e_1 := d_0 g_1$ *with* $\mathrm{im}(e_1) = U_1$ *are constructed according to the preceding lemma. Then the map*

$$\varphi : \{h \in \mathrm{Hom}_A(F_0, F_1);\ d_0 h d_0 = 0\}/\{h \in \mathrm{Hom}_A(F_0, F_1);\ d_0 h = 0\}$$
$$\to \{e \in \mathrm{Hom}_A(F_0, F_0);\ e = e^2,\ U_1 = \mathrm{im}(e)\},\ \overline{h} \mapsto \varphi(\overline{h}) := e_1 + d_0 h,$$

is bijective. It furnishes a parametrization of the set of direct complements $U_2 = \ker(e)$ *with* $F_0 = U_1 \oplus U_2$ *by the finitely generated* A*-module on the left. If* A *is a field, then the right side is an affine open subset of the projective Grassmann variety of all* m*-dimensional subspaces of* $A^{1\times(p+m)}$.

Proof. 1. The equation $d_0 g d_0 = d_0$ is an inhomogeneous linear equation for g in the A-module $\mathrm{Hom}_A(F_0, F_1)$ and g_1 is one solution. Hence

$$\{g \in \mathrm{Hom}_A(F_0, F_1);\ d_0 g d_0 = d_0\} = g_1 + \{h \in \mathrm{Hom}_A(F_0, F_1);\ d_0 h d_0 = 0\}.$$

2. The map is well defined: If

$$d_0 h d_0 = 0, \text{ then } g_2 := g_1 + h \text{ satisfies } d_0 g_2 d_0 = d_0, \text{ and hence}$$
$$e_2 := d_0 g_2 = d_0 g_1 + d_0 h = e_1 + d_0 h$$

is an idempotent with $\mathrm{im}(e_2) = U_1$ according to the preceding lemma. If h_2 and h_3 are homogeneous solutions such that

$$\overline{h_2} = \overline{h_3} \text{ or } d_0(h_2 - h_3) = 0, \text{ then } e_1 + d_0 h_2 = e_1 + d_0 h_3.$$

3. It is obvious that the map φ is injective, and it is surjective by the preceding lemma. □

We reformulate the preceding theorem in matrix terms. We identify

$$A^{m\times n} = \mathrm{Hom}_A(A^{1\times m}, A^{1\times n}),\ X = \circ X = (\xi \mapsto \xi X),$$

and emphasize that $(\circ X)(\circ Y) = \circ(YX)$.

THEOREM 2.13. *Let* $\mathcal{B}_1 \subseteq \mathcal{F}^{p+m}$ *be an IO behavior with the transfer matrix* H_1 *and the data*

$$U_1 = \mathcal{B}_1^{\perp} = A^{1\times k_1} R_1,\ M_1 = A^{1\times l}/\mathcal{B}_1^{\perp},$$
$$R_1 = (P_1, -Q_1) \in A^{k_1\times(p+m)},\ \mathrm{rank}(P_1) = p,\ P_1 H_1 = Q_1,\ H_1 \in K^{p\times m}.$$

1. *The module M_1 or the behavior $\mathcal{B}_1$ is projective if and only if there is a matrix*

$$G_1 \in A^{l\times k_1} \text{ with } R_1G_1R_1 = R_1 \text{ or, equivalently, with } (\mathrm{id}_p, -H_1)G_1P_1 = \mathrm{id}_p. \tag{25}$$

Then $E_1 := G_1R_1 = E_1^2 \in A^{l\times l}$ is an idempotent matrix with $\mathcal{B}_1^\perp = A^{1\times l}E_1$.

This algorithm is related to the algorithms of [33]*; its idea goes back at least to MacLane* [9] *as explained above.*

2. *Assume that $\mathcal{B}_1$ is projective with the data from* 1. *Then the map*

$$\begin{aligned}\varphi : \{X \in A^{l\times k_1};\ R_1XR_1 = 0\}/\{X \in A^{l\times k_1};\ XR_1 = 0\}\\ \to \{E \in A^{l\times l};\ E = E^2,\ \mathcal{B}_1^\perp = A^{1\times l}E\},\ \overline{X} \mapsto \varphi(\overline{X}) := E_1 + XR_1,\end{aligned} \tag{26}$$

is bijective. Moreover,

(27)
$$R_1XR_1 = 0 \text{ if and only if } (\mathrm{id}_p, -H_1)XP_1 = 0 \text{ if and only if } (t\,\mathrm{id}_p, -tH_1)XP_1 = 0 \text{ and } XR_1 = 0 \text{ if and only if } XP_1 = 0,$$

where $0 \neq t \in A$ is a common denominator of the entries of H_1, i.e., $tH_1 \in A^{p\times m}$. The direct complement behavior $\mathcal{B}_2$ of $\mathcal{B}_1$ in $\mathcal{F}^{p+m}$, which is constructed by means of the idempotent $E = E_1 + XR_1$, is

$$\begin{aligned}\mathcal{B}_2 := \{w \in \mathcal{F}^{p+m};\ (\mathrm{id}_l - E_1 - XR_1)\circ w = 0\} = U_2^\perp,\ \mathcal{B}_1 \oplus \mathcal{B}_2 = \mathcal{F}^{p+m},\\ \text{where } U_2 := \ker(\circ(E_1 + XR_1)) = A^{1\times l}(\mathrm{id}_l - E_1 - XR_1).\end{aligned} \tag{28}$$

3. *Since $\mathcal{B}_1^\perp = A^{1\times l}E_1$, the bijection* (26) *holds if R_1 is replaced with E_1.*

4. *If U_1 is even free, and if the rows of R_1 are a basis of U_1, i.e., if $R_1 = (P_1, -Q_1) \in A^{p\times(p+m)}$ and $\det(P_1) \neq 0$, then the situation of* (26) *simplifies to*

$$\begin{aligned}G_1 \in A^{l\times p},\ R_1G_1 = \mathrm{id}_p,\ E_1 = G_1R_1,\ \text{and}\\ \varphi : \{X \in A^{l\times k};\ R_1X = 0\} \cong \{E \in A^{l\times l};\ E = E^2,\ \mathcal{B}_1^\perp = A^{1\times l}E\},\\ X \mapsto E_1 + XR_1.\end{aligned} \tag{29}$$

Proof. The equivalence of (25) and (27) follows from

$$R_1 = (P_1, -Q_1) = P_1(\mathrm{id}_p, -H_1) \text{ and } \mathrm{rank}(P_1) = \mathrm{rank}(\mathrm{id}_p, -H_1) = p,$$

which imply that P_1 (resp., $(\mathrm{id}_p, -H_1)$) can be cancelled as a left (resp., right) factor. □

Of course, each direct complement behavior

$$\mathcal{B}_2 = \left\{ w_2 = \begin{pmatrix} u_2 \\ y_2 \end{pmatrix} \in \mathcal{F}^{p+m};\ (\mathrm{id}_l - E)\circ w_2 = 0 \right\} \text{ with}$$
$$\mathrm{rank}(\mathrm{id}_l - E) = l - \mathrm{rank}(E) = l - p = m$$

of the preceding theorem admits an IO structure, but not necessarily that with u_2 as inputs, as needed for the feedback construction. To enforce this additional property we proceed as follows. Let $X_1, \ldots, X_n$ be a system of A-generators of the submodule

$$\{X \in A^{l\times k_1};\ R_1XR_1 = 0(\ \Leftrightarrow\ R_1XP_1 = 0)\}. \tag{30}$$

The same matrices generate $\{X \in K^{l\times k_1};\ (\mathrm{id}_p, -H_1)XP_1 = 0\}$ as a K-vector space. In the relevant examples the X_i can be computed by means of Gröbner bases. The linear map $\theta = (\theta_i)_{i=1,\dots,n} \mapsto \sum_{i=1}^n \theta_i X_i$ induces the A-isomorphism

$$\begin{aligned} &\varphi_1 : A^{1\times n}/V \cong \{X \in A^{l\times k_1};\ R_1XP_1 = 0\}/\{X \in A^{l\times k_1};\ XP_1 = 0\},\\ &\text{where } \varphi_1(\overline{\theta}) := \sum_{i=1}^n \theta_i \overline{X_i} \text{ and } V := \left\{\theta \in A^{1\times n};\ \sum_{i=1}^n \theta_i X_i P_1 = 0\right\}. \end{aligned} \tag{31}$$

Again, in the relevant examples the submodule V and its factor module $A^{1\times n}/V$ can be computed by means of Gröbner bases. In addition we consider the polynomial map

$$d : K^{l\times m} \to K^{\binom{l}{m}},\ Y \mapsto d(Y) = (d_\alpha(Y))_\alpha, \tag{32}$$

where the $d_\alpha(Y)$ are the $\binom{l}{m}$ $m \times m$ minors of the matrix Y. The function d is polynomial in the entries of Y and $d(Y) \neq 0$ if and only if $\mathrm{rank}(Y) = m$. With the data from above, we obtain the induced map

$$\{E \in A^{l\times l};\ E = E^2,\ \mathcal{B}_1^\perp = A^{1\times l}E\} \to A^{\binom{l}{m}},\ E \mapsto d\left((\mathrm{id}_l - E)\begin{pmatrix}0\\ \mathrm{id}_m\end{pmatrix}\right).$$

If

$$\mathrm{id}_l - E =: (-Q_2, P_2) \in A^{l\times(p+m)},\ \text{hence } (\mathrm{id}_l - E)\begin{pmatrix}0\\ \mathrm{id}_m\end{pmatrix} = P_2,$$

the behavior

$$\mathcal{B}_2 := \left\{w_2 = \begin{pmatrix}u_2\\ y_2\end{pmatrix} \in \mathcal{F}^{p+m};\ (\mathrm{id}_l - E)\circ w_2 = 0 \text{ or } P_2 \circ y_2 = Q_2 \circ u_2\right\}$$

is an IO behavior with input u_2 if and only if $\mathrm{rank}(P_2) = m$. Composing the maps just constructed, we obtain the map

$$\begin{aligned} &\Phi : K^{1\times n} \to K^{\binom{l}{m}},\ \theta \mapsto d\left((\mathrm{id}_l - E)\begin{pmatrix}0\\ \mathrm{id}_m\end{pmatrix}\right),\\ &\text{with } E := E_1 + XR_1,\ X := \sum_{i=1}^n \theta_i X_i, \end{aligned} \tag{33}$$

which is polynomial in the components of θ; i.e., its components are contained in $K[\theta]$. Summing up we obtain the final parametrization theorem.

THEOREM 2.14 (parametrization of trivializing behaviors). *Let $\mathcal{B}_1 = \{w_1 = \binom{y_1}{u_1} \in \mathcal{F}^{p+m}\}$ be a projective behavior as in Theorem 2.13, and assume that A is infinite. Then, with the data introduced above, the map*

$$\begin{aligned} &\overline{\theta} \mapsto \mathcal{B}_2 := \left\{w_2 = \begin{pmatrix}u_2\\ y_2\end{pmatrix} \in \mathcal{F}^{p+m};\ (\mathrm{id}_l - E)\circ w_2 = 0\right\},\\ &\textit{where } E := E_1 + XR_1,\ X := \sum_{i=1}^n \theta_i X_i, \end{aligned}$$

is a bijection from the nonempty set

$$\left\{\overline{\theta} \in A^{1\times n}/V;\ \Phi(\theta) = d\left((\mathrm{id}_l - E)\begin{pmatrix}0\\ \mathrm{id}_m\end{pmatrix}\right) \neq 0\right\}$$

onto the set of all IO behaviors $\mathcal{B}_2 \subseteq \mathcal{F}^{p+m}$*, which trivialize* $\mathcal{B}_1$*. This signifies that the feedback system* $\mathcal{B} := \text{feedback}(\mathcal{B}_1, \mathcal{B}_2)$ *is well-posed and trivial. In particular, such behaviors exist.*

Proof. It remains only to show that such behaviors exist. The matrix P_1 of rank p has a left inverse

$$S_1 \in K^{p\times k_1} \text{ with } S_1P_1 = \mathrm{id}_p. \tag{34}$$

Define

$$E := \begin{pmatrix}\mathrm{id}_p\\ 0\end{pmatrix}(\mathrm{id}_p, -H_1) = \begin{pmatrix}\mathrm{id}_p & -H_1\\ 0 & 0\end{pmatrix} \in K^{l\times l} \text{ and } G := \begin{pmatrix}\mathrm{id}_p\\ 0\end{pmatrix}S_1 \in K^{l\times k_1};$$
$$\text{hence } \mathrm{id}_l - E = \begin{pmatrix}0 & H_1\\ 0 & \mathrm{id}_m\end{pmatrix},\ (\mathrm{id}_l - E)\begin{pmatrix}0\\ \mathrm{id}_m\end{pmatrix} = \begin{pmatrix}H_1\\ \mathrm{id}_m\end{pmatrix},$$
$$\text{rank}\left((\mathrm{id}_l - E)\begin{pmatrix}0\\ \mathrm{id}_m\end{pmatrix}\right) = m,\ (\mathrm{id}_p, -H_1)GP_1 = \mathrm{id}_p, \text{ and } E := GR_1.$$

Thus $X := G - G_1 \in K^{l\times k_1}$ satisfies

$$(\mathrm{id}_p, -H_1)XP_1 = 0,\ E = E_1 + XR_1 \text{ and } \text{rank}\left((\mathrm{id}_l - E)\begin{pmatrix}0\\ \mathrm{id}_m\end{pmatrix}\right) = m;$$

in particular, X is of the form

$$X = \sum_{i=1}^{n} \theta_i X_i \text{ with } \theta \in K^{1\times n} \text{ and } \Phi(\theta) \neq 0.$$

Since the components of Φ are polynomials in $K[\theta]$ and since A is an infinite subset of K, there is also a parameter $\theta' \in A^{1\times n}$ with nonzero $\Phi(\theta')$, which induces an IO behavior $\mathcal{B}_2$ such that the feedback system $\text{feedback}(\mathcal{B}_1, \mathcal{B}_2)$ is well-posed and trivial. □

Remark 2.15. We remark that $\{\theta \in K^{1\times n};\ \Phi(\theta) \neq 0\}$ is a nonempty open subset of $K^{1\times n}$ with respect to the Zariski topology and is therefore dense. This signifies that, generically, the behaviors $\mathcal{B}_2$ with $\mathcal{F}^{p+m} = \mathcal{B}_1 \oplus \mathcal{B}_2$ are IO behaviors with the desired input $u_2 \in \mathcal{F}^p$.

3. Localization. The assumptions of the preceding section remain in force. Moreover, we assume that the ring A is *factorial*. We use Matlis' structure theory of injective modules over Noetherian rings and refer to [10, pp. 145–150] and [12, sec. 2], where this theory was used in the system-theoretic context. Moreover, we use Gabriel's theory of localization as detailed in the book [24, Chap. IX].

Let $\text{Spec}(A)$ (resp., $\text{Max}(A)$) denote the set of prime (resp., maximal) ideals of A. A prime ideal $\mathfrak{p}$ is *associated* with an A-module M if and only if there is an $x \in M$ such that $\mathfrak{p} = \text{ann}(x) = \{a \in A;\ ax = 0\}$ or, in other words, that $A/\mathfrak{p}$ is a submodule of M up to isomorphism. Let $\text{Ass}(M) \subset \text{Spec}(A)$ denote the set of prime ideals associated with M. A module M is $\mathfrak{p}$-*coprimary* if $\text{Ass}(M)$ consists exactly of one prime ideal $\mathfrak{p}$; then

$$a : M \to M,\ x \mapsto ax \text{ is } \begin{cases}\text{injective}\\ \text{locally nilpotent}\end{cases} \Leftrightarrow \begin{cases}a \notin \mathfrak{p}\\ a \in \mathfrak{p}\end{cases}. \tag{35}$$

Local or almost nilpotency of a on M means that for all $x \in M$ there is an index m such that $a^m x = 0$.

The injective module $\mathcal{F}$ is a cogenerator if and only if it contains all simple modules $A/\mathfrak{m}$, $\mathfrak{m} \in \operatorname{Max}(A)$, up to isomorphism, i.e., if $\operatorname{Max}(A) \subset \operatorname{Ass}(\mathcal{F})$. Each module M has an *injective envelope* $E(M) \supset M$ which is unique up to noncanonical isomorphism. This signifies that $E(M)$ is injective and that $V \cap M \neq 0$ for each nonzero submodule V of $E(M)$. Since A is Noetherian, a direct sum or coproduct of modules is injective if and only if each direct summand has this property. Each injective module E admits a direct sum decomposition into directly indecomposable injective modules, and this decomposition is unique up to an automorphism of E. An indecomposable injective module E is coprimary, and if $\mathfrak{p}$ is its unique associated prime ideal, then $E = E(A/\mathfrak{p})$. The map

$$\begin{gathered}\operatorname{Spec}(A) \to \{E;\ E \text{ indecomposable injective}\}/\text{isomorphism},\\ \mathfrak{p} \mapsto E(A/\mathfrak{p}),\ \operatorname{Ass}(E(A/\mathfrak{p})) = \{\mathfrak{p}\}\end{gathered} \tag{36}$$

is a bijection of the prime spectrum $\operatorname{Spec}(A)$ onto the set of indecomposable injectives up to isomorphism. Since $E(A/\mathfrak{p})$ is injective and indecomposable, the injective map

$$s : E(A/\mathfrak{p}) \to E(A/\mathfrak{p}),\ x \mapsto sx,\ s \in A \setminus \mathfrak{p},$$

is even bijective, and therefore $E(A/\mathfrak{p})$ is an $A_{\mathfrak{p}}$-module, where

$$A_{\mathfrak{p}} := \left\{ \frac{a}{s};\ a \in A,\ s \in A \setminus \mathfrak{p} \right\} \subset K = \operatorname{quot}(A)$$

is the local ring of the prime ideal $\mathfrak{p}$ with its unique maximal ideal $\mathfrak{p}_{\mathfrak{p}} = A_{\mathfrak{p}}\mathfrak{p}$. For $M \in \operatorname{Mod}_A$, the adjointness isomorphism

$$\begin{gathered}\operatorname{Hom}_A(M, E(A/\mathfrak{p})) \cong \operatorname{Hom}_{A_{\mathfrak{p}}}(M_{\mathfrak{p}}, E(A/\mathfrak{p})) = \operatorname{Hom}_A(M_{\mathfrak{p}}, E(A/\mathfrak{p})),\\ M_{\mathfrak{p}} := A_{\mathfrak{p}} \otimes_A M = \left\{ \frac{x}{s};\ x \in M,\ s \in A \setminus \mathfrak{p} \right\} \in \operatorname{Mod}_{A_{\mathfrak{p}}}\end{gathered} \tag{37}$$

holds. Together with $N = N_{\mathfrak{p}}$ for $N \in \operatorname{Mod}_{A_{\mathfrak{p}}}$ this shows that the duality functor $\operatorname{Hom}_{A_{\mathfrak{p}}}(-, E(A/\mathfrak{p}))$ on $\operatorname{Mod}_{A_{\mathfrak{p}}}$ is exact, and hence $E(A/\mathfrak{p})$ is an injective $A_{\mathfrak{p}}$-module. Since it contains the unique simple $A_{\mathfrak{p}}$-module $(A/\mathfrak{p})_{\mathfrak{p}} = A_{\mathfrak{p}}/\mathfrak{p}_{\mathfrak{p}}$, the module $E(A/\mathfrak{p})$ is the unique minimal injective cogenerator of the category $\operatorname{Mod}_{A_{\mathfrak{p}}}$ to which the considerations of section 2 are applicable. In particular,

$$M_{\mathfrak{p}} = 0 \quad \Leftrightarrow \quad \operatorname{Hom}_A(M, E(A/\mathfrak{p})) = 0. \tag{38}$$

Let

$$\mathcal{F} := \oplus_{i \in I} \mathcal{F}_i,\ \operatorname{Ass}(\mathcal{F}_i) = \{\mathfrak{p}_i\},\ \mathcal{P} := \operatorname{Ass}(\mathcal{F}) = \{\mathfrak{p}_i;\ i \in I\} \tag{39}$$

denote a direct sum decomposition of the injective cogenerator $\mathcal{F}$ into indecomposable injectives $\mathcal{F}_i$ and let

$$\mathcal{P} := \operatorname{Ass}(\mathcal{F}) = \mathcal{P}_1 \uplus \mathcal{P}_2,\ \mathcal{P}_1, \mathcal{P}_2 \neq \emptyset, \tag{40}$$

be a disjoint decomposition of $\operatorname{Ass}(\mathcal{F})$. *All subsequent objects depend on the choice of* $\mathcal{F}$ *and of the decompositions* (39) *and* (40).

In particular, the latter imply direct sum decompositions

$$\begin{gathered}\mathcal{F}=\oplus_{\mathfrak{p}\in\mathcal{P}}\mathcal{F}(\mathfrak{p})=\mathcal{F}_1\oplus\mathcal{F}_2 \text{ with } \mathcal{F}(\mathfrak{p}):=\oplus_{i\in I,\,\mathfrak{p}_i=\mathfrak{p}}\mathcal{F}_i\cong E(A/\mathfrak{p})^{(\mu(\mathfrak{p}))},\\ \mu(\mathfrak{p}):=|\{i\in I;\ \mathfrak{p}_i=\mathfrak{p}\}|,\ \mathcal{F}_j:=\oplus_{\mathfrak{p}\in\mathcal{P}_j}\mathcal{F}(\mathfrak{p}),\ j=1,2,\end{gathered}\tag{41}$$

where $E(A/\mathfrak{p})^{(\mu(\mathfrak{p}))}$ denotes the direct sum of $\mu(\mathfrak{p})$ copies of $E(A/\mathfrak{p})$. All modules in these direct sum decompositions are injective. Like $E(A/\mathfrak{p})$, the module $\mathcal{F}(\mathfrak{p})\cong E(A/\mathfrak{p})^{(\mu(\mathfrak{p}))}$ is an injective cogenerator of the category of $A_{\mathfrak{p}}$-modules. The decompositions (41) induce corresponding decompositions of $\mathcal{F}$ behaviors. Let

$$\begin{gathered}R\in A^{k\times l},\ U:=A^{1\times k}R,\ M:=A^{1\times l}/U,\\ \mathcal{B}:=U^{\perp}\underset{\text{ident.}}{=}\operatorname{Hom}_A(M,\mathcal{F})=\{w\in\mathcal{F}^l;\ R\circ w=0\}.\end{gathered}\tag{42}$$

Since M is finitely generated, the functor $\operatorname{Hom}_A(M,-)$ preserves direct sums, and therefore (41) induces direct decompositions

$$\begin{gathered}\mathcal{B}=\oplus_{i\in I}\mathcal{B}_i\subset\mathcal{F}^l=\oplus_{i\in I}\mathcal{F}_i^l,\\ \mathcal{B}_i:=\mathcal{B}\cap\mathcal{F}_i^l\underset{\text{ident.}}{=}\operatorname{Hom}_A(M,\mathcal{F}_i)\underset{\text{ident.}}{=}\{w\in\mathcal{F}_i^l;\ R\circ w=0\},\\ \mathcal{B}=\oplus_{\mathfrak{p}\in\mathcal{P}}\mathcal{B}(\mathfrak{p})=\mathcal{B}_1\oplus\mathcal{B}_2,\\ \mathcal{B}(\mathfrak{p}):=\mathcal{B}\cap\mathcal{F}(\mathfrak{p})^l=\operatorname{Hom}_A(M,\mathcal{F}(\mathfrak{p}))=\{w\in\mathcal{F}(\mathfrak{p})^l;\ R\circ w=0\}\\ \cong\operatorname{Hom}_{A_{\mathfrak{p}}}(M_{\mathfrak{p}},E(A/\mathfrak{p}))^{(\mu(\mathfrak{p}))},\\ \mathcal{B}_j:=\mathcal{B}\cap\mathcal{F}_j^l=\operatorname{Hom}_A(M,\mathcal{F}_j)=\{w\in\mathcal{F}_j^l;\ R\circ w=0\},\ j=1,2.\end{gathered}\tag{43}$$

We use the following suggestive system-theoretic terminology. The elements of $\mathcal{F}$ (resp., $\mathcal{F}_1$) are called *signals* (resp., *stable signals*). If $y=y_1+y_2\in\mathcal{F}=\mathcal{F}_1\oplus\mathcal{F}_2$ is a signal, then y_1 is called its *stable part* and y_2 its *steady state*.

Example 3.1. We indicate the data for the important complex continuous case. The algebra A is the complex polynomial algebra $\mathbb{C}[s]=\mathbb{C}[s_1,\dots,s_r]$. The map

$$\begin{gathered}\mathbb{C}^r\to\operatorname{Max}(\mathbb{C}[s]),\\ \lambda=(\lambda_1,\dots,\lambda_r)\mapsto\mathfrak{m}_\lambda:=\sum_{\rho=1}^{r}\mathbb{C}[s](s_\rho-\lambda_\rho)=\{t\in\mathbb{C}[s];\ t(\lambda)=0\}\end{gathered}$$

is bijective. As an injective cogenerator we take the module

$$\begin{gathered}\mathcal{F}:=\mathcal{D}'(\mathbb{R}^r)_{lf}:=\{y\in\mathcal{D}'(\mathbb{R}^r);\ [\mathbb{C}[s]\circ y:\mathbb{C}]<\infty\}=\oplus_{\lambda\in\mathbb{C}^r}\mathbb{C}[z]\exp(\lambda\bullet z),\\ z=(z_1,\dots,z_r)\in\mathbb{R}^r,\ \lambda\bullet z:=\lambda_1z_1+\cdots+\lambda_rz_r\end{gathered}\tag{44}$$

of *locally finite* distributions or *polynomial-exponential* functions [12, Thm. 6.6]. Then

$$\begin{gathered}\operatorname{Ass}(\mathcal{F})=\operatorname{Max}(\mathbb{C}[s])=\{\mathfrak{m}_\lambda;\ \lambda\in\mathbb{C}^r\},\\ \mathcal{F}(\lambda):=\mathcal{F}(\mathfrak{m}_\lambda)=\mathbb{C}[z]\exp(\lambda\bullet z)\cong E(\mathbb{C}[s]/\mathfrak{m}_\lambda);\end{gathered}\tag{45}$$

i.e., $\mathcal{F}$ is the unique minimal injective cogenerator of the category of $\mathbb{C}[s]$-modules. We choose a disjoint decomposition

$$\mathbb{C}^r=\Lambda_1\uplus\Lambda_2 \text{ and } \operatorname{Ass}(\mathcal{F})=\operatorname{Max}(\mathbb{C}[s])=\mathcal{P}_1\uplus\mathcal{P}_2,\ \mathcal{P}_j:=\{\mathfrak{m}_\lambda;\ \lambda\in\Lambda_j\}.\tag{46}$$

Standard choices for continuous stability theory are

$$\Lambda_2 := \overline{\mathbb{C}_+}^r, \text{ where } \mathbb{C}_+ := \{w \in \mathbb{C};\ \Re(w) > 0\},\ \overline{\mathbb{C}_+} := \{w \in \mathbb{C};\ \Re(w) \geq 0\}, \tag{47}$$
$$\text{or [29, Def. 3.1] } \Lambda_2 := \overline{\mathbb{C}_+} \times i\mathbb{R}^{r-1}.$$

A discrete analogue is $\Lambda_2 := \{w \in \mathbb{C};\ |w| \geq 1\}^r$; see the end of section 5.

The modules $\mathcal{F}_j$, $j = 1, 2$, are $\mathcal{F}_j = \oplus_{\lambda \in \Lambda_j} \mathbb{C}[z] \exp(\lambda \bullet z)$. For $r = 1$ and time $z = z_1$ the two sets Λ_2 from (47) coincide and yield

$$\mathcal{F} = \oplus_{\lambda \in \mathbb{C}} \mathbb{C}[z] \exp(\lambda z) = \mathcal{F}_1 \oplus \mathcal{F}_2 = \oplus_{\Re(\lambda) < 0} \mathbb{C}[z] \exp(\lambda z) \oplus \oplus_{\Re(\lambda) \geq 0} \mathbb{C}[z] \exp(\lambda z).$$

Then $\mathcal{F}_1 = \{y \in \mathcal{F};\ \lim_{z \to \infty} y(z) = 0\}$. Hence

$$\lim_{z \to \infty} y_1(z) = 0 \text{for} y = y_1 + y_2 \in \mathcal{F} = \mathcal{F}_1 \oplus \mathcal{F}_2.$$

For practical engineering applications the stable part y_1 of y is negligible and the signal y coincides with its steady state y_2. This justifies the suggestive terminology introduced above.

We go on with the general situation. The set

$$T := \cap_{\mathfrak{p}_2 \in \mathcal{P}_2} (A \setminus \mathfrak{p}_2) \subset A \tag{48}$$

is a multiplicative submonoid of A and saturated; i.e., each divisor of an element in T belongs to T. The set T gives rise to its quotient ring

$$A_T := \left\{ \frac{a}{t};\ a \in A,\ t \in T \right\} \subset A_{\mathfrak{p}} \subset \text{quot}(A),\ \mathfrak{p} \in \mathcal{P}_2, \text{ and } (A_T)_{\mathfrak{p}_T} = A_{\mathfrak{p}}. \tag{49}$$

LEMMA 3.2. $A_T = \cap_{\mathfrak{p} \in \mathcal{P}_2} A_{\mathfrak{p}} \subset \text{quot}(A)$.

Proof. The inclusion $\subseteq$ follows from (49). For the reverse inclusion we use that A is factorial. Let $x = \frac{a}{s} \in \text{quot}(A)$ with relatively prime a, s be contained in all

$$A_{\mathfrak{p}},\ \mathfrak{p} \in \mathcal{P}_2, \text{ hence } \frac{a}{s} = \frac{a_{\mathfrak{p}}}{s_{\mathfrak{p}}},\ s_{\mathfrak{p}} \in A \setminus \mathfrak{p},\ \mathfrak{p} \in \mathcal{P}_2.$$

Then

$$a_{\mathfrak{p}} s = s_{\mathfrak{p}} a,\ \gcd(a, s) = 1 \ \Rightarrow\ \forall \mathfrak{p} \in \mathcal{P}_2 :\ s \mid s_{\mathfrak{p}}$$
$$\Rightarrow\ \forall \mathfrak{p} \in \mathcal{P}_2 :\ s \in A \setminus \mathfrak{p} \ \Rightarrow\ s \in \cap_{\mathfrak{p} \in \mathcal{P}_2} (A \setminus \mathfrak{p}) = T \text{ and } x = \frac{a}{s} \in A_T. \qquad \square$$

In the context of Gabriel's localization theory the set $\mathcal{P}_2 \subset \text{Ass}(\mathcal{F})$ and its associated injective module $\mathcal{F}_2$ give rise to a full *localizing or Serre subcategory* or *hereditary torsion class* $\mathfrak{C}$ of Mod_A and a *Gabriel topology* $\mathfrak{T}$ [24, Thm. VI.5.1], where

$$\begin{aligned} \mathfrak{C} &:= \{C \in \text{Mod}_A;\ \text{Hom}_A(C, \mathcal{F}_2) = 0\} \\ &= \{C \in \text{Mod}_A;\ \forall \mathfrak{p} \in \mathcal{P}_2 :\ \text{Hom}_A(C, E(A/\mathfrak{p})) = 0\} \\ &= \{C \in \text{Mod}_A;\ \forall \mathfrak{p} \in \mathcal{P}_2 :\ C_{\mathfrak{p}} = 0\} \text{ and} \\ \mathfrak{T} &:= \{\mathfrak{a} \subseteq A;\ A/\mathfrak{a} \in \mathfrak{C}\}. \end{aligned} \tag{50}$$

Since $\mathcal{F}_2$ is injective, the class $\mathfrak{C}$ of $\mathfrak{T}$-*torsion modules* is obviously closed under taking submodules, factor modules, extensions, and direct sums; in particular

$$\mathfrak{C} = \{C \in \text{Mod}_A;\ \forall x \in C :\ \text{ann}(x) = \{a \in A;\ ax = 0\} \in \mathfrak{T}\} \tag{51}$$

and $\mathfrak{T}$ is directed downward. Moreover, $\mathfrak{C}$ is *stable*, i.e., closed under taking injective envelopes [24, Props. VI.7.1 and VII.4.5]. If M is a finitely generated A-module and $\mathfrak{a}$ an ideal of A, then

$$\begin{gathered} M \in \mathfrak{C},\ \text{resp.},\ \mathfrak{a} \in \mathfrak{T} \\ \Leftrightarrow\ \forall \mathfrak{p} \in \mathcal{P}_2\ \exists s_{\mathfrak{p}} \in A \setminus \mathfrak{p} \text{ such that } s_{\mathfrak{p}} M = 0,\ \text{resp.},\ s_{\mathfrak{p}} \in \mathfrak{a} \cap (A \setminus \mathfrak{p}). \end{gathered} \tag{52}$$

The largest submodule of M in $\mathfrak{C}$ is called the $\mathfrak{T}$-*torsion radical* of M and denoted by $\mathrm{t}_{\mathfrak{T}}(M)$. If $\mathrm{t}_{\mathfrak{T}}(M) = 0$, the module is called $\mathfrak{T}$-*torsion free*. Due to (52) a $\mathfrak{T}$-torsion module is a torsion module in the usual sense, and hence a torsion free module is $\mathfrak{T}$-torsion free. Every subcategory $\mathfrak{C}$ with the indicated properties arises from a suitable injective module $\mathcal{F}_2$; in other words, there are no other localization functors than those described below.

An A-module M also induces its quotient module

$$M_T = \left\{ \frac{x}{t};\ x \in M,\ t \in T \right\} = A_T \otimes_A M.$$

Since $M_{\mathfrak{p}} = (M_T)_{\mathfrak{p}_T}\ \forall \mathfrak{p} \in \mathcal{P}_2$, we see that any module with $M_T = 0$ is a $\mathfrak{T}$-torsion module.

An A-module N is called $\mathfrak{T}$-*closed* if

$$N \cong \mathrm{Hom}_A(\mathfrak{a}, N),\ x \mapsto (a \mapsto ax)\ \ \forall \mathfrak{a} \in \mathfrak{T}. \tag{53}$$

The full additive subcategory of Mod_A of all $\mathfrak{T}$-closed submodules is denoted by $\mathrm{Mod}_{A,\mathfrak{T}}$. According to [24, pp. 195–200; 213–216] the inclusion functor $\mathrm{inj} : \mathrm{Mod}_{A,\mathfrak{T}} \subset \mathrm{Mod}_A$ has an exact left adjoint functor

$$\begin{gathered} \mathrm{Mod}_A \to \mathrm{Mod}_{A,\mathfrak{T}},\ M \mapsto M_{\mathfrak{T}},\ \text{with the functorial adjunction morphism} \\ \eta_M : M \to M_{\mathfrak{T}},\ \text{i.e.,}\ \mathrm{Hom}_A(M_{\mathfrak{T}}, N) \cong \mathrm{Hom}_A(M, N),\ g \mapsto g\eta_M, \end{gathered} \tag{54}$$

for $M \in \mathrm{Mod}_A$ and $N \in \mathrm{Mod}_{A,\mathfrak{T}}$, and is given by the directed colimit [24, Prop. IX.1.7]

$$\begin{gathered} M_{\mathfrak{T}} = \operatorname*{colim}_{\mathfrak{a} \in \mathfrak{T}} \mathrm{Hom}_A(\mathfrak{a}, M) = \{\alpha : \mathfrak{a} \to M;\ \mathfrak{a} \in \mathfrak{T}\}/\sim \ni [\alpha : \mathfrak{a} \to M],\ \text{where} \\ (\alpha : \mathfrak{a} \to M) \sim (\beta : \mathfrak{b} \to M)\ \ \Leftrightarrow\ \ \exists \mathfrak{c} \in \mathfrak{T} \text{ with } \mathfrak{c} \subseteq \mathfrak{a} \cap \mathfrak{b},\ \alpha \mid \mathfrak{c} = \beta \mid \mathfrak{c},\ \text{and} \\ \eta_M : M \to M_{\mathfrak{T}},\ x \mapsto [A \to M,\ a \mapsto ax]. \end{gathered} \tag{55}$$

Moreover [24, IX.1.2,1.3],

$$\mathrm{t}_{\mathfrak{T}}(M) = \ker(\eta_M) \text{ and } M \in \mathfrak{C}\ \ \Leftrightarrow\ \ M = \mathrm{t}_{\mathfrak{T}}(M)\ \ \Leftrightarrow\ \ M_{\mathfrak{T}} = 0. \tag{56}$$

The functor $M \mapsto M_{\mathfrak{T}}$ is called *localization* with respect to $\mathcal{P}_2$, $\mathfrak{C}$, or $\mathfrak{T}$. A module N is $\mathfrak{T}$-closed if and only if η_N is an isomorphism [24, Prop. IX.1.8]; in particular $M_{\mathfrak{T}} = (M_{\mathfrak{T}})_{\mathfrak{T}}$. The category $\mathrm{Mod}_{A,\mathfrak{T}}$ is itself abelian with exact directed colimits; the localization functor is exact, but the inclusion functor inj is left exact only [24, p. 214]. This means that the kernels of an A-linear map between $\mathfrak{T}$-closed modules in Mod_A (resp., $\mathrm{Mod}_{A,\mathfrak{T}}$) are the same, but that an epimorphism in $\mathrm{Mod}_{A,\mathfrak{T}}$ is not surjective in general. Indeed, if $f : N_1 \to N_2$ is an A-linear map between $\mathfrak{T}$-closed modules and $C := \mathrm{cok}_A(f) := N_1/f(N_2)$ is its cokernel in Mod_A, the exact sequence

$$\begin{gathered} N_1 \xrightarrow{f} N_2 \xrightarrow{\mathrm{can}} C \to 0 \text{ in } \mathrm{Mod}_A \text{ induces the exact sequence} \\ N_1 = (N_1)_{\mathfrak{T}} \xrightarrow{f} N_2 = (N_2)_{\mathfrak{T}} \xrightarrow{\mathrm{can}} C_{\mathfrak{T}} \to 0 \text{ in } \mathrm{Mod}_{A,\mathfrak{T}}, \end{gathered} \tag{57}$$

and hence f is an epimorphism in the category $\mathrm{Mod}_{A,\mathfrak{T}}$ if and only if C is a $\mathfrak{T}$-torsion module.

LEMMA 3.3.

1. *The modules* $\mathcal{F}_2 = \oplus_{\mathfrak{p}\in\mathcal{P}_2}\mathcal{F}(\mathfrak{p})$ *and* $\oplus_{\mathfrak{p}\in\mathcal{P}_2}E(A/\mathfrak{p})$ *are injective cogenerators of the category* $\mathrm{Mod}_{A,\mathfrak{T}}$*; in particular, as already indicated,*

$$\mathrm{Hom}_A(M,\mathcal{F}_2)\cong\mathrm{Hom}_A(M_{\mathfrak{T}},\mathcal{F}_2)=0\ \Leftrightarrow\ M_{\mathfrak{T}}=0\ \Leftrightarrow\ M\in\mathfrak{C}. \tag{58}$$

2. *These modules are also injective* A_T*-modules. Only in important special cases are they* A_T*-cogenerators; see Theorem/Definition* 5.6 *of section* 5.
3. *The module* $\mathcal{F}_T\cong\oplus_i\{\mathcal{F}_i;\ \mathfrak{p}_i\cap T=\emptyset\}$ *is* A*- and* A_T*-injective.*

Proof.

1. This is shown in [24, Prop. X.1.9].
2. Since these A_T-modules are injective A-modules, the injectivity as A_T-modules follows from the identity

$$\mathrm{Hom}_A(N,\mathcal{F}_2)=\mathrm{Hom}_{A_T}(N,\mathcal{F}_2),\ N=N_T\in\mathrm{Mod}_{A_T}.$$

3. This follows from

$$E(A/\mathfrak{p})_T=\begin{cases}E(A/\mathfrak{p}) & \text{if } \mathfrak{p}\cap T=\emptyset\\ 0 & \text{if } \mathfrak{p}\cap T\neq\emptyset\end{cases}. \qquad \square$$

Since A is Noetherian and hence the functor $\mathrm{Hom}_A(\mathfrak{a},-)$ in (53) preserves direct sums, a direct sum of A-modules is $\mathfrak{T}$-closed if and only if all summands have this property. This implies in particular that the injection functor from $\mathrm{Mod}_{A,\mathfrak{T}}$ to Mod_A also preserves direct sums and that every projective A_T-module is contained in $\mathrm{Mod}_{A,\mathfrak{T}}$ since $A_T=A_{\mathfrak{T}}$ is $\mathfrak{T}$-closed (see Lemma 3.4).

The module $M_{\mathfrak{T}}$ is always an A_T-module, i.e., the multiplication with $t\in T$ is bijective [24, p. 196], but the functors $M\mapsto M_T$ and $M\mapsto M_{\mathfrak{T}}$ coincide only in exceptional cases [24, Prop. XI.3.4], for instance, for the principal ideal ring $\mathbb{C}[s_1]$ in one-dimensional systems theory. Again in Theorem/Definition 5.6 we characterize this exceptional situation in the most important case and show its relation to *ideal-convexity* in the sense of [29]. The difficulties of [29] with the possible absence of ideal-convexity are avoided in our theory by using $M_{\mathfrak{T}}$ instead of the standard M_T. But see the following lemma.

LEMMA 3.4. $A_T=A_{\mathfrak{T}}\subset K:=\mathrm{quot}(A)$.

Proof. For $\mathfrak{a}\in\mathfrak{T}$, the map

$$\mathrm{Hom}_A(\mathfrak{a},A)\to K,\ \alpha\mapsto x_\alpha:=\alpha(a)/a,\ \text{with}\ 0\neq a\in\mathfrak{a}, \tag{59}$$

is a well-defined A-monomorphism. Indeed, if

$$\begin{gathered}0\neq a_1,a_2\in\mathfrak{a},\ \text{then}\ \alpha(a_1a_2)=a_1\alpha(a_2)=a_2\alpha(a_1);\ \text{hence}\\ \alpha(a_2)/a_2=\alpha(a_1)/a_1\ \text{and}\ \alpha(a_2)=a_2\alpha(a_1)/a_1.\end{gathered}$$

Since directed colimits are exact, the injections (59) induce an injection

$$A_{\mathfrak{T}}=\operatorname*{colim}_{\mathfrak{a}\in\mathfrak{T}}\mathrm{Hom}_A(\mathfrak{a},A)\underset{\text{ident.}}{=}\{x_\alpha=\alpha(a)/a;\ 0\neq a\in\mathfrak{a}\xrightarrow{\alpha}A\}\subset K.$$

But according to (52) and Lemma 3.2,

$$\forall\mathfrak{p}\in\mathcal{P}_2\ \exists a_{\mathfrak{p}}\in\mathfrak{a}\cap(A\setminus\mathfrak{p})\neq\emptyset;\ \text{hence}\ x_\alpha=\alpha(a_{\mathfrak{p}})/a_{\mathfrak{p}}\in\cap_{\mathfrak{p}\in\mathcal{P}_2}A_{\mathfrak{p}}=A_T,$$

and thus $A_{\mathfrak{T}} \subseteq A_T$. If, conversely, $x = a/t \in A_T$, then

$$\forall \mathfrak{p} \in \mathcal{P}_2 : \ t \in At \cap (A \setminus \mathfrak{p}); \text{ hence}$$
$$At \in \mathfrak{T}, \ \alpha : At \to A, \ t \mapsto a, \text{ and } x = a/t = \alpha(t)/t = x_\alpha \in A_{\mathfrak{T}}. \qquad \square$$

As in the preceding lemma, we define for every A-module M and prime ideal $\mathfrak{p} \in \mathcal{P}_2$ the canonical A-linear map

$$\text{can}_{\mathfrak{p}} : M_{\mathfrak{T}} \to M_{\mathfrak{p}}, \ [\alpha : \mathfrak{a} \to M] \mapsto \alpha(s_{\mathfrak{p}})/s_{\mathfrak{p}}, \text{ with } s_{\mathfrak{p}} \in \mathfrak{a} \cap (A \setminus \mathfrak{p}), \tag{60}$$

independent of the choice of $s_{\mathfrak{p}}$.

LEMMA 3.5. *The map*

$$\text{can} : M_{\mathfrak{T}} \to \prod_{\mathfrak{p} \in \mathcal{P}_2} M_{\mathfrak{p}}, \ [\alpha] \mapsto (\alpha(s_{\mathfrak{p}})/s_{\mathfrak{p}})_{\mathfrak{p} \in \mathcal{P}_2},$$

is a functorial monomorphism.

Proof. Only the injectivity has to be shown. Assume therefore that

$$\forall \mathfrak{p} \in \mathcal{P}_2 : \alpha(s_{\mathfrak{p}})/s_{\mathfrak{p}} = 0, \text{ i.e., } \exists t_{\mathfrak{p}} \in A \setminus \mathfrak{p} \text{ such that}$$
$$t_{\mathfrak{p}} \alpha(s_{\mathfrak{p}}) = \alpha(t_{\mathfrak{p}} s_{\mathfrak{p}}) = 0.$$

The ideal $\mathfrak{a} := \sum_{\mathfrak{p} \in \mathcal{P}_2} At_{\mathfrak{p}} s_{\mathfrak{p}}$ belongs to $\mathfrak{T}$ since it contains the $t_{\mathfrak{p}} s_{\mathfrak{p}}$ and, by construction, $\alpha \mid \mathfrak{a} = 0$, and hence $[\alpha] = 0$ in $M_{\mathfrak{T}}$. $\square$

A further functorial homorphism is the map

$$\text{can} : M_T \to M_{\mathfrak{T}}, \ \frac{x}{t} \mapsto [\alpha : At \to M, \ t \mapsto x], \tag{61}$$

which, in general, is neither injective nor surjective. The kernel and cokernel of the canonical map $M \to M_T$ are modules C with $C_T = 0$ and hence $C_{\mathfrak{T}} = 0$, and are thus $\mathfrak{T}$-torsion modules. The same holds for the canonical map $\eta_M : M \to M_{\mathfrak{T}}$ [24, Lemmas IX.1.2, IX.1.5]. Application of the exact functors $(-)_{\mathfrak{T}}$ and $(-)_{\mathfrak{p}}$ thus yields canonical isomorphisms

$$M_{\mathfrak{T}} \cong (M_T)_{\mathfrak{T}} \text{ and } M_{\mathfrak{p}} \cong (M_T)_{\mathfrak{p}} \cong (M_{\mathfrak{T}})_{\mathfrak{p}} \text{ for } \mathfrak{p} \in \mathcal{P}_2,$$
$$K \otimes_A M \cong K \otimes_{A_{\mathfrak{p}}} M_{\mathfrak{p}} \cong K \otimes_A M_T \cong K \otimes_A M_{\mathfrak{T}}; \tag{62}$$
$$\text{hence } \operatorname{rank}(M) = \operatorname{rank}(M_T) = \operatorname{rank}(M_{\mathfrak{T}}) = \operatorname{rank}(M_{\mathfrak{p}}) = [K \otimes_A M : K].$$

For the data from (42), the inclusion $U \subset A^{1\times l}$ induces the inclusions

$$U_T = A_T U \subset U_{\mathfrak{T}} \subset A_T^{1\times l} = A_{\mathfrak{T}}^{1\times l}. \tag{63}$$

LEMMA AND DEFINITION 3.6. *For the data from* (42)*, the submodule* $U_{\text{st}} := U_{\mathfrak{T}} \cap A^{1\times l}$ *of* $A^{1\times l}$ *is the largest one such that*

$$(U_{\text{st}})_{\mathfrak{T}} = U_{\mathfrak{T}} \text{ or } (A^{1\times l}/U_{\text{st}})_{\mathfrak{T}} = M_{\mathfrak{T}}.$$

Moreover,

$$U_{\text{st}} = \cap_{\mathfrak{p} \in \mathcal{P}_2} U_{\mathfrak{p}} \cap A^{1\times l} = \{x \in A^{1\times l}; \ \forall \mathfrak{p} \in \mathcal{P}_2 \ \exists s_{\mathfrak{p}} \in A \setminus \mathfrak{p} \text{ with } s_{\mathfrak{p}} x \in U\},$$
$$U_{\mathfrak{T}} = (U_{\text{st}})_T = A_T U_{\text{st}} \text{ and } K \otimes_A U = K \otimes_A U_{\text{st}} \subset K^{1\times l}.$$

The last equality shows that the behavior $\mathcal{B}_{\rm st} := U_{\rm st}^{\perp}$ *is in the same transfer class, or has the same controllable subbehavior, as* $\mathcal{B}$.

Proof. The exactness of $(-)_{\mathfrak{T}}$ implies

$$(U_{\rm st})_{\mathfrak{T}} = (U_{\mathfrak{T}} \cap A^{1\times l})_{\mathfrak{T}} = (U_{\mathfrak{T}})_{\mathfrak{T}} \cap A_{\mathfrak{T}}^{1\times l} = U_{\mathfrak{T}} \cap A_T^{1\times l} = U_{\mathfrak{T}}.$$
$$\text{If } U_{\mathfrak{T}} = V_{\mathfrak{T}}, \text{ then } V \subset V_{\mathfrak{T}} \cap A^{1\times l} = U_{\mathfrak{T}} \cap A^{1\times l} = U_{\rm st}.$$

Finally,

$$U_{\mathfrak{T}} = A_T(U_{\mathfrak{T}} \cap A^{1\times l}) = A_T U_{\rm st} = (U_{\rm st})_T.$$

The last equations follow from the fact that $U_{\mathfrak{T}}$ is an A_T-submodule of $A_T^{1\times l}$ and that $V = A_T(V \cap A^{1\times l})$ for each A_T-submodule of $A_T^{1\times l}$.

The injection from Lemma 3.5 and the exact sequence

$$0 \to U \xrightarrow{\rm inj} A^{1\times l} \xrightarrow{\rm can} M \to 0$$

induce the exact sequence in Mod_A,

$$0 \to U_{\mathfrak{T}} \xrightarrow{\rm inj} A_T^{1\times l} \xrightarrow{\rm can} \prod_{\mathfrak{p}\in\mathcal{P}_2} A_{\mathfrak{p}}^{1\times l}/U_{\mathfrak{p}},$$

and this implies

$$U_{\rm st} = U_{\mathfrak{T}} \cap A^{1\times l} = \cap_{\mathfrak{p}\in\mathcal{P}_2} U_{\mathfrak{p}} \cap A^{1\times l}. \qquad \square$$

Remark 3.7. If the matrix R with $U = A^{1\times k}R$ is given it is, in general, a difficult problem to compute a matrix

$$R_{\rm st} \in A^{k_1\times l} \text{ such that } U_{\rm st} = A^{1\times k_1}R_{\rm st} \text{ and hence } U_{\mathfrak{T}} = A_T^{1\times k_1}R_{\rm st}.$$

4. Abstract stability and stabilization. The assumptions and notation of the preceding section remain in force. We apply the results of the preceding sections to stability questions, first in the abstract situation and then, in the next section, to multidimensional systems governed by partial differential or difference equations.

THEOREM AND DEFINITION 4.1 (equal steady state). 1. *Let*

$$\mathcal{B} := U^{\perp} = \{w \in \mathcal{F}^l;\ R \circ w = 0\} \text{ and } \mathcal{B}' := U'^{\perp} = \{w \in \mathcal{F}^l;\ R' \circ w = 0\}$$

be two behaviors as in (42) *with their corresponding decompositions* (43) *and the submodules* $U_{\rm st}$ *(resp.,* $U'_{\rm st}$*) according to Lemma/Definition* 3.6. *Then*

$$\mathcal{B}_2 := \mathcal{B} \cap \mathcal{F}_2^l = \mathcal{B}'_2 \ \Leftrightarrow\ U_{\mathfrak{T}} = U'_{\mathfrak{T}} \ \Leftrightarrow\ U_{\rm st} = U'_{\rm st} \ \Leftrightarrow\ M_{\mathfrak{T}} = M'_{\mathfrak{T}}.$$

Then we say that the behaviors $\mathcal{B}$ *and* $\mathcal{B}'$ *have the* same steady state.

2. *The behavior*

$$\mathcal{B}_{\rm st} := U_{\rm st}^{\perp} = \{w \in \mathcal{F}^l;\ R_{\rm st} \circ w = 0\} \text{ with } U_{\rm st} = A^{1\times k_1}R_{\rm st}$$

is the smallest one with the same steady state as $\mathcal{B}$.

Proof. 1. Replacing $\mathcal{B}$ with $\mathcal{B} + \mathcal{B}'$, we assume without loss of generality that $\mathcal{B}' \subseteq \mathcal{B}$ or $U \subseteq U'$. Let $f : U \subset U'$ (resp., $g : M \to M'$) be the canonical injection

(resp., surjection). Application of the exact functor $(-)_{\mathfrak{T}}$ furnishes the commutative diagram with exact rows in $\mathrm{Mod}_{A,\mathfrak{T}}$

$$\begin{array}{ccccccc} 0 & \to & U_{\mathfrak{T}} & \subset A_T^{1\times l} & \xrightarrow{\mathrm{can}_{\mathfrak{T}}} & M_{\mathfrak{T}} & \to & 0 \\ & & \downarrow f_{\mathfrak{T}} & \downarrow \mathrm{id} & & \downarrow g_{\mathfrak{T}} & & \\ 0 & \to & U'_{\mathfrak{T}} & \subset A_T^{1\times l} & \xrightarrow{\mathrm{can}'_{\mathfrak{T}}} & M'_{\mathfrak{T}} & \to & 0, \end{array}$$

where $f_{\mathfrak{T}} : U_{\mathfrak{T}} \subset U'_{\mathfrak{T}}$ and $g_{\mathfrak{T}}$ is the canonical epimorphism. Hence $U_{\mathfrak{T}} = U'_{\mathfrak{T}}$ if and only if $g_{\mathfrak{T}} : M_{\mathfrak{T}} \to M'_{\mathfrak{T}}$ is an isomorphism. Moreover,

$$\begin{gathered} \mathrm{Hom}(g, \mathcal{F}_2) \underset{\text{ident.}}{=} \mathrm{Hom}(g_{\mathfrak{T}}, \mathcal{F}_2) \underset{\text{ident.}}{=} \mathrm{inj} : \\ \mathcal{B}'_2 \underset{\text{ident.}}{=} \mathrm{Hom}_A(M', \mathcal{F}_2) \underset{\text{ident.}}{=} \mathrm{Hom}_A(M'_{\mathfrak{T}}, \mathcal{F}_2) \\ \to \mathcal{B}_2 \underset{\text{ident.}}{=} \mathrm{Hom}_A(M, \mathcal{F}_2) \underset{\text{ident.}}{=} \mathrm{Hom}_A(M_{\mathfrak{T}}, \mathcal{F}_2). \end{gathered}$$

By Lemma 3.3 $\mathcal{F}_2$ is an injective cogenerator in $\mathrm{Mod}_{A,\mathfrak{T}}$ and hence

$$\begin{gathered} \mathcal{B}'_2 = \mathcal{B}_2 \;\Leftrightarrow\; \mathrm{inj} = \mathrm{Hom}(g_{\mathfrak{T}}, \mathcal{F}_2) \text{ is an isomorphism} \\ \Leftrightarrow\; g_{\mathfrak{T}} : M_{\mathfrak{T}} \to M'_{\mathfrak{T}} \text{ is an isomorphism} \;\Leftrightarrow\; M_{\mathfrak{T}} = M'_{\mathfrak{T}}. \end{gathered}$$

2. This is a reformulation of Lemma/Definition 3.6. □

In what follows we assume that an IO system $\mathcal{B} \subset \mathcal{F}^l$ is given with the data

$$\begin{gathered} l = p + m,\ R = (P, -Q) \in A^{k\times(p+m)},\ \mathrm{rank}(P) = \mathrm{rank}(R) = p,\ PH = Q, \\ U := A^{1\times k}R \subset A^{1\times l},\ U^0 := A^{1\times k}P \subset A^{1\times p}, \\ M := A^{1\times l}/U,\ M^0 = A^{1\times p}/U^0, \\ \mathcal{B} := U^{\perp} = \left\{ w = \begin{pmatrix} y \\ u \end{pmatrix} \in \mathcal{F}^{p+m};\ P \circ y = Q \circ u \right\}, \\ \mathcal{B}^0 := \{ y \in \mathcal{F}^p;\ P \circ y = 0 \}. \end{gathered} \tag{64}$$

Theorem and Definition 4.2 (stable systems). *For the data from* (64) *the following assertions are equivalent:*

1. $\mathcal{B}^0 \subseteq \mathcal{F}_1^p$, *i.e.,* $\mathcal{B}_2^0 = 0$ *or* $\mathcal{B}^0(\mathfrak{p}) = 0\ \forall \mathfrak{p} \in \mathcal{P}_2$. *In other words, all trajectories of the autonomous part* $\mathcal{B}^0$ *of* $\mathcal{B}$ *are stable. Recall that the signals* $y \in \mathcal{F}_1$ *are suggestively called stable.*
2. $M_{\mathfrak{T}}^0 = 0$, *i.e., for all* $\mathfrak{p} \in \mathcal{P}_2$ $M_{\mathfrak{p}}^0 = 0$ *or* $A_{\mathfrak{p}}^{1\times k}P = A_{\mathfrak{p}}^{1\times p}$ *or, in the terminology of Theorem/Definition* 2.5, *the* $A_{\mathfrak{p}}$ *IO behavior*

$$\left\{ \begin{pmatrix} y \\ u \end{pmatrix} \in \mathcal{F}(\mathfrak{p})^{p+m};\ P \circ y = Q \circ u \right\} \text{ with the } A_{\mathfrak{p}}\text{-cogenerator } \mathcal{F}(\mathfrak{p})$$

   is trivial.
3. *For all* $\mathfrak{p} \in \mathcal{P}_2$ *the module* $M_{\mathfrak{p}}$ *is torsion free, and* $H \in A_{\mathfrak{p}}^{p\times m}$.
4. *The module* $M_{\mathfrak{T}}$ *is torsion free, and* $H \in A_T^{p\times m}$.

If these conditions are satisfied, the IO system $\mathcal{B}$ *is said to be* stable with respect to

the decompositions (39) and (40), *and then the A-linear map*

$$A^{1\times m} \to M,\ \eta \mapsto \overline{(0,\eta)},\ \textit{induces the isomorphisms}$$
$$A_T^{1\times m} \cong M_{\mathfrak{T}}\ \textit{and}$$
$$\text{(65)}\quad \operatorname{proj} = (0\,\mathrm{id}_m)\circ : \mathcal{B}_2 \to \mathcal{F}_2^m,\ \begin{pmatrix} y_2 \\ u_2 \end{pmatrix} \mapsto u_2,\ \textit{with the inverse}\ u_2 \mapsto \begin{pmatrix} H\circ u_2 \\ u_2 \end{pmatrix};$$
$$\textit{hence}\ \mathcal{B} := \mathcal{B}_1 \oplus \left\{ \begin{pmatrix} H\circ u_2 \\ u_2 \end{pmatrix};\ u_2 \in \mathcal{F}_2^m \right\}.$$

Here $\circ$ denotes the scalar multiplication of $\mathcal{F}_2$ as an A_T-module. In other words, the module $M_{\mathfrak{T}}$ is A_T-free of dimension m. For every input $u_2 \in \mathcal{F}_2^m$, $\binom{H\circ u_2}{u_2}$ is the unique trajectory in $\mathcal{B}\cap\mathcal{F}_2^l$ with input u_2. We remark that H acts on $\mathcal{F}_2^m$ as an operator although no analogue of the customary properness of H is assumed.

Proof. $1 \Leftrightarrow 2$: This follows from

$$\mathcal{B}^0(\mathfrak{p}) \cong \operatorname{Hom}_A(M^0, \mathcal{F}(\mathfrak{p})) \cong \operatorname{Hom}_{A_{\mathfrak{p}}}(M^0_{\mathfrak{p}}, \mathcal{F}(\mathfrak{p}))$$

and the cogenerator property of $\mathcal{F}(\mathfrak{p})$ as an $A_{\mathfrak{p}}$-module.

$2 \Leftrightarrow 3$: This is a special case of Theorem/Definition 2.5.

$3 \Leftrightarrow 4$: The property of H follows from $A_T = \cap_{\mathfrak{p}\in\mathcal{P}_2} A_{\mathfrak{p}}$ according to Lemma 3.2. If all $M_{\mathfrak{p}}$, $\mathfrak{p} \in \mathcal{P}_2$, are torsion free, Lemma 3.5 implies the same property for $M_{\mathfrak{T}}$. Conversely, if $M_{\mathfrak{T}}$ is torsion free, then so are all $M_{\mathfrak{p}} \cong (M_{\mathfrak{T}})_{\mathfrak{p}}$, $\mathfrak{p} \in \mathcal{P}_2$, according to (62).

The condition $M^0_{\mathfrak{T}} = 0$ and the application of the exact functors

$$(-)_{\mathfrak{T}} \text{ and } \operatorname{Hom}_A(-, \mathcal{F}_2) \cong \operatorname{Hom}_A((-)_{\mathfrak{T}}, \mathcal{F}_2)$$

to the exact IO sequence

$$0 \to A^{1\times m} \overset{\circ(0\,\mathrm{id}_m)}{\longrightarrow} M \overset{\text{can}}{\longrightarrow} M^0 \to 0$$

furnishes the isomorphisms (65).

Recall that $\mathcal{F}_2$ is $\mathfrak{T}$-closed and an A_T-module in particular; hence $a\circ y$ is defined for $a \in A_T$ and $y \in \mathcal{F}_2$. The equation $PH = Q$ of matrices with coefficients in A_T hence implies $P\circ(H\circ u_2) = Q\circ u_2$ for $u_2 \in \mathcal{F}_2^m$ and therefore the asserted inverse map of the projection $\operatorname{proj} = (0\,\mathrm{id}_m)\circ : \mathcal{B}_2 \cong \mathcal{F}_2^m$. ∎

THEOREM AND DEFINITION 4.3 (stabilizable systems). *An IO system as in* (64) *is called* stabilizable with respect to the decompositions (39) and (40) *if there is another IO system $\mathcal{B}' = \left\{\binom{u'}{y'} \in \mathcal{F}^{p+m};\ P'\circ y' = Q'\circ u'\right\}$ such that the feedback system $\mathcal{B}'' := \operatorname{feedback}(\mathcal{B},\mathcal{B}')$ according to* (20) *and* 21 *is well-posed and stable in the sense of Theorems* 2.7 *and* 4.2. *If this is the case, then*

$$\text{(66)}\qquad A_T^{1\times l} = U_{\mathfrak{T}} \oplus U'_{\mathfrak{T}}\ \textit{and}\ \mathcal{F}_2^{p+m} = \mathcal{B}_2 \oplus \mathcal{B}'_2,$$

and $\mathcal{B}'$ is called a stabilizing compensator *of $\mathcal{B}$.*

Proof. According to Theorem 2.7 the direct sum decomposition

$$(\mathcal{B}''^0)^\perp = \mathcal{B}^\perp \oplus \mathcal{B}'^\perp \text{ holds and implies } (\mathcal{B}''^0)^\perp_{\mathfrak{T}} = \mathcal{B}^\perp_{\mathfrak{T}} \oplus \mathcal{B}'^\perp_{\mathfrak{T}}.$$

The stability of $\mathcal{B}''$ signifies that $\mathcal{B}''^0_2 = 0$ or $(\mathcal{B}''^0)^\perp_{\mathfrak{T}} = A_T^{1\times l}$, and hence we have the assertion. ∎

Direct decompositions as in (66) appear in almost all stabilization theories, often disguised as Bezout identities for matrices. The next theorem contains a test for stabilizability of the IO system $\mathcal{B}$ and the construction of a stabilizing compensator. It is just a reformulation of Theorem 2.13.

Let

$$U_{\rm st} = A^{1\times k_1} R_{\rm st},\ R_{\rm st} = (P_{\rm st}, -Q_{\rm st}) \in A^{k_1\times(p+m)} \tag{67}$$

be the largest submodule of

$$\begin{gathered} A^{1\times l} \text{ with } U_{\mathfrak{T}} = (U_{\rm st})_{\mathfrak{T}} = A_T^{1\times k_1} R_{\rm st};\ \text{hence} \\ A_{\mathfrak{p}}^{1\times k} R = U_{\mathfrak{p}} = (U_{\rm st})_{\mathfrak{p}} = A_{\mathfrak{p}}^{1\times k_1} R_{\rm st}\ \forall \mathfrak{p} \in \mathcal{P}_2 \end{gathered} \tag{68}$$

according to (62) and Lemma/Definition 3.6. The use of $R_{\rm st}$ is necessary since epimorphisms in $\mathrm{Mod}_{A,\mathfrak{T}}$ are not surjective, and hence $U_{\mathfrak{T}}$ is not generated over A_T by the rows of R in general. Since $U \subset U_{\rm st}$, there is a matrix X such that

$$\begin{gathered} R = XR_{\rm st};\ \text{hence } P = XP_{\rm st} \text{ and } p = \mathrm{rank}(P) \le \mathrm{rank}(P_{\rm st}) \le \mathrm{rank}(R_{\rm st}). \\ \text{Moreover, } p = \mathrm{rank}(R) = \mathrm{rank}(U) = \mathrm{rank}(U_{\rm st}) = \mathrm{rank}(R_{\rm st}), \text{ and therefore} \\ p = \mathrm{rank}(P_{\rm st}) = \mathrm{rank}(R_{\rm st}). \end{gathered}$$

Thus the behavior

$$\mathcal{B}_{\rm st} := U_{\rm st}^{\perp} = \left\{ \begin{pmatrix} y \\ u \end{pmatrix};\ P_{\rm st} \circ y = Q_{\rm st} \circ u \right\} \subset \mathcal{B} \tag{69}$$

is an IO behavior with the same IO structure and steady state as $\mathcal{B}$. Due to $K \otimes_A U = K \otimes_A U_{\rm st}$ from Lemma/Definition 3.6, $\mathcal{B}$ and $\mathcal{B}_{\rm st}$ have also the same transfer matrix H.

THEOREM 4.4 (characterization of stabilizable behaviors). *The following assertions are equivalent for the IO behavior* (64)*:*

1. *The behavior $\mathcal{B}$ is stabilizable.*
2. *$U_{\mathfrak{T}} = A_T^{1\times k_1} R_{\rm st}$ is a direct summand of $A_T^{1\times l}$.*
3. *There is a matrix*

$$\begin{gathered} G_1 \in A_T^{l\times k_1} \text{ such that } R_{\rm st} = R_{\rm st} G_1 R_{\rm st}, \text{ and then} \\ E_1 := G_1 R_{\rm st} = E_1^2 \in A_T^{l\times l} \text{ with } U_{\mathfrak{T}} = A_T^{1\times l} E_1 = U_{\mathfrak{T}}. \end{gathered}$$

4. *With G_1 and E_1 from item 3 there is a matrix*

$$\begin{gathered} X \in A_T^{l\times k_1} \text{ with } R_{\rm st} X R_{\rm st} = 0 \text{ such that } E := E_1 + XR_{\rm st} = E^2 \in A^{l\times l}, \\ U_{\mathfrak{T}} = A_T^{1\times l} E \text{ and } \mathrm{rank}\left((\mathrm{id}_l - E) \begin{pmatrix} 0 \\ \mathrm{id}_m \end{pmatrix} \right) = m. \end{gathered}$$

If these conditions are satisfied, choose $E \in A_T^{l\times l}$ according to item 4. Let $t \in T$ be 1 or the greatest common divisor of the denominators of E. Define

$$\begin{gathered} R' := (-Q'P') := t(\mathrm{id}_l - E) \in A^{l\times(p+m)};\ \text{hence} \\ \mathrm{rank}(R') = l - \mathrm{rank}(E) = l - p = m = \mathrm{rank}(P') \text{ and} \\ \mathcal{B}' := \left\{ \begin{pmatrix} u' \\ y' \end{pmatrix} \in \mathcal{F}^{p+m};\ P' \circ y' = Q' \circ u' \right\}. \end{gathered}$$

Then $\mathcal{B}'$ is a stabilizing compensator *of $\mathcal{B}$, i.e., $\mathcal{B}'$ is an IO behavior with input u', and the feedback system $\mathcal{B}'' = \mathrm{feedback}(\mathcal{B}, \mathcal{B}')$ is well-posed and stable.*

Proof. $1 \Rightarrow 2$: This follows from Theorem 4.3.

$2 \Leftrightarrow 3$: This is an application of Theorem 2.13(1) to the A_T-module $A_T^{1\times l}/U_{\mathfrak{T}}$.

$3 \Rightarrow 4$: This implication follows from Theorem 2.14.

$4 \Rightarrow 1$: Construct R' and $\mathcal{B}'$ as indicated. The equalities $\mathrm{rank}(R') = \mathrm{rank}(P') = m$ show that $\mathcal{B}'$ is an IO system with the desired IO structure. By construction,

$$U_{\mathfrak{T}} = A_T^{1\times k_1} R_{\mathrm{st}} = A_T^{1\times l} E,\ p = \mathrm{rank}(U) = \mathrm{rank}(E),$$
$$U' := \mathcal{B}'^{\perp} = A^{1\times l} t(\mathrm{id}_l - E) \ \Rightarrow\ U'_{\mathfrak{T}} = A_T^{1\times l} t(\mathrm{id}_l - E) = A_T^{1\times l}(\mathrm{id}_l - E),$$
$$U \cap U' \subseteq U_{\mathfrak{T}} \cap U'_{\mathfrak{T}} = 0 \ \Rightarrow\ A^{1\times(k+l)} \begin{pmatrix} P & -Q \\ -Q' & P' \end{pmatrix} = U \oplus U'.$$

The last equation shows that $\mathcal{B}''$ is well-posed with

$$(\mathcal{B}''^0)^{\perp} = U \oplus U' \text{ and } (\mathcal{B}''^0)^{\perp}_{\mathfrak{T}} = U_{\mathfrak{T}} \oplus U'_{\mathfrak{T}} = A_T^{1\times l} E \oplus A_T^{1\times l}(\mathrm{id}_l - E) = A_T^{1\times l}.$$

The last equation signifies the stability of $\mathcal{B}''$. ∎

Remark 4.5. Condition 2 of the preceding theorem is equivalent to the A_T-projectivity of $A_T^{1\times l}/U_{\mathfrak{T}}$, and then this module coincides with $M_{\mathfrak{T}}$. This does not imply that U_T is a direct summand of $A_T^{1\times l}$ or that M_T is A_T-projective. If, however, this is the case, then condition 2 follows and $U_T = U_{\mathfrak{T}}$, $M_T = M_{\mathfrak{T}}$. We remark that, in general, A_T is not projective in $\mathrm{Mod}_{A,\mathfrak{T}}$ since epimorphisms are not surjective in this category. Therefore condition 2 has been expressed without using the notion of projectivity.

THEOREM 4.6 (parametrization of stabilizing controllers). *Assume that $\mathcal{B}$ from* (64) *is stabilizable and that E_1 is the matrix from item* 3 *of the preceding theorem. The steady state parts $\mathcal{B}'_2 \subset \mathcal{F}_2^l$ of the stabilizing compensators $\mathcal{B}'$ of $\mathcal{B}$ are uniquely determined by the idempotent matrices*

$$E = E^2 \in A_T^{l\times l} \ \textit{with}\ \mathrm{rank}\left((\mathrm{id}_l - E)\begin{pmatrix} 0 \\ \mathrm{id}_m \end{pmatrix}\right) = m,$$
$$\mathcal{B}^{\perp}_{\mathfrak{T}} = A_T^{1\times l} E,\ \mathcal{B}'^{\perp}_{\mathfrak{T}} = A_T^{1\times l}(\mathrm{id}_l - E),$$

and these are parametrized by the bijection of Theorem 2.14 *applied to the direct summand $\mathcal{B}^{\perp}_{\mathfrak{T}}$ of $A_T^{1\times l}$ or the projective A_T-module $A_T^{1\times l}/\mathcal{B}^{\perp}_{\mathfrak{T}}$.*

5. Continuous and discrete stability and stabilization. We specialize the results of the preceding section to complex partial differential equations on $\mathbb{R}^r \ni z$; i.e., we assume $A := \mathbb{C}[s] = \mathbb{C}[s_1, \dots, s_r]$, the data from (64), and Example 3.1 with an arbitrary decomposition

$$\mathbb{C}^r = \Lambda_1 \uplus \Lambda_2,\ \mathcal{F} := \mathcal{D}'(\mathbb{R}^r)_{\mathrm{lf}},\ \mathcal{F}(\lambda) := \mathbb{C}[z]\exp(\lambda \bullet z) \cong E(\mathbb{C}[s]/\mathfrak{m}_\lambda),$$
$$\mathrm{Ass}(\mathcal{F}) = \mathrm{Max}(\mathbb{C}[s]) = \mathcal{P}_1 \uplus \mathcal{P}_2,\ \mathcal{P}_j := \{\mathfrak{m}_\lambda;\ \lambda \in \Lambda_j\}, \tag{70}$$
$$\mathcal{F} = \oplus_{\lambda\in\mathbb{C}^r} \mathcal{F}(\lambda) = \mathcal{F}_1 \oplus \mathcal{F}_2,\ \mathcal{F}_1 := \oplus_{\lambda\in\Lambda_1} \mathcal{F}(\lambda),\ \mathcal{F}_2 := \oplus_{\lambda\in\Lambda_2} \mathcal{F}(\lambda).$$

Standard examples for such decompositions are those from (47).

The main goal of this section is to show that for these data the stable systems according to Theorem 4.2 have various stability properties known from the one-dimensional theory, and that therefore the stability terminology and the abstract

theorems of the preceding section are justified. At the end of this section we explain the necessary modifications for the discrete case.

For any polynomial ideal $\mathfrak{a} \subset \mathbb{C}[s]$ we define its *algebraic variety* as usual as

$$\begin{aligned} V(\mathfrak{a}) &:= \{\lambda \in \mathbb{C}^r;\ \forall t \in \mathfrak{a}:\ t(\lambda) = 0\}, \\ \text{in particular } V(t) &:= V(\mathbb{C}[s]t) = \{\lambda \in \mathbb{C}^r;\ t(\lambda) = 0\}. \end{aligned} \tag{71}$$

The maximal ideals of $A = \mathbb{C}[s]$ are the

$$\begin{gathered} \mathfrak{m}_\lambda := \{t \in \mathbb{C}[s];\ t(\lambda) = 0 \text{ or } \lambda \in V(t)\},\ \lambda \in \mathbb{C}^r;\ \text{hence} \\ \lambda \in V(\mathfrak{a}) \ \Leftrightarrow\ \mathfrak{a} \subseteq \mathfrak{m}_\lambda, \end{gathered}$$

and the multiplicative monoid T from (48) is

$$\begin{aligned} T &:= \cap_{\lambda \in \Lambda_2}(A \setminus \mathfrak{m}_\lambda) = \{t \in A;\ \forall \lambda \in \Lambda_2:\ t(\lambda) \neq 0\} \\ &= \{t \in A;\ V(t) \subset \Lambda_1\};\ \text{hence}\ \lambda \in \Lambda_2\ \Rightarrow\ \mathfrak{m}_\lambda \cap T = \emptyset. \end{aligned} \tag{72}$$

The quotient rings $A_\mathfrak{p}$, $\mathfrak{p} \in \mathcal{P}_2$, and A_T are

$$\begin{aligned} A(\lambda) &:= A_{\mathfrak{m}_\lambda} = \left\{\frac{a}{t} \in \mathbb{C}(s);\ t(\lambda) \neq 0\right\}, \\ A_T &= \left\{\frac{a}{t} \in \mathbb{C}(s);\ \forall \lambda \in \Lambda_2:\ t(\lambda) \neq 0\right\}. \end{aligned} \tag{73}$$

Quotient rings A_T of this type are customarily used in stabilization theory as rings of SISO-stable plants [26], [25]. From (70) and (43) we further obtain direct decompositions of $\mathcal{B}$ and likewise of $\mathcal{B}^0$:

$$\begin{gathered} \mathcal{B} := \oplus_{\lambda \in \mathbb{C}^r} \mathcal{B}(\lambda) = \mathcal{B}_1 \oplus \mathcal{B}_2,\ \text{where} \\ \mathcal{B}_1 := \mathcal{B} \cap \mathcal{F}_1^l,\ \mathcal{B}_2 := \mathcal{B} \cap \mathcal{F}_2^l,\ \mathcal{B}(\lambda) := \mathcal{B} \cap \mathcal{F}(\lambda)^l \\ \underset{\text{ident.}}{=} \operatorname{Hom}_{\mathbb{C}[s]}(M, \mathcal{F}(\lambda)) \underset{\text{ident.}}{=} \operatorname{Hom}_{A(\lambda)}(M_{\mathfrak{m}_\lambda}, \mathcal{F}(\lambda)). \end{gathered} \tag{74}$$

For the system $\mathcal{B}$ from (64) its variety $\operatorname{sing}(\mathcal{B})$ of *rank singularities* (resp., the *characteristic variety* $\operatorname{char}(M^0) = \operatorname{char}(\mathcal{B}^0)$) of its autonomous part are [11, Thm. 7.69, Cor. 7.71, Rem. 7.72, Cor. 7.78], [28, Thm. 4.4]

(75)

$$\begin{aligned} \operatorname{sing}(\mathcal{B}) &:= \{\lambda \in \mathbb{C}^r;\ M_{\mathfrak{m}_\lambda} \text{ is not free}\} = \{\lambda \in \mathbb{C}^r;\ \operatorname{rank}(R(\lambda)) < \operatorname{rank}(R) = p\}, \\ \operatorname{char}(\mathcal{B}^0) &:= \operatorname{char}(M^0) := \operatorname{sing}(\mathcal{B}^0) = \{\lambda \in \mathbb{C}^r;\ M^0_{\mathfrak{m}_\lambda} \neq 0\} \\ &= \{\lambda \in \mathbb{C}^r;\ \operatorname{rank}(P(\lambda)) < \operatorname{rank}(P) = p\} = V(\operatorname{ann}(M^0)), \\ &\text{where } \operatorname{ann}(M^0) := \{t \in A;\ tM^0 = 0\}. \end{aligned}$$

We remark that the characteristic variety of a nonautonomous system $\mathcal{B}$ coincides with $\mathbb{C}^r$ since $\operatorname{ann}(M) = 0$. The elements of $\operatorname{char}(\mathcal{B}^0)$ are called the *modes* or *poles* or *characteristic values* of $\mathcal{B}$. The decomposition (74) implies

$$\mathcal{B}^0 = \oplus_{\lambda \in \operatorname{char}(\mathcal{B}^0)} \mathcal{B}(\lambda). \tag{76}$$

We further need the controllable subbehavior $\mathcal{B}_{\text{cont}}$ of $\mathcal{B}$, its autonomous part $\mathcal{B}^0_{\text{cont}}$, and their dual modules M_{cont} (resp., M^0_{cont}). There are the exact sequences [28, diagram (5.1)]

$$\begin{gathered} 0 \to t(M) \to M^0 \xrightarrow{\text{can}} M^0_{\text{cont}} \to 0\ \text{ and hence, } \forall \lambda \in \Lambda_2, \\ 0 \to t(M)_{\mathfrak{m}_\lambda} = t(M_{\mathfrak{m}_\lambda}) \to M^0_{\mathfrak{m}_\lambda} \xrightarrow{\text{can}} M^0_{\text{cont},\mathfrak{m}_\lambda} \to 0, \end{gathered} \tag{77}$$

where $t(M)$ is the torsion submodule of M.

These exact sequences and (16) directly imply [28, Thm. 5.3, Cor. 5.4]

$$\begin{aligned}\operatorname{char}(\mathcal{B}^0_{\mathrm{cont}}) &= \text{set of poles of } H \subset \operatorname{char}(\mathcal{B}^0) = \operatorname{char}(\mathcal{B}^0_{\mathrm{cont}}) \cup \operatorname{char}(t(M)),\\ &\text{where } \operatorname{char}(t(M)) = \{\lambda \in \mathbb{C};\ t(M)_{\mathfrak{m}_\lambda} \neq 0\}.\end{aligned} \tag{78}$$

The modes or poles of $\mathcal{B}$ in $\operatorname{char}(\mathcal{B}^0_{\mathrm{cont}})$ are called *controllable* and coincide with the poles of H. In the trivial one-dimensional example $s_1^2 \circ y = s_1 \circ u$ we have

$$t(M) \cong A/As_1 \neq 0 \text{ and } \operatorname{char}(\mathcal{B}^0) = \operatorname{char}(\mathcal{B}^0_{\mathrm{cont}}) = \operatorname{char}(t(M)) = \{0\}.$$

The following simple theorem characterizes stable behaviors and is related to the principal Theorem 7.2 from [29] which has, however, been shown only for the cases $p = k = 1$ or $r \leq 2$ or for regions Λ_2 which are ideal-convex (see Theorem/Definition 5.6 and Example 5.7 below).

THEOREM AND DEFINITION 5.1 (Λ_2-stability). *For the behavior $\mathcal{B}$ from* (64) *and the decomposition* (70) *the following statements are equivalent:*

1. *$\mathcal{B}$ is stable in the sense of Theorem/Definition* 4.2*, i.e., $\mathcal{B}^0 \subset \mathcal{F}_1^p$ or $M^0_{\mathfrak{m}_\lambda} = 0$ $\forall \lambda \in \Lambda_2$.*
2. *$\operatorname{char}(\mathcal{B}^0) \subset \Lambda_1$ or $\operatorname{char}(\mathcal{B}^0) \cap \Lambda_2 = \emptyset$.*
3. *$M^0_{\mathrm{cont},\mathfrak{m}_\lambda} = t(M_{\mathfrak{m}_\lambda}) = 0$ $\forall \lambda \in \Lambda_2$ or, in other words,*
   (i) *$\operatorname{char}(\mathcal{B}^0_{\mathrm{cont}}) \cap \Lambda_2 = \emptyset$.*
   (ii) *For all $\lambda \in \Lambda_2$ the module $M_{\mathfrak{m}_\lambda}$ is torsion free.*
4. (i) *The transfer matrix H is stable; i.e., by definition, $H \in A_T^{p\times m}$.*
   (ii) *For all $\lambda \in \Lambda_2$ the module $M_{\mathfrak{m}_\lambda}$ is torsion free or the $\mathcal{F}(\lambda)$ behavior $\mathcal{B}(\lambda) := \left\{ \binom{y}{u} \in \mathcal{F}(\lambda)^{p+m};\ P \circ y = Q \circ u \right\}$ is controllable.*

Then $\mathcal{B}$ is called Λ_2-stable.

Proof. $1 \Leftrightarrow 2$ according to definition (75).

$1, 2 \Leftrightarrow 3$ follows from the exactness of the sequences in (77) and the equivalence $1 \Leftrightarrow 2$ applied to $\mathcal{B}^0_{\mathrm{cont}}$ instead of $\mathcal{B}^0$.

$1 \Leftrightarrow 4$ is a special case of Theorem/Definition 4.2, $1 \Leftrightarrow 4$. ∎

Remarks 5.2.

1. Once the data from (70) have been chosen we call the region Λ_1, the polynomials in T, the rational functions in A_T, and the polynomial-exponential functions in $\mathcal{F}_1$ *stable* and Λ_2 the *unstable* region or domain of instability [25, p. 1692]. Stable rational functions are those without poles in the unstable region. Of course, not all unstable regions Λ_2 are of practical importance.
2. The preceding theorem shows that stability of $\mathcal{B}$ in the sense of this paper is characterized both by properties 1 and 2 of its autonomous part, and by the stability of the transfer matrix H together with 4(ii), interpreted as *external* stability due to the following theorems.
3. Trivial systems satisfying $\mathcal{B}^0 = 0$ are stable for each Λ_2.
4. A one-dimensional IO system ($r = 1$) is stable with respect to $\Lambda_1 := \{z \in \mathbb{C};\ \Re(z) < 0\}$ if and only if its autonomous part is asymptotically stable or, equivalently, if its transfer matrix is stable and its singular variety is also contained in Λ_1. In this case, condition 4(ii) is equivalent to

$$\operatorname{sing}(\mathcal{B}) \cap \Lambda_2 = \emptyset \text{ or } \operatorname{rank}(R(\lambda)) = \operatorname{rank}(R)\ \forall \lambda \in \Lambda_2$$

since torsion freeness and freeness of $M_{\mathfrak{m}_\lambda}$ coincide in dimension 1. Recall that $\mathcal{B}$ is controllable if and only if $\operatorname{sing}(\mathcal{B}) = \emptyset$. Lemma 17 from [26, p. 103] is a special case of the implication $4 \Rightarrow 1$ of Theorem/Definition 5.1.

5. In most papers on multidimensional stabilization the systems are discrete and described by a transfer operator or IO map H, and stability signifies just the stability of H [26], [6], [23], [25], [31], [32], [7], [8], [17], [18], so our stability notion is stronger. We remark, however, that for multidimensional systems and nonproper H this transfer matrix cannot, in general, be considered as an operator on the usual function spaces, and therefore properness of H is usually required in the literature. We do not assume this since properness is rather restrictive for multidimensional systems in contrast to one-dimensional systems. For instance, none of the standard equations

$$P \circ y = u,\ P = s_1 + s_2, s_1 - s_2^2, s_1^2 + / - s_2^2$$

has a proper transfer function.
6. If the first independent variable z_1 is distinguished as time and if $\Lambda_2 = \mathbb{C}_+ \times i\mathbb{R}^{r-1}$, Wood, Sule, and Rogers [29, Def. 3.1] call the condition

$$\mathrm{char}(\mathcal{B}^0) \cap \Lambda_2 = \emptyset \ \ (\text{resp.},\ \mathrm{char}(\mathcal{B}^0_{\mathrm{cont}}) \cap \Lambda_2 = \emptyset)$$

the *CV condition* for the autonomous behavior $\mathcal{B}^0$ (resp., $\mathcal{B}^0_{\mathrm{cont}}$) and consider it as the stability condition for autonomous behaviors [29, p. 1500].
7. For the unstable regions Λ_2 from (47) and $r > 1$ the system $\mathcal{B}^0 \subset \mathcal{F}_1^p$ contains, in general, many polynomial-exponential functions which are not stable in a naive sense. This is unavoidable due to the interplay of conditions 2 and 4(i) of the theorem. Indeed, with increasing Λ_1 the sets of stable polynomial-exponential functions, polynomials, and rational functions also grow; hence the generally desired existence of sufficiently many stable rational functions implies the same for the stable polynomial-exponential functions. For instance, for $\Lambda_1 = \emptyset$ a stable system is trivial, whereas for $\Lambda_1 = \mathbb{C}^r$ each system is stable.
8. Consider $\Lambda_2 := \{(\lambda_1, \lambda_2) \in \mathbb{C}^2;\ \Re(\lambda_1), \Re(\lambda_2) \geq 0\}$ and the simple system

$$(s_1 + 1) \circ y = u$$

with the characteristic variety

$$\mathrm{char}(\mathcal{B}^0) = \{-1\} \times \mathbb{C} \text{ and } \mathcal{B}^0 = \oplus_{\lambda_2 \in \mathbb{C}} \mathbb{C}[z_2] \exp(-z_1) \exp(\lambda_2 z_2).$$

This is obviously Λ_2-stable and $\mathcal{B}^0$ contains the functions $f(z) = \exp(-z_1)g(z_2)$ with $g(z_2) := \exp(\lambda_2 z_2)$, $\Re(\lambda_2) > 0$, which grow exponentially with increasing z_2 and are not stable in a naive sense. However, they share this property with their *initial part* $f(0, z_2) = g(z_2)$ and such initial conditions are not permitted according to [29, pp. 1499–1500] and the idea that a *stable system should generate stable outputs for stable inputs and initial conditions.* This requires that the initial value problem can be formulated and uniquely solved. Open Problem 5.13 below addresses this problem for discrete systems.

We are going to show next that a stable system is also *IO stable* in the sense that inputs of various types generate outputs of the same type. Since the used signals are not necessarily bounded, we do not use the acronym BIBO.

The modules $\mathcal{F}(\lambda) = \mathbb{C}[z] \exp(\lambda \bullet z) = E(A/\mathfrak{m}_\lambda)$ (resp., $\mathcal{F}_2$) are $A(\lambda)$-modules (resp., A_T-modules). The module $\mathcal{F}(\lambda)$ has the canonical increasing filtration of

finite-dimensional $A(\lambda)$-submodules [12, Eq. 1.17, Thm. 1.25, Thm. 6.6]

$$\begin{gathered}\mathcal{F}(\lambda) = \cup_{k=0}^{\infty} \mathcal{F}(\lambda)_k \text{ with} \\ \mathcal{F}(\lambda)_k := \{y \in \mathcal{D}'(\mathbb{R}^r);\ \mathfrak{m}_\lambda^{k+1} \circ y = 0\} = \mathbb{C}[z]_{\le k} \exp(\lambda \bullet z), \text{ where} \\ \mathbb{C}[z]_{\le k} := \{f \in \mathbb{C}[z];\ \deg(f) \le k\}\end{gathered} \tag{79}$$

and deg denotes the total degree of a polynomial in $\mathbb{C}[z_1, \dots, z_r]$.

Theorem and Definition 5.3 (IO stability).

1. *Let $t \in A \setminus \mathfrak{m}_\lambda$ or $t(\lambda) \neq 0$ and $y \in \mathcal{F}(\lambda)_k$. Then $\bar{t}$ is invertible in the $\mathbb{C}$ finite-dimensional local ring $A/\mathfrak{m}_\lambda^{k+1}$ or $At + \mathfrak{m}_\lambda^{k+1} = A$. Via Gröbner bases one constructs $t_1 \in A$ such that*

$$t_1 t \equiv 1 (\mathfrak{m}_\lambda^{k+1}) \text{ or } \overline{t_1 t} = 1 \in A/\mathfrak{m}_\lambda^{k+1}.$$

Then the differential operator $t\circ : \mathcal{F}(\lambda)_k \to \mathcal{F}(\lambda)_k$ is bijective and its inverse is the differential operator $t_1\circ : \mathcal{F}(\lambda)_k \to \mathcal{F}(\lambda)_k$. Therefore the scalar multiplication with $\frac{a}{t} \in A(\lambda) = \mathbb{C}[s]_{\mathfrak{m}_\lambda}$ on $\mathcal{F}(\lambda)_k$ is given by the differential operator

$$\frac{a}{t}\circ : \mathcal{F}(\lambda)_k \to \mathcal{F}(\lambda)_k,\ y \mapsto (at_1) \circ y.$$

2. *If $H \in A_T^{p\times m}$ is a stable rational matrix and $u \in \mathcal{F}_2^m = \oplus_{\lambda\in\Lambda_2} \mathbb{C}[z]^m \exp(\lambda \bullet z)$ is an input of the form*

$$u = \sum_{\lambda\in\Lambda_2} f_\lambda(z) \exp(\lambda \bullet z) \text{ with } f_\lambda \in \mathbb{C}[z]^m_{\le k}\ \forall \lambda \in \Lambda_2$$

and $f_\lambda = 0$ for almost all λ, then the corresponding output $y := H \circ u$ has the same form

$$y = \sum_{\lambda\in\Lambda_2} g_\lambda(z) \exp(\lambda \bullet z) \text{ with } g_\lambda \in \mathbb{C}[z]^p_{\le k}\ \forall \lambda \in \Lambda_2$$

and can be computed with the algorithm from part 1. *This property of the operator $H\circ : \mathcal{F}_2^m \to \mathcal{F}_2^p$ is suggestively called its* IO stability *with respect to the decomposition* (70).

3. *Item* 2 *is applicable to any stable system $\mathcal{B}$ according to Theorem/Definition* 5.1 *with its stable transfer matrix H; in particular $\mathcal{B}_2 := \mathcal{B} \cap \mathcal{F}_2^l = \left\{\binom{H\circ u}{u};\ u \in \mathcal{F}_2^m\right\}$ is its steady state part.*

Proof. Item 1 follows from

$$tt_1 + a = 1,\ a \in \mathfrak{m}_\lambda^{k+1},\ \mathfrak{m}_\lambda^{k+1} \circ y = 0 \ \Rightarrow\ t_1 \circ t \circ y = y.$$

Items 2 and 3 are direct consequences of 1 and Theorem/Definition 4.2. ∎

The next IO stability theorems are just reformulations of the results [4, Thm. on p. 16 and Thm. 2 on p. 24]. These results also play an essential part in the stability paper [29, subsections 5, 6, 7]. As in [4, pp. 10–12] let $\mathcal{S}$ ($\supset C_0^\infty(\mathbb{R}^r)$) denote the space of rapidly decreasing C^∞ functions and $\mathcal{S}'$ ($\subset \mathcal{D}'(\mathbb{R}^r)$) its topological dual space of temperate distributions. Further we consider the space $\mathcal{O}$ ($\supset \mathcal{S}$) of slowly increasing C^∞ functions f for which there is an index $m > 0$ and $C > 0$ such that

$$|f^{(\mu)}(z)| \le C(1 + |z|)^m\ \forall\ z \in \mathbb{R}^r,\ \mu \in \mathbb{N}^r,$$

and finally the space $\mathcal{O}'$ ($\subset \mathcal{S}'$) of rapidly decreasing distributions. In the paper [29] the first variable $t := z_1$ is distinguished as time. In this case the spaces

$$\mathbb{R}^r_+ := \{z \in \mathbb{R}^r;\ t = z_1 \geq 0\} \text{ and}$$
$$\mathcal{F}_{3,+} := \{y \in \mathcal{F}_3;\ \operatorname{supp}(y) \subset \mathbb{R}^r_+\},\ \mathcal{F}_3 = \mathcal{S}, \mathcal{S}', \mathcal{O}, \mathcal{O}',$$

play an important part in [4] and [29]. In the next theorem we use the data from (70)–(79).

THEOREM 5.4 (IO stability).

1. *Let $\mathcal{F}_3$ be one of the spaces $\mathcal{S}, \mathcal{S}', \mathcal{O}, \mathcal{O}'$. If $\Lambda_2 \supset i\mathbb{R}^r$, then $\mathcal{F}_3$ is an A_T-module. In particular, if $H \in A_T^{p\times m}$ is a rational matrix and $u \in \mathcal{F}_3^m$ is an input, then $y := H \circ u \in \mathcal{F}_3^p$ is an output of the same type. If $\mathcal{B}$ is stable, then according to Theorem/Definition* 5.1 *this holds.*

2. *If the variable $t := z_1$ is distinguished and if*

$$\Lambda_2 \supset \overline{\mathbb{C}_+} \times i\mathbb{R}^{r-1},\ \overline{\mathbb{C}_+} := \{\lambda \in \mathbb{C};\ \Re(\lambda) \geq 0\}$$

as in [29]*, then the statement of item* 1 *applies to the spaces $\mathcal{S}_+$ and $(\mathcal{O}')_+$.*

If, in addition, $\mathcal{B}^0$ is time-autonomous in the sense of [29, *Def.* 2.1, *Thm.* 2.2]*, then*

$$\mathcal{F}_3^m \cong \mathcal{B} \cap ((\mathcal{D}')^p_+ \times \mathcal{F}_3^m),\ u \mapsto \begin{pmatrix} H \circ u \\ u \end{pmatrix},\ \mathcal{F}_3 = \mathcal{S}_+, (\mathcal{O}')_+. \tag{80}$$

3. *If in the situation of item* 2

$$\Lambda_2 \supset \mathbb{C}_+ \times i\mathbb{R}^{r-1},\ \mathbb{C}_+ := \{\lambda \in \mathbb{C};\ \Re(\lambda) > 0\},$$

then the statement of item 1 *applies to the space $(\mathcal{S}')_+$.*

Proof. 1. Since $i\mathbb{R}^r \subset \Lambda_2$, each $t \in T$ has no zero in $i\mathbb{R}^r$. According to [4, Thm. on p. 16] this is necessary and sufficient for $t\circ : \mathcal{F}_3 \to \mathcal{F}_3$ to be bijective, and this in turn implies that $\mathcal{F}_3$ is an A_T-module with the scalar multiplication

$$\frac{a}{t} \circ u =: y \text{ with } t \circ y = a \circ u.$$

2, 3. These assertions follow from [4, Thm. 2, p. 22] in the same fashion. It remains to show the surjectivity of (80). Assume that

$$u \in \mathcal{F}_3^m,\ y := H \circ u,\ y_1 \in (\mathcal{D}')^p_+, \text{ and } \begin{pmatrix} y_1 \\ u \end{pmatrix} \in \mathcal{B}, \text{ i.e., } P \circ y_1 = Q \circ u. \text{ Then}$$
$$y_1 - y \in (\mathcal{D}')^p_+ \text{ and } P \circ (y_1 - y) = 0.$$

The time-autonomy and [29, Thm. 2.2] imply $y_1 = y = H \circ u$ and hence the assertion. ∎

Remarks 5.5.

1. The preceding theorem suggests to require $i\mathbb{R}^r \subset \Lambda_2$ for the decompositions (70) in context with stability questions of partial differential equations. The standard set

$$\Lambda_2 := \{\lambda \in \mathbb{C}^r;\ \forall \rho = 1, \ldots, r:\ \Re(\lambda_\rho) \geq 0\} = \overline{\mathbb{C}_+}^r$$

satisfies the assumptions of items 1–3.

2. The condition $\binom{H\circ u}{u} \in \mathcal{B}\cap\mathcal{F}_3^{p+m}$ implies in particular that the input u can be freely chosen in $\mathcal{F}_3^m$ and therefore condition 1 of Theorem 7.2 of [29] which, however, was shown only for $p = m = 1$ or $r \le 2$. The isomorphism (80) is the IO stability of $\mathcal{B}$ according to [29, Def. 7.1]. Theorem/Definition 5.1 and Theorem 5.4 show that stability in the sense of the present paper for $\Lambda_2 = \mathbb{C}_+ \times i\mathbb{R}^{r-1}$ implies the various stability notions of that paper.

The next theorem characterizes those sets $\Lambda_2 \subset \mathbb{C}^r$ for which the localization functor $M \mapsto M_{\mathfrak{T}}$ from section 3 is *perfect*, i.e., isomorphic to $M \mapsto M_T$. It turns out that this coincides with *ideal-convexity* of Λ_2 in the sense of [23, Def. on p. 25] or [29, Def. 5.4]. Recall from (62) that $M_T = 0$ implies $M_{\mathfrak{T}} = (M_T)_{\mathfrak{T}} = 0$, in particular $\{\mathfrak{a};\ \mathfrak{a}\cap T \neq \emptyset\} \subseteq \mathfrak{T}$.

THEOREM AND DEFINITION 5.6 (perfect localization and ideal-convexity). *For the decomposition* (70) *and* $A := \mathbb{C}[s]$ *the following assertions are equivalent:*

1. *An A-module is T-torsion if and only if it is $\mathfrak{T}$-torsion, i.e.,*

$$M_T = 0 \ \Leftrightarrow\ M_{\mathfrak{T}} = 0 \underset{(50)}{\Leftrightarrow} \forall\lambda\in\Lambda_2:\ M_{\mathfrak{m}_\lambda} = 0.$$

2. $\mathfrak{T} = \{\mathfrak{a};\ \mathfrak{a}$ *ideal of* A, $T\cap\mathfrak{a} \neq 0\}$.
3. *For each* $M \in \mathrm{Mod}_A$ *the canonical map* (61) $M_T = A_T \otimes_A M \to M_{\mathfrak{T}}$ *is an isomorphism.*
4. $\mathrm{Mod}_{A_T} = \mathrm{Mod}_{A,\mathfrak{T}}$.
5. *The set* Λ_2 *is* ideal-convex *according to* [29, *Def.* 5.4]*; i.e., for each ideal* $\mathfrak{a}$ *of* A *the implication*

$$V(\mathfrak{a})\cap\Lambda_2 = \emptyset \ \Rightarrow\ \mathfrak{a}\cap T \neq \emptyset \text{ or } \exists t\in\mathfrak{a} \text{ with } V(t)\cap\Lambda_2 = \emptyset$$

   holds.
6. *The ideals* $(\mathfrak{m}_\lambda)_T \subset A_T$, $\lambda\in\Lambda_2$, *are the only maximal ideals of* A_T.
7. *The module* $\mathcal{F}_2$ *from* (70) *is a cogenerator in* Mod_{A_T}. *Recall from Lemma* 3.3 *that* $\mathcal{F}_2$ *is an injective A_T-module and an injective cogenerator in* $\mathrm{Mod}_{A,\mathfrak{T}}$.

Stenström [24, *Chap.* XI, *Prop.* 3.4] *talks about* perfect localization *in this context.*

Proof. The equivalence of items 1–4 follows from [24, Chap. XI, Prop. 3.4].

$2 \Leftrightarrow 5$ follows from the equivalences

$$V(\mathfrak{a})\cap\Lambda_2 = \emptyset \ \Leftrightarrow\ \forall\lambda\in\Lambda_2:\ \mathfrak{a}\not\subset\mathfrak{m}_\lambda \text{ or } (A/\mathfrak{a})_{\mathfrak{m}_\lambda} = 0 \underset{(50)}{\Leftrightarrow} \mathfrak{a}\in\mathfrak{T}.$$

The equivalence of items 5 and 6 is a consequence of [23, Prop. 3.1.19], but we give the short proof for completeness.

$5 \Rightarrow 6$: The maximal ideals of A_T are exactly the ideals $\mathfrak{n} = \mathfrak{m}_T$, where $\mathfrak{m}$ is an ideal of A maximal with respect to $\mathfrak{m}\cap T = \emptyset$. Such an $\mathfrak{m}$ is always prime, but not necessarily a maximal ideal of A [10, Thm. 4.1]. Recall that $\mathfrak{m}_\lambda\cap T = \emptyset$ for $\lambda\in\Lambda_2$. Consider such an $\mathfrak{n} = \mathfrak{m}_T$. If $V(\mathfrak{m})\cap\Lambda_2 = \emptyset$, condition 5 implies $\mathfrak{m}\cap T \neq \emptyset$, a contradiction. Hence $V(\mathfrak{m})\cap\Lambda_2 \neq \emptyset$ and therefore there is a $\lambda\in\Lambda_2$ such that $\mathfrak{m}\subseteq\mathfrak{m}_\lambda$ and $\mathfrak{m}_\lambda\cap T = \emptyset$; hence $\mathfrak{m} = \mathfrak{m}_\lambda$ by the maximality of $\mathfrak{m}$.

$6 \Rightarrow 5$: Assume indirectly that $\mathfrak{a}\cap T = \emptyset$ and let $\mathfrak{m}$ be maximal with $\mathfrak{a}\subset\mathfrak{m}$ and $\mathfrak{m}\cap T = \emptyset$. Then $\mathfrak{m}_T$ is a maximal ideal of A_T and therefore by 6 of the form

$$\mathfrak{m}_T = (\mathfrak{m}_\lambda)_T,\ \lambda\in\Lambda_2 \ \Rightarrow\ \mathfrak{a}\subset\mathfrak{m} = \mathfrak{m}_\lambda \ \Rightarrow\ \lambda\in V(\mathfrak{a})\cap\Lambda_2.$$

$4 \Rightarrow 7$: The module $\mathcal{F}_2 = \oplus_{\lambda\in\Lambda_2} E(A/\mathfrak{m}_\lambda)$ is an injective cogenerator in $\mathrm{Mod}_{A,\mathfrak{T}}$ and hence by 4 in Mod_{A_T}.

$7 \Rightarrow 6$: Let $\mathfrak{n} = \mathfrak{m}_T$ be a maximal ideal of A_T as before. The primeness of $\mathfrak{m}$ implies

$$A/\mathfrak{m} \subset (A/\mathfrak{m})_T = A_T/\mathfrak{m}_T = A_T/\mathfrak{n}.$$

Since $\mathcal{F}_2$ is an injective A_T-cogenerator it contains the simple A_T-module $A_T/\mathfrak{n}$ and thus $A/\mathfrak{m}$; hence

$$\mathfrak{m} \in \mathrm{Ass}_A(\mathcal{F}_2) = \{\mathfrak{m}_\lambda;\ \lambda \in \Lambda_2\} \text{ and } \mathfrak{m} = \mathfrak{m}_\lambda \text{ for some } \lambda \in \Lambda_2. \qquad \square$$

Examples 5.7.

1. If $\Lambda_2 \subset \mathbb{C}^r$ is ideal-convex, then

$$\Lambda_2 := \{\lambda \in \mathbb{C}^r;\ \forall t \in T :\ t(\lambda) \neq 0\} \text{ or } \Lambda_1 = \mathbb{C}^r \setminus \Lambda_2 = \cup_{t\in T} V(t), \tag{81}$$

   i.e., Λ_1 is a union of hypersurfaces. Equation (81) is false for

$$\Lambda_2 := \{\lambda \in \mathbb{C}^2;\ \Re(\lambda_1) \geq 0 \text{ or } \Re(\lambda_2) \geq 0\},$$
$$\Lambda_1 = \{\lambda \in \mathbb{C}^r;\ \Re(\lambda_1) < 0, \Re(\lambda_2) < 0\},\ T = \mathbb{C} \setminus \{0\},\ \cup_{t\in T} V(t) = \emptyset.$$

2. In dimension 1 each Λ_2 is ideal-convex.
3. If $r = 2$, (81) characterizes ideal-convexity. In particular, the noncompact regions $\overline{\mathbb{C}^2_+}$ and $\overline{\mathbb{C}_+} \times i\mathbb{R}$ from Theorem 5.4 are ideal-convex, whereas for $r > 2$ this is an open question [29, Thm. 5.5].
4. Each polynomially convex compact subset Λ_2 of $\mathbb{C}^r$ is ideal-convex [23, Prop. 3.1.20, Rem. on p. 28]. Polynomial convexity signifies that

$$\Lambda_2 = \left\{\lambda \in \mathbb{C}^r;\ \forall\ f \in \mathbb{C}[s] :\ |f(\lambda)| \leq \sup_{z\in\Lambda_2} |f(z)|\right\}.$$

   In particular, the closed unit polydisc $\overline{U}^r$, $\overline{U} := \{z \in \mathbb{C};\ |z| \leq 1\}$, is ideal-convex [23, Prop. 3.1.20, Rem. on p. 28].
5. Each compact cuboid Λ_2 of the form

$$\Lambda_2 := \{\lambda \in \mathbb{C}^r;\ \forall \rho = 1, \ldots, r :\ a_\rho \leq \Re(\lambda_\rho) \leq b_\rho,\ c_\rho \leq \Im(\lambda_\rho) \leq d_\rho\},$$
$$\text{where } a_\rho \leq b_\rho,\ c_\rho \leq d_\rho \text{ in } \mathbb{R},\ \rho = 1, \ldots, r, \tag{82}$$

   is ideal-convex. The proof is similar to that of the preceding item in [23] and uses the cohomological theorems A and B concerning coherent modules on Stein spaces for these cuboids and the approximation of holomorphic functions by polynomials on such Λ_2. The proof is omitted.

The proofs of the last two examples use the compactness of K in different places essentially, in particular for the approximation of analytic functions on Λ_2 by polynomials. It seems difficult to derive constructive algorithms from these proofs; see Remark/Open Problem 5.10 below. The theorems A and B, however, are valid in much more generality and can possibly be used to prove ideal-convexity also for certain noncompact subsets Λ_2 of $\mathbb{C}^r$.

THEOREM 5.8 (stabilizability and ideal-convexity).

1. *If $\mathcal{B}$ is stabilizable with respect to* (70)*, then*

$$\mathrm{sing}(\mathcal{B}) \cap \Lambda_2 = \emptyset \text{ or } \mathrm{rank}(R(\lambda)) = \mathrm{rank}(R)\ \forall \lambda \in \Lambda_2.$$

2. *If Λ_2 is ideal-convex, the following assertions are equivalent:*
   (a) *$\mathcal{B}$ is stabilizable.*
   (b) *M_T is a projective A_T-module.*
   (c) i. *The A_T-lattice $\mathcal{M} := A_T^{1\times(p+m)}\binom{H}{\mathrm{id}_m} = A_T^{1\times p}H + A_T^{1\times m} \subset \mathbb{C}(s)^{1\times m}$ is projective.*
   ii. *M_T is torsion free; i.e., $\mathcal{B}_2 := \mathcal{B} \cap \mathcal{F}_2^{p+m}$ is a controllable ${}_{A_T}\mathcal{F}_2$ behavior.*
   (d) $\mathrm{sing}(\mathcal{B}) \cap \Lambda_2 = \emptyset$ *or* $\mathrm{rank}(R(\lambda)) = \mathrm{rank}(R)\ \forall \lambda \in \Lambda_2$.

Proof. 1. According to Theorem 4.4, $U_{\mathfrak{T}}$ is a direct summand of $A_T^{1\times l}$. Hence for all $\lambda_2 \in \Lambda_2$ also $U_{\mathfrak{m}_\lambda} = (U_{\mathfrak{T}})_{\mathfrak{m}_{\lambda,T}}$ is a direct summand of $(A_T)^{1\times l}_{\mathfrak{m}_{\lambda,T}} = A^{1\times l}_{\mathfrak{m}_\lambda}$. Therefore $M_{\mathfrak{m}_\lambda} = A^{1\times l}_{\mathfrak{m}_\lambda}/U_{\mathfrak{m}_\lambda}$ is projective and thus free, and λ_2 is not contained in $\mathrm{sing}(\mathcal{B})$ according (75).

2. (a) $\Leftrightarrow$ (b): Due to the assumed ideal-convexity, we have

$$U_T = U_{\mathfrak{T}},\ M_T = M_{\mathfrak{T}} = A_T^{1\times l}/U_T. \text{ Hence}$$
$$\mathcal{B} \text{ is stabilizable } \underset{\text{Thm. 4.4}}{\Leftrightarrow} U_T \text{ is a direct summand } \Leftrightarrow M_T \text{ is projective.}$$

(b) $\Leftrightarrow$ (c): The assumed torsion freeness of M_T implies the exact sequence (13)

$$A_T^{1\times k} \overset{\circ(P,-Q)}{\longrightarrow} A_T^{1\times(p+m)} \overset{\circ\binom{H}{\mathrm{id}_m}}{\longrightarrow} \mathbb{C}(s)^{1\times m},\ \text{hence}$$
$$M_T = A_T^{1\times(p+m)}/A_T^{1\times k}(P,-Q) \cong A_T^{1\times(p+m)}\begin{pmatrix} H \\ \mathrm{id}_m \end{pmatrix} = \mathcal{M}.$$

Hence M_T is A_T-projective if and only if the lattice $\mathcal{M}$ has this property.

(a) $\Rightarrow$ (d) follows from 1.

(d) $\Rightarrow$ (b): Condition (d) implies that for all $\lambda \in \Lambda_2$ $M_{\mathfrak{m}_\lambda} = (M_T)_{\mathfrak{m}_{\lambda,T}}$ is projective. Since, by Theorem/Definition 5.6(6), the $\mathfrak{m}_{\lambda,T}$, $\lambda \in \Lambda_2$, are all maximal ideals of A_T, the projectivity of M_T follows from [10, Thm. 7.12]. □

Remarks 5.9.

1. For general, not ideal-convex unstable regions, stabilizability is characterized in Theorem/Definition 4.3 and Theorem 4.4.
2. For $r = 1$ and $\Lambda_2 := \{\lambda \in \mathbb{C};\ \Re(\lambda) \geq 0\}$ condition 2(d) coincides with condition 4(ii) from Theorem/Definition 5.1; see item 4 of Remark 5.2. The equivalence (a) $\Leftrightarrow$ (d) is Theorem 5.2.30 of [15], where the stabilizability of $\mathcal{B}$ is, however, defined by asymptotic controllability to zero of its trajectories.
3. The condition 2(c)i of the preceding theorem characterizes internally stabilizable systems according to Quadrat [17, Thm. 3, Eq. (38)] with A_T as a ring of SISO-stable plants.

Remarks and open problems 5.10 (algorithmic questions). The assumptions are those from (64) and (70)–(75). It turns out that *basic algorithmic problems cannot currently be solved.* Refer to [7] and to [30] where the history, the state of the art, and open problems concerning algorithms in multidimensional stability theory are described.

1. According to Theorem/Definition 5.1, the stability of $\mathcal{B}$ is checked via

$$\mathrm{char}(\mathcal{B}^0) \subset \Lambda_1 \text{ or } \mathrm{char}(\mathcal{B}^0) \cap \Lambda_2 = \emptyset, \text{ where}$$
$$\mathrm{char}(\mathcal{B}^0) = V(\mathfrak{a}) \text{ and } \mathfrak{a} := \mathrm{ann}(M^0) = \{f \in \mathbb{C}[s];\ fM^0 = 0\},$$

and $\mathfrak{a}$ can be computed from the matrix $P \in \mathbb{C}[s]^{k\times p}$ via Gröbner bases. Recall from Theorem/Definition 5.6 that

$$V(\mathfrak{a}) \cap \Lambda_2 = \emptyset \;\Leftrightarrow\; \mathfrak{a} \cap T \neq \emptyset \;\forall \text{ ideals } \mathfrak{a}$$

if and only if Λ_2 is ideal-convex. If this is not the case, it is the analogue of the open problem 3 from [7, p. 73] for Λ_2 instead of the closed unit polydisc to decide whether $V(\mathfrak{a}) \cap \Lambda_2 = \emptyset$. No algorithm is presently known. If Λ_2 is ideal-convex, then to decide $\mathfrak{a} \cap T \neq \emptyset$ and to actually construct a $t \in \mathfrak{a} \cap T$ is the analogue of the open problem 4 from [7, p. 73] or problem 1 from [30]. For compact, polynomially convex sets Λ_2, such as the closed unit polydisc, this requires a constructive version of the proof of Example 5.7(4), and even this seems hard to obtain. If

$$[M^0 : \mathbb{C}] < \infty \;\Leftrightarrow\; \mathfrak{a} \text{ is Krull–zero-dimensional } \Leftrightarrow\; V(\mathfrak{a}) = \operatorname{char}(\mathcal{B}^0) \text{ is finite,}$$

then the finite variety $V(\mathfrak{a})$ can be computed via Gröbner bases, and $V(\mathfrak{a}) \cap \Lambda_2 = \emptyset$ can be decided (compare [7, p. 73, Rem.]).

2. Theorem 4.4 is used to test stabilizability and to construct a stabilizing compensator. Presently the computation of a matrix $R_{\mathrm{st}} \in A^{k_{\mathrm{st}}\times l}$ such that

$$\begin{aligned} U_{\mathrm{st}} &= \{x \in A^{1\times l};\ \forall \lambda \in \Lambda_2\ \exists s_\lambda \in A \text{ with} \\ &\qquad s_\lambda(\lambda) \neq 0 \text{ and } s_\lambda x \in U = A^{1\times k}R\} \\ &= A^{1\times k_{\mathrm{st}}}R_{\mathrm{st}} \text{ and hence } U_{\mathfrak{T}} = A_T^{1\times k_{\mathrm{st}}}R_{\mathrm{st}} \end{aligned}$$

is unsolved. If, however, Λ_2 is ideal-convex and $M_{\mathfrak{T}} = M_T$ for all A-modules M, then $U_{\mathfrak{T}} = U_T = A_T^{1\times k}R$ and the construction of R_{st} is superfluous. See Theorem 5.14 for a partial result on the construction of R_{st}. If, in general, a matrix $R_{\mathrm{st}} \in A^{k_{\mathrm{st}}\times l}$ with $U_{\mathfrak{T}} = A_T^{1\times k_{\mathrm{st}}}R_{\mathrm{st}}$ is known, one computes the module L of all solutions $(G_1', t_1) \in A^{l\times k_{\mathrm{st}}} \times A$ of the polynomial linear system

$$R_{\mathrm{st}}G_1'R_{\mathrm{st}} - t_1R_{\mathrm{st}} = 0 \;\Leftrightarrow\; \text{if } t_1 \neq 0 : R_{\mathrm{st}}\frac{G_1'}{t_1}R_{\mathrm{st}} = R_{\mathrm{st}} \tag{83}$$

via Gröbner bases and obtains a system of generators of the ideal

$$\mathfrak{a} := \{t_1 \in A;\ \exists (G_1', t_1) \in L\}. \tag{84}$$

According to Theorem 4.4(3), the system is stabilizable if and only if $\mathfrak{a} \cap T \neq \emptyset$. This is again the open problem quoted in item 1. If

$$t_1 \in \mathfrak{a} \cap T \text{ and } (G_1', t_1) \in L,\ \text{then}\ G_1 := \frac{G_1'}{t_1} \in A_T^{l\times k_{\mathrm{st}}}$$

is a matrix according to Theorem 4.4(3), and

$$E_1 := G_1R_{\mathrm{st}} = E_1^2 \in A_T^{l\times l},\ U_{\mathfrak{T}} = A_T^{1\times l}E_1.$$

Generically, but not always, this matrix already satisfies the rank condition $\operatorname{rank}((\mathrm{id}_l - E_1)\binom{0}{\mathrm{id}_m}) = m$ and can be used to construct a stabilizing compensator of $\mathcal{B}$ according to Theorem 4.4.

3. All stabilizing compensators or idempotent matrices

$$E = E^2 \in A_T^{l\times l} \text{ with } U_{\mathfrak{T}} = A_T^{1\times l}E \text{ and } \operatorname{rank}\left((\mathrm{id}_l - E)\begin{pmatrix}0\\ \mathrm{id}_m\end{pmatrix}\right) = m$$

are constructed according to Theorems 2.14 and 4.6 in the form

$$E = E_1 + XR_{\mathrm{st}},\ X = \sum_{i=1}^{n} \Theta_i X_i,\ \Theta_i \in A_T,$$

where the X_i generate the solution module of the polynomial linear system $R_{\mathrm{st}}X'R_{\mathrm{st}} = 0,\ X' \in A^{l\times k_{\mathrm{st}}}$. Generically, these E satisfy the rank condition $\operatorname{rank}((\mathrm{id}_l - E)\binom{0}{\mathrm{id}_m}) = m$ and can be used to construct all stabilizing compensators of $\mathcal{B}$.

In the remainder of this section we indicate the necessary modifications of the preceding theory for the discrete case of complex *partial difference equations* and the locally finite elements of the A-module $\mathbb{C}^{\mathbb{N}^r}$ [12, Thm. 1.25, Cor. 1.26] with the left shift action

$$(s^\mu \circ y)(\nu) := y(\mu + \nu),\ y \in \mathbb{C}^{\mathbb{N}^r},\ \mu, \nu \in \mathbb{N}^r.$$

For

$$\begin{gathered}\alpha \in \mathbb{C},\ k, i \in \mathbb{N},\ \lambda \in \mathbb{C}^r,\ \mu, \nu \in \mathbb{N}^r \text{ define } e_{\alpha,k} \in \mathbb{C}^{\mathbb{N}},\ e_{\lambda,\mu} \in \mathbb{C}^{\mathbb{N}^r} \text{ by}\\ e_{\alpha,k}(i) := \begin{cases}\binom{i}{k}\alpha^{i-k} & \text{if } \alpha \neq 0\\ \delta_{i,k} & \text{if } \alpha = 0\end{cases},\ e_{\lambda,\mu}(\nu) := \prod_{\rho=1}^{r} e_{\lambda_\rho,\mu_\rho}(\nu_\rho). \text{ Then}\\ (s-\lambda)^\nu \circ e_{\lambda,\mu} = \begin{cases}e_{\lambda,\mu-\nu} & \text{if } \mu \in \nu + \mathbb{N}^r\\ 0 & \text{otherwise}\end{cases} \text{ and}\\ \mathcal{F} := \mathbb{C}_{\mathrm{lf}}^{\mathbb{N}^r} := \{y \in \mathbb{C}^{\mathbb{N}^r};\ [\mathbb{C}[s] \circ y : \mathbb{C}] < \infty\} = \oplus_{\lambda\in\mathbb{C}^r,\,\mu\in\mathbb{N}^r} \mathbb{C}e_{\lambda,\mu}.\end{gathered} \tag{85}$$

Again $\mathcal{F}$ is the minimal injective cogenerator in Mod_A; indeed

$$\mathcal{F}(\lambda) := \oplus_{\mu\in\mathbb{N}^r} \mathbb{C}e_{\lambda,\mu} = E(A/\mathfrak{m}_\lambda)\ \forall \lambda \in \mathbb{C}^r. \tag{86}$$

The Borel isomorphism

$$\mathbb{C}^{\mathbb{N}^r} = \mathbb{C}[[z]] \cong \mathbb{C}[[z]],\ y = \sum_{\mu\in\mathbb{N}^r} y(\mu)z^\mu \mapsto \sum_{\mu\in\mathbb{N}^r} y(\mu)\frac{z^\mu}{\mu!}$$

induces the $\mathbb{C}[s]$ isomorphism

$$\mathcal{F}(\lambda) = \oplus_{\mu\in\mathbb{N}^r} \mathbb{C}e_{\lambda,\mu} \cong \mathbb{C}[z]\exp(\lambda \bullet z),\ e_{\lambda,\mu} \mapsto \frac{z^\mu}{\mu!}\exp(\lambda \bullet z). \tag{87}$$

The decomposition $\mathbb{C}^r = \Lambda_1 \uplus \Lambda_2$ with its implied data from (70) is again arbitrary, but, of course, interesting choices in the discrete case are different from those in the continuous case. Equations (70) to (77) remain valid, and so do Theorems/Definitions 5.1 and 5.3 if $\mathcal{F}(\lambda)_k$ from (79) is replaced with

$$\mathcal{F}(\lambda)_k := \{y \in \mathbb{C}^{\mathbb{N}^r};\ \mathfrak{m}_\lambda^{k+1} \circ y = 0\} = \oplus_{\mu\in\mathbb{N}^r,\,|\mu|\le k} \mathbb{C}e_{\lambda,\mu},\ |\mu| := \mu_1 + \cdots + \mu_r. \tag{88}$$

A standard example for Λ_2 in the discrete case, in particular for $r = 1$, is

$$\Lambda_2 := \{w \in \mathbb{C};\ |w| \geq 1\}^r, \text{ but not } \overline{U}^r \text{ with } \overline{U} := \{w \in \mathbb{C};\ |w| \leq 1\}, \tag{89}$$

where $\overline{U}^r$ is the closed unit polydisc [7, p. 60], and for simplicity we assume this Λ_2 in what follows. This seeming contrast to [7] and most other papers in this field comes from the fact that these papers do not consider IO systems, but systems defined by a *proper* or *causal* IO map H [6], [32, sec. 3.2]. To explain this connection we identify

$$\begin{gathered} z_\rho := s_\rho^{-1},\ A := \mathbb{C}[s] \subset \mathbb{C}(s) = \mathbb{C}(z) = \operatorname{quot}(A),\ \mathbb{C}[z] \subset \mathbb{C}^{\mathbb{N}^r} = \mathbb{C}[[z]]. \text{ Let} \\ \mathfrak{n} :=_{\mathbb{C}[z]} \langle z_1, \ldots, z_r \rangle := \{g \in \mathbb{C}[z];\ g(0) = 0\} \end{gathered} \tag{90}$$

be the distinguished maximal ideal of $\mathbb{C}[z]$. Then [6, Def. 3.16], [11, sec. 6, Thm. 60]

$$\mathbb{C}[z]_{\mathfrak{n}} = \{n(z)/d(z);\ n, d \in \mathbb{C}[z],\ d(0) \neq 0\} = \operatorname{quot}(A) \cap \mathbb{C}[[z]] \tag{91}$$

is the ring of *proper or causal* rational functions where the term "causal" is due to the following property. The power series ring $\mathbb{C}^{\mathbb{N}^r} = \mathbb{C}[[z]]$ is a module over itself via convolution, also denoted by $\circ$, and therefore also a module over the ring of proper rational functions. In particular [11, sec. 6, Cor. 45], if the transfer matrix H of $\mathcal{B}$ is proper, any input $u \in (\mathbb{C}^{\mathbb{N}^r})^m = \mathbb{C}[[z]]^m$ gives rise to an output

$$y := H \circ u \in \mathbb{C}[[z]]^p \text{ with } P \circ y = P \circ (H \circ u) = (PH) \circ u = Q \circ u \text{ or } \begin{pmatrix} y \\ u \end{pmatrix} \in \mathcal{B}.$$

As noted before, properness is a rather restrictive property in the multidimensional situation and therefore we do not assume it in the present paper. For instance, the transfer functions $(s_1 + s_2)^{-1} = \frac{z_1 z_2}{z_1 + z_2}$ of $(s_1 + s_2) \circ y = u$ and of other standard partial difference or differential equations are not proper.

With the data from (89) and the terminology from [6, Def. 3.47], [7, p. 60], we see that

$$S := \left\{ h = \frac{n(z)}{d(z)} \in \mathbb{C}(z) = \mathbb{C}(s);\ \forall w \in \overline{U}^r :\ d(w) \neq 0 \right\} \subset \mathbb{C}[z]_{\mathfrak{n}} \tag{92}$$

is the ring of *structurally stable* rational functions, whereas the denominators $d(z)$ are called structurally stable polynomials.

LEMMA 5.11. $S \subseteq A_T \cap \mathbb{C}[z]_{\mathfrak{n}} = A_T \cap \mathbb{C}[[z]]$.

Proof. Let $h = \frac{n(z)}{d(z)} \in S$ be structurally stable with relatively prime n and d. Choose $\nu \in \mathbb{N}^r$ such $s^\nu n, s^\nu d \in \mathbb{C}[s]$; hence

$$h = \frac{n(z)}{d(z)} = \frac{s^\nu n(z)}{s^\nu d(z)} = \frac{p(s)}{q(s)} \text{ with relatively prime } p, q \in \mathbb{C}[s].$$

The factoriality of $\mathbb{C}[s]$ implies the existence of $f(s) \in \mathbb{C}[s]$ such that

$$\begin{gathered} q(s)f(s) = s^\nu d(z) \in \mathbb{C}[s], \text{ hence } q(\lambda)f(\lambda) = \lambda^\nu d(w) \neq 0\ \forall \\ \lambda \in \Lambda_2 \text{ or } |\lambda_\rho| \geq 1,\ \rho = 1, \ldots, r, \text{ and } w := (\lambda_1^{-1}, \ldots, \lambda_r^{-1}) \in \overline{U}^r, \end{gathered}$$

where $h \in S$ implies $d(w) \neq 0$. Hence $q \in T$ and $h \in A_T$ as asserted. ∎

Remarks 5.12.

1. Thus structural stability of h implies properness and stability, i.e., $h \in A_T$, in the sense of this paper. Equality holds in the preceding lemma if and only if an irreducible polynomial $d(z) \in \mathbb{C}[z]$ is already structurally stable if $d(0) \neq 0$ and if it has no zero w in $\overline{U}^r$ with $w_\rho \neq 0\ \forall \rho = 1, \ldots, r$. For $r = 1$ this is the case; in general it is unknown (to the author). This is another example of the difficulty of characterizing and manipulating the multiplicatively closed sets T of polynomials which have no zero in a given subset Λ_2 of $\mathbb{C}^r$.
2. The standard one-dimensional continuous (resp., discrete) stabilization theory for systems with a given proper transfer operator uses the Euclidean ring $S = A_T \cap \mathbb{C}[[z]]$ [26, Chap. 5] instead of A_T here with

$$\Lambda_2 := \{\lambda \in \mathbb{C};\ \Re(\lambda) \geq 0\},\ \text{resp.},\ \Lambda_2 := \{\lambda \in \mathbb{C};\ |\lambda| \geq 1\}.$$

A counterpart to Theorem 5.4 is the *BIBO stability* of structurally stable transfer matrices [6, sec. 3.4], i.e., the result that the space

$$l^\infty := \left\{ u = \sum_{\mu \in \mathbb{N}^r} u_\mu z^\mu \in \mathbb{C}^{\mathbb{N}^r} = \mathbb{C}[[z]];\ \exists M > 0\ \forall \mu \in \mathbb{N}^r :\ |u_\mu| \leq M \right\}$$

of bounded multisequences is an S-submodule of $\mathbb{C}^{\mathbb{N}^r}$. This is "well-known" and follows from the fact that a structurally stable rational function is a convergent power series in an open polydisc containing $\overline{U}^r$.

For general stable discrete systems, we pose the following open problem. Consider Λ_2 from (89), an arbitrary discrete IO system (64) with signals from $\mathbb{C}[[z]] = \mathbb{C}^{\mathbb{N}^r}$. Let $\Gamma \subset \{1, \ldots, p\} \times \mathbb{N}^r$ denote the associated *canonical initial region* [13, Eq. (14)] with respect to a chosen term order on $\{1, \ldots, p\} \times \mathbb{N}^r$. Then the *canonical Cauchy problem* [13, Thms. 5 and 8]

$$\begin{aligned} P \circ y = Q \circ u,\ u \in \mathbb{C}[[z]]^m,\ y = \left(\sum_{\mu \in \mathbb{N}^r} y_{i,\mu} z^\mu \right)_{i \leq p} \in \mathbb{C}[[z]]^p, \\ y \mid \Gamma = \left(\sum_{\mu} \{ y_{i,\mu} z^\mu;\ (i,\mu) \in \Gamma \} \right)_{i \leq p} = x \in \mathbb{C}^\Gamma \subset \mathbb{C}[[z]]^p \end{aligned} \tag{93}$$

has a unique solution y for given input u and *initial data* x, and this can be computed using Gröbner bases. The space $\mathbb{C}\langle z \rangle$ of *locally convergent* power series is [13, Eq. (54)]

$$\begin{aligned} \mathbb{C}\langle z \rangle = \Bigg\{ u = \sum_{\mu \in \mathbb{N}^r} u_\mu z^\mu \in \mathbb{C}[[z]];\ \exists M > 0\ \exists R \in \mathbb{R}^r_{>0}\ \forall \mu \in \mathbb{N}^r : \\ |u_\mu| \leq M R^\mu \Bigg\} = \left\{ u = \sum_{\mu \in \mathbb{N}^r} u_\mu z^\mu \in \mathbb{C}[[z]];\ \exists \widetilde{R} \in \mathbb{R}^r_{>0} :\ \sum_{\mu \in \mathbb{N}^r} |u_\mu| \widetilde{R}^\mu < \infty \right\} \\ \text{and } l^\infty,\ l^1 := \left\{ u = \sum_{\mu \in \mathbb{N}^r} u_\mu z^\mu \in \mathbb{C}[[z]];\ \sum_{\mu \in \mathbb{N}^r} |u_\mu| < \infty \right\} \subset \mathbb{C}\langle z \rangle \end{aligned}$$

are $\mathbb{C}[s]$-submodules of $\mathbb{C}\langle z\rangle$. The unique solvability of the Cauchy problem (93) also holds for $\mathbb{C}\langle z\rangle$ instead of $\mathbb{C}[[z]]$ [13, Cor. 25], especially

$$\mathcal{B}^0 = \{y \in \mathbb{C}\langle z\rangle^p;\ P \circ y = 0\}$$
$$\cong \left\{x \in \mathbb{C}^\Gamma;\ \forall i = 1,\dots,p:\ \sum_\mu \{x_{i,\mu} z^\mu;\ (i,\mu) \in \Gamma\} \in \mathbb{C}\langle z\rangle\right\},\ y \mapsto y \mid \Gamma.$$

In particular, if u and x have components in l^∞ or l^1, the unique power series solution y satisfies

$$|y_{i,\mu}| \le MR^\mu,\ \text{resp.},\ \sum_{\mu\in\mathbb{N}^r} |y_{i,\mu}|R^\mu < \infty\ \text{for } \textit{some}\ R \in \mathbb{R}^r_{>0}\ \text{and}\ M > 0. \tag{94}$$

If all components R_ρ are smaller (resp., greater) or equal to 1, then $y \in (l^\infty)^p$ (resp., $y \in (l^1)^p$). Now assume that the IO system $\mathcal{B}$ is Λ_2-stable for Λ_2 from (89), i.e., that conditions 2–4 of Theorem/Definition 5.1 are satisfied (the function space differs!!). With the idea from [29, pp. 1499–1500] that stability of a system should imply that *stable inputs and initial conditions generate stable outputs*, we pose the following.

Open problem 5.13. Consider $\Lambda_2 := \{\lambda \in \mathbb{C}^r;\ \forall \rho = 1,\dots,r : |\lambda_\rho| \ge 1\}$, $i = \infty, 1$, and a Λ_2-stable IO system $\mathcal{B}$ as above with input $u \in (l^i)^m$, initial data $x \in (l^i)^p$, and unique output $y \in \mathbb{C}\langle z\rangle^p$. When is $y \in (l^i)^p$, i.e., $R = (1,\dots,1)$ in (94) or, in other words, when is the stable system BIBO- or l^∞-IO-stable (resp., l^1-IO-stable)?

This is always true for one-dimensional discrete IO systems—the properness of the transfer matrix is not required. Compare [15, Thm. 7.6.2] for a continuous analogue under the assumption that the transfer matrix is proper.

The question can also be asked for other natural unstable regions and is also interesting and reasonable in the continuous case of partial differential equations for those spaces of analytic functions for which the Cauchy problem is uniquely solvable. In particular this holds for the space of entire functions of exponential type [13, Thm. 26] which, by means of the Borel isomorphism, is isomorphic to $\mathbb{C}\langle z\rangle$ with the shift action, and for the space $\mathbb{C}\langle z\rangle$, but now with the action by partial differentiation and under the assumption that the term order is graded [13, Thm. 29].

Consider, however, the trivial (in the sense of Theorem/Definition 2.5) and therefore stable one-dimensional system $y = s_1 \circ u$ with an empty initial condition and polynomial transfer function $H = s_1$. The analytic function $u := \exp(iz_1^2)$ is bounded on $\mathbb{R}$, but the output $y = u' = 2iz_1 u$ is not, so BIBO stability does not hold. Likewise, $u(z_1) := (1 + z_1^2)^{-1}\exp(iz_1^2)$ is in $L^1(\mathbb{R})$, but its derivative is not. So additional assumptions, for instance properness, have to be made in the analogue of the open problem for the general continuous case.

The following theorem without a detailed proof improves Theorem 5.8 and item 2 of Remarks/Open Problems 5.10 and was added during the revision process. The data are those from (64) and (70)–(78). According to Theorem/Definition 2.2 we construct the unique controllable realization $\mathcal{B}_{\text{cont}}$ of H via

$$U_{\text{cont}} := \mathcal{B}^\perp_{\text{cont}} := \ker\left(A^{1\times(p+m)} \xrightarrow{\circ\binom{H}{\mathrm{id}_m}} K^{1\times m}\right),\ \text{hence}$$
$$M/t(M) \cong M_{\text{cont}} := A^{1\times(p+m)}/U_{\text{cont}}, \tag{95}$$
$$t(M) = U_{\text{cont}}/U \subset M = A^{1\times(p+m)}/U,$$
$$\mathfrak{a} := \operatorname{ann}_A(t(M)).$$

The submodule U_{cont} and the annihilator $\mathfrak{a}$ of the torsion module $t(M) = U_{\mathrm{cont}}/U$ are computed via Buchberger's algorithm. For the Gabriel localization $U_{\mathfrak{T}}$, Lemma/Definition 3.6 implies

$$U_T \subset U_{\mathfrak{T}} = A_T^{1\times(p+m)} \cap \cap_{\lambda\in\Lambda_2} U_{\mathfrak{m}_\lambda} \subset A_T^{1\times(p+m)}. \tag{96}$$

Generators of $U_{\mathfrak{T}}$ are needed for the application of the algorithm in Remarks/Open Problems 5.10(2), and in general are hard to obtain. The next theorem gives a partial solution.

THEOREM 5.14. *We use data as just introduced.*

(1) *All localized modules $M_{\mathfrak{m}_\lambda}$, $\lambda \in \Lambda_2$, are torsion free if and only if $V(\mathfrak{a})\cap\Lambda_2 = \emptyset$. If this is the case, then $U_{\mathfrak{T}} = U_{\mathrm{cont},T}$, and $\mathcal{B}$ is stabilizable if and only if $M_{\mathrm{cont},T}$ is a projective A_T-module.*

(2) *The module M_T is torsion free if and only if $\mathfrak{a}\cap T \neq \emptyset$. If this is the case, then*

$$U_{\mathfrak{T}} = U_{\mathrm{cont},T} = U_T \text{ and } M_T \cong \mathcal{M} := A_T^{1\times p}H + A_T^{1\times m} \subset \mathbb{C}(s)^{1\times m},$$

and $\mathcal{B}$ is stabilizable if and only if the lattice $\mathcal{M}$ is a projective A_T-module. According to Quadrat [17, *Cor.* 3] *this characterizes the stabilizability of the transfer matrix H in the usual sense.*

6. Conclusion. In contrast to the literature on the stabilization of *discrete* multidimensional IO *maps*, the present paper developed the stabilization theory for *continuous or discrete* multidimensional IO *behaviors*. An important technical tool in this context was the generalized localization theory due to Gabriel. Algorithmic problems were addressed, but only partially solved. For a complete solution one needs constructive solutions for the following problems from algebraic and analytic geometry. Let Λ_2 be an arbitrary subset of the r-dimensional complex space and consider

$$T := \{t \in \mathbb{C}[s_1,\dots,s_r];\ \forall\lambda\in\Lambda_2 :\ t(\lambda)\neq 0\} =: \{\text{stable polynomials}\},$$
$$\text{nonzero polynomials } f \text{ and ideals } \mathfrak{a} \text{ in } \mathbb{C}[s].$$

OPEN ALGORITHMIC PROBLEMS 6.1 (compare [7], [30]).

1. *Decide $f \in T$.*
2. *Decide $V(\mathfrak{a}) \cap \Lambda_2 = \emptyset$.*
3. *Decide $\mathfrak{a}\cap T \neq \emptyset$ and construct $t \in \mathfrak{a}\cap T$.*
4. *The implication $\mathfrak{a}\cap T \neq \emptyset \ \Rightarrow\ V(\mathfrak{a})\cap\Lambda_2 = \emptyset$ is obvious. The reverse implication is true for all ideals $\mathfrak{a}$ if and only if $\mathfrak{a}$ is ideal-convex. Decide ideal-convexity constructively and construct $t \in \mathfrak{a}\cap T$ if $V(\mathfrak{a})\cap\Lambda_2 = \emptyset$.*
5. *Of course, the preceding tasks have to be solved only for suitable Λ_2, for instance for the typical continuous (resp., discrete) cases*

$$\Lambda_2 := \{z\in\mathbb{C};\ \Re(z)\geq 0\}^r,\ \textit{resp.},\ \Lambda_2 = \{z\in\mathbb{C};\ |z|\geq 1\}^r.$$

   As shown in Remarks/Open Problems 5.10 *and in Theorem* 5.14 *a special stabilization problem gives rise only to few ideals $\mathfrak{a}$ for which the preceding tasks have to be solved. The paper* [8] *treats these problems for the closed unit polydisc and a special class of ideals.*
6. *If $\mathfrak{a}$ is Krull–zero-dimensional or $V(\mathfrak{a})$ is finite, then this variety can be computed via Buchberger's algorithm and the constructive tasks can in general be solved.*

At the recent workshops D2 and D3 of the Gröbner semester in Linz, Austria (May 8–19, 2006), S. Tsarev (TU Berlin) pointed out the very interesting and highly useful fact that some of the preceding open problems can actually be constructively solved by means of the Tarski–Seidenberg theorem for real semi-algebraic geometry and cylindrical algebraic decomposition.

Acknowledgments. The author thanks the two referees for their reviewing work and critical comments which have been incorporated into the revised version of the paper.

A TWO-PERSON GAME FOR PRICING CONVERTIBLE BONDS*

MIHAI SÎRBU† AND STEVEN E. SHREVE‡

Abstract. A firm issues a convertible bond. At each subsequent time, the bondholder must decide whether to continue to hold the bond, thereby collecting coupons, or to convert it to stock. The bondholder wishes to choose a conversion strategy to maximize the bond value. Subject to some restrictions, the bond can be called by the issuing firm, which presumably acts to maximize the equity value of the firm by minimizing the bond value. This creates a two-person game. We show that if the coupon rate is below the interest rate times the call price, then conversion should precede call. On the other hand, if the dividend rate times the call price is below the coupon rate, call should precede conversion. In either case, the game reduces to a problem of optimal stopping.

Key words. convertible bonds, optimal stopping, two-person game, viscosity solutions, free boundary

1. Introduction.

Firms raise capital by issuing debt (bonds) and equity (shares of stock). The *convertible bond* is intermediate between these two instruments. A convertible bond is a bond in that it entitles its owner to receive coupons plus the return of principal at maturity. However, prior to maturity the holder may *convert* the bond, surrendering it for a preset number of shares of stock. The price of the bond is thus dependent on the price of the firm's stock. Finally, prior to maturity, the firm may *call* the bond, forcing the bondholder to either surrender it to the firm for a previously agreed price or convert it to stock as above.

After issuing a convertible bond, the firm's objective is to exercise its call option in order to maximize the value of shareholder equity. The bondholder's objective is to exercise the conversion option in order to maximize the value of the bond. Because the firm must pay coupons to the bondholder, it may call the bond if it can subsequently reissue a bond with a lower coupon rate. This happens as the firm's fortunes improve, for then the risk of default has diminished and investors will accept a lower coupon rate on the firm's bonds. In the case of a convertible bond, the firm has a second incentive to call: as the firm's fortunes improve, the investor may convert, becoming a shareholder of a profitable firm and diluting the value of the stock owned by the original shareholders. The firm can prevent this by calling the bond. The bondholder has an incentive to convert the bond to stock before maturity under exactly the same scenario; the bondholder may want to become a shareholder of a profitable firm, for the promise of future dividends may be more valuable than the promise of future coupons.

If stock and convertible bonds are the only assets issued by a firm, then the value of the firm is the aggregate value of these two types of assets. In idealized

markets, where the Miller–Modigliani [32], [33] assumptions hold (see Hennessy and Tserlukevich [20] for a model in which they do not), changes in corporate capital structure do not affect firm value. In particular, the value of the firm does not change at the time of conversion, and the only change in the value of the firm at the time of call is a reduction by the call price paid to the bondholder if the bondholder surrenders rather than converting the bond. By acting to maximize the value of equity, the firm is in fact minimizing the value of the convertible bond. By acting to maximize the value of the bond, the bondholder is in fact minimizing the value of equity. This creates a *two-person, zero-sum game*. The game is complicated by the fact that one can expect the dividend payment policy of the firm to depend on the bond price, a feature explicitly modeled in this paper. This feature causes the bond price to be governed by a *nonlinear* second-order partial differential equation, a novel feature of this paper.

This is a companion paper to Sîrbu, Pikovsky, and Shreve [36]. In [36], the bond did not mature and hence time was not a variable, whereas in the present paper, the bond has finite maturity and the bond price depends on the time to maturity.

Brennan and Schwartz [8] and Ingersoll [22] address the convertible bond pricing problem via the arbitrage pricing theory developed by Merton [30], [31] and underlying the option pricing formula of Black and Scholes [7]. In the Brennan–Schwartz [8] model, dividends and coupons are paid at discrete dates. Between these dates, the value of the firm is a geometric Brownian motion and the price of the convertible bond is governed by the *linear* partial differential equation developed by Black and Scholes [7]. This sets up a backward recursion over payment dates, which permits a numerical solution of the bond pricing problem but is not readily amenable to qualitative analysis. In Ingersoll [22], coupons are paid out continuously. For most of the results obtained in [22], dividends are zero, and because of this the bond price is again governed by a *linear* partial differential equation.

The present paper differs from the classical literature in a second respect. In [8], the bond should not be converted except possibly immediately prior to a dividend payment; in [22], the bond should not be converted except possibly at maturity. Therefore, neither of these papers needs to address the *free boundary problem* that arises if early conversion (other than at discrete dates) is optimal.

Ingersoll [22] provides a heuristic argument that the firm should call as soon as the conversion value of the bond (the value the bondholder would receive if he converts the bond to stock) rises to the call price. It is observed that firms tend to call later than this, and several reasons have been advanced to explain this departure from the model; see, e.g., [2], [3], [16], [19], [23]. We show here by a rigorous analysis of the model that, although the Ingersoll conclusion is often valid, it is also possible that the firm should call *before* the conversion value of the bond rises to the call price. In these cases, explanation of observed firm behavior is more difficult than previously believed.

The present paper assumes that a firm's value comprises equity and convertible bonds. To simplify the discussion, we assume that equity is in the form of a single share of stock, and that there is a single convertible bond. We assume that the value of the issuing firm has constant volatility, the bond continuously pays coupons at a fixed rate, and the firm continuously pays dividends at a rate that is a fixed fraction of equity. Default occurs if the coupon payments cause the firm value to fall to zero, in which case the bond has zero recovery. In this model, both the bond price and the stock price are functions of the underlying firm value. Because the stock price is the difference between firm value and bond price, and dividends are paid proportionally

to the stock price, the differential equation characterizing the bond price as a function of the firm value is *nonlinear*.

In section 2 we provide a no-arbitrage argument, which states that once the firm and the bondholder choose their call and conversion strategies, the price of the bond is the expected value under the *risk-neutral measure* of the cash flows that accrue from ownership of the bond. The determination of the optimal call and conversion strategies then becomes a Dynkin game between the firm and the bondholder, and the bond is almost a game option in the sense of Kifer [26]. In contrast to [26], here the evolution of the underlying process, the firm value, depends on the solution to the game. Kallsen and Kühn [24] consider a game option setting that includes this possibility.

Recognizing that convertible bond pricing is a game is implicit in previous work. For example, [8] observes that the pricing problem " ... results in a pair of conversion-call strategies which are in equilibrium in the sense that neither party could improve his position by adopting any other strategy." Here we make the game explicit and obtain a good qualitative description of its value. In particular, if the dividend rate is below the interest rate, then the game reduces to one of two possible optimal stopping problems, either the problem of optimal call or the problem of optimal conversion, and we are able to determine in advance from the model parameters which of these two problems is relevant.

Convertible bonds can have several features that must be captured by any model intended for practical application; see [29]. These include periods of call protection, time-dependent conversion factors, and exposure to interest rate and default risk. The model of this paper captures only the default risk, and that via a simple structural model in which default occurs at the time the firm value falls to zero. Loschak [27] allows nonconvertible senior debt and uses a more sophisticated structural model for default. Brennan and Schwartz [9] also allow senior debt. Another interesting issue is the process of conversion when bonds are held by competing investors; see Constantinides [11] and Constantinides and Rosenthal [12].

Practical models have been built around the idea that the cash flow from a convertible bond can be separated into an "equity" part, which should be discounted at the interest rate, and a "bond" part, which should be discounted at the interest rate plus a credit spread. Papers taking this approach are McConnell and Schwartz [28], Cheung and Nelken [10], Ho and Pteffer [21], Tsiveriotis and Fernandes [39], and Yigitbasioglu [40]. Ayache, Forsyth, and Vetzal [4] analyze some of this work and conclude that its failure to account for the effect of default on equity introduces significant pricing errors. This deficiency is corrected in Davis and Lischka [14], Takahashi, Kobayashi, and Nakagawa [38], and Andersen and Buffum [1], who build intensity-based models for default affecting equity value.

We describe our model in section 2 and report our main results in section 3. In particular, the Dynkin game that describes the bond price reduces to one of two optimal stopping problems and a fixed point problem. Section 4 provides a probabilistic justification for the reduction of the game to optimal stopping. Viscosity solution results concerning the Hamilton–Jacobi–Bellman equations governing the optimal stopping problems are provided in section 5. This permits the proof in section 6 of the existence and uniqueness of the solution to the fixed point problem, and this solution is the bond pricing function. Section 7 relates this paper to perpetual convertible bonds. In section 8 we provide some results on the nature of the stopping and continuation regions of the optimal stopping problems of this paper.

2. The model. We denote the value of the firm at each time t by X_t. We assume the value of the firm consists of equity and debt. The debt D_t is due to a single outstanding convertible bond. This assumption of a single bond means that all debt is called and/or converted simultaneously. We denote by S_t the total value of equity, which, following the standard finance model (e.g., Merton [31, bottom of p. 453]) is given by

$$S_t = X_t - D_t. \tag{2.1}$$

Equity owners receive dividends paid continuously over time at a rate δS_t, and the bondholder receives coupons paid continuously over time at a rate c. We assume that $\delta \geq 0$ and $c > 0$ are both constant. If there is no call or conversion prior to *maturity* T, then at maturity the bondholder receives the *par value* L from the firm, provided $X_T \geq L$. Otherwise, the bondholder receives X_T. However, at any time $t \in [0, T]$, the bondholder may *convert* the bond to stock, thereby immediately receiving stock valued at the *conversion factor* $\gamma \in (0, 1)$ times the firm value X_t. The firm value is not affected by this conversion. On the other hand, at any time t when $X_t \geq K$, the firm may *call* the bond, forcing the bondholder to either immediately surrender the bond in exchange for the *call price* K or else immediately convert the bond as described above. We assume $K \geq L > 0$; it is common to have $L = K$. If K were less than L, then L would be irrelevant since the firm could always call at maturity to avoid paying L.

In order to model the firm value process, which is the primitive in our analysis, we note that, prior to maturity, as long as the bond has not been called or converted and the firm value has not fallen to zero, there are three financial instruments in the market: the stock, the convertible bond(s), and a money market account with risk-free rate of interest $r > 0$. The wealth V_t of an investor holding Δ_t shares of stock and Γ_t convertible bonds at each time t, investing or borrowing in the money market account as necessary in order to finance this, evolves according to the stochastic differential equation

$$dV_t = \Delta_t[dS_t + \delta S_t\, dt] + \Gamma_t[dD_t + c\, dt] + r[V(t) - \Delta_t S_t - \Gamma_t D_t]\, dt, \tag{2.2}$$

and the discounted wealth thus satisfies

$$d\big(e^{-rt}V_t\big) = \Delta_t\big[d\big(e^{-rt}S_t\big) + e^{-rt}\delta S_t\, dt\big] + \Gamma_t\big[d\big(e^{-rt}D_t\big) + e^{-rt}c\, dt\big]. \tag{2.3}$$

Such an investor should not be able to produce arbitrage. To ensure this, according to the *first fundamental theorem of asset pricing*, both the discounted stock price plus the cumulative discounted dividend payments,

$$M_t = e^{-rt}S_t + \int_0^t e^{-ru}\delta S_u\, du,$$

and the discounted convertible bond price plus the cumulative discounted coupons,

$$N_t = e^{-rt}D_t + \int_0^t e^{-ru}c\, du,$$

must be local martingales under some *risk-neutral* probability measure $\mathbb{P}$ (see the argument due to [18] and developed in great generality by [15]). Adding the above equations, using the relation $X_t = S_t + D_t$, we obtain

$$dX_t = rX_t\, dt - c\, dt - \delta S_t\, dt + e^{rt}d(M_t + N_t). \tag{2.4}$$

Assuming constant volatility $\sigma > 0$ for X_t means that the local martingale term $e^{rt}d(M_t + N_t)$ is in fact equal to $\sigma X_t\, dW_t$, where W is a Brownian motion. To summarize, in our model the value of the firm evolves according to the equation

$$dX_t = rX_t\, dt - c\, dt - \delta S_t\, dt + \sigma X_t\, dW_t, \tag{2.5}$$

where W_t, $0 \le t \le T$, is a Brownian motion under the risk-neutral probability measure $\mathbb{P}$. This is the starting point of our model, and it is a common starting point for treatments of the convertible bond pricing problem; see, e.g., [8], [22]. Equation (2.5) says that under the risk-neutral measure the mean rate of growth of X_t is the interest rate r adjusted by the payouts being made.

Finally, we observe from (2.5) that $X_t \le X_0 e^{(r-\frac{1}{2}\sigma^2)t+\sigma W_t}$. Therefore, since $0 \le S_t \le X_t$ and $0 \le D_t \le X_t$, we conclude that the local martingales M_t and N_t are martingales under $\mathbb{P}$.

We adopt throughout the *standing assumption*

$$0 \le \delta < r, \tag{2.6}$$

but see Remark 3.5 below.

We generalize slightly the previous discussion by permitting the initial time to be $s \in [0,T]$ rather than requiring it to be 0. We shall price the bond at time s under the assumption that $X_s = x$. Given these initial conditions, we denote by $X_t^{s,x}$ the solution to (2.5) at time $t \in [s,T]$ and set

$$\theta_y^{s,x} \triangleq \min\{t \in [s,T] : X_t^{s,x} = y\}, \quad y \ge 0,$$

where we adopt the convention that $\min \emptyset = \infty$. The firm defaults on the bond at time $\theta_0^{s,x}$ if $\theta_0^{s,x} \le T$, and $\theta_0^{s,x} = \infty$ corresponds to no default.

The firm adopts a *call strategy* ρ and the bondholder adopts a *conversion strategy* τ. Both of these are stopping times for the filtration generated by $W_u - W_s$, $u \in [s,T]$ (augmented by $\mathbb{P}$-null sets), and they must satisfy $\rho, \tau \in [s, T \wedge \theta_0^{s,x}] \cup \{\theta_0^{s,x}\}$. We denote the set of all such stopping times by $\mathcal{S}^{s,x}$. We interpret ρ and τ to be the times of call and conversion, respectively, except on the set $\{\rho = \theta_0^{s,x}\}$, where there is no call. Similarly, on the set $\{\tau = \theta_0^{s,x}\}$, there is no conversion. On the set $\{\rho = \tau < \theta_0^{s,x}\}$, there is simultaneous call and conversion, and the conversion takes priority. This is the standard contractual specification for convertible bonds. There is no requirement that call or conversion must take place, and we capture the absence of call (respectively, conversion) by permitting $\rho = \infty$ (respectively, $\tau = \infty$) if $\theta_0^{s,x} = \infty$. The firm can call at time $\rho < \theta_0^{s,x}$ only if $X_\rho^{s,x} \ge K$. We denote by $\mathcal{S}_K^{s,x}$ the set of stopping times in $\mathcal{S}^{s,x}$ satisfying the additional condition that $X_\rho^{s,x} \ge K$ on $\rho < \theta_0^{s,x}$, and we require that $\rho \in \mathcal{S}_K^{s,x}$. Once the call and conversion strategies $\rho \in \mathcal{S}_K^{s,x}$ and $\tau \in \mathcal{S}^{s,x}$ are chosen, we use the fact that N_t stopped at $\rho \wedge \tau \wedge T$ is a martingale under $\mathbb{P}$ to write the value of the bond D_s at time s as

$$\begin{aligned} J(s,x;\rho,\tau) &\triangleq e^{rs}\mathbb{E}\left[\int_s^{\rho\wedge\tau\wedge T} e^{-ru}c\, du + e^{-r(\rho\wedge\tau\wedge T)}D_{\rho\wedge\tau\wedge T}\right] \\ &= e^{rs}\mathbb{E}\left[\int_s^{\rho\wedge\tau\wedge T} e^{-ru}c\, du + e^{-r(\rho\wedge\tau\wedge T)}\big(\mathbb{I}_{\{\tau\le\rho\wedge T\}}\gamma X_\tau^{s,x}\right. \\ &\qquad \left. + \mathbb{I}_{\{\rho<\tau\}}K + \mathbb{I}_{\{\rho\wedge\tau=\infty\}}(X_T^{s,x}\wedge L)\big)\right]. \end{aligned} \tag{2.7}$$

3. The method and principal results. We must deal with the fact that the process S_t in section 2 is endogenous. In fact, the bond price, the firm value, and the equity value S_t are related by (2.1). Just as in [8], [22], [31], and even [7], for the case of options rather than convertible bonds, we make the ansatz that there is a function $g(t,x)$ such that prior to call and conversion, $D_t = g(t, X_t)$ and hence $S_t = X_t - g(t, X_t)$. This is a reasonable step because the only source of uncertainty in the model is the uncertainty in the firm value (equivalently, the uncertainty in the Brownian motion driving the firm value), and thus all asset prices should depend on only this and the time variable.

We eventually see (Lemma 4.1 below) that if $\gamma X_t \geq K$, then it is optimal to convert, and hence $D_t = \gamma X_t$. Hence, the function $g(t,x)$ should satisfy

$$g(t,x) = \gamma x \text{ for } 0 \leq t \leq T \text{ and } x \geq \frac{K}{\gamma}. \tag{3.1}$$

Also, we expect both the value of the bond and the value of the equity to increase with increasing firm value, which is equivalent to

$$0 \leq g(t,y) - g(t,x) \leq y - x \text{ for } 0 \leq t \leq T \text{ and } 0 \leq x \leq y. \tag{3.2}$$

The bond is never worth less than its conversion value and never worth more than the firm value. Since the firm can always call when $\gamma x \leq K$, in which case the call does not result in conversion, the bond is not worth more than the call price. In other words,

$$\gamma x \leq g(t,x) \leq x \wedge K \text{ for } 0 \leq t \leq T \text{ and } 0 \leq x \leq \frac{K}{\gamma}. \tag{3.3}$$

We shall show that within the collection of functions

$$\mathcal{G} = \{g\colon [0,T] \times [0,\infty) \to [0,\infty) : g \text{ is continuous and (3.1)–(3.3) hold}\},$$

there exists a unique function g^* such that $g^*(t, X_t)$ gives a bond price consistent with our modeling assumptions.

To get started, we simply choose an arbitrary $g \in \mathcal{G}$ and define

$$S_t = X_t - g(t, X_t). \tag{3.4}$$

We substitute this value of S_t into (2.5), thereby obtaining a stochastic differential equation for X. The Lipschitz continuity (3.2) guarantees that corresponding to every initial condition $(s,x) \in [0,T] \times [0,\infty)$ this equation has a strong solution, and we thus obtain $X^{s,x}$. We proceed as in section 2 and conclude with the function J of (2.7), which we now denote J_g.

For each fixed $g \in \mathcal{G}$, we can construct a Dynkin game, where now the evolution of the underlying process is specified by (2.5) and (3.4). Kallsen and Kühn [24] show that the value of this game will be the no-arbitrage price of the bond, provided the function g has been chosen "correctly" (see the next paragraph). This game has lower and upper values

$$\underline{v}_g(s,x) \triangleq \sup_{\tau \in \mathcal{S}^{s,x}} \inf_{\rho \in \mathcal{S}_K^{s,x}} J_g(s,x;\rho,\tau), \quad \overline{v}_g(s,x) \triangleq \inf_{\rho \in \mathcal{S}_K^{s,x}} \sup_{\tau \in \mathcal{S}^{s,x}} J_g(s,x;\rho,\tau),$$

respectively. Clearly, $\underline{v}_g \leq \overline{v}_g$. In fact,

$$\underline{v}_g(s,x) = \overline{v}_g(s,x) \text{ for } 0 \leq s \leq T \text{ and } x \geq 0. \tag{3.5}$$

This is a consequence of the theory of Dynkin games, but rather than appeal to that theory, we obtain (3.5) as a by-product of our characterization of the solution of the game; see Lemma 4.1 and Propositions 4.5 and 4.6 below.

The function $\underline{v}_g = \overline{v}_g$ provides the price of the convertible bond if we choose g to be the pricing function of the convertible bond. That is to say, we want to find a function $g^* \in \mathcal{G}$ such that $\underline{v}_{g^*} = \overline{v}_{g^*} = g^*$. Let us define the operator $\mathcal{T}$ on $\mathcal{G}$ by $\mathcal{T}g \triangleq \underline{v}_g = \overline{v}_g$. We shall prove the following.

THEOREM 3.1. *$\mathcal{T}$ maps $\mathcal{G}$ into $\mathcal{G}$ and has a unique fixed point g^*.*

When $x = 0$, the only stopping time in $\mathcal{S}^{T,x}$ is $\tau \equiv T$, whereas when $0 < x \le \frac{K}{\gamma}$, the set $\mathcal{S}^{T,x}$ also contains the stopping time $\tau \equiv \infty$. When $x = 0$, the only stopping in $\mathcal{S}_K^{T,x}$ is $\rho = T$, whereas when $0 < x < K$, the only stopping time in $\mathcal{S}_K^{T,x}$ is $\rho \equiv \infty$. When $K \le x \le \frac{K}{\gamma}$, the set $\mathcal{S}_K^{T,x}$ consists of $\rho \equiv T$ and $\rho \equiv \infty$. We further have

$$J_g(T,x;\rho,\tau) = \mathbb{I}_{\{\tau \le \rho \wedge T\}} \gamma x + \mathbb{I}_{\{\rho < \tau\}} K + \mathbb{I}_{\{\rho \wedge \tau = \infty\}} (x \wedge L).$$

It is now straightforward to compute $\underline{v}_g(T,x)$ and $\overline{v}_g(T,x)$ for $0 \le x \le \frac{K}{\gamma}$, and irrespective of the choice of g, this results in the terminal convertible bond pricing function $g^*(T,\cdot)$ given by

$$g^*(T,x) = (x \wedge L) \vee (\gamma x) \text{ for } 0 \le x \le \frac{K}{\gamma}. \tag{3.6}$$

Because g^* also satisfies (3.1), we need only describe this function on $[0,T) \times \left[0, \frac{K}{\gamma}\right)$. From (3.3) we have the boundary conditions

$$g^*(t,0) = 0, \quad g^*\left(t, \frac{K}{\gamma}\right) = K \text{ for } 0 \le t \le T. \tag{3.7}$$

THEOREM 3.2 (Case I). *If $c \le rK$, the time of optimal call is the first time the conversion value γX_t rises to the call price K. The bond pricing function g^* is determined by solving the problem of optimal conversion in $[0,T] \times \left[0, \frac{K}{\gamma}\right]$. In particular, g^* is the unique continuous viscosity solution of the variational inequality*

$$\min\left\{-v_t + rv - (rx - c)v_x + \delta(x - v)v_x - \frac{1}{2}\sigma^2 x^2 v_{xx} - c, v - \gamma x\right\} = 0 \tag{3.8}$$

on $[0,T] \times [0, \frac{K}{\gamma}]$ satisfying (3.6) and (3.7).

(Case II). *If $\delta K \le c$, the time of optimal conversion is at the first time the conversion value γX_t rises to the call price K, or at maturity if the conversion value exceeds the par value. The bond pricing function g^* is determined by solving the problem of optimal call in $[0,T] \times \left[0, \frac{K}{\gamma}\right]$. In particular, g^* is the unique continuous viscosity solution of the variational inequality*

$$\max\left\{-v_t + rv - (rx - c)v_x + \delta(x - v)v_x - \frac{1}{2}\sigma^2 x^2 v_{xx} - c, v - K\right\} = 0 \tag{3.9}$$

on $[0,T] \times [0, \frac{K}{\gamma}]$ satisfying (3.6) and (3.7).

Remark 3.3. By a "continuous viscosity solution on $[0,T] \times [0, \frac{K}{\gamma}]$" we mean a continuous function on $[0,T] \times [0, \frac{K}{\gamma}]$ that is a solution in the interior of the domain, namely, $(0,T) \times (0, \frac{K}{\gamma})$.

Remark 3.4. Because of standing assumption (2.6), Cases I and II overlap. In other words, we can have $\delta K \le c \le rK$, and optimal call and conversion both occur the first time γX_t rises to K. In this case, g^* is the unique continuous viscosity solution on $[0,T] \times \left[0, \frac{K}{\gamma}\right]$ of the partial differential equation

$$-v_t + rv - (rv - c)v_x + \delta(x - v)v_x - \frac{1}{2}\sigma^2 x^2 v_{xx} = c$$

satisfying (3.6) and (3.7).

Remark 3.5. The proofs in this paper do not actually require standing assumption (2.6), but rather that either $c \le rK$ or $\delta K \le c$. Under either of these conditions, Theorems 3.1 and 3.2 hold. However, Theorem 3.6 below requires (2.6) for the pricing of the perpetual convertible bond; see [36].

THEOREM 3.6. *As the time to maturity approaches ∞, the price of the finite-maturity convertible bond approaches the price of the perpetual convertible bond of* [36]*, which is characterized in Theorem* 7.2 *below, and this convergence is uniform in the firm value.*

4. Construction and properties of v_g.

4.1. Reduction to $[0,T] \times \left[0, \frac{K}{\gamma}\right]$.

LEMMA 4.1. *Assume that g defined on $[0,T] \times [0,\infty)$ satisfies* (3.2)*, so that* (3.4) *and* (2.5) *uniquely determine a process $X^{s,x}$ for $(s,x) \in [0,T] \times [0,\infty)$. Then*

$$\underline{v}_g(s,x) = \overline{v}_g(s,x) = \gamma x \text{ for } 0 \le s \le T \text{ and } x \ge \frac{K}{\gamma}. \tag{4.1}$$

Proof. With $\tau \equiv s$, (2.7) implies $J_g(s,x;\rho,s) = \gamma x$ for $\rho \in \mathcal{S}_K^{s,x}$, and thus

$$\underline{v}_g(s,x) \ge \inf_{\rho \in \mathcal{S}_K^{s,x}} J_g(s,x;\rho,s) = \gamma x. \tag{4.2}$$

For $x \ge \frac{K}{\gamma}$, we may set $\rho \equiv s$ and then have for every $\tau \in \mathcal{S}^{s,x}$ that $J_g(s,x;s,\tau) = \gamma x \mathbb{I}_{\{\tau = s\}} + K\mathbb{I}_{\{s<\tau\}} \le \gamma x$, and hence

$$\overline{v}_g(s,x) \le \sup_{\tau \in \mathcal{S}_K^{s,x}} J_g(s,x;s,\tau) \le \gamma x. \tag{4.3}$$

But directly from their definitions, we know that $\underline{v}_g \le \overline{v}_g$. ∎

We fix a function $g \in \mathcal{G}$ for the remainder of section 4.

4.2. Modification of payoffs. The contractual features of convertible bonds require that we define the value of the bond by (2.7) once the call and conversion strategies ρ and τ are specified. This formulation is not readily amenable to analysis, since the stopping times are allowed to take the value ∞, the different players have different sets of stopping times at their disposal, and the payoff in the event of call is not always less than or equal to the payoff in the event of conversion. In this section we create an auxiliary problem that has all these desirable features, and we subsequently show in Propositions 4.5 and 4.6 that both problems have the same value.

We restrict our attention to stopping times in $\mathcal{S}_T^{s,x} \triangleq \{\theta \in \mathcal{S}^{s,x} : \theta \le T\}$. In particular, we do not allow stopping times to take the value ∞ and we do not require the call strategy ρ to satisfy $X_\rho^{s,x} \ge K$ on $\{\rho < \theta_0^{s,x}\}$. We also change the payoffs

appearing in (2.7). We define

$$\psi(t,x) \triangleq \begin{cases} \gamma x & \text{for } 0 \le t < T,\ x \ge 0, \\ (x \wedge L) \vee (\gamma x) & \text{for } t = T,\ x \ge 0, \end{cases}$$

$$\varphi(t,x) \triangleq \begin{cases} (x \wedge K) \vee (\gamma x) & \text{for } 0 \le t < T,\ x \ge 0, \\ (x \wedge L) \vee (\gamma x) & \text{for } t = T,\ x \ge 0. \end{cases}$$

Then $\psi < \varphi$ on $[0,T) \times \big(0, \frac{K}{\gamma}\big)$ and $\psi = \varphi$ on the parabolic boundary

$$\partial_p D_0 \triangleq \left([0,T) \times \left\{0, \frac{K}{\gamma}\right\} \right) \cup \left(\{T\} \times \left[0, \frac{K}{\gamma}\right] \right). \tag{4.4}$$

For $\rho, \tau \in \mathcal{S}_T^{s,x}$, we set

$$\begin{aligned} &\widetilde{J}_g(s,x;\rho,\tau) \\ &\triangleq e^{rs}\mathbb{E}\left[\int_s^{\rho\wedge\tau} e^{-ru} c\, du + e^{-r(\rho\wedge\tau)} \big(\mathbb{I}_{\{\tau<\rho\}} \psi(\tau, X_\tau^{s,x}) + \mathbb{I}_{\{\rho\le\tau\}} \varphi(\rho, X_\rho^{s,x}) \big) \right]. \end{aligned}$$

The interpretation of $\widetilde{J}_g$ is that if the firm value is insufficient to pay the call price at the time of the call, then the bondholder receives the firm value. Also, call takes priority over conversion, but the bondholder receives the conversion value if that is greater than the call price at the time of the call. We show in Propositions 4.5 and 4.6 that changing the payoffs in this way does not change the value of the convertible bond pricing problem. We begin with the following straightforward modification of Lemma 4.1.

LEMMA 4.2. *For $0 \le s \le T$ and $x \ge \frac{K}{\gamma}$, we have*

$$\inf_{\rho \in \mathcal{S}_T^{s,x}} \sup_{\tau \in \mathcal{S}_T^{s,x}} \widetilde{J}_g(s,x;\rho,\tau) = \sup_{\tau \in \mathcal{S}_T^{s,x}} \inf_{\rho \in \mathcal{S}_T^{s,x}} \widetilde{J}_g(s,x;\rho,\tau) = \gamma x.$$

4.3. Technical preparations. Itô's formula implies that if h is a continuous function on $[0,T] \times \big[0, \frac{K}{\gamma}\big]$, h is $C^{1,2}$ on the interior of its domain, and the derivatives of h have limits at the boundary of its domain, then for $(s,x) \in [0,T] \times \big[0, \frac{K}{\gamma}\big]$,

$$\begin{aligned} &d\left(\int_s^t e^{-ru} c\, du + e^{-rt} h(t, X_t^{s,x}) \right) \\ &\qquad = e^{-rt}\big[-\mathcal{L}_g h(t, X_t^{s,x}) + c \big]\, dt + e^{-rt} \sigma X_t^{s,x} h_x(t, X_t^{s,x})\, dW_t \end{aligned} \tag{4.5}$$

for $t \in [s, \theta_0^{s,x} \wedge \theta_{\frac{K}{\gamma}}^{s,x} \wedge T]$, where

$$\begin{aligned} \mathcal{L}_g h(t,x) \triangleq\ & -h_t(t,x) + rh(t,x) - (rx - c) h_x(t,x) \\ & + \delta\big(x - g(t,x)\big) h_x(t,x) - \frac{1}{2}\sigma^2 x^2 h_{xx}(t,x). \end{aligned} \tag{4.6}$$

LEMMA 4.3. *Let $\widetilde{c} > 0$ be given, and for $0 \le s \le T$ and $0 \le x \le \frac{K}{\gamma}$, define*

$$\begin{aligned} &k(s,x) \\ &\triangleq e^{rs}\mathbb{E}\left[\int_s^{\theta_0^{s,x} \wedge \theta_{\frac{K}{\gamma}}^{s,x} \wedge T} e^{-ru} \widetilde{c}\, du + e^{-r(\theta_0^{s,x} \wedge \theta_{\frac{K}{\gamma}}^{s,x} \wedge T)} \psi\left(\theta_0^{s,x} \wedge \theta_{\frac{K}{\gamma}}^{s,x} \wedge T, X_{\theta_0^{s,x} \wedge \theta_{\frac{K}{\gamma}}^{s,x} \wedge T}^{s,x} \right) \right] \\ &= e^{rs}\mathbb{E}\left[\int_s^{\theta_0^{s,x} \wedge \theta_{\frac{K}{\gamma}}^{s,x} \wedge T} e^{-ru} \widetilde{c}\, du + e^{-r(\theta_0^{s,x} \wedge \theta_{\frac{K}{\gamma}}^{s,x} \wedge T)} \varphi\left(\theta_0^{s,x} \wedge \theta_{\frac{K}{\gamma}}^{s,x} \wedge T, X_{\theta_0^{s,x} \wedge \theta_{\frac{K}{\gamma}}^{s,x} \wedge T}^{s,x} \right) \right], \end{aligned} \tag{4.7}$$

where we have used the fact that ψ and φ agree on the parabolic boundary $\partial_p D_0$. Then k is continuous and satisfies $k = \varphi = \psi$ on $\partial_p D_0$.

Remark 4.4. We would expect the function k to satisfy the partial differential equation $\mathcal{L}_g k = \widetilde{c}$, but since g is only continuous and not Hölder continuous with respect to time, we do not know that this equation has a classical solution. Hence, we give a probabilistic proof of Lemma 4.3.

Proof of Lemma 4.3. It is apparent that $k = \psi$ on $\partial_p D_0$. It remains to prove the continuity.

We extend g to a jointly continuous function, globally Lipschitz in its second variable, defined on $[0,T] \times \mathbb{R}$, so that for every $(s,x) \in [0,T] \times \left[0, \frac{K}{\gamma}\right]$, $X_t^{s,x}$ can be defined by (2.5) and (3.4) for all $t \in [s,T]$. We define $X_t^{s,x} = x$ for $t \in [0,s)$. All the processes $X^{s,x}$ are defined on the same probability space $(\Omega, \mathcal{F}, \mathbb{P})$ and take values in $C[0,T]$.

For $(s,x) \in [0,T] \times \left[0, \frac{K}{\gamma}\right]$, denote by $\mathbb{P}^{s,x}$ the distribution of $X^{s,x}$ on $C[0,T]$. According to [37, p. 152], $\mathbb{P}^{s,x}$ is continuous in (s,x). For $(s,x) \in [0,T] \times \mathbb{R}$, we define the measure $\mathbb{Q}^{s,x} \triangleq \delta_s \times \mathbb{P}^{s,x}$ on $[0,T] \times C[0,T]$, where δ_s denotes the unit point mass at s. Then $\mathbb{Q}^{s,x}$ is also continuous in (s,x) [6, Thm. 2.8, p. 23], which means that

$$\int_{C[0,T]} f(s_n, y)\, d\mathbb{P}^{s_n,x_n}(y) \to \int_{C[0,T]} f(s,y)\, d\mathbb{P}^{s,x}(y) \tag{4.8}$$

whenever $s_n \to s$, $x_n \to x$ and f defined on $[0,T] \times C[0,T]$ is a bounded function that is continuous except on a $\mathbb{Q}^{s,x}$-null set.

We define $\tau \colon [0,T] \times C[0,T] \to [0,T]$ by

$$\tau(s,y) \triangleq T \wedge \min\left\{ t \in [s,T] : y(t) \notin \left(0, \frac{K}{\gamma}\right) \right\},$$

so that $\theta_0^{s,x} \wedge \theta_{\frac{K}{\gamma}}^{s,x} \wedge T = \tau\big(s, X^{s,x}\big)$. For $\mathbb{P}$-almost every ω, if $\tau(s, X^{s,x}(\omega)) < T$, then there is a sequence $\epsilon_n \downarrow 0$, depending on s, x, and ω, such that $X^{s,x}_{\tau(s,X^{s,x}(\omega))+\epsilon_n} \notin \left[0, \frac{K}{\gamma}\right]$ for every n. Indeed, if $X^{s,x}(\omega)$ exits $\left(0, \frac{K}{\gamma}\right)$ at 0, this follows from the fact that $c > 0$ and all other terms on the right-hand side of (2.5) are zero at the time of exit. On the other hand, if $X^{s,x}(\omega)$ exits $\left(0, \frac{K}{\gamma}\right)$ at $\frac{K}{\gamma}$, this follows from the nondegeneracy of the diffusion term in (2.5). Because of the fact that, almost surely, if $X^{s,x}$ exits $(0, \frac{K}{\gamma})$ strictly prior to time T, then it also exits $[0, \frac{K}{\gamma}]$ immediately thereafter, a small perturbation of the path of $X^{s,x}$ results in a small perturbation of the time of exit. More precisely, for every $(s,x) \in [0,T] \times \mathbb{R}$, τ is continuous except on a $\mathbb{Q}^{s,x}$-null set. We conclude by rewriting (4.7) as

$$\begin{aligned} &k(s_n, x_n) \\ &= e^{rs_n} \int_{C[0,T]} \left[\int_{s_n}^{\tau(s_n,y)} e^{-ru} \widetilde{c}\, du + e^{-r\tau(s_n,y)} \psi\big(\tau(s_n,y), y(\tau(s_n,y))\big) \right] d\mathbb{P}^{s_n,x_n}(y) \end{aligned}$$

and observing that because the argument of ψ is in $\partial_p D_0$, where ψ is bounded and continuous, (4.8) implies $k(s_n,x_n) \to k(s,x)$ as $s_n \to s$, $x_n \to x$. ∎

4.4. Characterization of game value.

Proposition 4.5 (Case I). *Assume $c \le rK$. In this case, we define*

$$v_g(s,x) \triangleq \sup_{\tau \in \mathcal{S}_T^{s,x}, \tau \le \theta_{\frac{K}{\gamma}}^{s,x}} e^{rs} \mathbb{E}\left[\int_s^\tau e^{-ru} c\, du + e^{-r\tau} \psi(\tau, X_\tau^{s,x}) \right] \tag{4.9}$$

for $(s,x) \in [0,T] \times \left[0, \frac{K}{\gamma}\right]$, *and we define* $v_g(s,x) \triangleq \gamma x$ *for* $(s,x) \in [0,T] \times (\frac{K}{\gamma}, \infty)$. *Then* $v_g = \underline{v}_g = \overline{v}_g$ *on* $[0,T] \times \left[0,\infty\right)$. *Furthermore,*

$$v_g(s,x) = \inf_{\rho \in \mathcal{S}_T^{s,x}} \sup_{\tau \in \mathcal{S}_T^{s,x}} \widetilde{J}_g(s,x;\rho,\tau) = \sup_{\tau \in \mathcal{S}_T^{s,x}} \inf_{\rho \in \mathcal{S}_T^{s,x}} \widetilde{J}_g(s,x;\rho,\tau) \tag{4.10}$$

for $0 \le s \le T$ *and* $x \ge 0$.

Proof. The claims about v_g for $x > \frac{K}{\gamma}$ follow immediately from Lemmas 4.1 and 4.2. We thus restrict our attention to $0 \le x \le \frac{K}{\gamma}$.

Step 1: *Construction of an upper bound on* v_g. Define $h_1(t,x) \triangleq K$ and $h_2(t,x) \triangleq x$ for $0 \le t \le T$ and $0 \le x \le \frac{K}{\gamma}$. Both h_1 and h_2 dominate ψ on $[0,T] \times \left[0, \frac{K}{\gamma}\right]$. Because $c \le rK$, we have $-\mathcal{L}_g h_1 + c \le 0$. Therefore, for any stopping time $\tau \in \mathcal{S}_T^{s,x}$ satisfying $\tau \le \theta^{s,x}_{\frac{K}{\gamma}}$, (4.5) implies

$$\begin{aligned} h_1(s,x) &\ge e^{rs}\mathbb{E}\left[\int_s^\tau e^{-ru} c\, du + e^{-r\tau} h_1(\tau, X_\tau^{s,x})\right] \\ &\ge e^{rs}\mathbb{E}\left[\int_s^\tau e^{-ru} c\, du + e^{-r\tau} \psi(\tau, X_\tau^{s,x})\right]. \end{aligned} \tag{4.11}$$

It follows that $v_g \le h_1$ on $[0,T] \times \left[0, \frac{K}{\gamma}\right]$. On the other hand,

$$\mathcal{L}_g h_2 = c + \delta(x - g(x)) \ge c \tag{4.12}$$

because of (3.3), and the above argument applied with h_2 in place of h_1 yields $v_g \le h_2$ on $[0,T] \times \left[0, \frac{K}{\gamma}\right]$. We conclude that

$$v_g(s,x) \le x \wedge K \text{ for } 0 \le s \le T,\ 0 \le x \le \frac{K}{\gamma}. \tag{4.13}$$

By definition, $v_g(T,\cdot) = \psi(T,\cdot) = \varphi(T,\cdot)$. Because of this and (4.13),

$$v_g(s,x) \le \varphi(s,x) \text{ for } 0 \le s \le T,\ 0 \le x \le \frac{K}{\gamma}. \tag{4.14}$$

Step 2: *Optimal stopping time.* The theory of optimal stopping we use here requires that we replace ψ on the right-hand side of (4.9) with a continuous function. Let $\widetilde{c} \in (0,c)$ be given, and let k be the continuous function defined by (4.7). For $0 \le s < T$ and $0 < x < \frac{K}{\gamma}$, we have

$$\begin{aligned} k(s,x) &< e^{rs}\mathbb{E}\left[\int_s^{\theta_0^{s,x} \wedge \theta^{s,x}_{\frac{K}{\gamma}} \wedge T} e^{-ru} c\, du \right. \\ &\qquad \left. + e^{-r(\theta_0^{s,x} \wedge \theta^{s,x}_{\frac{K}{\gamma}} \wedge T)} \psi\left(\theta_0^{s,x} \wedge \theta^{s,x}_{\frac{K}{\gamma}} \wedge T, X^{s,x}_{\theta_0^{s,x} \wedge \theta^{s,x}_{\frac{K}{\gamma}} \wedge T}\right)\right] \\ &\le v_g(s,x). \end{aligned} \tag{4.15}$$

Set $\widetilde{\psi} = \psi \vee k$. Since $k(T,x) = \psi(T,x) \ge \gamma x$ for $0 \le x \le \frac{K}{\gamma}$ and $\psi(s,x) = \gamma x$ for $0 \le s < T$, $0 \le x \le \frac{K}{\gamma}$, we have $\widetilde{\psi}(s,x) = \max\{\gamma x, k(s,x)\}$ for $0 \le s \le T$, $0 \le x \le \frac{K}{\gamma}$. Being the maximum of two continuous functions, $\widetilde{\psi}$ is continuous. Also, $\psi \le \widetilde{\psi} \le v_g$.

According to the principle of dynamic programming,

$$v_g(s,x) = \sup_{\tau \in \mathcal{S}_T^{s,x}, \tau \le \theta^{s,x}_{\frac{K}{\gamma}}} e^{rs}\mathbb{E}\left[\int_s^\tau e^{-ru}c\,du + e^{-r\tau}v_g(\tau, X_\tau^{s,x})\right]. \tag{4.16}$$

Comparing (4.9) and (4.16), we see that

$$v_g(s,x) = \sup_{\tau \in \mathcal{S}_T^{s,x}, \tau \le \theta^{s,x}_{\frac{K}{\gamma}}} e^{rs}\mathbb{E}\left[\int_s^\tau e^{-ru}c\,du + e^{-r\tau}\widetilde{\psi}(\tau, X_\tau^{s,x})\right]. \tag{4.17}$$

We fix $(s,x) \in [0,T] \times \left[0, \frac{K}{\gamma}\right]$ and define

$$Y_t^{s,x} \triangleq e^{rs}\left[\int_s^t e^{-ru}c\,du + e^{-rt}v_g(t, X_t^{s,x})\right] \text{ for } s \le t \le \theta_0^{s,x} \wedge \theta^{s,x}_{\frac{K}{\gamma}} \wedge T.$$

We set $\overline{\tau} \triangleq \min\{t \in [s,T] : v_g(t, X_t^{s,x}) = \widetilde{\psi}(t, X_t^{s,x})\}$. Since $v_g = \widetilde{\psi}$ on $\partial_p D_0$, we have $\overline{\tau} \le \theta_0^{s,x} \wedge \theta^{s,x}_{\frac{K}{\gamma}} \wedge T$. According to the theory of optimal stopping applied to (4.17) (see, e.g., [25, Thms. D.12, D.13] or [35, pp. 124–127]), $Y^{s,x}_{t\wedge\theta_0^{s,x}\wedge\theta^{s,x}_{\frac{K}{\gamma}}}$ is a supermartingale and the stopped process $Y^{s,x}_{t\wedge\overline{\tau}}$ is a martingale.

Step 3: *Optimal strategies for the game.* From (4.15) and the fact that $\widetilde{\psi} = \psi \vee k$, we see that $\overline{\tau} = \min\{t \in [s,T] : v_g(t, X_t^{s,x}) = \psi(t, X_t^{s,x})\}$ and

$$v_g(\overline{\tau}, X_{\overline{\tau}}^{s,x}) = \psi(\overline{\tau}, X_{\overline{\tau}}^{s,x}) = \begin{cases} \gamma X_{\overline{\tau}}^{s,x} & \text{if } \overline{\tau} < T, \\ (X_T^{s,x} \wedge L) \vee (\gamma X_T^{s,x}) & \text{if } \overline{\tau} = T. \end{cases} \tag{4.18}$$

Define $\tau^* = \infty$ if $\overline{\tau} = T$ and $0 < X_T^{s,x} < \frac{L}{\gamma}$, and define $\tau^* = \overline{\tau}$ otherwise so that $\tau^* \in \mathcal{S}^{s,x}$ and $\overline{\tau} = \tau^* \wedge T$. We have

$$v_g(\tau^*, X_{\tau^*}^{s,x}) = \gamma X_{\tau^*}^{s,x} \text{ if } \tau^* \le T. \tag{4.19}$$

For every $\rho \in \mathcal{S}_K^{s,x}$, (4.19), (4.13), and the fact that $v_g(T,x) = x \wedge L$ when $0 \le x \le \frac{L}{\gamma}$ imply

$$\begin{aligned} &J_g(s,x;\rho,\tau^*) \\ &= e^{rs}\mathbb{E}\left[\int_s^{\rho\wedge\tau^*\wedge T} e^{-ru}c\,du + e^{-r(\rho\wedge\tau^*\wedge T)}\big(\mathbb{I}_{\{\tau^*\le\rho\wedge T\}}\gamma X_{\tau^*}^{s,x} + \mathbb{I}_{\{\rho<\tau^*\}}K \right. \\ &\qquad \left. + \mathbb{I}_{\{\rho\wedge\tau^*=\infty\}}(X_T^{s,x} \wedge L)\big)\right] \\ &\ge e^{rs}\mathbb{E}\left[\int_s^{\rho\wedge\tau^*\wedge T} e^{-ru}c\,du + e^{-r(\rho\wedge\tau^*\wedge T)}v_g(\rho\wedge\tau^*\wedge T, X^{s,x}_{\rho\wedge\tau^*\wedge T})\right] \\ &= \mathbb{E}Y^{s,x}_{\rho\wedge\overline{\tau}} = \mathbb{E}Y_s^{s,x} = v_g(s,x). \end{aligned} \tag{4.20}$$

This implies $\underline{v}_g(s,x) \ge v_g(s,x)$.

To show that $v_g(s,x) \geq \overline{v}_g(s,x)$, we set $\rho^* \triangleq \theta_0^{s,x} \wedge \theta_{\frac{K}{\gamma}}^{s,x}$, which is in $\mathcal{S}_K^{s,x}$. For every $\tau \in \mathcal{S}^{s,x}$, we have $\rho^* \wedge \tau \wedge T \in \mathcal{S}_T^{s,x}$, and thus

$$\begin{aligned}
&J_g(s,x;\rho^*,\tau)\\
&= e^{rs}\mathbb{E}\left[\int_s^{\rho^*\wedge\tau\wedge T} e^{-ru}c\,du + e^{-r(\rho^*\wedge\tau\wedge T)}\big(\mathbb{I}_{\{\tau\leq\rho^*\wedge T\}}\gamma X_\tau^{s,x} + \mathbb{I}_{\{\rho^*<\tau\}}K\right.\\
&\qquad\left. + \mathbb{I}_{\{\rho^*\wedge\tau=\infty\}}(X_T^{s,x}\wedge L)\big)\right]\\
&\leq e^{rs}\mathbb{E}\left[\int_s^{\rho^*\wedge\tau\wedge T} e^{-ru}c\,du + e^{-r(\rho^*\wedge\tau\wedge T)}\psi(\rho^*\wedge\tau\wedge T, X_{\rho^*\wedge\tau\wedge T}^{s,x})\right]\\
&\leq v_g(s,x). \qquad (4.21)
\end{aligned}$$

This implies $\overline{v}_g(s,x) \leq v_g(s,x)$. We conclude that $v_g = \underline{v}_g = \overline{v}_g$.

Step 4: *Proof of* (4.10). With $\overline{\tau} \in \mathcal{S}_T^{s,x}$ as defined in Step 2, we have from (4.14) and (4.18) that for every $\rho \in \mathcal{S}_T^{s,x}$,

$$\begin{aligned}
&\widetilde{J}_g(s,x;\rho,\overline{\tau})\\
&= e^{rs}\mathbb{E}\left[\int_s^{\rho\wedge\overline{\tau}} e^{-ru}c\,du + e^{-r(\rho\wedge\overline{\tau})}\big(\mathbb{I}_{\{\overline{\tau}<\rho\}}\gamma X_{\overline{\tau}}^{s,x} + \mathbb{I}_{\{\rho\leq\overline{\tau}\}}\varphi(\rho, X_\rho^{s,x})\big)\right]\\
&\geq e^{rs}\mathbb{E}\left[\int_s^{\rho\wedge\overline{\tau}} e^{-ru}c\,du + e^{-r(\rho\wedge\overline{\tau})}v_g(\rho\wedge\overline{\tau}, X_{\rho\wedge\overline{\tau}}^{s,x})\right]\\
&= \mathbb{E}Y_{\rho\wedge\overline{\tau}}^{s,x} \;=\; \mathbb{E}Y_s^{s,x} \;=\; v_g(s,x).
\end{aligned}$$

On the other hand, with ρ^* defined as in Step 3 and

$$\overline{\rho} \triangleq \rho^* \wedge T = \theta_0^{s,x} \wedge \theta_{\frac{K}{\gamma}}^{s,x} \wedge T \in \mathcal{S}_T^{s,x}, \qquad (4.22)$$

we have $\varphi(\overline{\rho}, X_{\overline{\rho}}^{s,x}) = \psi(\overline{\rho}, X_{\overline{\rho}}^{s,x})$. Thus, for every $\tau \in \mathcal{S}_T^{s,x}$,

$$\begin{aligned}
&\widetilde{J}_g(s,x;\overline{\rho},\tau)\\
&= e^{rs}\mathbb{E}\left[\int_s^{\overline{\rho}\wedge\tau} e^{-ru}c\,du + e^{-r(\overline{\rho}\wedge\tau)}\big(\mathbb{I}_{\{\tau<\overline{\rho}\}}\gamma X_\tau^{s,x} + \mathbb{I}_{\{\overline{\rho}\leq\tau\}}\varphi(\overline{\rho}, X_{\overline{\rho}}^{s,x})\big)\right]\\
&= e^{rs}\mathbb{E}\left[\int_s^{\overline{\rho}\wedge\tau} e^{-ru}c\,du + e^{-r(\overline{\rho}\wedge\tau)}\psi(\overline{\rho}\wedge\tau, X_{\overline{\rho}\wedge\tau}^{s,x})\right]\\
&\leq v_g(s,x). \qquad (4.23)
\end{aligned}$$

We complete the argument as in Step 3. □

PROPOSITION 4.6 (Case II). *Assume $\delta K \leq c$. In this case, we define*

$$v_g(s,x) \triangleq \inf_{\rho\in\mathcal{S}_T^{s,x},\rho\leq\theta_{\frac{K}{\gamma}}^{s,x}} e^{rs}\mathbb{E}\left[\int_s^\rho e^{-ru}c\,du + e^{-r\rho}\varphi(\rho, X_\rho^{s,x})\right] \qquad (4.24)$$

for $(s,x) \in [0,T]\times\big[0,\frac{K}{\gamma}\big]$, and we define $v_g(s,x) \triangleq \gamma x$ for $(s,x) \in [0,T]\times(\frac{K}{\gamma},\infty)$. Then $v_g = \underline{v}_g = \overline{v}_g$ on $[0,T]\times\big[0,\infty\big)$. Furthermore,

$$v_g(s,x) = \inf_{\rho\in\mathcal{S}_T^{s,x}}\sup_{\tau\in\mathcal{S}_T^{s,x}} \widetilde{J}_g(s,x;\rho,\tau) = \sup_{\tau\in\mathcal{S}_T^{s,x}}\inf_{\rho\in\mathcal{S}_T^{s,x}} \widetilde{J}_g(s,x;\rho,\tau) \qquad (4.25)$$

for $0 \leq s \leq T$ and $x \geq 0$.

Proof. The claims about v_g for $x > \frac{K}{\gamma}$ follow immediately from Lemmas 4.1 and 4.2. We thus restrict our attention to $0 \le x \le \frac{K}{\gamma}$.

