A REVIEW OF AN OPTIMAL DESIGN PROBLEM FOR A PLATE OF VARIABLE THICKNESS*

JULIO MUÑOZ† AND PABLO PEDREGAL‡

Abstract. We revisit a classic design problem for a plate of variable thickness under the model of Kirchhoff. Our main contribution has two goals. One is to provide a rather general existence result under a main assumption on the structure of the tensor of material constants. The other focuses on providing a minimal number of additional design variables for a relaxation of the problem when that assumption on the tensor of elastic constants does not hold. In both situations, the cost functional can be pretty general.

Key words. optimal design, direct method, existence, relaxation

1. Introduction.

The problem of the optimal design of a plate of variable thickness under Kirchhoff's model can be stated as finding the optimal, symmetric profile

$$h : \Omega \subset \mathbf{R}^2 \to \mathbf{R},$$

where Ω is supposed to be the midplane with respect to which the plate is symmetric, so that it minimizes the value of the compliance functional

$$I(h) = \int_\Omega f(x)u(x)\,dx,$$

where f is the vertical load over the plate, and u is the vertical displacement in equilibrium which is obtained from the profile h by solving the equation of equilibrium

$$\sum_{i,j,k,l} \frac{\partial^2}{\partial x_i \partial x_j}\left(h^3(x)\, M_{ijkl} \frac{\partial^2 u(x)}{\partial x_k \partial x_l}\right) = f(x)$$

in Ω, supplemented with clamped boundary conditions around $\partial\Omega$ by demanding $u = \nabla u = 0$ over $\partial\Omega$. Here the fourth-order tensor M encloses the various material constants for the type of elastic material the plate is made of. In addition, there should be some other constraints on the admissible profiles so that the problem is meaningful. On the one hand, we assume that there is a minimum and a maximum height for h so that

$$0 < h_- \le h(x) \le h_+$$

and h_-, h_+ are given parameters. On the other hand, we must limit the amount of material that can be used so that

$$\int_\Omega h(x)\,dx \le V\,|\Omega|$$

and $h_- < V < h_+$.

This problem has received some attention over the years in two different directions. First, it was noticed long ago that, at least in some situations, this problem is not well-posed in the sense that there might not exist optimal profiles (see [6], [7]). Today, this is a well-understood fact. It is typically associated with some lack of convexity, often taken in a suitable broad sense. This direction was further pursued and explored from the horizon of finding a minimal relaxation in the sense of using a minimal number of generalized design variables (see [5], [9]). Several later works emphasized this perspective and proved various types of results always trying to minimize in various ways the number of design variables needed to describe minimizing profiles. In many of these contributions, Young measures associated with minimizing profiles were used in one way or another (see [1], [3], [4], [11], [15]). Second, in some other situations, existence of optimal profiles has been shown despite the fact of the just-mentioned difficulties (see [14], [16], [17]), coming to a situation where it is not completely clear when, depending on the ingredients, one can trust existence results or else anticipate highly oscillating optimal profiles. Another point in many of these works is that the only cost functional considered is the compliance written before, along with some other variants of order zero (no derivatives of u).

The aim of our contribution here is twofold. First, we examine the structural ingredients of the problem that enable an existence result, and how existence of optimal profiles is compromised when such requirements are not fulfilled. As we will see, this is basically related to the structure of the tensor M of material constants so that the existence of optimal profiles for this problem depends (for many relevant cost functionals) on the elasticity properties of the material we use to manufacture the plate. Second, we would like to be able to examine more general cost functionals and not just the compliance. We will give results for much more general objective functionals in both existence as well as nonexistence cases.

Let $F(x,u,\lambda,\xi,h) : \Omega\times\mathbf{R}\times\mathbf{R}^2\times\mathbf{M}^{2\times 2}\times\mathbf{R}\to\mathbf{R}$ be a given integrand, continuous in the variables (u,λ,ξ,h) and measurable in x (here $\mathbf{M}^{2\times 2}$ is the space of the 2×2 real matrices). Define

$$I(h) = \int_\Omega F(x,u(x),\nabla u(x),\nabla^2 u(x),h(x))\,dx,$$

where u solves

$$\sum_{i,j,k,l}\frac{\partial^2}{\partial x_i\partial x_j}\left(h^3(x)M_{ijkl}\frac{\partial^2 u(x)}{\partial x_k\partial x_l}\right) = f(x) \text{ in } \Omega,$$

$$u(x) = \frac{\partial u(x)}{\partial n} = 0 \text{ on } \partial\Omega,$$

Specifically, we consider the following optimal design problem:

$$\begin{aligned} &\text{Minimize}\quad I(h)\\ &\text{subject to}\quad h_-\le h(x)\le h_+ \text{ in } \Omega,\quad \int_\Omega h(x)\,dx \le V\,|\Omega|\,. \end{aligned}$$

The main structural assumption to distinguish between existence and nonexistence of optimal solutions for this optimal design problem refers to the material tensor M. We will say that M is decomposable if

$$M = M_1 \otimes M_2,$$

where M_i are positive definite, second-order tensors (matrices). Notice how in this case the equilibrium equation basically reduces to the biharmonic operator. In this situation, we have a general existence result.

THEOREM 1. *Suppose that $M = M_1 \otimes M_2$, i.e., M is decomposable, and the integrand F in the cost functional I is such that the functions*

$$\xi \in \left\{ \mathbf{M}^{2\times 2} : \frac{c}{M_2 \cdot \xi} > 0 \right\} \mapsto F\left(x, u, \lambda, \xi, \frac{c}{(M_2 \cdot \xi)^{1/3}} \right)$$

and

$$(\xi, z) \in \left\{ \mathbf{M}^{2\times 2} : M_2 \cdot \xi = 0 \right\} \times \mathbf{R} \mapsto \min_{h \in [h_-, z] \cap Q} F(x, u, \lambda, \xi, h)$$

are convex for any constant c and fixed (x, u, λ). Then there are optimal profiles for the associated optimal design problem for the plate.

A corollary worth stating covers many situations of interest.

COROLLARY 2. *Suppose that the integrand F does not depend on ξ and h, and M is decomposable. Then for any such F (even nonconvex), the corresponding optimal design problem admits optimal solutions.*

Explicit cases like the compliance $F = f(x)u(x)$ are covered with this corollary. But also examples like $F = g(x)u(x)$, $F = |\nabla u(x)|^2$, etc., can be treated through this result as well.

When the tensor M is not decomposable, the situation is drastically different. In many cases, this fact is responsible for the lack of optimal solutions and the analysis is much more complex. See the references cited above. In the particular situation where we assume that the profile h is a function of x_1 alone, so that $h(x) = h(x_1)$, and the tensor M is that of an orthotropic material, a relaxed formulation of the problem can be pursued. It has been a principal goal over the years to find a minimal full relaxation of this problem, that is, one which requires the least number of additional design variables. For the compliance functional, the best result we know of has been obtained in [4] (also in [15] within a more general framework). Here, by revisiting some of our own old ideas [11], we are able to show that this same result holds true even for much more general functionals. Recall that M for orthotropic materials is defined in terms of two main material parameters: Young's modulus E, and Poisson's ratio r, so that the nonvanishing components of M are

$$M_{1111} = M_{2222} = \frac{2}{3}\frac{E}{1-r^2}, \quad M_{1122} = M_{2211} = \frac{2}{3}\frac{Er}{1-r^2},$$
$$M_{1212} = M_{1221} = M_{2112} = M_{2121} = \frac{1}{3}\frac{E}{1+r}.$$

THEOREM 3. *Let admissible profiles depend only on x_1, M corresponding to an orthotropic material, and let the integrand for the cost functional*

$$F(x, u, \lambda) : \Omega \times \mathbf{R} \times \mathbf{R}^2 \to \mathbf{R}$$

be measurable in $x \in \Omega$ and continuous (not necessarily convex) in the pairs (u, λ). Consider the optimal design problem

$$\text{Minimize in } (\theta, h): \quad J(\theta, h) = \int_\Omega F(x, u(x), \nabla u(x))\, dx$$

subject to

$$\theta \in [0,1], \quad h \in [h_-, h_+],$$
$$\int_\Omega \left[\theta(x) h_+ + (1-\theta(x)) h(x)\right] dx \leq V\,|\Omega|\,,$$

and where u solves

$$\sum_{i,j,k,l} \frac{\partial^2}{\partial x_i \partial x_j}\left(\overline{M}_{ijkl} \frac{\partial^2 u}{\partial x_k \partial x_l}\right) = f \text{ in } \Omega,$$
$$u = \frac{\partial u}{\partial n} = 0 \text{ on } \partial\Omega,$$

and the nonvanishing components of $\overline{M}$ depend on the design variables through formulae

$$\overline{M}_{1111} = \frac{2}{3} c(x) \frac{E}{1-r^2}, \quad \overline{M}_{2222} = \frac{2}{3} m(x) E + \frac{2}{3} c(x) \frac{E r^2}{1-r^2},$$
$$\overline{M}_{1122} = \overline{M}_{2211} = \frac{2}{3} c(x) \frac{E r}{1-r^2},$$
$$\overline{M}_{1212} = \overline{M}_{1221} = \overline{M}_{2112} = \overline{M}_{2121} = \frac{1}{3} m(x) \frac{E}{1+r},$$
$$m(x) = \theta(x) h_+^3 + (1-\theta(x)) h^3(x),$$
$$c(x)^{-1} = \theta(x) h_+^{-3} + (1-\theta(x)) h(x)^{-3}.$$

This problem is a full relaxation of the initial optimal design problem in the sense

$$\inf_h I(h) = \min_{(\theta,h)} J(\theta, h).$$

The relevance of this result is in the fact that only one additional design variable, θ (a certain weight), is required to produce a full relaxation of the problem, and this is so for a rather huge class of cost functionals and not only for the compliance. We will later provide further details as to how one is to interpret these pairs (θ, h) in terms of sequences of profiles for the original problem.

This work includes another three sections. The second one contains the full proof of Theorem 1 as well as some observations on some explicit examples. Section 3 covers a brief, elementary discussion on the structure of the material tensor M. Finally, the last section is devoted to the proof of Theorem 3. We will also dwell on the interpretation of the proposed relaxed formulation in terms of the ingredients of the original optimal design problem.

2. Existence results. It is our aim to study a type of design problem for plates whose state equation has the format

$$\operatorname{div}\left(\operatorname{div}\left(h^3(x)\,(M_1 \otimes M_2)\,\nabla^2 u\,(x)\right)\right) = f\,(x) \text{ in } \Omega. \tag{1}$$

It is assumed that $f \in L^2(\Omega)$ is the applied vertical load, Ω is a smooth bounded domain in $\mathbf{R}^2$ that represents the midplane of the plate, $h \in L^\infty(\Omega)$ is the design variable, and the tensors M_i are assumed to be positive and symmetric. To this equation we add the boundary conditions

$$u(x) = \frac{\partial u(x)}{\partial n} = 0 \text{ on } \partial\Omega \tag{2}$$

(clamped plate). We assume further natural constraints on the feasible designs by limiting the height of the thicknesses and the amount of material: the set $\mathcal{H}$ of admissible designs is defined as

$$\mathcal{H} = \left\{ h \in L^\infty(\Omega) : h(x) \in [h_-, h_+] \doteq Q \text{ a.e. } x \in \Omega,\ V(h) \doteq \int_\Omega h(x)dx \le V \right\} \tag{3}$$

(V, $0 < h_- < h_+$ are given positive constants). Associated with this state equation, we consider the general optimization problem

$$\min_{h\in\mathcal{H}} \left\{ L(h) \doteq \int_\Omega F\left(x, u, \nabla u(x), \nabla^2 u(x), h(x)\right) dx \right\}, \tag{4}$$

where u solves (1)–(2) and F is a given integrand such that

$$F : (x, u, \lambda, \xi, h) \in \Omega \times \mathbf{R} \times \mathbf{R}^2 \times \mathbf{M}^{2\times 2} \times Q \to \overline{\mathbf{R}} = \mathbf{R} \cup \{+\infty\}.$$

F is measurable in x and continuous in (u, λ, ξ, h).

Our goal is the optimization problem that consists of looking for an admissible h and the corresponding displacement u, the only weak solution of problem (1)–(2) in the Sobolev space $H_0^2(\Omega)$ (the subspace of $H^2(\Omega)$ under the constraints (2)), which minimizes the objective functional L defined in (4). We denote this problem by $(\mathcal{P})$.

For the study of the above minimization problem, we shall consider a new equivalent variational problem. The underlying idea is to use the differential expression (1) in order to define a new objective functional subject to a set of constraints which are easier to deal with. The construction of this equivalent problem is performed in an elementary way [13]:

1. We introduce an auxiliary function u_0: the solution of the elliptic problem

$$-\operatorname{div}(M_1 \nabla u_0) = f, \quad u_0 \in H_0^1(\Omega). \tag{5}$$

2. Equations (1) and (5) give

$$\operatorname{div}\operatorname{div}(h^3 (M_1 \otimes M_2) \nabla^2 u) + \operatorname{div}(M_1 \nabla u_0) = 0,$$

which is equivalent to writing

$$\operatorname{div}\left(M_1 \nabla (h^3 [\operatorname{div}(M_2 \nabla u)]) + M_1 \nabla u_0\right) = 0 \tag{6}$$

or even

$$\operatorname{div}\left(M_1 \nabla (h^3 \left[M_2 \cdot \nabla^2 u\right]) + M_1 \nabla u_0\right) = 0, \tag{7}$$

i.e.,

$$\operatorname{div}(M_1 \nabla v) = 0, \tag{8}$$

where

$$v = h^3 \operatorname{div}(M_2 \nabla u) + u_0 = h^3 M_2 \cdot \nabla^2 u + u_0. \tag{9}$$

3. The new optimization problem, denoted by $(\mathcal{EP})$, is described as follows. The new integrand for the cost functional is

$$\varphi(x,u,\lambda,\xi,v,z)=\min_{\widetilde{h}\in Q}\left\{F\left(x,u,\lambda,\xi,\widetilde{h}\right):v=\widetilde{h}^3\left(M_2\cdot\xi\right)+u_0\left(x\right),z\geq\widetilde{h}\right\},$$

understood as taking the value $+\infty$ whenever the set of admissible h's is empty, and the objective functional to be minimized in the variables (u,v,z) is

$$J(u,v,z)=\int_\Omega\varphi\left(x,u\left(x\right),\nabla u\left(x\right),\nabla^2u\left(x\right),v\left(x\right),z\left(x\right)\right)dx,$$

under the constraints

$$u\in H_0^2\left(\Omega\right),\ v\in H^1\left(\Omega\right),\ \operatorname{div}(M_1\nabla v)=0,\ z\in L^\infty\left(\Omega\right),\ \int_\Omega z(x)dx=V.$$

PROPOSITION 4. *The two optimization problems $(\mathcal{P})$ and $(\mathcal{EP})$ are equivalent in the following sense: for any admissible pair (h,u)[1] for $(\mathcal{P})$ there is a triplet (u,v,z) admissible for $(\mathcal{EP})$ such that*

$$L(h)\geq J(u,v,z).$$

Conversely, for any admissible triplet (u,v,z) for $(\mathcal{EP})$, there is an admissible pair (h,u) for $(\mathcal{P})$ and

$$L(h)=J(u,v,z).$$

In particular, if (u,v,z) is optimal for $(\mathcal{EP})$, then

$$h(x)=\left(\frac{v\left(x\right)-u_0\left(x\right)}{M_2\cdot\nabla^2u\left(x\right)}\right)^{\frac{1}{3}}$$

whenever $M_2\cdot\nabla^2u\left(x\right)\neq0$, and

$$h(x)=\arg\min_{\widetilde{h}\in Q}\left\{F\left(x,u(x),\nabla u\left(x\right),\nabla^2u\left(x\right),\widetilde{h}\right):z\left(x\right)\geq\widetilde{h}\right\}$$

otherwise, is an optimal profile for $(\mathcal{P})$.

Proof. The proof is almost straightforward. We include some details for the convenience of the reader.

Let (h,u) be admissible for $(\mathcal{P})$, so that problem (1)–(2) holds. We consider u_0 (solution of (5)), and

$$v\left(x\right)=h^3\left(x\right)\left(M_2\cdot\nabla^2u\left(x\right)\right)+u_0\left(x\right).$$

By following the construction explained above v solves (8) and the classical regularity results on elliptic systems ensure that v is in $H^2\left(\Omega\right)$. We select z verifying

$$z\left(x\right)\geq h\left(x\right),\quad z(x)\in Q,\quad\text{and}\quad\int_\Omega z(x)dx=V. \tag{10}$$

[1]Here (h,u) is said to be admissible in the sense that for any $h\in\mathcal{H}$ we find the only solution u of problem (1)–(2).

Then for any $x \in \Omega$,

$$\begin{aligned}
&\varphi\left(x, u\left(x\right), \nabla u\left(x\right), \nabla^2 u\left(x\right), v\left(x\right), z\left(x\right)\right) \\
&= \min_{\widetilde{h} \in Q} \left\{ F\left(x, u, \nabla u\left(x\right), \nabla^2 u\left(x\right), \widetilde{h}\right) : v\left(x\right) = \widetilde{h}^3 \left(M_2 \cdot \nabla^2 u\left(x\right)\right) + u_0\left(x\right), z\left(x\right) \geq \widetilde{h} \right\} \\
&\leq F\left(x, u, \nabla u\left(x\right), \nabla^2 u\left(x\right), h(x)\right).
\end{aligned}$$

It is clear that our triplet, (u, v, z), is admissible for $(\mathcal{EP})$ and $J(u, v, z) \leq L(h)$.

Let (u, v, z) now be admissible for $(\mathcal{EP})$. The multifunction H given by

$$\arg\min_{\widetilde{h} \in Q} \left\{ F\left(x, u(x), \nabla u\left(x\right), \nabla^2 u\left(x\right), \widetilde{h}\right) : v\left(x\right) = \widetilde{h}^3 \left(M_2 \cdot \nabla^2 u\left(x\right)\right) + u_0\left(x\right) z\left(x\right) \geq \widetilde{h} \right\}$$

is measurable and takes closed set values. Then H admits a measurable selection (see [10, Thm. 2.23]) and we can select a measurable function h such that $h(x) \in Q$, and for any $x \in \Omega$

$$\begin{aligned}
&\varphi\left(x, u\left(x\right), \nabla u\left(x\right), \nabla^2 u\left(x\right), v\left(x\right), z\left(x\right)\right) \\
&= \min_{\widetilde{h} \in Q} \left\{ F\left(x, u\left(x\right), \nabla u\left(x\right), \nabla^2 u\left(x\right), \widetilde{h}\right) : v\left(x\right) = \widetilde{h}^3 \left(M_2 \cdot \nabla^2 u\left(x\right)\right) + u_0\left(x\right), z\left(x\right) \geq \widetilde{h} \right\} \\
&= F\left(x, u\left(x\right), \nabla u\left(x\right), \nabla^2 u\left(x\right), h\left(x\right)\right).
\end{aligned}$$

Moreover, by definition we have $v\left(x\right) = h^3\left(x\right)\left(M_2 \cdot \nabla^2 u\left(x\right)\right) + u_0\left(x\right)$, $z\left(x\right) \geq h\left(x\right) \in Q$. This is enough to fulfill the state equation

$$\operatorname{div}\operatorname{div}(h^3 \left(M_1 \otimes M_2\right) \nabla^2 u) = f\left(x\right),$$

the bound on the volume

$$\int_\Omega h(x)dx \leq \int_\Omega z(x)dx = V,$$

and the equality $I(u, v, z) = L(h, u)$. □

We can now establish the existence of optimal solutions for $(\mathcal{EP})$.

THEOREM 5. *Assume that the two functions*

$$\xi \in \left\{ \mathbf{M}^{2\times 2} : \frac{c}{M_2 \cdot \xi} > 0 \right\} \mapsto F\left(x, u, \lambda, \xi, \frac{c}{\left(M_2 \cdot \xi\right)^{1/3}}\right)$$

and

$$(\xi, z) \in \left\{ \mathbf{M}^{2\times 2} : M_2 \cdot \xi = 0 \right\} \times \mathbf{R} \mapsto \min_{h \in [h_-, z] \cap Q} F(x, u, \lambda, \xi, h)$$

are convex for any constant c and fixed (x, u, λ). Problem $(\mathcal{EP})$,

$$\inf_{(u,v,z)} J(u, v, z) \doteq \int_\Omega \varphi\left(x, u\left(x\right), \nabla u\left(x\right), \nabla^2 u\left(x\right), v\left(x\right), z\left(x\right)\right) dx,$$

where

$$\varphi\left(x, u, \lambda, \xi, v, z\right) = \min_{h \in Q} \left\{ F\left(x, u, \lambda, \xi, h\right) : v = h^3 \left(M_2 \cdot \xi\right) + u_0\left(x\right), z \geq h \right\}$$

under the restrictions

$$u \in H_0^2(\Omega),\ v \in H^1(\Omega),\ \operatorname{div}(M_1 \nabla v) = 0,\ z \in L^\infty(\Omega),\ \int_\Omega z(x)dx = V,$$

has optimal solutions.

Proof. Let (u_j, v_j, z_j) be a minimizing sequence for $(\mathcal{EP})$. As we have seen in the proof of Proposition 4 we can build the corresponding sequence h_j such that

$$\operatorname{div}\operatorname{div}(h_j^3 (M_1 \otimes M_2) \nabla^2 u_j) = f(x),\ u_j \in H_0^2(\Omega).$$

Then we can ensure that u_j is uniformly bounded in $H^2(\Omega)$. This sequence converges to u weakly in $H_0^2(\Omega)$ and, consequently, u_j and ∇u_j converge strongly in $L^2(\Omega)$ to u and ∇u, respectively. On the other hand, by elliptic theory, $\operatorname{div}(M_1 \nabla v_j) = 0$ implies v_j converges almost everywhere to a function $v \in H^1(\Omega)$ verifying the same elliptic equation (see [16] for a very neat proof in the case of the Laplacian), so that v_j converges strongly to v. Finally, notice that because $\varphi(x, u, \lambda, \xi, v, z) = \varphi(x, u, \lambda, \xi, v, h_+)$ if $z_j \geq h_+$, we may assume without lost of generality that $h_j \leq z_j \leq h_+$. Then z_j converges to some z in $L^\infty(\Omega)$ weak-$\star$, and this limit must satisfy $\int_\Omega z(x)dx = V$.

On the basis of these remarks, it remains to prove that φ is jointly convex in (ξ, z) for fixed (x, u, λ, v). To do that, it is enlightening to rewrite φ as

$$\begin{cases} F\left(x, u, \lambda, \xi, \left(\frac{v-u_0(x)}{M_2 \cdot \xi}\right)^{1/3}\right), & M_2 \cdot \xi \neq 0,\ z \geq \left(\frac{v-u_0(x)}{M_2 \cdot \xi}\right)^{1/3} \in Q, \\ \min_{h \in [h_-, z] \cap Q} F(x, u, \lambda, \xi, h), & M_2 \cdot \xi = 0,\ v = u_0(x), \\ +\infty & \text{else} \end{cases}$$

and discuss the convexity by considering two main cases:

1. $v \neq u_0(x)$: in this case φ is given by

$$\begin{cases} F\left(x, u, \lambda, \xi, \left(\frac{v-u_0(x)}{M_2 \cdot \xi}\right)^{1/3}\right), & M_2 \cdot \xi \neq 0,\ z \geq \left(\frac{v-u_0(x)}{M_2 \cdot \xi}\right)^{1/3} \in Q, \\ +\infty & \text{else.} \end{cases}$$

   This is a convex function of (ξ, z), as the set where it is finite is convex, and, by hypothesis, the function on such a set is also convex. Checking this is elementary but a bit tedious.
2. $v = u_0(x)$: in this situation we have

$$\varphi(x, u, \lambda, \xi, v, z) = \begin{cases} \min_{h \in [h_-, z] \cap Q} F(x, u, \lambda, \xi, h), & M_2 \cdot \xi = 0, \\ +\infty & \text{else.} \end{cases}$$

   This is again convex by our main structural assumption on F. ∎

The proof of Theorem 1 is a direct consequence of Theorem 5 and Proposition 4.

The generality of the cost functional permits us to associate with the state equation a huge class of optimization problems. We give some examples of such densities: the compliance case $F = f(x)\, u(x)$ or some other typical densities like $F = g(x)u(x)$, $F = |\nabla u(x)|^2$, or the identification-type problem $F = |u(x) - u_d(x)|^2 + |\nabla u(x) - \nabla u_d(x)|^2$, where $u_d \in H^1(\Omega)$ is the observed deflection of the plate. Also, $F = F_1(x, u, \nabla u)$, where F_1 is continuous on the last two variables (but not necessarily

convex) or $F = F_2\left(x, u, \nabla u, \nabla^2 u\right)$, where F_2 is continuous on the last three variables and only convex in the $\nabla^2 u$ variable, are densities for which the existence is ensured. Even with $F = F_1\left(x, u, \nabla u\right) + F_3(h)$ or $F = F_2\left(x, u, \nabla u, \nabla^2 u\right) + F_3(h)$, where F_3 is any convex and nondecreasing function (F_1 and F_2 as above), the existence of optimal classical minimizers is guaranteed.

3. The structure of the tensor M. We have seen so far that the possibility of decomposing the tensor M as the tensor product of two matrices is the crucial ingredient for having existence of optimal profiles. This will be so for special types of materials. In many sources from mechanics this is assumed as part of the model. See [2], [8]. Indeed, the equilibrium equation for the plate is often taken as

$$D\Delta^2 u = f,$$

where the coefficient D is the so-called flexural rigidity or the bending stiffness given by

$$D = \frac{Eh^3}{12(1-r^2)},$$

where h is the (constant) thickness of the plate, and E and r are, as before, Young's modulus and Poisson's ratio. When h is nonconstant, then the equation of equilibrium must be written in the form

$$\overline{D}\Delta(h^3\Delta) = f.$$

This time

$$\overline{D} = \frac{E}{12(1-r^2)}.$$

Within this sort of model, the tensor M is clearly decomposable with M_1 and M_2 multiples of the identity. In these cases, we can apply Theorem 1 to ensure the existence of optimal profiles.

The case of orthotropic materials is, however, very different. In fact, an orthotropic tensor is not decomposable.

PROPOSITION 6. *An orthotropic tensor is never decomposable.*

The proof is elementary and well known to specialists. Indeed, by writing a fourth-order tensor as a 4×4 matrix in an organized way, we realize that the matrix corresponding to a orthotropic material is of the form

$$\frac{4}{9}\frac{E^4}{(1-r^2)(1+r)^2}\begin{pmatrix} 1 & 0 & 0 & r \\ 0 & 1 & 1 & 0 \\ 0 & 1 & 1 & 0 \\ r & 0 & 0 & 1 \end{pmatrix}.$$

If such an M were decomposable, this matrix would have to be a rank-one matrix, which is easily seen not to be the case.

4. Design with a nondecomposable tensor. We investigate in this section the same design problem for the plate under the assumption that the tensor of elastic constants is not decomposable so that Theorem 1 is not applicable. Indeed, it is well known, as indicated in the introduction, that in this situation nonexistence of an

optimal profile may result, as the creation of highly oscillatory stiffeners may favor the overall rigidity of the plate.

As before, the goal is to choose the half-thickness h and its corresponding deflection u, which minimizes an integral functional $L = L(h, u)$ given by

$$L(h,u) = \int_\Omega F(x, u(x), \nabla u(x))\, dx, \tag{11}$$

where F is assumed to be measurable in $x = (x_1, x_2)$ and continuous on the variables u and ∇u.

The class of materials is restricted by imposing an orthotropic condition, namely, the nonzero components of M_{ijkl} are

$$\begin{aligned} M_{1111} &= M_{2222} = \frac{2}{3}\frac{E}{1-r^2}, \\ M_{1122} &= M_{2211} = \frac{2}{3}\frac{Er}{1-r^2}, \\ M_{1212} &= M_{1221} = M_{2112} = M_{2121} = \frac{E}{3(1+r)}, \end{aligned}$$

where r and E stand for the Poisson ratio and the Young modulus, respectively. By our comments in the preceding section, this tensor is not decomposable.

We analyze this problem under the simplification that the thickness depends just on one variable $h(x) = h(x_1)$ for any x_1 in the interval

$$(a,b) \doteq \{x_1 : \text{ there exists } x_2 \in \mathbf{R} \text{ such that } (x_1, x_2) \in \Omega\}.$$

The design criterion is to minimize L among all the plates whose half-thickness h satisfies all the constraint indicated above. In other words, the aim is to solve

$$\min_{h \in \mathcal{H}} L, \tag{12}$$

where

$$\mathcal{H} = \left\{ h \in L^\infty(a,b) : h_- \le h(x_1) \le h_+ \text{ a.e. } x_1 \in (a,b),\ \int_\Omega h(x_1)\, dx_1 dx_2 \le V \right\}. \tag{13}$$

Here h_-, h_+, and V are as before.

As indicated before, it is widely recognized that the principle described in (12)–(13) may have no solution. At least, Theorem 1 cannot be applied. This fact suggests performing a relaxation of the design problem to understand the nature of minimizing sequences of profiles. This entails defining a new admissibility set $\overline{\mathcal{H}}$ containing $\mathcal{H}$, and an extension $\overline{L}$ of L such that

$$\inf_{\mathcal{H}} L = \min_{\overline{\mathcal{H}}} \overline{L}. \tag{14}$$

It is interesting to notice that by introducing the relaxation $\min_{\overline{\mathcal{H}}} \overline{L}$, we are considering a problem whose solutions provide information about minimizing sequences of (12). However, it is important to look for the (full) relaxation, which introduces a minimal number of additional design variables. Ideally, just one more variable would

be optimal. For the compliance functional, this was shown to be the case in [4] by making use of optimality conditions. We will prove that this is the case for many more cost functionals by revisiting some our our previous ideas on this problem [11].

The starting point for a relaxation is the lemma by Murat [12] and Tartar [18] related to H-convergence. It explains why the cubic-average and the harmonic cubic-average play an important role in the relaxation for this problem. This lemma is only valid under our assumption of profiles depending only on x_1. The reader can consult [5] for a detailed proof of this result.

LEMMA 7. *Let $\left\{M^{(r)}\right\}$ be a sequence of orthotropic tensors bounded uniformly by (d, D), i.e.,*

$$d\left|t\right|^2 \leq \sum_{i,j,k,l} M^{(r)}_{ijkl} t_{ij} t_{kl}, \quad \left|\sum_{ij} M^{(r)}_{ijkl} t_{ij}\right| \leq D\left|t\right| \text{ for every } k, l.$$

Suppose that $M^{(r)} = M^{(r)}(x_1)$ and

$$\begin{gathered}
\left(M^{(r)}_{1111}\right)^{-1} \overset{*}{\rightharpoonup} \left(M^{(\infty)}_{1111}\right)^{-1}, \\
\left(M^{(r)}_{1122}\right)\left(M^{(r)}_{1111}\right)^{-1} \overset{*}{\rightharpoonup} \left(M^{(\infty)}_{1122}\right)\left(M^{(\infty)}_{1111}\right)^{-1}, \\
\left(M^{(r)}_{2222}\right) - \left(M^{(r)}_{1122}\right)^2\left(M^{(r)}_{1111}\right)^{-1} \overset{*}{\rightharpoonup} \left(M^{(\infty)}_{2222}\right) - \left(M^{(\infty)}_{1122}\right)^2\left(M^{(\infty)}_{1111}\right)^{-1}, \\
M^{(r)}_{1212} \overset{*}{\rightharpoonup} M^{(\infty)}_{1212}.
\end{gathered}$$

If $u^{(r)}$ are the solutions of the equilibrium equation for the clamped plate with tensor $M^{(r)}$, and $u^{(\infty)}$ is the solution corresponding to $M^{(\infty)}$, then $u^{(r)} \rightharpoonup u^{(\infty)}$ in $H^2_0(\Omega)$.

Because of the structure of the components of an orthotropic tensor, it is elementary to check that for a given sequence of designs $\{h_j\}$, if we define (in a unique way) the pair (h, θ) by putting

$$\begin{aligned}
h_j^3 &\overset{*}{\rightharpoonup} \theta h_+^3 + (1-\theta)h^3, \\
h_j^{-3} &\overset{*}{\rightharpoonup} \theta h_+^{-3} + (1-\theta)h^{-3}
\end{aligned} \tag{15}$$

for $\theta \in [0,1]$, $h \in [h_-, h_+]$, and

$$\begin{aligned}
\overline{M}_{1111} &= \frac{2}{3} c \frac{E}{(1-r^2)}, \\
\overline{M}_{2222} &= \frac{2}{3} mE + \frac{2}{3} c \frac{Er^2}{1-r^2}, \\
\overline{M}_{1122} &= \overline{M}_{2211} = \frac{2}{3} c \frac{Er}{1-r^2}, \\
\overline{M}_{1212} &= \overline{M}_{1221} = \overline{M}_{2112} = \overline{M}_{2121} = \frac{1}{3} m \frac{E}{(1+r)},
\end{aligned} \tag{16}$$

where m and c denote the cubic average and the harmonic cubic-average of the pair (θ, h), respectively,

$$\begin{aligned}
m &= \theta h_+^3 + (1-\theta)h^3, \\
c &= \left(\theta h_+^{-3} + (1-\theta)h^{-3}\right)^{-1},
\end{aligned} \tag{17}$$

then

$$L(h_j, u_j) \to \overline{L}(\theta, h),$$

where

$$\overline{L}(\theta, h) = \int_\Omega F(x, \overline{u}, \nabla \overline{u})\, dx$$

and $\overline{u}$ is the solution of the plate equation corresponding to the tensor $\overline{M}$. Notice that weak convergence in $H_0^2(\Omega)$ implies strong convergence in $H^1(\Omega)$.

This discussion suggests defining a relaxation as an optimization problem for pairs (θ, h) in

$$\overline{\mathcal{H}} = \{(\theta, h) : 0 \le \theta \le 1, h_- \le h \le h_+\}$$

with cost

$$\overline{L}(\theta, h) = \int_\Omega F(x, \overline{u}, \nabla \overline{u})\, dx,$$

where as above $\overline{u}$ is the solution of the equilibrium plate problem for tensor $\overline{M}$ obtained from (θ, h) through the cubic-average and the harmonic cubic-average as in (16) and (17).

This would essentially be the proof of Theorem 3 except for the fact that the parameter V has not entered into our discussion. In fact, minimizing sequences of admissible designs must comply with

$$\int_\Omega h_j(x)\, dx \le V,$$

and we have not told how this parameter V enters into the relaxation. How is V to restrict further the pairs in $\overline{\mathcal{H}}$?

We observe that admissible pairs in $\overline{\mathcal{H}}$ come from the weak convergence of sequences $\left(h_j^3, h_j^{-3}\right)$. In order to relate h_j to $\left(h_j^3, h_j^{-3}\right)$, we will look for a function G so that

$$h = G(h^3, h^{-3}), \quad h \in [h_-, h_+],$$

and extend it by putting

$$G\left(\theta h_+^3 + (1-\theta)h^3, \theta h_+^{-3} + (1-\theta)h^{-3}\right) = \theta h_+ + (1-\theta)h.$$

If G so defined turns out to be convex, then by the weak convergences in (15),

(18)

$$\begin{aligned}
\lim_{j\to\infty} \int_\Omega h_j(x)\, dx &= \lim_{j\to\infty} \int_\Omega G\left(h_j^3(x), h_j^{-3}(x)\right) dx \\
&\ge \int_\Omega G\left(\theta(x)h_+^3 + (1-\theta(x))h(x)^3, \theta(x)h_+^{-3} + (1-\theta(x))h(x)^{-3}\right) dx \\
&= \int_\Omega \left[\theta(x)h_+ + (1-\theta(x))h(x)\right] dx,
\end{aligned}$$

so that we have

$$\int_\Omega \left[\theta(x)h_+ + (1-\theta(x))h(x)\right] dx \le V.$$

We then add this volume constraint to feasible pairs in $\overline{\mathcal{H}}$:

$$\overline{\mathcal{H}} = \left\{ (\theta, h) : 0 \le \theta \le 1, h_- \le h \le h_+, \int_\Omega [\theta(x)h_+ + (1-\theta(x))h(x)]\, dx \le V \right\}.$$

After the previous remarks, the full proof of Theorem 3 has been reduced to proving the convexity of the mapping G described above. This convexity property for G was proved in [11] (proof of Theorem 4.1). It is a nice, geometric argument, which we do not include here for the sake of brevity. It has nothing to do with the rest of the analysis in this work. One can also find in that paper how to recover admissible sequences of designs which are minimizing for the original problem from optimal pairs in $\overline{\mathcal{H}}$. This can be done in an elegant way by using Young measures associated with such sequences of designs.

CONVERGENCE OF THE PRIMAL-DUAL ACTIVE SET STRATEGY FOR DIAGONALLY DOMINANT SYSTEMS*

KAZUFUMI ITO† AND KARL KUNISCH‡

Abstract. Sufficient conditions for global convergence of the primal-dual active set strategy for finite and infinite dimensional quadratic, as well as nonlinear optimization, problems with affine equality and inequality constraints are presented. These conditions involve diagonal dominance and cone preserving properties of the operator defining the cost functional. Globalization strategies are also provided, and specific sufficient conditions for the primal-dual active set step to have a descent property are given.

Key words. primal-dual active set strategy, diagonally dominant systems, bilateral constraints, globalization

1. Introduction. In this paper we discuss the primal-dual active set method for variational problems with simple constraints in function space or in $\mathbb{R}^n$. Let us consider the quadratic programming problem

$$\begin{cases} \min_{x\in Z} \frac{1}{2}\langle Ax, x\rangle_Z - \langle a, x\rangle_Z \\ \\ \text{subject to} \quad \phi \le x \le \psi, \end{cases} \tag{1.1}$$

where $a \in Z$, $A \in \mathcal{L}(Z)$ is a self-adjoint operator, and $Z = \mathbb{R}^n$ or $Z = L^2(\Omega)$, endowed with the usual Hilbert space structure and the natural ordering, where Ω is a domain in $\mathbb{R}^d$. We assume that (1.1) admits a unique solution denoted again by x. If x is a regular point [MZ] with respect to the constraints in (1.1), then there exists a Lagrange multiplier $\mu \in Z$ such that

$$\begin{aligned} &Ax + \mu = a, \\ &\mu = \max(0, \mu + c\,(x - \psi)) + \min(0, \mu + c\,(x - \phi)), \end{aligned} \tag{1.2}$$

where $c > 0$ is a fixed constant and max, min are interpreted pointwise a.e. in Ω if $Z = L^2(\Omega)$ and coordinatewise if $Z = \mathbb{R}^n$. The second equation in (1.2) constitutes the complementarity condition associated with the inequality constraint in (1.1) [IK1]. We note that in iterative methods such as sequential quadratic programming or second order augmented Lagrangian methods, quadratic optimization problems with linear constraints must be solved which take the form of (1.1). The primal-dual active set method that will be analyzed in this paper is an efficient technique for solving (1.2).

‡Institut für Mathematik und Wissenschaftliches Rechnen, Universität Graz, Graz, Austria, and RICAM, Austrian Academy of Sciences, Linz, Austria (karl.kunisch@uni-graz.at).

While (1.2) is derived from (1.1) with A self-adjoint, this assumption is not essential in the remainder of this paper and we therefore drop it unless it is explicitly specified. If $\phi = -\infty$ or $\psi = \infty$, then (1.2) reduces to the unilaterally affine constraint case.

The primal-dual active set method uses the complementarity condition

$$\mu = \max(0, \mu + c\,(x - \psi)) + \min(0, \mu + c\,(x - \phi))$$

as a prediction strategy. Based on the current primal-dual pair (x, μ), the updates for the active and inactive sets are determined by

$$\mathcal{I} = \{\mu + c(x - \psi) \le 0\} \quad \text{and} \quad \mathcal{A} = \{\mu + c(x - \psi) > 0\},$$

where $\{\mu + c(x - \psi) \le 0\}$ is the abbreviation for $\{t : \mu(t) + c(x(t) - \psi(t)) \le 0\}$. This leads to the following Newton-like method.

Primal-dual active set method.

(1) Initialize x^0, μ^0. Set $k = 0$.

(2) Set $\mathcal{I}_k = \{\mu^k + c(x^k - \psi) \le 0 \le \mu^k + c(x^k - \phi)\}$, $\mathcal{A}_k^+ = \{\mu^k + c(x^k - \psi) > 0\}$, $\mathcal{A}_k^- = \{\mu^k + c(x^k - \phi) < 0\}$.

(3) Solve for (x^{k+1}, μ^{k+1})

$$Ax^{k+1} + \mu^{k+1} = a,$$

$$x^{k+1} = \psi \text{ in } \mathcal{A}_k^+, \quad x^{k+1} = \phi \text{ in } \mathcal{A}_k^-, \quad \text{and} \quad \mu^{k+1} = 0 \text{ in } \mathcal{I}_k.$$

(4) Stop, or set $k = k + 1$ and return to (4).

It was shown in [HIK] that the above algorithm can be interpreted as a semi-smooth Newton method for solving (1.2), and sufficient conditions were given for its local superlinear convergence. For related results in finite dimensions we refer to [FK], for example. The emphasis in this paper lies on providing sufficient conditions for global convergence without a globalization strategy such as a line search or a trust region method. This is motivated by the fact that global convergence was observed in many applications; see, e.g., [HIK, KR]. It appears to be difficult to find conditions which precisely describe this phenomenon. However, diagonal dominance and a structure which is close to the M-property appear to enhance this kind of unconditional convergence with respect to the initial condition.

We now describe the contributions of this paper. In section 2 we present motivating examples for the function space formulation of (1.1). We also consider the case where, in addition to the simple inequality constraints, equality constraints and a more general inequality constraint are present. A sufficient condition for the reduction of such problems to (1.1) is presented. Sufficient conditions for global convergence without globalization strategies of unilaterally constrained problems with arbitrary initialization are presented in section 3. In section 4 we analyze bilaterally constrained problems. Nonlinear problems are considered in section 5. As mentioned above, the primal-dual active set method converges for important practical problems without the necessity of introducing a globalization scheme. Of course, we cannot expect that this is universally true. Therefore, in section 6 we also consider a globalization strategy which can be utilized if the primal-dual active set strategy with full steps does not provide sufficient decrease. In particular we provide a sufficient condition, which guarantees that the direction supplied by the primal-dual active set strategy serves as a descent direction, and we describe alternative choices for obtaining descent directions.

2. Applications. Here we provide two motivating examples for studying the primal-dual active set strategy for (1.1) in function space. In Example 2.3, moreover, we consider a more general class of problems and their reduction to the form given by (1.1).

Example 2.1. Let us consider an optimal control problem with $\hat{\Omega} \subset \Omega$ as the control domain, Ω a bounded domain in a finite dimensional space, and $Z = L^2(\hat{\Omega})$:

$$\begin{cases} \min_{u\in X} \ \frac{1}{2}\int_\Omega |y-\bar{y}|^2\,dx + \frac{\alpha}{2}|u|_X^2 \\ \\ \text{subject to} \quad -\Delta y = Bu, \quad y = 0 \text{ on } \partial\Omega, \quad \text{and} \quad \phi \le u \le \psi, \end{cases}$$

where $\alpha > 0$, $\bar{y} \in L^2(\Omega), \phi \text{and} \psi \in Z$, and $B \in \mathcal{L}(Z, L^2(\Omega))$ is the extension-by-zero operator of the identity from $\hat{\Omega}$ to Ω. This problem can be formulated as (1.1), without equality constraint ($E = 0$), by setting

$$A = \alpha I + B^*(-\Delta)^{-2}B \quad \text{and} \quad a = B^*(-\Delta)^{-1}\bar{y},$$

where Δ denotes the Laplace operator with homogeneous Dirichlet boundary conditions. In this example A is an additive perturbation of a multiple of the identity operator, a situation which we shall return to in section 3. Note that A is also well defined from $L^p(\hat{\Omega})$ to $L^p(\hat{\Omega})$ for any $p \ge 1$. Moreover if B and B^* are positivity preserving, then A is positivity preserving, and discretizations of A have the property that off-diagonal elements are decaying at an α-dependent rate.

Example 2.2. Similarly we can consider the time-dependent problem

$$\begin{cases} \min_{u\in X} \ \frac{1}{2}\int_0^T \int_\Omega |y-\bar{y}|^2\,dx\,dt + \frac{\alpha}{2}|u|_X^2 \\ \\ \text{subject to} \quad \frac{d}{dt}y = \Delta y + Bu, \\ \\ y(0,\cdot) = y_0, \quad y = 0 \text{ on } (0,T)\times\partial\Omega, \quad \text{and} \quad \phi \le u \le \psi, \end{cases}$$

with $Z = L^2(0,T;L^2(\hat{\Omega})) = L^2((0,T)\times(\hat{\Omega})), \bar{y}$ and $y_0 \in L^2(\Omega)$, ϕ and $\psi \in Z$, $\alpha > 0$, and $B \in \mathcal{L}(Z, L^2(0,T;L^2(\Omega)))$ is the extension-by-zero operator of the identity from $(0,T)\times\hat{\Omega}$ to $(0,T)\times\Omega$. Again $A = \alpha I + ((\frac{d}{dt} - \Delta)^{-1}B)^*(\frac{d}{dt} - \Delta)^{-1}B$ is positivity preserving if B and B^* are positivity preserving, and off-diagonal elements of canonical discretizations of A are decaying at an α-dependent rate.

Example 2.3. Here we consider the quadratic programming problem

$$\begin{cases} \min_{x\in X} \ \frac{1}{2}\langle Ax, x\rangle_X - \langle a, x\rangle_X \\ \\ \text{subject to } Ex = b, \quad \phi \le Gx \le \psi, \end{cases} \tag{2.1}$$

where $a \in X, A \in \mathcal{L}(X)$ is a self-adjoint operator in the real Hilbert space X, $E \in \mathcal{L}(X,W)$, $G \in \mathcal{L}(X,Z)$, with W a real Hilbert space, and Z is as in (1.1). We assume that (2.1) admits a unique solution, denoted again by x. If x is a regular point [MZ] with respect to the constraints in (2.1), then there exists a Lagrange multiplier

$(\lambda, \mu) \in W^* \times Z$ such that

$$\begin{cases} Ax + E^*\lambda + G^*\mu = a, \\ Ex = b, \\ \mu = \max(0, \mu + c\,(Gx - \psi)) + \min(0, \mu + c\,(Gx - \phi)), \end{cases} \tag{2.2}$$

where $c > 0$ is a fixed constant as above.

We now derive sufficient conditions which allow us to transform (2.2) into (1.2). In a first step we assume that

$$G \text{ is surjective, } \operatorname{range}(G^*) \subset \ker E,\ E\bar{x} = b, \text{ where } \bar{x} \in (\ker E)^{\perp}. \tag{2.3}$$

Note that (2.3) implies that $G : N(E) \to Z$ is surjective. If not, then there exists a nonzero $z \in Z$ such that $(z, Gx)_Z = (G^*z, x)_X = 0$ for all $x \in \ker E$. If we let $x = G^*z$, then $|x|^2 = 0$ and $z = 0$, since G^* is injective. Let P_E denote the orthogonal projection in X onto $\ker E$. Then (2.2) is equivalent to

$$\mathcal{A}\hat{x} + G^*\mu = P_E(a - A\bar{x}), \quad \mu = \max(0, \mu + c\,(G\hat{x} - (\psi - G\bar{x}),$$

$$E^*\lambda = (I - P_E)(a - A(P_E\hat{x} + \bar{x})),$$

with $\mathcal{A} = P_E A P_E^*$ and $x = \hat{x} + \bar{x} \in \ker E + (\ker E)^{\perp}$. The first of the above equations is equivalent to the system

$$\begin{aligned} &(I - P_G)\mathcal{A}((I - P_G)\,\hat{x} + P_G\,\hat{x}) + G^*\mu = (I - P_G)P_E(a - A\,\bar{x}), \\ &P_G\,\mathcal{A}((I - P_G)\,\hat{x} + P_G\,\hat{x}) = P_G\,P_E\,(a - A\,\bar{x}), \end{aligned} \tag{2.4}$$

where $P_G = I - G^*(G\,G^*)^{-1}G$ is the orthogonal projection in $\ker E \subset X$ onto $\ker G$. Since G^* is injective, the first equation in (2.4) is equivalent to

$$(G\,G^*)^{-1}G\,\mathcal{A}(G^*(G\,G^*)^{-1}y + x_2) + \mu = (G\,G^*)^{-1}G\,P_E(a - A\,\bar{x}),$$

where $y = G\,x_1$ for $x_1 \in \ker E \cap (\ker G)^{\perp}$, $x_2 \in \ker G \cap \ker E$, and $\hat{x} = x_1 + x_2$. Let

$$A_{11} = (GG^*)^{-1}G\mathcal{A}G^*(GG^*)^{-1}, \ \ A_{12} = (GG^*)^{-1}G\mathcal{A}P_G, A_{22} = P_G\mathcal{A}P_G$$

and

$$a_1 = (GG^*)^{-1}GP_E(a - A\bar{x}),\ a_2 = P_GP_E(a - A\bar{x}).$$

Then (2.4) is equivalent to the following equation in $Z \times (\ker E \cap \ker G)$:

$$\begin{pmatrix} A_{11} & A_{12} \\ A_{12}^* & A_{22} \end{pmatrix} \begin{pmatrix} y \\ x_2 \end{pmatrix} + \begin{pmatrix} \mu \\ 0 \end{pmatrix} = \begin{pmatrix} a_1 \\ a_2 \end{pmatrix}. \tag{2.5}$$

Let us summarize the discussion so far. If $A \in \mathcal{L}(Z)$ and (2.3) holds, then (2.5), together with

$$\mu = \max(0, \mu + c(y - (\psi - G\bar{x}))), \tag{2.6}$$

and $E^*\lambda = (I - P_E)(a - A(\hat{x} + \bar{x}))$ are equivalent to (2.2), where $x = \hat{x} + \bar{x}$, with $\hat{x} = x_1 + x_2 \in \ker E$, $x_2 \in \ker E \cap \ker G$, $x_1 \in \ker E \cap (\ker G)^\perp$, $y = Gx_1$.

Note that the system matrix in (2.5) is positive definite if A restricted to $\ker E$ is positive definite.

Let us now further assume that

$$A_{22} \text{ is nonsingular.} \tag{2.7}$$

Then (2.5), (2.6) are equivalent to

$$(A_{11} - A_{12}A_{22}^{-1}A_{12}^*)y + \mu = a_1 - A_{12}A_{22}^{-1}a_2 \tag{2.8}$$

and (2.6), which is the desired form (1.2). In the finite dimensional case, (1.2) admits a unique solution for every $a \in \mathbb{R}^n$, if and only if A is a P-matrix (see [BP, Theorem 10.2.15]). Recall that A is called a P-matrix, if all its principal minors are positive. In view of the fact that the reduction of (2.5) to (2.8) was achieved by taking the Schur complement with respect to A_{22}, it is also worthwhile to recall that the Schur complement of a P-matrix (resp., M-matrix) is again a P-matrix (resp., M-matrix); see [BP, page 292]. If one does not carry out the reduction step from (2.5) to (2.8), then the coordinates corresponding to x_2 can be treated as inactive ones in the algorithm and the convergence analysis that we carry out for (1.2) remains valid for (2.5)–(2.6).

Let us specify the primal-dual active set method for the extended problem (2.2).

Primal-dual active set method (extended problem).

(1) Initialize x^0, μ^0. Set $k = 0$.

(2) Set $\mathcal{I}_k = \{\mu^k + c(Gx^k - \psi) \le 0 \le \mu^k + c(Gx^k - \phi)\}$, $\mathcal{A}_k^+ = \{\mu^k + c(Gx^k - \psi) > 0\}$, $\mathcal{A}_k^- = \{\mu^k + c(Gx^k - \phi) < 0\}$.

(3) Solve for $(x^{k+1}, \lambda^{k+1}, \mu^{k+1})$

$$Ax^{k+1} + E^*\lambda^{k^+1} + G^*\mu^{k+1} = a,$$

$$Ex^{k+1} = b,$$

$$Gx^{k+1} = \psi \text{ in } \mathcal{A}_k^+, \quad Gx^{k+1} = \phi \text{ in } \mathcal{A}_k^-, \quad \text{and} \quad \mu^{k+1} = 0 \text{ in } \mathcal{I}_k.$$

(4) Stop, or set $k = k + 1$ and return to (2).

Applying the algorithm for the extended system to (2.2), or utilizing the primal-dual algorithm for the reduced system (1.2), results in algebraically equivalent systems if (2.3) holds. The relationship between the two approaches is given by

$$x^{k+1} = x_1^{k+1} + x_2^{k+1} + \bar{x}, \text{ where } x_1^{k+1} \in \ker E \cap (\ker G)^\perp, \quad x_2^{k+1} \in \ker E \cap \ker G,$$
$$Gx_1^{k+1} = y, \quad \mu = 0 \text{ in } \mathcal{I}_k, \quad y^{k+1} = \psi - G\bar{x} \text{ in } \mathcal{A}_k^+, \quad y^{k+1} = \phi - G\bar{x} \text{ in } \mathcal{A}_k^-,$$
and (2.4) holds with $(y, x_2) = (y^{k+1}, x_2^{k+1})$.

3. Diagonally dominated class: Unilateral case. In this section we discuss the global convergence of the primal-dual active set method in the unilateral case, i.e.,

$$Ax + \mu = a, \quad \mu = \max(0, \mu + c(x - \psi)). \tag{3.1}$$

For the convenience of the reader we recall the algorithm for this case.

PRIMAL-DUAL ACTIVE SET METHOD (unilateral problem).
(1) Initialize x^0, μ^0. Set $k = 0$.
(2) Set $\mathcal{I}_k = \{\mu^k + c(x^k - \psi) \le 0\}, \quad \mathcal{A}_k = \{\mu^k + c(x^k - \psi) > 0\}$.
(3) Solve for (x^{k+1}, μ^{k+1})

$$Ax^{k+1} + \mu^{k+1} = a,$$

$$x^{k+1} = \psi \text{ in } \mathcal{A}_k, \quad \text{and} \quad \mu^{k+1} = 0 \text{ in } \mathcal{I}_k.$$

(4) Stop, or set $k = k + 1$ and return to (4).

Here we abbreviate $\mathcal{A}_k^+$ by $\mathcal{A}_k$. Sufficient conditions for global convergence were established in [HIK] for the finite dimensional case $Z = \mathbb{R}^n$. The sufficient condition we discuss here is more general. It is related to diagonal dominance of A and will imply that

$$\mathcal{M}(x^{k+1}, \mu^{k+1}) = \max\left(\beta \int_\Omega (x^{k+1} - \psi)^+ \, dx, \int_\Omega (\mu^{k+1})^- \, dx\right)$$

with $\beta > 0$ acting as a merit functional for the primal-dual algorithm, i.e., $\mathcal{M}(x^{k+1}, \mu^{k+1}) \le \rho \mathcal{M}(x^k, \mu^k)$, for some $\rho < 1$. Here we set $\phi^+ = \max(\phi, 0)$ and $\phi^- = -\min(\phi, 0)$. Note that by step (3) of the algorithm we have

$$\mathcal{M}(x^{k+1}, \mu^{k+1}) = \max\left(\beta \int_{\mathcal{I}_k} (x^{k+1} - \psi)^+ \, dx, \int_{\mathcal{A}_k} (\mu^{k+1})^- \, dx\right). \tag{3.2}$$

The natural norm associated with this merit functional is the $L^1(\Omega)$-norm, and consequently we assume that

$$A \in \mathcal{L}(L^1(\Omega)), \; a \in L^1(\Omega), \text{ and } \psi \in L^1(\Omega). \tag{3.3}$$

The analysis of this section can also be used to obtain convergence in the $L^p(\Omega)$-norm for any $p \in (1, \infty)$, if the norms in the integrands of $\mathcal{M}$ are replaced with $|\cdot|^p$-norms and the $L^1(\Omega)$-norms below are replaced with $L^p(\Omega)$-norms as well.

The results also apply for $Z = \mathbb{R}^n$. In this case the integrals in (3.2) must be replaced with sums over the respective index sets.

We assume that there exist constants $\rho_i, i = 1, \ldots, 5$, such that for all partitions $\mathcal{A}$ and $\mathcal{I}$ of Ω and for all $\phi_\mathcal{A} \ge 0$ in $L^2(\mathcal{A})$ and $\phi_\mathcal{I} \ge 0$ in $L^2(\mathcal{I})$,

$$\begin{aligned} |[A_\mathcal{I}^{-1} \phi_\mathcal{I}]^-| &\le \rho_1 \, |\phi_\mathcal{I}|, \\ |[A_\mathcal{I}^{-1} A_{\mathcal{I}\mathcal{A}} \phi_\mathcal{A}]^+| &\le \rho_2 \, |\phi_\mathcal{A}| \end{aligned} \tag{3.4}$$

and

$$\begin{aligned} |[A_\mathcal{A} \phi_\mathcal{A}]^-| &\le \rho_3 \, |\phi_\mathcal{A}|, \\ |[A_{\mathcal{A}\mathcal{I}} A_\mathcal{I}^{-1} \phi_\mathcal{I}]^-| &\le \rho_4 \, |\phi_\mathcal{I}|, \\ |[A_{\mathcal{A}\mathcal{I}} A_\mathcal{I}^{-1} A_{\mathcal{I}\mathcal{A}} \phi_\mathcal{A}]^+| &\le \rho_5 \, |\phi_\mathcal{A}|. \end{aligned} \tag{3.5}$$

Here $|\cdot|$ denotes the $L^1(\Omega)$-norm and $A_{\mathcal{I}} = R_{\mathcal{I}} A E_{\mathcal{I}}$, $A_{\mathcal{I}\mathcal{A}} = R_{\mathcal{A}} A E_{\mathcal{I}}$, where $E_{\mathcal{I}} : L^1(\mathcal{I}) \to L^1(\Omega)$ is the extension-by-zero operator and $R_{\mathcal{I}} : L^1(\Omega) \to L^1(\mathcal{I})$ the restriction operator from Ω to $\mathcal{I}$. The remaining symbols are defined by analogy. Assumption (3.4) requires in particular the existence of $A_{\mathcal{I}}^{-1}$. By a Schur-complement argument with respect to the sets $\mathcal{I}_k$ and $\mathcal{A}_k$ this implies existence of a solution to the linear systems in step (3) of the algorithm for every k.

THEOREM 3.1. *If* (3.3), (3.4), (3.5) *hold and* $\rho = \max(\beta\,\rho_1 + \rho_2, \frac{\rho_3}{\beta} + \rho_4 + \frac{\rho_5}{\beta}) < 1$, *then* $\mathcal{M}$ *is a merit function for the primal-dual algorithm of the reduced system, and* $\lim_{k\to\infty}(x^k, \mu^k) = (x^*, \mu^*)$ *in* $L^1(\Omega) \times L^1(\Omega)$, *with* (x^*, μ^*) *a solution to* (3.1).

Proof. Let $\delta x = x^{k+1} - x^k$ and $\delta\mu = \mu^{k+1} - \mu^k$. Then,

$$\begin{aligned} &A_{\mathcal{A}_k}\delta x_{\mathcal{A}_k} + A_{\mathcal{A}_k,\mathcal{I}_k}\delta x_{\mathcal{I}_k} + \delta\mu_{\mathcal{A}_k} = 0, \\ &A_{\mathcal{I}_k}\delta x_{\mathcal{I}_k} + A_{\mathcal{I}_k,\mathcal{A}_k}\delta x_{\mathcal{A}_k} - \mu^k_{\mathcal{I}_k} = 0. \end{aligned} \tag{3.6}$$

For every $k \geq 1$ we have $(x^{k+1} - \psi)^+ \leq (x^{k+1} - x^k)^+$ on $\mathcal{I}_k$ and $(\mu^{k+1})^- = (\delta\mu)^-$ on $\mathcal{A}_k$. Therefore

$$\mathcal{M}(x^{k+1}, \mu^{k+1}) \leq \max\left(\beta \int_{\mathcal{I}_k} (\delta x_{\mathcal{I}_k})^+, \int_{\mathcal{A}_k} (\delta\mu_{\mathcal{A}_k})^-\right). \tag{3.7}$$

From (3.6) we deduce that

$$\delta x_{\mathcal{I}_k} = -A^{-1}_{\mathcal{I}_k}(-\mu^k_{\mathcal{I}_k}) \,+\, A^{-1}_{\mathcal{I}_k} A_{\mathcal{I}_k\mathcal{A}_k}(-\delta x_{\mathcal{A}_k}),$$

with $\mu^k_{\mathcal{I}_k} \leq 0$ and $\delta x_{\mathcal{A}_k} \leq 0$. By (3.4) therefore

$$\begin{aligned} |(\delta x_{\mathcal{I}_k})^+| &\leq \rho_1 |\mu^k_{\mathcal{I}_k}| + \rho_2 |\delta x_{\mathcal{A}_k}| \\ &= \rho_1 \int_{\mathcal{I}_k \cap \mathcal{A}_{k-1}} |(\mu^k_{\mathcal{I}_k})^-| + \rho_2 \int_{\mathcal{A}_k \cap \mathcal{I}_{k-1}} (x^k - \psi)^+ \\ &\leq \left(\rho_1 + \frac{\rho_2}{\beta}\right) \mathcal{M}(x^k, \mu^k). \end{aligned} \tag{3.8}$$

Similarly by (3.6),

$$\delta\mu_{\mathcal{A}_k} = A_{\mathcal{A}_k}(-\delta x_{\mathcal{A}_k}) + A_{\mathcal{A}_k\mathcal{I}_k} A^{-1}_{\mathcal{I}_k}(-\mu^k_{\mathcal{I}_k}) - A_{\mathcal{A}_k\mathcal{I}_k} A^{-1}_{\mathcal{I}_k} A_{\mathcal{I}_k\mathcal{A}_k}(-\delta x_{\mathcal{A}_k}).$$

Since $\delta x_{\mathcal{A}_k} \leq 0$ and $\mu^k_{\mathcal{I}_k} \leq 0$, we find by (3.5)

$$|(\delta\mu_{\mathcal{A}_k})^-| \leq \rho_3 |\delta x_{\mathcal{A}_k}| + \rho_4 |\mu^k_{\mathcal{I}_k}| + \rho_5 |\delta x_{\mathcal{A}_k}| \leq \left(\frac{\rho_3 + \rho_5}{\beta} + \rho_4\right) \mathcal{M}(x^k, \mu^k), \tag{3.9}$$

and therefore

$$\mathcal{M}(x^{k+1}, \mu^{k+1}) \leq \max\left(\beta\rho_1 + \rho_2, \frac{\rho_3 + \rho_5}{\beta} + \rho_4\right) \mathcal{M}(x^k, \mu^k) = \rho\, \mathcal{M}(x^k, \mu^k).$$

Thus, if $\rho < 1$, then $\mathcal{M}$ is a merit functional. Furthermore $\mathcal{M}(x^{k+1}, \mu^{k+1}) \leq \rho^k \mathcal{M}(x^1, \mu^1)$. Together with (3.8), (3.9), and (3.6) it follows that (x^k, μ^k) is a Cauchy sequence. Hence there exists (x^*, μ^*) such that $\lim_{k\to\infty}(x^k, \mu^k) = (x^*, \mu^*)$ and

$Ax^* + \mu^* = a, \mu^*(x^* - \psi) = 0$ a.e. in Ω. Since $(x^k - \psi)^+ \to (x^* - \psi)^+$ as $k \to \infty$ and $\lim_{k\to\infty} \int_\Omega (x^{k+1} - \psi)^+ = 0$ it follows that $x^* \le \psi$. Similarly one argues that $\mu^* \ge 0$. Thus, (x^*, μ^*) is a solution to (3.1). ∎

Concerning the uniqueness of solutions to (3.1), assume that $A \in \mathcal{L}(L^2(\Omega))$ and that $(Ay, y)_{L^2(\Omega)} > 0$ for all $y \in L^2(\Omega)$ with $y \neq 0$. Assume further that (x^*, μ^*) and $(\hat{x}, \hat{\mu})$ are solutions to (3.1) with $\hat{x} - x^* \in L^2(\Omega)$. Then $(\hat{x} - x^*, A(\hat{x} - x^*))_{L^2(\Omega)} \le 0$ and therefore $\hat{x} - x^* = 0$.

Remark 3.1. In the finite dimensional case the integrals in the definition of $\mathcal{M}$ must be replaced with sums over the active/inactive index sets. If A is an M-matrix, then $\rho_1 = \rho_2 = 0$ and $\rho < 1$ if $\frac{\rho_3}{\beta} + \rho_4 + \frac{\rho_5}{\beta} < 1$. This is the case if A is diagonally dominant in the sense that $\rho_4 < 1$ and β is chosen sufficiently large. For such a matrix A the property $\rho < 1$ is stable under additive perturbations, which are not necessarily M-matrices.

Remark 3.2. Consider the infinite dimensional case with $A = \alpha I + K$, where $\alpha > 0$, $K \in \mathcal{L}(L^1(\Omega))$, and $K\phi \ge 0$ for all $\phi \ge 0$. This is the case for the operators in Example 2.1, as can be argued by using the maximum principle. Let $\|K\|$ denote the norm of $K \in \mathcal{L}(L^1(\Omega))$. For $\|K\| < \alpha$ and any $\mathcal{I} \subset \Omega$ we have $A_{\mathcal{I}}^{-1} = \frac{1}{\alpha} I_{\mathcal{I}} - \frac{1}{\alpha} K_{\mathcal{I}} A_{\mathcal{I}}^{-1}$, and hence $\rho_1 \le \frac{\|K\|}{\alpha(\alpha - \|K\|)}$. Moreover $\rho_3 = 0$. The conditions involving ρ_2, ρ_4, and ρ_5 are satisfied with $\rho_2 = \frac{\|K\|}{\alpha - \|K\|}$, $\rho_4 = \frac{\|K\|^2}{\alpha(\alpha - \|K\|)}$, and $\rho_5 = \frac{\|K\|^2}{\alpha - \|K\|}$, and $\rho < 1$ if α is sufficiently large.

4. Diagonally dominated class: Bilateral constraints. The primal-dual active set method for the bilateral constraint case was given in section 1. We now provide sufficient conditions for its global convergence. Analogously to section 3 we select the merit function $\mathcal{M}$ as

$$\mathcal{M}(x^{k+1}, \mu^{k+1}) = \max\Big(\int_{\mathcal{I}_k} ((x^{k+1} - \psi)^+ + (x^{k+1} - \varphi)^-)\, dx, \int_{\mathcal{A}_k^+} (\mu^{k+1})^-\, dx + \int_{\mathcal{A}_k^-} (\mu^{k+1})^+\, dx \Big). \tag{4.1}$$

In the finite dimensional case the integrals must be replaced with sums over the respective index sets. We note that step (3) of the algorithm implies the complementarity property

$$(x^k - \psi)(x^k - \varphi)\mu^k = 0 \text{ a.e. in } \Omega. \tag{4.2}$$

As in the previous section the merit function involves L^1-norms and accordingly we aim for convergence in $L^1(\Omega)$. We henceforth assume that

$$A \in \mathcal{L}(L^1(\Omega)),\ a \in L^1(\Omega),\ \psi \text{ and } \varphi \in L^1(\Omega). \tag{4.3}$$

Below, $\|\cdot\|$ denotes the norm of operators in $\mathcal{L}(L^1(\Omega))$. The following conditions will be used: There exist constants $\rho_i, i = 1, \dots, 5$, such that for arbitrary partitions $\mathcal{A} \cup \mathcal{I} = \Omega$ we have

$$\|A_{\mathcal{I}}^{-1}\| \le \rho_1, \qquad \|A_{\mathcal{I}}^{-1} A_{\mathcal{I}\mathcal{A}}\| \le \rho_2 \tag{4.4}$$

and

$$\|A_{\mathcal{A}} - c\,I\| \le \rho_3,$$

$$\|A_{\mathcal{A}\mathcal{I}} A_{\mathcal{I}}^{-1}\| \le \rho_4, \tag{4.5}$$

$$\|A_{\mathcal{A}\mathcal{I}} A_{\mathcal{I}}^{-1} A_{\mathcal{I}\mathcal{A}}\| \le \rho_5.$$

We further set $\rho = 2\max(\max(\rho_1, \rho_2, \frac{\rho_2}{c}), \max(\rho_3 + \rho_5, \rho_4), \frac{\rho_3+\rho_5}{c})$.

THEOREM 4.1. *If* (4.3), (4.4), (4.5) *hold and* $\rho < 1$, *then* $\mathcal{M}$ *is a merit function for the primal-dual algorithm applied to* (1.2) *and* $\lim_{k\to\infty}(x^k, \mu^k) = (x^*, \mu^*)$ *in* $L^1(\Omega) \times L^1(\Omega)$, *with* (x^*, μ^*) *a solution to* (1.2).

Proof. For $\delta x = x^{k+1} - x^k$ and $\delta\mu = \mu^{k+1} - \mu^k$ we have

$$\begin{aligned}
&A_{\mathcal{A}_k^+}\delta x_{\mathcal{A}_k^+} + A_{\mathcal{A}_k^+\mathcal{I}_k}\delta x_{\mathcal{I}_k} + A_{\mathcal{A}_k^+\mathcal{A}_k^-}\delta x_{\mathcal{A}_k^-} + \delta\mu_{\mathcal{A}_k^+} = 0,\\
&A_{\mathcal{I}_k}\delta x_{\mathcal{I}_k} + A_{\mathcal{I}_k\mathcal{A}_k^+}\delta x_{\mathcal{A}_k^+} + A_{\mathcal{I}_k\mathcal{A}_k^-}\delta x_{\mathcal{A}_k^-} - \mu^k_{\mathcal{I}_k} = 0, \qquad (4.6)\\
&A_{\mathcal{A}_k^-}\delta x_{\mathcal{A}_k^-} + A_{\mathcal{A}_k^-\mathcal{I}_k}\delta x_{\mathcal{I}_k} + A_{\mathcal{A}_k^-\mathcal{A}_k^+}\delta x_{\mathcal{A}_k^+} + \delta\mu_{\mathcal{A}_k^-} = 0
\end{aligned}$$

with

$$\mu^k_{\mathcal{A}_k^+} \begin{cases} > 0 & \text{on} \quad \mathcal{A}^+_{k-1} \cap \mathcal{A}^+_k, \\ = 0 & \text{on} \quad \mathcal{I}_{k-1} \cap A^+_k, \\ > c\,(\psi - \varphi) & \text{on} \quad \mathcal{A}^-_{k-1} \cap \mathcal{A}^+_k, \end{cases} \tag{4.7}$$

$$\mu^k_{\mathcal{I}_k} \in \begin{cases} [c(\varphi - \psi), 0) & \text{on} \quad \mathcal{A}^+_{k-1} \cap \mathcal{I}_k, \\ 0 & \text{on} \quad \mathcal{I}_{k-1} \cap \mathcal{I}_k, \\ (0, c(\psi - \varphi)] & \text{on} \quad \mathcal{A}^-_{k-1} \cap \mathcal{I}_k, \end{cases} \tag{4.8}$$

$$\mu^k_{\mathcal{A}_k^-} \begin{cases} < c\,(\varphi - \psi) & \text{on} \quad \mathcal{A}^+_{k-1} \cap \mathcal{A}^-_k, \\ = 0 & \text{on} \quad \mathcal{I}_{k-1} \cap A^-_k, \\ < 0 & \text{on} \quad \mathcal{A}^-_{k-1} \cap \mathcal{A}^-_k, \end{cases} \tag{4.9}$$

$$\delta x_{\mathcal{A}_k^+} \begin{cases} = 0 & \text{on} \quad \mathcal{A}^+_{k-1} \cap \mathcal{A}^+_k, \\ < 0 & \text{on} \quad \mathcal{I}_{k-1} \cap A^+_k, \\ = \psi - \varphi < \frac{\mu^k}{c} & \text{on} \quad \mathcal{A}^-_{k-1} \cap \mathcal{A}^+_k, \end{cases} \tag{4.10}$$

$$\delta x_{\mathcal{A}_k^-} \begin{cases} = \varphi - \psi > \frac{\mu^k}{c} & \text{on} \quad \mathcal{A}^+_{k-1} \cap \mathcal{A}^-_k, \\ > 0 & \text{on} \quad \mathcal{I}_{k-1} \cap A^-_k, \\ = 0 & \text{on} \quad \mathcal{A}^-_{k-1} \cap \mathcal{A}^-_k. \end{cases} \tag{4.11}$$

From (4.2)

$$(x^{k+1}_{\mathcal{I}_k} - \psi_{\mathcal{I}_k})^+ \le (\delta x_{\mathcal{I}_k})^+ \text{ and } (x^{k+1}_{\mathcal{I}_k} - \varphi_{\mathcal{I}_k})^- \le (\delta x_{\mathcal{I}_k})^-. \tag{4.12}$$

This implies that

$$\mathcal{M}(x^{k+1},\mu^{k+1}) \le \max\left(\int_{\mathcal{I}_k}|\delta x_{\mathcal{I}_k}|\,,\ \int_{\mathcal{A}_k^+}(\mu^{k+1})^- + \int_{\mathcal{A}_k^-}(\mu^{k+1})^+\right). \tag{4.13}$$

From (4.6), (4.4), (4.8), (4.10), and (4.11) we have

$$\begin{aligned}
|\delta x_{\mathcal{I}_k}| &\le \rho_1|\mu^k_{\mathcal{I}_k}| + \rho_2|\delta x_{\mathcal{A}_k}| \\
&\le \rho_1(|(\mu^k_{\mathcal{I}_k\cap\mathcal{A}^+_{k-1}})^-| + |(\mu^k_{\mathcal{I}_k\cap\mathcal{A}^-_{k-1}})^+|) + \rho_2(|\delta x_{\mathcal{A}^+_k}| + |\delta x_{\mathcal{A}^-_k}|) \\
&\le \rho_1(|(\mu^k_{\mathcal{I}_k\cap\mathcal{A}^+_{k-1}})^-| + |(\mu^k_{\mathcal{I}_k\cap\mathcal{A}^-_{k-1}})^+|) \\
&\quad + \rho_2\bigg(|(x^k-\psi)^+_{\mathcal{A}^+_k\cap\mathcal{I}_{k-1}}| + \frac{1}{c}|(\mu^k_{\mathcal{A}^+_k\cap\mathcal{A}^-_{k-1}})^+| + |(x^k-\varphi)^-_{\mathcal{A}^-_k\cap\mathcal{I}_{k-1}}| \\
&\qquad + \frac{1}{c}|(\mu^k_{\mathcal{A}^-_k\cap\mathcal{A}^+_{k-1}})^-|\bigg).
\end{aligned}$$

This implies

$$|\delta x_{\mathcal{I}_k}| \le 2\,\max\left(\rho_1,\rho_2,\frac{\rho_2}{c}\right)\,\mathcal{M}(x^k,\mu^k). \tag{4.14}$$

From (4.6) furthermore

$$\mu^{k+1}_{\mathcal{A}_k} - (\mu^k_{\mathcal{A}_k} - c\delta x_{\mathcal{A}_k}) = g, \tag{4.15}$$

where $g = (cI - A_{\mathcal{A}_k})\delta x_{\mathcal{A}_k} - A_{\mathcal{A}_k\mathcal{I}_k}A^{-1}_{\mathcal{A}_k}A_{\mathcal{I}_k\mathcal{A}_k}\delta x_{\mathcal{A}_k}$. By (4.7) and (4.10), we have

$$\mu^k_{\mathcal{A}^+_k} - c\,\delta x_{\mathcal{A}^+_k} \ge 0.$$

Similarly by (4.9) and (4.11), we have

$$\mu^k_{\mathcal{A}^-_k} - c\,\delta x_{\mathcal{A}^-_k} \le 0.$$

Consequently

$$\begin{aligned}
&|(\mu^{k+1}_{\mathcal{A}^+_k})^-| + |(\mu^{k+1}_{\mathcal{A}^-_k})^+| \le |g_{\mathcal{A}_k}| \le (\rho_3+\rho_5)|\delta x_{\mathcal{A}_k}| + \rho_4|\mu_{I_k}| \\
&\le 2\max\left(\rho_4,\rho_3+\rho_5,\frac{\rho_3+\rho_5}{c}\right)\mathcal{M}(x^k,\mu^k).
\end{aligned} \tag{4.16}$$

By (4.13), (4.14), and (4.16)

$$\mathcal{M}(x^{k+1},\mu^{k+1}) \le 2\max\left(\max\left(\rho_1,\rho_2,\frac{\rho_2}{c}\right),\max\left(\rho_4,\rho_3+\rho_5,\frac{\rho_3+\rho_5}{c}\right)\right)\mathcal{M}(x^k,\mu^k).$$

It follows that $\mathcal{M}(x^{k+1},\mu^{k+1}) \le \rho^k\mathcal{M}(x^1,\mu^1)$, and if $\rho < 1$, then $M(x^k,\mu^k) \to 0$ as $k \to \infty$. From the estimates leading to (4.14) it follows that x^k is a Cauchy sequence. Moreover μ^k is a Cauchy sequence by (4.6). Hence there exist (x^*,μ^*) such that $\lim_{k\to\infty}(x^k,\mu^k) = (x^*,\mu^*)$. By Lebesgue's bounded convergence theorem, and since $M(x^k,\mu^k) \to 0$, it follows that $\varphi \le x^* \le \psi$. Clearly $Ax^* + \mu^* = a$

and $(x^* - \psi)(x^* - \varphi)\mu^* = 0$ by (4.2). This last equation implies that $\mu^* = 0$ on $\mathcal{I}^* = \{\varphi < x^* < \psi\}$. It remains to show that $\mu^* \geq 0$ on $\mathcal{A}^{*,+} = \{x^* = \psi\}$ and $\mu^* \leq 0$ on $\mathcal{A}^{*,-} = \{x^* = \varphi\}$. Let $s \in \mathcal{A}^{*,+}$ be such that $x^k(s)$ and $\mu^k(s)$ converge. Then $\mu^*(s) \geq 0$. If not, then $\mu^*(s) < 0$ and there exists $\bar{k}$ such that $\mu^k(s) + c(x^k(s) - \psi(s)) \leq \frac{\mu^*(s)}{2} < 0$ for all $k \geq \bar{k}$. Then $s \in \mathcal{I}^k$ and $\mu^{k+1} = 0$ for $k \geq \bar{k}$, contradicting $\mu^*(s) < 0$. Analogously one shows that $\mu^* \leq 0$ on $\mathcal{A}^{*,-}$. ∎

We now specialize to perturbations A which are additive perturbations of a multiple of the identity operator.

THEOREM 4.2. *Assume that $A = cI + K$ with $K \in \mathcal{L}(L^1(\Omega))$ and $\|K\| < c$, and that (4.3), (4.4), (4.5) are satisfied. If $\bar{\rho} = 2\max(\max(\frac{\|K\|}{c}\rho_1, \rho_2), \max(\rho_3 + \rho_5, \rho_4), \frac{\rho_3+\rho_5}{c}) < 1$, then the conclusions of the previous theorem are valid.*

Proof. We follow the proof of Theorem 4.1 and eliminate the overestimate (4.12). Let $P = \{x^{k+1}_{\mathcal{I}_k} - \psi > 0\} \cap \mathcal{I}_k$. We find

$$x^{k+1} - \psi \begin{cases} \leq \delta x_{P \cap \mathcal{I}_{k-1}} & \text{on} \quad P \cap \mathcal{I}_{k-1}, \\ = \delta x_{P \cap \mathcal{A}^+_{k-1}} & \text{on} \quad P \cap \mathcal{A}^+_{k-1}, \\ \delta x_{P \cap \mathcal{A}^-_{k-1}} + (\varphi - \psi)_{P \cap \mathcal{A}^-_{k-1}} & \text{on} \quad P \cap \mathcal{A}^-_{k-1}. \end{cases}$$

This estimate, together with $A^{-1} = \frac{1}{c}I - \frac{1}{c}KA^{-1}$, implies that

$$\begin{aligned} \int_{\mathcal{I}_k} (x^{k+1} - \psi)^+ &\leq \int_P \delta x + \int_{P \cap A^-_{k-1}} \varphi - \psi \\ &\leq \int_P A^{-1}_{\mathcal{I}_k} \mu^k_{\mathcal{I}_k} - \int_P A^{-1}_{\mathcal{I}_k} A_{\mathcal{I}_k \mathcal{A}_k} \delta x_{\mathcal{A}_k} + \int_{P \cap A^-_{k-1}} \varphi - \psi \\ &= \frac{1}{c} \int_P \mu^k_{\mathcal{I}_k} + \int_{P \cap A^-_{k-1}} \varphi - \psi - \frac{1}{c} \int_P K_{\mathcal{I}_k} A^{-1}_{\mathcal{I}_k} \mu^k_{\mathcal{I}_k} - \int_P A^{-1}_{\mathcal{I}_k} A_{\mathcal{I}_k \mathcal{A}_k} \delta x_{\mathcal{A}_k} \\ &\leq -\frac{1}{c} \int_P K_{\mathcal{I}_k} A^{-1}_{\mathcal{I}_k} \mu^k_{\mathcal{I}_k} - \int_P A^{-1}_{\mathcal{I}_k} A_{\mathcal{I}_k \mathcal{A}_k} \delta x_{\mathcal{A}_k}, \end{aligned}$$

and hence

$$\int_{\mathcal{I}_k} (x^{k+1} - \psi)^+ \leq \frac{\|K\|}{c} \rho_1 |\mu^k_{\mathcal{I}_k}| + \rho_2 |\delta x_{\mathcal{A}_k}|.$$

An analogous estimate can be obtained for $\int_{\mathcal{I}_k} (x^{k+1} - \varphi)^-$, and we find

$$\int_{\mathcal{I}_k} (x^{k+1} - \psi)^+ \int_{\mathcal{I}_k} (x^{k+1} - \varphi)^- \leq \frac{\|K\|}{c} \rho_1 |\mu^k_{\mathcal{I}_k}| + \rho_2 |\delta x_{\mathcal{A}_k}|.$$

We can now proceed as in the proof of Theorem 4.1. ∎

Example 4.1. We apply Theorem 4.2 with $A = I + K \in \mathcal{L}(L^1(\Omega))$. By Neumann series arguments we find $\bar{\rho} = 2\max(\frac{\gamma}{1-\gamma}, \max(\gamma + \frac{\gamma^2}{1-\gamma}, \frac{\gamma}{1-\gamma})) = \frac{\gamma}{1-\gamma}$, where $\gamma = \|K\|$, and $\bar{\rho} < 1$ if $\|K\| < \frac{1}{3}$. If $A = I + K$ is replaced with $A = cI + K$, then $\bar{\rho} < 1$ if $\gamma < \frac{c}{2c+1}$, in case $c \geq 1$, and $\bar{\rho} < 1$ if $\frac{c^2}{c+2}$, in case $c \leq 1$.

Example 4.2. Consider the finite dimensional case $A = I + K \in \mathbb{R}^{n \times n}$, where $\mathbb{R}^n$ is endowed with the ℓ^1-norm. Again Theorem 4.2 is applicable and $\bar{\rho} < 1$, if $\|K\| < \frac{1}{3}$, where $\|\cdot\|$ denotes the matrix-norm subordinate to the ℓ^1-norm of $\mathbb{R}^n$. Recall that this norm is given by the maximum over the column sums of the absolute values of the matrix.

5. Nonlinear case. In this section we consider the nonlinear complementarity problem

$$x \in \mathcal{C}, \quad (f(x), y - x)_Z \geq 0 \text{ for } y \in \mathcal{C} = \{y \in Z : y \leq \psi\} \tag{5.1}$$

or equivalently,

$$f(x) + \mu = 0, \quad \mu = \max(0, \mu + x - \psi), \tag{5.2}$$

where f maps $L^2(\Omega)$ into itself and is C^1 from $L^1(\Omega)$ to itself. In this case step 3 of the primal-dual active set method is given by the following:

(3) Solve for (x^{k+1}, μ^{k+1})

$$\begin{aligned} &f'(x^k)(x^{k+1} - x^k) + f(x^k) + \mu^{k+1} = 0, \\ &x^{k+1} = \psi \text{ on } \mathcal{A}_k, \quad \mu^{k+1} = 0 \text{ on } \mathcal{I}_k. \end{aligned} \tag{5.3}$$

Let the pair (x^0, μ^0) satisfy $(x^0 - \psi)\mu^0 = 0$ (pointwise).

Throughout this section we assume that (5.3) admits a solution $(x^{k+1}, \mu^{k+1}) \in L^1(\Omega) \times L^1(\Omega)$, for every $k \geq 0$. We further assume that (3.4)–(3.5) hold and that

$$\|A_{\mathcal{I}}^{-1}\| \leq \hat{\rho}_1, \ \ \|A_{\mathcal{I}}^{-1} A_{\mathcal{I}\mathcal{A}}\| \leq \hat{\rho}_2, \quad \text{and} \quad \|A_{\mathcal{A}\mathcal{I}} A_{\mathcal{I}}^{-1}\| \leq \hat{\rho}_4, \tag{5.4}$$

with $A = f'(x)$ for all $x \in B(x^0, r)$ and all partitions $\mathcal{A} \cup \mathcal{I} = \Omega$. Here $B(x^0, r)$ denotes the open ball with center x^0 and radius r. Let $A^0 = f'(x^0)$. Then, $\delta x = x^1 - x^0$ and $\delta\mu = \mu^1 - \mu^0$ satisfy

$$A^0_{\mathcal{A}_0} \delta x_{\mathcal{A}_0} + A^0_{\mathcal{A}_0 \mathcal{I}_0} \delta x_{\mathcal{I}_0} + \delta\mu_{\mathcal{A}_0} + (f(x^0) + \mu^0)_{\mathcal{A}_0} = 0,$$

$$A^0_{\mathcal{I}_0} \delta x_{\mathcal{I}_0} + A^0_{\mathcal{I}_0 \mathcal{A}_0} \delta x_{\mathcal{A}_0} - \mu^0_{\mathcal{I}_0} + (f(x^0) + \mu^0)_{\mathcal{I}_0} = 0.$$

Since $x^0 - \psi > 0$ on $\mathcal{A}_0$ and $\mu^0 \leq 0$ on $\mathcal{I}_0$, $\delta x = \psi - x^0 < 0$ on $\mathcal{A}_0$ and $\delta\mu = 0 - \mu^0 \geq 0$ on $\mathcal{I}_0$. Referring to the arguments in the proof of Theorem 3.1, it follows from (3.4)–(3.5) and (5.4) that

$$\begin{aligned} &|\delta x_{\mathcal{I}_0}| \leq \hat{\rho}_1 \int_{\mathcal{I}_0} (|\mu^0| + |(f(x^0) + \mu^0)|)\, dx + \hat{\rho}_2\, |(x^0 - \psi)_{\mathcal{A}_0}|, \\ &|(\delta x_{\mathcal{I}_0})^+| \leq C_1 = \rho_1 \int_{\mathcal{I}_0} |\mu^0|\, dx + \rho_2 \int_{\mathcal{A}_0} |x^0 - \psi|\, dx + \hat{\rho}_1\, |(f(x^0) + \mu^0)_{\mathcal{I}_0}|, \\ &|(\delta\mu_{\mathcal{A}_0})^-| \leq C_2 = (\rho_3 + \rho_5)|(x^0 - \psi)_{\mathcal{A}_0}| + \rho_4 |\mu^0_{\mathcal{I}_0}| + |(f(x^0) + \mu^0)_{\mathcal{A}_0}| \\ &\qquad\qquad + \hat{\rho}_4\, |(f(x^0) + \mu^0)_{\mathcal{I}_0}|. \end{aligned} \tag{5.5}$$

Thus,

$$\begin{aligned} &|x^1 - x^0| \leq C_3 = \hat{\rho}_1 |\mu^0_{\mathcal{I}_0}| + (\hat{\rho}_2 + 1)\, |(x^0 - \psi)_{\mathcal{A}_0}| + \hat{\rho}_1\, |(f(x^0) + \mu^0)_{\mathcal{I}_0}|, \\ &\mathcal{M}(x^1, \mu^1) \leq \max(\beta\, C_1, C_2). \end{aligned} \tag{5.6}$$

Next, for $k = 1, 2, \ldots$, let $A^k = f'(x^k)$ and $\delta x = x^{k+1} - x^k$, $\mu = \mu^{k+1} - \mu^k$, and note that

$$A^k_{\mathcal{A}_k} \delta x_{\mathcal{A}_k} + A^k_{\mathcal{A}_k \mathcal{I}_k} \delta x_{\mathcal{I}_1} + \delta\mu_{\mathcal{A}_k} + \Delta_{\mathcal{A}_k} = 0,$$

$$A^k_{\mathcal{I}_k} \delta x_{\mathcal{I}_k} + A^k_{\mathcal{I}_k \mathcal{A}_k} \delta x_{\mathcal{A}_k} - \mu^k_{\mathcal{I}_k} + \Delta_{\mathcal{I}_k} = 0,$$

where $\Delta = f(x^k) - f(x^{k-1}) - f'(x^{k-1})(x^k - x^{k-1})$. We now assume that there exists γ such that for $x^k,\ x^{k-1} \in B(x^0, r)$

$$|\Delta| = |f(x^k) - f(x^{k-1}) - f'(x^{k-1})(x^k - x^{k-1})| \le \gamma\, |x^k - x^{k-1}|.$$

Again, from (3.4)–(3.5) and (5.4)

$$|\delta x_{\mathcal{I}_k}| \le \hat\rho_1 \left(\int_{\mathcal{I}_k} |\mu^k|\, dx + |\Delta_{\mathcal{I}_k}| \right) + \hat\rho_2 \int_{\mathcal{A}_k} |x^k - \psi|\, dx,$$

$$|(\delta x_{\mathcal{I}_k})^+| \le \rho_1 \int_{\mathcal{I}_k} |\mu^k|\, dx + \rho_2 \int_{\mathcal{A}_k} |\delta x|\, dx + \hat\rho_1\, |\Delta_{\mathcal{I}_k}|,$$

$$|(\delta \mu_{\mathcal{A}_k})^-| \le (\rho_3 + \rho_5) \int_{\mathcal{A}_k} |x^k - \psi|\, dx + \rho_4 \int_{\mathcal{I}_k} |\mu^k|\, dx + |\Delta_{\mathcal{A}_k}| + \hat\rho_4\, |\Delta_{\mathcal{I}_k}|.$$

Thus,

$$|x^{k+1} - x^k| \le \left(\frac{1}{\beta} + \hat\rho_1 + \frac{\hat\rho_2}{\beta} \right) \mathcal{M}(x^k, \mu^k) + \gamma \hat\rho_1\, |x^k - x^{k-1}|,$$

(5.7)

$$\mathcal{M}(x^{k+1}, \mu^{k+1}) \le \rho\, \mathcal{M}(x^k, \mu^k) + 2\hat\rho_1\, \gamma\, \max(\beta\, \hat\rho_1, 1, \hat\rho_4)\, \frac{|x^k - x^{k-1}|}{2\hat\rho_1},$$

where we used

$$\int_{\mathcal{A}_k} |x^k - \psi|\, dx \le \int_{\mathcal{I}_{k-1}} |x^k - \psi|\, dx \ \text{ and } \ \int_{\mathcal{I}_k} |\mu^k|\, dx \le \int_{\mathcal{A}_{k-1}} |\mu^k|\, dx,$$

and ρ is defined as in Theorem 3.1.

If we set

$$\omega = \max \left(\rho + 2\hat\rho_1 \gamma\, \max(\beta\, \hat\rho_1, 1, \hat\rho_4), \frac{1}{2} + \frac{1 + \hat\rho_2}{2\beta\hat\rho_1} + \gamma\hat\rho_1 \right), \tag{5.8}$$

then

$$\max \left(\frac{|x^{k+1} - x^k|}{2\hat\rho_1}, \mathcal{M}(x^{k+1},\, \mu^{k+1}) \right) \le \omega\, \max \left(\frac{|x^k - x^{k-1}|}{2\hat\rho_1},\, \mathcal{M}(x^k, \mu^k) \right). \tag{5.9}$$

Hence if $\omega < 1$ and $x^j \in B(x^0, r)$, for $j \le k$, then

$$\max \left(\frac{|x^{k+1} - x^k|}{2\hat\rho_1}, \mathcal{M}(x^{k+1}, \mu^{k+1}) \right) \le \omega^k\, \max \left(\frac{|x^1 - x^0|}{2\hat\rho_1},\, \mathcal{M}(x^1, \mu^1) \right)$$

and thus,

$$|x^{k+1} - x^0| \le \frac{1}{1 - \omega}\, \max(\, |x^1 - x^0|, 2\hat\rho_1\, \mathcal{M}(x^1, \mu^1)\,). \tag{5.10}$$

Let C_1, C_2, C_3 be as defined in (5.5)–(5.6), and assume that

$$\frac{2\hat\rho_1}{1 - \omega}\, \max \left(\beta\, C_1, C_2, \frac{C_3}{2\hat\rho_1} \right) \le r. \tag{5.11}$$

Then it follows from (5.6) and (5.10) that $|x^{k+1} - x^0| \le r$, and thus by induction in k we have $x^k \in B(x^0, r)$ for all $k \ge 1$ and (5.9) holds for all k. Hence x^k is Cauchy, and by (5.3) μ^k is a Cauchy sequence as well. It follows that $\lim(x^k, \mu^k)$ converges to a limit (x^*, μ^*) in $L^1(\Omega) \times L^1(\Omega)$. As in the proof of Theorem 3.1 one argues that (x^*, μ^*) satisfies (5.2). Moreover from (5.9)

$$|x^m - x^k| \le \sum_{j=k}^{m-1} |x^{j+1} - x^j| \le \sum_{j=k+1}^{m} \omega^{j-k} \max(|x^k - x^{k-1}|, 2\hat{\rho}_1 \mathcal{M}(x^k, \mu^k))$$

$$\le \frac{\omega}{1-\omega} \max(|x^k - x^{k-1}|, 2\hat{\rho}_1 \mathcal{M}(x^k, \mu^k)),$$

and therefore

$$|x^k - x^*| \le \frac{\omega}{1-\omega} \max(|x^k - x^{k-1}|, 2\hat{\rho}_1 \mathcal{M}(x^k, \mu^k)). \tag{5.12}$$

In summary we obtain the following.

THEOREM 5.1. *Given (x^0, μ^0) and $r > 0$, we assume that* (3.4)–(3.5) *and* (5.4) *hold with $A = f'(x)$ for all $x \in B(x^0, r)$ and all partitions $\mathcal{A} \cup \mathcal{I} = \Omega$, and that for $x, y \in B(x^0, r)$*

$$|f(x) - f(y) - f'(x)(x - y)| \le \gamma |x - y|.$$

Suppose further that $\omega < 1$, with ω as defined in (5.8)*, that (x^0, μ^0) satisfies $(x^0 - \psi)\mu_0 = 0$, and that* (5.11) *holds. Then (x^k, μ^k) converges in $L^1(\Omega) \times L^1(\Omega)$ to a solution (x^*, μ^*) of* (5.2)*, and* (5.12) *holds.*

Remark 5.1. If f is C^2, then γ can be chosen proportionally to r. Thus, referring to the choice of A discussed in Remark 3.1, we can choose $r > 0$ sufficiently small and β sufficiently large so that $\omega < 1$ provided that $\rho < 1$, where ρ is as defined in Theorem 3.1. Alternatively, referring to the situation in Remark 3.2 we have $\omega < 1$ provided that $\rho < 1$, and r and $\hat{\rho}_2$ are sufficiently small.

6. Globalization. In this section we consider the globalization of the primal-dual algorithm for the unilateral constraint case in the finite dimensional case, i.e., $X = \mathbb{R}^d$. The extension to the bilateral case is straightforward. The variational inequality (5.1) is equivalent to (5.2), i.e., $F(x, \mu) = 0$, where

$$F(x, \mu) = \begin{cases} f(x) + \mu, \\ \\ \max(0, \mu + (x - \psi)) - \mu = \max(-\mu, x - \psi), \end{cases}$$

where we set $c = 1$. We introduce

$$\theta(x, \mu) = |F(x, \mu)|^2$$

as a merit function. If we let

$$\mathcal{A} = \{\mu + (x - \psi) > 0\}, \ \mathcal{I}_1 = \{\mu + (x - \psi) = 0\}, \ \text{and} \ \mathcal{I}_2 = \{\mu + (x - \psi) < 0\},$$

then the directional derivative of F is given by

$$F'((x,\mu);d) = \begin{cases} f'(x)\delta x + \delta\mu, \\ \begin{pmatrix} \delta x & \text{on } \mathcal{A} \\ -\delta\mu & \text{on } \mathcal{I}_2 \\ \max(-\delta\mu, \delta x) & \text{on } \mathcal{I}_1 \end{pmatrix} \end{cases}$$

with $d = (\delta x, \delta\mu)$. Here and throughout this section we assume that $f \in C^1(\mathbb{R}^d, \mathbb{R}^d)$. We find that

$$\frac{1}{2}\,\theta'(x,\mu;d) = -|f(x)+\mu|^2 + ((x-\psi),\delta x)_{\mathcal{A}} + (\mu,\delta\mu)_{\mathcal{I}_2} - (\mu, \max(-\delta\mu,\delta x))_{\mathcal{I}_1}$$

if the direction $d = (\delta x, \delta\mu)$ satisfies

$$f'(x)\delta x + \delta\mu + f(x) + \mu = 0.$$

This implies that

$$\frac{1}{2}(|f(x)+\mu|^2)'(d) = (f(x)+\mu, f'(x;\delta x) + \delta\mu) = -|f(x)+\mu|^2.$$

We assume that the following assumptions (6.1)–(6.4) are satisfied:

(6.1) $\qquad S = \{(x,\mu) \in \mathbb{R}^d \times \mathbb{R}^d : \theta(x,\mu) \le |F(x^0,\mu^0)|\}$ is bounded.

There exists $\bar\sigma,\ b > 0$ such that for all $(x,\mu) \in S$ there is a direction $d = (\delta x, \delta\mu)$ depending on (x,μ) such that

(6.2) $$\begin{aligned} &f'(x)\delta x + \delta\mu + f(x) + \mu = 0, \\ &\theta'((x,\mu);d) \le -\bar\sigma\theta(x,\mu), \quad \text{and} \quad |d| \le b\,|F(x,\mu)|. \end{aligned}$$

(6.3) $$\begin{aligned} &\theta \text{ is subdifferentiably regular for all } x \in S, \text{ i.e.,} \\ &\theta^o(x;d) = \theta'(x;d) \text{ for all } d \in \mathbb{R}^d. \end{aligned}$$

Moreover we assume the following closure property:

(6.4) $\qquad$ If $(x,\mu) \to (\bar x, \bar\mu)$ and $d = d(x,\mu) \to \bar d$, then $\theta'((\bar x,\bar\mu);\bar d) \le -\bar\sigma\theta(\bar x,\bar\mu)$.

In (6.3) above the Clarke generalized directional derivative $\theta^o(x;d)$ of θ at x in the direction d is defined by

$$\theta^o(x;d) = \limsup_{y\to x,\ t\to 0^+} \frac{\theta(y+t\,d) - \theta(y)}{t}.$$

In (6.4) the direction $d = d(x,\mu)$ is chosen according to (6.2), but $\bar d$ need not be related to $(\bar x,\bar\mu)$.

ALGORITHM.

(i) Let β, $\gamma \in (0,1)$, and $\sigma \in (0, \bar{\sigma})$.

(ii) Apply the primal-dual active set method to determine (x^{k+1}, μ^{k+1}):

$$f'(x^k)(x^{k+1} - x^k) + f(x^k) + \mu^{k+1} = 0,$$

$$x^{k+1} = \psi \text{ on } \mathcal{A}_k, \quad \mu^{k+1} = 0 \text{ on } \mathcal{I}_k.$$

If $|F(x^{k+1}, \mu^{k+1})| < \gamma\, |F(x^k, \mu^k)|$ and $|(x^{k+1}, \mu^{k+1}) - (x^k, \mu^k)| \le b|F(x^k, \mu^k)|$, set $k = k+1$ and skip (iii).

(iii) Let d^k be a descent direction for θ at (x^k, μ^k) according to (6.2) and set $\alpha_k = \beta^{m_k}$, where m_k is the first positive integer m for which

$$\theta((x^k, \mu^k) + \beta^m\, d^k) - \theta(x^k, \mu^k) \le -\sigma\beta^m\, \theta(x^k, \mu^k).$$

Set $(x^{k+1}, \mu^{k+1}) = (x^k, \mu^k) + \alpha^k\, d^k$, $k = k+1$, and go to (ii).

THEOREM 6.1. *Suppose that $f : \mathbb{R}^d \to \mathbb{R}^d$ is C^1.*

(a) *Assume* (6.1)–(6.4) *hold. Then, the sequence $\{x^k\}$ generated by the algorithm is bounded, $|F(x^{k+1}, \mu^{k+1})| < |F(x^k, \mu^k)|$, for all $k \ge 0$, and each accumulation point (x^*, μ^*) of $\{(x^k, \mu^k)\}$ satisfies $F(x^*, \mu^*) = 0$.*

(b) *Moreover if for one such accumulation point*

$$|h| \le c\, |F'(x^*, \mu^*; h)| \quad \text{for all } h \in \mathbb{R}^d, \tag{6.5}$$

then the sequence (x^k, μ^k) converges superlinearly to (x^*, μ^*).

Proof. The proof follows from Theorem 2.1 in [IK2]. □

In [IK2] the reduced form of $F(x, \mu) = 0$, which is given by

$$-f(x) = \max(0, -f(x) + x - \psi),$$

is analyzed. In this case the new active set is determined on the basis of $\tilde{\mathcal{A}} = \{-f(x^k) + x^k - \psi > 0\}$. If the full step is taken, then this differs from the new active set $\mathcal{A}$ used in this paper in that $\mu^k = -f'(x^{k-1})(x^k - x^{k-1}) - f(x^{k-1})$ is replaced with $-f(x^k)$.

For related results on globalization of semismooth Newton methods applied to linear and nonlinear complementarity problems, we refer to [HP] and [DFK].

6.1. Descent directions. We turn to a discussion of directions which are descent directions satisfying (6.2)–(6.4). As for (6.3) we recall from [C] that convex locally Lipschitz continuous functions are subdifferentiably regular, and thus we concentrate on (6.2) and (6.4).

The direction $d = (\delta x, \delta\mu)$ defined by the primal-dual active set method satisfies

$$f'(x)\delta x + \delta\mu + f(x) + \mu = 0, \quad \delta x + x - \psi = 0 \text{ on } \mathcal{A}, \quad \delta\mu + \mu = 0 \text{ on } \mathcal{I}, \tag{6.6}$$

where we suppress the iteration index k. To estimate θ' observe that

$$((x - \psi), \delta x)_{\mathcal{A}} + (\mu, \delta\mu)_{\mathcal{I}_2} - (\mu, \max(-\delta\mu, \delta x))_{\mathcal{I}_1}$$

$$= -|x - \psi|^2_{\mathcal{A}} - |\mu|^2_{\mathcal{I}_2} - (\mu, \max(-\delta\mu, \delta x))_{\mathcal{I}_1}.$$

If $\delta\mu + \delta x \le 0$ on $\mathcal{I}_1$, then

$$-(\mu, \max(-\delta\mu, \delta x))_{\mathcal{I}_1} = (\mu, \delta\mu)_{\mathcal{I}_1} = -|\mu|^2_{\mathcal{I}_1}.$$

If $\delta\mu + \delta x > 0$ and $\delta\mu \le 0$ on $\mathcal{I}_1$, then

$$-(\mu, \max(-\delta\mu, \delta x))_{\mathcal{I}_1} = -(\mu, \delta x)_{\mathcal{I}_1} \le -|\mu|^2_{\mathcal{I}_1}.$$

Hence if

$$\{\delta\mu + \delta x > 0\} \cap \{\delta\mu > 0\} \cap \mathcal{I}_1 = \emptyset, \tag{6.7}$$

then

$$\theta'((x,\mu),(\delta x,\delta\mu)) \le -2\,|F(x,\mu)|^2,$$

and thus $d = (\delta x, \delta\mu)$ defined by (6.6) satisfies the first condition in (6.2). Note that if $(x,\mu) = (x^k,\mu^k)$ is chosen according to the primal-dual active set strategy without a subsequent line search, then $\mu^k = x^k - \psi = 0$ and $(\delta\mu)^{k+1} = 0$ on $(\mathcal{I}_k)_1$. In this case, (6.7) reduces to the assumption that $\{x^{k+1} > \psi\}$ on $(\mathcal{I}_k)_1$. As for the second condition in (6.2), let $R_{\mathcal{I}} : \mathbb{R}^d \to \mathbb{R}^{|\mathcal{I}|}$ denote the restriction matrix from $\mathbb{R}^d$ to the coordinates of active indices, and set $A_{\mathcal{I}}(x) = R_{\mathcal{I}} f'(x) R_{\mathcal{I}}^T$. If $\|(A_{\mathcal{I}}(x))^{-1}\| \le K$ for a constant K independent of $x \in S$ and the combination of inactive indices $\mathcal{I}$, then a Schur complement argument shows that the second condition in (6.2) holds.

Turning to the closure property (6.4), let $(x,\mu) \to (\bar{x},\bar{\mu})$ and $d(x,\mu) \to \bar{d} = (\overline{\delta x}, \overline{\delta\mu})$. As a consequence of the assignment on the active and inactive sets as expressed in (ii) of the algorithm, we have

$$(\bar{x} + \overline{\delta x} - \psi)(\bar{\mu} + \overline{\delta\mu}) = 0. \tag{6.8}$$

Let $\bar{\mathcal{A}} = \{\bar{x} - \psi + \bar{\mu} > 0\}$, $\bar{\mathcal{I}}_1 = \{\bar{x} - \psi + \bar{\mu} = 0\}$, and $\bar{\mathcal{I}}_2 = \{\bar{x} - \psi + \bar{\mu} < 0\}$. We shall give a sufficient condition which guarantees that $\theta'((\bar{x},\bar{\mu}),\bar{d}) \le -2\,|F(\bar{x},\bar{\mu})|^2$. The estimates on $\bar{\mathcal{A}}$ and $\bar{\mathcal{I}}_2$ are simple, and we turn to $\bar{\mathcal{I}}_1$. We assume that

$$\begin{aligned} &\{\overline{\delta\mu} + \overline{\delta x} < 0\} \cap \{\overline{\delta x} < 0\} \cap \mathcal{I}_1 = \emptyset \quad \text{and} \\ &\{\overline{\delta\mu} + \overline{\delta x} > 0\} \cap \{\overline{\delta\mu} > 0\} \cap \mathcal{I}_1 = \emptyset. \end{aligned} \tag{6.9}$$

If $\overline{\delta\mu} + \overline{\delta x} \le 0$ on $\mathcal{I}_1$, we have

$$-(\bar{\mu}, \max(-\overline{\delta\mu}, \overline{\delta x}))_{\mathcal{I}_1} = (\bar{\mu}, \overline{\delta\mu})_{\mathcal{I}_1}.$$

If moreover the second factor in (6.8) is 0, then

$$-(\bar{\mu}, \max(-\overline{\delta\mu}, \overline{\delta x}))_{\mathcal{I}_1} = -|\bar{\mu}|^2_{\mathcal{I}_1},$$

as desired. Otherwise $(\bar{x} + \overline{\delta x} - \psi) = -\bar{\mu} + \overline{\delta x} = 0$, and hence

$$-(\bar{\mu}, \max(-\overline{\delta\mu}, \overline{\delta x}))_{\mathcal{I}_1} = (\bar{\mu}, \overline{\delta\mu})_{\mathcal{I}_1} = (\overline{\delta x}, \overline{\delta\mu}),$$

and by (6.9)

$$-(\bar{\mu}, \max(-\overline{\delta\mu}, \overline{\delta x}))_{\mathcal{I}_1} \le -|\overline{\delta x}|^2_{\mathcal{I}_1} = -|\bar{\mu}|^2_{\mathcal{I}_1}.$$

The case $\overline{\delta\mu} + \overline{\delta x} > 0$ can be treated analogously and we arrive at $\theta'((\bar{x},\bar{\mu}),\bar{d}) \le -2\,|F(\bar{x},\bar{\mu})|^2$, as announced.

So far we provided sufficient conditions which guarantee that the direction given by the primal-dual active set strategy can serve as a descent direction. We proceed by describing alternative methods for selecting descent directions d. This will allow us to circumvent an assumption of types (6.7) and (6.9) at the expense of solving a nonlinear equation.

We commence by defining the function $G((x,\mu);d)$, with $d=(\delta x,\delta\mu)$ as follows:

$$G((x,\mu);d)=\begin{cases} f'(x)\delta x+\delta\mu, \\ \begin{pmatrix} \delta x & \text{on } S_1=\mathcal{A}\cap\{\mu\geq 0\} \\ -\delta\mu & \text{on } S_2=\mathcal{I}_2\cap\{x\leq\psi\} \\ \max(-\delta\mu,\delta x) & \text{on } S_3=(\mathcal{A}\cap\{\mu<0\})\cup(\mathcal{I}_2\cap\{x>\psi\})\cup\mathcal{I}_1. \end{pmatrix}. \end{cases}$$

Note that for a full step based on the primal-dual active set strategy without a subsequent line search we have $S_1=\mathcal{A}$ and $S_2=\mathcal{I}_2$ since $(x-\psi)\mu=0$. This structure is not maintained if the line search of step (iii) is used.

The mapping $G((x,\mu);d)$ is a quasi-directional derivative of $F(x,\mu)$ in the sense that

(1) $(F(x,\mu),F'((x,\mu);d))\leq(F(x,\mu),G((x,\mu);d))$ for all $(x,\mu)\in S$ and $d=(\delta x,\delta\mu)$;
(2) $G((x,\mu),td)=t\,G((x,\mu);d)$ for $t\geq 0$ and all $(x,\mu)\in S$ and d;
(3) $\lim_{((x,\mu),d)\to((\bar x,\bar\mu),\bar d)}(F(x,\mu),G((x,\mu);d))\geq(F(\bar x,\bar\mu),G((\bar x,\bar\mu);\bar d))$.

In fact, to verify (1) note that on $(\mathcal{A}\cap\{\mu<0\})\cup(\mathcal{I}_2\cap\{x>\psi\})$ we have $\max(-\mu,x-\psi)>0$, and thus

$$\begin{aligned}(\max(\max(-\mu,x-\psi),-\delta\mu),(\max(-\mu,x-\psi),\delta x))\\ \leq(\max(-\mu,x-\psi),\max(-\delta\mu,\delta x)).\end{aligned}$$

Hence we obtain

$$(F(x,\mu),F'((x,\mu);d))\leq(F(x,\mu),G((x,\mu);d)).$$

Property (2) is obvious. Next suppose that $(x,\mu)\to(\bar x,\bar\mu)$, $d\to\bar d$. For indices i such that $(\bar\mu+\bar x-\psi)_i\neq 0$, we have

$$G((x,\mu);d)_i\to G((\bar x,\bar\mu);\bar d)_i.$$

For indices i such that $(\bar\mu+\bar x-\psi)_i=0$ the case $x-\psi>0,\mu>0$ (and analogously $x-\psi<0,\mu<0$) for infinitely many (x,μ) in a neighborhood of $(\bar x,\bar\mu)$ is trivial since in this case $(F^{(2)}(\bar x,\bar\mu))_i=0$. We need to examine two more cases. First, for i such that $(\mu+x-\psi)_i>0$ and $\mu_i\geq 0$, we have $\max(-\mu,x-\psi)_i=(x-\psi)_i$, and thus $\max(-\bar\mu,\bar x-\psi)_i=(\bar x-\psi)_i=-(\bar\mu)_i\leq 0$ and

$$F^{(2)}(x,\mu)_iG^{(2)}((x,\mu);d)_i\to F^{(2)}(\bar x,\bar\mu)_i\overline{\delta x}_i\geq F^{(2)}(\bar x,\bar\mu)_i\max(-\overline{\delta\mu},\overline{\delta x})_i.$$

Second, for indices i such that $(\mu+x-\psi)_i<0$ and $x_i\leq\psi_i$, $\max(-\mu,x-\psi)_i=-\mu_i\leq 0$, and thus $\max(-\bar\mu,\bar x-\psi)_i=-\bar\mu_i=(\bar x-\psi)_i\leq 0$ and

$$F^{(2)}(x,\mu)_iG^{(2)}((x,\mu);d)_i\to F^{(2)}(\bar x,\bar\mu)_i(-\overline{\delta\mu})_i\geq F^{(2)}(\bar x,\bar\mu)_i\max(-\overline{\delta\mu},\overline{\delta x})_i.$$

Hence we obtain

$$\lim_{(x,\mu)\to(\bar{x},\bar{\mu}),\ d\to\bar{d}} (F(x,\mu), G((x,\mu);d)) \geq (F(\bar{x},\bar{\mu}), G((\bar{x},\bar{\mu});\bar{d})),$$

(3) is satisfied, and G is a quasi-directional derivative.

We turn to the description of two methods for selecting a descent direction using the quasi-directional derivative G.

Method 1 (Bouligand direction). Find $d = (\delta x, \delta\mu)$ such that $G((x,\mu);d) + F(x,\mu) = 0$, i.e.,

$$\left\{ \begin{array}{l} f'(x)\delta x + \delta\mu + f(x) + \mu = 0, \\ \left(\begin{array}{ll} \delta x + x - \psi = 0 & \text{on } S_1 \\ \delta\mu + \mu = 0 & \text{on } S_2 \\ \max(-\mu, x-\psi) + \max(-\delta\mu, \delta x) = 0 & \text{on } S_3. \end{array} \right) \end{array} \right. \tag{6.10}$$

Assume that for each $(x,\mu) \in S$

$$G((x,\mu);d) + F(x,\mu) = 0 \text{ has a solution } d = d(x,\mu) \tag{6.11}$$

satisfying

$$|d| \leq b\,|G((x,\mu);d)|. \tag{6.12}$$

For such d we have using (1) that

$$\theta'(x;d) = 2\,(F(x,\mu), F'((x,\mu),d)) \leq 2\,(F(x,\mu), G((x,\mu);d)) = -2\,\theta(x).$$

Moreover the closure property holds, i.e.,

$$\theta'(\bar{x},\bar{d}) \leq 2\,(F(\bar{x},\bar{\mu}), G((\bar{x},\bar{\mu}),\bar{d})) \leq 2 \lim_{(x,\mu)\to(\bar{x},\bar{\mu}),d\to\bar{d}} (F(x), G((x,\mu);d))$$

$$= -2 \lim_{(x,\mu)\to(\bar{x},\bar{\mu})} |F(x,\mu)|^2 = -2\theta(\bar{x},\bar{\mu}),$$

where we used (3). Together with (6.12) this implies that (6.2) and (6.4) hold.

Method 2 (gradient direction). For $(x,\mu) \in S$, $d = (\delta x, \delta\mu)$ is chosen as the solution to

$$\min_d \quad (F(x,\mu), G((x,\mu);d)) + \frac{\hat{\sigma}}{2}\,|d|^2. \tag{6.13}$$

If d is an optimal solution, then $\alpha = 1$ is optimal for

$$\min_{\alpha>0} \quad \alpha\,(F(x), G((x,\mu);d)) + \frac{\alpha^2\hat{\sigma}}{2}\,|d|^2,$$

and thus differentiating this with respect α we have

$$(F(x), G(x,\mu);d) + \hat{\sigma}\,|d|^2 = 0.$$

Hence

$$\begin{aligned}\theta'((x,\mu);d) &= 2(F(x,\mu), F'((x,\mu);d)) \\ &\le 2(F(x), G((x,\mu);d)) \le -2\hat\sigma\,|d|^2\end{aligned} \tag{6.14}$$

and

$$\hat\sigma\,|d|^2 \le -(F(x,\mu), F'((x,\mu);d)) \le |F'((x,\mu);d)||F(x,\mu)| \le M\,|d||F(x,\mu)|, \tag{6.15}$$

where M denotes the bound of $F'(x,\mu)$ on S. This gives the second condition in (6.2) with $b = \frac{M}{\hat\sigma}$. Moreover, if (6.11)–(6.12) hold, then

$$\begin{aligned}\frac{1}{2}\theta'((x,\mu);d) &= (F(x,\mu), F'((x,\mu);d)) \le (F(x,\mu), G((x,\mu);d)) \\ &= (F(x,\mu), G((x,\mu);d)) + \frac{\hat\sigma}{2}\,|d|^2 \le (F(x), G((x,\mu);\hat d)) + \frac{\hat\sigma}{2}\,|\hat d|^2 \\ &\le |F(x)|^2 + \frac{\hat\sigma}{2}b^2\,|F(x)|^2 = -\frac{1}{2}(2-\hat\sigma b^2)\,\theta(x),\end{aligned} \tag{6.16}$$

where $G((x,\mu);\hat d) + F(x,\mu) = 0$ and we assume that $2-\hat\sigma b^2 > 0$. Thus, the direction d defined by (6.13) satisfies (6.2) with $\bar\sigma = (2-\bar\sigma b^2))$. To verify the closure property note that

$$\begin{aligned}\frac{1}{2}\theta'(\bar x,\bar d) &= (F(\bar x,\bar\mu), F'((\bar x,\bar\mu);\bar d)) \le (F(\bar x,\bar\mu), G((\bar x,\bar\mu);\bar d)) \\ &= (F(\bar x,\bar\mu), G((\bar x,\bar\mu);\bar d)) + \frac{\hat\sigma}{2}|\bar d|^2 \le \lim_{(x,d)\to(\bar x,\bar\mu),d\to\bar d}(F(x,\mu), G((x,\mu),d)) + \frac{\hat\sigma}{2}|d|^2.\end{aligned}$$

On the other hand, we have

$$2(F(x,\mu), G((x,\mu);d)) + \hat\sigma|d|^2 \le 2(F(x,\mu), G((x,\mu);\hat d)) + \hat\sigma|\hat d|^2 \le -(2-\hat\sigma b^2)\,\theta(x).$$

It thus follows that

$$\theta'((\bar x,\bar\mu);\bar d) \le -(2-\hat\sigma b^2)\,\theta(\bar x).$$

Let $A = f'(x)$. Then, condition (6.10) reduces to a variational inequality for δx on S_3:

$$\max(B\delta x + b, \delta x) + \max(-\mu, x-\psi) = 0, \tag{6.17}$$

where

$$B = A_{S_3S_3} - A_{S_3S_2}A^{-1}_{S_2S_2}A_{S_2S_3}$$

and

$$b = -A_{S_3S_1}(x-\psi)_{S_1} - A_{S_3S_2}A^{-1}_{S_2S_2}f(x)_{S_2} + (f(x)+\mu)_{S_3}.$$

Hence (6.10) has a unique solution if A is symmetric and positive definite, for example. In fact (6.17) is equivalent to

$$\max(B\xi + z, \xi) = 0, \tag{6.18}$$

where $\xi = \delta x + c$, $z = b + c - Bc$, and $c = \max(-\mu, x - \psi)$. The variational inequality (6.18) in turn is equivalent to the equation for the Lagrange multiplier for the constrained problem

$$\begin{cases} \min \frac{1}{2}(B^{-1}y, y) + (B^{-1}z, y), \\ y \geq 0, \end{cases}$$

which clearly has a unique solution.

MORSE DECOMPOSITIONS FOR GENERAL DYNAMICAL SYSTEMS AND DIFFERENTIAL INCLUSIONS WITH APPLICATIONS TO CONTROL SYSTEMS*

DESHENG LI†

Abstract. The Morse decomposition theory for single-valued dynamical systems is extended to general dynamical systems and differential inclusions. Relations between chain recurrent sets, chain recurrent components (chain control sets), and Morse decompositions for open-loop systems are discussed. The robustness of feedback laws of closed-loop systems with respect to small time delays and sample-hold controls is also addressed.

Key words. Morse decomposition, general dynamical system, differential inclusion, control system

1. Introduction.

General dynamical systems (GDSs), also referred to as general control systems or set-valued dynamical systems, are basically used to describe the behavior of differential equations without uniqueness, differential inclusions, and control systems [6, 9, 12, 18, 28, 24, 31, 34, 36, 41] as well as dynamical economic phenomena [10]. They have been widely studied since the pioneering work in the 1960s [41, 42, 45].

In this article we want to take a step towards the Morse decomposition theory for GDSs as well as differential inclusions. Morse decomposition theory is a powerful tool for analyzing dynamical behavior of nonlinear systems inside invariant sets and attractors, and it has aroused an increasing interest in recent years. For single-valued dynamical systems, the Morse decomposition theory can be found in the original work of Conley [15] (see also [2] and [43]). Extensions to random dynamical systems can be found in the recent work of Crauel, Duc, and Siegmund [16] and Ochs [37], and extensions to nonautonomous dynamical systems can be found in Rasmussen [40].

Our purposes here are as follows. First, we extend the Morse decomposition theory for single-valued dynamical systems to GDSs. A key point in this part is to introduce a suitable notion of an attractor-repeller pair and overcome technical difficulties due to the lack of invariance properties of repellers, Morse sets, and limit sets (fortunately attractors of GDSs are invariant). One will see that the definition of an attractor-repeller pair given here for GDSs is somewhat different from that for single-valued systems. However, the two definitions coincide when we come back to the latter case.

Second, we are interested in the stability of Morse decompositions of attractors. Specifically, we prove that Morse decompositions of attractors for GDSs are stable under parameter perturbations (upper semicontinuity of Morse sets).

Third, we discuss Morse decompositions and their stability with respect to perturbations for differential inclusions by applying the abstract results on GDSs. Differential inclusions have a very rich background and successful applications in many different areas; see, for instance, [3, 4, 5, 11, 12, 17, 29], etc. In contrast to differential equations, the understanding of dynamical behavior for differential inclusions seems to be more difficult, and it has aroused an increasing interest in recent years.

Finally, we give some applications to control systems. First, we investigate relationships between chain recurrent sets, chain recurrent components (chain control sets), and Morse decompositions for open-loop systems under weaker assumptions. Then we discuss the robustness of feedback laws of closed-loop systems with respect to small time delays and sample-hold controls from the point of view of the stability of Morse decompositions.

This paper is organized as follows. Section 2 is concerned with preliminary work on GDSs. Section 3 is devoted to the Morse decompositions for GDSs. In section 4 we consider upper semicontinuity of Morse decompositions of attractors with respect to parameter perturbations for GDSs, and in section 5 we establish a Morse decomposition theory for differential inclusions. Section 6 consists of some applications to open-loop control systems. Robustness results on feedback laws of closed-loop systems are contained in section 7.

2. Preliminary work on GDSs. Let X be a complete locally compact metric space with metric $d(\cdot,\cdot)$. For any nonempty subsets A and B of X, define the Hausdorff semidistance and distance, respectively, as

$$d_{\mathrm{H}}(A,B)=\sup_{x\in A} d(x,B),\quad \delta_{\mathrm{H}}(A,B)=\max\left\{d_{\mathrm{H}}(A,B),d_{\mathrm{H}}(B,A)\right\},$$

where $d(x,B)=\inf_{b\in B} d(x,b)$. For convenience, we also assign $d_{\mathrm{H}}(\emptyset,B)=0$.

Let $A\subset X$. The closure of A is denoted by $\overline{A}$ or $\mathrm{cl}A$, and the interior of A is denoted by $\operatorname{int}A$. We denote by $\mathrm{B}(A,r)$ the neighborhood $\{y\in X:\ d(y,A)<r\}$ of radius $r>0$ of A. We say that a subset V of X is a neighborhood of A if $\overline{A}\subset \operatorname{int}V$.

Definition 2.1 (see [27]). *A set-valued mapping $G:\mathbb{R}^+\times X\to X$ with nonempty closed images is said to be a GDS if the following axioms hold:*

(1) *The semigroup property is*

$$G(0,x)=x,\quad G(t,G(s,x))=G(t+s,x)\qquad \forall x\in X,\ s,t\in\mathbb{R}^+;$$

(2) *$G(t,x)$ is continuous in t for each fixed x in the sense of Hausdorff distance;*

(3) *$G(t,x)$ is upper semicontinuous in x uniformly in t on any compact interval J.*

For a GDS G, we will also write $G(t,x)$ as $G(t)x$.

From now on we always assume that there has been given a GDS G on X.

For convenience, we denote by $G(I)V$ the set $\bigcup_{(t,x)\in I\times V} G(t)x$ for $V\subset X$ and $I\subset\mathbb{R}^+$.

Let A and V be two subsets of X. We say that A *attracts* V if

$$d_{\mathrm{H}}\left(G(t)V,\,A\right)\to 0\quad \text{as } t\to\infty.$$

The *attraction region* $\Omega(A)$ and *uniform attraction region* $\Omega_u(A)$ of A are defined, respectively, as

$$\Omega(A):=\{x\in X|\ \ A \text{ attracts } x\},$$

$$\Omega_u(A):=\{x\in X|\ \ A \text{ attracts a neighborhood } U \text{ of } x\}.$$

A is said to be *Lyapunov stable* if for all $\varepsilon > 0$ there exists $\delta > 0$ such that

$$G(\mathbb{R}^+)\mathrm{B}(A,\delta) \subset \mathrm{B}(A,\varepsilon).$$

If A is Lyapunov stable with $\Omega(A)$ (resp., $\Omega_u(A)$) being a neighborhood of A, then we say that A is *asymptotically stable* (resp., *uniformly asymptotically stable*).

Remark 2.2 (see [30]). If A is compact and asymptotically stable, then $\Omega(A) = \Omega_u(A)$. Therefore asymptotic stability and uniform asymptotic stability for compact sets are actually equivalent. We also know that A attracts each compact subset K of $\Omega_u(A)$.

Let $I \subset \mathbb{R}$ be an interval. A *trajectory* γ of G on I is a mapping $\gamma : I \to X$ satisfying $\gamma(t_2) \in G(t_2 - t_1)\gamma(t_1)$ for any $t_1, t_2 \in I$ with $t_1 \le t_2$.

In case $I = \mathbb{R}$, we will simply say that γ is a *complete trajectory*. A complete trajectory γ through $x \in X$ means a complete trajectory with $\gamma(0) = x$.

THEOREM 2.3 (see [41]). *Every trajectory is continuous. Further, let $y \in G(t_1 - t_0)x$, where $t_0 \le t_1$. Then there is a trajectory γ of G on $[t_0, t_1]$ such that $\gamma(t_0) = x$ and $\gamma(t_1) = y$.*

THEOREM 2.4 (see[41], Barbashin's theorem). *Let $[t_0, t_1]$ be a compact interval and γ_n be a sequence of trajectories of G on $[t_0, t_1]$ with $\gamma_n(t_0) \to x_0$. Then there is a subsequence γ_{n_i} and a trajectory γ_0 such that γ_{n_i} converges uniformly on $[t_0, t_1]$ to γ_0.*

A set $A \subset X$ is said to be *positively invariant*, *negatively invariant*, or *invariant*, if $G(t)A \subset A$, $G(t)A \supset A$, or $G(t)A = A$), respectively, for all $t \ge 0$.

A set A is said to be *weakly invariant* if, for any $x \in A$, there passes through x a complete trajectory γ with $\gamma(\mathbb{R}) \subset A$. In case A is compact, we infer from [30] that this amounts to saying that A is negatively invariant with $G(t)A \cap A \neq \emptyset$ for all $t \ge 0$.

The following basic fact is well known. See also [30].

PROPOSITION 2.5. *Let A be a nonempty compact subset of X. If A is negatively (resp., positively) invariant under G, then for any $x \in A$, there is a trajectory γ of G on $(-\infty, 0]$ (resp. $[0, \infty)$) which lies in A such that $\gamma(0) = x$.*

Let $A \subset X$, and let γ be a trajectory of G on $[a, +\infty)$. The *ω-limit sets* $\omega(A)$ and $\omega(\gamma)$ are defined, respectively, as

$$\omega(A) := \{y \in X : \ \exists t_n \to \infty \text{ and } y_n \in G(t_n)A \text{ such that } y_n \to y\},$$

$$\omega(\gamma) := \{x \in X| \ \ \exists t_n \to +\infty \text{ such that } \gamma(t_n) \to x\}.$$

Similarly one can define the *α-limit set* $\alpha(\gamma)$ of a trajectory γ on $(-\infty, a]$.

Remark 2.6. In case $G(\mathbb{R}^+)A$, $\gamma([a, \infty))$, and $\gamma((-\infty, a])$ are precompact, it can be easily shown that the limit sets defined above are nonempty compact weakly invariant sets [30].

DEFINITION 2.7. *Let $\mathcal{A}$ be a compact subset of X. If there is a neighborhood U of $\mathcal{A}$ such that $\mathcal{A} = \omega(U)$, then we say that $\mathcal{A}$ is an attractor of G, and U is called an attractor neighborhood of $\mathcal{A}$. A global attractor is an attractor $\mathcal{A}$ with $\Omega_u(\mathcal{A}) = X$.*

We allow the empty set $\emptyset$ to be an attractor of G with $\Omega_u(\emptyset) = \emptyset$.

Remark 2.8. In general limit sets of GDSs may fail to be invariant. However, if $\mathcal{A} = \omega(U)$ is an attractor of G, then it is invariant (see [30]).

An attractor $\mathcal{A}$ is necessarily uniformly asymptotically stable [30]. Thus by Remark 2.2 we have $\Omega(\mathcal{A}) = \Omega_u(\mathcal{A})$. So from now on we will not distinguish $\Omega(\mathcal{A})$ and $\Omega_u(\mathcal{A})$.

Let G_λ ($\lambda \in \Lambda$) be a family of GDSs, where Λ is a metric space with metric $\rho(\cdot, \cdot)$.

THEOREM 2.9 (see [31]). *Let $\lambda_0 \in \Lambda$. Assume the following continuity assumption holds:*

(C0) *For any $\varepsilon, T > 0$ and compact set A, there exists $\delta > 0$ such that, when $\rho(\lambda, \lambda_0) < \delta$,*

$$d_{\mathrm{H}}\left(G_\lambda(t)x,\, G_{\lambda_0}(t)B(x,\varepsilon)\right) < \varepsilon \qquad \forall x \in A,\ t \in [0,T].$$

Suppose G_{λ_0} has an attractor $\mathcal{A}$. Then the following hold:

(1) *there exists $\mu > 0$ such that, when $\rho(\lambda, \lambda_0) < \mu$, G_λ has an attractor $\mathcal{A}_\lambda$;*

(2) *$d_{\mathrm{H}}(\mathcal{A}_\lambda, \mathcal{A}) \to 0$ as $\lambda \to \lambda_0$;*

(3) *if $K \subset \Omega(\mathcal{A})$ is compact, then $K \subset \Omega(A_\lambda)$ provided $\rho(\lambda, \lambda_0)$ sufficiently small.*

3. Morse decompositions of invariant sets for GDSs.

3.1. Attractor-repeller pair. As usual, let X be a complete locally compact metric space, and let G be a GDS on X. We also assume that there has been given a compact invariant set S of G.

Denote by $G|_S$ the restriction of G on S. Since S is invariant, $G|_S$ is also a GDS on S.

We say that a compact set $\mathcal{A}$ is an *attractor of G in S*; by this we mean that it is an attractor of $G|_S$ in S. We denote by $\Omega^S(\mathcal{A})$ the attraction region of $\mathcal{A}$ in S (under the GDS $G|_S$). Then for any compact subset $K \subset \Omega^S(\mathcal{A})$, as $\mathcal{A}$ attracts K, we necessarily have $\omega(K) \subset \mathcal{A}$.

Let $\mathcal{A}$ be an attractor of G in S. Define

$$\mathcal{A}^* = \{x \in S |\ \omega(x) \setminus \mathcal{A} \neq \emptyset\}. \tag{3.1}$$

$\mathcal{A}^*$ is said to be the *repeller* of G in S dual to $\mathcal{A}$, and $(\mathcal{A}, \mathcal{A}^*)$ is said to be an *attractor-repeller pair* in S.

Remark 3.1. For single-valued dynamical systems, the repeller $\mathcal{A}^*$ of an attractor $\mathcal{A}$ in an invariant set S is defined by

$$\mathcal{A}^* = \{x \in S |\ \omega(x) \cap \mathcal{A} = \emptyset\}; \tag{3.2}$$

see [15, 43]. Here we have used a slightly relaxed condition "$\omega(x) \setminus \mathcal{A} \neq \emptyset$" to define a repeller for GDSs. One easily checks that the two definitions coincide when we come back to the situation of the single-valued case. Our definition seems to be more suitable for set-valued systems. This can be seen from the following easy example.

Example 3.1. Consider the scalar differential inclusion,

$$x'(t) \in f(x(t)), \qquad \text{where } f(x) = \begin{cases} [-8x(x+1)^2,\, 2], & -1 \le x \le 0; \\ -8x(x+1)^2, & \text{otherwise.} \end{cases}$$

This system generates a GDS G on $\mathbb{R}$ which has two equilibria -1 and 0, with 0 being asymptotically stable and -1 being unstable; see Figure 3.1.

The global attractor of G is the interval $[-1, 0]$. Define γ on $[0, \infty)$ as

$$\gamma(t) = -1 + 2t \quad (0 \le t \le 1/2) \quad \text{and} \quad \gamma(t) = 0 \quad (t > 1/2).$$

Then γ is a trajectory of G, which implies $0 \in \omega(-1)$.

Let $S = [-1, 0]$. It is easy to see that $\mathcal{A} = \{0\}$ is an attractor of G with $\Omega^S(\mathcal{A}) = (-1, 0]$. If we define the repeller $\mathcal{A}^*$ as in (3.1), then we have $\mathcal{A}^* = \{-1\}$. However, if we define $\mathcal{A}^*$ as in (3.2), then since $0 \in \omega(-1) \cap \mathcal{A} \neq \emptyset$, we have $\mathcal{A}^* = \emptyset$.

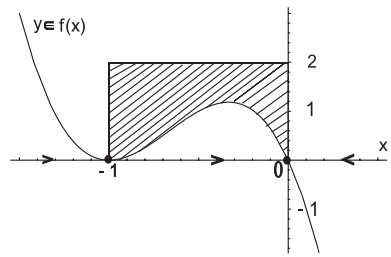

FIG. 3.1.

PROPOSITION 3.2. *Let $(\mathcal{A}, \mathcal{A}^*)$ be an attractor-repeller pair in S, and let U be a neighborhood of $\mathcal{A}^*$. Then for any $\varepsilon > 0$, there is a $T > 0$ such that*

$$G(t)x \subset B(\mathcal{A}, \varepsilon) \qquad \forall t > T,\ x \in S \setminus U.$$

Proof. Let $K = S \setminus \text{int}U$. Then $K \subset \Omega^S(\mathcal{A})$ and is compact. Hence $\mathcal{A}$ attracts K, and the conclusion follows. □

As a direct consequence of the above result, we have the following.

PROPOSITION 3.3. *Let $(\mathcal{A}, \mathcal{A}^*)$ be an attractor-repeller pair in S, and let B be a closed set distinct from $\mathcal{A}$. Then for every $\varepsilon > 0$, there is a $T > 0$ such that, whenever $x \in S$ and $t \geq T$ is such that $G(t)x \cap B \neq \emptyset$, we have $d(x, \mathcal{A}^*) < \varepsilon$.*

PROPOSITION 3.4. *Let $\mathcal{A}$ be an attractor of G in S. Then the following hold:*

(1) $\mathcal{A}^* = S \setminus \Omega^S(\mathcal{A}) = S \setminus \Omega(\mathcal{A})$;

(2) $\mathcal{A}^*$ *is compact and weakly invariant.*

Proof. (1) Assume $x \in S$. Then $\omega(x)$ is a nonempty compact set, and $\omega(x) \subset \mathcal{A}$ if and only if $x \in \Omega^S(\mathcal{A})$. This implies $\mathcal{A}^* = S \setminus \Omega^S(\mathcal{A})$.

Since S is invariant, we have $\Omega^S(\mathcal{A}) = S \cap \Omega(\mathcal{A})$. Hence the second equality follows.

(2) The compactness of $\mathcal{A}^*$ follows from (1).

To check the weak invariance of $\mathcal{A}^*$, we first show that $\mathcal{A}^*$ is negatively invariant. Indeed, we observe that

$$S = G(t)S = G(t)\left(\Omega^S(\mathcal{A}) \cup \mathcal{A}^*\right) = \left(G(t)\Omega^S(\mathcal{A})\right) \cup G(t)\mathcal{A}^* \subset \Omega^S(\mathcal{A}) \cup G(t)\mathcal{A}^*.$$

Since $\mathcal{A}^* \subset S$ and $\mathcal{A}^* \cap \Omega^S(\mathcal{A}) = \emptyset$, we necessarily have $\mathcal{A}^* \subset G(t)\mathcal{A}^*$.

Now assume that $x \in \mathcal{A}^*$. Then by Proposition 2.5 and the negative invariance of $\mathcal{A}^*$, there is a trajectory γ^- on $(-\infty, 0]$ such that $\gamma^-((-\infty, 0]) \subset \mathcal{A}^*$ and $\gamma^-(0) = x$.

To complete the proof, it suffices to show that there is also a trajectory γ^+ on $[0, \infty)$ such that $\gamma([0, \infty)) \subset \mathcal{A}^*$ with $\gamma(0) = x$.

Take an open neighborhood V of $\mathcal{A}^*$ and $\varepsilon > 0$ sufficiently small so that $\overline{V} \cap \mathrm{B}(\mathcal{A}, \varepsilon) = \emptyset$. By virtue of Proposition 3.2 there is a $T > 0$ such that

$$G(t)y \subset \mathrm{B}(\mathcal{A}, \varepsilon) \qquad \forall t > T,\ y \in S \setminus V. \tag{3.3}$$

Since $\omega(x)$ is compact, if $\omega(x) \subset \Omega^S(\mathcal{A})$, then $\mathcal{A}$ attracts $\omega(x)$ and consequently $\mathcal{A}$ attracts x, which implies $x \in \Omega^S(\mathcal{A})$ and leads to a contradiction. Therefore we deduce that $\omega(x) \cap \mathcal{A}^* \neq \emptyset$. It follows that there exist $t_n \to +\infty$ and $y_n \in G(t_n)x$ such that $y_n \in V$ for all n. Let γ_n be a trajectory of G on $[0, t_n]$ satisfying $\gamma_n(0) = x$ and $\gamma_n(t_n) = y_n$. Define

$$\tau_n = \sup\{\tau > 0 |\ \gamma_n([0, \tau]) \subset V\}.$$

Then $\gamma_n(\tau_n) \in \partial V \subset S \setminus V$. We claim that there is a subsequence of τ_n, still denoted by τ_n, such that $\tau_n \to +\infty$. Indeed, if τ_n is bounded, say, $\tau_n \le s$ for all n, then by (3.3) we have

$$y_n = \gamma_n(t_n) \in G(t_n - \tau_n)\gamma_n(\tau_n) \in \mathrm{B}(\mathcal{A}, \varepsilon)$$

for large n with $t_n > T + s$, which leads to a contradiction and thus proves our claim.

Now thanks to Barbashin's theorem (Theorem 2.4), one concludes that there is a trajectory γ^+ on $[0,\infty)$ such that $\gamma^+(0) = x$ and $\gamma^+([0,\infty)) \subset \overline{V}$. Note that we actually have $\gamma^+([0,\infty)) \subset \mathcal{A}^*$; otherwise, one will find $d(\gamma^+(t), \mathcal{A}) \to 0$ as $t \to \infty$, a contradiction!

The proof is complete. □

PROPOSITION 3.5. *Let $\mathcal{A}$ be an attractor of G in S, and let $\gamma : \mathbb{R} \to S$ be a complete trajectory through $x \in S$. Then the following properties hold:*

(1) *If $\omega(\gamma) \cap \mathcal{A}^* \neq \emptyset$, then $\gamma(\mathbb{R}) \subset \mathcal{A}^*$, and if $\alpha(\gamma) \cap \mathcal{A} \neq \emptyset$, then $\gamma(\mathbb{R}) \subset \mathcal{A}$;*

(2) *If $x \notin \mathcal{A}$, then $\alpha(\gamma) \subset \mathcal{A}^*$, and if $x \notin \mathcal{A}^*$, then $\omega(\gamma) \subset \mathcal{A}$.*

Proof. The proof is a slight modification of the corresponding one for single-valued systems (see, e.g., [43]). It is thus omitted. □

3.2. Morse decompositions of invariant sets.

DEFINITION 3.6. *Let S be a compact invariant set. An ordered collection $\mathcal{M} = \{M_1, \dots, M_n\}$ of subsets of S is called a Morse decomposition of S if there exists an increasing sequence $\emptyset = \mathcal{A}_0 \subset \mathcal{A}_1 \subset \cdots \subset \mathcal{A}_n = S$ of attractors of G in S such that*

$$M_k = \mathcal{A}_k \cap \mathcal{A}^*_{k-1}, \qquad 1 \le k \le n.$$

The sets M_k in Definition 3.6 are called *Morse sets*. For convenience in statement, we allow Morse sets to be empty. This occurs, say, for instance, in case $\mathcal{A}_j = \mathcal{A}_{j-1}$ for j (in which case $M_j = \mathcal{A}_j \cap \mathcal{A}^*_{j-1} = \emptyset$). However, if two Morse decompositions $\mathcal{M}$ and $\mathcal{M}'$ have the same nonempty Morse sets, they will be regarded as the same.

THEOREM 3.7. *Let $\mathcal{M} = \{M_1, \dots, M_n\}$ be a Morse decomposition of S with the corresponding attractor sequence $\emptyset = \mathcal{A}_0 \subset \mathcal{A}_1 \subset \cdots \subset \mathcal{A}_n = S$. Then the following hold:*

(1) *For each k, $(\mathcal{A}_{k-1}, M_k)$ is an attractor-repeller pair in $\mathcal{A}_k$;*

(2) *M_k are pairwise disjoint weakly invariant compact sets;*

(3) *If γ is a complete trajectory, then either $\gamma(\mathbb{R}) \subset M_k$ for some Morse set M_k or else there are indices $i < j$ such that $\alpha(\gamma) \subset M_j$ and $\omega(\gamma) \subset M_i$;*

(4) *The attractors $\mathcal{A}_k$ are uniquely determined by the Morse sets, i.e.,*

$$\mathcal{A}_k = \bigcup_{1 \le i \le k} W^u(M_i), \qquad 1 \le k \le n,$$

where $W^u(M_i) = \{x |$ there is a trajectory $\gamma : \mathbb{R} \to S$ through x with $\alpha(\gamma) \subset M_i\}$;

(5) *If S is isolated, then so is each $\mathcal{A}_k$.*

Proof. The proof of (1)–(5) except for the weak invariance of Morse sets M_k can be given in a quite similar manner as in the situation of single-valued dynamical systems (see [43, Chapter 3, Theorem 1.7]). We thus omit the details of the argument. □

The weak invariance of M_k is a consequence of (1) and the weak invariance of repellers.

The following result seems to be interesting, which demonstrates that (2) and (3) in Theorem 3.7 uniquely characterize a Morse decomposition.

THEOREM 3.8. *Let S be a compact invariant set of G, and let $\mathcal{M} = \{M_1, \dots, M_n\}$ be an ordered collection of pairwise disjoint compact and weakly invariant subsets of S. Suppose that for every $x \in S$ and every complete trajectory γ through x, we have either $\gamma(\mathbb{R}) \subset M_i$ for some i or else there are indices $i < j$ such that $\alpha(\gamma) \subset M_j$ and $\omega(\gamma) \subset M_i$. Then $\mathcal{M}$ is a Morse decomposition of S.*

Proof. Set $\mathcal{A}_0 = \emptyset$, and for $1 \le k \le n$ define $\mathcal{A}_k$ as

$$\mathcal{A}_k = \{x \in S| \quad \text{there is a complete trajectory } \gamma : \mathbb{R} \to S \text{ through } x \text{ satisfying } \alpha(\gamma) \subset (M_1 \cup \cdots \cup M_k)\}.$$

We will show that $\mathcal{A}_0 \subset \mathcal{A}_1 \subset \cdots \subset \mathcal{A}_n = S$ is an attractor sequence in S such that $\mathcal{A}_k \cap \mathcal{A}^*_{k-1} = M_k$, thus proving the result.

Step 1. We show that the sets $\mathcal{A}_k$ are closed.

It is clear that $\mathcal{A}_n = S$ is closed. We now proceed inductively and assume that $\mathcal{A}_{k+1}$ is closed. We prove that $\mathcal{A}_k$ is closed. Let $x_m \in \mathcal{A}_k$ with $x_m \to x \in S$. Then $x \in \mathcal{A}_{k+1}$, since $\mathcal{A}_k \subset \mathcal{A}_{k+1}$ and $\mathcal{A}_{k+1}$ is closed. For each x_m there is a complete trajectory $\gamma_m : \mathbb{R} \to S$ with $\gamma_m(0) = x_m$ and $\alpha(\gamma_m) \subset (M_1 \cup \cdots \cup M_k)$. Using Barbashin's compactness theorem one finds a subsequence of γ_m, still denoted by γ_m, such that γ_m converges uniformly on any compact interval of $\mathbb{R}$ to a complete trajectory $\gamma : \mathbb{R} \to S$ through x. We claim that $\alpha(\gamma) \subset (M_1 \cup \cdots \cup M_k)$, and hence $x \in \mathcal{A}_k$.

Indeed, since $\gamma_m(\mathbb{R}) \subset \mathcal{A}_{k+1}$ and $\mathcal{A}_{k+1}$ is closed, it follows that $\gamma(\mathbb{R}) \subset \mathcal{A}_{k+1}$ and so $\alpha(\gamma) \subset \mathcal{A}_{k+1}$. We first show that

$$M_j \cap \mathcal{A}_{k+1} = \emptyset \qquad \text{for } j > k+1. \tag{3.4}$$

Suppose the contrary, then there is a $y \in M_j \cap \mathcal{A}_{k+1}$ for some $j > k+1$. Since $y \in \mathcal{A}_{k+1}$, there is a complete trajectory $\sigma_1 : \mathbb{R} \to S$ such that $\alpha(\sigma_1) \subset (M_1 \cup \cdots \cup M_{k+1})$ and $\sigma_1(0) = y$. By $y \in M_j$ and the weak invariance of M_j, there is also a complete trajectory $\sigma_2 : \mathbb{R} \to M_j$ such that $\sigma_2(0) = y$. Define $\sigma : \mathbb{R} \to S$ as

$$\sigma(t) = \sigma_1(t) \text{ (for } t \le 0) \quad \text{and} \qquad \sigma(t) = \sigma_2(t) \text{ (for } t > 0).$$

Then σ is a complete trajectory of G. Note that $\alpha(\sigma) \subset (M_1 \cup \cdots \cup M_{k+1})$ and $\omega(\sigma) \subset M_j$. On the other hand by assumption in the theorem and $\alpha(\sigma) \subset (M_1 \cup \cdots \cup M_{k+1})$, we deduce that $\omega(\sigma) \subset M_i$ for some $i \le k+1$. This leads to a contradiction, as $M_i \cap M_j = \emptyset$.

Now because $\alpha(\gamma) \subset M_j$ for some j (by assumption in the theorem), we necessarily have by $\alpha(\gamma) \subset \mathcal{A}_{k+1}$ and (3.4) that $\alpha(\gamma) \subset M_1 \cup \cdots \cup M_k \cup M_{k+1}$. Consequently, either $\alpha(\gamma) \subset M_1 \cup \cdots \cup M_k$, in which case we are done, or else $\alpha(\gamma) \subset M_{k+1}$.

We prove that the latter case will not occur. Suppose the contrary. We take two open neighborhoods U, V of M_{k+1} with $\overline{U}$ and $\overline{V}$ compact such that $\overline{U} \subset V$ and $\overline{V} \cap M_j = \emptyset$ for $j \ne k+1$. Since $\alpha(\gamma) \subset M_{k+1}$, there is a $\tau > 0$ such that $\gamma((-\infty, -\tau]) \subset U$. Since $\gamma_m(-\tau) \to \gamma(-\tau)$, we may assume that $\gamma_m(-\tau) \in V$ for all m. Let

$$s_m = \sup\{s > \tau| \ \gamma_m([-s, -\tau]) \subset V\}.$$

Then $\gamma_m(-s_m) \in \partial V$. We claim that $s_m \to \infty$. Otherwise, say $s_m \le s$ for some $s > \tau$, due to the uniform convergence of γ_m to γ on $[-s, -\tau]$, one will find that $\gamma_m(-s_m) \in V$ for m sufficiently large, a contradiction! Now set

$$\sigma_m(t) = \gamma(-s_m + t), \qquad t \in [0, s_m - \tau_m].$$

Then by Barbashin's theorem there is a subsequence of σ_m, still denoted by σ_m, such that σ_m converges uniformly on any compact interval of $\mathbb{R}^+$ to a trajectory $\sigma : \mathbb{R}^+ \to \overline{V}$. Note that $\sigma(0) \in \partial V$ as $\sigma_m(0) = \gamma_m(-s_m) \in \partial V$. Since $\mathcal{A}_{k+1}$ is closed and $\gamma_m(\mathbb{R}) \subset \mathcal{A}_k \subset \mathcal{A}_{k+1}$, we conclude that $\sigma(t) \in \mathcal{A}_{k+1}$ for $t \geq 0$. In particular, $\sigma(0) \in \mathcal{A}_{k+1}$. Therefore by the definition of $\mathcal{A}_{k+1}$, there is also a complete trajectory $\widetilde{\sigma} : \mathbb{R} \to S$ through $\sigma(0)$ such that $\alpha(\widetilde{\sigma}) \subset M_1 \cup \cdots \cup M_k \cup M_{k+1}$. Define a complete trajectory $\sigma' : \mathbb{R} \to S$ as

$$\sigma'(t) = \widetilde{\sigma}(t) \text{ (for } t \leq 0) \quad \text{and} \qquad \sigma'(t) = \sigma(t) \text{ (for } t > 0).$$

Then $\alpha(\sigma') \subset M_1 \cup \cdots \cup M_k \cup M_{k+1}$. By $\sigma'(\mathbb{R}^+) \subset \overline{V}$ we also have $\omega(\sigma') \subset M_{k+1}$. Therefore by the assumption in the theorem we necessarily have $\sigma'(\mathbb{R}) \subset M_{k+1}$, which contradicts the fact $\sigma'(0) = \sigma(0) \in \partial V$.

Step 2. $\mathcal{A}_k$ is invariant. Indeed, if $y \in \mathcal{A}_k$, then there is a complete trajectory $\gamma : \mathbb{R} \to S$ through y such that $\alpha(\gamma) \subset M_1 \cup \cdots \cup M_k \subset \mathcal{A}_k$. It then follows that $\gamma(\mathbb{R}) \subset \mathcal{A}_k$. Consequently $y \in G(t)\gamma(\mathbb{R}) \subset G(t)\mathcal{A}_k$ for any $t \geq 0$. Hence $\mathcal{A}_k \subset G(t)\mathcal{A}_k$.

We check that the converse inclusion $G(t)\mathcal{A}_k \subset \mathcal{A}_k$ also holds true. Let $y \in G(t)\mathcal{A}_k$. Then $y \in G(t)x$ for some $x \in \mathcal{A}_k$. Since S is invariant, there is a trajectory $\gamma_3 : [t, \infty) \to S$ such that $\gamma_3(t) = y$. Thanks to Theorem 2.3, one can find a trajectory γ_2 on $[0, t]$ such that $\gamma_2(0) = x$ and $\gamma_2(t) = y$. By invariance of S, we necessarily have $\gamma_2([0, t]) \subset S$. As $x \in \mathcal{A}_k$, there is also a complete trajectory $\gamma_1 : \mathbb{R} \to S$ such that $\gamma_1(0) = x$ and $\alpha(\gamma) \subset M_1 \cup \cdots \cup M_k$. Now we define a complete trajectory $\gamma : \mathbb{R} \to S$ such that

$$\gamma|_{(-\infty,0]} = \gamma_1, \quad \gamma|_{[0,t]} = \gamma_2, \quad \gamma|_{[t,\infty)} = \gamma_3.$$

Then $\gamma(t) = y$ and $\alpha(\gamma) \subset M_1 \cup \cdots \cup M_k$, which implies $y \in \mathcal{A}_k$ and proves the conclusion.

Step 3. $\mathcal{A}_k$ is an attractor of G in S.

This is clearly true for $k = n$. We proceed by induction and assume $\mathcal{A}_{k+1}$ to be an attractor in S. Choose a neighborhood U_{k+1} of $\mathcal{A}_{k+1}$ such that $\overline{U}_{k+1}$ is compact and $\omega(U_{k+1} \cap S) = \mathcal{A}_{k+1}$. Since $\mathcal{A}_k$ is closed, $M_{k+1} \cup \mathcal{A}_k \subset \mathcal{A}_{k+1}$, and $M_{k+1} \cap \mathcal{A}_k = \emptyset$, we can choose a neighborhood U of $\mathcal{A}_k$ and neighborhoods V_0, V_1 of M_{k+1} contained in U_{k+1} such that $\overline{V}_0 \subset V_1$ and $\overline{U} \cap \overline{V}_1 = \emptyset$. We show that $\omega(U \cap S) = \mathcal{A}_k$ when U is chosen sufficiently small. Indeed, since $\mathcal{A}_k$ is invariant, we have $\mathcal{A}_k \subset \omega(U \cap S)$. There remains to check

$$\mathcal{A}_k \supset \omega(U \cap S). \tag{3.5}$$

Suppose $\omega(U \cap S) \setminus \mathcal{A}_k \neq \emptyset$, and choose a $y \in \omega(U \cap S) \setminus \mathcal{A}_k \neq \emptyset$. Then there are sequences $x_m \in U \cap S$, $t_m \to \infty$, and $y_m \in G(t_m)x_m$ such that $y_m \to y$. Let γ_m be a trajectory on $[0, t_m]$ with $\gamma_m(0) = x_m$ and $\gamma_m(t_m) = y_m$. We can extract a subsequence of γ_m, still denoted by γ_m, such that $\gamma_m(t_m + t)$ converges uniformly on any compact interval of $\mathbb{R}$ to a complete trajectory $\gamma(t)$ with $\gamma(\mathbb{R}) \subset S$ and $\gamma(0) = y$. Now $\omega(U \cap S) \subset \omega(U_{k+1} \cap S) = \mathcal{A}_{k+1}$ implies $\gamma(\mathbb{R}) \subset \mathcal{A}_{k+1}$, and hence $\alpha(\gamma) \subset \mathcal{A}_{k+1}$ (by Step 1). Therefore $\alpha(\gamma) \subset M_1 \cup \cdots \cup M_k \cup M_{k+1}$. As $y \notin \mathcal{A}_k$, we necessarily have $\alpha(\gamma) \subset M_{k+1}$ and so there is a $T > 0$ such that, when $t > T$, we have $\gamma(-t) \in V_0$. Since $\gamma_m(t_m + t)$ converges uniformly on any compact interval of $\mathbb{R}$ to $\gamma(t)$ for any $\tau > 0$, we can find a m_τ sufficiently large such that $\gamma_{m_\tau}([t_{m_\tau} - T - \tau,\, t_{m_\tau} - T]) \subset V_1$. Rewriting $t_{m_\tau} - T - \tau$ as s_{m_τ}, we obtain

$$\gamma_{m_\tau}([s_{m_\tau}\, s_{m_\tau} + \tau]) \subset V_1.$$

Now suppose (3.5) fails to be true for any U. Pick a sequence $\varepsilon_m \downarrow 0$ with

$$\overline{\mathrm{B}}(\mathcal{A}_k, \varepsilon_m) \cap \overline{V}_1 = \emptyset, \quad \mathrm{B}(\mathcal{A}_k, \varepsilon_m) \subset U_{k+1}.$$

Applying what we have just proved above for each $U = \mathrm{B}(\mathcal{A}_k, \varepsilon_m)$ and $\tau = 1/\varepsilon_m$, one obtains a sequence of trajectories denoted by γ_m such that, for each m,

$$\gamma_m(0) \in \mathrm{B}(\mathcal{A}_k, \varepsilon_m) \cap S, \qquad \gamma_m([s_m,\, s_m + 1/\varepsilon_m]) \subset V_1$$

for some $s_m \geq 0$. Let $\tau_m = \inf\{0 \leq \tau \leq s_m : \ \gamma_m([\tau,\, s_m + 1/\varepsilon_m]) \subset V_1\}$. Then $\gamma_m(\tau_m) \in \partial V_1$. We claim that $\tau_m \to \infty$. Otherwise, say $\tau_m \leq T < \infty$, γ_m will converge uniformly on $[0, T]$ to a trajectory γ. Since $d(\gamma_m(0), \mathcal{A}_k) \to 0$ and $\mathcal{A}_k$ is invariant, one necessarily has $\gamma([0, T]) \subset \mathcal{A}_k$. It then follows that $d(\gamma_m(\tau_m), \mathcal{A}_k) \to 0$, which contradicts $\gamma_m(\tau_m) \in \partial V_1$ and proves the claim.

We may assume that $\gamma_m(\tau_m) \to z$. Then since $\gamma_m(0) \in \mathrm{B}(\mathcal{A}_k, \varepsilon_m) \cap S \subset U_{k+1} \cap S$ and $\tau_m \to \infty$, we see that $z \in \omega(U_{k+1} \cap S) = \mathcal{A}_{k+1}$. Of course we also have $z \in \partial V_1$ (by $\gamma_m(\tau_m) \in \partial V_1$). Set $\widetilde{\gamma}_m(t) = \gamma_m(\tau_m + t)$. Noting that $s_m + 1/\varepsilon_m - \tau_m \geq 1/\varepsilon_m$, we see that $\widetilde{\gamma}_m$ is well defined at least on $[-\tau_m,\, 1/\varepsilon_m]$ with $\widetilde{\gamma}_m([0,\, 1/\varepsilon_m]) \subset V_1$. By Barbashin's theorem one can easily find a complete trajectory $\widetilde{\gamma} : \mathbb{R} \to S$ such that $\widetilde{\gamma}(0) = z \in \partial V_1$ and $\widetilde{\gamma}(\mathbb{R}^+) \subset \overline{V}_1$. Due to the assumption of the theorem we conclude

$$\omega(\widetilde{\gamma}) \subset M_{k+1}. \tag{3.6}$$

It is clear that $\widetilde{\gamma}(\mathbb{R}) \subset \mathcal{A}_{k+1}$ and so $\alpha(\widetilde{\gamma}) \subset M_1 \cup \cdots \cup M_k \cup M_{k+1}$. This and (3.6) as well as the assumption in the theorem imply that $\widetilde{\gamma}(\mathbb{R}) \subset M_{k+1}$, which contradicts $\widetilde{\gamma}(0) \in \partial V_1$.

Step 4. $M_k = \mathcal{A}_k \cap \mathcal{A}^*_{k-1}$ for all $1 \leq k \leq n$.

Indeed, if $x \in M_k$, then there is a complete trajectory $\gamma : \mathbb{R} \to M_k$ through x, and thus by definition of $\mathcal{A}_k$ we have $x \in \mathcal{A}_k$. If $x \notin \mathcal{A}^*_{k-1}$, then $\omega(x) \cap \mathcal{A}^*_{k-1} = \emptyset$, and hence $\omega(x) \subset \mathcal{A}_{k-1}$. It follows that $\omega(\gamma) \subset \mathcal{A}_{k-1}$; therefore, $\omega(\gamma) \subset M_i$ for some $1 \leq i \leq k-1$. This contradicts $\omega(\gamma) \subset M_k$. Thus $x \in \mathcal{A}^*_{k-1}$, i.e., $M_k \subset \mathcal{A}_k \cap \mathcal{A}^*_{k-1}$.

Conversely, let $x \in \mathcal{A}_k \cap \mathcal{A}^*_{k-1}$. Then by Proposition 3.4 there is a complete trajectory $\gamma : \mathbb{R} \to \mathcal{A}^*_{k-1}$. We have $\omega(\gamma) \cap (M_1 \cup \cdots \cup M_{k-1}) = \emptyset$ and so $\omega(\gamma) \subset M_j$ for some $j \geq k$. On the other hand $x \in \mathcal{A}_k$ implies $\alpha(\gamma) \subset M_1 \cup \cdots \cup M_k$. Consequently by the assumption of the theorem, we have $\gamma(\mathbb{R}) \subset M_k$, which implies $x \in M_k$. The proof is complete. □

3.3. The finest Morse decomposition. Let $\mathcal{M}_1$ and $\mathcal{M}_2$ be two Morse decompositions of a compact invariant $\mathcal{S}$. We say that $\mathcal{M}_2$ is *finer* than $\mathcal{M}_1$; this means that each Morse set $M \in \mathcal{M}_2$ is contained in a Morse set $M' \in \mathcal{M}_1$. A Morse decomposition $\mathcal{M}$ is said to be the *finest Morse decomposition* of $\mathcal{S}$ if $\widetilde{\mathcal{M}}$ is a finer Morse decomposition implies $\widetilde{\mathcal{M}} = \mathcal{M}$.

In general the finest Morse decomposition may fail to exist (see [13, Appendix B]).

LEMMA 3.9. *Let $\mathcal{S}$ be a compact invariant set, and let $\mathcal{M} = \{M_1, \ldots, M_m\}$ and $\mathcal{M}' = \{M'_1, \ldots, M'_n\}$ be two Morse decompositions of $\mathcal{S}$. Let M_{ij} be the maximal weakly invariant set contained in $M_i \cap M'_j$. Then the ordered collection*

$$\{M_{ij} |\ 1 \leq i \leq m,\ 1 \leq j \leq n\}$$

is a Morse decomposition of $\mathcal{S}$, where the order "$\preceq$" is given by

$$M_{ij} \preceq M_{kl} \iff \text{either } i < k \text{ or } i = k,\ j \leq l.$$

Proof. Let $A_{ij} = M_i \cap M_j$. Since $\mathcal{M}$ and $\mathcal{M}'$ are both Morse decompositions, it is trivial to check that, for any complete trajectory γ in $\mathcal{S}$, either $\gamma(\mathbb{R})$ is contained in some A_{ij} or there are indices $1 \le i, j \le m$ and $1 \le k, l \le n$ with $i \le k$ and $j \le l$ (in case $i = k$) such that $\omega(\gamma) \subset A_{ij},\ \alpha(\gamma) \subset A_{kl}$. Let $M_{ij} = \operatorname{cl} \widetilde{M}_{ij}$, where $\widetilde{M}_{ij}$ is the set of the union of all ω-limit sets and α-limit sets of complete trajectories in $\mathcal{S}$ that are contained in A_{ij} and the orbit of complete trajectories in A_{ij}. It is clear that $\widetilde{M}_{ij}$ is weakly invariant (see Remark 2.6). Therefore by Barbashin's theorem we easily know that M_{ij} is weakly invariant. By definition of M_{ij}, it is necessarily the maximal weakly invariant set in A_{ij}. It is also clear that the ordered collection $\{M_{ij} |\ 1 \le i \le m,\ 1 \le j \le n\}$ satisfies all the assumptions in Theorem 3.8; hence, it is a Morse decomposition of $\mathcal{S}$. □

Remark 3.10. We infer from Lemma 3.9 that the finest Morse decomposition, if it exists, is finer than any other Morse decomposition of $\mathcal{S}$.

PROPOSITION 3.11. *Morse sets in the finest Morse decomposition are connected.*

Proof. Let $\mathcal{M} = \{M_1, \dots, M_n\}$ be the finest Morse decomposition of $\mathcal{S}$. Suppose that there is a Morse set M_k which is not connected. Then there exist disjoint open sets U, V such that $M_k \subset U \cup V$ and $M_k \cap U \ne \emptyset \ne M_k \cap V$. Let $M_k^+ = M_k \cap U$, and let $M_k^- = M_k \cap V$. We claim that, for any complete trajectory γ in $\mathcal{S}$, none of the following cases will occur:

(1) $\omega(\gamma) \cap M_k^+ \ne \emptyset \ne \omega(\gamma) \cap M_k^-$, or $\alpha(\gamma) \cap M_k^+ \ne \emptyset \ne \alpha(\gamma) \cap M_k^-$;

(2) $\omega(\gamma) \subset M_k^+$ and $\alpha(\gamma) \subset M_k^-$, or $\omega(\gamma) \subset M_k^-$ and $\alpha(\gamma) \subset M_k^+$.

Indeed, the first case does not occur because the limit sets are connected. Suppose the latter case. Then we must have $\gamma(\mathbb{R}) \cap U \ne \emptyset \ne \gamma(\mathbb{R}) \cap V$ and $\gamma(\mathbb{R}) \subset M_k \subset U \cup V$. (The first inclusion is due to the fact that both ω- and α-limit sets of γ are contained in M_k.) This contradicts the connectedness of $\gamma(\mathbb{R})$. Hence the claim holds true.

Now let $\mathcal{M}' = \{M1, \dots, M_{k-1}, M_k^-, M_k^+, M_{k+1}, \dots, M_n\}$. One easily checks that $\mathcal{M}'$ is a Morse decomposition which is finer than $\mathcal{M}$, a contradiction! □

4. Stability of Morse decompositions of attractors for GDSs. We first state and prove the following basic results.

THEOREM 4.1. *Let $\mathcal{A}$ be an attractor of G, and let $\mathcal{A}_0 \subset \mathcal{A}$ be an attractor of G in $\mathcal{A}$. Then $\mathcal{A}_0$ is also an attractor of G (in X).*

Proof. We first show that $\mathcal{A}_0$ is Lyapunov stable in X. Suppose the contrary. Then one would find a $\delta > 0$ and an $\varepsilon_0 > 0$ such that, for any $0 < \varepsilon < \varepsilon_0$, there is an $x_\varepsilon \in \mathrm{B}(\mathcal{A}_0, \varepsilon)$ and a $t_\varepsilon > 0$ such that $G(t_\varepsilon)x_\varepsilon \setminus \mathrm{B}(\mathcal{A}_0, \delta) \ne \emptyset$. We may assume δ sufficiently small so that $\overline{\mathrm{B}}(\mathcal{A}_0, \delta) \subset \Omega(\mathcal{A})$, and $\overline{\mathrm{B}}(\mathcal{A}_0, \delta) \cap \mathcal{A}$ is a compact subset of $\Omega^{\mathcal{A}}(\mathcal{A}_0)$.

By Theorem 2.3 there is a trajectory γ_ε on $[0, t_\varepsilon]$ with $\gamma_\varepsilon(0) = x_\varepsilon \in \mathrm{B}(\mathcal{A}_0, \varepsilon)$ and $d\,(\gamma_\varepsilon(t_\varepsilon), \mathcal{A}_0) \ge \delta$. We may assume that

$$\gamma_\varepsilon([0, t_\varepsilon]) \subset \overline{\mathrm{B}}(\mathcal{A}_0, \delta);$$

otherwise, we can choose t_ε as $t_\varepsilon = \inf\{t > 0 |\ d\,(\gamma_\varepsilon(t), \mathcal{A}_0) \ge \delta\}$. We claim that $t_\varepsilon \to +\infty$ as $\varepsilon \to 0$. Indeed, if this is not the case, then there would exist a sequence $x_n := x_{\varepsilon_n} \to x_0 \in \mathcal{A}_0$ such that the sequence $t_n := t_{\varepsilon_n}$ is bounded. By axiom (3) in Definition 2.1,

$$d\,(\gamma_{\varepsilon_n}(t_n), \mathcal{A}_0) = d\,(\gamma_{\varepsilon_n}(t_n), G(t_n)\mathcal{A}_0) \le d_{\mathrm{H}}\,(G(t_n)x_n, G(t_n)x_0) \to 0$$

as $n \to \infty$, which leads to a contradiction and proves our claim. Now let

$$\sigma_\varepsilon(t) = \gamma_\varepsilon(t_\varepsilon + t) \qquad \text{for } t \in [-t_\varepsilon, 0].$$

Then σ_ε is a trajectory of G on $[-t_\varepsilon, 0]$. Invoking Barbashin's theorem, we can extract a subsequence $\sigma_n := \sigma_{\varepsilon_n}$ with $\varepsilon_n \to 0$ such that σ_n converges to some trajectory $\sigma : (-\infty, 0] \to \overline{\mathrm{B}}(\mathcal{A}_0, \delta)$ uniformly on any compact interval $[t, 0]$. Since $d(\sigma_n(0), \mathcal{A}_0) = \delta$, we necessarily have $d(\sigma(0), \mathcal{A}_0) = \delta$. Now we extend σ to a complete trajectory, still denoted by σ. Then since $\sigma(0) \in \Omega(\mathcal{A})$, we see that $\sigma(\mathbb{R}) \subset \Omega(\mathcal{A})$. We infer from

$$\sigma((-\infty, 0]) \subset \overline{\mathrm{B}}(\mathcal{A}_0, \delta) \subset \Omega(\mathcal{A})$$

that $\sigma(\mathbb{R}) \subset \mathcal{A}$. It follows that $\alpha(\sigma) \subset \overline{\mathrm{B}}(\mathcal{A}_0, \delta) \cap \mathcal{A}$. Using the same argument as in the proof of Proposition 3.5(1), one can easily check that $\sigma(\mathbb{R}) \subset \mathcal{A}_0$, which contradicts to $d(\sigma(0), \mathcal{A}_0) = \delta > 0$. Hence $\mathcal{A}_0$ is Lyapunov stable.

Now we proceed to prove that $\mathcal{A}_0$ is an attractor of G in X. Take $0 < \delta_0 < \delta_1 < \delta_2$ such that $\overline{\mathrm{B}}(\mathcal{A}_0, \delta_2) \subset \Omega(\mathcal{A})$ and $\overline{\mathrm{B}}(\mathcal{A}_0, \delta_2) \cap \mathcal{A}$ is a compact subset of $\Omega^{\mathcal{A}}(\mathcal{A}_0)$; moreover,

$$G(\mathbb{R}^+)\overline{\mathrm{B}}(\mathcal{A}_0, \delta_0) \subset \overline{\mathrm{B}}(\mathcal{A}_0, \delta_1), \quad G(\mathbb{R}^+)\overline{\mathrm{B}}(\mathcal{A}_0, \delta_1) \subset \overline{\mathrm{B}}(\mathcal{A}_0, \delta_2).$$

Note that $\mathcal{A}_0$ is an isolated invariant, as $\mathcal{A}$ is an attractor of G. We show that $\mathrm{B}(\mathcal{A}_0, \delta_0) \subset \Omega(\mathcal{A}_0)$, and thus $\mathcal{A}_0$ is an attractor of G in X.

For this purpose, we first check that

$$\omega(x) \subset \Omega(\mathcal{A}_0), \qquad x \in \mathrm{B}(\mathcal{A}_0, \delta_0). \tag{4.1}$$

Let $x \in \mathrm{B}(\mathcal{A}_0, \delta_0)$. Then $\omega(x)$ is a nonempty compact set, and $\omega(x) \subset \overline{\mathrm{B}}(\mathcal{A}_0, \delta_1)$. Let $y \in \omega(x)$. Since $\omega(x)$ is negatively invariant, there is a trajectory $\gamma : (-\infty, 0] \to \omega(x)$ with $\gamma(0) = y$. We extend γ to a complete trajectory, still denoted by γ. Then $\gamma(\mathbb{R}) \subset \overline{\mathrm{B}}(\mathcal{A}_0, \delta_2)$. As above, we can again show that γ is in fact contained in $\mathcal{A}_0$. Thus $y \in \mathcal{A}_0$.

Now $x \in \mathrm{B}(\mathcal{A}_0, \delta_0) \subset \Omega(\mathcal{A})$ implies $\omega(x) \subset \mathcal{A}$. This and (4.1) imply that $\omega(x) \subset \mathcal{A}_0$. □

THEOREM 4.2. *Let $\mathcal{A}$ be an attractor, and let $\mathcal{M} = \{M_1, \dots, M_n\}$ be a Morse decomposition of $\mathcal{A}$. Then for each trajectory $\gamma : \mathbb{R}^+ \to X$ with $\gamma(0) \in \Omega(\mathcal{A})$, there is a k such that*

$$\lim_{t \to \infty} d(\gamma(t), M_k) = 0.$$

Proof. Let $\emptyset = \mathcal{A}_0 \subset \mathcal{A}_1 \subset \cdots \subset \mathcal{A}_n = \mathcal{A}$ be the attractor sequence that corresponds to $\mathcal{M}$. Then there is a smallest k such that $\omega(\gamma) \subset \mathcal{A}_k$. A direct inspection shows that $\omega(\gamma) \subset M_k$, and the conclusion follows. □

The main result in this section is the following theorem.

THEOREM 4.3. *Let G_λ ($\lambda \in \Lambda$) be a family of GDS on X, where Λ is a metric space with metric $\rho(\cdot, \cdot)$. Assume G_λ satisfies the continuity assumption* (C0) *in Theorem* 2.9 *at $\lambda_0 \in \Lambda$.*

Let $\mathcal{A}$ be an attractor of $G = G_{\lambda_0}$ with Morse decomposition $\mathcal{M} = \{M_1, \dots, M_n\}$. Then when $\rho(\lambda, \lambda_0)$ is sufficiently small, G_λ has an attractor $\mathcal{A}(\lambda)$ with Morse decomposition $\mathcal{M}(\lambda) = \{M_1(\lambda), \dots, M_n(\lambda)\}$; moreover, for each $1 \le k \le n$, we have

$$\lim_{\lambda \to \lambda_0} d_{\mathrm{H}}(M_k(\lambda), M_k) = 0.$$

Proof. Let $\emptyset = \mathcal{A}_0 \subset \mathcal{A}_1 \subset \cdots \subset \mathcal{A}_n = \mathcal{A}$ be the increasing sequence of attractors associated with the Morse decomposition $\mathcal{M}$. Then $\mathcal{A}_k$ are also attractors of G in X.

Let $\varepsilon > 0$ be given arbitrarily. We may assume that ε is small so that $\overline{\mathrm{B}}(\mathcal{A}_k, \varepsilon) \subset \Omega(\mathcal{A}_k)$ for all $1 \le k \le n$ and are compact. Let $\widetilde{\mathcal{A}}^*_k = X \setminus \Omega(\mathcal{A}_k)$. Then it is trivial to verify that $M_k = \mathcal{A}_k \cap \widetilde{\mathcal{A}}^*_{k-1}$. We observe that

$$\mathrm{B}(\mathcal{A}_k, \varepsilon) \cap \mathrm{B}\left(\widetilde{\mathcal{A}}^*_{k-1}, \varepsilon\right) \subset \mathrm{B}(M_k, \varepsilon). \tag{4.2}$$

Let $V_k = \overline{\mathrm{B}}(\mathcal{A}_k, \varepsilon) \setminus \mathrm{B}(\widetilde{\mathcal{A}}^*_{k-1}, \varepsilon)$. Note that V_k is a compact subset of $\Omega(\mathcal{A}_{k-1})$. Thanks to Theorem 2.9, there is a $\delta > 0$ such that, when $\rho(\lambda, \lambda_0) < \delta$, G_λ has for each k an attractor $\mathcal{A}_k(\lambda)$ with

$$\mathcal{A}_k(\lambda) \subset \mathrm{B}(\mathcal{A}_k, \varepsilon), \quad V_k \subset \Omega\left(\mathcal{A}_{k-1}(\lambda)\right). \tag{4.3}$$

Since $\overline{\mathrm{B}}(\mathcal{A}_k, \varepsilon) \subset \Omega(\mathcal{A}_k)$ and is compact, we can also assume $\delta > 0$ is sufficiently small so that by Theorem 2.9 we also have $\overline{\mathrm{B}}(\mathcal{A}_k, \varepsilon) \subset \Omega(\mathcal{A}_k(\lambda))$ for $0 \le k \le n$, and consequently for each k fixed,

$$\mathcal{A}_i(\lambda) \subset \mathrm{B}(\mathcal{A}_i, \varepsilon) \subset \mathrm{B}(\mathcal{A}_k, \varepsilon) \subset \Omega(\mathcal{A}_k(\lambda)) \qquad \text{for } i \le k,$$

which implies $\mathcal{A}_i(\lambda) \subset \mathcal{A}_k(\lambda)$ for all $i \le k$. Therefore

$$\emptyset = \mathcal{A}_0(\lambda) \subset \mathcal{A}_1(\lambda) \subset \cdots \subset \mathcal{A}_n(\lambda) = \mathcal{A}(\lambda)$$

is an increasing sequence of attractors of G_λ.

Let $M_k(\lambda) = \mathcal{A}_k(\lambda) \cap \mathcal{A}^*_{k-1}(\lambda)$. Then $\mathcal{M}(\lambda) = \{M_1(\lambda), \ldots, M_n(\lambda)\}$ is a Morse decomposition of $\mathcal{A}(\lambda)$. There remains to check that $M_k(\lambda) \subset \mathrm{B}(M_k, \varepsilon)$. Indeed, by Theorem 3.7 we know that $M_k(\lambda)$ is the repeller of G_λ in $\mathcal{A}_k(\lambda)$ dual to $\mathcal{A}_{k-1}(\lambda)$. Therefore by Proposition 3.4(1),

$$M_k(\lambda) = \mathcal{A}_k(\lambda) \setminus \Omega^{\mathcal{A}_k(\lambda)}(\mathcal{A}_{k-1}(\lambda)) = \mathcal{A}_k(\lambda) \setminus \Omega(\mathcal{A}_{k-1}(\lambda)).$$

Further by (4.3) we find that

$$\begin{aligned} M_k(\lambda) &\subset \mathrm{B}(\mathcal{A}_k, \varepsilon) \setminus V_k = \mathrm{B}(\mathcal{A}_k, \varepsilon) \setminus \left(\overline{\mathrm{B}}(\mathcal{A}_k, \varepsilon) \setminus \mathrm{B}\left(\widetilde{\mathcal{A}}^*_{k-1}, \varepsilon\right)\right) \\ &\subset \mathrm{B}(\mathcal{A}_k, \varepsilon) \setminus \left(\mathrm{B}(\mathcal{A}_k, \varepsilon) \setminus \mathrm{B}\left(\widetilde{\mathcal{A}}^*_{k-1}, \varepsilon\right)\right) \\ &= \mathrm{B}(\mathcal{A}_k, \varepsilon) \cap \mathrm{B}\left(\widetilde{\mathcal{A}}^*_{k-1}, \varepsilon\right) \subset (\text{by (4.2)}) \subset \mathrm{B}(M_k, \varepsilon). \end{aligned}$$

The proof of the theorem is complete. □

Some results concerning the robustness of Morse decompositions under discretization for specific functional differential equations can be found in Gedeon and Hines [20, 21], etc.

Remark 4.4. We remark that some of the perturbed Morse sets $M_k(\lambda)$ in Theorem 4.3 may be $\emptyset$, even if each M_k is nonvoid. This can be seen by considering the scalar equation:

$$x'(t) = -(x+2)(x^2-1)x^2,$$

which has an equilibrium $E = 0$ that disappears when we add an arbitrary small positive number $\lambda > 0$ in the right-hand side.

THEOREM 4.5. *Assume the hypothesis in Theorem* 4.3. *Let $\mathcal{A}$ be an attractor of G_{λ_0} with Morse decomposition $\mathcal{M} = \{M_1, \ldots, M_n\}$. Then for any compact subset K*

of $\Omega(\mathcal{A})$ *and* $\varepsilon > 0$*, there exists* $\delta > 0$ *such that when* $\rho(\lambda, \lambda_0) < \delta$*, for any trajectory* γ *of* G_λ *with* $\gamma(0) \in K$*,*

$$\limsup_{t\to\infty} d\left(\gamma(t),\, M_k\right) \le \varepsilon$$

for some M_k*.*

Proof. It is a consequence of Theorems 2.9, 4.2, and 4.3. □

5. Morse decompositions for differential inclusions. Consider the differential inclusion on $\mathbb{R}^m$

$$x'(t) \in f(x(t)), \qquad t \ge 0, \tag{5.1}$$

where f is always assumed to satisfy the following assumptions:

(H1) $f(x)$ is a nonempty convex compact subset of $\mathbb{R}^m$ for every $x \in \mathbb{R}^m$;

(H2) f is upper semicontinuous.

Let I be an interval. A mapping $x(\cdot) : I \to \mathbb{R}^m$ is said to be a *solution* of (5.1) on I if it is absolutely continuous on any compact interval $J \subset I$ and solves (5.1) at a.e. $t \in I$.

A solution on $\mathbb{R}$ will be simply called a *complete solution*.

The *reachable mapping* $\mathcal{F}$ of (5.1) is defined as, for all $(t, x) \in \mathbb{R}^+ \times \mathbb{R}^m$,

$$\mathcal{F}(t)x = \{x(t)|\ x(\cdot) \text{ is a solution of (5.1) with } x(0) = x\}.$$

Although $\mathcal{F}$ is a GDS on $\mathbb{R}^m$ provided no solutions of (5.1) blow up in finite time [31], we prefer to introduce the dynamical concepts for (5.1) while disregarding the blowup of solutions which may be outside our interest. For instance, for two subsets A and V of $\mathbb{R}^m$ we say that A attracts V; this means no solutions $x(\cdot)$ with $x(0) \in V$ blow up in finite time, and $d_{\mathrm{H}}(\mathcal{F}(t)V,\, A) \to 0$ as $t \to \infty$. The other concepts such as attraction regions, asymptotic stability, limit sets, invariant sets, attractors, and Morse decompositions can also be defined in the same manner as we do in the situation of GDSs. We omit the details.

PROPOSITION 5.1. *Let* Ω *be a locally compact subset of* $\mathbb{R}^m$*. If* Ω *is positively invariant, then* $\mathcal{F}$ *is a GDS on* Ω*.*

Proof. The proof is a slight modification of the one for Theorem 5.4 in Li and Zhang [31]. □

Remark 5.2. Thanks to Proposition 5.1, one can immediately apply the abstract results in sections 3 and 4 (except Theorems 4.3 and 4.5) to system (5.1) restricted on any locally compact positively invariant sets to establish a Morse decomposition theory for differential inclusions (without any additional assumptions on $f(x)$). Since the results are just copies of those for GDSs, their statements are thus omitted. When referring to these results, we will directly consult the corresponding ones in previous sections.

Now let us give two simple examples on Morse decompositions.

Example 5.1 (gradient system). Let Ω be an open subset of $\mathbb{R}^m$. We say that (5.1) is a *gradient system* on Ω; there exists a function $V(x)$ on Ω such that, for any solution $x(\cdot)$ of (5.1) contained in Ω, $V(x(t))$ strictly decreases whenever $x(\cdot)$ is not an equilibrium. $V(x)$ is called a *Lyapunov function* of (5.1) on Ω.

An example for gradient systems is the one in which $f(x) = -\partial V(x)$, where $V : \mathbb{R}^m \to \mathbb{R}$ is a locally Lipschitz sleek function or a lower semicontinuous convex function and $\partial V(x)$ is the generalized gradient of $V(x)$; see [3, p. 341] and [4, p. 158] for details.

Suppose that (5.1) is a gradient system on Ω with a Lyapunov function $V(x)$ satisfying $V(x) \to +\infty$ as $x \to \partial\Omega$; i.e., for any $a > 0$ there is a compact subset K of Ω such that

$$V(x) > a \qquad \forall\, x \in \Omega \setminus K.$$

Then the set $\mathcal{E}$ of equilibria of the system in Ω is nonvoid, as the minimum point x_* of V in Ω exists and is necessarily an equilibrium. Furthermore, it can be easily shown that the system has an attractor $\mathcal{A}$ in Ω. If we further assume $\mathcal{E}$ to be finite,

$$\mathcal{E} = \{E_k|\ k = 1, 2, \ldots, n\},$$

where E_k $(k = 1, 2, \ldots, n)$ are ordered so that $V(E_i) \le V(E_j)$ when $i < j$, then by Theorem 3.8 (in fact, a copy of this theorem to differential inclusions) we easily deduce that $\{E_1, \ldots, E_n\}$ forms a natural Morse decomposition of $\mathcal{A}$.