Step 1: *Construction of bounds on* v_g. Define $h_3(t,x) \triangleq \gamma x$ and $h_2(t,x) \triangleq x$ for $0 \le t \le T$ and $0 \le x \le \frac{K}{\gamma}$, so that $h_3 \le \varphi \le h_2$. For $(t,x) \in [0,T] \times \left[0, \frac{K}{\gamma}\right]$, we have (4.12) and

$$\mathcal{L}_g h_3(t,x) = c\gamma + \delta\gamma\big(x - g(t,x)\big) \le c + (1-\gamma)(\delta\gamma x - c) \le c. \tag{4.26}$$

Let $\rho \in \mathcal{S}_T^{s,x}$ satisfy $\rho \le \theta_{\frac{K}{\gamma}}^{s,x}$, and apply (4.5) and (4.26) to conclude

$$\begin{aligned} h_3(s,x) &\le e^{rs}\mathbb{E}\left[\int_s^\rho e^{-ru}c\,du + e^{-r\rho}h_3(\rho, X_\rho^{s,x})\right] \\ &\le e^{rs}\mathbb{E}\left[\int_s^\rho e^{-ru}c\,du + e^{-r\rho}\varphi(\rho, X_\rho^{s,x})\right]. \end{aligned} \tag{4.27}$$

Taking the infimum over ρ, we obtain

$$\gamma x \le v_g(s,x) \text{ for } 0 \le s \le T,\ 0 \le x \le \frac{K}{\gamma}. \tag{4.28}$$

We repeat the above argument with h_2 and $\rho = \theta_0^{s,x} \wedge \theta_{\frac{K}{\gamma}} \wedge T$, using (4.12) to reverse the first inequality and $\varphi \le h_2$ to reverse the second, to obtain

$$\begin{aligned} h_2(s,x) &\ge e^{rs}\mathbb{E}\left[\int_s^\rho e^{-ru}c\,du + e^{-r\rho}h_2(\rho, X_\rho^{s,x})\right] \\ &\ge e^{rs}\mathbb{E}\left[\int_s^\rho e^{-ru}c\,du + e^{-r\rho}\varphi(\rho, X_\rho^{s,x})\right] \\ &\ge v_g(s,x) \text{ for } 0 \le s \le T,\ 0 \le x \le \frac{K}{\gamma}. \end{aligned} \tag{4.29}$$

In fact, since for $(s,x) \in [0,T) \times \left(0, \frac{K}{\gamma}\right)$, with positive probability $X^{s,x}$ exits $[0,T] \times \left(0, \frac{K}{\gamma}\right)$ through the set $\{T\} \times \left(L, \frac{K}{\gamma}\right]$, where h_2 is strictly greater than φ, the second inequality in (4.29) is strict for such (s,x). This implies

$$v_g(s,x) < x \text{ for } 0 \le s < T,\ 0 < x < \frac{K}{\gamma}. \tag{4.30}$$

Step 2: *Optimal stopping time.* Let $\widetilde{c} \in (c, \infty)$ be given and let k be defined by (4.7). For $0 \le s < T$ and $0 < x < \frac{K}{\gamma}$, using the second part of (4.7), we have

$$\begin{aligned} k(s,x) &> e^{rs}\mathbb{E}\left[\int_s^{\theta_0^{s,x} \wedge \theta_{\frac{K}{\gamma}}^{s,x} \wedge T} e^{-ru}c\,du \right. \\ &\qquad \left. + e^{-r(\theta_0^{s,x} \wedge \theta_{\frac{K}{\gamma}}^{s,x} \wedge T)} \varphi\left(\theta_0^{s,x} \wedge \theta_{\frac{K}{\gamma}}^{s,x} \wedge T, X_{\theta_0^{s,x} \wedge \theta_{\frac{K}{\gamma}}^{s,x} \wedge T}^{s,x}\right)\right] \\ &\ge v_g(s,x). \end{aligned} \tag{4.31}$$

We set $\widetilde{\varphi} = \varphi \wedge k$. Because $\varphi(T,x) = k(T,x) \le x \wedge K$ for $0 \le x \le \frac{K}{\gamma}$, and $\varphi(t,x) = x \wedge K$ for $0 \le t < T$, $0 \le x \le \frac{K}{\gamma}$, we have

$$\widetilde{\varphi}(t,x) = (x \wedge K) \wedge k(t,x) \text{ for } 0 \le t \le T,\ 0 \le x \le \frac{K}{\gamma}.$$

This shows that $\widetilde{\varphi}$ is continuous. From (4.24) we have $v_g \le \varphi$, and hence $v_g \le \widetilde{\varphi} \le \varphi$. According to the principle of dynamic programming,

$$v_g(s,x) \triangleq \inf_{\rho \in \mathcal{S}_T^{s,x}, \rho \le \theta_{\frac{K}{\gamma}}^{s,x}} e^{rs}\mathbb{E}\left[\int_s^\rho e^{-ru}c\,du + e^{-r\rho}v_g(\rho, X_\rho^{s,x})\right]. \tag{4.32}$$

Comparing (4.24) and (4.32), we see that

$$v_g(s,x) \triangleq \inf_{\rho \in \mathcal{S}_T^{s,x}, \rho \le \theta_{\frac{K}{\gamma}}^{s,x}} e^{rs}\mathbb{E}\left[\int_s^\rho e^{-ru}c\,du + e^{-r\rho}\widetilde{\varphi}(\rho, X_\rho^{s,x})\right]. \tag{4.33}$$

We fix $(s,x) \in [0,T] \times \left[0, \frac{K}{\gamma}\right]$ and define

$$Z_t^{s,x} = e^{rs}\left[\int_s^t e^{-ru}c\,du + e^{-rt}v_g(t, X_t^{s,x})\right] \text{ for } s \le t \le \theta_0^{s,x} \wedge \theta_{\frac{K}{\gamma}}^{s,x} \wedge T.$$

We set

$$\overline{\rho} \triangleq \min\{t \in [s,T] : v_g(t, X_t^{s,x}) = \widetilde{\varphi}(t, X_t^{s,x})\}. \tag{4.34}$$

Since $v_g = \widetilde{\varphi}$ on $\partial_p D_0$, we have $\overline{\rho} \le \theta_0^{s,x} \wedge \theta_{\frac{K}{\gamma}}^{s,x} \wedge T$. According to the theory of optimal stopping, $Z_{t \wedge \theta_0^{s,x} \wedge \theta_{\frac{K}{\gamma}}^{s,x}}^{s,x}$ is a submartingale and the stopped process $Z_{t \wedge \overline{\rho}}^{s,x}$ is a martingale.

Step 3: *Optimal strategies for the game.* Because of (4.31), we have that $\overline{\rho} = \min\{t \in [s,T] : v_g(t, X_t^{s,x}) = \varphi(t, X_t^{s,x})\}$. In particular, $v_g(\overline{\rho}, X_{\overline{\rho}}^{s,x}) = X_{\overline{\rho}}^{s,x} \wedge K$ on $\{\overline{\rho} < T\}$. Inequality (4.30) then implies

$$v_g(\overline{\rho}, X_{\overline{\rho}}^{s,x}) = K < X_{\overline{\rho}}^{s,x} \text{ on } \{\overline{\rho} < \theta_0^{s,x} \wedge T\}. \tag{4.35}$$

Define

$$\rho^* \triangleq \begin{cases} \infty & \text{if } \overline{\rho} = T \text{ and } X_{\overline{\rho}}^{s,x} > 0, \\ \overline{\rho} & \text{otherwise,} \end{cases}$$

so that $\rho^* \in \mathcal{S}_K^{s,x}$ and $\overline{\rho} = \rho^* \wedge T$. For every $\tau \in \mathcal{S}^{s,x}$, (4.28), (4.35), and the fact that $v_g(T,x) = \varphi(T,x) \ge x \wedge L$ when $0 \le x \le \frac{K}{\gamma}$ imply

$$\begin{aligned} &J_g(s,x;\rho^*,\tau) \\ &= e^{rs}\mathbb{E}\left[\int_s^{\rho^* \wedge \tau \wedge T} ce^{-ru}\,du + e^{-r(\rho^* \wedge \tau \wedge T)}\big(\mathbb{I}_{\{\tau \le \rho^* \wedge T\}}\gamma X_\tau^{s,x} + \mathbb{I}_{\{\rho^* < \tau\}}K \right. \\ &\qquad \left. + \mathbb{I}_{\{\rho^* \wedge \tau = \infty\}}(X_T^{s,x} \wedge L)\big)\right] \\ &\le e^{rs}\mathbb{E}\left[\int_s^{\rho^* \wedge \tau \wedge T} ce^{-ru}\,du + e^{-r(\rho^* \wedge \tau \wedge T)}v_g(\rho^* \wedge \tau \wedge T, X_{\rho^* \wedge \tau \wedge T}^{s,x})\right] \\ &= \mathbb{E}Z_{\overline{\rho} \wedge \tau}^{s,x} = Z_s^{s,x} = v_g(s,x). \end{aligned} \tag{4.36}$$

This implies $\overline{v}_g(s,x) \le v_g(s,x)$.

We set

$$\overline{\tau} \triangleq \theta_0^{s,x} \wedge \theta_{\frac{K}{\gamma}}^{s,x} \wedge T, \tag{4.37}$$

$$\tau^* \triangleq \begin{cases} \overline{\tau} & \text{if } \overline{\tau} < T, \\ T & \text{if } \overline{\tau} = T,\ X_T^{s,x} \geq \frac{L}{\gamma} \text{ or if } \overline{\tau} = T,\ X_T^{s,x} = 0, \\ \infty & \text{if } \overline{\tau} = T, 0 < X_T^{s,x} < \frac{L}{\gamma}, \end{cases} \tag{4.38}$$

so that $\tau^* \in \mathcal{S}^{s,x}$. For every $\rho \in \mathcal{S}_K^{s,x}$, we have

$$\begin{aligned} &J_g(s,x;\rho,\tau^*) \\ &= e^{rs}\mathbb{E}\left[\int_s^{\rho\wedge\tau^*\wedge T} ce^{-ru}\,du + e^{-r(\rho\wedge\tau^*\wedge T)}\big(\mathbb{I}_{\{\tau^*\leq\rho\wedge T\}}\gamma X_\tau^{s,x} + \mathbb{I}_{\{\rho<\tau^*\}}K \right. \\ &\qquad \left. + \mathbb{I}_{\{\rho\wedge\tau^*=\infty\}}(X_T^{s,x}\wedge L)\big)\right] \\ &\geq e^{rs}\mathbb{E}\left[\int_s^{\rho\wedge\tau^*\wedge T} ce^{-ru}\,du + e^{-r(\rho\wedge\tau^*\wedge T)}\varphi(\rho^*\wedge\tau\wedge T, X_{\rho\wedge\tau^*\wedge T}^{s,x})\right] \\ &\geq v_g(s,x). \end{aligned} \tag{4.39}$$

This implies $\underline{v}_g(s,x) \geq v_g(s,x)$. We conclude that $v_g = \underline{v}_g = \overline{v}_g$.

Step 4. *Proof of* (4.25). With $\overline{\rho} \in \mathcal{S}^{s,x}$ given by (4.34), we have $v_g(\overline{\rho}, X_{\overline{\rho}}^{s,x}) = \varphi(\overline{\rho}\wedge\tau, X_{\overline{\rho}\wedge\tau}^{s,x})$, and (4.28) implies that for $\tau \in \mathcal{S}_T^{s,x}$,

$$\begin{aligned} &\widetilde{J}_g(s,x;\overline{\rho},\tau) \\ &= e^{rs}\mathbb{E}\left[\int_s^{\overline{\rho}\wedge\tau} e^{-ru}c\,du + e^{-r(\overline{\rho}\wedge\tau)}\big(\mathbb{I}_{\{\tau<\overline{\rho}\}}\gamma X_\tau^{s,x} + \mathbb{I}_{\{\overline{\rho}\leq\tau\}}\varphi(\overline{\rho}, X_{\overline{\rho}}^{s,x})\big)\right] \\ &\leq e^{rs}\mathbb{E}\left[\int_s^{\overline{\rho}\wedge\tau} e^{-ru}c\,du + e^{-r(\overline{\rho}\wedge\tau)}v_g(\overline{\rho}\wedge\tau, X_{\overline{\rho}\wedge\tau}^{s,x})\right] \\ &= \mathbb{E}Z_{\overline{\rho}\wedge\tau}^{s,x} \;=\; Z_s^{s,x} \;=\; v_g(s,x). \end{aligned}$$

With $\overline{\tau} \in \mathcal{S}_T^{s,x}$ defined by (4.37), we have for every $\rho \in \mathcal{S}_T^{s,x}$,

$$\begin{aligned} &\widetilde{J}_g(s,x;\rho,\overline{\tau}) \\ &= e^{rs}\mathbb{E}\left[\int_s^{\rho\wedge\overline{\tau}} e^{-rs}c\,du + e^{-r(\rho\wedge\overline{\tau})}\big(\mathbb{I}_{\{\overline{\tau}<\rho\}}\gamma X_{\overline{\tau}}^{s,x} + \mathbb{I}_{\{\rho\leq\overline{\tau}\}}\varphi(\rho, X_\rho^{s,x})\big)\right] \\ &= e^{rs}\mathbb{E}\left[\int_s^{\rho\wedge\overline{\tau}} e^{-rs}c\,du + e^{-r(\rho\wedge\overline{\tau})}\varphi(\rho\wedge\overline{\tau}, X_{\rho\wedge\overline{\tau}}^{s,x})\right] \;\geq\; v_g(s,x). \end{aligned} \tag{4.40}$$

We complete the argument as in Step 3. □

PROPOSITION 4.7 (overlapping case). *Assume* $\delta K \leq c \leq rK$. *In this case,* v_g *defined by* (4.9) *agrees with* v_g *defined by* (4.24), *and for* $0 \leq s \leq T$ *and* $0 \leq x \leq \frac{K}{\gamma}$,

$$\begin{aligned} &v_g(s,x) \\ &= e^{rs}\mathbb{E}\left[\int_s^{\theta_0^{s,x}\wedge\theta_{\frac{K}{\gamma}}^{s,x}\wedge T} e^{-ru}c\,du + e^{-r(\theta_0^{s,x}\wedge\theta_{\frac{K}{\gamma}}^{s,x}\wedge T)}\psi\left(\theta_0^{s,x}\wedge\theta_{\frac{K}{\gamma}}^{s,x}\wedge T, X_{\theta_0^{s,x}\wedge\theta_{\frac{K}{\gamma}}^{s,x}\wedge T}^{s,x}\right)\right] \\ &= e^{rs}\mathbb{E}\left[\int_s^{\theta_0^{s,x}\wedge\theta_{\frac{K}{\gamma}}^{s,x}\wedge T} e^{-ru}c\,du + e^{-r(\theta_0^{s,x}\wedge\theta_{\frac{K}{\gamma}}^{s,x}\wedge T)}\varphi\left(\theta_0^{s,x}\wedge\theta_{\frac{K}{\gamma}}^{s,x}\wedge T, X_{\theta_0^{s,x}\wedge\theta_{\frac{K}{\gamma}}^{s,x}\wedge T}^{s,x}\right)\right]. \end{aligned} \tag{4.41}$$

Furthermore,

$$\gamma x < v_g(s,x) < x \wedge K \text{ for } 0 \le s < T \text{ and } 0 < x < \frac{K}{\gamma}. \tag{4.42}$$

Proof. The function v_g defined by (4.9) satisfies (4.10), the function v_g defined by (4.24) satisfies (4.25), and so these definitions of v_g coincide. With $\overline{\rho} \triangleq \overline{\tau}$ given by (4.22) and (4.37), inequalities (4.23) and (4.40) imply

$$\begin{aligned}
&e^{rs}\mathbb{E}\left[\int_s^{\overline{\rho}} e^{-ru}c\,du + e^{-r\overline{\rho}}\varphi(\overline{\rho}, X_{\overline{\rho}}^{s,x})\right] \\
&= e^{rs}\mathbb{E}\left[\int_s^{\overline{\rho}} e^{-ru}c\,du + e^{-r\overline{\rho}}\psi(\overline{\rho}, X_{\overline{\rho}}^{s,x})\right] \\
&\le v_g(s,x) \\
&\le e^{rs}\mathbb{E}\left[\int_s^{\overline{\rho}} e^{-ru}c\,du + e^{-r\overline{\rho}}\varphi(\overline{\rho}, X_{\overline{\rho}}^{s,x})\right],
\end{aligned}$$

which gives us (4.41).

We return to (4.11), replacing τ with $\overline{\rho}$ and using the fact that when $0 \le s < T$ and $0 < x < \frac{K}{\gamma}$, there is a positive probability that $X^{s,x}$ exits $[0,T] \times \left[0, \frac{K}{\gamma}\right]$ through the set $\left\{(t,x) : t = T, 0 < x < \frac{K}{\gamma}\right\}$, where $h_1 = K$ is strictly larger than ψ. This implies

$$K > e^{rs}\mathbb{E}\left[\int_s^{\overline{\rho}} e^{-ru}c\,du + e^{-r\overline{\rho}}\psi(\overline{\rho}, X_{\overline{\rho}}^{s,x})\right] = v_g(s,x).$$

The second inequality in (4.42) follows from this and (4.30). For the first inequality in (4.42), we replace ρ in (4.27) with $\overline{\rho}$ and use the fact that when $0 \le s < T$ and $0 < x < \frac{K}{\gamma}$, there is a positive probability that $X^{s,x}$ exits $[0,T] \times \left[0, \frac{K}{\gamma}\right]$ through the set $\left\{(t,x) : t = T, 0 < x < \frac{L}{\gamma}\right\}$, where $h_3 = \gamma x$ is strictly smaller than φ, to obtain

$$\gamma x < e^{rs}\mathbb{E}\left[\int_s^{\overline{\rho}} e^{-ru}c\,du + e^{-r\overline{\rho}}\varphi(\overline{\rho}, X_{\overline{\rho}}^{s,x})\right] = v_g(s,x). \qquad \square$$

4.5. Membership of v_g in $\mathcal{G}$. To show that $v_g \in \mathcal{G}$ whenever $g \in \mathcal{G}$, we must verify that v_g is continuous and satisfies (3.1)–(3.3). Property (3.1) is provided by Propositions 4.5 and 4.6. When $c \le rK$, we obtain the lower bound in (3.3) directly from (4.9) and the fact that $\psi \ge \gamma x$, and (4.13) provides the upper bound. When $\delta K \le C$, the upper bound in (3.3) comes from (4.24), the fact that $\varphi \le K$ on $[0,T] \times \left[0, \frac{K}{\gamma}\right]$, and (4.29). The lower bound comes from (4.28). It remains to verify that v_g is continuous and satisfies (3.2), which is the subject of this section.

LEMMA 4.8. *We have*

$$0 \le v_g(s,y) - v_g(s,x) \le y - x \text{ for } 0 \le s \le T \text{ and } 0 \le x \le y. \tag{4.43}$$

Proof. In Step 4 of the proofs of Propositions 4.5 and 4.6, we produced stopping times $\overline{\rho}, \overline{\tau} \in \mathcal{S}_T^{s,x}$ such that

$$\widetilde{J}_g(s,x;\overline{\rho},\tau) \le v_g(s,x) \le \widetilde{J}_g(s,x;\rho,\overline{\tau}) \text{ for all } \rho, \tau \in \mathcal{S}_T^{s,x}. \tag{4.44}$$

It follows from this that $v_g(s,x) = \widetilde{J}_g(s,x;\overline{\rho},\overline{\tau})$. Relation (4.44) was developed for $(s,x) \in [0,T] \times \left[0, \frac{K}{\gamma}\right]$, but in light of Lemma 4.2, it holds as well for $(s,x) \in [0,T] \times \left[\frac{K}{\gamma}, \infty\right)$ if we define $\overline{\rho} = \overline{\tau} = s$ in this case.

We note that ψ and φ satisfy (3.2), and we use the representations (4.10), (4.25) to show that v_g does as well. Without loss of generality, we consider only the case $s = 0$. We let $0 \le x \le y < \infty$ be given. Then $X_t^{0,x} \le X_t^{0,y}$ for $0 \le t \le T$, almost surely, and $\mathcal{S}_T^{0,x} \subset \mathcal{S}_T^{0,y}$.

Consider the nonnegative martingale $Z_t = e^{-\sigma W_t - \frac{1}{2}\sigma^2 t}$. We compute

$$\begin{aligned} d\big((X_t^{0,y} - X_t^{0,x})Z_t\big) &= (r-\sigma^2)(X_t^{0,y} - X_t^{0,x})Z_t\,dt \\ &\quad -\delta\big[(X_t^{0,y} - X_t^{0,x}) - \big(g(t,X_t^{0,y}) - g(t,X_t^{0,x})\big)\big]Z_t\,dt \\ &\le (r-\sigma^2)(X_t^{0,y} - X_t^{0,x})Z_t\,dt. \end{aligned}$$

Gronwall's inequality implies $(X_t^{0,y} - X_t^{0,x})Z_t \le (y-x)e^{(r-\sigma^2)t}$, or equivalently,

$$e^{-rt}\big(X_t^{0,y} - X_t^{0,x}\big) \le (y-x)e^{\sigma W_t - \frac{1}{2}\sigma^2 t},\ 0 \le t \le \tau_0^{0,x}.$$

Let $\overline{\tau}, \overline{\rho} \in \mathcal{S}_T^{0,x}$ be the stopping times appearing in (4.44) corresponding to the initial condition $(0,x)$. For every $\tau \in \mathcal{S}^{0,x}$, we have

$$\begin{aligned} &\widetilde{J}_g(0,x;\overline{\rho},\tau) \\ &= \mathbb{E}\left[\int_0^{\overline{\rho}\wedge\tau} ce^{-ru}\,du + e^{-r(\overline{\rho}\wedge\tau)}\big(\mathbb{I}_{\{\tau<\overline{\rho}\}}\psi(\tau, X_\tau^{0,x}) + \mathbb{I}_{\{\overline{\rho}\le\tau\}}\varphi(\overline{\rho}, X_{\overline{\rho}}^{0,x})\big)\right] \\ &= \widetilde{J}_g(0,y;\overline{\rho},\tau) - \mathbb{E}\left[e^{-r(\overline{\rho}\wedge\tau)}\Big(\mathbb{I}_{\{\tau<\overline{\rho}\}}\big(\psi(X_\tau^{0,y}) - \psi(X_\tau^{0,x})\big)\right. \\ &\qquad\qquad \left. +\mathbb{I}_{\{\overline{\rho}\le\tau\}}\big(\varphi(\overline{\rho}, X_{\overline{\rho}}^{0,y}) - \varphi(\overline{\rho}, X_{\overline{\rho}}^{0,x})\big)\Big)\right] \\ &\ge \widetilde{J}_g(0,y;\overline{\rho},\tau) - \mathbb{E}\left[e^{-r(\overline{\rho}\wedge\tau)}(X_{\overline{\rho}\wedge\tau}^{0,y} - X_{\overline{\rho}\wedge\tau}^{0,x})\right] \\ &\ge \widetilde{J}_g(0,y;\overline{\rho},\tau) - (y-x)\mathbb{E}e^{\sigma W(\overline{\rho}\wedge\tau) - \frac{1}{2}\sigma^2(\overline{\rho}\wedge\tau)} \\ &= \widetilde{J}_g(0,y;\overline{\rho},\tau) - (y-x). \end{aligned}$$

Furthermore, $\overline{\rho}\wedge\tau \in \mathcal{S}_T^{0,x}$ whenever $\tau \in \mathcal{S}_T^{0,y}$, and for $z = x$ and $z = y$, we have $\widetilde{J}_g(0,z;\overline{\rho},\tau) = \widetilde{J}_g(0,z;\overline{\rho},\overline{\rho}\wedge\tau)$. Therefore,

$$\begin{aligned} v_g(0,x) + y - x &= \widetilde{J}_g(0,x;\overline{\rho},\overline{\tau}) + y - x \\ &= \sup_{\tau\in\mathcal{S}_T^{0,x}} \widetilde{J}_g(0,x;\overline{\rho},\overline{\rho}\wedge\tau) + y - x \\ &\ge \sup_{\tau\in\mathcal{S}_T^{0,x}} \widetilde{J}_g(0,y;\overline{\rho},\overline{\rho}\wedge\tau) \\ &= \sup_{\tau\in\mathcal{S}_T^{0,y}} \widetilde{J}_g(0,y;\overline{\rho},\overline{\rho}\wedge\tau) \\ &= \sup_{\tau\in\mathcal{S}_T^{0,y}} \widetilde{J}_g(0,y;\overline{\rho},\tau) \\ &\ge \inf_{\rho\in\mathcal{S}_T^{0,y}} \sup_{\tau\in\mathcal{S}_T^{0,y}} \widetilde{J}_g(0,y;\rho,\tau) \\ &= v_g(0,y). \end{aligned}$$

This establishes the second inequality in (4.43).

The set of stopping times $\mathcal{S}_T^{0,x}$ is the set of all stopping times of the form $\tau \wedge \theta_0^{0,x}$, where τ is any stopping time in the set $\mathcal{S}_T$ of all stopping times satisfying $\tau \leq T$ almost surely. Therefore,

$$v_g(0,x) = \sup_{\tau \in \mathcal{S}_T} \inf_{\rho \in \mathcal{S}_T} \widetilde{J}_g(0,x;\rho \wedge \theta_0^{0,x}, \tau \wedge \theta_0^{0,x}),$$
$$v_g(0,y) = \sup_{\tau \in \mathcal{S}_T} \inf_{\rho \in \mathcal{S}_T} \widetilde{J}_g(0,y;\rho \wedge \theta_0^{0,y}, \tau \wedge \theta_0^{0,y}).$$

Thus, to prove the first inequality in (4.43), it suffices to show that

$$\widetilde{J}_g(0,x;\rho \wedge \theta_0^{0,x}, \tau \wedge \theta_0^{0,x}) \leq \widetilde{J}_g(0,y;\rho \wedge \theta_0^{0,y}, \tau \wedge \theta_0^{0,y})$$

for all $\rho, \tau \in \mathcal{S}_T$. This follows from the definition of $\widetilde{J}_g$ and $\theta_0^{0,x} \leq \theta_0^{0,y}$. □

The value functions of optimal stopping problems with continuous payoff functions are continuous (see [5]), and thus the representations (4.17) and (4.33) of v_g imply continuity of v_g. In this model, however, continuity can be proved without invoking the general theory. We have already shown in Lemma 4.8 that $v_g(s,x)$ is Lipschitz in $x \in [0,\infty)$, uniformly in $s \in [0,T]$. Given this, it is not difficult to show that $v_g(s,x)$ is jointly continuous in (s,x), and we do that here.

LEMMA 4.9. *The function v_g is continuous on $[0,T] \times [0,\infty)$.*

Proof. Because of Lemmas 4.1 and 4.8, we need only show for each fixed $x \in (0, \frac{K}{\gamma})$ that the function $s \mapsto v_g(s,x)$ is continuous. With x fixed, $s \in [0,T]$, $\epsilon > 0$, and $\delta > 0$, we define

$$A_{\epsilon,\delta}^{s,x} \triangleq \left\{ \max_{u \in [s, \theta_0^{s,x} \wedge \theta_{\frac{K}{\gamma}}^{s,x} \wedge (s+\delta) \wedge T]} \left| X_u^{s,x} - x \right| \leq \epsilon \right\}.$$

Because g is bounded on $[0,T] \times [0, \frac{K}{\gamma}]$, (3.4) and (2.5) imply

$$\lim_{\delta \downarrow 0} \min_{s \in [0,T]} \mathbb{P}(A_{\epsilon,\delta}^{s,x}) = 1 \text{ for every } \epsilon > 0. \tag{4.45}$$

We proceed under the Case II assumption $\delta K \leq c$; the argument in Case I is similar. In Case II, the submartingale $Z_{t \wedge \theta_0^{s,x} \wedge \theta_{\frac{K}{\gamma}}^{s,x}}^{s,x}$ of Step 2 of the proof of Proposition 4.6 is a martingale when stopped at $\overline{\rho}$ given by (4.34). Let s and t satisfy $0 \leq s < t \leq (s+\delta) \wedge T$. Then

$$\begin{aligned} & v_g(s,x) \\ & = e^{rs}\mathbb{E}\left[\int_s^{\overline{\rho} \wedge t} e^{-rs} c \, du + e^{-r(\overline{\rho} \wedge t)} v_g(\overline{\rho} \wedge t, X_{\overline{\rho} \wedge t}^{s,x}) \right] \\ & \leq e^{rs}\mathbb{E}\left[\int_s^{\rho \wedge t} e^{-ru} c \, du + e^{-r\rho} v_g(\rho \wedge t, X_{\rho \wedge t}^{s,x}) \right] \text{ for } \rho \in \mathcal{S}_T^{s,x}, \rho \leq \theta_{\frac{K}{\gamma}}^{s,x}. \end{aligned} \tag{4.46}$$

If $\overline{\rho} < t$, then $v_g(\overline{\rho} \wedge t, X_{\overline{\rho} \wedge t}^{s,x}) = \widetilde{\varphi}(\overline{\rho}, X_{\overline{\rho}}^{s,x})$. But $\widetilde{\varphi} = \varphi \wedge k$, and (4.31) shows that for $(u,y) \in [0,T) \times \left(0, \frac{K}{\gamma}\right)$, we have $v_g(u,y) = \widetilde{\varphi}(u,y)$ if and only if $v_g(u,y) = \varphi(u,y) = y \wedge K$. This observation combined with (4.30) yields

$$v_g(u,y) = \widetilde{\varphi}(u,y) \;\Leftrightarrow\; v_g(u,y) = K \text{ for } u \in [0,T),\ y \in \left(0, \frac{K}{\gamma}\right). \tag{4.47}$$

We now choose $\epsilon > 0$ so that $0 < x - \epsilon < x + \epsilon < \frac{K}{\gamma}$. On the set $\{\overline{\rho} < t\} \cap A^{s,x}_{\epsilon,\delta}$ we have $0 < X^{s,x}_{\overline{\rho}\wedge t} = X^{s,x}_{\overline{\rho}} < \frac{K}{\gamma}$, and thus

$$v_g(\overline{\rho} \wedge t, X^{s,x}_{\overline{\rho}\wedge t}) = v_g(\overline{\rho}, X^{s,x}_{\overline{\rho}}) = K \geq v_g(t,x) - \epsilon.$$

On the set $\{\overline{\rho} \geq t\} \cap A^{s,x}_{\epsilon,\delta}$, we also have $v_g(\overline{\rho}\wedge t, X^{s,x}_{\overline{\rho}\wedge t}) \geq v_g(t,x) - \epsilon$, this time because of the Lipschitz continuity (4.43). The equality in (4.46) implies

$$v_g(s,x) \geq e^{rs}\mathbb{E}\big[e^{-r(\overline{\rho}\wedge t)} v_g(\overline{\rho}\wedge t, X^{s,x}_{\overline{\rho}\wedge t})\big] \geq e^{-r\delta}\mathbb{P}(A^{s,x}_{\epsilon,\delta})\big[v_g(t,x) - \epsilon\big]. \tag{4.48}$$

On the other hand, on the set $A^{s,x}_{\epsilon,\delta}$, we have $\theta^{s,x}_0 \wedge \theta^{s,x}_{\frac{K}{\gamma}} \wedge t = t$, and the inequality in (4.46) implies

$$\begin{aligned}
&v_g(s,x)\\
&\leq e^{rs}\mathbb{E}\left[\int_s^{\theta^{s,x}_0 \wedge \theta^{s,x}_{\frac{K}{\gamma}} \wedge t} e^{-ru}c\,du + e^{-r(\theta^{s,x}_0 \wedge \theta^{s,x}_{\frac{K}{\gamma}} \wedge t)} v_g\left(\theta^{s,x}_0 \wedge \theta^{s,x}_{\frac{K}{\gamma}} \wedge t, X^{s,x}_{\theta^{s,x}_0 \wedge \theta^{s,x}_{\frac{K}{\gamma}} \wedge t}\right)\right]\\
&\leq e^{rs}\int_s^{s+\delta} e^{-ru}c\,du + \big[1 - \mathbb{P}(A^{s,x}_{\epsilon,\delta})\big]K + \mathbb{E}\left[\mathbb{I}_{A^{s,x}_{\epsilon,\delta}} v_g(t, X^{s,x}_t)\right]\\
&\leq \frac{c}{r}(1 - e^{-r\delta}) + [1 - \mathbb{P}(A^{s,x}_{\epsilon,\delta})]K + \mathbb{P}(A^{s,x}_{\epsilon,\delta})\big(v_g(t,x) + \epsilon\big).
\end{aligned} \tag{4.49}$$

From (4.48) and (4.49), using the fact that $0 \leq v_g(t,x) \leq K$, we obtain

$$-[1 - e^{-r\delta}\mathbb{P}(A^{s,x}_{\epsilon,\delta})]K - \epsilon \leq v_g(s,x) - v_g(t,x) \leq \frac{c}{r}(1 - e^{-r\delta}) + [1 - \mathbb{P}(A^{s,x}_{\epsilon,\delta})]K + \epsilon.$$

Continuity of $s \mapsto v_g(s,x)$ follows from this and (4.45). □

5. Viscosity solution characterization of v_g. Propositions 4.5 and 4.6 establish (3.5). Except for the fact that we have fixed a function $g \in \mathcal{G}$ that may not satisfy the fixed point condition $v_g = g$, Proposition 4.5 says further that when $c \leq rK$, the convertible bond pricing problem reduces to the problem of optimal conversion in the region $[0,T] \times \big[0, \frac{K}{\gamma}\big]$. In particular, (4.20) and (4.21) show that the firm should use the call strategy $\rho^* = \theta^{s,x}_0 \wedge \theta^{s,x}_{\frac{K}{\gamma}}$. Proposition 4.6 shows that when $\delta K \leq c$, the convertible bond pricing problem reduces to the problem of optimal call. In particular, (4.36) and (4.39) show that the bondholder should use the conversion strategy τ^* of (4.38). Note that at maturity, τ^* mandates conversion if and only if the conversion value $\gamma X^{s,x}_T$ exceeds the par value L. These are the main assertions of Theorem 3.2.

In this section, we examine the versions of (3.8) and (3.9) appropriate for the situation with $g \in \mathcal{G}$ chosen a priori. These equations are

$$\min\{\mathcal{L}_g v - c, v - \gamma x\} = 0, \tag{5.1}$$

$$\max\{\mathcal{L}_g v - c, v - K\} = 0, \tag{5.2}$$

where $\mathcal{L}_g$ is given by (4.6). The proofs that the value function of the optimal stopping problem (4.9) satisfies (5.1) and that the value function of problem (4.24) satisfies (5.2), both in the viscosity sense on $(0,T) \times \big(0, \frac{K}{\gamma}\big)$ (see Definition 5.1 below), are standard and are omitted. Uniqueness of the continuous viscosity solutions of (5.1)

and (5.2) subject to the boundary conditions (3.6) and (3.7) follows from Lemma 6.1 below; see Remark 6.2.

We refer the reader to [13] and [17] for a detailed development of the theory of second-order viscosity solutions for Hamilton–Jacobi–Bellman equations and to [34] for an application of this theory to optimal stopping.

DEFINITION 5.1. *Let v be a continuous function defined on $(0,T)\times\left(0,\frac{K}{\gamma}\right)$.*

(a) *The function v is a* viscosity subsolution *of* (5.1) (*respectively,* (5.2)) *if, for every point $(t_0,x_0)\in(0,T)\times\left(0,\frac{K}{\gamma}\right)$ and for every "test function" $h\in C^{1,2}\left((0,T)\times\left(0,\frac{K}{\gamma}\right)\right)$ satisfying $v\le h$ on $(0,T)\times\left(0,\frac{K}{\gamma}\right)$ and $v(t_0,x_0)=h(t_0,x_0)$, we have $\min\{\mathcal{L}_g h(t_0,x_0)-c, h(t_0,x_0)-\gamma x_0\}\le 0$ (respectively, $\max\{\mathcal{L}_g h(t_0,x_0)-c, h(t_0,x_0)-K\}\le 0$).*

(b) *The function v is a* viscosity supersolution *of* (5.1) (*respectively,* (5.2)) *if, for every point $(t_0,x_0)\in(0,T)\times\left(0,\frac{K}{\gamma}\right)$ and for every "test function" $h\in C^{1,2}\left((0,T)\times\left(0,\frac{K}{\gamma}\right)\right)$ satisfying $v\ge h$ on $(0,T)\times\left(0,\frac{K}{\gamma}\right)$ and $v(t_0,x_0)=h(t_0,x_0)$, we have $\min\{\mathcal{L}_g h(t_0,x_0)-c, h(t_0,x_0)-\gamma x_0\}\ge 0$ (respectively, $\max\{\mathcal{L}_g h(t_0,x_0)-c, h(t_0,x_0)-K\}\ge 0$).*

A function v is a viscosity solution *of one of these equations if it is both a viscosity subsolution and a viscosity supersolution.*

The pricing function for the convertible bond satisfies a variational inequality, and the solution of a variational inequality is often the solution to a *free boundary problem*, where the "free boundary" divides the region in which an action (conversion or call) should take place from a region in which no action should occur. We show in section 8 that the bond pricing function does indeed satisfy a free boundary problem, and we derive properties of the free boundary. To prepare for that analysis, we introduce the following sets.

In Case I ($c\le rK$) of Proposition 4.5, we define the *continuation set*

$$\begin{aligned}\mathcal{C}_T^I &\triangleq \left\{(t,x)\in(0,T)\times\left(0,\frac{K}{\gamma}\right) : v_g(t,x)>\gamma x\right\}\\ &= \left\{(t,x)\in(0,T)\times\left(0,\frac{K}{\gamma}\right) : v_g(t,x)>\widetilde{\psi}(t,x)\right\},\end{aligned}\tag{5.3}$$

where $\widetilde{\psi}(t,x)=\max\{\gamma x, k(t,x)\}$ is defined in Step 2 of the proof of Proposition 4.5. Because k satisfies (4.15), $v_g(t,x)>\gamma x$ if and only if $v_g(t,x)>\widetilde{\psi}(t,x)$. Because v_g and $\widetilde{\psi}$ are continuous, $\mathcal{C}_T^I$ is open. Define the *stopping set*

$$\begin{aligned}\mathcal{S}_T^I &\triangleq \left\{(t,x)\in[0,T]\times\left[0,\frac{K}{\gamma}\right] : v_g(t,x)=\psi(t,x)\right\}\\ &= \left\{(t,x)\in[0,T]\times\left[0,\frac{K}{\gamma}\right] : v_g(t,x)=\widetilde{\psi}(t,x)\right\}.\end{aligned}$$

The equality is justified by the same argument that justified the equality in (5.3) and the additional observation that $\psi(T,\cdot)=\widetilde{\psi}(T,\cdot)$. The set $\mathcal{S}_T^I$ is closed. Under the Case I assumption, v_g is a viscosity solution of (5.1), which is equivalent to the following three conditions:

(i) $v_g\ge\gamma x$ on $[0,T]\times\left[0,\frac{K}{\gamma}\right]$,

(ii) v_g is a viscosity supersolution of $\mathcal{L}_g v-c=0$ on $(0,T)\times\left(0,\frac{K}{\gamma}\right)$, and

(iii) v_g is a viscosity solution of $\mathcal{L}_g v - c = 0$ on $\mathcal{C}_T^I$.

In Case II ($\delta K \le c$) of Proposition 4.6, we define the *continuation set*

$$\begin{aligned}\mathcal{C}_T^{II} &\triangleq \left\{(t,x) \in (0,T) \times \left(0, \frac{K}{\gamma}\right) : v_g(t,x) < K\right\} \\ &= \left\{(t,x) \in (0,T) \times \left(0, \frac{K}{\gamma}\right) : v_g(t,x) < \widetilde{\varphi}(t,x)\right\}, \end{aligned} \tag{5.4}$$

where $\widetilde{\varphi} = \varphi \wedge k$ is defined in Step 2 of the proof of Proposition 4.6, and the equality in (5.4) is justified by (4.47). The set $\mathcal{C}_T^{II}$ is open. Define the *stopping set*

$$\begin{aligned}\mathcal{S}_T^{II} &\triangleq \left\{(t,x) \in [0,T] \times \left[0, \frac{K}{\gamma}\right] : v_g(t,x) = \varphi(t,x)\right\} \\ &= \left\{(t,x) \in [0,T] \times \left[0, \frac{K}{\gamma}\right] : v_g(t,x) = \widetilde{\varphi}(t,x)\right\}. \end{aligned}$$

The equality is justified by the argument that justified (5.4) and the additional observations that $\varphi(T,\cdot) = \widetilde{\varphi}(T,\cdot)$. The set $\mathcal{S}_T^{II}$ is closed. Under the Case II assumption, v_g is a viscosity solution of (5.2), which is equivalent to the following conditions:

(iv) $v_g \le K$ on $[0,T] \times \left[0, \frac{K}{\gamma}\right]$,

(v) v_g is a viscosity subsolution of $\mathcal{L}_g v - c = 0$ on $(0,T) \times \left(0, \frac{K}{\gamma}\right)$, and

(vi) v_g is a viscosity solution of $\mathcal{L}_g v - c = 0$ on $\mathcal{C}_T^{II}$.

Remark 5.2. In the overlapping case, $\delta K \le c \le rK$, we have from Proposition 4.7 that $\mathcal{C}_T^I = \mathcal{C}_T^{II} = (0,T) \times (0, \frac{K}{\gamma})$ and v_g is a viscosity solution of $\mathcal{L}_g u - c = 0$ on this set. Remark 4.4 applies in the overlapping case, which is why we require $\mathcal{L}_g v_g - c = 0$ to hold only in the viscosity sense.

6. Proof of Theorem 3.1. In this section we prove Theorem 3.1 and also prove that the continuous viscosity solutions of (5.1) and (5.2) with boundary conditions (3.6) and (3.7) are unique. In light of Propositions 4.5 and 4.6 and the discussion of section 5, this provides the final step in the proof of Theorem 3.2.

For $\epsilon \in \left[0, \frac{K}{\gamma}\right)$, we define the sets

$$D_\epsilon \triangleq [0,T] \times \left[\epsilon, \frac{K}{\gamma}\right], \quad \widetilde{D}_\epsilon \triangleq [0,T] \times \left[\log \epsilon, \log \frac{K}{\gamma}\right],$$

their parabolic boundaries

$$\begin{aligned}\partial_p D_\epsilon &\triangleq \left([0,T] \times \left\{\epsilon, \frac{K}{\gamma}\right\}\right) \cup \left(\{T\} \times \left(\epsilon, \frac{K}{\gamma}\right)\right) \\ \partial_p \widetilde{D}_\epsilon &\triangleq \left([0,T] \times \left\{\log \epsilon, \log \frac{K}{\gamma}\right\}\right) \cup \left(\{T\} \times \left(\log \epsilon, \log \frac{K}{\gamma}\right)\right), \end{aligned}$$

and their topological boundaries

$$\partial D_\epsilon \triangleq \partial_p D_\epsilon \cup \left(\{0\} \times \left(\epsilon, \frac{K}{\gamma}\right)\right), \quad \partial \widetilde{D}_\epsilon \triangleq \partial_p \widetilde{D}_\epsilon \cup \left(\{0\} \times \left(\log \epsilon, \log \frac{K}{\gamma}\right)\right).$$

In the above definitions, we use the convention $\log 0 = -\infty$, so $\widetilde{D}_0$, $\partial_p \widetilde{D}_0$, and $\partial \widetilde{D}_0$ are subsets of the extended real numbers. The following comparison lemma is a

modification of Theorem 8.2 of [13], differing by the fact that the functions u and v satisfy different equations rather than the same equation.

LEMMA 6.1 (comparison). *Let f, g in $C(D_0)$ be given. Let $u, v \in C(D_0)$ be respective viscosity sub- and supersolutions on $D_0 \setminus \partial D_0$ of the equations*

$$\min\{\mathcal{L}_f u - c, u - \gamma x\} = 0, \tag{6.1}$$

$$\min\{\mathcal{L}_g v - c, v - \gamma x\} = 0. \tag{6.2}$$

Alternatively, let u, v be respective viscosity sub- and supersolutions of the equations

$$\max\{\mathcal{L}_f u - c, u - K\} = 0, \tag{6.3}$$

$$\max\{\mathcal{L}_g v - c, v - K\} = 0. \tag{6.4}$$

Assume further that one of the functions u or v (let us say u) satisfies

$$0 \le u(t,y) - u(t,x) \le y - x \text{ for } (t,x), (t,y) \in D_0. \tag{6.5}$$

Then for every $\lambda \ge 0$, we have

$$\begin{aligned} &\max_{(t,x)\in D_0} e^{\lambda t}\big(u(t,x) - v(t,x)\big)^+ \\ &\le \max\left\{\frac{\delta}{r+\lambda} \max_{(t,x)\in D_0} e^{\lambda t}\big(f(t,x) - g(t,x)\big)^+, \max_{(t,x)\in \partial_p D_0} e^{\lambda t}\big(u(t,x) - v(t,x)\big)^+\right\}. \end{aligned} \tag{6.6}$$

Proof. We provide the proof under the assumptions that u is a subsolution of (6.1) and v is a supersolution of (6.2). Because f, g, u, and v are continuous, it suffices to prove

$$\begin{aligned} &\max_{(t,x)\in D_\epsilon} e^{\lambda t}\big(u(t,x) - v(t,x)\big)^+ \\ &\le \max\left\{\frac{\delta}{r+\lambda} \max_{(t,x)\in D_\epsilon} e^{\lambda t}\big(f(t,x) - g(t,x)\big)^+, \max_{(t,x)\in \partial_p D_\epsilon} e^{\lambda t}\big(u(t,x) - v(t,x)\big)^+\right\} \end{aligned}$$

for every $\epsilon \in \big(0, \frac{K}{\gamma}\big)$. To do this, we define $\widetilde{u}(t,\xi) \triangleq e^{\lambda t} u\big(t, e^\xi\big)$, $\widetilde{v}(t,\xi) \triangleq e^{\lambda t} v\big(t, e^\xi\big)$, $\widetilde{f}(t,\xi) \triangleq e^{\lambda t} f\big(t, e^\xi\big)$, and $\widetilde{g}(t,\xi) \triangleq e^{\lambda t} g\big(t, e^\xi\big)$. In terms of these functions, we need to prove that for every $\epsilon \in \big(0, \frac{K}{\gamma}\big)$,

$$\begin{aligned} &\max_{(t,\xi)\in \widetilde{D}_\epsilon} \big(\widetilde{u}(t,\xi) - \widetilde{v}(t,\xi)\big)^+ \\ &\le \max\left\{\frac{\delta}{r+\lambda} \max_{(t,\xi)\in \widetilde{D}_\epsilon} \big(\widetilde{f}(t,\xi) - \widetilde{g}(t,\xi)\big)^+, \max_{(t,\xi)\in \partial_p \widetilde{D}_\epsilon} \big(\widetilde{u}(t,\xi) - v(t,\xi)\big)^+\right\}. \end{aligned} \tag{6.7}$$

For $\eta > 0$, we define $\widetilde{u}^\eta(t,\xi) \triangleq \widetilde{u}(t,\xi) - \frac{\eta}{t}$, so that $\lim_{t\downarrow 0} \widetilde{u}^\eta(t,\xi) = -\infty$ uniformly in ξ. We will show for all $\epsilon \in \big(0, \frac{K}{\gamma}\big)$ that

$$\begin{aligned} &\max_{(t,\xi)\in \widetilde{D}_\epsilon} \big(\widetilde{u}^\eta(t,\xi) - \widetilde{v}(t,\xi)\big)^+ \\ &\le \max\left\{\frac{\delta}{r+\lambda} \max_{(t,\xi)\in \widetilde{D}_\epsilon} \big(\widetilde{f}(t,\xi) - \widetilde{g}(t,\xi)\big)^+, \max_{(t,\xi)\in \partial_p \widetilde{D}_\epsilon} \big(\widetilde{u}^\eta(t,\xi) - v(t,\xi)\big)^+\right\}. \end{aligned} \tag{6.8}$$

We can then let $\eta \downarrow 0$ in (6.8) to obtain (6.7) and conclude the proof.

The change of variable transforms (6.1) and (6.2) into

$$\min\Big\{ -\widetilde{u}_t + (r+\lambda)\widetilde{u} - \Big(r-\delta-\frac{1}{2}\sigma^2\Big)\widetilde{u}_\xi - \delta e^{-\lambda t-\xi}\widetilde{f}(t,\xi)\widetilde{u}_\xi + ce^{-\xi}\widetilde{u}_\xi \\ -\frac{1}{2}\sigma^2\widetilde{u}_{\xi\xi} - e^{\lambda t}c, \widetilde{u} - \gamma e^{\lambda t+\xi}\Big\} = 0,$$

$$\min\Big\{ -\widetilde{v}_t + (r+\lambda)\widetilde{v} - \Big(r-\delta-\frac{1}{2}\sigma^2\Big)\widetilde{v}_\xi - \delta e^{-\lambda t-\xi}\widetilde{g}(t,\xi)\widetilde{v}_\xi + ce^{-\xi}\widetilde{v}_\xi \\ -\frac{1}{2}\sigma^2\widetilde{v}_{\xi\xi} - e^{\lambda t}c, \widetilde{v} - \gamma e^{\lambda t+\xi}\Big\} = 0.$$

On the set

$$\widetilde{\mathcal{C}}_{\widetilde{u}} \triangleq \big\{(t,\xi) \in \widetilde{D}_0 \setminus \partial\widetilde{D}_0 : \widetilde{u}(t,\xi) > \gamma e^{\lambda t+\xi}\big\},$$

the function $\widetilde{u}$ is a viscosity subsolution of

(6.9)
$$-\widetilde{u}_t + (r+\lambda)\widetilde{u} - \Big(r-\delta-\frac{1}{2}\sigma^2\Big)\widetilde{u}_\xi - \frac{1}{2}\sigma^2\widetilde{u}_{\xi\xi} - e^{\lambda t}c = \delta e^{-\lambda t-\xi}\widetilde{f}(t,\xi)\widetilde{u}_\xi - ce^{-\xi}\widetilde{u}_\xi,$$

and so for $\eta > 0$, the function $\widetilde{u}^\eta$ is also a viscosity subsolution of this equation on $\widetilde{\mathcal{C}}_{\widetilde{u}}$. On $\widetilde{D}_0 \setminus \partial\widetilde{D}_0$, $\widetilde{v}(t,\xi) \geq \gamma e^{\lambda t+\xi}$, and $\widetilde{v}$ is a viscosity supersolution of

(6.10)
$$-\widetilde{v}_t + (r+\lambda)\widetilde{v} - \Big(r-\delta-\frac{1}{2}\sigma^2\Big)\widetilde{v}_\xi - \frac{1}{2}\sigma^2\widetilde{v}_{\xi\xi} - e^{\lambda t}c = \delta e^{-\lambda t-\xi}\widetilde{g}(t,\xi)\widetilde{v}_\xi - ce^{-\xi}\widetilde{v}_\xi.$$

Let us assume that (6.8) is violated for some $\eta > 0$ and $\epsilon \in \big(0, \frac{K}{\gamma}\big)$. This means that

$$\max_{(t,x)\in\widetilde{D}_\epsilon} \big(\widetilde{u}^\eta(t,\xi) - \widetilde{v}(t,\xi)\big)^+ > \frac{\delta}{r+\lambda} \max_{(t,\xi)\in\widetilde{D}_\epsilon} \big(\widetilde{f}(t,\xi) - \widetilde{g}(t,\xi)\big)^+. \tag{6.11}$$

Let $\alpha > 0$ be given, and set

$$M_\alpha \triangleq \max_{(t,\xi),(t,\zeta)\in\widetilde{D}_\epsilon} \Big(\widetilde{u}^\eta(t,\xi) - \widetilde{v}(t,\zeta) - \frac{\alpha}{2}|\xi-\zeta|^2\Big).$$

The maximum is attained at some point $(t_\alpha, \xi_\alpha, \zeta_\alpha)$. According to a slight variant of Lemma 3.1 of [13],

$$\lim_{\alpha\to\infty} \alpha|\xi_\alpha - \zeta_\alpha|^2 = 0 \text{ and } \lim_{\alpha\to\infty} M_\alpha = \max_{(t,\xi)\in\widetilde{D}_\epsilon} \big(\widetilde{u}^\eta(t,\xi) - \widetilde{v}(t,\xi)\big). \tag{6.12}$$

Violation of (6.8) implies that for large α, the points (t_α, ξ_α) and (t_α, ζ_α) are bounded away from the parabolic boundary $\partial_p\widetilde{D}_\epsilon$. Furthermore, because $\lim_{t\downarrow 0} \widetilde{u}^\eta(t,\xi) = -\infty$, these points are bounded away from the topological boundary $\partial\widetilde{D}_\epsilon$ as well.

There are two cases to consider. In the first case, $(t_\alpha, \xi_\alpha) \notin \widetilde{\mathcal{C}}_{\widetilde{u}}$, and so $\widetilde{u}^\eta(t_\alpha, \xi_\alpha) = \gamma e^{\lambda t_\alpha+\xi_\alpha} - \frac{\eta}{t_\alpha} \leq \gamma e^{\lambda t_\alpha+\xi_\alpha}$. We have

$$M_\alpha \leq \widetilde{u}^\eta(t_\alpha,\xi_\alpha) - \widetilde{v}(t_\alpha,\zeta_\alpha) \leq \gamma e^{\lambda t_\alpha}\big(e^{\xi_\alpha} - e^{\zeta_\alpha}\big). \tag{6.13}$$

In the other case, (t_α, ξ_α) is in $\widetilde{\mathcal{C}}_{\widetilde{u}}$. Because $\widetilde{u}^\eta$ is a subsolution of (6.9) in a neighborhood of (t_α, ξ_α), $\widetilde{v}$ is a supersolution of (6.10) in a neighborhood of (t_α, ζ_α), and these points are bounded away from $\partial\widetilde{D}_\epsilon$, condition (8.5) of Theorem 8.3 of [13] is satisfied (our time variable is reversed from that of [13]). That theorem with $\epsilon = \frac{1}{\alpha}$ implies the existence of numbers b, X, and Y such that $X \le Y$ and[1]

$$(b, \alpha(\xi_\alpha - \zeta_\alpha), X) \in \overline{\mathcal{P}}^{2,+}\widetilde{u}^\eta(t_\alpha, \xi_\alpha) \text{ and } (b, \alpha(\xi_\alpha - \zeta_\alpha), Y) \in \overline{\mathcal{P}}^{2,-}\widetilde{v}(t_\alpha, \zeta_\alpha)$$

(see the use of Theorem 8.3 on page 50 in [13]; see also page 17). Note that (t_α, ξ_α) and (t_α, ζ_α) are in the open set $\widetilde{D}_\epsilon \setminus \partial\widetilde{D}_\epsilon$. Moreover, they provide terms that can replace the time derivative, the spatial derivative, and the second spatial derivative in the subsolution and supersolution inequalities for (6.9) and (6.10):

$$\begin{aligned} -b + (r+\lambda)\widetilde{u}^\eta(t_\alpha, \xi_\alpha) - \left(r - \delta - \frac{1}{2}\sigma^2\right)\alpha(\xi_\alpha - \zeta_\alpha) - \frac{1}{2}\sigma^2 X - e^{\lambda t_\alpha}c \\ \le \delta e^{-\lambda t_\alpha - \xi_\alpha}\widetilde{f}(t_\alpha, \xi_\alpha)\alpha(\xi_\alpha - \zeta_\alpha) - ce^{-\xi_\alpha}\alpha(\xi_\alpha - \zeta_\alpha), \end{aligned} \tag{6.14}$$

$$\begin{aligned} -b + (r+\lambda)\widetilde{v}(t_\alpha, \zeta_\alpha) - \left(r - \delta - \frac{1}{2}\sigma^2\right)\alpha(\xi_\alpha - \zeta_\alpha) - \frac{1}{2}\sigma^2 Y - e^{\lambda t_\alpha}c \\ \ge \delta e^{-\lambda t_\alpha - \zeta_\alpha}\widetilde{g}(t_\alpha, \zeta_\alpha)\alpha(\xi_\alpha - \zeta_\alpha) - ce^{-\zeta_\alpha}\alpha(\xi_\alpha - \zeta_\alpha). \end{aligned} \tag{6.15}$$

Subtracting (6.15) from (6.14) and using $\sup_{\xi,\zeta \ge \log\epsilon, \xi\ne\zeta}\left|\frac{e^{-\xi} - e^{-\zeta}}{\xi - \zeta}\right| = \frac{1}{\epsilon}$, we obtain

$$\begin{aligned} M_\alpha &\le \widetilde{u}^\eta(t_\alpha, \xi_\alpha) - \widetilde{v}(t_\alpha, \zeta_\alpha) \\ &\le \frac{\delta}{r+\lambda}e^{-\lambda t_\alpha - \xi_\alpha}\big(\widetilde{f}(t_\alpha, \xi_\alpha) - \widetilde{g}(t_\alpha, \zeta_\alpha)\big)\alpha(\xi_\alpha - \zeta_\alpha) \\ &\quad + \frac{\delta}{\epsilon(r+\lambda)}e^{-\lambda t_\alpha}|\widetilde{g}(t_\alpha, \zeta_\alpha)|\alpha(\xi_\alpha - \zeta_\alpha)^2 + \frac{c}{\epsilon(r+\lambda)}\alpha(\xi_\alpha - \zeta_\alpha)^2. \end{aligned} \tag{6.16}$$

But also, (6.5) implies, at least formally, that $0 \le u_x(t,x) \le 1$, or equivalently, $0 \le \widetilde{u}_\xi(t,\xi) \le e^{\lambda t + \xi}$. Of course u_x and $\widetilde{u}_\xi$ may not exist, but (6.5) implies that $\alpha(\xi_\alpha - \zeta_\alpha)$, the surrogate for $\widetilde{u}_\xi(t_\alpha, \xi_\alpha)$, must satisfy $0 \le \alpha(\xi_\alpha - \zeta_\alpha) \le e^{\lambda t_\alpha + \xi_\alpha}$. Using this inequality in (6.16), we obtain

$$\begin{aligned} M_\alpha &\le \frac{\delta}{r+\lambda}\big(\widetilde{f}(t_\alpha, \xi_\alpha) - \widetilde{g}(t_\alpha, \zeta_\alpha)\big) + O\big(\alpha(\xi_\alpha - \zeta_\alpha)^2\big) \\ &= \frac{\delta}{r+\lambda}\big(\widetilde{f}(t_\alpha, \xi_\alpha) - \widetilde{g}(t_\alpha, \xi_\alpha)\big) + \frac{\delta}{r+\lambda}\big(\widetilde{g}(t_\alpha, \xi_\alpha) - \widetilde{g}(t_\alpha, \zeta_\alpha)\big) \\ &\quad + O\big(\alpha(\xi_\alpha - \zeta_\alpha)^2\big) \\ &\le \frac{\delta}{r+\lambda}\max_{(t,\xi)\in\widetilde{D}_\epsilon}\big(\widetilde{f}(t,\xi) - \widetilde{g}(t,\xi)\big)^+ + \frac{\delta}{r+\lambda}\big(\widetilde{g}(t_\alpha, \xi_\alpha) - \widetilde{g}(t_\alpha, \zeta_\alpha)\big) \\ &\quad + O\big((\xi_\alpha - \zeta_\alpha)^2\big). \end{aligned} \tag{6.17}$$

[1]Following [13], for a real-valued function u defined on a domain $D \subset \mathbb{R}^2$ and for (t,ξ) in the interior of D, we set $\mathcal{P}^{2,+}u(t,\xi) \triangleq \{(b,\alpha,X) \in \mathbb{R}^3 : u(s,y) \le u(t,\xi) + b(s-t) + \alpha(y-\xi) + \frac{1}{2}X(y-\xi)^2 + o(s-t) + o((y-x)^2) \text{ as } (s,y) \to (t,\xi)\}$ and define $\mathcal{P}^{2,-}u(t,\xi)$ analogously to $\mathcal{P}^{2,+}$ but with the inequality in the definition reversed. We next define $\overline{\mathcal{P}}^{2,\pm}u(t,\xi) \triangleq \{(b,\alpha,X) \in \mathbb{R}^3 : \text{there exists } (t_n, \xi_n, b_n, \alpha_n, X_n) \in D \times \mathbb{R}^3 \text{ such that } (b_n, \alpha_n, X_n) \in \mathcal{P}^{2,\pm}u(t_n, \xi_n) \text{ and } (t_n, \xi_n, u(t_n, \xi_n), b_n, \alpha_n, X_n) \to (t, \xi, u(t,\xi), b, \alpha, X)\}$.

Letting $\alpha \to \infty$ in (6.13) and (6.17), using (6.12), and using the uniform continuity of $\widetilde{g}$ on $\widetilde{D}_\epsilon$, we contradict (6.11). □

Proof of Theorem 3.1. Set $\lambda \triangleq \delta + 1$ and endow $\mathcal{G}$ with the metric

$$d(f,g) \triangleq \max_{(t,x)\in D_0} e^{\lambda t}|f(t,x) - g(t,x)| \text{ for all } f,g \in \mathcal{G}. \tag{6.18}$$

Under this metric, $\mathcal{G}$ is complete. Let $f, g \in \mathcal{G}$ be given, and define $u = \mathcal{T}f$ and $v = \mathcal{T}g$. According to subsection 4.5, u and v are in $\mathcal{G}$. In particular, (6.5) is satisfied. We apply Lemma 6.1, noting that u and v are viscosity solutions of (6.1) and (6.2), respectively, or viscosity solutions of (6.3) and (6.4), respectively, and they agree on $\partial_p D_0$, to conclude that

$$d(u,v) \le \frac{\delta}{r+\lambda} \max_{(t,x)\in D_0} e^{\lambda t}\big(f(t,x) - g(t,x)\big)^+.$$

Reversing the roles of f and g, we obtain the contraction property for $\mathcal{T}$. □

Remark 6.2. Uniqueness of the continuous viscosity solution of (6.1) or (6.3) with boundary conditions (3.6) and (3.7) follows from Lemma 6.1 with $f = g$.

7. Asymptotic behavior. We relate the problem of this paper to the perpetual convertible bond. To do this, we reverse time, denoting by $u_L(t,x)$ the price of the bond for fixed par value $L \in [0,K]$ when the time to maturity is t and the firm value is x. This section requires standing assumption (2.6). We have the following variation of Lemma 6.1.

LEMMA 7.1. *Fix $T > 0$ and let g_1 and g_2 in $C\big([0,T] \times \big[0, \frac{K}{\gamma}\big]\big)$ be a viscosity subsolution and a viscosity supersolution, respectively, of*

$$\min\{g_t + \mathcal{N}g - c, g - \gamma x\} = 0 \text{ on } (0,T) \times \left(0, \frac{K}{\gamma}\right) \tag{7.1}$$

or a viscosity subsolution and viscosity supersolution, respectively, of

$$\max\{g_t + \mathcal{N}g - c, g - K\} = 0 \text{ on } (0,T) \times \left(0, \frac{K}{\gamma}\right), \tag{7.2}$$

where $\mathcal{N}$ is the nonlinear operator

$$\begin{aligned}\mathcal{N}g(t,x) \triangleq\ & rg(t,x) - (rx - c)g_x(t,x) \\ & + \delta\big(x - g(t,x)\big)g_x(t,x) - \frac{1}{2}\sigma^2 x^2 g_{xx}(t,x).\end{aligned}$$

Assume that either g_1 or g_2 satisfies (3.2). *If $g_1(0,\cdot) \le g_2(0,\cdot)$ and*

$$g_1(t,0) \le g_2(t,0),\ g_1\Big(t, \frac{K}{\gamma}\Big) \le g_2\Big(t, \frac{K}{\gamma}\Big), \quad 0 \le t \le T, \tag{7.3}$$

then $g_1 \le g_2$. In particular, if g_1 and g_2 are viscosity solutions of (7.1) *or* (7.2), *$g_1(0,\cdot) = g_2(0,\cdot)$, and equality holds in both parts of* (7.3), *then $g_1 = g_2$.*

Proof. Apply the time-reversed version of Lemma 6.1 with $\lambda = 0$, $u = f = g_1$, and $v = g = g_2$ to conclude that

$$\max_{(t,x)\in[0,T]\times[0,\frac{K}{\gamma}]} \big(g_1(t,x) - g_2(t,x)\big)^+ \le \frac{\delta}{r} \max_{(t,x)\in[0,T]\times[0,\frac{K}{\gamma}]} \big(g_1(t,x) - g_2(t,x)\big)^+.$$

Since $\delta < r$, we have $g_1 \leq g_2$. □

Regardless of the initial time to maturity, as a function of the firm value and remaining time to maturity, the convertible bond price must satisfy one (or both) of (7.1) and (7.2), depending on whether $c \leq rK$ or $\delta K \leq c$. The uniqueness assertion in Lemma 7.1 guarantees that while the bond price does depend on the time to maturity, it does not depend on the time when the bond was issued, or equivalently, it does not depend on the *initial* time to maturity.

A perpetual convertible bond never matures, and hence the time variable and the par value are irrelevant. Its price $p(x)$ is a function of the underlying firm value alone. The following result is proved in [36].

THEOREM 7.2. *The perpetual convertible bond price function p is continuous on $[0,\infty)$, continuously differentiable on $\big(0, \frac{K}{\gamma}\big)$, and satisfies $0 \leq p'(x) \leq 1$ for $0 < x < \frac{K}{\gamma}$ and $p(x) = \gamma x$ for $x \geq \frac{K}{\gamma}$.*

If $c \leq rK$, then p, regarded as a function of (t,x) with $p_t = 0$, is a continuous viscosity solution of (7.1) *satisfying*

$$p(0) = 0, \quad p\left(\frac{K}{\gamma}\right) = K. \tag{7.4}$$

Furthermore, there exists $C_o^* \in \big(0, \frac{K}{\gamma}\big]$ such that p restricted to $(0, C_o^*)$ is strictly greater than γx and is a classical solution of $\mathcal{N}p = c$, whereas $p(x) = \gamma x$ for $x \geq C_o^*$.

If $\delta K \leq c$, then p is a continuous viscosity solution of (7.2) *satisfying* (7.4). *Furthermore, there exists $C_a^* \in \big(0, \frac{K}{\gamma}\big]$ such that p restricted to $(0, C_a^*)$ is strictly less than K and is a classical solution of $\mathcal{N}p = c$, whereas $p(x) = K$ for $C_a^* \leq x \leq \frac{K}{\gamma}$.*

Uniqueness of p in [36] is proved only in the class of functions that are smooth in the continuation region, not within the class of all continuous functions. We upgrade the uniqueness result to the larger class here.

LEMMA 7.3. *Let p be the perpetual convertible bond price function. If $c \leq rK$, then p is the unique viscosity solution of* (7.1) *on $\big(0, \frac{K}{\gamma}\big)$ that is continuous on $\big[0, \frac{K}{\gamma}\big]$ and satisfies* (7.4). *If $\delta K \leq c$, then p is the unique viscosity solution of* (7.2) *on $\big(0, \frac{K}{\gamma}\big)$ that is continuous on $\big[0, \frac{K}{\gamma}\big]$ and satisfies* (7.4).

Proof. We provide the proof for the case $c \leq rK$. In the second case, $\delta K \leq c$, a similar proof is possible.

Let $q \in C\big[0, \frac{K}{\gamma}\big]$ be a viscosity solution of (7.1) on $\big(0, \frac{K}{\gamma}\big)$ satisfying (7.4). Assume

$$\max_{x \in [0, \frac{K}{\gamma}]} \big(p(x) - q(x)\big) = p(x_0) - q(x_0) > 0. \tag{7.5}$$

Then $x_0 \in \big(0, \frac{K}{\gamma}\big)$ and $p(x_0) > q(x_0) \geq \gamma x_0$, so $x_0 \in (0, C_o^*)$. Because p is twice continuously differentiable in $(0, C_o^*)$, we can use $p + q(x_0) - p(x_0)$ as a test function for the viscosity supersolution q to obtain

$$rq(x_0) - (rx_0 - c)p'(x_0) + \delta\big(x_0 - q(x_0)\big)p'(x_0) - \frac{1}{2}\sigma^2 x_0^2 p''(x_0) \geq c.$$

But p satisfies $\mathcal{N}p(x_0) = c$, so

$$rp(x_0) - (rx_0 - c)p'(x_0) + \delta\big(x_0 - p(x_0)\big)p'(x_0) - \frac{1}{2}\sigma^2 x_0^2 p''(x_0) = c.$$

Subtracting these relations, we obtain

$$r\big(p(x_0) - q(x_0)\big) \leq \delta\big(p(x_0) - q(x_0)\big)p'(x_0).$$

But $0 \le p'(x_0) \le 1$ and $0 \le \delta < r$, so we have a contradiction to (7.5).

Assume on the other hand that

$$\max_{x \in [0, \frac{K}{\gamma}]} \big(q(x) - p(x)\big) = q(x_0) - p(x_0) > 0. \tag{7.6}$$

Then $x_0 \in \big(0, \frac{K}{\gamma}\big)$ and $q(x_0) > p(x_0) \ge \gamma x_0$. We have $q \le p + q(x_0) - p(x_0)$, and if $x_0 \ne C_o^*$, so that p is twice continuously differentiable in a neighborhood of x_0, we can use $p + q(x_0) - p(x_0)$ as a test function for the viscosity subsolution q to obtain

$$rq(x_0) - (rx_0 - c)p'(x_0) + \delta\big(x_0 - q(x_0)\big)p'(x_0) - \frac{1}{2}\sigma^2 x_0^2 p''(x_0) \le c. \tag{7.7}$$

But $\mathcal{N}p(x_0) \ge c$ means that

$$rp(x_0) - (rx_0 - c)p'(x_0) + \delta\big(x_0 - p(x_0)\big)p'(x_0) - \frac{1}{2}\sigma^2 x_0^2 p''(x_0) \ge c. \tag{7.8}$$

Subtracting these relations, we obtain

$$r\big(q(x_0) - p(x_0)\big) \le \delta\big(q(x_0) - p(x_0)\big)p'(x_0), \tag{7.9}$$

and we conclude as before.

The only other possibility is that (7.6) holds and $x_0 = C_o^* \in \big(0, \frac{K}{\gamma}\big)$. According to Theorem 7.2, p' is defined on $\big(0, \frac{K}{\gamma}\big)$, and using the equations $\mathcal{N}p = c$ to the left of C_o^* and $p(x) = \gamma x$ to the right of x_0, we see that the left- and right-hand second derivatives $p''(x_0-)$ and $p''(x_0+) = 0$ exist. Furthermore, $p(x) - \gamma x$ attains its minimum value of 0 at x_0, so $p''(x_0-) \ge 0$. We need only rule out the case $p''(x_0-) > 0$, for in the event $p''(x_0-) = 0$, the function p is twice continuously differentiable at x_0 and we can use $p + q(x_0) - p(x_0)$ as a test function as above.

Suppose $p''(x_0-) > 0 = p''(x_0+)$. Let $\underline{p}$ be the solution in $\big(0, \frac{K}{\gamma}\big]$ of the ordinary differential equation $\mathcal{N}\underline{p} = c$ satisfying $\underline{p}(x_0) = \gamma x_0$ and $\underline{p}'(x_0) = \gamma$. On $(0, x_0]$, p is a solution to this terminal value problem and hence agrees with $\underline{p}$. In particular, $\underline{p}''(x_0) = p''(x_0-) > 0$, and this implies $\underline{p}(x) > \gamma x = p(x)$ for x in some interval $(x_0, x_0+\epsilon)$, where $\epsilon > 0$. The function $q - \underline{p}$ attains a local maximum at x_0 because $q - p$ does, and we can use $\underline{p} + q(x_0) - p(x_0)$ as a test function for the viscosity subsolution q as above. This leads to (7.7), with $p''(x_0-)$ replacing $p''(x_0)$. Inequality (7.8) holds for all $x \in (0, x_0)$, and letting $x \uparrow x_0$, we obtain (7.8), with $p''(x_0-)$ replacing $p''(x_0)$ as well. This implies (7.9), and (7.6) is contradicted. □

Proof of Theorem 3.6. The terminal condition (3.6), with time reversed, states that for $0 \le L \le K$, we have

$$\gamma x = u_0(0, x) \le u_L(0, x) \le u_K(0, x) = x \wedge K, \quad 0 \le x \le \frac{K}{\gamma}.$$

The functions u_0, u_L, and u_K are continuous viscosity solutions of (7.1) or (7.2), depending on whether $c \le rK$ or $\delta K \le c$. Lemma 7.1 and the membership of u_0 and u_K in $\mathcal{G}$ (see, in particular, (3.3)) imply that for $0 \le L \le K$,

$$\gamma x \le u_0(t, x) \le u_L(t, x) \le u_K(t, x) \le x \wedge K, \quad t \ge 0,\ 0 \le x \le \frac{K}{\gamma}. \tag{7.10}$$

For $0 \le t_1 \le t_2$, we have $u_0(0, \cdot) = \gamma x \le u_0(t_2 - t_1, \cdot)$, and we can apply Lemma 7.1 with $g_1(0, \cdot) = u_0(0, \cdot)$ and $g_2(0, \cdot) = u_0(t_2 - t_1, \cdot)$ to conclude that $u_0(t_1, \cdot) \le u_0(t_2, \cdot)$.

In other words, $u_0(t,x)$ is nondecreasing in t for each fixed x. On the other hand, $u_K(0,x) = x \wedge K \geq u_K(t_2 - t_1, x)$, and this leads to the conclusion that $u_K(t,x)$ is nonincreasing in t for each fixed x. Both $u_0(t,\cdot)$ and $u_K(t,\cdot)$ are Lipschitz continuous with constant 1, and the Arzela–Ascoli theorem implies that they converge uniformly on $\left[0, \frac{K}{\gamma}\right]$ to Lipschitz continuous limits $u_-(\cdot)$ and $u_+(\cdot)$, respectively, as $t \to \infty$. Uniform convergence preserves the viscosity solution property (see [13]), and so u_- and u_+ are also continuous viscosity solutions of either (7.1) or (7.2). Lemma 7.3 implies $u_- = p = u_+$. Relation (7.10) then implies $\lim_{t\to\infty} u_L(t,x) = p(x)$ for all $x \in \left[0, \frac{K}{\gamma}\right]$, and the convergence is uniform in x. Of course, for $x \geq \frac{K}{\gamma}$, $u_L(t,x) = p(x) = \gamma x$. □

Remark 7.4. The proof of Theorem 3.6 shows that for all $t \geq 0$,

$$u_0(t,x) \leq \lim_{s\to\infty} u_0(s,x) = p(x) = \lim_{s\to\infty} u_K(s,x) \leq u_K(t,x) \tag{7.11}$$

and the convergence is uniform in $x \in \left(0, \frac{K}{\gamma}\right)$.

8. Continuation and stopping sets. We continue with the time reversal introduced in section 7, denoting by $u_L(t,x)$ the price of the convertible bond when time to maturity is t and the underlying firm value is x. Following section 5, in Case I ($c \leq rK$) of Proposition 4.5, we define

$$\mathcal{C}_L^I \triangleq \left\{(t,x) \in (0,\infty) \times \left(0, \frac{K}{\gamma}\right) : u_L(t,x) > \gamma x\right\}, \tag{8.1}$$

$$\mathcal{S}_L^I \triangleq \left\{(t,x) \in (0,\infty) \times \left(0, \frac{K}{\gamma}\right] : u_L(t,x) = \gamma x\right\}. \tag{8.2}$$

In Case II ($\delta K \leq c$) of Proposition 4.6, we define

$$\mathcal{C}_L^{II} \triangleq \left\{(t,x) \in (0,\infty) \times \left(0, \frac{K}{\gamma}\right) : u_L(t,x) < K\right\}, \tag{8.3}$$

$$\mathcal{S}_L^{II} \triangleq \left\{(t,x) \in (0,\infty) \times \left(0, \frac{K}{\gamma}\right] : u_L(t,x) = K\right\}. \tag{8.4}$$

To relate (8.4) to the definition of $\mathcal{S}_T^{II}$ in section 5, recall (4.47). The present section provides some information about the nature of the sets in (8.1)–(8.4).

LEMMA 8.1. *For all $t \geq 0$, the mapping $x \mapsto \frac{1}{x} u_L(t,x)$ is nonincreasing.*

Proof. We rescale u_L. Let $\ell > 0$ be given and define $\overline{u} : [0,\infty) \times \left[0, \frac{\ell K}{\gamma}\right] \to [0,\infty)$ by $\overline{u}(t,x) \triangleq \ell u\left(t, \frac{x}{\ell}\right)$. Because we have formally that $0 \leq u_x(t,x) \leq 1$, we also have formally that $0 \leq \overline{u}_x(t,x) \leq 1$. Furthermore,

$$\overline{u}_t(t,x) + \mathcal{N}\overline{u}(t,x) = \ell\left[u_t\left(t, \frac{x}{\ell}\right) + \mathcal{N}u\left(t, \frac{x}{\ell}\right)\right] + c(1-\ell)\overline{u}_x(t,x). \tag{8.5}$$

In Case I ($c \leq rK$) we let $0 < a < b < \frac{K}{\gamma}$ be given and set $\ell = \frac{b}{a} > 1$. Because $u_t + \mathcal{N}u \geq c$, (8.5) implies

$$\overline{u}_t(t,x) + \mathcal{N}\overline{u}(t,x) \geq \ell c + c(1-\ell)\overline{u}_x(t,x) \geq c. \tag{8.6}$$

In other words, $\overline{u}(t,x)$ is a viscosity supersolution of $\overline{u}_t + \mathcal{N}\overline{u} \geq c$ on $(0,\infty) \times \left(0, \frac{\ell K}{\gamma}\right)$. But also, $\overline{u}(t,x) \geq \gamma x$ for $0 \leq x \leq \frac{\ell K}{\gamma}$ because $u(t,x) \geq \gamma x$ for $0 \leq x \leq \frac{K}{\gamma}$. It

follows that for every $T > 0$, $\overline{u}$ is defined and continuous on $[0,T] \times \left[0, \frac{K}{\gamma}\right]$ and is a supersolution of (7.1). Furthermore, $\overline{u}(0,\cdot) \geq u(0,\cdot)$, $\overline{u}(t,0) = u(t,0) = 0$, and $\overline{u}\left(t, \frac{K}{\gamma}\right) \geq K = u\left(t, \frac{K}{\gamma}\right)$. Lemma 7.1 implies $\overline{u} \geq u$ on $[0,T] \times \left[0, \frac{K}{\gamma}\right]$ for every $T > 0$. In particular, $\frac{b}{a} u(t,a) = \overline{u}(t,b) \geq u(t,b)$, which yields the desired result.

In Case II ($\delta K \leq c$) we again let $0 < a < b < \frac{K}{\gamma}$ be given, but now set $\ell = \frac{a}{b} < 1$. In this case, $u_t + \mathcal{N}u \leq c$ and both inequalities in (8.6) are reversed. But also, $\overline{u} \leq \ell K \leq K$. It follow that $\overline{u}$ is a subsolution of (7.2), but it is defined only on the set $[0,\infty) \times \left[0, \frac{\ell K}{\gamma}\right] \subset [0,\infty) \times \left[0, \frac{K}{\gamma}\right]$. However, on the upper boundary $[0,\infty) \times \left\{\frac{\ell K}{\gamma}\right\}$ of this set, $\overline{u} = \ell K$ and $u\left(t, \frac{\ell K}{\gamma}\right) \geq \ell K$. The function $u(0,\cdot)$ also dominates $\overline{u}(0,\cdot)$. We fix an arbitrary $T > 0$ and apply Lemma 7.1 on the smaller domain $[0,T] \times \left[0, \frac{\ell K}{\gamma}\right]$ (just take γ in Lemma 7.1 to be $\frac{\gamma}{\ell}$) to conclude that $\overline{u} \leq u$ on this domain. In particular, $u(t,a) \geq \overline{u}(t,a) = \frac{a}{b} u(t,b)$, which yields the desired result. ∎

In Case I, we define the free boundary

$$c_L(t) \triangleq \inf\left\{x \in \left(0, \frac{K}{\gamma}\right] : u_L(t,x) = \gamma x\right\}, \quad t > 0, \tag{8.7}$$

and in Case II, we define the free boundary

$$d_L(t) \triangleq \inf\left\{x \in \left(0, \frac{K}{\gamma}\right] : u_L(t,x) = K\right\}, \quad t > 0. \tag{8.8}$$

In the overlapping case $\delta K \leq c \leq rK$, Remark 5.2 says that $c_L(t) = d_L(t) = \frac{K}{\gamma}$ for all $t > 0$. We see in Remark 8.4 below that $c_L(t)$ and $d_L(t)$ are positive, so inf could be replaced by min in (8.7) and (8.8).

Remark 8.2. Because $u_L(t,x)$ is nondecreasing in L, we have $\mathcal{S}_K^I \subset \mathcal{S}_L^I \subset \mathcal{S}_0^I$ in Case I and $\mathcal{S}_0^{II} \subset \mathcal{S}_L^{II} \subset \mathcal{S}_K^{II}$ in Case II. This implies that $c_L(t)$ is nondecreasing in L in Case I and $d_L(t)$ is nonincreasing in L in Case II. In the proof of Theorem 3.6 at the end of section 7, we saw $u_0(t,x)$ is nondecreasing in t and $u_K(t,x)$ is nonincreasing in t. This implies in Case I that $c_0(t)$ is nondecreasing and $c_K(t)$ is nonincreasing, while in Case II, $d_0(t)$ is nonincreasing and $d_K(t)$ is nondecreasing.

The following theorem asserts that the continuation set and stopping set are divided by the free boundary $c_L(\cdot)$ in Case I and $d_L(\cdot)$ in Case II.

THEOREM 8.3. *In Case* I ($c \leq rK$) *we have*

$$\mathcal{S}_L^I = \left\{(t,x) \in (0,\infty) \times \left(0, \frac{K}{\gamma}\right] : c_L(t) \leq x \leq \frac{K}{\gamma}\right\}.$$

In Case II ($\delta K \leq c$) *we have*

$$\mathcal{S}_L^{II} = \left\{(t,x) \in (0,\infty) \times \left(0, \frac{K}{\gamma}\right] : d_L(t) \leq x \leq \frac{K}{\gamma}\right\}.$$

Proof. In Case I, we must show that if $u_L(t,x) = \gamma x$ for some $x \in \left(0, \frac{K}{\gamma}\right)$, then $u_L(t,y) = \gamma y$ for all $y \in \left[x, \frac{K}{\gamma}\right]$. This follows immediately from Lemma 8.1. In Case II, the result follows from the nondecrease in x of $u_L(t,x)$. ∎

Remark 8.4. Consider Case I. If $(t_0,x_0) \in \mathcal{S}_L^I$, then $u_L(t_0,x_0) = \gamma x_0$. Because u_L is a viscosity solution of $\min\{u_t + \mathcal{N}u - c, u - \gamma x\} = 0$, we may use $h(x) = \gamma x$ as a "test function" at the point (t_0,x_0) for the viscosity supersolution property to obtain

$\mathcal{N}h(x_0) \geq c$, or equivalently, $x_0 \geq \frac{c}{\delta\gamma}$. It follows that $\min\left\{\frac{K}{\gamma}, \frac{c}{\delta\gamma}\right\} \leq c_L(t) \leq \frac{K}{\gamma}$ for every $t > 0$. In Case II, we have $K = u_L(t, d_L(t)) \leq d_L(t) \leq \frac{K}{\gamma}$.

THEOREM 8.5. *Let C_o^* and C_a^* be as in Theorem* 7.2. *In Case* I, *we have* $\lim_{t\to\infty} c_L(t) = C_o^*$. *In Case* II, *we have* $\lim_{t\to\infty} d_L(t) = C_a^*$.

Proof. In light of Remark 8.2, it suffices to prove the theorem for the limiting cases $L = 0$ and $L = \frac{K}{\gamma}$. We treat Case I only.

Since c_0 is nondecreasing and c_K is nonincreasing, these functions have limits $c_0(\infty)$, and $c_K(\infty)$ in $\left(0, \frac{K}{\gamma}\right]$ as $t \to \infty$, and we must show $c_0(\infty) = C_o^* = c_K(\infty)$. Because $C_o^* = \min\left\{x \in \left(0, \frac{K}{\gamma}\right] : p(x) = \gamma x\right\}$, we have from the first inequality in (7.11) that $c_0(t) \leq C_o^*$ and hence $c_0(\infty) \leq C_o^*$. But $u_0(t, c_0(t)) = \gamma c_0(t)$ and $u_0(t, \cdot)$ converges uniformly to $p(\cdot)$, so $c_0(\infty) \geq C_o^*$.

Using the second inequality in (7.11), we obtain $c_K(t) \geq C_o^*$, and hence $c_K(\infty) \geq C_o^*$. Assume $C_o^* < c_K(\infty) \leq \frac{K}{\gamma}$. Because $c_K(\cdot)$ is nonincreasing, u_K is a viscosity solution of $u_t + \mathcal{N}u = c$ on $(0,\infty) \times (0, c_K(\infty))$. Hence the limit $p(\cdot)$ is a viscosity solution of this equation on $(0, c_K(\infty))$. But $p(x) = \gamma x$ for $x \in (C_o^*, c_K(\infty))$, and this does not satisfy $\mathcal{N}p = c$. This contradiction implies $c_K(\infty) = C_0^*$. ∎

MODEL REDUCTION OF UNCERTAIN SYSTEMS WITH MULTIPLICATIVE NOISE BASED ON BALANCING*

LIQIAN ZHANG†, BIAO HUANG†, AND TONGWEN CHEN‡

Abstract. This paper investigates the problem of model reduction based on balancing for uncertain discrete-time systems with multiplicative noise. Such systems can be considered as linear systems with both deterministic and stochastic uncertainties. Two linear matrix inequalities (LMIs) are proposed to find the balancing transformation, through which the original uncertain model with multiplicative noise is balanced. The reduced order model with the same structure as that of the original one is obtained by truncating the balanced model. An upper bound of the model reduction error is guaranteed. Based on the derived model reduction error bound, an optimization problem is suggested so that the solutions of the LMIs can be uniquely found and the model reduction error is ensured to be small.

Key words. discrete-time systems, linear matrix inequalities, multiplicative noise, balanced truncation, model reduction, uncertain systems

1. Introduction.

Stochastic systems have received much attention since stochastic modeling has come to play an important role in many branches of science and engineering applications. One particular kind of stochastic model includes linear models whose parameter uncertainties are modeled as white noise processes in a linear setting, or simply, multiplicative noise. This kind of stochastic model uncertainty comes from dynamics driven by noise signals and uncertainties due to fast parameter variations. Linear systems with multiplicative noise have been widely studied in [2, 3, 5, 10, 18, 23], just to name a few, and have applications in many areas such as nuclear fission and heat transfer, population models, and immunology and gain scheduling (see [5] and the references therein). Other commonly studied uncertainties in the literature, which are deterministic in nature, result from unmodelled dynamics, modelling and linearization errors, and slow parameter deviations. Different kinds of descriptions have been introduced to account for deterministic uncertainties, such as norm-bounded uncertainties, polytopic uncertainties [2], and linear fractional transformation uncertainties [1]. As a result of the existence of the aforementioned stochastic uncertainties and deterministic uncertainties, in recent years, systems with both deterministic and stochastic uncertainties have drawn much attention. They were first studied in [9], and later they have been widely investigated, e.g., in [4, 17, 23] for the discrete-time case and [10, 12, 14, 18, 19, 20, 22] for the continuous-time case, with a variety of deterministic uncertainties.

Model reduction has also been an active topic for several decades. It is well known that a fundamental problem in system theory concerns the construction of mathematical models for physical processes. To describe such processes accurately, high order

finite dimensional models may be obtained through standard modeling procedures. These models may be unnecessarily complicated as far as representing the physical systems is concerned. Given a high order model, a logical way to take is therefore to look for possible simplified model descriptions. As far as deterministic linear models are concerned, model reduction has been well studied, and various efficient model reduction methods have been proposed based on different model reduction criteria. One of the most powerful methods for deterministic linear systems is model reduction based on balancing. Such work can be seen in [6, 11, 15, 16] for nominal linear systems and [1, 7, 8] for linear systems with deterministic uncertainties.

In spite of the wide study of control of stochastic systems and model reduction of deterministic systems, there are only a few pieces of work in the literature contributing to the model reduction of stochastic systems. The H_∞ model reduction for linear systems with only stochastic uncertainties (multiplicative noise) was investigated in [21], and the model reduction based on balancing still remains open for linear systems with multiplicative noise. Furthermore, the model reduction for linear systems with both deterministic and stochastic uncertainties has never been studied. In this paper, we consider the model reduction problem based on balancing for uncertain linear systems with multiplicative noise. It is assumed that the systems to be considered consist of norm-bounded time-varying deterministic uncertainties and stochastic uncertainties, namely, multiplicative noise. By solving two linear matrix inequalities (LMIs), two positive matrices are obtained. By balancing these two positive matrices, the uncertain model with multiplicative noise is balanced, and the reduced order model can be derived by truncating the balanced model. It is shown that the model reduction error between the original and truncated models is bounded. Numerical examples show the efficiency of the proposed model reduction method.

2. Preliminaries. Consider the following discrete-time system with norm-bounded time-varying uncertainties and multiplicative noise:

$$S:\begin{cases} x(k+1) = A(k)x(k) + B(k)u(k) + \displaystyle\sum_{i=1}^{L}(A_i x(k) + B_i u(k))p_i(k), \\ y(k) = C(k)x(k) + D(k)u(k) + \displaystyle\sum_{i=1}^{L}(C_i x(k) + D_i u(k))p_i(k), \end{cases}$$

where $x(k) \in R^n$ is the state, $u(k) \in R^{n_u}$ is the control input, $y(k) \in R^{n_y}$ is the output, the initial state is x_0, and $p(0), p(1), \ldots, p(L)$ are independent, identically distributed random variable sequences on a probability space $(\Omega, \mathcal{F}, \mathcal{P})$ satisfying

$$\mathcal{E}\{p(k)\} = 0, \quad \mathcal{E}\left\{p(k)p(k)^T\right\} = \Sigma = \operatorname{diag}(\sigma_1^2, \ldots, \sigma_L^2) \tag{1}$$

with $\mathcal{E}\{\cdot\}$ denoting the expectation operator and

$$p(k) = \begin{bmatrix} p_1(k) & p_2(k) & \cdots & p_L(k) \end{bmatrix}^T.$$

Denote $\mathbb{N} = \{0, 1, 2, \ldots\}$. Let $\mathcal{F}_k$ be the σ-algebras generated by $(p(k))_{k\in\mathbb{N}}$. We denote by $l_2(\Omega, R^k)$ the space of square-summable R^k-valued vector functions on $(\Omega, \mathcal{F}, \mathcal{P})$ and by $l_{e_2}([0,\infty); R^k)$ the space of k-dimensional nonanticipatory square-summable stochastic processes $f(\cdot) = (f(k))_{k\in\mathbb{N}}$ on $\mathbb{N}$ with respect to $\mathcal{F}_k$ satisfying

$$\|f\|_{e_2}^2 = \mathcal{E}\left\{\sum_{k\in\mathbb{N}} |f(k)|^2\right\} = \sum_{k\in\mathbb{N}} \mathcal{E}\left\{|f(k)|^2\right\} < \infty.$$

We assume that $u(k)$ belongs to $l_{e_2}([0,\infty);R^{n_u})$ and is $\mathcal{F}_{k-1}$ measurable for all $k\in\mathbb{N}$, and x_0 is independent of the random process p. $A_i,\ B_i,\ C_i,\ D_i\ (i=1,\dots,L)$ are constant matrices with appropriate dimensions, and $A(k)$, $B(k)$, $C(k)$, $D(k)$ are time-varying matrices with norm-bounded uncertainties, which are given by

$$\begin{bmatrix} A(k) & B(k) \\ C(k) & D(k) \end{bmatrix} = \begin{bmatrix} A & B \\ C & D \end{bmatrix} + \begin{bmatrix} U \\ V \end{bmatrix} E(k) \begin{bmatrix} M & N \end{bmatrix}, \tag{2}$$

where $E(k)\in R^{s_1\times s_2}$ is time-varying, and A,B,C,D,U,V,M,N are constant matrices with appropriate dimensions. The uncertainty matrix $E(k)$ is feasible if it satisfies

$$\|E(k)\|_2 \le 1,$$

where the norm used is the Euclidean one.

By rewriting stochastic system S as

$$\begin{cases} x(k+1) = \left(A + UE(k)M + \sum_{i=1}^{L} A_i p_i(k)\right) x(k) + (B + UE(k)N + \sum_{i=1}^{L} B_i p_i(k))u(k), \\ y(k) = \left(C + VE(k)M + \sum_{i=1}^{L} C_i p_i(k)\right) x(k) + \left(D + VE(k)N + \sum_{i=1}^{L} D_i p_i(k)\right) u(k), \end{cases}$$

it can be seen that system S can be considered as a linear system

$$\left(\begin{bmatrix} A & B \\ C & D \end{bmatrix}\right)$$

with deterministic time-varying uncertainty

$$\left(\begin{bmatrix} U \\ V \end{bmatrix} E(k) \begin{bmatrix} M & N \end{bmatrix}\right)$$

and stochastic uncertainty

$$\begin{pmatrix} \sum_{i=1}^{L} A_i p_i(k) & \sum_{i=1}^{L} B_i p_i(k) \\ \sum_{i=1}^{L} C_i p_i(k) & \sum_{i=1}^{L} D_i p_i(k) \end{pmatrix}.$$

We refer to

$$\begin{bmatrix} \begin{bmatrix} A(k) & B(k) \\ C(k) & D(k) \end{bmatrix} \\ \begin{bmatrix} A_1 & B_1 \\ C_1 & D_1 \end{bmatrix} \\ \cdots \\ \begin{bmatrix} A_L & B_L \\ C_L & D_L \end{bmatrix} \end{bmatrix} \tag{3}$$

as a realization of stochastic system S. Throughout this paper, we use the following definitions.

DEFINITION 2.1.

$$\left[\begin{array}{c} \left[\begin{array}{cc} \bar{A}(k) & \bar{B}(k) \\ \bar{C}(k) & \bar{D}(k) \end{array}\right] \\ \left[\begin{array}{cc} \bar{A}_1 & \bar{B}_1 \\ \bar{C}_1 & \bar{D}_1 \end{array}\right] \\ \cdots \\ \left[\begin{array}{cc} \bar{A}_L & \bar{B}_L \\ \bar{C}_L & \bar{D}_L \end{array}\right] \end{array}\right] \tag{4}$$

is an equivalent realization to (3) *if there exists a nonsingular matrix* T *such that*

$$\left[\begin{array}{cc} \bar{A}(k) & \bar{B}(k) \\ \bar{C}(k) & \bar{D}(k) \end{array}\right] = \left[\begin{array}{cc} T & 0 \\ 0 & I \end{array}\right] \left[\begin{array}{cc} A(k) & B(k) \\ C(k) & D(k) \end{array}\right] \left[\begin{array}{cc} T^{-1} & 0 \\ 0 & I \end{array}\right],$$

$$\left[\begin{array}{cc} \bar{A}_i & \bar{B}_i \\ \bar{C}_i & \bar{D}_i \end{array}\right] = \left[\begin{array}{cc} T & 0 \\ 0 & I \end{array}\right] \left[\begin{array}{cc} A_i & B_i \\ C_i & D_i \end{array}\right] \left[\begin{array}{cc} T^{-1} & 0 \\ 0 & I \end{array}\right], \ i = 1, \ldots, L.$$

In this case, T *is called an equivalent transformation, and* (4) *is one realization of the stochastic system* S.

It can be verified that equivalent realizations induce the same input-output behavior.

DEFINITION 2.2 (see [2, 21]). *The uncertain stochastic system* S *is said to be robustly mean-square stable if for any feasible* $E(k)$, *the following equation holds:*

$$\lim_{k\to\infty} \mathcal{E}\left\{x(k)x(k)^T\right\} = 0$$

when $u(k) = 0$.

DEFINITION 2.3 (see [4, 21]). *The uncertain stochastic system* S *is said to be externally stable if for every* $u(k) \in l_{e_2}([0,\infty); R^{n_u})$,

$$y(k) \in l_{e_2}([0,\infty); R^{n_y})$$

and there exists a scalar $\eta > 0$ *such that*

$$\|y\|_{e_2} \leq \eta \|u\|_{e_2}. \tag{5}$$

DEFINITION 2.4 (see [4, 21]). *Suppose that system* S *is externally stable. Under the zero initial condition, the operator*

$$\mathbb{L} : l_{e_2}([0,\infty); R^{n_u}) \to l_{e_2}([0,\infty); R^{n_y})$$

defined by

$$(\mathbb{L}u)(k) = y(k)$$

is called the perturbation operator of system S. *Its norm* $\|\mathbb{L}\|$ *is defined as the minimum* $\eta > 0$ *such that* (5) *is satisfied.*

For the mean-square stability, we have the following lemma.

LEMMA 2.5 (see [2]). *The uncertain stochastic system* S *is robustly mean-square stable if and only if there exists* $Q > 0$ *satisfying the inequality*

$$-Q + A(k)^T Q A(k) + \sum_{i=1}^{L} \sigma_i^2 A_i^T Q A_i < 0,$$

or dually there exists $P > 0$ *satisfying*

$$-P + A(k)PA(k)^T + \sum_{i=1}^{L} \sigma_i^2 A_i P A_i^T < 0$$

for any feasible $E(k)$.

The following lemmas will be useful to the derivation of our main results.

LEMMA 2.6 (see [21]). *The uncertain stochastic system* S *is robustly mean-square stable and* $\|\mathbb{L}\| < \gamma$ *if and only if there exists* $X > 0$ *satisfying*

$$-\begin{bmatrix} X & 0 \\ 0 & \gamma^2 I \end{bmatrix} + \begin{bmatrix} A(k) & B(k) \\ C(k) & D(k) \end{bmatrix}^T \begin{bmatrix} X & 0 \\ 0 & I \end{bmatrix} \begin{bmatrix} A(k) & B(k) \\ C(k) & D(k) \end{bmatrix} + \sum_{i=1}^{L} \sigma_i^2 \begin{bmatrix} A_i & B_i \\ C_i & D_i \end{bmatrix}^T \begin{bmatrix} X & 0 \\ 0 & I \end{bmatrix} \begin{bmatrix} A_i & B_i \\ C_i & D_i \end{bmatrix} < 0$$

for any feasible $E(k)$.

LEMMA 2.7 (see [13]). *Let* $\Sigma_1, \Sigma_2, \Sigma_3$, *and* Γ *be given constant matrices with appropriate dimensions such that* $\Gamma = \Gamma^T < 0$. *Then there exists a matrix* $\Lambda = \Lambda^T > 0$ *such that*

$$(\Sigma_1 + \Sigma_2 E(k) \Sigma_3)^T \Lambda (\Sigma_1 + \Sigma_2 E(k) \Sigma_3) + \Gamma < 0$$

for any feasible $E(k)$ *if and only if there exists a scalar* $\varepsilon > 0$ *such that the following condition holds:*

$$\begin{bmatrix} \Gamma + \varepsilon (\Sigma_3)^T \Sigma_3 & (\Sigma_1)^T \\ \Sigma_1 & -\Lambda^{-1} + \varepsilon^{-1} \Sigma_2 (\Sigma_2)^T \end{bmatrix} < 0.$$

Remark 1. The results to be developed in this paper can be extended to the case where there are also uncertainties in A_i, B_i, C_i, and D_i $(i = 1, \ldots, L)$, provided that the uncertainties have the same structures as those of $A(k), B(k), C(k)$, and $D(k)$, respectively. In this case, Lemma 2.7 should be extended as follows: Let $\Sigma_1^j, \Sigma_2^j, \Sigma_3^j$ $(j = 1, \ldots, L)$, and Γ be given constant matrices with appropriate dimensions such that $\Gamma = \Gamma^T$. Then there exists a matrix $\Lambda = \Lambda^T > 0$ such that

$$\sum_{j=1}^{N} \left(\Sigma_1^j + \Sigma_2^j E(k) \Sigma_3^j \right)^T \Lambda \left(\Sigma_1^j + \Sigma_2^j E(k) \Sigma_3^j \right) + \Gamma < 0 \tag{6}$$

for any $E(k) \in \Omega$ if there exist scalars $\varepsilon_1 > 0, \ldots, \varepsilon_L > 0$ such that the following condition holds:

$$\Gamma + \sum_{j=1}^{N} \left(\varepsilon_j^{-1} (\Sigma_3^j)^T \Sigma_3^j + (\Sigma_1^j)^T (\Lambda^{-1} - \varepsilon_j \Sigma_2^j (\Sigma_2^j)^T)^{-1} \Sigma_1^j \right) < 0. \tag{7}$$

It is noticed that in this case, (7) is only a sufficient condition for (6).

The model reduction problem for the uncertain stochastic system S can be stated as follows: for the robustly mean-square stable stochastic system S, find an uncertain mean-square stable stochastic system

$$S_r : \begin{cases} x_r(k+1) = A_r(k) x_r(k) + B_r(k) u(k) + \sum_{i=1}^{L} \left(A_{ri} x_r(k) + B_{ri} u(k) \right) p_i(k), \\ y_r(k) = C_r(k) x_r(k) + D_r(k) u(k) + \sum_{i=1}^{L} \left(C_{ri} x_r(k) + D_{ri} u(k) \right) p_i(k), \end{cases}$$

where $x_r(k) \in R^r$ and $y_r(k) \in R^{n_y}$ with $r < n$ such that S_r approximates S according to a certain criterion. In order to preserve the structure of S, it is also assumed that $A_r(k)$, $B_r(k)$, $C_r(k)$, and $D_r(k)$ are time-varying and have the structure of

$$\begin{bmatrix} A_r(k) & B_r(k) \\ C_r(k) & D_r(k) \end{bmatrix} = \begin{bmatrix} A_r & B_r \\ C_r & D_r \end{bmatrix} + \begin{bmatrix} U_r \\ V_r \end{bmatrix} E(k) \begin{bmatrix} M_r & N_r \end{bmatrix} \tag{8}$$

with $E(k)$ feasible. This assumption means that the uncertainties in both the original models and reduced order models should come from the same sources but with the different weighting matrices $\{U, V, M, N\}$ and $\{U_r, V_r, M_r, N_r\}$. A similar assumption was made in [1].

3. Balanced realization and truncation. Consider the robustly mean-square stable stochastic system S and the following two inequalities:

$$\begin{bmatrix} -P & 0 & \cdots & 0 \\ 0 & -P & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & -P \end{bmatrix} + \begin{bmatrix} A(k) & B(k) \\ \sigma_1 A_1 & \sigma_1 B_1 \\ \vdots & \vdots \\ \sigma_L A_L & \sigma_L B_L \end{bmatrix} \begin{bmatrix} P & 0 \\ 0 & I \end{bmatrix} \begin{bmatrix} A(k) & B(k) \\ \sigma_1 A_1 & \sigma_1 B_1 \\ \vdots & \vdots \\ \sigma_L A_L & \sigma_L B_L \end{bmatrix}^T < 0, \tag{9}$$

$$-Q + A(k)^T Q A(k) + C(k)^T C(k) + \sum_{i=1}^{L} \sigma_i^2 (A_i Q A_i^T + C_i^T C_i) < 0. \tag{10}$$

By Lemma 2.5, it can be seen from (9) and (10) that the robust mean-square stability is necessary for the feasibilities of (9) and (10) for $P > 0$ and $Q > 0$.

Remark 2. If no multiplicative noise, or stochastic uncertainty, appears in S, that is, $\sigma_i = 0$, then inequalities (9) and (10) reduce to

$$-P + A(k) P A(k)^T + B(k) B(k)^T < 0,$$
$$-Q + A(k)^T Q A(k) + C(k)^T C(k) < 0,$$

respectively, which coincide with the Lyapunov inequalities given in [1] for deterministic linear systems.

Assume that (9) and (10) are feasible for $P > 0$ and $Q > 0$. Since P and Q are positive definite, there exists a nonsingular matrix T such that P and Q are balanced; that is,

$$T P T^T = T^{-T} Q T^{-1} = \Sigma, \tag{11}$$

where Σ=diag$(\alpha_1, \alpha_2, \ldots, \alpha_n)$ with $\alpha_1 \geq \alpha_2 \geq \cdots \geq \alpha_n > 0$. The balanced realization of the stochastic system S is defined as follows.

DEFINITION 3.1. *Assume that* (9) *and* (10) *are feasible for* $P > 0$ *and* $Q > 0$ *and the nonsingular matrix* T *is such that* (11) *holds. Let*

$$\begin{bmatrix} A_b(k) & B_b(k) \\ C_b(k) & D_b(k) \end{bmatrix} := \begin{bmatrix} T & 0 \\ 0 & I \end{bmatrix} \begin{bmatrix} A(k) & B(k) \\ C(k) & D(k) \end{bmatrix} \begin{bmatrix} T^{-1} & 0 \\ 0 & I \end{bmatrix}, \tag{12}$$

$$\begin{bmatrix} A_{bi} & B_{bi} \\ C_{bi} & D_{bi} \end{bmatrix} := \begin{bmatrix} T & 0 \\ 0 & I \end{bmatrix} \begin{bmatrix} A_i & B_i \\ C_i & D_i \end{bmatrix} \begin{bmatrix} T^{-1} & 0 \\ 0 & I \end{bmatrix}, \ i = 1, \ldots, L. \tag{13}$$

Then

$$\begin{bmatrix} A_b(k) & B_b(k) \\ C_b(k) & D_b(k) \\ A_{b1} & B_{b1} \\ C_{b1} & D_{b1} \\ \vdots & \vdots \\ \vdots & \vdots \\ A_{bL} & B_{bL} \\ C_{bL} & D_{bL} \end{bmatrix} \tag{14}$$

is called a balanced realization of the stochastic system S.

By substituting (8) into (12) and defining

$$\begin{bmatrix} A_b & B_b \\ C_b & D_b \end{bmatrix} := \begin{bmatrix} T & 0 \\ 0 & I \end{bmatrix} \begin{bmatrix} A & B \\ C & D \end{bmatrix} \begin{bmatrix} T^{-1} & 0 \\ 0 & I \end{bmatrix}, \tag{15}$$

$$\begin{bmatrix} U_b \\ V_b \end{bmatrix} := \begin{bmatrix} T & 0 \\ 0 & I \end{bmatrix} \begin{bmatrix} U \\ V \end{bmatrix}, \tag{16}$$

$$\begin{bmatrix} M_b & N_b \end{bmatrix} := \begin{bmatrix} M & N \end{bmatrix} \begin{bmatrix} T^{-1} & 0 \\ 0 & I \end{bmatrix}, \tag{17}$$

we have

$$\begin{bmatrix} A_b(k) & B_b(k) \\ C_b(k) & D_b(k) \end{bmatrix} = \begin{bmatrix} A_b & B_b \\ C_b & D_b \end{bmatrix} + \begin{bmatrix} U_b \\ V_b \end{bmatrix} E(k) \begin{bmatrix} M_b & N_b \end{bmatrix}.$$

To find the balanced realization of the stochastic system S, the key is how to solve $P > 0$ and $Q > 0$ from (9) and (10) if they are feasible. It is noticed that inequalities (9) and (10) are nonlinear and time-varying, and hence they are difficult to solve with the current forms. The following theorem will give the equivalent time-invariant LMIs by the Schur complements and Lemma 2.7.

THEOREM 3.2. *Assume that* (9) *and* (10) *are feasible for* $P > 0$ *and* $Q > 0$. *Then* $P > 0$ *and* $Q > 0$ *can be solved from the following two LMIs:*

$$\begin{bmatrix} -P + \varepsilon_1 UU^T & 0 & \cdots & 0 & AP & B & 0 \\ 0 & -P & \cdots & 0 & \sigma_1 A_1 P & \sigma_1 B_1 & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \vdots \\ 0 & 0 & \cdots & -P & \sigma_L A_L P & \sigma_L B_L & 0 \\ PA^T & \sigma_1 PA_1^T & \cdots & \sigma_L PA_L^T & -P & 0 & PM^T \\ B^T & \sigma_1 B_1^T & \cdots & \sigma_L B_L^T & 0 & -I & N^T \\ 0 & 0 & \cdots & 0 & MP & N & -\varepsilon_1 I \end{bmatrix} < 0, \tag{18}$$

$$\begin{bmatrix} -Q + \sum_{i=1}^{L} \sigma_i^2 (A_i^T Q A_i + C_i^T C_i) + \varepsilon_2 M^T M & A^T Q & C^T & 0 \\ QA & -Q & 0 & QU \\ C & 0 & -I & V \\ 0 & U^T Q & V^T & -\varepsilon_2 I \end{bmatrix} < 0, \tag{19}$$

where $\varepsilon_1 > 0$ *and* $\varepsilon_2 > 0$ *are two scalar variables.*

Proof. Notice that (9) and (10) can be written, respectively, as

$$\begin{bmatrix} -P & 0 & \cdots & 0 \\ 0 & -P & \cdots & 0 \\ & & \ddots & \\ 0 & 0 & \cdots & -P \end{bmatrix} + \left(\begin{bmatrix} A(k) & B(k) \\ \sigma_1 A_1 & \sigma_1 B_1 \\ \vdots & \vdots \\ \sigma_L A_L & \sigma_L B_L \end{bmatrix} + \begin{bmatrix} U \\ 0 \\ \vdots \\ 0 \end{bmatrix} E(k) \begin{bmatrix} M & N \end{bmatrix} \right)$$
$$\times \begin{bmatrix} P & 0 \\ 0 & I \end{bmatrix} \left(\begin{bmatrix} A(k) & B(k) \\ \sigma_1 A_1 & \sigma_1 B_1 \\ \vdots & \vdots \\ \sigma_L A_L & \sigma_L B_L \end{bmatrix} + \begin{bmatrix} U \\ 0 \\ \vdots \\ 0 \end{bmatrix} E(k) \begin{bmatrix} M & N \end{bmatrix} \right)^T < 0,$$

$$-Q + \sum_{i=1}^{L} \sigma_i^2 (A_i^T Q A_i + C_i^2 C_i)$$
$$+ \left(\begin{bmatrix} A \\ C \end{bmatrix} + \begin{bmatrix} U \\ V \end{bmatrix} E(k) M \right)^T \begin{bmatrix} Q & 0 \\ 0 & I \end{bmatrix} \left(\begin{bmatrix} A \\ C \end{bmatrix} + \begin{bmatrix} U \\ V \end{bmatrix} E(k) M \right) < 0.$$

By Lemma 2.7, it can be seen that (9) and (10) are equivalent to

$$\begin{bmatrix} \begin{bmatrix} -P & 0 & \cdots & 0 \\ 0 & -P & \cdots & 0 \\ & & \ddots & \\ 0 & 0 & \cdots & -P \end{bmatrix} + \varepsilon_1 \begin{bmatrix} U \\ 0 \\ \vdots \\ 0 \end{bmatrix} \begin{bmatrix} U \\ 0 \\ \vdots \\ 0 \end{bmatrix}^T & \begin{bmatrix} A & B \\ \sigma_1 A_1 & \sigma_1 B_1 \\ \vdots & \vdots \\ \sigma_L A_L & \sigma_L B_L \end{bmatrix} \begin{bmatrix} P & 0 \\ 0 & I \end{bmatrix} \\ \begin{bmatrix} P & 0 \\ 0 & I \end{bmatrix} \begin{bmatrix} A & B \\ \sigma_1 A_1 & \sigma_1 B_1 \\ \vdots & \vdots \\ \sigma_L A_L & \sigma_L B_L \end{bmatrix}^T & -\begin{bmatrix} P & 0 \\ 0 & I \end{bmatrix} + \varepsilon_1^{-1} \begin{bmatrix} P & 0 \\ 0 & I \end{bmatrix} \begin{bmatrix} M^T \\ N^T \end{bmatrix} \\ & \times \begin{bmatrix} M & N \end{bmatrix} \begin{bmatrix} P & 0 \\ 0 & I \end{bmatrix} \end{bmatrix} < 0,$$

$$\begin{bmatrix} -Q + \sum_{i=1}^{L} \sigma_i^2 (A_i^T Q A_i + C_i^2 C_i) + \varepsilon_2 M^T M & \begin{bmatrix} A^T & C^T \end{bmatrix} \begin{bmatrix} Q & 0 \\ 0 & I \end{bmatrix} \\ \begin{bmatrix} Q & 0 \\ 0 & I \end{bmatrix} \begin{bmatrix} A \\ C \end{bmatrix} & -\begin{bmatrix} Q & 0 \\ 0 & I \end{bmatrix} + \varepsilon_2^{-1} \begin{bmatrix} Q & 0 \\ 0 & I \end{bmatrix} \begin{bmatrix} U \\ V \end{bmatrix} \\ & \times \begin{bmatrix} U \\ V \end{bmatrix}^T \begin{bmatrix} Q & 0 \\ 0 & I \end{bmatrix} \end{bmatrix} < 0,$$

respectively. By the Schur complements again, we obtain (18) and (19). ∎

Remark 3. It is noticed that when S has only stochastic uncertainty (multiplicative noise) and no deterministic uncertainty, that is, $E(k) = 0$, then (18) and (19) reduce to

$$\begin{bmatrix} -P & 0 & \cdots & 0 & AP & B \\ 0 & -P & \cdots & 0 & \sigma_1 A_1 P & \sigma_1 B_1 \\ \vdots & \vdots & \ddots & \vdots & \vdots & \vdots \\ 0 & 0 & \cdots & -P & \sigma_L A_L P & \sigma_L B_L \\ PA^T & \sigma_1 PA_1^T & \cdots & \sigma_L PA_L^T & -P & 0 \\ B^T & \sigma_1 B_1^T & \cdots & \sigma_L B_L^T & 0 & -I \end{bmatrix} < 0,$$

$$\begin{bmatrix} -Q + \sum_{i=1}^{L} \sigma_i^2 (A_i^T Q A_i + C_i^T C_i) & A^T Q & C^T \\ QA & -Q & 0 \\ C & 0 & -I \end{bmatrix} < 0,$$

respectively. On the contrary, when S has only deterministic uncertainty and no stochastic uncertainty, that is, $\sigma_i = 0$, then (18) and (19) reduce to

$$\begin{bmatrix} -P+\varepsilon_1 UU^T & AP & B & 0 \\ PA^T & -P & 0 & PM^T \\ B^T & 0 & -I & N^T \\ 0 & MP & N & -\varepsilon_1 I \end{bmatrix} < 0,$$

$$\begin{bmatrix} -Q+\varepsilon_2 M^T M & A^T Q & C^T & 0 \\ QA & -Q & 0 & QU \\ C & 0 & -I & V \\ 0 & U^T Q & V^T & -\varepsilon_2 I \end{bmatrix} < 0,$$

respectively.

Premultiplying and postmultiplying both sides of (10) by T^T and T, respectively, we have

$$-\Sigma + A_b(k)^T \Sigma A_b(k) + C_b(k)^T C_b(k) + \sum_{i=1}^{L} \sigma_i^2 (A_{bi}^T \Sigma A_{bi} + C_{bi}^T C_{bi}) < 0. \tag{20}$$

Similarly, (9) can be transformed to

$$\begin{bmatrix} -\Sigma & 0 & \cdots & 0 \\ 0 & -\Sigma & \cdots & 0 \\ & & \ddots & \\ 0 & 0 & \cdots & 0 \\ 0 & 0 & \cdots & -\Sigma \end{bmatrix} + \begin{bmatrix} A_b(k) & B_b(k) \\ \sigma_1 A_{b1} & \sigma_1 B_{b1} \\ \vdots & \vdots \\ \sigma_L A_{bL} & \sigma_L B_{bL} \end{bmatrix} \begin{bmatrix} \Sigma & 0 \\ 0 & I \end{bmatrix} \begin{bmatrix} A_b(k) & B_b(k) \\ \sigma_1 A_{b1} & \sigma_1 B_{b1} \\ \vdots & \vdots \\ \sigma_L A_{bL} & \sigma_L B_{bL} \end{bmatrix}^T < 0. \tag{21}$$

The balanced truncation is a simple but powerful model reduction method. In order to obtain an rth reduced order model S_r for the stochastic system S, partition $A_b(k)$, $B_b(k)$, $C_b(k)$, A_{b1}, B_{b1}, C_{b1} conformably as

$$A_b(k) = \begin{bmatrix} A_{11}(k) & A_{12}(k) \\ A_{21}(k) & A_{22}(k) \end{bmatrix}, \; B_b(k) = \begin{bmatrix} \tilde{B}_1(k) \\ \tilde{B}_2(k) \end{bmatrix}, \; C_b(k) = \begin{bmatrix} \tilde{C}_1(k) & \tilde{C}_2(k) \end{bmatrix}, \tag{22}$$

$$A_{bi} = \begin{bmatrix} A_{11}^i & A_{12}^i \\ A_{21}^i & A_{22}^i \end{bmatrix}, \; B_{bi} = \begin{bmatrix} \tilde{B}_1^i \\ \tilde{B}_2^i \end{bmatrix}, \; C_{bi} = \begin{bmatrix} \tilde{C}_1^i & \tilde{C}_2^i \end{bmatrix}, \; i = 1, \ldots, L, \tag{23}$$

$$A_b = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix}, \; B_b = \begin{bmatrix} \tilde{B}_1 \\ \tilde{B}_2 \end{bmatrix}, \; \Sigma = \begin{bmatrix} \Sigma_1 & 0 \\ 0 & \Sigma_2 \end{bmatrix}, \tag{24}$$

$$C_b = \begin{bmatrix} \tilde{C}_1 & \tilde{C}_2 \end{bmatrix}, \; U_b = \begin{bmatrix} U_1 \\ U_2 \end{bmatrix}, \; M_b = \begin{bmatrix} M_1 & M_2 \end{bmatrix}, \tag{25}$$

where $A_{11} \in R^{r\times r}$ and $A_{11}^i \in R^{r\times r}$ for $i = 1, \ldots, L$. Then an rth reduced order

stochastic model S_r is derived as

$$\begin{bmatrix} A_r(k) & B_r(k) \\ C_r(k) & D_r(k) \\ A_{r1} & B_{r1} \\ C_{r1} & D_{r1} \\ \vdots & \vdots \\ \vdots & \vdots \\ A_{rL} & B_{rL} \\ C_{rL} & D_{rL} \end{bmatrix}, \tag{26}$$

where

$$\begin{bmatrix} A_r(k) & B_r(k) \\ C_r(k) & D_r(k) \end{bmatrix}$$

has the structure of (8) with

$$\begin{bmatrix} A_r & B_r \\ C_r & D_r \end{bmatrix} = \begin{bmatrix} A_{11} & \tilde{B}_1 \\ \tilde{C}_1 & D_b \end{bmatrix}, \begin{bmatrix} A_{ri} & B_{ri} \\ C_{ri} & D_{ri} \end{bmatrix} = \begin{bmatrix} A_{11}^i & \tilde{B}_1^i \\ \tilde{C}_1^i & D_b^i \end{bmatrix}, \tag{27}$$

$$\begin{bmatrix} M_r & N_r \end{bmatrix} = \begin{bmatrix} M_1 & N_b \end{bmatrix}, \begin{bmatrix} U_r \\ V_r \end{bmatrix} = \begin{bmatrix} U_1 \\ V_b \end{bmatrix}, \ i = 1, \ldots, L. \tag{28}$$

For the obtained reduced order model, the following properties can be derived.

LEMMA 3.3. *For the balanced model with the realization in* (14)*, the truncated model with the realization in* (26) *is robustly mean-square stable.*

Proof. From the (1,1) block of (20), we have

$$\begin{aligned} &-\Sigma_1 + A_{11}(k)^T \Sigma_1 A_{11}(k) + A_{21}(k)^T \Sigma_2 A_{21}(k) + \tilde{C}_1(k)^T \tilde{C}_1(k) \\ &\quad + \sum_{i=1}^{L} \sigma_i^2 \left((A_{11}^i)^T \Sigma_1 A_{11}^i + (A_{21}^i)^T \Sigma_2 A_{21}^i + (\tilde{C}_1^i)^T \tilde{C}_1^i \right) < 0, \end{aligned}$$

which further implies

$$-\Sigma_1 + A_{11}(k)^T \Sigma_1 A_{11}(k) + \tilde{C}_1(k)^T \tilde{C}_1(k) + \sum_{i=1}^{L} \sigma_i^2 \left((A_{11}^i)^T \Sigma_1 A_{11}^i + (\tilde{C}_1^i)^T \tilde{C}_1^i \right) < 0.$$

From Lemma 2.5, it can be seen that the stochastic model in (26) is robustly mean-square stable. ∎

The following theorem shows that the balanced truncation of the uncertain stochastic systems can guarantee an upper bound of the model reduction error in the sense of perturbation operator norm. The proof is quite involved and is therefore given in the appendix.

THEOREM 3.4. *If the truncated model with the realization in* (26) *is denoted as* S_r*, then the* H_∞ *model reduction error between* S *and* S_r *satisfies*

$$\|\mathbb{L}_e\| < 2 \sum_{i=r+1}^{n} \alpha_i,$$

where $\mathbb{L}_e$ *is the perturbation operator of the error system between* S *and* S_r*.*

It is noticed that in this paper we use two Lyapunov inequalities for balanced truncation; the distinctness of α_i in Σ_1 and Σ_2 is not necessary for the proofs of stability and error bound, though it is necessary when two Lyapunov equations are used for the continuous-time linear time-invariant systems (see [16]).

4. Model reduction algorithm. It is noticed that the solutions of the LMIs in (18) and (19) are not unique, and this results in the nonuniqueness of the balanced realization and the truncated model. On the other hand, Theorem 3.4 notes that the model reduction error bound depends on α_i's, and it can be seen that α_i^2's are the eigenvalues of PQ. Thus, in order to achieve a small model reduction error bound, a reasonable way is to solve $P > 0$ and $Q > 0$ from the optimization

$$\min_{P>0,Q>0} \operatorname{trace}(PQ) \tag{29}$$

subject to (18) and (19). By linearization, the following LMI-based iterative algorithm is proposed.

LMI-based Iterative Algorithm. Given $A, B, C, D, A_1, B_1, C_1, D_1, \sigma_i, U, V, M, N$, and $\varepsilon > 0$,

Step 1 Solve $P_0 > 0$ and $Q_0 > 0$ from (18) and (19);

Step 2 Define the linear function

$$f_k(P, Q) \triangleq \operatorname{trace}(QP_k + PQ_k); \tag{30}$$

Step 3 Solve $P_{\min} > 0$ and $Q_{\min} > 0$ from the following convex minimization problem:

$$\min_{P>0,Q>0} f_k \tag{31}$$

$$\text{s.t. (18) and (19);} \tag{32}$$

let $P_{k+1} = P_{\min}$ and $Q_{k+1} = Q_{\min}$, and compute the minimum as

$$f_k^* = \operatorname{trace}(Q_{k+1}P_k + P_{k+1}Q_k);$$

Step 4 If $\left|f_{k+1}^* - f_k^*\right| < \varepsilon$, then $P = X_{k+1}, Q = Y_{k+1}$; otherwise, set $k = k + 1$, and go to Step 2.

It can be seen that Step 1 is a simple LMI problem, and Step 3 is a convex programming with LMI constraints. The proposed algorithm has the following properties:

(i) $0 < f_{k+1}^* \le f_k^*$.

(ii) If the minimization problem (31) is feasible, then it is also feasible for $k + 1$.

Property (i) can be simply obtained from the fact that (P_{k+1}, Q_{k+1}) is such that f_k is minimized and (P_k, Q_k) is such that f_{k-1} is minimized. It shows that $\{f_k^*\}$ converges. Property (ii) holds since (P_k, Q_k) is a feasible solution to (31) when k is set to $k+1$. Consequently, from these two properties, this algorithm can be iteratively implemented if (18) and (19) are feasible.

5. Numerical example.

Example 1. Consider the following stochastic system S without deterministic uncertainty:

$$A = \begin{bmatrix} 0 & 0 & 0.0267 & 0 & 0 \\ 1.1111 & 0 & -0.2889 & 0 & 0 \\ 0 & 1.1111 & 1 & 0 & 0 \\ 0 & 0 & 0.2222 & 0 & -0.0667 \\ 0 & 0 & 0.1667 & 1.1111 & 0.5556 \end{bmatrix},$$

$$B = \begin{bmatrix} 0.8 \\ 0.6 \\ 0.4 \\ 0.2 \\ 0.5 \end{bmatrix},\ B_1 = \begin{bmatrix} 0.1 \\ 0.04 \\ 0.06 \\ 0.2 \\ 0.1 \end{bmatrix},$$

$$A_1 = \begin{bmatrix} 0.3649 & 0.0081 & 0.2189 & 0.0906 & -0.0820 \\ -0.0722 & 0.2038 & -0.1152 & -0.0059 & 0.0340 \\ -0.1063 & 0.0137 & -0.0233 & -0.0450 & 0.0426 \\ 0.0254 & -0.0285 & 0.0271 & 0.1013 & 0.0073 \\ 0.1412 & 0.0370 & 0.1104 & 0.0642 & 0.1033 \end{bmatrix},$$

$$C = \begin{bmatrix} 0.2 \\ 0.4 \\ 0.6 \\ 0.8 \\ 1 \end{bmatrix}^T,\ C_1 = B_1^T,$$

$$D = 0.5,\ D_1 = 0.2,\ \sigma_1 = 1,\ U = 0,\ V = 0,\ M = 0,\ N = 0.$$

Our purpose is to find the 2nd and 3rd order reduced models without deterministic uncertainty using the proposed balanced truncation. By balancing P and Q, we obtain

$$\Sigma = \text{diag}\{4.2739, 0.6855, 0.0724, 0.0037, 0.0002\}.$$

The 2nd order reduced model is given by

$$A_r = \begin{bmatrix} 0.9097 & 0.1024 \\ -0.4046 & 0.6910 \end{bmatrix},\ A_{r1} = \begin{bmatrix} 0.2335 & 0.0032 \\ 0.0576 & 0.0840 \end{bmatrix},$$

$$B_r = \begin{bmatrix} -2.2336 \\ 0.1314 \end{bmatrix},\ B_{r1} = \begin{bmatrix} -0.3461 \\ 0.3163 \end{bmatrix},$$

$$C_r = \begin{bmatrix} -0.5390 & 0.3859 \end{bmatrix},\ C_{r1} = \begin{bmatrix} -0.1098 & 0.0856 \end{bmatrix},\ D_r = 0.5,\ D_{1r} = 0.2,$$

and the 3rd order reduced model has state matrices as

$$A_r = \begin{bmatrix} 0.9097 & 0.1024 & -0.0103 \\ -0.4046 & 0.6910 & 0.0644 \\ 0.6961 & -0.9390 & -0.2286 \end{bmatrix},\ A_{r1} = \begin{bmatrix} 0.2335 & 0.0032 & -0.0278 \\ 0.0576 & 0.0840 & -0.0917 \\ 0.0373 & 0.0044 & 0.1728 \end{bmatrix},$$

$$B_r = \begin{bmatrix} -2.2336 \\ 0.1314 \\ -0.4830 \end{bmatrix},\ B_{r1} = \begin{bmatrix} -0.3461 \\ 0.3163 \\ -0.0944 \end{bmatrix},$$

$$C_r = \begin{bmatrix} -0.5390 \\ 0.3859 \\ -0.1691 \end{bmatrix}^T,\ C_{r1} = \begin{bmatrix} -0.1098 \\ 0.0856 \\ 0.0334 \end{bmatrix}^T,\ D_r = 0.5,\ D_{r1} = 0.2.$$

The outputs of the original model and the 2nd and 3rd order reduced models are given in Figure 1 when the input is set to e^{-k}. It can be seen that the 3rd order reduced model approximates the original model better than the 2nd order reduced model.

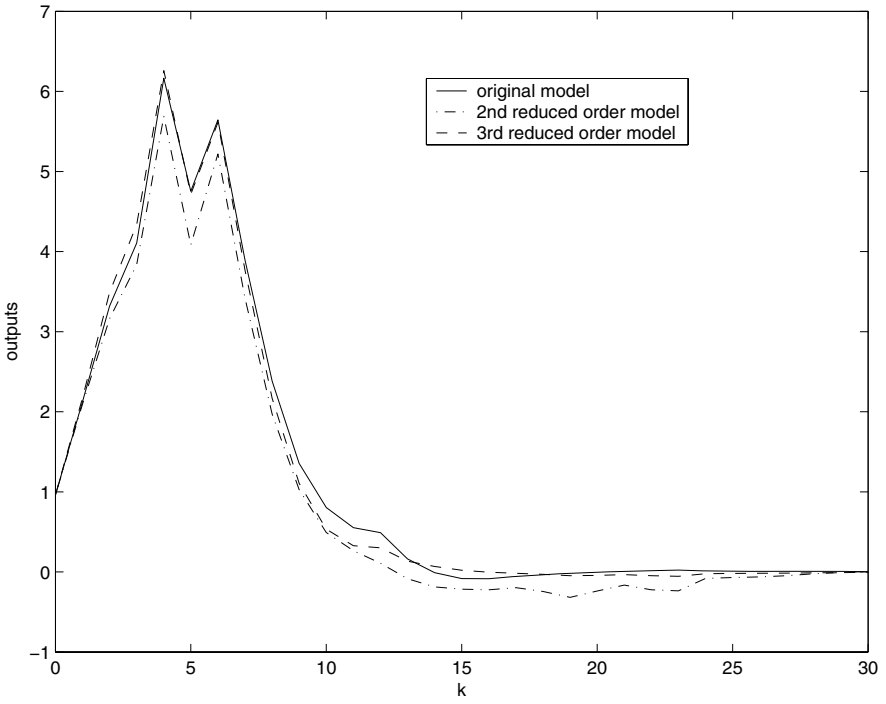

FIG. 1. *Comparison of the outputs: without uncertainty.*

Example 2. Consider the uncertain stochastic system S, in which $A, A_1, B, B_1, C, C_1, D$, and D_1 are given in Example 1, and U, V, M, N are

$$U = \begin{bmatrix} 0.1188 \\ 0.0289 \\ 0.0759 \\ 0.0607 \\ 0.1114 \end{bmatrix},\ V = -0.1618,\ M = \begin{bmatrix} 0.1191 \\ 0.0921 \\ -0.3434 \\ 0.0761 \\ -0.0009 \end{bmatrix},\ N = -0.0871.$$

By balancing P and Q, we obtain

$$\Sigma = \operatorname{diag}\{16.3927, 6.5846, 4.7287, 3.3965, 0.7145\}.$$

The 2nd order reduced model is given by

$$A_r = \begin{bmatrix} 0.7938 & -0.1855 \\ 0.1607 & 0.5968 \end{bmatrix},\ A_{r1} = \begin{bmatrix} 0.1532 & -0.0742 \\ -0.0903 & 0.1062 \end{bmatrix},$$
$$B_r = \begin{bmatrix} -1.3901 \\ 1.1269 \end{bmatrix},\ B_{r1} = \begin{bmatrix} -0.2208 \\ 0.0778 \end{bmatrix},$$
$$C_r = \begin{bmatrix} -1.8819 & -0.8822 \end{bmatrix},\ C_{r1} = \begin{bmatrix} -0.2338 & -0.0904 \end{bmatrix},\ D_r = 0.5,\ D_{1r} = 0.2,$$
$$U_r = \begin{bmatrix} -0.1935 \\ 0.1166 \end{bmatrix},\ V_r = -0.1618,\ M_r = \begin{bmatrix} 0.2850 & 0.5415 \end{bmatrix},\ N_r = -0.0871,$$

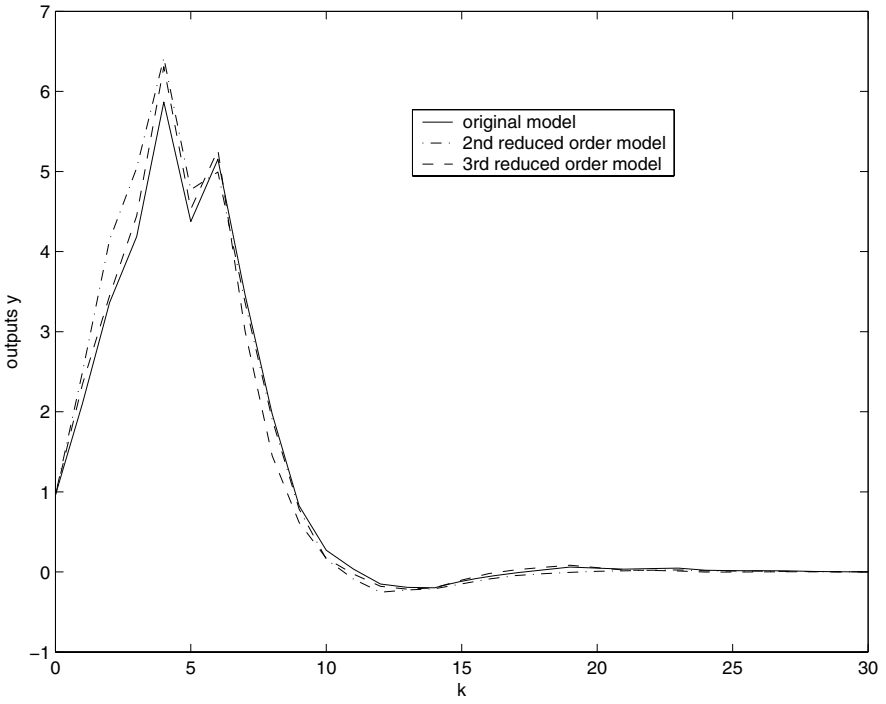

FIG. 2. *Comparison of the outputs: with uncertainty.*

and the 3rd order reduced model has state matrices as

$$A_r = \begin{bmatrix} 0.7938 & -0.1855 & -0.0950 \\ 0.1607 & 0.5968 & -0.4748 \\ -0.0373 & 0.3754 & 0.3300 \end{bmatrix},\ A_{r1} = \begin{bmatrix} 0.1532 & -0.0742 & 0.0178 \\ -0.0903 & 0.1062 & -0.0003 \\ 0.1267 & 0.1577 & 0.1645 \end{bmatrix},$$

$$B_r = \begin{bmatrix} -1.3901 \\ 1.1269 \\ 0.0363 \end{bmatrix},\ B_{r1} = \begin{bmatrix} -0.2208 \\ 0.0778 \\ -0.0452 \end{bmatrix},$$

$$C_r = \begin{bmatrix} -1.8819 \\ -0.8822 \\ -0.9196 \end{bmatrix}^T,\ C_{r1} = \begin{bmatrix} -0.2338 \\ -0.0904 \\ -0.2257 \end{bmatrix}^T,\ D_r = 0.5,\ D_{r1} = 0.2,$$

$$U_r = \begin{bmatrix} -0.1935 \\ 0.1166 \\ -0.0206 \end{bmatrix},\ V_r = -0.1618,\ M_r = \begin{bmatrix} 0.2850 & 0.5415 & -0.2667 \end{bmatrix},$$

$$N_r = -0.0871.$$

The outputs of the original model and the 2nd and 3rd order reduced models are given in Figure 2 when the input is set to e^{-k} and $E(k) = \sin(k)$. It can also be seen that the 3rd order reduced model approximates the original model better than the 2nd order reduced model.

6. Conclusions. In this paper, we have studied the model reduction problem based on balancing for uncertain linear systems with multiplicative noise, or linear systems with both deterministic and stochastic uncertainties. The deterministic un-

certainties are structured time-varying and norm-bounded, and the stochastic uncertainties are expressed as a multiplicative noise. The original model can be balanced through a balanced transformation, which can be found by balancing the solutions of two LMIs. By truncating the balanced model, the reduced model with a desired order is obtained. The upper bound of the model reduction error is guaranteed in the sense of perturbation operator norm. Since the solutions of the LMIs are not unique, an optimization problem that ensures small model reduction error bound has been proposed. Two numerical examples have been given for illustration of the main results.

Appendix: Proof of Theorem 3.4. For deterministic linear discrete-time systems, the model reduction based on balancing and LMIs was considered in [1]. Here, we will prove Theorem 3.4 by generalizing the technique given in [1]. For simplicity, the proof will be given in the case when $L = 1$. The case when $L > 1$ can be obtained similarly. The following definition and lemmas are essential for the proof.

DEFINITION 6.1. *A matrix set* $\{X_1, X_2, \ldots, X_s\}$ *is contractive if* $\sum_{i=1}^{s} X_i^T X_i \le I$ *and strictly contractive if* $\sum_{i=1}^{s} X_i^T X_i < I$.

When $s = 1$, Definition 6.1 reduces to the contractiveness of a matrix defined in [1]. Based on Definition 6.1 and Lemma 2.6, the following lemma follows.

LEMMA 6.2. *The uncertain stochastic system* S *is robustly mean-square stable and* $\|\mathbb{L}\| < \gamma$ *if and only if there exists one realization, denoted as*

$$\begin{bmatrix} \bar{A}(k) & \bar{B}(k) \\ \bar{C}(k) & \bar{D}(k) \\ \bar{A}_1 & \bar{B}_1 \\ \bar{C}_1 & \bar{D}_1 \end{bmatrix} \tag{33}$$

such that the matrix set

$$\left\{ \begin{bmatrix} \bar{A}(k) & \frac{1}{\sqrt{\gamma}}\bar{B}(k) \\ \frac{1}{\sqrt{\gamma}}\bar{C}(k) & \frac{1}{\gamma}\bar{D}(k) \end{bmatrix}, \begin{bmatrix} \sigma_1\bar{A}_1 & \frac{\sigma_1}{\sqrt{\gamma}}\bar{B}_1 \\ \frac{\sigma_1}{\sqrt{\gamma}}\bar{C}_1 & \frac{\sigma_1}{\gamma}\bar{D}_1 \end{bmatrix} \right\} \tag{34}$$

is strictly contractive.

Proof. From Lemma 2.6, $\|\mathbb{L}\| < \gamma$ if and only if there exists $X > 0$ such that

$$\begin{bmatrix} A(k)^T X A(k) + C(k)^T C(k) & A(k)^T X B(k) + C(k)^T D(k) \\ B(k)^T X A(k) + D(k)^T C(k) & B(k)^T X B(k) + D(k)^T D(k) \end{bmatrix} + \sigma_1^2 \begin{bmatrix} A_1^T X A_1 + C_1^T C_1 & A_1^T X B_1 + C_1^T D_1 \\ B_1^T X A_1 + D_1^T C_1 & B_1^T X B_1 + D_1^T D_1 \end{bmatrix} < \begin{bmatrix} X & 0 \\ 0 & \gamma^2 I \end{bmatrix}$$

holds. Premultiplying and postmultiplying the above inequality by

$$\begin{bmatrix} \frac{1}{\sqrt{\gamma}} I & 0 \\ 0 & \frac{1}{\gamma} I \end{bmatrix},$$

respectively, and letting $\tilde{X} = \frac{1}{\gamma} X$, we obtain

$$\begin{bmatrix} A(k)^T \tilde{X} A(k) + \frac{1}{\gamma} C(k)^T C(k) & \frac{1}{\sqrt{\gamma}} A(k)^T \tilde{X} B(k) + \frac{1}{\gamma\sqrt{\gamma}} C(k)^T D(k) \\ \frac{1}{\sqrt{\gamma}} B(k)^T \tilde{X} A(k) + \frac{1}{\gamma\sqrt{\gamma}} D(k)^T C(k) & \frac{1}{\gamma} B(k)^T \tilde{X} B(k) + \frac{1}{\gamma^2} D(k)^T D(k) \end{bmatrix} + \sigma_1^2 \begin{bmatrix} A_1^T \tilde{X} A_1 + \frac{1}{\gamma} C_1^T C_1 & \frac{1}{\sqrt{\gamma}} A_1^T \tilde{X} B_1 + \frac{1}{\gamma\sqrt{\gamma}} C_1^T D_1 \\ \frac{1}{\sqrt{\gamma}} B_1^T \tilde{X} A_1 + \frac{1}{\gamma\sqrt{\gamma}} D_1^T C_1 & \frac{1}{\gamma} B_1^T \tilde{X} B_1 + \frac{1}{\gamma^2} D_1^T D_1 \end{bmatrix} < \begin{bmatrix} \tilde{X} & 0 \\ 0 & I \end{bmatrix},$$

or equivalently,

$$\begin{bmatrix} A(k) & \frac{1}{\sqrt{\gamma}}B(k) \\ \frac{1}{\sqrt{\gamma}}C(k) & \frac{1}{\gamma}D(k) \end{bmatrix}^T \begin{bmatrix} \tilde{X} & 0 \\ 0 & I \end{bmatrix} \begin{bmatrix} A(k) & \frac{1}{\sqrt{\gamma}}B(k) \\ \frac{1}{\sqrt{\gamma}}C(k) & \frac{1}{\gamma}D(k) \end{bmatrix}$$
$$+\sigma_1^2 \begin{bmatrix} A_1 & \frac{1}{\sqrt{\gamma}}B_1 \\ \frac{1}{\sqrt{\gamma}}C_1 & \frac{1}{\gamma}D_1 \end{bmatrix}^T \begin{bmatrix} \tilde{X} & 0 \\ 0 & I \end{bmatrix} \begin{bmatrix} A_1 & \frac{1}{\sqrt{\gamma}}B_1 \\ \frac{1}{\sqrt{\gamma}}C_1 & \frac{1}{\gamma}D_1 \end{bmatrix} < \begin{bmatrix} \tilde{X} & 0 \\ 0 & I \end{bmatrix}.$$

Premultiplying and postmultiplying both sides of the above inequality by

$$\begin{bmatrix} \tilde{X}^{-\frac{1}{2}} & 0 \\ 0 & I \end{bmatrix}$$

and letting

$$\begin{bmatrix} \bar{A}(k) & \bar{B}(k) \\ \bar{C}(k) & \bar{D}(k) \end{bmatrix} = \begin{bmatrix} \tilde{X}^{\frac{1}{2}} & 0 \\ 0 & I \end{bmatrix} \begin{bmatrix} A(k) & B(k) \\ C(k) & D(k) \end{bmatrix} \begin{bmatrix} \tilde{X}^{-\frac{1}{2}} & 0 \\ 0 & I \end{bmatrix},$$

we have

$$\begin{bmatrix} \bar{A}_1 & \bar{B}_1 \\ \bar{C}_1 & \bar{D}_1 \end{bmatrix} = \begin{bmatrix} \tilde{X}^{\frac{1}{2}} & 0 \\ 0 & I \end{bmatrix} \begin{bmatrix} A_1 & B_1 \\ C_1 & D_1 \end{bmatrix} \begin{bmatrix} \tilde{X}^{-\frac{1}{2}} & 0 \\ 0 & I \end{bmatrix}.$$

It can be seen that (33) is one realization of S, and (34) is strictly contractive. ∎

LEMMA 6.3. *Given a balanced realization* (14) *with* (22)–(25), *if* $\Sigma_2 = I$, *the matrix set*

$$\left\{ \begin{bmatrix} \Sigma_1^{-\frac{1}{2}}A_{12}(k) & \Sigma_1^{-\frac{1}{2}}A_{11}(k)\Sigma_1^{\frac{1}{2}} & \Sigma_1^{-\frac{1}{2}}\tilde{B}_1(k) \\ A_{22}(k) & A_{21}(k)\Sigma_1^{\frac{1}{2}} & \tilde{B}_2(k) \end{bmatrix}, \right.$$
$$\left. \begin{bmatrix} \sigma_1\Sigma_1^{-\frac{1}{2}}A_{12}^1 & \sigma_1\Sigma_1^{-\frac{1}{2}}A_{11}^1\Sigma_1^{\frac{1}{2}} & \sigma_1\Sigma_1^{-\frac{1}{2}}\tilde{B}_1^1 \\ \sigma_1 A_{22}^1 & \sigma_1 A_{21}^1\Sigma_1^{\frac{1}{2}} & \sigma_1\tilde{B}_2^1 \end{bmatrix} \right\} \tag{35}$$

and

$$\left\{ \begin{bmatrix} A_{21}(k)\Sigma_1^{-\frac{1}{2}} & A_{22}(k) \\ \Sigma_1^{\frac{1}{2}}A_{11}(k)\Sigma_1^{-\frac{1}{2}} & \Sigma_1^{\frac{1}{2}}A_{12}(k) \\ \tilde{C}_1(k)\Sigma_1^{-\frac{1}{2}} & \tilde{C}_2(k) \end{bmatrix}, \begin{bmatrix} \sigma_1 A_{21}^1\Sigma_1^{-\frac{1}{2}} & \sigma_1 A_{22}^1 \\ \sigma_1\Sigma_1^{\frac{1}{2}}A_{11}^1\Sigma_1^{-\frac{1}{2}} & \sigma_1\Sigma_1^{\frac{1}{2}}A_{12}^1 \\ \sigma_1\tilde{C}_1^1\Sigma_1^{-\frac{1}{2}} & \sigma_1\tilde{C}_2^1 \end{bmatrix} \right\} \tag{36}$$

are strictly contractive.

Proof. By the Schur complements, (21) is equivalent to

$$\begin{bmatrix} -\Sigma^{-1} & 0 & A_b(k)^T & \sigma_1 A_{b1}^T \\ 0 & -I & B_b(k)^T & \sigma_1 B_{b1}^T \\ A_b(k) & B_b(k) & -\Sigma & 0 \\ \sigma_1 A_{b1} & \sigma_1 B_{b1} & 0 & -\Sigma \end{bmatrix} < 0,$$

or

$$\begin{bmatrix} -\Sigma^{-1} & 0 \\ 0 & -I \end{bmatrix} + \begin{bmatrix} A_b(k)^T & \sigma_1 A_{b1}^T \\ B_b(k)^T & \sigma_1 B_{b1}^T \end{bmatrix} \begin{bmatrix} -\Sigma^{-1} & 0 \\ 0 & -\Sigma^{-1} \end{bmatrix} \begin{bmatrix} A_b(k) & B_b(k) \\ \sigma_1 A_{b1} & \sigma_1 B_{b1} \end{bmatrix} < 0,$$

or

$$\begin{bmatrix} \Sigma^{\frac{1}{2}} & 0 \\ 0 & I \end{bmatrix} \left(\begin{bmatrix} A_b(k)^T \\ B_b(k)^T \end{bmatrix} \Sigma^{-1} \begin{bmatrix} A_b(k) & B_b(k) \end{bmatrix} + \begin{bmatrix} \sigma_1 A_{b1}^T \\ \sigma_1 B_{b1}^T \end{bmatrix} \Sigma^{-1} \begin{bmatrix} \sigma_1 A_{b1} & \sigma_1 B_{b1} \end{bmatrix} \right) \begin{bmatrix} \Sigma^{\frac{1}{2}} & 0 \\ 0 & I \end{bmatrix} < I,$$

which implies the strict contractiveness of

$$\left\{ \Sigma^{-\frac{1}{2}} \begin{bmatrix} A_b(k) & B_b(k) \end{bmatrix} \begin{bmatrix} \Sigma^{\frac{1}{2}} & 0 \\ 0 & I \end{bmatrix}, \Sigma^{-\frac{1}{2}} \begin{bmatrix} \sigma_1 A_{b1} & \sigma_1 B_{b1} \end{bmatrix} \begin{bmatrix} \Sigma^{\frac{1}{2}} & 0 \\ 0 & I \end{bmatrix} \right\}. \tag{37}$$

On the other hand, (20) gives

$$\Sigma^{-\frac{1}{2}} A_b(k)^T \Sigma A_b(k) \Sigma^{-\frac{1}{2}} + \Sigma^{-\frac{1}{2}} C_b(k)^T C_b(k) \Sigma^{-\frac{1}{2}} + \Sigma^{-\frac{1}{2}} \sigma_1^2 (A_{b1}^T \Sigma A_{b1} + C_{b1}^T C_{b1}) \Sigma^{-\frac{1}{2}} < I$$

or

$$\Sigma^{-\frac{1}{2}} \left(\begin{bmatrix} A_b(k)^T & C_b(k)^T \end{bmatrix} \begin{bmatrix} \Sigma & 0 \\ 0 & I \end{bmatrix} \begin{bmatrix} A_b(k) \\ C_b(k) \end{bmatrix} + \sigma_1^2 \begin{bmatrix} A_{b1}{}^T & C_{b1}{}^T \end{bmatrix} \begin{bmatrix} \Sigma & 0 \\ 0 & I \end{bmatrix} \begin{bmatrix} A_{b1} \\ C_{b1} \end{bmatrix} \right) \Sigma^{-\frac{1}{2}} < I.$$

This implies the strict contractiveness of

$$\left\{ \begin{bmatrix} \Sigma^{1/2} & 0 \\ 0 & I \end{bmatrix} \begin{bmatrix} A_b(k) \\ C_b(k) \end{bmatrix} \Sigma^{-\frac{1}{2}}, \sigma_1 \begin{bmatrix} \Sigma^{1/2} & 0 \\ 0 & I \end{bmatrix} \begin{bmatrix} A_{b1} \\ C_{b1} \end{bmatrix} \Sigma^{-\frac{1}{2}} \right\}. \tag{38}$$

Substituting (22)–(25) into (37) and (38) and permuting the rows of the resulting matrices, we can see the strict contractiveness of (35) and (36), respectively. □

LEMMA 6.4. *Suppose that the two matrix set*

$$\left\{ \begin{bmatrix} U_{11} & U_{12} \\ Z & U_{22} \end{bmatrix}, \begin{bmatrix} U_{11}^1 & U_{12}^1 \\ Z^1 & U_{22}^1 \end{bmatrix} \right\}$$

and

$$\left\{ \begin{bmatrix} V_{11} & Z \\ V_{21} & V_{22} \end{bmatrix}, \begin{bmatrix} V_{11}^1 & Z^1 \\ V_{21}^1 & V_{22}^1 \end{bmatrix} \right\}$$

are strictly contractive. Then

$$\{K_1, K_2\} := \left\{ \begin{bmatrix} 0 & \frac{1}{\sqrt{2}} U_{11} & U_{12} \\ \frac{1}{\sqrt{2}} V_{11} & Z & \frac{1}{\sqrt{2}} U_{22} \\ V_{21} & \frac{1}{\sqrt{2}} V_{22} & 0 \end{bmatrix}, \begin{bmatrix} 0 & \frac{1}{\sqrt{2}} U_{11}^1 & U_{12}^1 \\ \frac{1}{\sqrt{2}} V_{11}^1 & Z^1 & \frac{1}{\sqrt{2}} U_{22}^1 \\ V_{21}^1 & \frac{1}{\sqrt{2}} V_{22}^1 & 0 \end{bmatrix} \right\} \tag{39}$$

is strictly contractive.

Proof. Dilate the matrix set in (39) as

$$\left\{ \begin{bmatrix} 0 & \frac{1}{\sqrt{2}} U_{11} & U_{12} & \frac{1}{\sqrt{2}} U_{11} \\ \frac{1}{\sqrt{2}} V_{11} & Z & \frac{1}{\sqrt{2}} U_{22} & 0 \\ V_{21} & \frac{1}{\sqrt{2}} V_{22} & 0 & -\frac{1}{\sqrt{2}} V_{22} \\ \frac{1}{\sqrt{2}} V_{11} & 0 & -\frac{1}{\sqrt{2}} U_{22} & -Z \end{bmatrix}, \begin{bmatrix} 0 & \frac{1}{\sqrt{2}} U_{11}^1 & U_{12}^1 & \frac{1}{\sqrt{2}} U_{11}^1 \\ \frac{1}{\sqrt{2}} V_{11}^1 & Z^1 & \frac{1}{\sqrt{2}} U_{22}^1 & 0 \\ V_{21}^1 & \frac{1}{\sqrt{2}} V_{22}^1 & 0 & -\frac{1}{\sqrt{2}} V_{22}^1 \\ \frac{1}{\sqrt{2}} V_{11}^1 & 0 & -\frac{1}{\sqrt{2}} U_{22}^1 & -Z^1 \end{bmatrix} \right\},$$

and it can be verified that the resulting matrix set is strictly contractive. Thus, (39) is strictly contractive. □

Proof of Theorem 3.4. Without loss of generality, we assume that $\Sigma_2 = 1$; in this case, we need to show that

$$\|\mathbb{L}_e\| < 2. \tag{40}$$

The general case follows from scaling and applying this result recursively. It is noticed that one realization of the error system $S - S_r$ is given by

$$\begin{bmatrix} \begin{bmatrix} \begin{bmatrix} A_{11}(k) & 0 \\ 0 & A_b(k) \end{bmatrix} & \begin{bmatrix} \tilde{B}_1(k) \\ B_b(k) \end{bmatrix} \\ \begin{bmatrix} -\tilde{C}_1(k) & C_b(k) \end{bmatrix} & 0 \end{bmatrix} \\ \begin{bmatrix} \begin{bmatrix} A_{11}^1 & 0 \\ 0 & A_b^1 \end{bmatrix} & \begin{bmatrix} \tilde{B}_1^1 \\ B_b^1 \end{bmatrix} \\ \begin{bmatrix} -\tilde{C}_1^1 & C_b^1 \end{bmatrix} & 0 \end{bmatrix} \end{bmatrix}.$$

Letting T be an equivalent transformation, which is given by

$$T = \begin{bmatrix} -\frac{1}{\sqrt{2}}\Sigma_1^{1/2} & \frac{1}{\sqrt{2}}\Sigma_1^{1/2} & 0 \\ 0 & 0 & I \\ \frac{1}{\sqrt{2}}\Sigma_1^{-1/2} & \frac{1}{\sqrt{2}}\Sigma_1^{-1/2} & 0 \end{bmatrix},$$

the resulting equivalent realization is

$$\begin{bmatrix} \begin{bmatrix} \begin{bmatrix} \Sigma_1^{1/2}A_{11}(k)\Sigma_1^{-1/2} & \frac{1}{\sqrt{2}}\Sigma_1^{1/2}A_{12}(k) & 0 \\ \frac{1}{\sqrt{2}}A_{21}(k)\Sigma_1^{-1/2} & A_{22}(k) & \frac{1}{\sqrt{2}}A_{21}(k)\Sigma_1^{1/2} \\ 0 & \frac{1}{\sqrt{2}}\Sigma_1^{-1/2}A_{12}(k) & \Sigma_1^{-1/2}A_{11}(k)\Sigma_1^{1/2} \end{bmatrix} & \begin{bmatrix} 0 \\ \tilde{B}_2(k) \\ \frac{2}{\sqrt{2}}\Sigma_1^{-1/2}\tilde{B}_1(k) \end{bmatrix} \\ \begin{bmatrix} \frac{2}{\sqrt{2}}\tilde{C}_1\Sigma_1^{-1/2} & \tilde{C}_2 & 0 \end{bmatrix} & 0 \end{bmatrix} \\ \begin{bmatrix} \begin{bmatrix} \Sigma_1^{1/2}A_{11}^1\Sigma_1^{-1/2} & \frac{1}{\sqrt{2}}\Sigma_1^{1/2}A_{12}^1 & 0 \\ \frac{1}{\sqrt{2}}A_{21}^1\Sigma_1^{-1/2} & A_{22}^1 & \frac{1}{\sqrt{2}}A_{21}^1\Sigma_1^{1/2} \\ 0 & \frac{1}{\sqrt{2}}\Sigma_1^{-1/2}A_{12}^1 & \Sigma_1^{-1/2}A_{11}^1\Sigma_1^{1/2} \end{bmatrix} & \begin{bmatrix} 0 \\ \tilde{B}_2^1 \\ \frac{2}{\sqrt{2}}\Sigma_1^{-1/2}\tilde{B}_1^1 \end{bmatrix} \\ \begin{bmatrix} \frac{2}{\sqrt{2}}\tilde{C}_1^1\Sigma_1^{-1/2} & \tilde{C}_2^1 & 0 \end{bmatrix} & 0 \end{bmatrix} \end{bmatrix}.$$

By Lemma 6.2, if we can show that the matrix set

$$\{L_1, L_2\} := \left\{ \begin{bmatrix} \Sigma_1^{1/2}A_{11}(k)\Sigma_1^{-1/2} & \frac{1}{\sqrt{2}}\Sigma_1^{1/2}A_{12}(k) & 0 & 0 \\ \frac{1}{\sqrt{2}}A_{21}(k)\Sigma_1^{-1/2} & A_{22}(k) & \frac{1}{\sqrt{2}}A_{21}(k)\Sigma_1^{1/2} & \frac{1}{\sqrt{2}}\tilde{B}_2(k) \\ 0 & \frac{1}{\sqrt{2}}\Sigma_1^{-1/2}A_{12}(k) & \Sigma_1^{-1/2}A_{11}(k)\Sigma_1^{1/2} & \Sigma_1^{-1/2}\tilde{B}_1(k) \\ \tilde{C}_1(k)\Sigma_1^{-1/2} & \frac{1}{\sqrt{2}}\tilde{C}_2(k) & 0 & 0 \end{bmatrix}, \right.$$
$$\left. \sigma_1 \begin{bmatrix} \Sigma_1^{1/2}A_{11}^1\Sigma_1^{-1/2} & \frac{1}{\sqrt{2}}\Sigma_1^{1/2}A_{12}^1 & 0 & 0 \\ \frac{1}{\sqrt{2}}A_{21}^1\Sigma_1^{-1/2} & A_{22}^1 & \frac{1}{\sqrt{2}}A_{21}^1\Sigma_1^{1/2} & \frac{1}{\sqrt{2}}\tilde{B}_2^1 \\ 0 & \frac{1}{\sqrt{2}}\Sigma_1^{-1/2}A_{12}^1 & \Sigma_1^{-1/2}A_{11}^1\Sigma_1^{1/2} & \Sigma_1^{-1/2}\tilde{B}_1^1 \\ \tilde{C}_1^1\Sigma_1^{-1/2} & \frac{1}{\sqrt{2}}\tilde{C}_2^1 & 0 & 0 \end{bmatrix} \right\}$$

is strictly contractive, then the proof is obtained. By Lemmas 6.3 and 6.4, it can be

seen that the matrix set

$$\{\tilde{L}_1, \tilde{L}_2\} := \left\{ \begin{bmatrix} 0 & \frac{1}{\sqrt{2}}\Sigma_1^{-\frac{1}{2}} A_{12}(k) & \Sigma_1^{-1/2} A_{11}(k) \Sigma_1^{1/2} & \Sigma_1^{-1/2} \tilde{B}_1 \\ \frac{1}{\sqrt{2}} A_{21}(k) \Sigma_1^{-\frac{1}{2}} & A_{22}(k) & \frac{1}{\sqrt{2}} A_{21}(k) \Sigma_1^{1/2} & \frac{1}{\sqrt{2}} \tilde{B}_2(k) \\ \Sigma_1^{1/2} A_{11}(k) \Sigma_1^{-1/2} & \frac{1}{\sqrt{2}} \Sigma_1^{1/2} A_{12}(k) & 0 & 0 \\ \tilde{C}_1(k) \Sigma_1^{-1/2} & \frac{1}{\sqrt{2}} \tilde{C}_2(k) & 0 & 0 \end{bmatrix}, \right.$$
$$\left. \sigma_1 \begin{bmatrix} 0 & \frac{1}{\sqrt{2}}\Sigma_1^{-1/2} A_{12}^1 & \Sigma_1^{-1/2} A_{11}^1 \Sigma_1^{1/2} & \Sigma_1^{-1/2} \tilde{B}_1^1 \\ \frac{1}{\sqrt{2}} A_{21}^1 \Sigma_1^{-1/2} & A_{22}^1 & \frac{1}{\sqrt{2}} A_{21}^1 \Sigma_1^{1/2} & \frac{1}{\sqrt{2}} \tilde{B}_2^1 \\ \Sigma_1^{1/2} A_{11}^1 \Sigma_1^{-1/2} & \frac{1}{\sqrt{2}} \Sigma_1^{1/2} A_{12}^1 & 0 & 0 \\ \tilde{C}_1^1 \Sigma_1^{-1/2} & \frac{1}{\sqrt{2}} \tilde{C}_2^1 & 0 & 0 \end{bmatrix} \right\}$$

is strictly contractive. By permuting the rows of $\tilde{L}_1, \tilde{L}_2$, the strict contractiveness of $\{L_1, L_2\}$ is obtained. □

STABILITY AND INSTABILITY RESULTS OF THE WAVE EQUATION WITH A DELAY TERM IN THE BOUNDARY OR INTERNAL FEEDBACKS*

SERGE NICAISE† AND CRISTINA PIGNOTTI‡

Abstract. In this paper we consider, in a bounded and smooth domain, the wave equation with a delay term in the boundary condition. We also consider the wave equation with a delayed velocity term and mixed Dirichlet–Neumann boundary condition. In both cases, under suitable assumptions, we prove exponential stability of the solution. These results are obtained by introducing suitable energies and by using some observability inequalities. If one of the above assumptions is not satisfied, some instability results are also given by constructing some sequences of delays for which the energy of some solutions does not tend to zero.

Key words. wave equation, delay feedbacks, stabilization

1. Introduction.

We investigate the effect of time delay in boundary or internal stabilization of the wave equation in domains of $\mathbb{R}^n$. Such effects arise in many practical problems, and it is well known, at least in one dimension, that they can induce some instabilities; see [4, 5, 6, 17].

To our knowledge, analysis in higher dimensions has not yet been done. In this paper, we give some stability results under a sufficient condition, and we further show that if this condition is not satisfied, then there exist some delays for which the system is destabilized. So, in a certain sense, our sufficient condition is also necessary in order to have a general stability result.

Let $\Omega \subset \mathbb{R}^n$ be an open bounded set with a boundary Γ of class C^2. We assume that Γ is divided into two parts Γ_D and Γ_N, i.e., $\Gamma = \Gamma_D \cup \Gamma_N$, with $\overline{\Gamma}_D \cap \overline{\Gamma}_N = \emptyset$ and $\Gamma_D \neq \emptyset$.

In this domain Ω, we consider the initial boundary value problem

$$u_{tt}(x,t) - \Delta u(x,t) = 0 \quad \text{in} \quad \Omega \times (0,+\infty), \tag{1.1}$$

$$u(x,t) = 0 \quad \text{on} \quad \Gamma_D \times (0,+\infty), \tag{1.2}$$

$$\frac{\partial u}{\partial \nu}(x,t) = -\mu_1 u_t(x,t) - \mu_2 u_t(x,t-\tau) \quad \text{on} \quad \Gamma_N \times (0,+\infty), \tag{1.3}$$

$$u(x,0) = u_0(x) \quad \text{and} \quad u_t(x,0) = u_1(x) \quad \text{in} \quad \Omega, \tag{1.4}$$

$$u_t(x,t-\tau) = f_0(x,t-\tau) \quad \text{in } \Gamma_N \times (0,\tau), \tag{1.5}$$

where $\nu(x)$ denotes the outer unit normal vector to the point $x \in \Gamma$ and $\frac{\partial u}{\partial \nu}$ is the normal derivative. Moreover, $\tau > 0$ is the time delay, μ_1 and μ_2 are positive real numbers, and the initial data (u_0, u_1, f_0) belong to a suitable space.

We are interested in giving an exponential stability result for such a problem.

Let us denote by $\langle v, w\rangle$ or, equivalently, by $v \cdot w$ the Euclidean inner product between two vectors $v, w \in \mathbb{R}^n$.

We assume that there exists a scalar function $v \in C^2(\overline{\Omega})$ such that

(i) v is strictly convex in $\overline{\Omega}$; that is, there exists $\alpha > 0$ such that

$$\langle D^2(v)(x)\xi, \xi\rangle \geq 2\alpha|\xi|^2 \quad \forall x \in \overline{\Omega},\ \forall \xi \in \mathbb{R}^n, \tag{1.6}$$

where $D^2(v)$ denotes the Hessian matrix of v;

(ii) the vector field $H := \nabla v$ verifies

$$H(x) \cdot \nu(x) \leq 0 \quad \forall x \in \Gamma_D. \tag{1.7}$$

For the above assumptions see [14], where some observability estimates for second-order hyperbolic equations are given.

It is well known that if $\mu_2 = 0$, that is, in absence of delay, the energy of problem (1.1)–(1.5) is exponentially decaying to zero. See for instance Chen [2, 3], Lagnese [11, 12], Lasiecka and Triggiani [13], Komornik and Zuazua [10], and Komornik [8, 9]. On the contrary, if $\mu_1 = 0$, that is, if we have only the delay part in the boundary condition on Γ_N, system (1.1)–(1.5) becomes unstable. See, for instance Datko, Lagnese, and Polis [6].

Although these examples involve only one space dimension, we can expect a similar phenomenon to occur in higher space dimensions. So, it is interesting to seek a stabilization result when both μ_1 and μ_2 are nonzero. In this case, the boundary feedback is composed of two parts and only one of them has a delay.

This problem has been studied in one space dimension by Xu, Yung, and Li [17]. After a spectral analysis these authors proved a stability result for the case when $\mu_2 < \mu_1$. In their paper it is also shown that if $\mu_2 > \mu_1$, the system is unstable and if $\mu_1 = \mu_2$, some instabilities may occur.

Here, in agreement with [17] and assuming that

$$\mu_2 < \mu_1, \tag{1.8}$$

we obtain a stabilization result in a general space dimension by using a suitable observability estimate. This is done by applying inequalities obtained from Carleman estimates for the wave equation by Lasiecka, Triggiani, and Yao in [14] and by using compactness-uniqueness arguments. If $\mu_1 = \mu_2$, we further show that there exists a sequence of arbitrary small (and large) delays such that instabilities occur. In the case $\mu_2 > \mu_1$, we also obtain delays which destabilize the system. More precisely, we show the next results.

Under assumption (1.8) let us define the energy of a solution of problem (1.1)–(1.5) as

$$E(t) := \frac{1}{2}\int_\Omega \{u_t^2(x,t) + |\nabla u(x,t)|^2\}dx + \frac{\xi}{2}\int_{\Gamma_N}\int_0^1 u_t^2(x, t-\tau\rho)d\rho d\Gamma, \tag{1.9}$$

where ξ is a positive constant verifying

$$\tau\mu_2 < \xi < \tau(2\mu_1 - \mu_2). \tag{1.10}$$

Clearly this energy is larger than the standard energy

$$\frac{1}{2}\int_\Omega \{u_t^2(x,t) + |\nabla u(x,t)|^2\}dx$$

and contains an additional term that comes from the delay term.

THEOREM 1.1. *Assume that* (1.8) *holds. There exist positive constants* C_1, C_2 *such that, for any solution of problem* (1.1)–(1.5),

$$E(t) \le C_1 E(0) e^{-C_2 t} \qquad \forall t \ge 0. \tag{1.11}$$

THEOREM 1.2. *If* (1.8) *does not hold, there exist a sequence of delays, and solutions of problem* (1.1)–(1.5) *corresponding to these delays, such that their standard energy is constant.*

In this paper we also study the problem for the wave equation with internal feedback. In particular, we consider the system

$$u_{tt}(x,t) - \Delta u(x,t) + a(x)[\mu_1 u_t(x,t) + \mu_2 u_t(x,t-\tau)] = 0 \ \text{ in } \Omega \times (0,+\infty), \tag{1.12}$$

$$u(x,t) = 0 \quad \text{on} \quad \Gamma_D \times (0,+\infty), \tag{1.13}$$

$$\frac{\partial u}{\partial \nu}(x,t) = 0 \quad \text{on} \quad \Gamma_N \times (0,+\infty), \tag{1.14}$$

$$u(x,0) = u_0(x) \quad \text{and} \quad u_t(x,0) = u_1(x) \quad \text{in} \quad \Omega, \tag{1.15}$$

$$u_t(x,t-\tau) = g_0(x,t-\tau) \quad \text{in } \Omega \times (0,\tau), \tag{1.16}$$

where $a \in L^\infty(\Omega)$ is a function such that

$$a(x) \ge 0 \quad \text{a. e.} \quad \text{in} \quad \Omega, \tag{1.17}$$

and

$$a(x) > a_0 > 0 \quad \text{a. e.} \quad \text{in} \quad \omega, \tag{1.18}$$

where $\omega \subset \Omega$ is an open neighborhood of Γ_N.

Exponential stability results for the above problem in the case of $\mu_2 = 0$, that is, without delay, have been obtained by several authors. See for instance Zuazua [18] and Liu [16].

On the contrary, at least for the one-dimensional case, Datko [4] has shown that the wave equation with a velocity term and mixed Dirichlet–Neumann boundary condition is destabilized by a time delay in the velocity term.

In this paper, in the case $\mu_2 < \mu_1$, we show that the energy is exponentially decaying to zero. This is done, as for the problem with boundary feedback, by using a suitable observability estimate. If $\mu_2 \ge \mu_1$, we obtain an explicit sequence of arbitrary small delays that destabilize the system.

As before, under assumption (1.8) let us define the energy of a solution of (1.12)–(1.16) as

$$\mathcal{F}(t) := \frac{1}{2}\int_\Omega \{u_t^2(x,t) + |\nabla u(x,t)|^2\}dx + \frac{\xi}{2}\int_\Omega a(x)\int_0^1 u_t^2(x,t-\tau\rho)d\rho dx, \tag{1.19}$$

where ξ is a positive constant verifying (1.10). Again $\mathcal{F}$ is larger than the standard energy and contains an extra term due to the delay.

THEOREM 1.3. *Let assumption* (1.8) *be satisfied. Then there exist positive constants* C_1, C_2 *such that, for any solution of problem* (1.12)–(1.16),

$$\mathcal{F}(t) \le C_1 \mathcal{F}(0) e^{-C_2 t} \qquad \forall t \ge 0. \tag{1.20}$$

THEOREM 1.4. *If* (1.8) *does not hold, there exist a sequence of arbitrary small (or large) delays, and solutions of problem* (1.12)–(1.16) *corresponding to these delays, such that their standard energy does not tend to* 0.

Remark 1.5. In [14], in order to deal with variable coefficients, the authors assume that there exists a scalar function v strictly convex with respect to the Riemannian metric induced by the spatial operator. Here, we are principally interested in the effect of the delay term in the boundary or internal feedback. So, in order to avoid technicalities, we consider constant coefficients. Actually, our stability results hold even for variable coefficients under the assumption of [14].

The paper is organized as follows. Well-posedness of the problems is analyzed in section 2 using semigroup theory. In subsection 2.1 we study the well-posedness of problem (1.1)–(1.5), while in subsection 2.2 we concentrate on problem (1.12)–(1.16). In sections 3 and 4 we prove the exponential stability of the problem with boundary and internal feedbacks, respectively. Finally, section 5 is devoted to some instability examples.

2. Well-posedness of the problems. In this section we will give well-posedness results for problem (1.1)–(1.5) and problem (1.12)–(1.16) using semigroup theory.

2.1. Boundary feedback. Let us set

$$z(x,\rho,t) = u_t(x,t-\tau\rho), \quad x \in \Gamma_N,\ \rho \in (0,1),\ t>0. \tag{2.1}$$

Then, problem (1.1)–(1.5) is equivalent to

$$u_{tt}(x,t) - \Delta u(x,t) = 0 \quad \text{in} \quad \Omega \times (0,+\infty), \tag{2.2}$$

$$\tau z_t(x,\rho,t) + z_\rho(x,\rho,t) = 0 \quad \text{in} \quad \Gamma_N \times (0,1) \times (0,+\infty), \tag{2.3}$$

$$u(x,t) = 0 \quad \text{on} \quad \Gamma_D \times (0,+\infty), \tag{2.4}$$

$$\frac{\partial u}{\partial \nu}(x,t) = -\mu_1 u_t(x,t) - \mu_2 z(x,1,t) \quad \text{on} \quad \Gamma_N \times (0,+\infty), \tag{2.5}$$

$$z(x,0,t) = u_t(x,t) \quad \text{on} \quad \Gamma_N \times (0,\infty), \tag{2.6}$$

$$u(x,0) = u_0(x) \quad \text{and} \quad u_t(x,0) = u_1(x) \quad \text{in} \quad \Omega, \tag{2.7}$$

$$z(x,\rho,0) = f_0(x,-\rho\tau) \quad \text{in} \quad \Gamma_N \times (0,1). \tag{2.8}$$

If we denote

$$U := (u, u_t, z)^T,$$

then

$$U' := (u_t, u_{tt}, z_t)^T = \left(u_t, \Delta u, -\tau^{-1} z_\rho\right)^T.$$

Therefore, problem (2.2)–(2.8) can be rewritten as

$$\begin{cases} U' = \mathcal{A}U, \\ U(0) = (u_0, u_1, f_0(\cdot, -\cdot\,\tau))^T, \end{cases} \tag{2.9}$$

where the operator $\mathcal{A}$ is defined by

$$\mathcal{A}\begin{pmatrix} u \\ v \\ z \end{pmatrix} := \begin{pmatrix} v \\ \Delta u \\ -\tau^{-1} z_\rho \end{pmatrix},$$

with domain

(2.10)
$$\mathcal{D}(\mathcal{A}) := \Big\{ (u,v,z)^T \in \big(E(\Delta, L^2(\Omega)) \cap H^1_{\Gamma_D}(\Omega)\big) \times H^1(\Omega) \times L^2(\Gamma_N; H^1(0,1)) \ : \ \frac{\partial u}{\partial \nu} = -\mu_1 v - \mu_2 z(\cdot,1) \text{ on } \Gamma_N;\ v = z(\cdot,0) \text{ on } \Gamma_N \Big\},$$

where, as usual,

$$H^1_{\Gamma_D}(\Omega) = \{ u \in H^1(\Omega) \ : \ u = 0 \quad \text{on} \ \ \Gamma_D \},$$

and

$$E(\Delta, L^2(\Omega)) = \{u \in H^1(\Omega) : \Delta u \in L^2(\Omega)\}.$$

Recall that for a function $u \in E(\Delta, L^2(\Omega))$, $\frac{\partial u}{\partial \nu}$ belongs to $H^{-1/2}(\Gamma_N)$ and the next Green formula is valid (see section 1.5 of [7])

$$\int_\Omega \nabla u \nabla w dx = -\int_\Omega \Delta u w dx + \left\langle \frac{\partial u}{\partial \nu}; w \right\rangle_{\Gamma_N} \quad \forall w \in H^1_{\Gamma_D}(\Omega), \tag{2.11}$$

where $\langle \cdot; \cdot \rangle_{\Gamma_N}$ means the duality pairing between $H^{-1/2}(\Gamma_N)$ and $H^{1/2}(\Gamma_N)$.

Note further that for $(u,v,z)^T \in \mathcal{D}(\mathcal{A})$, $\frac{\partial u}{\partial \nu}$ belongs to $L^2(\Gamma_N)$ since $z(\cdot,1)$ is in $L^2(\Gamma_N)$.

Denote by $\mathcal{H}$ the Hilbert space

$$\mathcal{H} := H^1_{\Gamma_D}(\Omega) \times L^2(\Omega) \times L^2(\Gamma_N \times (0,1)). \tag{2.12}$$

Assuming that

$$\mu_2 \le \mu_1, \tag{2.13}$$

we will show that $\mathcal{A}$ generates a C_0 semigroup on $\mathcal{H}$.

Let ξ be a positive real number such that

$$\tau\mu_2 \le \xi \le \tau(2\mu_1 - \mu_2). \tag{2.14}$$

Note that, from (2.13), such a constant ξ exists.

Let us define on the Hilbert space $\mathcal{H}$ the inner product

(2.15)
$$\left\langle \begin{pmatrix} u \\ v \\ z \end{pmatrix}, \begin{pmatrix} \tilde{u} \\ \tilde{v} \\ \tilde{z} \end{pmatrix} \right\rangle_{\mathcal{H}} := \int_\Omega \{\nabla u(x) \nabla \tilde{u}(x) + v(x)\tilde{v}(x)\} dx + \xi \int_{\Gamma_N} \int_0^1 z(x,\rho)\tilde{z}(x,\rho) d\rho d\Gamma.$$

THEOREM 2.1. *For any initial datum $U_0 \in \mathcal{H}$ there exists a unique solution $U \in C([0,+\infty), \mathcal{H})$ of problem (2.9). Moreover, if $U_0 \in \mathcal{D}(\mathcal{A})$, then*

$$U \in C([0,+\infty), \mathcal{D}(\mathcal{A})) \cap C^1([0,+\infty), \mathcal{H}).$$

Proof. Take $U = (u,v,z)^T \in \mathcal{D}(\mathcal{A})$. Then

$$\begin{aligned}(\mathcal{A}U, U) &= \left\langle \begin{pmatrix} v \\ \Delta u \\ -\tau^{-1} z_\rho \end{pmatrix}, \begin{pmatrix} u \\ v \\ z \end{pmatrix} \right\rangle_{\mathcal{H}} \\ &= \int_\Omega \{\nabla v(x) \nabla u(x) + v(x) \Delta u(x)\} dx - \xi\tau^{-1} \int_{\Gamma_N} \int_0^1 z_\rho(x,\rho) z(x,\rho) d\rho d\Gamma.\end{aligned}$$

So, by Green's formula,

$$(\mathcal{A}U,U)=\int_{\Gamma_N}\frac{\partial u}{\partial\nu}(x)v(x)d\Gamma-\xi\tau^{-1}\int_{\Gamma_N}\int_0^1 z_\rho(x,\rho)z(x,\rho)d\rho d\Gamma. \tag{2.16}$$

Integrating by parts in ρ, we get

$$\int_{\Gamma_N}\int_0^1 z_\rho(x,\rho)z(x,\rho)d\rho d\Gamma=-\int_{\Gamma_N}\int_0^1 z_\rho(x,\rho)z(x,\rho)d\rho d\Gamma+\int_{\Gamma_N}\{z^2(x,1)-z^2(x,0)\}d\Gamma,$$

that is

$$\int_{\Gamma_N}\int_0^1 z_\rho(x,\rho)z(x,\rho)d\rho d\Gamma=\frac{1}{2}\int_{\Gamma_N}\{z^2(x,1)-z^2(x,0)\}d\Gamma. \tag{2.17}$$

Therefore, from (2.16) and (2.17),

$$\begin{aligned}(\mathcal{A}U,U)&=\int_{\Gamma_N}\frac{\partial u}{\partial\nu}(x)v(x)d\Gamma-\frac{\xi\tau^{-1}}{2}\int_{\Gamma_N}\{z^2(x,1)-z^2(x,0)\}d\Gamma\\&=-\int_{\Gamma_N}(\mu_1v(x)+\mu_2z(x,1))v(x)d\Gamma-\frac{\xi\tau^{-1}}{2}\int_{\Gamma_N}\{z^2(x,1)-z^2(x,0)\}d\Gamma\\&=-\mu_1\int_{\Gamma_N}v^2(x)d\Gamma-\mu_2\int_{\Gamma_N}z(x,1)v(x)d\Gamma-\frac{\xi\tau^{-1}}{2}\int_{\Gamma_N}z^2(x,1)d\Gamma+\frac{\xi\tau^{-1}}{2}\int_{\Gamma_N}v^2(x)d\Gamma,\end{aligned}$$

from which follows, using the Cauchy–Schwarz inequality,

$$(\mathcal{A}U,U)\le\left(-\mu_1+\frac{\mu_2}{2}+\frac{\xi\tau^{-1}}{2}\right)\int_{\Gamma_N}v^2(x)d\Gamma+\left(\frac{\mu_2}{2}-\frac{\xi\tau^{-1}}{2}\right)\int_{\Gamma_N}z^2(x,1)d\Gamma. \tag{2.18}$$

Now, observe that from (2.14),

$$-\mu_1+\frac{\mu_2}{2}+\frac{\xi\tau^{-1}}{2}\le 0,\quad \frac{\mu_2}{2}-\frac{\xi\tau^{-1}}{2}\le 0.$$

Then, $(\mathcal{A}U,U)\le 0$, which means that the operator $\mathcal{A}$ is dissipative.

Now, we will show that $\lambda I-\mathcal{A}$ is surjective for a fixed $\lambda>0$. Given $(f,g,h)^T\in\mathcal{H}$, we seek a $U=(u,v,z)^T\in\mathcal{D}(\mathcal{A})$ solution of

$$(\lambda I-\mathcal{A})\begin{pmatrix}u\\v\\z\end{pmatrix}=\begin{pmatrix}f\\g\\h\end{pmatrix},$$

that is, verifying

$$\begin{cases}\lambda u-v=f,\\ \lambda v-\Delta u=g,\\ \lambda z+\tau^{-1}z_\rho=h.\end{cases} \tag{2.19}$$

Suppose that we have found u with the appropriate regularity. Then,

$$v:=\lambda u-f \tag{2.20}$$

and we can determine z. Indeed, by (2.10),

$$z(x,0) = v(x) \quad \text{for} \quad x \in \Gamma_N, \tag{2.21}$$

and, from (2.19),

$$\lambda z(x,\rho) + \tau^{-1} z_\rho(x,\rho) = h(x,\rho) \quad \text{for} \quad x \in \Gamma_N,\ \rho \in (0,1). \tag{2.22}$$

Then, by (2.21) and (2.22), we obtain

$$z(x,\rho) = v(x)e^{-\lambda\rho\tau} + \tau e^{-\lambda\rho\tau} \int_0^\rho h(x,\sigma)e^{\lambda\sigma\tau} d\sigma.$$

So, from (2.20),

$$z(x,\rho) = \lambda u(x)e^{-\lambda\rho\tau} - f(x)e^{-\lambda\rho\tau} + \tau e^{-\lambda\rho\tau} \int_0^\rho h(x,\sigma)e^{\lambda\sigma\tau} d\sigma \quad \text{on } \Gamma_N \times (0,1), \tag{2.23}$$

and, in particular,

$$z(x,1) = \lambda u(x)e^{-\lambda\tau} + z_0(x), \quad x \in \Gamma_N, \tag{2.24}$$

with $z_0 \in L^2(\Gamma_N)$ defined by

$$z_0(x) = -f(x)e^{-\lambda\tau} + \tau e^{-\lambda\tau} \int_0^1 h(x,\sigma)e^{\lambda\sigma\tau} d\sigma, \quad x \in \Gamma_N. \tag{2.25}$$

By (2.20) and (2.19), the function u verifies

$$\lambda(\lambda u - f) - \Delta u = g,$$

that is,

$$\lambda^2 u - \Delta u = g + \lambda f. \tag{2.26}$$

Problem (2.26) can be reformulated as

$$\int_\Omega (\lambda^2 u - \Delta u) w dx = \int_\Omega (g + \lambda f) w dx \quad \forall w \in H^1_{\Gamma_D}(\Omega). \tag{2.27}$$

Integrating by parts,

$$\begin{aligned}
\int_\Omega (\lambda^2 u - \Delta u) w dx &= \int_\Omega (\lambda^2 uw + \nabla u \nabla w) dx - \int_{\Gamma_N} \frac{\partial u}{\partial \nu} w d\Gamma \\
&= \int_\Omega (\lambda^2 uw + \nabla u \nabla w) dx + \int_{\Gamma_N} (\mu_1 vw + \mu_2 z(x,1)) w d\Gamma \\
&= \int_\Omega (\lambda^2 uw + \nabla u \nabla w) dx + \int_{\Gamma_N} \{\mu_1(\lambda u - f)w + \mu_2(\lambda u e^{-\lambda\tau} + z_0)w\} d\Gamma,
\end{aligned}$$

where we have used (2.20) and (2.24). Therefore, (2.27) can be rewritten as

$$\begin{aligned}
&\int_\Omega (\lambda^2 uw + \nabla u \nabla w) dx + \int_{\Gamma_N} (\mu_1 + \mu_2 e^{-\lambda\tau}) \lambda uw d\Gamma \\
&\qquad = \int_\Omega (g + \lambda f) w dx + \mu_1 \int_{\Gamma_N} f w d\Gamma - \mu_2 \int_{\Gamma_N} z_0 w d\Gamma \quad \forall w \in H^1_{\Gamma_D}(\Omega).
\end{aligned} \tag{2.28}$$

As the left-hand side of (2.28) is coercive on $H^1_{\Gamma_D}(\Omega)$, the Lax–Milgram lemma guarantees the existence and uniqueness of a solution $u \in H^1_{\Gamma_D}(\Omega)$ of (2.28).

If we consider $w \in \mathcal{D}(\Omega)$ in (2.28), we have that u solves in $\mathcal{D}'(\Omega)$

$$\lambda^2 u - \Delta u = g + \lambda f, \tag{2.29}$$

and thus $u \in E(\Delta, L^2(\Omega))$.

Using Green's formula (2.11) in (2.28) and using (2.29), we obtain

$$\int_{\Gamma_N} (\mu_1 + \mu_2 e^{-\lambda\tau})\lambda u w d\Gamma + \left\langle \frac{\partial u}{\partial \nu}; w \right\rangle_{\Gamma_N} = \mu_1 \int_{\Gamma_N} f w d\Gamma - \mu_2 \int_{\Gamma_N} z_0 w d\Gamma,$$

from which follows

$$\frac{\partial u}{\partial \nu} + (\mu_1 + \mu_2 e^{-\lambda\tau})\lambda u = \mu_1 f - \mu_2 z_0 \quad \text{on} \quad \Gamma_N. \tag{2.30}$$

Therefore, from (2.30),

$$\frac{\partial u}{\partial \nu} = -\mu_1 v - \mu_2 z(\cdot, 1) \quad \text{on} \quad \Gamma_N,$$

where we have used (2.20) and (2.24). So, we have found $(u, v, z)^T \in \mathcal{D}(\mathcal{A})$, which verifies (2.19).

Now, the well-posedness result follows from the Hille–Yosida theorem. □

2.2. Internal feedback. Setting

$$z(x, \rho, t) = u_t(x, t - \tau\rho), \quad x \in \Omega, \ \rho \in (0, 1), \ t > 0, \tag{2.31}$$

problem (1.12)–(1.16) is equivalent to

$$u_{tt} - \Delta u + a(x)[\mu_1 u_t(x, t) + \mu_2 u_t(x, t - \tau)] = 0 \quad \text{in} \quad \Omega \times (0, +\infty), \tag{2.32}$$

$$\tau z_t(x, \rho, t) + z_\rho(x, \rho, t) = 0 \quad \text{in} \quad \Omega \times (0, 1) \times (0, +\infty), \tag{2.33}$$

$$u(x, t) = 0 \quad \text{on} \quad \Gamma_D \times (0, +\infty), \tag{2.34}$$

$$\frac{\partial u}{\partial \nu}(x, t) = 0 \quad \text{on} \quad \Gamma_N \times (0, +\infty), \tag{2.35}$$

$$z(x, 0, t) = u_t(x, t) \quad \text{on} \quad \Gamma_N \times (0, +\infty), \tag{2.36}$$

$$u(x, 0) = u_0(x) \quad \text{and} \quad u_t(x, 0) = u_1(x) \quad \text{in} \quad \Omega, \tag{2.37}$$

$$z(x, \rho, 0) = g_0(x, -\rho\tau) \quad \text{in} \quad \Omega \times (0, 1). \tag{2.38}$$

If we denote by

$$U := (u, u_t, z)^T,$$

then

$$U' := (u_t, u_{tt}, z_t)^T = \big(u_t, \Delta u - a(\mu_1 u_t + \mu_2 z(\cdot, 1, \cdot)), -\tau^{-1} z_\rho\big)^T.$$

Therefore, problem (2.32)–(2.38) can be rewritten as

$$\begin{cases} U' = \mathcal{A}^0 U, \\ U(0) = (u_0, u_1, g_0(\cdot, -\cdot\,\tau))^T, \end{cases} \tag{2.39}$$

where the operator $\mathcal{A}^0$ is defined by

$$\mathcal{A}^0 \begin{pmatrix} u \\ v \\ z \end{pmatrix} := \begin{pmatrix} v \\ \Delta u - a\mu_1 v - a\mu_2 z(\cdot,1) \\ -\tau^{-1} z_\rho \end{pmatrix},$$

with domain

$$\mathcal{D}(\mathcal{A}^0) := \Big\{ (u,v,z)^T \in \big(H^2(\Omega) \cap H^1_{\Gamma_D}(\Omega)\big) \times H^1(\Omega) \times L^2(\Omega; H^1(0,1)) \ : \ \frac{\partial u}{\partial \nu} = 0 \text{ on } \Gamma_N;\ v = z(\cdot,0) \text{ in } \Omega \Big\}. \tag{2.40}$$

Denote by $\mathcal{H}^0$ the Hilbert space

$$\mathcal{H}^0 := H^1_{\Gamma_D}(\Omega) \times L^2(\Omega) \times L^2(\Omega \times (0,1)), \tag{2.41}$$

equipped with the inner product

$$\left\langle \begin{pmatrix} u \\ v \\ z \end{pmatrix}, \begin{pmatrix} \tilde{u} \\ \tilde{v} \\ \tilde{z} \end{pmatrix} \right\rangle_{\mathcal{H}^0} := \int_\Omega \{\nabla u(x) \nabla \tilde{u}(x) + v(x)\tilde{v}(x)\} dx + \xi \int_\Omega \int_0^1 z(x,\rho)\tilde{z}(x,\rho) d\rho dx, \tag{2.42}$$

where ξ is a fixed positive number satisfying (2.14).

Arguing analogously to the previous case, we can show that the operator $\mathcal{A}^0$ generates a C_0 semigroup on $\mathcal{H}^0$. Consequently we have the following well-posedness result.

THEOREM 2.2. *For any initial datum $U_0 \in \mathcal{H}^0$ there exists a unique solution $U \in C([0,+\infty), \mathcal{H}^0)$ of problem* (2.39). *Moreover, if $U_0 \in \mathcal{D}(\mathcal{A}^0)$, then*

$$U \in C([0,+\infty), \mathcal{D}(\mathcal{A}^0)) \cap C^1([0,+\infty), \mathcal{H}^0).$$

3. Boundary stability result. In this section, in order to prove an exponential stability result for problem (1.1)–(1.5), we assume (1.8).

Let $E(\cdot)$ be the energy defined by (1.9) and (1.10). We have the following result.

PROPOSITION 3.1. *For any regular solution of problem* (1.1)–(1.5)*, the energy is decreasing and there exists a positive constant C such that*

$$E'(t) \le -C \int_{\Gamma_N} \{u_t^2(x,t) + u_t^2(x,t-\tau)\} d\Gamma. \tag{3.1}$$

Proof. Differentiating (1.9), we obtain

$$E'(t) = \int_\Omega \{u_t u_{tt} + \nabla u \nabla u_t\} dx + \xi \int_{\Gamma_N} \int_0^1 u_t(x,t-\tau\rho) u_{tt}(x,t-\tau\rho) d\rho d\Gamma,$$

and then, applying Green's formula,

$$E'(t) = \int_{\Gamma_N} u_t \frac{\partial u}{\partial \nu} d\Gamma + \xi \int_{\Gamma_N} \int_0^1 u_t(x,t-\tau\rho) u_{tt}(x,t-\tau\rho) d\rho d\Gamma. \tag{3.2}$$

Now, observe that

$$u_t(x,t-\tau\rho) = -\tau^{-1} u_\rho(x,t-\tau\rho)$$

and

$$u_{tt}(x,t-\tau\rho)=\tau^{-2}u_{\rho\rho}(x,t-\tau\rho).$$

Therefore,

(3.3)
$$\int_{\Gamma_N}\int_0^1 u_t(x,t-\tau\rho)u_{tt}(x,t-\tau\rho)d\rho d\Gamma=-\tau^{-3}\int_{\Gamma_N}\int_0^1 u_\rho(x,t-\tau\rho)u_{\rho\rho}(x,t-\tau\rho)d\rho d\Gamma.$$

Integrating by parts in ρ, we obtain

$$\begin{aligned}\int_{\Gamma_N}\int_0^1 u_\rho(x,t-\tau\rho)u_{\rho\rho}(x,t-\tau\rho)d\rho d\Gamma=&-\int_{\Gamma_N}\int_0^1 u_\rho(x,t-\tau\rho)u_{\rho\rho}(x,t-\tau\rho)d\rho d\Gamma\\&+\int_{\Gamma_N}\{u_\rho^2(x,t-\tau)-u_\rho^2(x,t)\}d\Gamma,\end{aligned}$$

that is,

$$\int_{\Gamma_N}\int_0^1 u_\rho(x,t-\tau\rho)u_{\rho\rho}(x,t-\tau\rho)d\rho d\Gamma=\frac{1}{2}\int_{\Gamma_N}\{u_\rho^2(x,t-\tau)-u_\rho^2(x,t)\}d\Gamma. \tag{3.4}$$

Then, from (3.3) and (3.4),

(3.5)
$$\begin{aligned}\int_{\Gamma_N}\int_0^1 u_t(x,t-\tau\rho)u_{tt}(x,t-\tau\rho)d\rho d\Gamma&=-\tau^{-3}\int_{\Gamma_N}\int_0^1 u_\rho(x,t-\tau)u_{\rho\rho}(x,t-\tau\rho)d\rho d\Gamma\\&=\frac{\tau^{-3}}{2}\int_{\Gamma_N}\{u_\rho^2(x,t)-u_\rho^2(x,t-\tau)\}d\Gamma=\frac{\tau^{-1}}{2}\int_{\Gamma_N}\{u_t^2(x,t)-u_t^2(x,t-\tau)\}d\Gamma.\end{aligned}$$

Using (3.2), (3.5), and the boundary condition (1.3) on Γ_N, we have

$$\begin{aligned}E'(t)=&-\mu_1\int_{\Gamma_N}u_t^2(x,t)d\Gamma-\mu_2\int_{\Gamma_N}u_t(x,t)u_t(x,t-\tau)d\Gamma\\&+\frac{\xi\tau^{-1}}{2}\int_{\Gamma_N}u_t^2(x,t)d\Gamma-\frac{\xi\tau^{-1}}{2}\int_{\Gamma_N}u_t^2(x,t-\tau)d\Gamma.\end{aligned} \tag{3.6}$$

From (3.6), applying the Cauchy–Schwarz inequality we obtain

$$E'(t)\le\left(-\mu_1+\frac{\mu_2}{2}+\frac{\xi\tau^{-1}}{2}\right)\int_{\Gamma_N}u_t^2(x,t)d\Gamma+\left(\frac{\mu_2}{2}-\frac{\xi\tau^{-1}}{2}\right)\int_{\Gamma_N}u_t^2(x,t-\tau)d\Gamma,$$

which implies

$$E'(t)\le-C\int_{\Gamma_N}\{u_t^2(x,t)+u_t^2(x,t-\tau)\}d\Gamma,$$

with

$$C=\min\left\{\left(\mu_1-\frac{\mu_2}{2}-\frac{\xi\tau^{-1}}{2}\right),\left(-\frac{\mu_2}{2}+\frac{\xi\tau^{-1}}{2}\right)\right\}.$$

Since ξ is chosen satisfying assumption (1.10), the constant C is positive. □

We can write

$$E(t) = \mathcal{E}(t) + E_N(t),$$

where $\mathcal{E}(t)$ is the standard energy for the wave equation

$$\mathcal{E}(t) := \frac{1}{2}\int_\Omega \{u_t^2(x,t) + |\nabla u(x,t)|^2\}dx, \tag{3.7}$$

and

$$E_N(t) := \frac{\xi}{2}\int_{\Gamma_N}\int_0^1 u_t^2(x,t-\tau\rho)d\rho d\Gamma. \tag{3.8}$$

With a change of variable we can rewrite

$$E_N(t) = \frac{\xi}{2\tau}\int_{\Gamma_N}\int_{t-\tau}^t u_t^2(x,s)dsd\Gamma. \tag{3.9}$$

We can now give a boundary observability inequality which we will use to prove the exponential decay of the energy $E(t)$.

PROPOSITION 3.2. *There exists a time $\overline{T} > 0$ such that for all times $T > \overline{T}$, there exists a positive constant C_0 (depending on T) for which*

$$E(0) \le C_0\int_0^T\int_{\Gamma_N}\{u_t^2(x,t) + u_t^2(x,t-\tau)\}d\Gamma dt \tag{3.10}$$

for any regular solution u of problem (1.1)–(1.5).

Proof. From Proposition 6.3 of [14], for T greater than a sufficiently large time T_0, and any $\varepsilon > 0$, we have

$$\mathcal{E}(0) \le c\int_0^T\int_{\Gamma_N}\Big\{\Big(\frac{\partial u}{\partial \nu}\Big)^2 + u_t^2\Big\}d\Gamma dt + c\|u\|_{H^{1/2+\varepsilon}(\Omega\times(0,T))} \tag{3.11}$$

for a suitable constant c (depending on T). Estimate (3.11) is obtained by Carleman estimates under the assumption that there exists a function v of class C^2 satisfying (1.6) and (1.7). The function v is needed to construct a suitable weight function for Carleman estimates (see the proof of Proposition 4.2 below). Then, by (3.11) and the boundary condition (1.3), we have

$$\mathcal{E}(0) \le c\int_0^T\int_{\Gamma_N}\{u_t^2(x,t) + u_t^2(x,t-\tau)\}d\Gamma dt + c\|u\|_{H^{1/2+\varepsilon}(\Omega\times(0,T))} \tag{3.12}$$

for a suitable positive constant c. From (3.9) we have that

$$E_N(0) \le c\int_{\Gamma_N}\int_{-\tau}^0 u_t^2(x,s)dsd\Gamma. \tag{3.13}$$

By a change of variable in (3.13) we obtain, for $T \ge \tau$,

$$E_N(0) \le c\int_0^T\int_{\Gamma_N} u_t^2(x,t-\tau)d\Gamma dt. \tag{3.14}$$

Denote $\overline{T} := \max\{\tau, T_0\}$. Then, from (3.12) and (3.14), for any $T > \overline{T}$ we have

$$\begin{aligned} E(0) &= \mathcal{E}(0) + E_N(0) \\ &\le c\int_0^T \int_{\Gamma_N} \{u_t^2(x,t) + u_t^2(x,t-\tau)\} d\Gamma dt + c\|u\|_{H^{1/2+\varepsilon}(\Omega\times(0,T))} \end{aligned} \tag{3.15}$$

for a suitable positive constant c depending on T.