Example 5.2. Consider the following differential inclusion which relates to the generalized equations governing Chua's circuit [8]:

$$\begin{pmatrix} \dot{x}_1 \\ \dot{x}_2 \\ \dot{x}_3 \end{pmatrix} \in A \begin{pmatrix} x_1 - k\,\mathrm{Sgn}(x_1) \\ x_2 \\ x_3 + k\,\mathrm{Sgn}\ (x_1) \end{pmatrix}, \quad A = \begin{pmatrix} -\alpha(b+1) & \alpha & 0 \\ 1 & -1 & 1 \\ 0 & -\beta & 0 \end{pmatrix}, \tag{5.2}$$

where $\dot{x}_i = x_i'(t)$ and $\mathrm{Sgn}(x)$ corresponds to the signal function,

$$\mathrm{Sgn}(x) = 1\ (x > 0), \quad \mathrm{Sgn}(x) = -1\ (x < 0), \quad \mathrm{Sgn}(0) = [-1, 1].$$

Taking $\alpha = -1$, $\beta = 288$, $b = -36$, and $k = 1$, the system reads as follows:

$$\begin{pmatrix} \dot{x}_1 \\ \dot{x}_2 \\ \dot{x}_3 \end{pmatrix} \in A_0 \begin{pmatrix} x_1 \\ x_2 \\ x_3 \end{pmatrix} + \begin{pmatrix} 35\mathrm{Sgn}(x_1) \\ 0 \\ 0 \end{pmatrix}, \quad A_0 = \begin{pmatrix} -35 & -1 & 0 \\ 1 & -1 & 1 \\ 0 & -288 & 0 \end{pmatrix}. \tag{5.3}$$

Simple computations show that all the eigenvalues of A_0 are negative, so the system (5.3) is dissipative and has a global attractor $\mathcal{A}$. (5.3) has three equilibria:

$$E_1 = (-1, 0, 1), \quad E_2 = (1, 0, -1), \quad E_3 = (0, 0, 0),$$

where E_1 and E_2 are asymptotically stable. Let $\mathcal{A}_0 = \emptyset$, $\mathcal{A}_1 = \{E_1\}$, $\mathcal{A}_2 = \{E_1, E_2\}$, and $\mathcal{A}_3 = \mathcal{A}$. Then $\{\mathcal{A}_k\}$ is an increasing attractor sequence which yields a Morse decomposition $\mathcal{M} = \{M_1, M_2, M_3\}$ of $\mathcal{A}$ with

$$M_1 = \{E_1\}, \quad M_2 = \{E_2\}, \quad E_3 \in M_3.$$

Concerning the stability of Morse decompositions, we have the following.

THEOREM 5.3. *Assume* (5.1) *has an attractor* $\mathcal{A}$ *with Morse decomposition* $\{M_1, \ldots, M_n\}$. *Then for any compact subset* K *of* $\Omega(\mathcal{A})$, *there exists a* $\delta > 0$ *such that, when* $0 \le \lambda < \delta$, *the inflated system*

$$x'(t) \in f_\lambda(x(t)), \qquad f_\lambda(x) = \overline{\mathrm{conv}}\ f\left(x + \lambda\overline{B}_1\right) + \lambda\overline{B}_1, \tag{5.4}$$

where B_r *denotes the ball* $B(0, r)$ *in* $\mathbb{R}^m$, *has an attractor* $\mathcal{A}(\lambda)$ *with* $K \subset \Omega(\mathcal{A}(\lambda))$ *and a Morse decomposition* $\{M_1(\lambda), \ldots, M_n(\lambda)\}$; *moreover,*

$$\lim_{\lambda \to 0} \delta_H\left(M_k(\lambda),\, M_k\right) = 0 \qquad \forall\ 1 \le k \le n. \tag{5.5}$$

Proof. The proof of the theorem can be obtained by slightly modifying the proof of Theorem 2.10 in [32] and applying Theorem 4.3. We omit the details. □

As a consequence of the above theorem and Theorem 4.2, we have the following.

THEOREM 5.4. *Assume* (5.1) *has an attractor* $\mathcal{A}$ *with Morse decomposition* $\{M_1, \dots, M_n\}$. *Let* $K \subset \Omega(\mathcal{A})$ *be compact. Then for any compact subset* K *of* $\Omega(\mathcal{A})$ *and* $\varepsilon > 0$, *there is a* $\delta > 0$ *such that when* $\lambda < \delta$, *for any solution* $x(\cdot)$ *of the perturbed system* (5.4) *with* $x(0) \in K$, *we have*

$$\limsup_{t\to\infty} d\,(x(t),\, M_k) \le \varepsilon$$

for some M_k.

6. Chain recurrent sets and Morse decompositions. This section is concerned with the open-loop system on $\mathbb{R}^m$:

$$x'(t) = f(x(t), u(t)), \qquad u \in \mathscr{U}, \tag{6.1}$$

where $\mathscr{U} = \{u \in L^\infty(\mathbb{R}; \mathbb{R}^d)|\ u(t) \in U \text{ for a.e. } t \in \mathbb{R}\}$ is the set of admissible controls (inputs), and $U \subset \mathbb{R}^d$ is the control range.

It is well known that chain recurrent sets, chain recurrent components, and chain control sets play a crucial role in the dynamical theory of control. As one of our main purposes here, we give a detailed discussion on the relations between these sets and Morse decompositions. In case one could associate the control system with a single-valued control flow defined on the lifted phase space $\mathscr{X} = \mathscr{U} \times \mathbb{R}^m$, where $\mathscr{U}$ is equipped with the weak*-topology [13, 14], all the results presented below can be obtained by applying some known ones in the theory of single-valued dynamical systems. However, to do so we have to impose on the system some strong assumptions to guarantee the continuity of the control flow. For instance, a typical assumption in this line is to assume that the system is affine in control [13], i.e.,

$$f(x, u) = h(x) + \sum_{1\le i\le d} u_i g_i(x).$$

Our approach here is to connect control systems directly with differential inclusions, which enables us to work under weaker conditions.

We first recall that a mapping $x(\cdot) : I \to \mathbb{R}^m$ is said to be a *solution* of (6.1) on I with input $u \in \mathscr{U}$, if it is absolutely continuous on any compact interval $J \subset I$ and the pair $(x(\cdot), u)$ solves (6.1) at a.e. $t \in I$.

We will denote by $\phi(t, x, u)$ a solution of (6.1) with input u and $\phi(0, x, u) = x$.

THEOREM 6.1 (see [36]). *Assume that the following assumptions hold:*

(C1) *The control* U *is compact;*

(C2) $f(x, u)$ *is continuous with* $F(x) := \{f(x, u)|\ u \in U\}$ *being convex for each* $x \in \mathbb{R}^m$.

Then the open-loop system (6.1) *is equivalent to the following differential inclusion:*

$$x'(t) \in F(x(t)). \tag{6.2}$$

Remark 6.2. Note that under the assumptions (C1) and (C2), $F(x)$ is a continuous set valued mapping with compact convex images.

There is an additional assumption "$f(x, u) \le c(1 + |x|)$ for all $x \in \mathbb{R}^m$" in [36]. However, we point out that this can be removed by using appropriate cutoff functions. In fact, if $x(\cdot)$ is a solution of (6.2) on $[0, T)$, then for any $\tau < T$, $x(\cdot)$ is bounded on

$[0,\tau]$. Assume that $|x(t)| \le R$ on $[0,\tau]$. Let $a(x)$ be a continuous function on $\mathbb{R}^m$ with $a(x) \equiv 1$ for $|x| \le R$ and $a(x) \equiv 0$ for $|x| > 2R$. Then $x(\cdot)$ solves $x'(t) \in a(x(t))F(x(t))$ on $[0,\tau]$. Noting that

$$a(x)F(x) = \{a(x)f(x,u)|\ u \in U\}$$

and that $a(x)f(x,u)$ is bounded, by the original result in [36] one immediately concludes that $x(\cdot)$ is a solution (6.1) on $[0,\tau]$. Since τ is arbitrary, we see that $x(\cdot)$ is a solution of (6.1) on $[0,T)$. Conversely, it is clear that any solution of (6.1) is a solution of (6.2).

Due to Theorem 6.1, we will not distinguish the control system (6.1) with differential inclusion (6.2) in the following argument, and all the dynamical concepts without definitions below are understood with respect to (6.2).

Throughout this section we will always assume and only assume that (C1), (C2), and a local Lipschitz continuity condition (C3) are satisfied, where (C3) is given as follows:

(C3) $f(x,u)$ is locally Lipschitz in x in a uniform manner with respect to $u \in U$; i.e., for any bounded set $B \subset \mathbb{R}^m$, there exists $L_B > 0$ such that

$$|f(x,u) - f(y,u)| \le L_B|x-y| \qquad \forall\, x,y \in B,\ u \in U. \tag{6.3}$$

We emphasize that in our case it is difficult to define a continuous control flow on the lifted space mentioned above. The main difficulty lies in verifying the continuity of the flow due to the nonlinearity of $f(x,u)$ in u (recall that $\mathscr{U}$ is equipped with the weak*-topology).

We denote by $\mathcal{F}$ the reachable mapping of (6.2).

DEFINITION 6.3. *Let K be a closed subset of $\mathbb{R}^m$. For $x,y \in \mathbb{R}^m$ and $\varepsilon, T > 0$, an (ε,T)-chain ζ in K from x to y is given by a positive integer $n \in \mathbb{N}$, $x_0,\dots,x_n \in \mathbb{R}^m$, $u_0,\dots,u_{n-1} \in \mathscr{U}$, and $T_0,\dots,T_{n-1} \ge T$ with $x_0 = x$, $x_n = y$ and*

$$\phi([0,T_i],\, x_i, u_i) \subset K, \quad |\phi(T_i,x_i,u_i) - x_{i+1}| < \varepsilon, \qquad i = 0,1,\dots,n-1.$$

If for all $\varepsilon, T > 0$ there is an (ε,T)-chain from x to y in K, then we say that x is chain controllable to y in K.

Remark 6.4. The set K can be viewed as a constraint. In case $K = \mathbb{R}^m$, we will simply drop the words "in K" in the above definition.

Let $K \subset \mathbb{R}^m$ be closed, $A \subset K$. Define the *K-chain limit set* $\mathscr{C}_K(A)$ as

$$\mathscr{C}_K(A) = \{y \in \mathbb{R}^m|\ \exists\, x \in A \text{ such that } x \text{ is chain controllable to } y \text{ in } K\}.$$

LEMMA 6.5. *Let K be a compact positively invariant set, $A \subset K$. Then $\mathscr{C}_K(A)$ is a compact invariant set with $\omega(A) \subset \mathscr{C}_K(A)$.*

Proof. We prove only the negative invariance of $\mathscr{C}_K(A)$. The closedness and positive invariance as well as inclusion "$\omega(A) \subset \mathscr{C}_K(A)$" can be easily examined.

Let $z \in \mathscr{C}_K(A)$ and $s > 0$. We need to check that there exits $w \in \mathscr{C}_K(A)$ such that $z \in F(s)w$.

Let $\varepsilon_k = 1/k$. Take a sequence of positive numbers $s \le \tau_k \to +\infty$. Then for each k there exists $0 < \delta_k < \varepsilon_k$ such that

$$|\phi(t,x,u) - \phi(t,y,u)| < \varepsilon_k \qquad \forall\, t \in [0,4\tau_k]\ \forall\, u \in \mathscr{U} \tag{6.4}$$

for all $x,y \in K$ with $|x-y| < \delta_k$ (this follows from the Lipschitz continuity property of f). Since $z \in \mathscr{C}_K(A)$, there is a $\widehat{x} \in A$ such that for each k one can find a

$(\delta_k, 2\tau_k)$-chain from $\widehat{x}$ to z in K given by

$$\widehat{x} = x_0, x_1, \ldots, x_{n_k-1}, x_{n_k} = z, \quad u_0, u_1, \ldots, u_{n_k-1} \in \mathscr{U}, \quad T_0, T_1, \ldots, T_{n_k-1} \geq 2\tau_k.$$

We may assume that $T_i \leq 4\tau_k$. Otherwise, since there is no limitation on the number n_k of "jumps," one could modify the original chain to such a one by just dividing the time intervals with length larger than $4\tau_k$.

Set $w_k = \phi(T_{n_k-1} - s, x_{n_k-1}, u_{n_k-1})$. Then $d\,(z, \mathcal{F}(s)w_k) \leq \delta_k$. Since K is compact, we may assume that $w_k \to w$. By upper semicontinuity of $\mathcal{F}$ we have $z \in \mathcal{F}(s)w$. There remains to verify that $w \in \mathscr{C}_K(A)$. For this purpose we first formulate for each w_k an (ε_k, τ_k)-chain from $\widehat{x}$ to w_k in K.

If $n_k = 1$, then clearly

$$\widetilde{x}_0 = \widehat{x}, \quad \widetilde{x}_1 = w_k \in \mathbb{R}^m, \quad \widetilde{T}_0 = T_0 - s \geq \tau_k, \quad \text{and} \quad \widetilde{u}_0 = u_0 \in \mathscr{U}$$

give an (ε_k, τ_k)-chain from $\widehat{x}$ to w_k. So we assume that $n_k \geq 2$. Define $\widetilde{u}_{n_k-2} \in \mathscr{U}$ as

$$\widetilde{u}_{n_k-2}(t) = u_{n_k-2}(t) \quad (t < T_{n_k-2}), \quad \widetilde{u}_{n_k-2}(t) = u_{n_k-1}(t - T_{n_k-2}) \quad (t \geq T_{n_k-2}).$$

Let $\widetilde{T}_{n_k-2} = T_{n_k-2} + (T_{n_k-1} - s)$. Then

$$\begin{aligned} & |\phi(\widetilde{T}_{n_k-2},\, x_{n_k-2}, \widetilde{u}_{n_k-2}) - w_k| \\ = \;& |\phi\left(T_{n_k-1} - s,\, \phi\left(T_{n_k-2},\, x_{n_k-2}, u_{n_k-2}\right),\, u_{n_k-1}\right) - \phi(T_{n_k} - s, x_{n_k-1}, u_{n_k-1})| \end{aligned}$$

Because

$$|\phi\left(T_{n_k-2},\, x_{n_k-2}, u_{n_k-2}\right) - x_{n_k-1}| < \delta_k,$$

by (6.4) we deduce that $|\phi(\widetilde{T}_{n_k-2},\, x_{n_k-2}, \widetilde{u}_{n_k-2}) - w_k| < \varepsilon_k$. It follows that

$$\widehat{x} = x_0, \ldots, x_{n_k-2}, w_k \in \mathbb{R}^m, \quad u_0, \ldots, u_{n_k-3}, \widetilde{u}_{n_k-2} \in \mathscr{U}, \quad T_0, \ldots, T_{n_k-3}, \widetilde{T}_{n_k-2} \geq \tau_k$$

is an (ε_k, τ_k)-chain from $\widehat{x}$ to w_k in K.

Now since $\omega_k \to w$, one easily sees that, for any $\varepsilon, T > 0$, there is an (ε, T)-chain from $\widehat{x}$ to w in K. Hence $w \in \mathscr{C}_K(A)$. □

THEOREM 6.6. *Let K be a compact positively invariant set. Let A be a closed subset of K. Then $\mathscr{C}_K(A)$ is the intersection of all attractors of* (6.2) *in K containing $\omega(A)$.*

Proof. For $\varepsilon, T > 0$, define

$$\mathscr{C}_K(A, \varepsilon, T) = \{y \in K|\ \ \exists\, x \in A \text{ and an } (\varepsilon, T)\text{-chain from } x \text{ to } y \text{ in } K\}.$$

Then $\mathscr{C}_K(A, \varepsilon, T)$ is open in K. Note that $\mathscr{C}_K(A) = \bigcap_{\varepsilon, T>0} \mathscr{C}_K(A, \varepsilon, T)$. Indeed, it is clear that $\mathscr{C}_K(A) \subset \bigcap_{\varepsilon, T>0} \mathscr{C}_K(A, \varepsilon, T)$. Suppose that $y \in \bigcap_{\varepsilon, T>0} \mathscr{C}_K(A, \varepsilon, T)$. Then for each $k \in \mathbb{N}$, there is a $(1/k, k)$-chain from some x_k to y. As K is compact, we can assume $x_k \to x \in A$. Now using some techniques used above, for any $\varepsilon, T > 0$ one can easily formulate an (ε, T)-chain in K from x to y. Hence $y \in \mathscr{C}_K(A)$.

For $\varepsilon, T > 0$, let $V := \overline{\mathscr{C}}_K(A, \varepsilon, T)$. We claim that

$$\omega(V) \subset \mathscr{C}_K(A, \varepsilon, T) \subset \operatorname{int}_K V, \tag{6.5}$$

where $\text{int}_K V$ is the interior of V with respect to K. The second inclusion in (6.5) is in fact obvious. Now let $z \in \omega(V)$. Then there are $x_n \in V$, $t_n \to +\infty$, and $u_n \in \mathscr{U}$ such that $\phi(t_n, x_n, u_n) \to z$. Choose $n_0 \in \mathbb{N}$, $\delta > 0$, and $p \in \mathscr{C}_K(A, \varepsilon, T)$ such that

$$|p - x_{n_0}| < \delta, \quad t_{n_0} > T, \quad \text{and} \quad |\phi(t_{n_0}, x_{n_0}, u_{n_0}) - z| < \varepsilon/2,$$

$$|\phi(t_{n_0}, x, u_{n_0}) - \phi(t_{n_0}, x_{n_0}, u_{n_0})| < \varepsilon/2 \qquad \forall\, x \in K \text{ with } |x - x_{n_0}| < \delta.$$

By definition of p there is an (ε, T)-chain from some $y \in Y$ to p in K. We observe that

$$\begin{aligned} |\phi(t_{n_0}, p, u_{n_0}) - z| &\le |\phi(t_{n_0}, p, u_{n_0}) - \phi(t_{n_0}, x_{n_0}, u_{n_0})| + |\phi(t_{n_0}, x_{n_0}, u_{n_0}) - z| \\ &< \varepsilon/2 + \varepsilon/2 = \varepsilon. \end{aligned}$$

Thus concatenation yields an (ε, T)-chain from y to z in K. This proves (6.5).

(6.5) implies that $\mathcal{A} = \omega(V)$ is an attractor in K. By invariance of $\mathscr{C}_K(A)$, we find that

$$\mathcal{A} = \omega(\overline{\mathscr{C}}_K(A, \varepsilon, T)) \supset \omega(\mathscr{C}_K(A)) = \mathscr{C}_K(A) \supset \omega(A).$$

Therefore we have shown that, for any $\varepsilon, T > 0$, there is an attractor $\mathcal{A}$ of (6.2) in K containing $\omega(A)$ such that $\mathcal{A} \subset \mathscr{C}_K(A, \varepsilon, T)$. Consequently the intersection of all attractors of (6.2) in K containing $\omega(A)$ is necessarily contained in $\mathscr{C}_K(A)$.

Now suppose that $\mathcal{A}$ is an attractor in K containing $\omega(A)$. Let $\delta > 0$ be given arbitrarily but sufficiently small so that

$$V_k := \overline{\mathrm{B}}(\mathcal{A}, k\delta) \cap K \subset \Omega^K(\mathcal{A}), \qquad k = 1, 2.$$

Then V_k are neighborhoods of $\mathcal{A}$ in K and $\mathcal{A}$ attracts V_2. Therefore there is a $t_0 > 0$ such that $\mathcal{F}(t)V_2 \subset V_1$ for all $t > t_0$. Choose a $T > t_0$ such that $\mathcal{F}(T)A \subset V_1$. Then it is trivial to check that, when $\varepsilon < \delta$, any (ε, T)-chain in K from A must end in V_1. It follows that $\mathscr{C}_K(A) \subset V_1$. Since δ is arbitrary, we find $\mathscr{C}_K(A) \subset \mathcal{A}$. The proof is complete. □

Definition 6.7. *Let K be a closed subset of $\mathbb{R}^m$. A K-chain control set $\mathcal{D}$ is a maximal set in K with the property that, for any $x, y \in \mathcal{D}$, x is controllable to y in K.*

The K-chain recurrent set $\mathcal{R}_K$ is defined as

$$\mathcal{R}_K = \{x \in K |\ x \in \mathscr{C}_K(x)\}.$$

The connected components of $\mathcal{R}_K$ is said to be K-chain recurrent components.

Proposition 6.8. *Let K be a compact positively invariant set. Then the following hold:*

(1) *$\mathcal{D}$ is a K-chain control set if and only if it is a K-chain recurrent component;*

(2) *any K-chain recurrent component $\mathcal{D}$ is compact and weakly invariant.*

Proof. (1) The proof of this conclusion is just a copy of the one for [13, Proposition B.2.21] and is thus omitted.

(2) We check only the weak invariance of $\mathcal{D}$. The verification of compactness is trivial.

Let $x \in \mathcal{D}$. We need to show that there is a complete solution through x which lies in $\mathcal{D}$. For this purpose, it suffices to prove that there is a solution $x(\cdot) : [0, 1] \to \mathcal{D}$ as well as a solution $\widetilde{x}(\cdot) : [-1, 0] \to \mathcal{D}$ of (6.2) with $x(0) = x = \widetilde{x}(0)$.

Since $x \in \mathcal{D}$, for each $k \in \mathbb{N}$ there is a $(1/k, k)$-chain from x to x in K given by

$$x_0^k, \dots, x_{n_k}^k \in K, \quad u_0^k, \dots, u_{n_k-1}^k \in \mathscr{U}, \quad T_0^k, \dots, T_{n_k-1}^k \geq k,$$

with $x_0^k = x = x_{n_k}^k$. We can assume that $x_k(\cdot) = \phi(\cdot, x, u_0^k)$ converges uniformly on $[0,1]$ to a solution $x(\cdot)$. We show that $x(s) \in \mathcal{D}$ for all $s \in [0,1]$.

Let $\varepsilon, T > 0$ be given arbitrarily. We formulate an (ε, T)-chain ζ in K from $x(s)$ to $x(s)$ as follows. First, since each solution $x_k(\cdot)$ is defined on $[0, T+1]$ for k sufficiently large, by Barbashin's theorem one can also assume $x(\cdot)$ is defined on $[0, T+1]$ and that $x_k(\cdot)$ converges uniformly on $[0, T+1]$ to $x(\cdot)$. Let $x(t) = \phi(t, x, \widetilde{u})$ for some $\widetilde{u} \in \mathscr{U}$. We choose a $k > 2T + 1$ with $1/k < \varepsilon$ such that

$$|\phi(t, y, u) - \phi(t, z, u)| < \varepsilon \qquad \forall t \in [0, T+1],\ u \in \mathscr{U} \tag{6.6}$$

for all $y, z \in K$ with $|y - z| < 1/k$ and

$$|x_k(t) - x(t)| < \varepsilon \qquad \forall t \in [0, T+1]. \tag{6.7}$$

Define ζ as

$$x_0 = x(s), \quad x_1 = \phi(T + s, x_0^k, u_0^k), \quad x_i = x_{i-1}^k \text{ (for } 2 \leq i \leq n_k), \quad x_{n_k+1} = x(s);$$

$$u_0 = \widetilde{u}, \quad u_1(t) = u_0^k(T + s + t), \quad u_i = u_{i-1}^k \text{ (for } 2 \leq i \leq n_k - 1),$$

$$u_{n_k}(t) = u_{n_k-1}^k(t) \text{ (for } t \leq T_{n_k-1}^k), \quad u_{n_k}(t) = \widetilde{u}(t - T_{n_k-1}^k) \text{ (for } t > T_{n_k-1}^k),$$

$$T_0 = T, \quad T_1 = T_0^k - T - s, \quad T_i = T_{i-1}^k \text{ (for } 2 \leq i \leq n_k - 1), \quad T_{n_k} = T_{n_k-1}^k + s.$$

We claim that ζ is an (ε, T)-chain from $x(s)$ to $x(s)$.

Indeed, simple computations show that

$$|\phi(T_0, x_0, u_0) - x_1| = |x(T + s) - x_k(T + s)| < (\text{by (6.7)}) < \varepsilon,$$

$$|\phi(T_1, x_1, u_1) - x_2| = |\phi(T_0^k, x_0^k, u_0^k) - x_1^k| < 1/k < \varepsilon.$$

We also have

$$\begin{aligned} |\phi(T_{n_k}, x_{n_k}, u_{n_k}) - x_{n_k+1}| &= |\phi\left(s, \phi(T_{n_k-1}^k, x_{n_k-1}^k, u_{n_k-1}^k), \widetilde{u}\right) - x(s)| \\ &= |\phi\left(s, \phi(T_{n_k-1}^k, x_{n_k-1}^k, u_{n_k-1}^k), \widetilde{u}\right) - \phi(s, x, \widetilde{u})|. \end{aligned}$$

Because $|\phi(T_{n_k-1}^k, x_{n_k-1}^k, u_{n_k-1}^k) - x| < 1/k$, by (6.6) we find

$$|\phi(T_{n_k}, x_{n_k}, u_{n_k}) - x_{n_k+1}| < \varepsilon.$$

This finishes the proof of our claim. □

The proof for the existence of a solution $\widetilde{x}(\cdot) : [-1, 0] \to \mathcal{D}$ with $\widetilde{x}(0) = x$ is parallel.

Remark 6.9. Since K-chain recurrent components are compact, they are pairwise disjoint.

PROPOSITION 6.10. *Let K be a compact positively invariant set, and let $x(\cdot)$ be a complete solution in K. Then there are K-chain recurrent components $\mathcal{D}_1$ and $\mathcal{D}_2$ of $\mathcal{R}_K$ such that $\omega(x(\cdot)) \subset \mathcal{D}_1$ and $\alpha(x(\cdot)) \subset \mathcal{D}_2$. Further if $\mathcal{D}_1 = \mathcal{D}_2 = \mathcal{D}$, then $x(\mathbb{R}) \subset \mathcal{D}$.*

Proof. One easily checks that $\omega(x(\cdot)), \alpha(x(\cdot)) \subset \mathcal{R}_K$. Since they are connected, each of them is naturally contained in a K-chain recurrent component of $\mathcal{R}_K$.

In case $\mathcal{D}_1 = \mathcal{D}_2 = \mathcal{D}$, it can be shown that $x(\cdot)$ is contained in $\mathcal{R}_K$ with $\mathcal{D} \cup x(\mathbb{R})$ being a K-chain recurrent component (using the fact that $\mathcal{D}$ is a K-chain control set). Hence by maximality of chain recurrent components we must have $x(\mathbb{R}) \subset \mathcal{D}$.

For K-chain recurrent components $\mathcal{D}_1, \mathcal{D}_2 \subset \mathcal{R}_K$, we denote by $[\mathcal{D}_1, \mathcal{D}_2]$ the set

$$\{x \in K| \quad \text{there is a complete solution } x(\cdot) \text{ in } K \text{ with } x(0) = x \text{ and } \alpha(x(\cdot)) \subset \mathcal{D}_1,\ \omega(x(\cdot)) \subset \mathcal{D}_2\ \}.$$

Then by Proposition 6.10 we have $[\mathcal{D}, \mathcal{D}] = \mathcal{D}$ if K is a compact positively invariant set. □

THEOREM 6.11. *Assume $\mathcal{S}$ is a compact invariant set of* (6.2). *Let $\mathscr{A}$ be the family of attractors of* (6.2) *in $\mathcal{S}$. Then $\mathcal{R}_{\mathcal{S}} = \bigcap_{\mathcal{A} \in \mathbb{A}} (\mathcal{A} \cup \mathcal{A}^*)$.*

Proof. The proof is a slight modification of that of Theorem B.2.26 in [13] (Theorem 6.6 here plays a key role). We omit the details. □

Now we state and prove the following theorem.

THEOREM 6.12. *Assume $\mathcal{S}$ is a compact invariant set of* (6.2). *Let $\mathscr{M}$ be the family of Morse decompositions of $\mathcal{S}$. Then the following assertions hold.*

(1) $\mathcal{R}_{\mathcal{S}} = \bigcap_{\mathcal{M} \in \mathbb{M}} \left(\bigcup_{M \in \mathcal{M}} M\right)$.

(2) *Let $\mathcal{M}$ be a Morse decomposition of $\mathcal{S}$. Then each $\mathcal{S}$-chain recurrent component is contained in some Morse set $M \in \mathcal{M}$. Furthermore, for each $M \in \mathcal{M}$, there is a family $\mathscr{D}$ of $\mathcal{S}$-chain recurrent components such that $M = \bigcup_{\mathcal{D}_1, \mathcal{D}_2 \in \mathbb{D}} [\mathcal{D}_1, \mathcal{D}_2]$.*

(3) *If $\mathcal{R}_{\mathcal{S}}$ has only a finite number of $\mathcal{S}$-chain recurrent components, then $\mathcal{S}$ has the finest Morse decomposition $\mathcal{M}$ with each Morse set being precisely the $\mathcal{S}$-chain recurrent components of $\mathcal{R}_{\mathcal{S}}$.*
Conversely if $\mathcal{S}$ has the finest Morse decomposition $\mathcal{M}$, then $\mathcal{R}_{\mathcal{S}}$ has only a finite number of $\mathcal{S}$-chain recurrent components.

Proof. (1) Since, for any attractor $\mathcal{A}$ in $\mathcal{S}$, $\mathcal{M} = \{\mathcal{A}, \mathcal{A}^*\}$ is a Morse decomposition of $\mathcal{S}$, we see that the intersection is contained in $\mathcal{R}_{\mathcal{S}}$.

Conversely, let $\mathcal{M} = \{M_1, \ldots, M_n\} \in \mathscr{M}$. Then a direct inspection shows that

$$\bigcup_{1 \le k \le n} M_k = \bigcap_{1 \le k \le n} (A_k \cup \mathcal{A}_k^*),$$

where $\emptyset = \mathcal{A}_0 \subset \mathcal{A}_1 \subset \cdots \subset \mathcal{A}_n = \mathcal{A}$ is the increasing attractor sequence which corresponds to $\mathcal{M}$. Due to Theorem 6.11 we see that $\mathcal{R}_{\mathcal{S}} \subset \bigcup_{1 \le k \le n} M_k$. Hence $\mathcal{R}_{\mathcal{S}}$ is also contained in the intersection.

(2) The first conclusion follows from (1) and the fact that Morse sets in the same Morse decomposition are disjoint. Now assume $M \in \mathcal{M}$, and let

$$\mathscr{D} = \{\mathcal{D} \subset M| \ \mathcal{D} \text{ is a } \mathcal{S}\text{-chain recurrent component}\}.$$

Then by Proposition 6.10 we easily see that $M = \bigcup_{\mathcal{D}_1, \mathcal{D}_2 \in \mathbb{D}} [\mathcal{D}_1, \mathcal{D}_2]$.

(3) Suppose that $\mathcal{R}_{\mathcal{S}}$ has n $\mathcal{S}$-chain recurrent components. Let $\mathcal{M}$ be the set of these chain recurrent components.

We first prove that there is a $M \in \mathcal{M}$ which will be marked as M_n such that, for any complete solution $x(\cdot)$ of (6.2), if $\omega(x(\cdot)) \subset M$, then we necessarily have $\alpha(x(\cdot)) \subset M$. Indeed, if this fails to be true, then by Proposition 6.10 one can easily

find $\mathcal{D}_1, \dots, \mathcal{D}_k \in \mathcal{M}$ for some $2 \le k \le n$ and complete solutions $x_i(\cdot)$ $(1 \le i \le k)$ in $\mathcal{S}$ such that

$$\omega(x_i(\cdot)) \subset \mathcal{D}_i \ (1 \le i \le k), \quad \alpha(x_i(\cdot)) \subset \mathcal{D}_{i+1} \ (1 \le i \le k-1), \quad \text{and} \quad \alpha(x_k(\cdot)) \subset \mathcal{D}_1.$$

However this implies that $\bigcup_{1 \le i \le k} \mathcal{D}_i$ is a $\mathcal{S}$-chain recurrent component, a contradiction!

The same argument applies to show that there is a $M_{n-1} \in \mathcal{M}$ such that if a complete solution $x(\cdot)$ satisfies $\omega(x(\cdot)) \subset M_{n-1}$, then $\alpha(x(\cdot)) \subset M_{n-1} \cup M_n$. Continuing the procedure, we finally find that $\mathcal{M}$ can be ordered as $\mathcal{M} = \{M_1, \dots, M_n\}$ with the following property holding: for any complete solution $x(\cdot)$ in $\mathcal{S}$, if $\omega(x(\cdot)) \subset M_k$, then $\alpha(x(\cdot)) \subset M_k \cup \cdots \cup M_n$. Now Theorem 3.8 and Proposition 6.10 imply that $\mathcal{M}$ is a Morse decomposition of $\mathcal{S}$.

We proceed to show that $\mathcal{M}$ is the finest Morse decomposition. We argue by contradiction and suppose that there is a finer Morse decomposition $\widetilde{\mathcal{M}}$. Then using the increasing attractor sequence corresponding to $\widetilde{\mathcal{M}}$, one would find an attractor A in $\mathcal{S}$ such that $M_k \cap A$ is a proper subset of M_k. Take a $y \in M_k \setminus A$. Then $\delta = d(y, A) > 0$. Choose a positive number $\varepsilon_0 < \delta/3$ such that $V := \mathcal{S} \cap \overline{\mathrm{B}}(A, 2\varepsilon_0)$ is a compact subset of $\Omega^{\mathcal{S}}(A)$. Then A attracts V. Thus there exists a $T > 0$ such that $\mathcal{F}(t)V \subset V_0 := \mathcal{S} \cap \mathrm{B}(A, \varepsilon_0)$ for all $t \ge T$. This implies that, when $\varepsilon < \varepsilon_0$, any (ε, T)-chain in $\mathcal{S}$ from V_0 will end in V_0. Consequently there is no (ε, T)-chain in $\mathcal{S}$ from $x \in M_k \cap A$ to y. This contradicts the chain controllability of M_k (see Proposition 6.8).

Now we turn to the proof of the converse conclusion. Assume $\mathcal{S}$ has the finest Morse decomposition $\mathcal{M} = \{M_1, \dots, M_n\}$. Then each M_k is connected. By Remark 3.10 we deduce that, for any Morse decomposition $\mathcal{M}'$, $\bigcup_{1 \le k \le n} M_k \subset \bigcup_{M \in \mathcal{M}'} M$. It then follows from (1) that $\mathcal{R}_{\mathcal{S}} = \bigcup_{1 \le k \le n} M_k$. Therefore each Morse set M_k is a $\mathcal{S}$-chain recurrent component.

The proof of the theorem is complete. □

The following result seems to be interesting, too.

THEOREM 6.13. *Assume $\mathcal{S}$ is a compact invariant set of* (6.2). *Let $\mathscr{M}$ be the family of Morse decompositions of $\mathcal{S}$. Then for all $\varepsilon > 0$, there exists $\mathcal{M} \in \mathscr{M}$ such that $\bigcup_{M \in \mathcal{M}} M \subset B(\mathcal{R}_{\mathcal{S}}, \varepsilon)$.*

Proof. As in [2, Proposition 4.8], it is not difficult to show that there are at most countably many attractors in $\mathcal{S}$. Consequently $\mathscr{M}$ is at most countable. If $\mathscr{M}$ is finite, then the finest Morse decomposition exists, and the conclusion clearly holds true. So we assume $\mathscr{M}$ is infinite. Let $\mathscr{M} = \{\mathcal{M}_1, \mathcal{M}_2, \dots\}$. We choose a sequence $\{\mathcal{M}_{n_k}\}$ as follows. First, we let $\mathcal{M}_{n_1} = \mathcal{M}_1$. Then by using Lemma 3.9 we pick a $\mathcal{M}_{n_2}$ such that $\mathcal{M}_{n_2}$ is finer than both $\mathcal{M}_{n_1}$ and $\mathcal{M}_2$. We proceed by induction and assume that $\mathcal{M}_{n_k}$ is chosen. Then we next pick a $\mathcal{M}_{n_{k+1}}$ from $\mathscr{M}$ such that it is finer than both $\mathcal{M}_{n_k}$ and $\mathcal{M}_{k+1}$ (by Lemma 3.9, this is always available).

Set $A_k = \bigcup_{M \in \mathcal{M}_{n_k}} M$. Then $\{A_k\}$ is a decreasing sequence of compact sets; moreover, $A_k \subset \bigcup_{M \in \mathcal{M}_k} M$ for each k. Thus we conclude that $\mathcal{R}_{\mathcal{S}} = \bigcap_{k \ge 1} A_k = \lim_{k \to \infty} A_k$. Now for any $\varepsilon > 0$, one can easily verify that $A_k \subset \mathrm{B}(\mathcal{R}_{\mathcal{S}}, \varepsilon)$ for k sufficiently large, which proves the validity of the conclusion. □

7. Robustness of feedback laws to small time delays and sample-hold controls. Consider the control system on $\mathbb{R}^m$:

$$x'(t) = f(x(t), u(t)), \quad u(t) \in U, \tag{7.1}$$

where the control range U is a metric space. Given a target set $\mathcal{A} \subset \mathbb{R}^m$, a basic task in feedback control is to design a feedback law $\kappa : \mathbb{R}^m \to U$ so that $\mathcal{A}$ is asymptotically stable (asymptotic controllability) under the closed-loop system

$$x'(t) \in f(x(t),\, \kappa(x(t))). \tag{7.2}$$

(Here we have written the closed-loop system in the form of a differential inclusion instead of a differential equation; this is mainly due to the fact that in many situations the feedback laws may be set-valued [2] or discontinuous [7, 25].) Such a feedback law can be designed via control-Lyapunov functions; see [1, 25]. One can also consult [11] and [29], etc., in the case where $\mathcal{A}$ is an equilibrium.

A very natural and interesting problem is to ask whether the feedback κ (or equivalently the asymptotic behavior of the closed-loop system) possesses some nice robustness properties so that it still works when small time delays are involved in the feedback loop, when one uses a sample-hold control, or when there are measurement errors as well as external disturbances. This problem has important practical sense and has been discussed in the literature by many authors (especially in the case where $\mathcal{A}$ is an equilibrium); see, e.g., [1, 11, 22, 23, 25, 29, 32] and references therein. Here we will try to readdress the problem and establish some new results from the point of view of stability of Morse decompositions. We hope that these results provide more detailed information and thus help us to have a better understanding of the robustness of feedback laws.

7.1. Robustness with respect to small time delays. Consider the closed-loop system with small-time-delay r:

$$x'(t) \in f\left(x(t), \kappa(x_t)\right), \qquad t \geq 0, \tag{7.3}$$

where $x_t = x(t - r(t))$ and $r \in C(\mathbb{R}^+;\, [0, \tau])$ for some $\tau > 0$.

Let $|\cdot|$ be the usual Euclidean norm on $\mathbb{R}^m$. We write $\mathcal{C}_K = C([-\tau, 0]; K)$ for any $K \subset \mathbb{R}^m$. In particular, $\mathcal{C} = \mathcal{C}_{\mathbb{R}^m}$, which is equipped with the norm $\|\cdot\|$ defined by $\|\xi\| = \max_{[-\tau,0]} |\xi(t)|$ for any $\xi \in \mathcal{C}$.

A *solution* of (7.3) with initial value $\xi \in \mathcal{C}$ is a function $x(\cdot) : [-\tau, T) \to \mathbb{R}^m$ which is absolutely continuous on any compact interval $J \subset [0, T)$ and solves (7.3) at a.e. $t \in (0, T)$ with $x(t) = \xi(t)$ for $t \in [-\tau, 0]$. The reader is referred to [4] for existence results on delay differential inclusions.

We denote by $\psi(t, \xi)$ any solution $x(\cdot)$ of (7.3) with initial value ξ.

THEOREM 7.1. *Assume that $f(x) := f(x, \kappa(x))$ satisfies* (H1) *and* (H2). *Suppose that $\mathcal{A}$ is an attractor of the nondelayed system* (7.2) *with Morse decomposition $\{M_1, \ldots, M_n\}$.*

Then for any compact subset K of $\Omega(\mathcal{A})$ and $\varepsilon > 0$, there exist $\tau > 0$ such that, for any delay $r \in C(\mathbb{R}^+;\, [0, \tau])$ and any solution $\psi(t, \xi)$ of (7.3) *with $\xi \in \mathcal{C}_K$, we have*

$$\limsup_{t \to \infty} d\left(\psi(t, \xi),\, M_k\right) \leq \varepsilon \tag{7.4}$$

for some $1 \leq k \leq n$.

Proof. Take an $\eta > 0$ sufficiently small so that $V := \overline{\mathrm{B}}(K, \eta) \subset \Omega(\mathcal{A})$ and is compact. Then $\mathcal{A}$ attracts V under (7.2). Invoking [31, Lemma 5.2], there exists a $R > 0$ such that

$$|x(t)| \leq R \qquad \forall t \geq 0 \tag{7.5}$$

for any solution $x(\cdot)$ of (7.2) with $x(0) \in V$. Hence $K \subset V \subset \overline{\mathrm{B}}_R$.

Let $a(x)$ be a continuous cutoff function on $\mathbb{R}^m$ satisfying

$$a(x) = 1 \text{ when } |x| \le 3R, \qquad a(x) = 0 \text{ when } |x| \ge 4R.$$

Consider the modified systems

$$x'(t) \in h\,(x(t), x_t)\,, \qquad h(x,y) = a(x)a(y)f(x,\kappa(y)), \tag{7.6}$$

$$x'(t) \in H(x(t)), \qquad H(x) = h(x,x). \tag{7.7}$$

Clearly $\mathcal{A}$ is an attractor of (7.7) with $V \subset \Omega_H(\mathcal{A})$. Here $\Omega_H(\mathcal{A})$ is the attraction region of $\mathcal{A}$ under (7.7). For $\lambda > 0$, consider the inflation of (7.7):

$$x'(t) \in H_\lambda(x(t)), \qquad H_\lambda(x) = \overline{\text{conv}}\ H\left(x + \lambda\overline{\text{B}}_1\right) + \lambda\overline{\text{B}}_1. \tag{7.8}$$

Let $\varepsilon > 0$ be given arbitrarily. We may assume $\varepsilon < R/2$. Thanks to Theorem 5.4, there is a $\delta > 0$ such that when $\lambda < \delta$, for any solution $x(\cdot)$ of (7.8) with $x(0) \in V$, we have

$$\limsup_{t\to\infty} d\,(x(t),\, M_k) \le \varepsilon \tag{7.9}$$

for some k. Moreover, by (7.5) we can restrict δ sufficiently small (as in [32, equation (3.6)]) so that

$$|x(t)| \le 2R \qquad \forall t \ge 0. \tag{7.10}$$

We fix a $\lambda = \lambda_1 < \delta$ such that both (7.9) and (7.10) hold.

Note that h is bounded on $\mathbb{R}^{2m}$, so there is a $c_0 > 0$ such that $|h(x,y)| \le c_0$ for all $x, y \in \mathbb{R}^m$. Let $x(t) = \widetilde{\psi}(t,\xi)$ be any solution of (7.6) with initial value $\xi \in \mathcal{C}_K$. Then

$$|x_t - x(t)| = |x'(\theta)|r(t) \le c_0\tau \qquad \text{for } t \ge \tau,$$
$$|x(t) - x(0)| = |x'(\theta)|t \le c_0\tau \qquad \text{for } t \in [0,\tau].$$

Therefore if $\tau > 0$ is taken sufficiently small so that $c_0\tau < \min\{\eta, \lambda_1\}$, then

$$x(t) \in V \text{ (for } 0 \le t \le \tau), \qquad x_t \in \overline{\text{B}}(x(t), \lambda_1) \text{ (for } t \ge \tau). \tag{7.11}$$

Setting $z(t) = x(t+\tau)$ for $t \ge 0$, by (7.11) and the definition of h and H, one sees that $z(t)$ is a solution of the system $(7.8)_{\lambda=\lambda_1}$ with initial value $z(0) \in V$ on any interval $[0,T)$ where $|z(t)| = |x(t+\tau)| \le 2R$. This, together with (7.10), in turn implies that $|z(t)| \le 2R$ for all $t \ge 0$, i.e.,

$$|x(t+\tau)| \le 2R \qquad \forall\ t \ge 0. \tag{7.12}$$

Thus $z(t)$ is a solution of $(7.8)_{\lambda=\lambda_1}$ on $\mathbb{R}^+$. By (7.9) we conclude that, for some $1 \le k \le n$,

$$\limsup_{t\to\infty} d\,(x(t),\, M_k) = \limsup_{t\to\infty} d\,(z(t-\tau),\, M_k) \le \varepsilon. \tag{7.13}$$

We infer from (7.11) and (7.12) that, for any solution $\widetilde{\psi}(t,\xi)$ of (7.6) with $\xi \in \mathcal{C}_K$,

$$|\widetilde{\psi}(t,\xi)| \le 2R \qquad \forall t \ge 0,$$

and hence it is a solution of (7.3). Conversely, using this basic fact one can also easily examine that any solution $\psi(t,\xi)$ of the original system (7.3) with initial value $\xi \in \mathcal{C}_K$ exists on $\mathbb{R}^+$ and is a solution of (7.6). This and (7.13) complete the proof of what we desired. □

Remark 7.2. The results can be extended without any difficulty to differential inclusion

$$x'(t) \in f(x(t), x(t-r_1(t)), \dots, x(t-r_k(t))), \qquad t \geq 0$$

with multiple small time delays. Here we omit the details.

Remark 7.3. A particular but interesting case is the one where each Morse set M_k consists of an equilibrium E_k, as in the situation of a gradient system. In such a case (7.4) reads

$$\limsup_{t\to\infty} d\left(\psi(t,\xi),\, E_k\right) \leq \varepsilon. \tag{7.14}$$

The robustness of asymptotic stability with respect to small time delays for scalar differential equations with multiple equilibria can be found in [38, 39, 44], etc., where the authors used some monotonicity method to show that each bounded solution of the small-time-delayed system approaches one of the equilibria. Similar results were also established in Friesecke [19] for a scalar parabolic equation with small time delays by using the special Lyapunov function of the system.

Remark 7.4. We refer the reader to [23, 26, 32, 33, 35] and the large number of references cited therein for the works and related discussions on robustness of asymptotic stability of a single equilibrium or a compact set with respect to small time delays.

7.2. Robustness with respect to sample-hold controls. We first recall the concept of π-solutions of the closed-loop system. Let

$$\pi:\ 0 = t_0 < t_1 < \cdots < t_i < t_{i+1} < \cdots, \quad \text{where } t_i \to \infty,$$

be a partition of $\mathbb{R}^+$, $||\pi|| = \sup_{i\geq 0} |t_{i+1} - t_i|$. Given an initial value $x_0 \in \mathbb{R}^m$, a *π-solution* of the closed-loop system (7.2) on $[0,T)$ is a function $x(\cdot) : [0,T) \to \mathbb{R}^m$ which is absolutely continuous on any compact interval $J \subset [0,T)$ and satisfies

$$x'(t) = f\left(x(t),\, \kappa\left(x(t_i)\right)\right), \quad x(0) = x_0, \qquad \text{a.e. } t \in [t_i, t_{i+1}] \cap [0,T)$$

for all $i \geq 0$ such that $t_{i+1} \leq T$.

THEOREM 7.5. *Assume that $f(x) := f(x,\kappa(x))$ satisfies* (H1) *and* (H2). *Suppose that $\mathcal{A}$ is an attractor of the closed-loop system* (7.2) *with a Morse decomposition $\{M_1, \dots, M_k\}$.*

Then for any compact subset $K \subset \Omega(\mathcal{A})$ and $\varepsilon > 0$, there is a $\delta > 0$ such that, when $||\pi|| < \delta$, any π-solution $x(\cdot)$ of (7.2) *with $x(0) \in K$ exists on $\mathbb{R}^+$ and satisfies*

$$\limsup_{t\to\infty} d(x(t), M_k) < \varepsilon$$

for some M_k.

Proof. We may assume that f is bounded on $\mathbb{R}^m \times U$; otherwise, we can employ the cutoff techniques used in the proof of Theorem 7.1.

Let $|f(x,u)| \leq c_0$ for all $(x,u) \in \mathbb{R}^m \times U$. Then for any $\lambda > 0$, when $||\pi|| < \lambda/c_0$ we find that any π-solution $x(\cdot)$ of (7.2) satisfies

$$|x(t_i) - x(t)| \leq c_0||\pi|| < \lambda \qquad \forall i \geq 0\ \forall t \in [t_i, t_{i+1}),$$

and hence $x(\cdot)$ solves

$$x'(t) \in f\left(x(t),\, \kappa(x(t) + \lambda \overline{\mathrm{B}}_1)\right), \qquad t \geq 0.$$

Now the conclusion follows immediately from Theorem 5.4. □

Remark 7.6. Similarly we could consider robustness of feedback laws with respect to measurement errors and external disturbances. In fact, results along this line are readily contained in Theorems 5.3 and 5.4.

Acknowledgments. First, I highly appreciate the work of the anonymous referees whose comments and suggestions have helped me greatly improve the paper in many ways. Second, I would like to express my gratitude to Professor P. E. Kloeden and Dr. Y. J. Wang for many helpful discussions. Finally, special thanks go to my wife, Q. P. Ren, Dr. A. Y. Zhang, and Z. Li for their constant support and encouragement in the past years. This work was carried out while I was visiting Chern Institute of Mathematics. I would like to express my sincere thanks to the support and hospitality of the Institute.

ON CONVERGENCE IN ELLIPTIC SHAPE OPTIMIZATION*

KARSTEN EPPLER†, HELMUT HARBRECHT‡, AND REINHOLD SCHNEIDER‡

Abstract. The present paper aims at analyzing the existence and convergence of approximate solutions in shape optimization. Motivated by illustrative examples, an abstract setting of the underlying shape optimization problem is suggested, taking into account the so-called two norm discrepancy. A Ritz–Galerkin-type method is applied to solve the associated necessary condition. Existence and convergence of approximate solutions are proved, provided that the infinite dimensional shape problem admits a stable second order optimizer. The rate of convergence is confirmed by numerical results.

Key words. shape optimization, shape calculus, existence and convergence of approximate solutions, optimality conditions

1. Introduction.

Shape optimization is quite important for aircraft design, bridge construction, electromagnetic shaping, etc. Many problems that arise in applications, particularly in structural mechanics, can be formulated as the minimization of functionals defined over a class of admissible domains. Such problems have been intensively studied in the literature in the past 25–30 years (see [14, 33, 35, 44, 47] and the references therein). In the majority of papers, the undiscretized problem has been studied. Only a few papers deal with the convergence of approximate solutions to the solution of the original shape optimization problem. For example, in [6, 7, 8] the question of convergence is considered on the fully discretized level. Therein, a grid is fixed in advance on the hold all and the admissible shapes are allowed to vary only *on* this predefined grid. Consequently, a *discrete* optimization problem has to be solved next. Further investigations on convergence of approximate solutions have been reported in [33, 44].

In [18, 19, 20, 22, 23, 24, 25], we considered the numerical solution of several elliptic shape optimization problems. Boundary variations were used to derive boundary integral representations of the shape gradient and the shape Hessian. This approach allows the embedding of a shape problem into a Banach space by identifying the domain with the parametrization of its boundary, i.e., with a function. Solving the shape optimization problem becomes equivalent to finding the parametrization of the minimizing domain. We applied a Ritz–Galerkin-type method to approximate this parametrization. All ingredients of the shape gradient and Hessian that arise from the state equation were computed with sufficiently high accuracy by a fast wavelet boundary element method. In this way, the discretization of the shape is decoupled

from the discretization of the state equation. Consequently, we may distinguish two types of errors.

First, the discretization error of the shape refers to the approximation error and determines the best possible rate of convergence. The present paper mainly tackles this issue by proving *existence* and *convergence* of approximate solutions. To this end, it is assumed that the objective, the constraints, and the state are given exactly.

Second, solving the state equation numerically induces a consistency error. Consistency errors are also caused by the approximate computation of the objective and constraints by, e.g., numerical quadrature. We present a Strang-type lemma to incorporate the error arising from numerical approximation. It gives a sufficient condition for realizing the best order of convergence.

When identifying the boundary of the regular $C^{k,\alpha}$-domain with its parametrization with respect to a fixed reference manifold $\widehat{\Gamma}$, a shape calculus based on boundary variational fields of prescribed smoothness leads to a second order Frechét calculus in a Banach space. For applications of interest, the space $C^{2,\alpha}(\widehat{\Gamma})$ for a certain $\alpha \in (0,1]$ is appropriate; cf. [15, 16, 17]. Since shape optimization problems are highly nonlinear, we are looking for domains that satisfy the first order necessary condition. These solutions are called stationary domains. To verify their local optimality, the second order Frechét derivative has to be coercive. However, for *integral objectives* in elliptic shape optimization it turns out that coercivity cannot be expected in the norm of the space of differentiation $C^{2,\alpha}(\widehat{\Gamma})$. Instead, coercivity of the shape Hessian at $\Omega^\star$ can be usually shown only in a *weaker* Sobolev space $H^s(\widehat{\Gamma})$. This *lack of coercivity* is known from other PDE-constrained optimal control problems as the so-called *two norm discrepancy*; cf. [4, 5, 28, 29]. The two norm discrepancy in shape optimization was first observed in [10, 11, 12, 15, 17]. It will play a key role in our convergence analysis.

Our investigations concentrate on the optimization of shapes and are not applicable to dealing with topological changes. Certainly, dealing with variable topologies is of enormous practical interest, and much important work has been done for the theoretical foundation and development of algorithms; see the monograph [3] for the state of the art. The so-called topological derivative has been addressed in [27, 31, 37, 39, 48, 49, 39] (we mention only some of the related papers). Related necessary optimality conditions for simultaneous shape and topology optimization have been investigated in [50], but the study of sufficient optimality conditions seems to be a challenging problem.

Concerning the present paper, section 2 is dedicated to a summary of second order shape calculus. Additionally, some examples are presented to illustrate the two norm discrepancy. First, we consider shape functionals based on a simple domain or boundary integral. Then, we treat PDE-constrained shape optimization problems by means of elliptic free boundary problems. In addition to the problem with simple constraints on the domain, we also discuss shape optimization problems subject to further functional constraints.

Motivated by these examples, we present in section 3 an abstract setting for the investigation of the second order sufficient optimality condition to verify stable minimizers. Then we introduce suitable trial spaces to discretize the shape optimization problem by means of a Ritz–Galerkin method for solving the necessary condition. The Ritz–Galerkin method solves a finite dimensional optimization problem that arises from restricting the class of admissible domains to domains given by the trial space. We show that there exist approximate solutions, provided that the level of discretization is sufficiently large, and prove convergence of the approximate solutions $\Omega_N^\star$ to

$\Omega^\star$, the optimal solution of the original infinite dimensional shape problem. The approximate solution behaves like the best approximation in the trial space to $\Omega^\star$, with respect to the natural space of coercivity of the shape Hessian. Therefore, the computation of the rate of convergence is along the lines of conventional approximation theory.

In section 4, we present two numerical examples that confirm our analysis. The first one is a simple shape problem based on a domain integral minimization, which is mainly incorporated for illustration. The second is a more advanced PDE-constrained shape optimization problem, with several additional functional constraints. Both examples are chosen such that the optimal domain is known a priori. We observe rates of convergence which verify the present theory.

2. Motivation and background.

2.1. Shape calculus. Shape optimization is concerned with the minimization of the shape functional

$$J(\Omega) = \int_\Omega j(u, \nabla u, \mathbf{x}) d\mathbf{x} \to \min, \qquad \Omega \in \Upsilon, \tag{2.1}$$

where Υ is a suitable class of admissible domains $\Omega \in \mathbb{R}^n$. The so-called *state* u satisfies an abstract boundary value problem

$$\mathcal{A}u = f \text{ in } \Omega, \qquad \mathcal{B}u = g \text{ on } \Gamma, \tag{2.2}$$

where $\mathcal{A}$ corresponds to a well-posed elliptic partial differential operator in the domain Ω, and $\mathcal{B}$ operates on the functions supported at the free boundary $\Gamma \subset \partial\Omega$. For the sake of simplicity, we restrict ourselves to finding solutions with known topology and assume that all involved functions and data are sufficiently smooth.

Generally, problem (2.1) is highly implicit, with respect to the shape of the domain, and has to be solved iteratively. The canonical way to solve the minimization problem is to determine its stationary points. Then, via the second order optimality condition, regular minimizers of second order are verified. To this end, we will briefly survey shape calculus. In particular, we refer the reader to Murat and Simon [38], Simon [46], Pironneau [44], Sokołowski and Zolésio [47], Delfour and Zolésio [14], and the references therein. Herein, two basic concepts are considered, namely, the perturbation of identity (Murat and Simon) and the speed method (Sokołowski and Zolésio).

For example, the perturbation of identity exploits a smooth perturbation field $\mathbf{U} : \Omega \to \mathbb{R}^n$ and defines the standard domain perturbation as

$$\Omega_\varepsilon[\mathbf{U}] := \{(\mathbf{I} + \varepsilon\mathbf{U})(\mathbf{x}) : \mathbf{x} \in \Omega\}.$$

Then the directional derivative of $J(\Omega)$ is computed as

$$\nabla J(\Omega)[\mathbf{U}] := \lim_{\varepsilon \to 0} \frac{J(\Omega_\varepsilon[\mathbf{U}]) - J(\Omega)}{\varepsilon}.$$

Ever since Hadamard [32] it has been known that $\nabla J(\Omega)[\mathbf{U}]$ is a distribution living only on the free boundary of the domain Ω, provided that $J(\Omega)$ is shape differentiable; see also [13].

The latter observation leads to the idea of considering only boundary variations for the update in the optimization algorithm. Therefore, we shall directly apply

boundary variations for the computation of the boundary integral representations of the shape gradient and Hessian. To this end, we introduce a reference manifold $\widehat{\Gamma} \subset \mathbb{R}^n$ and consider a fixed boundary perturbation field, for example, in the direction of the outer normal $\widehat{\mathbf{n}}$. We suppose that the free boundary of each domain $\Omega \in \Upsilon$ can be parametrized via a sufficiently smooth function r in terms of

$$\boldsymbol{\gamma} : \widehat{\Gamma} \to \Gamma, \quad \boldsymbol{\gamma}(\mathbf{x}) = \mathbf{x} + r(\mathbf{x})\widehat{\mathbf{n}}(\mathbf{x}).$$

That is, we can identify a domain with the scalar function r. Defining the standard variation

$$\boldsymbol{\gamma}_\varepsilon : \widehat{\Gamma} \to \Gamma_\varepsilon, \quad \boldsymbol{\gamma}_\varepsilon(\mathbf{x}) := \boldsymbol{\gamma}(\mathbf{x}) + \varepsilon dr(\mathbf{x})\widehat{\mathbf{n}}(\mathbf{x}),$$

where dr is again a sufficiently smooth scalar function, we obtain the perturbed domain Ω_ε. Consequently both the shape and its increment can be seen as elements of a Banach space X. We will specify the notion of "sufficiently smooth" in the next subsections.

2.2. Optimization of domain or boundary integrals. First, we introduce some notation. For a given domain $D \in \mathbb{R}^n$, the space $C^2(\overline{D})$ consists of all two times continuously differentiable functions $f : \overline{D} \to \mathbb{R}^m$. A function $f \in C^2(\overline{D})$ belongs to $C^{2,\alpha}(\overline{D})$ if the (spatial) Hessian $\nabla^2 f$ is Hölder continuous with coefficient $0 < \alpha \leq 1$. A domain $D \in \mathbb{R}^n$ is of class $C^{2,\alpha}$ if for each $\mathbf{x} \in \partial D$ a neighborhood $U(\mathbf{x}) \subseteq \partial\Omega$ and a diffeomorphism $\boldsymbol{\gamma} : [0,1]^{n-1} \to \overline{U(\mathbf{x})}$ exist such that $\boldsymbol{\gamma} \in C^{2,\alpha}([0,1]^{n-1})$; see [52], for example.

For the sake of clearness, we present here two elementary shape problems, since both the shape calculus and the analysis become much more evident in comparison with the more advanced shape optimization problems presented in the subsequent subsections. To this end, let $n = 2$, $\Omega \in C^1$, and consider the following shape optimization problem of domain integral type:

$$J(\Omega) = \int_\Omega h(\mathbf{x}) d\mathbf{x} \to \min, \tag{2.3}$$

where $h \in C^1(\mathbb{R}^2)$ are given data. We choose the class of admissible domains as the set of all domains that are star-shaped with respect to the origin. Then we can choose $\widehat{\Gamma}$ as the unit circle. Equivalently, we can parametrize $\Gamma = \partial\Omega$ via polar coordinates

$$\Gamma := \Big\{ \boldsymbol{\gamma}(\phi) = r(\phi) \left[\begin{smallmatrix} \cos\phi \\ \sin\phi \end{smallmatrix} \right] : \phi \in [0, 2\pi] \Big\},$$

where $r \in C^1_{\mathrm{per}}([0,2\pi])$ is a positive function. Here and in what follows, the space $C^{k,\alpha}_{\mathrm{per}}$ is defined as

$$C^{k,\alpha}_{\mathrm{per}}([0,2\pi]) = \{ f \in C^{k,\alpha}([0,2\pi]) : f^{(i)}(0) = f^{(i)}(2\pi) \text{ for all } i = 0, \ldots, k \},$$

and likewise $C^k_{\mathrm{per}}([0,2\pi])$. Let us further remark that the tangent and the outward normal at Γ are computed by

$$\mathbf{t} = \frac{r' \left[\begin{smallmatrix} \cos\phi \\ \sin\phi \end{smallmatrix} \right] + r \left[\begin{smallmatrix} -\sin\phi \\ \cos\phi \end{smallmatrix} \right]}{\sqrt{r^2 + r'^2}}, \qquad \mathbf{n} = \frac{r' \left[\begin{smallmatrix} \sin\phi \\ -\cos\phi \end{smallmatrix} \right] + r \left[\begin{smallmatrix} \cos\phi \\ \sin\phi \end{smallmatrix} \right]}{\sqrt{r^2 + r'^2}}. \tag{2.4}$$

We consider $dr \in C^1_{\mathrm{per}}([0,2\pi])$ as a standard variation for perturbed domains Ω_ε, respectively, boundaries Γ_ε, defined by $r_\varepsilon(\phi) = r(\phi) + \varepsilon dr(\phi)$, where $\boldsymbol{\gamma}_\varepsilon(\phi) = r_\varepsilon(\phi)\widehat{\mathbf{n}}(\phi)$

is always a Jordan curve. Herein, $\widehat{\mathbf{n}}(\phi) = [\cos\phi, \sin\phi]^T$ denotes the outward normal vector to the reference manifold $\widehat{\Gamma}$.

LEMMA 2.1 (see [16]). *The shape functional from* (2.3) *is twice Frechét differentiable with respect to* $C^1_{\mathrm{per}}([0,2\pi])$*, where the shape gradient and Hessian read as*

$$\nabla J(\Omega)[dr] = \int_0^{2\pi} r(\phi) dr(\phi) h\big(r(\phi),\phi\big) d\phi,$$
$$\nabla^2 J(\Omega)[dr_1, dr_2] = \int_0^{2\pi} dr_1(\phi) dr_2(\phi) \left\{ h\big(r(\phi),\phi\big) + r(\phi) \frac{\partial h}{\partial \widehat{\mathbf{n}}}\big(r(\phi),\phi\big) \right\} d\phi.$$

Consider now a stationary domain $\Omega^\star$, which means $\nabla J(\Omega^\star)[dr] = 0$ for all $dr \in C^1([0,2\pi])$. Of course, the latter equation implies that $h|_{\Gamma^\star} \equiv 0$. Hence, as one readily verifies, it holds that

$$\nabla^2 J(\Omega^\star)[dr_1, dr_2] = \int_0^{2\pi} dr_1(\phi) dr_2(\phi) \left\{ \frac{r^{\star 2}(\phi)}{\sqrt{r^{\star 2}(\phi) + r^{\star\prime 2}(\phi)}} \frac{\partial h}{\partial \mathbf{n}}\big(r^\star(\phi),\phi\big) \right\} d\phi.$$

Optimality usually can be guaranteed by coercivity of the second order Frechét derivative. However, it is impossible to realize coercivity with respect to $C^1_{\mathrm{per}}([0,2\pi])$; only an estimate

$$\nabla^2 J(\Omega^\star)[dr, dr] \geq c_E \|dr\|^2_{L^2([0,2\pi])}$$

for some $c_E > 0$ can be expected. Note that we have such an estimate if $(\partial h/\partial \mathbf{n})|_{\Gamma^\star} \geq c_E > 0$. This lack of regularity is known from other control problems as the so-called *two norm discrepancy*. Nevertheless, the bilinear form imposed by the shape Hessian $\nabla^2 J(\Omega)$ is obviously also continuous on $L^2([0,2\pi]) \times L^2([0,2\pi])$, that is,

$$|\nabla^2 J(\Omega)[dr_1, dr_2]| \leq c_S(\Omega) \|dr_1\|_{L^2([0,2\pi])} \|dr_2\|_{L^2([0,2\pi])}$$

for all $dr_1, dr_2 \in L^2([0,2\pi])$. Notice that it is generally impossible to extend the domain of definition $C^1([0,2\pi])$ to $L^2([0,2\pi])$. In other words, J is only densely defined with respect to $L^2([0,2\pi])$.

Also, in the case of a shape optimization problem of boundary integral type

$$J(\Omega) = \int_\Gamma g(\mathbf{x}) d\sigma \to \min, \tag{2.5}$$

where $g \in C^2(\mathbb{R}^2)$ are given data, one makes the above observations concerning the coercivity. Similarly to above, coercivity cannot be realized in $C^1_{\mathrm{per}}([0,2\pi])$. The energy space of the bilinear form imposed by the shape Hessian $\nabla^2 J(\Omega)$ is the Sobolev space $H^1_{\mathrm{per}}([0,2\pi])$; see [16] for details.

2.3. PDE-constrained shape optimization problems. We shall consider free elliptic boundary problems as the most illustrative model problem for PDE-constrained shape optimization problems. Let $T \subset \mathbb{R}^n$ denote a bounded domain with boundary $\partial T = \Gamma$. Inside the domain T we assume the existence of a simply connected subdomain $S \subset T$ with fixed boundary $\partial S = \Sigma$. We denote the annular domain $T \setminus \overline{S}$ by Ω; see also Figure 2.1.

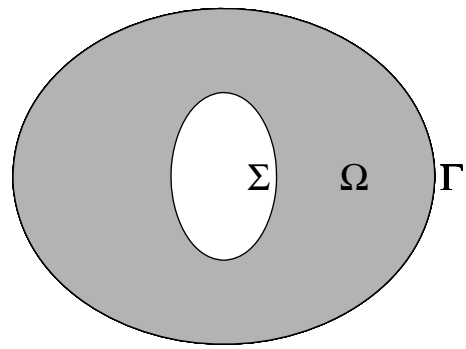

FIG. 2.1. *The domain* Ω *and its boundaries* Γ *and* Σ.

We consider the following overdetermined boundary value problem in the annular domain Ω:

$$\begin{aligned} -\Delta u &= f && \text{in } \Omega, \\ \|\nabla u\| &= g && \text{on } \Gamma, \\ u &= 0 && \text{on } \Gamma, \\ u &= h && \text{on } \Sigma, \end{aligned} \tag{2.6}$$

where $f \geq 0$ and $g, h > 0$ are sufficiently smooth functions such that the shape differentiability of the objective (2.7) is provided up to second order. We like to stress that the positivity of the data implies that u is positive in Ω. Hence, there holds the identity

$$\|\nabla u\| \equiv -\frac{\partial u}{\partial \mathbf{n}} \qquad \text{on } \Gamma$$

since u admits homogeneous Dirichlet data on Γ.

We arrive at a free boundary problem if the boundary Γ is the unknown. In other words, we seek a domain Ω with fixed boundary Σ and unknown boundary Γ such that the overdetermined boundary value problem (2.6) is solvable. For the existence of solutions we refer the reader to, e.g., [1, 26].

Shape optimization provides an efficient tool for solving such free boundary value problems; cf. [14, 34, 47, 51]. Considering the cost functional

$$J(\Omega) = \int_\Omega \|\nabla u\|^2 - 2fu + g^2 d\mathbf{x} \tag{2.7}$$

with underlying *state equation*

$$\begin{aligned} -\Delta u &= f && \text{in } \Omega, \\ u &= 0 && \text{on } \Gamma, \\ u &= h && \text{on } \Sigma, \end{aligned} \tag{2.8}$$

the solution of the free boundary problem is equivalent to the shape optimization problem

$$J(\Omega) \to \min. \tag{2.9}$$

This issues from the necessary condition of a minimizer to the cost functional (2.7); that is,

$$\nabla J(\Omega)[\mathbf{U}] = \int_\Gamma \langle \mathbf{U}, \mathbf{n}\rangle \left\{ g^2 - \left[\frac{\partial u}{\partial \mathbf{n}}\right]^2 \right\} d\sigma = 0 \tag{2.10}$$

has to be valid for all sufficiently smooth perturbation fields $\mathbf{U}$. Hence, shape optimization induces a variational formulation of the condition

$$\frac{\partial u}{\partial \mathbf{n}} = -g \qquad \text{on } \Gamma. \tag{2.11}$$

However, a stationary domain $\Omega^\star$ of the minimization problem (2.7), (2.8) will be a stable minimum if and only if the shape Hessian is strictly $H^{1/2}([0,2\pi])$-coercive at this domain (see below).

It suffices to consider $S \in C^{0,1}$, but due to a second order boundary perturbation calculus, we have to assume $T \in C^{2,\alpha}$ for some fixed $\alpha \in (0,1)$. We assume, similarly to the previous subsection, that the domain T is star-shaped with respect to $\mathbf{0}$, and we apply the same shape calculus. The shape gradient of the cost functional in (2.7) becomes, in polar coordinates,

$$\langle \nabla J(\Omega), dr\rangle = \int_0^{2\pi} dr\, r \left\{ g^2 - \left[\frac{\partial u}{\partial \mathbf{n}}\right]^2 \right\} d\phi. \tag{2.12}$$

According to [15, 16] the shape Hessian reads as

$$\begin{aligned} \langle \nabla^2 J(\Omega)\cdot dr_1, dr_2\rangle = \int_0^{2\pi} dr_1 dr_2 \Bigg\{ & g^2 - \left[\frac{\partial u}{\partial \mathbf{n}}\right]^2 + 2rg\langle \nabla g, \widehat{\mathbf{n}}\rangle \\ & - \frac{2r}{\sqrt{r^2+r'^2}} \frac{\partial u}{\partial \mathbf{n}} \left[r\frac{\partial^2 u}{\partial \mathbf{n}^2} + r' \frac{\partial^2 u}{\partial \mathbf{n}\partial \mathbf{t}} \right] \Bigg\} - 2r\, dr_1 \frac{\partial u}{\partial \mathbf{n}} \cdot \frac{\partial du[dr_2]}{\partial \mathbf{n}} d\phi. \end{aligned} \tag{2.13}$$

Herein, the *local shape derivative* $du = du[dr_2]$ of the state function satisfies

$$\begin{aligned} \Delta du &= 0 && \text{in } \Omega, \\ du &= 0 && \text{on } \Sigma, \\ du &= -dr_2\, \langle \widehat{\mathbf{n}}, \mathbf{n}\rangle \tfrac{\partial u}{\partial \mathbf{n}} && \text{on } \Gamma. \end{aligned} \tag{2.14}$$

Notice that $\partial^2 u/\partial \mathbf{n}^2 := \langle \nabla^2 u \cdot \mathbf{n}, \mathbf{n}\rangle$ and $\partial^2 u/(\partial \mathbf{n}\partial \mathbf{t}) := \langle \nabla^2 u \cdot \mathbf{n}, \mathbf{t}\rangle$.

LEMMA 2.2 (see [15, 25]). *The shape Hessian $\nabla^2 J(\Omega)$ defines a continuous bilinear form on $H^{1/2}([0,2\pi]) \times H^{1/2}([0,2\pi])$; that is, there exists a constant $c_S(\Omega)$ depending only on the actual domain Ω such that*

$$|\nabla^2 J(\Omega)[dr_1, dr_2]| \le c_S(\Omega) \|dr_1\|_{H^{1/2}([0,2\pi])} \|dr_2\|_{H^{1/2}([0,2\pi])}.$$

In accordance with this lemma, we observe that the shape Hessian is a pseudo-differential operator of order one, i.e., $\nabla^2 J(\Omega) : H^{1/2}([0,2\pi]) \to H^{-1/2}([0,2\pi])$. In particular the last term in (2.13) implies that the shape Hessian is a nonlocal operator.

According to [25] the following sufficient criterion concerning the $H^{1/2}([0,2\pi])$-coercivity holds.

LEMMA 2.3. *The shape Hessian $\nabla^2 J(\Omega^\star)$ is $H^{1/2}([0,2\pi])$-coercive; that is, there exists a constant $c_E > 0$ such that*

$$\nabla^2 J(\Omega^\star)[dr, dr] \ge c_E \|dr\|^2_{H^{1/2}([0,2\pi])}$$

if

$$\kappa + \left[\frac{\partial g}{\partial \mathbf{n}} - f\right] \Big/ g \geq 0 \qquad \text{on } \Gamma^\star.$$

In particular, in the case when $f \equiv 0$ and $g \equiv$ const., the shape Hessian is $H^{1/2}([0, 2\pi])$-coercive if the boundary $\Gamma^\star$ is convex (seen from inside).

The problem under consideration can be viewed as the prototype of a free boundary problem arising in many applications. For example, the growth of anodes in electrochemical processing might be modeled as above with $f \equiv 0$ and $g, h \equiv 1$.

In the two-dimensional exterior magnetic shaping of liquid metals, the state equation is an exterior Poisson equation and the uniqueness is ensured by a volume constraint of the domain Ω [9, 20, 41, 43]; see also the following subsection. However, since the shape functional involves the perimeter, which corresponds to the surface tension of the liquid, the energy space of the shape Hessian will be $H^1([0, 2\pi])$.

The detection of voids or inclusions in two- or three-dimensional electrical impedance tomography is slightly different since the roles of Σ and Γ are interchanged [23, 24, 45]. Particularly, this inverse problem is severely ill-posed, in contrast to the present class of problems. It has been proven in [23] that the shape Hessian is *not* strictly coercive in any $H^s([0, 2\pi])$ for all $s \in \mathbb{R}$.

2.4. Shape problems with additional functional constraints. We consider the following shape optimization problem:

$$J(\Omega) = \int_\Omega j(u, \nabla u, \mathbf{x}) d\mathbf{x} \to \min,$$

subject to L domain or boundary integral equality constraints

$$J_i(\Omega) = \int_\Omega h_i(\mathbf{x}) d\mathbf{x} = c_i, \quad 1 \leq i \leq K,$$
$$J_i(\Omega) = \int_\Gamma g_i(\mathbf{x}) d\sigma = c_i, \quad K < i \leq L.$$

We suppose that all functionals J and J_i, $1 \leq i \leq L$, are twice Frechét differentiable in a certain Banach space X. Moreover, let the Sobolev space H^s denote the strongest energy space of the bilinear forms imposed by the shape Hessians of *all* the above shape functionals.

Along the lines of standard optimization theory, one considers the free minimization of the Lagrangian

$$L(\Omega, \lambda_1, \ldots, \lambda_L) := J(\Omega) + \sum_{i=1}^{L} \lambda_i \big(J_i(\Omega) - c_i\big)$$

if Kuhn–Tucker regularity is provided. Hence, it is well known that the necessary and sufficient optimality condition for a regular local optimal shape $\Omega^\star$ reads as

LEMMA 2.4. *Let $\Omega^\star \in X$ satisfy*

$$\nabla L(\Omega^\star, \lambda_1^\star, \ldots, \lambda_L^\star)[dr] = 0 \quad \text{for all } dr \in X$$

for certain $\lambda_i^\star \in \mathbb{R}$. Moreover, define the linearizing cone

$$Y := \{dr \in X : \nabla J_i(\Omega^\star)[dr] = 0 \text{ for all } 1 \leq i \leq L\} \subset X,$$

and assume the linear independence of all gradients $\nabla J_i(\Omega^\star)$ at $\Omega^\star$.

Then $\Omega^\star$ is a regular local minimizer of second order if and only if the following coercivity condition is satisfied:

$$\nabla^2 L(\Omega^\star, \lambda_1^\star, \dots, \lambda_L^\star)[dr, dr] \geq c_E \|dr\|_{H^s}^2 \quad \textit{for all } dr \in Y.$$

Here, the techniques of the proof from [17, subsection 4.3] remain directly applicable, including the case of integral constraints that depend again on a PDE solution.

Remark 2.5. The linear independent constraint qualification (LICQ) implies in particular that the (vector valued) gradient of the constraints is a mapping onto $\mathbb{R}^L$. Hence, Y is a closed subspace of X of finite codimension L.

Consequently, the general concept developed in section 3 keeps applicable with respect to the Banach space Y. We mention that the treatment of inequality constraints is obvious and related modifications are well established in theory.

3. Approximation theory in shape optimization.

3.1. Assumptions on the optimization problem. Let us first introduce the abstract setting needed for our theory. To this end, let X denote a Banach space, where we shall denote the ball $\{h \in X : \|r - h\|_X < \delta\}$ by $B_\delta^X(r)$.

We consider the following optimization problem in the Banach space X:

$$(P) \qquad J(r) \to \min, \qquad r \in X.$$

Herein, $J : X \mapsto \mathbb{R}$ defines a two times continuously differentiable functional; i.e., the gradient $\nabla J(r) \in X^\star$ as well as the Hessian $\nabla^2 J(r) \in L(X, X^\star)$ exist for all $r \in X$, and the mappings $\nabla J(\cdot) : X \to X^\star$, $\nabla J^2(\cdot) : X \to L(X, X^\star)$ are continuous.

We assume that the necessary first order optimality condition holds in $r^\star$:

$$(\text{A1}) \qquad \nabla J(r^\star)[dr] = 0 \qquad \text{for all } dr \in X.$$

As illustrated in the previous section, we have to take the two norm discrepancy into account; i.e., the coercivity estimate holds only in a weaker Sobolev space $H^s \supset X$, $s \geq 0$. Therefore, we shall assume that there is a constant $c_S > 0$, depending *continuously* on the actual variable r, such that the continuous bilinear form imposed by the shape Hessian on $X \times X$ extends continuously to a bilinear form on $H^s \times H^s$, i.e.,

$$(\text{A2}) \qquad |\nabla^2 J(r)[h_1, h_2]| \leq c_S(r) \|h_1\|_{H^s} \|h_2\|_{H^s} \quad \text{for all } h_1, h_2 \in H^s,$$

if $r \in \overline{B_\delta^X(r^\star)}$. Of course, there exists an absolute constant C_S, defined by

$$(3.1) \qquad C_S := \max \left\{ c_S(r) : r \in \overline{B_\delta^X(r^\star)} \right\},$$

such that $c_S(r) \leq C_S$ for all $r \in \overline{B_\delta^X(r^\star)}$. Moreover, we assume that $\nabla^2 J$ is strongly coercive at $r^\star$, that is,

$$(\text{A3}) \qquad \nabla^2 J(r^\star)[h, h] \geq c_E \|h\|_{H^s}^2 \quad \text{for all } h \in H^s$$

for some $c_E > 0$.

Remark 3.1. The existence of a continuous extension for the objective J from X to H^s is not assumed throughout this paper since this is, in general, not realistic for shape problems; cf. subsection 2.2. That is, J remains only "densely defined" with respect

to H^s; this holds similarly for ∇J, $\nabla^2 J$. As it turns out, by our investigations a complete convergence analysis is possible without assuming a continuation property.

As a first consequence of our assumptions we have the following lemma concerning Lipschitz continuity of the shape gradient with respect to the topology that is induced by the coercivity space of the shape Hessian.

LEMMA 3.2. *The gradient is locally Lipschitz as a mapping in the* (H^{-s}, H^s)*-duality* ($H^{-s} := (H^s)'$)*, that is,*

$$\|\nabla J(r+h) - \nabla J(r)\|_{H^{-s}} \leq C_S \|h\|_{H^s} \tag{3.2}$$

for all $r, r+h \in \overline{B_\delta^X(r^\star)}$*. Herein, the constant* C_S *is given by* (3.1).

Proof. The assertion follows immediately from the following estimate:

$$|\nabla J(r+h)[dr] - \nabla J(r)[dr]| = \left| \int_0^1 \langle \nabla^2 J(r+th)\cdot h, dr\rangle dt \right| \leq C_S \|h\|_{H^s} \|dr\|_{H^s}$$

for all $r, r+h \in \overline{B_\delta^X(r^\star)}$, and $dr \in H^s$. ∎

Notice that the twice differentiability of J provides only the Lipschitz continuity of the shape gradient in the $(X^\star, X)$-duality, i.e.,

$$\|\nabla J(r+h) - \nabla J(r)\|_{X^\star} \leq C_S \|h\|_X$$

for all $r, r+h \in \overline{B_\delta^X(r^\star)}$.

3.2. Sufficient conditions. The above assumptions allow the following statement on the regular local optimality of second order of $r^\star$. Although this is rather standard, we recall it for convenience.

THEOREM 3.3 (sufficient second order optimality condition). *Let the necessary condition* (A1) *hold for a certain* $r^\star \in X$*. For all* $r \in \overline{B_\delta^X(r^\star)}$ *suppose that the bilinear form imposed by the shape Hessian satisfies* (A2) *and the following remainder estimate:*

$$\begin{aligned} &|\nabla^2 J(r)[h_1,h_2] - \nabla^2 J(r^\star)[h_1,h_2]| \\ &\qquad \leq \eta(\|r-r^\star\|_X)\|h_1\|_{H^s}\|h_2\|_{H^s} \quad \text{for all } h_1, h_2 \in H^s, \end{aligned} \tag{A4}$$

where $\eta : \mathbb{R}_0^+ \to \mathbb{R}_0^+$ *is a decreasing function that satisfies* $\eta(t) \to 0$ *as* $t \to 0$*. Then, the domain* $r^\star$ *is a strong regular local optimum of second order with respect to certain constants* $\widehat{c}_E > 0$*,*

$$J(r) - J(r^\star) \geq \widehat{c}_E \|r - r^\star\|_{H^s}^2 \quad \text{for all } r \in \overline{B_{\widehat{\delta}}^X(r^\star)}, \tag{3.3}$$

if and only if the shape Hessian satisfies the strong coercivity estimate (A3).

Proof. For all $r = r^\star + h \in \overline{B_\delta^X(r^\star)}$ the following Taylor expansion holds:

$$J(r) - J(r^\star) = 0 + \frac{1}{2}\nabla^2 J(r^\star + \xi h)[h,h], \quad \xi \in (0,1).$$

According to (A3) and (A4), one infers on the one hand,

$$\begin{aligned} J(r) - J(r^\star) &\geq \frac{1}{2}\nabla^2 J(r^\star)[h,h] - |\nabla^2 J(r^\star+\xi h)[h,h] - \nabla^2 J(r^\star)[h,h]| \\ &\geq \frac{1}{2}\nabla^2 J(r^\star)[h,h] - \eta(\|h\|_X)\|h\|_{H^s}^2 \\ &\geq \frac{1}{2}\big(c_E - \eta(\|h\|_X)\big)\|h\|_{H^s}^2. \end{aligned}$$

Supposing $0 < \widehat{\delta} \leq \delta$ to be chosen such that $\eta(\|r - r^\star\|_X) \leq c_E/2$ for all $r \in \overline{B^X_{\widehat{\delta}}(r^\star)}$, we arrive at

$$J(r) - J(r^\star) \geq \frac{c_E}{4}\|r - r^\star\|^2_{H^s} \quad \text{for all } r \in \overline{B^X_{\widehat{\delta}}(r^\star)}.$$

On the other hand, we choose $r = r^\star + h \in \overline{B_{\widehat{\delta}}(r^\star)}$ arbitrarily but fixed. Combining the Taylor expansion

$$J(r) - J(r^\star) = \frac{1}{2}\nabla^2 J(r^\star + \xi h)[h,h] \geq \widehat{c}_E\|h\|^2_{H^s}, \quad \xi \in (0,1),$$

with (A4) yields

$$\begin{aligned}\nabla^2 J(r^\star)[h,h] &= \nabla^2 J(r^\star + \xi h)[h,h] + \nabla^2 J(r^\star)[h,h] - \nabla^2 J(r^\star + \xi h)[h,h] \\ &\geq \big(2\widehat{c}_E - \eta(\|h\|_X)\big)\|h\|^2_{H^s}.\end{aligned}$$

Fixing, similarly to the above, $0 < \delta \leq \widehat{\delta}$ such that $\eta(\|h\|_X) \leq \widehat{c}_E/2$ yields the coercivity estimate (A3) with $c_E := 3\widehat{c}_E/2$ for all $h \in \overline{B^X_\delta(0)}$. This finishes the proof since X is dense in H^s and $\nabla^2 J(r^\star) : H^s \times H^s \to \mathbb{R}$ is bilinear. ∎

Let us remark that the verification of (A4) turns out to be rather technical in the case of PDE-constrained shape optimization problems. For the presented model problems, (A4) has been proven in [10, 11, 12], whereas the verification of (A2) is much simpler (see, e.g., [15]) but already an indicator of the two norm discrepancy.

Combining the assumptions (A2) (together with (3.1)), (A3), and (A4) leads to the following corollary by repeating a portion of the preceding proof.

COROLLARY 3.4. *For $\widehat{\delta} > 0$ sufficiently small, the shape Hessian is strongly coercive in the whole ball $\overline{B^X_{\widehat{\delta}}(r^\star)}$, that is,*

$$\nabla^2 J(r)[h,h] \geq \frac{c_E}{2}\|h\|^2_{H^s} \quad \textit{for all } h \in H^s,\ r \in \overline{B^X_{\widehat{\delta}}(r^\star)}. \tag{3.4}$$

Moreover, with respect to the objective, the following upper and lower quadratic bound

$$\frac{c_E}{4}\|r - r^\star\|^2_{H^s} \leq J(r) - J(r^\star) \leq \frac{C_S}{2}\|r - r^\star\|^2_{H^s} \tag{3.5}$$

holds for all $r \in \overline{B^X_{\widehat{\delta}}(r^\star)}$.

3.3. Ritz–Galerkin discretization. We shall consider a Ritz–Galerkin scheme to solve the necessary condition (A1); i.e., we replace the given infinite dimensional optimization problem with a finite dimensional problem. The trial space should provide sufficient regularity in order to approximate functions in X. To this end, we introduce an appropriate Hilbert space $H^k \subset X$, continuously embedded in X, i.e.,

$$\|r\|_X \leq c_{H^k \to X}\|r\|_{H^k} \qquad \text{for all } r \in H^k. \tag{V1}$$

Then we shall consider a sequence of nested finite dimensional trial spaces,

$$V_0 \subset V_1 \subset \cdots \subset V_N \subset \cdots \subset H^k \subset X, \quad \bigcap_{N\geq 0} V_N = V_0, \quad \overline{\bigcup_{N\geq 0} V_N}^{H^k} = H^k, \tag{V2}$$

providing the following inverse estimate:

$$\|r_N\|_{H^k} \leq E(N)\|r_N\|_{H^s} \quad \text{for all } r_N \in V_N. \tag{V3}$$

Moreover, we assume that there exists an $L > k$ such that the following approximation property holds:

$$\text{(V4)} \qquad \inf_{r_N \in V_N} \|r - r_N\|_{H^s} = o\left(\frac{1}{E(N)}\right) \|r\|_{H^\ell} \quad \text{if } r \in H^\ell \ (k < \ell \leq L).$$

Herein, the Landau symbol $g(x) = o(f(x))$ means that $\lim_{x\to\infty} g(x)/f(x) = 0$.

Remark 3.5. Suppose $X = C^{2,\alpha}([0,1])$ for some $\alpha \in (0,1)$. Then the Sobolev space $H^k([0,1])$ with $3 \geq k > 2 + \alpha$ provides a continuous embedding in accordance with (V1). Choosing $V_N \subset C^{2,1}([0,1])$ as the space of smoothest cubic splines on the uniform subdivision with step width $h_N := 2^{-N}/4$, we have the approximation property

$$\inf_{r_N \in V_N} \|r - r_N\|_{H^s} \lesssim h_N^{\ell-s} \|r\|_{H^\ell} \quad \text{if } r \in H^\ell \ (k < \ell \leq 4)$$

uniformly in N, provided that $s < k$. The inverse estimate reads as

$$\|r_N\|_{H^k} \lesssim h_N^{s-k} \|r_N\|_{H^s} \quad \text{for all } r_N \in V_N$$

uniformly in N, provided that $s \leq k$. Hence, we conclude that the trial spaces $(V_N)_{N\geq 0}$ satisfy (V2)–(V4).

The Ritz–Galerkin scheme reads as follows. In order to solve

$$(P_N) \qquad J(r_N) \to \min, \qquad r_N \in V_N,$$

one seeks an approximate solution $r_N^\star \in V_N$ such that the discretized necessary condition

$$\nabla J(r_N^\star)[q_N] = 0 \tag{3.6}$$

holds for all $q_N \in V_N$.

There exist different strategies for finding $r_N \in V_N$ such that (3.6) holds. In general, suppose that r_N has N degrees of freedom; i.e., there exist $\varphi_1, \varphi_2, \ldots, \varphi_N$ such that

$$V_N = \operatorname{span}\{\varphi_1, \varphi_2, \ldots, \varphi_N\}.$$

One makes the ansatz $r_N = \sum_{i=1}^N r_i \varphi_i$ and considers an iterative scheme

$$\mathbf{r}^{(n+1)} = \mathbf{r}^{(n)} - h^{(n)} \mathbf{M}^{(n)} \mathbf{G}^{(n)}, \tag{3.7}$$

where $h^{(n)}$ is a suitable step width and

$$\mathbf{r}^{(n)} = \big(r_i^{(n)}\big)_{i=1,\ldots,N}, \quad \mathbf{G}^{(n)} := \big(\nabla J(r_N^{(n)})[\varphi_i]\big)_{i=1,\ldots,N}.$$

First order methods are the gradient method ($\mathbf{M}^{(n)} := \mathbf{I}$) and the quasi-Newton method, where $\mathbf{M}^{(n)}$ denotes a suitable approximation to the inverse shape Hessian. Choosing

$$\mathbf{M}^{(n)} := \big(\nabla^2 J(r_N^{(n)})[\varphi_i, \varphi_j]\big)_{i,j=1,\ldots,N}^{-1}$$

yields the Newton method, which converges much faster compared to first order methods; see [19] for an example.

3.4. Existence of approximate solutions. We will consider the existence of solutions of (3.6) and the question of the accuracy of approximate solutions $r_N^\star$. Since the solutions of (3.6) are only stationary points, it is reasonable to consider only local optimization problems. Therefore, we replace the global problems (P) and (P_N) with the local optimization problem

$$(P^\delta) \qquad J(r) \to \min, \quad r \in \overline{B_\delta^X(r^\star)},$$

and its discrete variant

$$(P_N^\delta) \qquad J(r_N) \to \min, \qquad r_N \in V_N \cap \overline{B_\delta^X(r^\star)},$$

where $\delta = \widehat{\delta}$ is chosen in accordance with the estimates (3.4), (3.5) and is *independent* of N. Obviously, the solution of (P^δ) is $r^\star$, since J is strictly coercive on the convex set $\overline{B_\delta^X(r^\star)}$. Moreover, we have as a first consequence the following lemma.

LEMMA 3.6. *Problem (P_N^δ) always admits a solution $r_N^\star \in V_N \cap \overline{B_\delta^X(r^\star)}$. Any point $r_N^\star \in V_N \cap \overline{B_\delta^X(r^\star)}$ satisfying* (3.6) *is a local regular optimizer of second order. Moreover, the coercivity implies the uniqueness of $r_N^\star$.*

Proof. The existence of $r_N^\star$ is obvious since the admissible set $V_N \cap \overline{B_\delta^X(r^\star)}$ is compact. It follows for all $r_N := r_N^\star + h_N \in V_N \cap \overline{B_\delta^X(r^\star)}$ that $r_N^\star + \xi h_N \in V_N \cap \overline{B_\delta^X(r^\star)}$ is always satisfied for all $\xi \in (0,1)$ by convexity of the admissible set. Consequently, if $r_N^\star$ also satisfies (3.6), we deduce from (3.4) that

$$J(r_N) - J(r_N^\star) = \frac{1}{2}\nabla^2 J(r_N^\star + \xi h_N)[h_N, h_N] \geq \frac{c_E}{4}\|r_N - r_N^\star\|_{H^s}^2, \quad \xi \in (0,1),$$

for all $r_N = r_N^\star + h_N \in V_N \cap \overline{B_\delta^X(r^\star)}$. Uniqueness of $r_N^\star$ is an immediate consequence of the strict convexity of J (ensured again by (3.4)) on the convex set $V_N \cap \overline{B_\delta^X(r^\star)}$. ∎

Nevertheless, if $r_N^\star$ remains at the "artificial" boundary $\partial\{V_N \cap \overline{B_\delta^X(r^\star)}\} = V_N \cap \partial B_\delta^X(r^\star)$, only a related variational inequality holds instead of (3.6). Furthermore, $\|r_N^\star - r^\star\|_X = \delta$ for $N \to \infty$ contradicts convergence on its own. Consequently, we have to ensure that $r_N^\star$ is an *interior* point of the set $V_N \cap \overline{B_\delta^X(r^\star)}$, i.e.,

$$\|r_N^\star - r^\star\|_X < \delta,$$

at least for all sufficiently large $N \geq N_0$. This result is provided by the next theorem.

THEOREM 3.7. *Let* (A1)–(A4) *and* (V1)–(V4) *hold. Then, if $r^\star \in H^\ell$ for some $\ell > k$, there exists an N_0 such that*

$$r_N^\star \in V_N \cap B_\delta^X(r^\star) \quad \textit{for all } N \geq N_0.$$

Proof. We split the proof into four parts.

(i) We define $P_N : L^2 \to V_N$ as the L^2-orthogonal projection onto V_N. Then, by our assumptions (V1), (V2) we have

$$\|P_N(r^\star) - r^\star\|_X \leq c_{H^k \to X}\|P_N(r^\star) - r^\star\|_{H^k} \lesssim \inf_{r_N \in V_N} \|r_N - r^\star\|_{H^k} \overset{N\to\infty}{\longrightarrow} 0$$

and likewise by (V4),

$$\|P_N(r^\star) - r^\star\|_{H^s} \lesssim \inf_{r_N \in V_N} \|r_N - r^\star\|_{H^s} \overset{N\to\infty}{\longrightarrow} 0.$$

Hence, we deduce that there exists an N_0 such that $V_N \cap \overline{B_\delta^X(r^\star)} \neq \emptyset$ for all $N \geq N_0$. Without loss of generality we assume that $N_0 = 0$.

(ii) Recall that

$$J(r^\star) = \inf\big\{J(r) : r \in \overline{B_\delta^X(r^\star)}\big\},$$
$$J(r_N^\star) = \inf\big\{J(r_N) : r_N \in V_N \cap \overline{B_\delta^X(r^\star)}\big\},$$

and define $J_\delta(N) \geq J(r_N^\star) \geq J(r^\star)$ via

$$J_\delta(N) := \inf\big\{J(r_N) : r_N \in V_N \cap \partial B_\delta^X(r^\star)\big\}.$$

Since $J\big(P_N(r^\star)\big) \geq J(r_N^\star)$, we conclude the assertion $\|r_N^\star - r^\star\|_X < \delta$ if we can prove

$$J_\delta(N) > J\big(P_N(r^\star)\big) \quad \text{for all } N \geq N_0. \tag{3.8}$$

On the one hand, (3.5) implies

$$J\big(P_N(r^\star)\big) - J(r^\star) \leq \frac{C_S}{2}\|P_N(r^\star) - r^\star\|_{H^s}^2. \tag{3.9}$$

On the other hand, by introducing the quantity

$$\begin{aligned} F_\delta^X(N) &:= \inf\big\{\|r_N - r^\star\|_{H^s} : r_N \in V_N \cap \partial B_\delta^X(r^\star)\big\} \\ &= \inf\big\{\|r_N - r^\star\|_{H^s} : r_N \in V_N \setminus B_\delta^X(r^\star)\big\}, \end{aligned}$$

we derive from (3.5)

$$J_\delta(N) - J(r^\star) \geq \frac{c_E}{4} F_\delta^X(N)^2. \tag{3.10}$$

Combining (3.9) and (3.10), we see that the inequality

$$\|P_N(r^\star) - r^\star\|_{H^s} < C^\star \cdot F_\delta^X(N), \quad C^\star := \sqrt{\frac{c_E}{2C_S}}, \tag{3.11}$$

will imply (3.8) and, thus, $\|r_N^\star - r^\star\|_X < \delta$.

(iii) We shall establish a relation between $F_\delta^X(N)$, $\|r^\star - P_N(r^\star)\|_{H^s}$, and $E(N)$ from the inverse estimate (V3). For the sake of simplicity, we assume without loss of generality that the constant $c_{H^k \to X}$ from (V1) is less than one such that

$$B_\delta^{H^k}(r^\star) \subseteq B_\delta^X(r^\star). \tag{3.12}$$

Introducing

$$\begin{aligned} F_\delta^{H^k}(N) &:= \inf\big\{\|r_N - r^\star\|_{H^s} : r_N \in V_N \cap \partial B_\delta^{H^k}(r^\star)\big\} \\ &= \inf\big\{\|r_N - r^\star\|_{H^s} : r_N \in V_N \setminus B_\delta^{H^k}(r^\star)\big\}, \end{aligned}$$

there follows from (3.12) the relation

$$F_\delta^{H^k}(N) \leq F_\delta^X(N).$$

We shall now compute a lower bound for $F_\delta^{H^k}(N)$. From

$$\|r_N - P_N(r^\star)\|_{H^s} - \|P_N(r^\star) - r^\star\|_{H^s} \leq \|r_N - r^\star\|_{H^s}$$

one infers the inequality

$$F_\delta^{H^k}(N) \geq \inf\big\{\|r_N - P_N(r^\star)\|_{H^s} : r_N \in V_N \setminus B_\delta^{H^k}(r^\star)\big\} - \|P_N(r^\star) - r^\star\|_{H^s}. \tag{3.13}$$

We choose N_0 sufficiently large to ensure

$$\|P_N(r^\star) - r^\star\|_{H^k} \leq \delta/2 \quad \text{for all } N \geq N_0.$$

Then it holds that $B_{\delta/2}^{H^k}\big(P_N(r^\star)\big) \subset B_\delta^{H^k}(r^\star)$, and we arrive at

$$\begin{aligned}
&\inf\big\{\|r_N - P_N(r^\star)\|_{H^s} : r_N \in V_N \setminus B_\delta^{H^k}(r^\star)\big\} \\
&\quad \geq \inf\big\{\|r_N - P_N(r^\star)\|_{H^s} : r_N \in V_N \setminus B_{\delta/2}^{H^k}\big(P_N(r^\star)\big)\big\} \\
&\quad \geq \inf_{r_N \in V_N} \{\|r_N\|_{H^s} : \|r_N\|_{H_k} = \delta/2\} \\
&\quad \geq \frac{\delta}{2E(N)}.
\end{aligned}$$

Inserting this estimate into (3.13), we deduce

$$F_\delta^X(N) \geq F_\delta^{H^k}(N) \geq \frac{\delta}{2E(N)} - \|P_N(r^\star) - r^\star\|_{H^s} \quad \text{for all } N \geq N_0. \tag{3.14}$$

(iv) Observing

$$\|P_N(r^\star) - r^\star\|_{H^s} \lesssim \inf_{r_N \in V_N} \|r_N - r^\star\|_{H^s},$$

we infer from (V4) that we can increase N_0 such that

$$\|P_N(r^\star) - r^\star\|_{H^s} < \frac{\delta}{2E(N)} \cdot \frac{C^\star}{C^\star + 1} \quad \text{for all } N \geq N_0.$$

Thus, in view of (3.14), we arrive at

$$\|P_N(r^\star) - r^\star\|_{H^s} < C^\star \left(\frac{\delta}{2E(N)} - \|P_N(r^\star) - r^\star\|_{H^s} \right) < C^\star F_\delta^X(N),$$

that is, (3.11), for all $N \geq N_0$, which finishes the proof according to part (ii). ∎

Remark 3.8. Obviously, by means of standard optimization theory, (3.3) and (3.6) imply well-posedness of the finite dimensional optimization problem; that is, existence and (local) uniqueness of minimizers are ensured. In particular, the strict coercivity of (P_N^δ), induced by the coercivity of (P^δ), provides the convergence

$$r_N^{(n)} \to r_N^\star \quad \text{as } n \to \infty$$

of the iterative scheme (3.7); see, e.g., [30, 40].

3.5. Convergence. The above theorem ensures the *existence* of an approximate solution $r_N^\star$ to the finite dimensional problems (P_N^δ) that satisfies the necessary condition (3.6), provided that N is sufficiently large. The next theorem estimates the distance $\|r_N^\star - r^\star\|_{H^s}$.

THEOREM 3.9. *The approximate solution $r_N^\star$ of the finite dimensional problem (P_N^δ) satisfies the error estimate*

$$\|r_N^\star - r^\star\|_{H^s} \leq \frac{2C_S}{c_E} \inf_{r_N \in V_N} \|r_N - r^\star\|_{H^s}$$

uniformly with the number of unknowns N.

Proof. For the sake of clearness in the representation, let $\langle\cdot,\cdot\rangle$ denote the duality pairing between H^s and its dual space H^{-s}.

On the one hand, observing (3.2), Galerkin orthogonality implies

$$\begin{aligned}\langle\nabla J(r_N^\star)-\nabla J(r^\star),r_N^\star-r^\star\rangle &= \langle\nabla J(r_N^\star)-\nabla J(r^\star),r_N-r^\star\rangle\\ &\le C_S\|r_N^\star-r^\star\|_{H^s}\|r_N-r^\star\|_{H^s}\end{aligned}$$

for all $r_N\in V_N$. On the other hand, by introducing

$$j(t):=\langle\nabla J\big(tr_N^\star+(1-t)r^\star\big),r_N^\star-r^\star\rangle,$$

we derive the estimate

$$\begin{aligned}\langle\nabla J(r_N^\star)-\nabla J(r^\star),r_N^\star-r^\star\rangle &= j(1)-j(0)=\int_0^1 j'(t)\,dt\\ &=\int_0^1\langle\nabla^2 J(tr_N^\star+(1-t)r^\star\big)\cdot(r_N^\star-r^\star),r_N^\star-r^\star\rangle\,dt\ge\frac{c_E}{2}\|r_N^\star-r^\star\|_{H^s}^2.\end{aligned}$$

Combining both estimates yields

$$\|r_N^\star-r^\star\|_{H^s}^2\le\frac{2C_S}{c_E}\|r_N^\star-r^\star\|_{H^s}\|r_N-r^\star\|_{H^s}$$

for all $r_N\in V_N$, which is equivalent to the assertion. ∎

Of course, from this theorem one can determine the *rate of convergence* if one estimates $\inf_{r_N\in V_N}\|r_N-r^\star\|_{H^s}$.

3.6. The fully discretized problem. Up to now, we investigated only the discretization with respect to the shape. Hence, we neglected consistency errors arising from the approximate solution of the state equation or from computing the objective and constraints by, e.g., quadrature. Consequently, we shall focus on the following further modification of problem (P_N^δ):

$(P_{N\epsilon}^\delta)$ seek $r_{N\epsilon}^\star\in V_N\cap\overline{B_\delta^X(r_N^\star)}$ such that $\langle\nabla J_\epsilon(r_N^\star),q_N\rangle=0$ for all $q_N\in V_N$,

where ϵ is an approximation parameter referring to the inexact computation of the gradient. We prove the following Strang-type lemma which estimates the consistency error induced by solving $(P_{N\epsilon}^\delta)$.

LEMMA 3.10. *Assume that the estimate*

$$|\langle[\nabla J_\epsilon(r_N)-\nabla J(r_N)]-[\nabla J_\epsilon(q_N)-\nabla J(q_N)],s_N\rangle|\le\epsilon\|r_N-q_N\|_{H^s}\|s_N\|_{H^s}\tag{3.15}$$

holds for all $r_N,q_N\in V_N\cap\overline{B_\delta^X(r_N^\star)}$ and $s_N\in V_N$. Then, provided that ϵ is sufficiently small, $(P_{N\epsilon}^\delta)$ admits a unique solution $r_{N\epsilon}^\star\in V_N\cap\overline{B_\delta^X(r_N^\star)}$ which satisfies the a priori estimate

$$\|r^\star-r_{N\epsilon}^\star\|_{H^s}\le\left(1+\frac{2\max\{1,C_S\}}{c_E-2\epsilon}\right)\left\{\|r^\star-r_N\|_{H^s}+\sup_{q_N\in V_N}\frac{\langle\nabla J(r_N)-\nabla J_\epsilon(r_N),q_N\rangle}{\|q_N\|_{H^s}}\right\}.$$

Proof. Due to our assumptions from the previous subsections, the unperturbed Richardson iteration

$$r_N^{(n+1)}=r_N^{(n)}-\alpha\sum_{i=1}^N\nabla J(r_N^{(n)})[\varphi_i]\varphi_i,\quad n=0,1,\dots,$$

defines a contraction of $V_N \cap \overline{B_\delta^X(r_N^\star)}$ onto itself for a whole range of $\alpha \in [\underline{\alpha}, \overline{\alpha}]$. Estimate (3.15) ensures that the perturbed Richardson iteration

$$r_{N\epsilon}^{(n+1)} = r_{N\epsilon}^{(n)} - \alpha \sum_{i=1}^{N} \nabla J_\epsilon(r_{N\epsilon}^{(n)})[\varphi_i]\varphi_i, \quad n = 0, 1, \ldots,$$

is still a contraction of $V_N \cap \overline{B_\delta^X(r_N^\star)}$ onto itself for $\alpha := (\underline{\alpha} + \overline{\alpha})/2$, provided that ϵ is sufficiently small. This proves existence and uniqueness of the perturbed solution $r_{N\epsilon}^\star$.

Next, using again (3.15), we find

$$\begin{aligned}
&\langle \nabla J_\epsilon(r_N) - \nabla J_\epsilon(q_N), r_N - q_N \rangle \\
&\quad \geq \langle \nabla J(r_N) - \nabla J(q_N), r_N - q_N \rangle - \epsilon \|r_N - q_N\|_{H^s}^2 \\
&\quad \geq \Big(\frac{c_E}{2} - \epsilon \Big) \|r_N - q_N\|_{H^s}^2,
\end{aligned}$$

where $\widetilde{c}_E := c_E/2 - \epsilon > 0$ holds if ϵ is sufficiently small.

Due to Galerkin orthogonality, the Ritz–Galerkin solution $r_{N\epsilon}^\star$ of $(P_{N\epsilon}^\delta)$ satisfies

$$\begin{aligned}
\widetilde{c}_E \|r_{N\epsilon}^\star - r_N\|_{H^s}^2 &\leq \langle \nabla J_\epsilon(r_{N\epsilon}^\star) - \nabla J_\epsilon(r_N), r_{N\epsilon}^\star - r_N \rangle \\
&\leq \langle \nabla J(r^\star) - \nabla J(r_N), r_{N\epsilon}^\star - r_N \rangle + \langle \nabla J(r_N) - \nabla J_\epsilon(r_N), r_{N\epsilon}^\star - r_N \rangle \\
&\leq C_S \|r^\star - r_N\|_{H^s} \|r_{N\epsilon}^\star - r_N\|_{H^s} + \langle \nabla J(r_N) - \nabla J_\epsilon(r_N), r_{N\epsilon}^\star - r_N \rangle,
\end{aligned}$$

that is,

$$\|r_{N\epsilon}^\star - r_N\|_{H^s} \leq \frac{\max\{1, C_S\}}{\widetilde{c}_E} \left\{ \|r^\star - r_N\|_{H^s} + \sup_{q_N \in V_N} \frac{\langle \nabla J(r_N) - \nabla J_\epsilon(r_N), q_N \rangle}{\|q_N\|_{H^s}} \right\}.$$

Since $r_N \in V_N \cap \overline{B_\delta^X(r_N^\star)}$ is arbitrary, we arrive at the assertion using the triangle inequality

$$\|r^\star - r_{N\epsilon}^\star\|_{H^s} \leq \|r^\star - r_N\|_{H^s} + \|r_N - r_{N\epsilon}^\star\|_{H^s}. \qquad \square$$

4. Numerical results.

4.1. An unconstrained shape optimization problem. For comparison we shall employ model problems, where the solution is known analytically. To this end, we choose the shape optimization problem (2.3) based on the domain integral

$$J(\Omega) = \int_\Omega \Big(\frac{x^2}{8} + \frac{y^2}{4} - 2 \Big) d\mathbf{x}$$

as our first numerical example. In accordance with subsection 2.2, the ellipse centered in $\mathbf{0}$ with semiaxes $2\sqrt{2}$ and 2 is a strict minimizer of second order.

The numerical setting is as follows. We subdivide the parameter interval $[0, 2\pi]$ equidistantly into N intervals. With respect to this subdivision, the radial function $r \in X := C_{\mathrm{per}}^1([0, 2\pi])$ is then approximated periodically by N cubic B-splines B_i^3, $i = 1, \ldots, N$, that is,

$$r_N = \sum_{i=1}^{N} a_i B_i^3 \in C_{\mathrm{per}}^{2,1}([0, 2\pi]).$$

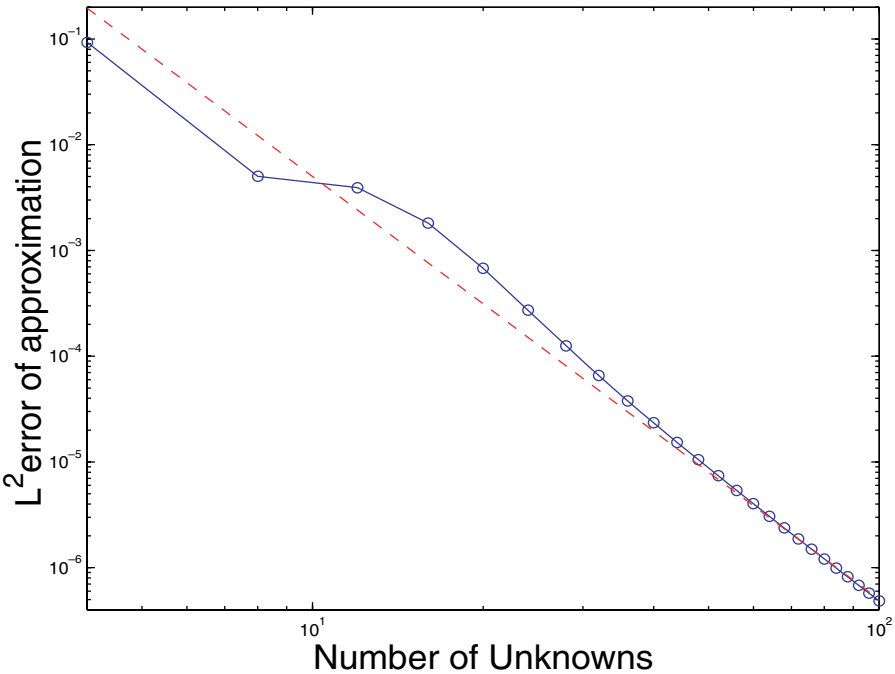

FIG. 4.1. *L^2-error of the approximate solution.*

We employ a Newton method to iteratively solve the necessary condition $\nabla J(\Omega) \equiv 0$, using the circle with radius 2 as an initial guess.

Since the energy space for the shape Hessian is $L^2([0, 2\pi])$, we measure the L^2-norm of the approximation error given by

$$\|r - r_N\|^2_{L^2([0,2\pi])} = \int_0^{2\pi} |r - r_N|^2 d\phi.$$

The measurements are shown in Figure 4.1. We observe, as predicted, the rate of convergence N^{-4}, indicated by the dashed line.

4.2. A constrained shape optimization problem. We consider next a cylindric circular bar which is homogeneous and isotropic with a planar, simply connected cross section $\Omega \in \mathbb{R}^2$. We follow Banichuk and Karihaloo [2], but normalize the shear modulus $G = 1$ and the elastic modulus $E = 1$. We want to solve the problem of maximizing the torsional rigidity of the bar subject to given equality constraints on the bending stiffness and the volume.

First, we briefly recall the mathematical formulation of the quantities. The torsional rigidity is calculated by

$$T(\Omega) = 2 \int_\Omega u(\mathbf{x}) d\mathbf{x},$$

where the stress function $u = u(\Omega)$ satisfies

$$-\Delta u = 2 \text{ in } \Omega, \qquad u = 0 \text{ on } \Gamma.$$

The bending rigidity with respect to a fixed barycenter in the origin is given by

$$B(\Omega) = \int_\Omega y^2 d\mathbf{x}.$$

The volume of the domain and its (simplified) barycenter coordinates read as

$$V(\Omega) = \int_\Omega d\mathbf{x}, \qquad S_x(\Omega) = \int_\Omega x d\mathbf{x}, \qquad S_y(\Omega) = \int_\Omega y d\mathbf{x}.$$

Consequently, we arrive at the following constraint shape optimization problem:

$$J(\Omega) := -T(\Omega) \to \min$$

subject to

$$B(\Omega) = B_0, \qquad V(\Omega) = V_0, \qquad S_x(\Omega) = 0, \qquad S_y(\Omega) = 0.$$

Choosing $B_0 = \sqrt{2}\pi/4$, $V_0 = \pi$, we see that the necessary condition is fulfilled by the ellipse with semiaxes $h_x = 2^{-1/4}$ and $h_y = 2^{1/4}$. The associated Lagrange multipliers are $\lambda_B = -4/9$, $\lambda_V = 8\sqrt{2}/9$, and $\lambda_{S_x} = \lambda_{S_y} = 0$; cf. [2]. From the identity

$$T(\Omega) = \int_\Omega \|\nabla u(\mathbf{x})\|^2 d\mathbf{x},$$

we deduce that $\nabla T(\Omega)[dr]$ and $\nabla^2 T(\Omega)[dr_1, dr_2]$ are given as in (2.12) and (2.13) with $g \equiv 0$ and

$$\Delta du = 0 \text{ in } \Omega, \qquad du = -dr_2 \, \langle \widehat{\mathbf{n}}, \mathbf{n} \rangle \frac{\partial u}{\partial \mathbf{n}} \text{ on } \Gamma.$$

Recall that twice differentiability needs $r \in X := C^{2,\alpha}_{\mathrm{per}}([0, 2\pi])$; cf. subsection 2.3. The computation of the other gradients and Hessians is straightforward; see [18, 19] for the details.

We approximate the radial function r similarly to our first example by periodic cubic splines on the interval $[0, 2\pi]$. Even though the sufficient optimality condition has not yet been proven, our experience indicates coercivity in the energy space $H^{1/2}([0, 2\pi])$; cf. [18, 19, 21]. More precisely, coercivity of the Lagrangian at $(\Omega^\star, \lambda^\star)$ has to hold on the closed subspace $Y \subseteq C^{2,\alpha}_{\mathrm{per}}([0, 2\pi])$, where

$$\begin{aligned} Y := \{dr \in C^{2,\alpha}_{\mathrm{per}}([0, 2\pi]) : \nabla B(\Omega^\star)[dr] = 0 \wedge \nabla V(\Omega^\star)[dr] = 0 \\ \wedge \nabla S_x(\Omega^\star)[dr] = 0 \wedge \nabla S_y(\Omega^\star)[dr] = 0\}. \end{aligned}$$

However, the pure Lagrangian is introduced only for investigating the sufficient optimality condition. In order to numerically solve the discretized constrained shape optimization problem, we need to find the stationary points of the following augmented Lagrange functional:

$$L_c(\Omega, \boldsymbol{\lambda}) := -T(\Omega) + \boldsymbol{\lambda}^T \begin{bmatrix} B(\Omega) - B_0 \\ V(\Omega) - V_0 \\ S_x(\Omega) \\ S_y(\Omega) \end{bmatrix} + \frac{c}{2} \left\| \begin{bmatrix} B(\Omega) - B_0 \\ V(\Omega) - V_0 \\ S_x(\Omega) \\ S_y(\Omega) \end{bmatrix} \right\|^2,$$

where $\boldsymbol{\lambda} := (\lambda_B, \lambda_V, \lambda_{S_x}, \lambda_{S_y})$ and $c > 0$ is an appropriate chosen penalty parameter. The optimization algorithm then reads as follows:

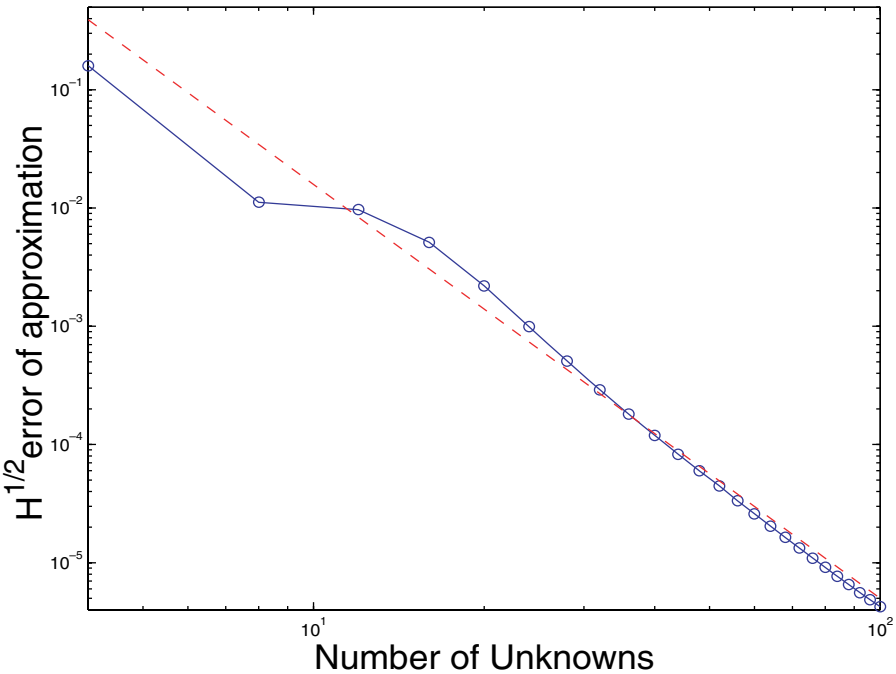

FIG. 4.2. *$H^{1/2}$-error of the approximate solution.*

- initialization: choose initial guess $(\Omega^{(0)}, \boldsymbol{\lambda}^{(0)})$ for $(\Omega^\star, \boldsymbol{\lambda}^\star)$.
- inner iteration: solve $\Omega^{(n+1)} := \operatorname{argmin} L_c(\Omega, \boldsymbol{\lambda}^{(n)})$ with initial guess $\Omega^{(n)}$.
- outer iteration: update

$$\lambda^{(n+1)} := \lambda^{(n)} - c \begin{bmatrix} B(\Omega^{(n+1)}) - B_0 \\ V(\Omega^{(n+1)}) - V_0 \\ S_x(\Omega^{(n+1)}) \\ S_y(\Omega^{(n+1)}) \end{bmatrix}.$$

In the inner iteration, we employ a Newton scheme combined with a quadratic line-search. Instead of the first order update rule described above, we use a second order Lagrange multiplier method introduced in [36] (see also [21]), which provides faster convergence of the dual parameters. The state equation is solved by using a boundary element method; cf. [18, 19] for the details. Notice that about 2000 boundary elements are required to solve the state equation sufficiently accurately if we discretize the free boundary by $N = 100$ B-splines.

According to our convergence result we shall observe the rate of convergence

$$\|r - r_N\|_{H^{1/2}([0,2\pi])} \lesssim N^{-3.5} \|r\|_{H^4([0,2\pi])}.$$

We measure this norm via the approximation

$$\|r - r_N\|^2_{H^{1/2}([0,2\pi])} \sim \|r - r_N\|^2_{L^2([0,2\pi])} + \int_0^{2\pi} |r - r_N||r' - r'_N| d\phi.$$

The results are presented in Figure 4.2. As predicted, the error decreases like $N^{-3.5}$, which is indicated by the dashed line.

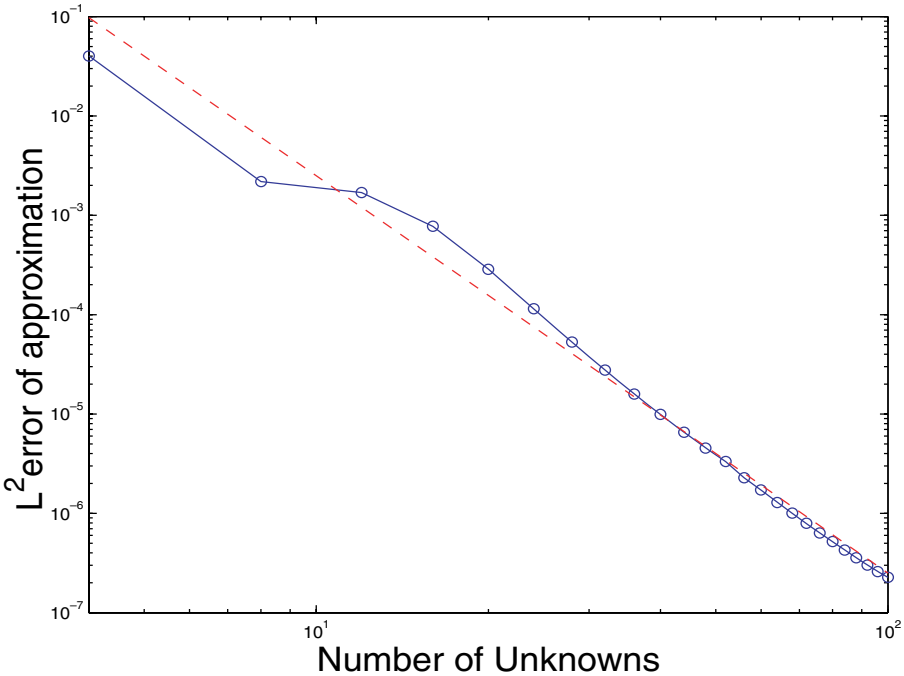

FIG. 4.3. *L^2-error of the approximate solution.*

In addition we also measured the L^2-norm of the approximation error, visualized in Figure 4.3. In fact, even though we have not proven the Aubin–Nitsche trick, we observe the higher rate of convergence N^{-4}, indicated by the dashed line.

5. Concluding remarks. In the present paper we established a complete convergence analysis for approximate solutions of shape optimization problems. In particular, we incorporated the two norm discrepancy. We presented numerical results which verify the predicted rates of convergence. We would like to point out that our analysis applies also to p-discretizations of the domain's parametrization, for example, finite dimensional Fourier sequences for the discretization of the radial function. For several applications we refer to [9, 18, 19, 20]; see also [22, 24, 42] for related problems in three dimensions.

LYAPUNOV-BASED DESIGN OF iISS FEEDFORWARD SYSTEMS WITH UNCERTAINTY AND NOISY MEASUREMENTS*

STEFANO BATTILOTTI†

Abstract. We study the problem of achieving integral input to state stability (iISS) with respect to noise for a class of upper triangular nonlinear systems with uncertainty and measurement noise. We propose a novel step-by-step Lyapunov-based design, consisting of (1) splitting an n-dimensional system into n one-dimensional systems, each with its own state, inputs, and measurement, (2) constructing a one-dimensional measurement feedback controller for each one-dimensional system, according to a certainty equivalence principle, and (3) selecting the parameters of these controllers so that their interconnection gives a measurement feedback controller for the n-dimensional system. The stability analysis is performed through *filtered* Lyapunov functions, which are Lyapunov functions with parameters being the output of suitable dynamical filters.

Key words. measurement feedback, bounded feedback, feedforward systems, uncertain systems

1. Introduction and main results. In practical applications the controlled output of a system is in general different from the measured output (*measurement*), and, moreover, the measured output is affected by noise and uncertainty. In this paper we study the problem of achieving integral input to state stability (iISS) in the sense of [1] with respect to noise by means of measurement feedback. To this aim, consider the class of systems

$$\dot{x}_j = x_{j+1} + \psi_{js}(x, x_{n+1}, w), \quad \mu_j = x_j + \psi_{jm}(x, x_{n+1}, w), \quad j = 1, \dots, n, \tag{1.1}$$

with states $x = (x_1 \ \cdots \ x_n)^T$, control $u := x_{n+1}$, noise $w \in \mathcal{L}_2^r(\mathbb{R}^{\geq})$ (space of functions $w : [0, \infty) \to \mathbb{R}^r$ such that $\int_0^\infty \|w(s)\|^2 ds < \infty$), uncertainties $\psi_{js}(x, x_{n+1}, w)$ and $\psi_{jm}(x, x_{n+1}, w)$, and measurements $\mu = (\mu_1 \ \cdots \ \mu_n)^T$, with continuous functions $\psi_{ji} : \mathbb{R}^n \times \mathbb{R} \times \mathbb{R}^r \to \mathbb{R}$ such that for $j = 1, \dots, n$, $i = s, m$, and $h = j+1, \dots, n+1$,

$$\begin{aligned} &|\psi_{ji}|_{w=0} - \psi_{ji}|_{x_h=\overline{x}_h, w=0}|^2 \leq |x_h - \overline{x}_h|^2 a_{jih}(\overline{x}_h, x_{j+1}, \dots, x_{n+1}), \\ &|\psi_{ji}(x, x_{n+1}, w) - \psi_{ji}|_{w=0}|^2 \leq \|w\|^2 b_{ji}(x_{j+1}, \dots, x_{n+1}), \\ &a_{js,j+1}(0, 0, \dots, 0) = 0, \quad \psi_{ji}|_{x_h=0, h=j+1,\dots,n+1; w=0} = 0 \end{aligned} \tag{1.2}$$

for all $x \in \mathbb{R}^n, w \in \mathbb{R}^r$, and $x_{n+1}, \overline{x}_h \in \mathbb{R}$ and for some smooth functions $a_{jih} : \mathbb{R}^{n-j+2} \to \mathbb{R}^{\geq}$ and $b_{ji} : \mathbb{R}^{n-j+1} \to \mathbb{R}^{\geq}$, where $\psi_{ji}|_{x_h=\overline{x}_h}$ denotes the function $\psi_{ji}(x, x_{n+1}, w)$ evaluated for $x_h = \overline{x}_h$. In particular, if each function $\psi_{ji}(x, x_{n+1}, w)$, $i = s, m$, does not depend on $x_1, \dots, x_j$, then the first two inequalities of (1.2) are satisfied as long as $\psi_{ji}(x, x_{n+1}, w)$, $i = s, m$, is smooth and grows at most linearly with respect to w. The linear growth with respect to w is required only for simplicity and can be relaxed, by replacing $\|w\|^2$ with $\alpha(\|w(s)\|)$, $\alpha \in \mathcal{K}$, such that $\int_0^\infty \alpha(\|w(s)\|) ds < \infty$. On the other hand, $a_{js,j+1}(0, 0, \dots, 0) = 0$ requires that for

†Dipartimento di Informatica e Sistemistica "Antonio Ruberti," Università di Roma La Sapienza, Via Eudossiana 18, 00184 Rome, Italy (battilotti@dis.uniroma1.it).

$x_l = 0$, $l = j+2, \dots, n+1$, the incremental ratio of $\psi_{ji}(x, x_{n+1}, 0)$ between x_{j+1} and $\overline{x}_{j+1}$ can be made in norm as small as desired by making small x_{j+1} and $\overline{x}_{j+1}$. For smooth ψ_{ji} this means that ψ_{ji} does not contain, for $x_l = 0$, $l = j+2, \dots, n+1$, linear terms in x_{j+1}. The example

$$\begin{aligned} \dot{x}_1 &= x_2 + x_2^2 \sin(x_1 x_2) + x_2 x_3 w, \quad \mu_1 = x_1, \\ \dot{x}_2 &= x_3, \quad \mu_2 = x_2 + x_3^4 \sin(x_2) + x_3^2 w, \\ \dot{x}_3 &= u + u^2 \cos(x_1 x_3), \quad \mu_3 = x_3 + w \end{aligned} \tag{1.3}$$

clearly satisfies (1.2) with $a_{1s2} = 2(x_2 + \overline{x}_2)^2 + 2\overline{x}_2^4 \max_{x_1, x_2, \overline{x}_2}[(\sin(x_1 x_2) - \sin(x_1 \overline{x}_2)) / (x_2 - \overline{x}_2)]^2$, $a_{2m3} = (x_3 + \overline{x}_3)^2 (x_3^2 + \overline{x}_3^2)^2$, $a_{3s4} = (u + \overline{u})^2$, $b_{1s} = x_2^2 x_3^2$, $b_{2m} = x_3^4$, and $b_{3m} = 1$. The main result of this paper for the class of systems (1.1) is the following theorem. Let $\widetilde{x}_1 := 0$, $\widetilde{x}_{n+1} := x_{n+1} = u$, and $G(s) = \frac{s}{\sqrt{1+s^2}}$.

THEOREM 1.1. *Under assumptions* (1.2) *there exist* $h_j \in (0,1)$ *and* $R_j \geq 1$, $j = 1, \dots, n$, *such that the feedback controller* $\mathcal{C}$,

$$\widetilde{x}_{j+1} = -\frac{G(\sigma_j)}{2R_j},\ \dot{\sigma}_j = \frac{1}{2R_j}\Big[(h_j - 1)G(\sigma_j) + \frac{1}{h_j} G(\mu_j - \widetilde{x}_j - \sigma_j)\Big],\ j = 1, \dots, n, \tag{1.4}$$

renders (1.1) *iISS with respect to* w.

We recall that a system $\Sigma : \dot{z} = f(z, w)$ is *iISS* if there exist functions $\alpha_1, \alpha_2 \in \mathcal{K}_\infty$ and $\beta \in \mathcal{KL}$ such that $\alpha_1(\|z(t)\|) \leq \beta(\|z(0)\|, t) + \int_0^t \alpha_2(\|w(s)\|) ds$ holds for all $t \geq 0$ along the trajectories of Σ. Note the "nested" structure of the controller (1.4), in the sense that the dynamics of $\dot{\sigma}_j$ depends on σ_{j-1} through the term $\widetilde{x}_j$.

With full state information (i.e., $\mu = x$) and without noise (i.e., $w = 0$) systems (1.1) have been studied in [7], [12] and extensively in the textbook [13]. On the other hand, with full state information iISS properties with respect to w have been obtained in [14]: we remark that Theorem 1.1 gives an improvement over [14] even with state feedback, since we do not require in (1.2) that $b_{ji}(0, \dots, 0) = 0$. However, these results cannot be applied to (1.1)–(1.2) since the measurements μ may differ significantly from the states x due to unbounded noise w and large uncertainty and, moreover, the coordinate change, as introduced in section 6.2 of [13], is a function of the noise and uncertainty and can hardly be implemented as a (smooth) function of the measurements. Moreover, even an observer-based control design is not feasible since the observer design for (1.1) is highly nontrivial. Note also that the systems (1.1)–(1.2) may be not in feedforward form, which is a substantial improvement over the above results.

Following [3] we implement a "dynamic" backstepping design in which $\widetilde{x}_{j+1}$ is used as the control for each dynamics $\dot{z}_j$, $j = 1, \dots, n$, where $z_j := x_j - \widetilde{x}_j$ is the backstepping coordinate, and for each state z_j we implement a robust observer to obtain an estimate of z_j to be used in $\widetilde{x}_{j+1}$ according to a certainty equivalence strategy (see (1.4)). In accordance with previous contributions on the subject, the boundedness of $\widetilde{x}_{j+1}$ in (1.4) is crucial due to the presence of terms $\mathcal{O}(|x_{j+1}|)$ in ψ_{js} (assumption $a_{js,j+1}(0, 0, \dots, 0) = 0$ in (1.2)), such as x_2^2 and u^2 in $\dot{x}_1$ and, respectively, $\dot{x}_3$ of (1.3) ($\mathcal{O}(|x_{j+1}|)$ means infinitesimals with order greater than $|x_{j+1}|$). Bounded backstepping with full state information has been also studied in [6] and [11].

The novelty with respect to previous contributions is the boundedness of the function $G(\mu_j - \widetilde{x}_j - \sigma_j)$ in $\dot{\sigma}_j$ of (1.4). This boundedness is crucial due to the nonlinear terms containing x_j fed back in $\dot{z}_j$ through $\dot{\widetilde{x}}_j$ (and thus, according to (1.4), through μ_{j-1}) and which could not be otherwise counteracted by the bounded control

$\widetilde{x}_{j+1}$ of $\dot{z}_j$. In example (1.3) with a controller (1.4) the term $x_3^4 \sin x_2$ in $\dot{\sigma}_2$ cannot be counteracted by the bounded control term $u + u^2 \cos(x_1 x_3)$ in $\dot{z}_3$ unless $G(s)$ is bounded for all s.

The proof of the main Theorem 1.1 is organized along the following lines.

• Define a system as characterized by states z, inputs ι, measurements ς, and uncertainty (section 3); both the inputs and measurements can be distinguished as endogenous (i.e., from inside the system) and exogenous (i.e., from outside the system) type. The endogenous inputs are the controls, and the endogenous measurements are the measured outputs. The rate of the uncertainty with respect to each state and input is quantified by the *incremental rates*.

• Split (1.1) into n one-dimensional systems Σ_j, $j = 1, \dots, n$ (section 4), each one with state $z_j := x_j - \widetilde{x}_j$, inputs ι_j (of which only one controls $\widetilde{x}_{j+1}$), and measurements ς_j (of which only one is an endogenous measurement $\widetilde{\mu}_j := x_j - \widetilde{x}_j + \psi_{jm}$).

• Find a one-dimensional measurement feedback controller $\mathcal{C}_j$ (each $\widetilde{x}_{j+1}$ and $\dot{\sigma}_j$ in (1.4)) and a Lyapunov function W_j for each one-dimensional system $\Sigma_j \circ \mathcal{C}_j$ (section 5) according to a certainty equivalence design (Theorem 3.1 of [4]).

• Take the interconnection $\mathcal{C}_j$, $j = 1, \dots, n$ (the controller (1.4)), as candidate controller $\mathcal{C}$ for (1.1) (section 8).

• Prove the iISS properties of the closed-loop system $\Sigma_j \circ \mathcal{C}_j$, $j = 1, \dots, n$, by suitably selecting the parameters of the controllers $\mathcal{C}_j$, $j = 1, \dots, n$, in such a way as to enlarge the stability margins of each $\Sigma_j \circ \mathcal{C}_j$ and compensate for the incremental rates of the exogenous inputs in the time derivatives $\dot{W}_i$, $i = 1, \dots, n$ and $i \neq j$ (section 8). A Lyapunov function W for the closed-loop system Σ is obtained from W_j, $j = 1, \dots, n$, according to Theorem 7.4 in section 7. Theorem 7.4 gives the procedure for obtaining a Lyapunov function under the quite general assumptions that the state trajectories are bounded and definitely enter a neighborhood of the origin, where a small gain condition is met. With respect to the small gain theorem of [8] which assesses only the existence of a Lyapunov function W for the interconnection, application of Theorem 7.4 to systems (1.1)–(1.4) gives a Lyapunov function W consisting of a "filtered" combination of $W_1, \dots, W_n$, i.e., $\theta[W_1 + \tau_2[W_2 + \tau_3[\cdots + \cdots]]]$, where $\tau_2, \dots, \tau_n > 0$ and θ is the output of a filter implemented by explicitly using the stability margins and incremental rates of each $\Sigma_j \circ \mathcal{C}_j$, $j = 1, \dots, n$, in the time derivatives $\dot{W}_j$, $j = 1, \dots, n$. This leads to the notion of *filtered Lyapunov functions* (section 6) which give a new tool for the stability analysis of interconnected systems like (1.1)–(1.4). These systems are not triangular and, thus, the results for the design of composite Lyapunov functions given in [7] cannot be applied (Example 6.1 in section 6).

2. Notation. • $\|v\| = \sqrt{v^T v}$ denotes the euclidean norm of any given vector v and $\|v\|_A := \sqrt{v^T A v}$ for any positive semidefinite matrix A. $\mathbb{R}^s$ is the vector space of s-dimensional real column vectors; $\mathbb{R}^+$ (resp., $\mathbb{R}^{\geq}$) denotes the set of positive (resp., nonnegative) real numbers; I_n is the $n \times n$ identity matrix; and $\mathbb{R}^{n \times n}$ denotes the set of $n \times n$ matrices.

• For any continuous function $f : \mathbb{R}^q \times \mathbb{R}^l \to \mathbb{R}^r$, $(s, r) \mapsto f(s, r)$, we denote by $f(z, r)$ or $f|_{s=z}$ the function $f(s, r)$ with $s = z$. A continuous function $\alpha : \mathbb{R}^{\geq} \to \mathbb{R}^{\geq}$ is said to be of class $\mathcal{K}$ (or $\alpha \in \mathcal{K}$) if $\alpha(0) = 0$ and it is increasing; a function $\alpha : \mathbb{R}^{\geq} \to \mathbb{R}^{\geq}$ is said to be of class $\mathcal{K}_\infty$ (or $\alpha \in \mathcal{K}_\infty$) if $\alpha \in \mathcal{K}$ and $\lim_{s \to +\infty} \alpha(s) = +\infty$; a function $\alpha : \mathbb{R}^{\geq} \times \mathbb{R}^{\geq} \to \mathbb{R}^{\geq}$ is said to be of class $\mathcal{KL}$ (or $\alpha \in \mathcal{KL}$) if for each r, $\alpha(s, r)$ is of class $\mathcal{K}$ and for each s it is decreasing and $\lim_{r \to +\infty} \alpha(s, r) = 0$; $\mathcal{K}_\infty^0$ is the class of continuous functions $f : \mathbb{R} \to \mathbb{R}^{\geq}$ such that $f \in \mathcal{K}_\infty$ when restricted to $[0, \infty)$.

• $\mathcal{L}_2^s(\mathbb{R}^{\geq})$ is the class of measurable and square integrable functions $\chi : \mathbb{R}^{\geq} \to \mathbb{R}^s$, and the norm of $\chi(t)$ in $\mathcal{L}_2^s(\mathbb{R}^{\geq})$ is $\|\chi\|_2 = \sqrt{\int_0^\infty \|\chi(\tau)\|^2 d\tau}$. We simply write $\mathcal{L}_2(\mathbb{R}^{\geq})$ when $s = 1$.

• For any given functions $h_j : \mathbb{R}^q \to \mathbb{R}$, $j = 1, 2$, we say that $h_1(s)$ *is of the same order as* $h_2(s)$ (in $\mathcal{S} \subset \mathbb{R}^q$) if there exists $\kappa_1, \kappa_2 > 0$ such that $\kappa_1 h_2(s) \leq h_1(s) \leq \kappa_2 h_2(s)$ for all s ($\in \mathcal{S}$) and we write $h_1 \sim h_2$. Moreover, we say that $h_1(s)$ *is less than or equal to* $h_2(s)$ (in $\mathcal{S} \subset \mathbb{R}^q$) if there exists $\kappa > 0$ such that $h_1(s) \leq \kappa h_2(s)$ for all s ($\in \mathcal{S}$) and we write $h_1 \preceq h_2$.

• For any smooth functions $V : \mathbb{R} \to \mathbb{R}^{\geq}$, $s \mapsto V(s)$, we denote by $\nabla_r V(r)$ the derivative of $V(r)$ with respect to r and by $\nabla_s V|_r$ the derivative of $V(s)$ with respect to s evaluated for $s = r$.

3. Complex dynamics as interconnection of simpler dynamics. In view of a general approach to the stabilization of an interconnected system such as (1.3) we consider it as the interconnection of three one-dimensional systems:

$$\Sigma_1 : \dot{x}_1 = x_2 + x_2^2 \sin(x_1 x_2) + x_2 x_3 w, \quad \mu_1 = x_1$$

with state x_1, control x_2, and measurement μ_1;

$$\Sigma_2 : \dot{x}_2 = x_3, \quad \mu_2 = x_2 + x_3^4 \sin(x_2) + x_3^2 w$$

with state x_2, control x_3, and measurement μ_2; and

$$\Sigma_3 : \dot{x}_3 = u + u^2 \cos(x_1 x_3), \quad \mu_3 = x_3 + w$$

with state x_3, control u, and measurement μ_3. Note that in each system Σ_j the following hold.

– We can distinguish the inputs into *control (or endogenous) inputs* v (such as x_2 for Σ_1) and *exogenous inputs* χ (such as x_3 and w for Σ_1). We denote all the inputs, endogenous and exogenous, by ι.

– We can distinguish the measurements into *endogenous measurements* μ (available from the system itself such as μ_3 for Σ_3) and *exogenous measurements* ν (available from other systems such as μ_3 for Σ_1). We denote all the measurements, endogenous and exogenous, by ς.

– State, inputs and measurements satisfy some constraints, given by the measurement equations and differential equations of the other systems such as $x_2 = \mu_2 - x_3^4 \sin(x_2) - x_3^2 w$ and $x_3 = \mu_3 - w$ for Σ_2 or $\dot{x}_2 = x_3$ for Σ_1. Note that on account of these constraints $|x_2| \leq |\mu_2| + 8\mu_3^4 + 4w^4 + w^2$. We will refer to this entire set of constraints by saying that *a system* Σ *with states* $x \in \mathbb{R}^n$*, inputs* $\iota = (v^T \ \chi^T)^T \in \mathcal{I} \subseteq \mathbb{R}^m \times \mathbb{R}^r$*, and measurements* $\varsigma = (\mu^T \ \nu^T)^T \in \mathcal{Z} \subseteq \mathbb{R}^p \times \mathbb{R}^s$ *satisfies a set of constraints* $\mathcal{M}$ *among the state, inputs, and measurements or* $(x, \iota, \varsigma) \in \mathcal{M}$.

– State and measurement uncertainty ψ_{js} and ψ_{jm} can be accommodated into a vector Ψ, which denotes the "uncertainty" of a system. The uncertainty can be seen as a locally Lipschitz continuous function $\Psi : \mathbb{R}^n \times \mathcal{I} \to \mathbb{R}^q$, $(x, \iota) \mapsto \Psi(x, \iota)$, such that $\Psi(0, 0) = 0$. We will denote the uncertainty by Ψ or, when needed, more explicitly with ψ_{js} and ψ_{jm}.

Thus, any interconnected n-dimensional system such as (1.3) can be viewed as the interconnection of n one-dimensional systems, each one with a state z, a control v, an endogenous measurement μ, uncertainty Ψ, some exogenous inputs χ, some exogenous measurements ν, and a set of constraints $\mathcal{M}$ among the state, inputs, and measurements. It is important for the controller design to evaluate the effect of the

uncertainty Ψ on the system under the constraints $\mathcal{M}$. Indeed, the constraints $\mathcal{M}$ allow us to either get suitable bounds depending only on the measurements, which can be used in the design of a controller for the system itself (internal stability properties), or bound some state-dependent terms by means of the exogenous inputs which can be related to the stability properties of other interconnected systems (external stability properties). In the case of Σ_1 with state x_1, measurements ς_1 (endogenous μ_1 and exogenous $\nu_1 = (\mu_2\ \mu_3)^T$), inputs ι_1 (control $v = x_2$ and exogenous $\chi_1 = (x_3\ w)^T$), uncertainty $\Psi_1 = (x_2^2 \sin(x_1 x_2) + x_2 x_3 w \quad 0)^T$, and constraint $\mathcal{M}_1 = \{\mu_3 = x_3 + w,\ \mu_2 = x_2 + x_3^4 \sin(x_2) + x_3^2 w,\ |w| \le 1\}$, we have $(\|\Psi_1\| - \|\Psi_1|_{w=0}\|)^2 \le a[\mu_3^2 + 1][\mu_2^2 + \mu_3^8 + 1]^2 w^2$ for some $a > 0$ and for all $(x_1, \iota_1, \varsigma_1) \in \mathcal{M}_1$. Note that the function $\gamma_1^w(\varsigma_1) = a[\mu_3^2+1][\mu_2^2+\mu_3^8+1]^2$ gives a "worst case" bound of the "incremental term" $(\|\Psi_1\| - \|\Psi_1|_{w=0}\|)^2/w^2$ under the constraints $\mathcal{M}_1$. Note also that the constraint $\mathcal{M}_1$ has been used in γ_1^w to bound the inputs x_2, x_3 in terms of the measurements μ_2, μ_3 so that γ_1^w can be used in the design of a controller for Σ_1. This motivates the following definition, which we recall here from [4] for extensive use.

DEFINITION 3.1 (incremental rate). *We will say that a system Σ with states $x \in \mathbb{R}^n$, inputs $\iota \in \mathcal{I} \subseteq \mathbb{R}^m \times \mathbb{R}^r$, measurements $\varsigma \in \mathcal{Z} \subseteq \mathbb{R}^p \times \mathbb{R}^s$, uncertainty $\Psi \in \mathbb{R}^q$, and constraints $\mathcal{M}$ has (smooth) incremental rate γ^z if there exist a nonempty subvector z of $(x^T\ \iota^T)^T$ and a (smooth) nonnegative function $\gamma^z : \mathbb{R}^n \times \mathcal{I} \times \mathcal{Z} \to \mathbb{R}^{\ge}$ such that $(\|\Psi\| - \|\Psi|_{z=0}\|)^2 \le \gamma^z(x, \iota, \varsigma)\|z\|^2$ for all $(x, \iota, \varsigma) \in \mathcal{M}$.*

Since $\Psi|_{x,v,\chi=0} = 0$ and $\|\Psi\| \le \|\Psi - \Psi|_{x=0}\| + \|\Psi|_{x=0} - \Psi|_{x,v=0}\| + \|\Psi|_{x,v=0} - \Psi|_{x,v,\chi=0}\|$, for a system Σ with states x, inputs ι, measurements ς, uncertainty Ψ, and constraints $\mathcal{M}$ we expect to have the following general relation among Ψ on one side, and x, ι, ς on the other, under the constraints $\mathcal{M}$:

$$\gamma^2(\varsigma)\|\Psi\|^2 \le \gamma^x(x,\varsigma)\|x\|^2 + \gamma^v(\varsigma)\|v\|^2 + \sum_{j\in J} \gamma^{\chi_j}(x,\iota,\varsigma)\chi_j^2 \quad \forall (x,\iota,\varsigma) \in \mathcal{M}, \tag{3.1}$$

where χ_j is the jth element of χ, $j \in J := \{1, \dots, r\}$, and $\gamma^x : \mathbb{R}^n \times \mathcal{Z} \to \mathbb{R}^{\ge}$, $\gamma^v : \mathcal{Z} \to \mathbb{R}^+$, and $\gamma^{\chi_j} : \mathbb{R}^n \times \mathcal{I} \times \mathcal{Z} \to \mathbb{R}^{\ge}$ are (smooth) incremental rates ("rescaled" by the square of a smooth function $\gamma : \mathcal{Z} \to \mathbb{R}^+$). The inequality (3.1) means that the uncertainty Ψ is known up to the square of the states and the inputs, weighted by the corresponding incremental rates evaluated under some constraints $\mathcal{M}$. This approach is inspired by an $\mathcal{H}_\infty$-control problem formulation, with Ψ having the role of a "disturbance," the right-hand side of (3.1) having the role of a "penalty index," and γ having the role of an "attenuation level" [2]. Note that the incremental rate γ^v is assumed (without loss of generality) to be a positive real function. Note also that, by use of the constraints $\mathcal{M}$ in (3.1), the incremental rate γ^v depends only on the measurements, so that it can be used directly in designing the controller gains.

DEFINITION 3.2 (incremental rates and scaling of Σ). *We will say that a system Σ with states $x \in \mathbb{R}^n$, inputs $\iota \in \mathcal{I} \subseteq \mathbb{R}^m \times \mathbb{R}^r$, measurements $\varsigma \in \mathcal{Z} \subseteq \mathbb{R}^p \times \mathbb{R}^s$, uncertainty $\Psi \in \mathbb{R}^q$, and constraints $\mathcal{M}$ has (smooth) incremental rates γ^x, γ^v, and γ^{χ_j}, $j \in J$, with scaling γ if* (3.1) *holds for some (smooth) nonnegative functions $\gamma^x : \mathbb{R}^n \times \mathcal{Z} \to \mathbb{R}^{\ge}$, $\gamma^{\chi_j} : \mathbb{R}^n \times \mathcal{I} \times \mathcal{Z} \to \mathbb{R}^{\ge}$ and positive $\gamma^v, \gamma : \mathcal{Z} \to \mathbb{R}^+$.*

Throughout the paper, *when an incremental rate is not explicitly cited in the context, we consider it equal to zero.*

4. Splitting systems into simpler dynamics. In this section, using the general framework introduced in section 3, we split the dynamics (1.1) into n one-dimensional systems having a "canonical" form. To do this we change coordinate x_j into *backstepping coordinate* $z_j := x_j - \widetilde{x}_j$, $j = 1, \dots, n$, $\widetilde{x}_1 := 0$, to use $\widetilde{x}_{j+1}$ as the

control for $\dot z_j$ instead of x_{j+1} (which is a state for (1.1)) as the control for $\dot x_j$. Also we change each measurement μ_j into $\widetilde\mu_j := \mu_j - \widetilde x_j$, $j = 1, \dots, n$, to have z_j as the "nominal part" of the measurement $\widetilde\mu_j$. Since by (1.2) each ψ_{ji} contains terms $\mathcal{O}(|\widetilde x_{j+1}|)$, to control $\dot z_j$ through $\widetilde x_{j+1}$ it is thus important to keep $\widetilde x_{j+1}$ as small as possible (see [14]). This accounts for introducing the *constraints* $\{|\widetilde x_{i+1}| \le \Delta_i \in (0,1], i = 1, \dots, n\}$. We see that in *backstepping coordinates* z_j, $j = 1, \dots, n$, and with *measurement change* $\widetilde\mu_j$, $j = 1, \dots, n$, (1.1) can be split into n one-dimensional systems of the form

$$\Sigma_j : \dot z_j = \widetilde x_{j+1} + \widetilde\psi_{js},\ \widetilde\mu_j = z_j + \psi_{jm} \tag{4.1}$$

with state z_j, control $\widetilde x_{j+1}$ with $\widetilde x_{n+1} := u$, (endogenous) measurement $\widetilde\mu_j$, and exogenous inputs $z_1, \dots, z_{j-1}, z_{j+1}, \dots, z_n, \widetilde x_2, \dots, \widetilde x_j, \dot{\widetilde x}_j, \widetilde x_{j+2}, \dots, \widetilde x_{n+1}$ and w; uncertainties ψ_{jm} and $\widetilde\psi_{js} := \psi_{js} + z_{j+1} - \dot{\widetilde x}_j$, with $\dot{\widetilde x}_1 := 0$ and $z_{n+1} := 0$; and constraints $\widetilde M_j := \{|\widetilde x_{i+1}| \le \Delta_i \in (0,1], i = 1, \dots, n\}$. Moreover, by using (1.2) and Lemma A.1 we find $\gamma_{ji}^{\widetilde x_h}(\Delta_j, \dots, \Delta_{h-1}) \ge 0$, $h = j+1, \dots, n+1$, $i = s, m$, and smooth functions $\gamma_{ji}^{z_h} : \mathbb{R}^{n-h+1} \to \mathbb{R}^{\ge}$, $h = j+1, \dots, n$, and $\gamma_{ji}^{w} : \mathbb{R}^{n-j} \to \mathbb{R}^{\ge}$, $i = s, m$, such that (A.1)–(A.3) hold true for $j = 1, \dots, n$ and for all $w \in \mathbb{R}^r$, $x_h, \widetilde x_h \in \mathbb{R}$, $h = 1, \dots, n+1$, $\dot{\widetilde x}_h \in \mathbb{R}$, $h = 1, \dots, n$, such that $|\widetilde x_h| \le \Delta_{h-1}$. As a consequence of (A.2)–(A.3) $\gamma_{js}^{\dot{\widetilde x}_j} := 2$, $\gamma_{jm}^{\dot{\widetilde x}_j} := 0$, $\gamma_{ji}^{\widetilde x_h}$, $h = j+1, \dots, n+1$, $i = s, m$, $\gamma_{ji}^{z_h}$, $h = j+1, \dots, n$, and γ_{ji}^{w}, $i = s, m$, are the incremental rates of Σ_j. We remark that the incremental rates of $z_1, \dots, z_{j-1}$ and $\widetilde x_2, \dots, \widetilde x_j$ are set to zero on account of the same Lemma A.1. Note also that the input $\dot{\widetilde x}_j$ will be specified later. When in the proof of Theorem 1.1 we will define $\widetilde x_j$ as a function of σ_{j-1} (see (1.4)), we will consider z_{j-1} and $z_{j-1} - \sigma_{j-1}$ as exogenous inputs for Σ_j and express $\dot{\widetilde x}_j$ and $\widetilde x_j$ in terms of the incremental rates of z_{j-1} and $z_{j-1} - \sigma_{j-1}$.

Example 4.1. In the case of (1.3) we get the three one-dimensional systems Σ_1 : $\dot z_1 = \widetilde x_2 + \widetilde\psi_{1s}$, $\widetilde\mu_1 = z_1$, with $\widetilde\psi_{1s} = z_2 + (z_2 + \widetilde x_2)^2 \sin(z_1(z_2 + \widetilde x_2)) + (z_2 + \widetilde x_2)(z_3 + \widetilde x_3)w$ and incremetal rates $\gamma_{1s}^{z_2} \sim 1 + z_2^2$, $\gamma_{1s}^{\widetilde x_2} \sim \Delta_1^2$, and $\gamma_{1s}^{w} \sim (z_2^2 + 1)(z_3^2 + 1)$ under the constraints $\{|\widetilde x_{i+1}| \le \Delta_i \in (0,1], i = 1, 2, 3\}$; $\Sigma_2 : \dot z_2 = \widetilde x_3 + \widetilde\psi_{2s}$, $\widetilde\mu_2 = z_2 + \psi_{2m}$, with $\widetilde\psi_{2s} = z_3 - \dot{\widetilde x}_2$, $\psi_{2m} = (z_3 + \widetilde x_3)^4 \sin(z_2 + \widetilde x_2) + (z_3 + \widetilde x_3)^2 w$ and incremetal rates $\gamma_{2s}^{z_3}, \gamma_{2s}^{\dot{\widetilde x}_2} \sim 1$, $\gamma_{2m}^{w} \sim (z_3 + 1)^4$, $\gamma_{2m}^{z_2} \sim 1 + z_3^6$, and $\gamma_{2m}^{\widetilde x_3} \sim \Delta_2^6$ under the constraints $\{|\widetilde x_{i+1}| \le \Delta_i \in (0,1], i = 1, 2, 3\}$; and $\Sigma_3 : \dot z_3 = u + \widetilde\psi_{3s}$, $\widetilde\mu_3 = z_3 + \psi_{3m}$, with $\widetilde\psi_{3s} = u^2 \cos(z_1(z_3 + \widetilde x_3)) - \dot{\widetilde x}_3$, $\psi_{3m} = w$ and incremetal rates $\gamma_{3s}^{u} \sim \Delta_3^2$ and $\gamma_{3s}^{\dot{\widetilde x}_3}, \gamma_{3m}^{w} \sim 1$ under the constraints $\{|\widetilde x_{i+1}| \le \Delta_i \in (0,1], i = 1, 2, 3\}$. As already stipulated regarding the other incremental rates which are not explicitly cited in the context, we consider them equal to zero.

In the next section we address the problem of controlling simple dynamics like (4.1).

5. Controlling simple dynamics. In this section we apply Theorem 3.1 of [4] for obtaining a measurement feedback controller $\mathcal{C}_j$ and a Lyapunov function W_j for any one-dimensional system Σ_j like (4.1). This result, although applied in our case to one-dimensional systems, can be used to extend Theorem 1.1 to block-feedforward systems, for which each system Σ_j in (4.1) has dimension possibly greater than one. By smooth *measurement feedback controller* $\mathcal{C}_j$ for Σ_j we mean

$$\dot\sigma_j = H_j(\sigma_j) + G_j(\widetilde\mu_j - \sigma_j), \quad \widetilde x_{j+1} = F_j(\sigma_j) \tag{5.1}$$

with $\sigma_j \in \mathbb{R}$ and smooth $H_j : \mathbb{R} \to \mathbb{R}$ and $G_j : \mathbb{R} \to \mathbb{R}$, vanishing at the origin and satisfying the *constraints*

$$|F_j(\sigma_j)| \le \Delta_{jf} \in (0,\infty], \quad |G_j(\widetilde{\mu}_j - \sigma_j)| \le \Delta_{jm} \in (0,\infty] \quad \forall \sigma_j, \widetilde{\mu}_j, \tag{5.2}$$

for some given $\Delta_{jf}, \Delta_{jm} \in (0,\infty]$. This definition extends without further remarks to the case of n-dimensional systems Σ_j. Note that the structure of the controller (5.1) is based on a *certainty equivalence principle*, consisting of replacing in the state feedback controller $\widetilde{x}_{j+1} = F_j(z_j)$ the state z_j with an estimate σ_j. The numbers Δ_{jf} and Δ_{jm} characterize, respectively, the maximum level allowed for the control input $\widetilde{x}_{j+1}$ and for the innovations $\widetilde{\mu}_j - \sigma_j$ fed back into the control loop by (5.1).

Definition 5.1 (controller levels). *We say that a smooth measurement feedback controller* (5.1) *has control input level* Δ_{jf} *and innovations level* Δ_{jm} *(or simply levels* $(\Delta_{jf}, \Delta_{jm})$*) if there exist* $\Delta_{jf}, \Delta_{jm} \in (0,\infty]$ *such that* (5.2) *holds true.*

We recall that any system Σ_j like (4.1) has state z_j, control $\widetilde{x}_{j+1}$, (endogenous) measurement $\widetilde{\mu}_j$, and among its exogenous inputs $z_{j+1}, \dots, z_n, \widetilde{x}_j, \dot{\widetilde{x}}_j, \widetilde{x}_{j+2}, \dots, \widetilde{x}_{n+1}$ and w. Throughout, we will denote by χ_{ji}, $i \in J_j$, any one of these exogenous inputs. Also, set $\gamma_{js}^{\dot{\widetilde{x}}_j} = 2$ and $\gamma_{jm}^{\dot{\widetilde{x}}_j} = 0$, and let $G(s)$ be as in Theorem 1.1.

Theorem 5.2. *For any system* Σ_j *like* (4.1) *satisfying* (A.1) *and* (A.2)–(A.3) *for* $j = 1, \dots, n$ *and for all* $w \in \mathbb{R}^r$*;* $x_h, \widetilde{x}_h \in \mathbb{R}$*,* $h = 1, \dots, n+1$*; and* $\dot{\widetilde{x}}_h \in \mathbb{R}$*,* $h = 1, \dots, n$*, such that* $|\widetilde{x}_h| \le \Delta_{h-1}$*, there exist* $\Delta_j, h_{js}, h_{jm} \in (0,1)$ *and* $R'_{j1} \ge 1$ *such that for all* $R_{j1} \ge R'_{j1}$ *the smooth measurement feedback controller*

$$\mathcal{C}_j : \widetilde{x}_{j+1} = -\frac{1}{2R_{j1}} G(\sigma_j), \quad \dot{\sigma}_j = \frac{1}{2R_{j1}} \Big[(h_{js} - 1) G(\sigma_j) + \frac{1}{h_{js}} G(\widetilde{\mu}_j - \sigma_j) \Big] \tag{5.3}$$

has levels $(\Delta_j, \Delta_j/h_{js})$ *and* $W_j(z_j, \sigma_j) = \sqrt{1+z_j^2} + \sqrt{1+(z_j-\sigma_j)^2} - 2$ *is smooth, proper, and positive definite and satisfies along the trajectories of* $\Sigma_j \circ \mathcal{C}_j$

$$\dot{W}_j \le -\varphi_{js}(z_j) z_j^2 - \varphi_{jm}(z_j - \sigma_j)(z_j - \sigma_j)^2 + \sum_{i \in J_j} \gamma_j^{\chi_{ji}} \chi_{ji}^2 \tag{5.4}$$

with stability margins

$$\varphi_{js}(z_j) := \frac{1 - h_{js}}{8R_{j1}(1+z_j^2)}, \quad \varphi_{jm}(z_j - \sigma_j) := \frac{1 - 16h_{js}}{32R_{j1}h_{js}[1+(z_j-\sigma_j)^2]} \tag{5.5}$$

and incremental rates

$$\gamma_j^{\chi_{ji}} := \frac{R_{j1}}{h_{js}} [\gamma_{js}^{\chi_{ji}} + h_{jm} \gamma_{jm}^{\chi_{ji}}]. \tag{5.6}$$

Proof. First we rewrite Σ_j as a system Σ of the form (1) in [4]; then we check the assumptions of Theorem 3.1 of [4] on Σ. By (A.1) there exist $\Delta_j \in (0,1)$ and $h_{js}, h_{jm} > 0$ such that

$$\gamma_{js}^{\widetilde{x}_{j+1}}(\Delta_j) + h_{jm} \gamma_{jm}^{\widetilde{x}_{j+1}}(\Delta_j) \le h_{js} \le 1/80. \tag{5.7}$$

Let

$$R_{j1} > R'_{j1} := \max \left\{ \frac{1}{\Delta_j}, \frac{1}{\sqrt{h_{jm}}} \right\}, \quad \gamma_j^2 = \frac{R_{j1}}{h_{js}}, \tag{5.8}$$

$$C_2 = B_2 = 1, \quad B_1 = \begin{pmatrix} 1 & 0 \end{pmatrix}, \quad C_1 = \begin{pmatrix} 0 & 1 \end{pmatrix} R_{j1}, \quad \Psi_j = \begin{pmatrix} \widetilde{\psi}_{js} & \dfrac{\psi_{jm}}{R_{j1}} \end{pmatrix}^T. \tag{5.9}$$

Along with positions (5.9), Σ_j reads out as a system Σ of the form (1) of [4] with $B_1C_1^T = 0$, $R_2 := C_1C_1^T = R_{j1}^2 > 0$, with state $x = z_j$, control $v = \widetilde{x}_{j+1}$, uncertainty $\Psi = \Psi_j$, and exogenous inputs χ_{ji}, $i \in J_j$. Moreover, from (A.2)–(A.3), the first inequality in (5.7), the fact that $h_{jm} > 1/R_{j1}^2$ and $h_{js}\gamma_j^2 = R_{j1}$ by (5.8), and having "rescaled" ψ_{jm} as in (5.9), we obtain under the constraints $\widetilde{M}_j := \{|\widetilde{x}_{i+1}| \le \Delta_i \in (0,1], i = 1,\dots,n\}$

$$\gamma_j^2\|\Psi_j\|^2 = \gamma_j^2\left[\widetilde{\psi}_{js}^2 + \frac{\psi_{jm}^2}{R_{j1}^2}\right] \le R_{j1}\widetilde{x}_{j+1}^2 + \frac{R_{j1}}{h_{js}}\Big[(\gamma_{js}^{\dot{\widetilde{x}}_j} + h_{jm}\gamma_{jm}^{\dot{\widetilde{x}}_j})|\dot{\widetilde{x}}_j|^2$$

$$(5.10)\quad + \sum_{h=j+1}^{n} z_h^2(\gamma_{js}^{z_h} + h_{jm}\gamma_{jm}^{z_h}) + \sum_{h=j+2}^{n+1} \widetilde{x}_h^2(\gamma_{js}^{\widetilde{x}_h} + h_{jm}\gamma_{jm}^{\widetilde{x}_h}) + (\gamma_{js}^{w} + h_{jm}\gamma_{jm}^{w})\|w\|^2\Big];$$

i.e., the incremental rates of Σ are $\gamma^v := R_{j1}$ and $\gamma^{\chi_{ji}} := \gamma_j^{\chi_{ji}}$ as in (5.6) with scaling $\gamma := \gamma_j$. We check the assumptions of Theorem 3.1 of [4] on Σ. Let $P_m = 1$ and $V_s(s) = V_m(s) = \widetilde{V}_m(s) = \frac{1}{2}[\sqrt{1+s^2} - 1]$. The functions $V_s(r)$ and $V_m(r)$ are proper and positive definite, and, moreover, $\nabla_s\widetilde{V}_m(s)/s := 1/[2\sqrt{1+s^2}] \in (0,1]$ for all s, and is even and nonincreasing for all $s \ge 0$. By direct calculations with $R_2 = R_{j1}^2$, we obtain that the inequalities (3) and (10) of [4] with $n = 1$ are satisfied, respectively, with $\varphi_s(s) = \varphi_{js}(s)$ and $\varphi_m(s) = \varphi_{jm}(s)$, where $\varphi_{js}(s)$ and $\varphi_{jm}(s)$ are as in (5.5) and, by the second inequality of (5.7), are positive for all z_j and σ_j. Also (12) and (13) of [4] follow from direct calculation of $\nabla_s\widetilde{V}_m(s)$, $\nabla_{ss}^2\widetilde{V}_m(s)$, and $\nabla_{sss}^3\widetilde{V}_m(s)$. Finally, since $R_{j1} > 1/\Delta_j > 1$ by (5.8) and since $\Delta_j \in (0,1)$, also the feedback constraints $|F(s,\varsigma)| \le \Delta_f$ and $|G(s,\varsigma)| \le \Delta_m$ in Theorem 3.1 of [4] are met for all s, with

$$(5.11)\qquad F(s,\varsigma) := -\frac{s}{2R_{j1}\sqrt{1+s^2}},$$
$$G(s,\varsigma) := \frac{s}{2R_{j1}h_{js}\sqrt{1+s^2}}, \quad \Delta_f = \Delta_j,\ \Delta_m = \frac{\Delta_j}{h_{js}}.$$

Finally, it is not difficult to see that

$$f_1(s_1,s_2) = \left[\frac{(s_1-s_2)}{\sqrt{1+(s_1-s_2)^2}} - \frac{s_1}{\sqrt{1+s_1^2}}\right]^2$$

has for each s_2 a global maximum for $s_1 = s_2/2$. Using this fact and the second inequality of (5.7), for all z_j, e_j

$$\frac{2}{\gamma_j^2}\nabla_{e_j}V_m(e_j)B_1B_1^T\Big[\nabla_{z_j}V_s(z_j) - \nabla_{z_j-e_j}V_s(z_j-e_j) - \nabla_{e_j}V_s(e_j)\Big]^T$$
$$+ \gamma^v(\|\ F(z_j-e_j) - F(z_j)\|^2 - \|F(e_j)\|^2)$$
$$\le \left[\frac{h_{js}}{R_{j1}} + \frac{1}{4R_{j1}}\right]\left[\frac{(z_j-e_j)}{\sqrt{1+(z_j-e_j)^2}} - \frac{z_j}{\sqrt{1+z_j^2}}\right]^2$$
$$\le \left[\frac{h_{js}}{R_{j1}} + \frac{1}{4R_{j1}}\right]\frac{e_j^2}{1+e_j^2/4} \le \frac{2}{R_{j1}}\frac{e_j^2}{1+e_j^2} \le \varphi_{jm}(e_j)e_j^2,$$

which implies (14) of [4] with $n = 1$. Application of Theorem 3.1 of [4] and (16) therein gives the controller $\mathcal{C}_j$ in (5.3) with levels $(\Delta_j, \Delta_j/h_{js})$ by (5.12) and that the smooth, proper, and positive definite $W_j(z_j,\sigma_j)$ satisfies (5.4) along the trajectories of $\Sigma_j \circ \mathcal{C}_j$. □

6. Filtered Lyapunov functions. The Lyapunov functions used in Theorem 5.2 cover with enough generality the stability analysis of systems of the form $\Sigma_j \circ \mathcal{C}_j$. However, when interconnecting more systems $\Sigma_i \circ \mathcal{C}_i$, $i = 1, \dots, n$, each one with Lyapunov function W_i, $i = 1, \dots, n$, a simple combination $\sum_{i=1}^{r} W_i \theta_i$, $\theta_i > 0$, may be not satisfactory for being a candidate Lyapunov function for the system interconnection Σ_i, $i = 1, \dots, n$ (see [7]). However, these interconnected systems are not necessarily triangular and, thus, even the results for the design of composite Lyapunov functions given in [7], [13] or [12] cannot be applied.

Example 6.1. Consider the system Σ:

$$\dot{z}_1 = -\frac{2z_1}{\sqrt{1+z_1^2}} + z_2^2 \sin(z_1), \quad \dot{z}_2 = -\frac{2z_2}{\sqrt{1+z_2^2}} + \varepsilon_2 \frac{z_1}{\sqrt{1+z_1^2}} \cos(z_1 z_2) \tag{6.1}$$

with $\varepsilon_2 \in (0, 1/2)$. If $W_j(z_j) = (1+z_j^2)^{1/2} - 1$, $j = 1, 2$, then after some computations

$$\begin{aligned} &\dot{W}_j \le -\varphi_j(z_j) z_j^2 + \gamma_j^{z_i}(z_i) z_i^2, \ j \neq i, \\ &\varphi_1(z_1) = \frac{1}{(1+z_1^2)}, \quad \gamma_1^{z_2}(z_2) = z_2^2, \quad \varphi_2(z_2) = \frac{1}{(1+z_2^2)}, \quad \gamma_2^{z_1}(z_1) = \frac{\varepsilon_2}{(1+z_1^2)}. \end{aligned} \tag{6.2}$$

Note that neither $\theta_1 W_1(z_1) + \theta_2 W_2(z_2)$, $\theta_1, \theta_2 > 0$, is a Lyapunov function for (6.1) nor the results of [7] can be applied to derive from $W_1(z_1)$ and $W_2(z_2)$ a composite Lyapunov function for (6.1).

Thus, we look for a "filtered" combination $\sum_{i=1}^{r} W_i \theta_i$, where θ_i are dynamical parameters which may depend on the system trajectories. The parameter $\theta_i(t)$, $i = 1, \dots, n$, should be positive along the system trajectories for $\sum_{i=1}^{r} W_i(t)\theta_i(t)$ being positive as well, and its time derivative should be nonpositive along the system trajectories for dominating the cross terms $\gamma_j^{z_i}(z_i) z_i^2$ in $\dot{W}_j$ and $\gamma_i^{z_j}(z_j) z_j^2$ in $\dot{W}_i$, $i, j = 1, \dots, n$, $i \neq j$.

Example 6.1 *(continued).* Let $c_2 := [1/(1-2\varepsilon_2)^{1/2} - 1]$ and assume that ε_2 is sufficiently small so that $(1+c_2)^2[(1+c_2)^2 - 1] < 1/2$. Moreover, let

$$\begin{aligned} &c_1 := 1/(1 - 2(1+c_2)^2[(1+c_2)^2 - 1])^{1/2} - 1, \\ &\kappa_1 := \tau_1(c_2), \quad \tau_1(s) := (1+s)^2[(1+s)^2 - 1], \quad \kappa_2 := \varepsilon_2. \end{aligned} \tag{6.3}$$

It can be easily seen that the trajectories of (6.1) are bounded, enter in finite time the set $\mathcal{R} = \{(z_1, z_2) : W_j(z_j) \le c_j, j = 1, 2\}$, and remain thereinafter. Boundedness of the trajectories of (6.1) follows from the fact that for each $i \neq j$ while $z_j(t)$ approaches the set $\{W_j(z_j) \le c_j\}$, $z_i(t)$ has infinite escape time. If, in addition, ε_2 is sufficiently small so that $\kappa_1 \kappa_2 < 1$, the "filtered" linear combination of W_1 and W_2,

$$\widetilde{W}(z_1, z_2, \theta) = \theta(W_1(z_1) + d_2 W_2(z_2)), \ d_2 \in (\kappa_1, 1/\kappa_2), \tag{6.4}$$

$$\dot{\theta} = -[\theta / \min\{c_1, d_2 c_2\}] \max\{\tau_1(W_2(z_2)) - \tau_1(c_2), 0\} \varphi_2(z_2) z_2^2, \ \theta(0) = 1, \tag{6.5}$$

satisfies

$$\dot{\widetilde{W}} \le -\theta[(1 - \kappa_2 d_2)\varphi_1 z_1^2 + (d_2 - \kappa_1)\varphi_2 z_2^2] \tag{6.6}$$

along the trajectories of (6.1) and (6.5). Also, since the trajectories of (6.1) are captured in finite time by $\mathcal{R}$ and $\tau_1(s)$ is nondecreasing for all $s \ge 0$, for each trajectory $(z_1(t), z_2(t))$ of (6.1)

$$\theta(t) = \exp\left\{ -[1/\min\{c_1, d_2 c_2\}] \int_0^t \max\{\tau_1(W_2(z_2(s))) - \tau_1(c_2), 0\} \varphi_2(z_2(s)) z_2^2(s) ds \right\}$$

for all $t \geq 0$, and, moreover, there exists $T > 0$ such that $\theta(t) = \theta(T)$ for all $t \geq T$. Thus, $\theta(t)$ is bounded and positive for all $t \geq 0$ and definitely approaches a constant positive value. For this reason, the filtered Lyapunov function $\widetilde{W}$ is a linear combination of W_1 and W_2 locally around the origin. Moreover, since $\theta(t)$ is positive for all $t \geq 0$ and $1 - \kappa_2 d_2 > 0$ and $d_2 - \kappa_1 > 0$ by (6.5), it follows from (6.6) that $\widetilde{W}(z_1(t), z_2(t), \theta(t))$ decreases along the trajectories of (6.1) and (6.5).

Although once the trajectories are trapped closely to the origin the stability analysis can be performed locally with a quadratic Lyapunov function, filtered Lyapunov functions unify the local and global dynamic behavior of interconnected systems and can be used in a Lyapunov based controller design to stabilize the interconnection itself (if not stable) or in small gain theorems for the stability analysis. The above discussion motivates the following definition. Let Σ be any given system with controller $\mathcal{C}$ and let z and σ be their corresponding (n-dimensional) states, with components z_j and, respectively, σ_j, $j = 1, \ldots, n$, and let χ be the exogenous inputs of Σ, with component χ_j, $j \in J$.

Definition 6.1 (filtered Lyapunov functions). *We say that* $\widetilde{W} : \mathbb{R}^n \times \mathbb{R}^n \times \Theta \to \mathbb{R}^{\geq}$, $(z, \sigma, \theta) \mapsto \widetilde{W}(z, \sigma, \theta) = \theta W(z, \sigma)$, $\Theta \subseteq \mathbb{R}$, *is a smooth filtered Lyapunov function for* $\Sigma \circ \mathcal{C}$ *with stability margins* $\theta\varphi_{sj}$, $\theta\varphi_{mj}$, $j = 1, \ldots, n$, *and incremental rates* $\theta\gamma^{\chi_j}$, $j \in J$, *if*

(i) $W(z, \sigma)$ *is smooth, proper and positive definite,*

(ii) $\dot{\theta}(t) \leq 0$ *and* $\theta(t) > 0$ *along the trajectories of* $\Sigma \circ \mathcal{C}$, *and*

(iii) *along the trajectories of* $\Sigma \circ \mathcal{C}$

$$\dot{\widetilde{W}} \leq -\theta \left\{ \sum_{j=1}^{n} [\varphi_{sj}(z) z_j^2 + \varphi_{mj}(z - \sigma)(z_j - \sigma_j)^2] + \sum_{j \in J} \gamma^{\chi_j}(z, \iota, \varsigma) \chi_j^2 \right\} \tag{6.7}$$

for some continuous positive (definite) functions $\varphi_{sj}, \varphi_{mj} : \mathbb{R}^n \to \mathbb{R}^{\geq}$ *and continuous functions* $\gamma^{\chi_j} : \mathbb{R}^n \times \mathcal{I} \times \mathcal{Z} \to \mathbb{R}^{\geq}$.

Clearly, by Theorem 5.2 W_j is a (filtered) Lyapunov function for $\Sigma_j \circ \mathcal{C}_j$ with stability margins (5.5) and incremental rates as in (5.6). If $\theta = 1$ and γ^{χ_j} are functions only of χ, then our filtered Lyapunov functions are *iISS Lyapunov functions* [1]. A smooth, proper, and positive definite function $\widetilde{W} : \mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R}^{\geq}$ for which there exist positive definite $\alpha : \mathbb{R}^{\geq} \to \mathbb{R}^{\geq}$ and $\beta \in \mathcal{K}_\infty$ such that $\dot{\widetilde{W}} \leq -\alpha(\widetilde{W}) + \beta(\|\chi\|)$ along the trajectories of $\Sigma \circ \mathcal{C}$ is said to be an *iISS Lyapunov function* for $\Sigma \circ \mathcal{C}$.

As already remarked, (ii) and (6.7) imply that $\widetilde{W}(z(t), \sigma(t), \theta(t))$ decreases along the trajectories of $\Sigma \circ \mathcal{C}$. However, this is not enough for inferring stability properties on the system trajectories of $\Sigma \circ \mathcal{C}$, since $\theta(t)$ varies itself along the trajectories of $\Sigma \circ \mathcal{C}$. The following results clarify the stability issues related to the existence of a filtered Lyapunov function and will be used to prove Theorem 1.1. Let χ be the exogenous inputs of Σ. We will say that $\Sigma \circ \mathcal{C}$ is 0-*GAS* if there exists $\beta \in \mathcal{KL}$ such that $\|z(t), \sigma(t)\| \leq \beta(\|z(0), \sigma(0)\|, t)$ for all $t \geq 0$ along the trajectories of $\Sigma \circ \mathcal{C}$ with $\chi = 0$, i.e., the origin of $\Sigma \circ \mathcal{C}$ is globally asymptotically stable. The following stability result can be proved as Theorem 4.1 of [9].

Lemma 6.2 (0-GAS). *Assume the existence of* $\alpha_1 \in \mathcal{K}$ *and* $\alpha_2, \alpha_3 \in \mathcal{K}_\infty$ *for which a smooth filtered Lyapunov function* $\widetilde{W} : \mathbb{R}^n \times \mathbb{R}^n \times \Theta \to \mathbb{R}^{\geq}$ *for* $\Sigma \circ \mathcal{C}$ *satisfies*

$$\dot{\widetilde{W}}(z(t), \sigma(t), \theta(t)) \leq -\alpha_1(\widetilde{W}(z(t), \sigma(t), \theta(t))), \tag{6.8}$$

$$\widetilde{W}(z(0), \sigma(0), \theta(0)) \leq \alpha_2(\|z(0), \sigma(0)\|), \tag{6.9}$$

$$\widetilde{W}(z(t),\sigma(t),\theta(t)) \geq \alpha_3(\|z(t),\sigma(t)\|) \tag{6.10}$$

for all $t \geq 0$ along the trajectories of $\Sigma \circ \mathcal{C}$. Then $\Sigma \circ \mathcal{C}$ is 0-GAS.

The iISS properties are then inferred through the following lemma. Let $\chi \in \mathcal{L}_2^r(\mathbb{R}^{\geq})$ be the exogenous inputs of Σ. We will say that $\Sigma \circ \mathcal{C}$ is *UBEBS* if there exist $\alpha_1, \alpha_2 \in \mathcal{K}_\infty$ and $\alpha_3 > 0$ such that $\|z(t),\sigma(t)\| \leq \alpha_1(\|z(0),\sigma(0)\|) + \alpha_2(\|\chi\|_2) + \alpha_3$ for all $\chi \in \mathcal{L}_2^r(\mathbb{R}^{\geq})$ and $t \geq 0$ along the trajectories of $\Sigma \circ \mathcal{C}$ [1].

LEMMA 6.3 (iISS [1]). *Assume that $\Sigma \circ \mathcal{C}$ is 0-GAS and UBEBS. Then $\Sigma \circ \mathcal{C}$ is iISS.*

In the next section we show how to construct filtered Lyapunov functions for complex systems, resulting from interconnecting dynamics like (4.1), using the filtered Lyapunov functions of the simpler dynamics in which these systems can be decomposed.

7. Filtered Lyapunov functions for interconnected systems. Let Σ_j, $j = 1, 2$, be given systems with controller $\mathcal{C}_j$ and smooth filtered Lyapunov function $\widetilde{W}_j(z_j,\sigma_j,\theta_j) = \theta_j W_j(z_j,\sigma_j)$ with stability margins $\theta_j\varphi_{jls}$, $\theta_j\varphi_{jlm}$, $l = 1,\dots,n_j$, and incremental rates $\theta_j\gamma_j^{\chi_{jl}}$, $l \in J_j := \{1,\dots,r_j\}$ (n_j is the dimension of the state vector z_j). In other words, along the trajectories of $\Sigma_j \circ \mathcal{C}_j$

$$\dot{\widetilde{W}}_j \leq -\theta_j \left\{ \sum_{l=1}^{n_j} [\varphi_{jls}(z_j) z_{jl}^2 + \varphi_{jlm}(e_j) e_{jl}^2] + \sum_{l \in J_j} \gamma_j^{\chi_{jl}}(z_j,\iota_j,\varsigma_j)\chi_{jl}^2 \right\}, \tag{7.1}$$

where $e_j := z_j - \sigma_j$ and e_{jl} and z_{jl} are the lth elements of e_j and z_j, respectively. We also assume that z_j, e_j are exogenous inputs of Σ_i and that μ_j, σ_j are exogenous measurements of Σ_i for $j \neq i$. Thus, z_j and e_j are elements of χ_i, and μ_j and σ_j are elements of ν_i for $j \neq i$. Moreover, wherever possible we will denote $\widetilde{W}_j(z_j(t),\sigma_j(t),\theta_j(t))$, $W_j(z_j(t),\sigma_j(t))$, φ_{jls} $(z_j(t))$, and $\varphi_{jlm}(e_j(t))$ simply by $\widetilde{W}_j(t)$, $W_j(t)$, $\varphi_{jls}(t)$, and $\varphi_{jlm}(t)$. We will also omit the arguments $z_j \in \mathbb{R}^{n_j}, \varsigma_j \in \mathcal{Z}_j, \iota_j \in \mathcal{I}_j$ of the functions whenever there is no ambiguity. In this section, we study the problem of finding a filtered Lyapunov function for the interconnection of $\Sigma_j \circ \mathcal{C}_j$, $j = 1, 2$. We start with the following definition.

DEFINITION 7.1 (local saturation). *Let $j, i = 1, 2$ with $i \neq j$. We say that φ_{jls} (resp., φ_{jlm}) locally saturates $\gamma_i^{z_{jl}}$ (resp., $\gamma_i^{e_{jl}}$) with levels (c_j, κ_i) if there exist $c_j > 0$ and a continuous nondecreasing function $\tau_i : \mathbb{R}^{\geq} \to \mathbb{R}^+$ such that $\tau_i(c_j) \leq \kappa_i$ and $\gamma_i^{z_{jl}} \leq \tau_i(W_j)\varphi_{jls}$ (resp., $\gamma_i^{e_{jl}} \leq \tau_i(W_j)\varphi_{jlm}$) for all ι_l, ς_l, $l = 1, 2$.*

Thus, "local saturation" in our context means that the ratio between $\gamma_i^{z_{jl}}$ and φ_{jls}, $j \neq i$, is, for $W_j \leq c_j$, locally bounded by κ_i and globally bounded by $\tau_i(W_j)$. If the function $\tau_i : \mathbb{R}^{\geq} \to \mathbb{R}^+$ can be taken constant, we have the following stronger property.

DEFINITION 7.2 (saturation). *Let $j, i = 1, 2$ with $i \neq j$. We say that φ_{jls} (resp., φ_{jlm}) saturates $\gamma_i^{z_{jl}}$ (resp., $\gamma_i^{e_{jl}}$) with level κ_i if there exist $\kappa_i > 0$ such that $\gamma_i^{z_{jl}} \leq \kappa_i\varphi_{jls}$ (resp., $\gamma_i^{e_{jl}} \leq \kappa_i\varphi_{jlm}$) for all ι_l, ς_l, $l = 1, 2$.*

In Example 6.1, $\gamma_2^{z_1}$ is saturated by φ_1 with levels (c_1, κ_2) and $\gamma_1^{z_2}$ is locally saturated by φ_2 with levels (c_2, κ_1), where $\tau_2(s) = \kappa_2$ and κ_1, κ_2, and $\tau_1(s)$ are as in (6.3).

The main result of this section points out the construction of a filtered Lyapunov function for the interconnection of $\Sigma_j \circ \mathcal{C}_j$, $j = 1, 2$, when each $\gamma_i^{z_{jl}}$ (resp., $\gamma_i^{e_{jl}}$) is locally saturated by φ_{jls} (resp., φ_{jlm}), $j \neq i$, with levels (c_j, κ_i) satisfying the small gain condition $\kappa_1\kappa_2 < 1$ and under the assumption that the trajectories of $\Sigma_j \circ \mathcal{C}_j$,

$j = 1, 2$, are bounded, enter in finite time a set in which $W_j \le c_j$, $j = 1, 2$, and remain thereinafter. This result will be applied in section 8 for constructing a filtered Lyapunov function for the interconnection of $\Sigma_j \circ \mathcal{C}_j$, $j = 1, 2$. It gives a filtered Lyapunov function W as a "filtered" linear combination of W_j, $j = 1, 2$. The design of composite Lyapunov functions has been widely studied in [8] for general systems and [12], [7], and [13] in the case of triangular systems $\dot z = f(z) + \psi(z, \xi)$, $\dot\xi = a(\xi)$. However, while the result of [8] does not lead to a constructive procedure, the constructive procedures of [12], [7], and [13] cannot be applied here since, as already remarked, the control design is not performed in our case by using feedforwarding [13] and rather relies on a backstepping-like strategy. As a consequence of this, in backstepping coordinates $z_j := z_j - \widetilde x_j$, $j = 1, \dots, n$, from (1.1)–(1.4) we get interconnected systems of the more general form $\dot z = f(z) + \psi(z, \xi)$, $\dot\xi = a(\xi) + \zeta(z, \xi)$. As a particular case, if $\zeta(z, \xi) \equiv 0$, we obtain the same class of interconnected systems considered in [7] and [13], and our filtered Lyapunov functions are alternative to the composite Lyapunov functions proposed in [7] and [13].

We have already seen in Lemma 6.2 that from the point of view of the asymptotic stability properties of the system trajectories it is important that $\widetilde W(t)$ be lower bounded uniformly with respect to $\theta(t)$ and that $\dot{\widetilde W}(t)$ be bounded by a definite negative function uniformly with respect to $\theta(t)$. In the case of the interconnection of two systems as in Example 6.1, $\widetilde W(t)$ is the filtered combination of two Lyapunov functions and has uniform (with respect to θ) upper and lower bounds since the system trajectories are bounded for all times and enter some "invariant" set, where a small gain condition is met. To formalize these "capture" and "invariance" properties we introduce the notions of traps and recurrence. A set $\mathcal{W}$ is a *trap* relative to a system Σ if the trajectories of Σ are captured by $\mathcal{W}$ for all times, while a system Σ is *recurrent* relative to a set $\mathcal{W}$ if each trajectory of Σ ensuing from outside $\mathcal{W}$ hits $\mathcal{W}$ at some time T.

DEFINITION 7.3 (recurrence and traps). *Let Σ be a given system with state $z \in \mathbb{R}^n$ and exogenous inputs $\chi \in \mathcal{X} \subseteq \mathbb{R}^r$. We say that $\mathcal{R} \subseteq \mathbb{R}^n$ is a trap for $\mathcal{W} \subseteq \mathcal{R}$ if for each $z_0 \in \mathcal{W}$, exogenous input $\chi(t)$, and $T \ge 0$ the trajectory $z(t)$ of Σ ensuing from $z(T) = z_0$ satisfies $z(t) \in \mathcal{R}$ for all $t \ge T$. We say that a system Σ is recurrent relative to a closed set $\mathcal{W} \subseteq \mathbb{R}^n$ if for each $z_0 \in \mathbb{R}^n \backslash \mathcal{W}$ and exogenous input $\chi(t)$ the trajectory $z(t)$ of Σ ensuing from $z(0) = z_0$ is defined for all $t \ge 0$ and there exists $T > 0$ (recurrence time) such that $z(T) \in \mathcal{W}$. If, in addition, $\mathcal{R} \subseteq \mathbb{R}^n$ is a trap for $\mathcal{W} = \mathcal{R}$, then we say that Σ is recurrent relative to the trap $\mathcal{R}$.*

We are ready to state and prove the main result of this section. For any $c_j, d_j > 0$ and continuous nondecreasing functions $\tau_j : \mathbb{R}^{\ge} \to \mathbb{R}^+$ and $I_j \subseteq \{1, \dots, n_j\}$, $j = 1, 2$, let

$$
\begin{aligned}
a(z_1, z_2, e_1, e_2) &:= d_1 \max\{\tau_1(W_2(z_2, \sigma_2)) - \tau_1(c_2), 0\} \sum_{l \in I_2} (\varphi_{2ls}(z_2) z_{2l}^2 + \varphi_{2lm}(e_2) e_{2l}^2) \\
&+ d_2 \max\{\tau_2(W_1(z_1, \sigma_1)) - \tau_2(c_2), 0\} \sum_{r \in I_1} (\varphi_{1rs}(z_1) z_{1r}^2 + \varphi_{1rm}(e_1) e_{1r}^2). \qquad (7.2)
\end{aligned}
$$

In what follows we will denote $a(z_1(t), z_2(t), e_1(t), e_2(t))$ simply by $a(t)$.

THEOREM 7.4. *Assume that $\Sigma_j \circ \mathcal{C}_j$, $j = 1, 2$, has smooth (filtered) Lyapunov function $\widetilde W_j$ with stability margins $\theta_j \varphi_{jls}$, $\theta_j \varphi_{jlm}$, $l = 1, \dots, n_j$, and incremental rates $\theta_j \gamma_j^{\chi_{jl}}$, $l \in J_j$, and let $I_j \subseteq \{1, \dots, n_j\}$, $j = 1, 2$. Assume also that*

(i) *φ_{1rs} and φ_{1rm}, $r \in I_1$, locally saturate $\gamma_2^{z_{1r}}$ and $\gamma_2^{e_{1r}}$, with levels (c_1, κ_2),*

(ii) φ_{2ls} *and* φ_{2lm}, $l \in I_2$, *locally saturate* $\gamma_1^{z_{2l}}$ *and* $\gamma_1^{e_{2l}}$, *with levels* (c_2, κ_1),
(iii) $\kappa_1\kappa_2 < 1$,
(iv) *for each* $j = 1, 2$, $\Sigma_j \circ \mathcal{C}_j$ *is recurrent relative to the trap* $\mathcal{R}_j = \{(z_j, \sigma_j) : W_j(z_j, \sigma_j) \le c_j\}$.
There exist $d_1 > 0$ *and* $d_2 \in (d_1\kappa_1, d_1/\kappa_2)$ *such that* $\widetilde{W} = \theta[d_1W_1 + d_2W_2]$, *with* $\theta = \theta_0\theta_1\theta_2$ *and*

$$\dot\theta_0 = -[a(z_1, z_2, e_1, e_2)/\min_j\{d_jc_j\}]\theta_0, \theta_0(0) > 0, \tag{7.3}$$

is a smooth filtered Lyapunov function for the interconnection Σ *of* $\Sigma_j \circ \mathcal{C}_j$, $j = 1, 2$, *with stability margins*

$$\begin{aligned} &\theta\delta_{jl}\varphi_{jls}, \quad \theta\delta_{jl}\varphi_{jlm}, \quad l = 1, \dots, n_j,\ j = 1, 2, \\ &\delta_{1r} = d_1 - \kappa_2 d_2,\ r \in I_1, \quad \delta_{2l} = d_2 - \kappa_1 d_1,\ l \in I_2, \quad \delta_{jl} = d_j \text{ otherwise} \end{aligned} \tag{7.4}$$

and incremental rates

$$\theta d_j\gamma_j^{\chi_{jl}},\ \chi_{jl} \notin H := \{z_{1r}, z_{2l}, e_{1r}, e_{2l} : r \in I_1, l \in I_2\};$$

i.e.,

$$\dot{\widetilde{W}} \le \theta \sum_{j=1,2} \left\{ -\sum_{j=1}^{n_j} \delta_{jl}[\varphi_{jls}z_{jl}^2 + \varphi_{jlm}e_{jl}^2] + \sum_{\chi_{jl}\notin H} d_j\gamma_j^{\chi_{jl}}\chi_{jl}^2 \right\} \tag{7.5}$$

along the trajectories of Σ *and* (7.3). *Moreover, the interconnection* Σ *is recurrent relative to the trap* $\mathcal{R} = \{(z_1, z_2, \sigma_1, \sigma_2) : d_1W_1 + d_2W_2 \le d_1c_1 + d_2c_2\}$, *and along each trajectory of* Σ *and* (7.3) *there exists* $T, \overline\theta > 0$ *such that* $\theta_0(t) = \overline\theta$ *for all* $t \ge T$. *In particular,*

$$\begin{aligned} \theta_0(0) = \exp\left(\int_0^\infty a(s)ds\right) \\ \Rightarrow a(t) \ge 0, \quad \theta_0(t) \ge 1\ \forall t \ge 0, \quad a(t) = 0, \quad \theta_0(t) = 1\ \forall t \ge T. \end{aligned} \tag{7.6}$$

Proof. We will prove the theorem with $\theta_0(0) = \exp(\int_0^\infty a(s)ds)$ in (7.3). By (iii) it is possible to select $d_1 > 0$ and $d_2 \in (d_1\kappa_1, d_1/\kappa_2)$ in such a way that

$$\delta_{1r}, \delta_{2l} > 0, \quad r \in I_1, \quad l \in I_2. \tag{7.7}$$

Since $W_j(z_j, \sigma_j)$, $j = 1, 2$, is smooth, proper, and positive definite, then also $W = \sum_{j=1}^2 d_jW_j$ is smooth, proper, and positive definite. Let $\tau_j : \mathbb{R}^{\ge} \to \mathbb{R}^+$, $j = 1, 2$, be continuous nondecreasing functions such that

$$\begin{aligned} \gamma_2^{z_{1r}} \le \tau_2(W_1)\varphi_{1rs}, \quad \gamma_2^{e_{1r}} \le \tau_2(W_1)\varphi_{1rm}, \\ \gamma_1^{z_{2r}} \le \tau_1(W_2)\varphi_{2rs}, \quad \gamma_1^{e_{2r}} \le \tau_1(W_2)\varphi_{2rm}, \end{aligned} \tag{7.8}$$

which indeed exist by (i) and (ii). By (iv) each trajectory $(z_j(t), \sigma_j(t))$ of $\Sigma_j \circ \mathcal{C}_j$, $j = 1, 2$, is defined for all $t \ge 0$, and for each such trajectory there exists $T_j > 0$ such that $W_j(z_j(t), \sigma_j(t)) \le c_j$ for all $t \ge T_j$. This, together with $\tau_j(s)$, $j = 1, 2$, being nondecreasing and positive for all $s \ge 0$, implies that

$$a(t) \ge 0\ \forall t \ge 0, \quad a(t) = 0\ \forall t \ge T := \max\{T_1, T_2\} \tag{7.9}$$

and, thus, $0 \le \int_0^\infty a(s)ds = \int_0^T a(s)ds < \infty$. This gives from (7.3), together with $\theta_0(0) = \exp(\int_0^\infty a(s)ds)$,

$$\theta_0(t) = \theta_0(0)\exp\left\{-\int_0^t a(s)ds\right\} = \exp\left\{-\int_{\min\{t,T\}}^T a(s)ds\right\}, \quad t \ge 0. \tag{7.10}$$

Thus, $\theta_0(t)$ is bounded and positive for all $t \ge 0$ along each trajectory of Σ and (7.7) holds true. Also, by (iv) the interconnection Σ is recurrent relative to the trap $\mathcal{R}$.

We are left with proving (7.5). Taking into account that for all $t \ge 0$ along the trajectories of $\Sigma_j \circ \mathcal{C}_j$, we have $\theta_j(t) > 0, \dot\theta_j(t) \le 0$, $j = 1, 2$, since W_j, $j = 1, 2$, is a filtered Lyapunov function for $\Sigma_j \circ \mathcal{C}_j$, and $\theta_0(t) > 0, \dot\theta_0(t) \le 0$ by (7.3), (7.9), and (7.10), we get from (7.1), (7.2), and (7.9) that

(7.11)

$$\begin{aligned}\dot{\widetilde{W}} &\le \theta\left\{\sum_{j=1,2}\left\{-\sum_{j=1}^{n_j} d_j[\varphi_{jls}z_{jl}^2 + \varphi_{jlm}e_{jl}^2] + \sum_{l\in J_j} d_j\gamma_j^{\chi_{jl}}\chi_{jl}^2\right\} + \frac{\dot\theta_0}{\theta_0}\sum_{j=1}^2 d_jW_j\right\}\\ &\le \theta\left\{\sum_{j=1,2}\left\{-\sum_{j=1}^{n_j}\delta_{jl}[\varphi_{jls}z_{jl}^2 + \varphi_{jlm}e_{jl}^2] + \sum_{\chi_{jl}\notin H} d_j\gamma_j^{\chi_{jl}}\chi_{jl}^2\right\} + a + \frac{\dot\theta_0}{\theta_0}\sum_{j=1}^2 d_jW_j\right\}\end{aligned}$$

along the trajectories of Σ, with δ_{jl}, δ_{1r} as in (7.4) and $\delta_{jl}, \delta_{1r} > 0$, $r \in I_1, l \in I_2$, by (7.7). Since $\sum_{j=1}^2 d_jW_j \ge \min_j\{d_jc_j\}$ whenever either $W_1 \ge c_2$ or $W_2 \ge c_1$ and, moreover, $a \equiv 0$ when $W_i \le c_i$, $i = 1, 2$, from (7.3) and (7.11) we obtain (7.5). □

8. Proof of Theorem 1.1. The proof goes as follows. For each system Σ_j, $j = 1, \dots, n$, in (4.1) we apply Theorem 5.2 to obtain a measurement feedback controller $\mathcal{C}_j$ and take the interconnection $\mathcal{C}$ of $\mathcal{C}_j$, $j = 1, \dots, n$, as measurement feedback controller for the interconnection Σ of Σ_j, $j = 1, \dots, n$, i.e., the controller (1.4) (see part A below). Theorem 1.1 follows from Lemma 6.3, once we prove that (1.1)–(1.4) is 0-GAS and UBEBS (see part B). First, we show that (1.1)–(1.4) is UBEBS. Instrumental to this and since $w \in \mathcal{L}_2^r(\mathbb{R}^{\ge})$, we prove that $\Sigma_i \circ \mathcal{C}_i$, $i = j, \dots, n$, for each $j = 1, \dots, n$ is recurrent relative to some compact trap $\mathcal{T}_j(\|w\|_2)$ (see Lemma 8.1). Finally, we show that (1.1)–(1.4) is 0-GAS (see part C). Instrumental to this, we use the traps $\mathcal{T}_j(0)$, $j = 1, \dots, n$, to define a filtered Lyapunov function $\widetilde{W}$ for (1.1)–(1.4), with $w = 0$, by repeated applications of Theorem 7.4 (see Lemma 8.2) and then we prove that $\widetilde{W}$ satisfies Lemma 6.2.

A. *Controller definition for* (1.1). Set $e_j := z_j - \sigma_j$, $j = 1, \dots, n$, and let $G(s)$ be defined as in Theorem 1.1.

Step 1. Application of Theorem 5.2 to Σ_1 in (4.1) gives $\Delta_1, h_{1s}, h_{1m} \in (0, 1]$ and $R'_{11} \ge 1$ such that for all $R_{11} \ge R'_{11}$ the controller $\mathcal{C}_1$ in (5.3), with $j = 1$, has levels $(\Delta_1, \Delta_1/h_{1s})$ and

$$W_1(z_1, \sigma_1) = \sqrt{1 + z_1^2} + \sqrt{1 + e_1^2} - 2 \tag{8.1}$$

is a smooth filtered Lyapunov function for $\Sigma_1 \circ \mathcal{C}_1$ with stability margins

$$\varphi_{1s} \sim 1/[R_{11}(1 + z_1^2)], \quad \varphi_{1m} \sim 1/[R_{11}(1 + e_1^2)] \tag{8.2}$$

and, by (5.6), smooth incremental rates

$$\gamma_1^{z_l} \sim R_{11}[\gamma_{1s}^{z_l} + \gamma_{1m}^{z_l}], \quad l = 2, \dots, n,$$
$$\gamma_1^{w} \sim R_{11}[\gamma_{1s}^{w} + \gamma_{1m}^{w}], \quad \gamma_1^{\widetilde{x}_l} \sim R_{11}[\gamma_{1s}^{\widetilde{x}_l} + \gamma_{1m}^{\widetilde{x}_l}], \quad l = 3, \dots, n+1. \tag{8.3}$$

In other words,

$$\dot{W}_1 \leq -\varphi_{1s} z_1^2 - \varphi_{1m} e_1^2 + \sum_{l=2}^{n} [\gamma_1^{z_l} z_l^2 + \gamma_1^{\widetilde{x}_{l+1}} \widetilde{x}_{l+1}^2] + \gamma_1^{w} \|w\|^2. \tag{8.4}$$

Moreover, on account of

$$G\left(\left|\sum_{l=1}^{2} s_l\right|\right) \leq \sum_{l=1}^{2} G(|s_l|) \; \forall s_l, \; l = 1, 2, \tag{8.5}$$

and by Lemma A.2 with $j = 1$, we obtain that $\widetilde{x}_2$ and $\dot{\widetilde{x}}_2$ satisfy

$$\widetilde{x}_2^2 \leq \frac{1}{R_{11}^2} \left[G^2(z_1) + G^2(e_1)\right], \tag{8.6}$$
$$\dot{\widetilde{x}}_2^2 \preceq \frac{1}{R_{11}^4} \left[\sum_{l=1}^{2} (G^2(z_l) + G^2(e_l)) + \sum_{l=3}^{n} z_l^2 + \sum_{l=3}^{n+1} \widetilde{x}_l^2 + \|w\|^2\right].$$

Step 2. Given $j = 2, \dots, n$, let

$$\varepsilon^{n-1} = \frac{R_{11}}{R'_{11}}, \quad R_{l1} = R'_{l1} \varepsilon^{n-l}, \quad l = 1, \dots, j-1, \tag{8.7}$$

and assume that

$$\widetilde{x}_l^2 \leq \frac{1}{R_{l-1,1}^2} [G^2(z_{l-1}) + G^2(e_{l-1})], \quad l = 2, \dots, j, \tag{8.8}$$

$$|\dot{\widetilde{x}}_j|^2 \preceq \frac{1}{R_{j-1,1}^4} \left[\sum_{l=j-1}^{j} (G^2(z_l) + G^2(e_l)) + \sum_{l=j+1}^{n} z_l^2 + \sum_{l=j+1}^{n+1} \widetilde{x}_l^2 + \|w\|^2\right]. \tag{8.9}$$

By application of Theorem 5.2 to Σ_j in (4.1) with the additional constraints (8.8)–(8.9) we get $\Delta_j, h_{js}, h_{jm} \in (0, 1]$ and $R'_{j1} \geq 1$ such that for all $R_{j1} \geq R'_{j1}$ the controller $\mathcal{C}_j$ (5.3) has levels $(\Delta_j, \Delta_j / h_{js})$ and

$$W_j(z_j, \sigma_j) = \sqrt{1 + z_j^2} + \sqrt{1 + e_j^2} - 2 \tag{8.10}$$

is a smooth filtered Lyapunov function for $\Sigma_j \circ \mathcal{C}_j$ with stability margins

$$\varphi_{js} \sim 1/[R_{j1}(1 + z_j^2)], \quad \varphi_{jm} \sim 1/[R_{j1}(1 + e_j^2)] \tag{8.11}$$

and, by (5.6) and (8.9), smooth incremental rates

$$\gamma_j^{z_l} \sim \frac{R_{j1}}{R_{j-1,1}^4 (1 + z_l^2)}, \quad \gamma_j^{e_l} \sim \frac{R_{j1}}{R_{j-1,1}^4 (1 + e_l^2)}, \quad l = j-1, j, \tag{8.12}$$
$$\gamma_j^{z_l} \sim R_{j1}[\gamma_{js}^{z_l} + \gamma_{jm}^{z_l} + 1], \quad l = j+1, \dots, n, \tag{8.13}$$
$$\gamma_j^{w} \sim R_{j1}[\gamma_{js}^{w} + \gamma_{jm}^{w} + 1], \quad \gamma_j^{\widetilde{x}_l} \sim R_{j1}[\gamma_{js}^{\widetilde{x}_l} + \gamma_{jm}^{\widetilde{x}_l} + 1], \quad l = j+2, \dots, n+1. \tag{8.14}$$

In other words,

$$\dot{W}_j \le -[\varphi_{js} - \gamma_j^{z_j}]z_j^2 - [\varphi_{jm} - \gamma_j^{e_j}]e_j^2 + \gamma_j^{z_{j-1}} z_{j-1}^2 + \gamma_j^{e_{j-1}} e_{j-1}^2 + \sum_{l=j+1}^{n} [\gamma_j^{z_l} z_l^2 + \gamma_j^{\widetilde{x}_{l+1}} \widetilde{x}_{l+1}^2] + \gamma_j^w \|w\|^2. \tag{8.15}$$

Set

$$R_{j1} = R'_{j1}\varepsilon^{n-j}. \tag{8.16}$$

By (8.7), (8.11), (8.12), and (8.16) we can select $\varepsilon_j \ge 1$ such that

$$\varphi_{js} - \gamma_j^{z_j} \ge \varphi_{js}/2, \quad \varphi_{jm} - \gamma_j^{e_j} \ge \varphi_{jm}/2 \tag{8.17}$$

for all $\varepsilon \ge \varepsilon_j$. Moreover, by (8.5) and Lemma A.2, $\widetilde{x}_{j+1}$ and $\dot{\widetilde{x}}_{j+1}$ satisfy

$$\widetilde{x}_l^2 \le \frac{1}{R_{l-1,1}^2}[G^2(z_{l-1}) + G^2(e_{l-1})], \quad l = 2, \dots, j+1, \tag{8.18}$$

$$|\dot{\widetilde{x}}_{j+1}|^2 \preceq \frac{1}{R_{j1}^4}\left[\sum_{l=j}^{j+1}(G^2(z_l) + G^2(e_l)) + \|w\|^2 + \sum_{l=j+2}^{n} z_l^2 + \sum_{l=j+2}^{n+1} \widetilde{x}_l^2\right]. \tag{8.19}$$

Using the constraints (8.6) and (8.18) we can express the terms $\widetilde{x}_{l+1}^2$ in (8.4) and (8.15) in terms of the exogenous inputs z_l and e_l, so that we can assume that the incremental rates are finally given for $j = 1$ by

$$\gamma_1^{z_l}, \gamma_1^{e_l} \sim R_{11}[\gamma_{1s}^{z_l} + \gamma_{1m}^{z_l} + \gamma_{1s}^{\widetilde{x}_{l+1}} + \gamma_{1m}^{\widetilde{x}_{l+1}}], \quad l = 2, \dots, n, \ \gamma_1^w \sim R_{11}[\gamma_{1s}^w + \gamma_{1m}^w] \tag{8.20}$$

and for $j = 2, \dots, n$ by

$$\gamma_j^{z_{j-1}} \sim R_{j1}/[R_{j-1,1}^4(1 + z_{j-1}^2)], \quad \gamma_j^{e_{j-1}} \sim R_{j1}/[R_{j-1,1}^4(1 + e_{j-1}^2)], \tag{8.21}$$

$$\gamma_j^{z_l}, \gamma_j^{e_l} \sim R_{j1}[\gamma_{js}^{z_l} + \gamma_{jm}^{z_l} + \gamma_{js}^{\widetilde{x}_{l+1}} + \gamma_{jm}^{\widetilde{x}_{l+1}} + 1], \quad l = j+1, \dots, n,$$

$$\gamma_j^w \sim R_{j1}[\gamma_{js}^w + \gamma_{jm}^w + 1]. \tag{8.22}$$

After performing n steps, we obtain the controller (1.4) as the interconnection of $\mathcal{C}_j$, $j = 1, \dots, n$.

B. (1.1)–(1.4) *is UBEBS.* The exogenous inputs of (1.1)–(1.4) are w. To prove that (1.1)–(1.4) is UBEBS, we need the following lemma, which is proved in the appendix. We will often use the notation $W_j(t)$ in place of $W_j(z_j(t), \sigma_j(t))$. Moreover, let $Z_j = (z_j \ \cdots \ z_n)^T$ and $S_j = (\sigma_j \ \cdots \ \sigma_n)^T$, with $Z_1 = Z$ and $S_1 = S$. Denote by $(\mathbb{R}^{\ge})^q$ the q-times vector space product $\mathbb{R}^{\ge} \times \cdots \times \mathbb{R}^{\ge}$.

LEMMA 8.1. *There exist continuous* $c_j : \mathbb{R}^+ \to \mathbb{R}^+$, $\varrho_j : (\mathbb{R}^{\ge})^{n-j+2}\mathbb{R}^{\ge} \to \mathbb{R}^{\ge}$, *nondecreasing with respect to each argument and* $\varrho_j(0, \dots, 0) = 0$, *and* $\varepsilon_j^* > 0$, $j = 1, \dots, n$, *such that for all* $\varepsilon \ge \varepsilon_j^*$, *for each* $w \in \mathcal{L}_2^r(\mathbb{R}^{\ge})$, *and* $j = 1, \dots, n$ *the interconnection* $\Sigma_i \circ \mathcal{C}_i$, $i = j, \dots, n$, *is recurrent relative to the trap* $\mathcal{T}_j(\|w\|_2) := \{(Z_j, S_j) : W_i(z_i, \sigma_i) \le \varrho_i(c_i(\varepsilon), \dots, c_n(\varepsilon), \|w\|_2), \ i = j, \dots, n\}$ *and*

$$c_1 < 1, \quad c_i \sim \prod_{l=2}^{i} \frac{R_{l1}^2}{R_{l-1,1}^4}, \quad i = 2, \dots, n. \tag{8.23}$$

Moreover, for all $t \geq 0$ along the trajectories of (1.1)–(1.4)

$$W_i(t) \leq \varrho_i(W_i(0), \dots, W_n(0), \|w\|_2), \quad i = j, \dots, n. \tag{8.24}$$

Since $W_j(z_j, \sigma_j)$, $j = 1, \dots, n$, is proper and positive definite,

$$\beta_{j1}(\|z_j, \sigma_j\|) \leq W_j(z_j, \sigma_j) \leq \beta_{j2}(\|z_j, \sigma_j\|), \quad j = 1, \dots, n, \tag{8.25}$$

for some $\beta_{j1}, \beta_{j2} \in \mathcal{K}_\infty$, $j = 1, \dots, n$, and for all z_j, σ_j. Moreover, for any continuous $\alpha : \mathbb{R}^{\geq} \times \mathbb{R}^{\geq} \to \mathbb{R}^{\geq}$ such that $\alpha(s, r)$ and $\alpha(r, s)$ are nondecreasing for each $r \geq 0$ and $\alpha(0, 0) = 0$,

$$\alpha(r, s) \leq \alpha(s, s) + \alpha(r, r) \quad \forall r, s \geq 0 \tag{8.26}$$

and $\alpha(s) := \alpha(s, s)$ is $\mathcal{K}$-class. Thus, from (8.24)–(8.26) and since $\beta_{j1}^{-1}(\varrho_j(s_j, \dots, s_{n+1}))$ is nondecreasing with respect to each argument s_i and $\beta_{j1}^{-1}(\varrho_j(0, \dots, 0)) = 0$, we have along the trajectories of (1.1)–(1.4)

$$\begin{aligned} \|z_j(t), \sigma_j(t)\| &\leq \beta_{j1}^{-1}(\varrho_j(W_j(0), \dots, W_n(0), \|w\|_2)) \\ &\leq \sum_{i=j}^{n} 2^{n+2-j} \beta_{j1}^{-1}(\varrho_j(W_i(0), \dots, W_i(0))) \\ &+ \sum_{i=j}^{n} 2^{n+2-j} \beta_{j1}^{-1}(\varrho_j(\|w\|_2, \dots, \|w\|_2)) \\ &\leq \alpha_{j1}(\|Z_j(0), S_j(0)\|) + \alpha_{j2}(\|w\|_2), \end{aligned} \tag{8.27}$$

where $\alpha_{j1}(s) := \sum_{i=j}^{n} 2^{n+2-j} \beta_{j1}^{-1}(\varrho_j(\beta_{i2}(s), \dots, \beta_{i2}(s)))$ and $\alpha_{j2}(s) := \sum_{i=j}^{n} 2^{n+2-j} \beta_{j1}^{-1}(\varrho_j(s, \dots, s))$ for $j = 1, \dots, n$. Let $\alpha_1(s) := \sum_{j=1}^{n} \alpha_{j1}(s) + s$, and $\alpha_2(s) := \sum_{j=1}^{n} \alpha_{j2}(s) + s$ and note that $\alpha_1, \alpha_2 \in \mathcal{K}_\infty$, since $\alpha_{j1}, \alpha_{j2} \in \mathcal{K}$. We obtain from (8.27) that

$$\|Z(t), S(t)\| \leq \alpha_1(\|Z(0), S(0)\|) + \alpha_2(\|w\|_2) \tag{8.28}$$

for all $t \geq 0$ along the trajectories (1.1)–(1.4). This proves that (1.1)–(1.4) is UBEBS.

C. (1.1)–(1.4) *is* 0*-GAS.* To prove that (1.1)–(1.4) is 0-GAS we construct a filtered Lyapunov function $\widetilde{W}$ for (1.1)–(1.4), with $w = 0$, and prove that it satisfies (6.8)–(6.10). To this aim, we need the following lemma, which is proved in the appendix. Let $Z_j := (z_j \ \cdots \ z_n)^T$ and $S_j = (\sigma_j \ \cdots \ \sigma_n)^T$ and set $Z = Z_1$ and $S = S_1$. Moreover, from now on we take $w = 0$.

Lemma 8.2. *Let $c_j : \mathbb{R}^+ \to \mathbb{R}^+$, $\varrho_j : (\mathbb{R}^{\geq})^{n-j+2} \to \mathbb{R}^{\geq}$, and $\varepsilon_j^* > 0$, $j = 1, \dots, n$, be as in Lemma* 8.1. *There exist $\varepsilon^{**} \geq \max_j \varepsilon_j^*$ and continuous and nondecreasing $\tau_j : \mathbb{R}^{\geq} \to [1, \infty)$, $j = 1, \dots, n$, such that*

$$\begin{aligned} \widetilde{W}(Z, S, \theta) &:= \theta W(Z, S), \\ W(Z, S) &:= W_1(z_1, \sigma_1) + \sum_{j=2}^{n} 2^{j-1} W_j(z_j, \sigma_j) \tau_1(c^{(2)}) \cdots \tau_{j-1}(c^{(j)}), \\ c^{(n)} &:= \overline{c}_n, \quad c^{(i)} := \overline{c}_i + 2\tau_i(c^{(i+1)}) c^{(i+1)}, \quad i = 2, \dots, n-1, \\ \overline{c}_i &:= \varrho_i(c_i, \dots, c_n, 0) \end{aligned} \tag{8.29}$$

is for all $\varepsilon \geq \varepsilon^{**}$ *a smooth filtered Lyapunov function for* (1.1)–(1.4) *and*

$$\dot{\widetilde{W}} \leq -\theta \sum_{i=1}^{n} [\widetilde{\varphi}_{is} z_i^2 + \widetilde{\varphi}_{im} e_i^2] \tag{8.30}$$

along the trajectories of (1.1)–(1.4)*, where*

$$\widetilde{\varphi}_{1l} \sim \varphi_{1l}, \quad \widetilde{\varphi}_{il} \sim \tau_{i-1}(c^{(i)}) \cdots \tau_{n-1}(c^{(n)}) \varphi_{il}, \quad i = 2, \ldots, n, \quad l = s, m. \tag{8.31}$$

Moreover, for each trajectory of (1.1)–(1.4) *there exists* $T > 0$ *such that*

$$\begin{aligned} &\theta(t) \geq 1 \ \forall t \geq 0; \\ &\theta(t) = 1 \ \forall t \geq T. \end{aligned} \tag{8.32}$$

First, we prove (6.8). Since

$$(1+s)^{1/2} - 1 \leq s \ \forall s \geq 0, \ \frac{r_1 + r_2}{1 + r_1 + r_2} \leq \frac{r_1}{1 + r_1} + \frac{r_2}{1 + r_2} \ \forall r_1, r_2 \geq 0, \tag{8.33}$$

it is easy to see by (8.2), (8.11), and (8.31) that

$$\tau_{i-1}(c^{(i)}) \cdots \tau_{n-1}(c^{(n)}) W_i(z_i, \sigma_i)/[1 + W_i(z_i, \sigma_i] \preceq \widetilde{\varphi}_{is}(z_i) z_i^2 + \widetilde{\varphi}_{im}(e_i) e_i^2 \tag{8.34}$$

for all z_i, σ_i and for each $i = 1, \ldots, n$. By the definition of $\widetilde{W}$ in (8.29), (8.34) and since $\tau_1(s), \ldots, \tau_{n-1}(s) \geq 1$ for all $s \geq 0$,

$$\theta \geq 1 \Rightarrow \widetilde{W}(Z, S, \theta)/[1 + \widetilde{W}(Z, S, \theta)] \preceq \theta \sum_{i=1}^{n} [\widetilde{\varphi}_{is}(z_i) z_i^2 + \widetilde{\varphi}_{im}(e_i) e_i^2]. \tag{8.35}$$

From (8.30), (8.32), with $j = 1, \ldots, n-1$, and (8.35) follows the existence of $\alpha_0 > 0$ such that $\dot{\widetilde{W}} \leq -\alpha_0 \widetilde{W}(Z, S, \theta)/[1 + \widetilde{W}(Z, S, \theta)]$ along the trajectories of (1.1)–(1.4). This proves (6.8) with $\alpha_1(s) = \alpha_0 s/[1 + s]$.

Next, we show (6.9)–(6.10). By continuity of the trajectories $(Z(t), S(t))$ of (1.1)–(1.4) with respect to $(Z(0), S(0))$ over finite intervals $[0, T]$, it follows that $\theta(0)$ is a continuous function of $(Z(0), S(0))$. Indeed, according to the proof of Lemma 8.2, $\theta = \widetilde{\theta}_1 := \theta_1 \cdots \theta_{n-1}$, with θ_i and $a_i(Z_{i+1}, S_{i+1})$, $i = 1, \ldots, n-1$, defined as in (A.54) and $\theta_i(0) := \exp^{\int_0^\infty a_i(Z_{i+1}(s), S_{i+1}(s))ds}$. Since by definition of $a_i(Z_{i+1}, S_{i+1})$ for each $(Z_{i+1,0}, S_{i+1,0}) \in \mathbb{R}^{n-i} \times \mathbb{R}^{n-i}$ and $i = 1, \ldots, n-1$ there exist $T_i^\circ \in \mathbb{R}^{\geq}$ and an open ball $\mathcal{B}(Z_{i+1,0}, S_{i+1,0})$ around $(Z_{i+1,0}, S_{i+1,0})$ such that $a_i(Z_{i+1}(s), S_{i+1}(t)) = 0$ for all $t \geq T_i^\circ$ and trajectory $(Z_{i+1}(s), S_{i+1}(t))$ ensuing from $\mathcal{B}(Z_{i+1,0}, S_{i+1,0})$, then $\theta_i(0) := \exp^{\int_0^\infty a_i(Z_{i+1}(s), S_{i+1}(s))ds} = \exp^{\int_0^{T_i^\circ} a_i(Z_{i+1}(s), S_{i+1}(s))ds}$ for all $(Z_{i+1}(0), S_{i+1}(0)) \in \mathcal{B}(Z_{i+1,0}, S_{i+1,0})$, $i = 1, \ldots, n-1$. As in the proof of Theorem 1(i) of [7], we conclude that $\theta_i(0)$ is a continuous function of $(Z_{i+1}(0), S_{i+1}(0))$ and thus, as claimed, $\theta(0)$ is a continuous function of $(Z(0), S(0))$. By this we can find a continuous and increasing function $\beta : \mathbb{R}^{\geq} \to \mathbb{R}^{+}$ such that

$$\theta(0) \leq \beta(\|Z(0), S(0)\|) \tag{8.36}$$

for all $(Z(0), S(0))$. Indeed, let $\alpha(s) = \int_s^{s+1} \max_{W(Z(0),S(0)) \leq r} \{\theta(0)\} dr$ and $\widetilde{\alpha}(s) = \alpha(s) + s$. Since $W(Z, S)$ (defined as in (8.29)) is proper and positive definite being the linear combination of proper and positive definite functions $W_j(z_j, \sigma_j)$, $\alpha(s)$ is

continuous and nondecreasing for all $s \geq 0$, and $\widetilde{\alpha}(s)$ is continuous and increasing for all $s \geq 0$. Moreover, by construction $\theta(0) \leq \alpha(W(Z(0), S(0))) \leq \widetilde{\alpha}(W(Z(0), S(0)))$ for all $Z(0), S(0)$. The desired function is $\beta(s) = \widetilde{\alpha}(\widetilde{\beta}_1(s))$, where $\widetilde{\beta}_1 \in \mathcal{K}_\infty$ is such that $W(Z, S) \leq \widetilde{\beta}_1(\|Z, S\|)$ for all (Z, S), which exists since $W(Z, S)$ is proper and positive definite. This with (8.29) and (8.36) gives (6.9) with $\alpha_2(s) = \beta(s)\widetilde{\beta}_1(s)$.

Finally, from (8.29) and (8.32), we obtain $\widetilde{W}(Z(t), S(t), \theta(t)) \geq \widetilde{\beta}_2(\|Z(t), S(t)\|)$ for all $t \geq 0$ along the trajectories of (1.1)–(1.4), with $\widetilde{\beta}_2 \in \mathcal{K}_\infty$ such that $W(Z, S) \geq \widetilde{\beta}_2(\|Z, S\|)$ for all (Z, S), which exists since $W(Z, S)$ is proper and positive definite. This implies (6.10) with $\alpha_3(s) = \widetilde{\beta}_2(s)$. By Lemma 6.2 we conclude that (1.1)–(1.4) is 0-GAS.

Appendix.

LEMMA A.1. *Let $w \in \mathbb{R}^r$, $x_h, \widetilde{x}_h \in \mathbb{R}$, $h = 1, \ldots, n+1$, $\dot{\widetilde{x}}_h \in \mathbb{R}$, $h = 1, \ldots, n$, $\widetilde{x}_1 = \dot{\widetilde{x}}_1 := 0$, $x_{n+1} = \widetilde{x}_{n+1}$, and $z_j := x_j - \widetilde{x}_j$, $j = 1, \ldots, n$, $z_{n+1} := 0$. For any continuous functions $\psi_{ji} : \mathbb{R}^n \times \mathbb{R} \times \mathbb{R}^r \to \mathbb{R}$, $j = 1, \ldots, n$, $i = s, m$, satisfying (1.2) and for each $\Delta_1, \ldots, \Delta_n \in (0, 1]$ there exist $\gamma_{ji}^{\widetilde{x}_h}(\Delta_j, \ldots, \Delta_{h-1}) > 0$, $h = j+1, \ldots, n+1$, $i = s, m$, and smooth $\gamma_{ji}^{w} : \mathbb{R}^{n-j} \to \mathbb{R}^{\geq}$ and $\gamma_{ji}^{z_h} : \mathbb{R}^{n-h+1} \to \mathbb{R}^{\geq}$, $h = j+1, \ldots, n$, $i = s, m$, such that for each $j = 1, \ldots, n$*

$$\lim_{\Delta_j \to 0^+} \gamma_{js}^{\widetilde{x}_{j+1}}(\Delta_j) = 0 \tag{A.1}$$

and

$$\begin{aligned}[\psi_{js} + z_{j+1} - \dot{\widetilde{x}}_j]^2 \leq 2|\dot{\widetilde{x}}_j|^2 + \sum_{h=j+1}^{n} z_h^2 \gamma_{js}^{z_h}(z_h, \ldots, z_n) + \sum_{h=j+1}^{n+1} \widetilde{x}_h^2 \gamma_{js}^{\widetilde{x}_h}(\Delta_j, \ldots, \Delta_{h-1}) \\ + \gamma_{js}^{w}(z_{j+1}, \ldots, z_n)\|w\|^2,\end{aligned} \tag{A.2}$$

$$\psi_{jm}^2 \leq \sum_{h=j+1}^{n} z_h^2 \gamma_{jm}^{z_h}(z_h, \ldots, z_n) + \sum_{h=j+1}^{n+1} \widetilde{x}_h^2 \gamma_{jm}^{\widetilde{x}_h}(\Delta_j, \ldots, \Delta_{h-1}) + \gamma_{jm}^{w}(z_{j+1}, \ldots, z_n)\|w\|^2 \tag{A.3}$$

for all $w \in \mathbb{R}^r$, $x_h, \widetilde{x}_h \in \mathbb{R}$, $h = 1, \ldots, n+1$, $\dot{\widetilde{x}}_h \in \mathbb{R}$, $h = 1, \ldots, n$, such that $|\widetilde{x}_h| \leq \Delta_{h-1}$, $h = 2, \ldots, n+1$.

Proof. We will prove only (A.1) and (A.2) (the other inequality, (A.3), can be proved in the same way as (A.2)). Fix $j = 1, \ldots, n$. Since $\psi_{js}|_{x_i=0, i=j+1, \ldots, n+1; w=0} = 0$ for all $x_1, \ldots, x_j \in \mathbb{R}$ by (1.2) and using the first relation of (1.2), we get for all $x \in \mathbb{R}^n$, $w \in \mathbb{R}^r$, and $\widetilde{x}_h \in \mathbb{R}$, $h = j+1, \ldots, n+1$, that

$$\begin{aligned}|\psi_{js}|^2 \preceq |\psi_{js} - \psi_{js}|_{w=0}|^2 + \sum_{h=j+1}^{n} |\psi_{js}|_{x_i=\widetilde{x}_i, i=j+1, \ldots, h; w=0} - \psi_{js}|_{x_i=\widetilde{x}_i, i=j+1, \ldots, h-1; w=0}|^2 \\ + \sum_{h=j+1}^{n+1} |\psi_{js}|_{x_i=\widetilde{x}_i, i=j+1, \ldots, h; x_i=0, i=h+1, \ldots, n+1; w=0} \\ - \psi_{js}|_{x_i=\widetilde{x}_i, i=j+1, \ldots, h-1; x_i=0, i=h, \ldots, n+1; w=0}|^2 \\ \leq b_{js}(x_{j+1}, \ldots, x_{n+1})\|w\|^2 + \sum_{h=j+1}^{n} |z_h|^2 a_{jsh}(\widetilde{x}_h, \widetilde{x}_{j+1}, \ldots, \widetilde{x}_{h-1}, x_h, \ldots, x_{n+1})\end{aligned}$$

$$+\sum_{h=j+1}^{n+1}|\widetilde{x}_h|^2 a_{jsh}(0,\widetilde{x}_{j+1},\dots,\widetilde{x}_h,0,\dots,0). \tag{A.4}$$

Moreover, for any smooth function $q:\mathbb{R}^s\times\mathbb{R}^r\to\mathbb{R}$ there exist smooth $f:\mathbb{R}^s\to\mathbb{R}^+$ and $g:\mathbb{R}^r\to\mathbb{R}^+$ such that $q(x,y)\le f(x)g(y)$ for all $x\in\mathbb{R}^s$ and $y\in\mathbb{R}^r$ [10], [5]. By this, let $h=j+1,\dots,n+1$ and let $f_{jsh}:\mathbb{R}^{h-j+1}\to\mathbb{R}^+$, $g_{jsh}:\mathbb{R}^{n-h+1}\to\mathbb{R}^+$, and $\varrho_{js},\xi_{js}:\mathbb{R}^{n-h+1}\to\mathbb{R}^+$ be smooth functions such that

$$\begin{aligned}
&a_{jsh}(\widetilde{x}_h,\widetilde{x}_{j+1},\dots,\widetilde{x}_{h-1},x_h,\dots,x_{n+1})\\
&\qquad\le g_{jsh}(z_h,\dots,z_n)\max_{|\widetilde{x}_{i+1}|\le\Delta_i\in(0,1]:i=j,\dots,n} f_{jsh}(\widetilde{x}_{j+1},\dots,\widetilde{x}_n,x_{n+1}),\\
&b_{js}(x_{j+1},\dots,x_{n+1})\\
&\qquad\le \varrho_{js}(z_{j+1},\dots,z_n)\max_{|\widetilde{x}_{i+1}|\le\Delta_i\in(0,1]:i=j,\dots,n} \xi_{js}(\widetilde{x}_{j+1},\dots,\widetilde{x}_n,x_{n+1})
\end{aligned} \tag{A.5}$$

for all $\widetilde{x}_{j+1},\dots,\widetilde{x}_h,x_h,\dots,x_{n+1}$ such that $|\widetilde{x}_{i+1}|\le\Delta_i$, $i=j,\dots,n$. Moreover, let

$$\alpha_{js,j+1}(r):=\max_{|\widetilde{x}_{j+1}|\le r} a_{js,j+1}(0,\widetilde{x}_{j+1},0,\dots,0). \tag{A.6}$$

The function $\alpha_{js,j+1}:\mathbb{R}^{\ge}\to\mathbb{R}^{\ge}$ is nondecreasing for all $r\ge 0$ and continuous at $r=0$, and

$$a_{js,j+1}(0,\widetilde{x}_{j+1},0,\dots,0)\le\alpha_{js,j+1}(|\widetilde{x}_{j+1}|)\le\alpha_{js,j+1}(\Delta_j) \tag{A.7}$$

for all $\widetilde{x}_{j+1}$ such that $|\widetilde{x}_{j+1}|\le\Delta_j$. From (A.4)–(A.7) we get (A.2). Moreover, (A.1) follows by (A.7), the continuity of $\alpha_{js,j+1}(r)$ at $r=0$ and since $a_{js,j+1}(0,0,\dots,0)=0$ by (1.2). □

LEMMA A.2. *Let $w\in\mathbb{R}^r$, $x_h,\widetilde{x}_h\in\mathbb{R}$, $h=1,\dots,n+1$, $\widetilde{x}_1:=0$, $x_{n+1}=\widetilde{x}_{n+1}$, and $z_j:=x_j-\widetilde{x}_j$, $j=1,\dots,n$. For any continuous functions $\psi_{jm}:\mathbb{R}^n\times\mathbb{R}\times\mathbb{R}^r\to\mathbb{R}$, $j=1,\dots,n-1$, satisfying (1.2), for each $j=1,\dots,n-1$, and $\Delta_1,\dots,\Delta_n\in(0,1]$*

$$G^2(e_j+\psi_{jm})\preceq G^2(e_j)+G^2(z_{j+1})+\sum_{l=j+2}^{n}z_l^2+\sum_{l=j+1}^{n+1}\widetilde{x}_l^2+\|w\|^2 \tag{A.8}$$

for all $w\in\mathbb{R}^r$, $e_j,x_h,\widetilde{x}_h\in\mathbb{R}$, $h=1,\dots,n+1$, such that $|\widetilde{x}_h|\le\Delta_{h-1}$, $h=2,\dots,n+1$.

Proof. Under assumption (1.2), (A.3) holds true by Lemma A.1. Moreover, for each continuous function $f:\mathbb{R}^q\to\mathbb{R}^{\ge}$ there exists $a>0$ such that

$$\frac{f(s)\|s\|^2}{1+f(s)\|s\|^2}\le\frac{a\|s\|^2}{1+\|s\|^2} \tag{A.9}$$

for all $s\in\mathbb{R}^q$. Indeed, pick $\delta>0$ and let $a_0>0$ be such that (A.9) holds true for all $s\in\mathbb{R}^q:\|s\|\le\delta$ with $a=a_0$. Since $f(s)(1+\|s\|^2)/[1+f(s)\|s\|^2]\le\frac{1}{\delta^2}+1$ for all $s\in\mathbb{R}^q:\|s\|\ge\delta$, then clearly (A.9) holds true with $a=\max\{a_0,\frac{1}{\delta^2}+1\}$ for all $s\in\mathbb{R}^q$. Using repeatedly $\frac{s_1}{1+s_1}\le\frac{s_2}{1+s_2}$ for all $s_2\ge s_1\ge 0$ and $\frac{\sum_l s_l}{1+\sum_l s_l}\le\sum_l\frac{s_l}{1+s_l}$ for all $s_l\ge 0$ and (A.9) with $s:=(z_{j+1}\ \cdots\ z_n\ \widetilde{x}_{j+1}\ \cdots\ \widetilde{x}_{n+1}\ w)^T$ and $f(s):=\sum_{l=j+1}^{n}\gamma_{jm}^{z_l}+\sum_{l=j+1}^{n+1}\gamma_{jm}^{\widetilde{x}_l}+\gamma_{jm}^{w}$, from (A.3) we get

$$\begin{aligned}
G^2(e_j+\psi_{jm})&\preceq G^2(e_j)+G^2(\psi_{jm})\preceq G^2(e_j)+G^2(\sqrt{f(s)}\|s\|)\\
&\preceq G^2(e_j)+G^2(\|s\|)\preceq G^2(e_j)+G^2(z_{j+1})+\sum_{l=j+2}^{n}z_l^2+\sum_{l=j+1}^{n+1}\widetilde{x}_l^2+\|w\|^2,
\end{aligned} \tag{A.10}$$

i.e., (A.8). □

LEMMA A.3. *For any continuous* $\gamma : \mathbb{R}^n \to \mathbb{R}^{\geq}$, *positive* $\varphi : \mathbb{R}^n \to \mathbb{R}^+$, *and smooth, proper, and positive definite* $W : \mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R}^{\geq}$ *there exists a continuous nondecreasing function* $\tau : \mathbb{R}^{\geq} \to [1, \infty)$ *such that* $\gamma(x) \leq \tau(W(x,y))\varphi(x)$ *for all* $x, y \in \mathbb{R}^n$.

Proof. Let $\alpha \in \mathcal{K}_\infty$ be such that $W(x,y) \geq \alpha(\|x,y\|)$ for all $x, y \in \mathbb{R}^n$, which indeed exists since W is proper and positive definite. Let $\max_{0\leq\|x\|\leq r} \frac{\gamma(x)}{\varphi(x)} := \beta(r)$ and $\widetilde{\tau}(s) = \int_s^{s+1} \beta(r)dr$. The function $\widetilde{\tau} : \mathbb{R}^{\geq} \to \mathbb{R}^{\geq}$ is continuous and nondecreasing for all $s \geq 0$ and $\dfrac{\gamma(x)}{\varphi(x)} \leq \widetilde{\tau}(\|x\|) \leq \widetilde{\tau}(\|x,y\|) \leq \widetilde{\tau}(\alpha^{-1}(W(x,y))) + 1$ for all x and y. Thus, our lemma follows with $\tau(s) = \widetilde{\tau}(\alpha^{-1}(s)) + 1$. □

Proof of Lemma 8.1. First, we prove the lemma for $j = n, n-1$, and then proceed by induction. We construct a sequence of compact traps $\mathcal{T}_n^{(k)}(\|w\|_2)$ and $\mathcal{T}_{n-1}^{(k)}(\|w\|_2)$ for $\Sigma_n \circ \mathcal{C}_n$ and $\Sigma_i \circ \mathcal{C}_i$, $i = n-1, n$, respectively, parametrized by some numbers $c_n^{(k)}$ and $c_{n-1}^{(k)}$, getting smaller as k gets larger and converging to c_n and c_{n-1} satisfying (8.23). Note that since

$$\text{(A.11)} \quad \frac{(r_1+r_2+1)^2-1}{(r_1+r_2+1)^2} \leq 2\left[\frac{(r_1+1)^2-1}{(r_1+1)^2} + \frac{(r_2+1)^2-1}{(r_2+1)^2}\right] \quad \forall r_1, r_2 \geq 0$$

and $W_n(z_n, \sigma_n) = [\sqrt{1+z_n^2} - 1] + [\sqrt{1+e_n^2} - 1]$, then

$$\text{(A.12)} \qquad 2\left[\frac{z_n^2}{1+z_n^2} + \frac{e_n^2}{1+e_n^2}\right] \geq \frac{(W_n(z_n,\sigma_n)+1)^2-1}{(W_n(z_n,\sigma_n)+1)^2} \geq \frac{W_n(z_n,\sigma_n)}{1+W_n(z_n,\sigma_n)}$$

for all z_n, σ_n. Thus, from (8.7), (8.8)–(8.11), (8.15), and (8.21)–(8.22), with $j = n$, we infer the existence of $\varepsilon_n^{(0)} \geq \varepsilon_n$ and $b_n, l_n > 0$ such that for all $\varepsilon \geq \varepsilon_n^{(0)}$

$$\text{(A.13)} \quad \dot{W}_n \leq -\frac{l_n W_n}{R_{n1}(W_n+1)} + \frac{6b_n R_{n1}}{R_{n-1,1}^4} + b_n R_{n1}\|w\|^2, \quad c_n^{(0)} := \frac{24R_{n1}^2 b_n}{l_n R_{n-1,1}^4} < 1$$

along the trajectories of (1.1)–(1.4). Let $\varepsilon \geq \varepsilon_n^{(0)}$ and $s \geq t_0 \geq 0$. Note that $0 \leq a \leq 1 \Rightarrow a/[a+1] \geq a/2$ and

$$\text{(A.14)} \qquad W_n \geq c_n^{(0)} \Rightarrow -l_n W_n/[R_{n1}(W_n+1)] + 12b_n R_{n1}/R_{n-1,1}^4 \leq 0.$$

For each trajectory of (1.1)–(1.4) and $r \geq s$ such that $W_n(t) \geq c_n^{(0)}$ for all $t \in [s,r]$ along such trajectory and since $\int_s^r \|w(\lambda)\|^2 d\lambda \leq \|w\|_2^2 < \infty$, by integrating (A.13) over $[s,r]$ we obtain

$$\text{(A.15)} \quad W_n(t) \leq -\frac{6b_n R_{n1}(t-s)}{R_{n-1,1}^4} + W_n(s) + b_n R_{n1}\|w\|_2^2 \quad \forall t \in [s,r],\ W_n(s) \geq c_n^{(0)}.$$

It is easy to see that for each $s \geq t_0 \geq 0$ and trajectory of (1.1)–(1.4) such that $W_n(s) > c_n^{(0)}$ there exists $\overline{r} \geq s$ such that

$$\text{(A.16)} \qquad W_n(\overline{r}) = c_n^{(0)}.$$

Indeed, if not there would exist a trajectory of (1.1)–(1.4) such that $W_n(t) > c_n^{(0)}$ and (A.15) holds for all $t \geq s$. From (A.15) we get $W_n(\overline{r}) = c_n^{(0)}$ for $\overline{r} := s +$

$R_{n-1,1}^4/(6b_nR_{n1})][W_n(s)-c_n^{(0)}+b_n\|w\|_2^2]$, which gives a contradiction. Thus, (A.15) and (A.16) imply for each trajectory of (1.1)–(1.4) starting at $t_0\geq 0$ the existence of $T_n^{(0)}\geq t_0$ such that

$$\begin{aligned} &W_n(t)\leq \varrho_n^{(0)}(W_n(t_0),\|w\|_2):=W_n(t_0)+b_nR_{n1}\|w\|_2^2 \quad \forall t\geq t_0,\\ &W_n(t)\leq \varrho_n^{(0)}(c_n^{(0)},\|w\|_2) \quad \forall t\geq T_n^{(0)}, \end{aligned} \tag{A.17}$$

where $\varrho_n^{(0)}(\lambda_1,\cdot)$ and $\varrho_n^{(0)}(\cdot,\lambda_2)$ are nondecreasing for each $\lambda_1,\lambda_2\geq 0$ and $\varrho_n^{(0)}(0,0)=0$. In other words, $\Sigma_n\circ\mathcal{C}_n$ is recurrent relative to the trap $\mathcal{T}_n^{(0)}(\|w\|_2):=\{(z_n,\sigma_n): W_n(z_n,\sigma_n)\leq \varrho_n^{(0)}(c_n^{(0)},\|w\|_2)\}$ for all $\varepsilon\geq\varepsilon_n^{(0)}$, with $c_n^{(0)}\preceq\frac{R_{n1}^2}{R_{n-1,1}^4}$ by (A.13). Moreover, since $W_n(z_n,\sigma_n)\geq 0$ for all z_n,σ_n, from (A.13) and the definition of $c_n^{(0)}$

$$\begin{aligned} W_n(t)\geq c_n^{(0)}\ \forall t\in[s,r]&\Rightarrow \int_s^t \frac{W_n(\lambda)}{W_n(\lambda)+1}d\lambda\\ &\leq \xi_n^{(0)}(W_n(s),\|w\|_2):=\frac{2R_{n1}}{l_n}[W_n(s)+R_{n1}b_n\|w\|_2^2] \quad \forall t\in[s,r] \end{aligned} \tag{A.18}$$

along the trajectories (1.1)–(1.4), where $\xi_n^{(0)}(\lambda_1,\cdot)$ and $\xi_n^{(0)}(\cdot,\lambda_2)$ are nondecreasing for each $\lambda_1,\lambda_2\geq 0$ and $\xi_n^{(0)}(0,0)=0$. Now, we prove the existence of $\varepsilon_{n-1}^{(0)}>0$ such that for all $\varepsilon\geq\varepsilon_{n-1}^{(0)}$, $\Sigma_i\circ\mathcal{C}_i$, $i=n-1,n$, is recurrent relative to the trap $\mathcal{T}_{n-1}^{(0)}(\|w\|_2):=\{(Z_{n-1},S_{n-1}): W_{n-1}(z_{n-1},\sigma_{n-1})\leq \varrho_{n-1}^{(0)}(c_{n-1}^{(0)},c_n^{(0)},\|w\|_2), W_n(z_n,\sigma_n)\leq\varrho_n^{(0)}(c_n^{(0)},\|w\|_2)\}$ with $\varrho_{n-1}^{(0)}:(\mathbb{R}^{\geq})^3\to\mathbb{R}^{\geq}$, nondecreasing with respect to each argument and $\varrho_{n-1}^{(0)}(0,0,0)=0$, and with

$$c_{n-1}^{(0)}<1,\ c_n^{(0)}\preceq\frac{R_{n1}^2}{R_{n-1,1}^4}. \tag{A.19}$$

Let

$$\alpha_{n-1}(s):=\int_s^{s+1}\max_{W_n(z_n,\sigma_n)\leq r}\overline{\alpha}_{n-1}(z_n,\sigma_n)dr$$

with $\overline{\alpha}_{n-1}(z_n,\sigma_n):=[(\gamma_{n-1,s}^{z_n}+\gamma_{n-1,m}^{z_n}+\gamma_{n-1,s}^{\widetilde{x}_{n+1}}+\gamma_{n-1,m}^{\widetilde{x}_{n+1}}+1)(W_n(z_n,\sigma_n)+2)^2+\gamma_{n-1}^w]$. The function $\alpha_{n-1}:\mathbb{R}^{\geq}\to\mathbb{R}^{\geq}$ is continuous and nondecreasing since $\alpha_{n-1}(s)\geq\max_{W_n(z_n,\sigma_n)\leq s}\overline{\alpha}_{n-1}(z_n,\sigma_n)$ for all $s\geq 0$. Moreover, by (8.22), with $j=n-1$ and $l=n$, the nonnegativity of $W_n(z_n,\sigma_n)$, and since $z_n^2,e_n^2\leq(1+W_n(z_n,\sigma_n))^2-1$ for all z_n,σ_n,

$$\begin{aligned} \gamma_{n-1}^{z_n}z_n^2+\gamma_{n-1}^{e_n}e_n^2+\gamma_{n-1}^w\|w\|^2&\preceq R_{n-1,1}\Bigg[(\gamma_{n-1,s}^{z_n}+\gamma_{n-1,m}^{z_n}+\gamma_{n-1,s}^{\widetilde{x}_{n+1}}+\gamma_{n-1,m}^{\widetilde{x}_{n+1}}+1)\\ &\quad\cdot\frac{[(W_n+1)^2-1](2+W_n)}{W_n}+\gamma_{n-1}^w\Bigg]\left[\frac{W_n}{W_n+1}+\|w\|^2\right]\\ &\leq R_{n-1,1}\alpha_{n-1}(W_n)\left[\frac{W_n}{W_n+1}+\|w\|^2\right] \end{aligned}$$

for all z_n,σ_n,w. Note that $c_n^{(0)}<1$, $R_{n1}\geq 1$, and $W_n(z_n,\sigma_n)\leq c_n^{(0)}\Rightarrow z_n^2,e_n^2,\widetilde{x}_{n+1}^2\leq 2[(c_n^{(0)}+1)^2-1]\leq 6$ by (8.18) and the second relation of (A.13). Thus, from (8.7),

(8.10), (8.11), (8.15)–(8.17), and (8.21)–(8.22), with $j = n-1$, we derive the existence of $\varepsilon^{(0)}_{n-1} > 0$ and $b_{n-1}, l_{n-1} > 0$ such that for all $\varepsilon \geq \varepsilon^{(0)}_{n-1}$

$$c^{(0)}_{n-1} := \frac{4R^2_{n-1,1}b_{n-1}}{l_{n-1}}\left[\frac{6}{R^4_{n-2,1}} + 2n^3\alpha_{n-1}(2n)c^{(0)}_n\right] < 1 \tag{A.20}$$

and along the trajectories of (1.1)–(1.4)

$$\begin{aligned}\dot{W}_{n-1} \leq -\frac{l_{n-1}W_{n-1}}{R_{n-1,1}(W_{n-1}+1)} + 6b_{n-1}\frac{R_{n-1,1}}{R^4_{n-2,1}} \\ + b_{n-1}R_{n-1,1}\alpha_{n-1}(W_n)\left[\frac{W_n}{W_n+1} + \|w\|^2\right].\end{aligned} \tag{A.21}$$

Assume that $W_{n-1}(t) \geq c^{(0)}_{n-1}$ for all $t \in [s,r]$, $s \geq t_0$. Since $\alpha_{n-1}(a)$ is nondecreasing for all $a \geq 0$ and $c^{(0)}_n \leq 1$, by the nonnegativity of W_i and (A.17) and (A.18) we obtain for all $t \in [s,r]$

$$\begin{aligned}&\int_s^t \alpha_{n-1}(W_n(\lambda))\left[\frac{W_n(\lambda)}{W_n(\lambda)+1} + \|w(\lambda)\|^2\right]d\lambda \\ &\leq \alpha_{n-1}(2n\varrho^{(0)}_n(W_n(s),\|w\|_2))[2n^2\xi^{(0)}_n(W_n(s),\|w\|_2) + \|w\|^2_2]\end{aligned} \tag{A.22}$$

if $W_n(t) \geq c^{(0)}_n$ for all $t \in [s,r]$,

$$\alpha_{n-1}(W_n(t))\left[\frac{W_n(t)}{W_n(t)+1} + \|w(t)\|^2\right] \leq n\alpha_{n-1}(2n)[2n^2c^{(0)}_n + \|w(t)\|^2] \tag{A.23}$$

if $W_n(t) \leq c^{(0)}_n$ for all $t \in [s,r]$. Thus, using the definition of $c^{(0)}_{n-1}$ in (A.20) and by integrating (A.21) over $[s,r]$, we have that

$$\begin{aligned}&W_{n-1}(t) \geq c^{(0)}_{n-1} \quad \forall t \in [s,r] \Rightarrow W_{n-1}(t) \leq -\frac{6b_{n-1}R_{n-1,1}(t-s)}{R^4_{n-2,1}} \\ &+ \varrho^{(0)}_{n-1}(W_{n-1}(s), W_n(s), \|w\|_2)\ \forall t \in [s,r]\end{aligned} \tag{A.24}$$

with

$$\begin{aligned}\varrho^{(0)}_{n-1}(W_{n-1}(s), W_n(s), \|w\|_2) := W_{n-1}(s) + b_{n-1}R_{n-1,1}\Big\{n\alpha_{n-1}(2n)\|w\|^2_2 \\ + \alpha_{n-1}(2n\varrho^{(0)}_n(W_n(s),\|w\|_2))[2n^2\xi^{(0)}_n(W_n(s),\|w\|_2) + \|w\|^2_2]\Big\}.\end{aligned} \tag{A.25}$$

From (A.24) follows for each trajectory of (1.1)–(1.4) starting at t_0 the existence of continuous $\varrho^{(0)}_{n-1} : (\mathbb{R}^{\geq})^3 \to \mathbb{R}^{\geq}$, nondecreasing with respect to each argument and $\varrho^{(0)}_{n-1}(0,0,0) = 0$, and for each trajectory (1.1)–(1.4) the existence of $T^{(0)}_{n-1} \geq T^{(0)}_n \geq t_0$ such that

$$\begin{aligned}&W_{n-1}(t) \leq \varrho^{(0)}_{n-1}(W_{n-1}(t_0), W_n(t_0), \|w\|_2) \quad \forall t \geq t_0, \\ &W_{n-1}(t) \leq \varrho^{(0)}_{n-1}(c^{(0)}_{n-1}, c^{(0)}_n, \|w\|_2) \quad \forall t \geq T^{(0)}_{n-1}.\end{aligned} \tag{A.26}$$

Moreover, $c_n^{(0)}$ and $c_{n-1}^{(0)}$ satisfy (A.19) by (A.13) and (A.20). This proves that $\Sigma_i \circ \mathcal{C}_i$, $i = n-1, n$, is recurrent relative to the trap $\mathcal{T}_{n-1}^{(0)}(\|w\|_2)$. We also claim the existence of continuous $\xi_{n-1}^{(0)} : \mathbb{R}^{\geq} \times \mathbb{R}^{\geq} \times \mathbb{R}^{\geq} \to \mathbb{R}^{\geq}$, nondecreasing with respect to each argument and $\xi_{n-1}^{(0)}(0,0,0) = 0$, such that

$$\begin{aligned} & W_{n-1}(t) \geq c_{n-1}^{(0)} \quad \forall t \in [s,r] \\ & \Rightarrow \int_s^t \frac{W_n(\lambda)}{W_n(\lambda)+1} d\lambda \leq \xi_{n-1}^{(0)}(W_{n-1}(s), W_n(s), \|w\|_2) \quad \forall t \in [s,r] \end{aligned} \tag{A.27}$$

along the trajectories (1.1)–(1.4). Indeed, assume that $W_{n-1}(t) \geq c_{n-1}^{(0)}$ for all $t \in [s,r]$, $s \geq t_0$. Integrating (A.21) over $[s,r]$ and on account of (A.22) and (A.23), by the definition of $c_{n-1}^{(0)}$ in (A.20) and the nonnegativity of W_{n-1}, we obtain

$$\int_s^t \frac{W_n(\lambda)}{W_n(\lambda)+1} d\lambda \leq \frac{2R_{n-1,1}}{l_{n-1}} \{W_{n-1}(s) + \varrho_{n-1}^{(0)}(0, W_n(s), \|w\|_2)\} \quad \forall t \in [s,r], \tag{A.28}$$

which, upon setting $\xi_{n-1}^{(0)}(W_{n-1}(s), W_n(s), \|w\|_2)) := [2R_{n-1,1}/l_{n-1}]\{W_{n-1}(s) + \varrho_{n-1}^{(0)}(0, W_n(s), \|w\|_2)\}$, proves (A.27). Next, we prove by induction that for each $k \geq 0$ it is possible to construct smaller and smaller $c_n^{(k+1)}$ and $c_{n-1}^{(k+1)}$ and, thus, traps $\mathcal{T}_n^{(k+1)}(\|w\|_2)$ and $\mathcal{T}_{n-1}^{(k+1)}(\|w\|_2)$ for $\Sigma_n \circ \mathcal{C}_n$ and $\Sigma_i \circ \mathcal{C}_i$, $i = n-1, n$, by using $c_n^{(k)}$ and $c_{n-1}^{(k)}$. For some sufficiently large k, these $c_n^{(k+1)}$ and $c_{n-1}^{(k+1)}$ will satisfy (8.23) for $i = n-1, n$. Let $k \geq 0$.

Induction step. There exist $\varepsilon_i^{(k)} > 0$, continuous functions $c_i^{(k)} : \mathbb{R}^+ \to \mathbb{R}^+$, $\varrho_i^{(k)}, \xi_i^{(k)} : (\mathbb{R}^{\geq})^3 \to \mathbb{R}^{\geq}$, $i = n-1, n$, nondecreasing with respect to each argument and $\varrho_i^{(k)}(0,0,0) = \xi_i^{(k)}(0,0,0) = 0$, and for each trajectory of (1.1)–(1.4) starting at $t_0 \geq 0$ there exist $T_{n-1}^{(k)} \geq T_n^{(k)} \geq t_0$, such that (A.17), (A.18), (A.19), (A.26), and (A.27) hold along the trajectories of (1.1)–(1.4), with $^{(0)}$ replaced by $^{(k)}$ and for all $\varepsilon \geq \varepsilon_i^{(k)}$.

By (A.19) and since $W_{n-1}(z_{n-1}, \sigma_{n-1}) \leq c_{n-1}^{(k)} \Rightarrow z_{n-1}^2,\ e_{n-1}^2, \widetilde{x}_n^2 \leq 2[(c_{n-1}^{(k)} + 1)^2 - 1] \leq 6c_{n-1}^{(k)}$ by (8.18), from (8.7), (8.8)–(8.15), with $j = n$, and (8.21)–(8.22) we get the existence of $\varepsilon_n^{(k+1)} \geq \varepsilon_n^{(k)}$ such that for all $\varepsilon \geq \varepsilon_n^{(k+1)}$

$$\dot{W}_n \leq -\frac{l_n W_n}{R_{n1}(W_n+1)} + \frac{6b_n R_{n1} c_{n-1}^{(k)}}{R_{n-1,1}^4} + b_n R_{n1} \|w\|^2, \quad c_n^{(k+1)} := \frac{24 R_{n1}^2 b_n c_{n-1}^{(k)}}{l_n R_{n-1,1}^4} < 1, \tag{A.29}$$

$$\begin{aligned} \dot{W}_{n-1} \leq & -\frac{l_{n-1} W_{n-1}}{R_{n-1,1}(W_{n-1}+1)} + \frac{6b_{n-1} R_{n-1,1}}{R_{n-2,1}^4} \\ & + b_{n-1} R_{n-1,1} \alpha_{n-1}(W_n) \left[\frac{W_n}{W_n+1} + \|w\|^2 \right], \\ c_{n-1}^{(k+1)} := & \frac{4R_{n-1,1}^2 b_{n-1}}{l_{n-1}} \left[\frac{6}{R_{n-2,1}^4} + 2n^3 \alpha_{n-1}(2n) c_n^{(k)} \right] < 1. \end{aligned} \tag{A.30}$$

Note that in (A.13) we used the weaker bound $W_{n-1}(z_{n-1}, \sigma_{n-1}) \leq c_{n-1}^{(0)} \Rightarrow z_{n-1}^2, e_{n-1}^2, \widetilde{x}_n^2 \leq 6$ instead of $W_{n-1}(z_{n-1}, \sigma_{n-1}) \leq c_{n-1}^{(k)} \Rightarrow z_{n-1}^2, e_{n-1}^2, \widetilde{x}_n^2 \leq 6c_{n-1}^{(k)}$ as in

(A.29). Reasoning as in the case $k=0$ above, we obtain the existence of $\varepsilon_i^{(k+1)}>0$, continuous functions $\varrho_i^{(k+1)},\xi_i^{(k+1)}:(\mathbb{R}^{\geq})^{n-i+2}\to\mathbb{R}^{\geq}$, $i=n-1,n$, nondecreasing with respect to each argument and $\varrho_n^{(k+1)}(0,0,0)=0$, and for each trajectory of (1.1)–(1.4) the existence of $T_{n-1}^{(k+1)},T_n^{(k+1)}\geq T_{n-1}^{(k)}$ such that the induction step holds true with $\varepsilon_i^{(k)}$, $c_i^{(k)}$, $T_i^{(k)}$, $\varrho_i^{(k)}$, and $\xi_i^{(k)}$ replaced by $\varepsilon_i^{(k+1)}$, $c_i^{(k+1)}$, $T_i^{(k+1)}$, $\varrho_i^{(k+1)}$, and $\xi_i^{(k+1)}$, $i=n-1,n$. Thus, since, as already shown, the induction step also holds for $k=0$, it holds for all $k\geq 0$. We prove Lemma 8.1 for $j=n-1,n$ if we prove that $c_n^{(k)}$ and $c_{n-1}^{(k)}$ in (A.29) and (A.30) satisfy (8.23) for $j=n-1,n$ for sufficiently large k and ε. To this aim, we claim that there exist $\varepsilon_{n-1}^*>0$ and $k_{n-1}^*>0$ such that for all $\varepsilon\geq\varepsilon_{n-1}^*$ and $k\geq k_{n-1}^*$

$$c_i^{(k)}\sim\prod_{l=n-1}^{i}\frac{R_{l1}^2}{R_{l-1,1}^4},\quad i=n-1,n, \tag{A.31}$$

$$c_n^{(k+1)}:=\frac{24R_{n1}^2b_nc_{n-1}^{(k)}}{l_nR_{n-1,1}^4}<1,\ c_{n-1}^{(k+1)}:=\frac{4R_{n-1,1}^2b_{n-1}}{l_{n-1}}\Big[\frac{6}{R_{n-2,1}^4}+2n^3\alpha_{n-1}(2n)c_n^{(k)}\Big]<1 \tag{A.32}$$

with $c_n^{(0)}$ as in (A.13) and $c_{n-1}^{(0)}$ as in (A.20), since then Lemma 8.1 for $j=n-1,n$ follows with ε_{n-1}^*, $c_i:=c_i^{(k_{n-1}^*)}$ and $\varrho_i:=\varrho_i^{(k_{n-1}^*)}$, $j=n-1,n$. The equations (A.32), which hold for all $k\geq 0$ on account of (A.29)–(A.30), can be described by a linear discrete-time system $x(k+1)=Ax(k)+Bu(k)$ with state $x(k)=(c_n^{(k)}\ c_{n-1}^{(k)})^T$, initial condition $x(0)=(c_n^{(0)}\ c_{n-1}^{(0)})^T$, input $u(k)=24R_{n-1,1}^2b_{n-1}/[R_{n-2,1}^4l_{n-1}]$. Using induction and by (8.7) and (8.16), with $j=n$, we prove for all $k\geq 1$

$$\begin{aligned}\begin{pmatrix}c_n^{(k)}\\ c_{n-1}^{(k)}\end{pmatrix}&=A^k\begin{pmatrix}c_n^{(0)}\\ c_{n-1}^{(0)}\end{pmatrix}+[I+A+A^2+\cdots+A^{k-1}]\begin{pmatrix}0\\1\end{pmatrix}u(k)\\ &\sim\begin{pmatrix}\mathcal{O}(\varepsilon^{-(k+1)})\\ \mathcal{O}(\varepsilon^{-(k+1)})\end{pmatrix}+\begin{pmatrix}[R_{n1}^2/R_{n-1,1}^4][1+\mathcal{O}(\varepsilon^{-1})]\\ 1+\mathcal{O}(\varepsilon^{-1})\end{pmatrix}\frac{R_{n-1,1}^2}{R_{n-2,1}^4},\end{aligned} \tag{A.33}$$

where $\mathcal{O}(r)$ means infinitesimals with order greater than r and $\sim$ is meant componentwise. This proves (A.31) for some sufficiently large $\varepsilon_{n-1}^*,k_{n-1}^*$ and Lemma 8.1 for $j=n-1,n$. We complete the proof of Lemma 8.1 by induction on the number $n-j+1$, $j=1,\dots,n-1$, of systems $\Sigma_i\circ\mathcal{C}_i$ in $\Sigma_i\circ\mathcal{C}_i$, $i=j,\dots,n$. To this aim we formulate the induction step as follows, letting $j=2,\dots,n-1$.

Induction step. There exist $\varepsilon_j^*>0$, $k_j^*\geq 1$, continuous functions $\varrho_i^{(k)},\xi_i^{(k)}:(\mathbb{R}^{\geq})^{n-i+2}\to\mathbb{R}^{\geq}$, $i=j,\dots,n$, $k\geq k_j^*$, nondecreasing with respect to each argument and $\varrho_i^{(k)}(0,\dots,0)=\xi_i^{(k)}(0,\dots,0)=0$, and for each trajectory of (1.1)–(1.4) starting at $t_0\geq 0$ there exist $T_i^{(k)}\geq t_0$, $i=j,\dots,n$, $k\geq k_j^*$, such that for all $i=j,\dots,n$, $k\geq k_j^*$, and $\varepsilon\geq\varepsilon_j^*$,

$$\begin{aligned}&W_i(t)\leq\varrho_i^{(k)}(W_i(t_0),\dots,W_n(t_0),\|w\|_2)\quad\forall t\geq t_0,\\ &W_i(t)\leq\varrho_i^{(k)}(c_i^{(k)},\dots,c_n^{(k)},\|w\|_2)\quad\forall t\geq T_i^{(k)},\\ &W_i(t)\geq c_n^{(k)}\quad\forall t\in[s,r]\end{aligned} \tag{A.34}$$

$$\Rightarrow\int_s^t\frac{W_i(\lambda)}{W_i(\lambda)+1}d\lambda\leq\xi_i^{(k)}(W_i(s),\dots,W_n(s),\|w\|_2)\quad\forall t\in[s,r] \tag{A.35}$$

hold along the trajectories of (1.1)–(1.4) and

$$c_i^{(k)} \sim \prod_{l=j}^{i} \frac{R_{l1}^2}{R_{l-1,1}^4},\ i=j,\dots,n,\ c_j^{(k)} \geq c_{j+1}^{(k)} \geq \cdots \geq c_n^{(k)}, \tag{A.36}$$

$$c_n^{(k+1)} := \frac{24R_{n1}^2 b_n c_{n-1}^{(k)}}{l_n R_{n-1,1}^4} < 1,$$

$$c_i^{(k+1)} := \frac{4R_{i1}^2 b_i}{l_i}\left[\frac{6c_{i-1}^{(k)}}{R_{i-1,1}^4} + 2n^3\alpha_i(2n)c_{i+1}^{(k)}\right] < 1,\ i=j,\dots,n. \tag{A.37}$$

Let $k \geq k_j^*$ and $\varepsilon \geq \varepsilon_j^*$. We distinguish the cases $j=3,\dots,n$ and $j=2$. Assume first that $j=3,\dots,n$. Let

$$\alpha_{j-1}(s) := \int_s^{s+1} \max_{\sum_{i=j}^n W_i(z_i,\sigma_i)\leq r} \overline{\alpha}_{j-1}(Z_j,S_j)dr$$

with $\overline{\alpha}_{j-1}(Z_j,S_j) := \sum_{i=j}^n[(\gamma_{j-1,s}^{z_i} + \gamma_{j-1,m}^{z_i} + \gamma_{j-1,s}^{\widetilde{x}_{i+1}} + \gamma_{j-1,m}^{\widetilde{x}_{i+1}} + 1)(\sum_{i=j}^n W_i(z_i,\sigma_i) + 2)^2 + \gamma_{j-1}^w]$ and, thus,

$$\sum_{i=j}^n(\gamma_{j-1}^{z_i}z_i^2 + \gamma_{j-1}^{e_i}e_i^2) + \gamma_{n-1}^w\|w\|^2 \leq R_{j-1,1}\alpha_{j-1}\left(\sum_{i=j}^n W_i\right)\left[\frac{\sum_{i=j}^n W_i}{\sum_{i=j}^n W_i + 1} + \|w\|^2\right]$$

for all z_i,σ_i,w, $i=j\dots,n$. Thus, from (8.7), (8.8)–(8.11), (8.15), and (8.21)–(8.22), we derive the existence of $\varepsilon_{j-1}^{(k_j^*)} > 0$ and $b_{j-1}, l_{j-1} > 0$ such that for all $\varepsilon \geq \varepsilon_{j-1}^{(k_j^*)}$

$$c_{j-1}^{(k_j^*)} := \frac{4R_{j-1,1}^2 b_{j-1}}{l_{j-1}}\left[\frac{6}{R_{j-2,1}^4} + 2n^3\alpha_{j-1}(2n)c_j^{(k_j^*)}\right] < 1 \tag{A.38}$$

and along the trajectories of (1.1)–(1.4)

$$\begin{aligned}\dot{W}_{j-1} \leq\ & -\frac{l_{j-1}W_{j-1}}{R_{j-1,1}(W_{j-1}+1)} + 6b_{j-1}\frac{R_{j-1,1}}{R_{j-2,1}^4} \\ & + b_{j-1}R_{j-1,1}\alpha_{j-1}\left(\sum_{i=j}^n W_i\right)\left[\frac{\sum_{i=j}^n W_i}{\sum_{i=j}^n W_i + 1} + \|w\|^2\right].\end{aligned} \tag{A.39}$$

Assume that $W_{j-1}(t) \geq c_{j-1}^{(k_j^*)}$, $W_i(t) \geq c_i^{(k_j^*)}$, $i \in J \subseteq \{j,\dots,n\}$, and $W_i(t) \leq c_i^{(k_j^*)}$, $i \in \{j,\dots,n\}\backslash J$, for all $t \in [s,r]$, $s \geq t_0$. Since $\alpha_{j-1}(\sum_{i=j}^n a_i)[\sum_{i=j}^n a_i]/[\sum_{i=j}^n a_i + 1]$ is nondecreasing with respect to each $a_i \geq 0$ and on account of (8.26)

$$\frac{\sum_{i=j}^n a_i}{\sum_{i=j}^n a_i + 1}\alpha_{j-1}\left(\sum_{i=j}^n a_i\right) \leq \sum_{i=j}^n \frac{2n^2 a_i}{a_i+1}\alpha_{j-1}(2na_i) \tag{A.40}$$

for all $a_i \geq 0$, and since $c_i^{(k_j^*)} \leq 1$, $j,\dots,n$, using the induction step and the nonnegativity of W_i we obtain for all $t \in [s,r]$, $i=j\dots,n$, and for any set $J \subseteq \{j,\dots,n\}$

$$\alpha_{j-1}\left(\sum_{i=j}^{n} W_i(t)\right)\left[\frac{\sum_{i=j}^{n} W_i(t)}{\sum_{i=j}^{n} W_i(t)+1}+\|w(t)\|^2\right]$$

$$\leq 2n^2\sum_{i=j}^{n}\alpha_{j-1}(2nW_i(t))\left[\frac{W_i}{W_i+1}+\|w(t)\|^2\right], \tag{A.41}$$

$$\sum_{i\in J}\int_s^t \alpha_{j-1}(2nW_i(\lambda))\left[\frac{W_i(\lambda)}{W_i(\lambda)+1}+\|w(\lambda)\|^2\right]d\lambda$$

$$\leq \sum_{i=j}^{n}\alpha_{j-1}(2n\varrho_i^{(k_j^*)}(W_i(s),\dots,W_n(s),\|w\|_2))[\xi_i^{(k_j^*)}(W_i(s),\dots,W_n(s),\|w\|_2)+\|w\|_2^2], \tag{A.42}$$

$$\sum_{i\in\{j,\dots,n\}\setminus J}\alpha_{j-1}(2nW_i(t))\left[\frac{W_i(t)}{W_i(t)+1}+\|w(t)\|^2\right]\leq \alpha_{j-1}(2n)\sum_{i=j}^{n}[c_i^{(k_j^*)}+\|w(t)\|^2]$$

$$\leq n\alpha_{j-1}(2n)[c_j^{(k_j^*)}+\|w(t)\|^2]. \tag{A.43}$$

The last passage in (A.43) follows from being $c_j^{(k)}\geq c_{j+1}^{(k)}\geq\cdots\geq c_n^{(k)}$ in (A.37). Thus, using the definition of $c_{n-1}^{(k_j^*)}$, by integrating (A.39) over $[s,r]$

$$W_{j-1}(t)\geq c_{j-1}^{(k_j^*)}\quad\forall t\in[s,r]\Rightarrow W_{j-1}(t)\leq -\frac{6b_{n-1}R_{j-1,1}(t-s)}{R_{j-2,1}^4}$$

$$+\,\varrho_{j-1}^{(k_j^*)}(W_{j-1}(s),\dots,W_n(s),\|w\|_2)\quad\forall t\in[s,r] \tag{A.44}$$

with

$$\varrho_{j-1}^{(k_j^*)}(W_{j-1}(s),\dots,W_n(s),\|w\|_2):=W_{j-1}(s)+2n^2b_{n-1}R_{j-1,1}\Big\{n\alpha_{j-1}(2n)\|w\|_2^2$$

$$+\,\alpha_{j-1}(2n\varrho_i^{(k_j^*)}(W_i(s),\dots,W_n(s),\|w\|_2))\sum_{i=j}^{n}[\xi_i^{(k_j^*)}(W_i(s),\dots,W_n(s),\|w\|_2)+\|w\|_2^2]\Big\}.$$

From (A.44) follow the existence of $\varepsilon_{j-1}^{(k_j^*+1)}>0$ and for each trajectory of (1.1)–(1.4) starting at $t_0\geq 0$ the existence of $T_{j-1}^{(k_j^*+1)}\geq t_0$ such that (A.34) hold true for all $i=j-1,\dots,n$ with $k=k_j^*+1$. Next, we show that also (A.35) holds true for all $i=j-1,\dots,n$ with $k=k_j^*+1$. Assume that $W_{j-1}(t)\geq c_{j-1}^{(k_j^*)}$, $W_i(t)\geq c_i^{(k_j^*)}$, $i\in J\subseteq\{j,\dots,n\}$, and $W_i(t)\leq c_i^{(k_j^*)}$, $i\in\{j,\dots,n\}\setminus J$, for all $t\in[s,r]$, $s\geq t_0$. Integrating (A.39) over $[s,r]$ and using the induction step, by the definition of $c_{j-1}^{(k_j^*)}$ in (A.38) and the nonnegativity of W_{j-1}, we obtain for any set $J\subseteq\{j,\dots,n\}$

$$\int_s^t\frac{W_i(\lambda)}{W_i(\lambda)+1}d\lambda\leq\frac{2R_{j-1,1}}{l_{j-1}}\{W_{j-1}(s)+\varrho_{j-1}^{(k_j^*)}(0,W_j(s),\dots,W_n(s),\|w\|_2)\}\ \forall t\in[s,r],$$

which, upon setting $\xi_{j-1}^{(k_j^*)}(W_j(s),\dots,W_n(s),\|w\|_2):=[2R_{j-1,1}/l_{j-1}]\{W_{j-1}(s)+\varrho_{j-1}^{(k_j^*)}(0,W_j(s),\dots,W_n(s),\|w\|_2)\}$, gives (A.35) for all $i=j-1,\dots,n$ with $k=k_j^*+1$.

The case $j = 2$ can be carried out in the same way as the case $j = 3, \dots, n$ with the only difference being that

$$c_1^{(k_2^*)} := 8R_{11}^2 b_1 n^3 \alpha_1(2n) c_2^{(k_2^*)}/l_1 < 1. \tag{A.45}$$

By iterating the above arguments for $k > k_j^* + 1$ and using the bounds $W_i(z_i, \sigma_i) \le c_i^{(k)} \Rightarrow z_i^2, e_i^2, \widetilde{x}_{i+1}^2 \le 6c_i^{(k)}$, $i = j, \dots, n$, in (A.39), we obtain (A.34)–(A.35) for all $i = j-1, \dots, n$ and $k \ge k_j^*$ with $c_i^{(k)}$ defined by the following equations for $k \ge k_j^*$:

$$c_n^{(k+1)} := \frac{24R_{n1}^2 b_n c_{n-1}^{(k)}}{l_n R_{n-1,1}^4}, \quad c_i^{(k+1)} := \frac{4R_{i1}^2 b_i}{l_i}\left[\frac{6c_{i-1}^{(k)}}{R_{i-1,1}^4} + 2n^3\alpha_i(2n)c_{i+1}^{(k)}\right], \quad i = j, \dots, n, \tag{A.46}$$

and

$$\begin{aligned} c_{j-1}^{(k+1)} &:= \frac{4R_{j-1,1}^2 b_{j-1}}{l_{j-1}}\left[\frac{6}{R_{j-2,1}^4} + 2n^3\alpha_{j-1}(2n)c_j^{(k)}\right] \quad \text{if j} \ge 3, \\ c_1^{(k+1)} &:= \frac{8R_{11}^2 b_1 n^3 \alpha_1(2n) c_2^{(k)}}{l_1} \quad \text{if j} = 2, \end{aligned} \tag{A.47}$$

where the $c_i^{(k_j^*)}$, $i = j, \dots, n$, are defined (on account of the induction step) as

$$c_i^{(k_j^*)} \sim \prod_{l=j}^{i} \frac{R_{l1}^2}{R_{l-1,1}^4},\ i = j, \dots, n, \quad c_j^{(k_j^*)} \ge c_{j+1}^{(k_j^*)} \ge \cdots \ge c_n^{(k_j^*)}, \tag{A.48}$$

and $c_{j-1}^{(k_j^*)}$ as in (A.38) if $j \ge 3$ and $c_1^{(k_2^*)}$ as in (A.45) if $j = 2$. The equations (A.46) can be described by a linear discrete-time system $x(k+1) = Ax(k) + Bu(k)$ with state $x(k) = (c_n^{(k)} \ \cdots \ c_{j-1}^{(k)})^T$, initial condition $x(0) = (c_n^{(k_j^*)} \ \cdots \ c_{j-1}^{(k_j^*)})^T$, input $u(k) = 0$ if $j = 2$, and $24R_{j-1,1}^2 b_{j-1}/[l_{j-1}R_{j-2,1}^4]$ if $j \ge 3$. Thus, for all $k \ge k_j^* + 1$

$$\begin{aligned} &\begin{pmatrix} c_n^{(k)} & \cdots & c_{j-1}^{(k)} \end{pmatrix}^T = A^{k-k_j^*} \begin{pmatrix} c_n^{(k_j^*)} & \cdots & c_{j-1}^{(k_j^*)} \end{pmatrix}^T \\ &+[I + A + A^2 + \cdots + A^{k-k_j^*-1}] \begin{pmatrix} 0 & \cdots & u(k) \end{pmatrix}^T, \end{aligned}$$

where the last term is zero if $j = 2$. It is not difficult to prove that if $j \ge 3$ and for $1 \le r \le j-1$

$$[I + A + A^2 + \cdots + A^r] \begin{pmatrix} 0 \\ \vdots \\ u(k) \end{pmatrix} \sim \begin{pmatrix} 0 \\ \vdots \\ \displaystyle\prod_{h=j-1}^{r+j-1} \frac{R_{h1}^2}{R_{h-1,1}^4}\left[1 + \mathcal{O}\Big(\frac{1}{\varepsilon}\Big)\right] \\ \vdots \\ \displaystyle\frac{R_{j-1,1}^2}{R_{j-2,1}^4}\left[1 + \mathcal{O}\Big(\frac{1}{\varepsilon}\Big)\right] \end{pmatrix},$$

and for $1 \le r \le j-1$ and $s \ge 0$

$$A^{sj+r} \begin{pmatrix} 0 & \cdots & u(k) \end{pmatrix}^T \sim \varepsilon^{-2s} A^r \begin{pmatrix} 0 & \cdots & u(k) \end{pmatrix}^T, \tag{A.49}$$

where $\sim$ is meant componentwise. Moreover, for $1 \le r \le j-1$

$$A^r \begin{pmatrix} c_n^{(k_j^*)} & \cdots & c_{j-1}^{(k_j^*)} \end{pmatrix}^T$$
$$= \begin{pmatrix} \mathcal{O}\left(\varepsilon^{-(n-j+2)} \prod_{h=j}^{n} R_{h-1,1}^{-2}\right) & \cdots & \mathcal{O}\left(\varepsilon^{-2} R_{j-1,1}^{-2}\right) & \mathcal{O}\left(\varepsilon^{-1}\right) \end{pmatrix}^T$$

and for $1 \le r \le j-1$ and $s \ge 0$

$$A^{sj+r} \begin{pmatrix} c_n^{(k_j^*)} & \cdots & c_{j-1}^{(k_j^*)} \end{pmatrix}^T \sim \varepsilon^{-2s} A^r \begin{pmatrix} c_n^{(k_j^*)} & \cdots & c_{j-1}^{(k_j^*)} \end{pmatrix}^T. \tag{A.50}$$

From this follows the existence of $\varepsilon_{j-1}^* \ge \varepsilon_j^*$ and $k_{j-1}^* \ge k_j^*$ such that the induction step (A.34)–(A.35) and (A.37) hold true with j replaced by $j-1$, and $c_i^{(k)}$, $i = j-1, \dots, n$, satisfy (A.36) if $j \ge 3$; otherwise $c_1^{(k)} < 1$ if $j = 2$. Thus, since (A.34)–(A.35) and (A.37) hold true for $j = n-1$ with (A.31), they hold true for all $j = 1, \dots, n$. Moreover, $c_i^{(k)}$, $i = 2, \dots, n$, satisfy (A.36) and $c_1^{(k)} < 1$ for all $\varepsilon \ge \varepsilon_1^*$ and $k \ge k_1^*$. This also concludes the proof of Lemma 8.1 with $c_j := c_j^{(k_1^*)}$ and $\varrho_j := \varrho_j^{(k_1^*)}$, $j = 1, \dots, n$. □

Proof of Lemma 8.2. Let ε_i^*, ϱ_i, and c_i, $i = 1, \dots, n$, be as in Lemma 8.1. Moreover, let

$$\overline{c}_i(\varepsilon) := \varrho_i(c_i(\varepsilon), \dots, c_n(\varepsilon), 0),\ \mathcal{T}_j(0) := \{(Z_j, S_j) : W_i(z_i, \sigma_i) \le \overline{c}_i(\varepsilon),\ i = j, \dots, n\}$$

and set $w = 0$ (we are proving internal stability). Define recursively a filtered Lyapunov function for (1.1)–(1.4) by using Theorem 7.4. First, find a filtered Lyapunov function for $\Sigma_i \circ \mathcal{C}_i$, $i = n-1, n$; then proceed by induction on the number $n-j+1$, $j = 1, \dots, n-1$, of systems $\Sigma_i \circ \mathcal{C}_i$ in $\Sigma_i \circ \mathcal{C}_i$, $i = j, \dots, n$. By (8.15) and (8.17), with $j = n, n-1$, $\Sigma_n \circ \mathcal{C}_n$ has for all $\varepsilon \ge \max_i \varepsilon_i^*$ filtered Lyapunov function W_n, stability margins $\varphi_{ns}/2$, $\varphi_{nm}/2$, and incremental rates $\gamma_n^{z_{n-1}}$, $\gamma_n^{e_{n-1}}$ (given in (8.21)), while $\Sigma_{n-1} \circ \mathcal{C}_{n-1}$ has for all $\varepsilon \ge \max_i \varepsilon_i^*$ Lyapunov function W_{n-1}, stability margins $\varphi_{n-1,s}/2$, $\varphi_{n-1,m}/2$, and incremental rates $\gamma_{n-1}^{z_{n-2}}$, $\gamma_{n-1}^{e_{n-2}}$, $\gamma_{n-1}^{z_n}$, $\gamma_{n-1}^{e_n}$ (given in (8.21)–(8.22)). Choose $\varepsilon_{n-1}^{**} \ge \max_i \varepsilon_i^*$ such that for all $\varepsilon \ge \varepsilon_{n-1}^{**}$ the following hold:

(1) $\varphi_{ns}/2$ and $\varphi_{nm}/2$ locally saturate $\gamma_{n-1}^{z_n}$ and $\gamma_{n-1}^{e_n}$, respectively, with levels $(\overline{c}_n, \tau_{n-1}\ (\overline{c}_n))$, where $\tau_{n-1} : \mathbb{R}^{\ge} \to [1, \infty)$ is a continuous nondecreasing function such that $\gamma_{n-1}^{z_n} \le \tau_{n-1}(W_n)\varphi_{ns}/2$ and $\gamma_{n-1}^{e_n} \le \tau_{n-1}(W_n)\varphi_{nm}/2$ for all z_n, σ_n: by (8.22), with $j = n-1$ and $l = n$, and Lemma A.3 this can be done by taking $\tau_{n-1}(s) \sim R_{n-1,1} R_{n1} \widetilde{\tau}_{n-1}(s)$, with $\widetilde{\tau}_{n-1} : \mathbb{R}^{\ge} \to [1, \infty)$ a continuous nondecreasing function such that

$$[(1 + W_n(z_n, \sigma_n))^2 - 1][\gamma_{n-1,s}^{z_n} + \gamma_{n-1,m}^{z_n} + \gamma_{n-1,s}^{\widetilde{x}_{n+1}} + \gamma_{n-1,m}^{\widetilde{x}_{n+1}} + 1] \le \widetilde{\tau}_{n-1}(W_n(z_n, \sigma_n))$$

for all z_n, σ_n.

(2) $\varphi_{n-1,s}/2$ and $\varphi_{n-1,m}/2$ saturate $\gamma_n^{z_{n-1}}$ and $\gamma_n^{e_{n-1}}$ with level $1/[3\tau_{n-1}(\overline{c}_n)]$: this follows since $\widetilde{\tau}_{n-1}(\overline{c}_n) \preceq 1$ (by continuity of $\widetilde{\tau}_{n-1}(s)$ and $\overline{c}_n \preceq 1$) and from (8.21) with $j = n$, by (8.7) and (8.16) with $j = n$.

(3) $\Sigma_n \circ \mathcal{C}_n$ is recurrent relative to the trap $\mathcal{T}_n(0)$, and $\Sigma_{n-1} \circ \mathcal{C}_{n-1}$ is recurrent relative to the trap $\{(z_{n-1}, \sigma_{n-1}) : W_{n-1}(z_{n-1}, \sigma_{n-1}) \le \overline{c}_{n-1}\}$: this follows by Lemma 8.1.

Application of Theorem 7.4 to $\Sigma_i \circ \mathcal{C}_i$, $i = n-1, n$, with $c_1 \to \overline{c}_{n-1}, c_2 \to \overline{c}_n, \kappa_2 \to 1/[3\tau_{n-1}(\overline{c}_n)], \kappa_1 \to \tau_{n-1}(\overline{c}_n)$, $d_1 \to 1$, $d_2 \to 2\tau_{n-1}(\overline{c}_{n-1})$, $\theta_1, \theta_2 \to 1$, $\theta_0 \to \theta_{n-1}$,

$\tau_2(s) \to \kappa_n$, and $\tau_1(s) \to \tau_{n-1}(s)$, gives that

$$\begin{aligned}
&\widetilde{W}^{(n-1)}(Z_{n-1}, S_{n-1}, \theta_{n-1}) = \theta_{n-1} W^{(n-1)}(Z_{n-1}, S_{n-1}),\\
&W^{(n-1)}(Z_{n-1}, S_{n-1}) = W_{n-1}(z_{n-1}, \sigma_{n-1}) + 2\tau_{n-1}(\overline{c}_n) W_n(z_n, \sigma_n),\\
&\dot{\theta}_{n-1} = -[a_{n-1}(z_n, \sigma_n)/\min\{\overline{c}_{n-1}, 2\overline{c}_n \tau_{n-1}(\overline{c}_n)\}]\theta_{n-1},\ \theta_{n-1}(0) = e^{\int_0^\infty a_{n-1}(\tau)d\tau},
\end{aligned}$$

with $a_{n-1}(z_n, \sigma_n) = \max\{\tau_{n-1}(W_n(z_n, \sigma_n)) - \tau_{n-1}(\overline{c}_n), 0\}[\varphi_{ns} z_n^2/2 + \varphi_{nm} e_n^2/2]$, is for all $\varepsilon \geq \varepsilon_n^{**}$ a smooth filtered Lyapunov function for the interconnection $\Sigma_j \circ \mathcal{C}_j$, $j = n-1, n$, with

$$\dot{\widetilde{W}}^{(n-1)} \leq \theta_{n-1} \left\{ -\sum_{i=n-1}^{n} [\varphi_{is}^{(n-1)} z_i^2 + \varphi_{im}^{(n-1)} e_i^2] + \gamma_{n-1}^{z_{n-2}} z_{n-2}^2 + \gamma_{n-1}^{e_{n-2}} e_{n-2}^2 \right\} \tag{A.51}$$

along the trajectories of $\Sigma_j \circ \mathcal{C}_j$, $j = n-1, n$, where $\varphi_{n-1,l}^{(n-1)} \sim \varphi_{n-1,l}$ and $\varphi_{nl}^{(n-1)} \sim \tau_{n-1}(\overline{c}_n)\varphi_{nl}$, $l = s, m$. Moreover, the interconnection $\Sigma_j \circ \mathcal{C}_j$, $j = n-1, n$, is recurrent relative to the trap $\{(Z_{n-1}, S_{n-1}) : W^{(n-1)}(Z_{n-1}, S_{n-1}) \leq c^{(n-1)} := \overline{c}_{n-1} + 2\tau_{n-1}(\overline{c}_n)\}$ and for each trajectory of $\Sigma_j \circ \mathcal{C}_j$, $j = n-1, n$, there exists $T_{n-1} > 0$ such that

$$\theta_{n-1}(t) \geq 1 \quad \forall t \geq 0, \qquad \theta_{n-1}(t) = 1 \quad \forall t \geq T_{n-1}. \tag{A.52}$$

For each $j = 2, \ldots, n-1$ and $i = j, \ldots, n-1$ let

$$\begin{aligned}
&\varphi_{nl}^{(n)} \sim \varphi_{nl},\ \varphi_{il}^{(i)} \sim \varphi_{il},\ \varphi_{hl}^{(i)} \sim \tau_i(c^{(i+1)}) \cdots \tau_{n-1}(c^{(n)})\varphi_{hl}, \quad h = i+1, \ldots, n; l = s, m,\\
&\widetilde{W}^{(n)}(Z_n, S_n) = W_n(z_n, \sigma_n), \quad c^{(n)} = \overline{c}_n, \quad c^{(i)} = \overline{c}_i + 2\tau_i(c^{(i+1)})c^{(i+1)},
\end{aligned} \tag{A.53}$$

and

$$\begin{aligned}
&\widetilde{W}^{(j)}(Z_j, S_j, \widetilde{\theta}_j) = \widetilde{\theta}_j W^{(j)}(Z_j, S_j), \quad \widetilde{\theta}_j = \theta_j \cdots \theta_{n-1},\\
&W^{(i)}(Z_i, S_i) = W_i(z_i, \sigma_i) + 2\tau_i(c^{(i+1)}) W^{(i+1)}(Z_{i+1}, S_{i+1}),\\
&\dot{\theta}_i = -[a_i(Z_{i+1}, S_{i+1})/\min\{\overline{c}_i, 2c^{(i+1)}\tau_i(c^{(i+1)})\}]\theta_i, \quad \theta_i(0) = e^{\int_0^\infty a_i(\tau)d\tau},\\
&i = j, \ldots, n-1,
\end{aligned} \tag{A.54}$$

where $a_i(Z_{i+1}, S_{i+1}) = \max\{\tau_i(W^{(i+1)}(Z_{i+1}, S_{i+1})) - \tau_i(c^{(i+1)}), 0\} \sum_{l=i+1}^{n} [\varphi_{ls}^{(l+1)} z_l^2 + \varphi_{lm}^{(l+1)} e_l^2]$ and $\tau_i : \mathbb{R}^{\geq} \to [1, \infty)$, $i = j, \ldots, n-1$, are continuous nondecreasing functions.

Induction hypothesis. Let $j = 2, \ldots, n-1$. Assume the existence of $\varepsilon_j^{**} \geq \max_i \varepsilon_i^*$ such that for all $\varepsilon_j \geq \varepsilon_j^{**}$

$$\tau_i(s) \sim R_{i1} R_{i+1,1} \widetilde{\tau}_i(s), \quad i = j, \ldots, n-1, \tag{A.55}$$

with $\widetilde{\tau}_i, \tau_i : \mathbb{R}^{\geq} \to [1, \infty)$ continuous nondecreasing functions such that $\gamma_i^{z_{i+1}} \leq \tau_i(W^{(i+1)})\varphi_{i+1,s}^{(i)}$, $\gamma_i^{e_{i+1}} \leq \tau_i(W^{(i+1)})\varphi_{i+1,m}^{(i)}$ and

$$[(1 + W_{i+1}(z_{i+1}, \sigma_{i+1}))^2 - 1][\gamma_{is}^{z_{i+1}} + \gamma_{im}^{z_{i+1}} + \gamma_{is}^{\widetilde{x}_{i+2}} + \gamma_{im}^{\widetilde{x}_{i+2}} + 1] \leq \widetilde{\tau}_i(W^{(i+1)}(Z_{i+1}, S_{i+1}))$$

for all Z_{i+1}, S_{i+1}. Assume also that for all $\varepsilon \geq \varepsilon_j^{**}$

$$\dot{\widetilde{W}}^{(j)} \leq \widetilde{\theta}_j \left\{ -\sum_{i=j}^{n} [\varphi_{is}^{(j)} z_i^2 + \varphi_{im}^{(j)} e_i^2] + \gamma_j^{z_{j-1}} z_{j-1}^2 + \gamma_j^{e_{j-1}} e_{j-1}^2 \right\} \tag{A.56}$$

along the trajectories of $\Sigma_i \circ \mathcal{C}_i$, $i = j, \dots, n$, and, moreover, the interconnection $\Sigma_j \circ \mathcal{C}_j$, $i = j, \dots, n$, is recurrent relative to the trap $\{(Z_j, S_j) : W^{(j)}(Z_j, S_j) \le c^{(j)}\}$ and for each trajectory of $\Sigma_i \circ \mathcal{C}_i$, $i = j-1, \dots, n$, there exists $T_j > 0$ such that

$$\theta_i(t) \ge 1 \quad \forall t \ge 0, \quad \theta_i(t) = 1 \quad \forall t \ge T_j, \quad i = j, \dots, n-1. \tag{A.57}$$

Note that by (8.15) and (8.17), with j replaced by $j-1$, for all $\varepsilon \ge \varepsilon_j^{**}$

$$\begin{aligned}\dot W_{j-1} \le & -[\varphi_{j-1,s} z_{j-1}^2/2 + \varphi_{j-1,m} e_{j-1}^2/2] + \gamma_{j-1}^{z_{j-2}} z_{j-2}^2 + \gamma_{j-1}^{e_{j-2}} e_{j-2}^2 \\ & + \sum_{l=j}^{n} [\gamma_{j-1}^{z_l} z_l^2 + \gamma_{j-1}^{e_l} e_l^2]\end{aligned}$$

along the trajectories of $\Sigma_i \circ \mathcal{C}_i$, $i = j-1, \dots, n$. Choose $\varepsilon_{j-1}^{**} \ge \varepsilon_j^{**}$ such that for all $\varepsilon \ge \varepsilon_{j-1}^{**}$ the following hold:

(1) $\varphi_{is}^{(j)}/2$ and $\varphi_{im}^{(j)}/2$, $i = j, \dots, n$, locally saturate $\gamma_{j-1}^{z_i}$ and $\gamma_{j-1}^{e_i}$, respectively, with levels $(c^{(j)}, \tau_{j-1}(c^{(j)}))$, where $\tau_{j-1} : \mathbb{R}^{\ge} \to [1, \infty)$ is a continuous nondecreasing function such that $\gamma_{j-1}^{z_j} \le \tau_{j-1}(W^{(j)})\varphi_{js}/2$ and $\gamma_{j-1}^{e_j} \le \tau_{j-1}(W^{(j)})\varphi_{jm}/2$ for all Z_j, S_j: by Lemma A.3 and since $\tau_i(s) \ge 1$ for all s, $i = j, \dots, n$, this can be done by taking $\tau_{j-1}(s) \sim R_{j-1,1} R_{j1} \widetilde\tau_{j-1}(s)$, with $\widetilde\tau_{j-1} : \mathbb{R}^{\ge} \to [1, \infty)$ a continuous nondecreasing function such that for all Z_j, S_j

$$[(1 + W_j(z_j, \sigma_j))^2 - 1][\gamma_{j-1,s}^{z_j} + \gamma_{j-1,m}^{z_j} + \gamma_{j-1,s}^{\widetilde x_{j+1}} + \gamma_{j-1,m}^{\widetilde x_{j+1}} + 1] \le \widetilde\tau_{j-1}(W^{(j)}(Z_j, S_j)). \tag{A.58}$$

(2) $\varphi_{j-1,s}/2$ and $\varphi_{j-1,m}/2$ saturate $\gamma_j^{z_{j-1}}$ and $\gamma_j^{e_{j-1}}$ with level $1/[3\tau_{j-1}(c^{(j)})]$: this follows from (A.55), (8.21), and (A.58) and since $\widetilde\tau_{j-1} \preceq 1$.

(3) $\Sigma_i \circ \mathcal{C}_i$, $i = j, \dots, n$, is recurrent relative to the trap $\{(Z_j, S_j) : W^{(j)}(Z_j, S_j) \le c_i^{(j)}\}$, and $\Sigma_{j-1} \circ \mathcal{C}_{j-1}$ is recurrent relative to the trap $\{(z_{j-1}, \sigma_{j-1}) : W_{j-1}(z_{j-1}, \sigma_{j-1}) \le \bar c_{j-1}\}$: this follows from Lemma 8.1 and the induction step.

By application of Theorem 7.4 to $\Sigma_i \circ \mathcal{C}_i$, $i = j-1, \dots, n$, we prove that there exists $\varepsilon_{j-1}^{**} \ge \varepsilon_{j-1}^{*}$ such that (A.53)–(A.57) hold for all $\varepsilon \ge \varepsilon_{j-1}^{**}$ with j replaced by $j-1$, the interconnection $\Sigma_j \circ \mathcal{C}_j$, $i = j-1, \dots, n$, is recurrent relative to the trap $\{(Z_{j-1}, S_{j-1}) : W^{(j-1)}(Z_{j-1}, S_{j-1}) \le c^{(j-1)}\}$, and for each trajectory of $\Sigma_i \circ \mathcal{C}_i$, $i = j-1, \dots, n$, there exist $T_{j-1} > 0$ such that $\theta_{j-1}(t) \ge 1$ for all $t \ge 0$ and $\theta_{j-1}(t) = 1$ for all $t \ge T_{j-1}$. Thus, since the induction step holds true for $j = n-1$, it holds true for all $j = 1, \dots, n-1$. This completes the proof of Lemma 8.2 with $\varepsilon^{**} = \varepsilon_1^{**}$, $\widetilde W = \widetilde W^{(1)}$, $\theta = \widetilde\theta_1$, and $\widetilde\varphi_{il} = \varphi_{il}^{(1)}$. □

ADAPTIVE SPACE-TIME FINITE ELEMENT METHODS FOR PARABOLIC OPTIMIZATION PROBLEMS*

DOMINIK MEIDNER† AND BORIS VEXLER‡

Abstract. In this paper we derive a posteriori error estimates for space-time finite element discretizations of parabolic optimization problems. The provided error estimates assess the discretization error with respect to a given quantity of interest and separate the influences of different parts of the discretization (time, space, and control discretization). This allows us to set up an efficient adaptive algorithm which successively improves the accuracy of the computed solution by construction of locally refined meshes for time and space discretizations.

Key words. parabolic equations, optimal control, parameter identification, a posteriori error estimation, mesh refinement

1. Introduction.

In this paper we develop an adaptive algorithm for efficient solution of time-dependent optimization problems governed by parabolic partial differential equations. The optimization problems are formulated in a general setting including optimal control as well as parameter identification problems. Both, time and space discretization of the state equation are based on the finite element method as proposed, e.g., in [10, 11]. In [2] we have shown that this type of discretization allows for a natural translation of the optimality conditions from the continuous to the discrete level. This gives rise to exact computation of the derivatives required in the optimization algorithms on the discrete level.

The main goal of this paper is to derive a posteriori error estimates which assess the error between the solution of the continuous and the discrete optimization problem with respect to a given quantity of interest. This quantity of interest may coincide with the cost functional or express another goal for the computation. In order to set up an efficient adaptive algorithm we will separate the influences of the time and space discretizations on the error in the quantity of interest. This allows us to balance different types of errors and successively to improve the accuracy by construction of locally refined meshes for time and space discretizations.

The use of adaptive techniques based on a posteriori error estimation is well accepted in the context of finite element discretization of partial differential equations; see, e.g., [9, 28, 3]. In the past several years the application of these techniques has also been investigated for optimization problems governed by partial differential equations. Energy-type error estimators for the error in the state, control, and adjoint variable are developed in [20, 21] in the context of distributed elliptic optimal control problems subject to pointwise control constraints. Recently, these techniques were also applied in the context of optimal control problems governed by linear parabolic equations; see [19]. In a recent preprint [24] an anisotropic error estimate is derived

for the error due to the space discretization of an optimal control problem governed by the linear heat equation.

However, in many applications, the error in global norms does not provide useful error bounds for the error in the quantity of physical interest. In [1, 3] a general concept for a posteriori estimation of the discretization error with respect to the cost functional in the context of optimal control problems is presented. In papers [4, 5], this approach is extended to the estimation of the discretization error with respect to an arbitrary functional depending on both the control and state variables, i.e., with respect to a quantity of interest. This allows, among other things, an efficient treatment of parameter identification and model calibration problems.

The main contribution of this paper is the extension of these approaches to optimization problems governed by parabolic partial differential equations.

In this paper, we consider optimization problems under constraints of (nonlinear) parabolic differential equations

$$\begin{aligned} \partial_t u + A(q,u) &= f \\ u(0) &= u_0(q). \end{aligned} \tag{1.1}$$

Here, the state variable is denoted by u and the control variable by q. Both, the differential operator A and the initial condition u_0 may depend on q. This allows a simultaneous treatment of both optimal control and parameter identification problems. For optimal control problems, the operator A is typically given by

$$A(q,u) = \bar{A}(u) - B(q),$$

with a (nonlinear) operator $\bar{A}$ and a (usually linear) control operator B. In parameter identification problems, the variable q denotes the unknown parameters to be determined and may enter the operator A in a nonlinear way. The case of initial control is included via the q-dependent initial condition $u_0(q)$.

The target of the optimization is to minimize a given cost functional $J(q,u)$ subject to the state equation (1.1).

For the numerical solution of this optimization problem the state variable has to be discretized in space and in time. Moreover, if the control (parameter) space is infinite dimensional, it has to be discretized too. For fixed time, space, and control discretizations this leads to a finite dimensional optimization problem. We introduce σ as a general discretization parameter including the space, time, and control discretizations and denote the solution of the discrete problem by (q_σ, u_σ). For this discrete solution we derive an a posteriori error estimate with respect to the cost functional J of the following form:

$$J(q,u) - J(q_\sigma, u_\sigma) \approx \eta_k^J + \eta_h^J + \eta_d^J. \tag{1.2}$$

Here, η_k^J, η_h^J, and η_d^J denote the error estimators, which can be evaluated from the computed discrete solution; η_k^J assesses the error due to the time discretization, η_h^J due to the space discretization, and η_d^J due to the discretization of the control space. The structure of the error estimate (1.2) allows for equilibration of different discretization errors within an adaptive refinement algorithm to be described in the following discussion.

For many optimization problems the quantity of physical interest coincides with the cost functional, which explains the choice of the error measure (1.2). However, in the case of parameter identification or model calibration problems, the cost functional is only an instrument for the estimation of the unknown parameters. Therefore, the

value of the cost functional in the optimum and the corresponding discretization error are of secondary importance. This motivates error estimation with respect to a given functional I depending on the state and control (parameter) variables. In this paper we extend the corresponding results from [4, 5, 29] to parabolic problems and derive an a posteriori error estimator of the form

$$I(q,u) - I(q_\sigma, u_\sigma) \approx \eta_k^I + \eta_h^I + \eta_d^I,$$

where again η_k^I and η_h^I estimate the temporal and spatial discretization errors and η_d^I estimates the discretization error due to the discretization of the control space.

In section 5.2 we will describe an adaptive algorithm based on these error estimators. Within this algorithm the time, space, and control discretizations are separately refined for efficient reduction of the total error equilibrating different types of the error. This local refinement relies on the computable representation of the error estimators as a sum of local contributions (error indicators), see the discussion in section 5.1.

To the authors' knowledge, this is the first paper describing the a posteriori error estimation for optimization problems governed by parabolic differential equations including the separation of different types of the discretization error.

The outline of the paper is as follows: In the next section we describe necessary optimality conditions for the problem under consideration and sketch the Newton-type optimization algorithm on the continuous level. This algorithm will be applied on the discrete level for fixed discretizations within an adaptive refinement procedure. In section 3 we present the space-time finite element discretization of the optimization problem. Section 4 is devoted to the derivation of the error estimators in a general setting. In section 5 we discuss numerical evaluation of these error estimators and the adaptive algorithm in details. In the last section we present two numerical examples illustrating the behavior of the proposed methods. The first example deals with boundary control of the heat equation, whereas the second one is concerned with the identification of Arrhenius parameters in a simplified gaseous combustion model by means of point measurements of the concentrations.

2. Optimization. The optimization problems considered in this paper are formulated in the following abstract setting: Let Q be a Hilbert space for the controls (parameters) with scalar product $(\cdot,\cdot)_Q$. Moreover, let V and H be Hilbert spaces, which build together with the dual space V^* of V a Gel'fand triple $V \hookrightarrow H \hookrightarrow V^*$. The duality pairing between the Hilbert spaces V and its dual V^* is denoted by $\langle\cdot,\cdot\rangle_{V^*\times V}$, and the scalar product in H is denoted by $(\cdot,\cdot)_H$. A typical choice for these spaces could be

$$V = \left\{ v \in H^1(\Omega) \,\middle|\, v\big|_{\partial\Omega_{\mathrm{D}}} = 0 \right\} \text{ and } H = L^2(\Omega), \tag{2.1}$$

where $\partial\Omega_{\mathrm{D}}$ denotes the part of the boundary of Ω with prescribed Dirichlet boundary conditions.

For a time interval $(0,T)$ we introduce the Hilbert space $X := W(0,T)$ defined as

$$W(0,T) = \left\{ v \,\middle|\, v \in L^2((0,T),V) \text{ and } \partial_t v \in L^2((0,T),V^*) \right\}. \tag{2.2}$$

It is well known that the space X is continuously embedded in $C([0,T],H)$; see, e.g., [8]. Furthermore, we use the inner product of $L^2((0,T),H)$ given by

$$(u,v) := (u,v)_{L^2((0,T),H)} = \int_0^T (u(t),v(t))_H \, dt \tag{2.3}$$

for setting up the weak formulation of the state equation.

By means of the spatial semilinear form $\bar{a}\colon Q\times V\times V \to \mathbb{R}$ defined for a differential operator $A\colon Q \times V \to V^*$ by

$$\bar{a}(q,\bar{u})(\bar{\varphi}) := \langle A(q,\bar{u}),\bar{\varphi}\rangle_{V^*\times V},$$

we can define the semilinear form $a(\cdot,\cdot)(\cdot)$ on $Q \times X \times X$ as

$$a(q,u)(\varphi) := \int_0^T \bar{a}(q,u(t))(\varphi(t))\,dt$$

which is assumed to be three times Gâteaux differentiable and linear in the third argument.

Remark 2.1. If the control variable q depends on time, this has to be incorporated by an obvious modification of the definitions of the semilinear forms.

After these preliminaries, we pose the *state equation* in a weak form: Find for given control $q \in Q$ the *state variable* $u \in X$ such that

$$\begin{aligned}(\partial_t u,\varphi) + a(q,u)(\varphi) &= (f,\varphi) \quad \forall \varphi \in X,\\ u(0) &= u_0(q),\end{aligned} \tag{2.4}$$

where $f \in L^2((0,T),V^*)$ represents the right-hand side of the state equation and $u_0\colon Q \to H$ denotes a three times Gâteaux differentiable mapping describing parameter-dependent initial conditions. The usage of the inner product $(\cdot,\cdot)$ defined in (2.3) for stating the formulation (2.4) is possible since the inner product on H is an equivalent representation of the duality pairing of V and V^* due to the properties of the Gel'fand triple.

Remark 2.2. There are several sets of assumptions on the nonlinearity in $\bar{a}(\cdot,\cdot)(\cdot)$ and its dependence on the control variable q allowing the state equation (2.4) to be well-posed. Typical examples are different semilinear equations, where the form $\bar{a}(\cdot,\cdot)(\cdot)$ consists of a linear elliptic part and a nonlinear term depending on u and ∇u. Due to the fact that the development of the proposed adaptive algorithm does not depend on the particular structure of the nonlinearity in $\bar{a}$, we do not specify a set of assumptions on it but assume that the state equation (2.4) possesses a unique solution $u = S(q) \in X$ for each $q \in Q$.

The cost functional $J\colon Q \times X \to \mathbb{R}$ is defined using two three times Gâteaux differentiable functionals $J_1\colon V \to \mathbb{R}$ and $J_2\colon H \to \mathbb{R}$ by

$$J(q,u) = \int_0^T J_1(u)\,dt + J_2(u(T)) + \frac{\alpha}{2}\|q-\bar{q}\|_Q^2, \tag{2.5}$$

where the regularization (or cost) term is added which involves $\alpha \geq 0$ and a reference parameter $\bar{q} \in Q$.

The corresponding optimization problem is formulated as follows:

$$\text{Minimize } J(q,u) \text{ subject to the state equation (2.4), } (q,u) \in Q \times X. \tag{2.6}$$

The question of existence and uniqueness of solutions to such optimization problems is discussed, e.g., in [18, 13, 27]. Throughout the paper, we assume problem (2.6) to admit a (locally) unique solution. Moreover, we assume the existence of a neighborhood $W \subset Q\times X$ of the optimal solution, such that the linearized form $\bar{a}'_u(q,u(t))(\cdot,\cdot)$ considered as a linear operator

$$\bar{a}'_u(q,u(t))\colon V \to V^*$$

is an isomorphism for all $(q,u) \in W$ and almost all $t \in (0,T)$. This assumption will allow all considered linearized and adjoint problems to be well-posed.

Provided the existence of a solution operator $S\colon Q \to X$ for the state equation (2.4) (see Remark 2.2), we can define the reduced cost functional $j\colon Q \to \mathbb{R}$ by $j(q) = J(q, S(q))$. This definition allows us to reformulate problem (2.6) as an unconstrained optimization problem:

$$\text{Minimize } j(q), \quad q \in Q. \tag{2.7}$$

We assume the solution operator S to be two times differentiable; see, e.g., [27] for a discussion of this issue.

For the reduced optimization problem (2.7) we apply Newton's method to reach a control q which satisfies the first order necessary optimality condition

$$j'(q)(\tau q) = 0 \quad \forall \tau q \in Q.$$

Starting with an initial guess q^0, the next Newton iterate is obtained by $q^{i+1} = q^i + \delta q$, where the update $\delta q \in Q$ is the solution of the linear problem:

$$j''(q)(\delta q, \tau q) = -j'(q)(\tau q) \quad \forall \tau q \in Q. \tag{2.8}$$

Thus, we need suitable expressions for the first and second derivatives of the reduced cost functional j. To this end, we introduce the Lagrangian $\mathcal{L}\colon Q \times X \times X \to \mathbb{R}$, defined as

$$\mathcal{L}(q,u,z) = J(q,u) + (f - \partial_t u, z) - a(q,u)(z) - (u(0) - u_0(q), z(0))_H. \tag{2.9}$$

With its aid, we obtain the following standard representation of the first derivative $j'(q)(\tau q)$.

THEOREM 2.1.

- *If for given $q \in Q$ the state $u \in X$ fulfills the state equation*

$$\mathcal{L}'_z(q,u,z)(\varphi) = 0 \quad \forall \varphi \in X,$$

  with $(q,u) \in W \subset Q \times X$,
- *and if additionally $z \in X$ is chosen as a solution of the adjoint state equation*

$$\mathcal{L}'_u(q,u,z)(\varphi) = 0 \quad \forall \varphi \in X,$$

then the following expression of the first derivative of the reduced cost functional holds:

$$\begin{aligned} j'(q)(\tau q) &= \mathcal{L}'_q(q,u,z)(\tau q) \\ &= \alpha(q - \bar{q}, \tau q)_Q - a'_q(q,u)(\tau q, z) + (u'_0(q)(\tau q), z(0))_H. \end{aligned}$$

Remark 2.3. The optimality system of the considered optimization problem (2.6) is given by the derivatives of the Lagrangian used in Theorem 2.1 above:

$$\begin{aligned} &\mathcal{L}'_z(q,u,z)(\varphi) = 0 \quad \forall \varphi \in X && \text{(State equation)}, \\ &\mathcal{L}'_u(q,u,z)(\varphi) = 0 \quad \forall \varphi \in X && \text{(Adjoint state equation)}, \\ &\mathcal{L}'_q(q,u,z)(\psi) = 0 \quad \forall \psi \in Q && \text{(Gradient equation)}. \end{aligned} \tag{2.10}$$

For the explicit formulation of the dual equation in this setting, see, e.g., [2].

In the same manner one can gain representations of the second derivatives of j in terms of the Lagrangian; see, e.g., [2] where two different kinds of expressions are discussed: Either one can build up the whole Hessian and solve the system (2.8) by an arbitrary linear solver, or one can just compute matrix-vector products of the Hessian times a given vector and use this to solve (2.8) by the conjugate gradient method.

The presented Newton's method will be used to solve discrete optimization problems arising from discretizing the states and the controls as, e.g., shown in the following section. In practical realizations, Newton's method has to be combined with some globalization techniques such as line search or trust region to enlarge its area of convergence; see, e.g., [23, 7].

Remark 2.4. The solution u of the underlying state equation is typically required in the whole time interval for the computation of the adjoint solution z. If all data are stored, the storage grows linearly with respect to the number of time intervals in the time discretization. For reducing the required memory one can apply checkpointing techniques; see, e.g., [15, 14]. In [2] we analyze such a strategy in the context of space-time finite element discretization of parabolic optimization problems.

3. Discretization. In this section, we discuss the discretization of the optimization problem (2.6). To this end, we use Galerkin finite element methods in space and time to discretize the state equation. This allows us to give a natural computable representation of the discrete gradient and Hessian in the same manner as shown in section 2 for the continuous problem. The use of exact discrete derivatives is important for the convergence of the optimization algorithms. Moreover, our systematic approach to a posteriori error estimation relies on using the Galerkin-type discretizations.

The first of the following subsections is devoted to semidiscretization in time by *continuous Galerkin* (cG) and *discontinuous Galerkin* (dG) methods. Section 3.2 deals with the space discretization of the semidiscrete problems arising from time discretization. For the numerical analysis of these schemes we refer to [10].

The discretization of the control space Q is kept rather abstract by choosing a finite dimensional subspace $Q_d \subset Q$. A possible concretion of this choice is shown in the numerical examples in section 6. For the variational discretization concept, where the control variable is not discretized explicitly, we refer to [16]; for a superconvergence based discretization of the control variable, see [22].

3.1. Time discretization of the states. To define a semidiscretization in time, let us partition the time interval $[0,T]$ as

$$[0,T] = \{0\} \cup I_1 \cup I_2 \cup \cdots \cup I_M$$

with subintervals $I_m = (t_{m-1}, t_m]$ of size k_m and time points

$$0 = t_0 < t_1 < \cdots < t_{M-1} < t_M = T.$$

We define the discretization parameter k as a piecewise constant function by setting $k\big|_{I_m} = k_m$ for $m = 1, \ldots, M$.

By means of the subintervals I_m, we define for $r \in \mathbb{N}_0$ two semidiscrete spaces X_k^r and $\widetilde{X}_k^r$:

$$X_k^r = \left\{ v_k \in C([0,T], H) \,\middle|\, v_k\big|_{I_m} \in \mathcal{P}^r(I_m, V) \right\} \subset X,$$
$$\widetilde{X}_k^r = \left\{ v_k \in L^2((0,T), V) \,\middle|\, v_k\big|_{I_m} \in \mathcal{P}^r(I_m, V) \text{ and } v_k(0) \in H \right\}.$$

Here, $\mathcal{P}^r(I_m, V)$ denotes the space of polynomials up to order r defined on I_m with values in V. Thus, X_k^r consists of piecewise polynomials which are continuous in time and will be used as trial space in the cG method, whereas the functions in $\widetilde{X}_k^r$ may have discontinuities at the edges of the subintervals I_m. This space will be used in what follows as test space in the cG method and as trial and test space in the dG method.

3.1.1. Continuous Galerkin methods. Using the semidiscrete spaces defined above, the cG(r) formulation of the state equation can be directly stated as follows: Find for given control $q_k \in Q$ a state $u_k \in X_k^r$ such that

$$\begin{aligned} (\partial_t u_k, \varphi) + a(q_k, u_k)(\varphi) &= (f, \varphi) \quad \forall \varphi \in \widetilde{X}_k^{r-1}, \\ u_k(0) &= u_0(q_k). \end{aligned} \tag{3.1}$$

Remark 3.1. This equation is assumed to posses a unique solution for each $q \in Q$, cf. Remark 2.2. In special cases the existence and uniqueness can be shown by separation of variables and by using the fact that $\widetilde{X}_k^r$ is finite dimensional with respect to time.

The corresponding semidiscretized optimization problem reads

(3.2) Minimize $J(q_k, u_k)$ subject to the state equation (3.1), $(q_k, u_k) \in Q \times X_k^r$.

Since the state equation semidiscretized by the cG(r) method has the same form as in the continuous setting, the corresponding Lagrangian is analogically defined on $Q \times X_k^r \times \widetilde{X}_k^{r-1}$ as

$$\mathcal{L}(q_k, u_k, z_k) = J(q_k, u_k) + (f - \partial_t u_k, z_k) - a(q_k, u_k)(z_k) - (u_k(0) - u_0(q_k), z_k(0))_H.$$

3.1.2. Discontinuous Galerkin methods. To define the dG(r) discretization we employ the following definition for functions $v_k \in \widetilde{X}_k^r$:

$$v_{k,m}^+ := \lim_{t \to 0^+} v_k(t_m + t), \quad v_{k,m}^- := \lim_{t \to 0^+} v_k(t_m - t) = v_k(t_m), \quad [v_k]_m := v_{k,m}^+ - v_{k,m}^-.$$

Then, the dG(r) semidiscretization of the state equation (2.4) reads as follows: Find for given control $q_k \in Q$ a state $u_k \in \widetilde{X}_k^r$ such that

$$\begin{aligned} \sum_{m=1}^{M} \int_{I_m} (\partial_t u_k, \varphi)_H \, dt + a(q_k, u_k)(\varphi) + \sum_{m=0}^{M-1} ([u_k]_m, \varphi_m^+)_H &= (f, \varphi) \quad \forall \varphi \in \widetilde{X}_k^r, \\ u_{k,0}^- &= u_0(q_k). \end{aligned} \tag{3.3}$$

This equation is assumed to be well-posed, cf. Remark 3.1.

The semidiscrete optimization problem for the dG(r) time discretization has the form

(3.4) Minimize $J(q_k, u_k)$ subject to the state equation (3.3), $(q_k, u_k) \in Q \times \widetilde{X}_k^r$.

Then we pose the Lagrangian $\widetilde{\mathcal{L}}\colon Q \times \widetilde{X}_k^r \times \widetilde{X}_k^r \to \mathbb{R}$ associated with the dG(r) time discretization for the state equation as

$$\begin{aligned} \widetilde{\mathcal{L}}(q_k, u_k, z_k) = J(q_k, u_k) + (f, z_k) - \sum_{m=1}^{M} \int_{I_m} (\partial_t u_k, z_k)_H \, dt \\ - a(q_k, u_k)(z_k) - \sum_{m=0}^{M-1} ([u_k]_m, z_{k,m}^+)_H - (u_{k,0}^- - u_0(q_k), z_{k,0}^-)_H. \end{aligned}$$

3.2. Space discretization of the states. In this subsection, we first describe the finite element discretization in space. To this end, we consider two- or three-dimensional shape-regular meshes; see, e.g., [6]. A mesh consists of quadrilateral or hexahedral cells K, which constitute a nonoverlapping cover of the computational domain $\Omega \subset \mathbb{R}^n$, $n \in \{2, 3\}$. The corresponding mesh is denoted by $\mathcal{T}_h = \{K\}$, where we define the discretization parameter h as a cellwise constant function by setting $h\big|_K = h_K$ with the diameter h_K of the cell K.

On the mesh $\mathcal{T}_h$ we construct a conform finite element space $V_h \subset V$ in a standard way:

$$V_h^s = \left\{ v \in V \,\middle|\, v\big|_K \in \mathcal{Q}^s(K) \text{ for } K \in \mathcal{T}_h \right\}.$$

Here, $\mathcal{Q}^s(K)$ consists of shape functions obtained via bi- or trilinear transformations of polynomials in $\widehat{\mathcal{Q}^s}(\widehat{K})$ defined on the reference cell $\widehat{K} = (0,1)^n$.

To obtain the fully discretized versions of the time discretized state equations (3.1) and (3.3), we utilize the space-time finite element spaces

$$X_{k,h}^{r,s} = \left\{ v_{kh} \in C([0,T], V_h^s) \,\middle|\, v_{kh}\big|_{I_m} \in \mathcal{P}^r(I_m, V_h^s) \right\} \subset X_k^r$$

and

$$\widetilde{X}_{k,h}^{r,s} = \left\{ v_{kh} \in L^2((0.T), V_h^s) \,\middle|\, v_{kh}\big|_{I_m} \in \mathcal{P}^r(I_m, V_h^s) \text{ and } v_{kh}(0) \in V_h^s \right\} \subset \widetilde{X}_k^r.$$

Remark 3.2. By the above definition of the discrete spaces $X_{k,h}^{r,s}$ and $\widetilde{X}_{k,h}^{r,s}$, we have assumed that the spatial discretization is fixed for all time intervals. However, in many application problems the use of different meshes $\mathcal{T}_h^m$ for each of the subintervals I_m will lead to more efficient adaptive discretizations. The consideration of such dynamically changing meshes can be included in the formulation of the dG(r) schemes in a natural way. The corresponding formulation of the cG(r) method is more involved due to the continuity requirement in the trial space. The treatment of dynamic meshes for the forward simulation of parabolic problems within an adaptive algorithm is discussed in [26]. It will be analyzed in a forthcoming paper in the context of parabolic optimization problems.

Then, the so-called cG(s)cG(r) discretization of the state equation (2.4) can be stated as follows: Find for given control $q_{kh} \in Q$ a state $u_{kh} \in X_{k,h}^{r,s}$ such that

$$(3.5)\quad (\partial_t u_{kh}, \varphi) + a(q_{kh}, u_{kh})(\varphi) + (u_{kh}(0), \varphi(0))_H = (f, \varphi) + (u_0(q_{kh}), \varphi(0))_H \quad \forall \varphi \in \widetilde{X}_{k,h}^{r-1,s}.$$

The cG(s)dG(r) discretization has the following form: Find for given control $q_{kh} \in Q$ a state $u_{kh} \in \widetilde{X}_{k,h}^{r,s}$ such that

$$(3.6)\quad \sum_{m=1}^{M} \int_{I_m} (\partial_t u_{kh}, \varphi)_H \, dt + a(q_{kh}, u_{kh})(\varphi) + \sum_{m=0}^{M-1} ([u_{kh}]_m, \varphi_m^+)_H + (u_{kh,0}^-, \varphi_0^-)_H = (f, \varphi) + (u_0(q_{kh}), \varphi_0^-)_H \quad \forall \varphi \in \widetilde{X}_{k,h}^{r,s}.$$

These fully discretized state equations are assumed to posses unique solutions for each $q_{kh} \in Q$; see Remark 3.1.

Thus, the optimization problems with fully discretized states are given by

(3.7)
Minimize $J(q_{kh}, u_{kh})$ subject to the state equation (3.5), $(q_{kh}, u_{kh}) \in Q \times X_{k,h}^{r,s}$,

for the cG(s)cG(r) discretization and by

(3.8)
Minimize $J(q_{kh}, u_{kh})$ subject to the state equation (3.6), $(q_{kh}, u_{kh}) \in Q \times \widetilde{X}_{k,h}^{r,s}$,

for the cG(s)dG(r) discretization of the state space.

The definition of the Lagrangians $\mathcal{L}$ and $\widetilde{\mathcal{L}}$ for fully discretized states can be directly transferred from the formulations for semidiscretization in time just by restriction of the state spaces X_k^r and $\widetilde{X}_k^r$ to the subspaces $X_{k,h}^{r,s}$ and $\widetilde{X}_{k,h}^{r,s}$, respectively. With the aid of these Lagrangians, the derivatives of the reduced functionals $j_k(q_k) = J(q_k, S_k(q_k))$ and $j_{kh}(q_{kh}) = J(q_{kh}, S_{kh}(q_{kh}))$ on the different discretization levels can be expressed in the same manner as described on the continuous level in Theorem 2.1. Thus, we obtain exact derivatives of the reduced cost functional on the discrete level; see [2] for details.

Remark 3.3. The dG(r) and cG(r) schemes are known to be time discretization schemes of order $r+1$. The cG(r) schemes lead to a A-stable discretization whereas the dG(r) schemes are even strongly A-stable.

Remark 3.4. Due to the fact that the test space is discontinuous in time for both dG(r) and cG(r) discretization, these methods (although globally formulated) can be interpreted as time-stepping schemes. To illustrate this fact, we present the time-stepping scheme for the low order cG(s)dG(0) method: For the state equation we obtain with the abbreviations $U_0 := u_{kh}(0)$ and $U_m := u_{hk}\big|_{I_m}$ for $m = 1, \dots, M$ the following time-stepping formulation:

- $m = 0$:

$$(U_0, \varphi)_H = (u_0(q), \varphi)_H \quad \forall \varphi \in V_h^s,$$

- $m = 1, \dots, M$:

$$(U_m, \varphi)_H + k_m \bar{a}(q, U_m)(\varphi) = (U_{m-1}, \varphi)_H + \int_{I_m} (f(t), \varphi)_H \, dt \quad \forall \varphi \in V_h^s.$$

This scheme is a variant of the implicit Euler scheme. If the time integrals are approximated by the box rule, then the resulting scheme is equivalent to the implicit Euler method. However, a better approximation of these time integrals leads to a scheme which allows for better error estimates with respect to the required smoothness of the solution and has advantages in the case of long time integration ($T \gg 1$); see, e.g., [12].

The exact computation of the derivatives on the discrete level mentioned above is not disturbed even by the numerical integration. This can be shown by computing the schemes for the auxiliary equations by means of the inner product based on the underlying quadrature rule (e.g., the box rule or the trapezoidal rule).

3.3. Discretization of the controls. As proposed in the beginning of the current section, the discretization of the control space Q is kept rather abstract. It is done by choosing a finite dimensional subspace $Q_d \subset Q$. Then, the formulation of the state equation, the optimization problems, and the Lagrangians defined on the fully discretized state space can be directly transferred to the level with fully discretized control and state spaces by replacing Q by Q_d. The full discrete solutions will be indicated by the subscript σ which collects the discretization indices k, h, and d.

4. Derivation of the a posteriori error estimator. In this section, we will establish a posteriori error estimators for the error arising due to the discretization of the control and state spaces in terms of the cost functional J and an arbitrary quantity of interest I.

For this, we first recall a modification of an abstract result from [3] which we will later use to establish the desired a posteriori error estimators.

PROPOSITION 4.1. *Let Y be a function space and L a three times Gâteaux differentiable functional on Y. We seek a stationary point y_1 of L on a subspace $Y_1 \subset Y$, i.e.,*

$$L'(y_1)(\hat{y}_1) = 0 \quad \forall \hat{y}_1 \in Y_1. \tag{4.1}$$

This equation is approximated by a Galerkin method using a subspace $Y_2 \subset Y$. The approximative problem seeks $y_2 \in Y_2$ satisfying

$$L'(y_2)(\hat{y}_2) = 0 \quad \forall \hat{y}_2 \in Y_2. \tag{4.2}$$

If the continuous solution fulfills additionally

$$L'(y_1)(\hat{y}_2) = 0 \quad \forall \hat{y}_2 \in Y_2, \tag{4.3}$$

then we have for arbitrary $\hat{y}_2 \in Y_2$ the error representation

$$L(y_1) - L(y_2) = \frac{1}{2} L'(y_2)(y_1 - \hat{y}_2) + \mathcal{R}, \tag{4.4}$$

where the remainder term $\mathcal{R}$ is given with $e := y_1 - y_2$ by

$$\mathcal{R} = \frac{1}{2} \int_0^1 L'''(y_2 + se)(e, e, e) \cdot s \cdot (s-1)\, ds.$$

Proof. Even if the assumptions are weakened compared to the variant in [3], the proof presented there can be transferred directly. ∎

Remark 4.1. Usually this proposition is formulated for the case $Y_1 = Y$; then condition (4.3) is automatically fulfilled.

In what follows, we present the derivation of an error estimator for the fully discrete optimization problem in the case of dG time discretization only. The cG time discretization can be treated in a similar way.

4.1. Error estimator for the cost functional. In what follows, we use the abstract result of Proposition 4.1 for derivation of error estimators in terms of the cost functional J:

$$J(q, u) - J(q_\sigma, u_\sigma).$$

Here, $(q, u) \in Q \times X$ denotes the continuous optimal solution of (2.6), and $(q_\sigma, u_\sigma) = (q_{khd}, u_{khd}) \in Q_d \times \widetilde{X}_{k,h}^{r,s}$ is the optimal solution of the full discretized problem.

To separate the influences of the different discretizations on the discretization error we are interested in, we split

$$\begin{aligned} J(q, u) - J(q_\sigma, u_\sigma) = \quad & J(q, u) - J(q_k, u_k) \\ & + J(q_k, u_k) - J(q_{kh}, u_{kh}) \\ & + J(q_{kh}, u_{kh}) - J(q_\sigma, u_\sigma), \end{aligned}$$

where $(q_k, u_k) \in Q \times \widetilde{X}_k^r$ is the solution of the time discretized problem (3.4) and $(q_{kh}, u_{kh}) \in Q \times \widetilde{X}_{k,h}^{r,s}$ is the solution of the time and space discretized problem (3.8) with still undiscretized control space Q.

THEOREM 4.1. *Let (q,u,z), (q_k,u_k,z_k), (q_{kh},u_{kh},z_{kh}), and $(q_\sigma,u_\sigma,z_\sigma)$ be stationary points of $\mathcal{L}$, resp., $\widetilde{\mathcal{L}}$ on the different levels of discretization, i.e.,*

$$\begin{aligned}
\mathcal{L}'(q,u,z)(\hat{q},\hat{u},\hat{z}) = \widetilde{\mathcal{L}}'(q,u,z)(\hat{q},\hat{u},\hat{z}) = 0 \quad & \forall (\hat{q},\hat{u},\hat{z}) \in Q \times X \times X,\\
\widetilde{\mathcal{L}}'(q_k,u_k,z_k)(\hat{q}_k,\hat{u}_k,\hat{z}_k) = 0 \quad & \forall (\hat{q}_k,\hat{u}_k,\hat{z}_k) \in Q \times \widetilde{X}_k^r \times \widetilde{X}_k^r,\\
\widetilde{\mathcal{L}}'(q_{kh},u_{kh},z_{kh})(\hat{q}_{kh},\hat{u}_{kh},\hat{z}_{kh}) = 0 \quad & \forall (\hat{q}_{kh},\hat{u}_{kh},\hat{z}_{kh}) \in Q \times \widetilde{X}_{k,h}^{r,s} \times \widetilde{X}_{k,h}^{r,s},\\
\widetilde{\mathcal{L}}'(q_\sigma,u_\sigma,z_\sigma)(\hat{q}_\sigma,\hat{u}_\sigma,\hat{z}_\sigma) = 0 \quad & \forall (\hat{q}_\sigma,\hat{u}_\sigma,\hat{z}_\sigma) \in Q_d \times \widetilde{X}_{k,h}^{r,s} \times \widetilde{X}_{k,h}^{r,s}.
\end{aligned}$$

Then there holds for the errors with respect to the cost functional due to the time, space, and control discretizations

$$\begin{aligned}
J(q,u) - J(q_k,u_k) &= \frac{1}{2}\widetilde{\mathcal{L}}'(q_k,u_k,z_k)(q-\hat{q}_k, u-\hat{u}_k, z-\hat{z}_k) + \mathcal{R}_k,\\
J(q_k,u_k) - J(q_{kh},u_{kh}) &= \frac{1}{2}\widetilde{\mathcal{L}}'(q_{kh},u_{kh},z_{kh})(q_k-\hat{q}_{kh}, u_k-\hat{u}_{kh}, z_k-\hat{z}_{kh}) + \mathcal{R}_h,\\
J(q_{kh},u_{kh}) - J(q_\sigma,u_\sigma) &= \frac{1}{2}\widetilde{\mathcal{L}}'(q_\sigma,u_\sigma,z_\sigma)(q_{kh}-\hat{q}_\sigma, u_{kh}-\hat{u}_\sigma, z_{kh}-\hat{z}_\sigma) + \mathcal{R}_d.
\end{aligned}$$

Here, $(\hat{q}_k,\hat{u}_k,\hat{z}_k) \in Q \times \widetilde{X}_k^r \times \widetilde{X}_k^r$, $(\hat{q}_{kh},\hat{u}_{kh},\hat{z}_{kh}) \in Q \times \widetilde{X}_{k,h}^{r,s} \times \widetilde{X}_{k,h}^{r,s}$, and $(\hat{q}_\sigma,\hat{u}_\sigma,\hat{z}_\sigma) \in Q_d \times \widetilde{X}_{k,h}^{r,s} \times \widetilde{X}_{k,h}^{r,s}$ can be chosen arbitrarily, and the remainder terms $\mathcal{R}_k$, $\mathcal{R}_h$, and $\mathcal{R}_d$ have the same form as given in Proposition 4.1 *for $L = \widetilde{\mathcal{L}}$.*

Proof. Since all the used solution pairs are optimal solutions of the optimization problem on different discretizations levels, we obtain for arbitrary $z \in X$, $z_k \in \widetilde{X}_k^r$, and $z_{kh}, z_\sigma \in \widetilde{X}_{k,h}^{r,s}$

$$J(q,u) - J(q_k,u_k) = \widetilde{\mathcal{L}}(q,u,z) - \widetilde{\mathcal{L}}(q_k,u_k,z_k), \tag{4.5a}$$

$$J(q_k,u_k) - J(q_{kh},u_{kh}) = \widetilde{\mathcal{L}}(q_k,u_k,z_k) - \widetilde{\mathcal{L}}(q_{kh},u_{kh},z_{kh}), \tag{4.5b}$$

$$J(q_{kh},u_{kh}) - J(q_\sigma,u_\sigma) = \widetilde{\mathcal{L}}(q_{kh},u_{kh},z_{kh}) - \widetilde{\mathcal{L}}(q_\sigma,u_\sigma,z_\sigma), \tag{4.5c}$$

whereas the identity

$$J(q,u) = \mathcal{L}(q,u,z) = \widetilde{\mathcal{L}}(q,u,z)$$

follows from the fact that the $u \in X$ is continuous, and thus the additional jump terms in $\widetilde{\mathcal{L}}$ compared to $\mathcal{L}$ vanish.

To apply the abstract error identity (4.4) on the three right-hand sides in (4.5), we choose the spaces Y_1 and Y_2 of Proposition 4.1 as

$$\begin{aligned}
&\text{for (4.5a)}: && Y_1 = Q \times X \times X, && Y_2 = Q \times \widetilde{X}_k^r \times \widetilde{X}_k^r,\\
&\text{for (4.5b)}: && Y_1 = Q \times \widetilde{X}_k^r \times \widetilde{X}_k^r, && Y_2 = Q \times \widetilde{X}_{k,h}^{r,s} \times \widetilde{X}_{k,h}^{r,s},\\
&\text{for (4.5c)}: && Y_1 = Q \times \widetilde{X}_{k,h}^{r,s} \times \widetilde{X}_{k,h}^{r,s}, && Y_2 = Q_d \times \widetilde{X}_{k,h}^{r,s} \times \widetilde{X}_{k,h}^{r,s}.
\end{aligned}$$

Hence, for the second and third pairing we have $Y_2 \subset Y_1$, since we have $\widetilde{X}_{k,h}^{r,s} \subset \widetilde{X}_k^r$ and $Q_d \subset Q$. Thus we can choose $Y = Y_1$ in these cases. For the choice of the spaces

for (4.5a), we have to take into account the fact that $\widetilde{X}_k^r \not\subset X$. Thus, we choose $Y = Y_1 + Y_2$ and have to ensure condition (4.3):

$$\widetilde{\mathcal{L}}'(q,u,z)(\hat{q},\hat{u},\hat{z}) = 0 \quad \forall (\hat{q},\hat{u},\hat{z}) \in Q \times \widetilde{X}_k^r \times \widetilde{X}_k^r.$$

Since the solutions $u \in X$ and $z \in X$ are continuous in time with respect to H, the additional jump terms in $\widetilde{\mathcal{L}}$ compared to $\mathcal{L}$ vanish, and we may prove equivalently

$$\begin{aligned}
\mathcal{L}_z'(q,u,z)(\hat{z}) &= 0 \quad \forall \hat{z} \in \widetilde{X}_k^r,\\
\mathcal{L}_u'(q,u,z)(\hat{u}) &= 0 \quad \forall \hat{u} \in \widetilde{X}_k^r,\\
\mathcal{L}_q'(q,u,z)(\hat{q}) &= 0 \quad \forall \hat{q} \in Q.
\end{aligned}$$

We demonstrate the details of the construction for the adjoint state equation

$$\mathcal{L}_u'(q,u,z)(\hat{u}) = 0 \quad \forall \hat{u} \in \widetilde{X}_k^r$$

which we can write after integration by parts in time as

$$\begin{aligned}
-\sum_{m=1}^{M} \int_{I_m} (\hat{u}, \partial_t z)_H \, dt + a_u'(q,u)(\hat{u},z)& \\
+ (\hat{u}_M^-, z(T))_H = \int_I J_1'(u)(\hat{u})\, dt + J_2'(u(T))(\hat{u}_M^-) \quad \forall \hat{u} \in \widetilde{X}_k^r.&
\end{aligned}$$

Since the continuous adjoint solution z fulfills

$$(\varphi, z(T))_H = J_2'(u(T))(\varphi) \quad \forall \varphi \in H,$$

the terms containing $\hat{u}_M^- \in V \subset H$ cancel out, and we have to ensure

$$-\sum_{m=1}^{M} \int_{I_m} (\hat{u}, \partial_t z)_H \, dt + a_u'(q,u)(\hat{u},z) = \int_I J_1'(u)(\hat{u})\, dt \quad \forall \hat{u} \in \widetilde{X}_k^r.$$

Since we have that X is dense in $L^2((0,T),V)$ in regards to the $L^2((0,T),V)$ norm and due to $\widetilde{X}_k^r \subset L^2((0,T),V)$, we obtain then directly the stated condition

$$\mathcal{L}_u'(q,u,z)(\hat{u}) = 0 \quad \forall \hat{u} \in \widetilde{X}_k^r.$$

The remaining derivatives of $\mathcal{L}$ can be treated in a similar matter. The assertion of the theorem follows then by application of Proposition 4.1. ∎

By means of the residuals of the three equations building the optimality system (2.10),

$$\begin{aligned}
\tilde{\rho}^u(q,u)(\varphi) &:= \widetilde{\mathcal{L}}_z'(q,u,z)(\varphi),\\
\tilde{\rho}^z(q,u,z)(\varphi) &:= \widetilde{\mathcal{L}}_u'(q,u,z)(\varphi),\\
\tilde{\rho}^q(q,u,z)(\varphi) &:= \widetilde{\mathcal{L}}_q'(q,u,z)(\varphi),
\end{aligned}$$

the statement of Theorem 4.1 can be rewritten as

(4.6a)
$$J(q,u) - J(q_k,u_k) \approx \frac{1}{2}\Big(\tilde{\rho}^u(q_k,u_k)(z-\hat{z}_k) + \tilde{\rho}^z(q_k,u_k,z_k)(u-\hat{u}_k)\Big),$$

(4.6b)
$$J(q_k,u_k) - J(q_{kh},u_{kh}) \approx \frac{1}{2}\Big(\tilde{\rho}^u(q_{kh},u_{kh})(z_k-\hat{z}_{kh}) + \tilde{\rho}^z(q_{kh},u_{kh},z_{kh})(u_k-\hat{u}_{kh})\Big),$$

(4.6c)
$$J(q_{kh},u_{kh}) - J(q_\sigma,u_\sigma) \approx \frac{1}{2}\tilde{\rho}^q(q_\sigma,u_\sigma,z_\sigma)(q_{kh}-\hat{q}_\sigma).$$

Here, we employed the fact that the terms

$$\begin{aligned} &\tilde{\rho}^q(q_k,u_k,z_k)(q-\hat{q}_k), \qquad &&\tilde{\rho}^q(q_{kh},u_{kh},z_{kh})(q_k-\hat{q}_{kh}),\\ &\tilde{\rho}^u(q_\sigma,u_\sigma)(z_{kh}-\hat{z}_\sigma), \qquad &&\tilde{\rho}^z(q_\sigma,u_\sigma,z_\sigma)(u_{kh}-\hat{u}_\sigma) \end{aligned}$$

are zero for the choice

$$\begin{aligned} &\hat{q}_k = q \in Q, \qquad &&\hat{q}_{kh} = q_k \in Q,\\ &\hat{z}_\sigma = z_{kh} \in \widetilde{X}^{r,s}_{k,h}, \qquad &&\hat{u}_\sigma = u_{kh} \in \widetilde{X}^{r,s}_{k,h}. \end{aligned}$$

This is possible since for the errors $J(q,u)-J(q_k,u_k)$ and $J(q_k,u_k)-J(q_{kh},u_{kh})$ only the state space is discretized, and for $J(q_{kh},u_{kh}) - J(q_\sigma,u_\sigma)$ we keep the discrete state space while discretizing the control space Q.

4.2. Error estimator for an arbitrary functional. We now tend toward an error estimation of the different types of discretization errors in terms of a given functional $I\colon Q \times X \to \mathbb{R}$ describing the quantity of interest. This will be done using solutions of some auxiliary problems. In order to ensure the solvability of these problems we assume that the semidiscrete and the full discrete optimal solutions (q_k,u_k), (q_{kh},u_{kh}), and (q_σ,u_σ) are in the neighborhood $W \subset Q \times X$ of the optimal solution (q,u) introduced in section 2.

We define exterior Lagrangians $\mathcal{M}\colon [Q\times X\times X]^2 \to \mathbb{R}$ and $\widetilde{\mathcal{M}}\colon [Q\times \widetilde{X}^r_k\times \widetilde{X}^r_k]^2 \to \mathbb{R}$ as

$$\mathcal{M}(\xi,\chi) = I(q,u) + \mathcal{L}'(\xi)(\chi),$$

with $\xi = (q,u,z), \chi = (p,v,y)$, and

$$\widetilde{\mathcal{M}}(\xi_k,\chi_k) = I(q_k,u_k) + \widetilde{\mathcal{L}}'(\xi_k)(\chi_k),$$

with $\xi_k = (q_k,u_k,z_k), \chi_k = (p_k,v_k,y_k)$.

Now we are in a similar setting to that in the preceding subsection: We split the total discretization error with respect to I as

$$\begin{aligned} I(q,u) - I(q_\sigma,u_\sigma) = \quad & I(q,u) - I(q_k,u_k)\\ &+ I(q_k,u_k) - I(q_{kh},u_{kh})\\ &+ I(q_{kh},u_{kh}) - I(q_\sigma,u_\sigma) \end{aligned}$$

and obtain the following theorem.

THEOREM 4.2. *Let (ξ,χ), (ξ_k,χ_k), (ξ_{kh},χ_{kh}), and (ξ_σ,χ_σ) be stationary points of $\mathcal{M}$, resp., $\widetilde{\mathcal{M}}$ on the different levels of discretization, i.e.,*

$$\begin{aligned}
\mathcal{M}'(\xi,\chi)(\hat\xi,\hat\chi) = \widetilde{\mathcal{M}}'(\xi,\chi)(\hat\xi,\hat\chi) = 0 \quad & \forall(\hat\xi,\hat\chi)\in[Q\times X\times X]^2,\\
\widetilde{\mathcal{M}}'(\xi_k,\chi_k)(\hat\xi_k,\hat\chi_k) = 0 \quad & \forall(\hat\xi_k,\hat\chi_k)\in[Q\times \widetilde{X}_k^r\times \widetilde{X}_k^r]^2,\\
\widetilde{\mathcal{M}}'(\xi_{kh},\chi_{kh})(\hat\xi_{kh},\hat\chi_{kh}) = 0 \quad & \forall(\hat\xi_{kh},\hat\chi_{kh})\in[Q\times \widetilde{X}_{k,h}^{r,s}\times \widetilde{X}_{k,h}^{r,s}]^2,\\
\widetilde{\mathcal{M}}'(\xi_\sigma,\chi_\sigma)(\hat\xi_\sigma,\hat\chi_\sigma) = 0 \quad & \forall(\hat\xi_\sigma,\hat\chi_\sigma)\in[Q_d\times \widetilde{X}_{k,h}^{r,s}\times \widetilde{X}_{k,h}^{r,s}]^2.
\end{aligned}$$

Then there holds for the errors with respect to the quantity of interest due to the time, space, and control discretizations

$$\begin{aligned}
I(q,u)-I(q_k,u_k) &= \frac{1}{2}\widetilde{\mathcal{M}}'(\xi_k,\chi_k)(\xi-\hat\xi_k,\chi-\hat\chi_k)+\mathcal{R}_k,\\
I(q_k,u_k)-I(q_{kh},u_{kh}) &= \frac{1}{2}\widetilde{\mathcal{M}}'(\xi_{kh},\chi_{kh})(\xi_k-\hat\xi_{kh},\chi_k-\hat\chi_{kh})+\mathcal{R}_h,\\
I(q_{kh},u_{kh})-I(q_\sigma,u_\sigma) &= \frac{1}{2}\widetilde{\mathcal{M}}'(\xi_\sigma,\chi_\sigma)(\xi_{kh}-\hat\xi_\sigma,\chi_{kh}-\hat\chi_\sigma)+\mathcal{R}_d.
\end{aligned}$$

Here, $(\hat\xi_k,\hat\chi_k)\in[Q\times\widetilde{X}_k^r\times\widetilde{X}_k^r]^2$, $(\hat\xi_{kh},\hat\chi_{kh})\in[Q\times\widetilde{X}_{k,h}^{r,s}\times\widetilde{X}_{k,h}^{r,s}]^2$, and $(\hat\xi_\sigma,\hat\chi_\sigma)\in[Q_d\times\widetilde{X}_{k,h}^{r,s}\times\widetilde{X}_{k,h}^{r,s}]^2$ can be chosen arbitrarily, and the remainder terms $\mathcal{R}_k$, $\mathcal{R}_h$, and $\mathcal{R}_d$ have the same form as given in Proposition 4.1 for $L=\widetilde{\mathcal{M}}$.

Proof. Due to the optimality of the solution pairings on the different discretization levels, we have the representations

$$I(q,u)-I(q_k,u_k) = \widetilde{\mathcal{M}}(\xi,\chi)-\widetilde{\mathcal{M}}(\xi_k,\chi_k), \tag{4.7a}$$

$$I(q_k,u_k)-I(q_{kh},u_{kh}) = \widetilde{\mathcal{M}}(\xi_k,\chi_k)-\widetilde{\mathcal{M}}(\xi_{kh},\chi_{kh}), \tag{4.7b}$$

$$I(q_{kh},u_{kh})-I(q_\sigma,u_\sigma) = \widetilde{\mathcal{M}}(\xi_{kh},\chi_{kh})-\widetilde{\mathcal{M}}(\xi_\sigma,\chi_\sigma), \tag{4.7c}$$

where the identity

$$I(q,u)=\mathcal{M}(\xi,\chi)=\widetilde{\mathcal{M}}(\xi,\chi)$$

again follows from the fact that the $u\in X$ is continuous and thus the additional jump terms in $\widetilde{\mathcal{M}}$ compared to $\mathcal{M}$ vanish.

Similar to the proof of Theorem 4.1, we choose the spaces Y_1 and Y_2 for application of Proposition 4.1 as

$$\begin{aligned}
&\text{for (4.7a)}: && Y_1=[Q\times X\times X]^2, && Y_2=[Q\times\widetilde{X}_k^r\times\widetilde{X}_k^r]^2,\\
&\text{for (4.7b)}: && Y_1=[Q\times\widetilde{X}_k^r\times\widetilde{X}_k^r]^2, && Y_2=[Q\times\widetilde{X}_{k,h}^{r,s}\times\widetilde{X}_{k,h}^{r,s}]^2,\\
&\text{for (4.7c)}: && Y_1=[Q\times\widetilde{X}_{k,h}^{r,s}\times\widetilde{X}_{k,h}^{r,s}]^2, && Y_2=[Q_d\times\widetilde{X}_{k,h}^{r,s}\times\widetilde{X}_{k,h}^{r,s}]^2,
\end{aligned}$$

and we end up with the stated error representations. ∎

To apply Theorem 4.2 for instance to $I(q_{kh},u_{kh})-I(q_\sigma,u_\sigma)$, we have to require that

$$\widetilde{\mathcal{M}}'(\xi_\sigma,\chi_\sigma)(\hat\xi_\sigma,\hat\chi_\sigma)=0 \quad \forall(\hat\xi_\sigma,\hat\chi_\sigma)\in[\widetilde{X}_{k,h}^{r,s}\times\widetilde{X}_{k,h}^{r,s}\times Q_d]^2.$$

For solving this system, we have to consider the concrete form of $\widetilde{\mathcal{M}}'$:

$$\begin{aligned}
&\widetilde{\mathcal{M}}'(\xi_\sigma,\chi_\sigma)(\delta\xi_\sigma,\delta\chi_\sigma) =\\
&\qquad I_q'(q_\sigma,u_\sigma)(\delta q_\sigma)+I_u'(q_\sigma,u_\sigma)(\delta u_\sigma)+\widetilde{\mathcal{L}}'(\xi_\sigma)(\delta\chi_\sigma)+\widetilde{\mathcal{L}}''(\xi_\sigma)(\chi_\sigma,\delta\xi_\sigma).
\end{aligned}$$

Since $\xi_\sigma = (q_\sigma, u_\sigma, z_\sigma)$ is the solution of the discrete optimization problem, it fulfills already $\widetilde{\mathcal{L}}'(\xi_\sigma)(\delta\chi_\sigma) = 0$. Thus, the solution triple $\chi_\sigma = (p_\sigma, v_\sigma, y_\sigma) \in Q_d \times \widetilde{X}_{k,h}^{r,s} \times \widetilde{X}_{k,h}^{r,s}$ has to fulfill

$$\begin{aligned}(4.8)\quad \widetilde{\mathcal{L}}''(\xi_\sigma)(\chi_\sigma, \delta\xi_\sigma) = \\ - I_q'(q_\sigma, u_\sigma)(\delta q_\sigma) - I_u'(q_\sigma, u_\sigma)(\delta u_\sigma) \quad \forall \delta\xi_\sigma \in Q_d \times \widetilde{X}_{k,h}^{r,s} \times \widetilde{X}_{k,h}^{r,s}.\end{aligned}$$

Solving this system of equations is—apart from a different right-hand side—equivalent to the execution of one step of a (reduced) SQP-type method.

After splitting $y_\sigma = y_\sigma^{(0)} + y_\sigma^{(1)}$, where $y_\sigma^{(0)} \in \widetilde{X}_{k,h}^{r,s}$ is the solution of

$$\widetilde{\mathcal{L}}_{zu}''(\xi_\sigma)(y_\sigma^{(0)}, \varphi) = -I_u'(q_\sigma, u_\sigma)(\varphi) \quad \forall \varphi \in \widetilde{X}_{k,h}^{r,s},$$

we can rewrite system (4.8) in terms of the full discrete reduced Hessian $j_\sigma''(q)$ as

$$j_\sigma''(q_\sigma)(p_\sigma, \delta q_\sigma) = -I_q'(q_\sigma, u_\sigma)(\delta q_\sigma) - \mathcal{L}_{zq}''(\xi_\sigma)(y_\sigma^{(0)}, \delta q_\sigma) \quad \forall \delta q_\sigma \in Q_d,$$

where $j_\sigma''(q_\sigma)(p_\sigma, \delta q_\sigma)$ can be expressed as

$$\widetilde{\mathcal{L}}_{qq}''(\xi_\sigma)(p_\sigma, \delta q_\sigma) + \widetilde{\mathcal{L}}_{uq}''(\xi_\sigma)(v_\sigma, \delta q_\sigma) + \widetilde{\mathcal{L}}_{zq}''(\xi_\sigma)(y_\sigma^{(1)}, \delta q_\sigma).$$

The computation of $j_\sigma''(q_\sigma)(p_\sigma, \cdot)$ requires here the solution of the two auxiliary equations for $v_\sigma \in \widetilde{X}_{k,h}^{r,s}$ and $y_\sigma^{(1)} \in \widetilde{X}_{k,h}^{r,s}$:

$$\begin{aligned}\widetilde{\mathcal{L}}_{uz}''(\xi_\sigma)(v_\sigma, \varphi) &= -\widetilde{\mathcal{L}}_{qz}''(\xi_\sigma)(p_\sigma, \varphi) \quad \forall \varphi \in \widetilde{X}_{k,h}^{r,s}, \\ \widetilde{\mathcal{L}}_{zu}''(\xi_\sigma)(y_\sigma^{(1)}, \varphi) &= -\widetilde{\mathcal{L}}_{qu}''(\xi_\sigma)(p_\sigma, \varphi) - \widetilde{\mathcal{L}}_{uu}''(\xi_\sigma)(v_\sigma, \varphi) \quad \forall \varphi \in \widetilde{X}_{k,h}^{r,s}.\end{aligned}$$

By means of the residuals of the presented equations for p, v, and y, i.e.,

$$\begin{aligned}\tilde{\rho}^v(\xi, p, v)(\varphi) &:= \widetilde{\mathcal{L}}_{uz}''(\xi)(v, \varphi) + \widetilde{\mathcal{L}}_{qz}''(\xi)(p, \varphi), \\ \tilde{\rho}^y(\xi, p, v, y)(\varphi) &:= \widetilde{\mathcal{L}}_{zu}''(\xi)(y, \varphi) + \widetilde{\mathcal{L}}_{qu}''(\xi)(p, \varphi) + \widetilde{\mathcal{L}}_{uu}''(\xi)(v, \varphi) + I_u'(q, u)(\varphi), \\ \tilde{\rho}^p(\xi, p, v, y)(\varphi) &:= \widetilde{\mathcal{L}}_{qq}''(\xi)(p, \varphi) + \widetilde{\mathcal{L}}_{uq}''(\xi)(v, \varphi) + \widetilde{\mathcal{L}}_{zq}''(\xi)(y, \varphi) + I_q'(q, u)(\varphi),\end{aligned}$$

and the already defined residuals $\tilde{\rho}^u$, $\tilde{\rho}^z$, and $\tilde{\rho}^q$, the result of Theorem 4.2 can be expressed as

$$\begin{aligned}I(q, u) - I(q_k, u_k) \approx \frac{1}{2}\Big(&\tilde{\rho}^u(q_k, u_k)(y - \hat{y}_k) + \tilde{\rho}^z(q_k, u_k, z_k)(v - \hat{v}_k) \\ &+ \tilde{\rho}^v(\xi_k, p_k, v_k)(z - \hat{z}_k) + \tilde{\rho}^y(\xi_k, p_k, v_k, y_k)(u - \hat{u}_k)\Big), \\ I(q_k, u_k) - I(q_{kh}, u_{kh}) \approx \frac{1}{2}\Big(&\tilde{\rho}^u(q_{kh}, u_{kh})(y_k - \hat{y}_{kh}) + \tilde{\rho}^z(q_{kh}, u_{kh}, z_{kh})(v_k - \hat{v}_{kh}) \\ &+ \tilde{\rho}^v(\xi_{kh}, p_{kh}, v_{kh})(z_k - \hat{z}_{kh}) \\ &+ \tilde{\rho}^y(\xi_{kh}, p_{kh}, v_{kh}, y_{kh})(u_k - \hat{u}_{kh})\Big), \\ I(q_{kh}, u_{kh}) - I(q_\sigma, u_\sigma) \approx \frac{1}{2}\Big(&\tilde{\rho}^q(q_\sigma, u_\sigma, z_\sigma)(p_{kh} - \hat{p}_\sigma) + \tilde{\rho}^p(\xi_\sigma, p_\sigma, v_\sigma, y_\sigma)(q_{kh} - \hat{q}_\sigma)\Big).\end{aligned}$$

As for the estimator for the error in the cost functional, we employed here the fact that the terms

$$\begin{aligned}
\tilde{\rho}^q(q_k,u_k,z_k)(p-\hat{p}_k), &\qquad \tilde{\rho}^p(\xi_k,p_k,v_k,y_k)(q-\hat{q}_k),\\
\tilde{\rho}^q(q_{kh},u_{kh},z_{kh})(p_k-\hat{p}_{kh}), &\qquad \tilde{\rho}^p(\xi_{kh},p_{kh},v_{kh},y_{kh})(q_k-\hat{q}_{kh}),\\
\tilde{\rho}^u(q_\sigma,u_\sigma)(y_{kh}-\hat{y}_\sigma), &\qquad \tilde{\rho}^z(q_\sigma,u_\sigma,z_\sigma)(v_{kh}-\hat{v}_\sigma),\\
\tilde{\rho}^v(\xi_\sigma,p_\sigma,v_\sigma)(z_{kh}-\hat{z}_\sigma), &\qquad \tilde{\rho}^y(\xi_\sigma,p_\sigma,v_\sigma,y_\sigma)(u_{kh}-\hat{u}_\sigma)
\end{aligned}$$

vanish if $\hat{p}_k$, $\hat{q}_k$, $\hat{p}_{kh}$, $\hat{q}_{kh}$, $\hat{y}_\sigma$, $\hat{v}_\sigma$, $\hat{z}_\sigma$, $\hat{u}_\sigma$ are chosen appropriately.

Remark 4.2. As already mentioned in the introduction of this section, we obtain almost identical results for the time discretization by the cG method to those presented here. The difference simply consists in the tilde on the variables. The arguments of the proofs are exactly the same.

Remark 4.3. For the error estimation with respect to the cost functional no additional equations have to be solved. The error estimation with respect to a given quantity of interest requires the computation of the auxiliary variables p_σ, v_σ, y_σ. The additional numerical effort is similar to the execution of one step of the SQP or Newton's method.

5. Numerical realization.

5.1. Evaluation of the error estimators. In this subsection, we concretize the a posteriori error estimator developed in the previous section for the cG(1)cG(1) and cG(1)dG(0) space-time discretizations on quadrilateral meshes in two space dimensions. That is, we consider the combination of cG(1) or dG(0) time discretization with piecewise bilinear finite elements for the space discretization. As in the previous section, we will present only the concrete expressions for the dG time discretization; the cG discretization can be treated in exactly the same manner.

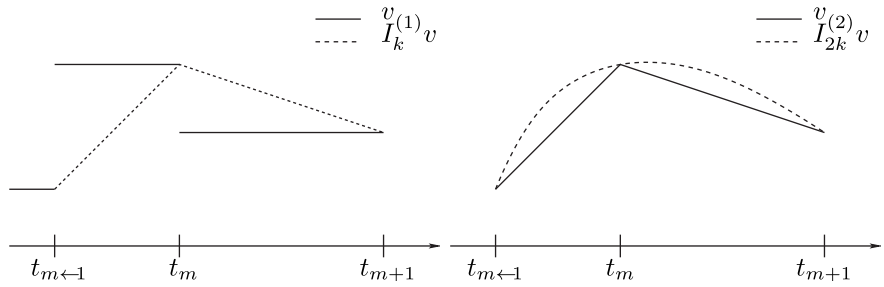
The error estimates presented in the previous section involve interpolation errors of the time, space, and the control discretizations. We approximate these errors using interpolations in higher order finite element spaces. To this end, we introduce linear operators Π_h, Π_k, and Π_d, which will map the computed solutions to the approximations of the interpolation errors:

$$\begin{aligned}
z-\hat{z}_k &\approx \Pi_k z_k, & u-\hat{u}_k &\approx \Pi_k u_k,\\
z_k-\hat{z}_{kh} &\approx \Pi_h z_{kh}, & u_k-\hat{u}_{kh} &\approx \Pi_h u_{kh},\\
q_{kh}-\hat{q}_\sigma &\approx \Pi_d q_\sigma,
\end{aligned}$$

$$\begin{aligned}
y-\hat{y}_k &\approx \Pi_k y_k, & v-\hat{v}_k &\approx \Pi_k v_k,\\
y_k-\hat{y}_{kh} &\approx \Pi_h y_{kh}, & v_k-\hat{v}_{kh} &\approx \Pi_h v_{kh},\\
p_{kh}-\hat{p}_\sigma &\approx \Pi_d p_\sigma.
\end{aligned}$$

For the case of cG(1)cG(1) and cG(1)dG(0) discretizations of the state space considered here, the operators are chosen depending on the test and trial space as

$$\begin{aligned}
\Pi_k &= I_k^{(1)} - \mathrm{id} \quad \text{with} \quad I_k^{(1)}\colon \widetilde{X}_k^0 \to X_k^1,\\
\Pi_k &= I_{2k}^{(2)} - \mathrm{id} \quad \text{with} \quad I_{2k}^{(2)}\colon X_k^1 \to X_{2k}^2,\\
\Pi_h &= I_{2h}^{(2)} - \mathrm{id} \quad \text{with} \quad I_{2h}^{(2)}\colon \begin{cases} X_{k,h}^{1,1} \to X_{k,2h}^{1,2}\\ \widetilde{X}_{k,h}^{0,1} \to \widetilde{X}_{k,2h}^{0,2}. \end{cases}
\end{aligned}$$



(a) *Piecewise linear interpolation of a piecewise constant function.*

(b) *Piecewise quadratic interpolation of a piecewise linear function.*

FIG. 5.1. *Temporal interpolation.*

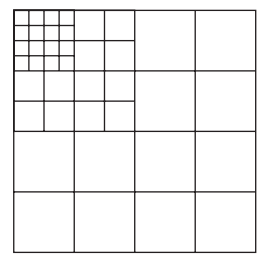


FIG. 5.2. *Patched mesh.*

The action of the piecewise linear and piecewise quadratic interpolation operators $I_k^{(1)}$ and $I_{2k}^{(2)}$ in time is depicted in Figure 5.1. The piecewise biquadratic spatial interpolation $I_{2h}^{(2)}$ can be easily computed if the underlying mesh provides a patch structure. That is, one can always combine four adjacent cells to a macrocell on which the biquadratic interpolation can be defined. An example of such a patched mesh is shown in Figure 5.2.

The choice of Π_d depends on the discretization of the control space Q. If the finite dimensional subspaces Q_d are constructed similar to the discrete state spaces, one can directly choose for Π_d a modification of the operators Π_k and Π_h defined above. If, e.g., the controls q depend only on time and the discretization is done with piecewise constant polynomials, we can choose $\Pi_d = I_d^{(1)} - \mathrm{id}$. If the control space Q is already finite dimensional, which is usually the case in the context of parameter estimation, it is possible to choose $\Pi_d = 0$, and thus, the estimator for the error $J(q_{kh}, u_{kh}) - J(q_\sigma, u_\sigma)$ is zero—as well as this discretization error itself.

In order to make the error representations from the previous section computable, we replace the residuals linearized on the solution of semidiscretized problems by the linearization at full discrete solutions.

We finally obtain the following computable a posteriori error estimator for the cost functional J:

$$J(q,u) - J(q_\sigma, u_\sigma) \approx \eta_k^J + \eta_h^J + \eta_d^J,$$

with

$$\eta_k^J := \frac{1}{2}\Big(\tilde{\rho}^u(q_\sigma,u_\sigma)(\Pi_k z_\sigma) + \tilde{\rho}^z(q_\sigma,u_\sigma,z_\sigma)(\Pi_k u_\sigma)\Big),$$
$$\eta_h^J := \frac{1}{2}\Big(\tilde{\rho}^u(q_\sigma,u_\sigma)(\Pi_h z_\sigma) + \tilde{\rho}^z(q_\sigma,u_\sigma,z_\sigma)(\Pi_h u_\sigma)\Big),$$
$$\eta_d^J := \frac{1}{2}\tilde{\rho}^q(q_\sigma,u_\sigma,z_\sigma)(\Pi_d q_\sigma).$$

For the quantity of interest I the error estimator is given by

$$I(q,u) - I(q_\sigma,u_\sigma) \approx \eta_k^I + \eta_h^I + \eta_d^I,$$

with

$$\begin{aligned}\eta_k^I := \frac{1}{2}\Big(&\tilde{\rho}^u(q_\sigma,u_\sigma)(\Pi_k y_\sigma) + \tilde{\rho}^z(q_\sigma,u_\sigma,z_\sigma)(\Pi_k v_\sigma)\\ &+ \tilde{\rho}^v(\xi_\sigma,v_\sigma,p_\sigma)(\Pi_k z_\sigma) + \tilde{\rho}^y(\xi_\sigma,v_\sigma,y_\sigma,p_\sigma)(\Pi_k u_\sigma)\Big),\\ \eta_h^I := \frac{1}{2}\Big(&\tilde{\rho}^u(q_\sigma,u_\sigma)(\Pi_h y_\sigma) + \tilde{\rho}^z(q_\sigma,u_\sigma,z_\sigma)(\Pi_h v_\sigma)\\ &+ \tilde{\rho}^v(\xi_\sigma,v_\sigma,p_\sigma)(\Pi_h z_\sigma) + \tilde{\rho}^y(\xi_\sigma,v_\sigma,y_\sigma,p_\sigma)(\Pi_h u_\sigma)\Big),\\ \eta_d^I := \frac{1}{2}\Big(&\tilde{\rho}^q(q_\sigma,u_\sigma,z_\sigma)(\Pi_d p_\sigma) + \tilde{\rho}^p(\xi_\sigma,v_\sigma,y_\sigma,p_\sigma)(\Pi_d q_\sigma)\Big).\end{aligned}$$

To give an impression of the terms that have to be evaluated for the error estimators, we present for the implicit Euler variant of the cG(1)dG(0) discretization the explicit form of the state residuals $\tilde{\rho}^u(q_\sigma,u_\sigma)(\Pi_k z_\sigma)$ and $\tilde{\rho}^u(q_\sigma,u_\sigma)(\Pi_h z_\sigma)$ and the adjoint state residuals $\tilde{\rho}^z(q_\sigma,u_\sigma,z_\sigma)(\Pi_k u_\sigma)$ and $\tilde{\rho}^z(q_\sigma,u_\sigma,z_\sigma)(\Pi_h u_\sigma)$. For simplicity of notation, we assume here q to be independent on time. Since we evaluate the arising integrals over time for the residuals weighted with z_σ or u_σ by the right endpoint rule and for the residuals weighted with $I_k^{(1)} z_\sigma$ or $I_k^{(1)} u_\sigma$ by the trapezoidal rule, we have to ensure the right-hand side f to be continuous in time, i.e., $f \in C([0,T],H)$. Then we obtain with the abbreviations $U_0 := u_\sigma(0)$, $U_m := u_\sigma\big|_{I_m}$, $Z_0 := z_\sigma(0)$, and $Z_m = z_\sigma\big|_{I_m}$ the following parts of the error estimators:

$$\begin{aligned}\tilde{\rho}^u(q_\sigma,u_\sigma)(\Pi_k z_\sigma) = \sum_{m=1}^{M}\Big\{&(U_m - U_{m-1}, Z_m - Z_{m-1})_H\\ &+ \frac{k_m}{2}\bar{a}(q_\sigma,U_m)(Z_m - Z_{m-1})\\ &+ \frac{k_m}{2}(f(t_{m-1}),Z_{m-1})_H - \frac{k_m}{2}(f(t_m),Z_m)_H\Big\},\end{aligned}$$

$$\begin{aligned}\tilde{\rho}^z(q_\sigma,u_\sigma,z_\sigma)(\Pi_k u_\sigma) = \sum_{m=1}^{M}\Big\{&\frac{k_m}{2}\bar{a}'_u(q_\sigma,U_m)(U_m,Z_m)\\ &- \frac{k_m}{2}\bar{a}'_u(q_\sigma,U_{m-1})(U_{m-1},Z_m)\\ &+ \frac{k_m}{2}J_1'(U_{m-1})(U_{m-1}) - \frac{k_m}{2}J_1'(U_m)(U_m)\Big\},\end{aligned}$$

$$\begin{aligned}\tilde{\rho}^u(q_\sigma,u_\sigma)(\Pi_h z_\sigma) = \sum_{m=1}^{M} \Big\{ & k_m(f(t_m), I_{2h}^{(2)} Z_m - Z_m)_H \\ & - k_m \bar{a}(q_\sigma, U_m)(I_{2h}^{(2)} Z_m - Z_m) \\ & - (U_m - U_{m-1}, I_{2h}^{(2)} Z_m - Z_m)_H \Big\} \\ & - (U_0 - u_0(q_\sigma), I_{2h}^{(2)} Z_0 - Z_0)_H,\end{aligned}$$

$$\begin{aligned}\tilde{\rho}^z(q_\sigma,u_\sigma,z_\sigma)(\Pi_h u_\sigma) = \sum_{m=1}^{M} \Big\{ & k_m J_1'(U_m)(I_{2h}^{(2)} U_m - U_m) \\ & - k_m \bar{a}_u'(q_\sigma, U_m)(I_{2h}^{(2)} U_m - U_m, Z_m) \\ & + (I_{2h}^{(2)} U_{m-1} - U_{m-1}, Z_m - Z_{m-1})_H \Big\} \\ & + J_2'(U_M)(I_{2h}^{(2)} U_M - U_M) - (I_{2h}^{(2)} U_M - U_M, Z_M)_H.\end{aligned}$$

For the cG(1)cG(1) discretization the terms that have to be evaluated are very similar and the evaluation can be treated as presented here for the cG(1)dG(0) discretization. The presented a posteriori error estimators are directed towards two aims: assessment of the discretization error and improvement of the accuracy by local refinement. For the second aim the information provided by the error estimator has to be localized to cellwise or nodewise contributions (local error indicators). For details of the localization procedure we refer, e.g., to [3].

5.2. Adaptive algorithm. The goal of the adaption of the different types of discretizations has to be the equilibrated reduction of the corresponding discretization errors. If a given tolerance (TOL) has to be reached, this can be done by refining each discretization as long as the value of this part of the error estimator is greater than $\frac{1}{3}$TOL. We want to present here a strategy which will equilibrate the different discretization errors even if no tolerance is given.

The aim of the equilibration algorithm presented in what follows is to obtain discretization such that

$$|\eta_k| \approx |\eta_h| \approx |\eta_d|$$

and to keep this property during the further refinement. Here, the estimators η_i denote the estimators η_i^J for the cost functional J or η_i^I for the quantity of interest I.

For doing this equilibration, we choose an "equilibration factor" $e \approx 1-5$ and propose the following strategy: We compute a permutation (a,b,c) of the discretization indices (k,h,d) such that

$$|\eta_a| \geq |\eta_b| \geq |\eta_c|,$$

and we define the relations

$$\gamma_{ab} := \left|\frac{\eta_a}{\eta_b}\right| \geq 1, \qquad \gamma_{bc} := \left|\frac{\eta_b}{\eta_c}\right| \geq 1.$$

Then we decide by means of Table 5.1 in every repetition of the adaptive refinement algorithm given by Algorithm 5.1 which discretization shall be refined. For every discretization to be adapted we select by means of the local error indicators the cells for refinement. For this purpose there are several strategies available; see, e.g., [3].

TABLE 5.1
Equilibration strategy.

Relation between the estimators	Discretizations to be refined

    break
  else
    Determine the discretization(s) to be refined by means of Table 5.1.
  end if
  Refine $\mathcal{T}_{\sigma_n} \to \mathcal{T}_{\sigma_{n+1}}$ depending on the size of η_{k_n}, η_{h_n}, and η_{d_n} to equilibrate the three discretization errors.
  Increment n.
end loop

6. Numerical examples. This section is devoted to the numerical validation of the theoretical results presented in the previous sections. This will be done by means of an optimal control problem with time-dependent boundary control (see section 6.1) and a parameter estimation problem (see section 6.2).

6.1. Example 1: Neumann boundary control problem. We consider the linear parabolic state equation on the two-dimensional unit square $\Omega := (0,1)^2$ (see Figure 6.1) with final time $T = 1$ given by

$$\begin{aligned} \partial_t u - \nu \Delta u + u &= f && \text{in } \Omega \times (0,T), \\ \partial_n u(x,t) &= 0 && \text{on } \Gamma_0 \times (0,T), \\ \partial_n u(x,t) &= q_i(t) && \text{on } \Gamma_i \times (0,T), i = 1,2, \\ u(x,0) &= 0 && \text{on } \Omega. \end{aligned} \tag{6.1}$$

The control $q = (q_1, q_2)$ acts as a purely time-dependent boundary control of Neumann type on the two parts of the boundary denoted by Γ_1 and Γ_2. Thus, the control space Q is chosen as $[L^2(0,T)]^2$, and the spaces V and H used in the definition of the state space X are set to $V = H^1(\Omega)$ and $H = L^2(\Omega)$.

As the cost functional J to be minimized subject to the state equation, we choose the functional

$$J(q,u) := \frac{1}{2} \int_0^T \int_\Omega (u(x,t) - 1)^2 \, dx \, dt + \frac{\alpha}{2} \int_0^T \{q_1^2(t) + q_2^2(t)\} \, dt$$

of the tracking type endowed with a $L^2(0,T)$-regularization.

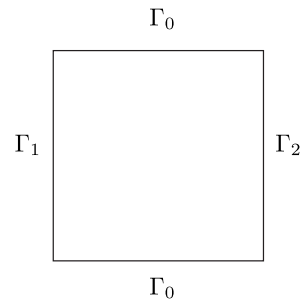

FIG. 6.1. *Example* 1: *Computational domain* Ω.

For the computations, the right-hand side of f is chosen as

$$f(x,t) = 10t \exp\left(1 - \frac{1}{1 - 100\|x - \tilde{x}\|^2}\right), \quad \tilde{x} = \left(\frac{2}{3}, \frac{1}{2}\right),$$

and the parameters α and ν are set to

$$\alpha = 0.1, \quad \nu = 0.1.$$

The discretization of the state space is done here via the cG(1)cG(1) space-time Galerkin method which is a variant of the Crank–Nicolson scheme. Consequently, the state is discretized in time by piecewise linear polynomials and the adjoint state by piecewise constant polynomials. The controls are discretized using piecewise constant polynomials on a partition of the time interval $(0,T)$ which has to be at most as fine as the time discretization of the states.

Remark 6.1. If the discretization of the control is chosen such that the gradient equation

$$\int_{\Gamma_i} z(x,t)\,dx + \alpha q_i(t) = 0, \qquad i = 1,2, \quad t \in (0,T),$$

can be fulfilled pointwise on the discrete level, the residual ρ^q of this equation as well as the error due to discretization of the control space vanish; cf. (4.6c). Thus, it is only reasonable to discretize the controls at most as fine as the adjoint state.