In order to obtain (3.10) we need to absorb the lower order term $\|u\|_{H^{1/2+\varepsilon}(\Omega\times(0,T))}$. To do this, we argue by contradiction. Suppose that (3.10) is not true. Then, there exists a sequence $\{u_n\}_n$ of solutions of problem (1.1)–(1.5) such that, denoting by $E^n(0)$ the energy E related to u_n at the time 0,

$$E^n(0) > n\int_0^T \int_{\Gamma_N} \{u_{nt}^2(x,t) + u_{nt}^2(x,t-\tau)\} d\Gamma dt. \tag{3.16}$$

From (3.15), we have

$$E^n(0) \le c\left\{\int_0^T \int_{\Gamma_N} \{u_{nt}^2(x,t) + u_{nt}^2(x,t-\tau)\} d\Gamma dt + \|u_n\|_{H^{1/2+\varepsilon}(\Omega\times(0,T))}\right\}. \tag{3.17}$$

Then, from (3.16) and (3.17),

$$\begin{aligned} n\int_0^T \int_{\Gamma_N} &\{u_{nt}^2(x,t) + u_{nt}^2(x,t-\tau)\} d\Gamma dt \\ &< c\left\{\int_0^T \int_{\Gamma_N} \{u_{nt}^2(x,t) + u_{nt}^2(x,t-\tau)\} d\Gamma dt + \|u_n\|_{H^{1/2+\varepsilon}(\Omega\times(0,T))}\right\}, \end{aligned}$$

that is,

$$(n-c)\int_0^T \int_{\Gamma_N} \{u_{nt}^2(x,t) + u_{nt}^2(x,t-\tau)\} d\Gamma dt < c\|u_n\|_{H^{1/2+\varepsilon}(\Omega\times(0,T))}. \tag{3.18}$$

Renormalizing, we obtain a sequence $\{w_n\}_n$ of solutions of problem (1.1)–(1.5) verifying

$$\|w_n\|_{H^{1/2+\varepsilon}(\Omega\times(0,T))} = 1, \tag{3.19}$$

and

$$\int_0^T \int_{\Gamma_N} \{w_{nt}^2(x,t) + w_{nt}^2(x,t-\tau)\} d\Gamma dt < \frac{c}{n-c}. \tag{3.20}$$

From (3.19), (3.20), and (3.17), it follows that the sequence $\{w_n\}_n$ is bounded in $H^1(\Omega\times(0,T))$. Since $H^1(\Omega\times(0,T))$ is compactly embedded in $H^{1/2+\varepsilon}(\Omega\times(0,T))$, there exists a subsequence which, for simplicity of notation, we still denote by $\{w_n\}_n$ such that

$$w_n \longrightarrow w \qquad \text{strongly in} \quad H^{1/2+\varepsilon}(\Omega\times(0,T)).$$

Then, from (3.19),

$$\|w\|_{H^{1/2+\varepsilon}(\Omega\times(0,T))} = 1. \tag{3.21}$$

Moreover, by (3.20),

$$\int_0^T \int_{\Gamma_N} \{w_t^2(x,t) + w_t^2(x,t-\tau)\} d\Gamma dt = 0.$$

Therefore, we have that

$$w_t = 0 \quad \text{on } \Gamma_N \times (0,T)$$

and

$$\frac{\partial w}{\partial \nu} = 0 \quad \text{on } \Gamma_N \times (0,T).$$

Putting $v := w_t$, v solves in a distributional sense

$$v'' - \Delta v = 0 \quad \text{in } \Omega \times (0,T),$$

with

$$v = 0 \quad \text{on } \Gamma \times (0,T), \quad \frac{\partial v}{\partial \nu} = 0 \quad \text{on } \Gamma_N \times (0,T).$$

Therefore, from Holmgren's uniqueness theorem (see [15, Chap. I, Thm. 8.2, p. 92]) $v \equiv 0$. This implies that

$$w(x,t) = w(x).$$

Thus, w verifies

$$\begin{cases} -\Delta w = 0 & \text{in } \Omega, \\ w = 0 & \text{on } \Gamma_D, \\ \dfrac{\partial w}{\partial \nu} = 0 & \text{on } \Gamma_N, \end{cases}$$

and so $w \equiv 0$. This is in contradiction with (3.21). Then, the observability inequality (3.10) is proved. □

From (3.10) easily follows the stability result.

Proof of Theorem 1.1. From (3.1), we have

$$E(T) - E(0) \le -C \int_0^T \int_{\Gamma_N} \{u_t^2(x,t) + u_t^2(x,t-\tau)\} d\Gamma dt. \tag{3.22}$$

By (3.22) and the observability estimate (3.10), we obtain

$$E(T) \le E(0) \le C_0 \int_0^T \int_{\Gamma_N} \{u_t^2(x,t) + u_t^2(x,t-\tau)\} d\Gamma dt \le C_0 C^{-1} (E(0) - E(T));$$

then

$$E(T) \le \tilde{C} E(0),$$

with $\tilde{C} < 1$. This easily implies the stability estimate (1.11), since our system (1.1)–(1.5) is invariant by translation and the energy E is decreasing. □

Remark 3.3. Analogous arguments apply if we have more than one delay term in the boundary feedback, that is, if condition (1.3) is substituted by

$$\frac{\partial u}{\partial \nu}(x,t) = -\mu_0 u_t(x,t) - \sum_{i=1}^{k} \mu_i u_t(x,t-\tau_i) \quad \text{on} \quad \Gamma_N \times (0,+\infty),$$

with $\mu_0, \mu_i, \tau_i, i = 1, \dots, k$, positive parameters. In this case, the right energy for our problem is

$$E(t) := \frac{1}{2}\int_\Omega \{u_t^2(x,t) + |\nabla u(x,t)|^2\}dx + \sum_{i=1}^{k} \frac{\xi_i}{2}\int_{\Gamma_N}\int_0^1 u_t^2(x,t-\rho\tau_i)d\rho d\Gamma,$$

with suitable positive constants $\xi_i, i = 1, \dots, k$. Indeed, if

$$\mu_0 > \sum_{i=1}^{k} \mu_i,$$

choosing ξ_i such that

$$\mu_i < \xi_i \tau_i^{-1}, \ i = 1, \dots, k, \quad \text{and} \quad \sum_{i=1}^{k} \xi_i \tau_i^{-1} < 2\mu_0 - \sum_{i=1}^{k} \mu_i,$$

we can prove that the energy is exponentially decaying to zero.

Remark 3.4. If $\overline{\Gamma}_D \cap \overline{\Gamma}_N \neq \emptyset$, the strong solution of (1.1)–(1.5) has a singular behavior along $\overline{\Gamma}_D \cap \overline{\Gamma}_N$ since $u(t) \in E(\Delta, L^2(\Omega))$ with $\frac{\partial u}{\partial \nu} \in L^2(\Gamma_N)$ and $u = 0$ on Γ_D (see, for instance, [7] for two-dimensional domains). Therefore the results from [14] cannot be invoked. For the standard feedback law (i.e., the case $\mu_2 = 0$), the multiplier method has been used as an alternative in [1] to obtain stability results under strong geometrical conditions. Unfortunately that approach cannot be directly applied here because for $\mu_2 > 0$, we have only $\frac{\partial u}{\partial \nu} \in L^2(\Gamma_N)$, which forbids the use of the multiplier identity.

4. Internal stability result. In this section, under assumption (1.8) we want to prove exponential stability for problem (1.12)–(1.16).

We first show that the energy $\mathcal{F}$, defined by (1.19) and (1.10), is decreasing.

PROPOSITION 4.1. *For any regular solution of problem* (1.12)–(1.16)*, the energy is decreasing and there exists a positive constant C such that*

$$\mathcal{F}'(t) \leq -C\int_\Omega a(x)\{u_t^2(x,t) + u_t^2(x,t-\tau)\}dx. \tag{4.1}$$

Proof. Differentiating (1.19), we obtain

$$\mathcal{F}'(t) = \int_\Omega \{u_t u_{tt} + \nabla u \nabla u_t\}dx + \xi\int_\Omega a(x)\int_0^1 u_t(x,t-\tau\rho)u_{tt}(x,t-\tau\rho)d\rho dx,$$

and then, applying Green's formula,

$$\mathcal{F}'(t) = \int_\Omega u_t(u_{tt} - \Delta u)dx + \xi\int_\Omega a(x)\int_0^1 u_t(x,t-\tau\rho)u_{tt}(x,t-\tau\rho)d\rho dx, \tag{4.2}$$

where we have used the boundary conditions (1.13) and (1.14).

As in the proof of Proposition 3.1, we can compute

$$\begin{aligned}\int_\Omega a(x)\int_0^1 u_t(x,t-\tau\rho)u_{tt}(x,t-\tau\rho)d\rho dx&\\ &= -\tau^{-3}\int_\Omega a(x)\int_0^1 u_\rho(x,t-\tau)u_{\rho\rho}(x,t-\tau\rho)d\rho dx\\ &= \frac{\tau^{-3}}{2}\int_\Omega a(x)\{u_\rho^2(x,t)-u_\rho^2(x,t-\tau)\}dx\\ &= \frac{\tau^{-1}}{2}\int_\Omega a(x)\{u_t^2(x,t)-u_t^2(x,t-\tau)\}d\Gamma.\end{aligned} \tag{4.3}$$

Now, using (4.3) and (1.12) in identity (4.2), we have

$$\begin{aligned}\mathcal{F}'(t) = &-\mu_1\int_\Omega a(x)u_t^2(x,t)dx-\mu_2\int_\Omega a(x)u_t(x,t)u_t(x,t-\tau)dx\\ &+\frac{\xi\tau^{-1}}{2}\int_\Omega a(x)u_t^2(x,t)dx-\frac{\xi\tau^{-1}}{2}\int_\Omega a(x)u_t^2(x,t-\tau)dx.\end{aligned} \tag{4.4}$$

From (4.4), applying the Cauchy–Schwarz inequality and recalling (1.10), we obtain estimate (4.1). □

We can write

$$\mathcal{F}(t) = \mathcal{E}(t) + E^0(t),$$

where $\mathcal{E}(t)$ is the standard energy for the wave equation defined in (3.7) and where

$$E^0(t) := \frac{\xi}{2}\int_\Omega a(x)\int_0^1 u_t^2(x,t-\tau\rho)d\rho dx. \tag{4.5}$$

With a change of variable, we can rewrite

$$E^0(t) = \frac{\xi}{2\tau}\int_\Omega a(x)\int_{t-\tau}^t u_t^2(x,s)dsdx. \tag{4.6}$$

Let w be the solution of the homogeneous problem for the wave equation with mixed Dirichlet–Neumann boundary condition,

$$w_{tt}(x,t)-\Delta w(x,t)=0 \quad \text{in} \quad \Omega\times(0,+\infty), \tag{4.7}$$

$$w(x,t)=0 \quad \text{on} \quad \Gamma_D\times(0,+\infty), \tag{4.8}$$

$$\frac{\partial w}{\partial\nu}(x,t)=0 \quad \text{on} \quad \Gamma_N\times(0,+\infty), \tag{4.9}$$

$$w(x,0)=w_0(x) \quad \text{and} \quad w_t(x,0)=w_1(x) \quad \text{in} \quad \Omega. \tag{4.10}$$

Denote by $\mathcal{E}_w(t)$ the standard energy for the wave equation corresponding to w, that is,

$$\mathcal{E}_w(t) = \frac{1}{2}\int_\Omega\{w_t^2(x,t)+|\nabla w(x,t)|^2\}dx. \tag{4.11}$$

Note that $\mathcal{E}_w(t)$ is constant.

We can give an observability inequality for problem (4.7)–(4.10).

PROPOSITION 4.2. *There exists a time T_0 such that for all times $T > T_0$, there exists a positive constant C_1 (depending on T) for which*

$$\mathcal{E}_w(0) \le C_1 \int_0^T \int_\omega w_t^2(x,t)dxdt \tag{4.12}$$

for any regular solution w of problem (4.7)–(4.10).

Proof. Inequality (4.12) easily follows from some estimates of [14] and standard arguments with multipliers. We give the proof for the reader's convenience.

Let $\omega_0,\ \omega_1$ be open neighborhoods of Γ_N such that

$$\omega \supset\supset \omega_0 \supset\supset \omega_1 \supset \Gamma_N. \tag{4.13}$$

Let φ be a smooth function such that

$$0 \le \varphi(x) \le 1, \quad \varphi \equiv 0 \quad \text{on } \Omega \setminus \omega_0, \quad \varphi \equiv 1 \quad \text{on } \omega_1. \tag{4.14}$$

Then, the function φw verifies

$$(\varphi w)_{tt} - \Delta(\varphi w) = F(w),$$

where $F(w) = w\Delta\varphi + 2\nabla\varphi\nabla w$, with the same boundary conditions as w. Therefore, we can apply to φw the result of Proposition 4.2.1 in [14].

Let us recall some notation from [14]. Without loss of generality, we can suppose that the function v satisfying assumptions (1.6) and (1.7) is nonnegative on Ω.

Denote

$$T_0 = 2\left(\frac{\max_{x\in\overline{\Omega}}\ v(x)}{\alpha}\right)^{1/2}, \tag{4.15}$$

with α as in (1.6). Define the function $\phi : \Omega \times \mathbb{R} \to \mathbb{R}$ by

$$\phi(x,t) := v(x) - c_*\left(t - \frac{T}{2}\right)^2, \tag{4.16}$$

where $T > T_0$ is fixed and the constant c_* is chosen as follows. From (4.15), there exists a constant $\delta > 0$ such that

$$\alpha T^2 > 4 \max_{x\in\overline{\Omega}}\ v(x) + 4\delta.$$

For fixed δ, there is c_* such that

$$c_* T^2 > 4 \max_{x\in\overline{\Omega}}\ v(x) + 4\delta, \quad c_* \in (0,\alpha). \tag{4.17}$$

Note that

$$\phi(x,0) < -\delta \quad \text{and} \quad \phi(x,T) < -\delta \quad \text{uniformly in} \quad \Omega. \tag{4.18}$$

Set

$$\begin{aligned} BTw|_{\Gamma\times(0,T)} &= \frac{1}{2}\int_0^T \int_{\Gamma_D} e^{\gamma\phi} H\cdot\nu \left(\frac{\partial w}{\partial\nu}\right)^2 d\Gamma dt \\ &\quad + \frac{1}{2}\int_0^T \int_{\Gamma_N} e^{\gamma\phi} H\cdot\nu (w_t^2 - |\nabla_{\mathcal{T}} w|^2) d\Gamma dt, \end{aligned} \tag{4.19}$$

where $\nabla_{\mathcal{T}} w$ denotes the tangential gradient of w.

Then, from Proposition 4.2.1 of [14], using (4.18), and recalling that $\mathcal{E}_w(t)$ is constant, we have

$$\begin{aligned} BTw|_{\Gamma\times(0,T)} &\le c\left\{\int_0^T\int_\Omega e^{\gamma\phi}|\nabla(\varphi w)|^2dxdt+\int_0^T\int_\Omega \varphi^2 w_t^2dxdt\right.\\ &\qquad\left.+\int_0^T\int_\Omega \varphi^2 w^2dxdt+e^{-\gamma\delta}\mathcal{E}_w(0)\right\}\\ &\le c\left\{\int_0^T\int_{\omega_0} e^{\gamma\phi}|\nabla w|^2dxdt+\int_0^T\int_\omega w_t^2dxdt\right.\\ &\qquad\left.+\int_0^T\int_\Omega w^2dxdt+e^{-\gamma\delta}\mathcal{E}_w(0)\right\} \end{aligned} \tag{4.20}$$

for a suitable positive constant c, where the parameter γ can be chosen sufficiently large in order to have the desired inequality.

Now, consider another smooth cut-off function ψ such that

$$0\le\psi(x)\le 1,\quad \psi\equiv 0\quad \text{on } \Omega\setminus\omega,\quad \psi\equiv 1\quad \text{on } \omega_0. \tag{4.21}$$

Integrating by parts,

$$\begin{aligned} \int_0^T\int_\Omega (w_{tt}-\Delta w)\psi we^{\gamma\phi}dxdt &= \left[\int_\Omega \psi w w_t e^{\gamma\phi}dx\right]_0^T\\ &\quad+\int_0^T\int_\Omega \nabla w\nabla(\psi we^{\gamma\phi})dxdt-\int_0^T\int_\Omega w_t(\psi we^{\gamma\phi})_t dxdt\\ &= \left[\int_\Omega \psi w w_t e^{\gamma\phi}dx\right]_0^T-\int_0^T\int_\Omega \psi w_t(w_t e^{\gamma\phi}+we^{\gamma\phi}\gamma\phi_t)dxdt\\ &\quad+\int_0^T\int_\Omega \psi e^{\gamma\phi}|\nabla w|^2dxdt+\int_0^T\int_\Omega w\nabla w\nabla(\psi e^{\gamma\phi})dxdt. \end{aligned} \tag{4.22}$$

Then, from (4.22), recalling that w satisfies (4.7), we have

$$\begin{aligned} \int_0^T\int_\Omega \psi e^{\gamma\phi}|\nabla w|^2dxdt &= \int_0^T\int_\Omega(\psi w_t^2e^{\gamma\phi}+ww_t\psi e^{\gamma\phi}\gamma\phi_t)dxdt\\ &\quad-\left[\int_\Omega \psi w w_t e^{\gamma\phi}dx\right]_0^T-2\int_0^T\int_\Omega \sqrt{\psi}w\nabla w\nabla(\sqrt{\psi})e^{\gamma\phi}dxdt\\ &\quad-\int_0^T\int_\Omega \psi w\nabla w\nabla e^{\gamma\phi}dxdt. \end{aligned} \tag{4.23}$$

Since $\mathcal{E}_w(t)$ is constant, by using the Cauchy–Schwarz inequality and Poincaré's theorem, we can estimate

$$\left[\int_\Omega \psi w w_t e^{\gamma\phi}dx\right]_0^T\le ce^{-\delta\gamma}\mathcal{E}_w(0),$$

and so, from (4.23), we obtain

$$\begin{aligned} \int_0^T\int_\Omega \psi e^{\gamma\phi}|\nabla w|^2dxdt &\le ce^{-\delta\gamma}\mathcal{E}_w(0)+\frac{1}{2}\int_0^T\int_\Omega \psi e^{\gamma\phi}|\nabla w|^2dxdt\\ &\quad+c\left\{\int_0^T\int_\omega w_t^2dxdt+\int_0^T\int_\Omega w^2dxdt\right\} \end{aligned} \tag{4.24}$$

for a suitable positive constant c. By (4.24) we deduce

$$\int_0^T \int_{\omega_0} e^{\gamma\phi}|\nabla w|^2 dxdt \le c\left\{\int_0^T \int_\omega w_t^2 dxdt + \int_0^T \int_\Omega w^2 dxdt + e^{-\delta\gamma}\mathcal{E}_w(0)\right\},$$

which, used in (4.20), gives

$$BTw|_{\Gamma\times(0,T)} \le c\left\{\int_0^T \int_\omega w_t^2 dxdt + \int_0^T \int_\Omega w^2 dxdt + e^{-\delta\gamma}\mathcal{E}_w(0).\right\} \tag{4.25}$$

Then, from (4.25) and Theorem 3.4 of [14] (Carleman estimate (3.14)), taking γ sufficiently large, we obtain

$$\mathcal{E}_w(0) \le c\int_0^T \int_\omega w_t^2(x,t)dxdt + c\|w\|^2_{L^2(\Omega\times(0,T))}.$$

Now, estimate (4.12) follows from compactness-uniqueness arguments. □

PROPOSITION 4.3. *There exists a time $\overline{T}$ such that for all times $T > \overline{T}$, there exists a positive constant C_0 (depending on T) for which*

$$\mathcal{F}(0) \le C_0 \int_0^T \int_\Omega a(x)\{u_t^2(x,t) + u_t^2(x,t-\tau)\}dxdt \tag{4.26}$$

for any regular solution u of problem (1.12)–(1.16).

Proof. Following Zuazua [18], we can decompose the solution u of problem (1.12)–(1.16) as

$$u = w + \tilde{w},$$

where w solves (4.7)–(4.9) with initial condition

$$w(x,0) = u_0(x), \quad w_t(x,0) = u_1(x) \quad \text{in } \Omega,$$

and $\tilde{w}$ verifies

$$\tilde{w}_{tt} - \Delta\tilde{w} = -a(x)[\mu_1 u_t(x,t) + \mu_2 u_t(x,t-\tau)] \quad \text{in} \quad \Omega\times(0,+\infty), \tag{4.27}$$

$$\tilde{w}(x,t) = 0 \quad \text{on} \quad \Gamma_D\times(0,+\infty), \tag{4.28}$$

$$\frac{\partial\tilde{w}}{\partial\nu}(x,t) = 0 \quad \text{on} \quad \Gamma_N\times(0,+\infty), \tag{4.29}$$

$$\tilde{w}(x,0) = 0 \quad \text{and} \quad \tilde{w}_t(x,0) = 0 \quad \text{in} \quad \Omega. \tag{4.30}$$

Then, from (4.5) and (4.11),

$$\mathcal{F}(0) = \mathcal{E}(0) + E^0(0) = \mathcal{E}_w(0) + \frac{\xi}{2}\int_\Omega a(x)\int_0^1 u_t^2(x,-\rho\tau)d\rho dx. \tag{4.31}$$

If we take $T > \overline{T} := \max\{T_0, \tau\}$, from (4.31) with a change of variable we obtain

$$\mathcal{F}(0) \le \mathcal{E}_w(0) + c\int_\Omega a(x)\int_0^T u_t^2(x,t-\tau)dtdx,$$

and then, from (4.12),

$$\begin{aligned}\mathcal{F}(0) &\le c\int_\Omega a(x)\int_0^T \{w_t^2(x,t)+u_t^2(x,t-\tau)\}dtdx\\ &\le c\int_\Omega a(x)\int_0^T \{\tilde{w}_t^2(x,t)+u_t^2(x,t)+u_t^2(x,t-\tau)\}dtdx\end{aligned} \tag{4.32}$$

for a suitable positive constant c. Therefore, from standard energy estimates for $\tilde{w}$, we obtain

$$\mathcal{F}(0) \le C_0\int_0^T\int_\Omega a(x)\{u_t^2(x,t)+u_t^2(x,t-\tau)\}dxdt. \qquad \square$$

Now, using estimate (4.26), as in the case of boundary feedback we obtain the exponential stability result of Theorem 1.3.

Remark 4.4. Analogous arguments apply if we have more than one delay term in the internal feedback, that is, if (1.12) is replaced with

$$u_{tt}(x,t)-\Delta u(x,t)+a(x)\Big[\mu_0 u_t(x,t)+\sum_{i=1}^k \mu_i u_t(x,t-\tau_i)\Big]=0 \quad \text{in } \Omega\times(0,+\infty),$$

with $\mu_0,\mu_i,\tau_i, i=1,\dots,k$, positive parameters. In this case, if

$$\mu_0 > \sum_{i=1}^k \mu_i,$$

the right energy to consider, in order to prove exponential decay, is

$$E(t) := \frac{1}{2}\int_\Omega \{u_t^2(x,t)+|\nabla u(x,t)|^2\}dx + \sum_{i=1}^k \frac{\xi_i}{2}\int_\Omega a(x)\int_0^1 u_t^2(x,t-\rho\tau_i)d\rho dx,$$

with constants $\xi_i, i=1,\dots,k$, chosen as in Remark 3.3.

Remark 4.5. In the case $\overline{\Gamma}_D\cap\overline{\Gamma}_N\neq\emptyset$, since for internal feedbacks we have $\frac{\partial u}{\partial\nu}=0$ on Γ_N, we can use the multiplier identity from [1] and then obtain stability results under the same geometrical conditions as those from [1].

5. Some instability examples. In this section we will give some instability examples for the case $\mu_2\ge\mu_1$.

5.1. Boundary feedback. In this subsection we consider problem (1.1)–(1.5) with boundary feedback, and we prove Theorem 1.2.

Let us consider the spectral problem for the system

$$\begin{cases} u_{tt}(x,t)-\Delta u(x,t)=0 \quad \text{in } \Omega\times(0,+\infty),\\ u(x,t)=0 \quad \text{on } \Gamma_D\times(0,+\infty),\\ \dfrac{\partial u}{\partial\nu}(x,t)=-\mu_1 u_t(x,t)-\mu_2 u_t(x,t-\tau) \quad \text{on } \Gamma_N\times(0,+\infty).\end{cases} \tag{5.1}$$

We seek a solution of (5.1) in the form

$$u(x,t)=e^{\lambda t}\varphi(x), \quad \lambda\in\mathbb{C}.$$

Then, φ has to be a solution of the eigenvalue problem

$$\begin{cases} -\Delta\varphi + \lambda^2\varphi = 0 \quad \text{in } \Omega, \\ \varphi = 0 \quad \text{on } \Gamma_D, \\ \dfrac{\partial\varphi}{\partial\nu} = -(\mu_1 + \mu_2 e^{-\lambda\tau})\lambda\varphi \quad \text{on } \Gamma_N, \end{cases} \tag{5.2}$$

which can be reformulated, in a variational form, as

$$\int_\Omega \nabla\varphi\nabla\overline{v}dx + \lambda^2\int_\Omega \varphi\overline{v}dx + (\mu_1 + \mu_2 e^{-\lambda\tau})\lambda\int_{\Gamma_N}\varphi\overline{v}d\Gamma = 0 \quad \forall v \in H^1_{\Gamma_D}(\Omega). \tag{5.3}$$

We want to find a solution for $\lambda := ib$, with $b \in \mathbb{R}$. For this choice of λ, problem (5.3) can be rewritten as

$$\int_\Omega \nabla\varphi\nabla\overline{v}dx - b^2\int_\Omega \varphi\overline{v}dx + (\mu_1 + \mu_2 e^{-ib\tau})ib\int_{\Gamma_N}\varphi\overline{v}d\Gamma = 0 \quad \forall v \in H^1_{\Gamma_D}(\Omega). \tag{5.4}$$

Assume that

$$\cos(b\tau) = -\frac{\mu_1}{\mu_2}. \tag{5.5}$$

Note that, since we are considering the case $\mu_2 \geq \mu_1$, there exist b, τ such that (5.5) holds. Then, we choose

$$\mu_2 \sin(b\tau) = \sqrt{\mu_2^2 - \mu_1^2}. \tag{5.6}$$

Under these assumptions, (5.4) becomes

$$\int_\Omega \nabla\varphi\nabla\overline{v}dx - b^2\int_\Omega \varphi\overline{v}dx + b\sqrt{\mu_2^2 - \mu_1^2}\int_{\Gamma_N}\varphi\overline{v}d\Gamma = 0 \quad \forall v \in H^1_{\Gamma_D}(\Omega). \tag{5.7}$$

In particular, for $v = \varphi$, (5.7) gives

$$\int_\Omega |\nabla\varphi|^2dx - b^2\int_\Omega |\varphi|^2dx + b\sqrt{\mu_2^2 - \mu_1^2}\int_{\Gamma_N}|\varphi|^2d\Gamma = 0. \tag{5.8}$$

Without loss of generality, we can assume

$$\|\varphi\|_2^2 := \int_\Omega |\varphi|^2dx = 1, \tag{5.9}$$

and then the identity (5.8) can be rewritten as

$$b^2 - b\sqrt{\mu_2^2 - \mu_1^2}q_0(\varphi) - q_1(\varphi) = 0, \tag{5.10}$$

where

$$q_0(\varphi) := \int_{\Gamma_N}|\varphi|^2d\Gamma, \quad q_1(\varphi) := \int_\Omega |\nabla\varphi|^2dx. \tag{5.11}$$

Now we distinguish two cases.

Case (a): $\mu_1 = \mu_2$. In this case, under our assumptions, (5.10) becomes

$$b^2 = q_1(\varphi). \tag{5.12}$$

Define

$$b^2 := \min_{\substack{w\in H^1_{\Gamma_D}(\Omega)\\ \|w\|_2=1}} q_1(w). \tag{5.13}$$

If φ verifies

$$q_1(\varphi) = \min_{\substack{w\in H^1_{\Gamma_D}(\Omega)\\ \|w\|_2=1}} q_1(w),$$

then it easy to see that φ is a solution of (5.4) with b as in (5.13). Then φ verifies (5.2), and so

$$u(x,t) := e^{ibt}\varphi(x) \tag{5.14}$$

is a solution of problem (5.1). Therefore, we have found a solution of our boundary problem, whose energy is constant. Indeed, an easy computation shows that, for the function u defined in (5.14),

$$\int_\Omega (|\nabla u(x,t)|^2 + |u_t(x,t)|^2)dx = 2b^2 > 0 \quad \forall t \geq 0.$$

Note that, from our assumptions ($\lambda = ib$, $\cos(b\tau) = -1$, $\sin(b\tau) = 0$), problem (5.2) becomes the classical eigenvalue problem for the Laplace operator with a mixed Dirichlet–Neumann boundary condition. So, we can take a sequence $\{b_n\}_n$ of positive real numbers defined by

$$b_n^2 = \Lambda_n^2, \quad n \in \mathbb{N},$$

where Λ_n^2, $n \in \mathbb{N}$, are the eigenvalues for the Laplace operator. Then, putting

$$b_n\tau = (2l+1)\pi, \quad l \in \mathbb{N},$$

we obtain a sequence of delays

$$\tau_{n,l} = \frac{(2l+1)\pi}{b_n}, \quad l, n \in \mathbb{N},$$

which become arbitrarily small (or large) for suitable choices of the indices $n, l \in \mathbb{N}$. Therefore, in the case $\mu_1 = \mu_2$, we have found a set of time delays for which problem (1.1)–(1.5) is not asymptotically stable.

Case (b): $\mu_2 > \mu_1$. In this case, from (5.10) we have

$$b = \frac{1}{2}\left(\sqrt{\mu_2^2-\mu_1^2}q_0(\varphi) \pm \sqrt{(\mu_2^2-\mu_1^2)q_0^2(\varphi) + 4q_1(\varphi)}\right).$$

Define

$$b := \frac{1}{2}\min_{\substack{w\in H^1_{\Gamma_D}(\Omega)\\ \|w\|_2=1}} \left(\sqrt{\mu_2^2-\mu_1^2}q_0(w) + \sqrt{(\mu_2^2-\mu_1^2)q_0^2(w) + 4q_1(w)}\right). \tag{5.15}$$

We now prove that if the minimum in the right–hand side of (5.15) is attained at φ, that is,

(5.16)
$$\sqrt{\mu_2^2-\mu_1^2}q_0(\varphi)+\sqrt{(\mu_2^2-\mu_1^2)q_0^2(\varphi)+4q_1(\varphi)} := \min_{\substack{w\in H^1_{\Gamma_D}(\Omega)\\ \|w\|_2=1}} \left(\sqrt{\mu_2^2-\mu_1^2}q_0(w)+\sqrt{(\mu_2^2-\mu_1^2)q_0^2(w)+4q_1(w)}\right),$$

then φ is a solution of (5.7) with b as in (5.15). To show this, take for $\varepsilon\in\mathbb{R}$,

$$w=\varphi+\varepsilon v, \quad \text{with} \quad v\in H^1_{\Gamma_D}(\Omega) \ \text{ such that } \ \int_\Omega \varphi\overline{v}dx=0. \tag{5.17}$$

Then,

$$\|w\|_2^2=\|\varphi\|_2^2+\varepsilon^2\|v\|_2^2=1+\varepsilon^2\|v\|_2^2.$$

If we denote

(5.18)
$$g(\varepsilon):=\frac{1}{1+\varepsilon^2\|v\|_2^2}\left(\sqrt{\mu_2^2-\mu_1^2}q_0(\varphi+\varepsilon v)+\sqrt{(\mu_2^2-\mu_1^2)q_0^2(\varphi+\varepsilon v)+4q_1(\varphi+\varepsilon v)}\right),$$

then, by definition (5.16),

$$g(\varepsilon)\geq g(0)=\left(\sqrt{\mu_2^2-\mu_1^2}q_0(\varphi)+\sqrt{(\mu_2^2-\mu_1^2)q_0^2(\varphi)+4q_1(\varphi)}\right).$$

So, we have that

$$\left.\frac{dg(\varepsilon)}{d\varepsilon}\right|_{\varepsilon=0}=0,$$

which, after an easy computation, gives

$$\int_\Omega \nabla\varphi\nabla\overline{v}dx+b\sqrt{\mu_2^2-\mu_1^2}\int_{\Gamma_N}\varphi\overline{v}d\Gamma=0. \tag{5.19}$$

Since any function $\tilde{v}\in H^1_{\Gamma_D}(\Omega)$ can be decomposed as

$$\tilde{v}=\gamma\varphi+v, \qquad \gamma\in\mathbb{R}, \quad v\in H^1_{\Gamma_D}(\Omega) \ \text{ with } \ \int_\Omega\varphi\overline{v}dx=0,$$

from (5.19) and (5.8) we obtain that φ satisfies (5.7) with b defined in (5.15). So, for such positive b,

$$b\tau=\arccos\left(-\frac{\mu_1}{\mu_2}\right)+2l\pi, \quad l\in\mathbb{N},$$

defines a sequence of time delays for which problem (1.1)–(1.5) is not asymptotically stable.

The above examples prove Theorem 1.2.

5.2. Internal feedback. In this subsection we will give instability examples for problem (1.12)–(1.16) with internal feedback, proving Theorem 1.4.

Let us consider the spectral problem for the system

(5.20)
$$\begin{cases} u_{tt}(x,t) - \Delta u(x,t) + a(x)[\mu_1 u_t(x,t) + \mu_2 u_t(x,t-\tau)] = 0 \quad \text{in } \Omega \times (0,+\infty), \\ u(x,t) = 0 \quad \text{on } \Gamma_D \times (0,+\infty), \\ \dfrac{\partial u}{\partial \nu}(x,t) = 0 \quad \text{on } \Gamma_N \times (0,+\infty). \end{cases}$$

We restrict our analysis to the case $a(x) \equiv 1$ in Ω.

We seek a solution of (5.20) in the form

$$u(x,t) = e^{\lambda t}\varphi(x), \quad \lambda \in \mathbb{C}.$$

Then, φ has to solve the eigenvalue problem

(5.21)
$$\begin{cases} \Delta\varphi = [\lambda^2 + (\mu_1 + \mu_2 e^{-\lambda\tau})\lambda]\varphi \quad \text{in } \Omega, \\ \varphi = 0 \quad \text{on } \Gamma_D, \\ \dfrac{\partial \varphi}{\partial \nu} = 0 \quad \text{on } \Gamma_N. \end{cases}$$

Let us consider the standard problem for the Laplace operator with a mixed Dirichlet–Neumann boundary condition

(5.22)
$$\begin{cases} \Delta\varphi = -\mu^2\varphi \quad \text{in } \Omega, \\ \varphi = 0 \quad \text{on } \Gamma_D, \\ \dfrac{\partial \varphi}{\partial \nu} = 0 \quad \text{on } \Gamma_N. \end{cases}$$

We want to show that for any Λ^2 eigenvalue of problem (5.22), there exists a $\lambda \in \mathbb{C}$ solution of the equation

$$\lambda^2 + (\mu_1 + \mu_2 e^{-\lambda\tau})\lambda = -\Lambda^2. \tag{5.23}$$

We seek a solution $\lambda = \alpha + i\beta,\ \alpha, \beta \in \mathbb{R}$, with

$$\beta\tau = (2l+1)\pi, \quad l \in \mathbb{N}. \tag{5.24}$$

Under this assumption, (5.23) becomes

(5.25)
$$\begin{cases} \alpha^2 + \beta^2 = \Lambda^2, \\ \mu_2 e^{-\alpha\tau} = 2\alpha + \mu_1. \end{cases}$$

Now we distinguish two cases.

Case (a): $\mu_1 = \mu_2$. In this case, from (5.25) we have

$$\alpha = 0, \quad \beta^2 = \Lambda^2.$$

Therefore, for any Λ_n^2 eigenvalue of problem (5.22), if $\beta_n \in \mathbb{R}$ verifies

$$\beta_n^2 = \Lambda_n^2,$$

then for $\lambda = i\beta_n$ problem (5.21) admits a nonzero solution.

Take β_n positive. From our assumption (5.24),

$$\tau_{n,l} = \frac{(2l+1)\pi}{\beta_n}, \quad n, l \in \mathbb{N},$$

is a set of time delays that become arbitrarily small (or large) for suitable choices of the indices $n, l \in \mathbb{N}$. For such delays, problem (1.12)–(1.16) admits solutions in the form

$$u(x,t) = e^{i\beta t}\varphi(x),$$

whose energy is constant and strictly positive. So, system (1.12)–(1.16) is not asymptotically stable.

Case (b): $\mu_2 > \mu_1$. For a fixed $\alpha > 0$, from the second equation of (5.25), we obtain

$$\tau(\alpha) = \frac{1}{\alpha} \ln\left(\frac{\mu_2}{\mu_1 + 2\alpha}\right), \tag{5.26}$$

and so, in order to have $\tau(\alpha) > 0$, we consider

$$0 < \alpha < \frac{1}{2}(\mu_2 - \mu_1).$$

From (5.24), the first equation of (5.25) becomes

$$\alpha^2 + \frac{(2l+1)^2\pi^2}{\tau^2(\alpha)} = \Lambda^2, \tag{5.27}$$

where $\tau(\alpha)$ is given by (5.26).

Denoting

$$g(\alpha) := \alpha^2 + \frac{(2l+1)^2\pi^2}{\tau^2(\alpha)} \qquad \forall \alpha \in \left(0, \frac{\mu_2 - \mu_1}{2}\right),$$

we have

$$\tau(\alpha) \to +\infty \quad \text{and} \quad g(\alpha) \to 0^+ \text{ as } \alpha \to 0^+,$$

while

$$\tau(\alpha) \to 0^+ \quad \text{and} \quad g(\alpha) \to +\infty \text{ as } \alpha \to \frac{1}{2}(\mu_2 - \mu_1)^-.$$

Since g is a continuous function of α, for any fixed Λ^2 eigenvalue of problem (5.22) there exists α $(0 < \alpha < (\mu_2 - \mu_1)/2)$ such that (5.27) is verified. Therefore, for such α there exists a delay $\tau(\alpha)$ (defined by (5.26)) such that a function of the form

$$e^{\alpha + i\beta}\varphi(x)$$

solves problem (1.12)–(1.16). Since $\alpha \geq 0$, the energy of such a solution is not decaying to zero. So, this solution is not asymptotically stable.

Note that, for any Λ_n^2 eigenvalue of problem (5.22) and for any $l \in \mathbb{N}$, there exist $\alpha_{n,l}$ and a delay $\tau_{n,l} = \tau(\alpha_{n,l})$ such that (5.25) is verified with

$$\beta_{n,l} = \frac{(2l+1)\pi}{\tau_{n,l}}.$$

From the first equation of (5.25),

$$\frac{(2l+1)^2\pi^2}{\tau_{n,l}^2} \leq \Lambda_n^2.$$

Then, for a fixed $l \in \mathbb{N}$, if $n \to +\infty$, then $\tau_{n,l} \to 0^+$. On the contrary, for a fixed $n \in \mathbb{N}$, if $l \to +\infty$, then $\tau_{n,l} \to +\infty$. Therefore, we have instability phenomena for a sequence of arbitrarily small or large time delays.

The examples of Case (a) and (b) prove Theorem 1.4.

Acknowledgments. We thank E. Zuazua for bringing our attention to reference [17] and suggesting we consider the stabilization of the wave equation with delay in general domains of $\mathbb{R}^n$.

ERROR ESTIMATES FOR THE NUMERICAL APPROXIMATION OF DIRICHLET BOUNDARY CONTROL FOR SEMILINEAR ELLIPTIC EQUATIONS*

EDUARDO CASAS† AND JEAN-PIERRE RAYMOND‡

Abstract. We study the numerical approximation of boundary optimal control problems governed by semilinear elliptic partial differential equations with pointwise constraints on the control. The control is the trace of the state on the boundary of the domain, which is assumed to be a convex, polygonal, open set in $\mathbb{R}^2$. Piecewise linear finite elements are used to approximate the control as well as the state. We prove that the error estimates are of order $O(h^{1-1/p})$ for some $p > 2$, which is consistent with the $W^{1-1/p,p}(\Gamma)$-regularity of the optimal control.

Key words. Dirichlet control, semilinear elliptic equation, numerical approximation, error estimates

1. Introduction.

In this paper we study an optimal control problem governed by a semilinear elliptic equation. The control is the Dirichlet datum on the boundary of the domain. Bound constraints are imposed on the control. The cost functional involves the control in a quadratic way and the state in a general way. The goal is to derive error estimates for the discretization of the control problem.

There are not many papers devoted to the derivation of error estimates for the discretization of control problems governed by partial differential equations; see the pioneering works by Falk [19] and Geveci [21]. However, recently some papers have appeared, providing new methods and ideas. Arada, Casas, and Tröltzsch [1] derived error estimates for the controls in the L^∞ and L^2 norms for distributed control problems. Similar results for an analogous problem, but also including integral state constraints, were obtained by Casas [8]. The case of a Neumann boundary control problem has been studied by Casas, Mateos, and Tröltzsch [11]. The novelty of our paper with respect to the previous ones is twofold. First, here we deal with a Dirichlet problem, the control being the value of the state on the boundary. Second, we consider piecewise linear continuous functions to approximate the optimal control, which is necessary because of the Dirichlet nature of the control, but it introduces some new difficulties. In the previous papers the controls were always approximated by piecewise constant functions. In the present situation we have developed new methods, which can be used in the framework of distributed or Neumann controls to consider piecewise linear approximations. This could lead to better error estimates than those deduced for piecewise controls.

As far as we know, there is another paper dealing with the numerical approximation of a Dirichlet control problem of Navier–Stokes equations, by Gunzburger,

Hou, and Svobodny [23]. Their procedure of proof does not work when the controls are subject to bound constraints, as considered in our problem. To deal with this difficulty we assume that sufficient second order optimality conditions are satisfied. We also see that the gap between the necessary and sufficient optimality conditions is very narrow. It is of the same type as in the finite dimensional case.

Let us mention some recent papers which provide some new ideas for deriving optimal error estimates. Hinze [26] suggested discretizing the state equation but not the control space. In some cases, including the case of semilinear equations, it is possible to solve the incompletely discretized problem on a computer. However, we believe this process offers no advantages for our problem because the discretization of the states forces the discretization of the controls. Another idea, due to Meyer and Rösch [33], works for linear-quadratic control problems in the distributed case, but we do not know if it is possible to adapt it to the general case.

In the case of parabolic problems, the theory is far from being complete, but some research has been carried out; see Knowles [27], Lasiecka [28], [29], McKnight and Bosarge [32], Tiba and Tröltzsch [36], and Tröltzsch [38], [39], [40], [41].

In the context of control problems of ordinary differential equations, great work has been done by Hager [24], [25] and Dontchev and Hager [16], [17]; see also the work by Malanowski, Büskens, and Maurer [31]. The reader is also referred to the detailed bibliography in [17].

The plan of the paper is as follows. In section 2 we set the optimal control problem and we establish the results we need for the state equation. In section 3 we write the first and second order optimality conditions. The first order conditions allow us to deduce some regularity results of the optimal control, which are necessary to derive the error estimates of the discretization. The second order conditions are also essential to prove the error estimates. The discrete optimal control problem is formulated in section 4 and the first order optimality conditions are given. To write these conditions we have defined a discrete normal derivative for piecewise linear functions, which are solutions of some discrete equation. Sections 6 and 7 are devoted to the analysis of the convergence of the solutions of the discrete optimal control problems and to the proof of error estimates. The main result is Theorem 7.1, where we establish $\|\bar{u} - \bar{u}_h\|_{L^2(\Gamma)} = O(h^{1-1/p})$.

The numerical tests we have performed confirm our theoretical estimates. For a detailed report we refer to [12]. A simple example is reported in section 8.

2. The control problem. Throughout this paper, Ω denotes an open convex bounded polygonal set of $\mathbb{R}^2$, and Γ denotes its boundary. In this domain we formulate the following control problem:

$$
(\mathrm{P}) \begin{cases} \inf \quad J(u) = \displaystyle\int_\Omega L(x, y_u(x))\,dx \; + \frac{N}{2} \int_\Gamma u^2(x)\,dx \\ \qquad \text{subject to } (y_u, u) \in L^\infty(\Omega) \times L^\infty(\Gamma), \\ u \in U^{ad} = \{u \in L^\infty(\Gamma) \mid \alpha \le u(x) \le \beta \;\; \text{a.e. } x \in \Gamma\}, \\ (y_u, u) \;\; \text{satisfying the state equation (2.1)}, \end{cases}
$$

$$
-\Delta y_u(x) = f(x, y_u(x)) \;\; \text{in } \Omega, \qquad y_u(x) = u(x) \;\; \text{on } \Gamma, \tag{2.1}
$$

where $-\infty < \alpha < \beta < +\infty$ and $N > 0$. Here u is the control, while y_u is the associated state. The following hypotheses are assumed about the functions involved in the control problem (P).

(A1) The function $L : \Omega \times \mathbb{R} \longrightarrow \mathbb{R}$ is measurable with respect to the first component and is of class C^2 with respect to the second one, $L(\cdot, 0) \in L^1(\Omega)$, and for all $M > 0$ there exist a function $\psi_{L,M} \in L^{\bar{p}}(\Omega)$ ($\bar{p} > 2$) and a constant $C_{L,M} > 0$ such that

$$\left|\frac{\partial L}{\partial y}(x,y)\right| \le \psi_{L,M}(x), \quad \left|\frac{\partial^2 L}{\partial y^2}(x,y)\right| \le C_{L,M},$$
$$\left|\frac{\partial^2 L}{\partial y^2}(x,y_2) - \frac{\partial^2 L}{\partial y^2}(x,y_1)\right| \le C_{L,M}|y_2 - y_1|,$$

for a.e. $x \in \Omega$ and $|y|, |y_i| \le M$, $i = 1, 2$.

(A2) The function $f : \Omega \times \mathbb{R} \longrightarrow \mathbb{R}$ is measurable with respect to the first variable and is of class C^2 with respect to the second one,

$$f(\cdot, 0) \in L^{\bar{p}}(\Omega) \ \ (\bar{p} > 2), \quad \frac{\partial f}{\partial y}(x,y) \le 0 \ \text{ a.e. } x \in \Omega \text{ and } y \in \mathbb{R}.$$

For all $M > 0$ there exists a constant $C_{f,M} > 0$ such that

$$\left|\frac{\partial f}{\partial y}(x,y)\right| + \left|\frac{\partial^2 f}{\partial y^2}(x,y)\right| \le C_{f,M} \text{ a.e. } x \in \Omega \text{ and } |y| \le M,$$
$$\left|\frac{\partial^2 f}{\partial y^2}(x,y_2) - \frac{\partial^2 f}{\partial y^2}(x,y_1)\right| < C_{f,M}|y_2 - y_1| \ \text{ a.e. } x \in \Omega \text{ and } |y_1|, |y_2| \le M.$$

Let us finish this section by proving that problem (P) is well defined. We will say that an element $y_u \in L^\infty(\Omega)$ is a solution of (2.1) if

(2.2)
$$\int_\Omega -\Delta w\, y\, dx = \int_\Omega f(x, y(x))w(x)dx - \int_\Gamma u(x)\partial_\nu w(x)dx, \quad \forall w \in H^2(\Omega) \cap H_0^1(\Omega),$$

where ∂_ν denotes the normal derivative on the boundary Γ. This is the classical definition in the transposition sense. To study (2.1), we state an estimate for the linear equation

$$-\Delta z(x) = b(x)z(x) \ \text{ in } \Omega, \qquad z(x) = u(x) \ \text{ on } \Gamma, \tag{2.3}$$

where b is a nonpositive function belonging to $L^\infty(\Omega)$.

LEMMA 2.1. *For every $u \in L^\infty(\Gamma)$, the linear equation* (2.3) *has a unique solution $z \in L^\infty(\Omega)$ (defined in the transposition sense), and it satisfies*

(2.4)
$$\|z\|_{L^2(\Omega)} \le C\|u\|_{H^{-1/2}(\Gamma)}, \ \|z\|_{H^{1/2}(\Omega)} \le C\|u\|_{L^2(\Gamma)} \text{ and } \|z\|_{L^\infty(\Omega)} \le \|u\|_{L^\infty(\Gamma)}.$$

The proof is standard: the first inequality is obtained by using the transposition method (see Lions and Magenes [30]), the second inequality is deduced by interpolation, and the last one is obtained by applying the maximum principle.

THEOREM 2.2. *For every $u \in L^\infty(\Gamma)$, the state equation* (2.1) *has a unique solution $y_u \in L^\infty(\Omega) \cap H^{1/2}(\Omega)$. Moreover the following Lipschitz properties hold:*

$$\begin{aligned} &\|y_u - y_v\|_{L^\infty(\Omega)} \le \|u - v\|_{L^\infty(\Gamma)}, \\ &\|y_u - y_v\|_{H^{1/2}(\Omega)} \le C\|u - v\|_{L^2(\Gamma)} \quad \forall u, v \in L^\infty(\Gamma). \end{aligned} \tag{2.5}$$

Finally if $u_n \rightharpoonup u$ *weakly** *in* $L^\infty(\Gamma)$, *then* $y_{u_n} \to y_u$ *strongly in* $L^r(\Omega)$ *for all* $r < +\infty$.

Proof. Let us introduce the following problems:

$$-\Delta z = 0 \ \text{ in } \Omega, \qquad z = u \ \text{ on } \Gamma, \tag{2.6}$$

and

$$-\Delta \zeta = g(x,\zeta) \ \text{ in } \Omega, \qquad \zeta = 0 \ \text{ on } \Gamma, \tag{2.7}$$

where $g : \Omega \times \mathbb{R} \mapsto \mathbb{R}$ is given by $g(x,t) = f(x, z(x) + t)$, with z being the solution of (2.6). Lemma 2.1 implies that (2.6) has a unique solution in $L^\infty(\Omega) \cap H^{1/2}(\Omega)$. It is obvious that assumption (A2) is fulfilled by g and that (2.7) is a classically well-set problem having a unique solution in $H_0^1(\Omega) \cap L^\infty(\Omega)$. Moreover, since Ω is convex, we know that $\zeta \in H^2(\Omega)$; see Grisvard [22]. Finally the solution y_u of (2.1) can be written as $y_u = z + \zeta$. Estimates (2.5) follow from Lemma 2.1; see Arada and Raymond [2] for a detailed proof in the parabolic case. The continuous dependence in $L^r(\Omega)$ follows in a standard way by using (2.5) and the compactness of the inclusion $H^{1/2}(\Omega) \subset L^2(\Omega)$ along with the fact that $\{y_{u_n}\}$ is bounded in $L^\infty(\Omega)$, as deduced from the first inequality of (2.5). ∎

Now the following theorem can be proved by standard arguments.

THEOREM 2.3. *Problem* (P) *has at least one solution.*

3. Optimality conditions. Before writing the optimality conditions for (P) let us state the differentiability properties of J.

THEOREM 3.1. *The mapping* $G : L^\infty(\Gamma) \longrightarrow L^\infty(\Omega) \cap H^{1/2}(\Omega)$ *defined by* $G(u) = y_u$ *is of class* C^2. *Moreover, for all* $u, v \in L^\infty(\Gamma)$, $z_v = G'(u)v$ *is the solution of*

$$-\Delta z_v = \frac{\partial f}{\partial y}(x, y_u) z_v \ \text{ in } \Omega, \qquad z_v = v \ \text{ on } \Gamma, \tag{3.1}$$

and for every $v_1, v_2 \in L^\infty(\Omega)$, $z_{v_1 v_2} = G''(u)v_1 v_2$ *is the solution of*

$$\begin{cases} -\Delta z_{v_1 v_2} &= \dfrac{\partial f}{\partial y}(x, y_u) z_{v_1 v_2} + \dfrac{\partial^2 f}{\partial y^2}(x, y_u) z_{v_1} z_{v_2} & \text{in} \quad \Omega, \\ z_{v_1 v_2} &= 0 & \text{on} \quad \Gamma, \end{cases} \tag{3.2}$$

where $z_{v_i} = G'(u)v_i$, $i = 1, 2$.

Proof. Let us define the space

$$V = \{ y \in H^{1/2}(\Omega) \cap L^\infty(\Omega) : \Delta y \in L^2(\Omega) \}$$

endowed with the natural graph norm. Now we consider the function $F : L^\infty(\Gamma) \times V \longrightarrow L^\infty(\Gamma) \times L^2(\Omega)$ defined by $F(u,y) = (y|_\Gamma - u, \Delta y + f(x,y))$. It is obvious that F is of class C^2 and that for every pair (u,y) satisfying (2.1) we have $F(u,y) = (0,0)$. Furthermore

$$\frac{\partial F}{\partial y}(u,y) \cdot z = \left(z|_\Gamma, \Delta z + \frac{\partial f}{\partial y}(x,y) z \right).$$

By using Lemma 2.1 we deduce that $(\partial F/\partial y)(u,y) : V \longrightarrow L^\infty(\Gamma) \times L^2(\Omega)$ is an isomorphism. Then the implicit function theorem allows us to conclude that G is of class C^2, and now the rest of the theorem follows easily. ∎

Theorem 3.1, along with the chain rule, leads to the following result.

THEOREM 3.2. *The functional $J : L^\infty(\Gamma) \to \mathbb{R}$ is of class C^2. Moreover, for every $u, v, v_1, v_2 \in L^\infty(\Gamma)$,*

$$J'(u)v = \int_\Gamma (Nu - \partial_\nu \phi_u)\, v\, dx \tag{3.3}$$

and

$$J''(u)v_1v_2 = \int_\Omega \left[\frac{\partial^2 L}{\partial y^2}(x, y_u)z_{v_1}z_{v_2} + \phi_u \frac{\partial^2 f}{\partial y^2}(x, y_u)z_{v_1}z_{v_2}\right] dx + \int_\Gamma N v_1 v_2\, dx, \tag{3.4}$$

where $z_{v_i} = G'(u)v_i$, $i = 1, 2$, $y_u = G(u)$, and the adjoint state $\phi_u \in H^2(\Omega)$ is the unique solution of the problem

$$-\Delta\phi = \frac{\partial f}{\partial y}(x, y_u)\phi + \frac{\partial L}{\partial y}(x, y_u) \quad \text{in } \Omega, \qquad \phi = 0 \quad \text{on } \Gamma. \tag{3.5}$$

The first order optimality conditions for problem (P) follow readily from Theorem 3.2.

THEOREM 3.3. *Assume that $\bar u$ is a local solution of problem* (P) *and let $\bar y$ be the corresponding state. Then there exists $\bar\phi \in H^2(\Omega)$ such that*

$$-\Delta\bar\phi = \frac{\partial f}{\partial y}(x, \bar y)\bar\phi + \frac{\partial L}{\partial y}(x, \bar y) \text{ in } \Omega, \qquad \bar\phi = 0 \text{ on } \Gamma, \tag{3.6}$$

and

$$\int_\Gamma \left(N\bar u - \partial_\nu \bar\phi\right)(u - \bar u)\, dx \ge 0, \quad \forall u \in U^{ad}, \tag{3.7}$$

which is equivalent to

$$\bar u(x) = \mathrm{Proj}_{[\alpha,\beta]}\Big(\frac{1}{N}\partial_\nu\bar\phi(x)\Big) = \max\Big\{\alpha, \min\Big\{\beta, \frac{1}{N}\partial_\nu\bar\phi(x)\Big\}\Big\}. \tag{3.8}$$

THEOREM 3.4. *Assume that $\bar u$ is a local solution of problem* (P) *and let $\bar y$ and $\bar\phi$ be the corresponding state and adjoint state. Then there exists $p \in (2, \bar p]$ (with $\bar p > 2$ as introduced in assumptions* (A1) *and* (A2)*) depending on the measure of the angles of the polygon Ω such that $\bar y \in W^{1,p}(\Omega)$, $\bar\phi \in W^{2,p}(\Omega)$, and $\bar u \in W^{1-1/p,p}(\Gamma) \subset C(\Gamma)$.*

Proof. From assumption (A1) and using elliptic regularity results, it follows that $\bar\phi$ belongs to $W^{2,p}(\Omega)$ for some $p \in (2, \bar p]$ depending on the measure of the angles of Γ; see Grisvard [22, Chapter 4]. To prove that $\bar u$ belongs to $W^{1-1/p,p}(\Gamma)$ we recall the norm in this space,

$$\|\bar u\|_{W^{1-1/p,p}(\Gamma)} = \left\{\int_\Gamma |\bar u(x)|^p dx + \int_\Gamma\int_\Gamma \frac{|\bar u(x) - \bar u(\xi)|^p}{|x - \xi|^p}\, dx\, d\xi\right\}^{1/p},$$

where we have used the fact that $\Omega \subset \mathbb{R}^2$. Due to [22, Theorem 1.5.2.3] and the fact that $\bar\phi = 0$ on Γ, it can be shown that $\partial_\nu\bar\phi$ belongs to $W^{1-1/p,p}(\Gamma)$. With the relation (3.8) and

$$\left|\mathrm{Proj}_{[\alpha,\beta]}\left(\frac{1}{N}\partial_\nu\bar\phi(x)\right) - \mathrm{Proj}_{[\alpha,\beta]}\left(\frac{1}{N}\partial_\nu\bar\phi(\xi)\right)\right| \le \frac{1}{N}|\partial_\nu\bar\phi(x) - \partial_\nu\bar\phi(\xi)|,$$

one can prove that the integrals in the above norm are finite.

Finally, decomposing (2.1) into two problems as in the proof of Theorem 2.3, we get that $\bar{y} = \bar{z} + \bar{\zeta}$, with $\bar{\zeta} \in H^2(\Omega)$ and $\bar{z} \in W^{1,p}(\Omega)$, which completes the proof. □

In order to establish the second order optimality conditions, we define the cone of critical directions

$$C_{\bar{u}} = \{v \in L^2(\Gamma) \text{ satisfying (3.9) and } v(x) = 0 \text{ if } |\bar{d}(x)| > 0\},$$

$$v(x) = \begin{cases} \geq 0 & \text{where } \bar{u}(x) = \alpha \\ \leq 0 & \text{where } \bar{u}(x) = \beta \end{cases} \quad \text{for a.e. } x \in \Gamma, \tag{3.9}$$

where $\bar{d}$ denotes the derivative $J'(\bar{u})$,

$$\bar{d}(x) = N\bar{u}(x) - \partial_\nu \bar{\phi}(x). \tag{3.10}$$

Now we formulate the second order necessary and sufficient optimality conditions.

THEOREM 3.5. *If $\bar{u}$ is a local solution of* (P), *then $J''(\bar{u})v^2 \geq 0$ holds for all $v \in C_{\bar{u}}$. Conversely, if $\bar{u} \in U^{ad}$ satisfies the first order optimality conditions provided by Theorem* 3.3 *and the coercivity condition*

$$J''(\bar{u})v^2 > 0, \quad \forall v \in C_{\bar{u}} \setminus \{0\}, \tag{3.11}$$

then there exist $\mu > 0$ and $\varepsilon > 0$ such that $J(u) \geq J(\bar{u}) + \mu\|u - \bar{u}\|^2_{L^2(\Gamma)}$ is satisfied for every $u \in U^{ad}$ obeying $\|u - \bar{u}\|_{L^\infty(\Omega)} \leq \varepsilon$.

The necessary condition provided in the theorem is quite easy to get. The sufficient conditions are proved by Casas and Mateos [9, Theorem 4.3] for distributed control problems with integral state constraints. The proof can be translated in a straightforward way into the case of boundary controls; see also Bonnans and Zidani [4].

Remark 3.6. It can be proved (see Casas and Mateos [9, Theorem 4.4]) that the following two conditions are equivalent:

(1) $J''(\bar{u})v^2 > 0$ for every $v \in C_{\bar{u}} \setminus \{0\}$.

(2) There exist $\delta > 0$ and $\tau > 0$ such that $J''(\bar{u})v^2 \geq \delta\|v\|^2_{L^2(\Gamma)}$ for every $v \in C^\tau_{\bar{u}}$, where

$$C^\tau_{\bar{u}} = \{v \in L^2(\Gamma) \text{ satisfying (3.9) and } v(x) = 0 \text{ if } |\bar{d}(x)| > \tau\}.$$

It is clear that $C^\tau_{\bar{u}}$ contains strictly $C_{\bar{u}}$, so condition (2) seems to be stronger than (1), but in fact they are equivalent. For the proof of this equivalence, we use the fact that u appears linearly in the state equation and quadratically in the cost functional.

4. Numerical approximation of (P). Let us consider a family of triangulations $\{\mathcal{T}_h\}_{h>0}$ of $\bar{\Omega}$: $\bar{\Omega} = \cup_{T\in\mathcal{T}_h} T$. With each element $T \in \mathcal{T}_h$, we associate two parameters $\rho(T)$ and $\sigma(T)$, where $\rho(T)$ denotes the diameter of the set T, and $\sigma(T)$ is the diameter of the largest ball contained in T. Let us define the size of the mesh by $h = \max_{T\in\mathcal{T}_h} \rho(T)$. For fixed $h > 0$, we denote by $\{T_j\}_{j=1}^{N(h)}$ the family of triangles belonging to $\mathcal{T}_h$ and having a side included in the boundary Γ. If the vertices of $T_j \cap \Gamma$ are x^j_Γ and x^{j+1}_Γ, then $[x^j_\Gamma, x^{j+1}_\Gamma] := T_j \cap \Gamma$, $1 \leq j \leq N(h)$, with $x^{N(h)+1}_\Gamma = x^1_\Gamma$. We will also follow the notation $x^0_\Gamma = x^{N(h)}_\Gamma$. We assume that every vertex of the polygon Ω is one of these boundary points x^j_Γ of the triangulation and that the numbering of

the nodes $\{x_\Gamma^j\}_{j=1}^{N(h)}$ is made counterclockwise. The length of the interval $[x_\Gamma^j, x_\Gamma^{j+1}]$ is denoted by $h_j = |x_\Gamma^{j+1} - x_\Gamma^j|$. The following hypotheses on the triangulation are also assumed.

(H1) There exists a constant $\rho > 0$ such that $h/\rho(T) \leq \rho$ for all $T \in \mathcal{T}_h$ and $h > 0$.

(H2) All the angles of all triangles are less than or equal to $\pi/2$.

The first assumption is not a restriction in practice and it is the usual one. The second assumption is going to allow us to use the discrete maximum principle and it is actually not too restrictive.

Given two points ξ_1 and ξ_2 of Γ, we denote by $[\xi_1, \xi_2]$ the part of Γ obtained by running the boundary from ξ_1 to ξ_2 counterclockwise. With this convention we have $(\xi_2, \xi_1) = \Gamma \setminus [\xi_1, \xi_2]$. According to this notation,

$$\int_{\xi_1}^{\xi_2} u(x)\,dx \quad \text{and} \quad \int_{\xi_2}^{\xi_1} u(x)\,dx$$

denote the integrals of a function $u \in L^1(\Gamma)$ on the parts of Γ defined by $[\xi_1, \xi_2]$ and $[\xi_2, \xi_1]$, respectively. In particular we have

$$\int_{\xi_1}^{\xi_2} u(x)\,dx = \int_\Gamma u(x)\,dx - \int_{\xi_2}^{\xi_1} u(x)\,dx.$$

Associated with this triangulation, we consider the sets

$$U_h = \Big\{u_h \in C(\Gamma) : u_h|_{[x_\Gamma^j, x_\Gamma^{j+1}]} \in \mathcal{P}_1 \text{ for } 1 \leq j \leq N(h)\Big\},$$
$$Y_h = \Big\{y_h \in C(\bar\Omega) : y_h|_T \in \mathcal{P}_1 \ \forall\, T \in \mathcal{T}_h\Big\},$$
$$Y_{h0} = \Big\{y_h \in Y_h : y_h|_\Gamma = 0\Big\},$$

where $\mathcal{P}_1$ is the space of polynomials of degree less than or equal to 1. The space U_h is formed by the restrictions to Γ of the functions of Y_h.

Let us consider the projection operator $\Pi_h : L^2(\Gamma) \longmapsto U_h$,

$$(\Pi_h v, u_h)_{L^2(\Gamma)} = (v, u_h)_{L^2(\Gamma)} \quad \forall u_h \in U_h.$$

The following approximation property of Π_h is well known (see for instance [20, Lemma 3.1]):

$$\|y - \Pi_h y\|_{L^2(\Gamma)} + h^{1/2}\|y - \Pi_h y\|_{H^{1/2}(\Gamma)} \leq Ch^{s-1/2}\|y\|_{H^s(\Omega)}, \quad \forall y \in H^s(\Omega),$$

and for every $1 \leq s \leq 2$. Observing that, for $1/2 < s \leq 3/2$,

$$u \longmapsto \inf_{y|_\Gamma = u} \|y\|_{H^s(\Omega)}$$

is a norm equivalent to the usual one of $H^{s-1/2}(\Gamma)$, we deduce from the above inequality that

$$\|u - \Pi_h u\|_{L^2(\Gamma)} + h^{1/2}\|u - \Pi_h u\|_{H^{1/2}(\Gamma)} \leq Ch^s\|u\|_{H^s(\Gamma)}, \quad \forall u \in H^s(\Gamma), \tag{4.1}$$

and for every $1/2 < s \leq 3/2$.

Let $a : Y_h \times Y_h \longmapsto \mathbb{R}$ be the bilinear form given by

$$a(y_h, z_h) = \int_\Omega \nabla y_h(x) \nabla z_h(x)\, dx.$$

For all $u \in L^\infty(\Gamma)$, we consider the following problem:

$$\text{(4.2)} \qquad \begin{cases} \text{Find } y_h(u) \in Y_h, \text{ such that } y_h = \Pi_h u \text{ on } \Gamma, \text{ and} \\ a(y_h(u), w_h) = \displaystyle\int_\Omega f(x, y_h(u)) w_h\, dx \quad \forall w_h \in Y_{h0}. \end{cases}$$

PROPOSITION 4.1. *For every $u \in L^\infty(\Gamma)$, (4.2) admits a unique solution $y_h(u)$.*

Proof. Let z_h be the unique element in Y_h satisfying $z_h = \Pi_h u$ on Γ, and let $z_h(x_i) = 0$ for all vertices x_i of the triangulation $\mathcal{T}_h$ not belonging to Γ. The equation

$$\zeta_h \in Y_{h0}, \quad a(\zeta_h, w_h) = -a(z_h, w_h) + \int_\Omega f(x, z_h + \zeta_h) w_h\, dx, \quad \forall w_h \in Y_{h0},$$

admits a unique solution (it is a consequence of the Minty–Browder theorem; see Brézis [7]). The function $z_h + \zeta_h$ is clearly a solution of (4.2). The uniqueness of the solution to (4.2) also follows from the Minty–Browder theorem. □

Due to Proposition 4.1, we can define a functional J_h in $L^\infty(\Gamma)$ by

$$J_h(u) = \int_\Omega L(x, y_h(u)(x))\, dx + \frac{N}{2} \int_\Gamma u^2(x)\, dx.$$

The finite dimensional control problem approximating (P) is

$$(\mathrm{P}_h) \begin{cases} \min J_h(u_h) = \displaystyle\int_\Omega L(x, y_h(u_h)(x))\, dx + \frac{N}{2} \int_\Gamma u_h^2(x)\, dx \\ \text{subject to } u_h \in U_h^{ad}, \end{cases}$$

where

$$U_h^{ad} = U_h \cap U^{ad} = \{u_h \in U_h \mid \alpha \le u_h(x) \le \beta \ \forall\ x \in \Gamma\}.$$

The existence of a solution of (P_h) follows from the continuity of J_h in U_h and the fact that U_h^{ad} is a nonempty compact subset of U_h. Our next goal is to write the conditions for optimality satisfied by any local solution $\bar{u}_h$. First, we have to obtain an expression for the derivative of $J_h : L^\infty(\Gamma) \to \mathbb{R}$ analogous to the one of J given by formula (3.3). Given $u \in L^\infty(\Gamma)$ we consider the adjoint state $\phi_h(u) \in Y_{h0}$ solution of the equation

$$\text{(4.3)} \qquad a(w_h, \phi_h(u)) = \int_\Omega \left[\frac{\partial f}{\partial y}(x, y_h(u)) \phi_h(u) + \frac{\partial L}{\partial y}(x, y_h(u)) \right] w_h\, dx \quad \forall w_h \in Y_{h0}.$$

To obtain the analogous expression to (3.3) we have to define a discrete normal derivative $\partial_\nu^h \phi_h(u)$.

PROPOSITION 4.2. *Let u belong to $L^\infty(\Gamma)$ and let $\phi_h(u)$ be the solution of* (4.3). *There exists a unique element $\partial^h_\nu \phi_h(u) \in U_h$ verifying*

$$
\begin{aligned}
&(\partial^h_\nu \phi_h(u), w_h)_{L^2(\Gamma)} = a(w_h, \phi_h(u)) \\
&- \int_\Omega \left[\frac{\partial f}{\partial y}(x, y_h(u))\phi_h(u) + \frac{\partial L}{\partial y}(x, y_h(u)) \right] w_h \, dx \quad \forall w_h \in Y_h.
\end{aligned} \tag{4.4}
$$

Proof. The trace mapping is a surjective mapping from Y_h on U_h; therefore the linear form

$$
L(w_h) = a(w_h, \phi_h(u)) - \int_\Omega \left[\frac{\partial f}{\partial y}(x, y_h(u))\phi_h(u) + \frac{\partial L}{\partial y}(x, y_h(u)) \right] w_h \, dx
$$

is well defined on U_h, and it is continuous on U_h. Let us remark that if in (4.4) the trace of w_h on Γ is zero, then (4.3) leads to

$$
L(w_h) = 0.
$$

Hence L can be identified with a unique element of U_h, which proves the above proposition. □

Now the function G introduced in Theorem 3.1 is approximated by the function $G_h : L^\infty(\Gamma) \longmapsto Y_h$ defined by $G_h(u) = y_h(u)$. We can easily verify that G_h is of class C^2 and that for $u, v \in L^\infty(\Gamma)$, the derivative $z_h = G_h'(u)v \in Y_h$ is the unique solution of

$$
\begin{cases}
a(z_h, w_h) = \displaystyle\int_\Omega \frac{\partial f}{\partial y}(x, y_h(u)) z_h w_h \, dx, \quad \forall w_h \in Y_{h0}, \\
z_h = \Pi_h v \quad \text{on } \Gamma.
\end{cases} \tag{4.5}
$$

From here we deduce

$$
J_h'(u)v = \int_\Omega \frac{\partial L}{\partial y}(x, y_h(u)) z_h \, dx + N \int_\Gamma uv \, dx.
$$

Now (4.4) and the definition of Π_h lead to

$$
J_h'(u)v = N \int_\Gamma uv \, dx - \int_\Gamma \partial^h_\nu \phi_h(u) \Pi_h v \, dx = \int_\Gamma (Nu - \partial^h_\nu \phi_h(u)) v \, dx \tag{4.6}
$$

for all $u, v \in L^\infty(\Gamma)$.

Finally, we can write the first order optimality conditions.

THEOREM 4.3. *Let us assume that $\bar u_h$ is a local solution of* (P_h) *and $\bar y_h$ the corresponding state; then there exists $\bar\phi_h \in Y_{h0}$ such that*

$$
a(w_h, \bar\phi_h) = \int_\Omega \left[\frac{\partial f}{\partial y}(x, \bar y_h)\bar\phi_h + \frac{\partial L}{\partial y}(x, \bar y_h) \right] w_h \, dx \quad \forall w_h \in Y_{h0} \tag{4.7}
$$

and

$$
\int_\Gamma (N\bar u_h - \partial^h_\nu \bar\phi_h)(u_h - \bar u_h) \, dx \geq 0 \quad \forall u_h \in U_h^{ad}. \tag{4.8}
$$

This theorem follows readily from (4.6).

Remark 4.4. The reader could think that a projection property for $\bar{u}_h$ similar to that obtained for $\bar{u}$ in (3.8) can be deduced from (4.8). Unfortunately this property does not hold because $u_h(x)$ cannot be taken arbitrarily in $[\alpha, \beta]$. Functions $u_h \in U_h$ are determined by their values at the nodes $\{x_\Gamma^j\}_{j=1}^{N(h)}$. If we consider the basis of U_h $\{e_j\}_{j=1}^{N(h)}$ defined by $e_j(x_\Gamma^i) = \delta_{ij}$, then we have

$$u_h = \sum_{j=1}^{N(h)} u_{h,j} e_j \quad \text{with} \quad u_{h,j} = u_h(x_\Gamma^j), \quad 1 \le j \le N(h).$$

Now (4.8) can be written

$$\sum_{j=1}^{N(h)} \int_\Gamma (N\bar{u}_h - \partial_\nu^h \bar{\phi}_h) e_j \, dx (u_{h,j} - \bar{u}_{h,j}) \ge 0, \quad \forall \{u_{h,j}\}_{j=1}^{N(h)} \subset [\alpha, \beta], \tag{4.9}$$

where $\bar{u}_{h,j} = \bar{u}_h(x_\Gamma^j)$. Then (4.9) leads to

$$\bar{u}_{h,j} = \begin{cases} \alpha & \text{if} \quad \int_\Gamma (N\bar{u}_h - \partial_\nu^h \bar{\phi}_h) e_j \, dx > 0, \\ \beta & \text{if} \quad \int_\Gamma (N\bar{u}_h - \partial_\nu^h \bar{\phi}_h) e_j \, dx < 0. \end{cases} \tag{4.10}$$

In order to characterize $\bar{u}_h$ as the projection of $\partial_\nu^h \bar{\phi}_h / N$, let us introduce the operator $\mathrm{Proj}_h : L^2(\Gamma) \longmapsto U_h^{ad}$ as follows. Given $u \in L^2(\Gamma)$, $\mathrm{Proj}_h u$ denotes the unique solution of the problem

$$\inf_{v_h \in U_h^{ad}} \|u - v_h\|_{L^2(\Gamma)},$$

which is characterized by the relation

$$\int_\Gamma (u(x) - \mathrm{Proj}_h u(x))(v_h(x) - \mathrm{Proj}_h u(x)) \, dx \le 0 \quad \forall v_h \in U_h^{ad}. \tag{4.11}$$

Then (4.8) is equivalent to

$$\bar{u}_h = \mathrm{Proj}_h \left(\frac{1}{N} \partial_\nu^h \bar{\phi}_h \right). \tag{4.12}$$

Let us recall the result in [13, Lemma 3.3], where a characterization of $\mathrm{Proj}_h(u_h)$ is stated. Given $u_h \in U_h$ and $\bar{u}_h = \mathrm{Proj}_h(u_h)$, $\bar{u}_h$ is then characterized by the inequalities

$$\begin{aligned} &h_{j-1}[(u_{h,j-1} - \bar{u}_{h,j-1}) + 2(u_{h,j} - \bar{u}_{h,j})](t - \bar{u}_{h,j}) \\ &\quad + h_j[2(u_{h,j} - \bar{u}_{h,j}) + (u_{h,j+1} - \bar{u}_{h,j+1})](t - \bar{u}_{h,j}) \le 0 \end{aligned}$$

for all $t \in [\alpha, \beta]$ and $1 \le j \le N(h)$.

5. Numerical analysis of the state and adjoint equations. Throughout the following, the operator $I_h \in \mathcal{L}(W^{1,p}(\Omega), Y_h)$ denotes the classical interpolation operator [6]. We also need the interpolation operator $I_h^\Gamma \in \mathcal{L}(W^{1-1/p,p}(\Gamma), U_h)$. Since we have

$$I_h^\Gamma(y|_\Gamma) = (I_h y)|_\Gamma, \quad \forall y \in W^{1,p}(\Omega),$$

we shall use the same notation for both interpolation operators. The reader can observe that this abuse of notation does not lead to any confusion.

The goal of this section is to obtain the error estimates of the approximations $y_h(u)$ given by (4.2) to the solution y_u of (2.1). In order to carry out this analysis we decompose (2.1) into two problems, as in the proof of Theorem 2.3. We take $z \in H^{1/2}(\Omega) \cap L^\infty(\Omega)$ and $\zeta \in H_0^1(\Omega) \cap H^2(\Omega)$ as the solutions of (2.6) and (2.7), respectively. Then we have $y_u = z + \zeta$.

Let us consider now the discretizations of (2.6) and (2.7):

$$\begin{cases} \text{Find } z_h \in \ Y_h \text{ such that } \ z_h = \Pi_h u \text{ on } \Gamma \text{ and} \\ a(z_h, w_h) = 0, \quad \forall w_h \in Y_{h0}, \end{cases} \tag{5.1}$$

and

$$\begin{cases} \text{Find } \zeta_h \in Y_{h0} \text{ such that} \\ a(\zeta_h, w_h) = \displaystyle\int_\Omega g_h(x, \zeta_h(x)) w_h(x)\, dx, \quad \forall w_h \in Y_{h0}, \end{cases} \tag{5.2}$$

where $g_h(x,t) = f(x, z_h(x) + t)$. Now the solution $y_h(u)$ of (4.2) is decomposed as follows: $y_h(u) = z_h + \zeta_h$. The following lemma provides the estimates for $z - z_h$.

LEMMA 5.1. *Let $u \in U^{ad}$, and let z and z_h be the solutions of* (2.6) *and* (5.1), *respectively; then*

$$\|z_h\|_{L^\infty(\Omega)} \le \|\Pi_h u\|_{L^\infty(\Gamma)} \le C(\alpha,\beta) \text{ and } \|z_h\|_{W^{1,r}(\Omega)} \le C\|\Pi_h u\|_{W^{1-1/r,r}(\Gamma)}, \tag{5.3}$$

$$\|z_h\|_{L^2(\Omega)} \le C\|\Pi_h u\|_{H^{-1/2}(\Gamma)}, \tag{5.4}$$

where $1 < r \le p$ is arbitrary, with p being as given in Theorem 3.4. *If, in addition, $u \in H^s(\Gamma) \cap U^{ad}$, with $0 \le s \le 1$, then we also have*

$$\|z - z_h\|_{L^2(\Omega)} \le Ch^{s+1/2}\|u\|_{H^s(\Gamma)} \quad \forall h > 0 \text{ and } 0 \le s \le 1. \tag{5.5}$$

Proof. The first inequality of (5.3) is proved in Ciarlet and Raviart [14]; we have only to notice that

$$\|\Pi_h u\|_{L^\infty(\Gamma)} \le C\|u\|_{L^\infty(\Gamma)} \le C(\alpha,\beta), \tag{5.6}$$

where C is independent of h and $u \in U^{ad}$; see Douglas, Dupont, and Wahlbin [18].

Inequality (5.5) can be found in French and King [20, Lemma 3.3] by just taking into account that

$$\|z\|_{H^{s+1/2}(\Omega)} \le C\|u\|_{H^s(\Gamma)}.$$

The second inequality of (5.3) is established in Bramble, Pasciak, and Schatz [5, Lemma 3.2] for $r = 2$. Let us prove it for all r in the range $(1, p]$. Let us consider the $z^h \in H^1(\Omega)$ solution of the problem

$$-\Delta z^h = 0 \quad \text{in } \Omega, \qquad z^h = \Pi_h u \quad \text{on } \Gamma.$$

This is a standard Dirichlet problem with the property (see Dauge [15])

$$\|z^h\|_{W^{1,r}(\Omega)} \le C\|\Pi_h u\|_{W^{1-1/r,r}(\Gamma)}.$$

Let us denote by $\hat{I}_h : W^{1,r}(\Omega) \longmapsto Y_h$ the generalized interpolation operator, due to Scott and Zhang [35], that preserves piecewise-affine boundary conditions. More

precisely, it has the properties $\hat{I}_h(y_h) = y_h$ for all $y_h \in Y_h$ and $\hat{I}_h(W_0^{1,r}(\Omega)) \subset Y_{h0}$. These properties imply that $\hat{I}_h(z^h) = \Pi_h u$ on Γ. Thus we have

$$-\Delta(z^h - \hat{I}_h(z^h)) = \Delta \hat{I}_h(z^h) \quad \text{in } \Omega, \qquad z^h - \hat{I}_h(z^h) = 0 \quad \text{on } \Gamma,$$

and $z_h - \hat{I}_h(z^h) \in Y_{h0}$ satisfies

$$a(z_h - \hat{I}_h(z^h), w_h) = -a(\hat{I}_h(z^h), w_h) \ \ \forall w_h \in Y_{h0}.$$

Then by using the L^p estimates (see, for instance, Brenner and Scott [6, Theorem 7.5.3]), we get

$$\begin{aligned}&\|z_h - \hat{I}_h(z^h)\|_{W^{1,r}(\Omega)} \le C\|z^h - \hat{I}_h(z^h)\|_{W^{1,r}(\Omega)}\\ &\le C(\|z^h\|_{W^{1,r}(\Omega)} + \|\hat{I}_h(z^h)\|_{W^{1,r}(\Omega)}) \le C\|z^h\|_{W^{1,r}(\Omega)} \le C\|\Pi_h u\|_{W^{1-1/r,r}(\Gamma)}.\end{aligned}$$

Then we conclude the proof as follows:

$$\|z_h\|_{W^{1,r}(\Omega)} \le \|\hat{I}_h(z^h)\|_{W^{1,r}(\Omega)} + \|z_h - \hat{I}_h(z^h)\|_{W^{1,r}(\Omega)} \le C\|\Pi_h u\|_{W^{1-1/r,r}(\Gamma)}.$$

Finally, let us prove (5.4). Using (5.5) with $s = 0$, (2.4), and an inverse inequality, we get

$$\begin{aligned}&\|z_h\|_{L^2(\Omega)} \le \|z^h - z_h\|_{L^2(\Omega)} + \|z^h\|_{L^2(\Omega)}\\ &\le C(h^{1/2}\|\Pi_h u\|_{L^2(\Gamma)} + \|\Pi_h u\|_{H^{-1/2}(\Gamma)}) \le C\|\Pi_h u\|_{H^{-1/2}(\Gamma)}. \qquad \square\end{aligned}$$

Remark 5.2. The inverse estimate used in the proof,

$$\|u\|_{L^2(\Gamma)} \le Ch^{-1/2}\|u\|_{H^{-1/2}(\Gamma)}, \quad \forall u \in U_h,$$

can be derived from the well-known inverse estimate [3],

$$\|u\|_{H^{1/2}(\Gamma)} \le Ch^{-1/2}\|u\|_{L^2(\Gamma)}, \quad \forall u \in U_h,$$

and from the equality

$$\|u\|^2_{L^2(\Gamma)} = \|u\|_{H^{1/2}(\Gamma)}\|u\|_{H^{-1/2}(\Gamma)}.$$

Now we obtain the estimates for $\zeta - \zeta_h$.

LEMMA 5.3. *There exist constants $C_i = C_i(\alpha, \beta) > 0$ $(i = 1, 2)$ such that, for all $u \in U^{ad} \in H^s(\Gamma)$, the following estimates hold:*

$$\|\zeta_h\|_{L^\infty(\Omega)} \le C_1, \quad \forall h > 0 \text{ and } s = 0, \tag{5.7}$$

$$\|\zeta - \zeta_h\|_{L^2(\Omega)} \le C_2 h^{s+1/2}(1 + \|u\|_{H^s(\Gamma)}), \quad \forall h > 0 \text{ and } 0 \le s \le 1, \tag{5.8}$$

where ζ and ζ_h are the solutions of (2.7) *and* (5.2)*, respectively.*

Proof. We are going to introduce an intermediate function $\zeta^h \in H^2(\Omega)$ satisfying

$$-\Delta\zeta^h = g_h(x, \zeta^h(x)) \quad \text{in } \Omega, \qquad \zeta^h = 0 \quad \text{on } \Gamma. \tag{5.9}$$

By using classical methods (see for instance Stampacchia [34]), we get the boundedness of ζ and ζ^h in $L^\infty(\Omega)$ for some constants depending on $\|u\|_{L^\infty(\Gamma)}$ and $\|\Pi_h u\|_{L^\infty(\Gamma)}$,

which are uniformly estimated by a constant depending only on α and β; see (5.6). On the other hand, from (2.7), (5.9), and assumption (A2), we deduce

$$
\begin{aligned}
&C_1\|\zeta-\zeta^h\|^2_{H^1(\Omega)} \le a(\zeta-\zeta^h,\zeta-\zeta^h)\\
&= \int_\Omega [g(x,\zeta(x)) - g_h(x,\zeta^h(x))](\zeta(x)-\zeta^h(x))\,dx\\
&= \int_\Omega [g(x,\zeta(x)) - g(x,\zeta^h(x))](\zeta(x)-\zeta^h(x))\,dx\\
&\quad + \int_\Omega [g(x,\zeta^h(x)) - g_h(x,\zeta^h(x))](\zeta(x)-\zeta^h(x))\,dx\\
&\le \int_\Omega [g(x,\zeta^h(x)) - g_h(x,\zeta^h(x))](\zeta(x)-\zeta^h(x))\,dx \le C_2\|z-z_h\|_{L^2(\Omega)}\|\zeta-\zeta^h\|_{L^2(\Omega)}\\
&\le C_3\|z-z_h\|^2_{L^2(\Omega)} + \frac{C_1}{2}\|\zeta-\zeta^h\|^2_{L^2(\Omega)}.
\end{aligned}
$$

This inequality, along with (5.5), implies

$$
\|\zeta-\zeta^h\|_{H^1(\Omega)} \le Ch^{s+1/2}\|u\|_{H^s(\Gamma)}. \tag{5.10}
$$

Thanks to the convexity of Ω, ζ^h belongs to $H^2(\Omega)$ (see Grisvard [22]) and

$$
\|\zeta^h\|_{H^2(\Omega)} \le C\|g_h(x,\zeta^h)\|_{L^2(\Omega)} = C(\|u\|_{L^\infty(\Gamma)}, \|\Pi_h u\|_{L^\infty(\Gamma)}).
$$

Now using the results of Casas and Mateos [10, Lemma 4 and Theorem 1] we deduce that

$$
\|\zeta^h-\zeta_h\|_{L^2(\Omega)} \le Ch^2, \tag{5.11}
$$

$$
\|\zeta^h-\zeta_h\|_{L^\infty(\Omega)} \le Ch. \tag{5.12}
$$

Finally (5.8) follows from (5.10) and (5.11), and (5.7) is a consequence of the boundedness of $\{\zeta^h\}_{h>0}$ and (5.12). ∎

THEOREM 5.4. *There exist constants $C_i = C_i(\alpha,\beta) > 0$ $(i=1,2)$ such that for every $u \in U^{ad} \cap H^s(\Gamma)$, with $0 \le s \le 1$, the following inequalities hold:*

$$
\|y_h(u)\|_{L^\infty(\Omega)} \le C_1, \quad \forall h>0 \text{ and } s=0, \tag{5.13}
$$

$$
\|y_u - y_h(u)\|_{L^2(\Omega)} \le C_2 h^{s+1/2}(1+\|u\|_{H^s(\Gamma)}) \quad \forall h>0 \text{ and } 0\le s\le 1. \tag{5.14}
$$

Furthermore if $u_h \rightharpoonup u$ weakly in $L^2(\Gamma)$, $\{u_h\}_{h>0} \subset U^{ad}$, then $y_h(u_h) \to y_u$ strongly in $L^r(\Omega)$ for every $r < +\infty$.

Proof. Remembering that $y_u = z+\zeta$ and $y_h(u) = z_h+\zeta_h$, we see that (5.3), (5.5), (5.7), and (5.8) lead readily to inequalities (5.13) and (5.14). To prove the last part of the theorem, it is enough to use Theorem 2.2 and (5.14) with $s=0$ as follows:

$$
\|y_u - y_h(u_h)\|_{L^2(\Omega)} \le \|y_u - y_{u_h}\|_{L^2(\Omega)} + \|y_{u_h} - y_h(u_h)\|_{L^2(\Omega)} \longrightarrow 0 \quad \text{as } h \longrightarrow 0.
$$

The convergence in $L^r(\Omega)$ follows from (5.13). ∎

COROLLARY 5.5. *There exists a constant $C = C(\alpha,\beta) > 0$ such that, for all $u \in U^{ad}$ and $v \in U^{ad} \cap H^s(\Gamma)$, with $0 \le s \le 1$, we have*

$$
\|y_u - y_h(v)\|_{L^2(\Omega)} \le C\big\{\|u-v\|_{L^2(\Gamma)} + h^{s+1/2}(1+\|v\|_{H^s(\Gamma)})\big\}. \tag{5.15}
$$

This corollary is an immediate consequence of the second estimate in (2.5) and of (5.14).

Let us finish this section by establishing some estimates for the adjoint states.

THEOREM 5.6. *Given $u, v \in U^{ad}$, let ϕ_u and $\phi_h(v)$ be the solutions of* (3.5) *and* (4.3) *with u replaced by v in the last equation. Then there exist some constants $C_i = C_i(\alpha, \beta) > 0$ $(1 \le i \le 3)$ such that*

$$\|\phi_h(v)\|_{L^\infty(\Omega)} \le C_1 \quad \forall h > 0, \tag{5.16}$$

$$\|\phi_u - \phi_h(v)\|_{L^2(\Omega)} \le C_2(\|u - v\|_{L^2(\Gamma)} + h^2), \tag{5.17}$$

$$\|\phi_u - \phi_h(v)\|_{L^\infty(\Omega)} + \|\phi_u - \phi_h(v)\|_{H^1(\Omega)} \le C_3(\|u - v\|_{L^2(\Gamma)} + h). \tag{5.18}$$

Proof. All the inequalities follow from the results of Casas and Mateos [10] just by taking into account that

$$\|\phi_u - \phi_h(v)\|_X \le \|\phi_u - \phi_v\|_X + \|\phi_v - \phi_h(v)\|_X \le C(\|y_u - y_v\|_{L^2(\Omega)} + \|\phi_v - \phi_h(v)\|_X),$$

with X equal to $L^\infty(\Omega)$, $L^2(\Omega)$, and $H^1(\Omega)$, respectively. ∎

Now we provide an error estimate for the discrete normal derivative of the adjoint state defined by Proposition 4.2.

THEOREM 5.7. *There exists a constant $C = C(\alpha, \beta) > 0$ such that the following estimate holds:*

$$\|\partial_\nu \phi_u - \partial_\nu^h \phi_h(u)\|_{L^2(\Gamma)} \le \begin{cases} Ch^{1/2} & \forall u \in U^{ad}, \\ C(\|u\|_{H^{1/2}(\Gamma)} + 1)h^{1-1/p} & \forall u \in U^{ad} \cap H^{1/2}(\Gamma). \end{cases} \tag{5.19}$$

Proof. First, let us remember that $\phi_u \in H^2(\Omega)$ and therefore $\partial_\nu \phi_u \in H^{1/2}(\Gamma)$. Observe that the definition of the projection operator Π_h leads to

$$\int_\Gamma \left|\partial_\nu \phi_u - \partial_\nu^h \phi_h(u)\right|^2 = \int_\Gamma \left|\partial_\nu \phi_u - \Pi_h \partial_\nu \phi_u\right|^2 + \int_\Gamma \left|\Pi_h \partial_\nu \phi_u - \partial_\nu^h \phi_h(u)\right|^2 = I_1 + I_2.$$

Since $\partial_\nu^h \phi_h(u)$ belongs to U_h, we can write

$$I_2 = \int_\Gamma (\partial_\nu \phi_u - \partial_\nu^h \phi_h(u))(\Pi_h \partial_\nu \phi_u - \partial_\nu^h \phi_h(u)).$$

Let us introduce $z_h \in Y_h$ as the solution to the variational equation

$$\begin{cases} a(z_h, w_h) = 0 & \forall w_h \in Y_{h0}, \\ z_h = \Pi_h \partial_\nu \phi_u - \partial_\nu^h \phi_h(u) & \text{on } \Gamma. \end{cases}$$

From (5.3) it follows that

$$\|z_h\|_{H^1(\Omega)} \le C\|\Pi_h \partial_\nu \phi_u - \partial_\nu^h \phi_h(u)\|_{H^{1/2}(\Gamma)}. \tag{5.20}$$

Now using the definition of $\partial_\nu^h \phi_h(u)$ stated in Proposition 4.2 and a Green formula for ϕ_u, we can write

$$\begin{aligned} I_2 = a(z_h, \phi_u - \phi_h(u)) &+ \int_\Omega \left(\frac{\partial f}{\partial y}(x, y_h(u))\phi_h(u) - \frac{\partial f}{\partial y}(x, y_u)\phi_u\right) z_h \\ &+ \int_\Omega \left(\frac{\partial L}{\partial y}(x, y_h(u)) - \frac{\partial L}{\partial y}(x, y_u)\right) z_h. \end{aligned} \tag{5.21}$$

Due to the equation satisfied by z_h,

$$a(z_h, I_h\phi_u) = a(z_h, \phi_h(u)) = 0,$$

we also have

(5.22)
$$I_2 = a(z_h, \phi_u - I_h\phi_u) + \int_\Omega \left(\frac{\partial f}{\partial y}(x, y_h(u)) - \frac{\partial f}{\partial y}(x, y_u)\right)\phi_u z_h + \int_\Omega \frac{\partial f}{\partial y}(x, y_h(u))(\phi_h(u) - \phi_u)z_h + \int_\Omega \left(\frac{\partial L}{\partial y}(x, y_h(u)) - \frac{\partial L}{\partial y}(x, y_u)\right)z_h.$$

From well-known interpolation estimates, the second inequality of (5.3), and an inverse inequality, it follows that

$$\begin{aligned} &a(z_h, \phi_u - I_h\phi_u) \le \|z_h\|_{W^{1,p'}(\Omega)}\|\phi_u - I_h\phi_u\|_{W^{1,p}(\Omega)} \\ &\le Ch\|\phi_u\|_{W^{2,p}(\Omega)}\|z_h|_\Gamma\|_{W^{1-1/p',p'}(\Gamma)} \le Ch\|z_h|_\Gamma\|_{H^{1-1/p'}(\Gamma)} \\ &\le Ch^{1/p'}\|z_h|_\Gamma\|_{L^2(\Gamma)} = Ch^{1/p'}\sqrt{I_2}, \end{aligned} \tag{5.23}$$

where $p' = p/(p-1)$.

From assumptions (A1) and (A2) and inequalities (5.13), (5.14) with $s = 0$, (5.16), and (5.17), we get

$$\left|\int_\Omega \left(\frac{\partial f}{\partial y}(x, y_h(u)) - \frac{\partial f}{\partial y}(x, y_u)\right)\phi_u z_h\right| \le Ch^{1/2}\|z_h\|_{L^2(\Omega)}, \tag{5.24}$$

$$\begin{aligned} &\left|\int_\Omega \frac{\partial f}{\partial y}(x, y_h(u))(\phi_h(u) - \phi_u)z_h\right| \le C\|\phi_h(u) - \phi_u\|_{L^2(\Omega)}\|z_h\|_{L^2(\Omega)} \\ &\le Ch^2\|z_h\|_{L^2(\Omega)}, \end{aligned} \tag{5.25}$$

and

$$\left|\int_\Omega \left(\frac{\partial L}{\partial y}(x, y_h(u)) - \frac{\partial L}{\partial y}(x, y_u)\right)z_h\right| \le Ch^{1/2}\|z_h\|_{L^2(\Omega)}. \tag{5.26}$$

Collecting together the estimates (5.23)–(5.26) and using (5.20) and the fact that $p' < 2$, we obtain

$$\begin{aligned} I_2 &\le Ch^{1/p'}\sqrt{I_2} + Ch^{1/2}\|z_h\|_{L^2(\Omega)} \\ &\le C(h^{1/p'}\sqrt{I_2} + h^{1/2}\|\Pi_h\partial_\nu\phi_u - \partial_\nu^h\phi_h(u)\|_{L^2(\Gamma)}) \le Ch^{1/2}\sqrt{I_2}, \end{aligned} \tag{5.27}$$

which implies that

$$I_2 \le Ch. \tag{5.28}$$

Using again that $\phi_u \in W^{2,p}(\Omega)$, we get that $\partial_\nu\phi_u \in W^{1-1/p,p}(\Gamma) \subset H^{1-1/p}(\Gamma)$. Hence from (4.1) with $s = 1 - 1/p$, we can derive

$$I_1 \le Ch\|\partial_\nu\phi_u\|^2_{H^{1/2}(\Gamma)} \le Ch\|\phi_u\|^2_{H^2(\Omega)} \le Ch^{2(1-1/p)}. \tag{5.29}$$

So the first estimate in (5.19) is proved.

To complete the proof let us assume that $u \in H^{1/2}(\Gamma)$; then we can use (5.14) with $s = 1/2$ to estimate $y_u - y_h(u)$ in $L^2(\Omega)$ by Ch. This allows us to change $h^{1/2}$ in (5.24) and (5.26) by h. Therefore (5.27) can be replaced with $I_2 \le Ch^{1/p'} = Ch^{1-1/p}$; thus $I_2 \le Ch^{2(1-1/p)}$. So the second estimate in (5.19) is proved. ∎

COROLLARY 5.8. *There exists a constant C independent of h such that*

$$\begin{cases} \|\partial_\nu^h \phi_h(u)\|_{H^{1/2}(\Gamma)} \le C \quad \forall u \in U^{ad}, \\ \|\partial_\nu^h \phi_h(u)\|_{W^{1-1/p,p}(\Gamma)} \le C(\|u\|_{H^{1/2}(\Gamma)} + 1) \quad \forall u \in U^{ad} \cap H^{1/2}(\Gamma), \\ \|\partial_\nu \phi_u - \partial_\nu^h \phi_h(v)\|_{L^2(\Gamma)} \le C\left\{\|u - v\|_{L^2(\Gamma)} + h^\kappa\right\} \quad \forall u, v \in U^{ad}, \end{cases} \tag{5.30}$$

where $\kappa = 1 - 1/p$ if $v \in H^{1/2}(\Gamma)$ and $\kappa = 1/2$ otherwise.

Proof. Let us make the proof in the case when $u \in U^{ad} \cap H^{1/2}(\Gamma)$. The case when $u \in U^{ad}$ can be treated similarly. We know that

$$\|\partial_\nu \phi_u\|_{W^{1-1/p,p}(\Gamma)} \le C\|\phi_u\|_{W^{2,p}(\Omega)} \le C \quad \forall u \in U^{ad}.$$

On the other hand, the projection operator Π_h is stable in the Sobolev spaces $W^{s,q}(\Gamma)$, for $1 \le q \le \infty$ and $0 \le s \le 1$ (see Casas and Raymond [13]); therefore

$$\|\Pi_h \partial_\nu \phi_u\|_{W^{1-1/p,p}(\Gamma)} \le C\|\partial_\nu \phi_u\|_{W^{1-1/p,p}(\Gamma)}.$$

Finally, with an inverse inequality and the estimate $I_2 \le Ch^{2-2/p}$ obtained in the previous proof, we deduce

$$\begin{aligned} &\|\partial_\nu^h \phi_h(u)\|_{W^{1-1/p,p}(\Gamma)} \le \|\Pi_h \partial_\nu \phi_u - \partial_\nu^h \phi_h(u)\|_{W^{1-1/p,p}(\Gamma)} + \|\Pi_h \partial_\nu \phi_u\|_{W^{1-1/p,p}(\Gamma)} \\ &\le C\|\Pi_h \partial_\nu \phi_u - \partial_\nu^h \phi_h(u)\|_{H^{1-1/p}(\Gamma)} + \|\Pi_h \partial_\nu \phi_u\|_{W^{1-1/p,p}(\Gamma)} \\ &\le Ch^{-1+1/p}\|\Pi_h \partial_\nu \phi_u - \partial_\nu^h \phi_h(u)\|_{L^2(\Gamma)} + \|\partial_\nu \phi_u\|_{W^{1-1/p,p}(\Gamma)} \le C. \end{aligned}$$

The third inequality of (5.30) is an immediate consequence of Theorem 5.7. ∎

6. Convergence analysis for (P_h). In this section we will prove the strong convergence in $L^2(\Gamma)$ of the solutions $\bar u_h$ of discrete problems (P_h) to the solutions of (P). Moreover, we will first prove that $\{\bar u_h\}_h$ remains bounded in $H^{1/2}(\Gamma)$, and then that it is also bounded in $W^{1-1/p,p}(\Gamma)$. Finally, we will prove the strong convergence of the solutions $\bar u_h$ of discrete problems (P_h) to the solutions of (P) in $C(\Gamma)$.

THEOREM 6.1. *For every $h > 0$ let $\bar u_h$ be a global solution of problem (P_h). Then there exist weakly*-converging subsequences of $\{\bar u_h\}_{h>0}$ in $L^\infty(\Gamma)$ (still indexed by h). If the subsequence $\{\bar u_h\}_{h>0}$ is converging weakly* in $L^\infty(\Gamma)$ to some $\bar u$, then $\bar u$ is a solution of* (P),

$$\lim_{h\to 0} J_h(\bar u_h) = J(\bar u) = \inf(P) \quad \textit{and} \quad \lim_{h\to 0} \|\bar u - \bar u_h\|_{L^2(\Gamma)} = 0. \tag{6.1}$$

Proof. Since $U_h^{ad} \subset U^{ad}$ holds for every $h > 0$ and U^{ad} is bounded in $L^\infty(\Gamma)$, $\{\bar u_h\}_{h>0}$ is also bounded in $L^\infty(\Gamma)$. Therefore, there exist weakly*-converging subsequences as claimed in the statement of the theorem. Let $\{\bar u_h\}$ be one of these subsequences and let $\bar u$ be the weak* limit. It is obvious that $\bar u \in U^{ad}$. Let us prove that $\bar u$ is a solution of (P). Let us take a solution of (P), $\tilde u \in U^{ad}$; therefore $\tilde u \in W^{1-1/p,p}(\Gamma)$ for some $p > 2$; see Theorem 3.4. Let us take $u_h = I_h \tilde u$. Then

$u_h \in U_h^{ad}$ and $\{u_h\}_h$ tends to $\tilde{u}$ in $L^\infty(\Gamma)$; see Brenner and Scott [6]. By taking $u = \tilde{u}$, $v = u_h$, and $s = 0$ in (5.15) we deduce that $y_h(u_h) \to y_{\tilde{u}}$ in $L^2(\Omega)$. Moreover, (5.13) implies that $\{y_h(u_h)\}_{h>0}$ is bounded in $L^\infty(\Omega)$. On the other hand, Theorem 5.4 implies that $\bar{y}_h = y_h(\bar{u}_h) \to \bar{y} = y_{\bar{u}}$ strongly in $L^2(\Omega)$, and $\{\bar{y}_h\}_{h>0}$ is also bounded in $L^\infty(\Omega)$. Then we have

$$J(\bar{u}) \le \liminf_{h\to 0} J_h(\bar{u}_h) \le \limsup_{h\to 0} J_h(\bar{u}_h) \le \limsup_{h\to 0} J_h(I_h\tilde{u}) = J(\tilde{u}) = \inf(P).$$

This proves that $\bar{u}$ is a solution of (P) as well as the convergence of the optimal costs, which leads to $\|\bar{u}_h\|_{L^2(\Gamma)} \longrightarrow \|\bar{u}\|_{L^2(\Gamma)}$; hence we deduce the strong convergence of the controls in $L^2(\Gamma)$. □

THEOREM 6.2. *Let $p > 2$ be as in Theorem* 3.4*, and for every h let $\bar{u}_h$ denote a local solution of* (P_h)*. Then there exists a constant $C > 0$ independent of h such that*

$$\|\bar{u}_h\|_{W^{1-1/p,p}(\Gamma)} \le C \quad \forall h > 0. \tag{6.2}$$

Moreover, the convergence of $\{\bar{u}_h\}_{h>0}$ to $\bar{u}$ stated in Theorem 6.1 *holds in $C(\Gamma)$.*

Proof. By using the stability in $H^{1/2}(\Gamma)$ of the $L^2(\Gamma)$-projections on the sets U_h^{ad} (see Casas and Raymond [13]) along with (4.12) and the first inequality of (5.30), we get that $\{\bar{u}_h\}_{h>0}$ is uniformly bounded in $H^{1/2}(\Gamma)$. Using now the second inequality of (5.30) and the stability of Π_h in $W^{1-1/p,p}(\Gamma)$, we deduce (6.2). Finally, the convergence is a consequence of the compactness of the imbedding $W^{1-1/p,p}(\Gamma) \subset C(\Gamma)$ for $p > 2$. □

7. Error estimates. The goal in this section is to prove the following theorem.

THEOREM 7.1. *Let us assume that $\bar{u}$ is a local solution of* (P) *satisfying the sufficient second order optimality conditions provided in Theorem* 3.5*, and let $\bar{u}_h$ be a local solution of* (P_h) *such that $\bar{u}_h \to \bar{u}$ in $L^2(\Gamma)$; see Theorem* 6.1*. Then the following inequality holds:*

$$\|\bar{u} - \bar{u}_h\|_{L^2(\Gamma)} \le Ch^{1-1/p}, \tag{7.1}$$

where $p > 2$ is given by Theorem 3.4*.*

We will prove the theorem arguing by contradiction. The statement of the theorem can be stated as follows. There exists a positive constant C such that for all $0 < h < 1/C$, we have

$$\frac{\|\bar{u} - \bar{u}_h\|_{L^2(\Gamma)}}{h^{1-1/p}} \le C.$$

Thus if (7.1) is false, for all $k > 0$, there exists $0 < h_k < 1/k$ such that

$$\frac{\|\bar{u} - \bar{u}_{h_k}\|_{L^2(\Gamma)}}{h_k^{1-1/p}} > k.$$

Therefore there exists a sequence of h such that

$$\lim_{h\to 0} \frac{1}{h^{1-1/p}} \|\bar{u} - \bar{u}_h\|_{L^2(\Gamma)} = +\infty. \tag{7.2}$$

We will obtain a contradiction for this sequence. For the proof of this theorem, we need some lemmas.

LEMMA 7.2. *Let us assume that* (7.1) *is false. Let* $\delta > 0$ *as given by Remark* 3.6(2). *Then there exists* $h_0 > 0$ *such that*

$$\frac{1}{2}\min\{\delta, N\}\|\bar{u} - \bar{u}_h\|^2_{L^2(\Gamma)} \le (J'(\bar{u}_h) - J'(\bar{u}))(\bar{u}_h - \bar{u}) \quad \forall h < h_0. \tag{7.3}$$

Proof. Let $\{\bar{u}_h\}_h$ be a sequence satisfying (7.2). By applying the mean value theorem, we get for some $\hat{u}_h = \bar{u} + \theta_h(\bar{u}_h - \bar{u})$,

$$(J'(\bar{u}_h) - J'(\bar{u}))(\bar{u}_h - \bar{u}) = J''(\hat{u}_h)(\bar{u}_h - \bar{u})^2. \tag{7.4}$$

Let us take

$$v_h = \frac{1}{\|\bar{u}_h - \bar{u}\|_{L^2(\Gamma)}}(\bar{u}_h - \bar{u}).$$

Taking a subsequence if necessary, we can assume that $v_h \rightharpoonup v$ in $L^2(\Gamma)$. Let us prove that v belongs to the critical cone $C_{\bar{u}}$ defined in section 3. First, we remark that every v_h satisfies the sign condition (3.9); hence v also does. Let us prove that $v(x) = 0$ if $\bar{d}(x) \neq 0$, with $\bar{d}$ being defined by (3.10). We will use the interpolation operator $I_h \in \mathcal{L}(W^{1-1/p,p}(\Gamma), U_h)$, with $p > 2$ given in Theorem 3.4. Since $\bar{u} \in U^{ad}$, it is obvious that $I_h\bar{u} \in U_h^{ad}$. For any $y \in W^{1,p}(\Omega)$ such that $y|_\Gamma = \bar{u}$, it is clear that $I_h\bar{u}$ is the trace of $I_h y$ (see the beginning of section 5). Now, by using a result of Grisvard [22, Chapter 1], we get

$$\|\bar{u} - I_h\bar{u}\|^p_{L^p(\Gamma)} \le C\left(\varepsilon^{1-1/p}\|y - I_h y\|^p_{W^{1,p}(\Omega)} + \varepsilon^{-1/p}\|y - I_h y\|^p_{L^p(\Omega)}\right)$$

for every $\varepsilon > 0$ and for some constant $C > 0$ independent of ε and y. Setting $\varepsilon = h^p$ and using that (see, for instance, Brenner and Scott [6])

$$\|y - I_h y\|_{L^p(\Omega)} \le C_1 h\|y\|_{W^{1,p}(\Omega)}, \quad \|I_h y\|_{W^{1,p}(\Omega)} \le C_2\|y\|_{W^{1,p}(\Omega)},$$

and

$$\inf_{y|_\Gamma = \bar{u}} \|y\|_{W^{1,p}(\Omega)} \le C_3\|\bar{u}\|_{W^{1-1/p}(\Gamma)},$$

we conclude that

$$\|\bar{u} - I_h\bar{u}\|_{L^2(\Gamma)} \le |\Gamma|^{\frac{p-2}{2p}}\|\bar{u} - I_h\bar{u}\|_{L^p(\Gamma)} \le Ch^{1-1/p}\|\bar{u}\|_{W^{1-1/p,p}(\Gamma)}. \tag{7.5}$$

Let us define

$$\bar{d}_h(x) = N\bar{u}_h(x) - \partial^h_\nu\bar{\phi}_h(x). \tag{7.6}$$

The third inequality of (5.30) implies that $\bar{d}_h \to \bar{d}$ in $L^2(\Gamma)$. Now we have

$$\begin{aligned}\int_\Gamma \bar{d}(x)v(x)\,dx &= \lim_{h\to 0}\int_\Gamma \bar{d}_h(x)v_h(x)\,dx \\ &= \lim_{h\to 0}\frac{1}{\|\bar{u}_h - \bar{u}\|_{L^2(\Gamma)}}\left\{\int_\Gamma \bar{d}_h(I_h\bar{u} - \bar{u})\,dx + \int_\Gamma \bar{d}_h(\bar{u}_h - I_h\bar{u})\,dx\right\}.\end{aligned}$$

From (4.8), (7.2), and (7.5) we deduce

$$\int_\Gamma \bar d(x)v(x)\,dx \le \lim_{h\to 0} \frac{1}{\|\bar u_h-\bar u\|_{L^2(\Gamma)}} \int_\Gamma \bar d_h(x)(I_h\bar u(x)-\bar u(x))\,dx$$
$$\le \lim_{h\to 0} \frac{Ch^{1-1/p}}{\|\bar u_h-\bar u\|_{L^2(\Gamma)}} = 0.$$

Since v satisfies the sign condition (3.9), then $\bar d(x)v(x)\ge 0$; hence the above inequality proves that v is zero whenever $\bar d$ is not, which allows us to conclude that $v\in C_{\bar u}$. Now from the definition of v_h, (3.4), and (3.11) we get

$$\lim_{h\to 0} J''(\hat u_h)v_h^2 = \lim_{h\to 0}\left\{\int_\Omega \left[\frac{\partial^2 L}{\partial y^2}(x,y_{\hat u_h})+\phi_{\hat u_h}\frac{\partial^2 f}{\partial y^2}(x,y_{\hat u_h})\right] z_{v_h}^2\,dx + N\right\}$$
$$= \int_\Omega \left[\frac{\partial^2 L}{\partial y^2}(x,\bar y)+\bar\phi\frac{\partial^2 f}{\partial y^2}(x,\bar y)\right] z_v^2\,dx + N$$
$$= J''(\bar u)v^2 + N(1-\|v\|^2_{L^2(\Gamma)}) \ge N + (\delta - N)\|v\|^2_{L^2(\Gamma)}.$$

Taking into account that $\|v\|_{L^2(\Gamma)}\le 1$, these inequalities lead to

$$\lim_{h\to 0} J''(\hat u_h)v_h^2 \ge \min\{\delta, N\} > 0,$$

which proves the existence of $h_0>0$ such that

$$J''(\hat u_h)v_h^2 \ge \frac{1}{2}\min\{\delta,N\} \quad \forall h<h_0.$$

From this inequality, the definition of v_h, and (7.4) we deduce (7.3). ∎

LEMMA 7.3. *There exists a constant $C>0$ independent of h such that for every $v\in L^\infty(\Gamma)$,*

$$|(J_h'(\bar u_h)-J'(\bar u_h))v| \le Ch^{1-1/p}\|v\|_{L^2(\Gamma)}. \tag{7.7}$$

Proof. From (3.3), (4.6), (7.6), (6.2), and Theorem 5.7 we get

$$(J_h'(\bar u_h)-J'(\bar u_h))v = \int_\Gamma (\partial_\nu\phi_{\bar u_h}-\partial_\nu^h\bar\phi_h)v\,dx \le \|\partial_\nu\phi_{\bar u_h}-\partial_\nu^h\bar\phi_h\|_{L^2(\Gamma)}\|v\|_{L^2(\Gamma)}$$
$$\le C(\|\bar u_h\|_{H^{1/2}(\Gamma)}+1)h^{(1-1/p)}\|v\|_{L^2(\Gamma)} \le Ch^{(1-1/p)}\|v\|_{L^2(\Gamma)}. \quad ∎$$

LEMMA 7.4. *There exists a constant $C>0$ independent of h such that for every $v\in L^\infty(\Gamma)$,*

$$|(J_h'(\bar u_h)-J'(\bar u))v| \le \Big(N\|\bar u-\bar u_h\|_{L^2(\Gamma)}+Ch^{1-1/p}\Big)\|v\|_{L^2(\Gamma)}. \tag{7.8}$$

Proof. Arguing in a way similar to the previous proof, and using (5.30) and (6.2), we have

$$(J_h'(\bar u_h)-J'(\bar u))v = \int_\Gamma \Big(N\bar u_h-\partial_\nu^h\bar\phi_h\Big)\Pi_h v\,dx - \int_\Gamma \Big(N\bar u-\partial_\nu\bar\phi\Big)v\,dx$$
$$= N\int_\Gamma(\bar u_h-\bar u)v\,dx + \int_\Gamma\Big(\partial_\nu\bar\phi-\partial_\nu^h\bar\phi_h\Big)v\,dx$$
$$\le \Big(N\|\bar u_h-\bar u\|_{L^2(\Gamma)}+Ch^{(1-1/p)}\Big)\|v\|_{L^2(\Gamma)}. \quad ∎$$

One key point in the proof of the error estimates is to get a discrete control $u_h \in U_h^{ad}$ that approximates $\bar{u}$ conveniently and satisfies $J'(\bar{u})\bar{u} = J'(\bar{u})u_h$. Let us find such a control. For every $1 \le j \le N(h)$, let us set

$$I_j = \int_{x_\Gamma^{j-1}}^{x_\Gamma^{j+1}} \bar{d}(x)e_j(x)\,dx.$$

Now we define $u_h \in U_h$ with $u_h(x_\Gamma^j) = u_{h,j}$ for every node $x_\Gamma^j \in \Gamma$ by the expression

$$u_{h,j} = \begin{cases} \dfrac{1}{I_j}\displaystyle\int_{x_\Gamma^{j-1}}^{x_\Gamma^{j+1}} \bar{d}(x)\bar{u}(x)e_j(x)\,dx & \text{if } I_j \neq 0, \\ \dfrac{1}{h_{j-1}+h_j}\displaystyle\int_{x_\Gamma^{j-1}}^{x_\Gamma^{j+1}} \bar{u}(x)\,dx & \text{if } I_j = 0. \end{cases} \tag{7.9}$$

Remember that the measure of $[x_\Gamma^{j-1}, x_\Gamma^{j+1}]$ is $h_{j-1}+h_j = |x_\Gamma^j - x_\Gamma^{j-1}| + |x_\Gamma^{j+1} - x_\Gamma^j|$, which coincides with $|x_\Gamma^{j+1} - x_\Gamma^{j-1}|$ if x_Γ^j is not a vertex of Ω.

In the following lemma, we state that the function u_h defined by (7.9) satisfies our requirements.

LEMMA 7.5. *There exists $h_0 > 0$ such that, for every $0 < h < h_0$, the element $u_h \in U_h$ defined by* (7.9) *obeys the following properties:*

1. $u_h \in U_h^{ad}$.
2. $J'(\bar{u})\bar{u} = J'(\bar{u})u_h$.
3. *The approximation property*

$$\|\bar{u} - u_h\|_{L^2(\Gamma)} \le Ch^{1-1/p} \tag{7.10}$$

is fulfilled for some constant $C > 0$ independent of h.

Proof. Since $\bar{u}$ is continuous on Γ, there exists $h_0 > 0$ such that

$$|\bar{u}(\xi_2) - \bar{u}(\xi_1)| \le \frac{\beta - \alpha}{2}, \quad \forall h < h_0, \quad \forall \xi_1, \xi_2 \in [x_\Gamma^{j-1}, x_\Gamma^{j+1}],\ 1 \le j \le N(h),$$

which implies that $\bar{u}$ cannot admit both the values α and β on one segment $[x_\Gamma^{j-1}, x_\Gamma^{j+1}]$ for any $h < h_0$. Hence the sign of $\bar{d}$ on $[x_\Gamma^{j-1}, x_\Gamma^{j+1}]$ must be constant due to (3.7). Therefore, $I_j = 0$ if and only if $\bar{d}(x) = 0$ for all $x \in [x_\Gamma^{j-1}, x_\Gamma^{j+1}]$. Moreover if $I_j \neq 0$, then $\bar{d}(x)/I_j \ge 0$ for every $x \in [x_\Gamma^{j-1}, x_\Gamma^{j+1}]$. As a first consequence of this we get that $\alpha \le u_{h,j} \le \beta$, which means that $u_h \in U_h^{ad}$. On the other hand,

$$J'(\bar{u})u_h = \sum_{j=1}^{N(h)} \int_{x_\Gamma^{j-1}}^{x_\Gamma^{j+1}} \bar{d}(x)e_j(x)\,dx\,u_{h,j} = \sum_{j=1}^{N(h)} \int_{x_\Gamma^{j-1}}^{x_\Gamma^{j+1}} \bar{d}(x)\bar{u}(x)e_j(x)\,dx = J'(\bar{u})\bar{u}.$$

Finally, let us prove (7.10). Let us remember that $\bar{u} \in W^{1-1/p,p}(\Gamma) \subset H^{1-1/p}(\Gamma)$ and $p > 2$. We note that the norm in $H^s(\Gamma)$, $0 < s < 1$, is given by

$$\|u\|_{H^s(\Gamma)} = \left(\|u\|_{L^2(\Gamma)}^2 + \int_\Gamma \int_\Gamma \frac{|u(x) - u(\xi)|^2}{|x - \xi|^{1+2s}}\,dx\,d\xi \right)^{1/2}. \tag{7.11}$$

Using that $\sum_{j=1}^{N(h)} e_j(x) = 1$ and $0 \le e_j(x) \le 1$ we get

$$
\begin{aligned}
\|\bar u - u_h\|^2_{L^2(\Gamma)} &= \int_\Gamma \Big| \sum_{j=1}^{N(h)} (\bar u(x) - u_{h,j}) e_j(x) \Big|^2 \, dx \\
&\le \sum_{j=1}^{N(h)} \int_{x_\Gamma^{j-1}}^{x_\Gamma^{j+1}} |\bar u(x) - u_{h,j}|^2 e_j(x)\, dx \le \sum_{j=1}^{N(h)} \int_{x_\Gamma^{j-1}}^{x_\Gamma^{j+1}} |\bar u(x) - u_{h,j}|^2 \, dx.
\end{aligned} \tag{7.12}
$$

Let us estimate every term of the sum.

Let us start by assuming that $I_j = 0$ so that $u_{h,j}$ is defined by the second relation in (7.9). Then we have

$$
\begin{aligned}
&\int_{x_\Gamma^{j-1}}^{x_\Gamma^{j+1}} |\bar u(x) - u_{h,j}|^2 \, dx = \int_{x_\Gamma^{j-1}}^{x_\Gamma^{j+1}} \Big| \frac{1}{h_{j-1} + h_j} \int_{x_\Gamma^{j-1}}^{x_\Gamma^{j+1}} (\bar u(x) - \bar u(\xi))\, d\xi \Big|^2 \, dx \\
&\le \int_{x_\Gamma^{j-1}}^{x_\Gamma^{j+1}} \frac{1}{h_{j-1} + h_j} \int_{x_\Gamma^{j-1}}^{x_\Gamma^{j+1}} |\bar u(x) - \bar u(\xi)|^2 \, d\xi \, dx \\
&\le (h_{j-1} + h_j)^{2(1-1/p)} \int_{x_\Gamma^{j-1}}^{x_\Gamma^{j+1}} \int_{x_\Gamma^{j-1}}^{x_\Gamma^{j+1}} \frac{|\bar u(x) - \bar u(\xi)|^2}{|x - \xi|^{1+2(1-1/p)}} \, dx \, d\xi \\
&\le (2h)^{2(1-1/p)} \|\bar u\|^2_{H^{1-1/p}(x_\Gamma^{j-1}, x_\Gamma^{j+1})}.
\end{aligned} \tag{7.13}
$$

Now let us consider the case $I_j \ne 0$:

$$
\begin{aligned}
&\int_{x_\Gamma^{j-1}}^{x_\Gamma^{j+1}} |\bar u(x) - u_{h,j}|^2 \, dx = \int_{x_\Gamma^{j-1}}^{x_\Gamma^{j+1}} \Big| \frac{1}{I_j} \int_{x_\Gamma^{j-1}}^{x_\Gamma^{j+1}} \bar d(\xi) e_j(\xi) (\bar u(x) - \bar u(\xi))\, d\xi \Big|^2 \, dx \\
&\le \int_{x_\Gamma^{j-1}}^{x_\Gamma^{j+1}} \Big| \int_{x_\Gamma^{j-1}}^{x_\Gamma^{j+1}} \sqrt{\frac{\bar d(\xi) e_j(\xi)}{I_j}} |\bar u(x) - \bar u(\xi)| \sqrt{\frac{\bar d(\xi) e_j(\xi)}{I_j}}\, d\xi \Big|^2 \, dx \\
&\le \int_{x_\Gamma^{j-1}}^{x_\Gamma^{j+1}} \int_{x_\Gamma^{j-1}}^{x_\Gamma^{j+1}} |\bar u(x) - \bar u(\xi)|^2 \frac{\bar d(\xi) e_j(\xi)}{I_j} \, d\xi \, dx \\
&\le \Big(\int_{x_\Gamma^{j-1}}^{x_\Gamma^{j+1}} \frac{\bar d(\xi) e_j(\xi)}{I_j} \, d\xi \Big) \sup_{\xi \in [x_\Gamma^{j-1}, x_\Gamma^{j+1}]} \int_{x_\Gamma^{j-1}}^{x_\Gamma^{j+1}} |\bar u(x) - \bar u(\xi)|^2 \, dx \\
&= \sup_{\xi \in [x_\Gamma^{j-1}, x_\Gamma^{j+1}]} \int_{x_\Gamma^{j-1}}^{x_\Gamma^{j+1}} |\bar u(x) - \bar u(\xi)|^2 \, dx.
\end{aligned} \tag{7.14}
$$

To obtain the estimate for the last term we are going to use Lemma 7.6 stated below, with

$$
f(\xi) = \int_{x_\Gamma^{j-1}}^{x_\Gamma^{j+1}} |\bar u(x) - \bar u(\xi)|^2 \, dx.
$$

Since $H^{1-1/p}(\Gamma) \subset C^{0,\theta}(\Gamma)$ for $\theta = 1/2 - 1/p$ (see, e.g., [37, Theorem 2.8.1]), it is

easy to check that

$$|f(\xi_2)-f(\xi_1)| \le \int_{x_\Gamma^{j-1}}^{x_\Gamma^{j+1}} \Big|[\bar u(x)-\bar u(\xi_1)]+[\bar u(x)-\bar u(\xi_2)]\Big|\,\Big|\bar u(\xi_2)-\bar u(\xi_1)\Big|\,dx$$
$$\le 2(h_{j-1}+h_j)^{1+2\theta} C_{\theta,p}\|\bar u\|^2_{H^{1-1/p}(x_\Gamma^{j-1},x_\Gamma^{j+1})}.$$

On the other hand, we have

$$\int_{x_\Gamma^{j-1}}^{x_\Gamma^{j+1}} f(\xi)\,d\xi = \int_{x_\Gamma^{j-1}}^{x_\Gamma^{j+1}}\int_{x_\Gamma^{j-1}}^{x_\Gamma^{j+1}} \frac{|\bar u(x)-\bar u(\xi)|^2}{|x-\xi|^{1+2(1-1/p)}}|x-\xi|^{1+2(1-1/p)}\,dx\,d\xi$$
$$\le (h_{j-1}+h_j)^{1+2(1-1/p)}\int_{x_\Gamma^{j-1}}^{x_\Gamma^{j+1}}\int_{x_\Gamma^{j-1}}^{x_\Gamma^{j+1}} \frac{|\bar u(x)-\bar u(\xi)|^2}{|x-\xi|^{1+2(1-1/p)}}\,dx\,d\xi$$
$$\le (h_{j-1}+h_j)^{2+(1-2/p)}\|\bar u\|^2_{H^{1-1/p}(x_\Gamma^{j-1},x_\Gamma^{j+1})}.$$

Then we can apply Lemma 7.6 to the function f, with

$$M=(h_{j-1}+h_j)^{2\theta}\max\{4C_{\theta,p},1\}\|\bar u\|^2_{H^{1-1/p}(x_\Gamma^{j-1},x_\Gamma^{j+1})} \le Ch^{2\theta}\|\bar u\|^2_{H^{1-1/p}(x_\Gamma^{j-1},x_\Gamma^{j+1})},$$

to deduce that

$$f(\xi) \le C\|\bar u\|^2_{H^{1-1/p}(x_\Gamma^{j-1},x_\Gamma^{j+1})}h^{1+2\theta}. \tag{7.15}$$

This inequality, along with (7.14), leads to

$$\int_{x_\Gamma^{j-1}}^{x_\Gamma^{j+1}} |\bar u(x)-u_{h,j}|^2\,dx \le C\|\bar u\|^2_{H^{1-1/p}(x_\Gamma^{j-1},x_\Gamma^{j+1})}h^{1+2\theta} \tag{7.16}$$

in the case when $I_j \neq 0$.

Since

$$\sum_{j=1}^{N(h)} \|\bar u\|^2_{H^{1-1/p}(x_\Gamma^{j-1},x_\Gamma^{j+1})} \le 2\|\bar u\|^2_{H^{1-1/p}(\Gamma)},$$

inequality (7.10) follows from (7.12), (7.13), (7.16), and the fact that $1+2\theta = 2(1-1/p)$. ∎

LEMMA 7.6. *Given $-\infty < a < b < +\infty$ and $f : [a,b] \longmapsto \mathbb{R}^+$, a function satisfying*

$$|f(x_2)-f(x_1)| \le \frac{M}{2}(b-a) \quad \textit{and} \quad \int_a^b f(x)\,dx \le M(b-a)^2,$$

we have that $f(x) \le 2M(b-a)$ for all $x \in [a,b]$.

Proof. We argue by contradiction and we assume that there exists a point $\xi \in [a,b]$ such that $f(\xi) > 2M(b-a)$; then

$$\int_a^b f(x)\,dx = \int_a^b \{[f(x)-f(\xi)]+f(\xi)\}\,dx > -\frac{M}{2}(b-a)^2 + 2M(b-a)^2 = \frac{3M}{2}(b-a)^2,$$

which contradicts the second assumption on f. ∎

Proof of Theorem 7.1. Setting $u = \bar{u}_h$ in (3.7), we get

$$J'(\bar{u})(\bar{u}_h - \bar{u}) = \int_\Gamma \left(N\bar{u} - \partial_\nu \bar{\phi}\right)(\bar{u}_h - \bar{u})\, dx \geq 0. \tag{7.17}$$

From (4.8) with u_h defined by (7.9), it follows that

$$J_h'(\bar{u}_h)(u_h - \bar{u}_h) = \int_\Gamma \left(N\bar{u}_h - \partial_\nu^h \bar{\phi}_h\right)(u_h - \bar{u}_h)\, dx \geq 0$$

and then that

$$J_h'(\bar{u}_h)(\bar{u} - \bar{u}_h) + J_h'(\bar{u}_h)(u_h - \bar{u}) \geq 0. \tag{7.18}$$

By adding (7.17) and (7.18) and using Lemma 7.5(2), we derive

$$(J'(\bar{u}) - J_h'(\bar{u}_h))(\bar{u} - \bar{u}_h) \leq J_h'(\bar{u}_h)(u_h - \bar{u}) = (J_h'(\bar{u}_h) - J'(\bar{u}))(u_h - \bar{u}).$$

For $h < h_0$, this inequality and (7.3) lead to

$$\begin{aligned} &\frac{1}{2}\min\{N, \delta\}\|\bar{u} - \bar{u}_h\|^2_{L^2(\Gamma)} \leq (J'(\bar{u}) - J'(\bar{u}_h))(\bar{u} - \bar{u}_h) \\ &\leq (J_h'(\bar{u}_h) - J'(\bar{u}_h))(\bar{u} - \bar{u}_h) + (J_h'(\bar{u}_h) - J'(\bar{u}))(u_h - \bar{u}). \end{aligned} \tag{7.19}$$

Now from (7.7) and Young's inequality, we obtain

$$\begin{aligned} &|(J_h'(\bar{u}_h) - J'(\bar{u}_h))(\bar{u} - \bar{u}_h)| \leq Ch^{1-1/p}\|\bar{u} - \bar{u}_h\|_{L^2(\Gamma)} \\ &\leq Ch^{2(1-1/p)} + \frac{1}{8}\min\{N, \delta\}\|\bar{u} - \bar{u}_h\|^2_{L^2(\Gamma)}. \end{aligned} \tag{7.20}$$

On the other hand, using again Young's inequality, (7.8), and (7.10), we deduce

$$\begin{aligned} |(J_h'(\bar{u}_h) - J'(\bar{u}))(u_h - \bar{u})| &\leq \left(N\|\bar{u} - \bar{u}_h\|_{L^2(\Gamma)} + Ch^{1-1/p}\right)\|\bar{u} - u_h\|_{L^2(\Gamma)} \\ &\leq \left(N\|\bar{u} - \bar{u}_h\|_{L^2(\Gamma)} + Ch^{1-1/p}\right)h^{1-1/p} \\ &\leq \frac{1}{8}\min\{N, \delta\}\|\bar{u} - \bar{u}_h\|^2_{L^2(\Gamma)} + Ch^{2(1-1/p)}. \end{aligned} \tag{7.21}$$

From (7.19)–(7.21) we get

$$\frac{1}{4}\min\{N, \delta\}\|\bar{u} - \bar{u}_h\|^2_{L^2(\Gamma)} \leq Ch^{2(1-1/p)},$$

which contradicts (7.2). ∎

8. Numerical tests. In this section we present some numerical tests which illustrate our theoretical results. Let Ω be the unit square $(0,1)^2$. Consider

$$y_d(x_1, x_2) = \frac{1}{(x_1^2 + x_2^2)^{1/3}}.$$

We are going to solve the following problem:

$$\text{(P)} \begin{cases} \text{Min } J(u) = \dfrac{1}{2}\displaystyle\int_\Omega (y_u(x) - y_d(x))^2 dx + \frac{1}{2}\int_\Gamma u(x)^2 dx, \\ u \in U_{ad} = \{u \in L^2(\Gamma) :\ -1 \leq u(x) \leq 2 \text{ a.e. } x \in \Gamma\}, \\ -\Delta y_u = 0 \text{ in } \Omega,\ y_u = u \text{ on } \Gamma. \end{cases}$$

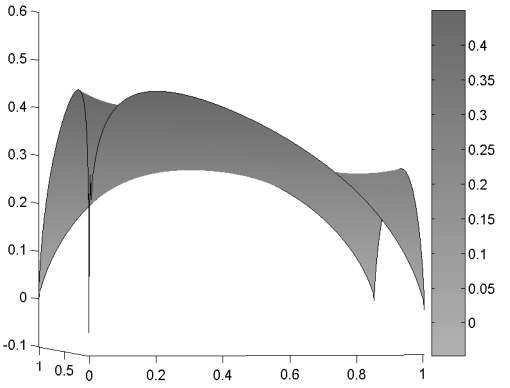

FIG. 8.1.

We remark that $y_d \in L^p(\Omega)$ for all $p < 3$, but $y_d \notin L^3(\Omega)$; therefore the optimal adjoint state $\bar{\varphi}$ is actually in $W^{2,p}(\Omega)$ for $p < 3$. Consequently we can deduce that the optimal control belongs to $W^{1-1/p,p}(\Gamma)$, but $W^{1-1/p,p}(\Gamma)$ is not included in $H^1(\Gamma)$. There is no reason for the normal derivative $\partial_\nu \bar{\varphi}$ to be more regular than $W^{1-1/p,p}(\Gamma)$. For our problem, the plot in Figure 8.1 shows that the optimal control has a singularity in the corner at the origin, and it seems that $\bar{u} \notin H^1(\Gamma)$. So we cannot hope to have a convergence order of $O(h)$. Instead of that, we have a convergence of order $O(h^{1-1/p})$ for some $p > 2$, as predicted by the theory.

Since we do not have an exact solution for (P), we have solved it numerically for $h = 2^{-9}\sqrt{2}$, and we have used this solution for comparison with other solutions for bigger values of h. We have solved it using an active set strategy, as is explained in [11]. Figure 8.1 shows a plot of the optimal solution. The control constraints are not active at the optimal control. In Table 8.1 we show the norm in $L^2(\Gamma)$ of the error of the control and the order of convergence step by step. The order of convergence is measured as

$$o_i = \frac{\log(\|\bar{u}_{h_i} - \bar{u}\|_{L^2(\Gamma)}) - \log(\|\bar{u}_{h_{i-1}} - \bar{u}\|_{L^2(\Gamma)})}{\log(h_i) - \log(h_{i-1})}.$$

Let us remark that $1 - 1/p < 2/3$ for $p < 3$. The values o_i are approximately $2/3$. We believe that the order of convergence could be closer to $2/3$ if we could compare the computed controls with the true optimal control instead of with its numerical approximation. We refer to [12] for more details and numerical tests.

OPTIMAL ENERGY DECAY RATE FOR PARTIALLY DAMPED SYSTEMS BY SPECTRAL COMPENSATION*

PAOLA LORETI† AND BOPENG RAO‡

Abstract. We study the stability of weakly coupled and partially damped systems by means of the Riesz basis approach in higher dimensional spaces. We propose a weaker structural damping that compensates for the behavior of the eigenvalues of the system, therefore giving the optimal polynomial energy decay rate for smooth initial data.

Key words. weaker damping, spectral compensation, optimal energy decay rate, Riesz basis in higher dimensional space

DOI. 10.1137/S0363012903437319

1. Introduction.

The aim of this paper, the results of which were announced in [25], is to investigate the energy decay rate of the weakly coupled and partially damped system

$$\begin{cases} y_{tt} + Ay + By_t + au = 0, \\ u_{tt} + Au + ay = 0, \end{cases} \tag{1.1}$$

where a is a real number, A is a self-adjoint coercive operator, and B is a linear bounded positive operator in a separated Hilbert space H. Assume furthermore that the resolvent of A is compact in H. Then there exists an increasing sequence $\mu_n^2 \to +\infty$ and an orthonormal sequence $e_n \in H$ such that

$$Ae_n = \mu_n^2 e_n \qquad \forall n \geq 1. \tag{1.2}$$

Write (1.1) as

$$\frac{d}{dt}\begin{pmatrix} y \\ z \\ u \\ v \end{pmatrix} = \begin{pmatrix} z \\ -Ay - Bz - au \\ v \\ -Au - ay \end{pmatrix} =: \mathcal{A}\begin{pmatrix} y \\ z \\ u \\ v \end{pmatrix}. \tag{1.3}$$

For the case when a is small enough, it was shown in [3] that (1.3) generates a C_0-semigroup of contractions on the Hilbert space

$$\mathcal{H} = D(A^{\frac{1}{2}}) \times H \times D(A^{\frac{1}{2}}) \times H.$$

Moreover, let

$$w_n = \frac{1}{\sqrt{2}}\begin{pmatrix} 0 \\ 0 \\ \frac{e_n}{i\mu_n} \\ e_n \end{pmatrix}.$$

‡Institut de Recherche Mathématique Avancée, Université Louis Pasteur de Strasbourg, 7 Rue René-Descartes, 67084 Strasbourg, France (rao@math.u-strasbg.fr).

Then using (1.2) a straightforward computation gives

$$\|w_n\|_{\mathcal{H}} = 1, \qquad \|(i\mu_n - \mathcal{A})w_n\|_{\mathcal{H}}^2 = \frac{a^2}{2\mu_n^2} \to 0.$$

This shows that the resolvent of $\mathcal{A}$ is not uniformly bounded on the imaginary axis. Following [15] and [27] (see also [24] for applications) the system (1.3) is not uniformly stable in $\mathcal{H}$.

The fractional order damping of the type $B = A^\gamma$, arising from the material property, has been introduced in [7]. The cases $\gamma = 0, 1/2, 1$ include so-called viscous damping, "square-root" damping or structural damping, and Kelvin–Voigt damping. Especially for $\gamma = 1/2$ it was shown in [7] that the semigroup corresponding to the damped elastic model

$$y_{tt} + Ay + A^\gamma y_t = 0 \tag{1.4}$$

is analytical, while the subsequent works in [8] and [9] showed that the semigroup is still analytical for $1/2 \le \gamma \le 1$ but only of Gevrey class for $0 < \gamma < 1/2$. Moreover, the optimal regularity of solutions of system (1.8) with boundary control was also obtained in [14].

Now assume that $B = I$; then the spectrum of $\mathcal{A}$ has asymptotic expansions

$$\lambda_{1,n} \sim \pm i\mu_n - \frac{1}{2}, \quad \lambda_{2,n} \sim \pm i\mu_n - \frac{a^2}{2\mu_n^2}. \tag{1.5}$$

Then the energy corresponding to the first branch of eigenvalues decays exponentially and the energy corresponding to the second branch of eigenvalues decays only at the rate of $1/t$. Therefore the total energy decays at the rate of $1/t$.

Inspired by this remark, we look for a weaker damping operator for $\gamma < 0$. In that case, we have the following asymptotic expansions of the eigenvalues:

$$\begin{cases} \lambda_{1,n}^{\pm} \sim \pm i\mu_n - \frac{\mu_n^{2\gamma}}{2}, \quad \lambda_{2,n}^{\pm} \sim \pm i\mu_n - \frac{a^2}{2\mu_n^{2\gamma+2}}, & 2\gamma + 1 > 0, \\ \lambda_{1,n}^{\pm} \sim \pm i\mu_n - \frac{\mu_n^{2\gamma}}{2}, \quad \lambda_{2,n}^{\pm} \sim \pm i\mu_n - \frac{\mu_n^{2\gamma}}{2}, & 2\gamma + 1 < 0, \end{cases} \tag{1.6}$$

and the eigenvectors

$$e_{1,n}^{\pm} \sim \frac{1}{\sqrt{2}} \begin{pmatrix} \frac{e_n}{\pm i\mu_n} \\ e_n \\ 0 \\ 0 \end{pmatrix}, \quad e_{2,n}^{\pm} \sim \frac{1}{\sqrt{2}} \begin{pmatrix} 0 \\ 0 \\ \frac{e_n}{\pm i\mu_n} \\ e_n \end{pmatrix}, \quad 2\gamma + 1 > 0, \tag{1.7}$$

$$e_{1,n}^{\pm} \sim \frac{1}{2} \begin{pmatrix} \frac{e_n}{\pm i\mu_n} \\ e_n \\ \frac{e_n}{\pm i\mu_n} \\ e_n \end{pmatrix}, \qquad e_{2,n}^{\pm} \sim \frac{1}{2} \begin{pmatrix} \frac{e_n}{\mp i\mu_n} \\ -e_n \\ \frac{e_n}{\pm i\mu_n} \\ e_n \end{pmatrix}, \qquad 2\gamma + 1 < 0. \tag{1.8}$$

If $2\gamma + 1 > 0$, then the real part of $\lambda_{1,n}^{\pm}$ is of order $\mu_n^{2\gamma}$, and $\lambda_{2,n}^{\pm}$ is of order $\frac{1}{\mu_n^{2\gamma+2}}$. Therefore the energy corresponding to the first branch decays at the rate of $t^{\frac{1}{\gamma}}$, and the energy corresponding to the second branch decays at the rate of $t^{-\frac{1}{\gamma+1}}$. Since $-\frac{1}{\gamma+1} > \frac{1}{\gamma}$, the total energy decays only at the rate of $t^{-\frac{1}{\gamma+1}}$. In this case, the eigenvectors $e_{1,n}^{\pm}, e_{2,n}^{\pm}$ are asymptotically decoupled, and the two equations of (1.1) are very weakly coupled or almost independent.

If $2\gamma + 1 < 0$, then the real parts of $\lambda_{1,n}^{\pm}$ and $\lambda_{2,n}^{\pm}$ are of the same order $\mu_n^{2\gamma}$. The total energy decays at the rate of $t^{\frac{1}{\gamma}}$ and achieves the maximum decay $1/t^2$ for $2\gamma + 1 = 0$. In that case, the eigenvectors $e_{1,n}^{\pm}$ are effectively involved with the eigenvectors $e_{2,n}^{\pm}$, and the two equations are really coupled.

The unbalanced distribution of energy is a natural phenomenon for partially damped systems. The essential question is, how is the dissipation transmitted from one equation to another? Using the spectral compensation, we show that this depends on the damping and the coupling. Lebeau and Zuazua [17] (see also [6] for the generalization) estimated the total energy of the three-dimensional thermoelastic system by means of the energy concentrated on its longitudinal component. By a construction of geometric optics, they shown that there exist solutions whose energy is mostly concentrated on the transversal component. Consequently, the energy concentrated on the transversal component decays very slowly. From this point of view, the nonuniform decay is due to the unbalanced distribution of energy. The same phenomenon was observed for a magneto-elastic system [11]. Also the transmission of the dissipation plays an important role in the theory of control of networks as the controllers are enacted on only a part of the network. We refer to [10] for the network of elastic strings and to [18] for the network of Saint-Venant system of unsteady flows.

The paper is organized as follows. In section 2, we establish a general result on a polynomial decay rate of energy by a spectral approach. Section 3 is devoted to the study of the optimal decay rate of system (1.1) with a weaker damping $B = A^{\gamma}$ for $\gamma < 0$. Under a suitable framework, we can establish the asymptotic expansions for the eigenvalues and the eigenvectors as in (1.6)–(1.7). But these expansions could not give the desired quadratical convergence for the usual Riesz basis approach, except in one dimension. We will construct a sequence of pairwise orthogonal subspaces. In this way, we reduced the quadratical convergence to the Parseval equality. In order to obtain a Riesz basis we need only some weaker asymptotic expansions on the subspaces. In section 4, we give some examples of application.

There are many results concerning the polynomial decay rate. The majority were obtained by spectral approaches [16], [19], [33], [34]. Others results were obtained by frequency domain methods [5], [22], [23] and multiplier methods [3], [29], [30]. In particular, the method of weak observability inequality used in [4] and [31] works also, but it yields a lower decay rate than that obtained with our spectral method. Finally, we mention [32] for a general formulation for indirectly damped systems and [21] for the exact controllability and the observability of coupled distributed systems.

2. Optimal polynomial energy decay rate by spectral approach. In this section, we give a spectral approach for the polynomial energy decay rate of C_0-semigroups.

THEOREM 2.1. *Let $S(t)$ be a C_0-semigroup of contractions generated by the operator $\mathcal{A}$ on a Hilbert space $\mathcal{H}$. Let $\lambda_{k,n}(1 \le k \le K)$ denote the kth branch of eigenvalues of $\mathcal{A}$ and $\{e_{k,n}\}_{1\le k\le K, n\ge 1}$ the system of eigenvectors which forms a Riesz basis in $\mathcal{H}$. Assume that for each $1 \le k \le K$ there exist a positive sequence $\mu_{k,n} \to +\infty$ as $n \to +\infty$ and two positive constants $\alpha_k \ge 0, \beta_k > 0$ such that*

$$Re\lambda_{k,n} \le -\frac{\beta_k}{\mu_{k,n}^{\alpha_k}} \quad \text{and} \quad \left|Im\lambda_{k,n}\right| \ge \mu_{k,n} \qquad \forall n \ge 1. \tag{2.1}$$

Then for any $u_0 \in D(\mathcal{A}^{\theta})$ with $\theta > 0$, there exists a constant $M > 0$ independent of u_0 such that

$$\|S(t)u_0\|_{\mathcal{H}}^2 \le \|\mathcal{A}^{\theta}u_0\|_{\mathcal{H}}^2 \frac{M}{t^{2\theta\delta}} \qquad \forall t > 0, \tag{2.2}$$

where the decay rate δ is given by

$$\delta := \min_{1\le k\le K} \frac{1}{\alpha_k} = \frac{1}{\alpha_l}. \tag{2.3}$$

Moreover, if there exists a constant $c_1 > 0, c_2 > 0$ such that

$$Re\lambda_{l,n} \ge -\frac{c_1}{\mu_{l,n}^{\alpha_l}} \quad \text{and} \quad \left|Im\lambda_{l,n}\right| \le c_2\mu_{l,n} \qquad \forall n \ge 1, \tag{2.4}$$

then the decay rate δ given in (2.3) *is optimal.*

Proof. Since $\{e_{k,n}\}_{1\le k\le K, n\ge 1}$ is a Riesz basis in $\mathcal{H}$, any $u_0 \in D(\mathcal{A}^\theta)$ can be written as

$$u_0 = \sum_{k=1}^{K}\sum_{n=1}^{+\infty} a_{k,n}e_{k,n}. \tag{2.5}$$

Moreover, there exist two constants $C_1 > 0, C_2 > 0$ such that

$$C_1\sum_{k=1}^{K}\sum_{n=1}^{+\infty}|a_{k,n}|^2 \le \|u_0\|_{\mathcal{H}}^2 \le C_2\sum_{k=1}^{K}\sum_{n=1}^{+\infty}|a_{k,n}|^2. \tag{2.6}$$

Using expansion (2.5) and the continuity of the semigroup $S(t)$, we get

$$S(t)u_0 = \sum_{k=1}^{K}\sum_{n=1}^{+\infty} a_{k,n}e^{\lambda_{k,n}t}e_{k,n}. \tag{2.7}$$

Then using the first conditions of (2.1) and the second inequality of (2.6) in (2.7), we obtain

$$\|S(t)u_0\|_{\mathcal{H}}^2 \le \sup_{1\le k\le K}\sup_{n\ge 1}\left(\frac{C_2}{\mu_{k,n}^{2\theta}\exp\left(\frac{2\beta_k t}{\mu_{k,n}^{\alpha_k}}\right)}\right)\sum_{k=1}^{K}\sum_{n=1}^{+\infty}|a_{k,n}|^2\mu_{k,n}^{2\theta}. \tag{2.8}$$

On the other hand, the conditions of (2.1) imply that there exists a positive constant $C_3 > 0$ such that

$$\sum_{k=1}^{K}\sum_{n=1}^{+\infty}\mu_{k,n}^{2\theta}|a_{k,n}|^2 \le C_3\sum_{k=1}^{K}\sum_{n=1}^{+\infty}|\lambda_{k,n}|^{2\theta}|a_{k,n}|^2 \le \frac{C_3}{C_1}\|\mathcal{A}^\theta u_0\|_{\mathcal{H}}^2. \tag{2.9}$$

Then inserting (2.9) into (2.8), we get

$$\|S(t)u_0\|_{\mathcal{H}}^2 \le \sup_{1\le k\le K}\sup_{n\ge 1}\left(\frac{C_2C_3}{C_1\mu_{k,n}^{2\theta}\exp\left(\frac{2\beta_k t}{\mu_{k,n}^{\alpha_k}}\right)}\right)\|\mathcal{A}^\theta u_0\|_{\mathcal{H}}^2. \tag{2.10}$$

If $\alpha_k = 0$ for some $1 \le k \le K$, since $\inf_{n\ge 1}\mu_{k,n} > 0$, then it is easy to find a constant $M_k > 0$ such that

$$\frac{1}{\mu_{k,n}^{2\theta}\exp\left(2\beta_k t\right)} \le \frac{M_k}{t^{2\theta\delta}} \qquad \forall n \ge 1. \tag{2.11}$$

If $\alpha_k > 0$ for some $1 \le k \le K$, then putting

$$\frac{t}{\mu_{k,n}^{\alpha_k}} = \frac{1}{x}, \qquad f_k(x) = x^{\frac{2\theta}{\alpha_k}} e^{\frac{2\beta_k}{x}},$$

we rewrite

$$\mu_{k,n}^{2\theta} \exp\Big(\frac{2\beta_k t}{\mu_{k,n}^{\alpha_k}}\Big) = f_k(x) t^{\frac{2\theta}{\alpha_k}}. \tag{2.12}$$

Then a straightforward computation gives

$$f_k'(x) = 2e^{\frac{\beta_k}{x}} x^{\frac{2\theta}{\alpha_k}-2}\Big(\frac{\theta}{\alpha_k}x - \beta_k\Big) \quad \begin{cases} > 0, & x > \frac{\alpha_k\beta_k}{\theta}, \\ < 0, & x < \frac{\alpha_k\beta_k}{\theta}. \end{cases}$$

It follows that

$$\inf_{x>0} f_k(x) = f_k\Big(\frac{\alpha_k\beta_k}{\theta}\Big) = \Big(\frac{\alpha_k\beta_k}{\theta}\Big)^{\frac{2\theta}{\alpha_k}} e^{\frac{2\theta}{\alpha_k}} := M_k^{-1} > 0. \tag{2.13}$$

Inserting (2.13) into (2.12) gives that

$$\frac{1}{\mu_{k,n}^{2\theta} \exp\Big(\frac{2\beta_k t}{\mu_{k,n}^{\alpha_k}}\Big)} \le \frac{M_k}{t^{\frac{2\theta}{\alpha_k}}}, \qquad n \ge 1. \tag{2.14}$$

Finally, combining the cases (2.11) and (2.14), we get the polynomial energy decay rate (2.2), with the constant M given by

$$M = \frac{C_2 C_3}{C_1} \max_{1\le k\le K} M_k. \tag{2.15}$$

Now we consider the optimality of δ. To simplify the notation, we write

$$\alpha_l = \alpha, \quad \mu_{l,n} = \mu_n, \quad \lambda_{l,n} = \lambda_n, \quad e_{l,n} = e_n.$$

Since $\mu_n \to +\infty$, then for any $\epsilon > 0$, we can find a subsequence, still denoted by μ_n, such that

$$\sum_{n=1}^{\infty} \frac{1}{\mu_n^{\alpha\epsilon}} < +\infty. \tag{2.16}$$

Then putting

$$u_0 = \sum_{n=1}^{\infty} \frac{C_4}{\mu_n^{(\theta+\alpha\epsilon/2)}} e_n, \tag{2.17}$$

we see that $u_0 \in D(\mathcal{A}^\theta)$ due to the convergence (2.16). On the other hand, thanks to the second condition of (2.4), we can choose a constant $C_4 > 0$ such that $\|\mathcal{A}^\theta u_0\|_{\mathcal{H}} = 1$. Now using the first condition of (2.4), we get

$$\|S(t)u_0\|_{\mathcal{H}}^2 = \Big\| \sum_{n=1}^{\infty} \frac{C_4 e^{\lambda_n t} e_n}{\mu_n^{(\theta+\alpha\epsilon/2)}} \Big\|_{\mathcal{H}}^2 \ge \frac{C_1 C_4^2}{\mu_m^{2\theta+\alpha\epsilon} \exp\Big(\frac{2c_1 t}{\mu_m^\alpha}\Big)} \qquad \forall m \ge 1. \tag{2.18}$$

Finally, setting $t_m = \mu_m^\alpha$ in (2.18), we obtain that

$$\|S(t_m)u_0\|_{\mathcal{H}}^2 \geq \frac{C_1 C_4^2}{e^{2c_1}\mu_m^{2\theta+\alpha\epsilon}} = \frac{C_1 C_4^2}{e^{2c_1} t_m^{2\theta\delta+\epsilon}} \qquad \forall m \geq 1. \tag{2.19}$$

This means that the trajectory $S(t)u_0$ decays slower than $\frac{1}{t^{2\theta\delta+\epsilon}}$ on the time sequence $t_m \to +\infty$. Then for any $\epsilon > 0$, we cannot expect the decay rate $\frac{1}{t^{2\theta\delta+\epsilon}}$ for all initial data $u_0 \in D(\mathcal{A}^\theta)$ and for all $t > 0$. The proof is thus complete. □

Remark 2.1. If $\lambda_{k,n}$ is an eigenvalue of algebraic multiplicity $d > 1$, then the corresponding factors in (2.8) and (2.14) will be replaced by

$$\frac{|p(t)|^2}{\mu_{k,n}^{2\theta} \exp\left(\frac{2\beta_k t}{\mu_{k,n}^{\alpha_k}}\right)} \leq \frac{M_k}{t^{2\theta\delta}},$$

where $p(t)$ is a polynomial of degree $d-1$ and $M_k > 0$ is a constant. Therefore, Theorem 2.1 remains valid if the operator $\mathcal{A}$ admits a finite number of algebraically multiple eigenvalues and the system of root vectors forms a Riesz basis in $\mathcal{H}$.

Remark 2.2. Theorem 2.1 is valid for all initial data $u_0 \in D(\mathcal{A}^\theta)$ with $\theta > 0$. This is different from an earlier result of Littman and Markus in [20], where the initial data u_0 satisfies some stronger conditions.

3. Spectral compensation for weakly damped systems. Let A be a densely defined closed self-adjoint operator in a Hilbert space H such that for some positive constant c, we have

$$(Au, u) \geq c\|u\|_H^2 \qquad \forall u \in D(A). \tag{3.1}$$

Let $\gamma \leq 0$, and let a be a small real number. We consider the weakly coupled equations

$$y_{tt} + Ay + A^\gamma y_t + au = 0, \tag{3.2}$$

$$u_{tt} + Au + ay = 0. \tag{3.3}$$

In order to curry the explicit computation of the eigenvalues, we have chosen the same operator A in the two equations of system (3.2)–(3.3). The results of this section complete and improve a recent work of Alabau, Cannarsa, and Komornik [3].

Define the Hilbert space

$$\mathcal{H} = D(A^{\frac{1}{2}}) \times H \times D(A^{\frac{1}{2}}) \times H$$

equipped with the equivalent inner product

$$\begin{aligned}\langle (y,z,u,v), (f,g,p,q)\rangle_{\mathcal{H}} =& (A^{\frac{1}{2}}y, A^{\frac{1}{2}}f) + (z,g) + (A^{\frac{1}{2}}u, A^{\frac{1}{2}}p) + (v,q) \\ &+ a\big((y,p) + (u,f)\big).\end{aligned}$$

Setting

$$D(\mathcal{A}) = \{w = (y,z,u,v)^T \in \mathcal{H} \quad z, v \in D(A^{\frac{1}{2}}), \quad y, u \in D(A)\},$$

$$\mathcal{A}\begin{pmatrix} y \\ z \\ u \\ v \end{pmatrix} = \begin{pmatrix} z \\ -Ay - A^\gamma z - au \\ v \\ -Au - ay \end{pmatrix},$$

we can write system (3.2)–(3.3) as an evolution equation

$$\frac{d}{dt}w = \mathcal{A}w, \qquad w(0) = w_0. \tag{3.4}$$

Under condition (3.1), we can prove easily that $\mathcal{A}$ is a maximal dissipative operator on $\mathcal{H}$, provided that a is small enough (e.g., $|a| < c$). Therefore $\mathcal{A}$ generates a C^0-semigroup of contractions on $\mathcal{H}$ (see Theorem 1.4.3 in [26]). Moreover, if we set the energy as

$$E(t) = \frac{1}{2}\Big(\|A^{\frac{1}{2}}y\|^2 + \|y_t\|^2 + \|A^{\frac{1}{2}}u\|^2 + \|u_t\|^2 + a(y,u) + a(u,y)\Big),$$

then a straightforward computation gives that

$$\frac{d}{dt}E(t) = -\|A^{\gamma}y_t\|^2 \le 0.$$

Assume furthermore that the resolvent of A is compact in H. Then there exists an increasing sequence $\mu_n^2 \to +\infty$ and an orthonormal sequence $e_n \in H$ such that

$$Ae_n = \mu_n^2 e_n \qquad \forall n \ge 1. \tag{3.5}$$

Moreover, the system $\{e_n\}_{n\ge1}$ forms a Hilbert basis on H.

Now let λ be an eigenvalue and (y,z,u,v) be the associated eigenvector of the operator $\mathcal{A}$. Then we have

$$\begin{cases} z = \lambda y, \\ -Ay - A^{\gamma}z - au = \lambda z, \\ v = \lambda u, \\ -Au - ay = \lambda v. \end{cases} \tag{3.6}$$

We will see in Proposition 3.3 that all eigenvectors of $\mathcal{A}$ are of the form

$$y = \alpha_n e_n, \qquad z = \lambda\alpha_n e_n, \qquad u = \beta_n e_n, \qquad v = \lambda\beta_n e_n. \tag{3.7}$$

Inserting (3.7) into (3.6), we get

$$\begin{cases} (\lambda^2 + \mu_n^2 + \lambda\mu_n^{2\gamma})\alpha_n + a\beta_n = 0, \\ a\alpha_n + (\lambda^2 + \mu_n^2)\beta_n = 0, \end{cases} \tag{3.8}$$

which has nontrivial solution $(\alpha_n, \beta_n) \neq (0,0)$ if and only if λ is a solution of the equation

$$(\lambda^2 + \lambda\mu_n^{2\gamma} + \mu_n^2)(\lambda^2 + \mu_n^2) = a^2. \tag{3.9}$$

PROPOSITION 3.1. *For each $\mu_n > 0$, the corresponding eigenvalues $\lambda_{1,n}^{\pm}, \lambda_{2,n}^{\pm}$ of the system* (3.2)–(3.3) *satisfy the following asymptotic expansions.*

I. *If $-1/2 < \gamma \le 0$, then*

$$\lambda_{1,n}^{\pm} = \pm i\mu_n - \frac{\mu_n^{2\gamma}}{2} + O\Big(\frac{1}{\mu_n}\Big), \tag{3.10}$$

$$\lambda_{2,n}^{\pm} = \pm i\mu_n - \frac{a^2}{2\mu_n^{2\gamma+2}} + O\Big(\frac{1}{\mu_n^{6\gamma+4}}\Big). \tag{3.11}$$

II. *If* $\gamma < -1/2$, *then*

$$\lambda_{1,n}^{\pm} = \pm i\sqrt{\mu_n^2 + a} - \frac{\mu_n^{2\gamma}}{2} + O(\mu_n^{4\gamma+1}), \tag{3.12}$$

$$\lambda_{2,n}^{\pm} = \pm i\sqrt{\mu_n^2 - a} - \frac{\mu_n^{2\gamma}}{2} + O(\mu_n^{4\gamma+1}). \tag{3.13}$$

III. *If* $\gamma = -1/2$, *then*

$$\lambda_{1,n}^{\pm} = \pm i\mu_n - \frac{1 \pm \sqrt{1-4a^2}}{4\mu_n} + O\Big(\frac{1}{\mu_n^2}\Big), \tag{3.14}$$

$$\lambda_{2,n}^{\pm} = \pm i\mu_n - \frac{1 \mp \sqrt{1-4a^2}}{4\mu_n} + O\Big(\frac{1}{\mu_n^2}\Big). \tag{3.15}$$

Proof. First, let λ_n be one of the four solutions of (3.9). If $|\lambda_n^2 + \mu_n^2| \le 1$, then it follows that

$$\frac{\lambda_n}{\mu_n} = \pm i + O(\mu_n^{-2}). \tag{3.16}$$

If $|\lambda_n^2 + \mu_n^2| \ge 1$, then from (3.9) we get

$$\Big(\frac{\lambda_n}{\mu_n}\Big)^2 + \frac{\lambda_n}{\mu_n}\mu_n^{2\gamma-1} + 1 = O(\mu_n^{-2}).$$

It follows that

$$\frac{\lambda_n}{\mu_n} = \pm i + O(\mu_n^{2\gamma-1}). \tag{3.17}$$

Combining (3.16) and (3.17), we get

$$\frac{\lambda_n}{\mu_n} = \pm i + O(\mu_n^{2\gamma-1}) + O(\mu_n^{-2}). \tag{3.18}$$

Next, solving (3.9), we get

$$2(\lambda^2 + \mu_n^2) = -\lambda\mu_n^{2\gamma} \mp \sqrt{\lambda^2\mu_n^{4\gamma} + 4a^2}. \tag{3.19}$$

The symbol $a \sim b$ means that $a - b \to 0$. In the following computations we will use often the expansion $\sqrt{1+z} = 1 + z/2 + O(z^2)$.

Case I. $-1/2 < \gamma \le 0$. From (3.18), we have

$$|\lambda_n\mu_n^{2\gamma}| \sim \mu_n^{1+2\gamma} \to +\infty. \tag{3.20}$$

Using the asymptotic expansion (3.20) in (3.19), we get

$$\begin{cases} \lambda_{1,n}^2 = -\mu_n^2 - \lambda_{1,n}\mu_n^{2\gamma} + O\Big(\frac{1}{\mu_n^{2\gamma+1}}\Big), \\ \lambda_{2,n}^2 = -\mu_n^2 + \dfrac{a^2}{\lambda_{2,n}\mu_n^{2\gamma}} + O\Big(\dfrac{1}{\mu_n^{6\gamma+3}}\Big). \end{cases} \tag{3.21}$$

It follows from (3.21) that

$$\begin{cases} \lambda_{1,n}^{\pm} = \pm i\mu_n \pm \dfrac{i\lambda_{1,n}\mu_n^{2\gamma-1}}{2} + O\Big(\dfrac{1}{\mu_n}\Big), \\ \lambda_{2,n}^{\pm} = \pm i\mu_n \mp \dfrac{ia^2}{2\lambda_{2,n}\mu_n^{2\gamma+1}} + O\Big(\dfrac{1}{\mu_n^{6\gamma+4}}\Big). \end{cases} \tag{3.22}$$

In particular, we get

$$\begin{cases} \lambda_{1,n}^{\pm} = \pm i\mu_n + O(\mu_n^{2\gamma}), \\ \lambda_{2,n}^{\pm} = \pm i\mu_n + O\Big(\frac{1}{\mu_n^{2\gamma+2}}\Big). \end{cases} \tag{3.23}$$

Inserting (3.23) into (3.22) gives that

$$\lambda_{1,n}^{\pm} = \pm i\mu_n - \frac{\mu_n^{2\gamma}}{2} + O\Big(\frac{1}{\mu_n}\Big), \tag{3.24}$$

$$\lambda_{2,n}^{\pm} = \pm i\mu_n - \frac{a^2}{2\mu_n^{2\gamma+2}} + O\Big(\frac{1}{\mu_n^{6\gamma+4}}\Big). \tag{3.25}$$

Case II. $\gamma < -1/2$. From (3.18) we have

$$|\lambda_n \mu_n^{2\gamma}| \sim |\mu_n^{1+2\gamma}| \to 0. \tag{3.26}$$

Using the asymptotic expansion (3.26) in (3.19), we have

$$\begin{cases} \lambda_{1,n}^2 = -(\mu_n^2 + a) - \dfrac{\lambda_{1,n}\mu_n^{2\gamma}}{2} + O\Big(\mu_n^{4\gamma+2}\Big), \\ \lambda_{2,n}^2 = -(\mu_n^2 - a) - \dfrac{\lambda_{1,n}\mu_n^{2\gamma}}{2} + O\Big(\mu_n^{4\gamma+2}\Big). \end{cases} \tag{3.27}$$

It follows from (3.27) that

$$\begin{cases} \lambda_{1,n}^{\pm} = \pm i\sqrt{\mu_n^2 + a} \pm \dfrac{i\lambda_{1,n}\mu_n^{2\gamma}}{2\sqrt{\mu_n^2 + a}} + O(\mu_n^{4\gamma+1}), \\ \lambda_{2,n}^{\pm} = \pm i\sqrt{\mu_n^2 - a} \pm \dfrac{i\lambda_{1,n}\mu_n^{2\gamma}}{2\sqrt{\mu_n^2 - a}} + O(\mu_n^{4\gamma+1}). \end{cases} \tag{3.28}$$

In particular, we get

$$\begin{cases} \lambda_{1,n}^{\pm} = \pm i\sqrt{\mu_n^2 + a} + O(\mu_n^{2\gamma}), \\ \lambda_{2,n}^{\pm} = \pm i\sqrt{\mu_n^2 - a} + O(\mu_n^{2\gamma}). \end{cases} \tag{3.29}$$

Inserting (3.29) into (3.28), we have

$$\begin{cases} \lambda_{1,n}^{\pm} = \pm i\sqrt{\mu_n^2 + a} - \dfrac{\mu_n^{2\gamma}}{2} + O(\mu_n^{4\gamma+1}), \\ \lambda_{2,n}^{\pm} = \pm i\sqrt{\mu_n^2 - a} - \dfrac{\mu_n^{2\gamma}}{2} + O(\mu_n^{4\gamma+1}). \end{cases} \tag{3.30}$$

Case III. $\gamma = -1/2$. From (3.18) we have

$$\frac{\lambda_{1,n}^{\pm}}{\mu_n} \sim \pm i + O\Big(\frac{1}{\mu_n^2}\Big), \qquad \frac{\lambda_{2,n}^{\pm}}{\mu_n} \sim \pm i + O\Big(\frac{1}{\mu_n^2}\Big). \tag{3.31}$$

Using the asymptotic expansion (3.31) in (3.19), we have

$$\begin{cases} \lambda_{1,n}^2 = -\mu_n^2 \mp \dfrac{i}{2}(1 \pm \sqrt{1-4a^2}) + O\Big(\dfrac{1}{\mu_n^2}\Big), \\ \lambda_{2,n}^2 = -\mu_n^2 \mp \dfrac{i}{2}(1 \mp \sqrt{1-4a^2}) + O\Big(\dfrac{1}{\mu_n^2}\Big). \end{cases} \tag{3.32}$$

It follows from (3.32) that

$$\lambda_{1,n}^{\pm} = \pm i\mu_n - \frac{1 \pm \sqrt{1-4a^2}}{4\mu_n} + O\Big(\frac{1}{\mu_n^3}\Big), \tag{3.33}$$

$$\lambda_{2,n}^{\pm} = \pm i\mu_n - \frac{1 \mp \sqrt{1-4a^2}}{4\mu_n} + O\Big(\frac{1}{\mu_n^3}\Big). \tag{3.34}$$

The proof is thus complete. □

If $\lambda_{1,n}^{\pm}, \lambda_{2,n}^{\pm}$ are simple eigenvalues, then by setting

$$\beta_{1,n}^{\pm} = -\frac{a}{(\lambda_{1,n}^{\pm})^2 + \mu_n^2}\alpha_{1,n}^{\pm}, \tag{3.35}$$

$$\alpha_{2,n}^{\pm} = -\frac{(\lambda_{2,n}^{\pm})^2 + \mu_n^2}{a}\beta_{2,n}^{\pm} \tag{3.36}$$

in (3.8), we get

$$e_{1,n}^{\pm} = \alpha_{1,n}^{\pm} \begin{pmatrix} \frac{e_n}{\lambda_{1,n}^{\pm}} \\ e_n \\ -\frac{ae_n}{\lambda_{1,n}^{\pm}((\lambda_{1,n}^{\pm})^2+\mu_n^2)} \\ -\frac{ae_n}{(\lambda_{1,n}^{\pm})^2+\mu_n^2} \end{pmatrix}, \quad e_{2,n}^{\pm} = \beta_{2,n}^{\pm} \begin{pmatrix} -\frac{((\lambda_{2,n}^{\pm})^2+\mu_n^2)e_n}{a\lambda_{2,n}^{\pm}} \\ -\frac{((\lambda_{2,n}^{\pm})^2+\mu_n^2)e_n}{a} \\ \frac{e_n}{\lambda_{2,n}^{\pm}} \\ e_n \end{pmatrix}. \tag{3.37}$$

Now let us denote by V_n the eigenspace corresponding to the four eigenvalues $\lambda_{1,n}^{\pm}, \lambda_{2,n}^{\pm}$:

$$V_n = \mathrm{Sp}\{e_{1,n}^{+}, e_{2,n}^{+}, e_{1,n}^{-}, e_{2,n}^{-}\}.$$

From the expressions in (3.37), the subspaces $\{V_n\}_{n\geq 1}$ are clearly pairwise orthogonal in $\mathcal{H}$. It is possible that (3.9) has multiple solutions for some special parameters μ_n, a. However, for a small enough the Rouché theorem shows that (3.9) admits at most a double solution for the first branch of eigenvalues $\lambda_{1,n}^{\pm} = \lambda_{1,n}, e_{1,n}^{\pm} = e_{1,n}$, which satisfies the equation of derivation

$$(2\lambda + \mu_n^{2\gamma})(\lambda^2 + \mu_n^2) + 2\lambda(\lambda^2 + \lambda\mu_n^{2\gamma} + \mu_n^2) = 0. \tag{3.38}$$

In that case, we look for the corresponding root vector $\widetilde{e}_{1,n} = (\widetilde{y}_n, \widetilde{z}_n, \widetilde{u}_n, \widetilde{v}_n)$ such that

$$(I - \lambda_{1,n}\mathcal{A})\widetilde{e}_{1,n} = e_{1,n},$$

which involves that

$$\begin{cases} \widetilde{z}_n - \lambda_{1,n}\widetilde{y}_n = \frac{e_n}{\lambda_{1,n}}, \\ -A\widetilde{y}_n - A^\gamma \widetilde{z}_n - a\widetilde{u}_n - \lambda\widetilde{z}_n = e_n, \\ \widetilde{v}_n - \lambda_{1,n}\widetilde{u}_n = -\frac{ae_n}{\lambda_{1,n}(\lambda_{1,n}^2+\mu_n^2)}, \\ -A\widetilde{u}_n - a\widetilde{y}_n - \lambda\widetilde{v}_n = -\dfrac{ae_n}{(\lambda_{1,n}^2+\mu_n^2)}. \end{cases} \tag{3.39}$$

Setting

$$\widetilde{y}_n = \alpha_{1,n}e_n, \qquad \widetilde{u}_n = \beta_{1,n}e_n \tag{3.40}$$

in (3.39), we get

$$\begin{cases} \widetilde{z}_n = \alpha_{1,n}\lambda_{1,n}e_n + \dfrac{e_n}{\lambda_{1,n}}, \\ \widetilde{v}_n = \beta_{1,n}\lambda_{1,n}e_n - \dfrac{ae_n}{\lambda_{1,n}(\lambda_{1,n}^2+\mu_n^2)}, \end{cases} \tag{3.41}$$

where the constants $\alpha_{1,n}$ and $\beta_{1,n}$ satisfy

$$\begin{cases} -(\mu^2 + \lambda_{1,n}\mu^{2\gamma} + \lambda_{1,n}^2)\alpha_{1,n} - a\beta_{1,n} = \dfrac{2\lambda_{1,n} + \mu^{2\gamma}}{\lambda_{1,n}}, \\ -a\alpha_{1,n} - (\mu^2 + \lambda_{1,n}^2)\beta_{1,n} = -\dfrac{2a}{\lambda_{1,n}^2 + \mu_n^2}. \end{cases} \tag{3.42}$$

Since $\lambda_{1,n}$ satisfies (3.9) and (3.38), the first equation of (3.42) can be reduced to the second one. Therefore, choosing

$$\alpha_{1,n} = \frac{2}{\lambda_{1,n}^2 + \mu_n^2}, \qquad \beta_{1,n} = 0 \tag{3.43}$$

in (3.40)–(3.41), we get the corresponding root vector

$$\widetilde{e}_{1,n} = \begin{pmatrix} \frac{2}{\lambda_{1,n}^2+\mu_n^2}e_n \\ \left(\frac{2a\lambda_{1,n}}{\lambda_{1,n}^2+\mu_n^2} + \frac{1}{\lambda_{1,n}}\right)e_n \\ 0 \\ -\frac{a}{\lambda_{1,n}(\lambda_{1,n}^2+\mu_n^2)}e_n \end{pmatrix}. \tag{3.44}$$

Accordingly, we modify the subspace V_n as

$$V_n = \mathrm{Sp}\{e_{1,n}, e_{2,n}^+, \widetilde{e}_{1,n}, e_{2,n}^-\}.$$

Once again, expression (3.44) shows that the subspaces $\{V_n\}_{n\geq 1}$ are still pairwise orthogonal in $\mathcal{H}$.

PROPOSITION 3.2. *Let $E_{1,n}^\pm, E_{2,n}^\pm$ be the eigenvectors of the decoupled system (corresponding to $a = 0$)*

$$E_{1,n}^\pm = \frac{1}{\sqrt{2}}\begin{pmatrix} \frac{e_n}{\pm i\mu_n} \\ e_n \\ 0 \\ 0 \end{pmatrix}, \qquad E_{2,n}^\pm = \frac{1}{\sqrt{2}}\begin{pmatrix} 0 \\ 0 \\ \frac{e_n}{\pm i\mu_n} \\ e_n \end{pmatrix}. \tag{3.45}$$

Then the following relationship holds:

$$(e^+_{1,n}, e^+_{2,n}, e^-_{1,n}, e^-_{2,n}) = (E^+_{1,n}, E^+_{2,n}, E^-_{1,n}, E^-_{2,n})L_n, \tag{3.46}$$

where L_n is a 4×4 matrix such as

$$L_n = \begin{pmatrix} 1 & 0 & 0 & 0\\ 0 & 1 & 0 & 0\\ 0 & 0 & 1 & 0\\ 0 & 0 & 0 & 1 \end{pmatrix} + O\Big(\frac{1}{\mu_n^{2\gamma+1}}\Big), \quad 2\gamma+1>0, \tag{3.47}$$

$$L_n = \frac{1}{\sqrt{2}}\begin{pmatrix} 1 & -1 & 0 & 0\\ 1 & 1 & 0 & 0\\ 0 & 0 & 1 & -1\\ 0 & 0 & 1 & 1 \end{pmatrix} + O\Big(\frac{1}{\mu_n^{\min\{2,-(2\gamma+1)\}}}\Big), \quad 2\gamma+1<0, \tag{3.48}$$

$$L_n = \sqrt{2}\begin{pmatrix} \sqrt{a}_+ & \sqrt{a}_- & 0 & 0\\ \frac{ia}{\sqrt{a}_+} & \frac{ia}{\sqrt{a}_-} & 0 & 0\\ 0 & 0 & \sqrt{a}_- & \sqrt{a}_+\\ 0 & 0 & -\frac{ia}{\sqrt{a}_-} & -\frac{ia}{\sqrt{a}_+} \end{pmatrix} + O\Big(\frac{1}{\mu_n^2}\Big), \quad 2\gamma+1=0, \tag{3.49}$$

where we have put

$$a_\pm = \frac{1\pm\sqrt{1-4a^2}}{2}. \tag{3.50}$$

Proof. For $2\gamma+1>0$, using the asymptotic expansions (3.10)–(3.11), we have

$$\frac{1}{(\lambda^\pm_{1,n})^2+\mu_n^2} = O\Big(\frac{1}{\mu_n^{2\gamma+1}}\Big), \qquad \frac{1}{\lambda^\pm_{1,n}} = \frac{1}{\pm i\mu_n} + O(\mu_n^{2\gamma-2}), \tag{3.51}$$

$$(\lambda^\pm_{2,n})^2+\mu_n^2 = O\Big(\frac{1}{\mu_n^{2\gamma+1}}\Big), \qquad \frac{1}{\lambda^\pm_{2,n}} = \frac{1}{\pm i\mu_n} + O\Big(\frac{1}{\mu_n^{2\gamma+4}}\Big). \tag{3.52}$$

Inserting (3.51)–(3.52) into (3.37) gives

$$e^\pm_{1,n} = \frac{1}{\sqrt{2}}\begin{pmatrix} \frac{e_n}{\pm i\mu_n}\\ e_n\\ 0\\ 0 \end{pmatrix} + O\Big(\frac{1}{\mu_n^{2\gamma+1}}\Big), \tag{3.53}$$

$$e^\pm_{2,n} = \frac{1}{\sqrt{2}}\begin{pmatrix} 0\\ 0\\ \frac{e_n}{\pm i\mu_n}\\ e_n \end{pmatrix} + O\Big(\frac{1}{\mu_n^{2\gamma+1}}\Big). \tag{3.54}$$

For $2\gamma+1<0$, using (3.12)–(3.13), we have

$$\frac{1}{(\lambda^\pm_{1,n})^2+\mu_n^2} = -\frac{1}{a} + O(\mu_n^{2\gamma+1}), \quad \frac{1}{\lambda^\pm_{1,n}} = \frac{1}{\pm i\mu_n} + O\Big(\frac{1}{\mu_n^3}\Big), \tag{3.55}$$

$$\frac{1}{\lambda^\pm_{2,n}} = \frac{1}{\pm i\mu_n} + O\Big(\frac{1}{\mu_n^3}\Big), \quad (\lambda^\pm_{2,n})^2+\mu_n^2 = a + O(\mu_n^{2\gamma+1}). \tag{3.56}$$

Inserting (3.55)–(3.56) into (3.37) gives

$$e^{\pm}_{1,n} = \frac{1}{2}\begin{pmatrix} \frac{e_n}{\pm i\mu_n} \\ e_n \\ \frac{e_n}{\pm i\mu_n} \\ e_n \end{pmatrix} + O(\mu_n^{2\gamma+1}) + O\Big(\frac{1}{\mu_n^2}\Big), \tag{3.57}$$

$$e^{\pm}_{2,n} = \frac{1}{2}\begin{pmatrix} \frac{e_n}{\mp i\mu_n} \\ -e_n \\ \frac{e_n}{\pm i\mu_n} \\ e_n \end{pmatrix} + O(\mu_n^{2\gamma+1}) + O\Big(\frac{1}{\mu_n^2}\Big). \tag{3.58}$$

For $2\gamma + 1 = 0$, using (3.14)–(3.15), we have

$$(\lambda^{\pm}_{1,n})^2 + \mu_n^2 = \mp i a_{\pm} + O\Big(\frac{1}{\mu_n^2}\Big), \quad \frac{1}{\lambda^{\pm}_{1,n}} = \frac{1}{\pm i\mu_n} + O\Big(\frac{1}{\mu_n^3}\Big), \tag{3.59}$$

$$(\lambda^{\pm}_{2,n})^2 + \mu_n^2 = \mp i a_{\mp} + O\Big(\frac{1}{\mu_n^2}\Big), \quad \frac{1}{\lambda^{\pm}_{2,n}} = \frac{1}{\pm i\mu_n} + O\Big(\frac{1}{\mu_n^3}\Big). \tag{3.60}$$

Inserting (3.59)–(3.60) into (3.37) gives

$$e^{\pm}_{1,n} = \sqrt{a}_{\pm}\begin{pmatrix} \frac{e_n}{\pm i\mu_n} \\ e_n \\ -\frac{ae_n}{a_{\pm}\mu_n} \\ \frac{ae_n}{\pm i a_{\pm}} \end{pmatrix} + O\Big(\frac{1}{\mu_n^2}\Big), \tag{3.61}$$

$$e^{\pm}_{2,n} = \sqrt{a}_{\mp}\begin{pmatrix} \frac{e_n}{\pm i\mu_n} \\ e_n \\ -\frac{ae_n}{a_{\mp}\mu_n} \\ \frac{ae_n}{\pm i a_{\mp}} \end{pmatrix} + O\Big(\frac{1}{\mu_n^2}\Big). \tag{3.62}$$

The proof is thus complete. □

Remark 3.1. If $2\gamma + 1 > 0$, the leading term of the eigenvectors $e^{\pm}_{1,n}$ and $e^{\pm}_{2,n}$ are decoupled. System (3.2)–(3.3) is overdamped and "essentially decoupled." If $2\gamma + 1 < 0$, the leading term of $e^{\pm}_{1,n}$ and $e^{\pm}_{2,n}$ are well coupled. System (3.2)–(3.3) is right-damped in that case. In particular, when $2\gamma + 1 = 0$ the parameter a appears explicitly in the leading term of the matrix L_n.

LEMMA 3.1. *Let $\{X_n\}_{n\geq 1}$ be a Riesz basis of subspaces in a Hilbert space X and $\{Y_n\}_{n\geq 1}$ a Riesz sequence of subspaces in X. Assume that there exist a sequence of isomorphisms $\{L_n\}_{n\geq 1}$ from X_n onto Y_n and positive constants $m > 0, M > 0$ independent of n such that*

$$m\|x_n\| \leq \|L_n x_n\| \leq M\|x_n\| \qquad \forall x_n \in X_n, \quad \forall n \geq 1. \tag{3.63}$$

Assume furthermore that there exist a Riesz basis $\{f_{n,i}\}_{1\leq l\leq I_n}(I_n \leq +\infty)$ in each X_n and positive constants $c > 0, C > 0$ independent of n such that

$$c\sum_{i=1}^{I_n} |\alpha_{n,i}|^2 \leq \|x_n\|^2 \leq C\sum_{i=1}^{I_n} |\alpha_{n,i}|^2 \qquad \forall x_n = \sum_{i=1}^{I_n} \alpha_{n,i} f_{n,i}. \tag{3.64}$$

Then the sequence

$$g_{n,i} = L_n f_{n,i} \qquad \forall n \geq 1, \quad 1 \leq i \leq I_n, \tag{3.65}$$

forms a Riesz basis in X.

Proof. Since $\{X_n\}_{n\geq 1}$ is a Riesz basis of subspaces in X, then for any $x \in X$ there exists a unique sequence $\{x_n\}_{n\geq 1}$ with $x_n \in X_n$ such that

$$x = \sum_{n=1}^{\infty} x_n, \qquad c' \sum_{n=1}^{\infty} \|x_n\|^2 \leq \|x\|^2 \leq C' \sum_{n=1}^{\infty} \|x_n\|^2. \tag{3.66}$$

This combined with (3.64) implies that the sequence $\{f_{n,i}\}_{n\geq 1, 1\leq i\leq I_n}$ forms a Riesz basis in X.

Now define the application L in X as

$$Lx = \sum_{n=1}^{\infty} L_n x_n, \qquad x = \sum_{n=1}^{\infty} x_n. \tag{3.67}$$

It is obvious that L is a linear application in X. Moreover, since $\{Y_n\}_{n\geq 1}$ is a Riesz sequence of subspaces in X, we get

$$c'' \sum_{n=1}^{\infty} \|L_n x_n\|^2 \leq \|Lx\|^2 \leq C'' \sum_{n=1}^{\infty} \|L_n x_n\|^2. \tag{3.68}$$

Combining (3.63), (3.66), and (3.68) we get

$$\frac{mc''}{C'} \|x\|^2 \leq \|Lx\|^2 \leq \frac{MC''}{c'} \|x\|^2 \quad \forall x \in X. \tag{3.69}$$

It follows that L is an isomorphism in X. Thus the sequence $\{g_{n,i}\}_{n\geq 1, 1\leq i\leq I_n}$, being the image of the Riesz basis $\{f_{n,i}\}_{n\geq 1, 1\leq i\leq I_n}$ by the isomorphism L, forms a Riesz basis in X. This achieves the proof. □

PROPOSITION 3.3. *Let $\gamma \leq 0$ and a be a real number small enough. Then the system of eigenvectors $\{e^+_{1,n}, e^+_{2,n}, e^-_{2,n}, e^-_{2,n}\}_{n\geq 1}$ of $\mathcal{A}$ forms a Riesz basis in $\mathcal{H}$. In particular, all eigenvectors of $\mathcal{A}$ are of the form* (3.7).

Proof. For all $n \geq 1$ let

$$W_n = \mathrm{Sp}\{E^+_{1,n}, E^+_{2,n}, E^-_{2,n}, E^-_{1,n}\}. \tag{3.70}$$

It is clear that $\{W_n\}_{n\geq 1}$ forms a Hilbert basis of subspaces and $\{V_n\}_{n\geq 1}$ is a Hilbert sequence of subspaces in $\mathcal{H}$. The condition (3.64) is trivial since $E^+_{1,n}, E^+_{2,n}, E^-_{2,n}, E^-_{2,n}$ is a Hilbert basis in the subspace W_n. Let L_n be defined as in (3.46). Following Proposition 3.2, L_n has a constant leading term, which is invertible. This, together with the fact that L_n is invertible for all $n \geq 1$, implies the condition (3.63). Then applying Lemma 3.1, we get that the system of eigenvectors $\{e^+_{1,n}, e^+_{2,n}, e^-_{2,n}, e^-_{2,n}\}_{n\geq 1}$ forms a Riesz basis in $\mathcal{H}$. In particular, all eigenvectors of $\mathcal{A}$ are of the form (3.7). The proof is thus completed. □

Remark 3.2. There are many papers based on the Riesz basis approach in which the essential part is to show that the sequence of the root vectors is quadratically close to a known Riesz basis. This approach requires a very long calculation and is limited to one-dimensional problems (see [13] and the successions).

The idea of Proposition 3.3 lies in constructing the pairwise orthogonal subspaces V_n without the eigenvectors $e^+_{1,n}, e^+_{2,n}, e^-_{1,n}, e^-_{2,n}$ being orthogonal. In this way, we reduced the quadratical convergence to the Parseval equality. In order to get condition (3.64), we need only some asymptotic expansions such as (3.47)–(3.49), which do not give any quadratical convergence.

To fix the idea, we consider the case where $A := -\Delta$ is the Laplacian on a bounded open set $\Omega \subset \mathbb{R}^N$, with the homogeneous Dirichlet boundary condition as in Example 4.1. Following a classical result of Agmon (Theorem 14.6 in [2]), we know that $\mu_n \sim n^{1/N}$. Let $2\gamma + 1 > 0$; then the series of general term

$$\|e^{\pm}_{k,n} - E^{\pm}_{k,n}\| = O\Big(\frac{1}{n^{(2\gamma+1)/N}}\Big) \tag{3.71}$$

converges in l^2 if and only if $N < 2(2\gamma + 1)$. This is never true if $-1/2 < \gamma \le -1/4$, even in one dimension. In the best case $\gamma = 0$, which corresponds to the usual damping y_t, the series of general terms in (3.71) converges in l^2 if and only if $N < 2$. This confirms that the quadratical convergence could be expected only in one dimension.

THEOREM 3.1. *Let $\gamma \le 0$ and a be a real number small enough. Then for all $y_0, z_0 \in D(A)$ and $y_1, u_1 \in D(A^{\frac{1}{2}})$, the energy of system* (3.2)–(3.3) *has the polynomial decay rate*

$$E(t) \le C(\|Ay_0\|^2_H + \|Au_0\|^2_H + \|A^{\frac{1}{2}}y_1\|^2_H + \|A^{\frac{1}{2}}u_1\|^2_H)\frac{1}{t^{\delta(\gamma)}} \qquad \forall t > 0, \tag{3.72}$$

where

$$\delta(\gamma) = \begin{cases} \frac{1}{\gamma+1}, & 2\gamma + 1 > 0, \\ -\frac{1}{\gamma}, & 2\gamma + 1 < 0, \\ 2, & 2\gamma + 1 = 0. \end{cases} \tag{3.73}$$

Proof. Following Proposition 3.1, the eigenvalues of $\mathcal{A}$ satisfy the asymptotic expansions (2.1) with

$$\begin{cases} \alpha_1 = -2\gamma, \quad \alpha_2 = 2(\gamma + 1), & \delta = \frac{1}{\gamma+1}, \quad 2\gamma + 1 > 0, \\ \alpha_1 = \alpha_2 = -2\gamma, & \delta = \frac{1}{-\gamma}, \quad 2\gamma + 1 < 0, \\ \alpha_1 = \alpha_2 = 1, & \delta = 2, \quad 2\gamma + 1 = 0. \end{cases} \tag{3.74}$$

On the other hand, following Proposition 3.3 the system of eigenvectors of $\mathcal{A}$ forms a Riesz basis in $\mathcal{H}$. Then applying Theorem 2.1, we get the polynomial energy decay rate (3.72)–(3.73). The proof is thus achieved. ∎

The following theorem gives the repartition of energy within the two equations of the system (3.2)–(3.3).

THEOREM 3.2. *Assume the same conditions as in Theorem* 3.1. *Let $w_0 \in D(\mathcal{A})$ be initial data and*

$$E_1(t) = \frac{1}{2}(\|A^{\frac{1}{2}}y(t)\|^2_H + \|z(t)\|^2_H), \tag{3.75}$$

$$E_2(t) = \frac{1}{2}(\|A^{\frac{1}{2}}u(t)|^2_H + \|v(t)\|^2_H) \tag{3.76}$$

be the corresponding energy of the first equation (respectively, the second equation). Then the following estimates hold:

$$E_1(t) \le C\|\mathcal{A}w_0\|^2\frac{1}{t^2}, \qquad E_2(t) \le C\|\mathcal{A}w_0\|^2\frac{1}{t^{\frac{1}{\gamma+1}}}, \quad 2\gamma + 1 > 0, \tag{3.77}$$

$$E_1(t) \le C\|\mathcal{A}w_0\|^2\frac{1}{t^{\frac{1}{-\gamma}}}, \quad E_2(t) \le C\|\mathcal{A}w_0\|^2\frac{1}{t^{\frac{1}{-\gamma}}}, \qquad 2\gamma + 1 \le 0. \tag{3.78}$$

Proof. Developing $e^{\pm}_{1,n}, e^{\pm}_{2,n}$ on the basis of $E^{\pm}_{1,n}, E^{\pm}_{2,n}$, we get

$$e^{\pm}_{1,n} = \alpha^{\pm}_{1,n}E^{\pm}_{1,n} + \alpha^{\pm}_{2,n}E^{\pm}_{2,n}, \quad e^{\pm}_{2,n} = \beta^{\pm}_{1,n}E^{\pm}_{1,n} + \beta^{\pm}_{2,n}E^{\pm}_{2,n}. \tag{3.79}$$

Writing

$$w_0 = \sum_{n=1}^{\infty} a_{1,n}^{\pm} e_{1,n}^{\pm} + \sum_{n=1}^{\infty} a_{2,n}^{\pm} e_{2,n}^{\pm}, \tag{3.80}$$

we then have

$$\begin{aligned} w(t) &= \sum_{n=1}^{\infty} a_{1,n}^{\pm} e^{\lambda_{1,n}^{\pm} t} e_{1,n}^{\pm} + \sum_{n=1}^{\infty} a_{2,n}^{\pm} e^{\lambda_{2,n}^{\pm} t} e_{2,n}^{\pm} \\ &= \sum_{n=1}^{\infty} (a_{1,n}^{\pm} \alpha_{1,n}^{\pm} e^{\lambda_{1,n}^{\pm} t} + a_{2,n}^{\pm} \beta_{1,n}^{\pm} e^{\lambda_{2,n}^{\pm} t}) E_{1,n}^{\pm} \\ &\quad + \sum_{n=1}^{\infty} (a_{1,n}^{\pm} \alpha_{2,n}^{\pm} e^{\lambda_{1,n}^{\pm} t} + a_{2,n}^{\pm} \beta_{2,n}^{\pm} e^{\lambda_{2,n}^{\pm} t}) E_{2,n}^{\pm}. \end{aligned} \tag{3.81}$$

The orthogonality of $E_{1,n}^{\pm}, E_{2,n}^{\pm}$ implies

$$E_1(t) = \frac{1}{2} \sum_{n=1}^{\infty} |a_{1,n}^{\pm} \alpha_{1,n}^{\pm} e^{\lambda_{1,n}^{\pm} t} + a_{2,n}^{\pm} \beta_{1,n}^{\pm} e^{\lambda_{2,n}^{\pm} t}|^2, \tag{3.82}$$

$$E_2(t) = \frac{1}{2} \sum_{n=1}^{\infty} |a_{1,n}^{\pm} \alpha_{2,n}^{\pm} e^{\lambda_{1,n}^{\pm} t} + a_{2,n}^{\pm} \beta_{2,n}^{\pm} e^{\lambda_{2,n}^{\pm} t}|^2. \tag{3.83}$$

If $2\gamma + 1 > 0$, then from (3.47) we get

$$\alpha_{1,n}^{\pm} = O(1), \quad \alpha_{2,n}^{\pm} = O\Big(\frac{1}{\mu_n^{2\gamma+1}}\Big), \quad \beta_{1,n}^{\pm} = O\Big(\frac{1}{\mu_n^{2\gamma+1}}\Big), \quad \beta_{2,n}^{\pm} = O(1). \tag{3.84}$$

Inserting (3.84) into (3.82)–(3.83), we get

$$E_1(t) \le C \sum_{n=1}^{\infty} \left(\frac{|\mu_n a_{1,n}^{\pm}|^2}{\mu_n^2 e^{\mu_n^{2\gamma} t}} + \frac{|\mu_n a_{2,n}^{\pm}|^2}{\mu_n^{4\gamma+4} e^{\frac{a^2 t}{\mu_n^{2\gamma+2}}}} \right), \tag{3.85}$$

$$E_2(t) \le C \sum_{n=1}^{\infty} \frac{|\mu_n a_{1,n}^{\pm}|^2}{\mu_n^{4\gamma+4} e^{\mu_n^{2\gamma} t}} + \frac{|\mu_n a_{2,n}^{\pm}|^2}{\mu_n^2 e^{\frac{a^2 t}{\mu_n^{2\gamma+2}}}}. \tag{3.86}$$

Using the estimate

$$\mu_n^{2\theta} e^{\frac{t}{\mu_n^{\alpha}}} \ge C t^{\frac{2\theta}{\alpha}} \qquad \forall\ \theta > 0, \alpha > 0 \tag{3.87}$$

in (3.85)–(3.86), it follows that

$$E_1(t) \le C \|\mathcal{A} w_0\|^2 \left(\frac{1}{t^{\frac{1}{-\gamma}}} + \frac{1}{t^2} \right) \le C \|\mathcal{A} w_0\|^2 \frac{1}{t^2}, \tag{3.88}$$

$$E_2(t) \le C \|\mathcal{A} w_0\|^2 \left(\frac{1}{t^{\frac{2(\gamma+1)}{-\gamma}}} + \frac{1}{t^{\frac{1}{\gamma+1}}} \right) \le C \|\mathcal{A} w_0\|^2 \frac{1}{t^{\frac{1}{\gamma+1}}}. \tag{3.89}$$

If $2\gamma + 1 \le 0$, then from (3.48)–(3.49) we get

$$\alpha_{1,n}^{\pm} = O(1), \quad \alpha_{2,n}^{\pm} = O(1), \quad \beta_{1,n}^{\pm} = O(1), \quad \beta_{2,n}^{\pm} = O(1). \tag{3.90}$$

Inserting (3.90) into (3.82)–(3.83), we get

$$E_{1,2}(t) \le C \sum_{n=1}^{\infty} (|\mu_n a_{1,n}^{\pm}|^2 + |\mu_n a_{2,n}^{\pm}|^2) \frac{1}{\mu_n^2 e^{\mu_n^{2\gamma} t}}. \tag{3.91}$$

Then using (3.87) in (3.91) gives (3.78). The proof is thus complete. □

Comments on Theorems 3.1 and 3.2. From (3.73) we see that the decay rate $\delta(\gamma)$ is an increasing function for $-\infty < \gamma \le -1/2$, decreasing for $-1/2 \le \gamma \le 0$, and achieves the maximum 2 at $\gamma = -1/2$. The best decay rate $\delta = 2$ occurs for $\gamma = -1/2$.