In Table 6.1 we show the development of the discretization error and the a posteriori error estimators during an adaptive run with local refinement of all three types of discretizations. Here, M denotes the number of time steps, N denotes the number of nodes in the spatial mesh, and $\dim Q_d$ is the number of degrees of freedom for the discretization of the control. The effectivity index given in the last column of this table is defined as usual by

$$I_{\text{eff}} := \frac{J(q,u) - J(q_\sigma, u_\sigma)}{\eta_k^J + \eta_h^J + \eta_d^J}.$$

The table also demonstrates the desired equilibration of the different discretization errors and the sufficient quality of the error estimators. Here and in what follows, the "exact" values $J(q,u)$ and $I(q,u)$ are obtained approximatively by extrapolation of the values of these functionals computated on a sequence of fine discretizations.

A comparison of the error $J(q,u) - J(q_\sigma, u_\sigma)$ for the different refinement strategies is depicted in Figure 6.2:

TABLE 6.1

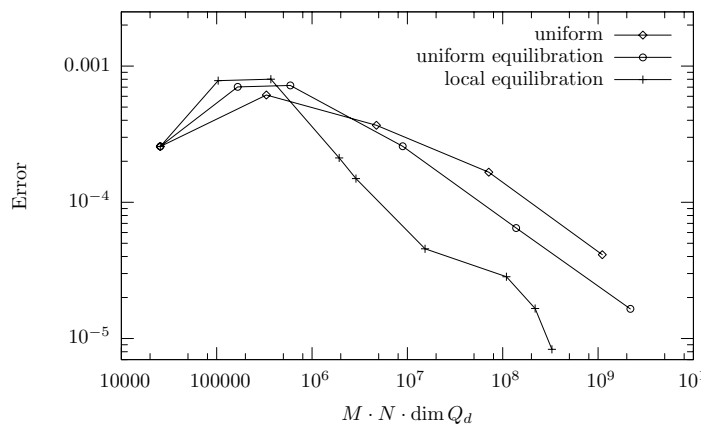

FIG. 6.2. *Example* 1: *Comparison of different refinement strategies.*

- "Uniform": Here, we apply uniform refinement of all discretizations after each run of the optimization loop.
- "Uniform equilibration": Here, we also allow for only uniform refinements but use the error estimators within the equilibration strategy (Table 5.1) to decide which discretizations have to be refined.
- "Local equilibration": Here, we combine local refinement of all discretizations with the proposed equilibration strategy.

It shows, e.g., that to reach a discretization error of $4 \cdot 10^{-5}$ the uniform refinement needs about 70 times the number of degrees of freedom the fully adaptive refinement needs.

In Table 6.2 we present the numerical justification for splitting the total discretization error in three parts regarding the discretization of time, space, and control: The table demonstrates the independence of each part of the error estimator on the refinement of the other parts. This feature is especially important to reach a equilibration of the discretization errors by applying the adaptive refinement algorithm.

6.2. Example 2: Parameter estimation. The state equation for the following example is taken from [17]. It describes the major part of gaseous combustion under the low Mach number hypothesis. Under this assumption, the motion of the fluid becomes independent from temperature and species concentration. Hence, one can solve the temperature and the species equation alone specifying any solenoidal velocity field.

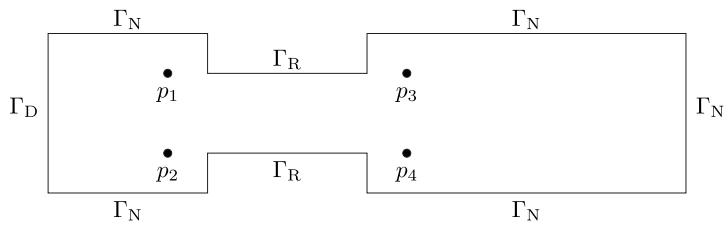

FIG. 6.3. *Example* 2: *Computational domain* Ω *and measurement points* p_i.

Introducing the dimensionless temperature $\theta = \frac{T-T_{\text{unburnt}}}{T_{\text{burnt}}-T_{\text{unburnt}}}$, denoting by Y the species concentration, and assuming constant diffusion coefficients yields

$$\begin{aligned} \partial_t\theta - \Delta\theta &= \omega(Y,\theta) && \text{in } \Omega\times(0,T),\\ \partial_t Y - \frac{1}{\mathrm{Le}}\Delta Y &= -\omega(Y,\theta) && \text{in } \Omega\times(0,T), \end{aligned} \tag{6.2}$$

where the Lewis number Le is the ratio of diffusivity of heat and diffusivity of mass. We use a simple one-species reaction mechanism governed by an Arrhenius law

$$\omega(Y,\theta) = \frac{\beta^2}{2\mathrm{Le}} Y \mathrm{e}^{\frac{\beta(\theta-1)}{1+\alpha(\theta-1)}}$$

in which an approximation for large activation energy has been employed.

Here, we consider a freely propagating laminar flame described by (6.2) and its response to a heat absorbing obstacle, a set of cooled parallel rods with rectangular cross section (cf. Figure 6.3). Thus, the boundary conditions are chosen as

$$\begin{aligned} \theta &= 1 && \text{on } \Gamma_D\times(0,T),\\ Y &= 0 && \text{on } \Gamma_D\times(0,T),\\ \partial_n\theta &= 0 && \text{on } \Gamma_N\times(0,T),\\ \partial_n Y &= 0 && \text{on } \Gamma_N\times(0,T),\\ \partial_n\theta &= -k\theta && \text{on } \Gamma_R\times(0,T),\\ \partial_n Y &= 0 && \text{on } \Gamma_R\times(0,T), \end{aligned}$$

where the heat absorption is modeled by Robin boundary conditions on Γ_R.

The initial condition is the analytical solution of a one-dimensional right-traveling flame in the limit $\beta \to \infty$ located left of the obstacle:

$$\theta(0,x) = \begin{cases} 1 & \text{for } x_1 \le \tilde{x}_1 \\ \mathrm{e}^{\tilde{x}_1 - x_1} & \text{for } x_1 > \tilde{x}_1 \end{cases} \qquad \text{on } \Omega,$$

$$Y(0,x) = \begin{cases} 0 & \text{for } x_1 \le \tilde{x}_1 \\ 1 - \mathrm{e}^{\mathrm{Le}(\tilde{x}_1 - x_1)} & \text{for } x_1 > \tilde{x}_1 \end{cases} \qquad \text{on } \Omega.$$

For the computations, the occurring parameters are set to

$$\mathrm{Le} = 1, \qquad \beta = 10, \qquad k = 0.1, \qquad \tilde{x}_1 = 9,$$

whereas the parameter α occurring in the Arrhenius law will be the objective of the parameter estimation.

To use the same notations as in the theoretical parts of this article, we define the pair of solution components $u := (\theta, Y) \in \hat{u} + X^2$ and denote the parameter α to be estimated by $q \in Q := \mathbb{R}$. For definition of the state space X we use the spaces V and H as given by (2.1). The function $\hat{u}$ is defined to fulfill the prescribed Dirichlet data as $\hat{u}\big|_{\Gamma_{\mathrm{D}}} = (1, 0)$.

The unknown parameter α is estimated here using information from pointwise measurements of θ and Y at four measurement points $p_i \in \Omega$ $(i = 1, \ldots, 4)$ at final time $T = 60$. This parameter identification problem can be formulated as a cost functional of least squares type:

$$J(q,u) = \frac{1}{2} \sum_{i=1}^{4} \Big\{ (\theta(p_i, T) - \tilde{\theta}_i)^2 + (Y(p_i, T) - \tilde{Y}_i)^2 \Big\}.$$

The values of artificial measurements $\tilde{\theta}_i$ and $\tilde{Y}_i$ $(i = 1, \ldots, 4)$ are obtained from a reference solution computed on fine discretizations.

The consideration of point measurements does not fulfill the assumption on the cost functional in (2.5), since the point evaluation is not bounded as a functional on $H = L^2(\Omega)$. Therefore, the point functionals here may be understood as regularized functionals defined on $L^2(\Omega)$. For an a priori error estimate of elliptic parameter identification problems with pointwise measurements, we refer to [25].

For this type of parameter estimation problem one is usually not interested in reducing the discretization error measured in terms of the cost functional. The focus is rather on reducing the error in the parameter q to be estimated. Hence, we use the quantity of interest I given by

$$I(q,u) = q$$

and apply the techniques presented in section 4.2 for estimating the discretization error with respect to I. Since the control space Q in this application is given as $Q = \mathbb{R}$, it is not necessary to discretize Q. Thus, there is no discretization error due to the Q-discretization and the a posteriori error estimator consists only of η_k^I and η_h^I.

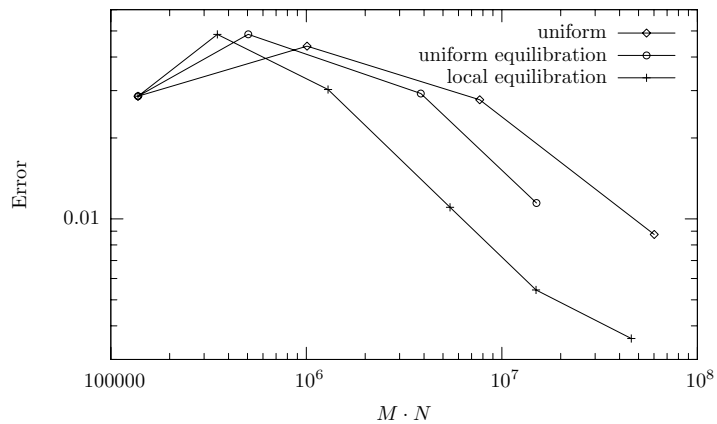

FIG. 6.4. *Example* 2: *Comparison of different refinement strategies.*

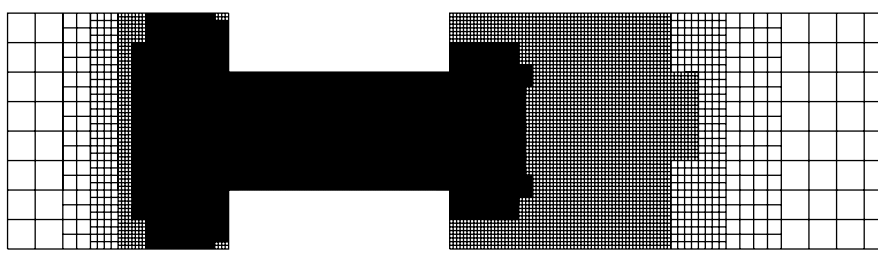

FIG. 6.5. *Example* 2: *Local refined mesh.*

The results of a computation with equilibrated adaption of the space and time discretization using cG(1)dG(0) are shown in Table 6.3. The discretization parameters M and N as well as the effectivity index I_{eff} are defined as in section 6.1.

Similar to section 6.1, we compare in Figure 6.4 the fully adaptive refinement with equilibration and uniform refinements with and without equilibration. By local refinement of all involved discretizations we reduce the necessary degrees of freedom to reach a total error of 10^{-2} by a factor of 11 compared to a uniform refinement without equilibration.

Finally, we present in the Figures 6.5 and 6.6 a typical locally refined spatial mesh and a distribution of the time step size obtained by the space-time-adaptive refinement.

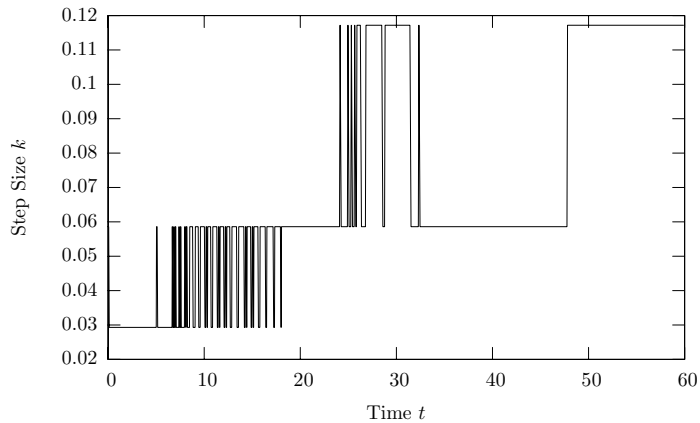

FIG. 6.6. *Example* 2: *Visualization of the adaptively determined time step size* k.

EXTENDED KRONECKER SUMMATION FOR CLUSTER TREATMENT OF LTI SYSTEMS WITH MULTIPLE DELAYS*

ALI FUAT ERGENC†, NEJAT OLGAC†, AND HASSAN FAZELINIA†

Abstract. A new procedure is presented for determining the kernel and the offspring hypersurfaces for general linear time invariant (LTI) dynamics with multiple delays. These hypersurfaces, as they have very recently been introduced in a concept paper [R. Sipahi and N. Olgac, *Automatica*, 41 (2005), pp. 1413–1422], form the basis of the overriding paradigm which is called the cluster treatment of characteristic roots (CTCR). In fact, these two sets of hypersurfaces exhaustively represent the locations in the domain of the delays where the system possesses at least one pair of imaginary characteristic roots. To determine the kernel and offspring we use the extraordinary features of the "extended Kronecker summation" operation in this paper. The end result is that the infinite-dimensional problem reduces to a finite-dimensional one (and preferably into an eigenvalue problem). Following the procedure described in this paper, we are able to shorten the computational time considerably in determining these hypersurfaces. We demonstrate these concepts via some example case studies. One of the examples treats a 3-delay system. For this case another interesting perspective, called the "building block," is also utilized to display the kernel in three-dimensional space in the domain of "spectral delays."

Key words. linear time-delayed systems, Kronecker sum, multiple delays, stability, robust stability

1. Introduction and the problem statement.

We consider linear time invariant, retarded multiple time-delayed systems (LTI-MTDS), the general form of which is given as

$$\dot{\mathbf{x}}(t) = \mathbf{A}\mathbf{x}(t) + \sum_{j=1}^{p} \mathbf{B}_j \mathbf{x}(t-\tau_j), \tag{1}$$

where $\mathbf{x} \in \mathbb{R}^n$, $\mathbf{A}$, $\mathbf{B}_j$, $j = 1 \dots p$, are all constant matrices in $\mathbb{R}^{n\times n}$ and the vector of time delays $\boldsymbol{\tau} = (\tau_1, \tau_2, \dots, \tau_p) \in \mathbb{R}^{p+}$ of which the elements are rationally independent from each other. As a note of formalism we use boldface capital notation for vector and matrix quantities in the text. We refer to the right (and left) half open complex plane as $\mathbb{C}^+$ ($\mathbb{C}^-$), while $\mathbb{C}^0$ is used to indicate the imaginary axis. Therefore $\mathbb{C}^+ \bigcup \mathbb{C}^- \bigcup \mathbb{C}^0 = \mathbb{C}$ represents the entire complex plane.

The characteristic equation of the system in (1) is

$$\begin{aligned} CE(s, \tau_1, \dots, \tau_p) &= \det\left[s\mathbf{I} - \mathbf{A} - \sum_{j=1}^{p} \mathbf{B}_j e^{-\tau_j s} \right] \\ &= \mathbf{A_0}(s) + \mathbf{A}_{p+1}(s, \tau_1, \dots, \tau_p) + \sum_{j=1}^{p} e^{-n_j \tau_j s} \mathbf{A}_j \left(s, \tau_1, \dots, \tau_{j-1}, \tau_{j+1}, \dots, \tau_p\right), \end{aligned} \tag{2}$$

where $A_0(s)$ is an nth degree polynomial in s and $\mathbf{A}_j$'s ($j = 1 \dots p$) are quasi polynomials in s and all the delays except τ_j. n_j is the highest order of commensuracy of delay τ_j in the dynamics ($n_j \leq n$). $\mathbf{A}_j$ contains s terms with the highest degree of $n-1$ and they are the factors multiplying the representative exponential of the highest commensuracy of τ_j, i.e., $e^{-n_j \tau_j s}$. Since the system is "retarded" the s^n term appears only in $\mathbf{A}_0(s)$ which is free of delays. $\mathbf{A}_{p+1}$ is another quasi polynomial which contains all the remaining terms with lower commensuracy levels (in τ_j) than n_j, $j = 1 \dots p$.

The stability robustness of this general class of systems has been studied for over four decades, resulting in some respectable volumes of literature [11, 13, 7, 15, 18]. One of the mainstream research foci has been the stability assessment of these systems for a given delay vector, $\boldsymbol{\tau}$. The determination of the robustness of such systems against uncertainties in delay and other parameters (i.e., uncertain $\boldsymbol{\tau}$, $\mathbf{A}$, and $\mathbf{B}_j$) are also widely investigated [5, 10, 17, 16, 20, 21]. The class, with delay uncertainty only, is declared to be an *N-P* hard (nondeterministic-polynomial time hard) problem [27]. Many further investigations appeared later on some simplified forms of the problem given here [25, 12, 4]. A very recent paradigm which is introduced by the authors, cluster treatment of characteristic roots (CTCR), brought a practical and numerically efficient procedure for the problem when there are only two delays ($p = 2$) [23, 24, 22]. In fact, this procedure produces a unique stability robustness tableau in the domain of uncertain delays, $\boldsymbol{\tau} \in \mathbb{R}^{p+}$. The numerical efficiency is comfortably demonstrated for cases $n = 3$, $p = 2$ [23], still respecting the difficulties attributed to the *N-P* hardness of the problem. That is, the CTCR method solves the stability robustness problem completely in the delay space, however, with nondeterministic polynomial time hard numerical complexity still remaining. The most critical step in CTCR is the *exhaustive* determination of the stability switching trajectories in the delay space. The primary contributions of the present paper are on this issue.

The key novelties introduced by the CTCR paradigm are the concept of "*kernel* and *offspring* hypersurfaces" and their intriguing characteristics, which were unrecognized earlier. Leaving the details to later segments of the paper, we simply describe the *kernel* hypersurface as the creating loci of *all* the points in $\boldsymbol{\tau} \in \mathbb{R}^{p+}$ space, which render at least one pair of imaginary characteristic roots ($\pm\omega i$) of (2) (or a root at the origin, $s = 0$). Let us denote a generic point on the *kernel* with τ_{ker}. This *kernel* point has an important descriptor: there is no $\boldsymbol{\tau} \in \mathbb{R}^{p+}$, which generates the same imaginary root $\pm\omega i$ and is closer to the origin than $\boldsymbol{\tau}_{\text{ker}}$. This is equivalent to stating that the set $\{\boldsymbol{\tau} | CE(\boldsymbol{\tau}, \omega i) = 0, CE(\boldsymbol{\tau}_{\text{ker}}, \omega i) = 0, |\boldsymbol{\tau}| < |\boldsymbol{\tau}_{\text{ker}}|\}$ is an empty set. When the inequality condition is reversed, we find the *offspring* hypersurfaces of the system on which τ's generate the same imaginary root, $\pm\omega i$. That is, the points on the offspring satisfy the following property: $\{\boldsymbol{\tau} | CE(\boldsymbol{\tau}, \omega i) = 0, CE(\boldsymbol{\tau}_{\text{ker}}, \omega i) = 0, |\boldsymbol{\tau}| > |\boldsymbol{\tau}_{\text{ker}}|\}$. We will give a summary of the outstanding features of the *kernel* and the *offspring* hypersurfaces later in the text for the completeness of the presentation.

A critical and comforting observation under the CTCR paradigm is the claim that (2) can possess imaginary characteristic roots only at some manageably small number of *kernel* hypersurface segments in the domain of the delays. And this number is shown to be upper bounded by n^2. Indeed this finite number of hypersurface segments constitutes the "*kernel* hypersurface set" as explained in section 2.

The text is structured as follows: Section 2 reviews the concept of "*kernel*" and "*offspring*" hypersurfaces under the umbrella of the CTCR paradigm. Section 3 states the two fundamental propositions as the foundation of the new paradigm and presents

the steps of the CTCR procedure for the stability robustness assessment of LTI-MDTS. In the same section, we take advantage of an intriguing procedure called the "Kronecker sum" of matrices. We show that it provides considerable computational advantage over the alternative procedure called the "Rekasius substitution," which was utilized in earlier pursuit of CTCR. This point constitutes the main contribution of the paper. We also present a different perspective on the problem, using the domain of "spectral delays" as a companion computational effort. It is referred to as "building block" representation. Section 4 contains example case studies including one with three delays, $p = 3$.

2. Review of CTCR paradigm. We present an overview of the CTCR paradigm borrowing from [23, 24, 22]. The underlying philosophy can be expressed via the following interlinked observations: (i) The system (1) is infinite-dimensional. That is, it has infinitely many characteristic roots in the finite complex plane, $\mathbb{C}$. (ii) Its stability is guaranteed if there exist no characteristic roots in the open right half plane, $\mathbb{C}^+$. (iii) It is impossible to track all of the infinitely many roots. (iv) One has to focus *only* on the occurrence of the imaginary root crossings at $\pm\omega i$, which can be encountered only at some special settings of $\boldsymbol{\tau} \in \mathbb{R}^{p+}$ [11, 13, 18]. (v) These points show continuous variations resulting in continuously varying imaginary roots. Those surfaces are the only locations where the stability switching can take place: let us call them the "switching hypersurfaces." (vi) One must determine, then, *exhaustively* all such hypersurfaces in $\boldsymbol{\tau} \in \mathbb{R}^{p+}$ space. (vii) However, there is still a countably infinite number of these hypersurfaces [11, 13]. (viii) One has to introduce a feature-based discipline, what we call "the clustering" operation, to those crossings in order to bring the analysis to a manageable size. Clearly, this route can be taken only if there is such a discipline in the root formation.

CTCR achieves precisely this objective, determining the two extraordinary "clustering features" of LTI-MDTS as described in detail later. The deployment of these features on the single delay and two-delay cases has already been reported in earlier investigations [23, 24, 19]. This document presents the first generalized treatment for systems with nth order-p delay treatment and offers an example with three delays.

We state a series of relevant postulates and propositions first. As discussed above, the imaginary characteristic roots, $\pm\omega i$, play a critical role. Let us define a set, which exhaustively contains *all* such frequencies ω for the entire parameter space $\boldsymbol{\tau} \in \mathbb{R}^{p+}$:

$$\Omega = \left\{\omega \,|CE\left(s = \omega i, \boldsymbol{\tau}\right) = 0, \boldsymbol{\tau} \in \mathbb{R}^{p+}, \omega \in \mathbb{R}\right\}. \tag{3}$$

It is intuitively obvious that, except degeneracies (such as a standing root at $s = 0$), Ω contains a continuum of ω values, not discrete [11, 13, 18]. That is, if there is a $\langle \boldsymbol{\tau}, \omega \rangle$ correspondence, $\boldsymbol{\tau} + \boldsymbol{\varepsilon}$ should result in another imaginary root, $\langle \boldsymbol{\tau} + \boldsymbol{\varepsilon}, \omega + \varepsilon_\omega \rangle$. Clearly, $\langle \bullet, \bullet \rangle$ notation implies a causal relation that the p members of the first argument result in the second argument as the imaginary root. The in-depth analysis of existence/uniqueness of $\boldsymbol{\varepsilon}$ and ε_ω correspondence is beyond the scope of this presentation, and therefore it is suppressed.

POSTULATE 1. *The stability posture of the system in* (1) *is determined by the number of open right half plane characteristic roots of* (2)*, which we call NU (abbreviated from* ***N****umber of* ***U****nstable roots). This number is naturally a function of the delays, which are the only parameters in* (1)*, i.e., NU* $(\tau_1, \ldots, \tau_p)$*. Wherever NU* $= 0$*, the system is labeled as "stable." For any change in NU one has to pass through a point on the switching hypersurfaces,* $\boldsymbol{\tau} = (\tau_1, \ldots, \tau_p)$*, for which a characteristic root* $\pm\omega i$ *exists. This is a direct result of the "root continuity" argument in the parametric*

space $\boldsymbol{\tau} \in \mathbb{R}^{p+}$ [11, 13]. *Obviously* $\Delta NU = \pm 2$ *if* $\omega \neq 0$, *and* $\Delta NU = \pm 1$ *if* $\omega = 0$ *is a simple root crossing. As a critical side note, if* $s = 0$ *is a simple root, it is a stationary one independent of* $\boldsymbol{\tau}$. *Therefore when there is a crossing at* $s = 0$, *it has to appear in the form of a multiple root. That is, at least* $CE(\boldsymbol{\tau}, s)|_{s=0} = 0$ *and* $\frac{d}{ds} CE(\boldsymbol{\tau}, s)|_{s=0} = 0$ *must be satisfied jointly for the same delay set* $\boldsymbol{\tau}$. *As stated above we represent such occurrences of* $\boldsymbol{\tau}$ *yielding* $\pm\omega i$ *as a characteristic root, with the notation* $\langle \boldsymbol{\tau}, \omega \rangle$.

As per El'sgol'ts's D-subdivison principle [8] one can state that a region in $\boldsymbol{\tau} \in \mathbb{R}^{p+}$ space where NU is constant has to be enclosed by hypersurfaces which belong to either one of the following two general classes:

H_1: a hypersurface on which $\langle \boldsymbol{\tau}, \omega \rangle$ occurrence is encountered.

H_2: a hypersurface defined by one or more of the delays being zero, where $\langle \boldsymbol{\tau}, \omega \rangle$ correspondence does not necessarily occur.

We iterate some more on these classes next.

POSTULATE 2. *The* H_2 *class of hypersurfaces is clearly arising from the hard bounds of* $\tau_j \geq 0$, $j = 1 \ldots p$, *posed by the problem statement, and these hypersurfaces are uniquely defined. The* H_1 *class, however, represents a countably infinite number of hypersurfaces possessing the feature*

$$\left\langle \tau_1 \pm \frac{2\pi}{\omega} j_1, \tau_2 \pm \frac{2\pi}{\omega} j_2, \ldots, \tau_p \pm \frac{2\pi}{\omega} j_p, \omega \right\rangle, \quad j_k = 0, 1, \ldots \quad k = 1, \ldots, p. \tag{4}$$

This equation indicates that if $s = \omega i$ occurred at a point $(\tau_1, \ldots, \tau_p)$, infinitely many equidistance grid points in $\boldsymbol{\tau} \in \mathbb{R}^{p+}$ (with the grid size $\frac{2\pi}{\omega}$) would also result in the same characteristic root. Small perturbations on $(\tau_1, \ldots, \tau_p)$ would yield small perturbations on the resultant imaginary root as per the root continuity argument [8]. They sprout in a set of countably infinite number of hypersurfaces which are pointwise equidistant as per (4).

As such the boundaries of the closed regions mentioned above would duplicate themselves as infinitely many hypersurfaces. In order to successfully complete the stability robustness analysis one has to determine *all* of the hypersurfaces where $\langle \boldsymbol{\tau}, \omega \rangle$ correspondence occurs and *all* of these closed regions. This is an impossible task to undertake, unless a well-structured approach is followed. This line of rationale is precisely what prompts the CTCR paradigm.

DEFINITION 1 (kernel hypersurfaces). *Those hypersurfaces which consist of all the points in* $\boldsymbol{\tau} \in \mathbb{R}^{p+}$ *as per* (4) *complying with* $\langle \boldsymbol{\tau}, \omega \rangle$ *correspondence except with the constraint that*

$$0 \leq \tau_k < \frac{2\pi}{\omega} \quad \forall k = 1, \ldots, p \tag{5}$$

are called the kernel hypersurfaces. *This constraint implies that the points on the* kernel hypersurface *exhibit the smallest positive member for each one of its p elements. Notice that there are* ∞^p *(p-dimensional infinite) candidate points in* $\boldsymbol{\tau} = \mathbb{R}^{p+}$ *defined by* (4) *resulting in the same imaginary root,* ωi. *All of these points are represented by a single point on the* kernel hypersurface. *And similar unique points on the* kernel hypersurface *(call it the "*kernel *points") exist for all possible* $\omega \in \Omega$. *Consequently, this hypersurface formation is unique for a given system* (1). *The following notation encapsulates the complete definition of the* kernel hypersurfaces*:*

$$\wp_{\text{ker}} = \textit{kernel hypersurfaces} = \left\{ \boldsymbol{\tau} | \langle \boldsymbol{\tau}, \omega \rangle, \boldsymbol{\tau} \in \mathbb{R}^{p+}, \omega \in \Omega, 0 \leq \tau_k < \frac{2\pi}{\omega} \ \forall k = 1, 2, \ldots, p \right\}. \tag{6}$$

DEFINITION 2 (offspring hypersurfaces). *Those* ∞^p *hypersurfaces which are obtained from the* kernel hypersurface *by a pointwise nonlinear transformation given in* (4) *are called the* offspring. *This definition simply utilizes the fact that a point on the* kernel *will result in* ∞^p *(p-dimensional infinity)* offspring. *The complete formalism for* offspring hypersurfaces *can be given as*

$$\wp_{\text{off}} = \textit{offspring hypersurfaces} = \left\{ \boldsymbol{\tau} | \, \langle \boldsymbol{\tau}, \omega \rangle, \boldsymbol{\tau} \in \mathbb{R}^{p+}, \omega \in \Omega \right\} \setminus \textit{kernel}. \tag{7}$$

3. Determination of the kernel and the offspring hypersurfaces. As per the earlier discussions for the stability robustness of the system we need to determine *all* the kernel and offspring hypersurfaces exhaustively. That amounts to determining the complete set of $\langle \boldsymbol{\tau}, \omega \rangle$ correspondence for the entire $\boldsymbol{\tau} = \mathbb{R}^{p+}$ domain. This mission is computationally very demanding. In our earlier research we utilized a holographic mapping procedure called the Rekasius substitution for this purpose [23]. An alternate procedure is studied here: the extended Kronecker sum method. It is based on the properties of the Kronecker summation of matrices as described for single delay systems in [6, 26]. The treatment prescribed here is an extended version of the process to multiple rationally independent delay cases, and therefore the name "extended Kronecker sum method." We first describe the Kronecker summation operation for clarity and state the main theorem of the paper. A Lyapunov function-based study, which is conducted by another researcher, independently from the authors, has recently been presented at an international conference [14]. It results in the similar outcome of the Kronecker summation method here. Separately, we also recognize that, from the numerical perspective, this process identically coincides with a new concept called the *building block*, which offers a very interesting yet simple representation of the kernel and offspring hypersurfaces [22, 9].

Kronecker summation of two matrices and its properties. In matrix algebra [2, 3] the Kronecker sum of two square matrices $\mathbf{M}_1$ $(n_1 \times n_1)$ and $\mathbf{M}_2$ $(n_2 \times n_2)$ is defined as

$$\mathbf{M}_1 \oplus \mathbf{M}_2 = \mathbf{M}_1 \otimes \mathbf{I}_{n_2} + \mathbf{I}_{n_1} \otimes \mathbf{M}_2, \quad \text{where } \mathbf{M}_1 \in \mathbb{R}^{n_1 \times n_1}, \mathbf{M}_2 \in \mathbb{R}^{n_2 \times n_2}.$$

Here $\oplus$ denotes the *Kronecker summation* and $\otimes$ the *Kronecker product* operations. The most critical feature of the Kronecker summation of $\mathbf{M}_1$ and $\mathbf{M}_2$ is that this new square matrix

$$\mathbf{M}_1 \oplus \mathbf{M}_2 \in \mathbb{R}^{(n_1 \cdot n_2) \times (n_1 \cdot n_2)}$$

has $n_1 \cdot n_2$ eigenvalues which are indeed pairwise combinatoric summations of the n_1 eigenvalues of $\mathbf{M}_1$ and n_2 eigenvalues of $\mathbf{M}_2$. That is, the Kronecker sum operation, in fact, induces the "eigenvalue addition" character to the matrices. We take advantage of this feature as discussed next in a definition and the highlight theorem.

DEFINITION 3. *We define the auxiliary characteristic equation (ACE) of the system in* (1)*, with* $z_j = e^{-\tau_j s}$*:*

$$ACE(\mathbf{z}) = \det \left[\mathbf{A} \otimes \mathbf{I} + \mathbf{I} \otimes \mathbf{A} + \sum_{j=1}^{p} (\mathbf{B}_j \otimes \mathbf{I} z_j + \mathbf{I} \otimes \mathbf{B}_j z_j^{-1}) \right] = 0. \tag{8}$$

THEOREM 1. *For the system given in* (1) *the following findings are equivalent:*

(a) *A vector of p-dimensional unitary complex numbers* $\mathbf{z} = \{z_j\} \in \mathbb{C}_u^p$, $|z_j| = 1$ *for all* $j = 1 \dots p$ *satisfies ACE.* $\mathbb{C}_u^p$ *is the complete set of such complex numbers.*

(b) *There exists at least one pair of imaginary characteristic roots,* $\pm\omega i$, *of* (2).

(c) *There exists a corresponding delay vector* $\boldsymbol{\tau} = \{\tau_j\} \in \wp_{\text{ker}} \bigcup \wp_{\text{off}}$, *where* $\langle \boldsymbol{\tau}, \omega \rangle$ *holds.*

Proof of Theorem 1. The Laplace transformation of the LTI-MTDS equation (1) is

$$sX(s) = \mathbf{A}X(s) + \sum_{j=1}^{p} \mathbf{B}_j X(s) z_j, \tag{9}$$

where the $z_j = e^{-\tau_j s}$, $j = 1 \dots p$, represents p unitary complex numbers for $s = \omega i$. The following equation is directly obtained from (9):

$$(s\mathbf{I} - \Delta(\mathbf{z}(s)))X(s) = 0, \tag{10}$$

$$\Delta(\mathbf{z}(s)) = \mathbf{A} + \sum_{j=1}^{p} \mathbf{B}_j z_j \in \mathbb{R}^{n \times n}, \quad \text{where } \mathbf{z} = \{z_j\} \in \mathbb{C}_u^p.$$

In order to find nontrivial solution of $X(s)$ the matrix $(s\mathbf{I} - \Delta(\mathbf{z}(s)))$ should be singular, in other words, $\det \Delta(\mathbf{z}(s)) = 0$, or

$$\det \left[s\mathbf{I} - \mathbf{A} - \sum_{j=1}^{p} \mathbf{B}_j z_j \right] = 0. \tag{11}$$

Due to the fact that $\mathbf{A}$, $\mathbf{B}_j$, $j = 1 \dots p$, are all constant matrices in $\mathbb{R}^{n \times n}$, the complex conjugates of s and (indirectly) of z_j also satisfy (11):

$$\det \left[s^*\mathbf{I} - \mathbf{A} - \sum_{j=1}^{p} \mathbf{B}_j z_j^* \right] = 0. \tag{12}$$

For a point on the $\wp_{\text{ker}} \bigcup \wp_{\text{off}}$ hypersurface set $\boldsymbol{\tau} = (\tau_1, \dots, \tau_p) \in \wp_{\text{ker}} \bigcup \wp_{\text{off}}$, $s = \omega i$ is an element of the spectrum. Therefore $s^* = -\omega i$, $z_j = \left\{e^{-\tau_j \omega i}\right\}$ and $z_j^* = \left\{e^{\tau_j \omega i}\right\} = z_j^{-1}$, $j = 1 \dots p$. Since the sum of the two certain eigenvalues of $\Delta(s, \mathbf{z})$ and $\Delta(s^*, \mathbf{z}^*)$ is zero, then the Kronecker sum of these two matrices must be singular when such $\langle \boldsymbol{\tau}, \omega \rangle$ correspondence occurs. That is,

$$\det \left[\left(\mathbf{A} + \sum_{j=1}^{p} \mathbf{B}_j z_j \right) \oplus \left(\mathbf{A} + \sum_{j=1}^{p} \mathbf{B}_j z_j^* \right) \right] = 0. \tag{13}$$

Note that in (13) all the s and $\boldsymbol{\tau}$ terms are incorporated into z_j, where z_j represents the unitary complex numbers, i.e., $|z_j| = 1$. The task of determining $\wp_{\text{ker}} \bigcup \wp_{\text{off}}$ in $\boldsymbol{\tau} \in \mathbb{R}^{p+}$ space is now reduced to evaluating the solution set of $\mathbf{z} \in \mathbb{C}_u^p$ which satisfies (13). Using the Kronecker summation definition, (13) can be rewritten as

$$ACE(\mathbf{z}) = \det \left[\mathbf{A} \otimes \mathbf{I} + \sum_{j=1}^{p} (\mathbf{B}_j \otimes \mathbf{I}) z_j + \mathbf{I} \otimes \mathbf{A} + \sum_{j=1}^{p} (\mathbf{I} \otimes \mathbf{B}_j z_j^*) \right] = 0. \tag{14}$$

Equation (14) is in fact a multinomial in terms of the n components of $\mathbf{z}$, and the highest degree of any one of these components is n^2 in this multinomial. We denote the complete solution set for (14) by $\mathbf{Z}$. That is,

$$\mathbf{Z} = \{\mathbf{z} \,|ACE\,(\mathbf{z}) = 0,\ \mathbf{z} \in \mathbb{C}_u^p\}, \quad \mathbf{Z} \in \mathbb{C}_u^p. \tag{15}$$

Inversely it is trivial to prove that for every solution $\mathbf{z} \in \mathbb{C}_u^p$ of (15) there exists at least one imaginary characteristic root, $s = \pm\omega i$. □

In other words, (8) is both a necessary and sufficient condition for a point $\boldsymbol{\tau} = (\tau_1, \ldots, \tau_p) \in \mathbb{R}^{p+}$ to be on either the kernel or the offspring hypersurfaces. Since this equation is completely free from the delays, and only a function of $\mathbf{z}$, the procedure is now considerably simplified to find $\mathbf{z} \in \mathbb{C}_u^p$ solutions of (8) exhaustively. To determine the imaginary characteristic roots of (2) one simply plugs such a $\mathbf{z}$ into (11) and solves for s. These roots reveal the crossing frequencies we are interested in and form the earlier-mentioned set in (3), i.e.,

$$\Omega = \{\omega \,|CE\,(s = \omega i, \mathbf{z}) = 0, \mathbf{z} \in \mathbf{Z}\}\,. \tag{16}$$

One then uses the individual components of s to determine the respective delays which are

$$\tau_{jk} = \frac{\arg(z_j) \mp 2k\pi}{\omega}, \quad j = 1 \ldots p, \quad k = 0, 1, 2, \ldots, \tag{17}$$

where τ_{jk} implies the jth delay value for various k values. One of these delays forms the $\tau_{j\,\mathrm{ker}}$, via the feature described in (5). The remaining delays form an infinitely many equidistant grid in $\mathbb{R}^{p+}$ for the same crossing root, ωi, as also expressed in (4).

Definition 4 (the building blocks). *The complex vector $\mathbf{z} \in \mathbb{C}_u^p$ can be identified exactly by a p-dimensional real vector $\boldsymbol{\tau}\omega \in \mathbb{R}^p$ (i.e., the fundamental phase angle of each component) as per* (17). *The complete solution set $\mathbf{Z}$ of* (15) *corresponds to some hypersurfaces in p-dimensional space of $\boldsymbol{\tau}\omega$. These hypersurfaces are called the "building blocks (BBs)."*

Due to the constraint on $\tau_j\omega \in [0, 2\pi]$ for the fundamental phase angle (also see the discussion below on $\tau_{\mathrm{ker,j}}$), however, the complete BB set can now be confined to a p-dimensional generalized cube of size 2π. This encapsulated BB set on the new domain has recently been studied by the authors' group in [22, 9]. There are some interesting features of BBs which are proven in [9]. The interested reader is referred to that document.

Definition 5 (spectral delay space). *We name the p-dimensional space of $\boldsymbol{\tau}\omega \in \mathbb{R}^p$ the spectral delay space (SDS), as it is the domain of BB representation.*

Determination of the Kernel and the Offspring. The explicit representation $ACE(\mathbf{z}) = 0$ of (14) is, in fact, a class of holographic mappings from $\boldsymbol{\tau} \in \mathbb{R}^{p+}$ space to $\mathbf{z} \in \mathbb{C}_u^p$ space. Every single $\boldsymbol{\tau}$ which renders an imaginary root for (2) creates a corresponding $\mathbf{z}$ which is unique, and it satisfies (14). Inversely, however, for each $\mathbf{z}$ that satisfies (14) one can find infinitely many equidistant $\boldsymbol{\tau}$ points but only one single imaginary root, ωi. Thus $\mathbf{z} \leftrightarrow \boldsymbol{\tau}$ mapping is of "holographic" class [1].

Consequently, if one obtains the complete solution set $\mathbf{Z}$ as given in (15) it would be sufficient to create the kernel and the offspring hypersurfaces we seek. For this, one has to create the transition

$$\mathbf{z} \rightarrow \omega \rightarrow \boldsymbol{\tau}$$

as described in the proof of Theorem 1. The hypersurfaces created in $\boldsymbol{\tau} \in \mathbb{R}^{p+}$ form the complete set of hypersurfaces $\wp_{\text{ker}} \bigcup \wp_{\text{off}}$. The *kernel* is simply identified using the pointwise feature, which selects the minimum positive delay set for any given ω root crossing frequency (or a solution vector $\mathbf{z}$ of (15)). In mathematical formalism the *kernel hypersurfaces* are made of points defined by

$$\tau_{\text{ker}} = \{\min \tau_{jk}\}, \quad j = 1 \dots p, \quad k = 0, 1, 2, \dots, \quad 0 \leq \tau_{\text{ker,j}} < \frac{2\pi}{\omega}, \tag{18}$$

as indicated without details in section 1. Notice that the min operation in (18) is componentwise applied to all p elements of the vector. And the remaining τ_{jk} values from (17) will create the points on the *offspring hypersurfaces,* and these points correspond to the same ω. In short, $\mathbf{z} \rightarrow \boldsymbol{\tau}_{\text{ker}}$ correspondence is one-to-one; one point in the BB corresponds to one point on the kernel hypersurface.

Corollary 1. *The number of kernel hypersurface segments is upperbounded by* n^2.

Proof. The proof is simply by recognizing the fact that the number of BBs is upperbounded by n^2. If we fix $z_1, \dots, z_{p-1}$ in (14), there can be at most n^2 unitary solutions for z_p. This fact implies that there can be a maximum of n^2 layers of the BBs. One-to-one correspondence from these BBs to the kernel hypersurfaces results in the conclusion that kernel hypersurfaces can have at most n^2 segments. ∎

The numerical procedure with Kronecker summation for obtaining the *kernel* and the *offspring* can be performed very efficiently. We will demonstrate this capability in some example case studies next, with a companion treatment of the BB concept and the SDS.

4. Example case studies.

Example 1. A case is borrowed from [23], with $n = 3$ and $p = 2$:

$$\mathbf{A} = \begin{pmatrix} -1 & 13.5 & -1 \\ -3 & -1 & -2 \\ -2 & -1 & -4 \end{pmatrix}, \quad \mathbf{B}_1 = \begin{pmatrix} -5.9 & 0 & 0 \\ 2 & 0 & 0 \\ 2 & 0 & 0 \end{pmatrix}, \quad \mathbf{B}_2 = \begin{pmatrix} 0 & 7.1 & -70.3 \\ 0 & -1 & 5 \\ 0 & 0 & 6 \end{pmatrix}. \tag{19}$$

The corresponding characteristic equation is

$$\begin{aligned} CE(s, \tau_1, \tau_2) = {} & s^3 + 6s^2 + 45.5s + 111 + (96.9s + 18.3)e^{-(\tau_1+\tau_2)s} + (-5s^2 - 121.3s + \\ & 20.1)e^{-\tau_2 s} + (5.9s^2 + 4.5s - 42.2)e^{-\tau_1 s} + (-6s - 203.4)e^{-2\tau_2 s} + 119.4e^{-(\tau_1+2\tau_2)s} = 0. \end{aligned} \tag{20}$$

This quasi polynomial contains all types of complex formations of transcendental terms, such as individual delays, their commensurate forms (e.g., $e^{-2\tau_2 s}$), cross-talk terms (e.g., $e^{-(\tau_1+\tau_2)s}$), and both cross-talk with commensuracy (e.g., $e^{-(\tau_1+2\tau_2)s}$). As it is accepted in the delay differential equations literature, such a formation presents a very complex problem.

Using Theorem 1 *ACE* is obtained as follows:

(21)

$$
\begin{aligned}
ACE(z_1,z_2) = &\left(\begin{array}{l} 1.7022z_2^6 + 9.0713z_2^5 + 40.7183z_2^4 - 21.1282z_2^3 - 40.1780z_2^2 \\ -123.5525z_2 - 34.0495 + 4.3008z_2^{-1} + 50.1953z_2^{-2} + 7.2436z_2^{-3} \\ +8.6351z_2^{-4} \end{array}\right) z_1^6 \\
+ &\left(\begin{array}{l} -9.2124z_2^6 - 34.3982z_2^5 - 164.0727z_2^4 + 309.8357z_2^3 + 308.8355z_2^2 + 340.0104z_2 \\ -93.5932 - 455.9817z_2^{-1} - 2.4843z_2^{-2} - 85.8515z_2^{-3} + 17.8037z_2^{-4} \\ -7.3179z_2^{-5} \end{array}\right) z_1^5 \\
+ &\left(\begin{array}{l} 16.2587z_2^6 + 19.9951z_2^5 + 204.5044z_2^4 - 883.9491z_2^3 - 429.7956z_2^2 + 26.9372z_2 \\ +763.3490 + 964.9333z_2^{-1} - 78.4191z_2^{-2} - 63.6748z_2^{-3} - 22.3465z_2^{-4} \\ -37.63910z_2^{-5} - 1.4883z_2^{-6} \end{array}\right) z_1^4 \\
+ &\left(\begin{array}{l} -8.5227z_2^6 + 45.9059z_2^5 - 69.8016z_2^4 + 773.7642z_2^3 + 75.7380z_2^2 - 631.0328z_2 \\ -1340.0621 - 631.03287z_2^{-1} + 75.7380z_2^{-2} + 773.7642z_2^{-3} - 69.8016z_2^{-4} \\ +45.9059z_2^{-5} - 8.5227z_2^{-6} \end{array}\right) z_1^3 \\
+ &\left(\begin{array}{l} -1.4883z_2^6 - 37.63910z_2^5 - 22.3465z_2^4 - 63.6748z_2^3 - 78.4191z_2^2 + 964.9333z_2 \\ +763.3490 + 26.9372z_2^{-1} - 429.7956z_2^{-2} - 883.9491z_2^{-3} + 204.5044z_2^{-4} \\ +19.9951z_2^{-5} + 16.2587z_2^{-6} \end{array}\right) z_1^2 \\
+ &\left(\begin{array}{l} -7.3179z_2^5 + 17.8037z_2^4 - 85.8515z_2^3 - 2.4843z_2^2 - 455.9817z_2 - 93.5932 \\ +340.0104z_2^{-1} + 308.8355z_2^{-2} + 309.8357z_2^{-3} - 164.0727z_2^{-4} - 34.3982z_2^{-5} \\ -9.2124z_2^{-6} \end{array}\right) z_1^1 \\
+ &\left(\begin{array}{l} 8.6351z_2^4 + 7.2436z_2^3 + 50.1953z_2^2 + 4.3008z_2 - 34.0495 - 123.5525z_2^{-1} \\ -40.1780z_2^{-2} - 21.1282z_2^{-3} + 40.7183z_2^{-4} + 9.0713z_2^{-5} + 1.7022z_2^{-6} \end{array}\right).
\end{aligned}
$$

For a numerical algorithm to obtain the $(z_1, z_2) \in \mathbb{C}_u^2$ exhaustively, the following steps are followed:

1. Select z_2 using a secondary parameter, θ, as $z_2 = e^{i\theta}$, $\theta \in [0, 2\pi]$; start with $\theta = 0$.
2. With this value of z_2, solve the roots of (21). Those roots with unity magnitude will form the corresponding z_1 values. Obviously, there can be a maximum of 6 such solutions which is less than $n^2 = 9$.
3. Substitute z_1 (for $e^{-\tau_1 \omega i}$) and z_2 (for $e^{-\tau_2 \omega i}$) into (20) and solve for ω, the imaginary spectrum of the system.
4. Then increase θ by a desired resolution, $\Delta\theta$, and repeat steps 1–3.
5. As θ reaches 2π a complete set of imaginary spectra and the corresponding kernel points $(\tau_1, \tau_2) \in \wp_{\text{ker}}$ are obtained using (17). The offspring $\wp_{\text{off}}$ is trivially generated using (17) again.

Notice that ACE is a self-inversive polynomial with interspersed zeros on the unit circle. Although not used here, this feature may be of some computational value in future studies.

Further deployment of Postulates 1 and 2 of CTCR results in the stability robustness tableau of Figure 1 against delay uncertainties. The stable regions are shaded, and the number of unstable roots, NU, is shown sparingly on the figure. The stability outlook matches with that of [23] precisely.

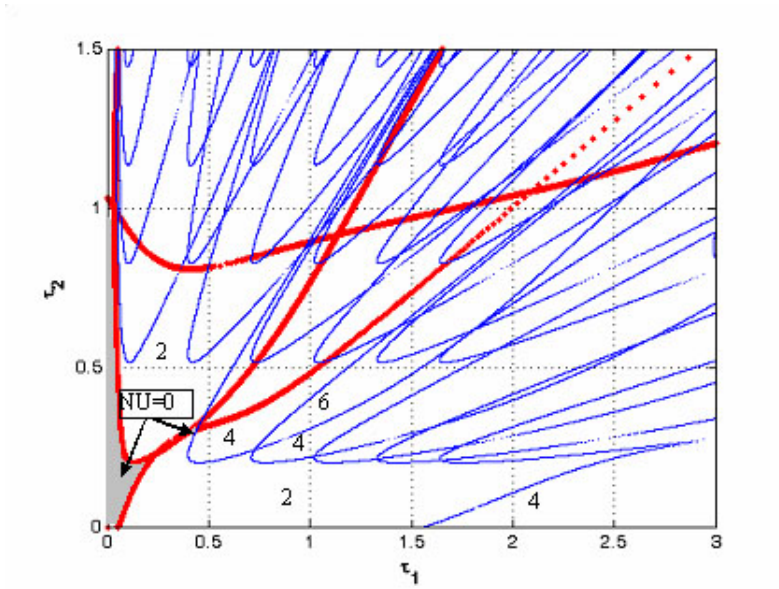

FIG. 1. *Kernel (red, thick) and offspring hyperplanes of Example* 1.

Two main objectives of this example are the following:

1. To demonstrate that the extended Kronecker summation method coincides with the earlier Rekasius-based determination of $\wp_{\text{ker}}$ and $\wp_{\text{off}}$. Clearly both of these procedures are serving for the initial step of the CTCR paradigm.
2. To show substantial computational improvement by utilizing the Kronecker summation method. The computation of kernel and offspring hypersurfaces takes 0.7 seconds on a PC with Pentium-Centrino 2.13 GHz and 1 GB RAM, as opposed to 19.2 sec as stated in [23] which is based on Rekasius substitution. We make a qualified remark that such CPU times can vary considerably for various code writing styles. Nevertheless, we wish to give the reader a comparative perspective.

Example 2. We take a challenging case with three delays $(n = 2, p = 3)$ next:

$$\mathbf{A} = \begin{pmatrix} 0 & 1 \\ -8 & -3 \end{pmatrix}, \quad \mathbf{B}_1 = \begin{pmatrix} 0 & 0 \\ -1 & -3 \end{pmatrix}, \quad \mathbf{B}_2 = \begin{pmatrix} 0 & 0 \\ -8 & 1 \end{pmatrix}, \quad \mathbf{B}_3 = \begin{pmatrix} 0 & 0 \\ -5 & 0 \end{pmatrix}$$

with the corresponding characteristic equation

$$CE(s, \tau_1, \tau_2, \tau_3) = s^2 + 3s + 8 + (3s + 1)e^{-\tau_1 s} + (-s + 8)e^{-\tau_2 s} + 5e^{-\tau_3 s} = 0.$$

For this system the $ACE(z_1, z_2, z_3)$ is trivial to obtain from (14), but it is not given here to conserve space. For this example case study, we display in Figure 2 the BB in the SDS, $(\tau_1\omega, \tau_2\omega, \tau_3\omega)$. Notice that for each $(z_1, z_2, z_3) \in \mathbb{C}_u^3$ solution of ACE one obtains a $\langle(\tau_1, \tau_2, \tau_3), \omega\rangle$ correspondence. The relation between z_j and $\tau_j\omega$, $j = 1, 2, 3$, is trivial:

$$\tau_j\omega = \arg(z_1), \quad 0 < \arg(z_1) < 2\pi.$$

The BB represents the complete kernel hypersurface set in the SDS. Every point on the BB has an ω root crossing frequency (which are not shown here), and the BB

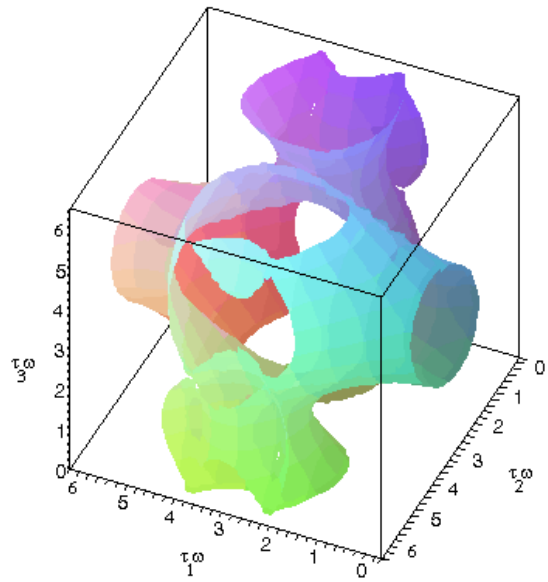

FIG. 2. *BB representation of the system in Example* 2.

traces the hypersurfaces with the following property:

$$\{\omega | \boldsymbol{\tau}\omega \in BB\} = \Omega.$$

That is, the BB represents the complete kernel. For easier visualization, selected cross-sections of Figure 2 are given in Figure 3 for $\tau_3\omega = 0, \frac{\pi}{2}, \pi$, and $\frac{3\pi}{2}$. The offspring form by simple shift operations (by 2π) in any of the three SDS coordinates in accordance with (17); see Figure 3 (blue). The BB in Figure 2 can be transformed into the (τ_1, τ_2, τ_3) delay space to create the ultimate kernel and offspring as shown in Figure 4 for various levels of τ_3. The cross-sections of hypersurfaces with the $\tau_3 =$ constant planes (the kernel and offspring hypercurves) are shown in red and black, respectively. The stable regions are shaded. Notice several small regions of stability (such as $\tau_1 = 1.5, \tau_2 = 0.2, \tau_3 = 2$ or $\tau_1 = 2, \tau_2 = 0.4, \tau_3 = 2.5$) which are easily detected by the CTCR procedure. Computationally this operation is quite efficient. Just to give an idea to the reader, each one of the frames in Figure 4 is obtained within 0.8 sec CPU time. Therefore, it is only a matter of computational capacity to create a sufficiently dense cross-section of the kernel and the offspring even in the case of three independent delays. Another study of the authors' group, on a simpler dynamics with three delays (without cross-talk), was also presented at a recent conference [28].

5. Conclusions. This paper presents the stability robustness of LTI systems with multiple delays against uncertainties in delays. The main contribution is in the utilization of some intriguing properties of the Kronecker summation of matrices. One of them (the eigenvalue summation feature) yields a numerically efficient process for determining the stability switching hypersurfaces, which are called the kernel and the offspring hypersurfaces. This effort constitutes the initial step for the umbrella paradigm, the CTCR, which, in turn, resolves the stability robustness of LTI systems with multiple delays against delay uncertainties. Numerical efficiency improvement is the main benefit of using the Kronecker summation property. A companion perspective, the BB representation, is also given for a three-delay example case study.

MEAN-VARIANCE PORTFOLIO SELECTION UNDER PARTIAL INFORMATION*

JIE XIONG† AND XUN YU ZHOU‡

Abstract. This paper is concerned with a continuous-time mean-variance portfolio selection problem in a (possibly incomplete) market with multiple stocks and a bond. Only the past price movements of the stocks and the bond are the information available to the investors. A separation principle is shown to hold in this setting. Efficient strategies based on the aforementioned partial information are derived, which involve the optimal filter of the stock appreciation rate processes. The main methodological contribution of the paper is to employ the particle system representation to develop analytical and numerical approaches in obtaining the filter as well as solving the related backward stochastic differential equation.

Key words. mean-variance portfolio selection, continuous time, partial information, nonlinear filtering, backward stochastic differential equation, particle system representation

DOI. 10.1137/050641132

1. Introduction.

In the Nobel Prize winning work [19], Markowitz proposed the mean-variance portfolio selection model for a single investment period, where an agent seeks to minimize the risk of his investment, measured by the variance of his return, subject to a given mean return. The dynamic extension of the Markowitz model, especially in continuous time, has been studied extensively in recent years; see, e.g., Li and Ng [15], Zhao and Ziemba [30], Zhou and Li [31], Lim [16], Bielecki et al. [2], and Xia [25]. (In particular, refer to Steinbach [23] and Bielecki et al. [2] for elaborative discussions on the history of the mean-variance model.) In many of these works, explicit, analytic forms of efficient portfolios have been obtained. However, in all these works it is assumed that the driving Brownian motions are completely observable by an investor, which in reality is more of an exception than a rule. Practically, the investor can observe only the stock prices (including past and present) on which he will base his investment decisions. This leads to the so-called partially observed portfolio selection problem, and this paper aims to solve the problem in the realm of mean variance. An important finding in this paper is that the separation principle (for separating filtering and optimization) turns out to hold in the mean-variance setting, which in turn greatly simplifies the problem. Another main contribution of the paper is to employ the particle system representation, which has been developed quite recently for solving stochastic partial differential equations (SPDEs), to develop analytical and numerical approaches in obtaining the filter as well as solving the related backward stochastic differential equation (BSDE).

Asset allocation and asset pricing based on partial information under various setups have been studied extensively in the financial economics literature; see, for example, Lakner [14], Brennan and Xia [3], Xia [26], Rogers [22], Nagai and Peng [20], and Yang and Xiong [27]. Detemple [4], Dothan and Feldman [5], and Gennotte [7] established a separation principle. However, all these works are predominantly done within the expected utility framework. (Refer to [2, 23, 30] for discussions on crucial differences between the utility and mean-variance models.) Pham [21] considered a mean-variance hedging problem for a general semimartingale model and proved a separation principle for a diffusion model (though it is not a multidimensional geometric Brownian motion as in the present paper). Although in theory a mean-variance problem a là Markowitz can be formulated as a mean-variance hedging problem, there are subtleties that must be considered such as the feasibility and the determination of the Lagrange multiplier (see [2, 16]). Moreover, the analysis in [21] is rather involved due to the martingale method employed, whereas here we will give a very direct, clean, and short proof for a separation principle.

The rest of this article is organized as follows. In section 2, we formulate the mean-variance portfolio selection model under partial information. In section 3, we derive the innovation process associated with the filtering problem, which leads to the separation principle. Section 4 studies the optimal filter in details for two cases. Section 5 is devoted to the optimization part as well as the final solution to the partially observed mean-variance problem. A numerical solution to a related BSDE is presented, which is of independent interest.

2. The model. We consider a market consisting of d stocks and a bond whose prices are stochastic processes $S_i(t)$, $i = 0, 1, \dots, d$, governed by the following SDEs:

$$\begin{cases} dS_i(t) = S_i(t)\left(\mu_i(t)dt + \sum_{j=1}^m \tilde{\sigma}_{ij}(t)d\tilde{W}_j(t)\right), & i = 1, 2, \dots, d, \\ dS_0(t) = S_0(t)\mu_0(t)dt, \quad t \geq 0, \end{cases}$$

where $\tilde{W} := (\tilde{W}_1, \dots, \tilde{W}_m)^*$ is a standard Brownian motion defined on a filtered complete probability space $(\Omega, \mathcal{F}, P; \{\mathcal{F}_t\}_{t\geq 0})$; $\mu_i(t)$, $i = 1, 2, \dots, d$, are the appreciation rate processes of the stocks; $\mu_0(t)$ is the interest rate process; and the $d \times m$ matrix valued process $\tilde{\Sigma}(t) := (\tilde{\sigma}_{ij}(t))$ is the volatility process. Here and throughout the paper A^* denotes the transpose of a matrix A.

Let

$$\mathcal{G}_t := \sigma(S_i(s) : \ s \leq t, \ i = 0, 1, 2, \dots, d), \ \ t \geq 0.$$

In our model $\mathcal{G}_t$, rather than $\mathcal{F}_t^{\tilde{W}}$ (the filtration generated by $\tilde{W}$), is the only information available to the investors at time t.

By Itô's formula, we have

$$d\log S_i(t) = \left(\mu_i(t) - \frac{1}{2}a_{ii}(t)\right)dt + \sum_{j=1}^m \tilde{\sigma}_{ij}(t)d\tilde{W}_j(t), \ \ i = 1, 2, \dots, d, \tag{2.1}$$

where

$$a_{ij}(t) := \sum_{k=1}^m \tilde{\sigma}_{ik}(t)\tilde{\sigma}_{jk}(t), \ \ i, j = 1, 2, \dots, d.$$

The following assumptions on the market coefficients will be in force throughout this paper.

Assumption (*ND*). For any $t \geq 0$, the $d \times d$ matrix $A(t) := (a_{ij}(t))$ is of full rank a.s. (almost surely).

Assumption (*BC*). There exists a finite constant C such that $\forall\ t \geq 0$, $\forall i, j$,

$$|\tilde{\sigma}_{ij}(t)| \leq C \qquad \text{a.s.}$$

Assumption (*IC*). $\mathbb{E}\int_0^T (\mu_0(t)^2 + |\mu(t)|^2)dt < \infty$.

Remark 2.1. In this article, we allow $d < m$ as long as condition (ND) is satisfied; in other words, the market itself is allowed to be incomplete. It is interesting to note that, unlike the full information case, the incompleteness of the market does not impose essential difficulty in the partial information case. This can be explained as follows. In the classical model of incomplete market (with full information), there are vast amounts of information available. Namely, one has to seek optimal portfolios in the class of all $\mathcal{F}_t^{\tilde{W}}$-adapted portfolios. When $m > d$, the number of available stocks is fewer than that of the (independent) random factors and hence, some of the market risks cannot be completely eliminated by composing an appropriate stock portfolio. As a result, portfolio selection problems become harder than the case with a complete market because some contingent claims cannot be replicated. In our current setup, the available information comes *only* from the stocks themselves, and any other information is not observable anyway. Therefore, the model is essentially complete, as also will be evident in what follows, although the market is indeed incomplete in the conventional sense.

It is easy to show that the quadratic covariation process between $\log S_i(t)$ and $\log S_j(t)$ is given by $\int_0^t a_{ij}(s)ds$. Therefore, the matrix valued process $(a_{ij}(t))$ is $\mathcal{G}_t$-adapted. Let $\Sigma(t) \equiv (\sigma_{ij}(t))$ be the square root of $A(t)$. Then, $\sigma_{ij}(t)$ is $\mathcal{G}_t$-adapted, i.e., it is completely observable. As we shall see in (3.5) below, the stock price $S_i(t)$ satisfies an equivalent SDE which depends on $\sigma_{ij}(t)$ instead of $\tilde{\sigma}_{ij}(t)$. Moreover, $\mu_0(t) = \frac{d}{dt}\log S_0(t)$ is also $\mathcal{G}_t$-adapted. Therefore, we do not need to consider the filtering problem for the stochastic interest rate and volatility processes.

However, the stochastic process $\mu(t) := (\mu_1(t), \ldots, \mu_d(t))^*$ is not necessarily $\mathcal{G}_t$-adapted and hence, its value is not available to the investors. Note that $\mu(t)$, being a very general process, does not need to be even $\mathcal{F}_t^{\tilde{W}}$-adapted.

Denote by $L^2_{\mathcal{G}}(0,T;\mathbb{R}^n)$ the set of $\mathbb{R}^n$-valued, $\mathcal{G}_t$-adapted processes $f(t)$ with $\mathbb{E}\int_0^T |f(t)|^2 dt < \infty$. (Similar notation $L^2_{\mathcal{H}}(0,T;\mathbb{R}^n)$ can be defined for any filtration $\mathcal{H}_t$.) $L^2_{\mathcal{G}}(0,T;\mathbb{R}^n)$ becomes a Hilbert space endowed with the norm $\| f \|_{L^2_{\mathcal{G}}(0,T;\mathbb{R}^n)} := (\mathbb{E}\int_0^T |f(t)|^2 dt)^{\frac{1}{2}}$.

We now define the class of admissible portfolios (investment strategies).

Definition 2.2. *A d-dimensional process $u(t) \equiv (u_1(t), \ldots, u_d(t))^*$ is an* admissible portfolio *if $u(t) \in L^2_{\mathcal{G}}(0,T;\mathbb{R}^d)$.*

In the preceding definition, $u_i(t)$ represents the worth (dollar amount) of an agent's wealth in the ith stock, $i = 1, 2, \ldots, d$. It is well known that under a so-called self-financed portfolio, the wealth process of an agent, starting with an initial wealth x_0, satisfies the following *wealth equation* (see, e.g., [11]):

$$\begin{cases} dx(t) = \big(\mu_0(t)x(t) + \sum_{i=1}^d (\mu_i(t) - \mu_0(t))u_i(t)\big)dt \\ \qquad\qquad + \sum_{i=1}^d \sum_{j=1}^m \tilde{\sigma}_{ij}(t)u_i(t)d\tilde{W}_j(t), \quad t \geq 0, \\ x(0) = x_0. \end{cases} \tag{2.2}$$

The partially observed mean-variance portfolio selection model is formulated as the following optimization model:

$$\text{Minimize} \quad \mathrm{Var}(x(T)) = \mathbb{E}(x(T) - \mathbb{E}x(T))^2$$

$$\text{subject to} \quad \begin{cases} u(t) \text{ is self-financed and admissible,} \\ (x(t), u(t)) \text{ satisfies (2.2) with initial wealth } x_0, \\ \mathbb{E}x(T) = z, \end{cases} \tag{2.3}$$

where $x_0, z \in \mathbb{R}$ are given constants.

3. Separation principle. In this section, we consider the filtering problem associated with our model (2.3) and establish a separation principle. Specifically, we define the innovation process for the filtering problem. Based on this process, we will derive a $\mathcal{G}_t$-adapted representation for the wealth process corresponding to any self-financed admissible portfolio.

THEOREM 3.1. *Under any self-financed admissible portfolio $u(t)$, the corresponding wealth process $x(t)$ satisfies the following SDE:*

$$\begin{cases} dx(t) = \left(x(t)\mu_0(t) + \sum_{i=1}^d (\bar{\mu}_i(t) - \mu_0(t))u_i(t)\right) dt + \sum_{i,j=1}^d \sigma_{ij}(t)u_i(t)d\nu_j(t), \ t \geq 0, \\ x(0) = x_0, \end{cases} \tag{3.1}$$

where $\bar{\mu}_i(t) := \mathbb{E}(\mu_i(t)|\mathcal{G}_t)$ is the optimal filter of $\mu_i(t)$, and the innovation process *$\nu(t) \equiv (\nu_1(t), \ldots, \nu_d(t))^*$ is a d-dimensional Brownian motion given by*

$$d\nu(t) := \Sigma(t)^{-1} d\log S(t) - \Sigma(t)^{-1} \left(\bar{\mu}(t) - \frac{1}{2}\tilde{A}(t)\right) dt, \tag{3.2}$$

where

$$S(t) := (S_1(t), \ldots, S_d(t))^*, \quad \log S(t) := (\log S_1(t), \ldots, \log S_d(t))^*,$$
$$\bar{\mu}(t) := (\bar{\mu}_1(t), \ldots, \bar{\mu}_d(t))^*, \quad \text{and } \tilde{A}(t) := (a_{11}(t), \ldots, a_{dd}(t))^*.$$

Proof. From (2.1), we see that

$$\log S_i(t) - \log S_i(0) - \int_0^t \left(\mu_i(s) - \frac{1}{2}a_{ii}(s)\right) ds = \sum_{j=1}^m \int_0^t \tilde{\sigma}_{ij}(s) d\tilde{W}_j(s), \quad i = 1, 2, \ldots, d,$$

are martingales with a quadratic covariation process $\int_0^t A(s)ds = \int_0^t \Sigma(s)^2 ds$. By the martingale representation theorem, there exists a standard Brownian motion $W \equiv (W_1, \ldots, W_d)$ on $(\Omega, \mathcal{F}, P)$ such that

$$\sum_{j=1}^m \tilde{\sigma}_{ij}(t) d\tilde{W}_j(t) = \sum_{j=1}^d \sigma_{ij}(t) dW_j(t), \qquad i = 1, \ \ldots, \ d. \tag{3.3}$$

Thus,

$$d\log S_i(t) = \left(\mu_i(t) - \frac{1}{2}a_{ii}(t)\right) dt + \sum_{j=1}^d \sigma_{ij}(t) dW_j(t), \qquad i = 1, \ \ldots, \ d. \tag{3.4}$$

Equivalently, the stock prices satisfy the following modified SDE:

$$dS_i(t) = S_i(t)\left(\mu_i(t)dt + \sum_{j=1}^{d}\sigma_{ij}(t)dW_j(t)\right), \qquad i = 1, \ldots, d. \tag{3.5}$$

Note that $\Sigma(t)$ is invertible. Let $\tilde{S}(t)$ be defined by

$$d\tilde{S}(t) := \Sigma(t)^{-1} d\log S(t).$$

We can write the observation equation (3.4) in the classical form (cf. (8.1.1) in [10]):

$$\tilde{S}(t) = \tilde{S}(0) + \int_0^t \Sigma(s)^{-1}\left(\mu(s) - \frac{1}{2}\tilde{A}(s)\right)ds + W(t) \tag{3.6}$$

with the observation σ-field $\mathcal{G}_t$. By Theorem 8.1.3 and Remark 8.1.1 in Kallianpur [10], $(\nu(t), \mathcal{G}_t)$ is a d-dimensional Brownian motion such that $\sigma(\nu(u) - \nu(s) : u \geq s \geq t)$ is independent of $\mathcal{G}_t$.

By (3.6) and (3.2), we get

$$\Sigma(t)dW(t) = \Sigma(t)d\nu(t) + (\bar{\mu}(t) - \mu(t))dt. \tag{3.7}$$

The desired form of wealth equation (3.1) then follows from (2.2), (3.3), and (3.7). □

Remark 3.2. A notorious difficulty in tackling general stochastic optimization problems with partial information is that one usually cannot separate the filtering and optimization, except for some very rare situations. The significance of Theorem 3.1 is that for the specific mean-variance portfolio selection problem, the separation principle happens to hold: one can simply replace the appreciation rate with its filter in the wealth equation and then solve the resulting optimization problem as in the complete information case.

4. Filtering. In this section, we study the filtering problem (for the appreciation rate process) by considering two cases associated with the volatility processes. The aim is to study the optimal filter $U(t)$ given by

$$\langle U(t), f\rangle := \mathbb{E}(f(\mu(t))|\mathcal{G}_t) \qquad \forall\, f \in C_b(\mathbb{R}^d).$$

4.1. Case 1: Nonrandom $\tilde{\Sigma}$. In this subsection we consider the case when the original volatility process $\tilde{\Sigma}(t)$ is a deterministic matrix valued function of t and $\mu(t)$ a d-dimensional Markov process (with a generator L) independent of $\tilde{W}$. By the definitions of $\Sigma(t)$ and W, where W is defined via (3.3), it is clear that $\Sigma(t)$ is also nonrandom and $\mu(t)$ is independent of W. Then the filtering problem becomes a classical one with the signal $\mu(t)$ and observation $\tilde{S}(t)$ given by (3.6). In this case, $\mathcal{G}_t = \mathcal{F}_t^{\tilde{S}}$.

Remark 4.1. By Theorem 8.3.1 in [10], every square integrable $\mathcal{F}_t^{\tilde{S}}$-martingale (and hence, in the present case every $\mathcal{G}_t$-martingale) Y_t can be represented as

$$Y_t = \mathbb{E}(Y_0) + \int_0^t \Phi(s)^* d\nu(s), \tag{4.1}$$

where $\Phi(s) \in L^2_{\mathcal{F}^{\tilde{S}}}(0, T; \mathbb{R}^d)$. This fact will be useful in Proposition 5.5 below in establishing an optimal portfolio since $\mathbb{H} = AC(\mathcal{G})$ in this case (cf. Definition 5.1). Namely, the market is complete in the sense of Definition 5.2.

In Kurtz and Xiong [12, 13], a large class of SPDEs, with the filtering equations as a special case, and their numerical solutions are studied based on a technique called the particle system representation. In this subsection, we demonstrate that the particle system representation itself can be used to derive the filtering equations directly. Note that the generator L of the appreciation rate process $\mu(t)$ is not required to be a second-order differential operator. In fact, even the continuity of $\mu(t)$ in t need not to be assumed. It is also worth mentioning that the results in this and the next subsections are not covered by those of [12, 13].

Introduce the following integrability condition:

$$\int_0^T \left| \left(\mu(s)^* - \frac{1}{2}\tilde{A}(s)^* \right) \Sigma(s)^{-1} \right|^2 ds < \infty \qquad \text{a.s.} \tag{4.2}$$

Applying Girsanov's formula to (3.6) and noting that μ and W are independent, under the probability $\tilde{P}$ defined below, we get that $\tilde{S}(t)$ is a Brownian motion independent of $\mu(t)$, where $dP = M(T)d\tilde{P}$ with

$$M(t) := \exp\biggl(\int_0^t \left(\mu(s)^* - \frac{1}{2}\tilde{A}(s)^* \right) \Sigma(s)^{-1} d\tilde{S}(s) - \frac{1}{2} \int_0^t \left| \left(\mu(s)^* - \frac{1}{2}\tilde{A}(s)^* \right) \Sigma(s)^{-1} \right|^2 ds \biggr).$$

By the Kallianpur–Striebel formula, we can represent the optimal filter $U(t)$ as

$$\langle U(t), f \rangle = \frac{\langle V(t), f \rangle}{\langle V(t), 1 \rangle}, \tag{4.3}$$

where for $f \in C_b(\mathbb{R}^d)$,

$$\langle V(t), f \rangle := \tilde{\mathbb{E}} \left(M(t) f(\mu(t)) | \mathcal{G}_t \right)$$

is the unnormalized filter. Here $\tilde{\mathbb{E}}$ refers to the expectation under the new probability measure $\tilde{P}$.

LEMMA 4.2. *Suppose that $\mu(t)$ is a d-dimensional Markov process (with generator L) independent of W satisfying* (4.2). *Then, $V(t)$ is represented as*

$$\langle V(t), f \rangle = \lim_{n \to \infty} \frac{1}{n} \sum_{i=1}^{n} M^i(t) f(\mu^i(t)), \tag{4.4}$$

where $\mu^1(t)$, $\mu^2(t)$, ... are independent copies of $\mu(t)$ and

$$M^i(t) := \exp\biggl(\int_0^t \left(\mu^i(s)^* - \frac{1}{2}\tilde{A}(s)^* \right) \Sigma(s)^{-1} d\tilde{S}(s) - \frac{1}{2} \int_0^t \left| \left(\mu^i(s)^* - \frac{1}{2}\tilde{A}(s)^* \right) \Sigma(s)^{-1} \right|^2 ds \biggr). \tag{4.5}$$

Proof. Note that

$$dM^i(t) = M^i(t) \left(\mu^i(t)^* - \frac{1}{2}\tilde{A}(t)^* \right) \Sigma(t)^{-1} d\tilde{S}(t). \tag{4.6}$$

Denote by $\mathcal{X}$ the collection of all those processes $\mu(t)$ satisfying (4.2) and by $\mathcal{Y}$ the collection of all measurable $\mathbb{R}^{2d}$-valued random vectors. Then $\mathcal{X}$ and $\mathcal{Y}$ are measurable spaces. For $\mu^i \in \mathcal{X}$, the SDE (4.6) has a unique strong solution. Therefore, for each fixed $t \in [0,T]$ there is a measurable functional $F_t : C([0,T],\mathbb{R}^d) \times \mathcal{X} \to \mathcal{Y}$ such that $(\mu^i(t), M^i(t)) = F_t(\tilde{S}, \mu^i)$. As a consequence, under the conditional probability $\tilde{P}(\cdot|\mathcal{F}_t^{\tilde{S}})$, $(\mu^i(t), M^i(t))$ is completely determined by μ^i, $i = 1, 2, \ldots$. Since $\tilde{S}, \mu^1, \mu^2, \ldots$ are independent, the strong law of large numbers yields

$$\lim_{n\to\infty} \frac{1}{n} \sum_{i=1}^{n} M^i(t) f(\mu^i(t)) = \tilde{\mathbb{E}}\left(M(t) f(\mu(t)) | \mathcal{F}_t^{\tilde{S}} \right). \tag{4.7}$$

Since $\mathcal{F}_t^{\tilde{S}} = \mathcal{G}_t$, we obtain (4.4). □

Now we derive via Itô's formula and (4.4)–(4.5) an SPDE for the unnormalized filter $V(t)$. Let $\mu^i(t)$, $i = 1, 2, \ldots$, be as in Lemma 4.2. It is well known (see the standard textbooks of Ethier and Kurtz [6] or Stroock and Varadhan [24]) that there are independent martingales $N_f^i(t)$ such that

$$df(\mu^i(t)) = Lf(\mu^i(t))dt + dN_f^i(t), \quad f \in D(L), \tag{4.8}$$

where $D(L)$ is the domain of L.

Applying Itô's formula to (4.6) and (4.8), we get

$$\begin{aligned} d(M^i(t) f(\mu^i(t))) &= M^i(t) \left(Lf(\mu^i(t))dt + dN_f^i(t) \right) \\ &\quad + M^i(t) f(\mu^i(t)) \left(\left(\mu^i(t)^* - \frac{1}{2}\tilde{A}(t)^* \right) \Sigma(t)^{-1} d\tilde{S}(t) \right). \end{aligned}$$

Taking an average for $i = 1, 2, \ldots, k$, letting $k \to \infty$, and applying Lemma 4.2, we see that $V(t)$ satisfies the following Zakai equation:

$$d\langle V(t), f\rangle = \langle V(t), Lf\rangle\, dt + \langle V(t), G_t f\rangle\, d\tilde{S}(t), \tag{4.9}$$

where

$$G_t f(\mu) := f(\mu) \left(\mu^* - \frac{1}{2}\tilde{A}(t)^* \right) \Sigma(t)^{-1}.$$

Making use of (4.3), by Itô's formula, we have

$$\begin{aligned} d\langle U(t), f\rangle &= \langle U(t), Lf\rangle\, dt \\ &\quad + \left(\langle U(t), G_t f\rangle - \langle U(t), G_t 1\rangle \langle U(t), f\rangle \right) \left(d\tilde{S}(t) - \langle U(t), G_t 1\rangle\, dt \right). \end{aligned}$$

Note that

$$\begin{aligned} \langle U(t), G_t 1\rangle &= \mathbb{E}\left(\left(\mu(t)^* - \frac{1}{2}\tilde{A}(t)^* \right) \Sigma(t)^{-1} \middle| \mathcal{G}_t \right) \\ &= \left(\bar{\mu}(t)^* - \frac{1}{2}\tilde{A}(t)^* \right) \Sigma(t)^{-1}. \end{aligned}$$

Hence (3.2) can be rewritten as

$$d\tilde{S}(t) - \langle U(t), G_t 1\rangle\, dt = d\nu(t).$$

Therefore, $U(t)$ satisfies the following Fujisaki–Kallianpur–Kunita (FKK) equation:

$$d\langle U(t), f\rangle = \langle U(t), Lf\rangle\, dt + (\langle U_t, G_t f\rangle - \langle U(t), G_t 1\rangle \langle U(t), f\rangle)\, d\nu(t). \tag{4.10}$$

Remark 4.3. Since L is not necessarily a second-order differential operator, which was used heavily in [12] in proving that an SPDE of the form (4.10) has a unique strong solution, we cannot establish such a property for a general L by the same argument in [12]. However, by Theorem 9.1 in [1], under suitable conditions, the solution to (4.10) is indeed unique.

Next, let us discuss the numerical implementation of the preceding filter. Recall that $\mu^1(t)$, $\mu^2(t)$, ... are independent copies of $\mu(t)$. For $\delta > 0$, let $\eta_\delta(t) := j\delta$ for $j\delta \le t < (j+1)\delta$, $j = 0, 1, \ldots$. We approximate $M^i(t)$ by the Euler scheme:

$$M^{\delta,i}(t) := \exp\Bigg(\int_0^t \left(\mu^i(\eta_\delta(s))^* - \frac{1}{2}\tilde{A}(\eta_\delta(s))^*\right)\Sigma(s)^{-1} d\tilde{S}(s) - \frac{1}{2}\int_0^t \left|\left(\mu^i(\eta_\delta(s))^* - \frac{1}{2}\tilde{A}(\eta_\delta(s))^*\right)\Sigma(s)^{-1}\right|^2 ds\Bigg).$$

Define

$$\left\langle V^{n,\delta}(t), f\right\rangle := \frac{1}{n}\sum_{i=1}^n M^{\delta,i}(t) f(\mu^i(t)) \text{ and } \langle V^n(t), f\rangle := \frac{1}{n}\sum_{i=1}^n M^i(t) f(\mu^i(t)).$$

We then combine both approximations by using $\bar{V}^n := V^{n,1/n^{1/2\alpha}}$ to approximate the unnormalized filter, where $\alpha > 0$ is given in (4.11) below.

Although we did not assume the sample path continuity of $\mu(t)$, we need some kind of continuity in the sense of moments. We assume that $|\Sigma(t)^{-1}| \le K$ and with some $\alpha > 0$,

$$\mathbb{E}\left(|\mu(t) - \mu(s)|^2\right) \le |t - s|^\alpha. \tag{4.11}$$

For example, if $\mu(t)$ is a compound Poisson process, then (4.11) holds with $\alpha = 1$.

Let $\bar{\mathbb{R}}^d$ be the one-point compactification of $\mathbb{R}^d$. Then $C_b(\bar{\mathbb{R}}^d)$ is a separable Banach space. Let $\mathcal{M}_F(\bar{\mathbb{R}}^d)$ be the space of finite Borel measures on $\bar{\mathbb{R}}^d$, and let d be a distance defined on $\mathcal{M}_F(\bar{\mathbb{R}}^d)$ whose topology coincides with the weak convergence topology. More precisely, let $\{f_k\} \subset C_b^1(\bar{\mathbb{R}}^d)$ be a dense subset of $C_b(\bar{\mathbb{R}}^d)$. We define

$$d(\nu_1, \nu_2) := \sum_{k=1}^\infty \frac{|\langle \nu_1 - \nu_2, f_k\rangle|}{2^k \|f_k\|_L}, \quad \nu_1, \nu_2 \in \mathcal{M}_F(\bar{\mathbb{R}}^d),$$

where

$$\|f\|_L := \sup_{x\in\bar{\mathbb{R}}^d} |f(x)| + \sup_{x,y\in\bar{\mathbb{R}}^d} \frac{|f(x) - f(y)|}{|x - y|}, \quad f \in C_b^1(\bar{\mathbb{R}}^d).$$

THEOREM 4.4. *Suppose that* $|\Sigma(t)^{-1}| \le K$ *and* (4.11) *holds. Then, for each fixed* t, *there exists* $M > 0$, *such that* $\forall\, n$,

$$\tilde{\mathbb{E}}\left(d(\bar{V}^n(t), V(t))\right) \le \frac{M}{\sqrt{n}}. \tag{4.12}$$

Proof. By the conditional independence, it is easy to show that $\forall\ f \in C_b(\bar{\mathbb{R}}^d)$,

$$\tilde{\mathbb{E}}\left(\langle V^n(t) - V(t), f\rangle^2\right) \le \frac{c_1(T)^2\|f\|_\infty^2}{n}.$$

Next we note that

$$\begin{aligned}
&\tilde{\mathbb{E}}\left\{\left|\log M^{\delta,i}(t) - \log M^i(t)\right|^2\right\}\\
&\le 2\int_0^T \mathbb{E}\left|\left(\mu^i(\eta_\delta(s))^* - \frac{1}{2}\tilde{A}(\eta_\delta(s))^*\right)\Sigma(s)^{-1} - \left(\mu^i(s)^* - \frac{1}{2}\tilde{A}(s)^*\right)\Sigma(s)^{-1}\right|^2 ds\\
&\quad + T\int_0^T \mathbb{E}\left|\left|\left(\mu^i(\eta_\delta(s))^* - \frac{1}{2}\tilde{A}(\eta_\delta(s))^*\right)\Sigma(s)^{-1}\right|^2 - \left|\left(\mu^i(s)^* - \frac{1}{2}\tilde{A}(s)^*\right)\Sigma(s)^{-1}\right|^2\right|^2 ds\\
&\le c_2(T)\delta^\alpha.
\end{aligned}$$

Let $\tilde{d}$ be the Waserstein metric on $\mathcal{M}_F(\bar{\mathbb{R}}^d)$, namely,

$$\tilde{d}(v_1, v_2) := \inf\left\{|\langle v_1 - v_2, f\rangle| :\ \ |f(x)| \le 1\ \forall x,\ \ |f(x) - f(y)| \le |x - y|\ \forall x, y\right\}.$$

Then

$$\begin{aligned}
&\tilde{d}(V^{n,\delta}(t), V^n(t))\\
&\le \frac{1}{n}\sum_{i=1}^n \left(M^{\delta,i}(t) \vee M^i(t)\right)\left(|\mu^{\delta,i}(t) - \mu^i(t)| + |\log M^{\delta,i}(t) - \log M^i(t)|\right).
\end{aligned}$$

Thus

$$\tilde{\mathbb{E}}\tilde{d}(V^{n,\delta}(t), V^n(t)) \le c_3(T)\delta^\alpha.$$

It is clear that $d \le \tilde{d}$. So

$$\begin{aligned}
\tilde{\mathbb{E}}\left(d(\bar{V}^n(t), V(t))\right) &\le \tilde{\mathbb{E}}\tilde{d}(V^{n,1/n^{1/2\alpha}}, V^n(t)) + \tilde{\mathbb{E}}d(V^n(t), V(t))\\
&\le c_2(T)(n^{-1/2\alpha})^\alpha + \frac{c_1(T)}{\sqrt{n}} = \frac{c_3(T)}{\sqrt{n}}. \qquad \square
\end{aligned}$$

4.2. Case 2: Random $\tilde{\Sigma}$. In this subsection we discuss a case when the volatility is a random process with the following structure: $\sigma(t)$ is a function of $\mu(t)$ plus a white noise, namely,

$$d\sigma_{ij}(t) = h^{ij}(\mu(t))dt + dB^{ij}(t), \qquad 1 \le i \le j \le d, \tag{4.13}$$

where $B^{ij}(t)$, $1 \le i \le j \le d$, are independent Brownian motions. Note that the independence assumption is imposed for ease of presentation only. In fact, the arguments below remain valid if we replace the $\frac{d(d+1)}{2}$-dimensional Brownian motion $(B^{ij}(t),$ $1 \le i \le j \le d)$ with a linear transformation of this process.

In this case, we have a classical filtering problem with observations $\tilde{S}(t)$ and $\Sigma(t) \equiv (\sigma_{ij}(t))$ given by (3.6) and (4.13), respectively. Then

$$\tilde{B}_{ij}(t) := \sigma_{ij}(t) - \int_0^t \left\langle U(s), h^{ij}\right\rangle ds$$

are Brownian motions adapted to $\mathcal{G}_t$ and are independent of $\nu(t)$. Namely, $\tilde{\nu}(t) :=$ $(\tilde{B}_{ij}(t), \nu(t); 1 \le i \le j \le d)$ forms the $\left(\frac{d(d+1)}{2} + d\right)$-dimensional innovation process for

the filtering problem. The FKK equation can be derived similarly to the arguments as in subsection 4.1 leading to (4.10). Namely, we need only replace $\nu(t)$ and $\big(\mu(t) - \frac{1}{2}\tilde{A}(t)\big)^*\Sigma(t)^{-1}$ with $\tilde{\nu}(t)$ and $\big(h_{ij}(\mu(t)),\ \big(\mu(t) - \frac{1}{2}\tilde{A}(t)\big)^*\Sigma(t)^{-1},\ 1 \le i \le j \le d\big)$, respectively. The numerical scheme can also be given by employing a similar method from subsection 4.1. We leave the details to the interested reader.

Remark 4.5. The condition (4.1) does not hold for the present model. In fact, $\tilde{B}_{ij}(t)$ is a $\mathcal{G}_t$-martingale independent of $\nu(t)$; hence, it cannot be represented as the stochastic integrals with respect to $\nu(t)$.

5. Optimization. In this section, we derive the optimal strategy of the partially observed mean-variance problem (2.3) in three steps. First, we derive from (3.1) a constraint on the terminal wealth $x(T)$. Then, we solve a static optimization problem under this constraint to find the best terminal wealth, $x^*(T)$. After that, we show that there is a portfolio such that $x^*(T)$ is its terminal wealth. Finally, we give a numerical scheme in solving the BSDE involved in deriving the optimal portfolio and prove the convergence of the proposed scheme.

5.1. The optimal value of $x(T)$. Let

$$\rho(t) := \exp\bigg(-\int_0^t \mu_0(s)ds - \sum_{i,j=1}^d \int_0^t \sigma_{ij}^{-1}(s)(\bar{\mu}_i(s) - \mu_0(s))d\nu_j(s) - \frac{1}{2}\sum_{j=1}^d \int_0^t \bigg|\sum_{i=1}^d \sigma_{ij}^{-1}(s)(\bar{\mu}_i(s) - \mu_0(s))\bigg|^2 ds\bigg),$$

where, with an abuse of notation, $\sigma_{ij}^{-1}(s)$ denotes the ijth element of $\Sigma(s)^{-1}$. Denote

$$\theta_j(t) := \sum_{i=1}^d \sigma_{ij}^{-1}(t)(\bar{\mu}_i(t) - \mu_0(t)). \tag{5.1}$$

By Itô's formula, we get

$$d\rho(t) = -\rho(t)\mu_0(t)dt - \sum_{j=1}^d \rho(t)\theta_j(t)d\nu_j(t), \quad \rho(0) = 1. \tag{5.2}$$

Applying Itô's formula to (5.2) and (3.1), we have

$$d(x(t)\rho(t)) = \rho(t)\sum_{i,j=1}^d \sigma_{ij}(t)u_i(t)d\nu_j(t) - x(t)\sum_{j=1}^d \rho(t)\theta_j(t)d\nu_j(t). \tag{5.3}$$

Therefore, $x(t)\rho(t)$ is a $\mathcal{G}_t$-martingale and hence,

$$x(t) = \rho(t)^{-1}\mathbb{E}(\rho(T)x(T)|\mathcal{G}_t).$$

In particular, taking $t = 0$ we have

$$\mathbb{E}(\rho(T)x(T)) = x(0) = x_0. \tag{5.4}$$

Definition 5.1. *A contingent claim $v \in \mathbb{H} := L^2(\Omega, \mathcal{G}_T, P)$ is called* attainable *if there is $\Phi(s) \in L^2_{\mathcal{G}}(0, T; \mathbb{R}^d)$ such that*

$$v\rho(T) = \mathbb{E}(v\rho(T)) + \int_0^T \Phi(s)^* d\nu(s).$$

Denote the collection of all attainable contingent claims by $AC(\mathcal{G})$. It is easy to see that $AC(\mathcal{G})$ is a subspace of $\mathbb{H}$. Denote by $\mathbb{H}_0$ the closure of $AC(\mathcal{G})$.

DEFINITION 5.2. *The market is complete if* $AC(\mathcal{G}) = \mathbb{H}$.

Remark 5.3. If $\Sigma(t)$ is nonrandom as in subsection 4.1, then the market is complete.

Now we seek

$$\min_{v\in\mathbb{H}_0} \mathbb{E}(v-z)^2 \tag{5.5}$$

subject to constraints

$$\mathbb{E}v = z \quad \text{and} \quad \mathbb{E}(\rho(T)v) = x_0. \tag{5.6}$$

THEOREM 5.4. *Let* α *and* β *be the orthogonal projections on* $\mathbb{H}_0$ *of* 1 *and* $\rho(T)$*, respectively. Then the optimal solution to the optimization problem* (5.5) *under constraint* (5.6) *is given by*

$$v = \frac{(z\langle\beta,\beta\rangle_{\mathbb{H}} - x_0\langle\alpha,\beta\rangle_{\mathbb{H}})\,\alpha + (-z\langle\alpha,\beta\rangle_{\mathbb{H}} + x_0\langle\alpha,\alpha\rangle_{\mathbb{H}})\,\beta}{\langle\alpha,\alpha\rangle_{\mathbb{H}}\langle\beta,\beta\rangle_{\mathbb{H}} - \langle\alpha,\beta\rangle_{\mathbb{H}}^2}. \tag{5.7}$$

Proof. Note that

$$\mathbb{E}(v-z)^2 = \mathbb{E}(v-z\alpha)^2 + z^2\mathbb{E}(1-\alpha)^2.$$

So, the optimization problem becomes

$$\min_{v\in\mathbb{H}_0} \|v-z\alpha\|_{\mathbb{H}}^2$$

subject to constraints

$$\langle v,\alpha\rangle_{\mathbb{H}} = z \quad \text{and} \quad \langle v,\beta\rangle_{\mathbb{H}} = x_0. \tag{5.8}$$

Using Lagrange multipliers, we define

$$f(v,\lambda_1,\lambda_2) := \|v-z\alpha\|_{\mathbb{H}}^2 - 2\lambda_1(\langle v,\alpha\rangle_{\mathbb{H}} - z) - 2\lambda_2(\langle v,\beta\rangle_{\mathbb{H}} - x_0),\ (v,\lambda_1,\lambda_2)\in\mathbb{H}\times\mathbb{R}^2.$$

Taking the Fréchet derivative and setting it to be zero, we have

$$2(v-z\alpha) - 2\lambda_1\alpha - 2\lambda_2\beta = 0.$$

This implies

$$v = z\alpha + \lambda_1\alpha + \lambda_2\beta.$$

Plugging the above into the constraints (5.8), we obtain the values of λ_1 and λ_2, which lead to (5.7). ∎

5.2. Replicate v. In this subsection, we seek the wealth process $x(t)$ which satisfies (3.1) and $x(T) = v$, where $v \in \mathbb{H}_0$ is given by (5.7). Namely, we seek a solution to the following BSDE:

$$\begin{cases} dx(t) = \big(x(t)\mu_0(t) + \sum_{j=1}^d(\bar{\mu}_j(t) - \mu_0(t))u_j(t)\big)dt + \sum_{i,j=1}^d \sigma_{ij}(t)u_i(t)d\nu_j(t),\ 0\le t\le T, \\ x(T) = v. \end{cases} \tag{5.9}$$

Let

$$Z_j(t) := \sum_{i=1}^{d} \sigma_{ij}(t) u_i(t).$$

Then

$$u_i(t) = \sum_{j=1}^{d} \sigma_{ij}^{-1}(t) Z_j(t) \tag{5.10}$$

and (5.9) becomes

(5.11)
$$\begin{cases} dx(t) = \left(x(t)\mu_0(t) + \sum_{j=1}^{d} \theta_j(t) Z_j(t) \right) dt + \sum_{j=1}^{d} Z_j(t) d\nu_j(t), \ 0 \le t \le T, \\ x(T) = v. \end{cases}$$

If $\mathcal{F}_t^{\nu} = \mathcal{G}_t$, then (5.11) is the usual BSDE whose solution exists, assuming that $\mu_0(t)$ and $\theta_j(t)$ are essentially bounded (cf. [28]). However, it is well known that, in general, $\mathcal{F}_t^{\nu} \neq \mathcal{G}_t$.

Now we prove the existence of a unique square integrable solution for the BSDE (5.11), under the following additional condition.

Assumption (*UB*). For some $\delta > 0$, $A(t) \ge \delta I$ a.s., almost every $t \ge 0$, and $\mu_0(t)$ and $\mu(t)$ are essentially bounded.

Under this assumption, $\theta_j(t)$ is also essentially bounded.

PROPOSITION 5.5. *If $v \in \mathbb{H}_0$, then* (5.11) *has a unique $\mathcal{G}_t$-adapted, square integrable solution* $(x(t), Z_j(t),\ j = 1, 2, \ldots, d)$.

Proof. If $(x(t), Z_j(t),\ j = 1, 2, \ldots, d)$ is a $\mathcal{G}_t$-adapted, square integrable solution to (5.11), as in (5.3), we have that

$$x(t)\rho(t) = x_0 + \sum_{j=1}^{d} \int_0^t \rho(s) \left(\sum_{i=1}^{d} \sigma_{ij}(s) u_i(s) - x(s)\theta_j(s) \right) d\nu_j(s)$$

is a $\mathcal{G}_t$-local martingale. Hence, there is an increasing sequence of $\mathcal{G}_t$-stopping times $\{\tau_n\}$ with $\tau_n \to T$ as $n \to \infty$ such that for each n,

$$x(t \wedge \tau_n)\rho(t \wedge \tau_n) = \mathbb{E}(x(T \wedge \tau_n)\rho(T \wedge \tau_n) | \mathcal{G}_t).$$

For any fixed $t \in [0, T]$,

$$x(t \wedge \tau_n)\rho(t \wedge \tau_n) \le \sup_{0 \le s \le T} x(s) \sup_{0 \le s \le T} \rho(s),$$

whereas the right-hand side of the above is a square integrable random variable by virtue of the Cauchy–Schwarz inequality and the standard L^2 estimation on the supernorm of the solutions to SDEs. Hence, we obtain by the dominated convergence theorem that

$$x(t)\rho(t) = \mathbb{E}(x(T)\rho(T) | \mathcal{G}_t).$$

Namely,

$$x(t) = \rho(t)^{-1} \mathbb{E}(v\rho(T) | \mathcal{G}_t). \tag{5.12}$$

This implies the uniqueness of the solution.

To prove the existence we first assume that $v \in AC(\mathcal{G})$. We show that $x(t)$ given by (5.12) is a solution to (5.11). As $v \in AC(\mathcal{G})$, $v\rho(T)$ is square integrable in view of Definition 5.1, and we have the representation

$$\mathbb{E}(v\rho(T)|\mathcal{G}_t) = \mathbb{E}(v\rho(T)) + \sum_{j=1}^{d} \int_0^t \Phi^j(s) d\nu_j(s), \tag{5.13}$$

where each Φ^j is square integrable. Define

$$Z_j(t) := x(t)\theta_j(t) + \rho(t)^{-1}\Phi^j(t), \quad 0 \le t \le T. \tag{5.14}$$

By Itô's formula, it is easy to show that $(x(t), Z(t)) \equiv (x(t), Z_j(t),\ j = 1, 2, \ldots, d)$ satisfies (5.11). Moreover, a stopping time argument exactly as in [28, pp. 352–353] establishes the square integrability of $(x(t), Z(t))$.

Next, let $v \in \mathbb{H}_0$. Then there is a sequence $\{v_n\} \subset AC(\mathcal{G})$ such that $v_n \to v$ in $\mathbb{H}$. By the above proof there is a unique square integrable solution $(x_n(t), Z_n(t))$ to (5.11) with $x_n(T) = v_n$. Moreover,

$$\sup_n \mathbb{E} \int_0^T (|x_n(t)|^2 + |Z_n(t)|^2) dt \le K \sup_n \mathbb{E}|v_n|^2 < +\infty;$$

see page 349, Theorem 2.2 in [28]. This implies that $(x_n(t), Z_n(t))$ is a bounded sequence in $L^2_{\mathcal{G}}(0, T; \mathbb{R}^{d+1})$. Hence there is a subsequence (still denoted as $(x_n(t), Z_n(t))$), along with $(x(t), Z(t)) \in L^2_{\mathcal{G}}(0, T; \mathbb{R}^{d+1})$, so that

$$(x_n(t), Z_n(t)) \to (x(t), Z(t)) \quad \text{weakly in } L^2_{\mathcal{G}}(0, T; \mathbb{R}^{d+1}).$$

By Mazur's theorem there is a sequence $(\tilde{x}_n(t), \tilde{Z}_n(t))$, each element of which is a convex combination of those in $\{(x_n(t), Z_n(t))\}$, so that

$$(\tilde{x}_n(t), \tilde{Z}_n(t)) \to (x(t), Z(t)) \quad \text{(strongly) in } L^2_{\mathcal{G}}(0, T; \mathbb{R}^{d+1}).$$

Since (5.11) is a linear equation, by a standard technique we conclude that $(x(t), Z(t))$ is a square integrable solution to (5.11). □

Summarizing, we get the following.

THEOREM 5.6. *For every z, there exists an optimal portfolio to the mean-variance problem* (2.3)*, which is a self-financed, admissible portfolio replicating v given by* (5.7)*. Moreover, this optimal portfolio $u(t)$ is given by* (5.10) *and the corresponding optimal wealth process is $x(t)$, where $(x(t), Z_j(t),\ j = 1, 2, \ldots, d)$ is the square integrable solution to* (5.11)*.*

So solving our partially observed mean-variance problem boils down to solving the BSDE (5.11). Numerical solutions to some classes of nonlinear BSDEs have been developed lately [29, 8]. However, in those works the drift coefficients of the BSDEs are assumed to be deterministic functions. In our model, the coefficients $\mu_0(t)$ and $\theta_j(t)$ are random in general. To the best of our knowledge, solving such a BSDE numerically remains open. In the next subsection, we shall give a numerical solution to this BSDE based upon the constructive proof of the last theorem.

5.3. Numerical solution. In this subsection, we assume that the market is complete (see Definition 5.2) and seek a numerical solution to (5.11). By virtue of the constructive proof of Proposition 5.5 the solution is given by (5.12) and (5.14). We now propose a numerical scheme to approximate (5.12) and (5.14).

To start with, note that as the market is complete, $\alpha = 1$ and $\beta = \rho(T)$. By (5.7), we get

$$v = z + \frac{x_0 - z\mathbb{E}\rho(T)}{\mathrm{Var}(\rho(T))}(\rho(T) - \mathbb{E}\rho(T)). \tag{5.15}$$

As in the proof of Proposition 5.5, the key to solving (5.11) is the martingale representation of the $\mathcal{G}_t$-martingale $\mathbb{E}(\rho(T)v|\mathcal{G}_t)$. We will establish a particle representation for this martingale.

Let (θ^1, ν^1), (θ^2, ν^2), ... be independent copies of (θ, ν) which appeared in (5.2). Now we define $\rho^i(t, t')$, $t, t' \geq 0$, in two steps. First, for $t \leq t'$, let $\rho^i(t, t') := \rho(t)$ which is given by (5.2). Second, for $t > t'$, let $\rho^i(t, t')$ be given by (5.2) with (b, ν) replaced by (b^i, ν^i):

$$d\rho^i(t, t') = -\rho^i(t, t')\mu_0(t)dt - \sum_{j=1}^{d} \rho^i(t, t')\theta_j^i(t)d\nu_j^i(t), \quad \rho^i(t', t') = \rho(t'). \tag{5.16}$$

Let $v^i(T, t)$ be given by (5.15) with $\rho(T)$ replaced by $\rho^i(T, t)$:

$$v^i(T, t) = z + \frac{x_0 - z\mathbb{E}\rho(T)}{\mathrm{Var}(\rho(T))}(\rho^i(T, t) - \mathbb{E}\rho(T)). \tag{5.17}$$

THEOREM 5.7. *Let v be given by* (5.15). *Then*

$$\mathbb{E}(\rho(T)v|\mathcal{G}_t) = \lim_{n\to\infty} \frac{1}{n} \sum_{i=1}^{n} \rho^i(T, t)v^i(T, t). \tag{5.18}$$

Proof. Note that the SDE (5.16) has a unique strong solution. Therefore, there exists a measurable functional $F_{t,T}$ such that

$$(\rho^i(T, t), v^i(T, t)) = F_{t,T}(\theta|_{[0,t]}, \nu|_{[0,t]}, \theta^i|_{[t,T]}, \nu^i|_{[t,T]}).$$

Note that $(\bar{\mu}(t), \nu(t))$ are $\mathcal{G}_t$-measurable. Further, as discussed in section 2, $\sigma_{ij}^{-1}(t)$ and $\mu_0(t)$ are also $\mathcal{G}_t$-measurable. Thus, $\theta(t)$ defined by (5.1) is $\mathcal{G}_t$-measurable and we have

$$(\rho^i(T, t), v^i) = G_{t,T}(S|_{[0,t]}, \theta^i|_{[t,T]}, \nu^i|_{[t,T]})$$

for a measurable functional $G_{t,T}$. By the independence of $S|_{[0,t]}$, $(\theta^i|_{[t,T]}, \nu^i|_{[t,T]})$, $i = 1, 2, \ldots$, it follows from the strong law of large numbers under the conditional probability (given $\mathcal{G}_t$) that (5.18) holds. ∎

For notational simplicity, we now assume $d = T = 1$. Denote the process in (5.18) by $N(t)$. By (5.13), we have

$$\langle N, \nu \rangle_t = \int_0^t \Phi(s) ds$$

which can be approximated by (cf. Jacod and Shiryaev [9, Theorem 1.4.47])

$$\sum_{k=1}^{m} (N(t_k) - N(t_{k-1}))(\nu(t_k) - \nu(t_{k-1}).$$

Based on the above, we now approximate Φ by piecewise constants, i.e., approximate Φ on $(\frac{k}{n}, \frac{k+1}{n})$ by

$$\begin{aligned} \Phi^n\left(\frac{k}{n}\right) := n \sum_{j=1}^{m} & \left(N\left(\frac{k-1}{n} + \frac{j}{mn}\right) - N\left(\frac{k-1}{n} + \frac{j-1}{mn}\right)\right) \\ & \times \left(\nu\left(\frac{k-1}{n} + \frac{j}{mn}\right) - \nu\left(\frac{k-1}{n} + \frac{j-1}{mn}\right)\right), \\ & n = 1, 2, \ldots, \end{aligned} \tag{5.19}$$

where $m = m_n$ is to be chosen later.

LEMMA 5.8. *For $1 < p < 2$, we have*

$$\begin{aligned} & \mathbb{E}\left| \Phi^n\left(\frac{k}{n}\right) - n \int_{\frac{k-1}{n}}^{\frac{k}{n}} \Phi(s) ds \right|^p \\ & \quad \le c\left(m^{\epsilon - p} + n^{\frac{p}{2}} m^{-\frac{p}{2}}\right) \left(\mathbb{E} \int_{\frac{k-1}{n}}^{\frac{k}{n}} \Phi(t)^2 dt \right)^{\frac{p}{2}}, \end{aligned} \tag{5.20}$$

for any $\epsilon > 0$, where c depends only on p.

Proof. Let

$$\pi(t) := \frac{k-1}{n} + \frac{j-1}{mn}, \qquad \text{for } \frac{k-1}{n} + \frac{j-1}{mn} \le t < \frac{k-1}{n} + \frac{j}{mn}.$$

Apply Itô's formula, we have

$$\begin{aligned} & \Phi^n\left(\frac{k}{n}\right) - n \int_{\frac{k-1}{n}}^{\frac{k}{n}} \Phi(s) ds \\ & \quad = n \int_{\frac{k-1}{n}}^{\frac{k}{n}} \left\{ \Phi(t)(\nu(t) - \nu(\pi(t))) + (N(t) - N(\pi(t))) \right\} d\nu(t). \end{aligned}$$

For $p \in (1,2)$, by Doob's inequality, we have

$$\begin{aligned}
&\mathbb{E}\left(\left|\Phi^n\left(\frac{k}{n}\right) - n\int_{\frac{k-1}{n}}^{\frac{k}{n}} \Phi(s)ds\right|^p\right) \\
&\quad \le c_p n^p \mathbb{E}\left(\int_{\frac{k-1}{n}}^{\frac{k}{n}} \left\{\Phi(t)^2(\nu(t)-\nu(\pi(t)))^2 + (N(t)-N(\pi(t)))^2\right\} dt\right)^{\frac{p}{2}} \\
&\quad \le c_p n^p \mathbb{E}\left(\left(\int_{\frac{k-1}{n}}^{\frac{k}{n}} \Phi(t)^2 dt\right)^{\frac{p}{2}} \sup_{\frac{k-1}{n}\le t\le \frac{k}{n}} (\nu(t)-\nu(\pi(t)))^p\right) \\
&\qquad + c_p n^p \mathbb{E}\left(\int_{\frac{k-1}{n}}^{\frac{k}{n}} (N(t)-N(\pi(t)))^2 dt\right)^{\frac{p}{2}} \\
&\quad \le c_p n^p \left(\mathbb{E}\int_{\frac{k-1}{n}}^{\frac{k}{n}} \Phi(t)^2 dt\right)^{\frac{p}{2}} \left(\mathbb{E}\sup_{\frac{k-1}{n}\le t\le \frac{k}{n}} (\nu(t)-\nu(\pi(t)))^{\frac{2p}{2-p}}\right)^{\frac{2-p}{2}} \\
&\qquad + c_p n^p \left(\mathbb{E}\int_{\frac{k-1}{n}}^{\frac{k}{n}} (N(t)-N(\pi(t)))^2 dt\right)^{\frac{p}{2}}.
\end{aligned}$$

Note that for independent, identically distributed (i.i.d.) normal random variables ξ_i with mean 0 and variance σ^2, we have

$$\mathbb{E}\sup_{1\le i\le m} \xi_i^p \le \left(\mathbb{E}\sup_{1\le i\le m} \xi_i^{p/\epsilon}\right)^{\epsilon} \le \left(\mathbb{E}\sum_{i=1}^m \xi_i^{p/\epsilon}\right)^{\epsilon} \le cm^{\epsilon}\sigma^p$$

for any $\epsilon > 0$. Thus

$$\left(\mathbb{E}\sup_{\frac{k-1}{n}\le t\le \frac{k}{n}} (\nu(t)-\nu(\pi(t)))^{\frac{2p}{2-p}}\right)^{\frac{2-p}{2}} \le \frac{cm^{\epsilon}}{(nm)^p}.$$

On the other hand,

$$\begin{aligned}
\mathbb{E}\int_{\frac{k-1}{n}}^{\frac{k}{n}} (N(t)-N(\pi(t)))^2 dt &= \mathbb{E}\int_{\frac{k-1}{n}}^{\frac{k}{n}} \int_{\pi(t)}^t \Phi(s)^2 ds dt \\
&= \mathbb{E}\sum_{j=1}^m \int_{\frac{k-1}{n}+\frac{j-1}{mn}}^{\frac{k-1}{n}+\frac{j}{mn}} \int_{\frac{k-1}{n}+\frac{j-1}{mn}}^t \Phi(s)^2 ds dt \\
&\le \frac{1}{nm}\mathbb{E}\int_{\frac{k-1}{n}}^{\frac{k}{n}} \Phi(t)^2 dt.
\end{aligned}$$

Equation (5.20) then follows easily. □

Next we need to approximate $N(k\delta)$, $k = 0, 1, \ldots, mn$, where $\delta = \frac{1}{mn}$. To this end, we need to approximate $\rho^i(t,t')$ by time-discretization. Recall that $\rho^i(t,t')$ is given by (5.2) for $t \le t'$ and (5.16) for $t > t'$.

For $j \le k$, let

$$\begin{aligned}
\rho^{i,\delta}(j\delta, k\delta) := \rho^i((j-1)\delta, k\delta) &- \rho^i((j-1)\delta, k\delta)\mu_0((j-1)\delta)\delta \\
&- \rho^i((j-1)\delta, k\delta)\theta((j-1)\delta)(\nu(j\delta) - \nu((j-1)\delta)),
\end{aligned}$$

with $\rho^{i,\delta}(0,k\delta) := 1$. For $j > k$, let

$$\begin{aligned}\rho^{i,\delta}(j\delta,k\delta) := \rho^i((j-1)\delta,k\delta) - \rho^i((j-1)\delta,k\delta)\mu_0((j-1)\delta)\delta \\ -\rho^i((j-1)\delta,k\delta)\theta((j-1)\delta)(\nu^i(j\delta)-\nu^i((j-1)\delta)).\end{aligned}$$

Let

$$v^{i,\delta}(T,k\delta) := z + \frac{x_0 - z\mathbb{E}\rho(T)}{\mathrm{Var}(\rho(T))}(\rho^{i,\delta}(T,k\delta) - \mathbb{E}\rho(T)),$$

and

$$N^{n,\delta}(k\delta) := \frac{1}{n}\sum_{i=1}^{n}\rho^{i,\delta}(T,k\delta)v^{i,\delta}(T,k\delta). \tag{5.21}$$

Now, in view of (5.14), we define

$$Z^n(t) := \rho^n\left(\frac{[nt]}{n}\right)^{-1}\left(\theta^n\left(\frac{[nt]}{n}\right)N^{n,\delta}\left(\frac{[nt]}{n}\right) + \Phi^{n,\delta}\left(\frac{[nt]}{n}\right)\right), \tag{5.22}$$

where $\delta = \frac{1}{m_n n}$ (with m_n suitably chosen), $\Phi^{n,\delta}$ is defined as in (5.19) for Φ^n with N replaced by $N^{n,\delta}$, the approximate θ^n and ρ^n of θ and ρ can be defined by the same method as in section 4.1 such that $\forall\ \beta > 1$,

$$\mathbb{E}\sup_{0\le t\le T}\left|\rho^n\left(\frac{[nt]}{n}\right)^{-1}\theta^n\left(\frac{[nt]}{n}\right)N^{n,\delta}\left(\frac{[nt]}{n}\right) - \rho(t)^{-1}\theta(t)N(t)\right|^{\beta} \to 0, \tag{5.23}$$

and

$$\mathbb{E}\sup_{0\le t\le T}\left|\rho^n\left(\frac{[nt]}{n}\right)^{-1} - \rho(t)^{-1}\right|^{\beta} \to 0. \tag{5.24}$$

Finally, we define the *approximate portfolio* by

$$u^n(t) := \Sigma(t)^{-1}Z^n(t).$$

Since we do not know the continuity of $\Phi(s)$, we cannot obtain $\Phi^n(s) \to \Phi(s)$ (cf. (5.23)). Therefore, it is not clear whether $u^n(t) \to u(t)$. However, we have the convergence of their corresponding terminal wealths.

THEOREM 5.9. *Suppose that* $\mathbb{E}(|v\rho(T)|^2) < \infty$. *Then*

$$\mathbb{E}|x^n(T) - x(T)| \to 0 \quad \text{as } n \to \infty. \tag{5.25}$$

Proof. For simplicity of notation, we assume $\mu_0(t) \equiv 0$. Then by (5.11), we have

$$\begin{aligned}\mathbb{E}|x^n(T) - x(T)| \le c\mathbb{E}\int_0^T |\theta^n(t)Z^n(t) - \theta(t)Z(t)|^2dt \\ +c\mathbb{E}\left(\int_0^T |Z^n(t) - Z(t)|^2dt\right)^{1/2}.\end{aligned}$$

We estimate only the second term (the first can be evaluated similarly). Note that by (5.22) and (5.19),

$$|Z^n(t) - Z(t)| \le \left| \rho^n \left(\frac{[nt]}{n} \right)^{-1} \theta^n \left(\frac{[nt]}{n} \right) N^{n,\delta} \left(\frac{[nt]}{n} \right) - \rho(t)^{-1} \theta(t) N(t) \right| + \left| \rho^n \left(\frac{[nt]}{n} \right)^{-1} \Phi^{n,\delta} \left(\frac{[nt]}{n} \right) - \rho(t)^{-1} \Phi(t) \right|.$$

By (5.23), the first term on the right-hand side of the above inequality tends to 0. Note that

$$\begin{aligned}
&\mathbb{E}\left[\left(\int_0^T \left| \rho^n \left(\frac{[nt]}{n} \right)^{-1} \Phi^{n,\delta} \left(\frac{[nt]}{n} \right) - \rho(t)^{-1} \Phi(t) \right|^2 dt \right)^{\frac{1}{2}} \right] \\
&\quad \le \mathbb{E}\left[\left(\int_0^T \rho^n \left(\frac{[nt]}{n} \right)^{-2} \left| \Phi^{n,\delta} \left(\frac{[nt]}{n} \right) - \Phi^n \left(\frac{[nt]}{n} \right) \right|^2 dt \right)^{\frac{1}{2}} \right] \\
&\qquad + \mathbb{E}\left[\left(\int_0^T \left| \rho^n \left(\frac{[nt]}{n} \right)^{-2} - \rho(t)^{-2} \right| \Phi^n \left(\frac{[nt]}{n} \right)^2 dt \right)^{\frac{1}{2}} \right] \\
&\qquad + \mathbb{E}\left[\left(\frac{1}{n} \sum_{k=1}^n \left| \Phi^n \left(\frac{k}{n} \right) - \int_{\frac{k-1}{n}}^{\frac{k}{n}} \Phi(s) ds \right|^2 \sup_{0 \le t \le T} \rho(t)^{-2} \right)^{\frac{1}{2}} \right] \\
&\qquad + \mathbb{E}\left[\left(\sum_{k=1}^n \int_{\frac{k-1}{n}}^{\frac{k}{n}} \left| \Phi(t) - n \int_{\frac{k-1}{n}}^{\frac{k}{n}} \Phi(s) ds \right|^2 \sup_{0 \le t \le T} \rho(t)^{-2} \right)^{\frac{1}{2}} \right].
\end{aligned}$$

The convergence of the first term follows from similar arguments in subsection 4.1, that of the second term from (5.24), and that of the fourth term from the same arguments as in the proof of Lebesgue's continuity theorem; namely, first approximate Φ by uniformly continuous functions and then prove the conclusion for such functions. Finally, the third term is dominated by

$$\begin{aligned}
&\mathbb{E} \max_{1 \le k \le n} \left| \Phi^n \left(\frac{k}{n} \right) - \int_{\frac{k-1}{n}}^{\frac{k}{n}} \Phi(s) ds \right| \sup_{0 \le t \le T} \rho(t)^{-1} \\
&\quad \le \left(\mathbb{E} \sum_{k=1}^n \left| \Phi^n \left(\frac{k}{n} \right) - \int_{\frac{k-1}{n}}^{\frac{k}{n}} \Phi(s) ds \right|^p \right)^{\frac{1}{p}} \left(\mathbb{E} \sup_{0 \le t \le T} \rho(t)^{-\frac{p}{p-1}} \right)^{\frac{p-1}{p}} \\
&\quad \le cn \left(m^{\epsilon - p} + n^{\frac{p}{2}} m^{-p} \right)
\end{aligned}$$

which converges to 0 if we take $m = n^\beta$ with $\beta > \max(\frac{1+\epsilon}{p}, \frac{1}{2})$. □

Remark 5.10. It follows from (5.25) that $\mathbb{E}x^n(T) \to \mathbb{E}x(T)$. However, it is not clear whether $\mathrm{Var}(x^n(T)) \to \mathrm{Var}(x(T))$. To achieve this, we need a higher moment (in p) in (5.20) for which we require $\int_0^T \Phi(s)^2 ds$ to have a higher moment. To be

precise, if we assume that $v\rho(T)$ has a moment of order $p' > 2$, then

$$\mathbb{E}\left[\left(\int_0^T \Phi(s)^2 ds\right)^{p'/2}\right] < \infty.$$

The proof of (5.20) can be adapted for $2 < p < p'$ and, hence, (5.25) can be strengthened to

$$\mathbb{E}\left(|x^n(T) - x(T)|^2\right) \to 0.$$

In this case we get the convergence of both $\mathbb{E}x^n(T)$ and $\mathrm{Var}(x^n(T))$.

Remark 5.11. If the market is not complete, the numerical approximation of this section remains valid if we replace 1 and $\rho^i(T,t)$ with their projections α and β^i on $\mathbb{H}_0$ (i.e., use the formula (5.7) instead of (5.15)). However, it remains *open* how to calculate α and β^i numerically.

PARTIALLY OBSERVED INVENTORY SYSTEMS: THE CASE OF ZERO-BALANCE WALK*

ALAIN BENSOUSSAN†, METIN ÇAKANYILDIRIM‡, AND SURESH P. SETHI§

Abstract. In many inventory control contexts, inventory levels are only partially (i.e., not fully) observed. This may be due to nonobservation of demand, spoilage, misplacement, or theft of inventory. We study a partially observed inventory system where the demand is not observed, inventory level is noticed when it reaches zero, the unmet demand is lost, and replenishment orders must be decided so as to minimize the total discounted costs over an infinite horizon. This problem has an infinite-dimensional state space, and for it we establish the existence of a feedback policy when single-period costs are bounded or when the discount factor is sufficiently small. We also provide an approximately optimal feedback policy that uses a finite state representation.

Key words. stochastic inventory problem, partial observations, the Zakai equation, lost sales

1. Introduction.

Inventory control is among the most important topics in operations research because of large investments in inventory and their effect on the profitability of the firms. In 1999, for example, the investment into the inventory by U.S. businesses alone amounted to 1.1 trillion dollars [31]. Because of the importance of inventory control decisions, there has resulted an extensive literature on the topic [3, 31]. For the motivation of our research, one of the critical assumptions in the vast inventory literature, dating back to at least the Harris lot size model of 1913 [17], has been that the level of inventory at any given time is fully observed. Some of the most celebrated results, such as the optimality of the base stock policy [1], have been obtained under the assumption of full observation. Yet the inventory level is often not fully observed in practice, as elaborated below. In such cases, most of the well-known inventory policies are not even admissible, let alone optimal.

The study of systems with partially observed inventories is important in many real-life situations. We shall introduce some of the possible instances where inventories can only be partially observed by the inventory manager (IM).

Transaction errors. Unintentional mistakes happen from time to time during inventory transactions. Some of these transactions are inventory counting, receiving, checking out at the cash register, etc. An example is checking out at a grocery store. If a customer buys two types of different soups each at the same price, the sales clerk often scans only one soup type twice. A similar example with different types of yogurts can be found in Raman, DeHoratius, and Ton [26]. In such cases, the recorded inventory levels of the items involved will differ from their actual levels.

When stock-keeping units are discrete, it may be possible to eliminate counting errors. On the other hand, when they are not discrete, such as oil in a refinery, exact measurements are difficult to obtain. While measurement errors cause inventory to be not fully observed, it is often the mistakes in reporting transactions that lead to partial observation of inventories. Raman, DeHoratius, and Ton [26] report a retailer who has inaccurate inventory records for 65% of its stock-keeping units. It is roughly estimated that the retailer loses 10% of its current profit due to these inaccuracies. They go on to say: "[this particular retailer] is not an isolated case; this [inaccuracy] problem is common at other retailers." Common use of modern information technology tends to reduce transaction errors. However, as pointed out by Axsäter [3], deployment of big-ticket computer technology is not always economically feasible.

Misplaced inventory. When a part of the inventory on hand is misplaced, it is not available to meet a demand until it is found. Often the misplaced inventories are not immediately found, and thus they remain unobserved to the IM. This causes the total inventory that is available to meet the demand to become partially observed. Misplaced inventory can be quite large and have a significant impact on the bottom line. It is reported in [26] that customers of a "leading retailer" cannot find 16% of the items in the stores because those items are misplaced. Misplacement of the items reduces the profit by roughly 25% at this retailer.

Misplacement is more likely when the location of items in storage is altered dynamically. According to [3], "It is easier to keep the records accurate if the items have fixed locations. On the other hand, this can lead to inefficient space utilization. By dynamically locating items, the same item can be stored in more than one location." The recent trends in supply chain management such as crossdocking (see, e.g., p. 412 of [13]) also cause dynamic locations.

Misplaced inventories are eventually discovered either by inspection or by chance. When the misplaced items are placed in their proper shelves, they become available once again to meet customer demands. Thus, misplacements and their recoveries can cause the actual inventory to be, respectively, less and more than the recorded inventory.

Spoilage. Products can naturally lose their properties while they are held in the inventory [25]. Examples with limited lifetime are drugs, chemicals, and food products. If the lifetime is limited and not immediately observed, then the actual inventory is less than the recorded inventory, and it is partially observed.

If the lifetime is deterministic as in the case of drugs, an implementation of RFID (radio frequency identification) tags called SMC (smart medicine cabinet) can be used to track the expired drugs [28]. Thus, the SMC can make drug spoilage fully observed. However, investments into technology such as SMC must be justified with an economic analysis, which requires the evaluation of the optimal cost under partial observations [9]. As an example of random lifetime, consider the number of batteries in a Sears retail store. Only when these batteries are inspected (say by measuring their voltage, one by one) does the inventory level of fully functioning batteries become known. When the spoiled inventory is observed immediately, the associated model (e.g., [24]), in spite of being challenging to work with, has full observations.

In retail stores, customers can cause damage to products, making them unsuitable for sale. Some examples are tearing of a package to try on the contained cloth item, wearing down a shoe by trying it on and walking, erasing software on computers on demonstration, spilling food on clothes, and scratching a car during a test drive. So long as the damages are not detected by the IM, the actual inventory is not fully observed.

Product quality and yield. When the product quality is low or a production process has a low yield [29], the actual inventory is not known. Receipts at a warehouse can include products that are defective or that do not conform to quality standards. It is very often the case that nonconformance of a product is not immediately observed by the IM. Receipts are usually added to the inventory at the warehouse without full inspection. As a result, the inventory on record may consist of both nondefective products (available to meet customer demands) and defective products (not fit for sale). Since the defective products are not immediately observed, the actual (nondefective) inventory becomes partially observed.

If production lead times are long, an IM may have to place a particular order before observing the yields from previous orders, so that the production of the particular order is completed by a given due date. Thus, partial observability of inventory can be caused by due dates and long production lead times as well as process yields.

Theft. The items in the inventory can be stolen by thieves who violently break into the inventory storage, by the warehouse employees who calmly pilfer, or by the customers who shoplift. Since violent break-ins are generally investigated, they are usually observed and therefore not relevant for our study. We focus more on continuous pilferage or shoplifting, because they are not always observed without inventory inspections. Instances of theft at furniture retailers and at food wholesalers have been documented in [12, 23]. Axsäter [3] says: "... thefts may be a major problem. Apart from the loss in value, thefts ... also lead to inaccurate inventory records." Thus, the IM relying on inventory records ends up overestimating the available inventory until a stockout occurs. In this case, there are shortage costs in addition to costs of reordering, expediting, and re-receiving items to replace the stolen units. Typically, costs of the expedited items to urgently meet backlogged demands are much more than their regular costs.

When there is no physical inventory, i.e., the inventory is zero or negative, then none of the following would happen: transaction errors, misplaced inventories, spoilage, inventory level uncertainty due to yield and quality, or theft. Most companies pay utmost attention to an item when its inventory reaches zero. At these companies, employees walk around the shelves to identify the stocked-out items and verify the inventory levels for those items. This process is implemented at the office supplies store Staples and is called "zero-balance walk" in [16, 26]. Thus, a model based on a zero-balance walk process can be built by assuming that the inventory levels are fully observed when they are zero. It is the purpose of this paper to formulate and analyze a zero-balance walk model. This paper is part of a greater effort to build a comprehensive theory of inventory control under partial observations. In related works, we study some of the other inventory models with partial observations [6, 7, 8].

There have been a few studies of partial observations in the inventory control context. In these studies, partial observations are about demands rather than inventories. Among these, a common assumption is that of unobserved demands in the periods when lost sales occur. That is, the demand is observed fully when it is smaller than the available inventory. Otherwise, only the event that it is larger than the inventory is observed. When the underlying demand distribution is not known but estimated from the demand observations, partial demand observations limit the data available for estimation. This is called estimation with censored (demand) data. Ding, Puterman, and Bisi [14] and Lu, Song, and Zhu [22] have a multiperiod newsvendor model with censored demand. They assume the leftover inventory in a period to be salvaged entirely so that every period starts with zero inventory. This assumption decouples the periods from each other as far as the inventory evolution is concerned. However,

the periods are still coupled together by the current estimate of the demand distribution. The demand distribution is updated in a Bayesian fashion in each period with that period's demand or the observation of the lost sales event. Thus, there is an evolution equation that maps one period's demand distribution to the next period's. This evolution is affected by the choice of the order quantity. Before [14], Lariviere and Porteus [21] treated a similar problem for the restricted case of exponential demand distributions with gamma conjugate priors.

Treharne and Sox [27] study a periodic review inventory model with Markov modulated demand. A simple example of such a demand occurs when there are two demand states—High and Low—of a Markov chain and there are two demand distributions, one for each state. Unlike the Markovian demand cases (treated, e.g., in [10, 11]), it is not observed whether the demand state is High or Low. Instead, probabilities are used to represent the event that the demand state is High or Low. These probabilities along with the current level of inventory constitute the state of the system. The probabilities are updated in each period in accordance with that period's demand. Neither the current level of inventory nor the order size affects the probability updates. Evolution of the probabilities that capture partial observability is totally independent of the order quantities. The evolution equations can be written down in the first period, and they will include the random demands in the forthcoming periods. To make the discussion simple, here we mention only two demand states, but Treharne and Sox consider finitely many demand states. Consequently, they have a finite-dimensional state for their system.

The models we have described above make simplifying assumptions to end up with an easily workable setup. Ding, Puterman, and Bisi assume that the leftover inventory is salvaged every period, while Treharne and Sox have updates of the probabilities which are independent of the controls. Thus, they can capture only a limited amount of the dynamics associated with partial observations. Besides, they do not consider the issue of existence of optimal policies. Consequently, they do not require the methodology developed in this paper. Without such a methodology, however, inventory models with partial observations will remain largely unexplored.

A main reason for why the analysis of inventory problems under partial observations has been neglected lies in its mathematical difficulty. Whereas one works with a finite-dimensional state space in the full observation case, one usually has to deal with an infinite-dimensional state space in the partial observation setting. More specifically, the inventory level at a given time is no longer a system state in $\Re^n$; it must now be represented by its conditional probability given some limited information available at that time. Thus, the analysis takes place in the space of probability distributions. This is, of course, inevitable, and simplifies only in particular situations when, for instance, the separation principle applies; see [5] for an example.

Concerning controls of dynamic systems in general, a great step forward was achieved in the applied mathematics and engineering control literature, when the Zakai equation [30] was discovered. Prior to that, the evolution of the conditional probability had been studied with the highly nonlinear Kushner equation [18]. The Zakai equation uses a transformation that changes the Kushner equation into a pair of linear equations. This transformation corresponds to the concept of "change of measure" [15]. While it does not remove the infinite dimensionality, the linearity has permitted a number of important control problems with partial observations to be solved [5]. Of course, there remain numerical difficulties due to the infinite dimensionality of the state. Nevertheless, a sound theory is available.

The key idea in going from the Kushner equation to the Zakai equation is in in-

troducing unnormalized conditional probabilities in place of conditional probabilities. This linearizes the state equation, and the problem becomes much simpler to study. Ideas of this kind have not been introduced yet in the context of solving partial observation control problems in management. While the standard Zakai setup cannot be directly applied to inventory problems, we show that unnormalized conditional probabilities can be introduced and are indeed quite appropriate.

In the next section, we formulate the problem with normalized probabilities and switch to unnormalized probabilities. In sections 3 and 4, we examine the existence and uniqueness of the solution under the assumptions of bounded costs, bounded order quantities, and small discount rates. An asymptotically optimal control scheme is provided in section 5. Section 6 includes a brief conclusion and directions for future research.

2. The zero-balance walk model. We study a periodic review inventory problem with partially observed inventory levels. In our model, the inventory levels are not automatically observed by the IM who decides on order quantities. The order of events in any given period t is as follows: The IM observes the event when the inventory level falls to zero, but he does not observe the inventory level when it is positive. The manager determines how much to order and the order is delivered instantaneously. Next the customer demand occurs, but it is not observed by the IM unless the inventory level drops to zero. In each period, the IM incurs inventory related costs, but he does not observe these costs immediately. Lastly the state defining the inventory level is updated for the next period.

In classical inventory settings, the inventory level I_t at the beginning of period t is observed, and is used to determine the order quantity q_t in period t. Each period t has a random demand D_t defined on the probability space $(\Omega, \mathcal{F}, P)$. The demand is met, to the extent possible, from the on-hand stock $I_t + q_t$. We suppose that the demand that is not immediately met from the on-hand stock is lost. Then the evolution of inventory dynamics is given as follows:

$$I_{t+1} = (I_t + q_t - D_t)^+ \quad \text{for } t \geq 1. \tag{1}$$

We assume demand D_t to be independently and identically distributed (i.i.d.) random variables with the same distribution as D, where the density and the cumulative distribution function of D are denoted by f and F, respectively. Let $\bar{F} = 1 - F$.

When the demand is met entirely, inventory holding costs apply to the remaining inventory. Otherwise, there are lost sales costs. It is well known that a base stock (or an order up to S) policy is optimal for this setting. We investigate the validity of the optimality of a base stock policy, or lack of it, for the zero-balance walk model.

In the zero-balance walk model, the inventory levels are partially observed by the IM as follows:

$$I_1 \text{ is either 0 or its distribution is known.} \tag{2}$$

In general, the IM does not observe the demand or the inventory level. However, looking at empty shelves and concluding $I_t = 0$ does not take much effort, and constitutes a free observation. Thus, we allow I_t to be observed only when the inventory shelf is empty, i.e., $[I_t = 0]$. To study such partial observations of the inventory levels, we introduce a signal (message) random variable

$$z_t := \mathbb{1}_{I_t=0}, \quad t \geq 1. \tag{3}$$

The signal z_t is a discrete-time Markov chain with the state space $\{0,1\}$: 1 means an empty shelf and 0 means a nonempty shelf.

When the inventory levels are fully observed, the order q_t is adapted to the sigma field $\mathcal{F}_t := \sigma(\{I_j : 1 \le j \le t\})$ generated by the inventory levels observed by period t. Note that the demand observations up to and including the beginning of period t also generate the same field, i.e., $\mathcal{F}_t = \sigma(\{I_1, D_j : 1 \le j \le t-1\})$. With our partial observations model, q_t is adapted to $\mathcal{Z}_t := \sigma(\{z_j : 1 \le j \le t\})$. Clearly $\mathcal{Z}_t \subset \mathcal{F}_t$, so our partial observations model must decide on order quantities on the basis of less than full information.

Given a stationary cost function $c(I_t, q_t)$ that depends on the beginning inventory level I_t and the order size q_t in period t, and with $\tilde{q}$ defining the admissible sequence of actions $\tilde{q} = \{q_1, q_2, \dots\}$, the total discounted cost is defined by

$$J(\zeta, \pi, \tilde{q}) := \mathrm{E} \sum_{t=1}^{\infty} \alpha^t c(I_t, q_t), \tag{4}$$

where $\alpha < 1$ is the discount factor. The initial conditions are a pair $(\zeta, \pi(x))$, where ζ is 1 or 0. If ζ is 1, then $I_1 = 0$. If ζ is 0, then $I_1 > 0$ and $\pi(\cdot)$ is the probability distribution of I_1. We look for an admissible control $\tilde{q} = \{q_1, q_2, \dots\}$, with q_t adapted to $\mathcal{Z}_t$, $t \ge 1$, such that $J(\zeta, \pi, \tilde{q})$ is minimized.

Special cases. To make the form of the single-period cost $c(I, q)$ concrete, we can consider $c(I, q) = c_1 q + hI + b\mathrm{E}[(D - I - q)^+]$, which is often used in the inventory control literature [11]. The cost parameters c_1, h, and b can be interpreted as the cost of purchasing an item, the cost of holding an item in the inventory charged at the beginning of a period, and the opportunity cost of not selling an item when there is demand for it. Since $b\mathrm{E}[(D - I - q)^+] \le b\mathrm{E}[D]$, $c(I, q)$ is of linear growth in I and q. Another example includes a nonzero fixed cost of ordering. These observations will inspire an assumption on the bounds of the general single-period cost $c(I, q)$ in section 3.

2.1. Evolution of state probabilities. We now develop the conditional probability density $\pi_t(.)$ of I_t given $\mathcal{Z}_{t-1}$ and $I_t > 0$. By definition,

$$\int_0^x \pi_t(y)dy = \mathrm{P}(I_t \le x | \mathcal{Z}_{t-1}, I_t > 0).$$

Since the event $[I_t = 0]$ is observable, conditional probabilities are needed only when $I_t > 0$.

For any real and bounded test function $\varphi(.)$, we can use the conditional Bayes theorem (e.g., [15]) to obtain

$$\int_0^\infty \varphi(x)\pi_t(x)dx = \mathrm{E}[\varphi(I_t)|\mathcal{Z}_{t-1}, I_t > 0] = \frac{\mathrm{E}[\varphi(I_t)\mathbb{1}_{I_t>0}|\mathcal{Z}_{t-1}]}{\mathrm{E}[\mathbb{1}_{I_t>0}|\mathcal{Z}_{t-1}]} = \frac{\mathrm{E}[\varphi(I_t)\mathbb{1}_{I_t>0}|\mathcal{Z}_{t-1}]}{\mathrm{P}(I_t > 0|\mathcal{Z}_{t-1})}. \tag{5}$$

In order to obtain a recursive expression for π_t in terms of π_{t-1}, we begin with expressing $\mathrm{E}(\varphi(I_t)|\mathcal{Z}_t)$ in terms of conditional expectations with respect to $\mathcal{Z}_{t-1}$ in the next lemma.

Lemma 1.

$$\begin{aligned} E(\varphi(I_t)|\mathcal{Z}_t) &= \mathbb{1}_{I_t=0}\varphi(0) + \mathbb{1}_{I_t>0}\frac{E(\varphi(I_t)\mathbb{1}_{I_t>0}|\mathcal{Z}_{t-1})}{P(I_t > 0|\mathcal{Z}_{t-1})} \\ &= \mathbb{1}_{I_t=0}\varphi(0) + \mathbb{1}_{I_t>0}E(\varphi(I_t)|\mathcal{Z}_{t-1}, I_t > 0). \end{aligned} \tag{6}$$

Proof. Beginning with the left-hand side of (6), we have

$$\mathrm{E}(\varphi(I_t)|\mathcal{Z}_t) = \mathrm{E}[\varphi(I_t)(\mathbb{1}_{I_t=0} + \mathbb{1}_{I_t>0})|\mathcal{Z}_t)] = \varphi(0)\mathbb{1}_{I_t=0} + \mathrm{E}[\varphi(I_t)\mathbb{1}_{I_t>0}|\mathcal{Z}_t]. \tag{7}$$

Now take the last term in (7) and obtain

$$\begin{aligned}\mathrm{E}(\varphi(I_t)\mathbb{1}_{I_t>0}|\mathcal{Z}_t) &= \mathbb{1}_{I_t>0}\mathrm{E}(\varphi(I_t)|\mathcal{Z}_t)\\ &= \mathbb{1}_{I_t>0}\psi(z_1,\dots,z_{t-1},z_t)\\ &= \mathbb{1}_{I_t>0}\psi(z_1,\dots,z_{t-1},0),\end{aligned} \tag{8}$$

where the first equality follows from $\mathcal{Z}_t$-measurability of $\mathbb{1}_{I_t>0}$. The second equality merely expresses $\mathrm{E}(\varphi(I_t)|\mathcal{Z}_t)$ as $\psi(z_1,\dots,z_{t-1},z_t)$ for some measurable function ψ. The last equality follows from the fact that $I_t > 0 \Leftrightarrow z_t = 0$.

We now take the expectation of (8) with respect to $\mathcal{Z}_{t-1}$. Since $\mathcal{Z}_{t-1} \subseteq \mathcal{Z}_t$ and since $\psi(z_1,\dots,z_{t-1},0)$ is $\mathcal{Z}_{t-1}$-measurable, we obtain

$$\mathrm{E}[\varphi(I_t)\mathbb{1}_{I_t>0}|\mathcal{Z}_{t-1}] = \psi(z_1,\dots,z_{t-1},0)\mathrm{E}[\mathbb{1}_{I_t>0}|\mathcal{Z}_{t-1}] = \psi(z_1,\dots,z_{t-1},0)\mathrm{P}(I_t>0|\mathcal{Z}_{t-1}) \tag{9}$$

or

$$\psi(z_1,\dots,z_{t-1},0) = \frac{\mathrm{E}(\varphi(I_t)\mathbb{1}_{I_t>0}|\mathcal{Z}_{t-1})}{\mathrm{P}(I_t>0|\mathcal{Z}_{t-1})}. \tag{10}$$

Using (10) in (8) and substituting into (7) the resulting expression for $\mathrm{E}[\varphi(I_t)\mathbb{1}_{I_t>0}|\mathcal{Z}_t]$, we obtain the first equality in (6). Using (5) gives the second equality. □

Instead of the conditional expectations in Lemma 1, the left-hand side in (6) can also be expressed by using the conditional density function π_t. Using (5) on the right-hand side of (6) gives

$$\mathrm{E}(\varphi(I_t)|\mathcal{Z}_t) = \mathbb{1}_{I_t=0}\varphi(0) + \mathbb{1}_{I_t>0}\int_0^\infty \varphi(z)\pi_t(z)dz. \tag{11}$$

The density π_t is obtained by setting (6) and (11) to be equal. For $I_t = 0$, this equality yields $\pi_t = \delta$, which is the Dirac delta function taking the value of zero everywhere except at 0, where it is infinite. For the more interesting case of $I_t > 0$, the next lemma molds (6) into a convenient form to set (11) equal to (6) and solve for π_t.

Lemma 2.

$$\begin{aligned}E(\varphi(I_t)|\mathcal{Z}_t)\mathbb{1}_{I_t>0} &= \mathbb{1}_{I_{t-1}=0}\frac{\int_0^\infty \varphi(z)f(q_{t-1}-z)\mathbb{1}_{q_{t-1}\geq z}dz}{F(q_{t-1})}\\ &\quad + \mathbb{1}_{I_{t-1}>0}\frac{\int_0^\infty \varphi(z)\int_{(z-q_{t-1})^+}^\infty f(y+q_{t-1}-z)\pi_{t-1}(y)dydz}{\int_0^\infty F(y+q_{t-1})\pi_{t-1}(y)dy}.\end{aligned} \tag{12}$$

Proof. Consider the numerator in the second term on the right-hand side of (6). We see that

$$
\begin{aligned}
\mathrm{E}(\varphi(I_t)\mathbb{1}_{I_t>0}|\mathcal{Z}_{t-1}) &= \mathrm{E}(\varphi(I_{t-1}+q_{t-1}-D_{t-1})\mathbb{1}_{I_{t-1}+q_{t-1}-D_{t-1}>0}|\mathcal{Z}_{t-1}) \\
&= \mathrm{E}\left(\mathrm{E}(\varphi(I_{t-1}+q_{t-1}-D_{t-1})\mathbb{1}_{I_{t-1}+q_{t-1}-D_{t-1}>0}|\mathcal{Z}_{t-1},I_{t-1})|\mathcal{Z}_{t-1}\right) \\
&\qquad \text{because } \mathcal{Z}_{t-1}=\sigma(\{z_1,\dots,z_{t-1}\})\subseteq\sigma(\{z_1,\dots,z_{t-1},I_{t-1}\}) \\
&= \mathrm{E}\left(\int_0^{\infty}\varphi(I_{t-1}+q_{t-1}-y)\mathbb{1}_{I_{t-1}+q_{t-1}-y>0}f(y)dy|\mathcal{Z}_{t-1}\right) \\
&= \mathrm{E}\left(\int_0^{q_{t-1}+I_{t-1}}\varphi(I_{t-1}+q_{t-1}-y)f(y)dy|\mathcal{Z}_{t-1}\right) \\
&= \mathrm{E}\left(\int_0^{q_{t-1}+I_{t-1}}\varphi(x)f(I_{t-1}+q_{t-1}-x)dx|\mathcal{Z}_{t-1}\right) \\
&\qquad \text{set } x:=I_{t-1}+q_{t-1}-y \\
&= \mathrm{E}\left(\int_0^{\infty}\varphi(x)f(I_{t-1}+q_{t-1}-x)\mathbb{1}_{I_{t-1}+q_{t-1}-x\geq 0}dx|\mathcal{Z}_{t-1}\right) \\
&= \int_0^{\infty}\varphi(x)\mathrm{E}\left(f(I_{t-1}+q_{t-1}-x)\mathbb{1}_{I_{t-1}+q_{t-1}-x\geq 0}|\mathcal{Z}_{t-1}\right)dx. \qquad (13)
\end{aligned}
$$

Use (11) with the time index $t-1$ instead of t and replace $\varphi(I_{t-1})$ with $f(I_{t-1}+q_{t-1}-x)\mathbb{1}_{I_{t-1}+q_{t-1}-x\geq 0}$ to obtain

$$
\begin{aligned}
&\mathrm{E}(f(I_{t-1}+q_{t-1}-x)\mathbb{1}_{I_{t-1}+q_{t-1}-x\geq 0}|\mathcal{Z}_{t-1}) \\
&\quad = \mathbb{1}_{I_{t-1}=0}f(q_{t-1}-x)\mathbb{1}_{q_{t-1}-x\geq 0} \\
&\quad\quad + \mathbb{1}_{I_{t-1}>0}\int_0^{\infty}f(y+q_{t-1}-x)\mathbb{1}_{y+q_{t-1}-x\geq 0}\pi_{t-1}(y)dy. \qquad (14)
\end{aligned}
$$

Inserting (14) into (13), we obtain

$$
\begin{aligned}
\mathrm{E}(\varphi(I_t)\mathbb{1}_{I_t>0}|\mathcal{Z}_{t-1}) &= \mathbb{1}_{I_{t-1}=0}\int_0^{\infty}\varphi(x)f(q_{t-1}-x)\mathbb{1}_{x\leq q_{t-1}}dx \\
&\quad + \mathbb{1}_{I_{t-1}>0}\int_0^{\infty}\varphi(x)\left(\int_{(x-q_{t-1})^+}^{\infty}f(y+q_{t-1}-x)\pi_{t-1}(y)dy\right)dx.
\end{aligned}
$$

Now consider the denominator in the second term on the right-hand side of (6) to obtain

$$
\begin{aligned}
\mathrm{P}(I_t>0|\mathcal{Z}_{t-1}) &= \mathrm{E}(\mathbb{1}_{I_{t-1}+q_{t-1}-D_{t-1}>0}|\mathcal{Z}_{t-1}) \\
&= \mathrm{E}\{\mathrm{E}(\mathbb{1}_{I_{t-1}+q_{t-1}-D_{t-1}>0}|\mathcal{Z}_{t-1},I_{t-1})|\mathcal{Z}_{t-1}\} \\
&= \mathrm{E}\{F(I_{t-1}+q_{t-1})|\mathcal{Z}_{t-1}\} \\
&= \mathbb{1}_{I_{t-1}=0}F(q_{t-1})+\mathbb{1}_{I_{t-1}>0}\int_0^{\infty}F(y+q_{t-1})\pi_{t-1}(y)dy.
\end{aligned}
$$

Inserting the numerator and the denominator into (6) yields the desired result. ∎

Having obtained the conditional expectation in Lemma 2, we go back to the conditional probability π_t as defined in (11) for $I_t>0$. Setting the second term on the right-hand side of (11) equal to (12), we have

$$
\pi_t(x)=\mathbb{1}_{I_{t-1}=0}\left\{\frac{f(q_{t-1}-x)\mathbb{1}_{x\leq q_{t-1}}}{F(q_{t-1})}\right\}+\mathbb{1}_{I_{t-1}>0}\left\{\frac{\int_{(x-q_{t-1})^+}^{\infty}f(y+q_{t-1}-x)\pi_{t-1}(y)dy}{\int_0^{\infty}F(y+q_{t-1})\pi_{t-1}(y)dy}\right\}. \qquad (15)
$$

This expression specializes to the conditional probabilities stated in the next theorem.

THEOREM 1. *The conditional probability π_t can be expressed recursively as follows:*

$$\pi_t(x) = \left\{ \begin{array}{ll} \mathbb{1}_{x \le q_{t-1}} \dfrac{f(q_{t-1}-x)}{F(q_{t-1})} & \text{if } I_{t-1}=0 \\ \dfrac{\int_{(x-q_{t-1})^+}^{\infty} \pi_{t-1}(y) f(y+q_{t-1}-x)dy}{\int_0^{\infty} \pi_{t-1}(y)F(y+q_{t-1})dy} & \text{if } I_{t-1}>0 \end{array} \right\}. \tag{16}$$

Note that the denominators in (16) are $\mathrm{P}(D_{t-1} < I_{t-1}+q_{t-1})$, which is $\mathrm{P}(I_t > 0)$.

When $I_t > 0$, π_t is an absolutely continuous p.d.f. (probability density function). Note that the recursive equations for $I_{t-1} > 0$ and $I_{t-1} = 0$ coincide for $\pi_{t-1} = \delta$, so the equation for $I_{t-1} > 0$ applies even when $I_{t-1} = 0$. Since the largest value of I_t is $I_{t-1} + q_{t-1}$, π_t has a support of $[0, \sum_{i=1}^{t-1} q_i]$. If $I_{t'} = 0$ for some $t' < t$, then the support is $[0, \sum_{i=t'}^{t-1} q_i]$. Since π_1, f, and F are all given, the evolution of π_t can be controlled only by $\tilde{q} = \{q_1, q_2, \dots\}$.

The conditional probability evolves according to a highly nonlinear equation,

$$\begin{aligned} \pi_t(x) &= z_{t-1}\frac{f(q_{t-1}-x)\mathbb{1}_{x\le q_{t-1}}}{F(q_{t-1})} \\ &\quad + (1-z_{t-1})\frac{\int_{(x-q_{t-1})^+}^{\infty} f(y+q_{t-1}-x)\pi_{t-1}(y)dy}{\int_0^{\infty} F(q_{t-1}+y)\pi_{t-1}(y)dy}, \qquad t \ge 2, \\ \pi_1(x) &= \pi(x), \end{aligned} \tag{17}$$

which corresponds to the Kushner equation [18] in our inventory context.

We can linearize (17) as follows. Set

$$p_t(x) := \lambda_t \pi_t(x), \tag{18}$$

where λ_t is a *weighting factor* to be defined shortly. On account of this weighting, $p_t(x)$ can be viewed as unnormalized probability. Furthermore, it evolves according to the linear equation

$$\begin{aligned} p_t(x) &= z_{t-1} f(q_{t-1}-x)\mathbb{1}_{x\le q_{t-1}} + (1-z_{t-1})\int_{(x-q_{t-1})^+}^{\infty} f(y+q_{t-1}-x)p_{t-1}(y)dy, \\ p_1(x) &= \pi(x). \end{aligned} \tag{19}$$

This equation corresponds to the Zakai equation for systems with diffusions in [30, 5]. By integrating both sides of (18),

$$\begin{aligned} \lambda_t &= \int_0^{\infty} p_t(x)dx \\ &\overset{(19)}{=} z_{t-1}F(q_{t-1}) + (1-z_{t-1})\int_0^{\infty} F(q_{t-1}+y)p_{t-1}(y)dy \\ &\overset{(18)}{=} z_{t-1}F(q_{t-1}) + (1-z_{t-1})\lambda_{t-1}\int_0^{\infty} F(q_{t-1}+y)\pi_{t-1}(y)dy. \end{aligned}$$

The last equation defines λ_t recursively starting with $\lambda_1 = 1$. However, note that λ_t depends on π_{t-1} on the right-hand side. The normalized probabilities can easily be

computed from the unnormalized probabilities as follows:

$$\pi_t(x) = \frac{p_t(x)}{\int_0^\infty p_t(x)dx}. \tag{20}$$

These equations can be written in the operator form in the space

$$\mathcal{H} := \left\{ p \in L^1(\Re^+) \ : \ \int_0^\infty x|p(x)|dx < \infty \right\},$$

where $L^1(\Re^+)$ is the space of integrable functions whose domain is the set of nonnegative real numbers. If we define regular addition and multiplication by a scalar on $\mathcal{H}$ and include negative valued functions in $\mathcal{H}$, then $\mathcal{H}$ becomes a subspace of $L^1(\Re^+)$. Working with the subspace $\mathcal{H}$ is convenient for some of our arguments. However, we are ultimately interested in unnormalized probabilities, which are nonnegative. For them, we will specify an appropriate subset of $\mathcal{H}$ in section 2.2.

Let us equip the subspace $\mathcal{H}$ with the norm

$$||p|| = \int_0^\infty |p(x)|dx + \int_0^\infty x|p(x)|dx. \tag{21}$$

The dual space of $\mathcal{H}$ is denoted by $\mathcal{H}_*$, and it is the space of functions ϕ with linear growth, i.e.,

$$\mathcal{H}_* = \left\{ \phi \ : \ \sup_{x>0} \frac{|\phi(x)|}{1+x} < \infty \right\}.$$

Furthermore, we have the inner product

$$\langle p, \phi \rangle = \int_0^\infty p(x)\phi(x)dx \quad \text{for } p \in \mathcal{H},\ \phi \in \mathcal{H}_*.$$

For any scalar $q > 0$ and $p \in \mathcal{H}$, we define the linear operator ρ as

$$\rho(q,p)(x) = \int_{(x-q)^+}^\infty f(y+q-x)p(y)dy,$$

which is established in section 2.2 to be from $\mathcal{H}$ to $\mathcal{H}$. For the Dirac delta function $\delta \notin \mathcal{H}$, we define $\rho(q,\delta)(x) = f(q-x)\mathbb{1}_{x \le q}$. This gives us $\rho(0,\delta)(x) = 0$ almost everywhere in $\Re^+$. Define the nonlinear operator θ as

$$\theta(q,p)(x) = \frac{\rho(q,p)(x)}{\langle \rho(q,p), 1 \rangle}. \tag{22}$$

With these notations, we can write (17) and (19) in the operator form:

$$\pi_t(x) = z_{t-1}\theta(q_{t-1},\delta)(x) \ + \ (1-z_{t-1})\theta(q_{t-1},\pi_{t-1})(x), \tag{23}$$

$$p_t(x) = z_{t-1}\rho(q_{t-1},\delta)(x) \ + \ (1-z_{t-1})\rho(q_{t-1},p_{t-1})(x), \tag{24}$$

with the initial conditions

$$\pi_1 = p_1 = \pi. \tag{25}$$

Once again, we emphasize that (24) is a linear equation, while (23) is nonlinear.

2.2. Properties of the operators. In preparation to obtain some required operator properties, we need some identities and inequalities. By changing the order of integration, we obtain

$$\begin{aligned}\int_0^\infty |\rho(q,p)(x)|dx &\le \int_0^\infty \int_{(x-q)^+}^\infty f(y+q-x)|p(y)|dydx \\ &= \int_0^\infty \int_0^{y+q} f(y+q-x)|p(y)|dxdy \\ &= \int_0^\infty |p(y)| \int_0^{y+q} f(y+q-x)dxdy = \int_0^\infty |p(y)|F(y+q)dy. \end{aligned} \tag{26}$$

Using similar operations, we see that

$$\begin{aligned}\int_0^\infty x|\rho(q,p)(x)|dx &\le \int_0^\infty \int_{(x-q)^+}^\infty xf(y+q-x)|p(y)|dydx \\ &= \int_0^\infty \int_0^{y+q} xf(y+q-x)|p(y)|dxdy \\ &= \int_0^\infty p(y) \int_0^{y+q} (y+q-z)f(z)dzdy \\ &= \int_0^\infty (y+q)|p(y)|F(y+q)dy. \end{aligned} \tag{27}$$

Furthermore,

$$\begin{aligned}\int_0^\infty |\theta(q,p)(x)|dx &= \int_0^\infty \left|\frac{\rho(q,p)(x)}{\int_0^\infty \rho(q,p)(x)dx}\right| dx = \frac{\int_0^\infty |\rho(q,p)(x)|dx}{|\int_0^\infty \rho(q,p)(x)dx|} \\ &\overset{(26)}{\le} \frac{\int_0^\infty F(y+q)|p(y)|dy}{|\int_0^\infty F(y+q)p(y)dy|} \end{aligned} \tag{28}$$

and

$$\begin{aligned}\int_0^\infty x|\theta(q,p)(x)|dx &= \int_0^\infty \left|\frac{x\rho(q,p)(x)}{\int_0^\infty \rho(q,p)(x)dx}\right| dx = \frac{\int_0^\infty x|\rho(q,p)(x)|dx}{|\int_0^\infty \rho(q,p)(x)dx|} \\ &\overset{(26,27)}{\le} \frac{\int_0^\infty (y+q)|p(y)|F(y+q)dy}{|\int_0^\infty p(y)F(y+q)dy|} \\ &= q + \frac{\int_0^\infty y|p(y)|F(y+q)dy}{|\int_0^\infty p(y)F(y+q)dy|}. \end{aligned} \tag{29}$$

Next we derive some properties for nonnegative p. For this, we define

$$\mathcal{H}^+ := \{p \in \mathcal{H} : p \ge 0\}.$$

Note that $\mathcal{H}^+$ is not a subspace, as it does not include $-p$ for any $p > 0$.

Properties.

- Operator $\theta(q,p)$ is well defined if $\langle \rho(q,p), 1\rangle > 0$, i.e.,

$$\langle \rho(q,p), 1\rangle = \int_0^\infty p(y)F(y+q)dy \ne 0. \tag{30}$$

This property is satisfied if $p \neq 0$, $p \in \mathcal{H}^+$, and $F(y) > 0$ for all $y > 0$. Then, $\int_0^\infty p(y)F(y+q)dy > 0$. Otherwise, $p(y)F(y+q) = 0$ is a.e. satisfied, which along with $F(y) > 0$ for all $y > 0$ implies $p(y) = 0$ a.e. This contradicts $p \neq 0$.

Moreover, the operator ρ preserves the nonzero property: $p \neq 0 \implies \rho(q,p) \neq 0$. We establish the contrapositive of this statement. If $\rho(q,p) = 0$, then $\langle \rho(q,p), 1\rangle = 0$, which is possible only under $p = 0$.

Furthermore, note that the equality in (30) specializes to $\langle \rho(q,\delta), 1\rangle = F(q)$.

- Operator $\theta(q,p)(x)$ yields a valid p.d.f. if $p \in \mathcal{H}^+$. Clearly, $\theta(q,p)(x) \geq 0$ and $\int_0^\infty \theta(q,p)(x)dx = 1$.
- Operator $\rho(q,p)$ is a linear operator from $L^1(\Re^+)$ to $L^1(\Re^+)$ and also from $\mathcal{H}$ to $\mathcal{H}$. Moreover, $\mathcal{H}^+$ is closed under the operator ρ: $\rho(q,p) \in \mathcal{H}^+$ when $p \in \mathcal{H}^+$, because

$$\begin{aligned} ||\rho(q,p)|| &= \int_0^\infty |\rho(q,p)(x)|dx + \int_0^\infty x|\rho(q,p)(x)|dx \\ &\overset{(26,27)}{\leq} \int_0^\infty F(y+q)|p(y)|dy + \int_0^\infty (y+q)F(y+q)|p(y)|dy \\ &\leq \int_0^\infty |p(y)|dy + \int_0^\infty y|p(y)|dy + q\int_0^\infty |p(y)|dy < \infty, \end{aligned}$$

where the last less-than-or-equal-to relation is due to $F(y+q) \leq 1$.

- Operator $\theta(q,p)$ maps each element p, satisfying $\langle \rho(q,p), 1\rangle \neq 0$, from $L^1(\Re^+)$ to $L^1(\Re^+)$ and also from $\mathcal{H}$ to $\mathcal{H}$. Moreover, $\mathcal{H}^+$ is closed under the operator θ: $\theta(q,p) \in \mathcal{H}^+$ when $p \in \mathcal{H}^+$, because

$$\begin{aligned} ||\theta(q,p)|| &= \int_0^\infty |\theta(q,p)(x)|dx + \int_0^\infty x|\theta(q,p)(x)|dx \\ &\overset{(28,29)}{\leq} \frac{\int_0^\infty F(y+q)|p(y)|dy}{|\int_0^\infty F(y+q)p(y)dy|} + q + \frac{\int_0^\infty y|p(y)|F(y+q)dy}{|\int_0^\infty p(y)F(y+q)dy|} \\ &\leq \frac{\int_0^\infty |p(y)|dy}{|\int_0^\infty F(y)p(y)dy|} + q + \frac{\int_0^\infty y|p(y)|dy}{|\int_0^\infty p(y)F(y)dy|}. \end{aligned}$$

Because of (30), the denominator is positive. Consequently, the right-hand side is finite and $\theta(q,p) \in \mathcal{H}^+$.

- Operator $\rho(q,p)$ when $q = 0$ is a contraction mapping: when no order is made, the inventory distribution shifts to the left. This follows from

$$\begin{aligned} ||\rho(0,p)|| &= \left\| \int_x^\infty f(y-x)p(y)dy \right\| \\ &\leq \int_0^\infty \int_x^\infty f(y-x)|p(y)|dydx + \int_0^\infty x\int_x^\infty f(y-x)|p(y)|dydx \\ &= \int_0^\infty |p(y)| \int_0^y f(y-x)dxdy + \int_0^\infty |p(y)| \int_0^y xf(y-x)dxdy \\ &\leq \int_0^\infty |p(y)|F(y)dy + \int_0^\infty |p(y)|yF(y)dy \\ &\leq \int_0^\infty |p(y)|dy + \int_0^\infty |p(y)|ydy \qquad \text{(since } F \leq 1\text{)} \\ &= ||p||. \end{aligned} \tag{31}$$

- Operator θ is homogenous of degree 0 in p because

$$\langle \theta(q,p),1\rangle = \int_0^\infty \frac{\rho(q,p)}{\langle \rho(q,p),1\rangle} dx = 1 \quad \text{and}$$

$$\theta(q,\lambda p) = \theta(q,p) \quad \text{for each constant } \lambda \in \Re.$$

2.3. The Bellman equation. We write $p_t(\tilde{q})$ and $\pi_t(\tilde{q})$ to emphasize the dependence of the states p_t or π_t on the control policy. We assume that $c(I_t, q_t)$ has linear growth in I_t for every fixed q_t, i.e., $c(.,q_t) \in \mathcal{H}_*$. The cost function can be written as follows:

$$\begin{aligned} J(\zeta,\pi,\tilde{q}) &= \sum_{t=1}^{\infty} \alpha^t \mathrm{E}[\mathrm{E}[c(I_t,q_t)|\mathcal{Z}_t]] \\ &= \sum_{t=1}^{\infty} \alpha^t \mathrm{E}\{z_t c(0,q_t) + (1-z_t)\langle c(I_t,q_t), \pi_t(\tilde{q})\rangle\}, \end{aligned}$$

where $\pi_t(\tilde{q})$ is the solution of (17). Recall that the initial conditions $\zeta_1 = \zeta \in \{0,1\}$ and $\pi_1 = \pi$ are given. In what follows, we study only the discounted infinite horizon costs, so the time index t is suppressed. We define the value function

$$V(\zeta,\pi) := \inf_{\tilde{q}} J(\zeta,\pi,\tilde{q}).$$

Looking one period ahead from period one,

$$V(\zeta,\pi) = \inf_q \{\zeta c(0,q) + (1-\zeta)\langle c(.,q),\pi(\cdot)\rangle + \alpha \mathrm{E}[V(\zeta_2,\pi_2)|\zeta,\pi]\},$$

where

$$\begin{aligned} \mathrm{E}[V(\zeta_2,\pi_2)|\zeta,\pi] &= \mathrm{E}[V(\zeta_2, \zeta\theta(q,\delta) + (1-\zeta)\theta(q,\pi))|\zeta,\pi] \\ &= \mathrm{P}(I_2 = 0|\zeta) V(1, \zeta\theta(q,\delta) + (1-\zeta)\theta(q,\pi)) \\ &\quad + \mathrm{P}(I_2 > 0|\zeta) V(0, \zeta\theta(q,\delta) + (1-\zeta)\theta(q,\pi)). \end{aligned}$$

Then $V(\zeta,\pi)$ can be written more explicitly, depending on ζ, as follows:

$$\begin{aligned} V(0,\pi) = \inf_q \Bigg\{ &\langle c(.,q),\pi(.)\rangle + \alpha V(1,\theta(q,\pi)) \int_0^\infty \bar{F}(y+q)\pi(y)dy \\ &+ \alpha V(0,\theta(q,\pi)) \int_0^\infty F(y+q)\pi(y)dy \Bigg\}, \\ V(1,\pi) = \inf_q \left\{ c(0,q) + \alpha V(1,\theta(q,\delta))\bar{F}(q) + \alpha V(0,\theta(q,\delta))F(q) \right\}. \end{aligned}$$

If we write $v := V(1,\pi)$ which, in fact, is not dependent on π, and $V(\pi) := V(0,\pi)$, then we obtain the following system:

$$\begin{aligned} V(\pi) = \inf_q \Bigg\{ &\langle c(.,q),\pi(.)\rangle \\ &+ \alpha v \int_0^\infty \bar{F}(y+q)\pi(y)dy + \alpha V(\theta(q,\pi)) \int_0^\infty F(y+q)\pi(y)dy \Bigg\}, \end{aligned} \tag{32}$$

$$v = \inf_q \left\{ c(0,q) + \alpha v \bar{F}(q) + \alpha V(\theta(q,\delta))F(q) \right\}. \tag{33}$$

A direct study of the system in (32)–(33) is not very easy. The matters simplify considerably when working with the unnormalized probability $p \in \mathcal{H}^+$. The unnormalized probability evolves in accordance with the linear operator ρ. To make ideas concrete, we define a new value function $Z(\cdot)$ as follows:

$$Z(p) := V\left(\frac{p}{\lambda}\right)\lambda, \quad \lambda := \int_0^\infty p(x)dx.$$

It follows from (32) that

(34)

$$\begin{aligned} Z(p) &= \lambda \inf_q \left\{ \langle c(.,q), p(.)/\lambda\rangle \ + \alpha v \int_0^\infty \bar{F}(y+q)(p(y)/\lambda)dy \right. \\ &\qquad \left. + \alpha V(\theta(q,p/\lambda)) \int_0^\infty F(y+q)(p(y)/\lambda)dy \right\} \\ &= \inf_q \left\{ \langle c(.,q), p(.)\rangle \ + \alpha v \int_0^\infty \bar{F}(y+q)p(y)dy + \alpha V(\theta(q,p)) \int_0^\infty F(y+q)p(y)dy \right\}, \end{aligned}$$

where we use the fact that θ is a homogenous operator of degree 0. Now consider the term $V(\theta(q,\pi))$ on the right-hand side. Recall that the λ value corresponding to $\rho(q,p)$ is $\langle \rho(q,p), 1\rangle$. Thus,

$$\begin{aligned} Z(\rho(q,p)) &= \left\{ \int_0^\infty \rho(q,p)(x)dx \right\} \left\{ V\left(\frac{\rho(q,p)}{\langle \rho(q,p), 1\rangle} \right) \right\} \\ &= \left\{ \int_0^\infty F(y+q)p(y)dy \right\} \{V\left(\theta(q,p)\right)\}. \end{aligned}$$

This equality can be used to eliminate $V(\theta(q,p))$ from (34). It can be specialized for $p = \delta$ to eliminate $V(\theta(q,\delta))$ from the expression for v. Eventually, we obtain the following new system of equations:

(35)

$$Z(p) = \inf_q \left\{ \langle c(.,q), p(.)\rangle \ + \alpha v \int_0^\infty \bar{F}(y+q)p(y)dy + \alpha Z(\rho(q,p)) \right\} \quad \text{for all } p \in \mathcal{H}^+,$$

(36)

$$v = \inf_q \left\{ c(0,q) + \alpha v \bar{F}(q) + \alpha Z(\rho(q,\delta)) \right\}.$$

Recall that for the Dirac delta function $\delta \notin \mathcal{H}^+ \subseteq \mathcal{H}$, we have defined $\rho(q,\delta)(x) = f(q-x)\mathbb{1}_{x\le q}$ and $\rho(0,\delta) = 0$ almost everywhere.

From (35) and (36), it follows that

$$Z(\mu p) = \mu Z(p) \quad \text{for every } \mu > 0. \tag{37}$$

Thus, $Z(0) = 0$.

Unlike the operator θ, ρ is a linear operator. Thus, it is easier to study the system in (35)–(36) than that in (32)–(33). The linearity facilitates our arguments dealing with the existence of an optimal feedback control and our discussion when it is finite. Furthermore, it helps in studying finite approximations of the infinite-dimensional state space as well as in building associated approximate solutions to (35)–(36).

We conclude this section by remarking that this problem and the methodology developed here have not appeared before in the inventory control literature.

3. Existence of a solution to the Bellman equation.

3.1. Bounded costs. For the existence result, we bound the single-period cost. To include the special cases given in section 2, we consider positive constants c, c_0, c_1, c_2, and h such that

$$c_2 + cq < c(I,q) \leq c_0 + c_1 q + hI \quad \text{for } I \geq 0. \tag{38}$$

To include the special cases, it is sufficient to set $c_0 \geq c(0,0)$, where $c(0,0)$ represents the maximum expected cost of lost sales that can be incurred in a period. Let $a_0 := \max\{c_0/(1-\alpha), h\}$.

In the subsequent analysis, we shall assume $c(I,q)$ to be continuous in I. Furthermore, we shall assume continuity in q for convenience in exposition. In the case when there is a fixed cost of ordering, $c(I,q)$ will be discontinuous in q at $q=0$. However, the affected proofs can be easily extended to handle this case.

To accommodate our unnormalized conditional probabilities, we define the functional space

$$\mathcal{B} := \left\{ \phi(p) : \mathcal{H}^+ \to \Re : \sup_{p \in \mathcal{H}^+} \frac{|\phi(p)|}{||p||} < \infty \right\} \tag{39}$$

equipped with the norm

$$||\phi||_{\mathcal{B}} := \sup_{p \in \mathcal{H}^+} \frac{|\phi(p)|}{||p||}, \tag{40}$$

where $||p||$ still refers to the norm that we initially defined in $\mathcal{H} \supseteq \mathcal{H}^+$. For any $\phi \in \mathcal{B}$, we must have $\phi(0) = 0$.

We will often speak of a pair (v, Z), which is made of a scalar $v \in \Re$ and an element $Z \in \mathcal{B}$. As such, (v, Z) can be considered as an element in the functional space $\Re \times \mathcal{B}$. We suppress the argument p in $Z(p)$ when Z is considered as a functional. Thus, when the existence, uniqueness, or continuity of Z is under consideration, we only write Z in what follows. For example, a solution of (35)–(36) will be a pair of the form (v, Z). We will write $(v_1, Z_1) \leq (v_2, Z_2)$ to mean $(v_1, Z_1(p)) \leq (v_2, Z_2(p))$ for any given $p \in \mathcal{H}^+$.

We search for a solution (v, Z) of (35)–(36) in $\Re \times \mathcal{B}$. A property of this solution is presented next.

LEMMA 3. *Each solution (v, Z) of (35)–(36) in $\Re \times \mathcal{B}$ satisfies $||Z||_{\mathcal{B}} \leq a_0/(1-\alpha)$.*

Proof. For any given $p \in \mathcal{H}^+$, by setting $q = 0$, we obtain

$$Z(p) \leq \left\{ \langle c(.,0), p(.) \rangle + \alpha v \int_0^\infty \bar{F}(y) p(y) dy + \alpha Z(\rho(0,p)) \right\}. \tag{41}$$

From (38) and the fact that $\bar{F} \leq 1$, we can write

$$\begin{aligned} Z(p) &\leq c_0 \int_0^\infty p(x)dx + h \int_0^\infty x p(x)dx + \alpha v \int_0^\infty p(x)dx + \alpha Z(\rho(0,p)) \qquad (42) \\ &\overset{(40)}{\leq} (c_0 + \alpha v) \int_0^\infty p(x)dx + h \int_0^\infty x p(x)dx + \alpha ||Z||_{\mathcal{B}} ||\rho(0,p)|| \\ &\overset{(31)}{\leq} (c_0 + \alpha v) \int_0^\infty p(x)dx + h \int_0^\infty x p(x)dx + \alpha ||Z||_{\mathcal{B}} ||p||. \qquad (43) \end{aligned}$$

Now use the Bellman equation for v along with $\rho(0,\delta)=0$ and $Z(0)=0$ to obtain the second inequality:

$$0 \le v \le c(0,0) + \alpha v \le c_0 + \alpha v.$$

This implies $v \le c_0/(1-\alpha)$. Then $c_0 + \alpha v \le c_0 + \alpha c_0/(1-\alpha) = c_0/(1-\alpha)$, which can be inserted into the upper bound for $Z(p)$ above to obtain

$$Z(p) \le (c_0/(1-\alpha)) \int_0^\infty p(x)dx + h \int_0^\infty xp(x)dx + \alpha ||Z||_{\mathcal{B}} ||p||$$

and, in turn,

$$Z(p) \le a_0||p|| + \alpha||Z||_{\mathcal{B}}||p||.$$

By dividing both sides by $||p||$ and taking the supremum over $p \in \mathcal{H}^+$, we obtain

$$||Z||_{\mathcal{B}} \le a_0 + \alpha||Z||_{\mathcal{B}},$$

which implies $||Z||_{\mathcal{B}} \le a_0/(1-\alpha)$. □

Define the function $G : \Re \times \mathcal{H} \to \Re$, given (v, Z), as

$$G(q,p;v,Z) := \langle c(.,q), p(.)\rangle + \alpha v \int_0^\infty \bar{F}(y+q)p(y)dy + \alpha Z(\rho(q,p)).$$

For $p = \delta$,

$$G(q,\delta;v,Z) = c(0,q) + \alpha v\bar{F}(q) + \alpha Z(\rho(q,\delta)).$$

Define the map $T : \Re \times \mathcal{B} \to \Re \times \mathcal{B}$ as

$$T\begin{pmatrix} v \\ Z(p) \end{pmatrix} := \begin{pmatrix} \inf_q G(q,\delta;v,Z) \\ \inf_q G(q,p;v,Z) \end{pmatrix}. \tag{44}$$

Define Z_0 as the value function that solves the Bellman equations when $q = 0$. Then it must solve

$$\langle c(.,0), p(.)\rangle + \alpha v_0 \int_0^\infty \bar{F}(y)p(y)dy + \alpha Z_0(\rho(0,p)) = Z_0(p), \tag{45}$$

where $v_0 := Z_0(p=\delta)$. By (36) and $Z(0)=0$, we have $v_0 = c_0 + \alpha v_0$. The existence and uniqueness of the functional Z_0 are established in the next lemma.

LEMMA 4. *Z_0 exists and is uniquely defined.*

Proof. First, we look for a solution of (45). Consider a linear and bounded map $U : \mathcal{H} \to \Re$. We can locally define the norm of U as

$$||U||_{\mathcal{B}^-} = \sup_{p\in\mathcal{H}} |U(p)|/||p||. \tag{46}$$

This norm is defined on the functional space $\mathcal{B}^-$, which can be constructed like $\mathcal{B}$ but with $\mathcal{H}$ instead of $\mathcal{H}^+$ in (39). In comparison to $\phi \in \mathcal{B}$ and Z_0, U has a larger domain that includes negative p. Here it is more convenient to work in the subspace $\mathcal{H}$ instead of $\mathcal{H}^+$.

Define

$$\tau(U)(p) := \langle c(.,0), p(.)\rangle + \alpha v_0 \int_0^\infty \bar{F}(y)p(y)dy + \alpha U(\rho(0,p)).$$

The map τ is an affine function of U and it is linear in p. For linear maps $U_1, U_2 \in \mathcal{B}^-$, we have

$$\begin{aligned} |\tau(U_1)(p) - \tau(U_2)(p)| &= \alpha|U_1(\rho(0,p)) - U_2(\rho(0,p))| \\ &= \alpha|(U_1 - U_2)(\rho(0,p))| \\ &\leq \alpha||\rho(0,p)|| \cdot ||U_1 - U_2||_{\mathcal{B}^-} \\ &\overset{(31)}{\leq} \alpha||p|| \cdot ||U_1 - U_2||_{\mathcal{B}^-}. \end{aligned}$$

This equality above follows from the linearity of U_1 and U_2. Using the inequality above, we can deduce that

$$\sup_{p\in\mathcal{H}} \frac{|\tau(U_1)(p) - \tau(U_2)(p)|}{||p||} \leq \alpha||U_1 - U_2||_{\mathcal{B}^-}.$$

The left-hand side above is the norm $||\tau(U_1) - \tau(U_2)||$ of $\tau(U_1) - \tau(U_2)$, so we arrive at

$$||\tau(U_1) - \tau(U_2)|| \leq \alpha||U_1 - U_2||_{\mathcal{B}^-}.$$

It follows that τ is a contraction mapping and it has a unique fixed point U_0 such that $\tau(U_0) = U_0$. By restricting the domain of U_0 to $\mathcal{H}^+$, we uniquely obtain Z_0. Thus, Z_0 is a fixed point for T when $q = 0$, and it solves (45). □

If $v \leq v_0$, $Z(p) \leq Z_0(p)$, and

$$\begin{pmatrix} \tilde{v} \\ \tilde{Z}(p) \end{pmatrix} := T \begin{pmatrix} v \\ Z(p) \end{pmatrix},$$

then $\tilde{v} \leq c(0,0) + \alpha v \leq c_0 + \alpha v_0 = v_0$. Also,

$$\begin{aligned} \tilde{Z}(p) &\leq \langle c(.,0), p(.)\rangle + \alpha v \int_0^\infty \bar{F}(y)p(y)dy + \alpha Z(\rho(0,p)) \\ &\leq \langle c(.,0), p(.)\rangle + \alpha v_0 \int_0^\infty \bar{F}(y)p(y)dy + \alpha Z_0(\rho(0,p)) \\ &\overset{(45)}{=} Z_0(p). \end{aligned}$$

For $0 \leq v \leq v_0$ and $0 \leq Z(p) \leq Z_0(p)$, we have just shown that

$$T \begin{pmatrix} v \\ Z(p) \end{pmatrix} \leq \begin{pmatrix} v_0 \\ Z_0(p) \end{pmatrix}. \tag{47}$$

This inspires the next theorem, which proves the existence of a solution of the system (35)–(36) by using a value iteration scheme. The solution is denoted as $(\bar{v}, \bar{Z})$.

THEOREM 2. *Under assumption* (38)*, a solution of* (35)–(36) *exists.*

Proof. Let

$$\begin{pmatrix} v_{n+1} \\ Z_{n+1}(p) \end{pmatrix} := T \begin{pmatrix} v_n \\ Z_n(p) \end{pmatrix}.$$

Starting with v_0 and Z_0 defined by (45), we first claim that

$$\begin{pmatrix} v_{n+1} \\ Z_{n+1}(p) \end{pmatrix} \leq \begin{pmatrix} v_n \\ Z_n(p) \end{pmatrix}.$$

The claim can be established recursively. First consider $n = 0$. Then, by setting $q = 0$, we have

$$v_1 \leq c_0 + \alpha v_0 + \alpha Z_0(\rho(0, \delta)) = v_0,$$

$$Z_1(p) \leq \langle c(.,0), p(.) \rangle + \alpha v_0 \int_0^\infty \bar{F}(y)p(y)dy + \alpha Z_0(\rho(0,p)) = Z_0(p),$$

where the equalities are due to (45). Now we assume that the claim holds for $n = k$, and then establish it for $n = k + 1$. If $v \leq v'$ and $Z(p) \leq Z'(p)$, then it follows from the definition of T that

$$T\begin{pmatrix} v \\ Z(p) \end{pmatrix} \leq T\begin{pmatrix} v' \\ Z'(p) \end{pmatrix}.$$

By the recursion hypothesis $(v_{k+1}, Z_{k+1}) \leq (v_k, Z_k)$. Take $v = v_{k+1}$, $Z = Z_{k+1}$, $v' = v_k$, and $Z' = Z_k$ in the above inequality to finish the proof of the claim.

Since (v_n, Z_n) is a nonincreasing sequence with a lower bound of $(0, 0)$, it has a limit $(\bar{v}, \bar{Z})$: $(v_n, Z_n) \downarrow (\bar{v}, \bar{Z})$. In other words,

$$\begin{pmatrix} \bar{v} \\ \bar{Z}(p) \end{pmatrix} = \lim_{n\to\infty} T_n \begin{pmatrix} v_0 \\ Z_0(p) \end{pmatrix},$$

where T_n is the n times composition of T. Since T is not known to be continuous, the above equality does not yield $(\bar{v}, \bar{Z})$ as a fixed point. But, for a finite n,

$$\begin{pmatrix} v_{n+1} \\ Z_{n+1}(p) \end{pmatrix} \geq T\begin{pmatrix} \bar{v} \\ \bar{Z}(p) \end{pmatrix}.$$

Applying T infinitely many times on both sides, we arrive at

$$\begin{pmatrix} \bar{v} \\ \bar{Z}(p) \end{pmatrix} \geq T\begin{pmatrix} \bar{v} \\ \bar{Z}(p) \end{pmatrix}. \tag{48}$$

On the other hand, by arbitrarily picking a q in (44), we see that

$$v_{n+1} \leq c(0, q) + \alpha v_n \bar{F}(q) + \alpha Z_n(\rho(q, \delta)),$$

$$Z_{n+1}(p) \leq \langle c(., q), p(.) \rangle + \alpha v_n \int_0^\infty \bar{F}(y + q)p(y)dy + \alpha Z_n(\rho(q, p)).$$

Specializing these inequalities for $v_n = \bar{v}$ and $Z_n(p) = \bar{Z}(p)$, we obtain

$$\begin{pmatrix} \bar{v} \\ \bar{Z}(p) \end{pmatrix} \leq T\begin{pmatrix} \bar{v} \\ \bar{Z}(p) \end{pmatrix}. \tag{49}$$

Combining (48) and (49), we establish that $(\bar{v}, \bar{Z})$ is a fixed point. The fixed point is not necessarily unique, but it is the maximum solution in the following sense. Any solution (v, Z) that satisfies $(v, Z) \leq (v_0, Z_0)$ also satisfies $(v, Z) \leq (\bar{v}, \bar{Z})$. □

Backward interpretation of the monotone iterative process (v_n, Z_n). Recall the monotone iterative process on (v_n, Z_n), which starts with $v_0 = c_0/(1-\alpha)$ and Z_0 as given in (45), and continues with $(v_{n+1}, Z_{n+1}) = T(v_n, Z_n)$.

Now consider a new sequence $(v_{n,N+1}, Z_{n,N+1})$ constructed by starting with

$$Z_{N+1,N+1}(p) = Z_0(p), \quad v_{N+1,N+1} = v_0$$

and by moving backwards recursively:

$$\begin{pmatrix} v_{n+1,N+1} \\ Z_{n+1,N+1}(p) \end{pmatrix} \leq T \begin{pmatrix} v_{n,N+1} \\ Z_{n,N+1}(p) \end{pmatrix}.$$

Then $Z_{n,N+1}(p) = Z_{N+1-n}(p)$ and $v_{n,N+1} = v_{N+1-n}$.

We define the total discounted cost as

$$J_{n,N+1}(\zeta, \pi, \tilde{q}) := \mathrm{E}\left[\sum_{t=n}^{N} \alpha^{t-n} c(I_t, q_t) + \sum_{t=N+1}^{\infty} \alpha^{t-n} c(I_t, 0)\right],$$

with $z_n = \zeta$ and $\pi_n = \pi$. Then we have the validation of the backward monotone process:

$$\inf_{\tilde{q}} J_{n,N+1}(\zeta, \pi, \tilde{q}) = \zeta v_{n,N+1} + (1-\zeta) Z_{n,N+1}(\pi).$$

Note that the cost $c(.,.)$ is bounded. Then, $J_{1,N+1}(\zeta, \pi, \tilde{q})$ converges to $J(\zeta, \pi, \tilde{q})$ as N increases. Thus, one has the option of finding the optimal order quantities either by a forward or a backward recursion.

Bounding the optimal order quantity. Start by setting $q = 0$ in (35) and obtain

$$\begin{aligned}
Z(p) &\leq \langle c(.,0), p(.,0) \rangle \; + \alpha v \int_0^\infty \bar{F}(y) p(y) dy + \alpha Z(\rho(0,p)) \\
&\leq c_0 \int_0^\infty p(x) dx \\
&\quad + h \int_0^\infty x p(x) dx + \alpha \frac{c_0}{1-\alpha} \int_0^\infty p(x) dx + \alpha \left(\sup_{p \in \mathcal{H}^+} \frac{|Z(\rho(0,p))|}{||\rho(0,p)||} \right) ||\rho(0,p)|| \\
&\leq c_0 \int_0^\infty p(x) dx + h \int_0^\infty x p(x) dx + \alpha \frac{c_0}{1-\alpha} \int_0^\infty p(x) dx + \alpha \left(\frac{a_0}{1-\alpha} \right) ||p|| \\
&\leq c_0 \int_0^\infty p(x) dx + h \int_0^\infty x p(x) dx \\
&\quad + \alpha \frac{c_0}{1-\alpha} \int_0^\infty p(x) dx + \alpha \frac{a_0}{1-\alpha} \left(\int_0^\infty p(x) dx + \int_0^\infty x p(x) dx \right) \\
&\leq \left(\frac{c_0}{1-\alpha} + \frac{a_0 \alpha}{1-\alpha} \right) \int_0^\infty p(x) dx + \left(h + \frac{a_0 \alpha}{1-\alpha} \right) \int_0^\infty x p(x) dx \\
&\leq \frac{a_0}{1-\alpha} \left\{ \int_0^\infty p(x) dx + \int_0^\infty x p(x) dx \right\}.
\end{aligned}$$

With an arbitrary order quantity q, the cost has a lower bound of $cq \int_0^\infty p(x) dx$. If this bound exceeds $Z(p)$, then q cannot be optimal. Hence, the optimal order quantity

satisfies $cq\int_0^\infty p(x)dx \le Z(p)$, which along with the above inequality implies

$$q \le \frac{a_0}{c(1-\alpha)}\left\{1+\frac{\int_0^\infty xp(x)dx}{\int_0^\infty p(x)dx}\right\}. \tag{50}$$

Note that the bound depends on the unnormalized probability p and can be arbitrarily large as $p \to 0$. Because of this observation, we choose to assume a bound on the order quantity in the next subsection.