If $2\gamma + 1 > 0$, system (3.2)–(3.3) is *overdamped* in the sense that the eigenvectors $e_{1,n}^{\pm}$ are asymptotically decoupled from the eigenvectors $e_{2,n}^{\pm}$. In that case, the interferences between the two equations are very weak and the wave propagates *almost independently* in the two equations. The energy of the first equation, $E_1(t)$, decays more quickly than $E_2(t)$, the energy of the second equation.

If $2\gamma + 1 \le 0$, system (3.2)–(3.3) is *right-damped* in the sense that the eigenvectors $e_{1,n}^{\pm}$ are involved with the eigenvectors $e_{2,n}^{\pm}$. In that case, the damping applied to the first equation is well transmitted to the second equation and the system is *really coupled*. Consequently, the energies $E_1(t), E_2(t)$ of the two equations decay at the same rate. This balanced repartition of energies within the two equations is due to the compensation of real parts of the two branches of the eigenvalues.

A stronger damping $A^{\gamma} y_t$ does not necessarily give a better total decay rate of energy. A good damping should provide a compensation of the real parts of the two branches of eigenvalues and carry the transmission of the damping from one equation to another. This can be done by means of a suitably weaker damping.

We believe that the spectrum compensation is a natural phenomenon for partially damped distributed systems. It seems interesting to consider coupled systems with different operators A_1, A_2 as in [3]. Indeed the same results could be obtained without essential difficulty in the case $A_2 = A_1^2$ or other similar situations in [1]. But in general we can no long calculate explicitly the eigenvalues as in Proposition 3.1.

4. Examples of application. Let $\Omega \subset \mathbb{R}^N$ be a bounded open set with smooth boundary Γ. We denote by $\|\cdot\|_{0,\Omega},\ \|\cdot\|_{1,\Omega},\ \|\cdot\|_{2,\Omega} \cdots$ the norms of the Sobolev spaces $L^2(\Omega), H^1(\Omega), H^2(\Omega) \cdots$, respectively.

Example 4.1. Let us consider the system of weakly coupled wave equations

$$\begin{cases} y_{tt} - \Delta y + (-\Delta)^{-1/2} y_t + au = 0 & \text{in} \quad \Omega, \\ u_{tt} - \Delta u + ay = 0 & \text{in} \quad \Omega, \\ y = u = 0 & \text{on} \quad \Gamma, \end{cases} \tag{4.1}$$

where $a \in \mathbb{R}$ is small enough, and where $(-\Delta)^{-1/2}$ is a linear continuous operator from $L^2(\Omega)$ onto $H_0^1(\Omega)$.

Defining the operator A in $L^2(\Omega)$ by

$$A = -\Delta \quad \text{with} \quad D(A) = H^2(\Omega) \cap H_0^1(\Omega), \tag{4.2}$$

we easily check that A is a densely defined closed self-adjoint operator with compact resolvent in $L^2(\Omega)$. Then applying Theorem 3.1 we get the optimal polynomial energy decay rate

$$\begin{aligned} &\|y(t)\|_{1,\Omega}^2 + \|y_t(t)\|_{0,\Omega}^2 + \|u(t)\|_{1,\Omega}^2 + \|u_t(t)\|_{0,\Omega}^2 \\ &\quad \le \frac{c}{t^2} \Big(\|y_0\|_{2,\Omega}^2 + \|z_0\|_{1,\Omega}^2 + \|u_0\|_{2,\Omega}^2 + \|v_0\|_{1,\Omega}^2 \Big) \end{aligned} \tag{4.3}$$

for all smooth initial data

$$\begin{cases} y(x,0) = y_0(x) \in H^2(\Omega) \cap H_0^1(\Omega), & y_t(x,0) = z_0(x) \in H_0^1(\Omega), \\ u(x,0) = u_0(x) \in H^2(\Omega) \cap H_0^1(\Omega), & u_t(x,0) = v_0(x) \in H_0^1(\Omega). \end{cases} \tag{4.4}$$

If we had taken a stronger damping y_t as was done in [3], instead of $1/t^2$ we could get only $1/t$ as the energy decay rate for the same initial data.

Example 4.2. Now we consider the system of weakly coupled plate equations

$$\begin{cases} y_{tt} + \Delta^2 y + (\Delta^2)^{-1/2} y_t + au = 0 & \text{in} \quad \Omega, \\ u_{tt} + \Delta^2 u + ay = 0 & \text{in} \quad \Omega, \\ y = \frac{\partial y}{\partial n} = u = \frac{\partial u}{\partial n} = 0 & \text{on} \quad \Gamma, \end{cases} \tag{4.5}$$

where $a \in \mathbb{R}$ is small enough, and where $(\Delta^2)^{-1/2}$ is a linear continuous operator from $L^2(\Omega)$ onto $H_0^2(\Omega)$.

Defining the operator A in $L^2(\Omega)$ by

$$A = \Delta^2 \quad \text{with} \quad D(A) = H^4(\Omega) \cap H_0^2(\Omega), \tag{4.6}$$

we can easily check all the conditions of Theorem 3.1. Then for any smooth initial data

$$\begin{cases} y(x,0) = y_0(x) \in H^4(\Omega) \cap H_0^2(\Omega), & y_t(x,0) = z_0(x) \in H_0^2(\Omega), \\ u(x,0) = u_0(x) \in H^4(\Omega) \cap H_0^2(\Omega), & u_t(x,0) = v_0(x) \in H_0^2(\Omega), \end{cases} \tag{4.7}$$

we have

$$\|y(t)\|_{2,\Omega}^2 + \|y_t(t)\|_{0,\Omega}^2 + \|u(t)\|_{2,\Omega}^2 + \|u_t(t)\|_{0,\Omega}^2 \tag{4.8}$$

$$\le \frac{c}{t^2}\Big(\|y_0\|_{4,\Omega}^2 + \|z_0\|_{2,\Omega}^2 + \|u_0\|_{4,\Omega}^2 + \|v_0\|_{2,\Omega}^2\Big). \tag{4.9}$$

Similarly, if we had taken a stronger feedback control y_t as was done in [3], we could get only $1/t$ as the energy decay rate for the same initial data.

In [3] more general systems with different operators A_1, A_2 were considered under an artificial condition $D(A_2^{j/2}) \subset D(A_1)$, $j \ge 2$, which restricts the applications to the distributed systems of the same kind of boundary conditions (see Examples 6.1–6.5 in [3]). The following example shows that the above-mentioned condition is not necessary, and the polynomial energy decay rate should be true for more general coupled systems. In order to make the computation as clear as possible, we have chosen the special boundary conditions.

Example 4.3. Consider the following system of compactly coupled and partially damped Euler–Bernoulli beam equations:

$$\begin{cases} y_{tt} + y_{xxxx} + by_t + au_x = 0, & 0 < x < \pi, \\ u_{tt} + u_{xxxx} - ay_x = 0, & 0 < x < \pi, \\ y_x(0) = y_{xxx}(0) = y_x(\pi) = y_{xxx}(\pi) = 0, \\ u(0) = u_{xx}(0) = u(\pi) = u_{xx}(\pi) = 0. \end{cases} \tag{4.9}$$

Putting

$$\widetilde{L}^2(0,1) = \left\{ y \in L^2(0,\pi), \quad \int_0^\pi y(x)dx = 0 \right\},$$

$$V = \left\{ y \in H^2(0,\pi), \quad y'(0) = y'(\pi) = 0, \quad \int_0^\pi y(x)dx = 0 \right\},$$

$$W = \{ u \in H^2(0,\pi), \quad u(0) = u(\pi) = 0 \}$$

we define the energy space

$$\mathcal{H} = V \times \widetilde{L}^2(0,\pi) \times W \times L^2(0,\pi).$$

It is easy to prove that the system (4.9) generates a C_0-semigroup of contractions on the space $\mathcal{H}$ for $b > 0$ and a small enough. Moreover, setting the energy

$$E(t) = \frac{1}{2}\int_0^\pi (|y_{xx}|^2 + |y_t|^2 + |u_{xx}|^2 + |u_t|^2 - ay_x\overline{u} - au\overline{y}_x)dx, \tag{4.10}$$

we have

$$\frac{d}{dt}E(t) = -b\int_0^\pi |y_t|^2 dx \le 0. \tag{4.11}$$

Now we consider the associated eigenproblem

$$\begin{cases} \lambda^2 y + y_{xxxx} + b\lambda y + au_x = 0 & 0 < x < \pi, \\ \lambda^2 u + u_{xxxx} - ay_x = 0 & 0 < x < \pi, \\ y_x(0) = y_{xxx}(0) = y_x(\pi) = y_{xxx}(\pi) = 0, \\ u(0) = u_{xx}(0) = u(\pi) = u_{xx}(\pi) = 0. \end{cases} \tag{4.12}$$

Let

$$y = \alpha_n \cos nx, \qquad u = \beta_n \sin nx, \qquad n \ge 1, \tag{4.13}$$

be an eigenfunction. Then λ must satisfy the system

$$\begin{cases} \alpha_n(\lambda^2 + b\lambda + n^4) + \beta_n an = 0, \\ \beta_n(\lambda^2 + n^4) + \alpha_n an = 0, \end{cases} \tag{4.14}$$

which has a nontrivial solution if and only if

$$(\lambda^2 + n^4)(\lambda^2 + b\lambda + n^4) - a^2n^2 = 0. \tag{4.15}$$

Proceeding as in Proposition 3.1, we find easily that

$$\lambda_{1,n}^{\pm} = \pm in^2 - \frac{b}{2} + O\Big(\frac{1}{n^2}\Big), \tag{4.16}$$

$$\lambda_{2,n}^{\pm} = \pm in^2 - \frac{a^2}{2bn^2} + O\Big(\frac{1}{n^6}\Big). \tag{4.17}$$

Then for $\lambda = \lambda_{1,n}^{\pm}$, taking

$$\alpha_{1,n}^{\pm} = \frac{1}{\sqrt{2}}, \quad \beta_{1,n}^{\pm} = -\frac{an}{(\lambda_{1,n}^{\pm})^2 + n^4}\alpha_{1,n}^{\pm} = O\Big(\frac{1}{n}\Big)$$

in (4.13) we get the corresponding eigenvector

$$e_{1,n}^{\pm} = \frac{1}{\sqrt{\pi}}\begin{pmatrix} \frac{\cos nx}{\pm in^2} \\ \cos nx \\ 0 \\ 0 \end{pmatrix} + O\Big(\frac{1}{n}\Big) \quad \forall n \ge 1. \tag{4.18}$$

For $\lambda = \lambda_{2,n}^{\pm}$, taking

$$\beta_{2,n}^{\pm} = \frac{1}{\sqrt{\pi}}, \quad \alpha_{2,n}^{\pm} = -\frac{(\lambda_{2,n}^{\pm})^2 + n^4}{an}\beta_{2,n}^{\pm} = O\Big(\frac{1}{n}\Big)$$

in (4.13), we get the corresponding eigenvector

$$e_{2,n}^{\pm} = \frac{1}{\sqrt{\pi}} \begin{pmatrix} 0 \\ 0 \\ \frac{\sin n\pi x}{\pm i n^2} \\ \sin n\pi x \end{pmatrix} + O\Big(\frac{1}{n}\Big) \quad \forall n \geq 1. \tag{4.19}$$

Using the same procedure as in Proposition 3.3, we can prove that the system $\{e_{1,n}^{\pm}, e_{2,n}^{\pm}\}_{n\geq 1}$ forms a Riesz basis in $\mathcal{H}$. But in the one-dimensional case, the Riesz basis property is evident because the eigenvectors $e_{1,n}^{\pm}, e_{2,n}^{\pm}$ are quadratically close to a Hilbert basis, due to the expansions (4.18)–(4.19), and therefore form a Riesz basis in $\mathcal{H}$ (see Theorem 4.2.3 in [12] and Theorem 4.1 in [28] for the original idea on the eigenvalues of lower frequencies). Moreover, (4.16)–(4.17) show that the eigenvalues of system (4.12) satisfy condition (2.1) with $\mu_{1,n} = \mu_{2,n} = n^2$ and $\alpha_1 = 0, \alpha_2 = 1$. Then applying Theorem 2.1, we get the polynomial energy decay rate

$$E(t) \leq C(\|y_0\|_4^2 + \|z_0\|_2^2 + \|u_0\|_4^2 + \|v_0\|_2^2)\frac{1}{t^2} \qquad \forall t > 0. \tag{4.20}$$

for the solution of system (4.9) with smooth initial data $y_0 \in H^4(0,\pi) \cap V, u_0 \in H^4(0,\pi) \cap W$ and $z_0 \in V, v_0 \in W$.

Remark 4.1. The coupling terms ay_x, au_x do not appear in expression (4.11). Nevertheless, the energy decays at the rate of $1/t^2$ instead of $1/t$ for the system coupled through the displacements ay, au.

Acknowledgments. The authors would like to thank the referees for very valuable comments and suggestions. B. Rao thanks E. Zuazua for a fruitful discussion on the topic of this work.

SIMULATION-BASED UNIFORM VALUE FUNCTION ESTIMATES OF MARKOV DECISION PROCESSES*

RAHUL JAIN† AND PRAVIN P. VARAIYA†

Abstract. The value function of a Markov decision process (MDP) assigns to each policy its expected discounted reward. This expected reward can be estimated as the empirical average of the reward over many independent simulation runs. We derive bounds on the number of runs needed for the uniform convergence of the empirical average to the expected reward for a class of policies, in terms of the Vapnik-Chervonenkis or P-dimension of the policy class. Further, we show through a counterexample that whether we get uniform convergence or not for an MDP depends on the simulation method used. Uniform convergence results are also obtained for the average-reward case, for partially observed Markov decision processes, and can be easily extended to Markov games. The results can be viewed as a contribution to empirical process theory and as an extension of the probably approximately correct (PAC) learning theory for partially observable MDPs and Markov games.

Key words. Markov decision processes, Markov games, empirical process theory, PAC learning, value function estimation, uniform rate of convergence

DOI. 10.1137/040619508

1. Introduction.

We address the following question:

Given a Markov decision process (MDP) with an unknown policy from a given set of policies, how can we estimate its value function from computer simulations?

The question is motivated by the system identification problem in stochastic dynamical systems, such as pursuit-evasion games [38], and the estimation problem in econometric analysis [32].

The question is intimately related to empirical process theory (EPT) [35, 44], which studies the uniform behavior of a class $\mathcal{G}$ of measurable functions in the law of large numbers [34] (as well as the central limit theorem [15]) regime. In particular, EPT studies the conditions for which

$$\Pr\left\{\sup_{g\in\mathcal{G}}\left|\frac{1}{n}\sum_{i=1}^{n}g(X_i)-\mathbb{E}_P[g(X)]\right|>\epsilon\right\}\to 0 \tag{1.1}$$

and the rate of convergence. Convergence results in EPT typically use concentration of measure inequalities such as those of Chernoff [11] and Hoeffding [19]. The rate of convergence of an empirical average to the expected value depends on the exponent in the upper bound of such inequalities. Thus, there has been an effort to improve the exponent [23]. Talagrand [40] introduced new concentration of measure inequalities for product probability spaces that are significantly tighter than the Hoeffding–Chernoff type inequalities. The setting of general product probability spaces [27, 41] instead of just independent, identically distributed (i.i.d.) product probability spaces [11,

19] has greatly expanded the applications [28, 39]. Moreover, many applications involve dependent processes. The Hoeffding inequality has been extended to various dependent cases [8, 26, 43], while an extension of Talagrand's inequality for Markov chains and certain mixing processes was provided by [37].

The goal of this paper is to extend the reach of this rich and rapidly developing theory in a new direction. We provide the beginnings of an empirical process theory for MDPs. This essentially involves considering empirical averages of iterates of functions; i.e., if f is a map from $\mathbb{R}$ to itself, then we consider $g = f^t$ for some fixed integer t, where f^t denotes $f \circ \cdots \circ f$, with iteration being done t times. This case is not subsumed in the existing results in the empirical process theory discussed above (see also [13]). Interestingly, we discover that the method used to obtain the sample trajectories of the MDPs from computer simulation affects the rate of convergence. Thus, such a theory fills an important void in the EPT [35, 44] and the stochastic control literatures [36]. It also underlines the importance of choosing a suitable computer simulation.

We now make the question above more precise and explain the contribution of this paper.

Consider an MDP with a set of policies Π. The value function assigns to each $\pi \in \Pi$ its expected discounted reward $V(\pi)$. We estimate V from independent samples of the discounted reward by the empirical mean, $\hat{V}(\pi)$. We obtain the number of samples $n(\epsilon, \delta)$ (or sample complexity) needed so that the probability

$$\Pr\left\{\sup_{\pi\in\Pi} |\hat{V}(\pi) - V(\pi)| > \epsilon\right\} < \delta. \tag{1.2}$$

Our approach is broadly inspired by [17, 45, 46] and influenced by [21]. Thus, we would like to reduce the problem in (1.2) to understanding the geometry of Π in terms of its covering number. (If the covering number is finite, it is the minimal number of elements of a set needed to approximate any element in the set Π with a given accuracy.) We first relate the covering numbers of the space of stationary stochastic policies and the space of Markov chains that they induce. We relate these to the space of simulation functions that simulate the Markov chains when the set of transition probabilities of the latter is convex. These results together yield the rate of convergence of the empirical estimate to the expected value for the discounted-reward MDPs. What makes the problem nontrivial is that obtaining an empirical discounted reward from simulation involves an iteration of simulation functions. The geometry of the space of iterated simulation functions is much more complex than that of the original space.

One of the key contributions of this paper is the observation that how we simulate an MDP matters for obtaining uniform estimates. We show through an example (see Example 5.4) that uniform estimates of an MDP may converge under one simulation model but fail to do so under another. This is a new (and surprising) observation in the Markov decision theory as well as in the EPT literature.

We then consider the average-reward case. This appears to be the first attempt at nonparametric uniform value estimation for the average-reward case when simulation is done with just one sample path. Ergodicity and weak mixing are exploited to obtain uniform rates of convergence of estimates to expected values. We extend the results to dynamic Markov games and to the case when the Markov decision process is partially observable and policies are nonstationary and have memory.

The problem of uniform convergence of the empirical average to the value function for discounted MDPs was studied in [20, 30] in a machine learning context. While [20] considered only finite state and action spaces, [30] obtains the conditions for uniform

convergence in terms of the simulation model rather than the geometric characteristics (such as covering numbers or the P-dimension) of the simulation function space as opposed to that of the more natural policy space. Large-deviations results for finite state and action spaces for the empirical state-action frequencies and general reward functions were obtained in [4, 24]. A different approach more akin to importance sampling is explored in [33].

While the problem of uniform estimation of the value function for discounted and average-reward partially observed MDPs is of interest in itself, it is also connected with the system identification problem [10, 48]. Also interesting and important for many applications are computationally tractable methods (such as through simulation) for approximating the optimal policy [31]. The simulation-based estimates, such as those proposed in this paper, have been used in a gradient-based method for finding Nash equilibrium policies in a pursuit-evasion game problem [38], though the theoretical understanding is far from complete. Other simulation-based methods for finding approximations to the optimal policy include [25], a likelihood-ratio type gradient estimation method for finite state spaces, and [6], which imposes certain differentiability and regularity assumptions on the derivatives of the policies with respect to the parameters.

The rest of the paper is organized as follows. Section 2 relates the work to the probably approximately correct (PAC) learning model and the system identification problem. Section 3 is a warm-up section presenting preliminaries and relating the covering numbers of the space of transition probabilities of the induced Markov chains and the policy space. Section 4 presents the estimation methodology using the "simple" simulation model and discusses its combinatorial complexity. Section 5 obtains uniform sample complexity results for estimation of values of discounted-reward MDPs. Section 6 considers average-reward MDPs. Section 7 provides the extension to partially observed MDPs with general policies. Some proofs are relegated to the appendices to maintain a smooth exposition.

2. Relation to PAC learning and system identification. System identification is studied in a general function learning setting in the PAC learning model [17, 42]. A fundamental relationship between system identification and empirical process theory was established by Vapnik and Chervonenkis in [47].

Consider a bounded real-valued measurable function $f \in \mathcal{F}$ over a set $\mathbb{X}$ with a probability measure P. We equip $\mathcal{F}$ with a pseudometric such as the one defined in (2.1) below. Unless necessary, we ignore all measurability issues throughout the paper. These have been discussed at length in [15, 34].

The goal is to estimate or "learn" f from independent samples $S = \{(x_1, f(x_1)), \ldots, (x_n, f(x_n))\}$. Say that $\mathcal{F}$ is *PAC-learnable* if there is an algorithm that maps S to $h_{n,f} \in \mathcal{F}$ such that for any $\epsilon > 0$, the probability that the empirical error

$$\operatorname{err}(f, h_{n,f}) := \int |f(x) - h_{n,f}(x)| P(dx) \tag{2.1}$$

is greater than ϵ goes to zero as $n \to \infty$. (Note that $h_{n,f}$ is a function of S.) In other words, for n large enough the probability that the error is larger than ϵ is smaller than some given $\delta > 0$.

The class of functions $\mathcal{F}$ has the *uniform convergence of empirical means (UCEM) property* if

$$\sup_{f \in \mathcal{F}} \left| \frac{1}{n} \sum_{i=1}^{n} f(X_i) - \mathbb{E}_P[f(X)] \right| \to 0$$

in probability. It is known that a class of bounded real-valued functions with the UCEM property is not only PAC-learnable but *PUAC (probably uniformly approximately correct)-learnable* [47], i.e.,

$$\lim_{n\to\infty} \mathrm{P}^n \left\{ \sup_{f\in\mathcal{F}} \mathrm{err}(f, h_{n,f}) > \epsilon \right\} = 0.$$

Thus if the mean value of each function in a family can be determined with small error and high probability, the function itself can be "identified" with small error and high probability [45, 46, 47, 49]. One such (minimum empirical risk) algorithm was discovered in [7] when the function class $\mathcal{F}$ satisfies a certain (finite covering number) condition.

The PAC learning model has been generalized to the case when the inputs are Markovian [1, 16], but it has not been extended to MDPs and games. We provide that extension in this paper.

3. Preliminaries. Consider an *MDP* M with countable state space $\mathbb{X}$ and action space $\mathbb{A}$, transition probability function $P_a(x, x')$, initial state distribution λ, and a measurable reward function $r(x)$ with values in $[0, R]$. The value function for a policy π is the expected discounted reward

$$V(\pi) = \mathbb{E}\left[\sum_{t=1}^{\infty} \gamma^t r(x_t)\right],$$

where $0 < \gamma < 1$ is a discount factor and x_t is the state at time t under policy π. For the average-reward case the value function is

$$V(\pi) = \mathbb{E}\left[\liminf_{T\to\infty} \frac{1}{T} \sum_{t=1}^{T} r(x_t)\right].$$

Let Π_0 denote the space of all *stationary stochastic policies* $\{\pi(x, a) : a \in \mathbb{A}, x \in \mathbb{X}, \sum_a \pi(x, a) = 1\}$ and let $\Pi \subseteq \Pi_0$ be the subset of policies of interest. The MDP M under a fixed stationary policy π induces a Markov chain with transition probability function $P_\pi(x, x') = \sum_a P_a(x, x')\pi(x, a)$. The initial distribution on the Markov chains is λ, and we identify P_π with the Markov chain. Denote $\mathcal{P} := \{P_\pi : \pi \in \Pi\}$.

We seek conditions on the policy space Π such that a simulation-based estimate $\hat{V}(\pi)$ converges to the value function $V(\pi)$ in probability uniformly over all policies in Π. For this, as we will see in section 5, it is essential to understand the geometry of the space $\mathcal{P}$, and hence of Π. We do this by relating the *covering numbers* of Π with that of $\mathcal{P}$, which are then related to a space of (simulation) functions $\mathcal{F}$ that we define in section 4.

Let $\mathbb{X}$ be an arbitrary set and let λ be a probability measure on $\mathbb{X}$. Given a set $\mathcal{F}$ of real-valued functions on $\mathbb{X}$, ρ a metric on $\mathbb{R}$, let $d_{\rho(\lambda)}$ be the pseudometric on $\mathcal{F}$ with respect to measure λ,

$$d_{\rho(\lambda)}(f, g) = \int \rho(f(x), g(x))\lambda(dx).$$

A subset $\mathcal{G} \subseteq \mathcal{F}$ is an ϵ-*net* for $\mathcal{F}$ if $\forall f \in \mathcal{F}$, $\exists g \in \mathcal{G}$ with $d_{\rho(\lambda)}(f, g) < \epsilon$. The size of the minimal ϵ-net is the ϵ-*covering number*, denoted $N(\epsilon, \mathcal{F}, d_{\rho(\lambda)})$. The ϵ-*capacity* of $\mathcal{F}$ under the ρ metric is $C(\epsilon, \mathcal{F}, \rho) = \sup_\lambda N(\epsilon, \mathcal{F}, d_{\rho(\lambda)})$. Essentially, the ϵ-net can be

seen as a subset of functions that can ϵ-approximate any function in $\mathcal{F}$. The covering number is a measure of the richness of the function class. The richer it is, the more approximating functions we will need for a given measure of approximation ϵ. The capacity makes it independent of the underlying measure λ on $\mathbb{X}$. (See [21] for an elegant treatment of covering numbers.)

Let σ be a probability measure on $\mathbb{A}$. We now define the following L_1-pseudometric on Π:

$$d_{L_1(\sigma\times\lambda)}(\pi,\pi') := \sum_{a\in\mathbb{A}} \sigma(a) \sum_{x\in\mathbb{X}} \lambda(x)|\pi(x,a) - \pi'(x,a)|,$$

and the total variation pseudometric on $\mathcal{P}$,

$$d_{TV(\lambda)}(P,P') := \sum_{y\in\mathbb{X}} \left| \sum_{x\in\mathbb{X}} \lambda(x)(P(x,y) - P'(x,y)) \right|.$$

Note that covering numbers of function spaces can be defined for pseudometrics, and a metric structure is not necessary (see [17, 21, 49]).

Bounds on covering numbers are obtained in terms of various combinatorial dimensions.[1] Thus, we first relate the covering number of $\mathcal{P}$ with a combinatorial dimension of Π. Recall some measures of combinatorial dimension.

Let $\mathcal{F}$ be a set of binary-valued functions from $\mathbb{X}$ to $\{0,1\}$. Say that $\mathcal{F}$ *shatters* $\{x_1,\ldots,x_n\}$ if the set $\{(f(x_1),\ldots,f(x_n)), f\in\mathcal{F}\}$ has cardinality 2^n. The largest such n is the VC-dim($\mathcal{F}$). Intuitively, this means that the function class $\mathcal{F}$ can distinguish between a set of n points from the set $\mathbb{X}$.

Let $\mathcal{F}$ be a set of real-valued functions from $\mathbb{X}$ to $[0,1]$. Say that $\mathcal{F}$ *P-shatters* $\{x_1,\ldots,x_n\}$ if there exists a witness vector $c=(c_1,\ldots,c_n)$ such that the set $\{(\eta(f(x_1)-c_1),\ldots,\eta(f(x_n)-c_n)), f\in\mathcal{F}\}$ has cardinality 2^n; $\eta(\cdot)$ is the sign function. The largest such n is the P-dim($\mathcal{F}$). This is a generalization of VC-dim, and for $\{0,1\}$-valued functions, the two definitions are equivalent.

Other combinatorial dimensions such as the fat-shattering dimension introduced in [2] yield both an upper and lower bound on the covering numbers but in this paper we will use the P-dim. Results using fat-shattering dimension can be established similarly.

Given a policy space Π, let $\mathcal{P}$ denote the set of transition probabilities of the Markov chains it induces. We relate the covering numbers of the two spaces under the pseudometrics defined above.

LEMMA 3.1. *Suppose* P-dim(Π) $= d$. *Suppose there is a probability measure* λ *on* $\mathbb{X}$ *and a probability measure* σ *on* $\mathbb{A}$ *such that* $\pi(x,a)/\sigma(a) \le K\ \forall x\in\mathbb{X}, a\in\mathbb{A}, \pi\in\Pi$. *Then, for* $0<\epsilon<e/4\log_2 e$,

$$N(\epsilon,\mathcal{P},d_{TV(\lambda)}) \le N\left(\epsilon,\frac{\Pi}{\sigma},d_{L_1(\sigma\times\lambda)}\right) \le 2\left(\Phi\left(\frac{2eK}{\epsilon}\right)\right)^d,$$

where $\Phi(x) = x\log x$.

The proof is in the appendix.

We now give an example illustrating the intuition behind the concept of P-dim. It is similar in spirit to well-known results about finite-dimensional linear spaces. It

[1] These are different from the algebraic dimension. Examples of combinatorial dimensions are VC-dimension and P-dimension. A class of real-valued functions may have infinite algebraic dimension but finite P-dimension. See [3, 49] for more details.

shows that for an MDP with finite state and action spaces, the set of all stationary stochastic policies has a finite P-dimension equal to the number of free parameters needed to represent the set of policies being considered.

Example 3.2. Let $\mathbb{X} = \{1, \ldots, N\}$ and $\mathbb{A} = \{1, \ldots, M\}$. Then, P-dim $(\Pi_0) = N(M-1)$ for $M > 1$.

Proof. Consider the set of all stochastic policies:

$$\Pi_0 = \left\{ \pi : \mathbb{X} \times \mathbb{A} \to [0,1] \mid \sum_{a \in \mathbb{A}} \pi(x,a) = 1 \ \forall x \in \mathbb{X} \right\}.$$

Let $S = \{(x_1, a_1), \ldots, (x_N, a_1), \ldots, (x_1, a_{M-1}), \ldots, (x_N, a_{M-1})\}$. We can find $c_{11}, \ldots, c_{NM-1}$ such that the $N(M-1)$-dimensional vector

$$\begin{gathered}(\ \eta(\pi(x_1,a_1) - c_{11}), \ldots, \eta(\pi(x_1,a_{M-1}) - c_{1M-1}), \ldots \\ \vdots \quad \vdots \\ \ldots, \eta(\pi(x_N,a_1) - c_{N1}), \ldots, \eta(\pi(x_N,a_{M-1}) - c_{NM-1}) \ )\end{gathered}$$

yields all possible binary vectors as π runs over Π; $\eta(\cdot)$ is the sign function. Consider the first row. Note that the probabilities there together with $\pi(x_1, a_M)$ sum to 1. Choose all c_{1j} to be $1/M$. Then, we can get all possible binary vectors in the first row. Since the subsequent rows are independent, we can do the same for all of them. Thus, we can get all possible binary vectors of length $N(M-1)$. So Π_0 shatters S.

However, if we add another point, say (x_1, a_M), to S, the first row will sum to 1. In this case we cannot get all the 2^M possible binary vectors. Thus, the P-dimension of Π_0 is $N(M-1)$. □

4. The simulation model. We estimate the value $V(\pi)$ of policy $\pi \in \Pi$ from independent samples of the discounted rewards. The samples are generated by a simulation "engine" h. This is a deterministic function to which we feed a "noise" sequence $\omega = (\omega_1, \omega_2, \ldots)$ (with ω_i being i.i.d. from uniform distribution over $\Omega = [0,1]$) and an initial state x_0 (drawn from distribution λ). The engine h generates a sample trajectory with the same distribution as the Markov chain corresponding to π. The function $h : \mathbb{X} \times \mathbb{A} \times \Omega \to \mathbb{X}$ gives the next state x' given the current state x, action taken a, and noise ω_i. Several such sample trajectories are generated using i.i.d. noise sequences and initial states. Each sample trajectory yields an empirical total discounted reward. The estimate of $V(\pi)$, $\hat{V}(\pi)$ is the average of the empirical total discounted reward for the various sample trajectories.

Because simulation cannot be performed indefinitely, we stop the simulation at some time T, after which the contribution to the total discounted reward falls below $\epsilon/2$ for required estimation error bound ϵ. T is the $\epsilon/2$-*horizon time*.

Many simulation functions are possible. We will work with the following simple simulation model. For the rest of this paper, we consider the state space to be $\mathbb{X} = \mathbb{N}$.

DEFINITION 4.1 (simple simulation model). *The* simple *simulation model h for a given MDP is given by*

$$h(x, a, \omega) = \inf\{y \in \mathbb{X} : \omega \in [F_{a,x}(y-1), F_{a,x}(y))\},$$

in which $F_{a,x}(y) := \sum_{y' \le y} P_a(x, y')$ is the cummulative distribution function (c.d.f.) corresponding to the transition probability function $P_a(x, y)$.

Similarly, with a slight abuse of notation, we define the simple *simulation model h for the Markov chain P as*

$$h(x, P, \omega) = \inf\{y \in \mathbb{X} : \omega \in [F_{P,x}(y-1), F_{P,x}(y))\},$$

where $F_{P,x}(y) := \sum_{y' \le y} P(x, y')$ *is the c.d.f. corresponding to the transition probability function* $P(x, y)$.

This is the simplest method of simulation. For example, to simulate a probability distribution on a discrete state space, we partition the unit interval so that the first subinterval has length equal to the mass on the first state, the second subinterval has length equal to the mass on the second state, and so on. Perhaps surprisingly, there are other simulation functions h' that generate the same Markov chain, but which have a much larger complexity than h.

The sample trajectory $\{x_t\}$ for policy π is obtained by

$$x_{t+1} = f_{P_\pi}(x_t, \omega_{t+1}) = h(x_t, P_\pi, \omega_{t+1}),$$

in which P_π is the transition probability function of the Markov chain induced by π and $\omega_{t+1} \in \Omega$ is noise. The initial state x_0 is drawn according to the given initial state distribution λ. The function $f_{P_\pi} : \mathbb{X} \times \Omega \to \mathbb{X}$ is called the *simulation function* for the Markov chain transition probability function P_π. (The reader may note that the above definition is to ease understanding in this section. In the next section, we will redefine the domain and range of the simulation functions.) As before, $\mathcal{P} = \{P_\pi : \pi \in \Pi\}$. We denote by $\mathcal{F} = \{f_P : P \in \mathcal{P}\}$ the set of all simulation functions induced by $\mathcal{P}$.

To every $P \in \mathcal{P}$, there corresponds a function $f \in \mathcal{F}$. Observe that $f \in \mathcal{F}$ simulates $P \in \mathcal{P}$ given by

$$P(x, y) = \mu_0\{\omega : f(x, \omega) = y\},$$

where μ_0 is the Lebesgue measure on Ω. Unless specified otherwise, $\mathcal{F}$ will denote the set of simulation functions for the class $\mathcal{P}$ under the simple simulation model.

In the previous section, we related the covering numbers of policy space Π and $\mathcal{P}$. However, as we shall see in the next section, the convergence properties of our estimate of the value function really depend on the covering number of $\mathcal{F}$. Thus, we now show that the complexity of the space $\mathcal{F}$ is the same as that of $\mathcal{P}$ if $\mathcal{P}$ is convex.

The result is in the same spirit as Theorem 13.9 in [12] for finite-dimensional linear vector spaces. However, the setting here is different. We provide an independent proof.

LEMMA 4.2. *Suppose* $\mathcal{P}$ *is convex (being generated by a convex space of policies) with* P*-dimension* d. *Let* $\mathcal{F}$ *be the corresponding space of simple simulation functions induced by* $\mathcal{P}$. *Then,* P-dim $(\mathcal{F}) = d$. *Moreover, the algebraic dimension of* $\mathcal{P}$ *is also* d.

Proof. There is a one-to-one map between the space of simple simulation functions $\mathcal{F}$ and the space of c.d.f.'s $\tilde{\mathcal{F}}$ corresponding to $\mathcal{P}$. ($\tilde{\mathcal{F}} = \{\tilde{F} : \tilde{F}(x, y) = \sum_{y' \le y} P(x, y'), P \in \mathcal{P}\}$.) $\mathcal{F}$ and $\tilde{\mathcal{F}}$ have the same P-dimension because, for any $F \in \mathcal{F}$, $F(x, \omega) > y$ if and only if for the corresponding $\tilde{F} \in \tilde{\mathcal{F}}$, $\tilde{F}(x, y) < \omega$. Thus, $\tilde{\mathcal{F}}$ shatters $\{(x_1, y_1), \ldots, (x_d, y_d)\}$ with witness vector $(\omega_1, \ldots, \omega_d)$ if and only if $\mathcal{F}$ shatters $\{(x_1, \omega_1), \ldots, (x_d, \omega_d)\}$ with witness vector $(y_1, \ldots, y_d)$. So in the following discussion we treat them as the same space $\mathcal{F}$.

Because $\mathcal{P}$ has P-dimension d, there exists $S = \{(x_1, y_1), \ldots, (x_d, y_d)\}$ that is shattered by $\mathcal{P}$ with some witness vector $c = (c_1, \ldots, c_d)$. Consider the projection of the set $\mathcal{P}$ on the S coordinates: $\mathcal{P}|_S = \{(P(x_1, y_1), \ldots, P(x_d, y_d)) : P \in \mathcal{P}\}$. The definition of shattering implies that there is a d-dimensional hypercube contained in $\mathcal{P}|_S$ with center c. Also note that $\mathcal{P}|_S$ is convex and its algebraic dimension is d. To argue that the algebraic dimension of $\mathcal{P}$ cannot be $d + 1$, suppose that it is. Then it would contain $d+1$ coordinates such that the projection of $\mathcal{P}$ along those coordinates contains a hypercube of dimension $d+1$. Thus, $\mathcal{P}$ would shatter $d+1$ points with the

center of the hypercube being a witness vector. But that contradicts the assumption that the P-dimension of $\mathcal{P}$ is d.

Thus for convex spaces, the algebraic dimension and P-dimension are equal.

Next, $\mathcal{F}$ is obtained from $\mathcal{P}$ by an invertible linear transformation; hence its algebraic dimension is also d. Thus, it has d coordinates S such that the projected space $\mathcal{F}|_S$ has algebraic dimension d. Moreover, it contains a hypercube of dimension d. Hence, its P-dimension is at least d. Since the argument is reversible starting from space $\mathcal{F}$ to space $\mathcal{P}$, it implies P-dim $(\mathcal{P})$ = P-dim $(\mathcal{F})$. □

It may be noted that convexity is essential to the above argument. From several examples it appears that the result is not true without convexity. But we are unable to offer a concrete counterexample.

5. Discounted-reward MDPs. We now consider uniform value function estimation from simulation for discounted-reward MDPs.

For the rest of the paper, we redefine $\mathcal{F}$ to be a set of measurable functions from $Y := \mathbb{X} \times \Omega^\infty$ onto itself which simulate $\mathcal{P}$, the transition probabilities induced by Π under the simple simulation model. However, each function depends only on the first component of the sequence $\omega = (\omega_1, \omega_2, \ldots)$. Thus the results and discussion of the previous section hold. Let θ be the left-shift operator on Ω^∞, $\theta(\omega_1, \omega_2, \ldots) = (\omega_2, \omega_3, \ldots)$. For a policy π, our simulation system is

$$(x_{t+1}, \theta\omega) = f_{P_\pi}(x_t, \omega),$$

in which x_{t+1} is the next state starting from x_t and the simulator also outputs the shifted noise sequence $\theta\omega$. This definition of the simulation function is introduced to facilitate the iteration of simulation functions. Denote $\mathcal{F} := \{f_P : \mathbb{X} \times \Omega^\infty \to \mathbb{X} \times \Omega^\infty, P \in \mathcal{P}\}$ and $\mathcal{F}^2 := \{f \circ f : Y \to Y, f \in \mathcal{F}\}$ and $\mathcal{F}^t$ its generalization to t iterations. Similarly, we redefine the reward function as $r : \mathbb{X} \times \Omega^\infty \to [0, R]$.

The estimation procedure is the following. Obtain n initial states $x_0^1, \ldots, x_0^n$ drawn as i.i.d. according to λ, and n noise sequences $\omega^1, \ldots, \omega^n \in \Omega^\infty$ drawn according to μ. Denote the samples by $S = \{(x_0^1, \omega^1), \ldots, (x_0^n, \omega^n)\}$. Under the simple simulation model, $f_P(x, \omega) := (h(x, P, \omega_1), \theta\omega)$ and as before, $\mathcal{F} := \{f_P : P \in \mathcal{P}\}$. For a given initial state and noise sequence, the simulation function yields a reward sequence, the reward at time t given by $R_t(x_0, \omega) := r \circ f_P \circ \cdots \circ f_P(x_0, \omega)$, with f_P composed t times. The empirical total discounted reward for a given state sequence then is $\sum_{t=0}^\infty \gamma^t R_t(x_0, \omega)$. Our estimate of $V(\pi)$ from n simulations, each conducted for $\epsilon/2$-horizon time T, is $\hat{V}_n(\pi) := \frac{1}{n} \sum_{i=1}^n [\sum_{t=0}^T \gamma^t R_t^\pi(x_0^i, \omega^i)]$.

We first present a key technical result which relates the covering number of the iterated functions $\mathcal{F}^t$ under the ρ pseudometric with the covering number for $\mathcal{F}$ under the L_1 pseudometric, for which bounds are known in terms of the P-dim of $\mathcal{F}$.

Let μ be any probability measure on Ω^∞ and λ the initial distribution on $\mathbb{X}$. Denote the product measure on Y by $\mathbb{P} = \lambda \times \mu$, and on Y^n by $\mathbb{P}^n$. Define two pseudometrics on $\mathcal{F}$,

$$\rho_{\mathbb{P}}(f, g) = \sum_x \lambda(x) \mu\{\omega : f(x, \omega) \neq g(x, \omega)\}$$

and

$$d_{L_1(\mathbb{P})}(f, g) := \sum_x \lambda(x) \int |f(x, \omega) - g(x, \omega)| d\mu(\omega).$$

Here, we take $|f(x,\omega)-g(x,\omega)|$ to denote $|x'-x''|+||\theta\omega-\theta\omega||$, where $f(x,\omega)=(x',\theta\omega)$ and $g(x,\omega)=(x'',\theta\omega)$, and $||\cdot||$ is the l_1-norm on Ω^∞. Recall that $x',x''\in\mathbb{N}$. Then, $|f(x,\omega)-g(x,\omega)|=|x'-x''|$, the usual l_1 distance.

LEMMA 5.1. *Let λ be the initial distribution on $\mathbb{X}$ and let λ_f be the (one-step) distribution given by $\lambda_f(y)=\sum_x \lambda(x)\mu\{\omega : f(x,\omega)=(y,\theta\omega)\}$ for $f\in\mathcal{F}$. Suppose that*

$$K := \max\left\{\sup_{f\in\mathcal{F},y\in\mathbb{X}} \frac{\lambda_f(y)}{\lambda(y)}, 1\right\} < \infty. \tag{5.1}$$

Then,

$$\rho_{\mathbb{P}}(f^t,g^t) \le K^t d_{L_1(\mathbb{P})}(f,g)$$

and

$$N(\epsilon,\mathcal{F}^t,\rho_{\mathbb{P}}) \le N(\epsilon/K^t,\mathcal{F},d_{L_1(\mathbb{P})}).$$

The proof is in the appendix.

The condition of the lemma essentially means that under distribution λ the change in the probability mass on any state under any policy after one transition is bounded. It should be noted that for simulation, we can choose the initial state distribution and it should be such that $\lambda(y)>0\ \forall\ y$. Further, if $\lambda(y)=0$, the Markov chains are such that we must have $\lambda_f(y)=0$ as well, i.e., $\lambda_f\ll\lambda$. A particular case where this is satisfied is a set of positive recurrent Markov chains, say with the same invariant distribution π. If we choose $\lambda=\pi$, then $\lambda_f=\pi$ and the condition is trivially satisfied.

We now show that the estimate converges to the expected discounted reward uniformly over all policies in Π, and we also obtain the uniform rate of convergence.

THEOREM 5.2. *Let $(\mathbb{X},\Gamma,\lambda)$ be a measurable state space. Let $\mathbb{A}$ be the action space and r the $[0,R]$-valued reward function. Let $\Pi\subseteq\Pi_0$ be the space of stationary stochastic policies, $\mathcal{P}$ the space of Markov chain transition probabilities induced by Π, and $\mathcal{F}$ the space of simulation functions of $\mathcal{P}$ under the simple simulation model h. Suppose that* P-dim$(\mathcal{F})\le d$ *and the initial state distribution λ is such that $K:=\max\{\sup_{f\in\mathcal{F},x\in\mathbb{X}}\frac{\lambda_f(x)}{\lambda(x)},1\}$ is finite. Let $\hat{V}_n(\pi)$ be the estimate of $V(\pi)$ obtained by averaging the reward from n samples. Then, given any $\epsilon,\delta>0$,*

$$\mathbb{P}^n\left\{\sup_{\pi\in\Pi}|\hat{V}_n(\pi)-V(\pi)|>\epsilon\right\}<\delta$$

for

$$n \ge \frac{32R^2}{\alpha^2}\left(\log\frac{4}{\delta}+2d\left(\log\frac{32eR}{\alpha}+T\log K\right)\right). \tag{5.2}$$

T is the $\epsilon/2$-horizon time and $\alpha=\epsilon/2(T+1)$.

Proof. Fix a policy π. Let P be the induced Markov chain transition probability function simulated by the simple simulation function f_P. Let $R_t(x_0,\omega):=r\circ f_P\circ\cdots\circ f_P(x_0,\omega)$, with f_P composed t times, be the reward at time t, and denote $\mathcal{R}_t:=\{R_t : \mathbb{X}\times\Omega^\infty\to[0,R], P\in\mathcal{P}\}$. Let $V^T(\pi)$ be the expected discounted reward truncated up to T steps and $\hat{V}_n(\pi)=\frac{1}{n}\sum_{i=1}^n[\sum_{t=0}^T\gamma^t R_t^\pi(x_0^i,\omega^i)]$ its estimate from n finite time

simulations. Then,

$$\begin{aligned}|V(\pi)-\hat{V}_n(\pi)| &\le |V(\pi)-V^T(\pi)|+|V^T(\pi)-\hat{V}_n(\pi)|,\\ &\le |V^T(\pi)-\hat{V}_n^T(\pi)|+\frac{\epsilon}{2},\\ &\le \sum_{t=0}^{T}\left|\frac{1}{n}\sum_{i=1}^{n}[R_t^\pi(x_0^i,\omega^i)-\mathbb{E}(R_t^\pi)]\right|+\frac{\epsilon}{2}.\end{aligned}$$

Here, the expectation is with respect to the product measure $P_\pi^t\times\lambda\times\mu$. We show that with high probability, each term in the sum over t is bounded by $\alpha=\epsilon/2(T+1)$.

Note that

$$\int |r(f^t(x,\omega))-r(g^t(x,\omega))|d\mu(\omega)d\lambda(x)\le R\cdot\sum_x\lambda(x)\mu\{\omega: f^t(x,\omega)\ne g^t(x,\omega)\},$$

which as in Lemma 5.1 implies that

$$d_{L_1(\mathbb{P})}(r\circ f^t, r\circ g^t)\le R\cdot\rho_{\mathbb{P}}(f^t,g^t)\le R\cdot K^T d_{L_1(\mathbb{P})}(f,g).$$

Applying Theorem 3 from [17] with the "α" in the statement of that theorem set equal to $\epsilon/4R$ and $\nu=2R$, and using Lemma 5.1 and the inequality above, we get

$$\begin{aligned}&\mathbb{P}^n\left\{\sup_{R_t\in\mathcal{R}_t}\left|\frac{1}{n}\sum_{i=1}^{n}R_t(x_0^i,\omega^i)-\mathbb{E}(R_t)\right|>\alpha\right\}\\ &\le 2\mathbb{E}\left[\min\left(2N\left(\frac{\alpha}{16},\mathcal{R}_t|_S,d_{l_1}\right)e^{(-\frac{n\alpha^2}{32R^2})},1\right)\right]\\ &\le 4\sup_{\mathbb{P}}N\left(\frac{\alpha}{16},\mathcal{R}_t,d_{L_1(\mathbb{P})}\right)\exp\left(-\frac{n\alpha^2}{32R^2}\right)\\ &\le 4C\left(\frac{\alpha}{16},\mathcal{R}_t,d_{L_1}\right)\exp\left(-\frac{n\alpha^2}{32R^2}\right)\\ &\le 4\left(\frac{32eRK^T}{\alpha}\log\frac{32eRK^T}{\alpha}\right)^d\exp\left(-\frac{n\alpha^2}{32R^2}\right).\end{aligned}$$

This implies that the estimation error is bounded by α, with probability at least δ, if the number of samples is

$$n\ge\frac{32R^2}{\alpha^2}\left(\log\frac{4}{\delta}+2d\left(\log\frac{32eR}{\alpha}+T\log K\right)\right).\qquad\square$$

Remarks. 1. Theorem 5.2 implies that $\sup_{\pi\in\Pi}|\hat{V}_n(\pi)-V(\pi)|$ converges to zero in probability; hence the policy space Π is PAC-learnable. As in [30], the theorem assumes that the P-dimension of the $\mathcal{F}$ space is finite. Combined with Lemma 4.2, this gives the following corollary.

COROLLARY 5.3. *Under assumption* (5.1) *and if* $\mathcal{P}$ *is convex with* P-dim$(\mathcal{P})=d$, *result* (5.2) *of Theorem* 5.2 *holds.*

2. Our sample complexity is of the same order, in terms of δ,ϵ,T,R, and d, as the results of [30], but the two results are not directly comparable due to the different assumptions made. In fact, the major challenge in obtaining the uniform rate of convergence is relating the covering numbers and P-dimensions of the policy space Π

and $\mathcal{P}$ with the space $\mathcal{F}$. This is what we accomplished in this paper and what is missing in [30]. Also, unlike in [30], we do not require the simulation functions to be Lipschitz continuous. For a discrete state space, this is not a realistic assumption, as the following examples show.

(a) Consider the Markov chain on $\mathbb{N}$ such that the only transitions are from state 1 to state 2 with probability 1/2, to state 4 with probability $1/4, \ldots$, to state 2^k with probability $1/2^k$, etc. Let $\omega_l^k = \sum_{i=1}^{k+l-1} 2^{-i}$ and $\epsilon_l^k = 2^{-(k+l)}$ and define $\hat{\omega}^k = (\omega_1^k - \epsilon_1^k/2, \omega_2^k - \epsilon_2^k/2, \ldots)$ and $\check{\omega}^k = (\omega_1^k + \epsilon_1^k/2, \omega_2^k + \epsilon_2^k/2, \ldots)$. Thus, with noise sequence $\hat{\omega}^k$, the transition from state 1 is to state $\hat{x} = 2^k$, while with noise sequence $\check{\omega}^k$, the transition from state 1 is to state $\check{x} = 2^{k+1}$. Define the metric ρ on $\mathbb{X} \times \Omega^\infty$, $\rho((x_1, \hat{\omega}^k), (x_2, \check{\omega}^k)) = |x_1 - x_2| + |\hat{\omega}_1 - \check{\omega}_1|$. Then, it can be verified that

$$\rho(f(1, \hat{\omega}^k), f(1, \check{\omega}^k)) = |\hat{x} - \check{x}| + \epsilon_2^k \geq 2^k \ \forall k,$$

whereas Lipschitz continuity would require that it be less that $C2^{-(k+1)}$ for some positive constant C and every k. Thus, f is not Lipschitz continuous on Ω^∞.

(b) Consider the following Markov chain: state space $\mathbb{X} = \mathbb{N}$ again endowed with the same metric ρ as in the above example. Transitions are deterministic: transition from an even state n is to state $2n$, and from an odd state $n+1$ is to $3n$. Then, $\rho(f(n+1, \omega), f(n, \omega)) = n$ and so is not Lipschitz continuous on $\mathbb{X}$.

These examples demonstrate that Lipschitz continuity of the simulation functions on a discrete state space is not the right assumption to make.

3. *Markov games.* The generalization of the results of this section to discounted-reward Markov games is relatively straightforward. It is of considerable interest for many applications [38, 32]. Consider two players playing a Markov game with action spaces $\mathbb{A}_1$ and $\mathbb{A}_2$, state space $\mathbb{X}$, and transition function $P_{a_1,a_2}(x, y), a_1 \in \mathbb{A}_1, a_2 \in \mathbb{A}_2$. We consider only stationary policy spaces Π_1 and Π_2. The two reward functions r_1 and r_2 depend only on the state and have values in $[0, R]$. Denote the discounted-reward functions by $V_1(\pi_1, \pi_2)$ and $V_2(\pi_1, \pi_2)$ with discount factor $0 < \gamma < 1$. Denote the set of Markov chains induced by the policies in $\Pi_1 \times \Pi_2$ by $\mathcal{P} = \{P_{\pi_1,\pi_2} : (\pi_1, \pi_2) \in \Pi_1 \times \Pi_2)\}$ with $P_{\pi_1,\pi_2}(x, y) = \sum_{a_1,a_2} P_{a_1,a_2}(x, y)\pi_1(x, a_1)\pi_2(x, a_2)$.

Of interest is a uniform sample complexity bound such that the error in estimating both $V_1(\pi_1, \pi_2)$ and $V_2(\pi_1, \pi_2)$ is within ϵ with probability at least $1 - \delta$. This is now easily obtained by using Theorem 5.2 and bounding the maximum of the estimation error in V_1 and V_2. Such estimates may be used to compute the Nash equilibria [38].

A bound on the ϵ-covering number of $\mathcal{P}$ can be easily obtained by constructing $\epsilon/2$-covers for Π_1 and Π_2 under the L_1 metric, and then the ϵ cover for $\Pi_1 \times \Pi_2$ is obtained by taking the product of the two sets. The rest of the argument is the same as in Lemma 3.1.

4. We now show through two examples that the choice of simulation model to use for generating the sample trajectories affects whether we get uniform convergence or not.

Example 5.4. (i) Consider the three-state Markov chain in Figure 5.1 with the following transition matrix:

$$P = \begin{bmatrix} 0 & p & 1-p \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

and with state 0 always the initial state. Let $\mathcal{P} = \{P \text{ as defined above with } 0 \leq p \leq 1\}$ denote the set of all such Markov chains as p varies. It is easy to check that $\mathcal{P}$ is

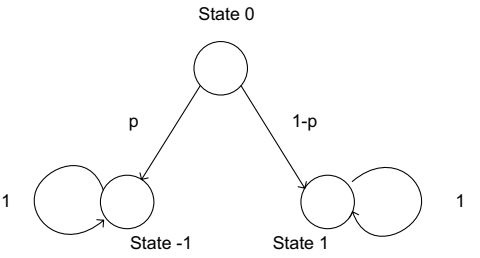

FIG. 5.1. *A three-state Markov chain with initial state* 0.

convex and has P-dimension 1. Let the reward in state 0 be 0, in state -1 be -1, and in state 1 be 1. This defines a Markov reward process, and for a given p we get the value $V_p = 1 - 2p$. Let $\mathcal{F}$ be the set of simple simulation functions that simulate the Markov chains in $\mathcal{P}$. By Lemma 4.2, P-dim($\mathcal{F}$) is 1 as well.

Now, consider the following set of simulations functions. Fix $p \in [0,1]$. Let $x_1, x_2, \ldots$ be rational numbers in $[0,1]$ such that

$$0 \le x_1 \le x_1 + p/2 \le x_2 \le x_2 + p/4 \le \cdots \le 1. \tag{5.3}$$

Generate a uniform $[0,1]$ random number ω. If it falls in $[x_1, x_1+p/2] \cup [x_2, x_2+p/4] \cup \cdots$, then the next state is -1; otherwise it is 1. This simulation function simulates a Markov chain with parameter p. Let $\tilde{\mathcal{F}}$ denote the set of all such simulation functions as p varies in $[0,1]$ and for every possible sequence of rational numbers satisfying (5.3). It is easy to check that P-dim($\tilde{\mathcal{F}}$) is not finite. Now, consider any $\omega_1, \omega_2, \ldots, \omega_n \in [0,1]$. Then, there exists a p and $x_1, x_2, \ldots$ such that $\omega_k \in [x_k, x_k + p/2^k]$, which means there is a simulation function which always goes to state -1 for this sequence of random numbers. Since n is arbitrary, this implies $\hat{V}_p = -1 \neq V_p$ for some p. Thus, in this case, even though the second set of simulation functions $\tilde{\mathcal{F}}$ simulates the same set of Markov chains $\mathcal{P}$, we do not get uniform convergence.

In the example above, there are many simulation functions in $\mathcal{F}$ that simulate the same Markov chain in $\mathcal{P}$. We now modify the example so that there is only one simulation function for each Markov chain.

(ii) Fix a positive integer m. Consider the $[0,1]$ interval divided into m^2 subintervals of length $1/m^2$. Pick any m of these subintervals, which can be done in $\binom{m^2}{m}$ ways. Arrange these choices in any order. Define

$$p_{m,k} = \frac{1}{m+1} + \frac{k}{\binom{m^2}{m} m(m+1)} \le \frac{1}{m}, \qquad k = 1, \ldots, \binom{m^2}{m}.$$

Scale the length of each of the m subintervals of the kth such choice to $p_{m,k}/m \le 1/m^2$, keeping the beginning point of the subintervals the same. Now, for every $p_{m,k}$ as defined above with $k = 1, \ldots, \binom{m^2}{m}$, and $m = 1, 2, \ldots$, define a simulation function $f_{m,k}$ such that for the Markov chain with parameter $p_{m,k}$, if the current state is zero, and the uniform $[0,1]$ random number falls in any of the subintervals, then the next state is -1; otherwise it is 1. All other Markov chains are simulated according to the simple simulation model. Thus, we get a new set of simulation functions $\bar{\mathcal{F}}$ with each Markov chain being simulated by only one simulation function. It is easy to check that P-dim($\bar{\mathcal{F}}$) is not finite. Further, given any $\omega_1, \omega_2, \ldots, \omega_n \in [0,1]$, we can always

pick an m large enough such that there is a k_m so that all of the ω_i lie outside the m subintervals, each of length $p_{m,k_m}/m$. Thus, the simulation goes to state -1 for each of the ω_i. Thus, $\hat{V}_{p_{m,k_m}} \neq V_{p_{m,k_m}}$ and we do not get uniform convergence.

These examples demonstrate that uniform convergence for MDPs depends not only on the geometry of the policy space but also on how the MDP is simulated to obtain the sample trajectories. The simple simulation model is in some sense the best model since it has the same complexity under convexity as the set of Markov chains it simulates (Lemma 4.2). However, these examples do not satisfy the conditions provided in Theorem 5.2. Note that those are sufficient conditions only.

An alternative simulation method for finite-dimensional convex spaces. An important special case is when the policy space is the convex hull of a finite number of policies, i.e., when all policies are (random) mixtures of finitely many policies. While the previous simulation method would still work, we present an alternative simulation method that exploits the convex structure.

The simulation method is the following. Suppose there are two policies π_i for $i = 0, 1$, each inducing a Markov chain P_i with simulation function f_i. Consider the mixture $\pi_w = w\pi_0 + (1-w)\pi_1$, so $P_w = wP_0 + (1-w)P_1$. For t steps, we have

$$P_w^t = w^t P_0^t + w^{t-1}(1-w)P_0^{t-1}P_1 + w^{t-1}(1-w)P_0^{t-2}P_1P_0 + \cdots + (1-w)^t P_1^t.$$

Note that P_0 and P_1 need not commute. To obtain $\hat{V}_n(\pi)$, we first determine the rewards at time t for $t = 0, \ldots, T$. To estimate the rewards, first draw the initial states $x_0^1, \ldots, x_0^n$ from λ, and the noise sequences $\omega^1, \ldots, \omega^n$ from μ. Then carry out 2^t simulations, one for each term in the sum of the equation above. For example, if $i_t \cdots i_1$ is the binary representation of k, then the contribution to reward from the kth term is determined by $r \circ f_{i_t} \circ \cdots \circ f_{i_1}(x_0^i, \omega^i)$. The estimate of the contribution to reward from the kth term, $\hat{R}_t^k$, is the mean over the n initial state and noise sequence pairs. The estimate of the reward at time t is

$$\hat{R}_t = w^t \hat{R}_t^0 + w^{t-1}(1-w)\hat{R}_t^1 + \cdots + (1-w)^t \hat{R}_t^{2^t-1}$$

and the value function estimate $\hat{V}_n(\pi)$ is $\sum_{t=0}^T \gamma^t \hat{R}_t$. This can be generalized to a policy space which is a convex hull of any finite number of policies.

THEOREM 5.5. *Let $\Pi = conv\{\pi_0, \ldots, \pi_{d-1}\}$, $\mathcal{P} = conv\{P_0, \ldots, P_{d-1}\}$ be the space of Markov chains induced by Π, and $\mathcal{F}$ be the space of simulation functions of $\mathcal{P}$ under the simple simulation model. Let $\hat{V}_n(\pi)$ be the estimate of $V(\pi)$ obtained from n samples. Then, given any $\epsilon, \delta > 0$*

$$\mathbb{P}^n \left\{ \sup_{\pi \in \Pi} |\hat{V}_n(\pi) - V(\pi)| > \epsilon \right\} < \delta$$

for $n \geq \frac{R^2}{2\alpha^2}\left(\log\frac{1}{\delta} + T\log 2d\right)$, where T is the $\epsilon/2$-horizon time and $\alpha = \epsilon/2(T+1)$.

Proof. Consider any $\pi \in \Pi$ and the corresponding $P \in \mathcal{P}$. Let $P = \sum_{i=0}^{d-1} a_i P_i$ with $a_i \geq 0$ and $\sum_i a_i = 1$. Thus, P^t can be written as

$$P^t = \sum_{k=0}^{d^t-1} w_k^t P_{i_t} \cdots P_{i_1}, \tag{5.4}$$

where $i_t \cdots i_1$ is a d-ary representation of k and the nonnegative weights w_k^t are such that $\sum_{k=0}^{d^t-1} w_k^t = 1$ and can be determined easily.

To obtain $\hat{V}_n(\pi)$, we need to simulate P for T steps as before. The t-step reward is determined by the state at time t, whose distribution is given by $\nu_t = P^t\lambda$. To estimate the reward, first draw the initial states $x_0^1, \ldots, x_0^n$ from λ, and the noise sequence $\omega^1, \ldots, \omega^n$ from μ. We carry out d^t simulations, one for each term in the sum of (5.4). Recall that $i_t \cdots i_1$ is a d-ary representation of k. Thus, to determine the contribution to the empirical reward at time t due to the kth term in (5.4), the state at time t is determined by $r \circ f_{i_t} \circ \cdots \circ f_{i_1}(x_0^i, \omega^i)$. Thus, an estimate of the expected reward at time t is

$$\hat{R}_t(w^t) = \sum_{k=0}^{d^t-1} w_k^t \left(\frac{1}{n} \sum_{i=1}^{n} r \circ f_{i_t} \circ \cdots \circ f_{i_1}(x_0^i, \omega^i) \right), \tag{5.5}$$

a consistent estimator of $\mathbb{E}_{P^t\lambda}[r(x)]$. $\hat{V}_n(\pi)$ is now given by $\sum_{t=0}^{T} \gamma^t \hat{R}_t(w^t(\pi))$, where $w^t(\pi)$ are the weights determined in 5.4 by policy π at time t. Denote $W_t := \{w^t(\pi) : \pi \in \Pi\}$.

Note that

$$\mathbb{E}_{P^t\lambda}[r(x)] = \sum_{k=0}^{d^t-1} w_k^t \left(\mathbb{E}_{P_{i_t} \cdots P_{i_1}\lambda}[r(x)] \right), \tag{5.6}$$

where the quantity in the brackets of (5.5) (denote it by $\hat{R}_t^k$) is an estimator for the quantity in the brackets of (5.6). Thus,

$$\begin{aligned} \mathbb{P}^n \left\{ \sup_{\pi \in \Pi} |\hat{V}_n(\pi) - V(\pi)| > \epsilon \right\} &\le \mathbb{P}^n \left\{ \sup_{w^t \in W_t} |\hat{R}_t(w^t) - \mathbb{E}_{P^t\lambda}[r(x)]| > \alpha \right\} \\ &\le d^T \max_k \mathbb{P}^n \{ |\hat{R}_t^k - \mathbb{E}_{P_{i_t} \cdots P_{i_1}\lambda}[r(x)]| > \alpha \} \\ &\le 2d^T \exp\left(-\frac{2n\alpha^2}{R^2} \right), \end{aligned}$$

where $\alpha = \epsilon/2(T+1)$ and the last inequality follows from Hoeffding's inequality. From the above, the sample complexity can be obtained as in the proof of Theorem 5.2. □

Remarks. This alternative simulation model has the same order of sample complexity as in the earlier case, but it has greater computational complexity since, for each chain, d^T simulations need to be carried out. However, if several Markov chains need to be simulated, as when performing an optimal policy search, the simulation is carried out only *once* for all the chains because the estimates for various mixtures are obtained by appropriately weighing the d^t estimates, $\hat{R}_t^k$.

Also, to obtain the estimates for $t \le T$, one need not repeat the simulation for each t. Instead, the T-step simulation suffices to yield the t-step estimate by simply ignoring the simulation beyond $t+1$. Thus, only d^T simulations are needed to obtain an estimate for a reward for any step $t \le T$ and any $P \in \mathcal{P}$.

6. Average-reward MDPs. Some MDP problems use the average-reward criterion. However, there are no published results on simulation-based uniform estimates of value functions of average-reward MDPs. We present such a result in this section.

Unlike the discounted-reward case, where we simulated several different sample paths, starting with different initial states, here the estimate is obtained from only one sample path. This is possible only when the policies we consider are such that

the Markov chains are stationary, ergodic, and weakly mixing. (The conditions under which a policy induces a stationary, ergodic Markov chain can be found in Chapter 5 of [9].) A related problem is addressed in [22], which uses Csiszer's concentration inequality to bound reward functionals for Doeblin chains. However, the bound is not uniform and distribution dependent.

Let λ_π denote the invariant measure of the Markov chain $\{X_k\}_{k=0}^\infty$ with transition probability function P_π, and Λ be the set of all such invariant measures. Let $\mathbb{P}$ denote the probability measure for the process. We assume that there is a Markov chain $\mathbb{P}_0$ with invariant measure (steady state distribution) λ_0 such that $\lambda_\pi \ll \lambda_0$, i.e., λ_π is absolutely continuous with respect to λ_0, meaning that $\lambda_\pi(A) = 0$ if $\lambda_0(A) = 0$ for any measurable set A [18]. We call such a chain a *reference* Markov chain. Let $\hbar_\pi(x) := \lambda_\pi(x)/\lambda_0(x)$ be the Radon–Nikodym derivative and assume that it is uniformly bounded, $\hbar_\pi(x) \le K \ \forall\ x$ and π. Let $\mathcal{H}$ be the set of all such Radon–Nikodym derivatives.

Our simulation methodology is to generate a sequence $\{x_k\}_{k=1}^n$ according to $\mathbb{P}_0$. We then multiply $r(x_t)$ by $\hbar_\pi(x_t)$ to obtain the tth-step reward for the Markov chain induced by policy π. The estimate of the value function is then obtained by taking an empirical average of the rewards, i.e.,

$$\hat{V}_n(\pi) = \frac{1}{n}\sum_{t=1}^{n} \tilde{r}_\pi(x_t),$$

in which $\tilde{r}_\pi(x) := r_\pi(x)\hbar_\pi(x)$. Let $\mathcal{R} = \{\tilde{r}_\pi : \pi \in \Pi\}$. Furthermore, in some problems, such as when the state space is multidimensional or complex, it may not be possible to integrate the reward function with respect to the stationary measure. In such cases, Monte Carlo type methods such as importance sampling are useful for estimating integrals. The method proposed here falls into such a category, and we present a uniform rate of convergence result for it. This approach is useful when it is difficult to sample from the stationary distributions of the Markov chains but easy to compute the derivative $\hbar_\pi(x)$.

We first state some definitions and results needed in the proof below. Let $\{X_n\}_{n=-\infty}^\infty$ be a process on the measurable space $(\mathbb{X}_{-\infty}^\infty, \mathcal{S}_{-\infty}^\infty)$. Consider a stationary, ergodic process with measure $\mathbb{P}$. Let P be the one-dimensional marginal, and $\bar{\mathbb{P}} = \prod_{-\infty}^\infty P$, the product measure under which the process is i.i.d.

Let $\mathbb{P}_{-\infty}^0$ and $\mathbb{P}_1^\infty$ be the semi-infinite marginals of $\mathbb{P}$. Define the *β-mixing coefficients* [14] as

$$\beta(k) := \sup\{|\mathbb{P}(A) - \mathbb{P}_{-\infty}^0 \times \mathbb{P}_1^\infty(A)| : A \in \sigma(X_{-\infty}^0, X_k^\infty)\}.$$

If $\beta(k) \to 0$ as $k \to \infty$, the process is said to be *β-mixing (or weakly mixing)*. From the definition of the β-mixing coefficients we get the following.

FACT 1 (see [29, 50]). *If $A \in \sigma(X_0, X_k, \ldots, X_{(m-1)k})$, $|\mathbb{P}(A) - \bar{\mathbb{P}}(A)| \le m\beta(k)$.*

We assume that the Markov chain $\mathbb{P}_0$ is β-mixing with mixing coefficients β_0. We also need the following generalization of Hoeffding's bound.

FACT 2 (McDiarmid–Azuma inequality [5, 27]). *Let $X_1, \ldots, X_n$ be i.i.d. drawn according to P and $g : X^n \to \mathbb{R}$. Suppose g has bounded differences, i.e.,*

$$|g(x_1, \ldots, x_i, \ldots, x_n) - g(x_1, \ldots, x_i', \ldots, x_n)| \le c_i.$$

Then, $\forall \tau > 0$,

$$P^n\{g(X^n) - \mathbb{E}g(X^n) \ge \tau\} \le \exp\left(-\frac{2\tau^2}{\sum_{i=1}^n c_i^2}\right).$$

We now show that the estimation procedure enunciated above for the average-reward case produces estimates $\hat{V}(\pi)$ that converge uniformly over all policies to the true value $V(\pi)$. Moreover, we can obtain the rate of convergence, whose explicit form depends on the specific problem.

THEOREM 6.1. *Suppose the Markov chains induced by $\pi \in \Pi$ are stationary and ergodic. Assume there exists a Markov chain $\mathbb{P}_0$ with invariant measure λ_0 and mixing coefficient β_0 such that $\lambda_\pi \ll \lambda_0$ and the $\hbar_\pi$ are bounded by a constant K with* P-dim$(\mathcal{H}) \leq d$. *Denote by $\hat{V}_n(\pi)$ the estimate of $V(\pi)$ from n samples. Then, given any $\epsilon, \delta > 0$,*

$$\mathbb{P}_0 \left\{ \sup_{\pi \in \Pi} |\hat{V}_n(\pi) - V(\pi)| > \epsilon \right\} < \delta,$$

for n large enough such that $\gamma(m) + Rm\beta_0(k) + \tau(n) \leq \epsilon$, where $\tau(n) := (\frac{2R^2}{n} \log \frac{1}{\delta})^{1/2}$ and

$$\gamma(m) := \inf_{\alpha > 0} \left\{ \alpha + 8R \left(\frac{32eRK}{\alpha} \log \frac{32eRK}{\alpha} \right)^d \exp\left(-\frac{m\alpha^2}{32R^2} \right) \right\},$$

with $n = m_n k_n$ such that $m_n \to \infty$ and $k_n \to \infty$ as $n \to \infty$.

Proof. The idea of the proof is to use the β-mixing property and reduce the problem to one with i.i.d. samples. We then use techniques similar to those used in the proof of Theorem 5.2. The problem of iteration of simulation functions does not occur in this case, which makes the proof easier.

Let $x_1, x_2, \ldots, x_n$ be the state sequence generated according to $\mathbb{P}_0$ which can be done using the simple simulation model. Note that

$$E_0[r(x)\hbar_\pi(x)] = E_{\lambda_\pi}[r(x)],$$

in which E_{λ_π} and E_0 denote expectation taken with respect to the stationary measures λ_π and λ_0, respectively. Denote $\hat{\mathbb{E}}_n[\tilde{r}_\pi; x^n] := \frac{1}{n} \sum_{t=1}^n \tilde{r}_\pi(x_t)$ and observe that

$$\begin{aligned}
\mathbb{E}_0 \left[\sup_{\pi \in \Pi} |\hat{\mathbb{E}}_n[\tilde{r}_\pi; x^n] - E_0[\tilde{r}_\pi(x)]| \right] &\overset{(1)}{\leq} \frac{1}{k} \sum_{j=0}^{k-1} \mathbb{E}_0 \left[\sup_{\pi \in \Pi} \left| \frac{1}{m} \sum_{l=0}^{m-1} \tilde{r}_\pi(x_{lk+j}) - E_0[\tilde{r}_\pi(x)] \right| \right] \\
&\overset{(2)}{\leq} \alpha + R\mathbb{P}_0 \left\{ \sup_{\pi \in \Pi} \left| \frac{1}{m} \sum_{l=0}^{m-1} \tilde{r}_\pi(x_{lk}) - E_0[\tilde{r}_\pi(x)] \right| > \alpha \right\} \\
&\overset{(3)}{\leq} \alpha + Rm\beta_0(k) \\
&\quad + R\bar{\mathbb{P}}_0 \left\{ \sup_{\pi \in \Pi} \left| \frac{1}{m} \sum_{l=0}^{m-1} \tilde{r}_\pi(x_{lk}) - E_0[\tilde{r}_\pi(x)] \right| > \alpha \right\},
\end{aligned}$$

in which $\mathbb{E}_0$ is expectation with respect to $\mathbb{P}_0$, and $\bar{\mathbb{P}}_0$ is the i.i.d. product measure corresponding to $\mathbb{P}_0$. Inequality (1) follows by triangle inequality, (2) by stationarity and the fact that the reward function is bounded by R, and (3) by definition of the β-mixing coefficients.

CLAIM 1. *Suppose $\hbar_\pi(x) \leq K$ for all x and π and that* P-dim$(\mathcal{H}) \leq d$. *Then, $\forall \alpha > 0$*

$$C(\alpha, \mathcal{R}, d_{L_1}) \leq 2 \left(\frac{2eRK}{\alpha} \log \frac{2eRK}{\alpha} \right)^d.$$

Proof. Let λ_0 be a probability measure on $\mathbb{X}$. Observe that for $\tilde{r}_1, \tilde{r}_2 \in \mathcal{R}$,

$$\begin{aligned} d_{L_1(\lambda_0)}(\tilde{r}_1, \tilde{r}_2) &= \sum_x |\tilde{r}_1(x) - \tilde{r}_2(x)| \lambda_0(x) \\ &\le R \cdot \sum_x |\hbar_1(x) - \hbar_2(x)| \lambda_0(x) \\ &= R \cdot d_{L_1(\lambda_0)}(\hbar_1, \hbar_2). \end{aligned}$$

As argued for similar results earlier in the paper, this implies the desired conclusion. □

From Theorem 5.7 in [49], we then get

$$\begin{aligned} \bar{\mathbb{P}}_0 \left\{ \sup_{\pi \in \Pi} \left| \frac{1}{m} \sum_{l=0}^{m-1} \tilde{r}_\pi(x_{lk}) - E_0[\tilde{r}_\pi(x)] \right| > \alpha \right\} &\le 4C\left(\frac{\alpha}{16}, \mathcal{R}, d_{L_1}\right) \exp\left(-\frac{m\alpha^2}{32R^2}\right) \\ &\le 8\left(\frac{32eRK}{\alpha} \log \frac{32eRK}{\alpha}\right)^d \exp\left(-\frac{m\alpha^2}{32R^2}\right). \end{aligned}$$

Substituting above, we get

$$\mathbb{E}_0 \left[\sup_{\pi \in \Pi} |\hat{\mathbb{E}}_n[\tilde{r}_\pi; x^n] - E_0[\tilde{r}_\pi(x)]| \right] \le \gamma(m) + Rm\beta_0(k).$$

Now, defining $g(x^n)$ as the argument of $\mathbb{E}_0$ above and using the McDiarmid–Azuma inequality with $c_i = R/n$, we obtain that

$$\mathbb{P}_0 \left\{ \sup_{\pi \in \Pi} |\hat{\mathbb{E}}_n[\tilde{r}_\pi; x^n] - E_0[\tilde{r}_\pi(x)]| \ge \gamma(m) + Rm\beta_0(k) + \tau(n) \right\} < \delta,$$

where $\delta = \exp(-2n\tau^2(n)/R^2)$, and hence we get the desired result. □

Note that by assumption of the mixing property, $\beta_0(k_n) \to 0$, and for fixed ϵ and δ, $\gamma(m_n), \tau(n) \to 0$ as $n \to \infty$. The sample complexity result is implicit here since given functions γ, β_0, and τ, we can determine n, m_n, and k_n such that $n = m_n k_n$, $m_n \to \infty$, $k_n \to \infty$, and $\gamma(m_n) + Rm_n\beta_0(k_n) + \tau \le \epsilon$ for given ϵ and δ. The existence of m_n and k_n sequences such that $m_n\beta(k_n) \to 0$ is guaranteed by Lemma 3.1 in [49]. This implies $\delta \to 0$ as $n \to \infty$, and thus the policy space Π is PAC-learnable under the hypothesis of the theorem.

One of the assumptions we have made is that for policy π, the Radon–Nikodym derivative $\hbar_\pi$ is bounded by K. This essentially means that all the Markov chains are close to the *reference* Markov chain in the sense that the probability mass on any state does not differ by more than a multiplicative factor of K from that of $\mathbb{P}_0$. The assumption that $\mathcal{H}$ has finite P-dimension is less natural but essential to the argument. Let us now show the existence of reference Markov chains through an example.

Example 6.2. Consider any Markov chain with invariant measure λ_0. Consider any parametrized class of functions $\hbar_\pi : \mathbb{X} \to [0, 1]$, $\pi \in \Pi$ such that $\sum_x \lambda_0(x)\hbar_\pi(x) = 1$, and P-dim$(\{\hbar_\pi : \pi \in \Pi\}) = d$. Denote $\lambda_\pi(x) = \lambda_0(x)\hbar_\pi(x)$ and consider a set of Markov chains $\mathcal{P}$ with invariant measures λ_π. Then, clearly, λ_0 is an invariant measure of a *reference* Markov chain for the set $\mathcal{P}$ of Markov chains.

7. Partially observable MDPs with general policies. We now consider partially observed discounted-reward MDPs with general policies (nonstationary with

memory). The setup is as before, except that the policy depends on observations $y \in \mathbb{Y}$, governed by the (conditional) probability $\nu(y|x)$ of observing $y \in \mathbb{Y}$ when the state is $x \in \mathbb{X}$. Let h_t denote the history $(y_0, a_1, y_1, \ldots, a_t, y_t)$ of observations and actions up to time t.

The results of section 5 extend when the policies are nonstationary; however, there are many subtleties regarding the domain and range of simulation functions, and measures, and some details are different. Let $\mathcal{H}_t = \{h_t = (y_0, a_1, y_1, \ldots, a_t, y_t) : a_s \in \mathbb{A}, y_s \in \mathbb{Y}, 0 \le s \le t\}$. Let Π be the set of policies $\pi = (\pi_1, \pi_2, \ldots)$, with $\pi_t : \mathcal{H}_t \times \mathbb{A} \to [0,1]$ a probability measure on $\mathbb{A}$ conditioned on $h_t \in \mathcal{H}_t$. Let Π_t denote the set of all policies π_t at time t with $\pi \in \Pi$. This gives rise to a conditional state transition function $P_t(x, x'; h_t)$, the probability of transition from state x to x' given history h_t up to time t. Under π,

$$P_t(x, x'; h_t) = \sum_a P_a(x, x')\pi_t(h_t, a).$$

Let $\mathcal{P}_t$ denote the set of all P_{π_t} induced by the policies π_t with $\pi \in \Pi$. Then, defining the usual $d_{TV(\lambda)}$ metric on $\mathcal{P}_t$ and the usual L_1 metric on Π_t, we get the next result.

LEMMA 7.1. *Suppose Π_t and $\mathcal{P}_t$ are as defined above with* P-dim$(\Pi_t) = d$. *Assume λ and ρ are probability measures on $\mathbb{X}$ and $\mathcal{H}_t$, respectively, and σ a probability measure on $\mathbb{A}$ such that $\pi_t(h_t, a)/\sigma(a) \le K \ \forall h_t \in \mathcal{H}_t, a \in \mathbb{A}, \pi_t \in \Pi_t$. Then, for $0 < \epsilon < e/4 \log_2 e$,*

$$N(\epsilon, \mathcal{P}_t, d_{TV(\lambda\times\rho)}) \le N(\epsilon, \Pi_t/\sigma, d_{L_1(\sigma\times\rho)}) \le \left(\frac{2eK}{\epsilon} \log \frac{2eK}{\epsilon}\right)^d.$$

The proof can be found in the appendix.

Let $\mathcal{F}_t$ be the set of simulation functions of $\mathcal{P}_t$ under the simple simulation model. Thus, $f_t \in \mathcal{F}_t$ for $t \ge 2$ is defined on $f_t : \mathbb{X} \times \mathcal{H}_{t-1} \times \Omega^\infty \to \mathbb{X} \times \mathcal{H}_t \times \Omega^\infty$, while $f_1 \in \mathcal{F}_1$ shall be defined on $f_1 : \mathbb{X} \times \Omega^\infty \to \mathbb{X} \times \mathcal{H}_1 \times \Omega^\infty$. This is because at time $t = 1$, there is no history, and the state transition depends only on the initial state and the noise. For $t > 1$, the state transition depends on the history as well. Further, the function definitions have to be such that the composition $f_t \circ f_{t-1} \circ \cdots \circ f_1$ is well defined.

It is straightforward to verify that Lemma 4.2 extends to Lemma 7.2.

LEMMA 7.2. *Suppose $\mathcal{P}$ is convex (being generated by a convex space of policies Π). Let* P-dim$(\mathcal{P}_t) = d$. *Let $\mathcal{F}_t$ be the corresponding space of simple simulation functions induced by $\mathcal{P}_t$. Then,* P-dim$(\mathcal{F}_t) = d$.

By $\mathcal{F}^t$ we shall denote the set of functions $f^t = f_t \circ \cdots \circ f_1$, where $f_s \in \mathcal{F}_s$ and they arise from a common policy π. Note that $f^t : \mathbb{X} \times \Omega^\infty \to \mathcal{Z}_t \times \Omega^\infty$, where $\mathcal{Z}_t = \mathbb{X} \times \mathcal{H}_t$. We shall consider the following pseudometric on $\mathcal{F}_t$ with respect to a measure λ_t on $\mathcal{Z}_{t-1}$ for $t \ge 2$ and measure σ on Ω^∞,

$$\rho_t(f_t, g_t) := \sum_{z \in \mathcal{Z}_{t-1}} \lambda_t(z)\sigma\{\omega : f_t(z, \omega) \ne g_t(z, \omega)\}.$$

We shall take ρ_1 as the pseudometric on $\mathcal{F}^t$ with respect to the product measure $\lambda \times \sigma$. Let

$$\lambda_{f^t}(z) := \sum_{z \in \mathcal{Z}_t} \lambda(x)\sigma\{\omega : f^t(x, \omega) = (z, \theta^t\omega)\}$$

be a probability measure on $\mathcal{Z}_t$. We now state the extension of the technical lemma needed for the main theorem of this section.

LEMMA 7.3. *Let λ be a probability measure on $\mathbb{X}$ and λ_{f^t} be the probability measure on $\mathcal{Z}_t$ as defined above. Suppose that* P-dim $(\mathcal{F}_t) \le d$ *and there exists probability measures λ_t on $\mathcal{Z}_t$ such that $K := \max\{\sup_t \sup_{f^t \in \mathcal{F}^t, z \in \mathcal{Z}_t} \frac{\lambda_{f^t}(z)}{\lambda_{t+1}(z)}, 1\} < \infty$. Then, for $1 \le t \le T$,*

$$N(\epsilon, \mathcal{F}^t, \rho_1) \le N\left(\frac{\epsilon}{Kt}, \mathcal{F}_t, \rho_t\right) \cdots N\left(\frac{\epsilon}{Kt}, \mathcal{F}_1, \rho_1\right) \le \left(\frac{2eKt}{\epsilon} \log \frac{2eKt}{\epsilon}\right)^{dt}.$$

The proof can be found in the appendix. We now obtain our sample complexity result.

THEOREM 7.4. *Let $(\mathbb{X}, \Gamma, \lambda)$ be the measurable state space, $\mathbb{A}$ the action space, $\mathbb{Y}$ the observation space, $P_a(x, x')$ the state transition function, and $\nu(y|x)$ the conditional probability measure that determines the observations. Let $r(x)$ be the real-valued reward function bounded in $[0, R]$. Let Π be the set of stochastic policies (nonstationary and with memory in general), $\mathcal{P}_t$ be the set of state transition functions induced by Π_t, and $\mathcal{F}_t$ the set of simulation functions of $\mathcal{P}_t$ under the simple simulation model. Suppose that* P-dim $(\mathcal{P}_t) \le d$. *Let λ and σ be probability measures on $\mathbb{X}$ and $\mathbb{A}$, respectively, and λ_{t+1} a probability measure on $\mathcal{Z}_t$ such that $K := \max\{\sup_t \sup_{f^t \in \mathcal{F}^t, z \in \mathcal{Z}_t} \frac{\lambda_{f^t}(z)}{\lambda_{t+1}(z)}, 1\}$ is finite, where λ_{f^t} is as defined above. Let $\hat{V}_n(\pi)$ be the estimate of $V(\pi)$ obtained from n samples. Then, given any $\epsilon, \delta > 0$, and with probability at least $1 - \delta$,*

$$\sup_{\pi \in \Pi} |\hat{V}_n(\pi) - V(\pi)| < \epsilon$$

for $n \ge \frac{32R^2}{\alpha^2}\left(\log \frac{4}{\delta} + 2dT(\log \frac{32eR}{\alpha} + \log KT)\right)$, where T is the $\frac{\epsilon}{2}$-horizon time and $\alpha = \frac{\epsilon}{2}(T+1)$.

Remarks. A special case is when the policies are *stationary and memoryless*, i.e., $\pi_t = \pi_1 \; \forall\, t$, and $\pi_1 : \mathbb{Y} \times \mathbb{A} \to [0, 1]$ depends only on the current observation. Let Π_1 be the set of all π_1. Then, each policy $\pi \in \Pi$ induces a time-homogeneous Markov chain with probability transition function given by $P_\pi(x, x') = \sum_{a,y} P_a(x, x')\pi_1(y, a)\nu(y|x)$. Let $\mathcal{P}$ denote the set of all probability transition functions induced by Π. In general if Π is convex, $\mathcal{P}$ is convex. We will denote the set of simulation functions under the simple simulation model for $P \in \mathcal{P}$ by $\mathcal{F}$. Suppose that P-dim $(\mathcal{P}) = d$; then by Lemma 4.2, P-dim $(\mathcal{P})$ = P-dim $(\mathcal{F}) = d$. This implies that the sample complexity result of Theorem 5.2 for discounted-reward MDPs holds for the case when the state is partially observable and the policies are stationary and memoryless. Thus, for uniform convergence and estimation, partial observability of the state does not impose any extra cost in terms of sample complexity. Note that in the case of general polices, the sample complexity is $O(T \log T)$ times more.

8. Conclusions. The paper considers simulation-based value function estimation methods for Markov decision processes (MDPs). Uniform sample complexity results are presented for the discounted-reward case. The combinatorial complexity of the space of simulation functions under the proposed simple simulation model is shown to be the same as that of the underlying space of induced Markov chains when the latter is convex. Using ergodicity and weak mixing leads to similar uniform sample complexity result for the average-reward case, when a *reference* Markov chain exists.

Extensions of the results are obtained when the MDP is partially observable with general policies. Remarkably, the sample complexity results have the same order for both completely and partially observed MDPs when stationary and memoryless

policies are used. Sample results for discounted-reward Markov games can be deduced easily as well.

The results can be seen as an extension of the theory of PAC (probably approximately correct) learning for partially observable Markov decision processes (POMDPs) and games. PAC theory is related to the system identification problem.

One of the key contributions of this paper is the observation that how we simulate an MDP matters for obtaining uniform estimates. This is a new (and surprising) observation. Thus, the results of this paper can also be seen as the first steps towards developing an empirical process theory for MDPs. Such a theory would go a long way in establishing a theoretical foundation for computer simulation of complex engineering systems.

We have used Hoeffding's inequality in obtaining the rate of convergence for discounted-reward MDPs and used the McDiarmid–Azuma inequality for the average-reward MDPs, though more sophisticated and tighter inequalities of Talagrand [41] (see also Samson [37]) can be used as well. This would yield better results and is part of future work.

Appendix A. Proof of Lemma 3.1.

Proof. We first relate the $d_{TV(\lambda)}$ pseudometric on $\mathcal{P}$ with the $d_{L_1(\lambda\times\sigma)}$ pseudometric on Π. Pick any $\pi, \pi' \in \Pi$ and denote $P = P_\pi$ and $P' = P_{\pi'}$. Then,

$$\begin{aligned} d_{TV(\lambda)}(P,P') &= \sum_y \left| \sum_x \lambda(x) \sum_a P_a(x,y)(\pi(x,a) - \pi'(x,a)) \right| \\ &\le \sum_a \sum_x \sum_y \lambda(x) P_a(x,y) |\pi(x,a) - \pi'(x,a)| \\ &\le \sum_a \sigma(a) \sum_x \lambda(x) |\pi(x,a) - \pi'(x,a)| / \sigma(a) \\ &= d_{L_1(\sigma\times\lambda)}(\pi/\sigma, \pi'/\sigma). \end{aligned}$$

The second inequality above follows from the triangle inequality and the fact that the order of the sums over y, x, and a can be changed by Fubini's theorem [18] and noting that $\sum_y P_a(x,y) = 1$. Thus, if $\Pi'/\sigma \subseteq \Pi/\sigma$ is an ϵ-net for Π/σ, $\{P_\pi, \pi \in \Pi'\}$ is an ϵ-net for $\mathcal{P}$. Further, the spaces Π and Π/σ have the same P-dimension, as can be easily verified. The bound on the covering number is then given by a standard result (see Theorem 4.3 of [49]). □

Appendix B. Proof of Lemma 5.1.

Proof. Consider any $f, g \in \mathcal{F}$, and $x \in \mathcal{X}$. Then,

$$\begin{aligned} &\mu\{\omega : f^t(x,\omega) \ne g^t(x,\omega)\} \\ &= \mu\{\omega : f^t(x,\omega) \ne g^t(x,\omega), f^{t-1}(x,\omega) = g^{t-1}(x,\omega)\} \\ &\quad + \mu\{\omega : f^t(x,\omega) \ne g^t(x,\omega), f^{t-1}(x,\omega) \ne g^{t-1}(x,\omega)\} \\ &= \mu\{\cup_y (\omega : f^t(x,\omega) \ne g^t(x,\omega), f^{t-1}(x,\omega) = g^{t-1}(x,\omega) = (y,\theta^{t-1}\omega))\} \\ &\quad + \mu\{\cup_y (\omega : f^t(x,\omega) \ne g^t(x,\omega), f^{t-1}(x,\omega) \ne g^{t-1}(x,\omega), f^{t-1}(x,\omega) = (y,\theta^{t-1}\omega))\} \\ &\le \mu\{\cup_y (\omega : f(y,\theta^{t-1}\omega) \ne g(y,\theta^{t-1}\omega), f^{t-1}(x,\omega) = g^{t-1}(x,\omega) = (y,\theta^{t-1}\omega))\} \\ &\quad + \mu\{\cup_y (\omega : f^{t-1}(x,\omega) \ne g^{t-1}(x,\omega), f^{t-1}(x,\omega) = (y,\theta^{t-1}\omega))\} \\ &\le \sum_y \mu\{\omega : f(y,\theta^{t-1}\omega) \ne g(y,\theta^{t-1}\omega) | f^{t-1}(x,\omega) = (y,\theta^{t-1}\omega)\} \mu\{\omega : f^{t-1}(x,\omega) = y\} \\ &\quad + \mu\{\omega : f^{t-1}(x,\omega) \ne g^{t-1}(x,\omega)\}. \end{aligned}$$

It is easy to argue that $\lambda_{f^{t-1}}(y) \le K^{t-1}\lambda(y)$, where $\lambda_{f^{t-1}}(y) = \sum_x \lambda(x)\mu\{\omega : f^{t-1}(x,\omega) = (y,\theta^{t-1}\omega)\}$. Thus, multiplying both sides of the above sequence of inequalities and summing over x, and observing that

$$\mu\{\omega : f(y,\theta^{t-1}\omega) \ne g(y,\theta^{t-1}\omega)\} = \mu\{\omega' : f(y,\omega') \ne g(y,\omega')\},$$

we get that the first part of the right side is

$$\sum_y \lambda_{f^{t-1}}(y)\mu\{\omega' : f(y,\omega') \ne g(y,\omega')\} \le K^{t-1} \cdot \sum_y \lambda(y)\mu\{\omega' : f(y,\omega') \ne g(y,\omega')\}.$$

This implies that

$$\begin{aligned}\rho_{\mathbb{P}}(f^t, g^t) &\le K^{t-1}\rho_{\mathbb{P}}(f,g) + \rho_{\mathbb{P}}(f^{t-1}, g^{t-1}) \\ &\le (K^{t-1} + K^{t-2} + \cdots + 1)\rho_{\mathbb{P}}(f,g) \\ &\le K^t \rho_{\mathbb{P}}(f,g),\end{aligned}$$

where the second inequality is obtained by induction. Now,

$$\sum_x \lambda(x)\mu\{\omega : f(x,\omega) \ne g(x,\omega)\} \le \sum_x \lambda(x) \int |f(x,\omega) - g(x,\omega)| d\mu(\omega),$$

and thus $\rho_{\mathbb{P}}(f^t, g^t) \le K^t \cdot d_{L_1}(f,g)$, which proves the required assertion. □

Appendix C. Proof of Lemma 7.1.

Proof. Pick any $\pi_t, \pi'_t \in \Pi_t$, and denote $P = P_{\pi_t}$ and $P' = P_{\pi'_t}$. Then,

$$\begin{aligned}d_{TV(\lambda\times\rho)}(P,P') &= \sum_x \lambda(x) \sum_{x'\in\mathbb{X}} \left| \sum_{a\in\mathbb{A}, h_t\in\mathcal{H}_t} P_a(x,x')(\pi_t(h_t,a) - \pi'_t(h_t,a)) \right| \rho(h_t) \\ &\le \sum_{h_t} \rho(h_t) \sum_x \lambda(x) \sum_a \sum_{x'} P_a(x,x') |\pi_t(h_t,a) - \pi'_t(h_t,a)| \\ &\le \sum_{h_t} \rho(h_t) \sum_a \sigma(a) \left| \frac{\pi_t(y,a)}{\sigma(a)} - \frac{\pi'_t(y,a)}{\sigma(a)} \right| \\ &= d_{L_1(\sigma\times\rho)} \left(\frac{\pi_t}{\sigma}, \frac{\pi'_t}{\sigma} \right).\end{aligned}$$

The second inequality above follows by changing the order of the sums over a and x', noting that $\sum_{x'} P_a(x,x') = 1$ and denoting $\sum_x \lambda(x) = 1$. The rest of the argument is the same as in Lemma 3.1. □

Appendix D. Proof of Lemma 7.3. The proof of Lemma 7.3 is similar but the details are somewhat more involved.

Proof. Consider any $f^t, g^t \in \mathcal{F}^t$, and $x \in \mathcal{X}$. Then,

$$\begin{aligned}&\mu\{\omega : f^t(x,\omega) \ne g^t(x,\omega)\} \\ &\quad = \mu\{\omega : f^t(x,\omega) \ne g^t(x,\omega), f^{t-1}(x,\omega) = g^{t-1}(x,\omega)\} \\ &\qquad + \mu\{\omega : f^t(x,\omega) \ne g^t(x,\omega), f^{t-1}(x,\omega) \ne g^{t-1}(x,\omega)\} \\ &\quad = \mu\{\cup_{z\in\mathcal{Z}_{t-1}}(\omega : f^t(x,\omega) \ne g^t(x,\omega), f^{t-1}(x,\omega) = g^{t-1}(x,\omega) = (z,\theta^{t-1}\omega))\} \\ &\qquad + \mu\{\cup_{z\in\mathcal{Z}_{t-1}}(\omega : f^t(x,\omega) \ne g^t(x,\omega), f^{t-1}(x,\omega) \\ &\qquad\qquad \ne g^{t-1}(x,\omega), f^{t-1}(x,\omega) = (z,\theta^{t-1}\omega))\}\end{aligned}$$

$$\begin{aligned}
&\leq \mu\{\cup_{z\in\mathcal{Z}_{t-1}}(\omega : f^t(x,\omega) \neq g^t(x,\omega), f^{t-1}(x,\omega) = g^{t-1}(x,\omega) = (z,\theta^{t-1}\omega))\} \\
&\quad + \mu\{\cup_{z\in\mathcal{Z}_{t-1}}(\omega : f^{t-1}(x,\omega) \neq g^{t-1}(x,\omega), f^{t-1}(x,\omega) = (z,\theta^{t-1}\omega))\} \\
&\leq \sum_{z\in\mathcal{Z}_{t-1}} \mu\{\omega : f_t(z,\theta^{t-1}\omega) \neq g_t(z,\theta^{t-1}\omega) | f^{t-1}(x,\omega) \\
&\qquad\qquad = (z,\theta^{t-1}\omega)\}\mu\{\omega : f^{t-1}(x,\omega) = (z,\theta^{t-1}\omega)\} \\
&\quad + \mu\{\omega : f^{t-1}(x,\omega) \neq g^{t-1}(x,\omega)\}.
\end{aligned}$$

Multiplying both sides of the above sequence of inequalities and summing over x, and observing again that

$$\mu\{\omega : f_t(z,\theta^{t-1}\omega) \neq g_t(z,\theta^{t-1}\omega)\} = \mu\{\omega' : f_t(z,\omega') \neq g_t(z,\omega')\},$$

we get that the first part of the right side is

$$\sum_{z\in\mathcal{Z}_{t-1}} \lambda_{f^{t-1}}(z)\mu\{\omega' : f_t(z,\omega') \neq g_t(z,\omega')\} \leq K\cdot \sum_{z\in\mathcal{Z}_{t-1}} \lambda_t(z)\mu\{\omega' : f_t(z,\omega') \neq g_t(z,\omega')\}.$$

This by induction implies

$$\rho_1(f^t, g^t) \leq K(\rho_t(f_t, g_t) + \cdots + \rho_1(f_1, g_1)),$$

which implies the first inequality. For the second inequality, note that the ρ pseudometric and the L_1 pseudometric are related; thus,

$$\sum_z \lambda_t(z)\mu\{\omega : f_t(z,\omega) \neq g_t(z,\omega)\} \leq \sum_z \lambda_t(z) \int |f_t(z,\omega) - g_t(z,\omega)| d\mu(\omega),$$

which relates their covering numbers. Also, the covering number under the L_1 pseudometric can be bounded in terms of the P-dim of appropriate spaces. □

Acknowledgments. We thank Peter Bartlett, Tunc Simsek, and Antonis Dimakis for many helpful discussions. The counterexample 5.4(ii) was jointly developed with Antonis Dimakis. We also thank the anonymous referees for their comments which helped to greatly improve the quality of the paper.

MAXIMIZING VISIBILITY IN NONCONVEX POLYGONS: NONSMOOTH ANALYSIS AND GRADIENT ALGORITHM DESIGN*

ANURAG GANGULI†, JORGE CORTÉS‡, AND FRANCESCO BULLO§

Abstract. This paper presents a motion control algorithm for a planar mobile observer such as a mobile robot equipped with an omnidirectional camera. We propose a nonsmooth gradient algorithm for the problem of maximizing the area of the region visible to the observer in a non-self-intersecting nonconvex polygon. First, we show that the visible area is almost everywhere a locally Lipschitz function of the observer location. Second, we provide a novel version of the LaSalle invariance principle for discontinuous vector fields and Lyapunov functions with a finite number of discontinuities. Finally, we establish the asymptotic convergence properties of the nonsmooth gradient algorithm and illustrate numerically its performance.

1. Introduction.

Consider a single-point mobile robot in a planar nonconvex environment modeled as a non-self-intersecting polygon: how should the robot move in order to monotonically increase the area of its visible region (i.e., the region within its line of sight)? This problem is the subject of this paper. The following are the modeling assumptions in our method of approach. The dynamical model for the robot's motion is a first-order system of the form $\dot{p} = u$, where p refers to the position of the robot in the environment and u is the driving input. The robot is equipped with an omnidirectional line-of-sight range sensor; the range of the sensor is larger than the diameter of the environment. The robot does not know the entire environment nor its position in it, and its instantaneous motion depends only on what is within its line of sight (this assumption restricts our attention to memoryless feedback laws).

In broad terms, this work is related to numerous references on optimal sensor location and motion planning coming from the computational geometry, geometric optimization, and robotics literature. The problem we consider is akin to the next best view problems in robotics for two-dimensional map building. In these map-building problems the objective is to compute the next position of a robot in an environment with obstacles that maximizes the gain in visible area. A heuristic is proposed and simulated in [10] and in the early work [13]. Other relevant references can be found in computational geometry. For example, the classic art gallery problem is to find the smallest number of such guards necessary for each point of the environment to be visible to at least one guard; see [7, 1]. Also studied in computational geometry is the

problem of locating a guard in a non-self-intersecting polygon so as to maximize the visible area. This problem is still open to the best of our knowledge and is the subject of ongoing research; see [12, 16, 4]. Key differences exist between the computational geometric approach to this problem and our sensor-based feedback approach. In the computational geometric version, the data about the entire polygon is available a priori, the difficulties are of combinatorial nature, and the solutions can be thought of as open loop. In the problem of interest in this paper, we consider the feedback control problem for a mobile robot based upon only local knowledge of the environment and without recollection of past trajectories. The work that is perhaps closest in spirit to our work is the numerical approach proposed in [3].

A second set of relevant references are those on nonsmooth stability analysis. Indeed, our approach to maximizing visible area is to design a nonsmooth gradient flow. To define our proposed algorithm we rely on the notions of generalized gradient [5] and of Filippov solutions for differential inclusions [9]. To study our proposed algorithm we extend recent results on the stability and convergence properties of nonsmooth dynamical systems, as presented in [15, 2]. Finally, the present work has some interesting connections with the study of the behavior of certain territorial animals. A particularly relevant reference is the study of the effect of visibility on space use by red-capped cardinals [8]. These are birds that defend territories along shorelines of rivers and lakes and tend to spend the majority of their time near peninsulas (areas that offer greater amount of visibility of their respective territories) rather than bays.

The contributions of this paper are threefold. First, we prove some basic properties of the area visible from a point observer in a nonconvex polygon Q; see Figure 1.1. Namely, we show that the area of the visibility polygon, as a function of the observer position, is a locally Lipschitz function almost everywhere and that the finite point set of discontinuities consists of the reflex vertices of the polygon Q. Additionally, we compute the generalized gradient of the function and show that the function is not, in general, regular.

Second, we provide a generalized version of certain stability theorems for discontinuous vector fields available in the literature [15, 2]. Specifically, we provide a generalized nonsmooth LaSalle invariance principle for discontinuous vector fields, Filippov solutions, and Lyapunov functions that are locally Lipschitz almost every-

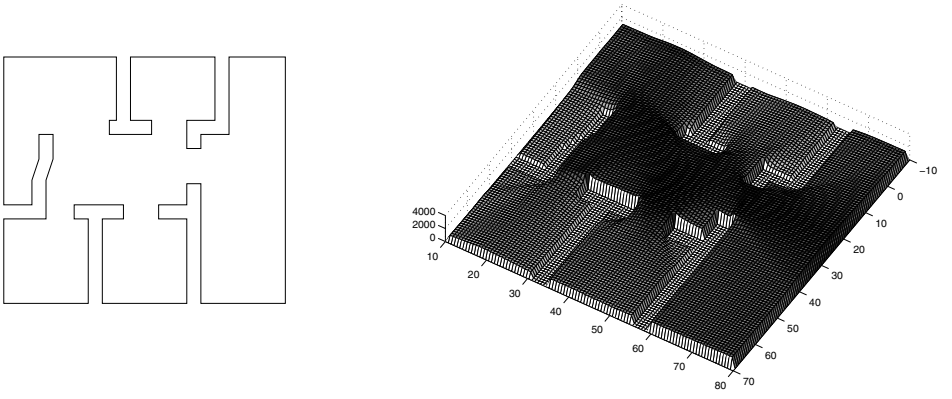

FIG. 1.1. *The image on the left shows a nonconvex polygonal environment shaped like a typical floor plan. The image on the right shows the variation of the visible area in the environment as a function of the position of a point observer.*

where (except for a finite set of discontinuities).

Third and last, we use these novel results to design a nonsmooth gradient algorithm that monotonically increases the area visible to a point observer. To the best of our knowledge, this is the first provably correct algorithm for this version of the next best view problem. We illustrate the performance of our algorithm via simulations for some interesting polygons.

Before proceeding with the technical content, we provide here a detailed comparison between our proposed local feedback method and a two-phase approach, where the guard first explores the entire environment and later finds the approximate location of the maximum. The approximate global maximum could be computed using, for example, the method in [4]. Let us refer to the latter approach as the *explore and optimize method*. Clearly in this latter method, the optimal location of the observer is a global maximum, whereas in the former it is a local maximum. However, our approach does not require any memory for the observer. In the explore and optimize method, the observer needs to remember the environment as it is being explored. As the size of the environment increases, so does the amount of memory and run time required by the observer. Another problem that arises in the exploration of unknown environments in the absence of accurate global positioning is that of *simultaneous location and mapping (SLAM).* To explain briefly, to build a map of the environment accurately, one needs an accurate estimate of the position of the observer. This is not available due to odometry errors and lack of global positioning ability. Therefore, to accurately localize the observer inside the environment, an accurate map of the environment is needed but which is again unavailable due to measurement sensor errors. Various approaches to solving the SLAM problem have been studied, but most of the accurate approaches again are intensive in terms of computation and memory. In contrast, the fact that our approach is local and requires no memory renders it more robust to errors in computation and sensor measurements. Another advantage of being memoryless is that it works for environments that may change quasi-statically, whereas any other method relying on memory is ineffective in this case. Finally, note that out local optimization approach might be used in conjunction with a global search method to find the globally optimum position. For example, after finding the position of a local optimum, the observer could perform a random walk in the environment. While executing the random walk, the observer must compare the magnitude of the visible area with the value at the previously discovered optimum. If the value is greater, find the local optimum using the approach in the paper. This procedure is repeated, and one can expect to find the global optimum after sufficient time has elapsed.

The paper is organized as follows. Section 2 contains the analysis of the smoothness properties and of the generalized gradient of the function of interest. Section 3 contains the novel results on nonsmooth stability analysis. Section 4 presents the nonsmooth gradient algorithm and the properties of the resulting closed-loop system. Finally, the simulations in section 5 illustrate the convergence properties of the algorithm.

2. The area visible from an observer. In this section we study the area of the region visible to a point observer equipped with an omnidirectional camera. We show that the visible area, as a function of the location of the observer, is locally Lipschitz, except at a finite point set. We prove that, for general nonconvex polygons, the function is not regular. We also provide expressions for the generalized gradient of the visible area function wherever it is locally Lipschitz. We have included the notions of locally Lipschitz functions and related concepts whenever they first appear

in the text of the paper.

Let us start by introducing the set of lines on the plane $\mathbb{R}^2$. For $(a,b,c) \in \mathbb{R}^3 \setminus \{(0,0,c) \in \mathbb{R}^3 \mid c \in \mathbb{R}\}$, define the equivalence class $[(a,b,c)]$ by

$$[(a,b,c)] = \{(a',b',c') \in \mathbb{R}^3 \mid (a,b,c) = \lambda(a',b',c'),\ \lambda \in \mathbb{R}\}.$$

The *set of lines on* $\mathbb{R}^2$ is defined as

$$\mathbb{L} = \{[(a,b,c)] \subset \mathbb{R}^3 \mid (a,b,c) \in \mathbb{R}^3,\ a^2 + b^2 \neq 0\}.$$

It is possible to show that $\mathbb{L}$ is a two-dimensional manifold, sometimes referred to as the affine Grassmannian of lines in $\mathbb{R}^2$; see [11].

Next, two useful functions are defined. Let $f_{\mathrm{pl}} : \mathbb{R}^2 \times \mathbb{R}^2 \setminus \{(p,p) \in \mathbb{R}^2 \times \mathbb{R}^2 \mid p \in \mathbb{R}^2\} \to \mathbb{L}$ map two distinct points in $\mathbb{R}^2$ to the line passing through them. Given distinct $(x_1,y_1),(x_2,y_2) \in \mathbb{R}^2$, we have that

$$f_{\mathrm{pl}}((x_1,y_1),(x_2,y_2)) = [(y_2 - y_1, x_1 - x_2, y_1x_2 - x_1y_2)].$$

If $l_1 \parallel l_2$ denotes that two lines $l_1, l_2 \in \mathbb{L}$ are parallel, then let $f_{\mathrm{lp}} : \mathbb{L}^2 \setminus \{(l_1,l_2) \in \mathbb{L}^2 \mid l_1 \parallel l_2\} \to \mathbb{R}^2$ map two nonparallel lines to their unique intersection point. Given two lines $[(a_1,b_1,c_1)]$ and $[(a_2,b_2,c_2)]$, we have that

$$f_{\mathrm{lp}}([(a_1,b_1,c_1)],[(a_2,b_2,c_2)]) = \left(\frac{b_2c_1 - b_1c_2}{a_2b_1 - a_1b_2}, \frac{a_1c_2 - a_2c_1}{a_2b_1 - a_1b_2}\right).$$

Note that the maps f_{pl} and f_{lp} are class C^ω; i.e., they are analytic over their domains.

Now, let us turn our attention to the polygonal environment. Let Q be a non-self-intersecting polygon, possibly nonconvex. A polygon is said to be non-self-intersecting if the only points in the plane belonging to two polygon edges are the polygon vertices. Such a polygon has a well-defined interior and exterior. Note that a non-self-intersecting polygon can contain holes. Let $\mathring{Q}$ and ∂Q denote the interior and the boundary of Q, respectively. Let $\mathrm{Ve}(Q) = (v_1,\dots,v_n)$ be the list of vertices of Q ordered counterclockwise. The *interior angle of a vertex* v of Q is the angle formed inside Q by the two edges of the boundary of Q incident at v. The point $v \in \mathrm{Ve}(Q)$ is a *reflex vertex* if its interior angle is strictly greater than π. Let $\mathrm{Ve}_r(Q)$ be the list of reflex vertices of Q. If S is a finite set, then let $|S|$ denote its cardinality.

A point $q \in Q$ is *visible from* $p \in Q$ if the segment between q and p is contained in Q. The *visibility polygon* $S(p) \subset Q$ from a point $p \in Q$ is the set of points in Q visible from p. It is convenient to think of $p \mapsto S(p)$ as a map from Q to the set of polygons contained in Q. It must be noted that the visibility polygon is not necessarily a non-self-intersecting polygon.

DEFINITION 2.1. *Let v be a reflex vertex of Q, and let $w \in \mathrm{Ve}(Q)$ be visible from v. The* (v,w)-generalized inflection segment $I(v,w)$ *is the set*

$$I(v,w) = \{q \in S(v) \mid q = \lambda v + (1-\lambda)w,\ \lambda \geq 1\}.$$

A reflex vertex v of Q is an anchor of $p \in Q$ *if it is visible from p and if $\{q \in S(v) \mid q = \lambda v + (1-\lambda)p, \lambda > 1\}$ is not empty.*

In other words, a reflex vertex is an anchor of p if it occludes a portion of the environment from p. Figure 2.1 illustrates the various notions defined above. Given a point q and a line l, let $\mathrm{dist}(q,l)$ denote the distance between them.

Note that any generalized inflection segment $I(v,w)$ splits the polygonal environment into two smaller polygons. The vertex w is visible from any point on $I(v,w)$

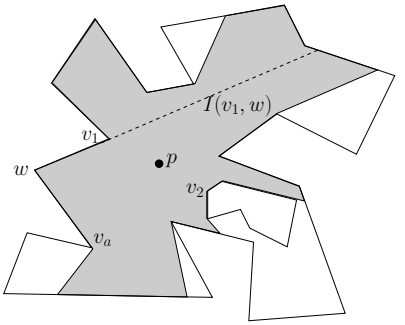

FIG. 2.1. *Reflex vertices v_1 and v_2, a generalized inflection segment $I(v_1, w)$, an anchor v_a of p, and the visibility polygon (shaded region) from p. Note that the polygonal environment has a hole.*

and from the interior of only *one* of the two smaller polygons. Intuitively, it then follows that if p belongs to the interior of a polygon and does not lie on a generalized inflection segment, then in a neighborhood of p the number of vertices of the visibility polygon does not change and their positions vary smoothly as a function of p. This is described formally in the following theorem.

THEOREM 2.2. *Let $\{I_\alpha\}_{\alpha\in\mathcal{A}}$ be the set of generalized inflection segments of Q, and let P be a connected component of $Q \setminus \bigcup_{\alpha\in\mathcal{A}} I_\alpha$. For all $p \in P$, the visibility polygon $S(p)$ is non-self-intersecting and has a constant number of vertices, say $\mathrm{Ve}(S(p)) = \{u_1(p), \ldots, u_k(p)\}$. For all $i \in \{1, \ldots, k\}$, the map $P \ni p \mapsto u_i(p)$ is C^ω and*

$$\mathrm{d}u_i(p) = \begin{cases} 0, & u_i(p) \in \mathrm{Ve}(Q), \\ \dfrac{\mathrm{dist}(v_a, l)}{(\mathrm{dist}(p, l) - \mathrm{dist}(v_a, l))^2 \sqrt{a^2 + b^2}} \begin{bmatrix} -b \\ a \end{bmatrix} \begin{bmatrix} y - y_a \\ x_a - x \end{bmatrix}^T, & u_i(p) = f_{\mathrm{lp}}(f_{\mathrm{pl}}(v_a, p), l), \end{cases}$$

where $v_a = (x_a, y_a)$ is an anchor of p and where $l = [(a, b, c)]$ is a line defined by an edge of Q.

Proof. The first part of the proof is by contradiction. Let $|\mathrm{Ve}(S(p'))| > |\mathrm{Ve}(S(p))|$ for some point $p' \in P$. This means that at least one additional vertex is visible from p' that was occluded by an anchor of p. Two cases may arise. First, when the additional vertex belongs to $\mathrm{Ve}(Q)$, then by our definition, p and p' must lie on opposite sides of a generalized inflection segment. This is a contradiction. Second, if the additional vertex does not belong to $\mathrm{Ve}(Q)$, it must be the projection of a reflex vertex (acting as an anchor). Here again two cases may arise: (1) the reflex vertex is visible from p, and (2) it is not. The first case is possible only if the reflex vertex is visible but does not act as an anchor. So, positive lengths of both sides adjoining the reflex vertex must also be visible from p and at least one of the sides is completely not visible from p', since there is a projection. This means that p and p' lie on opposite sides of a generalized inflection segment generated by the reflex vertex and one of its adjacent vertices. This is a contradiction. The second case is possible if the reflex vertex in question is occluded by another reflex vertex. But this means that p and p' lie on opposite sides of the generalized inflection segment from the reflex vertex to the anchor occluding the reflex vertex; again this is a contradiction. If, on the other hand, $|\mathrm{Ve}(S(p'))| < |\mathrm{Ve}(S(p))|$, then the above arguments hold by interchanging p and p'.

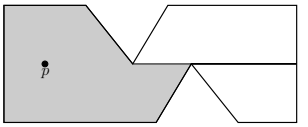

FIG. 2.2. *The visibility polygon of the point represented by p. Note that there exists a ray emanating from p which intersects the environment at three points, and hence the corresponding visibility polygon is self-intersecting.*

Hence, p and p' lie on opposite sides of a generalized inflection segment, which is a contradiction. This completes the proof that $|\operatorname{Ve}(S(p'))|$ is constant for all $p' \in P$.

Let $p \in P$. Since the visibility polygon $S(p)$ is star-shaped and since any ray emanating from p can intersect Q at most at two distinct points, then $S(p)$ is non-self-intersecting. (Indeed, if the ray emanating from p intersects the environment at three or more points inside $S(p)$, then p must belong to a generalized inflection segment. See Figure 2.2.)

Regarding the second statement, it is clear that if $u_i(p)$ is a vertex of Q, then it is independent of p. Instead, if $u_i(p) \notin \operatorname{Ve}(Q)$, then

$$u_i(p) = f_{\mathrm{lp}}(f_{\mathrm{pl}}((x,y),(x_a,y_a)),\ell),$$

where $p = (x,y)$, $v_a = (x_a, y_a)$ is an anchor of p, and ℓ is the line, determined by an edge of Q, that identifies u_i. Now, $p \in P$ implies $p \neq v_a$. It follows that $f_{\mathrm{pl}}(p, v_a)$ is C^ω for all $p \in P$. Also, from the definition of $u_i(p)$, it is clear that $f_{\mathrm{pl}}(p, v_a) \nparallel \ell$. Therefore, for all $p \in P$, $f_{\mathrm{lp}}(f_{\mathrm{pl}}(p, v_a), \ell)$ is C^ω; this implies that $p \mapsto u_i(p)$ is also C^ω. The formula for the derivative can be verified directly. □

Next, the area of a visibility polygon as a function of the observer location is studied; see Figure 1.1. Recall that the area of a non-self-intersecting polygon Q with counterclockwise-ordered vertices $\operatorname{Ve}(Q) = ((x_1,y_1),\dots,(x_n,y_n))$ is given by

$$A(Q) = \frac{1}{2}\sum_{i=1}^{n} x_i(y_{i-1} - y_{i+1}),$$

where $(x_0,y_0) = (x_n,y_n)$ and $(x_{n+1},y_{n+1}) = (x_1,y_1)$. As in the previous theorem, let $\{I_\alpha\}_{\alpha\in\mathcal{A}}$ be the set of generalized inflection segments of Q, and let P be a connected component of $Q \setminus \bigcup_{\alpha\in\mathcal{A}} I_\alpha$. Next, if $p \in P$, the visibility polygon from p has a constant number of vertices, say $k = |\operatorname{Ve}(S(p))|$, is non-self-intersecting, and satisfies $A\circ S(p) = \sum_{i=1}^{k} x_i(y_{i-1} - y_{i+1})$, where $\operatorname{Ve}(S(p)) = (u_1,\dots,u_k)$ are ordered counterclockwise, $u_i(p) = (x_i, y_i)$, $u_0 = u_k$, and $u_{k+1} = u_1$. Therefore, $P \ni p \mapsto A\circ S(p)$ is also C^ω and

$$\mathrm{d}(A\circ S)(p) = \sum_{i=1}^{k} \frac{\partial A(u_1,\dots,u_k)}{\partial u_i}\mathrm{d}u_i(p). \tag{2.1}$$

Remark 2.3. For any $u_i(p) \notin \operatorname{Ve}(Q)$, we have

$$\frac{\partial(A\circ S)}{\partial u_i}\mathrm{d}u_i(p) = \frac{\operatorname{dist}(v_a,l)}{2}\frac{\operatorname{dist}(u_{i+1},l) - \operatorname{dist}(u_{i-1},l)}{(\operatorname{dist}(p,l) - \operatorname{dist}(v_a,l))^2}\begin{bmatrix} y - y_a \\ x_a - x \end{bmatrix}^T. \tag{2.2}$$

Note here that $\frac{\partial(A\circ S)}{\partial u_i}\mathrm{d}u_i(p)$ is perpendicular to $p - v_a$.

To illustrate (2.1) and (2.2), it is convenient to introduce the *versor* operator defined by $\operatorname{vers}(X) = X/\|X\|$ if $X \in \mathbb{R}^2 \setminus \{0\}$ and by $\operatorname{vers}(0) = 0$. We depict the normalized gradient $\operatorname{vers}(\mathrm{d}(A\circ S))$ of the visible area function in Figure 2.3.

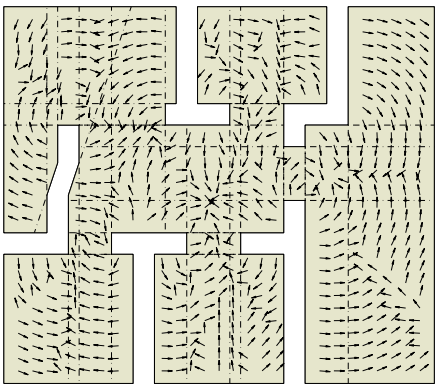

FIG. 2.3. *Normalized gradient of the visible area function over the nonconvex polygon depicted in Figure* 1.1. *The dashed lines represent some of the generalized inflection segments.*

We will now characterize the smoothness properties of the map $A \circ S$ over a polygon Q excluding the set of reflex vertices. Before that, we present the following notion.

DEFINITION 2.4. *A function* $f : \mathbb{R}^N \to \mathbb{R}$ *is said to be* locally Lipschitz near $x \in \mathbb{R}^N$ *if there exist positive constants* L_x *and* ϵ *such that* $|f(y) - f(y')| \leq L_x \|y - y'\|$ *for all* $y, y' \in B(x, \epsilon)$, *where* $B(x, \epsilon)$ *is an* N*-dimensional open ball of radius* ϵ *and centered at* x.

Note that continuously differentiable functions at x are locally Lipschitz near x.

THEOREM 2.5. *The map* $A \circ S$ *restricted to* $Q \setminus \mathrm{Ve}_r(Q)$ *is locally Lipschitz.*

Proof. By Theorem 2.2, it suffices to consider points lying on generalized inflection segments. Let p belong to multiple, say m, generalized inflection segments $\{I_\alpha\}_{\alpha \in \{1,\ldots,m\}}$. Let ϵ be small enough such that no generalized inflection segments intersect $B(p, \epsilon)$ other than $\{I_\alpha\}_{\alpha \in \{1,\ldots,m\}}$. For $\alpha \in \{1, \ldots, m\}$, let v_{k_α} be the anchor determining the generalized inflection segment I_α. Without loss of generality, it can be assumed that no anchor is visible from p other than $v_{k_1}, \ldots, v_{k_m}$. For $\alpha \in \{1, \ldots, m\}$, lines $l_\alpha \perp f_{\mathrm{pl}}(p, v_{k_\alpha})$ can be constructed with the property that $l_\alpha \cap Q = \emptyset$ and the vector $v_{k_\alpha} - p$ points toward l_α. Let h_α be the line parallel to l_α, tangent to $B(\epsilon, p)$, and intersecting the segment from p to v_{k_α}. Let p' and p'' belong to $B(p, \epsilon) \cap (Q \setminus \mathrm{Ve}_r(Q))$. Next, let $q'_\alpha = f_{\mathrm{lp}}(f_{\mathrm{pl}}(p', v_{k_\alpha}), l_\alpha)$ and $q''_\alpha = f_{\mathrm{lp}}(f_{\mathrm{pl}}(p'', v_{k_\alpha}), l_\alpha)$; see Figure 2.4. Let v'_α and v''_α be the intersections between h_α and the lines $f_{\mathrm{pl}}(p', v_{k_\alpha})$ and $f_{\mathrm{pl}}(p'', v_{k_\alpha})$, respectively.

Now, $|A(v_{k_\alpha}, q'_\alpha, q''_\alpha)| = \frac{1}{2}\|q'_\alpha - q''_\alpha\| \operatorname{dist}(v_{k_\alpha}, l_\alpha)$. But from Figure 2.4, it is easy to see that $\|q'_\alpha - q''_\alpha\| = \frac{\operatorname{dist}(v_{k_\alpha}, l_\alpha)}{\|v_{k_\alpha} - p\| - \epsilon} \|v'_\alpha - v''_\alpha\|$ and that $\|v'_\alpha - v''_\alpha\| < \|p' - p''\|$. For $K_\alpha(p) = \frac{1}{2} \frac{\operatorname{dist}(v_{k_\alpha}, l_\alpha)^2}{\|v_{k_\alpha} - p\| - \epsilon}$, the following is true:

$$\begin{aligned} |A(S(p')) - A(S(p''))| &\leq \sum_{\alpha=1}^{m} |A(v_{k_\alpha}, q'_\alpha, q''_\alpha)| \\ &\leq \sum_{\alpha=1}^{m} K_\alpha(p) \|p' - p''\|. \end{aligned}$$

This fact is illustrated by Figure 2.5. This completes the proof that $Q \setminus \mathrm{Ve}_r(Q) \ni p \mapsto A \circ S(p)$ is locally Lipschitz. ∎

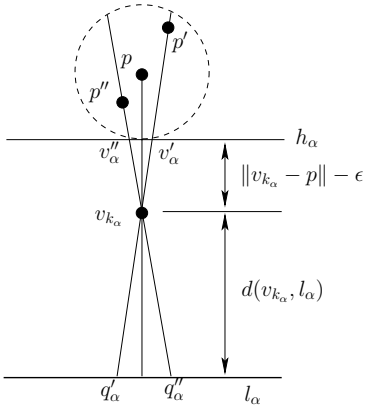

FIG. 2.4. *Definition of the lines l_α, h_α and the points $q'_\alpha, q''_\alpha, v'_\alpha, v''_\alpha$.*

It is clear that the map $A \circ S$ is not differentiable everywhere. However, other notions of derivatives might still be defined for it. The usual *right directional derivative* and the *generalized directional derivative* of any function f at x in the direction of $v \in \mathbb{R}^N$ are defined, respectively, as

$$f'(x;v) = \lim_{t \to 0^+} \frac{f(x+tv) - f(x)}{t}, \qquad f^o(x;v) = \limsup_{\substack{y \to x \\ t \to 0^+}} \frac{f(y+tv) - f(y)}{t}.$$

For a locally Lipschitz function, the limit in the definition of $f'(x;v)$ does not always exist, whereas the limit in $f^o(x;v)$ is always well defined. Also, from Rademacher's theorem [5], we know that locally Lipschitz functions are continuously differentiable almost everywhere (in the sense of Lebesgue measure). If Ω_f denotes the set of points

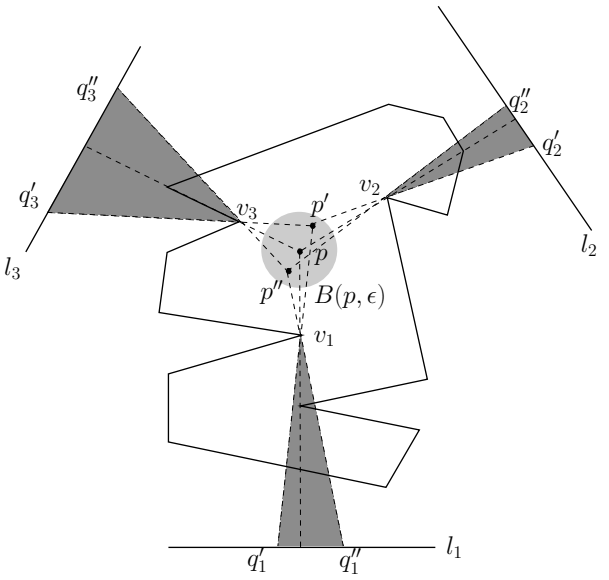

FIG. 2.5. *Upper bounds on the change in area. Here $m = 3$.*

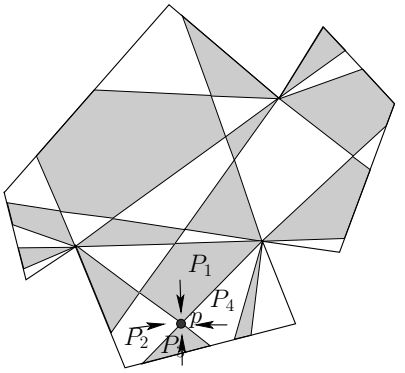

FIG. 2.6. *Partition of Q. The generalized gradient of the area function at p is the convex hull of the gradient of four functions $A_1, \ldots, A_4$ at p.*

in $\mathbb{R}^N$ at which f fails to be differentiable, and S denotes any other set of measure zero, the *generalized gradient* of f is defined by

$$\partial f(x) = \operatorname{co}\left\{ \lim_{i \to +\infty} \mathrm{d}f(x_i) \mid x_i \to x\,,\ x_i \notin S \cup \Omega_f \right\}.$$

Note that this definition coincides with $\mathrm{d}f(x)$ if f is continuously differentiable at x. The generalized gradient and the generalized directional derivative (cf. Proposition 2.1.2 in [5]) are related by $f^o(x; v) = \max\{\zeta \cdot v \mid \zeta \in \partial f(x)\}$ for each $v \in \mathbb{R}^N$.

To obtain the expression for the generalized gradient of $A \circ S$, the polygon Q is partitioned as follows.

LEMMA 2.6. *Let $\{I_\alpha\}_{\alpha \in \mathcal{A}}$ be the set of generalized inflection segments of Q. There exists a unique partition $\{\overline{P}_\beta\}_{\beta \in \mathcal{B}}$ of Q, where P_β is a connected component of $Q \setminus \bigcup_{\alpha \in A} I_\alpha$ and $\overline{P}_\beta$ denotes its closure.*

Figure 2.6 illustrates this partition for the given nonconvex polygon. For $\beta \in \mathcal{B}$, define $A_\beta : \overline{P}_\beta \to \mathbb{R}_+$ by

$$A_\beta(p) = A \circ S(p), \quad \text{for } p \in P_\beta,$$

and by continuity on the boundary of P_β. It turns out that the maps A_β, $\beta \in \mathcal{B}$, are continuously differentiable[1] on $\overline{P}_\beta$. Equation (2.1) gives the value of the gradient for $p \in P_\beta$. However, in general, for $p \in \overline{P}_{\beta_1} \bigcap \cdots \bigcap \overline{P}_{\beta_m} \setminus \mathrm{Ve}_r(Q)$, based on Theorem 2.5 and Lemma 2.6, we can write

$$\partial(A \circ S)(p) = \operatorname{co}\left\{ \mathrm{d}A_{\beta_1}(p), \ldots, \mathrm{d}A_{\beta_m}(p) \right\}. \tag{2.3}$$

This completes our study of the generalized gradient of the locally Lipschitz function $A \circ S$. Apart from differentiability, another smoothness property of $A \circ S$ that we will characterize is the one of regularity. As will be clear later, this will be crucial in constructing a set-valued estimate of the rate at which $A \circ S$ changes as the observer moves. We define regularity first and then show how $A \circ S$ is not regular in many interesting situations.

[1] A function is continuously differentiable on a closed set if (1) it is continuously differentiable on the interior, and (2) the limit of the derivative at a point in the boundary does not depend on the direction from which the point is approached.

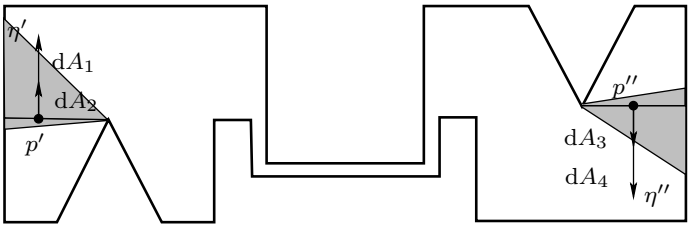

FIG. 2.7. *Example polygon for which $A \circ S$ and $-A \circ S$ restricted to $Q \setminus \mathrm{Ve}_r(Q)$ are not regular. Note here that $\mathrm{d}A_1$ and $\mathrm{d}A_2$ are not perfectly aligned with η'. Also, $\mathrm{d}A_3$ and $\mathrm{d}A_4$ are not perfectly aligned with η''.*

DEFINITION 2.7. *A function $f : \mathbb{R}^N \to \mathbb{R}$ is said to be* regular at $x \in \mathbb{R}^N$ *if for all $v \in \mathbb{R}^N$, $f'(x; v)$ exists and $f^o(x; v) = f'(x; v)$.*

Again, a continuously differentiable function at x is regular at x. Also, a locally Lipschitz function at x which is convex is also regular (cf. Proposition 2.3.6 in [5]).

LEMMA 2.8. *There exists a nonconvex polygon Q such that the maps $A \circ S$ and $-A \circ S$ restricted to $Q \setminus \mathrm{Ve}_r(Q)$ are not regular.*

Proof. We present an example to justify the above statement. In Figure 2.7, $\partial(A \circ S)(p') = \mathrm{co}\{\mathrm{d}A_1, \mathrm{d}A_2\}$, where $\|\mathrm{d}A_1\| \gg \|\mathrm{d}A_2\|$. Take a vector η' perpendicular to the generalized inflection segment to which p' belongs (see Figure 2.7). It is clear that $(A \circ S)'(p; \eta') = \mathrm{d}A_2 \cdot \eta'$. However, $(A \circ S)^0(p'; \eta') = \max\{\zeta \cdot \eta' | \zeta \in \partial(A \circ S)(p')\} = \mathrm{d}A_1 \cdot \eta' > \mathrm{d}A_2 \cdot \eta'$. Again, in Figure 2.7, $\partial(-A \circ S)(p'') = \mathrm{co}\{-\mathrm{d}A_3, -\mathrm{d}A_4\}$, where $\| - \mathrm{d}A_4\| \gg \| - \mathrm{d}A_3\|$. Take a vector η'' perpendicular to the generalized inflection segment to which p'' belongs (see Figure 2.7). It is clear that $-(A \circ S)'(p''; \eta'') = -\mathrm{d}A_4 \cdot \eta''$. However, $(A \circ S)^0(p''; \eta'') = \max\{\zeta \cdot \eta'' | \zeta \in \partial(A \circ S)(p'')\} = -\mathrm{d}A_3 \cdot \eta'' > -\mathrm{d}A_4 \cdot \eta''$. ∎

3. An invariance principle in nonsmooth stability analysis. This section presents results on stability analysis for discontinuous vector fields via nonsmooth Lyapunov functions. The results extend the work in [2] and will be useful in the next control design section; see also [6]. We refer the reader to [9] and to Appendix A for some useful nonsmooth analysis concepts that we have not included in the main body of the paper.

In what follows we shall study differential equations of the form

$$\dot{x}(t) = X(x(t)), \tag{3.1}$$

where $X : \mathbb{R}^N \to \mathbb{R}^N$ is a measurable and essentially locally bounded, possibly discontinuous vector field. We understand the solution of this equation in the Filippov sense following [9]. For each $x \in \mathbb{R}^N$, consider the set

$$K[X](x) = \bigcap_{\delta > 0} \bigcap_{\mu(S)=0} \mathrm{co}\{X(B(x, \delta) \setminus S)\},$$

where μ denotes the usual Lebesgue measure in $\mathbb{R}^N$. Alternatively, one can show [14] that there exists a set S_X of measure zero such that

$$K[X](x) = \mathrm{co}\left\{ \lim_{i \to +\infty} X(x_i) \mid x_i \to x\,,\ x_i \notin S \cup S_X \right\},$$

where S is any set of measure zero. A Filippov solution (see Appendix A) of (3.1) on an interval $[t_0, t_1] \subset \mathbb{R}$ is defined as a solution of the differential inclusion

$$\dot{x} \in K[X](x)\,. \tag{3.2}$$

Since the set-valued map $K[X] : \mathbb{R}^N \to 2^{\mathbb{R}^N}$ is upper semicontinuous with nonempty, compact, convex values and locally bounded (cf. [9]), the existence of Filippov solutions of (3.1) is guaranteed by Lemma A.3. A set M is *weakly invariant* (respectively, *strongly invariant*) for (3.1) if for each $x_0 \in M$, M contains a maximal solution (respectively, all maximal solutions) of (3.1).

We now introduce another useful tool. Given a locally Lipschitz function $f : \mathbb{R}^N \to \mathbb{R}$, the *set-valued Lie derivative of f with respect to X* at x is defined as

$$\widetilde{\mathcal{L}}_X f(x) = \{a \in \mathbb{R} \mid \exists v \in K[X](x) \text{ such that } \zeta \cdot v = a \ \ \forall \zeta \in \partial f(x)\}\ .$$

For each $x \in \mathbb{R}^N$, $\widetilde{\mathcal{L}}_X f(x)$ is a closed and bounded interval in $\mathbb{R}$, possibly empty. If f is continuously differentiable at x, then $\widetilde{\mathcal{L}}_X f(x) = \{\mathrm{d}f \cdot v \mid v \in K[X](x)\}$. If, in addition, X is continuous at x, then $\widetilde{\mathcal{L}}_X f(x)$ corresponds to the singleton $\{\mathcal{L}_X f(x)\}$, the usual Lie derivative of f in the direction of X at x.

We are now ready to state the first result in this section.

LEMMA 3.1. *Let $X : \mathbb{R}^N \to \mathbb{R}^N$ be measurable and essentially locally bounded, and let $f : \mathbb{R}^N \to \mathbb{R}$ be locally Lipschitz. Let $\gamma : [t_0, t_1] \to \mathbb{R}^N$ be a Filippov solution of X such that $f(\gamma(t))$ is regular for almost all $t \in [t_0, t_1]$. Then*

(i) $\frac{\mathrm{d}}{\mathrm{d}t}(f(\gamma(t)))$ *exists for almost all $t \in [t_0, t_1]$, and*

(ii) $\frac{\mathrm{d}}{\mathrm{d}t}(f(\gamma(t))) \in \widetilde{\mathcal{L}}_X f(\gamma(t))$ *for almost all $t \in [t_0, t_1]$.*

Proof. The result is an immediate consequence of Lemma 1 in [2]. □

The following result is a generalization of the classic LaSalle invariance principle for smooth vector fields and smooth Lyapunov functions to the setting of discontinuous vector fields and nonsmooth Lyapunov functions.

THEOREM 3.2 (LaSalle invariance principle). *Let $X : \mathbb{R}^N \to \mathbb{R}^N$ be measurable and essentially locally bounded, and let $S \subset \mathbb{R}^N$ be compact and strongly invariant for X. Let $C \subset S$ consist of a finite number of points, and let $f : S \to \mathbb{R}$ be locally Lipschitz on $S \setminus C$ and bounded from below on S. Assume the following properties hold:*

(A1) *if $x \in S \setminus C$, then either $\max \widetilde{\mathcal{L}}_X f(x) \le 0$ or $\widetilde{\mathcal{L}}_X f(x) = \emptyset$;*

(A2) *if $x \in C$ and if γ is a Filippov solution of X with $\gamma(0) = x$, then $\lim_{t \to 0^-} f(\gamma(t)) \ge \lim_{t \to 0^+} f(\gamma(t))$; and*

(A3) *if $\gamma : \overline{\mathbb{R}}_+ \to S$ is a Filippov solution of X, then $f \circ \gamma$ is regular almost everywhere.*

Define $Z_{X,f} = \{x \in S \setminus C \mid 0 \in \widetilde{\mathcal{L}}_X f(x)\}$, and let M be the largest weakly invariant set contained in $(\overline{Z}_{X,f} \cup C)$. Then the following statements hold:

(i) *if $\gamma : \overline{\mathbb{R}}_+ \to S$ is a Filippov solution of X, then $f \circ \gamma$ is monotonically nonincreasing;*

(ii) *each Filippov solution of X with initial condition in S approaches M as $t \to +\infty$; and*

(iii) *if M consists of a finite number of points, then each Filippov solution of X with initial condition in S converges to a point of M as $t \to +\infty$.*

Proof. Fact (i) is a consequence of Assumptions (A1), (A2), and (A3) and of Lemma 3.1.

In what follows we shall require the following notion. Given a curve $\gamma : \mathbb{R}_+ \to \mathbb{R}^N$, the positive limit set of γ, denoted by $\Omega(\gamma)$, is the set of $y \in \mathbb{R}^N$ for which there

exists a sequence $\{t_k\}_{k\in\mathbb{N}} \subset \mathbb{R}$ such that $t_k < t_{k+1}$, for $k \in \mathbb{N}$, $\lim_{k\to+\infty} t_k = +\infty$, and $\lim_{k\to+\infty} \gamma(t_k) = y$. For $x \in S$, let γ_1 be a Filippov solution of X with $\gamma_1(0) = x$, and let $\Omega(\gamma_1)$ be the limit set of γ_1. Under this setting, $\Omega(\gamma_1)$ is nonempty, bounded, connected, and weakly invariant; see [9]. Furthermore, $\Omega(\gamma_1) \subset S$ because S is strongly invariant and closed.

To prove fact (ii), it suffices to show that $\Omega(\gamma_1) \subset \overline{Z}_{X,f} \cup C$. Trivially, $\Omega(\gamma_1) \cap C \subset C$. Let $y \in \Omega(\gamma_1)\backslash C$ so that f is locally Lipschitz at y. There exists a sequence $\{t_k\}_{k\in\mathbb{N}}$ such that $\lim_{k\to+\infty} \gamma_1(t_k) = y$. Because $f \circ \gamma_1$ is monotonically nonincreasing and f is bounded from below, $\lim_{t\to+\infty} f(\gamma_1(t))$ exists and is equal to, say, $a \in \mathbb{R}$. Now, by continuity of f, $a = \lim_{k\to+\infty} f \circ \gamma_1(t_k) = f(y)$. This proves that $f(y) = a$ for all $y \in \Omega(\gamma_1) \setminus C$. At this point we distinguish two cases. First, assume that y is an isolated point in $\Omega(\gamma_1)$. Then, clearly, there exists a Filippov solution of X, say γ_2, such that $\gamma_2(t) = y$ for all $t \geq 0$. Hence $\frac{\mathrm{d}}{\mathrm{d}t} f(\gamma_2(t)) = 0$, and, by Lemma 3.1, $0 \in \widetilde{\mathcal{L}}_X f(\gamma_2(t))$, or in other words $y \in Z_{X,f}$. Second, assume that y is not isolated in $\Omega(\gamma_1)$, and let γ_2 be a Filippov solution of X with $\gamma_2(0) = y$. Since f is continuous at y and $\Omega(\gamma_1)$ contains a finite number of points of discontinuity of f, there exists $\delta > 0$ such that $f(y') = a$ for all $y' \in B(y, \delta) \cap \Omega(\gamma_1)$. Therefore, there exists $t' > 0$ such that $f(\gamma_2(t)) = a$ for all $t \in [0, t']$. Hence, we have $\frac{\mathrm{d}}{\mathrm{d}t} f(\gamma_2(t)) = 0$ for all $t \in [0, t']$. It follows from Lemma 3.1 that for all $t \in [0, t']$, we have $0 \in \widetilde{\mathcal{L}}_X f(\gamma_2(t))$, or in other words $\gamma_2(t) \in Z_{X,f}$. By continuity of γ_2 at $t = 0$, we have that $\gamma_2(0) = y \in \overline{Z}_{X,f}$. Since $\Omega(\gamma_1)$ is weakly invariant, we have $\Omega(\gamma_1) \subset M$, and hence γ_2 approaches M.

We now prove fact (iii). If M consists of a finite number of points, and since $\Omega(\gamma_1) \subset M$ is connected, $\Omega(\gamma_1)$ is a point. Hence, by the argument in the preceding paragraph, each Filippov solution of X approaches a point of M. In other words, it converges to a point of M. □

COROLLARY 3.3. *The LaSalle invariance principle is valid under the following relaxed assumption:*

(A3) *if $\gamma : \overline{\mathbb{R}}_+ \to S$ is a Filippov solution of X, then almost everywhere either $f \circ \gamma$ or $-f \circ \gamma$ is regular.*

Proof. The proof is a consequence of the fact that $\frac{\mathrm{d}}{\mathrm{d}t}(f(\gamma(t)))$ exists and belongs to $\widetilde{\mathcal{L}}_X f(\gamma(t))$ if and only if $\frac{\mathrm{d}}{\mathrm{d}t}(-f(\gamma(t)))$ exists and belongs to $\widetilde{\mathcal{L}}_X(-f)(\gamma(t))$. Thus result (ii) of Lemma 3.1 still holds and the proof of the LaSalle invariance principle remains unchanged. □

4. Maximizing the area visible from a mobile observer. In this section we build on the analysis results obtained thus far to design an algorithm that maximizes the area visible to a mobile observer. We aim to reach local maxima of the visible area $A \circ S$ by designing some appropriate form of a gradient flow for the discontinuous function $A \circ S$. We now present an *introductory and incomplete* version of the algorithm: the objective is to steer the mobile observer along a path for which the visible area is guaranteed to be nondecreasing (see Algorithm 1 on next page).

The remainder of this section is dedicated to formalizing this loose description.

4.1. A modified gradient vector field. Before describing the algorithm to maximize the area visible to the mobile observer, we introduce the following useful notions. Given a non-self-intersecting polygon Q with $\mathrm{Ve}(Q) = (v_1, \ldots, v_n)$ and $\epsilon > 0$, define the following quantities:

(i) let the *ϵ-expansion of Q* be $Q^\epsilon = \{p \mid ||p - q|| \leq \epsilon \text{ for some } q \in Q\}$;

(ii) for $i \in \{1, \ldots, n\}$, let P_i^ϵ be the open set delimited by the edge $\overline{v_i v_{i+1}}$, the bisectors of the external angles at v_i and v_{i+1}, and the boundary of Q^ϵ;

ALGORITHM 1

Name:	Increase visible area for Q
Goal:	Maximize the area visible to a mobile observer
Assumption:	Generalized inflection segments of Q do not intersect. Initial position does not belong to a generalized inflection segment.

Let $p(t)$ denote the observer position at time t inside the nonconvex polygon Q. The observer performs the following tasks at each time instant:

compute visibility polygon $S(p(t)) \subset Q$,
if $p(t)$ does not belong to any generalized inflection segment or to the boundary of Q, **then**
move along the versor of the gradient $\mathrm{d}(A \circ S)$

end if

(iii) for ϵ small enough and for any point p in Q^ϵ, let $\mathrm{prj}_Q(p)$ be uniquely equal to $\arg\min\{||p' - p|| \mid p' \in \partial Q\}$; and
(iv) for $p \in \cup_{i\in\{1,\dots,n\}} P_i^\epsilon$, let the *outward normal* $n(\mathrm{prj}_Q(p))$ be the unit vector directed from $\mathrm{prj}_Q(p)$ to p.

We illustrate these notions in Figure 4.1. Note that $\mathrm{prj}_Q(p)$ can never be a reflex vertex. We can now define a vector field on Q^ϵ as follows:

$$X_Q(p) = \begin{cases} \mathrm{vers}(\mathrm{d}(A \circ S)(p)) & \text{if } p \in \mathring{Q} \setminus \{I_\alpha\}_{\alpha\in\mathcal{A}}, \\ -n(\mathrm{prj}_Q(p)) & \text{if } p \in P_i^\epsilon, \\ 0 & \text{otherwise.} \end{cases}$$

(Recall that the versor operator is defined by $\mathrm{vers}(Y) = Y/\|Y\|$ if $Y \in \mathbb{R}^2 \setminus \{0\}$ and by $\mathrm{vers}(0) = 0$.) Note that X_Q is well defined because at $p \in \mathring{Q} \setminus \{I_\alpha\}_{\alpha\in\mathcal{A}}$ the function $A \circ S$ is analytic. Clearly, X_Q is not continuous on Q^ϵ. However, the set of points where it is discontinuous is of measure zero. Almost everywhere in the interior of Q, the vector field X_Q is equal to the normalized gradient of $A \circ S$, as depicted in Figure 2.3.

Remark 4.1. An important observation in this setting is that at all points p where $A \circ S$ is locally Lipschitz, we have $K[\mathrm{d}(A \circ S)](p) = \partial(A \circ S)(p)$. In such a case it is also true that for all $\eta \in \partial(A \circ S)(p)$, there exists at least one $\delta > 0$ such that $\delta\eta \in K[X_Q](p)$ and vice versa.

We now present the differential equation describing the motion of the observer:

$$\dot{p}(t) = X_Q(p(t)). \tag{4.1}$$

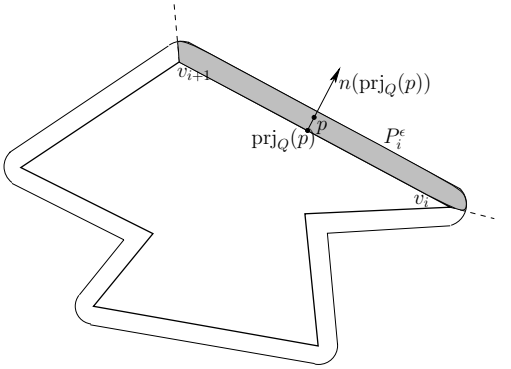

FIG. 4.1. *The ϵ-expansion Q^ϵ of the non-self-intersecting polygon Q, an open set P_i^ϵ, and the corresponding outward normal $n(\mathrm{prj}_Q(p))$.*

A Filippov solution of (4.1) on an interval $[t_0, t_1] \subset \mathbb{R}$ is defined as a solution of the differential inclusion

$$\dot{p}(t) \in K[X_Q](p(t)), \tag{4.2}$$

where $K[X_Q]$ is the usual Filippov differential inclusion associated with X_Q; see Appendix A. Since X_Q is measurable and bounded, the existence of a Filippov solution is guaranteed. We study uniqueness and completeness of Filippov solutions in the following lemma.

LEMMA 4.2. *The following statements hold true:*

(i) *there exists a non-self-intersecting polygon Q for which the corresponding vector field X_Q admits multiple Filippov solutions starting from the same initial condition; and*

(ii) *any non-self-intersecting polygon Q is a strongly invariant set for the corresponding vector field X_Q and, therefore, any Filippov solution is defined over $\overline{\mathbb{R}}_+$.*

Proof. We present an example to justify the statement (i). In Figure 4.2, at the point p_0 on the generalized inflection segment, both directions η_1 and η_2 belong to $\partial(A \circ S)(p_0)$. Three distinct Filippov solutions of (4.1) exist. Two of the solutions start from p_0 along the two directions η_1 and η_2, while the third solution is $p(t) = p_0$ for all $t \geq 0$. Statement (ii) is a consequence of the definition of X_Q on P_i^ϵ for $i \in \{1, \ldots, n\}$. ∎

We now claim that any solution of the differential inclusion (4.2) has the property that the visible area increases monotonically. To prove these desirable properties, we first present the following results in nonsmooth analysis.

4.2. Properties of solutions and convergence analysis. To prove the convergence properties of the solution of (4.2) using the results presented in section 3, we must first define a suitable Lyapunov function. Intuitively, since our objective is

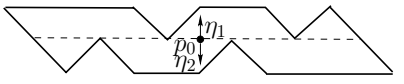

FIG. 4.2. *Three Filippov solutions exist starting from the point p_0.*

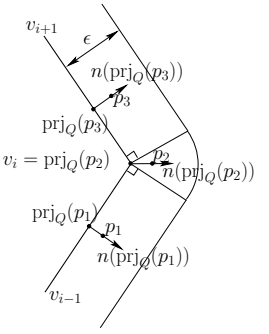

FIG. 4.3. *Extending the function $A \circ S$ to A_Q^ϵ. Note the direction of $n(\mathrm{prj}_Q(p_i))$ at all points p_i.*

to maximize the visible area, our Lyapunov function should be closely related to it. For $\epsilon > 0$, we now define the *extended area function* A_Q^ϵ at all points $p \in Q \bigcup \{\cup_i P_i^\epsilon\}$. The extended function coincides with the original function on the interior and on the boundary of Q and is defined appropriately outside:

$$A_Q^\epsilon(p) = \begin{cases} A \circ S(p) & \text{if } p \in Q, \\ A \circ S(\mathrm{prj}_Q(p)) - ||p - \mathrm{prj}_Q(p)|| & \text{if } p \in \cup_i P_i^\epsilon. \end{cases}$$

For all $p \in \partial Q \setminus \mathrm{Ve}\, Q$, A_Q^ϵ satisfies (see Figure 4.3)

$$A_Q^\epsilon{}'(p; n(\mathrm{prj}_Q(p))) = -1.$$

Remark 4.3. The extended area function A_Q^ϵ is locally Lipschitz on $(Q \setminus \mathrm{Ve}_r(Q)) \bigcup \{\cup_i P_i^\epsilon\}$ and analytic almost everywhere on $Q \bigcup \{\cup_i P_i^\epsilon\}$.

The following theorem characterizes the regularity of the map $p \mapsto -A_Q^\epsilon(p)$ along a Filippov solution of X_Q. This is important to prove that the area of the visibility polygon is nondecreasing along any Filippov solution of X_Q

THEOREM 4.4. *Let $G(Q)$ be the subset of Q where both maps $p \mapsto -A_Q^\epsilon(p)$ and $p \mapsto A_Q^\epsilon(p)$ are not regular. Then any Filippov solution $\gamma : \overline{\mathbb{R}}_+ \to Q$ of X_Q has the property that $\gamma(t) \notin G(Q)$ for almost all $t \in \overline{\mathbb{R}}_+$ unless γ reaches a critical point of $K[X_Q]$.*

Proof. Note that $G(Q)$ is a subset of $\cup_{\alpha \in \mathcal{A}} I_\alpha$. This is a consequence of Theorem 2.2 and the fact that functions are regular at points of differentiability. Given a generalized inflection segment I_α, let l_α be the line extending I_α, and let t_α be one of the two unit tangent vectors to I_α. A Filippov solution γ of X_Q slides along I_α starting from $p_0 \in I_\alpha$ only if $\partial A_Q^\epsilon(p_0)$ contains either t_α or $-t_\alpha$. It then suffices to show that if $\partial A_Q^\epsilon(p_0)$ contains t_α or $-t_\alpha$, then either A_Q^ϵ or $-A_Q^\epsilon$ is regular at p_0. Let us also assume that p_0 does not belong to any other generalized inflection segment. If this were not the case, then either p_0 is a critical point or the Filippov solution does not belong to the point of intersection for almost all $t \in \overline{\mathbb{R}}_+$.

Let l_α divide $\mathbb{R}^2$ into two open half planes H_1 and H_2. There exists $\delta > 0$ such that A_Q^ϵ is analytic on $H_i \cap B(p_0, \delta)$, $i \in \{1, 2\}$; see Figure 4.4. On l_α, we have $(A_Q^\epsilon)_1 = (A_Q^\epsilon)_2$, where $(A_Q^\epsilon)_i$ is the function A_Q^ϵ restricted to H_i. Let $p' \in B(p_0, \delta)$ and, without loss of generality, let $p' \in H_2$. Let n be the normal to I_α at p_0 pointing away from p'. Note that in terms of the notation introduced in section 4.1, $n = -n(\mathrm{prj}_{l_\alpha}(p'))$, where $\mathrm{prj}_{l_\alpha}(p') = \arg\min\{||p' - p|| \mid p \in l_\alpha\}$. Now, $(A_Q^\epsilon)_1$ can be extended to $H_2 \cap B(p_0, \delta)$ by analyticity. Likewise, $(A_Q^\epsilon)_2$ can be extended to $H_1 \cap B(p_0, \delta)$. Since the functions

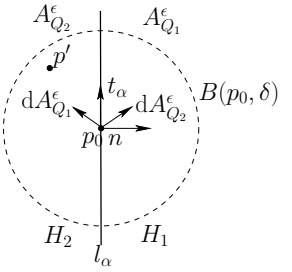

FIG. 4.4. *The point p_0 lies on the generalized inflection segment l. H_1 and H_2 are half planes on either side of l. n and t are normal and parallel to l, respectively. The other arrows indicate the directions of $\mathrm{d}A^\epsilon{}_Q(p)$ on either side of l.*

$(A^\epsilon_Q)_i$, $i \in \{1, 2\}$, are analytic, they can be written as the expansions of their Taylor series:

$$(A^\epsilon_Q)_i(p') = (A^\epsilon_Q)_i(p_0) + \mathrm{d}((A^\epsilon_Q)_i)(p_0) \cdot (p' - p_0) + O(\|p' - p_0\|^2).$$

It follows from the above set of equations that

$$(A^\epsilon_Q)_2(p') - (A^\epsilon_Q)_1(p') = \big(\mathrm{d}((A^\epsilon_Q)_2) - \mathrm{d}((A^\epsilon_Q)_1)\big) \cdot (p' - p_0) + O(\|p' - p_0\|^2).$$

Note that n is the same for all $p' \in H_2$. Now, $p' - p_0 = -c_1 n + c_2 t_\alpha$ such that $c_1 \geq 0$. Also, $\mathrm{d}(A^\epsilon_Q)_1(p_0) \cdot t_\alpha = \mathrm{d}(A^\epsilon_Q)_2(p_0) \cdot t_\alpha$, since $(A^\epsilon_Q)_1(p) = (A^\epsilon_Q)_2(p)$ for $p \in I_\alpha$. Therefore,

$$(A^\epsilon_Q)_2(p') - (A^\epsilon_Q)_1(p') = c_1 \left(\mathrm{d}(A^\epsilon_Q)_1(p_0) \cdot n - \mathrm{d}(A^\epsilon_Q)_2(p_0) \cdot n\right) + O(\|p' - p_0\|^2).$$

Now, either t_α or $-t_\alpha$ belongs to $\partial A^\epsilon_Q(p_0) = \mathrm{co}\{\mathrm{d}(A^\epsilon_Q)_1, \mathrm{d}(A^\epsilon_Q)_2\}$ if and only if the product of $\mathrm{d}(A^\epsilon_Q)_1(p_0) \cdot n$ and $\mathrm{d}(A^\epsilon_Q)_2(p_0) \cdot n$ is less than or equal to zero (see Figure 4.4). If $\mathrm{d}(A^\epsilon_Q)_1(p_0) \cdot n = 0$ and $\mathrm{d}(A^\epsilon_Q)_2(p_0) \cdot n = 0$, then clearly A^ϵ_Q is C^1 at p_0 and hence regular. Otherwise, let us assume, without loss of generality, that $\mathrm{d}(A^\epsilon_Q)_1(p_0) \cdot n - \mathrm{d}(A^\epsilon_Q)_2(p_0) \cdot n < 0$. Therefore, there exists $\eta_2 > 0$ such that $(A^\epsilon_Q)_2(p') - (A^\epsilon_Q)_1(p') \leq 0$ for $p' \in H_2 \cap B(p_0, \eta_2)$. Similarly, there exists $\eta_1 > 0$ such that for $p' \in H_1 \cap B(p_0, \eta_1)$, we have $(A^\epsilon_Q)_1(p') - (A^\epsilon_Q)_2(p') \leq 0$. Thus, there exists a neighborhood around p_0 where $A^\epsilon_Q(p) = \min\{(A^\epsilon_Q)_1(p), (A^\epsilon_Q)_2(p)\}$ or $-A^\epsilon_Q(p) = \max\{-(A^\epsilon_Q)_1(p), -(A^\epsilon_Q)_2(p)\}$. Since $(A^\epsilon_Q)_i$, $i \in \{1, 2\}$, are smooth functions, it follows from Proposition 2.3.12 in [5] that $-A^\epsilon_Q$ is regular at p_0. On the other hand, if we assume that $\mathrm{d}(A^\epsilon_Q)_1(p_0) \cdot n - \mathrm{d}(A^\epsilon_Q)_2(p_0) \cdot n > 0$, then we get that A^ϵ_Q is regular at p_0. □

In the following theorem, the functions A^ϵ_Q and $-A^\epsilon_Q$ are used as candidate Lyapunov functions to show the convergence properties of Filippov solutions of X_Q.

THEOREM 4.5. *Any Filippov solution $\gamma : \overline{\mathbb{R}}_+ \to Q$ of X_Q has the following properties:*

(i) *$t \mapsto A \circ S(\gamma(t))$ is continuous and monotonically nondecreasing; and*

(ii) *γ approaches the set of critical points of $K[X_Q]$.*

Proof. Let us start by showing that if γ is a Filippov solution of X_Q, then $A \circ S \circ \gamma$ is continuous. The reader is referred to Figure 4.5 for an introduction of notations used. Let X^r_Q and X^θ_Q be the components of X_Q parallel and perpendicular to $p - v$, respectively. Similarly, let $\mathrm{d}(A \circ S(p))^r$ and $\mathrm{d}(A \circ S(p))^\theta$ be the components of $\mathrm{d}(A \circ S(p))$ parallel and perpendicular to $p - v$, respectively. Note

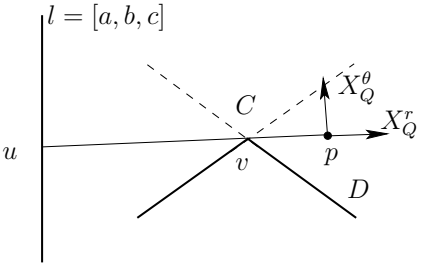

FIG. 4.5. *Illustration of various notions used in Theorem* 4.5. *The dashed lines represent generalized inflection segments generated by the reflex vertex* v *and vertices adjacent to it. These divide the region around* v *that is inside* Q *into three subregions* C, D, *and* E. $u \in \mathrm{Ve}(S(p))$ *lies on the line* l. *The generalized inflection segments including the vertex* v *are assumed to belong to region* C. *Note that* $D \cap C = \emptyset$.

that if $\|\mathrm{d}(A \circ S(p))\| \neq 0$, then $\|X_Q^r\| = \frac{\|\mathrm{d}(A \circ S(p))^r\|}{(\|\mathrm{d}(A \circ S(p))^r\|^2 + \|\mathrm{d}(A \circ S(p))^\theta\|^2)^{1/2}}$ and $\|X_Q^\theta\| = \frac{\|\mathrm{d}(A \circ S(p))^\theta\|}{(\|\mathrm{d}(A \circ S(p))^r\|^2 + \|\mathrm{d}(A \circ S(p))^\theta\|^2)^{1/2}}$. Let $\epsilon > 0$ be such that $\|\mathrm{d}(A \circ S(p))\| \neq 0$ for all $p \in B(v, \epsilon) \cap D$. For now, let us also assume that $\{\cup_{\alpha \in \mathcal{A}} I_\alpha\} \cap B(v, \epsilon) \cap D = \emptyset$. We now claim that in $B(v, \epsilon) \cap D$, $\mathrm{d}(A \circ S(p))^\theta = \Omega(1/\|p - v\|)$ and $\mathrm{d}(A \circ S(p))^r = O(1)$. In other words there exist constants $k_\theta > 0$ and $k_r > 0$ such that $\|\mathrm{d}(A \circ S(p))^\theta\| \geq \frac{k_\theta}{\|p - v\|}$ and $\|\mathrm{d}(A \circ S(p))^r\| \leq k_r$. Notice that $\mathrm{d}(A \circ S(p)) = \mathrm{d}(A \circ S(p))^r + \mathrm{d}(A \circ S(p))^\theta = \sum_i \frac{\partial(A \circ S)}{\partial u_i} \mathrm{d}u_i(p)$. Let $u_1 = u$. From (2.2), it is clear that $\frac{\partial(A \circ S)}{\partial u} \mathrm{d}u(p)$ is perpendicular to $p - v$ and hence contributes only to $\mathrm{d}(A \circ S(p))^\theta$. Also $\| \sum_{i \geq 2} \frac{\partial(A \circ S)}{\partial u_i} \mathrm{d}u_i(p)\|$ is bounded for all $p \in B(v, \epsilon) \cap D$. Therefore, $\mathrm{d}(A \circ S(p))^\theta = \frac{\partial(A \circ S)}{\partial u} \mathrm{d}u(p) + \Omega(1) = \Omega(\| \frac{\partial(A \circ S)}{\partial u} \mathrm{d}u(p)\|)$ and $\mathrm{d}(A \circ S(p))^r = O(1)$. Again from (2.2), we have

$$\left\| \frac{\partial(A \circ S)}{\partial u} \mathrm{d}u(p) \right\| = \frac{\mathrm{dist}(v, l)}{2} \frac{\|p - v\| |\,\mathrm{dist}(u_2, l) - \mathrm{dist}(u_n, l)|}{(\mathrm{dist}(p, l) - \mathrm{dist}(v, l))^2}.$$

Now, $|\,\mathrm{dist}(p, l) - \mathrm{dist}(v, l)| \leq \|p - v\|$. Therefore,

$$\left\| \frac{\partial(A \circ S)}{\partial u} \mathrm{d}u(p) \right\| = \Omega\left(\frac{|\,\mathrm{dist}(u_2, l) - \mathrm{dist}(u_n, l)|}{\|p - v\|} \right).$$

Since p does not lie on a generalized inflection segment, either $u_n = v$ or $u_2 = v$. Without loss of generality, let $u_n = v$. Since u belongs to l, clearly u_2 must belong to l. Hence $|\,\mathrm{dist}(u_2, l) - \mathrm{dist}(u_n, l)| = \mathrm{dist}(v, l)$ and is a constant for all $p \in B(v, \epsilon) \cap D$. Thus

$$\left\| \frac{\partial(A \circ S)}{\partial u} \mathrm{d}u(p) \right\| = \Omega\left(\frac{1}{\|p - v\|} \right).$$

Hence, $\mathrm{d}(A \circ S(p))^\theta = \Omega(\frac{1}{\|p - v\|})$. Therefore $\frac{\|\mathrm{d}(A \circ S(p))^\theta\|}{\|\mathrm{d}(A \circ S(p))^r\|} \geq \frac{k_\theta}{k_r \|p - v\|}$. It follows that

$$\|X_Q^r\| = \frac{1}{(1 + \frac{\|\mathrm{d}(A \circ S(p))^\theta\|^2}{\|\mathrm{d}(A \circ S(p))^r\|^2})^{1/2}} \leq \frac{1}{(1 + \frac{k_\theta^2}{k_r^2 \|p - v\|^2})^{1/2}} = \frac{k_r \|p - v\|}{(k_\theta^2 + k_r^2 \|p - v\|^2)^{1/2}}$$
$$\leq \frac{k_r \|p - v\|}{k_\theta}.$$

Note that a convex combination of finitely many X_Q^r will also admit a similar inequality, and so the assumption that $\{\cup_{\alpha\in\mathcal{A}} I_\alpha\}\cap B(v,\epsilon)\cap D = \emptyset$ is not limiting. Now let $\gamma(t)$ be a solution of X_Q such that $\gamma(0) = v$. Let T be any time such that $\|\gamma(T) - v\| = R$ and for all $t \in [0,T]$, $\gamma(t) \in B(v,\epsilon)\cap D$ and $X_Q^r(\gamma(t))$ is directed away from v. Then, clearly, $R = \int_0^T X_Q^r \mathrm{d}t \le R\frac{k_r}{k_\theta}T$. In other words the time T taken for a trajectory to travel any distance R is greater than $\frac{k_\theta}{k_r}$. This is a contradiction. Therefore, our assumption that for all $t \in [0,T]$, $\gamma(t) \in B(v,\epsilon)\cap D$ is false. So, the trajectory must belong to C for some finite time interval contained in $[0,T]$. We can choose R as small as possible, and this implies that there exists a finite time interval $[0,T_C]$ for which $\gamma(t) \in C$. It follows trivially that $t \mapsto A\circ S(\gamma(t))$ is right continuous at t, where $\gamma(t) = v$. We can prove similarly that $t \mapsto A\circ S(\gamma(t))$ is left continuous at t, where $\gamma(t) = v$ by considering the vector field $-X_Q$ in place of X_Q. This completes the proof that $t \mapsto A\circ S(\gamma(t))$ is continuous.

Next, we show that Assumptions (A1), (A2), and (A3) in Theorem 3.2 hold. Let $p \in Q \setminus \mathrm{Ve}_r(Q)$, and take $a \in \widetilde{\mathcal{L}}_{X_Q}(-A_Q^\epsilon)(p)$. By definition, there exists $k \in K[X_Q](p)$ such that $a = k\cdot\zeta$ for all $\zeta \in -\partial A_Q^\epsilon(p)$. In particular, it is true for $\zeta = -\delta k$, for some $\delta > 0$; see Remark 4.1. Therefore, $a = -\delta\|k\|^2 \le 0$. This proves that either $\max \widetilde{\mathcal{L}}_{X_Q}(-A_Q^\epsilon)(p) \le 0$ or $\widetilde{\mathcal{L}}_{X_Q}(-A_Q^\epsilon)(p) = \emptyset$; i.e., Assumption (A1) is satisfied. Assumption (A2) is a consequence of the continuity of $A\circ S\circ\gamma$. Finally, Assumption (A3) is a consequence of Theorem 4.4. Applying now Theorem 3.2 and its corollary, we conclude that fact (i) holds. Moreover, we also deduce that any Filippov solution of X_Q converges to the largest weakly invariant set M contained in $\overline{Z}_{X_Q,-A_Q^\epsilon} \cup \mathrm{Ve}_r(Q)$.

To prove fact (ii), let us show that $M = \{p \in Q \mid 0 \in K[X_Q](p)\}\cap(\overline{Z}_{X_Q,-A_Q^\epsilon} \cup \mathrm{Ve}_r(Q))$. Based on Theorem 4.4, Theorem 3.2, and Corollary 3.3, it suffices to show that M is contained in $\{p \in Q \mid 0 \in K[X_Q](p)\}$. Let us note that the set $\{p \in Q \mid 0 \in K[X_Q](p)\}$ is weakly invariant and can be established to be closed following the same reasoning as in Proposition 2.1.1 in [6]. Let $x \in Z_{X_Q,-A_Q^\epsilon}$. Then, $0 \in \widetilde{\mathcal{L}}_{X_Q}(-A_Q^\epsilon)(x)$; i.e., there exists $k \in K[X_Q](x)$ such that $\zeta\cdot k = 0$ for all $\zeta \in -\partial A_Q^\epsilon(x)$. But, $k \in K[X_Q](x)$ implies that there exists $\delta > 0$ such that $\delta k \in -\partial A_Q^\epsilon(x)$; see Remark 4.1. Thus, for $\zeta = \delta k$, we get $\delta\|k\|^2 = 0$, that is, $0 \in K[X_Q](x)$. This shows that $Z_{X_Q,-A_Q^\epsilon} \subset \{p \in Q \mid 0 \in K[X_Q](x)\}$. Next, let $x \in \mathrm{Ve}_r(Q)\cap M$. If the set $\{x\}$ is weakly invariant, then by definition $0 \in K[X_Q](x)$. If, on the other hand, x is not isolated in M, then there exists a sequence of points $\{x_m\}_{m\in\mathbb{N}}$ converging to x such that $x_m \in Z_{X_Q,-A_Q^\epsilon}$ or, alternatively, $0 \in K[X_Q](x_m)$. Because $\{p \in Q \mid 0 \in K[X_Q](p)\}$ is closed, it follows that $0 \in K[X_Q](x)$. Thus we proved that any weakly invariant set contained in $Z_{X_Q,-A_Q^\epsilon} \cup \mathrm{Ve}_r(Q)$ is a subset of $\{p \in Q \mid 0 \in K[X_Q](p)\}$. Again, as in Proposition 2.1.1 in [6], it can be shown that $Z_{X_Q,-A_Q^\epsilon}$ is a closed set, and hence the claim that $M \subset \{p \in Q \mid 0 \in K[X_Q](p)\}$ follows. □

Theorem 4.5 implies that the single observer converges to a critical point of $A\circ S$ or to a reflex vertex of Q. However, as shown in Figure 5.2, the presence of noise or computational inaccuracies actually works to drive the observer away from a reflex vertex that is not a local maximum. This will also be true for other critical points that are not local maxima.

5. Simulation results. To conduct experiments, a simulation environment has been developed in MATLAB. There are two levels of the code. The lower level consists of a library containing routines to answer queries such as whether two points in

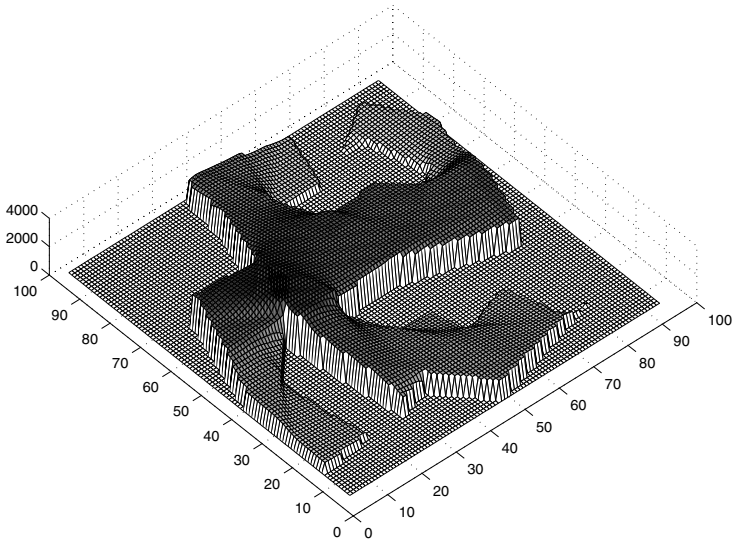

FIG. 5.1. *Example of visible area function over a typical nonconvex polygon.*

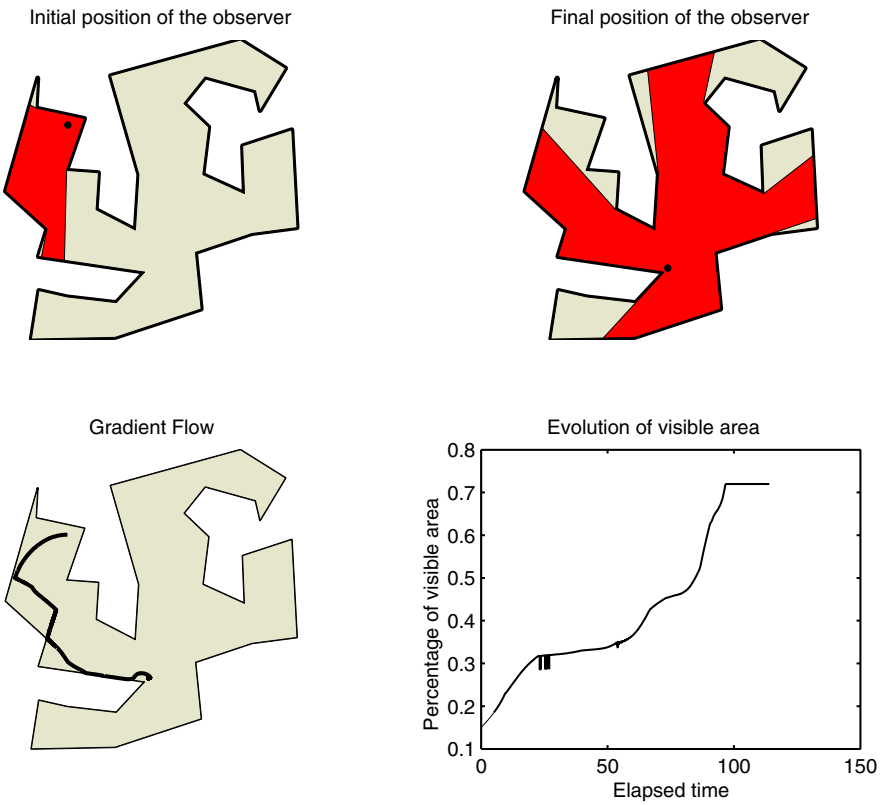

FIG. 5.2. *Simulation results of the gradient algorithm for the nonconvex polygon depicted in Figure* 5.1. *The observer arrives, in finite time, at a local maximum. Note here that the observer visits a reflex vertex at some point in its trajectory but comes out of it due to computational inaccuracies because it is not a local maximum.*

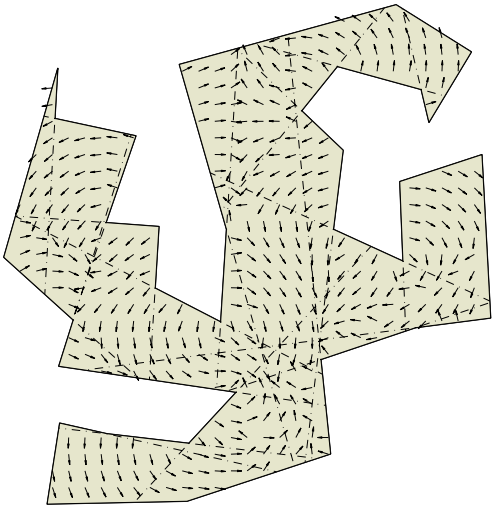

FIG. 5.3. *Example of vector field over the nonconvex polygon in Figure* 5.1.

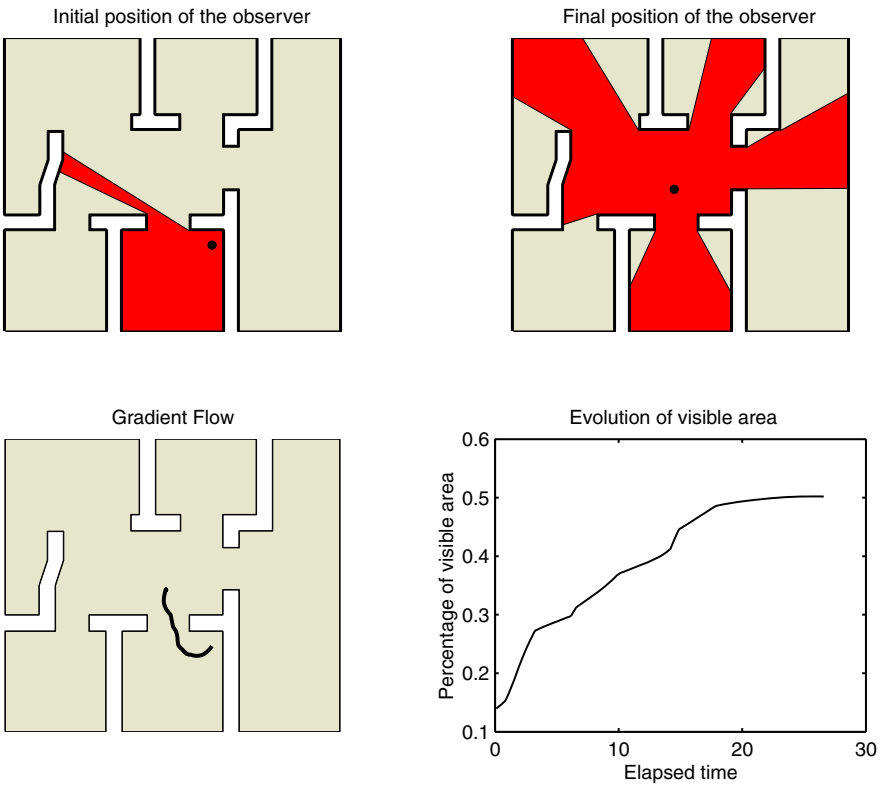

FIG. 5.4. *Simulation results of the gradient algorithm for the nonconvex polygon in Figure* 1.1. *The observer arrives, in finite time, at a local maximum.*

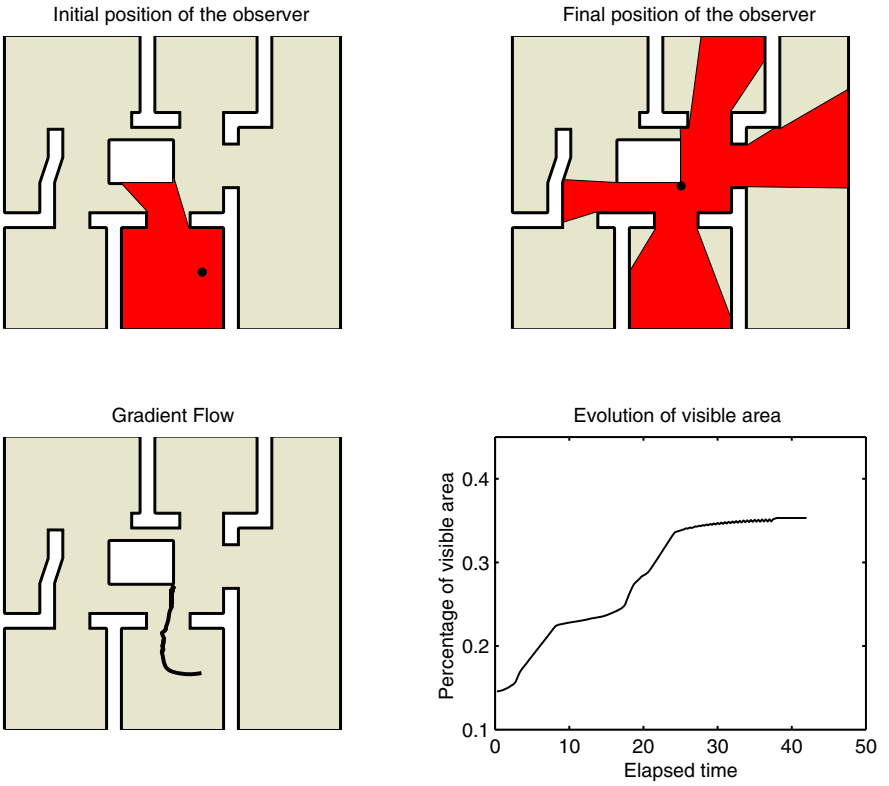

FIG. 5.5. *Simulation results of the gradient algorithm for an observer in a nonconvex environment with a hole. The observer arrives, in finite time, at a reflex vertex.*

a two-dimensional polygonal environment are visible to each other. The higher level utilizes these routines and consists of two major portions. In the first, the vertices of the visibility polygon are obtained by means of an $O(n^2)$ algorithm, where n is the number of vertices of the polygonal environment. These are then sorted in counterclockwise order to compute the visibility polygon. The second consists of the controller which decides the direction and the step size of the observer motion at each time instant. The main task of the controller is the calculation of the generalized gradient of the visible area function which is a natural outcome of (2.1) and (2.3). *Such a framework gives the flexibility to easily implement other visibility-based algorithms for single or multiple observers in a polygonal environment. This can be done by extracting the appropriate information using the low level functions and implementing the desired controller.*

Figure 5.1 illustrates a typical nonconvex polygon; see Figure 5.3 for the phase portrait of the vector field X_Q for the same polygon. Figures 5.2 and 5.4 illustrate the performance of the gradient algorithm in equation (4.2) for the environments in Figures 5.1 and 1.1, respectively. Computational inaccuracies in the implementation of the algorithm to calculate the visibility polygon have been noticed in some configurations; see the plot of the evolution of visible area with time in Figure 5.2. Simulation results for an observer in a polygonal environment containing a hole is shown in Figure 5.5. Our experiments suggest that the observer reaches a local maximum of the visible area in finite time; however, this can be shown not to be true in general.

6. Conclusions. This paper introduces a gradient-based algorithm to optimally locate a mobile observer in a nonconvex environment. We have presented nonsmooth analysis and control design results. The simulation results illustrate that, in the presence of noise, the observer reaches a local maximum of the visible area. In a "highly nonconvex" environment, a single observer may not be able to see a large fraction of the environment. In such a case, a team of observers can be deployed to achieve the same task. We therefore plan to investigate this same visibility objective for teams of observers. Other directions of future research include practical robotic implementation issues as well as other combined mobility and visibility problems.

Appendix A. Nonsmooth analysis and discontinuous vector fields. In this appendix we review some basic facts and standard notation from nonsmooth analysis [5].

Given a locally Lipschitz function $f : \mathbb{R}^N \to \mathbb{R}$, a point $x \in \mathbb{R}^N$ which verifies that $0 \in \partial f(x)$ is called a *critical point of* f. The extrema of Lipschitz functions are characterized by the following result.

PROPOSITION A.1. *Let f be a locally Lipschitz function at $x \in \mathbb{R}^N$. If f attains a local minimum or maximum at x, then $0 \in \partial f(x)$; i.e., x is a critical point.*

Let $\mathrm{Ln} : 2^{\mathbb{R}^N} \to 2^{\mathbb{R}^N}$ be the set-valued map that associates with each closed subset S of $\mathbb{R}^N$ the set of its least-norm elements $\mathrm{Ln}(S)$. For a locally Lipschitz function f, we consider the *generalized gradient vector field* $\mathrm{Ln}(\partial f) : \mathbb{R}^N \to \mathbb{R}^N$ given by $x \mapsto \mathrm{Ln}(\partial f)(x) = \mathrm{Ln}(\partial f(x))$.

THEOREM A.2. *Let f be a locally Lipschitz function at x. Assume that $0 \notin \partial f(x)$. Then, there exists $T > 0$ such that $f(x - t\,\mathrm{Ln}(\partial f)(x)) \leq f(x) - \frac{t}{2}\|\mathrm{Ln}(\partial f)(x)\|^2$, $0 < t < T$. The vector $-\mathrm{Ln}(\partial f)(x)$ is called a* direction of descent.

For differential equations with discontinuous right-hand sides we understand the solutions in terms of differential inclusions following [9]. Let $F : \mathbb{R}^N \to 2^{\mathbb{R}^N}$ be a set-valued map. Consider the differential inclusion

$$\dot{x} \in F(x)\,. \tag{A.1}$$

A solution to this equation on an interval $[t_0, t_1] \subset \mathbb{R}$ is defined as an absolutely continuous function $x : [t_0, t_1] \to \mathbb{R}^N$ such that $\dot{x}(t) \in F(x(t))$ for almost all $t \in [t_0, t_1]$. Given $x_0 \in \mathbb{R}^N$, the existence of at least a solution with initial condition x_0 is guaranteed by the following lemma.

LEMMA A.3. *Let the map F be upper semicontinuous with nonempty, compact, and convex values. Then, given $x_0 \in \mathbb{R}^N$, there exists at least a solution of* (A.1) *with initial condition x_0.*

Acknowledgments. We would like to express our thanks to the referees and the associate editor handling this paper for their thoughtful comments that helped us improve the presentation of the paper.

STABILITY ROBUSTNESS OF RETARDED LTI SYSTEMS WITH SINGLE DELAY AND EXHAUSTIVE DETERMINATION OF THEIR IMAGINARY SPECTRA*

RIFAT SIPAHI† AND NEJAT OLGAC‡

Abstract. In this paper we consider the stability robustness of the general class of vector LTI (linear time invariant) equations with a single delay, $\dot{\mathbf{x}}(t) = \mathbf{A}\mathbf{x}(t) + \mathbf{B}\mathbf{x}(t-\tau)$, $\mathbf{x} \in \mathbf{R}^n$. The robustness is against the uncertain, but constant delay, $\tau \in \mathbf{R}^+$. We first present a set of novel propositions and state that the solution must start from the complete knowledge of imaginary spectra of the system, and the corresponding delays. The propositions claim that such spectra form a set of manageably small number of members, and this number is upper bounded by n^2 regardless of the composition of $\mathbf{A}$ and $\mathbf{B}$ matrices. They also claim that the infinite-dimensional system at hand has an outstanding discipline regarding these imaginary spectra. This discipline invites the recently developed concept called the cluster treatment of characteristic roots (CTCR). The CTCR procedure requires a complete and precise determination of the imaginary spectra of the system. There are many procedures in the literature to achieve this. They are, in fact, some variations of the five main methods of different levels of precision and complexity. There is, however, no study known to the authors for presenting a comparison among these methods. This paper addresses this need. We first offer an overview of each of the five methods and then compare their numerical performances over an example case study.

Key words. linear time-delayed dynamics, quasi polynomial, imaginary spectra detection, robust stability

DOI. 10.1137/050633238

1. Problem statement and an explicit function for stability.

The stability of linear time invariant retarded time delayed systems (LTI–TDS) has been a very active research topic during the past several decades [1, 2, 3, 4, 5]. Numerous contributions by renowned investigators can be found in the literature on the subject. Although at present the focus of attention in the time delayed systems (TDS) community is directed toward much more complex dynamics (such as parametric uncertainties, robustness, time-varying time delays, nonlinear TDS), the LTI–TDS has an undisputed knowledge base which offers plenty of insight into some realistic problems. Furthermore it is the authors' belief that the LTI–TDS field still remains rich with challenging and unsolved problems. Some existing methods, for instance, present new knowledge, which have not been recognized until recently [4, 6, 7, 26]. Some others suggest variations on the earlier techniques—to overcome some subtle and hidden impracticalities—mainly from a numerical deployment point of view [8].

The general dynamics in question is

$$\dot{\mathbf{x}}(t) = \mathbf{A}\mathbf{x}(t) + \mathbf{B}\mathbf{x}(t-\tau), \tag{1.1}$$

where $\mathbf{x} \in \mathbf{R}^n$, $\mathbf{A}$ and $\mathbf{B} \in \mathbf{R}^{n\times n}$ are known matrices with ranks n and p ($\leq n$), respectively, and $\tau \in \mathbf{R}^+$, which is the only free parameter in (1.1). The question is to determine the stability outlook of the system in the semi-infinite τ domain. The characteristic equation of the system is

$$CE(s,\tau) = \det(s\,\mathbf{I} - \mathbf{A} - \mathbf{B}\,e^{-\tau s}) = 0, \tag{1.2}$$

and it contains time delays of a commensurate nature with degree up to p; i.e., there exist exponential terms $e^{-k\tau s}$, $k = 0, 1, \ldots, p$, in (1.2), where $p = \text{rank}(\mathbf{B}) \leq n$. The system is infinite dimensional and as such possesses infinitely many characteristic roots, also known as the spectrum $\sigma(\tau)$ of the system. The question of stability for systems of this class translates into some conditions on τ to guarantee that all the infinitely many characteristic roots lie on the stable left half of the complex plane ($\mathbf{C}^-$). In pursuit of this, we present a remark and two relevant propositions next, partially following [6, 15] which contain the highlights of the CTCR paradigm.

Remark 1. If a delay, τ_0, results in a spectrum, which contains an imaginary root, i.e., $s = \omega i \in \sigma(\tau)$, there exist infinitely many delays

$$\tau_k = \tau_0 \mp \frac{2\pi}{\omega}k, \quad k = 0, 1, 2, \ldots, \tag{1.3}$$

which impart the same $s = \omega i \in \sigma(\tau_k)$. In short, the intersection of these infinitely many spectra contains a pair of imaginary roots,

$$(\mp\omega i) \in \bigcap_{k=0}^{\infty} \sigma(\tau_k). \tag{1.4}$$

Notice that these τ_k values corresponding to a single $s = \omega i$ are separated by $2\pi/\omega$. We name the smallest positive of them the *kernel delay value*, τ_{ker}. τ_{ker} begets all the other delays as per (1.3), and we call them the *offspring delay values*. Briefly, the set of infinitely many delay values

$$\left\{\tau_{ker} + \frac{2\pi}{\omega}k,\ k = 0, 1, 2, \ldots\right\} \text{ all result in } s = \omega i \in \sigma\left(\tau_{ker} + \frac{2\pi}{\omega}k\right). \tag{1.5}$$

PROPOSITION 1. *For the entire $\tau \in \mathbf{R}^+$ domain,*

(i) *there is a manageably small number, say m, of imaginary roots, $s = \omega i$, of* (1.1)*;*

(ii) *this number is upper bounded by n^2, i.e., $m \leq n^2$, regardless of the composition of the constant matrices $\mathbf{A}$ and $\mathbf{B}$.*

We will present the proof of Proposition 1 later in the text. We wish to state here, however, that this proposition brings an extraordinary mathematical confinement to the otherwise vastly distributed delay values creating a spectrum, which contains an imaginary root, i.e., $\{\tau > 0 \mid \sigma(\tau) \cap \mathbf{C}^0 \neq 0\}$, where $\mathbf{C}^0$ represents the imaginary axis.

PROPOSITION 2. *Assume that all m of the imaginary roots $\{\omega\} \in \mathbf{R}^{m+}$ and all corresponding* kernel delay values *$\{\tau_{ker}\} \in \mathbf{R}^{m+}$ are known. The* root tendency*, which is defined as*

$$RT|_k = sgn\left[\text{Re}\left(\left.\frac{\partial s}{\partial \tau}\right|_{\substack{s=\omega i \\ \tau = \tau_{ker} + \frac{2\pi}{\omega}j}}\right)\right], \quad j = 0, 1, 2, \ldots, \tag{1.6}$$

is invariant with respect to the counter j.

Proof of Proposition 2. The characteristic equation of (1.2) can be rewritten as

$$CE(s,\tau)=\sum_{k=0}^{p}a_k(s)e^{-k\tau s}=0, \tag{1.7}$$

where $p=\text{rank}(\mathbf{B})$, $p\le n$, is the degree of commensuracy in the dynamics and $a_k(s)$ are polynomials of degree $n-k$. A variational form of this equation is

$$\sum_{k=0}^{p}([a_k'(s)-a_k(s)k\tau]e^{-k\tau s}ds-a_k(s)kse^{-k\tau s}d\tau)=0, \tag{1.8}$$

where $a_k'(s)=da_k(s)/ds$. The root sensitivities at a point $s=\omega i$ corresponding to the delays given in (1.5) are derived from (1.8) as

$$\left.\frac{ds}{d\tau}\right|_{\substack{s=\omega i\\ \tau=\tau_{ker}+\frac{2\pi}{\omega}j}}=\left.\frac{\sum_{k=0}^{p}a_k(s)kse^{-k\tau s}}{\sum_{k=0}^{p}[a_k'(s)-a_k(s)k\tau]e^{-k\tau s}}\right|_{\substack{s=\omega i\\ \tau=\tau_{ker}+\frac{2\pi}{\omega}j}}. \tag{1.9}$$

It is trivial to show that

$$sgn\left[\text{Re}\left(\left.\frac{ds}{d\tau}\right|_{\substack{s=\omega i\\ \tau=\tau_{ker}+\frac{2\pi}{\omega}j}}\right)\right]=sgn[H(s)|_{s=\omega i}], \tag{1.10}$$

where

$$H(s)=\text{Im}\left(\left.\frac{\sum_{k=0}^{p}a_k'(s)e^{-k\tau s}}{\sum_{k=0}^{p}a_k(s)ke^{-k\tau s}}\right|_{\substack{s=\omega i\\ \tau=\tau_{ker}+\frac{2\pi}{\omega}j}}\right).$$

To obtain (1.10), one can divide the numerator and the denominator of (1.9) by $\sum_{k=0}^{n}a_k(s)kse^{-k\tau s}$ and study the real part of the new expression. Expression (1.10) is obviously independent of the counter j. We call this feature the *root tendency invariance property.* □

Proposition 2 simply implies that the root transition at ωi is either destabilizing ($RT=+1$) or stabilizing ($RT=-1$) for a given τ_{ker} and its offspring $\tau_{ker}+\frac{2\pi}{\omega}j$, $j=0,1,2,\ldots$, which render this particular imaginary root.