3.2. Bounded order quantities. In this section we assume that there is a finite bound on the order quantity q in addition to the cost bounds in the previous section. The finite bound can be due to the supplier's limited production or transportation capacity, or the storage capacity IM can use. Let the capacity be m and let the corresponding Z and v be denoted by Z^m and v^m. Then (35)–(36) is written as

$$\begin{aligned} &Z^m(p)\\ &= \inf_{q\le m}\left\{\langle c(.,q),p(.)\rangle + \alpha v^m\int_0^\infty \bar F(y+q)p(y)dy + \alpha Z^m(\rho(q,p))\right\} \quad \text{for all } p\in\mathcal{H}^+,\\ &v^m = \inf_{q\le m}\left\{c(0,q)+\alpha v^m\bar F(q)+\alpha Z^m(\rho(q,\delta))\right\}. \end{aligned} \tag{51}$$

We shall prove that the functional Z^m is Lipschitz continuous on $\mathcal{H}$, i.e., there exist constants A^m and B^m such that

$$|Z^m(p)-Z^m(p')| \le A^m\int_0^\infty |p(y)-p'(y)|dy + B^m\int_0^\infty y|p(y)-p'(y)|dy \tag{52}$$

for any $p, p' \in \mathcal{H}$. This additional smoothness property allows us to establish the uniqueness of a solution of the system in (35)–(36). The next lemma illustrates how the constants A^m and B^m can be chosen.

LEMMA 5. *For a fixed m, Z^m is Lipschitz continuous, where the constants A^m and B^m in* (52) *should be chosen as*

$$A^m = \frac{c_0}{(1-\alpha)^2} + \frac{m}{1-\alpha}\left(c_1+\frac{\alpha h}{1-\alpha}\right) \quad \textit{and} \quad B^m = \frac{h}{1-\alpha}.$$

Proof. To bound the differences of Z^m, we construct

$$Z^{m,n+1}(p) = \inf_{q\le m} G(q,p;v^m,Z^{m,n})$$

by starting with $Z^{m,0}$, which solves

$$\langle c(.,0),p(.)\rangle + \alpha v^m\int_0^\infty \bar F(y)p(y)dy + \alpha Z^{m,0}(\rho(0,p)) = Z^{m,0}(p). \tag{53}$$

Since $Z^{m,n}$ converges to Z^m as n goes to infinity, it suffices to prove that $Z^{m,n}$ is Lipschitz continuous with constants independent of n. This proof is by induction on n. In other words, Lipschitz continuity must be preserved as n grows and it must hold when we start at $n=0$. These two requirements correspond respectively to the following two claims, which are proved below.

Claim 1. $Z^{m,n+1}$ is Lipschitz continuous with constants A^m and B^m, if $Z^{m,n}$ is Lipschitz continuous with the same constants.

Claim 2. $Z^{m,0}$ is Lipschitz continuous with constants A^m and B^m.

Proof of Claim 1. We start by bounding $G(q,p;;v^m,Z^{m,n}) - G(q,p';v^m,Z^{m,n})$ as follows. In the first inequality below, we use $v^m \le c_0/(1-\alpha)$ and the fact that ρ is a linear operator:

$$\begin{aligned}
& |G(q,p;v^m,Z^{m,n}) - G(q,p';v^m,Z^{m,n})| \\
\le\ & (c_0 + c_1 q)\int_0^\infty |p(y)-p'(y)|dy + h\int_0^\infty y|p(y)-p'(y)|dy \\
& + \frac{\alpha c_0}{1-\alpha}\int_0^\infty |p(y)-p'(y)|dy \\
& + \alpha\left\{A^m\int_0^\infty |\rho(q,p-p')(y)|dy + B^m\int_0^\infty y|\rho(q,p-p')(y)|dy\right\} \\
\overset{(26,27)}{\le}\ & \left(\frac{c_0}{1-\alpha} + c_1 q\right)\int_0^\infty |p(y)-p'(y)|dy + h\int_0^\infty y|p(y)-p'(y)|dy \\
& + \alpha\left\{(A^m + B^m q)\int_0^\infty |p(y)-p'(y)|dy + B^m\int_0^\infty y|p(y)-p'(y)|dy\right\} \\
\le\ & \left(\frac{c_0}{1-\alpha} + c_1 m + \alpha(A^m + B^m m)\right)\int_0^\infty |p(y)-p'(y)|dy \\
& + (h + \alpha B^m)\int_0^\infty y|p(y)-p'(y)|dy.
\end{aligned}$$

Note that the right-hand side of the last inequality is independent of q, provided that $0 \le q \le m$. Hence,

$$\begin{aligned}
|Z^{m,n+1}(p) - Z^{m,n+1}(p')| &= |\inf_{q\le m} G(q,p;v^m,Z^{m,n}) - \inf_{q\le m} G(q,p';v^m,Z^{m,n})| \\
&\le \left(\frac{c_0}{1-\alpha} + c_1 m + \alpha(A^m + B^m m)\right)\int_0^\infty |p(y)-p'(y)|dy \\
&\quad + (h + \alpha B^m)\int_0^\infty y|p(y)-p'(y)|dy \\
&\le A^m\int_0^\infty |p(y)-p'(y)|dy + B^m\int_0^\infty y|p(y)-p'(y)|dy.
\end{aligned}$$

The last inequality holds only if

$$h + \alpha B^m \le B^m,$$

so we set $B^m = h/(1-\alpha)$. Then, we have the equality below and we require the inequality below:

$$\frac{c_0}{1-\alpha} + c_1 m + \alpha(A^m + B^m m) = \frac{c_0}{1-\alpha} + c_1 m + \alpha(A^m + mh/(1-\alpha)) \le A^m.$$

This inequality yields the condition on A^m and completes the proof of Claim 1. □

Proof of Claim 2. We prove the claim by using another induction. Consider the following iteration:

$$
\begin{aligned}
Z^{m,0,0}(p) &= \langle c(.,0), p(.)\rangle + \alpha v^m \int_0^\infty \bar{F}(y)p(y)dy,\\
Z^{m,0,n}(p) &= G(0,p;v^m, Z^{m,0,n-1})\\
&= \langle c(.,0), p(.)\rangle + \alpha v^m \int_0^\infty \bar{F}(y)p(y)dy + \alpha Z^{m,0,n-1}(\rho(0,p)).
\end{aligned}
$$

It is immediate that $Z^{m,0,n}(p) \geq Z^{m,0,n-1}(p)$, and we can also show that $Z^{m,0,n}(p)$ is bounded. Thus, $Z^{m,0,n}(p)$ converges to $Z^{m,0}(p)$, which is the unique solution of (53). We know from Claim 1 that G preserves Lipschitz continuity. Thus, it suffices to show that $Z^{m,0,0}$ is Lipschitz. This follows from

$$
\begin{aligned}
&|Z^{m,0,0}(p) - Z^{m,0,0}(p')|\\
&\quad\leq c_0 \int |p(y) - p'(y)|dy + h\int y|p(y) - p'(y)|dy + \frac{\alpha c_0}{1-\alpha}|p(y) - p'(y)|dy\\
&\quad\leq \underbrace{\frac{c_0}{1-\alpha}}_{\leq A^m}\int |p(y) - p'(y)|dy + \underbrace{h}_{\leq B^m}\int y|p(y) - p'(y)|dy.
\end{aligned}
$$

This completes the proof of Claim 2. Thus, the lemma is proved. □

Existence of a solution to (51) can be proved by following the steps in Theorem 2. The more interesting issue is whether the respective solutions of (35)–(36) and (51) coincide as the bound on the order quantity is removed. To make ideas concrete, define the map T^m similar to T in (44):

$$
T^m \begin{pmatrix} v \\ Z(p) \end{pmatrix} := \begin{pmatrix} \inf_{q\leq m} G(q,\delta;v,Z) \\ \inf_{q\leq m} G(q,p;v,Z) \end{pmatrix}. \tag{54}
$$

Let T_n^m be n compositions of T^m. Thus, (v_n^m, Z_n^m) can be obtained by applying T_n^m on (v_0, Z_0). By the arguments in Theorem 2, (v_n^m, Z_n^m) is a nonincreasing sequence, and it converges to, say, $(\bar{v}^m, \bar{Z}^m)$. We next establish that $(\bar{v}^m, \bar{Z}^m)$ converges to $(\bar{v}, \bar{Z})$, which is the maximal solution of the system in (35)–(36).

LEMMA 6. *$(\bar{v}^m, \bar{Z}^m) \downarrow (\bar{v}, \bar{Z})$ as m increases to ∞.*

Proof. Because of the constraint $q \leq m$,

$$
T^m \begin{pmatrix} v \\ Z(p) \end{pmatrix} \geq T^{m+1} \begin{pmatrix} v \\ Z(p) \end{pmatrix}
$$

for any (v, Z). Starting the value iteration with (v_0, Z_0),

$$
\begin{pmatrix} v_1^m \\ Z_1^m(p) \end{pmatrix} = T^m \begin{pmatrix} v_0 \\ Z_0(p) \end{pmatrix} \geq T^{m+1} \begin{pmatrix} v_0 \\ Z_0(p) \end{pmatrix} = \begin{pmatrix} v_1^{m+1} \\ Z_1^{m+1}(p) \end{pmatrix}.
$$

Applying T^m on the right and T^{m-1} on the left as many times as necessary, we set

$$
(\bar{v}^m, \bar{Z}^m) = \lim_{n\to\infty} T_n^m(v_0, Z_0) \geq \lim_{n\to\infty} T_n^{m+1}(v_0, Z_0) = (\bar{v}^{m+1}, \bar{Z}^{m+1}).
$$

In particular, $(\bar{v}^m, \bar{Z}^m) \geq (\bar{v}, \bar{Z})$. In addition, $(\bar{v}^m, \bar{Z}^m)$ is nonincreasing in m, so it has a limit, say $(\tilde{v}, \tilde{Z})$. Clearly, $(\tilde{v}, \tilde{Z}) \geq (\bar{v}, \bar{Z})$.

Recall that $(\bar{v}, \bar{Z})$ is the maximal fixed point of T. To finish the proof, it suffices to argue that $(\tilde{v}, \tilde{Z})$ is also a fixed point of T. Since $(\tilde{v}, \tilde{Z}) \leq (v_0, Z_0)$, we can repeat

the initial steps in the proof of Theorem 2 to obtain the following inequality, which is analogous to (48):

$$\begin{pmatrix} \tilde{v} \\ \tilde{Z}(p) \end{pmatrix} \geq T \begin{pmatrix} \tilde{v} \\ \tilde{Z}(p) \end{pmatrix}.$$

On the other hand, for any q and $q \leq m$, we have

$$\begin{aligned} Z^m(p) &\leq G(q, p; v^m, Z^m), \\ v^m &\leq G(q, \delta; v^m, Z^m). \end{aligned}$$

Hence,

$$\begin{pmatrix} \tilde{v} \\ \tilde{Z}(p) \end{pmatrix} \leq T \begin{pmatrix} \tilde{v} \\ \tilde{Z}(p) \end{pmatrix}.$$

Thus, $(\tilde{v}, \tilde{Z})$ is a fixed point of T. □

So far, we have studied the existence and the convergence of (v^m, Z^m). The next theorem validates the monotone iterative process, that is, (v^m, Z^m) minimizes the total discounted cost. As a side product of the theorem, v^m and Z^m turn out to be unique because they are equal to the minimum costs, which are unique by definition.

THEOREM 3. *The solution* (v^m, Z^m) *of* (51) *gives the minimum total discounted cost as follows:*

$$\begin{aligned} Z^m(\pi) &= \inf_{\tilde{q}: q_t \leq m} J(0, \pi, \tilde{q}), \\ v^m &= \inf_{\tilde{q}: q_t \leq m} J(1, \delta, \tilde{q}). \end{aligned}$$

Proof. The proof has two parts. We first show that $Z^m(\pi)$ and v^m are, respectively, smaller than $J(0, \pi, \tilde{q})$ and $J(1, \delta, \tilde{q})$ for any $\tilde{q}$ such that $q_t \leq m$. For an arbitrary $q \leq m$,

$$Z^m(p) \leq \langle c(., q), p(.) \rangle + \alpha v^m \int_0^\infty \bar{F}(y + q) p(y) dy + \alpha Z^m(\rho(q, p)).$$

Take $p = \pi_t$ and $q = q_t$ so that

$$Z^m(\pi_t) \leq \langle c(., q_t), \pi_t(.) \rangle + \alpha v^m \int_0^\infty \bar{F}(y + q_t) \pi_t(y) dy + \alpha Z^m(\rho(q_t, \pi_t)),$$

$$v^m \leq c(0, q_t) + \alpha v^m \bar{F}(q_t) + \alpha Z^m(\rho(q_t, \delta)).$$

Note that by (51) and (37), $Z^m(\lambda p) = \lambda Z^m(p)$ for any scalar $\lambda > 0$. Taking $\lambda = \int F(y + q_t) \pi_t(y) dy$, we obtain

$$\begin{aligned} Z^m(\pi_t) \leq \langle c(., q_t), \pi_t(.) \rangle &+ \alpha v^m \int_0^\infty \bar{F}(y + q_t) \pi_t(y) dy \\ &+ \alpha Z^m(\theta(q_t, \pi_t)) \int_0^\infty F(y + q_t) \pi_t(y) dy, \end{aligned}$$

$$v^m \leq c(0, q_t) + \alpha v^m \bar{F}(q_t) + \alpha Z^m(\theta(q_t, \delta)) F(q_t).$$

Now combine these two inequalities by using the weights $1 - z_t$ and z_t, respectively, and obtain

$$\begin{aligned}(1 - z_t)Z^m(\pi_t) + z_t v^m &\le z_t c(0, q_t) + (1 - z_t)\langle c(., q_t), \pi_t(.)\rangle \\ &\quad + \alpha \left\{ (1 - z_t) \left[v^m \int_0^\infty \bar{F}(y + q_t)\pi_t(y)dy \right.\right. \\ &\quad \left.\left. + Z^m(\theta(q_t, \pi_t)) \int_0^\infty F(y + q_t)\pi_t(y)dy \right] + z_t \left[v^m \bar{F}(q_t) + Z^m(\theta(q_t, \delta))F(q_t) \right] \right\}. \qquad (55)\end{aligned}$$

Consider the relation

$$\begin{aligned}&\mathrm{E}[(1 - z_{t+1})Z^m(\pi_{t+1}) + z_{t+1}v^m|\mathcal{Z}_t] \\ &\quad = \mathrm{P}(I_{t+1} > 0|\mathcal{Z}_t)Z^m(\pi_{t+1}) + \mathrm{P}(I_{t+1} = 0|\mathcal{Z}_t)v^m \\ &\quad = \left[z_t F(q_t) + (1 - z_t) \int_0^\infty F(q_t + y)\pi_t(y) \right] Z^m(\pi_{t+1}) \\ &\qquad + \left[z_t \bar{F}(q_t) + (1 - z_t) \int_0^\infty \bar{F}(q_t + y)\pi_t(y)dy \right] v^m \\ &\quad = \left[z_t F(q_t) + (1 - z_t) \int_0^\infty F(q_t + y)\pi_t(y) \right] Z^m(z_t\theta(q_t, \delta) + (1 - z_t)\theta(q_t, \pi_t)) \\ &\qquad + \left[z_t \bar{F}(q_t) + (1 - z_t) \int_0^\infty \bar{F}(q_t + y)\pi_t(y)dy \right] v^m \\ &\quad = z_t \left[Z^m(\theta(q_t, \delta))F(q_t) + v^m \bar{F}(q_t) \right] \\ &\qquad + (1 - z_t) \left[Z^m(\theta(q_t, \pi_t)) \int_0^\infty F(q_t + y)\pi_t(y)dy + v^m \int_0^\infty \bar{F}(q_t + y)\pi_t(y)dy \right].\end{aligned}$$

Now insert this equality into the curly brackets in (55) to obtain

$$\begin{aligned}(1 - z_t)Z^m(\pi_t) + z_t v^m &\le z_t c(0, q_t) + (1 - z_t)\langle c(., q_t), \pi_t(.)\rangle \\ &\quad + \alpha \left\{ \mathrm{E}[(1 - z_{t+1})Z^m(\pi_{t+1}) + z_{t+1}v^m|\mathcal{Z}_t] \right\}.\end{aligned}$$

By multiplying both sides by α^t and taking expected values, we get

$$\begin{aligned}\alpha^t \mathrm{E}[(1 - z_t)Z^m(\pi_t) + z_t v^m] &\le \alpha^t \mathrm{E}[z_t c(0, q_t) + (1 - z_t)\langle c(., q_t), \pi_t(.)\rangle] \\ &\quad + \alpha^{t+1} \mathrm{E}[(1 - z_{t+1})Z^m(\pi_{t+1}) + z_{t+1}v^m] \quad \text{for } t \ge 1.\end{aligned}$$

Now sum up both sides for $t \ge 1$ to obtain

$$\begin{aligned}\sum_{t=1}^\infty \alpha^t \mathrm{E}[(1 - z_t)Z^m(\pi_t) + z_t v^m] &\le \sum_{t=1}^\infty \alpha^t \mathrm{E}[z_t c(0, q_t) + (1 - z_t)\langle c(., q_t), \pi_t(.)\rangle] \\ &\quad + \sum_{t=1}^\infty \alpha^{t+1} \mathrm{E}[(1 - z_{t+1})Z^m(\pi_{t+1}) + z_{t+1}v^m]. \qquad (56)\end{aligned}$$

The second term on the right-hand side is next argued to be finite, so that it can be deducted from both sides of the inequality.

We now construct an upper bound for $\mathrm{E}Z^m(\pi_{t+1})$. First note that

$$\mathrm{E}Z^m(\pi_{t+1}) \le |\mathrm{E}Z^m(\pi_{t+1})| \le ||Z^m||_{\mathcal{B}} ||\mathrm{E}\pi_{t+1}|| = ||Z^m||_{\mathcal{B}} \mathrm{E}||\pi_{t+1}||,$$

where

$$\mathrm{E}||\pi_{t+1}|| = 1 + \mathrm{E}\int_0^\infty x\pi_{t+1}(x)dx.$$

But

$$\mathrm{E}\int_0^\infty x\pi_{t+1}(x)dx = \mathrm{E}(1-z_{t+1})\mathrm{E}[I_{t+1}|\mathcal{Z}_{t+1}] \le \mathrm{E}I_{t+1} \le I_0 + m(t+1),$$

where the last inequality follows from $q_t \le m$. Therefore, as $t \to \infty$,

$$\begin{aligned}\alpha^{t+1}\mathrm{E}[(1-z_{t+1})Z^m(\pi_{t+1}) + z_{t+1}v^m] &\le \alpha^{t+1}\mathrm{E}[Z^m(\pi_{t+1})] + \alpha^{t+1}v^m \\ &\le \alpha^{t+1}\frac{a_0}{1-\alpha}\mathrm{E}[\pi_{t+1}] + \alpha^{t+1}v^m \\ &\qquad\qquad \text{by Lemma 3} \\ &\le \alpha^{t+1}\frac{a_0}{1-\alpha}(I_0 + m(t+1)) + \alpha^{t+1}v^m.\end{aligned}$$

Since $\sum_t \alpha^{t+1}\frac{a_0}{1-\alpha}(I_0 + m(t+1)) + \alpha^{t+1}v^m < \infty$, the second term on the right-hand side of (56) is finite. Now deduct it from the left-hand side to obtain

$$\alpha\mathrm{E}[(1-z_1)Z^m(\pi_1) + z_1v^m] \le \sum_{t=1}^\infty \alpha^t\mathrm{E}[z_tc(0,q_t) + (1-z_t)\langle c(.,q_t),\pi_t(.)\rangle]. \tag{57}$$

From (57), it follows that

$$\begin{aligned}(1-\zeta)Z^m(\pi) + \zeta v^m &= \mathrm{E}[(1-z_1)Z^m(\pi) + z_1v^m] \\ &\le \sum_{t=1}^\infty \alpha^t[z_tc(0,q_t) + (1-z_t)\langle c(.,q_t),\pi_t(.)\rangle] = J(\zeta,\pi,\tilde{q}).\end{aligned}$$

This finishes the first part of the proof.

For the second part of the proof, we construct an optimal solution by considering an optimal feedback control $\hat{q}^m(p)$ and $\hat{q}^m$ such that

$$Z^m(p) = \langle c(.,\hat{q}^m(p)),p(.)\rangle + \alpha v^m\int_0^\infty \bar{F}(y+\hat{q}^m(p))p(y)dy + \alpha Z^m(\rho(\hat{q}^m(p),p)),$$

$$v^m = c(0,\hat{q}^m) + \alpha v^m\bar{F}(\hat{q}^m) + \alpha Z^m(\rho(\hat{q}^m,\delta)).$$

Existence of an optimal feedback control follows from the continuity of $c(\cdot,\cdot)$, the continuity of $\bar{F}(\cdot)$, and the Lipschitz continuity of Z^m in Lemma 5.

We associate these feedbacks with a stochastic process $\{\hat{\tilde{q}}_t^m\}$, which is adapted to $\mathcal{Z}_t$ and defined recursively as follows:

$$\hat{\tilde{q}}_1^m := \zeta\hat{q}^m + (1-\zeta)\hat{q}^m(\pi),$$

$$\hat{\tilde{q}}_{t+1}^m := z_t\hat{q}^m + (1-z_t)\hat{q}^m(\pi_t).$$

The definitions of $\hat{q}^m(p)$, $\hat{q}^m$, and $\hat{\tilde{q}}^m$ yield the next two equalities:

$$
\begin{aligned}
&(1-z_t)Z^m(\pi_t)+z_tv^m\\
&\quad=(1-z_t)\langle c(.,\hat{q}^m(\pi_t)),\pi_t(.)\rangle+\alpha(1-z_t)v^m\int_0^\infty \bar{F}(y+\hat{q}^m(\pi_t))\pi_t(y)dy\\
&\qquad+\alpha(1-z_t)Z^m(\rho(\hat{q}^m(\pi_t),\pi_t))+z_tc(0,\hat{q}^m)+\alpha z_tv^m\bar{F}(\hat{q}^m)+\alpha z_tZ^m(\rho(\hat{q}^m,\delta))\\
&\quad=(1-z_t)\langle c(.,\hat{\tilde{q}}^m_{t+1}),\pi_t(.)\rangle+\alpha(1-z_t)v^m\int_0^\infty \bar{F}(y+\hat{\tilde{q}}^m_{t+1})\pi_t(y)dy\\
&\qquad+\alpha(1-z_t)Z^m(\rho(\hat{\tilde{q}}^m_{t+1},\pi_t))+z_tc(0,\hat{\tilde{q}}^m_{t+1})+\alpha z_tv^m\bar{F}(\hat{\tilde{q}}^m_{t+1})+\alpha z_tZ^m(\rho(\hat{\tilde{q}}^m_{t+1},\delta))\\
&\quad=(1-z_t)\langle c(.,\hat{\tilde{q}}^m_{t+1}),\pi_t(.)\rangle+z_tc(0,\hat{\tilde{q}}^m_{t+1})\\
&\qquad+\alpha(1-z_t)\left[v^m\int_0^\infty \bar{F}(y+\hat{\tilde{q}}^m_{t+1})\pi_t(y)dy+Z^m(\rho(\hat{\tilde{q}}^m_{t+1},\pi_t))\right]\\
&\qquad+\alpha z_t[v^m\bar{F}(\hat{\tilde{q}}^m_{t+1})+Z^m(\rho(\hat{\tilde{q}}^m_{t+1},\delta))].
\end{aligned}
$$

Specializing for $t=1$ and taking the infimum over $\tilde{q}$ yields

$$(1-\zeta)Z^m(\pi)+\zeta v^m\geq J(\zeta,\pi,\hat{\tilde{q}}^m).$$

Combining the two parts of the proof we have

$$(1-\zeta)Z^m(\pi)+\zeta v^m=J(\zeta,\pi,\hat{\tilde{q}}^m).\qquad\square$$

Since $Z^m(\pi)$ and v^m are defined as a solution of (51) and they are given by the infima in Theorem 3, both $Z^m(\pi)$ and v^m are unique. As m increases, we have

$$\inf_{\tilde{q}:q_t\leq m}J(0,\pi,\tilde{q})\downarrow\inf_{\tilde{q}}J(0,\pi,\tilde{q}),$$

$$\inf_{\tilde{q}:q_t\leq m}J(1,\pi,\tilde{q})\downarrow\inf_{\tilde{q}}J(1,\pi,\tilde{q}).$$

These imply

$$Z(\pi)=\inf_{\tilde{q}}J(0,\pi,\tilde{q}),$$

$$v=\inf_{\tilde{q}}J(1,\pi,\tilde{q}).$$

Thus, $Z(\pi)$ and v are interpreted as the infima of the costs even when m disappears. However, a corresponding feedback solution that yields $Z(\pi)$ and v may not exist unless m is finite.

In this section, we have established that Z^m is continuous and that it converges to Z. However, these results do not guarantee the continuity of Z. Nevertheless, we have the weaker form of continuity as presented in the next lemma.

LEMMA 7. *Z is upper semicontinuous, i.e.,*

$$\limsup_{p_k\to p}Z(p_k)\leq Z(p).$$

Proof. Since $Z(p_k)\leq Z^m(p_k)$ for each k and Z^m is continuous,

$$\limsup_{p_k\to p}Z(p_k)\leq\limsup_{p_k\to p}Z^m(p_k)=Z^m(p).$$

Now take the limit as $m\to\infty$ to obtain the desired result. $\square$

4. A sufficiently small discount rate. We argue that T is a contraction map for a sufficiently small α. Namely, we let $M := 1 + a_0/(c(1-\alpha))$ and require that $\alpha(1+M) < 1$. In this case, the solution of the system (35)–(36), whose existence follows from Theorem 2, is unique.

Consider the difference

$$G(q,p;v,Z) - G(q,p;v',Z') = \alpha(v-v')\int_0^\infty \bar{F}(y+q)p(y)dy + \alpha[Z(\rho(q,p)) - Z'(\rho(q,p))].$$

Let us define a distance in the space $\Re \times \mathcal{B}$ by

$$\eta = d\left(\begin{pmatrix} v \\ Z(p) \end{pmatrix}, \begin{pmatrix} v' \\ Z'(p) \end{pmatrix}\right) := \max\left\{\sup_{p\in\mathcal{H}^+} \frac{|Z(p)-Z'(p)|}{||p||},\ |v-v'|\right\}.$$

Since $Z \in \mathcal{B}$ and $\eta < \infty$, we have

$$\begin{aligned} |G(q,p;v,Z) - G(q,p;v',Z')| &\le \alpha|v-v'|\int_0^\infty p(y)dy + \alpha||Z-Z'||_{\mathcal{B}}||\rho(q,p)|| \\ &\le \eta\alpha\int_0^\infty p(y)dy + \eta\alpha||\rho(q,p)||. \end{aligned} \tag{58}$$

On the other hand, by (50),

$$q \le \frac{a_0}{c(1-\alpha)}\frac{||p||}{\int_0^\infty p(y)dy},$$

or, equivalently,

$$q\int_0^\infty p(y)dy \le \frac{a_0}{c(1-\alpha)}||p||.$$

Using (26) and (27), we obtain

$$\begin{aligned} ||\rho(q,p)|| &\le \int_0^\infty |p(y)|dy + \int_0^\infty (y+q)|p(y)|F(y+q)dy \\ &\le ||p|| + q\int_0^\infty |p(y)|dy \\ &\le ||p||\left(1 + \frac{a_0}{c(1-\alpha)}\right) \\ &= M||p||. \end{aligned} \tag{59}$$

Now insert (59) into (58) to obtain

$$|G(q,p;v,Z) - G(q,p;v',Z')| \le \eta\alpha(1+M)||p||.$$

Hence, it follows that

$$|\inf_q G(q,p;v,Z) - \inf_q G(q,p;v',Z')| \le \eta\alpha(1+M)||p||.$$

Recalling $||\delta|| = 1$ and specializing to $p = \delta$, we have

$$|\inf_q G(q,\delta;v,Z) - \inf_q G(q,\delta;v',Z')| \le \eta\alpha(1+M).$$

In summary, we have proved

$$d\left(T\begin{pmatrix} v \\ Z(p) \end{pmatrix}, T\begin{pmatrix} v' \\ Z'(p) \end{pmatrix}\right) \leq \alpha(1+M)d\left(\begin{pmatrix} v \\ Z(p) \end{pmatrix}, \begin{pmatrix} v' \\ Z'(p) \end{pmatrix}\right).$$

In addition, if $\alpha(1+M) < 1$ as required at the beginning of this section, T is a contraction map on $\Re \times \mathcal{B}$. It is also a contraction on $\Re \times \mathcal{B}_c$, where $\mathcal{B}_c$ denotes the closed subset containing the continuous functions in $\mathcal{B}$. Therefore, when $\alpha(1+M) < 1$, (35)–(36) have a unique fixed point in $\Re \times \mathcal{B}_c$.

4.1. Relaxing the condition on the discount rate. We relax the condition $\alpha(1+M) < 1$ to $\alpha M < 1$ by measuring the distance d in $\Re \times \mathcal{B}$ for a fixed λ. Namely, we consider the projection of $\Re \times \mathcal{B}$ onto $\{\lambda\} \times \mathcal{B}$. For any λ, we define the projected value function Z^λ as the solution of

$$Z^\lambda(p) = \inf_q \left\{ \langle c(.,q), p(.)\rangle \ + \alpha\lambda \int_0^\infty \bar{F}(y+q)p(y)dy + \alpha Z^\lambda(\rho(q,p)) \right\}. \tag{60}$$

Note by (37) that $Z^\lambda(\mu p) = \mu Z^\lambda(p)$, and thus $Z^\lambda(0) = 0$.

LEMMA 8. *If $\lambda < v_0 = c_0/(1-\alpha)$, then $Z^\lambda(p) \leq Z_0(p)$ for all $p \in \mathcal{H}^+$.*

Proof. First note that

$$Z^\lambda(p) \leq \langle c(.,0), p(.)\rangle + \alpha v_0 \int_0^\infty \bar{F}(y)p(y)dy + \alpha Z^\lambda(\rho(0,p)),$$

$$Z_0(p) = \langle c(.,0), p(.)\rangle + \alpha v_0 \int_0^\infty \bar{F}(y)p(y)dy + \alpha Z_0(\rho(0,p)).$$

Now take the difference to obtain $Z^\lambda(p) - Z_0(p) \leq \alpha(Z^\lambda(\rho(0,p)) - Z_0(\rho(0,p)))$. Taking the positive parts, we obtain $[Z^\lambda(p) - Z_0(p)]^+ \leq \alpha[Z^\lambda(\rho(0,p)) - Z_0(\rho(0,p))]^+$. Divide both sides by $||p||$ and take the supremum over $p \in \mathcal{H}^+$ to obtain

$$\begin{aligned} \sup_{p\in\mathcal{H}^+} \frac{[Z^\lambda(p) - Z_0(p)]^+}{||p||} &\leq \alpha \sup_{p\in\mathcal{H}^+} \frac{[Z^\lambda(\rho(0,p)) - Z_0(\rho(0,p))]^+}{||p||} \\ &\leq \alpha||Z^\lambda - Z_0||_{\mathcal{B}} \sup_{p\in\mathcal{H}^+} \frac{||\rho(0,p)||}{||p||} \leq \alpha||Z^\lambda - Z_0||_{\mathcal{B}} \\ &\leq \alpha \left\{ \sup_{p\in\mathcal{H}^+} \frac{[Z^\lambda(p) - Z_0(p)]^+}{||p||} \right\}. \end{aligned} \tag{61}$$

By recursing (61) N times, we get

$$\sup_{p\in\mathcal{H}^+} \frac{[Z^\lambda(p) - Z_0(p)]^+}{||p||} \leq \alpha^N \left\{ \sup_{p\in\mathcal{H}^+} \frac{[Z^\lambda(p) - Z_0(p)]^+}{||p||} \right\}.$$

Thus, $[Z^\lambda(p) - Z_0(p)]^+ = 0$ or $Z^\lambda(p) \leq Z_0(p)$. ∎

Define, for $\lambda \leq v_0$ and $Z \leq Z_0$,

$$T^\lambda(Z)(p) := \inf_q \left\{ \langle c(.,q), p(.)\rangle \ + \alpha\lambda \int_0^\infty \bar{F}(y+q)p(y)dy + \alpha Z(\rho(q,p)) \right\}.$$

Use $v = v' = \lambda$ in the steps used in obtaining (58) to arrive at

$$|T^\lambda(Z)(p) - T^\lambda(Z')(p)| \leq \alpha||Z - Z'||_{\mathcal{B}}||\rho(q,p)|| \leq \alpha||Z - Z'||_{\mathcal{B}}M||p||.$$

The second inequality is due to $||\rho(q,p)|| \leq M||p||$, where $M = 1 + a_0/(c(1-\alpha))$. Then it is immediate that

$$||T^\lambda(Z_1) - T^\lambda(Z_2)||_{\mathcal{B}} \leq \alpha M||Z_1 - Z_2||_{\mathcal{B}}.$$

If $\alpha M < 1$, then $T^\lambda(Z)$ is a contraction mapping. Thus, $T^\lambda(Z)$ has a fixed point in $\Re \times \mathcal{B}_c$. Consequently, Z^λ is uniquely defined. It is shown to be nondecreasing with respect to λ in the next lemma.

LEMMA 9. *$Z^\lambda(p)$ is nondecreasing in λ for each $p \in \mathcal{H}^+$.*

Proof. For any λ, define

$$Z_n^\lambda(p) := T^\lambda Z_{n-1}^\lambda(p), \quad Z_0^\lambda(p) := Z_0(p).$$

Then $Z_n^\lambda(p) \downarrow Z^\lambda(p)$. Suppose $\lambda' > \lambda$. By induction, if

$$Z_{n-1}^{\lambda'}(p) \geq Z_{n-1}^\lambda(p),$$

then

$$Z_n^{\lambda'}(p) = T^{\lambda'}(Z_{n-1}^{\lambda'})(p) \geq T^\lambda(Z_{n-1}^{\lambda'})(p) \geq T^\lambda(Z_{n-1}^\lambda)(p) = Z_{n-1}^\lambda(p).$$

Going to the limit yields $Z^{\lambda'}(p) \geq Z^\lambda(p)$. □

Now consider the function $g(\lambda)$ for $\lambda \geq 0$ defined by

$$g(\lambda) := \inf_q \left\{ c(0,q) + \alpha\lambda\bar{F}(q) + \alpha Z^\lambda(\rho(q,\delta)) \right\}, \tag{62}$$

where Z^λ is given by (60). By Lemma 9, the map $g(\lambda)$ is nondecreasing. It is concave with a rate of increase of at most α, by the next theorem.

THEOREM 4. *The system in* (35)–(36) *has a unique solution.*

Proof. We first establish the concavity of $Z^\lambda(p)$ in λ for each fixed $p \in \mathcal{H}^+$:

$$Z^{\beta\lambda_1+(1-\beta)\lambda_2}(p) \geq \beta Z^{\lambda_1}(p) + (1-\beta)Z^{\lambda_2}(p).$$

This will be proved by induction on n in Z_n^λ, where $Z_n^\lambda = T^\lambda Z_{n-1}^\lambda$. For $n = 0$, $Z_0^\lambda(p) = Z_0(p)$, so it is a constant and hence concave. If the concavity holds for $Z_{n-1}^\lambda(p)$ then,

$$\begin{aligned}
Z_n^{\beta\lambda_1+(1-\beta)\lambda_2}(p) &= \inf_q \Bigg\{ \langle c(.,q), p(.)\rangle \; + \alpha(\beta\lambda_1 + (1-\beta)\lambda_2) \int_0^\infty \bar{F}(y+q)p(y)dy \\
&\qquad + \alpha Z_{n-1}^{\beta\lambda_1+(1-\beta)\lambda_2}(\rho(q,p)) \Bigg\} \\
&\geq \inf_q \Bigg\{ \beta\langle c(.,q), p(.)\rangle \; + \alpha\beta\lambda_1 \int_0^\infty \bar{F}(y+q)p(y)dy + \alpha\beta Z_{n-1}^{\lambda_1}(\rho(q,p)) \\
&\qquad + (1-\beta)\langle c(.,q), p(.)\rangle \; + \alpha(1-\beta)\lambda_2 \int_0^\infty \bar{F}(y+q)p(y)dy \\
&\qquad + \alpha(1-\beta)Z_{n-1}^{\lambda_2}(\rho(q,p)) \Bigg\} \\
&\geq \beta Z_n^{\lambda_1}(p) + (1-\beta)Z_n^{\lambda_2}(p).
\end{aligned}$$

Since T^λ preserves the concavity and Z_n^λ converge to Z^λ, we can conclude that $Z^\lambda(p)$ is concave in λ for every $p \in \mathcal{H}^+$.

We repeat the steps above with $g(\lambda)$ to see the following:

$$\begin{aligned}
&g(\beta\lambda_1 + (1-\beta)\lambda_2)\\
&\quad = \inf_q \Big\{ c(0,q) \ + \alpha(\beta\lambda_1 + (1-\beta)\lambda_2)\bar{F}(q) + \alpha Z^{\beta\lambda_1+(1-\beta)\lambda_2}(\rho(q,\delta)) \Big\}\\
&\quad \geq \inf_q \big\{ \beta c(0,q) \ + \alpha\beta\lambda_1\bar{F}(q) + \alpha\beta Z^{\lambda_1}(\rho(q,\delta))\\
&\qquad\qquad + (1-\beta)c(0,q) \ + \alpha(1-\beta)\lambda_2\bar{F}(q)p(y)dy + \alpha(1-\beta)Z^{\lambda_2}(\rho(q,\delta)) \big\}\\
&\quad \geq \beta g(\lambda_1) + (1-\beta)g(\lambda_2).
\end{aligned}$$

Hence, $g(\lambda)$ inherits concavity from $Z^\lambda(p)$ for every $p \in \mathcal{H}^+$.

By setting $q = 0$ in (62) and recalling that $Z^\lambda(\rho(0,\delta)) = Z^\lambda(0) = 0$, we obtain

$$g(\lambda) \leq c(0,0) + \alpha\lambda, \tag{63}$$

which shows that the function $g(\lambda)$ has a rate of growth of at most α. Furthermore, ignoring the last two terms in (62) and using (38), we get

$$g(0) \geq \inf_q c(0,q) \geq c_2 > 0. \tag{64}$$

We already know that there exists a solution to (60). Since $g(0) > 0$, and $g(\lambda)$ is concave and has a growth rate of at most α, the equation $g(\lambda) = \lambda$ has a unique solution v. Thus, setting $Z = Z^v$, we obtain a unique pair (v, Z) which solves (35)–(36). □

5. Abridged optimal control. Let $\hat{q}^k$ be the abridged feedback control defined as

$$\hat{q}^k = \{\hat{q}_1(\pi_1), \hat{q}_2(\pi_2), \dots, \hat{q}_k(\pi_k), \hat{q}^\infty, \dots, \hat{q}^\infty, \dots\}.$$

It is important to note that $\hat{q}^k$ is defined by k functions mapping $\mathcal{H}^+$ to $\Re$ and a scalar $\hat{q}^\infty$. After period k, the same scalar $\hat{q}^\infty$ is applied repeatedly without regard to the current state, so $\hat{q}_t$ is adapted to $\mathcal{Z}_t$ only for $t \leq k$.

Consider the *abridged* monotone iterative process starting with

$$\begin{aligned}
v_0 &= c(0,0) + \alpha v_0,\\
Z_0(p) &= \langle c(.,0), p(.)\rangle \ + \alpha v_0 \int_0^\infty \bar{F}(y)p(y)dy + \alpha Z_0(\rho(0,p))
\end{aligned}$$

by iterating with the feedback $\hat{q}_n(p)$ for $n \leq k$, which solves

$$\left.\begin{aligned}
v_{n+1} &= \inf_q \big\{ c(0,q) + \alpha v_n \bar{F}(q) + \alpha Z_n(\rho(q,\delta)) \big\}\\
Z_{n+1}(p) &= \inf_q \big\{ \langle c(.,q), p(.)\rangle \ + \alpha v_n \textstyle\int \bar{F}(y+q)p(y)dy + \alpha Z_n(\rho(q,p)) \big\}
\end{aligned}\right\} \quad \text{for } n \leq k. \tag{65}$$

Afterwards, the monotone iterative process applies the scalar $\hat{q}^\infty$, so we have

$$\left.\begin{aligned}
v_{n+1} &= \big\{ c(0,\hat{q}^\infty) + \alpha v_n \bar{F}(\hat{q}^\infty) + \alpha Z_n(\rho(\hat{q}^\infty,\delta)) \big\}\\
Z_{n+1}(p) &= \big\{ \langle c(.,\hat{q}^\infty), p(.)\rangle \ + \alpha v_n \textstyle\int \bar{F}(y+\hat{q}^\infty)p(y)dy + \alpha Z_n(\rho(\hat{q}^\infty,p)) \big\}
\end{aligned}\right\} \quad \text{for } n > k.$$

One can improve the value functions by choosing $\hat{q}^\infty$ as good as possible. For example, take

$$\hat{q}^\infty = \arg\inf_q \mathrm{E}\sum_{t=1}^{\infty} \alpha^t c(I_t, q) \text{ with } I_1 = I_{k+1}.$$

The scalar $\hat{q}^\infty$ exists because q can be bounded in the minimization of the sum of continuous functions $c(.,q)$ above.

The scalar $\hat{q}^\infty$ can be found by an alternative procedure. For a fixed q, define (v_q, Z_q) by

$$Z_q(p) = \langle c(.,q), p(.)\rangle + \alpha v_q \int_0^\infty \bar{F}(y+q)p(y)dy + \alpha Z_q(\rho(q,p)),$$
$$v_q = c(0,q) + \alpha v_q \bar{F}(q) + \alpha Z_q(\rho(q,\delta)).$$

Once the functional Z_q is obtained, we choose $\hat{q}^\infty$ as

$$\hat{q}^\infty = \arg\inf_q Z_q(\pi_{k+1}).$$

The abridged iterative process preserves the continuity of Z_n as established next.

LEMMA 10. *If Z_n is continuous over $\mathcal{H}^+ \setminus \{0\}$, then Z_{n+1} is continuous over the same set.*

Proof. Indeed if Z_n is continuous, then the function

$$G(q,p;v_n,Z_n) = \langle c(.,q), p(.)\rangle + \alpha v_n \int_0^\infty \bar{F}(y+q)p(y)dy + \alpha Z_n(\rho(q,p))$$

is continuous in $\Re^+ \times \mathcal{H}^+$. In view of (50), we can moreover assume that the order quantity q is bounded above by

$$q \le \frac{a_0}{c(1-\alpha)}\left\{1 + \frac{\int_0^\infty xp(x)dx}{\int_0^\infty p(x)dx}\right\}.$$

This bound depends on p and it is well defined for $p \in \mathcal{H}^+ \setminus \{0\}$. Then there exist $\hat{q}_n(p)$ and $\hat{q}_n$ achieving the infima such that

$$v_{n+1} = c(0,\hat{q}_n) + \alpha v_n \bar{F}(\hat{q}_n) + \alpha Z_n(\rho(\hat{q}_n,\delta)),$$
$$Z_{n+1}(p) = \langle c(.,\hat{q}_n(p)), p(.)\rangle + \alpha v_n \int_0^\infty \bar{F}(y+\hat{q}_n(p))p(y)dy + \alpha Z_n(\rho(\hat{q}_n(p),p)).$$

Hence, Z_{n+1} is continuous in $\hat{q}_n(p)$.

To complete the proof, we need to show continuity in p. Suppose that $p_k \to p$ in $\mathcal{H}^+$. For an arbitrary q,

$$Z_{n+1}(p_k) \le \langle c(.,q), p_k(.)\rangle + \alpha v_n \int_0^\infty \bar{F}(y+q)p_k(y)dy + \alpha Z_n(\rho(q,p_k)).$$

Take the lim sup of both sides and note that the right-hand side is continuous in p_k to obtain

$$\limsup_{k\to\infty} Z_{n+1}(p_k) \le \limsup_{k\to\infty}\left\{\langle c(.,q), p_k(.)\rangle + \alpha v_n \int_0^\infty \bar{F}(y+q)p_k(y)dy + \alpha Z_n(\rho(q,p_k))\right\}$$
$$\le \langle c(.,q), p(.)\rangle + \alpha v_n \int_0^\infty \bar{F}(y+q)p(y)dy + \alpha Z_n(\rho(q,p)).$$

Inserting $q = \hat{q}_n(p)$ into the right-hand side gives

$$\limsup_{k\to\infty} Z_{n+1}(p_k) \le Z_{n+1}(p). \tag{66}$$

Next

$$Z_{n+1}(p_k) = \langle c(.,\hat{q}(p_k)), p_k(.)\rangle + \alpha v_n \int_0^\infty \bar{F}(y+\hat{q}(p_k))p_k(y)dy + \alpha Z_n(\rho(\hat{q}(p_k),p)).$$

Since $p_k \to p$, we can extract a subsequence p_{k_l} indexed by k_l such that $p_{k_l} \to p$ and $\lim_{l\to\infty} Z_{n+1}(p_{k_l}) = \liminf_k Z_{n+1}(p_k)$. Using the standard arguments and the fact that $\hat{q}_n(p_{k_l})$ remains bounded, we can guarantee that the subsequence $\hat{q}_n(p_{k_l})$ converges to a number, say $\hat{q}'$. By continuity of Z_n,

$$\begin{aligned}\lim_{l\to\infty} Z_{n+1}(p_{k_l}) &= \langle c(.,\hat{q}'), p(.)\rangle + \alpha v_n \int_0^\infty \bar{F}(y+\hat{q}')p_k(y)dy + \alpha Z_n(\rho(\hat{q}',p)) \\ &\ge Z_{n+1}(p),\end{aligned}$$

where the inequality is due to the fact that $\hat{q}'$ may differ from $\hat{q}_n(p)$. Using the inequality along with the definition of the subsequence p_{k_l}, we have

$$\liminf_{k\to\infty} Z_{n+1}(p_k) = \lim_{l\to\infty} Z_{n+1}(p_{k_l}) \ge Z_{n+1}(p). \tag{67}$$

Combining (66) and (67), we obtain that $\limsup_k Z_{n+1}(p_k) = \liminf_k Z_{n+1}(p_k)$, so that Z_{n+1} is continuous. □

In this section, we have introduced an abridged optimal control for our inventory problem. The choice of k for the abridged control $\hat{q}^k$ is an important practical question. Note that v_n and $Z_{n+1}(p)$ decrease as k increases for any $p \in \mathcal{H}^+$. Moreover, these values cannot fall below the inventory cost of the corresponding fully observed system. The gap between these costs is an upper bound on the cost savings achievable by increasing k. A manager may use this bound to determine whether a given value of k is suitable. An alternative approach is to increase k until the reduction in the costs v_n and $Z_{n+1}(p)$ for any $p \in \mathcal{H}^+$ become less than a specified amount.

6. Conclusion and extensions. This paper has provided a rigorous treatment of inventory problems with partial observations. The observation process is a binary valued Markov chain, which arises from the zero-balance walk approach to inventory management. Since the inventory level is often not observed, its distribution is used to represent the state of the system. This approach immediately results in a dynamic program in a functional space. The dynamic programming equations are simplified by using unnormalized probabilities. By doing so, a Zakai-type system of equations are derived for our inventory problem. This simplification has allowed us to prove the existence of a value function under various assumptions. We also established the uniqueness of the function in some cases.

This paper is part of a greater effort [6] that aims to study inventory problems with partial observations. As such, it represents an important step in the study of inventory problems with partial observations. It treats a specific binary observation process. We plan to investigate the effect of other observation processes on inventory policies.

Search for a sufficient statistic. An interesting area of research is to classify those partial observation processes for which a sufficient statistic exists. While it

is not so in the general case, such statistics exist; see [7, 8], for example. When a sufficient statistic exists, the system becomes finite-dimensional, and the analysis can be carried much further.

Approximation algorithms. When a sufficient statistic does not exist, which is often the case, the analysis in this paper becomes very relevant. Furthermore, our analysis directly shows how successive approximations can lead to an optimal solution. In devising approximate optimal solutions and heuristic procedures, one can also benefit from the books [19, 20].

Finer interval observations. We have supposed in this paper that only events $[I_t = 0]$ and $[I_t > 0]$ are observed. This corresponds to observing if the inventory falls into the intervals $[0, 0]$ or $(0, \infty)$. When there is a finite storage capacity a, the inventory can take values in the interval $[0, a]$. This interval can be partitioned into $N + 2$ disjoint intervals, namely,

$$\mathcal{I}_0 := [a_0, a_0],\ \mathcal{I}_1 := (a_0, a_1],\ \mathcal{I}_2 := (a_1, a_2], \ldots,\ \mathcal{I}_N := (a_{N-1}, a_N),\ \mathcal{I}_{N+1} := [a_N, a_N]$$

for $0 = a_0 < a_1 < \cdots < a_{N-1} < a_N = a$. The signals associated with the observation of inventory in these intervals will be

$$z_t = n \quad \text{if } I_t \in \mathcal{I}_n \quad \text{for } 0 \le n \le N + 1.$$

Clearly this new signal process provides more information than the binary signal we have studied. However, we expect that the Bellman equations can still be linearized by using unnormalized probabilities.

In practice, the interval observations as defined above would happen when the inventory is stored in modules, e.g., bins, shelves, or different locations. The IM can see empty and full bins by simply walking in the storage area. In a typical case, the bins may be prioritized in such a way that the items in bin i are not used until the items in bin $i + 1$ are finished. Then a_1 would be the first bin's capacity, a_2 would be the first and second bins' cumulative capacity, etc. If three bins are full, the fourth is semifull, and the others are empty, the IM would conclude that $I_t \in \mathcal{I}_4 = (a_3, a_4]$ and observe the signal $z_t = 4$.

Stock-taking and inspections. Perpetual growth in the uncertainty of the actual inventories can lead to poor decisions and therefore higher costs. In practice, actual inventories are counted and/or inspected often periodically to reduce uncertainty [2]. Since stock-counting and inspections may require testing and disrupt other activities, they are expensive. Consequently, the inventory is not counted or inspected every period. Also, only a part of the inventory (partial inspection) may be examined to reduce the uncertainty to a reasonable level. The counting and inspection costs typically have both fixed and proportional components. The optimal timing and the amount of inspections, whose study would require the use of quasi-variational inequalities [4], is an interesting topic for future research.

Acknowledgments. We thank Guillermo Gallego for his constructive input during the development phase of our problem. The authors thank J. Adolfo Minjarés-Sosa, the anonymous referees, and the editor for their suggestions, which have improved the exposition of the paper.

TRACKING WITH PRESCRIBED TRANSIENT BEHAVIOR FOR NONLINEAR SYSTEMS OF KNOWN RELATIVE DEGREE*

ACHIM ILCHMANN†, EUGENE P. RYAN‡, AND PHILIP TOWNSEND‡

Abstract. Tracking of a reference signal (assumed bounded with essentially bounded derivative) is considered in the context of a class Σ_ρ of multi-input, multi-output dynamical systems, modelled by functional differential equations, affine in the control and satisfying the following structural assumptions: (i) arbitrary—but known—relative degree $\rho \geq 1$; (ii) the "high-frequency gain" is sign definite—but possibly of unknown sign. The class encompasses a wide variety of nonlinear and infinite-dimensional systems and contains (as a prototype subclass) all finite-dimensional, linear, m-input, m-output, minimum-phase systems of known strict relative degree. The first control objective is tracking, by the output y, with prescribed accuracy: given $\lambda > 0$ (arbitrarily small), determine a feedback strategy which ensures that, for every reference signal r and every system of class Σ_ρ, the tracking error $e = y - r$ is ultimately bounded by λ (that is, $\|e(t)\| < \lambda$ for all t sufficiently large). The second objective is guaranteed output transient performance: the tracking error is required to evolve within a prescribed performance funnel $\mathcal{F}_\varphi$ (determined by a function φ). Both objectives are achieved using a filter in conjunction with a feedback function of the tracking error, the filter states, and the funnel parameter φ.

Key words. output feedback, nonlinear systems, functional differential equations, transient behavior, tracking, high relative degree

1. Introduction.

In [5], a class of infinite-dimensional, m-input ($u(t) \in \mathbb{R}^m$), m-output ($y(t) \in \mathbb{R}^m$), nonlinear systems (with finite memory) given by a controlled functional differential equation of the form $\dot{y}(t) = g(p(t), (Ty)(t), u(t))$ is considered, where g is a continuous function, p represents a bounded disturbance, and T is a causal operator with a bounded-input bounded-output property: an output feedback control structure is developed which ensures approximate asymptotic tracking, with prescribed transient behavior, of any absolutely continuous bounded reference signal with essentially bounded derivative. Here we extend these investigations to incorporate higher-order systems, affine in the control, of the form

$$y^{(\rho)}(t) = R_1\, y(t) + R_2\, y^{(1)}(t) + \cdots + R_\rho\, y^{(\rho-1)}(t) + g(p(t), (Ty)(t)) + \Gamma u(t), \tag{1.1}$$

where $\rho \in \mathbb{N}$ is known, $y^{(i)}$ denotes the ith derivative of y, and the matrix Γ is assumed to be sign definite (equivalently, $\langle v, \Gamma v \rangle = 0 \;\Leftrightarrow\; v = 0$).

In an early contribution by Miller and Davison [12], the attainment of prescribed transient behavior is considered for a class of single-input, single-output, linear, minimum-phase systems with known high-frequency gain: a controller is introduced which guarantees the "error to be less than an (arbitrarily small) prespecified constant

after an (arbitrarily small) prespecified period of time, with an (arbitrarily small) prespecified upper bound on the amount of overshoot." However, the controller is adaptive with nondecreasing gain k, invokes a piecewise-constant switching strategy, and is less flexible in its scope for shaping transient behavior (in particular, an a priori bound on the initial data is required) when compared to the nonadaptive approach in [6].

The results of this paper generalize the main ideas in [6], where tracking with prescribed transient behavior is considered in a more restricted context of linear systems of known relative degree, subject to "mild" nonlinear perturbations: the generality of the operator T in (1.1) allows for a considerable diversity of nonlinear and infinite-dimensional effects, including delays and hysteresis phenomena. We implement a "backstepping" procedure in conjunction with a filter/precompensator in the construction of a nonadaptive controller. The backstepping procedure is akin to that of [17, 9, 12].

We briefly digress to review the literature on tracking and stabilization of high relative degree systems. Unless otherwise stated, all results relate to single-input, single-output systems. Bullinger and Allgöwer [1] introduce a high-gain observer in conjunction with an adaptive controller to achieve tracking with prescribed asymptotic accuracy $\lambda > 0$ (λ-tracking). This is achieved for a class of systems which are affine in the control, of known relative degree, and with affine linearly bounded drift term. Paper [17] considers linear minimum-phase systems with nonlinear perturbation; the control objective is (continuous) adaptive λ-tracking with nondecreasing gain. The class of allowable nonlinearities is considerably smaller than that of the present paper. Stabilization for systems of maximum relative degree in the so-called parametric strict feedback form is achieved in [18] via a piecewise constant adaptive switching strategy. Both these contributions use a backstepping procedure. Nonadaptive contributions are found in the work by Byrnes and Isidori [2] with extensions in [3]. They cover stabilization and tracking for a class of relative-degree-one nonlinear systems, with an exosystem, the positive orbits of which lie in a compact set: systems of higher relative degree are also considered (see in particular [2, eq. (33)]), and the authors state (without proof) that "these systems can [be] reduced to systems of (relative degree 1) by means of the semiglobal back-stepping Lemma." The main result in [2, Prop. 7.1] pertains to practical tracking and applies high-gain principles in conjunction with an internal model: the multilayered nature of the assumptions determining the system class makes it difficult to assess the overlap with the class considered in the present paper. Related investigations, based on high-gain properties and/or an internal model principle, can be found in [10, 13, 9]: we will have occasion to comment further on the latter in section 3.1.3 below.

The paper is organized as follows. Sections 2 and 3 introduce the control objectives and the system class: section 3.1 highlights several particular subclasses. In section 4, the control and feedback laws are constructed: an existence theorem for the resulting closed-loop system is provided in section 4.3. Our main results on transient and asymptotic behavior of the closed-loop are given in section 5 and illustrated in an example in section 6. All proofs are relegated to the appendix.

We close this introduction with remarks on notation. Throughout, $\mathbb{R}_+ := [0, \infty)$ and $\mathbb{C}_-$ denotes the open left half complex plane $\{\lambda \in \mathbb{C} |\ \operatorname{Re}\lambda < 0\}$. The Euclidean inner product and induced norm on $\mathbb{R}^n$ are denoted by $\langle \cdot, \cdot \rangle$ and $\| \cdot \|$, respectively. The open ball of radius $\delta > 0$ centered at $x \in \mathbb{R}^n$ is denoted by $\mathbb{B}_\delta(x)$. For an interval $I \subset \mathbb{R}$, $C(I, \mathbb{R}^n)$ is the space of continuous functions $I \to \mathbb{R}^n$, $L^\infty(I, \mathbb{R}^n)$

is the space of essentially bounded measurable functions $x\colon I \to \mathbb{R}^n$ with norm $\|x\|_\infty := \text{ess-sup}_{t\in I}\|x(t)\|$, $L^1(I,\mathbb{R}^n)$ is the space of integrable functions $x\colon I \to \mathbb{R}^n$ with norm $\|x\|_1 := \int_I \|x(t)\|\mathrm{d}t < \infty$, $L^\infty_{\text{loc}}(I,\mathbb{R}^n)$ (respectively, $L^1_{\text{loc}}(I,\mathbb{R}^n)$) is the space of measurable, locally essentially bounded (respectively, locally integrable) functions $I \to \mathbb{R}^n$, and $W^{1,\infty}(I,\mathbb{R}^n)$ is the space of absolutely continuous functions $x\colon I \to \mathbb{R}^n$ with $x, \dot{x} \in L^\infty(I,\mathbb{R}^n)$. The spectrum of $A \in \mathbb{R}^{n\times n}$ is denoted by $\text{spec}(A)$.

2. Control objectives and the performance funnel. There are two control objectives: (i) approximate tracking, by the output, of reference signals $r \in \mathcal{R} := W^{1,\infty}(\mathbb{R}_+,\mathbb{R}^m)$ (in particular, for arbitrary $\lambda > 0$, we seek an output feedback strategy which ensures that, for every $r \in \mathcal{R}$, the closed-loop system has bounded solution and the tracking error $e(t) = y(t) - r(t)$ is ultimately bounded by λ (that is, $\|e(t)\| \le \lambda$ for all t sufficiently large)) and (ii) prescribed transient behavior of the tracking error.

Both objectives are captured in the concept of a performance funnel

$$\mathcal{F}_\varphi := \big\{(t,e) \in \mathbb{R}_+ \times \mathbb{R}^m \big|\ \varphi(t)\|e\| < 1\big\}$$

associated with a function φ of the following class:

$$\Phi := \big\{\varphi \in W^{1,\infty}(\mathbb{R}_+,\mathbb{R}) \ \big|\ \ \varphi(0) = 0, \quad \varphi(s) > 0 \quad \forall\, s > 0 \text{ and } \liminf_{s\to\infty} \varphi(s) > 0\big\}.$$

The aim is an output feedback strategy ensuring that, for every reference signal $r \in \mathcal{R}$, the tracking error $e = y - r$ evolves within the funnel $\mathcal{F}_\varphi$; see Figure 1. For example, if $\liminf_{t\to\infty} \varphi(t) \ge 1/\lambda$, then evolution within the funnel ensures that the first control objective is achieved. If φ is chosen as the function $t \mapsto \min\{t/\tau, 1\}/\lambda$, then evolution within the funnel ensures that the prescribed tracking accuracy $\lambda > 0$ is achieved within the prescribed time $\tau > 0$. The feedback structure incorporates a filter and essentially exploits an intrinsic high-gain property of the system/filter interconnection to ensure that, if $(t, e(t))$ approaches the funnel boundary, then an appropriately generated gain attains values sufficiently large to preclude boundary contact.

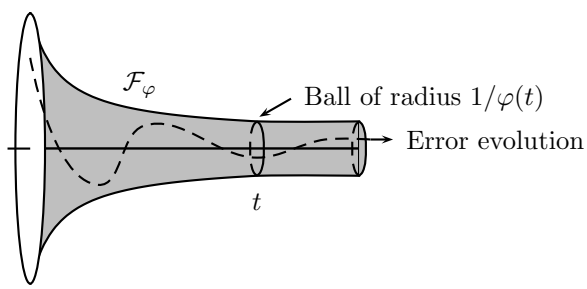

FIG. 1. *Prescribed performance funnel* $\mathcal{F}_\varphi$.

3. Class of systems. We subsume (1.1) in the following:

$$\left\{\begin{array}{l} \dot{x}(t) = Ax(t) + f(p(t),(Ty)(t),x(t)) + Bu(t), \\ y(t) = Cx(t), \\ x|_{[-h,0]} = x^0 \in C([-h,0],\mathbb{R}^{\rho m}), \end{array}\right. \tag{3.1}$$

$$A = \begin{bmatrix} 0 & I & 0 & \cdots & 0 \\ 0 & 0 & I & & 0 \\ \vdots & & \ddots & \ddots & \vdots \\ 0 & 0 & \cdots & 0 & I \\ R_1 & R_2 & \cdots & R_{\rho-1} & R_\rho \end{bmatrix} \in \mathbb{R}^{\rho m \times \rho m}, \quad B = \begin{bmatrix} 0 \\ 0 \\ \vdots \\ 0 \\ \Gamma \end{bmatrix} \in \mathbb{R}^{\rho m \times m}, \tag{3.2}$$

$$C = \begin{bmatrix} I & 0 & \cdots & 0 & 0 \end{bmatrix} \in \mathbb{R}^{m \times \rho m}, \quad f\colon \mathbb{R}^m \times \mathbb{R}^q \times \mathbb{R}^{\rho m} \to \mathbb{R}^{\rho m} \text{ continuous.} \tag{3.3}$$

Observe that $\Gamma = CA^{\rho-1}B$. In the special case wherein f is given by

$$f(p, w, x) = \begin{bmatrix} 0 \\ \vdots \\ 0 \\ g(p, w) \end{bmatrix}, \tag{3.4}$$

it is clear that (1.1) and (3.1) are equivalent. Next, we define the class of operators T allowable in (3.1).

DEFINITION 3.1 (operator class $\mathcal{T}_h$). *Let $h \geq 0$. An operator T is said to be of class $\mathcal{T}_h$ if, and only if, for some $l, q \in \mathbb{N}$, the following hold:*

(i) $T\colon C([-h, \infty), \mathbb{R}^l) \to L^\infty_{\mathrm{loc}}(\mathbb{R}_+, \mathbb{R}^q)$.

(ii) *For every $\delta > 0$, there exists $\Delta > 0$ such that, for all $\zeta \in C([-h, \infty), \mathbb{R}^l)$,*

$$\sup_{t \in [-h, \infty)} \|\zeta(t)\| \leq \delta \quad \Longrightarrow \quad \|(T\zeta)(t)\| \leq \Delta \quad \text{for almost all } t \geq 0\,.$$

(iii) *For all $t \in \mathbb{R}_+$, the following hold:*

(a) *for all $\zeta, \psi \in C([-h, \infty), \mathbb{R}^l)$,*

$$\zeta(\cdot) \equiv \psi(\cdot) \text{ on } [-h, t] \quad \Longrightarrow \quad (T\zeta)(s) = (T\psi)(s) \quad \text{for almost all } s \in [0, t];$$

(b) *for all continuous functions $\beta\colon [-h, t] \to \mathbb{R}^l$, there exist $\tau, \delta, c > 0$ such that, for all $\zeta, \psi \in C([-h, \infty), \mathbb{R}^l)$ with $\zeta|_{[-h,t]} = \beta = \psi|_{[-h,t]}$ and $\zeta(s), \psi(s) \in \mathbb{B}_\delta(\beta(t))$ for all $s \in [t, t + \tau]$,*

$$\operatorname{ess-sup}_{s \in [t, t+\tau]} \|(T\zeta)(s) - (T\psi)(s)\| \;\leq\; c \sup_{s \in [t, t+\tau]} \|\zeta(s) - \psi(s)\|\,.$$

Remark 3.2. Property (ii) is a bounded-input, bounded-output assumption on the operator T. Property (iii)(a) is a natural assumption of causality. Property (iii)(b) is a technical assumption of local Lipschitz type which is used in establishing well-posedness of the closed-loop system (defined later in section 4.3).

We are now in a position to make precise the system class.

DEFINITION 3.3 (system class Σ_ρ). *For $\rho \in \mathbb{N}$, Σ_ρ is the class of m-input, m-output systems (A, B, C, f, p, T, h) of the form (3.1), where $h \geq 0$ quantifies the memory of the system, and A, B, and C are structured as in (3.2)–(3.3) and satisfy*

(A1) *sign-definite high-frequency gain: $\Gamma = CA^{\rho-1}B$ is either positive definite or negative definite (equivalently, $\langle v, \Gamma v \rangle = 0 \;\Leftrightarrow\; v = 0$).*

The functions f, p and operator T are such that

(A2) $p \in L^\infty(\mathbb{R}_+, \mathbb{R}^m)$,

(A3) *for some $q \in \mathbb{N}$, $T\colon C([-h, \infty), \mathbb{R}^m) \to L^\infty_{\mathrm{loc}}(\mathbb{R}_+, \mathbb{R}^q)$ is of class $\mathcal{T}_h$,*

(A4) *$f\colon \mathbb{R}^m \times \mathbb{R}^q \times \mathbb{R}^{\rho m} \to \mathbb{R}^{\rho m}$ is continuous and, for all nonempty compact sets $P \subset \mathbb{R}^m$, $W \subset \mathbb{R}^q$, and $Y \subset \mathbb{R}^m$, there exists a constant $c_0 = c_0(P, W, Y) > 0$ such that $\|f(p, w, x)\| \leq c_0$ for all $(p, w, x) \in P \times W \times \{v \in \mathbb{R}^{\rho m} \mid Cv \in Y\}$.*

Remark 3.4. (i) Due to the presence of the nonlinear function f, the (vector) relative degree of (3.1) at some point $x^0 \in \mathbb{R}^{\rho m}$ may not be defined; see [7, pp. 137 and 220]. However, if $f \equiv 0$, then it follows from assumption (A1) that the vector relative degree of the linear system (3.1) is $(\rho, \dots, \rho) \in \mathbb{R}^m$ at each point $x^0 \in \mathbb{R}^{\rho m}$ and, in particular,

$$CA^iB = 0 \quad \text{for } i = 1, \dots, \rho - 2 \text{ and } \Gamma = CA^{\rho-1}B \text{ is invertible.} \tag{3.5}$$

The linear system (A, B, C) is said to have *strict relative degree* ρ if, and only if, (3.5) holds. Note that assumption (A1) requires the strengthened assumption that $CA^{\rho-1}B$ is either positive definite or negative definite. In the multi-input, multi-output case, (A1) is rather restrictive. By contrast, in the single-input, single-output case, the assumption of sign definiteness is redundant and (A1) is simply equivalent to positing that the relative degree of the linear triple (A, B, C) is known.

(ii) Recall that a linear system (A, B, C) is said to be *minimum phase* if, and only if,

$$\det \begin{bmatrix} sI - A & B \\ C & 0 \end{bmatrix} \neq 0 \quad \forall\, s \in \mathbb{C} \text{ with } \mathrm{Re}(s) \geq 0. \tag{3.6}$$

Due to the structure of the matrices A, B, and C in (3.2)–(3.3) and assumption (A1), (A, B, C) is minimum phase.

(iii) Assumption (A4) constrains the nature of the dependence of f on its third argument: in particular, for compact sets P, W, and Y, it posits boundedness of f on $P \times W \times \{v \in \mathbb{R}^{\rho m} \mid Cv \in Y\}$. For example, (A4) holds if there exists a continuous function $\pi : \mathbb{R}^m \times \mathbb{R}^q \times \mathbb{R}^m \to \mathbb{R}_+$ such that $\|f(p, w, x)\| \leq \pi(p, w, Cx)$ for all (p, w, x). Assumption (A4) plays a crucial role in the later analysis: in its absence (i.e., if f is merely assumed to be continuous), it is not difficult to construct examples for which the performance objectives cannot be achieved (indeed, finite escape times can occur).

(iv) With reference to Figure 2, the system (3.1) can be thought of as the interconnection of two blocks. The dynamical system represented by block Λ_1, which can be influenced directly by the system control u, is also driven by the output w from the dynamic block Λ_2, as shown in Figure 2. The block Λ_2 can be considered as a causal operator mapping the system output y to w (an internal quantity, unavailable for feedback purposes); it allows for infinite-dimensional (e.g., delays, diffusions) and hysteresis (e.g., backlash) effects, some examples of which are given in section 3.1.

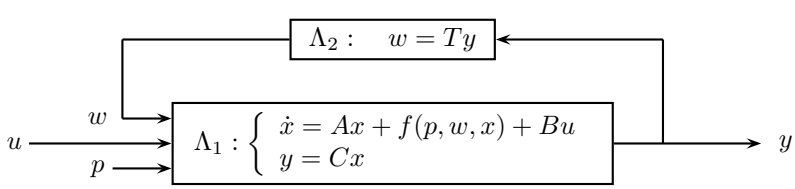

FIG. 2. *System of class* Σ_ρ.

3.1. Subclasses of Σ_ρ.

3.1.1. Finite-dimensional linear prototype. For motivational purposes, we first examine a prototype linear system and show that all finite-dimensional linear

systems of this form are incorporated into the class Σ_ρ. Consider an m-input, m-output linear system of the form

$$\dot{w}(t) = \tilde{A}\, w(t) + \tilde{B}\, u(t), \quad w(0) = w^0 \in \mathbb{R}^n, \quad y(t) = \tilde{C}\, w(t), \tag{3.7}$$

with strict relative degree $\rho \geq 1$, $\tilde{A} \in \mathbb{R}^{n\times n}$, $\tilde{B} \in \mathbb{R}^{n\times m}$, $\tilde{C} \in \mathbb{R}^{m\times n}$, $n \geq \rho m$, and positive-definite or negative-definite high-frequency gain $\tilde{C}\tilde{A}^{\rho-1}\tilde{B}$. To show that the system (3.7) belongs to the class Σ_ρ, we present the following lemma, a proof of which can be found in the appendix.

LEMMA 3.5. *Consider a linear system of the form* (3.7) *with strict relative degree* $\rho \in \mathbb{N}$. *Define*

$$\mathcal{C} := \begin{bmatrix} \tilde{C} \\ \tilde{C}\tilde{A} \\ \vdots \\ \tilde{C}\tilde{A}^{\rho-1} \end{bmatrix} \in \mathbb{R}^{\rho m\times n}, \quad \mathcal{B} := [\tilde{B} \,\vdots\, \tilde{A}\tilde{B} \,\vdots\, \cdots \,\vdots\, \tilde{A}^{\rho-1}\tilde{B}] \in \mathbb{R}^{n\times \rho m}$$

and let $\mathcal{V} \in \mathbb{R}^{n\times(n-\rho m)}$ *be such that* $\operatorname{im} \mathcal{V} = \ker \mathcal{C}$. *Then*

(i) $\mathbb{R}^n = \ker \mathcal{C} \oplus \operatorname{im} \mathcal{B}$;

(ii) *the matrix*

$$\mathcal{U} = \begin{bmatrix} \mathcal{C} \\ \mathcal{N} \end{bmatrix} \in \mathbb{R}^{n\times n}, \quad \textit{where} \quad \mathcal{N} = (\mathcal{V}^T\mathcal{V})^{-1}\mathcal{V}^T[I - \mathcal{B}(\mathcal{C}\mathcal{B})^{-1}\mathcal{C}] \in \mathbb{R}^{(n-\rho m)\times n},$$

is invertible, with inverse $\mathcal{U}^{-1} = [\mathcal{B}(\mathcal{C}\mathcal{B})^{-1} \,\vdots\, \mathcal{V}]$, *and the triple*

$$(\hat{A}\,,\, \hat{B}\,,\, \hat{C}) := \big(U\tilde{A}U^{-1},\, U\tilde{B}\,,\, \tilde{C}U^{-1}\big) \tag{3.8}$$

has the following structure (wherein I *and* 0 *denote the* $m \times m$ *identity matrix and zero matrix, respectively):*

(3.9)

$$\hat{A} = \begin{bmatrix} 0 & I & 0 & \cdots & 0 & 0 \\ 0 & 0 & I & & & 0 \\ \vdots & & \ddots & \ddots & & \vdots \\ 0 & 0 & \cdots & 0 & I & 0 \\ R_1 & R_2 & \cdots & R_{\rho-1} & R_\rho & S \\ P & 0 & \cdots & 0 & 0 & Q \end{bmatrix}, \quad \hat{B} = \begin{bmatrix} 0 \\ 0 \\ \vdots \\ 0 \\ \Gamma \\ 0 \end{bmatrix}, \quad \hat{C} = [I \,\vdots\, 0 \,\vdots\, \cdots \,\vdots\, 0 \,\vdots\, 0 \,\vdots\, 0\,],$$

with $[R_1 \,\vdots\, \cdots \,\vdots\, R_\rho \,\vdots\, S] = \tilde{C}\tilde{A}^\rho\mathcal{U}^{-1}$, $\Gamma = \tilde{C}\tilde{A}^{\rho-1}\tilde{B}$, $P = \mathcal{N}\tilde{A}^\rho\tilde{B}\Gamma^{-1}$, *and* $Q = \mathcal{N}\tilde{A}\mathcal{V}$;

(iii) *if the system* (3.7) *is minimum phase, then* $\operatorname{spec}(Q) \subset \mathbb{C}_-$.

We remark that, in the case $\rho = 1$, (3.9) is to be interpreted as

$$\hat{A} = \begin{bmatrix} R_1 & S \\ P & Q \end{bmatrix}, \quad \hat{B} = \begin{bmatrix} \Gamma \\ 0 \end{bmatrix}, \quad \hat{C} = [I \,\vdots\, 0\,]. \tag{3.10}$$

Invoking the similarity transformation (3.8)–(3.9) and writing $x^0 := \mathcal{C}w^0$, $z^0 := \mathcal{N}w^0$, $x(t) := \mathcal{C}w(t)$, it is readily verified that system (3.7) is equivalent to

$$\dot{x}(t) = Ax(t) + f(p(t), (Ty)(t), x(t)) + Bu(t), \quad x(0) = x^0, \quad y(t) = Cx(t), \tag{3.11}$$

where A, B, and C are as in (3.2)–(3.3), $p\colon t \mapsto S(\exp Qt)z^0$, T is the linear operator given by

$$(Ty)(t) = S\left(\int_0^t \exp(Q(t-s))Py(s)\mathrm{d}s\right), \quad t \geq 0,$$

and the function f takes the special form (3.4) with $g : \mathbb{R}^m \times \mathbb{R}^m \to \mathbb{R}^m$ given by $g(p,w) := p + w$.

If (3.7) has sign-definite high-frequency gain, then $\tilde{C}\tilde{A}^{\rho-1}\tilde{B} = \Gamma = CA^{\rho-1}B$ is either positive definite or negative definite, and hence assumption (A1) is satisfied. If we assume that (3.7) has the minimum-phase property, then by Lemma 3.5 (iii), Q has spectrum in $\mathbb{C}_-$: it follows that $p \in L^\infty(\mathbb{R}_+, \mathbb{R}^m)$ and T belongs to the class of operators $\mathcal{T}_0$, and so assumptions (A2) and (A3) are satisfied. Assumption (A4) is trivially satisfied. Therefore, the system class Σ_ρ contains all m-input, m-output, finite-dimensional, linear, minimum-phase systems of strict relative degree ρ with sign-definite high-frequency gain.

3.1.2. Infinite-dimensional linear systems. The finite-dimensional class of systems of the form (3.8) can be extended to infinite dimensions by reinterpreting the operators Q, P, and S as the generating operators of a regular linear system (regular in the sense of [16]). In the infinite-dimensional setting, Q is assumed to be the generator of a strongly continuous semigroup $\mathbf{S} = (\mathbf{S}_t)_{t\in\mathbb{R}_+}$ of bounded linear operators and a Hilbert space X with norm $\|\cdot\|_X$. Let X_1 denote the space $\mathrm{dom}(Q)$ endowed with the graph norm and let X_{-1} denote the completion of X with respect to the norm $\|z\|_{-1} = \|(s_0 I - Q)^{-1}z\|_X$, where s_0 is any fixed element of the resolvent set of Q. Then P is assumed to be a bounded linear operator from $\mathbb{R}^m$ to X_{-1} and S is assumed to be a bounded linear operator from X_1 to $\mathbb{R}^m$. Assuming that the semigroup $\mathbf{S}$ is exponentially stable and that S extends to a bounded linear operator (again denoted by S) from X to $\mathbb{R}^m$, then the operator T given by

$$(Ty)(t) := S\left(\int_0^t \mathbf{S}_{t-s}Py(s)\,\mathrm{d}s\right)$$

is of class $\mathcal{T}_0$ (see [14] for details) and, writing $p(t) := S\,\mathbf{S}_t z^0$, we again arrive at the structure of (3.11).

3.1.3. Nonlinear systems. In [9, eq. (1)] the following class of systems is studied:

$$\left\{\begin{aligned} \dot{x}_1(t) &= x_2(t) + f_1(w(t), y(t)) \\ &\vdots \\ \dot{x}_{\rho-1}(t) &= x_\rho(t) + f_{\rho-1}(w(t), y(t)) \\ \dot{x}_\rho(t) &= \gamma\, u(t) + f_\rho(w(t), y(t)) \\ \dot{w}(t) &= q(w(t), y(t)) \\ y(t) &= x_1(t) \\ (x_1(0), \ldots, x_\rho(0), w(0)) &= (x_1^0, \ldots, x_\rho^0, w^0) \end{aligned}\right. \tag{3.12}$$

where $\gamma \in \mathbb{R}\setminus\{0\}$, $q\colon \mathbb{R}^p \times \mathbb{R} \to \mathbb{R}^p$, and $f_i\colon \mathbb{R}^p \times \mathbb{R} \to \mathbb{R}$, $i = 1, \ldots, \rho$, are locally Lipschitz functions. Denote, by T, the mapping $y \mapsto w$ induced by the subsystem $\dot{w} = q(w, y)$ with initial condition $w(0) = w^0$. Then (3.12) is equivalent to (3.1)

(with $h = 0$ and $m = 1$). Moreover, if we assume that the subsystem $\dot{w} = q(w, y)$ is input-to-state stable (ISS), then, as shown in [4, sect. 2.3], the operator T is of class $\mathcal{T}_0$, in which case system (3.12), interpreted in its equivalent form (3.1), is of class Σ_ρ.

We remark that, in [9, eq. (1)], an assumption of *integral* input-to-state stability (iISS) (strictly weaker than our assumption of ISS) is imposed on the subsystem $\dot{w} = q(w, y)$. In this respect, the full generality of the system class in [9] is not captured by the class considered in the present paper.

3.1.4. Nonlinear delay systems. Let functions $\mathcal{G}_i \colon \mathbb{R} \times \mathbb{R}^l \to \mathbb{R}^q : (t, \zeta) \mapsto \mathcal{G}_i(t, \zeta)$, $i = 0, \dots, n$, be measurable in t and locally Lipschitz in ζ uniformly with respect to t: precisely, (i) for each fixed ζ, $\mathcal{G}_i(\cdot, \zeta)$ is measurable and (ii) for every compact $\mathcal{K} \subset \mathbb{R}^l$ there exists a constant c such that

$$\|\mathcal{G}_i(t, \zeta) - \mathcal{G}_i(t, \psi)\| \le c \, \|\zeta - \psi\| \quad \text{for almost all } t \text{ and} \quad \forall \, \zeta, \psi \in \mathcal{K} \, .$$

For $i = 0, \dots, n$, let $h_i \in \mathbb{R}_+$ and define $h := \max_i h_i$. For $\zeta \in C([-h, \infty), \mathbb{R}^l)$, let

$$(T\zeta)(t) := \int_{-h_0}^{0} \mathcal{G}_0(s, \zeta(t + s)) \, \mathrm{d}s + \sum_{i=1}^{n} \mathcal{G}_i(t, \zeta(t - h_i)) \quad \forall \, t \ge 0 \, .$$

The operator T, so defined, is of class $\mathcal{T}_h$: for details see [14].

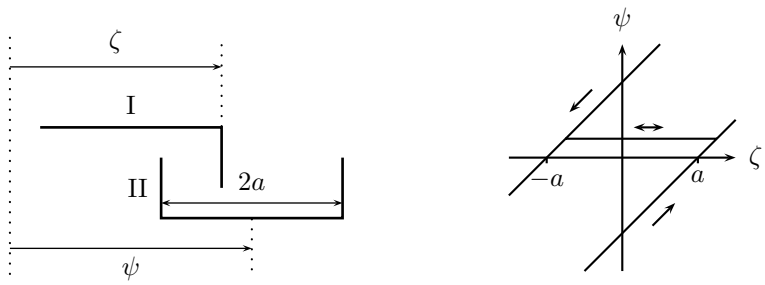
3.1.5. Systems with hysteresis. A general class of hysteresis operators, which includes many physically motivated hysteretic effects, is discussed in [11]. Examples of such operators include backlash hysteresis, elastic-plastic hysteresis, and Preisach operators. In [5], it is pointed out that these operators are of class $\mathcal{T}_0$. For illustration, we describe a particular example of a hysteresis operator.

Backlash hysteresis. Consider a one-dimensional mechanical link consisting of two components, denoted I and II (of width $2a$) and illustrated in Figure 3(a). The displacements of each part (with respect to some fixed datum) at time $t \ge 0$ are given by $\zeta(t)$ and $\psi(t)$ with $|\zeta(t) - \psi(t)| \le a$ for all t, and $\psi(0) := \zeta(0) + b$ for some prespecified $b \in [-a, a]$. Within the link there is mechanical play: that is to say, the position $\psi(t)$ of II remains constant as long as the position $\zeta(t)$ of I remains within the interior of II. Thus, assuming continuity of ζ, we have $\dot{\psi}(t) = 0$ whenever $|\zeta(t) - \psi(t)| < a$. Given a continuous input $\zeta \in C(\mathbb{R}_+, \mathbb{R})$, describing the evolution of the position of I, denote the corresponding position of II by $\psi = T\zeta$. The operator T (in effect we define a family $T_{a,b}$ of operators parameterized by $a > 0$ and $b \in [-a, a]$), so defined, is known as *backlash* or *play* and is of class $\mathcal{T}_0$.

4. The control. Let $\varphi \in \Phi$ determine a performance funnel $\mathcal{F}_\varphi$. We proceed to construct a feedback structure which ensures that, for every reference $r \in \mathcal{R}$ and when applied to any system of class Σ_ρ, the tracking error $e = y - r$ evolves within $\mathcal{F}_\varphi$. We initially assume $\rho \ge 2$; the case of systems with strict relative degree $\rho = 1$ will be treated separately in due course.

4.1. Filter. Fix $\mu > 0$ (arbitrarily) and introduce the filter

$$\begin{aligned} \dot{\xi}_i(t) &= -\mu \, \xi_i(t) + \xi_{i+1}, & \xi_i(0) &= \xi_i^0 \in \mathbb{R}^m \, , & i &= 1, \dots, \rho - 2, \\ \dot{\xi}_{\rho-1}(t) &= -\mu \, \xi_{\rho-1}(t) + u(t), & \xi_{\rho-1}(0) &= \xi_{\rho-1}^0 \in \mathbb{R}^m \, , \end{aligned}$$



(a) (b)

FIG. 3. *Backlash hysteresis.*

which, on writing (wherein I and 0 denote the $m \times m$ identity and zero matrices)

$$\xi(t) = \begin{bmatrix} \xi_1(t) \\ \xi_2(t) \\ \xi_3(t) \\ \vdots \\ \xi_{\rho-2}(t) \\ \xi_{\rho-1}(t) \end{bmatrix}, \quad F = \begin{bmatrix} -\mu I & I & 0 & \cdots & 0 & 0 \\ 0 & -\mu I & I & \cdots & 0 & 0 \\ 0 & 0 & -\mu I & \cdots & 0 & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & 0 & \cdots & -\mu I & I \\ 0 & 0 & 0 & \cdots & 0 & -\mu I \end{bmatrix}, \quad G = \begin{bmatrix} 0 \\ 0 \\ 0 \\ \vdots \\ 0 \\ I \end{bmatrix},$$

may be expressed as

$$\begin{cases} \dot{\xi}(t) = F\xi(t) + Gu(t), & \xi(0) = \xi^0 \in \mathbb{R}^{(\rho-1)m}, \\ \xi_1(t) = H\xi(t), & H := \big[I \vdots 0 \vdots 0 \vdots \cdots \vdots 0 \vdots 0\big]. \end{cases} \tag{4.1}$$

4.2. Feedback. Define

$$s(\Gamma) := \begin{cases} +1\,, & \Gamma \text{ positive definite,} \\ -1\,, & \Gamma \text{ negative definite.} \end{cases}$$

Let $\nu\colon \mathbb{R} \to \mathbb{R}$ be any C^∞ function with the following property:

$$\begin{cases} \text{there exists a strictly increasing unbounded sequence } (k_j) \text{ such that} \\ \text{the sequence } \big(s(\Gamma)\nu(k_j)\big) \text{ is strictly decreasing and unbounded.} \end{cases} \tag{4.2}$$

Introduce the projections

$$\pi_i\colon \mathbb{R}^{(\rho-1)m} \to \mathbb{R}^{im}, \quad \xi = (\xi_1, \ldots, \xi_{\rho-1}) \mapsto (\xi_1, \ldots, \xi_i), \qquad i = 1, \ldots, \rho-1,$$

and define the C^∞ function

$$\gamma_1\colon \mathbb{R} \times \mathbb{R}^m \to \mathbb{R}^m, \quad (k, e) \mapsto \gamma_1(k, e) := -\nu(k)e\,, \tag{4.3}$$

with derivative (Jacobian matrix function) $D\gamma_1$. Next, for $i = 2, \ldots, \rho-1$, define the C^∞ function $\gamma_i\colon \mathbb{R} \times \mathbb{R}^m \times \mathbb{R}^{(i-1)m} \to \mathbb{R}^m$ by the recursion

$$\begin{aligned} \gamma_i(k, e, \pi_{i-1}\xi) := \gamma_{i-1}(k, e, \pi_{i-2}\xi) + \|D\gamma_{i-1}(k, e, \pi_{i-2}\xi)\|^2\, k^4\, (1 + \|\pi_{i-1}\xi\|^2) \\ \times \Big(\mu^{2-i}\xi_{i-1} + \gamma_{i-1}(k, e, \pi_{i-2}\xi)\Big)\,, \end{aligned} \tag{4.4}$$

wherein we adopt the notational convention $\gamma_1(k,e,\pi_0\xi) := \gamma_1(k,e)$. Define the C^∞ function $\gamma_\rho\colon \mathbb{R}\times\mathbb{R}^m\times\mathbb{R}^{(\rho-1)m}\to\mathbb{R}^m$ as follows:

$$\begin{aligned}\gamma_\rho(k,e,\xi) :=& \mu^{\rho-1}\gamma_{\rho-1}(k,e,\pi_{\rho-2}\xi) + \mu^{\rho-1}\|D\gamma_{\rho-1}(k,e,\pi_{\rho-2}\xi)\|^2 k^4\,(1+\|\xi\|^2)\\ &\times\Big(\mu^{2-\rho}\xi_{\rho-1}+\gamma_{\rho-1}(k,e,\pi_{\rho-2}\xi)\Big).\end{aligned}\tag{4.5}$$

Finally, we introduce the bijection

$$\alpha : [0,1)\to[1,\infty),\quad s\mapsto 1/(1-s).\tag{4.6}$$

For arbitrary $r\in\mathcal{R}$, the *control strategy* is given by

$$u(t) = -\gamma_\rho\big(k(t), Cx(t)-r(t), \xi(t)\big),\quad k(t)=\alpha\big(\varphi^2(t)\|Cx(t)-r(t)\|^2\big).\tag{4.7}$$

Remark 4.1. (i) If $s(\Gamma)$ is known a priori, then the function $\nu\colon k\mapsto -s(\Gamma)k$ is sufficient to ensure property (4.2); if $s(\Gamma)$ is unknown, then the function $\nu\colon k\mapsto k\cos k$ suffices. In the latter case, the role of the function ν is similar to that of a "Nussbaum" function in adaptive control. Note, however, that the requisite property (4.2) is less restrictive than (a) the "Nussbaum properties" as required in [17], for example, or (b) the stronger "scaling invariant Nussbaum properties", as required in [9], for example.

(ii) The function α in (4.6) may be generalized to any C^∞ bijection $\alpha:[0,1)\to[1,\infty)$ with the property that $\alpha' = d(\alpha)$ for some function d: the particular choice $d(\cdot)=(\cdot)^2$ yields the specific function adopted in (4.6) for simplicity of presentation. In the case of general α, the term k^4 in (4.4) and (4.5) should be replaced by $d^2(k)$.

(iii) In the specific case of a system of relative degree $\rho=2$, writing $e(t)=Cx(t)-r(t)$ and omitting the argument t for simplicity, the control strategy takes the explicit form

$$\begin{cases} u = \mu\,\nu(k)e - \mu\big[(\nu'(k)\|e\|)^2+(\nu(k))^2\big]\,k^4\,[1+\|\xi\|^2]\theta,\\ k=\alpha\big(\varphi^2\|e\|^2\big), \qquad \theta=\xi-\nu(k)e\,,\\ \dot\xi = -\mu\,\xi+u, \qquad \xi(0)=\xi^0.\end{cases}\tag{4.8}$$

We will adopt this controller in the example in section 6.

4.3. Well-posedness of the closed-loop system. The conjunction of the filter (4.1) and the feedback (4.7) applied to (3.1) yields the initial-value problem

$$\begin{cases}\dot x(t) = A\,x(t)+f(p(t),(TCx)(t),x(t)) - B\gamma_\rho(k(t),Cx(t)-r(t),\xi(t)),\\ \dot\xi(t)=F\xi(t)-G\gamma_\rho(k(t),Cx(t)-r(t),\xi(t)),\\ k(t)=\alpha\big(\varphi^2(t)\|Cx(t)-r(t)\|^2\big)\,,\\ x|_{[-h,0]}=x^0\in C([-h,0],\mathbb{R}^{\rho m}),\quad \xi(s)=\xi^0\in\mathbb{R}^{(\rho-1)m}\quad\forall\ s\in[-h,0]\,.\end{cases}\tag{4.9}$$

By a solution of (4.9) on $[-h,\omega)$ we mean a function $(x,\xi)\in C([-h,\omega),\mathbb{R}^{\rho m}\times\mathbb{R}^{(\rho-1)m})$, with $0<\omega\le\infty$, $x|_{[-h,0]}=x^0$, and $\xi(s)=\xi^0$ for all $s\in[-h,0]$, such that $(x,\xi)|_{[0,\omega)}$ is absolutely continuous, satisfies the differential equations in (4.9) for almost all $t\in[0,\omega)$, and avoids the singularity in α in the sense that $\varphi(t)\|Cx(t)-r(t)\|<1$ for all $t\in[0,\omega)$. To answer affirmatively the question of well-posedness of the closed loop, we provide an existence theorem for a class of initial-value problems of sufficient generality to incorporate (4.9). For $h\ge 0$, consider the initial-value problem

$$\begin{cases}\dot\zeta(t)=Z(t,(\widehat T\zeta)(t),\zeta(t)), & \zeta(t)\in\mathcal{D},\\ \zeta|_{[-h,0]}=\zeta^0\in C([-h,0],\mathbb{R}^N), & \zeta^0(0)\in\mathcal{D},\end{cases}\tag{4.10}$$

where $\mathcal{D} \subset \mathbb{R}^N$ is a nonempty, open set, $Z\colon [-h,\infty)\times\mathbb{R}^q\times\mathcal{D}\to\mathbb{R}^N$ is a Carathéodory function, and $\widehat{T}$ is a causal operator of class $\mathcal{T}_h$. By a solution of (4.10) on $[-h,\omega)$ we mean a function $\zeta\in C([-h,\omega),\mathbb{R}^N)$, with $0<\omega\le\infty$, and $\zeta|_{[-h,0]}=\zeta^0$ such that $\zeta|_{[0,\omega)}$ is absolutely continuous and satisfies the differential equations in (4.10) for almost all $t\in[0,\omega)$ and $\zeta(t)\in\mathcal{D}$ for all $t\in[0,\omega)$. A solution of (4.9) or of (4.10) is *maximal* if, and only if, it has no proper right extension that is also a solution.

THEOREM 4.2. *Let $\mathcal{D}\subset\mathbb{R}^N$ be nonempty and open, let $\widehat{T}$ be an operator of class $\mathcal{T}$, and let $Z\colon[-h,\infty)\times\mathbb{R}^q\times\mathcal{D}\to\mathbb{R}^N$ be a Carathéodory function. Then, for each $\zeta^0\in C([-h,0],\mathbb{R}^N)$ with $\zeta(0)\in\mathcal{D}$, there exists a solution $\zeta\colon[-h,\omega)\to\mathbb{R}^N$, $\zeta([0,\omega))\subset\mathcal{D}$, of the initial-value problem* (4.10) *and every solution can be extended to a maximal solution. Moreover, if Z is locally essentially bounded and $\zeta\colon[-h,\omega)\to\mathbb{R}^N$, $\zeta([0,\omega))\subset\mathcal{D}$, is a maximal solution with $\omega<\infty$, then, for every compact set $\mathcal{K}\subset\mathcal{D}$, there exists $\hat{t}\in[0,\omega)$ such that $\zeta(\hat{t})\notin\mathcal{K}$.*

Proof. The proof is a straightforward modification of that of [5, Thm. 5]. ∎

We apply this result to our closed-loop system (4.9).

COROLLARY 4.3. *Let $(A,B,C,f,p,T,h)\in\Sigma_\rho$ with $\rho\ge1$ and let $\varphi\in\Phi$. For every $r\in\mathcal{R}$ and $(x^0,\xi^0)\in C([-h,0],\mathbb{R}^{\rho m}\times\mathbb{R}^{(\rho-1)m})$, application of the feedback* (4.7) *in conjunction with the filter* (4.1) *to the system* (3.1) *yields the initial-value problem* (4.9)*, which has a solution, and every solution can be extended to a maximal solution. If a maximal solution of* (4.9) *on $[-h,\omega)$ is bounded and such that the associated gain function k is also bounded, then $\omega=\infty$.*

The proof is in the appendix.

5. Main results.

5.1. Preliminary lemmas. Let $(A,B,C,f,p,T,h)\in\Sigma_\rho$ with $\rho\ge2$. Rewriting the conjunction of the nonlinear system (3.1) and the filter (4.1) as

$$\left\{\begin{array}{l}\begin{bmatrix}\dot{x}(t)\\ \dot{\xi}(t)\end{bmatrix}=\begin{bmatrix}A&0\\0&F\end{bmatrix}\begin{bmatrix}x(t)\\ \xi(t)\end{bmatrix}+\begin{bmatrix}I\\0\end{bmatrix}f(p(t),(Ty)(t),x(t))+\begin{bmatrix}B\\G\end{bmatrix}u(t),\\ \qquad y(t)=[\,C\,\vdots\,0\,]\begin{bmatrix}x(t)\\ \xi(t)\end{bmatrix},\end{array}\right. \tag{5.1}$$

we have the following technicality, a proof of which can be found in the appendix.

LEMMA 5.1. *For system* (5.1)*, there exist $K\in\mathbb{R}^{\rho m\times(\rho-1)m}$ and $N\in\mathbb{R}^{(\rho-1)m\times\rho m}$ such that*

$$L:=\begin{bmatrix}C&0\\N&-NK\\0&I\end{bmatrix}\in\mathbb{R}^{(2\rho-1)m\times(2\rho-1)m}$$

is invertible and

$$L\begin{bmatrix}A&0\\0&F\end{bmatrix}L^{-1}=\begin{bmatrix}A_1&A_2&\tilde{\Gamma}\\A_3&A_4&0\\0&0&F\end{bmatrix},\quad L\begin{bmatrix}B\\G\end{bmatrix}=\begin{bmatrix}0\\G\end{bmatrix},\quad [\,C\,\vdots\,0\,]\,L^{-1}=[\,I\,\vdots\,0\,\vdots\,0\,],$$

where $\tilde{\Gamma}:=\begin{bmatrix}\Gamma\,\vdots\,0\end{bmatrix}\in\mathbb{R}^{m\times(\rho-1)m}$, $\Gamma:=CA^{\rho-1}B$, and $A_4\in\mathbb{R}^{(\rho-1)m\times(\rho-1)m}$ is such that $\operatorname{spec}(A_4)\subset\mathbb{C}_-$.

In view of Lemma 5.1, there exist K and N such that, under the coordinate change

$$\begin{bmatrix} y(t) \\ z(t) \\ \xi(t) \end{bmatrix} = L \begin{bmatrix} x(t) \\ \xi(t) \end{bmatrix}, \quad \begin{bmatrix} y^0 \\ z^0 \\ \xi^0 \end{bmatrix} = L \begin{bmatrix} x^0 \\ \xi^0 \end{bmatrix}, \quad L := \begin{bmatrix} C & 0 \\ N & -NK \\ 0 & I \end{bmatrix}, \tag{5.2}$$

the conjunction (5.1) of system (3.1) and filter (4.1) can be represented by

$$\begin{cases} \dot{y}(t) = A_1 y(t) + A_2 z(t) + Cf(p(t), (Ty)(t), x(t)) + \Gamma\xi_1(t), \\ \dot{z}(t) = A_3 y(t) + A_4 z(t) + Nf(p(t), (Ty)(t), x(t)), \\ \dot{\xi}(t) = F\xi(t) + Gu(t), \\ (y, z, \xi)|_{[-h,0]} = (y^0, z^0, \xi^0) \in C([-h, 0], \mathbb{R}^m \times \mathbb{R}^{(\rho-1)m} \times \mathbb{R}^{(\rho-1)m}), \end{cases} \tag{5.3}$$

where $A_4 \in \mathbb{R}^{(\rho-1)m\times(\rho-1)m}$ has spectrum in $\mathbb{C}_-$. If $(x, \xi)\colon [0, \omega) \to \mathbb{R}^{\rho m} \times \mathbb{R}^{(\rho-1)m}$ is a maximal solution of the nonlinearly perturbed closed-loop system (4.9), then, in view of (5.3) and writing

$$y(t) = Cx(t), \qquad e(t) = y(t) - r(t), \quad e|_{[-h,0]} = e^0(\cdot) = y^0(\cdot) - r(0)\,, \tag{5.4}$$

we arrive at the following equivalent to (4.9):

$$\begin{cases} \dot{e}(t) = A_1 e(t) + A_2 z(t) + f_1(t) + \Gamma\xi_1(t), \\ \dot{z}(t) = A_3 e(t) + A_4 z(t) + f_2(t), \\ \dot{\xi}(t) = F\xi(t) - G\gamma_\rho(k(t), e(t), \xi(t)), \\ k(t) = \alpha\big(\varphi^2(t)\|e(t)\|^2\big), \\ (e, z, \xi)|_{[-h,0]} = (e^0, z^0, \xi^0) \in C([-h, 0], \mathbb{R}^m \times \mathbb{R}^{(\rho-1)m} \times \mathbb{R}^{(\rho-1)m}), \end{cases} \tag{5.5}$$

where the functions f_1 and f_2 are given by

$$\begin{cases} f_1(t) := A_1 r(t) + Cf(p(t), (Ty)(t), x(t)) - \dot{r}(t), \\ f_2(t) := A_3 r(t) + Nf(p(t), (Ty)(t), x(t)). \end{cases} \tag{5.6}$$

Since $(\varphi(t)\|e(t)\|)^2 < 1$ for all $t \in [0, \omega)$, the properties of $\varphi \in \Phi$ yield boundedness of the function e which, together with boundedness of r, implies boundedness of y. Since T is of class $\mathcal{T}_h$ and y is bounded, Ty is essentially bounded. By boundedness of r, essential boundedness of $\dot{r}$ and p, and assumption (A4), we may now conclude (essential) boundedness of the functions f_1 and f_2. Observing that A_4 is Hurwitz and f_2 bounded, the second of the differential equations in (5.5) yields boundedness of z. These observations are recorded in the following lemma.

LEMMA 5.2. *Let $(A, B, C, f, p, T, h) \in \Sigma_\rho$ with $\rho \geq 2$. Let $\varphi \in \Phi$, $r \in \mathcal{R}$, and $(x^0, \xi^0) \in C([-h, 0], \mathbb{R}^{\rho m} \times \mathbb{R}^{(\rho-1)m})$. If $(x, \xi)\colon [-h, \omega) \to \mathbb{R}^{\rho m} \times \mathbb{R}^{(\rho-1)m}$ is a maximal solution of* (4.9)*, then the functions y, z, and e, given by* (5.2) *and* (5.4)*, are bounded. Furthermore, the functions f_1 and f_2, given by* (5.6)*, are essentially bounded and bounded, respectively.*

The proofs of our main results (Theorems 5.4 and 5.5 below) rely crucially on a further technicality: the signals $\theta_i = \mu^{1-i}\xi_i + \gamma_i(k, e, \pi_{i-1}\xi)$, $i = 1, \ldots, \rho - 1$, are bounded. More precisely, we have the following (with proof in the appendix).

LEMMA 5.3. *Let $(A,B,C,f,p,T,h) \in \Sigma_\rho$ with $\rho \geq 2$. Let $\varphi \in \Phi$, $r \in \mathcal{R}$, and $(x^0,\xi^0) \in C([-h,0],\mathbb{R}^{\rho m}\times\mathbb{R}^{(\rho-1)m})$. If $(x,\xi)\colon [-h,\omega) \to \mathbb{R}^{\rho m}\times\mathbb{R}^{(\rho-1)m}$ is a maximal solution of (4.9), then the function $\theta = (\theta_1,\dots,\theta_{\rho-1})\colon [0,\omega) \to \mathbb{R}^{(\rho-1)m}$ is bounded, where*

$$\theta_i(t) := \mu^{1-i}\,\xi_i(t) + \gamma_i(k(t),e(t),\pi_{i-1}\xi(t))\,, \qquad i = 1,\dots,\rho-1, \tag{5.7}$$

with the notational convention $\gamma_1(k,e,\pi_0\xi) := \gamma_1(k,e)$.

5.2. Relative degree 1 case. We are now in a position to state our main result for the case when the system has strict relative degree 1; in this case, a filter is not necessary and the controller (4.7) simplifies to

$$u(t) = \nu(k(t))(Cx(t)-r(t)), \quad k(t) = \alpha\big(\varphi^2(t)\|Cx(t)-r(t)\|^2\big)\,. \tag{5.8}$$

The closed-loop initial-value problem then becomes

$$\begin{cases} \dot{x}(t) = Ax(t) + B\nu(k(t))(Cx(t)-r(t)) + f(p(t),T(Cx)(t),x(t)),\\ k(t) = \alpha\big(\varphi^2(t)\|Cx(t)-r(t)\|^2\big)\,,\\ x|_{[-h,0]} = x^0 \in C([-h,0],\mathbb{R}^m). \end{cases} \tag{5.9}$$

THEOREM 5.4. *Let $(A,B,C,f,p,T,h) \in \Sigma_1$ and $\varphi \in \Phi$ with associated performance funnel $\mathcal{F}_\varphi$. For each reference signal $r \in \mathcal{R}$, and initial data $(x^0,\xi^0) \in C([-h,0],\mathbb{R}^{\rho m}\times\mathbb{R}^{(\rho-1)m})$, application of the feedback (5.8) to (3.1) yields the initial-value problem (5.9), which has a solution, and every solution can be maximally extended. Every maximal solution $x\colon [-h,\omega) \to \mathbb{R}^m$ has the following properties:*

(i) *$\omega = \infty$;*

(ii) *x, k, and u are bounded;*

(iii) *the tracking error evolves within the funnel $\mathcal{F}_\varphi$ and is bounded away from the funnel boundary; i.e., there exists $\varepsilon > 0$ such that, for all $t \geq 0$, $\varphi(t)\|Cx(t)-r(t)\| \leq 1-\varepsilon$.*

The proof of Theorem 5.4 follows easily by modifying (all vestiges of the filter equations are excised) the proof of Theorem 5.5. The latter proof is in the appendix.

5.3. Relative degree $\rho \geq 2$ case. We now arrive at the main result of the paper (with proof in the appendix).

THEOREM 5.5. *Let $(A,B,C,f,p,T,h) \in \Sigma_\rho$ with $\rho \geq 2$ and let $\varphi \in \Phi$ with associated performance funnel $\mathcal{F}_\varphi$. For each reference signal $r \in \mathcal{R}$ and initial data $(x^0,\xi^0) \in C([-h,0],\mathbb{R}^{\rho m}\times\mathbb{R}^{(\rho-1)m})$, application of the feedback (4.7), in conjunction with the filter (4.1), to (3.1) yields the initial-value problem (4.9), which has a solution, and every solution can be maximally extended. Every maximal solution $(x,\xi)\colon [-h,\omega) \to \mathbb{R}^{\rho m}\times\mathbb{R}^{(\rho-1)m}$ has the following properties:*

(i) *$\omega = \infty$;*

(ii) *x, ξ, k, and u are bounded;*

(iii) *the tracking error evolves within the funnel $\mathcal{F}_\varphi$ and is bounded away from the funnel boundary; i.e., there exists $\varepsilon > 0$ such that, for all $t \geq 0$, $\varphi(t)\|Cx(t)-r(t)\| \leq 1-\varepsilon$.*

6. Example. We illustrate the controller strategy (4.7) applied to the following single-input, single-output system of relative degree $\rho = 2$:

$$\ddot{y}(t) + b_0 \sin y(t) + b_1 y(t)|y(t)| + (T_{a,b}\,y)(t) = b_2\,u(t)\,, \tag{6.1}$$

where b_0, b_1, and $b_2 \neq 0$ are unknown real parameters and $T_{a,b}$ represents the backlash operator, as defined in section 3.1.5, with parameters $a > 0$ and $b \in [-a, a]$. Equation (6.1) is equivalent to (3.1) with

$$x(t) = \begin{bmatrix} y(t) \\ \dot{y}(t) \end{bmatrix}, \quad A = \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix}, \quad B = \begin{bmatrix} 0 \\ b_2 \end{bmatrix}, \quad C = [1 \,\vdots\, 0], \quad f(p, w, x) = \begin{bmatrix} 0 \\ 1 \end{bmatrix} w,$$

and the operator T given by $(Ty)(t) = b_0 \sin y(t) + b_1 y(t)|y(t)| + (T_{a,b}y)(t)$, $t \in \mathbb{R}_+$. Setting $h = 0$ and $p = 0$, the resulting system $(A, B, C, f, 0, T, 0)$ is of class Σ_2.

Fix $\tau > 0$ arbitrarily and define $\varphi \in \Phi$ by

$$t \mapsto \varphi(t) = \begin{cases} 20(1 - (\frac{t}{\tau} - 1)^2), & 0 \leq t < \tau, \\ 20, & t \geq \tau. \end{cases} \tag{6.2}$$

Evolution within the associated performance funnel $\mathcal{F}_\varphi$ ensures a tracking accuracy $|e(t)| < 0.05$ for all $t \geq \tau$. Choosing $\nu\colon k \mapsto k \cos k$, $\xi^0 = 0$, writing $e(t) = y(t) - r(t)$, and suppressing the argument t for simplicity, the control strategy (4.8) is

$$\begin{cases} u = \mu(k \cos k)e - \mu\big[(\cos k - k \sin k)^2 e^2 + k^2 \cos^2 k\big] k^4 [1 + \xi^2]\theta\,, \\ k = \big[1 - \varphi^2 e^2\big]^{-1}\,, \qquad \theta = \xi - (k \cos k)e\,, \\ \dot{\xi} = -\mu\,\xi + u, \qquad\qquad \xi(0) = 0. \end{cases} \tag{6.3}$$

For purposes of illustration, as reference signal $r \in \mathcal{R}$, we take the first component ζ_1 of the solution (chaotic and bounded; see [15, appx. C]) of the following Lorenz system of equations:

$$\begin{cases} \dot{\zeta}_1(t) = \frac{1}{2}\zeta_2(t) - \zeta_1(t), & \zeta_1(0) = \frac{1}{2}, \\ \dot{\zeta}_2(t) = \frac{28}{5}\zeta_1(t) - \frac{1}{10}\zeta_2(t) - 2\zeta_1(t)\zeta_3(t), & \zeta_2(0) = 0, \\ \dot{\zeta}_3(t) = 2\zeta_1(t)\zeta_2(t) - \frac{8}{30}\zeta_3(t), & \zeta_3(0) = 3. \end{cases} \tag{6.4}$$

Setting $b_0 = \frac{1}{2}$, $b_1 = 1 = b_2$, $\mu = 10$, $\tau = 50$ and adopting backlash hysteresis with parameters $a = 1/2$, $b = 0$ and initial data $(y(0), \dot{y}(0)) = (0, 0)$, the behavior of the closed-loop system (6.1)–(6.3) is depicted in Figure 4.

7. Appendix.

7.1. Proof of Lemma 3.5. Parts of the following proof are implicit in the proofs of [7, Lem. 4.1.1] and [8, Prop. 11.5.1 and 11.5.2] (in a general context of nonlinear systems); here, we provide a simple, self-contained proof in the restricted context of linear systems.

Step (i). First, note that

$$\mathcal{CB} = \begin{bmatrix} 0 & & \Gamma \\ & \iddots & \\ \Gamma & & * \end{bmatrix},$$

and, since Γ is invertible, we see that $\mathcal{CB} \in \mathrm{GL}_{\rho m}(\mathbb{R})$. Furthermore, $\mathcal{NB} = 0$. Assertion (i) then follows from the observation that, for any $x \in \mathbb{R}^n$, we have $v := (I - \mathcal{B}(\mathcal{CB})^{-1}\mathcal{C})x \in \ker \mathcal{C}$ and $w := \mathcal{B}(\mathcal{CB})^{-1}\mathcal{C}x \in \operatorname{im} \mathcal{B}$, and so $x = v + w$.

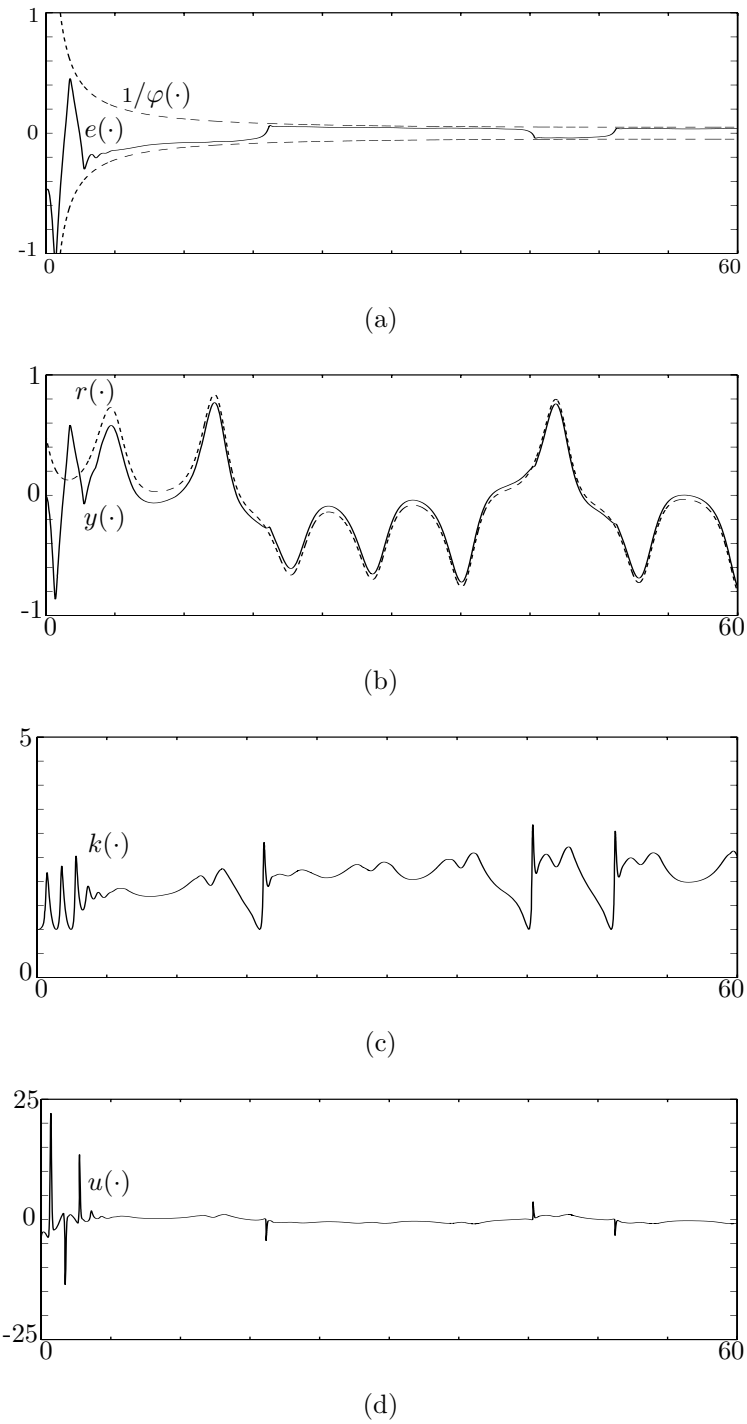


FIG. 4. *Tracking of a Lorenz component reference signal; system* (6.1) *with unknown sign* $b_2 \neq 0$ *and control strategy* (6.3). (a) *The funnel and tracking error* e. (b) *The reference* r *and output* y. (c) *The function* k. (d) *The control* u.

Step (ii). We now prove assertion (ii). It is clear that $\mathcal{U}^{-1} = [\mathcal{B}(\mathcal{CB})^{-1} \vdots \mathcal{V}]$. It is also immediate that $\hat{B} := \mathcal{U}\tilde{B}$ and $\hat{C} := \tilde{C}\mathcal{U}^{-1}$ have the structure given in (3.9). Furthermore,

$$\mathcal{U}\,\tilde{A} = \hat{A}\mathcal{U} \tag{7.1}$$

for some $\hat{A}$ of the form

$$\hat{A} = \begin{bmatrix} 0 & I & 0 & \dots & 0 & 0 \\ 0 & 0 & I & & & 0 \\ \vdots & & \ddots & \ddots & & \vdots \\ 0 & 0 & \dots & 0 & I & 0 \\ R_1 & R_2 & \dots & R_{\rho-1} & R_\rho & S \\ P_1 & P_2 & \dots & P_{\rho-1} & P_\rho & Q \end{bmatrix},$$

with $R_i \in \mathbb{R}^{m\times m}$, $P_i \in \mathbb{R}^{(n-\rho m)\times m}$, $i = 1,\dots,\rho$, $S \in \mathbb{R}^{m\times(n-\rho m)}$, $Q = \mathcal{N}\tilde{A}\mathcal{V} \in \mathbb{R}^{(n-\rho m)\times(n-\rho m)}$, and $[R_1 \vdots \cdots \vdots R_\rho \vdots S] = \tilde{C}\tilde{A}^\rho\mathcal{U}^{-1}$. If $\rho = 1$, then $\hat{A}$ takes the form shown in (3.10).

Recalling that $\mathcal{NB} = 0$, we see that

$$[P_1 \vdots \cdots \vdots P_\rho] = \mathcal{N}\tilde{A}\mathcal{B}(\mathcal{CB})^{-1} = [0 \vdots \cdots \vdots 0 \vdots \mathcal{N}\tilde{A}^\rho\tilde{B}] \begin{bmatrix} * & & \Gamma^{-1} \\ & \iddots & \\ \Gamma^{-1} & & 0 \end{bmatrix},$$

and hence $P_i = 0$ for $i = 2,\dots,\rho$. Writing $P = P_1$, it follows that $\hat{A}$ takes the form in (3.9) and $P = \mathcal{N}\tilde{A}^\rho\tilde{B}\Gamma^{-1}$.

Step (iii). Finally, we prove part (iii) of the lemma. Writing

$$M_1(s) = \begin{bmatrix} sI - \tilde{A} & \tilde{B} \\ \tilde{C} & 0 \end{bmatrix}, \quad M_2(s) = \begin{bmatrix} \mathcal{U} & 0 \\ 0 & I \end{bmatrix} M_1(s) \begin{bmatrix} \mathcal{U}^{-1} & 0 \\ 0 & I \end{bmatrix} = \begin{bmatrix} sI - \hat{A} & \hat{B} \\ \hat{C} & 0 \end{bmatrix},$$

and

$$M_3(s) = \begin{bmatrix} \hat{C} & 0 \\ \hat{A} - sI & -\hat{B} \end{bmatrix} = \begin{bmatrix} I & 0 & 0 & \dots & 0 & 0 & 0 \\ -sI & I & 0 & \dots & 0 & 0 & 0 \\ 0 & -sI & I & & 0 & 0 & 0 \\ \vdots & & \ddots & \ddots & & \vdots & \vdots \\ 0 & 0 & \dots & -sI & I & 0 & 0 \\ R_1 & R_2 & \dots & R_{\rho-1} & R_\rho - sI & S & -\Gamma \\ P & 0 & \dots & 0 & 0 & Q - sI & 0 \end{bmatrix},$$

we see that $|\det M_1(s)| = |\det M_2(s)| = |\det M_3(s)| = |\det\Gamma\,\det(sI - Q)|$.

By the minimum-phase property of $(\tilde{A}, \tilde{B}, \tilde{C})$, we have $\det(M_1(s)) \neq 0$ for all $s \in \mathbb{C} \setminus \mathbb{C}_-$, and so $\det(sI - Q) \neq 0$ for all $s \in \mathbb{C} \setminus \mathbb{C}_-$. It follows that $\operatorname{spec}(Q) \subset \mathbb{C}_-$, and hence assertion (iii) holds. ∎

7.2. Proof of Corollary 4.3. Introducing the open set

$$\mathcal{D} := \Big\{(x,\xi,\eta) \in \mathbb{R}^{\rho m} \times \mathbb{R}^{(\rho-1)m} \times \mathbb{R} \,\Big|\, \varphi(|\eta|)\,\|Cx - r(|\eta|)\| < 1\Big\}$$

and defining, on $\mathcal{D}$,

$$\gamma_\rho^*\colon (x,\xi,\eta)\mapsto \gamma_\rho\big(\alpha(\varphi^2(|\eta|)\,\|Cx-r(|\eta|)\|^2)\,,\,Cx-r(|\eta|)\,,\,\xi\big),$$

the initial-value problem (4.9) may be recast on $\mathcal{D}$ as

$$\text{(7.2)}\qquad \begin{cases} \dot{x}(t)=Ax(t)+f(p(t),T(Cx)(t),x(t))-B\gamma_\rho^*(x(t),\xi(t),\eta(t)),\\ \dot{\xi}(t)=F\xi(t)-G\gamma_\rho^*(x(t),\xi(t),\eta(t)),\\ \dot{\eta}(t)=1,\\ (x,\xi,\eta)|_{[-h,0]}=(x^0,\xi^0,0)\in C([-h,0],\mathbb{R}^{\rho m}\times\mathbb{R}^{(\rho-1)m}\times\mathbb{R}). \end{cases}$$

Setting $\zeta=(x,\xi,\eta)$ and defining the Carathéodory function

$$\begin{aligned} &Z\colon [-h,\infty)\times\mathbb{R}^q\times\mathbb{R}^{2(\rho-1)m+1}\to\mathbb{R}^{(2\rho-1)m+1},\\ &(t,w,\zeta)\mapsto Z(t,w,\zeta):=\begin{bmatrix}A&0&0\\0&F&0\\0&0&0\end{bmatrix}\zeta+\begin{bmatrix}I\\0\\0\end{bmatrix}f(p(t),w,x)-\begin{bmatrix}B\\G\\0\end{bmatrix}\gamma_\rho^*(\zeta)+\begin{bmatrix}0\\0\\1\end{bmatrix} \end{aligned}$$

we can rewrite (7.2) as follows:

$$\text{(7.3)}\qquad \dot{\zeta}(t)=Z(t,(\widehat{T}\zeta)(t),\zeta(t)),\quad \zeta|_{[-h,0]}=\zeta^0\in C([-h,0],\mathbb{R}^{(2\rho-1)m+1}),$$

where the operator $\widehat{T}$, given by $(\widehat{T}\zeta)(t)=(TCx)(t)$, is of class $\mathcal{T}_h$. We then apply the existence result, Theorem 4.2, to establish: (i) the existence of a solution $t\mapsto\zeta(t)\in\mathcal{D}$ to (7.2) and that (ii) every solution can be extended to a maximal solution $\zeta\colon[-h,\omega)\to\mathcal{D}$. Furthermore, if there exists a compact set $\mathcal{C}\subset\mathcal{D}$ such that $(x(t),\xi(t),\eta(t))\in\mathcal{C}$ for all $t\in[0,\omega)$, then $\omega=\infty$.

Clearly, if $\zeta=(x,\xi,\eta)\colon[-h,\omega)\to\mathcal{D}$ is a solution of (7.3), then $(x,\xi)\colon[-h,\omega)\to\mathbb{R}^{\rho m}\times\mathbb{R}^{(\rho-1)m}$ is a solution of (4.9); conversely, if $(x,\xi)\colon[-h,\omega)\to\mathbb{R}^{\rho m}\times\mathbb{R}^{(\rho-1)m}$ is a solution of (4.9), then $\zeta=(x,\xi,\eta)\colon[-h,\omega)\to\mathbb{R}^{\rho m}\times\mathbb{R}^{(\rho-1)m}\times\mathbb{R}$, with component η given by $\eta(t)=t$, is a solution of (7.3). We may now conclude that, for each $(x^0,\xi^0)\in C([-h,0],\mathbb{R}^{\rho m}\times\mathbb{R}^{(\rho-1)m})$, (4.9) has a solution and every solution can be maximally extended.

Let $(x,\xi)\colon[-h,\omega)\to\mathbb{R}^{\rho m}\times\mathbb{R}^{(\rho-1)m}$ be a maximal solution of (4.9) (and so $t\mapsto\zeta(t)=(x(t),\xi(t),t)$ is a maximal solution of (4.10)). Assume that (x,ξ) is bounded and that the gain function $t\mapsto k(t)=\alpha\big(\varphi^2(t)\|Cx(t)-r(t)\|^2\big)$ is also bounded. Then there exist $c>0$ and $\varepsilon>0$ such that $\|(x(t),\xi(t))\|\le c$ and $\varphi(t)\|Cx(t)-r(t)\|\le 1-\varepsilon$ for all $t\in[0,\omega)$. Seeking a contradiction, suppose that $\omega<\infty$. It then follows that $\mathcal{K}:=\big\{(\hat{x},\hat{\xi},\hat{\eta})\in\mathcal{D}\big|\ \varphi(|\hat{\eta}|)\|C\hat{x}-r(|\hat{\eta}|)\|\le 1-\varepsilon,\ \|(\hat{x},\hat{\xi})\|\le c,\ \hat{\eta}\in[-h,\omega]\big\}$ is a compact subset of $\mathcal{D}$ which contains the trajectory $\zeta([-h,\omega))$ of the maximal solution ζ of (4.10). This contradicts the last assertion of Theorem 4.2, and so $\omega=\infty$. ∎

7.3. Proof of Lemma 5.1. Define

$$K:=\big[[\mu\,I+A]^{\rho-2}B\,\vdots\,[\mu\,I+A]^{\rho-3}B\,\vdots\,\cdots\,\vdots\,[\mu\,I+A]B\,\vdots\,B\big]\in\mathbb{R}^{\rho m\times(\rho-1)m}$$

and note that

$$AK-KF=\big[[\mu\,I+A]^{\rho-1}B\,\vdots\,0\,\vdots\,\cdots\,\vdots\,0\big],\quad KG=B,\quad\text{and}\quad CK=0.$$

Writing $\tilde{B} := (\mu I + A)^{\rho-1}B$, we have $C\tilde{B} = CA^{\rho-1}B = \Gamma$, and so the triple $(A, \tilde{B}, C)$ defines a linear system of relative degree one. Let $V \in \mathbb{R}^{\rho m \times (\rho-1)m}$ be such that $\operatorname{im} V = \ker C$. By Lemma 3.5 applied in the context of the system $(A, \tilde{B}, C)$, the matrix $\left[\begin{smallmatrix} C \\ N \end{smallmatrix}\right]$, with $N := (V^TV)^{-1}V^T\,[I - \tilde{B}\Gamma^{-1}C]$, is invertible, with inverse $\left[\tilde{B}\Gamma^{-1} \vdots V\right]$. Writing

$$L = \begin{bmatrix} C & 0 \\ N & -NK \\ 0 & I \end{bmatrix} \quad \text{with} \quad L^{-1} = \begin{bmatrix} \tilde{B}\Gamma^{-1} & V & K \\ 0 & 0 & I \end{bmatrix}$$

and recalling that $KG = B$, $CB = 0$, and $CK = 0$, we have

$$L \begin{bmatrix} B \\ G \end{bmatrix} = \begin{bmatrix} 0 \\ G \end{bmatrix} \quad \text{and} \quad \begin{bmatrix} C \vdots 0 \end{bmatrix} L^{-1} = \begin{bmatrix} I \vdots 0 \end{bmatrix}.$$

Moreover, noting that $CAK = \begin{bmatrix} \Gamma \vdots 0 \vdots \cdots \vdots 0 \end{bmatrix} =: \tilde{\Gamma}$ and $N[AK - KF] = 0$, we have

$$L \begin{bmatrix} A & 0 \\ 0 & F \end{bmatrix} L^{-1} = \begin{bmatrix} CA\tilde{B}\Gamma^{-1} & CAV & CAK \\ NA\tilde{B}\Gamma^{-1} & NAV & N[AK - KF] \\ 0 & 0 & F \end{bmatrix} = \begin{bmatrix} A_1 & A_2 & \tilde{\Gamma} \\ A_3 & A_4 & 0 \\ 0 & 0 & F \end{bmatrix},$$

where $\tilde{\Gamma} = [\Gamma \vdots 0 \vdots \cdots \vdots 0]$. It remains to show that A_4 has spectrum in $\mathbb{C}_-$. Writing

$$M_4(s) = \begin{bmatrix} sI - A & B \\ C & 0 \end{bmatrix} \quad \text{and} \quad M_5(s) = \begin{bmatrix} sI - A & 0 & B \\ 0 & sI - F & -G \\ C & 0 & 0 \end{bmatrix},$$

we have

$$M_6(s) := \begin{bmatrix} I & K & 0 \\ 0 & I & 0 \\ 0 & 0 & I \end{bmatrix} M_5(s) \begin{bmatrix} I & K & 0 \\ 0 & I & 0 \\ 0 & 0 & I \end{bmatrix}^{-1} = \begin{bmatrix} sI - A & AK - KF & 0 \\ 0 & sI - F & -G \\ C & 0 & 0 \end{bmatrix}.$$

In view of the particular structure of F, G, and $AK - KF$, it is readily verified that $|\det M_6(s)| = |\det M_7(s)|$, where

$$M_7(s) = \begin{bmatrix} sI - A & [\mu I + A]^{\rho-1}B \\ C & 0 \end{bmatrix}.$$

Define

$$M_8(s) := \begin{bmatrix} C & 0 \\ N & 0 \\ 0 & I \end{bmatrix} M_7(s) \begin{bmatrix} \tilde{B}\Gamma^{-1} & V & 0 \\ 0 & 0 & I \end{bmatrix} = \begin{bmatrix} sI - A_1 & -A_2 & \Gamma \\ -A_3 & sI - A_4 & 0 \\ I & 0 & 0 \end{bmatrix}.$$

By the minimum-phase property of the triple (A, B, C) (recall Remark 3.4(ii)), for all $s \in \mathbb{C} \setminus \mathbb{C}_-$, we have $\det M_4(s) \neq 0$. We may now conclude that, for all $s \in \mathbb{C} \setminus \mathbb{C}_-$,

$$\begin{aligned} |\det \Gamma \det(sI - A_4)| &= |\det M_8(s)| = |\det M_7(s)| \\ &= |\det M_6(s)| = |\det M_5(s)| = |\det(sI - F) \det M_4(s)| \neq 0, \end{aligned}$$

and so $\operatorname{spec}(A_4) \subset \mathbb{C}_-$. This completes the proof. ∎

7.4. Proof of Lemma 5.3. Assume that $(x,\xi)\colon [-h,\omega)\to\mathbb{R}^{\rho m}\times\mathbb{R}^{(\rho-1)m}$ is a maximal solution of (4.9). Write $y(t)=Cx(t)$ and $e(t)=y(t)-r(t)$ for all $t\in[-h,\omega)$. By Lemma 5.1, there exists an invertible linear transformation L under which the closed-loop system (4.9) may be expressed in the form (5.5), wherein, by Lemma 5.2, e and z are bounded and the functions f_1 and f_2 given by (5.6) are essentially bounded and bounded, respectively. By boundedness of z, essential boundedness of f_1, and the first of equations (5.5), we may infer the existence of $c_1>0$ such that

$$\|\dot e(t)\|\le c_1\big(1+\|\xi_1(t)\|\big)\quad\text{for a.a. } t\in[0,\omega).$$

By boundedness of φ, e, essential boundedness of $\dot\varphi$, and recalling that $\alpha'(s)=\alpha^2(s)\ge 1$ for all $s\in[0,1)$, there exists a constant $c_2>0$ such that

$$\begin{aligned}|\dot k(t)| &= 2\alpha'(\varphi^2(t)\|e(t)\|^2)\big|\varphi^2(t)\langle e(t),\dot e(t)\rangle+\varphi(t)\dot\varphi(t)\|e(t)\|^2\big|\\ &\le c_2k^2(t)\,(1+\|\xi_1(t)\|)\quad\text{for a.a. } t\in[0,\omega).\end{aligned}$$

Since $k(t)\ge 1$ for all $t\in[0,\omega)$, we may now conclude the existence of a constant $c_3>0$ such that

$$\|(\dot k(t),\dot e(t))\|^2\le c_3\,\Delta(t)\quad\text{for a.a. } t\in[0,\omega),\quad\text{where } \Delta(t):=k^4(t)\big(1+\|\xi_1(t)\|^2\big).$$

Then, invoking (4.4), (5.7), and writing $c_{4,1}:=c_3/\mu>0$, we have

$$\begin{aligned}\langle\theta_1(t),\dot\theta_1(t)\rangle &\le \langle\theta_1(t)\,,\,-\mu\xi_1(t)+\xi_2(t)\rangle+\|\theta_1(t)\|\|D\gamma_1(k(t),e(t))\|\|(\dot k(t),\dot e(t))\|\\ &\le \langle\theta_1(t)\,,\,-\mu\theta_1(t)+\mu\gamma_1(k(t),e(t))\rangle+\langle\theta_1(t),\xi_2(t)\rangle\\ &\qquad+\sqrt{\mu}\,\|\theta_1(t)\|\,\|D\gamma_1(k(t),e(t))\|\,\sqrt{(c_3/\mu)\,\Delta(t)}\\ &\le c_{4,1}-\mu\|\theta_1(t)\|^2+\langle\theta_1(t),\xi_2(t)\rangle+\mu\langle\theta_1(t),\gamma_1(k(t),e(t))\rangle\\ &\qquad+\mu\|\theta_1(t)\|^2\,\|D\gamma_1(k(t),e(t))\|^2\,\Delta(t)\\ &= c_{4,1}-\mu\|\theta_1(t)\|^2+\big\langle\theta_1(t),\xi_2(t)+\mu\gamma_2(k(t),e(t),\xi_1(t))\big\rangle\\ &= c_{4,1}-\mu\|\theta_1(t)\|^2+\mu\langle\theta_1(t),\theta_2(t)\rangle\quad\text{for a.a. } t\in[0,\omega).\end{aligned}$$

Analogous calculations yield the existence of constants $c_{4,2},\dots,c_{4,\rho-1}>0$, such that

$$\langle\theta_i(t),\dot\theta_i(t)\rangle\le c_{4,i}-\mu\|\theta_i(t)\|^2+\mu\langle\theta_i(t),\theta_{i+1}(t)\rangle\quad\text{for a.a. } t\in[0,\omega),\ \ i=2,\dots,\rho-2,$$

and, using (4.5), $\langle\theta_{\rho-1}(t),\dot\theta_{\rho-1}(t)\rangle\le c_{4,\rho-1}-\mu\|\theta_{\rho-1}(t)\|^2$ for almost all $t\in[0,\omega)$. Writing $c_4=c_{4,1}+\cdots+c_{4,\rho-1}$, we have

$$\begin{aligned}\tfrac12\tfrac{\mathrm{d}}{\mathrm{d}t}\|\theta(t)\|^2 &\le c_4-\mu\|\theta(t)\|^2+\mu\langle\theta_1(t),\theta_2(t)\rangle+\cdots+\mu\langle\theta_{\rho-2}(t),\theta_{\rho-1}(t)\rangle\\ &\le c_4-\mu\langle\theta(t),P\theta(t)\rangle\quad\text{for a.a. } t\in[0,\omega),\end{aligned}$$

where P is a positive-definite, symmetric, tridiagonal matrix with all diagonal entries equal to 1 and all sub- and superdiagonal entries equal to $-1/2$. By positivity of P, it follows that θ is bounded. This completes the proof of the lemma. □

7.5. Proof of Theorem 5.5. Let (x^0,ξ^0) be arbitrary. By Corollary 4.3, (4.9) has a solution and every solution can be maximally extended. Let (x,ξ) be a maximal solution of (4.9) with interval of existence $[-h,\omega)$. Writing $y(t)=Cx(t)$, $e(t)=y(t)-r(t)$ for all $t\in[0,\omega)$ and invoking Lemma 5.1, there exists an invertible linear transformation L which takes (4.9) into the equivalent form (5.5)–(5.6). Introducing

$\theta_1\colon [0,\omega) \to \mathbb{R}^m$ given by (5.7), namely, $\theta_1(t) = \xi_1(t) - \nu(k(t))e(t)$, then the first of equations (5.5) yields

$$\dot{e}(t) = f_3(t) + \nu(k(t))\,\Gamma\, e(t) \quad \text{for a.a. } t \in [0,\omega), \tag{7.4}$$

with $f_3(t) := A_1 e(t) + A_2 z(t) + \Gamma\theta_1(t) + f_1(t)$. By Lemmas 5.2 and 5.3, the functions y, z, e and $\theta = (\theta_1, \dots, \theta_{\rho-1})$, given by (5.7), are bounded, which, together with essential boundedness of f_1, implies essential boundedness of f_3. Therefore, there exists $c_5 > 0$ such that

$$\langle e(t), \dot{e}(t)\rangle \le c_5 + \nu(k(t))\,\langle e(t), \Gamma e(t)\rangle \quad \text{for a.a. } t \in [0,\omega). \tag{7.5}$$

We are now in a position to prove boundedness of k. Recalling that Γ is either positive definite or negative definite, there exist constants $\beta_0, \beta_1 > 0$ such that

$$\beta_0\|e\|^2 \le |\langle e, \Gamma e\rangle| \le \beta_1\|e\|^2 \quad \forall\, e \in \mathbb{R}^m.$$

Define the continuous function $\tilde{\nu}\colon \mathbb{R} \to \mathbb{R}$ as follows:

$$\tilde{\nu}(k) := \begin{cases} -\beta_1\nu(k), & s(\Gamma)\nu(k) \ge 0\,, \\ -\beta_0\nu(k), & s(\Gamma)\nu(k) < 0\,. \end{cases}$$

Observe that

$$\nu(k)\langle e, \Gamma e\rangle \le -s(\Gamma)\tilde{\nu}(k)\|e\|^2 \quad \forall\, e \in \mathbb{R}^m\,,\ \forall\, k \ge 0\,,$$

which, together with boundedness of e, φ, essential boundedness of $\dot{\varphi}$, and (7.5), implies the existence of $c_6 > 0$ such that

$$\tfrac{\mathrm{d}}{\mathrm{d}t}\,(\varphi(t)\|e(t)\|)^2 \le c_6 - 2s(\Gamma)\,\tilde{\nu}(k(t))\,\big(\varphi(t)\|e(t)\|\big)^2 \quad \text{for a.a. } t \in [0,\omega).$$

In view of property (4.2) of ν, there exists a strictly increasing unbounded sequence (k_j) in $(1,\infty)$ such that the sequence $\big(s(\Gamma)\tilde{\nu}(k_j)\big)$ is also strictly increasing, unbounded, and such that $s(\Gamma)\tilde{\nu}(k_j) > 0$ for all $j \in \mathbb{N}$. Seeking a contradiction, suppose k is unbounded on $[0,\omega)$. For each $j \in \mathbb{N}$, define $\tau_j := \inf\{t \in [0,\omega)|\ k(t) = k_{j+1}\}$ and $\sigma_j := \sup\{t \in [0,\tau_j]|\ \tilde{\nu}(k(t)) = \tilde{\nu}(k_j)\}$. It is readily verified that $\sigma_j < \tau_j$ and $k(\sigma_j) < k(\tau_j)$; moreover, for all $j \in \mathbb{N}$ and all $t \in [\sigma_j, \tau_j]$, $k(t) \ge k_j$ and $s(\Gamma)\tilde{\nu}(k(t)) \ge s(\Gamma)\tilde{\nu}(k_j)$. Therefore,

$$(\varphi(t)\|e(t)\|)^2 \ge \alpha^{-1}(k_j) \ge \alpha^{-1}(k_1) = 1 - \frac{1}{k_1} =: c_7 > 0 \quad \forall\, t \in [\sigma_j, \tau_j],\ \forall\, j \in \mathbb{N},$$

where $\alpha^{-1}\colon [1,\infty) \to [0,1)$ is the inverse of the bijection α. Thus,

$$\tfrac{\mathrm{d}}{\mathrm{d}t}\,(\varphi(t)\|e(t)\|)^2 \le c_6 - 2c_7 s(\Gamma)\tilde{\nu}(k(t)) \quad \forall\, t \in [\sigma_j, \tau_j],\ \ \forall\, j \in \mathbb{N}.$$

Let $j^* \in \mathbb{N}$ be sufficiently large so that $c_6 - 2c_7 s(\Gamma)\tilde{\nu}(k_{j^*}) < 0$. Then

$$\big(\varphi(\tau_{j^*})\|e(\tau_{j^*})\|\big)^2 < \big(\varphi(\sigma_{j^*})\|e(\sigma_{j^*})\|\big)^2,$$

whence the contradiction

$$0 > \alpha\big(\varphi^2(\tau_{j^*})\|e(\tau_{j^*})\|^2\big) - \alpha\big(\varphi^2(\sigma_{j^*})\|e(\sigma_{j^*})\|^2\big) = k(\tau_{j^*}) - k(\sigma_{j^*}) > 0.$$

This proves boundedness of k. Therefore, there exists $\varepsilon > 0$ such that $\varphi(t)\|e(t)\| \leq 1 - \varepsilon$ for all $t \in [0, \omega)$. By boundedness of θ, e, and k, together with continuity of the functions γ_i, it follows from the recursive construction in (5.7) that, for $i = 1, \ldots, \rho-1$, ξ_i is bounded. We may now deduce that x and ξ are bounded, and, by (4.3), (4.4), (4.5), and (4.7), we may also infer boundedness of u. Finally, by boundedness of x, ξ, and k, together with Corollary 4.3, we conclude that $\omega = \infty$. ∎

INFINITE HORIZON RISK SENSITIVE CONTROL OF DISCRETE TIME MARKOV PROCESSES UNDER MINORIZATION PROPERTY*

GIOVANNI B. DI MASI† AND ŁUKASZ STETTNER‡

Abstract. Risk sensitive control of Markov processes satisfying the minorization property is studied using splitting techniques. Existence of solutions to the multiplicative Poisson equation is shown. Approximation by uniformly ergodic controlled Markov processes is introduced, which allows us to show the existence of solutions to the infinite horizon risk sensitive Bellman equation.

Key words. risk sensitive control, discrete time Markov processes, splitting, Poisson equation, Bellman equation

1. Introduction.

On a probability space $(\Omega, \mathcal{F}, P)$ consider a controlled Markov process $X = (x_n)$ taking values on a complete separable metric state space E endowed with the Borel σ-algebra $\mathcal{E}$. Assume that x_n has a controlled transition operator $P^{a_n}(x_n, \cdot)$, where a_n is the control at time n taking values on a compact metric space U and adapted to the σ-algebra $\sigma\{x_0, x_1, \ldots, x_n\}$.

Let $c : E \times U \to R$ be a continuous and bounded function. Our aim is to minimize the exponential ergodic performance criterion,

$$J_x^{\gamma}\big((a_n)\big) = \lim_{t\to\infty} \sup \frac{1}{t} \ln E_x^{(a_n)} \left\{ \exp\left\{ \sum_{i=0}^{t-1} \gamma c(x_i, a_i) \right\} \right\}, \tag{1}$$

with risk factor $\gamma > 0$. In what follows we shall distinguish the following special classes of admissible controls (a_n): *Markov controls* $\mathcal{U}_M = \{(a_n) : a_n = u_n(x_n)\}$, where $u_n : E \mapsto U$ is a sequence of Borel measurable functions, and *stationary controls* $\mathcal{U}_s = \{(a_n) : a_n = u(x_n)\}$, where $u : E \mapsto U$ is a Borel measurable function.

Consider the following assumptions:

(A1) $\exists_{\beta>0}$ $\exists_{C compact \in \mathcal{E}}$ $\exists_{\nu\in\mathcal{P}(E)}$ with $\nu(C) = 1$ such that $\forall_{A\in\mathcal{E}}$

$$\inf_{x\in C} \inf_{a\in U} P^a(x, A) \geq \beta\nu(A).$$

(A2) C given in (A1) is ergodic, i.e., $\forall_{(a_n)\in\mathcal{U}_M}$ $\forall_{x\in E}$ $E_x^{(a_n)}, \{\tau_C\} < \infty$, where $\tau_C = \inf\{i > 0 : x_i \in C\}$, and furthermore $\sup_{x\in C} E_x^{(a_n)}\{\tau_C\} < \infty$.

In this paper the risk sensitive control problem with cost functional (1) and general state space is studied. The paper generalizes [12] and [13] where uniform ergodicity assumption was required. Instead of uniform ergodicity we require minorization property (A1), which allows us to use splitting technique arguments described in [21] and

[22]. Risk sensitive discrete time control problems have been studied in a number of papers [1], [5], [6], [7], [8], [9], [10], [11], [14], [15], [16] for finite or countable state spaces. The general state space model in discrete time was considered in [12] and [13] only. Financial applications of risk sensitive control problems were introduced in [3] and continued in various papers; see, e.g., [23] and [25] and the references therein. Splitting techniques for controlled problems were used in a number of papers; see, e.g., [20] for the case of average cost per unit time and [4] for partially observed ergodic control problems. The first part of this paper studies the so-called Poisson equation. This equation was considered in particular in [17], [18], [5], [2], and [22]. Here we present a rather simple probabilistic characterization (based on splitting arguments) of its solution, which in some sense generalizes Theorem 5.1 of [22] and Proposition 2.8 of [18], where an operator form of the solution was considered. The main result of the paper concerns the existence of solutions to the Bellman equation corresponding to the risk sensitive control problem with a general state space (under minorization property) and is obtained using a uniformly ergodic approximating process. The idea of the approximation of general Markov processes by Markov processes with nice ergodic properties has been exploited in various papers, particularly in [18], where multiplicative Poisson equations are studied, while in [16] ideas based on the spectral theory are used. In this paper we show that the approximation by uniformly ergodic controlled Markov processes is also a useful tool to study risk sensitive Bellman equations.

2. Splitting of Markov processes. Let $\hat{E} = \{C \times \{0\} \cup C \times \{1\} \cup E \setminus C \times \{0\}\}$ and $\hat{x}_n = (x_n^1, x_n^2) \in \hat{E}$. Given a Markov control $a_n = u_n(x_n^1)$, where $u_n : E \mapsto U$ is a sequence of Borel measurable functions, consider the following Markov process defined on $\hat{E}$ (compare to [22] and [17]):

(i) When $(x_n^1, x_n^2) \in C \times \{0\}$, x_n^1 moves to y according to $(1-\beta)^{-1}(P^{a_n}(x_n^1, dy) - \beta\nu(dy))$, and whenever $y \in C$, x_n^2 is changed into $x_{n+1}^2 = \beta_{n+1}$, where β_n is independently and identically distributed (i.i.d.) and $P\{\beta_n = 0\} = 1 - \beta$, $P\{\beta_n = 1\} = \beta$.

(ii) When $(x_n^1, x_n^2) \in C \times \{1\}$, x_n^1 moves to y according to ν and $x_{n+1}^2 = \beta_{n+1}$.

(iii) When $(x_n^1, x_n^2) \in E \setminus C \times \{0\}$, x_n^1 moves to y according to $P^{a_n}(x_n^1, dy)$, and whenever $y \in C$, x_n^2 is changed into $x_{n+1}^2 = \beta_{n+1}$.

In what follows we shall write that the control (a_n) of $(\hat{x}_n)$ is in the class $\mathcal{U}_M$ whenever there is a sequence of Borel measurable functions $u_n : E \mapsto U$ such that $a_n = u_n(x_n^1)$.

Let $C_0 = C \times \{0\}$, $C_1 = C \times \{1\}$. By direct calculation we obtain the following.

LEMMA 1. *For $n = 1, 2 \ldots$ we have almost surely*

$$P\{\hat{x}_n \in C_0 | \hat{x}_n \in C_0 \cup C_1, \hat{x}_{n-1}, \ldots, \hat{x}_0\} = 1 - \beta,$$

$$P\{\hat{x}_n \in C_1 | \hat{x}_n \in C_0 \cup C_1, \hat{x}_{n-1}, \ldots, \hat{x}_0\} = \beta.$$

Furthermore we have the following.

LEMMA 2. *Under Markov control $(a_n) \in \mathcal{U}_M$ the process $(\hat{x}_n = (x_n^1, x_n^2))$ is Markov with transition operator $\hat{P}^{a_n}(\hat{x}_n, dy)$ defined by* (i)–(iii) *and if $(a_n) \in \mathcal{U}_s$, it has a unique invariant measure $\Psi^{(a_n)}$ given by*

$$\Psi^{(a_n)}(A) = \frac{\hat{E}_z^{(a_n)}\left\{\sum_{i=1}^{\tau_{C_1}} \chi_A(\hat{x}_i)\right\}}{\hat{E}_z^{(a_n)}\{\tau_{C_1}\}}, \tag{2}$$

with $z \in C_1$, for any Borel subset A of $\hat{E}$, where $\hat{E}_z^{(a_n)}$ stands for conditional law of Markov process $\hat{x}_n$ with initial state z. Furthermore the first coordinate (x_n^1) is also a Markov process with transition operator $P^{a_n}(x_n^1, dy)$.

Proof. The Markov property of $(\hat{x}_n)$ follows from the construction (i)–(iii) above of the split Markov process. One can easily verify that $\Psi^{(a_n)}$ is in fact an invariant measure if we know that $\hat{E}_z^{(a_n)}\{\tau_{C_1}\}$ is finite. To show this, notice first that for $x \notin C$ and positive integer m

$$\hat{E}_{(x,0)}^{(a_n)}\{\tau_C \chi_{\tau_C \le m}\} = E_x^{(a_n)}\{\tau_C \chi_{\tau_C \le m}\},$$

where τ_C in the left-hand side is the first time in which (x_n^1) hits C, while in the right-hand side it is the analogous hitting time for (x_n). Therefore by (A2) letting $n \to \infty$ we obtain that for $x \notin C$

$$\hat{E}_{(x,0)}^{(a_n)}\{\tau_C\} = E_x^{(a_n)}\{\tau_C\}. \tag{3}$$

For $\hat{x} = (x^1, 0) \in C_0$ by (i), (3), and (A2) there is an $M > 0$ such that

$$\hat{E}_{\hat{x}}\{\tau_C\} = \frac{P(x,C)-\beta}{1-\beta} + \hat{E}_{\hat{x}}\left\{\chi_{E\setminus C}(x_1^1)(1+\hat{E}_{\hat{x}_1}\{\tau_C\})\right\}$$

$$= \frac{P(x,C)-\beta}{1-\beta} + \hat{E}_{\hat{x}}\left\{\chi_{E\setminus C}(x_1^1)(1+E_{x_1^1}\{\tau_C\})\right\}$$

$$\le \frac{P(x,C)-\beta}{1-\beta} + \frac{1}{1-\beta} E_{x^1}\{\tau_C\} \le M.$$

Let $\tau_1 = \tau$ and $\tau_{n+1} = \tau_n + \theta_{\tau_n} \circ \tau$ for $n = 1, 2 \ldots$. Then for $\hat{x} \in C_0$ we have

$$\hat{E}_{\hat{x}}\{\tau_{C_1}\} = \hat{E}_x\left\{\sum_{i=1}^{\infty} \chi_{C_1^c}(\hat{x}_{\tau_1}) \cdots \chi_{C_1^c}(x_{\tau_{i-1}}) \chi_{C_1}(\hat{x}_{\tau_i}) \tau_i\right\}$$

$$\le \sum_{i=1}^{\infty} \beta(1-\beta)^{i-1} i M = \frac{M}{\beta},$$

and since for $\hat{x} \in C_1$

$$\hat{E}_x\{\tau_{C_1}\} = \beta + \hat{E}_x\left\{\chi_{C_0}(x_1^1)(1+\hat{E}_{(x_1^1,0)}\{\tau_{C_1}\})\right\},$$

we have that $\hat{E}_z^{(a_n)}\{\tau_{C_1}\}$ is in fact finite.

To prove the second statement of Lemma 2 notice that for $A \in \mathcal{E}$

$$\begin{aligned} &P\{x_{n+1}^1 \in A | x_n^1, x_{n-1}^1, \ldots, x_0^1\} \\ &= P\{x_{n+1}^1 \in A | x_n^1, x_n^2 = 0, x_{n-1}^1, \ldots, x_0^1\} P\{x_n^2 = 0 | x_n^1, x_{n-1}^1, \ldots, x_0^1\} \\ &\quad + P\{x_{n+1}^1 \in A | x_n^1, x_n^2 = 1, x_{n-1}^1, \ldots, x_0^1\} P\{x_n^2 = 1 | x_n^1, x_{n-1}^1, \ldots, x_0^1\}. \end{aligned} \tag{4}$$

In the case when $x_n^1 \in C$, (4) is equal to

$$\frac{P^{a_n}(x_n^1, A) - \beta\nu(A)}{1-\beta}(1-\beta) + \beta\nu(A) = P^{a_n}(x_n^1, A).$$

For $x_n^1 \notin C$, (4) is equal to $P^{a_n}(x_n^1, A)$, which completes the proof of the Markov property of (x_n^1). □

The following corollary explains the meaning of the splitting.

COROLLARY 1. *For any bounded Borel measurable function* $f : E^m \mapsto R$, $m = 1, 2, \ldots,$ *and control* $(a_n) \in \mathcal{U}_M$ *we have*

$$E_x^{(a_n)} \{f(x_1, x_2, \ldots, x_m)\} = \hat{E}_{\delta_x^*}^{(a_n)} \left\{f(x_1^1, x_2^1, \ldots, x_m^1)\right\}, \tag{5}$$

where $\delta_x^* = \delta_{(x,0)}$ *for* $x \in E \setminus C$ *and* $\delta_x^* = (1-\beta)\delta_{(x,0)} + \beta\delta_{(x,1)}$ *for* $x \in C$ *and* $\hat{E}_\mu$ *stands for the conditional law of Markov process* $(\hat{x}_n)$ *with initial law* $\mu \in \mathcal{P}(\hat{E})$.

Proof. It follows from (4) that for a bounded Borel measurable $g : E \mapsto R$

$$\begin{aligned}
&\hat{E}\left\{g(x_{i+1}^1)|x_i^1, x_{i-1}^1, \ldots, x_0^1\right\} \\
&= \hat{E}\left\{\hat{E}\left\{g(x_{i+1}^1)|\hat{x}_i, \hat{x}_{i-1}, \ldots, \hat{x}_0\right\}|x_i^1, x_{i-1}^1, \ldots, x_0^1\right\} \\
&= \hat{E}\left\{\hat{E}_{\hat{x}_i}\left\{g(x_1^1)\right\}|x_i^1, x_{i-1}^1, \ldots, x_0^1\right\} = \hat{E}_{\delta^*_{x_i^1}}\left\{g(x_1^1)\right\}. \qquad (6)
\end{aligned}$$

On the other hand by the Markov property of (x_n^1) we have

$$\hat{E}\left\{g(x_{i+1}^1)|x_i^1, x_{i-1}^1, \ldots, x_0^1\right\} = \int_E g(y)P^{a_i}(x_i^1, dy). \tag{7}$$

Consequently applying (6) and (7) to function $f : E^m \mapsto R$ we obtain (5). □

3. Multiplicative Poisson equation. In this section we shall assume that

(A3) $\forall_{(a_n)\in\mathcal{U}_s}$ $\exists_d$ such that $\forall_{x\in\hat{E}}$

$$\hat{E}_x^{(a_n)}\left\{\exp\left\{\sum_{i=1}^{\tau_{C_1}}\left(\gamma c(x_i^1, a_i) - d\right)\right\}\right\} < \infty$$

and for $x \in C_1$

$$\hat{E}_x^{(a_n)}\left\{\exp\left\{\sum_{i=1}^{\tau_{C_1}}\left(\gamma c(x_i^1, a_i) - d\right)\right\}\right\} \geq 1.$$

LEMMA 3. *Under* (A3) *for* $(a_n) \in \mathcal{U}_s$ *there is a unique* $\lambda^\gamma((a_n))$ *such that*

$$\hat{E}_x^{(a_n)}\left\{\exp\left\{\sum_{i=1}^{\tau_{C_1}}\left(\gamma c(x_i^1, a_i) - \lambda^\gamma((a_n))\right)\right\}\right\} = 1 \tag{8}$$

for $x \in C_1$.

Proof. Notice that for $x \in C_1$ the mapping

$$D : \lambda \mapsto \hat{E}_x^{(a_n)}\left\{\exp\left\{\sum_{i=1}^{\tau_{C_1}}\gamma c(x_i^1, a_i) - \lambda\right\}\right\}$$

is strictly decreasing whenever it is finite. Moreover by (A3) we have that $\infty > D(d) \geq 1$. Since $\lim_{b\to\infty} D(b) = 0$ by continuity of D (which follows by the monotone convergence theorem) there is a unique $\lambda^\gamma((a_n))$ for which (8) holds. □

Remark 1. Notice that by letting $d = \inf_{x\in E, a\in U}\gamma c(x, a)$ we have a sufficient condition for (A3) in the form

(D1) $\hat{E}_x^{(a_n)}\{\exp\{\gamma\|c\|_{sp}\tau_{C_1}\}\} < \infty$ for $x \in \hat{E}$,

where $\|c\|_{sp} := \sup_{x\in E, a\in U} c(x,a) - \inf_{x\in E, a\in U} c(x,a)$. In section 6 we shall formulate a sufficient condition for (D1) in terms of the expected value of the functional with respect to the original Markov process (x_n).

For Borel measurable $u : E \mapsto U$ let

$$e^{\hat{w}^u(x)} = \hat{E}_x^u\left\{\exp\left\{\sum_{i=0}^{\tau_{C_1}}\left(\gamma c(x_i^1, u(x_i^1)) - \lambda^\gamma(u)\right)\right\}\right\}, \tag{9}$$

where by $\lambda^\gamma(u)$ we denote the value of $\lambda^\gamma((u(x_n^1))$ and the expected value $\hat{E}_x^u$ stands for $\hat{E}_x^{(u(x_n^1))}$.

By (A3) clearly $\lambda^\gamma(u) \geq d$ and therefore $\hat{w}^u$ is well defined. For a Borel measurable function $\tilde{w} : \hat{E} \mapsto R$ define the operator $\Phi(\tilde{w})$ by the formula

$$e^{\Phi(\tilde{w})} = (1-\beta)\int_C e^{\tilde{w}(x,0)}\nu(dx) + \beta\int_C e^{\tilde{w}(x,1)}\nu(dx) \tag{10}$$

whenever it is well defined. Notice that

$$e^{\Phi(\tilde{w})} = \hat{E}_x\{\exp\{\tilde{w}(\hat{x}_1)\}\} \tag{11}$$

for $x \in C_1$. We have the following analogue of Theorem 5.1 of [22] and Proposition 2.8 of [18].

LEMMA 4. *Function $\hat{w}^u$ defined in* (9) *is a solution to the multiplicative Poisson equation (MPE) for the split Markov process $(\hat{x}_n)$:*

$$e^{\hat{w}^u(x)} = e^{\gamma c(x^1, u(x^1)) - \lambda^\gamma(u)}\int_{\hat{E}} e^{\hat{w}^u(y)}\hat{P}^{u(x^1)}(x, dy). \tag{12}$$

Moreover $\Phi(\hat{w}^u) = 0$, and for any other solution $\tilde{w}^u$ to (12) *we have*

$$\tilde{w}^u(x) - \Phi(\tilde{w}^u) \geq \hat{w}^u(x) \tag{13}$$

with equality for Ψ^u almost all $x \in \hat{E}$. Furthermore, if $\tilde{w}$ and λ satisfy the equation

$$e^{\tilde{w}(x)} = e^{\gamma c(x^1, u(x^1)) - \lambda}\int_{\hat{E}} e^{\tilde{w}(y)}\hat{P}^{u(x^1)}(x, dy), \tag{14}$$

then $\lambda \geq \lambda^\gamma(u)$.

Proof. In fact, using (6) we have

$$\hat{E}_x^u\{\exp\{w(\hat{x}_1)\}\} = \hat{E}_x^u\left\{\chi_{\hat{x}_1\in C_1}\hat{E}_{x_1}^u\left\{\exp\left\{\sum_{i=0}^{\tau_{C_1}}\gamma c(x_i^1, u(x_i^1)) - \lambda^\gamma(u)\right\}\right\}\right\}$$

$$+\ \hat{E}_x^u\left\{\chi_{\hat{x}_1\notin C_1}\hat{E}_{x_1}^u\left\{\exp\left\{\sum_{i=0}^{\tau_{C_1}}\gamma c(x_i^1, u(x_i^1)) - \lambda^\gamma(u)\right\}\right\}\right\} = \hat{E}_x^u\{\chi_{\hat{x}_1\in C_1},$$

$$\exp\left\{\gamma c(x_1^1, u(x_1^1)) - \lambda^\gamma(u)\right\}\} + \hat{E}_x^u\left\{\chi_{\hat{x}_1\notin C_1}\exp\left\{\sum_{i=1}^{\tau_{C_1}}\gamma c(x_i^1, u(x_i^1)) - \lambda^\gamma(u)\right\}\right\}$$

$$= \hat{E}_x^u\left\{\exp\left\{\sum_{i=0}^{\tau_{C_1}}\gamma c(x_i^1, u(x_i^1)) - \lambda^\gamma(u)\right\}\right\}\exp\left\{-(\gamma c(x^1, u(x^1)) - \lambda^\gamma(u))\right\},$$

from which (12) follows. Furthermore we clearly see that $\Phi(\hat{w}) = 0$. If $\tilde{w}^u$ is a solution to (12), then by (11) $\Phi(\tilde{w}^u)$ is well defined and by iteration, for a positive integer $m = 1, 2, \ldots,$

$$e^{\tilde{w}^u(x)} = \hat{E}^u_x \left\{ \exp\left\{ \sum_{i=0}^{\tau_{C_1}\wedge m} \left(\gamma c(x^1_i, u(x^1_i)) - \lambda^\gamma(u)\right)\right\} \hat{E}^u_{\hat{x}_{\tau_{C_1}\wedge m}} \left\{\exp\left\{\tilde{w}^u(\hat{x}(1))\right\}\right\}\right\}.$$

By Fatou's lemma

$$e^{\tilde{w}^u(x)} \geq \hat{E}^u_x \left\{ \exp\left\{ \sum_{i=0}^{\tau_{C_1}} \left(\gamma c(x^1_i, u(x^1_i)) - \lambda^\gamma(u)\right)\right\} \hat{E}^u_{\hat{x}_{\tau_{C_1}}} \left\{\exp\left\{\tilde{w}^u(\hat{x}(1))\right\}\right\}\right\}$$

$$= \hat{E}^u_x \left\{ \exp\left\{ \sum_{i=0}^{\tau_{C_1}} \left(\gamma c(x^1_i, u(x^1_i)) - \lambda^\gamma(u)\right)\right\}\right\} e^{\Phi(\tilde{w}^u)},$$

from which we immediately obtain (13). For $\varepsilon > 0$ let

$$Z_\varepsilon = \left\{ x \in \hat{E} : \tilde{w}^u(x) - \Phi(\tilde{w}^u) \geq \hat{w}^u(x) + \varepsilon \right\}.$$

If $\Psi^u(Z_\varepsilon) > 0$, then there is a positive integer n such that $\hat{P}^u_z\left\{\hat{x}_{\tau_{C_1}\wedge n}\right\} > 0$ for $z \in C_1$. Consequently

$$e^{\tilde{w}^u(z) - \Phi(\tilde{w}^u)} = \hat{E}^u_z \left\{ \exp\left\{ \sum_{i=0}^{\tau_{C_1}\wedge n-1} \left(\gamma c(x^1_i, u(x^1_i)) - \lambda^\gamma(u)\right)\right\} \exp\left\{\tilde{w}^u(\hat{x}_{\tau_{C_1}\wedge n})\right\}\right\}$$

$$> \hat{E}^u_z \left\{ \exp\left\{ \sum_{i=0}^{\tau_{C_1}\wedge n-1} \left(\gamma c(x^1_i, u(x^1_i)) - \lambda^\gamma(u)\right)\right\} \exp\left\{\hat{w}^u(\hat{x}_{\tau_{C_1}\wedge n})\right\}\right\} = e^{\hat{w}^u(z)}.$$

Since by (11) we have that $e^{\tilde{w}^u(z) - \Phi(\tilde{w}^u)} = e^{\hat{w}^u(z)} = e^{\gamma c(z^1, u(z^1)) - \lambda^\gamma(u)}$ we obtained a contradiction. Consequently $\Psi^u(Z_\varepsilon) = 0$ for each $\varepsilon > 0$.

Assume now that $\tilde{w}$ and λ satisfy (14). Let $\tau_1 = \tau_{C_1}$, $\tau_{n+1} = \tau_n + \theta_{\tau_n} \circ \tau_{C_1}$ for $n = 1, 2, \ldots$. Then for a positive integer m

$$e^{\tilde{w}(x)} = \hat{E}^u_x \left\{ \exp\left\{ \sum_{i=0}^{\tau_n\wedge m} \left(\gamma c(x^1_i, u(x^1_i)) - \lambda\right)\right\} \hat{E}^u_{\hat{x}_{\tau_n\wedge m}} \left\{\exp\left\{\tilde{w}(\hat{x}(1))\right\}\right\}\right\},$$

and letting $m \to \infty$, by Fatou's lemma

$$e^{\tilde{w}(x)} \geq \hat{E}^u_x \left\{ \exp\left\{ \sum_{i=0}^{\tau_n} \left(\gamma c(x^1_i, u(x^1_i)) - \lambda\right)\right\} \hat{E}^u_{\hat{x}_{\tau_n}} \left\{\exp\left\{\tilde{w}(\hat{x}(1))\right\}\right\}\right\}$$

$$= \hat{E}^u_x \left\{ \exp\left\{ \sum_{i=0}^{\tau_{C_1}} \left(\gamma c(x^1_i, u(x^1_i)) - \lambda\right)\right\}\right\} D^{n-1}(\lambda) e^{\Phi(\tilde{w})},$$

with function D defined in the proof of Lemma 3. Since the right-hand side of the above inequality remains bounded as $n \to \infty$ we should have $D(\lambda) \leq 1$, and this means that $\lambda \geq \lambda^\gamma(u)$. □

There is a $1:1$ correspondence between the solutions to the MPE for the split Markov process and the solution to the MPE corresponding to the original Markov process.

COROLLARY 2. *Given a solution $\tilde{w}^u : \hat{E} \mapsto R$ and λ to the MPE* (14) *we have that w^u defined for $x \in E$ by*

$$e^{w^u(x)} := e^{\tilde{w}^u(x,0)} + 1_C(x)\beta(e^{\tilde{w}^u(x,1)} - e^{\tilde{w}^u(x,0)}) \tag{15}$$

is a solution to the MPE for the original Markov process (x_n)

$$e^{w^u(x)} = e^{\gamma c(x,u(x))-\lambda} \int_E e^{w^u(y)} P^{u(x)}(x, dy). \tag{16}$$

Furthermore if w^u is a solution to (16)*, then $\tilde{w}^u$ defined by*

$$e^{\tilde{w}^u(x^1,x^2)} = e^{\gamma c(x^1,u(x^1))-\lambda} \hat{E}_{x^1,x^2}\left\{e^{w^u(x_1^1)}\right\} \tag{17}$$

is a solution to (14).

Proof. By Lemma 1 we have

$$\begin{aligned}\hat{E}_x^u\left\{e^{\tilde{w}^u(\hat{x}_1)}\right\} &= \hat{E}_x^u\left\{\hat{E}_x^u\left\{e^{\tilde{w}^u(\hat{x}_1)}|x_1^1\right\}\right\}\\ &= \hat{E}_x^u\left\{\chi_C(x_1^1)((1-\beta)e^{\tilde{w}^u(x_1^1,0)} + \beta e^{\tilde{w}^u(x_1^1,1)})\right.\\ &\left. + \chi_{E\setminus C}(x_1^1)e^{\tilde{w}^u(x_1^1,0)}\right\} = \hat{E}_x^u\left\{e^{w^u(x_1^1)}\right\}. \end{aligned} \tag{18}$$

Therefore by (14) taking into account (5) we obtain that w^u defined in (15) is a solution to (16). Assume now that w^u is a solution to (16). Then by (5)

$$\hat{E}_{\delta_x^*}^u\left\{e^{w^u(x_1^1)}\right\} = E_x^u\left\{e^{w^u(x_1^1)}\right\},$$

and for $\tilde{w}^u$ given in (17) we obtain (15). From (15) we obtain (18), which in turn by (17) shows that $\tilde{w}^u$ is a solution to (14). □

Furthermore we have the following.

COROLLARY 3. *If $\lambda(u)$ and w^u is a solution to the MPE*

$$e^{w^u(x)} = e^{\gamma c(x,u(x))-\lambda(u)} \int_E e^{w^u(y)} P^{u(x)}(x, dy),$$

w^u is a bounded Borel measurable function, and the family

$$\left\{\exp\left\{\sum_{i=1}^{\tau_{C_1}\wedge N}\left(\gamma c(x_i^1, u(x_i^1)) - \lambda(u)\right)\right\}; N = 1, 2, \ldots\right\}$$

is uniformly integrable with respect to $\hat{P}_z^u$ with $z \in C_1$, then $\lambda(u) = \lambda^\gamma(u)$.

Proof. By Corollary 2 the function $\tilde{w}^u$ defined in (17) and $\lambda(u)$ is a solution to the MPE (14). Clearly $\tilde{w}$ is also a bounded function. Moreover,

$$e^{\tilde{w}^u(x)} = \hat{E}_x^u\left\{\exp\left\{\sum_{i=0}^{\tau_{C_1}\wedge N}\left(\gamma c(x_i^1, u(x_i^1)) - \lambda(u)\right)\right\}\hat{E}_{\hat{x}_{\tau_{C_1}\wedge N}}^u\left\{\exp\left\{\tilde{w}^u(\hat{x}(1))\right\}\right\}\right\}.$$

By the dominated convergence theorem, letting $N \to \infty$ and using uniform integrability of $\{\exp\{\sum_{i=1}^{\tau_{C_1}\wedge N}(\gamma c(x_i^1, u(x_i^1)) - \lambda(u))\}; N = 1, 2, \ldots\}$ and the fact that $\tilde{w}$ is bounded we obtain

$$e^{\tilde{w}^u(z)} = \hat{E}_z^u \left\{ \exp\left\{ \sum_{i=0}^{\tau_{C_1}} \left(\gamma c(x_i^1, u(x_i^1)) - \lambda(u)\right) \right\} \right\} e^{\Phi(\tilde{w}^u)}$$

for $z \in C_1$. Consequently, since by the MPE we have that $\tilde{w}^u(z) - \Phi(\tilde{w}^u) = c(z^1, u(z^1)) - \lambda(u)$, for $z = (z^1, 1) \in C_1$ we obtain

$$\hat{E}_z^u \left\{ \exp\left\{ \sum_{i=1}^{\tau_{C_1}} \left(\gamma c(x_i^1, u(x_i^1)) - \lambda(u)\right) \right\} \right\} = 1,$$

from which, by Lemma 3, we immediately have that $\lambda(u) = \lambda^\gamma(u)$. □

Remark 2. Notice that $\lambda^\gamma(u)$ is the minimal solution to the MPE (14). However, solutions may be well defined $\forall\, \lambda \geq \lambda^\gamma(u)$, as shown in the example below.

Example. Consider the following model: $E = \{0, 1, 2, \ldots\}$, $\gamma = 1$, there is no control, $c(x) \equiv c$ for $x \in E$, and the transition probabilities are $P(0, 1) = 1 - \alpha_0$, $P(0, 0) = \alpha_0$, $P(x, 0) = \alpha$, $P(x, x + 1) = 1 - \alpha$ for $x = 1, 2, \ldots$, with $0 < \alpha_0, \alpha < 1$. The MPE Bellman equation is of the form

$$e^{w(x)} = e^{c-\lambda} E_x \left\{ e^{w(x_1)} \right\}. \tag{19}$$

Clearly the pair $\lambda = c$ and $w \equiv 0$ is a solution to (19). We shall identify other solutions. Taking into account the form of transition probabilities, from (19) we obtain

$$e^{w(0)} = e^{c-\lambda} \left(\alpha_0 e^{w(0)} + (1 - \alpha_0) e^{w(1)} \right),$$

and for $n = 1, 2, \ldots$

$$e^{w(n)} = e^{c-\lambda} \left(\alpha e^{w(0)} + (1 - \alpha) e^{w(n+1)} \right).$$

The first equation has a solution whenever

$$\lambda > c + \ln \alpha_0. \tag{20}$$

Iterating the second equation we obtain that

$$e^{w(n)} = \frac{1}{1 - \alpha} \left(e^{\lambda - c + \kappa} q^{n-2} - \alpha(q^{n-2} + \cdots + 1) \right) e^{w(0)}, \tag{21}$$

with $\kappa = \ln(\frac{e^{\lambda-c} - \alpha_0}{1-\alpha_0})$ and $q = \frac{e^{\lambda-c}}{1-\alpha}$. Whenever $q \leq 1$ the right-hand side of (21) is negative for a sufficiently large n, so that there are no solutions. Whenever $q > 1$ we have

$$e^{w(n)} = \frac{w^{w(0)}}{(1 - \alpha)(q - 1)} \left((e^{\lambda - c + \kappa}(q - 1) - \alpha q) q^{n-2} + \alpha \right), \tag{22}$$

and the above equation has a solution only when $e^{\lambda-c+\kappa}(q-1) - \alpha q \geq 0$. Taking into account the form of κ, this leads to the quadratic inequality

$$e^{2(\lambda-c)} - (\alpha_0 + 1 - \alpha) e^{\lambda - c} + \alpha_0 - \alpha \geq 0,$$

from which we in turn obtain that $e^{\lambda-c} \leq \alpha_0 - \alpha$ or $e^{\lambda-c} \geq 1$. In view of (20) the first inequality is not satisfied. From the second inequality we obtain $\lambda \geq c$, and then we clearly see that (20) also holds. Finally, $\forall\, \lambda \geq c$ we have solutions to (14) which are unbounded whenever $\lambda > c$.

The value $\lambda^\gamma(u)$ defined in Lemma 3 has (under some additional assumptions) the following important interpretation.

PROPOSITION 1. *If for Borel measurable $u : E \mapsto U$*

(B1) *the family*

$$\left\{ \exp\left\{ \sum_{i=1}^{\tau_{C_1}\wedge N} \left(\gamma c(x_i^1, u(x_i^1)) - \lambda^\gamma(u)\right) \right\}; N = 1, 2, \dots \right\} \tag{23}$$

is uniformly integrable with respect to $\hat{P}_z^u$ measure with $z \in C_1$,

(B2) *for $x \in \hat{E}$*

$$\inf_N \hat{E}_x^u \left\{ \exp\left\{ \sum_{i=1}^{\sigma_{C_1}\wedge N-1} \left(\gamma c(x_i^1, u(x_i^1)) - \lambda^\gamma(u)\right) \right\} \right\} > 0 \tag{24}$$

with $\sigma_{C_1} = \inf\{i \geq 0 : \hat{x}(i) \in C_1\}$, and

(B3) *for $x \in \hat{E}$*

$$\sup_N \hat{E}_x^u \left\{ \exp\left\{ \sum_{i=1}^{\sigma_{C_1}\wedge N-1} \left(\gamma c(x_i^1, u(x_i^1)) - \lambda^\gamma(u)\right) \right\} \right\} < \infty, \tag{25}$$

then for $x \in E$

$$\lambda^\gamma(u) = \lim_{n\to\infty} \frac{1}{n} \ln E_x^u \left\{ \exp\left\{ \sum_{i=0}^{n-1} \gamma c(x_i, u(x_i)) \right\} \right\}. \tag{26}$$

Proof. Let $\lambda > \lambda^\gamma(u)$. For $z \in C_1$ we have

$$\hat{E}_z^u \left\{ \exp\left\{ \sum_{i=1}^{\tau_{C_1}} \left(\gamma c(x_i^1, u(x_i^1)) - \lambda\right) \right\} \right\} < 1$$

and consequently by the dominated convergence theorem and (23) for $N \geq N_0$, with N_0 sufficiently large,

$$\hat{E}_z^u \left\{ \exp\left\{ \sum_{i=1}^{\tau_{C_1}\wedge N} \left(\gamma c(x_i^1, u(x_i^1)) - \lambda\right) \right\} \right\} \leq 1. \tag{27}$$

Let

$$e^{w_N^u(x)} = \hat{E}_x^u \left\{ \exp\left\{ \sum_{i=0}^{\sigma_{C_1}\wedge N-1} \left(\gamma c(x_i^1, u(x_i^1)) - \lambda\right) \right\} \right\}. \tag{28}$$

By (B3) w_N^u is well defined. For $x \notin C_1$

$$e^{w^u_{N+1}(x)} = \hat{E}^u_x \left\{ e^{\gamma c(x_0^1, u(x_0^1)) - \lambda} \hat{E}^u_{\hat{x}_1} \left\{ \exp\left\{ \sum_{i=0}^{\sigma_{C_1} \wedge N-1} \big(\gamma c(x_i^1, u(x_i^1)) - \lambda\big) \right\} \right\} \right\}$$

$$= \hat{E}^u_x \left\{ e^{\gamma c(x_0^1, u(x_0^1)) - \lambda} e^{w^u_N(\hat{x}_1)} \right\}, \tag{29}$$

and for $x \in C_1$ by (27) we have

$$e^{w^u_{N+1}(x)} = e^{\gamma c(x_0^1, u(x_0^1)) - \lambda}$$

$$\geq e^{\gamma c(x_0^1, u(x_0^1)) - \lambda} \hat{E}^u_x \left\{ \exp\left\{ \sum_{i=1}^{\sigma_{C_1} \wedge N} \big(\gamma c(x_i^1, u(x_i^1)) - \lambda\big) \right\} \right\}$$

$$= \hat{E}^u_x \left\{ e^{\gamma c(x_0^1, u(x_0^1)) - \lambda} e^{w^u_N(\hat{x}_1)} \right\}. \tag{30}$$

Consequently

$$e^{w^u_{N+1}(x)} \geq \hat{E}^u_x \left\{ e^{\gamma c(x_0^1, u(x_0^1)) - \lambda} e^{w^u_N(\hat{x}_1)} \right\},$$

and by iteration for $N \geq N_0$

$$e^{w^u_{N+k}(x)} \geq \hat{E}^u_x \left\{ e^{\sum_{i=0}^{k-1} (\gamma c(x_i^1, u(x_i^1)) - \lambda)} e^{w^u_N(\hat{x}_k)} \right\}$$

$$\geq \hat{E}^u_x \left\{ e^{\sum_{i=0}^{k-1} (\gamma c(x_i^1, u(x_i^1)) - \lambda)} e^{-\gamma \|c\| N} \right\}.$$

Therefore

$$\frac{1}{k} \ln \hat{E}^u_x \left\{ e^{\gamma \sum_{i=0}^{k-1} c(x_i^1, u(x_i^1))} \right\} \leq \frac{1}{k} \gamma \|c\| N$$

$$+ \frac{1}{k} \sup_N \ln \hat{E}^u_x \left\{ \exp\left\{ \sum_{i=0}^{\sigma_{C_1} \wedge N-1} \big(\gamma c(x_i^1, u(x_i^1)) - \lambda^\gamma(u)\big) \right\} \right\} + \lambda,$$

and by (B3)

$$\limsup_{k \to \infty} \frac{1}{k} \ln \hat{E}^u_x \left\{ e^{\gamma \sum_{i=0}^{k-1} c(x_i^1, u(x_i^1))} \right\} \leq \lambda.$$

Consequently, letting λ decrease to $\lambda^\gamma(u)$, we obtain

$$\limsup_{k \to \infty} \frac{1}{k} \ln \hat{E}^u_x \left\{ e^{\gamma \sum_{i=0}^{k-1} c(x_i^1, u(x_i^1))} \right\} \leq \lambda^\gamma(u). \tag{31}$$

Assume now that $\lambda < \lambda^\gamma(u)$. By Fatou's lemma for $z \in C_1$ and $N \geq N_0$, with N_0 sufficiently large, we have

$$\hat{E}^u_z \left\{ \exp\left\{ \sum_{i=1}^{\tau_{C_1} \wedge N} \big(\gamma c(x_i^1, u(x_i^1)) - \lambda\big) \right\} \right\} \geq 1. \tag{32}$$

Therefore for w_N^u given by (28) (with λ as above) similarly as in (29) and (30) we have

$$e^{w_{N+1}^u(x)} \le \hat{E}_x^u \left\{ e^{\gamma c(x_0^1, u(x_0^1)) - \lambda} e^{w_N^u(\hat{x}_1)} \right\}, \tag{33}$$

and by iteration for $N \ge N_0$

$$\begin{aligned} e^{w_{N+k}^u(x)} &\le \hat{E}_x^u \left\{ e^{\sum_{i=0}^{k-1} (\gamma c(x_i^1, u(x_i^1)) - \lambda)} e^{w_N^u(\hat{x}_k)} \right\} \\ &\le \hat{E}_x^u \left\{ e^{\sum_{i=0}^{k-1} (\gamma c(x_i^1, u(x_i^1)) - \lambda)} e^{\gamma \|c\| N} \right\}. \end{aligned}$$

Therefore

$$\begin{aligned} &\frac{1}{k} \ln \hat{E}_x^u \left\{ e^{\gamma \sum_{i=0}^{k-1} c(x_i^1, u(x_i^1))} \right\} \ge -\frac{1}{k} \gamma \|c\| N \\ &+ \frac{1}{k} \inf_N \ln \hat{E}_x^u \left\{ \exp \left\{ \sum_{i=0}^{\sigma_{C_1} \wedge N - 1} \left(\gamma c(x_i^1, u(x_i^1)) - \lambda^\gamma(u) \right) \right\} \right\} + \lambda, \end{aligned}$$

and by (B2)

$$\liminf_{k \to \infty} \frac{1}{k} \ln \hat{E}_x^u \left\{ e^{\gamma \sum_{i=0}^{k-1} c(x_i^1, u(x_i^1))} \right\} \ge \lambda,$$

and finally

$$\liminf_{k \to \infty} \frac{1}{k} \ln \hat{E}_x^u \left\{ e^{\gamma \sum_{i=0}^{k-1} c(x_i^1, u(x_i^1))} \right\} \ge \lambda^\gamma(u), \tag{34}$$

which together with (31) using (5) completes the proof. □

Remark 3. Notice that under (D1) assumptions (B1) and (B3) are satisfied. By the Hölder inequality, using the fact that $\lambda^\gamma(u) \le \sup_{x \in E, a \in U} \gamma c(x, a)$ we have that

$$\begin{aligned} 1 \le &\left(\hat{E}_x^u \left\{ \exp \left\{ \sum_{i=1}^{\sigma_{C_1} \wedge N - 1} \left(-\gamma c(x_i^1, u(x_i^1)) + \lambda^\gamma(u) \right) \right\} \right\} \right)^{\frac{1}{2}} \\ &\times \left(\hat{E}_x^u \left\{ \exp \left\{ \sum_{i=1}^{\sigma_{C_1} \wedge N - 1} \left(\gamma c(x_i^1, u(x_i^1)) - \lambda^\gamma(u) \right) \right\} \right\} \right)^{\frac{1}{2}} \le \left(\hat{E}_x^u \left\{ e^{\gamma \|c\|_{sp} \tau_{C_1}} \right\} \right)^{\frac{1}{2}} \\ &\times \left(\hat{E}_x^u \left\{ \exp \left\{ \sum_{i=1}^{\sigma_{C_1} \wedge N - 1} \left(\gamma c(x_i^1, u(x_i^1)) - \lambda^\gamma(u) \right) \right\} \right\} \right)^{\frac{1}{2}}, \end{aligned}$$

from which, under (D1), inequality (24) holds, and in conclusion (26) holds.

Furthermore notice that

$$M_N := e^{-\hat{w}^u(z)} \exp \left\{ \sum_{i=0}^{\tau_{C_1} \wedge N} \left(\gamma c(x_i^1, u(x_i^1)) - \lambda^\gamma(u) \right) \right\} e^{\hat{w}^u(x_{\tau_{C_1} \wedge N + 1})}$$

is a positive martingale that converges almost surely to M_∞ as $N \to \infty$. Since by the choice of $\lambda^\gamma(u)$ we have that $\hat{E}_z^u M_N = 1 = \hat{E}_z^u M_\infty$, from Theorem II 21 of [19] it follows that the family $\{M_N, N = 1, 2, \ldots\}$ is uniformly integrable. When $\hat{w}^u$ is bounded we then immediately obtain (B1).

Finally, by the Jensen inequality we can easily formulate a sufficient condition for (B2) as follows: for $x \in \hat{E}$

$$\inf_N \hat{E}_x^u \left\{ \sum_{i=1}^{\sigma_{C_1} \wedge N-1} \left(\gamma c(x_i^1, u(x_i^1)) - \lambda^\gamma(u) \right) \right\} > -\infty.$$

4. Uniformly ergodic approximation of controlled Markov processes. We shall now assume that

(A4) for $x \in E$, $A \in \mathcal{E}$

$$P^a(x, A) = \int_A p(x, a, y)\nu(dy), \tag{35}$$

where p is a positive continuous function of its coordinates.

Denote by $|x|$ the value of $\rho(x, \theta)$, where ρ is a metric on E compatible with the topology of E and $\theta \in E$ is a fixed point.

Let

$$\tilde{p}_N(x, a, y) = \begin{cases} \frac{p(x,a,y)}{\Delta_N^a(x)} & \text{for} \quad |y| \le N, \\ \frac{p(\theta,\bar{a},y)}{\Delta_N^a(x)} & \text{for} \quad |y| \ge N+1, \\ \frac{p(x,a,y)(N+1-|y|)+p(\theta,\bar{a},y)(|y|-N)}{\Delta_N^a(x)} & \text{elsewhere,} \end{cases}$$

with $\Delta_N^a(x) = P^a(x, B_N) + P^{\bar{a}}(\theta, B_{N+1}^c) + \int_{B_{N+1}\setminus B_N} [p(x, a, y)(N+1-|y|) + p(\theta, \bar{a}, y)(|y| - N)]\nu(dy)$, where $B_N = \{x \in E : |x| \le N\}$ and $\bar{a}$ is a fixed element of U.

Let

$$p_N(x, a, y) = \tilde{p}_N(x, a, y) \text{ if } |x| \le N,$$
$$p_N(x, a, y) = \tilde{p}_N\left(\frac{x}{|x|}N, a, y\right) \text{ for } |x| > N$$

and define

$$P_N^a(x, dy) = p_N(x, a, y)\nu(dy). \tag{36}$$

We clearly have the following.