Using Propositions 1 and 2, one can create an explicit function of τ for the number of unstable roots (i.e., the number of roots in the set $\sigma(\tau)\cap\mathbf{C}^+$) as follows:

$$NU(\tau)=NU(0)+\sum_{k=1}^{m}\left[\Gamma\left(\frac{\tau-\tau_{ker}}{\Delta\tau_k}\right)\cdot U(\tau,\tau_{ker})\cdot RT_k\right]_k, \tag{1.11}$$

where $NU(0)$ is the number of unstable roots when $\tau=0$, $U(\tau,\tau_{ker})=$ step function in τ with the step taking place at τ_{ker}:

$$U(\tau,\tau_{ker})=\begin{cases}0, & 0<\tau<\tau_{ker},\\ 1 \quad \text{for} & \tau\ge\tau_{ker},\ \omega=0,\\ 2, & \tau\ge\tau_{ker},\ \omega\neq 0.\end{cases} \tag{1.12}$$

$\Gamma(x)=$ ceiling function of x, and Γ returns the smallest integer greater than or equal to x. The $[\,]_k$ notation in (1.11) is simply used to re-emphasize that τ_{ker} needs to be changed by the counter k. The $NU(\tau)$ expression requires only knowledge of the following:

(i) NU(0);
(ii) τ_{ker}, $k = 1, \ldots, m$, the smallest τ values corresponding to each ω (m of them) as per Proposition 1;
(iii) $\Delta\tau_k = 2\pi/\omega_k$, $k = 1, \ldots, m$;
(iv) $RT|_k$, $k = 1, \ldots, m$, the invariant root tendencies, as per Proposition 2.

The τ intervals, where $NU = 0$, render stable behavior for the system. $NU > 0$, on the other hand, would mean instability. Since the *kernel delay set* and the corresponding m crossing roots are all known, expression (1.11) exhaustively defines all the stable regions of the system in the delay space, $\tau \in \mathbf{R}^+$.

It is obvious from (1.11) that the stability robustness declaration is possible only if and only if the m members of the $\{\tau_{ker}\}$ kernel delay set and the corresponding m crossing roots $s = \omega i$ are exhaustively and accurately determined. We devote the rest of the paper to reviewing the five distinctive methodologies to achieve this. We also include their comparisons based on accuracy and efficiency. These methodologies are

(a) the Schur–Cohn method (Hermite matrix formation) [3, 11];
(b) elimination of transcendental terms [5];
(c) the matrix pencil–Kronecker sum method [3, 12];
(d) the Kronecker multiplication/elementary transformation method [13];
(e) Rekasius substitution [14].

2. Brief review of the methodologies. In this section we revisit the five main methodologies mentioned to prepare for the comparative work. Let us take the expanded form of (1.2) and explain each method based on that.

(a) Schur–Cohn criterion as per [3, 11]. The formation starts with rewriting (1.7), multiplying it by $e^{k\tau s}$, $k = 0, 1, \ldots, p-1$. This generates p equations in terms of $e^{k\tau s}$, $k = -p, \ldots, -1, 0, 1, \ldots, p-2, p-1$, which are $2p$ linearly independent terms. Next let us consider the companion equation, $CE(-s, \tau) = 0$, which is also satisfied for $s = \omega i$ due to the fact that the imaginary characteristic root ωi always appears as a complex conjugate pair,

$$\overline{CE}(s, \tau) = CE(-s, \tau) = \sum_{k=0}^{p} a_k(s) e^{-k\tau s} = \sum_{k=0}^{p} \overline{a}_k(s) e^{k\tau s}, \tag{2.1}$$

where $\overline{f}(s) = f(-s)$ is indeed the conjugate operation when $s = \omega i$. We then multiply $\overline{CE}(s, \tau)$ with $e^{-k\tau s}$, $k = 1, 2, \ldots, p$, generating additional p equations in terms of the same $2p$ linearly independent terms $e^{k\tau s}$, $k = -p, -p+1, \ldots, p-1$. Both of these sets of p equations can be combined into a single matrix equation as

(2.2)

$$\begin{bmatrix}
0 & 0 & 0 & \ldots & a_0 & a_1 & a_2 & \ldots & \ldots & a_p \\
0 & 0 & \ldots & a_0 & a_1 & a_2 & \ldots & & a_p & 0 \\
\vdots & & \ddots & \ddots & \vdots & \vdots & & \ddots & & \vdots \\
\vdots & \ddots & \ddots & & \vdots & \vdots & \ddots & & & \vdots \\
a_0 & a_1 & a_2 & & a_{p-1} & a_p & \ldots & \ldots & \ldots & 0 \\
0 & 0 & & 0 & \overline{a}_p & \overline{a}_{p-1} & \overline{a}_{p-2} & \ldots & \ldots & \overline{a}_0 \\
0 & 0 & \ldots & \overline{a}_p & \overline{a}_{p-1} & \overline{a}_{p-2} & \ldots & & \overline{a}_0 & 0 \\
\vdots & & \ddots & \ddots & \vdots & \vdots & \ddots & & \vdots & \vdots \\
\vdots & \ddots & \ddots & & \vdots & \vdots & & & \ddots & \vdots \\
\overline{a}_p & \overline{a}_{p-1} & \ldots & \ldots & \overline{a}_1 & \overline{a}_0 & 0 & \ldots & \ldots & 0
\end{bmatrix}
\begin{bmatrix}
e_{p-1} \\ e_{p-2} \\ \vdots \\ \vdots \\ \vdots \\ e_1 \\ e_0 \\ \vdots \\ \vdots \\ e_{-p}
\end{bmatrix}
= \mathbf{A}_1 \mathbf{E}_1 = \mathbf{0},$$

where e_k represents $e^{k\tau s}$ as shorthand notation to prevent cluttering the equation, and $\mathbf{A}_1$, $\mathbf{E}_1$ are evidently the $(2p \times 2p)$ matrix and the $(2p \times 1)$ vector, respectively. If one rewrites this equation by rearranging the exponential terms, it can be cast in the form

(2.3)
$$\begin{bmatrix} a_0 & 0 & 0 & \dots & 0 & a_p & a_{p-1} & \dots & a_2 & a_1 \\ a_1 & a_0 & 0 & \dots & 0 & 0 & a_p & a_{p-1} & \dots & a_2 \\ \vdots & & \ddots & \ddots & \vdots & \vdots & & \ddots & & \vdots \\ \vdots & \ddots & \ddots & & \vdots & \vdots & \ddots & & & \vdots \\ a_{p-1} & a_{p-2} & \dots & \dots & a_0 & 0 & 0 & \dots & 0 & a_p \\ \overline{a}_p & 0 & \dots & \dots & 0 & \overline{a}_0 & \overline{a}_1 & \dots & \dots & \overline{a}_{p-1} \\ \overline{a}_{p-1} & \overline{a}_p & \dots & \dots & \dots & 0 & \overline{a}_0 & \dots & \dots & \overline{a}_{p-2} \\ \vdots & & \ddots & \ddots & \vdots & \vdots & \ddots & & \vdots & \vdots \\ \vdots & \ddots & \ddots & & \vdots & \vdots & & & \ddots & \vdots \\ \overline{a}_1 & \overline{a}_2 & \dots & \dots & \overline{a}_p & 0 & \dots & \dots & 0 & \overline{a}_0 \end{bmatrix} \begin{bmatrix} e_0 \\ e_1 \\ \vdots \\ \vdots \\ e_{p-1} \\ e_{-p} \\ e_{-p+1} \\ \vdots \\ \vdots \\ e_{-1} \end{bmatrix} = \mathbf{A}_2\mathbf{E}_2 = \mathbf{0}.$$

Obviously for a nontrivial solution of $\mathbf{E}_2$, the $\mathbf{A}_2$ matrix must be singular:

$$\det \mathbf{A}_2(s) = 0. \tag{2.4}$$

This matrix, $\mathbf{A}_2$, is known to be the Schur–Cohn matrix. Notice the favorable fragmentation of $\mathbf{A}_2$ into four $p \times p$ segments in the rearranged form as

$$\mathbf{A}_2 = \begin{bmatrix} \Lambda_1 & \Lambda_2 \\ \Lambda_2^H & \Lambda_1^H \end{bmatrix}, \tag{2.5}$$

where Λ^H implies the Hermitian of Λ, and (2.5) presents a compact form adopted by [3, 11].[1] Λ_1 and Λ_2 are evidently matrices from (2.3).

This method suggests that if (1.7) has any imaginary root pair $s = \mp\omega i$, it should also satisfy (2.4). Consequently, the question of finding all the imaginary roots of (1.2) reduces to finding the imaginary roots of (2.4), which is a polynomial of s with degree $2np$. Notice that the original system (1.1) is a retarded time delayed system. Thus the nondelayed term of the characteristic equation (1.7), $a_0(s)$, is an nth degree polynomial of s. So the problem is cast into determining the purely imaginary roots of the $2np$ degree polynomial equation (2.4), which can produce maximum np pairs of imaginary roots. For cases when $p = \operatorname{rank}(\mathbf{B}) = n$, the supremum of this number becomes n^2.

Evaluation of the $\det \mathbf{A}_2(s)$, however, needs a symbolic operation, while $2p$ terms are multiplied and added $2p$ times for expanding the determinant. Each of these $2p$ multiplications would create some round-off errors, eventually resulting in a polynomial of s with erroneous coefficients. This operation ultimately yields poor precision in determining the desired imaginary roots.

An alternative to this symbolic evaluation of a determinant is to determine the eigenvalues of a constant matrix (see Theorem 2.1 of [3]). Namely,

$$\det[\omega \mathbf{I} - \mathbf{P}] \equiv \det(\mathbf{P}_n^{-1}) \det(\mathbf{A}_2)|_{s=\omega i}, \tag{2.6}$$

[1] We wish to make a remark on the formulation error of equations (3.79) and (3.80) in [11], which need to be corrected according to (2.3) above.

where

$$\mathbf{P} = \begin{bmatrix} \mathbf{0} & \mathbf{I} & \mathbf{0} & \dots & \dots & \mathbf{0} \\ \vdots & \mathbf{0} & \mathbf{I} & \mathbf{0} & \dots & \mathbf{0} \\ \vdots & \vdots & \ddots & \ddots & \ddots & \vdots \\ \vdots & \vdots & \vdots & \ddots & \mathbf{I} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} & \dots & \dots & \mathbf{0} & \mathbf{I} \\ -\mathbf{P}_n^{-1}\mathbf{P}_0 & -\mathbf{P}_n^{-1}\mathbf{P}_1 & \dots & \dots & \dots & -\mathbf{P}_n^{-1}\mathbf{P}_{n-1} \end{bmatrix}, \tag{2.7}$$

$$\mathbf{P}_k = \begin{pmatrix} i^k\mathbf{T}_k & i^k\mathbf{H}_k \\ (-i)^k\mathbf{H}_k^T & (-i)^k\mathbf{T}_k^T \end{pmatrix}, \quad k = 0, 1, 2, \dots, n,$$

$$\mathbf{H}_k = \begin{bmatrix} a_{pk} & a_{p-1,k} & \dots & a_{1k} \\ 0 & \ddots & \ddots & a_{2k} \\ \vdots & \ddots & \ddots & \vdots \\ 0 & \dots & 0 & a_{pk} \end{bmatrix}, \quad \mathbf{T}_k = \begin{bmatrix} a_{0k} & 0 & \dots & 0 \\ a_{1k} & \ddots & \ddots & \vdots \\ \vdots & \ddots & \ddots & 0 \\ a_{p-1,k} & \dots & a_{1k} & a_{0k} \end{bmatrix} \tag{2.8}$$

with $k = 0, 1, \dots, n-1$ and $a_j(s) = \sum_{k=0}^{p} a_{jk}s^k$ which are the terms defined in (1.7). Notice that (2.6) indicates that the imaginary roots of $\det \mathbf{A}_2 = 0$ are identical to the real eigenvalues of $\mathbf{P}$, which is a constant matrix. So the numerical procedure is now converted into a simpler and more precise one, i.e., "real eigenvalue" determination of a constant matrix.

(b) Elimination of transcendental terms (as introduced by [5] and utilized in [16, 17, 18, 19, 20, 21]). This procedure follows a starting premise similar to that in the Schur–Cohn methodology in (a). If $CE(s, \tau)$ of (1.7) has an imaginary root, then, correspondingly, $\overline{CE}(s, \tau)$ of (2.1) should have the same root. Multiplying (2.1) by $e^{-p\tau s}$, we obtain

$$e^{-p\tau s}\overline{CE}(s, \tau) = \sum_{k=0}^{p} \overline{a}_k(s)e^{(k-p)\tau s} = 0. \tag{2.9}$$

One can then eliminate the highest commensuracy term (i.e., $e^{-p\tau s}$) between (1.7) and (2.9), yielding a new equation

$$CE_1(s, \tau) = \sum_{k=0}^{p-1} a_k^{(1)}e^{-k\tau s} = 0, \tag{2.10}$$

which is of commensuracy degree $p - 1$. If one repeats this procedure of eliminating the highest degree commensuracy terms p times successively, one arrives at

$$CE_p(s) = a_0^{(p)}(s) = 0, \tag{2.11}$$

an algebraic characteristic equation in which no transcendentality remains. One can show that $a_0^{(p)}(s)$ is a polynomial of degree $n2^p$, of which purely imaginary roots are in question. Notice that due to the successive substitution of "s" with "$-s$" during the manipulations, the imaginary roots of the original characteristic equation CE are preserved, although the degree of the s terms in polynomials $CE_i(s)$ continuously increases. Ultimately there remains only $n2^p$ finite roots of (2.11) instead of the

infinitely many roots of the original equation (1.7). It is guaranteed that only the imaginary roots of these two equations are identical. Therefore searching for the imaginary roots of (2.11) is a sufficient procedure for the mission. The practical usage of this analytically elegant procedure in the literature is very limited [16, 18, 20, 21] because of the round-off errors it invites during the successive evaluation of $CE_p(s)$, albeit in alphanumeric form.

One can further prove that the $CE_p(s)$ and $\det \mathbf{A}_2(s)$ in (2.4) have a common factor, which is the complete polynomial of $\det \mathbf{A}_2(s)$, because they are obtained based on the same fundamental premise of $s \to -s$ substitution, and they represent the same system of (1.1). When numerically executed, however, this factorization disappears due to successive round-off errors. Ultimately one finds two sets of roots, which may be close to one another but not identical.

Clearly, for $n = p = 1, 2$ the degrees of the polynomials of (2.4) and (2.11) are identical, and they are equal to 2. For these cases, the equations are indeed identical. For $n = p > 2$, which implies the case of full rank $\mathbf{B}$ matrix ($p = n$), $n2^n > 2n^2$, and clearly the procedure in (a) is a much more favorable proposition for determining the purely imaginary roots. Notice that the $n2^n - 2n^2$ excess roots may also contain some false imaginary roots, which should not appear at all. We suppress the proofs of these statements, but we will revisit them for example case studies later.

(c) Matrix pencil–Kronecker sum method introduced in [3, 12]. This procedure departs from (1.2), which is rewritten as

$$\det[s\,\mathbf{I} - (\mathbf{A} + \mathbf{B}z)] = 0, \quad z = e^{-\tau s}. \tag{2.12}$$

Using the argument that if $s = \omega i$ is a root of (2.12), we see that so is $s = -\omega i$ when z is replaced with $1/z$. One can say that the eigenvalues of $\mathbf{A} + \mathbf{B}z$ and $\mathbf{A} + \mathbf{B}z^{-1}$ must be $s = \mp\omega i$, which can also be expressed using the property of the Kronecker sum of matrices (see the appendix for a definition). A commonly known property of this operation is that the eigenvalues of the Kronecker sum of two matrices are equal to the pairwise sum of the individual eigenvalues of the matrices [22, 23]. That is, at least one of the eigenvalues of the following matrix has to be zero:

$$(\mathbf{A} + \mathbf{B}z) \oplus (\mathbf{A} + \mathbf{B}z^{-1}), \tag{2.13}$$

where $\oplus$ represents the Kronecker summation. In other words,

$$\det[(\mathbf{A} + \mathbf{B}z) \oplus (\mathbf{A} + \mathbf{B}z^{-1})] = 0. \tag{2.14}$$

This equation gives rise to a polynomial in z of degree $2n^2$ for $n = p$. One needs to solve the $2n^2$ roots of (2.14) and determine those which have the unity magnitude $|z| = 1$. Only those roots represent $s = \omega i$ eigenvalues as per (2.12). For the roots which satisfy this condition, one next solves the imaginary roots $s = \omega i$ from (2.12). Notice that by substituting z as a complex number in (2.12), one obtains a polynomial with complex but constant coefficients. Therefore, most of the neat features of ordinary polynomials with constant coefficients disappear. For instance, there is no guarantee of the complex conjugate feature of the roots. Therefore to decide whether an imaginary root $s = \omega i + \epsilon$, $\epsilon << 1$, is really an imaginary root, except that it is displaced infinitesimally due to numerical/computational error, is not a trivial task. This particular point alone, from the numerical deployment point of view, suggests a drawback.

Similarly to the methodology explained for (a), one can convert the symbolic determinant evaluation of (2.14) into an equivalent eigenvalue determination of a

constant matrix; see Theorem 3.1 of [3] or [24]. In this new form, a generalized eigenvalue problem appears as

$$\det[z\mathbf{U}-\mathbf{V}] = z^{n^2}\det[(\mathbf{A}+\mathbf{B}z)\oplus(\mathbf{A}+\mathbf{B}z^{-1})] = 0, \tag{2.15}$$

where

$$\mathbf{U} = \begin{bmatrix} \mathbf{I} & \mathbf{0} \\ \mathbf{0} & \mathbf{B}_2 \end{bmatrix}_{2n^2\times 2n^2}, \quad \mathbf{V} = \begin{bmatrix} \mathbf{0} & \mathbf{I} \\ -\mathbf{B}_0 & -\mathbf{B}_1 \end{bmatrix}_{2n^2\times 2n^2},$$

and $\mathbf{B}_0 = \mathbf{I}\otimes\mathbf{B}^T$, $\mathbf{B}_1 = \mathbf{A}\otimes\mathbf{A}^T$, $\mathbf{B}_2 = \mathbf{B}\otimes\mathbf{I}$, all of which have dimensions of $(n^2\times n^2)$. Again the generalized eigenvalue operation is numerically a much more reliable and efficient operation than evaluating the roots of the determinant in (2.14). We now wish to utilize these findings to prove Proposition 1.

Proof of Proposition 1. It is clear that (2.15) results in a polynomial of z with degree $2n^2$. Consequently, there can be at most n^2 pairs of complex conjugate unitary solutions for z, and that is the upper bound of the number of root crossings claimed in Proposition 1. Similar arguments can be made following the discussions in section 2(a) immediately after (2.5). The maximum possible number of imaginary eigenvalues for $\mathbf{A}_2$ in (2.3) is n^2 (when $p = n$). □

(d) Kronecker multiplication/elementary transformation method [13]. Before we proceed with this method, we wish to define a critical elementary vectorization transformation, $\xi : \mathbf{C}^{n\times n} \to \mathbf{C}^{n^2\times 1}$ [22, 23]. The ξ operation converts a matrix $\mathbf{M}^{(n\times n)} = [\mathbf{m}_1, \mathbf{m}_2, \ldots, \mathbf{m}_n]^T_{n\times n}$ into $(\xi\mathbf{M})^{(n^2\times 1)} = [\mathbf{m}_1^T, \mathbf{m}_2^T, \ldots, \mathbf{m}_n^T]^T_{1\times n^2}$ and the multiplication of three $n\times n$ matrices $\mathbf{P}_1, \mathbf{P}_2, \mathbf{P}_3$ into a Kronecker product of dimension $n^2\times n^2$ [22, 23], which is given as

$$\xi(\mathbf{P}_1\mathbf{P}_2\mathbf{P}_3) = (\mathbf{P}_1\otimes\mathbf{P}_3^T)\xi\mathbf{P}_2, \tag{2.16}$$

where $(\bullet)^T$ denotes the transpose of $(\bullet)$. The aim is to form a $\mathbf{P}_1\mathbf{P}_2\mathbf{P}_3$ product, which will then be mapped into the right-hand side of (2.16). This mapping, as explained below, brings convenience to solving the pure imaginary roots of dynamics (1.1).

The procedure departs from (1.1), for which a solution of the form $\mathbf{x}(t) = e^{st}\mathbf{v}$ is suggested, where $(s, \mathbf{v}^{(n\times 1)})$ is an eigenvalue-eigenvector pair (both of which are complex in general). Differentiating this expression and substituting in (1.1), one gets

$$(s\mathbf{I}-\mathbf{A}-\mathbf{B}e^{-\tau s})\mathbf{v} = 0, \tag{2.17}$$

which can be rewritten as

$$(s\mathbf{I}-\mathbf{A})\mathbf{v} = e^{-\tau s}\mathbf{B}\mathbf{v}. \tag{2.18}$$

If $s = \omega i$ is a root of (2.18), then so is its conjugate $s = -\omega i$. We can express this by conjugating the complex equation in (2.18),

$$\mathbf{v}^*(-s\mathbf{I}-\mathbf{A}^T) = e^{\tau s}\mathbf{v}^*\mathbf{B}^T, \tag{2.19}$$

where $(\bullet)^*$ denotes the conjugate transpose of $(\bullet)$. One can now multiply (2.18) and (2.19) side by side to get

$$(s\,\mathbf{I}-\mathbf{A})\;\mathbf{V}\;(s\,\mathbf{I}+\mathbf{A}^T) \;=\; -\mathbf{B}\,\mathbf{V}\,\mathbf{B}^T \quad \text{with } \mathbf{V}^{(n\times n)} \;=\; \mathbf{v}\mathbf{v}^*. \tag{2.20}$$

Equation (2.20) is exactly in the form to be transformed by using ξ as defined in (2.16). It returns

$$\begin{aligned} &\{(s\,\mathbf{I}-\mathbf{A})\otimes(s\,\mathbf{I}+\mathbf{A})+\mathbf{B}\otimes\mathbf{B}\}\,\xi\mathbf{V}=0\\ &\Rightarrow\ \boldsymbol{\lambda}(s)\,\xi\mathbf{V}=0, \end{aligned} \tag{2.21}$$

where $\boldsymbol{\lambda}(s)$ is evidently the matrix operation. For nontrivial solutions of $\xi\mathbf{V}\neq\mathbf{0}$, the only way to satisfy (2.21) is to set

$$\det\boldsymbol{\lambda}(s)=0. \tag{2.22}$$

We can conclude that the desired imaginary roots are determined by solving the roots of a $2n^2$ degree polynomial (2.22). However, one should take notice that this root-finding algorithm for higher dimensions ($2n^2>10$) becomes numerically unreliable due to repeated round-off errors in the determinant expansion procedure unless the operation is performed using a very large number of significant digits. In that case, however, excessive computational cost will appear. In order to circumvent this difficulty using lower precision calculations, one can expand (2.21) using Kronecker product identities as defined in [22, 23]. The outcome of this is a matrix polynomial as follows:

$$\boldsymbol{\lambda}(s)=\mathbf{G}_0\,s^2+\mathbf{G}_1\,s+\mathbf{G}_2, \tag{2.23}$$

where $\mathbf{G}_0=\mathbf{I}\otimes\mathbf{I}$, $\mathbf{G}_1=\mathbf{I}\otimes\mathbf{A}-\mathbf{A}\otimes\mathbf{I}$, $\mathbf{G}_2=\mathbf{B}\otimes\mathbf{B}-\mathbf{A}\otimes\mathbf{A}$. Then this matrix polynomial can be linearized [24] by the fact that $\mathbf{G}_0$ is an invertible matrix. The linearized form of (2.23) is expressed as

$$\mathbf{F}=\begin{bmatrix}\mathbf{0}&\mathbf{T}_0\\ -\mathbf{T}_2&-\mathbf{T}_1\end{bmatrix}\quad\text{with }\mathbf{T}_0=\mathbf{I}\otimes\mathbf{I},\ \mathbf{T}_1=\mathbf{G}_0^{-1}\mathbf{G}_1,\ \mathbf{T}_2=\mathbf{G}_0^{-1}\mathbf{G}_2, \tag{2.24}$$

where the zeros of $\det(\boldsymbol{\lambda}(s))=0$ are the eigenvalues of $\mathbf{F}$, i.e., $\det(\boldsymbol{\lambda}(s))=\det(s\mathbf{I}-\mathbf{F})=0$. The imaginary roots of dynamics (1.1) have to be among the eigenvalues of $\mathbf{F}$, which can be computed by many practical and efficient routines such as the *eig*($\mathbf{F}$) subroutine of MATLAB or *eigenvalues*($\mathbf{F}$) subroutine of Maple. Eventually, one can arrive at a numerically more reliable set of imaginary roots of dynamics (1.1), as demonstrated in the example section.

(e) Rekasius substitution as introduced in [14] and utilized by [6, 8, 25]. This critical procedure is an exact substitution of transcendental terms in (1.7) with

$$e^{-\tau s}=\frac{1-Ts}{1+Ts}\quad\text{when } s=\omega\,i\ \textit{only}, \tag{2.25}$$

where $T\in\Re$ and

$$\tau=\frac{2}{\omega}\left[\tan^{-1}(\omega T)\mp\ell\pi\right],\quad \ell=0,1,\ldots. \tag{2.26}$$

This exact substitution creates a new characteristic equation,

$$CE(s,T)=\sum_{k=0}^{p}a_k(s)\left(\frac{1-Ts}{1+Ts}\right)^k=0. \tag{2.27}$$

Multiplying (2.27) by $(1+T\,s)^p$, one obtains

$$\sum_{k=0}^{p} a_k(s)\,(1+T\,s)^{p-k}(1-T\,s)^k \;=\; 0. \tag{2.28}$$

Considering that $a_k(s)$ are ordinary polynomials, (2.28) is nothing other than a polynomial in s with parameterized coefficients in T. Since the system in (1.1) is of retarded type, the highest degree term of s is n and it is in $a_0(s)$. Equation (2.28), therefore, contains a polynomial of s with degree $n+p$. The problem is to determine *all* $T \in \mathbf{R}$ values, which cause imaginary roots of $s = \omega\, i$ for this equation. This can be done by forming the Routh array of (2.28) and setting the only term in the s^1 row to zero [9, 10, 26]. It can be shown that this polynomial is of degree $n\,p$ in T, of which only the real roots are searched. Once these roots are determined, the corresponding crossing frequencies ($s = \omega\, i$) can be found using the auxiliary equation, which is formed by the s^2 row of the Routh array [9, 26]. Notice that the s^2 row has two terms, which are functions of T. They must agree in sign for those T values to yield imaginary roots. Final results are exhaustive in detecting all the imaginary characteristic roots we set out to solve, and their number is upper bounded by n^2 (again in support of Proposition 1).

We wish to discuss two limiting cases here. The first has to do with the extrema of the T domain, namely $T = \mp\infty$. It is easy to check whether these unbounded T values are of interest to us or not. That is, if $T \to \mp\infty$ and there is a finite imaginary root s, the corresponding $e^{-\tau s} \to -1$ (from (2.25)) leaves $CE\,(s\,,\,\tau\,)$ as a simple polynomial of s. The roots of this polynomial can be found easily. If any one of these roots is purely imaginary, that root becomes part of the solution of interest.

The second limiting case is for the imaginary root(s) appearing at the origin, $s = \omega\, i$ with $\omega = 0$, which makes $e^{-\tau s} = 1$ as per (2.25). Consequently one needs to check if

$$\sum_{k=0}^{p} a_k(0) = 0 \tag{2.29}$$

holds from (1.7). If it does, there should be at least one stationary root at $s = 0$, which remains there for all $\tau \in \mathbf{R}^+$. It is easy to determine the multiplicity of this root for some τ values simply by checking if the successive derivatives of (1.7) with respect to s are also zero for the same τ values. For instance, if $s = 0$ is a double root, the second root may cross over the imaginary axis, altering the stability of the system, as the stationary one remains fixed at the origin.

Both of these limiting cases can appear, regardless of the methods (a)–(e). That is, $e^{-\tau s} \to \pm 1$ can occur as a property of the system at hand.

3. A numerical case study and comparative observations. We now take an example case study to display a comparison among the five methodologies we discussed above. Consider the numerical example in [6] which has $p = \mathrm{rank}(\mathbf{B}) = 3 = n$:

$$\mathbf{A} = \begin{pmatrix} -1 & 13.5 & -1 \\ -3 & -1 & -2 \\ -2 & -1 & -4 \end{pmatrix}, \qquad \mathbf{B} = \begin{bmatrix} -5.9 & 7.1 & -70.3 \\ 2 & -1 & 5 \\ 2 & 0 & 6 \end{bmatrix}. \tag{3.1}$$

The respective characteristic equation is

$$\begin{aligned} CE(s,\ \tau) \ &= \ s^3 + 6\,s^2 + 45.5\,s + 111 \ + \ (0.9\,s^2 - 116.8\,s - 22.1)\,e^{-\tau s} \\ &\quad + (90.9\,s - 185.1)\,e^{-2\tau s} + \ 119.4\,e^{-3\tau s} = 0, \end{aligned} \tag{3.2}$$

in which $a_k(s)$, $k = 0, \ldots, 3$, expressions are readily identified as represented in (1.7). For this system the following exhaustive list of (τ_{ker}, ω) is given in [6]. We cross-check this list, using a sufficiently high number of digits in performing the methodologies (a)–(e), and obtain Table 3.1.

TABLE 3.1
The fundamental delays and the imaginary spectra.

τ_{ker}	ω
7.208	0.8404
0.8725	2.1109
0.1859	2.9123
0.1624	3.0351
0.2219	15.5032

Here the notation $(\tau_{ker,j}, \omega_j)$ implies the minimum positive delay, $\tau_{ker,j}$, defined by (1.3) and the corresponding root at $\omega_j\, i$. In (3.2) we now start utilizing the five methodologies as described earlier. The main point of comparison is to be able to precisely declare the complete Table 3.1. Computational efficiency may also be considered as a basis for comparison, and we will address this point later in the text. In order to conserve space, the numerical results are given in truncated forms at the fourth decimal except where necessary for the arguments.

(a) Schur–Cohn procedure. $\mathbf{\Lambda}_1$ and $\mathbf{\Lambda}_2$ matrices of (2.5) are readily formed using the terms of $a_0(s), \ldots, a_3(s)$. Notice that the degree of $\det(\mathbf{A}_2)$ of (2.4) is $2np = 18$. Thus the mission is reduced to determining the purely imaginary roots of

$$\begin{aligned} \det(A_2) \ &= \ s^{18} + \ 10^{-8}\ s^{17} + 165.81\ \ s^{16} + 0.3\ 10^{-4}\, s^{15} - 18681.53\, s^{14} \\ &+ 0.022\ s^{13} - 248693.82\ \ s^{12} + \ 4.5\ s^{11} + 35141.36\ \ s^{10} + 330.83\ s^9 \\ &+ 0.41\ 10^{10}\ s^8 + 8671.27\ s^7 + \ 0.94\ \ 10^{11}\ \ s^6 + \ 72932.09\ s^5 + 0.71\ \ 10^{12}\ s^4 \\ &+ 148284.13\ s^3 + 0.19\ \ 10^{13} s^2 + 29249.72\ s\ \ + 0.1\ 10^{13} = 0 \end{aligned} \tag{3.3}$$

which displays two major obstacles as follows:

(i) Equation (3.3) is expected to have only even powers of s. Due to the accumulated numerical error in the symbolic manipulations, one cannot achieve this even with 60-digit precision (for this exercise). The trial-based determination of the significant digits needed is an important hindrance. For comparison purposes, we consider the numerical errors at the level of up to 1/4 of significant digits as acceptable accuracy. For a 20-digit operation, any error of 10^{-15} or less is considered to be zero.

(ii) Evaluation of the imaginary roots of (3.3) results in the form of $s = \omega\, i + \varepsilon$, $\varepsilon << 1$, lending themselves to another question for the number of significant digits needed. For instance, using 20 *digits* of precision in Maple, (3.3) gives the following apparently imaginary roots:

$$\begin{aligned} &0.21\ 10^{-7} \mp 0.8404i, \quad 0.28\ 10^{-6} \mp 2.1109i, \quad -0.55\ 10^{-8} \mp 15.5032i, \\ &-0.13\ 10^{-5} \mp 2.9123i, \quad 0.69\ 10^{-6} \mp 3.0351i. \end{aligned}$$

As can be seen, the numerical errors in real parts (which are supposed to be zero) are at least of the order of 10 magnitudes larger than the computational precision, and they all violate the 1/4-digit rule. This point makes it necessary to adjust the accuracy in calculations.

An alternative but more reliable procedure along this line was described earlier over (2.6)–(2.8). Accordingly, the real eigenvalues of a matrix are evaluated instead of the roots of a polynomial. Using this procedure, one obtains the five crossing frequencies (which correspond to the real eigenvalues of $\mathbf{P}$) as $0.8404 - 0.44\ 10^{-17}\, i$, $2.1109{+}0.66\ 10^{-16}\, i$, $2.9123{+}0.63\ 10^{-15}\, i$, $3.0351{+}0.68\ 10^{-15}\, i$, $15.5032{+}0.72\ 10^{-17}\, i$, still with 20-digit precision. These numbers are all acceptably close to the desired results under the proposed 1/4-digit rule.

(b) Elimination of transcendental terms. Starting from the characteristic equation (3.2) and following the three steps as described in section 2(b), one can sequentially eliminate $e^{-3\,\tau\, s}$, $e^{-2\,\tau\, s}$, and $e^{-\tau\, s}$. Notice that these steps preserve the purely imaginary roots of the characteristic equation. The final form should contain only even powers of s:

$$\begin{aligned} CE_p(s) &= s^{24} + 220.81\ s^{22} - 8823.73\ s^{20} - 0.12\ 10^{7}\ s^{18} - 0.27\ 10^{8}\ s^{16} \\ &+ 0.39\ 10^{10}\ s^{14} + 0.32\ 10^{12}\ s^{12} + 0.89\ 10^{13}\ s^{10} + 0.12\ 10^{15}\ s^{8} \\ &+ 0.81\ 10^{15}\ s^{6} + 0.28\ 10^{16}\ s^{4} + 0.44\ 10^{16}\ s^{2} + 0.2\ 10^{16} = 0. \end{aligned} \tag{3.4}$$

The imaginary roots of the original system have to be among the roots of this polynomial. We again use 20 significant digits of precision in Maple during the symbolic manipulations. The same level of precision is used in the following steps of root finding. (Cautionary note: Even for the case of up to 18 digits of precision in Maple, one can still observe odd powered terms appearing in (3.4).)

Equation (3.4) results in 24 symmetric roots with respect to the origin, of which only the purely imaginary ones are important. They are

$$\begin{aligned} &\mp 5.9977i, \quad \mp 3.9460i, \quad \mp 1.8587i, \quad \mp 0.8404i, \\ &\mp 2.1109i, \quad \mp 2.9123i, \quad \mp 3.0351i, \quad \mp 15.5032i. \end{aligned} \tag{3.5}$$

It is easy to demonstrate that the first three roots on the first row are faulty findings and do not represent true crossings. To see that, one can substitute them into the original characteristic equation (3.2) just to show that they do not satisfy this equation. On the other hand, the remaining five roots do. They also yield $|\, e^{-\tau\, \omega\, i}\, | = 1$ from which one can determine the respective time delays.[2]

One can also observe that the difference between the degrees of (3.3) and (3.4) is 6. In fact the relation between the two polynomials is described as

$$CE_p(s,\ \tau)\ =\ P_1(s)\ \det(\mathbf{A}_2), \tag{3.6}$$

where the degree $(P_1) = 6$, and its roots result in the three false pairs of imaginary roots for the specific numerical example, as mentioned above.

[2]Incidentally, the procedure described in [5, eq. (48)] yields incorrect time delays due to the accumulation of numerical error. Primarily an ill conditioning occurs due to some coefficients in (2.11) being 15–16 orders of magnitude apart from one another.

(c) Matrix pencil–Kronecker sum application. Deploying (2.14) we obtain

$$
\begin{aligned}
&\det\left[(\mathbf{A}+\mathbf{B}\,z)\oplus(\mathbf{A}+\mathbf{B}\,z^{-1})\right] \;=\; (0.17\;10^{7}\;z^{18}-141137.96\;z^{17}\\
&+0.23\;10^{8}\;z^{16}-0.17\;10^{9}\;z^{15}+0.52\;10^{9}\;z^{14}-0.81\;10^{9}\;z^{13}+0.62\;10^{9}\;z^{12}\\
&-0.32\;10^{8}\;z^{11}-0.43\;10^{9}\;z^{10}+0.56\;10^{9}\;z^{9}\;-0.43\;10^{9}\;z^{8}-0.32\;10^{8}\;z^{7}\\
&+0.62\;10^{9}\;z^{6}-0.81\;10^{9}\;z^{5}+0.52\;10^{9}\;z^{4}-0.17\;10^{9}\;z^{3}+0.22\;10^{8}\;z^{2}\\
&-141137.96\;z+0.17\;10^{7})/z^{9}=0.
\end{aligned}
\tag{3.7}
$$

We are seeking the roots of (3.7) with magnitude equal to 1. There is a major difficulty, specifically in deciding the tolerance level of $|\,z\,|=1$. This difficulty disappears, however, when higher precision (above 20 digits) is used. For example, with 20 digits of precision, the errors in the magnitudes of the five roots become precisely zero. They are listed in Table 3.2, together with their corresponding five imaginary roots, which are obtained by replacing $z=e^{-\tau\,\omega\,i}$, $|\,z\,|=1$, in (3.2) and solving for ω.

TABLE 3.2
The tolerances in evaluating z's and the imaginary spectra.

$\lvert 1-z\rvert$	Imaginary spectra
0	$-0.57\;10^{-19}+0.8404i$
0	$0.47\;10^{-20}+2.1109i$
0	$-0.73\;10^{-19}+2.9123i$
0	$0.5\;10^{-19}+3.0352i$
0	$-10^{-21}+15.5032i$

Notice that the cumulative effects of numerical error in imaginary spectra are all acceptable in 1/4-digit sense. However, with up to 13 digits of precision, one observes relatively large accumulated errors (violating the 1/4-digit rule) in the computation of imaginary roots. Therefore if a root of z displays $|\,z\,|-1=\varepsilon$, it is quite difficult to assess whether we should take it as an indicator of crossing or not. Increasing the digits higher than 14 (obviously including 20) this concern disappears for this case study.

When the more reliable procedure is followed, as mentioned in section 2(c), $\mathbf{U}$ and $\mathbf{V}$ matrices are trivially obtained from their definitions. The generalized eigenvalues of the $(\mathbf{U},\mathbf{V})$ pair, which have unitary magnitudes (obtained with 20-digit precision again) are listed in Table 3.3.

TABLE 3.3
The tolerances in evaluating z's and the corresponding imaginary spectra.

$\lvert 1-z\rvert$	Imaginary spectra
$-0.14\;10^{-17}$	$-0.25\;10^{-17}\mp 0.8404i$
$-0.34\;10^{-17}$	$0.27\;10^{-17}\mp 2.1109i$
$0.12\;10^{-16}$	$0.18\;10^{-16}\mp 2.9123i$
$-0.78\;10^{-17}$	$0.31\;10^{-16}\mp 3.0351i$
$0.4\;10^{-18}$	$-0.95\;10^{-18}\mp 15.5032i$

Interestingly, on this implementation one can use 9-digit precision and can still obtain acceptable errors looking at the real parts of the imaginary roots, as shown in Table 3.4. This table indicates that the generalized eigenvalue computation can be

performed with a much smaller number of digits, such as 9, without sacrificing the accuracy of the roots.

TABLE 3.4
The tolerances in evaluating z's and the imaginary spectra.

$\lvert 1-z\rvert$	Imaginary spectra
0	$-0.15\ 10^{-7} \mp 0.8404i$
-10^{-8}	$0.66\ 10^{-8} \mp 2.1109i$
-10^{-8}	$0.4\ 10^{-7} \mp 2.9123i$
$-0.18\ 10^{-7}$	$-0.42\ 10^{-7} \mp 3.0351i$
0	$0.27\ 10^{-7} \mp 15.5032i$

(d) Kronecker multiplication/elementary transformation method. Following the procedure given in section 2(d), one obtains (2.22), again with 20-digit precision, as

$$\begin{aligned}\det\ \boldsymbol{\lambda}(s)\ =\ & s^{18} + 0.3\ 10^{-9}\ s^{17} + 165.81\ s^{16}\ + 0.99\ 10^{-6}\ s^{15} - 18681.53\ s^{14}\\ & + 0.0007\ s^{13} -\ 248693.48\ s^{12}\ + 0.16\ s^{11}\ + 35183.49\ s^{10} +\ 12.97\ s^{9}\\ & + 0.41\ 10^{10}\ s^{8} + 370.2\ s^{7} + 0.94\ 10^{11}\ s^{6} + 3348.51\ s^{5}\ + 0.71\ 10^{12}\ s^{4}\\ & + 7209.8\ s^{3} + 0.19\ 10^{13}\ s^{2} + 1480\ s + 0.1\ 10^{13} = 0.\end{aligned} \tag{3.8}$$

Purely imaginary roots of this equation are the expected crossing frequencies as given in Table 3.5. With this precision level, the accumulated errors in the real parts are relatively large (in the 1/4-digit sense) in magnitude as can be seen in this table. As mentioned in section 2(d), in order to improve the accuracy of the imaginary roots of (1.1), we pursue computing the eigenvalues of matrix $\mathbf{F}$, eig($\mathbf{F}$). For this computation, 10- and 20-digit precision are used separately. The results are given in Table 3.6, with the error terms in the real parts being acceptably small. Thus we conclude that this method can produce the imaginary roots accurately even with 10-digit operations.

TABLE 3.5

Imaginary spectra

(e) Rekasius substitution. In this procedure, at least 13 digits of precision are required in order to obtain the crossing frequencies as listed in the beginning of this section. The characteristic equation of (3.2) is rewritten after the Rekasius transformation as

$$\begin{aligned} CE(s,T) \;=\; & T^3 s^6 \;+\; (5.1\,T^3 + 3\,T^2)\,s^5 + (253.2\,T^3 + 17.1\,T^2 + 3\,T)\,s^4 \\ & + (-171.4\,T^3 + 162.4\,T^2 + 18.9\,T + 1)\,s^3 \\ & + (898.4\,T^2 - 71.2\,T + 6.9)\,s^2 \;+ (137.8\,T + 19.6)\,s \;+ 23.2 = 0 \end{aligned} \tag{3.9}$$

for which we need all $T \in \Re$ values yielding the imaginary roots. The numerator of the only term of the s^1 row of the respective Routh array in (3.9) is set to zero for this:

$$\begin{aligned} & T^3\,(0.4004\;10^7\,T^9 \;-\; 0.5418\;10^6\;T^8 \;-\; 0.1060\;10^7\;T^7 \;-\; 0.7869\;10^5\;T^6 \\ & \quad - 0.1501\;10^5\;T^5 \;+\; 0.1216\;10^4\;T^4 \;+\; 0.4011\;10^3\;T^3 \\ & \quad - 0.1025\;10^2\,T^2 \;+\; 0.1197\;T \;-\; 0.1120) \;=\; 0. \end{aligned} \tag{3.10}$$

Notice that we are seeking the real roots of (3.10), and three of them are at $T = 0$. The remaining roots, i.e., 9 $(= n^2)$ of them, have to be solved. Out of these nine roots only five happen to be real and all five satisfy the sign agreement condition in the s^2 row of the Routh array (see the note in section 2(e)). They concur with the results of [6] which uses a slightly different procedure to arrive at these T values. An auxiliary equation is formed by the terms of the s^2 row generating the crossing frequencies, ω. The T versus ω correspondence is shown in (3.11):

$$[T] = \begin{bmatrix} -0.4269 \\ -0.1332 \\ 0.0828 \\ 0.0952 \\ 0.6232 \end{bmatrix} \rightarrow [\omega] = \begin{bmatrix} 15.5032 \\ 0.8404 \\ 3.0351 \\ 2.9123 \\ 2.1109 \end{bmatrix}. \tag{3.11}$$

Note that by using T and ω, one can also find the respective delays τ as per (2.26).

4. Comparative comments and conclusions. The five procedures described above reduce the problem at hand to the following solutions:

(a) Schur–Cohn: Roots of the $2n^2$ degree complex polynomial are solved for purely imaginary roots.
(b) Elimination of transcendental terms: The $n\,2^n$ degree real polynomial is solved for imaginary roots.
(c) Kronecker sum: The $2n^2$ degree polynomial is solved for complex roots with $|\,z\,| = 1$.
(d) Kronecker multiplication: The $2n^2$ degree polynomial is solved for imaginary roots.
(e) Rekasius: The n^2 degree polynomial is solved for real roots ($T \in \mathbf{R}$).

From the perspective of developmental steps, the least involved path appears to be in (e). Nevertheless, utilizing the appropriate matrix operations, methods (a), (c), and (d) prove to be equally potent, producing the desired results. In fact for the example case, method (d) generates the results with the smallest number of significant digits among the five. Method (b) is the one that requires special attention, avoiding the false solutions. As the dimension n increases, method (b) becomes more problematic to process, leaving the other four methods as plausible paths to follow.

We wish to mention two attractive features of method (e): First, the degree of the polynomial in question is considerably smaller than all the other four. Second, we seek the real roots (T) only, not the complex ones. This is a great relief from a numerical perspective, as complex (particularly purely imaginary) roots are very hard to detect when numerical errors creep in. A similar hardship appears when the test of $|z| = 1$ is performed in method (c).

We should also make note of the fact that methods (b) and (e) have a symbolic segment in the deployment, as the remaining three methods are numerical. Upon the request of one of the reviewers, we performed a study of efficiency on all of the methods (i.e., the CPU times consumed) including the symbolic as well as numerical operations. These CPU costs did not show noteworthy variations from one method to another. For instance, the tabulations given in section 3 for all five methods were obtained within 1 sec. on a PC with an Intel Centrino 1.6 MHz processor with 512 MB RAM. It is clear that this efficiency measure is not as important as the accuracy of the findings unless the operation is repeated a large number of times for some parametric studies. But this subject is outside the scope of the present paper.

It is also noteworthy that the authors are engaged in expanding the procedures described here to systems with multiple independent delays. In fact, [10] is a document which utilizes procedure (e) for systems with two independent delays. Several other studies on the deployment of procedure (c) for multiple delay cases are also in progress.

Appendix. Let $\mathbf{A} = [a_{ij}] \in \mathbf{R}^{k \times \ell}$, $\mathbf{B} = [b_{ij}] \in \mathbf{R}^{m \times n}$. Then the Kronecker product of $\mathbf{A}$ and $\mathbf{B}$, denoted by $\mathbf{A} \otimes \mathbf{B}$, is defined as follows:

$$\mathbf{A} \otimes \mathbf{B} = \begin{bmatrix} a_{11}\mathbf{B} & \cdots & a_{1n}\mathbf{B} \\ \vdots & & \vdots \\ a_{n1}\mathbf{B} & \cdots & a_{nn}\mathbf{B} \end{bmatrix} \in \mathbf{R}^{km \times \ell n}. \tag{A.1}$$

If $k = \ell$ and $m = n$, then the Kronecker sum of $\mathbf{A}$ and $\mathbf{B}$, denoted by $\mathbf{A} \oplus \mathbf{B}$, is defined by

$$\mathbf{A} \oplus \mathbf{B} = \mathbf{A} \otimes \mathbf{I}_m + \mathbf{I}_k \otimes \mathbf{B} \in \mathbf{R}^{km \times km}. \tag{A.2}$$

Acknowledgment. The authors wish to thank James Louisell for valuable contributions in the section related to Kronecker multiplication.

NONPOSITIVE CURVATURE AND PARETO OPTIMAL COORDINATION OF ROBOTS*

ROBERT GHRIST† AND STEVEN M. LAVALLE‡

Abstract. Given a collection of robots sharing a common environment, assume that each possesses a graph (a one-dimensional complex also known as a *roadmap*) approximating its configuration space and, furthermore, that each robot wishes to travel to a goal while optimizing elapsed time. We consider vector-valued (or *Pareto*) optima for collision-free coordination on the product of these roadmaps with collision-type obstacles. Such optima are by no means unique: in fact, continua of Pareto optimal coordinations are possible. We prove a finite bound on the number of optimal coordinations in the physically relevant case where all obstacles are *cylindrical* (i.e., defined by pairwise collisions). The proofs rely crucially on perspectives from geometric group theory and $CAT(0)$ *geometry*. In particular, the finiteness bound depends on the fact that the associated *coordination space* is devoid of positive curvature. We also demonstrate that the finiteness bound holds for systems with moving obstacles following known trajectories.

Key words. $CAT(0)$ *geometry*, Pareto optimality, configuration space, nonpositive curvature

1. Introduction.

1.1. Motivation.

In numerous settings, the coordination of multiple robots remains a basic and challenging research issue. Autonomous guided vehicles (AGVs) are used in a wide variety of industrial settings for problems such as material handling, palletizing, paper roll handling, assembly, conveying, and people moving. Typically, AGVs reliably traverse a fixed roadmap of paths in a complicated factory environment. Although the paths avoid collisions with obstacles in the workspace, the efforts of numerous AGVs may have to be coordinated in a way that avoids collisions between AGVs while at the same time maximizing productivity.

If we wish to coordinate the motions of N robots in a common environment, what is an appropriate notion of optimality? Minimizing the average time robots take to reach their goal? Minimizing the time that the last robot takes? Such approaches are common (e.g., [16, 20, 29]) and may be appropriate in some cases; however, it is important to recognize that scalarization of a vector of N criteria occurs in this process. Each robot has its own cost function, e.g., elapsed time. These N criteria are then converted—often in an arbitrary manner—into a single criterion to be optimized.

In this paper, we investigate the optimization problem for multiple robot coordination without scalarizing the vector-valued cost function. This centers on the notion of *Pareto optimality* [24, 26], a concept which is widely used in mathematical economics to model individual consumers striving to optimize distinct economic goals. This brand of optimization is richer in the sense that no choice of scalarization is

involved. In particular the following hold:

1. Any optimum of *any* scalarization of the vector-valued cost function (which is monotone increasing in the components) is in fact one of the Pareto optima; see Lemma 2.6.
2. For settings in which priorities change over time, knowledge of the Pareto optima allows for easy adaptation. This is particularly relevant in automation settings where priority changes arise from, say, changing needs for parts delivery or output.
3. By filtering out all of the motion plans that are not worth considering and presenting the user with a small set of the best alternatives, additional criteria, such as priority or the amount of sacrifice one robot makes, can be applied to automatically select a particular motion plan.

Given the desire to filter the space of all possible coordination schemes to a small set of best cases independent of biases on the robots, we are certainly most interested in the cases where this collection of optima is *finite*. A finiteness criterion is the principal result of this paper.

1.2. Contributions. In section 2 we will phrase the coordination problem as an optimal path-planning problem on a *roadmap coordination space* $\mathcal{X}$: a product of finite metric graphs $\{\Gamma_i\}_1^N$ with obstacle sets removed. The optimization criteria are distinct for each robot. Thus, the appropriate category of optimal paths is that of the so-called *Pareto optimal* solutions. Roughly speaking, a path between fixed endpoints is *locally Pareto optimal* if and only if deforming it to any path which decreases one of the goal times increases some other goal time. A path is *globally Pareto optimal* if and only if any other path which decreases one goal time increases some other. Paths are *Pareto equivalent* if and only if they are connected by a 1-parameter family of paths that preserve all goal times; this equivalence generates Pareto optimal *classes*. (See section 2.2 for precise definitions.)

Depending on the coordination space, nonequivalent Pareto optimal classes may be isolated or may appear in uncountable continuous families. Examples appear in section 3. Most desirable for classification and cataloging purposes are those coordination spaces which admit a finite number of globally Pareto optimal classes.

The principal optimization result of this paper is that for coordination spaces which possess "cylindrical" obstacles—those defined by pairwise collisions between robots—there is a complete classification of locally Pareto optimal classes and a finite bound on the global Pareto optima.

Main Theorem. *Let $\mathcal{X}$ be a cylindrical coordination space. The the following hold:*

1. *Fixing endpoints, the locally Pareto optimal path classes are in bijective correspondence with homotopy classes of paths.*
2. *There is a finite bound on the number of globally Pareto optimal path classes.*

The first statement implies that the set of Pareto optimal paths within a fixed homotopy classes of paths is connected in this space of paths. The second statement means that only a finite number of these local optima are in fact globally Pareto optimal. Proofs appear in section 5.

Furthermore, we extend the finiteness bound to a class of systems involving moving obstacles; see section 7. Remarkably, our techniques easily adapt to problems for which obstacles of varying shape, speed, and trajectory can interfere with the robot motion.

The proof of the Main Theorem uses in an essential manner certain techniques

from geometric group theory, namely, the geometry of $CAT(0)$ *spaces* (see, e.g., [8]) and certain *normal forms* for groups acting on $CAT(0)$ cubical complexes (as in [21]). These tools are applicable to the proof of the Main Theorem thanks to the following lemma.

MAIN LEMMA. *Let $\mathcal{X}$ be a cylindrical coordination space. Then $\mathcal{X}$ is locally $CAT(0)$.*

This lemma is a broad generalization of the result by Abrams [1] that configuration spaces of graphs are locally $CAT(0)$ in the product metric.

Though it falls outside the scope of this paper, the $CAT(0)$ techniques we develop here are directly applicable to the problem of *computing* normal forms of Pareto optimal paths. See [14] for an exact algorithm for computing Pareto optimal paths in a cylindrical coordination space.

1.3. History. The problem of coordinating robots along fixed roadmaps can be considered as a special case of general motion planning for multiple robots. Previous approaches to multiple-robot motion planning are often categorized as *centralized* or *decoupled*. A centralized approach typically constructs a path in a composite configuration space, which is derived from the Cartesian product of the configuration spaces of the individual robots (see, e.g., [5, 6, 27]). A decoupled approach typically generates paths for each robot independently and then considers the interactions between the robots (see, e.g., [9, 12, 22]). The results of this paper are for decoupled coordination.

The approach in [12] prioritizes the robots and defines a sequence of planning problems for which each problem involves moving one robot while those with higher priority are considered as predictable, moving obstacles. This involves the construction of two-dimensional path-time space [17] over which the velocity of the robot is tuned to avoid collisions with the moving obstacles.

In [3, 7, 11, 25, 22, 28] robot paths are independently determined, and a coordination diagram is used to plan a collision-free trajectory along the paths. The approaches in [3, 25] additionally consider dynamics. In [18, 30], an independent roadmap is computed for each robot, and coordination occurs on the Cartesian product of the roadmap path domains. The suitability of one approach over the other is usually determined by the trade-off between computational complexity associated with a given problem and the amount of completeness that is lost. In some applications, such as the coordination of automated guided vehicles, the roadmap might represent all allowable mobility for each robot.

2. Definitions.

2.1. Coordination spaces. This paper concerns the coordination of N robots, each having a roadmap Γ_i (a graph within the configuration space of the ith robot) precomputed independently of the other robots. All graphs are assumed finite and possessed of an intrinsic metric (inherited from the configuration space in which it resides).

DEFINITION 2.1. *A* roadmap coordination space *of graphs $\{\Gamma_i\}_1^N$ is any space of the form*

$$\mathcal{X} = \left(\prod_{i=1}^{N} \Gamma_i \right) - \mathcal{O}, \tag{2.1}$$

where $\mathcal{O}$ denotes an (open) obstacle set.

Assumption 2.2. For the remainder of the paper, all coordination spaces are assumed to have obstacle sets which are sufficiently nice. Namely, the boundary

of the obstacle set, $\partial\mathcal{O}$, is piecewise real-analytic and *collared*: there exists some embedding of $\partial\mathcal{O} \times [0,1] \hookrightarrow \mathcal{X}$ which takes $\partial\mathcal{O} \times \{0\} \to \partial\mathcal{O}$ via the identity map.

This assumption rules out obstacle sets $\mathcal{O}$ for which the system "locks up" in a singular configuration. The piecewise smoothness condition for $\partial\mathcal{O}$ is imposed to avoid discussions of *chattering* and nonrectifiable paths.

Example 2.3. A special class of a roadmap coordination space arises when all of the graphs Γ_i are identical and the obstacle set is an open neighborhood of the collision set $\{x_i = x_j : \text{for some } x_i \in \Gamma_i\,;\, x_j \in \Gamma_j\,;\, i \neq j\}$. In this case, one can consider the workspace to be the graph itself, and the roadmap coordination space is precisely the configuration space of N labeled points on the graph.

In practice, a large class of coordination spaces arise by assigning as illegal states $\mathcal{O}$ those configurations for which there is a collision between robots in the common workspace. For such a system, the obstacle set $\mathcal{O}$ has a very particular "cylindrical" structure since all collisions are determined by pairwise data.

DEFINITION 2.4. *A coordination space $\mathcal{X}$ is said to be* cylindrical *if $\mathcal{O}$ is of the form*

$$\mathcal{O} = \bigcup_{i<j} \left\{ (x_k)_1^N \in \prod_{k=1}^{N} \Gamma_i \,:\, (x_i, x_j) \in \Delta_{i,j} \right\} \tag{2.2}$$

for some (open) sets $\Delta_{i,j} \subset \Gamma_i \times \Gamma_j$, where $1 \leq i < j \leq N$.

That is to say, a cylindrical coordination space is one for which illegal states are determined by pairwise configurations. If two robots have collided, it makes no difference what the positions or configurations of the remaining robot are—this state still counts as an illegal "collision" state.

Configuration spaces of graphs are examples of cylindrical coordination spaces, since the obstacle set $\mathcal{O}$ is the union of (neighborhoods of) sets of the form $\{x_i = x_j : i \neq j\}$. Noncylindrical coordination spaces arise when the legality of a potential collision between two robots is dependent upon the configuration of a third, e.g., hallways in the workspace through which two but not three robots can squeeze.

2.2. Pareto optimality. Pareto optimization refers to optimization of vector-valued functions [23]. In the context of robotics applications, Pareto optimization arises when distinct robots possess distinct goals and cost functions for evaluating performance. Each robot wishes to optimize its cost function independently of the others.

Mathematically, this is characterized as follows. Given a parameterized path $\gamma : [0,T] \to \mathcal{X}$ in a coordination space, each robot executes the projected path $\gamma_i = \text{PROJ}_i \circ \gamma$, where PROJ_i denotes projection onto the ith factor. Given cost functions $\{\tau_i\}$, $i = 1, \ldots, N$, the cost vector for γ is the vector $\tau(\gamma) = (\tau_i(\gamma_i))_i^N$. The case in which τ_i measures *elapsed time* from start to goal is an important and characteristic example, though more general cost functions are allowed.

Assumption 2.5. We restrict our attention to parameterized paths which are *admissible*, meaning that velocity vectors have all components bounded above by one. There are no restrictions on acceleration: only velocity is bounded. It will be assumed for simplicity that the cost functions τ_i agree with elapsed time. To change the velocity bound or the cost function, one can perform a simple rescaling of the geometry of the coordination space.[1]

[1]The assumption about potentially unbounded acceleration is not so easily skirted. The results of this paper are unknown in that case.

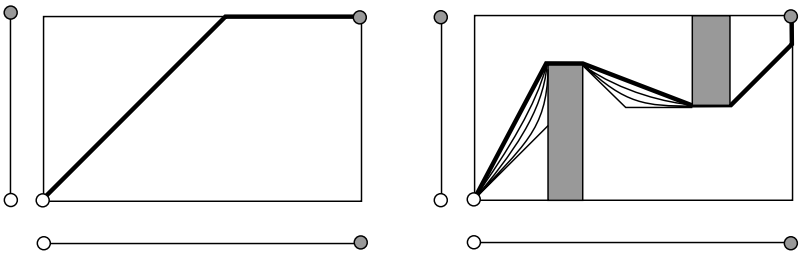

FIG. 1. *Left: the unique locally and globally Pareto optimal path between corners of a rectangle with regards to elapsed time; right: an envelope of Pareto optimal paths weaving through obstacles forms a single equivalence class.*

A path $\gamma : [0, T] \to \mathcal{X}$ is *Pareto optimal* if and only if $\tau(\gamma)$ is minimal with respect to the partial order on vectors:

$$\tau(\gamma) \leq \tau(\gamma') \Leftrightarrow \tau_i(\gamma_i) \leq \tau_i(\gamma'_i) \quad \forall\, i = 1, \ldots, N. \tag{2.3}$$

The local Pareto optima compose the set of all optima for all monotone scalarizations (such as, e.g., average time-to-goal and nonlinear generalizations thereof) as stated in the following theorem.

LEMMA 2.6. *For any scalarization $f : \mathbb{R}^n \to \mathbb{R}$ with $\partial f / \partial x_i > 0$, all minima of $f \circ \tau$ are global Pareto optima.*

Proof. Given any minimizer for $f \circ \tau$ which is not globally Pareto optimal, there exists a path which decreases some τ_i without increasing any of the others; by monotonicity, this decreases the f-value of the path, which is a contradiction. □

In some cases, locally Pareto optimal paths are unique. In the rectangular coordination space of Figure 1 (left), there is a unique locally (and globally) Pareto optimal path. The diagonal of the rectangle is not locally Pareto optimal unless the rectangle is a square.

Locally Pareto optimal paths are usually not unique. Two paths γ and γ' are *Pareto equivalent* if and only if they are homotopic through locally Pareto optimal paths which are equal in the partial order; i.e., $\tau(\gamma) = \tau(\gamma')$. Figure 1 (right) illustrates a single locally Pareto optimal class with many representatives. We show in section 3 that certain roadmap coordination spaces admit a continuum of locally/globally Pareto optimal *classes*.

2.3. A little topology. Experts can safely bypass this brief primer of the topological concepts used throughout the paper. See, e.g., [15] for a comprehensive treatment.

Given a topological space X, a *path* is a (continuous) map $\alpha : [0, 1] \to X$. Two paths α and α' sharing identical endpoints are said to be *homotopic* if there exists a continuous 1-parameter family of paths $\{\alpha_t\}_0^1$ satisfying (1) $\alpha_0 = \alpha$; (2) $\alpha_1 = \alpha'$; and (3) α_t has the same endpoints for all t.

Topologists keep track of different homotopy classes of paths by computing a more general object: the fundamental group. Given a fixed basepoint $x_0 \in X$, the *fundamental group* $\pi_1(X, x_0)$ is defined to be the set of homotopy equivalence classes of paths in X which have endpoints at x_0. The group operation is concatenation of paths: $\alpha * \beta$ means "do α then do β." This is well defined (since all endpoints are x_0) and yields a group with identity element the *contractible* loops in x. For path-connected spaces, $\pi_1(X, x_0)$ is independent of the basepoint x_0 (up to isomorphism of

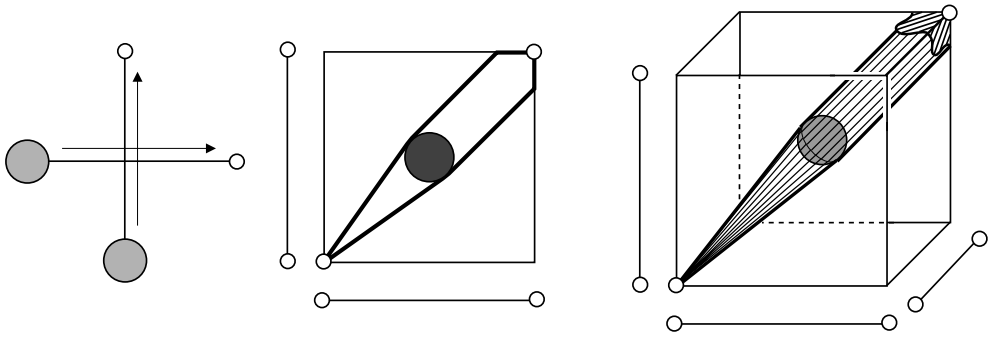

FIG. 2. *The case of two disc-like robots translating along edges (left) yields a two-dimensional coordination space with a disc obstacle possessing two globally Pareto optimal classes (center). Three robots with a spherical obstacle possess a continuum of globally Pareto optimal classes (right).*

groups), and one may unambiguously denote the fundamental group $\pi_1(X)$. A *simply connected* space X is one which is connected and has $\pi_1(X)$ a trivial group.

Any space X which has a reasonably nice local structure (e.g., a cell complex) and a nontrivial fundamental group can be "unwrapped" to a larger simply connected space which is locally indistinguishable from X. The *universal cover* of X, $\tilde{X}$, is defined to be a simply connected space along with a projection map $p : \tilde{X} \to X$ which is locally a homeomorphism. For example, the universal cover of the circle S^1 is $\mathbb{R}$ with the projection $p : x \mapsto x \mod 1$.

3. Examples. We illustrate a few examples of simple coordination spaces and globally Pareto optimal path classes.

Example 3.1. Consider the case where $N = 2$, $\Gamma_1 = \Gamma_2 = [-2, 2]$, and $\mathcal{O} = \{(x, y) : x^2 + y^2 < 1\}$, which corresponds to a pair of identical disc-shaped robots sliding along interval roadmaps which intersect in the workspace at right angles. There are exactly two globally Pareto optimal classes of paths from $(-2, -2)$ to $(2, 2)$, as illustrated in Figure 2 (left). The difference between these two paths lies in which robot decides to pause in order to allow the other to pass through the intersection. Note also that this is a cylindrical coordination space and hence satisfies the Main Theorem above.

Example 3.2. We modify the previous example by letting $N = 3$ and choosing $\mathcal{O}$ to be a round ball of radius 1 at the origin. By the symmetry of $\mathcal{X}$ about the diagonal of the cube, it is clear that there is a circle's worth of paths which begin at $(-2, -2)$, trace a straight line which is tangent to $\mathcal{O}$, and then exit this sphere tangentially with slope 1. The projection of this family of paths to the first two coordinates includes as special cases the distinct Pareto optima of Example 3.1, as well as a continuum of paths whose goal times continuously interpolate the two. Hence, there is a continuum of globally Pareto optimal classes.

Note that the symmetry in these problems is not crucial: the number of globally Pareto optima in both examples is robust to small perturbations in $\mathcal{O}$. Note as well that the obstacle set in Example 3.2 is not generated by pairwise collisions of the robots; the obstacle set is determined by the positions of all three robots.

Example 3.3. Coordination problems without the fixed path constraint can have continua of optima more easily than in the fixed path case. Consider the problem of translating two unit squares in the plane in such a way as to exchange their positions.

Assume that the squares are centered at $(-1, 0)$ and $(1, 0)$. It is straightforward to exhibit a continuous family of distinct globally Pareto optimal classes. Extrema of this family consist of those coordinations for which one square translates exclusively in the horizontal direction, while the other square moves vertically in order to get out of the way. The intermediate coordinations involve one square translating up by an amount $0 < h < 1$ and the other translating down by a total amount $1 - h$. This example works with arbitrary translations or with translations restricted to coordinate axis directions.

4. Discretization. Coordination spaces come equipped with a natural geometry as a subset of a (flat) product of metric graphs. For the remainder of this paper, we consider the *path metric*—the distance between points is defined in terms of the length of a shortest path (geodesic) between the points. Our tools for dealing with coordination spaces stem from knowledge of the geometry of the path metric.

4.1. Nonpositive curvature. Let (X, d) denote a complete metric space for which local geodesics exist: between any two sufficiently close points $p, q \in X$, there exists a path in X whose length is equal to $d(p, q)$. The notion of curvature bounds for such spaces is classical and can be found in the work of, e.g., Alexandrov (see [8] for references and a comprehensive introduction). We repeat that it is not necessary for X to be a manifold, much less smooth. In this "synthetic" approach to geometry, one interrogates a space with geodesic triangles.

For each triple of points $p, q, r \in X$, draw the triangle in X with geodesics $\overline{pq}$, $\overline{qr}$, and $\overline{rp}$. Let p', q', and r' denote three points in the Euclidean plane $\mathbb{E}^2$ forming a *comparison triangle* whose edges have length $d(p, q)$, $d(q, r)$, and $d(r, p)$, respectively. Choose a pair on points s and t on the edges of the geodesic triangle in X; then, consider the corresponding points s' and t' in $\mathbb{E}^2$. The $CAT(0)$ *inequality*[2] for X is the following: for every p, q, r in X, and for every s, t, one has $d(s, t) \leq \|s' - t'\|$, where $\|\cdot\|$ denotes the Euclidean norm in $\mathbb{E}^2$.

DEFINITION 4.1. *A complete geodesic space X is $CAT(0)$ if the $CAT(0)$ inequality holds for each geodesic triangle in X. A geodesic space X is* nonpositively curved *or* NPC *if it is locally $CAT(0)$, that is, if the $CAT(0)$ inequality holds for sufficiently small geodesic triangles in X.*

Otherwise said, X has nowhere positive curvature if small geodesic triangles in X are "no fatter" than similar triangles in the Euclidean plane: see Figure 3. By assigning the appropriate definition of angles in a geodesic metric space [8], this condition translates into saying that the sum of the angles of a geodesic triangle in an NPC space is no larger than π. It is a standard fact that X is $CAT(0)$ if and only if it is NPC and simply connected [8].

The existence of *some* metric of nonpositive curvature on a space X implies several strong results about the topology and geometry of X. For example [8]: (1) the universal cover of X is contractible; (2) the fundamental group $\pi_1(X)$ has no torsional elements; and, most importantly for our purposes, (3) geodesics on X are unique up to homotopy, fixing the endpoints.

The problem of determining when a space is $CAT(0)$ or NPC is surprisingly easy for piecewise-Euclidean cube complexes, that is, spaces built from Euclidean cubes glued together along faces. Since the individual cubes are flat, any nonzero curvature, if it exists in the complex, must be focused along the faces and detectable at the

[2]The term "CAT" is Gromov's, used in deference to the work of Cartan, Alexandrov, and Toponogov. Alternately, one can take this as *comparare ab triangulos* ("to compare by triangles").

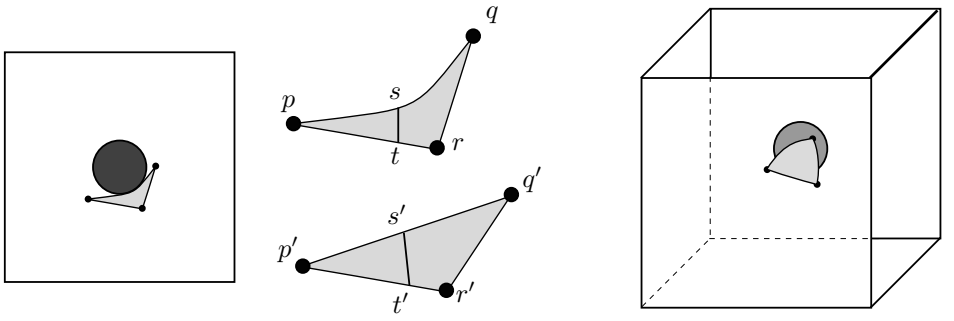

FIG. 3. *The coordination space of Example* 3.1 *is NPC (left) since triangles are "skinnier" than their Euclidean counterparts (center), whereas that of Example* 3.2 *is not NPC (right).*

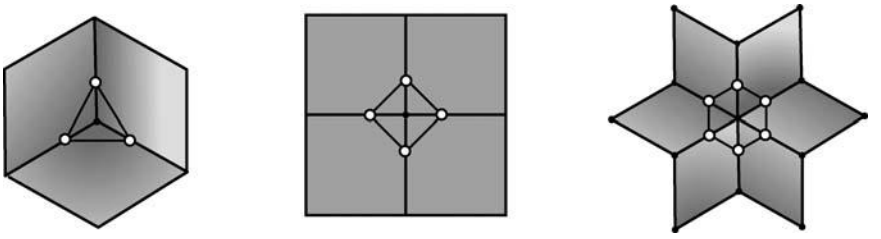

FIG. 4. *Vertices detect curvature for a cube complex: from left to right, positive, zero, and negative curvature in two-dimensional cube complexes. The link condition holds for the latter two of these complexes.*

vertices of the cube complex. Intuitively, positive curvature arises whenever there is a convex "corner" in the complex.

More specifically, let v denote a vertex of a cube complex X. The number and types of cubes in X which have a corner at v are encoded in a combinatorial object called the *link* of v; see, e.g., [8] for details. The following result of Gromov (which we have translated into simpler language for clarity) characterizes nonpositive curvature in terms of this structure and is therefore called the *link condition*.

THEOREM 4.2 (Gromov's link condition). *A piecewise Euclidean cube complex is NPC if and only if the following holds for each vertex v. Given any set of $K \geq 3$ edges of X incident to v, any pair of which are part of a square in X, all K edges are part of a K-dimensional cube with corner at v.*

This is illustrated for several two-dimensional complexes in Figure 4. The intuition behind this theorem is that positive curvature in a cube complex is entirely determined by the presence of a "sharp" corner.

4.2. Discretized coordination spaces. The key step in our analysis of cylindrical coordination spaces is a spatial discretization of them into cubical complexes. Discretized configuration spaces have recently been used in other robotics contexts [1, 2, 13].

Consider a coordination space $\mathcal{X}$ for roadmaps $\{\Gamma_i\}$. For simplicity, assume that all the edge lengths of the graphs Γ_i are rationally related. Because of this, one may choose a length $\delta > 0$ so that all edge lengths are integer multiples of δ. Denote by $\Gamma_i^{(n)}$ the graph obtained from Γ_i by subdividing it into edges of length $2^{-n}\delta$.

DEFINITION 4.3. *For each $n \geq 0$, denote by $\mathcal{X}^{(n)} \subset \Gamma_1^{(n)} \times \cdots \times \Gamma_N^{(n)}$ the maximal closed subcomplex of the product cubical complex which does not intersect the obstacle set $\mathcal{O}$. This cubical complex is called the* stage-n discretized coordination space.

The cubical nature of these spaces forms a convenient structure with which to manipulate paths. Our strategy is to approximate locally Pareto optimal paths with paths which follow along the diagonals of cubes in $\mathcal{X}^{(n)}$ for n sufficiently large. Working with these *cube paths* will allow us to skirt such technical issues as regularity of paths. The following result is crucial.

THEOREM 4.4. *Cylindrical coordination spaces are NPC.*

Proof. By assumption, all coordination spaces in this paper are complete geodesic metric spaces under the path metric. We begin by showing that $\mathcal{X}^{(n)}$ converges to $\mathcal{X}$ in the Hausdorff sense; i.e., given any point $p \in \mathcal{X}$ and an $\epsilon > 0$, there exists an $M > 0$ such that an ϵ-neighborhood of p intersects $\mathcal{X}^{(n)}$ for all $n > M$. This is certainly true for p in the interior of $\mathcal{X}$, since p is bounded away from $\mathcal{O}$. Since $\mathcal{X}$ is collared, points in the boundary of $\mathcal{X}$ are limits of points in the interior, and convergence follows.

It is known that a complete NPC space which is the Hausdorff limit of NPC spaces is itself NPC (see [8, Lemma II.3.10(1)], which is stated for $CAT(0)$ spaces; apply this to the universal covers of $\mathcal{X}$ and $\mathcal{X}^{(n)}$ to obtain the result). Hence, it suffices to show that $\mathcal{X}^{(n)}$ is NPC.

Since these are cubical complexes, Gromov's link condition is necessary and sufficient to show NPC. Therefore, let v be any vertex of $\mathcal{X}^{(n)}$. Assume that there is a collection of $K \geq 3$ edges $\{e_i\}_1^K$ incident to v that pairwise bound squares in $\mathcal{X}^{(n)}$. Each e_i corresponds to an edge of $\Gamma_{\alpha(i)}$ for some indexing α satisfying $\alpha(i) \neq \alpha(j)$ for all $i \neq j$. The square bound by edges e_j and e_k corresponds to a square in

$$\Gamma_{\alpha(j)} \times \Gamma_{\alpha(k)} - \Delta_{\alpha(j),\alpha(k)}$$

for each j and k. By the cylindrical structure of the holes in $\mathcal{X}$, the product of the edges $\{e_i\}$ is a K-dimensional cube in $\prod_1^m \Gamma_{\alpha(i)}$ which does not intersect $\Delta_{\alpha(j),\alpha(k)}$ for any pair j, k. This therefore defines a K-dimensional cube in $\mathcal{X}^{(n)}$ spanning the edges. The link condition is satisfied. □

Theorem 4.4 generalizes a number of known results about NPC configuration spaces, especially the results of [1] about configuration spaces of points on graphs, and more general "colored" configuration spaces of graphs.[3]

4.3. Cube paths. The spatial discretization of coordination spaces extends to a discrete version of paths. The following notion of discrete paths is crucial to future proofs.

DEFINITION 4.5. *Let X denote a cubical complex. A* cube path *from vertices v_0 to v_N in X is an ordered sequence of closed cubes $\mathcal{C} = \{C_i\}_1^N$ of X which satisfy* (1) *$C_i \cap C_{i+1} = \{v_i\}$, a vertex; and* (2) *$C_i$ is the smallest cube of X containing v_{i-1} and v_i. A cube path is said to be* normal *if in addition for all i,* (3) *$C_{i+1} \cap \mathsf{St}(C_i) = v_i$, where $\mathsf{St}(C_i)$ is the* star *of C_i (all cubes in X, including C_i, which have C_i as a face).*

To each cube path is associated a piecewise linear (PL) path in X given by the chain of straight line segments from v_i to v_{i+1} for $i = 0, \ldots, N-1$: see Figure 5. Roughly speaking, a normal cube path is one which uses the highest dimensional cubes as early as possible in the path.[4] This hints at the intuition of normal paths as

[3]This proof is simpler than that of Abrams in that it requires no direction computation of the homotopy groups of the Hausdorff limit.

[4]These paths are called "normal" in [21] since they are used to generate normal forms for languages of fundamental groups acting on $CAT(0)$ cube complexes.

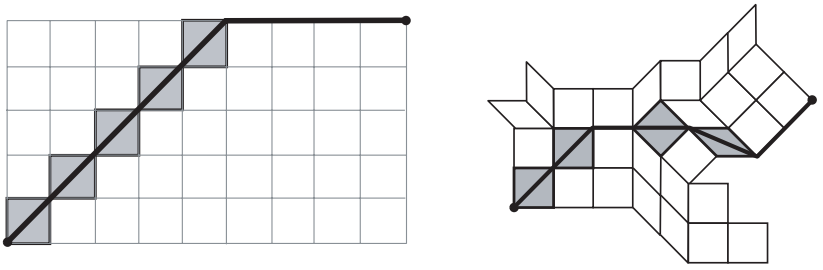

FIG. 5. *Examples of normal cube paths (with the diagonals highlighted).*

locally Pareto optimal, an intuition which we demonstrate is entirely justified. The key fact about normal cube paths is that, like geodesics on an NPC space, they are unique up to homotopy.

COROLLARY 4.6. *Any cube path between vertices of $\mathcal{X}^{(n)}$ is homotopic to a unique normal cube path.*

Proof. This is true for any NPC cube complex via Proposition 3.3 of [21]. By Theorem 4.4, this holds for $\mathcal{X}^{(n)}$. □

5. Topological bounds on Pareto optima. In this section we demonstrate a uniqueness result for locally Pareto optimal classes. The strategy of our proof is to show that any locally Pareto optimal path class in $\mathcal{X}$ contains a representative which is a limit of normal cube paths in $\mathcal{X}^{(n)}$. For the remainder of the paper, $\mathcal{X}$ will denote a cylindrical roadmap coordination space.

The geometry on $\mathcal{X}$ is that defined by the path metric: the metric distance between points of $\mathcal{X}$ is defined to be the length of a geodesic path between the points. Unless otherwise noted, the default notion of length is the standard length obtained by integrating the ℓ^2 norm of the velocity vectors over the path. Other notions of length are useful. Given a velocity vector, the ℓ^∞ norm of that vector is the usual definition: in this case, the maximal speed of the AGVs is traveling at that instant. The ℓ^∞ length of a path in $\mathcal{X}$ is the integral of the ℓ^∞ norm of the velocity vectors over the path. This ℓ^∞ length measures the total elapsed time that the AGVs take to execute the coordination implied by the path. As such, ℓ^∞ geodesics between points correspond to "fastest" coordinations.

LEMMA 5.1. *Any ℓ^∞ geodesic path on $\mathcal{X}$ can be C^0- and ℓ^∞-approximated by a cube path in $\mathcal{X}^{(n)}$ for n sufficiently large.*

Proof. Given an ℓ^∞ geodesic α, those portions of the curve which lie near $\partial\mathcal{O}$ may not be in $\mathcal{X}^{(n)}$. However, given the embedded collar $\Phi : \partial\mathcal{O} \times [0,1] \hookrightarrow \mathcal{X}$ from Assumption 2.2, the curve α can be pushed into the interior of $\mathcal{X}$ by increasing the second coordinate of Φ. This yields a curve β which avoids $\partial\mathcal{O}$, is freely homotopic to α, and is both C^0 and ℓ^∞-close.

We next approximate β by a cube path. Since the image of β is compact, there exists an $\epsilon > 0$ so that a tube of radius ϵ about the image of β does not intersect $\partial\mathcal{O}$. Choose n so that the grid size $\delta = 2^{-n}$ is less than ϵ. Modify β so that its endpoints are at vertices of $\mathcal{X}^{(n)}$. Consider the vertex $v^0 = \beta(0)$ and the ℓ^∞ balls $B_r = B_r^\infty(v^0)$ of radius r about v^0 in $\mathcal{X}^{(n)}$. Let $w^1 = \beta \cap \partial B_\delta$ and $w^2 = \beta \cap \partial B_{2\delta}$.

Let $F = B_\delta(v^0) \cap B_\delta(w^2)$. Clearly, $w^1 \in F$, and for any $x \in F$ it holds that the PL path $v^0 \to x \to w^2$ is of the same ℓ^∞ length as the restriction of β to this neighborhood. We claim that F contains a vertex of the grid structure on $\mathcal{X}^{(n)}$. To see this, note that F is a subset of some face of B_δ defined by the set of all points

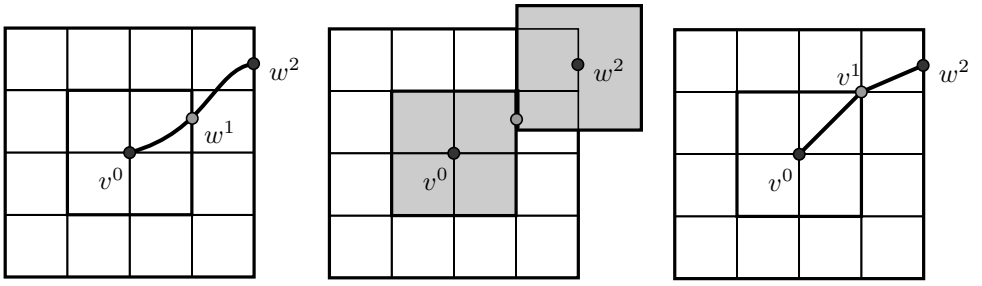

FIG. 6. *Approximation of a path by a cube path.*

$x = (x_i)$ such that

$$x_i \in [v_i^0 - \delta, v_i^0 + \delta] \cap [w_i^2 - \delta, w_i^2 + \delta], \qquad i = 1, \ldots, N. \tag{5.1}$$

Since these intervals have the same length, it follows that either $v_i^0 - \delta$ or $v_i^0 + \delta$ lies within the intersection for each i. Therefore, F contains a gridpoint v^1 of $\mathcal{X}^{(n)}$, and we may replace the segment of the path β with a PL path from v^0 to v^1 to w^2: see Figure 6. Repeat the argument inductively, beginning at the vertex v^1 and considering the ℓ^∞ balls about v^1 of radius δ and 2δ.

Marching along yields a PL path passing through vertices of $\mathcal{X}^{(n)}$ which are sequentially of ℓ^∞ distance δ. This is therefore a cube path in $\mathcal{X}^{(n)}$. This completes the proof of the lemma, as all modifications are homotopies within a neighborhood of the initial path α. □

LEMMA 5.2. *Let α be a locally Pareto optimal path on $\mathcal{X}$. One can find homotopic cube paths with endpoints close to those of α such that all the goal times approximate those of α.*

Proof. Any locally Pareto optimal path is a concatenation of paths which go from the attainment of the ith goal to the $(i+1)$st goal. Each of these subpaths is an ℓ^∞ geodesic whose ℓ^∞ length contributes to the elapsed time. Applying Lemma 5.1 inductively to these subpaths gives a path which approximates all the elapsed times. □

A simple algorithm, `LeftGreedy`, converts a cube path $\mathcal{C}$ into a normal cube path by sweeping along $\mathcal{C}$ from left to right, comparing the star of each cube with its neighbor to the right (line 3) and shifting the common directions to the left cube (lines 4–5).

ALGORITHM **1.** `LeftGreedy`($\mathcal{C}$).

Require: $\mathcal{C} = \{C_i\}_1^m$ is an ℓ^∞ geodesic cube path
1: **while** $\mathcal{C}$ is not normal **do**
2: **for** $i = 1, \ldots, m$ **do**
3: $Z \leftarrow C_{i+1} \cap \mathsf{St}(C_i)$
4: $C_{i+1} \leftarrow C_{i+1}/Z$
5: $C_i \leftarrow C_i \times Z$
6: **end for**
7: **end while**

LEMMA 5.3. *Given a locally Pareto optimal cube path $\mathcal{C}$,* `LeftGreedy`($\mathcal{C}$) *is a normal cube path which is Pareto equivalent to $\mathcal{C}$.*

Proof. Since common directions are shifted to the left, each sweep through $\mathcal{C}$ for which $C_{i+1} \cap \mathsf{St}(C_i) \neq \{v_i\}$ for some i strictly decreases the positive integer-valued function $\sum_i i \cdot \dim(C_i)$; hence, convergence.

To argue that `LeftGreedy` can be executed through Pareto equivalence, note first that the shifting process of lines 4–5 results in a homotopic path, since all modifications take place within $\mathsf{St}(C_i) \cup C_{i+1}$. If the jth coordinate x_j reaches its goal at vertex v_i of $\mathcal{C}$, then all subsequent vertices v_k $(k \geq i)$ lie within the hyperplane of $\mathcal{X}$ having the same jth coordinate. Hence, in line 3, the common factor Z is trivial in the j^{th} coordinate for v_i and beyond. Thus, the time-to-goal for x_j is unchanged by steps 4–5. □

We now may prove the Main Theorem.

THEOREM 5.4. *Locally Pareto optimal path classes on $\mathcal{X}$ are in bijective correspondence with homotopy classes of paths (fixing the endpoints).*

Proof. Existence of a locally Pareto optimum does not rely on the cylindrical nature of $\mathcal{X}$, but rather on the fact that it is compact and piecewise real-analytic. Via Lemma 2.6 applied to each homotopy class, the existence of a locally Pareto optimal path is guaranteed by the existence of a path which minimizes some monotone scalarization of the cost function, e.g., average time-to-goal. For fixed endpoints, this scalar function is positive and bounded below over the space of piecewise real-analytic paths in a given homotopy class.

The classification theorem relies on the cylindrical nature of $\mathcal{X}$. Assume there are two locally Pareto optimal paths, α and α', which are homotopic. Approximate these paths by cube paths $\mathcal{C}$ and $\mathcal{C}'$ on $\mathcal{X}^{(n)}$ for some large n via Lemma 5.2. The approximations $\mathcal{C}$ and $\mathcal{C}'$ are homotopic in $\mathcal{X}$ to α and α', respectively: we claim that $\mathcal{C}$ and $\mathcal{C}'$ are homotopic in $\mathcal{X}^{(n)}$. Since α and α' are homotopic in $\mathcal{X}$, there exists a map of a closed disc into $\mathcal{X}$ whose boundary is sent to $\alpha * (\alpha')^{-1}$ (that is, the loop obtained by concatenating loop α with the reverse of the loop α'). The collar Φ from Assumption 2.2 which is used to push α and α' into the interior of $\mathcal{X}^{(n)}$ also pushes this spanning disc into the interior. Thus, the paths $\mathcal{C}$ and $\mathcal{C}'$ are homotopic within $\mathcal{X}^{(n)}$.

Feed these cube paths into the algorithm `LeftGreedy`. Via Lemma 5.3, the outputs are normal cube paths which are Pareto equivalent to $\mathcal{C}$ and $\mathcal{C}'$, respectively. By Corollary 4.6, $\mathcal{C}$ and $\mathcal{C}'$ are the same path and hence have the same output times. Therefore, α and α' have output times which are arbitrarily close. □

This implies that the locally Pareto optimal classes are "discrete" and cannot arise in continua as in the noncylindrical case. It does not automatically follow that there is a bound on the number of globally Pareto optimal paths, since any cylindrical coordination space $\mathcal{X}$ which is not simply connected must have a countably infinite number of homotopy classes of paths. However, since the obstacle set is collared, the fundamental group of $\mathcal{X}$ is finitely generated, and, apart from this finite collection of generators, all other paths "wrap around" a loop multiple times. One rightly suspects that such repetition makes everyone's arrival times later and thus cannot be a globally Pareto optimal solution. We make this intuition rigorous below.

THEOREM 5.5. *The number of globally Pareto optimal paths between fixed endpoints on $\mathcal{X}$ is finite.*

Proof. Fix endpoints and consider $\{\gamma_i\}_1^\infty$ an infinite collection of nonequivalent globally Pareto optimal paths. By Theorem 5.4, all these are in different homotopy classes. The endpoints of these paths in the universal cover must be an unbounded discrete set, whose ℓ^∞ lengths tend uniformly to infinity, after taking a subsequence and reordering.

Denote by $\{T_i^j\}_{i=1,\dots,\infty}^{j=1,\dots,N}$ the $j = 1, \dots, N$ goal times of the path γ_i. By the pigeonhole principle, one may assume (after taking a subsequence) that for some k, $T_i^{k+1} \geq T_i^k + i$ for all i. By compactness of $\mathcal{X}$, the set of points $\{\gamma_i(T_i^k)\}$ has an accumulation point x_k. Likewise, the set of points $\{\gamma_i(T_i^{k+1})\}$ has an accumulation point x_{k+1}. For all i large, a small perturbation to the path γ_i after T_i^k in a neighborhood of x_k and x_{k+1} reduces T_i^j by more than $i-1$ for each $j > k$, without increasing any other goal times. This contradicts the assumption of globally Pareto optimal paths. □

COROLLARY 5.6. *There exists a finite bound on the number of globally Pareto optimal classes on $\mathcal{X}$ between fixed endpoints which is independent of the endpoints.*

Proof. For each fixed pair of endpoints in $\mathcal{X} \times \mathcal{X}$, there is a finite number of globally Pareto optimal classes via Theorem 5.5. The bound extends to small open neighborhoods in $\mathcal{X} \times \mathcal{X}$ via the same argument. Thanks to the compactness of $\mathcal{X}$, this open cover restricts to a finite subcover. □

This completes the proof of the Main Theorem.

6. Computing locally Pareto optima. The proof of the Main Theorem reveals a technique for computing "canonical" representatives for the locally Pareto optimal classes. One observes from the proof that passing to a sufficiently fine cubical discretization of the coordination space and choosing a normal cube path between endpoints yields an approximation to a locally Pareto optimal path. Normal cube paths are not difficult to compute, given the cubical approximation—one simply cuts across as many diagonals as early as possible in the path.

However, this procedure is not optimal as a means of generating representatives of a Pareto equivalence class, since it involves a potentially large and expensive discretization step and yields only an approximation to the desired optimum. A less expensive approach that yields the true locally Pareto optimal representative path comes from deriving a "continuous" version of a normal cube path which does not rely on having a cubical structure at all. These paths, called *left-greedy normal* paths, are well defined, unique up to homotopy, and locally Pareto optimal.

A companion paper [14] to this one gives proper definitions of left-greedy normal paths, along with algorithms for their computation, complexity bounds, and implementation in the context of coordinating several irregular-shaped robots translated along planar tracks. It is an interesting feature that the algorithms for computing these locally Pareto optimal paths rely crucially on the nonpositive curvature of the underlying coordination space.

7. Moving obstacles. Assume that, as before, we have N robots which traverse roadmaps $\{\Gamma_i\}_1^N$. If, as will typically occur, the obstacle set $\mathcal{O}$ is defined by pairwise collisions, then the resulting coordination space $\mathcal{X}$ will be cylindrical and the finiteness bounds apply.

Assume now that there are additional objects which, like the robots, move through the shared environment but, unlike the robots, are not controllable. These objects move along predetermined trajectories in the workspace. We make no assumptions about their speed, shape, or motion.[5] We assume *only* that the trajectory through the workspace is a fixed function of time. Such a system gives rise to a roadmap coordination system with moving obstacles.

We consider the problem of determining locally Pareto optimal coordinations of the N robots through the workspace, where all admissible paths are those which avoid

[5]Indeed, the moving obstacles may, during their trajectory, change shape, speed, or even connectivity.

collision with the moving obstacles. Our strategy is to augment the coordination space by adding one dimension for time, similar to the methods used in [17, 25].

THEOREM 7.1. *Any roadmap coordination system with moving obstacles possesses a finite number of globally Pareto optimal classes of paths.*

Proof. Let $\mathcal{X}$ denote the coordination space of the N robots obtained by ignoring the additional obstacles. We will build an augmented coordination space of the form $\overline{\mathcal{X}} \subset [0,T] \times \left(\prod_{k=1}^{N} \Gamma_k\right)$. Encode the positions of the moving objects as a time-parameterized subset of the workspace (where, without loss of generality, $0 \leq t \leq T$ for some T). For each $1 \leq i \leq N$, denote by $\overline{\mathcal{O}}_i \subset [0,T] \times \Gamma_i$ the set of points of the form (t, x_i), where the ith robot in configuration x_i is in collision with the moving obstacles' positions at time t. We define $\overline{\mathcal{X}}$ via the obstacle set

$$\overline{\mathcal{O}} = ([0,T] \times \mathcal{O}) \bigcup_i \left\{ (t, x_1, \ldots, x_N) \in [0,T] \times \prod_{k=1}^{N} \Gamma_k \,:\, (t, x_i) \in \mathcal{O}_i \right\}. \tag{7.1}$$

Claim 1. The augmented coordination space $\overline{\mathcal{X}}$ is cylindrical.

To prove this, note that $\overline{\mathcal{X}}$ is obtained from $[0,T] \times \prod_i \Gamma_i$ by removing sets defined either from $\mathcal{O}$ or from $\mathcal{O}_i$. These are all pairwise defined cylindrical subsets.

This completes Claim 1.

We now apply the same proof to $\overline{\mathcal{X}}$ with two key modifications. The first is that the time direction $[0,T]$ in $\overline{\mathcal{X}}$ is rigid: all admissible paths in $\overline{\mathcal{X}}$ must travel with unit speed in the t-direction. The second is that the endpoint is variable: paths start at the point $(0,p)$ and end at (T',q) for some fixed $p, q \in \mathcal{X}$ and for some variable $T' \leq T$.

For the moment, assume that T' is fixed.

Claim 2:. The number of admissible globally Pareto optimal paths from $(0,p)$ to (T',q) is finite.

To prove this, one shows that the proofs of Theorems 5.4 and 5.5 apply to admissible paths (those with unit speed in the t-direction). Not all homotopy classes of $\overline{\mathcal{X}}$ are represented, but only those which have unit speed in the t-direction. The crucial observation for the analogue of Theorem 5.4 is that Algorithm 1 applied to a path with unit speed in the t-direction preserves this property. The analogue of Theorem 5.5 in this setting is unchanged.

This completes Claim 2.

In the general case, the endpoint has t-coordinate T'. For each such T' there is a finite set of globally Pareto optimal paths in $\overline{\mathcal{X}}$.

Claim 3. The projections of these globally Pareto optimal paths in $\overline{\mathcal{X}}$ to $\mathcal{X}$ are independent of T' for T' sufficiently large.

To prove this, assume that $\mathcal{C}'$ is a normal cube path from $(0,p)$ to (T',q) in $\overline{\mathcal{X}}$. Let $\mathcal{C}$ denote the cube path obtained by appending to $\mathcal{C}'$ the straight line segment from (T',q) to (T,q). Claim 3 follows if $\mathcal{C}$ is also a normal cube path.

Assume that $\mathcal{C}$ is not normal. Then, since both pieces of $\mathcal{C}$ are normal ($\mathcal{C}'$ and the segment $(T',q) \to (T,q)$), the normal condition must fail precisely at the vertex (T',q). This would imply that the star of the last cube in $\mathcal{C}'$ intersects the segment $(T',q) \to (T,q)$; hence, the last cube of $\mathcal{C}'$ had no component in the t-direction. However, this is a contradiction, since $\mathcal{C}'$ is an admissible path with constant speed 1 in the t-direction.

This completes Claim 3 and the theorem. □

The problem of computing locally Pareto optimal paths in this case is no different from that in the stationary obstacle case of the previous sections. The motion of

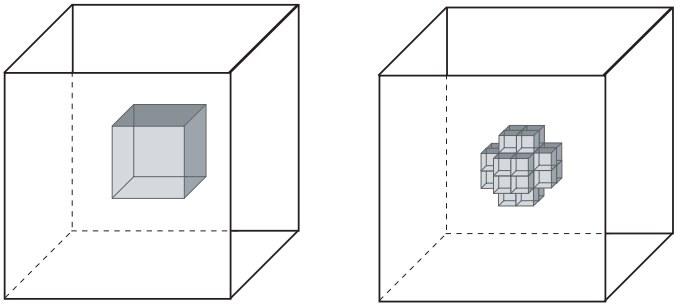

FIG. 7. *As one approximates the obstacle of Example* 3.2 *by finer and finer cubes, the number of normal cube paths from one corner to its antipode grows exponentially.*

the obstacles is incorporated in the geometry of the coordination space in the time-dimension.

8. On positive curvature. We claim that the crucial reason for the finiteness bound is that the cylindrical coordination spaces can be approximated by cubical complexes without any vertices of positive curvature. For more general coordination spaces, all the steps of the proof of the finiteness bound hold *except* the uniqueness of normal cube paths up to homotopy.

For example, if one approximates the space of Example 3.2 by discretizations $\mathcal{X}^{(n)}$, then, as before, there are a finite number of normal cube paths. For example, in $\mathcal{X}^{(2)}$, $\mathcal{O}$ is approximated by a cube and there are exactly three normal cube paths. However, they are not unique up to homotopy, and the number of such paths grows exponentially in the discretization step n, giving rise to the continuum of optima in the limit; see Figure 7.

The positive curvature in Example 3.2 is transparent: the obstacle set $\mathcal{O}$ clearly has a positively curved boundary. But in Example 3.3, the positive curvature is more subtle and arises from the fact that the obstacle set $\mathcal{O}$ is not axis-aligned. Consider first the case in which the squares have full mobility in all directions. We discretize this $\mathcal{X}$ to a cube complex by letting edges correspond to sliding a square in either the horizontal or vertical direction. Higher dimensional cubes correspond to slides which "commute" (they are compatible without causing a collision between the two squares).

We claim that positive curvature is created in the discretization. It suffices to demonstrate the failure of the link condition, namely, to show that there exists a triple of edges which pairwise commute but which together yield an illegal state. This is illustrated in Figure 8. Each pair of the three moves exhibited there commutes (with one pair generating a diagonal slide), but all three performed simultaneously generates a collision.

There is one last type of failure on which we remark. If we modify Example 3.3 so that squares are constrained to slide solely in the horizontal and vertical directions, then, indeed, the discretized cube complex now has no positive curvature, since sliding the same square horizontally and vertically no longer constitutes commutative moves. Because of this, however, there are nontrivial loops in $\pi_1(\mathcal{X})$ generated by moving a single square north-east-south-west in turn. There is one such loop for each vertex in $\mathcal{X}^{(n)}$, and the length of the loop is four times the discretized edge length. As $n \to \infty$, the number of such loops becomes arbitrarily large while their lengths become arbitrarily small: there is a "froth" of π_1. Even though normal cube paths (and hence

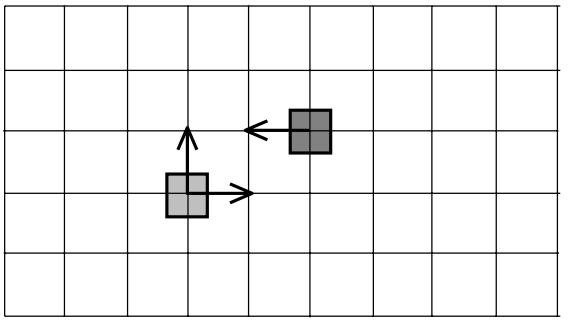

FIG. 8. *The link condition fails for cubical approximations to the coordination space of Example* 3.3*: the three translations shown can be performed simultaneously pairwise, but performing all three at once causes a collision.*

locally Pareto optimal representatives) are unique up to homotopy, the number of such homotopy classes blows up exponentially. In this case, the argument involving π_1 being finitely generated no longer holds, and, indeed, there are an uncountably infinite number of globally Pareto optimal paths in the limit.

9. Conclusion. The techniques we have introduced here—$CAT(0)$ geometry and nonpositive curvature—are very classical concepts. Yet their applications outside of geometry and algebra are in the very beginning stages, and we are hopeful that other problems in robotics and optimization will benefit from these perspectives. We end by noting that the problem of computing global Pareto optima is not dissimilar to that of computing Euclidean geodesics. It is well known that computing shortest paths in three dimensions is NP-hard in general [10] (see, e.g., [19] for an up-to-date account of hardness results for geodesics). It is worth noting that every example surveyed in [19] which has an NP-hard geodesic problem is not a $CAT(0)$ space. It would be a good omen for the applicability of $CAT(0)$ techniques if the geodesic problem simplified in the case of $CAT(0)$ spaces in general. In a parallel application, pursuit-evasion problems on domains of dimension greater than two depend crucially on the geometry and topology of the domain. For certain pursuit games, the existence of a successful pursuit strategy can be guaranteed on a $CAT(0)$ space [4].

FEEDBACK AND FEEDFORWARD OUTPUT REGULATION OF BOUNDED UNIFORMLY CONTINUOUS SIGNALS FOR INFINITE-DIMENSIONAL SYSTEMS*

EERO IMMONEN† AND SEPPO POHJOLAINEN†

Abstract. This article presents a state space output regulation theory for linear infinite-dimensional systems (with bounded control, observation, and feedthrough operators) in which the reference and disturbance signals are bounded and uniformly continuous. Output regulation problems are posed and solved for both feedforward and error feedback controllers. Furthermore, under certain assumptions necessary conditions are obtained for those controllers which solve these output regulation problems. One consequence of these necessary conditions is a generalization of the well-known internal model principle. A key feature in our theory is that the exogenous system generating the reference and disturbance signals is infinite-dimensional.

Key words. output regulation, infinite-dimensional systems, infinite-dimensional exogenous systems, bounded uniformly continuous signals, strong stability, regulator equations

1. Introduction.

The term output regulation is usually associated with the stabilization of a dynamical system and asymptotic tracking of a given class of reference signals under a given class of disturbances. Controllers which achieve output regulation are often either of feedforward or feedback type. For finite-dimensional linear systems and simple reference/disturbance signals generated by systems of linear ordinary differential equations, such output regulation problems were studied intensively in the 1970s. A complete solution now exists for both feedback and feedforward controllers, e.g., in the work of Francis, Wonham, and Davison [8, 10, 11, 26]. In addition to this, the necessary structure of a feedback controller which solves the output regulation problem is well known; it is formulated as the internal model principle—one of the cornerstones in classical automatic control theory. The principle asserts, roughly, that output regulation can be achieved only if the control system encapsulates a model of the dynamical structure of the reference/disturbance signals [10, 11].

The work of Francis and Wonham initiated what is nowadays known as geometric output regulation theory. This terminology stems from the fact that they studied output regulation problems in geometric terms, such as subspace inclusions. During the past two decades several authors have extended this theory to infinite-dimensional systems. In the early 1980s Schumacher [21] constructed finite-dimensional controllers for infinite-dimensional plants in which the system operator has compact resolvent and a complete set of generalized eigenfunctions. His solution of the output regulation problem is also expressed in geometric terms (cf. Theorem 3.1 in [21]). Several years later Byrnes et al. [3] generalized Francis's theory [10] for infinite-dimensional systems in such a way that the geometric conditions were replaced by the so-called regulator equations. These equations (which are in fact also present in the finite-dimensional case [10] and in a certain form in [21]) express the geometric conditions in an alge-

†Institute of Mathematics, Tampere University of Technology, PL 553, 33101 Tampere, Finland (Eero.Immonen@tut.fi, seppo.pohjolainen@tut.fi).

braic way, hence simplifying solution of the output regulation problem. Byrnes et al. [3] showed that solvability of the feedforward regulation problem, solvability of the error feedback regulation problem, and solvability of the regulator equations are all equivalent to each other provided that the plant and the finite-dimensional exogenous signal generator have sufficient stabilizability properties.

In the above approaches towards solving output regulation problems the class of admissible signals is rather small: The reference/disturbance signals are assumed to be generated by finite-dimensional exogenous systems, and they can be, e.g., ramps, constant signals, or sinusoids. Recently the feedforward output regulation theory of Byrnes et al. [3] was generalized for infinite-dimensional exogenous systems in [4, 5, 14, 15, 16]. In [4, 5] the one-dimensional wave equation is generating reference signals. In the present paper, as well as in [14], the exogenous system is *purpose-built* so that any bounded and uniformly continuous reference functions can be treated. This class of reference signals is essentially larger than that resulting from the use of a finite-dimensional exosystem; for example, it is possible to consider the asymptotic tracking of arbitrary sufficiently smooth periodic reference signals, as was done in [15, 16].

While in [14, 15, 16] only the use of feedforward control was considered, in this article we also extend the error feedback regulation theory of [3] to allow for any bounded uniformly continuous reference signals. The generalization is, however, not at all straightforward. In the case of a finite-dimensional exogenous system [3] it is reasonable to require the closed loop semigroup to be exponentially stable. However, in our setting this is not so; one may be required to stabilize an operator having an unbounded spectrum on the imaginary axis (see subsection 2.4). Since the error feedback regulation problem is solved by considering it as a feedforward control problem for the extended system, we are forced to solve both the feedforward (see section 3) and the error feedback (see section 4) regulation problems under the weaker assumption of strong closed loop stability. It turns out that, even under this weaker stability assumption, the regulator equations provide a solution to the output regulation problems. Yet their solvability is no longer necessary for output regulation unless certain additional conditions hold (see section 6).

The main results of this article are Theorems 3.1, 4.1, and 7.2:

- Theorem 3.1 provides a solution to the feedforward regulation problem. It shows that if the pair (A, B) in the plant is strongly stabilizable, then the feedforward control problem can be solved if the regulator equations (3.1) can be solved. In particular, this result generalizes Theorem IV.1 in [3], Theorem 3.1 in [16], and Corollary 3.3 in [14] for plants which are not necessarily exponentially stabilizable.
- Theorem 4.1 provides a solution to the error feedback regulation problem. It shows that if the closed loop system operator consisting of the plant and the controller generates a strongly stable semigroup, then output regulation occurs if two coupled pairs of regulator equations are satisfied—one for the plant (see (3.1)) and one for the controller (see (4.1)). A key feature in this result is that the controller structure is fixed, but the parameters can be freely chosen as long as the conditions are met. This result seems to be new even for finite-dimensional plants, and in particular its Corollary 4.2 generalizes Theorem IV.2 in [3], where the parameters of the controller are chosen to yield an observer.
- Theorem 7.2 is a direct generalization of the internal model principle in [10] for infinite-dimensional plants and bounded uniformly continuous ref-

erence/disturbance signals. Roughly stated, this result asserts that under certain auxiliary conditions the dynamics of the exogenous system must be embedded in the dynamics of the controller in order to obtain asymptotic tracking and closed loop stability. In the present form Theorem 7.2 seems to be new even for finite-dimensional plants, because the proof is new also for finite-dimensional exosystems (it utilizes semigroup methods, while matrix methods are used in [10]) and because the result also applies for general bounded and uniformly continuous reference/disturbance signals.

We conclude this introductory section with some remarks concerning the relation of our work to the so-called repetitive control scheme. Repetitive control is a frequency domain–based error feedback control technique introduced by Hara et al. [12] for the asymptotic tracking of periodic signals for finite-dimensional systems. Consequently the results of this paper partially overlap those in the repetitive control literature (see, e.g., [12, 27, 28] and the references therein). However, this overlap is not very large, as there are also some crucial differences between the present paper and the repetitive control literature. The most notable differences are the following: We work in the state space domain, we also allow for infinite-dimensional plants (this is not the case, e.g., in [12]), we consider both feedforward and error feedback control, and, finally, we also treat exogenous signals which are not periodic. Moreover, while in our case there is freedom in the choice of the parameters of the dynamic controller, the structure of a repetitive controller is fixed as it incorporates the internal model $\frac{1}{1-e^{-sp}}$ of p-periodic signals in the feedback loop. Yamamoto and Hara [28] have actually shown that it is also necessary to use this internal model if asymptotic tracking is to be achieved. Unfortunately, it turns out that the closed loop in a repetitive control system is notoriously difficult to stabilize, because this internal model is difficult to stabilize. Consequently in engineering applications one often resorts to the use of ad hoc design techniques to overcome this stabilizability problem; see, e.g., [25]. A similar stabilizability problem also arises in our work (section 5), although in our view the problem is not as severe in this paper as it is in the repetitive control literature. This is because the parameters of the controller are not fixed and because we only require strong stability of the semigroup generated by the closed loop system operator; for example, Yamamoto and Hara [28] require exponential stability (i.e., internal stability of the closed loop), which is difficult to achieve in practice. However, they could also conclude exponential decay of the tracking error.

1.1. Notation. For Banach spaces E and F, $\mathcal{L}(E,F)$ denotes the space of bounded linear operators $E \to F$ (all Banach spaces in this article are complex). The resolvent set of a closed linear operator $A : E \to F$ is denoted by $\rho(A)$, whereas $\sigma(A)$ denotes its spectrum. The approximate point spectrum of A is denoted by $\sigma_A(A)$ [9]. $R(\lambda, A)$ denotes (whenever it exists) the resolvent operator $(\lambda I - A)^{-1}$. If $\widetilde{E}$ is a subspace of E, then $A|_{\widetilde{E}}$ denotes the restriction of A to $\widetilde{E}$. The range of A is denoted by $\mathrm{ran}(A)$. A strongly continuous (or C_0) semigroup $T_A(t)$ in E is strongly stable if $\lim_{t\to\infty}\|T_A(t)x\| = 0$ for each $x \in E$. $T_A(t)$ is weakly stable if $\lim_{t\to\infty} f(T_A(t)x) = 0$ for each $x \in E$ and every functional $f \in \mathcal{L}(E,\mathbb{C})$. If A generates a C_0-semigroup in E and $B \in \mathcal{L}(F,E)$, then the pair (A,B) is strongly stabilizable if there exists $K \in \mathcal{L}(E,F)$ such that $A+BK$ generates a strongly stable semigroup in E. If $C \in \mathcal{L}(E,F)$, then the pair (A,C) is approximately observable if $\{\, x \in E \mid CT_A(t)x = 0 \text{ for all } t \geq 0 \,\} = \{0\}$. $\Re(z)$ denotes the real part of a complex number z and $i\mathbb{R}$ denotes the imaginary axis. $BUC(\mathbb{R},E)$ denotes the Banach space (with respect to sup-norm) of bounded uniformly continuous functions $f : \mathbb{R} \to E$.

The Carleman transform of $f \in BUC(\mathbb{R}, E)$ is defined by

$$\widetilde{f}(\lambda) = \begin{cases} \int_0^\infty e^{-\lambda t} f(t)dt, & \Re(\lambda) > 0, \\ -\int_{-\infty}^0 e^{-\lambda t} f(t)dt, & \Re(\lambda) < 0. \end{cases} \tag{1.1}$$

A point $\lambda_0 \in \mathbb{R}$ is called a regular point of f if $\widetilde{f}$ can be continued analytically into a neighborhood of $i\lambda_0$. The complement in $\mathbb{R}$ of the set of regular points is called the Carleman spectrum of f and it is denoted by $sp(f)$ [1, 24]. A function is almost periodic if it can be uniformly approximated by trigonometric polynomials [1].

2. Formulation of the output regulation problems. In this section we formulate the feedforward and error feedback output regulation problems. We begin by defining the plant and the exogenous system that generates the reference and disturbance signals.

2.1. The plant. We consider a plant described by the following (possibly infinite-dimensional) control system:

$$\dot{z}(t) = Az(t) + Bu(t) + \mathcal{U}_{dist}(t), \quad z(0) \in Z, \quad t \geq 0, \tag{2.1a}$$

$$y(t) = Cz(t) + Du(t), \quad t \geq 0. \tag{2.1b}$$

Here A generates a C_0-semigroup $T_A(t)$, $t \geq 0$, in a complex Banach space Z. The continuous input $u : \mathbb{R}_+ \to H$ and continuous output $y : \mathbb{R}_+ \to H$ take values in a complex Banach space H. The control operator $B \in \mathcal{L}(H, Z)$, the observation operator $C \in \mathcal{L}(Z, H)$, and the feedthrough operator $D \in \mathcal{L}(H)$ (bounded linear operators are denoted by $\mathcal{L}$). The continuous function $\mathcal{U}_{dist}$ is a disturbance (to be defined shortly). Equation (2.1a) is to be considered in the mild sense.

2.2. The exogenous system. Let $\mathcal{H}$ be a Banach space which is continuously embedded in $BUC(\mathbb{R}, H)$, the space of bounded uniformly continuous H-valued functions on $\mathbb{R}$ endowed with the sup-norm ($\mathcal{H}$ need not have the sup-norm). In symbols, let $\mathcal{H} \hookrightarrow BUC(\mathbb{R}, H)$. We let $T_S(t)$ denote the shift C_0-group in $BUC(\mathbb{R}, H)$ defined as $T_S(t)f = f(\cdot + t)$; its infinitesimal generator is $S = \frac{d}{dx}$ with the domain of definition $\mathcal{D}(S) = \{ f \in BUC(\mathbb{R}, H) \mid Sf \in BUC(\mathbb{R}, H) \} \subset BUC(\mathbb{R}, H)$. If $\mathcal{H}$ is invariant for $T_S(t)$ and the restrictions $T_S(t)|_{\mathcal{H}}$ to $\mathcal{H}$ constitute an isometric C_0-group, we denote this by $\mathcal{H} \overset{s}{\hookrightarrow} BUC(\mathbb{R}, H)$. In this case the generator of $T_S(t)|_{\mathcal{H}}$ is denoted by $S|_{\mathcal{H}}$.

Let $\mathcal{H} \overset{s}{\hookrightarrow} BUC(\mathbb{R}, H)$, and let Q denote the point evaluation at the origin in $\mathcal{H}$, i.e., $Qf = f(0)$ for $f \in \mathcal{H}$. Clearly Q is linear and $\|Qf\|_H = \|f(0)\|_H \leq \|f\|_\infty \leq c\|f\|_{\mathcal{H}}$ for some $c \geq 0$ (because $\mathcal{H} \hookrightarrow BUC(\mathbb{R}, H)$) and so $Q \in \mathcal{L}(\mathcal{H}, H)$. Moreover, $QT_S(t)|_{\mathcal{H}} f = f(x + t)|_{x=0} = f(t)$ for every $f \in \mathcal{H}$ and $t \in \mathbb{R}$. This leads us to the following definition.

DEFINITION 2.1 (the exogenous system). *Let $\mathcal{H} \overset{s}{\hookrightarrow} BUC(\mathbb{R}, H)$ and let $P \in \mathcal{L}(\mathcal{H}, Z)$ be a known disturbance operator. The exogenous system generating reference signals y_{ref} and disturbance signals $\mathcal{U}_{dist}$ is defined on the state space $\mathcal{H}$ as*

$$\dot{w}(t) = S|_{\mathcal{H}} w(t), \quad w(0) = w_0 \in \mathcal{H}, \tag{2.2a}$$

$$y_{ref}(t) = Qw(t), \quad t \in \mathbb{R}, \tag{2.2b}$$

$$\mathcal{U}_{dist}(t) = Pw(t), \quad t \in \mathbb{R}, \tag{2.2c}$$

where (2.2a) *is to be considered in the mild sense.*

By the above discussion it is easy to see that every reference signal y_{ref} in $\mathcal{H}$ can be obtained from (2.2b) by choosing $w(0) = y_{ref}$. Although we do not have such

precise knowledge of the disturbance signals $\mathcal{U}_{dist}$, the relation (2.2c) implies that the dynamical behavior of the disturbances must be similar to that of the reference signals: For example, if $\mathcal{H}$ consists of only p-periodic functions, then also every disturbance is a p-periodic function.

2.3. The feedforward regulation problem (FRP).

DEFINITION 2.2 (FRP). *The task in the feedforward regulation problem is to find operators $K \in \mathcal{L}(Z,H)$ and $L \in \mathcal{L}(\mathcal{H},H)$ having the following properties:*

1. *The pair (A,B) is strongly stabilizable using K, i.e., $A+BK$ generates a strongly stable C_0-semigroup T_{A+BK} on Z.*
2. *As the control law $u(t) = Kz(t) + Lw(t)$ is applied, in the extended system on $Z \times \mathcal{H}$ given by*

$$\dot{z}(t) = (A+BK)z(t) + (BL+P)w(t), \quad t \geq 0, \tag{2.3a}$$

$$\dot{w}(t) = S|_{\mathcal{H}} w(t) \tag{2.3b}$$

the tracking error $e(t) = y(t) - y_{ref}(t) = (C+DK)z(t) + (DL-Q)w(t) \to 0$ as $t \to \infty$ regardless of the initial conditions $z(0) \in Z$ and $w(0) \in \mathcal{H}$.

We hasten to emphasize that in the formulation of the FRP above, we do not require exponential stabilizability of the pair (A,B), as in [3, 16]. The concept of strong stability is more general than that of exponential stability, and it may be the more realistic one in applications. For example, for many partial differential equations it is known that solutions are stable, but no uniform decay rate exists [19]. Furthermore, that we do not require exponential stabilizability of (A,B) turns out to be important in the solution of the error feedback regulation problem described in the next subsection.

2.4. The error feedback regulation problem (EFRP). In practice the state $z(t)$ of the plant, which is used in the FRP, is usually not directly available for measurement. In this subsection we pose an output regulation problem which relies only on information on the outputs of the systems.

DEFINITION 2.3 (EFRP). *The task is to find an error feedback controller of the form*

$$\dot{x}(t) = Fx(t) + Ge(t), \quad x(0) \in X, \quad t \geq 0, \tag{2.4a}$$

$$u(t) = Jx(t) \tag{2.4b}$$

on some Banach state space X where F generates a C_0-semigroup, $G \in \mathcal{L}(H,X)$, and $J \in \mathcal{L}(X,H)$. The controller must satisfy the following requirements:

1. *In the closed loop system for $t \geq 0$,*

$$\dot{z}(t) = Az(t) + BJx(t) + Pw(t), \tag{2.5a}$$

$$\dot{x}(t) = GCz(t) + (F+GDJ)x(t) - GQw(t), \tag{2.5b}$$

$$\dot{w}(t) = S|_{\mathcal{H}} w(t), \tag{2.5c}$$

$$e(t) = Cz(t) + DJx(t) - Qw(t), \tag{2.5d}$$

the semigroup $T_{\mathcal{A}}(t)$ generated by $\mathcal{A} = \left(\begin{smallmatrix} A & BJ \\ GC & F+GDJ \end{smallmatrix}\right)$ in $Z \times X$ is strongly stable.

2. *The tracking error $e(t) \to 0$ as $t \to \infty$ for any initial conditions $z(0) \in Z$, $x(0) \in X$, and $w(0) \in \mathcal{H}$.*

Remark 2.4. Byrnes et al. [3] considered a similar error feedback regulation problem for finite-dimensional exosystems. However, they require exponential stability of $T_{\mathcal{A}}(t)$ and zero feedthrough, i.e., $D = 0$. It turns out that in our case exponential stability of $T_{\mathcal{A}}(t)$ is an unrealistic requirement if we plan to use the controller proposed by Byrnes et al. [3]. This is because their operator F (and hence also the closed loop system operator $\mathcal{A}$) contains a copy of $S|_{\mathcal{H}}$ according to the internal model principle. But it is well known that if $\mathcal{H}$ is infinite-dimensional, then $S|_{\mathcal{H}} + \Delta$ does not generate an exponentially stable C_0-semigroup for any compact operator $\Delta \in \mathcal{L}(\mathcal{H})$ (cf. Corollary 3.58 in [18]). Fortunately, although by the above we cannot in general require exponential stability of $T_{\mathcal{A}}(t)$ if $\mathcal{H}$ is infinite-dimensional, it is quite often possible to achieve strong stability of this closed loop semigroup even for infinite-dimensional spaces $\mathcal{H}$.

3. Sufficient conditions for the solvability of the FRP. In this section we show that if the so-called regulator equations can be solved, and if the pair (A, B) can be strongly stabilized, then the FRP can be solved. It is known that if (A, B) can actually be exponentially stabilized, then also a converse result is true, namely, that in this case exponentially fast output regulation implies solvability of the regulator equations (see [14]). However, in the case that (A, B) is only strongly stabilizable, solvability of the FRP alone does not imply solvability of the regulator equations; necessary conditions for the solvability of the regulator equations and the FRP are presented in section 6.

THEOREM 3.1. *Assume that the pair (A, B) is strongly stabilizable using $K \in \mathcal{L}(H, Z)$. If there exist $\Pi \in \mathcal{L}(\mathcal{H}, Z)$ and $\Gamma \in \mathcal{L}(\mathcal{H}, H)$ such that $\Pi(\mathcal{D}(S|_{\mathcal{H}})) \subset \mathcal{D}(A)$ and the regulator equations*

$$A\Pi + B\Gamma + P = \Pi S|_{\mathcal{H}} \quad \text{in } \mathcal{D}(S|_{\mathcal{H}}), \tag{3.1a}$$

$$C\Pi + D\Gamma = Q \quad \text{in } \mathcal{H} \tag{3.1b}$$

are satisfied, then the control law $u(t) = Kz(t) + (\Gamma - K\Pi)w(t)$ solves the FRP.

Proof. Since by assumption $A + BK$ generates the strongly stable C_0-semigroup $T_{A+BK}(t)$, we only need to verify condition 2 in Definition 2.2. Let $L = \Gamma - K\Pi \in \mathcal{L}(\mathcal{H}, H)$. Since $\Pi S|_{\mathcal{H}} = (A + BK)\Pi + BL + P$ in $\mathcal{D}(S|_{\mathcal{H}})$, it is easy to see that

$$\begin{aligned}
&\int_0^t T_{A+BK}(t-\tau)(BL+P)T_S(\tau)|_{\mathcal{H}} w\,d\tau \\
&\quad = \int_0^t T_{A+BK}(t-\tau)\big[\Pi S|_{\mathcal{H}} - (A+BK)\Pi\big]T_S(\tau)|_{\mathcal{H}} w\,d\tau && (3.2)\\
&\quad = \int_0^t \frac{d}{d\tau} T_{A+BK}(t-\tau)\Pi T_S(\tau)|_{\mathcal{H}} w\,d\tau && (3.3)\\
&\quad = \Pi T_S(t)|_{\mathcal{H}} w - T_{A+BK}(t)\Pi w && (3.4)
\end{aligned}$$

for every $w \in \mathcal{D}(S|_{\mathcal{H}})$ and $t \geq 0$. By suitable density arguments it is in fact true that

$$\int_0^t T_{A+BK}(t-\tau)(BL+P)T_S(\tau)|_{\mathcal{H}} w\,d\tau = \Pi T_S(t)|_{\mathcal{H}} w - T_{A+BK}(t)\Pi w \tag{3.5}$$

for every $w \in \mathcal{H}$ and $t \geq 0$.

Consider then the composite operator $\mathcal{A}$ on the extended state space $Z \times \mathcal{H}$ (see (2.3)) defined as

$$\mathcal{A} = \begin{pmatrix} A + BK & BL + P \\ 0 & S|_{\mathcal{H}} \end{pmatrix}. \tag{3.6}$$

Since $A+BK$ generates the C_0-semigroup $T_{A+BK}(t)$ on Z and $S|_{\mathcal{H}}$ generates the C_0-(semi)group $T_S(t)|_{\mathcal{H}}$ on $\mathcal{H}$, it is clear that $\mathcal{A}$ generates a C_0-semigroup $T_{\mathcal{A}}(t)$ on $Z\times\mathcal{H}$, because $BL+P\in\mathcal{L}(\mathcal{H},Z)$ (see also [6, Lemma 3.2.2]). An easy calculation reveals that this semigroup is given by

$$T_{\mathcal{A}}(t)=\begin{pmatrix} T_{A+BK}(t) & \int_0^t T_{A+BK}(t-\tau)(BL+P)T_S(\tau)|_{\mathcal{H}}\,d\tau \\ 0 & T_S(t)|_{\mathcal{H}}\end{pmatrix} \tag{3.7}$$

$$=\begin{pmatrix} T_{A+BK}(t) & \Pi T_S(t)|_{\mathcal{H}}-T_{A+BK}(t)\Pi \\ 0 & T_S(t)|_{\mathcal{H}}\end{pmatrix}. \tag{3.8}$$

Let $z(0)=z_0\in Z$ and $w(0)=w_0\in\mathcal{H}$ be arbitrary. Then

$$T_{\mathcal{A}}(t)\left(\begin{smallmatrix} z_0\\ w_0\end{smallmatrix}\right)=\begin{pmatrix} T_{A+BK}(t)(z_0-\Pi w_0)+\Pi T_S(t)|_{\mathcal{H}}w_0\\ T_S(t)|_{\mathcal{H}}w_0\end{pmatrix}. \tag{3.9}$$

Since by (3.1b) we have $(C+DK)\Pi+DL-Q=C\Pi+D\Gamma-Q=0$, the explicit expression for the norm of the tracking error $e(t)$ is as follows:

$$\|e(t)\|=\|(C+DK)T_{A+BK}(t)(z_0-\Pi w_0)+(C\Pi+D\Gamma-Q)T_S(t)|_{\mathcal{H}}w_0\| \tag{3.10}$$

$$=\|(C+DK)T_{A+BK}(t)(z_0-\Pi w_0)\|\quad\forall t\geq 0 \tag{3.11}$$

Since $T_{A+BK}(t)$ is strongly stable and $C+DK\in\mathcal{L}(Z,H)$, we have that $e(t)\to 0$ as $t\to\infty$. This shows that the tracking condition of Definition 2.2 is also satisfied. The proof is then complete. □

Remark 3.2. In the case of a finite-dimensional space $H=\mathbb{C}^M$, $M\in\mathbb{N}$, it is sufficient in Theorem 3.1 for asymptotic tracking to occur that the pair (A,B) is merely weakly stabilizable. In this case $C+DK\in\mathcal{L}(Z,\mathbb{C}^M)$ and so $P_{e_k}(C+DK)\in\mathcal{L}(Z,\mathbb{C})$ for all $1\leq k\leq M$. Here $(e_j)_{1\leq j\leq N}$ is the canonical orthonormal basis of $\mathbb{C}^M$ and $P_{e_k}=\langle\cdot,e_k\rangle\in\mathcal{L}(\mathbb{C}^M,\mathbb{C})$. Hence for every $z\in Z$ and for every $1\leq k\leq M$ we have $\lim_{t\to\infty}P_{e_k}(C+DK)T_{A+BK}(t)z=0$ (see (3.11)). Thus also $\lim_{t\to\infty}(C+DK)T_{A+BK}(t)z=0$.

4. Sufficient conditions for the solvability of the EFRP. In this section we show that the regulator equations can be used to solve the EFRP too. In addition, it turns out to be possible to obtain a rather complete description of suitable error feedback controllers (2.4) in terms of solutions to another regulator equations—the so-called regulator equations for the error feedback controller—which have the same form as (3.1). We point out that to our knowledge no such description has been available for infinite-dimensional plants: Byrnes et al. [3], for example, give *one possible choice* for the stabilizing and regulating dynamic controller (2.4).

Our main result in this section is Theorem 4.1 below. Notable in its proof is the use of a marvelous argument due to Francis (see also Byrnes et al. [3]): The error feedback control problem is interpreted as a feedforward control problem for the extended system, and this problem is then solved in terms of the FRP.

THEOREM 4.1. *Assume that there exist* $\Pi\in\mathcal{L}(\mathcal{H},Z)$ *and* $\Gamma\in\mathcal{L}(\mathcal{H},H)$ *such that* $\Pi(\mathcal{D}(S|_{\mathcal{H}}))\subset\mathcal{D}(A)$ *and the regulator equations* (3.1) *are satisfied. If the parameters* F, G, *and* J *of the controller* (2.4) *can be chosen such that*

1. *the operator* $\mathcal{A}=\left(\begin{smallmatrix} A & BJ\\ GC & F+GDJ\end{smallmatrix}\right)$ *generates a strongly stable* C_0*-semigroup* $T_{\mathcal{A}}(t)$ *on* $Z\times X$*; and*
2. *there exists* $\Lambda\in\mathcal{L}(\mathcal{H},X)$ *such that* $\Lambda(\mathcal{D}(S|_{\mathcal{H}}))\subset\mathcal{D}(F)$ *and the regulator equations for the error feedback controller,*

$$F\Lambda=\Lambda S|_{\mathcal{H}}\quad\text{in }\mathcal{D}(S|_{\mathcal{H}}), \tag{4.1a}$$

$$J\Lambda = \Gamma \quad \text{in } \mathcal{H}, \tag{4.1b}$$

are satisfied, then with this triplet (F, G, J) the EFRP is solvable.

Proof. Let $\Theta(t) = \binom{z(t)}{x(t)} \in Z \times X$ and define

$$\mathcal{A} = \begin{pmatrix} A & BJ \\ GC & F + GDJ \end{pmatrix}, \quad \mathcal{B} = \begin{pmatrix} 0 \\ 0 \end{pmatrix}, \quad \mathcal{P} = \begin{pmatrix} P \\ -GQ \end{pmatrix}, \quad \mathcal{C} = \begin{pmatrix} C & DJ \end{pmatrix}, \quad \mathcal{D} = 0. \tag{4.2}$$

Then consider the system

$$\dot{\Theta}(t) = \mathcal{A}\Theta(t) + \mathcal{B}u(t) + \mathcal{P}w(t), \quad \Theta(0) \in Z \times X, \quad t \geq 0, \tag{4.3a}$$

$$y(t) = \mathcal{C}\Theta(t) + \mathcal{D}u(t), \quad t \geq 0, \tag{4.3b}$$

with $\dot{w}(t) = S|_{\mathcal{H}} w(t)$. Since the regulator equations (3.1) and the regulator equations (4.1) for the error feedback controller are satisfied, we have $\Pi S|_{\mathcal{H}} = A\Pi + BJ\Lambda + P$ and $\Lambda S|_{\mathcal{H}} = F\Lambda = GC\Pi + (F + GDJ)\Lambda - GQ$ in $\mathcal{D}(S|_{\mathcal{H}})$. Hence

$$\begin{pmatrix} \Pi \\ \Lambda \end{pmatrix} S|_{\mathcal{H}} = \begin{pmatrix} A & BJ \\ GC & F + GDJ \end{pmatrix} \begin{pmatrix} \Pi \\ \Lambda \end{pmatrix} + \begin{pmatrix} P \\ -GQ \end{pmatrix} \quad \text{in } \mathcal{D}(S|_{\mathcal{H}}), \tag{4.4}$$

$$Q = \begin{pmatrix} C & DJ \end{pmatrix} \begin{pmatrix} \Pi \\ \Lambda \end{pmatrix} \quad \text{in } \mathcal{H}, \tag{4.5}$$

which shows that the regulator equations (3.1) for the system (4.3) have a solution. Consequently, by Theorem 3.1 and the strong stability assumption, for the system (4.3) the FRP is solvable for the control law $u(t) = \mathcal{K}\Theta(t) + \mathcal{L}w(t) \equiv 0$ (recall that $\mathcal{B} = 0$ and $\mathcal{D} = 0$). This implies that in (2.5d) the tracking error $e(t) = Cz(t) + DJx(t) - Qw(t) = (\mathcal{C} + \mathcal{D}\mathcal{K})\Theta(t) + (\mathcal{D}\mathcal{L} - Q)w(t) \to 0$ as $t \to \infty$ regardless of the initial conditions $z(0)$, $x(0)$, and $w(0)$. ∎

The following corollary generalizes heorem IV.2 in [3]. It presents one possible choice for the triplet (F, G, J) in the solution of EFRP under two stability assumptions and the assumption $D = 0$.

COROLLARY 4.2. *Let $X = Z \times \mathcal{H}$. Assume that $D = 0$ and that*

1. *there exist $\Pi \in \mathcal{L}(\mathcal{H}, Z)$ and $\Gamma \in \mathcal{L}(\mathcal{H}, H)$ which solve the regulator equations (3.1);*
2. *the pair (A, B) is exponentially stabilizable using $K \in \mathcal{L}(Z, H)$; and*
3. *there exist $G_1 \in \mathcal{L}(H, Z)$ and $G_2 \in \mathcal{L}(H, \mathcal{H})$ such that the operator $\mathcal{A}_s = \begin{pmatrix} A - G_1 C & P + G_1 Q \\ -G_2 C & S|_{\mathcal{H}} + G_2 Q \end{pmatrix}$ generates a strongly stable C_0-semigroup $T_{\mathcal{A}_s}(t)$ in X.*

Let

$$F = \begin{pmatrix} A + BK - G_1 C & P + B(\Gamma - K\Pi) + G_1 Q \\ -G_2 C & S|_{\mathcal{H}} + G_2 Q \end{pmatrix}, \quad J = \begin{pmatrix} K & \Gamma - K\Pi \end{pmatrix}, \quad \text{and} \quad G = \begin{pmatrix} G_1 \\ G_2 \end{pmatrix}. \tag{4.6}$$

Then with this choice of (F, G, J) the EFRP is solvable.

Proof. Let $\Lambda = \binom{\Pi}{I} \in \mathcal{L}(\mathcal{H}, Z \times \mathcal{H})$. Then $J\Lambda = K\Pi + \Gamma - K\Pi = \Gamma$ and it is elementary to verify that $\Lambda S|_{\mathcal{H}} = F\Lambda$ in $\mathcal{D}(S|_{\mathcal{H}})$. Hence Λ solves the regulator equations (4.1) for the error feedback controller (4.6).

Consider the operator

$$\mathcal{A} = \begin{pmatrix} A & BJ \\ GC & F \end{pmatrix} = \begin{pmatrix} A & BK & B(\Gamma - K\Pi) \\ G_1 C & A + BK - G_1 C & P + B(\Gamma - K\Pi) + G_1 Q \\ G_2 C & -G_2 C & S|_{\mathcal{H}} + G_2 Q \end{pmatrix}. \tag{4.7}$$

If we can establish that $\mathcal{A}$ generates a strongly stable C_0-semigroup $T_{\mathcal{A}}(t)$, then the error feedback controller (4.6) solves the EFRP by Theorem 4.1.

Applying a similarity transform U given as

$$U = \begin{pmatrix} I & 0 & 0 \\ I & -I & 0 \\ 0 & 0 & -I \end{pmatrix} \tag{4.8}$$

on $Z \times Z \times \mathcal{H}$ to $\mathcal{A}$ we obtain the operator $\widetilde{\mathcal{A}} = U\mathcal{A}U$ having the expression

$$\widetilde{\mathcal{A}} = \begin{pmatrix} A+BK & -BK & -B(\Gamma - K\Pi) \\ 0 & A - G_1C & P + G_1Q \\ 0 & -G_2C & S|_{\mathcal{H}} + G_2Q \end{pmatrix} := \begin{pmatrix} A+BK & \Delta \\ 0 & \mathcal{A}_s \end{pmatrix}. \tag{4.9}$$

By our assumption $\mathcal{A}_s$ generates a strongly stable C_0-semigroup in X and $A + BK$ generates an exponentially stable C_0-semigroup in Z. Clearly the C_0-semigroup generated by $\widetilde{\mathcal{A}}$ on $Z \times X$ is given by

$$T_{\widetilde{\mathcal{A}}}(t) = \begin{pmatrix} T_{A+BK}(t) & \int_0^t T_{A+BK}(t-s)\Delta T_{\mathcal{A}_s}(s)ds \\ 0 & T_{\mathcal{A}_s}(t) \end{pmatrix}. \tag{4.10}$$

Consequently $T_{\widetilde{\mathcal{A}}}(t)$ is strongly stable if

$$\lim_{t\to\infty} \int_0^t T_{A+BK}(t-s)\Delta T_{\mathcal{A}_s}(s)xds = 0 \quad \forall x \in X. \tag{4.11}$$

But (4.11) holds by Proposition 5.6.1 in [1]. This proves that also $T_{\mathcal{A}}(t)$ is strongly stable. □

5. When does $\mathcal{A}_s$ generate a strongly stable semigroup? In this section we discuss the strong detectability of the pair $(\mathcal{A}_0, \mathcal{C})$ where $\mathcal{A}_0 = \left(\begin{smallmatrix} A & P \\ 0 & S|_{\mathcal{H}} \end{smallmatrix}\right)$ and $\mathcal{C} = \begin{pmatrix} C & -Q \end{pmatrix}$. In other words, we want to find $\mathcal{G} \in \mathcal{L}(H, Z\times\mathcal{H})$ such that $\mathcal{A}_s = \mathcal{A}_0 + \mathcal{G}\mathcal{C}$ generates a strongly stable C_0-semigroup $T_{\mathcal{A}_s}(t)$. This is assumption 3 in Corollary 4.2 and consequently the question deserves some attention.

In the finite-dimensional case it is well known that the pair $(\mathcal{A}_0, \mathcal{C})$ is strongly (and hence also exponentially) detectable if the pair $(\mathcal{A}_0, \mathcal{C})$ is observable. However, the infinite-dimensional setting is much more complicated [6]. In the case of an infinite-dimensional plant and a finite-dimensional exogenous system Byrnes et al. [3] state that undetectability of the pair $(\mathcal{A}_0, \mathcal{C})$ indicates a redundancy in the exogenous system, which can be removed by eliminating superfluous exosystem variables. Based on this remark they assume that the pair $(\mathcal{A}_0, \mathcal{C})$ is exponentially detectable. However, if the exogenous system is not finite-dimensional, then it is unreasonable to assume that the pair $(\mathcal{A}_0, \mathcal{C})$ would be exponentially detectable. In fact, if $\mathcal{H}$ is infinite-dimensional, then by Corollary 3.58 in [18] the operator $S|_{\mathcal{H}} + \Delta$ does not generate an exponentially stable semigroup for any compact $\Delta \in \mathcal{L}(\mathcal{H})$; hence it is not realistic to assume exponential detectability of $(\mathcal{A}_0, \mathcal{C})$ if $\mathcal{H}$ is infinite-dimensional.

In the following two subsections we discuss the strong detectability of the pair $(\mathcal{A}_0, \mathcal{C})$. First, a method based on the use of a Riccati equation is presented. Thereafter we propose a direct approach in which we assume the pair (A, C) in the plant to be exponentially detectable.

5.1. Strong stability via a Riccati equation. Algebraic Riccati equations provide a useful method for the study of strong detectability of the pair $(\mathcal{A}_0, \mathcal{C})$. Using this approach, in Proposition 5.1 we present sufficient conditions for the existence of a strongly stabilizing output injection operator; the operator itself can be found by solving a suitable Riccati equation. Recall in that if H is a Hilbert space, then $U \in \mathcal{L}(H)$ is coercive provided $\langle Uh, h\rangle \geq \epsilon \|h\|^2$ for some $\epsilon > 0$ and all $h \in H$. In the following $\mathcal{A}_0^*$ denotes the adjoint operator of $\mathcal{A}_0$.

PROPOSITION 5.1. *Assume the following:*

1. *H and $Z \times \mathcal{H}$ are (separable) Hilbert spaces.*
2. *$\mathcal{A}_0$ generates a contraction C_0-semigroup in $Z \times \mathcal{H}$.*
3. *The pair $(\mathcal{A}_0^*, \mathcal{C})$ is approximately observable.*
4. *$\mathcal{A}_0$ has compact resolvent.*

Then for any coercive operators $U = U^* \in \mathcal{L}(H)$ and $R = R^* \in \mathcal{L}(H)$ the Riccati equation

$$\mathcal{A}_0 \Delta z + \Delta \mathcal{A}_0^* z - \Delta \mathcal{C}^* R^{-1} \mathcal{C} \Delta z + \mathcal{C}^* U^{-1} \mathcal{C} z = 0 \quad \forall z \in \mathcal{D}(\mathcal{A}_0) \tag{5.1}$$

has a unique self-adjoint solution $\Delta \in \mathcal{L}(Z \times \mathcal{H})$ such that $\mathcal{A}_s = \mathcal{A}_0 - \Delta^* \mathcal{C}^* (R^{-1})^* \mathcal{C}$ generates a strongly stable C_0-semigroup.

Proof. It is evident that since $\mathcal{A}_0$ has compact resolvent, so does $\mathcal{A}_0^*$ because for real $\alpha \in \rho(\mathcal{A}_0)$ we have $R(\alpha, \mathcal{A}_0^*) = R(\alpha, \mathcal{A}_0)^*$ (cf. Lemma A.3.65 in [6], Theorem 7.3 in [22], and equality (A.3.15) in [6]). Furthermore, $\mathcal{A}_0^*$ also generates a contraction semigroup on $Z \times \mathcal{H}$ because $\|T_{\mathcal{A}_0}(t)\| = \|T_{\mathcal{A}_0^*}(t)\| \leq 1$ for each $t \geq 0$. By Theorem 4 in [7], the algebraic Riccati equation (3.1) has a unique self-adjoint solution $\Delta \in \mathcal{L}(Z \times \mathcal{H})$. By Corollary 5 in [7] the operator $\mathcal{A}_s^* = \mathcal{A}_0^* - \mathcal{C}^* R^{-1} \mathcal{C} \Delta$ generates a strongly stable C_0-semigroup. Consequently its adjoint $\mathcal{A}_s = \mathcal{A}_0 - \Delta \mathcal{C}^* (R^{-1})^* \mathcal{C}$ generates a weakly stable C_0-semigroup. But since $\mathcal{A}_0$ has compact resolvent, the boundedly perturbed operator $\mathcal{A}_s$ also has compact resolvent (cf. [9, p. 159]). This implies that the semigroup generated by $\mathcal{A}_s$ is in fact strongly stable (see, e.g., [7, Lemma 1] or [18, Proposition 3.21]). ∎

If the assumptions of Proposition 5.1 are met, we may choose as the strongly stabilizing output injection $\mathcal{G} = -\Delta \mathcal{C}^* (R^{-1})^*$.

Although neither exponential stabilizability nor detectability is required of the plant, the assumptions of Proposition 5.1 may seem somewhat restrictive. However, assumption 1 can be met if H and Z are Hilbert spaces, and if one considers the asymptotic tracking of periodic reference signals; the state space $\mathcal{H}$ can then be chosen as some Sobolev-type space of periodic functions (cf. [16]). Assumptions 2 and 3 are of a technical nature, but they are easy to verify if, say, there are no disturbances. Observe that $S|_{\mathcal{H}}$ always generates a contraction C_0-group. On the other hand, $\mathcal{A}_0$ has compact resolvent if $S|_{\mathcal{H}}$ and A have compact resolvents. In the case of periodic reference signals (i.e., whenever $T_S(t)|_{\mathcal{H}}$ is periodic), $S|_{\mathcal{H}}$ often has compact resolvent [9]. Moreover many differential operators A have compact resolvents [9]. Hence assumptions 2–4 of Proposition 5.1 can be met in many important special cases.

5.2. A direct method for exponentially detectable pairs (A, C). The difficulty in obtaining stability of $T_{\mathcal{A}_s}(t)$ lies in the fact that $\mathcal{A}_0$ contains a copy of $S|_{\mathcal{H}}$ which is hard to stabilize. We next show that this unfortunate state of matters can be, up to a certain point, compensated by good stabilizability properties of the plant.

THEOREM 5.2. *Let $G_1 \in \mathcal{L}(H,Z)$ be such that $A+G_1C$ generates an exponentially stable C_0-semigroup $T_{A+G_1C}(t)$. Define the bounded linear operator $Y : \mathcal{H} \to Z$ as*

$$Yw = \int_0^\infty T_{A+G_1C}(t)(G_1Q-P)T_S(-t)|_{\mathcal{H}} w dt \quad \forall w \in \mathcal{H}. \tag{5.2}$$

If $S|_{\mathcal{H}} - G_2(CY+Q)$ generates a strongly stable C_0-semigroup, then so does $\mathcal{A}_s = \mathcal{A} + \mathcal{GC}$. Here

$$\mathcal{G} = \left(\begin{smallmatrix} G_1 - YG_2 \\ G_2 \end{smallmatrix}\right). \tag{5.3}$$

Proof. By the results of [23] we know that $YS|_{\mathcal{H}} = (A+G_1C)Y + G_1Q - P$ in $\mathcal{D}(S|_{\mathcal{H}})$. It is then easy to see that

$$\begin{pmatrix} I & Y \\ 0 & I \end{pmatrix} \left[\begin{pmatrix} A & P \\ 0 & S|_{\mathcal{H}} \end{pmatrix} + \begin{pmatrix} G_1 - YG_2 \\ G_2 \end{pmatrix} \begin{pmatrix} C & -Q \end{pmatrix} \right] \begin{pmatrix} I & -Y \\ 0 & I \end{pmatrix} \tag{5.4}$$

$$= \begin{pmatrix} A+G_1C & 0 \\ G_2C & S|_{\mathcal{H}} - G_2(CY+Q) \end{pmatrix} = \mathcal{A}^s \tag{5.5}$$

so that $\mathcal{A}_s$ is similar to the operator $\mathcal{A}^s$ in (5.5). The semigroup $T_{\mathcal{A}^s}(t)$ generated by $\mathcal{A}^s$ is given by

$$T_{\mathcal{A}^s}(t) = \begin{pmatrix} T_{A+G_1C}(t) & 0 \\ \int_0^t T_{S|_{\mathcal{H}}-G_2(CY+Q)}(t-s)G_2CT_{A+G_1C}(s)ds & T_{S|_{\mathcal{H}}-G_2(CY+Q)}(t) \end{pmatrix}, \quad t \geq 0, \tag{5.6}$$

where $T_{S|_{\mathcal{H}}-G_2(CY+Q)}(t)$ is the strongly stable C_0-semigroup generated by $S|_{\mathcal{H}} - G_2(CY+Q)$. Since by our assumption $T_{A+G_1C}(t)$ is exponentially stable, we only need to show that

$$\lim_{t\to\infty} \int_0^t T_{S|_{\mathcal{H}}-G_2(CY+Q)}(t-s)G_2CT_{A+G_1C}(s)wds = 0 \quad \forall w \in \mathcal{H} \tag{5.7}$$

to ensure that $\mathcal{A}^s$ (and hence also $\mathcal{A}_s$) generates a strongly stable C_0-semigroup. However, the fact that (5.7) holds for each $w \in \mathcal{H}$ follows immediately from [1, Proposition 5.6.4.]. ∎

Remark 5.3. The result of Theorem 5.2 could also be formulated as follows. Assume that for some $G_1 \in \mathcal{L}(H,Z), G_2 \in \mathcal{L}(H,\mathcal{H})$, and $R \in \mathcal{L}(\mathcal{H},H)$ the operator $A+G_1C$ generates an exponentially stable C_0-semigroup on Z and that $S|_{\mathcal{H}} - G_2R$ generates a strongly stable C_0-semigroup on $\mathcal{H}$. If the operator equations

$$YS|_{\mathcal{H}} = AY + G_1R - P \quad \text{in } \mathcal{D}(S|_{\mathcal{H}}), \tag{5.8a}$$

$$R = CY + Q \quad \text{in } \mathcal{H} \tag{5.8b}$$

have a solution Y, then $\mathcal{A}_s = \mathcal{A} + \mathcal{GC}$ generates a strongly stable C_0-semigroup on $Z \times \mathcal{H}$ if we utilize the operator $\mathcal{G}$ of (5.3). Observe that now $(A+G_1C)Y + G_1Q - P = AY + G_1R - P = YS|_{\mathcal{H}}$ in $\mathcal{D}(S|_{\mathcal{H}})$, so that the solution operator Y (if it exists) is given by (5.2).

6. Characterizations for the solvability of the regulator equations and the regulation problems. In the results of sections 3 and 4 there are two key ingredients in the solution of the output regulation problems: strong stability of an appropriate semigroup and solvability of the regulator equations. In particular, if

strong stability of the semigroup has been established, then the output regulation problem is solvable provided that certain regulator equations are solvable. In this section we discuss a converse question: Is it necessary to solve the regulator equations in order to solve the corresponding output regulation problem? An answer to this question also provides a deeper insight into what happens in the closed loop control system after the application of a control law involving solutions of the regulator equations. For example, it is well known [3, 16] that the regulator equations express the existence of a subspace in the extended system on which the actual and reference outputs coincide and which is invariant for the extended semigroup.

For exponentially stabilizable pairs (A, B) and finite-dimensional exogenous systems it has been shown in [3] that solvability of the FRP is equivalent to solvability of the regulator equations (3.1). This result was generalized for the infinite-dimensional exogenous systems (2.1) in [14]. We shall see in this section that in the case of strongly stabilizable pairs (A, B) things get slightly more complicated. In order to study the problem, we need some preliminary results and definitions. An important role in this section will be played by closed, translation invariant, operator invariant spaces (CTO spaces) [24]. We will show that if $\mathcal{H}$ is a CTO space which does not contain functions vanishing at $+\infty$, then solvability of the output regulation problems FRP and EFRP imply solvability of the regulator equations under certain additional conditions *not including* that of exponential stabilizability.

DEFINITION 6.1. *A subspace $\mathcal{H} \subset BUC(\mathbb{R}, H)$ is CTO if*

1. *the space $\mathcal{H}$ is closed with respect to* sup*-norm and translation invariant (i.e., invariant for $T_S(t)$);*
2. *the space $\mathcal{H}$ is operator invariant, i.e., for every $f \in \mathcal{H}$ and every $R \in \mathcal{L}(\mathcal{H}, H)$ the function $g : t \to RT_S(t)|_{\mathcal{H}} f$ is in $\mathcal{H}$.*

Example 6.2. The space $\mathcal{H} = P_p(\mathbb{R}, H) = \{ f \in BUC(\mathbb{R}, H) \mid f(x + p) = f(x)$ for all $x \in \mathbb{R} \}$ of p-periodic H-valued bounded uniformly continuous functions is evidently a CTO space.

Example 6.3. The space $\mathcal{H} = AP(\mathbb{R}, H) \subset BUC(\mathbb{R}, H)$ of H-valued almost periodic functions is a CTO space. In fact, clearly $AP(\mathbb{R}, H)$ is closed and translation invariant [1, 13]. Moreover, by definition, any almost periodic function $f \in AP(\mathbb{R}, H)$ can be approximated in the sup-norm by trigonometric polynomials $\sum_{n \in I} f_n e^{i\omega_n \cdot}$ (where I is a finite set of indices). Since $\|RT_S(t)|_{\mathcal{H}}\| \leq \|R\|$ for all $t \in \mathbb{R}$ and since $RT_S(t)|_{\mathcal{H}} \sum_{n \in I} f_n e^{i\omega_n \cdot}$ is again a trigonometric polynomial, it is evident that $RT_S(t)|_{\mathcal{H}} f$ can be uniformly approximated by trigonometric polynomials whenever the same is true for f. In conclusion, $AP(\mathbb{R}, H)$ is a CTO space.

Example 6.4. An even less trivial example of a CTO space is $\mathcal{H} = \{ f \in BUC(\mathbb{R}, H) \mid \mathrm{sp}(f) \subset \Lambda \}$, where $sp(f)$ denotes the Carleman spectrum of f [13, 24] and $\Lambda \subset \mathbb{R}$ is a closed set. We refer the reader to [24, 13] for more details (see in particular [24, Example 1]).

In what follows we derive necessary conditions for output regulation in the case that the reference signals are in some fixed CTO space $\mathcal{H}$. The following concept of regular admissibility of an operator will be crucial.

DEFINITION 6.5. *An operator $\Delta \in \mathcal{L}(\mathcal{H}, Z)$ is said to be regularly admissible for the semigroup $T_A(t)$ if there exists $\Pi \in \mathcal{L}(\mathcal{H}, Z)$ such that $\Pi(\mathcal{D}(S|_{\mathcal{H}})) \subset \mathcal{D}(A)$ and such that for every $w \in \mathcal{H}$ the function $t \to z(t) = \Pi T_S(t)|_{\mathcal{H}} w$ is a mild solution of the differential equation $\dot{z}(t) = Az(t) + \Delta T_S(t)|_{\mathcal{H}} w$ on the whole real line, i.e., z satisfies*

$$z(t) = T_A(t - s)z(s) + \int_s^t T_A(t - \tau)\Delta T_S(\tau)|_{\mathcal{H}} w d\tau \quad \forall t \geq s. \tag{6.1}$$

Remark 6.6. In (6.1) t and s need not be nonnegative. Moreover, $z(t) = \Pi T_S(t)|_{\mathcal{H}} w$, with $w \in \mathcal{H}$, need not be the *only* mild solution of the differential equation $\dot{z}(t) = Az(t) + \Delta T_S(t)|_{\mathcal{H}} w$ on the real line.

Remark 6.7. The significance of the concept of regular admissibility in our analysis is, roughly stated, the following: If an operator $\Delta \in \mathcal{L}(\mathcal{H}, Z)$ is regularly admissible for $T_A(t)$, then the dynamical behavior of some mild solution (namely, $\Pi T_S(t)|_{\mathcal{H}} w$) of the differential equation $\dot{z}(t) = Az(t) + \Delta T_S(t)|_{\mathcal{H}} w$ on the whole real line is solely determined by the dynamical behavior of the exosystem (2.2). For example, if $\mathcal{H} = P_p(\mathbb{R}, H)$ as in Example 6.2 and if $\Delta \in \mathcal{L}(\mathcal{H}, Z)$ is regularly admissible for $T_A(t)$, then the above differential equation has at least one p-periodic mild solution on the whole real line. This feature will be utilized in the subsequent results.

Lemma 6.8 below is one of the main results in this section. Observe that we do not need exponential stability of $T_A(t)$ in it.

LEMMA 6.8. *The operator equation* $\Pi S|_{\mathcal{H}} = A\Pi + \Delta$ *in* $\mathcal{D}(S|_{\mathcal{H}})$ *has a solution* $\Pi \in \mathcal{L}(\mathcal{H}, Z)$ *if and only if* $\Delta \in \mathcal{L}(\mathcal{H}, Z)$ *is regularly admissible for* $T_A(t)$.

Proof. Let $\Pi \in \mathcal{L}(\mathcal{H}, Z)$ such that $\Pi(\mathcal{D}(S|_{\mathcal{H}})) \subset \mathcal{D}(A)$ and $\Pi S|_{\mathcal{H}} = A\Pi + \Delta$ in $\mathcal{D}(S|_{\mathcal{H}})$. Let $w \in \mathcal{H}$ be arbitrary and set $z(t) = \Pi T_S(t)|_{\mathcal{H}} w$. Then it is easy to see that

$$\int_s^t T_A(t-\tau)\Delta T_S(\tau)|_{\mathcal{H}} w d\tau = \Pi T_S(t)|_{\mathcal{H}} w - T_A(t-s)\Pi T_S(s)|_{\mathcal{H}} w \tag{6.2}$$

for every $t \geq s$. Hence for every $t \geq s$, we have

$$z(t) = T_A(t-s)\Pi T_S(s)|_{\mathcal{H}} w + \Pi T_S(t)|_{\mathcal{H}} w - T_A(t-s)\Pi T_S(s)|_{\mathcal{H}} w \tag{6.3}$$

$$= T_A(t-s)z(s) + \int_s^t T_A(t-\tau)\Delta T_S(\tau)|_{\mathcal{H}} w d\tau \tag{6.4}$$

so that $z(t)$ is a mild solution of the differential equation $\dot{z}(t) = Az(t) + \Delta T_S(t)|_{\mathcal{H}} w$ on the whole real line. In other words, Δ is regularly admissible for $T_A(t)$.

Conversely, suppose that there exists $\Pi \in \mathcal{L}(\mathcal{H}, Z)$ such that $\Pi(\mathcal{D}(S|_{\mathcal{H}})) \subset \mathcal{D}(A)$ and such that for every $w \in \mathcal{H}$ the function $t \to z(t) = \Pi T_S(t)|_{\mathcal{H}} w$ is a mild solution of the differential equation $\dot{z}(t) = Az(t) + \Delta T_S(t)|_{\mathcal{H}} w$ on the whole real line. Let $w \in \mathcal{D}(S|_{\mathcal{H}})$. Then since $\Pi(\mathcal{D}(S|_{\mathcal{H}})) \subset \mathcal{D}(A)$ and since $\mathcal{D}(S|_{\mathcal{H}})$ is invariant for $T_S(t)|_{\mathcal{H}}$, the function $t \to \Delta T_S(t)|_{\mathcal{H}} w$ is continuously differentiable, and we can differentiate both sides of the identity

$$\Pi T_S(t)|_{\mathcal{H}} w = T_A(t)\Pi w + \int_0^t T_A(t-\tau)\Delta T_S(\tau) w d\tau \quad \forall t \geq 0 \tag{6.5}$$

(cf. Proposition 1.3.6 in [1]) and set $t = 0$ to obtain $\Pi S|_{\mathcal{H}} = A\Pi + \Delta$ in $\mathcal{D}(S|_{\mathcal{H}})$. The proof is complete. □

Remark 6.9. If $T_A(t)$ is exponentially stable, then by Corollary 8 in [23] the operator equation $\Pi S|_{\mathcal{H}} = A\Pi + \Delta$ in $\mathcal{D}(S|_{\mathcal{H}})$ has a unique solution $\Pi \in \mathcal{L}(\mathcal{H}, Z)$ for every $\Delta \in \mathcal{L}(\mathcal{H}, Z)$. Consequently, *every* $\Delta \in \mathcal{L}(\mathcal{H}, Z)$ is regularly admissible for an exponentially stable C_0-semigroup $T_A(t)$.

Lemma 6.8 shows that if $T_{A+BK}(t)$ is strongly stable and if we can solve the regulator equations (3.1), then we in fact obtain more than just the existence of a solution to the FRP: The operator $BL + P = B(\Gamma - K\Pi) + P$ is regularly admissible for $T_{A+BK}(t)$. In the case of p-periodic reference signals (with $\mathcal{H}$ as in Example 6.2) this implies that for every $w(0) \in \mathcal{H}$ equation (2.3a) has a p-periodic mild solution $z(t)$ in the sense of (6.1).

We now come to the other main results of this section. They provide—via Lemma 6.8—characterizations for the solvability of the output regulation problems FRP and EFRP. In the following we set $C_0^+(\mathbb{R},H)=\{\,f\in BUC(\mathbb{R},H)\mid f(t)\to 0 \text{ as } t\to+\infty\,\}$. The next theorem generalizes the results of [3, 14, 16] to the case in which the pair (A,B) is not necessarily exponentially stabilizable.

THEOREM 6.10. *Assume that $\mathcal{H}$ is a CTO space such that $\mathcal{H}\cap C_0^+(\mathbb{R},H)=\{0\}$. Let the pair (A,B) be strongly stabilizable using $K\in\mathcal{L}(Z,H)$. Then the FRP is solvable using the control law $u(t)=Kz(t)+Lw(t)$, where $L\in\mathcal{L}(\mathcal{H},H)$ and $BL+P$ is regularly admissible for $T_{A+BK}(t)$, if and only if there exists $\Pi\in\mathcal{L}(\mathcal{H},Z)$ and $\Gamma\in\mathcal{L}(\mathcal{H},H)$ such that $\Pi(\mathcal{D}(S|_{\mathcal{H}}))\subset\mathcal{D}(A)$, $L=\Gamma-K\Pi$ and the regulator equations* (3.1) *are satisfied.*

Proof. If $\Pi S|_{\mathcal{H}}=A\Pi+B\Gamma+P$ in $\mathcal{D}(S|_{\mathcal{H}})$ and if $L=\Gamma-K\Pi$, then also $\Pi S|_{\mathcal{H}}=(A+BK)\Pi+BL+P$ in $\mathcal{D}(S|_{\mathcal{H}})$. Theorem 3.1 and Lemma 6.8 now directly yield the "if" part of the result, so we turn our attention to the "only if" part.

Now, Lemma 6.8 implies that whenever $BL+P$ is regularly admissible for $T_{A+BK}(t)$, there exists $\Pi\in\mathcal{L}(\mathcal{H},Z)$ such that $\Pi(\mathcal{D}(S|_{\mathcal{H}}))\subset\mathcal{D}(A+BK)=\mathcal{D}(A)$ and $\Pi S|_{\mathcal{H}}=(A+BK)\Pi+BL+P$ in $\mathcal{D}(S|_{\mathcal{H}})$. Let $\Gamma=L+K\Pi\in\mathcal{L}(\mathcal{H},H)$. Then Π and Γ solve the first regulator equation (3.1a) and $L=\Gamma-K\Pi$.

We next show that also the second regulator equation (3.1b) is satisfied. Observe that since $\Pi S|_{\mathcal{H}}=(A+BK)\Pi+BL+P$ in $\mathcal{D}(S|_{\mathcal{H}})$, we have for every $w\in\mathcal{H}$ and every $t\geq 0$ that

$$\int_0^t T_{A+BK}(t-\tau)(BL+P)T_S(\tau)|_{\mathcal{H}}w\,d\tau=\Pi T_S(t)|_{\mathcal{H}}w-T_{A+BK}(t)\Pi w. \tag{6.6}$$

Consider then the composite operator $\mathcal{A}$ on the extended state space $Z\times\mathcal{H}$ (see (2.3)) defined as

$$\mathcal{A}=\begin{pmatrix}A+BK & BL+P\\ 0 & S|_{\mathcal{H}}\end{pmatrix}. \tag{6.7}$$

An easy calculation reveals that $\mathcal{A}$ generates the C_0-semigroup given as

$$T_{\mathcal{A}}(t)=\begin{pmatrix}T_{A+BK}(t) & \Pi T_S(t)|_{\mathcal{H}}-T_{A+BK}(t)\Pi\\ 0 & T_S(t)|_{\mathcal{H}}\end{pmatrix}. \tag{6.8}$$

Since the FRP is solved, for arbitrary $w(0)=w\in\mathcal{H}$ and $z(0)=\Pi w\in Z$ we have $\left(\begin{smallmatrix}z(t)\\ w(t)\end{smallmatrix}\right)=T_{\mathcal{A}}(t)\left(\begin{smallmatrix}\Pi w\\ w\end{smallmatrix}\right)=\left(\begin{smallmatrix}\Pi T_S(t)|_{\mathcal{H}}w\\ T_S(t)|_{\mathcal{H}}w\end{smallmatrix}\right)$ and the corresponding tracking error satisfies

$$e(t)=\big((C+DK)\Pi+DL-Q\big)T_S(t)|_{\mathcal{H}}w=(C\Pi+D\Gamma-Q)T_S(t)|_{\mathcal{H}}w\to 0 \text{ as } t\to\infty, \tag{6.9}$$

which implies that this tracking error function $e\in C_0^+(\mathbb{R},H)$. Furthermore, since $\mathcal{H}$ is CTO and $(C\Pi+D\Gamma-Q)\in\mathcal{L}(\mathcal{H},H)$, the function $t\to(C\Pi+D\Gamma-Q)T_S(t)|_{\mathcal{H}}w$ is also in $\mathcal{H}$. In other words, $e\in C_0^+(\mathbb{R},H)\cap\mathcal{H}=\{0\}$. Consequently $e(0)=(C\Pi+D\Gamma-Q)w=0$, and so also the second regulator equation (3.1b) is satisfied. ∎

Remark 6.11. Our assumption that $\mathcal{H}\cap C_0^+(\mathbb{R},H)=\{0\}$ corresponds to the assumption in [3] that the (finite-dimensional) exogenous system is neutrally stable. In [3] neutral stability means that the origin is Lyapunov stable forward and backward in time; it implies that the spectrum of the exosystem's generator is located on the

imaginary axis and that this matrix cannot have nontrivial Jordan blocks [3]. This, on the other hand, implies that no reference function can vanish at $+\infty$, which is precisely our assumption $\mathcal{H}\cap C_0^+(\mathbb{R},H)=\{0\}$. This assumption is very mild, because such functions could be asymptotically tracked using a control law $u(t)=Kz(t)$ where $K\in\mathcal{L}(Z,H)$ stabilizes the pair (A,B) strongly.

Theorem 3.1, Remark 6.9, and Theorem 6.10 immediately yield the following corollary; it was also proved in [14], with the assumption that $\mathcal{H}$ is a CTO space replaced by the requirement for exponentially fast tracking/rejection of the exogenous signals.

COROLLARY 6.12. *Assume that $\mathcal{H}$ is a CTO space such that $\mathcal{H}\cap C_0^+(\mathbb{R},H)=\{0\}$. Let the pair (A,B) be exponentially stabilizable using $K\in\mathcal{L}(Z,H)$. Then the FRP is solvable using the control law $u(t)=Kz(t)+Lw(t)$, where $L\in\mathcal{L}(\mathcal{H},H)$, if and only if there exists $\Pi\in\mathcal{L}(\mathcal{H},Z)$ and $\Gamma\in\mathcal{L}(\mathcal{H},H)$ such that $\Pi(\mathcal{D}(S|_{\mathcal{H}}))\subset\mathcal{D}(A)$, $L=\Gamma-K\Pi$ and the regulator equations* (3.1) *are satisfied.*

For the solution of the EFRP we next obtain similar results. The following theorem generalizes the results in [3] to the case in which the closed loop system is not necessarily exponentially stable, the controller's parameters F,G, and J are not fixed, and the exogenous system may be infinite-dimensional.

THEOREM 6.13. *Let $\mathcal{H}$ be a CTO space such that $\mathcal{H}\cap C_0^+(\mathbb{R},H)=\{0\}$. Assume that the triplet (F,G,J) has been chosen such that $\mathcal{A}=\left(\begin{smallmatrix}A & BJ\\ GC & F+GDJ\end{smallmatrix}\right)$ generates a strongly stable C_0-semigroup on $Z\times\mathcal{H}$. Then the EFRP is solvable with this choice of (F,G,J) and the operator $\mathcal{P}=\left(\begin{smallmatrix}P\\ -GQ\end{smallmatrix}\right)$ is regularly admissible for the semigroup $T_{\mathcal{A}}(t)$ if and only if the regulator equations* (3.1) *and regulator equations* (4.1) *for the error feedback controller are satisfied for some $\Pi\in\mathcal{L}(\mathcal{H},Z)$, $\Gamma\in\mathcal{L}(\mathcal{H},H)$, and $\Lambda\in\mathcal{L}(\mathcal{H},X)$.*

Proof. If there exist Π,Γ, and Λ such that (3.1) and (4.1) are satisfied, then by Theorem 4.1 the triplet (F,G,J) solves the EFRP. Moreover, (4.4) and Lemma 6.8 show that $\mathcal{P}$ is regularly admissible for $T_{\mathcal{A}}(t)$. Therefore, we have proved the "if" part of the result, and we can turn our attention to the "only if" part.

Assume that the EFRP is solvable using a controller of the form (2.4) and that $\mathcal{P}$ is regularly admissible for $T_{\mathcal{A}}(t)$. Let $\Theta(t)=\left(\begin{smallmatrix}z(t)\\ x(t)\end{smallmatrix}\right)\in Z\times X$ and consider the system (4.3) with notation as in (4.2). Let $\mathcal{K}\in\mathcal{L}(Z\times X,H)$ and $\mathcal{L}\in\mathcal{L}(\mathcal{H},H)$ be arbitrary. Then a control law $u(t)=\mathcal{K}\Theta(t)+\mathcal{L}w(t)$ solves the FRP for the system (4.3) and $\mathcal{P}=\mathcal{B}\mathcal{L}+\mathcal{P}$ is regularly admissible for the semigroup generated by $\mathcal{A}+\mathcal{B}\mathcal{K}=\mathcal{A}$. Hence by Theorem 6.10 there exist $\left(\begin{smallmatrix}\Pi_1\\ \Pi_2\end{smallmatrix}\right)\in\mathcal{L}(\mathcal{H},Z\times X)$ and $\Gamma_0\in\mathcal{L}(\mathcal{H},H)$ such that $\left(\begin{smallmatrix}\Pi_1\\ \Pi_2\end{smallmatrix}\right)(\mathcal{D}(S|_{\mathcal{H}}))\subset\mathcal{D}(\mathcal{A})$ and

$$\begin{pmatrix}\Pi_1\\ \Pi_2\end{pmatrix}S|_{\mathcal{H}}=\begin{pmatrix}A & BJ\\ GC & F+GDJ\end{pmatrix}\begin{pmatrix}\Pi_1\\ \Pi_2\end{pmatrix}+\begin{pmatrix}0\\ 0\end{pmatrix}\Gamma_0+\begin{pmatrix}P\\ -GQ\end{pmatrix} \tag{6.10}$$

$$=\begin{pmatrix}A & BJ\\ GC & F+GDJ\end{pmatrix}\begin{pmatrix}\Pi_1\\ \Pi_2\end{pmatrix}+\begin{pmatrix}P\\ -GQ\end{pmatrix}\quad\text{in } \mathcal{D}(S|_{\mathcal{H}}), \tag{6.11}$$

$$Q=\begin{pmatrix}C & DJ\end{pmatrix}\begin{pmatrix}\Pi_1\\ \Pi_2\end{pmatrix}+0\Gamma_0=\begin{pmatrix}C & DJ\end{pmatrix}\begin{pmatrix}\Pi_1\\ \Pi_2\end{pmatrix}\quad\text{in } \mathcal{H}. \tag{6.12}$$

Letting $\Pi=\Pi_1$ and $\Gamma=J\Pi_2$, we immediately see that the regulator equations (3.1) are satisfied. Moreover, for $\Lambda=\Pi_2$ the regulator equations (4.1) for the error feedback controller are also satisfied. The proof is complete. ∎

The following corollary is evident by Theorem 4.1, Remark 6.9, and Theorem 6.13.

COROLLARY 6.14. *Let $\mathcal{H}$ be a CTO space such that $\mathcal{H} \cap C_0^+(\mathbb{R}, H) = \{0\}$. Assume that the triplet (F, G, J) has been chosen such that $\mathcal{A} = \left(\begin{smallmatrix} A & BJ \\ GC & F+GDJ \end{smallmatrix}\right)$ generates an exponentially stable C_0-semigroup on $Z \times \mathcal{H}$. Then the EFRP is solvable with this choice of (F, G, J) if and only if the regulator equations* (3.1) *and regulator equations* (4.1) *for the error feedback controller are satisfied for some $\Pi \in \mathcal{L}(\mathcal{H}, Z)$, $\Gamma \in \mathcal{L}(\mathcal{H}, H)$ and $\Lambda \in \mathcal{L}(\mathcal{H}, X)$.*

7. The internal model principle. One of the cornerstones in the classical automatic control theory of finite-dimensional systems is the internal model principle of Francis and Wonham [10, 11]. The principle asserts that closed loop stability and asymptotic tracking can be achieved only if the control system encapsulates a suitably reduplicated model of the dynamic structure of the exogenous signals which the regulator is required to process. Using frequency domain methods Yamamoto and Hara [28] generalized this principle for infinite-dimensional systems having a pseudorational impulse response (e.g., delay-differential systems). In the dynamic compensator of Corollary 4.2 the effect of this principle can be seen in the $(2, 2)$-block of F in (4.6): the internal model is just $S|_{\mathcal{H}}$.

In Theorem 7.2 below we show, using state space methods, that the existence of an internal model in the controller is—under some additional conditions—necessary for the solvability of the EFRP. In particular, we formalize the above idea that F must contain a copy of $S|_{\mathcal{H}}$. In order to do that, we need the following assumption.

ASSUMPTION 7.1. *The pair $\left(\left(\begin{smallmatrix} A & P \\ 0 & S|_{\mathcal{H}} \end{smallmatrix}\right), \left(\begin{smallmatrix} C & -Q \end{smallmatrix}\right)\right)$ is approximately observable.*

In finite dimensions Assumption 7.1 implies that the pair $\left(\left(\begin{smallmatrix} A & P \\ 0 & S|_{\mathcal{H}} \end{smallmatrix}\right), \left(\begin{smallmatrix} C & -Q \end{smallmatrix}\right)\right)$ is exponentially detectable. This was also assumed in the result of Francis [10], which Theorem 7.2 generalizes.

THEOREM 7.2. *Let Assumption* 7.1 *hold and let $\mathcal{H}$ be a CTO space such that $\mathcal{H} \cap C_0^+(\mathbb{R}, H) = \{0\}$. Assume that the EFRP is solvable for some triplet (F, G, J) and that $\mathcal{P} = \left(\begin{smallmatrix} P \\ -GQ \end{smallmatrix}\right)$ is regularly admissible for $\mathcal{A} = \left(\begin{smallmatrix} A & BJ \\ GC & F+GDJ \end{smallmatrix}\right)$. Then there exists a subspace $X_0 \subset X$ which is invariant for the semigroup $T_F(t)$ generated by F on X, and there exists a linear bijection $M : \mathcal{H} \to X_0$ such that $M \in \mathcal{L}(\mathcal{H}, X)$ and $T_S(t)|_{\mathcal{H}} = M^{-1} T_F(t) M$.*

Proof. By Theorem 6.13, there exist bounded linear operators Π, Γ, and Λ such that

$$\Pi S|_{\mathcal{H}} = A\Pi + BJ\Lambda + P \quad \text{in } \mathcal{D}(S|_{\mathcal{H}}), \tag{7.1a}$$

$$\Lambda S|_{\mathcal{H}} = F\Lambda \quad \text{in } \mathcal{D}(S|_{\mathcal{H}}), \tag{7.1b}$$

$$Q = C\Pi + DJ\Lambda \quad \text{in } \mathcal{H}. \tag{7.1c}$$

Since $\Lambda(\mathcal{D}(S|_{\mathcal{H}})) \subset \mathcal{D}(F)$, from (7.1b) we see that for every $w \in \mathcal{D}(S|_{\mathcal{H}})$ and every $t \geq 0$

(7.2)

$$\Lambda T_S(t)|_{\mathcal{H}} w - T_F(t)\Lambda w = \Big|_0^t T_F(t-\tau)\Lambda T_S(\tau)|_{\mathcal{H}} w = \int_0^t \frac{d}{d\tau} T_F(t-\tau)\Lambda T_S(\tau)|_{\mathcal{H}} w \, d\tau$$

$$= \int_0^t T_F(t-\tau)[\Lambda S|_{\mathcal{H}} - F\Lambda] T_S(\tau)|_{\mathcal{H}} w \, d\tau = 0. \tag{7.3}$$

A suitable density argument shows that $\Lambda T_S(t)|_{\mathcal{H}} w - T_F(t)\Lambda w = 0$ for every $w \in \mathcal{H}$ and every $t \geq 0$.

We now show that Λ is injective. If $\Lambda w = 0$ for some $w \neq 0$, then by the above $BJ\Lambda T_S(t)|_{\mathcal{H}} w = 0$ and $DJ\Lambda T_S(t)|_{\mathcal{H}} w = 0$ for every $t \geq 0$. Consider the semigroup

$$T(t) = \begin{pmatrix} T_A(t) & \int_0^t T_A(t-s) P T_S(s)|_{\mathcal{H}} ds \\ 0 & T_S(t)|_{\mathcal{H}} \end{pmatrix} \tag{7.4}$$

generated by $\left(\begin{smallmatrix} A & P \\ 0 & S|_{\mathcal{H}} \end{smallmatrix}\right)$ on $Z \times \mathcal{H}$. We immediately see by (7.1a) and (7.1c) that

$$T(t)\left(\begin{smallmatrix} \Pi w \\ w \end{smallmatrix}\right) = \begin{pmatrix} T_A(t)\Pi w + \int_0^t T_A(t-s)(BJ\Lambda + P) T_S(s)|_{\mathcal{H}} w ds \\ T_S(t)|_{\mathcal{H}} w \end{pmatrix} \tag{7.5}$$

$$= \begin{pmatrix} T_A(t)\Pi w + \Pi T_S(t)|_{\mathcal{H}} w - T_A(t)\Pi w \\ T_S(t)|_{\mathcal{H}} w \end{pmatrix} \tag{7.6}$$

$$= \begin{pmatrix} \Pi T_S(t)|_{\mathcal{H}} w \\ T_S(t)|_{\mathcal{H}} w \end{pmatrix}. \tag{7.7}$$

Hence $\begin{pmatrix} C & -Q \end{pmatrix} T(t) \left(\begin{smallmatrix} \Pi w \\ w \end{smallmatrix}\right) = (C\Pi + DJ\Lambda - Q) T_S(t)|_{\mathcal{H}} w = 0$ for every $t \geq 0$. This violates the approximate observability assumption. Hence Λ is injective.

By the fact that $\Lambda T_S(t)|_{\mathcal{H}} = T_F(t)\Lambda$ in $\mathcal{H}$, it is evident that $X_0 = \operatorname{ran}(\Lambda)$ is a $T_F(t)$-invariant subspace of X. Consequently $M = \Lambda$ is a bounded linear bijection $\mathcal{H} \to X_0$ and $T_S(t)|_{\mathcal{H}} = M^{-1} T_F(t) M$, as was claimed. ∎

Using Remark 6.9, we obtain the following corollary which can be applied whenever $\mathcal{A}$ generates an exponentially stable semigroup—especially in the setting of Byrnes et al. [3], where $\mathcal{H}$ is finite-dimensional.

COROLLARY 7.3. *Let Assumption 7.1 hold and let $\mathcal{H}$ be a CTO space such $\mathcal{H} \cap C_0^+(\mathbb{R}, H) = \{0\}$. Assume that the EFRP is solvable for some triplet (F, G, J) such that $\mathcal{A} = \left(\begin{smallmatrix} A & BJ \\ GC & F + GDJ \end{smallmatrix}\right)$ generates an exponentially stable C_0-semigroup. Then there exists a subspace $X_0 \subset X$ which is invariant for the semigroup $T_F(t)$ generated by F on X, and there exists a linear bijection $M : \mathcal{H} \to X_0$ such that $M \in \mathcal{L}(\mathcal{H}, X)$ and $T_S(t)|_{\mathcal{H}} = M^{-1} T_F(t) M$.*

8. Examples. In this section we shall present three examples to illustrate the theory. Each of these examples elucidates some novel feature of the present paper, especially in relation to [3, 14, 15, 16]. The first example concerns the design of a feedforward controller for the asymptotic tracking of periodic signals for a plant in which the semigroup is not exponentially stable (or exponentially stabilizable as in [3, 14, 15, 16]) but only strongly stable. The second example concerns the design of a dynamic error feedback controller for the asymptotic tracking of periodic signals for a delay-differential equation; the same example was studied in [16] in the context of an open loop (i.e., feedforward) control. The last example of this section illustrates, for the case of a finite-dimensional plant, that the output regulation theory developed in this article is not confined to just periodic signals as in [15, 16], but the reference signals can also have uncountable Carleman spectrum (as opposed to [3, 15, 16]).

Example 8.1. The following is a model for a weakly damped string of unit length, with clamped ends [19, Example 1.1.1].

$$\frac{\partial^2 v(x,t)}{\partial t^2} + M \frac{\partial v(x,t)}{\partial t} = \frac{\partial^2 v(x,t)}{\partial x^2} \quad \text{for } t \geq 0 \text{ and } 0 \leq x \leq 1, \tag{8.1a}$$

$$v(0,t) = v(1,t) = 0 \quad \text{for } t \geq 0. \tag{8.1b}$$

Here M is a damping operator which will be defined shortly. We define the operator U by $Uv = -\frac{\partial^2 v}{\partial x^2}$ with $\mathcal{D}(U) = \{\, v \in H^2(0,1) \mid v(0) = v(1) = 0 \,\}$, where $H^2(0,1)$

denotes the standard Sobolev space on the unit interval. It can be shown that U has eigenvalues $\lambda_k = k^2\pi^2$, $k = 1, 2, \ldots$, and the corresponding eigenvectors $\phi_k(x) = \sqrt{2}\sin(k\pi x)$ constitute an orthonormal basis in $L^2(0,1)$ [19].

The damping operator M is defined by $Mv = \epsilon\langle g, v\rangle_{L^2(0,1)} g$, where $\epsilon > 0$ and

$$g = \sum_{k=1}^{\infty} \gamma_k \phi_k, \tag{8.2}$$

with γ_k satisfying $0 < |\gamma_k| \leq \frac{m}{\sqrt{\lambda_k}}$ (for example, $\gamma_k = \frac{1}{k}$) for some $m > 0$. Next we define the Hilbert space $Z = L^2(0,1) \times L^2(0,1)$ with the natural inner product $\langle \cdot, \cdot \rangle$ and introduce

$$z(t) = \begin{pmatrix} U^{\frac{1}{2}} v(x,t) \\ \frac{\partial v(x,t)}{\partial t} \end{pmatrix} \quad \text{and} \quad A = \begin{pmatrix} 0 & U^{\frac{1}{2}} \\ -U^{\frac{1}{2}} & M \end{pmatrix}. \tag{8.3}$$

Then (8.1) can be rewritten as $\dot{z}(t) = Az(t)$, $z(0) \in Z$, and it can be shown [19] that A generates a strongly (but not exponentially) stable C_0-semigroup $T_A(t)$ in Z. Furthermore, A is a Riesz spectral operator [6] with eigenvalues

$$\nu_k = ik\pi - \frac{\epsilon}{2}\gamma_{|k|}^2 + \mathcal{O}\left(\frac{\epsilon^2}{k^2\pi^2}\right), \quad k \neq 0, \tag{8.4}$$

all of which have negative real parts. The corresponding eigenvectors $(\psi_k)_{k\neq 0}$ form a Riesz basis in Z (the biorthogonal sequence is denoted by $(\psi_k^*)_{k\neq 0}$).

Consider, then, application of distributed control and observation to the system (8.1) in the following sense. For a control operator $B \in \mathcal{L}(\mathbb{C}, Z)$ and an observation operator $C \in \mathcal{L}(Z, \mathbb{C})$ the SISO plant is given as

$$\dot{z}(t) = Az(t) + Bu(t), \quad z(0) \in Z, \quad t \geq 0, \tag{8.5a}$$

$$y(t) = Cz(t), \quad t \geq 0. \tag{8.5b}$$

Here $Bu(t) = bu(t)$ for some $b = \sum\langle b, \psi_k^*\rangle\psi_k \in Z$ and $Cz(t) = \langle z(t), c\rangle$ for some $c = \sum\langle c, \psi_k\rangle\psi_k^* \in Z$. We study the FRP for p-periodic reference signals in the Sobolev space $\mathcal{H} = H(f_n, \omega_n)$ [16].

DEFINITION 8.2. *Let $I \subset \mathbb{Z}$, let $p > 0$, and let $\omega_n = \frac{2\pi n}{p}$ for every $n \in I$. Let $(f_n)_{n\in I} \subset \mathbb{R}$ such that $f_n \geq 1$ for each $n \in I$ and $(f_n^{-1})_{n\in I} \in \ell^2$. The Sobolev space $H(f_n, \omega_n)$ is defined as $\left\{ u : \mathbb{R} \to \mathbb{C} \;\middle|\; u(t) = \sum_{n\in I} a_n e^{i\omega_n t}$ for each $t \in \mathbb{R}$, $\sum_{n\in I} |f_n|^2|a_n|^2 < \infty$ and $(a_n)_{n\in I} \subset \mathbb{C} \right\}$.*

It has been shown in [16] that $\mathcal{H}$ is continuously embedded in $BUC(\mathbb{R}, \mathbb{C})$. Moreover, $H(f_n, \omega_n)$ is a Hilbert space with respect to the inner product $\langle u, v\rangle_f = \sum_{n\in I} a_n\overline{b_n}|f_n|^2$. Here $u(t) = \sum_{n\in I} a_n e^{i\omega_n t}$ and $v(t) = \sum_{n\in I} b_n e^{i\omega_n t}$ for every $t \in \mathbb{R}$, and $\overline{b_n}$ denotes the complex conjugate of b_n.

The transfer function of the system (8.5) is given for $\Re(s) \geq 0$ as $H(s) = CR(s, A)B$. We assume that $H(i\omega_n) \neq 0$ for each $n \in I$, i.e., that the transfer function of the system (8.5) does not have a zero at the frequencies of the reference signals.

Remark 8.3. One possible situation in which $H(i\omega) \neq 0$ for each $\omega \in \mathbb{R}$ is the following: The control and observation elements b and c are such that

$$\langle b, \psi_k^*\rangle > 0 \quad \text{and} \quad \langle \psi_k, c\rangle > 0 \quad \forall k \neq 0. \tag{8.6}$$

In fact, in this case we have

$$\begin{aligned} H(i\omega) &= CR(i\omega, A)B \\ &= \sum_n \frac{\langle b, \psi_n^* \rangle \langle \psi_n, c \rangle}{i\omega - \nu_n} = \sum_n \frac{d_n(\alpha_n - i\beta_n)}{\alpha_n^2 + \beta_n^2} \\ &= \sum_n \frac{d_n \alpha_n}{\alpha_n^2 + \beta_n^2} - i \sum_n \frac{d_n \beta_n}{\alpha_n^2 + \beta_n^2}, \end{aligned} \tag{8.7}$$

where $\omega \in \mathbb{R}$, $d_n = \langle b, \psi_n^* \rangle \langle \psi_n, c \rangle > 0$, $\alpha_n = \frac{\epsilon}{2}\gamma_{|n|}^2 - \delta_{n,\epsilon} > 0$ for some $\delta_{n,\epsilon}$, and $\beta_n = \omega - n\pi$. Clearly $\Re(CR(i\omega, A)B) > 0$ so that $H(i\omega) \neq 0$ for every $\omega \in \mathbb{R}$.

This allows us to solve the regulator equations (3.1) as in [15, 16]. If $(\theta_n)_{n\in I}$ is the canonical orthonormal basis of exponentials for $\mathcal{H} = H(f_n, \omega_n)$, then it is readily verified that a suitable pair (Π, Γ) of operators is

$$\Gamma y = \sum_{n\in I} y_n \frac{Q\theta_n}{H(i\omega_n)} \quad \forall y \in \mathcal{H}, \tag{8.8}$$

$$\Pi y = \sum_{n\in I} y_n R(i\omega_n, A)B\Gamma\theta_n \quad \forall y \in \mathcal{H}, \tag{8.9}$$

where $\omega_n = \frac{2\pi n}{p}$, $n \in I$, and y_n is the nth Fourier coefficient of $y \in \mathcal{H}$ in the basis $(\theta_n)_{n\in I}$. For a suitable weighting sequence $(f_n)_{n\in I}$ in the space $H(f_n, \omega_n)$ these operators Π and Γ are bounded [16]. Hence by Theorem 3.1 the feedforward control law which achieves the asymptotic tracking of $y \in \mathcal{H}$ for such $(f_n)_{n\in I}$ is given by

$$\begin{aligned} u(t) = \Gamma w(t) = \Gamma T_S(t)|_{\mathcal{H}} y = \Gamma \sum_{n\in I} y_n T_S(t)|_{\mathcal{H}} \theta_n = \sum_{n\in I} \frac{y_n}{H(i\omega_n)} Q T_S(t)|_{\mathcal{H}} \theta_n \\ = \sum_{n\in I} \frac{y_n}{H(i\omega_n)} \theta_n(t). \end{aligned} \tag{8.10}$$

In conclusion, in order to asymptotically track (a sufficiently smooth) p-periodic function y, we apply a p-periodic feedforward control whose nth Fourier coefficient is that of y multiplied by the reciprocal of the transfer function of the plant evaluated at $i\omega_n$. The use of an error feedback controller in this case may be difficult, because the closed loop system is difficult to stabilize.

Example 8.4. Let $a > 0$, $r \neq 0$, $\tau_1 > \tau_2 > 0$. Consider the following scalar delay differential equation with control and observation:

$$\dot{x}(t) = -ax(t) - b\big[x(t - \tau_1) + x(t - \tau_2)\big] + u(t), \tag{8.11a}$$

$$y(t) = rx(t), \quad t \geq 0. \tag{8.11b}$$

Our goal is to build, using Corollary 4.2, a dynamic controller (2.4) which solves the EFRP for this plant and p-periodic reference signals in the standard Sobolev spaces $\mathcal{H} = H^\alpha_{per}(0, p)$ for $\alpha > \frac{1}{2}$ [17].

Taking initial conditions for $x(\cdot)$ into account, the pair (8.11) can be formulated as a plant of the form (2.1) in which $D = 0$ and $\mathcal{U}_{dist} = 0$ [6]. Moreover, it can be shown (see, e.g., [6, Lemma 4.3.9]) that the transfer function $H(s) = CR(s, A)B$ of this plant is given by

$$H(s) = \frac{r}{s + a + b(e^{-s\tau_1} + e^{-s\tau_2})} \tag{8.12}$$

for those $s \in \mathbb{C}$ at which the denominator is not equal to zero.

The semigroup generated by A is exponentially stable if and only if $s + a + b(e^{-s\tau_1} + e^{-s\tau_2}) \neq 0$ for all $s \in \{ z \in \mathbb{C} \mid \Re(z) \geq 0 \}$ [6, Theorem 5.1.7]. Ruan and Wei [20] give a complete characterization (in terms of a, b, τ_1, and τ_2) of those instances in which all roots of equation $s + a + b(e^{-s\tau_1} + e^{-s\tau_2}) = 0$ have negative real parts. In their characterization, the parameter b lies on an interval (b_0^-, b_0^+). We assume that the semigroup generated by A is exponentially stable. By the above discussion, then $i\omega_n = i\frac{2\pi n}{p} \in \rho(A)$ and $H(i\omega_n) \neq 0$ for every $n \in \mathbb{Z}$.

It is evident that for every $\alpha > \frac{3}{2}$, $\sum_{n=-\infty}^{\infty} |H(i\omega_n)^{-1}|^2 (1 + \omega_n^2)^{-\alpha} < \infty$. Hence for $\alpha > \frac{3}{2}$ we can solve the regulator equations (3.1) for bounded operators Π and Γ as in [16]. We obtain

$$\Gamma y = \sum y_n \frac{Q\theta_n}{H(i\omega_n)} \quad \forall y \in \mathcal{H}, \tag{8.13}$$

$$\Pi y = \sum y_n R(i\omega_n, A) B\Gamma\theta_n \quad \forall y \in \mathcal{H}, \tag{8.14}$$

where $(\theta_n)_{n\in\mathbb{Z}}$ is the natural orthonormal basis for $\mathcal{H}$ and y_n is the nth Fourier coefficient of y with respect to this basis.

It is easy to see using Theorem 14 of [2] that $S|_{\mathcal{H}} - Q^*Q$ generates a strongly stable C_0-semigroup. Hence we may use Corollary 4.2 to deduce that an error feedback controller (2.4) with

$$F = \begin{pmatrix} A & B\Gamma \\ Q^*C & S|_{\mathcal{H}} - Q^*Q \end{pmatrix}, \quad J = \begin{pmatrix} 0 & \Gamma \end{pmatrix}, \quad \text{and} \quad G = \begin{pmatrix} 0 \\ -Q^* \end{pmatrix} \tag{8.15}$$

solves the EFRP.

Example 8.5. Let $H(s) = CR(s, A)B$ be a transfer function of an exponentially stable disturbance-free finite-dimensional SISO system (2.1) with $D = 0$. Let γ be a compact subset of $\mathbb{R}$. Consider reference signals in the space $\mathcal{H} = \{ f \in BUC(\mathbb{R}, \mathbb{C}) \mid sp(f) \subset \gamma \}$, where $sp(f)$ denotes the Carleman spectrum of f. Then $S|_{\mathcal{H}} \in \mathcal{L}(\mathcal{H})$ and $\sigma(S|_{\mathcal{H}}) = i\gamma$. Let δ be a smooth contour surrounding $\sigma(S|_{\mathcal{H}})$ such that it does not enclose any eigenvalues of A. Assume that $\inf_{i\omega\in\sigma(S|_{\mathcal{H}})} |H(i\omega)| > 0$. Then the linear operator $V \in \mathcal{L}(\mathcal{H})$ defined as

$$Vf = \frac{1}{2\pi i} \oint_\delta H(s) R(s, S|_{\mathcal{H}}) f ds \quad \forall f \in \mathcal{H} \tag{8.16}$$

is boundedly invertible (cf. Theorem 8.2 in [22]).

It is a straightforward calculation to show that the bounded operators Π and Γ defined as

$$\Gamma f = QV^{-1} \quad \forall f \in \mathcal{H}, \tag{8.17}$$

$$\Pi f = \frac{1}{2\pi i} \oint_\delta R(\lambda, A) B\Gamma R(s, S|_{\mathcal{H}}) f ds \quad \forall f \in \mathcal{H} \tag{8.18}$$

solve the regulator equations (3.1). Hence it is possible to track all reference signals in $\mathcal{H}$ using a feedforward control law $u(t) = \Gamma w(t)$. Such reference signals need not be periodic, but they are infinitely smooth because $S|_{\mathcal{H}} \in \mathcal{L}(\mathcal{H})$.