LEMMA 5.

$$\sup_{a \in U} \|P_N^a(x, \cdot) - P^a(x, \cdot)\|_{var} \to 0 \tag{37}$$

as $N \to \infty$, uniformly in x from compact sets. Furthermore for each N

$$\sup_{a,a' \in U} \sup_{x,x' \in E} \sup_{y \in E} \frac{p_N(x, a, y)}{p_N(x', a', y)} < \infty. \tag{38}$$

For $(a_n) \in \mathcal{U}_s$ let

$$F_{Nx}^{(a_n)}(\lambda) = \hat{E}_x^{(a_n),N} \left\{ \exp\left\{ \sum_{i=1}^{\tau_{C_1}} (\gamma c(x_i^1, a_i) - \lambda) \right\} \right\} \tag{39}$$

and

$$F_x^{(a_n)}(\lambda) = \hat{E}_x^{(a_n)}\left\{\exp\left\{\sum_{i=1}^{\tau_{C_1}}(\gamma c(x_i^1, a_i) - \lambda)\right\}\right\}, \tag{40}$$

where $\hat{P}_x^{(a_n),N}$ is the conditional probability of the split Markov process $(\hat{x}_n)$ corresponding to Markov process (x_n) with transition probability $P_N^{a_n}$ at time n.

Notice that whenever $x \in C_1$ the functions in (39) and (40) do not depend on x and will be denoted by $F_N^{(a_n)}$ and $F^{(a_n)}$. We have the following.

PROPOSITION 2. *Assume that there exist N_0 and $d_1 < d_2$ such that for $N \geq N_0$, $(a_n) \in \mathcal{U}_s$, and $x \in C_1$ we have*

$$F_N^{(a_n)}(d_2) = F_{Nx}^{(a_n)}(d_2) \leq 1 \leq F_{Nx}^{(a_n)}(d_1) < \infty, \tag{41}$$

$F_{Nx}^{(a_n)}(\lambda) \to F_x^{(a_n)}(\lambda)$ for $x \in C_1$ uniformly in $(a_n) \in \mathcal{U}_s$ and $\lambda \in [d_1, d_2]$, and furthermore

$$\sup_{(a_n)} |F^{(a_n)\prime}(d_1)| < \infty, \tag{42}$$

where $'$ stands for the derivative with respect to λ. Then

$$\lambda_N^\gamma((a_n)) := \left(F_N^{(a_n)}\right)^{-1}(1) \to \left(F^{(a_n)}\right)^{-1}(1) = \lambda^\gamma((a_n)) \tag{43}$$

uniformly in $(a_n) \in \mathcal{U}_s$ as $N \to \infty$.

Proof. Assume that there exist $\varepsilon > 0$, a sequence (a_n^k) of strategies from $\mathcal{U}_s$, and a sequence $N_k \to \infty$ such that

$$|\lambda_{N_k}^\gamma((a_n^k)) - \lambda^\gamma((a_n^k))| > \varepsilon. \tag{44}$$

By assumption we have that

$$|F_{N_k x}^{(a_n^k)}(\lambda_{N_k}((a_n^k))) - F_x^{(a_n^k)}(\lambda_{N_k}((a_n^k)))| \to 0$$

and therefore

$$F_x^{(a_n^k)}(\lambda_{N_k}^\gamma((a_n^k))) \to 1 = F_{N_k x}^{(a_n^k)}(\lambda_{N_k}^\gamma((a_n^k))) \tag{45}$$

as $k \to \infty$. Since $F_x^{(a_n^k)}(\lambda^\gamma((a_n^k))) = 1$ and $\sup_{(a_n^k)} |F^{(a_n^k)\prime}(\lambda)|$ is bounded for $\lambda \in [d_1, d_2]$ (by (42)), we should have $|\lambda_{N_k}^\gamma((a_n^k)) - \lambda^\gamma((a_n^k))| \to 0$ as $k \to \infty$, which contradicts (44). □

Remark 4. Notice that the choice of d_1 and d_2 in (41) is uniform with respect to $(a_n) \in \mathcal{U}_s$. Two natural candidates are $d_1 = \inf_{x \in E, a \in U} \gamma c(x, a)$ and $d_2 = \sup_{x \in E, a \in U} \gamma c(x, a)$.

To have convergence $F_{Nx}^{(a_n)}(\lambda) \to F_x^{(a_n)}(\lambda)$ for $x \in C_1$ uniform in $(a_n) \in \mathcal{U}_s$ and $\lambda \in [d_1, d_2]$ we have to assume for $x \in C_1$ that

$$\sup_{(a_n) \in \mathcal{U}_s} \hat{E}_x^{(a_n)}\left\{\exp\left\{\gamma \|c\|_{sp} \tau_{C_1}\right\}\right\} < \infty,$$

and

(D2) $\sup_N \sup_{(a_n)\in\mathcal{U}_s} \hat{E}_x^{(a_n),N}\{\exp\{\gamma\|c\|_{sp}\tau_{C_1}\}\} < \infty$.

Since

$$|F_x^{(a_n)\prime}(\lambda)| = \hat{E}_x^{(a_n)}\left\{\tau_{C_1}\exp\left\{\sum_{i=1}^{\tau_{C_1}}(\gamma c(x_i^1,h_i)-\lambda)\right\}\right\}$$

$$\leq \hat{E}_x^{(a_n)}\{\tau_{C_1}\exp\{\gamma\|c\|_{sp}\tau_{C_1}\}\}$$

$$\leq K\hat{E}_x^{(a_n)}\{\exp\{(1+\varepsilon)\gamma\|c\|_{sp}\tau_{C_1}\}\}$$

for $\varepsilon > 0$ and $K > 0$, to have (42) it is sufficient to assume for $x \in C_1$ that

(D3) $\sup_{(a_n)\in\mathcal{U}_s} \hat{E}_x^{(a_n)}\{\exp\{(1+\varepsilon)\gamma\|c\|_{sp}\tau_{C_1}\}\} < \infty$ for a sufficiently small $\varepsilon > 0$.

We have the following.

PROPOSITION 3. *For each N there are λ_N^γ and $w_N \in C(E)$ such that*

$$e^{w_N(x)} = \inf_{a\in U}\left[e^{\gamma c(x,a)-\lambda_N^\gamma}\int_E e^{w_N(y)}P_N^a(x,dy)\right], \tag{46}$$

and consequently

$$\lambda_N^\gamma = \inf_{a_n} J_x^{\gamma,N}((a_n)), \tag{47}$$

where

$$J_x^{\gamma,N}((a_n)) := \limsup_{t\to\infty}\frac{1}{t}\ln E_x^{(a_n),N}\left\{\exp\left\{\sum_{i=0}^{t-1}\gamma c(x_i,a_i)\right\}\right\}$$

and the infimum is taken over all admissible controls (a_n).

Moreover the strategy $\hat{a}_n^N = u_N(x_n)$, where $u_N : E \mapsto U$ is a Borel measurable function for which the infimum in equation (46) *is attained, is optimal and if $\hat{E}_x^{(\hat{a}_n^N),N}\{\exp\{\gamma\|c\|_{sp}\tau_{C_1}\}\} < \infty$, we have additionally that $\lambda_N^\gamma = \lambda_N^\gamma(u_N)$ with $\lambda_N^\gamma(u_N)$ defined in Lemma* 3 *for a Markov process with transition operator $P_N^{u_N}$.*

Proof. In view of (38) and Theorem 1 of [12] it remains only to show that $\lambda_N^\gamma = \lambda_N^\gamma(u_N)$, which in turn follows directly from Corollary 3. □

COROLLARY 4. *Under* (D2) *and* (D3) *we have that*

$$\lambda^\gamma := \inf_{(a_n)\in\mathcal{U}_s} J_x^\gamma((a_n)) = \lim_{N\to\infty}\lambda_N^\gamma \tag{48}$$

for $x \in E$.

Proof. By Remark 4 and Proposition 2

$$\sup_{(a_n)\in\mathcal{U}_s}|\lambda_N^\gamma((a_n)) - \lambda^\gamma((a_n))| \to 0.$$

Since by Remark 3 and Propositions 1 and 2 $\lambda_N^\gamma((a_n)) = \inf_{(a_n)\in\mathcal{U}_s}\lambda_N^\gamma((a_n)) = \lambda_N^\gamma$, we obtain (48). □

5. Risk sensitive Bellman equation. Let u_N be an optimal control function corresponding to $P_N^a(x,dy)$. Furthermore assume that

(A5) $\exists_{\epsilon>0}$ such that $\forall_{K\ compact\subset \hat{E}}$

$$\sup_{a\in U}\sup_{x\in K}\sup_{N}\hat{E}_x^{a,N}\left\{\exp\left\{\sum_{i=1}^{\tau_{C_1}}(\gamma c(x_i^1,u_N(x_i^1))-\lambda_N^\gamma(u_N))(1+\epsilon)\right\}\right\}$$

$$= M(K)<\infty, \tag{49}$$

where above we control the split Markov process $(\hat{x}_n)$ using at time 0 control $a_0=a$ and then $a_n=u_N(x_n^1)$ for $n\geq 1$, with u_N as in Proposition 3.

THEOREM 1. *Under* (A1)–(A5) *there exist* λ^γ *and a continuous function* $w: E\mapsto R$ *such that*

$$e^{w(x)}=\inf_{a\in U}\left[e^{\gamma c(x,a)-\lambda^\gamma}\int_E e^{w(y)}P^a(x,dy)\right]. \tag{50}$$

Moreover, under (D2)–(D3) *we have that*

$$\lambda^\gamma=\inf_{(a_n)\in\mathcal{U}_s}J_x^\gamma((a_n))=\lim_{N\to\infty}\lambda_N^\gamma(u_N). \tag{51}$$

Assuming additionally that (*D*1) *is satisfied for* $\hat{a}_n=\hat{u}(x_n)$, *where* $\hat{u}$ *is a Borel measurable function for which the infimum on the right-hand side of* (50) *is attained, we have that* $\lambda^\gamma=\lambda^\gamma(\hat{u})$. *Furthermore, if for an admissible control* (a_n) *we have*

$$\limsup_{t\to\infty}E_x^{(a_n)}\left\{\left(E_{x_t}^{a_t}\left\{e^{w(x_1)}\right\}\right)^\alpha\right\}<\infty$$

for every $\alpha>1$, *then* $\lambda^\gamma\leq J_x^\gamma((a_n))$.

Proof. The proof consists of several steps.

Step 1. We prove first that $\sup_N\hat{E}_x^{a,N}\{\exp\{\hat{w}_N^{u_N}(\hat{x}_1\}\}$ is bounded uniformly on compact subsets of $(E_0\cup C_1)\times U$, where $\hat{w}_N^{u_N}$ is a solution to the multiplicative Poisson equation corresponding to the transition operator $P_N^a(x,dy)$ with control function u_N with $\Phi(\hat{w}_N^{u_N})=0$.

In fact,

$$\hat{E}_x^{a,N}\{\exp\{\hat{w}_N^{u_N}(\hat{x}_1)\}\}=\hat{E}_x^{a,N}\left\{\chi_{C_1}(\hat{x}_1)e^{\gamma c(x_1^1,u_N(x_1^1))-\lambda_N^\gamma(u_N)}\right\}$$

$$+\ \hat{E}_x^{a,N}\left\{\chi_{C_1^c}(\hat{x}_1)\exp\left\{\sum_{i=1}^{\tau_{C_1}}(\gamma c(x_i^1,u_N(x_i^1))-\lambda_N^\gamma(u_N))\right\}\right\}, \tag{52}$$

and by (A5) the required boundedness follows.

Step 2. We show now that for $N=1,2\ldots$, functions $\hat{E}_x^{a,N}\{\chi_{C_1}(\hat{x}_1)\exp\{\hat{w}_N^{u_N}(\hat{x}_1)\}\}$, $\hat{E}_x^{a,N}\{\chi_{C_0}(\hat{x}_1)\exp\{\hat{w}_N^{u_N}(\hat{x}_1)\}\}$, and $\hat{E}_x^{a,N}\left\{\chi_{(E\setminus C)_0}(\hat{x}_1)\exp\{\hat{w}_N^{u_N}(\hat{x}_1)\}\right\}$ are equicontinuous in x and a from compact subsets of $E_0\cup C_1$ and U, respectively.

Notice first that by (37) for each compact set $K\subset E_0\cup C_1$, $\varepsilon'>0$ there is a compact set $K_1\supset C_0\cup C_1$ such that

$$\sup_{a\in U}\sup_{x\in K}\sup_{N}\hat{P}_x^{aN}\{\hat{x}_1\in K_1^c\}<\varepsilon'. \tag{53}$$

Furthermore by the Hölder inequality

$$\sup_{a\in U}\sup_{x\in K}\sup_{N}\hat{E}_x^{a,N}\left\{\chi_{K_1^c}(\hat{x}_1)\exp\left\{\sum_{i=1}^{\tau_{C_1}}(\gamma c(x_i^1,u_N(x_i^1))-\lambda_N^\gamma(u_N))\right\}\right\} \tag{54}$$

$$\leq \sup_{a\in U}\sup_{x\in K}\sup_{N}\left(\hat{P}_x^{a,N}\{\hat{x}_1\in K_1^c\}\right)^{\frac{\varepsilon}{1+\varepsilon}},$$

$$\sup_{a\in U}\sup_{x\in K}\sup_{N}\left(\hat{E}_x^{a,N}\left\{\exp\left\{\sum_{i=1}^{\tau_{C_1}}(\gamma c(x_i^1,u_N(x_i^1))-\lambda_N^\gamma(u_N))(1+\epsilon)\right\}\right\}\right)^{\frac{1}{1+\varepsilon}}$$

$$\leq {\varepsilon'}^{\frac{\varepsilon}{1+\varepsilon}}(M(K))^{\frac{1}{1+\varepsilon}}.$$

Consequently

$$|\hat{E}_x^{a,N}\{\chi_{C_1}(\hat{x}_1)\exp\{\hat{w}_N^{u_N}(\hat{x}_1)\}\}-\hat{E}_{x'}^{a',N}\{\chi_{C_1}(\hat{x}_1)\exp\{\hat{w}_N^{u_N}(\hat{x}_1)\}\}|$$

$$\leq e^{|\gamma|\|c\|}\|\hat{P}^{aN}(x,C_1\cap\cdot)-\hat{P}^{a'N}(x',C_1\cap\cdot)\|_{var}$$

and by (53)–(54)

$$|\hat{E}_x^{a,N}\{\chi_{C_0}(\hat{x}_1)\exp\{\hat{w}_N^{u_N}(\hat{x}_1)\}\}-\hat{E}_{x'}^{a',N}\{\chi_{C_0}(\hat{x}_1)\exp\{\hat{w}_N^{u_N}(\hat{x}_1)\}\}|$$

$$\leq 2{\varepsilon'}^{\frac{\varepsilon}{1+\varepsilon}}(M(K))^{\frac{1}{1+\varepsilon}}+|\hat{E}_x^{a,N}\{\chi_{K_1}(\hat{x}_1)\exp\{\hat{w}_N^{u_N}(\hat{x}_1)\}\}$$

$$-\hat{E}_{x'}^{a',N}\{\chi_{K_1}(\hat{x}_1)\exp\{\hat{w}_N^{u_N}(\hat{x}_1')\}\}|$$

and

$$|\hat{E}_x^{a,N}\left\{\chi_{(E\setminus C)_0}(\hat{x}_1)\exp\{\hat{w}_N^{u_N}(\hat{x}_1)\}\right\}-\hat{E}_{x'}^{a',N}\left\{\chi_{(E\setminus C)_0}(\hat{x}_1)\exp\{\hat{w}_N^{u_N}(\hat{x}_1)\}\right\}|$$

$$\leq 2{\varepsilon'}^{\frac{\varepsilon}{1+\varepsilon}}(M(K))^{\frac{1}{1+\varepsilon}}+|\hat{E}_x^{a,N}\left\{\chi_{K_1\cap(E\setminus C)_0}(\hat{x}_1)\exp\{\hat{w}_N^{u_N}(\hat{x}_1)\}\right\}$$

$$-\hat{E}_{x'}^{a',N}\left\{\chi_{K_1\cap(E\setminus C)_0}(\hat{x}_1)\exp\{\hat{w}_N^{u_N}(\hat{x}_1')\}\right\}|.$$

For $\delta>0$ choose K_1 in (52) such that ${\varepsilon'}^{\frac{\varepsilon}{1+\varepsilon}}(M(K))^{\frac{1}{1+\varepsilon}}<\frac{\delta}{3}$. Since

$$\max\Big\{|\hat{E}_x^{a,N}\{\chi_{K_1}(\hat{x}_1)\exp\{\hat{w}_N^{u_N}(\hat{x}_1)\}\}-\hat{E}_{x'}^{a',N}\{\chi_{K_1}(\hat{x}_1)\exp\{\hat{w}_N^{u_N}(\hat{x}_1')\}\}|,$$

$$|\hat{E}_x^{a,N}\left\{\chi_{K_1\cap(E\setminus C)_0}(\hat{x}_1)\exp\{\hat{w}_N^{u_N}(\hat{x}_1)\}\right\}-\hat{E}_{x'}^{a',N}\left\{\chi_{K_1\cap(E\setminus C)_0}(\hat{x}_1)\exp\{\hat{w}_N^{u_N}(\hat{x}_1')\}\right\}|\Big\}$$

$$\leq \sup_{x\in K_1}\exp\{\hat{w}_N^{u_N}(x)\}\,\|\hat{P}^{aN}(x,K_1\cap\cdot)-\hat{P}^{a'N}(x',K_1\cap\cdot)\|_{var}$$

for x, $x'\in E_0\cup C_1$, and a, $a'\in U$ such that

$$\|\hat{P}^{aN}(x,C_1\cap\cdot)-\hat{P}^{a'N}(x',C_1\cap\cdot)\|_{var}\leq\frac{\delta}{3e^{\gamma\|c\|}} \tag{55}$$

and

$$\|\hat{P}^{aN}(x,K_1\cap\cdot)-\hat{P}^{a'N}(x',K_1\cap\cdot)\|_{var}\leq\frac{\delta}{3\sup_{z\in K_1}e^{\hat{w}_N^{u_N}(z)}} \tag{56}$$

we obtain that

$$|\hat{E}_x^{a,N}\{\chi_{C_1}(\hat{x}_1)\exp\{\hat{w}_N^{u_N}(\hat{x}_1)\}\} - \hat{E}_{x'}^{a',N}\{\chi_{C_1}(\hat{x}_1)\exp\{\hat{w}_N^{u_N}(\hat{x}_1)\}\}| \le \delta,$$

$$|\hat{E}_x^{a,N}\{\chi_{C_0}(\hat{x}_1)\exp\{\hat{w}_N^{u_N}(\hat{x}_1)\}\} - \hat{E}_{x'}^{a',N}\{\chi_{C_0}(\hat{x}_1)\exp\{\hat{w}_N^{u_N}(\hat{x}_1)\}\}| \le \delta,$$

and

$$|\hat{E}_x^{a,N}\left\{\chi_{(E\setminus C)_0}(\hat{x}_1)\exp\{\hat{w}_N^{u_N}(\hat{x}_1)\}\right\} - \hat{E}_{x'}^{a',N}\left\{\chi_{(E\setminus C)_0}(\hat{x}_1)\exp\{\hat{w}_N^{u_N}(\hat{x}_1)\}\right\}| \le \delta.$$

Now by (A5) $\sup_{z\in K_1} e^{\hat{w}_N^{u_N}(z)}$ is bounded in N, and therefore by (37) we can choose x, x' and a, a' in (55) and (56) uniformly in N, which completes the proof of the equicontinuity.

Step 3. By Steps 1 and 2 and by (5) and (15) we immediately see that

$$E_x^{a,N}\{\exp\{w_N^{u_N}(x_1)\}\}$$

is uniformly (in N) bounded and equicontinuous on compact subsets of $E\times U$. Since u_N is optimal for $P_N^a(x,dy)$ we have that $w_N^{u_N} = w_N$. Therefore by Ascoli's theorem (Theorem 33 of [24]) there is a subsequence N_k such that

$$E_x^{a,N_k}\{\exp\{w_{N_k}(x_1)\}\}$$

converges uniformly in $a\in U$ and x from compact subsets of E and $\lambda_{N_k}^{\gamma}(u_{N_k})\to\lambda$ (since $\lambda_N^{\gamma}(u_n)\in[\inf_{x\in E,a\in U}\gamma c(x,a), \sup_{x\in E,a\in U}\gamma c(x,a)]$). Consequently there is a continuous function w such that

$$e^{w(x)} = \inf_{a\in U}\left[e^{\gamma c(x,a)-\lambda}\lim_{k\to\infty}\int_E e^{w_{N_k}(y)}P_{N_k}^a(x,dy)\right]. \tag{57}$$

Moreover, using the fact that $w_N^{u_N} = w_N$ is a solution to the Bellman equation (46) we obtain

$$\begin{aligned} e^{w(x)} &= \lim_{k\to\infty}\inf_{a\in U}\left[e^{\gamma c(x,a)-\lambda}\int_E e^{w_{N_k}(y)}P_{N_k}^a(x,dy)\right] \\ &= \lim_{k\to\infty} e^{\lambda-\lambda_{N_k}^{\gamma}(u_{N_k})}e^{w_{N_k}(x)} = \lim_{k\to\infty} e^{w_{N_k}(x)} \end{aligned} \tag{58}$$

with the convergence uniform on compact sets.

Step 4. To prove that function w defined in (57) is a solution to the Bellman equation (50) it remains to show that

$$\lim_{k\to\infty} E_x^{a,N_k}\{\exp\{w_{N_k}(x_1)\}\} = E_x^a\left\{e^{w(x_1)}\right\}. \tag{59}$$

In fact, by Fatou's lemma

$$E_x^a\left\{e^{w(x_1)}\right\} \le \lim_{k\to\infty} E_x^{a,N_k}\{\exp\{w_{N_k}(x_1)\}\} < \infty. \tag{60}$$

By Steps 1 and 2 one can find a compact set $K_1\supset C$ such that

$$\sup_N\sup_{a\in U} E_x^{a,N}\left\{\chi_{K_1^c}(x_1)\exp\{w_N(x_1)\}\right\} \le \frac{\varepsilon}{3} \tag{61}$$

and

$$\sup_{a\in U} E_x^a\left\{\chi_{K_1^c}(x_1)\exp\{w(x_1)\}\right\} \le \frac{\varepsilon}{3}. \tag{62}$$

Therefore

$$\begin{aligned}
&|E_x^a\{\exp\{w(x_1)\}\} - E_x^{a,N_k}\{\exp\{w_{N_k}(x_1)\}\}|\\
&\le |E_x^a\{\chi_{K_1}(x_1)\exp\{w(x_1)\}\} - E_x^{a,N_k}\{\chi_{K_1}(x_1)\exp\{w(x_1)\}\}|\\
&\quad + |E_x^{a,N_k}\{\chi_{K_1}(x_1)(\exp\{w(x_1)\} - \exp\{w_{N_k}(x_1)\})\}|\\
&\quad + E_x^{a,N_k}\left\{\chi_{K_1^c}(x_1)\exp\{w_{N_k}(x_1)\}\right\} + E_x^a\left\{\chi_{K_1^c}(x_1)\exp\{w(x_1)\}\right\}\\
&\le \sup_{x\in K_1} e^{w(x)}\|P^a(x,K_1\cap\cdot) - P^{aN}(x,K_1\cap\cdot)\|_{var} + \sup_{x\in K_1}|e^{w(x)} - e^{w_{N_k}(x)}| + \frac{2\varepsilon}{3}.
\end{aligned}$$

Consequently letting $k\to\infty$ and taking into account that ε may be arbitrarily small we obtain the convergence (59). By the continuity in x and a of the right-hand side of (50) we have the existence of a Borel measurable function $\hat{u}$ for which the infimum is attained. Identity (51) follows immediately from Corollary 4. From Remark 3 and Proposition 1 (under (D1)) we obtain that $\lambda^\gamma = \lambda^\gamma(\hat{u})$.

Step 5. If for an admissible control (a_n) we have $\limsup_{t\to\infty} E_x^{(a_n)}\{(E_{x_t}^{a_t}\{e^{w(x_1)}\})^\alpha\} < \infty$ for every $\alpha > 1$, then by the Hölder inequality we have from (50)

$$\begin{aligned}
w(x) &\le \ln E_x^{(a_n)}\left\{\exp\left\{\sum_{i=0}^{t-1}(\gamma c(x_i,a_i) - \lambda^\gamma)\right\} E_{x_t}^{a_t}\left\{e^{w(x_1)}\right\}\right\}\\
&\le -t\lambda^\gamma + \ln\left(E_x^{(a_n)}\left\{\exp\left\{\sum_{i=0}^{t-1}\gamma c(x_i,a_i)(1+\epsilon)\right\}\right\}\right)^{\frac{1}{1+\epsilon}}\\
&\quad + \ln\left(E_x^{(a_n)}\left\{\left(E_{x_t}^{a_t}\left\{e^{w(x_1)}\right\}\right)^{1+\frac{1}{\epsilon}}\right\}\right)^{\frac{\epsilon}{1+\epsilon}}.
\end{aligned}$$

Dividing both sides of the last inequality by t and letting t go to infinity, we obtain that $\frac{1}{1+\epsilon}J_x^{\gamma(1+\epsilon)}((a_n)) \ge \lambda^\gamma$ for any $\epsilon > 0$. It remains to show that the mapping $\gamma \mapsto J_x^\gamma((a_n))$ is a continuous function for $\gamma > 0$ since then letting $\epsilon\to 0$ we obtain $J_x^\gamma((a_n)) \ge \lambda^\gamma$. To prove continuity notice that for $\gamma_1,\gamma_2 > 0$, $\gamma_1 \le \gamma_2$

$$\begin{aligned}
|J_x^{\gamma_1}((a_n)) - J_x^{\gamma_2}((a_n))| &\le \limsup_{t\to\infty}\frac{1}{t}\left|\ln E_x^{(a_n)}\left\{\exp\left\{\sum_{i=0}^{t-1}\gamma_1 c(x_i,a_i)\right\}\right\}\right.\\
&\left. - \ln E_x^{(a_n)}\left\{\exp\left\{\sum_{i=0}^{t-1}\gamma_2 c(x_i,a_i)\right\}\right\}\right| \le \limsup_{t\to\infty}\frac{1}{t}|\gamma_1-\gamma_2|\sup_{\gamma\in[\gamma_1,\gamma_2]}|g_t'(\gamma)|\\
&\le \|c\||\gamma_1-\gamma_2|,
\end{aligned}$$

since the derivative of the function

$$g_t(\gamma) := \ln E_x^{(a_n)}\left\{\exp\left\{\sum_{i=0}^{t-1}\gamma c(x_i,a_i)\right\}\right\}$$

is bounded by $t\|c\|$. □

Remark 5. A sufficient condition for (A5) can be formulated as follows:

(D4) There is $\varepsilon > 0$ such that for each compact set $K \subset \hat{E}$

$$\sup_{a\in U}\sup_{x\in K}\sup_{N} \hat{E}_x^{a,N}\left\{\exp\left\{(1+\varepsilon)|\gamma|\|c\|_{sp}\tau_{C_1}\right\}\right\} < \infty,$$

where the split Markov process $(\hat{x}_n)$ after control a at time 0 is controlled using the control function u_N.

6. Remarks on assumptions and an example. We shall formulate first a sufficient condition for (A3). It is worth noting that the assumption (63) below corresponds to geometrical regularity of the set C with a constant $\gamma\|c\|_{sp}$, as considered in [18].

PROPOSITION 4. *If for $x \in E$ and $(a_n) \in \mathcal{U}_s$*

$$E_x^{(a_n)}\left\{\exp\left\{\gamma\|c\|_{sp}\tau_C\right\}\right\} < \infty \tag{63}$$

and

$$\sup_{x\in C} E_x^{(a_n)}\left\{\exp\left\{\gamma\|c\|_{sp}\tau_C\right\}\right\} - \beta\exp\left\{\gamma\|c\|_{sp}\right\} < 1, \tag{64}$$

then (A3) *holds.*

Proof. Notice first that by Corollary 1 for $z \notin C$ and positive integer m we have

$$\hat{E}_{(z,0)}^{(a_n)}\left\{\exp\left\{\gamma\|c\|_{sp}\tau_C\right\}\chi_{\tau_C\le m}\right\} = E_z^{(a_n)}\left\{\exp\left\{\gamma\|c\|_{sp}\tau_C\right\}\chi_{\tau_C\le m}\right\}. \tag{65}$$

Letting $m \to \infty$ by (63) we obtain

$$\hat{E}_{(z,0)}^{(a_n)}\left\{\exp\left\{\gamma\|c\|_{sp}\tau_C\right\}\right\} = E_z^{(a_n)}\left\{\exp\left\{\gamma\|c\|_{sp}\tau_C\right\}\right\}. \tag{66}$$

Now for $(a_n) \in \mathcal{U}_M$ and $x \in C$, using the definition of split Markov process and (64) we have

$$\begin{aligned}
&\hat{E}_{(x,0)}^{(a_n)}\left\{\exp\left\{\gamma\|c\|_{sp}\tau_C\right\}\right\} \\
&= \hat{E}_{(x,0)}^{(a_n)}\left\{\chi_C(x_1^1)e^{\gamma\|c\|_{sp}} + \chi_{C^c}(x_1^1)\hat{E}_{\hat{x}_1}^{(a_n)}\left\{\exp\left\{\gamma\|c\|_{sp}\tau_C\right\}\right\}\right\} \\
&= e^{\gamma\|c\|_{sp}}\frac{P^{a_0}(x,C)-\beta}{1-\beta} + e^{\gamma\|c\|_{sp}}\int_{C^c} E_z^{(a_n)}\left\{\exp\left\{\gamma\|c\|_{sp}\tau_C\right\}\right\}\frac{P^{a_0}(x,dz)}{1-\beta} \\
&= \frac{1}{1-\beta}\left[e^{\gamma\|c\|_{sp}}(P^{a_0}(x,C)-\beta) - E_x^{(a_n)}\left\{\chi_C(x_1)e^{\gamma\|c\|_{sp}}\right\} + E_x\left\{e^{\gamma\|c\|_{sp}\tau_C}\right\}\right] \\
&< \frac{1}{1-\beta}.
\end{aligned} \tag{67}$$

Let $\tau_1 = \tau_C := \{i \ge 0 : x_i^1 \in C\}$, $\tau_{n+1} = \tau_n + \tau_1 \circ \theta_{\tau_n}$.

For $x \in \hat{E}$ and $L = \sup_{z\in C}\hat{E}_{(z,0)}^{(a_n)}\left\{e^{\gamma\|c\|_{sp}\tau_C}\right\}$, using Lemma 1 we have

$$\begin{aligned}
\hat{E}_x^{(a_n)}\left\{e^{\gamma\|c\|_{sp}\tau_{C_1}}\right\} &= \hat{E}_x\left\{\sum_{i=1}^{\infty}\chi_{C_1^c}(\hat{x}_{\tau_1})\dots\chi_{C_1^c}(x_{\tau_{i-1}})\chi_{C_1}(\hat{x}_{\tau_i})e^{\gamma\|c\|_{sp}\tau_i}\right\} \\
&\le \sum_{i=1}^{\infty}\hat{E}_x^{(a_n)}\left\{\chi_{C_1^c}(\hat{x}_{\tau_1})\dots\chi_{C_1^c}(\hat{x}_{\tau_{i-1}})e^{\gamma\|c\|_{sp}\tau_{i-1}}\right\}L\beta \\
&\le \hat{E}_x^{(a_n)}\left\{e^{\gamma\|c\|_{sp}\tau_C}\right\}\sum_{i=1}^{\infty}(1-\beta)^{i-1}\beta L^{i-1} = \hat{E}_x^{(a_n)}\left\{e^{\gamma\|c\|_{sp}\tau_C}\right\}\frac{\beta}{1-(1-\beta)L}.
\end{aligned}$$

Taking into account (66), (63), (64) we obtain (D1), which completes the proof. □

Taking Remark 4 into account, by the proof of Proposition 4 we easily obtain a sufficient condition for (A5).

COROLLARY 5. *If there is an $\varepsilon > 0$ such that for any compact set $K \subset E$, we have*

$$\sup_{a\in U}\sup_{x\in K}\sup_{N} E_x^{a,N}\left\{\exp\left\{(1+\varepsilon)\gamma\|c\|_{sp}\tau_C\right\}\right\} < \infty \tag{68}$$

and

$$\sup_{a\in U}\sup_{x\in C}\sup_{N} E_x^{a,N}\left\{\exp\left\{(1+\varepsilon)\gamma\|c\|_{sp}\tau_C\right\}\right\} - \beta\exp\left\{\varepsilon\gamma\|c\|_{sp}\right\} < 1, \tag{69}$$

where the Markov process (x_n) is controlled using constant a at time 0 and $a_n = u_N(x_n)$ afterwards, then (A5) *holds.*

Consequently we see that the assumptions imposed in the paper are satisfied for a class of processes for which $f(\gamma) := E_x\{e^{\gamma\tau_C}\}$ is finite, provided we choose γ sufficiently small (to guarantee (64) and (69)). As an example one can consider a discretized ergodic diffusion (x_n) in R^d given by the following equation:

$$x_{n+1} = x_n + Ax_n + b(x_n, a_n) + D(x_n, a_n)w_n, \tag{70}$$

where (w_n) is a sequence of i.i.d. standard normal random vectors in R^d, A is a stable matrix, $b(x,a)$ is a continuous bounded vector function of $x \in R^d$ and $a \in U$, and $D(x,a)$ is a continuous bounded matrix-valued function which is uniformly elliptic, i.e., $\inf_{x\in R^d}\inf_{a\in U} trD(x,a)D(x,a)^T > 0$. Notice that by the nondegeneracy of D the minorization property (A1) is satisfied for any closed ball C in R^d. The stability of the matrix A and boundedness of b imply that if C is sufficiently large, the controlled process, no matter what control is used, is pushed to C. For completeness we add the following Lyapunov-type criterion (more detailed analysis of geometric regularity assumption can be found in Chapter 15 of [21]).

LEMMA 6. *If for $(a_n) \in \mathcal{U}_s$*

$$\sup_{x\notin C} E_x^{(a_n)}\left\{\|x_{\tau_C}\|^{-1}\right\} < \infty \tag{71}$$

and for $\gamma > 0$

$$\sup_{x\notin C}\sup_{a\in U} E_x^a\{\|x_1\|\} \le e^{-4\gamma}\|x\|, \tag{72}$$

then

$$E_x^{(a_n)}\{e^{\gamma\tau_C}\} < \infty. \tag{73}$$

Proof. Define a Lyapunov function $V(s,x) := e^{2\gamma(s+1)}\|x\|$. For $x \notin C$ by (72) we have

$$E_x^{(a_n)}\{V(s+1,x_1)\} - V(s,x) \le e^{2\gamma(s+2)}E_x^{(a_n)}\{\|x_1\|\} - e^{2\gamma(s+1)}\|x\|$$
$$\le -(e^{2\gamma(s+1)} - e^{2\gamma s})\|x\|.$$

Consequently

$$E_{x_m}^{(a_n)}\{V(m+1,x_1)\} - V(m,x_m) \le -(e^{2\gamma(m+1)} - e^{2\gamma m})\|x_m\|,$$

$$E^{(a_n)}_{x_{m-1}}\{V(m,x_1)\} - V(m-1,x_{m-1}) \le -(e^{2\gamma m} - e^{2\gamma(m-1)})\|x_{m-1}\|,$$

and summing up the above inequalities till the process (x_n) enters the set C and taking the expected value, we obtain

$$E^{(a_n)}_{x_{\tau_C}}\{V(\tau,x_\tau)\} - V(0,x) \le -E^{(a_n)}_x\left\{\|x_{\tau_C}\|(e^{2\gamma\tau_C}-1)\right\}, \tag{74}$$

from which by nonnegativity of V we have that

$$E^{(a_n)}_x\left\{e^{2\gamma\tau_C}\|x_{\tau_C}\|\right\} \le V(0,x). \tag{75}$$

By the Hölder inequality

$$E^{(a_n)}_x\{e^{\gamma\tau_C}\} \le \left(E^{(a_n)}_x\left\{e^{2\gamma\tau_C}\|x_{\tau_C}\|\right\}\right)^{\frac{1}{2}}\left(E^{(a_n)}_x\left\{\|x_{\tau_C}\|^{-1}\right\}\right)^{\frac{1}{2}},$$

and from (71) we obtain (73). □

In section 4 we introduced a uniformly ergodic approximation. One can consider more general, i.e., v-separable, approximations, as studied in [18]. Following Theorem 2.4 of [18] we then have that the Lyapunov drift criterion (DV3) holds and consequently the local multiplicative mean ergodic Theorem 3.4 of [18] is satisfied. The transition kernel of the original Markov process (x_n), although quite regular under assumption (A4), may not be itself v-separable. The latter property would require uniform approximation of the transition kernel, while we can show only an approximation which is uniform on compact subsets. A useful sufficient condition for v-separability is formulated in Lemma B.3 of [18].

Acknowledgments. The authors would like to thank both reviewers and the Associate Editor for valuable comments and references and in particular for pointing out a gap in the proofs of Lemma 4 and Theorem 1.

STABILITY AND UNIQUENESS FOR THE CRACK IDENTIFICATION PROBLEM*

ZAKARIA BELHACHMI† AND DORIN BUCUR†

Abstract. This paper deals with the identifiability of nonsmooth defects by boundary measurements, and the stability of their detection. We introduce and analyze a new pointwise regularity concept at the boundary of an open set which turns out to play a crucial role in the identifiability of defects by two boundary measurements. As a consequence, we prove the unique identifiability for a large class of closed sets, including sets with an infinite number of connected components of positive capacity and totally disconnected sets. In order to rigorously justify numerical approximation results of defects by optimal design methods, we prove a geometric stability result of the defect identification process, without any a priori smoothness assumptions.

Key words. defect identification, conductivity, uniqueness, stability

AMS subject classifications. 35R30, 49Q10

DOI. 10.1137/S0363012904441179

1. Introduction.

This paper deals with the defect identification problem by boundary measurements. Roughly speaking, the problem can be formulated as follows: Given a smooth bounded domain $\Omega \subseteq \mathbb{R}^2$, find a closed set $K \subseteq \Omega$ knowing the traces on the boundary $w_{i|\partial\Omega}$ of the solutions of

$$\left\{ \begin{array}{ll} -\Delta w_i & = 0 \text{ in } \Omega \setminus K, \\ \frac{\partial w_i}{\partial n} & = 0 \text{ on } \partial K, \\ \frac{\partial w_i}{\partial n} & = \psi_i \text{ on } \partial\Omega \end{array} \right. \tag{1}$$

for *several inputs* ψ_i. We refer the reader to the paper [4] for a complete review of the most important and up-to-date results concerning this problem.

There are three main challenges when dealing with such a problem:

- The uniqueness of the defect for a given number of measures: May different defects give the same measures?
- Stability with respect to the measurements: Do close measures give "close" cracks? There is a subsequent question: What is the right sense of closeness for defects: close in geometry or in behavior (like γ-convergence)?
- (Numerical) reconstruction of the defects and rigorous convergence results.

A way to tackle this geometric inverse problem is to use optimal design methods. From this viewpoint, one needs to understand the three items above in the context of minimal regularity assumptions for defects. Dropping a priori regularity assumptions for the stability purpose allows us, for example, to give a formal justification to the convergence of the approximation process by a shape optimization approach.

The purpose of this paper is twofold. First, we introduce and analyze a new pointwise regularity concept at the boundary of an open set, called *conductivity*, which plays a crucial role in the identifiability of defects by two boundary measurements.

It is known that one measure cannot uniquely determine even a smooth curve K, and, following Alessandrini and Diaz Valenzuela [1], two suitably chosen inputs can uniquely determine closed sets K which can be decomposed in a finite union of disjoint continua (see also [17]). Roughly speaking, we prove that unique identification holds for the family of defects which are conductive at quasi-every point of their boundaries (see Theorem 3.9). As a consequence, we prove unique identifiability by two boundary measurements for a large class of closed sets, including sets with an infinite number of connected components of positive capacity and totally disconnected sets. Our proof uses the scheme of Alessandrini and Diaz Valenzuela based on nonexistence of critical points for suitable holomorphic functions. The construction of critical points relies on the conductivity regularity concept. With respect to the proof of Alessandrini and Diaz Valenzuela several new technical difficulties appear, which are related to the fact that harmonic conjugates of solutions are not Hölder continuous up to the boundary and information given by the unique continuation principle cannot be propagated "across" the defects. The conductivity regularity concept has several features in common with the Dirichlet regularity related to the Wiener criterion, but we are not able to prove or disprove their equivalence. Nevertheless, our result associated with the Kellogg property also shows that the equivalence of the two regularity concepts (conductivity and Dirichlet regularity) would straightforwardly imply the conjecture that *all* closed sets are uniquely identifiable, up to a set of zero capacity, by two boundary measurements.

The second purpose of the paper is to investigate the stability of the detection from the shape optimization point of view. Precisely, we prove that asymptotic geometric stability holds in the class of defects having a uniform bound on the number of connected components (see Theorem 4.3). Roughly speaking, convergence of the measures in the space of traces implies geometric convergence of the defects (this is the framework of the so-called Tikhonov principle [20]). All previous stability results (see [2, 4, 11, 18] and references therein) require us to know a priori a quantitative estimate of the smoothness of the defects, and provide quantitative estimates for the stability. By dropping the a priori smoothness hypotheses we lose any quantitative estimate but—and here is the main interest of such a result—we can rigorously justify that suitable numerical approximations of the defects are convergent (see Theorems 5.1 and 5.3). This result is to be compared to the one obtained in [8] for shape optimization problems associated with the Dirichlet–Laplacian and relies deeply on the shape stability result of [6] and on the elimination of the smoothness hypotheses (see also [7, 9, 15]). Stability results based on a priori smoothness cannot be used to achieve shape convergence for numerical approximations in the optimal design framework.

2. Setting the problem. Throughout the paper, Ω denotes a bounded simply connected open set in $\mathbb{R}^2$ with smooth boundary. By $|E|$ we denote the Lebesgue measure of the set E and by cap (E) its capacity, i.e.,

$$\text{cap}\,(E) = \inf\left\{\int_{\mathbb{R}^2} |\nabla u|^2 + |u|^2 dx, \quad u \in \mathcal{U}_E\right\},$$

where $\mathcal{U}_E$ is the class of all functions $u \in C_c^\infty(\mathbb{R}^2)$ such that $u \geq 1$ a.e. in a neighborhood of E. It is said that a property $p(x)$ holds quasi everywhere on E (q.e. on E) if the set of all points $x \in E$ for which $p(x)$ does not hold has capacity zero. We refer to [14] for details concerning capacity.

A function u is said to be *quasi-continuous* if for every $\epsilon > 0$ there exists an open set A_ϵ such that cap $(A_\epsilon) < \epsilon$ and $u|_{\Omega \setminus A_\epsilon}$ is continuous in $\Omega \setminus A_\epsilon$. Throughout the

paper, every time we refer to pointwise properties of Sobolev functions, we implicitly consider quasi-continuous representatives.

The usual Sobolev space is denoted by $H^1(\Omega)$. Recall that every function $u \in H^1(\Omega)$ has a quasi-continuous representative, unique up to a set of zero capacity. Considering quasi-continuous representatives, one can define the trace (as restriction) of a function $u \in H^1(\Omega)$ on every continuum of positive diameter. We recall the following result (see [6]).

LEMMA 2.1. *Let $u \in H^1(\Omega)$ and let K_1, K_2 be two compact connected sets in Ω with positive diameter. If there exist two different constants $c_1, c_2 \in \mathbb{R}$ such that $u(x) = c_1$ q.e. on K_1 and $u(x) = c_2$ q.e. on K_2, then $K_1 \cap K_2 = \emptyset$.*

We also recall the definition of the following functional space. Let $U \subseteq \mathbb{R}^2$ be an open set; the Dirichlet space $\mathcal{L}^{1,2}(U)$ is defined as [14].

$$\mathcal{L}^{1,2}(U) = \{u \in L^2_{loc}(U) : \nabla u \in [L^2(U)]^2\}, \tag{2}$$

where the gradient of u is taken in the sense of distributions. Introducing the equivalence relation

$$u\mathcal{R}v \text{ if } \int_U |\nabla(u-v)|^2 dx = 0,$$

we see that the quotient space $\mathcal{L}^{1,2}(U)_{/\mathcal{R}} := L^{1,2}(U)$ is a Hilbert space for the scalar product

$$(u,v)_{L^{1,2}(U)} = \int_U \nabla u \nabla v dx.$$

Let C be a connected component of U and let $u, v \in \mathcal{L}^{1,2}(U)$ such that $u\mathcal{R}v$. Then $u - v$ is constant a.e. on C.

Following [12, Corollary 2.2], if U is smooth enough (e.g., with Lipschitz continuous boundary), then $\mathcal{L}^{1,2}(U) = H^1(U)$. If U is not smooth, then $H^1(U)$ might be strictly contained in $\mathcal{L}^{1,2}(U)$. Observe also that if U is not smooth enough, several "well-known" properties of H^1-spaces fail to be true, e.g., the Poincaré–Wirtinger inequality.

For an arbitrary set $F \subseteq \mathbb{R}^2$ and for $\varepsilon > 0$ let us denote the dilation of F by ε, $F^\varepsilon = \cup_{x \in F} B(x, \varepsilon)$ being the union of all open balls centered in points of F with radius ε, and denote by $\overline{F}^\varepsilon$ its closure. Clearly the following holds for $\varepsilon < \nu$: $F^\varepsilon = (\overline{F})^\varepsilon \subseteq \overline{(F^\varepsilon)} \subseteq F^\nu$.

DEFINITION 2.2. *The Hausdorff distance between two compact sets $K_1, K_2 \subseteq \mathbb{R}^2$ is defined by*

$$d_H(K_1, K_2) = \inf\{\varepsilon > 0 : K_1 \subseteq K_2^\varepsilon \, , K_2 \subseteq K_1^\varepsilon\}.$$

Note that the family of closed subsets of a given compact of $\mathbb{R}^2$ is compact for the Hausdorff metric. We refer to [6] and [19] for more details on the Hausdorff metric and on the following.

LEMMA 2.3. *Let $\{u_n\}_{n\in\mathbb{N}} \subseteq H^1(\Omega)$, $\{K_n\}_{n\in\mathbb{N}}$ be a sequence of compact connected sets in Ω, and $\{c_n\}_{n\in\mathbb{N}}$ be a sequence of constants such that $u_n(x) = c_n$ q.e. on K_n. If $K_n \xrightarrow{H} K$, then K is connected. Suppose that $u_n \overset{H^1(\Omega)}{\rightharpoonup} u$. Then there exists a constant $c \in \mathbb{R}$ such that $c_n \longrightarrow c$ and $u(x) = c$ q.e. on $K \cap \Omega$.*

Let $K \subset \Omega$ be compact and $\psi \in L^2(\partial\Omega)$ be such that $\int_{\partial\Omega} \psi = 0$. We consider in what follows *the perfectly insulating problem*

$$\begin{cases} -\Delta w &= 0 \text{ in } \Omega \setminus K, \\ \frac{\partial w}{\partial n} &= 0 \text{ on } \partial K, \\ \frac{\partial w}{\partial n} &= \psi \text{ on } \partial\Omega. \end{cases} \tag{3}$$

Since K is the unknown of the problem and may vary, if ambiguity occurs on the choice of K, this solution will be denoted $w_{\psi,K}$. It is clear that using the usual tools (e.g., the Lax–Milgram theorem [3]; see also [6]) one has the following.

PROPOSITION 2.4. *There exists a unique solution $u \in L^{1,2}(\Omega \setminus K)$ obtained by solving the following minimization problem:*

$$\min_{\phi \in L^{1,2}(\Omega\setminus K)} \frac{1}{2} \int_{\Omega\setminus K} |\nabla\phi|^2 dx - \int_{\partial\Omega} \phi\psi d\sigma.$$

Let us denote by 1_U the characteristic function of the set U. The following result has a simple proof (see section 4 and [6, 10]).

PROPOSITION 2.5. *The following holds for $\varepsilon \to 0$:*

$$\nabla w_{\psi,\overline{K}^\varepsilon} 1_{\Omega\setminus\overline{K}^\varepsilon} \overset{L^2(\Omega,\mathbb{R}^2)}{\longrightarrow} \nabla w_{\psi,K} 1_{\Omega\setminus K}.$$

Note also that for $\varepsilon > 0$ the function $w_{\psi,\overline{K}^\varepsilon}$ has a harmonic conjugate in $\Omega\setminus\overline{K}^\varepsilon$ (see [1], for example), i.e., is the real part of a holomorphic function. Following Proposition 2.5 and the usual properties of holomorphic functions, the function $w_{\psi,K}$ also has a harmonic conjugate. The problem which is solved by the conjugate functions will be clarified by studying the following.

The perfectly conducting problem. A dual problem, called "the perfectly conducting case" has been introduced in [11] for one connected crack and extended in [1] for a finite number of connected cracks, say, $K = \cup_{i=1}^k K_i$. In this case, the problem is formulated as follows (see, for instance, [1]):

$$\begin{cases} -\Delta u = 0 \text{ in } \ \Omega \setminus K, \\ u = c_i \text{ q.e. on } K_i, \\ \frac{\partial u}{\partial n} = \psi \text{ on } \partial\Omega. \end{cases} \tag{4}$$

The constants c_i are uniquely determined by the no-flux condition that the solution u has to satisfy: for every smooth Jordan curve $\gamma \subseteq \Omega \setminus K$ $\int_\gamma \frac{\partial u}{\partial n} d\sigma = 0$.

Moreover, the solution of this problem is given by the minimization of the following energy functional:

$$\min \left\{ \frac{1}{2} \int_{\Omega\setminus K} |\nabla u|^2 dx - \int_{\partial\Omega} u\psi d\sigma : u \in H^1(\Omega), u \text{ q.e. constant on } \ K_i \right\}. \tag{5}$$

Details concerning the equivalence of the formulations (4) and (5) can be found in [1] (see also [6] for more details concerning the formulation via quasi-continuous functions).

Here is the main key to understanding the uniqueness of the inverse problem for arbitrary compact sets. We manage the perfectly conductive case for arbitrary K by introducing the following Sobolev-like space. Let Ω be a bounded open set, and $F \subseteq \overline{\Omega}$ an arbitrary set. We define

$$H^1_{cond,F}(\Omega) = cl_{H^1(\Omega)}\{u \in H^1(\Omega) : \exists \varepsilon > 0, \nabla u = 0 \text{ a.e. on } F^\varepsilon \cap \Omega\}. \tag{6}$$

Let us denote by $u(F)$ the image of the set F by u. For sets F which have a certain regularity (e.g., a finite number of Lipschitz connected components), the previous definition coincides with

$$cl_{H^1(\Omega)}\{u \in H^1(\Omega) : u(F) \text{ is finite}\} \tag{7}$$

and

$$cl_{H^1(\Omega)}\{u \in C^\infty(\Omega) \cap H^1(\Omega) : u(F) \text{ finite}\},$$

but it is not clear whether this holds for arbitrary F. Of course, in (7) we consider quasi-continuous representatives. Observe also that if $u \in H^1_{cond,F}(\Omega)$, then $|u| \in H^1_{cond,F}(\Omega)$.

Note that the following inequality holds for every function $u \in H^1(\Omega)$ such that $\int_{\partial\Omega} u d\sigma = 0$:

$$\int_{\partial\Omega} u^2 dx \le C \int_\Omega |\nabla u|^2 dx, \tag{8}$$

where C is a constant depending only on Ω. This is a consequence of the trace theorem and the Poincaré inequality in $H^1(\Omega)$. Note also that $u \mapsto \int_\Omega |\nabla u|^2 dx$ is a norm on $\{u \in H^1(\Omega), \int_{\partial\Omega} u d\sigma = 0\}$ and that for every $u \in H^1_{cond,K}(\Omega)$ we have $\nabla u = 0$ a.e. on K.

We see problem (4) for an arbitrary K only by its variational formulation

$$\min\left\{\frac{1}{2}\int_{\Omega\setminus K} |\nabla u|^2 dx - \int_{\partial\Omega} u\psi d\sigma : u \in H^1_{cond,K}(\Omega)\right\}. \tag{9}$$

Proposition 2.6. *Problem* (9) *has a unique solution such that* $\int_{\partial\Omega} u d\sigma = 0$.

Note that the gradient of the solution is unique. We can fix a representative such that $\int_{\partial\Omega} u d\sigma = 0$.

Proof. To prove the existence of a solution for problem (9), the Lax–Milgram theorem can be directly used. Nevertheless, in order to familiarize the reader with the space $H^1_{cond,K}(\Omega)$, we show this by using the direct methods of the calculus of variations.

Let $u_n \in H^1_{cond,K}(\Omega)$ be a minimizing sequence. We can assume that $\int_{\partial\Omega} u_n d\sigma = 0$; if not, we simply add suitable constants. Since $0 \in H^1_{cond,K}(\Omega)$, we can also assume

$$\frac{1}{2}\int_{\Omega\setminus K} |\nabla u_n|^2 dx - \int_{\partial\Omega} u_n\psi d\sigma \le 0.$$

Using the Cauchy inequality together with (8) there exists a constant M depending only on Ω such that

$$\int_{\Omega\setminus K} |\nabla u_n|^2 dx \le M.$$

There exists $u \in H^1_{cond,K}(\Omega)$ such that $\nabla u_n \overset{L^2(\Omega,\mathbb{R}^2)}{\rightharpoonup} \nabla u$ and $u_{n|\partial\Omega} \overset{L^2(\partial\Omega)}{\longrightarrow} u_{|\partial\Omega}$. Consequently,

$$\frac{1}{2}\int_{\Omega\setminus K} |\nabla u|^2 dx - \int_{\partial\Omega} u\psi d\sigma \le \liminf_{n\to\infty} \frac{1}{2}\int_{\Omega\setminus K} |\nabla u_n|^2 dx - \int_{\partial\Omega} u_n\psi d\sigma,$$

and hence u is a solution of (9).

The uniqueness of the solution comes from the convexity of the energy functional. □

Note the following facts: The solution given by Proposition 2.6 satisfies $-\Delta u = 0$ on $\Omega \setminus K$ in the sense of distributions and $\frac{\partial u}{\partial n} = \psi$ on $\partial\Omega$ in the weak sense of traces; for every $x \in K$ such that $x \in U_x \subseteq K$, where U_x is a continuum, the solution of (9) is constant q.e. on U_x.

We give the following proposition which has a simple direct proof, and refer to section 4 for a more detailed discussion of the stability question.

PROPOSITION 2.7. *The following holds for $\varepsilon \to 0$:*

$$\nabla u_{\psi,\overline{K}^\varepsilon} \overset{L^2(\Omega,\mathbb{R}^2)}{\longrightarrow} \nabla u_{\psi,K}.$$

Proof. For simplicity, let us denote $u_\varepsilon = u_{\psi,\overline{K}^\varepsilon}$. As in Proposition 2.6, there exists a constant M independent on ε such that

$$\int_\Omega |\nabla u_\varepsilon|^2 dx \le M.$$

There exists $u \in H^1(\Omega)$ such that $\nabla u_\varepsilon \overset{L^2(\Omega,\mathbb{R}^2)}{\rightharpoonup} \nabla u$ and $u_{\varepsilon|\partial\Omega} \overset{L^2(\partial\Omega)}{\longrightarrow} u_{|\partial\Omega}$. We get

$$\frac{1}{2}\int_\Omega |\nabla u|^2 dx - \int_{\partial\Omega} u\psi d\sigma \le \liminf_{\varepsilon\to 0} \frac{1}{2}\int_\Omega |\nabla u_\varepsilon|^2 dx - \int_{\partial\Omega} u_\varepsilon \psi d\sigma. \tag{10}$$

Note that $u \in H^1_{cond,K}(\Omega)$ since $u_\varepsilon \in H^1_{cond,\overline{K}^\varepsilon}(\Omega) \subseteq H^1_{cond,K}(\Omega)$. Let u^* be the solution of (9) in $H^1_{cond,K}(\Omega)$. Then

$$\frac{1}{2}\int_\Omega |\nabla u^*|^2 dx - \int_{\partial\Omega} u^*\psi d\sigma \le \frac{1}{2}\int_\Omega |\nabla u|^2 dx - \int_{\partial\Omega} u\psi d\sigma.$$

From the definition of $H^1_{cond,K}(\Omega)$, there exists a sequence $\phi_n \in H^1(\Omega)$, such that $\nabla\phi_n = 0$ a.e. on $K^{1/n}$, such that $\int_{\partial\Omega}\phi_n d\sigma = 0$ and $\phi_n \longrightarrow u^*$ in $H^1(\Omega)$-strong. Choosing suitable couples (ε, n) such that $\varepsilon < 1/n$, we get $\phi_n \in H^1_{cond,\overline{K}^\varepsilon}(\Omega)$. Consequently,

$$\begin{aligned}\limsup_{\varepsilon\to 0} \frac{1}{2}\int_\Omega |\nabla u_\varepsilon|^2 dx - \int_{\partial\Omega} u_\varepsilon\psi d\sigma &\le \lim_{n\to\infty} \frac{1}{2}\int_\Omega |\nabla\phi_n|^2 dx - \int_{\partial\Omega}\phi_n\psi d\sigma \\ &= \frac{1}{2}\int_\Omega |\nabla u^*|^2 dx - \int_{\partial\Omega} u^*\psi d\sigma.\end{aligned} \tag{11}$$

From (10) and (11) we get $u = u^* = u_{\psi,K}$, and from the convergence of the L^2-norms of the gradients we get that

$$\nabla u_\varepsilon \longrightarrow \nabla u_{\psi,K}\text{-strong } L^2. \qquad \square$$

The result of Proposition 2.7 is still true if on $\partial\Omega$ one considers Dirichlet boundary conditions.

PROPOSITION 2.8 (existence of stream functions). *Let w and u be the solutions of* (3) *and* (4)*, respectively. There exists holomorphic functions W and U in $\Omega \setminus K$ such that $w = \operatorname{Re} W$ and $u = \operatorname{Re} U$. Moreover,* $\operatorname{Im} W$ *and* $\operatorname{Im} U$ *solve problems* (12)

and (13) *below, respectively. Let* Ψ *a primitive of* ψ *on* $\partial\Omega$. *The problem solved by* $\operatorname{Im} W$ *is*

$$\min\left\{\int_\Omega |\nabla\phi|^2 dx : \phi \in H^1_{cond,K}(\Omega), \phi = \Psi \text{ on } \partial\Omega\right\}, \tag{12}$$

and the problem solved by $\operatorname{Im} U$ *is*

$$\begin{cases} -\Delta\phi &= 0 \text{ in } \Omega\setminus K,\\ \frac{\partial\phi}{\partial n} &= 0 \text{ on } \partial K,\\ \phi &= \Psi \text{ on } \partial\Omega. \end{cases} \tag{13}$$

Proof. For $\varepsilon > 0$, the result is true in $\Omega\setminus\overline{K}^{\varepsilon}$ by [1, 6]. Making $\varepsilon\to 0$, the result is true in $\Omega\setminus K$ as a consequence of Propositions 2.5 and 2.7. □

3. Unique identifiability by two boundary measurements. In a first step we introduce a regularity notion, called *conductivity*, for a point of the boundary of an open set U; this kind of regularity should be related to the notion of Wiener regular point, rather than to the usual smoothness of the boundary.

In a second step, we prove that all sets which q.e. satisfy this regularity assumption on their boundaries are uniquely (up to a set of zero capacity) identifiable by two boundary measurements. The proof follows the same steps as in [1], and essentially is obtained by approximating these sets with sets that have a finite number of connected components.

Definition 3.1. *Let* K *be a compact subset of* Ω. *A point* $x\in K$ *is a capacity point for* K *if* $\forall r>0$, $\operatorname{cap}(B_{x,r}\cap K)>0$.

Proposition 3.2. *The set* K^* *of capacity points of a compact set* K *is compact and* $\operatorname{cap}(K\setminus K^*)=0$.

Proof. The compactness comes directly and the relation $\operatorname{cap}(K\setminus K^*)=0$ follows from the Lindelöf property and the subadditivity of the capacity. □

Remark 3.3. From now on, every time we consider a compact set K, we replace it implicitly with K^*. Since $\operatorname{cap}(K\setminus K^*)=0$, problems (3) and (4) have the same solutions on $\Omega\setminus K$ and $\Omega\setminus K^*$, respectively. From a practical point of view, every time an open set $U\subseteq\Omega$ is considered, it is replaced with $\Omega\setminus(\overline{\Omega}\setminus U)^*$.

Definition 3.4. *Let* U *be an open subset of* Ω *and* $x\in\partial U$. *We say that* x *is conductive for* U *if for every* $r>0$ *and for every* $\varphi\in C(\overline{U})\cap H^1_{cond,\partial U\cap B_{x,r}}(\Omega)$,

$$\liminf_{\substack{y\to x\\ y\in\partial U}} \frac{|\varphi(y)-\varphi(x)|}{|y-x|} = 0. \tag{14}$$

Roughly speaking, x is a conductivity point if there exists a "path" of conductivity on ∂U passing through x and having locally positive capacity. Note that every conductivity point is a capacity point for U^c.

Proposition 3.5. *Let* K *be a compact subset of* Ω *such that* $\Omega\setminus K$ *is connected and* F *a continuum of positive diameter such that* $x\in F\subseteq\partial(\Omega\setminus K)$. *Then* x *is a conductivity point for* $\Omega\setminus K$.

Proof. Let $\varphi\in C(\overline{\Omega\setminus K})\cap H^1_{cond,\partial(\Omega\setminus K)\cap B_{x,r}}(\Omega)$. Then, φ is q.e. constant on the continuum of positive diameter $\tilde{F}$ passing through x and contained in $F\cap B_{x,r}$. Indeed, if ϕ is a quasi-continuous representative of φ on Ω, then ϕ is finely continuous q.e. (see [16]) and coincides q.e. with φ on $\Omega\setminus K$. Since every point of $\partial(\Omega\setminus K)$ is

thick with respect to $\Omega \setminus K$ (which is connected), we conclude that $\phi(x) = \varphi(x)$ q.e. on $\partial(\Omega \setminus K)$. Therefore φ is q.e. constant on $\tilde{F}$ and relation (14) holds. □

In what follows we give two examples of the form $U = \Omega \setminus K$ with points $x \in \partial K$ which are disconnected from the rest of the set K; in one of them we show that such a point may be conductive despite the fact it is not contained in any continuum of positive diameter (subset of K).

Example 3.6. Let $\Omega = [-2, 2] \times [-2, 2]$ and

$$K = \{(0,0)\} \bigcup_{n \in \mathbb{N}^*} \frac{1}{n} \times \left[0, \frac{1}{n}\right].$$

Then $(0,0)$ is not a conductivity point for $\Omega \setminus K$; consider, for example, $u(x,y) = x$. Obviously $u \in C(\overline{\Omega})$ and it is easy to see (cf., e.g., [5, 6]) that $u \in H^1_{cond,K}(\Omega)$ by approaching u strongly in $H^1(\Omega)$ by the sequence u_n of solutions of the following equations. Let $K_n = \bigcup_{k=1}^{n} [\frac{1}{k} - \frac{1}{n^2}, \frac{1}{k} + \frac{1}{n^2}] \times [0, \frac{1}{k}]$ and let u_n solve $-\Delta u_n = 0$ in $\Omega \setminus K_n$, $u_n = u$ on $\partial\Omega$ and $u_n = \frac{1}{k}$ on $[\frac{1}{k} - \frac{1}{n^2}, \frac{1}{k} + \frac{1}{n^2}] \times [0, \frac{1}{k}]$.

On the other hand, (14) does not hold, since $\frac{|u(x,y)-u(0)|}{|(x,y)|} \geq \sqrt{2}^{-1}$, for every $(x,y) \in K$.

Example 3.7. Now let

$$K = \{(0,0)\} \bigcup_{n \in \mathbb{N}^*} \{b_n\} \times \left[0, r_n\right],$$

where

$$b_n = \sum_{k=n}^{\infty} \frac{1}{k^2(k+1)^3}$$

and

$$r_n = \frac{1}{n}.$$

Then $(0,0)$ is a conductivity point for $\Omega \setminus K$ which is not contained in a continuum of positive capacity of K.

The proof needs some computation. We give it in the appendix at the end of the paper.

We also prove in the appendix the following proposition, which is an extension of Proposition 3.5.

PROPOSITION 3.8. *Let K be a compact subset of Ω such that $\Omega \setminus K$ is connected. Every $x \in \partial(\Omega \setminus K)$ for which there exists a continuum of positive diameter U_x, such that $x \in U_x \subseteq K$, is a conductivity point for $\Omega \setminus K$.*

In particular, if K is a continuum of positive diameter, then $\Omega \setminus K$ is conductive at every point of $\partial(\Omega \setminus K)$. As well, if K is a compact set having a finite number of connected components, then $\Omega \setminus K$ is conductive at quasi-every point of its boundary (except the isolated points).

Note that if K is a compact subset of Ω, the only detectable part of ∂K is the one contained in the boundary of the connected component of $\Omega \setminus K$ which touches $\partial\Omega$. For this reason, we shall assume (only) in the following theorem that $\Omega \setminus K$ is connected.

The fluxes we consider are defined as in [1]. Consider a division of $\partial\Omega$ into three connected disjoint parts $\Gamma_0, \Gamma_1, \Gamma_2$. For $i = 0, 1, 2$ we consider on $\partial\Omega$ a nonnegative

function η_i such that supp $\eta_i \subseteq \Gamma_i$, $\eta_i \in L^2(\partial\Omega)$, $\int_{\partial\Omega} \eta_i = 0$. We take for $k = 1, 2$, $\psi_k = \eta_0 - \eta_k$.

THEOREM 3.9. *Let $K, \tilde{K}$ be two compact subsets of Ω such that $\Omega \setminus K$, $\Omega \setminus \tilde{K}$ are connected. Let ψ_1, ψ_2 be two fluxes on $\partial\Omega$ chosen as above. Suppose that for $k = 1, 2$ either $w_{\psi_k,K|\partial\Omega} = w_{\psi_k,\tilde{K}|\partial\Omega}$ or $u_{\psi_k,K|\partial\Omega} = u_{\psi_k,\tilde{K}|\partial\Omega}$. If $\Omega \setminus K$ and $\Omega \setminus \tilde{K}$ are conductive at quasi-every point of their boundaries, then $K = \tilde{K}$ q.e.*

Proof. The proof relies on the nonexistence of geometrical critical points for particular holomorphic functions. Let us first prove that if $K \neq \tilde{K}$ q.e., then we may find a geometrical critical point for the solution of (3) (or (4)) with a boundary data of the form $\alpha\psi_1 + \beta\psi_2$, for a certain couple α, β which satisfies $\alpha^2 + \beta^2 = 1$. The proof follows along the same lines as in [1], in the new hypotheses on the conductivity of the sets K and $\tilde{K}$. A new kind of difficulty appears, since the unique continuation property does not give information over all $\Omega \setminus (K \cup \tilde{K})$.

We shall consider only problem (3) (the case (4) follows the same ideas). For $k = 1, 2$, let w_k^*, $\tilde{w}_k^*$ be the conjugate functions of $w_k = w_{\psi_k,K}$, $\tilde{w}_k = w_{\psi_k,\tilde{K}}$, such that $w_k + iw_k^*$ are holomorphic in $\Omega \setminus K$ and $\tilde{w}_k + i\tilde{w}_k^*$ are holomorphic in $\Omega \setminus \tilde{K}$, respectively. Note that for the boundary condition $\alpha\psi_1 + \beta\psi_2$ the solution of (3) on $\Omega \setminus K$ is $\alpha w_1 + \beta w_2$ and that the harmonic conjugate of this function in $\Omega \setminus K$ is $\alpha w_1^* + \beta w_2^*$.

From the unique continuation property, we get as in [1] that $w_k = \tilde{w}_k$ on G, where G is the connected component of $\Omega \setminus (K \cup \tilde{K})$ satisfying $\partial\Omega \subseteq \partial G$ (the functions w_k and $\tilde{w}_k$ have the same Cauchy data on $\partial\Omega$). The main difficulty is that the information is not obtained over all $\Omega \setminus (K \cup \tilde{K})$. In [1], using the particular structure of K and $\tilde{K}$, the information could be extended in $\Omega \setminus (K \cup \tilde{K})$.

Let us suppose that $\Omega \setminus K \neq \Omega \setminus \tilde{K}$, say, $\Omega \setminus K \not\subseteq \Omega \setminus \tilde{K}$. There exists $x \in \Omega \setminus K$ such that $x \notin \Omega \setminus \tilde{K}$ (i.e., $x \in \tilde{K}$). Since $\Omega \setminus K$ is connected and $\partial\Omega$ is smooth, there exists a smooth curve $\gamma : [0, 1] \to \overline{\Omega} \setminus K$ such that $\gamma(0) = x$, $\gamma((0, 1)) \subseteq \Omega \setminus K$, $\gamma(1) \in \partial\Omega$. Let $x_0 = \gamma(t_0)$, where

$$t_0 = \sup\{t \in [0, 1] : \gamma(t) \in \tilde{K}\}.$$

Obviously, $x_0 \in \partial\tilde{K}$ and also $x_0 \in \partial G$. Since $d(x_0, K) > 0$, there exists a ball $B_{x_0,r}$ such that $B_{x_0,r} \cap K = \emptyset$.

We prove the following.

LEMMA 3.10. *For every $\delta > 0$, G has a conductivity point on $\partial G \cap B_{x_0,\delta}$.*

Proof. For every $\varepsilon > 0$ we consider the open set $\tilde{K}^\varepsilon$. There exists an open polygonal set V_ε such that

$$\tilde{K}^{\varepsilon/2} \subseteq V_\varepsilon \subseteq \tilde{K}^\varepsilon.$$

Let U_ε be the connected component of V_ε which contains x_0. Choosing a sequence (ε_n) such that $\varepsilon_n \to 0$, $\varepsilon_{n+1} < \varepsilon_n/2$ we get

$$U_{\varepsilon_{n+1}} \subseteq U_{\varepsilon_n}.$$

There are two possibilities:

1. diam $(U_{\varepsilon_n}) \to 0$;
2. diam $(U_{\varepsilon_n}) \to \eta > 0$.

The first case. Suppose that diam $(U_{\varepsilon_n}) \to 0$. For n large enough we have $U_{\varepsilon_n} \subseteq B_{x_0,r/2}$. Let A_n be the connected component of $\Omega \setminus \overline{U}_{\varepsilon_n}$ such that $\partial\Omega \subseteq \partial A_n$.

Let $P_n = \partial A_n \setminus \partial\Omega$. Then P_n is a closed polygonal Jordan curve, which separates Ω in two regions. We observe that $P_n \subseteq \Omega \setminus (K \cup \tilde{K})$ because $P_n \cap K = \emptyset$ (since $P_n \subseteq \overline{B}_{x_0,r/2}$) and $P_n \cap \tilde{K} = \emptyset$ since ($P_n \subseteq \partial U_{\varepsilon_n}$ and $d(\partial U_{\varepsilon_n}, \tilde{K}) = \varepsilon_n/2$).

Since P_n intersects γ, and γ lies in G, the connectedness of G implies that P_n is entirely in G. Therefore, for ξ small enough, we have that

$$G \cap B_{x_0,\xi} = (\Omega \setminus \tilde{K}) \cap B_{x_0,\xi}, \tag{15}$$

$$\partial G \cap B_{x_0,\xi} = \partial(\Omega \setminus \tilde{K}) \cap B_{x_0,\xi}. \tag{16}$$

In this case two possibilities may hold: either x_0 is a conductivity point or it is not. If it is not a conductivity point, we replace it with a close point of ∂G which is conductive. Such a point exists, since following [5, Lemma 4.5] x_0 is a capacity point also for ∂G, and the family of points of ∂G which are not conductive is, by hypothesis, of zero capacity (note that ∂G coincides locally with $\partial(\Omega \setminus \tilde{K})$).

The second case. Suppose that diam $(U_{\varepsilon_n}) \to \eta > 0$. We observe that $\bigcap_n U_{\varepsilon_n} = C$, where C is a continuum such that $x \in C \subseteq \tilde{K}$, diam $C = \eta$. Let $0 < \xi < \eta/2$. Then $C \cap \partial B_{x_0,\xi} \neq \emptyset$.

Denoting again by A_n the connected component of $\Omega \setminus \overline{U}_{\varepsilon_n}$ such that $\partial\Omega \subseteq \partial A_n$, let us set again $P_n = \partial A_n \setminus \partial\Omega$. Then P_n is a polygonal Jordan curve satisfying $P_n \cap \tilde{K} = \emptyset$. Let us denote $z_n = \gamma(t_n)$, where

$$t_n = \min\{t \in [0,1], \gamma(t) \in P_n\}. \tag{17}$$

We observe that z_n is well defined and $z_n \to x_0$ for $n \to \infty$.

Since P_n contains in its "interior" region the continuum C and $P_n \cap \tilde{K} = \emptyset$ and $(P_n \cap B_{x_0,\xi}) \cap K = \emptyset$, there exists a connected component F_n of P_n passing through z_n which is contained in G and cuts $\partial B_{x_0,\xi}$ into at least two points. For $n \to \infty$, we have that F_n converges in the Hausdorff sense to a continuum F which contains x_0 and lies in the boundary of G. From Proposition 3.5 x_0 is a conductivity point for G. □

Proof of Theorem 3.9 (continuation). Let x_0 be the conductive point given by Lemma 3.10. Up to translation by constants, we can assume that for $k = 1, 2$ $w_k(x_0) = w_k^*(x_0) = 0$. Note that the function $|\tilde{w}_1^*| + |\tilde{w}_2^*|$ belongs to $H^1_{cond,\tilde{K}}(\Omega)$ and equals $|w_1^*| + |w_2^*|$ on G. This last function is continuous in a neighborhood of x_0, and hence we can apply the conductivity property to $|w_1^*| + |w_2^*|$ in x_0.

There exists a sequence of points x_n such that $x_n \in \partial G$, $x_n \to x_0$, and

$$\frac{|w_1^*(x_n)| + |w_2^*(x_n)|}{|x_n - x_0|} \to 0. \tag{18}$$

Hence, for $k = 1, 2$,

$$\frac{w_k^*(x_n)}{|x_n - x_0|} \to 0. \tag{19}$$

We suitably chose values α_n, β_n, such that $\alpha_n^2 + \beta_n^2 = 1$ and $\alpha_n w_1(x_n) + \beta_n w_2(x_n) = 0$. Choosing a subsequence of $(\alpha_n)_n, (\beta_n)_n$ such that $\alpha_n \to \alpha_0$, $\beta_n \to \beta_0$ and using relations (19), we have that the sequence of holomorphic functions

$$f_n = (\alpha_n w_1 + \beta_n w_2) + i(\alpha_n w_1^* + \beta_n w_2^*)$$

satisfies

$$\frac{f_n(x_n) - f_n(x_0)}{|x_n - x_0|} \to 0.$$

Consequently, x_0 is a geometrical critical point for $f_0 = (\alpha_0 w_1 + \beta_0 w_2) + i(\alpha_0 w_1^* + \beta_0 w_2^*)$. Indeed, we have, for $n \to \infty$,

$$\begin{aligned}&\frac{f_0(x_n) - f_0(x_0)}{|x_n - x_0|}\\ &= \frac{f_n(x_n) - f_n(x_0)}{|x_n - x_0|} - (\alpha_n - \alpha_0)\frac{w_1(x_n) + iw_1^*(x_n)}{|x_n - x_0|} - (\beta_n - \beta_0)\frac{w_2(x_n) + iw_2^*(x_n)}{|x_n - x_0|} \to 0.\end{aligned}$$

The last two terms converge to zero thanks to the holomorphy in x_0 of the functions $w_k + iw_k^*$.

To get the contradiction we observe that f_0 cannot have geometrical critical points in $\Omega \setminus K$. Indeed, this is a consequence of the result of [1] applied on $\Omega \setminus \overline{K^\varepsilon}$ by passing to the limit $K^\varepsilon \to K$ and using the continuity property of critical points. □

The main difficulty in the proof of this theorem is the fact that the unique continuation property gives information only in the connected component of $\Omega \setminus (K \cup \tilde{K})$ touching $\partial\Omega$. In [1], this information is extended over all $\Omega \setminus (K \cup \tilde{K})$ by using the connectedness of the cracks. Here we are not able to do that, and for this reason we can use information only "on one side" of the crack $\tilde{K}$, namely, on G. Since the conductivity hypothesis is formulated in $\Omega \setminus \tilde{K}$ and not in G, we are brought to discussing the two cases of Lemma 3.10. □

Remark 3.11. The conductivity property is somehow related to the thickness property relying on the Wiener criterion. It would be of interest to characterize all sets which are q.e. conductive at the boundary, and in this way to characterize all detectable sets by two boundary measurements. Even an example of a compact set which is not conductive q.e. would be of interest.

Remark 3.12. Notice from relations (15)–(16) that the density of the conductive points of ∂G into ∂G is sufficient for carrying out the proof. In the appendix, we give an example of a Cantor set which is conductive in a dense set of its boundary points, and consequently the unique identifiability for this totally disconnected set holds true (see Example 6.2).

4. Sequential stability of the inverse problems. Let ψ_1, ψ_2 be two fluxes on $\partial\Omega$ which uniquely identify q.e. conductive sets (Theorem 3.9) for problem (3) as well as for (4). For a compact set $K \subseteq \Omega$ and a sequence of compacts $(K_n)_n$ such that

$$w_{\psi_i, K_n|\partial\Omega} \overset{L^2(\partial\Omega)}{\longrightarrow} w_{\psi_i, K|\partial\Omega}, \quad i = 1, 2,$$

or

$$u_{\psi_i, K_n|\partial\Omega} \overset{L^2(\partial\Omega)}{\longrightarrow} u_{\psi_i, K|\partial\Omega}, \quad i = 1, 2,$$

we wonder if $K_n \overset{H}{\to} K$.

This assertion is in general false. First, the convergence in the Hausdorff metric does not have much in common with the behavior of the PDE on "moving" cracks.

For this reason, it is not senseless to think of stability in terms of *behavior*, i.e., two close measurements should give cracks such that *all* measurements are close. This approach is to be compared to the γ-convergence of sets (see [5]) which has a certain relation to the geometric convergence but is not at all equivalent. This kind of approach seems necessary as soon as one deals with "wild" cracks without any a priori structure. Nevertheless, we restrict ourselves to the Hausdorff metric because it seems quite difficult to describe the general behavior of sets. Note that for homogeneous Neumann boundary conditions the general behavior of the direct problem for moving domains is not, to our knowledge, known.

Second, uniqueness holds for sets $\Omega \setminus K$ which are q.e. conductive with the convention that $\Omega \setminus K$ is connected. If $\Omega \setminus K$ is disconnected, the only identifiable part is the connected component "touching" $\partial\Omega$. From a purely geometric point of view, this means that different geometries for K may give similar measures. Here we explain what can happen, from the information we have, namely, the coincidence of the identifiable connected components. Under mild assumptions on K, our result becomes a standard stability result.

In order to understand the sequential stability for the crack identification problem, the usual tool relies on the stability of the direct problem associated with compactness and uniqueness of the identification. Compactness is a geometric property of the Hausdorff convergence, and for uniqueness we rely on Theorem 3.9. The geometric stability of the direct problems (3) and (4) relies on the Mosco convergence of the Sobolev spaces $H^1(\Omega \setminus K_n)$ for problem (3) and $H^1_{cond,K_n}(\Omega)$ for problem (4). Ultimately, because of the existence of harmonic conjugates for solutions of problem (3), the only important case to be studied is the Mosco convergence of $H^1_{cond,K_n}(\Omega)$ (see [6]).

Let X be a Hilbert space and $\{G_n\}_{n\in\mathbb{N}}$ a sequence of subsets of X. The weak upper and strong lower limits in the sense of Kuratowski are defined as follows:

$$w - \limsup_{n\to\infty} G_n = \{u \in X : \exists\{n_k\}_k, \exists u_{n_k} \in G_{n_k} \text{ such that } u_{n_k} \overset{w-X}{\rightharpoonup} u\},$$

$$s - \liminf_{n\to\infty} G_n = \{u \in X : \exists u_n \in G_n \text{ such that } u_n \overset{s-X}{\longrightarrow} u\}.$$

If $\{G_n\}_{n\in\mathbb{N}}$ are closed subspaces in X, it is said that G_n converges in the sense of Mosco to G if

(M_1) $G \subseteq s - \liminf_{n\to\infty} G_n$,

(M_2) $w - \limsup_{n\to\infty} G_n \subseteq G$.

Note that in general $s - \liminf_{n\to\infty} G_n \subseteq w - \limsup_{n\to\infty} G_n$. Therefore, if G_n converges in the sense of Mosco to G, then

$$s - \liminf_{n\to\infty} G_n = G = w - \limsup_{n\to\infty} G_n.$$

For our purposes, we consider the compact sets $K_n, K \subseteq \Omega$ and wonder if $G_n := H^1_{cond,K_n}(\Omega)$ converges in the sense of Mosco to $H^1_{cond,K}(\Omega)$ into the space $X := H^1(\Omega)$.

Assume that $K_n \overset{H}{\to} K$. Then condition M_1 is immediately satisfied. Indeed, using density, it is enough to consider $u \in H^1_{cond,K}(\Omega)$ such that $\nabla u = 0$ a.e. on K^ε, for some $\varepsilon > 0$. Following the Hausdorff convergence, for n large enough we have $K_n \subseteq K^{\frac{\varepsilon}{2}}$; hence $K_n^{\frac{\varepsilon}{2}} \subseteq K^\varepsilon$ and so $\nabla u = 0$ a.e. on $K_n^{\frac{\varepsilon}{2}}$, and therefore $u \in H^1_{cond,K_n}(\Omega)$.

In general, condition M_2 is not true. Take for example $\Omega = (-2,2)\times(-2,2)$, $K_n = \cup_{k=0}^{n}\{\frac{k}{n}\}\times[0,1]$, and $u_n(x,y) = x$. A second example which typically restricts M_2 from holding is when K_n consists of many small disconnected sets, e.g., $K_n = \cup_{k,p=0}^{n}\overline{B}((\frac{k}{n},\frac{p}{n}),\varepsilon_n)$, $\varepsilon_n > 0$, $\varepsilon_n \to 0$. Then

$$K_n \xrightarrow{H} [0,1]\times[0,1],$$

but for a suitable choice of ε_n every function of $H^1(\Omega)$ can be written as a limit of a sequence of $H^1_{cond,K_n}(\Omega)$ (choose ε_n such that cap $(K_n)\to 0$).

THEOREM 4.1. *Let $K_n, K \subseteq \Omega$, $K_n \xrightarrow{H} K$. If M_2 occurs, then for every $\psi \in L^2(\partial\Omega)$ such that $\int_{\partial\Omega}\frac{\partial\psi}{\partial n}d\sigma = 0$, we have*

1. $u_{K_n,\psi|\partial\Omega} \xrightarrow{L^2(\partial\Omega)} u_{K,\psi|\partial\Omega}$,
2. $w_{K_n,\psi|\partial\Omega} \xrightarrow{L^2(\partial\Omega)} w_{K,\psi|\partial\Omega}$.

Proof. Let us prove assertion 1. For simplicity, we set $u_n = u_{K_n,\psi}$ and $u = u_{K,\psi}$. As in Propositions 2.6, and 2.7 there exists a uniform bound M such that

$$\int_\Omega |\nabla u_n|^2 dx \le M.$$

For a subsequence (still denoted using the same index), we can write $u_n \rightharpoonup \tilde{u}$ weakly $H^1(\Omega)$. From the second Mosco condition, which is assumed by hypothesis, we get $\tilde{u}\in H^1_{cond,K}(\Omega)$. In order to prove that $\tilde{u} = u$, we observe that

$$\begin{aligned}(20)\qquad &\frac{1}{2}\int_\Omega |\nabla u|^2 dx - \int_{\partial\Omega} u\psi d\sigma \\ &\quad\le \frac{1}{2}\int_\Omega |\nabla\tilde{u}|^2 dx - \int_{\partial\Omega}\tilde{u}\psi d\sigma \le \liminf_{n\to\infty}\frac{1}{2}\int_\Omega |\nabla u_n|^2 dx - \int_{\partial\Omega} u_n\psi d\sigma.\end{aligned}$$

We also note that the first Mosco condition is a direct consequence of the geometric convergence $K_n \xrightarrow{H} K$. Indeed, for proving M_1 it is enough to consider $\phi\in H^1_{cond,K}(\Omega)$ such that $\nabla\phi = 0$ a.e. on K^ε, for some $\varepsilon > 0$ (this set is dense in $H^1_{cond,K}(\Omega)$). Indeed, for n large enough such that $K_n \subseteq K^{\varepsilon/2}$ we get that $\nabla\phi = 0$ a.e. on $K_n^{\varepsilon/2}$; hence $\phi\in H^1_{cond,K_n}(\Omega)$.

Let $\phi_n \in H^1_{cond,K_n}(\Omega)$ such that $\phi_n \longrightarrow u$ in $H^1(\Omega)$-strong. We get

$$\begin{aligned}(21)\qquad \limsup_{n\to\infty}\frac{1}{2}\int_\Omega |\nabla u_n|^2 dx - \int_{\partial\Omega} u_n\psi d\sigma &\le \lim_{n\to\infty}\frac{1}{2}\int_\Omega |\nabla\phi_n|^2 dx - \int_{\partial\Omega}\phi_n\psi d\sigma \\ &= \frac{1}{2}\int_\Omega |\nabla u|^2 dx - \int_{\partial\Omega} u\psi d\sigma.\end{aligned}$$

From (20) and (21) we get $\tilde{u} = u$ and the strong H^1-convergence $u_n \longrightarrow u$. The convergence $u_{K_n,\psi|\partial\Omega} \xrightarrow{L^2(\partial\Omega)} u_{K,\psi|\partial\Omega}$ follows from the trace theorem.

To prove assertion 2 of the theorem, namely, $w_{K_n,\psi|\partial\Omega} \xrightarrow{L^2(\partial\Omega)} w_{K,\psi|\partial\Omega}$, one has to use the following duality argument, which was already applied in [6].

Following Proposition 2.8, let v_n be the conjugate function of $w_{K_n,\psi|\partial\Omega}$ in $\Omega\setminus K_n$. Then v_n solves the following problem (set as an energy minimization):

$$\min\left\{\int_\Omega |\nabla v|^2 dx : v\in H^1_{cond,K_n}(\Omega), v = \Psi \text{ on } \partial\Omega\right\},$$

where Ψ is a primitive of ψ on $\partial\Omega$.

Note that v_n solves a problem very similar to (9), with the only difference that on the fixed boundary $\partial\Omega$, the Neumann condition is replaced with a Dirichlet one. The same proof as for the first point of this theorem can be repeated. We get

$$\nabla v_n \overset{L^2(\Omega,\mathbb{R}^2)}{\longrightarrow} \nabla v$$

and

$$\nabla v_n 1_{\Omega\setminus K_n} \overset{L^2(\Omega,\mathbb{R}^2)}{\longrightarrow} \nabla v 1_{\Omega\setminus K},$$

since $\nabla v_n = 0$ a.e. on K_n. In terms of conjugate functions, this gives

$$\nabla w_{K_n,\psi|\partial\Omega} 1_{\Omega\setminus K_n} \overset{L^2(\Omega,\mathbb{R}^2)}{\longrightarrow} w_{K,\psi|\partial\Omega} 1_{\Omega\setminus K}.$$

Applying the trace theorem for $w_{K_n,\psi|\partial\Omega}$ into a smooth neighborhood U of $\partial\Omega$, we get $w_{K_n,\psi|\partial\Omega} \overset{L^2(\partial\Omega)}{\longrightarrow} w_{K,\psi|\partial\Omega}$. □

In the next proposition we prove that condition M_2 is satisfied, provided that the number of connected components of K_n and K are uniformly bounded (we denote by $\sharp K$ the number of connected compoenents of K).

PROPOSITION 4.2. *Let $K \subseteq \Omega, K_n \overset{H}{\longrightarrow} K$, $\sharp K_n \leq M$. Then the second Mosco condition holds for $H^1_{cond,K_n}(\Omega)$ and $H^1_{cond,K}(\Omega)$.*

Proof. Let $\phi_n \in H^1_{cond,K_n}(\Omega)$ such that $\phi_n \rightharpoonup \phi$ in $H^1(\Omega)$-weak. Let K_α be a connected component of K. We observe first that ϕ is q.e. constant on K_α. Indeed, from the Hausdorff convergence, K_α can be written $K_\alpha = \cup_{i=1}^M K^i_\alpha$, where (up to subsequences) $K^i_\alpha = H - \lim_{n\to\infty} K^i_n$, where K^i_n are connected components of K_n. In our notation, some of these components can be chosen empty sets. Following Lemma 2.3 (see also [19] and [6]) we get ϕ q.e. constant on K^i_α, and following Lemma 2.1 we get ϕ q.e. constant on K_α.

In order to prove that $\phi \in H^1_{cond,K}(\Omega)$ we use Hedberg's result [13], which asserts that ϕ can be approached strongly in $H^1(\Omega)$ by a sequence of functions which for every α are constant q.e. (hence a.e.) on a neighborhood of K_α. □

In what follows we give several situations when stability occurs. To simplify the notation, for every compact $K \subseteq \Omega$ we denote by G_K the connected component of $\Omega \setminus K$ which "touches" $\partial\Omega$.

THEOREM 4.3. *Let ψ_1, ψ_2 be as in Theorem 3.9. Suppose F is a compact subset of Ω and that (K_n) is a family of compact subsets of F such that*

$$\exists M > 0 \quad \forall n \in \mathbb{N} \quad \sharp K_n \leq M.$$

If either

$$u_{K_n,\psi_i|\partial\Omega} \overset{L^2(\partial\Omega)}{\longrightarrow} u_i, \quad i = 1, 2,$$

or

$$w_{K_n,\psi|\partial\Omega} \overset{L^2(\partial\Omega)}{\longrightarrow} w_i, \quad i = 1, 2,$$

holds, then there exists a compact set $K \subseteq \Omega$ such that we have $\sharp K \leq M$ and a subsequence $K_{n_k} \overset{H}{\to} K$, and that for $i = 1, 2$, we have $u_i = u_{\psi_i,K|\partial\Omega}$ (respectively, $w_i = w_{\psi_i,K|\partial\Omega}$).

If for another subsequence, we have $K_{n'_k} \overset{H}{\to} \tilde{K}$, *then* $G_K = G_{\tilde{K}}$ *q.e.*

Proof. By the compactness of the Hausdorff convergence we can write $K_{n_k} \xrightarrow{H} K$, with $K \subseteq F$, and $\sharp K \leq M$. Using Theorem 4.1 and Proposition 4.2 we get $u_{K_{n_k},\psi_i|\partial\Omega} \overset{L^2(\partial\Omega)}{\longrightarrow} u_{K,\psi_i|\partial\Omega}$ (and the same for w). Hence $u_i = u_{K,\psi_i|\partial\Omega}$ (and the same for w).

If for another subsequence we have $K_{n'_k} \overset{H}{\to} \tilde{K}$, we use the uniqueness theorem, Theorem 3.9, and get the conclusion. □

Remark 4.4. Theorem 4.3 is not a standard stability result, as one might expect. It is rather a description of possible situations regarding stability. Nevertheless, under mild assumptions on K, this becomes a usual sequential stability result.

In the following, K, K_n, and $\tilde{K}$ are as in Theorem 4.3.

COROLLARY 4.5. *Let* K *be such that* $\sharp K = M$, $\Omega \setminus K$ *is connected, and* $\overset{\circ}{K} = \emptyset$. *Then* $\tilde{K} = K$ *and the hole sequence* K_n *converges into the Hausdorff metric to* K.

Proof. From Theorem 4.3,

$$G_{\tilde{K}} = G_K = \Omega \setminus K \text{ q.e.} \tag{22}$$

Moreover, thanks to the hypothesis $\sharp K = M$, K has M connected components and each one has a positive diameter. Consequently, equality (22) holds everywhere. From the definition of $G_{\tilde{K}}$, relation (22) implies $\tilde{K} \subseteq K$. The converse is also true since $K = \partial K = \partial G_{\tilde{K}} \setminus \partial\Omega \subseteq \partial\tilde{K} \subseteq \tilde{K}$. □

Example 4.6. In order to give geometric intuition on the sense in which Theorem 4.3 should be understood, we give in Figures 1 and 2 two examples of cracks and cavities which give close measurements.

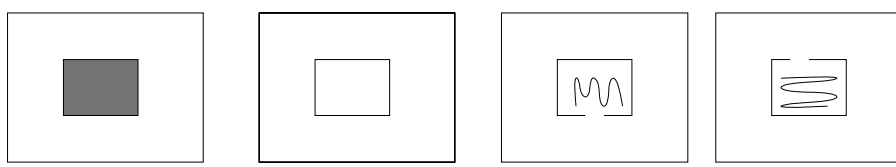

FIG. 1. *Four compacts giving "close" measures: Cavity* (a) *gives the same measure as crack* (b)*; asymptotically, cracks* (c) *and* (d) *give the same measures (as soon as the apertures of the rectangular cracks go to zero).*

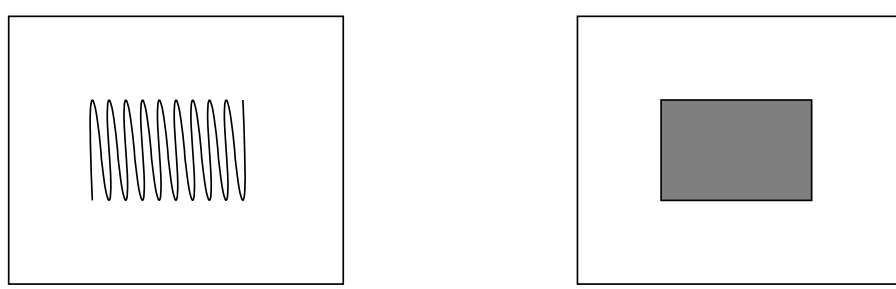

FIG. 2. *Two compacts giving "close" measures; on the left a "long and dense" curve and on the right a cavity.*

We give an example in which stability comes from the structure of K and requires that all K_n satisfy a uniform identifiability assumption. From a practical point of view this result might be helpful if all cracks do not have interior points, and locally their diameters are beyond a detectability level.

DEFINITION 4.7. *Let $\varepsilon > 0$. A compact set K is ε-detectable if for every $x \in K$, the diameter of the connected component of K containing x is greater than or equal to ε. A compact set $K \subseteq \Omega$ is called ε-stable if*

(23)
$$H^1_{cond,K}(\Omega) = \{u \in H^1(\Omega) \forall x \in K, \exists U_x \text{ continuum, diam } (U_x) \geq \varepsilon \text{ s.t. } u = c_x \text{ q.e. on } U_x\}.$$

To simplify, let us denote the space on the right-hand side as $H^1_\varepsilon(\Omega)$. Notice that if K is arbitrary, equality (23) does not occur; e.g., if K has an interior point. Take, for example, $\Omega = [-2,2] \times [-2,2]$, $K = [0,1] \times [0,1]$, and $u(x,y) = x$.

An example of ε-stable K is $K = \{\bigcup_{n=1}^{\infty} \{\frac{1}{n}\} \times [0,1]\} \bigcup \{0\} \times [0,1]$. Indeed, continua on lines are intervals. Hence on each vertical segment a function $u \in H^1_\varepsilon(\Omega)$ can take only a finite number of values. Using Lemma 2.1 it follows that u is q.e. constant on each vertical segment. Using the same argument as in Example 3.6 we get $u \in H^1_{cond,K}(\Omega)$.

PROPOSITION 4.8. *Suppose there exists $\varepsilon > 0$ such that K_n are ε-detectable. The conclusion of Theorem* 4.3 *holds, provided that K and $\tilde{K}$ are ε-stable.*

5. Application: Approximation by finite elements. We prove in this section that the unknown defects can be formally approached using finite elements, regardless of their regularity. Basically, this is one of the main applications of the stability result established in the previous section. All previous stability results, which give finer estimates for the stability, assume a priori the smoothness of the defects and suppose known their (uniform) Lipschitz character. In this regard, Theorem 4.3 does not give a quantitative estimate for the stability, but provides a rigorous justification of the approach by finite elements. For a similar argument related to shape optimization problems with homogeneous Dirichlet conditions on the free boundaries, we refer to [8].

We discuss both problems (3) and (4). It will be quite surprising to notice that, formally, problem (4) is easier to treat from a numerical point of view, since a unique mesh can be used at each step for both capturing the defect Γ and computing the finite element approximation of the solution. This is also the case for homogeneous Dirichlet problems [8]. For problem (3) the defect Γ is captured on a mesh, while the finite element approximation of the solution needs a refinement of the mesh. This is precisely what is done in practice.

Let F be "the design region," i.e., a subdomain of Ω containing all defects. Let $(\mathcal{T}_h)_h$ denote a family of triangulations of Ω made of elements which are triangles (the extension to quadrilaterals is standard). The maximal size of elements is the discretization parameter, denoted by h. In addition, we assume that each triangulation satisfies the usual admissibility assumptions, i.e., the intersection of two different elements is either empty, a vertex, or a whole edge, and $\mathcal{T}_h$ is assumed to be "regular," i.e., the ratio between the diameter of any element $K \in \mathcal{T}_h$ and the diameter of its largest inscribed ball is bounded by a constant σ independent of K and h.

Let $K^* \subseteq F$ be a defect such that $\sharp K^* \leq M$ which gives the measures w_1, w_2 corresponding to the input fluxes, ψ_1, ψ_2, respectively. We solve the finite dimensional

problem

$$\min_{\substack{K\subset\mathcal{T}_h\cap F\\ \#K\le M}} \int_{\partial\Omega} |w_{K,\psi_1}-w_1|^2\,d\sigma + \int_{\partial\Omega} |w_{K,\psi_2}-w_2|^2\,d\sigma, \tag{24}$$

which admits at least one solution, denoted K_h. The following convergence result holds.

THEOREM 5.1. *For $h\to 0$, there exists a subsequence such that*

$$K_h \overset{H}{\to} \tilde{K} \quad \textit{and} \quad G_{K^*} = G_{\tilde{K}}.$$

Proof. By compactness we can extract a subsequence $K_h \overset{H}{\to} \tilde{K}$. First, we notice that

$$\int_{\partial\Omega} |w_{K_h,\psi_1}-w_1|^2 + \int_{\partial\Omega} |w_{K_h,\psi_2}-w_2|^2 \longrightarrow 0 \text{ as } h\longrightarrow 0. \tag{25}$$

Indeed, we define

$$K_h^* = \bigcup_{\substack{T\in\mathcal{T}_h\cap F\\ \overline{T}\cap K^*\neq\emptyset}} \overline{T}. \tag{26}$$

Then, $d(K_h^*, K^*)\le h$, $\#K_h^*\le M$, and $K_h^*\subset F$. Moreover, $K_h^*\overset{H}{\to} K^*$, and following the stability result for the direct problem [6], we have

$$\int_{\partial\Omega} |w_{K_h,\psi_1}-w_1|^2 + \int_{\partial\Omega} |w_{K_h,\psi_2}-w_2|^2 \longrightarrow 0 \text{ as } h\longrightarrow 0.$$

By the choice of K_h in (24) we get (25). Second, since (25) holds, we use Theorem 4.3 and get $G_{K^*}=G_{\tilde{K}}$, which means that K_h is an approximation of K^*. ∎

Remark 5.2. Notice that in the least square approximation (problem (24)), the continuous solutions $w_{K,\psi_1}, w_{K,\psi_2}$ are chosen to be compared to the measures w_1, w_2. In practice, instead of w_{K_h,ψ_i}, we use a finite element approximation, say $w^j_{K_h,\psi_i}$, obtained on a finer mesh. This approximation can be chosen such that $\|w^j_{K_h,\psi_i} - w_{K_h,\psi_i}\|_{L^2(\partial\Omega)}\le j$, $j<h$. Consequently, as h goes to zero, the result of Theorem 5.1 still holds.

In what follows we consider the approximation problem for the perfectly conducting case. Let $K^*\subseteq F$ be a defect such that $\sharp K^*\le M$ which gives the measures u_1, u_2 corresponding to the input fluxes ψ_1, ψ_2, respectively. We solve the following finite dimensional problem:

$$\min_{\substack{K\subset\mathcal{T}_h\cap F\\ \#K\le M}} \int_{\partial\Omega} |u^h_{K,\psi_1}-u_1|^2\,d\sigma + \int_{\partial\Omega} |u^h_{K,\psi_2}-u_2|^2\,d\sigma. \tag{27}$$

THEOREM 5.3. *For $h\longrightarrow 0$, there exists a subsequence such that*

$$K_h \overset{H}{\to} \tilde{K} \quad \textit{and} \quad G_{K^*} = G_{\tilde{K}}.$$

Proof. By compactness, we can extract a subsequence $K_h \overset{H}{\to} \tilde{K}$. We prove that for the continuous solutions we have

$$\int_{\partial\Omega} |u_{K_h,\psi_1} - u_1|^2 \, d\sigma + \int_{\partial\Omega} |u_{K_h,\psi_2} - u_2|^2 \, d\sigma \longrightarrow 0 \text{ as } h \longrightarrow 0. \tag{28}$$

For $i = 1, 2$ we have that

$$\int_{\partial\Omega} |u_{K_h,\psi_i} - u_i|^2 \, d\sigma \leq 2 \left(\int_{\partial\Omega} |u^h_{K_h,\psi_i} - u_i|^2 \, d\sigma + \int_{\partial\Omega} |u_{K_h,\psi_i} - u^h_{K_h,\psi_i}|^2 \, d\sigma \right).$$

We construct K_h^* as in (26). Then, for $i = 1, 2$,

$$\begin{aligned} \int_{\partial\Omega} |u^h_{K_h,\psi_i} - u_i|^2 \, d\sigma &\leq \int_{\partial\Omega} |u^h_{K_h^*,\psi_i} - u_i|^2 \, d\sigma \\ &\leq 2 \left(\int_{\partial\Omega} |u_{K_h^*,\psi_i} - u_i|^2 \, d\sigma + \int_{\partial\Omega} |u^h_{K_h^*,\psi_i} - u_{K_h^*,\psi_i}|^2 \, d\sigma \right). \end{aligned}$$

From the stability of the direct problem (see [6]) we get

$$\int_{\partial\Omega} |u_{K_h^*,\psi_i} - u_i|^2 \, d\sigma \longrightarrow 0 \text{ as } h \longrightarrow 0.$$

In order to get (28) we have to prove that

$$\int_{\partial\Omega} |u_{K_h,\psi_i} - u^h_{K_h,\psi_i}|^2 \, d\sigma + \int_{\partial\Omega} |u_{K_h^*,\psi_i} - u^h_{K_h^*,\psi_i}|^2 \, d\sigma \longrightarrow 0 \text{ as } h \longrightarrow 0.$$

In fact, it is enough to prove that if

$$K_h \overset{H}{\to} \tilde{K}, \ \#K_h \leq M, \ K_h \subset F,$$

then $u^h_{K_h,\psi_i} \overset{L^2(\partial\Omega)}{\to} u_{\tilde{K},\psi_i}$. This is a consequence of the Mosco convergence of the spaces

$$V_h = \left\{ u \in C(\overline{\Omega}), \ u \in P_1(T) \, \forall T \in \mathcal{T}_h, u = \text{constant on each connected component of } K_h \right\}$$

to $H^1_{cond,\tilde{K}}(\Omega)$.

Indeed, let $v_h \in V_h$, $v_h \overset{H^1(\Omega)}{\rightharpoonup} u$. Following [6], $u \in H^1(\Omega)$, u is constant on each connected component of $\tilde{K}$, and hence $u \in H^1_{cond,\tilde{K}}(\Omega)$. Now let $u \in H^1_{cond,\tilde{K}}(\Omega)$. Applying Hedberg's result [13] locally in a neighborhood of each connected component of $\tilde{K}$, for every $\epsilon > 0$, there exists $\delta > 0$ and $u_\delta \in H^1_{cond,\overline{\tilde{K}^\delta}}(\Omega) \cap C^\infty(\overline{\Omega})$, such that $|u_\delta - u|_{H^1(\Omega)} < \epsilon$. Then, $u_\delta \in H^1_{cond,K_h}(\Omega)$ for h small enough. Thus, for the finite element approximation $u^h_\delta \in V_h$ we have the error estimate $|u_\delta - u^h_\delta| \leq h \|u_\delta\|_{H^2(\Omega)}$. By a diagonal procedure, we construct $u^h_{\delta_h} \in V_h$, and $u^h_{\delta_h} \overset{H^1(\Omega)}{\to} u$. ∎

Remark 5.4. In Theorem 5.3, we have the approximation of $u_{K^*,\psi}$ obtained on $\mathcal{T}_h$, which means that no refinement is necessary. This is mainly due to the Dirichlet-type boundary conditions, which are easier to handle than the Neumann ones.

6. Appendix.

Proof of Example 3.7. We start with the following simple result.

LEMMA 6.1. *Let $(c_n)_n$ and $(r_n)_n$ be two sequences of real numbers such that $\forall\, n$, $0 < r_n \le c_n$, $(r_n)_n$ is decreasing, and $(c_n)_n$ converges to zero. Then, there exists a subsequence $(c_{n_k})_{n_k}$ such that $|c_{n_k} - c_{n_k+1}| \ge \frac{r_{n_k} - r_{n_k+1}}{2}$.*

Proof. Assume for contradiction that there exists n_0 such that

$$\forall n \ge n_0, \quad |c_n - c_{n+1}| < \frac{r_n - r_{n+1}}{2}.$$

Then, $\forall\, k > n_0$, we have

$$|c_{n_0} - c_k| < \frac{r_{n_0} - r_k}{2},$$

which yields, when k goes to $+\infty$, $c_{n_0} \le \frac{r_{n_0}}{2}$, in contradiction with the hypothesis of the lemma. □

Now choose r_n as in Example 3.7. Then $\overline{\Omega \setminus K} = \overline{\Omega}$ and take $\phi \in C(\overline{\Omega}) \cap H^1_{cond,K\cap B_{0,r}}(\Omega)$ such that $\phi(0) = 0$. Suppose for contradiction that 0 is not conductive. Then there exists $C, \delta > 0$ such that $\phi(x) \ge C|x|$ for $x \in K \cap B_{0,\delta}$. Since $\phi \in H^1_{cond,K\cap B_{0,r}}(\Omega)$ we have that ϕ is constant on every vertical line. Let us denote by c_n this constant. Writing $\phi(b_n, r_n) \ge C\sqrt{b_n^2 + r_n^2}$ we get that $c_n \ge \sqrt{b_n^2 + r_n^2} \ge r_n$.

We prove that the gradient of ϕ has an infinite L^2-norm, and this will contradict the hypothesis $\phi \in H^1_{cond,K\cap B_{0,r}}(\Omega)$. We have the following:

$$\begin{aligned}
\int_\Omega |\nabla\phi|^2 dx &\ge \sum_{n_0}^{\infty} \int_{[b_{n+1}, b_n]\times r_{n+1}} |\nabla\phi|^2 dx \\
&\ge \sum_{n_0}^{\infty} \int_{[b_{n+1}, b_n]\times r_{n+1}} \Big(\frac{c_{n+1} - c_n}{b_n - b_{n+1}}\Big)^2 dx \\
&\ge \sum_{n_0}^{\infty} \frac{r_{n+1}}{b_n - b_{n+1}} (c_{n+1} - c_n)^2.
\end{aligned}$$

Using Lemma 6.1, there exists a subsequence such that

$$\frac{r_{n_k+1}}{b_{n_k} - b_{n_k+1}} (c_{n_k+1} - c_{n_k})^2 \ge \frac{r_{n_k+1}}{4(b_{n_k} - b_{n_k+1})} (r_{n_k+1} - r_{n_k})^2.$$

We observe from the definition of b_n and r_n that $b_n - b_{n+1} = r_{n+1}(r_{n+1} - r_n)^2$; therefore the series above cannot converge since its general term does not converge to zero.

Proof of Proposition 3.8. Let K be a compact subset of Ω such that $\Omega \setminus K$ is connected, and let $x \in \partial(\Omega \setminus K)$ such that $x \in U_x \subseteq K$, where U_x is a continuum of positive diameter. Following Proposition 3.5, in order to prove that x is conductive for $\Omega \setminus K$ it is enough to prove the existence of a continuum of positive diameter F such that $x \in F \subseteq \partial(\Omega \setminus K)$.

One can mimic the proof of the second case in the proof of Theorem 3.9. The only difference is that a curve γ joining x to $\partial\Omega$ and lying in $\Omega \setminus K$ may not exist. Nevertheless, there exists a sequence of points $y_n \in \Omega \setminus K$, $y_n \to x$ and smooth curves γ_n joining y_n to a point of the $\partial\Omega$ and lying in $\Omega \setminus K$. Choosing ε_n as in Theorem 3.9 and choosing y_n such that $|x - y_n| < \varepsilon_n/2$, we define

$$t_n = \min\{t \in [0,1], \gamma_n(t) \in P_n\}. \tag{29}$$

We observe that z_n is well defined, but we do not have necessarily $z_n \to x$. Nevertheless, $\gamma_n([0,t_n])$ is a continuum containing y_n and z_n, and lying in $(\Omega \setminus K) \cap \overline{K}^{\varepsilon_n}$. Two possibilities occur: either for a subsequence we have $z_n \to x$ and apply the same argument as in Theorem 3.9, or $|z_n - x| \geq \alpha > 0$ and any Hausdorff limit of $\gamma_n([0,t_n])$ is a continuum of diameter greater than or equal to α contained in $\partial(\Omega \setminus K)$ and passing through x.

Example 6.2 (example of a Cantor set which is uniquely identifiable by two boundary measurements). Let $\Omega = B(0,2)$ and define

$$F_1 = [0,1] \times \{0\},$$

$$F_2 = \left\{ \left[0, \frac{1}{2} - \varepsilon_1\right] \cup \left[\frac{1}{2} + \varepsilon_1, 1\right] \right\} \times \{0\},$$

$$F_3 = \left\{ \left[0, \frac{1}{2}\left(\frac{1}{2} - \varepsilon_1\right) - \varepsilon_2\right] \cup \left[\frac{1}{2}\left(\frac{1}{2} - \varepsilon_1\right) + \varepsilon_2, \frac{1}{2} - \varepsilon_1\right] \right.$$
$$\left. \cup \left[\frac{1}{2} + \varepsilon_1, \frac{1}{2}\left(\frac{1}{2} + \varepsilon_1 + 1\right) - \varepsilon_2\right] \cup \left[\frac{1}{2}\left(\frac{1}{2} + \varepsilon_1 + 1\right) + \varepsilon_2, 1\right] \right\} \times \{0\},$$

etc. Let $(c_n)_n$ be an increasing sequence of positive numbers converging to 1. The value of ε_1 is chosen such that $\forall \varphi \in H^1_{cond,F_1}(\Omega \setminus F_1) \cap C(\overline{\Omega})$, $\varphi(0,0) = 0, \int_\Omega |\nabla \varphi|^2 dx \leq 1$ we have for every $t \in [0,1]$ $\int_0^t \varphi^2(s,0) ds \leq c_1 t^4$. Such a constant ε_1 exists; if it does not, for a sequence φ_k corresponding to $\varepsilon_1^k \to 0$ we would have

$$\int_0^{t_k} \varphi_k^2(s,0) ds > c_1 t_k^4.$$

Assuming $t_k \to t$, we clearly have $t \geq 1/2$ and for the limit function we get (by the continuity of the trace operator) $\int_0^t \varphi^2(s,0) ds \geq c_1 t^4$. But from Lemma 2.1 we have $\varphi = 0$ on $[0,1] \times \{0\}$, and hence we get a contradiction.

Note that ε_1 can be chosen such that

$$\forall \varphi \in H^1_{cond,F_1}(\Omega \setminus F_1) \cap C(\overline{\Omega}),\ \varphi(1,0) = 0, \int_\Omega |\nabla \varphi|^2 dx \leq 1, \tag{30}$$

we have

$$\forall t \in [0,1], \int_t^1 \varphi^2(s,0) ds \leq c_1 t^4. \tag{31}$$

As well, we define $\varepsilon_2 > 0$ such that $\forall \varphi \in H^1_{cond,F_1}(\Omega \setminus F_1) \cap C(\Omega)$, $\varphi(0,0) = 0, \int_\Omega |\nabla \varphi|^2 dx \leq 1$, we have for every $t \in [0,1]$ $\int_0^t \varphi^2(s,0) ds \leq c_2 t^4$. Note that ε_2 can be chosen such that similar relations as in (30)–(31) hold for the points $(1/2 - \varepsilon_1, 0)$, $(1,0)$ in the "left" direction and for $(1/2 + \varepsilon_1, 0)$ in the "right" direction.

By induction, we define F_n and set $F = \cap_{n \in \mathbb{N}} F_n$, which is a totally disconnected Cantor set. Since $\cup_{n \in \mathbb{N}} \partial F_n$ is dense in F, it is enough to prove that F is conductive at every point of ∂F_n. So fix n and choose $x_0 \in \partial F_n$. There are two possibilities: either x_0 is a left end point of an interval of F_n or a right end point. Thanks to the construction of ε_k, both situations are treated in the same way. If it is a left end point, the proof is similar to the conductivity of 0 that we give in the following.

Let $u \in H^1_{cond,F}(\Omega \setminus F) \cap C(\overline{\Omega})$. There exists $\varphi_\varepsilon \in H^1(\Omega)$ such that $\nabla\varphi_\varepsilon = 0$ on F^ε, $\varphi_\varepsilon \to u$ in $H^1(\Omega)$. Moreover, the functions φ_ε can be chosen continuous and may be translated by a constant such that $\varphi_\varepsilon(0) = 0$. It is clear that, even after translations, $\nabla\varphi_\varepsilon \to \nabla u$ strongly in L^2. Since for every $\varepsilon > 0$ we have for n large enough $F_n \subseteq F^\varepsilon$ we have from the previous construction that for every $t \in [0,1]$ $\int_0^t \varphi_\varepsilon^2(s,0)ds \leq (M+1)t^4$, where $M = \limsup_{n\to\infty} \int_\Omega |\nabla\varphi_n|^2 dx$. This implies (for a subsequence) that φ_ε converges weakly in $H^1(\Omega)$ to $\tilde{u} = u + c$, where c is a constant. The continuity of the trace operator gives

$$\forall t \in [0,1],\ \int_0^t \tilde{u}^2(s,0)ds \leq (M+1)t^4, \tag{32}$$

and the continuity of $\tilde{u}$ implies $\tilde{u}(0,0) = 0$, hence $c = 0$, and thus u satisfies (32). Consequently $\liminf_{t\to 0} \frac{|u(t,0)|}{t} = 0$, and hence $(0,0)$ is conductive; otherwise $|u(t,0)| \geq c|t|$ in a neighborhood of 0, which contradicts (32).

OPTIMAL BILINEAR CONTROL OF AN ABSTRACT SCHRÖDINGER EQUATION*

KAZUFUMI ITO† AND KARL KUNISCH‡

Abstract. Well-posedness of abstract quantum mechanical systems is considered and the existence of optimal control of such systems is proved. First order optimality systems are derived. Convergence of the monotone scheme for the solution of the optimality system is proved.

Key words. Schrödinger equation, C_0-groups, optimal control, optimality systems, monotone scheme

1. Introduction.

We consider a quantum mechanical system with internal Hamiltonian H_0 prepared in the initial state $\Psi_0(x)$, where x denotes the relevant spatial coordinate. The state $\Psi(x,t)$ satisfies the time-dependent Schrödinger equation (we set $h=1$). In the presence of an external interaction taken as an electric field, modeled by a coupling operator with amplitude $\epsilon(t) \in \mathbb{R}$ and a time-independent dipole moment operator $\hat{\mu}$, the new Hamiltonian $H_0 - \mu(t)$ gives rise to the control system

$$i\,\frac{\partial}{\partial t}\Psi(x,t) = (H_0 - \mu(t))\Psi(x,t), \quad \Psi(x,0) = \Psi_0(x), \tag{1.1}$$

where $\mu(t) = \epsilon(t)\hat{\mu}$. Here $\mu(t)$ represents a controlled Hamiltonian which can be a distributed control. The optimal control approach (see, e.g., [MT], [PDR], [TKO], [ZR]) allows us to assess the fitness of the final state $\Psi(T)$ to a prescribed goal. This is achieved through the introduction of a performance index J which is maximized. One possible choice for a cost functional is given by

$$J(\mu) = \frac{1}{2}\langle \Psi(T)|O|\Psi(T)\rangle - \frac{\alpha}{2}\int_0^T |\mu(t)|^2\,dt, \tag{1.2}$$

where $\alpha > 0$ and O is the observable operator that encodes the goal. The larger the value $\langle \Psi(T)|O|\Psi(T)\rangle$ is, the better the control objective is met. Here we used the notation $\langle \Psi(T)|O|\Psi(T)\rangle = \int_\Omega \overline{\Psi(T,x)}\,O\Psi(T,x)\,dx$. The conditions that we utilize for H_0, $\mu(\cdot)$ and O will be given in the following section. Maximization of $\langle \Psi(T)|O|\Psi(T)\rangle$ is at the price of a large laser influence $\int_0^T |\mu(t)|^2\,dt$. The optimally controlled evolution must therefore balance between the expense for the laser influence and the desire that the observable has an acceptably large value.

An alternative cost is given by

$$J(\mu) = -\frac{1}{2}\left(|\Psi(T) - \bar{\Psi}(T)|^2 + \alpha \int_0^T |\mu(t)|^2 \, dt \right),$$

where $\bar{\Psi}$ is a target state. Since $|\Psi|_{L^2} = 1$, it is equivalent to

$$J(\mu) = \mathrm{Re}\,(\Psi, \bar{\Psi}) - \frac{\alpha}{2} \int_0^T |\mu(t)|^2 \, dt. \tag{1.3}$$

In section 2 we shall establish well-posedness results for (1.1) based on a semigroup framework in a form that will facilitate the optimal control treatment. Section 3 is devoted to the precise statement of the optimal control problem, including the class of admissible control operators μ which are considered, and a proof for the existence of optimal solutions. First order necessary optimality conditions are derived in section 4. In section 5 we describe the monotone scheme for the general class of optimal problems that is considered in this paper. Well-posedness and subsequential convergence of the scheme are proved.

To point at some of the relevant literature for the problem under investigation we mention the pioneering work of Rabitz and collaborators; see, e.g., [PDR], [ZR], and the references given there. For existence of optimal controls we refer to [BP]. Differently from our semigroup approach, the work in [BP] is based on partial differential equation techniques, and requires higher regularity in time. Many important aspects of the monotone scheme for the solution of the optimality system were investigated in, e.g., [MST], [MT], [S], [TKO]. However, except for [S], which treats the case of scalar-valued controls, convergence proofs of the optimal controls and states have received little attention so far. The technique of proof in [S] and in the present work are different. While the key ingredient for the convergence proof in [S] is a convergence result in [BMS] for the convolution of a Hilbert-space valued function with a sequence of weakly convergent scalar-valued functions, our results are based on compactness arguments. This allows for finite dimensional (in space) as well as infinite dimensional (distributed) control action.

2. Well-posedness. Setting $\Psi(t,x) = \Psi_1(t,x) + \Psi_2(t,x)$ and $\Psi = (\Psi_1, \Psi_2)$, system (1.1) can equivalently be written as

$$\begin{aligned} \frac{\partial}{\partial t}\Psi_1(t,x) &= (H_0 - \mu(t))\,\Psi_2(t,x), \\ \frac{\partial}{\partial t}\Psi_2(t,x) &= -(H_0 - \mu(t))\,\Psi_1(t,x) \quad \text{for } (t,x) \in (0,T] \times \Omega. \end{aligned} \tag{2.1}$$

Here $T > 0$ and $\Omega = \mathbb{R}^n$ or Ω is a bounded subset of $\mathbb{R}^n$. The behavior of Ψ at the boundary of Ω is defined through the domain of the operator H_0. We refer to section 3 for specific examples. Throughout it is assumed that H_0 is a densely defined, self-adjoint positive semidefinite operator in a real Hilbert space H, consisting of functions defined over the domain Ω. Typically H is $L^2(\Omega)$. If H_0 satisfies the above assumptions it is necessarily closed. We define the closed linear operator A_0 in $X = H \times H$ by

$$A_0 = \begin{pmatrix} 0 & H_0 \\ -H_0 & 0 \end{pmatrix},$$

with $dom\,(A_0) = dom\,(H_0) \times dom\,(H_0)$. Note that A_0 is skew-adjoint, i.e.,

$$(A_0\Psi, \hat{\Psi}) = -(A_0\hat{\Psi}, \Psi) \text{ for all } \Psi, \hat{\Psi} \in dom\,(A_0).$$

Consequently by Stone's theorem [HP] A_0 generates a C_0-group $S(t)$ on X satisfying $|S(t)\Psi|_X = |\Psi|_X$ for all $\Psi \in X$ and $t \geq 0$. Let

$$V = dom\,(H_0^{\frac{1}{2}}) \quad \text{and} \quad \mathcal{V} = V \times V.$$

Then $H_0 \in \mathcal{L}(V, V^*)$ and thus $A_0 \in \mathcal{L}(\mathcal{V}, \mathcal{V}^*)$, where

$$V^* \quad \text{and} \quad \mathcal{V}^* = V^* \times V^*$$

denote the dual space of V and $\mathcal{V}$, respectively, with H and X as pivot spaces. V is equipped with

$$|\phi|_V^2 = \langle H_0\phi, \phi\rangle_{V^*\times V} + |\phi|_H^2$$

as norm. Then the restriction of $S(t)$ to $\mathcal{V}$ is again a C_0-group. The dual $S^*(-t)$ is the extension of $S(t)$ to $\mathcal{V}^*$ and forms a C_0-group on $\mathcal{V}^*$. Moreover, for the extension group on $\mathcal{V}^*$ the domain of the generator is given by $dom_{\mathcal{V}^*}(A_0) = \mathcal{V}^*$.

Suppose that $\mu(t) \in \mathcal{L}(H)$ is self-adjoint for almost every $t \in (0, T)$ and define

$$B(t) = \begin{pmatrix} 0 & \mu(t) \\ -\mu(t) & 0 \end{pmatrix}.$$

In the context of an external interaction with an electric field, as mentioned in the introduction, $\mu(t) = \epsilon(t)\hat{\mu}$, where ϵ denotes a scalar-valued amplitude and $\hat{\mu} = \hat{\mu}(x)$ is a multiplication operator representing the dipole moment [MT], [MST], [ZR].

By a fixed point argument it can be argued that for every $T > 0$, $\mu \in L^2(0, T; \mathcal{L}(H))$, and $\Psi_0 \in X$ there exists a unique mild solution $\Psi \in C(0, T; X)$ to (2.1) satisfying

$$\Psi(t) = S(t)\Psi_0 - \int_0^t S(t-s)\, B(s)\Psi(s)\, ds \quad \text{for} \quad t \in [0, T]. \tag{2.2}$$

Here $C(0, T; X)$ stands for $C([0, T]; X)$. Moreover, if $\hat{\Psi} \in C(0, T; X)$ denotes the mild solution to (2.1) corresponding to $(\hat{\Psi}_0, \hat{\mu}) \in X \times L^2(0, T; H)$, then by Gronwall's inequality

$$|\Psi - \hat{\Psi}|_{C(0,T;X)} \leq \tilde{M} \left(|\Psi_0 - \hat{\Psi}_0|_X + \int_0^T |\mu(t) - \hat{\mu}(t)|_{\mathcal{L}(H)}\, dt \right), \tag{2.3}$$

for a constant $\tilde{M}$ depending continuously on $|\mu|_{L^1(0,T;\mathcal{L}(H))}$ and $|\Psi_0|_X$.

THEOREM 2.1. *If $\Psi_0 \in \mathcal{V}$ and $\mu \in L^2(0, T; \mathcal{L}(V) \cap \mathcal{L}(H))$, then the mild solution $\Psi \in C(0, T; X)$ to (2.2) satisfies*

$$\Psi(t) \in H^1(0, T; \mathcal{V}^*) \cap C(0, T; \mathcal{V})$$

and

$$\frac{d}{dt}\Psi(t) = (A_0 - B(t))\Psi(t) \text{ a.e. in } (0, T).$$

Moreover $|\Psi(t)|_X = |\Psi_0|_X$ *for all* $t \in [0,T]$*;*

$$|\Psi(t)|_{\mathcal{V}} \le K_1 \exp\left(K_2 \int_0^t |\mu(s)|_{\mathcal{L}(V)}\, ds\right) |\Psi_0|_{\mathcal{V}}$$

for constants K_i *independent of* μ *and* Ψ_0*, and for some* M_1 *depending continuously on its arguments*

$$\left|\frac{d}{dt}\Psi(t)\right|_{L^2(0,T;\mathcal{V}^*)} \le M_1\left(|\mu|_{L^2(0,T;\mathcal{L}(\mathcal{V})\cap\mathcal{L}(H))}, |\Psi_0|_{\mathcal{V}}\right). \tag{2.4}$$

Proof. Consider

$$A_0\Psi(t) = S(t)A_0\Psi_0 - \int_0^t S(t-s)\, A_0 B(s)\Psi(s)\, ds \text{ in } \mathcal{V}^*. \tag{2.5}$$

Adding this equation to (2.2) we find the a priori estimate

$$|\Psi(t)|_{\mathcal{V}} \le K_1|\Psi_0|_{\mathcal{V}} + K_2 \int_0^t |B(s)|_{\mathcal{L}(\mathcal{V})}|\Psi(s)|_{\mathcal{V}}\, ds$$

for embedding constants K_1, K_2. By Gronwall's inequality we have

$$|\Psi(t)|_{\mathcal{V}} \le K_1|\Psi_0|_{\mathcal{V}} \exp\left(K_2 \int_0^t |\mu(s)|_{\mathcal{L}(V)}\, ds\right) \text{ for } t \in (0,T).$$

This estimate allows us to verify existence of a solution to (2.5) in $C(0,T;\mathcal{V})$, which coincides with the solution to (2.2). By construction we have that $\Psi \in C(0,T; dom_{\mathcal{V}^*}(A_0))$. It follows with standard arguments (see, e.g., [P, p. 107]) applied to (2.2) that Ψ is differentiable almost everywhere in $(0,T)$ and that

$$\frac{d}{dt}\Psi(t) = A_0\Psi(t) - B(t)\Psi(t) \text{ in } \mathcal{V}^* \text{ for a.e. in } (0,T).$$

Hence $\Psi \in H^1(0,T;X) \cap C(0,T;\mathcal{V})$. In fact we have

$$\left|\frac{d}{dt}\Psi\right|_{L^2(0,T;\mathcal{V}^*)} \le K(|\Psi|_{L^2(0,T;\mathcal{V})} + |\mu|_{L^2(0,T;\mathcal{L}(H))}|\Psi|_{C(0,T;H)}),$$

which implies (2.4). Since

$$\frac{1}{2}\frac{d}{dt}|\Psi(t)|_X^2 = \left\langle \frac{d}{dt}\Psi(t), \Psi(t)\right\rangle_{\mathcal{V}^*,\mathcal{V}} = \langle (A_0 - B(t))\,\Psi(t), \Psi(t)\rangle_{\mathcal{V}^*,\mathcal{V}} = 0$$

for a.e. $t \in (0,T)$, it follows that $|\Psi(t)|_X = |\Psi_0|_X$ for all $t \in [0,T]$. □

3. Existence of an optimal solution. In this section we provide sufficient conditions for the existence of a solution to

$$\begin{cases} \max\, J(\mu) \text{ over } \mu \in L^2(0,T;U) \\ \text{subject to (2.2),} \end{cases} \tag{3.1}$$

where $J(\mu) = \frac{1}{2}\langle\Psi(T)|O|\Psi(T)\rangle - \frac{\alpha}{2}\int_0^T |\mu(t)|^2\, dt$, with $O \in \mathcal{L}(X)\cap\mathcal{L}(\mathcal{V})$ a self-adjoint positive definite operator. Here $\langle\Psi(T)|O|\Psi(T)\rangle$ stands for $(\Psi(T), O\Psi(T))_X$, with $(\cdot,\cdot)_X$ denoting the inner product in X.

Here U is a closed Hilbert space continuously embedded in $\{\mu \in \mathcal{L}(H) \cap \mathcal{L}(V) : \mu \text{ is self-adjoint}\}$. We assume that there exists a closed subspace $H_1 \subset H$ such that for $X_1 = H_1 \times H_1$ we have

$$\mathcal{V} \cap X_1 \text{ is compactly embedded into } X \tag{3.2}$$

and

$$|\Psi|_{L^2(0,T;\mathcal{V}\cap X_1)} \leq M\,(|\Psi_0|_{\mathcal{V}\cap X_1},\, |\mu|_{L^2(0,T;U)}), \tag{3.3}$$

where M depends continuously on its arguments, and Ψ denotes the solution to (2.2). Since

$$J(\mu) \to -\infty \text{ as } |\mu|_{L^2(0,T;U)} \to \infty,$$

there exists a maximizing sequence $\{\mu_n\}$ to (3.1), i.e.,

$$\lim_{n\to\infty} J(\mu_n) = \sup_{\mu\in L^2(0,T;U)} J(\mu) \quad \text{and} \quad |\mu_n|_{L^2(0,T;U)} \leq K,$$

for some K independent of n. Hence there exists a subsequence of $\{\mu_n\}$ denoted by the same symbol and $\bar{\mu} \in L^2(0,T;U)$ such that

$$\mu_n \to \bar{\mu} \text{ weakly in } L^2(0,T;U). \tag{3.4}$$

By (2.4) and (3.3) the sequence $\{\Psi_n\}$ is bounded in $L^2(0,T;X_1\cap\mathcal{V})$ and the sequence $\{\frac{d}{dt}\Psi_n\}$ is bounded in $L^2(0,T;\mathcal{V}^*)$, where $\Psi_n = \Psi(\mu_n)$ denotes the solution to (2.2) with μ replaced by μ_n. By Aubin's lemma, e.g., [CF], there exists $\bar{\Psi} \in H^1(0,T;\mathcal{V}^*)\cap L^2(0,T;\mathcal{V}\cap X_1)$ such that for a further subsequence

$$\Psi_n \to \bar{\Psi} \text{ strongly in } L^2(0,T;X) \tag{3.5}$$

and weakly in $L^2(0,T;\mathcal{V})$. For φ and ψ in X the mapping $B \to (B\varphi,\psi)_X, B \in U$, defines a bounded linear functional in U. Hence by the Riesz representation theorem there exists $F = F(\varphi,\psi) \in U$ such that

$$(B\varphi,\psi)_X = (F(\varphi,\psi),\mu)_U \text{ for all } \mu \in U, \text{ where } B = \begin{pmatrix} 0 & \mu \\ -\mu & 0 \end{pmatrix}. \tag{3.6}$$

Note that $F : X \times X \to U$ is a continuous, bilinear mapping satisfying

$$F(\varphi,\psi) = -F(\psi,\varphi).$$

Moreover, if $\psi_n \to \psi$ strongly in $L^2(0,T;X)$ and $\varphi_n \to \varphi$ strongly in $C(0,T;X)$ we have

$$F(\varphi_n,\psi_n) \to F(\varphi,\psi) \text{ in } L^2(0,T;U). \tag{3.7}$$

Taking the inner product in $L^2(0,T;X)$ of

$$\Psi_n(t) = S(t)\Psi_0 - \int_0^t S(t-s)\,B_n(s)\,\Psi_n(s)\,ds$$

with an arbitrary $\Phi \in L^2(0,T;X)$ implies that

$$\int_0^T (\Psi_n(t),\Phi(t))_X\,dt = \int_0^T (S(t)\Psi_0,\Phi(t))_X\,dt + \int_0^T \left(F\left(\int_\cdot^T S^*(t-\cdot)\Phi(t)\,dt,\Psi_n\right),B_n\right)_U ds.$$

From (3.4), (3.5), and (3.7) we deduce that

$$\begin{aligned}\int_0^T (\Psi(t),\Phi(t))_X\,dt &= \int_0^T (S(t)\Psi_0,\Phi(t))_X\,dt \\ &\quad + \int_0^T \left(F\left(\int_\cdot^T S^*(t-\cdot)\Phi(t)\,dt,\Psi\right),B\right)_U ds \\ &= \int_0^T (S(t)\Psi_0,\Phi(t))_X\,dt \\ &\quad - \int_0^T \left(\int_0^t S(t-s)\,B(s)\,\Psi(s)\,ds,\Phi(t)\right)_X dt.\end{aligned}$$

Since Φ was arbitrary we find

$$\bar\Psi(t) = S(t)\Psi_0 - \int_0^t S(t-s)\,\bar B(s)\,\bar\Psi(s)\,ds,$$

and thus $\bar\Psi$ is the unique solution to (2.2) with μ replaced by $\bar\mu$.

We next verify that

$$\Psi_n(T) \to \bar\Psi(T) \text{ strongly in } X. \tag{3.8}$$

For this purpose set $\Phi_n = \Psi_n - \bar\Psi$, and choose K such that

$$\max(|\Phi_n|_{L^2(0,T;\mathcal{V}^*)}, |\Phi_n|_{C(0,T;\mathcal{V}\cap X_1)}) \le K.$$

Due to (3.2) there exists [CF, p. 96], for every $\epsilon > 0$, a constant c_ϵ such that

$$|\Phi_n(T)|_X \le \epsilon|\Phi_n(T)|_{\mathcal{V}\cap X_1} + c_\epsilon|\Phi_n(T)|_{\mathcal{V}^*} \le \epsilon K + c_\epsilon|\Phi_n(T)|_{\mathcal{V}^*}. \tag{3.9}$$

By Hölder's inequality we have

$$\begin{aligned}|\,\Phi_n(T)|_{\mathcal{V}^*} &= \left|\frac{1}{\epsilon}\int_{T-\epsilon}^T \Phi_n(s)\,ds + \frac{1}{\epsilon}\int_{T-\epsilon}^T (s-T+\epsilon)\frac{d}{ds}\Phi_n'(s)\,ds\right|_{\mathcal{V}^*} \\ &\le \frac{1}{\epsilon}\left|\int_{T-\epsilon}^T \Phi_n(s)\,ds\right|_{\mathcal{V}^*} + \frac{1}{\epsilon}\left(\int_{T-\epsilon}^T (s-T+\epsilon)^2\,ds\right)^{\frac12}\left(\int_{T-\epsilon}^T \left|\frac{d}{ds}\Phi'(s)\right|_{\mathcal{V}^*} ds\right)^{\frac12} \\ &\le \frac{1}{\epsilon}\left|\int_{T-\epsilon}^T \Phi_n(s)\,ds\right|_{\mathcal{V}^*} + \frac{\sqrt{\epsilon}\,K}{\sqrt{3}},\end{aligned}$$

and with (3.9)

$$|\Phi_n(T)|_X \le \epsilon K + \frac{\sqrt{\epsilon}\,K}{\sqrt{3}} + \frac{1}{\epsilon}\left|\int_{T-\epsilon}^{T} \Phi_n(s)\,ds\right|_{\mathcal{V}^*}.$$

Since $\Phi_n \to 0$ weakly in $L^2(0,T;\mathcal{V})$ we have $\frac{1}{\epsilon}|\int_{T-\epsilon}^{T} \Phi_n(s)\,ds|_{\mathcal{V}^*} \to 0$ as $n \to \infty$ for every fixed $\epsilon > 0$. We conclude that (3.8) holds.

Weak lower-semicontinuity of norms and (3.8) imply that

$$J(\bar{\mu}) \ge \sup_{\mu} J(\mu)$$

and hence $\bar{\mu}$ is an optimal solution to (3.1). We thus proved the following result.

THEOREM 3.1. *If $\Psi_0 \in X_1 \cap \mathcal{V}$ and* (3.2), (3.3) *hold, then* (3.1) *admits a solution $\bar{\mu} \in L^2(0,T;U)$.*

Example 3.1. The control space in (3.1) is $\mathcal{U} = L^2(0,T;U)$. Here we consider the special case of a scalar-valued control coupling a time-dependent control amplitude ϵ with a fixed time-independent self-adjoint moment operator $\tilde{\mu} \in \mathcal{L}(V) \cap \mathcal{L}(H)$, i.e., we consider the closed subspace of $\mathcal{U}$ given by

$$\widehat{\mathcal{U}} = \{\epsilon\tilde{\mu} : \epsilon \in L^2(0,T;\mathbb{R})\},$$

which is isomorphic to $L^2(0,T;\mathbb{R})$. In this case U is the one dimensional space $\{\epsilon\tilde{\mu} : \epsilon \in \mathbb{R}\}$, which is endowed with the inner product of $\mathbb{R}$. The resulting control cost is $\frac{\alpha}{2}\int_0^T |\epsilon(t)|^2 dt$ and the bilinear mapping $F : X \times X \to U = \mathbb{R}$ is given by

$$F(\phi,\psi) = (\tilde{B}\phi,\psi)_X = (\tilde{\mu}(\phi_2),\psi_1)_H - (\tilde{\mu}(\phi_1),\psi_2)_H,$$

with $\tilde{B} = \left(\begin{smallmatrix} 0 & \tilde{\mu} \\ -\tilde{\mu} & 0 \end{smallmatrix}\right)$. The resulting optimality condition has the form

$$\alpha\bar{\epsilon} + (\tilde{B}\bar{\Psi}(t),\bar{\chi})_X = 0.$$

Example 3.2. Let $H = L^2(\Omega)/\mathbb{R}$ with $\Omega = (0,1)$ and $H_0 = -\Delta$ with periodic boundary conditions. Then $V = H_P^1(\Omega)$, the space of $H^1(\Omega)$ functions with periodic boundary conditions $\phi(0) = \phi(1)$. The control space is taken as multiplication operators by elements $\mu \in H_P^1(\Omega)$ and we identify U with $H^1(\Omega)_p$. Note that $\phi \to \mu\phi$ defines a self-adjoint element in $\mathcal{L}(H) \cap \mathcal{L}(V)$, since $H^1(\Omega)$ is a Banach algebra in dimension one. For $\phi \in X = H \times H$ and $\psi \in X = H \times H$ the element $F(\phi,\psi) \in V$ is the solution to

$$(F(\phi,\psi),\mu)_{H^1} = (\mu\phi^2,\psi^1)_H - (\mu\phi^1,\psi^2)_H \text{ for all } \mu \in V.$$

Thus the optimality condition can be expressed as

$$\alpha\mu(t) + (-\Delta + I)^{-1}(\Psi^2(t)\chi^1(t) - \Psi^1(t)\chi^2(t)) = 0,$$

where $\Psi, \chi \in C(0,T;\mathcal{V})$. Note that this implies additional spatial regularity of the optimal solution.

Example 3.3. Let H_0, H, V, and Ω be as in the previous example. Define

$$\tilde{U} = \{\tilde{\mu} \in L^2(\Omega) : \tilde{\mu}(x) = \tilde{\mu}(-x) \text{ for } x \in \Omega\}$$

endowed with the canonical inner product. Each $\tilde{\mu}$ can be uniquely identified with a self-adjoint operator $\mu \in \mathcal{L}(H)$ given by

$$\mu(\phi)(x) = \int_\Omega \tilde{\mu}(x-y)\phi(y)\,dy,$$

where $\tilde{\mu}$ is extended periodically from Ω to $\mathbb{R}$. All such operators also satisfy $\mu \in \mathcal{L}(V)$. The set of all these operators constitutes the control space U. The resulting penalty term in the cost functional J has the form

$$\frac{\alpha}{2}\int_0^T |\tilde{\mu}(t,\cdot)|^2_{L^2(\Omega)}\,dt.$$

Using symmetry of $\tilde{\mu}$ it can be shown that for ϕ, ψ in $X = H \times H$ the element $F \in L^2(\Omega)$ satisfying

$$(F(\phi,\psi),\tilde{\mu})_{L^2(\Omega)} = (\mu\phi^2,\psi^1)_{L^2(\Omega)} - (\mu\phi^1,\psi^2)_{L^2(\Omega)} \text{ for all } \mu \in U$$

is given by

$$F(\phi,\psi)(x) = \frac{1}{2}\int_\Omega \big(\phi^2(y)\psi^1(x+y) + \phi^2(y)\psi^1(-x+y) - \phi^1(y)\psi^2(x+y) - \phi^1(y)\psi^2(-x+y)\big)\,dy.$$

The resulting optimality condition is

$$\alpha\tilde{\mu}(t,x) + \frac{1}{2}\int_\Omega \big(\Psi^2(t,y)\chi^1(t,x+y) + \Psi^2(t,y)\chi^1(t,-x+y) - \Psi^1(t,y)\chi^2(t,x+y) - \Psi^1(t,y)\chi^2(t,-x+y)\big)\,dy = 0.$$

Analogous results can be obtained with $\Omega = (0,1)$ replaced by bounded cubes in $\mathbb{R}^n$ with H_0 satisfying periodic boundary conditions, or with $\Omega = \mathbb{R}^n$.

Example 3.4. Let $H_0 = -\Delta$ in $H = L^2(\mathbb{R}^n)$. Then H_0 is densely defined with $dom(H_0) = H^2(\mathbb{R}^n)$ and self-adjoint (see, e.g., [K]), with spectrum consisting of continuous spectrum given by $[0,\infty)$. We set $\mathcal{H} = \{\varphi \in L^2(\mathbb{R}^n) : \int_{\mathbb{R}^n}(1+|x|^2)\varphi(x)^2 < \infty\}$. To verify (3.2) let $\{f_n\}_{n=1}^\infty$ be a bounded sequence in $H_1 = V \cap \mathcal{H} = dom(H_0^{\frac{1}{2}}) \cap \mathcal{H}$. For $r \in N$ set $\Omega_r = \{x \in \mathbb{R}^n : |x|_{\mathbb{R}^n} \le r\}$. Extract a subsequence of $\{f_n\}$ that converges weakly in H_1 to some $f \in H_1$. Using compactness of $\{\phi|_{\Omega_r} : \phi \in V\}$ in $L^2(\Omega_r)$ successively extract further subsequences whose restriction to Ω_r converges strongly in $L^2(\Omega_r)$ to f, for $r = 1, 2, \ldots$. Let $\{f_{n_k}\}$ denote the sequence which arises from diagonalization of the above procedure. The restriction to Ω_r of this sequence converges strongly in $L^2(\Omega_r)$ to the restriction of f to Ω_r for each $r \in N$. Strong convergence of $\{f_{n_k}\}$ to $\{f\}$ in $L^2(\mathbb{R}^n)$ follows from the following estimate:

$$\int_{\mathbb{R}^n} |f - f_{n_k}|^2\,dx = \int_{\Omega_r} |f - f_{n_k}|^2\,dx + \int_{\mathbb{R}^n\setminus\Omega_r} |f - f_{n_k}|^2\,|x|^2\,\frac{dx}{|x|^2}$$

$$\le \int_{\Omega_r} |f - f_{n_k}|^2\,dx + \frac{1}{r^2}\int_{\mathbb{R}^n\setminus\Omega_r} |f - f_{n_k}|^2|x|^2\,dx \le \int_{\Omega_r} |f - f_{n_k}|^2\,dx + \frac{4}{r^2}C,$$

where C is the common bound for $\{f_{n_k}\}$ and f in H_1. Hence $dom(H_0^{\frac{1}{2}}) \cap \mathcal{H}$ is compactly embedded in H and (3.2) follows.

Turning to (3.3), consider, for $X = L^2(\mathbb{R}^n) \times L^2(\mathbb{R}^n)$,

$$\langle \tfrac{d}{dt}\Psi(t), |x|^2\Psi(t)\rangle = \tfrac{1}{2}\tfrac{d}{dt}\langle \Psi(t), |x|^2\Psi(t)\rangle$$
$$= \langle A_0\Psi(t), |x|^2\Psi(t)\rangle - (B(t)\Psi(t), |x|^2\Psi(t))_X$$
$$= (-\Delta\Psi_2, |x|^2\Psi_1)_H + (\Delta\Psi_1, |x|^2\Psi_2)_H - ((\mu(t)\Psi_2, |x|^2\Psi_1)_H - (\mu(t)\Psi_1, |x|^2\Psi_2)_H)$$
$$= 2(\nabla\Psi_2(t), x\Psi_1(t))_H - 2(\nabla\Psi_1(t), x\Psi_2(t))_H$$
$$\le |\nabla\Psi_1(t)|_H^2 + |\nabla\Psi_2(t)|_H^2 + \big|\, |x|\Psi_1(t)\big|_H^2 + \big|\, |x|\Psi_2(t)\big|_H^2,$$

and hence

$$\frac{1}{2}\frac{d}{dt}\big|\, |x|\Psi(t)\big|_X^2 \le K|\Psi|_{\mathcal{V}}^2 + \big|\, |x|\Psi(t)\big|_X^2$$

for a constant K satisfying $|\nabla\phi| \le K|\phi|_{\mathcal{V}}$ for all $\phi \in \mathcal{V}$. Gronwall's inequality and Theorem 2.1 imply the existence of a constant $\tilde{M} = \tilde{M}(|\Psi_0|_{\mathcal{V}\cap X_1}, |B|_{L^2(0,T;\mathcal{L}(\mathcal{V})\cap\mathcal{L}(X))})$ such that

$$|\Psi|_{C(0,T;\mathcal{V}\cap X_1)} \le \tilde{M},$$

which, in particular, implies (3.3).

4. Necessary optimality condition. We now derive a first order necessary optimality system for (3.1).

THEOREM 4.1. *Let* $(\bar\mu, \bar\Psi) = (\bar\mu, \Psi(\bar\mu))$ *be an optimal pair for* (3.1) *and assume that* $\Psi_0 \in \mathcal{V}$ *and* $O\,\bar\Psi(T) \in \mathcal{V}$. *Then*

$$\tfrac{d}{dt}\,\bar\Psi(t) = (A_0 - \bar B(t))\bar\Psi(t), \qquad \bar\Psi(0) = \Psi_0 \qquad \textit{(primal equation)},$$
$$\tfrac{d}{dt}\,\bar\chi(t) = (A_0 - \bar B(t))\bar\chi(t), \qquad \chi(T) = O\bar\Psi(T) \qquad \textit{(adjoint equation)},$$
$$\alpha\bar\mu(t) + F(\bar\Psi(t),\, \bar\chi(t)) = 0 \qquad \textit{(optimality)},$$

where the adjoint state satisfies $\bar\chi \in H^1(0,T;\mathcal{V}^*) \cap C(0,T;\mathcal{V})$ *and* $\bar B = \left(\begin{smallmatrix} 0 & \bar\mu \\ -\bar\mu & 0 \end{smallmatrix}\right)$.

Proof. For any $\mu \in L^2(0,T;U)$ we have

$$J(\mu) - J(\bar\mu) = -\alpha\,(\bar\mu, \mu - \bar\mu)_{L^2(0,T;U)} - \frac{\alpha}{2}|\mu - \bar\mu|^2_{L^2(0,T;U)}$$
$$+(\Psi(T) - \bar\Psi(T), O\bar\Psi(T))_X + \frac{1}{2}(\Psi(T) - \bar\Psi(T), O(\Psi(T) - \bar\Psi(T))\,)_X.$$

Let $\bar\chi(t) \in H^1(0,T;\mathcal{V}^*) \cap C(0,T;dom\,\mathcal{V})$ be the solution to the adjoint equation

$$\frac{d}{dt}\bar\chi(t) = (A_0 - \bar B(t))\bar\chi(t), \quad \chi(T) = O\bar\Psi.$$

Then,

$$(\Psi(T) - \bar\Psi(T), O\bar\Psi(T)) = \int_0^T \left\langle \frac{d}{dt}(\Psi(t) - \bar\Psi(t)), \bar\chi(t) \right\rangle + \left\langle \Psi(t) - \bar\Psi(t), \frac{d}{dt}\bar\chi(t) \right\rangle dt$$
$$= \int_0^T [\langle (A_0 - B(t))\Psi(t) - (A_0 - \bar B(t))\bar\Psi(t), \bar\chi(t)\rangle + \langle \Psi(t) - \bar\Psi(t), (A_0 - \bar B(t))\bar\chi(t)\rangle]\, dt$$
$$= -\int_0^T ((B(t) - \bar B(t))\Psi(t), \bar\chi(t))_X\, dt$$
$$= -\int_0^T \big((B(t) - \bar B(t))(\Psi(t) - \bar\Psi(t)), \bar\chi(t)\big)_X\, dt - \int_0^T \big((B(t) - \bar B(t))\bar\Psi(t), \bar\chi(t)\big)_X\, dt,$$

where $\langle\cdot,\cdot\rangle$ denotes the duality pairing between $\mathcal{V}$ and $\mathcal{V}^*$. Hence

$$J(\mu) - J(\bar\mu) = -\int_0^T \big(\alpha\bar\mu(t) + F(\bar\Psi(t),\bar\chi(t)), \mu(t)-\bar\mu(t)\big)_U$$
$$-\int_0^T \big((B(t)-\bar B(t))(\Psi(t)-\bar\Psi(t)),\bar\chi(t)\big)_X\, dt$$
$$-\frac{\alpha}{2}\,|\mu-\bar\mu|^2_{L(0,T;U)} + \frac{1}{2}\,(\Psi(T)-\bar\Psi(T), O(\Psi(T)-\bar\Psi(T))\,)_X.$$

Taking the limit $\mu\to\bar\mu$ and using (2.3) we obtain the claim. □

5. An algorithm and its convergence. The following algorithm for solving the optimality system in case of scalar-valued controls was proposed in [ZR] and further developed in [TKO], [MT].

ALGORITHM.

(i) Choose $\delta\in[0,2]$, $\eta\in[0,2]$, $\tilde\mu^0\in L^2(0,T;U)$, $\chi^0\in C(0,T;X)$.

For $k=1,2,\dots$ until convergence

(ii)

$$\tfrac{d}{dt}\Psi^k(t) = (A_0 - B^k(t))\Psi^k(t), \quad \Psi^k(0)=\Psi_0,$$

$$\mu^k = (1-\delta)\tilde\mu^{k-1} - \tfrac{\delta}{\alpha}F(\Psi^k,\chi^{k-1}),$$

(iii)

$$\tfrac{d}{dt}\chi^k(t) = (A_0 - \tilde B^k(t))\chi^k(t), \quad \chi^k(T) = O\Psi^k(T),$$

$$\tilde\mu^k = (1-\eta)\,\mu^k - \tfrac{\eta}{\alpha}F(\Psi^k,\chi^k).$$

First we prove the well-posedness of the algorithm.

PROPOSITION 5.1. *Let $\psi_0\in\mathcal{V}$, $\mu\in L^2(0,T;U)$, and $\chi\in C(0,T;X)$. Then there exists a unique solution $\Psi\in H^1(0,T;\mathcal{V}^*)\cap C(0,T;\mathcal{V})$ to*

$$\Psi(t) = S(t)\Psi_0 - \int_0^t S(t-s)B(\Psi)(s)\Psi(s)\,ds, \tag{5.1}$$

where $B=B(\mu)$, with $\mu(\Psi)(t) = (1-\delta)\mu(t) - \frac{\delta}{\alpha}F(\Psi(t),\chi(t))$. Analogously, if $\Psi\in C(0,T;X)$, then there exists a unique solution $\chi\in H^1(0,T;\mathcal{V}^*)\cap C(0,T;\mathcal{V})$ to

$$\chi(t) = S^*(T-t)O\Psi(T) + \int_t^T S^*(s-t)\tilde\mu(\chi)(s)\,ds,$$

where $\tilde\mu(\chi)(t) = (1-\eta)\mu(t) - \frac{\eta}{\alpha}F(\Psi(t),\chi(t))$.

Proof. We verify the first claim by a continuation argument. The second one can be proved analogously. For any Ψ and $\hat\Psi$ in $C(0,T;X)$ we have

$$|B(\Psi)(t) - B(\hat\Psi)(t)| \le M|\Psi(t)-\hat\Psi(t)|_X,$$

where $M = \tilde M\frac{\delta}{\alpha}|\chi|_{C(0,T;X)}$ and $\tilde M$ is an embedding constant. Consider the iteration

$$\Psi_n = S(t)\Psi_0 + \int_0^t S(t-s)B(\Psi_{n-1})(s)\Psi_n(s)\,ds,$$

which is initialized by the constant with value Ψ_0. It is well defined by Theorem 2.1, and $|\Psi_n(t)|_X = |\Psi_0|_X$ for all n and $t \geq 0$. For consecutive iterates we find

$$\begin{aligned}
&\tfrac{1}{2}\tfrac{d}{dt}|\Psi_{n+1}(t) - \Psi_n(t)|_X^2 \\
&= ((A_0 - B(\Psi_n))(t)(\Psi_{n+1}(t) - \Psi_n(t)) \\
&\qquad -(B(\Psi_n)(t) - B(\Psi_{n-1})(t))\Psi_n(t), \Psi_{n+1}(t) - \Psi_n(t)) \\
&\qquad \leq \tfrac{M^2}{2}|\Psi_{n+1}(t) - \Psi_n(t)|^2 + \tfrac{1}{2}\,|\Psi_n(t) - \Psi_{n-1}(t)|^2.
\end{aligned}$$

Hence for every $\tau \in (0, T]$ and $t \in (0, \tau]$

$$|\Psi_{n+1}(t) - \Psi_n(t)|_X^2 \leq \frac{1}{M^2}(e^{M^2\tau} - 1) \max_{t\in[0,\tau]} |\Psi_n(t) - \Psi_{n-1}(t)|_X.$$

Selecting $\tau > 0$ sufficiently small so that $\theta = \frac{1}{M^2}(e^{M^2\tau} - 1) < 1$ implies that

$$|\Psi_{n+1} - \Psi_n|_{C(0,\tau;X)} \leq \theta^n\,|\Psi_1 - \Psi_0|_{C(0,T;X)} \to 0$$

as $n \to \infty$. By standard arguments existence of a solution to (5.1) on $[0, \tau]$ follows. Since τ only depends on M, this solution can be extended to a solution $\Psi \in C(0, T; X)$. Uniqueness follows by Gronwall's inequality. Another application of Theorem 2.1 guarantees that $\Psi \in H^1(0, T; \mathcal{V}^*) \cap C(0, T; \mathcal{V})$. □

THEOREM 5.2. *Assume that $(\delta, \eta) \neq (0, 0)$, that $\Psi_0 \in \mathcal{V} \cap X_1$, and that (3.2), (3.3) hold. Then the sequence $\{\mu^k, \tilde{\mu}^k, \Psi^k, \chi^k\}$ contains a subsequence which converges strongly in $L^2(0, T; U) \times L^2(0, T; U) \times C(0, T; X) \times C(0, T; X)$ and every such subsequence converges to some (μ, μ, Ψ, χ), where (μ, Ψ, χ) is a solution of the optimality system.*

Proof. For $k \geq 2$ and $\delta, \eta \in [0, 2]$

$$\begin{aligned}
&J(\mu^k) - J(\mu^{k-1}) = \tfrac{1}{2}(\,\Psi^k(T) - \Psi^{k-1}(T), O\,(\Psi^k(T) - \Psi^{k-1}(T))\,)_X \\
&+\tfrac{\alpha}{2}\int_0^T (\tfrac{2}{\delta} - 1)\,|\mu^k - \tilde{\mu}^{k-1}|_U^2 + (\tfrac{2}{\eta} - 1)\,|\mu^{k-1} - \tilde{\mu}^{k-1}|_U^2\,dt \geq 0.
\end{aligned} \tag{5.2}$$

If $\delta = 0$ or $\eta = 0$, then $\mu^k = \tilde{\mu}^{k-1}$, respectively, $\mu^{k-1} = \tilde{\mu}^{k-1}$, and the corresponding terms in (5.2) are dropped. This inequality will be verified at the end of the proof, in an analogous way as in the scalar case which was treated in [ZR], [MT].

From (5.2) it follows that $J(\mu^k)$ is monotonically increasing. Since $J(\mu)$ is bounded from above this implies that $\lim_{k\to\infty} J(\mu^k)$ exists. Recall that $|\Psi^k(t)|_X = |\Psi_0|_X$ and $|\chi^k(t)|_X \leq \|O\||\Psi_0|_X$ for all k and $t \in [0, T]$. It thus follows that

$$J(\mu^0) \leq J(\mu^k) = \frac{1}{2}(\Psi^k(T), O\Psi^k(T))_X - \frac{\alpha}{2}|\mu^k|^2_{L^2(0,T;U)},$$

and hence

$$\frac{\alpha}{2}|\mu^k|^2_{L^2(0,T;U)} \leq \frac{1}{2}|\Psi_0|_X^2\|O\|_{\mathcal{L}(X)} - J(\mu^0).$$

Moreover,

$$|\tilde{\mu}^k|_{L^2(0,T;U)} \leq |1 - \eta|\,|\mu^k|_{L^2(0,T;U)} + \frac{\eta}{2}|\Psi_0|_X^2\|O\|_{\mathcal{L}(X)},$$

and hence

$$\{\mu^k\}_{k=1}^\infty \text{ and } \{\tilde{\mu}^k\}_{k=1}^\infty \text{ are bounded in } L^2(0, T; U). \tag{5.3}$$

From Theorem 2.1 and assumptions (3.2) and (3.3), therefore,

$$\{\Psi^k\}_{k=1}^{\infty} \text{ and } \{\chi^k\}_{k=1}^{\infty} \text{ are bounded in } H^1(0,T;\mathcal{V}^*) \cap L^2(0,T;\mathcal{V} \cap X_1).$$

By Aubin's lemma there exists a subsequence $\{k^n\}$ of $\{k\}$ and $\Psi \in C(0,T;X)$, $\chi \in C(0,T;X)$ such that

$$\Psi^{k_n} \to \Psi \text{ and } \chi^{k_n} \to \chi \text{ strongly in } L^2(0,T;X).$$

Using the boundedness of $\{\Psi^{k_n}\}$ and $\{\chi^{k_n}\}$ in $C(0,T;X)$ and the properties of F one argues that $F(\Psi^{k_n},\chi^{k_n}) \to F(\Psi,\chi)$ strongly in $L^2(0,T;U)$. From (iii) of the algorithm we have

$$\eta\mu^{k_n} = \mu^{k_n} - \tilde{\mu}^{k_n} - \frac{\eta}{\alpha}F(\Psi^{k_n},\chi^{k_n}).$$

Since $\mu^{k_n} - \tilde{\mu}^{k_n} \to 0$ in $L^2(0,T;U)$ by (5.2), it follows, for $\eta \neq 0$, that μ^{k_n} converges strongly in $L^2(0,T;U)$ to some μ, as $k_n \to \infty$. For each k_n we have the following by (ii) of the algorithm:

$$\Psi^{k_n}(t) = S(t)\Psi_0 - \int_0^t S(t-s)B^{k_n}(s)\Psi^{k_n}(s)\,ds. \tag{5.4}$$

Let $\Psi \in C(0,T;X)$ denote the solution to

$$\Psi(t) = S(t)\Psi_0 - \int_0^t S(t-s)B(s)\Psi(s)\,ds. \tag{5.5}$$

From Gronwall's inequality it follows that $\Psi^{k_n} \to \Psi$ in $C(0,T;X)$. By (5.2) the sequence $\{\tilde{\mu}^{k_n}\}$ converges strongly in $L^2(0,T;U)$ to μ. Step (iii) of the algorithm implies that

$$\chi^{k_n}(t) = S^*(T-t)O\Psi^{k_n}(T) + \int_t^T S^*(s-t)\tilde{B}^{k_n}(s)\chi^{k_n}(s)\,ds. \tag{5.6}$$

Let χ in $C(0,T;X)$ denote the solution to

$$\chi(t) = S^*(T-t)O\Psi(T) + \int_t^T S^*(s-t)B(s)\chi(s)\,ds. \tag{5.7}$$

Again by Gronwall's lemma we find that $\chi^{k_n} \to \chi$ in $C(0,T;X)$. Passing to the limit in the second equation of (iii) implies that

$$\alpha B + F(\Psi,\chi) = 0. \tag{5.8}$$

For $\eta = 0$ there exists a subsequence $\{k^n\}$ of $\{k\}$ and $\bar{\Psi} \in C(0,T;X)$, $\bar{\chi} \in C(0,T;X)$ such that

$$\Psi^{k_n} \to \bar{\Psi} \text{ and } \chi^{k_n} \to \bar{\chi} \text{ strongly in } L^2(0,T;X).$$

By (5.2) and since $\tilde{\mu}^k = \mu^k$ for $\eta = 0$ we have $\lim_{n\to\infty} \mu^{k_n-1} - \mu^{k_n} = 0$ in $L^2(0,T;U)$. From

$$\mu^{k_n} = (1-\delta)\mu^{k_n-1} - \frac{\delta}{\alpha}F(\Psi^{k_n},\chi^{k_n-1})$$

it therefore follows that μ^{k_n-1} converges strongly to some μ in $L^2(0,T;U)$. By (5.2) also $\lim_{n\to\infty}\mu^{k_n} = \mu$ in $L^2(0,T;U)$. As before, the solutions to (5.4) and (5.6) converge strongly in $C(0,T;X)$ to the solutions of (5.5) and (5.7), and (5.8) also holds for $\eta = 0$. From (5.5), (5.7), and (5.8) we conclude that (μ,Ψ,χ) is a solution to the optimality system.

We now provide the proof of (5.2) for the case $\eta \neq 0, \delta \neq 0$. The remaining cases follow easily. We have

$$J(\mu^{k+1}) - J(\mu^k) = \frac{1}{2}(\,\Psi^{k+1}(T) - \Psi^k(T), O\,(\Psi^{k+1}(T) - \Psi^k(T))\,)_X$$
$$+(\Psi^{k+1}(T) - \Psi^k(T), O\,\Psi^k(T))_X + \frac{\alpha}{2}\int_0^T |\mu^{k+1}|^2 - \frac{\alpha}{2}\int_0^T |\mu^k|^2.$$

Suppressing the dependence of Ψ^k and μ^k on t we find

$$(\Psi^{k+1}(T) - \Psi^k(T), O\,\Psi^k(T))_X = (\Psi^{k+1}(T) - \Psi^k(T), \chi^k(T))_X$$
$$= \int_0^T \left(\frac{\partial}{\partial t}(\Psi^{k+1} - \Psi^k), \chi^k\right)_X + \left(\Psi^{k+1} - \Psi^k, \frac{\partial}{\partial t}\chi^k\right)_X$$
$$= \int_0^T ((A_0 - B^{k+1})\Psi^{k+1} - (A_0 - B^k)\Psi^k, \chi^k)_X + (\Psi^{k+1} - \Psi^k, (A_0 - \tilde{B}^k)\chi^k)_X$$
$$= \int_0^T ((\tilde{B}^k - B^{k+1})\Psi^{k+1}, \chi^k)_X + ((B^k - \tilde{B}^k)\Psi^k, \chi^k)_X$$
$$= \int_0^T (F(\Psi^{k+1}, \chi^k), \tilde{\mu}^k - \mu^{k+1})_U + (F(\Psi^k, \chi^k), \mu^k - \tilde{\mu}^k)_U$$
$$= \alpha\int_0^T \frac{1}{\delta}(\tilde{\mu}^k - \mu^{k+1}, (1-\delta)\tilde{\mu}^k - \mu^{k+1})_U + \frac{1}{\eta}(\tilde{\mu}^k - \mu^k, (1-\eta)\mu^k - \tilde{\mu}^k)_U$$
$$= \alpha\int_0^T \frac{1}{\delta}|\tilde{\mu}^k - \mu^{k+1}|_U^2 + \frac{1}{\eta}|\tilde{\mu}^k - \mu^k|_U^2 - (\tilde{\mu}^k - \mu^{k+1}, \tilde{\mu}^k)_U - (\mu^k - \tilde{\mu}^k, \mu^k)_U.$$

Hence we find

$$J(\mu^{k+1}) - J(\mu^k) = \frac{1}{2}(\,\Psi^{k+1}(T) - \Psi^k(T), O\,(\Psi^{k+1}(T) - \Psi^k(T))\,)_X$$
$$+(\,\Psi^{k+1}(T) - \Psi^k(T), O\,\Psi^k(T)\,)_X - \frac{\alpha}{2}\int_0^T |\mu^{k+1}|_U^2 + \frac{\alpha}{2}\int_0^T |\mu^k|^2$$
$$= \frac{1}{2}(\,\Psi^{k+1}(T) - \Psi^k(T), O\,(\Psi^{k+1}(T) - \Psi^k(T))\,)_X$$
$$+\frac{\alpha}{2}\int_0^T \left(\left(\frac{2}{\delta} - 1\right)|\tilde{\mu}^k - \mu^{k+1}|_U^2 + \left(\frac{2}{\eta} - 1\right)|\mu^k - \tilde{\mu}^k|_U^2\right) dt \geq 0. \qquad \square$$

In [S] it is argued that the set of limit points is in fact compact. Moreover, if the penalty parameter α is sufficiently large, then the limit set consists of a singleton.

In the previous theorem subsequential convergence followed under the assumption of compactness of the orbits implied by (3.2), (3.3). Alternatively a compactness assumption for U as a subset of $\mathcal{L}(X)$ also implies convergence.

THEOREM 5.3. *Assume that $(\delta,\eta) \neq (0,0)$, that $\Psi_0 \in \mathcal{V}$, $\chi^0 \in H^1(0,T;X)$, $\tilde{\mu} \in H^1(0,T;U)$, and that U is a compact subset of $\mathcal{L}(X)$. Then the conclusion of Theorem* 5.2 *holds.*

Proof. As in the proof of Theorem 5.2 $\{\mu^k\}_{k=1}^\infty$ and $\{\tilde\mu^k\}_{k=1}^\infty$ are bounded in $L^2(0,T;U)$, and by Theorem 3.1

$$\{\Psi^k\}_{k=1}^\infty \text{ and } \{\chi^k\}_{k=1}^\infty \text{ are bounded in } H^1(0,T;\mathcal{V}^*)\cap C(0,T;\mathcal{V}).$$

This implies that $\{F(\Psi^k,\chi^{k-1})\}_{k=1}^\infty$ and $\{F(\Psi^k,\chi^k)\}_{k=1}^\infty$ are bounded in $H^1(0,T;U)$. If $\delta=\eta=1$, then $\{\mu^k\}$ and $\{\tilde\mu^k\}$ are bounded in $H^1(0,T;U)$. Otherwise

$$\tilde\mu^k=(1-\eta)(1-\delta)\tilde\mu^{k-1}+(1-\eta)\frac{\delta}{\alpha}F(\Psi^k,\chi^{k-1})-\frac{\eta}{\alpha}F(\Psi^k,\chi^k),$$

with $|(1-\eta)(1-\delta)|<1$. It follows that μ^k and $\tilde\mu^k$ are bounded in $H^1(0,T;U)$. Hence there exists a subsequence $\{k_n\}$ of $\{k\}$ and $\mu\in H^1(0,T;U), \tilde\mu\in H^1(0,T;U)$ such that

$$\mu^{k_n}\to\mu, \quad \text{and} \quad \tilde\mu^{k_n}\to\tilde\mu \text{ strongly in } L^2(0,T;\mathcal{L}(X)).$$

By (5.2) we have $|\mu_k-\tilde\mu_k|_{L^2(0,T;\mathcal{L}(X))}\to 0$ if $\eta\neq 0$, whereas $\mu_k=\tilde\mu_k$ if $\eta=0$. In either case it follows that $\mu=\tilde\mu$. The proof can now be completed as the one for Theorem 5.2. ∎

Acknowledgments. We would like to thank Prof. A. Borzi for interesting discussions on various aspects of this paper and Dr. J. Salomon for providing us with a preprint of [S].

STATE AGREEMENT FOR CONTINUOUS-TIME COUPLED NONLINEAR SYSTEMS*

ZHIYUN LIN†, BRUCE FRANCIS†, AND MANFREDI MAGGIORE†

Abstract. Two related problems are treated in continuous time. First, the state agreement problem is studied for coupled nonlinear differential equations. The vector fields can switch within a finite family. Associated to each vector field is a directed graph based in a natural way on the interaction structure of the subsystems. Generalizing the work of Moreau, under the assumption that the vector fields satisfy a certain subtangentiality condition, it is proved that asymptotic state agreement is achieved if and only if the dynamic interaction digraph has the property of being sufficiently connected over time. The proof uses nonsmooth analysis. Second, the rendezvous problem for kinematic point-mass mobile robots is studied when the robots' fields of view have a fixed radius. The circumcenter control law of Ando et al. [*IEEE Trans. Robotics Automation*, 15 (1999), pp. 818–828] is shown to solve the problem. The rendezvous problem is a kind of state agreement problem, but the interaction structure is state dependent.

Key words. state agreement, rendezvous, interacting nonlinear systems, time-varying interaction, asymptotical stability

1. Introduction.

This paper studies a dynamical system that is the interconnection of subsystems. Examples are abundant in biology, physics, engineering, ecology, and social science: e.g., a biochemical reaction network [14], coupled Kuramoto oscillators [17, 39], arrays of chaotic systems [44, 45], a swarm of organisms [12, 13], and a group of autonomous agents [16, 22, 23]. We model such systems by coupled nonlinear differential equations in state form. Pioneering work on such coupled dynamical systems from a structural point of view is that of Siljak, e.g., [35, 36].

State agreement means that the states of the subsystems are all equal. For example, [11] studies a group of individuals who must act together as a team; each individual has its own subjective probability distribution for the unknown value of some parameter. How the group might reach a consensus and form a common subjective probability distribution for the parameter is a state agreement problem. In other contexts, state agreement arises as *synchronization* in theoretical physics, e.g., [5, 30, 39, 42, 43], and *consensus* in computer science, particularly in distributed computing, e.g., [25].

Central to the state agreement problem is the graph describing the interaction structure in the interconnected system—that is, who is coupled to whom. And a central question is, What properties of the interaction graph lead to state agreement? Most existing work has dealt with static graphs with a particular topology, such as rings [6, 30], cyclic digraphs [32], and fully connected graphs [12, 13, 34], or with static graphs having an unspecified topology but a certain connectedness. Example frameworks are coupled cell systems [38], coupled oscillators [17, 45], multiagent systems [4, 31], and formations of unicycles [23]. Of course, a static graph simplifies the

state agreement problem and allows one to focus on the difficulties caused by the nonlinear dynamics of the nodes.

The more interesting situation is when the interaction graph is time varying. From the point of view of control theory, the most suitable mathematical model for these setups is a switched interconnected system. However, attempts to understand how the switching affects the collective system behavior had been hampered by the lack of suitable analysis tools. Recently, however, great strides have been made [16] by characterizing the convergence of infinite products of certain types of nonnegative matrices in a linear discrete-time setup with an undirected interaction graph. For the switched linear continuous-time system model and a directed graph, [22] uses the graph Laplacian and the properties of some special matrices to prove asymptotic state agreement under certain graphical conditions. In addition, [29] uses the common Lyapunov function technique for the switched linear continuous-time system and shows that balanced digraphs play a key role in addressing the average-consensus problem. Two other works on state agreement for linear continuous-time systems are [15], which deals with random networks, and [26], which addresses the deterministic time-varying case.

However, many real systems are nonlinear in addition to having time-varying interaction among subsystems. Examples are systems of coupled oscillators. For nonlinear interconnected systems with time-varying interaction, new tools are required. A novel approach is taken by Moreau in [27]: The framework is nonlinear and discrete-time, and the stability analysis is based upon a blend of graph-theoretic and system-theoretic tools, with the notion of convexity being key. The idea is, roughly speaking, that if every agent always moves toward the relative interior of the convex hull of the set of neighbor agents at each step, state agreement will be achieved. The result in [27] was recently generalized in [2] as follows: The setup is still a discrete-time system, but each agent moves towards the relative interior of a set which is a function, not necessarily the convex hull, of the present and past states of neighbor agents. In this way communication delays can be accommodated.

One concrete instance of the state agreement problem is the rendezvous problem for autonomous mobile robots. Suppose the robots' fields of view have a fixed radius. Then the robots may come into and go out of sensor range of each other, and the interaction graph is therefore state dependent instead of time dependent. For this problem, some distributed algorithms were proposed in [1, 41], with the objective of getting the robots to congregate at a common location (achieving *rendezvous*). These algorithms were extended to various synchronous and asynchronous stop-and-go strategies in [9, 19, 20].

This paper makes two main contributions. The first is the continuous-time counterpart to the result of Moreau [27]. We borrow heavily from Moreau's geometric concepts and proof structure; we suggest, however, that the continuous-time case presents some considerable challenges, as one will see from the details of our proof. Thus our contribution to this problem is primarily technical in nature. As an example application, we apply our result to make new conclusions about synchronization of coupled Kuramoto oscillators. The second contribution of this paper is a solution of the continuous-time rendezvous problem for kinematic point-mass robots; we use the circumcenter control law of Ando et al. [1] and give the first proof of convergence in continuous time.

2. Preliminaries. Here we assemble some known and some novel concepts related to convex sets and tangent cones, directed graphs, and Dini derivatives. In

addition, we provide some fundamental properties associated with them.

2.1. Convex sets and tangent cones. References for this subsection are [3,37].

The convex hull of $\mathcal{S} \subset \mathbb{R}^m$ is denoted $\mathrm{co}(\mathcal{S})$. The convex hull of a finite set of points $x_1, \ldots, x_n \in \mathbb{R}^m$ is a *polytope*, denoted $\mathrm{co}\{x_1, \ldots, x_n\}$.

Let $\mathcal{S} \subset \mathbb{R}^m$ be convex. If $\mathcal{S}$ contains the origin, the smallest subspace containing $\mathcal{S}$ is the *carrier subspace*, denoted $\mathrm{lin}(\mathcal{S})$. The *relative interior* of $\mathcal{S}$, denoted $\mathrm{ri}(\mathcal{S})$, is the interior of $\mathcal{S}$ when it is regarded as a subset of $\mathrm{lin}(\mathcal{S})$ and the relative topology is used, and likewise for the *relative boundary*, denoted $\mathrm{rb}(\mathcal{S})$. If $\mathcal{S}$ does not contain the origin, it must be translated by an arbitrary vector: Let v be any point in $\mathcal{S}$ and let $\mathrm{lin}(\mathcal{S})$ denote the smallest subspace containing $\mathcal{S} - v$. Then $\mathrm{ri}(\mathcal{S})$ is the interior of $\mathcal{S}$ when it is regarded as a subset of the affine subspace $v + \mathrm{lin}(\mathcal{S})$, and similarly for $\mathrm{rb}(\mathcal{S})$.

A nonempty set $\mathcal{K} \subset \mathbb{R}^m$ is a *cone* if $\lambda y \in \mathcal{K}$ when $y \in \mathcal{K}$ and $\lambda > 0$. Let $\mathcal{S} \subset \mathbb{R}^m$ be a closed convex set and $y \in \mathcal{S}$. The *tangent cone* (often referred to as *contingent cone*) to $\mathcal{S}$ at y is the set

$$\mathcal{T}(y, \mathcal{S}) = \left\{ z \in \mathbb{R}^m : \liminf_{\lambda \to 0} \frac{\|y + \lambda z\|_{\mathcal{S}}}{\lambda} = 0 \right\},$$

where $\|y + \lambda z\|_{\mathcal{S}}$ denotes the distance from $y + \lambda z$ to $\mathcal{S}$. The *normal cone* to $\mathcal{S}$ at y is

$$\mathcal{N}(y, \mathcal{S}) = \{ z^* : \langle z, z^* \rangle \leq 0 \ \forall z \in \mathcal{T}(y, \mathcal{S}) \}.$$

Note that if y is in the interior of $\mathcal{S}$, then $\mathcal{T}(y, \mathcal{S}) = \mathbb{R}^m$. Thus the set $\mathcal{T}(y, \mathcal{S})$ is nontrivial only on $\partial\mathcal{S}$, the boundary of $\mathcal{S}$. In particular, if $\mathcal{S}$ contains only one point, y, then $\mathcal{T}(y, \mathcal{S}) = \{0\}$. In geometric terms the tangent cone for $y \in \partial\mathcal{S}$ is a cone centered at the origin which contains all vectors whose directions point from y "inside" (or they are "tangent to") the set $\mathcal{S}$.

LEMMA 2.1 (see [3]). *Let $\mathcal{S}_i, i = 1, \ldots, n$ be convex sets in $\mathbb{R}^m$.*

(i) *If $y \in \mathcal{S}_1 \subset \mathcal{S}_2$, then*

$$\mathcal{T}(y, \mathcal{S}_1) \subset \mathcal{T}(y, \mathcal{S}_2) \quad \textit{and} \quad \mathcal{N}(y, \mathcal{S}_2) \subset \mathcal{N}(y, \mathcal{S}_1).$$

(ii) *If $x_i \in \mathcal{S}_i$ $(i = 1, \ldots, n)$, then*

$$\begin{aligned} \mathcal{T}\left((x_1, \ldots, x_n), \mathcal{S}_1 \times \cdots \times \mathcal{S}_n\right) &= \mathcal{T}(x_1, \mathcal{S}_1) \times \cdots \times \mathcal{T}(x_n, \mathcal{S}_n), \\ \mathcal{N}\left((x_1, \ldots, x_n), \mathcal{S}_1 \times \cdots \times \mathcal{S}_n\right) &= \mathcal{N}(x_1, \mathcal{S}_1) \times \cdots \times \mathcal{N}(x_n, \mathcal{S}_n). \end{aligned}$$

2.2. Directed graphs. For a directed graph (digraph for short) $\mathcal{G} = (\mathcal{V}, \mathcal{E})$, where $\mathcal{V} = \{1, \ldots, n\}$ is the set of nodes and $\mathcal{E}$ is the set of arcs, we write $i \to j$ if there is a path from node i to node j. By definition, $i \to i$ for every node i. A *center* is a node i such that $i \to j$ for every node j, and $\mathcal{G}$ is *quasi-strongly connected* (QSC) if it has a center [7]. Finally, $\mathcal{G}$ is *fully connected* if for every two nodes i and j there is an arc from i to j.

2.3. Dini derivatives. Consider the nonautonomous system

$$\dot{y} = f(t, y), \tag{2.1}$$

where $\mathcal{D} \subset \mathbb{R}^m$ is a domain and $f : \mathbb{R} \times \mathcal{D} \to \mathbb{R}^m$. Let $V(t, y) : \mathbb{R} \times \mathcal{D} \to \mathbb{R}$ be a continuous function satisfying a local Lipschitz condition for y, uniformly with respect to t. Then we define

$$D_f^+ V(t, y) = \limsup_{\tau \to 0^+} \frac{V(t + \tau, y + \tau f(t, y)) - V(t, y)}{\tau}.$$

The function D_f^+V is called the *upper Dini derivative* of V along the trajectory of (2.1). Suppose that for an initial condition $y(0) = y^0$, (2.1) has a solution $y(t)$ defined on an interval $[0, \epsilon)$ and let $D^+V(t, y(t))$ be the upper Dini derivative of $V(t, y(t))$ with respect to t, i.e.,

$$D^+V(t, y(t)) = \limsup_{\tau \to 0^+} \frac{V(t+\tau, y(t+\tau)) - V(t, y(t))}{\tau}.$$

Let $t^* \in [0, \epsilon)$ and put $y(t^*) = y^*$. Then one has that (see [33])

$$D^+V(t^*, y(t^*)) = D_f^+V(t^*, y^*).$$

LEMMA 2.2. *Let $\mathcal{I}_0 = \{1, 2, \ldots, n\}$ and suppose for each $i \in \mathcal{I}_0$, $V_i : \mathbb{R} \times \mathcal{D} \to \mathbb{R}$ is of class C^1; let $V(t, y) = \max_{i \in \mathcal{I}_0} V_i(t, y)$; and let $\mathcal{I}(t) = \{i \in \mathcal{I}_0 : V_i(t, y(t)) = V(t, y(t))\}$ be the set of indices where the maximum is reached at time t. Then $D^+V(t, y(t))$ satisfies*

$$D^+V(t, y(t)) = \max_{i \in \mathcal{I}(t)} \dot{V}_i(t, y(t)).$$

The proof can be obtained from Danskin's theorem [8, 10].

3. The state agreement problem: Main results. Our setup is a general interconnection of nonlinear subsystems, where the vector fields can switch within a finite family. We associate to each vector field a directed graph based in a natural way on the interaction structure of the subsystems; this is called an *interaction digraph* in the present paper. Assuming that the vector fields satisfy a certain subtangentiality condition, we show that asymptotic state agreement is achieved if and only if the dynamic interaction digraph has the property of being sufficiently connected over time, in a certain technical sense. Most of the proofs are deferred to section 5.

To formalize the notion of a switched interconnected system, first consider a family of systems

$$\begin{aligned} \dot{x}_1 &= f_p^1(x_1, \ldots, x_n) \\ &\vdots \\ \dot{x}_n &= f_p^n(x_1, \ldots, x_n), \end{aligned}$$

where $x_i \in \mathbb{R}^m$ is the state of subsystem i and where the index p belongs to a finite set $\mathcal{P}$. Notice that the subsystems share a common state space, $\mathbb{R}^m$. Introducing the *aggregate state* $x \in \mathbb{R}^{mn}$, we have the concise form

$$\dot{x} = f_p(x), \quad p \in \mathcal{P}, \tag{3.1}$$

where for each $p \in \mathcal{P}$, $f_p : \mathbb{R}^{mn} \to \mathbb{R}^{mn}$.

We now associate to each vector field f_p an interaction digraph $\mathcal{G}_p$ capturing the interaction structure of the n subsystems (agents).

DEFINITION 3.1 (interaction digraph). *The interaction digraph $\mathcal{G}_p = (\mathcal{V}, \mathcal{E}_p)$ consists of*

- *a finite set $\mathcal{V}$ of n nodes, each node i modeling agent i;*
- *an arc set $\mathcal{E}_p$ representing the links between agents. An arc from node j to node i indicates that agent j is a neighbor of agent i in the sense that f_p^i depends on x_j; i.e., there exist $x_j^1, x_j^2 \in \mathbb{R}^m$ such that*

$$f_p^i(x_1, \ldots, x_j^1, \ldots, x_n) \neq f_p^i(x_1, \ldots, x_j^2, \ldots, x_n).$$

The set of neighbors of agent i is denoted $\mathcal{N}_i(p)$.

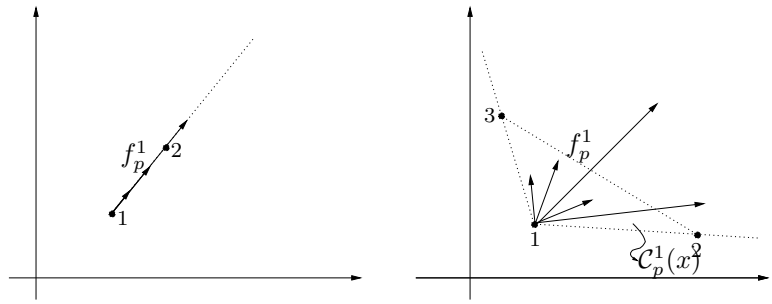

FIG. 3.1. *Some examples of vector fields f_p^i satisfying assumption* A2.

Let $\mathcal{C}_p^i(x) = \text{co}\{x_i, x_j : j \in \mathcal{N}_i(p)\}$ denote the polytope in $\mathbb{R}^m$ formed by the states of agent i and its neighbors. Also, it is convenient to introduce a subset $\mathcal{S} \subset \mathbb{R}^m$ of the common state space that plays the role of a region of focus. In our state agreement problem, initial states of the agents will be in $\mathcal{S}$ and agreement will occur in $\mathcal{S}$. Let $\mathcal{I}_0$ denote the index set $\{1, \ldots, n\}$ and assume that, for each $i \in \mathcal{I}_0$ and each $p \in \mathcal{P}$, the vector fields $f_p^i : \mathbb{R}^{mn} \to \mathbb{R}^m$ satisfy the following two assumptions:

A1. f_p^i is locally Lipschitz on $\mathcal{S}^n$.

A2. For all $x \in \mathcal{S}^n$, $f_p^i(x) \in \text{ri}\left(\mathcal{T}(x_i, \mathcal{C}_p^i(x))\right)$.

Assumption A2 is sometimes referred to as a *strict subtangentiality condition*. Figure 3.1 illustrates two example situations of A2. In the left-hand example, agent 1 has only one neighbor, agent 2; the convex hull $\mathcal{C}_p^1(x)$ is the line segment joining x_1 and x_2; the tangent cone $\mathcal{T}(x_1, \mathcal{C}_p^1(x))$ is the closed ray $\{\lambda(x_2 - x_1) : \lambda \geq 0\}$ (in the figure it is shown translated to x_1); the relative interior $\text{ri}\left(\mathcal{T}(x_1, \mathcal{C}_p^1(x))\right)$ is the open ray $\{\lambda(x_2 - x_1) : \lambda > 0\}$; and A2 means that f_p^1 is nonzero and points in the direction of $x_2 - x_1$. In the right-hand example, agent 1 has two neighbors, agents 2 and 3; the convex hull $\mathcal{C}_p^1(x)$ is the triangle with vertices x_1, x_2, x_3; the tangent cone $\mathcal{T}(x_1, \mathcal{C}_p^1(x))$ is

$$\{\lambda_1(x_2 - x_1) + \lambda_2(x_3 - x_1) : \lambda_1, \lambda_2 \geq 0\}$$

(again, it is shown translated to x_1); the relative interior $\text{ri}\left(\mathcal{T}(x_1, \mathcal{C}_p^1(x))\right)$ is

$$\{\lambda_1(x_2 - x_1) + \lambda_2(x_3 - x_1) : \lambda_1, \lambda_2 > 0\};$$

and A2 means that f_p^1 points into this open cone. In general, A2 requires that $f_p^i(x)$ have the form

$$\sum_{j \in \mathcal{N}_i(p)} \alpha_j(x)(x_j - x_i),$$

where $\alpha_j(x)$ are nonnegative scalar functions, and that $f_p^i(x)$, now viewed as a vector applied at the vertex x_i, not be tangent to the relative boundary of the convex set $\mathcal{C}_p^i(x)$.

When the index p in (3.1) is replaced by a piecewise constant function $\sigma : [0, \infty) \to \mathcal{P}$, we obtain a *switched interconnected system*

$$\dot{x}(t) = f_{\sigma(t)}\left(x(t)\right). \tag{3.2}$$

The function σ is called a *switching signal*. The case of infinitely fast switching (chattering), which would call for a concept of generalized solution, is not considered here. As a matter of fact, it can be shown that even piecewise constant switching signals $\sigma(t)$ do not have sufficient regularity for asymptotic agreement of the switched interconnected system (3.2) [21]. Let $\mathcal{S}_{dwell}$ denote the class of piecewise constant switching signals such that any consecutive discontinuities are separated by no less than some fixed positive constant τ_D, the *dwell time*. We make the following assumption:

A3. $\sigma(t) \in \mathcal{S}_{dwell}$.

Having replaced p by a switching signal $\sigma(t)$, we similarly replace the interaction digraph $\mathcal{G}_p$ by a dynamic interaction digraph $\mathcal{G}_{\sigma(t)}$.

DEFINITION 3.2 (dynamic interaction digraph and union digraph). *Given a switching signal $\sigma(t)$, the* dynamic interaction digraph $\mathcal{G}_{\sigma(t)}$ *is the pair* $\left(\mathcal{V}, \mathcal{E}_{\sigma(t)}\right)$. *Given two real numbers $t_1 \leq t_2$,* the union digraph $\mathcal{G}\left([t_1, t_2]\right)$ *is the digraph whose arcs are obtained from the union of the arcs in $\mathcal{G}_{\sigma(t)}$ over the time interval $[t_1, t_2]$.*

DEFINITION 3.3. *A dynamic interaction digraph $\mathcal{G}_{\sigma(t)}$ is* uniformly quasi-strongly connected (UQSC) *if there exists $T > 0$ such that for all $t \geq 0$, the union digraph $\mathcal{G}([t, t+T])$ is QSC.*

Our main result, Theorem 3.8, is that the switched interconnected system achieves asymptotic state agreement on $\mathcal{S}$ if and only if the dynamic interaction digraph $\mathcal{G}_{\sigma(t)}$ is UQSC.

But first, the precise meaning of state agreement is given in the following definition.

DEFINITION 3.4. *The switched interconnected system* (3.2) *has the property of*

(i) state agreement on $\mathcal{S}$ *if* $\forall \zeta \in \mathcal{S},\ \forall \varepsilon > 0,\ \exists \delta > 0$ *such that* $\forall t_0 \geq 0$,

$$(\forall i)\ \ (\|x_i(t_0) - \zeta\| \leq \delta) \wedge (x_i(t_0) \in \mathcal{S}) \Longrightarrow (\forall t \geq t_0)(\forall i)\ \|x_i(t) - \zeta\| \leq \varepsilon;$$

(ii) asymptotic state agreement on $\mathcal{S}$ *if it has the property of state agreement on $\mathcal{S}$ and in addition* $\forall \varepsilon > 0,\ \forall c > 0,\ \exists T > 0$ *such that* $\forall t_0 \geq 0$,

$$(\forall i)\ (\|x_i(t_0)\| \leq c) \wedge (x_i(t_0) \in \mathcal{S}) \Longrightarrow (\exists \zeta \in \mathcal{S})(\forall t \geq t_0 + T)(\forall i)\ \|x_i(t) - \zeta\| \leq \varepsilon;$$

(iii) global asymptotic state agreement *if it has the property of asymptotic state agreement on $\mathbb{R}^m$.*

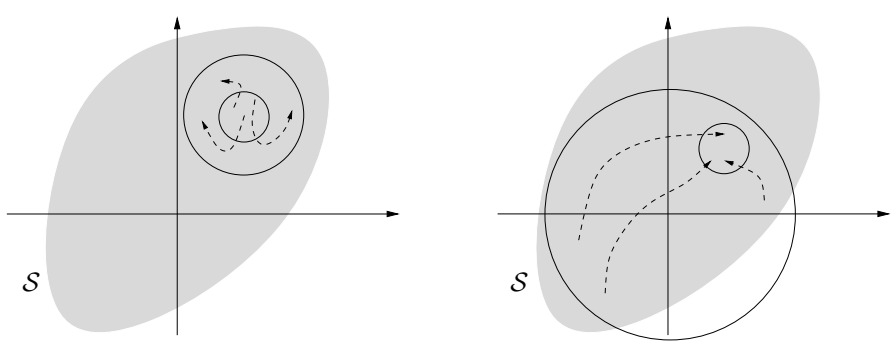

FIG. 3.2. *Asymptotic state agreement on $\mathcal{S}$.*

These definitions are illustrated in Figure 3.2 and can be stated, roughly speaking, as follows. State agreement (the left-hand figure) means that, for every point ζ in $\mathcal{S}$, the agents stay arbitrarily close to ζ if they start sufficiently close to ζ, uniformly with

respect to the starting time. Asymptotic state agreement (the two figures together) means, in addition, that the agents converge to a common location in $\mathcal{S}$.

These state agreement definitions are related to stability with respect to a set. Let Ω denote the set of aggregate states such that the subsystem states are all equal and in $\mathcal{S}$, i.e.,

$$\Omega = \{x \in \mathbb{R}^{nm} : x_1 = \cdots = x_n \in \mathcal{S}\}.$$

Then state agreement is equivalent to uniform stability with respect to Ω.

Finally, we give the following new definition of positive invariance specially for interconnected systems.

DEFINITION 3.5. *A set $\mathcal{A} \subset \mathbb{R}^m$ is said to be* positively invariant *for the switched interconnected system* (3.2) *if*

$$(\forall t_0 \geq 0)(\forall i)\ x_i(t_0) \in \mathcal{A} \implies (\forall t \geq t_0)(\forall i)\ x_i(t) \in \mathcal{A}.$$

Our first result establishes the positive invariance property of any compact convex set in $\mathcal{S}$ without needing any property of the interaction digraph. This result can perhaps be understood intuitively as follows. For $m = 2$, all agents move in the plane. Let $\mathcal{A}$ be a compact convex set in $\mathcal{S}$ and assume all agents start in $\mathcal{A}$. Let $\mathcal{C}(t)$ denote the convex hull of the agents' locations at time t. Because $\mathcal{A}$ is convex, clearly $\mathcal{C}(0) \subset \mathcal{A}$. Now invoke assumption A2. An agent that is initially in the interior of $\mathcal{C}(0)$ can head off in any direction at $t = 0$, but an agent that is initially on the boundary of $\mathcal{C}(0)$ is constrained to head into its interior. In this way, $\mathcal{C}(t)$ is nonincreasing (if $t_2 > t_1$, then $\mathcal{C}(t_2) \subset \mathcal{C}(t_1)$), and $\mathcal{A}$ is therefore positively invariant for the switched interconnected system (3.2).

THEOREM 3.6. *Let $\mathcal{A} \subset \mathcal{S}$ be a compact convex set. Then $\mathcal{A}$ is positively invariant for the switched interconnected system* (3.2).

The second result establishes state agreement of the system, again without needing any property of the interaction digraph.

THEOREM 3.7. *Suppose $\mathcal{S}$ is closed and convex. The switched interconnected system* (3.2) *has the property of state agreement on $\mathcal{S}$.*

Proof. Let $\zeta \in \mathcal{S}$ and $\varepsilon > 0$ be arbitrary, and let

$$\mathcal{A}_\varepsilon(\zeta) = \{y \in \mathcal{S} : \|y - \zeta\| \leq \varepsilon\}. \tag{3.3}$$

By Theorem 3.6, it follows that $\mathcal{A}_\varepsilon(\zeta)$ is positively invariant since it is a compact convex set in $\mathcal{S}$. We have thus proved that $\forall \zeta \in \mathcal{S},\ \forall \varepsilon > 0,\ \exists \delta = \varepsilon$ such that $\forall t_0 \geq 0$,

$$(\forall i)\ \ (\|x_i(t_0) - \zeta\| \leq \delta) \wedge (x_i(t_0) \in \mathcal{S}) \Longrightarrow (\forall t \geq t_0)(\forall i)\ \|x_i(t) - \zeta\| \leq \varepsilon.$$

The conclusion follows by Definition 3.4. ∎

Now comes our main result.

THEOREM 3.8. *Suppose $\mathcal{S}$ is closed and convex. The switched interconnected system* (3.2) *has the property of asymptotic state agreement on $\mathcal{S}$ if and only if the dynamic interaction digraph $\mathcal{G}_{\sigma(t)}$ is UQSC.*

This section concludes with a few remarks.

If $\mathcal{S} = \mathbb{R}^m$ in assumptions A1 and A2, then the switched interconnected system (3.2) has the global asymptotic state agreement property if and only if $\mathcal{G}_{\sigma(t)}$ is UQSC.

When the vector fields in the family (3.1) are nonautonomous, suppose assumptions A1 and A2 are replaced by the following (keeping assumption A3 the same):

A1′. $f_p^i(t,x)$ is locally Lipschitz with respect to x on $\mathcal{S}^n$ and piecewise continuous with respect to t.

A2′. For all $x \in \mathcal{S}^n$ and all $t \in \mathbb{R}$, $f_p^i(t,x) \in \text{ri}\left(\mathcal{T}(x_i, \mathcal{C}_p^i(x))\right)$.

It can be shown [21] that Theorem 3.8 no longer holds in general.

In the special case that the interaction graph is fixed ($\sigma(t)$ is a constant signal), then the property of UQSC is equivalent to QSC. Thus, we arrive at the following special result.

COROLLARY 3.9. *Suppose $\sigma(t) = p$ and $\mathcal{S} = \mathbb{R}^m$. Then, the interconnected system* (3.2) *has the globally asymptotic state agreement property if and only if $\mathcal{G}_p$ is QSC.*

For this special case we can actually relax the assumptions on the vector fields $f_p^i : \mathbb{R}^{mn} \to \mathbb{R}^m$ as follows:

A1″. f_p^i is continuous on $\mathbb{R}^{mn}$.

A2″. For all $x \in \mathbb{R}^{mn}$, $f_p^i(x) \in \mathcal{T}\left(x_i, \mathcal{C}_p^i(x)\right)$. Moreover, $f_p^i(x) \neq 0$ if $\mathcal{C}_p^i(x)$ is not a singleton and x_i is its vertex.

A sketch of the proof can be found in [24]. Unlike the proof of Theorem 3.8 here (see section 5), the proof in [24] relies on LaSalle's invariance principle. Finally, it is worth pointing out that assumption A1″ is too weak for sufficiency in Theorem 3.8 when the interaction digraph is dynamic [21].

Application: Synchronization of coupled oscillators. The Kuramoto model [17, 39] describes the dynamics of a set of n oscillators with angles θ_i with natural frequencies ω_i. The time evolution of the ith oscillator is given by

$$\dot{\theta}_i = \omega_i + k_i \sum_{j \in \mathcal{N}_i(t)} \sin(\theta_j - \theta_i),$$

where $k_i > 0$ is the coupling strength and $\mathcal{N}_i(t)$ is the set of neighbors of oscillator i at time t. The interaction structure can be general up to this point in the paper; that is, $\mathcal{N}_i(t)$ can be an arbitrary set of other nodes and can be dynamic.

The neighbor sets $\mathcal{N}_i(t)$ define $\mathcal{G}_{\sigma(t)}$ and the switched interconnected system

$$\dot{\theta}(t) = f_{\sigma(t)}\left(\theta(t)\right),$$

where $\theta = (\theta_1, \ldots, \theta_n)$ and $\sigma(t)$ is a suitable switching signal. For identical frequencies (i.e., $\omega_i = \omega \ \forall i$), the transformation $x_i = \theta_i - \omega t$ yields

$$\dot{x}_i = k_i \sum_{j \in \mathcal{N}_i(t)} \sin(x_j - x_i), \quad i = 1, \ldots, n. \tag{3.4}$$

Let a, b be any real numbers such that $0 \leq b - a < \pi$, and define $\mathcal{S} = [a, b]$. It can be checked that A1 and A2 are satisfied. Suppose $\sigma(t)$ here is regular enough to satisfy A3. Then from Theorem 3.8 it follows that, if and only if $\mathcal{G}_{\sigma(t)}$ is UQSC, the switched interconnected system (3.4) has the property of asymptotic state agreement on $\mathcal{S}$. This implies that there exists $\bar{x} \in \mathbb{R}$ such that the oscillators asymptotically synchronize:

$$\theta_i(t) \to \bar{x} + \omega t, \quad \dot{\theta}_i(t) \to \omega.$$

This extends Theorem 1 in [17], which assumes the interaction graph is undirected and static and the initial state $\theta_i(0) \in \left(-\frac{\pi}{2}, \frac{\pi}{2}\right)$ for all i.

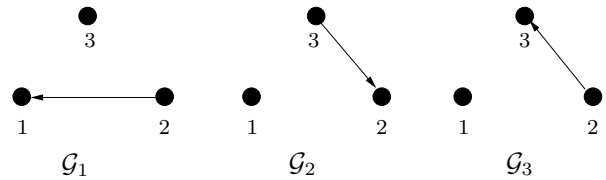

FIG. 3.3. *Three interaction digraphs* $\mathcal{G}_p$, $p = 1, 2, 3$.

As an example, three Kuramoto oscillators with time-varying interaction are simulated. The initial conditions are $\theta_1 = 0$, $\theta_2 = 1$, $\theta_3 = -1$. The natural frequency ω_i equals 1, and the coupling strength k_i is set to 1 for all i. The interaction structure switches among three possible interaction structures periodically, as shown in Figure 3.3. It can be checked that $\mathcal{G}_{\sigma(t)}$ is UQSC. Thus these three oscillators achieve asymptotical synchronization by the main theorem. Figure 3.4 shows the plots of $\sin(\theta_i)$, $i = 1, 2, 3$, and of the switching signal $\sigma(t)$. Synchronization is evident.

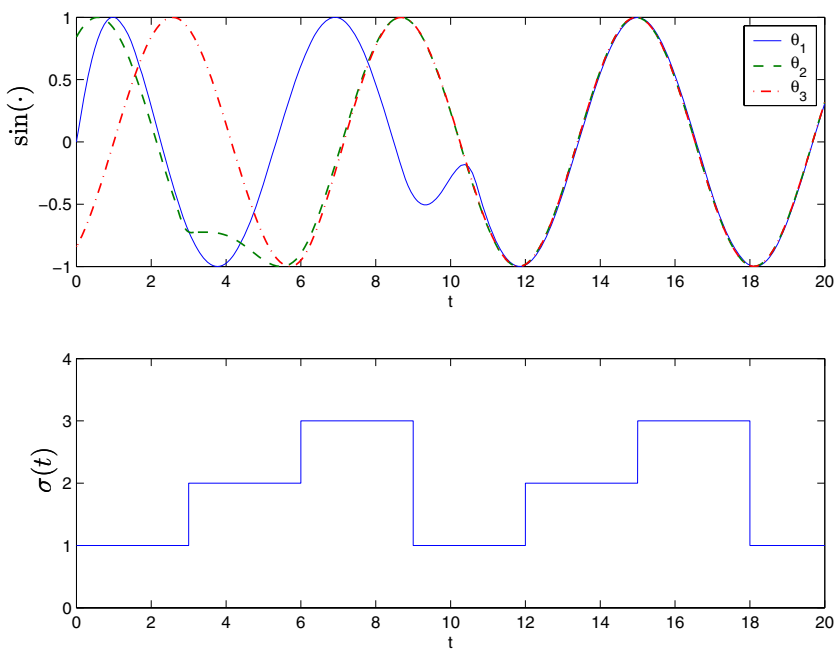

FIG. 3.4. *Synchronization of three oscillators with a dynamic interaction structure.*

4. The rendezvous problem. Now we turn to the second main topic: the rendezvous problem for autonomous mobile robots moving in continuous time. The problem here is different because connectivity is state dependent instead of time dependent a priori.

Suppose there are n robots, each having the simple kinematic model of velocity control: $\dot{x}_i = u_i$, where $x_i \in \mathbb{R}^m$ is the position of robot i. Assume that, due to the limited field of view of its sensor, each robot can sense only the relative positions of its neighbor robots within radius r. Letting $\mathcal{N}_i(x)$ denote the set of neighbors of robot i, where x is the aggregate state of n robots, we thus have that $\{y_{ij} = x_j - x_i : \ j \in$

$\mathcal{N}_i(x)\}$ is the information available to robot i. The *rendezvous problem* is to design local distributed control laws u_i, functions of $\{y_{ij} : j \in \mathcal{N}_i(x)\}$, such that all states $\{x_i : i = 1, \dots, n\}$ converge to a common value $\bar{x} \in \mathbb{R}^m$.

The interaction digraph is state dependent, $\mathcal{G}_{\sigma(x)}$, because of the proximity sensors, and the switched interconnected system takes the form

$$\dot{x} = f_{\sigma(x)}(x), \tag{4.1}$$

where $\sigma : \mathbb{R}^{mn} \to \mathcal{P}$. Let us *fix an initial state* $x^0 \in \mathbb{R}^{mn}$ and assume that (4.1) has a solution $x(t)$ defined for all $t \geq 0$. Then the state-dependent switching rule can be viewed as a time-dependent switching rule $\sigma(x(t))$, and the interaction graph becomes time dependent too, $\mathcal{G}_{\sigma(x(t))}$.

If some robots are initialized so far away from the rest that they never acquire information from them, then the rendezvous problem obviously cannot be solved. This corresponds to the situation where $\mathcal{G}_{\sigma(x(0))}$ is not QSC. Thus it is natural to assume that $\mathcal{G}_{\sigma(x(0))}$ *is* QSC. Moreover, we wish the control laws u_i to be devised such that $\mathcal{G}_{\sigma(x(t))}$ does not lose this property in the future, even though the controller may cause changes in $\mathcal{G}_{\sigma(x(t))}$. Intuitively, u_i should make the maximum distance between robot i and its neighbors nonincreasing.

Let $\mathcal{I}_i(x)$ denote the set of neighbor robots $j \in \mathcal{N}_i(x)$ that have maximum distance from robot i (generically $\mathcal{I}_i(x)$ is a singleton).

PROPOSITION 4.1. *Assume that for each i the control law u_i satisfies*

$$(\forall x) \quad \max_{j \in \mathcal{I}_i(x)} (x_i - x_j)^T u_i \leq 0. \tag{4.2}$$

If $\mathcal{G}_{\sigma(x^0)}$ is QSC and a solution $x(t)$ to (4.1) exists for all $t \geq 0$, then $\mathcal{G}_{\sigma(x(t))}$ is QSC for all $t \geq 0$.

Proof. Define

$$V(x) = \max_i \max_{j \in \mathcal{N}_i(x)} \|x_i - x_j\|^2.$$

Notice that $V(x) \leq r$, where r is the radius of the field of view of each robot. Also, define

$$\mathcal{I}(x) = \left\{(i,j) : \ V(x) = \|x_i - x_j\|^2, \ j \in \mathcal{N}_i(x)\right\},$$

the set of pairs of indices where the maximum is reached. By Lemma 2.2

$$\begin{aligned} D^+V(x(t)) &= 2 \max_{(i,j) \in \mathcal{I}(x)} \left[(x_i - x_j)^T u_i + (x_j - x_i)^T u_j\right] \\ &\leq 2 \max_{(i,j) \in \mathcal{I}(x)} (x_i - x_j)^T u_i + 2 \max_{(i,j) \in \mathcal{I}(x)} (x_j - x_i)^T u_j. \end{aligned}$$

It follows from (4.2) that

$$\max_{(i,j) \in \mathcal{I}(x)} (x_i - x_j)^T u_i \leq 0 \quad \text{and} \quad \max_{(i,j) \in \mathcal{I}(x)} (x_j - x_i)^T u_j \leq 0.$$

Hence $D^+V(x(t)) \leq 0$ for all $t \geq 0$, which means the already linked arcs will never be disconnected and therefore the conclusion follows. ∎

Next, we show that if the distributed control law u_i satisfies (4.2) as well as assumptions A1″ and A2″, then a solution $x(t)$ to (4.1) exists for all $t \geq 0$, and the robots rendezvous.

PROPOSITION 4.2. *Suppose $\mathcal{G}_{\sigma(x^0)}$ is QSC. If u_i satisfies* (4.2) *as well as* A1″ *and* A2″, *then the robots rendezvous.*

Proof. If $\mathcal{G}_{\sigma(x^0)}$ is fully connected, then $\mathcal{G}_{\sigma(x(t))}$ is fixed for all time $t \geq 0$ since no link will be dropped, by Proposition 4.1, and no link can be added. Then the conclusion follows from Corollary 3.9.

If instead $\mathcal{G}_{\sigma(x^0)}$ is not fully connected, then $\mathcal{G}_{\sigma(x(t))}$ is dynamic and switches for a finite number of times. To prove this, suppose by contradiction that for all $t \geq 0$, $\mathcal{G}_{\sigma(x(t))} = \mathcal{G}_{\sigma(x^0)}$. Then by Corollary 3.9, all the robots converge to a common location. So $\mathcal{G}_{\sigma(x(t))}$ will become fully connected at some time t, which contradicts the assumption that $\mathcal{G}_{\sigma(x(t))} = \mathcal{G}_{\sigma(x^0)}$ is not fully connected. Hence, there is a $t_1 \geq 0$ such that $\mathcal{G}_{\sigma(x(t_1))}$ has more links than $\mathcal{G}_{\sigma(x^0)}$ because no link will be dropped by Proposition 4.1. Repeating this argument a finite number of times eventually leads to the existence of t_i such that $\mathcal{G}_{\sigma(x(t_i))}$ is fully connected, and thus, it is fixed after t_i. Then the conclusion follows from Corollary 3.9 by treating $(t_i, x(t_i))$ as the initial condition. □

The control law given next is based on the algorithm first proposed in [1].

PROPOSITION 4.3. *A possible choice of u_i satisfying condition* (4.2) *as well as assumptions* A1″ *and* A2″ *is $u_i = e(0, y_{ij} : j \in \mathcal{N}_i(x))$, the Euclidean center of the set $\mathcal{Z} = \{0, y_{ij}, j \in \mathcal{N}_i(x)\}$.*

Proof. The Euclidean center of the set $\mathcal{Z}$ is the unique point w that minimizes the function $g(w) := \max_{z \in \mathcal{Z}} \|w - z\|$. Interpreted geometrically, $e(\cdot)$ is the center of the smallest m-sphere that contains the set of points $\{0, y_{ij}, j \in \mathcal{N}_i(x)\}$. Furthermore, it can be easily shown that it lies in the polytope $\widetilde{\mathcal{C}}_p^i = \text{co}\{0, y_{ij}, j \in \mathcal{N}_i(x)\}$ but not at its vertices if the polytope is not a singleton. Thus,

$$e\left(0, y_{ij} : j \in \mathcal{N}_i(x)\right) = \arg\min_{w \in \widetilde{\mathcal{C}}_p^i} \left(\max_{z \in \mathcal{Z}} \|w - z\| \right).$$

Then, by the maximum theorem [40], the function $e(\cdot)$ is continuous (but not locally Lipschitz by some other arguments), and hence u_i satisfies assumption A1″.

Next, $e(\cdot) \in \widetilde{\mathcal{C}}_p^i$ implies $e(\cdot) \in \mathcal{T}(0, \widetilde{\mathcal{C}}_p^i)$. Also, notice that $\mathcal{C}_p^i(x) = \text{co}\{x_i, x_j : \ j \in \mathcal{N}_i(x)\}$ is the translation of $\widetilde{\mathcal{C}}_p^i$ to the point x_i. Hence, $e(\cdot) \in \mathcal{T}(x_i, \mathcal{C}_p^i(x))$. In addition, if $\mathcal{C}_p^i(x)$ is not a singleton and x_i is its vertex, this means that $\widetilde{\mathcal{C}}_p^i$ is not a singleton and 0 is its vertex. Then by the fact that $e(\cdot)$ lies in $\widetilde{\mathcal{C}}_p^i$ but not at its vertices, it follows that $u_i = e(\cdot) \neq 0$. Thus u_i satisfies assumption A2″.

Finally, u_i satisfies (4.2). This can be seen from geometry. We show the case $m = 2$ for illustration. If $u_i = 0$, then it trivially satisfies (4.2). If $u_i \neq 0$, then the picture is as in Figure 4.1. The solid circle C_1 is the smallest circle enclosing the points 0 and $y_{ij}, j \in \mathcal{N}_i(x)$. The dotted circle C_2 is centered at the origin and goes through the intersection points between C_1 and its diameter, which is perpendicular to u_i. We know that if there are some y_{ij} in the closed shaded area, then one of them achieves the maximal distance from the origin among all $y_{ij}, j \in \mathcal{N}_i(x)$. On the other hand, there is at least one $j \in \mathcal{N}_i(x)$ such that y_{ij} is in the closed semicircle of C_1, since otherwise it is not the smallest circle. Hence, y_{ij} lies in the closed shaded area if $j \in \mathcal{I}_i(x)$. Moreover, the angle between u_i and such y_{ij} is less than $\pi/2$. This implies that $\max_{j \in \mathcal{I}_i(x)} (x_i - x_j)^T u_i \leq 0$. □

5. Proofs of the main results in section 3. Our proofs rely heavily on nonsmooth analysis involving the Dini derivative. They are partly inspired by a result of Narendra and Annaswamy [28], who show that with $\dot{V}(x,t) \leq 0$ uniform

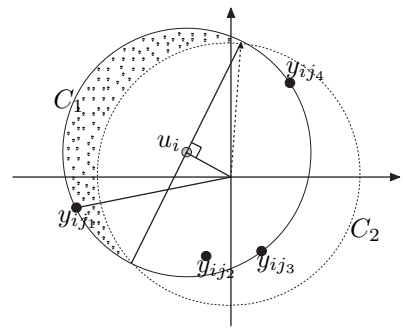

FIG. 4.1. *The smallest enclosing circle.*

asymptotic stability can be proved if there exists a positive T such that for all t, $V(x(t+T),t+T) - V(x(t),t) \leq -\gamma(\|x(t)\|) < 0$, where γ is a class $\mathcal{K}$ function. The difference here is that we deal with stability with respect to a *set*—the set of aggregate states where the subsystem states are all equal—rather than stability of an equilibrium point; an additional complication is that the natural V-functions are nondifferentiable.

Nagumo's theorem concerning set invariance is stated first, for later reference.

THEOREM 5.1 (see [3]). *Consider the system $\dot{y} = F(y)$, with $F : \mathbb{R}^l \to \mathbb{R}^l$, and let $\mathcal{Y} \subset \mathbb{R}^l$ be a closed convex set. Assume that, for each y^0 in $\mathcal{Y}$, there exists $\epsilon(y^0) > 0$ such that the system admits a unique solution $y(t, y^0)$ defined for all $t \in [0, \epsilon(y^0))$. Then,*

$$y^0 \in \mathcal{Y} \Longrightarrow \big(\forall t \in [0, \epsilon(y^0))\big)\ \ y(t, y^0) \in \mathcal{Y}$$

if and only if $F(y) \in \mathcal{T}(y, \mathcal{Y})$ for all $y \in \mathcal{Y}$.

Proof of Theorem 3.6. Let $\mathcal{A}$ be any compact convex set in $\mathcal{S}$ and consider any initial state $x^0 \in \mathcal{A}^n$ and any initial time t_0. For any piecewise constant switching signal $\sigma(t)$, let $x(t, t_0, x^0)$ be the solution of the switched interconnected system (3.2) with $x(t_0) = x^0$, and let $[t_0, t_0 + \epsilon(t_0, x^0))$ be its maximal interval of existence.

For any point $x \in \mathcal{A}^n$, it is obvious that $\mathcal{C}_p^i(x) \subset \mathcal{A}$ for all $i \in \mathcal{I}_0$ and $p \in \mathcal{P}$, by convexity of $\mathcal{A}$. Thus, by property (i) in Lemma 2.1,

$$f_p^i(x) \in \mathrm{ri}\left(\mathcal{T}(x_i, \mathcal{C}_p^i(x))\right) \subset \mathcal{T}(x_i, \mathcal{A})\ \forall i \in \mathcal{I}_0,\ \forall p \in \mathcal{P},$$

and by property (ii) in the same lemma,

$$g(t,x) := f_{\sigma(t)}(x) \in \mathcal{T}(x, \mathcal{A}^n)\ \forall t \in \mathbb{R},\ \forall x \in \mathcal{A}^n.$$

Set $y = (t, x)$ and construct the augmented system

$$\dot{y} = F(y) := \begin{bmatrix} 1 \\ g(y) \end{bmatrix}. \tag{5.1}$$

Since $g(t,x)$ admits a unique solution $x(t, t_0, x^0)$ defined for all $t \in [t_0, t_0 + \epsilon(t_0, x^0))$, it follows that for all $y^0 = (t_0, x^0) \in \mathbb{R} \times \mathcal{A}^n$, the augmented system (5.1) has a unique solution $y(t, y^0)$ defined on $[0, \epsilon(y^0))$. Moreover,

$$F(y) \in \mathcal{T}(t, \mathbb{R}) \times \mathcal{T}(x, \mathcal{A}^n) = \mathcal{T}(y, \mathbb{R} \times \mathcal{A}^n)\ \forall y \in \mathbb{R} \times \mathcal{A}^n.$$

Since $\mathbb{R} \times \mathcal{A}^n$ is closed and convex, by Theorem 5.1 it follows that

$$y^0 = (t_0, x^0) \in \mathbb{R} \times \mathcal{A}^n \Longrightarrow (\forall \tau \in [0, \epsilon(y^0)))\ y(\tau) \in \mathbb{R} \times \mathcal{A}^n. \tag{5.2}$$

The solution $y(\tau)$ to (5.1) with initial condition $y^0 = (t_0, x^0)$ is related to the solution $x(t)$ to $\dot{x} = g(t, x)$ with initial condition $x(t_0) = x^0$ as follows:

$$(\forall t \in [t_0, t_0 + \epsilon(t_0, x^0)))\ (t, x(t)) = y(t - t_0).$$

We thus rewrite condition (5.2) as

$$t_0 \in \mathbb{R} \text{ and } x^0 \in \mathcal{A}^n \Longrightarrow (\forall t \in [t_0, t_0 + \epsilon(t_0, x^0)))\ x(t) \in \mathcal{A}^n.$$

Since the set $\mathcal{A}^n$ is compact, it follows by Theorem 2.4 in [18] that, for all $x^0 \in \mathcal{A}^n$ and all t_0, $\epsilon(t_0, x^0) = \infty$ and the set $\mathcal{A}$ is positively invariant for the switched interconnected system (3.2) by definition 3.5. □

Now we need some additional notation. First, a hypercube in $\mathbb{R}^m$:

$$\mathcal{A}_r(z) = \{y \in \mathbb{R}^m : \|y - z\|_\infty \leq r\}.$$

Let $c > 0$ be large enough that $\mathcal{S}_c := \mathcal{S} \cap \mathcal{A}_c(0)$ is not empty. Now consider any $x = (x_1, \ldots, x_n)$, $x_i \in \mathcal{S}_c$. Each x_i lives in $\mathbb{R}^m$. Let $\mathcal{C}(x)$ denote the convex hull of the points $x_1, \ldots, x_n$; $\mathcal{C}(x)$ is a polytope in $\mathbb{R}^m$.

To simplify notation, we focus on the first axis in $\mathbb{R}^m$. Along this axis, let $a_1(x)$ and $b_1(x)$ denote the upper and lower ordinates of $\mathcal{C}(x)$, as in Figure 5.1. The set $\{y \in \mathcal{C}(x) : y_1 = a_1(x)\}$ is the first upper boundary of $\mathcal{C}(x)$. Finally, for small enough $r > 0$, define

$$\mathcal{H}_r(x) = \{y \in \mathcal{C}(x) : y_1 \leq a_1(x) - r\}.$$

The setup is summarized in Figure 5.1.

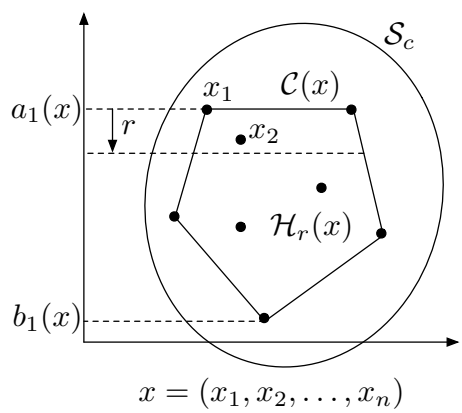

FIG. 5.1. *Illustration to define notation: $\mathcal{C}(x)$ is the convex hull of the points $x_1, \ldots, x_n$; $a_1(x), b_1(x)$ are its upper and lower ordinates; $\mathcal{H}_r(x)$ is the part of the convex hull below the line with ordinate $a_1(x) - r$.*

Now we need two technical lemmas for which we assume that the hypotheses of Theorem 3.8 hold. Due to space limitation, we have to omit the proofs and refer the reader to [21].

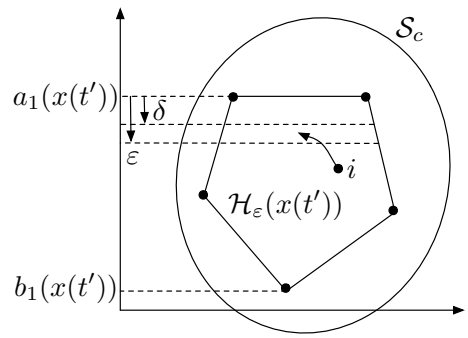

FIG. 5.2. *Illustration for Lemma* 5.2*: Agent i is in $\mathcal{H}_\varepsilon(x(t'))$ at time t_1, and it cannot get into the upper layer of width δ in the near future.*

The first lemma is illustrated in Figure 5.2.

LEMMA 5.2. *For every sufficiently large $c > 0$, there exists a class $\mathcal{KL}$ function $\gamma : [0, 2c] \times [0, \infty) \to [0, \infty)$ such that $\gamma(\triangle, 0) = \triangle$ and such that the following is true: For every $(t', x(t')) \in \mathbb{R} \times \mathcal{S}_c^n$, every $\varepsilon > 0$ sufficiently small, and every $T > 0$, if $x_i(t_1) \in \mathcal{H}_\varepsilon(x(t'))$ at $t_1 \geq t'$, then $x_i(t) \in \mathcal{H}_\delta(x(t'))$ for all $t \in [t_1, t_1 + T]$, where $\delta = \gamma(\varepsilon, T)$.*

The second lemma is illustrated in Figure 5.3.

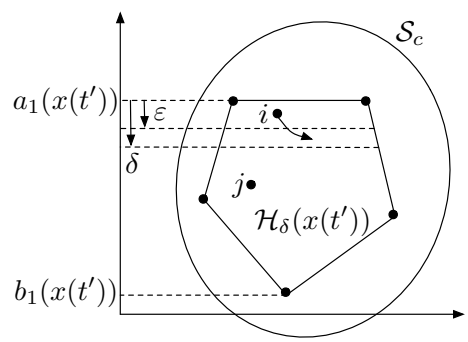

FIG. 5.3. *Illustration for Lemma* 5.3*: Agent i has the neighbor j in $\mathcal{H}_\delta(x(t'))$ and will consequently be pulled into $\mathcal{H}_\varepsilon(x(t'))$.*

LEMMA 5.3. *For every sufficiently large $c > 0$, there exists a class $\mathcal{K}$ function $\varphi : [0, 2c] \to [0, \infty)$ such that $\varphi(\triangle) < \triangle$ for $\triangle \neq 0$ and such that the following is true: For every $(t', x(t')) \in \mathbb{R} \times \mathcal{S}_c^n$ and every $\delta > 0$ sufficiently small, if there exist a pair (i, j) and a $t_1 \geq t'$ such that $j \in \mathcal{N}_i(t)$ and $x_j(t) \in \mathcal{H}_\delta(x(t'))$ for all $t \in [t_1, t_1 + \tau_D]$, then there exists a $t_2 \in [t', t_1 + \tau_D]$ such that $x_i(t_2) \in \mathcal{H}_\varepsilon(x(t'))$, where $\varepsilon = \varphi(\delta)$.*

Proof of Theorem 3.8. (Necessity.) To prove the contrapositive form, assume that $\mathcal{G}_{\sigma(t)}$ is not UQSC. That is, for every $T > 0$ there exists $t^* \geq 0$ such that $\mathcal{G}([t^*, t^* + T])$ is not QSC; i.e., it does not have a center. Then, in $\mathcal{G}([t^*, t^* + T])$ there are two nodes i^* and j^* such that for every node k either $k \not\rightarrow i^*$ or $k \not\rightarrow j^*$. Let $\mathcal{V}_1$ be the set of

nodes l such that $l \to i^*$ and let $\mathcal{V}_2$ be the set of nodes l such that $l \to j^*$. Obviously, $\mathcal{V}_1$ and $\mathcal{V}_2$ are disjoint. Moreover, for each node $i \in \mathcal{V}_1$ (resp., $\mathcal{V}_2$), the set of neighbors of agent i in $\mathcal{G}([t^*, t^* + T])$ is a subset of $\mathcal{V}_1$ (resp., $\mathcal{V}_2$). This implies that, for all $t \in [t^*, t^* + T]$ and for all $(i, j) \in \mathcal{V}_1 \times \mathcal{V}_2$,

$$\mathcal{N}_i(\sigma(t)) \subseteq \mathcal{V}_1 \quad \text{and} \quad \mathcal{N}_j(\sigma(t)) \subseteq \mathcal{V}_2.$$

Choose any $z_1, z_2 \in \mathcal{S}$ such that $z_1 \neq z_2$. Let $t_0 = t^*$ and pick any initial condition $x(t_0)$ such that

$$x_i(t_0) = \begin{cases} z_1 & \text{if } i \in \mathcal{V}_1, \\ z_2 & \text{if } i \in \mathcal{V}_2. \end{cases}$$

Then, by assumption A2, for all $t \in [t_0, t_0 + T]$,

$$x_i(t) = \begin{cases} z_1 & \forall i \in \mathcal{V}_1, \\ z_2 & \forall i \in \mathcal{V}_2. \end{cases}$$

Let $c = \max_i \|x_i(t_0)\|$ and let ε be a positive scalar smaller than $\|z_1 - z_2\|/2$. We have thus found $\varepsilon > 0$ and $c > 0$ such that, for all $T > 0$, there exists $t_0 = t^*$ such that

$$(\forall i)\ (\|x_i(t_0)\| \leq c) \wedge (x_i(t_0) \in \mathcal{S}),\ \text{but}\ (\forall \zeta \in \mathcal{S})(\exists t = t_0 + T)(\exists i)\ \|x_i(t) - \zeta\| > \epsilon.$$

Thus system (3.2) does not have the property of asymptotic state agreement on $\mathcal{S}$.

(Sufficiency.) Assume $\mathcal{G}_{\sigma(t)}$ is UQSC. By Theorem 3.7 the switched interconnected system (3.2) has the property of state agreement on $\mathcal{S}$, so it remains to show that $\forall \varepsilon > 0,\ \forall c > 0,\ \exists T^* > 0$ such that $\forall t_0 \geq 0$

$$(\forall i)\ x_i(t_0) \in \mathcal{S}_c \Longrightarrow (\exists \zeta \in \mathcal{S})(\forall t \geq t_0 + T^*)(\forall i)\ x_i(t) \in \mathcal{A}_\varepsilon(\zeta). \tag{5.3}$$

Let $\varepsilon > 0,\ c > 0$ be arbitrary. There exist a class $\mathcal{KL}$ function γ and a class $\mathcal{K}$ function φ satisfying the properties in Lemmas 5.2 and 5.3, respectively. For any given $t_0 \geq 0$ and $x^0 \in \mathcal{S}_c^n$, consider the solution $x(t)$ of (3.2) with $x(t_0) = x^0$ and the nonnegative function $V_j(x) := a_j(x) - b_j(x)$, $j = 1, \ldots, m$. Thus $V_j(x(t))$ equals the width in the jth direction of the convex hull of the agents at time t. By Theorem 3.6, for every $t \geq t' \geq t_0$, $x_i(t) \in \mathcal{C}(x(t')) \subset \mathcal{S}_c$ for all i. It follows that $V_j(x(t))$ is nonincreasing along the trajectory $x(t)$.

Since $\mathcal{G}_{\sigma(t)}$ is UQSC, there is a $T' > 0$ such that for each t the union digraph $\mathcal{G}([t, t + T'])$ is QSC. Let $T = T' + 2\tau_D$, where τ_D is the dwell time.

Claim. There exists a class $\mathcal{K}$ function η such that for every $t' \geq t_0$

$$V_1(x(t' + \bar{T})) - V_1(x(t')) \leq -\eta\left(V_1(x(t'))\right), \tag{5.4}$$

where $\bar{T} = 2nT$.

Let us postpone the proof of this claim and see how the theorem follows from the claim. From (5.4) we have

$$V_1\left(x(t_0 + k\bar{T})\right) \leq V_1\left(x(t_0)\right) - \eta\left(V_1(x(t_0))\right) - \cdots - \eta\left(V_1(x(t_0 + (k-1)\bar{T}))\right).$$

Notice that $x^0 \in \mathcal{S}_c^n(0)$ implies $V_1(x^0) \leq 2c$. In addition, considering the facts that η is a class $\mathcal{K}$ function and that $V_1(x(t))$ is nonincreasing, one obtains

$$V_1(x(t_0 + k\bar{T})) \leq 2c - k\eta(V_1(x(t_0 + k\bar{T}))).$$

This means there is a $T_1^* = k\bar{T} > 0$ (k large enough) such that $V_1(x(t)) < 2\varepsilon$ for all $t \geq t_0 + T_1^*$. For each $j = 2, \ldots, m$, by the same argument, there is a $T_j^* > 0$ such that $V_j(x(t)) < 2\varepsilon$ for all $t \geq t_0 + T_j^*$. Let $T^* = \max_j T_j^*$. Thus $V_j(x(t)) < 2\varepsilon$ for all $t \geq t_0 + T^*$ and all $j = 1, \ldots, m$. This in turn implies that there exists a $\zeta \in \mathcal{S}$ such that $x_i(t) \in \mathcal{A}_\varepsilon(\zeta)$ for all i and all $t \geq t_0 + T^*$. This proves (5.3).

Now we prove the claim. Inequality (5.4) says that the width, along the first axis, of the convex hull of the agents reduces measurably from time t' to time $t' + \bar{T}$. The proof is intricate and involves applying Lemmas 5.2 and 5.3 alternately.

We begin by constructing a family of parameters, $\varepsilon_1, \delta_1, \varepsilon_2, \ldots, \varepsilon_{n-1}, \delta_{n-1}, \varepsilon_n$. First, ε_1 is taken to be half the width at time t': $\varepsilon_1 = V_1(x(t'))/2$. Then δ_1 is produced by applying Lemma 5.2: $\delta_1 = \gamma(\varepsilon_1, \bar{T})$. Then ε_2 comes from Lemma 5.3, $\varepsilon_2 = \varphi(\delta_1)$, and δ_2 comes from Lemma 5.2, $\delta_2 = \gamma(\varepsilon_2, \bar{T})$. Continuing, we set

$$\begin{aligned}
\varepsilon_3 &= \varphi(\delta_2), \\
\delta_3 &= \gamma(\varepsilon_3, \bar{T}) \\
&\vdots \\
\varepsilon_{n-1} &= \varphi(\delta_{n-2}), \\
\delta_{n-1} &= \gamma(\varepsilon_{n-1}, \bar{T}), \\
\varepsilon_n &= \varphi(\delta_{n-1}).
\end{aligned}$$

Define $\bar{\gamma}(\cdot) := \gamma(\cdot, \bar{T})$. Then ε_n can be written as

$$\varepsilon_n = \eta\left(V_1(x(t'))\right),$$

where $\eta(\cdot) := \varphi \circ \bar{\gamma} \circ \cdots \circ \varphi \circ \bar{\gamma}(\cdot/2)$. It is a class $\mathcal{K}$ function since $\bar{\gamma}$ and φ both are. Since γ is class $\mathcal{KL}$ with the property $\gamma(\triangle, 0) = \triangle$ and $\bar{T} > 0$, it follows that $\delta_k < \varepsilon_k$. In addition, $\varepsilon_{k+1} < \delta_k$ because $\varphi(\triangle) < \triangle$ for $\triangle \neq 0$. Thus,

$$0 < \varepsilon_n < \delta_{n-1} < \cdots < \delta_1 < \varepsilon_1.$$

These parameters are used as in Figure 5.4.

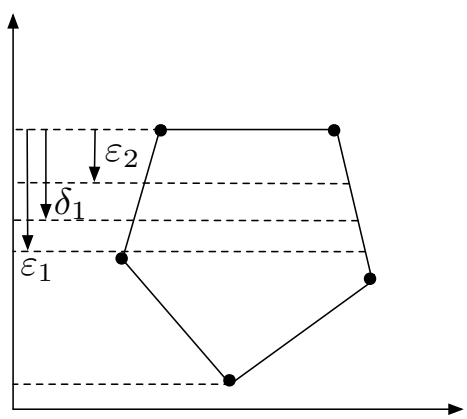

FIG. 5.4. *The parameters $\varepsilon_1, \delta_1, \varepsilon_2, \ldots, \varepsilon_{n-1}, \delta_{n-1}, \varepsilon_n$ with respect to the convex hull and the first axis.*

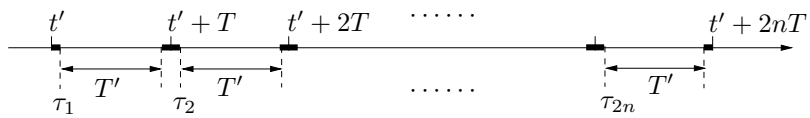

FIG. 5.5. *The time interval* $[t', t'+\bar{T}]$.

Let $\mathcal{V}_1$ and $\mathcal{V}_1^*$ be a partition of the node set $\mathcal{V}$ such that $i \in \mathcal{V}_1$ if $x_i(t') \in \mathcal{H}_{\varepsilon_1}$ and $i \in \mathcal{V}_1^*$ otherwise. Thus $\mathcal{V}_1$ is the set of agents located in the lower half of the convex hull in Figure 5.4 at time t'.

Next, we apply the two lemmas to construct a sequence of times at which certain events are known to occur. In what follows, hopefully without causing confusion, we use $\mathcal{H}_r$ to denote $\mathcal{H}_r(x(t'))$ for simplicity. As shown in Figure 5.5, let

$$\begin{aligned}\tau_1 &= t' + \tau_D,\\ \tau_2 &= t' + T + \tau_D\\ &\vdots\\ \tau_{2n} &= t' + (2n-1)T + \tau_D.\end{aligned}$$

For each $k = 1, \ldots, 2n$, the digraph $\mathcal{G}([\tau_k, \tau_k + T'])$ is QSC, and therefore it has a center, say c_k. Now c_k is either in $\mathcal{V}_1$ or in $\mathcal{V}_1^*$; thus at least n elements in $\{c_1, \ldots, c_{2n}\}$ lie in either $\mathcal{V}_1$ or $\mathcal{V}_1^*$. Assume without loss of generality that they lie in $\mathcal{V}_1$; thus there exist indices $1 \le k_1 < \cdots < k_n \le 2n$ such that $c_{k_i} \in \mathcal{V}_1$.

At time t', by definition, $\mathcal{H}_{\varepsilon_1}$ has at least one agent (see Figure 5.4). Moreover, by Lemma 5.2, for all i

$$x_i(t') \in \mathcal{H}_{\varepsilon_1} \Longrightarrow x_i(t) \in \mathcal{H}_{\delta_1} \ \forall t \in [t', t'+\bar{T}]. \tag{5.5}$$

Since $\mathcal{G}([\tau_{k_1}, \tau_{k_1} + T'])$ has a center c_{k_1} in $\mathcal{V}_1$, there exists a pair $(i,j) \in \mathcal{V}_1^* \times \mathcal{V}_1$ such that j is a neighbor of i in this digraph; otherwise there is no link from j to i for any $i \in \mathcal{V}_1^*$ and $j \in \mathcal{V}_1$, which contradicts the fact that the digraph has a center in $\mathcal{V}_1$. This further implies that there is a $\tau \in [\tau_{k_1}, \tau_{k_1} + T']$ such that $j \in \mathcal{N}_i(\tau)$. Since $\tau \in [\tau_{k_1}, \tau_{k_1} + T'] = [t' + (k_1 - 1)T + \tau_D, t' + k_1 T - \tau_D]$, it follows that $[\tau - \tau_D, \tau + \tau_D] \subset [t' + (k_1 - 1)T, t' + k_1 T]$. Since $\sigma(t) \in \mathcal{S}_{dwell}(\tau_D)$, there is an interval $[\bar{\tau}, \bar{\tau} + \tau_D]$, which contains τ and is a subinterval of $[t', t' + k_1 T]$, such that $j \in \mathcal{N}_i(t)$ for all $t \in [\bar{\tau}, \bar{\tau} + \tau_D]$. In addition, since $j \in \mathcal{V}_1$ or, what is the same, $x_j(t') \in \mathcal{H}_{\varepsilon_1}$, from (5.5) we know that $x_j(t) \in \mathcal{H}_{\delta_1}$ for all $t \in [t', t' + \bar{T}]$ (and of course for all $t \in [\bar{\tau}, \bar{\tau} + \tau_D]$). Thus, by Lemma 5.3, there exists $t_1 \in [t', \bar{\tau} + \tau_D] \subseteq [t', t' + k_1 T]$ such that $x_i(t_1) \in \mathcal{H}_{\varepsilon_2}$.

So we have shown on the one hand that the agents not in $\mathcal{H}_{\varepsilon_1}$ at t' are in $\mathcal{H}_{\varepsilon_2}$ at t_1. On the other hand, the agents in $\mathcal{H}_{\varepsilon_1}$ at t' remain in $\mathcal{H}_{\delta_1}$ at t_1 from (5.5), and therefore remain in $\mathcal{H}_{\varepsilon_2}$ at t_1 because $\mathcal{H}_{\delta_1} \subset \mathcal{H}_{\varepsilon_2}$. Hence, at time t_1, $\mathcal{H}_{\varepsilon_2}(x(t'))$ has at least two agents.

Let $\mathcal{V}_2$ and $\mathcal{V}_2^*$ be a partition of the node set $\mathcal{V}$ such that $i \in \mathcal{V}_2$ if $x_i(t_1) \in \mathcal{H}_{\varepsilon_2}$ and $i \in \mathcal{V}_2^*$ otherwise. Note that by (5.5)

$$k \in \mathcal{V}_1 \Longrightarrow x_k(t') \in \mathcal{H}_{\varepsilon_1} \underset{(5.5)}{\Longrightarrow} x_k(t_1) \in \mathcal{H}_{\delta_1} \subset \mathcal{H}_{\varepsilon_2} \Longrightarrow k \in \mathcal{V}_2,$$

so $\mathcal{V}_1 \subset \mathcal{V}_2$. In particular c_{k_2}, the center node of $\mathcal{G}([\tau_{k_2}, \tau_{k_2} + T'])$, is in $\mathcal{V}_2$ because it is in $\mathcal{V}_1$. Then we can apply the same argument to conclude that there are a

$t_2 \in [t_1, t' + k_2 T]$ and an i in $\mathcal{V}_2^*$ such that $x_i(t_2) \in \mathcal{H}_{\varepsilon_3}$ and therefore, $\mathcal{H}_{\varepsilon_3}$ has at least three agents at t_2.

Repeating this argument $n-1$ times leads to the result that there is a $t_{n-1} \in [t', t' + k_{n-1}T] \subset [t', t' + \bar{T}]$ such that $\mathcal{H}_{\varepsilon_n}$ has n agents at t_{n-1}. Hence,

$$V_1(x(t_{n-1})) \leq V_1(x(t')) - \varepsilon_n = V_1(x(t')) - \eta(V_1(x(t'))),$$

and (5.4) follows. □

6. Conclusions. In this paper we first studied the state agreement problem for a class of switched interconnected large-scale systems with a family of admissible vector fields. The interconnection structure is time varying and independent of the state. The key assumption about the vector fields, A2, generalizes Moreau's assumption in discrete time. Necessary and sufficient conditions, in terms of the interaction graph, are obtained to assure that the system achieves asymptotic state agreement. These results can be understood as connective stability, as in the framework of [36]. Achieving asymptotic state agreement of a large-scale interconnected system is robust with respect to either the coupling structure or parameter values. In addition, our results and analysis may be of independent interest in the field of switched systems.

Second, we studied the rendezvous problem in continuous time. The interconnection structure is defined in terms of the distances between agents and hence is state independent. We proved that the circumcenter control law is a solution to the problem.

The notion of state agreement in this paper is that the states of the subsystems are all equal and constant. This notion can potentially be generalized in the following two directions. First, state agreement could mean equality of all the trajectories of the subsystems. In other words, the trajectories of a collection of subsystems will follow, after some transient, the same path in time. This would be of interest in formation control of multiagent systems. Second, state agreement could mean equality of all the states after suitable state transformations. An example is a biochemical reaction network studied in [21].

In many state-agreement problems, the interaction graphs are bidirectional. For such cases, it is reasonable to conjecture that interconnected systems enjoy several special properties. For instance, results similar to those in Theorem 3.8 may be obtained with weaker assumptions on the smoothness of the vector fields.

Finally, we conjecture in the spirit of [2] that our result could be generalized by replacing $\mathcal{C}_p^i(x)$ in assumption A2 by a set-valued map satisfying suitable properties.

QUICKEST DETECTION OF A MINIMUM OF TWO POISSON DISORDER TIMES*

ERHAN BAYRAKTAR† AND H. VINCENT POOR‡

Abstract. A multisource quickest detection problem is considered. Assume there are two independent Poisson processes X^1 and X^2 with disorder times θ_1 and θ_2, respectively; i.e., the intensities of X^1 and X^2 change at random unobservable times θ_1 and θ_2, respectively. θ_1 and θ_2 are independent of each other and are exponentially distributed. Define $\theta \triangleq \theta_1 \wedge \theta_2 = \min\{\theta_1, \theta_2\}$. For any stopping time τ that is measurable with respect to the filtration generated by the observations, define a penalty function of the form

$$R_\tau = \mathbb{P}(\tau < \theta) + c\mathbb{E}\left[(\tau - \theta)^+\right],$$

where $c > 0$ and $(\tau - \theta)^+$ is the positive part of $\tau - \theta$. It is of interest to find a stopping time τ that minimizes the above performance index. This performance criterion can be useful, e.g., in the following scenario: There are two assembly lines that produce products A and B, respectively. Assume that the malfunctioning (disorder) of the machines producing A and B are independent events. Later, the products A and B are to be put together to obtain another product C. A product manager who is worried about the quality of C will want to detect the minimum of the disorder times (as accurately as possible) in the assembly lines producing A and B. Another problem to which we can apply our framework is the Internet surveillance problem: A router receives data from, say, n channels. The channels are independent, and the disorder times of channels are $\theta_1, \ldots, \theta_n$. The router is said to be under attack at $\theta = \theta_1 \wedge \cdots \wedge \theta_n$. The administrator of the router is interested in detecting θ as quickly as possible. Since both observations X^1 and X^2 reveal information about the disorder time θ, even this simple problem is more involved than solving the disorder problems for X^1 and X^2 separately. This problem is formulated in terms of a three-dimensional sufficient statistic, and the corresponding optimal stopping problem is examined. The solution is characterized by iterating a suitable functional operator.

Key words. change detection, Poisson processes, optimal stopping

DOI. 10.1137/050630933

1. Introduction.

Consider two independent Poisson processes $X^i = \{X_t^i : t \geq 0\}$ $i \in \{1, 2\}$ with the same arrival rate β. At some random unobservable times θ_1 and θ_2, with distributions

$$\mathbb{P}(\theta_i = 0) = \pi_i, \quad \mathbb{P}(\theta_i > t) = (1 - \pi_i)e^{-\lambda t} \text{ for } t \geq 0, \tag{1.1}$$

the arrival rates of the Poisson processes X^1 and X^2 change from β to α, respectively, i.e.,

$$X_t^i - \int_0^t h_i(s)ds, \quad t \geq 0,\ i = 1, 2, \tag{1.2}$$

are martingales in which

$$h_i(t) = [\beta 1_{\{s<\theta_i\}} + \alpha 1_{\{s\geq\theta_i\}}], \quad t \geq 0,\ i = 1, 2. \tag{1.3}$$

‡School of Engineering and Applied Science, Princeton University, Princeton, NJ 08544 (poor@princeton.edu).

Here α and β are known positive constants. We seek a stopping rule τ that detects the instant $\theta = \theta_1 \wedge \theta_2$ of the first regime change as accurately as possible given the past and the present observations of the processes X^1 and X^2. More precisely, we wish to choose a stopping time τ of the history of the processes X^1 and X^2 that minimizes the following penalty function:

$$R_\tau = \mathbb{P}(\tau < \theta) + c\mathbb{E}\left[(\tau - \theta)^+\right]. \tag{1.4}$$

The first term in (1.4) penalizes the frequency of false alarms, and the second term penalizes the detection delay. The disorder time demarcates two regimes, and in each of these regimes the decision maker uses distinctly different strategies. Therefore, it is in the decision maker's interest to detect the disorder time as accurately as possible from its observations. Here, we are solving the case when a decision maker has two identical and independent sources to process. In section 9 we discuss how our analysis can be extended to nonidentical sources.

Quickest detection problems arise in a variety of applications such as seismology, machine monitoring, finance, health, and surveillance, among others (see, e.g., [1], [10], [7], [11], and [14]). Because Poisson processes are often used to model abrupt changes, Poisson disorder problems have potential applications to, e.g., to the effective control and prevention of infectious diseases, the quickest detection of quality and reliability problems in industrial processes, and the surveillance of Internet traffic to protect network servers from the attacks of malicious users. This is because the number of patients infected, the number of defected items produced, and the number of packets arriving at a network node are usually modeled by Poisson processes. In these examples the disorder time corresponds to the time when an outbreak occurs, when a machine in an assembly line breaks down, or when a router is under attack, respectively. The multisource quickest detection problem considered here can be applied to tackle these problems when there are multiple sources of information. For example, in the monitoring of industrial processes the minimum of disorder times represents the first time when one of many assembly lines in a plant breaks down during the production of a certain type of item. Let us be more specific: Assume that there are two assembly lines that produce products A and B, respectively. Assume also that the malfunctioning (disorder) of the machines producing A and B are independent events. Later, the products A and B are to be put together to obtain another product C. A product manager who is worried about the quality of C will want to detect the minimum of the disorder times (as accurately as possible) in the assembly lines producing A and B. The performance function (1.4) is an appropriate choice because the product manager will worry about the quality of the end product C, not of the individual pieces seperately. Another problem to which we can apply our framework is the Internet surveillance problem: A router receives data from, say, n channels. The channels are independent and the disorder times of the channels are $\theta_1, \ldots, \theta_n$. The router is said to be under attack at $\theta = \theta_1 \wedge \cdots \wedge \theta_n$. The administrator of the router is interested in detecting θ as quickly as possible.

The one-dimensional Poisson disorder problem, i.e., the problem of detecting θ_1 as accurately as possible given the observations from the Poisson process X^1, has recently been solved (see [2] and [3] and the references therein). The two-dimensional disorder problem we have introduced cannot be reduced to solving the corresponding one-dimensional disorder problems since both X^1 and X^2 reveal some information about θ whenever these processes jump. That is, if we take the minimum of the optimal stopping times that solve the one-dimensional Poisson disorder problems, then we obtain a stopping time that is a suboptimal solution to (1.4) (see Remark 4.1).

We will show that the quickest detection problem of (1.4) can be reduced to an optimal stopping problem for a three-dimensional piecewise-deterministic Markov process. Continuous-time Markov optimal stopping problems are typically solved by formulating them as free boundary problems associated with the infinitesimal generator of the Markov process. In this case, however the infinitesimal generator contains differential delay operators. Solving free boundary problems involving differential delay operators is a challenge even in the one-dimensional case, and the smooth fit principle is expected to fail (see [2] and [3] and the references therein). Instead as in [4] and [6] we work with an integral operator, iteration of which generates a monotonically increasing sequence of functions converging exponentially to the value function of the optimal stopping problem. That is, using the integral operator we reduce the problem to a sequence of deterministic optimization problems. This approach provides a new numerical method for calculating and characterizing the value function and the continuation region in addition to providing information about the shape and the location of the optimal continuation region. Using the structure of the paths of the piecewise-deterministic Markov process, we also provide a nontrivial bound on the optimal stopping time which can be used to obtain approximate stopping strategies.

The remainder of this paper is organized as follows: In sections 2 and 3, we restate the problem of interest under a suitable reference measure $\mathbb{P}_0$ that is equivalent to $\mathbb{P}$. Working under the reference measure $\mathbb{P}_0$ reduces the computations considerably, since under this measure the observations X^1 and X^2 are simple Poisson processes that are independent of the disorder times. Here we show that the quickest detection problem reduces to solving an optimal stopping problem for a three-dimensional statistic. In section 4, we analyze the path behavior of this sufficient statistic. In section 5, we provide a tight upper bound on the continuation region of the optimal stopping problem, which can be used to determine approximate detection rules besides helping us to determine the location and the shape of the continuation region. Here, we also show that the smallest optimal stopping time of the problem under consideration has finite expectation. In section 6, we convert the optimal stopping problem into sequences of deterministic optimal stopping problems using a suitably defined integral operator. In section 7, we construct optimal stopping times from sequences of stopping (alarm) times that sound before the processes X^1 and X^2 jump a certain number of times. In section 8 we discuss the structure of the optimal stopping regions. And finally, we discuss how to extend our approach to the case with more than two sources and to the case when the jump sizes are random and the jump size distribution changes at the time of disorder.

2. Problem description. Let us start with a probability space $(\Omega, \mathcal{F}, \mathbb{P}_0)$ that hosts two independent Poisson processes X^1 and X^2, both of which have rate β, as well as two independent random variables θ_1 and θ_2 independent of the Poisson processes with distributions

$$\mathbb{P}_0(\theta_i = 0) = \pi_i \quad \text{and} \quad \mathbb{P}_0(\theta_i > t) = (1 - \pi_i)e^{-\lambda_i t} \tag{2.1}$$

for $0 \leq t < \infty$, $i \in \{1, 2\}$, and for some known constants $\pi_i \in [0, 1)$ and $\lambda > 0$ for $i \in \{1, 2\}$. We denote by $\mathbb{F} = \{\mathcal{F}_t\}_{0 \leq t < \infty}$ the filtration generated by X^1 and X^2, i.e., $\mathcal{F}_t = \sigma(X^1_s, X^2_s, 0 \leq s \leq t)$, and denote by $\mathbb{G} = \{\mathcal{G}_t\}_{0 \leq t < \infty}$ the initial enlargement of $\mathbb{F}$ by θ_1 and θ_2, i.e., $\mathcal{G}_t \triangleq \sigma(\theta_1, \theta_2, X^2_s, X^2_s : 0 \leq s \leq t)$. The processes X^1 and X^2 satisfy (1.2) under a new probability measure $\mathbb{P}$, which is characterized by

$$\left.\frac{d\mathbb{P}}{d\mathbb{P}_0}\right|_{\mathcal{G}_t} \triangleq Z_t \triangleq Z^1_t Z^2_t, \tag{2.2}$$

where

$$Z_t^i \triangleq \exp\left(\int_0^t \log\left(\frac{h_i(s-)}{\beta}\right) dX_s^i - \int_0^t [h_i(s)-\beta]ds\right) \tag{2.3}$$

for $t \geq 0$ and $i \in \{1,2\}$ are exponential martingales (see, e.g., [5]). Under this new probability measure $\mathbb{P}$ of (2.2), θ_1 and θ_2 have the same distribution as they have under the measure $\mathbb{P}_0$, i.e., their distribution is given by (1.1). This holds because θ_1 and θ_2 are $\mathcal{G}_0$-measurable and $d\mathbb{P}/d\mathbb{P}_0|_{\mathcal{G}_0} = 1$, i.e., $\mathbb{P}$ and $\mathbb{P}_0$ coincide on $\mathcal{G}_0$. Under the new probability measure $\mathbb{P}$ the processes X^1 and X^2 have measurable intensities h_1 and h_2, respectively. That is to say that (1.2) holds. In other words, the probability space $(\Omega, \mathcal{F}, \mathbb{P})$ describes the model posited in (1.1) and (1.2). Now, our problem is to find a quickest detection rule for the disorder times $\theta_1 \wedge \theta_2$, which is *adapted to* the history $\mathcal{F}$ generated by the observed processes X^1 and X^2 because the complete information (concerning θ_1 and θ_2) embodied in $\mathcal{G}$ is not available. We will achieve our goal by finding an $\mathcal{F}$-stopping time that minimizes (1.4).

In terms of the exponential likelihood processes

$$L_t^i \triangleq \left(\frac{\alpha}{\beta}\right)^{X_t^i} \exp(-(\alpha-\beta)t), \qquad t \geq 0,\ i \in \{1,2\}, \tag{2.4}$$

we can write

$$Z_t^i = 1_{\{\theta_i > t\}} + 1_{\{\theta_i \leq t\}} \frac{L_t^i}{L_{\theta_i}^i}. \tag{2.5}$$

Let us introduce the posterior probability process

$$\Pi_t \triangleq \mathbb{P}\left(\theta \leq t \middle| \mathcal{F}_t\right) = \frac{\mathbb{E}_0\left[Z_t 1_{\{\theta \leq t\}} \middle| \mathcal{F}_t\right]}{\mathbb{E}_0\left[Z_t \middle| \mathcal{F}_t\right]}, \tag{2.6}$$

where the second equality follows from the Bayes formula (see, e.g., [9]). Then it follows from (2.5) and (2.6) that

$$1 - \Pi_t = \frac{(1-\pi)e^{-2\lambda t}}{\mathbb{E}_0\left[Z_t \middle| \mathcal{F}_t\right]}, \quad \text{where} \tag{2.7}$$

$$\pi \triangleq 1 - (1-\pi_1)(1-\pi_2). \tag{2.8}$$

Let us now introduce the odds-ratio process

$$\Phi_t \triangleq \frac{\Pi_t}{1-\Pi_t}, \qquad 0 \leq t < \infty. \tag{2.9}$$

Then observe from (2.6) and (2.7) that

$$\mathbb{E}_0\left[Z_t 1_{\{\theta \leq t\}} | \mathcal{F}_t\right] = (1-\pi)e^{-\lambda t}\Phi_t, \tag{2.10}$$

$t \geq 0$. Now, we will write the penalty function of (1.4) in terms of the odds-ratio process:

$$\begin{aligned} \mathbb{E}\left[(\tau-\theta)^+\right] &= \mathbb{E}\left[\int_0^\infty 1_{\{\tau>t\}} 1_{\{\theta \leq t\}} dt\right] = \int_0^\infty \mathbb{E}_0\left[1_{\{\tau>t\}} \mathbb{E}_0\left[Z_t 1_{\{\theta\leq t\}} \middle| \mathcal{F}_t\right]\right] dt \\ &= (1-\pi)\mathbb{E}_0 \int_0^\tau e^{-2\lambda t}\Phi_t dt. \end{aligned} \tag{2.11}$$

Since $\{\tau < \theta\} \in \mathcal{G}_\theta$ we can write

$$\mathbb{P}(\tau < \theta) = \mathbb{E}_0\left[Z_\theta 1_{\{\tau<\theta\}}\right] = \mathbb{P}_0(\tau < \theta) = (1-\pi)\left(1 - \lambda\mathbb{E}_0\left[\int_0^\tau e^{-2\lambda t}dt\right]\right), \tag{2.12}$$

where the second equality follows since $Z_\theta = 1$ almost surely under P_0. Using (2.11) and (2.12) we can write the penalty function as

$$R_\tau(\pi_1, \pi_2) = 1 - \pi + c(1-\pi)\mathbb{E}_0\left[\int_0^\tau e^{-2\lambda t}\left(\Phi_t - \frac{\lambda}{c}\right)dt\right]. \tag{2.13}$$

On the other hand the following lemma obtains a representation for the odds-ratio process Φ.

LEMMA 2.1. *Let us denote*

$$\Phi_t^i \triangleq \frac{e^{\lambda t}}{1-\pi_i}\mathbb{E}_0\left[1_{\{\theta_i \le t\}}\frac{L_t^i}{L_{\theta_i}^i}\Big|\mathcal{F}_t^i\right] = \frac{\mathbb{P}(\theta_i \le t|\mathcal{F}_t)}{1-\mathbb{P}(\theta_i \le t|\mathcal{F}_t)} \tag{2.14}$$

for $t \ge 0$ and $i \in \{1,2\}$. Then we can write the odds-ratio process Φ as

$$\Phi_t = \Phi_t^1 + \Phi_t^2 + \Phi_t^1\Phi_t^2, \quad t \ge 0. \tag{2.15}$$

Proof. From (2.10)

$$\begin{aligned}
\Phi_t &= \frac{e^{2\lambda t}}{(1-\pi)}\mathbb{E}_0\left[Z_t 1_{\{\theta\le t\}}|\mathcal{F}_t\right] \\
&= \frac{e^{2\lambda t}}{(1-\pi)}\left\{\mathbb{P}_0(\theta_1 > t)\mathbb{E}_0\left[1_{\{\theta_1\le t\}}\frac{L_t^1}{L_{\theta_1}^1}\Big|\mathcal{F}_t^1\right] + \mathbb{P}(\theta_2 > t)\mathbb{E}_0\left[1_{\{\theta_2\le t\}}\frac{L_t^2}{L_{\theta_i}^2}\Big|\mathcal{F}_t^i\right]\right. \\
&\quad \left. + \mathbb{E}_0\left[1_{\{\theta_1\le t\}}\frac{L_t^1}{L_{\theta_1}^1}\Big|\mathcal{F}_t^1\right]\mathbb{E}_0\left[1_{\{\theta_2\le t\}}\frac{L_t^2}{L_{\theta_2}^2}\Big|\mathcal{F}_t^2\right]\right\}.
\end{aligned} \tag{2.16}$$

The second equality follows from (2.2), (2.5), and the independence of the sigma algebras $\mathcal{F}_t^1$ and $\mathcal{F}_t^2$. Now the claim follows from (2.1), (2.8), and (2.14). □

Using the fact that the likelihood ratio process L^i is the unique solution of the equation

$$dL_t^i = [(\alpha/\beta) - 1]L_{t-}^i(dX^i - \alpha\, dt), \quad L_0^i = 1 \tag{2.17}$$

(see, e.g., [13]) and by means of the chain-rule, we obtain

$$d\Phi_t^i = (\lambda + (\lambda - \alpha + \beta)\Phi_t^i)dt + [(\alpha/\beta) - 1]\Phi_t^i dX_t^i, \quad \Phi_0^i = \frac{\pi_i}{1-\pi_i} \tag{2.18}$$

for $t \ge 0$ and $i \in \{1,2\}$ (see [3]). If we let

$$\Phi_t^+ \triangleq \Phi_t^1 + \Phi_t^2, \;\; \Phi_t^\times \triangleq \Phi_t^1\Phi_t^2, \;\; t \ge 0, \tag{2.19}$$

then using a change of variable formula for jump processes gives

$$\begin{aligned}
d\Phi_t^\times &= [\lambda\Phi_t^+ + 2a\Phi_t^\times]dt + ((\alpha/\beta) - 1)\Phi_t^\times d(X_t^1 + X_t^2), \\
d\Phi_t^+ &= [2\lambda + a\Phi_t^+]dt + ((\alpha/\beta) - 1)[\Phi_t^1 dX_t^1 + \Phi_t^2 dX_t^2],
\end{aligned} \tag{2.20}$$

with $\Phi_0^\times = \pi_1\pi_2/[(1-\pi_1)(1-\pi_2)]$ and $\Phi_0^+ = \pi_1/(1-\pi_1) + \pi_2/(1-\pi_2)$, where $a \triangleq \lambda - \alpha + \beta$. Note that $X_t \triangleq X_t^1 + X_t^2$, $t \geq 0$, is a Poisson process with rate 2β under $\mathbb{P}_0$.

It is clear from (2.18) and (2.20) that

$$\Upsilon \triangleq (\Phi^\times, \Phi^+, \Phi^1) \tag{2.21}$$

is a piecewise-deterministic Markov process; therefore, the original change detection problem with penalty function (1.4) has been reformulated as (2.13) and (2.18)–(2.21), which is an optimal stopping problem for a two-dimensional Markov process driven by a three-dimensional piecewise-deterministic Markov process.

We will denote by $\mathcal{A}$ the infinitesimal generator of Υ. Its action on a smooth test function $f : \mathbb{B}_+^3 \to \mathbb{R}$ is given by

$$\begin{aligned}
&[\mathcal{A}f](\phi^\times, \phi^+, \phi^1) = D_{\phi^\times} f(\phi^\times, \phi^+, \phi^1)[\lambda\phi^+ + 2a\phi^+] + D_{\phi^+} f(\phi^\times, \phi^+, \phi^1)[2\lambda + a\phi^+] \\
&+ D_{\phi^1} f(\phi^\times, \phi^+, \phi^1)[\lambda + a\phi^1] + \beta\left[f\left(\frac{\alpha}{\beta}\,\phi^\times, \phi^+ + \left(\frac{\alpha}{\beta} - 1\right)\phi^1, \frac{\alpha}{\beta}\,\phi^1\right) - f(\phi^\times, \phi^+, \phi^1)\right] \\
&+ \beta\left[f\left(\frac{\alpha}{\beta}\,\phi^\times, \frac{\alpha}{\beta}\,\phi^+ - \left(\frac{\alpha}{\beta} - 1\right)\phi^1, \phi^1\right) - f(\phi^\times, \phi^+, \phi^1)\right].
\end{aligned} \tag{2.22}$$

Let us denote

$$\mathbb{B}_+^2 \triangleq \{(x,y) \in \mathbb{R}_+^2 : y \geq 2\sqrt{x}\} \quad \text{and} \tag{2.23}$$

$$\mathbb{B}_+^3 \triangleq \{(x,y,z) \in \mathbb{R}_+^3 : y \geq 2\sqrt{x}, y \geq z\}. \tag{2.24}$$

Now, for every $(\phi^\times, \phi^+, \phi^1) \in \mathbb{B}_+^3$, let us denote by $x(t, \phi^\times)$, $y(t, \phi^+)$, and $z(t, \phi^1)$, $t \in \mathbb{R}$, the solutions of

$$\begin{aligned}
&\frac{d}{dt}x(t,\phi^\times) = [\lambda y(t,\phi^+) + 2ax(t,\phi^\times)]dt, \quad x(0,\phi^\times) = \phi^\times, \\
&\frac{d}{dt}y(t,\phi^+) = [2\lambda + ay(t,\phi^+)]dt, \quad y(0,\phi^+) = \phi^+, \\
&\frac{d}{dt}z(t,\phi^1) = [\lambda + az(t,\phi^1)]dt, \quad z(0,\phi^1) = \phi^1.
\end{aligned} \tag{2.25}$$

The solutions of (2.25), when $a \neq 0$, are explicitly given by

$$\begin{aligned}
x(t,\phi^\times) &= \frac{\lambda^2}{a^2} + e^{2at}\left[\phi^\times - \frac{\lambda^2}{a^2}\right] + e^{2at}(1 - e^{-at})\frac{\lambda}{a}\left(\phi^+ + \frac{2\lambda}{a}\right), \\
y(t,\phi^+) &= -\frac{2\lambda}{a} + e^{at}\left(\phi^+ + \frac{2\lambda}{a}\right), \\
z(t,\phi^1) &= -\frac{\lambda}{a} + e^{at}\left(\phi^+ + \frac{\lambda}{a}\right).
\end{aligned} \tag{2.26}$$

Otherwise, $x(t,\phi^\times) = \phi^\times + \lambda t\phi^\times + \lambda^2 t^2$, $y(t,\phi^+) = \phi^+ + 2\lambda t$, and $z(t,\phi^1) = \phi^1 + \lambda t$. Note that the solution (x,y,z) of the system of equations in (2.25) satisfies the semigroup property, i.e., for every $s, t \in \mathbb{R}$,

$$\begin{aligned}
&x(t+s,\phi_0) = x(s,x(t,\phi_0)), \quad y(t+s,\phi_1) = y(s,y(t,\phi_1)), \\
&\text{and} \quad z(t+s,\phi_1) = z(s,z(t,\phi_1)).
\end{aligned} \tag{2.27}$$

Note from (2.18), (2.20), and (2.26) that

$$\Phi_t^{\times} = x(t-\sigma_n, \Phi_{\sigma_n}^{\times}), \qquad , \Phi_t^{+} = y(t-\sigma_n, \Phi_{\sigma_n}^{+}), \qquad \Phi_t^{1} = z(t-\sigma_n, \Phi_{\sigma_n}^{1}), \quad \sigma_n \le t < \sigma_{n+1},\ n \in \mathbb{N}, \tag{2.28}$$

and

$$\begin{aligned} \Phi_{\sigma_{n+1}}^{\times} &= \frac{\alpha}{\beta}\,\Phi_{\sigma_{n+1}-}^{\times}, \quad \Phi_{\sigma_{n+1}}^{1} = \frac{\alpha}{\beta}\,\Phi_{\sigma_{n+1}}^{1} 1_{\{X_{\sigma_{n+1}}^1 \neq X_{\sigma_{n+1}-}^1\}}, \quad \text{and} \\ \Phi_{\sigma_{n+1}}^{+} &= \left[\Phi_{\sigma_{n+1}-}^{+} + \left(\frac{\alpha}{\beta}-1\right)\Phi_{\sigma_{n+1}-}^{1}\right] 1_{\{X_{\sigma_{n+1}}^1 \neq X_{\sigma_{n+1}-}^1\}} \\ &\quad + \left[\frac{\alpha}{\beta}\,\Phi_{\sigma_{n+1}-}^{+} - \left(\frac{\alpha}{\beta}-1\right)\Phi_{\sigma_{n+1}-}^{1}\right] 1_{\{X_{\sigma_{n+1}}^2 \neq X_{\sigma_{n+1}-}^2\}}. \end{aligned} \tag{2.29}$$

Here, for any function h, $h(t-) \triangleq \lim_{s\uparrow t} h(t)$. Note that an observer watching Υ is able to tell whenever the processes X^1 and X^2 jump (see (2.18) and (2.20)), i.e., the filtration generated by Υ is the same as $\mathbb{F}$.

3. An optimal stopping problem. Let us denote the set of $\mathbb{F}$-stopping times by $\mathcal{S}$. The value function of the quickest detection problem

$$U(\pi_1, \pi_2) \triangleq \inf_{\tau \in \mathcal{S}} R_\tau(\pi_1, \pi_2) \tag{3.1}$$

can be written as

$$U(\pi_1, \pi_2) = (1-\pi)\left[1 + cV\left(\frac{\pi_1\pi_2}{1-\pi}, \frac{\pi_1+\pi_2-2\pi_1\pi_2}{1-\pi}, \frac{\pi_1}{1-\pi_1}\right)\right], \tag{3.2}$$

where V is the value function of the optimal stopping problem

$$V(\phi^{\times}, \phi^{+}, \phi^{1}) \triangleq \inf_{\tau \in \mathcal{S}} \mathbb{E}_0^{(\phi^{\times}, \phi^{+}, \phi^{1})}\left[\int_0^{\tau} e^{-\lambda t} h\left(\Phi_t^{\times}, \Phi_t^{+}\right) dt\right] \tag{3.3}$$

in which $(\phi^{\times}, \phi^{+}, \phi^{1}) \in \mathbb{D}_+^3$ and $h(x,y) \triangleq x + y - \lambda/c$. Here $\mathbb{E}_0^{(\phi^{\times}, \phi^{+}, \phi^{1})}$ is the expectation under $\mathbb{P}_0$ given that $\Phi_0^{\times} = \phi^{\times}$, $\Phi_0^{+} = \phi^{+}$, and $\Phi_0^{1} = \phi^{1}$.

It is clear from (3.3) that for both optimal stopping problems it is not optimal to stop before $(\Phi_t^{\times}, \Phi_t^{+})$, $t \ge 0$, leaves the *advantageous region* defined by

$$\mathbb{C}_0 \triangleq \{(\phi^{\times}, \phi^{+}) \in \mathbb{B}_+^2 : \phi^{\times} + \phi^{+} \le \lambda/c\}. \tag{3.4}$$

Let us also denote

$$\mathbb{C} \triangleq \{(\phi^{\times}, \phi^{+}, \phi^{1}) \in \mathbb{B}_+^3 : \phi^{\times} + \phi^{+} \le \lambda/c\}. \tag{3.5}$$

Also note that the only reason not to stop at the time of the first exit from the region $\mathbb{C}_0$ is the prospect of $(\Phi_t^{\times}, \Phi_t^{+})$, $t \ge 0$, returning to $\mathbb{C}_0$ at a future time.

Remark 3.1. It is reasonable to question our choice of statisitc, since it is clear that $(\Phi_t^1, \Phi_t^2)_{t\ge 0}$ contains all the information X has to offer. Our choice $(\Upsilon_t)_{t\ge 0}$, which is defined in (2.21), is motivated by the mere desire of having a concave value function U and a convex optimal stopping region. The concavity is due to the linearity of the function h (see Lemma 6.2 and its proof along with Lemma 6.1, (6.1), and Theorem 6.1).

If we had chosen to work with $(\Phi_t^1, \Phi_t^2)_{t\geq 0}$, then the relevant optimal stopping problem becomes

$$W(a,b) \triangleq \inf_{\tau\in\mathcal{S}} \mathbb{E}_0^{(a,b)} \left[\int_0^\tau e^{-\lambda t}\tilde{h}\left(\Phi_t^1, \Phi_t^2\right) dt\right] \tag{3.6}$$

in which

$$\tilde{h}(x,y) \triangleq x + y + xy, \quad (x,y) \in \mathbb{R}_+^2. \tag{3.7}$$

Since $h(\cdot,\cdot)$ is nonlinear the concavity of the value function, i.e., $W(\cdot,\cdot)$, is not concave. In fact, $W(x,y) = V(xy, x+y, x)$. The function V is concave, but W is not. So there is a trade-off between concavity and the dimension of the statistic to be used.

In what follows, for the sake of the simplicity of notation, when the meaning is clear, we will drop the superscripts of the expectation operators $\mathbb{E}_0^{(\phi^\times, \phi^+, \phi^1)}$.

4. Sample paths of $\Psi = (\Phi^\times, \Phi^+)$. It is illustrative to look at the sample paths of the sufficient statistic Ψ to understand the nature of the problem. Indeed, this way, for a certain parameter range, we will be able to identify the optimal stopping time without any further analysis.

From (2.26), we see that, if $a > 0$, then the paths of the processes $\Phi^\times$ and Φ^+ increase between the jumps, and otherwise the paths of the processes $\Phi^\times$ and Φ^+ mean-revert to the levels $2\lambda^2/a^2$ and $-2\lambda/a$, respectively. Also observe that $\Phi^\times$ and Φ^+ increase (decrease) with a jump if $\alpha \geq \beta$ ($\beta > \alpha$). See (2.20).

Case 1 ($\alpha \geq \beta$, $a > 0$). The following theorem follows from the description of the behavior of the paths above.

THEOREM 4.1. *If $\alpha > \beta$ and $a > 0$, then the stopping rule*

$$\tau_0 \triangleq \inf\{t \geq 0 : \Phi_t^\times + \Phi_t^+ \geq \lambda/c\} \tag{4.1}$$

is optimal for (3.3).

Proof. Under the hypothesis of the theorem and whenever a path of $(\Phi^\times, \Phi^+)$ leaves $\mathbb{C}_0$, it never returns. □

In section 5, we will identify another case (another range of parameters) in which the advantageous region $\mathbb{C}_0$ is the optimal continuation region and the stopping time τ_0 is optimal (see Cases 2B1a and 2B2a).

Remark 4.1. Let $\kappa_i \triangleq \inf\{t \geq 0 : \Phi_t^i \geq \lambda/c\}$. If $\alpha \geq \beta$ and $a > 0$, then κ_i is the optimal stopping time for the one-dimensional disorder problem with disorder time θ_i (see [3]). Let us define $\kappa \triangleq \kappa_1 \wedge \kappa_2$. Since with this choice of parameters $\Phi_\kappa^\times + \Phi_\kappa^+ > \lambda/c$, it follows that $\tau_0 < \kappa$ almost surely. Therefore, if we follow the rule dictated by the stopping time κ, then we pay an extra penalty for detection delay. This example illustrates that solving the two one-dimensional quickest detection problems separately in order to minimize the penalty function of (1.4) is suboptimal.

In what follows, we will consider the remaining cases: $\alpha \geq \beta$ and $a < 0$; $\alpha < \beta$.

5. Construction of a bound on the continuation region. In this section the purpose is to show that the continuation region of (3.3) is bounded. The construction of upper bounds is carried out in the next two theorems. These upper bounds are tight as the next theorem shows and might be used to construct useful approximations to the two optimal stopping times solving the problems defined in (3.3). We will carry out the analysis for $a = \lambda - \alpha + \beta \neq 0$. A similar analysis for this case can be similarly performed. As a result of Theorem 5.3 we are also able to conclude that the (smallest) optimal stopping time has a finite expectation.

The first two theorems in this section assume that an optimal stopping time of (3.3) exists and in particular the stopping time

$$\tau^*(a,b,c) \triangleq \inf\{t \geq 0 : V(\Upsilon_t) = 0, \qquad \Upsilon_0 = (a,b,c)\}, \tag{5.1}$$

is optimal. In section 7, we will verify that this assumption holds. We will denote by

$$\mathbf{\Gamma} \triangleq \{(a,b,c) \in \mathbb{B}_+^3 : v(a,b,c) = 0\}, \quad \mathbf{C} \triangleq \mathbb{B}_+^3 - \mathbf{\Gamma} \tag{5.2}$$

the optimal stopping region and optimal continuation region of (3.3), respectively.

THEOREM 5.1. *In this theorem the standing assumption is that $\alpha \geq \beta$ and that $a < 0$ (Case 2).*

Case 2A. Let us further assume that $\lambda/a^2 - 2/a \leq 1/c$ and denote

$$\mathbb{D}_0 \triangleq \left\{(x,y) \in \mathbb{B}_+^2 : x \cdot \left(\frac{1}{2(\lambda-a)}\right) + y \cdot \left(\frac{3\lambda - 2a}{2(\lambda-a)(2\lambda-a)}\right) + k > 0\right\} \tag{5.3}$$

in which

$$k \triangleq \frac{\lambda}{2a^2} - \frac{1}{a} - \frac{1}{2c} + \frac{\lambda^2}{2a^2(\lambda-a)} + \frac{1}{2\lambda - a} + 2\left(\frac{\lambda}{a} - \frac{\lambda^2}{a^2}\right). \tag{5.4}$$

Let $(\phi_0, \phi_1) \in \mathbb{D}_0 \cap (\mathbb{B}_+^2 - \mathbb{C}_0)$. Then for any $\phi_2 \leq \phi_1$, (ϕ_0, ϕ_1, ϕ_2) is in the stopping region of (3.3).

Case 2B. Assume that $\lambda/a^2 - 2/a \geq 1/c$ (standing assumption in the rest of the theorem). Consider the four different possible ranges of parameters.

Case 2B1. If $\lambda + a \leq 0$

- and if $-a/c - 1 \leq 0$ (*Case* 2B1a), then $\mathbb{C}$ in (3.5) is the optimal continuation region for (3.3);
- else if $-a/c - 1 > 0$ (*Case* 2B1b), then a superset of the continuation region can be constructed as follows. Let us introduce the line segment

$$C \triangleq \{(x,y) \in \mathbb{B}_+^2 : x + y = \lambda/c\} \tag{5.5}$$

and define

(5.6)
$$C_1 \triangleq \left\{(x,y) \in \mathbb{B}_+^2 : x = x(t,x^*), y = y(t,0) \text{ for } t \in [0,t^*]\right\} \bigcup \left\{(x,y) \in C : x < \frac{\lambda}{c} + \frac{2\lambda}{\lambda-a}\left(1 + \frac{a}{c}\right),\ y > -\frac{2\lambda}{\lambda-a}\left(1 + \frac{a}{c}\right)\right\}.$$

Here, t^* is the solution of $y(-t^*, -\frac{2\lambda}{\lambda-a}(1+\frac{a}{c})) = 0$, and $x^* = x(-t^*, \frac{\lambda}{c} + \frac{2\lambda}{\lambda-a}(1+\frac{a}{c}))$. The curve C_1 separates $\mathbb{R}_+^2$ into two connected regions. Let us denote the region that lies above the curve C_1 by

$$\mathbb{D}_1 \triangleq \{(x,y) \in \mathbb{B}_+^2 : \text{there exists a positive number } \tilde{y}(x) < y \text{ such that } (x, \tilde{y}(x)) \in C_1\}. \tag{5.7}$$

Then $[(\mathbb{B}_+^2 - \mathbb{D}_1) \times \mathbb{R}_+] \cap \mathbb{B}_+^3$ is an upper bound on the continuation region of (3.3).

Case 2B2. If $\lambda + a > 0$

- and if $-a/c - 1 < 0$ (*Case* 2B2a), then $\mathbb{C}$ in (3.5) is the optimal continuation region for (3.3);
- else if $-a/c - 1 > 0$, then $[(\mathbb{B}_+^2 - \mathbb{D}_1) \times \mathbb{R}_+] \cap \mathbb{B}_+^3$ is an upper bound on the continuation region of (3.3).

Note that all the supersets of the continuation we constructed are bounded subsets of $\mathbb{R}_+^3$.

Proof. Note that

$$\Phi_t^+ \geq y(t, \phi_1), \quad \Phi_t^\times \geq x(t, \phi_0), \quad t \geq 0, \tag{5.8}$$

almost surely if $\Phi_0^+ = \phi_1$ and $\Phi_0^\times = \phi_0$. This is because $\Phi^\times$ and Φ^+ increase with jumps.

From this observation we obtain the following inequality:

$$\inf_{\tau \in \mathcal{S}} \mathbb{E}_0 \left[\int_0^\tau e^{-2\lambda s} h(\Phi_s^\times, \Phi_s^+) ds \right] \geq \inf_{\tau \in \mathcal{S}} \mathbb{E}_0 \left[\int_0^\tau e^{-2\lambda s} h(x(s, \phi_0), y(s, \phi_1)) ds \right] \tag{5.9}$$

$$= \inf_{t \in [0, \infty]} \int_0^t e^{-2\lambda s} h(x(s, \phi_0), y(s, \phi_1)) ds. \tag{5.10}$$

Note that if for a given (ϕ_0, ϕ_1) the expression in (5.10) is equal to zero, then the infimum on the left-hand side of (5.9) is attained by setting $\tau = 0$. In what follows we will find a subset of the stopping region of the optimal stopping problem using this argument.

Case 2A ($\lambda/a^2 - 2/a \leq 1/c$). In this case the mean reversion level of the path $(x(\cdot, \phi_0), y(\cdot, \phi_1))$, $(\phi_0, \phi_1) \in \mathbb{B}_+^2$, namely, $(\lambda^2/a^2, -2\lambda/a)$, is inside the region $\mathbb{C}_0$ which is defined in (3.4). In this case, for any $(\phi_0, \phi_1) \in \mathbb{B}_+^2 - \mathbb{C}_0$ the minimizer $t_{\text{opt}}(\phi_0, \phi_1)$ of the expression in (5.10) is either 0 or ∞ by the following argument: For any $(\phi_0, \phi_1) \in \mathbb{B}_+^2 - \mathbb{C}_0$ the path $(x(\cdot, \phi_0), y(\cdot, \phi_1))$ is in the advantageous region $\mathbb{C}_0$ all the time except for possibly a finite duration. Therefore if

$$\int_0^\infty e^{-2\lambda s} h(x(s, \phi_0), y(s, \phi_1)) ds < 0, \tag{5.11}$$

then in order to minimize (5.10) it is never optimal to stop. On the other hand if (5.11) is positive, then it is not worth taking the journey into the advantageous region, and it is optimal to stop immediately in order to minimize (5.10).

We shall find the pairs (ϕ_0, ϕ_1) for which $t_{\text{opt}} = 0$. Using (2.26) we can write

$$\int_0^\infty e^{-2\lambda s} h(x(s, \phi_0), y(s, \phi_1)) ds = \phi_0 \left(-\frac{1}{\alpha - \beta} \right) + \phi_1 \left(\frac{a}{(\alpha - \beta)^2} \right) + k, \tag{5.12}$$

where k is given by (5.4). Note that if $(\phi_0, \phi_1) \in \mathbb{D}_0 \cap (\mathbb{B}_+^2 - \mathbb{C}_0)$, then by (5.9) and (5.10) we can see that the infimum in (5.10) is equal to 0. Therefore $[((\mathbb{B}_+^2 - \mathbb{D}_0) \cup \mathbb{C}_0) \times \mathbb{R}_+] \cap \mathbb{B}_+^3$ is a superset of the optimal continuation region of (3.3).

Case 2B ($\lambda/a^2 - 2/a \geq 1/c$). In this case the mean reversion level of $t \to (x(t, \phi_0), y(t, \phi_1))$ is outside $\mathbb{C}_0$. Therefore, the minimizer of (5.10) is $t_{\text{opt}}(\phi_0, \phi_1) \in \{0, t_c(\phi_0, \phi_1), \infty\}$, where $t_c(\phi_0, \phi_1)$ is the exit time of the path $(x(t, \phi_0), y(t, \phi_1))$ from $\mathbb{C}_0$. The derivative

$$\frac{d}{dt}[x(t, \phi_0) + y(t, \phi_1)] = (\lambda + a) y(t, \phi_1) + 2a x(t, \phi_1) + 2\lambda \tag{5.13}$$

vanishes if $(x(t,\phi_0), y(t,\phi_1))$ meets the line segment

$$L = \{(x,y) \in \mathbb{B}_+^2 : (\lambda + a)y + 2ax + 2\lambda = 0\}. \tag{5.14}$$

Note that the mean reversion level belongs to L, i.e.,

$$\left(\frac{\lambda^2}{a^2}, -\frac{2\lambda}{a}\right) \in L. \tag{5.15}$$

Case 2B1 ($\lambda + a < 0$). (In addition to $\alpha > \beta$, $a < 0$ and $\lambda/a^2 - 2/a \geq 1/c$.) In this case the line L is decreasing (as a function of x).

Case 2B1a ($-a/c - 2 < 0$). (In addition to $\alpha > \beta$, $a < 0$, $\lambda/a^2 - 2/a \geq 1/c$, and $\lambda + a < 0$.) In this case the line segment C in (5.5) lies entirely below L. Assume that a path $(x(\cdot,\phi_0), y(\cdot,\phi_1))$ originating at $(\phi_0,\phi_1) \in \mathbb{B}_+^2 - \mathbb{C}_0$ enters $\mathbb{C}_0$ at time $t_0 > 0$. This path must leave $\mathbb{C}_0$ at time $t_1 < \infty$ since the mean reversion level $(\lambda^2/a^2, -\lambda/a) \notin \mathbb{C}_0$. This implies that, for any $t \in (t_0, t_1)$, $x(t,\phi_0) + y(t,\phi_1) < \lambda/c$ and $x(t_0,\phi_0) + y(t_0,\phi_1) = \lambda/c$. This yields a contradiction, because $\lambda + a < 0$ together with (5.13) implies that $t \to x(t,\phi_0) + y(t,\phi_1)$ is increasing below the line segment L. Therefore the minimizer $t_{\text{opt}}(\phi_0,\phi_1)$ of (5.10) is equal to 0 if $(\phi_0,\phi_1) \notin \mathbb{C}_0$, and it is equal to $t_c(\phi_0,\phi_1)$ if $(\phi_0,\phi_1) \in \mathbb{C}_0$. From (5.9) we can conclude that $\mathbb{C}$ is equal to the optimal continuation region of (3.3).

Case 2B1b ($-a/c - 1 > 0$). In this case the line segments C and L intersect at $I = (x^I, y^I) \triangleq (\frac{\lambda}{c} + \frac{2\lambda}{\lambda - a}(1 + \frac{a}{c}), -\frac{2\lambda}{\lambda - a}(1 + \frac{a}{c}))$. By running the paths backward in time, we can find x^* such that

$$(x^*, 0) = \left(x\left(-t^*, x^I\right), y\left(-t^*, y^I\right)\right). \tag{5.16}$$

By the semigroup property (2.27), we have

$$\begin{aligned} x(t^*, x^*) &= x\left(t^*, x\left(-t^*, x^I\right)\right) = x\left(t^* + (-t^*), x^I\right) \\ &= x\left(0, x^I\right) = x^I. \end{aligned} \tag{5.17}$$

Similarly, $y(t^*, 0) = y^I$. The function $t \to x(t,x^*) + y(t,0)$ is decreasing on $(0,t^*)$ and increasing on (t^*,∞). It follows that the path $t \to (x(t,x^*), y(t,0))$ is tangential to C at I and lies above the region $\mathbb{C}_0$.

We will now show that if a path $(x(\cdot,\phi_0), y(\cdot,\phi_1))$ originates in $\mathbb{D}_1$, then it stays in $\mathbb{D}_1$. Let us first consider a pair $(\phi_0,\phi_1) \in \mathbb{D}_1$ such that $\phi_1 < -2\lambda/a$. Consider the curve

$$P \triangleq \left\{(x,y) \in \mathbb{B}_+^2 : x = x(t,x^*), y = y(t,0) \text{ for } t \in [0,\infty)\right\}. \tag{5.18}$$

The following remark will be useful in completing the proof.

Remark 5.1. The semigroup property in (2.27) implies that two distinct curves $(x(\cdot,\phi_0^a), y(\cdot,\phi_1^a))$ and $(x(\cdot,\phi_0^b), y(\cdot,\phi_1^b))$ do not intersect. If

$$(x(t^a,\phi_0^a), y(t^a,\phi_1^a)) = (x(t^b,\phi_0^b), y(t^b,\phi_1^b)) = (\phi_0,\phi_1) \tag{5.19}$$

for some $t^a, t^b \in \mathbb{R}$, then (2.27) implies that

$$\begin{aligned} (x(t,\phi_0^a), y(t,\phi_1^a)) &= (x(t^a + (t - t^a), \phi_0^a), y(t^a + (t - t^a), \phi_1^a)) \\ &= (x(t - t^a, \phi_0), y(t - t^a, \phi_1)) \\ &= (x(t^b + (t - t^a), \phi_0^b), y(t^b + (t - t^a), \phi_1^b)) \\ &= (x(t^b - t^a + t, \phi_0^b), y(t^b - t^a + t, \phi_1^b)) \quad \text{for all} \quad t \in \mathbb{R}, \end{aligned} \tag{5.20}$$

i.e., the two curves are identical after a reparametrization.

If the point (ϕ_0, ϕ_1) lies above P and we recall that P lies above $\mathbb{C}_0$, then by Remark 5.1 the path $(x(\cdot, \phi_0), y(\cdot, \phi_1))$ will lie above $\mathbb{C}_0$. If the point (ϕ_0, ϕ_1) lies between P and $\mathbb{C}_0$, then the path $(x(\cdot, \phi_0), y(\cdot, \phi_1))$ will lie below the line segment L. This observation together with the fact that $\lambda + a < 0$ implies (using (5.13)) that the function $t \to x(t, \phi_0) + y(t, \phi_1)$ is increasing. Therefore the path $(x(\cdot, \phi_0), y(\cdot, \phi_1))$ cannot intersect $\mathbb{C}_0$.

Now let us consider a pair $(\phi_0, \phi_1) \in \mathbb{D}_1$ such that $\phi_1 > -2\lambda/a$. If (ϕ_0, ϕ_1) lies above L, then the function $t \to x(t, \phi_0) + y(t, \phi_1)$ is decreasing and its range is $[\phi_0 + \phi_1, 2\lambda/a(\lambda/a - 1))$, which is always above λ/c, and therefore the path $(x(\cdot, \phi_0), y(\cdot, \phi_1))$ does not enter $\mathbb{C}_0$. If the point (ϕ_0, ϕ_1) lies below L, then $t \to x(t, \phi_0) + y(t, \phi_1)$ is increasing. This monotonicity implies that the path $(x(\cdot, \phi_0), y(\cdot, \phi_1))$ cannot visit $\mathbb{C}_0$. If $\phi_1 = -2\lambda/a$, then $y(t, \phi_1) = -2\lambda/a$ for all $t \geq 0$. $x(t, \phi_0)$ increases or decreases depending on whether $(\phi_0, -2\lambda/a)$ is below or above L. Therefore if $(\phi_0, -2\lambda/a) \notin \mathbb{C}_0$, then $(x(\cdot, \phi_0), y(\cdot, \phi_1))$ never visits $\mathbb{C}_0$. These arguments show that if a path $(x(\cdot, \phi_0), y(\cdot, \phi_1))$ originates in $\mathbb{D}_1$, then it stays in $\mathbb{D}_1$. Therefore if $(\phi_0, \phi_1) \in \mathbb{D}_1$, then the infimum in (5.10) is equal to 0 (by (5.9) and (5.10)). Therefore $[(\mathbb{B}^2_+ - \mathbb{D}_1) \times \mathbb{R}_+] \cap \mathbb{B}^3_+$ is a superset of the optimal continuation region of (3.3).

Case 2B2 ($\lambda + a > 0$). In this case L is increasing (as a function of x). The function $t \to x(t, \phi_0) + y(t, \phi_1)$ is increasing if (ϕ_0, ϕ_1) lies above L, and it is decreasing otherwise.

Case 2B2a ($-a/c - 1 \leq 0$). In this case the line segments L and C do not intersect. Let us first consider a pair $(\phi_0, \phi_1) \in \mathbb{B}^2_+$ such that $\phi_1 < -2\lambda/a$. If $(\phi_0, \phi_1) \notin \mathbb{C}_0$ lies above the line segment L, then $t \to x(t, \phi_0) + y(t, \phi_1)$ is increasing and the path $(x(\cdot, \phi_0), y(\cdot, \phi_1))$ cannot enter $\mathbb{C}_0$. Consider the curve

$$\tilde{P} \triangleq \left\{ (x, y) \in \mathbb{B}^2_+ : x = x\left(t, -\frac{\lambda}{a}\right), y = y(t, 0) \text{ for } t \in [0, \infty) \right\}, \tag{5.21}$$

which starts at the intersection of L with the x-axis. The semigroup property Remark 5.1 implies that no path starting to the right of $\tilde{P}$ intersects $\tilde{P}$ and therefore lies to the right of the region $\mathbb{C}_0$. Therefore, if (ϕ_0, ϕ_1) is below the line segment L, then the path $(x(\cdot, \phi_0), y(\cdot, \phi_1))$ never visits the advantageous region $\mathbb{C}_0$. (Note that if the path $(x(\cdot, \phi_0), y(\cdot, \phi_1))$ meets the line L at time $t_L(\phi_0, \phi_1)$, then $t \to (x(t, \phi_0) + y(t, \phi_1))$ is decreasing (increasing) on $[0, t_L]$ ($[t_L, \infty)$).

Now let us consider a point $(\phi_0, \phi_1) \in \mathbb{B}^2_+ - \mathbb{C}_0$ such that $\phi_1 > -2\lambda/a$. Then $t \to (x(t, \phi_0) + y(t, \phi_1))$ is increasing on $[0, t_L(\phi_0, \phi_1)]$ and is decreasing on $(t_L(\phi_0, \phi_1), \infty)$ (it decreases to $-2\lambda/a + \lambda^2/a^2 > \lambda/c$). And the monotonicity of $t \to x(t, \phi_0) + y(t, \phi_1)$ on $[0, t_L(\phi_0, \phi_1)]$ implies that $x(t, \phi_0) + y(t, \phi_1) > \lambda/c$ for $t \in [0, t_L(\phi_0, \phi_1)]$. If $\phi_1 = -2\lambda/a$, then $y(t, \phi_1) = -2\lambda/a$ for all $t \geq 0$. $x(t, \phi_0)$ increases (decreases) depending on whether $(\phi_0, -2\lambda/a)$ is above or below L. These arguments show that if a path $(x(\cdot, \phi_0), y(\cdot, \phi_1))$ originates in $\mathbb{B}^2_+ - \mathbb{C}_0$, then it stays in $\mathbb{B}^2_+ - \mathbb{C}_0$. Therefore the minimizer $t_{\text{opt}}(\phi_0, \phi_1)$ of (5.10) for any $\phi_0, \phi_1 \in \mathbb{B}^2_+ - \mathbb{C}_0$ is equal to zero. Now using (5.9) and (5.10) the optimal continuation region of (3.3) is equal to $\mathbb{C}$.

Case 2B2b ($-a/c - 1 > 0$). In this case the line segments C and L intersect at $I = (x^I, y^I)$. Arguments similar to those of Case 2B1b show that $[(\mathbb{B}^2_+ - \mathbb{D}_1) \times \mathbb{R}_+] \cap \mathbb{B}^3_+$, in which $\mathbb{D}_1$ is defined in (5.7), is a superset of the optimal continuation region of (3.3). □

THEOREM 5.2. *Let us assume that* $\alpha < \beta$ *(*Case 3, $\alpha < \beta$*) and define*

$$\mathbb{D}_2 \triangleq \left\{ (x, y) \in \mathbb{B}^2_+ : x + y \geq \frac{\lambda + 2\beta}{c} \right\}. \tag{5.22}$$

Then $[(\mathbb{B}^2_+ - \mathbb{D}_1) \times \mathbb{R}_+] \cap \mathbb{B}^3_+$, *which is a bounded region in* $\mathbb{R}^3_+$, *is an upper bound on the continuation region of* (3.3).

Proof. Note that in this case $a > 0$. The paths of the processes $\Phi^\times$ and Φ^+ increase between the jumps and decrease with a jump. If $\tau \in \mathcal{S}$, then there is a constant $t \geq 0$ such that $\tau \wedge \sigma_1 = t \wedge \sigma_1$ almost surely. Hence we can write

(5.23)
$$\begin{aligned}
\mathbb{E}_0\left[\int_0^\tau e^{-\lambda s} h(\Psi_s) ds\right] &= \mathbb{E}_0\left[\int_0^{\tau\wedge\sigma_1} e^{-\lambda s} h(\Psi_s) ds\right] + \mathbb{E}_0\left[1_{\{\tau \geq \sigma_1\}} \int_{\sigma_1}^\tau e^{-\lambda s} h(\Psi_s) ds\right] \\
&= \mathbb{E}_0\left[\int_0^{t\wedge\sigma_1} e^{-\lambda s} h(\Psi_s) ds\right] + \mathbb{E}_0\left[1_{\{t \geq \sigma_1\}} \int_{\sigma_1}^\tau e^{-\lambda s} h(\Psi_s) ds\right] \\
&\geq \mathbb{E}_0\left[\int_0^{t\wedge\sigma_1} e^{-\lambda s} h(\Psi_s) ds\right] - \frac{1}{c}\mathbb{E}_0\left[1_{\{t \geq \sigma_1\}} e^{-\lambda\sigma_1}\right] \\
&= \int_0^t e^{-(\lambda+2\beta)s}\left[h(x(s,\phi_0), y(s,\phi_1)) - \frac{2\beta}{c}\right] ds
\end{aligned}$$

using also the fact that σ_1 has exponential distribution with rate 2β. From (5.23) it follows that if $x(s,\phi_0) + y(s,\phi_1) - (\lambda + 2\beta)/c > 0$, then $\mathbb{E}_0\left[\int_0^\tau e^{-\lambda s} h(\Psi_s) ds\right] > 0$ for every stopping time $\tau \neq 0$, $\tau \in \mathcal{S}$. Since the paths $x(t,\phi_0)$ and $y(t,\phi_1)$ are increasing, we can conclude that stopping immediately is optimal for (3.3). That is, $\tau = 0$ is optimal for (3.3) if $(\phi_0, \phi_1) \in \mathbb{D}_2$ and $\phi_2 \leq \phi_1$, in which $\mathbb{D}_2$ is as in (5.22). □

Theorems 5.1 and 5.2 can be used to determine approximate detection rules besides helping us to determine the location and the shape of the continuation region. As we have seen in Cases 2B1a and 2B2a, these approximate rules turn out to be tight. The next theorem is essential in proving the fact that the smallest optimal stopping time of (3.3) has a finite expectation.

THEOREM 5.3. *Let* τ_D *be the exit time of the process* Υ *from a bounded region* $D \subset \mathbb{B}^3_+$. *Then* $E_0^{\phi^\times,\phi^+,\phi^1}[\tau_D] < \infty$ *for every* $(\phi^\times, \phi^+, \phi^1) \in \mathbb{B}^3_+$. *Hence* τ^* *defined in* (5.1) *has a finite expectation.*

Proof. Let $f(\phi^\times, \phi^+, \phi^1) \triangleq \phi^\times + \phi^+$. Then it follows from (2.22) that

(5.24)
$$\begin{aligned}
[\mathcal{A}f](\phi^\times, \phi^+, \phi^1) &= \lambda\phi^+ + 2a\phi^\times + 2\lambda + a\phi^+ \\
&\quad + \beta\left[\frac{\alpha}{\beta}\phi^+ + \phi^\times + \left(\frac{\alpha}{\beta} - 1\right)\phi^1 - \phi^\times - \phi^+\right] \\
&\quad + \beta\left[\frac{\alpha}{\beta}\phi^+ + \frac{\alpha}{\beta}\phi^\times - \left(\frac{\alpha}{\beta} - 1\right)\phi^1 - \phi^\times - \phi^+\right] = 2\lambda(\phi^\times + \phi^+ + 1) \geq 2\lambda
\end{aligned}$$

for every $(\phi^\times, \phi^+, \phi^1) \in \mathbb{B}^3_+$. Since f is bounded on D and $\tau_D \wedge t$ is a bounded $\mathbb{F}$-stopping time, we have

$$\mathbb{E}_0\left[f(\Upsilon_{\tau_D\wedge t})\right] = f(\Upsilon_0) + \mathbb{E}_0\left[\int_0^{\tau_D\wedge t} [Af](\Upsilon_s) ds\right] \geq 2\lambda E_0[\tau_D \wedge t]. \tag{5.25}$$

On the other hand

$$\mathbb{E}_0\left[f(\Upsilon_{\tau_D\wedge t})\right] \leq \frac{\alpha}{\beta}\xi$$

in which $\xi = \min\{a \in \mathbb{R}_+ : \text{for any } (x,y,z) \in D, \max(x,y,z) \leq a\} < \infty$. An application of the monotone convergence theorem implies that $E_0[\tau_D] < \infty$. □

The results of this section can be used to determine approximate detection rules besides helping us to determine the location and the shape of the continuation region. As we have seen in Cases 2B1a and 2B2a, these approximate rules turn out to be tight.

6. Optimal stopping with time horizon σ_n. In this section, we will first approximate the optimal stopping problem (3.3) by a sequence of optimal stopping problems. Let us denote

$$V_n(a,b,c) \triangleq \inf_{\tau\in\mathcal{S}} \mathbb{E}_0^{a,b,c}\left[\int_0^{\tau\wedge\sigma_n} e^{-\lambda t} h\left(\Phi_t^{\times}, \Phi_t^{+}\right) dt\right] \tag{6.1}$$

for all $(a,b,c)\in\mathbb{B}_+^3$ and $n\in\mathbb{N}$. Here, σ_n is the nth jump time of the process X.

Observe that $(V_n)_{n\in\mathbb{N}}$ is a decreasing sequence and that each of its members satisfies $-1/c < V_n < 0$. Therefore the pointwise limit $\lim_n V_n$ exists. It can be shown that more is true using the fact that the function h is bounded from below and σ_n is a sum of independent exponential random variables.

LEMMA 6.1. *For any $(a,b,c)\in\mathbb{B}_+^3$,*

$$0 \le V_n(a,b,c) - V(a,b,c) \le \frac{1}{c}\left(\frac{2\beta}{2\beta+\lambda}\right)^n. \tag{6.2}$$

Proof. For any $\tau\in\mathcal{S}$,

$$\begin{aligned}\mathbb{E}_0\left[\int_0^{\tau} e^{-\lambda t} h\left(\Phi_t^{\times}, \Phi_t^{+}\right) dt\right] &= \mathbb{E}_0\left[\int_0^{\tau\wedge\sigma_n} e^{-\lambda t} h\left(\Phi_t^{\times}, \Phi_t^{+}\right) dt\right] \\ &\quad + \mathbb{E}_0\left[1_{\{\tau\ge\sigma_n\}}\int_{\sigma_n}^{\tau} e^{-\lambda t} h(\Phi_t^{\times}, \Phi_t^{+}) dt\right].\end{aligned} \tag{6.3}$$

The first term on the right-hand side of (6.3) is greater than V_n. Since $h(\cdot,\cdot) > -\lambda/c$ we can show that the second term is greater than

$$-\frac{\lambda}{c}\mathbb{E}_0^{\phi_0,\phi_1}\left[1_{\{\tau\ge\sigma_n\}}\int_{\sigma_n}^{\tau} e^{-\lambda s} ds\right] \ge -\frac{1}{c}\mathbb{E}_0^{\phi_0,\phi_1}\left[e^{-\lambda\sigma_n}\right] \ge -\frac{1}{c}\left(\frac{2\beta}{\lambda+2\beta}\right)^n. \tag{6.4}$$

To show the last inequality we have used the fact that σ_n is a sum of n independent and identically distributed exponential random variables with rate 2β. Now, the proof of the lemma follows immediately. □

As in [4] and [6], to calculate the value functions V_n iteratively we introduce the functional operators J, J_t. These operators are defined through their actions on bounded functions $g:\mathbb{B}_+^3\to\mathbb{R}$ as follows:

(6.5)

$$[Jg](t,a,b,c) \triangleq \mathbb{E}_0^{a,b,c}\left[\int_0^{t\wedge\sigma_1} e^{-\lambda s} h(\Phi_s^{\times}, \Phi_s^{+}) ds + 1_{\{t\ge\sigma_1\}} e^{-\lambda\sigma_1} g(\Phi_{\sigma_1}^{\times}, \Phi_{\sigma_1}^{+}, \Phi_{\sigma_1}^{1})\right], \text{ and}$$

$$[J_t g](a,b,c) \triangleq \inf_{s\in[t,\infty]} [Jg](s,a,b,c), \quad t\in[0,\infty].$$

Observe that

(6.6)
$$\begin{aligned}
&\mathbb{E}_0\left[1_{\{t\geq\sigma_1\}}e^{-\lambda\sigma_1}g(\Phi^{\times}_{\sigma_1},\Phi^{+}_{\sigma_1},\Phi^{1}_{\sigma_1})\right]\\
&=\mathbb{E}_0\Bigg[\left(g\left(\frac{\alpha}{\beta}\Phi^{\times}_{\sigma_1-},\Phi^{+}_{\sigma_1-}+\left(\frac{\alpha}{\beta}-1\right)\Phi^{1}_{\sigma_1-},\frac{\alpha}{\beta}\Phi^{1}_{\sigma_1-}\right)1_{\{X^1_{\sigma_1}\neq X^1_{\sigma_1-}\}}\\
&\quad+g\left(\frac{\alpha}{\beta}\Phi^{\times}_{\sigma_1-},\frac{\alpha}{\beta}\Phi^{+}_{\sigma_1-}-\left(\frac{\alpha}{\beta}-1\right)\Phi^{1}_{\sigma_1-},\Phi^{1}_{\sigma_1-}\right)1_{\{X^2_{\sigma_1}\neq X^2_{\sigma_1-}\}}\Bigg)1_{\{t\geq\sigma_1\}}e^{-\lambda\sigma_1}\Bigg]\\
&=\frac{1}{2}\int_0^t 2\beta e^{-(\lambda+2\beta)s}g\left(\frac{\alpha}{\beta}\,x(s,a),y(s,b)+\left(\frac{\alpha}{\beta}-1\right)z(s,c),\frac{\alpha}{\beta}\,z(s,c)\right)ds\\
&\quad+\frac{1}{2}\int_0^t 2\beta e^{-(\lambda+2\beta)s}g\left(\frac{\alpha}{\beta}\,x(s,a),\frac{\alpha}{\beta}\,y(s,b)-\left(\frac{\alpha}{\beta}-1\right)z(s,c),z(s,c)\right)ds.
\end{aligned}$$

To derive (6.6) we used the fact that σ_1 has exponential distribution with rate 2β; the dynamics in (2.20); and the fact that conditioned on the event in which there is a jump, it has $1/2$ probability of coming from X^1.

Using (6.6) and Fubini's theorem we can write

$$[Jg](t,a,b,c)=\int_0^t e^{-(\lambda+2\beta)s}(h+\beta\cdot g\circ(F_1+F_2))(x(s,a),y(s,b),z(s,c))ds, \tag{6.7}$$

where

$$F_i(a,b,c)=\left(\frac{\alpha}{\beta}\,a,\left(\frac{\alpha}{\beta}\right)^{i-1}b+(-1)^i\left(\frac{\alpha}{\beta}-1\right)c,\left(\frac{\alpha}{\beta}\right)^{2-i}c\right),\quad i\in\{1,2\}. \tag{6.8}$$

Using (2.26) it can be shown that

$$\lim_{t\to\infty}[Jg](t,a,b,c)=[Jg](\infty,a,b,c)<\infty. \tag{6.9}$$

LEMMA 6.2. *For every bounded function f, the mapping J_0f is bounded. If f is a concave function, then J_0f is also a concave function. If $f_1\leq f_2$, then $J_0f_1\leq J_0f_2$.*

Proof. The third assertion of the lemma directly follows from the representation (6.7). The first assertion holds since h is bounded from below and $J_0f(a,b,)\leq Jf(0,a,b,c)=0$. The second assertion follows from the linearity of the functions $x(t,\cdot)$, $y(t,\cdot)$, $h(\cdot,\cdot)$, $F_1(\cdot,\cdot,\cdot)$, and $F_2(\cdot,\cdot,\cdot)$. □

Using Lemma 6.2 we can prove the following corollary.

COROLLARY 6.1. *Let us define the sequences of function $(v_n)_{n\in\mathbb{N}}$ by*

$$v_0\triangleq 0,\quad v_n\triangleq J_0v_{n-1}. \tag{6.10}$$

Then every $n\in\mathbb{N}$, v_n is bounded and concave, and $v_{n+1}\leq v_n$. Therefore, the limit $v=\lim_n v_n$ exists and is bounded and concave. Moreover, v_n for all $n\in\mathbb{N}$ and v are increasing in each of their arguments.

Proof. The proof of the first part directly follows from Lemma 6.2. That v_n for all $n\in\mathbb{N}$ and v are increasing in each of their arguments follows from the fact that these functions are bounded from above and below and that they are concave. □

We will need the following lemma to give a characterization of the stopping times of the filtration $\mathbb{F}$ (see [5]).

LEMMA 6.3. *For every $\tau\in\mathcal{S}$, there are $\mathcal{F}_{\sigma_n}$-measurable random variables $\xi_n:\Omega\to\infty$ such that $\tau\wedge\sigma_{n+1}=(\sigma_n+\xi_n)\wedge\sigma_{n+1}$ $\mathbb{P}_0$ almost surely on $\{\tau\geq\sigma_n\}$.*

The main theorem of this section can be proven by induction using Lemma 6.3 and the strong Markov property.

THEOREM 6.1. *For every $n \in \mathbb{N}$, v_n defined in Corollary* 6.1 *is equal to V_n. For $\varepsilon \geq 0$, let us denote*

$$r_n^\varepsilon(a,b,c) \triangleq \inf\{t \in (0,\infty] : [Jv_n](t,(a,b,c)) \leq [J_0 v_n](a,b,c) + \varepsilon\}. \tag{6.11}$$

And let us define a sequence of stopping times by $S_1^\varepsilon \triangleq r_0^\varepsilon(\Upsilon_0) \wedge \sigma_1$ and

$$S_{n+1}^\varepsilon \triangleq \begin{cases} r_n^{\varepsilon/2}(\Upsilon_0) & \text{if } \sigma_1 \geq r_n^{\varepsilon/2}(\Upsilon_0), \\ \sigma_1 + S_n^{\varepsilon/2} \circ \theta_{\sigma_1} & \text{otherwise.} \end{cases} \tag{6.12}$$

Here θ_s is the shift operator on Ω, i.e., $X_t \circ \theta_s = X_{s+t}$. Then S_n^ε is an ε-optimal stopping time of (6.1)*, i.e.,*

$$\mathbb{E}_0^{a,b,c}\left[\int_0^{S_n^\varepsilon} e^{-\lambda t} h(\Psi_t)dt\right] \leq v_n(a,b,c) + \varepsilon \tag{6.13}$$

in which $\Psi_t = (\Phi_t^\times, \Phi_t^+)$, $t \geq 0$.

Proof. See the appendix. □

Theorem 6.1 shows that the value function V_n of the optimal stopping problem defined in (6.1) and the function v_n introduced in Corollary 6.1 by an iterative application of the operator J_0 are equal. This implies that the value function of the optimal stopping problem of (6.1) can be found by solving a sequence of deterministic minimization problems.

7. Optimal stopping time.

THEOREM 7.1. *τ^* defined in* (5.1) *is the smallest optimal stopping time for* (3.3).

This theorem shows that Γ defined in (5.2) is indeed an optimal stopping region. We will divide the proof of this theorem into several lemmas.

The following dynamic programming principle can be proven by the special representation of the stopping times of a jump process (Lemma 6.3) and the strong Markov property.

LEMMA 7.1. *For any bounded function $g : \mathbb{B}_+^3 \to \mathbb{R}$ we have*

$$[J_t g](a,b,c) = [Jg](t,a,b,c) + e^{-(\lambda+2\beta)t}[J_0 g](x(t,a), y(t,b), z(t,c)). \tag{7.1}$$

Let us denote

$$r_n(a,b,c) \triangleq r_n^0(a,b,c), \tag{7.2}$$

which is well defined because of (6.9) and the continuity of the function $t \to [Jf](t,a,b,c)$, $t \geq 0$. (See (6.11) for the definition of r_n^0.) Let us also denote

$$r(a,b,c) \triangleq \inf\{t \geq 0 : [JV](t,a,b,c) = J_0 V(a,b,c)\}. \tag{7.3}$$

COROLLARY 7.1. *The functions r_n and r defined by* (7.2) *and* (7.3)*, respectively, satisfy*

$$\begin{aligned} r_n(a,b,c) &= \{t \geq 0 : v_{n+1}(x(t,a), y(t,b), z(t,c)) = 0\}, \\ r(a,b,c) &= \{t \geq 0 : v(x(t,a), y(t,b), z(t,c)) = 0\}, \end{aligned} \tag{7.4}$$

with the convention that $\inf \emptyset = 0$. *Together with* (7.4), *Corollary* 6.1 *implies that* $r_n(a,b,c) \uparrow r(a,b,c)$ *as* $n \uparrow \infty$.

Proof. Suppose that $r_n(a,b,c) < \infty$. Then from (6.11) it follows that

$$\begin{aligned}
&[Jv_n](r_n(a,b,c),a,b,c) = [J_0 v_n](a,b,c) = [J_{r_n(a,b,c)} v_n](a,b,c) \\
&= [Jv_n](r_n(a,b,c),a,b,c) \\
&\quad + e^{-(\lambda+2\beta)r_n(a,b,c)} v_{n+1}(x(r_n(a,b,c),a), y(r_n(a,b,c),b), z(r_n(a,b,c),c)).
\end{aligned} \tag{7.5}$$

Here the second equality follows from the definition of the operator J_t in (6.5), and the third equation follows from Lemma 7.1 and the fact that $J_0 v_n = v_{n+1}$. From (7.5) it follows that $v_{n+1}(x(r_n(a,b,c),a),\ y(r_n(a,b,c),b), z(r_n(a,b,c),c)) = 0$. For $t \in (0, r_n(a,b,c))$ we have $[Jv_n](t,a,b,c) > [J_0 v_n](a,b,c) = [J_{r_n(a,b,c)} v_n](a,b,c) = J_t v_n(a,b,c)$, since the function $s \to [J_s v_n](a,b,c)$ is nondecreasing. Using Lemma 7.1 we can write

$$[J_0 v_n](a,b,c) = [J_t v_n](a,b,c) = [Jv_n](t,a,b,c) + e^{-(\lambda+2\beta)} v_{n+1}(x(t,a), y(t,b), z(t,c)), \tag{7.6}$$

which implies that $v_{n+1}(x(t,a), y(t,b), z(t,c)) < 0$ for all $t < r_n(a,b,c)$.

Now, suppose that $r_n(a,b,c) = \infty$. Then $v_{n+1}(x(t,a), y(t,b), z(t,c)) < 0$ for every $t \in (0,\infty)$ which can be shown using the same arguments as above. Therefore $\{t > 0 : v_{n+1}(x(t,a), y(t,b), z(t,c)) = 0\} = \emptyset$, and (7.4) holds.

The proof for the representation of r can be proven using the same line of argument and the fact that $J_0 V = V$. The fact that $J_0 V = V$ can be proven by the dominated convergence theorem, since the sequences $(v_n(a,b,c))_{n\geq 0}$ and $([Jv_n](t,a,b,c))_{n\geq 0}$ are decreasing and since v_n is a bounded function for all $n \in \mathbb{N}$. □

In the next lemma we construct optimal stopping times for the family of problems introduced in (6.1).

LEMMA 7.2. *Let us denote* $S_n \triangleq S_n^0$, *where* S_n^ε *is defined in Theorem* 6.1 *for* $\varepsilon \geq 0$. *Then the sequence* $(S_n)_{n\in\mathbb{N}}$ *is an almost surely increasing sequence. Moreover* $S_n < \tau^*$ *almost surely for all* n.

Proof. Since $r_1 > 0$, using Corollary 7.1 we can write

$$S_2 - S_1 = \left\{ \begin{array}{ll} r_1 - r_0 & \text{if } \sigma_1 > r_1 \\ \sigma_1 - r_0 + S_1 \circ \theta_{\sigma_1} & \text{if } r_0 < \sigma_1 \leq r_1 \\ S_1 \circ \theta_{\sigma_1} & \text{if } \sigma_1 \leq r_0 \end{array} \right\} > 0. \tag{7.7}$$

Now, let us assume that $S_n - S_{n-1} > 0$ almost surely. From Lemma 7.1 we have that $r_n > r_{n-1}$. Using this fact and the induction hypothesis we can write

$$S_{n+1} - S_n = \left\{ \begin{array}{ll} r_n - r_{n-1} & \text{if } \sigma_1 > r_n \\ \sigma_1 - r_{n-1} + S_n \circ \theta_{\sigma_1} & \text{if } r_{n-1} < \sigma_1 \leq r_n \\ (S_n - S_{n-1}) \circ \theta_{\sigma_1} & \text{if } \sigma_1 \leq r_{n-1} \end{array} \right\} > 0, \tag{7.8}$$

which proves the first assertion of the lemma.

From Corollary 7.1 and the definition of τ^* it follows that $\tau^* \wedge \sigma_1 = r \wedge \sigma_1$. Therefore $\tau^* \wedge \sigma_1 > r_0 \wedge \sigma_1 = S_1$ since $r_0 < r$. Now, we will assume that $S_n < \tau^*$ and show that $S_{n+1} < \tau^*$. On $\{\sigma_1 \leq r_n\}$ we have that

$$S_{n+1} = \sigma_1 + S_n \circ \theta_{\sigma_1} < \sigma_1 + \tau^* \circ \theta_{\sigma_1}. \tag{7.9}$$

Since $\tau^* \wedge \sigma_1 = r \wedge \sigma_1$ and $r > r_n$, if $\sigma_1 \leq r_n$, then $\tau^* \wedge \sigma_1 = \sigma_1$. Because τ^* is a hitting time, on the set $\{\sigma_1 \leq r_n\} \subset \{\sigma_1 \leq \tau^*\}$ the following holds:

$$S_{n+1} \leq \sigma_1 + \tau^* \circ \theta_{\sigma_1} = \tau^*.$$

On the other hand if $\sigma_1 > r_n$, then $\tau^* \wedge \sigma_1 = r \wedge \sigma_1 > r_n$. Therefore on $\{\sigma_1 > r_n\}$, $S_{n+1} = r_n < \tau^*$. This concludes the proof of the second assertion. □

LEMMA 7.3. *Let us denote* $\Psi_t = (\Phi_t^{\times}, \Phi_t^{+})$, $t \geq 0$. *If* $S^* \triangleq \lim_n S_n$, *then* $S^* = \tau^*$ *almost surely. Moreover,* τ^* *is an optimal stopping time, i.e.,*

$$V(a,b,c) = \mathbb{E}_0^{a,b,c}\left[\int_0^{S^*} e^{-\lambda s} h(\Psi_s) ds\right].$$

Proof. The limit $S^* \triangleq \lim_n S_n$ exists since $(S_n)_{n\in\mathbb{N}}$ is increasing and $S_n \leq \tau^* < \infty$ (as a corollary of Theorem 5.3) for all n. Let us show that S^* is optimal.

$$\begin{aligned} \mathbb{E}_0\left[\lim_n \int_0^{S_n} e^{-\lambda t} h(\Psi_t) dt\right] &\leq \liminf_n \mathbb{E}_0\left[\int_0^{S_n} e^{-\lambda t} h(\Psi_t) dt\right] \\ &= \lim_n V_n(a,b,c) = V(a,b,c). \end{aligned} \tag{7.10}$$

The first inequality follows from Fatou's lemma, which we can apply since

$$\int_0^{S_n} e^{-\lambda t} h(\Psi_t) dt \geq \int_0^{\infty} e^{-\lambda t} h(\Psi_t) dt \geq -\frac{\sqrt{2}}{c} \quad \text{almost surely.}$$

The first equality in (7.10) follows from Theorem 6.1. Now it can be seen from (7.10) that S^* is an optimal stopping time. Taking the limit of (6.12) as $n \to \infty$ and using Corollary 7.1, we conclude that $\tau^* = S^*$. □

Proof of Theorem 7.1. The proof of the optimality of τ^* follows directly from Lemma 7.3. We will show that τ^* is the smallest optimal stopping time.

Given any $\mathbb{F}$-stopping time $\tau < \tau^*$, let us define

$$\tilde{\tau} \triangleq \tau + \tau^* \circ \theta_\tau. \tag{7.11}$$

Then the stopping time $\tilde{\tau}$ satisfies

(7.12)

$$\begin{aligned} \mathbb{E}_0^{a,b,c}\left[\int_0^{\tilde{\tau}} e^{-\lambda s} h(\Psi_s) ds\right] &= \mathbb{E}_0^{a,b,c}\left[\int_0^{\tau} e^{-\lambda s} h(\Psi_s) ds + \int_\tau^{\tilde{\tau}} e^{-\lambda s} h(\Psi_s) ds\right] \\ &= \mathbb{E}_0^{a,b,c}\left[\int_0^{\tau} e^{-\lambda s} h(\Psi_s) ds + e^{-\lambda\tau} \int_0^{\tau^*\circ\theta_\tau} e^{-\lambda s} h(\Psi_{s+\tau}) ds\right] \\ &= \mathbb{E}_0^{a,b,c}\left[\int_0^{\tau} e^{-\lambda s} h(\Psi_s) ds + e^{-\lambda\tau} V(\Upsilon_\tau)\right] \\ &< \mathbb{E}_0^{a,b,c}\left[\int_0^{\tau} e^{-\lambda s} h(\Psi_s) ds\right]. \end{aligned}$$

Here the third equality follows from the strong Markov property of the process Υ, and the inequality follows since $V(\Upsilon_\tau) < 0$. Equation (7.12) shows that any optimal stopping time $\tau < \tau^*$ cannot be optimal. □

8. Structure of the continuation and stopping regions. Let us recall (5.2) and denote

$$\mathbf{\Gamma_n} \triangleq \{(a,b,c) \in \mathbb{B}_+^3 : v_n(a,b,c) = 0\}, \quad \mathbf{C}_n \triangleq \mathbb{B}_+^3 - \mathbf{\Gamma_n}. \tag{8.1}$$

We have shown in Theorem 7.1 that the Γ of (5.2) is the optimal stopping region for (3.3) and the first hitting time τ^* of Υ to this set is optimal. On the other hand although Γ_n is an optimal stopping region for (6.1), the description of the optimal stopping times S_n^0 (see (6.12)) is more involved. These optimal stopping times are not hitting times of the sets Γ_n. S_n^0 prescribes to stop if Υ hits Γ_n before it jumps. Otherwise if there is a jump before Υ reaches Γ_n, then S_n^0 prescribes to stop when the process hits Γ_{n-1} before the next jump, and so on.

Theorem 6.1 shows that V_n of (6.1) and the functions v_n introduced in Corollary 6.1 are equal. Therefore, their respective limits V and v are also equal. Recall that V^n converges to V uniformly and the convergence rate is exponential (see Lemma 6.1). Since $(v_n)_{n\in\mathbb{N}}$ is a decreasing sequence with limit v, the stopping regions in (8.1) are nested and satisfy $\Gamma \subset \cdots \subset \Gamma_n \subset \Gamma_{n-1} \subset \cdots \Gamma_1$ and $\Gamma = \cap_{n=1}^{\infty} \Gamma_n$.

By Corollary 6.1 we know that each v_n is concave and bounded, which also implies that the limit v is concave and bounded. This in turn implies that the stopping regions Γ_n and Γ are convex and closed. Since we show in section 5 that the continuation region is bounded, it can readily be shown that the stopping regions Γ_n and Γ are the epigraphs of some mappings γ_n and γ which are convex and strictly decreasing and the numbers $x_n \triangleq \inf\{y \in \mathbb{R}_+ : \gamma_n(y) = 0\}$ and $x \triangleq \inf\{y \in \mathbb{R}_+ : \gamma(x) = 0\}$ are finite.

9. Extensions.

9.1. Nonidentical sources. Consider two independent Poisson processes X^1 and X^2 with arrival rates β_1 and β_2, respectively. At some random unobservable times θ_1 and θ_2, with distributions

$$\mathbb{P}(\theta_i = 0) = \pi_i, \quad \mathbb{P}(\theta_i > t) = (1-\pi_i)e^{-\lambda_i t} \text{ for } t \geq 0, \tag{9.1}$$

the arrival rates of the Poisson processes X^1 and X^2 change from β_i to α_i, respectively, i.e.,

$$X_t^i - \int_0^t h_i(s)ds, \quad t \geq 0,\, i = 1,2, \tag{9.2}$$

are martingales, in which

$$h_i(t) = [\beta_i 1_{\{s<\theta_i\}} + \alpha_i 1_{\{s\geq\theta_i\}}], \quad t \geq 0,\, i = 1,2. \tag{9.3}$$

Here α_1, α_2, β_1, and β_2 are known positive constants. Then the dynamics of $\Phi^\times$ defined in (2.19) becomes

$$d\Phi_t^\times = [\lambda_2\Phi_t^1 + \lambda_1\Phi_t^2 + (a_1+a_2)\Phi_t^+]dt + \Phi_t^\times\left[((\alpha_1/\beta_1)-1)dX_t^1 + ((\alpha_2/\beta_2)-1)dX_t^2\right] \tag{9.4}$$

in which $a_i = \lambda_i - \alpha_i + \beta_i$, $i \in \{1,2\}$. Let us introduce

$$x(t,\phi_0) = e^{(a_1+a_2)t}\phi_0 + \int_0^t e^{(a_1+a_2)(t-u)}(\lambda_2 y(u,\phi_1) + \lambda_1 z(u,\phi_2))du \quad \text{in which} \tag{9.5}$$

$$y(t,\phi_1) = -\frac{\lambda_1}{a_1} + e^{a_1 t}\left(\phi_1 + \frac{\lambda}{a}\right), \quad z(t,\phi_2) = -\frac{\lambda_2}{a_2} + e^{a_2 t}\left(\phi_2 + \frac{\lambda_2}{a_2}\right).$$

Then $\Phi_t^{\times}$, Φ_t^1, and Φ_t^2, $t \geq 0$, can be written as

$$\Phi_t^{\times} = x(t-\sigma_n, \Phi_{\sigma_n}^{\times}), \qquad \Phi_t^1 = y(t-\sigma_n, \Phi_{\sigma_n}^{+}), \qquad \Phi_t^2 = z(t-\sigma_n, \Phi_{\sigma_n}^1), \quad \sigma_n \leq t < \sigma_{n+1},\ n \in \mathbb{N}, \tag{9.6}$$

and

$$\begin{aligned} \Phi_{\sigma_{n+1}}^{\times} &= \left(\frac{\alpha_1}{\beta_1} 1_{\{X^1_{\sigma_{n+1}} \neq X^1_{\sigma_{n+1-}}\}} + \frac{\alpha_2}{\beta_2} 1_{\{X^2_{\sigma_{n+1}} \neq X^2_{\sigma_{n+1-}}\}}\right) \Phi_{\sigma_{n+1-}}^{\times}, \\ \Phi_{\sigma_{n+1}}^1 &= \frac{\alpha_1}{\beta_1} 1_{\{X^1_{\sigma_{n+1}} \neq X^1_{\sigma_{n+1-}}\}} \Phi_{\sigma_{(n+1)-}}^1, \quad \Phi_{\sigma_{n+1}}^2 = \frac{\alpha_2}{\beta_2} 1_{\{X^2_{\sigma_{n+1}} \neq X^2_{\sigma_{n+1-}}\}} \Phi_{\sigma_{(n+1)-}}^1. \end{aligned} \tag{9.7}$$

Choosing $\Upsilon_t = \left(\Phi_t^{\times}, \Phi_t^1, \Phi_t^2\right)$, $t \geq 0$, as the Markovian statistic to work with, we can extend our analysis to deal with nonidentical sources.

9.2. When there are more than two sources. We have solved a two-source quickest detection problem in which the aim is to detect the minimum of two disorder times. Our approach can easily be generalized to problems including several dimensions. To clarify how this generalization works, let us show what the sufficient statistics are when there are three independent sources. Assume that the observations come from the independent sources X^1, X^2, and X^3. Let Φ_t be the odds ratio defined in (2.9). Then

$$\Phi_t = \Phi_t^1 + \Phi_t^2 + \Phi_t^3 + \Phi_t^1\Phi_t^2 + \Phi_t^1\Phi_t^3 + \Phi_t^2\Phi_t^3 + \Phi_t^1\Phi_t^2\Phi_t^3 \tag{9.8}$$

in which Φ^i, $i \in \{1,2,3\}$, is defined as in (2.14). Let us denote $\Phi_t^{(i,j)} \triangleq \Phi_t^i\Phi_t^j$, $i,j \in \{1,2,3\}$, and $\Phi_t^{(x)} \triangleq \Phi_t^1\Phi_t^2\Phi_t^3$, $t \geq 0$. The dynamics of these processes can be written as

$$\begin{aligned} d\Phi_t^{(i,j)} &= [\lambda(\Phi_t^i + \Phi_t^j) + 2(\lambda - \alpha + \beta)\Phi_t^{(i,j)}]dt + \left(\frac{\alpha}{\beta} - 1\right)\Phi_t^{(i,j)} d(X_t^i + X_t^j), \\ d\Phi_t^{(x)} &= \left[\lambda\left(\Phi_t^{(1,2)} + \Phi_t^{(1,3)} + \Phi_t^{(2,3)}\right) + 3(\lambda - \alpha + \beta)\Phi_t^{(x)}\right] dt \\ &\quad + \left(\frac{\alpha}{\beta} - 1\right)\Phi_t^{(x)} d(X_t^1 + X_t^2 + X_t^3). \end{aligned} \tag{9.9}$$

We can see from (2.13) and (9.9) that $\Upsilon \triangleq (\Phi^1, \Phi^2, \Phi^3, \Phi_t^{(1,2)}, \Phi_t^{(1,3)}, \Phi_t^{(2,3)}, \Phi^{(x)})$ is a seven-dimensional Markovian statistic whose natural filtration is equal to the filtration generated by X^1, X^2, and X^3. From this one can see that the results of sections 6 and 7 can be extended to the three-dimensional case since these results rely only on the fact that the sufficient statistic Υ is a strong Markov process. The boundedness of the continuation region can also be shown as in section 5 since these results can be derived from the sample path properties of the sufficient statistic.

As a result, our results are applicable for decision making with large-scale distributed networks of information sources. In the future, using the techniques developed here, we would like to solve a multisource detection problem where the observations come from correlated sources. We also would like to extend our results and develop change detection algorithms that can be applied effectively to multiple source data that involves both continuous and discrete event phenomena.

9.3. When the jump sizes of the observations are random. Consider two independent *compound* Poisson processes $X^i = \{X_t^i : t \geq 0\}$, $i \in \{1,2\}$, where

$$X_t^i = X_0^i + \sum_{j=1}^{N_t^i} Y_j^i \tag{9.10}$$

in which N^i, $i \in \{1,2\}$, are two independent Poisson processes whose common rate $\beta > 0$ changes to α at some random unobservable times θ_i, $i \in \{1,2\}$, respectively. The random variables $Y_j^i \in \mathbb{R}^d$, $i \in \{1,2\}$, which are also termed as "marks," are independent and identically distributed with a common distribution, ν, which is called as the "mark distribution." At the change time θ_i the mark distribution of the process X^i changes from ν to μ. We will assume that μ is absolutely continuous with respect to ν and denote the Radon–Nikodym derivative by $r(y) \triangleq \frac{d\mu}{d\nu}(y),\ y \in \mathbb{R}^d$. In this case L_t^i in (2.4) becomes

$$L_t^i = e^{-(\alpha-\beta)t} \prod_{k=1}^{N_t^i} \left(\frac{\alpha}{\beta}\, r(Y_k^i) \right). \tag{9.11}$$

The likelihood ratio process L^i is the unique solution of the stochastic differential equation (see, e.g., [8])

$$dL_t^i = L_t^i \left(-(\alpha-\beta)dt + \int_{y\in\mathbb{R}^d} \left(\frac{\alpha}{\beta}\, r(y) - 1 \right) p(dtdy) \right), \quad L_0^i = 1, \tag{9.12}$$

where p is a random measure that is defined as

$$p^i((0,t] \times A) \triangleq \sum_{k=1}^{\infty} 1_{\{\sigma_k^i \leq t\}} 1_{\{Y_k^i \in A\}}, \quad t \geq 0, \tag{9.13}$$

and for any A that is a Borel measurable subset of $\mathbb{R}^d$. Here σ_k^i is the kth jump time of the process X^i. Now using the change of variable formula for semimartingales (see, e.g., [12]), we can write

$$d\Phi_t^i = (\lambda + (\lambda - \alpha + \beta)\Phi_t^i)dt + \Phi_{t-}^i \int_{y\in\mathbb{R}^d} \left(\frac{\alpha}{\beta}\, r(y) - 1 \right) p^i(dtdy), \quad \Phi_0^i = \frac{\pi_i}{1-\pi_i} \tag{9.14}$$

for $t \geq 0$ and $i \in \{1,2\}$. Note that $\Phi_{\sigma_n}^i = \frac{\alpha}{\beta}\, r(Y_n)\Phi_{\sigma_n -}^i$ at the nth jump time of the process X^i. Using a change of variable formula for semimartingales, the dynamics of $\Phi^\times$ and Φ^+ in (2.19) can be written as

$$\begin{aligned} d\Phi_t^\times &= [\lambda\Phi_t^+ + a\Phi_t^\times]dt + \Phi_{t-}^\times \int_{y\in\mathbb{R}^d} \left(\frac{\alpha}{\beta}\, r(y) - 1 \right) (p^1 + p^2)(dtdy), \\ d\Phi_t^+ &= [2\lambda + a\Phi_t^+]dt + \Phi_{t-}^1 \int_{y\in\mathbb{R}^d} \left(\frac{\alpha}{\beta}\, r(y) - 1 \right) p^1(dtdy) \\ &\quad + \Phi_{t-}^2 \int_{y\in\mathbb{R}^d} \left(\frac{\alpha}{\beta}\, r(y) - 1 \right) p^2(dtdy), \end{aligned} \tag{9.15}$$

with initial conditions $\Phi_0^\times = \pi_1\pi_2/[(1-\pi_1)(1-\pi_2)]$ and $\Phi_0^+ = \pi_1/(1-\pi_1) + \pi_2/(1-\pi_2)$.

The bounds on the continuation region constructed for the simple Poisson disorder problem in section 5 can also be shown to bound the continuation region of the compound Poisson disorder problem. On the other hand the results in sections 6 and 7 can be shown to hold. The only change will be the form of the operator J in (6.7). But this new operator can be shown to share the same properties as its counterpart for the unmarked case.

10. Appendix.

Proof of Theorem 6.1. We will prove only that $V_n = v_n$ and S_n^ε is an ε-optimal stopping time of (6.1).

The proof will be carried out in three steps.

(i) First we will show that $V_n \geq v_n$. To establish this fact, it is enough to show that for any stopping time $\tau \in \mathcal{S}$

$$\mathbb{E}_0^{a,b,c}\left[\int_0^{\tau\wedge\sigma_n} e^{-\lambda t}h(\Psi_t)dt\right] \geq v_n(a,b,c). \tag{10.1}$$

In order to prove (10.1) we will show that

$$\begin{aligned}&\mathbb{E}_0\left[\int_0^{\tau\wedge\sigma_n} e^{-\lambda t}h(\Psi_t)dt\right]\\ &\quad\geq \mathbb{E}_0\left[\int_0^{\tau\wedge\sigma_{n-k+1}} e^{-\lambda t}h(\Psi_t)dt + 1_{\{\tau\geq\sigma_{n-k+1}\}}e^{-\lambda\sigma_{n-k+1}}v_{k-1}(\Upsilon_{\sigma_{n-k+1}})\right]\end{aligned} \tag{10.2}$$

for $k \in \{1,2,\ldots,n+1\}$. Note that (10.1) follows from (10.2) if we set $k = n+1$. In what follows we will show (10.2) by induction.

When $k = 1$, (10.2) is satisfied since $v_0 = 0$. Assume that (10.2) holds for $1 \leq k \leq n+1$. Let us denote the right-hand side of (10.2) by ρ_{k-1}. We can write $\rho_{k-1} = \rho_{k-1}^1 + \rho_{k-1}^2$, where

$$\begin{aligned}\rho_{k-1}^1 &\triangleq \mathbb{E}_0\left[\int_0^{\tau\wedge\sigma_{n-k}} e^{-\lambda t}h(\Psi_t)dt\right] \quad \text{and}\\ \rho_{k-1}^2 &\triangleq \mathbb{E}_0\left[1_{\{\tau\geq\sigma_{n-k}\}}\left(\int_{\sigma_{n-k}}^{\tau\wedge\sigma_{n-k+1}} e^{-\lambda t}h(\Psi_t)dt\right.\right.\\ &\qquad\left.\left.+\,1_{\{\tau\geq\sigma_{n-k+1}\}}e^{-\lambda\sigma_{n-k+1}}v_{k-1}(\Upsilon_{\sigma_{n-k+1}})\right)\right].\end{aligned} \tag{10.3}$$

Now by Lemma 6.3, there exists an $\mathcal{F}_{\sigma_{n-k}}$-measurable random variable ξ_{n-k} such that

$$\tau\wedge\sigma_{n-k+1} = (\sigma_{n-k}+\xi_{n-k})\wedge\sigma_{n-k+1} \quad \text{almost surely on } \{\tau\geq\sigma_{n-k}\}. \tag{10.4}$$

Equation (10.4) together with the strong Markov property of Υ (with respect to the filtration $\mathbb{F}$) implies that

$$\rho_{k-1}^2 = \mathbb{E}_0\left[1_{\{\tau\geq\sigma_{n-k}\}}e^{-\lambda\sigma_{n-k}}f_{k-1}(\xi_{n-k},\Upsilon_{\sigma_{n-k}})\right] \tag{10.5}$$

in which

$$\begin{aligned}f_{k-1}(r,(a,b,c)) &\triangleq \mathbb{E}_0^{a,b,c}\left[\int_0^{r\wedge\sigma_1} e^{-\lambda t}h(\Psi_t)dt + 1_{\{r\geq\sigma_1\}}e^{-\lambda\sigma_1}v_{k-1}(\Upsilon_{\sigma_1})\right]\\ &= Jv_{k-1}(r,(a,b,c)) \geq J_0v_{k-1}(a,b,c) = v_k(a,b,c)\end{aligned} \tag{10.6}$$

in which the second equality and the first inequality follow from (6.5) and the last equality follows from (6.10). Therefore

$$\rho_{k-1}^2 \geq \mathbb{E}_0\left[1_{\{\tau \geq \sigma_{n-k}\}} e^{-\lambda \sigma_{n-k}} v_k(\Upsilon_{\sigma_{n-k}})\right]. \tag{10.7}$$

Now using (10.2), (10.3), and (10.7) we obtain that (10.2) holds when k is replaced by $k+1$. At this point we have proved by induction that (10.2) holds for $k = 1, 2, \ldots, n+1$.

(ii) The converse of (i), $V_n \leq v_n$, follows from (6.13) since $S_n^\varepsilon \leq \sigma_n$ by construction (see (6.12)).

(iii) What is left to prove is (6.13). If $n = 1$, then the left-hand side of (6.13) becomes

$$\begin{aligned}\mathbb{E}_0^{a,b,c}\left[\int_0^{r_0^\varepsilon(a,b,c)\wedge\sigma_1} e^{-\lambda t} h(\Psi_t)dt\right] &= Jv_0(r_0^\varepsilon(a,b,c),a,b,c) \\ &\leq J_0 v_0(a,b,c) + \varepsilon = v_1(a,b,c) + \varepsilon.\end{aligned} \tag{10.8}$$

Now, suppose that (6.13) holds for all $\varepsilon > 0$ for some n. Using the fact that $S_{n+1}^\varepsilon \wedge \sigma_1 = r_n^{\varepsilon/2} \wedge \sigma_1$ almost surely and the strong Markov property of Υ, we can write

$$\begin{aligned}&\mathbb{E}_0\left[\int_0^{S_{n+1}^\varepsilon} e^{-\lambda t} h(\Psi_t)dt\right] \\ &\quad= \mathbb{E}_0\left[\int_0^{S_{n+1}^\varepsilon\wedge\sigma_1} e^{-\lambda t} h(\Psi_t)dt + 1_{\{S_{n+1}^\varepsilon \geq \sigma_1\}} \int_{\sigma_1}^{S_{n+1}^\varepsilon} e^{-\lambda t} h(\Psi_t)dt\right] \\ &\quad= \mathbb{E}_0\left[\int_0^{r_n^{\varepsilon/2}(a,b,c)\wedge\sigma_1} e^{-\lambda t} h(\Psi_t)dt\right] + \mathbb{E}_0\left[1_{\{r_n^{\varepsilon/2}(a,b,c)\geq\sigma_1\}} e^{-\lambda\sigma_1} g_n(\Upsilon_{\sigma_1})\right]\end{aligned} \tag{10.9}$$

in which

$$g_n(a,b,c) \triangleq \mathbb{E}_0^{a,b,c}\left[\int_0^{S_n^{\varepsilon/2}} e^{-\lambda t} h(\Psi_t)dt\right] \leq v_n(a,b,c) + \varepsilon/2. \tag{10.10}$$

The inequality in (10.10) follows from the induction hypothesis. Using (10.10) we can write (10.9) as

$$\begin{aligned}&\mathbb{E}_0^{a,b,c}\left[\int_0^{S_{n+1}^\varepsilon} e^{-\lambda t} h(\Psi_t)dt\right] \\ &\quad\leq \mathbb{E}_0^{a,b,c}\left[\int_0^{r_n^{\varepsilon/2}(a,b,c)\wedge\sigma_1} e^{-\lambda t} h(\Psi_t)dt + 1_{\{r_n^{\varepsilon/2}(a,b,c)\geq\sigma_1\}} e^{-\lambda\sigma_1} v_n(\Upsilon_{\sigma_1})\right] + \varepsilon/2 \\ &\quad= Jv_n(r_n^{\varepsilon/2}(a,b,c),a,b,c) + \varepsilon/2 \leq v_{n+1}(a,b,c) + \varepsilon.\end{aligned} \tag{10.11}$$

This proves (6.13) when n is replaced by $n+1$. □

UNIQUENESS OF CONSTRAINED VISCOSITY SOLUTIONS IN HYBRID CONTROL SYSTEMS*

MINYI HUANG†

Abstract. We study constrained viscosity solutions with an unbounded growth for a class of first order Hamilton–Jacobi–Bellman equations arising in hybrid control systems. To deal with the boundary constraint and rapid growth of the solutions, we construct a particular set of test functions and under very mild conditions establish a comparison theorem which gives the estimate of distance between the subsolution and the supersolution. The comparison theorem implies uniqueness of the constrained viscosity solution if its existence is ensured; and under some additional assumptions we give an existence result by showing that the value function is a constrained viscosity solution. We then apply the obtained uniqueness results to an optimal scheduling problem and finally to stochastic manufacturing systems.

Key words. hybrid control systems, optimal control, HJB equations, constrained viscosity solutions, fluid models, manufacturing systems

1. Introduction.

This paper is concerned with the analysis of a class of first order Hamilton–Jacobi–Bellman (HJB) equations with discrete transitions and state constraints. Such equations arise naturally in the optimal control of stochastic systems with random structural changes in dynamics, which are modeled as Markovian jumps. These systems involve both continuum and discrete components in their evolution and are referred to as hybrid systems, and they have been investigated from a wide range of backgrounds including production planning subject to random machine breakdown and repair [20] and the control of fluid queueing models for communication networks [19, 7, 17], among others [6, 9, 14, 24, 28]. Due to physical limitation, a typical feature for many control models is that the system state is restricted to a certain set; for instance, the level for buffers must be maintained nonnegative [20, 25]. To deal with the resulting HJB equation, one needs to take into account both the discrete transitions and the state space constraints and to adopt the notion of appropriately defined constrained viscosity solutions first introduced in [22].

Specifically, Soner studied an optimal control problem and introduced first order constrained viscosity solutions in [22], where the deterministic state trajectory is restricted to a given subset of $\mathbb{R}^n$, and in a companion work [23] along this line, viscosity solutions were analyzed for controlled piecewise deterministic Markov processes [6] defined on a subset of $\mathbb{R}$, which leads to an integral HJB equation. Later on, the result in [22] was generalized in [18] by identifying weaker sufficient conditions for ensuring continuity of the value function and in [12] by an additional boundary characterization of the subsolution via a so-called inward Hamiltonian reflecting boundary constraints.

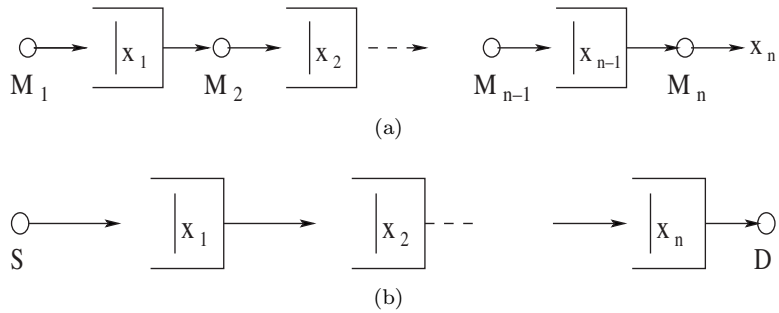

FIG. 1. (a) *A manufacturing system with n machines (M_i, $1 \le i \le n$) and $n-1$ buffers;* (b) *a multihop communication network where the source S and destination D are connected by n buffers.*

For HJB equations involving finite state Markov chains, viscosity solutions have been studied in [20, 8, 26, 27]. In particular, the authors in [26, 27] considered controlled random transitions but there were no state constraints.

Although viscosity solutions with state constraints are of importance and have their primary motivation in optimal control, in many application problems, the existing results face limitation. Notably, in the sequence of work [22, 18, 12] considering first order HJB equations for deterministic systems, uniqueness is obtained for uniformly continuous and bounded solutions. In [15] and [5], bounded continuous solutions were analyzed on a bounded domain. Also, in a singular perturbation control problem with partial state constraints [1], uniqueness and existence theorems were established with bounded continuous solutions. For illustrating the limitation of those previous results, we consider the optimal control of a single buffer fluid model with controlled input and output and, as a well-motivated practice, introduce a linear holding cost for a positive buffer level (see section 6 for details). This readily leads to unbounded value functions, and existing results for constrained viscosity solutions are difficult to apply.

In this work we study uniqueness of constrained viscosity solutions for a class of stochastic hybrid systems. We concentrate our attention to two concrete types of domains for the state variable. The particular structure of the state space has adequate generality and is frequently encountered in a wide range of application problems arising in manufacturing systems and communication networks [20, 25, 19] (see Figure 1 for illustration), though a generalization of the state space to other forms is possible. In introducing our solution notion, we generalize the definition of constrained viscosity solutions for standard HJB equations of deterministic models to a coupled HJB equation system. Resulting from the state space constraints, this definition leads to specifying the viscosity sub/supersolution in two different regions, respectively, i.e., characterizing the subsolution in a smaller region—the interior of the constrained state space. Such a differentiation by two regions is important for developing a solution framework for uniqueness analysis. We prove uniqueness of the solution within the class of functions satisfying a polynomial growth and local Hölder continuity. In establishing the comparison result in this paper, a crucial step is to obtain suitable test functions involved in the definition of constrained viscosity solutions. Towards this end, we construct the auxiliary function Φ by first dominating the sub/supersolution growth by an exponential function and then introducing a pair of perturbation parameters (τ, ε) [see (11)] such that the resulting maxima (w.r.t. x) can be tuned to the interior of the state space to generate desired test functions for the subsolution.

The proof of the comparison theorem depends on generalizing typical techniques for deterministic systems [22, 2].

For proving existence results in the general model, a quite difficult step is to show continuity of the value function. The key idea in our analysis is to truncate a small time interval by the jump time of the Markov chain so that locally the system dynamics act like a time-invariant model. This resulting feature enables us to use a certain time-shifting technique to construct auxiliary admissible controls for cost estimates. In particular, using a recursive estimation procedure, we obtain Hölder continuity of the value function, and we mention that as a byproduct this method can be used to strengthen some existing continuity results in the literature for state constrained optimal control problems.

Our work differs from most existing analysis on constrained viscosity solutions for deterministic systems in that we need to deal with a system of coupled equations and the solution growth is rapid. Our solution notion for the coupled HJB equation system and the uniqueness results provide a unified analytical basis for the optimal control of this class of hybrid systems. In particular, our uniqueness results are applicable to classical stochastic manufacturing models (see, e.g., [20]), where to our best knowledge the existing work has not provided uniqueness results for the coupled HJB equations when nonnegative buffer level constraints are imposed.

The organization of the paper is as follows. In section 2, we first describe the optimal control problem for the hybrid system and introduce the notion of constrained viscosity solutions. The comparison result and uniqueness theorem are stated in section 3. The proof of the comparison theorem is technical and postponed to section 4. For the general hybrid system model, section 5 first shows Hölder continuity of the value function under some technical conditions and proves that it is the unique constrained viscosity solution. In section 6, we study an optimal data traffic scheduling problem and prove the existence and uniqueness of constrained viscosity solutions by applying the result in section 3. In section 7, we further apply the results in section 3 to a well-studied stochastic manufacturing system, which complements existence theorems in the manufacturing literature [20]. Finally, a few concluding remarks are presented in section 8.

2. The HJB equation and constrained viscosity solutions. Consider a hybrid control system described by the following differential equation:

$$\frac{dX(t)}{dt} = F(X(t), \theta(t), u(t)), \qquad t \geq 0, \tag{1}$$

with initial condition $X(0) \in \bar{Q}$. Here X and θ are called the state and mode variables, respectively. The trajectory of X on $[0, \infty)$ is required to be in $\bar{Q}$, which is a closed subset of $\mathbb{R}^n$ with a nonempty interior Q. Moreover, θ is a continuous time Markov chain with state space $\Theta = \{1, 2, \ldots, m\}$ and transition probability rate matrix $\Pi_\theta = (\pi_{ij})_{m\times m}$, which is also called the generator. It is assumed that, with probability one, the trajectory of θ is right continuous with left limit. Given $\theta(t) = k$, the control $u(t)$ takes values from a compact set $U_k \subset \mathbb{R}^d$. Let $\mathcal{F}_t$ denote the σ-algebra generated by the Markov chain θ up to time t, i.e., $\mathcal{F}_t = \sigma(\theta(s), s \leq t)$. Associated with $X(0) = x$ and $\theta(0) = k$, the admissible control set is written as $\mathcal{U}_{x,k}$ consisting of all controls $u(\cdot)$ satisfying $u(t) \in U_{\theta(t)}$ and adapted to $\mathcal{F}_t$ such that $P\{X(t) \in \bar{Q},\ \forall\ t \geq 0\} = 1$. We make the convention that for all $(x, k) \in \bar{Q} \times \Theta$, $\mathcal{U}_{x,k}$ is nonempty and that the state process $X(t)$ associated with an admissible control is uniquely determined on $[0, \infty)$ with exception on a null set of samples. Given initial condition $(x, k) \in \bar{Q} \times \Theta$

at $t = 0$, let the cost function be given by

$$\begin{aligned} v(x,k) &= \inf_{u\in\mathcal{U}_{x,k}} J(x,k,u) \\ &\triangleq \inf_{u\in\mathcal{U}_{x,k}} E\Big[\int_0^\infty e^{-\rho t}L(X(t),\theta(t),u(t))dt|X(0)=x,\theta(0)=k\Big], \end{aligned} \tag{2}$$

where $\rho > 0$ is a discount factor and L is the cost integrand before discount.

To facilitate the subsequent analysis, we set some convention on notation. We may alternatively denote $X(t)$ as X_t with a real-valued subscript $t \geq 0$, and the same convention holds for $u(t)$ and $\theta(t)$, etc. The letter u may stand for a value in U_k for a certain $k \in \Theta$ or a control adapted to $\mathcal{F}_t$; the specific interpretation should be clear from the context. Throughout the paper, for a real-valued vector y, $|y|$ denotes its Euclidean norm.

For any function $\varphi : \Theta \to \mathbb{R}$, we define the map

$$[\Pi_\theta\varphi(\cdot)](i) = \sum_{j\neq i}\pi_{ij}[\varphi(j)-\varphi(i)], \tag{3}$$

where $\pi_{ii} + \sum_{j\neq i}\pi_{ij} = 0$.

We assume for any given $k \in \Theta$, both $F(x,k,u)$ and $L(x,k,u)$ are continuous in $(x,u) \in \bar{Q}\times U_k$. A formal application of dynamic programming leads to the following equation system:

$$\rho v(x,k) = \inf_{u\in U_k}\Big[v_x^T(x,k)F(x,k,u) + [\Pi_\theta v(x,\cdot)](k) + L(x,k,u)\Big], \tag{4}$$

where $(x,k) \in \bar{Q}\times\Theta$ and the superscript $(\cdot)^T$ denotes the transpose of a vector or matrix. Note that due to the action of the generator, (4) gives a system of m coupled equations. For convenience of exposition, we simply refer to (4) as the HJB equation for the underlying optimal control problem. Write

$$\tilde{H}(x,k,v_x(x,k),v(x,\cdot),u) = v_x^T(x,k)F(x,k,u) + [\Pi_\theta v(x,\cdot)](k) + L(x,k,u).$$

Then the HJB equation (4) may be written in the compact form:

$$\begin{aligned} \rho v(x,k) &= \inf_{u\in U_k}\tilde{H}(x,k,v_x(x,k),v(x,\cdot),u) \\ &\triangleq H(x,k,v_x(x,k),v(x,\cdot)), \qquad (x,k)\in\bar{Q}\times\Theta, \end{aligned} \tag{5}$$

where the dot entry in (5) indicates that for each fixed k, the term H depends on the whole vector $[v(x,1),\ldots,v(x,m)]$.

DEFINITION 1. *Let $\underline{v}(x,k)$, $\overline{v}(x,k)$, and $v(x,k)$ be functions from $\bar{Q}\times\Theta$ to $\mathbb{R}$, each being continuous in x for all $k \in \Theta$.*

(i) *$\underline{v}(x,k)$ is a viscosity subsolution to (5) on $Q\times\Theta$ if for any $k_0 \in \Theta$ and any function $\phi \in C^1(\bar{Q})$, we have*

$$\rho\underline{v}(x_0,k_0) - H(x_0,k_0,\phi_x(x_0),\underline{v}(x_0,\cdot)) \leq 0 \tag{6}$$

at x_0, whenever $\underline{v}(x,k_0)-\phi(x)$ attains a local maximum at $x = x_0 \in Q$.

(ii) *$\overline{v}(x,k)$ is a viscosity supersolution to (5) on $\bar{Q}\times\Theta$ if for any $k_0 \in \Theta$ and $\phi \in C^1(\bar{Q})$, we have*

$$\rho\overline{v}(x_0,k_0) - H(x_0,k_0,\phi_x(x_0),\overline{v}(x_0,\cdot)) \geq 0 \tag{7}$$

at x_0, whenever $\overline{v}(x,k_0)-\phi(x)$ attains a local minimum at $x = x_0 \in \bar{Q}$.

(iii) $v(k,x)$ *is called a constrained viscosity solution on* $\bar{Q}\times\Theta$ *to* (5) *if it is both a viscosity subsolution on* $Q\times\Theta$ *and a viscosity supersolution on* $\bar{Q}\times\Theta$.

In the definition of the viscosity supersolution, the minima x_0 may lie on the boundary of $\bar{Q}$. The function ϕ involved in either (i) or (ii) in Definition 1 is called the test function.

Denote by $C_p(\bar{Q}\times\Theta)$ the set of functions $g(x,k)$ from $\bar{Q}\times\Theta$ to $\mathbb{R}$, which are continuous in $x\in\bar{Q}$ for any given $k\in\Theta$ and have a polynomial growth rate, i.e., for any $g\in C_p(\bar{Q}\times\Theta)$, one can find positive constants C and b, depending on that particular function, such that $|g(x,k)|\le C(1+|x|^b)$ for all $(x,k)\in\bar{Q}\times\Theta$. For $a_1,a_2\in\mathbb{R}$, denote $a_1\vee a_2=\max\{a_1,a_2\}$, and $a_1\wedge a_2=\min\{a_1,a_2\}$. Given $\gamma\in(0,1]$ and $g\in C_p(\bar{Q}\times\Theta)$, define

$$Hol(g,\gamma,R)\stackrel{\triangle}{=}\sup_{k\in\Theta}\sup_{|x|\vee|x'|\le R}\frac{|g(k,x')-g(k,x)|}{|x'-x|^{\gamma}},$$

where $x,x'\in\bar{Q}$ and $0<R<\infty$. The value $Hol(g,\gamma,R)\le\infty$ is called the local Hölder constant for g associated with $R>0$, where γ is the Hölder exponent. For the case $\gamma=1$, $Hol(g,1,R)$ reduces to the local Lipschitz constant and is denoted as $Lip(g,R)$.

Define $C^{loc}_{p,Hol}(\bar{Q}\times\Theta)$ as the class of functions $g\in C_p(\bar{Q}\times\Theta)$ satisfying local Hölder continuity; i.e., there exists a Hölder exponent $\gamma\in(0,1]$ such that $Hol(g,\gamma,R)<\infty$ for all $R>0$. Furthermore, we define $C^{loc}_{p,Lip}(\bar{Q}\times\Theta)$ as the class of functions $g\in C_p(\bar{Q}\times\Theta)$ satisfying local Lipschitz continuity in x; i.e., $Lip(g,R)<\infty$ for all $R>0$.

Obviously, $C^{loc}_{p,Lip}(\bar{Q}\times\Theta)\subset C^{loc}_{p,Hol}(\bar{Q}\times\Theta)$. In addition, if $g\in C^{loc}_{p,Hol}(\bar{Q}\times\Theta)$ with Hölder exponent γ_2 and $0<\gamma_1<\gamma_2\le 1$, g is also locally Hölder continuous with exponent γ_1.

In establishing our main results, we concentrate on two types of structures for $\bar{Q}$.

Case (i). For state constraint in a subspace:

$$\bar{Q}_a\stackrel{\triangle}{=}[0,\infty)^{n-1}\times(-\infty,\infty),$$

where the integer $n\ge 2$. The interior of the set is $Q_a=(0,\infty)^{n-1}\times(-\infty,\infty)$.

Case (ii). For state constraint in full space:

$$\bar{Q}_b\stackrel{\triangle}{=}[0,\infty)^{n},$$

where $n\ge 1$. The interior of the set is $Q_b=(0,\infty)^n$.

Corresponding to $\bar{Q}_a$ and $\bar{Q}_b$, the state variable x is restricted to the *positive orthant* of $\mathbb{R}^n$ or its $n-1$-dimensional subspace. Indeed, cases (i) and (ii) can cover fairly general application models as shown in Figure 1, and they are also applicable to systems with more complicated buffer interconnection; see, e.g., [21]. It is worth noting that in the manufacturing fluid model given by Figure 1(a), the first $n-1$ entries in x correspond to buffer levels and must be positive; the last entry x_n, which denotes the inventory level of the final product, however, can be negative and interpreted as backlog. Although our technique developed in this paper may be extended to deal with other forms of $\bar{Q}$, we do not intend to treat the most general form.

3. The comparison theorem and uniqueness of solutions. The objective of this section is to establish a comparison result which plays an important role in proving uniqueness. Existence analysis will be presented for the general model in section 5 and for more concrete models in sections 6 and 7.

Let $L_i(x,k,u)$, $i=1,2$, be two functions with $u \in U_k$ and $(x,k) \in \bar{Q} \times \Theta$. Replacing $L(x,k,u)$ by $L_i(x,k,u)$ in the original HJB equation (4), we write two new equations:

$$\rho v(x,k) = H_1(x,k,v_x(x,k),v(x,\cdot)), \tag{8}$$

$$\rho v(x,k) = H_2(x,k,v_x(x,k),v(x,\cdot)), \tag{9}$$

where $(x,k) \in \bar{Q} \times \Theta$ and the construction for H_i, $i=1,2$, is obvious.

3.1. Main results. We make the following assumptions.

(A1) For any given $k \in \Theta$, $F(x,k,u)$ and $L_i(x,k,u)$, $i=1,2$, are continuous in $(x,u) \in \bar{Q} \times U_k$.

(A1′) For any given $k \in \Theta$, $F(x,k,u)$ and $L(x,k,u)$ are continuous in $(x,u) \in \bar{Q} \times U_k$.

(A2) $F_{\max} \stackrel{\triangle}{=} \sup_{(x,k)\in\bar{Q}\times\Theta} \sup_{u\in U_k} |F(x,k,u)| < \infty$.

Under (A1) and (A1′), we have the following equicontinuity in x on compact sets. Let φ stand for F, L, or L_i. For a given compact subset $B_{\bar{Q}}$ of $\bar{Q}$, when $x, x' \in B_{\bar{Q}}$ and $|x-x'| \to 0$, we have

$$|\varphi(x,k,u) - \varphi(x',k,u)| \to 0 \tag{10}$$

with a vanishing rate not depending on (k,u).

THEOREM 2. *Let $\bar{Q}$ be either $\bar{Q}_a$ or $\bar{Q}_b$, and suppose* (A1)–(A2) *hold. If v_1, $v_2 \in C^{loc}_{p,Hol}(\bar{Q}\times\Theta)$ are, respectively, a viscosity subsolution to* (8) *on $Q\times\Theta$ and a viscosity supersolution to* (9) *on $\bar{Q}\times\Theta$, then the inequality holds:*

$$\sup_{\bar{Q}\times\Theta} [v_1(x,k) - v_2(x,k)] \le \rho^{-1} \sup_{\bar{Q}\times\Theta} \sup_{U_k} [L_1(x,k,u) - L_2(x,k,u)].$$

Theorem 2 is the so-called comparison theorem, and it immediately implies the following uniqueness theorem.

THEOREM 3. *Let $\bar{Q}$ be either $\bar{Q}_a$ or $\bar{Q}_b$, and suppose* (A1′) *and* (A2) *hold. If $v \in C^{loc}_{p,Hol}(\bar{Q}\times\Theta)$ is a constrained viscosity solution to* (5)*, then it is unique in the function class $C^{loc}_{p,Hol}(\bar{Q}\times\Theta)$.*

3.2. Some preliminary lemmas. To prove Theorem 2, we need to establish a sequence of preliminary results. The basic approach is to introduce a suitable comparison function Φ for the construction of smooth test functions ϕ to generate the local minima and maxima and then to apply the definition of viscosity sub/supersolutions. A key technique will be developed such that the obtained maxima for $v_1 - \phi$, as specified during the proof of Theorem 2, do not occur at the boundary of $\bar{Q}$, which is crucial for subsequently applying the definition of viscosity subsolutions.

Let v_1 and v_2 be the viscosity sub/supersolution, respectively. For both Case (i) $\bar{Q} = \bar{Q}_a = [0,\infty)^{n-1} \times (-\infty,\infty)$ and Case (ii) $\bar{Q} = \bar{Q}_b = [0,\infty)^n$, we use the same function $\Phi(x,y,k)$ constructed as follows. Denote $\mathbf{1}_n = (1,1,\dots,1)^T$, and for $v_1, v_2 \in C^{loc}_{p,Hol}(\bar{Q}\times\Theta)$, let

$$\Phi(x,y,k) = v_1(x,k) - v_2(y,k) - \left|\frac{x-y}{\varepsilon} - \tau\mathbf{1}_n\right|^2 - \alpha[\zeta(x)+\zeta(y)], \qquad x,y \in \bar{Q}, \tag{11}$$

where $\zeta(x) = \exp(\beta\sqrt{|x|^2+1})$, with $\beta = \rho F_{\max}^{-1}$, and $\varepsilon, \tau, \alpha$ are all parameters chosen within the interval $(0,1]$ throughout sections 3 and 4.

The construction of Φ is based on the methods in [20, 22, 11, 5]; however, with the simultaneous appearance of state constraints and rapid growth, it is necessary to predominate v_1 and v_2 by the exponential term $\zeta(x)$ and subsequently insert the small perturbation term $\tau\mathbf{1}_n$, the magnitude of which can be adjusted independently. This differs from the technique in [22, 5]. During the maximization of Φ, τ causes a useful asymmetry between x and y in producing the increment of Φ. Such an effect is further amplified by reducing ε provided that τ is fixed first, and this ensures that x can be tuned to the interior of $\bar{Q}$ leading to desired test functions.

Since both v_1 and v_2 have a polynomial growth rate, it is clear that there exists $(\hat{x}, \hat{y}, \hat{k}) \in \bar{Q} \times \bar{Q} \times \Theta \stackrel{\triangle}{=} \Gamma$ such that

$$\Phi(\hat{x}, \hat{y}, \hat{k}) = \sup_{(x,y,k)\in\Gamma} \Phi(x, y, k), \tag{12}$$

where the values of $\hat{x}$, $\hat{y}$, and $\hat{k}$ depend on ε, τ and α. However, for a given $\alpha \in (0, 1]$, we may obtain a uniform bound for $|\hat{x}|$ and $|\hat{y}|$ when the value of ε and τ varies on $(0, 1]$.

LEMMA 4. *Suppose $\bar{Q} = \bar{Q}_a$ or $\bar{Q}_b$. Let $v_1, v_2 \in C^{loc}_{p,Hol}(\bar{Q} \times \Theta)$ be given in* (11) *and $(\hat{x}, \hat{y}, \hat{k})$ be obtained from* (12). *Then there exists a positive constant, depending only on α and denoted as C_α, such that*

$$|\hat{x}| \vee |\hat{y}| \le C_\alpha.$$

Proof. It suffices to analyze for $\bar{Q} = \bar{Q}_a$. Since $\Phi(\hat{x}, \hat{y}, \hat{k}) \ge \Phi(0, 0, \hat{k})$, it follows that

$$\begin{aligned} &v_1(\hat{x}, \hat{k}) - v_2(\hat{y}, \hat{k}) - \left|\frac{\hat{x} - \hat{y}}{\varepsilon} - \tau\mathbf{1}_n\right|^2 - \alpha[\zeta(\hat{x}) + \zeta(\hat{y})] \\ &\ge v_1(0, \hat{k}) - v_2(0, \hat{k}) - n\tau^2 - \alpha[\zeta(0) + \zeta(0)], \end{aligned}$$

which gives

$$\begin{aligned} &\alpha[\zeta(\hat{x}) + \zeta(\hat{y})] + \left|\frac{\hat{x} - \hat{y}}{\varepsilon} - \tau\mathbf{1}_n\right|^2 \\ &\le v_1(\hat{x}, \hat{k}) - v_1(0, \hat{k}) - v_2(\hat{y}, \hat{k}) + v_2(0, \hat{k}) + n\tau^2 + \alpha[\zeta(0) + \zeta(0)]. \end{aligned}$$

Without loss of generality, assume $C_0 > 0$ and $b_0 > 0$ have been found such that $|v_1(x, k)| \vee |v_2(x, k)| \le C_0(1 + |x|^{b_0})$, for $(x, k) \in \bar{Q} \times \Theta$. Since

$$\alpha[\zeta(\hat{x}) + \zeta(\hat{y})] \le C_0(4 + |\hat{x}|^{b_0} + |\hat{y}|^{b_0}) + n + [\zeta(0) + \zeta(0)],$$

there exists $C_\alpha > 0$, depending on α but not on ε and τ, such that $|\hat{x}| \vee |\hat{y}| \le C_\alpha$. □

Notice that the selection of C_α implicitly depends on the associated parameters C_0 and b_0. However, for convenience of presentation, in our analysis we simply say it depends only on α, since v_1 and v_2 are assumed to be picked out from $C^{loc}_{p,Hol}(\bar{Q} \times \Theta)$ and hence fixed.

LEMMA 5. *Suppose $\bar{Q} = \bar{Q}_a$ or $\bar{Q}_b$ and fix $\alpha \in (0, 1]$. For $(\hat{x}, \hat{y}, \hat{k})$ given in* (12), *the following properties hold:* (i) $\sup_{\varepsilon\in(0,1]} \varepsilon^{-1}|\hat{x} - \hat{y}| = O(1)$, *where the right-hand side is independent of τ, and* (ii) $\lim_{\varepsilon\to 0+} |\hat{x} - \hat{y}| = 0$ *uniformly w.r.t. τ.*

Proof. It is adequate to consider $\bar{Q} = \bar{Q}_a$. Since $2\Phi(\hat{x}, \hat{y}, \hat{k}) \geq \Phi(\hat{x}, \hat{x}, \hat{k}) + \Phi(\hat{y}, \hat{y}, \hat{k})$, we get

$$\begin{aligned} &2v_1(\hat{x}, \hat{k}) - 2v_2(\hat{y}, \hat{k}) - 2\left|\frac{\hat{x} - \hat{y}}{\varepsilon} - \tau \mathbf{1}_n\right|^2 - 2\alpha[\zeta(\hat{x}) + \zeta(\hat{y})] \\ &\geq v_1(\hat{x}, \hat{k}) - v_2(\hat{x}, \hat{k}) - n\tau^2 - 2\alpha\zeta(\hat{x}) + v_1(\hat{y}, \hat{k}) - v_2(\hat{y}, \hat{k}) - n\tau^2 - 2\alpha\zeta(\hat{y}). \end{aligned}$$

Suppose v_1, v_2 have exponent $\gamma_1, \gamma_2 \in (0, 1]$, respectively, for local Hölder continuity. Hence

$$\begin{aligned} \left|\frac{\hat{x} - \hat{y}}{\varepsilon} - \tau \mathbf{1}_n\right|^2 &\leq \frac{1}{2}[v_1(\hat{x}, \hat{k}) - v_1(\hat{y}, \hat{k}) + v_2(\hat{x}, \hat{k}) - v_2(\hat{y}, \hat{k})] + n\tau^2 \\ &\leq \frac{1}{2}[Hol(v_1, \gamma_1, C_\alpha)|\hat{x} - \hat{y}|^{\gamma_1} + Hol(v_2, \gamma_2, C_\alpha)|\hat{x} - \hat{y}|^{\gamma_2}] + n\tau^2 \\ &\leq (1 + C_\alpha)[Hol(v_1, \gamma_1, C_\alpha) + Hol(v_2, \gamma_2, C_\alpha)] + n\tau^2, \end{aligned} \tag{13}$$

since $\hat{x} \vee \hat{y} \leq C_\alpha$ by Lemma 4.

By use of the triangular inequality for norms, for $\tau \in (0, 1]$, we get

$$\begin{aligned} \left|\frac{\hat{x} - \hat{y}}{\varepsilon}\right| &\leq \left|\frac{\hat{x} - \hat{y}}{\varepsilon} - \tau \mathbf{1}_n\right| + |\tau \mathbf{1}_n| \\ &\leq \sqrt{(1 + C_\alpha)[Hol(v_1, \gamma_1, C_\alpha) + Hol(v_2, \gamma_2, C_\alpha)] + n\tau^2} + n\tau \\ &\leq \sqrt{(1 + C_\alpha)[Hol(v_1, \gamma_1, C_\alpha) + Hol(v_2, \gamma_2, C_\alpha)] + n} + n, \end{aligned}$$

which implies assertion (i) and subsequently (ii). This completes the proof. □

The proof of Lemmas 4 and 5 adopts the techniques in [11, 20] dealing with unbounded viscosity solutions for first order HJB equations. The next lemma is essential for deriving the comparison result in section 4.

LEMMA 6. *Let* $(\hat{x}, \hat{y}, \hat{k})$ *be given by* (12) *and* $\hat{x} = [\hat{x}_1, \ldots, \hat{x}_n]^T$, $\hat{y} = [\hat{y}_1, \ldots, \hat{y}_n]^T$. *For given* $\tau, \alpha \in (0, 1]$, *if* $\varepsilon > 0$ *is sufficiently small, we have* (i) $\hat{x}_i > \hat{y}_i$ *for* $1 \leq i \leq n - 1$, *if* $\bar{Q} = \bar{Q}_a$, *or* (ii) $\hat{x}_i > \hat{y}_i$ *for* $1 \leq i \leq n$, *if* $\bar{Q} = \bar{Q}_b$, *which further implies* $\hat{x} \in Q$ *for both cases.*

Proof. We give only the proof for assertion (i). The proof for assertion (ii) can be handled similarly. The proof is quite technical, and we break it into three steps.

Step 1. Let α and τ be given with $\bar{Q} = \bar{Q}_a$. We assume assertion (i) is invalid, and hence there exists a sequence $\varepsilon_i \downarrow 0$, $i \geq 1$, such that there is at least one (denoted as the n_ith) coordinate component satisfying

$$\hat{x}_{n_i}^{(i)} - \hat{y}_{n_i}^{(i)} \leq 0, \tag{14}$$

where $(\hat{x}^{(i)}, \hat{y}^{(i)}, \hat{k}^{(i)})$ is determined from (12) by taking $\varepsilon = \varepsilon_i$. Obviously, each n_i is picked out from the index set $\{1, 2, \ldots, n - 1\}$.

If necessary, we may take a subsequence $S_J \triangleq \{\varepsilon_{i_j}, j \geq 1\}$ such that both the coordinate index n_i and $\hat{k}^{(i)}$ take constant values along S_J. In all of the following we base the analysis on the subsequence S_J; however, to simplify the notation we simply represent S_J using the sequence $\{\varepsilon_i, i \geq 1\}$ and without loss of generality take $n_i \equiv 1$ and $\hat{k}^{(i)} = \hat{k}$.

Hence, we rewrite (14) as

$$\hat{x}_1^{(i)} - \hat{y}_1^{(i)} \leq 0, \qquad i \geq 1. \tag{15}$$

By definition, we have

$$\Phi(\hat{x}^{(i)},\hat{y}^{(i)},\hat{k}) = \sup_{\bar{Q}\times\bar{Q}\times\Theta} \Phi(x,y,k) \geq \Phi(\hat{x}^{(i)}+\chi_\delta,\hat{y}^{(i)},\hat{k}) \tag{16}$$

for any $0<\delta\leq 1$, where we denote the vector $\chi_\delta=(\delta,0,\ldots,0)^T$. Since $\hat{x}^{(i)}\in\bar{Q}$, it is clear that $\hat{x}^{(i)}+\chi_\delta\in\bar{Q}$.