We remark that although the plant is exponentially stable and the regulator equations (3.1) can be solved, the corresponding EFRP may be difficult to solve. This is because $\sigma(S|_{\mathcal{H}})$, although compact, may be an uncountable set in $i\mathbb{R}$. The authors are not aware of any stabilization results in Banach spaces allowing for an uncountable spectrum in $\{ s \in \mathbb{C} \mid \Re(s) \geq 0 \}$; hence closed loop stability may be difficult to obtain.

9. Conclusions. In this article we have developed a state space output regulation theory for linear infinite-dimensional systems and bounded uniformly continuous exogenous reference/disturbance signals. We have solved both feedforward and error feedback output regulation problems; we have provided complete characterizations for the solvability of these problems in terms of certain regulator equations; and we have provided several examples to illustrate the theory. In this article we have also discussed strong stabilizability of the closed loop error feedback control system, which is an important problem in our case due to the following reasons:

- The exogenous signals are, in general, generated by an infinite-dimensional exosystem.
- The system operator of such an infinite-dimensional exosystem is often impossible to stabilize exponentially.
- The closed loop error feedback control system must (under certain assumptions) contain a copy of this exosystem operator in order that error feedback output regulation is possible.

The third item above is the well-known internal model principle, and we have generalized it in this article for infinite-dimensional plants and infinite-dimensional exosystems.

Interesting directions for future research include a detailed study of robustness issues and an extension of the results of this paper for unbounded operators B and C in the plant. In this way the output regulation theory of the present paper could be extended for many important boundary control and point observation problems not covered by the theory of this article.

Acknowledgments. The authors thank the reviewers for their many useful comments for improving the original manuscript.

ROBUSTNESS IN THE GRAPH TOPOLOGY OF A COMMON ADAPTIVE CONTROLLER*

MARK FRENCH†, ACHIM ILCHMANN‡, AND EUGENE P. RYAN§

Abstract. For any m-input, m-output, finite-dimensional, linear, minimum-phase plant P with first Markov parameter having spectrum in the open right half complex plane, it is well known that the adaptive output feedback control C, given by $u = -ky$, $\dot{k} = \|y\|^2$, yields a closed-loop system $[P, C]$ for which the state converges to zero, the signal k converges to a finite limit, and all other signals are of class L^2. It is first shown that these properties continue to hold in the presence of L^2-input and L^2-output disturbances. Working within the conceptual framework of the nonlinear gap metric approach to robust stability, and by establishing gain function stability of an appropriate closed-loop operator, it is proved that these properties also persist when the plant P is replaced with a stabilizable and detectable linear plant P_1 within a sufficiently small neighborhood of P in the graph topology, provided that the plant initial data and the L^2 magnitude of the disturbances are sufficiently small. Example 9 of Georgiou and Smith [*IEEE Trans. Automat. Control*, 42 (1997), pp. 1200–1221] is revisited. Unstable behavior for large initial conditions and/or large L^2 disturbances is shown, demonstrating that the bounds obtained from the L^2 theory are qualitatively tight: this contrasts with the L^∞-robustness analysis of Georgiou and Smith, which is insufficiently tight, to predict the stable behavior for small initial conditions and zero disturbances.

Key words. adaptive control, gap metric, robust stability

1. Introduction.

In an important paper in 1997, the well-established concept of the gap metric for linear systems (see, e.g., [19, 5, 6, 18, 2]) was extended to a nonlinear setting by Georgiou and Smith [7]. Further developments can be found in [8, 16, 1, 4]. The central property analyzed in the nonlinear gap framework is that of robust stability, i.e., the property that, if $\mathcal{W}$ is some requisite class (for example, L^∞ or L^2) to which the signals of a nominal closed-loop plant/controller configuration belong, then the closed-loop signals remain in $\mathcal{W}$ if the nominal plant is replaced with another plant which is sufficiently close in the gap sense. Gain function stability (gf-stability) a concept made precise in subsection 2.3, of the closed-loop operator mapping external disturbances to the input and output of the nominal plant provides a sufficient condition for robust stability (however, in contrast with the results in the linear setting, gf-stability is not a necessary condition for robust stability in the nonlinear setting). The nonlinear gap framework has been used to investigate the robustness (or lack of robustness) of certain classical adaptive controllers and variants thereof.

In an L^∞ setting, Example 9 of [7] (see also [9]) considers the controller (ubiqui-

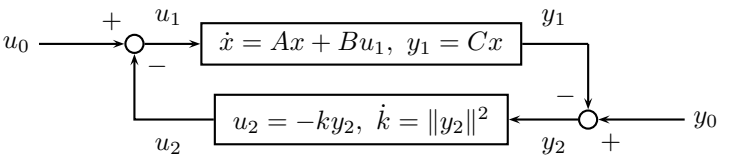

FIG. 1.1. *The adaptive closed-loop system.*

tous in the adaptive control literature)

$$u = -ky, \quad \dot{k} = y^2 \tag{1.1}$$

applied to the scalar linear plant $\dot{y} = ay + u$, for some $a \in \mathbb{R}$, and shows that the closed-loop operator mapping external disturbances onto the input and output of the nominal plant is not gain function stable (gf-stable). While the lack of gf-stability does not preclude robust stability, numerical and other informal evidence was presented which suggested that, with nonzero initial conditions, the closed-loop system is not robustly stable, even in the absence of disturbances. One consequence of the results of the present paper is to clarify the latter suggestion: we prove that, in the absence of disturbances, the closed-loop system is—with sufficiently small initial data—robustly stable but fails to be robustly stable for large initial data.

In [4], the nonlinear gap framework is used in an L^2 setting to establish robust stability properties of the controller $u = -k^{\frac{1}{4}}y$, $\dot{k} = y^2$ when applied to (a) single-input, single-output, linear, minimum-phase, relative-degree-one, nominal plants with positive high-frequency gain, and (b) a class of perturbed plants, where the gap metric distance between the nominal and perturbed plants is constrained by a function of the norms of the external disturbances. The present paper shows that the analysis developed in [4] can also be applied to the more familiar adaptive controller (1.1) (and its multivariable counterpart). This is considered to be important, as such controllers form the basis for many adaptive designs; see, e.g., [13, 14]. For example, adaptive backstepping designs [14, p. 100] reduce to (1.1) when applied to first-order linear plants. From an applied point of view, many application studies of such controllers exist in the literature (see, for example, [14] and the bibliography therein).

The analysis of the controller (1.1) differs significantly from that of the controllers in [4], requiring a different technique to establish the required gf-stability (Propositions 3.3, 3.5). In particular, in an L^2 setting, we establish a robust stability result for nominal m-input, m-output, finite-dimensional, stabilizable and detectable linear plants (A, B, C) which are minimum phase and are such that the first Markov parameter CB has its spectrum in the open right half complex plane (we denote the class of such plants by $\mathcal{M}$). With reference to Figure 1.1, in the absence of external disturbances (that is, with $u_0 = 0 = y_0$), it is well known (see, for example, [11, Theorem 4.2.1]) that, for every plant in $\mathcal{M}$ and all initial plant/controller data $(x^0, k^0) \in \mathbb{R}^n \times \mathbb{R}_+$ ($\mathbb{R}_+ := [0, \infty)$), the closed loop is such that (i) $u_1, y_1 \in L^2(\mathbb{R}_+, \mathbb{R}^m)$, (ii) $x(t) \to 0$ as $t \to \infty$, and (iii) $k(t) \to k^\infty \in \mathbb{R}_+$ as $t \to \infty$. First, we show that properties (i)–(iii) persist under external disturbances $u_0, y_0 \in L^2(\mathbb{R}_+, \mathbb{R}^m)$. Second, we consider the question of robust stability of the closed loop with respect to both external L^2 disturbances and perturbations of the plant (A, B, C), i.e., to what extent do the above properties (i)–(iii) persist if $(A, B, C) \in \mathcal{M}$ is perturbed to another m-input, m-output, linear, finite-dimensional, stabilizable and detectable plant $(A_p, B_p, C_p) \notin \mathcal{M}$? An appropriate conceptual framework in which to pose and answer such questions is provided by the gap metric. We show that properties (i)–(iii) persist if (A, B, C)

and (A_p, B_p, C_p) are sufficiently close in the gap metric. The associated bounds on the robust stability margin have a semiglobal nature insofar as they depend on the "size" of the external disturbances and initial data. In the case of zero initial conditions, the linear gap metric δ_0 measures the size of the smallest stable coprime factor perturbation between plants. Thus, the stability results of the present paper can be interpreted within the framework of linear robust control, where coprime factor perturbations form the widely accepted model for unstructured uncertainties.

We emphasize that the principal contribution of [4] and the present paper is to obtain robust stability results for adaptive controllers for this general description of unmodeled dynamics. This contrasts with other results in adaptive control (see, for example, [13, Chapters 8 and 9], [10]), which are far more restricted in the class of unmodeled dynamics considered and which typically consider robust "modifications" to the underlying adaptive law, which can introduce conservativeness (see [4] for a full discussion).

For purposes of illustration, one expression for the linear gap δ_0 is given in the frequency domain as follows. Let (A_1, B_1, C_1) and (A_2, B_2, C_2) be single-input, single-output stabilizable linear systems with respective transfer functions $\hat{P}_1$ and $\hat{P}_2$. Then $\hat{P}_1$ and $\hat{P}_2$ admit normalized right coprime factorizations over RH^∞, the class of rational functions that are analytic and bounded on the open half plane $\mathbb{C}_+ := \{\lambda \in \mathbb{C} \mid \mathrm{Re}(\lambda) > 0\}$. In particular, there exist $N_i, D_i \in RH^\infty$ such that

$$\hat{P}_i = N_i D_i^{-1}, \qquad N_i^* N_i + D_i^* D_i = 1, \qquad i = 1, 2. \tag{1.2}$$

For $(i, j) = (1, 2), (2, 1)$, define the directed gap

$$\vec{\delta}_0(\hat{P}_i, \hat{P}_j) := \inf \left\{ \|(\Delta_N, \Delta_D)\|_{H^\infty} \,\middle|\, \Delta_N, \Delta_D \in RH^\infty,\ \hat{P}_j = (N_i + \Delta_N)(D_i + \Delta_D)^{-1} \right\}$$

(with the convention $\inf \emptyset := +\infty$). The linear gap between $\hat{P}_1$ and $\hat{P}_2$ is given by

$$\delta_0(\hat{P}_1, \hat{P}_2) \equiv \delta_0(\hat{P}_2, \hat{P}_1) = \max \left\{ \vec{\delta}_0(\hat{P}_1, \hat{P}_2), \vec{\delta}_0(\hat{P}_2, \hat{P}_1) \right\}. \tag{1.3}$$

We remark that the gap between the following plants $\hat{P}_1$ and $\hat{P}_2$ tends to zero as $\varepsilon \to 0$:

	$\hat{P}_1(s)$	$\hat{P}_2(s)$		Reference
(i)	$\dfrac{1}{s-\theta}$	$\dfrac{\lvert\lambda\rvert^2}{(s-\lambda)(s-\bar{\lambda})(s-\theta)}$,	$\mathrm{Re}(\lambda) \le -\varepsilon^{-1}$	[4]
(ii)	$\dfrac{1}{s-\theta}$	$\dfrac{N(M-s)}{(N+s)(M+s)(s-\theta)}$,	$N, M \ge \varepsilon^{-1}$	section 3.4, Example 3.10

Example (i) is the classical Rohrs' example [15] which first drew the attention of the adaptive control community to the robustness issue. As observed in [4], example (ii) is of particular interest since $\hat{P}_2$ exhibits none of the classical assumptions of adaptive control: in particular, the sign of the high-frequency gain and the relative degree of $\hat{P}_2$ differ from those of the nominal plant $\hat{P}_1$ and, moreover, $\hat{P}_2$ is not minimum phase. Example (ii) is considered in more detail in section 3.4. Example (iii) is comprised of an all-pass factor in series with the nominal plant and is considered extensively in section 4. Example (iii) also coincides with Example 9 in [7], to which our general L^2 theory applies to conclude robust stability provided the initial data and L^2 disturbance

norms are sufficiently small. In section 4, we additionally prove the lack of robustness when the initial data or the L^2 disturbances are large. Moreover, we clarify some of the informal arguments in the L^∞ setting of [7].

The paper is structured as follows. In section 2 we introduce the notation and background theory: notions of well posedness and gf-stability of plant/controller interconnections are made precise, and the nonlinear gap is defined; this material is based on [7, section II] and [4, section 2]. Section 3 establishes the main robust stability result for the adaptive controller (1.1) (Theorem (3.8)) via the general framework of [4]. By considering example (iii) above in detail in section 4, we show that the bounds obtained in Theorem 3.8 are qualitatively tight in the sense that examples (i)–(iii) show that the robustness margin necessarily depends on the size of the disturbances and initial conditions.

2. Background concepts and terminology.

2.1. Preliminaries. While our goal is to establish stability of various configurations of plant and controller, the nonlinear nature of the controller is such that finite-time blow up of solutions of the closed-loop system cannot be ruled out a priori. To accommodate the potential for such behavior in the analysis, we introduce the following notions. Let $\mathcal{X}$ be a nonempty set and, for $0 < \omega \le \infty$, let $\mathcal{S}_\omega$ denote the set of locally integrable maps $[0,\omega) \to \mathcal{X}$. For simplicity, we write $\mathcal{S} := \mathcal{S}_\infty$. For $0 < \tau < \omega \le \infty$, $T_\tau : \mathcal{S}_\omega \to \mathcal{S}$ denotes the operator given by

$$T_\tau v \;:=\; \begin{cases} v(t), & t \in [0,\tau), \\ 0, & \text{otherwise.} \end{cases}$$

With $\mathcal{V} \subset \mathcal{S}$ we associate spaces as follows: $\mathcal{V}_e = \{v \in \mathcal{S} \big|\ T_\tau v \in \mathcal{V} \text{ for all } \tau > 0\}$, *the extended space*; $\mathcal{V}_\omega = \{v \in \mathcal{S}_\omega \big|\ T_\tau v \in \mathcal{V} \text{ for all } \tau \in (0,\omega)\}$, $0 < \omega \le \infty$; $\mathcal{V}_a = \cup_{\omega \in (0,\infty]} \mathcal{V}_\omega$, *the ambient space*. If $v, w \in \mathcal{V}_a$ with $v|_I = w|_I$ on $I = \mathrm{dom}(v) \cap \mathrm{dom}(w)$, then we write $v = w$. Note that $\mathcal{V} \subset \mathcal{V}_e \subset \mathcal{V}_a$ are strict inclusions and $\mathcal{V}_\infty = \mathcal{V}_e$. For $(f,g) \in \mathcal{V}_a \times \mathcal{V}_a$, the domains of f and g may be different; we adopt the convention $\mathrm{dom}(f,g) := \mathrm{dom}(f) \cap \mathrm{dom}(g)$. We define $\mathcal{V} \subset \mathcal{S}$ to be a *signal space* if and only if it is a vector space. In our applications, frequently $\mathcal{V}$ will be a normed signal space, such as $L^p(\mathbb{R}_+, \mathbb{R}^m)$ for $1 \le p \le \infty$, in which case $\mathcal{V}_e = L^p_{\mathrm{loc}}(\mathbb{R}_+, \mathbb{R}^m)$, $\mathcal{V}_\omega = L^p_{\mathrm{loc}}([0,\omega), \mathbb{R}^m)$ for $\omega \in (0,\infty]$, and $\mathcal{V}_a = \cup_{0<\omega\le\infty} L^p_{\mathrm{loc}}([0,\omega), \mathbb{R}^m)$. It is important to note that $\mathcal{V}_\omega \ne L^p([0,\omega), \mathbb{R}^m)$. Throughout the paper we consider only those normed signal spaces $\mathcal{V}$ which have the property that $\sup_{\tau \ge 0} \|T_\tau x\| < \infty$ implies $x \in \mathcal{V}$. We observe that $L^p(\mathbb{R}_+, \mathbb{R}^m)$ for $1 \le p \le \infty$ is such a normed signal space. We will often write $\|x\|_\tau = \|T_\tau x\|$. For a normed signal space $\mathcal{U}$ and a Euclidean space $\mathbb{R}^n$, we will also consider subsets of spaces of the form $\mathcal{V} = \mathbb{R}^n \times \mathcal{U}$ which, on identifying each $\theta \in \mathbb{R}^n$ with the constant signal $t \mapsto \theta$, can be thought of as a normed signal space with norm given by $\|(\theta, x)\| = \sqrt{|\theta|^2 + \|x\|^2_{\mathcal{U}}}$.

2.2. Well-posedness. A mapping $Q\colon \mathcal{X}_1 \to \mathcal{X}_2$ between signal spaces is said to be *causal* if and only if for all $\tau > 0$, $x, y \in \mathcal{X}_1$, $T_\tau x = T_\tau y$ implies $T_\tau Q x = T_\tau Q y$. Let $\mathcal{U}$ and $\mathcal{Y}$ be normed signal spaces and let $P\colon \mathcal{U}_a \to \mathcal{Y}_a$ and $C\colon \mathcal{Y}_a \to \mathcal{U}_a$ be causal mappings representing a plant and controller, respectively. Our central concern is the system of equations

$$[P,C] \;:\quad y_1 = P u_1, \quad u_2 = C y_2, \quad u_0 = u_1 + u_2, \quad y_0 = y_1 + y_2 \tag{2.1}$$

corresponding to the closed-loop feedback configuration as depicted in Figure 2.1. By a solution of (2.1) we mean the following. For $w_0 = (u_0, y_0) \in \mathcal{W} := \mathcal{U} \times \mathcal{Y}$, a pair

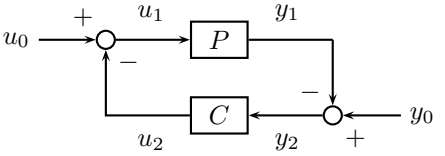

FIG. 2.1. *The closed-loop system* $[P, C]$.

$(w_1, w_2) = \big((u_1, y_1), (u_2, y_2)\big) \in \mathcal{W}_a \times \mathcal{W}_a$, $\mathcal{W}_a := \mathcal{U}_a \times \mathcal{Y}_a$, is a *solution* of (2.1) if and only if (2.1) holds on $\operatorname{dom}(w_1, w_2)$. The (possibly empty) set of all solutions is denoted by $\mathcal{X}_{w_0} := \big\{(w_1, w_2) \in \mathcal{W}_a \times \mathcal{W}_a |\ (w_1, w_2) \text{ solves } (2.1)\big\}$. The closed-loop system $[P, C]$, given by (2.1), is said to have (a) the *existence property* if and only if $\mathcal{X}_{w_0} \neq \emptyset$; (b) the *uniqueness property* if and only if for each $w_0 \in \mathcal{W}$,

$$(\hat{w}_1, \hat{w}_2), (\tilde{w}_1, \tilde{w}_2) \in \mathcal{X}_{w_0} \Rightarrow (\hat{w}_1, \hat{w}_2) = (\tilde{w}_1, \tilde{w}_2) \ \text{ on } \ \operatorname{dom}(\hat{w}_1, \hat{w}_2) \cap \operatorname{dom}(\tilde{w}_1, \tilde{w}_2).$$

Assume that $[P, C]$ has the existence and uniqueness properties. For each $w_0 \in \mathcal{W}$, define ω_{w_0}, $0 < \omega_{w_0} \leq \infty$, by the property $[0, \omega_{w_0}) := \cup_{(\hat{w}_1, \hat{w}_2) \in \mathcal{X}_{w_0}} \operatorname{dom}(\hat{w}_1, \hat{w}_2)$, and define $(w_1, w_2) \in \mathcal{W}_a \times \mathcal{W}_a$, with $\operatorname{dom}(w_1, w_2) = [0, \omega_{w_0})$, by the property $(w_1, w_2)|_{[0,t)} \in \mathcal{X}_{w_0}$ for all $t \in [0, \omega_{w_0})$. This construction induces an operator $H_{P,C} : \mathcal{W} \to \mathcal{W}_a \times \mathcal{W}_a$, $w_0 \mapsto (w_1, w_2)$. The closed-loop system $[P, C]$, given by (2.1), is said to be

- *locally well posed* if and only if it has the existence and uniqueness properties and the operator $H_{P,C} \colon \mathcal{W} \to \mathcal{W}_a \times \mathcal{W}_a$, $w_0 \mapsto (w_1, w_2)$, is causal;
- *globally well posed* if and only if it is locally well posed and $\operatorname{im} H_{P,C} \subset \mathcal{W}_e \times \mathcal{W}_e$;
- $\mathcal{W}$*-stable* if and only if it is locally well posed and $\operatorname{im} H_{P,C} \subset \mathcal{W} \times \mathcal{W}$;
- *regularly well posed* if and only if it is locally well posed and

$$\forall\, w_0 \in \mathcal{W} \quad \big[\ \omega_{w_0} < \infty \quad \Longrightarrow \quad T_{\omega_{w_0}} H_{P,C}(w_0) \notin \mathcal{W} \times \mathcal{W}\big]\,. \tag{2.2}$$

If $[P, C]$ is globally well posed, then for each $w_0 \in \mathcal{W}$ the solution $H_{P,C}(w_0)$ exists on the half line $\mathbb{R}_+$. Regular well posedness means that if the closed-loop system has a finite escape time $\omega > 0$ for some disturbance $(u_0, y_0) \in \mathcal{W}$, then at least one of the signals (u_1, y_1) or (u_2, y_2) is not a restriction to $[0, \omega)$ of a function in $\mathcal{W}$. If $[P, C]$ is regularly well posed and satisfies

$$\forall\, w_0 \in \mathcal{W} \quad \big[\ \omega_{w_0} < \infty \quad \Longrightarrow \quad T_{\omega_{w_0}} H_{P,C}(w_0) \in \mathcal{W} \times \mathcal{W}\big]\,,$$

then there does not exist a solution of $[P, C]$ with a finite escape time, and therefore $[P, C]$ is globally well posed. However, global well posedness does not guarantee that each solution belongs to $\mathcal{W} \times \mathcal{W}$; the latter is ensured by $\mathcal{W}$-stability of $[P, C]$. Note also that neither regular nor global well posedness implies the other. Our main concern will be the situation wherein the closed-loop system $[P, C]$ is generated by a system of (nonlinear) differential equations. In this context, a globally well-posed system is a system with the property of existence and uniqueness of solutions and for which finite-time blow up does not occur: all (forward) solutions have a maximal interval of existence $[0, \infty)$. Regular well posedness usually follows from standard existence theory for differential equations when $\mathcal{W} = L^\infty \times L^\infty$. However, when $\mathcal{W} \neq L^\infty \times L^\infty$ (in this paper we are primarily interested in $\mathcal{W} = L^2 \times L^2$), stronger properties of the underlying differential equations are required. As will be shown, all closed-loop systems considered in this paper are regularly well posed.

2.3. Graphs and gf-stability. In our investigation of robustness of stability properties of a closed-loop system, the concept of graphs and gf-stability will play a central role. Corresponding to a plant operator P (respectively, the controller operator C) is a subset of $\mathcal{W}$, called the *graph* of the plant $\mathcal{G}_P$ (respectively, the controller $\mathcal{G}_C$), defined as

$$\mathcal{G}_P = \left\{ \begin{pmatrix} u \\ Pu \end{pmatrix} \;\middle|\; u \in \mathcal{U},\ Pu \in \mathcal{Y} \right\} \subset \mathcal{W}, \quad \mathcal{G}_C = \left\{ \begin{pmatrix} Cy \\ y \end{pmatrix} \;\middle|\; Cy \in \mathcal{U},\ y \in \mathcal{Y} \right\} \subset \mathcal{W}.$$

Note that in general, $\mathcal{G}_P, \mathcal{G}_C \neq \mathcal{W}$. A causal operator $F\colon \mathcal{X} \to \mathcal{V}_a$, where $\mathcal{X}, \mathcal{V}$ are subsets of normed signal spaces, is said to be gf-stable if and only if $\operatorname{im} F \subset \mathcal{V}$ and if the following nonlinear so-called *gain function* is well defined:

$$(2.3) \quad g[F]\colon (r_0, \infty) \to \mathbb{R}_+,$$
$$r \mapsto g[F](r) = \sup \left\{ \|T_\tau F x\| \,\middle|\, x \in \mathcal{X}\ ,\ \|T_\tau x\| \in (r_0, r],\ \tau > 0 \right\},$$

where $r_0 := \inf_{x \in \mathcal{X}} \|x\| < \infty$. Observe that $\|Fx\|_\tau \leq g[F](\|x\|_\tau)$. A closed-loop system $[P, C]$ is said to be *gf-stable* if and only if it is globally well posed and $H_{P,C}\colon \mathcal{W} \to \mathcal{W}_e \times \mathcal{W}_e$ is gf-stable. Note the following facts: (i) global well posedness of $[P, C]$ implies that $\operatorname{im} H_{P,C} \subset \mathcal{W}_e \times \mathcal{W}_e$; (ii) gf-stability of $[P, C]$ implies $\mathcal{W}$-stability of $[P, C]$; (iii) if $[P, C]$ is $\mathcal{W}$-stable, then $H_{P,C} : \mathcal{W} \to \mathcal{G}_P \times \mathcal{G}_C$ is a bijective operator with inverse $H_{P,C}^{-1} : (w_1, w_2) \mapsto w_1 + w_2$. To see (iii), note that $\operatorname{im} H_{P,C} \subset \mathcal{W} \times \mathcal{W}$ implies that $\operatorname{im} H_{P,C} \subset \mathcal{G}_P \times \mathcal{G}_C$, and since for any $w_1 \in \mathcal{G}_P \subset \mathcal{W}$, $w_2 \in \mathcal{G}_C \subset \mathcal{W}$ we have $w_1 + w_2 \in \mathcal{W}$, it follows that $\operatorname{im} H_{P,C} \supset \mathcal{G}_P \times \mathcal{G}_C$. Therefore, we can think of a gf-stable $H_{P,C}$ as a surjective operator $H_{P,C}\colon \mathcal{W} \to \mathcal{G}_P \times \mathcal{G}_C$. The inverse of $H_{P,C} : \mathcal{W} \to \mathcal{G}_P \times \mathcal{G}_C$ is obviously $H_{P,C}^{-1} : (w_1, w_2) \mapsto w_1 + w_2$. Finally, with a closed-loop system $[P, C]$ we associate the following two parallel projection operators: $\Pi_{P//C} : \mathcal{W} \to \mathcal{W}_a$, $w_0 \mapsto w_1$ and $\Pi_{C//P} : \mathcal{W} \to \mathcal{W}_a$, $w_0 \mapsto w_2$. Clearly, $H_{P,C} = \left(\Pi_{P//C}\,, \Pi_{C//P}\right)$ and $\Pi_{P//C} + \Pi_{C//P} = I$. Therefore, gf-stability of one of the operators $\Pi_{P//C}$ and $\Pi_{C//P}$ implies the gf-stability of the other, and so gf-stability of either operator implies gf-stability of the closed-loop system $[P, C]$.

2.4. The nonlinear gap. The essence of the paper is a study of robust stability in a specific adaptive control context. Robust stability is the property that the stability properties of a globally well-posed closed-loop system $[P, C]$ persist under "sufficiently small" perturbations of the plant. In other words robust stability is the property that $[P_1, C]$ inherits the stability properties of $[P, C]$ when the plant P is replaced with any plant P_1 sufficiently "close" to P. In the context of this paper, plants P_1 and P_2 are deemed to be close if and only if the nonlinear gap [7] between P_1 and P_2 is small, where the nonlinear gap is defined as follows. Let $\Gamma := \left\{ P : \mathcal{U}_a \to \mathcal{Y}_a \,\middle|\, P \text{ is causal} \right\}$ and, for $P_1, P_2 \in \Gamma$, define the (possibly empty) set $\mathcal{O}_{P_1,P_2} := \left\{ \Phi\colon \mathcal{G}_{P_1} \to \mathcal{G}_{P_2} \,\middle|\, \Phi \text{ is causal, bijective, and } \Phi(0) = 0 \right\}$. Write

$$\vec{\delta}(P_1, P_2) := \inf_{\Phi \in \mathcal{O}_{P_1,P_2}} \sup_{x \in \mathcal{G}_{P_1} \setminus \{0\},\ \tau > 0} \left(\frac{\|(\Phi - I)|_{\mathcal{G}_{P_1}} x\|_\tau}{\|x\|_\tau} \right),$$

with the convention that $\vec{\delta}(P_1, P_2) := \infty$ if $\mathcal{O}_{P_1,P_2} = \emptyset$. The *nonlinear gap* δ is

$$(2.4) \quad \delta\colon \Gamma \times \Gamma \to [0, \infty], \qquad (P_1, P_2) \mapsto \delta(P_1, P_2) := \max\{\vec{\delta}(P_1, P_2), \vec{\delta}(P_2, P_1)\}.$$

The nonlinear gap provides a generalization of the standard definition of the linear gap δ_0 (previously discussed briefly in the introduction). To explain this, some notation

is needed. For $q, m \in \mathbb{N}$, let $R_{q,m}$ denote the set of proper, rational, $(q \times m)$-matrix-valued functions and let $H^\infty_{q,m}$ denote the set of analytic and bounded $\mathbb{C}^{q\times m}$-valued functions on the open right half plane $\mathbb{C}_+ := \{\lambda \in \mathbb{C} |\ \mathrm{Re}(\lambda) > 0\}$. By $RH^\infty_{q,m}$, we denote the class of functions in $R_{q,m}$ that are analytic in $\mathbb{C}_+$. It is known (see, for example, [17, pp. 74–75; 261–262]) that any $P \in R_{q,m}$ has a normalized right coprime factorization, that is, $P = ND^{-1}$, where $N \in RH^\infty_{q,m}$, $D \in RH^\infty_{m,m}$, D has an inverse in $R_{m,m}$, and $N^*N + D^*D = I_m$, where $N^*(s) := \overline{N(-\bar{s})}^T$. Let $\mathcal{U} = L^2(\mathbb{R}_+, \mathbb{R}^m)$, $\mathcal{Y} = L^2(\mathbb{R}_+, \mathbb{R}^q)$ for some $m, q \in \mathbb{N}$ and associate with $\hat{P} \in R_{q,m}$ the linear operator $P\colon \mathcal{U}_e \to \mathcal{Y}_e,\ u \mapsto y := \mathbf{L}^{-1}(\hat{P}) \star u$, where $\mathbf{L}$ denotes the Laplace transform and $\star$ denotes convolution. We refer to P as a linear plant with associated transfer function $\hat{P} \in R_{q,m}$. For $i = 1, 2$, let $P_i\colon \mathcal{U}_e \to \mathcal{Y}_e$ be linear plants with associated strictly proper rational transfer functions $\hat{P}_i = N_i D_i^{-1}$, where $(N_i, D_i) \in RH^\infty_{q,m} \times RH^\infty_{m,m}$ are right coprime factors (analogous to (1.2)), and let $\Pi_i : \mathcal{U}_e \times \mathcal{Y}_e \to \mathcal{G}_{P_i}$ denote the orthogonal projection onto the closed subspace $\mathcal{G}_{P_i}$. The linear gap between these plants is defined as in (1.3), with

$$\vec{\delta}_0(\hat{P}_i, \hat{P}_j) := \inf\big\{\|(\Delta_N, \Delta_D)\|_{H^\infty}\big|\ \ \Delta_N \in RH^\infty_{q,m},\ \Delta_D \in RH^\infty_{m,m},\ \hat{P}_j = (N_i + \Delta_N)(D_i + \Delta_D)^{-1}\big\}.$$

In [7, Proposition 5] it is shown that if $\max\{\|(\Pi_2 - \Pi_1)\,\Pi_1\|, \|(\Pi_1 - \Pi_2)\,\Pi_2\|\} < 1$, then $\vec{\delta}(P_1, P_2) = \|(\Pi_2 - \Pi_1)\,\Pi_1\|$, and in [5, Lemma 2] it is shown that $\|(\Pi_2 - \Pi_1)\,\Pi_1\| = \vec{\delta}_0(\hat{P}_1, \hat{P}_2)$ if $\vec{\delta}_0(\hat{P}_1, \hat{P}_2) < 1$, the conjunction of which yields

$$\vec{\delta}(P_1, P_2) \ = \ \vec{\delta}_0(\hat{P}_1, \hat{P}_2) \qquad \text{if } \ \delta_0(\hat{P}_1, \hat{P}_2) < 1. \tag{2.5}$$

The topology induced on $R_{q,m}$ by the gap δ_0 is called the graph topology [17, p. 235]; note that the graph topology on Γ induces the graph topology on $R_{q,m}$ via the subset topology and the Laplace transform $\mathbf{L}$. Robust stability with respect to gap perturbations has been extensively studied in the linear setting; see, e.g., [18] and the references therein. In a nonlinear setting, sufficient conditions for robust gain stability were given in [7]. The adaptive controllers considered in this paper and in [4] do not meet any of the sufficient conditions of [7] and hence require a further development of the robust stability theory in section 5 of [4], as given in Theorem 3.11 of the present paper.

3. System classes and the adaptive controller. We are interested in the control of linear m-input, m-output stabilizable n-dimensional state space realizations of transfer functions in $R_{m,m}$, i.e., systems of the form

$$\dot{x}(t) = A\,x(t) + B\,u_1(t), \qquad x(0) \in \mathbb{R}^n, \qquad y_1(t) = Cx(t). \tag{3.1}$$

Henceforth, we fix (arbitrarily) the number $m \geq 1$ of inputs/outputs but allow for a variation in the state space dimension n. We denote this system class by

$$\mathcal{P}_n \ = \ \{(A, B, C) \in E_n \ \mid \ n \geq m,\ (A, B, C) \ \text{ is stabilizable and detectable}\}, \tag{3.2}$$

where $E_n := \mathbb{R}^{n\times n} \times \mathbb{R}^{n\times m} \times \mathbb{R}^{m\times n}$, and write $\mathcal{P} := \cup_{n\geq m}\mathcal{P}_n$. We define the subclass of minimum-phase systems with "high-frequency gain" CB having spectrum in $\mathbb{C}_+$,

$$\widetilde{\mathcal{M}}_n \ = \ \left\{(A, B, C) \in \mathcal{P}_n \ \middle|\ \ \sigma(CB) \subset \mathbb{C}_+, \ \ \det\begin{bmatrix} sI_n - A & B \\ C & 0 \end{bmatrix} \neq 0\ \forall s \in \overline{\mathbb{C}}_+\right\}. \tag{3.3}$$

Observe that for each $(A, B, C) \in \widetilde{\mathcal{M}}_n$, there exists an element of its similarity orbit $\{(TAT^{-1}, TB, CT^{-1}) |\ T \in \mathbb{R}^{n\times n} \text{ invertible}\}$ such that

$$TAT^{-1} = \begin{bmatrix} A_1 & A_2 \\ A_3 & A_4 \end{bmatrix}, \quad TB = \begin{bmatrix} 0 \\ B_2 \end{bmatrix} = \begin{bmatrix} 0 \\ CB \end{bmatrix}, \quad CT^{-1} = \begin{bmatrix} 0 & I \end{bmatrix},$$

where $\sigma(B_2) \subset \mathbb{C}_+$ and, by the minimum-phase property, A_1 has a spectrum in the open left half complex plane $\mathbb{C}_-$. Therefore, we introduce

$$\mathcal{M}_n := \left\{ (A, B, C) \in \mathcal{P}_n \;\middle|\; \begin{array}{l} A = \begin{bmatrix} A_1 & A_2 \\ A_3 & A_4 \end{bmatrix},\ B = \begin{bmatrix} 0 \\ B_2 \end{bmatrix},\ C = [0 \ \ I], \\ B_2, A_4 \in \mathbb{R}^{m\times m},\ \sigma(A_1) \subset \mathbb{C}_-,\ \sigma(B_2) \subset \mathbb{C}_+ \end{array} \right\} \tag{3.4}$$

and write $\mathcal{M} := \cup_{n\geq m} \mathcal{M}_n$. For a system of class $\mathcal{M}_n$, (3.1) may be expressed in the equivalent form

$$\left.\begin{array}{ll} \dot{z}(t) = A_1 z(t) + A_2 y_1(t), & z(0) = z^0 \in \mathbb{R}^{n-m} \\ \dot{y_1}(t) = A_3 z(t) + A_4 y_1(t) + B_2 u_1(t), & y_1(0) = y_1^0 \in \mathbb{R}^m \end{array}\right\}, \quad (z^0, y_1^0) = x^0. \tag{3.5}$$

We will have occasion to identify $\mathcal{P}_n$ with a subspace of a Euclidean space $\mathbb{R}^{n^2+2mn}$ by identifying a plant $\theta = (A, B, C)$ with a vector θ consisting of the elements of the plant matrices, ordered lexicographically. With normed signal spaces $\mathcal{U}$ and $\mathcal{Y}$ and $(\theta, x^0) \in \mathcal{P}_n \times \mathbb{R}^n$, we associate the causal plant operator

$$\widetilde{P}(\theta, x^0) :\ \mathcal{U}_a \to \mathcal{Y}_a, \quad u_1 \mapsto \widetilde{P}(\theta, x^0)(u_1) := y_1\,, \tag{3.6}$$

where, for $u_1 \in \mathcal{U}_a$ with $\mathrm{dom}(u_1) = [0, \omega)$, we have $y_1 = Cx$, x being the unique solution of (3.1) on $[0, \omega)$. Note that $\widetilde{P}$ is a map from $\bigcup_{n\geq m}(\mathcal{P}_n \times \mathbb{R}^n)$ to the space of maps $\mathcal{U}_a \to \mathcal{Y}_a$. Furthermore, for $(\theta, x^0) = (A, B, C, x^0) \in \mathcal{P}_n \times \mathbb{R}^n$, $\widetilde{P}(\theta, x^0)$ corresponds to a stabilizable and detectable realization of $C(sI_n - A)^{-1}B \in R_{m,m}$. Our objective is to study, in the context of systems of form (3.1), the adaptive strategy

$$u_2(t) = -k(t)y_2(t), \quad \dot{k}(t) = \|y_2(t)\|^2, \quad k(0) = k^0 \in \mathbb{R}_+\,, \tag{3.7}$$

with the associated control operator, parameterized by k^0, denoted by

$$\widetilde{C}(k^0) : \mathcal{Y}_a \to \mathcal{U}_a, \qquad y_2 \mapsto \widetilde{C}(k^0)(y_2) := u_2. \tag{3.8}$$

Note that $\widetilde{C}$ is a map from $\mathbb{R}_+$ to the space of causal maps $\mathcal{Y}_a \to \mathcal{U}_a$. In particular and with reference to Figure 2.1, we will study properties of the closed-loop system $[\widetilde{P}(\theta, x^0), \widetilde{C}(k^0)]$, generated by the application of the controller (3.8) to system (3.1), in the presence of disturbances $(u_0, y_0) \in \mathcal{W}$ satisfying the interconnection equations

$$u_0 \ = \ u_1 + u_2, \qquad y_0 \ = \ y_1 + y_2\,. \tag{3.9}$$

Results will be given for systems (3.5) of class $\mathcal{M}_n$ (such systems will later play the role of the nominal plant) and for the more general class of systems (3.1), (3.2) (such systems will later play the role of the perturbed plant).

3.1. Properties of the interconnection of the adaptive controller with the general linear plant. In this section we investigate the interconnection of the adaptive controller (3.7) (with associated operator $\widetilde{C}(k^0)$) and any plant in the form (3.1) (with associated operator $\widetilde{P}(\theta, x^0)$), where $(\theta, x^0, k^0) \in \mathcal{P}_n \times \mathbb{R}^n \times \mathbb{R}_+$.

PROPOSITION 3.1. *Let $n \geq m$, $(\theta, x^0, k^0) \in \mathcal{P}_n \times \mathbb{R}^n \times \mathbb{R}_+$, and $u_0, y_0 \in L^\infty_{\mathrm{loc}}(\mathbb{R}_+, \mathbb{R}^m)$. Then the closed-loop initial-value problem given by* (3.1), (3.7), (3.9) *has the following properties:*

(i) *There exists a unique maximal solution $(x, k) : [0, \omega) \to \mathbb{R}^n \times \mathbb{R}_+$, $0 < \omega \leq \infty$;*
(ii) *if $k \in L^\infty([0, \omega), \mathbb{R}_+)$, then $\omega = \infty$;*
(iii) *if $y_2 \in L^2([0, \omega), \mathbb{R}^m)$, then $\omega = \infty$.*

Proof. (i) follows from the theory of ordinary differential equations.

(ii) If $k \in L^\infty([0, \omega), \mathbb{R}_+)$, then consider the following subsystem of the initial-value problem (3.1), (3.7): $\dot{x}(t) = Ax(t) + B\big[u_0(t) + k(t)y_2(t)\big]$. Integration, together with elementary estimates, yields the existence of constants $c_0, c_1 > 0$ such that

$$\|x(t)\| \leq c_0 \left(e^{c_1 t} + \int_0^t e^{c_1(t-s)} \big(\|u_0(s)\| + \|y_2(s)\|\big) \mathrm{d}s \right) \quad \forall\, t \in [0, \omega). \tag{3.10}$$

Suppose $\omega < \infty$. Since $y_2 \in L^2([0, \omega), \mathbb{R}^m)$ (which is equivalent to $k \in L^\infty([0, \omega), \mathbb{R}_+)$) and since $u_0 \in L^\infty_{\mathrm{loc}}(\mathbb{R}_+, \mathbb{R}^m)$, it follows from the convolution in (3.10) that the right-hand side of (3.10) is bounded on $[0, \omega)$, which contradicts maximality of the solution x. Therefore, $\omega = \infty$.

(iii) By assumption, $y_2 \in L^2([0, \omega), \mathbb{R}^m)$, and so $t \mapsto k(t) = k^0 + \|y_2\|^2_{L^2([0,t), \mathbb{R}^m)}$ is bounded on $[0, \omega)$, and thus assertion (iii) follows from (ii). ∎

COROLLARY 3.2. *Let $\mathcal{U} = \mathcal{Y} = L^2(\mathbb{R}_+, \mathbb{R}^m)$, $n \geq m$, $(\theta, x^0, k^0) \in \mathcal{P}_n \times \mathbb{R}^n \times \mathbb{R}_+$. Then the closed-loop initial-value problem $[\widetilde{P}(\theta, x^0), \widetilde{C}(k^0)]$ given by* (2.1), (3.6), *and* (3.8) *is regularly well posed.*

Proof. Let $\mathcal{W} = L^2(\mathbb{R}_+, \mathbb{R}^m) \times L^2(\mathbb{R}_+, \mathbb{R}^m)$. The closed-loop $[\widetilde{P}(\theta, x^0), \widetilde{C}(k^0)]$ is locally well posed by Proposition 3.1(i). To prove that $[\widetilde{P}(\theta, x^0), \widetilde{C}(k^0)]$ is regularly well posed, it suffices to show that (2.2) holds. Let $w_0 = (u_0, y_0) \in \mathcal{W}$. Consider $(w_1, w_2) = H_{\widetilde{P}(\theta, x^0), \widetilde{C}(k^0)}(w_0)$, where $\mathrm{dom}\,(w_1, w_2) = [0, \omega)$ and is maximal. Suppose $T_\omega(w_1, w_2) \in \mathcal{W} \times \mathcal{W}$. Then we have $y_1 \in L^2([0, \omega), \mathbb{R}^m)$, which, in view of Proposition 3.1(iii) yields $\omega = \infty$. Hence as $w_0 \in \mathcal{W}$ is arbitrary, it follows that the closed-loop system is regularly well posed. ∎

3.2. Properties of the interconnection of the adaptive controller with the nominal plant. In this section we consider the closed-loop behavior of the nominal plant and controller interconnection given by (3.5), (3.7), and perturbations u_0, y_0 satisfying (3.9). The L^2 bounds obtained in [4] do not directly generalize to the controller (1.1), even in the single-input, single-output (SISO) case. Hence the results in this subsection are obtained via an alternative (and tighter) series of bounds than those considered in the results of [4].

PROPOSITION 3.3. *Let $n \geq m$, $(A, B, C) \in \mathcal{M}_n$, $(x^0, k^0) \in \mathbb{R}^n \times \mathbb{R}_+$, and $u_0, y_0 \in L^2([0, \infty), \mathbb{R}^m)$. Then the closed-loop initial-value problem* (3.5), (3.7), (3.9) *has the following properties:*

(i) *There exists a unique solution $(z, y_1, k) : [0, \infty) \to \mathbb{R}^n \times \mathbb{R}_+$;*
(ii) *the limit $\lim_{t\to\infty} k(t)$ exists and is finite;*
(iii) *$u_1, y_1 \in L^2(\mathbb{R}_+, \mathbb{R}^m)$, $z \in L^2(\mathbb{R}_+, \mathbb{R}^{n-m})$;*
(iv) *$\lim_{t\to\infty}(z(t), y_1(t)) = 0$.*

Proof. The closed-loop equations (3.5), (3.7), (3.9) may be expressed as

$$\left\{\begin{array}{l} \dot{z}(t) = A_1 z(t) + A_2 y_1(t)\,, \\ \dot{y_1}(t) = A_3 z(t) + A_4 y_1(t) + B_2\left(u_0(t) + k(t)\,[y_0(t) - y_1(t)]\right), \\ \dot{k}(t) = \|y_0(t) - y_1(t)\|^2, \\ u_1(t) = u_0(t) + k(t)\,[y_0(t) - y_1(t)]\,, \\ (z(0), y_1(0), k(0)) = (z^0, y_1^0, k^0) \in \mathbb{R}^{n-m} \times \mathbb{R}^m \times \mathbb{R}_+\,, \end{array}\right. \tag{3.11}$$

where $x^0 = (z^0, y_1^0)$. By Proposition 3.1 there exists a unique maximal solution $(z, y_1, k) : [0, \omega) \to \mathbb{R}^n \times \mathbb{R}_+$ of the initial-value problem (3.11) for some $\omega \in (0, \infty]$. To prove the proposition, we claim that it suffices to show that $y_1 \in L^2([0,\omega), \mathbb{R}^m)$. To argue this claim, assume that $y_1 \in L^2([0,\omega), \mathbb{R}^m)$ and first note that, by Proposition 3.1, $\omega = \infty$, and so assertion (i) holds. Assertion (ii) follows from the third of equations (3.11). Since $u_0, y_0, y_1 \in L^2(\mathbb{R}_+, \mathbb{R}^m)$ and k is bounded, we have $u_0 + k[y_0 - y_1] = u_1 \in L^2(\mathbb{R}_+, \mathbb{R}^m)$ and, since $\sigma(A_1) \subset \mathbb{C}_-$, it follows from the first of equations (3.11) that $z \in L^2(\mathbb{R}_+, \mathbb{R}^{n-m})$ and $z(t) \to 0$ as $t \to \infty$, whence we get assertion (iii). Finally, writing the second of equations (3.11) in the form

$$\dot{y}_1(t) = -y_1(t) + f(t), \quad f : t \mapsto (I + A_4) y_1(t) + A_3 z(t) + B_2\big(u_0(t) + k(t)[y_0(t) - y_1(t)]\big),$$

and noting that $f \in L^2(\mathbb{R}_+, \mathbb{R}^m)$, we conclude $y_1(t) \to 0$ as $t \to \infty$, and so (iv) holds. We proceed to show that $y_1 \in L^2([0,\omega), \mathbb{R}^m)$. First, we assemble some useful inequalities. Recalling that $\sigma(A_1) \subset \mathbb{C}_-$, we have

$$M_p := \left(\int_{\mathbb{R}_+} \|e^{A_1 t}\|^p dt\right)^{1/p} < \infty \;\; \forall\, p \in [1, \infty), \quad M_\infty := \sup_{t \in \mathbb{R}_+} \|e^{A_1 t}\| < \infty,$$

and, by the first of equations (3.11) (together with elementary estimates),

$$\|z(t)\|^2 \;\le\; 2\left[M_\infty^2 \|z^0\|^2 + M_2^2 \|A_2\|^2 \|y_1\|^2_{L^2([0,t),\mathbb{R}^m)}\right] \qquad \forall\, t \in [0, \omega). \tag{3.12}$$

Introduce the convolution operator $L : L^2(\mathbb{R}_+, \mathbb{R}^{n-m}) \to L^2(\mathbb{R}_+, \mathbb{R}^{n-m})$, given by

$$(Lv)(t) := \int_0^t e^{A_1(t-\tau)} v(\tau) d\tau\,.$$

Then $\|Lv\|_{L^2(I,\mathbb{R}^{n-m})} \le M_1 \|v\|_{L^2(I,\mathbb{R}^{n-m})}$ for every bounded interval $I \subset \mathbb{R}_+$ and all $v \in L^2_e(\mathbb{R}_+, \mathbb{R}^{n-m})$, which, with the first of equations (3.11), yields

$$\|z\|^2_{L^2([s,t],\mathbb{R}^{n-m})} \le 2M_1^2\left[\|z(s)\|^2 + \|A_2\|^2 \|y_1\|^2_{L^2([s,t],\mathbb{R}^m)}\right]$$

for all s, t with $0 \le s \le t < \omega$. Writing

$$c_1 := \frac{1}{2} + M_1^2\left[1 + \|A_2\|^2\right], \tag{3.13}$$

we may infer

$$\begin{aligned} \int_s^t \|z(\tau)\|\|y_1(\tau)\| d\tau &\le \frac{1}{2}\left[\|z\|^2_{L^2([s,t],\mathbb{R}^{n-m})} + \|y_1\|^2_{L^2([s,t],\mathbb{R}^m)}\right] \\ &\le c_1\left[\|z(s)\|^2 + \|y_1\|^2_{L^2([s,t],\mathbb{R}^m)}\right] \;\text{ for all } s, t \text{ with } 0 \le s \le t < \omega. \end{aligned} \tag{3.14}$$

Also, observe that, for all s, t with $0 \le s \le t < \infty$,

$$k(t) = k(s) + \|y_0 - y_1\|^2_{L^2([s,t],\mathbb{R}^m)} \le k(s) + \|y_0\|^2_{L^2([s,t],\mathbb{R}^m)} + \|y_1\|^2_{L^2([s,t],\mathbb{R}^m)}. \tag{3.15}$$

Since $\sigma(B_2) \subset \mathbb{C}_+$, the Lyapunov equation $QB_2 + B_2^T Q - 2I = 0$ has a unique positive-definite symmetric solution Q. From the second of equations (3.11), noting that $\|QB_2\| = 1$ and invoking elementary estimates, we have

$$\begin{aligned}\langle y_1(t), Q\dot{y}_1(t)\rangle \le \|QA_3\|\|z(t)\|\|y_1(t)\| - \frac{1}{2}\big[k(t) - 2\|QA_4\| - 1\big]\|y_1(t)\|^2 \\ + \frac{1}{2}k(t)\|y_0(t)\|^2 + \frac{1}{2}\|u_0(t)\|^2 \ \forall\ t \in [0,\omega)\end{aligned}$$

which, on integration, using (3.14), (3.15) and invoking monotonicity of k, yields

$$\begin{aligned}0 \le \langle y_1(t), Qy_1(t)\rangle \le \langle y_1(s), Qy_1(s)\rangle + 2c_1\|QA_3\|\big(\|z(s)\|^2 + \|y_1\|^2_{L^2([s,t],\mathbb{R}^m)}\big) \\ + \big(k(s) + \|y_0\|^2_{L^2([s,t],\mathbb{R}^m)} + \|y_1\|^2_{L^2([s,t],\mathbb{R}^m)}\big)\|y_0\|^2_{L^2(\mathbb{R}_+,\mathbb{R}^m)} + \|u_0\|^2_{L^2(\mathbb{R}_+,\mathbb{R}^m)} \\ - \big(k(s) - 2\|QA_4\| - 1\big)\|y_1\|^2_{L^2([s,t],\mathbb{R}^m)} \ \ \forall\ s, t \text{ with } 0 \le s \le t < \omega.\end{aligned}$$

Defining

$$c_2 := 2c_1\|QA_3\| + 2\|QA_4\| + 2 + \|y_0\|^2_{L^2(\mathbb{R}_+,\mathbb{R}^m)}, \tag{3.16}$$

we have

$$\begin{aligned}0 \le \langle y_1(t), Qy_1(t)\rangle \le \langle y_1(s), Qy_1(s)\rangle + 2c_1\|QA_3\|\|z(s)\|^2 + \|u_0\|^2_{L^2(\mathbb{R}_+,\mathbb{R}^m)} \\ - \big(k(s) - c_2 + 1\big)\|y_1\|^2_{L^2([s,t],\mathbb{R}^m)} \ \forall\ s, t \text{ with } 0 \le s \le t < \omega.\end{aligned} \tag{3.17}$$

Next, observe that

$$\|y_1\|^2_{L^2([0,t),\mathbb{R}^m)} \le \|y_0\|^2_{L^2([0,t),\mathbb{R}^m)} + \|y_2\|^2_{L^2([0,t),\mathbb{R}^m)} = \|y_0\|^2_{L^2([0,t),\mathbb{R}^m)} + k^0 + k(t)$$

for all $t \in [0,\omega)$. We consider two possible cases.

Case 1. Assume $k(t) \le c_2$ for all $t \in [0,\omega)$. Then $\|y_1\|^2_{L^2([0,\omega),\mathbb{R}^m)} \le \|y_0\|^2_{L^2(\mathbb{R}_+,\mathbb{R}^m)} + c_2$.

Case 2. Assume $k(\tau) = c_2$ for some $\tau \in [0,\omega)$. Then, by (3.17) with $s = \tau$, we have

$$\|y_1\|^2_{L^2([\tau,\omega),\mathbb{R}^m)} \le \langle y_1(\tau), Qy_1(\tau)\rangle + 2c_1\|QA_3\|\|z(\tau)\|^2 + \|u_0\|^2_{L^2(\mathbb{R}_+,\mathbb{R}^m)}.$$

By monotonicity, $k(t) \le c_2$ for all $t \in [0,\tau]$, and so $\|y_1\|^2_{L^2([0,\tau],\mathbb{R}^m)} \le \|y_0\|^2_{L^2(\mathbb{R}_+,\mathbb{R}^m)} + c_2$. By (3.17) with $s = 0$ and $t = \tau$, we now have

$$\begin{aligned}\langle y_1(\tau), Qy_1(\tau)\rangle \le c_3 := \langle y_1^0, Qy_1^0\rangle + 2c_1\|QA_3\|\|z^0\|^2 + \|u_0\|^2_{L^2(\mathbb{R}_+,\mathbb{R}^m)} \\ + (c_2 + 1)\big(\|y_0\|^2_{L^2(\mathbb{R}_+,\mathbb{R}^m)} + c_2\big).\end{aligned} \tag{3.18}$$

By (3.12), we have

$$\|z(\tau)\|^2 \le c_4 := 2\big[M_\infty^2\|z^0\|^2 + M_2^2\|A_2\|^2\|y_0\|^2_{L^2(\mathbb{R}_+,\mathbb{R}^m)} + c_2M_2^2\|A_2\|^2\big]. \tag{3.19}$$

We may now conclude that

$$\|y_1\|^2_{L^2([0,\tau],\mathbb{R}^m)} + \|y_1\|^2_{L^2([\tau,\omega),\mathbb{R}^m)} \leq c_5 := c_2 + c_3 + 2c_1c_4\|QA_3\| + \|(u_0,y_0)\|^2_{L^2(\mathbb{R}_+,\mathbb{R}^{2m})}. \tag{3.20}$$

Therefore, in both Cases 1 and 2, we have $\|y_1\|^2_{L^2([0,\omega),\mathbb{R}^m)} \leq c_5$. ∎

Proposition 3.3 immediately implies the following.

COROLLARY 3.4. *Let $n \geq m$, $\mathcal{U} = \mathcal{Y} = L^2(\mathbb{R}_+,\mathbb{R}^m)$, $\theta = (A,B,C) \in \mathcal{M}_n$, and $(x^0,k^0) \in \mathbb{R}^n \times \mathbb{R}_+$. Then the closed loop $[\widetilde{P}(\theta,x^0),\widetilde{C}(k^0)]$ given by* (3.1) (*equivalently,* (3.5)), (3.6), (3.8), (3.9) *is globally well posed and $(\mathcal{U}\times\mathcal{Y})$-stable.*

PROPOSITION 3.5. *Let $n \geq m$ and define*

$$\mathcal{D} := \mathcal{M}_n \times \mathbb{R}^n \times \mathbb{R}_+ \times L^2(\mathbb{R}_+,\mathbb{R}^m) \times L^2(\mathbb{R}_+,\mathbb{R}^m). \tag{3.21}$$

There exists a continuous map $\nu : \mathcal{D} \to \mathbb{R}_+$ such that, for all

$$d = (A,B,C,x^0,k^0,u_0,y_0) \in \mathcal{D},$$

the closed-loop system (3.11) *is such that $\|(u_1,y_1)\|_{L^2(\mathbb{R}_+,\mathbb{R}^{2m})} \leq \nu(d)$.*

Proof. Observe that the parameters c_i, $i = 1,\dots,5$, defined in (3.13), (3.16), (3.18), (3.19), and (3.20), depend continuously on the data $d = (A,B,C,x^0,k^0,u_0,y_0)$. In particular, the map $\hat{\nu} : d \mapsto \sqrt{c_5}$ is continuous. Let $d \in \mathcal{D}$ be arbitrary. Then, by Proposition 3.3 (and recalling (3.20)), we have $\|y_1\|_{L^2(\mathbb{R}_+,\mathbb{R}^m)} \leq \hat{\nu}(d)$. Now,

$$k(t) = k^0 + \|y_0 - y_1\|^2_{L^2([0,t),\mathbb{R}^m)} \leq \nu^*(d) := k^0 + 2\|y_0\|^2_{L^2(\mathbb{R}_+,\mathbb{R}^m)} + 2(\hat{\nu}(d))^2 \quad \forall\, t \in \mathbb{R}_+.$$

Therefore,

$$\begin{aligned}\|u_1\|_{L^2([0,t),\mathbb{R}^m)} &= \|u_0 + k(t)[y_0(t) - y_1(t)]\|_{L^2([0,t),\mathbb{R}^m)} \\ &\leq \tilde{\nu}(d) := \|u_0\|_{L^2(\mathbb{R}_+,\mathbb{R}^m)} + \nu^*(d)\big(\|y_0\|_{L^2(\mathbb{R}_+,\mathbb{R}^m)} + \hat{\nu}(d)\big) \ \ \forall\, t \in [0,\omega).\end{aligned}$$

We may now infer that $\|(u_1,y_1)\|_{L^2(\mathbb{R}_+,\mathbb{R}^{2m})} \leq \nu(d) := \sqrt{(\hat{\nu}(d))^2 + (\tilde{\nu}(d))^2}$. ∎

Remark 3.6. It is worthwhile to note that $\nu(d) \to \infty$ as the data approach the boundary of $\mathcal{M}_n$: for example, if some eigenvalues of A_1 approach the imaginary axis, then $\|L\| \to \infty$ and so c_1, given by (3.13), grows unboundedly; if $\|B_2\| \to 0$, then $\|Q\| \to \infty$ and so c_2, given by (3.16), grows unboundedly. Specifically, there exists a *bounded* sequence (d_j) in $\mathcal{D}$ such that $\nu(d_j) \to \infty$ as $j \to \infty$. However, if $\Omega \subset \mathcal{M}_n$ is closed and (d_j) is a bounded sequence in $\Omega \times \mathbb{R}^n \times \mathbb{R}_+ \times L^2(\mathbb{R}_+,\mathbb{R}^m) \times L^2(\mathbb{R}_+,\mathbb{R}^m) \subset \mathcal{D}$, then $(\nu(d_j))$ is bounded.

3.3. Construction of a gain function. To establish gap margin results, we will need to construct augmented plant and controller operators, as in [4]. Reiterating earlier remarks, we may consider $\mathcal{M}_n$ to be a subset of the Euclidean space $E_n = \mathbb{R}^{n^2+2mn}$, with the standard Euclidean norm, by identifying a plant $\theta = (A,B,C) \in \mathcal{M}_n$ with a vector $\theta \in E_n$ consisting of the $n^2 + 2mn$ elements of the plant matrices ordered lexicographically. Note that $0 \notin \mathcal{M}_n$. Let $\mathcal{U} = \mathcal{Y} = L^2(\mathbb{R}_+,\mathbb{R}^m)$ and define $\widetilde{\mathcal{U}} := \mathbb{R}^{n^2+2mn} \times \mathcal{U}$ and $\widetilde{\mathcal{W}} := \widetilde{\mathcal{U}} \times \mathcal{Y}$, which can be considered as signal spaces by identifying $\theta \in \mathbb{R}^{n^2+2mn}$ with the constant function $t \mapsto \theta$ and endowing $\widetilde{\mathcal{U}}$ with the norm $\|(\theta,u)\|_{\widetilde{\mathcal{U}}} := \sqrt{\|\theta\|^2 + \|u\|^2_{L^2(\mathbb{R}_+,\mathbb{R}^m)}}$. For given $\widetilde{P}(\theta,0)$ as in (3.6), we define the (augmented) plant operator as

$$P : \widetilde{\mathcal{U}}_a \to \mathcal{Y}_a, \quad (\theta,u_1) = \widetilde{u}_1 \mapsto y_1 = P(\widetilde{u}_1) := \widetilde{P}(\theta,0)(\widetilde{u}_1). \tag{3.22}$$

Fix $k^0 \geq 0$ and define, for $\widetilde{C}(k^0)$ as in (3.8), the (augmented) controller operator as

$$C:\ \mathcal{Y}_a \to \widetilde{\mathcal{U}}_a, \quad y_2 \mapsto \widetilde{u}_2 = C(y_2) := (0, \widetilde{C}(k^0)(y_2)). \tag{3.23}$$

For each nonempty $\Omega \subset \mathcal{M}_n$, define $\mathcal{W}^\Omega := (\Omega \times \mathcal{U}) \times \mathcal{Y}$ and $H^\Omega_{P,C} := H_{P,C}|_{\mathcal{W}^\Omega}$. It easily follows from Corollary 3.4 that $H^\Omega_{P,C}\colon \mathcal{W}^\Omega \to \widetilde{\mathcal{W}} \times \widetilde{\mathcal{W}}$ is a causal operator for any $\Omega \subset \mathcal{M}_n$. We now establish gf-stability.

PROPOSITION 3.7. *Let $n \geq m$, $k^0 \geq 0$, and assume $\Omega \subset \mathcal{M}_n$ is closed. Then, for the closed-loop system $[P, C]$ given by* (2.1), (3.22), *and* (3.23), *the operator $H^\Omega_{P,C}$ is gf-stable.*

Proof. For $\nu : \mathcal{D} \to \mathbb{R}_+$ as in Proposition 3.5 we have, for all $(\theta, u_0, y_0) \in \mathcal{W}^\Omega$,

$$\begin{aligned}\|H^\Omega_{P,C}(\theta, u_0, y_0)\|_{\widetilde{\mathcal{W}}\times\widetilde{\mathcal{W}}} &\leq \|(\theta, u_0, y_0)\|_{\widetilde{\mathcal{W}}} + 2\|(\theta, u_1, y_1)\|_{\widetilde{\mathcal{W}}} \\ &\leq \|(u_0, y_0)\|_{\mathcal{W}} + 3\,\|\theta\| + 2\,\nu(\theta, 0, k^0, u_0, y_0)\,,\end{aligned}$$

and so, for $r_0 := \inf_{w\in\mathcal{W}^\Omega} \|w\|_{\widetilde{\mathcal{W}}}$ and $\alpha \in (r_0, \infty)$, closedness of Ω yields

$$\gamma(\alpha) := \sup\left\{ \|(u_0, y_0)\|_{\mathcal{W}} + 3\|\theta\| + 2\,\nu(\theta, 0, k^0, u_0, y_0) \,\middle|\, \begin{array}{l}(\theta, u_0, y_0) \in \mathcal{W}^\Omega, \\ \|(\theta, u_0, y_0)\|_{\widetilde{\mathcal{W}}} \leq \alpha\end{array} \right\} < \infty.$$

Therefore, a gain function for $H^\Omega_{P,C}$ exists, and the proof is complete. ∎

3.4. Robust stability. In Proposition 3.3 and Corollary 3.4 we have established that, for $k^0 \geq 0$, $(\theta, x^0) \in \mathcal{M}_n \times \mathbb{R}^n$ for some $n \geq m$, and $u_0, y_0 \in L^2(\mathbb{R}_+, \mathbb{R}^m)$, the closed-loop system $[\widetilde{P}(\theta, x^0), \widetilde{C}(k^0)]$ is globally well posed and has desirable stability properties. The purpose of this section is to determine conditions under which these properties are maintained when the plant $\widetilde{P}(\theta, x^0)$ is perturbed to a plant $\widetilde{P}(\theta_1, x^0_1)$, where $(\theta_1, x^0_1) \in \mathcal{P}_q \times \mathbb{R}^q$ for some $q \geq m$, in particular when $\theta_1 \notin \mathcal{M}_q$. The essence of the main result, Theorem 3.8, is that the stability properties persist if (a) the plants $\widetilde{P}(\theta_1, 0)$ and $\widetilde{P}(\theta, 0)$ are sufficiently close (in the gap sense) and (b) the initial data x^0_1 and disturbance $w_0 = (u_0, y_0)$ are sufficiently small.

THEOREM 3.8. *Let $m, n, q \in \mathbb{N}$ with $n \geq m$, $q \geq m$, $\mathcal{U} = \mathcal{Y} = L^2(\mathbb{R}_+, \mathbb{R}^m)$, $\mathcal{W} = \mathcal{U} \times \mathcal{Y}$, and $\theta \in \mathcal{M}_n$. For (ϑ, x^0) in $\mathcal{P}_q \times \mathbb{R}^q$ or $\mathcal{P}_n \times \mathbb{R}^n$ and $k^0 \geq 0$, consider $\widetilde{P}(\vartheta, x^0)\colon \mathcal{U}_a \to \mathcal{Y}_a$ and $\widetilde{C}(k^0)\colon \mathcal{Y}_a \to \mathcal{U}_a$ as defined by* (3.6) *and* (3.8), *respectively. There exist a continuous function $\eta\colon \mathbb{R}_+ \to (0, \infty)$ and a function $\lambda : \mathcal{P}_q \to (0, \infty)$ such that the following holds. For all $(\theta_1, x^0_1, w_0, r) \in \mathcal{P}_q \times \mathbb{R}^q \times \mathcal{W} \times (0, \infty)$,*

$$\left.\begin{array}{l}\vec{\delta}(\widetilde{P}(\theta, 0), \widetilde{P}(\theta_1, 0)) \leq\ \eta(r) \\ \lambda(\theta_1)\|x^0_1\| + \|w_0\|_{\mathcal{W}} \leq r\end{array}\right\} \quad \Longrightarrow \quad H_{\widetilde{P}(\theta_1, x^0_1), \widetilde{C}(k^0)}(w_0)\ \in\ \mathcal{W} \times \mathcal{W}. \tag{3.24}$$

Remark 3.9. In the setup of Theorem 3.8, if $H_{\widetilde{P}(\theta_1, x^0_1), \widetilde{C}(k^0)}(w_0) \in \mathcal{W} \times \mathcal{W}$ with $\theta_1 = (A, B, C) \in \mathcal{P}_q$, then the following hold:

(i) If $u_1, y_1 \in L^2(\mathbb{R}_+, \mathbb{R}^m)$, then detectability of (A, C) yields that the solution x of (3.1) belongs to $x \in L^2(\mathbb{R}_+, \mathbb{R}^m)$. Since $x, \dot{x} \in L^2(\mathbb{R}_+, \mathbb{R}^m)$, it follows that $x(t) \to 0$ as $t \to \infty$. Moreover, the monotone controller gain k, given by (3.7), converges to a finite limit.

(ii) If $u_0, y_0 \in (L^2 \cap L^\infty)(\mathbb{R}_+, \mathbb{R}^m)$, then $u_1, y_1 \in L^\infty(\mathbb{R}_+, \mathbb{R}^m)$. This follows from the fact that $x \in L^\infty(\mathbb{R}_+, \mathbb{R}^m)$ by (i), and so $y_1 \in L^\infty(\mathbb{R}_+, \mathbb{R}^m)$. Furthermore, $y_2 \in L^2(\mathbb{R}_+, \mathbb{R}^m)$, and so $k \in L^\infty(\mathbb{R}_+, \mathbb{R})$, which, by $u_2 = k\, y_2$, yields $u_2 \in L^\infty(\mathbb{R}_+, \mathbb{R}^m)$, whence $u_1 \in L^\infty(\mathbb{R}_+, \mathbb{R}^m)$.

(iii) If $u_0, y_0 \in L^2(\mathbb{R}_+, \mathbb{R}^m)$ and $\lim_{t\to\infty} u_0(t) = \lim_{t\to\infty} y_0(t) = 0$, then $\lim_{t\to\infty} u_1(t) = 0$. This is a consequence of (i), which gives $\lim_{t\to\infty} y_1(t) = 0$, and therefore $\lim_{t\to\infty} y_2(t) = 0$, which, together with boundedness of k, yields $\lim_{t\to\infty} u_2(t) = 0$ and $\lim_{t\to\infty} u_1(t) = 0$.

Example 3.10. As an illustrative example, we consider example (ii) from the table in the introduction, where P and P_1 are specified in the frequency domain by the associated transfer functions

$$\hat{P}_1(s) = \frac{1}{s-\theta}, \qquad \hat{P}_2(s) = \frac{N(M-s)}{(N+s)(M+s)(s-\theta)}, \quad N, M \geq \varepsilon^{-1}\,,\ \varepsilon > 0.$$

Note that $\hat{P}_1$ has a realization $\widetilde{P}(\theta, 0) \in \mathcal{M}_1$ and $\hat{P}_2$ has a realization $\widetilde{P}(\theta_1, 0) \in \mathcal{P}_3 \setminus \mathcal{M}_3$. We claim that $\vec{\delta}_0(\hat{P}_1, \hat{P}_2) \to 0$ as $\varepsilon \to 0+$. To prove this assertion, note that

$$A(s) = \frac{s-\theta}{s+\sqrt{\theta^2+1}}, \qquad B(s) = \frac{1}{s+\sqrt{\theta^2+1}}$$

satisfy $\hat{P}_1(s) = B(s)A(s)^{-1}$, $A, B \in H^\infty$, and $A^*(s)A(s) + B^*(s)B(s) = I$. Therefore, A, B form a normalized right coprime factorization of $\hat{P}_1$. Since

$$\hat{P}_2(s) = \frac{B(s) + \Delta_B(s)}{A(s)}, \quad \text{where} \qquad \Delta_B(s) = \left(\frac{N(M-s)}{(s+N)(s+M)} - 1\right) B(s),$$

and $\Delta_B \in H^\infty$, by (2.5) it suffices to show that

$$\left\| \begin{pmatrix} 0 \\ \Delta_B \end{pmatrix} \right\|_{H^\infty} = \left\| \left(\frac{N(M-s)}{(s+N)(s+M)} - 1 \right) B(s) \right\|_{H^\infty} \to 0 \quad \text{as } \varepsilon \to 0+, \tag{3.25}$$

and this follows from a routine calculation. Thus the claim is proved. To apply Theorem 3.8 to conclude robust stability, it would suffice to show that $\vec{\delta}(\hat{P}_1, \hat{P}_2) \to 0$ as $\varepsilon \to 0^+$. In view of the equivalence (2.5), the latter could be shown by establishing that the directed gap $\vec{\delta}_0(\hat{P}_2, \hat{P}_1)$ is less than 1 (recall that $\vec{\delta}_0(\hat{P}_1, \hat{P}_2) \to 0$ as $\varepsilon \to 0^+$). Alternatively, anticipating Lemma 4.5, we can adapt the proof of that lemma (to the case wherein A, B are defined as above and $A' = A$, $B' = B + \Delta_B$, $(V, U) := (A^*, B^*)$), and invoke (3.25), to conclude that

$$\vec{\delta}(\widetilde{P}(\theta, 0), \widetilde{P}(\theta_1, 0)) \leq \left\| \begin{pmatrix} 0 \\ \Delta_B \end{pmatrix} \right\| \cdot \|(A^*, B^*)\|_{H^\infty} = \left\| \begin{pmatrix} 0 \\ \Delta_B \end{pmatrix} \right\| \to 0 \quad \text{as } \varepsilon \to 0+.$$

Thus, under the conditions of Theorem 3.8, the controller $\widetilde{C}(k^0)\colon \mathcal{Y}_a \to \mathcal{U}_a$ defined by (3.6), (3.8) stabilizes any stabilizable and detectable realization of $\hat{P}_2$. As observed in the introduction, $\hat{P}_2$ is an example of a plant which violates all the classical assumptions of adaptive control.

To prove Theorem 3.8 we need to show how the gf-stability of the augmented closed loop $[P, C]$ as given in (3.22) and (3.23) yields the robustness property (3.24) for the unaugmented closed loop $[\widetilde{P}(\theta_1, x_1^0), \widetilde{C}(k^0)]$. This follows from the next result, which is a direct consequence of Theorems 5.2 and 5.3 in [4].

THEOREM 3.11. *Let $m, n, q \in \mathbb{N}$ with $n \geq m$, $q \geq m$, $\mathcal{U} = \mathcal{Y} = L^p(\mathbb{R}_+, \mathbb{R}^m)$, $1 \leq p \leq \infty$, and $\mathcal{W} = \mathcal{U} \times \mathcal{Y}$. Let $\widetilde{K}\colon \mathcal{Y}_a \to \mathcal{U}_a$ be causal, and consider $\widetilde{P}(\vartheta, 0)\colon \mathcal{U}_a \to \mathcal{Y}_a$ defined in* (3.6) *for (ϑ, x^0) in $\mathcal{P}_q \times \mathbb{R}_q$ or $\mathcal{P}_n \times \mathbb{R}_n$. Assume that $[\widetilde{P}(\vartheta, 0), \widetilde{K}]$ is regularly well posed for all $\vartheta \in \mathcal{P}_q$ and let $\Omega \subset \mathcal{M}_n$ be closed. Define*

$$\begin{aligned} P\colon \mathcal{P}_n \times \mathcal{U}_a \to \mathcal{Y}_a, \qquad (\vartheta, u_1) \mapsto P(\vartheta, u_1), &= \widetilde{P}(\vartheta, 0)(u_1), \\ C\colon \mathcal{Y}_a \to \mathcal{P}_n \times \mathcal{U}_a, \qquad y_2 \mapsto C(y_2) &= (0, \widetilde{K}(y_2)). \end{aligned}$$

If $H_{P,C}|_{\Omega\times\mathcal{W}}$ is gf-stable and $T_\tau\Pi_{P//C}$ is continuous for all $\tau>0$, then there exist a continuous function $\mu\colon \mathbb{R}_+\times\Omega\to(0,\infty)$ and a function $\lambda:\mathcal{P}_q\to(0,\infty)$ such that, for all $(\theta_1,\theta,x_1^0,w_0,r)\in\mathcal{P}_q\times\Omega\times\mathbb{R}^q\times\mathcal{W}\times(0,\infty)$,

$$\left.\begin{array}{l}\vec{\delta}(\widetilde{P}(\theta,0),\widetilde{P}(\theta_1,0))\le\mu\big(r\,,\,\theta\big)\\ \lambda(\theta_1)\|x_1^0\|+\|w_0\|_{\mathcal{W}}\le r\end{array}\right\}\quad\Longrightarrow\quad H_{\widetilde{P}(\theta_1,x_1^0),\widetilde{K}}(w_0)\;\in\;\mathcal{W}\times\mathcal{W}. \tag{3.26}$$

We are now in a position to prove Theorem 3.8.

Proof of Theorem 3.8. Let $\theta\in\mathcal{M}_n$ and define $\Omega=\{\theta\}$. Consider Theorem 3.11 with $p=2$ and $\widetilde{K}=\widetilde{C}(k^0)$, where $\widetilde{C}(k^0)$ is given by (3.8). Note that by Corollary 3.2, the closed loop $[\widetilde{P}(\vartheta,0),\widetilde{C}(k^0)]$ is regularly well posed for all $\vartheta\in\mathcal{P}_q$. For P and C as defined in Theorem 3.11, the operator $H^{\Omega}_{P,C}$ is gf-stable by Proposition 3.7. By, for example, the proof of Theorem 4.D in [20], $T_\tau\Pi_{\widetilde{P}(\theta,0)//\widetilde{C}(k^0)}$ is continuous for all $\tau>0$, and therefore $T_\tau\Pi_{P//C}|_{\Omega\times\mathcal{W}}$ is continuous for all $\tau>0$. Now all hypotheses of Theorem 3.11 are in place and so there exist a continuous function $\mu\colon\mathbb{R}_+\times\Omega\to(0,\infty)$ and a function $\lambda:\mathcal{P}_q\to(0,\infty)$ such that (3.26) holds. Statement (3.24) follows on setting $\eta(\cdot)=\mu(\cdot,\theta)$. ∎

4. Georgiou and Smith's example revisited. In this section we reconsider Example 9 in the paper by Georgiou and Smith [7] (see also [9]). This serves two purposes, which are to clarify some of the informal arguments therein in relation to robustness with respect to initial data, and to demonstrate that, in the L^2 setting of the present paper, the robustness bound in Theorem 3.8 is qualitatively tight in the sense that it is necessarily dependent on the data u_0, y_0, x_1^0. In those cases where we demonstrate a lack of stability, namely for large initial conditions, large L^2 disturbances, or L^∞ disturbances, the instability is caused by the adaptive gain k undergoing the well-known phenomena of "parameter drift" [13, p. 545], leading to k passing some critical value, thus inducing instability. The conditions given for stability, namely small initial conditions and small L^2 disturbances, prevent this instability mechanism by ensuring that the adaptive gain k never reaches criticality. In general, the issue of "drift-inducing" disturbances has led to various "robustifying" modifications to adaptive designs: one such modification is the introduction of a dead-zone in the second of equations (1.1), to become $\dot{k}=|y|\max\{0,|y|-\lambda\}$, with parameter $\lambda>0$. Such a modification has led to practical applications to, for example, exothermic chemical reactors [12]. The robustness in the graph topology of such modifications remains to be investigated.

4.1. The nominal and perturbed closed-loop systems. After appropriate rescaling and relabeling of variables, the first-order linear plant $\widetilde{P}(a,y_1^0)$, considered in [7, Example 9], can be parameterized by $a\in\mathbb{R}$ and $y_1^0\in\mathbb{R}$ and expressed as

$$\widetilde{P}\big(a,y_1^0\big)\colon\mathcal{U}_a\to\mathcal{Y}_a,\quad u_1\mapsto y_1,\quad\text{where }\dot{y}_1=ay_1+u_1,\;\;y_1(0)=y_1^0, \tag{4.1}$$

and so, for $u_1\in\mathcal{U}_a$, $y_1=\widetilde{P}(a,y_1^0)(u_1):\mathrm{dom}(u_1)\to\mathbb{R}$ is the unique maximal solution of the initial-value problem in (4.1). The controller, parameterized by $k^0\in\mathbb{R}_+$, is

$$\widetilde{C}(k^0)\colon\;\mathcal{Y}_a\to\mathcal{U}_a,\;y_2\mapsto u_2:=-k\,y_2,\quad\text{where }\dot{k}=y_2^2,\;\;k(0)=k^0, \tag{4.2}$$

and so, for $y_2\in\mathcal{Y}_a$, $-ky_2=u_2=\widetilde{C}(k^0)(y_2):\mathrm{dom}(y_2)\to\mathbb{R}$, where k is the unique maximal solution of the initial-value problem in (4.2). The closed-loop system $[\widetilde{P}(a,y_1^0),\widetilde{C}(k^0)]$ will be analyzed in the two settings of $\mathcal{U}=\mathcal{Y}=L^2(\mathbb{R}_+,\mathbb{R})$ and

$\mathcal{U} = \mathcal{Y} = L^\infty(\mathbb{R}_+, \mathbb{R})$. In view of Proposition 3.1(i), for all $a, y_1^0 \in \mathbb{R}$ and $k^0 \in \mathbb{R}_+$, the closed-loop system $[\widetilde{P}(a, y_1^0), \widetilde{C}(k^0)]$ is locally well posed in both settings; moreover, by Proposition 3.3, in the former L^2 setting, the closed-loop system is globally well posed, and the signals y_1 and k are bounded, with $y_1(t) \to 0$ and $k(t) \to k^\infty \in \mathbb{R}$ as $t \to \infty$. As in [7, Example 9], consider a perturbation of the plant $\widetilde{P}(a, y_1^0)$ consisting of the series connection of $1/(s-a)$ (i.e., the transfer function associated with $\widetilde{P}(a, y_1^0)$) and an all-pass factor $(M-s)/(M+s)$ with $M > 0$. As a realization of this series connection, consider

$$\dot{y}_1 = a\, y_1 + z - u_1\,, \quad \dot{z} = -M\,[z - 2\,u_1]\,, \quad (y_1(0), z(0)) = (y_1^0, z^0)\,.$$

This series connection is denoted by

$$\widetilde{P}_1\left(a, M, y_1^0, z^0\right) : \mathcal{U}_a \to \mathcal{Y}_a, \quad u_1 \mapsto y_1\,. \tag{4.3}$$

The closed-loop equations for $[\widetilde{P}_1\left(a, M, y_1^0, z^0\right), \widetilde{C}(k^0)]$ are given by

$$\left\{\begin{array}{ll} \dot{y}_1(t) = [a + k(t)]\, y_1(t) + z(t) - k(t) y_0(t) - u_0(t)\,, & y_1(0) = y_1^0, \\ \dot{z}(t) = -2Mk(t) y_1(t) - Mz(t) + 2Mk(t) y_0(t) + 2M u_0(t)\,, & z(0) = z^0, \\ \dot{k}(t) = (y_0(t) - y_1(t))^2\,, & k(0) = k^0, \\ u_1(t) = u_0(t) + k(t)\, y_0(t) - k(t)\, y_1(t). & \end{array}\right. \tag{4.4}$$

For fixed (but arbitrary) $a \in \mathbb{R}$ and $k^0 \in \mathbb{R}_+$, and applying Theorem 3.8, we may conclude the existence of a continuous function $\eta : \mathbb{R}_+ \to (0, \infty)$ and a function $\lambda_1 : \mathbb{R} \to (0, \infty)$ such that, if $\vec{\delta}(\widetilde{P}(a, 0), \widetilde{P}_1(a, M, 0, 0)) \leq \eta(r)$ for some $r > 0$, then, for all initial data $x_1^0 = (y_1^0, z^0)$ and all disturbances $u_0, y_0 \in L^2(\mathbb{R}_+, \mathbb{R})$ satisfying $\lambda_1(M)\|x_1^0\| + \|(u_0, y_0)\|_{L^2(\mathbb{R}_+, \mathbb{R}^2)} \leq r$, the closed-loop system is globally well posed and is such that $(y_1(t), z(t)) \to (0, 0)$ as $t \to \infty$, and the monotone gain k converges to a finite limit. At this point, we briefly digress to prove a technicality which will prove convenient in later analyses.

LEMMA 4.1. *Let $M > 0$, $a = 0$, $u_0, y_0 \in L^2(\mathbb{R}_+, \mathbb{R}) \cup L^\infty(\mathbb{R}_+, \mathbb{R})$, and $(y_1^0, z^0, k^0) \in \mathbb{R} \times \mathbb{R} \times \mathbb{R}_+$. Let $(y_1, z, k) : [0, \omega) \to \mathbb{R} \times \mathbb{R} \times \mathbb{R}_+$ be the unique maximal solution to the closed-loop initial-value problem* (4.4). *If there exists $T \in [0, \omega)$ such that $k(T) \geq 4M$, $(y_0(T) - y_1(T), z(T)) \neq (0, 0)$, and $(u_0(t), y_0(t)) = (0, 0)$ for all $t \in [T, \infty)$, then*

(i) *$u_1, y_1 \notin L^\infty([0, \omega), \mathbb{R})$ and*

(ii) *$k \notin L^\infty([0, \omega), \mathbb{R}_+)$.*

Proof. Writing $y_2 := y_0 - y_1$, then, by the hypotheses, we get

$$\left.\begin{array}{l} \dot{y}_2(t) = k(t) y_2(t) - z(t), \quad \dot{z}(t) = 2Mk(t) y_2(t) - Mz(t) \\ \dot{k}(t) = \big(y_2(t)\big)^2 \end{array}\right\} \quad \forall\ t \in [T, \omega). \tag{4.5}$$

Defining $\eta := y_2 - z/(2M)$, we have

$$\left.\begin{array}{l} \dot{y}_2(t) = \big[k(t) - 2M\big] y_2(t) + 2M\eta(t) \\ \dot{\eta}(t) = -My_2(t) + M\eta(t), \quad \dot{k}(t) = \big(y_2(t)\big)^2 \end{array}\right\} \quad \forall\ t \in [T, \omega). \tag{4.6}$$

Introduce $W : [T, \omega) \to \mathbb{R}_+$, $t \mapsto \frac{1}{2}\big[y_2^2 + 2\eta^2\big](t)$. By hypothesis, $(y_2(T), z(T)) \neq (0, 0)$ and so $W(T) > 0$. Moreover, since $k(T) \geq 4M$, we have

$$\dot{W}(t) = \big(k(t) - 2M\big)(y_2(t))^2 + 2M(\eta(t))^2 \geq 2MW(t) \quad \forall\ t \in [T, \omega)\,.$$

Therefore,

$$W(t) \geq e^{2M(t-T)}W(T) \quad \forall\, t \in [T,\omega), \qquad W(T) > 0. \tag{4.7}$$

Seeking a contradiction, suppose that y_2 is bounded on $[T,\omega)$. Then $\omega = \infty$ (to see this, simply note that, if ω is finite, then y_2 is square integrable and so k is bounded, which, together with Proposition 3.1(ii), yields a contradiction). Let $c_0 > 0$ be such that $\big(y_2(t)\big)^2 \leq c_0$ for all $t \in [T,\infty)$, and so $0 \leq k(t) \leq k(T) + c_0[t-T]$ for all $t \geq 0$. By (4.5), there exists $c_1 > 0$ such that $|z(t)| \leq c_1\big[1+t\big]$ for all $t \in [T,\infty)$. Hence, there exists $c_2 > 0$ such that $|\eta(t)| \leq c_2[1+t]$ for all $t \in [T,\infty)$. Therefore, it follows that $W(t) \leq \frac{1}{2}\big[c_0 + 2c_2^2(1+t)^2\big]$ for all $t \geq T$, which contradicts (4.7). Therefore, y_2 is unbounded on $[T,\omega)$ and so, since $y_1(t) = -y_2(t)$ for all $t \in [T,\omega)$, we have $y_1 \notin L^\infty([0,\omega),\mathbb{R})$. Finally, and again seeking a contradiction, suppose that k is bounded. Then, by Proposition 3.1(ii), $\omega = \infty$. By the third of equations (4.5), $y_2 \in L^2([T,\infty),\mathbb{R})$. By the second of equations (4.5), we may conclude that $z \in L^2([T,\infty),\mathbb{R})$ and $z(t) \to 0$ as $t \to \infty$. Rewriting the first of equations (4.5) in the form $\dot{y}_2(t) = -y_2(t) + \zeta(t)$, with $\zeta(t) := [1+k(t)]y_2(t) - z(t)$, and noting that $\zeta \in L^2(\mathbb{R}_+,\mathbb{R})$, it follows that $y_2(t) \to 0$ as $t \to \infty$. Therefore, $W(t) \to 0$ as $t \to \infty$, which contradicts (4.7). Therefore, k is unbounded, and so property (ii) holds. Since both k, y_1 are unbounded and k is monotone, and $u_1(t) = k(t)y_1(t)$ for all $t \geq T$, it follows that $u_1 \notin L^\infty([0,\omega),\mathbb{R})$. Therefore, property (i) holds. ∎

4.2. Nonrobustness with respect to large initial conditions.

PROPOSITION 4.2. *For $M, a, y_1^0, z^0, k^0 \in \mathbb{R}$ and $u_0, y_0 \in L^2(\mathbb{R}_+,\mathbb{R})$, consider the closed-loop system $[\widetilde{P}_1\left(M,a,y_1^0,z^0\right), \widetilde{C}(k^0)]$ defined by (2.1), (4.4), (4.2), (4.3) in the specific case wherein $M > 0$, $a = z^0 = k^0 = 0$, and $u_0 = y_0 = 0$.*

There exists $\chi > 0$ such that, if $(y_1^0)^2 > \chi$, then the unique maximal solution $(y_1, z, k) : [0,\omega) \to \mathbb{R}^2 \times \mathbb{R}_+$, $0 < \omega \leq \infty$, of the closed-loop system $[\widetilde{P}_1\left(M,0,y_1^0,0\right), \widetilde{C}(0)]$ has the following properties:

(i) *$u_1, y_1 \notin L^\infty([0,\omega),\mathbb{R})$;*

(ii) *$k \notin L^\infty([0,\omega),\mathbb{R}_+)$.*

Proof. Under the above hypothesis, the initial-value problem (4.4) is given by

$$\begin{cases} \dot{y}_1(t) = k(t)y_1(t) + z(t), \quad \dot{z}(t) = -2Mk(t)y_1(t) - Mz(t), \ \dot{k}(t) = (y_1(t))^2, \\ (y_1(0), z(0), k(0)) = (y_1^0, 0, 0). \end{cases} \tag{4.8}$$

Let $(y_1, z, k) : [0,\omega) \to \mathbb{R}^2 \times \mathbb{R}_+$ be the unique maximal solution of (4.8) with

$$\big(y_1^0\big)^2 > \chi := \big(32M^2\big(1+64M^2\big) + 4\big(1+8M^2\big)^2\big)/\big(1-e^{-4M}\big). \tag{4.9}$$

We will consider separately the two possible cases (a) $\omega < \infty$, and (b) $\omega = \infty$.

Case (a). Assume $\omega < \infty$. Then, by Proposition 3.1, the monotone function k is unbounded. This, in turn, implies that $y_1 \notin L^2([0,\omega),\mathbb{R})$, and so $y_1 \notin L^\infty([0,\omega),\mathbb{R})$. Therefore, properties (i) and (ii) hold.

Case (b). Now assume $\omega = \infty$. For later convenience, we observe that, by (4.8),

$$\|z\|_{L^2([0,t);\mathbb{R})} \leq 2\,\|ky_1\|_{L^2([0,t),\mathbb{R})} \quad \forall\, t \geq 0. \tag{4.10}$$

First, we will show that $k(1) > 4M$. For contradiction, suppose otherwise. Then, $\|y_1\|^2_{L^2([0,1],\mathbb{R})} = k(1) \leq 4M$ and, by monotonicity of k, $k(t) \in [0,4M]$ for all $t \in [0,1]$. From (4.10), it now follows that

$$\|y_1\|^2_{L^2([0,1],\mathbb{R})} + \|z\|^2_{L^2([0,1];\mathbb{R})} \leq 4M\big[1+64M^2\big]. \tag{4.11}$$

Define $V : [0,1] \to \mathbb{R}_+$, $t \mapsto \frac{1}{2}\big(y_1^2 + z^2\big)(t)$. Then,

$$\begin{aligned}\dot V(t) &= k(t)(y_1(t))^2 + \big(1 - 2Mk(t)\big)y_1(t)z(t) - M(z(t))^2\\ &\geq -(1+8M^2)|y_1(t)z(t)| - M(z(t))^2\\ &\geq -2M(z(t))^2 - (4M)^{-1}\big[(1+8M^2)y_1(t)\big]^2\\ &\geq -4MV(t) - (4M)^{-1}\big[(1+8M^2)y_1(t)\big]^2 \quad \forall\, t \in [0,1].\end{aligned}$$

Therefore,

$$\begin{aligned}\|V\|_{L^1([0,1],\mathbb{R}_+)} &\geq (4M)^{-1}\big(1 - e^{-4M}\big)\, V(0) - (4M)^{-2}(1+8M^2)^2\, \|y_1\|^2_{L^2([0,1],\mathbb{R})}\\ &\geq (8M)^{-1}\big(1 - e^{-4M}\big)\, \chi - (4M)^{-1}(1+8M^2)^2 > 2M\big(1+64M^2\big),\end{aligned}$$

which, in conjunction with (4.11), yields the contradiction

$$4M\big(1+64M^2\big) \geq \|y_1\|^2_{L^2([0,1],\mathbb{R})} + \|z\|^2_{L^2([0,1],\mathbb{R})} = 2\|V\|_{L^1([0,\tau],\mathbb{R}_+)} > 4M\big(1+64M^2\big).$$

Therefore, $k(1) > 4M$. Moreover, since $y_1^0 \neq 0$, we may infer from (4.8) that $(y_1(1), z(1)) \neq (0,0)$. The result follows by application of Lemma 4.1 (with $T = 1$). □

4.3. Nonrobustness with respect to large L^2 disturbances.

PROPOSITION 4.3. *For $M, a, y_1^0, z^0, k^0 \in \mathbb{R}$ and $u_0, y_0 \in L^2(\mathbb{R}_+, \mathbb{R})$, consider the closed-loop system $[\widetilde P_1\,(M, a, y_1^0, z^0)\,, \widetilde C(k^0)]$ defined by (2.1), (4.4), (4.2), (4.3) in the specific case wherein $M > 0$, $a = y_1^0 = z^0 = k^0 = 0$, and $y_0 = 0$.*

There exists $u_0 \in L^2(\mathbb{R}_+, \mathbb{R})$ such that the unique maximal solution $(y_1, z, k) : [0, \omega) \to \mathbb{R}^2 \times \mathbb{R}_+$ of the closed-loop system $[\widetilde P_1\,(M,0,0,0)\,, \widetilde C(0)]$ has the following properties:

(i) $y_1 \notin L^\infty([0,\omega), \mathbb{R})$;

(ii) $k \notin L^\infty([0,\omega), \mathbb{R}_+)$.

Proof. Let $a = y_1^0 = z^0 = k^0 = 0$, $M > 0$, and $y_0 = 0$. Fix $r \neq 0$, and denote, by $(\tilde y_1, \tilde z, \tilde k) : [0, \tilde\omega) \to \mathbb{R} \times \mathbb{R} \times \mathbb{R}_+$, the unique maximal solution of (4.4) with u_0 given by $u_0(t) = r$ for all $t \geq 0$, in which case we have

$$\left\{\begin{array}{l}\frac{d}{dt}\,[\tilde y_1(t) - r] = -[\tilde y_1(t) - r] + [1 + \tilde k(t)]\,\tilde y_1(t) + [\tilde z(t) - 2r],\\ \frac{d}{dt}\,[\tilde z(t) - 2r] = -M\,[\tilde z(t) - 2r] - 2M\tilde k(t)\,\tilde y_1(t),\\ \frac{d}{dt}\,\tilde k(t) = (\tilde y_1(t))^2, \qquad (\tilde y_1(0), \tilde z(0), \tilde k(0)) = (0,0,0).\end{array}\right. \tag{4.12}$$

For contradiction, suppose that the component $\tilde k$ is bounded. Then, by Proposition 3.1, $\tilde\omega = \infty$. Since $\tilde k \in L^\infty(\mathbb{R}_+)$, it follows that $\tilde y_1 \in L^2(\mathbb{R}_+)$ and so, by the second differential equation in (4.12), we may infer that $\tilde z(\cdot) - 2r \in L^2(\mathbb{R}_+)$. Noting that $[1 + \tilde k(\cdot)]\tilde y_1(\cdot) + [\tilde z(\cdot) - 2r] \in L^2(\mathbb{R}_+)$, it follows from the first equation in (4.12) that $\tilde y_1(t) \to r \neq 0$ as $t \to \infty$, which contradicts the fact that $\tilde y_1 \in L^2(\mathbb{R}_+)$. Therefore, the solution component $\tilde k$ is unbounded. Unboundedness of $\tilde k$, together with the third differential equation in (4.12), implies the existence of $T \in [0, \tilde\omega)$ such that $k(T) > 4M$ and $\tilde y_1(T) \neq 0$. Let $u_0 \in L^2(\mathbb{R}_+, \mathbb{R})$ be the piecewise constant function $u_0 := T_T r$ (viz. $u_0(t) = r$ on $[0,T)$ and $u_o(t) = 0$ on $[T, \infty)$), and denote by $(y_1, z, k) : [0,\omega) \to \mathbb{R} \times \mathbb{R} \times \mathbb{R}_+$ the unique maximal solution of

$$\begin{array}{ll}\dot y_1(t) = k(t)\, y_1(t) + z(t) - u_0(t), & y_1(0) = 0,\\ \dot z(t) = -2Mk(t)\, y_1(t) - Mz(t) + 2Mu_0(t), & z(0) = 0,\\ \dot k(t) = y_1(t)^2, & k(0) = 0.\end{array}$$

Clearly, $\tilde{\omega} \leq \omega$ and $(\tilde{y}_1(t), \tilde{z}(t), \tilde{k}(t)) = (y_1(t), z(t), k(t))$ for all $t \in [0, \tilde{\omega})$. Therefore, $y_1(T) = \tilde{y}_1(T) \neq 0$ and $k(T) = \tilde{K}(T) > 4M$. An application of Lemma 4.1 completes the proof. ∎

4.4. Nonrobustness with respect to L^∞ disturbances. The initial calculation in [7, Example 9] (see also [9]) shows that arbitrarily small L^∞ disturbances u_0, $y_0 \in L^\infty(\mathbb{R}_+, \mathbb{R})$ can cause $\|u_1\|_{L^\infty(\mathbb{R}_+,\mathbb{R})}$ to be arbitrarily large, and so $H_{P,C}$ is not gf-stable in an L^∞ sense, whence we get the claim that the (L^∞) "robustness margin... should be assigned the value zero." Note that the gf-stability of $H_{P,C}$ is only a sufficient condition for robust stability. In this context, we next show that any constant nonzero input disturbance (and zero output disturbance) leads to unbounded signals in the perturbed closed loop $[\widetilde{P}_1(a, M, y_1^0, z^0), \widetilde{C}(k^0)]$. This is not surprising in view of [7, Example 9], where it is shown that the unperturbed closed loop $[\widetilde{P}(a, y_1^0), \widetilde{C}(k^0)]$ is nonrobust with respect to L^∞ disturbances.

PROPOSITION 4.4. *For $M, a, y_1^0, z^0, k^0 \in \mathbb{R}$ and $u_0, y_0 \in L^2(\mathbb{R}_+, \mathbb{R})$, consider the closed-loop system $[\widetilde{P}_1\left(M, a, y_1^0, z^0\right), \widetilde{C}(k^0)]$ defined by (2.1), (4.4), (4.2), (4.3) in the specific case wherein $M > 0$, $a = y_1^0 = z^0 = k^0 = 0$, and $y_0 = 0$.*

For any $r > 0$, there exists $u_0 \in L^\infty(\mathbb{R}_+, \mathbb{R})$ with $\|u_0\|_{L^\infty(\mathbb{R}_+,\mathbb{R})} \leq r$, such that the unique maximal solution $(y_1, z, k) : [0, \omega) \to \mathbb{R}^2 \times \mathbb{R}_+$ of the closed-loop system $[\widetilde{P}_1\left(M, 0, 0, 0\right), \widetilde{C}(0)]$ has the following properties:

(i) *$u_1, y_1 \notin L^\infty([0, \omega), \mathbb{R})$;*

(ii) *$k \notin L^\infty([0, \omega), \mathbb{R}_+)$.*

Proof. This follows directly from the proof of Proposition 4.3, wherein it was shown that for each, $r > 0$, there exists $T \in (0, \omega)$ such that the disturbance $u_0 \in L^\infty(\mathbb{R}_+, \mathbb{R})$, given by $u_0 := T_T r$ and with norm $\|u_0\|_{L^\infty(\mathbb{R}_+,\mathbb{R})} = r$, is such that properties (i) and (ii) hold. ∎

Interestingly, our analysis in subsections 4.2, 4.3, and 4.4 has not established whether a finite escape time can occur within these closed loops. Simulation evidence presented in [7] makes this plausible, but the question remains open.

4.5. Robustness with respect to small L^2 disturbances and small initial conditions. Having noted in subsection 4.4 that the L^∞ robustness margin should be assigned the value zero, our next task is to show that, in the L^2 setting of the current paper, the situation is less pessimistic. In the L^∞ framework, one last remark is warranted. In [7, Example 9], and based on informal numerical evidence, there is a suggestion that—even with zero disturbances—the closed-loop system fails to be robustly stable if the initial conditions are nonzero. Proposition 4.2 confirms this in the case of *large* initial conditions. However, Proposition 4.6 below subsumes the following observation: With zero disturbances, the closed-loop system is robustly stable for *sufficiently small* initial conditions. As noted in [7, Example 8], in the L^∞ framework, $\vec{\delta}\big(\widetilde{P}(a, 0), \widetilde{P}_1(a, M, 0, 0)\big) \to 0$ as $M \to \infty$. We now show that this result also holds true in the L^2 framework.

LEMMA 4.5. *For $M, a, y_1^0, z^0 \in \mathbb{R}$ and $u_0, y_0 \in L^2(\mathbb{R}_+, \mathbb{R})$, consider $\widetilde{P}(a, y_1^0)$ and $\widetilde{P}_1\left(M, a, y_1^0, z^0\right)$ given by (4.1) and (4.3), respectively, in the specific case wherein $M > 0$ and $y_1^0 = z^0 = 0$. Then $\vec{\delta}\big(\widetilde{P}(a, 0), \widetilde{P}_1(a, M, 0, 0)\big) \to 0$ as $M \to \infty$.*

Proof. It will be convenient to utilize a frequency domain representation of linear operators. Firstly, let $c > 0$, and define the rational functions A, A', B, B' by $A(s) = A'(s) := (s-a)/(s+c)$, $B(s) := 1/(s+c)$, and $B'(s) := (M-s)/(s+c)(s+M)$. For $n, m \in \mathbb{N}$, let H^2 denote the set of all analytic functions $f : \mathbb{C}_+ \to \mathbb{C}^{n\times m}$ so that $\int_{\mathbb{R}} \|f(\alpha + i\beta\|^2 \mathrm{d}\beta$ is finite for all $\alpha > 0$. Since, by Paley and Wiener (see, for example,

[3, Thm. 11.9]), the extended Laplace transform $\mathbf{L}$ on $L^2(\mathbb{R}_+,\mathbb{R})$ yields an isometric isomorphism between $L^2(\mathbb{R}_+,\mathbb{R})$ and H^2, we may observe (see [17, p. 234]) that the graphs corresponding to $\widetilde{P}(a,0)$, $\widetilde{P}_1(M,a,0,0)$ can be written as:

$$\mathbf{L}\left(\mathcal{G}_{\widetilde{P}}\right) \;=\; \begin{pmatrix} A \\ B \end{pmatrix} H^2 \quad \text{and} \quad \mathbf{L}\left(\mathcal{G}_{\widetilde{P}_1}\right) \;=\; \begin{pmatrix} A' \\ B' \end{pmatrix} H^2.$$

Let $(V,U) := (1, c+a)$, and define the mappings $\Phi, \tilde{\Phi}$:

$$\tilde{\Phi}\colon \mathbf{L}\left(\mathcal{G}_{\widetilde{P}(a,0)}\right) \to \mathbf{L}\left(\mathcal{G}_{\widetilde{P}_1(M,a,0,0)}\right), \quad \begin{pmatrix} u \\ y \end{pmatrix} \mapsto \tilde{\Phi}\begin{pmatrix} u \\ y \end{pmatrix} := \begin{pmatrix} A' \\ B' \end{pmatrix}(V,U)\begin{pmatrix} u \\ y \end{pmatrix},$$
$$\Phi\colon \mathcal{G}_{\widetilde{P}(a,0)} \to \mathcal{G}_{\widetilde{P}_1(M,a,0,0)}, \qquad \Phi := \mathbf{L}^{-1}\tilde{\Phi}\mathbf{L}.$$

Since $(V,U)\binom{A}{B} = 1$, A', B' are coprime, and $\mathbf{L}$ is an isometric isomorphism, it follows that $\Phi \in \mathcal{O}_{\widetilde{P},\widetilde{P}_1}$. Additionally, since every element of $\mathbf{L}\left(\mathcal{G}_{\widetilde{P}}\right)$ is of the form $y = \binom{A}{B}x$, where $x \in H^2$, it follows that

$$(\tilde{\Phi} - I)|_{\mathbf{L}(\mathcal{G}_{\widetilde{P}})} y = \left(I - \begin{pmatrix} A' \\ B' \end{pmatrix}(V,U)\right)\begin{pmatrix} A \\ B \end{pmatrix} x = \begin{pmatrix} A - A' \\ B - B' \end{pmatrix} x = \begin{pmatrix} A - A' \\ B - B' \end{pmatrix}(V,U)y,$$

and since $(\Phi - I)|_{\mathcal{G}_{\widetilde{P}}} = \mathbf{L}^{-1}(\tilde{\Phi} - I)|_{\mathbf{L}(\mathcal{G}_{\widetilde{P}})}\mathbf{L}$, we have

$$\vec{\delta}(\widetilde{P},\widetilde{P}_1) \le \left\| \mathbf{L}^{-1}\left(\begin{pmatrix} A - A' \\ B - B' \end{pmatrix}(V,U)\right)\mathbf{L} \right\|_{L^2} = \left\| \begin{pmatrix} A - A' \\ B - B' \end{pmatrix}(V,U) \right\|_{H^\infty}.$$

Hence,

$$\vec{\delta}(\widetilde{P},\widetilde{P}_1) \le \left\| \begin{pmatrix} 0 \\ \frac{2s}{(s+c)(s+M)} \end{pmatrix}(1, c+a) \right\|_{H^\infty} \le 2\sqrt{1+(c+a)^2}\left\| \frac{s}{(s+c)(s+M)} \right\|_{H^\infty}.$$

A straightforward computation confirms that the right-hand side in the above goes to 0 as M tends to ∞. This completes the proof. ∎

The final result states that for any disturbance level, M can be chosen to ensure stability of the perturbed closed-loop system; furthermore, this stability is local with respect to initial conditions.

PROPOSITION 4.6. *Let $a \in \mathbb{R}$. For any $M > 0$, $y_1^0, z^0 \in \mathbb{R}$, $k^0 > 0$, consider the closed-loop system $[\widetilde{P}_1\left(M, a, y_1^0, z^0\right), \widetilde{C}(k^0)]$ as defined by* (2.1), (4.4), (4.3), *and* (4.2). *For any $r > 0$ there exists $\hat{M} > 0$, and for any $M \ge \hat{M}$ there exists $\varepsilon > 0$ such that, if $\|(y_1^0, z^0)\| \le \varepsilon$ and $\|(u_0, y_0)\|_{L^2(\mathbb{R}_+,\mathbb{R}^2)} \le r$, then the closed-loop system $[\widetilde{P}_1\left(M, a, y_1^0, z^0\right), \widetilde{C}(k^0)]$ has the following properties:*

(i) *There exists a unique solution $(y_1, z, k) : \mathbb{R}_+ \to \mathbb{R}^2 \times \mathbb{R}_+$;*
(ii) *$(u_1, y_1) \in L^2(\mathbb{R}_+, \mathbb{R}^2)$;*
(iii) *$\lim_{t\to\infty}(y_1(t), z(t)) = 0$;*
(iv) *$k \in L^\infty(\mathbb{R}_+, \mathbb{R}_+)$.*

Proof. Properties (i), (ii), and (iv) follow from Lemma 4.5 and Theorem 3.8. Therefore, $y_1, y_0, u_0, ky_0, ky_1 \in L^2(\mathbb{R}_+)$. Invoking the second differential equation of (4.4), we have $z \in L^2(\mathbb{R}_+)$ and $\lim_{t\to\infty} z(t) = 0$. By the first equation in (4.4) we have $\dot{y}_1 \in L^2(\mathbb{R}_+)$. It now follows that $\lim_{t\to\infty} y_1(t) = 0$, whence we get property (iii). ∎

5. Summary. In subsection 3.4, we developed a general result establishing a robust stability margin (whose size is dependent on the L^2 disturbance level and size of the initial condition) for the class of m-input, m-output, relative degree one, nonminimum phase plants, whose first Markov parameter lies in the open right half plane, when controlled by the "standard" adaptive output feedback controller (1.1). In section 4 we have given a qualitative analysis of a first-order system $\widetilde{P}(0, y_1^0)$ perturbed by an all-pass factor $\frac{M-s}{M+s}$ and controlled by a standard adaptive controller as considered by Georgiou and Smith [7, Ex. 9]. The results of section 4 are summarized in the following table:

Disturbances and initial data	Stability	Internal signals	Controller gain
For any small L^2 disturbance (u_0, y_0) and any small initial condition (y_1^0, z^0)	stable	$(u_1, y_1) \in L^2$	$k \in L^\infty$
There exists large L^2 disturbance $(u_0, 0)$	unstable	$(u_1, y_1) \notin L^\infty$	$k \notin L^\infty$
For any large initial condition $(y_1^0, 0)$	unstable	$(u_1, y_1) \notin L^\infty$	$k \notin L^\infty$
There exists an L^∞ disturbance $(u_0, 0)$ (of any nonzero size)	unstable	$(u_1, y_1) \notin L^\infty$	$k \notin L^\infty$

It is worth noting that the L^2 analysis in this paper provides a mechanism to prove the stability of the disturbance-free system in the presence of small initial conditions. The informal plausibility arguments presented in [7] for the lack of robustness of a closed-loop system in the presence of nonzero initial conditions do not predict the stable behavior of the closed-loop system when the initial conditions are small. This case study highlights the critical role played by the choice of signal space—alternative signal spaces may give different robust stability guarantees (in particular, in the disturbance-free case, we have seen that the L^∞ analysis does not give any indication of the robustness of the closed-loop system under gap perturbations with nonzero initial conditions; however, the L^2 analysis does establish robustness). This highlights the importance of an L^2 analysis for considering response to initial conditions. The second and third entries in the above table illustrate that the sufficient conditions for robust stability given by the gap analysis in section 3.4 cannot be improved qualitatively and emphasize the complementary role of initial conditions and disturbances. It is also important to note that zero L^∞ robustness margins are not inevitable. An example of an adaptive controller exhibiting a nonzero L^∞ margin is given in [4].

INSENSITIZING CONTROLS FOR THE 1-D WAVE EQUATION*

RENÉ DÁGER†

Abstract. We study the insensitizing controllability property of the one-dimensional wave equation observed in some open set in two cases: when the control acts in an interior region and when it acts on the boundary. In both cases, when the control time is sufficiently large the ϵ-insensitizing controllability holds. Moreover, for the boundary controlled equation the (exact) insensitizing controllability also holds.

Key words. wave equation, insensitizing control, controllability, unique continuation

1. Introduction.

Consider the controlled wave equations with partially known initial data,

$$\begin{cases} y_{tt} - \Delta y = \xi + f\mathbf{1}_\omega & \text{in } \mathbb{R}\times(0,1),\\ y = 0 & \text{in } \mathbb{R}\times\{0,1\},\\ y(0,x) = y^0 + \tau_0 z^0 & \text{in } (0,1),\\ y_t(0,x) = y^1 + \tau_1 z^1 & \text{in } (0,1), \end{cases} \tag{1}$$

where ω is an open subset of $[0,1]$, and

$$\begin{cases} y_{tt} - \Delta y = \xi & \text{in } \mathbb{R}\times(0,1),\\ y(t,0) = 0, \quad y(t,1) = g(t) & \text{in } \mathbb{R},\\ y(0,x) = y^0 + \tau_0 z^0 & \text{in } (0,1),\\ y_t(0,x) = y^1 + \tau_1 z^1 & \text{in } (0,1). \end{cases} \tag{2}$$

In both (1) and (2) y^0, y^1, and $\xi \in L^2(\mathbb{R}\times(0,1))$ are fixed functions. The last two equations in (1) or (2) indicate that the initial data are not exactly known. The terms $\tau_0 z^0, \tau_1 z^1$ with $\tau_0, \tau_1 \in \mathbb{R}$ and z^0, z^1 satisfying

$$\left\|z^0\right\|_a = \left\|z^1\right\|_b = 1 \tag{3}$$

(in appropriate norms $\|.\|_a$ and $\|.\|_b$ guaranteeing the well-posedness of the corresponding equations) are small unknown perturbations of the original initial data y^0, y^1. Finally, $f \in L^2(\mathbb{R}\times(0,1))$ and $g \in L^2(\mathbb{R})$ are control functions. The only difference between (1) and (2) is the location of the control: in (1) the control f acts in an interior region ω, while in (2) the control g acts through a part of the boundary.

Let Φ be the functional defined on the solutions of the controlled equations (1) or (2) by

$$\Phi(y) = \frac{1}{2}\int_0^T \int_{\mathcal{O}} y^2 dxdt,$$

where $T > 0$ and $\mathcal{O}$ is an open subset of $[0,1]$. Note that Φ corresponds to observations of the solutions made in the interval $\mathcal{O}$ during a time interval of length T.

Given a control f (resp., g) we say that f (resp., g) insensitizes Φ if for every pair z^0, z^1 satisfying (3) the corresponding solution of (1) (resp., (2)) satisfies

$$\frac{d}{d\tau_0}\Phi(y)\bigg|_{\tau_0=\tau_1=0} = \frac{d}{d\tau_1}\Phi(y)\bigg|_{\tau_0=\tau_1=0} = 0. \tag{4}$$

The concept of insensitizing control was introduced by Lions in [9]. Later on, Bodart and Fabre in [3] proposed the weakened notion of ε-insensitizing control. Given $\varepsilon > 0$, the control f (resp., g) is said to ε-insensitize Φ if for every pair z^0, z^1 satisfying (3) the corresponding solution of (1) (resp., (2)) satisfies

$$\left|\frac{d}{d\tau_0}\Phi(y)\bigg|_{\tau_0=\tau_1=0}\right| \le \varepsilon, \quad \left|\frac{d}{d\tau_1}\Phi(y)\bigg|_{\tau_0=\tau_1=0}\right| \le \varepsilon. \tag{5}$$

In this paper we study the existence of insensitizing or ε-insensitizing controls for systems (1) and (2). Our main results are the following (see Theorems 7 and 13):

Let $\omega, \mathcal{O}$ be nonempty open subsets of $[0,1]$ and $T \ge 4$. Then

- *for any $\varepsilon > 0$ there exist controls that ε-insensitize Φ along the solutions of (1);*
- *there exist controls that insensitize Φ along the solutions of (2).*

To prove these results we use the technique proposed by Lions in [9]. For this concrete choice of Φ, finding insensitizing controls is equivalent to finding controls driving the solutions of an auxiliary cascade system to rest, i.e., to a usual controllability problem, which is reduced to proving observability properties for the adjoint control-free cascade system. In particular, the existence of ε-insensitizing controls follows from a unique continuation property for the adjoint system. The main difficulty in this latter problem arises due to the nonstandard coupling in the cascade system.

We have to note that insensitizing or ε-insensitizing controllability properties have been generally studied in considerably more complex situations, namely, nonlinear parabolic equations in $\mathbb{R}^n$ (see [1, 2, 3, 4, 6, 7, 8, 9, 10, 11]). In this context our problem looks fairly simple. However, all those papers assume the observation and control regions to have nonempty intersection ($\omega \cap \mathcal{O} \neq \varnothing$). In this sense, the wave equation provides the first example when ε-insensitizing controls exist for arbitrarily chosen observation and control regions. Up to now, the only known example of such situation was given in [10] for the one-dimensional (1-D) linear heat equation with interior control and a particular choice of ω and $\mathcal{O}$. Besides, as far as we know, this is the first attempt to consider insensitizing controllability problems for the wave equation.

On the other hand, the existence of insensitizing controls for all the initial data for (2) is an interesting fact, since up to now the insensitizing controls have been found as the limit of a sequence of ε-insensitizing controls for some particular choices of the initial data (see, e.g., [1, 2, 7, 8]).

2. Interior control. In this section we concentrate ourselves in system (1). This is precisely the choice of control made in all the preceding works related to the insensitizing controllability of parabolic equations.

We assume $y^0 \in H_0^1(0,1), y^1 \in L^2(0,1)$. Then system (1) has a unique solution of finite energy that satisfies, for every $T > 0$, $y \in C([0,T], H_0^1(0,1)) \cap$

$C^1([0,T],L^2(0,1))$. In this case, the norms appearing in (3) are $\|.\|_a = \|.\|_{H_0^1(0,1)}$ and $\|.\|_b = \|.\|_{L^2(0,1)}$. In what follows, to simplify notation we denote

$$\|.\|_1 := \|.\|_{H_0^1(0,1)}, \quad \|.\|_0 := \|.\|_{L^2(0,1)}, \quad \|.\|_{-1} := \|.\|_{H^{-1}(0,1)},$$
$$\|.\|_{1,0} := \left(\|.\|_1^2 + \|.\|_0^2\right)^{\frac{1}{2}}, \quad \|.\|_{0,-1} := \left(\|.\|_0^2 + \|.\|_{-1}^2\right)^{\frac{1}{2}}.$$

2.1. Reduction to a unique continuation problem. As stated above, the main technique for proving the existence of ε-insensitizing controls is to reduce the problem to proving a uniqueness result for the solutions of a cascade system. In this subsection we describe such a reduction. These facts are well known in the context of parabolic equations, and we use the same ideas here. Although this scheme is rather standard, we include the details here since, as far as we know, they have never been written for the wave equation.

The first step is to reduce the problem to an approximate controllability problem. Consider the following controlled cascade system of wave equations:

$$\begin{cases} \bar{y}_{tt} - \Delta \bar{y} = \xi + f\mathbf{1}_\omega & \text{in } \mathbb{R}\times(0,1), \\ \bar{y} = 0 & \text{in } \mathbb{R}\times\{0,1\}, \\ \bar{y}(0,x) = y^0, \quad \bar{y}_t(0,x) = y^1 & \text{in } (0,1), \end{cases} \tag{6}$$

$$\begin{cases} q_{tt} - \Delta q = \bar{y}\mathbf{1}_{\mathcal{O}} & \text{in } \mathbb{R}\times(0,1), \\ q = 0 & \text{in } \mathbb{R}\times\{0,1\}, \\ q(T,x) = 0, \quad q_t(T,x) = 0 & \text{in } (0,1). \end{cases} \tag{7}$$

Note that, since $\bar{y}\mathbf{1}_{\mathcal{O}} \in L^2(\mathbb{R}\times(0,1))$, system (7) has a unique solution $q \in C([0,T], H_0^1(0,1)) \cap C^1([0,T],L^2(0,1))$. In particular, $(q(0,.), q_t(0,.)) \in H_0^1(0,1)\times L^2(0,1)$.

The following proposition holds.

PROPOSITION 1. *Given $y^0 \in H_0^1(0,1), y^1 \in L^2(0,1)$, and $\xi \in L^2(\mathbb{R}\times(0,1))$, the control f ε-insensitizes Φ along the solutions of* (1) *if and only if the corresponding solution $(\bar{y},q)$ of the cascade system* (6)–(7) *satisfies*

$$\|q(0,x)\|_0 < \varepsilon, \|q_t(0,x)\|_{-1} < \varepsilon. \tag{8}$$

Proof. A simple calculation yields

$$\frac{d}{d\tau_0}\Phi(y)\Big|_{\tau_0=\tau_1=0} = \int_0^T \int_{\mathcal{O}} \bar{y}\theta dxdt, \tag{9}$$

where $\theta = \frac{dy}{d\tau_0}$ is the solution of the equation

$$\begin{cases} \theta_{tt} - \Delta\theta = 0 & \text{in } \mathbb{R}\times(0,1), \\ \theta = 0 & \text{in } \mathbb{R}\times\{0,1\}, \\ \theta(0,x) = z^0, \quad \theta_t(0,x) = 0 & \text{in } (0,1). \end{cases} \tag{10}$$

On the other hand, integrating by parts in account of the boundary and initial (final) conditions in (7) and (10) we get

$$\int_0^T \int_{\mathcal{O}} \bar{y}\theta dxdt = \int_0^T \int_0^1 \bar{y}\mathbf{1}_{\mathcal{O}}\theta dxdt = \int_0^T \int_0^1 (q_{tt} - q_{xx})\theta dxdt = -\int_0^1 q_t(0,x)z^0 dx,$$

and thus (9) becomes

$$\frac{d}{d\tau_0}\Phi(y)\Big|_{\tau_0=\tau_1=0} = -\int_0^1 q_t(0,x)z^0dx. \tag{11}$$

In the same way we can prove that

$$\frac{d}{d\tau_1}\Phi(y)\Big|_{\tau_0=\tau_1=0} = \int_0^1 q(0,x)z^1dx. \tag{12}$$

Finally, since z^0, z^1 are arbitrary functions satisfying

$$\left\|z^0\right\|_1 = \left\|z^1\right\|_0 = 1,$$

from (11) and (12) the assertion of the proposition holds. □

The next step is to characterize the approximate controllability property of Proposition 1 in terms of the adjoint system to (6)–(7):

$$\begin{cases} p_{tt} - \Delta p = 0 & \text{in } \mathbb{R}\times(0,1),\\ p = 0 & \text{in } \mathbb{R}\times\{0,1\},\\ p(0,x) = p^0, \quad p_t(0,x) = p^1 & \text{in } (0,1), \end{cases} \tag{13}$$

$$\begin{cases} z_{tt} - \Delta z = p\mathbf{1}_{\mathcal{O}} & \text{in } \mathbb{R}\times(0,1),\\ z = 0 & \text{in } \mathbb{R}\times\{0,1\},\\ z(T,x) = 0, \quad z_t(T,x) = 0 & \text{in } (0,1). \end{cases} \tag{14}$$

We assume $\left(p^0,p^1\right) \in H_0^1(0,1)\times L^2(0,1)$. Thus system (13)–(14) has a unique solution (p,z), which satisfies

$$p, z \in C([0,T], H_0^1(0,1)) \cap C^1([0,T], L^2(0,1)).$$

In particular, $z \in L^2([0,T]\times(0,1))$.

The following result is easily proved by multiplying (6) by z and integrating by parts.

PROPOSITION 2. *The following duality identity for the solutions of* (6)–(7), (13)–(14) *holds for every* $f \in L^2(\mathbb{R}\times(0,1))$, $\left(y^0,y^1\right), \left(p^0,p^1\right) \in H_0^1(0,1)\times L^2(0,1)$*:*

$$\begin{aligned}\int_{[0,T]\times\omega} fz dxdt + \int_{[0,T]\times(0,1)} \xi z dxdt = &\int_0^1 \left(y^0 z_t(0,x) - y^1 z(0,x)\right) dx\\ &+ \int_0^1 \left(p^0 q_t(0,x) - p^1 q(0,x)\right) dx.\end{aligned} \tag{15}$$

PROPOSITION 3. *The set* $\mathcal{B} = \left\{(q(0,.), q_t(0,.)) : f \in L^2(\mathbb{R}\times(0,1))\right\}$ *is dense in* $L^2(0,1)\times H^{-1}(0,1)$*, and then the approximate controllability property* (8) *holds if and only if the following unique continuation property is true for every* $\left(p^0,p^1\right) \in H_0^1(0,1)\times L^2(0,1)$*:*

$$z \equiv 0 \text{ in } [0,T]\times\omega \text{ implies } z \equiv p \equiv 0 \text{ in } [0,T]\times(0,1). \tag{16}$$

Proof. Assume that $\left(p^0,p^1\right) \in H_0^1(0,1)\times L^2(0,1)$ satisfies

$$\int_0^1 \left(p^0 q_t(0,x) - p^1 q(0,x)\right) dx = 0$$

for every $f \in L^2(\mathbb{R}\times(0,1))$ and $\left(y^0,y^1\right) \in H_0^1(0,1)\times L^2(0,1)$. Then, in view of (15),

$$\int_{[0,T]\times\omega} fz dxdt = -\int_{[0,T]\times(0,1)} \xi z dxdt + \int_0^1 \left(y^0 z_t(0,x) - y^1 z(0,x)\right) dx.$$

But the right-hand term of this equality does not depend on f, so choosing $f=0$ it follows that

$$\int_{[0,T]\times\omega} fz dxdt = 0 \quad \text{for every } f \in L^2(\mathbb{R}\times(0,1)),$$

and then, since $z \in L^2([0,T]\times\omega)$, it follows that $z=0$ in $[0,T]\times\omega$. Next, the unique continuation property implies $p\equiv 0$ in $[0,T]\times(0,1)$, and hence $p^0=p^1=0$. Therefore, from the Hahn–Banach theorem it follows that $\mathcal{B}$ is dense in $L^2(0,1)\times H^{-1}(0,1)$.

For the converse assertion, assume that there exists $\left(p^0,p^1\right) \neq (0,0)$ such that $z\equiv 0$ in $[0,T]\times\omega$, and pick $\left(y^0,y^1\right)$ such that

$$\int_{[0,T]\times(0,1)} \xi z dxdt = \int_0^1 \left(y^0 z_t(0,x) - y^1 z(0,x)\right) dx.$$

Then from (15) we obtain

$$\int_0^1 \left(p^0 q_t(0,x) - p^1 q(0,x)\right) dx = 0,$$

and this means that $\mathcal{B}$ is not dense in $L^2(0,1)\times H^{-1}(0,1)$. □

Gathering the results of Propositions 2 and 3 we obtain the following.

PROPOSITION 4. *If the solutions of* (13)–(14) *satisfy the unique continuation property* (16)*, then for every* $\varepsilon>0$, $\xi \in L^2(\mathbb{R}\times(0,1))$*, and* $\left(y^0,y^1\right) \in H_0^1(0,1)\times L^2(0,1)$ *there exists a control* $f^\varepsilon \in L^2(\mathbb{R}\times(0,1))$ *such that along the corresponding solution* y^ε *of system* (1) *the functional* Φ *verifies* (5)*.*

Remark 5. When $\omega\cap\mathcal{O}\neq\varnothing$ the unique continuation property (16) is reduced to a unique continuation property for the usual wave equation. Indeed, if $z\equiv 0$ in $[0,T]\times(\omega\cap\mathcal{O})$, so is p in view of (14). Therefore, if $[0,T]\times(\omega\cap\mathcal{O})$ is an appropriate unique continuation region for the wave equation (that is, if the solution vanishes in $[0,T]\times(\omega\cap\mathcal{O})$, then it vanishes in $[0,T]\times(0,1)$), then $p\equiv 0$ in $[0,T]\times(0,1)$ and thus $z\equiv 0$ in $[0,T]\times(0,1)$. The same occurs in the case of heat equations considered in the literature.

Note that for the wave equation in $\mathbb{R}^n$ the unique continuation property from a region $[0,T]\times U$ depends on both T and the geometry of U. For the 1-D wave equation considered here, unique continuation from a region $[t_1,t_2]\times U$ holds whenever $t_2-t_1\geq 2$ (twice the length of the interval $(0,1)$).

When $\omega\cap\mathcal{O}=\varnothing$ such arguments cannot be applied, and the problem becomes more difficult.

2.2. Unique continuation results. In this subsection we show that the unique continuation property (16) is true for sufficiently large T for arbitrarily chosen ω and $\mathcal{O}$, independently of whether their intersection is void or not. Indeed, the following holds.

PROPOSITION 6. *Let* $\omega,\mathcal{O}$ *be nonempty open subsets of* $[0,1]$ *and* $T\geq 4$*. Then the unique continuation property* (16) *holds for the solutions of system* (13)–(14)*.*

As a consequence of Propositions 4 and 6 we obtain the existence of ε-insensitizing controls.

THEOREM 7. *Let $\omega, \mathcal{O}$ be nonempty open subsets of $[0,1]$ and $T \geq 4$. Then, for every $\varepsilon > 0$, $\xi \in L^2(\mathbb{R} \times (0,1))$, and $\left(y^0, y^1\right) \in H_0^1(0,1) \times L^2(0,1)$, there exists a control $f^\varepsilon \in L^2(\mathbb{R} \times (0,1))$ that ε-insensitizes functional Φ along the solutions of* (1).

Proposition 6 is an immediate consequence of the following observability inequality.

PROPOSITION 8. *Let $\omega, \mathcal{O}$ be nonempty open subsets of $[0,1]$ and $T \geq 4$. Then there exists a positive constant C, such that for every solution of* (13)–(14),

$$C \left\|(p^0, p^1)\right\|_{1,0}^2 \int_0^T \int_\omega z^2 dt dx \geq \left\|(p^0, p^1)\right\|_{0,-1}^4 .$$

Proof. We use in an essential way the fact that the first equation in (13) is the 1-D linear homogeneous wave equation

$$\text{(17)} \qquad \begin{cases} p_{tt} - \Delta p = 0 & \text{in } \mathbb{R} \times (0,1), \\ p = 0 & \text{in } \mathbb{R} \times \{0,1\}, \\ p(0,x) = p^0, \quad p_t(0,x) = p^1 & \text{in } (0,1). \end{cases}$$

Let us recall some known facts that are used in the proof. The solutions of (17) are periodic in time with period equal to 2, which may be easily obtained, e.g., from the fact that the solutions are of the form

$$\text{(18)} \qquad p(t,x) = g(t+x) - g(t-x),$$

with g being a 2-periodic function.

Note that the derivatives p_x and p_t have the same periodicity property.

Moreover, from representation formula (18) one can prove the following well-known unique continuation property for the solutions of (17): *If $t^* - t_* \geq 2$, then any of the equalities $p = 0$ in $[t_*, t^*] \times \omega$ or $p_x(t,1) = 0$ in $[t_*, t^*]$ implies $p = 0$ in $[t_*, t^*] \times (0,1)$.* This fact may be quantified by means of observability inequalities: *There exist positive constants C_1, C_2 such that for every solution p of* (17)

$$\text{(19)} \qquad C_1 \int_{t_*}^{t^*} \int_\omega p^2 dx dt \geq \left\|(p^0, p^1)\right\|_{0,-1}^2 ,$$

$$\text{(20)} \qquad C_2 \int_{t_*}^{t^*} p_x^2(t,1) dt \geq \left\|(p^0, p^1)\right\|_{1,0}^2 .$$

In addition, the following conservation laws are true for the solutions of (17):

$$\text{(21)} \qquad \left\|(p(\mu,.), p_t(\mu,.))\right\|_{1,0} = \left\|(p^0, p^1)\right\|_{1,0} ,$$

$$\text{(22)} \qquad \left\|(p(\mu,.), p_t(\mu,.))\right\|_{0,-1} = \left\|(p^0, p^1)\right\|_{0,-1}$$

for every $\mu \in \mathbb{R}$

Now we proceed to the proof of the proposition. Let T_0 be the smallest positive number such that $T - T_0 \in 2\mathbb{Z}$. The inequality stated in the proposition is obtained from the following two inequalities:

$$\text{(23)} \qquad C_1 \int_0^T \int_\omega z^2 dt dx \geq \left\|(z(T_0), z_t(T_0))\right\|_{0,-1}^2 ,$$

$$\text{(24)} \qquad C_2 \left\|(z(T_0), z_t(T_0))\right\|_{0,-1} \left\|(p^0, p^1)\right\|_{1,0} \geq \left\|(p^0, p^1)\right\|_{0,-1}^2 ,$$

which hold for every solution (p,z) of (13)-(14) with positive constants C_1, C_2 independent of (p,z).

In order to prove inequality (23), we define the linear operator ℓ acting on a function $u(t)$ by

$$(\ell u)(t) = u(t-1) - u(t+1).$$

Note that ℓ is continuous from $L^2(\alpha,\beta)$ to $L^2(\alpha+1,\beta-1)$ for any $\alpha,\beta \in \mathbb{R}$ with $\beta \geq \alpha+2$.

Further, for the solution z of (14) we denote

$$\psi(t,x) = (\ell z)(t,x) = z(t+1,x) - z(t-1,x).$$

The continuity of ℓ implies

$$C\int_0^T \int_\omega z^2 dxdt \geq \int_1^{T-1} \int_\omega \psi^2 dxdt \tag{25}$$

for some positive constant C independent of z .

On the other hand, in view of the time periodicity of p, it follows that ψ is a solution of the equation

$$\begin{cases} \psi_{tt} - \Delta\psi = 0 & \text{in } \mathbb{R}\times(0,1), \\ \psi = 0 & \text{in } \mathbb{R}\times\{0,1\}, \end{cases}$$

and then, since $(T-1)-1 = T-2 \geq 2$, inequality (19) and (22) yield

$$C\int_1^{T-1} \int_\omega \psi^2 dxdt \geq \|(\psi(\mu,.),\psi_t(\mu,.))\|^2_{0,-1} \tag{26}$$

for every $\mu \in \mathbb{R}$.

Now denote $n = (T-T_0)/2$ and observe that

$$\begin{aligned} \|z(T)-z(T_0)\|^2 &= \left\| \sum_{k=0}^{n-1} (z(T-2k) - z(T-2k-2)) \right\|^2 \\ &\leq \left(\sum_{k=0}^{n-1} \|z(T-2k) - z(T-2k-2)\| \right)^2 \\ &\leq n \sum_{k=0}^{n-1} \|z(T-2k) - z(T-2k-2)\|^2 \\ &= n \sum_{k=0}^{n-1} \|\psi(T-2k-1)\|^2 . \end{aligned}$$

Thus, from inequality (26) we get

$$\|z(T)-z(T_0)\|_0^2 \leq n^2 C \int_1^{T-1} \int_\omega \psi^2 dxdt.$$

Exactly in the same way it follows that

$$\|z_t(T)-z_t(T_0)\|_{-1}^2 \leq n^2 C \int_1^{T-1} \int_\omega \psi^2 dxdt.$$

From the last two inequalities, the fact that $z(T,x) = z_t(T,x) = 0$, and (25) we obtain inequality (23).

To prove inequality (24) we multiply (14) by p and integrate over $[T_0, T] \times (0,1)$. After integration by parts it follows that

$$\int_{T_0}^{T} \int_{\mathcal{O}} p^2 dxdt = \int_0^1 (z_t(T_0)p(T_0) - z(T_0)p_t(T_0))\, dx. \tag{27}$$

Now observe that, on one hand,

$$\int_0^1 (z_t(T_0)p(T_0) - z(T_0)p_t(T_0))\, dx \le \|(z(T_0), z_t(T_0))\|_{0,-1} \|(p(T_0), p_t(T_0))\|_{1,0},$$

and, on the other hand, from inequality (19),

$$\int_{T_0}^{T} \int_{\mathcal{O}} p^2 dxdt \ge C \left\|(p^0, p^1)\right\|_{0,-1}^2.$$

Thus, from (27) inequality (24) is obtained. □

Remark 9. Although the observability inequality provided by Proposition 8 allows us to ensure the appropriate unique continuation property and then the approximate controllability of system (6)–(7), it is not good enough to guarantee the exact controllability of that system, since it does not allow us to estimate a norm of (p^0, p^1) in terms of the observed quantity $\int_0^T \int_\omega z^2 dtdx$.

3. Boundary control. In this section we consider the boundary controlled system (2). We follow the same scheme as in the previous section. The main difference is that in this case we are able to prove the existence of (exact) insensitizing controls.

3.1. Reduction to a controllability problem. The proofs of the assertions given below use essentially the same arguments as in section 2.

Consider the following controlled cascade system of wave equations:

$$\begin{cases} \bar{y}_{tt} - \Delta \bar{y} = \xi & \text{in } \mathbb{R} \times (0,1), \\ \bar{y}(t,0) = 0, \quad \bar{y}(t,1) = g(t) & \text{in } \mathbb{R}, \\ \bar{y}(0,x) = y^0, \quad \bar{y}_t(0,x) = y^1 & \text{in } (0,1), \end{cases} \tag{28}$$

$$\begin{cases} q_{tt} - \Delta q = \bar{y}\mathbf{1}_{\mathcal{O}} & \text{in } \mathbb{R} \times (0,1), \\ q = 0 & \text{in } \mathbb{R} \times \{0,1\}, \\ q(T,x) = 0, \quad q_t(T,x) = 0 & \text{in } (0,1). \end{cases} \tag{29}$$

Proposition 10. *Given $y^0 \in H_0^1(0,1), y^1 \in L^2(0,1)$, and $\xi \in L^2(\mathbb{R} \times (0,1))$, the control f insensitizes Φ along the solutions of* (2) *if and only if the corresponding solution $(\bar{y}, q)$ of the cascade system* (28)–(29) *satisfies*

$$q(0,x) = q_t(0,x) = 0. \tag{30}$$

The latter exact controllability property may be characterized with the help of the adjoint cascade system

$$\begin{cases} p_{tt} - \Delta p = 0 & \text{in } \mathbb{R} \times (0,1), \\ p = 0 & \text{in } \mathbb{R} \times \{0,1\}, \\ p(0,x) = p^0, \quad p_t(0,x) = p^1 & \text{in } (0,1), \end{cases} \tag{31}$$

$$(32)\qquad \begin{cases} z_{tt} - \Delta z = p\mathbf{1}_{\mathcal{O}} & \text{in } \mathbb{R}\times(0,1),\\ z = 0 & \text{in } \mathbb{R}\times\{0,1\},\\ z(T,x) = 0, \quad z_t(T,x) = 0 & \text{in } (0,1). \end{cases}$$

The following proposition holds.

PROPOSITION 11. *Given* $\left(y^0, y^1\right) \in H_0^1(0,1)\times L^2(0,1)$ *and* $g \in L^2(\mathbb{R})$, *the solution* $(\overline{y}, q)$ *of* (28)–(29) *satisfies* (30) *if and only if the following duality identity holds for every* $\left(p^0, p^1\right) \in L^2(0,1)\times H^{-1}(0,1)$*:*

$$(33)\qquad \int_0^T g(t) z_x(1,t)dt + \int_0^T\int_0^1 \xi z dxdt = \int_0^1 \left(y^0 z_t(0,x) - y^1 z(0,x)\right) dx.$$

3.2. Observability inequalities.

PROPOSITION 12. *Let* $\mathcal{O}$ *be a nonempty open subset of* $[0,1]$ *and let* $T \geq 4$. *Then there exists a positive constant* C, *such that for every solution of* (31)–(32),

$$C\int_0^T z_x^2(1,t)dt \geq \left\|(p^0,p^1)\right\|_{0,-1}^2.$$

Proof. The inequality given in the proposition is a consequence of the fact that there exist positive constants C_1, C_2, such that for every solution of (31)–(32),

$$C_1\int_0^T z_x^2(1,t)dt \geq \left\|(z(T_0), z_t(T_0))\right\|_{1,0}^2,$$
$$C_2\left\|(z(T_0), z_t(T_0))\right\|_{1,0} \geq \left\|(p^0,p^1)\right\|_{0,-1},$$

where T_0 is the smallest positive number such that $T - T_0 \in 2\mathbb{Z}$.

These inequalities are proved using the same arguments as in Proposition 8. ∎

3.3. Existence of insensitizing controls. Using Proposition 12 we can prove the following result.

THEOREM 13. *Let* $\mathcal{O}$ *be a nonempty open subset of* $[0,1]$ *and let* $T \geq 4$. *Then for every* $\xi \in L^2(\mathbb{R}\times(0,1))$ *and* $\left(y^0, y^1\right) \in H_0^1(0,1)\times L^2(0,1)$ *there exists a control* $g \in L^2(\mathbb{R}\times(0,1))$ *that insensitizes* Φ *along the solutions of* (2).

Proof. Consider the quadratic functional $J : L^2(0,1)\times H^{-1}(0,1) \to \mathbb{R}$ defined by

$$J(p^0,p^1) = \frac{1}{2}\int_0^T z_x^2(1,t)dt + \int_0^T\int_0^1 \xi z dxdt - \int_0^1 \left(y^0 z_t(0,x) - y^1 z(0,x)\right) dx,$$

where z is the corresponding solution of (32). Let $(\hat{p}^0, \hat{p}^1)$ be the minimizer of J provided by Proposition 14 (see below):

$$J(\hat{p}^0,\hat{p}^1) = \min\left\{J(p^0,p^1) : (p^0,p^1) \in L^2(0,1)\times H^{-1}(0,1)\right\}.$$

Then for every $(p^0,p^1) \in L^2(0,1)\times H^{-1}(0,1)$ the function $\phi(h) = J(\hat{p}^0 + hp^0, \hat{p}^1 + hp^1)$ has a minimum at $h = 0$ and thus

$$0 = \phi'(0) = \int_0^T \hat{z}_x(1,t) z_x(1,t)dt + \int_0^T\int_0^1 \xi\hat{z} dxdt - \int_0^1 \left(y^0\hat{z}_t(0,x) - y^1\hat{z}(0,x)\right) dx,$$

where $\hat{z}$ is the solution of (31)–(32) with initial data $(\hat{p}^0, \hat{p}^1)$. Consequently, if we choose $g(t) = \hat{z}_x(1,t)$, equality (33) is verified. Therefore, the control $g(t) = \hat{z}_x(1,t)$ insensitizes Φ. ∎

PROPOSITION 14. *The functional J has a minimizer $(\hat{p}^0, \hat{p}^1) \in L^2(0,1)\times H^{-1}(0,1)$.*

Proof. J in continuous and convex. So, to guarantee the existence of a minimizer it is sufficient to prove that J is coercive, i.e., $J \to \infty$ as $\left\|(p^0,p^1)\right\|_{0,-1} \to \infty$.

Let us note first that z verifies

$$\int_0^T \int_0^1 z^2 dxdt \le C \int_0^T \int_{\mathcal{O}} p^2 dxdt \le C \left\|(p^0,p^1)\right\|_{0,-1}^2,$$
$$\left\|(z(0), z_t(0))\right\|_{1,0} \le C \int_0^T \int_{\mathcal{O}} p^2 dxdt \le C \left\|(p^0,p^1)\right\|_{0,-1}^2.$$

Consequently,

$$\left|\int_0^T \int_0^1 \xi z dxdt\right| \le \left(\int_0^T \int_0^1 \xi^2 dxdt\right)^{\frac{1}{2}} \left(\int_0^T \int_0^1 z^2 dxdt\right)^{\frac{1}{2}} \le C_1 \left\|\xi\right\|_{L^2((0,T)\times(0,1))} \left\|(p^0,p^1)\right\|_{0,-1}, \tag{34}$$

$$\left|\int_0^1 \left(y^0 z_t(0) - y^1 z(0,x)\right) dx\right| \le \left\|(y^0,y^1)\right\|_{0,-1} \left\|(z(0), z_t(0))\right\|_{1,0} \le C_2 \left\|(y^0,y^1)\right\|_{0,-1} \left\|(p^0,p^1)\right\|_{0,-1}, \tag{35}$$

where C_1 and C_2 are positive constants.

From Proposition 12, (34), and (35) we get

$$\left|J(p^0,p^1)\right| \ge \left\|(p^0,p^1)\right\|_{0,-1} \left(C \left\|(p^0,p^1)\right\|_{0,-1} - C_1 \left\|\xi\right\|_{L^2((0,T)\times(0,1))} - C_2 \left\|(y^0,y^1)\right\|_{0,-1}\right)$$

and this implies that $J \to \infty$ as $\left\|(p^0,p^1)\right\|_{0,-1} \to \infty$. Hence the assertion of the proposition is proved. □

4. Final remarks. The condition that the observation time be large ($T \ge 4$), which does not appear in previous papers in the context of the heat equations, is natural for the wave equation due to the finite speed of propagation of its solutions. Indeed, it is possible to prove that, for every $T < 2$ one can choose an observation region $\mathcal{O}$ such that a certain nontrivial solution of (17) satisfies $p = 0$ in $[0,T]\times\mathcal{O}$, and then $z = 0$ in $[0,T]\times(0,1)$. This means that the unique continuation property is not verified. One may expect, however, the property to be true for $2 < T < 4$, and in fact we do not know whether the property is true in this case or not. Nevertheless, the condition $T \ge 4$ (twice the sum of the lengths of the strings) appears to be natural in the context of coupled wave equations. Several examples of this situation are given in [5] (see, for instance, section 4.9 in Chapter 4). Note, however, that for every particular choice of the observation interval $\mathcal{O}$ the minimal observation time to guarantee the unique continuation property is strictly smaller than 4.

Of course, it would be of interest to study the insensitizing properties of the controlled systems for other choice of the observation functionals, in particular,

$$\Phi(y) = \frac{1}{2} \int_0^T \int_{\mathcal{O}} \left(y_t^2 + y_x^2\right) dxdt,$$

which may be understood as the mean value of the energy of the portion $\mathcal{O}$ of the string in a time interval of length T. This problem turns out to be more difficult, at least at the level of reducing it to a controllability property.

It is clear that the method we have used to prove the unique continuation does not apply to other 1-D equations, for which the time periodicity property is not valid. However, it does not mean that the results are not valid for those equations. We hope that the existence of ε-insensitizing controls for nonintersecting observation and control regions is not restricted to the 1-D wave equation, and the example given in [10] suggests that this property is also true for the 1-D heat equation.

Acknowledgments. The author would like to express his gratitude to Enrique Zuazua for valuable discussions on this problem and also to the referees for their help in improving the presentation of the paper.

CONEWISE LINEAR SYSTEMS: NON-ZENONESS AND OBSERVABILITY*

M. KANAT CAMLIBEL†, JONG-SHI PANG‡, AND JINGLAI SHEN§

Abstract. Conewise linear systems are dynamical systems in which the state space is partitioned into a finite number of nonoverlapping polyhedral cones on each of which the dynamics of the system is described by a linear differential equation. This class of dynamical systems represents a large number of piecewise linear systems, most notably, linear complementarity systems with the P-property and their generalizations to affine variational systems, which have many applications in engineering systems and dynamic optimization. The challenges of dealing with this type of hybrid system are due to two major characteristics: mode switchings are triggered by state evolution, and states are constrained in each mode. In this paper, we first establish the absence of Zeno states in such a system. Based on this fundamental result, we then investigate and relate several state observability notions: short-time and T-time (or finite-time) local/global observability. For the short-time observability notions, constructive, finitely verifiable algebraic (both sufficient and necessary) conditions are derived. Due to their long-time mode-transitional behavior, which is very difficult to predict, only partial results are obtained for the T-time observable states. Nevertheless, we completely resolve the T-time local observability for the bimodal conewise linear system, for finite T, and provide numerical examples to illustrate the difficulty associated with the long-time observability.

Key words. piecewise linear systems, conewise linear systems, hybrid systems, Zeno behavior, observability

1. Introduction.

A conewise linear system (CLS) is a hybrid dynamical system consisting of a finite number of linear ordinary differential equations (ODEs) that are active on certain polyhedral cones which partition the whole Euclidean state space. Each of these cones is called a *mode* of the system; transitions between modes occur along a state trajectory. Many piecewise linear systems can be formulated as CLSs; among these, linear complementarity systems (LCSs) [15, 6] are perhaps the most prominent. Specifically, an LCS is defined by a linear time-invariant ODE containing an algebraic variable that is required to be a solution to a finite-dimensional linear complementarity problem (LCP). Collectively, these piecewise linear systems and their generalizations, such as the differential variational inequalities (DVIs) [25], have found a wide range of applications in nonsmooth mechanical systems, switched electrical

networks and control systems, and dynamic optimization in operations research and economics. See the two surveys [4, 31] and the recent papers [7, 8, 16, 17] as well as the references therein.

As with all switched dynamical systems, a critical issue associated with a CLS is whether infinitely many mode transitions exist in any finite time along a state trajectory, i.e., the *Zeno behavior* of the CLS. Such an issue was studied in a different setting for piecewise analytic systems in [5, 35] two decades ago. It has regained considerable attention and received extensive treatment in the hybrid system literature in the past few years, e.g., [19, 32, 37], due to its fundamental role in the study of numerical simulations and basic system and control properties of hybrid systems. Adding to the recent study of the Zeno issue [7] for complementarity systems, the paper [33] introduces several important notions of non-Zenoness and non-Zeno states of an LCS and establishes the "strong non-Zenoness" for an LCS with the P-property and the "weak non-Zenoness" for a broader class of LCSs. The paper [24] further extends the Zeno study to a nonlinear complementarity system (NCS) and to the DVI; it shows the strong non-Zenoness for an NCS satisfying the strong regularity condition and investigates certain system properties using these non-Zeno results.

Having its roots in the very early stages of modern control theory [20], observability is a fundamental concept in systems and control. Roughly speaking, observability refers to the ability of reconstructing the initial state from given output observations. This notion is well understood for linear systems [10]. However, characterization of observability of nonlinear systems (with control inputs) becomes a very hard problem. For instance, one has to analyze many different observability concepts of nonlinear systems, and only local sufficient conditions are available for small-time observability [23]; see the algebraic approach for analytic systems [2]. Moreover, checking these conditions can become a computationally untractable task [3].

The observability of hybrid systems has attracted growing attention in recent years. Mode and state observability of discrete-time switched linear systems are studied in [1], under the assumption that mode sequences are arbitrary; linear algebraic tests are provided, and the decidability is discussed. The paper [36] analyzes the observability of jump-linear systems and linear hybrid systems; necessary and sufficient conditions in terms of algebraic tests are given. Several observability notions are proposed for piecewise affine hybrid systems in [12]; sufficient conditions are obtained for the observability test and are used for observer design. Other related results include observability of Turing machines and its connection to hybrid systems [11]. For more discussions on observability analysis and observer design, see the references cited in the above-mentioned papers.

The present paper deals with the non-Zenoness and state observability of CLSs, assuming a linear system output. Compared with the observability results in the literature, there are two unique characteristics of the CLS that make the observability analysis challenging and different from the prior results: (i) mode switchings are triggered by state evolution instead of being arbitrarily chosen; (ii) the state is restricted to a cone in each mode. Due to the first property, the issues of well-posedness and Zenoness of system solutions become nontrivial. The second property implies that classical matrix rank conditions are insufficient to characterize observability properties. Moreover, a state trajectory is at best only once differentiable with respect to time and is not differentiable with respect to the initial condition. These properties necessitate the development of new tools to handle observability issues for this class of nonsmooth systems.

The organization of the paper is as follows. In section 2, we begin with the introduction of the main object of the study, CLSs, and discuss certain fundamental properties of the solutions. We then prove the non-Zenoness and piecewise analyticity of such solutions in section 3. Various kinds of observability notions are investigated, and the relation between them is discussed in section 4. It is shown that the linear dynamics, together with the conic state space partition, is instrumental in the derivation of constructive necessary and sufficient conditions for certain observability notions, particularly for short-time observability. Detailed investigation of T-time local observability of bimodal CLSs is given in section 5. For the long-time observability, we present examples to demonstrate several interesting properties that make this observability notion challenging to characterize, even for bimodal CLSs.

2. Conewise linear systems. Consider the ODE

$$\dot{x} = f(x), \tag{2.1}$$

where $x \in \mathbb{R}^n$ and $f : \mathbb{R}^n \to \mathbb{R}^n$ is a piecewise affine (PA) function; i.e.,

(a) f is continuous, and
(b) a positive integer m and a family of affine functions $\{f_i\}_{i=1}^m$ exist such that $f(x) \in \{f_i(x)\}_{i=1}^m$ for all $x \in \mathbb{R}^n$.

We call systems of the form (2.1) *piecewise affine* systems. The representation (2.1) describes the system at hand in an implicit way via the component functions $\{f_i\}_{i=1}^m$. Alternatively, a geometric representation of (2.1) can be obtained by invoking well-known properties of PA functions (see, e.g., [14]). To elaborate on this, we recall that a finite collection of polyhedra in $\mathbb{R}^n$, denoted Ξ, is a *polyhedral subdivision* of $\mathbb{R}^n$ if

(a) the union of all polyhedra in Ξ is equal to $\mathbb{R}^n$,
(b) each polyhedron in Ξ is of dimension n, and
(c) the intersection of any two polyhedra in Ξ is either empty or a common proper face of both polyhedra.

For every PA function f, one can find a polyhedral subdivision of $\mathbb{R}^n$ and a finite family of affine functions $\{g_i\}$ such that f coincides with one of the functions $\{g_i\}$ on each polyhedron in Ξ [14, Proposition 4.2.1]. Let such a polyhedral subdivision be given by $\Xi = \{\mathcal{X}_i\}_{i=1}^m$, where each polyhedron $\mathcal{X}_i$, called a *piece* of the system, is described by a finite system of linear inequalities:

$$\mathcal{X}_i = \{x \mid C_i x + d_i \geqslant 0\} \tag{2.2}$$

for a certain matrix $C_i \in \mathbb{R}^{m_i \times n}$ and vector $d_i \in \mathbb{R}^{m_i}$; also write $g_i(x) = A_i x + b_i$ for some matrix A_i and vector b_i. With these definitions, we can write the system (2.1) in the equivalent form

$$\dot{x} = A_i x + b_i \quad \text{if } x \in \mathcal{X}_i. \tag{2.3}$$

In this case, continuity of the function f is equivalent to the following implication:

$$x \in \mathcal{X}_i \cap \mathcal{X}_j \Rightarrow A_i x + b_i = A_j x + b_j. \tag{2.4}$$

Since a PA function must be globally Lipschitz continuous (see, e.g., [14]), it follows from well-known ODE theory that the PA system (2.1) must admit a unique solution, which is denoted by $x(t, \xi)$, that is continuously differentiable (i.e., C^1) in time for any initial state $x(0) = \xi$. Moreover, it was recently proved in [26] that for each t, $x(t, \cdot)$

is a "semismooth" function on $\mathbb{R}^n$, meaning that it is "B(ouligand)-differentiable" (i.e., locally Lipschitz continuous and directionally differentiable) everywhere with the directional derivative along a prescribed direction given as the unique solution of a "first-order variational equation."

Throughout this paper, we focus on a particular type of PA system obtained by taking $b_i = d_i = 0$ for all i in (2.2) and (2.3). In this case, the system takes the form

$$\dot{x} = A_i x \quad \text{if } x \in \mathcal{X}_i \equiv \{x \mid C_i x \geqslant 0\}. \tag{2.5}$$

The continuity requirement of the right-hand side of (2.5) reduces to

$$x \in \mathcal{X}_i \cap \mathcal{X}_j \Rightarrow A_i x = A_j x; \tag{2.6}$$

i.e., $\mathcal{X}_i \cap \mathcal{X}_j \subseteq \ker(A_i - A_j)$, where ker denotes the kernel of a matrix. Since the pieces $\mathcal{X}_i$ are cones in this case, we call the system (2.5) a *conewise linear system* (CLS). Without loss of generality, we assume throughout that each matrix C_i contains no zero rows. Under this assumption, and by the fact that $\mathcal{X}_i$ is full dimensional, it follows that for each index $\ell = 1, \ldots, m_i$, there exists a vector $\widehat{x}^\ell \in \mathcal{X}_i$ such that $(C_i \widehat{x}^\ell)_\ell > 0$. Therefore, we must have

$$\varnothing \neq \operatorname{int} \mathcal{X}_i = \{x \mid C_i x > 0\}, \tag{2.7}$$

where int denotes the interior of a set. By property (c) of a polyhedral subdivision, it follows that $\mathcal{X}_j \cap \operatorname{int} \mathcal{X}_i = \varnothing$ for all $i \neq j$.

Associated with the "forward-time" system (2.5) is a *backward-time* system that allows us to obtain reverse-time results easily from a forward-time analysis. Specifically, for any given $T > 0$, define $x^{\mathrm{r}}(t) \equiv x(T - t)$. We have $x^{\mathrm{r}}(0) = x(T)$ and

$$\dot{x}^{\mathrm{r}} = \widetilde{A}_i \, x^{\mathrm{r}} \quad \text{if } x^{\mathrm{r}} \in \mathcal{X}_i, \tag{2.8}$$

where $\widetilde{A}_i \equiv -A_i$. Obviously, the latter system remains a CLS. The reverse-time system can be used to derive backward-time results pertaining to the forward-time trajectory. For instance suppose that $x(t_0, \xi) = x(t_0, \eta) = z^0$ for some $t_0 > 0$ and some ξ and η in $\mathbb{R}^n$. By considering the reverse-time trajectory starting at time t_0 and going backwards in time until the initial time $t = 0$ and by using the uniqueness of the solution to the reverse-time system given an initial condition, it follows that $\xi = x^{\mathrm{r}}(t_0, z^0) = \eta$. In words, this observation says that if two forward-time trajectories starting at two initial conditions ξ and η ever intersect at some common future time, then these two trajectories must in fact be identical at all times.

CLSs form a special class of linear hybrid systems (see, for instance, [22]). In fact, they can be cast as hybrid automata for which

(a) the vector fields in each location are linear,
(b) the invariant sets are solid polyhedral cones,
(c) the guard sets are the boundaries of these cones, and
(d) the reset maps are all identity.

In what follows, we look at two specific examples of CLSs.

Example 2.1. Bimodal CLSs are the simplest CLSs with only 2 pieces; i.e., $m = 2$ and $\Xi = \{\mathcal{X}_1, \mathcal{X}_2\}$. We claim that any such system can be described by the ODE

$$\dot{x} = Ax + b \max(0, c^T x) \tag{2.9}$$

for some $n \times n$ matrix A and n-vectors b and c. This is a nontrivial assertion; indeed, we need to show that given (2.5) and (2.6), we can identify the matrix A and the two

vectors b and c such that (2.9) is equivalent to the given bimodal CLS. The proof is as follows. Since $\Xi = \{\mathcal{X}_1, \mathcal{X}_2\}$ is a polyhedral division of $\mathbb{R}^n$, it follows that

$$\operatorname{int} \mathcal{X}_1 \cap \operatorname{int} \mathcal{X}_2 = \varnothing, \tag{2.10}$$

$$\mathcal{X}_1 \cup \mathcal{X}_2 = \mathbb{R}^n. \tag{2.11}$$

In view of (2.10), it follows from [34, Theorem 3.3.4] that there exists a hyperplane, say $\mathcal{H} = \{x \in \mathbb{R}^n \mid c^T x = 0\}$, such that $\mathcal{X}_1 \subseteq \mathcal{H}_+ \equiv \{x \in \mathbb{R}^n \mid c^T x \geqslant 0\}$ and $\mathcal{X}_2 \subseteq \mathcal{H}_- \equiv \{x \in \mathbb{R}^n \mid c^T x \leqslant 0\}$. We claim that $\mathcal{X}_1 = \mathcal{H}_+$. To see this, note that

$$(\operatorname{int} \mathcal{H}_+ \setminus \mathcal{X}_1) \cap \mathcal{X}_1 = \varnothing, \tag{2.12}$$

$$(\operatorname{int} \mathcal{H}_+ \setminus \mathcal{X}_1) \cap \mathcal{X}_2 \subseteq \operatorname{int} \mathcal{H}_+ \cap \mathcal{H}_- = \varnothing. \tag{2.13}$$

Then, (2.11) together with (2.12)–(2.13) implies that $\operatorname{int} \mathcal{H}_+ \setminus \mathcal{X}_1 = \varnothing$, i.e., $\operatorname{int} \mathcal{H}_+ \subseteq \mathcal{X}_1$. Since $\mathcal{X}_1$ is contained in $\mathcal{H}_+$ and it is a closed set, we get $\mathcal{X}_1 = \mathcal{H}_+$. In a similar fashion, one can show that $\mathcal{X}_2 = \mathcal{H}_-$. Then, we get $\mathcal{X}_1 \cap \mathcal{X}_2 = \mathcal{H}_+ \cap \mathcal{H}_- = \mathcal{H} = \ker(c^T)$. Hence, we can write (2.5)–(2.6) as

$$\dot{x} = \begin{cases} A_1 x & \text{if} \quad c^T x \geqslant 0, \\ A_2 x & \text{if} \quad c^T x \leqslant 0, \end{cases} \tag{2.14}$$

where A_1 and A_2 satisfy $c^T x = 0 \Rightarrow A_1 x = A_2 x$. Equivalently, $A_1 - A_2 = bc^T$ for some n-vector b. Thus, (2.14) becomes (2.9) with $A \equiv A_2$.

Example 2.2. A broad class of CLSs consists of the following *linear cone complementarity system* (LCCS):

$$\begin{aligned} \dot{x} &= Ax + Bz, \\ \mathcal{C} \ni z &\perp Cx + Dz \in \mathcal{C}^*, \end{aligned} \tag{2.15}$$

where $x \in \mathbb{R}^n$, $z \in \mathbb{R}^p$, $\mathcal{C}$ is a polyhedral cone and $\mathcal{C}^*$ is its dual (as in convex analysis [27]), and $a \perp b$ means $a^T b = 0$. A wealth of examples, from various areas of engineering as well as operations research, of these piecewise linear (hybrid) systems can be found in [31, 30, 16]. For references on the analysis of the general LCCS, we refer the reader to [8, 17, 7, 28, 29, 18]. A special case of interest emerges when $\mathcal{C} = \mathbb{R}^p_+$; the resulting LCCS is called simply a *linear complementarity system* (LCS). A fundamental subclass of the LCSs arises when all the principal minors of the matrix D are positive. Such matrices are called P-matrices in the literature of mathematical programming. The class of P-matrices is very broad (see [13]); in particular, it includes the class of positive definite (not necessarily symmetric) matrices. Most importantly, P-matrices play a fundamental role in the LCP, i.e., the problem of finding a p-vector z satisfying

$$0 \leqslant z \perp q + Dz \geqslant 0 \tag{2.16}$$

for a given p-vector q and a $p \times p$ matrix D. We denote the latter problem by $\mathrm{LCP}(q, D)$. It is well known that the $\mathrm{LCP}(q, D)$ admits a unique solution for all $q \in \mathbb{R}^p$ if and only if D is a P-matrix; see [13, Theorem 3.3.7]. Moreover, for each q there exists an index set $\alpha \subseteq \{1, 2, \ldots, p\}$ with complement $\bar{\alpha}$ such that

(a) $-(D_{\alpha\alpha})^{-1} q_\alpha \geqslant 0$ and $q_{\bar{\alpha}} - D_{\bar{\alpha}\alpha}(D_{\alpha\alpha})^{-1} q_\alpha \geqslant 0$,

(b) the unique solution z of the LCP (q, D) is given by $z_\alpha = -(D_{\alpha\alpha})^{-1} q_\alpha$ and $z_{\bar{\alpha}} = 0$.

This shows that the solution mapping $q \mapsto z$ is a piecewise linear function on $\mathbb{R}^p$. Based on the above facts, we can rewrite the LCS (2.15) in the form of the CLS (2.5) as follows:

(2.17)
$$\dot{x} = (A - B_{\bullet\alpha}(D_{\alpha\alpha})^{-1}C_{\alpha\bullet})x \quad \text{if} \quad \begin{bmatrix} -D_{\alpha\alpha}^{-1} & 0 \\ -D_{\bar{\alpha}\alpha}(D_{\alpha\alpha})^{-1} & I_{\bar{\alpha}\bar{\alpha}} \end{bmatrix} \begin{bmatrix} C_{\alpha\bullet} \\ C_{\bar{\alpha}\bullet} \end{bmatrix} x \geqslant 0.$$

There are generalizations of the LCP results to the linear cone complementarity problem (LCCP), which can then be applied to the LCCS. In what follows, we discuss one such generalization that does not require the LCCP to have a unique solution. Let us denote by $\mathrm{SOL}(\mathcal{C}, q, D)$ the solution set of the LCCP

$$\mathcal{C} \ni z \perp q + Dz \in \mathcal{C}^*.$$

It has been observed [9, 25] that the LCCS (2.15) has a unique C^1 trajectory $x(t)$ for all initial conditions $x(0) = x^0 \in \mathbb{R}^n$ if and only if $B\mathrm{SOL}(\mathcal{C}, Cx, D)$ is a singleton for all $x \in \mathbb{R}^n$. If the latter singleton condition holds, then it follows that (2.15) is equivalent to

$$\dot{x} = Ax + B\mathrm{SOL}(\mathcal{C}, Cx, D), \tag{2.18}$$

where the right-hand side is a piecewise linear function of x on $\mathbb{R}^n$. Thus (2.18) is a CLS. A special case where $B\mathrm{SOL}(\mathcal{C}, Cx, D)$ is a singleton for all $x \in \mathbb{R}^n$ occurs when D is positive semidefinite (albeit not necessarily symmetric), $C\mathbb{R}^n \subseteq -D\mathcal{C} + \mathcal{C}^*$, and $(\mathcal{C} - \mathcal{C}) \cap \ker(D + D^T) \subseteq \ker B$. The first two conditions imply that $\mathrm{SOL}(\mathcal{C}, Cx, D)$ is a nonempty polyhedron for all $x \in \mathbb{R}^n$, and the last assumption ensures that $B\mathrm{SOL}(\mathcal{C}, Cx, D)$ is a singleton; see [14] for a proof of these facts.

Unlike the LCS with a P-matrix D, it is not straightforward to write down the pieces of the system (2.18); nevertheless, this can be achieved by introducing multipliers to the constraints defining the cone $\mathcal{C}$, which we write as

$$\mathcal{C} = \{ z \,|\, Gz \geqslant 0 \} \tag{2.19}$$

for some matrix $G \in \mathbb{R}^{r \times p}$. Letting $\lambda \in \mathbb{R}^r$ be the vector of multipliers corresponding to the constraint $Gz \geqslant 0$, the complementarity condition $\mathcal{C} \ni z \perp Cx + Dz \in \mathcal{C}^*$ is equivalent to

$$0 = Cx + Dz - G^T\lambda \quad \text{and} \quad 0 \leqslant \lambda \perp Gz \geqslant 0.$$

The pieces of the CLS (2.18) can be identified as follows. Define for each index subset α of $\{1, \ldots, r\}$, with complement $\bar{\alpha}$, the polyhedral cone $\widehat{\mathcal{X}}_\alpha \subset \mathbb{R}^n$ consisting of all vectors x for which there exist (z, λ_α) such that

$$\begin{aligned} 0 &= Cx + Dz - (G_{\alpha\bullet})^T\lambda_\alpha, \\ \lambda_\alpha \geqslant 0 &= G_{\alpha\bullet}z, \quad \text{and} \quad \lambda_{\bar{\alpha}} = 0 \leqslant G_{\bar{\alpha}\bullet}z. \end{aligned}$$

While there may be multiple pairs (z, λ_α) satisfying the above linear inequality system for a given x (which explains why $\widehat{\mathcal{X}}_\alpha$ is a polyhedral cone), the vector Bz is a constant among all such pairs, as long as $B\mathrm{SOL}(\mathcal{C}, Cx, D)$ is a singleton. Moreover, with some linear algebraic manipulations, it can be deduced that $Ax + B\mathrm{SOL}(\mathcal{C}, Cx, D) = \widehat{A}_\alpha x$ for some matrix $\widehat{A}_\alpha$ for all $x \in \widehat{\mathcal{X}}_\alpha$. Notice that the family $\{\widehat{\mathcal{X}}_\alpha\}$ for α ranging over all subsets of $\{1, \ldots, r\}$ may not form a polyhedral subdivision of $\mathbb{R}^r$ (for one thing, some of them could overlap); nevertheless, they are enough to show that the right-hand side of (2.18) is a piecewise linear function of x.

2.1. Some structural properties. In this subsection, we establish some basic structural properties of the CLS (2.5). First we review some well-known concepts. An ordered tuple $a \equiv (a_1, \ldots, a_k)$ of real numbers is said to be *lexicographically nonnegative* if either $a = 0$ or its first nonzero component is positive. In this case, we write $a \succcurlyeq 0$. If a is nonzero and lexicographically nonnegative, we say that a is lexicographically positive. In this case, we write $a \succ 0$. Sometimes, we also use the signs "$\preccurlyeq$" and "$\prec$" with the obvious meanings. The set of lexicographically nonnegative k-tuples forms a convex, albeit not closed, cone in $\mathbb{R}^k$. A finite collection of n-dimensional vectors $(y^1, y^2, \ldots, y^k)$ for some positive integer k is said to be lexicographically nonnegative (positive), denoted $(y^1, y^2, \ldots, y^k) \succcurlyeq (\succ) 0$, if for each $j = 1, \ldots, n$, the k-dimensional tuple $(y^1_j, \ldots, y^k_j)$ is lexicographically nonnegative (positive).

For a given $x^0 \in \mathbb{R}^n$, the solution trajectory $x(t, x^0)$ of the CLS (2.5) does not necessarily stay in the same piece as the initial state x^0 for all sufficiently small $t > 0$. To ensure the latter persistence property, we define the following sets: for all $i = 1, \ldots, m$,

$$\mathcal{Y}_i \equiv \left\{ x \in \mathbb{R}^n \,\middle|\, \left(C_i x, C_i A_i x, \ldots, C_i A_i^{n-1} x \right) \succcurlyeq 0 \right\}. \tag{2.20}$$

Obviously, $\mathcal{Y}_i$ is a convex, albeit not closed, cone in $\mathbb{R}^n$; it bears a close connection with the set $\mathcal{X}_i$ as described in the following result, whose proof is elementary and thus omitted. In the result, we let cl denote the closure of a set.

LEMMA 2.3. *Assume that every matrix C_i has no zero rows. The following statements hold for all $i = 1, \ldots, m$:* (a) $\mathcal{Y}_i \subseteq \mathcal{X}_i$; (b) $\operatorname{int} \mathcal{X}_i \subseteq \mathcal{Y}_i$; (c) $\operatorname{cl} \mathcal{Y}_i = \mathcal{X}_i$; *and* (d) $\mathcal{Y}_i - \mathcal{Y}_i = \mathcal{X}_i - \mathcal{X}_i = \mathbb{R}^n$.

The next lemma characterizes the elements of the set $\mathcal{Y}_i$; it shows in particular that the solution trajectory $x(t, x^0)$ stays in one piece, say $\mathcal{X}_i$, for all $t > 0$ sufficiently small if and only if $x^0 \in \mathcal{Y}_i$.

LEMMA 2.4. *The three statements below are equivalent for any vector $x^0 \in \mathbb{R}^n$:*

(a) $x^0 \in \mathcal{Y}_i$;

(b) *there exists a positive number ε such that $x(t, x^0) \in \mathcal{X}_i$ for all $t \in [0, \varepsilon]$;*

(c) *for some (equivalently, any) positive n-vector $c = (c_1, \ldots, c_n)$, there exists a number $\mu_0 > 0$ such that $\sum_{k=0}^{n-1} c_{k+1}\, \mu^k A_i^k x^0 \in \mathcal{X}_i$ for all $\mu \in [0, \mu_0]$.*

Proof. The equivalence of (a) and (b) is easy. We prove only the equivalence of (a) and (c). Observe that (c) is equivalent to $\sum_{k=0}^{n-1} c_{k+1}\, \mu^k (C_i A_i^k x^0)_\ell \geqslant 0$ for each index $\ell = 1, \ldots, m_i$ and all $\mu \in [0, \mu_0]$. Therefore, the positivity of $c_1, \ldots, c_n$ and μ implies $((C_i x^0)_\ell, \ldots, (C_i A_i^{n-1} x^0)_\ell) \succcurlyeq 0$ for all indices $\ell = 1, \ldots, m_i$. Hence $x^0 \in \mathcal{Y}_i$. Conversely, suppose (c) holds, but (a) does not. Then there exist an index $\ell \in \{1, \ldots, m_i\}$ and an integer $0 \leq k \leq n-1$ such that $(C_i A_i^k x^0)_\ell < 0$ and $(C_i A_i^j x^0)_\ell = 0$ for all $j = 0, \ldots, k-1$. Therefore, for sufficiently small $\mu > 0$, $\sum_{k=0}^{n-1} c_{k+1} \mu^k (C_i A_i^k x^0)_\ell < 0$. This contradicts (c). ∎

In general, a given initial state x^0 may be contained in multiple cones $\mathcal{X}_i$ and $\mathcal{Y}_i$. This motivates the definition of the following index sets. Given $\xi \in \mathbb{R}^n$, define

$$\mathcal{I}(\xi) \equiv \{i \mid \xi \in \mathcal{X}_i\} \quad \text{and} \quad \mathcal{J}(\xi) \equiv \{i \mid \xi \in \mathcal{Y}_i\}. \tag{2.21}$$

Basic relations between these sets are summarized in the following lemma.

LEMMA 2.5. *The following statements hold for any $\xi \in \mathbb{R}^n$:*

(a) *a neighborhood $\mathcal{N}$ of ξ exists such that $\mathcal{N} \subseteq \bigcup_{i \in \mathcal{I}(\xi)} \mathcal{X}_i$;*

(b) $\mathcal{J}(\xi) \subseteq \mathcal{I}(\xi)$;

(c) $A_i \xi = A_j \xi$ *if* $i, j \in \mathcal{I}(\xi)$;

(d) $A_i^k \xi = A_j^k \xi$ *for all positive integers k if* $i, j \in \mathcal{J}(\xi)$.

Proof. The proof is easy and omitted. ∎

With respect to the reverse-time system (2.8) where $\widetilde{A}_i = -A_i$, both sets

$$\mathcal{Y}_i^{\mathrm{r}} \equiv \left\{ x \in \mathbb{R}^n \,|\, (C_i x, C_i \widetilde{A}_i x, \ldots, C_i \widetilde{A}_i^{n-1} x) \succcurlyeq 0 \right\} \text{ and } \mathcal{J}^{\mathrm{r}}(\xi) \equiv \{ i \,|\, \xi \in \mathcal{Y}_i^{\mathrm{r}} \}$$

are not necessarily equal to the respective sets $\mathcal{Y}_i$ and $\mathcal{J}(\xi)$ that are defined with respect to the original forward-time system (2.5). Nevertheless, the forward-time trajectory and the reverse-time trajectory are equal in any interval. In particular, if $i \in \mathcal{J}^{\mathrm{r}}(x(t_*, \xi))$, where $t_* > 0$, then there exists $\varepsilon > 0$ such that $C_i x(t, \xi) \geqslant 0$ for all $t \in [t_* - \varepsilon, t_*]$.

3. Non-Zeno property of CLSs. In the hybrid systems literature, the occurrence of an infinite number of mode transitions within a finite time interval is called the *Zeno behavior* with reference to the ancient Greek philosopher Zeno's paradoxes.[1] Our goal in this section is to show that the CLS does not exhibit such behavior. At the end of the section, we will compare the main result specialized to the LCS with those obtained in [33].

DEFINITION 3.1. *The PA system* (2.1) *is said to satisfy the* (forward and backward) non-Zeno property *if for any* $x^0 \in \mathbb{R}^n$ *and any* $t' \geq 0$*, there exist* $\varepsilon_\pm > 0$ *and* $\mathcal{X}_{i^\pm} \in \Xi$ *such that* $x(t, x^0) \in \mathcal{X}_{i^+}$ *for all* $t \in [t', t' + \varepsilon_+]$ *(forward-time non-Zeno) and, for* $t' > 0$*,* $x(t, x^0) \in \mathcal{X}_{i^-}$ *for all* $t \in [t' - \varepsilon_-, t']$ *(backward-time non-Zeno).*

(Note: the backward-time non-Zeno property is not defined at the initial time $t' = 0$; since the trajectory $x(t, x^0)$ is in principle defined only for $t \geqslant 0$, in the backward-time non-Zeno property at the time $t' > 0$, the scalar $\varepsilon_- > 0$ is taken to be less than t'.)

The following result shows that the backward non-Zeno property of the forward-time CLS (2.5) is equivalent to the forward non-Zeno property of the reverse-time CLS (2.8). It allows us to focus our attention on the forward non-Zeno property subsequently.

PROPOSITION 3.2. *The system* (2.5) *has the backward non-Zeno property if and only if the system* (2.8) *has the forward non-Zeno property.*

Proof. Suppose that (2.5) has the backward non-Zeno property. Let $x^0 \in \mathbb{R}^n$ and $t' \geqslant 0$ be given. Consider the reverse-time trajectory $x^{\mathrm{r}}(t, x^0)$ beginning at x^0 and terminating at a state $\xi^0 \equiv x^{\mathrm{r}}(T, x^0)$ at time $T > t'$. We then have $x^{\mathrm{r}}(t', x^0) = x(T - t', \xi^0)$. It follows by the backward non-Zeno property of the forward CLS (2.5) that an $\varepsilon > 0$ and an $\mathcal{X}_{i^-}$ exist such that $x(t, x^0) \in \mathcal{X}_{i^-}$ for all $t \in [T - t' - \varepsilon, T - t']$. Hence $x^{\mathrm{r}}(\widetilde{t}, x^0) = x(T - \widetilde{t}, \xi^0) \in \mathcal{X}_{i^-}$ for all $\widetilde{t} \in [t', t' + \varepsilon]$. Therefore, the system (2.8) has the forward non-Zeno property. The converse can be proved similarly. ∎

The next lemma is the first step in showing that the CLSs do not have the Zeno behavior.

LEMMA 3.3. *The following three statements are equivalent.*

(a) *The CLS* (2.5) *satisfies the forward non-Zeno property.*

(b) $\cup_{i=1}^m \mathcal{Y}_i = \mathbb{R}^n$.

(c) *For every* $\xi \in \mathbb{R}^n$*,* $\mathcal{J}(\xi) \neq \varnothing$.

Proof. Suppose (a) holds. Since for an arbitrary $x^0 \in \mathbb{R}^n$, there exist an $\varepsilon > 0$ and a piece $\mathcal{X}_i$ such that $x(t, x^0) \in \mathcal{X}_i$ for all $t \in [0, \varepsilon]$, we have $x^0 \in \mathcal{Y}_i$ by Lemma 2.4. Thus $\mathbb{R}^n \subseteq \cup_{i=1}^m \mathcal{Y}_i$, which clearly yields (b). For the converse, let $x^0 \in \mathbb{R}^n$ and $t' \geqslant 0$ be given. By (b), the vector $\xi \equiv x(t', x^0)$ belongs to some $\mathcal{Y}_{i^+}$. Hence Lemma 2.4 implies the existence of $\varepsilon_+ > 0$ such that $x(t, \xi) = x(t' + t, x^0) \in \mathcal{X}_{i^+}$ for all $t \in [0, \varepsilon_+]$. Thus (a) and (b) are equivalent. The equivalence of (b) and (c) is clear. ∎

[1] The most well known of these four paradoxes dealing with counterintuitive aspects of space and time is Achilles and the turtle.

We need another technical lemma in order to prove the main result of this section.

LEMMA 3.4. *Let $\xi \in \mathbb{R}^n$ be arbitrary. For any polynomial $p : \mathbb{R} \to \mathbb{R}^n$ with $p(0) = \xi$, there exists $i \in \mathcal{I}(\xi)$ such that $p(\mu) \in \mathcal{X}_i$ for all sufficiently small $\mu > 0$.*

Proof. Let $p(\mu)$ be a polynomial satisfying $p(0) = \xi$. For each index $i \in \mathcal{I}(\xi)$, there are only three possible cases:

(i) $p(\mu) \in \mathcal{X}_i$ for all sufficiently small $\mu > 0$;
(ii) $p(\mu) \notin \mathcal{X}_i$ for all sufficiently small $\mu > 0$;
(iii) there exists an infinite sequence of positive scalars $\{\mu_k\}$ all distinct and converging to zero as $k \uparrow \infty$ such that, for all $k = 1, 2, \ldots$, $p(\mu_{2k-1}) \in \mathcal{X}_i$ and $p(\mu_{2k}) \notin \mathcal{X}_i$.

If the claim of the lemma does not hold, then for each index $i \in \mathcal{I}(\xi)$ either (ii) or (iii) must hold. We claim that (iii) must hold at least for one $i \in \mathcal{I}(\xi)$ in this case. To show this, it is enough to prove that (ii) cannot hold for all $i \in \mathcal{I}(\xi)$. Suppose, on the contrary, that (ii) holds for all $i \in \mathcal{I}(\xi)$. Then, one gets $p(\mu) \notin \cup_{i \in \mathcal{I}(\xi)} \mathcal{X}_i$ for all sufficiently small $\mu > 0$. This, however, contradicts part (a) of Lemma 2.5. Therefore, there exists $i \in \mathcal{I}(\xi)$ such that (iii) holds. Without loss of generality, we may assume that the sequence $\{\mu_k\}$ is strictly decreasing. For each k, since $p(\mu_{2k}) \notin \mathcal{X}_i$, there exists an index ℓ_k such that $(C_i p(\mu_{2k}))_{\ell_k} < 0$. Since there are only finitely many such indices ℓ_k, there exists an index ℓ_0 such that $(C_i p(\mu_{2k}))_{\ell_0} < 0$ for infinitely many k's. Without loss of generality, we may assume that $(C_i p(\mu_{2k}))_{\ell_0} < 0$ for all k. Since $(C_i p(\mu_{2k-1}))_{\ell_0} \geqslant 0$, it follows that for all k, there exists $\bar{\mu}_k \in [\mu_{2k-1}, \mu_{2k})$ such that $(C_i p(\bar{\mu}_k))_{\ell_0} = 0$. Since the $\bar{\mu}_k$'s are all distinct (because the sequence $\{\mu_k\}$ is strictly decreasing) and $(C_i p(\mu))_{\ell_0}$ is a polynomial in μ with finitely many roots, we have $(C_i p(\mu))_{\ell_0} \equiv 0$ for all μ. This is a contradiction. □

With the help of the last two lemmas, we can now formally state and prove the absence of Zeno behavior in the CLS.

THEOREM 3.5. *The CLS* (2.5) *has the non-Zeno property; i.e., $\cup_{i=1}^m \mathcal{Y}_i = \mathbb{R}^n = \cup_{i=1}^m \mathcal{Y}_i^{\mathrm{r}}$.*

Proof. In view of Proposition 3.2, it suffices to show that any CLS has the forward non-Zeno property. In turn, by Lemma 3.3, it is enough to show that $\cup_{i=1}^m \mathcal{Y}_i = \mathbb{R}^n$. Take any $\xi \in \mathbb{R}^n$. Set $\eta_0 = \xi$ and $\mathcal{I}_0 = \mathcal{I}(\xi)$. The continuity implies that $A_i \eta_0 = A_j \eta_0$ for all $i, j \in \mathcal{I}_0$. Define

$$\mathcal{I}_1 \equiv \{i \in \mathcal{I}_0 \mid \eta_0 + \mu\eta_1 \in \mathcal{X}_i \ \forall \text{ sufficiently small } \mu > 0\},$$

where $\eta_1 \equiv A_i \eta_0$ for any $i \in \mathcal{I}_0$. Lemma 3.4 guarantees that $\mathcal{I}_1 \neq \varnothing$. Note that

$$A_i(\eta_0 + \mu\eta_1) = A_j(\eta_0 + \mu\eta_1) \tag{3.1}$$

for all $i, j \in \mathcal{I}_1$ and for all sufficiently small $\mu > 0$. Since $\mathcal{I}_1 \subseteq \mathcal{I}_0$, (3.1) implies that $A_i \eta_1 = A_j \eta_1$ for all $i, j \in \mathcal{I}_1$. Define

$$\mathcal{I}_2 \equiv \{i \in \mathcal{I}_0 \mid \eta_0 + \mu\eta_1 + \mu^2\eta_2 \in \mathcal{X}_i \ \forall \text{ sufficiently small } \mu > 0\},$$

where $\eta_2 \equiv A_i \eta_1$ for any $i \in \mathcal{I}_1$. Again, Lemma 3.4 guarantees that this set is nonempty. We claim that $\mathcal{I}_2 \subseteq \mathcal{I}_1$. To see this, let $i \in \mathcal{I}_2$. We need to show that $C_i(\eta_0 + \mu\eta_1) \geqslant 0$ for all $\mu > 0$ sufficiently small. Since $i \in \mathcal{I}_2$, we must have $C_i \eta_0 \geqslant 0$. If ℓ is an index such that $(C_i \eta_0)_\ell = 0$, then we must have $(C_i \eta_1)_\ell \geqslant 0$. Hence the claim holds. Therefore, for all $i, j \in \mathcal{I}_2$, we have $A_i(\eta_0 + \mu\eta_1 + \mu^2\eta_2) = A_j(\eta_0 + \mu\eta_1 + \mu^2\eta_2)$ for all $\mu > 0$ sufficiently small. Since $\mathcal{I}_2 \subseteq \mathcal{I}_1$, we deduce $A_i \eta_2 = A_j \eta_2$. Next, define

$$\mathcal{I}_3 \equiv \{i \in \mathcal{I}_0 \mid \eta_0 + \mu\eta_1 + \mu^2\eta_2 + \mu^3\eta_3 \in \mathcal{X}_i \ \forall \text{ sufficiently small } \mu > 0\},$$

where $\eta_3 \equiv A_i\eta_2$ for any $i \in \mathcal{I}_2$. In a similar fashion, we can show that $\mathcal{I}_3 \subseteq \mathcal{I}_2$ and $A_i\eta_3 = A_j\eta_3$ for all $i, j \in \mathcal{I}_3$. Continuing this process, we can eventually define $\mathcal{I}_{n-1}$, which is nonempty and is contained in $\mathcal{I}_{n-2} \subseteq \cdots \subseteq \mathcal{I}_1 \subseteq \mathcal{I}_0$. We claim that $i \in \mathcal{I}_{n-1}$ implies that $\xi \in \mathcal{Y}_i$. To see this, note that

$$\eta_0 + \mu\eta_1 + \cdots + \mu^{n-1}\eta_{n-1} \;=\; \xi + \mu A_i\xi + \cdots + \mu^{n-1}A_i^{n-1}\xi$$

for any $i \in \mathcal{I}_{n-1}$ because of the nested inclusions of the index sets $\mathcal{I}_j$ for $j = 0, 1, \ldots, n-1$. Hence, $i \in \mathcal{I}_{n-1}$ implies that $\sum_{k=0}^{n-1} \mu^k A_i^k \xi \in \mathcal{X}_i$ for all $\mu > 0$ sufficiently small; thus condition (c) of Lemma 2.4 is satisfied with c being the vector of all ones. Consequently, $\xi \in \mathcal{Y}_i$. □

The non-Zeno property is closely related to the boundedness of the number of "mode transitions" defined as follows.

DEFINITION 3.6. *Let $x(t, x^0)$ be a solution trajectory of the CLS* (2.5) *over a time interval $[0, T]$, $T > 0$, and let $t_* \in (0, T)$. We say that t_* is* not *a switching time if there exist $i \in \{1, \ldots, m\}$ and $\varepsilon > 0$ such that $x(t, x^0) \in \mathcal{X}_i$ for all $t \in [t_* - \varepsilon, t_* + \varepsilon]$; otherwise, we say that t_* is a* switching time*, and that the CLS has a mode transition or* mode switching *at t_*.*

With this definition, we easily obtain the following result from the non-Zeno property of the CLS. The proof is by a compactness argument and resembles that of Proposition 8 in [33].

THEOREM 3.7. *Let $x(t, x^0)$ be a solution trajectory of the CLS* (2.5) *on an open time interval containing $[0, T]$. Then there is a finite number of switching times in $[0, T]$. Hence, any such trajectory $x(\bullet, x^0)$ is a continuous, piecewise analytic function on $[0, T]$.*

Proof. See the cited proposition for a proof of the assertion about switching times. To prove the piecewise analyticity assertion, it suffices to note that if $x(t, x^0) \in \mathcal{X}_j$ for some j and all t in a subinterval $[t_{i-1}, t_i]$, where t_{i-1} and t_i are any two consecutive switching times, then $x(t, x^0) = e^{A_j(t-t_{i-1})}x(t_{i-1}, x^0)$ for all t in this subinterval. Hence $x(t, x^0)$ is an analytic function for $t \in (t_{i-1}, t_i)$. Since there are finitely many such subintervals, the piecewise analyticity of $x(\bullet, x^0)$ follows. □

For the bimodal system (2.9), we can say more; see Proposition 5.3. For now, we specialize Theorem 3.7 to the CLS (2.18), obtaining the following corollary.

COROLLARY 3.8. *Let $\mathcal{C}$ be given by* (2.19)*. Assume that $B\mathrm{SOL}(\mathcal{C}, Cx, D)$ is a singleton for all $x \in \mathbb{R}^n$. For every $x^0 \in \mathbb{R}^n$ and $T > 0$, there exist a pair of functions $(z, \lambda) : [0, T] \mapsto \mathcal{C} \times \mathbb{R}^r_+$ with $Bz(t)$ being continuous, a partition*

$$0 \;=\; t_0 \;<\; t_1 \;<\; \cdots \;<\; t_{N-1} \;<\; t_N \;=\; T \tag{3.2}$$

of the interval $[0, T]$, and index subsets $\alpha_j \subseteq \{1, \ldots, r\}$ each with complement $\bar{\alpha}_j$ for $j = 1, \ldots, N$, such that on each subinterval $[t_j, t_{j+1}]$, the triple $(x(t, x^0), z(t), \lambda(t))$ satisfies the linear differential algebraic equation

$$\begin{aligned} \dot{x}(t, x^0) &= Ax(t, x^0) + Bz(t), \\ 0 \quad &= Cx(t, x^0) + Dz(t) - G^T\lambda(t), \\ 0 \quad &= G_{\alpha_j \bullet} z(t) \quad \text{and} \quad \lambda_{\bar{\alpha}_j}(t) \;=\; 0. \end{aligned}$$

It is interesting to compare the above corollary with the non-Zenoness results in [33], which address only the LCS:

$$\dot{x} \;=\; Ax + Bz \quad \text{and} \quad 0 \;\leqslant\; z \;\perp\; Cx + Dz \;\geqslant\; 0.$$

There are some obvious similarities and subtle differences that are worth noting. The most obvious similarity is that all the results assert the finite number of switch times of some kind. The major difference lies in the treatment of the algebraic variable z. In Corollary 3.8, which is based on a hybrid system approach, z is treated implicitly; whereas in the treatment of [33], which originates from the P-matrix case and focuses on the fundamental triple of index sets

$$\begin{aligned} \alpha(t) &\equiv \{\, j \,|\, z_j(t) \,>\, 0 \,=\, (\, Cx(t,x^0) + Dz(t)\,)_j \,\}, \\ \beta(t) &\equiv \{\, j \,|\, z_j(t) \,=\, 0 \,=\, (\, Cx(t,x^0) + Dz(t)\,)_j \,\}, \\ \gamma(t) &\equiv \{\, j \,|\, z_j(t) \,=\, 0 \,<\, (\, Cx(t,x^0) + Dz(t)\,)_j \,\}, \end{aligned} \tag{3.3}$$

the switch times are defined with regard to a given trajectory $z(t)$. As a result of this difference in the points of view, the former corollary asserts the *existence* of a trajectory $z(t)$ satisfying the specified switching property; in contrast, the results in [33] start with a fixed but arbitrary trajectory $z(t)$ and establish the finite number of switch times for the pair $(x(t,x^0), z(t))$. The latter treatment has a price associated with it, namely, a restriction placed on the triple (B, C, D); such a restriction is not needed here. In the special case where D is a P-matrix (thus the trajectory $z(t)$ is unique), Theorem 9 in [33] is stronger than Corollary 3.8 here (for the LCS) in that the former asserts the constancy of the triple of index sets $(\alpha(t), \beta(t), \gamma(t))$ on the subintervals, whereas the latter pays no attention to the degenerate index set $\beta(t)$. As it is well known from finite-dimensional complementarity theory [14], the elements of $\beta(t)$ are most critical when one is interested in the sensitivity analysis of the system subject to parameter perturbations. The detailed exploration of this issue in a dynamic setting is beyond the scope of the present paper.

Not surprisingly, we can also establish the constancy of index sets for the CLS (2.5) similar to that for the P-matrix case of the LCS. We first establish the following proposition that pertains to an individual state.

PROPOSITION 3.9. *Let $x(t,x^0)$ be a solution trajectory of the CLS* (2.5) *over a time interval $[0,T]$. The following two statements hold.*

(a) *For every $t_* \in [0,T)$, there exists $\varepsilon_+ > 0$ such that $\mathcal{J}(x(t,x^0)) = \mathcal{J}(x(t_*,x^0))$ for all $t \in [t_*, t_* + \varepsilon_+]$.*

(b) *For every $t_* \in (0,T]$, there exists $\varepsilon_- > 0$ such that $\mathcal{J}(x(t,x^0)) = \mathcal{J}^{\,\mathrm{r}}(x(t_*,x^0))$ for all $t \in [t_* - \varepsilon_-, t_*)$.*

Proof. We prove only statement (a); the proof of (b) is similar. Write $\xi \equiv x(t_*,x^0)$. For each $i \in \mathcal{J}(\xi)$, Lemma 2.4 implies that there exist $\varepsilon_i > 0$ and $\mathcal{X}_i \in \Xi$ such that $x(t,x^0) \in \mathcal{X}_i$ for all $t \in [t_*, t_* + \varepsilon_i]$. Hence $x(t,x^0) \in \mathcal{Y}_i$ or, equivalently, $i \in \mathcal{J}(x(t,x^0))$ for all $t \in [t_*, t_* + \varepsilon_i/2]$. By letting $\varepsilon_+ \equiv \min_{1 \leqslant i \leqslant |\mathcal{J}(\xi)|} \varepsilon_i/2$, where $|\mathcal{J}(\xi)|$ denotes the cardinality of the set $\mathcal{J}(\xi)$, it follows that $\mathcal{J}(\xi) \subseteq \mathcal{J}(x(t,x^0))$ for all $t \in [t_*, t_* + \varepsilon_+]$. Conversely, consider an index $j \notin \mathcal{J}(\xi)$. If $(C_j\xi, C_jA_i\xi, \ldots, C_jA_i^{n-1}\xi) \succcurlyeq 0$ for some $i \in \mathcal{J}(\xi)$, then $C_jx(t,x^0) = C_je^{A_i(t-t_*)}\xi \geqslant 0$ for all $t \geqslant t_*$ sufficiently near t_*. Hence $j \in \mathcal{J}(\xi)$, which is a contradiction. Thus, $(C_j\xi, C_jA_i\xi, \ldots, C_jA_i^{n-1}\xi) \not\succcurlyeq 0$ for all $i \in \mathcal{J}(\xi)$. Hence, an index ℓ_i exists such that $(C_j\xi, C_jA_i\xi, \ldots, C_jA_i^{n-1}\xi)_{\ell_i} \prec 0$. By the non-Zenoness property, $\xi \in \mathcal{Y}_{i_0}$ for some $i_0 \in \mathcal{J}(\xi)$, which implies that $x(t,x^0) = e^{A_{i_0}(t-t_*)}\xi$ for all $t > t_*$ sufficiently near t_*. Hence $C_jx(t,x^0) = C_je^{A_{i_0}(t-t_*)}\xi$ for all such t. Since the tuple $(C_j\xi, C_jA_{i_0}\xi, \ldots, C_jA_{i_0}^{n-1}\xi)_{\ell_{i_0}}$ is nonzero and its first nonzero component is negative, it follows that $(C_jx(t,x^0))_{\ell_{i_0}} < 0$ for all $t > t_*$ sufficiently near t_*. Hence $j \notin \mathcal{J}(x(t,x^0))$ for all such t. Consequently, we must have $\mathcal{J}(\xi) \supseteq \mathcal{J}(x(t,x^0))$, and thus $\mathcal{J}(\xi) = \mathcal{J}(x(t,x^0))$, for all $t \in [t_*, t_* + \varepsilon_+]$, provided that $\varepsilon_+ > 0$ is further restricted if necessary. ∎

Extending the above proposition to a compact interval and using the reverse-time trajectory (2.8), we have the following result.

COROLLARY 3.10. *Let $x(t, x^0)$ be a solution trajectory of the CLS* (2.5) *on an open time interval containing $[0, T]$. There exists a partition* (3.2) *of the interval $[0, T]$ such that for every $i = 0, 1, \ldots, N-1$, $\mathcal{J}(x(t, x^0))$ is a constant for all $t \in [t_i, t_{i+1})$.*

Proof. By Proposition 3.9, we deduce that for every $t \in [0, T]$, there exists $\varepsilon_t > 0$ such that $\mathcal{J}(x(t', x^0)) = \mathcal{J}(x(t, x^0))$ for every $t' \in [t, t + \varepsilon_t]$ and $\mathcal{J}(x(\widetilde{t}, x^0)) = \mathcal{J}^{\,\mathrm{r}}(x(t, x^0))$ for every $\widetilde{t} \in [t - \varepsilon_t, t)$. We can now employ the same covering argument as in [33, Proposition 8] to complete the proof of the corollary. ∎

Switching times can also be expressed in terms of forward-time and backward-time index sets shown as follows.

PROPOSITION 3.11. *Let $x(t, x^0)$ be a solution trajectory of the CLS* (2.5). *Then a time $t_* > 0$ is a switching time if and only if $\mathcal{J}(x(t_*, x^0)) \cap \mathcal{J}^{\,\mathrm{r}}(x(t_*, x^0)) = \varnothing$.*

Proof. "Sufficiency." Suppose $\mathcal{J}(x(t_*, x^0)) \cap \mathcal{J}^{\,\mathrm{r}}(x(t_*, x^0)) = \varnothing$ but t_* is not a switching time. Then by Definition 3.6, there exist $i \in \{1, \ldots, m\}$ and $\varepsilon > 0$ such that $x(t, x^0) \in \mathcal{X}_i$ for all $t \in [t_* - \varepsilon, t_* + \varepsilon]$. This implies that $x(t_*, x^0) \in \mathcal{Y}_i \cap \mathcal{Y}_i^{\mathrm{r}}$ by taking derivatives of the forward-time trajectory at t_* and of the reverse-time trajectory at t_*, respectively. Thus $i \in \mathcal{J}(x(t_*, x^0)) \cap \mathcal{J}^{\,\mathrm{r}}(x(t_*, x^0))$. This results in a contradiction.

"Necessity." Suppose t_* is a switching time but $\mathcal{J}(x(t_*, x^0)) \cap \mathcal{J}^{\,\mathrm{r}}(x(t_*, x^0)) \neq \varnothing$. Let $i \in \mathcal{J}(x(t_*, x^0)) \cap \mathcal{J}^{\,\mathrm{r}}(x(t_*, x^0))$. Then $x(t_*, x^0) \in \mathcal{Y}_i \cap \mathcal{Y}_i^{\mathrm{r}}$. By Lemma 2.4 and the reverse-time argument, we deduce the existence of $\varepsilon > 0$ such that $x(t, x^0) \in \mathcal{X}_i$ for all $t \in [t_* - \varepsilon, t_* + \varepsilon]$. This contradicts the assumption that t_* is a switching time. ∎

One interesting observation about the CLS (2.5) is that a state trajectory may have boundary crossing, i.e., crossing a boundary of one cone and entering another cone, at a *nonswitching time* in the sense of Definition 3.6. We illustrate this observation by the following example.

Example 3.12. Consider a 3-dimensional CLS with the polyhedral subdivision:

$$\mathcal{X}_1 = \mathbb{R}_- \times \mathbb{R}^2, \quad \mathcal{X}_2 = \mathbb{R}_+ \times \mathbb{R} \times \mathbb{R}_+, \quad \mathcal{X}_3 = \mathbb{R}_+ \times \mathbb{R} \times \mathbb{R}_-,$$

where $\mathbb{R}_\pm$ denote the nonnegative and nonpositive rays on the real line, respectively, and

$$A_1 = A_2 = A_3 = A = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 1 & 0 \end{bmatrix}.$$

It is easy to show that for any $x^0 \in \mathbb{R}^3$, $x(t, x^0) = e^{At} x^0 = \left(x_1^0\, e^t, x_2^0, x_3^0 + x_2^0 t \right)$ for all t. Now consider $x^0 = \left(0, 1, -1\right)$. Thus $x(t, x^0) = \left(0, 1, t - 1\right)$. Hence, $x(t, x^0) \in \mathcal{X}_1$ for all t and $x(t, x^0) \in \mathcal{X}_2$ for all $t \geqslant 1$, but $x(t, x^0) \notin \mathcal{X}_2$ for all $t < 1$. Consequently, $t_* = 1$ is *not* a switching time, but $x(t, x^0)$ crosses the boundary of $\mathcal{X}_2$ and $\mathcal{X}_3$ at $t_* = 1$.

We further illustrate this property via the index sets. Recall from Proposition 3.9 that for any given t_*, the index set $\mathcal{J}(x(t, x^0))$ remains constant for all t sufficiently close to t_*, both in the forward-time direction and in the backward-time direction. Note that the two constant index sets $\mathcal{J}(x(t_*, x^0))$ and $\mathcal{J}^{\,\mathrm{r}}(x(t_*, x^0))$ may not be equal in general. In fact, expressing in terms of these index sets for this example, we have $\mathcal{J}^{\,\mathrm{r}}(x(1, x^0)) = \{1, 3\}$ and $\mathcal{J}(x(1, x^0)) = \{1, 2\}$. Notice that $\mathcal{J}^{\,\mathrm{r}}(x(1, x^0)) \cap \mathcal{J}(x(1, x^0)) = \{\,1\,\}$, but $\mathcal{J}^{\,\mathrm{r}}(x(1, x^0)) \neq \mathcal{J}(x(1, x^0))$.

The following proposition, however, shows that the LCS with the P-property, which is a special class of CLSs discussed previously, does not have the problem shown above and therefore exhibits relatively "simpler" switching behavior than general CLSs.

PROPOSITION 3.13. *Consider the LCS* (2.17) *with the P-property. If, for any* $t_* > 0$, $\mathcal{J}(x(t_*, x^0)) \cap \mathcal{J}^{\,\mathrm{r}}(x(t_*, x^0))$ *is nonempty, then* $\mathcal{J}(x(t_*, x^0)) = \mathcal{J}^{\,\mathrm{r}}(x(t_*, x^0))$. *In other words, if* t_* *is not a switching time, then* $\mathcal{J}(x(t_*, x^0)) = \mathcal{J}^{\,\mathrm{r}}(x(t_*, x^0))$.

Proof. It is shown in [33] that the LCS satisfying the P-property possesses the strong non-Zenoness at each state; i.e., for any t_*, there exist $\varepsilon_t > 0$ and two triples of index sets, $(\alpha_+, \beta_+, \gamma_+)$ and $(\alpha_-, \beta_-, \gamma_-)$, such that

$$\big(\,\alpha(t),\,\beta(t),\gamma(t)\,\big) = (\alpha_-, \beta_-, \gamma_-) \quad \forall\, t \in [t_* - \varepsilon_t, t_*),$$

$$\big(\,\alpha(t),\,\beta(t),\gamma(t)\,\big) = (\alpha_+, \beta_+, \gamma_+) \quad \forall\, t \in (t_*, t_* + \varepsilon_t],$$

where the index triple (α, β, γ) is defined in (3.3) for the associated LCP. For notational convenience, we denote each complementary cone in (2.17) by $\mathcal{X}_\delta = \{x \in \mathbb{R}^n \mid C_\delta\, x \geqslant 0\}$, where

$$C_\delta \equiv \begin{bmatrix} -D_{\delta\delta}^{-1} & 0 \\ -D_{\bar\delta\delta}(D_{\delta\delta})^{-1} & I_{\bar\delta\bar\delta} \end{bmatrix} \begin{bmatrix} C_{\delta\bullet} \\ C_{\bar\delta\bullet} \end{bmatrix}$$

and δ is a subset of $\{1, \ldots, m\}$. By the uniqueness of the solution of the LCS, it is clear that for all $t \in [t_* - \varepsilon_t, t_*)$, $x(t, x^0)$ is only in the cones $\mathcal{X}_\delta$'s with $\delta = \alpha_- \cup \beta_-^1$ and $\bar\delta = \gamma_- \cup \big(\beta_- \setminus \beta_-^1\big)$, where β_-^1 is a subset of β_-. Hence,

$$\mathcal{J}^{\,\mathrm{r}}(x(t_*, x^0)) \;=\; \{\, \delta \;=\; \alpha_- \cup \beta_-^1 \;\mid\; \beta_-^1 \;\subseteq\; \beta_- \,\}. \tag{3.4}$$

Similarly, we have

$$\mathcal{J}(x(t_*, x^0)) \;=\; \{\, \delta \;=\; \alpha_+ \cup \beta_+^1 \;\mid\; \beta_+^1 \;\subseteq\; \beta_+ \,\}. \tag{3.5}$$

Let $\delta_i \in \mathcal{J}(x(t_*, x^0)) \cap \mathcal{J}^{\,\mathrm{r}}(x(t_*, x^0))$ with $\mathcal{X}_{\delta_i} = \{x \in \mathbb{R}^n \mid C_{\delta_i}\, x \geqslant 0\}$ and $\dot x = A_{\delta_i} x$ being the corresponding cone and dynamics, respectively. By the time-continuity of the state trajectory, it is easy to verify that there exists an $\varepsilon' > 0$ such that $x(t, x^0) \in \mathcal{X}_{\delta_i}$ for all $t \in [\,t_* - \varepsilon',\, t_* + \varepsilon'\,]$. Letting $\xi^* = x(t_*, x^0)$, we have

$$\big(\,(C_{\delta_i}\xi^*)_{\alpha_-},\, (C_{\delta_i}(-A_{\delta_i})\xi^*)_{\alpha_-}, \ldots, (C_{\delta_i}(-A_{\delta_i})^{n-1}\xi^*)_{\alpha_-}\,\big) \succ 0,$$

$$\big(\,(C_{\delta_i}\xi^*)_{\beta_-},\, (C_{\delta_i}(-A_{\delta_i})\xi^*)_{\beta_-}, \ldots, (C_{\delta_i}(-A_{\delta_i})^{n-1}\xi^*)_{\beta_-}\,\big) = 0,$$

$$\big(\,(C_{\delta_i}\xi^*)_{\gamma_-},\, (C_{\delta_i}(-A_{\delta_i})\xi^*)_{\gamma_-}, \ldots, (C_{\delta_i}(-A_{\delta_i})^{n-1}\xi^*)_{\gamma_-}\,\big) \succ 0,$$

which further implies that

$$\big(\,(C_{\delta_i}\xi^*)_{\alpha_-},\, (C_{\delta_i}(A_{\delta_i})\xi^*)_{\alpha_-}, \ldots, (C_{\delta_i}(A_{\delta_i})^{n-1}\xi^*)_{\alpha_-}\,\big) \neq 0,$$
$$\big(\,(C_{\delta_i}\xi^*)_{\beta_-},\, (C_{\delta_i}(A_{\delta_i})\xi^*)_{\beta_-}, \ldots, (C_{\delta_i}(A_{\delta_i})^{n-1}\xi^*)_{\beta_-}\,\big) = 0,$$
$$\big(\,(C_{\delta_i}\xi^*)_{\gamma_-},\, (C_{\delta_i}(A_{\delta_i})\xi^*)_{\gamma_-}, \ldots, (C_{\delta_i}(A_{\delta_i})^{n-1}\xi^*)_{\gamma_-}\,\big) \neq 0.$$

The second equality shows that $\beta_+ \supseteq \beta_-$, and the first and third inequalities show that $\beta_+ \subseteq \beta_-$. Hence $\beta_+ = \beta_-$. Moreover, we deduce from $\delta_i \in \mathcal{J}(x(t_*, x^0))$ that

$$\big(\,(C_{\delta_i}\xi^*)_{\alpha_-},\, (C_{\delta_i}(A_{\delta_i})\xi^*)_{\alpha_-}, \ldots, (C_{\delta_i}(A_{\delta_i})^{n-1}\xi^*)_{\alpha_-}\,\big) \succ 0,$$

$$\big(\,(C_{\delta_i}\xi^*)_{\gamma_-},\, (C_{\delta_i}(A_{\delta_i})\xi^*)_{\gamma_-}, \ldots, (C_{\delta_i}(A_{\delta_i})^{n-1}\xi^*)_{\gamma_-}\,\big) \succ 0.$$

Thus, by the uniqueness of the solution pair $\big(x(t), z(t)\big)$ at each t, we deduce that there is an $\varepsilon_+ > 0$ such that $z_{\alpha_-}(t) > 0$ and $(Cx(t) + Dz(t))_{\gamma_-} > 0$ for all $t \in (t_*, t_* + \varepsilon_+]$. This suggests $\alpha_- \subseteq \alpha_+$ and $\gamma_- \subseteq \gamma_+$. Since $z_{\beta_-}(t) = z_{\beta_+}(t) = \big(Cx(t)+Dz(t)\big)_{\beta_-} = \big(Cx(t)+Dz(t)\big)_{\beta_+} = 0$ for all $t \in [t_*, t_*+\varepsilon_+]$, we must have $\alpha_+ \equiv \alpha_-$ and $\gamma_+ \equiv \gamma_-$. By (3.4) and (3.5), we conclude that $\mathcal{J}(x(t_*, x^0)) = \mathcal{J}^{\,\mathrm{r}}(x(t_*, x^0))$. The second statement thus easily follows from Proposition 3.11. □

4. Observability of CLSs. In this section, we treat another fundamental property of the CLS, namely, observability with respect to a linear output. In the recent paper [24], we have treated this property rather extensively for the LCS (2.15); the treatment herein extends the previous analysis in several major ways. One, we deal with a general conewise linear system; two, Theorem 4.5 when specialized to the LCS closes a gap that was unresolved in [24]; three, we also treat other observability notions in detail. To be fair to [24], the approach used there is based on a general result for a nonlinear ODE with a nondifferentiable right-hand side and is applicable to nonlinear systems such as the nonlinear complementarity system; in contrast, the approach used below takes full advantage of the (piecewise) linear structure of the CLS. Most importantly, the notion of lexicographic ordering that has played a fundamental role in [24] remains the key to the present extended treatment.

Throughout the rest of this paper, let $H \in \mathbb{R}^{r\times n}$ be a given matrix that induces the linear output $Hx(t,\xi)$ associated with the solution trajectory $x(t,\xi)$ of (2.5). With respect to this matrix H, we formally introduce the observability concepts (see Definitions 4.2 and 4.3) to be analyzed subsequently, all of which are based on the following indistinguishability definition, which is classical in systems theory.

DEFINITION 4.1. *We say that a pair of states* $(\xi, \eta) \in \mathbb{R}^{n+n}$ *is*

- short-time indistinguishable *if* $\varepsilon > 0$ *exists such that* $Hx(t,\xi) = Hx(t,\eta)$ *for all* $t \in [0, \varepsilon]$*;*
- T-time indistinguishable *for a given* $T > 0$ *if* $Hx(t,\xi) = Hx(t,\eta)$ *for all* $t \in [0, T]$*;*
- long-time indistinguishable *if* $Hx(t,\xi) = Hx(t,\eta)$ *for all* $t \geqslant 0$.

Clearly, long-time indistinguishability $\Rightarrow$ T-time indistinguishability $\Rightarrow$ short-time indistinguishability for any pair of states.

DEFINITION 4.2. *We say that a state* $\xi \in \mathbb{R}^n$ *is*

- short-time locally observable *if there exists a neighborhood* $\mathcal{N}$ *of* ξ *such that no pair* (ξ, η) *with* $\eta \in \mathcal{N} \setminus \{\xi\}$ *is short-time indistinguishable;*
- short-time globally observable *if there exists no state* $\eta \neq \xi$ *such that the pair* (ξ, η) *is short-time indistinguishable;*
- T-time locally observable *for a given* $T > 0$ *if there exists a neighborhood* $\mathcal{N}$ *of* ξ *such that no pair* (ξ, η) *with* $\eta \in \mathcal{N} \setminus \{\xi\}$ *is* T*-time indistinguishable;*
- T-time globally observable *for a given* $T > 0$ *if there exists no state* $\eta \neq \xi$ *such that the pair* (ξ, η) *is* T*-time indistinguishable;*
- long-time locally observable *if there exists a neighborhood* $\mathcal{N}$ *of* ξ *such that no pair* (ξ, η) *with* $\eta \in \mathcal{N} \setminus \{\xi\}$ *is long-time indistinguishable;*
- long-time globally observable *if there exists no state* $\eta \neq \xi$ *such that the pair* (ξ, η) *is long-time indistinguishable.*

Clearly, the following implications hold for any state $\xi \in \mathbb{R}^n$:

$$\begin{array}{ccc}
\text{short-time global observability} & \Rightarrow & \text{short-time local observability} \\
\Downarrow & & \Downarrow \\
T\text{-time global observability} & \Rightarrow & T\text{-time local observability} \\
\Downarrow & & \Downarrow \\
\text{long-time global observability} & \Rightarrow & \text{long-time local observability.}
\end{array}$$

The above definitions pertain to individual states. At the system level, we have the following concepts. For simplicity, we define only the short-time version of the concepts.

DEFINITION 4.3. *The CLS* (2.5) *is said to be*

- short-time locally observable *if all states are short-time locally observable.*
- short-time globally observable *if all states are short-time globally observable.*

Recall that for a given pair of matrices $M \in \mathbb{R}^{n\times n}$ and $N \in \mathbb{R}^{m\times n}$, the unobservable space of (N, M), denoted $\overline{O}(N, M)$, is the set of vectors $\xi \in \mathbb{R}^n$ such that $NM^j\xi = 0$ for all $j = 0, 1, 2, \ldots$. By the well-known Cayley–Hamilton theorem in linear algebra, it follows that $\xi \in \overline{O}(N, M)$ if and only if $NM^j\xi = 0$ for all $j = 0, 1, 2, \ldots, n-1$. Elements of the space $\overline{O}(N, M)$ are said to be *unobservable* with respect to the pair (N, M). If $\overline{O}(N, M)$ consists only of the zero vector, then (N, M) is called an *observable pair*. We remark that a vector $\xi \in \overline{O}(H, A)$ if and only if for every $t_* \geqslant 0$, a scalar $\varepsilon_* > 0$ exists such that $He^{A(t-t_*)}x(t_*, \xi) = 0$ for all $t \in [t_*, t_* + \varepsilon_*]$. More generally, for any two vectors u and v, any scalar $\varepsilon > 0$, and two square matrices A and B,

$$\left\{He^{A(t-t_*)}u = He^{B(t-t_*)}v \ \forall t \in [t_*, t_* + \varepsilon]\right\} \Leftrightarrow \left[HA^k u = HB^k v \ \forall k = 0, \ldots, n-1\right].$$

This follows easily by differentiating the expression involving the exponential functions and then substituting $t = t_*$. This equivalence allows one to check the left-hand condition, which involves a continuum of times t, by a finite set of linear equations.

4.1. Short-time observability. We begin our investigation of various observability properties with the discussion of state short-time observability.

THEOREM 4.4. *A state ξ is short-time globally observable for the CLS* (2.5) *if and only if there exists no triple (η, i, j) satisfying $\eta \neq \xi$, $i \in \mathcal{J}(\eta)$, $j \in \mathcal{J}(\xi)$, and*

$$\begin{pmatrix} \eta \\ \xi \end{pmatrix} \in \overline{O}\left(\begin{bmatrix} H & -H \end{bmatrix}, \begin{bmatrix} A_i & 0 \\ 0 & A_j \end{bmatrix} \right). \tag{4.1}$$

Proof. Suppose one such triple (η, i, j) exists. From Lemma 2.4, we know that there exists a positive number ε such that $x(t, \eta)$ and $x(t, \xi)$ lie in the cones $\mathcal{X}_i$ and $\mathcal{X}_j$ for all $t \in [0, \varepsilon]$, respectively. Therefore, $x(t, \eta) = \exp(A_i t)\eta$ and $x(t, \xi) = \exp(A_j t)\xi$ on the same interval. This, together with (4.1), implies that $Hx(t, \xi) = Hx(t, \eta)$ for all $t \in [0, \varepsilon]$. Hence, the pair (ξ, η) is short-time indistinguishable. Consequently, ξ is not short-time globally observable. Conversely, suppose that ξ is short-time globally unobservable. There must exist a state $\eta \neq \xi$ such that the pair (ξ, η) is short-time indistinguishable, i.e., $Hx(t, \xi) = Hx(t, \eta)$ on an interval $[0, \varepsilon']$ for some $\varepsilon' > 0$. Let $\eta \in \mathcal{Y}_i$ and $\xi \in \mathcal{Y}_j$ for some $i, j \in \{1, \ldots, m\}$. By Lemma 2.4, there exists a positive number ε such that $H \exp(A_i t)\eta = H \exp(A_j t)\xi$ on the interval $[0, \varepsilon]$. Taking derivatives and evaluating at $t = 0$ show that the membership (4.1) holds. This leads to a contradiction. ∎

Toward the characterization of short-time local observability, we define, for each $i = 1, \ldots, m$ and each subset $\mathcal{L}$ of $\{1, \ldots, m_i\}$,

$$\mathcal{Y}_{i,\mathcal{L}} \equiv \left\{ x \,\middle|\, \left((C_i x)_\ell, (C_i A_i x)_\ell, \ldots, (C_i A_i^{n-1} x)_\ell\right) \succcurlyeq 0, \ \forall \ell \in \mathcal{L} \right\} \supseteq \mathcal{Y}_i.$$

The equality $\mathcal{Y}_{i,\mathcal{L}} = \mathcal{Y}_i$ holds when $\mathcal{L} = \{1, \ldots, m_i\}$; by convention, we let $\mathcal{Y}_{i,\varnothing} = \mathbb{R}^n$. To obtain a local version of Theorem 4.4, we need to define several index sets

associated with a given state $\xi \in \mathbb{R}^n$. The first one is

$$\mathcal{K}(\xi) \equiv \left\{ i \in \mathcal{I}(\xi) \,\middle|\, \begin{pmatrix} \xi \\ \xi \end{pmatrix} \in \overline{O}\left(\begin{bmatrix} H & -H \end{bmatrix}, \begin{bmatrix} A_i & 0 \\ 0 & A_j \end{bmatrix} \right) \text{ for some } j \in \mathcal{J}(\xi) \right\}$$
$$= \left\{ i \in \mathcal{I}(\xi) \,\middle|\, \exists\, j \in \mathcal{J}(\xi) \text{ such that } HA_i^k\xi = HA_j^k\xi \;\forall k \geqslant 0 \right\}.$$

By part (d) of Lemma 2.5 and the above definition, the following inclusions are clear:

$$\mathcal{J}(\xi) \subseteq \mathcal{K}(\xi) \subseteq \mathcal{I}(\xi) \quad \forall \xi \in \mathbb{R}^n.$$

As it turns out (see Theorem 4.5), the pieces $\mathcal{X}_i$ for $i \notin \mathcal{K}(\xi)$ play no role in the short-time local observability of ξ. Indeed, the set $\mathcal{K}(\xi)$ is the key to a complete characterization of the short-time local observability of ξ; this set was not discovered in [24] for the LCS.

For each $i \in \mathcal{I}(\xi)$, define the index set $\mathcal{I}_{i0}(\xi) \equiv \{\ell \mid (C_i\xi)_\ell = 0\} \subseteq \{1, \ldots, m_i\}$. Note that if $\mathcal{I}_{i0}(\xi) = \varnothing$ (a case which we call *nondegenerate*), we must have $\xi \in \operatorname{int} \mathcal{X}_i$ by (2.7), which implies $\mathcal{I}(\xi) = \mathcal{J}(\xi) = \mathcal{K}(\xi) = \{i\}$. If $\mathcal{J}(\xi)$ is a proper subset of $\mathcal{K}(\xi)$, we define, for each $i \in \mathcal{K}(\xi) \setminus \mathcal{J}(\xi)$,

$$\vartheta_i(\xi) \equiv \{\, \ell \;\big|\; \big((C_i\xi)_\ell,\ (C_iA_i\xi)_\ell, \ldots, (C_iA_i^{n-1}\xi)_\ell\big) \prec 0 \,\},$$

which must be nonempty. Since $\mathcal{K}(\xi) \subseteq \mathcal{I}(\xi)$, we have $C_i\xi \geqslant 0$ for all $i \in \mathcal{K}(\xi) \setminus \mathcal{J}(\xi)$, which implies $(C_i\xi)_{\vartheta_i(\xi)} = 0$; thus $\vartheta_i(\xi) \subseteq \mathcal{I}_{i0}(\xi)$. For each $\ell \in \vartheta_i(\xi)$, we let μ_ℓ^i be the first nonnegative integer k such that $(C_iA_i^k\xi)_\ell < 0$. We must have $1 \leq \mu_\ell^i \leq n-1$ for all $\ell \in \vartheta_i(\xi)$. Let $\overline{\vartheta}_i(\xi)$ be the complement of $\vartheta_i(\xi)$ in $\{1, \ldots, m_i\}$. Clearly,

$$\xi \in \mathcal{Y}_{i,\overline{\vartheta}_i(\xi)} = \left\{ x \,\middle|\, \big((C_ix)_\ell,\ (C_iA_ix)_\ell, \ldots, (C_iA_i^{n-1}x)_\ell\big) \succcurlyeq 0 \quad \forall\, \ell \in \overline{\vartheta}_i(\xi) \right\}.$$

Finally, we define

$$\widetilde{\mathcal{Y}}_{i,\vartheta_i(\xi)} \equiv \left\{ x \,\middle|\, \big((C_ix)_\ell,\ (C_iA_ix)_\ell, \ldots, (C_iA_i^{\mu_\ell^i - 1}x)_\ell\big) \succ 0 \quad \forall\, \ell \in \vartheta_i(\xi) \right\}$$

for each $i \in \mathcal{K}(\xi) \setminus \mathcal{J}(\xi)$. Note that $0 \notin \widetilde{\mathcal{Y}}_{i,\vartheta_i(\xi)}$. Moreover, it is easy to see that the following implication holds:

$$\eta \in \widetilde{\mathcal{Y}}_{i,\vartheta_i(\xi)} \;\Leftrightarrow\; \xi + \tau\eta \in \mathcal{Y}_{i,\vartheta_i(\xi)} \quad \forall\, \tau > 0 \text{ sufficiently small.} \tag{4.2}$$

With the above preparation, we are ready to establish a necessary and sufficient condition for a given state of the CLS (2.5) to be short-time locally observable.

THEOREM 4.5. *A state ξ is short-time locally observable for the CLS* (2.5) *if and only if*

$$\begin{aligned} \overline{O}(H, A_i) \cap (\, \mathcal{Y}_{i,\mathcal{I}_{i0}(\xi)} - \xi \,) &= \{\, 0 \,\} \quad \forall\, i \in \mathcal{J}(\xi), \\ \overline{O}(H, A_i) \cap \widetilde{\mathcal{Y}}_{i,\vartheta_i(\xi)} \cap (\, \mathcal{Y}_{i,\overline{\vartheta}_i(\xi)} - \xi \,) &= \varnothing \quad \forall\, i \in \mathcal{K}(\xi) \setminus \mathcal{J}(\xi). \end{aligned} \tag{4.3}$$

Proof. "Sufficiency." Suppose that the state ξ is not short-time locally observable. Since $\cup_{i=1}^m \mathcal{Y}_i = \mathbb{R}^n$, by Lemma 2.5(a), there exist an index $i \in \mathcal{I}(\xi)$ and a sequence $\{\xi^\nu\}$ converging to ξ such that $\xi \neq \xi^\nu \in \mathcal{Y}_i$ and the pair (ξ, ξ^ν) is short-time indistinguishable for all ν. We claim that, for all ν sufficiently large, the nonzero vector $\eta^\nu \equiv \xi^\nu - \xi$ violates one of the two conditions in (4.3). Let $j \in \mathcal{J}(\xi)$ such that $\xi \in \mathcal{Y}_j$. By the proof of Theorem 4.4, we deduce that, for all ν,

$$\begin{pmatrix} \xi^\nu \\ \xi \end{pmatrix} \in \overline{O}\left(\begin{bmatrix} H & -H \end{bmatrix}, \begin{bmatrix} A_i & 0 \\ 0 & A_j \end{bmatrix} \right).$$

By taking the limit $\nu \to \infty$, we get

$$\begin{pmatrix} \xi \\ \xi \end{pmatrix} \in \overline{O}\left(\begin{bmatrix} H & -H \end{bmatrix}, \begin{bmatrix} A_i & 0 \\ 0 & A_j \end{bmatrix} \right).$$

Thus, i must belong to $\mathcal{K}(\xi)$. This implies that, for all nonnegative integers k, $HA_i^k\xi^\nu = HA_j^k\xi = HA_i^k\xi$; thus η^ν belongs to $\overline{O}(H, A_i)$. Since $\xi \neq \xi^\nu \in \mathcal{Y}_i \subseteq \mathcal{Y}_{i,\mathcal{I}_{i0}(\xi)}$, we see that the first condition in (4.3) is violated if $i \in \mathcal{J}(\xi)$. Now suppose i belongs to $\mathcal{K}(\xi)\setminus\mathcal{J}(\xi)$. To see that this contradicts the second condition in (4.3), it remains to verify that $\eta^\nu \in \widetilde{\mathcal{Y}}_{i,\vartheta_i(\xi)}$ and $\xi^\nu \in \mathcal{Y}_{i,\overline{\vartheta}_i(\xi)}$. The latter membership is obvious because $\xi^\nu \in \mathcal{Y}_i$ for all ν. To prove the former membership, suppose that an index $\bar{\ell} \in \vartheta_i(\xi)$ exists satisfying $((C_i\eta^\nu)_{\bar{\ell}}, (C_iA_i\eta^\nu)_{\bar{\ell}}, \ldots, (C_iA_i^{\mu^i_{\bar{\ell}}-1}\eta^\nu)_{\bar{\ell}}) \preceq 0$, where $\mu^i_{\bar{\ell}}$ is the first nonnegative integer k such that $(C_iA_i^k\xi)_{\bar{\ell}} < 0$ defined before. Since $((C_i\xi)_{\bar{\ell}}, (C_iA_i\xi)_{\bar{\ell}}, \ldots, (C_iA_i^{\mu^i_{\bar{\ell}}-1}\xi)_{\bar{\ell}}) = 0$, we deduce that $((C_i\xi^\nu)_{\bar{\ell}}, (C_iA_i\xi^\nu)_{\bar{\ell}}, \ldots, (C_iA_i^{\mu^i_{\bar{\ell}}-1}\xi^\nu)_{\bar{\ell}}) \preceq 0$. Hence $(C_iA_i^k\xi^\nu)_{\bar{\ell}} = 0$ for all $k = 0, 1, \ldots, \mu^i_{\bar{\ell}} - 1$. But since $(C_iA_i^{\mu^i_{\bar{\ell}}}\xi)_{\bar{\ell}} < 0$, which implies $(C_iA_i^{\mu^i_{\bar{\ell}}}\xi^\nu)_{\bar{\ell}} < 0$ for all ν sufficiently large, it follows that $((C_i\xi^\nu)_{\bar{\ell}}, (C_iA_i\xi^\nu)_{\bar{\ell}}, \ldots, (C_iA_i^{\mu^i_{\bar{\ell}}}\xi^\nu)_{\bar{\ell}}) \prec 0$, which contradicts $\xi^\nu \in \mathcal{Y}_i$.

"Necessity." We show in what follows that the violation of either one of the two conditions in (4.3) leads to a contradiction to short-time local observability of ξ. Suppose that there exist an index $i \in \mathcal{J}(\xi)$ and a nonzero vector $\eta \in \overline{O}(H, A_i) \cap (\mathcal{Y}_{i,\mathcal{I}_{i0}(\xi)} - \xi)$. We have $\eta + \xi \in \mathcal{Y}_{i,\mathcal{I}_{i0}(\xi)}$. Since $\xi \in \mathcal{Y}_i \subseteq \mathcal{Y}_{i,\mathcal{I}_{i0}(\xi)}$ and $\mathcal{Y}_{i,\mathcal{I}_{i0}(\xi)}$ is convex, it follows that $\xi + \tau\eta \in \mathcal{Y}_{i,\mathcal{I}_{i0}(\xi)}$ for all $\tau \in [0, 1]$. Thus, for each such τ, there exists $\varepsilon_\tau > 0$ such that $(C_ie^{A_it}[\xi + \tau\eta])_{\mathcal{I}_{i0}(\xi)} \geq 0$ for all $t \in [0, \varepsilon_\tau]$. Since $(C_i\xi)_j > 0$ for all $j \in \{1, \ldots, m_i\}\setminus\mathcal{I}_{i0}(\xi)$, it follows that $(C_ie^{A_it}[\xi + \tau\eta])_j \geq 0$ for all such j and all $(t, \tau) > 0$ sufficiently small. Consequently, for every $\tau > 0$ sufficiently small, there exists $\varepsilon_\tau > 0$ such that $x(t, \xi+\tau\eta) = e^{A_it}[\xi+\tau\eta]$ for all $t \in [0, \varepsilon_\tau]$. Since $\eta \in \overline{O}(H, A_i)$, we deduce $Hx(t, \xi + \tau\eta) = Hx(t, \xi)$ for all such pairs (τ, t). Hence the pair $(\xi + \tau\eta, \xi)$ is short-time indistinguishable, contradicting the short-time local observability of ξ.

Next, suppose that a nonzero vector $\eta \in \overline{O}(H, A_i) \cap \widetilde{\mathcal{Y}}_{i,\vartheta_i(\xi)} \cap (\mathcal{Y}_{i,\overline{\vartheta}_i(\xi)} - \xi)$ exists for some $i \in \mathcal{K}(\xi) \setminus \mathcal{J}(\xi)$. By (4.2), we deduce that $\xi + \tau\eta \in \mathcal{Y}_{i,\vartheta_i(\xi)}$ for all $\tau > 0$ sufficiently small. Moreover, since $\xi + \eta \in \mathcal{Y}_{i,\overline{\vartheta}_i(\xi)}$ and $\xi \in \mathcal{Y}_{i,\overline{\vartheta}_i(\xi)}$, it follows that $\xi + \tau\eta \in \mathcal{Y}_{i,\overline{\vartheta}_i(\xi)}$ for all $\tau \in [0, 1]$. Consequently, $\xi + \tau\eta \in \mathcal{Y}_i$ for all $\tau > 0$ sufficiently small. We can now apply the same argument as before to deduce a contradiction to the short-time local observability of ξ. □

The next result is an immediate corollary of Theorem 4.5 that pertains to a nondegenerate state $\xi \in \operatorname{int}\mathcal{X}_i$ for some i. No proof is needed.

COROLLARY 4.6. *A nondegenerate state $\xi \in \operatorname{int}\mathcal{X}_i$ is short-time locally observable for the CLS* (2.5) *if and only if $\overline{O}(H, A_i) = \{0\}$.*

We apply Theorem 4.5 to the bimodal CLS (2.9) with the two pieces $\mathcal{X}_1 = \{x | c^Tx \geqslant 0\}$ and $\mathcal{X}_2 = \{x | c^Tx \leqslant 0\}$, and the two matrices $A_1 = A + bc^T$ and $A_2 = A$. Let $\xi \in \mathbb{R}^n$ be arbitrary. The cases where $c^T\xi > 0$ and $c^T\xi < 0$ are covered by Corollary 4.6. We focus on the case where $c^T\xi = 0$. In this case, we have $\mathcal{I}(\xi) = \{1, 2\}$, $\mathcal{I}_{10}(\xi) = \{1\}$, $\mathcal{I}_{20}(\xi) = \{2\}$,

$$\mathcal{Y}_{1,\mathcal{I}_{10}(\xi)} = \left\{ x \,|\, (\, c^Tx, c^T(A + bc^T)x, \ldots, c^T(A + bc^T)^{n-1}x \,) \succcurlyeq 0 \right\} = \mathcal{Y}_1$$

and

$$\mathcal{Y}_{2,\mathcal{I}_{20}(\xi)} = \{x | (c^Tx, c^TAx, \ldots, c^TA^{n-1}x) \preceq 0\} = \mathcal{Y}_2.$$

The tuple $Y(\xi) \equiv (c^T\xi, c^TA\xi, \ldots, c^TA^{n-1}\xi)$ plays a central role in the following corollary of Theorem 4.5.

COROLLARY 4.7. *The following statements hold for the bimodal CLS* (2.9).

(a) *If* $Y(\xi) \succ 0$, *then* ξ *is short-time locally observable if and only if* $\overline{O}(H, A + bc^T) = \{0\}$.

(b) *If* $Y(\xi) \prec 0$, *then* ξ *is short-time locally observable if and only if* $\overline{O}(H, A) = \{0\}$.

(c) *If* $Y(\xi) = 0$, *then* ξ *is short-time locally observable if and only if* $\overline{O}(H, A + bc^T) = \{0\}$ *and* $\overline{O}(H, A) = \{0\}$.

Proof. It suffices to consider the case where $c^T\xi = 0$. We prove (a) only as the proofs of (b) and (c) are similar. Suppose $Y(\xi) \succ 0$, which implies $\mathcal{J}(\xi) = \{1\}$ and $\xi \notin \overline{O}(c^T, A)$. It can be verified by the definition of $\mathcal{Y}_{1,\mathcal{I}_{10}(\xi)}$ that, for any $\eta \in \mathbb{R}^n$, either $\xi + \tau\eta \in \mathcal{Y}_{1,\mathcal{I}_{10}(\xi)}$ for all $\tau > 0$ sufficiently small or $\xi - \tau\eta \in \mathcal{Y}_{1,\mathcal{I}_{10}(\xi)}$ for all $\tau > 0$ sufficiently small. Hence, for any linear subspace S of $\mathbb{R}^n$, $S \cap (\mathcal{Y}_{1,\mathcal{I}_{10}(\xi)} - \xi) = \{0\}$ if and only if $S = \{0\}$. From this observation, it follows that the first condition in (4.3) is equivalent to

$$\overline{O}(H, A + bc^T) \cap (\mathcal{Y}_{1,\mathcal{I}_{10}(\xi)} - \xi) = \{0\} \Leftrightarrow \overline{O}(H, A + bc^T) = \{0\}. \tag{4.4}$$

There are two subcases to consider: (i) $b \notin \overline{O}(H, A)$ and (ii) $b \in \overline{O}(H, A)$. In subcase (i), it is easy to show, using $\xi \notin \overline{O}(c^T, A)$, that there must exist a positive integer k such that $H(A + bc^T)^k\xi \neq HA^k\xi$. This means that $\mathcal{K}(\xi) = \mathcal{J}(\xi) = \{1\}$. In subcase (ii), we have $H(A + bc^T)^k v = HA^k v$ for all nonnegative integers k and all $v \in \mathbb{R}^n$; thus $\overline{O}(H, A + bc^T) = \overline{O}(H, A)$, which further implies $\mathcal{K}(\xi) = \{1, 2\}$ and $\overline{\vartheta}_2(\xi) = \varnothing$. In both subcases, assertion (a) follows readily from Theorem 4.5 using (4.4), and $\overline{O}(H, A) \cap \widetilde{\mathcal{Y}}_{2,\vartheta_2(\xi)} = \overline{O}(H, A) \setminus \{0\}$. ∎

Corollary 4.7 recovers Proposition 19 in [24], which was obtained by specializing a theory for nonsmooth systems that in turn was based on a differential approach. The purpose of including the above proof of Corollary 4.7 is to illustrate the application of Theorem 4.5 in the case of a bimodal CLS. The corollary also identifies the key vector $Y(\xi)$ that was not explicitly employed in [24]. It follows from this corollary that if both $\overline{O}(H, A) \neq \{0\}$ and $\overline{O}(H, A + bc^T) \neq \{0\}$, then the bimodal CLS (2.9) has no short-time locally observable state; see Theorem 4.9 below for a general result.

We can employ the state short-time local/global observability characterizations to deduce some corresponding system short-time local/global observability results. The first such result pertains to short-time global observability and requires no proof.

THEOREM 4.8. *The CLS* (2.5) *is short-time globally observable if and only if*

$$\overline{O}\left(\begin{bmatrix} H & -H \end{bmatrix}, \begin{bmatrix} A_i & 0 \\ 0 & A_j \end{bmatrix} \right) \bigcap (\mathcal{Y}_i \times \mathcal{Y}_j) \subseteq \{(\xi, \xi) \,|\, \xi \in \mathbb{R}^n\} \tag{4.5}$$

for all i *and* j.

It turns out that the characterization of system short-time local observability is quite simple, involving only linear subspace conditions that are easily verifiable.

THEOREM 4.9. *The CLS* (2.5) *is short-time locally observable if and only if*

$$\overline{O}(H, A_i) = \{0\}, \quad i \in \{1, \ldots, m\}. \tag{4.6}$$

Proof. The sufficiency is clear. For the necessity, let ξ be an arbitrary interior point of the cone $\mathcal{X}_i$ for each $i = 1, \ldots, m$. For such a vector, we have $\mathcal{J}(\xi) = \mathcal{I}(\xi) = \mathcal{K}(\xi) = \{i\}$ and $\mathcal{Y}_{i,\mathcal{I}_{i0}(\xi)} = \mathbb{R}^n$. The necessity of (4.6) now follows readily. ∎

4.2. Finite verification. The characterizations of short-time observation beg the question of whether the necessary and sufficient conditions in Theorems 4.4, 4.5, and 4.8 can be verified by a finite procedure (it is obvious for Theorem 4.9). Note that we are not concerned about the computational complexity of the procedure, knowing that any such procedure is very likely to be exponential in the case of the LCS. We begin with the first condition in (4.3).

For each $i \in \mathcal{J}(\xi)$ and each $\ell \in \mathcal{I}_{i0}(\xi)$ for a given $\xi \in \mathbb{R}^n$, let μ_ℓ^i be the observability degree of the pair $((C_i)_{\ell\bullet}, A_i)$ at ξ (i.e., μ_ℓ^i is the first positive integer k such that $(C_i)_{\ell\bullet}A_i^k\xi > 0$); we set $\mu_\ell^i = n$ if $(C_i)_{\ell\bullet}A_i^k\xi = 0$ for all k. We claim that for each $i \in \mathcal{J}(\xi)$,

$$\overline{O}(H, A_i) \cap (\mathcal{Y}_{i,\mathcal{I}_{i0}(\xi)} - \xi) = \{0\} \Leftrightarrow \overline{O}(H, A_i) \bigcap \left(\bigcap_{\ell \in \mathcal{I}_{i0}(\xi)} \mathcal{Y}^\ell_{i,\mathcal{I}_{i0}(\xi)} \right) = \{0\}, \tag{4.7}$$

where $\mathcal{Y}^\ell_{i,\mathcal{L}} \equiv \left\{ v | ((C_i)_{\ell\bullet}v, (C_i)_{\ell\bullet}A_i v, \ldots, (C_i)_{\ell\bullet}A_i^{\mu_\ell^i - 1}v) \succcurlyeq 0 \right\}$ for any $\mathcal{L} \subseteq \{1, \ldots, m_i\}$ and each $\ell \in \mathcal{L}$. The claim (4.7) is a direct consequence of the first statement of the following lemma; the second statement of the lemma is used in the subsequent development (see Proposition 5.10).

LEMMA 4.10. *Let $\mathcal{L} \subseteq \{1, \ldots, m_i\}$, $\xi \in \mathcal{Y}_{i,\mathcal{L}}$, and $\ell \in \mathcal{L}$. It holds that*

(a) *$v \in \cap_{\ell \in \mathcal{L}} \mathcal{Y}^\ell_{i,\mathcal{L}} \Leftrightarrow \xi + \tau v \in \mathcal{Y}_{i,\mathcal{L}}$ for all $\tau > 0$ sufficiently small;*

(b) *for any $v \in \cap_{\ell \in \mathcal{L}} \mathcal{Y}^\ell_{i,\mathcal{L}}$, there exist $\tau_0 > 0$ and $\varepsilon_0 > 0$ (possibly dependent on τ_0) such that $\left(C_i e^{A_i t}[\xi + \tau v]\right)_{\mathcal{L}} \geqslant 0$ for all $(t, \tau) \in [0, \varepsilon_0] \times (0, \tau_0]$.*

Proof. The first statement is obvious, following from an argument similar to (4.2). We next show the second statement. Consider the case where the vector v is nonzero and $\mu_\ell^i < n$ for all ℓ; the other cases can easily be shown in a similar fashion. For each $\ell \in \mathcal{L}$, $v \in \bigcap_{\ell \in \mathcal{L}} \mathcal{Y}^\ell_{i,\mathcal{L}}$ implies that there exists an integer $0 \leqslant k \leqslant \mu_i^\ell - 1$ such that $(C_i A_i^k v)_\ell > 0$ and $(C_i A_i^j v)_\ell = 0$ for all $j = 0, \ldots, k-1$. Hence,

$$\left(C_i e^{A_i t}[\xi + \tau v]\right)_\ell = \tau \sum_{s=k}^{\mu_\ell^i - 1} \frac{(C_i A_i^s v)_\ell}{s!}\, t^s \;+\; \sum_{j=\mu_\ell^i}^{\infty} \frac{(C_i A_i^j [\xi + \tau v])_\ell}{j!}\, t^j.$$

The first summation is positive for all $\tau > 0$ and $t > 0$ sufficiently small, and since $(C_i A_i^{\mu_\ell^i}\xi)_\ell > 0$, it follows that for some positive ε_ℓ and τ_ℓ, the second summation

$$\sum_{j=\mu_\ell^i}^{\infty} \frac{(C_i A_i^j [\xi + \tau v])_\ell}{j!}\, t^j = t^{\mu_\ell^i} \left\{ \frac{(C_i A_i^{\mu_\ell^i}\xi)_\ell}{j!} + O(t) + \tau \left[\frac{(C_i A_i^{\mu_\ell^i} v)_\ell}{j!} + O(t) \right] \right\} \geqslant 0$$

for all $(t, \tau) \in [0, \varepsilon_\ell] \times (0, \tau_\ell]$. Hence, $\left(C_i e^{A_i t}[\xi + \tau v]\right)_\ell \geqslant 0$ for all $(t, \tau) \in [0, \varepsilon_\ell] \times (0, \tau_\ell]$. Finally, letting $\varepsilon_0 = \min_{\ell \in \mathcal{L}} \varepsilon_\ell$ and $\tau_0 = \min_{\ell \in \mathcal{L}} \tau_\ell$, we obtain the desired result. ∎

As explained in [24] in the context of the "semi-unobservable cones," checking the right-hand condition in (4.7) can be accomplished by solving finitely many linear programs; hence so can the first condition in (4.3). Indeed, a vector v belongs to $\mathcal{Y}^\ell_{i,\mathcal{I}_{i0}(\xi)}$ if and only if either $(C_i)_{\ell\bullet}A_i^k v = 0$ for all $k \in \{0, 1, \ldots, \mu_\ell^i - 1\}$ or there exists $k' \in \{0, 1, \ldots, \mu_\ell^i - 1\}$ such that $(C_i)_{\ell\bullet}A_i^k v = 0$ for all $k \in \{0, 1, \ldots, k' - 1\}$ and $(C_i)_{\ell\bullet}A_i^{k'} v > 0$. Hence, one can easily formulate finitely many linear inequality systems to determine if the right-hand condition in (4.7) holds. A similar procedure can be applied to check the conditions (4.1), (4.5), and the second condition in (4.3).

4.3. *T*-time and long-time observability. It has been pointed out at the beginning of section 4 that if a state $\xi = x(0,\xi)$ is short-time locally observable, then ξ is T-time locally observable for all $T > 0$, including $T = \infty$. The following result extends this observation to the case where a certain state $x(t,\xi)$ along the nominal solution trajectory is short-time locally observable for some $t \in (0,T)$.

PROPOSITION 4.11. *Let $0 < T \leqslant \infty$ and $\xi \in \mathbb{R}^n$ be given. If for some t_0 in $[0,T)$, the state $x(t_0,\xi)$ is short-time locally observable, then ξ is T-time locally observable.*

Proof. The short-time local observability of the state $x^0 \equiv x(t_0,\xi)$ means that there exists a neighborhood $\widetilde{\mathcal{N}}$ of x^0 such that for all $\widetilde{x} \in \widetilde{\mathcal{N}}$,

$$[\, Hx(t,x^0) = Hx(t,\widetilde{x}) \;\forall\, t \geqslant 0 \text{ sufficiently small}\,] \;\Rightarrow\; x^0 = \widetilde{x}.$$

Since the CLS is an ODE with a globally Lipschitz continuous right-hand side, there is a constant $L > 0$ such that $\|x(t,\xi) - x(t,\xi')\| \leqslant e^{Lt}\|\xi - \xi'\|$ for all $t > 0$. Hence, a neighborhood $\mathcal{N}_0$ of ξ exists such that $x(t_0,\xi') \in \widetilde{\mathcal{N}}$ for all $\xi' \in \mathcal{N}_0$. Let $\xi' \in \mathcal{N}_0$ be such that $Hx(t,\xi) = Hx(t,\xi')$ for all $t \in [0,T]$. Hence, we have, for all $\tau \in [0, T - t_0]$,

$$Hx(\tau,x^0) = Hx(\tau,x(t_0,\xi)) = Hx(t_0+\tau,\xi) = Hx(t_0+\tau,\xi') = Hx(\tau,x(t_0,\xi')).$$

Therefore, it follows that $x^0 = x(t_0,\xi) = x(t_0,\xi')$. Hence by considering the reverse-time system (2.8) starting at x^0 and noting that both ξ and ξ' are states on this reverse-time trajectory at time t_0, we easily obtain $\xi = \xi'$. ∎

Proposition 4.11 can be used to show, via the example below, that T-time local observability of a state does not imply short-time local observability of the given state.

Example 4.12. Consider the LCS(A,B,C,D) with the P-property where

$$A = \begin{bmatrix} \lambda_1 & 0 \\ 0 & \lambda_2 \end{bmatrix},\; B = \begin{bmatrix} 0 & b_{12} \\ 0 & 0 \end{bmatrix},\; C = \begin{bmatrix} 1 & 0 \\ 1 & 1 \end{bmatrix},\; D = \begin{bmatrix} 1 & -1 \\ 1 & 1 \end{bmatrix},\; H = \begin{bmatrix} h_1 & 0 \end{bmatrix}$$

with $\lambda_2 > \lambda_1 > 0$, and both b_{12} and h_1 nonzero. As shown in (2.17), the LCS is in the form of the CLS with four pieces:

$$\mathcal{X}_1 = \{x \in \mathbb{R}^2 \mid x_1 \geq 0,\, x_1 + x_2 \geq 0\}, \qquad \mathcal{X}_2 = \{x \in \mathbb{R}^2 \mid x_1 \leq 0,\, x_2 \geq 0\},$$

$$\mathcal{X}_3 = \{x \in \mathbb{R}^2 \mid 2x_1 + x_2 \leq 0,\, x_2 \leq 0\}, \qquad \mathcal{X}_4 = \{x \in \mathbb{R}^2 \mid 2x_1 + x_2 \geq 0,\, x_1 + x_2 \leq 0\},$$

which correspond to $\alpha = \varnothing$, $\alpha = \{1\}$, $\alpha = \{1,2\}$, $\alpha = \{2\}$ in (2.17), respectively, and their respective state matrices are

$$A_1 = A_2 = \begin{bmatrix} \lambda_1 & 0 \\ 0 & \lambda_2 \end{bmatrix}, \quad A_3 = \begin{bmatrix} \lambda_1 & -\frac{1}{2}b_{12} \\ 0 & \lambda_2 \end{bmatrix}, \quad A_4 = \begin{bmatrix} \lambda_1 & -b_{12} \\ 0 & \lambda_2 \end{bmatrix}.$$

Moreover, $\overline{O}(H,A_i) = \operatorname{span}\{(0,1)\}$ for $i = 1,2$ and $\overline{O}(H,A_i) = \{0\}$ for $i = 3,4$. Consider $\xi = (\xi_1,\xi_2)$ with $\xi_1 > 0 > \xi_2$ and $\xi_1 + \xi_2 > 0$. Since $\xi \in \operatorname{int}\mathcal{X}_1$ and $\overline{O}(H,A_1) \neq \{0\}$, Corollary 4.6 implies that ξ is not short-time locally observable. However, it can be seen that $t_1 > 0$ exists such that $x(t,\xi) \in \operatorname{int}\mathcal{X}_4$ for all $t > t_1$ sufficiently close to t_1. Hence, the condition $\overline{O}(H,A_4) = \{0\}$ implies the short-time local observability at $\widehat{x} = x(t_*,\xi)$ for some $t_* > t_1$. Consequently, ξ is T-time locally observable for any $T \in (t_1,\infty]$ by Proposition 4.11.

In light of Proposition 4.11, the challenge in establishing the T-time local observability of a given state $\xi \in \mathbb{R}^n$ occurs when none of the states $x(t,\xi)$ for $t \in [0,T)$ is short-time locally observable. In general, this is a rather difficult case to analyze fully,

due to the mode switchings along the nominal state trajectory $x(t,\xi)$ and perturbed state trajectories in the interval $[0,T]$. Our approach to dealing with this challenge is to invoke a result in [24] that pertains to an ODE with a B-differentiable right-hand side, which includes the CLS (2.5) as a special case. In what follows, after presenting a slight improvement of this result, we identify a class of initial states for which necessary and sufficient conditions for T-time local observability can be derived; see Proposition 4.13.

As mentioned in section 2, the solution map $\xi \mapsto x(t,\xi)$ is B-differentiable for all fixed $t \geqslant 0$; in particular, the directional derivative

$$x'_\xi(t,\xi;\eta) \equiv \lim_{\tau \downarrow 0} \frac{x(t,\xi+\tau\eta) - x(t,\xi)}{\tau}$$

of $x(t,\cdot)$ at $\xi \in \mathbb{R}^n$ along any direction $\eta \in \mathbb{R}^n$ exists and satisfies a certain first-order time-dependent variational ODE. In terms of such a derivative, define the set

$$\mathcal{Z}_T^\xi \equiv \left\{ v \in \mathbb{R}^n \,|\, Hx'_\xi(t,\xi;v) = 0 \;\forall\, t \in [0,T] \right\},$$

which is a closed, albeit not necessarily convex, cone. It was proved in [24, Theorem 10] that $\mathcal{Z}_T^\xi = \{0\}$ is a sufficient condition for the T-time local observability of ξ.

We next derive an improvement of the above result via the introduction of the set Ω_T^ξ consisting of all T-time indistinguishable states from ξ. Thus $\eta \in \Omega_T^\xi$ if and only if $Hx(t,\xi) = Hx(t,\eta)$ for all $t \in [0,T]$. Clearly, $\xi \in \Omega_T^\xi$. As such we can speak of the *feasible cone*, denoted $\mathcal{F}(\Omega_T^\xi,\xi)$, and the *tangent cone*, denoted $\mathcal{T}(\Omega_T^\xi,\xi)$, of Ω_T^ξ at ξ. Specifically, v is an element of the former cone if a $\bar\tau > 0$ exists such that $Hx(t,\xi+\tau v) = Hx(t,\xi)$ for all $(t,\tau) \in [0,T] \times [0,\bar\tau]$; w is an element of the latter cone if a sequence of vectors $\{\eta^k\} \subset \Omega_T^\xi$ converging to ξ and a sequence of positive scalars $\{\tau_k\}$ converging to zero exist such that $w = \lim_{k\to\infty} \frac{\eta^k - \xi}{\tau_k}$. We have

$$\mathcal{F}(\Omega_T^\xi,\xi) \subseteq \mathcal{T}(\Omega_T^\xi,\xi) \subseteq \mathcal{Z}_T^\xi. \tag{4.8}$$

Indeed, the first inclusion holds with Ω_T^ξ replaced by any set containing ξ; the second inclusion holds by the approximation

$$Hx(t,\eta) = Hx(t,\xi) + Hx'_\xi(t,\xi;\eta-\xi) + o_t(\|\,\eta-\xi\,\|), \tag{4.9}$$

where the error function $o_t(\tau)$ satisfies $\lim_{\tau\downarrow 0} \frac{o_t(\tau)}{\tau} = 0$. In turn, (4.9) is the consequence of the B-differentiability of the solution map $x(t,\cdot)$. We have the following result.

PROPOSITION 4.13. *Let $0 < T \leqslant \infty$ and $\xi \in \mathbb{R}^n$ be given. The following implications hold for the solution trajectory $x(t,\xi)$ of the CLS* (2.5)*:*

$$\mathcal{T}(\Omega_T^\xi,\xi) = \{0\} \;\Rightarrow\; \xi \text{ is } T\text{-time locally observable} \;\Rightarrow\; \mathcal{F}(\Omega_T^\xi,\xi) = \{0\}. \tag{4.10}$$

Hence, the following two statements are equivalent.

(a) $\mathcal{F}(\Omega_T^\xi,\xi) = \mathcal{T}(\Omega_T^\xi,\xi)$ *and* ξ *is T-time locally observable.*

(b) $\mathcal{F}(\Omega_T^\xi,\xi) = \mathcal{T}(\Omega_T^\xi,\xi) = \{0\}$.

Proof. Based on the same proof as in [24, Theorem 10], the first implication in (4.10) follows from (4.9). The equivalence of the two statements (a) and (b) is obvious. ∎

Admittedly, the condition $\mathcal{F}(\Omega_T^\xi, \xi) = \mathcal{T}(\Omega_T^\xi, \xi)$, while simple, is practically not easy to verify, due to the difficulty of complete characterization of the set Ω_T^ξ, except in special cases; see Theorem 5.6 and Corollary 5.7. Thus, rather than investigating this condition in its full generality, we devote section 5 to a detailed study of the bimodal CLS (2.9).

Before ending the discussion on the general CLS, we state the following sufficient condition for a state to be long-time locally observable.

COROLLARY 4.14. *Suppose that there exists* $T \in (0, \infty)$ *such that* $\mathcal{T}(\Omega_T^\xi, \xi) = \{0\}$*; then* ξ *is long-time locally observable for the CLS* (2.5).

Proof. This is obvious because $\Omega_\infty^\xi \subseteq \Omega_T^\xi$ for any finite $T > 0$. Thus the assumption implies $\mathcal{T}(\Omega_\infty^\xi, \xi) = \{0\}$ which holds because $\mathcal{T}(\Omega_\infty^\xi, \xi) = \{0\} \subseteq \mathcal{T}(\Omega_T^\xi, \xi) = \{0\}$. The long-time local observability of ξ now follows from Proposition 4.13. ∎

5. Bimodal CLSs. Currently, the results for T-time and long-time observability of a general CLS are limited to those in subsection 4.3. Further results, in particular, complete characterizations and finite verifications, appear difficult. Nevertheless, much more can be obtained for the bimodal CLS (2.9), whose detailed analysis is the subject of this section that is divided into several subsections. As we will see, even this simplified case is not easy to analyze, and some unsolved issues remain.

5.1. *T*-time local observability. For the analysis to be of interest, we make the blanket assumption throughout this section that $b \neq 0$ and do not repeat the assumption. We begin by giving two necessary conditions for the bimodal system (2.9) to have a T-time locally observable state for any $T \in [0, \infty]$. The first condition (a) is a minor variant of Proposition 13 in [24] specialized to the bimodal CLS. A proof of this part can be found in the reference.

PROPOSITION 5.1. *For the bimodal system* (2.9) *to have a* T*-time locally observable state, for any* $T \in [0, \infty]$*, it is necessary that* (a) $\overline{O}(H, A) \cap \overline{O}(c^T, A) = \{0\}$ *and* (b) $b \notin \overline{O}(H, A)$.

Proof. We prove only (b). Assume that $0 \neq b \in \overline{O}(H, A)$. By induction, it can be shown that $HA^k = H(A+bc^T)^k$ for all nonnegative k. (Indeed, assume that this holds for some i; we have $HA^{i+1} = H(A + bc^T)^i A = H(A + bc^T)^{i+1} - HA^i bc^T = H(A + bc^T)^{i+1}$, completing the inductive step.) Hence, $\overline{O}(H, A) = \overline{O}(H, A + bc^T)$. Thus $He^{At}\xi = He^{(A+bc^T)t}\xi$ for all $t \geqslant 0$ and all $\xi \in \mathbb{R}^n$, which implies $Hx(t, \xi) = He^{At}\xi$ for all $t \geqslant 0$ and all $\xi \in \mathbb{R}^n$. Since $0 \neq b \in \overline{O}(H, A) = \overline{O}(H, A + bc^T)$, we can similarly deduce $He^{At}\xi = He^{At}(\xi + \tau b) = He^{(A+bc^T)t}(\xi + \tau b)$ for all $t \geqslant 0$, all $\xi \in \mathbb{R}^n$, and all $\tau \in \mathbb{R}$. Consequently, $Hx(t, \xi) = Hx(t, \xi + \tau b)$ for all such triples (t, ξ, τ). Since $b \neq 0$, no state ξ can be T-time globally/locally observable. ∎

It is useful to record a corollary of the above proposition, which becomes yet another necessary condition for (2.9) to have a T-time locally observable state.

PROPOSITION 5.2. *Under conditions* (a) *and* (b) *of Proposition* 5.1, *it holds that* $\overline{O}(H, A) \cap \overline{O}(H, A + bc^T) = \{0\}$. *Conversely, if the latter holds, then* $b \notin \overline{O}(H, A)$.

Proof. Assume by way of contradiction that $0 \neq v \in \overline{O}(H, A) \cap \overline{O}(H, A + bc^T)$. Then $v \notin \overline{O}(c^T, A)$ by (a). Hence, a first nonnegative integer ℓ exists such that $c^T A^\ell v \neq 0$. Similarly, since $b \notin \overline{O}(H, A)$, we have the first nonnegative integer k satisfying $HA^k b \neq 0$. By expanding $(A + bc^T)^{k+\ell+1}$, it can easily be verified that $H(A + bc^T)^{k+\ell+1} v = (HA^k b)(c^T A^\ell v) \neq 0$ by the choice of k and ℓ. This contradicts $v \in \overline{O}(H, A + bc^T)$. The second assertion of the proposition can be easily argued as follows. If $b \in \overline{O}(H, A)$, then by the proof of Proposition 5.1, we have $0 \neq b \in \overline{O}(H, A) = \overline{O}(H, A) \cap \overline{O}(H, A + bc^T)$. ∎

We next establish two basic properties of a solution trajectory to the bimodal system (2.9). Stated in Proposition 5.3, the first property pertains to an individual trajectory $x(t,\xi)$; the second property pertains to perturbed trajectories $x(t,\eta)$ where the initial condition η is sufficiently close to ξ.

PROPOSITION 5.3. *If $x(t,\xi)$ is a solution of the bimodal CLS (2.9) such that $c^T x(t,\xi)$ is not identically zero on the interval $[0,T]$ with $T \in (0,\infty)$, then a partition (3.2) of the interval $[0,T]$ exists such that $c^T x(t,\xi)$ does not have a zero, and thus is persistently positive or negative, in each of the open subintervals (t_{i-1},t_i) for all $i = 1,\ldots,N$. Moreover, for every positive $\varepsilon < \frac{1}{2}\min_{1\leqslant i\leqslant N}(t_i - t_{i-1})$, there exists a neighborhood $\mathcal{N}$ of ξ such that for any $\eta \in \mathcal{N}$, $\min_{1\leqslant i\leqslant N}\min_{t\in[t_{i-1}+\varepsilon,t_i-\varepsilon]}\big(c^T x(t,\xi)\big)\big(c^T x(t,\eta)\big) > 0$.*

Proof. By the partition in Theorem 3.7, we deduce the existence of finitely many time instants t_i for $i = 1,\ldots,N$ with $t_0 = 0$ and $t_N = T$ such that $c^T x(t,\xi) = c^T e^{A_i(t-t_{i-1})}x(t_{i-1},\xi)$ for all $t \in [t_{i-1},t_i]$, where A_i is either A or $A + bc^T$. Since the right-hand function is analytic on the real line, it has finitely many zeros in the compact subinterval $[t_{i-1},t_i]$, unless the function is identically zero. In the latter case, $c^T x(t,\xi)$ is identically zero on $[t_{i-1},t_i]$, which implies that $x(t_{i-1},\xi) \in \overline{O}(c^T,A_i) = \overline{O}(c^T,A)$. Proceeding forward and backward in time, we can establish that $\xi \in \overline{O}(c^T,A)$ so that $c^T x(t,\xi)$ is identically zero on the entire interval $[0,T]$, contradicting the assumption. Thus, by refining the partition (3.2) of the interval $[0,T]$ if necessary, we readily obtained the desired conclusions of the proposition. ∎

Noticing that the right-hand side of the bimodal ODE (2.9) is the sum of a linear function and the max function whose directional derivative is trivial to write down, we can invoke the results in [26] to obtain the directional derivative $x'_\xi(t,\xi;\eta)$ of the solution function $x(t,\cdot)$ at a vector $\xi \in \mathbb{R}^n$ along a direction $\eta \in \mathbb{R}^n$. To describe this derivative succinctly, consider the function $g^\xi : [0,T]\times\mathbb{R}^n \to \mathbb{R}^n$ defined by

$$g^\xi(t,y) \equiv \begin{cases} Ay & \text{if } c^T x(t,\xi) < 0, \\ Ay + b\max(0,c^T y) & \text{if } c^T x(t,\xi) = 0, \\ (A + bc^T)y & \text{if } c^T x(t,\xi) > 0 \end{cases}$$

and the time-dependent ODE

$$\dot{y}(t) = g^\xi(t,y), \quad y(0) = \eta. \tag{5.1}$$

Note that the function $g^\xi(t,y)$ is only piecewise continuous in t. In fact, by Proposition 5.3, if $c^T x(t,\xi)$ is not identically zero on the interval $[0,T]$, where $T \in [0,\infty)$, there exists a partition (3.2) of the interval $[0,T]$ such that $c^T x(t,\xi)$ has no zero in (t_{i-1},t_i) and $c^T x(t,\xi) = 0$ for all $t \in \{t_1,\ldots,t_{N-1}\}$. The case where $c^T x(t,\xi)$ is identically equal to zero can be made to be part of this treatment by taking $N = 0$ (the vacuous partition). Note that the case where $c^T x(t,\xi)$ does not change sign, but can have (isolated) zeros, in $[0,T]$ is clearly permitted. We call the subinterval (t_{i-1},t_i) *positive* (*negative*) if $c^T x(t,\xi)$ is positive (negative, respectively) throughout (t_{i-1},t_i). Note that this terminology refers to the given trajectory $x(t,\xi)$. In terms of the partition (3.2), we can write

$$g^\xi(t,y) \equiv \begin{cases} Ay & \text{if } t \text{ is in a negative subinterval } (t_{i-1},t_i), \\ Ay + b\max(0,c^T y) & \text{if } t \in \{t_1,\ldots,t_{N-1}\}, \\ (A + bc^T)y & \text{if } t \text{ is in a positive subinterval } (t_{i-1},t_i), \end{cases}$$

which shows that $g^\xi(t,y)$ is in general discontinuous at the times t_i, $i = 1,\ldots,N-1$. By Theorem 3.2 in [21], the time-varying ODE (5.1) has a unique solution, which we

denote $y^\xi(t;\eta)$, for every initial η that is continuous on $[0,T]$; moreover, by Theorem 7 in [26], this unique solution is equal to $x'_\xi(t,\xi;\eta)$. Therefore, we obtain

$$x'_\xi(t,\xi;\eta) = \begin{cases} e^{A(t-t_i)}x'_\xi(t_{i-1},\xi;\eta) & \text{if } t \text{ is in a negative subinterval } (t_{i-1},t_i), \\ e^{(A+bc^T)(t-t_i)}x'_\xi(t_{i-1},\xi;\eta) & \text{if } t \text{ is in a positive subinterval } (t_{i-1},t_i). \end{cases}$$

From this expression, we deduce that $x(t,\xi)+x'_\xi(t,\xi;\eta-\xi) = y^\xi(t;\eta)$ for all $t \in [0,T]$. This equality remains valid if $c^T x(t,\xi)$ is identically equal to zero on the entire interval $[0,T]$. Note that $y^\xi(t;\eta) \neq x(t,\eta)$ in general. As proved in Proposition 5.5 below, these two functions will coincide if the states ξ and η are T-time mode consistent with respect to the bimodal CLS (2.9) as defined below.

DEFINITION 5.4. *Two states ξ and η are said to be* mode consistent *on an interval $\mathcal{I}$ with respect to the bimodal CLS* (2.9) *if $(c^T x(t,\xi))(c^T x(t,\eta)) \geqslant 0$ for all times $t \in \mathcal{I}$. If $\mathcal{I} = [0,T]$, we say that ξ and η are* T-time mode consistent.

According to Proposition 5.3, η is mode consistent with ξ on the subintervals $[t_{i-1}+\varepsilon, t_i-\varepsilon]$ for all $i = 1,\ldots,N$, provided that η is sufficiently near ξ. The difficulty with analyzing the perturbed trajectory $x(t,\eta)$ lies in the subintervals $(t_i-\varepsilon, t_i+\varepsilon)$ which are ε-neighborhoods of the critical times t_i. Due to its importance, we introduce the notation $\mathcal{M}_T^\xi$ to denote the set of all states that are T-time mode consistent with ξ. The next result asserts that $\mathcal{M}_T^\xi \cap \Omega_T^\xi = \mathcal{M}_T^\xi \cap (\xi + \mathcal{Z}_T^\xi)$.

PROPOSITION 5.5. *Two T-time mode consistent states ξ and η of the bimodal CLS* (2.9) *are T-time indistinguishable if and only if $Hx'_\xi(t,\xi;\eta-\xi) = 0$ for all $t \in [0,T]$.*

Proof. Under the mode consistency assumption, we have $x(t,\eta) = x(t,\xi) + x'_\xi(t,\xi;\eta-\xi)$ for all $t \in [0,T]$. The desired equivalence follows readily. ∎

Based on Propositions 5.1 and 5.5, the following result pertains to a special class of initial states ξ such that the trajectory $x(t,\xi)$ remains on the boundary of the two pieces at all times.

THEOREM 5.6. *Suppose $c^T x(t,\xi) = 0$ for all $t \in [0,T]$ with $0 < T \leqslant \infty$. The following six statements are equivalent.*

(a) *ξ is T-time globally observable for the bimodal CLS* (2.9).
(b) $\mathcal{Z}_T^\xi = \{0\}$.
(c) *$Hx(t,\eta) = 0$ for all $t \in [0,T]$ implies $\eta = 0$; i.e., the zero state is T-time globally (or locally) observable.*
(d) $\mathcal{F}(\Omega_T^\xi,\xi) = \mathcal{T}(\Omega_T^\xi,\xi) = \{0\}$.
(e) *ξ is T-time locally observable.*
(f) $\overline{O}(H,A) \cap \overline{O}(H,A+bc^T) = \{0\}$,

$$\begin{aligned} \overline{O}(H,A) \cap \left\{ v \mid c^T e^{At} v \leqslant 0 \ \forall\ t \in [0,T] \right\} &= \{0\}, \\ \overline{O}(H,A+bc^T) \cap \left\{ v \mid c^T e^{(A+bc^T)t} v \geqslant 0 \ \forall\ t \in [0,T] \right\} &= \{0\}. \end{aligned} \tag{5.2}$$

Proof. Under the assumption, all states are T-time mode consistent with ξ. Therefore, the equivalence of (a) and (b) follows from Proposition 5.5. Moreover, $x'_\xi(t,\xi;\eta) = x(t,\eta)$ for all $t \in [0,T]$. Therefore, (b) and (c) are equivalent. Statement (b) clearly implies (d) by (4.8); (d) implies (e) by Proposition 4.13. Finally, we show that (e) implies (b). Suppose (e) holds, but $\mathcal{Z}_T^\xi$ has a nonzero vector v. Then $Hx'_\xi(t,\xi;v) = 0$ for all $t \in [0,T]$. Let $\eta \equiv \xi + \tau v$, where $\tau > 0$ is chosen so that η falls in the neighborhood of ξ where its T-time local observability holds. Since

$Hx'_\xi(t,\xi;\eta-\xi)=0$ for all $t\in[0,T]$, Proposition 5.5 implies that η is T-time indistinguishable from ξ. By the T-time local observability of ξ, we deduce that $\eta-\xi$, and thus v is equal to zero, which is a contradiction. Hence (b) holds. The first five statements of the corollary are thus equivalent.

Suppose that any one of the five equivalent statements (a)–(e) holds. By Propositions 5.1 and 5.2, $\overline{O}(H,A)\cap\overline{O}(H,A+bc^T)=\{0\}$. Moreover, if either condition in (5.2) does not hold, then we have a nonzero vector v belonging to the left-hand set of one of these two expressions. It follows that $Hx(t,v)=0$ for all $t\in[0,T]$, which contradicts (c). Conversely, suppose that (f) holds. It suffices to show that any state η such that $Hx(t,\eta)=0$ for all $t\in[0,T]$ must satisfy $c^Tx(t,\eta)\geqslant 0$ for all $t\in[0,T]$ or $c^Tx(t,\eta)\leqslant 0$ for all $t\in[0,T]$; i.e., $c^Tx(t,\eta)$ remains in one piece over $[0,T]$. Suppose the claim does not hold. Then there is a switching time $t_*\in(0,T)$. This means that $\delta>0$ exists such that $c^Tx(t,\eta)$ is of one nonzero sign in $(t_*-\delta,t_*)$ and of a different nonzero sign in $(t_*,t_*+\delta)$. This implies in particular that $x(t,\eta)\neq 0$ for all $t\geqslant 0$. Without loss of generality, we may assume that $c^Tx(t,\eta)>0$ for all $t\in(t_*-\delta,t_*)$ and $c^Tx(t,\eta)<0$ for all $t\in(t_*,t_*+\delta)$. Hence, the indistinguishability condition $Hx(t,\eta)=0$ for all $t\in[0,T]$ yields $x(t_*,\eta)\in\overline{O}(H,A+bc^T)\cap\overline{O}(H,A)$, which is a contradiction because $x(t_*,\eta)\neq 0$. □

It is interesting to note that conditions (c) and (f) are independent of the state ξ. Clearly, elements of the set $\{v\mid c^Te^{At}v\leqslant 0\ \forall\, t\in[0,T]\}$ are vectors v in the half-plane $\mathcal{X}_2=\{v\mid c^Tv\leqslant 0\}$ such that a trajectory, when initiated at v, remains in the same half-plane. Thus the first condition in (5.2) stipulates that the zero vector is the only such vector that also lies in the unobservable space of the pair (H,A), which is the mode to which the trajectory in question belongs. A similar interpretation applies to the second condition. A local version of Theorem 5.6 is as follows.

COROLLARY 5.7. *Suppose that all states sufficiently near ξ are T-time mode consistent with ξ. The following statements are equivalent.*

(a) *ξ is T-time locally observable for the bimodal CLS* (2.9).

(b) $\mathcal{Z}_T^\xi=\{0\}$.

(c) $\mathcal{F}(\Omega_T^\xi,\xi)=\mathcal{T}(\Omega_T^\xi,\xi)=\{0\}$.

Proof. (a) ⇒ (b). This basically follows the same proof as in the previous proof. Suppose $Hx'_\xi(t,\xi;v)=0$ for all $t\in[0,T]$. Let $\eta\equiv\xi+\tau v$, where $\tau>0$ is chosen so that η is T-time mode consistent with ξ and that η falls in the neighborhood of ξ where its T-time local observability holds. Proposition 5.5 implies that η is T-time indistinguishable from ξ. By the T-time local observability of ξ, we then have $v=0$. The implications (b) ⇒ (c) ⇒ (a) require no proof. □

The condition that $c^Tx(t,\xi)=0$ for all $t\in[0,T]$ with $0<T\leqslant\infty$ in Theorem 5.6 is equivalent to $\xi\in\overline{O}(c^T,A)$, which is further equivalent to $x(t,\xi)\in\overline{O}(c^T,A)$ for all $t\in[0,T]$. The T-time (local or global) observability of such a state is completely resolved by the corollary. Note that for a state $\xi\in\overline{O}(c^T,A)$, the set $\mathcal{M}_T^\xi=\mathbb{R}^n$. The next result treats the case where $\xi\notin\overline{O}(c^T,A)$; the key condition in this result is the generalization of condition (c) in Theorem 5.6 to condition (b) in the theorem below.

THEOREM 5.8. *Suppose that $\xi\notin\overline{O}(c^T,A)$. The two conditions,*

(a) $\overline{O}(H,A)\cap\overline{O}(H,A+bc^T)=\{0\}$,

(b) *a neighborhood $\mathcal{N}$ of ξ exists such that $\mathcal{M}_T^\xi\cap(\,\xi+\mathcal{Z}_T^\xi\,)\cap\mathcal{N}=\{\xi\}$,*

are necessary for ξ to be T-time locally observable for the bimodal CLS (2.9) *for any $T\in(0,\infty]$, and sufficient for any $T\in(0,\infty)$.*

We first establish a lemma that is the key to the proof of the sufficiency part of Theorem 5.8.

LEMMA 5.9. *If $\xi \notin \overline{O}(c^T, A)$, then, under condition* (a) *in Theorem* 5.8, *for every finite $T > 0$, there exists a neighborhood $\mathcal{N}_0$ of ξ such that $\Omega_T^\xi \cap \mathcal{N}_0 \subseteq \mathcal{M}_T^\xi$.*

Proof. Since $\xi \notin \overline{O}(c^T, A)$, it follows that $x(t, \xi) \notin \overline{O}(c^T, A)$ for all $t \geqslant 0$. Furthermore, by Proposition 5.2, $b \notin \overline{O}(H, A)$. Consequently, for each $t \geqslant 0$, there exists an integer $\ell_t \geqslant 0$ such that $HA^{\ell_t}x(t, \xi) \neq H(A + bc^T)^{\ell_t}x(t, \xi)$. We claim that a neighborhood $\widetilde{\mathcal{N}}$ of ξ exists such that for every $t \in [0, T]$ and every $\eta \in \widetilde{\mathcal{N}}$, an integer $\ell \in \{0, 1, \ldots, n-1\}$ exists such that

$$HA^\ell x(t, \xi) \neq H(A + bc^T)^\ell x(t, \eta) \quad \text{and} \quad HA^\ell x(t, \eta) \neq H(A + bc^T)^\ell x(t, \xi).$$

Indeed, if no such neighborhood exists, then there exist a sequence of vectors $\{\eta^k\}$ converging to ξ and a sequence of times $\{t_k\} \subset [0, T]$ such that for each $\ell \in \{0, 1, \ldots, n-1\}$, either $HA^\ell x(t_k, \xi) = H(A+bc^T)^\ell x(t_k, \eta^k)$ or $HA^\ell x(t_k, \eta^k) = H(A+bc^T)^\ell x(t_k, \xi)$. The sequence $\{t_k\}$ accumulates to some time t_* in $[0, T]$; for any such time, we must have $HA^\ell x(t_*, \xi) = H(A + bc^T)^\ell x(t_*, \xi)$ for all nonnegative integers ℓ. This contradiction establishes the claim.

Let $t_i, i = 1, \ldots, N$ be finitely many time instants in $[0, T]$ described in Proposition 5.3 such that $c^T x(t_i, \xi) = 0$. Let ε be a positive scalar and $\widehat{\mathcal{N}}$ be a neighborhood of ξ such that every $\eta \in \widehat{\mathcal{N}}$ is mode consistent with ξ on all the subintervals $[t_{i-1} + \varepsilon, t_i - \varepsilon]$ for all $i = 1, \ldots, N$; the existence of ε and $\widehat{\mathcal{N}}$ is due to Proposition 5.3. Let $\mathcal{N}_0 \equiv \widetilde{\mathcal{N}} \cap \widehat{\mathcal{N}}$, where $\widetilde{\mathcal{N}}$ is established above. By way of contradiction, suppose that there exists a sequence of vectors $\{\eta^k\} \in \mathcal{N}_0$ converging to ξ such that each η^k is T-time indistinguishable from but not T-time mode consistent with ξ. Hence, there exists $\widetilde{t}_k \in (t_{i_k} - \varepsilon, t_{i_k} + \varepsilon)$ for some $i_k \in \{1, \ldots, N-1\}$ or $\widetilde{t}_k \in [0, \varepsilon)$ or $\widetilde{t}_k \in (T - \varepsilon, T]$ such that $(c^T x(\widetilde{t}_k, \xi))(c^T x(\widetilde{t}_k, \eta^k)) < 0$ for every k. We may assume without loss of generality that $\widetilde{t}_k \in [0, T)$ is such that for some $\delta_k > 0$, $c^T x(t, \xi) > 0$ and $c^T x(t, \eta^k) < 0$ for all $t \in (\widetilde{t}_k, \widetilde{t}_k + \delta_k)$ (if $\widetilde{t}_k = T$, we consider the interval $(\widetilde{t}_k - \delta_k, \widetilde{t}_k)$ and use the reverse-time argument). Hence, we have $x(t, \xi) = e^{(A+bc^T)(t-\widetilde{t}_k)}x(\widetilde{t}_k, \xi)$ and $x(t, \eta) = e^{A(t-\widetilde{t}_k)}x(\widetilde{t}_k, \eta^k)$ for all such t. Thus $He^{(A+bc^T)(t-\widetilde{t}_k)}x(\widetilde{t}_k, \xi) = He^{A(t-\widetilde{t}_k)}x(\widetilde{t}_k, \eta^k)$ for all $t \in (\widetilde{t}_k, \widetilde{t}_k + \delta_k)$, which yields $H(A + bc^T)^\ell x(\widetilde{t}_k, \xi) = HA^\ell x(\widetilde{t}_k, \eta^k)$ for all nonnegative integers ℓ. But this contradicts the claim established above because $\eta^k \in \widetilde{\mathcal{N}}$. ∎

Proof of Theorem 5.8. Suppose that ξ is T-time locally observable for $T \in [0, \infty]$. By Propositions 5.1 and 5.2, condition (a) is necessary. To prove (b), choose a neighborhood $\mathcal{N}$ of ξ so that $\Omega_T^\xi \cap \mathcal{N} = \{\xi\}$. Since $\mathcal{M}_T^\xi \cap (\xi + \mathcal{Z}_T^\xi) = \Omega_T^\xi$ by Proposition 5.5, we have

$$\mathcal{M}_T^\xi \cap (\xi + \mathcal{Z}_T^\xi) \cap \mathcal{N} = \mathcal{M}_T^\xi \cap \Omega_T^\xi \cap \mathcal{N} = \{\xi\}.$$

Conversely, let $T < \infty$. Assume that (a) and (b) hold and let $\mathcal{N}$ be the neighborhood of ξ described in (b). By Lemma 5.9, a neighborhood $\mathcal{N}_0$ of ξ exists such that $\Omega_T^\xi \cap \mathcal{N}_0 \subseteq \mathcal{M}_T^\xi$. So, by (b),

$$\Omega_T^\xi \cap \mathcal{N} \cap \mathcal{N}_0 \subseteq \Omega_T^\xi \cap \mathcal{M}_T^\xi \cap \mathcal{N} \cap \mathcal{N}_0 = (\xi + \mathcal{Z}_T^\xi) \cap \mathcal{M}_T^\xi \cap \mathcal{N} \cap \mathcal{N}_0 = \{\xi\}.$$

Hence ξ is T-time observable within the neighborhood $\mathcal{N} \cap \mathcal{N}_0$. ∎

It is important to note that the sufficient part of Theorem 5.8 requires T to be finite. We will discuss more about the case where $T = \infty$ in subsection 5.3.

5.2. More on mode consistency. From condition (b) in Theorem 5.8, the important role of mode consistency in T-time local observability is amply evident. In what follows, we discuss this condition in greater detail. Specifically, our goal is to generalize the two conditions in (5.2) to the case where $\xi \notin \overline{O}(c^T, A)$. As it turns out, such a generalization is not trivial because we need to deal with various mode transitions, which necessitate the introduction of the "mode-transition matrices" $\Phi_\xi^{\mathrm{n}}(t)$ associated with the nominal trajectory $x(t,\xi)$.

Recall that Proposition 5.3 implies the existence of a partition of the finite interval $[0,T]$, where $T \in (0,\infty)$, such that $c^T x(t,\xi)$ is persistently positive or negative in (t_{i-1}, t_i) for all $i = 1,\dots,N$. In other words, $c^T x(t,\xi) = 0$ only at t_i's. For each i, define

$$(\mathbf{c}^i, S_i) \equiv \begin{cases} (-c^T, A) & \text{if } (t_i, t_{i+1}) \text{ is a negative subinterval,} \\ (c^T, A + bc^T) & \text{if } (t_i, t_{i+1}) \text{ is a positive subinterval,} \end{cases} \qquad i = 0,\dots,N-1,$$

and $\mathcal{Y}(S_i) \equiv \left\{ x \,\middle|\, \left(\mathbf{c}^i x,\ \mathbf{c}^i S_i x, \dots, \mathbf{c}^i S_i^{n-1} x \right) \succcurlyeq 0 \right\}$. The nominal state trajectory on $[0,T]$ can be written as $x(t,\xi) = \Phi_\xi^{\mathrm{n}}(t)\xi$, where

$$\Phi_\xi^{\mathrm{n}}(t) \equiv \begin{cases} \text{the identity matrix} & \text{for } t = 0, \\ e^{S_k(t-t_k)} \displaystyle\prod_{i=1}^{k} e^{S_{i-1}(t_i - t_{i-1})} & \text{for } t \in [t_k, t_{k+1}],\ k = 0,\dots,N-1, \end{cases}$$

is a *mode-transition matrix*. It is clear that $\Phi_\xi^{\mathrm{n}}(t)$ is invertible for all t.

PROPOSITION 5.10. *Let $T \in (0,\infty)$. If $\xi \notin \overline{O}(H,A)$, then Theorem* 5.8(b) *is equivalent to the following: with $\widehat{x}_i = \Phi_\xi^{\mathrm{n}}(t_i)\xi$ for $i = 0,\dots,N$, and $S_{-1} = S_N \equiv 0$,*

$$\bigcap_{i=0}^{N} \left\{ \left[\Phi_\xi^{\mathrm{n}}(t_i)\right]^{-1} \left[\overline{O}(H,S_i) \cap \left(\mathcal{Y}(S_i) - \widehat{x}_i\right) \cap \overline{O}(H,-S_{i-1}) \cap \left(\mathcal{Y}(-S_{i-1}) - \widehat{x}_i\right) \right] \right\} = \{0\}.$$

Proof. Suppose that Theorem 5.8(b) does not hold. Then for any neighborhood $\mathcal{N}$ of ξ, there is $\eta \in \mathcal{N}$ other than ξ such that $\eta \in \mathcal{M}_T^\xi \cap (\xi + \mathcal{Z}_T^\xi)$. Hence, by Proposition 5.5, it follows that ξ and η are T-time mode consistent states and $Hx'_\xi(t,\xi;\eta-\xi) = 0$ for all $t \in [0,T]$. This implies that $x(t,\eta) = \Phi_\xi^{\mathrm{n}}(t)\eta$ and $Hx'_\xi(t,\xi;\eta-\xi) = H\Phi_\xi^{\mathrm{n}}(t)[\eta-\xi] = 0$ on $[0,T]$. Let $v = \eta - \xi$. The mode consistency condition further implies that for all $i = 1,\dots,N$,

$$\Phi_\xi^{\mathrm{n}}(t_i)\eta = \Phi_\xi^{\mathrm{n}}(t_i)[v+\xi] = \Phi_\xi^{\mathrm{n}}(t_i)v + \widehat{x}_i \in \mathcal{Y}(S_i).$$

Similarly, $\Phi_\xi^{\mathrm{n}}(t_i)\eta = \Phi_\xi^{\mathrm{n}}(t_i)v + \widehat{x}_i \in \mathcal{Y}(-S_{i-1})$. Moreover, for any $t \in (t_i, t_{i+1})$ and $i = 0,\dots,N-1$, $H\Phi_\xi^{\mathrm{n}}(t)v = He^{S_i(t-t_i)}\Phi_\xi^{\mathrm{n}}(t_i)v$. Hence, $H\Phi_\xi^{\mathrm{n}}(t)v = 0$ for all $t \in [0,T]$ implies that $\Phi_\xi^{\mathrm{n}}(t_i)v \in \overline{O}(H,S_i)$. Using the reverse-time argument, one can also deduce $\Phi_\xi^{\mathrm{n}}(t_i)v \in \overline{O}(H,-S_{i-1})$. Consequently, we have

$$0 \neq v \in \bigcap_{i=1}^{N} \left\{ \left[\Phi_\xi^{\mathrm{n}}(t_i)\right]^{-1} \left[\overline{O}(H,S_i) \cap \left(\mathcal{Y}(S_i) - \widehat{x}_i\right) \cap \overline{O}(H,-S_{i-1}) \cap \left(\mathcal{Y}(-S_{i-1}) - \widehat{x}_i\right) \right] \right\},$$

which is a contradiction.

Conversely, suppose Theorem 5.8(b) holds, but there is a nonzero vector v belonging to the above intersection. We therefore have $\Phi_\xi^{\mathrm{n}}(t_i)[\xi+v] \in \mathcal{Y}(S_i) \cap \mathcal{Y}(-S_{i-1})$ for

all $i = 0, \ldots, N-1$. Since $\Phi^{\rm n}_\xi(t_i)\xi \in \mathcal{Y}(S_i) \cap \mathcal{Y}(-S_{i-1})$, it is clear that $\Phi^{\rm n}_\xi(t_i)[\xi + \kappa v] \in \mathcal{Y}(S_i) \cap \mathcal{Y}(-S_{i-1})$ for all $0 \leqslant \kappa \leqslant 1$, following the same argument in the proof of Theorem 4.5. For each i, we can apply the second statement of Lemma 4.10 to obtain two positive pairs $(\varepsilon_{i+}, \tau_{i+})$ and $(\varepsilon_{i-}, \tau_{i-})$ such that $\mathbf{c}^i e^{S_i(t-t_i)}\Phi^{\rm n}_\xi(t_i)[\xi + \kappa v] \geqslant 0$ for all $(t, \kappa) \in [t_i, t_i + \varepsilon_{i+}] \times (0, \tau_{i+}]$ and $\mathbf{c}^i e^{S_{i-1}(t_i-t)}\Phi^{\rm n}_\xi(t_i)[\xi + \kappa v] \geqslant 0$ for all $(t, \kappa) \in [t_i - \varepsilon_{i-}, t_i] \times (0, \tau_{i-}]$. Define $\varepsilon' = \min_{1 \leqslant i \leqslant N} \varepsilon_{i\pm}$ and $\tau' = \min_{1 \leqslant i \leqslant N} \tau_{i\pm}$. As a result, for all $t \in \cup_{1 \leqslant i \leqslant N}[t_i - \varepsilon', t_i + \varepsilon']$ and all $0 \leqslant \kappa \leqslant \tau'$,

$$\big(c^T x(t, \xi)\big)\big(c^T x(t, \xi + \kappa v)\big) \geqslant 0. \tag{5.3}$$

By Proposition 5.3, a neighborhood $\mathcal{N}$ of ξ and a positive number $\tau_0 \leqslant \tau'$ exist such that $\xi + \kappa v \in \mathcal{N}$ for all $\kappa \in [0, \tau_0]$ and that $\big(c^T x(t, \xi)\big)\big(c^T x(t, \xi + \kappa v)\big) > 0$ for all $t \in \cup_{1 \leqslant i \leqslant N}[t_{i-1} + \varepsilon', t_i - \varepsilon']$. Since (5.3) also holds for $0 \leqslant \kappa \leqslant \tau_0$, we have $\big(c^T x(t, \xi)\big)\big(c^T x(t, \xi + \kappa\, v)\big) \geqslant 0$ for all $t \in [0, T]$ and $0 \leqslant \kappa \leqslant \tau_0$. Hence $(\xi, \xi + \kappa\, v)$ are two T-time mode consistence states for all $0 \leqslant \kappa \leqslant \tau_0$. Thus, for all $0 \leqslant \kappa \leqslant \tau_0$, $Hx(t, \xi + \kappa v) = H\Phi^{\rm n}_\xi(t)[\xi + \kappa v] = H\Phi^{\rm n}_\xi(t)\xi + \kappa H\Phi^{\rm n}_\xi(t)v$. Notice that for any $t \in [t_i, t_{i+1}]$, we have $H\Phi^{\rm n}_\xi(t)v = He^{S_i(t-t_i)}\Phi^{\rm n}_\xi(t_i)v$. Since $\Phi^{\rm n}_\xi(t_i)v \in \overline{O}(H, S_i) \cap \overline{O}(H, -S_i)$, $He^{S_i(t-t_i)}\Phi^{\rm n}_\xi(t_i)v \equiv 0$ for all $t \in [t_i, t_{i+1}]$ and all $i = 0, \ldots, N-1$. Consequently, $H\Phi^{\rm n}_\xi(t)v \equiv 0$ on $[0, T]$. This suggests that $(\xi, \xi + \kappa\, v)$ are two T-time indistinguishable states for all $0 \leqslant \kappa \leqslant \tau_0$. By Proposition 5.5, $v \in \mathcal{Z}^\xi_T$ and thus $(\xi + \kappa v) \in \mathcal{M}^\xi_T \cap (\xi + \mathcal{Z}^\xi_T) \cap \mathcal{N}$ for all $0 \leqslant \kappa \leqslant \tau_0$. As a result, for any small neighborhood of $\mathcal{V} \subseteq \mathcal{N}$, $(\xi + \kappa v) \in \mathcal{M}^\xi_T \cap (\xi + \mathcal{Z}^\xi_T) \cap \mathcal{V}$ for some $0 < \kappa \leqslant \tau_0$. This contradicts Theorem 5.8(b). ∎

5.3. Long-time observability. The finiteness of T is needed to ensure the applicability of Lemma 5.9 in the proof of the sufficiency part of Theorem 5.8. In what follows, we establish the long-time (i.e., $T = \infty$) local observability of ξ for the bimodal CLS (2.9) under various conditions, one of which postulates that the trajectory $x(t, \xi)$ has a switching time $t_* > 0$; this is a time for which $\delta > 0$ exists such that $c^T x(t, \xi)$ is of one nonzero sign in $(t_* - \delta, t_*)$ and of a different nonzero sign in $(t_*, t_* + \delta)$. Note that any trajectory $x(t, \xi)$ such that $c^T x(t, \xi)$ changes sign at least once must have a switching time, provided that $\xi \notin \overline{O}(c^T, A)$.

PROPOSITION 5.11. *Any of the conditions* (a), (b), *and* (c) *below is sufficient for* ξ *to be long-time locally observable for the bimodal system* (2.9)*:*

(a) $\overline{O}(H, A) = \{0\}$ *and there exists* $t_* \geqslant 0$ *such that* $c^T x(t_*, \xi) < 0$*;*
(b) $\overline{O}(H, A + bc^T) = \{0\}$ *and there exists* $t_* \geqslant 0$ *such that* $c^T x(t_*, \xi) > 0$*;*
(c) $\overline{O}(H, A) \cap \overline{O}(H, A + bc^T) = \{0\}$ *and the trajectory* $x(t, \xi)$ *has a switching time.*

Proof. Under condition (a) or (b), the state $x(t_*, \xi)$ is short-time, and thus long-time, locally observable, by Corollary 4.7 and Proposition 4.11. To prove the same under condition (c), we assume without loss of generality that for some $\delta > 0$, $c^T x(t, \xi)$ is positive on $[t_* - \delta, t_*)$ and negative on $(t_*, t_* + \delta]$. Localizing the proof of Lemma 5.9 to the compact interval $\mathcal{T}_* \equiv [t_* - \delta, t_* + \delta]$ and using the time invariance of the bimodal system, we deduce the existence of a neighborhood $\mathcal{N}$ of ξ such that any state $\eta \in \mathcal{N}$ that is indistinguishable from ξ in the interval $\mathcal{T}_*$ must be mode consistent with ξ on the same interval. Suppose that ξ is not long-time locally observable. There exists a sequence of vectors $\{\eta^k\} \subset \Omega^\xi_\infty$ converging to ξ such that $\eta^k \neq \xi$ for all k. It follows that for k sufficiently large, η^k must be mode consistent with ξ on the interval $\mathcal{T}_*$.

Hence we have

$$He^{(A+bc^T)(t-t_*+\delta)}x(t_*-\delta,\xi) = He^{(A+bc^T)(t-t_*+\delta)}x(t_*-\delta,\eta^k) \quad \forall\,[\,t_*-\delta,t_*\,),$$
$$He^{A(t-t_*)}x(t_*,\xi) = He^{A(t-t_*)}x(t_*,\eta^k) \qquad \forall\,(\,t_*,t_*+\delta\,].$$

It follows that $x(t_*,\xi)-x(t_*,\eta^k) \in \overline{O}(H,A+bc^T)\cap\overline{O}(H,A)$. Hence $x(t_*,\xi)=x(t_*,\eta^k)$, which yields $\xi=\eta^k$, a contradiction! □

We close this section by presenting numerical examples to illustrate several counter-intuitive properties of the long-time observability of an initial state ξ as well as the states along the trajectory $x(t,\xi)$. These examples also demonstrate the difficulties of designing constructive tests for long-time observability. The first example shows that in order for ξ to be long-time locally observable, it is possible that no state on the trajectory $x(t,\xi)$ is short-time observable. This example strengthens Example 4.12 which concerns mainly properties of the initial state.

Example 5.12. Consider a bimodal system in $\mathbb{R}^3$ with

$$A=\begin{bmatrix}\lambda_1 & 0 & 0\\ 0 & \lambda_2 & 0\\ 0 & 0 & \lambda_3\end{bmatrix},\ b=\begin{pmatrix}b_1\\0\\0\end{pmatrix},\ c=\begin{pmatrix}c_1\\c_2\\c_3\end{pmatrix},\ \text{and } H=\begin{bmatrix}h_1 & h_2 & 0\end{bmatrix},$$

where $\lambda_3>\lambda_2>\lambda_1>0$, $b_1\neq 0$, $c_1c_2c_3\neq 0$, $h_1h_2\neq 0$,

$$\lambda_2\,\lambda_3\,(\,\lambda_3-\lambda_2\,)+\lambda_1\,\lambda_2\,(\,\lambda_2-\lambda_1\,)+\lambda_3\,\lambda_1\,(\,\lambda_1-\lambda_3\,)\neq 0, \tag{5.4}$$

and $h_2(\lambda_1-\lambda_2+b_1c_1)=h_1b_1c_2$. Straightforward computations show that

$$\overline{O}(H,A)=\text{span}\,\{(0,0,1)\} \quad \text{and} \quad \overline{O}(H,A+bc^T)=\text{span}\{(h_2,-h_1,0)\}.$$

Notice that $\overline{O}(H,A)\cap\overline{O}(H,A+bc^T)=\{0\}$. Since both of the above two subspaces contain nonzero states, it follows from Corollary 4.7 that the bimodal CLS has no short-time local observable states. However, the condition (5.4) ensures that $\overline{O}(c^T,A)=\{0\}$. Hence for any $\xi\neq 0$, the trajectory $c^Tx(t,\xi)$ can have only isolated zeros. Pick an initial state ξ such that $c^T\xi<0$ but $c_3\xi_3>0$. Then $c^Tx(t,\xi)<0$ for all $t\geqslant 0$ sufficiently small, but $c^Tx(t,\xi)$ must eventually become positive. Thus the trajectory $x(t,\xi)$ must have a switching time. By Proposition 5.11, such an initial state must be long-time locally observable.

The next example shows that the long-time local observability of a state does not imply its long-time global observability.

Example 5.13. Consider a bimodal system in $\mathbb{R}^2$ with

$$A=\begin{bmatrix}\lambda & 0\\ 0 & \lambda-b_2c_2\end{bmatrix},\ b=\begin{pmatrix}0\\b_2\end{pmatrix},\ c=\begin{pmatrix}c_1\\c_2\end{pmatrix},\ \text{and } H=\begin{bmatrix}1 & 1\end{bmatrix},$$

where $\lambda>0$, $b_2\neq 0$, $c_1c_2<0$, and $b_2c_2>0$. It is clear that $\overline{O}(H,A)=\{0\}$. Choose $\xi=(\xi_1,0)$ with $c_1\xi_1<0$. Hence, $c^Te^{At}\xi=e^{\lambda t}c_1\xi_1\leqslant c_1\xi_1<0$ for all $t\geq 0$, implying that $x(t,\xi)=e^{At}\xi=(e^{\lambda t}\xi_1,0)$ for all $t\geqslant 0$. Hence such a ξ is short-time, and thus long-time locally observable. Yet, ξ is not long-time globally observable because by considering $\eta=(0,\xi_1)$, we have $c^T\eta=c_2\xi_1>0$. Since $c^Te^{(A+bc^T)t}\eta=e^{\lambda t}c_2\xi_1>0$, implying that $x(t,\eta)=(0,e^{\lambda t}\xi_1)$ for all $t\geqslant 0$. Thus, ξ and η are long-time indistinguishable. Hence ξ is not long-time globally observable.

Our last example shows that for a state to be long-time locally observable, it is not necessary for this state and any future state along the nominal trajectory to be T-time locally observable for any finite $T \geqslant 0$. In other words, even if an initial state (and any future state along the nominal trajectory) is not T-time locally observable for any finite $T \geqslant 0$, it is still possible that the CLS is long-time locally observable at the initial state.

Example 5.14. Consider a bimodal system in $\mathbb{R}^3$ with

$$A = \begin{bmatrix} \lambda & 0 & 0 \\ 0 & \alpha & \omega \\ 0 & -\omega & \alpha \end{bmatrix},\ b = \begin{pmatrix} b_1 \\ 0 \\ 0 \end{pmatrix},\ c = \begin{pmatrix} c_1 \\ c_2 \\ 0 \end{pmatrix},\ \text{and } H = \begin{bmatrix} 1 & 0 & 0 \end{bmatrix},$$

where $\lambda < 0$, $\alpha > 0$, $\omega > 0$, $b_1 \neq 0$, and c_1 and c_2 are both nonzero. Let $\xi = (\xi_1, 0, 0)$ with $c_1\xi_1 < 0$. It follows that $x(t, \xi) = (e^{\lambda t}\xi_1, 0, 0)$ and $c^T x(t, \xi) = e^{\lambda t}c_1\xi_1 < 0$ for all $t \geqslant 0$. Let $v_I = (0, 1, 0)$ and $v_R = (0, 0, 1)$. It is easy to see that $\overline{O}(H, A) = \text{span}\{v_I, v_R\}$ and $\overline{O}(H, A + bc^T) = \{0\}$. Note that any $\eta \in \overline{O}(H, A)$ with $\|\eta\|_2 = 1$ can be written as $\eta(\phi) = v_I \sin\phi + v_R \cos\phi$ for some $\phi \in [0, 2\pi)$ and that

$$e^{At}\eta(\phi) = e^{\alpha t}\big[(-v_I \sin\phi + v_R \cos\phi)\sin(\omega t) + (v_R \sin\phi + v_I \cos\phi)\cos(\omega t)\big].$$

Moreover, any initial state that is indistinguishable over the time interval when the corresponding state trajectory is in the mode characterized by A must be of the form $\xi + \tau\eta(\phi)$ for some $\tau \in \mathbb{R}$ and $\phi \in [0, 2\pi)$. Hence, for any given $T \geqslant 0$, there is a $\tau_{_T} > 0$ such that for all $(t, \tau, \phi) \in [0, T] \times [-\tau_{_T}, \tau_{_T}] \times [0, 2\pi)$,

$$\begin{aligned} c^T x(t, \xi + \tau\eta(\phi)) &= c_1\xi_1 e^{\lambda t} + \tau c_2 e^{\alpha t}\big[-\sin\phi\sin(\omega t) + \cos\phi\cos(\omega t)\big] \\ &= c_1\xi_1 e^{\lambda t} + \tau c_2 e^{\alpha t}\cos(\omega t + \phi) < 0. \end{aligned}$$

Note that $Hx(t, \xi) = Hx(t, \xi + \tau\eta(\phi))$ for all such triples (t, τ, ϕ). Hence, ξ is not T-time locally observable. The same argument applies to any future state along the nominal trajectory. However, notice that no matter how small $|\tau| > 0$ is and what $\phi \in [0, 2\pi)$ is, $c^T x(t, \xi + \tau\eta(\phi))$ will become positive in some finite time. Hence, $x(t, \xi + \tau\eta(\phi))$ will switch to the mode characterized by $(A + bc^T)$ at some $t_* > 0$; i.e., $c^T x(t_*, \xi + \tau\eta(\phi)) = 0$ but $c^T x(t, \xi + \tau\eta(\phi)) > 0$ for all $t > t_*$ sufficiently close to t_*. Let $\widetilde{x} = x(t_*, \xi + \tau\eta(\phi))$. Note that $0 \neq \widetilde{x} \notin \overline{O}(c^T, A)$, which implies that $H(A+bc^T)^\ell\widetilde{x} \neq HA^\ell x(t_*, \xi)$ for some nonnegative integer ℓ. We have $x(t, \xi+\tau\eta(\phi)) = e^{(A+bc^T)(t-t_*)}\widetilde{x}$ for all $t > t_*$ sufficiently close to t_*. By the proof of Lemma 5.9, $Hx(t, \xi) \equiv Hx(t, \xi + \tau\eta(\phi))$ for all $t \geqslant 0$ only when $\tau = 0$. This establishes that ξ is long-time locally observable.

SPECTRAL FACTORIZATION OF A CLASS OF MATRIX-VALUED SPECTRAL DENSITIES*

HENDRA I. NURDIN†

Abstract. Recently, a necessary and sufficient uniform log-integrability condition has been established for the canonical spectral factorization mapping to be sequentially continuous. However, this condition, along with several other equivalent conditions, is not straightforward to verify. In this paper, we first derive a new set of easily checkable sufficient conditions which guarantee uniform log-integrability. Based on the newly derived conditions, we establish the existence of certain convergent rational approximations for a class of matrix-valued spectral densities. We then propose a new spectral factorization algorithm and provide convergence results. Our approach does not require the spectral density to be coercive. Numerical examples are given to illustrate the effectiveness and convergence of the proposed algorithm. In particular, we compute approximate spectral factors of the noncoercive and nonrational Kolmogorov and von Karman power spectra which arise in the study of turbulence.

Key words. spectral factorization, nonrational spectral density, rational approximation, rational covariance extension, second order stochastic processes

1. Background and motivation.

It is known that a discrete-time second order wide sense stationary stochastic process with a power spectral density, or simply a *spectral density* or *spectrum*, satisfying a certain Szegö or Paley–Wiener condition can be modeled as the output of a discrete-time causal linear time invariant system (i.e., a "shaping filter") driven by white noise [28]. If the spectral density is rational, then determining a shaping filter is possible by spectral factorization of the spectral density, and there are practical algorithms to do this. In the case when the spectral density is nonrational, obtaining a spectral factor is much more difficult, and explicit spectral factorization can be done only in special cases. Apart from deriving shaping filters, computation of spectral factors plays an important role in the theory of optimal and robust control. A survey of spectral factorization methods for both rational and nonrational spectral densities is given in [26].

Given a scalar spectral density W, a particular rational spectral density W_n, known as a *maximum entropy* spectrum, can be constructed whose first n terms of the covariance sequence match those of W. Matching of partial covariance sequences is a natural approach since every spectral density is associated with a unique covariance sequence, and both give a complete and equivalent characterization of some purely nondeterministic wide sense stationary stochastic process [24, 28]. H_n, the canonical

spectral factor of W_n, can be constructed recursively via the Szegö–Levinson algorithm (see, e.g., [11, 24]), and it is a well known that H_n converges to H, the canonical spectral factor of W, in $\mathcal{H}^2$ (see section 2 for notation) as $n \to \infty$; therefore also W_n converges to W in $\mathcal{L}^1$. However, H_n obtained in this way is an all-pole transfer function. Since H_n has no zeros, it has long been observed that $H_1, H_2, \ldots$ converges slowly to H when the latter has zeros on or close to the unit circle; some examples can be found in, e.g., [14, sect. IV], [5, pp. 214–217], and [6, section 6]. Intuitively, this is due to the inability of W_n to reproduce valleys of W (i.e., points for which W has a small value) for small or medium n. Similar slow convergence is also true when the matrix version of the Szegö–Levinson algorithm (see [29, 10]) is applied to a matrix-valued spectrum W with transmission zeros on or close to the unit circle [29]. More formally, it was shown in [13, 14] that if W is scalar and rational, then its zeros close to or on the unit circle decrease the rate of decay of the Schur parameters of W: the convergence rate decreases as a zero approaches the unit circle (see also [20]). In particular, when W has roots on the unit circle, the rate of convergence is no longer geometric. Consequently, good approximations can be achieved only for large n. This limitation of the maximum entropy spectra motivated research into the development of rational spectral densities which (1) matches the first few terms of the covariance sequence of W, and (2) has zeros at specified locations on the complex plane. A new theory of rational covariance extension with a degree constraint was later developed, which makes possible the construction of such spectra. Indeed, it has been demonstrated in [5, 6] that a finite dimensional spectrum constructed via the new theory, by suitably placing zeros on the unit disc, is a better estimate than the corresponding maximum entropy estimate, in the sense that it is able to better capture features of the true spectrum.

This paper develops a new approach to spectral factorization of a spectral density W based on constructing a sequence of rational approximations $\{W_n\}$ with freely specified zeros and which match partial covariance sequences of W. The construction is achieved by taking advantage of a recent result on continuity of the spectral factorization mapping given in [3] and the theory of degree constrained rational covariance extensions [13, 14, 7, 5, 6, 22, 21]. We derive theoretical results on convergence of this scheme for continuous W, and conditions on the zeros for convergence to be achieved, under further mild assumptions on W. Convergence of covariance matching approximations with freely specified zeros has not been studied in the literature; convergence results have been established only for the case when W_n has no zeros, i.e., the maximum entropy method/Szegö–Levinson algorithm. In particular, our results weaken some conditions previously derived by Anderson [1], Caines and Baykal-Gürsoy [8], and Mari, Dahlèn, and Lindquist [20] for convergence of $\{H_n\}$ to H in $\mathcal{H}^2$ or $\mathcal{H}^\infty$. Then in section 7 of this paper, several numerical examples are given that show the advantage of the proposed approach over the popular maximum entropy method: lower degree approximations with lower approximation error (defined in a certain sense).

The organization of this paper is as follows. In section 2 we introduce the notation and recall some definitions and results from the literature. Following that, in section 3 we discuss a result on sequential continuity of the spectral factorization mapping. In section 4 we derive a new set of easily checkable and sufficient conditions for uniform log-integrability of a sequence of spectral densities. In sections 5 and 6 we develop the theoretical foundation of a new approach to spectral factorization and introduce a new spectral factorization algorithm for a class of matrix-valued spectral densities. We then present a number of numerical examples using the proposed spectral factorization algorithm in section 7. Finally, in section 8 we give the conclusions of this paper and discuss potential applications of the results as well as directions for future research.

2. Main notation and basic definitions. In this section we introduce the main notation used throughout the paper and also recall some definitions and relevant results from the literature.

- $\mathbb{R}$, $\mathbb{C}$, $\mathbb{D}$, and $\mathbb{T}$ denote the set of real numbers, complex numbers, the open unit disc $= \{z \in \mathbb{C} : |z| < 1\}$, and the unit circle (the boundary of $\mathbb{D}$), respectively.
- $\overline{A}$ denotes the completion of A.
- A^* and $\Re\{A\} = A + A^*$ denote the Hermitian transpose and Hermitian part of a complex matrix A, respectively.
- $\mathbb{N}$ denotes the set of natural numbers $1, 2, 3, \ldots$.
- $\log c$ denotes the natural logarithm of c.
- A *pseudopolynomial* is a matrix-valued function f of the form

$$f(z) = \sum_{i=-m}^{n} A_i z^i,$$

  where $0 \le m, n < \infty$, and $A_i \in \mathbb{C}^{l\times l}$ $(l \in \mathbb{N})$ for $i = -m, \ldots, n$.
- The $\|\cdot\|_p$ norm of a matrix $A \in \mathbb{C}^{m\times n}$ is defined as [3]

$$\|A\|_p = \begin{cases} \left(\operatorname{tr}\{(A^*A)^{p/2}\}\right)^{1/p} & \text{if } 1 \le p < \infty, \\ \sup_{v\in\mathbb{C}^n, \|v\|\le 1} \|Av\| & \text{if } p = \infty. \end{cases}$$

- μ denotes the Lebesque measure on $\mathbb{T}$.
- $\mathcal{L}^p_{m\times n}$, $1 \le p \le \infty$, denotes the space of measurable functions mapping from $\mathbb{T}$ to $\mathbb{C}^{m\times n}$ with a finite $\|\cdot\|_p$ norm defined by

$$\|f\|_p = \begin{cases} \left(\frac{1}{2\pi}\int_{\mathbb{T}} \|f(z)\|_p^p d\mu\right)^{1/p} & \text{if } 1 \le p < \infty, \\ \operatorname{ess\,sup}_{z\in\mathbb{T}} \|f(z)\|_\infty & \text{if } p = \infty. \end{cases}$$

  If $n = 1$, we write $\mathcal{L}^p_{m\times n}$ simply as $\mathcal{L}^p_m$.
- $\mathcal{H}^p_{m\times n}$, $1 \le p \le \infty$, denotes the subspace of functions in $\mathcal{L}^p_{m\times n}$ having an analytic continuation from $\mathbb{T}$ to $\mathbb{D}$. If $n = 1$, we write $\mathcal{H}^p_{m\times n}$ simply as $\mathcal{H}^p_m$.
- H_* denotes the *para-Hermitian conjugate* of H: $H_*(z) = H(z^{*-1})^*$.

If H is a rational element of $\mathcal{H}^p_{n\times n}$ or $\mathcal{L}^p_{n\times n}$, then the degree of H, denoted by $\deg(H)$, is defined to be the McMillan degree of H. Let $\mathcal{P}_n$ denote the linear space of $\mathbb{C}^n$-valued trigonometric polynomials on $\mathbb{T}$. It is well known that this space is dense in $\mathcal{L}^p_n$ for all $p \in [1, \infty)$. In a similar fashion we define the linear space $\mathcal{P}^+_n$ to be the set of $\mathbb{C}^n$-valued polynomials on $\mathbb{C}$. We may view $\mathcal{P}^+_n$ as a linear subspace of $\mathcal{P}_n$. A function $\rho \in \mathcal{H}^2_{n\times n}$ is said to be *outer* if $\overline{\rho\mathcal{P}^+_n} = \mathcal{H}^2_n$, i.e., the set of products $\rho\mathcal{P}^+_n$ is dense in $\mathcal{H}^2_n$ [3]. In the special case when $n = 1$ (the scalar case) and ρ is a rational function, it is known that ρ is outer if and only if all its zeros and poles lie in $\mathbb{C}\backslash\mathbb{D}$.

A function W which maps from $\mathbb{T}$ to $\mathbb{C}^{n\times n}$ is a *spectral density* if (1) it is in $\mathcal{L}^1_{n\times n}$, and (2) there exists an outer function $H \in \mathcal{H}^2_{n\times n}$ such that $W(e^{i\theta}) = H(e^{i\theta})^* H(e^{i\theta})$. Note that the definition implies that $W^* = W$ and W is nonnegative definite almost everywhere (a.e.) $\mathbb{T}$. The function H is called a *spectral factor* of W. A spectral factor can be uniquely specified if a condition is imposed on its value at the origin. We call the *unique* spectral factor, which is positive definite at the origin, the *canonical spectral factor* (CSF). We say that W is *rational* if each element W_{ij} is of the form $W_{ij}(e^{i\theta}) = \frac{P_{ij}(e^{i\theta})}{Q_{ij}(e^{i\theta})}$ for some scalar pseudopolynomials P_{ij} and Q_{ij}, and *coercive* if

W has no zeros on $\mathbb{T}$. A precise characterization of spectral densities is given in the following classical result.

THEOREM 2.1 (see [27, 18, 28, 26]). *A nonnegative definite function $W \in \mathcal{L}^1_{n\times n}$ is a spectral density if and only if $\int_{\mathbb{T}} |\log\det W(z)|\,\mu(dz) < \infty$.*

For a function $f : \mathbb{T} \to \mathbb{R}$ we write $f > 0$ ($f \geq 0$) if f is positive (nonnegative) definite a.e. $\mathbb{T}$, and $f > g$ ($f \geq g$) will be taken to mean $f - g > 0$ ($f - g \geq 0$).

3. Sequential continuity of the spectral factorization mapping. Let W be a spectral density and let $\Phi(W)$ denote its unique CSF. Then the mapping $\Phi : W \mapsto \Phi(W)$ is called the *spectral factorization mapping*. It was recently shown in [3] that the mapping Φ is *sequentially continuous*; see the following theorem.

THEOREM 3.1. *Let W be a spectral density, and let $\{W_r\}_{r\in\mathbb{N}}$ be a sequence of spectral densities such that $W_r \to W$ in $\mathcal{L}^1_{n\times n}$ as $r \to \infty$. Then the following are equivalent:*

1. *The sequence $\{\log\det W_r\}_{r\in\mathbb{N}}$ is uniformly integrable.*
2. *$\Phi(W_r) \to \Phi(W)$ in $\mathcal{H}^2_{n\times n}$ as $r \to \infty$.*

Recall that a family of scalar measurable functions $\{X_\gamma \mid \gamma \in \Gamma\}$ parametrized by a nonempty set Γ on a measurable space $(\Omega, \mathcal{F})$ with measure M is said to be *uniformly integrable* if $\lim_{\alpha\to\infty} \sup_{\gamma\in\Gamma} \int_{\{\omega\in\Omega||X_\gamma(\omega)|>\alpha\}} |X_\gamma(\omega)|M(d\omega) = 0$.

Remark 3.2. We shall refer to the condition in point 1 of Theorem 3.1 as *uniform log-integrability*.

Several conditions which are equivalent to uniform log-integrability are given in [3, Prop. 4.2]. However, these conditions are general and do not indicate how to construct a uniformly log-integrable sequence $\{W_r\}_{r\in\mathbb{N}}$ which converges to W in $\mathcal{L}^1_{n\times n}$. For this reason, we shall shortly develop more explicit sufficient conditions.

4. A sufficient and verifiable set of conditions for uniform log-integrability. In this section we shall derive a new set of conditions on the sequence of convergent spectral densities *and* the limiting spectral density which ensures that the uniform log-integrability condition of Theorem 3.1 is satisfied. To this end, for $\alpha \geq 0$, let us define

$$\begin{aligned} A_r(\alpha) &= \{z \in \mathbb{T} \mid |\log\det W_r(z)| > \alpha\}, \\ A_{r+}(\alpha) &= \{z \in \mathbb{T} \mid \det W_r(z) > e^{\alpha}\}, \\ A_{r-}(\alpha) &= \left\{z \in \mathbb{T} \mid \det W_r(z) < e^{-\alpha}\right\}, \end{aligned}$$

and note that $A_{r+}(\alpha) \cap A_{r-}(\alpha) = \phi$ and $A_r(\alpha) = A_{r+}(\alpha) \cup A_{r-}(\alpha)$. The set $A_{r+}(\alpha)$ is the collection of points at which $\det W_r$ has "large" values and which may grow to ∞ as $\alpha \to \infty$, while $A_{r-}(\alpha)$ is the set of points where $\det W_r$ take on "small" values and can diminish to 0 as $\alpha\to\infty$. Then we have the following inequality:

$$\begin{aligned} \sup_{r\in\mathbb{N}} \int_{A_r(\alpha)} |\log\det W_r(z)|d\mu \leq\ & \sup_{r\in\mathbb{N}} \int_{A_{r+}(\alpha)} \log\det W_r(z)d\mu \\ & + \sup_{r\in\mathbb{N}} \int_{A_{r-}(\alpha)} -\log\det W_r(z)d\mu. \end{aligned} \tag{4.1}$$

The main idea here is to derive sufficient conditions for each of the two terms on the right-hand side of (4.1) such that they go to 0 as $\alpha \to \infty$. It turns out that finding conditions to guarantee the desired effect on the first term is relatively easy. As for the second term, the conditions are more complicated. To have that term go to 0 as $\alpha \to \infty$, the idea is to impose conditions which exclude the existence of a set

of positive Lebesque measure on which $\det W_r$ decays to zero as $r \to \infty$. Before going into the formal details, we note the following matrix inequality.

LEMMA 4.1. *For any nonnegative definite matrix* $A \in \mathbb{C}^{n\times n}$, $\log\det A \le \|A\|_1$.

Proof. Note that the result is trivial if A is singular, since in this case we have $\log\det A = -\infty$. Therefore we assume that A is *positive definite*. Let $\sigma_1, \sigma_2, \ldots, \sigma_n$ be the singular values of A, with $\sigma_1 \ge \sigma_2 \ge \cdots > 0$. Since A is positive definite, we have that $\det(A^*) = \det(A)$ and $\log\det A = \frac{1}{2}\log\det(AA^*) = \sum_{k=1}^n \log\sigma_k$. On the other hand, we also have that $\|A\|_1 = \operatorname{tr}((AA^*)^{\frac{1}{2}}) = \sum_{k=1}^n \sigma_k$, and the result follows since $\log\sigma_k \le \sigma_k$ for $k = 1, \ldots, n$. ∎

First, let us make the following assumptions.

A1. $\operatorname{ess\,sup}_{z\in\mathbb{T}} \|W_r(z)\|_1 < \infty$ for all $r \in \mathbb{N}$.

A2. The sequence $\{W_r\}_{r\in\mathbb{N}}$ converges in $\mathcal{L}^1_{n\times n}$ to W as $r \to \infty$.

Now we can show the following result.

LEMMA 4.2. *Under* assumptions A1–A2*,*

$$\lim_{\alpha\to\infty} \sup_{r\in\mathbb{N}} \int_{A_{r+}(\alpha)} \log\det W_r(z)\mu(dz) = 0.$$

Proof. By assumptions A1 and A2 we have (i) $\lim_{\alpha\to\infty}\sup_{r\in\mathbb{N}}\int_{A_{r+}(\alpha)} \|W(z) - W_r(z)\|_1\mu(dz) = 0$, and (ii) $\lim_{\alpha\to\infty}\sup_{r\in\mathbb{N}}\mu(A_{r+}(\alpha)) = 0$ (if the latter is not true, then we have $\sup_{r\in\mathbb{N}}\|W_r\|_1 = \infty$, which contradicts A1 and A2). It then follows from (ii) that (iii) $\lim_{\alpha\to\infty}\sup_{r\in\mathbb{N}}\int_{A_{r+}(\alpha)}\|W(z)\|_1\mu(dz) = 0$. Since $\|W_r(z)\|_1 \le \|W(z) - W_r(z)\|_1 + \|W(z)\|_1$, we get from (i) and (iii) that $\lim_{\alpha\to\infty}\sup_{r\in\mathbb{N}}\int_{A_{r+}(\alpha)} \|W_r(z)\|_1\mu(dz) = 0$. Lemma 4.1 then gives $\lim_{\alpha\to\infty}\sup_{r\in\mathbb{N}}\int_{A_{r+}(\alpha)}\log\det W_r(z)\mu(dz) = 0$, as desired. ∎

Let us impose three further assumptions on $\{W_r\}_{r\in\mathbb{N}}$.

A3. $W_r(e^{i\theta})$ is a piecewise continuous function of θ for each $r \in \mathbb{N}$.

A4. Let Z_a be the set defined by

$$Z_a = \Big\{ z_0 \in \mathbb{T} \mid \liminf_r f_r = 0 \ \forall \text{ neighborhoods } U \text{ of } z_0, f_r = \inf_{z\in U\cap\mathbb{T}} \det W_r(z) \Big\}.$$

Then the cardinality of Z_a is finite.

A5. Let Z_r be the set of all zeros of $\det W_r$ (i.e., all points $z_0 \in \mathbb{T}$ for which $\inf_{z\in U\cap\mathbb{T}}\det W_r(z) = 0$ for all neighborhoods U of z_0). Then there exists $M_1, M_2, \Delta_1, \Delta_2 > 0$ such that for any $r \in \mathbb{N}$ and any $\theta_{0,r} \in (-\pi, \pi]$ such that $e^{i\theta_{0,r}} \in Z_r \cup Z_a$,

$$\det W_r(e^{i\theta}) \ge M_1 |\theta - \theta_{0,r}|^{M_2} \ \forall \theta \in [\theta_{0,r} - \Delta_1, \theta_{0,r} + \Delta_2] \cap (-\pi, \pi]. \tag{4.2}$$

Remark 4.3. Assumption A5 implies that the cardinality of Z_r is uniformly bounded (away from ∞).

We have the following result.

LEMMA 4.4. *Under assumptions* A3–A5*,*

$$\lim_{\alpha\to\infty} \sup_{r\in\mathbb{N}} \int_{A_{r-}(\alpha)} -\log\det W_r(z)\mu(dz) = 0.$$

Proof. Let $\theta_{r,1},\dots,\theta_{r,n_r}$ be the angles (in $(-\pi,\pi]$) of elements of $Z_r \cup Z_a$. Then $n_r \le L$ for all r, where L is some finite positive integer. Define

$$\tilde{A}_{r-}(\alpha) = \left\{\theta \in (-\pi,\pi] \mid e^{i\theta} \in A_{r-}(\alpha)\right\} \text{ and}$$
$$\tilde{A}_{r-,k}(\alpha) = \tilde{A}_{r-}(\alpha) \bigcap \{\theta \in (-\pi,\pi] \mid -\Delta_1 \le \theta - \theta_{r,k} \le \Delta_2\}$$

for $i = 1,\dots,n_r$. Note that $\theta_{r,k} \in \tilde{A}_{r-}(\alpha)$ for $k = 1,\dots,n_r$ and that $\tilde{A}_{r-,k}$ can be empty for some k's. Clearly, assumptions A3–A5 imply that for some α_0 large enough and $\alpha > \max\{\alpha_0, -\log(M_1(\min\{\Delta_1,\Delta_2\})^{M_2})\}$, $\tilde{A}_{r-,k}(\alpha)$ are disjoint for $k = 1,\dots,n_r$, independently of r, and $\tilde{A}_{r-}(\alpha) = \bigcup_{k=1}^{n_r} \tilde{A}_{r-,k}(\alpha)$. Furthermore, without loss of generality we may take M_1 to have a value less than 1. Hence the following holds:

$$\begin{aligned}
\int_{A_{r-}(\alpha)} -\log\det W_r(z)d\mu &= \sum_{k=1}^{n_r} \int_{\tilde{A}_{r-,k}(\alpha)} -\log\det W_r(e^{i\theta})d\theta, \\
&\le \sum_{k=1}^{n_r} \int_{\tilde{A}_{r-,k}(\alpha)} -\log\left(M_1|\theta-\theta_{r,k}|^{M_2}\right) d\theta, \\
&\le -\mu(A_{r-}(\alpha))\log M_1 \\
&\quad + M_2 \sum_{k=1}^{n_r} \int_{\tilde{A}_{r-,k}(\alpha)} -\log|\theta-\theta_{r,k}|\, d\theta. \qquad (4.3)
\end{aligned}$$

Let $\alpha_1 = \max\{\alpha_0, -\log(M_1(\min\{\Delta_1,\Delta_2\})^{M_2})\}$. Assumptions A3–A5 also imply that for $\alpha > \alpha_1$ there exists a number $\epsilon(\alpha) > 0$, dependent on α, such that $\lim_{\alpha\to\infty} \epsilon(\alpha) = 0$ and $\tilde{A}_{r-,k}(\alpha) \subset \theta_{r,k} + B(\alpha) = \{\theta \in (-\pi,\pi] \mid \theta = \theta_{r,k} + \omega; \omega \in B(\alpha)\}$, where $B(\alpha)$ is a set independent of r defined by $B(\alpha) = \{\theta \in (-\pi,\pi] \mid -\epsilon(\alpha)\Delta_1 \le \theta \le \epsilon(\alpha)\Delta_2\}$. Therefore from (4.3) we have

$$\begin{aligned}
\int_{A_{r-}(\alpha)} -\log\det W_r(z)d\mu &\le -\sum_{k=1}^{n_r} \Lambda(\theta_{r,k} + B(\alpha))\log M_1 \\
&\quad + M_2 \sum_{k=1}^{n_r} \int_{\theta_{r,k}+B(\alpha)} -\log|\theta-\theta_{r,k}| d\theta, \\
&\le -L\Lambda(B(\alpha))\log M_1 + LM_2 \int_{B(\alpha)} -\log|\theta| d\theta,
\end{aligned}$$

where Λ denotes the Lebesque measure on $(-\pi,\pi]$. Since the right-hand side of the last inequality $\to 0$ as $\alpha \to \infty$ independently of r, we conclude that

$$\lim_{\alpha\to\infty} \sup_{r\in\mathbb{N}} \int_{A_{r-}(\alpha)} -\log\det W_r(z)\mu(dz) = 0,$$

which is the statement we had set out to prove. ∎

A direct consequence of Lemmas 4.2 and 4.4 is the following theorem.

THEOREM 4.5. *Under assumptions* A1–A5*,*

$$\lim_{\alpha\to\infty} \sup_{r\in\mathbb{N}} \int_{A_r(\alpha)} |\log\det W_r(z)|\mu(dz) = 0,$$

i.e., the sequence $\{\log\det W_r\}_{r\in\mathbb{N}}$ *is uniformly integrable.*

Proof. This follows directly from Lemmas 4.2 and 4.4 by taking the limit $\alpha \to \infty$ on both sides of inequality (4.1). ∎

The above theorem has the following important corollary.

COROLLARY 4.6. *Let $W \in \mathcal{L}^1_{n\times n}$ with $\|\det W - f\|_1 = 0$ for some spectral density $f \in \mathcal{L}^1$ having a finite number of zeros on $\mathbb{T}$ (a zero is as defined in assumption* A5*). If $\{W_r\}_{r\geq 1}$ is a sequence of piecewise continuous spectral densities such that $\lim_{r\to\infty} \operatorname{ess\,sup}_{z\in\mathbb{T}} \|W(z) - W_r(z)\|_1 = 0$, then $\lim_{r\to\infty} \|\Phi(W) - \Phi(W_r)\|_2 = 0$.*

The corollary is a simple but useful result and relaxes the requirement $W > 0$ in [1, Thm. 1] (or [3, Cor. 6.2] with $p = 2$). We shall prove later on that a sequence satisfying the conditions of the corollary can be explicitly constructed under some regularity conditions on W.

5. Construction of convergent rational spectral densities with converging CSFs. In this section we give the main ideas for the construction of a sequence of rational spectral densities with CSFs converging to the true CSF. Let $\{W_r\}_{r\in\mathbb{N}}$ be a sequence of rational spectral densities having no poles on $\mathbb{T}$. We define

$$c_k = \frac{1}{2\pi}\int_{\mathbb{T}} W(z) z^{-k} \mu(dz) \quad \text{and} \quad c_{k,r} = \frac{1}{2\pi}\int_{\mathbb{T}} W_r(z) z^{-k} \mu(dz), \quad k = 0, 1, \dots .$$

The sequences $\{c_k\}_{k\in\mathbb{N}}$ and $\{c_{k,r}\}_{k\in\mathbb{N}}$ are the unique covariance sequences associated with W and W_r, respectively. By the Riemann–Lebesque lemma, $c_k \to 0$ as $k \to \infty$. The covariance sequence $c_{k,r}$ has the form

$$c_{k,r} = C_r A_r^k B_r + \sum_{m=0}^{m_r} D_{m,r} \Delta(k - m), \tag{5.1}$$

where A_r, B_r, C_r, and $D_{0,r}, D_{1,r}, \dots, D_{m_r,r}$ are $n \times n$ matrices with A_r having eigenvalues in $\mathbb{D}$, (A_r, B_r, C_r) is a minimal realization, and

$$\Delta(m) = \begin{cases} 1 & \text{if } m = 0, \\ 0 & \text{otherwise.} \end{cases}$$

The central idea of our construction is to require the sequence $\{W_r\}_{r\in\mathbb{N}}$ to satisfy

$$\deg \Phi(W_r) \leq n d_r, \tag{5.2a}$$

$$c_{k,r} = c_k \quad \text{for} \quad k = 0, 1, \dots, d_r, \tag{5.2b}$$

where $\{d_r\}_{r\in\mathbb{N}}$ is an increasing sequence of positive integers. That a sequence $\{W_r\}_{r\in\mathbb{N}}$ satisfying (5.2) exists and is computable is the content of the theory of a rational covariance extension with a degree constraint [14, 7, 6, 15, 22, 21]. Since $\|W - W_r\|_1 \geq \sup_{k\geq 0} \|c_k - c_{k,r}\|_1 \geq \sup_{0\leq k\leq d_r} \|c_k - c_{k,r}\|_1$, we see that the discrepancy between the first few terms of the covariance sequence of W and W_r yields a lower bound for the approximation error in $\mathcal{L}^1_{n\times n}$. Therefore, it makes sense to impose condition (5.2b). Moreover, since it is desirable to have W_r be as "simple" as possible, the constraint (5.2a) is also well motivated. Plugging the Fourier series expansion of W_r into the

definition of $\|W - W_r\|_1$, we obtain

$$\begin{aligned}\int_{\mathbb{T}} \|W(z) - W_r(z)\|_1 \mu(dz) &\le \int_{\mathbb{T}} \left\| W(z) - \sum_{k=0}^{d_r} \Re\{c_k z^k\} \right\|_1 \mu(dz) \\ &\quad + \left\| \int_{\mathbb{T}} \Re\Big\{ C_r A_r^{d_r+1} (I - A_r z)^{-1} B_r \right. \\ &\quad \left. + I_{\{d_r \le m_r - 1\}}(d_r) \sum_{m=d_r+1}^{m_r} D_{m,r} z^m \Big\} \mu(dz) \right\|_1 \\ &\le \int_{\mathbb{T}} \left\| W(z) - \sum_{k=0}^{d_r} \Re\{c_k z^k\} \right\|_1 \mu(dz) + \mathrm{R}(W_r, d_r), \end{aligned} \tag{5.3}$$

where $I_A(x)$ is the indicator function for the set A and

$$\mathrm{R}(W_r, d_r) = \left\| \Re\Big\{ C_r A_r^{d_r+1} \int_{\mathbb{T}} (I - A_r z)^{-1} \mu(dz) B_r \Big\} \right\|_1.$$

If W satisfies $\operatorname{ess\,sup}_{z\in\mathbb{T}} \|W(z)\|_1 < \infty$, the Fourier series of W converges to W in $\mathcal{L}^2_{n\times n}$, hence also in $\mathcal{L}^1_{n\times n}$. Therefore, the first term on the right-hand side of (5.3) goes to 0 as $r \to \infty$, and the following theorem is immediate.

THEOREM 5.1. *Suppose* $\operatorname{ess\,sup}_{z\in\mathbb{T}} \|W(z)\|_1 < \infty$ *and let* $\{W_r\}_{r\in\mathbb{N}}$ *be a sequence of rational spectral densities satisfying assumptions* A4–A5 *and the interpolation constraints of* (5.2). *If* $\lim_{r\to\infty} \mathrm{R}(W_r, d_r) = 0$, *then assumption* A2 *holds and* $\lim_{r\to\infty} \|\Phi(W) - \Phi(W_r)\|_2 = 0$.

It is reasonable to expect, at least intuitively, that there could be "many" sequences which satisfy the condition of Theorem 5.1 if the spectral density W is not too "irregular." Indeed, we see later in Corollaries 5.3 and 5.5 particular instances where this is true. Moreover, we will show that the approximating sequence $\{W_r\}$ can be constructed explicitly under some further, yet mild, assumptions on W.

5.1. The scalar case. We shall give a constructive proof of the following result.

THEOREM 5.2. *Let* W *be a continuous scalar spectral density and* $\|W - U/V\|_\infty = 0$, *where* U *and* V *are, respectively, continuous and Lipschitz spectral densities. If* $\{U_r\}_{r\ge1}$ *is a sequence of nonnegative definite pseudopolynomials converging uniformly to* U, *then the following statements hold:*

1. *If* $V > 0$, *there is a sequence* $\{V_r\}_{r\ge1}$ *of nonnegative pseudopolynomials such that* $W_r = U_r (V_r)^{-1}$ *satisfies* (5.2b) (*with* $n = 1$) *for all* r *sufficiently large.*

2. *If* $V \not> 0$, *but* (i) U (*hence also* V) *is zero only at a finite number of points on* $\mathbb{T}$, (ii) $W(e^{i\theta}) = 0$ *whenever* $V(e^{i\theta}) = 0$, (iii) $U_r(e^{i\theta}) = 0$ *only if* $U(e^{i\theta}) = 0$, *and* (*iv*) $\sup_r \|U_r/U\|_\infty < \infty$, *there is a sequence* $\{V_r\}_{r\ge1}$ *of nonnegative pseudopolynomials such that* $W_r = U_r(V_r)^{-1}$ *satisfies* $\frac{1}{2\pi}\int_{\mathbb{T}} W_r(z) z^{-k} \mu(dz) = c_k - s_{k,r}$, *where* $s_{k,r} = \sum_{l=1}^{k_r} K_l e^{ik\theta_l}$, $k_r \in \mathbb{N}$, *is at most* $d_r - 1$, $K_1, \dots, K_{k_r}$ *are some nonnegative constants, and* $\theta_1, \dots, \theta_{k_r} \in (-\pi, \pi]$ *with* $\theta_i \ne \theta_j$ *if* $i \ne j$.

In either case, $\{V_r\}_{r\ge1}$ *and* $\{W_r\}_{r\ge1}$ *converge in* $\mathcal{L}^\infty$ *to* V *and* W, *respectively. Moreover, if* $\deg U_r \le 2d_r$, *then* W_r *also satisfies* (5.2a).

Let l^2 denote the (standard) set of all square-summable infinite sequences. Let Γ_c denote the real linear space of all real-valued continuous functions on $\mathbb{T}$. Define the real linear space $\mathcal{F}_c$ as

$$\mathcal{F}_c = \left\{ (q_0, q_1, \dots) \in l^2 \,\middle|\, q_k = \frac{1}{2\pi}\int_{-\pi}^{\pi} e^{-ik\theta} W(e^{i\theta}) d\theta \ \forall k \ge 0, \text{ for some } W \in \Gamma_c \right\}.$$

Since a continuous function f is uniquely determined by its Fourier coefficients [19, Theorem 2.4] and since the negative Fourier coefficients are merely conjugates of the positive Fourier coefficients whenever f is a real-valued function, $\mathcal{F}_c$ is actually isomorphic to Γ_c. Therefore, we may uniquely identify any element of $\mathcal{F}_c$ with an element of Γ_c, and vice versa. By endowing Γ_c with a topology induced by the supremum norm and endowing $\mathcal{F}_c$ with a topology induced by the norm

$$\|q\| = \operatorname*{ess\,sup}_{\theta\in(-\pi,\pi]} \left| \sum_{k=0}^{\infty} \Re\{q_k e^{ik\theta}\} \right|$$

(since any element of Γ_c is continuous, the infinite sum converges pointwisely for almost all $z \in \mathbb{T}$ [19, Chapter 19]), we in fact have a homeomorphism from $\mathcal{F}_c$ to Γ_c. Moreover, $\mathcal{F}_c$ is then a closed set since Γ_c is. In what follows, we denote the homeomorphic map from $\mathcal{F}_c$ to Γ_c by Q. The map Q is linear: $Q(a_1 f_1 + a_2 f_2) = a_1 Q(f_1) + a_2 Q(f_2)$ for any $a_1, a_2 \in \mathbb{R}$ and any $f_1, f_2 \in \mathcal{F}_c$. We now define some relevant convex subsets of Γ_c and $\mathcal{F}_c$. Define Γ_c^+ to be the convex cone consisting of elements of Γ_c which are nonnegative on $\mathbb{T}$. We define the convex cone $\mathcal{F}_c^+$ analogously to $\mathcal{F}_c$ by replacing Γ_c with Γ_c^+. In a similar manner, we see that $\mathcal{F}_c^+$ is isomorphic to Γ_c^+. Endowing Γ_c^+ (resp., $\mathcal{F}_c^+$) with a topology derived from Γ_c (resp., $\mathcal{F}_c$), we also get that $\mathcal{F}_c^+$ is homeomorphic to Γ_c^+ under Q; i.e., if Q^+ is the restriction of Q to $\mathcal{F}_c^+$, then Q^+ is a homeomorphism from $\mathcal{F}_c^+$ to Γ_c^+. Define D_r to be the subset of $\mathcal{F}_c^+$ consisting of all $q = (q_0, q_1, \dots) \in \mathcal{F}_c^+$ such that $q_k = 0$ for all $k > r$ and the trigonometric polynomial $\sum_{k=0}^{r} \Re\{q_k e^{ik\theta}\} \geq 0$ for all $\theta \in (-\pi, \pi]$. Clearly, $D_s \supset D_r$ if $s > r$. Moreover, since the partial Fejér sums of any $f \in \Gamma_c^+$ are nonnegative pseudopolynomials and approximate f arbitrarily closely (for details on Fejér sums, see [19]), it is immediate that $\overline{\cup_{r\geq 0} D_r} = \mathcal{F}_c^+$.

Recall that a function f on $\mathbb{T}$ is *Lipschitz* if $\|f(e^{i\theta}) - f(e^{i\psi})\|_1 \leq K|\theta - \psi|$ for all $\theta, \psi \in (-\pi, \pi]$ for some positive constant K, and observe that a scalar spectral density $W \in \Gamma_c^+$ can be written as $W = U/V$ a.e., where V is any Lipschitz scalar spectral density and $U = WV$. Let W have the covariance sequence $\mathbf{c} = \{c_0, c_1, \dots\} \in l^2$. Define $\mathbf{c}_r = \operatorname{col}(c_0, c_1, \dots, c_r)$ to be the partial covariance sequence of $\mathbf{c}$ up to the rth term, and let $\mathbf{d}_r$ be an arbitrary element of D_r. The functional $\mathbb{J}^r : D_r \to \mathbb{R} \cup \{\infty\}$, parametrized by $\mathbf{c}_r$ and $\mathbf{d}_r$ is defined as

$$\mathbb{J}^r(q; \mathbf{c}_r, \mathbf{d}_r) = \Re\left\{ \sum_{k=0}^{r} \min\{k+1, 2\} c_k^* q_k - \langle Q_r(\mathbf{d}_r), \log Q_r(q) \rangle \right\}, \tag{5.4}$$

where $\langle f, g \rangle = \frac{1}{2\pi} \int_{-\pi}^{\pi} f(e^{i\theta}) g_*(e^{i\theta}) d\theta$ and Q_r is a map with domain D_r defined by

$$Q_r(q_0, q_1, \dots, q_r, 0, 0, \dots)(e^{i\theta}) = \sum_{k=0}^{r} \Re\{q_k e^{ik\theta}\}.$$

Notice that Q_r can be viewed as the restriction of Q to D_r. The functional $\mathbb{J}^r$ first appeared in [5, 6] and was studied further in [22, 21], so we shall not repeat the analysis of its properties here (actually, our formulation is slightly different. However, it causes no difficulty since the functionals studied in [5, 6, 22, 21] can be recovered by application of the linear invertible transformation $(q_0, q_1, \dots, q_r) \mapsto (q_0, \frac{1}{2}q_1, \dots, \frac{1}{2}q_r)$ and redefining D_r in an obvious way). $\mathbb{J}^r$ has the following properties:

P1. $\mathbb{J}^r$ is strictly convex on D_r and is continuous at all points except the origin.

P2. $\mathbb{J}^r$ has compact sublevel sets and a unique minimizer in D_r.

P3. $\mathbb{J}^r$ is infinitely differentiable along any line lying in the interior of D_r. Moreover, if $\mathbb{J}^r$ has a minimizer q_s which is stationary (i.e., the gradient is zero at q_s) then $\frac{Q(d_r)}{Q(q_s)}$ satisfies $\langle \frac{Q(d_r)}{Q(q_s)}, g_k\rangle = c_k$ for $k = 0, 1, \ldots, r$, where $g_k(z) = z^k$. Note that q_s is always a stationary point whenever $Q(\mathbf{d}_r)$ is positive definite [6, Thm. 4.10].

Let us now consider another functional $\mathbb{J} : \mathcal{F}_c^+ \to \mathbb{R} \cup \{\infty\}$ parametrized by the covariance sequence $\mathbf{c}$ and an infinite sequence $\mathbf{d} \in \mathcal{F}_c^+$ such that $Q(\mathbf{d}) = U$. It is defined as

$$\mathbb{J}(q; \mathbf{c}, \mathbf{d}) = \Re\{\mathrm{H}(q; \mathbf{c}) - \langle Q(\mathbf{d}), \log Q(q)\rangle\}, \tag{5.5}$$

where $\mathrm{H}(\cdot; \mathbf{c})$ is a linear function on $\mathcal{F}_c$, parametrized by $\mathbf{c}$, defined by

$$\mathrm{H}(q; \mathbf{c}) = \lim_{r\to\infty} \sum_{k=0}^{r} \min\{k+1, 2\} c_k^* q_k. \tag{5.6}$$

Since $q \in l^2$ whenever $q \in \mathcal{F}_c$ (recall the definition of $\mathcal{F}_c$) and $\mathbf{c} \in l^2$, it follows that $\sum_{k=0}^{\infty} \min\{k+1, 2\} c_k^* q_k < \infty$. Therefore, $\mathrm{H}(\cdot; \mathbf{c})$ is well defined for all $q \in \mathcal{F}_c$. Let us define the convex set $D_e(\mathbb{J}) = \{q \in \mathcal{F}_c^+ \mid \int_{\mathbb{T}} \log^- Q(q)(z)\mu(dz) < \infty\}$ (where $\log^- x = \max\{0, -\log x\}$); $D_e(\mathbb{J})$ is actually the *effective domain* (see, for example, [25]) of $\mathbb{J}$. Then clearly $\cup_{r\geq 1} D_r \subset D_e(\mathbb{J})$. Since $\|\cdot\|$ is also a norm on $D_e(\mathbb{J})$, we endow $D_e(\mathbb{J})$ with the topology induced by the $\|\cdot\|$ norm (this is precisely the relative topology of $D_e(\mathbb{J})$ as a subset of $\mathcal{F}_c^+$: open sets in $D_e(\mathbb{J})$ are sets of the form $D_e(\mathbb{J}) \cap O$ for any O which is an open set of $\mathcal{F}_c^+$). Continuing along the same line of argument as for $\mathbb{J}^r$, we may verify that $\mathbb{J}$ has property P4 (given below) and property P3 with $\mathbb{J}^r$ and D_r replaced by $\mathbb{J}$ and $D_e(\mathbb{J})$, respectively (an analogue of property P2 need not hold for $\mathbb{J}$ and will not be required in the following).

P4. $\mathbb{J}$ is strictly convex on $D_e(\mathbb{J})$ and continuous on the interior of $D_e(\mathbb{J})$.

In the remaining analysis, let us view $\mathbb{J}_\Psi$ as a convex functional that maps from the convex set $D_e(\mathbb{J})$ to $\mathbb{R}$. We now derive an expression for the directional derivatives of $\mathbb{J}$ following [22, 21]. Define

$$\mathcal{M}_{\mathbf{d}} = \Big\{ q \in D_e(\mathbb{J}) \mid \operatorname*{ess\,sup}_{\theta\in(-\pi,\pi]} Q(\mathbf{d})(e^{i\theta})(Q(q)(e^{i\theta}))^{-1} < \infty \Big\}.$$

Let $q' \in \mathcal{F}_c^+$, $0 < h < 1$, and suppose that $q \in \mathcal{M}_{\mathbf{d}}$. We observe that if $Q(q + h(q'-q))(z) = (1-h)Q(q)(z) + hQ(q')(z_0) = 0$ for some $z_0 \in \mathbb{T}$ and all $0 < h < 1$, then $Q(q)$ and $Q(q')$ must share a zero at the point z_0. On the other hand, if $Q(q+h(q'-q))(z) > 0$ for all $z \in \mathbb{T}$, then $Q(q)$ and $Q(q')$ cannot possibly have a zero in common on $\mathbb{T}$. As a result, by the mean-value theorem of calculus, we obtain

$$\begin{aligned} &Q(\mathbf{d})(z)\frac{\log Q(q+h(q'-q))(z) - \log Q(q)(z)}{h} \\ &\quad = Q(\mathbf{d})(z)\frac{\partial}{\partial v}\log Q(q+v(q'-q))(z)\Big|_{v=\eta(h,z)} \\ &\quad = Q(\mathbf{d})(z)\frac{Q(q') - Q(q)}{Q(q)(z) + \eta(h,z)Q(q'-q)(z)} \end{aligned} \tag{5.7}$$

for all $z \in \mathbb{T}$ such that $Q(q)(z) > 0$ (hence for almost all $z \in \mathbb{T}$ since $q \in \mathcal{M}_{\mathbf{d}}$), where $0 < \eta(h,z) \leq h$. Moreover, $q \in \mathcal{M}_{\mathbf{d}}$ implies that

$$\operatorname*{ess\,sup}_{(h,z)\in[0,\frac{1}{2}]\times\mathbb{T}} \frac{Q(\mathbf{d})(z)}{Q(q)(z) + \eta(h,z)Q(q'-q)(z)} < \infty. \tag{5.8}$$

Now, the directional derivative $\nabla_{q'-q}\mathbb{J}$ at q in the direction $q'-q$ is defined as

$$\nabla_{q'-q}\mathbb{J}(q;\mathbf{c},\mathbf{d}) = \lim_{h\downarrow 0}\frac{\mathbb{J}(q+h(q'-q);\mathbf{c},\mathbf{d})-\mathbb{J}(q;\mathbf{c},\mathbf{d})}{h}. \tag{5.9}$$

Plugging the definition of $\mathbb{J}$ into (5.9), and using (5.7) and (5.8) with the Lebesque dominated convergence theorem to bring h under the integral (this is essentially the same argument used in [22]), and finally evaluating the limit as $h \downarrow 0$, we obtain $\nabla_{q'-q}\mathbb{J}(q;\mathbf{c},\mathbf{d}) = H(q'-q) - \langle \frac{\Psi}{Q(q)}, Q(q') - Q(q)\rangle$. Let $\mathcal{F}_{c,\infty}^{+}$ denote the set of all elements a in $D_e(\mathbb{J})$ for which $Q(a)(e^{i\theta})$ is infinitely differentiable with respect to θ, and suppose that $Q(q)$ is Lipschitz and $Q(q')$ in $\mathcal{F}_{c,\infty}^{+}$. Then $\sum_{k=0}^{r} q_k e^{ik\theta}$ (resp., $\sum_{k=0}^{r} q_k' e^{ik\theta}$) converges uniformly to $Q(q)$ (resp., $Q(q')$) [9, Thm. 2, p. 142]. By plugging in the definition of H and using another application of the Lebesque dominated convergence theorem, we get

$$\nabla_{q'-q}\mathbb{J}(q;\mathbf{c},\mathbf{d}) = \lim_{r\to\infty}\sum_{k=0}^{r}\min\{k+1,2\}\Re\left\{\left(c_k^* - \int_{\mathbb{T}}\frac{Q(\mathbf{d})(z)}{Q(q)(z)}z^k\mu(dz)\right)(q_k'-q_k)\right\}$$

for all $q \in \mathcal{M}_{\mathbf{d}}$ and all $q' \in \mathcal{F}_{c,\infty}^{+}$. However, since $\mathcal{F}_{c,\infty}^{+}$ is dense in $\mathcal{F}_{c}^{+}$ (hence also in $D_e(\mathbb{J})$), the preceding expression for $\nabla_{q'-q}\mathbb{J}(q;\mathbf{c},\mathbf{d})$ is valid for all $q \in \mathcal{M}_{\mathbf{d}}$ and all $q' \in \mathcal{F}_{c}^{+}$. Now, setting $q_{\#} = Q^{-1}(V)$ (hence $Q(q_{\#})$ is Lipschitz and $q_{\#} \in \mathcal{M}_{\mathbf{d}}$), we obtain

$$\sum_{k=0}^{r}\min\{k+1,2\}\left(c_k - \int_{\mathbb{T}}\frac{Q(\mathbf{d})(z)}{Q(q_{\#})(z)}z^{-k}\mu(dz)\right)^{*} = 0\,\forall\, r.$$

It therefore follows that $\nabla_{q'-q_{\#}}\mathbb{J}(q_{\#};\mathbf{c},\mathbf{d}) = 0$ for all $q' \in \mathcal{F}_{c}^{+}$, so $q_{\#}$ is a stationary point of $\mathbb{J}$ and, by property P4, must also be the unique minimizer of $\mathbb{J}$.

Suppose now that $\{\mathbf{d}_r\}_{r\in\mathbb{N}}$ is such that $\lim_{r\to\infty}\|\mathbf{d}_r - \mathbf{d}\| = 0$ with $\mathbf{d} = Q^{-1}(U)$ as defined previously. Let $\mathbb{J}\big|_{D_r}\colon D_r \to \mathbb{R}\cup\{\infty\}$ denote the restriction of $\mathbb{J}$ to D_r defined by

$$\mathbb{J}\big|_{D_r}(q;\mathbf{c},\mathbf{d}) = \Re\left\{\sum_{k=0}^{r}\min\{k+1,2\}c_k^* q_k - \langle Q(\mathbf{d}), \log Q_r(q)\rangle\right\}.$$

Since $Q(d) = U$ is continuous on $\mathbb{T}$ and is zero only on a subset of $\mathbb{T}$ of μ-measure zero, the analysis of $\mathbb{J}^r$ in [5, 6, 22] readily carries over to $\mathbb{J}\,|_{D_r}$ to show that the latter also has properties P1, P2, and P3 (with $\mathbb{J}^r$ replaced by $\mathbb{J}\big|_{D_r}$). Moreover, defining

$$s_r = \arg\min_{q\in D_r}\mathbb{J}\big|_{D_r}(q;\mathbf{c},\mathbf{d}),$$

it is then clear that $\lim_{r\to\infty} s_r = q_{\#}$. Hence, for any $\epsilon > 0$ we will have $\|q_{\#} - s_r\| < \frac{\epsilon}{2}$ by taking large enough r. Then also $\|q - q_{\#}\| \le \|q - s_r\| + \|s_r - q_{\#}\| \le \epsilon$ whenever $\|q - s_r\| \le \frac{\epsilon}{2}$ (recall that $q, q_{\#}, s_r \in D_e(\mathbb{J})$). Therefore, for all r large enough, $\{q \in D_r \mid \|q - s_r\| \le \frac{\epsilon}{2}\} \subset \{q \in D_e(\mathbb{J}) \mid \|q - q_{\#}\| \le \epsilon\}$ and

$$\begin{aligned}\sup_{\{q\in D_r, \|q-s_r\|\le\frac{\epsilon}{2}\}}|\mathbb{J}\big|_{D_r} - \mathbb{J}^r| &= \sup_{\{q\in D_r \mid \|q-s_r\|\le\frac{\epsilon}{2}\}}|\langle Q(\mathbf{d}) - Q(\mathbf{d}_r), \log Q_r(q)\rangle| \\ &\le \sup_{\{q\in D_e(\mathbb{J})\mid\|q-q_{\#}\|\le\epsilon\}}|\langle Q(\mathbf{d}) - Q(\mathbf{d}_r), \log Q(q)\rangle| \\ &\le \|Q(\mathbf{d}) - Q(\mathbf{d}_r)\|D,\end{aligned}$$

where $D = \max_{\{q\in D_e(\mathbb{J})|\|q-q_\#\|\le\epsilon\}} |\int_{-\pi}^{\pi} \log Q(q)(e^{i\theta})d\theta|$. Since $\lim_{r\to\infty} \|Q(\mathbf{d})-Q(\mathbf{d}_r)\| = 0$, it then follows that

$$\lim_{r\to\infty} \max_{\{q\in D_r|\|q-s_r\|\le\frac{\epsilon}{2}\}} \left|\mathbb{J}\big|_{D_r}(q;\mathbf{c},\mathbf{d}) - \mathbb{J}^r(q;\mathbf{c}_r,\mathbf{d}_r)\right| = 0$$

for any $\epsilon > 0$. Due to properties P1, P2, and P3 of $\mathbb{J}\big|_{D_r}$ and $\mathbb{J}^r$, the preceding limit implies that $\lim_{r\to\infty}\|s_r - q_{\#,r}\| = 0$, where $q_{\#,r} = \arg\min_{q\in D_r} \mathbb{J}^r(q;\mathbf{c}_r,\mathbf{d}_r)$; for the details see a proof of [22, Theorem 13] (replace Ψ, Ψ_k, $\mathbb{J}_\Psi$, and $\mathbb{J}_{\Psi_k}$ with $Q(\mathbf{d})$, $Q(\mathbf{d}_k)$, $\mathbb{J}\big|_{D_k}$ and $\mathbb{J}^k$, respectively). Furthermore, since $\|q_\# - q_{\#,r}\| \le \|q_\# - s_r\| + \|s_r - q_{\#,r}\|$ and both terms on the right tend to 0 as $r\to\infty$, we get $\lim_{r\to\infty}\|q_\# - q_{\#,r}\| = 0$ and $\lim_{r\to\infty}\|Q(q_\#) - Q(q_{\#,r})\| = 0$. Consequently, if $V > 0$, then $q_\#$ is in the interior of $D_e(\mathbb{J})$ and the same is true for $q_{\#,r}$ for all r sufficiently large. Therefore, W_r satisfies (5.2) for all r sufficiently large, and $W_r = \frac{Q(\mathbf{d}_r)}{Q(q_{\#,r})} \to W = \frac{Q(\mathbf{d})}{Q(q_\#)}$ uniformly as $r\to\infty$.

If $V \not> 0$, but assumptions (i)–(iv) in Theorem 5.2 (2) are satisfied, convergence of $\{W_r\}$ to W in $\mathcal{L}^\infty$ can again be established. Let $V_r = Q(q_{\#,r})$. Since $V_r \to V$ uniformly, we have that for any $\delta > 0$ $\exists R(\delta)\in\mathbb{N}$ such that $-\delta < V_r(e^{i\theta}) - V(e^{i\theta}) < \delta$ for all θ and for all $r > R(\delta)$. However, since $V, V_r \ge 0$ and V, V_r are continuous for all r, and $\exists R'\in\mathbb{N}$ such that $V_r(e^{i\theta}) > 0$ for all $r > R'$ whenever $V(e^{i\theta}) > 0$ (due to assumptions (i) and (iii) and the observation that all zeros of V_r on $\mathbb{T}$ are also zeros of U_r [22, 21] and $V_r \to V$ uniformly), there is a *continuous* function $f_\delta : \mathbb{T}\to[0,1]$ such that (a) $V - \delta f_\delta \ge 0$, (b) $(V-\delta f_\delta)(e^{i\theta}) = 0$ if and only if $V(e^{i\theta}) = 0$, and (c) $-\delta f_\delta < V_r - V < \delta$ for all θ and for all $r > \max\{R(\delta), R'\}$. In particular, letting $S(\delta) = \max\{R(\delta), R'\}$ we may always take f_δ to be $f_\delta = \sup_{r>S(\delta)}(V - V_r)/\delta$ (and we shall do so in what follows) and satisfy all the requirements. Then $V/V_r < V/(V-\delta f_\delta) = 1/(1-\delta f_\delta/V)$ a.e. $\mathbb{T}$ for all $r > S(\delta)$. Moreover, $1/(1-g_\delta/V)\in\mathcal{L}^\infty$ for all δ sufficiently small, where $g_\delta = \delta f_\delta = \sup_{r>S(\delta)}(V - V_r)$. To see this, first observe that property (a) of f_δ implies $g_\delta/V \le 1$ a.e. $\mathbb{T}$. Then we observe that $g_\delta \downarrow 0$ (i.e., g converges monotonically to 0) uniformly on $\mathbb{T}$ as $\delta\downarrow 0$ and hence, since also $g_\delta \le V$ for all $\delta > 0$, for sufficiently small δ we will have $g_\delta < V$ for all $z\in\mathbb{T}$ except those for which $V(z) = 0$. Therefore, $\|g_\delta/V\|_\infty < 1$ and $1/(1-g_\delta/V) < \infty$ a.e. for sufficiently small δ, as claimed, and it follows that $\sup_{r>S(\delta)}\|V/V_r\|_\infty < \infty$. Now, let $N_{\delta'}(z) = \{y\in\mathbb{T} \mid |z-y| < \delta'\}$ for any $z\in\mathbb{T}$ and $\delta' > 0$. Then we note that V/V_r (resp., $V/V_r - 1$) converges uniformly to 1 (resp., 0) on $\mathbb{T}\setminus\cup_{k=1}^m N_{\delta'}(z_k)$, where $z_1,\ldots,z_m\in\mathbb{T}$ are all zeros of V, for δ' small enough such that $\cup_{k=1}^m N_{\delta'}(z_k)$ is a strict subset of $\mathbb{T}$. By uniform convergence of U_r to U and assumption (iv), an analogous remark is also true for U_r/U. Next, we make the observation that $|W_r - W| = |U_r/V_r - U/V| \le W|U_r/U - 1|V/V_r + W|V/V_r - 1|$. Then the properties of V/V_r and U_r/U just stated, along with assumptions (i)–(ii) and the continuity of W, imply that both $W|U_r/U-1|V/V_r$ and $W|V/V_r-1|$ converge uniformly to 0 as $r\to\infty$. To see this, let us consider the term $W|U_r/U-1|V/V_r$ and let R'' be large enough such that $M = \sup_{r>R''}\|U_r/U-1\|_\infty\|V/V_r\|_\infty < \infty$ (recall that $\sup_{r>S(\delta)}\|V/V_r\|_\infty < \infty$). Then, by assumption (ii) and the continuity of W, for any $\epsilon > 0$ we may choose $\delta' > 0$ small enough such that $\sup_{\{z\in\cup_{k=1}^m N_{\delta'}(z_k)\}} W(z) < \epsilon/M$ a.e. followed by choosing $r > R''$ which is large enough such that $\sup_{\{z\in\mathbb{T}\setminus\cup_{k=1}^m N_{\delta'}(z_k)\}}|U_r(z)/U(z)-1|V(z)/V_r(z) < \epsilon/\|W\|_\infty$. In other words, for any $\epsilon > 0$ $\exists R'''(\epsilon)$ such that $\|W|U_r/U-1|V/V_r\|_\infty < \epsilon$ for all $r > R'''(\epsilon)$. The same line of arguments may then be applied to $W|V/V_r-1|$. In conclusion, we again have $W_r \overset{\mathcal{L}^\infty}{\to} W$ as $r\to\infty$. The fact that $\frac{1}{2\pi}\int_{\mathbb{T}} W_r(z)z^{-k}\mu(dz) = c_k - s_{k,r}$ as stated in the theorem has been shown in the proof of [21, Thm. 8].

Finally, we note that the preceding analysis remains valid if $\mathbf{d}_r \in D_r$ is replaced with $\mathbf{d}_r \in \cup_{k>r} D_k$. To see this, let $\mathbf{d}_r$ be any pseudopolynomial, *not necessarily* of degree at most r, and define $\mathbb{J}^r$ as in (5.4). Then it may be verified that $\mathbb{J}^r$ again has properties P1, P2, and P3, and if q_s is a stationary point minimizer of $\mathbb{J}^r$, then $\frac{Q(d_r)}{Q(q_s)}$ once more satisfies $\langle \frac{Q(d_r)}{Q(q_s)}, g_k \rangle = c_k$ for $k = 0, 1, \ldots, r$. The rest of the analysis follows mutatis mutandis. This completes the proof of Theorem 5.2. □

An important consequence of the theorem combined with Corollary 4.6 and [1, Theorem 2] is the following.

COROLLARY 5.3. *Suppose $W \in \mathcal{L}^1$ is a continuous spectral density with a finite number of zeros on $\mathbb{T}$ and let $\{W_r\}_{r\geq 1}$ be a sequence as defined in Theorem* 5.2. *Then* $\lim_{r\to\infty} \|\Phi(W_r) - \Phi(W)\|_2 = 0$. *If, in addition, $W > 0$ and $\frac{d}{d\theta} W(e^{i\theta}) \in \mathcal{L}^2$, then also* $\lim_{r\to\infty} \|\Phi(W_r) - \Phi(W)\|_\infty = 0$.

Notice that the corollary gives a weaker condition for convergence in the $\|\cdot\|_\infty$ norm than analyticity (resp., rationality and boundedness) and positivity of W given in [8, Thm. 1] (resp., [20, Thm. 3.4]) for the Szegö–Levinson algorithm and does not restrict $\Phi(W_r)$ to have all its zeros at the origin. Note that we say W is analytic if it can be continued analytically from all points in $\mathbb{T}$.

5.2. The matrix case. For a matrix-valued spectral density W, the situation is slightly more complicated. If W is a matrix-valued Lipschitz spectral density, then we may write $W = (W^{-1})^{-1} = \det(W)\mathrm{adj}(W)^{-1}$, where $\mathrm{adj}(W)$ denotes the adjoint of W. Define $U = P \det W$ and $V = P\,\mathrm{adj}(W)$ for any arbitrary scalar spectral density P which is Lipschitz and positive definite. Then U and V are Lipschitz. The representation $W = UV^{-1}$ a.e. can be viewed as the matricial counterpart of the scalar fractional representation. If W is positive definite, then so is V and, in this case, by suitably redefining the sets Γ_c, $\mathcal{F}_c$, Γ_c^+, $\mathcal{F}_c^+$, D_r and the associated norms with their respective matricial counterparts, as well as suitably modifying the functionals $\mathbb{J}^r$ and $\mathbb{J}$ (see [4, eq. (V.5), p. 2180]), it is a relatively straightforward, but tedious, exercise to adapt the analysis developed in deriving Theorem 5.2 to the matrix case. Then we may show the following counterpart of Theorem 5.2.

THEOREM 5.4. *Let $W = UV^{-1} \in \mathcal{L}^1_{n\times n}$ be a matrix-valued positive definite Lipschitz spectral density, where $U = P \det W$ and $V = P\mathrm{adj}(W)$ for some positive definite Lipschitz scalar spectral density P. If $\{U_r\}_{r\geq 1}$ is a sequence of positive definite pseudopolynomials converging uniformly to U, then there exists a (unique) sequence $\{V_r\}_{r\geq 1}$ of positive definite pseudopolynomials such that*

1. *$W_r = U_r(V_r)^{-1}$ satisfies* (5.2b) *for all r. If, in addition,* $\deg U_r \leq 2nd_r$, *then* (5.2a) *is also satisfied.*
2. *$\{V_r\}_{r\geq 1}$ and $\{W_r\}_{r\geq 1}$ converge uniformly to V and W, respectively.*

We then get the following from Corollary 4.6 and [1, Thm. 2].

COROLLARY 5.5. *Let $\{W_r\}_{r\in\mathbb{N}}$ be a sequence as defined in Theorem* 5.4. *Then* $\lim_{r\to\infty} \|\Phi(W_r) - \Phi(W)\|_2 = 0$. *If, in addition, $W > 0$ and $\frac{d}{d\theta} W(e^{i\theta}) \in \mathcal{L}^2_{n\times n}$, then also* $\lim_{r\to\infty} \|\Phi(W_r) - \Phi(W)\|_\infty = 0$.

It is plausible that Theorem 5.4 and Corollary 5.5 can be extended to the case where U has zeros on $\mathbb{T}$. However, to do this, we must allow some spectral zeros (see [4]) of W_r to be on $\mathbb{T}$. This is currently an open problem.

6. A spectral factorization algorithm. We now introduce a new algorithm for spectral factorization of a special class $\mathcal{W}_n$ of spectral densities. $\mathcal{W}_1$ denotes the set of spectral densities $W \in \mathcal{L}^1$ which can be continued analytically from every point $z \in \mathbb{T}$, except from a finite number of points $w_k = e^{i\theta_k}$, $k = 1, \ldots, M$, for which

$W(w_k)=0$ and $\lim_{z\in\mathbb{T},z\to w_k}\frac{|z-w_k|^{m_k}}{W(z)}<\infty$ for some integer $m_k\geq 1$. For $n>1$, $\mathcal{W}_n$ denotes the set of spectral densities in $\mathcal{L}^1_{n\times n}$ which are positive definite and can be continued analytically from every point on $\mathbb{T}$. We state the algorithm below followed by a discussion of the steps involved and a convergence analysis.

6.1. The algorithm.

Given: A spectral density $W\in\mathcal{W}_n$, the desired accuracy $\epsilon>0$ and maximum number of iterations $r_{\max}$.

Initialize: Normalize W so that $c_0=I$. Let $e^{i\lambda_1},\dots,e^{i\lambda_L}\in\mathbb{T}$ be the local minima of $\det W$ satisfying $0\leq\det W(e^{i\lambda_l})\leq\alpha$ ($\alpha\in\mathbb{R}$, $\alpha\geq 0.2$. The rule of thumb is $\alpha=0.2$). Let $\mathcal{V}_1$ be all points in $\{e^{i\lambda_1},\dots,e^{i\lambda_L}\}$ from which $\det W$ does not have an analytic continuation and $\mathcal{V}_2=\{e^{i\lambda_1},\dots,e^{i\lambda_L}\}\backslash\mathcal{V}_1$. For $l=1,\dots,L$, define $m_l=\min\{k\in\mathbb{N}\mid\lim_{z\in\mathbb{T},z\to e^{i\lambda_l}}\frac{|z-e^{i\lambda_l}|^k}{W(z)}<\infty\}$ if $e^{i\lambda_l}\in\mathcal{V}_1$ and $m_l=\min\{k\in\mathbb{N}\mid D^k_\theta\det W(e^{i\lambda_l})\neq 0\}$ if $e^{i\lambda_l}\in\mathcal{V}_2$ (here $D^m_\theta\det W(e^{i\lambda_l})=\frac{d^m\det W(e^{i\theta})}{d\theta^m}\big|_{\theta=\lambda_l}$). Let $\eta_0(z)=\prod_{l=1}^L(z-v_l)^{\frac{m_l}{2}}$, where $v_l=\max\{0,r_l\}e^{i\lambda_l}$ $\big($with $r_l=1-\big(\frac{\det W(e^{i\lambda_l})}{D^{m_l}_\theta\det W(e^{i\lambda_l})}\big)^{\frac{1}{m_l}}\big)$ if $e^{i\lambda_l}\in\mathcal{V}_2$, and $v_l=e^{i\lambda_l}$ if $e^{i\lambda_l}\in\mathcal{V}_1$. Set $r=1$, $d_0=L$, and compute $c_0,c_1,\dots,c_L$ and the outer polynomial matrix $R_0=\phi(V_0)$, where $V_0=Q(\arg\min_{q\in D_{d_0}}\mathbb{J}^{d_0}(q))$ (see section 5).

Step 1. Select a point $z_r\in\mathbb{D}$. Then

1. if W is symmetric (i.e., $W(e^{-i\theta})=W(e^{i\theta})$) or $\theta_r\notin\{0,\pi\}$, set $d_r=d_{r-1}+2$ and $\eta_r=\eta_{r-1}(z-z_r)(z-z_r^*)$; otherwise
2. set $d_r=d_{r-1}+1$, and $\eta_r=\eta_{r-1}(z-z_r)$.

Step 2. Compute $c_{d_{r-1}+1},\dots,c_{d_r}$ and the outer matrix polynomial $R_r=\phi(V_r)$, where $V_r=Q(\arg\min_{q\in D_{d_r}}\mathbb{J}^{d_r}(q))$.

Step 3. Compute $e_r=\frac{1}{2}\|W-W_r\|_1+\frac{1}{2}\|\Phi(W_r)-\Phi(W_{r-1})\|_2$, where $W_r=\eta_{r*}\eta_r(R_rR_{r*})^{-1}$. If $e_r>\epsilon$ and $r\leq r_{\max}$, set $r=r+1$ and return to Step 1.

End: $z^{d_r}\eta_{r*}(R_r)^{-1}\sqrt{c_0}$ is the approximate CSF.

Computation of the polynomial matrix R_r, $r=0,1,2,\dots$, is given in [12, 4]. By the analysis of [22], the method of [12] is applicable to the case when η_r has zeros on $\mathbb{T}$ if the optimization problem defined in [12] has a stationary point minimizer (which is true whenever $V_r>0$); that the minimizer is in fact always stationary is shown in [23]. The main idea of the algorithm is to find a sequence $z_1,z_2,\dots\in\overline{\mathbb{D}}$ such that $W_r=U_rV_r^{-1}$ satisfies (5.2) and $W_r\to W$ in $\mathcal{L}^\infty_{n\times n}$, where $U_r(z)=\eta_0\eta_{0*}\Pi_{k=1}^{d_r-L}(z-z_k)(z-z_k)_*$. It works as follows. Suppose $e^{i\lambda_l}\in\mathcal{V}_2$; then $\det W$ has an analytic continuation to some open set containing $e^{i\lambda_l}$. Moreover, if $D^m_\theta\det W(e^{i\lambda})=0$ for $m=1,\dots,l$, then also $(\det W)^{(m)}(e^{i\theta})=(\det W)^{(m)}(z)\big|_{z=e^{i\lambda_l}}=0$ ($(\det W)^{(m)}$ denotes the mth derivative of the analytic continuation of $\det W$). Since $e^{i\lambda_l}$ is a local minimum, we have that $D^{m_l}_\theta\det W(e^{i\lambda_l})>0$. Let us take care of points $z\in\mathbb{T}$ for which $\det W(z)\approx 0$. We take these to be the points $e^{i\lambda_1},\dots,e^{i\lambda_L}$ as defined in the algorithm. For $e^{i\lambda_l}\in\mathcal{V}_2$, the Taylor series expansion of $\det W(z)$ about $e^{i\lambda_l}$ gives $\det W(z)\approx\det W(e^{i\lambda_l})+(-ie^{-i\theta})^{m_l}D^{m_l}_\theta\det W(e^{i\lambda_l})(z-e^{i\lambda_l})^{m_l}$ for z sufficiently close to $e^{i\lambda_l}$. To estimate a zero of $\det W(z)$ about $e^{i\lambda_l}$, we set $\det W(z)=0$ to get $|z-e^{i\lambda_l}|\approx\big(\frac{\det W(e^{i\lambda_l})}{D^{m_l}_\theta\det W(e^{i\lambda_l})}\big)^{\frac{1}{m_l}}$. Assuming $z_l=r_le^{i\lambda_l}$ with $0\leq r_l\leq 1$ for our zero estimate, we obtain $|1-r_l|=\big(\frac{\det W(e^{i\lambda_l})}{D^{m_l}_\theta\det W(e^{i\lambda_l})}\big)^{\frac{1}{m_l}}$. Thus, we choose $r_l=1-\big(\frac{\det W(e^{i\lambda_l})}{D^{m_l}_\theta\det W(e^{i\lambda_l})}\big)^{\frac{1}{m_l}}$ and set $v_l=\max\{0,r_l\}e^{i\lambda_l}$ (hence, automatically $v_l=e^{i\lambda_l}$ if

$\det W(e^{i\lambda_l}) = 0$). As elaborated in section 1, points $z \in \mathbb{T}$ for which $\det W(z) \approx 0$ slow down convergence significantly due to slow decay of the so-called Schur parameters [14]. The main idea in the algorithm is to reduce their influence by suitably placing a zero of η_0 in their vicinity as in [14, 5, 6], but here we allow the degree of the approximation W_r to increase as required.

Remark 6.1. $v_1, \dots, v_L$ in $\mathbb{D}$ actually serve as estimates of zeros of $\det W$ in some open annulus $\{z \in \mathbb{C} \mid 1 - \delta < |z| < 1\}$ $(0 < \delta < 1)$. As such, other schemes can be used to determine these points. The "rule of thumb" $\alpha = 0.2$ is based on the subjective view that it is "not too small" and "not too large." If convergence of the algorithm is slow, say, $e_r > 10^{-2}$ in the first few (5–10) iterations, one may try restarting the algorithm with α increased, or the next remark may be taken into consideration.

Remark 6.2. If $\det W$ has thin and sharp "spectral line"–like peaks, then the algorithm may perform poorly. This is because such a peak indicates the possible presence of a (noncancelling) pole and zero close to each other and to the unit circle, while the zero is not included in η_0 [14]. To remedy the situation, let $H \in \mathcal{H}^2$ be a scalar notch filter with narrow stop bands around frequencies corresponding to the peaks, $P = H_* H$, and apply the algorithm to $W' = WP$. Then $\Phi(W) \approx \frac{\Phi(W')}{H}$ in $\mathcal{H}^2$.

The following theorem gives a requirement on $z_1, z_2, \dots$ for convergence:

THEOREM 6.3. *Let η_r be as defined in the algorithm. Suppose that the polynomial $\rho_r(z) = z^{d_r} \frac{\eta_{r*}(z)}{\eta_{0*}(z)} \overset{\mathcal{L}^\infty}{\to} \rho$, where ρ is continuous and has no zeros on $\mathbb{T}$. Let $W \in \mathcal{W}_1$ (resp., $\mathcal{W}_n$, $n > 1$), $U_r(z) = \eta_{r*}(z)\eta_r(z)$, and let V_r be as defined in Theorem* 5.2 *(resp., Theorem* 5.4*). Then $z^{d_r}\eta_{r*}(\Phi(V_r))^{-1}$ converges to $\Phi(W)$ in $\mathcal{H}^2$ (resp., $\mathcal{H}^2_{n\times n}$) and also in $\mathcal{H}^\infty$ (resp., $\mathcal{H}^\infty_{n\times n}$) if $W > 0$ and, when $n = 1$, $\frac{d}{d\theta}W(e^{i\theta}) \in \mathcal{L}^2$.*

Proof. Assume that W has been normalized so that $c_0 = I$. Let $U = \eta_0 \rho_* \rho \eta_{0*}$ and define V by $V(e^{i\theta}) = \lim_{\lambda \to \theta} U_*(e^{i\lambda})U(e^{i\lambda})W(e^{i\lambda})^{-1}$. Then, by definition, $V \in \mathcal{L}^\infty_{n\times n}$ and $\|W - UV^{-1}\|_\infty = 0$. Note that $\eta_r = z^{d_r}\eta_0\rho_{r*}$ and let $U_r = \eta_{r*}\eta_r$. Then, since $\rho_r \overset{\mathcal{L}^\infty}{\to} \rho$, we have that $U_r \overset{\mathcal{L}^\infty}{\to} U$. By Theorem 5.2 and Corollary 5.3, or Theorem 5.4 and Corollary 5.5 (whichever pair is applicable), it follows that V_r and $W_r = U_r V_r^{-1}$ converge in $\mathcal{L}^\infty_{n\times n}$, respectively, to V and W, and $\Phi(W_r)$ converges to $\Phi(W)$ in $\mathcal{H}^2_{n\times n}$ and also in $\mathcal{H}^\infty_{n\times n}$ if $W > 0$ and, when $n = 1$, $\frac{d}{d\theta}W(e^{i\theta}) \in \mathcal{L}^2$ (by the definition of $\mathcal{W}_n$, $\frac{d}{d\theta}W(e^{i\theta}) \in \mathcal{L}^2_{n\times n}$ is automatically satisfied when $W \in \mathcal{W}_n$, $n > 1$). Since $\Phi(W_r) = \Phi(U_r)(\Phi(V_r))^{-1} = z^{d_r}\eta_{r*}(\Phi(V_r))^{-1}$, scaling back by multiplication of both $\Phi(W)$ and $\Phi(W_r)$ on the right with $\sqrt{c_0}$ gives the desired result. ∎

Remark 6.4. Clearly, if $z_r = 0$ for all $r > R$ $(R \in \mathbb{N})$, then ρ_r converges uniformly to the analytic function $\rho = \prod_{k=1}^{R}(1 - z_k^* z)$, and the algorithm converges.

6.2. General approximation strategy. The algorithm requires $W \in \mathcal{W}_n$ for some $n \in \mathbb{N}$. If this is not the case, but W is continuous and has a finite number of zeros, then the strategy would be to first construct an approximating analytic spectral density (which need not be rational) in $\mathcal{L}^\infty_{n\times n}$. Then we apply the spectral factorization algorithm to the approximation to obtain an approximate CSF of $\Phi(W)$. The fact that the analytic approximation does not have to be rational affords us flexibility in choosing a set of basis functions for the approximation.

6.3. Heuristic scheme for selection of spectral zeros. In Theorem 6.3 we gave an explicit condition on the spectral zeros $z_1, z_2, \dots$ for the spectral factorization algorithm to converge, and we mentioned a particular situation when this condition is automatically met. In the following we give an intuitive heuristic scheme for choosing

$z_1, z_2, \ldots$ for scalar W. The idea goes as follows. For each r (including $r = 0$) we have at Step 1 that $\int_{-\pi}^{\pi} \big(W_r(e^{i\theta}) - W(e^{i\theta})\big)\, d\theta = 0$. If $W_r - W$ is not identically zero (for which the algorithm then terminates), then it is easy to show, using the mean-value theorem of calculus, that $\exists\theta$ such that $W_r(e^{i\theta}) - W(e^{i\theta}) > 0$. Since a zero of W_r can decrease the magnitude of W_r in certain regions of $\mathbb{T}$, the main idea now is to try to reduce the excess (or overshoot) of W_r over W at a point θ_r for which the excess is relatively large (preferably the largest). If W is not symmetric or $\theta_r \in \{0, \pi\}$, then we place a zero at $z_r = Re^{i\theta_r}$ (with $0 < R < 1$ so that $z_r \in \mathbb{D}$) such that $\frac{W_{r-1}(z)|z-z_r|^2}{W(z)}\big|_{z=e^{i\theta_r}} = \frac{W_{r-1}(e^{i\theta_r})}{W(e^{i\theta_r})}(1-R)^2 = 1$. From the last equality we obtain the required value of R for Step 1. In the case when W is symmetric and $\theta_r \notin \{0, \pi\}$, we must place two zeros at z_r and z_r^* to ensure W_r is also symmetric. By a procedure similar to the symmetric case, we find that a quartic equation $|1-R|^2|1-Re^{-i2\theta_r}|^2 - \frac{W_{r-1}(e^{i\theta_r})}{W(e^{i\theta_r})} = 0$ must be solved for R and a real solution satisfying $0 < R < 1$ is chosen. It is easy to see, since $\frac{W_{r-1}(e^{i\theta_r})}{W(e^{i\theta_r})} < 1$, that the quartic solution always has such a solution. It is not theoretically guaranteed that spectral zeros chosen by the scheme satisfy the requirements of Theorem 6.3 for convergence. However, in accordance with Remark 6.1, we may always proceed with the heuristic for a *finite* number of steps before terminating the selection by setting $z_r = 0$ for the remaining iterations. Simulation results, to be given in section 7, indicate however that this heuristic seems to work reasonably well.

6.4. Reduction of computational time. The computationally intensive part in the proposed algorithm is Step 2 for computing R_r. This is because the homotopy continuation algorithms described in [12, 4] involve solving a finite sequence of convex optimization problems. However, it is important to note that the computation can be substantially reduced at higher iterations down to solving only *one* convex optimization problem. To see this, consider the case when the algorithm is convergent and $E_r = \|z^{d_r}\eta_{r*}R_r^{-1} - z^{d_{r-1}}(\eta_{r-1})_*R_{r-1}^{-1}\|_\infty \to 0$ as $r \to \infty$. Since R_r is invertible a.e. $\mathbb{T}$ and $\sup_{r\geq 1}\|R_r\|_\infty < \infty$, we also have $E_r' = \|z^{d_r}\eta_{r*}R_{r-1} - z^{d_{r-1}}(\eta_{r-1})_*R_r\|_\infty \to 0$ as $r \to \infty$ (by noting $E_r' \leq \|R_{r-1}\|_\infty E_r \|R_r\|_\infty$). Assuming for the moment that $z_r \in \mathbb{R}$ and recalling that $\eta_r(z) = (z - z_r)\eta_{r-1}(z)$ and $d_r = d_{r-1} + 1$, we get that $\|(1 - z_r^* z)R_{r-1} - R_r\|_\infty \to 0$. Therefore, $\|(1 - z_r^* z)R_{r-1} - R_r\|_\infty$ will be small for all r sufficiently large. In that case, we simply set the homotopy step-size parameter ρ (resp., λ) in [12] (resp., [4]) to 1 and use the coefficients of $(1 - z_r^* z)R_{r-1}$ as an initial point in the algorithm for solving the *single* convex optimization problem which gives the coefficients of R_r. If $z_r \notin \mathbb{R}$, then replace $(1 - z_r^* z)$ with $(1 - z_r z)(1 - z_r^* z)$. This reduction scheme can be executed when $e_r \leq \delta$ for some small $\delta > 0$.

If required, further reduction is possible. We note that the Hessian of the functional to be minimized has a Hankel-plus-Toeplitz structure which can be inverted (or solved if it is the coefficient matrix in a system of linear equations) with fast algorithms given in [16, 17]. More important, however, is that these algorithms have *parallel* (i.e., Schur-type) versions which can be implemented on parallel computers.

7. Numerical examples. In this section we apply the new spectral factorization algorithm and heuristic of the last section to compute approximate CSFs of some rational and nonrational noncoercive spectral densities. In each example, three different simulations are carried out as follows:

1. Simulation A: The spectral zero selection heuristic is applied at Step 1 until termination of the algorithm.

TABLE 7.1
Simulation results.

	Number of iterations	Final value of e_r	Degree of approximation	Running time (seconds)
Simulation A	10	4.12909×10^{-5}	10	8.53
Simulation B	10	4.14906×10^{-5}	10	7.593
Simulation C	151	1.98136×10^{-3}	151	73.063

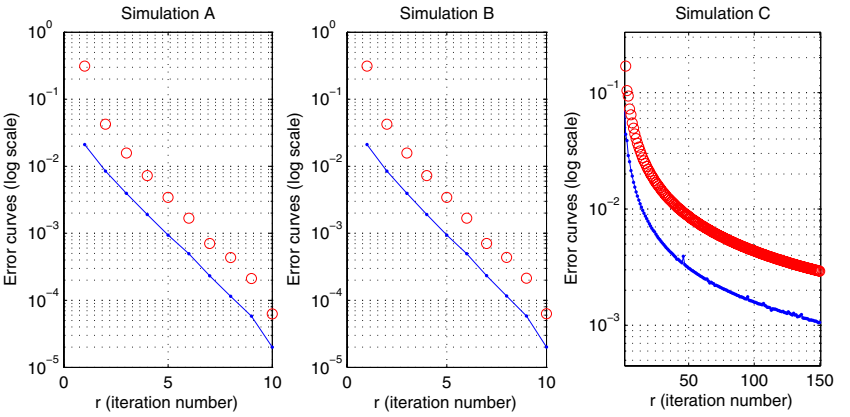

FIG. 7.1. *Plots of Simulation A (left), B (center), C (right):* $\|W - W_r\|_1$ *(dashed-dotted lines),* $\|\Phi(W_r) - \Phi(W_{r-1})\|_2$ *(circle).*

2. Simulation B: The spectral zero selection heuristic is applied at Step 1 for a finite, prespecified number of steps after which z_r is set to 0.

3. Simulation C: All of **Initialize** is skipped except the computation of c_0, z_r is set to 0 in Step 1 for all r, and R_r in Step 2 is computed recursively via the Szegö–Levinson algorithm. Step 3 is unaltered.

We set $\epsilon = 10^{-4}$ in all simulations and apply the computational reduction scheme of section 6.4 in Simulation A and B when $e_r \leq 10^{-2}$ is satisfied. The algorithm was implemented in MATLAB and executed on a computer with a Pentium 4 processor with a clock speed of 3.2 GHz and 1 GB of RAM.

Example 7.1. Consider the rational spectral density $W(e^{i\theta}) = \frac{2+\cos\theta-2\cos 2\theta}{24.1-18.9\cos\theta+2\cos 2\theta}$ which is noncoercive with a zero at $z = -1$. The exact CSF of W is known to be $\Phi(W)(z) = -\sqrt{10}\frac{(z-2)(z+1)}{(z-4)(z-5)}$. The results of Simulation A, B, and C are shown in Table 7.1 and Figure 7.1 (in simulation B, only five zeros are selected with the heuristic scheme). The exact error $\|\Phi(W_{10}) - \Phi(W)\|_2$ for Simulation A was 4.74526×10^{-5}.

Example 7.2. The *Kolmogorov* spectral density, which is the spectral density of a continuous time stochastic process arising in the study of turbulence, is defined along the imaginary axis as $W_K(i\omega;\sigma) = \frac{1}{\sqrt{1-\sigma(i\omega)^2}}$, where σ is a positive parameter. To use our approach, we first transform the spectral density from the imaginary axis to the unit circle via the (invertible) bilinear transformation $e^{i\theta} = \frac{1-i\omega}{1+i\omega}$. After applying the transformation we get a spectral density W_K^d on $\mathbb{T}$ given by $W_K^d(e^{i\theta};\sigma) = \sqrt{\frac{1+\cos\theta}{1+\cos\theta+\sigma(1-\cos\theta)}}$. Notice that W_K^d has a zero at $z = -1$ and cannot be continued analytically from that point. Setting $\sigma = 2$, we show results from Simulation A, B, and C are shown in Table 7.2 and Figure 7.2 (in Simulation B, only 10 zeros are selected with the heuristic scheme).

TABLE 7.2
Simulation results.

	Number of iterations	Final value of e_r	Degree of approximation	Running time (seconds)
Simulation A	22	9.32203×10^{-5}	43	239.269
Simulation B	29	9.31331×10^{-5}	39	294.741
Simulation C	151	2.11347×10^{-3}	151	44.86

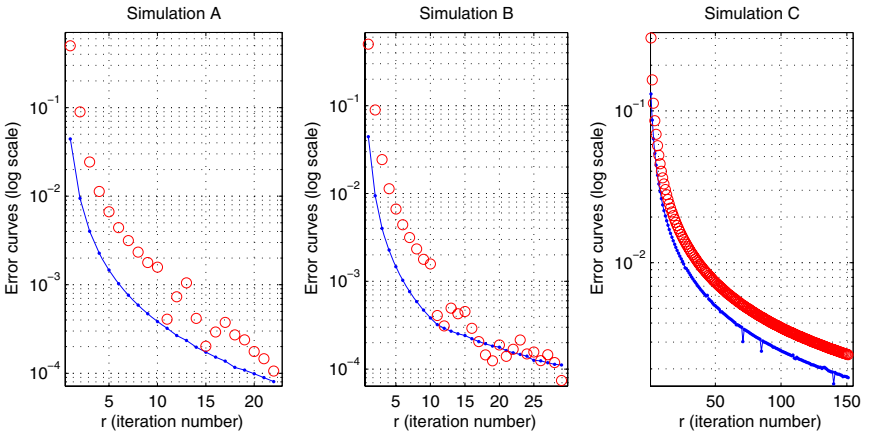

FIG. 7.2. *Plots of Simulation A (left), B (center), C (right):* $\|W - W_r\|_1$ *(dashed-dotted lines),* $\|\Phi(W_r) - \Phi(W_{r-1})\|_2$ *(circles).*

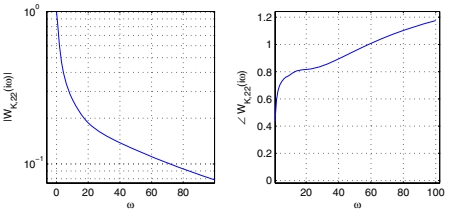

FIG. 7.3. *Frequency response of approximate CSF from Simulation A.*

Transforming the approximate CSF of Simulation A from the unit circle back to the imaginary axis gives us the frequency response shown in Figure 7.3.

Example 7.3. The *von Karman* spectral density [2, p. 73] is the spectral density of a continuous time stochastic process defined along the imaginary axis as

$$W_{vK}(i\omega;\sigma) = 2\sigma \frac{1 - \frac{8}{3}\sigma^2(1.339)^2(i\omega)^2}{(1 - \sigma^2(1.339)^2(i\omega)^2)^{\frac{11}{6}}},$$

where σ is a positive parameter. It is often used as a substitute for the Kolmogorov power spectral density of the previous example. After a transformation from the real line to the unit circle, we obtain a spectral density W^d_{vK} on $\mathbb{T}$ given by

$$W^d_{vK}(e^{i\theta};\sigma) = 2\sigma \frac{1 + \cos\theta + \frac{8}{3}\sigma^2(1.339)^2(1 - \cos\theta)}{(1 + \cos\theta + \sigma^2(1.339)^2(1 - \cos\theta))^{\frac{11}{6}}} (1 + \cos\theta)^{\frac{5}{6}}.$$

TABLE 7.3
Simulation results.

	Number of iterations	Final value of e_r	Degree of approximation	Running time (seconds)
Simulation A	30	6.54517×10^{-5}	49	926.656
Simulation B	47	8.97805×10^{-5}	47	1014.2
Simulation C	151	7.98211×10^{-3}	151	64.392

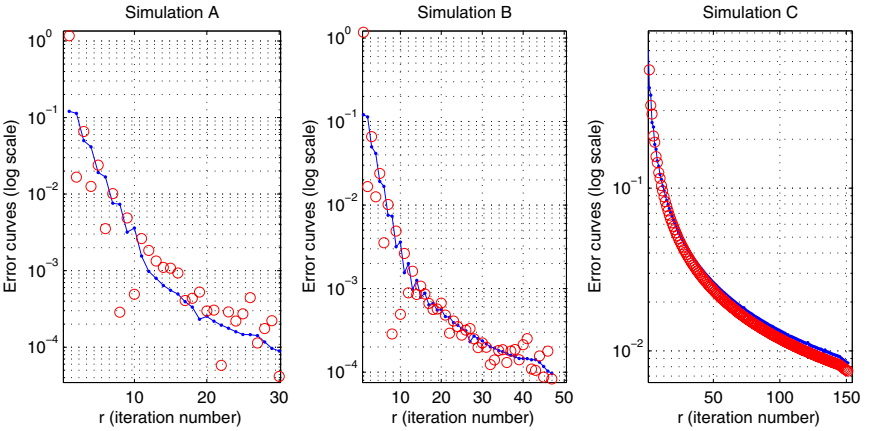

FIG. 7.4. *Plots of Simulation A (left), B (center), C (right):* $\|W - W_r\|_1$ *(dashed-dotted lines),* $\|\Phi(W_r) - \Phi(W_{r-1})\|_2$ *(circles).*

W_{vK}^d has a zero at $z = -1$ and cannot be continued analytically from that point. Setting $\sigma = 2$, the results of Simulation A, B, and C are shown in Table 7.3 and Figure 7.4 (in Simulation B, only 10 zeros are selected with the heuristic scheme).

Transforming the approximate CSF of Simulation A from the unit circle to the imaginary axis gives us the frequency response as shown in Figure 7.5.

All examples show that both Simulations A and B give better results than Simulation C (the Szegö–Levinson algorithm). Despite producing an approximation of substantially higher order, Simulation C gives a final error e_r of magnitude 10^2 higher, and it would seem many hundred more iterations are required to achieve $e_r < 10^{-4}$ as in Simulations A and B. In Example 7.1 for a simple second-order spectral factor, Simulation C also runs much longer. Simulation A runs faster than B but gives an approximation of slightly higher degree. The latter is not unexpected since Simulation B selects more real-valued zeros (i.e., at the origin). The simulations do suggest that

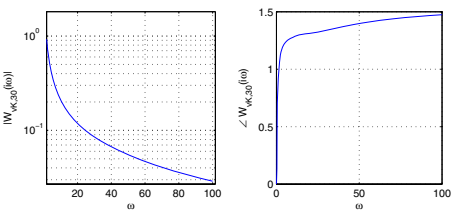

FIG. 7.5. *Frequency response of approximate CSF from Simulation A.*

the heuristic is practically useful and quite effective, regardless of whether a limited or indefinite number of spectral zeros is selected.

8. Conclusions and further research. This paper makes three primary contributions. First and foremost, we have derived a set of sufficient, easy to verify conditions for uniform log-integrability of a sequence of matrix-valued spectral densities. Second, we establish theoretical results on the existence of certain approximating rational sequences for a class of matrix-valued spectral densities. Finally, we propose a new spectral factorization algorithm for a more specific class of matrix-valued spectral densities based on degree constrained rational covariance extensions, and establish convergence results. Our approach does not require the spectral density to be coercive. There is freedom to choose a sequence of spectral zeros in the algorithm, and a heuristic has been proposed for choosing them. The performance of the new algorithm is demonstrated in a number of numerical examples, where it performed favorably compared to the popular Szegö–Levinson algorithm/maximum entropy method. In particular, the algorithm was successfully applied to the nonrational and noncoercive Kolmogorov and von Karman spectral densities. Possible topics for future research include development of fast algorithms for computing degree constrained covariance extensions, relaxations of the conditions of this paper, and development of better heuristics for selection of spectral zeros.

The results and algorithm of this paper may be useful in applications in which spectral factorization plays a prominent role, such as in computation of approximate solutions of algebraic Riccati equations (AREs) in optimal control of linear systems, or in which signals with nonrational power spectra is a central theme (e.g., control of aircraft subject to windgust, adaptive optics, and laser scintillation [2]). It may also prove to be useful in spectral estimation and system identification research.

Acknowledgments. The author thanks the reviewers for their feedback, and the associate and corresponding editors for their role in the peer-review process. He also thanks Prof. John B. Moore for helpful remarks on the first draft of this paper.

OPTIMAL CONTROL FOR A STATIONARY MHD SYSTEM IN VELOCITY-CURRENT FORMULATION*

ROLAND GRIESSE† AND KARL KUNISCH‡

Abstract. An optimal control problem for the equations governing the stationary problem of magnetohydrodynamics (MHD) is considered. Control mechanisms by external and injected currents and magnetic fields are treated. An optimal control problem is formulated. First order necessary and second order sufficient conditions are developed. An operator splitting scheme for the numerical solution of the MHD state equations is analyzed.

Key words. optimal control, magnetohydrodynamics, necessary optimality conditions, operator splitting

1. Introduction. Magnetohydrodynamics, or MHD, deals with the mutual interaction of electrically conducting fluids and magnetic fields. In particular the magnetic field interacts with the current in the fluid by exerting a Lorentz force. This feature renders it phenomenally attractive for exploitation, especially in metallurgical processes. The Lorentz force offers a unique possibility of generating a volume force in the fluid and hence to control its motion in a contactless fashion and without any mechanical interference. Therefore MHD technology is used routinely today by engineers, for instance, to stir molten metals during solidification, dampen their undesired convection-driven flow during casting, filter out impurities, and melt and even levitate metals.

With the present paper, we wish to contribute to the application of the powerful methods from mathematical optimization to compute tailored magnetic fields for MHD flow control. Although this work intends primarily to lay the mathematical foundations of MHD optimal control, we believe we have chosen a problem setup of practical relevance, allowing our results to be directly exploited in numerical methods and applications.

Before we turn to the problem description, let us put our work into perspective. Throughout we always refer to stationary incompressible MHD involving viscous fluids. Instationary problems will require an investigation in their own right, and compressible MHD mostly occurs in the realm of plasma physics, whereas we focus on the engineering aspects of MHD. While a remarkable amount of attention in the past decade was devoted to the analysis of optimal control of the Navier–Stokes equations (see, e.g., [9, 10, 11, 14] and the references therein), we are aware of only a few contributions so far concerning the optimal control of the MHD system [13, 16, 17, 18, 19, 24]. The majority of these papers treat the case of low magnetic Reynolds numbers or use either the velocity-potential or the velocity-magnetic field

formulation, which both result in the necessity of using artificial boundary conditions. The MHD state equations alone have been investigated in a number of papers, including [22, 21, 12].

We organized the material as follows: In the remainder of this section, we briefly recall the stationary MHD state equations and their velocity-current formulation. In section 2 the variational form of the state equations following [22] are introduced. Our main results are given in section 3, where we consider an optimal control problem for the MHD system. We derive the first order necessary optimality system and establish second order sufficient conditions. In section 4, we analyze an operator splitting scheme for the solution of the MHD state equation which makes use of existing solvers for the Navier–Stokes equations and div-curl systems. We conclude with an outlook on follow-up work in section 5.

Essentially, the MHD system consists of the Navier–Stokes equation with Lorentz force, yielding the fluid velocity $\boldsymbol{u}$ and its pressure p, plus Maxwell's equations describing the interaction of the electric field $\boldsymbol{E}$ and the magnetic field $\boldsymbol{B}$.[1] In the stationary case, the complete MHD system is given by

$$\begin{aligned} \nabla \cdot \boldsymbol{J} &= 0 && \nabla \times \boldsymbol{E} = 0 \\ &\text{(charge conservation)} && \text{(Faraday's law)}, \end{aligned} \tag{1.1}$$

$$\begin{aligned} \nabla \cdot \boldsymbol{B} &= 0 && \nabla \times (\mu^{-1}\boldsymbol{B}) = \boldsymbol{J} \\ &\text{(No magnetic monopoles)} && \text{(Ampère's Law)}, \end{aligned} \tag{1.2}$$

$$\begin{aligned} \boldsymbol{J} &= \sigma(\boldsymbol{E} + \boldsymbol{u} \times \boldsymbol{B}) \\ &\text{(Ohm's law)}, \end{aligned} \tag{1.3}$$

together with the Navier–Stokes system with Lorentz force

$$\varrho(\boldsymbol{u} \cdot \nabla)\boldsymbol{u} - \eta\Delta\boldsymbol{u} + \nabla p = \boldsymbol{J} \times \boldsymbol{B}, \tag{1.4}$$

$$\nabla \cdot \boldsymbol{u} = 0. \tag{1.5}$$

We refer to [25, 4] for more details. Here μ denotes the magnetic permeability of the matter occupying a certain point in space, and ϱ, η, and σ denote the fluid's density, viscosity, and conductivity. All of these numbers are positive. We emphasize that we consider μ to be constant throughout space; hence we assume a nonmagnetic fluid and no magnetic material present in its relevant vicinity.

It is an outstanding feature in magnetohydrodynamics that, from the set of state variables $(\boldsymbol{u}, p, \boldsymbol{E}, \boldsymbol{B}, \boldsymbol{J})$, the electric and magnetic fields $\boldsymbol{E}$ and $\boldsymbol{B}$ extend to all of $\mathbb{R}^3$, whereas the velocity $\boldsymbol{u}$ and pressure p are confined to the bounded region $\Omega \subset \mathbb{R}^3$ occupied by the fluid. The current density $\boldsymbol{J}$ is defined within the fluid region and possibly also in external conductors.

Rather than treating the full set of variables $(\boldsymbol{u}, p, \boldsymbol{E}, \boldsymbol{B}, \boldsymbol{J})$, researchers often describe MHD systems by a properly chosen subset, which is frequently taken as the pair of primal variables $(\boldsymbol{u}, \boldsymbol{B})$. This entails that either $\boldsymbol{B}$ has to be considered on all of $\mathbb{R}^3$, or that artificial shielding boundary conditions have to be assigned on $\partial\Omega$ so that the coupled system can be considered on the fluid region Ω alone. Physically, shielding boundary conditions represent a fluid being surrounded on all sides by a perfectly conducting vessel. Such boundary conditions exclude the control action

[1] Strictly speaking, $\boldsymbol{B}$ should be called the magnetic induction, while $\boldsymbol{H} = \mu^{-1}\boldsymbol{B}$ is the magnetic field. It is, however, common usage in MHD literature to call $\boldsymbol{B}$ the magnetic field.

by means of distant magnetic fields. This is an especially attractive feature of MHD control. In what appear to be the practically more relevant cases, where the outside of the fluid region Ω is finitely conducting or nonconducting, hence permitting control by distant magnetic fields, the proper boundary condition for $\boldsymbol{B}$ is an interface condition requiring $\boldsymbol{B}$ to be continuous across $\partial\Omega$ in both its normal and tangential components, i.e.,

$$[\boldsymbol{B}]_{\partial\Omega} = 0, \tag{1.6}$$

where $[\cdot]_{\partial\Omega}$ denotes the jump of any quantity when going from the interior of Ω to its exterior. As a consequence, $\boldsymbol{B}$ has to be considered on all of $\mathbb{R}^3$.

These shortcomings of the $(\boldsymbol{u}, \boldsymbol{B})$ formulation are not present in the velocity-current formulation in the variables $(\boldsymbol{u}, \boldsymbol{J})$ of the state equation system (1.1)–(1.5) as introduced in [22]. In this formulation, the magnetic field $\boldsymbol{B}$ is eliminated by means of a solution operator $\widetilde{\mathcal{B}}(\boldsymbol{J})$ which solves the div-curl system (1.2) for divergence-free currents $\boldsymbol{J}$ and respects the interface condition (1.6). With the condition that it vanishes at infinity, the solution is unique. Moreover, the irrotational electric field $\boldsymbol{E}$ is replaced with its potential ϕ (unique only up to a constant). In our case of constant permeability μ, the operator $\widetilde{\mathcal{B}}(\boldsymbol{J})$ is given by the Biot–Savart law,

$$\widetilde{\mathcal{B}}(\boldsymbol{J})(\boldsymbol{x}) = -\frac{\mu}{4\pi}\int_{\mathbb{R}^3} \frac{\boldsymbol{x}-\boldsymbol{y}}{|\boldsymbol{x}-\boldsymbol{y}|^3} \times \boldsymbol{J}(\boldsymbol{y})\, d\boldsymbol{y}. \tag{1.7}$$

Inserting $\boldsymbol{B} = \widetilde{\mathcal{B}}(\boldsymbol{J})$ into (1.1)–(1.5) results in the velocity-current formulation of the stationary MHD system,

$$\varrho(\boldsymbol{u}\cdot\nabla)\boldsymbol{u} - \eta\Delta\boldsymbol{u} + \nabla p - \boldsymbol{J}\times\widetilde{\mathcal{B}}(\boldsymbol{J}) = 0, \qquad \nabla\cdot\boldsymbol{u} = 0, \tag{1.8}$$

$$\sigma^{-1}\boldsymbol{J} + \nabla\phi - \boldsymbol{u}\times\widetilde{\mathcal{B}}(\boldsymbol{J}) = 0, \qquad \nabla\cdot\boldsymbol{J} = 0 \tag{1.9}$$

for the unknowns $(\boldsymbol{u}, p, \boldsymbol{J}, \phi)$. Here $\boldsymbol{u}$ and p and the electric potential ϕ are confined to the region Ω occupied by our conducting fluid, while $\boldsymbol{J}$ may additionally extend to external conductors.

In general, the total magnetic field $\boldsymbol{B}$ is a superposition of the induced magnetic field $\widetilde{\mathcal{B}}(\boldsymbol{J})$ and other magnetic fields, for instance, those belonging to permanent magnets or fields generated by *given* electric currents; see (3.7). We note in passing that in the case of weakly conducting fluids, such as, for example, salt water, or more generally, in the case of low magnetic Reynolds numbers $R_m = \mu\sigma u l$ (where u and l are typical velocity and length scales), the magnetic field associated with the induced current is negligible in comparison with an imposed field [4]. Hence, $\widetilde{\mathcal{B}}(\boldsymbol{J})$ can be replaced with a *given* field $\boldsymbol{B}_0$. We refer to [19, 24, 17] concerning the optimal control of weakly conducting fluids and to [15] for control approaches concerning the instationary von Kármán flow for a weakly conducting fluid with given Lorentz force.

2. Function spaces and operators. In this section, we present the proper functional analytic setting for the stationary MHD problem following [22]. Throughout, let Ω denote a bounded domain in $\mathbb{R}^3$ with Lipschitzian boundary, and let $L^2(\Omega)$, $H^1(\Omega)$, and $H^1_0(\Omega)$ and, in general, $W^{1,p}(\Omega)$ and $W^{1,p}_0(\Omega)$ denote the usual Sobolev spaces [1] for $1 < p < \infty$. In addition, for $l = 1, 2$, let $V^l(\mathbb{R}^3)$ stand for the completion of $H^l(\mathbb{R}^3)$ with respect to the seminorm which measures only the lth order derivatives [21]. Furthermore, $H^{1/2}(\partial\Omega)$ is the trace space of $H^1(\Omega)$, endowed with the norm

$$\|\phi\|_{H^{1/2}(\partial\Omega)} = \inf \|\Phi\|_{H^1(\Omega)},$$

where the infimum extends over all Φ whose trace coincides with ϕ. The norm duals of $H_0^1(\Omega)$ and $H^{1/2}(\partial\Omega)$ are $H^{-1}(\Omega)$ and $H^{-1/2}(\partial\Omega)$, respectively. The norm dual of $W_0^{1,p}(\Omega)$ is $W^{-1,p'}(\Omega)$, where p' is the dual of p, i.e., $p' = p/(p-1)$. Boldface notation indicates the triple Cartesian product of a space with itself, e.g., $\boldsymbol{L}^2(\Omega) = [L^2(\Omega)]^3$, and the symbol $\boldsymbol{L}^2_{\mathrm{div}}(\Omega)$ denotes the subspace of divergence-free (solenoidal) functions in $\boldsymbol{L}^2(\Omega)$. Finally, we denote by $A^\star$ the adjoint of a bounded linear operator A and by X' the dual of a normed linear space X.

We will consider solutions

$$\begin{aligned} &\boldsymbol{u} \in \boldsymbol{H}^1(\Omega) \cap \boldsymbol{L}^2_{\mathrm{div}}(\Omega), && \boldsymbol{J} \in \boldsymbol{L}^2_{\mathrm{div}}(\Omega), \\ &p \in L^2(\Omega)/\mathbb{R}, && \phi \in H^1(\Omega)/\mathbb{R}, \end{aligned}$$

which satisfy (1.8)–(1.9) in variational form. In order to obtain the variational formulation, we multiply (1.8)–(1.9) by smooth test functions $(\boldsymbol{v}, q, \boldsymbol{K}, \psi)$, where $\boldsymbol{v}$ has zero Dirichlet boundary values. Integration by parts yields

(2.1)
$$\begin{aligned} &\varrho \int_\Omega (\boldsymbol{u}\cdot\nabla)\boldsymbol{u}\cdot\boldsymbol{v} + \eta \int_\Omega \nabla\boldsymbol{u} \,:\, \nabla\boldsymbol{v} - \int_\Omega (\nabla\cdot\boldsymbol{v})\,\mathcal{P}(p) - \int_\Omega (\boldsymbol{J}\times\widetilde{\mathcal{B}}(\boldsymbol{J}))\cdot\boldsymbol{v} - \int_\Omega (\nabla\cdot\boldsymbol{u})\,q \\ &\qquad + \sigma^{-1}\int_\Omega \boldsymbol{J}\cdot\boldsymbol{K} + \int_\Omega \boldsymbol{K}\cdot(\nabla\phi) - \int_\Omega (\boldsymbol{u}\times\widetilde{\mathcal{B}}(\boldsymbol{J}))\cdot\boldsymbol{K} + \int_\Omega \boldsymbol{J}\cdot\nabla\psi = \int_{\partial\Omega} j\,\psi, \end{aligned}$$

where $j = \boldsymbol{J}\cdot\boldsymbol{n}$ denotes the given boundary values in the normal direction for the current $\boldsymbol{J}$. In (2.1),

$$\int_\Omega \nabla\boldsymbol{u} \,:\, \nabla\boldsymbol{v} = \sum_{i=1}^3 \int_\Omega \nabla\boldsymbol{u}_i\cdot\nabla\boldsymbol{v}_i,$$

and $\mathcal{P}(p)$ denotes the projection of p on the functions with zero mean,

$$\mathcal{P}(p) = p - \frac{1}{|\Omega|}\int_\Omega p.$$

Based on (2.1), we introduce the bilinear forms

$$\begin{aligned} &a_1(\boldsymbol{u},\boldsymbol{v}) = \eta\int_\Omega (\nabla\boldsymbol{u} \,:\, \nabla\boldsymbol{v}), && a_2(\boldsymbol{J},\boldsymbol{K}) = \sigma^{-1}\int_\Omega \boldsymbol{J}\cdot\boldsymbol{K}, \\ &d_1(\boldsymbol{u},p) = -\int_\Omega (\nabla\cdot\boldsymbol{u})\,\mathcal{P}(p), && d_2(\boldsymbol{J},\phi) = \int_\Omega \boldsymbol{J}\cdot(\nabla\phi) \end{aligned}$$

and trilinear forms

$$b(\boldsymbol{u},\boldsymbol{v},\boldsymbol{w}) = \varrho\int_\Omega (\boldsymbol{u}\cdot\nabla)\boldsymbol{v}\cdot\boldsymbol{w}, \qquad c(\boldsymbol{u},\boldsymbol{v},\boldsymbol{w}) = \int_\Omega (\boldsymbol{u}\times\boldsymbol{v})\cdot\boldsymbol{w},$$

where $\boldsymbol{u},\boldsymbol{v},\boldsymbol{w} \in \boldsymbol{H}^1(\Omega)$, $\boldsymbol{J},\boldsymbol{K} \in \boldsymbol{L}^2(\Omega)$, $p \in L^2(\Omega)/\mathbb{R}$, and $\phi \in H^1(\Omega)/\mathbb{R}$. Note that c is defined on any $\boldsymbol{L}^{p_1}(\Omega)\times\boldsymbol{L}^{p_2}(\Omega)\times\boldsymbol{L}^{p_3}(\Omega)$, where $1/p_1 + 1/p_2 + 1/p_3 = 1$.

Let us now turn to the forms introduced above. Besides the obvious continuity properties, they satisfy the following.

LEMMA 2.1 (LBB conditions [7]). *The constraint forms d_1 and d_2 satisfy the following Ladyzhenskaya–Babuska–Brezzi (LBB) conditions on $\boldsymbol{H}^1_0(\Omega) \times L^2(\Omega)/\mathbb{R}$, and on $\boldsymbol{L}^2(\Omega) \times H^1(\Omega)/\mathbb{R}$, respectively:*

$$\inf_{p \in L^2(\Omega)/\mathbb{R}} \sup_{\boldsymbol{u} \in \boldsymbol{H}^1_0(\Omega)} \frac{d_1(\boldsymbol{u}, p)}{\|\boldsymbol{u}\|_{\boldsymbol{H}^1(\Omega)} \|p\|_{L^2(\Omega)/\mathbb{R}}} \geq \beta_1,$$
$$\inf_{\phi \in H^1(\Omega)/\mathbb{R}} \sup_{\boldsymbol{J} \in \boldsymbol{L}^2(\Omega)} \frac{d_2(\boldsymbol{J}, \phi)}{\|\boldsymbol{J}\|_{\boldsymbol{L}^2(\Omega)} \|\phi\|_{H^1(\Omega)/\mathbb{R}}} \geq \beta_2$$

for some $\beta_1, \beta_2 > 0$.

Let us define the following spaces associated with the constraint forms d_1 and d_2:

$$V_1 = \{\boldsymbol{v} \in \boldsymbol{H}^1_0(\Omega) \,:\, d_1(\boldsymbol{v}, p) = 0 \text{ for all } p \in L^2(\Omega)/\mathbb{R}\},$$
$$V_1^0 = \{\Phi_1 \in \boldsymbol{H}^{-1}(\Omega) \,:\, \langle \Phi_1, \boldsymbol{v} \rangle = 0 \text{ for all } \boldsymbol{v} \in V_1\},$$
$$V_2 = \{\boldsymbol{K} \in \boldsymbol{L}^2(\Omega) \,:\, d_2(\boldsymbol{K}, \phi) = 0 \text{ for all } \phi \in H^1(\Omega)/\mathbb{R}\},$$
$$V_2^0 = \{\Phi_2 \in \boldsymbol{L}^2(\Omega)' \,:\, \langle \Phi_2, \boldsymbol{K} \rangle = 0 \text{ for all } \boldsymbol{K} \in V_2\}.$$

Note that [26]

$$V_1 = \{\boldsymbol{v} \in \boldsymbol{H}^1_0(\Omega) \,:\, \nabla \cdot \boldsymbol{v} = 0 \text{ on } \Omega\},$$
$$V_2 = \{\boldsymbol{K} \in \boldsymbol{L}^2(\Omega) \,:\, \nabla \cdot \boldsymbol{K} = 0 \text{ on } \Omega \text{ and } \boldsymbol{K} \cdot \boldsymbol{n} = 0 \text{ on } \partial\Omega\}.$$

LEMMA 2.2 (properties of constraint forms). *If $\Phi_1 \in V_1^0$ and $\Phi_2 \in V_2^0$, then the equations*

$$d_1(\boldsymbol{v}, p) = \langle \Phi_1, \boldsymbol{v} \rangle \text{ for all } \boldsymbol{v} \in \boldsymbol{H}^1_0(\Omega),$$
$$d_2(\boldsymbol{K}, \phi) = \langle \Phi_2, \boldsymbol{K} \rangle \text{ for all } \boldsymbol{K} \in \boldsymbol{L}^2(\Omega)$$

are uniquely solvable for $p \in L^2(\Omega)/\mathbb{R}$ and $\phi \in H^1(\Omega)/\mathbb{R}$, and $\|p\|_{L^2(\Omega)/\mathbb{R}} \leq c_1 \|\Phi_1\|_{\boldsymbol{H}^{-1}(\Omega)}$ and $\|\phi\|_{H^1(\Omega)/\mathbb{R}} \leq c_2 \|\Phi_2\|_{\boldsymbol{L}^2(\Omega)'}$ hold for some $c_1, c_2 > 0$.

Proof. See [7, Chap. I, Lem. 4.1]. ∎

LEMMA 2.3 (passing to the limit in c).

(1) *Let $\boldsymbol{u}^n \rightharpoonup \boldsymbol{u}$ in $\boldsymbol{L}^2(\Omega)$, $\boldsymbol{v}^n \to \boldsymbol{v}$ in $\boldsymbol{L}^3(\Omega)$, and $\boldsymbol{w} \in \boldsymbol{L}^6(\Omega)$. Then $c(\boldsymbol{u}^n, \boldsymbol{v}^n, \boldsymbol{w}) \to c(\boldsymbol{u}, \boldsymbol{v}, \boldsymbol{w})$.*

(2) *Let $\boldsymbol{u} \in \boldsymbol{L}^2(\Omega)$, $\boldsymbol{v}^n \to \boldsymbol{v}$ in $\boldsymbol{L}^3(\Omega)$, and $\boldsymbol{w}^n \rightharpoonup \boldsymbol{w}$ in $\boldsymbol{L}^6(\Omega)$. Then $c(\boldsymbol{u}, \boldsymbol{v}^n, \boldsymbol{w}^n) \to c(\boldsymbol{u}, \boldsymbol{v}, \boldsymbol{w})$.*

Proof. For the first claim, we use the estimate

$$|c(\boldsymbol{u}^n, \boldsymbol{v}^n, \boldsymbol{w}) - c(\boldsymbol{u}, \boldsymbol{v}, \boldsymbol{w})| \leq \left| \int_\Omega (\boldsymbol{u}^n \times (\boldsymbol{v}^n - \boldsymbol{v})) \cdot \boldsymbol{w} \right| + \left| \int_\Omega ((\boldsymbol{u}^n - \boldsymbol{u}) \times \boldsymbol{v}) \cdot \boldsymbol{w} \right|.$$

We apply Hölder's inequality to the first term, using the native norms of all three factors involved. It converges to zero since $\|\boldsymbol{v}^n - \boldsymbol{v}\|_{\boldsymbol{L}^3(\Omega)}$ converges to zero and $\|\boldsymbol{u}^n\|_{\boldsymbol{L}^2(\Omega)}$ is bounded by assumption (1). Hölder's inequality again shows that $\int_\Omega (\cdot \times \boldsymbol{v}) \cdot \boldsymbol{w}$ is a continuous linear functional on $\boldsymbol{L}^2(\Omega)$ so that also the second term converges to zero. The second claim follows similarly, using the splitting

$$|c(\boldsymbol{u}, \boldsymbol{v}^n, \boldsymbol{w}^n) - c(\boldsymbol{u}, \boldsymbol{v}, \boldsymbol{w})| \leq \left| \int_\Omega (\boldsymbol{u} \times (\boldsymbol{v}^n - \boldsymbol{v})) \cdot \boldsymbol{w}^n \right| + \left| \int_\Omega (\boldsymbol{u} \times \boldsymbol{v}) \cdot (\boldsymbol{w}^n - \boldsymbol{w}) \right|. \qquad ∎$$

LEMMA 2.4 (properties of $\widetilde{\mathcal{B}}$). *The following properties hold:*

(1) *The Biot–Savart operator* (1.7) *maps any given* $\boldsymbol{J} \in \boldsymbol{L}^2(\mathbb{R}^3)$ *to* $\widetilde{\mathcal{B}}(\boldsymbol{J}) \in \boldsymbol{V}^1(\mathbb{R}^3)$. *The restriction of* $\widetilde{\mathcal{B}}(\boldsymbol{J})$ *to* Ω *lies in* $\boldsymbol{H}^1(\Omega)$.
In this sense, the Biot–Savart operator defines a continuous linear map between $\boldsymbol{L}^2(\mathbb{R}^3)$ *and* $\boldsymbol{H}^1(\Omega)$, *i.e.,*

$$\|\widetilde{\mathcal{B}}(\boldsymbol{J})\|_{\boldsymbol{H}^1(\Omega)} \le c_B \|\boldsymbol{J}\|_{\boldsymbol{L}^2(\Omega)}$$

for all $\boldsymbol{J} \in \boldsymbol{L}^2(\Omega)$ *and some* $c_B > 0$.

(2) *If* $\boldsymbol{J} \in \boldsymbol{L}^2_{\mathrm{div}}(\Omega)$, *then* $\widetilde{\mathcal{B}}(\boldsymbol{J})$ *is the unique solution of the* div-curl *system* (1.2) *vanishing at infinity.*
The operator $\widetilde{\mathcal{B}}$ *is self-adjoint in* $\boldsymbol{L}^2(\mathbb{R}^3)$.

Remark 2.5. Whenever $\boldsymbol{J}$ has compact support, as will be the case in our applications, $\widetilde{\mathcal{B}}(\boldsymbol{J})$ belongs to $\boldsymbol{H}^1(\mathbb{R}^3)$. However, it is sufficient for our purpose that the restriction of $\widetilde{\mathcal{B}}(\boldsymbol{J})$ to Ω is in $\boldsymbol{H}^1(\Omega)$, as guaranteed by the lemma.

Proof of Lemma 2.4. Consider the Newton potential

$$(\mathcal{L}_0 \boldsymbol{J})(\boldsymbol{x}) = -\frac{\mu}{4\pi} \int_{\mathbb{R}^3} \frac{1}{|\boldsymbol{x}-\boldsymbol{y}|} \boldsymbol{J}(\boldsymbol{y})\, d\boldsymbol{y},$$

which defines an isomorphism from $\boldsymbol{L}^2(\mathbb{R}^3)$ to $\boldsymbol{V}^2(\mathbb{R}^3)$ [21, 3]. One argues that $\widetilde{\mathcal{B}}(\boldsymbol{J}) = \nabla \times \mathcal{L}_0(\boldsymbol{J})$ holds for all $\boldsymbol{J} \in \boldsymbol{L}^2(\mathbb{R}^3)$. This implies that $\boldsymbol{B}(\boldsymbol{J}) \in \boldsymbol{V}^1(\mathbb{R}^3)$.

Since $\boldsymbol{V}^1(\mathbb{R}^3)$ embeds into $\boldsymbol{H}^1_{\mathrm{loc}}(\mathbb{R}^3)$ [3], claims (1) and (2) follow. Theorem 2.7 and Remark 2.8(b) in [21] imply that (3) holds. To prove self-adjointness, we multiply $\widetilde{\mathcal{B}}(\boldsymbol{J})$ by a function $\boldsymbol{C} \in \boldsymbol{L}^2(\Omega)$ and integrate over $\mathbb{R}^3$:

$$\begin{aligned}
\int_{\mathbb{R}^3} \boldsymbol{C} \cdot \widetilde{\mathcal{B}}(\boldsymbol{J}) &= -\frac{\mu}{4\pi} \int_{\mathbb{R}^3} \boldsymbol{C}(\boldsymbol{x}) \cdot \left(\int_{\mathbb{R}^3} \frac{\boldsymbol{x}-\boldsymbol{y}}{|\boldsymbol{x}-\boldsymbol{y}|^3} \times \boldsymbol{J}(\boldsymbol{y})\, d\boldsymbol{y} \right) d\boldsymbol{x} \\
&= -\frac{\mu}{4\pi} \int_{\mathbb{R}^3} \int_{\mathbb{R}^3} \boldsymbol{C}(\boldsymbol{x}) \cdot \left(\frac{\boldsymbol{x}-\boldsymbol{y}}{|\boldsymbol{x}-\boldsymbol{y}|^3} \times \boldsymbol{J}(\boldsymbol{y}) \right) d\boldsymbol{x}\, d\boldsymbol{y} \\
&= -\frac{\mu}{4\pi} \int_{\mathbb{R}^3} \boldsymbol{J}(\boldsymbol{y}) \cdot \left(\int_{\mathbb{R}^3} \boldsymbol{C}(\boldsymbol{x}) \times \frac{\boldsymbol{x}-\boldsymbol{y}}{|\boldsymbol{x}-\boldsymbol{y}|^3}\, d\boldsymbol{x} \right) d\boldsymbol{y}. \\
&= -\frac{\mu}{4\pi} \int_{\mathbb{R}^3} \boldsymbol{J}(\boldsymbol{x}) \cdot \left(\int_{\mathbb{R}^3} \frac{\boldsymbol{x}-\boldsymbol{y}}{|\boldsymbol{x}-\boldsymbol{y}|^3} \times \boldsymbol{C}(\boldsymbol{y})\, d\boldsymbol{y} \right) d\boldsymbol{x}.
\end{aligned}$$

Since the left-hand side by definition equals $\int_{\mathbb{R}^3} \boldsymbol{J} \cdot \widetilde{\mathcal{B}}^\star(\boldsymbol{C})$, we have found $\widetilde{\mathcal{B}}^\star(\boldsymbol{C}) = \widetilde{\mathcal{B}}(\boldsymbol{C})$. ∎

We conclude this section by a compact embedding result whose proof can be found in [7].

LEMMA 2.6 (compact maps and embeddings). *For a bounded domain* $\Omega \subset \mathbb{R}^3$ *with Lipschitz boundary, the embeddings* $H^1(\Omega) \hookrightarrow L^{6-\varepsilon}(\Omega)$ *and* $L^2(\Omega) \hookrightarrow W^{-1,6-\varepsilon}(\Omega)$ *are compact for all* $\varepsilon > 0$. *In addition, the pointwise product map* $(u, v) \mapsto u\, v$ *is continuous from* $H^1(\Omega) \times H^1(\Omega)$ *to* $W^{1,3/2}(\Omega)$, *and the latter embeds compactly into* $L^{3-\varepsilon}(\Omega)$ *for all* $\varepsilon > 0$.

3. The optimal control problem. We analyze an optimal control problem for the stationary MHD system motivated by the applications described in [4]. A typical geometry that we have in mind is depicted in Figure 3.1. We assume that the electrically conducting fluid, e.g., a liquid metal, is contained in a vessel occupying

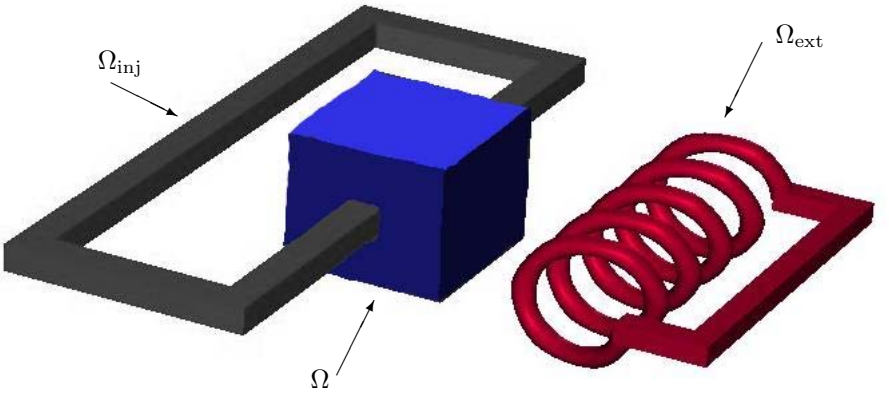

FIG. 3.1. *General setup: Fluid region Ω (cube), external conductor Ω_{inj} attached to the fluid region, and external conductor Ω_{ext} separate from the fluid region.*

the domain Ω. On part of the boundary $\partial\Omega$, an external conductor Ω_{inj} is attached. The current distribution in Ω_{inj} is assumed to be known, but its magnitude can be adjusted. The purpose of such a propulsion device is to drive the fluid in Ω in a desired way, both through the action of the magnetic field induced by the current in Ω_{inj} and through the current, which is "injected" into the fluid region Ω through the electrodes attached to its surface. The same assembly can be found in electromagnetic filtration devices. Since in some cases it may be undesirable to attach the external conductor to the surface of the fluid vessel, we included a second conductor Ω_{ext} separately from the fluid region in which, again, the current distribution is given but its magnitude can be controlled. This external conductor has an impact on the fluid motion in Ω solely through its induced magnetic field. An assembly in which a number of such coils is distributed around the fluid vessel can be found, e.g., in electromagnetic stirring devices [4, 23], albeit their magnetic field is usually amplified by yokes in the coil centers, which are currently not included in our model in view of the assumption that the permeability μ is constant. In addition, we allow for another external magnetic field $\boldsymbol{B}_{\text{ext}}$ which is subject to optimization. In practice such a field cannot be shaped at will. We consider it as originating from a permanent magnet whose field is again known except for its magnitude, which serves as an optimization parameter.

From (1.8)–(1.9) we recall the stationary MHD system in velocity-current formulation,

$$\varrho(\boldsymbol{u}\cdot\nabla)\boldsymbol{u} - \eta\Delta\boldsymbol{u} + \nabla p = \boldsymbol{J}\times\boldsymbol{B}, \qquad \nabla\cdot\boldsymbol{u} = 0 \quad \text{on } \Omega, \tag{3.1}$$

$$\sigma^{-1}\boldsymbol{J} - \boldsymbol{u}\times\boldsymbol{B} + \nabla\phi = 0, \qquad \nabla\cdot\boldsymbol{J} = 0 \quad \text{on } \Omega. \tag{3.2}$$

We will consider solutions

$$y = (\boldsymbol{u}, p, \boldsymbol{J}, \phi) \tag{3.3}$$

with

$$\boldsymbol{u} \in \boldsymbol{H}^1(\Omega)\cap\boldsymbol{L}^2_{\text{div}}(\Omega), \qquad \boldsymbol{J}\in\boldsymbol{L}^2_{\text{div}}(\Omega),$$
$$p\in L^2(\Omega)/\mathbb{R}, \qquad \phi\in H^1(\Omega)/\mathbb{R},$$

which satisfy (3.1)–(3.2) in variational form, together with the following boundary conditions:

$$\boldsymbol{J}\cdot\boldsymbol{n} = \boldsymbol{J}_{\mathrm{inj}}\cdot\boldsymbol{n} \quad \text{on } \partial\Omega_{\mathrm{inj}}\cap\partial\Omega, \tag{3.4}$$

$$\boldsymbol{J}\cdot\boldsymbol{n} = 0 \quad \text{on } \partial\Omega\setminus\partial\Omega_{\mathrm{inj}}, \tag{3.5}$$

with the injected current $\boldsymbol{J}_{\mathrm{inj}}$ specified below. For the fluid velocity, we impose Dirichlet boundary conditions

$$\boldsymbol{u} = \boldsymbol{h} \quad \text{on } \partial\Omega. \tag{3.6}$$

For our setup the total magnetic field $\boldsymbol{B}$ is the superposition of the field $\widetilde{\mathcal{B}}(\boldsymbol{J})$ induced by the current $\boldsymbol{J}$ inside the fluid domain, the fields $\widetilde{\mathcal{B}}(\boldsymbol{J}_{\mathrm{ext}})$ and $\widetilde{\mathcal{B}}(\boldsymbol{J}_{\mathrm{inj}})$ induced by the currents in the external conductors (whether or not attached to the fluid domain), and the magnetic field $\boldsymbol{B}_{\mathrm{ext}}$ associated with the permanent magnet, i.e.,

$$\boldsymbol{B} = \widetilde{\mathcal{B}}(\boldsymbol{J}) + \widetilde{\mathcal{B}}(\boldsymbol{J}_{\mathrm{ext}}) + \widetilde{\mathcal{B}}(\boldsymbol{J}_{\mathrm{inj}}) + \boldsymbol{B}_{\mathrm{ext}}. \tag{3.7}$$

We repeat that the external magnetic field $\boldsymbol{B}_{\mathrm{ext}}$ and the current fields $\boldsymbol{J}_{\mathrm{ext}}$ and $\boldsymbol{J}_{\mathrm{inj}}$ are assumed known except for their magnitude. For instance, in the case of a smooth wire, the current field simply follows its shape, and thus

$$\boldsymbol{J}_{\mathrm{ext}} = I_{\mathrm{ext}}\cdot\widetilde{\boldsymbol{J}}_{\mathrm{ext}}, \qquad \boldsymbol{J}_{\mathrm{inj}} = I_{\mathrm{inj}}\cdot\widetilde{\boldsymbol{J}}_{\mathrm{inj}}, \qquad \boldsymbol{B}_{\mathrm{ext}} = B_{\mathrm{ext}}\cdot\widetilde{\boldsymbol{B}}_{\mathrm{ext}}, \tag{3.8}$$

where

$$u = (I_{\mathrm{ext}}, I_{\mathrm{inj}}, B_{\mathrm{ext}}) \in \mathbb{R}^3 \tag{3.9}$$

is the vector of control variables. Herein, I_{ext} and I_{inj} denote the adjustable scalar current strengths and $\widetilde{\boldsymbol{J}}_{\mathrm{ext}}$ and $\widetilde{\boldsymbol{J}}_{\mathrm{inj}}$ are the given solenoidal current field distributions in the external conductors Ω_{ext} and Ω_{inj}, respectively. In practice, these currents must be maintained by an adjustable voltage source. Likewise, B_{ext} relates to the strength of the external magnetic field (associated with a permanent magnet) $\boldsymbol{B}_{\mathrm{ext}}$. The boundary conditions (3.4)–(3.5), together with Assumption 3.1(3) below, close the current loop and ensure that the total current $\boldsymbol{J}+\boldsymbol{J}_{\mathrm{ext}}+\boldsymbol{J}_{\mathrm{inj}}$ is solenoidal on $\mathbb{R}^3$.

The restriction to finite-dimensional controls is motivated by applications. Nonparametrized distributed current and magnetic fields $(\boldsymbol{J}_{\mathrm{ext}}, \boldsymbol{J}_{\mathrm{inj}}, \boldsymbol{B}_{\mathrm{ext}}) \in \boldsymbol{L}^2_{\mathrm{div}}(\Omega)\times\big(\boldsymbol{H}^1(\Omega_{\mathrm{inj}})\cap\boldsymbol{L}^2_{\mathrm{div}}(\Omega_{\mathrm{inj}})\big)\times\boldsymbol{V}^1(\mathbb{R}^3)$ can be used as controls if the norms in the objective below are adjusted accordingly. Besides technical difficulties, the most significant change that will occur is in the necessary optimality conditions (3.28) (see Theorem 3.11 below), which will involve Poisson equations.

We are now prepared to state our optimal control problem as follows:

$$\begin{aligned}\text{Minimize } & \frac{\alpha_u}{2}\|\boldsymbol{u}-\boldsymbol{u}_{\mathrm{d}}\|^2_{L^2(\Omega_{u,\mathrm{obs}})} + \frac{\alpha_B}{2}\|\boldsymbol{B}-\boldsymbol{B}_{\mathrm{d}}\|^2_{L^2(\Omega_{B,\mathrm{obs}})} + \frac{\alpha_J}{2}\|\boldsymbol{J}-\boldsymbol{J}_{\mathrm{d}}\|^2_{L^2(\Omega_{J,\mathrm{obs}})} \\ & + \frac{\gamma_{\mathrm{ext}}}{2}|I_{\mathrm{ext}}|^2 + \frac{\gamma_{\mathrm{inj}}}{2}|I_{\mathrm{inj}}|^2 + \frac{\gamma_B}{2}|B_{\mathrm{ext}}|^2 \end{aligned} \tag{P}$$

subject to (3.1)–(3.7).

The control objective reflects the goal of steering the fluid velocities and the magnetic and current fields towards the given desired fields $\boldsymbol{u}_{\mathrm{d}}$, $\boldsymbol{B}_{\mathrm{d}}$, and $\boldsymbol{J}_{\mathrm{d}}$, possibly

only on subdomains $\Omega_{u,\mathrm{obs}} \subset \Omega$, $\Omega_{B,\mathrm{obs}} \subset \mathbb{R}^3$, and $\Omega_{J,\mathrm{obs}} \subset \Omega$ of interest. The desired fields are $\boldsymbol{L}^2$ functions in their respective domains of definition. One may choose among those goals by setting the respective weights α equal to zero. The control weights γ are assumed to be positive. Note that due to the "state times control" terms $\boldsymbol{u} \times \boldsymbol{B}$ (through Ohm's law (1.3)) and $\boldsymbol{J} \times \boldsymbol{B}$ (the Lorentz force), problem (P) is a particular type of bilinear control problem.

We shall require the following assumption for the analysis of the MHD system (3.1)–(3.7).

Assumption 3.1 (problem data).

1. Ω, Ω_{inj}, and Ω_{ext} are bounded mutually disjoint domains with $C^{0,1}$ boundary, such that Ω_{inj} and Ω have a part of their boundary of positive surface measure in common; see Figure 3.1.
2. The boundary velocity $\boldsymbol{h} \in \boldsymbol{H}^{1/2}(\partial\Omega)$ satisfies $\int_{\partial\Omega} \boldsymbol{h} \cdot \boldsymbol{n} = 0$.
3. $\widetilde{\boldsymbol{J}}_{\mathrm{ext}}$ and $\widetilde{\boldsymbol{J}}_{\mathrm{inj}}$ are (current) fields in $\boldsymbol{L}^2_{\mathrm{div}}(\Omega_{\mathrm{ext}})$ and $\boldsymbol{H}^1(\Omega_{\mathrm{inj}}) \cap \boldsymbol{L}^2_{\mathrm{div}}(\Omega_{\mathrm{inj}})$, respectively, satisfying $\int_{\partial\Omega\cap\partial\Omega_{\mathrm{inj}}} \widetilde{\boldsymbol{J}}_{\mathrm{inj}} \cdot \boldsymbol{n} = 0$.
4. $\widetilde{\boldsymbol{B}}_{\mathrm{ext}}$ is a divergence-free (magnetic) field on $\mathbb{R}^3$ such that its restriction to Ω lies in $\boldsymbol{L}^{3+\varepsilon}(\Omega)$ for some $\varepsilon > 0$.
5. The nonzero fields $\widetilde{\boldsymbol{B}}_{\mathrm{ext}}$, $\widetilde{\mathcal{B}}(\widetilde{\boldsymbol{J}}_{\mathrm{ext}})$, and $\widetilde{\mathcal{B}}(\widetilde{\boldsymbol{J}}_{\mathrm{inj}})$ are linearly independent.

The assumption $\widetilde{\boldsymbol{J}}_{\mathrm{inj}} \in \boldsymbol{H}^1(\Omega_{\mathrm{inj}})$ implies that the normal trace $\widetilde{\boldsymbol{J}}_{\mathrm{inj}} \cdot \boldsymbol{n}$, when restricted to the intersection $\partial\Omega \cap \partial\Omega_{\mathrm{inj}}$ and extended by zero, yields a function $j \in L^2(\partial\Omega)$; hence in particular $j \in H^{-1/2}(\partial\Omega)$ holds. The latter is needed to ensure the existence of a lifting $\boldsymbol{J}_0$ whose normal boundary values coincide with j, see Lemma 3.2 below. Note that $j \in H^{-1/2}(\partial\Omega)$ can in general not be achieved if merely $\widetilde{\boldsymbol{J}}_{\mathrm{inj}} \in \boldsymbol{L}^2_{\mathrm{div}}(\Omega_{\mathrm{inj}})$.

In order to eliminate the boundary conditions for the velocity and current and to homogenize the problem, we introduce liftings $\boldsymbol{u}_0$ and $\boldsymbol{J}_0$ of the given boundary data such that

$$\begin{aligned} &\boldsymbol{u}_0 \in \boldsymbol{H}^1(\Omega), && \boldsymbol{u}_0|_{\partial\Omega} = \boldsymbol{h}, && \nabla \cdot \boldsymbol{u}_0 = 0, \\ &\boldsymbol{J}_0 \in \boldsymbol{L}^2(\Omega), && \boldsymbol{J}_0 \cdot \boldsymbol{n}|_{\partial\Omega} = j, && \nabla \cdot \boldsymbol{J}_0 = 0, \end{aligned}$$

with

$$j = \boldsymbol{J}_{\mathrm{inj}} \cdot \boldsymbol{n} \text{ on } \partial\Omega \cap \partial\Omega_{\mathrm{inj}} \quad \text{and} \quad j = 0 \text{ on } \partial\Omega \setminus \partial\Omega_{\mathrm{inj}}. \tag{3.10}$$

Such a lifting exists according to the following lemma. Note that Assumption 3.1(3) implies that $\int_{\partial\Omega} j = 0$ as required in part (b) of Lemma 3.2 below.

LEMMA 3.2 (lifting). *Let β_i be the constants from the LBB condition (Lemma 2.1). Then we have the following:*

(a) *For every $\boldsymbol{h} \in \boldsymbol{H}^{1/2}(\partial\Omega)$, there exists $\boldsymbol{u}_0 \in \boldsymbol{H}^1(\Omega)$ such that $\boldsymbol{u}_0|_{\partial\Omega} = \boldsymbol{h}$ and $d_1(\boldsymbol{u}_0, q) = 0$ holds for all $q \in \boldsymbol{L}^2(\Omega)/\mathbb{R}$, i.e., $\nabla \cdot \boldsymbol{u}_0 = 0$. Moreover, the map $\boldsymbol{h} \mapsto \boldsymbol{u}_0$ can be chosen linearly and continuously, such that*

$$\|\boldsymbol{u}_0\|_{\boldsymbol{H}^1(\Omega)} \le (1 + \beta_1^{-1}) \|\boldsymbol{h}\|_{\boldsymbol{H}^{1/2}(\partial\Omega)}$$

is satisfied.

(b) *For every* $j \in H^{-1/2}(\partial\Omega)$ *which satisfies* $\langle j, 1\rangle_{\partial\Omega} = 0$, *there exists* $\boldsymbol{J}_0 \in \boldsymbol{L}^2(\Omega)$ *such that* $d_2(\boldsymbol{J}_0, \psi) = \langle j, \psi\rangle_{\partial\Omega}$ *holds for all* $\psi \in H^1(\Omega)/\mathbb{R}$, *i.e.,* $\nabla \cdot \boldsymbol{J}_0 = 0$ *and* $\boldsymbol{J}_0 \cdot \boldsymbol{n} = j$. *Moreover, the map* $j \mapsto \boldsymbol{J}_0$ *can be chosen linearly and continuously, such that*

$$\|\boldsymbol{J}_0\|_{\boldsymbol{L}^2(\Omega)} \le \beta_2^{-1} \|j\|_{H^{-1/2}(\partial\Omega)}$$

is satisfied.

Proof. The claim is a consequence of the LBB condition; see [22] for details. Note that for functions $\boldsymbol{J}_0 \in \boldsymbol{L}^2(\Omega)$ such that $\nabla \cdot \boldsymbol{J}_0 \in \boldsymbol{L}^2(\Omega)$, the normal trace $\boldsymbol{J}_0 \cdot \boldsymbol{n}$ exists with values in $H^{-1/2}(\partial\Omega)$ [7]. ∎

As a consequence, the fluid velocity and current can be written as

$$\boldsymbol{u} = \boldsymbol{u}_0 + \widehat{\boldsymbol{u}}, \qquad \boldsymbol{J} = \boldsymbol{J}_0 + \widehat{\boldsymbol{J}},$$

where $\widehat{\boldsymbol{u}} \in \boldsymbol{H}_0^1(\Omega)$ and $\widehat{\boldsymbol{J}} \cdot \boldsymbol{n} = 0$ on $\partial\Omega$. It is important to note that in view of the current boundary condition (3.4)–(3.5), the lifting $\boldsymbol{J}_0$ depends on the control variable I_{inj}. We emphasize this dependence whenever appropriate by writing

$$\boldsymbol{J}_0 = \Lambda(I_{\text{inj}} \widetilde{\boldsymbol{J}}_{\text{inj}} \cdot \boldsymbol{n}), \tag{3.11}$$

meaning that $\boldsymbol{J}_0$ is the lifting, according to Lemma 3.2(b), of the function j in (3.10).

We now consider the homogenized state equation to find

$$\widehat{y} = (\widehat{\boldsymbol{u}}, p, \widehat{\boldsymbol{J}}, \phi). \tag{3.12}$$

In its variational form, the homogenized system is given by

$$\begin{aligned} a_1(\widehat{\boldsymbol{u}} + \boldsymbol{u}_0, \boldsymbol{v}) - c(\widehat{\boldsymbol{J}} + \boldsymbol{J}_0, \boldsymbol{B}, \boldsymbol{v}) + b(\widehat{\boldsymbol{u}} + \boldsymbol{u}_0, \widehat{\boldsymbol{u}} + \boldsymbol{u}_0, \boldsymbol{v}) + d_1(\boldsymbol{v}, p) &= 0, \\ d_1(\widehat{\boldsymbol{u}}, q) &= 0, \\ a_2(\widehat{\boldsymbol{J}} + \boldsymbol{J}_0, \boldsymbol{K}) + c(\boldsymbol{K}, \boldsymbol{B}, \widehat{\boldsymbol{u}} + \boldsymbol{u}_0) + d_2(\boldsymbol{K}, \phi) &= 0, \\ d_2(\widehat{\boldsymbol{J}}, \psi) &= 0 \end{aligned} \tag{3.13}$$

for all $(\boldsymbol{v}, q, \boldsymbol{K}, \psi) \in \boldsymbol{H}_0^1(\Omega) \times L^2(\Omega)/\mathbb{R} \times \boldsymbol{L}^2(\Omega) \times H^1(\Omega)/\mathbb{R}$, where we set

$$\boldsymbol{B} = \widetilde{\mathcal{B}}(\Lambda(I_{\text{inj}} \widetilde{\boldsymbol{J}}_{\text{inj}} \cdot \boldsymbol{n})) + \widetilde{\mathcal{B}}(\widehat{\boldsymbol{J}}) + \widetilde{\mathcal{B}}(\boldsymbol{J}_{\text{ext}}) + \widetilde{\mathcal{B}}(\boldsymbol{J}_{\text{inj}}) + \boldsymbol{B}_{\text{ext}} \tag{3.14}$$

as an abbreviation. The homogeneous solution $\widehat{y}$ is sought in the space

$$\widehat{Y} = \boldsymbol{H}_0^1(\Omega) \times L^2(\Omega)/\mathbb{R} \times \boldsymbol{L}^2(\Omega) \times H^1(\Omega)/\mathbb{R}. \tag{3.15}$$

In its strong form, (3.13) corresponds to

$$\begin{aligned} -\eta\Delta\widehat{\boldsymbol{u}} + \rho(\widehat{\boldsymbol{u}} \cdot \nabla)\widehat{\boldsymbol{u}} + \rho(\widehat{\boldsymbol{u}} \cdot \nabla)\boldsymbol{u}_0 + \rho(\boldsymbol{u}_0 \cdot \nabla)\widehat{\boldsymbol{u}} + \nabla p \\ = \eta\Delta\boldsymbol{u}_0 - \rho(\boldsymbol{u}_0 \cdot \nabla)\boldsymbol{u}_0 + \boldsymbol{J} \times \boldsymbol{B} + \boldsymbol{J}_0 \times \boldsymbol{B}, \\ \sigma^{-1}\widehat{\boldsymbol{J}} - \widehat{\boldsymbol{u}} \times \boldsymbol{B} + \nabla\phi = -\sigma^{-1}\boldsymbol{J}_0 + \boldsymbol{u}_0 \times \boldsymbol{B} \end{aligned}$$

plus the incompressibility conditions $\nabla \cdot \widehat{\boldsymbol{u}} = 0$ and $\nabla \cdot \widehat{\boldsymbol{J}} = 0$ and boundary conditions $\widehat{\boldsymbol{J}} \cdot \boldsymbol{n} = 0$ and $\widehat{\boldsymbol{u}} = 0$ on $\partial\Omega$. We note that the velocity boundary condition is incorporated into the space $\boldsymbol{H}_0^1(\Omega)$, whereas the boundary condition for the current is of variational type.

We now comment on the solvability of (3.13)–(3.14) and thus of the original system (3.1)–(3.7). As was observed in [22] for the MHD system without $\boldsymbol{J}_{\text{ext}}$ and $\boldsymbol{B}_{\text{ext}}$, the existence of a solution seems to be contingent upon the smallness of the liftings $\boldsymbol{u}_0$ and $\boldsymbol{J}_0$, i.e., smallness of the boundary data $\boldsymbol{h}$ and $\boldsymbol{J}_{\text{inj}} \cdot \boldsymbol{n}$. Note that, while the Navier–Stokes nonlinearity $\rho(\widehat{\boldsymbol{u}} \cdot \nabla)\widehat{\boldsymbol{u}}$ is conservative in the sense that $b(\widehat{\boldsymbol{u}}, \widehat{\boldsymbol{u}}, \widehat{\boldsymbol{u}}) = 0$, this is not the case for the bilinear terms $\boldsymbol{J} \times \boldsymbol{B}$ and $\widehat{\boldsymbol{u}} \times \boldsymbol{B}$. The existence proof given in [22] uses the LBB theory [7, Chap. IV, Thm. 1.2], and it is based on a limiting process of Galerkin approximations. Applying this technique to the present situation likewise yields solvability, provided that the data $\boldsymbol{h}$ and $\boldsymbol{J}_{\text{inj}} \cdot \boldsymbol{n}$ are sufficiently small. Under stronger assumptions involving also the remaining controls $\boldsymbol{J}_{\text{ext}}$ and $\boldsymbol{B}_{\text{ext}}$, uniqueness of the solution can be proved using [7, Chap. IV, Thm. 1.3]. In any case, the required bounds on the data seem not exactly tangible since they involve the embedding constants of $H^1(\Omega) \hookrightarrow L^p(\Omega)$ and the constant in the Poincaré inequality, as well as the norms of the lifting operator Λ and the Biot–Savart operator $\widetilde{\mathcal{B}}$. This is the reason that we refrain from stating the exact conditions here.

We provide here an alternative existence proof based on the Leray–Schauder fixed point theorem; see, for instance, [6, p. 222]. Let us define the operator $A : \widehat{Y} \to \widehat{Y}'$ by its components:

$$\begin{aligned}
A^1(\delta\boldsymbol{u}, \delta p, \delta\boldsymbol{J}, \delta\phi)(\boldsymbol{v}) &= a_1(\delta\boldsymbol{u}, \boldsymbol{v}) + d_1(\boldsymbol{v}, \delta p),\\
A^2(\delta\boldsymbol{u}, \delta p, \delta\boldsymbol{J}, \delta\phi)(q) &= d_1(\delta\boldsymbol{u}, q),\\
A^3(\delta\boldsymbol{u}, \delta p, \delta\boldsymbol{J}, \delta\phi)(\boldsymbol{K}) &= a_2(\delta\boldsymbol{J}, \boldsymbol{K}) + d_2(\boldsymbol{K}, \delta\phi),\\
A^4(\delta\boldsymbol{u}, \delta p, \delta\boldsymbol{J}, \delta\phi)(\psi) &= d_2(\delta\boldsymbol{J}, \psi).
\end{aligned}$$

We observe that A is an isomorphism since $(A_1, A_2)(\cdot, \cdot, 0, 0)$ defined between $\boldsymbol{H}^1_0(\Omega) \times L^2(\Omega)/\mathbb{R} \times \{0\} \times \{0\}$ and its dual is an isomorphism, and so is $(A_3, A_4)(0, 0, \cdot, \cdot)$, defined between $\{0\} \times \{0\} \times \boldsymbol{L}^2(\Omega) \times H^1(\Omega)/\mathbb{R}$ and its dual; see [22].

PROPOSITION 3.3 (state equation). *Suppose that Assumption* 3.1 *holds and that* $\|\boldsymbol{u}_0\|_{\boldsymbol{H}^1(\Omega)}$ *and* $\|\boldsymbol{J}_0\|_{\boldsymbol{L}^2(\Omega)}$ *are sufficiently small. Then the homogenized state equations* (3.13)–(3.14)*, and hence the original system* (3.1)–(3.7)*, possess at least one variational solution. Every such solution satisfies the a priori bound*

$$\begin{aligned}
\|\boldsymbol{u}\|^2_{\boldsymbol{H}^1(\Omega)} + \|\boldsymbol{J}\|^2_{\boldsymbol{L}^2(\Omega)} &\le c_1 \|\boldsymbol{J}_0\|^2_{\boldsymbol{L}^2(\Omega)} \left(1 + \|\boldsymbol{J}_0\|^2_{\boldsymbol{L}^2(\Omega)} + |u|^2\right)\\
&\quad + c_2 \|\boldsymbol{u}_0\|^2_{\boldsymbol{H}^1(\Omega)} \left(1 + \|\boldsymbol{J}_0\|^2_{\boldsymbol{L}^2(\Omega)} + |u|^2\right).
\end{aligned} \tag{3.16}$$

Moreover, we have the bound

$$\|p\|_{L^2(\Omega)/\mathbb{R}} + \|\phi\|_{H^1(\Omega)/\mathbb{R}} \le c_3 \left(\|\boldsymbol{u}\|_{\boldsymbol{H}^1(\Omega)} + \|\boldsymbol{u}\|^2_{\boldsymbol{H}^1(\Omega)} + \|\boldsymbol{J}\|_{\boldsymbol{L}^2(\Omega)} + \|\boldsymbol{J}\|^2_{\boldsymbol{L}^2(\Omega)}\right). \tag{3.17}$$

Proof. The proof can be found in the appendix. ∎

Remark 3.4. The constants c_1 and c_2 are of the form $\overline{c}_i(1 - \|\boldsymbol{J}_0\| - \|\boldsymbol{u}_0\|)^{-1}$. From the proof we infer that the larger the viscosity η of the fluid is and the smaller the conductivity σ is, the larger the liftings $\boldsymbol{u}_0$ and $\boldsymbol{J}_0$ in Proposition 3.3 are allowed to become, and thus the larger the boundary data $\boldsymbol{h}$ and the control I_{inj} are allowed to become.

The variational form of the state equation (3.13) gives rise to the definition of the PDE constraint operator

$$e : \widehat{Y} \times \mathbb{R}^3 \to \widehat{Y}'. \tag{3.18}$$

The components $e^1(\widehat{y},u)(\boldsymbol{v}),\dots,e^4(\widehat{y},u)(\psi)$ are defined through the left-hand sides of (3.13). This concise form of the MHD system

$$e(\widehat{y},u)=0 \qquad \text{in } \widehat{Y}' \tag{3.19}$$

will be used below to argue existence of the Lagrange multipliers in the optimality system, based on the following results on the linearization of e whose proofs are only given as necessary.

LEMMA 3.5 (linearized PDE constraint). *The operator e is infinitely Fréchet differentiable. Its first order partial derivative with respect to the state variables in the direction of $\delta y=(\delta\boldsymbol{u},\delta p,\delta\boldsymbol{J},\delta\phi)$ is given by*

$$\begin{aligned}
e_y^1(\widehat{y},u)(\delta y)(\boldsymbol{v}) &= a_1(\delta\boldsymbol{u},\boldsymbol{v})-c(\delta\boldsymbol{J},\boldsymbol{B},\boldsymbol{v})-c(\widehat{\boldsymbol{J}}+\Lambda(I_{\mathrm{inj}}\widetilde{\boldsymbol{J}}_{\mathrm{inj}}\cdot\boldsymbol{n}),\widetilde{\mathcal{B}}(\delta\boldsymbol{J}),\boldsymbol{v})\\
&\quad+b(\delta\boldsymbol{u},\widehat{\boldsymbol{u}}+\boldsymbol{u}_0,\boldsymbol{v})+b(\widehat{\boldsymbol{u}}+\boldsymbol{u}_0,\delta\boldsymbol{u},\boldsymbol{v})+d_1(\boldsymbol{v},\delta p),\\
e_y^2(\widehat{y},u)(\delta y)(q) &= d_1(\delta\boldsymbol{u},q),\\
e_y^3(\widehat{y},u)(\delta y)(\boldsymbol{K}) &= a_2(\delta\boldsymbol{J},\boldsymbol{K})+c(\boldsymbol{K},\boldsymbol{B},\delta\boldsymbol{u})+c(\boldsymbol{K},\widetilde{\mathcal{B}}(\delta\boldsymbol{J}),\widehat{\boldsymbol{u}}+\boldsymbol{u}_0)+d_2(\boldsymbol{K},\delta\phi),\\
e_y^4(\widehat{y},u)(\delta y)(\psi) &= d_2(\delta\boldsymbol{J},\psi),
\end{aligned} \tag{3.20}$$

where we have set again $\boldsymbol{B}=\widetilde{\mathcal{B}}(\Lambda(I_{\mathrm{inj}}\widetilde{\boldsymbol{J}}_{\mathrm{inj}}\cdot\boldsymbol{n}))+\widetilde{\mathcal{B}}(\widehat{\boldsymbol{J}})+\widetilde{\mathcal{B}}(\boldsymbol{J}_{\mathrm{ext}})+\widetilde{\mathcal{B}}(\boldsymbol{J}_{\mathrm{inj}})+\boldsymbol{B}_{\mathrm{ext}}$. As for the control variables, the first order derivative in the direction of $\delta u=(\delta I_{\mathrm{ext}},\delta I_{\mathrm{inj}},\delta B_{\mathrm{ext}})$ is

$$\begin{aligned}
e_u^1(\widehat{y},u)(\delta u)(\boldsymbol{v}) &= -c(\delta I_{\mathrm{inj}}\cdot\Lambda(\widetilde{\boldsymbol{J}}_{\mathrm{inj}}\cdot\boldsymbol{n}),\boldsymbol{B},\boldsymbol{v})-c(\widehat{\boldsymbol{J}}+\Lambda(I_{\mathrm{inj}}\widetilde{\boldsymbol{J}}_{\mathrm{inj}}\cdot\boldsymbol{n}),\delta I_{\mathrm{inj}}\cdot\widetilde{\mathcal{B}}(\Lambda(\widetilde{\boldsymbol{J}}_{\mathrm{inj}}\cdot\boldsymbol{n}))\\
&\quad+\delta I_{\mathrm{ext}}\cdot\widetilde{\mathcal{B}}(\widetilde{\boldsymbol{J}}_{\mathrm{ext}})+\delta I_{\mathrm{inj}}\cdot\widetilde{\mathcal{B}}(\widetilde{\boldsymbol{J}}_{\mathrm{inj}})+\delta B_{\mathrm{ext}}\cdot\widetilde{\boldsymbol{B}}_{\mathrm{ext}},\boldsymbol{v}),\\
e_u^2(\widehat{y},u)(\delta u)(q) &= 0,\\
e_u^3(\widehat{y},u)(\delta u)(\boldsymbol{K}) &= a_2(\delta I_{\mathrm{inj}}\cdot\Lambda(\widetilde{\boldsymbol{J}}_{\mathrm{inj}}\cdot\boldsymbol{n}),\boldsymbol{K}),\\
&\quad+c(\boldsymbol{K},\delta I_{\mathrm{inj}}\cdot\widetilde{\mathcal{B}}(\Lambda(\widetilde{\boldsymbol{J}}_{\mathrm{inj}}\cdot\boldsymbol{n}))+\delta I_{\mathrm{ext}}\cdot\widetilde{\mathcal{B}}(\widetilde{\boldsymbol{J}}_{\mathrm{ext}})+\delta I_{\mathrm{inj}}\cdot\widetilde{\mathcal{B}}(\widetilde{\boldsymbol{J}}_{\mathrm{inj}})+\delta B_{\mathrm{ext}}\cdot\widetilde{\boldsymbol{B}}_{\mathrm{ext}},\widehat{\boldsymbol{u}}+\boldsymbol{u}_0)\\
e_u^4(\widehat{y},u)(\delta u)(\psi) &= 0.
\end{aligned} \tag{3.21}$$

We note that in its strong form, the system $e_y(\widehat{y},u)(\delta y)=(\bar{e},\bar{f},\bar{g},\bar{h})\in\widehat{Y}'$ corresponds to

$$\begin{aligned}
-\eta\Delta\delta\boldsymbol{u}+\rho(\delta\boldsymbol{u}\cdot\nabla)(\widehat{\boldsymbol{u}}+\boldsymbol{u}_0)+\rho((\widehat{\boldsymbol{u}}+\boldsymbol{u}_0)\cdot\nabla)\delta\boldsymbol{u}+\nabla\delta p &= \delta\boldsymbol{J}\times\boldsymbol{B}+(\widehat{\boldsymbol{J}}+\boldsymbol{J}_0)\times\widetilde{\mathcal{B}}(\delta\boldsymbol{J})+\bar{e},\\
\nabla\cdot\delta\boldsymbol{u} &= \bar{f},\\
\sigma^{-1}\delta\boldsymbol{J}-\delta\boldsymbol{u}\times\boldsymbol{B}-(\widehat{\boldsymbol{u}}+\boldsymbol{u}_0)\times\widetilde{\mathcal{B}}(\delta\boldsymbol{J})+\nabla\delta\phi &= \bar{g},\\
\nabla\cdot\boldsymbol{J} &= \bar{h}.
\end{aligned}$$

The first and third components of $e_u(\widehat{y},u)\delta u$ must be read as

$$\begin{aligned}
&-\delta I_{\mathrm{inj}}\cdot\Lambda(\widetilde{\boldsymbol{J}}_{\mathrm{inj}}\cdot\boldsymbol{n})\times\boldsymbol{B}-(\widehat{\boldsymbol{J}}+\Lambda(I_{\mathrm{inj}}\widetilde{\boldsymbol{J}}_{\mathrm{inj}}\cdot\boldsymbol{n}))\\
&\qquad\times\left(\delta I_{\mathrm{inj}}\cdot\widetilde{\mathcal{B}}(\Lambda(\widetilde{\boldsymbol{J}}_{\mathrm{inj}}\cdot\boldsymbol{n}))+\delta I_{\mathrm{ext}}\cdot\widetilde{\mathcal{B}}(\widetilde{\boldsymbol{J}}_{\mathrm{ext}})+\delta I_{\mathrm{inj}}\cdot\widetilde{\mathcal{B}}(\widetilde{\boldsymbol{J}}_{\mathrm{inj}})+\delta B_{\mathrm{ext}}\cdot\widetilde{\boldsymbol{B}}_{\mathrm{ext}}\right)
\end{aligned}$$

and

$$\begin{aligned}
&\sigma^{-1}\delta I_{\mathrm{inj}}\cdot\Lambda(\widetilde{\boldsymbol{J}}_{\mathrm{inj}}\cdot\boldsymbol{n})-(\widehat{\boldsymbol{u}}+\boldsymbol{u}_0)\\
&\qquad\times\left(\delta I_{\mathrm{inj}}\cdot\widetilde{\mathcal{B}}(\Lambda(\widetilde{\boldsymbol{J}}_{\mathrm{inj}}\cdot\boldsymbol{n}))+\delta I_{\mathrm{ext}}\cdot\widetilde{\mathcal{B}}(\widetilde{\boldsymbol{J}}_{\mathrm{ext}})+\delta I_{\mathrm{inj}}\cdot\widetilde{\mathcal{B}}(\widetilde{\boldsymbol{J}}_{\mathrm{inj}})+\delta B_{\mathrm{ext}}\cdot\widetilde{\boldsymbol{B}}_{\mathrm{ext}}\right),
\end{aligned}$$

respectively.

In preparation for the following proposition, let us define the operator $C : \widehat{Y} \to \widehat{Y}'$ by its components:

$$\begin{aligned}
C^1(\widehat{y},u)(\delta\boldsymbol{u},\delta p,\delta\boldsymbol{J},\delta\phi)(\boldsymbol{v}) &= -c(\delta\boldsymbol{J},\boldsymbol{B},\boldsymbol{v}) - c(\widehat{\boldsymbol{J}}+\boldsymbol{J}_0,\widetilde{\mathcal{B}}(\delta\boldsymbol{J}),\boldsymbol{v}) + b(\delta\boldsymbol{u},\widehat{\boldsymbol{u}}+\boldsymbol{u}_0,\boldsymbol{v}) \\
&\quad + b(\widehat{\boldsymbol{u}}+\boldsymbol{u}_0,\delta\boldsymbol{u},\boldsymbol{v}),\\
C^2(\widehat{y},u)(\delta\boldsymbol{u},\delta p,\delta\boldsymbol{J},\delta\phi)(q) &= 0,\\
C^3(\widehat{y},u)(\delta\boldsymbol{u},\delta p,\delta\boldsymbol{J},\delta\phi)(\boldsymbol{K}) &= c(\boldsymbol{K},\boldsymbol{B},\delta\boldsymbol{u}) + c(\boldsymbol{K},\widetilde{\mathcal{B}}(\delta\boldsymbol{J}),\widehat{\boldsymbol{u}}+\boldsymbol{u}_0),\\
C^4(\widehat{y},u)(\delta\boldsymbol{u},\delta p,\delta\boldsymbol{J},\delta\phi)(\psi) &= 0.
\end{aligned}$$

The quantities $\boldsymbol{u}_0$ and $\boldsymbol{J}_0$ are the liftings according to Lemma 3.2 for given arbitrary but fixed controls u and boundary data $\boldsymbol{h}$.

PROPOSITION 3.6 (linearized state equation). *For any given $\widehat{y} \in \widehat{Y}$, $u \in \mathbb{R}^3$, and $\boldsymbol{h} \in \boldsymbol{H}^{1/2}(\partial\Omega)$, the linearization with respect to the state variables of the operator e can be decomposed as*

$$e_y(\widehat{y},u) = A + C(\widehat{y},u), \tag{3.22}$$

where $A : \widehat{Y} \to \widehat{Y}'$ is an isomorphism, independent of $(\widehat{y},u)$, and $C(\widehat{y},u) : \widehat{Y} \to \widehat{Y}'$ is a compact linear operator.

Proof. The isomorphism property of A has been noted previously; see the definition of A immediately preceding Proposition 3.3. As for compactness of C, we recall that $\boldsymbol{B} \in \boldsymbol{L}^{3+\varepsilon}(\Omega)$ (see Lemma 2.4 and Assumption 3.1) and infer from Lemma 2.6 that $\delta\boldsymbol{J} \mapsto \delta\boldsymbol{J} \times \boldsymbol{B}$ is compact from $\boldsymbol{L}^2(\Omega)$ to $\boldsymbol{H}^{-1}(\Omega)$. Hence $\delta\boldsymbol{J} \mapsto c(\delta\boldsymbol{J},\boldsymbol{B},\cdot)$ is compact from $\boldsymbol{L}^2(\Omega)$ to $\boldsymbol{H}^{-1}(\Omega)$. Similarly, by Lemmas 2.4 and 2.6, $\delta\boldsymbol{J} \mapsto \boldsymbol{J} \times \widetilde{\mathcal{B}}(\delta\boldsymbol{J})$ is compact from $\boldsymbol{L}^2(\Omega)$ to $\boldsymbol{H}^{-1}(\Omega)$, and hence $\delta\boldsymbol{J} \mapsto c(\boldsymbol{J},\widetilde{\mathcal{B}}(\delta\boldsymbol{J}),\cdot)$ is compact from $\boldsymbol{L}^2(\Omega)$ to $\boldsymbol{H}^{-1}(\Omega)$. In addition, $\delta\boldsymbol{u} \mapsto b(\delta\boldsymbol{u},\widehat{\boldsymbol{u}}+\boldsymbol{u}_0,\cdot)$ and $\delta\boldsymbol{u} \mapsto b(\widehat{\boldsymbol{u}}+\boldsymbol{u}_0,\delta\boldsymbol{u},\cdot)$ are continuous from $\boldsymbol{H}^1_0(\Omega)$ to $\boldsymbol{L}^{3/2}(\Omega)$, which embeds compactly into $\boldsymbol{W}^{-1,3-\varepsilon}(\Omega)$ for all $\varepsilon > 0$ and thus into $\boldsymbol{H}^{-1}(\Omega)$. This completes the proof of compactness for C^1. As for C^3, we let $p = 2(3+\varepsilon)/(1+\varepsilon) < 6$ and observe that $\delta\boldsymbol{u} \mapsto c(\cdot,\boldsymbol{B},\delta\boldsymbol{u})$ is continuous from $\boldsymbol{L}^p(\Omega)$ to $\boldsymbol{L}^2(\Omega)$. In view of the compact embedding $\boldsymbol{H}^1_0(\Omega) \hookrightarrow \boldsymbol{L}^p(\Omega)$, this map is compact from $\boldsymbol{H}^1_0(\Omega)$ to $\boldsymbol{L}^2(\Omega)$. Finally, since $\delta\boldsymbol{J} \mapsto \widetilde{\mathcal{B}}(\delta\boldsymbol{J})$ is continuous from $\boldsymbol{L}^2(\Omega)$ to $V^1(\Omega)$, which embeds compactly into $\boldsymbol{L}^3(\Omega)$, the map $\delta\boldsymbol{J} \mapsto c(\cdot,\widetilde{\mathcal{B}}(\delta\boldsymbol{J}),\widehat{\boldsymbol{u}}+\boldsymbol{u}_0)$ is compact from $\boldsymbol{L}^2(\Omega)$ to $\boldsymbol{L}^2(\Omega)$, which completes the proof. ∎

The previous proposition allows us to draw the following conclusions about the properties of the linearized state operator $e_y(\widehat{y},u)$.

PROPOSITION 3.7 (bounded invertibility of $e_y(\widehat{y},u)$). *Except for a countable set of (η,σ) values, the operator $e_y(\widehat{y},u)$ is an isomorphism. Moreover, $e_y(\widehat{y},u)$ is an isomorphism whenever η is sufficiently large and σ is sufficiently small.*

Proof. For $(\bar{e},\bar{f},\bar{g},\bar{h}) \in \widehat{Y}'$, consider the equation

$$\left(A + C(\widehat{y},u)\right)(\delta\boldsymbol{u},\delta p,\delta\boldsymbol{J},\delta\phi) = (\bar{e},\bar{f},\bar{g},\bar{h}) \tag{3.23}$$

and define $\mathcal{A} : \widehat{Y} \to \widehat{Y}'$ through its coordinates

$$\begin{aligned}
\mathcal{A}^1(\delta\boldsymbol{u},\delta p,\delta\boldsymbol{J},\delta\phi)(\boldsymbol{v}) &= \int_\Omega \nabla\delta\boldsymbol{u} : \nabla\boldsymbol{v} - \int_\Omega (\nabla\cdot\boldsymbol{v})\,\mathcal{P}(\delta p),\\
\mathcal{A}^2 &= A^2,\\
\mathcal{A}^3(\delta\boldsymbol{u},\delta p,\delta\boldsymbol{J},\delta\phi)(\boldsymbol{K}) &= \int_\Omega \delta\boldsymbol{J}\cdot\boldsymbol{K} + \int_\Omega \boldsymbol{K}\cdot\nabla(\delta\phi),\\
\mathcal{A}^4 &= A^4,
\end{aligned}$$

where $(\boldsymbol{v}, \boldsymbol{K}) \in \boldsymbol{H}_0^1(\Omega) \times \boldsymbol{L}^2(\Omega)$, i.e., $\mathcal{A}$ arises from A by setting $\eta = \sigma = 1$. Multiplying the first two equations in (3.23) by η^{-1} and the last two by σ, we find that the following equation is equivalent to (3.23):

$$(\mathcal{A} + \eta^{-1}\mathcal{C}_1 + \sigma\mathcal{C}_2)(\delta\boldsymbol{u}, \widehat{\delta p}, \delta\boldsymbol{J}, \widehat{\delta\phi}) = (\eta^{-1}\bar{e}, \bar{f}, \sigma\bar{g}, \bar{h}), \tag{3.24}$$

where $\widehat{\delta p} = \eta^{-1}\delta p$ and $\widehat{\delta\phi} = \sigma\delta\phi$ and $\mathcal{C}_1 = (C_1, C_2, 0, 0)^\top$, $\mathcal{C}_2 = (0, 0, C_3, C_4)^\top$. From the proof of Proposition 3.6 we have that $\mathcal{A} : \widehat{Y} \to \widehat{Y}'$ is an isomorphism and that $\mathcal{C}_1$ and $\mathcal{C}_2$ are compact operators from $\widehat{Y}$ to $\widehat{Y}'$. Moreover, (3.24) is equivalent to

$$(I + \eta^{-1}\mathcal{K}_1 + \sigma\mathcal{K}_2)(\delta\boldsymbol{u}, \widehat{\delta p}, \delta\boldsymbol{J}, \widehat{\delta\phi}) = (e, f, g, h), \tag{3.25}$$

where $(e, f, g, h) = \mathcal{A}^{-1}(\eta^{-1}\bar{e}, \bar{f}, \sigma\bar{g}, \bar{h})$, and

$$\mathcal{K}_1 = \mathcal{A}^{-1}\mathcal{C}_1, \qquad \mathcal{K}_2 = \mathcal{A}^{-1}\mathcal{C}_2.$$

Hence, $\mathcal{K}_1$ and $\mathcal{K}_2$ are compact operators in $\widehat{Y}$. Therefore the spectrum of $\mathcal{K}_1$, denoted by $\sum(\mathcal{K}_1)$, consists of 0 and at most countably many eigenvalues, with 0 being the only possible accumulation point. For $-\eta \notin \sum(\mathcal{K}_1)$ we have

$$(I + \sigma(I + \eta^{-1}\mathcal{K}_1)^{-1}\mathcal{K}_2)(\delta\boldsymbol{u}, \widehat{\delta p}, \delta\boldsymbol{J}, \widehat{\delta\phi}) = (I + \eta^{-1}\mathcal{K}_1)^{-1}(e, f, g, h). \tag{3.26}$$

Since $(I + \eta^{-1}\mathcal{K}_1)$ has a continuous inverse, we find that (3.26), and hence (3.23) are solvable if $-\sigma^{-1} \notin \sum((I + \eta^{-1}\mathcal{K}_1)^{-1}\mathcal{K}_2)$. Since the set of points $\mathcal{S} := \{(\eta, \sigma^{-1}) : -\eta \in \Sigma(\mathcal{K}_1), -\sigma^{-1} \in \Sigma((I - \eta^{-1}\mathcal{K}_1)^{-1}\mathcal{K}_2)\}$ is countable in $\mathbb{R}^2$, the first claim follows. The second claim is a consequence of a Neumann series argument applied to (3.25). ∎

From the proof of Proposition 3.7 we conclude that $e_y(\widehat{y}, u)$, and therefore $e_x(\widehat{y}, u)$, is generically surjective. Lack of surjectivity of $e_y(\widehat{y}, u)$ occurs if and only if $(\eta, \sigma^{-1}) \in \mathcal{S}$. In that case, Fredholm's alternative provides another way to prove surjectivity of $e_x(\widehat{y}, u)$. Note that $e_u(\widehat{y}, u)\,\delta u$ can be written in the form

$$e_u(\widehat{y}, u)\,\delta u = \delta I_{\text{inj}}\,\psi_1 + \delta I_{\text{ext}}\,\psi_2 + \delta B_{\text{ext}}\,\psi_3$$

with $\psi_i \in \widehat{Y}'$. In the following proposition, $(A + C)^\star : \widehat{Y}' \to \widehat{Y}$ refers to the Hilbert space adjoint.

PROPOSITION 3.8 (surjectivity of $e_x(\widehat{y}, u)$). *If span* $\{\psi_1, \psi_2, \psi_3\} \supseteq \ker(A + C)^\star$, *then* $e_x(\widehat{y}, u)$ *is surjective.*

Proof. Since $A : \widehat{Y} \to \widehat{Y}'$ is an isomorphism and C is compact, the Fredholm alternative implies that the range of $A + C$ is closed and $R(A + C)^\perp = \ker(A + C)^\star$, with $\dim \ker(A + C)^\star =: L < \infty$. Let $\{\omega_i\}_{i=1}^L \subset \widehat{Y}'$ be a basis for $\ker(A + C)^\star$, orthonormalized such that $\langle \omega_i, \omega_j \rangle_{\widehat{Y}'} = \delta_{ij}$. For arbitrary $\widehat{f} \in \widehat{Y}'$, define $\widetilde{f} = \widehat{f} - \sum_{i=1}^L \langle \widehat{f}, \omega_i \rangle_{\widehat{Y}'} \cdot \omega_i$. Then $\widetilde{f} \in \ker(A+C)^{\star,\perp}$ and there exists $x_{\widetilde{f}}$ such that $(A+C)x_{\widetilde{f}} = \widetilde{f}$. By assumption there exist $(\delta I_{\text{inj}}, \delta I_{\text{ext}}, \delta\boldsymbol{B}_{\text{ext}})$ such that $e_u(\widehat{y}, u)\delta u = \widehat{f} - \widetilde{f}$ and the claim follows. ∎

Having established these properties for the stationary MHD system and its linearization, we now return to the optimal control problem. We recall that we aim to

$$
\begin{aligned}
&\text{minimize } f(\widehat{y},u) = \frac{\alpha_u}{2}\|\boldsymbol{u}-\boldsymbol{u}_{\mathrm{d}}\|^2_{L^2(\Omega_{u,\mathrm{obs}})} + \frac{\alpha_B}{2}\|\boldsymbol{B}-\boldsymbol{B}_{\mathrm{d}}\|^2_{L^2(\Omega_{B,\mathrm{obs}})} \\
\text{(P)}\qquad &\qquad + \frac{\alpha_J}{2}\|\boldsymbol{J}-\boldsymbol{J}_{\mathrm{d}}\|^2_{L^2(\Omega_{J,\mathrm{obs}})} + \frac{\gamma_{\mathrm{ext}}}{2}|I_{\mathrm{ext}}|^2 + \frac{\gamma_{\mathrm{inj}}}{2}|I_{\mathrm{inj}}|^2 + \frac{\gamma_B}{2}|B_{\mathrm{ext}}|^2 \\
&\qquad \text{over } \widehat{y}\in\widehat{Y} \text{ and } u\in U_{\mathrm{ad}} \\
&\qquad \text{subject to } e(\widehat{y},u)=0,
\end{aligned}
$$

where $\boldsymbol{u}=\widehat{\boldsymbol{u}}+\boldsymbol{u}_0$ and $\boldsymbol{J}=\widehat{\boldsymbol{J}}+\boldsymbol{J}_0$. $\boldsymbol{B}$ is defined in (3.14), and U_{ad} in Assumption 3.9 below. Recall also that the lifting $\boldsymbol{J}_0$, and hence $\boldsymbol{B}$, depends on the control I_{inj}. In order to ensure well-posedness of problem (P), we need the following assumption on the problem data.

Assumption 3.9 (control problem data). Assume that the boundary data

$$\|\boldsymbol{h}\|_{\boldsymbol{H}^{1/2}(\partial\Omega)}$$

is sufficiently small, and that for some fixed $r>0$ and all controls in the set

$$U_{\mathrm{ad}} = \{(I_{\mathrm{ext}}, I_{\mathrm{inj}}, B_{\mathrm{ext}})\in\mathbb{R}^3 \,:\, |I_{\mathrm{inj}}|\le r\},$$

the liftings $\boldsymbol{u}_0$ and $\boldsymbol{J}_0=\Lambda(I_{\mathrm{inj}}\widetilde{\boldsymbol{J}}_{\mathrm{inj}}\cdot\boldsymbol{n})$ allow the existence of a solution to the stationary MHD system.

In fact, smallness of $\boldsymbol{h}$ and I_{inj} implies by Lemma 3.2 smallness of $\boldsymbol{u}_0$ and $\boldsymbol{J}_0$, which in turn implies existence of solutions according to Proposition 3.3.

Proposition 3.10 (existence of a global minimum). *Under Assumptions* 3.1 *and* 3.9, *problem* (P) *possesses at least one global optimal solution in* $\widehat{Y}\times U_{\mathrm{ad}}$.

Proof. The proof follows along the usual lines. We set $m=\inf f(\widehat{y},u)$, where the infimum extends over all state/control pairs $(\widehat{y},u)\in\widehat{Y}\times U_{\mathrm{ad}}$ which satisfy the state equation (admissible pairs). Note that m is nonnegative and finite since f is nonnegative and the set of admissible pairs is nonempty (Assumption 3.9 and Proposition 3.3). Now if $\{(\widehat{y}^n,u^n)\}$ is a minimizing sequence, we can infer from the cost functional that the controls u^n are bounded in $\mathbb{R}^3$. By the a priori estimate (3.16), $\widehat{y}^n$ is bounded in $\widehat{Y}$. We extract weakly convergent subsequences, still denoted by index n, such that

$$
\begin{aligned}
&\widehat{\boldsymbol{u}}^n \rightharpoonup \widehat{\boldsymbol{u}} \quad \text{in } \boldsymbol{H}^1_0(\Omega), && p^n \rightharpoonup p \quad \text{in } L^2(\Omega)/\mathbb{R},\\
&\widehat{\boldsymbol{J}}^n \rightharpoonup \widehat{\boldsymbol{J}} \quad \text{in } \boldsymbol{L}^2(\Omega), && \phi^n \rightharpoonup \phi \quad \text{in } H^1(\Omega)/\mathbb{R},\\
&u^n \to u \quad \text{in } \mathbb{R}^3. &&
\end{aligned}
$$

Note that the lifting $\boldsymbol{u}_0$ is independent of n and that $\boldsymbol{J}_0^n=\Lambda(I_{\mathrm{inj}}^n\widetilde{\boldsymbol{J}}_{\mathrm{inj}}\cdot\boldsymbol{n})$ converges strongly to some $\boldsymbol{J}_0$ in $\boldsymbol{L}^2(\Omega)$. In order to pass to the limit in $e(\widehat{y}^n,u^n)$, we consider the individual terms in (3.13). For the terms involving the bilinear forms a_i and d_i, the convergence is evident. In addition, $b(\widehat{\boldsymbol{u}}^n,\widehat{\boldsymbol{u}}^n,\boldsymbol{v})\to b(\widehat{\boldsymbol{u}},\widehat{\boldsymbol{u}},\boldsymbol{v})$ is known from the theory of Navier–Stokes problems, see [7, Chap. IV, Thm. 2.1]. The convergence of all terms involving the trilinear form c follows from Lemmas 2.3 and 2.6. Consequently, the weak limit $(\widehat{y},u)$ satisfies the state equation $e(\widehat{y},u)=0$, and hence the weak limit $(\widehat{\boldsymbol{u}}+\boldsymbol{u}_0,p,\widehat{\boldsymbol{J}}+\boldsymbol{J}_0,\phi)$ satisfies our inhomogeneous MHD system. The claim now follows from the weak lower semicontinuity of the objective, by which

$$m\le f(\widehat{y},u)\le\liminf_{n\to\infty} f(\widehat{y}^n,u^n)=m. \qquad \square$$

THEOREM 3.11 (optimality system). *Let Assumptions* 3.1 *and* 3.9 *hold, and let the state* $\widehat{y} = (\widehat{\boldsymbol{u}}, p, \widehat{\boldsymbol{J}}, \phi) \in \widehat{Y}$ *and control* $u = (I_{\mathrm{ext}}, I_{\mathrm{inj}}, B_{\mathrm{ext}}) \in U_{\mathrm{ad}}$ *constitute a local optimal pair for problem* (P). *In addition, let* $e_x(\widehat{y}, u)$ *be surjective. Then there exists a unique Lagrange multiplier*

$$\lambda = (\boldsymbol{v}, q, \boldsymbol{K}, \psi) \in \widehat{Y}$$

which satisfies the adjoint equations

$$\begin{aligned} &a_1(\delta\boldsymbol{u}, \boldsymbol{v}) + b(\delta\boldsymbol{u}, \boldsymbol{u}, \boldsymbol{v}) + b(\boldsymbol{u}, \delta\boldsymbol{u}, \boldsymbol{v}) + d_1(\delta\boldsymbol{u}, q) + c(\boldsymbol{K}, \boldsymbol{B}, \delta\boldsymbol{u}) \\ &\qquad + \alpha_u \int_{\Omega_{u,\mathrm{obs}}} (\boldsymbol{u} - \boldsymbol{u}_{\mathrm{d}}) \cdot \delta\boldsymbol{u} = 0, \end{aligned} \tag{3.27a}$$

$$d_1(\boldsymbol{v}, \delta p) = 0, \tag{3.27b}$$

$$\begin{aligned} &-c(\delta\boldsymbol{J}, \boldsymbol{B}, \boldsymbol{v}) - c(\boldsymbol{J}, \widetilde{\mathcal{B}}(\delta\boldsymbol{J}), \boldsymbol{v}) + a_2(\delta\boldsymbol{J}, \boldsymbol{K}) + c(\boldsymbol{K}, \widetilde{\mathcal{B}}(\delta\boldsymbol{J}), \boldsymbol{u}) \\ &\quad + d_2(\delta\boldsymbol{J}, \psi) + \alpha_B \int_{\Omega_{B,\mathrm{obs}}} (\boldsymbol{B} - \boldsymbol{B}_{\mathrm{d}}) \cdot \widetilde{\mathcal{B}}(\delta\boldsymbol{J}) + \alpha_J \int_{\Omega_{J,\mathrm{obs}}} (\boldsymbol{J} - \boldsymbol{J}_{\mathrm{d}}) \cdot \delta\boldsymbol{J} = 0, \end{aligned} \tag{3.27c}$$

$$d_2(\boldsymbol{K}, \delta\phi) = 0 \tag{3.27d}$$

for all $(\delta\boldsymbol{u}, \delta p, \delta\boldsymbol{J}, \delta\phi) \in \boldsymbol{H}^1_0(\Omega) \times L^2(\Omega)/\mathbb{R} \times \boldsymbol{L}^2(\Omega) \times H^1(\Omega)/\mathbb{R}$, *and which satisfy the three scalar optimality conditions*

$$-c(\boldsymbol{J}, \widetilde{\mathcal{B}}(\widetilde{\boldsymbol{J}}_{\mathrm{ext}}), \boldsymbol{v}) + c(\boldsymbol{K}, \widetilde{\mathcal{B}}(\widetilde{\boldsymbol{J}}_{\mathrm{ext}}), \boldsymbol{u}) + \gamma_{\mathrm{ext}} I_{\mathrm{ext}} + \alpha_B \int_{\Omega_{B,\mathrm{obs}}} (\boldsymbol{B} - \boldsymbol{B}_{\mathrm{d}}) \cdot \widetilde{\mathcal{B}}(\widetilde{\boldsymbol{J}}_{\mathrm{ext}}) = 0, \tag{3.28a}$$

$$\begin{aligned} &\Big[-c(\boldsymbol{J}, \widetilde{\mathcal{B}}(\widetilde{\boldsymbol{J}}_{\mathrm{inj}}), \boldsymbol{v}) + c(\boldsymbol{K}, \widetilde{\mathcal{B}}(\widetilde{\boldsymbol{J}}_{\mathrm{inj}}), \boldsymbol{u}) + \gamma_{\mathrm{inj}} I_{\mathrm{inj}} + \alpha_B \int_{\Omega_{B,\mathrm{obs}}} (\boldsymbol{B} - \boldsymbol{B}_{\mathrm{d}}) \cdot \widetilde{\mathcal{B}}(\widetilde{\boldsymbol{J}}_{\mathrm{inj}}) \\ &\quad - \big\langle \widetilde{\boldsymbol{J}}_{\mathrm{inj}} \cdot \boldsymbol{n}, \psi \big\rangle_{\partial\Omega \cap \partial\Omega_{\mathrm{inj}}} \Big] (\overline{I}_{\mathrm{inj}} - I_{\mathrm{inj}}) \geq 0 \quad \textit{for all } |\overline{I}_{\mathrm{inj}}| \leq r, \end{aligned} \tag{3.28b}$$

$$-c(\boldsymbol{J}, \widetilde{\boldsymbol{B}}_{\mathrm{ext}}, \boldsymbol{v}) + c(\boldsymbol{K}, \widetilde{\boldsymbol{B}}_{\mathrm{ext}}, \boldsymbol{u}) + \gamma_{\mathrm{B}} B_{\mathrm{ext}} + \alpha_B \int_{\Omega_{B,\mathrm{obs}}} (\boldsymbol{B} - \boldsymbol{B}_{\mathrm{d}}) \cdot \widetilde{\boldsymbol{B}}_{\mathrm{ext}} = 0. \tag{3.28c}$$

Proof. Our proof relies on a classical abstract multiplier result; see, e.g., Maurer and Zowe [20]. Since f is Fréchet differentiable, e is continuously Fréchet differentiable, and e_x is assumed surjective at $(\widehat{y}, u)$, it follows that there exists a Lagrange multiplier $\lambda \in \widehat{Y}$, which satisfies

$$\begin{aligned} &f_y(\widehat{y}, u)(\delta y) + \big\langle \lambda, e_y(\widehat{y}, u)(\delta y) \big\rangle = 0 \qquad\qquad \text{for all } \delta y \in \widehat{Y}, \\ &f_u(\widehat{y}, u)(\overline{\delta u} - \delta u) + \big\langle \lambda, e_u(\widehat{y}, u)(\overline{\delta u} - \delta u) \big\rangle \geq 0 \text{ for all } \overline{\delta u} \in U_{\mathrm{ad}}. \end{aligned} \tag{3.29}$$

Above, the duality holds in $\widehat{Y} \times \widehat{Y}'$. It is now straightforward to verify that (3.29) is nothing else but (3.27)–(3.28). ∎

The elements of the Lagrange multiplier λ are termed the adjoint velocity $\boldsymbol{v}$, the adjoint pressure q, the adjoint current density $\boldsymbol{K}$, and the adjoint potential ψ, respectively, all defined on Ω.

In order to improve our understanding of the adjoint system (3.27), we also paraphrase it in its strong form. Exploiting the self-adjointness of the linear Biot–Savart

operator $\widetilde{\mathcal{B}}$, we obtain the dual state equations on Ω,

$$\begin{aligned} \varrho(\nabla \boldsymbol{u})^\top \boldsymbol{v} - \varrho(\boldsymbol{u}\cdot\nabla)\boldsymbol{v} - \eta\Delta\boldsymbol{v} + \nabla q - \boldsymbol{B}\times\boldsymbol{K} &= -\alpha_u \chi_{\Omega_{u,\mathrm{obs}}}(\boldsymbol{u}-\boldsymbol{u}_\mathrm{d}), \qquad (3.30)\\ \sigma^{-1}\boldsymbol{K} - \widetilde{\mathcal{B}}(\boldsymbol{K}\times\boldsymbol{u} + \boldsymbol{v}\times\boldsymbol{J}) + \nabla\psi - \boldsymbol{B}\times\boldsymbol{v} &= -\alpha_J\chi_{\Omega_{J,\mathrm{obs}}}(\boldsymbol{J}-\boldsymbol{J}_\mathrm{d}) - \alpha_B\chi_{\Omega_{B,\mathrm{obs}}\cap\Omega}\widetilde{\mathcal{B}}(\boldsymbol{B}-\boldsymbol{B}_\mathrm{d}), \qquad (3.31)\end{aligned}$$

plus incompressibility conditions

$$\nabla\cdot\boldsymbol{v} = 0 \quad \text{on } \Omega, \qquad\qquad \nabla\cdot\boldsymbol{K} = 0 \quad \text{on } \Omega \tag{3.32}$$

and boundary conditions

$$\boldsymbol{v} = 0 \quad \text{on } \partial\Omega, \qquad\qquad \boldsymbol{K}\cdot\boldsymbol{n} = 0 \quad \text{on } \partial\Omega. \tag{3.33}$$

The symbol χ_A denotes the characteristic function of a set A. Note that the controls I_ext, I_inj, and B_ext appear (hidden within $\boldsymbol{B}$) in the adjoint equations (3.27a) and (3.27c), or in (3.30)–(3.31) for that matter. The reason is that the state equations (3.1)–(3.2) contain the "state times control" terms $\boldsymbol{u}\times\boldsymbol{B}$ (through Ohm's Law (1.3)) and $\boldsymbol{J}\times\boldsymbol{B}$ (the Lorentz force).

Let us now turn to a condition which ensures the strict local optimality of a given point (y,u,λ) satisfying the first order optimality condition set forth in Theorem 3.11. To this end, we define the Lagrangian function for problem (P) as

$$\begin{aligned}\mathcal{L}(\widehat{y},u,\lambda) = {}& \frac{\alpha_u}{2}\|\boldsymbol{u}-\boldsymbol{u}_\mathrm{d}\|^2_{L^2(\Omega_{u,\mathrm{obs}})} + \frac{\alpha_B}{2}\|\boldsymbol{B}-\boldsymbol{B}_\mathrm{d}\|^2_{L^2(\Omega_{B,\mathrm{obs}})} + \frac{\alpha_J}{2}\|\boldsymbol{J}-\boldsymbol{J}_\mathrm{d}\|^2_{L^2(\Omega_{J,\mathrm{obs}})}\\ &+ \frac{\gamma_\mathrm{ext}}{2}|I_\mathrm{ext}|^2 + \frac{\gamma_\mathrm{inj}}{2}|I_\mathrm{inj}|^2 + \frac{\gamma_B}{2}|B_\mathrm{ext}|^2 + a_1(\widehat{\boldsymbol{u}}+\boldsymbol{u}_0,\boldsymbol{v}) - c(\widehat{\boldsymbol{J}}+\boldsymbol{J}_0,\boldsymbol{B},\boldsymbol{v})\\ &+ b(\widehat{\boldsymbol{u}}+\boldsymbol{u}_0,\widehat{\boldsymbol{u}}+\boldsymbol{u}_0,\boldsymbol{v}) + d_1(\boldsymbol{v},p) - d_1(\widehat{\boldsymbol{u}},q) + a_2(\widehat{\boldsymbol{J}}+\boldsymbol{J}_0,\boldsymbol{K})\\ &+ c(\boldsymbol{K},\boldsymbol{B},\widehat{\boldsymbol{u}}+\boldsymbol{u}_0) + d_2(\boldsymbol{K},\phi) - d_2(\widehat{\boldsymbol{J}},\psi) + \big\langle I_\mathrm{inj}\widetilde{\boldsymbol{J}}_\mathrm{inj}\cdot\boldsymbol{n},\psi\big\rangle_{\partial\Omega\cap\partial\Omega_\mathrm{inj}},\end{aligned}$$

where again $\boldsymbol{u} = \widehat{\boldsymbol{u}}+\boldsymbol{u}_0$, $\boldsymbol{J} = \widehat{\boldsymbol{J}}+\Lambda(I_\mathrm{inj}\widetilde{\boldsymbol{J}}_\mathrm{inj}\cdot\boldsymbol{n})$, and $\boldsymbol{B}$ is defined in (3.14). Moreover, $\boldsymbol{u}_0$ is the fixed lifting of the velocity boundary data $\boldsymbol{h}$ from Lemma 3.2, and $\boldsymbol{B}$ is still taken according to (3.14). It is readily checked that the following quadratic form is the Hessian of $\mathcal{L}$ with respect to the state/control pair:

$$\begin{aligned}\mathcal{L}''(\widehat{y},u,\lambda)[(\delta y,\delta u)]^2 = {}& \alpha_u\|\delta\boldsymbol{u}\|^2_{L^2(\Omega_{u,\mathrm{obs}})} + \alpha_J\|\delta\boldsymbol{J}\|^2_{L^2(\Omega_{J,\mathrm{obs}})} + \alpha_B\|\delta\widetilde{\mathcal{B}}\|^2_{L^2(\Omega_{B,\mathrm{obs}})}\\ &+ \gamma_\mathrm{ext}|\delta I_\mathrm{ext}|^2 + \gamma_\mathrm{inj}|\delta I_\mathrm{inj}|^2 + \gamma_B|\delta B_\mathrm{ext}|^2 + 2b(\delta\boldsymbol{u},\delta\boldsymbol{u},\boldsymbol{v})\\ &- 2c(\delta\boldsymbol{J},\delta\widetilde{\mathcal{B}},\boldsymbol{v}) + 2c(\boldsymbol{K},\delta\widetilde{\mathcal{B}},\delta\boldsymbol{u})\end{aligned}$$

with the abbreviation

$$\delta\widetilde{\mathcal{B}} = \widetilde{\mathcal{B}}(\delta\boldsymbol{J}) + \delta I_\mathrm{inj}\widetilde{\mathcal{B}}(\widetilde{\boldsymbol{J}}_\mathrm{inj}) + \delta I_\mathrm{ext}\widetilde{\mathcal{B}}(\widetilde{\boldsymbol{J}}_\mathrm{ext}) + \delta B_\mathrm{ext}\widetilde{\boldsymbol{B}}_\mathrm{ext}.$$

PROPOSITION 3.12 (second order sufficient conditions). *Suppose that $(\widehat{y},u,\lambda)$ satisfies the optimality system consisting of* (3.13)–(3.14), (3.27)–(3.28), *and that $e_y(\widehat{y},u)$ is boundedly invertible. If, moreover,*

$$\alpha_u\|\boldsymbol{u}-\boldsymbol{u}_\mathrm{d}\|^2_{L^2(\Omega_{u,\mathrm{obs}})} + \alpha_B\|\boldsymbol{B}-\boldsymbol{B}_\mathrm{d}\|^2_{L^2(\Omega_{B,\mathrm{obs}})} + \alpha_J\|\boldsymbol{J}-\boldsymbol{J}_\mathrm{d}\|^2_{L^2(\Omega_{J,\mathrm{obs}})}$$

is sufficiently small, then there exists a neighborhood $\mathcal{U}$ *of* $(\widehat{y},u)$ *and* $\kappa>0$ *such that*

$$f(\overline{y},\overline{u}) \geq f(\widehat{y},u) + \kappa\left(\|\overline{u}-u\|^2 + \|\overline{y}-\widehat{y}\|^2_{\widehat{Y}}\right)$$

holds for all $(\overline{y},\overline{u})\in\mathcal{U}$ *satisfying the state equation. In particular,* $(\widehat{y},u)$ *is a strict local optimum for* (P).

Proof. We shall argue that there exists $\rho>0$ such that the coercivity condition

$$\mathcal{L}''(\widehat{y},u,\lambda)[(\delta y,\delta u)]^2 \geq \rho\left(\|\delta y\|^2_{\widehat{Y}} + |\delta u|^2\right) \tag{3.34}$$

holds for all $(\delta y,\delta u)\in\widehat{Y}\times\mathbb{R}^3$, which satisfy the linear MHD system (see Lemma 3.5)

$$e_y(\widehat{y},u)\,\delta y + e_u(\widehat{y},u)\,\delta u = 0. \tag{3.35}$$

The claim then follows from a Taylor series expansion of $\mathcal{L}$ at $(\widehat{y},u,\lambda)$; see, e.g., [20, Thm. 5.6]. In fact, since $\|\delta p\|_{L^2(\Omega)/\mathbb{R}} + \|\delta\phi\|_{H^1(\Omega)/\mathbb{R}} \leq c\,(\|\delta\boldsymbol{u}\|_{\boldsymbol{H}^1(\Omega)} + \|\delta\boldsymbol{J}\|_{\boldsymbol{L}^2(\Omega)})$ holds (cf. Lemma 2.2), we need to verify (3.34) only for the components $\delta\boldsymbol{u}$ and $\delta\boldsymbol{J}$ of δy.

Since $e_y(\widehat{y},u)$ is surjective, $e_y^\star(\widehat{y},u):\widehat{Y}\to\widehat{Y}'$ has closed range and is continuously invertible on its range [2]. Hence in view of (3.30)–(3.33), there exists $\kappa_1>0$ such that

$$\begin{aligned}&\|\boldsymbol{v}\|_{\boldsymbol{H}^1(\Omega)} + \|\boldsymbol{K}\|_{\boldsymbol{L}^2(\Omega)}\\ &\quad\leq \kappa_1\left(\alpha_u\|\boldsymbol{u}-\boldsymbol{u}_{\mathrm{d}}\|^2_{L^2(\Omega_{u,\mathrm{obs}})} + \alpha_B\|\boldsymbol{B}-\boldsymbol{B}_{\mathrm{d}}\|^2_{L^2(\Omega_{B,\mathrm{obs}})} + \alpha_J\|\boldsymbol{J}-\boldsymbol{J}_{\mathrm{d}}\|^2_{L^2(\Omega_{J,\mathrm{obs}})}\right)\end{aligned}$$

holds. From (3.35) and the bounded invertibility of $e_y(\widehat{y},u)$, we have

$$\|\delta\boldsymbol{J}\|_{\boldsymbol{L}^2(\Omega)} + \|\delta\boldsymbol{u}\|_{\boldsymbol{H}^1(\Omega)} \leq 2\|\delta y\|_{\widehat{Y}} \leq \kappa_2|\delta u| \tag{3.36}$$

for a constant $\kappa_2>0$ independent of $\delta u\in\mathbb{R}^3$. Hence

$$\begin{aligned}&|b(\delta\boldsymbol{u},\delta\boldsymbol{u},\boldsymbol{v})| \leq \kappa_3|\delta u|^2\|\boldsymbol{v}\|_{\boldsymbol{H}^1(\Omega)}\\ &\leq \kappa_1\kappa_3|\delta u|^2\left(\alpha_u\|\boldsymbol{u}-\boldsymbol{u}_{\mathrm{d}}\|^2_{L^2(\Omega_{u,\mathrm{obs}})} + \alpha_B\|\boldsymbol{B}-\boldsymbol{B}_{\mathrm{d}}\|^2_{L^2(\Omega_{B,\mathrm{obs}})} + \alpha_J\|\boldsymbol{J}-\boldsymbol{J}_{\mathrm{d}}\|^2_{L^2(\Omega_{J,\mathrm{obs}})}\right).\end{aligned} \tag{3.37}$$

Further there exists κ_4 independent of δu such that

$$\begin{aligned}&|c(\delta\boldsymbol{J},\delta\widetilde{\mathcal{B}},\boldsymbol{v})| + |c(\boldsymbol{K},\delta\widetilde{\mathcal{B}},\delta\boldsymbol{u})|\\ &\quad\leq \kappa_4\left(\|\delta\boldsymbol{J}\|_{\boldsymbol{L}^2(\Omega)} + |\delta u|\right)\left(\|\delta\boldsymbol{J}\|_{\boldsymbol{L}^2(\Omega)}\|\boldsymbol{v}\|_{\boldsymbol{H}^1(\Omega)} + \|\boldsymbol{K}\|_{\boldsymbol{L}^2(\Omega)}\|\delta\boldsymbol{u}\|_{\boldsymbol{H}^1(\Omega)}\right)\\ &\quad\leq C\left(\alpha_u\|\boldsymbol{u}-\boldsymbol{u}_{\mathrm{d}}\|^2_{L^2(\Omega_{u,\mathrm{obs}})} + \alpha_B\|\boldsymbol{B}-\boldsymbol{B}_{\mathrm{d}}\|^2_{L^2(\Omega_{B,\mathrm{obs}})} + \alpha_J\|\boldsymbol{J}-\boldsymbol{J}_{\mathrm{d}}\|^2_{L^2(\Omega_{J,\mathrm{obs}})}\right),\end{aligned}$$

where $C=\kappa_1\kappa_2(\kappa_2+1)\kappa_4|\delta u|^2$. This last estimate, together with (3.36) and (3.37), implies (3.34). ∎

4. An operator splitting scheme. In this section, we address an operator splitting scheme for the numerical solution of the MHD state equations (3.13)–(3.14). Our approach is based on the hypothesis that one wants to decouple the system and

put to use existing and validated solvers for the Navier–Stokes equations and for div-curl systems. The same idea can be applied to the adjoint system. Different iterative schemes for MHD have been proposed; see, for instance [22, 5]. In [5] two decoupling algorithms for the velocity-magnetic field formulation are discussed and numerical examples are given. This work contains a stability result for a special geometry but no convergence analysis. The classical proofs (see, e.g., [8]) for general purpose decomposition techniques rely on monotonicity of the differential operators, not only in each variable separately, but also jointly in all variables simultaneously, to obtain unconditional convergence with respect to the problem data. This behavior is not possible for MHD systems, and localization naturally leads to smallness requirements.

With this in mind, we analyze the following iterative scheme to compute a solution of the MHD system for given controls $u = (I_{\mathrm{ext}}, I_{\mathrm{inj}}, B_{\mathrm{ext}}) \in U_{\mathrm{ad}}$ and given velocity boundary data $\boldsymbol{h}$. As before, $\boldsymbol{u}_0$ and $\boldsymbol{J}_0$ denote the liftings according to Lemma 3.2.

ALGORITHM 4.1 (operator splitting scheme).

(1) *Choose an initial guess* $\widehat{\boldsymbol{J}}^0 \in \boldsymbol{L}^2_{\mathrm{div}}(\Omega)$*; set* $n = 0$.

(2) *Solve the* div-curl *system for* $\boldsymbol{B}^{n+1} \in \boldsymbol{V}^1(\mathbb{R}^3)$,

$$\nabla \cdot \boldsymbol{B}^{n+1} = 0, \qquad \nabla \times (\mu^{-1}\boldsymbol{B}^{n+1}) = \widehat{\boldsymbol{J}}^n,$$

with the interface condition $[\boldsymbol{B}^{n+1}]_{\partial\Omega} = 0$.

(3) *Solve the Navier–Stokes system with Lorentz force for* $\widehat{\boldsymbol{u}}^{n+1} \in \boldsymbol{H}^1_0(\Omega)$ *and* $p^{n+1} \in L^2(\Omega)/\mathbb{R}$,

$$\begin{aligned} -\eta\Delta\widehat{\boldsymbol{u}}^{n+1} + \rho(\widehat{\boldsymbol{u}}^{n+1}\cdot\nabla)\widehat{\boldsymbol{u}}^{n+1} + \rho(\widehat{\boldsymbol{u}}^{n+1}\cdot\nabla)\boldsymbol{u}_0 + \rho(\boldsymbol{u}_0\cdot\nabla)\widehat{\boldsymbol{u}}^{n+1} + \nabla p^{n+1} \\ = \eta\Delta\boldsymbol{u}_0 - \rho(\boldsymbol{u}_0\cdot\nabla)\boldsymbol{u}_0 + (\widehat{\boldsymbol{J}}^n + \boldsymbol{J}_0)\times(\boldsymbol{B}^{n+1} + \boldsymbol{B}_0), \\ \nabla\cdot\widehat{\boldsymbol{u}}^{n+1} = 0 \end{aligned}$$

with homogeneous Dirichlet boundary data on $\partial\Omega$.

(4) *Solve for* $\widehat{\boldsymbol{J}}^{n+1} \in \boldsymbol{L}^2_{\mathrm{div}}(\Omega)$ *and* $\phi^{n+1} \in H^1(\Omega)/\mathbb{R}$

$$\begin{aligned} \sigma^{-1}\widehat{\boldsymbol{J}}^{n+1} + \nabla\phi^{n+1} &= (\widehat{\boldsymbol{u}}^{n+1} + \boldsymbol{u}_0)\times(\boldsymbol{B}^{n+1} + \boldsymbol{B}_0) - \sigma^{-1}\boldsymbol{J}_0, \\ \nabla\cdot\widehat{\boldsymbol{J}}^{n+1} &= 0 \end{aligned}$$

with boundary condition $\widehat{\boldsymbol{J}}^{n+1}\cdot\boldsymbol{n} = 0$ *on* $\partial\Omega$.

(5) *Unless* $\|\widehat{\boldsymbol{J}}^{n+1} - \widehat{\boldsymbol{J}}^n\|_{\boldsymbol{L}^2(\Omega)}$ *is sufficiently small, increase* n *and go to* (2).

Note that the solution to step (2) is given by the Biot–Savart operator $\widetilde{\mathcal{B}}(\widehat{\boldsymbol{J}}^n)$. In steps (3) and (4), $\boldsymbol{B}_0 = \widetilde{\mathcal{B}}(\boldsymbol{J}_0) + \widetilde{\mathcal{B}}(\boldsymbol{J}_{\mathrm{ext}}) + \widetilde{\mathcal{B}}(\boldsymbol{J}_{\mathrm{inj}}) + \boldsymbol{B}_{\mathrm{ext}}$ collects the constant contributions to the total magnetic field. Obviously, instead of computing the liftings $\boldsymbol{u}_0$ and $\boldsymbol{J}_0$ and repeatedly solving homogeneous problems in steps (3) and (4), one may directly address the inhomogeneous ones with unknowns $\widehat{\boldsymbol{u}}^{n+1} + \boldsymbol{u}_0$ and $\widehat{\boldsymbol{J}}^{n+1} + \boldsymbol{J}_0$. The same applies to the div-curl system in step (2), which yields $\boldsymbol{B}^{n+1} + \boldsymbol{B}_0 - \boldsymbol{B}_{\mathrm{ext}}$ if $\widehat{\boldsymbol{J}}^n$ is replaced with $\widehat{\boldsymbol{J}}^n + \boldsymbol{J}_0 + \boldsymbol{J}_{\mathrm{ext}} + \boldsymbol{J}_{\mathrm{inj}}$.

Remark 4.2 (alternative form of step (4)). Note that step (4) in Algorithm 4.1 above is equivalent to the solution of the div-curl system on Ω,

$$\begin{aligned} \nabla\cdot\widehat{\boldsymbol{J}}^{n+1} &= 0, \\ \nabla\times(\sigma^{-1}\widehat{\boldsymbol{J}}^{n+1}) &= \nabla\times\left[(\widehat{\boldsymbol{u}}^{n+1} + \boldsymbol{u}_0)\times(\boldsymbol{B}^{n+1} + \boldsymbol{B}_0)\right] - \nabla\times(\sigma^{-1}\boldsymbol{J}_0) \end{aligned}$$

with boundary condition $\widehat{\boldsymbol{J}}^{n+1}\cdot\boldsymbol{n}=0$ on $\partial\Omega$, provided that the right-hand side is in $\boldsymbol{L}^2(\Omega)$. This can be guaranteed if $\boldsymbol{J}_0$, $\boldsymbol{B}_{\rm ext}$, and $\partial\Omega$ are smooth enough.

For the proposed scheme, we have the following conditional convergence result.

PROPOSITION 4.3 (convergence of the operator splitting scheme). *Let $u\in\mathbb{R}^3$ and $\boldsymbol{h}\in\boldsymbol{H}^{1/2}(\partial\Omega)$ be a given control vector and boundary data and suppose that η is sufficiently large and σ is sufficiently small. Then there exists $\rho_J>0$ such that whenever the initial iterate $\widehat{\boldsymbol{J}}^0\in\boldsymbol{L}^2_{\rm div}(\Omega)$ satisfies $\|\widehat{\boldsymbol{J}}^0+\boldsymbol{J}_0\|_{\boldsymbol{L}^2(\Omega)}<\rho_J$, then the iterates $(\widehat{\boldsymbol{J}}^n,\widehat{\boldsymbol{u}}^n)$ of Algorithm 4.1 converge in $\boldsymbol{L}^2(\Omega)\times\boldsymbol{H}^1(\Omega)$ to the necessarily unique solution of (3.13)–(3.14) which satisfies $\|\widehat{\boldsymbol{J}}+\boldsymbol{J}_0\|_{\boldsymbol{L}^2(\Omega)}\le\rho_J$.*

Proof. The proof uses the Banach fixed point theorem. This choice is due to the fact that the nonlinearities in (3.13)–(3.14) are not of strictly monotone or energy preservation type, so that techniques analogous to those developed for decomposition methods, e.g., in [8], cannot be used. Let $T:\boldsymbol{L}^2_{\rm div}(\Omega)\to\boldsymbol{L}^2_{\rm div}(\Omega)$ denote the operator which assigns to $\widehat{\boldsymbol{J}}^n$ the value $\widehat{\boldsymbol{J}}^{n+1}$ defined by steps (2)–(4) of Algorithm 4.1. Let us denote by ρ_I a common bound for the inhomogeneities $\widetilde{u}=(I_{\rm ext},I_{\rm inj})$ and $\boldsymbol{h}$, i.e., $|\widetilde{u}|\le\rho_I$ and $\|\boldsymbol{h}\|_{\boldsymbol{H}^{1/2}(\partial\Omega)}\le\rho_I$. Given the solenoidal current field $\widehat{\boldsymbol{J}}^n$, we infer from Lemma 2.4 the existence of $\boldsymbol{B}^{n+1}$ satisfying the equations in step (2) and the a priori estimate

$$\|\boldsymbol{B}^{n+1}+\boldsymbol{B}_0\|_{\boldsymbol{L}^3(\Omega)}\le c_1\,\mu\left(\|\widehat{\boldsymbol{J}}^n+\boldsymbol{J}_0\|_{\boldsymbol{L}^2(\Omega)}+|\widetilde{u}|\right)+c_1|\boldsymbol{B}_{\rm ext}|.$$

Here and below, the constants c_i are independent of μ, η, σ, iteration index n, and controls u. Let us further assume that $\|\widehat{\boldsymbol{J}}^n+\boldsymbol{J}_0\|_{\boldsymbol{L}^2(\Omega)}\le\rho_J$. Then we have

$$\|\boldsymbol{B}^{n+1}+\boldsymbol{B}_0\|_{\boldsymbol{L}^3(\Omega)}\le c_1\big(\mu(\rho_J+\rho_I)+|B_{\rm ext}|\big). \tag{4.1}$$

Standard estimates for the Navier–Stokes equations in step (3) imply that

$$\begin{aligned}\|\widehat{\boldsymbol{u}}^{n+1}+\boldsymbol{u}_0\|_{\boldsymbol{H}^1(\Omega)}&\le\mu\eta^{-1}c_2\left(\|\widehat{\boldsymbol{J}}^n+\boldsymbol{J}_0\|^2_{\boldsymbol{L}^2(\Omega)}+|\widetilde{u}|^2\right)\\&\quad+c_2\|\widehat{\boldsymbol{J}}^n+\boldsymbol{J}_0\||B_{\rm ext}|+c_2\Big(\|\boldsymbol{h}\|_{\boldsymbol{H}^{1/2}(\partial\Omega)}+\|\boldsymbol{h}\|^2_{\boldsymbol{H}^{1/2}(\partial\Omega)}\Big)\\&\le c_2\Big(\mu\eta^{-1}(\rho_J^2+\rho_I^2)+\rho_J|B_{\rm ext}|+\rho_I+\rho_I^2\Big).\end{aligned} \tag{4.2}$$

By Lemma 2.1 and a direct computation (or by [7, Chap. I, Cor. 4.1]), the system

$$\sigma^{-1}\widehat{\boldsymbol{J}}+\nabla\phi=f\ \text{on}\ \Omega,\qquad\qquad\nabla\cdot\widehat{\boldsymbol{J}}=0\ \text{on}\ \Omega$$

with given $f\in\boldsymbol{L}^2(\Omega)$ has a unique solution $\boldsymbol{J}\in\boldsymbol{L}^2_{\rm div}(\Omega)$ and $\phi\in H^1(\Omega)/\mathbb{R}$ which satisfies $\|\boldsymbol{J}\|_{\boldsymbol{L}^2(\Omega)}\le\sigma\,\|f\|_{\boldsymbol{L}^2(\Omega)}$. Hence we conclude from step (4) and (4.1) and (4.2) that

$$\begin{aligned}\|\widehat{\boldsymbol{J}}^{n+1}+\boldsymbol{J}_0\|_{\boldsymbol{L}^2(\Omega)}&\le\sigma\,c_3'\,\|\widehat{\boldsymbol{u}}^{n+1}+\boldsymbol{u}_0\|_{\boldsymbol{L}^6(\Omega)}\|\boldsymbol{B}^{n+1}+\boldsymbol{B}_0\|_{\boldsymbol{L}^3(\Omega)}\\&\le\sigma\,c_3'\Big(\mu\eta^{-1}(\rho_J^2+\rho_I^2)+\rho_J|B_{\rm ext}|+\rho_I+\rho_I^2\Big)\Big(\mu(\rho_J+\rho_I)+|B_{\rm ext}|\Big)+c_3'|I_{\rm inj}|\\&\le\sigma\,c_3\Big(\mu^2\eta^{-1}(\rho_J^3+\rho_I^3)+|B_{\rm ext}|\Big(\mu\rho_J(\rho_J+\rho_I)+\mu\eta^{-1}(\rho_J^2+\rho_I^2)+\rho_J|B_{\rm ext}|\Big)\\&\qquad+(\rho_I+\rho_I^2)\big(\mu(\rho_J+\rho_I)+|B_{\rm ext}|\big)\Big)+c_3|I_{\rm inj}|.\end{aligned} \tag{4.3}$$

Concerning the initialization, note that $\widehat{\boldsymbol{J}}^0$ can be taken as zero. Then $\|\widehat{\boldsymbol{J}}^0+\boldsymbol{J}_0\|_{\boldsymbol{L}^2(\Omega)}$ is bounded by $c_3|I_{\mathrm{inj}}|$. Choosing $\rho_J := 2c_3|I_{\mathrm{inj}}|$ and assuming that $\|\widehat{\boldsymbol{J}}^n+\boldsymbol{J}_0\|_{\boldsymbol{L}^2(\Omega)} \le \rho_J$ by induction, we obtain from (4.3) that $\|\widehat{\boldsymbol{J}}^{n+1}+\boldsymbol{J}_0\|_{\boldsymbol{L}^2(\Omega)} \le \rho_J$, provided that, for instance, σ is sufficiently small, or μ and $|B_{\mathrm{ext}}|$ are sufficiently small. From (4.1) and (4.2) follows the existence of constants ρ_B and ρ_u independent of n such that

$$\|\boldsymbol{B}^n+\boldsymbol{B}_0\|_{\boldsymbol{L}^3(\Omega)} \le \rho_B \quad \text{and} \quad \|\widehat{\boldsymbol{u}}^n+\boldsymbol{u}_0\|_{\boldsymbol{H}^1(\Omega)} \le \rho_u \tag{4.4}$$

for all n. To prove that T is a contraction, let $\widehat{\boldsymbol{J}}_i \in \boldsymbol{L}^2_{\mathrm{div}}(\Omega)$, $i = 1, 2$, and let $\boldsymbol{K}_i$ be their images under T. Further let $\boldsymbol{B}_i$ and $\widehat{\boldsymbol{u}}_i$ denote the associated magnetic and velocity fields according to Algorithm 4.1. Then

$$\|\boldsymbol{B}_1 - \boldsymbol{B}_2\|_{\boldsymbol{H}^1(\Omega)} \le \mu\, c_4 \|\widehat{\boldsymbol{J}}_1 - \widehat{\boldsymbol{J}}_2\|_{\boldsymbol{L}^2(\Omega)}. \tag{4.5}$$

Here and below, the constants are also independent of $\widehat{\boldsymbol{J}}_1$ and $\widehat{\boldsymbol{J}}_2$. Moreover, $U = \widehat{\boldsymbol{u}}_1 - \widehat{\boldsymbol{u}}_2 \in \boldsymbol{H}^1_0(\Omega)$ satisfies

$$\begin{aligned} -\eta\Delta U + \rho(U\cdot\nabla)(\widehat{\boldsymbol{u}}_1+\boldsymbol{u}_0) + \rho((\widehat{\boldsymbol{u}}_2+\boldsymbol{u}_0)\cdot\nabla)U + \nabla P \\ = (\widehat{\boldsymbol{J}}_1 - \widehat{\boldsymbol{J}}_2)\times(\boldsymbol{B}_1+\boldsymbol{B}_0) + (\widehat{\boldsymbol{J}}_2+\boldsymbol{J}_0)\times(\boldsymbol{B}_1-\boldsymbol{B}_2) \end{aligned}$$

for some $P \in L^2(\Omega)/\mathbb{R}$. This implies that

$$\begin{aligned} \eta\|\nabla U\|^2_{\boldsymbol{L}^2(\Omega)} &\le c_5\Big(\rho_u\|\nabla U\|^2_{\boldsymbol{L}^2(\Omega)} + \rho_B\|\nabla U\|_{\boldsymbol{L}^2(\Omega)}\|\widehat{\boldsymbol{J}}_1 - \widehat{\boldsymbol{J}}_2\|_{\boldsymbol{L}^2(\Omega)} \\ &\qquad + \rho_J\|\nabla U\|_{\boldsymbol{L}^2(\Omega)}\|\boldsymbol{B}_1-\boldsymbol{B}_2\|_{\boldsymbol{L}^3(\Omega)}\Big) \\ &\le c_5\Big(\rho_u\|\nabla U\|^2_{\boldsymbol{L}^2(\Omega)} + \big(\rho_B + \mu\, c_4\,\rho_J\big)\|\nabla U\|_{\boldsymbol{L}^2(\Omega)}\|\widehat{\boldsymbol{J}}_1 - \widehat{\boldsymbol{J}}_2\|_{\boldsymbol{L}^2(\Omega)}\Big) \\ &\le c_5\Big(\rho_u\|\nabla U\|^2_{\boldsymbol{L}^2(\Omega)} + \eta/2\|\nabla U\|^2_{\boldsymbol{L}^2(\Omega)} + \big(\rho_B + \mu\, c_4\,\rho_J\big)^2/(2\eta)\|\widehat{\boldsymbol{J}}_1 - \widehat{\boldsymbol{J}}_2\|^2_{\boldsymbol{L}^2(\Omega)}\Big). \end{aligned}$$

Hence if η is sufficiently large, or ρ_u is sufficiently small (which can be achieved by μ, $|B_{\mathrm{ext}}|$, and ρ_I sufficiently small), we have

$$\|\nabla U\|_{\boldsymbol{L}^2(\Omega)} \le c_6\,\eta^{-1}(\rho_B + \mu\, c_4\,\rho_J)\|\widehat{\boldsymbol{J}}_1 - \widehat{\boldsymbol{J}}_2\|_{\boldsymbol{L}^2(\Omega)}. \tag{4.6}$$

Finally, we obtain from step (4)

$$\begin{aligned} \|\boldsymbol{K}_1 - \boldsymbol{K}_2\| &\le \sigma\, c_7'\Big(\|U\|_{\boldsymbol{H}^1(\Omega)}\|\boldsymbol{B}_1+\boldsymbol{B}_0\|_{\boldsymbol{L}^3(\Omega)} + \|\widehat{\boldsymbol{u}}_2+\boldsymbol{u}_0\|_{\boldsymbol{H}^1(\Omega)}\|\boldsymbol{B}_1-\boldsymbol{B}_2\|_{\boldsymbol{L}^3(\Omega)}\Big) \\ &\le \sigma\, c_7\Big(\eta^{-1}\rho_B(\rho_B + \mu\,\rho_J) + \mu\, c_4\,\rho_u\Big)\|\widehat{\boldsymbol{J}}_1 - \widehat{\boldsymbol{J}}_2\|_{\boldsymbol{L}^2(\Omega)}. \end{aligned} \tag{4.7}$$

Hence we conclude that if σ is sufficiently small, or if μ is sufficiently small and η sufficiently large, then T is a contraction on the ball $\{\boldsymbol{J} : \|\widehat{\boldsymbol{J}}+\boldsymbol{J}_0\|_{\boldsymbol{L}^2(\Omega)} < \rho_J\}$. ∎

5. Conclusion and outlook. In this paper, we have presented and analyzed an optimal control problem for the stationary MHD system. We derived necessary and sufficient conditions for local optimal solutions. In addition, we analyzed an iterative scheme for the numerical solution of the MHD state equations which is tailored to make use of existing Navier–Stokes and div-curl solvers. We believe that in the face of industrial MHD applications, there is ample room to extend our results in several directions. Of particular interest are the cases of instationary MHD flows,

unknown current densities in external conductors, flows with thermal coupling and Ohmic heating, and the case of material-dependent magnetic permeability. All of the above present additional technical difficulties, which are the subject of future investigations. Finally, devising an efficient numerical algorithm to solve optimal control problems involving MHD flows presents another challenging task.

Appendix. Proof of Proposition 3.3. Let us define $T : \widehat{Y} \to \widehat{Y}$ according to

$$(\delta \boldsymbol{u}, \delta p, \delta \boldsymbol{J}, \delta \phi) = T(\widehat{\boldsymbol{u}}, p, \widehat{\boldsymbol{J}}, \phi)$$

if and only if

$$A(\delta \boldsymbol{u}, \delta p, \delta \boldsymbol{J}, \delta \phi) = R(\widehat{\boldsymbol{u}}, p, \widehat{\boldsymbol{J}}, \phi) \tag{A.1}$$

holds in $\widehat{Y}'$. That is, T is the solution operator of a linear PDE, which depends nonlinearly on the data $(\widehat{\boldsymbol{u}}, p, \widehat{\boldsymbol{J}}, \phi)$. Defining the components of R as

$$\begin{aligned}
R^1(\widehat{\boldsymbol{u}}, p, \widehat{\boldsymbol{J}}, \phi)(\boldsymbol{v}) &= c(\widehat{\boldsymbol{J}} + \boldsymbol{J}_0, \widetilde{\mathcal{B}}(\boldsymbol{J}_0) + \widetilde{\mathcal{B}}(\widehat{\boldsymbol{J}}) + \widetilde{\mathcal{B}}(\boldsymbol{J}_{\mathrm{ext}}) + \widetilde{\mathcal{B}}(\boldsymbol{J}_{\mathrm{inj}}) + \boldsymbol{B}_{\mathrm{ext}}, \boldsymbol{v}) \\
&\quad - a_1(\boldsymbol{u}_0, \boldsymbol{v}) - b(\widehat{\boldsymbol{u}} + \boldsymbol{u}_0, \widehat{\boldsymbol{u}} + \boldsymbol{u}_0, \boldsymbol{v}), \\
R^2(\widehat{\boldsymbol{u}}, p, \widehat{\boldsymbol{J}}, \phi)(q) &= 0, \\
R^3(\widehat{\boldsymbol{u}}, p, \widehat{\boldsymbol{J}}, \phi)(\boldsymbol{K}) &= -c(\boldsymbol{K}, \widetilde{\mathcal{B}}(\boldsymbol{J}_0) + \widetilde{\mathcal{B}}(\widehat{\boldsymbol{J}}) + \widetilde{\mathcal{B}}(\boldsymbol{J}_{\mathrm{ext}}) + \widetilde{\mathcal{B}}(\boldsymbol{J}_{\mathrm{inj}}) + \boldsymbol{B}_{\mathrm{ext}}, \widehat{\boldsymbol{u}} + \boldsymbol{u}_0) \\
&\quad - a_2(\boldsymbol{J}_0, \boldsymbol{K}), \\
R^4(\widehat{\boldsymbol{u}}, p, \widehat{\boldsymbol{J}}, \phi)(\psi) &= 0,
\end{aligned}$$

we easily verify that the solutions to the homogenized problem (3.13)–(3.14) are exactly the fixed points of T. In view of Proposition 3.6 below, $A : \widehat{Y} \to \widehat{Y}'$ is an isomorphism, and hence T is well defined from $\widehat{Y}$ to itself. We now confirm that T is compact. To this end, we consider a bounded and weakly convergent sequence $(\widehat{\boldsymbol{u}}^n, p^n, \widehat{\boldsymbol{J}}^n, \phi^n) \rightharpoonup (\widehat{\boldsymbol{u}}, p, \widehat{\boldsymbol{J}}, \phi)$ in $\widehat{Y}$. Since the norm in $\widehat{Y}'$ of the right-hand side in (A.1) is a quadratic polynomial in the norms of $\widehat{\boldsymbol{u}}$ and $\widehat{\boldsymbol{J}}$, the sequence $(\delta \boldsymbol{u}^n, \delta p^n, \delta \boldsymbol{J}^n, \delta \phi^n) := T(\widehat{\boldsymbol{u}}^n, p^n, \widehat{\boldsymbol{J}}^n, \phi^n)$ is bounded in $\widehat{Y}$ and thus possesses a weakly convergent subsequence in $\widehat{Y}$, i.e., $(\delta \boldsymbol{u}^n, \delta p^n, \delta \boldsymbol{J}^n, \delta \phi^n) \rightharpoonup (\delta \boldsymbol{u}, \delta p, \delta \boldsymbol{J}, \delta \phi)$. Using Lemma 2.3, one confirms that the weak limit $(\delta \boldsymbol{u}, \delta p, \delta \boldsymbol{J}, \delta \phi)$ satisfies $(\delta \boldsymbol{u}, \delta p, \delta \boldsymbol{J}, \delta \phi) = T(\widehat{\boldsymbol{u}}, p, \widehat{\boldsymbol{J}}, \phi)$; i.e., T is weakly continuous. The difference $(\delta \boldsymbol{u}^n, \delta p^n, \delta \boldsymbol{J}^n, \delta \phi^n) - (\delta \boldsymbol{u}, \delta p, \delta \boldsymbol{J}, \delta \phi)$ satisfies (A.1) with right-hand side

$$R(\widehat{\boldsymbol{u}}, p, \widehat{\boldsymbol{J}}, \phi) - R(\widehat{\boldsymbol{u}}^n, p^n, \widehat{\boldsymbol{J}}^n, \phi^n),$$

which converges to zero strongly in $\widehat{Y}'$, as a straightforward application of Lemmas 2.3, 2.4, and 2.6 shows. Hence T is indeed compact.

Now let $(\widehat{\boldsymbol{u}}, p, \widehat{\boldsymbol{J}}, \phi)$ be a fixed point of $s \cdot T$ for any $s \in [0, 1]$; i.e., $(\widehat{\boldsymbol{u}}, p, \widehat{\boldsymbol{J}}, \phi)$ satisfies (A.1) with the right-hand side multiplied by s. Testing this system with $(\widehat{\boldsymbol{u}}, p, \widehat{\boldsymbol{J}}, \phi)$, we obtain

$$\begin{aligned}
\eta \, \|\nabla \widehat{\boldsymbol{u}}\|^2_{\boldsymbol{L}^2(\Omega)} + \sigma^{-1} \|\widehat{\boldsymbol{J}}\|^2_{\boldsymbol{L}^2(\Omega)} = s\big(&c(\boldsymbol{J}_0, \boldsymbol{B}, \widehat{\boldsymbol{u}}) - c(\widehat{\boldsymbol{J}}, \boldsymbol{B}, \boldsymbol{u}_0) - b(\widehat{\boldsymbol{u}}, \boldsymbol{u}_0, \widehat{\boldsymbol{u}}) \\
&- a_1(\boldsymbol{u}_0, \widehat{\boldsymbol{u}}) - a_2(\boldsymbol{J}_0, \widehat{\boldsymbol{J}})\big)
\end{aligned}$$

with $\boldsymbol{B}$ according to (3.14). By Poincaré's inequality $\|\widehat{\boldsymbol{u}}\|_{\boldsymbol{L}^2(\Omega)} \le c_P \|\nabla \widehat{\boldsymbol{u}}\|_{\boldsymbol{L}^2(\Omega)}$, one obtains

$$\frac{\eta}{1+c_P^2}\|\widehat{\boldsymbol{u}}\|^2_{\boldsymbol{H}^1(\Omega)} + \sigma^{-1}\|\widehat{\boldsymbol{J}}\|^2_{\boldsymbol{L}^2(\Omega)} \le s\big(c(\boldsymbol{J}_0,\boldsymbol{B},\widehat{\boldsymbol{u}}) - c(\widehat{\boldsymbol{J}},\boldsymbol{B},\boldsymbol{u}_0) - b(\widehat{\boldsymbol{u}},\boldsymbol{u}_0,\widehat{\boldsymbol{u}}) - a_1(\boldsymbol{u}_0,\widehat{\boldsymbol{u}}) - a_2(\boldsymbol{J}_0,\widehat{\boldsymbol{J}})\big). \tag{A.2}$$

The application of the Leray–Schauder fixed point theorem requires that the left-hand side be a priori bounded uniformly in $s \in [0,1]$. The bound may depend on the controls $(I_{\mathrm{ext}}, I_{\mathrm{inj}}, B_{\mathrm{ext}})$ and the boundary data $\boldsymbol{h}$. We observe that the right-hand side in (A.2) is bounded above by

$$\|\boldsymbol{J}_0\|_{\boldsymbol{L}^2(\Omega)}\|\widetilde{\mathcal{B}}(\widehat{\boldsymbol{J}})\|_{\boldsymbol{L}^3(\Omega)}\|\widehat{\boldsymbol{u}}\|_{\boldsymbol{L}^6(\Omega)} + \|\widehat{\boldsymbol{J}}\|_{\boldsymbol{L}^2(\Omega)}\|\widetilde{\mathcal{B}}(\widehat{\boldsymbol{J}})\|_{\boldsymbol{L}^3(\Omega)}\|\boldsymbol{u}_0\|_{\boldsymbol{L}^6(\Omega)} + \|\nabla \boldsymbol{u}_0\|_{\boldsymbol{L}^2(\Omega)}\|\widehat{\boldsymbol{u}}\|^2_{\boldsymbol{L}^4(\Omega)} \tag{A.3}$$

plus a number of terms which are at most linear in $\|\widehat{\boldsymbol{u}}\|$ and $\|\boldsymbol{J}\|$. The latter can be treated using Young's inequality according to the pattern $c\,\|\widehat{\boldsymbol{u}}\| \le \varepsilon\,\|\widehat{\boldsymbol{u}}\|^2 + c/(4\varepsilon)$, and $\varepsilon\,\|\widehat{\boldsymbol{u}}\|^2$ can then be absorbed into the left-hand side of (A.2) for sufficiently small $\varepsilon > 0$. However, in order for the terms in (A.3) to be likewise absorbed in the left-hand side of (A.2), the coefficients $\|\boldsymbol{J}_0\|_{\boldsymbol{L}^2(\Omega)}$, $\|\boldsymbol{u}_0\|_{\boldsymbol{L}^6(\Omega)}$, and $\|\nabla \boldsymbol{u}_0\|_{\boldsymbol{L}^2(\Omega)}$ must be sufficiently small. In this case, $\|\widehat{\boldsymbol{u}}\|_{\boldsymbol{H}^1(\Omega)}$ and $\|\widehat{\boldsymbol{J}}\|_{\boldsymbol{L}^2(\Omega)}$ are indeed a priori bounded by the right-hand side in (3.16). In view of Lemma 3.2, the same bound holds for the inhomogeneous solution $\boldsymbol{u}$ and $\boldsymbol{J}$. Finally, the bounds for the pressure p and potential ϕ follow from Lemma 2.2. Hence we conclude the applicability of the Leray–Schauder theorem which yields the existence of a fixed point of T.

BARRIER OPTION HEDGING UNDER CONSTRAINTS: A VISCOSITY APPROACH*

IMEN BENTAHAR† AND BRUNO BOUCHARD‡

Abstract. We study the problem of finding the minimal initial capital needed in order to hedge without risk a barrier option when the vector of proportions of wealth invested in each risky asset is constrained to lie in a closed convex domain. In the context of a Brownian diffusion model, we provide a PDE characterization of the superhedging price. This extends the result of Broadie, Cvitanič, and Soner [Rev. Financial Stud., 11 (1998), pp. 59–79] and Cvitanič, Pham, and Touzi [J. Appl. Probab., 36 (1999), pp. 523–545] which was obtained for plain vanilla options and provides a natural numerical procedure for computing the corresponding superhedging price. As a by-product, we obtain a comparison theorem for a class of parabolic PDEs with relaxed Dirichlet conditions involving a constraint on the gradient.

Key words. superreplication, barrier options, portfolio constraints, viscosity solutions

1. Introduction.

The problem of superhedging under portfolio constraints has attracted a lot of attention since the seminal work of Cvitanič and Karatzas [6]. One of the original motivations came from the hedging of plain vanilla options with discontinuous payoffs, such as digital options. For such options the delta and gamma may take very large values when the remaining maturity is small, which makes them difficult to delta-hedge.

Within diffusion models, the remarkable result of Broadie, Cvitanič, and Soner [4] shows that the optimal hedge under constraints is obtained by considering the Black–Scholes-type hedging strategy of some modified payoff. Thus, hedging the original claim under constraints corresponds to hedging a modified one without constraints. This is the "face-lifting" procedure. Within the Black–Scholes model, this allows one to find explicit optimal hedge. In more general Markov diffusion models, an explicit solution may not be available but the superhedging price can still be characterized as the solution of some Hamilton–Jacobi–Bellman equation; see Cvitanič, Pham, and Touzi [7] and the review paper Soner and Touzi [16]. In the general semi-martingale case, no explicit solution is available but a general dual formulation was obtained by Föllmer and Kramkov [8].

Similar problems may appear for path-dependent options such as barrier options. For instance, the delta of knock-out barrier options may explode when the maturity is small and the underlying asset is close to the barrier. This more difficult issue was recently considered by Shreve, Schmock, and Wystup [12]. In this paper, the authors solve the problem of hedging a knock-out call option in a one-dimensional Black–Scholes model under a constraint on the short position, i.e., the proportion of wealth invested in the risky asset is bounded from below. This result is obtained

by extending the dual formulation of Cvitanič and Karatzas [6] and by solving the associated stochastic control problem.

The aim of the present paper is to provide a PDE characterization of the superhedging price of barrier-type options. Our model is more general than the one studied in Shreve, Schmock, and Wystup [12] in two aspects. First, we consider general payoffs of the form $g(\tau, X_\tau)$, where τ is the first exit time of a d-dimensional price process X from a given domain $\mathcal{O}$. Second, our constraints on the proportions of wealth invested in the risky assets are described by a rather general closed convex set.

Our derivation of the associated PDE relies on the dual formulation of Cvitanič and Karatzas [6] as in Cvitanič, Pham, and Touzi [7]. Here, the main difficulty comes from the boundary condition on $\partial\mathcal{O}$ before maturity, a problem which does not appear in [7]. As in the vanilla option case, we have to consider as a boundary condition a "face-lifted" payoff, but in the case of barrier options this is not sufficient. Indeed, the example considered in Shreve, Schmock, and Wystup [12] shows that the boundary condition on $[0,T)\times\partial\mathcal{O}$ may not be assumed continuously by the value function, even when the payoff is "face-lifted" (in their case $g = 0$ before T). This implies that this boundary condition has to be considered in a weak sense.

In this paper, we give an appropriate sense to the boundary condition and show that the superhedging price is a (discontinuous) viscosity solution of the corresponding Hamilton–Jacobi–Bellman equation. We also show that it can actually be further characterized as its smallest viscosity supersolution. Finally, under mild additional assumptions, we prove a comparison theorem for the associated PDE which ensures uniqueness of the solution and opens the door to the implementation of a numerical scheme. Here, the difficulty comes from the constraint on the gradient of the value function which also appears in the relaxed boundary condition. To the best of our knowledge, this is the first time that such an equation has been considered.

To conclude this section, we observe that our results could be alternatively obtained by using the direct dynamic principle of [14], which was first used in [15] to derive the PDEs associated to general stochastic target problems with constraints on the control process in the case $\mathcal{O} = \mathbb{R}^d$; see also [3] for the case of diffusions with jumps.

The rest of the paper is organized as follows. The superhedging problem and its dual formulation are presented in section 2. In section 3, we describe the associated PDE and state our main results. A numerical application is presented in section 4. The remaining sections contain the proofs.

Notation. All elements $x = (x^i)_{i\le d}$ of $\mathbb{R}^d$ are identified with column vectors with Euclidean norm $|\cdot|$ and transposed vector x'. The positive orthant of $\mathbb{R}^d$ is denoted by $\mathbb{R}^d_+$ and the set of $d\times d$ matrices by $\mathbb{M}^d$. We write $\operatorname{diag}[x]$ to denote the diagonal matrix of $\mathbb{M}^d$ whose ith diagonal element is x^i. If $y\in\mathbb{R}^d$, we write xy for $(x^iy^i)_{i\le d}$, x^y for $\prod_{i\le d}(x^i)^{y^i}$, and xe^y for $(x^ie^{y^i})_{i\le d}$, whenever it is well defined. The trace of $M\in\mathbb{M}^d$ is denoted by $\operatorname{Tr}[M]$, and $|M|$ denotes its Euclidean norm when viewed as an element of $\mathbb{R}^{d^2}$. Given a family $(a^{ij})_{i,j\le d}$ of real numbers, we denote by $[a^{ij}]_{i,j}$ the matrix A whose component (i,j) is given by a^{ij}. The closure of a set $E\subset\mathbb{R}^d$ is denoted by $\bar E$, ∂E stands for its boundary, and $\operatorname{int}(E)$ for its interior. Given $\eta>0$, $B(x,\eta)$ denotes the open ball of radius η centered on x.

Given a smooth function $(t,x)\in[0,T]\times\mathbb{R}^d\mapsto\varphi(t,x)\in\mathbb{R}$, we denote by $D\varphi$ its (partial) Jacobian matrix with respect to x and by $D^2\varphi$ its (partial) Hessian matrix with respect to x. All inequalities involving random variables have to be understood in the $\mathbb{P}$-a.s. sense.

2. The superhedging price under constraints and its dual formulation. Throughout this paper, $T > 0$ is a finite time horizon and $W = (W_t)_{t \le T}$ is a d-dimensional Brownian motion defined on a complete probability space $(\Omega, \mathcal{F}, \mathbb{P})$. We assume that the $\mathbb{P}$-augmented filtration generated by W, $\mathbb{F} = (\mathcal{F}_t)_{t \le T}$ satisfies $\mathcal{F}_0 = \{\Omega, \emptyset\}$ and $\mathcal{F}_T = \mathcal{F}$.

2.1. The barrier option hedging problem. The financial market is composed of a nonrisky asset B with price process normalized to unity, i.e., $B_t = 1$ for all $t \le T$, and d risky assets $X = (X^1, \dots, X^d)$ whose dynamics are given by the stochastic differential equation

$$X(t) = X_0 + \int_0^t \operatorname{diag}[X(s)]\, \sigma(s, X(s)) dW_s, \quad t \le T\,, \tag{2.1}$$

for some $X_0 \in (0, \infty)^d$. Here, $\sigma : [0,T] \times \mathbb{R}^d_+ \mapsto \mathbb{M}^d$ is assumed to satisfy the following.

$$\left\{ \begin{array}{ll} \text{(i)} & \sigma \text{ is continuous, bounded, and invertible with bounded inverse.} \\ \text{(ii)} & \text{The map } (t,x) \in [0,T] \times \mathbb{R}^d_+ \;\mapsto\; \operatorname{diag}[x]\, \sigma(t,x) \\ & \text{is Lipschitz continuous in } x, \text{ uniformly in } t. \end{array} \right. \tag{2.2}$$

Remark 2.1. As usual there is no loss of generality in assuming that X is a local martingale since, under mild assumptions on the original dynamics, we can always reduce to this case by passing to an equivalent probability measure. The normalization $B = 1$ means that we consider discounted processes, i.e., we take B as a numéraire.

A *financial strategy* is described by a d-dimensional predictable process $\pi = (\pi^1, \dots, \pi^d)$ satisfying the integrability condition

$$\int_0^T |\pi_t|^2 dt \;<\; \infty \quad \mathbb{P}\text{-a.s.}, \tag{2.3}$$

where π^i_t is the proportion of wealth invested at time t in the risky asset X^i. To an initial capital $y \in \mathbb{R}$ and a financial strategy π, we associate the induced wealth process Y^π_y defined as the solution on $[0,T]$ of

$$Y(t) = y + \int_0^t Y(s) \pi_s' \operatorname{diag}[X(s)]^{-1} dX(s) = y + \int_0^t Y(s) \pi_s' \sigma(s, X(s)) dW_s, \tag{2.4}$$

where $'$ stands for transposition.

Remark 2.2. Since in our model the financial strategies are described by the proportions of total wealth invested in each risky asset, the no-bankruptcy condition always holds provided that the initial wealth is nonnegative. Indeed, it is clear from (2.4) that for $y \ge 0$, the induced wealth process satisfies $Y^\pi_y(t) \ge 0$ for all $t \in [0,T]$ almost surely.

The constraints on the portfolio strategy are described by a closed convex set $K \subset \mathbb{R}^d$. We say that a *financial strategy* π is *admissible* if it satisfies, in addition to the condition (2.3), the constraint

$$\pi \in K \;\; dt \times d \quad \mathbb{P}\text{-a.e.}, \tag{2.5}$$

and we denote by $\mathcal{K}$ the set of *admissible financial strategies*. Throughout this paper, we shall assume that

$$0 \in K \neq \mathbb{R}^d\,. \tag{2.6}$$

The left-hand side condition just means that $0 \in \mathcal{K}$, while the inequality is natural since otherwise there would be no constraint on the portfolio.

The *barrier option* is described by a map g defined on $[0,T] \times \mathbb{R}^d_+$ and an open domain $\mathcal{O}$ of $\mathbb{R}^d$ such that

$$g \geq 0 \ \text{ on } \bar{\mathcal{O}} \cap \mathbb{R}^d_+ \qquad \text{and} \qquad g = 0 \ \text{ on } [0,T] \times \bar{\mathcal{O}}^c \,, \tag{2.7}$$

where $\bar{\mathcal{O}}^c := (0,\infty)^d \setminus \bar{\mathcal{O}}$. The buyer of the option receives the payment $g(\tau, X(\tau))$ at the (stopping-)time τ defined as the first time when X exits $\mathcal{O}$ if this occurs before T and T otherwise:

$$\tau := \inf\{t \in [0,T] \ : \ X(t) \notin \mathcal{O}\} \wedge T \,,$$

with the usual convention $\inf \emptyset = \infty$. The superreplication cost under constraint of the claim $g(\tau, X(\tau))$ is thus defined as

$$v(0,X_0) := \inf\left\{y \in \mathbb{R}_+ \ : \ Y^\pi_y(\tau) \geq g(\tau, X(\tau)) \quad \text{for some } \pi \in \mathcal{K}\right\} \,. \tag{2.8}$$

Remark 2.3. The condition $g = 0$ on $[0,T] \times \bar{\mathcal{O}}^c$ can be seen as a convention. Indeed, it is clear that $v(0,X_0)$ does not depend on the value of g on this set when $X_0 \in \bar{\mathcal{O}}$, while for $X_0 \in \bar{\mathcal{O}}^c$ the problem has no interest.

Hereafter we present examples of barrier options which fit into our framework.

Example 2.1. *Up-and-out call.* Let $d = 1$. The payoff of an *up-and-out call* on a single asset X^1, with strike price κ and *knock-out barrier* B, is equal to

$$\left(X^1(T) - \kappa\right)^+ \mathbf{1}_{\left\{\max_{0\leq t\leq T} X^1(t) < B\right\}} \,.$$

In our framework this corresponds to $\mathcal{O} = (-\infty, B)$ and $g(t,x) = t(x-\kappa)^+ 1_{\{t=T, x<B\}}$.

Example 2.2. *Down-and-out basket put option.* A basket option is an option whose payoff depends on a weighted average of a set of underlying values. Letting $d = 2$, we consider the *down-and-out* barrier option whose payoff is given by

$$\left(\kappa - \frac{X^1(T) + X^2(T)}{2}\right)^+ \mathbf{1}_{\left\{min_{0\leq t\leq T} X^1(t) + X^2(t) > 2B\right\}} \,.$$

In our framework this corresponds to $\mathcal{O} = \left\{x \in (0,\infty)^2 \,,\ x^1 + x^2 > 2B\right\}$ and $g(t,x) = (\kappa - \frac{x^1+x^2}{2})^+ 1_{\{t=T, x^1+x^2>2B\}}$.

2.2. The dual formulation. The dual formulation for hedging problems under general convex constraint was first established by Cvitanič and Karatzas [6] in the diffusion case and then extended to the semimartingale case by Föllmer and Kramkov [8]; see also Karatzas and Shreve [10] and the review paper by Soner and Touzi [16].

To state the dual formulation, we first need the characterization of the closed convex set K in terms of its support function δ. For $\rho \in R^d$ set

$$\delta(\rho) = \sup_{\gamma \in K} \gamma' \rho \geq 0 \,, \tag{2.9}$$

where the last inequality follows from the left-hand side of (2.6), and define

$$\tilde{K} := \{\rho \in \mathbb{R}^d \ : \ \delta(\rho) < \infty\} \,,$$

the domain of δ. Observe that the right-hand side of (2.6) implies that $\tilde{K} \neq \{0\}$. Moreover, it is a standard result of convex analysis (see, e.g., [11]) that K can be characterized in terms of

$$\tilde{K}_1 := \{\rho \in \tilde{K} \ : \ |\rho| = 1\}$$

by

$$\gamma \in K \ \Leftrightarrow \ H(1,\gamma) \geq 0 \quad \text{and} \quad \gamma \in \text{int}(K) \ \Leftrightarrow \ H(1,\gamma) > 0, \tag{2.10}$$

where

$$H(u,p) \ := \ \inf\{\delta(\rho)u - \rho' p, \ \rho \in \tilde{K}_1\} \text{ for } (u,p) \in \mathbb{R} \times \mathbb{R}^d \ .$$

Remark 2.4. Assume for a while that $0 \in \text{int}(K)$. Then there is $c_K > 0$ such that $B(0, c_K) \subset K$. Thus, for all $\rho \in \tilde{K}_1$, $c_K \rho \in K$ and therefore

$$\delta(\rho) \geq c_K > 0 \ .$$

The dual formulation is constructed as follows. Let us denote by $\tilde{\mathcal{K}}$ the set of bounded adapted processes ϑ taking values in $\tilde{K}$. To such a process, we associate the martingale M^ϑ defined on $[0,T]$ as the solution of

$$M_t := 1 + \int_0^t M_s \left(\sigma(s, X(s))^{-1} \vartheta_s\right)' dW_s \ ;$$

recall (2.2). We then define the $\mathbb{P}$-equivalent probability measure $\mathbb{Q}^\vartheta$ by

$$\frac{\mathrm{d}\mathbb{Q}^\vartheta}{\mathrm{d}\mathbb{P}} = M_T^\vartheta \ .$$

It follows from Girsanov's theorem that the process W^ϑ defined by

$$W_t^\vartheta = W_t - \int_0^t \sigma(s, X(s))^{-1} \vartheta_s ds, \ \ t \leq T \ ,$$

is a Brownian motion under $\mathbb{Q}^\vartheta$. In the following, we shall denote by $\mathbb{E}^\vartheta$ the expectation operator associated to $\mathbb{Q}^\vartheta$.

To $\vartheta \in \tilde{\mathcal{K}}$, we finally associate the process $\mathcal{E}^\vartheta$ defined by

$$\mathcal{E}_t^\vartheta := e^{-\int_0^t \delta(\vartheta_s) ds}, \quad t \leq T \ .$$

THEOREM 2.1. *The following holds:*

$$v(0, X_0) = \sup_{\vartheta \in \tilde{\mathcal{K}}} \mathbb{E}^\vartheta \left[\mathcal{E}_\tau^\vartheta g\left(\tau, X(\tau)\right)\right] \ . \tag{2.11}$$

Proof. The above result is a direct consequence of Theorem 6.2 and Remark 6.11 in [10], as follows:

1. First observe that

$$v(0, X_0) = \inf\left\{y \in \mathbb{R}_+ \ : \ Y_y^\pi(T) \geq g(\tau, X(\tau)) \quad \text{for some } \pi \in \mathcal{K}\right\} \ .$$

Indeed, it follows from (2.4) and condition (2.3) that, for all $y \in \mathbb{R}_+$ and $\pi \in \mathcal{K}$, the process Y_y^π is a nonnegative local $\mathbb{P}$-martingale on $[t,T]$. Hence it is a

supermartingale and, by taking conditional expectation, $Y_y^\pi(T) \geq g(\tau, X(\tau))$ implies $Y_y^\pi(\tau) \geq g(\tau, X(\tau))$. From this we deduce the first inequality:

$$v(0, X_0) \leq \inf\left\{y \in \mathbb{R}_+ \ : \ Y_y^\pi(T) \geq g(\tau, X(\tau)) \quad \text{for some } \pi \in \mathcal{K}\right\} .$$

For the converse inequality, notice that if $Y_y^\pi(\tau) \geq g(\tau, X(\tau))$, then $Y_T^{y,\tilde{\pi}} \geq g(\tau, X(\tau))$, where $\tilde{\pi} = \pi \mathbf{1}_{[s,\tau]}$ belongs to $\mathcal{K}$.

2. Since $g \geq 0$ (see (2.7)), it follows from Theorem 6.2 and Remark 6.11 in [10] that

$$v(0, X_0) = \sup_{\vartheta \in \tilde{\mathcal{K}}} \mathbb{E}^\vartheta \left[\mathcal{E}_T^\vartheta g\left(\tau, X(\tau)\right)\right] .$$

Observe that the process $\mathcal{E}^\vartheta$ is positive, nonincreasing in time, and recall that $g \geq 0$; then the last equality leads to (2.11). □

In order to derive the PDE characterization of the superhedging price, we shall use a standard dynamic programming principle for the dual formulation of Theorem 2.1. Before stating it, we need to extend the definition of v to general initial conditions $(t, x) \in [0, T] \times (0, \infty)^d$. For $(t, x) \in [0, T] \times (0, \infty)^d$, $y \in \mathbb{R}_+$, and $\pi \in \mathcal{K}$, we define $(X_{t,x}, Y_{t,x,y}^\pi)$ as the solution of (2.1)–(2.4) on $[t, T]$ with initial condition $(X_{t,x}(t), Y_{t,x,y}^\pi(t)) = (x, y)$.

The value function v is then defined on $[0, T] \times (0, \infty)^d$ by

$$v(t, x) := \inf\left\{y \in \mathbb{R}_+ \ : \ Y_{t,x,y}^\pi(\tau_{t,x}) \geq g(\tau_{t,x}, X_{t,x}(\tau_{t,x})) \quad \text{for some } \pi \in \mathcal{K}\right\}, \tag{2.12}$$

where

$$\tau_{t,x} := \inf\{s \in [t, T] \ : \ X_{t,x}(s) \notin \mathcal{O}\} \wedge T .$$

Remark 2.5. Observe that for $(t, x) \in ([0, T] \times \partial\mathcal{O}) \cup (\{T\} \times \bar{\mathcal{O}})$, we have $v(t, x) = g(t, x)$ by construction.

In what follows, we shall denote by $\mathcal{T}_{t,T}$ the set of all stopping times with values in $[t, T]$. Given $\vartheta \in \tilde{K}$ and $t < T$, we also set

$$\mathcal{E}_s^{t,\vartheta} := \mathcal{E}_s^\vartheta / \mathcal{E}_t^\vartheta \quad \text{for } s \geq t .$$

The following result is a consequence of Proposition 6.5 in [10].

PROPOSITION 2.1. *For all $(t, x) \in [0, T) \times \mathcal{O}$ and $\theta \in \mathcal{T}_{t,T}$,*

$$v(t, x) = \sup_{\vartheta \in \tilde{\mathcal{K}}} \mathbb{E}^\vartheta \left[\mathcal{E}_\theta^{t,\vartheta} v\left(\theta, X_{t,x}(\theta)\right) \mathbf{1}_{\theta < \tau_{t,x}} + \mathcal{E}_{\tau_{t,x}}^{t,\vartheta} g\left(\tau_{t,x}, X_{t,x}(\tau_{t,x})\right) \mathbf{1}_{\theta \geq \tau_{t,x}}\right] . \tag{2.13}$$

Proof. It follows from Proposition 6.5 in [10] that

$$v(t, x) = \sup_{\vartheta \in \tilde{\mathcal{K}}} \mathbb{E}^\vartheta \left[\mathcal{E}_{\theta \wedge \tau_{t,x}}^{t,\vartheta} v\left(\theta \wedge \tau_{t,x}, X_{t,x}(\theta \wedge \tau_{t,x})\right)\right] ,$$

where by definition of v (see Remark 2.5) $v\left(\tau_{t,x}, X_{t,x}(\tau_{t,x})\right) = g(\tau_{t,x}, X_{t,x}(\tau_{t,x}))$. This provides the required result. □

3. The PDE characterization. Our main result consists of a PDE characterization of the value function v. Before stating it, we describe the PDE associated to v and explain in which sense it has to be considered.

3.1. The associated PDE. Set $\mathcal{O}^* = \mathcal{O} \cap (0,\infty)^d$. In view of [7] and [17], it is natural to expect that the value function v is a viscosity solution on

$$D := [0,T) \times \mathcal{O}^*$$

of the PDE

$$\min\{-\mathcal{L}v\ ,\ \mathcal{H}v\} = 0\ , \tag{3.1}$$

where for a smooth function φ on $[0,T] \times \mathbb{R}^d_+$ we set

$$\mathcal{H}\varphi(t,x) = \inf\left\{\delta(\rho)\varphi(t,x) - \rho' \mathrm{diag}\,[x]\, D\varphi(t,x),\ \rho \in \tilde{K}_1\right\}\ ,$$
$$\mathcal{L}\varphi(t,x) = \frac{\partial}{\partial t}\varphi(t,x) + \frac{1}{2}\mathrm{Tr}\left[a(t,x)D^2\varphi(t,x)\right]\ ,$$

with a defined on $[0,T] \times \mathbb{R}^d_+$ by

$$a(t,x) := \mathrm{diag}\,[x]\, \sigma(t,x)\sigma(t,x)' \mathrm{diag}\,[x]\ .$$

The first part of the equation corresponds to the usual Black–Scholes equation, while the second part is due to the portfolio constraint. Indeed, assuming that v is smooth and positive, and writing formally that the hedging portfolio satisfies $Y^\pi_y(t) = v(t, X(t))$, we deduce from Itô's lemma that π_t must coincide with $\mathrm{diag}\,[X(t)]\, Dv(t,X(t))/v(t, X(t))$. Since it has to belong to K, the characterization of K given by (2.10) implies that $H(1, \mathrm{diag}\,[X(t)]\, Dv(t,X(t))/\ v(t,X(t)))$, or equivalently $H(v(t,X(t)), \mathrm{diag}\,[X(t)]\ Dv(t,X(t)))$, must be nonnegative.

In order to provide a full characterization of v, it remains to define the boundary conditions on $\partial_x D^* := [0,T) \times \partial\mathcal{O}^*$ and $\partial_T D^* := \{T\} \times \bar{\mathcal{O}}^*$, where

$$\partial\mathcal{O}^* := \partial\mathcal{O} \cap (0,\infty)^d \qquad \text{and} \qquad \bar{\mathcal{O}}^* := \bar{\mathcal{O}} \cap (0,\infty)^d\ .$$

It is known from [7] (see also [16] and [17]) that the boundary condition on $\partial_T D^*$ has to be written as

$$v = \hat{g}, \tag{3.2}$$

where, for $x \in (0,\infty)^d$,

$$\hat{g}(T,x) = \sup_{\rho \in \tilde{K}} e^{-\delta(\rho)} g(T, xe^\rho)\ .$$

This corresponds to the "face-lifting" procedure, which was already observed by [4]. This "face-lifting" is due to the portfolio constraint, $\hat{g}$ being the smallest function above g which, in a sense, satisfies $D\hat{g}/\hat{g} \in K$.

Remark 3.1. Observe that (2.7) allows us to define $\hat{g}(T,\cdot)$ on $(0,\infty)^d$ as

$$\hat{g}(T,x) = \sup_{\rho \in \tilde{K}(x,\bar{\mathcal{O}})} e^{-\delta(\rho)} g(T, xe^\rho)\ , \tag{3.3}$$

with the convention $\sup\emptyset = 0$ and

$$\tilde{K}(x,E) := \left\{\rho \in \tilde{K}\ :\ xe^\rho \in E\right\} \quad \text{for } E \subset \bar{\mathcal{O}}\ . \tag{3.4}$$

The fact that v satisfy (3.1)–(3.2) in the viscosity sense can be shown by following the arguments of [7] and is not difficult.

The difficulty comes from the boundary condition on $\partial_x D^*$. In this paper, we shall show that g has also to be modified on $\partial_x D^*$, i.e., replaced by $\hat{g}$ defined on $[0,T) \times (0,\infty)^d$ by

$$\hat{g}(t,x) = \sup_{\rho \in \tilde{K}(x,\partial\mathcal{O})} e^{-\delta(\rho)} g(t, xe^{\rho}) \ , \tag{3.5}$$

with the convention $\sup \emptyset = 0$. This result is expected and will be obtained under a smoothness condition on $\mathcal{O}$; see $\mathbf{H}_{\mathcal{O}}$ below.

But this is only a first step in the derivation of the appropriate boundary condition. Actually, [12] provides an example of a superhedging price for an up-and-out call option for which $\hat{g}(t,x) = 0$ for $t < T$ and $v(t',x')$ does not converge to 0 when $(t',x') \in D$ goes to $(t,x) \in \partial_x D^*$. This shows that the constraint on the portfolio may prevent the value function from assuming the boundary condition continuously and leads to the natural formulation of a relaxed boundary condition on $\partial_x D^*$:

$$\min\{v - \hat{g} \ , \ \mathcal{H}v\} = 0 \ . \tag{3.6}$$

However, we shall see in Remark 6.1 below that the above equation has to be corrected in order to admit a viscosity supersolution and therefore makes sense. Given a smooth function φ, we therefore define

$$\mathcal{H}_{\rm d}\varphi(t,x) = \inf\Big\{\delta(\rho)\varphi(t,x) - \rho' \mathrm{diag}\,[x]\, D\varphi(t,x), \ \rho \in \tilde{K}_1(x,\bar{\mathcal{O}})\Big\} \ ,$$

where, for $x \in E \subset \bar{\mathcal{O}}$,

$$\tilde{K}_1(x,E) := \Big\{\rho \in \tilde{K}_1 \ : \ \exists\, \lambda_0 > 0 \text{ s.t. } \lambda\rho \in \tilde{K}(x,E) \text{ for all } \lambda \in [0,\lambda_0]\Big\} \ . \tag{3.7}$$

To sum up, we introduce the operators

$$\mathcal{B}\varphi := \begin{cases} \min\{-\mathcal{L}\varphi \ , \ \mathcal{H}\varphi\} & \text{on} \quad D \ , \\ \min\{\varphi - \hat{g} \ , \ \mathcal{H}\varphi\} & \text{on} \quad \partial_x D^* \ , \\ \varphi - \hat{g} & \text{on} \quad \partial_T D^* \ , \end{cases}$$

$$\mathcal{B}_{\rm d}\varphi := \begin{cases} \mathcal{B}\varphi & \text{on} \quad D \cup \partial_T D^* \ , \\ \min\{\varphi - \hat{g} \ , \ \mathcal{H}_{\rm d}\varphi\} & \text{on} \quad \partial_x D^* \ , \end{cases}$$

and we say that a locally bounded function w on D is a *discontinuous viscosity solution* of

$$\mathcal{B}_{\rm d}\varphi = 0 \tag{3.8}$$

on $\bar{D}^* := \bar{D} \cap ([0,T] \times (0,\infty)^d)$ if w_* and w^* defined on $\bar{D}$ as

$$w_*(t,x) \ := \ \liminf_{(\tilde{t},\tilde{x}) \in D, \ (\tilde{t},\tilde{x}) \to (t,x)} w(\tilde{t},\tilde{x}) \qquad \text{and} \qquad w^*(t,x) \ := \ \limsup_{(\tilde{t},\tilde{x}) \in D, \ (\tilde{t},\tilde{x}) \to (t,x)} w(\tilde{t},\tilde{x})$$

are, respectively, viscosity super- and subsolutions of $\mathcal{B}_{\rm d}\varphi = 0$ and $\mathcal{B}\varphi = 0$ on $\bar{D}^*$. More generally, we shall say that w is a (discontinuous) viscosity supersolution (resp., subsolution) of $\mathcal{B}\varphi = 0$ on $\bar{D}^*$ if w_* is a supersolution of $\mathcal{B}_{\rm d}\varphi = 0$ (resp., subsolution of $\mathcal{B}\varphi = 0$) on $\bar{D}^*$.

Remark 3.2. Assume that the conditions of Theorem 3.1 below hold. Let us write $\mathcal{B}\varphi(t,x)$ as $\mathcal{B}(t,x,\varphi(t,x),\frac{\partial}{\partial t}\varphi(t,x),D\varphi(t,x),D^2\varphi(t,x))$ and $\mathcal{B}_{\rm d}\varphi(t,x)$ similarly. Then one easily checks that the upper-semicontinuous envelope of $\mathcal{B}_{\rm d}$ as a map on $\bar{D}^*\times\mathbb{R}\times\mathbb{R}\times\mathbb{R}^d\times\mathbb{M}^d$ is given by

$$(\mathcal{B}_{\rm d})_+(t,x,\varphi(t,x),\tfrac{\partial}{\partial t}\varphi(t,x),D\varphi(t,x),D^2\varphi(t,x))) = \max\{\mathcal{B}_{\rm d}\varphi(t,x), \min\{-\mathcal{L}\varphi(t,x),\mathcal{H}\varphi(t,x)\}\},$$

and that its lower-semicontinuous envelope is

$$(\mathcal{B}_{\rm d})_-(t,x,\varphi(t,x),\frac{\partial}{\partial t}\varphi(t,x),D\varphi(t,x),D^2\varphi(t,x))) = \min\{\mathcal{B}\varphi(t,x),-\mathcal{L}\varphi(t,x)\}.$$

From the arguments of the proof of Propositions 6.3 and 6.6 below, we deduce that $(\mathcal{B}_{\rm d})_+\varphi=0$ (resp., $(\mathcal{B}_{\rm d})_-\varphi=0$) has the same supersolutions as $\mathcal{B}_{\rm d}\varphi=0$ (resp., subsolutions as $\mathcal{B}\varphi=0$) on $D\cup\partial_x D^*$ for the terminal condition $\varphi=\hat{g}$ at T. In other words, $\mathcal{B}_{\rm d}$ can be viewed as being upper-semicontinuous with lower-semicontinuous envelope given by $\mathcal{B}$. This justifies the above definition of a viscosity solution of $\mathcal{B}_{\rm d}\varphi=0$, and shows that it is in accordance with Definition 7.4 in [5]. This remak will be used in the example section to prove the convergence of the discretization scheme we shall consider for a particular example.

3.2. Main results. In order to establish that v is a discontinuous viscosity solution of (3.8), we shall appeal to the following additional assumptions.

Our first condition concerns the convex set K describing the portfolio constraints. It is stated in terms of $\tilde{K}(x,\mathcal{O})$; recall (3.4).

$\mathbf{H}_{\tilde{K}}$: (i) For all $x\in\mathcal{O}$, $\rho\in\tilde{K}(x,\mathcal{O})$ implies $\lambda\rho\in\tilde{K}(x,\mathcal{O})$ for all $\lambda\in[0,1)$.
(ii) For all $x\in\mathcal{O}$, the closure of $\tilde{K}(x,\mathcal{O})$ is equal to $\tilde{K}(x,\bar{\mathcal{O}})$.
(iii) If $(x_n)_n$ is a sequence in $\mathcal{O}$ such that $x_n\to x\in\partial\mathcal{O}$ and $\rho\in\tilde{K}(x,\bar{\mathcal{O}})$, then there exists a sequence $\rho_n\to\rho$ such that, up to a subsequence, $\rho_n\in\tilde{K}(x_n,\bar{\mathcal{O}})$ for all $n\geq 1$.

Remark 3.3. The conditions (i) and (ii) of $\mathbf{H}_{\tilde{K}}$ are automatically satisfied whenever the set $\ln(\mathcal{O})=\{(\ln(x^i))_{i\leq d},\ x\in\mathcal{O}\}$ is convex. Indeed, we easily check that in this case, for all $x\in\mathcal{O}$, $\tilde{K}(x,\mathcal{O})$ is convex, and since $0\in\tilde{K}(x,\mathcal{O})$, this provides (i). The convexity of $\ln(\mathcal{O})$ also implies that if $\rho\in\tilde{K}(x,\mathcal{O})$ and $\bar{\rho}\in\tilde{K}(x,\bar{\mathcal{O}})$, then $\lambda\rho+(1-\lambda)\bar{\rho}\in\tilde{K}(x,\mathcal{O})$ for all $\lambda\in(0,1)$. Since $0\in\tilde{K}$, this shows that for all $x\in\mathcal{O}$ the closure of $\tilde{K}(x,\mathcal{O})$ contains $\tilde{K}(x,\bar{\mathcal{O}})$, while the converse inclusion is obvious.

We shall also impose some regularity assumptions on g.

$\mathbf{H}_g$: (i) g is lower-semicontinuous on $[0,T]\times\partial\mathcal{O}^*$ and on $\{T\}\times\bar{\mathcal{O}}^*$.
(ii) There exist $C_g>0$ and $\bar{\gamma}\in K\cap\mathbb{R}^d_+$ s.t. $|g(\cdot,x)|\leq C_g(1+x^{\bar{\gamma}})$ for all $x\in\bar{\mathcal{O}}^*$.
(iii) $\hat{g}$ is upper-semicontinuous on $[0,T]\times(0,\infty)^d$ and has linear growth.

Under $\mathbf{H}_{\tilde{K}}$ and (i)–(ii) of $\mathbf{H}_g$, one can already derive the following qualitative properties of v.

PROPOSITION 3.1. *Assume that* $\mathbf{H}_{\tilde{K}}$ *and* (i)–(ii) *of* $\mathbf{H}_g$ *hold. Then, for all* $(t,x)\in D$, *we have*

$$v(t,x)\geq 0\,, \tag{3.9}$$

and there is a constant $C > 0$, independent of (t, x), such that

$$|v(t,x)| \le C\left(1 + x^{\bar\gamma}\right) . \tag{3.10}$$

Moreover, for all $(t, x) \in \bar D$,

$$v_*(t,x) = \sup_{\rho \in \tilde K(x,\bar{\mathcal{O}})} e^{-\delta(\rho)} v_*(t, xe^{\rho}) . \tag{3.11}$$

The proof will be provided in section 5.

In order to derive the appropriate boundary condition on $\partial_x D^*$, we shall also need some regularity on the domain $\mathcal{O}$.

$\mathbf{H}_{\mathcal{O}}$: There exists a map $d : (0,\infty)^d \mapsto \mathbb{R}$ such that
- (i) $\{x \in (0,\infty)^d \ : \ d(x) > 0\} = \mathcal{O}^*$.
- (ii) $\{x \in (0,\infty)^d \ : \ d(x) = 0\} = \partial\mathcal{O}^*$.
- (iii) For all $x \in \partial\mathcal{O}^*$, there exists $r > 0$ s.t. $d \in C^2(B(x,r))$.

This essentially amounts to saying that $\mathcal{O}$ is C^2; see [9].

Using $\mathbf{H}_{\tilde K}$, $\mathbf{H}_g$, and $\mathbf{H}_{\mathcal{O}}$, we can already characterize v not only as a discontinuous solution of (3.8) but also as its smallest supersolution.

THEOREM 3.1. *Assume that $\mathbf{H}_{\tilde K}$, $\mathbf{H}_g$, and $\mathbf{H}_{\mathcal{O}}$ hold. Then*
- (i) *v is a discontinuous viscosity solution of* (3.8)*;*
- (ii) *v is lower-continuous on D;*
- (iii) *v_* is the smallest supersolution of* (3.8) *in the class of locally bounded functions satisfying* (3.10).

Finally, under the following additional assumptions we will be able in section 7 to provide a comparison theorem for (3.8).

$\mathbf{H}'$:
- (i) Either $\bar{\mathcal{O}}$ is bounded or there exists $\underline{\varrho} > 1$ s.t. $\underline{\varrho}\bar\gamma \in K \cap (0,\infty)^d$.
- (ii) $\mathrm{int}(K) \neq \emptyset$ and either $0 \in \mathrm{int}(K)$ or $\bar{\mathcal{O}} \cap \partial\mathbb{R}^d_+ = \emptyset$.
- (iii) For all $x \in \partial\mathcal{O}^*$ there exists $\rho \in \tilde K_1$ s.t. $Dd(x)' \mathrm{diag}\,[x]\,\rho > 0$.

This will imply our last result, which characterizes v as the unique solution of (3.8) in a suitable class of functions.

THEOREM 3.2. *Let the conditions of Theorem* 3.1 *hold and assume further that $\mathbf{H}'$ is satisfied. Then*
- (i) *$v_* = v^*$ on $\bar D^*$;*
- (ii) *v is continuous on D;*
- (iii) *v is the unique discontinuous viscosity solution of* (3.8) *in the class of locally bounded function satisfying* (3.10).

Remark 3.4. Recall the examples of barrier options of section 2.
1. If we hedge the up-and-out call of the Example 2.1 with short-sale constraints, i.e., $K = [-\alpha, +\infty)$, with $\alpha > 0$, then it is easy to verify that all of the conditions $\mathbf{H}_{\tilde K}$, $\mathbf{H}_g$, $\mathbf{H}_{\mathcal{O}}$, and $\mathbf{H}'$ hold true.
2. These conditions are also satisfied when we hedge the down-and-out basket put of the Example 2.2 with a bounded portfolio, i.e., $K = \prod_{i=1}^2 [-\underline{\alpha}^i, \bar\alpha^i]$, $\underline{\alpha}^i, \bar\alpha^i > 0$ for $i = 1, 2$.

Remark 3.5. In [13], the authors consider example 1 of Remark 3.4 within a one-dimensional Black–Scholes model and use the PDE characterization of Theorem 3.2 to solve the problem explicitly; see [13, section 4.2.1]. They work in a case where

v is expected to be strictly positive while $g = 0$ for $t < T$. They therefore guess that the condition $\mathcal{H}w = 0$ should always hold at the boundary. Then they observe that, in their particular setting, $w := \mathcal{H}v$ actually solves $\mathcal{L}\varphi = 0$ if v does. Since by construction $w = 0$ on the boundary, it is easy to guess its explicit form; this is the price of a barrier option without constraint and a modified terminal payoff. The equation $\mathcal{H}v = w$ is then solved in v as an ordinary differential equation in x. They finally verify that this provides a solution to (3.8). This general methodology can be applied in various particular cases.

Remark 3.6. To conclude this section, let us comment on assumption $\mathbf{H}'$. As already mentioned, Theorem 3.2 is based on a comparison result for (3.8) stated in Theorem 7.1 below. A first difficulty in proving this theorem comes from the growth condition (3.10), which is nonstandard. In the case where $\bar{\mathcal{O}}$ is not bounded, the second assumption in (i) is used to construct a suitable penalty function which allows us to reduce to a bounded domain. The second difficulty comes from the term $\mathcal{H}\varphi$ appearing in $\mathcal{B}\varphi$. It is handled by using the first assertion of (ii) under which we can construct a strict supersolution of $\mathcal{H}\varphi = 0$. A third difficulty is due to the fact that the equation in written only on $\bar{\mathcal{O}} \cap (0,\infty)^d$. In the case where $\bar{\mathcal{O}} \cap \partial\mathbb{R}^d_+ \neq \emptyset$, we need to introduce another penalty function which permits us to reduce the analysis to $(0,\infty)^d$. We then appeal to the second assertion of (ii). Finally, a major difficulty comes from the boundary condition on $\partial_x D^*$, which is written in a weak sense. It is treated by using condition (iii), which allows us to "avoid" this boundary. We refer to step 4 of the proof of Theorem 7.1 below for a more detailed discussion of assumptions (i) and (ii).

4. A numerical application. In this section, we study a numerical scheme for the resolution of $\mathcal{B}_{\rm d}\varphi = 0$ in the simple example considered in [12]: superhedging of a knock-out call with a short-sale constraint. The general case will be discussed in the companion paper [2].

The model corresponds to our general framework with $d = 1$, $\sigma(t,x) = \sigma > 0$, a fixed constant, $\mathcal{O} = (-\infty, B)$, $K = [-\alpha, \infty)$, and $g(t,x) = [x-\kappa]^+ \mathbf{1}_{\{t=T,\, x<B\}}$, with $\alpha > 0$, $B > \kappa > 0$. In this case $\tilde{K} = (-\infty, 0]$, the function $\hat{g}(t,x)$ is equal to

$$\hat{g}(t,x) \;=\; e^{-\alpha\theta(x)}[xe^{-\theta(x)} - K]^+ \mathbf{1}_{t=T} \text{ with } \theta(x) = [-\ln(B/x)]^+ \,,$$

and all the assumptions of Theorem 3.2 are satisfied.

In order to solve numerically the equation $\mathcal{B}_{\rm d}\varphi = 0$, we propose the following discretization. We fix a regular grid $\pi_h = \{t_i := (ir_h) \wedge T,\ 0 \le i \le I_h\}$ of $[0,T]$ and $\Xi_h := \{x_i := (ih) \wedge B,\ 0 \le i \le N_h\}$ of $[0,B]$. Here, $h > 0$ is a fixed parameter, $N_h := \inf\{k \in \mathbb{N} \,:\, k \ge B/h\}$, and $I_h := \inf\{k \in \mathbb{N} \,:\, k \ge T/r_h\}$ with $r_h = h^2$. The approximation v^h of v is defined as follows.

1. For $i = I_h$, we use the boundary condition at $t = T$ to set $v^h(t_{I_h}, x_j) = \hat{g}(t_{I_h}, x_j)$, $j = 0, \dots, N_h$.
2. For $i = I_h - 1, \dots, 0$, we use the following procedure:
   (a) We initialize: $v^h(t_i, 0) = 0$.
   (b) Then we solve on $j = 1, \dots, N_h$ the system

$$v^h(t_i,x_j) = \begin{cases} \max\left\{A^h(v^h,i,j)\,;\ B^h(v^h,i,j)\right\} & \text{if } j \neq N_h\,, \\ \max\left\{0\,;\ B^h(v^h,i,j)\right\} & \text{otherwise}\,, \end{cases}$$

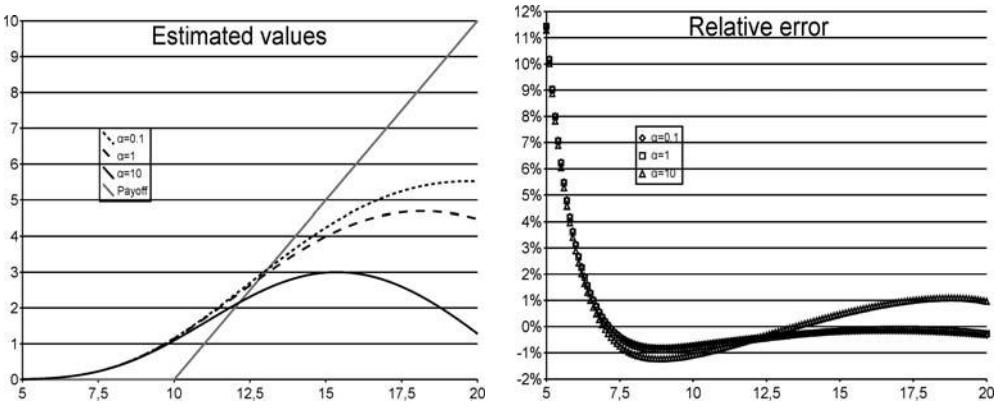

FIG. 1.

with

$$A^h(v^h,i,j) := \frac{(r_h)^{-1}v^h(t_{i+1},x_j) + (2h^2)^{-1}\sigma^2 x_j^2 (v^h(t_i,x_{j+1}) + v^h(t_i,x_{j-1}))}{(r_h)^{-1} + (h^2)^{-1}\sigma^2 x_j^2},$$

$$B^h(v^h,i,j) := \frac{x_j\, h^{-1} v^h(t_i,x_{j-1})}{\alpha + x_j\, h^{-1}}\ ,$$

The initialization of step 2(a) is justified by the continuity of v at 0, which is easily checked in this simple model by using the dual formulation of Theorem 2.1. The system given in 2(b) follows from the approximation of $\mathcal{H} = \mathcal{H}_d$ and $\mathcal{L}$ by

$$\mathcal{H}^h(t_i,x_j,v^h(t_i,x_j),v^h) = \alpha v^h(t_i,x_j) + x_j \frac{v^h(t_i,x_j) - v^h(t_i,x_{j-1})}{h}\ ,$$

$$\mathcal{L}^h(t_i,x_j,v^h(t_i,x_j),v^h) = \frac{v^h(t_{i+1},x_j) - v^h(t_i,x_j)}{r_h} + \frac{1}{2}\sigma^2 x_j^2 \frac{v^h(t_i,x_{j+1}) + v^h(t_i,x_{j-1}) - 2v^h(t_i,x_j)}{h^2}\ .$$

Observing that v^h is nonnegative and uniformly bounded from above by B, the convergence of the scheme easily follows from Remark 3.2, Theorem 3.2, Remark 7.1 below, and [1].

In Figure 1, we plot the estimation of v obtained with this scheme for $\sigma = 0.3$, $\kappa = 10$, $B = 20$, $T = 1$ and for $\alpha \in \{0.1, 1, 10\}$. The relative error is computed by using the closed-form solution obtained in [12]. We took $N_h = 200$. We observe that the estimation is very sharp with a relative error less than 1% in absolute value, except for small values of X_0, for which v is almost equal to 0.

5. Growth and monotonicity properties. In this section, we provide the proof of Proposition 3.1.

Proof of (3.9)–(3.10). The lower bound of (3.9) is an immediate consequence of the assumption $g \geq 0$ and the dual formulation (2.11). We now prove (3.10). Let $\pi \in \mathcal{K}$ be defined by $\pi_t = \bar{\gamma}$ for all $t \leq T$. Since σ is bounded (see (2.2)), one easily checks from the dynamics of the processes $X_{t,x}$ and $Y^{\pi}_{t,x,1}$ that

$$1 + \prod_{i=1}^{d} (X^i_{t,x}(u))^{\bar{\gamma}^i} \ \leq\ C\left(1 + \prod_{i=1}^{d} (x^i)^{\bar{\gamma}^i}\right) Y^{\pi}_{t,x,1}(u) \quad \text{for all } \ u \in [0,T]\ \mathbb{P}\text{-a.s.}\ ,$$

where $C > 0$ depends only on $|\bar\gamma|$ and the bound on $|\sigma|$. Then, after possibly changing the value of the constant C, $\mathbf{H}_g$-(ii) implies

$$g(u, X_{t,x}(u)) \;\le\; C\left(1 + x^{\bar\gamma}\right) Y^{\pi}_{t,x,1}(u) \quad \text{for all } \; u \in [0,T], \; \mathbb{P}\text{-a.s.}\,,$$

and since $yY^{\pi}_{t,x,1} = Y^{\pi}_{t,x,y}$ for $y > 0$, we deduce from the last inequality that $v(t,x) \le C\left(1 + x^{\bar\gamma}\right)$. □

Proof of (3.11). Since $0 \in \tilde K(x, \bar{\mathcal{O}})$, we only have to show that

$$v_*(t,x) \ge \sup_{\rho \in \tilde K(x,\bar{\mathcal{O}})} e^{-\delta(\rho)} v_*(t, xe^{\rho})\,.$$

1. We first consider the case where $(t,x) \in D$. Since by lower-semicontinuity of v_* and (ii) of $\mathbf{H}_{\tilde K}$

$$\sup_{\rho \in \tilde K(x,\mathcal{O})} e^{-\delta(\rho)} v_*(t, xe^{\rho}) = \sup_{\rho \in \tilde K(x,\bar{\mathcal{O}})} e^{-\delta(\rho)} v_*(t, xe^{\rho})\,,$$

it suffices to show that

$$v_*(t,x) \ge \sup_{\rho \in \tilde K(x,\mathcal{O})} e^{-\delta(\rho)} v_*(t, xe^{\rho})\,. \tag{5.1}$$

Fix $\rho \in \tilde K(x,\mathcal{O})$ and consider the sequence of processes ϑ^n in $\tilde{\mathcal{K}}$ defined on $[t,T]$ by $\vartheta^n := n\rho \mathbf{1}_{[t,t_n]}$ with $t_n := t + n^{-1}$ for n large enough so that $t_n < T$. By Proposition 2.1

$$\begin{aligned} v(t,x) \ge \mathbb{E}^{\vartheta^n}\Big[e^{-n\delta(\rho)(n^{-1}\wedge(\tau_{t,x}-t))} \Big(& v\left(t_n, X_{t,x}(t_n)\right) \mathbf{1}_{t_n < \tau_{t,x}} \\ & + g\left(\tau_{t,x}, X_{t,x}(\tau_{t,x})\right) \mathbf{1}_{t_n \ge \tau_{t,x}} \Big) \Big]\,. \end{aligned} \tag{5.2}$$

Let X^n be the solution on $[t,T]$ of

$$X^n(s) = x + \int_t^s \operatorname{diag}\left[X^n(r)\right] \vartheta^n_r dr + \int_t^s \operatorname{diag}\left[X^n(r)\right] \sigma(r, X^n(r)) dW_r$$

so that $X^n(s) = \beta^n_s H^n_s$ with

$$(H^n_s)^i \;:=\; \mathcal{E}\left(\sum_{j=1}^d \int_t^s \sigma^{ij}(r, X^n(r)) dW^j_r \right) \quad \text{and} \quad \beta^n_s \;:=\; xe^{\int_t^s \vartheta^n_r dr}\,,$$

where $\mathcal{E}$ denotes the Doleans–Dade exponential. By Girsanov's theorem, (5.2) can be rewritten as

$$\begin{aligned} v(t,x) \ge \mathbb{E}\Big[e^{-n\delta(\rho)(n^{-1}\wedge(\tau_n - t))} & \left(v\left(t_n, X^n(t_n)\right) \mathbf{1}_{t_n < \tau_n}\right. \\ & \left. + g\left(\tau_n, X^n(\tau_n)\right) \mathbf{1}_{t_n \ge \tau_n}\right) \Big]\,, \end{aligned} \tag{5.3}$$

where

$$\tau_n := \inf\left\{ s \in [t,T] \;:\; X^n(s) \notin \mathcal{O} \right\} \wedge T\,.$$

Since σ is bounded (see (2.2)), $H^n_{\tau_n \wedge t_n} \to (1, \dots, 1)$ $\mathbb{P}$-a.s., after possibly passing to a subsequence. Also observe that

$$\beta^n_{\tau_n \wedge t_n} = xe^{\rho[(n(\tau_n - t))\wedge 1]}\,.$$

By $\mathbf{H}_{\tilde{K}}$ and the assumption $\rho \in \tilde{K}(x, \mathcal{O})$, it follows that, $\mathbb{P}$-a.s., $X^n_{\tau_n \wedge t_n} \in \mathcal{O}$ and therefore $t_n < \tau_n$ for large values of n. In particular,

$$(X^n(t_n), \mathbf{1}_{t_n < \tau^n}) \longrightarrow (xe^{\rho}, 1) \ \ \mathbb{P}\text{-a.s.}$$

Thus, passing to the limit in (5.3) and applying Fatou's lemma shows the required result; recall (3.9).

2. We now consider the case where $(t, x) \in \partial D$. Let $(t_n, x_n)_n$ be a sequence in D that converges to (t, x) such that $v(t_n, x_n) \to v_*(t, x)$. Fix $\rho \in \tilde{K}(x, \bar{\mathcal{O}})$. By $\mathbf{H}_{\tilde{K}}$, there is a sequence $(\rho_n)_n$ with values in $\tilde{K}(x_n, \bar{\mathcal{O}})$ such that $\rho_n \to \rho$. Using Step 1 of this proof, we deduce that $v(t_n, x_n) \geq e^{-\delta(\rho_n)} v_*(t_n, x_n e^{\rho_n})$. Passing to the limit shows that $v_*(t, x) \geq e^{-\delta(\rho)} v_*(t, xe^{\rho})$ by lower-semicontinuity of v_*. □

Remark 5.1. Fix $(t, x) \in \bar{D}^*$ and assume that $(\lambda_0, \rho_0) \in \mathbb{R}_+ \times \tilde{K}$ are such that $xe^{\lambda_0 \rho_0} \in \bar{\mathcal{O}}$. By $\mathbf{H}_{\tilde{K}}$-(i), the map $\lambda \in [0, \lambda_0] \mapsto e^{-\lambda \delta(\rho_0)} v_*(t, xe^{\lambda \rho_0})$ is well defined and it follows from (3.11) that it is nonincreasing.

6. The viscosity solution property. In this section, we provide the proof of Theorem 3.1. We start with the supersolution and subsolution properties. Then we use an approximation argument combined with a comparison theorem to prove that v_* is the smallest supersolution of (3.8).

6.1. Supersolution property. In this section, we show that v_* is a supersolution of (3.8) on $\bar{D}^*$. This is a consequence of Propositions 6.1, 6.2, 6.3, and 6.4 below.

PROPOSITION 6.1. *Assume that* $\mathbf{H}_{\tilde{K}}$ *and* $\mathbf{H}_g$ *hold. Let* $(t_0, x_0) \in \bar{D}^*$ *and* $\varphi \in C^2(\bar{D}^*)$ *be such that* (t_0, x_0) *is a local minimum on* $\bar{D}^*$ *of* $v_* - \varphi$ *satisfying* $(v_* - \varphi)(t_0, x_0) = 0$. *Then*

$$\mathcal{H}_{\mathrm{d}} \varphi(t_0, x_0) \geq 0 \ .$$