Step 2. Now we show that (15) together with (16) leads to a contradiction. By (16), we have

$$\begin{aligned}
&\Phi(\hat{x}^{(i)},\hat{y}^{(i)},\hat{k})\\
&= v_1(\hat{x}^{(i)},\hat{k}) - v_2(\hat{y}^{(i)},\hat{k}) - \left|\frac{\hat{x}^{(i)}-\hat{y}^{(i)}}{\varepsilon_i}-\tau\mathbf{1}_n\right|^2 - \alpha[\zeta(\hat{x}^{(i)})+\zeta(\hat{y}^{(i)})]\\
&\geq v_1(\hat{x}^{(i)}+\chi_\delta,\hat{k}) - v_2(\hat{y}^{(i)},\hat{k}) - \left|\frac{\hat{x}^{(i)}+\chi_\delta-\hat{y}^{(i)}}{\varepsilon_i}-\tau\mathbf{1}_n\right|^2 - \alpha[\zeta(\hat{x}^{(i)}+\chi_\delta)+\zeta(\hat{y}^{(i)})],
\end{aligned}$$

which readily yields

$$\begin{aligned}
T_i \triangleq& \left|\frac{\hat{x}_1^{(i)}-\hat{y}_1^{(i)}}{\varepsilon_i}-\tau\right|^2 - \left|\frac{\hat{x}_1^{(i)}+\delta-\hat{y}_1^{(i)}}{\varepsilon_i}-\tau\right|^2\\
\leq& v_1(\hat{x}^{(i)},\hat{k}) - v_1(\hat{x}^{(i)}+\chi_\delta,\hat{k}) + \alpha\zeta(\hat{x}^{(i)}+\chi_\delta) - \alpha\zeta(\hat{x}^{(i)}).
\end{aligned} \tag{17}$$

Obviously, for $\delta\in(0,1]$ we have $|\hat{x}^{(i)}|\vee|\hat{x}^{(i)}+\chi_\delta|\leq C_\alpha+1$ by Lemma 4. Denote the constant $D_{\zeta,\alpha}=\sup_{|x|\leq C_\alpha+1}|\zeta'(x)|$.

By (15) and then using the local Hölder and local Lipschitz continuity of v_1 and ζ, respectively, it is easy to check that

$$T_i = -\frac{\delta^2}{\varepsilon_i^2} + \frac{2\delta}{\varepsilon_i}\left|\frac{|\hat{x}_1^{(i)}-\hat{y}_1^{(i)}|}{\varepsilon_i}+\tau\right| \leq \delta^{\gamma_1} Hol(v_1,\gamma_1,C_\alpha+1) + \delta\alpha D_{\zeta,\alpha},$$

where $\gamma_1\in(0,1]$ is the Hölder exponent for v_1, and therefore

$$\frac{2\delta\tau}{\varepsilon_i} \leq \frac{\delta^2}{\varepsilon_i^2} + \delta^{\gamma_1} Hol(v_1,\gamma_1,C_\alpha+1) + \delta\alpha D_{\zeta,\alpha}. \tag{18}$$

Since (18) holds for all $0<\delta\leq 1$, for the case with subscript index i, we take $\delta=\varepsilon_i^{\frac{2}{2-\gamma_1}}$ to obtain

$$2\tau\varepsilon_i^{\frac{-\gamma_1}{2-\gamma_1}} \leq 1 + Hol(v_1,\gamma_1,C_\alpha+1) + \varepsilon_i^{\frac{2(1-\gamma_1)}{2-\gamma_1}}\alpha D_{\xi,\alpha}. \tag{19}$$

Letting $i\to\infty$, since $\tau>0$ is fixed, (19) leads to

$$Hol(v_1,\gamma_1,C_\alpha+1)\geq\infty,$$

which is a contradiction since $v_1\in C^{loc}_{p,Hol}(\bar{Q}\times\Theta)$ with the exponent γ_1.

Step 3. Combining Steps 1 and 2 above, we see that the initial assumption that (i) is invalid does not hold. Hence assertion (i) is proven. Since $\hat{y}_i\geq 0$ for $1\leq i\leq n-1$, it follows that $\hat{x}_i>0$ for $i\leq n-1$, and consequently $\hat{x}\in Q$. □

Notice that in order to derive the contradiction in Step 2 of the proof, it is necessary to take τ as an independent variable such that its magnitude may be controlled separately.

4. Proof of Theorem 2. We give only the proof for Case (i) $\bar{Q} = \bar{Q}_a$, and Case (ii) $\bar{Q} = \bar{Q}_b$ can be treated without further difficulty. Let $(\hat{x}, \hat{y}, \hat{k})$ be obtained from (12). For given τ and α, by Lemma 6 we can pick a sufficiently small $\varepsilon_{\tau,\alpha}$ depending on the pair (τ, α) such that for all $0 < \varepsilon \le \varepsilon_{\tau,\alpha}$, its associated $(\hat{x}, \hat{y})$ is in the set $Q \times \bar{Q}$. In the following analysis we assume $\varepsilon \le \varepsilon_{\tau,\alpha}$ is always satisfied. In particular, $\hat{x}$ is in the open set Q.

Let $\phi_1(x) = v_2(\hat{y}) + |\frac{x-\hat{y}}{\varepsilon} - \tau \mathbf{1}_n|^2 + \alpha[\zeta(x) + \zeta(\hat{y})]$ and $\phi_2(y) = v_1(\hat{x}) - |\frac{\hat{x}-y}{\varepsilon} - \tau \mathbf{1}_n|^2 - \alpha[\zeta(\hat{x}) + \zeta(y)]$ be two test functions. Then on $\bar{Q}$, $v_1(x) - \phi_1(x)$ attains its maximum at $\hat{x} \in Q$, and $v_2(y) - \phi_2(y)$ attains its minimum at $\hat{y} \in \bar{Q}$. Hence we apply Definition 1 for viscosity sub/supersolutions to get

$$\rho v_1(\hat{x}, \hat{k}) - \inf_{u \in U_{\hat{k}}} \left\{ \left[2\left(\frac{\hat{x} - \hat{y}}{\varepsilon} - \tau \mathbf{1}_n \right) + \alpha \zeta'(\hat{x}) \right]^T F(\hat{x}, \hat{k}, u) + \Pi_\theta[v_1(\hat{x}, \cdot)](\hat{k}) + L_1(\hat{x}, \hat{k}, u) \right\} \le 0, \tag{20}$$

$$\rho v_2(\hat{y}, \hat{k}) - \inf_{u \in U_{\hat{k}}} \left\{ \left[2\left(\frac{\hat{x} - \hat{y}}{\varepsilon} - \tau \mathbf{1}_n \right) + \alpha \zeta'(\hat{y}) \right]^T F(\hat{y}, \hat{k}, u) + \Pi_\theta[v_2(\hat{y}, \cdot)](\hat{k}) + L_2(\hat{y}, \hat{k}, u) \right\} \ge 0. \tag{21}$$

The pair of inequalities (20) and (21) yields

$$\begin{aligned}
&\rho v_1(\hat{x}, \hat{k}) - \rho v_2(\hat{y}, \hat{k}) \\
&\le \inf_{u \in U_{\hat{k}}} \left\{ \left[2\left(\frac{\hat{x} - \hat{y}}{\varepsilon} - \tau \mathbf{1}_n \right) + \alpha \zeta'(\hat{x}) \right]^T F(\hat{x}, \hat{k}, u) + \Pi_\theta[v_1(\hat{x}, \cdot)](\hat{k}) + L_1(\hat{x}, \hat{k}, u) \right\} \\
&\quad - \inf_{u \in U_{\hat{k}}} \left\{ \left[2\left(\frac{\hat{x} - \hat{y}}{\varepsilon} - \tau \mathbf{1}_n \right) - \alpha \zeta'(\hat{y}) \right]^T F(\hat{y}, \hat{k}, u) + \Pi_\theta[v_2(\hat{y}, \cdot)](\hat{k}) + L_2(\hat{y}, \hat{k}, u) \right\} \\
&\le \sup_{u \in U_{\hat{k}}} 2 \left| \frac{\hat{x} - \hat{y}}{\varepsilon} - \tau \mathbf{1}_n \right| \cdot |F(\hat{x}, \hat{k}, u) - F(\hat{y}, \hat{k}, u)| \\
&\quad + \sup_{u \in U_{\hat{k}}} \alpha |F^T(\hat{x}, \hat{k}, u) \zeta'(\hat{x}) + F^T(\hat{y}, \hat{k}, u) \zeta'(\hat{y})| \\
&\quad + \sup_{u \in U_{\hat{k}}} [L_1(\hat{x}, \hat{k}, u) - L_2(\hat{y}, \hat{k}, u)] + \left\{ \Pi_\theta[v_1(\hat{x}, \cdot)](\hat{k}) - \Pi_\theta[v_2(\hat{y}, \cdot)](\hat{k}) \right\} \\
&\triangleq A_1(\varepsilon, \hat{x}, \hat{y}, \hat{k}) + A_2(\hat{x}, \hat{y}, \hat{k}) + A_3(\hat{x}, \hat{y}, \hat{k}) + A_4(\hat{x}, \hat{y}, \hat{k}).
\end{aligned} \tag{22}$$

Let α and τ be fixed first. Now in (22) we take a sequence $\varepsilon_i \downarrow 0$ with the associated $(\hat{x}_i, \hat{y}_i, \hat{k}_i)$ determined by (12). Here the subscript $i \ge 1$ in $\hat{x}_i$ is used to label the sequence and should not be confused as the index of a coordinate component. Since $|\hat{x}_i| \vee |\hat{y}_i| \le C_\alpha$ for all $i \ge 1$ by Lemma 4, there exists a subsequence denoted by

$S_{x,y,k} = \{(\hat{x}_{i_j}, \hat{y}_{i_j}, \hat{k}_{i_j}), j \geq 1\}$, which converges to a limit (x^*, x^*, k^*) in view of the fact that $\lim_{\varepsilon_i \to 0+} |\hat{x}_i - \hat{y}_i| = 0$ by Lemma 5. From (13) in the proof of Lemma 5, it is seen that

$$\left| \frac{\hat{x} - \hat{y}}{\varepsilon} - \tau \mathbf{1}_n \right| \leq \sqrt{(1 + C_\alpha)[Hol(v_1, \gamma_1, C_\alpha) + Hol(v_2, \gamma_2, C_\alpha)] + n\tau^2}, \tag{23}$$

where the fixed parameter γ_i is the Hölder exponent of $v_i \in C^{loc}_{p,Hol}(\bar{Q} \times \Theta)$, $i = 1, 2$. We combine (23) with the uniform continuity of $F(x, k, u)$ in x for $|x| \leq C_\alpha$ (see (10)) to get

$$\lim_{j \to \infty} A_1(\varepsilon_{i_j}, \hat{x}_{i_j}, \hat{y}_{i_j}, \hat{k}_{i_j}) = 0.$$

Using the continuity of F, L_1, and L_2 with respect to x, it can be checked that both $A_2(\hat{x}, \hat{y}, \hat{k})$ and $A_3(\hat{x}, \hat{y}, \hat{k})$ are continuous in the arguments $(\hat{x}, \hat{y})$. Then we have

$$\begin{aligned} \lim_{j \to \infty} (A_2 + A_3)(\hat{x}_{i_j}, \hat{y}_{i_j}, \hat{k}_{i_j}) = 2\alpha & \sup_{u \in U_{k^*}} |\zeta'(x^*) F(x^*, k^*, u)| \\ & + \sup_{u \in U_{k^*}} [L_1(x^*, k^*, u) - L_2(x^*, k^*, u)]. \end{aligned}$$

Now it readily follows from (22) that

$$\begin{aligned} \rho v_1(x^*, k^*) - \rho v_2(x^*, k^*) \leq 2\alpha & \sup_{u \in U_{k^*}} |\zeta'(x^*) F(x^*, k^*, u)| \\ & + \sup_{u \in U_{k^*}} [L_1(x^*, k^*, u) - L_2(x^*, k^*, u)] + A_4(x^*, x^*, k^*). \end{aligned} \tag{24}$$

On the other hand, for any $(x, x, k) \in \bar{Q} \times \bar{Q} \times \Theta$ and the set of parameters $(\varepsilon_{i_j}, \tau, \alpha)$, we have $\Phi(x, x, k) \leq \Phi(\hat{x}_{i_j}, \hat{y}_{i_j}, \hat{k}_{i_j})$, i.e.,

$$\begin{aligned} & v_1(x, k) - v_2(x, k) - n\tau^2 - 2\alpha\zeta(x) \\ & \leq v_1(\hat{x}_{i_j}, \hat{k}_{i_j}) - v_2(\hat{y}_{i_j}, \hat{k}_{i_j}) - \left| \frac{\hat{x}_{i_j} - \hat{y}_{i_j}}{\varepsilon_{i_j}} - \tau \mathbf{1}_n \right|^2 - \alpha(\zeta(\hat{x}_{i_j}) + \zeta(\hat{y}_{i_j})) \\ & \leq v_1(\hat{x}_{i_j}, \hat{k}_{i_j}) - v_2(\hat{y}_{i_j}, \hat{k}_{i_j}) - \alpha(\zeta(\hat{x}_{i_j}) + \zeta(\hat{y}_{i_j})). \end{aligned} \tag{25}$$

Taking $j \to \infty$ in (25) and invoking (24), we get

$$\begin{aligned} v_1(x, k) - v_2(x, k) & \leq v_1(x^*, k^*) - v_2(x^*, k^*) + n\tau^2 + 2\alpha\zeta(x) - 2\alpha\zeta(x^*) \\ & \leq 2\alpha\rho^{-1} \sup_{u \in U_{k^*}} |F(x^*, k^*, u)| \cdot |\zeta'(x^*)| \\ & \quad + \rho^{-1} \sup_{u \in U_{k^*}} [L_1(x^*, k^*, u) - L_2(x^*, k^*, u)] \end{aligned} \tag{26}$$

$$+ \rho^{-1} A_4(x^*, x^*, k^*) + n\tau^2 + 2\alpha\zeta(x) - 2\alpha\zeta(x^*). \tag{27}$$

By setting $x = x^*$ on both sides of (26), we have

$$v_1(x^*, k) - v_2(x^*, k) \leq v_1(x^*, k^*) - v_2(x^*, k^*) + n\tau^2$$

for all $k \in \Theta$, which gives

$$\begin{aligned} A_4(x^*, x^*, k^*) &= \sum_{k \neq k^*} \pi_{k^*k}[v_1(x^*, k) - v_1(x^*, k^*)] - \sum_{k \neq k^*} \pi_{k^*k}[v_2(x^*, k) - v_2(x^*, k^*)] \\ &= \sum_{k \neq k^*} \pi_{k^*k}\Big\{[v_1(x^*, k) - v_2(x^*, k)] - [v_1(x^*, k^*) - v_2(x^*, k^*)]\Big\} \\ &\leq n\tau^2 \sum_{k \neq k^*} \pi_{k^*k} = n\tau^2 |\pi_{k^*k^*}|. \end{aligned}$$

By use of the expression for $\zeta(x)$, it can be shown that

$$\rho^{-1} \sup_{k \in \Theta} \sup_{u \in U_k} |F(x, k, u)| \cdot |\zeta'(x)| \leq \zeta(x)$$

for all $x \in \mathbb{R}$, and hence it follows from (27) that

$$\begin{aligned} v_1(x, k) - v_2(x, k) &\leq n\tau^2 + 2\alpha\zeta(x) + \rho^{-1} \sup_{u \in U_{k^*}} [L_1(x^*, k^*, u) - L_2(x^*, k^*, u)] \\ &\quad + \rho^{-1} n\tau^2 |\pi_{k^*k^*}| \\ &\leq n\tau^2 + 2\alpha\zeta(x) + \rho^{-1} \sup_{\bar{Q} \times \Theta} \sup_{u \in U_k} [L_1(x, k, u) - L_2(x, k, u)] \\ &\quad + \rho^{-1} n\tau^2 \max_k |\pi_{kk}|. \end{aligned}$$

Taking $\tau \to 0+$ and then $\alpha \to 0+$, we get

$$v_1(x, k) - v_2(x, k) \leq \rho^{-1} \sup_{\bar{Q} \times \Theta} \sup_{u \in U_k} [L_1(x, k, u) - L_2(x, k, u)],$$

which completes the proof. □

5. The value function as a constrained viscosity solution. In this section we give an existence result by showing that the value function v associated with (1) and (2) gives a constrained viscosity solution. Under Definition 1, we first need to show that $v(x, k)$ is continuous in x, which is rather technical with the state constraints involved. To this end, we need some restrictions on the control set and the cost integrand in this general model. Here we take the state space to be $\bar{Q}_b$, and the case for $\bar{Q}_a$ can be treated analogously.

5.1. Hölder continuity of the value function and existence theorem. For deterministic systems, there has been a fair amount of work on continuity of infinite horizon value functions with state constraints, and usually only uniform continuity is proven; see [2] and references therein. By assuming a sufficiently large discount factor, Lipschitz continuity was obtained in [16, 12]. The proof in [12] made use of the viscosity sub/supersolution properties after showing that the value function is continuous and is the unique viscosity solution, and this method was extended to prove Hölder regularity in a state constrained diffusion model [13]. Here we take a different approach to obtain Hölder continuity by recursive upper bound estimates. Unlike [12, 16], our method does not involve the HJB equation and there is no restriction on the discount factor.

THEOREM 7. *Suppose $\bar{Q} = \bar{Q}_b$, and* (A1′)–(A2) *hold. In addition, we assume that:*

(i) *each U_k, $k \in \Theta$, is equal to the same compact set $U \subset \mathbb{R}^m$;*

(ii) *there exist positive constants* $K_i < \infty$, $i = 1, 2, 3$, *such that*

$$|F(x,u,k) - F(y,u,k)| \le K_1|x-y|, \qquad \forall\ x, y \in \mathbb{R}^n,\ u \in U,\ k \in \Theta,$$
$$\sup_{x\in\mathbb{R}^n, u\in U, k\in\Theta} |F(x,u,k)| \le K_2, \qquad \sup_{x\in\mathbb{R}^n, u\in U, k\in\Theta} |L(x,u,k)| \le K_3;$$

(iii) *there exist a continuous function* $h : \partial\bar{Q} \to U$ *and constant* $\beta_1 > 0$ *such that*

$$F_i(x, h(x), k) \ge \beta_1 \tag{28}$$

for $x \in \partial\bar{Q}$, $k \in \Theta$ *and each* $i \in \{1, \dots, n\}$, *where* $\partial\bar{Q}$ *denotes the boundary of* $\bar{Q}$, *and* F_i *is the* i*th component of* F.

Then for the value function v *defined in* (2), *we have the assertions:*

(a) v *is bounded and Hölder continuous on* $\bar{Q}$ *(w.r.t.* x*), and*

(b) v *is a unique constrained viscosity solution to* (5) *within the function class* $C^{loc}_{p,Hol}(\bar{Q} \times \Theta)$.

Remark. The proof of continuity relies on a modifying procedure, which consists of taking the control $u = h(\hat{x})$ for a short period when hitting $\hat{x} \in \partial\bar{Q}$ and switching back to a shifted version of the original control. Condition (i) ensures the admissibility of the modified control.

Remark. Condition (iii) is based on the idea of controllability on boundary initially due to Soner [22]; also see, e.g., [2, Chapter 5]. It means the state trajectory can be lifted inward at the boundary points and may be relaxed to other forms. For illustration, consider the example $\bar{Q} = [0, \infty) \times [0, \infty)$ and fix $r > 0$. Then in addition to (28) being restricted on $x \in \partial\bar{Q} \cap \{x, |x| \le r\}$, we may relax (iii) by only requiring $F_1(x, h(x), k) \ge \beta_1$ if $x = (0, x_2)$, where $x_2 \ge r$, and a similar requirement for F_2 in the case $x = (x_1, 0)$, $x_1 > r$.

Remark. We establish uniqueness in the class $C^{loc}_{p,Hol}(\bar{Q} \times \Theta)$, although v is bounded.

For the value function v and $r > 0$, define

$$\nu(r) = \sup\{|v(x,k) - v(y,k)| : |x-y| < r, \text{ and } x, y \in \bar{Q},\ k \in \Theta\}. \tag{29}$$

Before proving Theorem 7, we give the following lemma on Hölder continuity. The proof is based on recursive estimation by gradually approaching the origin with small intervals for r. As an interesting byproduct for deterministic problems, Lemma 8 implies that the uniform continuity results in [22, 2] may be strengthened to Hölder regularity.

LEMMA 8. *For* $\nu : (0, \infty) \to \mathbb{R}$ *defined in* (29), *suppose* v *is bounded and there exist constants* $C > 0$, $0 < \alpha < 1$, *and* $D > 1$ *such that*

$$\nu(r) \le Cr + \alpha\nu(Dr) \tag{30}$$

for all $r > 0$, *and let* ε_0 *be selected to satisfy either case* (i) $0 < \varepsilon_0 < -(\ln\alpha)/(\ln D)$ *and* $\varepsilon_0 \le 1$ *or case* (ii) $\varepsilon_0 = -(\ln\alpha)/(\ln D)$ *provided that* $-(\ln\alpha)/(\ln D) < 1$. *Then* v *is Hölder continuous on* $\bar{Q}$ *with exponent* ε_0, *i.e.,*

$$\sup_{k\in\Theta, x\ne y} \frac{|v(x,k) - v(y,k)|}{|x-y|^{\varepsilon_0}} < \infty.$$

Proof. Note that for sufficiently small $\varepsilon_0 > 0$, it always satisfies case (i). It is obvious that $\nu(r)$ monotonically increases with $r > 0$ and is bounded since v is

bounded. For the estimate below, it suffices to restrict r to the interval $(0,1]$. We denote $\Psi(r) = \nu(r)r^{-\varepsilon_0}$, and it follows from (30) that

$$\Psi(r) \le Cr^{1-\varepsilon_0} + \alpha D^{\varepsilon_0}\Psi(Dr). \tag{31}$$

We take the decomposition $(0,1] = \cup_{i=0}^{\infty} I_i$, where $I_i = (D^{-(i+1)}, D^{-i}]$. It is clear that $\sup_{r\in I_0}\Psi(r) < \infty$ since v is bounded. For $r \in (D^{-(i+2)}, D^{-(i+1)}]$ and $i \ge 0$, we have $Dr \in (D^{-(i+1)}, D^{-i}]$, which in conjunction with (31) gives

$$\sup_{r\in I_i}\Psi(r) \le CD^{-(1-\varepsilon_0)i} + \alpha D^{\varepsilon_0}\sup_{r\in I_{i-1}}\Psi(r), \qquad i \ge 1. \tag{32}$$

By iterating (32), it follows that

$$\sup_{r\in I_k}\Psi(r) \le C\sum_{i=0}^{k-1} D^{-(1-\varepsilon_0)(k-i)}(\alpha D^{\varepsilon_0})^i + (\alpha D^{\varepsilon_0})^k \sup_{r\in I_0}\Psi(r). \tag{33}$$

Denote $S_k = C\sum_{i=0}^{k-1} D^{-(1-\varepsilon_0)(k-i)}(\alpha D^{\varepsilon_0})^i$. For case (i), we have $\alpha D^{\varepsilon_0} < 1$ and $S_k \le C\sum_{i=0}^{\infty}(\alpha D^{\varepsilon_0})^i = C(1-\alpha D^{\varepsilon_0})^{-1}$. For case (ii), we have $\alpha D^{\varepsilon_0} = 1$, $1-\varepsilon_0 > 0$, and therefore $S_k = C\sum_{i=0}^{k-1} D^{-(1-\varepsilon_0)(k-i)} < C(D^{1-\varepsilon_0}-1)^{-1}$.

Combining cases (i) and (ii), we see that the right-hand side of (33) is bounded by a constant independent of k. Hence we conclude that

$$\sup_{k\in\Theta, 0<|x-y|\le 1}\frac{|v(x,k)-v(y,k)|}{|x-y|^{\varepsilon_0}} \le \sup_{r\in(0,1]}\Psi(r) < \infty,$$

for ε_0 determined by either case (i) or case (ii), which implies the Hölder continuity of v. □

Remark. If $\alpha D < 1$ holds, (30) implies Lipschitz continuity of v since we may take $\varepsilon_0 = 1$ for case (i).

5.2. Proof of Theorem 7. We begin by proving assertion (a), which is broken into two steps.

Step 1. Let $(z,k) \in \bar{Q}\times\Theta$ be the initial condition at $t=0$ and τ_k the first jump time of $\theta(t)$ starting from $k \in \Theta$. If k is an absorbing state of $\theta(t)$, we simply have $\tau_k \equiv \infty$. We write $\mathcal{U}_{z,k}$ as $\mathcal{U}_z$ since all $U_k = U$. Following the same method as in [22, 2], we first show that there exist a small $t^* > 0$ and a constant $C_1 > 0$ such that for all $(z,k) \in \bar{Q}\times\Theta$ and u adapted to $\mathcal{F}_t = \sigma(\theta(s), s \le t)$, there is $\bar{u} \in \mathcal{U}_z$ such that

$$|J_{t^*\wedge\tau_k}(z,k,u) - J_{t^*\wedge\tau_k}(z,k,\bar{u})| \le C_1 \sup_{0\le t\le t^*\wedge\tau_k} d(X(t,z,k,u),\bar{Q}), \tag{34}$$

where $J_{t^*\wedge\tau_k} = \int_0^{t^*\wedge\tau_k} e^{-\rho t}L(X,u,\theta)(t)dt$ with the initial condition (z,k) at $t=0$, $X(t,z,k,u)$ is the state at time t associated with the initial condition (z,k) and control u, and $d(X(t,z,k,u),\bar{Q})$ denotes the distance between the state and $\bar{Q}$ on that particular sample ω.

For proving (34), we need to determine two constants $t^*, \kappa > 0$ below. Before proceeding to do so, we set $t_0 = \tau_{z,k,u} \wedge t^*$, where we define $\tau_{z,k,u} = \inf\{0 \le t \le t^*, X(t,z,k,u) \in \partial\bar{Q}\}$, if $X(t,z,k,u)$ reaches $\partial\bar{Q}$ before t^*, or $\tau_{z,k,u} = t^*$, if $X(t,z,k,u) \in Q$ for all $t \le t^*$, and $\varepsilon = \sup_{0\le t\le t^*\wedge\tau_k} d(X(t,z,k,u),\bar{Q})$. Let u be any control adapted to $\mathcal{F}_t$. We construct the new control

$$\hat{u}(t) = u(t)1_{[0,t_0)} + h(X(t_0))1_{[t_0,t_0+\kappa\varepsilon]} + u(t-k\varepsilon)1_{(t_0+\kappa\varepsilon,\infty)}, \tag{35}$$

which is adapted to $\mathcal{F}_t$. Below we will show that $X(t,z,k,\hat{u}) \in \bar{Q}$ for all $t \le t^* \wedge \tau_k$ after t^* and κ are appropriately chosen; by repeating this construction procedure on successive small intervals covering $[0,\infty)$, we obtain $\bar{u} \in \mathcal{U}_z$ and $\bar{u} \equiv \hat{u}$ on $[0, t^* \wedge \tau_k]$. Once this is done, the nonemptiness of $\mathcal{U}_z$ and $\sup_{\bar{Q}\times U\times\Theta} |L(x,u,k)| < \infty$ implies that v is bounded on $\bar{Q}\times\Theta$.

By uniform continuity of F (w.r.t. x), there exists $\delta > 0$ such that $F_i(z, h(z_0), k) \ge \beta_1/2$ provided that $|z - z_0| \le \delta$ and $z_0 \in \partial\bar{Q}$.

We first make the restriction $t^* < \delta/(2K_2)$. If $d(z, \partial\bar{Q}) \ge \delta/2$, then $t_0 = t^*$ and $X(t,z,k,u) \in Q$ for $t \le t^*$. Now it suffices to consider the case $t_0 = \tau_{z,k,u} < t^* < \delta/(2K_2)$. It can be checked that $|X(t,z,k,\hat{u}) - X(t_0,z,k,u)| \le \delta$, and therefore $F_i(X(t,z,k,\hat{u}), h(X(t_0,z,k,u)), \theta_t) \ge \beta_1/2$, $1 \le i \le n$, for $t \le t^*$. It is obvious that $X(t,z,k,\hat{u}) \in \bar{Q}$ for all $t \le t^* \wedge (t_0 + \kappa\varepsilon)$ by the construction of $\hat{u}$; for the case $t^* \wedge \tau_k \le (t_0 + \kappa\varepsilon)$, we immediately have $X(t,z,k,\hat{u}) \in \bar{Q}$ for $t \le t^* \wedge \tau_k$.

If $t^* \wedge \tau_k > (t_0 + \kappa\varepsilon)$, we apply a similar method as in [2, pp. 272–274] to show that $X(t,z,k,\hat{u}) \in \bar{Q}$ for all $t \le t^* \wedge \tau_k$. Indeed, for $t_0 + \kappa\varepsilon \le t \le t^* \wedge \tau_k$, we may write

$$\begin{aligned}
\hat{X}_t^{(i)} &\ge X_{t_0}^{(i)} + \frac{\beta_1}{2}\kappa\varepsilon + \int_{t_0+\kappa\varepsilon}^{t} F_i(\hat{X}_s, \hat{u}_s, \theta_s)ds \\
&= X_{t_0}^{(i)} + \frac{\beta_1}{2}\kappa\varepsilon + \int_{t_0+\kappa\varepsilon}^{t} F_i(X_{s-\kappa\varepsilon}, \hat{u}_s, \theta_s)ds \\
&\quad + \int_{t_0+\kappa\varepsilon}^{t} F_i(\hat{X}_s, \hat{u}_s, \theta_s)ds - \int_{t_0+\kappa\varepsilon}^{t} F_i(X_{s-\kappa\varepsilon}, \hat{u}_s, \theta_s)ds, \qquad (36)
\end{aligned}$$

where $\hat{X}_t = X(t,z,k,\hat{u})$, $X_t = X(t,z,k,u)$, and we use the superscript i in $\hat{X}_t$, X_t to denote the ith component in the vector. Recalling the construction of $\hat{u}$ for $t_0 + \kappa\varepsilon \le t \le t^* \wedge \tau_k$, we have

$$\begin{aligned}
X_{t_0}^{(i)} + \int_{t_0+\kappa\varepsilon}^{t} F_i(X_{s-\kappa\varepsilon}, \hat{u}_s, \theta_s)ds &= X_{t_0}^{(i)} + \int_{t_0}^{t-\kappa\varepsilon} F_i(X_s, u_s, \theta_{s+\kappa\varepsilon})ds \\
&= X_{t_0}^{(i)} + \int_{t_0}^{t-\kappa\varepsilon} F_i(X_s, u_s, \theta_s)ds \\
&= X_{t-\kappa\varepsilon}^{(i)} \ge -\varepsilon, \qquad (37)
\end{aligned}$$

where the inequality in (37) holds by the definition of ε. On the other hand, by the Lipschitz continuity of F_i, we have

$$\begin{aligned}
&\left| \int_{t_0+\kappa\varepsilon}^{t} F_i(\hat{X}_s, \hat{u}_s, \theta_s)ds - \int_{t_0+\kappa\varepsilon}^{t} F_i(X_{s-\kappa\varepsilon}, \hat{u}_s, \theta_s)ds \right| \\
&\le K_1 \int_{t_0+\kappa\varepsilon}^{t} |\hat{X}_s - X_{s-\kappa\varepsilon}|ds \\
&\le K_1 |\hat{X}_{t_0+\kappa\varepsilon} - X_{t_0}| \int_{t_0+\kappa\varepsilon}^{t} e^{K_1(s-t_0-\kappa\varepsilon)}ds \qquad (38) \\
&\le |\hat{X}_{t_0+\kappa\varepsilon} - X_{t_0}|(e^{K_1(t-t_0-\kappa\varepsilon)} - 1) \le \kappa\varepsilon K_2(e^{K_1(t-t_0-\kappa\varepsilon)} - 1), \qquad (39)
\end{aligned}$$

where (38) is obtained by estimating $|\hat{X}_s - X_{s-\kappa\varepsilon}|$ via Gronwall inequality.

Hence for $t_0 + \kappa\varepsilon \le t \le t^* \wedge \tau_k$, it follows from (36), (37), and (39) that

$$\hat{X}_t^{(i)} \ge \frac{\beta_1}{2}\kappa\varepsilon - \varepsilon - \kappa\varepsilon K_2(e^{K_1(t-t_0-\kappa\varepsilon)} - 1). \qquad (40)$$

We conclude that if we take $t^* = \min\{\frac{1}{K_1}\ln(\frac{\beta_1}{4K_2}+1), \frac{\delta}{3K_2}\}$ and $\kappa = 4/\beta_1$, then $\hat{X}_t = X(t,z,k,\hat{u}) \in \bar{Q}$ for all $t \le t^* \wedge \tau_k$. This completes the construction of $\hat{u}$ and subsequently that of $\bar{u} \in \mathcal{U}_z$. The inequality (34) is obtained by use of the boundedness of L and simple integral estimates as in [2].

Step 2. Now we proceed to prove continuity of the value function. Let t^* be determined as above and $|z-y| < r$, where $z, y \in \bar{Q}$. For any $\delta_1 > 0$, by the optimality principle we may find $u \in \mathcal{U}_z$ such that

$$E[J_{t^*\wedge\tau_k}(z,k,u) + e^{-\rho(t^*\wedge\tau_k)}v(X(t^*\wedge\tau_k,z,k,u),\theta_{t^*\wedge\tau_k})] \le v(z,k)+\delta_1.$$

Based on u we construct $\bar{u} \in \mathcal{U}_y$ by use of (35). By basic estimates similar to those in [2, pp. 274–275] we can show $|X(t^*\wedge\tau_k,z,k,u) - X(t^*\wedge\tau_k,y,k,\bar{u})| \le C_2 r$ and $|J_{t^*\wedge\tau_k}(z,k,u) - J_{t^*\wedge\tau_k}(y,k,\bar{u})| \le C_3 r$ for constants $C_2 > 1, C_3 > 0$. Subsequently, we get

$$\begin{aligned} v(y,k) - v(z,k) \le\ & E[J_{t^*\wedge\tau_k}(y,k,\bar{u}) + e^{-\rho(t^*\wedge\tau_k)}v(X(t^*\wedge\tau_k,y,k,\bar{u}),\theta_{t^*\wedge\tau_k})] \\ & - E[J_{t^*\wedge\tau_k}(z,k,u) + e^{-\rho(t^*\wedge\tau_k)}v(X(t^*\wedge\tau_k,z,k,u),\theta_{t^*\wedge\tau_k})] + \delta_1. \end{aligned}$$

By arbitrariness of $\delta_1 > 0$, it follows that $\nu(r) \le C_3 r + Ee^{-\rho(t^*\wedge\tau_k)}\nu(C_2 r)$. If k is an absorbing state, we have $0 < Ee^{-\rho(t^*\wedge\tau_k)} = e^{-\rho t^*} \stackrel{\triangle}{=} \alpha_1 < 1$; otherwise, τ_k is exponentially distributed with the density function $\lambda_k e^{-\lambda_k t}$ on $[0,\infty)$, where $\lambda_k = -\pi_{kk} > 0$, and we have $Ee^{-\rho(t^*\wedge\tau_k)} = \lambda_k/(\lambda_k+\rho) + \rho e^{-(\lambda_k+\rho)t^*}/(\lambda_k+\rho) \le 1-\rho(1-e^{-\rho t^*})/(\lambda^*+\rho) \stackrel{\triangle}{=} \alpha_2 < 1$, where $\lambda^* = \max_{k\in\Theta}\{|\pi_{kk}|\}$. Hence we obtain

$$\nu(r) \le C_3 r + \alpha\nu(C_2 r), \tag{41}$$

where $\alpha = \max\{\alpha_1,\alpha_2\} < 1$ and $C_2 > 1$. This leads to Hölder continuity of v by Lemma 8.

For proving assertion (b), the verification of the constrained viscosity solution property is similar to the state unconstrained case, and we omit the details here. Uniqueness of the constrained viscosity solution follows from Theorem 3. □

Remark. For brevity, we only give a detailed proof of existence in Theorem 11 which deals with a composite mode variable, and the steps there can be adapted to this theorem in a straightforward manner to verify the constrained viscosity solution property of the value function.

Remark. For the estimation in section 5.2, it is necessary to apply truncation by the jump time τ_k; otherwise the derivation for (37) and (38) is invalid. Also note that F in the dynamics and the cost integrand L are restricted to be bounded. With a more general growth condition in x for F and L, the corresponding ODE estimates will be more challenging.

6. An optimal scheduling problem. As an application of the results in section 3, we consider a fluid buffer control problem for data traffic relay arising in communication networks; relevant background information can be found in the wireless application work [10] and references therein. Suppose a relay buffer is deployed to connect a source and a destination; see Figure 2. The incoming and outgoing links are described by two continuous time independent finite state Markov chains $y(t)$ and $z(t)$, indicating a certain channel quality. Suppose that $y(t)$ and $z(t)$ have state spaces $S_y = \{1,\dots,m_1\}$, $S_z = \{1,\dots,m_2\}$ and transition probability rate matrices $\Pi_y = (p_{ij})_{m_1\times m_1}, \Pi_z = (q_{ij})_{m_2\times m_2}$, respectively.

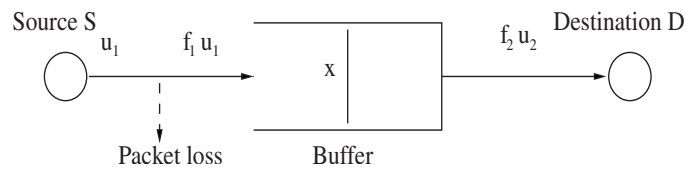

FIG. 2. *The fluid buffer model.*

Let $X \geq 0$ denote the buffer level (number of data packets), and let u_i, $i = 1, 2$, be the transmission rate (packets per second) at the incoming and outgoing links, respectively. Write the buffer level dynamics in the form:

$$\frac{dX(t)}{dt} = [u_1 f_1(y, u_1) - u_2 f_2(z, u_2)](t) \stackrel{\triangle}{=} F(y, z, u)(t), \qquad t \geq 0, \tag{42}$$

subject to $X \geq 0$. Here f_i, $i = 1, 2$, is the success probability of transmission given the link state y or z and rate u_i, and $u = [u_1, u_2]^T$. Notice that the buffer level decrease rate is only a fraction of u_2 since a packet which fails to reach the destination is not immediately deleted and will stay for retransmission. Furthermore, for limiting interference, at a given time it is allowed to transmit at only one link, either the incoming or the outgoing link [10].

We define the discounted *utility* function as

$$J_{ut}(x, i, j, u) = E\bigg[\int_0^\infty e^{-\rho t}[F_1(y, u_1) + F_2(z, u_2) - \lambda X](t)dt | X(0) = x, y(0) = i, z(0) = j\bigg], \tag{43}$$

where $\rho > 0$, $\lambda > 0$, $F_1(y, u_1) \stackrel{\triangle}{=} u_1 f_1(y, u_1)$, and $F_2(z, u_1) \stackrel{\triangle}{=} u_2 f_2(z, u_2)$. The term λX corresponds to a linear holding cost for the buffer level. The function $J^0(y, u_1, z, u_2) = F_1 + F_2$ is naturally interpreted as the instantaneous aggregate utility of the buffer in successfully transporting infinitesimal traffic volume by one hop—operating in either the receiving or the transmitting mode.

Let $U_i = [\underline{R}_i, \bar{R}_i]$, $i = 1, 2$, where $0 < \underline{R}_i < \bar{R}_i < \infty$. The control at a given time is denoted as $u = (u_1, u_2)^T \in U \stackrel{\triangle}{=} (U_1 \times \{0\}) \cup (\{0\} \times U_2)$. Define the σ-algebra $\mathcal{F}_t = \sigma(y(s), z(s), s \leq t)$.

The objective for the optimal scheduling problem is to maximize J_{ut} or, equivalently, to minimize $-J_{ut}$. Specializing the general formulation in section 2 to the current setting, we denote the admissible control set $\mathcal{U}_{x,i,j}$ with the initial condition (x, i, j) for $(X(t), y(t), z(t))$. Let $v(x, i, j)$ denote the value function for minimizing $J(x, i, j, u) \stackrel{\triangle}{=} -J_{ut}(x, i, j, u)$, where $x \in [0, \infty), i \in S_y$, and $j \in S_z$, and write $L(x, i, j, u) = -F_1(i, u_1) - F_2(j, u_2) + \lambda x$. The following assumption is used throughout this section.

(A3) f_1 (resp., f_2) is a function mapping $S_y \times U_1$(resp., $S_z \times U_2$) $\to [0, 1]$ and is continuous in u_1 (resp., u_2).

6.1. Existence and uniqueness of viscosity solutions. For a function $\varphi(x, i, j)$ continuous in $x \in [0, \infty)$, define the operator

$$[\Pi\varphi(x, \cdot, \cdot)](i, j) = \sum_{i' \neq i} p_{ii'}[\varphi(x, i', j) - \varphi(x, i, j)] + \sum_{j \neq j'} q_{jj'}[\varphi(x, i, j') - \varphi(x, i, j)],$$

where $\Pi_y = (p_{ij})_{m_1 \times m_1}$ and $\Pi_z = (q_{ij})_{m_2 \times m_2}$. For the value function v, we write the HJB equation in the compact form:

$$\begin{aligned}\rho v(x,i,j) &= [\Pi v(x,\cdot,\cdot)](i,j) + \inf_{u\in U}\Big[v_x(x,i,j)(F_1(i,u_1) - F_2(j,u_2)) + L(x,i,j,u)\Big] \\ &= H(x,i,j,v_x(x,i,j), v(x,\cdot,\cdot)). \qquad (44)\end{aligned}$$

Notice that after introducing a new set of indices for the joint Markov chain (y,z) with its associated transition probability rate matrix, (44) can be written in the standard form in section 2. The details for such a conversion are omitted here. Before proving that the value function v is a constrained viscosity solution to (44), we show that v is continuous in x.

LEMMA 9. *Let $0 \le \hat{x} < x < \infty$ be given and $(y(0), z(0)) = (i,j) \in S_y \times S_z$ be fixed. For any $u \in \mathcal{U}_{x,i,j}$, there exists $\hat{u} \in \mathcal{U}_{\hat{x},i,j}$ such that*

(i) $\sup_{t\ge 0} |\hat{X}(t) - X(t)| \le |\hat{x} - x|$, *and*

(ii) *with probability one, we have*

$$\Big| \int_0^t \big\{[F_1(y,\hat{u}_1) - F_1(y,u_1)] + [F_2(z,u_2) - F_2(z,\hat{u}_2)]\big\}(s)ds \Big| \le 2|\hat{x} - x|$$

for all $t > 0$, where $X(t)$ and $\hat{X}(t)$ are, respectively, the solution associated with the control u, $\hat{u}$ and the initial condition x, $\hat{x}$.

Proof. For $u \in \mathcal{U}_{x,i,j}$, let $X(t,\hat{x},u)$ denote the state at time t with the initial condition $\hat{x} \ge 0$ and control u. Let $\tau_1 = \inf\{t \ge 0 | X(t,\hat{x},u) = 0\}$ and $\tau_1 = \infty$ on $\{X(t,\hat{x},u) > 0,\ \forall\ t \ge 0\}$. Denote $\delta = |x - \hat{x}|/(\bar{R}_1 + \bar{R}_2)$. We construct the control $u^{(1)}$ as follows:

$$u^{(1)}(t) = \begin{cases} u(t) & \text{for } t < \tau_1, \\ [\bar{R}_1, 0]^T & \text{for } t \in [\tau_1, \tau_1 + \delta), \\ u(t) & \text{for } t \ge \tau_1 + \delta. \end{cases} \qquad (45)$$

Suppose τ_k and $u^{(k)}$, $k \ge 1$, have been constructed. Define $\tau_{k+1} = \inf\{t \ge \tau_k + \delta | X(t,\hat{x},u^{(k)}) = 0\}$ on $\{\tau_k < \infty\}$, $\tau_{k+1} = \infty$ on $\{\tau_k = \infty\} \cup \{\tau_k < \infty$, and $X(t,\hat{x},u^{(k)}) > 0,\ \forall\ t \ge \tau_k + \delta\}$; define $u^{(k+1)}$ by setting (u,τ_1) as $(u^{(k)},\tau_{k+1})$ on the right-hand side of (45). This procedure may be terminated if the stopping time τ_k at a certain stage k equals ∞ with probability one. Let $\hat{u}(t) = u^{(k)}(t)$ for $t \le \tau_{k+1}$, and it can be shown that this gives a well-defined control on $[0,\infty)$ and $\hat{u} \in \mathcal{U}_{\hat{x},i,j}$.

In (46) below, $X(t)$ and $\hat{X}(t)$ are associated with u and $\hat{u}$, respectively. By the construction of $\hat{u}$, it is easy to check that $\hat{X}(t) - X(t) \ge -|\hat{x} - x|$ for all $t \ge 0$. Now we show that for all $t \ge 0$, $\hat{X}(t) - X(t) \le |\hat{x} - x|$, which obviously holds for $t \le \tau_1$. Suppose $t \in [\tau_k, \tau_{k+1})$. Since $0 = \hat{X}(\tau_k) \le X(\tau_k)$, we have

$$\begin{aligned}\hat{X}(t) - X(t) &= \hat{X}(\tau_k) + \int_{\tau_k}^t (\hat{F}_1 - \hat{F}_2)(s)ds - X(\tau_k) - \int_{\tau_k}^t (F_1 - F_2)(s)ds \\ &\le \int_{\tau_k}^{t\wedge(\tau_k+\delta)} (\hat{F}_1 - \hat{F}_2)(s)ds - \int_{\tau_k}^{t\wedge(\tau_k+\delta)} (F_1 - F_2)(s)ds \\ &= \int_{\tau_k}^{t\wedge(\tau_k+\delta)} (\hat{F}_1 - F_1)(s)ds + \int_{\tau_k}^{t\wedge(\tau_k+\delta)} (F_2 - \hat{F}_2)(s)ds \\ &\le \bar{R}_1\delta + \bar{R}_2\delta = |\hat{x} - x|, \qquad (46)\end{aligned}$$

where we denote $F_1 = F_1(y, u_1)$, $\hat{F}_1 = F_1(y, \hat{u}_1)$, $F_2 = F_2(z, u_2)$, etc. Hence $\sup_{t\geq 0} |\hat{X}(t) - X(t)| \leq |\hat{x} - x|$, and (i) follows. On the other hand, we have

$$\hat{X}(t) - X(t) = \hat{x} - x + \int_0^t [(\hat{F}_1 - F_1) + (F_2 - \hat{F}_2)](s)ds. \tag{47}$$

By use of (47) and (i) we get

$$\sup_{t\geq 0} \Big| \int_0^t [(\hat{F}_1 - F_1) + (F_2 - \hat{F}_2)](s)ds \Big| \leq \sup_{t\geq 0} |\hat{X}(t) - X(t)| + |\hat{x} - x| \leq 2|\hat{x} - x|,$$

and (ii) follows. □

LEMMA 10. *The value function $v(x, i, j)$ is Lipschitz continuous with respect to $x \in [0, \infty)$.*

Proof. Take $0 \leq \hat{x} < x$. We need to estimate $|v(\hat{x}, i, j) - v(x, i, j)|$. For any $\varepsilon > 0$, there exists $u_\varepsilon \in \mathcal{U}_{x,i,j}$ such that $v(x, i, j) \leq J(x, i, j, u_\varepsilon) \leq v(x, i, j) + \varepsilon$. Based on u_ε, we construct $\hat{u}_\varepsilon \in \mathcal{U}_{\hat{x},i,j}$ satisfying (i) and (ii) in Lemma 9. Using the same set of notation as in (46) and noticing $\hat{F}_1 - F_1 \geq 0$, $F_2 - \hat{F}_2 \geq 0$, we have

$$\begin{aligned}
&\Big| \int_0^\infty e^{-\rho t}(\hat{F}_1 + \hat{F}_2)dt - \int_0^\infty e^{-\rho t}(F_1 + F_2)dt \Big| \\
= &\Big| \int_0^\infty e^{-\rho t}(\hat{F}_1 - F_1)dt + \int_0^\infty e^{-\rho t}(\hat{F}_2 - F_2)dt \Big| \\
\leq &\Big| \int_0^\infty e^{-\rho t}(\hat{F}_1 - F_1)dt + \int_0^\infty e^{-\rho t}(F_2 - \hat{F}_2)dt \Big| \\
\leq &\Big| \int_0^\infty [(\hat{F}_1 - F_1) + (F_2 - \hat{F}_2)]dt \Big| \leq 2|\hat{x} - x|, \qquad (48)
\end{aligned}$$

where the last inequality follows from Lemma 9(ii).

By (48) and Lemma 9(i), we can check that

$$\begin{aligned}
|J(\hat{x}, i, j, \hat{u}_\varepsilon) - J(x, i, j, u_\varepsilon)| &\leq 2|\hat{x} - x| + E\int_0^\infty e^{-\rho t}\lambda|\hat{X}(t) - X(t)|dt \\
&\leq (2 + \lambda/\rho)|\hat{x} - x|.
\end{aligned}$$

Hence $v(\hat{x}, i, j) \leq v(x, i, j) + \varepsilon + (2 + \lambda/\rho)|\hat{x} - x|$. On the other hand, suppose $\hat{u}_\varepsilon$ has been found such that $J(\hat{x}, i, j, \hat{u}_\varepsilon) \leq v(\hat{x}, i, j) + \varepsilon$; then obviously $\hat{u}_\varepsilon \in \mathcal{U}_{x,i,j}$, and we can verify that $J(x, i, j, \hat{u}_\varepsilon) \leq J(\hat{x}, i, j, \hat{u}_\varepsilon) + (\lambda/\rho)|\hat{x} - x|$ and hence $v(x, i, j) \leq v(\hat{x}, i, j) + \varepsilon + (\lambda/\rho)|\hat{x} - x|$.

Thus $|v(\hat{x}, i, j) - v(x, i, j)| \leq (2 + \lambda/\rho)|\hat{x} - x| + \varepsilon$. Since $\varepsilon > 0$ is arbitrary, we get $|v(\hat{x}, i, j) - v(x, i, j)| \leq (2 + \lambda/\rho)|\hat{x} - x|$, and the lemma follows. □

THEOREM 11. *The value function $v : [0, \infty) \times S_y \times S_z \to \mathbb{R}$ is a unique constrained viscosity solution to* (44) *in the function class $C^{loc}_{p,Lip}([0, \infty) \times S_y \times S_z)$.*

Proof. See the appendix. □

7. Application to stochastic manufacturing systems. In this section we consider production rate control involving n machines in a tandem queue with $n - 1$ buffers between neighboring machines. The associated optimal control problem has been well studied in the stochastic manufacturing literature; see [20, 21]. Let the system model be given as

$$\frac{dX(t)}{dt} = (Au + Bz)(t), \qquad t \geq 0, \tag{49}$$

where $X \in \mathbb{R}^n$, $u \in \mathbb{R}^n_+$, and $z \in \mathbb{R}_+$, and

$$A = \begin{bmatrix} 1 & -1 & 0 & \cdots & 0 \\ 0 & 1 & -1 & \cdots & 0 \\ \vdots & & & \vdots & \\ 0 & 0 & 0 & \cdots & 1 \end{bmatrix}, \qquad B = \begin{bmatrix} 0 \\ \vdots \\ 0 \\ -1 \end{bmatrix}.$$

Here all upper subdiagonal entries in A are -1. The state space for X is $\bar{Q} \stackrel{\triangle}{=} [0,\infty)^{n-1} \times (-\infty,\infty)$. Notice that the last component in X is the inventory level of the final product, which may be negative and accordingly interpreted as backlog. The first $n-1$ entries in X denote the buffer levels and hence are nonnegative. The variable z denotes a finite state Markov chain describing the random demanding rate. The cost function to be minimized is of the form

$$J(x,k,z,u) = E\bigg[\int_0^\infty e^{-\rho t} L(X(t),u(t))dt | X(0)=x, k(0)=k, z(0)=z\bigg],$$

where (x,k,z) is the initial condition. Here $k(t) \in \mathbb{R}^n$ is vector Markov process with discrete values describing the machine capacity. Let the state space and generator for (k,z) be denoted by $\mathcal{C} \times \mathcal{D}$ and Π, respectively. For the initial condition (x,k,z), the admissible control set $\mathcal{U}_{x,k,z}$ consists of controls such that (i) $u(t)$ is adapted to $\mathcal{F}_t = \sigma(k(s),z(s),s \le t)$, (ii) $0 \le u(t) \le k(t)$ (holding entrywise), and (iii) $X(t) \in \bar{Q}$ at all times $t \ge 0$. We also assume

$$|L(x,u) - L(x',u')| \le C(1+|x|^d + |x'|^d)(|x-x'| + |u-u'|),$$

where $d > 0$ is a constant. For a given mode $k(t) = k = (k_1,\dots,k_n) \in \mathcal{C}$, let the machine capacity region be denoted by $U_k = \{u = (u_1,\dots,u_n)^T | 0 \le u_i \le k_i, i = 1,\dots,n\}$. Let $v(x,k,z)$ be the value function associated with the cost $J(x,k,z,u)$ and the admissible control set $\mathcal{U}_{x,k,z}$. The interested reader is referred to [20, Chapter 4] for a detailed account of this class of problems.

We write the HJB equation

$$\rho v(x,k,z) = \inf_{u \in U_k} \Big[v_x(x,k,z)(Au+Bz) + [\Pi v(x,\cdot,\cdot)](k,z) + L(x,u)\Big], \tag{50}$$

where $(x,k,z) \in \bar{Q} \times \mathcal{C} \times \mathcal{D}$ and $\Pi v(x,\cdot,\cdot)$ is determined in an obvious manner. Set

$$\tilde{H}(x,k,z,v_x(x,k,z),v(x,\cdot,\cdot),u) = v_x(x,k,z)(Au+Bz) + [\Pi v(x,\cdot,\cdot)](k,z) + L(x,u).$$

Then (50) may be written in the compact form:

$$\begin{aligned} \rho v(x,k,z) &= \inf_{u \in U_k} \tilde{H}(x,k,z,v_x(x,k,z),v(x,\cdot,\cdot),u) \\ &\stackrel{\triangle}{=} H(x,k,z,v_x(x,k,z),v(x,\cdot,\cdot)), \quad (x,k,z) \in \bar{Q} \times \mathcal{C} \times \mathcal{D}. \end{aligned} \tag{51}$$

Now we apply the results in section 3 and characterize the value function as the unique constrained viscosity solution to (51).

THEOREM 12. *The value function $v : \bar{Q} \times \mathcal{C} \times \mathcal{D} \to \mathbb{R}$ is the unique constrained viscosity solution to the HJB equation* (51) *in the function class $C^{loc}_{p,Lip}(\bar{Q} \times \mathcal{C} \times \mathcal{D})$.*

Proof. The continuity and growth estimates have been given in [20, Chapter 4]. The viscosity sub/supersolution properties for v under Definition 1 can be verified

by a similar method as in proving Theorem 11, and uniqueness follows from Theorem 3. □

It is worthwhile to note that within our solution notion, for x on the boundary of $\bar{Q}$, the right-hand side of (50) is calculated by minimizing over U_k, and the state space constraint is not explicitly involved, which differs from [20, pp. 65–71] in dealing with state constraints. The key reason here is that the viscosity subsolution property is specified only on Q, and by use of this slightly weaker specification, we can still establish uniqueness on $\bar{Q}$ owing to the continuity of the solution.

8. Concluding remarks. In this paper we study optimal control of a class of stochastic hybrid systems with state space constraints. The notion of constrained viscosity solutions is introduced. We establish a comparison theorem for the subsolution and supersolution, and under some mild conditions for the general model, the value function is characterized as the unique constrained viscosity solution to the HJB equation. The uniqueness result obtained in the general setting is further applied to a communication buffer model and a standard manufacturing system.

For future research, it is of interest to generalize the state constrained viscosity solution analysis to systems with switch cost. To gain some motivation, we consider the fluid communication buffer model in section 6. Intuitively, a high buffer level will produce a high holding cost, and on the other hand, a very low buffer level limits the controller in choosing a more beneficial action. Hence, with a certain combination of values for the buffer level x and mode variable (y, z), the control may switch rapidly between positive u_1 and positive u_2 in order to attain or approximate the optimal cost. This leads to the so-called chattering effect, which is undesirable in practical applications. We note that this kind of chattering may also occur in manufacturing systems where the machine's operation switches between the production of multiple products [20]. It is of interest to develop numerical methods to identify the critical buffer levels where chattering may occur. Furthermore, for chattering avoidance, an effective means is to introduce a switch cost, and then one needs to deal with quasi-variational inequalities [3, 4] instead of a usual HJB equation. A detailed study of optimization and numerical computation of these hybrid systems with both state space constraints and switch cost will be reported in future work.

Appendix. Proof of Theorem 11.

It is obvious that $v \in C^{loc}_{p,Lip}([0,\infty) \times S_y \times S_z)$. It suffices to show that v is a constrained viscosity solution, and uniqueness follows from Theorem 3 since $C^{loc}_{p,Lip}([0,\infty) \times S_y \times S_z) \subset C^{loc}_{p,Hol}([0,\infty) \times S_y \times S_z)$.

We give the proof by carrying out elementary estimates. Denote $\bar{Q} = [0,\infty)$ and $Q = (0,\infty)$. After suitably labeling, we may denote the joint process $(y(t), z(t))$ by an equivalent integer-valued Markov chain $\theta(t)$ with state space $\mathcal{P} = \{1, 2, \ldots, m\}$ containing $m = m_1 \times m_2$ entries, and let the associated generator for $\theta(s)$ be $\Pi_\theta = (\pi_{ij})_{m\times m}$. All of our estimates below may easily translate into a form in terms of the process (y, z), and we omit the details. First, we show v is a subsolution on $Q \times \mathcal{P}$. The functions $v(x,k)$, $L(x,k,u)$, and $F(k,u)$, $k \geq 1$ (instead of $v(x,i,j)$, etc.), are used in an obvious manner. For any given $k_0 \in \mathcal{P}$, suppose $v(x,k_0) - \phi(x)$ attains a local maximum at $x_0 \in Q$ in a neighborhood $N_{x_0} \subset Q$, where $\phi \in C^1(\bar{Q})$. Without loss of generality, we assume $v(x_0,k_0) = \phi(x_0)$, since otherwise $\phi(x)$ may be replaced by $\phi(x) - \phi(x_0) + v(x_0,k_0)$. It is easy to check that $v(x,k_0) \leq v(x_0,k_0) - \phi(x_0) + \phi(x)$ for all $x \in N_{x_0}$.

For a given initial state $x_0 \in Q$ and any $\bar{u} \in U$, there exist a sufficiently small interval $[0, \delta]$ and an admissible control $\tilde{u}$ defined on $[0, \infty)$ such that $\tilde{u}(t) \equiv \bar{u}$ on $[0, \delta]$ and $x(t) \in N_{x_0}$ for all $0 < t \leq \delta$. For the given x_0, $\delta > 0$ may be selected independently of the control. Let τ be the first jump time of $\theta(t)$ with initial state $k_0 \in \mathcal{P}$. If k_0 is nonabsorbing, τ has an exponential probability density function $|\pi_{k_0 k_0}| e^{\pi_{k_0 k_0} t}$, $t \geq 0$. The estimates below are applicable to both nonabsorbing and absorbing k_0. By the dynamic programming principle, for $h \in (0, \delta)$, we have

$$\begin{aligned}
\phi(x_0) = v(x_0, k_0) &\leq E \int_0^h e^{-\rho s} L(X, \theta, \tilde{u})(s) ds + E e^{-\rho h} v(X(h), \theta(h)) \\
&\leq E \int_0^h e^{-\rho s} L(X, \theta, \tilde{u})(s) ds + E e^{-\rho h} v(X(h), \theta(h)) 1_{(h<\tau)} \\
&\quad + E e^{-\rho h} v(X(h), \theta(h)) 1_{(h \geq \tau)} \\
&\leq E \int_0^h e^{-\rho s} L(X, \theta, \tilde{u})(s) ds + E e^{-\rho h} v(x_0, k_0) 1_{(h<\tau)} \\
&\quad + E e^{-\rho h} [\phi(X(h)) - \phi(x_0)] 1_{(h<\tau)} + E e^{-\rho h} v(X(h), \theta(h)) 1_{(h \geq \tau)} \\
&\triangleq I_1 + I_2 + I_3 + I_4. \qquad \text{(A.1)}
\end{aligned}$$

It is easy to obtain the estimates

$$\begin{aligned}
I_1 &= L(x_0, k_0, \bar{u}) h + o(h), \\
I_2 &= [1 - \rho h + o(h)] v(x_0, k_0) e^{\pi_{k_0 k_0} h} \\
&= v(x_0, k_0) - \rho v(x_0, k_0) h + v(x_0, k_0) \pi_{k_0 k_0} h + o(h), \\
I_3 &= E e^{-\rho h} [\phi(X(h)) - \phi(x_0)] - E e^{-\rho h} [\phi(X(h)) - \phi(x_0)] 1_{(h \geq \tau)} \\
&= \phi_x(x_0) F(k_0, \bar{u}) h + o(h) + O\left(\left(E |\phi(X(h)) - \phi(x_0)|^2 \cdot E |1_{(h \geq \tau)}|^2 \right)^{\frac{1}{2}} \right) \\
&= \phi_x(x_0) F(k_0, \bar{u}) h + o(h), \\
I_4 &= E e^{-\rho h} v(x_0, \theta(h)) 1_{(h \geq \tau)} + E e^{-\rho h} [v(X(h), \theta(h)) - v(x_0, \theta(h))] 1_{(h \geq \tau)} \\
&= E e^{-\rho h} v(x_0, \theta(h)) 1_{(h \geq \tau)} \\
&\quad + O\left(\left(E |v(X(h), \theta(h)) - v(x_0, \theta(h))|^2 \cdot E |1_{(h \geq \tau)}|^2 \right)^{\frac{1}{2}} \right) \\
&= E e^{-\rho h} v(x_0, \theta(h)) 1_{(h \geq \tau)} + o(h) \qquad \text{(A.2)} \\
&= h \sum_{k \neq k_0} \pi_{k_0 k} v(x_0, k) + o(h),
\end{aligned}$$

where (A.2) is obtained by the continuity of v with respect to x. Recalling $v(x_0, k_0) = \phi(x_0)$, we get

$$\begin{aligned}
0 &\leq I_1 + I_2 + I_3 + I_4 - \phi(x_0) \\
&= L(x_0, k_0, \bar{u}) h - \rho v(x_0, k_0) h + v(x_0, k_0) h \pi_{k_0 k_0} \\
&\quad + \phi_x(x_0) F(k_0, \bar{u}) h + h \sum_{k \neq k_0} \pi_{k_0 k} v(x_0, k) + o(h) \\
&= -\rho v(x_0, k_0) h + \phi_x(x_0) F(k_0, \bar{u}) h + h \sum_{k \neq k_0} \pi_{k_0 k} [v(x_0, k) - v(x_0, k_0)] \\
&\quad + L(x_0, k_0, \bar{u}) h + o(h)
\end{aligned}$$

since $\pi_{k_0k_0} + \sum_{k\neq k_0} \pi_{k_0,k} = 0$. Letting $h \to 0$, we get the desired inequality for the viscosity subsolution since $\bar{u}$ is arbitrary.

Now we show v is also a viscosity supersolution. Suppose there exists a neighborhood N_{x_0} such that $v(x,k_0) - \phi(x)$ attains a local minimum at $x_0 \in N_{x_0} \cap \bar{Q}$ for a given $k_0 \in \mathcal{P}$; for any given $\varepsilon > 0$, we can find a sequence of admissible controls $u^{(i)}$, $i \geq 1$, such that

$$\begin{aligned} v(x_0,k_0) + \frac{\varepsilon}{i} &\geq E\int_0^{\frac{1}{i}} e^{-\rho s} L(X,\theta,u^{(i)})(s)ds + Ee^{-\frac{\rho}{i}} v(X(\tfrac{1}{i}),\theta(\tfrac{1}{i})) \\ &\triangleq I_1 + I_2 + I_3 + I_4, \end{aligned} \tag{A.3}$$

where we express the right-hand side by use of the same set of notation I_i, $1 \leq i \leq 4$, as in (A.1) with $\tilde{u}$ replaced by $u^{(i)}$. Now we give the estimates as follows:

$$\begin{aligned} I_1 + I_3 &= E\int_0^{\frac{1}{i}} e^{-\rho s} L(x_0,k_0,u^{(i)})(s)ds + Ee^{-\frac{\rho}{i}}[\phi(X(\tfrac{1}{i})) - \phi(x_0)] + o\left(\frac{1}{i}\right) \\ &= E\int_0^{\frac{1}{i}} L(x_0,k_0,u^{(i)})(s)ds + E[\phi(X(\tfrac{1}{i})) - \phi(x_0)] + o\left(\frac{1}{i}\right) \\ &= E\int_0^{\frac{1}{i}} [L(x_0,k_0,u^{(i)}) + \phi_x(X)F(k_0,u^{(i)})](s)ds + o\left(\frac{1}{i}\right) \\ &= E\int_0^{\frac{1}{i}} [L(x_0,k_0,u^{(i)}) + \phi_x(x_0)F(k_0,u^{(i)})](s)ds + o\left(\frac{1}{i}\right) \\ &\geq \frac{1}{i}\inf_{u\in U}[L(x_0,k_0,u^{(i)}) + \phi_x(x_0)F(k_0,u^{(i)})] + o\left(\frac{1}{i}\right), \end{aligned} \tag{A.4}$$

$$I_2 + I_4 = v(x_0,k_0) - \frac{\rho}{i}v(x_0,k_0) + \frac{1}{i}\sum_{k\neq k_0} \pi_{k_0k}[v(x_0,k) - v(x_0,k_0)] + o\left(\frac{1}{i}\right), \tag{A.5}$$

where the higher order term $o(\frac{1}{i})$ is derived via basic estimates using the dynamics of $X(t)$ and the Markov chain $\theta(t)$ and holds uniformly with respect to ε. Taking $i \to \infty$, it follows from (A.3)–(A.5) that

$$\rho v(x_0,k_0) + \varepsilon \geq \inf_{u\in U}\Big\{\phi_x(x_0)F(k_0,\bar{u}) + \sum_{k\neq k_0} \pi_{k_0k}[v(x_0,k) - v(x_0,k_0)] + L(x_0,k_0,\bar{u})\Big\}.$$

Since $\varepsilon > 0$ is arbitrary, it follows that v is a viscosity supersolution on $\bar{Q} \times \mathcal{P}$. □

NONLINEAR DIFFUSION GOVERNED BY MCKEAN–VLASOV EQUATION ON HILBERT SPACE AND OPTIMAL CONTROL*

N. U. AHMED†

Abstract. This paper deals with optimal feedback control of measure-valued solutions of nonlinear diffusion governed by McKean–Vlasov equations. Questions of existence, uniqueness, and regularity properties of measure-valued solutions are addressed. A class of feedback controls furnished with a weak topology is introduced, and some important topological properties of the attainable set corresponding to these controls are presented. We consider several typical control problems with objective functionals which are functions of measures and prove the existence of optimal controls.

Key words. McKean–Vlasov equation, stochastic control, attainable set, optimal control

1. Introduction. Let H be a separable Hilbert space, let $\mathcal{P}(H)$ the space of probability measures defined on $\mathcal{B}(H)$ (the Borel field of subsets of H), and let $C^k(H)$ the space of k-times Fréchet differentiable functions on H. In this paper we consider the control problem associated to a measure-valued function μ_t described by the following McKean–Vlasov equation (written in weak form) in $\mathcal{P}(H)$:

$$\begin{cases} \frac{d}{dt}\langle \mu_t, \varphi\rangle = \langle \mu_t, L^u(\mu_t)\varphi\rangle \ t \in [0,T], \\ \mu_0 = \nu \in \mathcal{P}(H) \quad \text{initial data}, \end{cases} \tag{1}$$

where $\varphi \in C(H)$ is a smooth test function, $u : I \times H \to E$ is a control law, and $\{L^u(\mu) : \mu \in \mathcal{P}\}$ is a family of second-order differential operators on $C^2(H)$ defined by

$$L^u(\mu)\varphi(x) = \frac{1}{2}\mathrm{Tr}(QD^2\varphi) + (A^*D\varphi, x) + (f(x,\mu), D\varphi) + (g(x,u), D\varphi), \tag{2}$$

where $A : D(A) \subset H \longrightarrow H$ is the infinitesimal generator of a C_0 semigroup of bounded linear operators $S(t), t \geq 0$ on H; $f : H \times \mathcal{P}(H) \longrightarrow H$ and $g : H \times E \longrightarrow H$ are suitable maps where E is a separable Banach space. The operator D^k denotes the Fréchet derivative of order $k = 1, 2, \ldots$. We shall make more precise assumptions on f and g later.

Under suitable conditions as shown in section 3, for each given initial data $\nu \in \mathcal{P}(H)$ and control u, (1) has a unique measure-valued solution $\{\mu_t^u : t \in [0,T]\}$. One of the control problems studied in this paper can be stated as follows: Find a feedback control law u so that the corresponding cost functional J defined by

$$J(u) \equiv \Phi(\mu_T^u) \tag{3}$$

is minimum, where Φ is a given real-valued function on $\mathcal{P}(H)$.

Three physically motivated examples are presented in section 5 illustrating the practical relevance of the theory developed in this paper. In general, motivations

for studying such control problems are twofold. First, control problems related to measure-valued functions are very interesting both mathematically and practically, and there are very few papers in the literature focusing on this area. For finite dimensional systems see [2]. Second, the above problem arises quite naturally in the study of stochastic control for nonlinear diffusion processes described by the following Ito stochastic equation in H:

$$(4)\quad \begin{cases} dX_t = AX_t dt + f(X_t, \mu_t)dt + g(X_t, u(t, X_t))dt + \sqrt{Q}dW \quad t \in [0, T], \\ \mu_t = \text{ probability law of } X_t, \\ X_0 = \xi \text{ has initial distribution } \nu, \end{cases}$$

where W is a H-valued cylindrical Wiener process, and ξ is a given H-valued random variable. For instance, one may be interested in finding a feedback control u to minimize the quantity

$$(5)\qquad E(C(X_T^u)),$$

where X_T^u denotes the value at time T of the solution process of (4) corresponding to a feedback control law u, and C is a given cost function. Using the Yosida approximation of the operator A and Ito's formula, it is easy to verify that the probability distribution of the solution process X^u satisfies the controlled McKean–Vlasov equation (1), and the cost functional (5) is a special case of (3) with $\Phi(\mu) = \langle \mu, C\rangle$. Another interesting situation is where the terminal probability distribution is required to approximate as closely as possible to a desired (target) probability measure μ_d. In this case Φ may be chosen as

$$\Phi(\mu) \equiv d_P(\mu, \mu_d),$$

where d_P is the Prohorov metric on $\mathcal{P}(H)$ or any other metric compatible with the weak topology. Since A is generally an unbounded operator, (1) needs delicate treatment. This can be done using the Ornstein–Uhlenbeck semigroup generated by the Gaussian process Y, which is given by the solution of the linear SDE

$$(6)\quad \begin{aligned} dY(t) &= AY(t)dt + \sqrt{Q}dW(t), \quad t \in I, \\ Y(0) &\equiv Y_0 = x. \end{aligned}$$

Let $\varphi \in BC(H)$ (space of bounded continuous real-valued functions on H) and define the transition (operator) semigroup $P_t, t \geq 0$, through the conditional expectation,

$$(P_t\varphi)(x) \equiv E\{\varphi(Y_t)|Y_0 = x\}, \quad t \geq 0.$$

It is clear that this is a contraction semigroup on $B(H)$ (bounded Borel measurable functions with the supnorm topology) but not strongly continuous. This is because A is generally an unbounded operator. It is known from a result of Da Prato and Zabczyk [3, 5] that if A is the generator of an exponentially stable C_0 semigroup $S(t), t \geq 0$ on H, and Q is a nuclear operator in H (or more generally $\sup_{t\geq 0} \mathrm{Tr} Q_t < \infty$, where $Q_t \equiv \int_0^t S(r)QS^*(r)dr$), then there exists an invariant measure μ^* associated with the operator P_t in the sense that

$$\mu^*(P_t\varphi) = \mu^*(\varphi) \;\forall\; \varphi \in B(H) \text{ and } t \geq 0,$$

where $\mu(\psi) \equiv \int_H \psi(x)\mu(dx)$. Using this invariant measure one can construct the Hilbert space $L_2(H, \mu^*) \supset B(H)$. Then the semigroup P_t admits a continuous extension to the Hilbert space $L_2(H, \mu^*)$ which we shall continue to denote by the same

symbol $P_t, t \geq 0$. The corresponding infinitesimal generator is the closed extension of the original generator $\mathcal{A}$ of the Markov process $\{Y\}$, where

$$\mathcal{A}\varphi(x) \equiv (1/2)\mathrm{Tr}(D^2\varphi(x)Q) + (A^*D\varphi(x), x). \tag{7}$$

We denote the closed extension by $\mathcal{A}$ itself. We introduce two other operators associated with (1) as follows:

$$F(\mu)\varphi(x) \equiv \langle f(x,\mu), D\varphi(x)\rangle_H, \quad G(u)\varphi(x) \equiv \langle g(x,u), D\varphi(x)\rangle_H \tag{8}$$

for $x \in H$ and $\varphi \in C^1(H)$. Then (1) can be written in the weak form as follows:

$$\begin{aligned} \frac{d}{dt}\mu_t(\varphi) &= \mu_t(\mathcal{A}\varphi) + \mu_t(F(\mu_t)\varphi) + \mu_t(G(u)\varphi), \\ \mu_0(\varphi) &= \nu(\varphi). \end{aligned} \tag{9}$$

Using the adjoint of the Ornstein–Uhlenbeck semigroup and the variation of constants formula, we can formulate the problem (9) as an integral equation

$$\mu_t = P_t^*\nu + \int_0^t P_{t-s}^* F^*(\mu_s)\mu_s ds + \int_0^t P_{t-s}^* G^*(u_s)\mu_s ds, \quad t \in I \tag{10}$$

on the space $M_{\lambda^2}(H)$. A solution of this equation (if one exists) is the mild solution of (9). We use this integral equation throughout the paper.

The McKean–Vlasov equation has been studied extensively in the literature starting from McKean himself [14], Dawson [6], Gärtner [11], Dawson and Gärtner [7], Léonard [13], Funaki [10], Ahmed and Ding [1, 2], and others (see the references therein). For linear diffusions in finite dimensional spaces, control theory is well developed as seen in Fleming [8] and Fleming and Soner [9]. Recently Mahmudov and McKibben [16] have considered a class of second-order evolution equations of the McKean–Vlasov type on Hilbert space proving the existence of solutions including some controllability results. Optimal control problems for nonlinear diffusions of the McKean–Vlasov type seem to have been treated only for finite dimensional systems [2]. To the knowledge of the author infinite dimensional problems seem to be untouched. Here we consider optimal control problems for nonlinear diffusions of the McKean–Vlasov type on infinite dimensional Hilbert spaces.

The rest of the paper is organized as follows. Basic notations and function spaces are introduced in section 2. In section 3, questions of the existence of solutions and their regularity properties are addressed. In section 4, some necessary topological properties of attainable sets are presented, and questions of existence of optimal controls for several control problems are studied.

2. Some basic notations. Define $\lambda(x) \equiv 1 + |x|_H = (1 + |x|)$ and introduce the family of Banach spaces

$$C_\rho(H) \equiv \left\{ \varphi \in C(H) : \| \varphi \|_\rho \equiv \sup_{x\in H} \frac{|\varphi(x)|}{\lambda^2(x)} + \sup_{x\neq y} \frac{|\varphi(x)-\varphi(y)|}{|x-y|} < \infty \right\}, \tag{11}$$

$$C_{\lambda^k}(H) \equiv \left\{ \varphi \in C(H) : \| \varphi \|_{\lambda^k} \equiv \sup_{x\in H} \frac{|\varphi(x)|}{\lambda^k(x)} < \infty \right\}, \quad k = 1, 2, \ldots, \tag{12}$$

and

$$C_\lambda^1(H) \equiv \left\{ \varphi \in C(H) : \| \varphi \|_{C_\lambda^1} \equiv \sup_{x\in H} \frac{|\varphi(x)|}{\lambda(x)} + \sup_{x\in H} \frac{|D\varphi(x)|_H}{\lambda(x)} < \infty \right\}. \tag{13}$$

It is easy to see that the embeddings $C^1_\lambda \hookrightarrow C_\lambda \hookrightarrow C_{\lambda^2}$ are continuous and that the embedding $C_\lambda \hookrightarrow C_{\lambda^2}$ is continuous and dense.

For $1 \le p < \infty$, let $M^s_{\lambda^p}(H)$ denote the Banach space of signed Borel measures on $\mathcal{B}(H)$ such that

$$\| \mu \|^p_{\lambda^p} \equiv \int_H \lambda^p(x)|\mu|(dx) < \infty,$$

and set $M_{\lambda^2}(H) \equiv M^s_{\lambda^2}(H) \cap \mathcal{P}(H)$, where $|\mu|(C), C \in \mathcal{B}(H)$, denotes the total variation of μ over C, $|\mu| = \mu_1 + \mu_2$ and $\mu = \mu_1 - \mu_2$ is the Jordan decomposition of μ, with μ_1, μ_2 being bounded positive measures. We furnish $M_{\lambda^2}(H)$ with the following metric topologies:

$$\text{(M1)}: \qquad \rho(\mu,\nu) \equiv \sup\{\langle \mu - \nu, \varphi\rangle, \varphi \in C_\rho(H) \text{ and } \| \varphi \|_\rho \le 1\}; \tag{14}$$

and

$$\text{(M2)}: \rho^*(\mu,\nu) \equiv \sup\{\langle \mu - \nu, \varphi\rangle, \varphi \in C_{\lambda^2}(H) \text{ and } \| \varphi \|_{C_{\lambda^2}(H)} \le 1\}. \tag{15}$$

Note that

$$\rho(\mu,\nu) \le \rho^*(\mu,\nu) \quad \forall \quad \mu,\nu \in M_{\lambda^2}(H).$$

Since solutions of (9) are expected to be functions of time taking values from the space of measures $M_{\lambda^2}(H)$, we need the topological spaces $C(I,(M_{\lambda^2}(H),\rho))$ and $C(I,(M_{\lambda^2}(H),\rho^*))$. It is easy to see that these are metric spaces with respect to the metric topologies: $d(\mu,\vartheta) \equiv \sup\{\rho(\mu_t,\vartheta_t), t \in I\}$ and $d^*(\mu,\vartheta) \equiv \sup\{\rho^*(\mu_t,\vartheta_t), t \in I\}$. Later in the paper we will have to consider a family of such metric spaces indexed by the end point of the interval $[0,\tau], 0 < \tau \le T$. We shall denote such spaces by

$$(C_\tau, d) \equiv C([0,\tau],(M_{\lambda^2}(H),\rho)), \quad (C_\tau, d^*) \equiv C([0,\tau],(M_{\lambda^2}(H),\rho^*)),$$

with d, d^* restricted to the time interval $[0,\tau]$. So in this notation the original spaces are denoted by (C_T, d) and (C_T, d^*), respectively. These function spaces were used in [1, 2].

3. Existence and regularity of solutions. First we introduce the class of admissible controls. Let E be a separable Banach space and denote $B_\lambda(H,E)$ to be the class of Borel measurable maps from H to E. Furnished with the norm topology

$$|u|_\lambda \equiv \sup\left\{\frac{|u(x)|_E}{\lambda(x)}, x \in H\right\},$$

this is a Banach space. Let $B(I, B_\lambda(H,E))$ denote the space of bounded Borel measurable functions from the interval I to the Banach space $B_\lambda(H,E)$. Again, furnished with the sup norm topology

$$\| u \|_\lambda \equiv \sup\big\{|u(t,\cdot)|_\lambda \equiv |u_t|_\lambda, t \in I\big\},$$

$B(I, B_\lambda(H,E))$ is also a Banach space. Note that $B(I, B_\lambda(H,E))$ is isometrically isomorphic with the space $B_\lambda(I \times H, E)$ of Borel measurable functions on $I \times H$ with values in E and furnished with the norm topology given by

$$\| u \|_{B_\lambda(I\times H,E)} \equiv \sup\left\{\frac{|u(t,x)|_E}{\lambda(x)}, (t,x) \in I \times H\right\}.$$

Later, for purposes of optimal controls, we will introduce a weaker topology on the Banach space $B_\lambda(I \times H, E)$.

Assumptions. The basic assumptions used in the paper are the following.

Assumption 1. A is the generator of an exponentially stable C_0 semigroup of operators $S(t), t \geq 0$, on H, and Q is a positive nuclear operator so that $\sup_{t\geq 0} \mathrm{Tr} Q_t < \infty$, where $Q_t \equiv \int_0^t S(r)QS^*(r)dr$ is the covariance operator of the Orstein–Uhlenbeck process Y.

Assumption 2. For all $t \geq 0$, $\mathrm{Im}S(t) \subset \mathrm{Im}Q_t^{1/2}$, and there exists a constant $c > 0$ and $\alpha \in [0, 1)$ so that $\parallel B(t) \parallel \equiv \parallel Q_t^{-1/2} S(t) \parallel \leq c/t^\alpha, t > 0$.

Assumption 3. $f : H \times (M_{\lambda^2}(H), \rho) \longrightarrow H$ satisfying the following properties: There exist $\ell, k > 0$ such that

(i): $|f(x,\mu)|_H \leq \ell(1 + |x| + \parallel \mu \parallel_\lambda),\ \forall\ x \in H, \mu \in (M_{\lambda^2}(H), \rho)$,

(ii): $|f(x,\mu) - f(y,\nu)| \leq k\big(|x-y| + \rho(\mu,\nu)\big)\ \forall x, y \in H, \mu, \nu \in (M_{\lambda^2}(H), \rho)$.

Assumption 4. $g : H \times E \longrightarrow H$ satisfying the following properties: There exist $L, K > 0$ such that

(i): $|g(x,u)| \leq L(1 + |x| + |u|_E),\ \forall\ x \in H, u \in E$,

(ii): $|g(x,u) - g(y,v)| \leq K(|x-y| + |u-v|_E),\ \forall\ x, y \in H$ and $u, v \in E$.

These are natural variations used in [1, 2] of standard assumptions used in the study of stochastic differential equations; see Da Prato and Zabczyk [3, 4, 5]. The first part of Assumption 2 is equivalent to null controllability of the linear system $\dot{x} = Ax + \sqrt{Q}u$ and the strong Feller property of the semigroup $P_t, t \geq 0$. The second part can be relaxed by simply requiring the function to be locally integrable. The first part of the assumption guarantees the existence of a unique invariant measure μ^* for the transition semigroup $P_t, t \geq 0$. For more details see Da Prato and Zabczyk [5, section 7.2]. Now we are prepared to prove the existence of a solution to (9). First we need an a priori bound.

LEMMA 3.1. *Suppose Assumptions* 1–4 *hold and let* μ *be a solution of* (9) *(weak sense) corresponding to a control* $u \in B_\lambda(I \times H, E)$ *and the initial state* $\nu \in M_{\lambda^2}(H)$. *Then for each* $t \in I$, $\mu_t \in M_{\lambda^2}(H)$, *and there exists a finite number* $R > 0$ *such that* $\parallel \mu_t \parallel_{M_{\lambda^2}(H)} \leq R$ *for all* $t \in I$.

Proof. First we replace the unbounded operator A by its Yosida approximation $A_n \equiv nAR(n, A)$, where $R(n, A)$ is the resolvent of the operator A corresponding to $n \in \rho(A) \cap N$, with $\rho(A)$ being the resolvent set of A. Then let μ^n be the corresponding weak solution of $(9)_n (\equiv (16))$, which is given by

$$\begin{aligned} \frac{d}{dt}\mu_t^n(\varphi) &= \mu_t^n(\mathcal{A}_n\varphi) + \mu_t^n(F(\mu_t^n)\varphi) + \mu_t^n(G(u)\varphi), \\ \mu_0^n(\varphi) &= \nu(\varphi), \end{aligned} \tag{16}$$

where $\mathcal{A}_n$ is the operator $\mathcal{A}$ given by the expression (7) with A replaced by A_n. Let $\{e_i\} \subset D(A)$ be a complete orthonormal basis of H. Take $\varphi_i(x) \equiv (x, e_i)^2$ and substitute in (17). By straightforward computation, one can verify that

$$\begin{aligned} \sum_{i\geq 1} \mu_t^n(\varphi_i) &= \sum_{i\geq 1} (Q_t^n e_i, e_i) \equiv \mathrm{Tr}(Q_t^n), \\ \sum_{i\geq 1} \mu_t^n(\mathcal{A}_n\varphi_i) &= \sum_{i\geq 1} (Qe_i, e_i) + 2\int_H \sum_{i\geq 1} \{(e_i, x)(e_i, A_n x)\}\mu_t^n(dx) \\ &= \mathrm{Tr}Q + \int_H (A_n x, x), \mu_t^n(dx), \end{aligned}$$

$$\sum_{i\geq 1}\mu_t^n(F(\mu_t^n)\varphi_i) = 2\int_H \sum_{i\geq 1}(f(x,\mu_t^n),e_i)(x,e_i)\mu_t^n(dx),$$
$$= 2\int_H (f(x,\mu_t^n),x)\mu_t^n(dx),$$

$$\sum_{i\geq 1}\mu_t^n(G(u)\varphi_i) = 2\int_H \sum_{i\geq 1}(g(x,u_t),e_i)(x,e_i)\mu_t^n(dx)$$
$$= 2\int_H (g(x,u_t),x)\mu_t^n(dx).$$

Substituting these in (17), we obtain the following identity:

$$\frac{d}{dt}\mathrm{Tr}(Q_t^n) = \mathrm{Tr}Q + \int_H (A_n x,x)\mu_t^n(dx)$$
$$+2\int_H (f(x,\mu_t^n),x)\mu_t^n(dx) + 2\int_H (g(x,u),x)\mu_t^n(dx),$$
$$\mathrm{Tr}Q_0^n = \mathrm{Tr}Q^\nu, \tag{17}$$

where Q^ν is given by

$$(Q^\nu h,h) \equiv \int_H (h,x)^2\nu(dx). \tag{18}$$

Since A is dissipative, it is not difficult to verify that its Yosida approximation A_n is also dissipative. Integrating (17) and employing the dissipativity property of A_n we obtain the following inequality:

$$\mathrm{Tr}Q_t^n \leq \mathrm{Tr}Q^\nu + t\ \mathrm{Tr}Q + 2\int_0^t\int_H (f(x,\mu_s^n),x)\mu_s^n(dx)ds$$
$$+2\int_0^t\int_H (g(x,u_s),x)\mu_s^n(dx)ds. \tag{19}$$

Using Assumption 3(i), one can easily verify that

$$2\left|\int_H (f(x,\mu_s^n),x)\mu_s^n(dx)\right| \leq 2\ell(1+3\mathrm{Tr}(Q_s^n)), \quad s\in I. \tag{20}$$

Since $u\in B_\lambda(I\times H,E)$ there exists a finite positive number r_u such that

$$|u_s(x)|_E \leq r_u\lambda(x) = r_u(1+|x|),\ \forall\ x\in H, s\in I.$$

Using this and Assumption 4(i), one can again verify that

$$2\left|\int_H (g(x,u_s),x)\mu_s^n(dx)\right| \leq L(1+r_u)(1+3\mathrm{Tr}Q_s^n). \tag{21}$$

Defining $a_1 \equiv 2\ell + L(1+r_u)$, $a_2 \equiv 6\ell + 3L(1+r_u)$, it follows from (19)–(21) that

$$\mathrm{Tr}Q_t^n \leq \mathrm{Tr}Q^\nu + t\mathrm{Tr}Q + a_1 t + a_2\int_0^t \mathrm{Tr}Q_s^n\ ds. \tag{22}$$

Hence by Gronwall's lemma we obtain

$$\mathrm{Tr}Q_t^n \le a_3 \exp a_2 t, \quad t \in I, \tag{23}$$

where $a_3 \equiv \mathrm{Tr}Q^\nu + T(a_1 + \mathrm{Tr}Q)$. Since the right-hand side of this expression is independent of n we have $\sup_{n\ge1} \mathrm{Tr}(Q_t^n) < \infty$. In other words,

$$\sup_{n\ge1} \int_H |x|_H^2 \mu_t^n(dx) < \infty. \tag{24}$$

Thus if $\mu_t^u, t \in I$, is any solution of (9) corresponding to any admissible control u, we have

$$\begin{aligned} \| \mu_t^u \|_{\lambda^2} &\equiv \int_H \lambda^2(x)\mu_t^u(dx) \le 2(1 + \mathrm{Tr}Q_t^u) \\ &\le 2(1 + a_3 \exp a_2 T) \equiv R < \infty, \ \forall\, t \in I = [0,T], \end{aligned} \tag{25}$$

where the constant R depends on the data $\{T, u, Q^\nu, Q\}$. This completes the proof. □

Corollary 3.2. *Suppose the assumptions of Lemma* 3.1 *hold, and let* $\Lambda \equiv \{\mu^n\} \subset (C_T, d^*)$ *be the family of probability measure-valued functions with* μ^n *solving the McKean–Vlasov equation* $(9)_n = (16)$ *over the time interval* $[0,T]$. *Then each* t*-section of* Λ *denoted by* $\Lambda(t)$ *is a relatively weakly compact subset of* $M_{\lambda^2}(H)$.

Proof. By Lemma 3.1 the set Λ is a bounded subset of (C_T, d^*). Thus each t-section $\Lambda(t) \equiv \{\mu_t^n : \mu^n \in \Lambda\}$ is a bounded subset of $M_{\lambda^2}(H)$. We have also seen that for each $t \in I$, $\sup_n \mathrm{Tr}Q_t^n < \infty$ for all positive integers n. Thus the family of covariance operators $\{Q_t^n\} (\in \mathcal{L}_N^+(H)$ the space of positive nuclear operators) are nuclear uniformly with respect to n. This means that $\Lambda(t)$ is tight and hence a relatively weakly compact subset of $M_{\lambda^2}(H)$. □

Now we are prepared to prove the existence and uniqueness of the solution of (9). We prove that it has a mild solution in the sense that the integral equation (10) has a solution. In our paper [1, Ahmed and Ding] the stochastic method, involving the Ito stochastic differential equation, was used to prove the existence of the solution. Here we use a direct analytic approach.

Theorem 3.3. *Suppose the assumptions of Lemma* 3.1 *hold. Then for every initial data* $\nu \in M_{\lambda^2}(H)$ *and control* $u \in B_\lambda(I \times H, E)$, (10) *has a unique solution* $\mu \equiv \mu^u \in C(I, (M_{\lambda^2}(H), \rho^*))$.

Proof. We use the integral equation (10) to prove existence. Let $\gamma \in (C_T, d^*)$, $u \in B_\lambda(I \times H, E)$ be fixed but arbitrary and consider the integral equation

$$\mu_t = P_t^*\nu + \int_0^t P_{t-s}^* F^*(\gamma_s)\mu_s ds + \int_0^t P_{t-s}^* G^*(u_s)\mu_s ds, \quad t \in I. \tag{26}$$

This is a linear integral equation on $M_{\lambda^2}(H)$, and it is relatively easy to verify that this equation has a unique solution $\mu \in (C_T, d^*)$. We present a brief outline of this. Define the operator Γ by

$$(\Gamma\mu)_t \equiv P_t^*\nu + \int_0^t P_{t-s}^* F^*(\gamma_s)\mu_s ds + \int_0^t P_{t-s}^* G^*(u_s)\mu_s ds, \quad t \in I. \tag{27}$$

We show that Γ has a unique fixed point in (C_T, d^*). Let $\mu, \vartheta \in (C_T, d^*)$; then

$$(\Gamma\mu)_t - (\Gamma\vartheta)_t = \int_0^t P^*_{t-s}\big(F^*(\gamma_s)(\mu_s - \vartheta_s)\big)ds + \int_0^t P^*_{t-s}\big(G^*(u_s)(\mu_s - \vartheta_s)\big)ds, \quad t \in I. \tag{28}$$

It is known from a result of Ahmed and Ding [1, Lemma 1(b), p. 79] that

$$P_t : C_\lambda(H) \longrightarrow C^1_\lambda(H)$$

and that there exists a constant $b > 0$ such that

$$\| P_t \|_{\mathcal{L}(C_\lambda(H), C^1_\lambda(H)} \leq b/t^\alpha, \quad t > 0,$$

where $\alpha \in [0, 1)$ is as given in Assumption 2. Thus $P^*_t : (C^1_\lambda(H))^* \longrightarrow (C_\lambda(H))^*$, and

$$\| P^*_t \|_{\mathcal{L}((C^1_\lambda(H))^*, (C_\lambda(H))^*)} \leq b/t^\alpha$$

also. Since $C_\lambda(H)$ is dense in $C_{\lambda^2}(H)$, we have

$$\| \Gamma\mu_t - \Gamma\vartheta_t \|_{(C_\lambda(H))^*} = \rho^*(\Gamma\mu_t, \Gamma\vartheta_t).$$

Using this and the preceding estimate it follows from (28) that

$$\rho^*(\Gamma\mu_t, \Gamma\vartheta_t) \leq \int_0^t (b/(t-s)^\alpha) \ \| (F^*(\gamma_s)(\mu_s - \vartheta_s) \|_{(C^1_\lambda)^*} \, ds + \int_0^t (b/(t-s)^\alpha) \ \| (G^*(u_s)(\mu_s - \vartheta_s) \|_{(C^1_\lambda)^*} \, ds. \tag{29}$$

Following similar steps as in [1] and using the fact that $\rho(\mu, \vartheta) \leq \rho^*(\mu, \vartheta)$ we find that

$$|\langle F^*(\gamma_s)\mu_s - F^*(\gamma_s)\vartheta_s, \varphi\rangle| \leq b_2 \rho^*(\mu_s, \vartheta_s) \| \varphi \|_{C^1_\lambda(H)}, \tag{30}$$

where $b_2 \equiv \ell(1 + R)$, and $R \equiv \sup\{|\gamma_s|_\lambda, s \in I\}$. Since $\gamma \in (C_T, d^*)$, $R < \infty$. Hence we conclude that

$$\| (F^*(\gamma_s)(\mu_s - \vartheta_s) \|_{(C^1_\lambda)^*} \ \leq \ b_2 \ \rho^*(\mu_s, \vartheta_s). \tag{31}$$

Similarly, considering the second term in (29) we find that

$$|\langle G^*(u_s)\mu_s - G^*(u_s)\vartheta_s, \varphi\rangle| = \left| \int_H (g(x, u_s), D\varphi)(\mu_s - \vartheta_s)(dx) \right| \leq L(1 + r_u)\rho^*(\mu_s, \vartheta_s)|\varphi|_{C^1_\lambda(H)}. \tag{32}$$

Hence we have

$$|G^*(u_s)\mu_s - G^*(u_s)\vartheta_s|_{(C^i_\lambda)^*} \ \leq \ b_3 \ \rho^*(\mu_s, \vartheta_s), \tag{33}$$

where $b_3 \equiv L(1 + r_u)$. Defining $b_4 \equiv b(b_2 + b_3)$ it follows from (29), (31), and (33) that

$$\rho^*(\Gamma\mu_t, \Gamma\vartheta_t) \ \leq \ b_4 \ \int_0^t (1/(t-s)^\alpha)\rho^*(\mu_s, \vartheta_s)ds, \quad t \in I. \tag{34}$$

By successive substitution of (34) into itself, after n steps one finds that, for $t \in I$,

$$\begin{aligned} &\rho^*(\Gamma^n \mu_t, \Gamma^n \vartheta_t) \\ &\leq b_4^n \prod_{m=1}^{n-1} \beta(1-\alpha, m(1-\alpha)) \int_0^t (t-s)^{n(1-\alpha)-1} \rho^*(\mu_s, \vartheta_s) ds, \end{aligned} \tag{35}$$

where $\beta(p,q)$ denotes the standard beta function. Using this expression, one can deduce that

$$d^*(\Gamma^n \mu, \Gamma^n \vartheta) \leq \ \eta_n \ d^*(\mu, \vartheta), \tag{36}$$

where η_n is given by the product

$$\eta_n \equiv \big(b_4^n T^{n(1-\alpha)}/n(1-\alpha)\big) \prod_{m=1}^{n-1} \beta(1-\alpha, m(1-\alpha)).$$

For sufficiently large n, we have $\eta_n < 1$, and hence the operator Γ^n is a contraction on (C_T, d^*). Thus by the Banach fixed point theorem Γ^n and hence Γ has a unique fixed point. This proves the existence of a unique mild solution of the linear integral equation (26) for every given $\gamma \in (C_T, d^*)$ and $u \in B_\lambda(I \times H, E)$. Now we are prepared to prove the existence of the solution of the nonlinear integral equation (10). For fixed initial data $\nu \in M_{\lambda^2}(H)$ and $u \in B_\lambda(I \times H, E)$, consider the map

$$\gamma \longrightarrow \mu^\gamma \equiv \Psi(\gamma)$$

from (C_T, d^*) to itself. This is the solution map determined by (26). Clearly it follows from the proof given above that this map is uniquely defined. For the proof of the existence of the solution of the nonlinear problem (10) it suffices to prove the existence of a fixed point of the operator Ψ. Let $\gamma, \theta \in (C_T, d^*)$, and let $\mu^\gamma \equiv \Psi(\gamma), \mu^\theta \equiv \Psi(\theta)$ denote the unique solutions of the following integral equations:

$$\mu_t^\gamma = P_t^* \nu + \int_0^t P_{t-s}^* F^*(\gamma_s) \mu_s^\gamma ds + \int_0^t P_{t-s}^* G^*(u_s) \mu_s^\gamma ds, \quad t \in I, \tag{37}$$

$$\mu_t^\theta = P_t^* \nu + \int_0^t P_{t-s}^* F^*(\theta_s) \mu_s^\theta ds + \int_0^t P_{t-s}^* G^*(u_s) \mu_s^\theta ds, \quad t \in I. \tag{38}$$

Since $\gamma, \mu^\gamma, \theta, \mu^\theta \in (C_T, d^*)$ there exists a positive number R (not necessarily the same R as used previously) such that

$$\sup\{\| \gamma_t \|_{M_{\lambda^2}}, \| \mu_t^\gamma \|_{M_{\lambda^2}}, \| \theta_t \|_{M_{\lambda^2}}, \| \mu_t^\theta \|_{M_{\lambda^2}}, t \in I\} \leq R.$$

Subtracting (38) from (37) we obtain

$$\begin{aligned} \mu_t^\gamma - \mu_t^\theta &= \int_0^t P_{t-s}^* \big(F^*(\gamma_s)\mu_s^\gamma - F^*(\theta_s)\mu_s^\theta\big) ds \\ &\quad + \int_0^t P_{t-s}^* G^*(u_s)(\mu_s^\gamma - \mu_s^\theta) ds, \quad t \in I. \end{aligned} \tag{39}$$

Using (39) and carrying out similar computations as in the first part of the proof, we obtain

$$\begin{aligned} \| \big(F^*(\gamma_s)\mu_s^\gamma - F^*(\theta_s)\mu_s^\theta\big) \|_{(C_\lambda^1)^*} &\leq \ell(1 + |\gamma_s|_\lambda)\rho^*(\mu_s^\gamma, \mu_s^\theta) + k|\mu_s^\theta|_\lambda \rho^*(\gamma_s, \theta_s) \\ &\leq \ell(1+R)\rho^*(\mu_s^\gamma, \mu_s^\theta) + kR\rho^*(\gamma_s, \theta_s), \end{aligned} \tag{40}$$

$$\| \left(G^*(u_s)[\mu_s^\gamma - \mu_s^\theta]\right) \|_{(C_\lambda^1)^*} \leq L(1 + |u_s|_\lambda)\rho^*(\mu_s^\gamma, \mu_s^\theta), \tag{41}$$

and hence

$$\begin{aligned} \rho^*(\mu_t^\gamma, \mu_t^\theta) \leq & \int_0^t (C_1/(t-s)^\alpha)\rho^*(\gamma_s, \theta_s)ds \\ & + \int_0^t (C_2/(t-s)^\alpha)\rho^*(\mu_s^\gamma, \mu_s^\theta)ds \end{aligned} \tag{42}$$

for $t > 0$, where $C_1 = bKR$ and $C_2 = b\{\ell(1+R) + L(1+ \| u \|_\lambda)\}$. For any $\tau \in (0, T]$ and any $\varrho, \sigma \in (C_T, d^*)$, define

$$d_\tau^*(\varrho, \sigma) \equiv \sup\{\rho^*(\varrho_s, \sigma_s), 0 \leq s \leq \tau\}.$$

Using this notation, one can readily deduce from (42) that

$$d_\tau^*(\mu^\gamma, \mu^\theta) \leq C_3(\tau)d_\tau^*(\gamma, \theta) + C_4(\tau)d_\tau^*(\mu^\gamma, \mu^\theta), \tag{43}$$

where

$$C_3(\tau) = (C_1/(1-\alpha))\tau^{1-\alpha}, \quad C_4(\tau) = (C_2/(1-\alpha))\tau^{1-\alpha}.$$

Since $\alpha \in [0, 1)$, it is clear that C_3 and C_4 are positive, increasing, and continuous functions of $\tau \in I$ starting from $C_3(0) = C_4(0) = 0$. Hence there exists a $\tau_1 \in (0, T]$ such that

$$C_3(\tau_1) < (1/2), \quad C_4(\tau_1) < (1/2).$$

For such a choice of τ_1, there exists a $\kappa \in (0, 1)$ such that (43) reduces to

$$d_{\tau_1}^*(\Psi(\gamma), \Psi(\theta)) \equiv d_{\tau_1}^*(\mu^\gamma, \mu^\theta) \ \leq \ \kappa \ d_{\tau_1}^*(\gamma, \theta). \tag{44}$$

Thus the map Ψ is a contraction on the metric space $(C_{\tau_1}, d_{\tau_1}^*)$, and hence it has a unique fixed point $\mu^o \in (C_{\tau_1}, d_{\tau_1}^*)$. Clearly $\mu_{\tau_1}^o \in M_{\lambda^2}(H)$. Starting with $\nu = \mu_{\tau_1}^o$ and continuing this process with the integral equation

$$\mu_t = P_{t-\tau_1}^* \mu_{\tau_1}^o + \int_{\tau_1}^t P_{t-s}^* F^*(\mu_s)\mu_s ds + \int_{\tau_1}^t P_{t-s}^* G^*(u_s)\mu_s ds$$

for $t \in (\tau_1, T]$, again we can find a nonempty interval $(\tau_1, \tau_2]$ on which the above equation has a unique solution. If $\tau_2 \geq T$, the process terminates; otherwise, it is continued. Since I is a compact interval, the process terminates in a finite number of steps. Piecing together the solutions constructed on each of the subintervals as indicated above, we obtain a unique solution μ^o defined for the entire interval I. Thus we have proved the existence of a unique solution of our original problem. We may denote this solution by $\mu^o \equiv \mu^u$ to indicate its dependence on the control. This completes the proof. □

Remark. Under an additional assumption we can prove that $w - \lim_{t \downarrow 0} \mu_t^o = \nu$. Indeed, suppose the assumptions of Theorem 3.3 hold and ν is absolutely continuous with respect to the invariant measure μ^* with the Radon–Nikodým derivative $d\nu/d\mu^* = h^* \in L_2(H, \mu^*)$. Then the solution of (10) satisfies the property

$$w - \lim_{t \downarrow 0} \mu_t^o = \nu.$$

4. Optimal control. First we introduce a weak topology on the Banach space $B_\lambda(I \times H, E)$. We recall our assumption that H is a separable Hilbert space and E is any separable Banach space. A sequence $\{u^n\}$ is said to converge weakly to an element $u \in B_\lambda(I \times H, E)$ if and only if for every $\eta \in B_\lambda(I \times H, E^*)$ and $\vartheta \in (C_T, d^*)$ we have

$$\int_{I \times H} \langle u^n(t,x) - u(t,x), \eta(t,x) \rangle \vartheta_t(dx)dt \longrightarrow 0.$$

Note that any weakly convergent sequence in the sense of the topology introduced above has a unique limit. Let U be a closed convex subset of E and r a finite positive number. Consider the set

$$\mathcal{U}_0 \equiv \Big\{ u \in B_\lambda(I \times H, E) : u(t,x) \in U \ \forall \ (t,x) \in I \times H, \\ \text{and} \ \ \| \ u \ \|_\lambda \leq r < \infty \Big\}.$$

We assume that it is furnished with the relative weak topology. Since U is a closed convex set, it follows from the Hahn–Banach theorem that $\mathcal{U}_0$ is weakly (sequentially) closed. For admissible controls we choose a weakly compact subset $\mathcal{U}_{ad}$ of the set $\mathcal{U}_0$.

For control problems considered in this paper we restrict ourselves to system (9) with g given by

$$g(x,u) = g_1(x) + g_0(x)u,$$

where $g_1 : H \longrightarrow H$ and $g_0(x) \in \mathcal{L}(E,H)$, with

$$\sup_{x \in H} \{ \| \ g_0(x) \ \|_{\mathcal{L}(E,H)} \} \leq K_0 < \infty.$$

Since g_1 can be included in f, without loss of generality we may assume that $g_1 = 0$. In this case the operator $G(u)$ is replaced by

$$G_0(u)\varphi = (g_0 u, D\varphi)_H = \langle u, g_0^* D\varphi \rangle_{E,E^*}.$$

In other words the system is linear in control. Let $\mathcal{L}_k(E,H)$ denote the class of compact operators from E to H, a subset of the space of bounded linear operators $\mathcal{L}(E,H)$. We introduce the following additional assumption on the operator-valued function g_0:

Assumption 5. $g_0 : H \longrightarrow \mathcal{L}_k(E,H)$ is bounded Borel measurable satisfying

$$\sup\{ \| \ g_0(x) \ \|_{\mathcal{L}(E,H)}, x \in H \} \leq K_0.$$

Control problems. Throughout this section we consider the system (9) replaced by the following system:

$$\begin{aligned} \frac{d}{dt}\mu_t(\varphi) &= \mu_t(\mathcal{A}\varphi) + \mu_t(F(\mu_t)\varphi) + \mu_t(G_0(u)\varphi), \\ \mu_0(\varphi) &= \nu(\varphi), \end{aligned} \tag{45}$$

where G_0 takes the place of the operator G. We are interested in the following control problems.

Problem 1. Find a control $u \in \mathcal{U}_{ad}$ that minimizes the functional

$$J(u) \equiv \Psi(\mu_T^u),$$

where Ψ is a real-valued function on $M_{\lambda^2}(H)$ and μ^u is the mild solution of system equation (45) corresponding to the control u.

Problem 2. Find a control $u \in \mathcal{U}_{ad}$ that maximizes the functional

$$J(u) \equiv F(\mu_{t_1}^u(\varphi_1), \mu_{t_2}^u(\varphi), \ldots, \mu_{t_m}^u(\varphi_m)),$$

where $F : R^m \longrightarrow \overline{R}$, $\{t_i, i = 1, 2, \ldots, m\}$ are distinct points from the interval I, and $\{\varphi_i, i = 1, 2, \ldots, m\}$ are elements of $BC(H)$, the space of bounded continuous functions on H.

Problem 3. Find a control $u \in \mathcal{U}_{ad}$ that minimizes the functional

$$J(u) \equiv \int_{I \times H} \big\{\ell_0(t, x, \mu_t^u) + |u_t(x)|_E\big\}\mu_t^u(dx)dt, \tag{46}$$

where μ^u is the mild solution of the system equation (45) corresponding to the control $u \in \mathcal{U}_{ad}$. Here $\ell_0 : I \times H \times M_{\lambda^2}(H) \longrightarrow R$ is the cost integrand.

In order to prove the existence of optimal controls we must prove that the attainable sets are closed. Denote by Ξ the family of (probability) measure-valued functions which are solutions of (45) corresponding to the admissible set of controls $\mathcal{U}_{ad}$. This is denoted by

$$\Xi \equiv \{\mu^u \in (C_T, d^*), \mu^u \text{ solves } (45) : u \in \mathcal{U}_{ad}\}.$$

Similarly, for each $t \in I$, define the attainable set as being the set of states in $M_{\lambda^2}(H)$ described by the system (45) at time t as u describes the set $\mathcal{U}_{ad}$. This is given by the t-section

$$\Xi(t) \equiv \{\mu_t^u : \mu^u \in \Xi\}$$

of the set Ξ. For attainable sets we have the following result.

THEOREM 4.1. *Consider the system* (45) *with the admissible controls* $\mathcal{U}_{ad}$ *as introduced above, and suppose that the assumptions of Theorem* 3.3 *hold and that the operator-valued function* g_0 *satisfies the hypothesis* 5. *Then for each* $t \in I$, *the attainable set* $\Xi(t)$ *is a weakly compact subset of* $M_{\lambda^2}(H)$.

Proof. We prove that the set $\Xi(t)$ is bounded and a relatively (weakly) compact subset of $M_{\lambda^2}(H)$. The proof is then concluded by demonstrating that it is also weakly closed. Considering the question of boundedness, it follows from Lemma 3.1 that

$$\sup\{\mathrm{Tr}Q_t^u, t \in I\} \leq a_3 \exp a_2 T, \tag{47}$$

where

$$a_3 = \mathrm{Tr}Q^\nu + T(a_1 + \mathrm{Tr}Q), \quad a_1 = 2\ell + L(1 + r_u), \quad a_2 = 6\ell + 3\ell(1 + r_u)$$

and

$$r_u = \| u \|_\lambda \equiv \sup\{|u(t, x)|_E/\lambda(x) : (t, x) \in I \times H\}.$$

By our choice of the set of admissible controls we have

$$\sup\{r_u, u \in \mathcal{U}_{ad}\} \leq r.$$

Hence all of the parameters $\{a_1, a_2, a_3\}$ are bounded above by a finite positive number, and therefore there exists a finite positive number $\tilde{R}$ such that

$$\sup_{u\in\mathcal{U}_{ad}}\sup_{t\in I}\{\mathrm{Tr}Q_t^u\}\leq \tilde{R}. \tag{48}$$

From this estimate two conclusions can be drawn. Since

$$\parallel \mu_t^u \parallel_{M_{\lambda^2}(H)}\leq 2(1+\mathrm{Tr}Q_t^u)$$

it follows from (48) that

$$\sup_{u\in\mathcal{U}_{ad}}\sup_{t\in I}\parallel \mu_t^u \parallel_{M_{\lambda^2}(H)}\leq 2(1+\tilde{R}).$$

This shows that the set Ξ and each of its t-sections $\Xi(t)$ are bounded. Since, for each $t\in I$,

$$\sup_{u\in\mathcal{U}_{ad}}\mathrm{Tr}(Q_t^u)\leq \tilde{R},$$

the family of covariance operators $\{Q_t^u, u\in\mathcal{U}_{ad}\}$ is a compact subset of the space $\mathcal{L}_N^+(H)$ (the space of positive, symmetric, nuclear operators on H). Then it follows from a well-known result on weak compactness of a subset of the space of probability measures on Hilbert spaces [12, Theorem 2, p. 377] that the set $\Xi(t)$ is relatively weakly compact. For compactness we must prove that it is weakly closed. Let $\sigma^n\in\Xi(t)$ with weak limit σ^o. We show that $\sigma^o\in\Xi(t)$. Since $\sigma^n\in\Xi(t)$, there exists an admissible control $u^n\in\mathcal{U}_{ad}$ and the corresponding (unique) mild solution $\mu^n\in(C_T,d^*)$ of Equation (10) with G replaced by G_0 (see Equation (45)) such that $\sigma^n=\mu_t^n$. Since $\mathcal{U}_{ad}$ is weakly compact, there exists a subsequence of the sequence $\{u_n\}$, relabeled as the original sequence, and an element $u^o\in\mathcal{U}_{ad}$ so that $u^n\xrightarrow{\tau_w}u^o$. Let $\mu^o\in(C_T,d^*)$ denote the solution of (10) corresponding to the control u^o. We show that $\mu_t^n\xrightarrow{\rho^*}\mu_t^o$. It follows from (10) that

$$\begin{aligned}\langle(\mu_t^n-\mu_t^o),\varphi\rangle &= \int_0^t\langle\big[F^*(\mu_s^n)\mu_s^n-F^*(\mu_s^o)\mu_s^o\big],P_{t-s}\varphi\rangle ds\\ &\quad+\int_0^t\langle\big[G_0^*(u_s^n)\mu_s^n-G_0^*(u_s^o)\mu_s^o\big],P_{t-s}\varphi\rangle ds.\end{aligned} \tag{49}$$

We split this into several parts as follows:

$$\begin{aligned}\langle(\mu_t^n-\mu_t^o),\varphi\rangle &= \int_0^t\int_H\langle(f(x,\mu_\theta^n)-f(x,\mu_\theta^o),DP_{t-\theta}\varphi\rangle\mu_\theta^n(dx)d\theta\\ &\quad+\int_0^t\int_H\langle f(x,\mu_\theta^o),DP_{t-\theta}\varphi\rangle(\mu_\theta^n-\mu_\theta^o)(dx)d\theta\\ &\quad+\int_0^t\int_H\langle g_0u_\theta^n,DP_{t-\theta}\varphi\rangle(\mu_\theta^n-\mu_\theta^o)(dx)d\theta\\ &\quad+\int_0^t\int_H\langle u_\theta^n-u_\theta^o,g_0^*DP_{t-\theta}\varphi\rangle\mu_\theta^o(dx)d\theta.\end{aligned} \tag{50}$$

Following similar computations as in the first part of the proof of Theorem 3.3, it follows from (50) that for each $t\in I$ we have

$$\rho^*(\mu_t^n,\mu_t^o)\leq\int_0^t(C/(t-\theta)^\alpha)\rho^*(\mu_\theta^n,\mu_\theta^o)d\theta+E_n(t), \tag{51}$$

where the constant C is dependent only on the parameters $\{\ell, k, r, \tilde{R}, b, K_0, T\}$, and the function E_n is given by

$$E_n(t) \equiv \sup\{e_n(t,\varphi) : \varphi \in B_1(C_\lambda(H))\},$$

with e_n given by

$$e_n(t,\varphi) = \int_0^t \int_H \langle u_\theta^n - u_\theta^o, g_0^* DP_{t-\theta}\varphi\rangle_{E,E^*} \mu_\theta^o(dx)d\theta. \tag{52}$$

It is well known that a bounded linear operator is compact if and only if its adjoint is compact. Thus $g_0^*(x)$ is compact for each $x \in H$, and hence $g_0^* : H \longrightarrow \mathcal{L}_k(H, E^*)$. Since u^n converges weakly to u^o, $g_0^*(x)$ is compact, and $P_t : C_\lambda(H) \longrightarrow C_\lambda^1(H)$, it follows from (52) that

$$e_n(t,\varphi) \longrightarrow 0 \quad \text{uniformly with respect to} \quad \varphi \in B_1(C_\lambda(H)).$$

Hence for any $t \in I$ we have

$$\lim_{n\to\infty} E_n(t) = 0. \tag{53}$$

Using (53) in (51) one can easily verify that for any $t \in I$

$$\lim_{n\to\infty} d_t^*(\mu^n, \mu^o) = 0. \tag{54}$$

Thus, in particular, $\mu_t^n \xrightarrow{w} \mu_t^o$. This, combined with the uniqueness of the weak limit, implies the identity $\sigma^o = \mu_t^o$ and therefore $\sigma^o \in \Xi(t)$ and so $\Xi(t)$ is weakly closed. Thus for each $t \in I$ the attainable set $\Xi(t)$ is a weakly compact subset of $M_{\lambda^2}(H)$. This completes our proof. □

The question of continuity of the map $u \longrightarrow \mu^u$ is very important in the study of control problems. As a corollary of the previous result we have the following result.

COROLLARY 4.2. *For the system* (45)*, the solution map $u \longrightarrow \mu^u$ is sequentially continuous with respect to the weak topology on $B_\lambda(I \times H, E)$ and the metric topology on $C(I, M_{\lambda^2}(H), \rho^*)$).*

Proof (outline). Let $u^n \in B_\lambda(I \times H, E)$, and suppose it converges to $u^o \in B_\lambda(I \times H, E)$ in the weak topology with μ^n and μ^o being the corresponding solutions of (45). Then following similar steps as in the preceding theorem one arrives at the same expression (51) leading to the conclusion (54). Since this is valid for every $t \in I$ and $d^* = d_T^*$, we have

$$\lim_{n\to\infty} d^*(\mu^n, \mu^o) \longrightarrow 0.$$

This completes the outline of the proof. □

Now we consider the following terminal control problem.

Problem 1. Find $u \in \mathcal{U}_{ad}$ that minimizes the functional

$$J(u) \equiv \Psi(\mu_T^u).$$

THEOREM 4.3. *Consider the system* (45) *and suppose the assumptions of Theorem* 4.1 *hold. Let Ψ be a weakly lower semicontinuous function on $M_{\lambda^2}(H)$ and*

$$\inf\{\Psi(\mu), \mu \in \Xi(T)\} > -\infty.$$

Then there exists an optimal control that solves Problem 1.

Proof. By hypothesis $\inf\{\Psi(\mu), \mu \in \Xi(T)\} \equiv m_0 > -\infty$. Let $\{\nu^n\}$, from the attainable set $\Xi(T)$, be a minimizing sequence for Ψ. Since this set is compact in the weak topology, there exists a subsequence of the sequence $\{\nu^n\}$, relabeled as the original sequence, and an element $\nu^o \in \Xi(T)$ so that $\nu^n \xrightarrow{w} \nu^o$. Now it follows from lower semicontinuity of Ψ and the minimizing property of the sequence $\{\nu^n\}$ that

$$\Psi(\nu^o) \leq \underline{\lim}_{n\to\infty}\Psi(\nu^n) = \lim_{n\to\infty} \Psi(\nu^n) = m_0.$$

Since $\nu^o \in \Xi(T)$, it is evident that $\Psi(\nu^o) \geq m_0$. Combining the above inequalities we obtain $\Psi(\nu^o) = m_0$. Thus Ψ attains its minimum on $\Xi(T)$. Since $\Xi(T)$ is the attainable set, there exists a control $u^o \in \mathcal{U}_{ad}$ so that the corresponding solution μ^{u^o} has the terminal value $\mu_T^{u^o} = \nu^o$. This proves the existence of an optimal control. □

Examples. Some simple examples of Ψ are the following.

Example 1. $\Psi(\mu) = \int_H V(x)\mu(dx)$ for $V \in C_{\lambda^2}(H)$.

Example 2. $\Psi(\mu) \equiv \mu(D)$, where D is any open set in H.

Example 3. $\Psi(\mu) \equiv \rho^*(\mu_d, \mu)$, where μ_d is the target measure. Clearly this is a continuous function.

Another control problem of similar nature is the following.

Problem 2. Find a control that maximizes the functional

$$J(u) \equiv F(\mu_{t_1}^u(\varphi_1), \mu_{t_2}^u(\varphi_2), \ldots, \mu_{t_m}^u(\varphi_m)),$$

where $\{t_1, t_2, \ldots, t_m\}$ are distinct points from the set I, $\{\varphi_i, i = 1, 2, \ldots m\}$ are elements of $BC(H)$, and

$$\mu(\varphi) \equiv \int_H \varphi(x)\mu(dx), \quad \mu \in M_{\lambda^2}(H).$$

THEOREM 4.4. *Consider the system* (45) *with the control problem* 2*, and suppose the assumptions of Theorem* 4.1 *hold. Let* $F : R^m \longrightarrow \overline{R}$ *be an upper semicontinuous function bounded on bounded sets and* $\{\varphi_i\} \in BC(H)$*. Then Problem* 2 *has a solution.*

Proof. Upper semicontinuity of F on R^m implies upper semicontinuity of J on $\mathcal{U}_{ad}$ in the weak topology. This follows from similar arguments as in the proof of Theorem 4.3 for a single index T. Since F is bounded on bounded sets of R^m and $\sup\{|\mu_t^u(\varphi_i)|, u \in \mathcal{U}_{ad}\} < \infty$ for each $t \in I$, we have

$$\sup\{J(u), u \in \mathcal{U}_{ad}\} < \infty.$$

The existence of optimal control now follows from weak compactness of the set of admissible controls $\mathcal{U}_{ad}$ and upper semicontinuity of J. □

One physical interpretation of Problem 2 is that it demands a control that maximizes the probability of visiting (or hitting) certain sites at specified points of time. Considering nonnegative functions $\{\varphi_i\}$, the sites are determined by the supports of the functions $\{\varphi_i\}$.

Now we consider the Lagrange problem 3.

THEOREM 4.5. *Consider the system* (45) *and the Lagrange problem* 3*, and suppose the assumptions of Theorem* 4.1 *hold with the exception that* E *is now a separable Hilbert space. Further suppose* $\ell_0 : I \times H \times M_{\lambda^2}(H) \longrightarrow R$ *is a nonnegative map satisfying the following conditions: There exists a positive number* L_0 *such that*

(C1): $|\ell_0(t, x, \nu) - \ell_0(t, x, \vartheta)| \leq L_0\ \rho^*(\nu, \vartheta)\ \forall \nu, \vartheta \in M_{\lambda^2}(H), (t, x) \in I \times H$;

(C2): $|\ell_0(t, x, \nu)| \leq L_0\ \left(\lambda^2(x) + |\nu|_\lambda^2\right)\ \forall\ (t, x) \in I \times H,$ *and* $\nu \in M_{\lambda^2}(H)$;

(C3): *$\nu \longrightarrow \ell_0(t,x,\nu)$ is lower semicontinuous on $(M_{\lambda^2}(H),\rho^*)$ for all $(t,x) \in I \times H$.*

Then there exists an optimal control for the Lagrange problem 3.

Proof. Since $\mathcal{U}_{ad}$ is weakly compact and $J(u) \geq 0$ for all $u \in \mathcal{U}_{ad}$, it suffices to prove that the functional $u \longrightarrow J(u)$, as given by (46), is lower semicontinuous. Let $\{u^n\}$ be a sequence of controls from $\mathcal{U}_{ad}$ which converges in the weak topology to an element $u^o \in \mathcal{U}_{ad}$, and let $\{\mu^n\}$ and μ^o denote the corresponding (mild) solutions of (45) associated with the controls $\{u^n\}$ and u^o, respectively. It follows from Corollary 4.2 that, along a subsequence if necessary, $\mu^n \xrightarrow{d^*} \mu^o$. Since $\{\mu^n\}$ is a convergent sequence and $\mu^o \in (C_T, d^*)$, there exists a finite positive number R (not necessarily the same as the previous ones) such that

$$\sup\{|\mu_t^n|_{\lambda^2}, |\mu_t^o|_{\lambda^2}, t \in I\} \leq R.$$

Consider the objective functional (46) decomposed into two parts $J(u) \equiv J_1(u)+J_2(u)$ evaluated at u^o. Focusing on the first part, we can rewrite this as follows:

$$\begin{aligned} J_1(u^o) &= \int_{I\times H} \ell_0(t,x,\mu_t^o)(\mu_t^o - \mu_t^n)(dx)dt \\ &\quad + \int_{I\times H} \big(\ell_0(t,x,\mu_t^o) - \ell_0(t,x,\mu_t^n)\big)\mu_t^n(dx)dt + J_1(u^n). \end{aligned} \tag{55}$$

Denoting the first term on the right by $J_{1,1}$ and the second by $J_{1,2}$, it is easy to verify that

$$|J_{1,1}| \leq L_0(1+R^2)\int_I \rho^*(\mu_t^n,\mu_t^o)\ dt, \tag{56}$$

$$|J_{1,2}| \leq L_0 R \int_I \rho^*(\mu_t^o,\mu_t^n)\ dt. \tag{57}$$

By Corollary 4.2, weak convergence of u^n to u^o implies d^* convergence of μ^n to μ^o. Thus $\rho^*(\mu_t^n,\mu_t^o) \longrightarrow 0$ for each $t \in I$. Further, as seen in Theorem 4.1, the set Ξ is bounded, and hence there exists a finite positive number $\hat{R}$ such that $\rho^*(\mu_t^n,\mu_t^o) \leq 2\hat{R}$ for all $n \in N$ and for all $t \in I$. Hence by the Lebesgue dominated convergence theorem

$$\int_I \rho^*(\mu_t^n,\mu_t^o)dt \longrightarrow 0 \quad \text{as } n \to \infty. \tag{58}$$

Clearly it follows from (55)–(58) that

$$J_1(u^o) \leq \liminf_{n\to\infty} J_1(u^n). \tag{59}$$

Now consider the part J_2 evaluated at u^o given by

$$J_2(u^o) \equiv \int_{I\times H} |u_t^o(x)|_E \ \ \mu_t^o(dx)dt. \tag{60}$$

By the Riesz representation theorem for Hilbert spaces, there exists a Borel measurable function $v_t^o(x)$ such that $|v_t^o(x)|_E = 1$ for all $(t,x) \in I \times H$. In fact one can choose

$$v_t^o(x) = \begin{cases} u_t^o(x)/|u_t^o(x)| & \text{if } |u_t^o(x)|_E \neq 0, \\ 0 & \text{otherwise.} \end{cases}$$

Clearly this is a Borel measurable function since u^o is. Thus J_2 can be written as

$$\begin{aligned} J_2(u^o) &\equiv \int_{I\times H} \langle u_t^o(x), v_t^o(x)\rangle_E \ \ \mu_t^o(dx)dt \\ &= \int_{I\times H} \langle u_t^o(x) - u_t^n(x), v_t^o(x)\rangle_E \ \ \mu_t^o(dx)dt \\ &\quad + \int_{I\times H} \langle u_t^n(x), v_t^o(x)\rangle_E \ \ (\mu_t^o - \mu_t^n)(dx)dt \\ &\quad + \int_{I\times H} \langle u_t^n(x), v_t^o(x)\rangle_E \ \ \mu_t^n(dx) \\ &\equiv J_{2,1} + J_{2,2} + J_{2,3}. \end{aligned} \tag{61}$$

Since $u^n \xrightarrow{\tau_w} u^o$, the first term converges to zero as $n \to \infty$. For the second term, it follows from boundedness of the set $\mathcal{U}_{ad}$ that

$$|J_{2,2}| \le r \int_I \rho^*(\mu_t^o, \mu_t^n)dt. \tag{62}$$

Hence again by the dominated convergence theorem we have

$$\int_I \rho^*(\mu_t^n, \mu_t^o)dt \longrightarrow 0 \quad \text{as } n \to \infty. \tag{63}$$

For the third term we have

$$|J_{2,3}| \le J_2(u^n). \tag{64}$$

Combining (60)–(63) we find that

$$J_2(u^o) \le \liminf_{n\to\infty} J_2(u^n). \tag{65}$$

Thus it follows from (59) and (65) that

$$J(u^o) \le \liminf_{n\to\infty} J(u^n),$$

and hence the functional J given by (46) is weakly lower semicontinuous on $\mathcal{U}_{ad}$. This completes the proof. □

Another control problem of significant interest is to find a control that maximizes the probability of following a moving (set-valued) target as closely as possible. Let $\Upsilon(t) \subset H$ denote a set-valued function (target). The problem is to find a control that maximizes the objective functional given by

$$J(u) \equiv \int_I w(t)\ \mu_t^u(\Upsilon(t))dt, \tag{66}$$

where w is a nonnegative weighting function.

THEOREM 4.6. *Consider the system* (45)*, and let* $t \to \Upsilon(t)$ *be a nonempty set-valued function with closed values in* H *and continuous in the Hausdorff metric, and let* w *be a continuous nonnegative real-valued function. Then there exists a control* $u^o \in \mathcal{U}_{ad}$ *at which* $J(u)$ *given by* (66) *attains its maximum.*

Proof. Clearly

$$0 \le J(u) \le \int_I w(t)dt < \infty.$$

Thus it suffices to prove that J is upper semicontinuous. Let $\{u^n\} \in \mathcal{U}_{ad}$, and suppose $u^n \xrightarrow{\tau_w} u^o$. Since $\mathcal{U}_{ad}$ is τ_w compact, $u^o \in \mathcal{U}_{ad}$. Let $\{\mu^n, \mu^o\}$ denote the corresponding solutions of (45). Then by Corollary 4.2, along a subsequence if necessary, $\mu^n \xrightarrow{d^*} \mu^o$. Since $\Upsilon(t)$ is closed-valued and $\mu_t^n \xrightarrow{w} \mu_t^o$ it follows from [15, Theorem 6.1, p. 40] that

$$\limsup_{n\to\infty} \mu_t^n(\Upsilon(t)) \le \mu_t^o(\Upsilon(t)) \ \forall\ t \in I.$$

Since w is nonnegative, it follows from the above inequality that

$$\limsup_{n\to\infty} w(t)\mu_t^n(\Upsilon(t)) \le w(t)\mu^o(\Upsilon(t)) \ \forall\ t \in I$$

also. Hence

$$\begin{aligned} \limsup_{n\to\infty} \int_I \{w(t)\mu_t^n(\Upsilon(t))\}dt &\le \int_I \limsup_{n\to\infty}\{w(t)\mu_t^n(\Upsilon(t))\}dt \\ &\le \int_I \{w(t)\mu_t^o(\Upsilon(t))\}dt. \end{aligned} \tag{67}$$

Clearly it follows from the definition of J (see (66)) and the inequality (67) that

$$\limsup_{n\to\infty} J(u^n) \le J(u^o),$$

proving upper semicontinuity of J. Hence there exists an admissible control maximizing J. This completes the proof. □

Remark 1. Theorem 4.6 holds under much more general conditions than those stated. For example, $w \in L_1^+(I)$ and $t \longrightarrow \Upsilon(t)$ a measurable multifunction with closed values.

Remark 2. Assuming continuity of the multifunction $t \longrightarrow \Upsilon(t)$ from I to $2^H \setminus \emptyset$ we can also admit J of the form

$$J(u) \equiv \int_I \mu_t^u(\Upsilon(t))\ \rho(dt)$$

provided ρ is a countably additive bounded positive measure on I having bounded total variation. For example, ρ may be given by a weighted sum of a finite number of Dirac measures.

Time optimal control is another interesting topic. Let $\mu_d \in M_{\lambda^2}(H)$ be a target measure, and suppose

$$\mu_d \in \bigcup_{0\le t<\infty} \Xi(t);$$

that is, the system is controllable in finite time.

Problem 4. The problem is to find a control $u^o \in \mathcal{U}_{ad}$ such that $\mu_d = \mu_{\tau^o}^{u^o}$ and $\mu_t^u \ne \mu_d$ for any $t < \tau^o$ and any $u \in \mathcal{U}_{ad}$. In other words, u^o is the time optimal control and τ^o is the optimal time.

THEOREM 4.7. *Consider the system* (45)*, suppose the assumptions of Theorem* 4.1 *hold, let* $\mu_d(\ne \nu) \in M_{\lambda^2}(H)$*, and suppose the system is controllable in finite time. Then Problem* 4 *has a solution.*

Proof. Define the function $\mathcal{T}$ given by

$$\mathcal{T}(t) \equiv \rho^*(\mu_d, \Xi(t)), \quad t \geq 0. \tag{68}$$

This is a well-defined continuous function since the solutions are elements of (C_T, d^*) for every finite $T > 0$. By assumption the system is controllable in finite time implying the existence of a finite $T > 0$ such that $\mu_d \in \bigcup_{t\in[0,T]} \Xi(t) \neq \emptyset$. This implies that the set $R_c \equiv \{t \geq 0 : \mathcal{T}(t) = 0\}$ is nonempty and $\inf R_c \equiv \tau^o < \infty$. The proof now follows from the facts that $\mathcal{T}$ is continuous and the attainable sets $\Xi(t), t \geq 0$, are closed. Thus there exists a control u^o so that the corresponding solution of (45) hits the target μ_d at time τ^o, and there exists no other control that drives the system to the target earlier. This completes the proof. □

5. Some examples. For illustration we present a few examples. We have already mentioned the general case in the introduction which says that any stochastic differential equation in which the coefficients are dependent on the probability law of the process itself gives rise to McKean–Vlasov diffusion. This phenomenon is common in physical sciences dealing with the dynamics of charge density waves (CDW), mean-field dynamics of soft spins (SDW), chemical reactions, population biology, power flow in mobile communication network, etc. Another example is Kushner's equation arising in the study of nonlinear filtering. Given the history of observation, the conditional probability law is governed by an equation of the McKean–Vlasov type. Here we present some simple examples that arise naturally from applications.

Example 1 (mobile communication). In the study of stochastic power control of a wireless network, Olama, Djouadi, and Charalambos [17] have proposed a stochastic differential equation model that describes the dynamics of power flow between mobile transreceivers and a base station. Considering radial distance r separating the transmitter from the base station (receiver) as the spatial coordinate, the logarithm of power denoted by $\{X(t,r)\}$ is a stochastic process governed by a differential equation of the form

$$dX(t,r) = \beta(t,r)(\overline{X(t,r)} - X(t,r))dt + \delta(t,r)dw(t) \tag{69}$$

for $r \in D \subset (0,R)$ and $t \geq 0$, where $\overline{X(t,r)}$ denotes the mean of the process X, w is the standard scalar Brownian motion, and the variables β and δ are certain given functions of space and time which we may assume to be bounded measurable. The authors call this mean-reverting SDE. Numerical results presented by the authors seem to indicate that the model is a good approximation of the power distribution actually measured on the site. Since the noise level may also depend on the geographical position, we propose to replace the stochastic term by a space-time Brownian motion and add a diffusion term representing dissipation of power in the environment, giving

$$\begin{aligned} \partial_t X(t,r) = {} & \partial/\partial r(e(r)\partial X/\partial r)dt + \beta(t,r)(\overline{X(t,r)} - X(t,r))dt \\ & + dW(t,r), \end{aligned} \tag{70}$$

where $e(r)$ is a strictly positive function representing the diffusivity property of the medium. We use a homogeneous Dirichlet boundary condition of the form

$$X(t,0) = 0, X(t,R) = 0, \tag{71}$$

and add a term u to represent the (log of) power transmitted which we may consider as the control variable. Thus the controlled version of (70) is given by

$$\begin{aligned} \partial_t Y(t,r) = {} & \partial/\partial r(e(r)\partial Y/\partial r)dt + \beta(t,r)(\overline{Y(t,r)} - Y(t,r))dt \\ & + u(t,r)dt + dW(t,r), \end{aligned} \tag{72}$$

with a homogeneous Dirichlet boundary condition. We introduce the Hilbert space $H \equiv L_2(D)$ and define the operator A by

$$D(A) \equiv H_0^1(D) \cap H^2(D), \tag{73}$$
$$(A\varphi)(r) \equiv \partial/\partial r\big(e(r)\partial\varphi/\partial r\big) \text{ for } \varphi \in D(A).$$

The operator $f : R_+ \times \mathcal{P}(H) \times H \longrightarrow H$ is given by

$$f(t,\mu,y) \equiv \beta(t,\cdot)\bigg(\int_H \xi\mu(d\xi) - y(\cdot)\bigg), \tag{74}$$

and the control operator is given by $Bu = u$ (B identity operator in H). We introduce the H-valued Brownian motion $W(t) \equiv \{W(t,r), r \in D\}$ with the covariance given by

$$E\{(W(t),h)(W(\tau),g)\} = t \wedge \tau(Qh,g),$$

where

$$(Qh,g) \equiv \int_{D\times D} q(r,s)h(r)g(s)drds,$$

with q being a positive symmetric Hilbert–Schmidt kernel belonging to $L_2(D \times D)$. Defining $y(t) \equiv Y(t,\cdot)$, using cylindrical Brownian motion, and denoting it by the same symbol W, we can rewrite the basic equation in our abstract form on the Hilbert space H as follows:

$$dy = Aydt + f(t,\mu_t,y)dt + Budt + \sqrt{Q}dW, \quad y(0) = y_0, \tag{75}$$
$$\mu_t = \mathcal{L}y(t), \quad t \geq 0. \tag{76}$$

Assuming $e(r) > \gamma > 0$, it is easy to verify that A generates an exponentially stable C_0 semigroup on H. The rest of the assumptions of our existence theorem are obviously satisfied since f is linear, the operator B is bounded in H, and $\sqrt{Q}$ is nuclear. An interesting control problem for the mobile station is to find a control law that maximizes the power delivery to the base station, at any given time, say, T. One may formulate the problem as follows. For the control space E choose $E = L_2(D) = H$. Since the transmitter power is limited, we may choose a closed bounded convex set $U \subset E$, and for admissible feedback policies we use the set

$$\mathcal{U}_{ad} \equiv \{u \in B_\lambda(I \times H, H) : u(t,y) \in U \ \forall\ (t,y) \in I \times H\}.$$

Then choose any $\varphi \in L_2(D)$ having support that contains the mobile, and choose a control from the admissible class $\mathcal{U}_{ad}$ that maximizes the functional

$$u \longrightarrow E\exp\bigg\{\int_D Y^u(T,r)\varphi(r)dr\bigg\} \equiv \int_H e^{(y,\varphi)}\mu_T^u(dy).$$

For example, let $\Gamma(t), t \geq 0$, be a closed convex set with values in $2^D \setminus \emptyset$ representing the closed neighborhood of the location of the mobile, and choose $\varphi(r) \equiv \chi_{\Gamma(t)}(r)$. In this case the problem looks like

$$u \longrightarrow E\exp\bigg(\int_{\Gamma(t)} Y^u(t,r)dr\bigg) = \int_H e^{(y,\varphi)}\mu_t^u(dy) \longrightarrow \sup.$$

This is a special case of Theorem 4.4 and hence the existence of optimal control follows from it.

Example 2 (Brussellator). In the study of chemical kinetics, certain trimolecular reactions are known to exhibit periodic behavior. This was discovered by a group of scientists from Brussell, and in their honor the name Brussellator was adopted. In the well-stirred case, this is described by a pair of stochastic ordinary differential equations containing the mean-field coupling:

$$dx_1 = (a - (b+1)x_1 + x_1^2 x_2)dt + D_1(\overline{x}_1 - x_1)dt + \sigma_1(x_1)dw_1, \tag{77}$$

$$dx_2 = (bx_1 - x_1^2 x_2)dt + D_2(\overline{x}_2 - x_2)dt + \sigma_2(x_2)dw_2, \tag{78}$$

where the vector $\{x_1, x_2\}$ denotes the concentration of the two chemicals (product of reaction). This model is obtained from the McKean–Vlasov limit of a model due to Dawson (see [6] and the references in [18]). For a complete justification of the model see [18]. Under certain assumptions on the parameters $\{a, b, D_1, D_2\}$ it was proved by Scheutzow [18, Theorem 3.4, p. 446] that the system has a solution whose law $\mu_t, t \geq 0$, is supported on $R_+ \times R_+$ and that this law is periodic in time. A self-organizing property is commonly observed in biological species. It is an amazing fact that this property has been observed in some chemical reactions also. This may have a profound significance on the origin of biological species.

The model described above is based on the assumption that the concentration of the chemicals is uniformly distributed throughout the volume of the reactor. This requires controlling the mixing by a stirrer and possibly by a heat source controlling the temperature. Thus in fact the concentration of the chemicals should be considered as functions of time and position in the reactor volume $\Omega \subset R^3$. Including a multiplicative control, and assuming uniform diffusivity, the PDE version of this, describing the evolution of concentration distribution in the reactor Ω, is given by

$$dx = Axdt + f(x, \mu)dt + G_0(x)udt + \sigma dW, \tag{79}$$

where the operator A is given by the matrix of Laplacians

$$A \equiv \begin{pmatrix} \Delta & 0 \\ 0 & \Delta \end{pmatrix}$$

subject to a homogeneous Dirichlet (zero) boundary condion on the boundary $\partial\Omega$. The drift f is easily identified from (77)–(78), the operator σ is identified as

$$\sigma \equiv \begin{pmatrix} \sigma_1 & 0 \\ 0 & \sigma_2 \end{pmatrix},$$

and W is the space-time Brownian motion. For the state space we choose $H \equiv L_2(\Omega) \times L_2(\Omega)$, for the control space $E \equiv L_p(\Omega), p \in [1, \infty)$, with G_0 a bounded operator-valued function on H with values in $\mathcal{L}(E, H)$. More specifically we assume that $\sup\{\| G_0(x) \|_{\mathcal{L}(E,H)}, x \in H\} < \infty$. This provides a multiplicative and possibly reactive control. Since σ is allowed to depend on the state and f has quadratic nonlinearity, strictly speaking our theory fails to cover this case. However, due to conservation of mass, the concentration of chemicals can never be unbounded. Thus by appropriate truncation we may replace f by $f_r(x) \equiv f(\rho_r(x))$, where ρ_r is the retract of the ball $B_r \subset H$ of radius r around the origin ($\infty > r \geq$ the total mass of the reactor including its contents). For this f_r with σ independent of the state and

$\sqrt{\sigma}\sigma^*$ positive nuclear our results hold. For example, let $\Gamma \subset H$ be a target set of concentration, and suppose it is required to reach this target at time T with maximum probability. The problem is to find a control law that maximizes the functional $J(u) \equiv \mu_T^u(\Gamma)$. Under the assumptions used for admissible controls (section 4), if Γ is a nonempty closed convex set, there is an optimal control that solves the problem.

Example 3 (charge density waves/spin density waves). The discrete mean-field version of the Fukuyama–Lee model for CDW as presented by Bonilla [19] is given by a system of coupled stochastic ordinary differential equations:

$$d\Theta_i = \left(E - \alpha \sin(\Theta_i - \beta) - K\left(\Theta_i - (1/N)\sum_1^N \Theta_j\right)\right) dt + \sqrt{\gamma} dw_i, \tag{80}$$

$$i = 1, 2, \ldots, N, \tag{81}$$

where Θ_i is the phase at the site i, K is the stiffnes of coupling of CDW, and E is the applied electric field which can be used as the control. Again the interaction is of the mean-field type. The parameters $\{\alpha, \beta, \gamma\}$ are fixed, α representing impurity potential and β the pinning angle, and $\{w_i\}$ are independent standard Brownian motions. Again the McKean–Vlasov limit ($N \to \infty$) of this equation is an equation of the form (9) describing the temporal evolution of phase density or the corresponding measure. The operators are identified as follows:

$$\mathcal{A}\varphi \equiv (1/2)\gamma D^2\varphi, \quad (F(\mu)\varphi)(\theta) = f(\theta, \bar{\theta})D\varphi, \quad G(u)\varphi \equiv uD\varphi,$$
$$\bar{\theta} \equiv \int_R \theta\mu(d\theta), \quad \mu \equiv \mathcal{L}(\theta), \quad f(y,z) \equiv -\alpha\sin(y-\beta) - K(y-z),$$

where $D\varphi$ and $D^2\varphi$ denote the first and second partials of φ with respect to θ, respectively. Note that this is a scalar McKean–Vlasov equation with $H = E = R$. For an excellent physical interpretation of this model the reader is referred to [19]. It is known that by slowly increasing the electric field $u = E$ to a threshold value, one can break free the CDW from impurities and force sliding, thereby causing flow of current. It is claimed by physicists that CDW has great industrial potential, with the prospect of developing switches, capacitors, detectors, superconductors, etc. Since all of our assumptions hold, without going into details we simply mention that our results on optimal control apply to this problem. For example, let Γ_0 denote the region of phase space in which the CDW behaves as an insulator and Γ_c the region in which it acts as a (super)conductor. Suppose at time zero $\mu_0(\Gamma_0) = 1$ and that the set

$$\{t \geq 0, u \in \mathcal{U}_{ad} : \mu_t^u(\Gamma_c) = 1\} \neq \emptyset.$$

The problem is to find a driving force that minimizes the transit time from the set Γ_0 to the set Γ_c. In other words, find a control policy that minimizes the cost functional

$$J(u) \equiv \inf\{t \geq 0 : \mu_t^u(\Gamma_c) = 1\}.$$

This is a time optimal control as treated in section 4.

Remark. In this paper we have been concerned with the questions of the existence of optimal controls. We have not attempted to develop necessary conditions of optimality. This remains an open problem for the future.

NULL CONTROLLABILITY OF SOME SYSTEMS OF TWO PARABOLIC EQUATIONS WITH ONE CONTROL FORCE*

SERGIO GUERRERO†

Abstract. In this paper we establish some exact controllability results for systems of two parabolic equations. First, we prove the existence of insensitizing controls for the L^2 norm of the gradient of solutions of linear heat equations. Then, in the worst situation where null controllability for a system of two parabolic equations can hold, we prove this result for some general couplings.

Key words. Carleman inequalities, system of parabolic equations, controllability

1. Introduction.

Let $\Omega \subset \mathbb{R}^N$ $(N \geq 1)$ be a bounded connected open set whose boundary $\partial\Omega$ is regular enough. Let $T > 0$, and let $\omega \subset \Omega$ be a (small) nonempty open subset which will usually be referred to as a *control domain*. We will use the notation $Q = \Omega \times (0,T)$ and $\Sigma = \partial\Omega \times (0,T)$.

The main objective of this paper is to establish some new controllability results for coupled parabolic equations.

The first main result of this paper concerns insensitizing controls. More precisely, we want to insensitize a functional associated with a state system, which is a linear parabolic equation. Let us introduce an open set $\mathcal{O} \subset \Omega$, which is called the *observatory* (or observation open set).

In order to state our problem, we introduce the following system:

$$\begin{cases} y_t - \Delta y + ay + B \cdot \nabla y = v1_\omega + f & \text{in } Q, \\ y = 0 & \text{on } \Sigma, \\ y|_{t=0} = y^0 + \tau\widehat{y}^0 & \text{in } \Omega. \end{cases} \tag{1}$$

Here, v is the control, $y^0 \in L^2(\Omega)$, and $a \in \mathbf{R}$ and $B \in \mathbf{R}^N$ are constants. Furthermore, we suppose that $\widehat{y}^0$ is unknown with $\|\widehat{y}^0\|_{L^2(\Omega)} = 1$ and that τ is a small unknown real number. Then, the interpretation of system (1) is that y is the temperature of a body, v is a localized heat source, (where we have access to the body) to be chosen, f is another heat source, and the initial state of the body is partially unknown.

In general, the functional J_τ we would like to insensitize (which is called *sentinel*) has to be differentiable. In this framework, the task is to find a control v such that the influence of the unknown data $\tau\widehat{y}^0$ is not perceptible for J_τ (see (3) below).

In the literature, the usual functional is given by the L^2 norm of the state (see [4], [6], or [19], for instance). Here, we are interested in insensitizing the L^2 norm of

the gradient of the state (solution of (1)). Thus, let us introduce the functional

$$J_\tau(y) = \iint_{\mathcal{O}\times(0,T)} |\nabla y|^2 \, dx\, dt, \tag{2}$$

where y is the solution of (1).

Our objective is to find a control v such that the presence of the unknown data is imperceptible for J_τ, that is to say, such that

$$\frac{\partial J_\tau}{\partial \tau}(y)|_{\tau=0} = 0 \quad \forall\, \widehat{y}^0 \in L^2(\Omega) \quad \text{such that } \|\widehat{y}^0\|_{L^2(\Omega)} = 1. \tag{3}$$

If this holds, we will say that the control v insensitizes the functional J_τ.

Usually, insensitizing problems are formulated in an equivalent way as a controllability problems of a cascade system (see, for instance, [17] and [4] for a rigorous deduction of this fact). Indeed, if we consider the adjoint state of (1) (or apply the Lagrange principle), it is very easy to see that condition (3) is equivalent to $w|_{t=0} \equiv 0$ in Ω, where w together with z fulfills

$$\begin{cases} z_t - \Delta z + az + B\cdot\nabla z = v1_\omega + f & \text{in } Q, \\ -w_t - \Delta w + aw - B\cdot\nabla w = \nabla\cdot(\nabla z 1_{\mathcal{O}}) & \text{in } Q, \\ z = 0,\ w = 0 & \text{on } \Sigma, \\ z|_{t=0} = y^0,\ w|_{t=T} = 0 & \text{in } \Omega. \end{cases} \tag{4}$$

Here, we have denoted $z \equiv y|_{\tau=0}$. Assume for a moment that $y^0 \in L^2(\Omega)$ and $f,\, v \in L^2(Q)$. Then, it is not difficult to prove that there exists a unique solution (z, w) of (4) which belongs to $L^2(0,T; H_0^1(\Omega))^2$ and depends continuously on (y^0, f, v) in $L^2(\Omega)\times L^2(Q)^2$.

To our best knowledge, the first time this kind of problem was addressed was in [18] for second and fourth order parabolic equations of the heat kind and for the Navier–Stokes system. As we said above, all results around this subject concern the functional $\tilde{J}_\tau(y) = \|y\|^2_{L^2(\mathcal{O}\times(0,T))}$ with y a solution of a parabolic system. In [4], the authors prove the existence of ε-insensitizing controls (i. e., such that $|J'_\tau(y)|_{\tau=0}| \le \varepsilon$) for solutions of a semilinear heat system with C^1 and globally Lipschitz nonlinearities. In [6], the author proved the existence of insensitizing controls for the same system. For an extension of this result to more general nonlinearities, see [5] and the references therein.

As we shall see in the statement of Theorem 1 below, we will take $y^0 \equiv 0$. For a justification of this fact and a possible choice of more general initial conditions, see [6].

Throughout this paper we will suppose that $\omega \cap \mathcal{O} \neq \emptyset$. This is a condition that has always been imposed in the literature where insensitizing controls are concerned. Recently, for the (simpler) situation of looking for an ε-insensitizing control and the functional $\tilde{J}_\tau$, it has been demonstrated that this condition is not necessary for solutions of linear heat equations (see [7]).

The controllability result for system (4) is given in the following theorem.

THEOREM 1. *Let $m > 3$ be a real number and $y^0 \equiv 0$. Then, there exists a constant $K_0 > 0$ depending on $\Omega, \omega, \mathcal{O}, T, a$, and B such that for any $f \in L^2(Q)$ satisfying $\|e^{K_0/t^m} f\|_{L^2(Q)} < +\infty$, there exists a control v such that the corresponding solution (w, z) of (4) satisfies $w|_{t=0} \equiv 0$ in Ω.*

COROLLARY 2. *There exists insensitizing controls v of the functional J_τ given by* (2).

Remark 1. The same result holds when a and B are functions which depends only on the time variable t and are in $L^\infty(0,T)$. The proof of this fact is direct from that of Theorem 1.

Let us briefly explain the difficulties a controllability result for system (4) possesses. For this, we introduce the associated adjoint system:

$$\begin{cases} -\psi_t - \Delta\psi + a\psi - B\cdot\nabla\psi = \nabla\cdot((\nabla\varphi)1_{\mathcal{O}}) & \text{in } Q, \\ \varphi_t - \Delta\varphi + a\varphi + B\cdot\nabla\varphi = 0 & \text{in } Q, \\ \psi = 0,\ \varphi = 0 & \text{on } \Sigma, \\ \psi|_{t=T} = 0,\ \varphi|_{t=0} = \varphi^0 & \text{in } \Omega. \end{cases} \tag{5}$$

It is by now a classical fact that the null controllability result we want to prove for system (4) is equivalent to the following *observability inequality*:

$$\iint_Q e^{-K_0/t^m}|\varphi|^2\,dx\,dt \le C\iint_{\omega\times(0,T)}|\psi|^2\,dx\,dt, \tag{6}$$

where m is some positive number and C and K_0 are two positive constants depending on $\Omega, \omega, \mathcal{O}, T$, a, and B but independent of φ^0 (see, for instance, [14] or [11]). The main idea one usually follows in order to prove (6) is a combination of observability inequalities for ψ and φ (as solutions of heat equations) and trying to eliminate the local term (concentrated in $\omega\times(0,T)$) concerning φ. The great difficulty one encounters when trying this for system (5) is that no local estimate of the kind

$$\iint_{\widetilde{\omega}\times(0,T)}|\varphi|^2\,dx\,dt \le C\iint_{\omega\times(0,T)}|\Delta\varphi|^2\,dx\,dt, \quad \widetilde{\omega}\subset\omega,$$

can be obtained using local arguments (observe that ω can be taken as small as we want, so we can always suppose that $\overline{\omega}\cap\partial\Omega = \emptyset$).

This means that we have to find another way to locally relate φ and ψ. The idea we follow here is to first obtain an observability inequality of the kind

$$\iint_Q e^{-K_1/t^m}|\varphi|^2\,dx\,dt \le C\iint_{\omega\times(0,T)}|\Delta\varphi|^2\,dx\,dt. \tag{7}$$

The reason why an estimate like (7) is not easy to prove relies on the fact that no boundary conditions are known for $\Delta\varphi$. More details about this are given in subsection 2.1, below.

Remark 2. Is this result true when the coefficients a and B depend on the space variable? We observe here that, in this situation, not even the following unique continuation property is known:

$$\psi = 0 \ \text{ in } \omega\times(0,T) \Rightarrow \varphi,\psi \equiv 0 \ \text{ in } \Omega\times(0,T).$$

As an extension of the result stated in Theorem 1, some insensibilization properties have recently been demonstrated for the more complicated situation of a system

of the Stokes kind. More precisely, we consider the functional $\tilde{J}_\tau$, with y the solution of

$$\begin{cases} y_t - \Delta y + ay + B \cdot \nabla y + \nabla p = v1_\omega + f & \text{in } Q, \\ \nabla \cdot y = 0 & \text{in } Q, \\ y = 0 & \text{on } \Sigma, \\ y|_{t=0} = \tau \widehat{y}^0 & \text{in } \Omega, \end{cases}$$

with a and B constants. In [13], the existence of controls insensitizing $\tilde{J}_\tau$ is established. See also [13] for an extension of this to more general functionals and further controllability results for coupled Stokes-like systems.

The second and main objective of this paper is to extend the previous controllability result to more intrinsic coupled parabolic systems. The question is, Which coupling do we need to be able to control the whole system with only one control force?

As far as the controllability of strongly coupled parabolic equations is concerned, in the literature the local exact controllability of phase field systems was proved in [3], while the global version was later proved in [1]. For more general coupled parabolic equations with only one control force, some results have been given in [2] and [12].

In this paper, we will concentrate on studying the null controllability of systems of two parabolic equations, where the coupling terms are first order space derivatives in one equation and second order space derivatives in the other. In this situation, we will be again interested in controlling only one of the two equations while driving both states to zero at $t = T$.

We consider, for instance, the case where we control the lower order coupling term equation. We set the following control coupled system:

$$\begin{cases} w_t - \Delta w + cw + E \cdot \nabla w = P_2(t,x;D)(z\,\theta_2) & \text{in } Q, \\ z_t - \Delta z + hz + K \cdot \nabla z = P_1(t,x;D)(w\,\theta_1) + v1_\omega & \text{in } Q, \\ w = z = 0 & \text{on } \Sigma, \\ w|_{t=0} = w^0, \quad z|_{t=0} = z^0 & \text{in } \Omega, \end{cases} \tag{8}$$

where c, E, h, and K are constants and $P_i(t,x;D)$ $(i = 1, 2)$ is a partial differential operator in the space variables of order i such that

$$P_i(t,x;D)u = \sum_{|\beta| \le i} m_{i,\beta}(t,x)\partial_x^\beta u, \quad m_{i,\beta} \in L^\infty(0,T;W^{2/i,\infty}(\Omega)) \tag{9}$$

(that is to say, $m_{2,\beta}$, $\partial_x(m_{2,\beta})$, $m_{1,\beta}$, $\partial_x(m_{1,\beta})$, $\partial_x^2(m_{1,\beta}) \in L^\infty(Q)$). In (8), $\theta_i \in C^2(\overline{\Omega})$ $(1 \le i \le 2)$. We assume that there exists a nonempty open set $\omega_2 \subset \omega$ and a constant $C > 0$ such that $|\theta_2| \ge C > 0$ in ω_2. Observe that, in particular, one can take θ_1 and θ_2 to have a support as small as we want (one can also take $\theta_1 \equiv \theta_2 \equiv 1$ in Ω, which is the best possible situation).

Also for system (8) we have the existence and uniqueness of solution (w, z). For instance, if $v \in L^2(Q)$ and $(w^0, z^0) \in L^2(\Omega)^2$, then $(w, z) \in L^2(0,T;H_0^1(\Omega))^2$, which depends continuously on $(v, w^0, z^0) \in L^2(Q) \times L^2(\Omega)^2$.

Our objective here is to drive both w and z to zero at time T by means of the control v. Accordingly, we consider the corresponding adjoint system:

$$\begin{cases} -\varphi_t - \Delta\varphi + c\varphi - E\cdot\nabla\varphi = (P_1^*(t,x;D)\psi)\theta_1 & \text{in } Q,\\ -\psi_t - \Delta\psi + h\psi - K\cdot\nabla\psi = (P_2^*(t,x;D)\varphi)\theta_2 & \text{in } Q,\\ \varphi = \psi = 0 & \text{on } \Sigma,\\ \varphi|_{t=T} = \varphi^0, \quad \psi|_{t=T} = \psi^0 & \text{in } \Omega, \end{cases} \tag{10}$$

where P_1^* and P_2^* are the adjoint operators of P_1 and P_2, respectively.

It is very easy to prove the classical fact that the previous controllability property is equivalent to the following observability inequality:

$$\|\varphi|_{t=0}\|^2_{L^2(\Omega)} + \|\psi|_{t=0}\|^2_{L^2(\Omega)} \le C \iint_{\omega\times(0,T)} |\psi|^2\,dx\,dt,$$

with $C = C(\Omega,\omega,T) > 0$ independent of (φ^0,ψ^0).

In order to achieve this, we need the following properties to hold for the differential operator P_2:

$$m_{2,\beta} \text{ are constant} \tag{11}$$

and

$$\|u\|_{H^2(\Omega)} \le C\|P_2^*u\|_{L^2(\Omega)} \quad \forall u \in H^2(\Omega)\cap H_0^1(\Omega), \tag{12}$$

for some $C = C(\Omega) > 0$.

Observe that no boundary condition for $P_2^*\varphi$ is demanded.

THEOREM 3. *Assume that conditions* (11)–(12) *hold. Then, there exists a control* v *such that the solution of* (8) *satisfies* $w|_{t=T} \equiv z|_{t=T} \equiv 0$ *in* Ω.

Remark 3. Other boundary conditions can be considered in system (8). For instance, if one imposes Neumann boundary conditions, Theorem 3 also holds when we impose

$$\|u\|_{H^2(\Omega)} \le C\|P_2^*u\|_{L^2(\Omega)} \quad \forall u \in H^2(\Omega),\ \frac{\partial u}{\partial n}|_\Sigma = 0 \tag{13}$$

instead of (12).

In general, if one imposes $Bw|_\Sigma = 0$ as a boundary condition for w in (8), Theorem 3 holds if

$$\|u\|_{H^2(\Omega)} \le C\|P_2^*u\|_{L^2(\Omega)} \quad \forall u \in H^2(\Omega),\ Bu|_\Sigma = 0. \tag{14}$$

Remark 4. One can extend the result stated in Theorem 3 to the case where c, E h, and K are functions which depend on time and belong to $L^\infty(0,T)$, no matter which boundary conditions are considered.

Remark 5. Instead of the operator P_2, one could have also considered an operator L containing a first order time derivative. Indeed, let

$$Lu = \sum_{|\gamma|\le 1} \ell_\gamma\,\partial_t^\gamma u, \quad \ell_\gamma \text{ constants.}$$

Then, Theorem 3 holds for L instead of P_2. Observe that the proof in this situation is simpler, since the boundary conditions satisfied by φ are also satisfied by $L^*\varphi$.

Remark 6. A combination of Theorem 3, Remark 3, and Remark 5 yields that when we consider the differential operator

$$Qu = \sum_{|\gamma|\leq 1, |\beta|\leq 2} (\ell_\gamma \, \partial_t^\gamma + m_\beta \partial_x^\beta) u, \quad \ell_\gamma, m_\beta \text{ constants}$$

instead of P_2, the result stated in Theorem 3 holds as long as

$$\|u\|_{H^2(\Omega)} \leq C \|Q^* u\|_{L^2(\Omega)} \quad C = C(\Omega) > 0,$$

for any $u \in H^2(\Omega)$ satisfying the same boundary conditions as w in (8).

Finally, we consider the situation where we control the higher order coupling term equation. Thus, let us introduce the following system:

$$\begin{cases} \mathbf{p}_t - \Delta \mathbf{p} + c\mathbf{p} + E \cdot \nabla \mathbf{p} = \overrightarrow{P_2}(t,x;D)(q\,\theta_4) + \mathbf{v}1_\omega & \text{in } Q, \\ q_t - \Delta q + hq + K \cdot \nabla q = P_1(t,x;D)(\mathbf{p}\,\theta_3) & \text{in } Q, \\ \mathbf{p} = q = 0 & \text{on } \Sigma, \\ \mathbf{p}|_{t=0} = \mathbf{p}^0, \quad q|_{t=0} = q^0 & \text{in } \Omega. \end{cases} \tag{15}$$

Here, $\mathbf{p}$ is a vector-valued function and $\overrightarrow{P_2}$ a vectorial differential operator of order 2 in space such that each component is given by (9) for $i = 2$. On the other hand, q is a scalar-valued function and P_1 is a divergence-type operator, that is to say, $P_1\mathbf{f} \in \mathbf{R}$ for $\mathbf{f}$ a vector-valued function. Finally, $\theta_i \in C^2(\overline{\Omega})$ $(3 \leq i \leq 4)$ and we assume the existence of a nonempty open subset $\omega_3 \subset \omega$ and a positive constant C such that $\theta_3 \geq C > 0$ in ω_3.

For $\mathbf{v} \in L^2(Q)^N$ and $(\mathbf{p}^0, q^0) \in L^2(\Omega)^{N+1}$, there exists a unique solution $(\mathbf{p}, q) \in L^2(0,T; H_0^1(\Omega))^{N+1}$ which depends continuously on $(\mathbf{v}, \mathbf{p^0}, q^0) \in L^2(Q)^N \times L^2(\Omega)^{N+1}$.

Observe that now we are controlling the first equation. Obviously, the adjoint system associated with (15) is again (10). In order to establish the corresponding null controllability result, this time we need to impose the following conditions on the operator P_1:

$$m_{1,\beta} \text{ are constant} \tag{16}$$

and

$$\|u\|_{L^2(0,T;H^1(\Omega))} \leq C \|\overrightarrow{P_1^*} u\|_{L^2(Q)^N} \quad \forall u \in H_0^1(\Omega). \tag{17}$$

The corresponding result in this situation is presented in the following theorem.

THEOREM 4. *Assume conditions* (16)–(17) *are satisfied. Then, there exists a control* v *such that the solution of* (15) *satisfies* $\mathbf{p}|_{t=T} \equiv q|_{t=T} \equiv 0$ *in* Ω.

Once Theorem 3 is demonstrated, one can follow the same ideas in order to prove Theorem 4 by just adapting the corresponding arguments.

For the sake of completeness, we present a system for which Theorem 4 applies (for simplicity, we take $\theta_3 \equiv \theta_4 \equiv 1$):

$$\begin{cases} \mathbf{p}_t - \Delta \mathbf{p} + c\mathbf{p} + E \cdot \nabla \mathbf{p} = (P_{2,1}, \dots, P_{2,N})q, + \mathbf{v}1_\omega & \text{in } Q, \\ q_t - \Delta q + hq + K \cdot \nabla q = \nabla \cdot \mathbf{p} & \text{in } Q, \\ \mathbf{p} = q = 0 & \text{on } \Sigma, \\ \mathbf{p}|_{t=0} = \mathbf{p}^0, \quad q|_{t=0} = q^0 & \text{in } \Omega, \end{cases}$$

with $P_{2,j}$ differential operators of order 2 in the x variable satisfying (9).

This paper is organized as follows. In section 2, we prove Theorem 1. In subsection 2.1 we prove new Carleman-type estimates, which will be crucial for this proof, and in subsection 2.2 we combine some results and conclude its proof. Finally, in section 3 we prove Theorem 3.

2. Insensitizing controls for the functional J_τ. As we saw in the introduction, we can restrict ourselves to proving the null controllability of the coupled system (4), that is to say, Theorem 1.

As usual, in order to prove this result we concentrate on the corresponding adjoint system:

$$\begin{cases} -\varphi_t - \Delta\psi + a\psi - B\cdot\nabla\psi = \nabla\cdot((\nabla\varphi)1_{\mathcal{O}}) & \text{in } Q,\\ \varphi_t - \Delta\varphi + a\varphi + B\cdot\nabla\varphi = 0 & \text{in } Q,\\ \psi = 0,\ \varphi = 0 & \text{on } \Sigma,\\ \psi|_{t=T} = 0,\ \varphi|_{t=0} = \varphi^0 & \text{in } \Omega, \end{cases} \tag{18}$$

where $\varphi^0 \in L^2(\Omega)$. As explained in the introduction, in the framework of controllability it is a classical fact that the null controllability property for system (4) is equivalent to the following observability inequality:

$$\iint_Q e^{-K_0/t^m}|\psi|^2\,dx\,dt \le C\iint_{\omega\times(0,T)}|\psi|^2\,dx\,dt, \tag{19}$$

for certain positive constants K_0 and C which are independent of ψ^0, and for some positive m.

For the proof of (19), we will follow a classical approach consisting of obtaining a suitable weighted-like estimate (the so-called *Carleman estimate*) similar to the observability inequality. For a systematic use of this kind of estimate see, for instance, [14] or [11].

In order to establish this Carleman inequality, we need to define some weight functions:

$$\begin{gathered} \alpha_m(x,t) = \frac{\exp\{\frac{k(m+1)}{m}\lambda\|\eta^0\|_\infty\} - \exp\{\lambda(k\|\eta^0\|_\infty + \eta^0(x))\}}{t^m(T-t)^m},\\ \alpha_m^*(t) = \max_{x\in\overline{\Omega}}\alpha_m(x,t) = \alpha_m|_{\partial\Omega}(x,t), \quad \xi_m(x,t) = \frac{e^{\lambda(k\|\eta^0\|_\infty+\eta^0(x))}}{t^m(T-t)^m},\\ \xi_m^*(t) = \min_{x\in\overline{\Omega}}\xi_m(x,t) = \xi_m|_{\partial\Omega}(x,t), \end{gathered} \tag{20}$$

where $m > 3$ and $k > m$ are fixed. Here, $\eta^0 \in C^2(\overline{\Omega})$ satisfies

$$|\nabla\eta^0| \ge C > 0 \ \text{ in } \Omega\setminus\overline{\omega_0}, \quad \eta^0 > 0 \ \text{ in } \Omega, \quad \text{and} \quad \eta^0 \equiv 0 \ \text{ on } \partial\Omega, \tag{21}$$

with $\emptyset \ne \omega_0 \subset \omega\cap\mathcal{O}$ an open set. The proof of the existence of such a function η^0 is given in [11]. The weights (20) were first considered in [10] in order to obtain Carleman estimates for the three-dimensional micropolar fluid model.

Accordingly, we define $I(s,\lambda;\cdot)$ as follows:

$$
\begin{aligned}
I(s,\lambda;g) := {} & s^{-1}\iint_Q e^{-2s\alpha_m}\xi_m^{-1}\left(|g_t|^2+|\Delta g|^2\right)\,dx\,dt \\
& + \ s\lambda^2\iint_Q e^{-2s\alpha_m}\xi_m|\nabla g|^2\,dx\,dt + s^3\lambda^4\iint_Q e^{-2s\alpha_m}\xi_m^3|g|^2\,dx\,dt.
\end{aligned}
\tag{22}
$$

Furthermore, we denote by $I_w(s,\lambda,\cdot)$ the terms in the expression of $I(s,\lambda,\cdot)$ concerning the $L^2(Q)$ and $L^2(0,T;H_0^1(\Omega))$ norms (that is, the integrals appearing in the second line of (22)).

With this notation, we can prove the following result.

PROPOSITION 5. *There exists a positive constant C which depends on Ω, ω, and T such that*

$$
\begin{aligned}
& I_w(\Delta\varphi) + s^2\lambda^4\iint_Q e^{-3s\alpha_m}\xi_m^2(s^2\lambda^2\xi_m^2|\psi|^2+|\nabla\psi|^2)\,dx\,dt \\
& \qquad \le C(1+T^2)s^7\lambda^8\iint_{\omega\times(0,T)} e^{-2s\alpha_m}\xi_m^7|\psi|^2\,dx\,dt,
\end{aligned}
\tag{23}
$$

for any $\lambda \ge C$ and $s \ge C(T^{2m}+T^m)$.

Remark 7. From the Carleman inequality (23), one can readily deduce the observability inequality (19). Indeed, it suffices to combine the fact that $\psi|_{t=T} \equiv 0$ with the dissipation of $\|\nabla\varphi(t)\|_{L^2(\Omega)}$ as t goes to T (see, for instance, [11]). As a consequence, the proof of Theorem 1 is achieved.

The proof of Proposition 5 is divided into two steps, which correspond to subsections 2.1 and 2.2. The first, and more important, step deals with the equation satisfied by φ (which is independent of ψ). In the second step, we combine both equations in order to conclude the desired inequality (23).

Before starting with this, we recall a Carleman estimate which will be essential in our proof.

This estimate concerns energy solutions of heat equations with nonhomogeneous Neumann boundary conditions.

LEMMA 6. *Let $u^0 \in L^2(\Omega)$, $f_1 \in L^2(Q)$, $f_2 \in L^2(Q)^N$, and $f_3 \in L^2(\Sigma)$. Then there exists a constant $C(\Omega,\omega_0) > 0$ such that the solution $u \in L^2(0,T;H^1(\Omega)) \cap L^\infty(0,T;L^2(\Omega))$ of*

$$
\begin{cases}
u_t - \Delta u = f_1 + \nabla\cdot f_2 & \text{in } Q,\\
\dfrac{\partial u}{\partial n} + f_2.n = f_3 & \text{on } \Sigma,\\
u|_{t=T} = u^0 & \text{in } \Omega
\end{cases}
$$

satisfies

$$
\begin{aligned}
I_w(u) \le C\Bigg(& s^3\lambda^4\iint_{\omega_0\times(0,T)} e^{-2s\alpha_m}\xi_m^3|u|^2\,dx\,dt \\
& + \iint_Q e^{-2s\alpha_m}|f_1|^2\,dx\,dt + s^2\lambda^2\iint_Q e^{-2s\alpha_m}\xi_m^2|f_2|^2\,dx\,dt \\
& + \ s\lambda\iint_\Sigma e^{-2s\alpha_m^*}\xi_m^*|f_3|^2\,d\sigma\,dt\Bigg)
\end{aligned}
$$

for any $\lambda \geq C$ *and* $s \geq C(T^{2m} + T^{2m-1})$.

This lemma was essentially proved in [8]. In fact, the inequality proved in [8] concerned the same weight functions as in (24), but with $m = 1$. Then one can follow the steps of the proof in [8] (see Theorem 1 in that reference) and adapt the arguments by just taking into account that

$$\partial_t \alpha_m := \alpha_{m,t} \leq CT\xi_m^{(m+1)/m} \quad \text{and} \quad \partial_{tt}\alpha_m := \alpha_{m,tt} \leq CT^2\xi_m^{(m+2)/m},$$

with $C > 0$ independent of s, λ, and T.

2.1. New Carleman estimate for φ. Here we deal with the problem

$$\begin{cases} \varphi_t - \Delta\varphi + a\varphi + B \cdot \nabla\varphi = 0 & \text{in } Q, \\ \varphi = 0 & \text{on } \Sigma, \\ \varphi|_{t=0} = \varphi^0 & \text{in } \Omega. \end{cases} \tag{24}$$

Recall that $a \in \mathbf{R}$ and $B \in \mathbf{R}^N$ are constants.

For this system, we prove the following estimate.

LEMMA 7. *There exists a positive constant* C *depending on* Ω *and* ω_0 *such that*

$$I_w(\Delta\varphi) \leq Cs^3\lambda^4 \iint_{\omega_0\times(0,T)} e^{-2s\alpha_m}\xi_m^3|\Delta\varphi|^2\,dx\,dt, \tag{25}$$

for any $\lambda \geq C$ *and* $s \geq C(T^{2m} + T^m)$.

Remark 8. Observe that, in particular, we deduce from this inequality the following well-known unique continuation property:

$$\Delta\varphi = 0 \ \text{ in } \omega_0 \times (0,T) \Rightarrow \varphi \equiv 0 \ \text{ in } \Omega \times (0,T). \tag{26}$$

As far as we know, it is a new fact that (26) can be quantified in terms of an inequality like (25). On the other hand, we do not know if (26) holds when a and B are not constant with respect to the space variable.

Proof of Lemma 7. We first look at the equation satisfied by $\Delta\varphi$:

$$(\Delta\varphi)_t - \Delta(\Delta\varphi) + a\Delta\varphi + B \cdot \nabla\Delta\varphi = 0 \quad \text{in } Q.$$

Observe that no boundary conditions are prescribed for $\Delta\varphi$. At this point, we can apply Lemma 6 (with $f_2 \equiv 0$) and deduce the existence of a constant $C = C(\Omega, \omega_0) > 0$ such that

$$\begin{aligned} I_w(\Delta\varphi) \leq C \Bigg(& s^3\lambda^4 \iint_{\omega_0\times(0,T)} e^{-2s\alpha_m}\xi_m^3|\Delta\varphi|^2\,dx\,dt \\ & + s\lambda \iint_\Sigma e^{-2s\alpha_m^*}\xi_m^* \left|\frac{\partial\Delta\varphi}{\partial n}\right|^2 \Bigg)\,dx\,dt \end{aligned} \tag{27}$$

for any $\lambda \geq C$ and $s \geq C(T^{2m} + T^{2m-1})$.

The next step will be to eliminate the last term in the right-hand side of (27). In order to do this, we introduce the function $\varphi^* := \eta(t)\varphi$, where

$$\eta(t) = s^{(1/2)-(1/m)}\lambda e^{-s\alpha_m^*(t)}(\xi_m^*)^{(1/2)-(1/m)}(t). \tag{28}$$

In view of (24), it fulfills

$$\begin{cases} \varphi_t^* - \Delta\varphi^* + a\varphi^* + B\cdot\nabla\varphi^* = \eta_t\varphi & \text{in } \Omega, \\ \varphi^* = 0 & \text{on } \partial\Omega, \\ \varphi^*|_{t=0} = 0 & \text{in } \Omega. \end{cases} \tag{29}$$

Thanks to (27), we are going to deduce that φ^* is a very regular function. In fact, we have that $\eta_t\varphi \in L^2(0,T;H^2(\Omega)\cap H_0^1(\Omega))$, since $\eta_t\Delta\varphi \in L^2(\Omega)$ and

$$\begin{aligned} \|\eta_t\Delta\varphi\|_{L^2(Q)} &\le CTs^{(3/2)-(1/m)}\lambda\|e^{-s\alpha_m^*}(\xi_m^*)^{3/2}\Delta\varphi\|_{L^2(Q)} \\ &\le Cs^{3/2}\lambda\|e^{-s\alpha_m^*}(\xi_m^*)^{3/2}\Delta\varphi\|_{L^2(Q)}, \end{aligned}$$

for $s \ge CT^m$. The square of this last quantity is bounded by the left-hand side of (27) (recall that $e^{-s\alpha_m^*}$ is the minimum of $e^{-s\alpha_m}$).

Consequently, we have that $\varphi^* \in L^2(0,T;(H^4\cap H_0^1)(\Omega))$ (see, for instance, [16]) and

$$\begin{aligned} \|\varphi^*\|^2_{L^2(0,T;H^4(\Omega))} &= s^{1-2/m}\lambda^2\int_0^T e^{-2s\alpha_m^*}(\xi_m^*)^{1-2/m}\|\varphi\|^2_{H^4(\Omega)}\,dt \\ &\le CI_w(\Delta\varphi). \end{aligned} \tag{30}$$

Taking this into account, by a simple integration by parts we deduce that

$$s^{2-1/m}\lambda^3\int_0^T e^{-2s\alpha_m^*}(\xi_m^*)^{2-1/m}\|\varphi\|^2_{H^3(\Omega)}\,dt \le CI_w(\Delta\varphi). \tag{31}$$

From (30) and (31), we obtain in particular that

$$s^{(3/2)-3/(2m)}\lambda^3\int_0^T e^{-2s\alpha_m^*}(\xi_m^*)^{(3/2)-3/(2m)}\left\|\frac{\partial\Delta\varphi}{\partial n}\right\|^2_{L^2(\Sigma)}\,dt \le CI_w(\Delta\varphi). \tag{32}$$

Since $m > 3$, this justifies that the second term in the right-hand side of (27) is absorbed by the left-hand side. As a conclusion, we obtain the desired inequality (25).

2.2. Carleman estimate for φ and conclusion. Finally, we will deal with the particular coupling of ψ and φ.

First, assuming φ is given, we apply a Carleman estimate to the weak solution ψ of (18) (observe that the right-hand side of the equation satisfied by ψ belongs, for instance, to $L^2(0,T;H^{-1}(\Omega))$), which can be found in [15] (for the explicit dependence with respect to λ and T, see [9]):

$$\begin{aligned} &s^4\lambda^6\iint_Q e^{-3s\alpha_m}\xi_m^4|\psi|^2\,dx\,dt + s^2\lambda^4\iint_Q e^{-3s\alpha_m}\xi_m^2|\nabla\psi|^2\,dx\,dt \\ &\qquad\le C\left(s^4\lambda^6\iint_{\omega_0\times(0,T)} e^{-3s\alpha_m}\xi_m^4|\psi|^2\,dx\,dt\right. \\ &\qquad\qquad\left. + s^3\lambda^4\iint_{\mathcal{O}\times(0,T)} e^{-3s\alpha_m}\xi_m^3|\nabla\varphi|^2\,dx\,dt\right), \end{aligned} \tag{33}$$

for any $\lambda \geq C$ and $s \geq C(T^{2m} + T^{2m-1})$. Observe that we have chosen to apply this result for smaller exponentials, that is to say, for $e^{-3s\alpha_m}$ instead of $e^{-2s\alpha_m}$.

Then we easily see that the last integral in the right-hand side of (33) is bounded by $I_w(\Delta\varphi)$, as long as λ is large enough. In fact, if we denote $\widehat{\alpha}_m(t) = \min_{x\in\overline{\Omega}} \alpha_m(x,t)$ and $\widehat{\xi}_m(t) = \max_{x\in\overline{\Omega}} \xi_m(x,t)$, we have

$$s^3\lambda^4 \iint_{\mathcal{O}\times(0,T)} e^{-3s\alpha_m}\xi_m^3 |\nabla\varphi|^2 \,dx\,dt \leq s^3\lambda^4 \int_0^T e^{-3s\widehat{\alpha}_m}(\widehat{\xi}_m)^3 \|\nabla\varphi\|^2_{L^2(\Omega)}\,dt$$
$$\leq Cs^3\lambda^4 \int_0^T e^{-3s\widehat{\alpha}_m}(\widehat{\xi}_m)^3 \|\Delta\varphi\|^2_{L^2(\Omega)}\,dt \leq Cs^3\lambda^4 \iint_Q e^{-2s\alpha_m}\xi_m^3|\Delta\varphi|^2\,dx\,dt,$$

for $\lambda \geq C$. Here we have used the fact that φ has null trace.

Combining this with (25) and (33), we obtain

$$\begin{aligned} &s^2\lambda^4 \iint_Q e^{-3s\alpha_m}\xi_m^2 (s^2\lambda^2\xi_m^2|\psi|^2 + |\nabla\psi|^2)\,dx\,dt + I_w(\Delta\varphi) \\ &\leq C\left(s^3\lambda^4 \iint_{\omega_0\times(0,T)} \xi_m^3 \left(s\lambda^2 e^{-3s\alpha_m}\xi_m|\psi|^2 + e^{-2s\alpha_m}|\Delta\varphi|^2\right)\,dx\,dt\right), \end{aligned} \tag{34}$$

for any $\lambda \geq C$ and $s \geq C(T^{2m} + T^m)$.

Now, since $\omega_0 \subset \mathcal{O}$, from the equation satisfied by ψ, we find

$$\Delta\varphi = -\psi_t - \Delta\psi + a\psi - B\cdot\nabla\psi \ \text{ in } \omega_0\times(0,T).$$

Then we plug this into the expression of the last integral in (34) and obtain

$$s^3\lambda^4 \iint_{\omega_0\times(0,T)} e^{-2s\alpha_m}\xi_m^3|\Delta\varphi|^2\,dx\,dt$$
$$= s^3\lambda^4 \iint_{\omega_0\times(0,T)} e^{-2s\alpha_m}\xi_m^3(\Delta\varphi)(-\psi_t - \Delta\psi + a\psi - B\cdot\nabla\psi)\,dx\,dt.$$

We define a positive function $\theta \in C_c^2(\omega)$ such that $\theta \equiv 1$ in ω_0. Then the task turns to estimating the following integral:

$$s^3\lambda^4 \iint_{\omega\times(0,T)} \theta e^{-2s\alpha_m}\xi_m^3(\Delta\varphi)(-\psi_t - \Delta\psi + a\psi - B\cdot\nabla\psi)\,dx\,dt.$$

After several integration by parts (getting all derivatives out of ψ) with respect to both space and time, we get

$$s^3\lambda^4 \iint_{\omega\times(0,T)} \theta e^{-2s\alpha_m}\xi_m^3(\Delta\varphi)(-\psi_t - \Delta\psi + a\psi - B\cdot\nabla\psi)\,dx\,dt$$
$$= s^3\lambda^4 \iint_{\omega\times(0,T)} \theta(e^{-2s\alpha_m}\xi_m^3)_t\,\Delta\varphi\,\psi\,dx\,dt$$
$$- s^3\lambda^4 \iint_{\omega\times(0,T)} \Delta(\theta e^{-2s\alpha_m}\xi_m^3)\,\Delta\varphi\,\psi\,dx\,dt$$
$$- 2s^3\lambda^4 \iint_{\omega\times(0,T)} \nabla(\theta e^{-2s\alpha_m}\xi_m^3)\cdot\nabla\Delta\varphi\,\psi\,dx\,dt$$
$$+ s^3\lambda^4 \iint_{\omega\times(0,T)} B\cdot\nabla(\theta e^{-2s\alpha_m}\xi_m^3)\,\Delta\varphi\,\psi\,dx\,dt.$$

Here, we have used the equation satisfied by φ and the fact that θ has compact support in ω. Let us do some computations involving the weight functions:

$$(e^{-2s\alpha_m}\xi_m^3)_t \leq CTse^{-2s\alpha_m}(\xi_m)^{4+1/m},$$

for $s \geq CT^{2m}$ and

$$\Delta(e^{-2s\alpha_m}\xi_m^3) \leq Cs^2\lambda^2 e^{-2s\alpha_m}\xi_m^5,$$

for $s \geq CT^{2m}$ and $\lambda \geq C$. With this, we obtain

$$\begin{aligned} &s^3\lambda^4 \iint_{\omega\times(0,T)} \theta e^{-2s\alpha_m}\xi_m^3(\Delta\varphi)(-\psi_t - \Delta\psi + a\psi - B\cdot\nabla\psi)\,dx\,dt \\ &\leq \varepsilon I_w(\Delta\varphi) + C(1+T^2)s^7\lambda^8 \iint_{\omega\times(0,T)} e^{-2s\alpha_m}\xi_m^7|\psi|^2\,dx\,dt, \end{aligned}$$

which, combined with (34), gives the desired inequality (23).

3. Proof of Theorem 3. In this section we will prove Theorem 3. As indicated in the introduction, in order to prove Theorem 4 one can follow the same ideas of the proof of Theorem 3.

For simplicity, in this section we will keep the notation η^0 for the function defined in (21). In the present situation, ω_0 will stand for an open set contained in ω_2, which was also contained in ω (see the paragraph between (9) and (10)).

Throughout this section we will work with the following system (see (10)):

$$\begin{cases} -\varphi_t - \Delta\varphi + c\varphi - E\cdot\nabla\varphi = (P_1^*(t,x;D)\psi)\theta_1 & \text{in } Q, \\ -\psi_t - \Delta\psi + h\psi - K\cdot\nabla\psi = (P_2^*\varphi)\theta_2 & \text{in } Q, \\ \varphi = \psi = 0 & \text{on } \Sigma, \\ \varphi|_{t=T} = \varphi^0, \quad \psi|_{t=T} = \psi^0 & \text{in } \Omega. \end{cases} \tag{35}$$

Recall that, by (11), P_2^* is a second order differential operator in space with constant coefficients.

In order to prove Theorem 3, it suffices to establish the following observability inequality for the solutions of (35).

PROPOSITION 8. *There exists $C(\Omega,\omega,T) > 0$ independent of (φ^0,ψ^0) such that*

$$\|\varphi|_{t=0}\|^2_{L^2(\Omega)} + \|\psi|_{t=0}\|^2_{L^2(\Omega)} \leq C\iint_{\omega\times(0,T)} |\psi|^2\,dx\,dt. \tag{36}$$

As in the previous section, the strategy will consist of proving the corresponding Carleman inequality for system (35). It is presented in the following lemma.

LEMMA 9. *There exists a positive constant $C(\Omega,\omega)$ such that*

$$\begin{aligned} &I_w(P_2^*\varphi) + s^6\lambda^8 \iint_Q e^{-2s\alpha_m}\xi_m^6|\psi|^2\,dx\,dt \\ &\qquad \leq C(1+T^2)s^{10}\lambda^8 \iint_{\omega\times(0,T)} e^{-6s\alpha_m+4s\alpha_m^*}\xi_m^{10}|\psi|^2\,dx\,dt \end{aligned} \tag{37}$$

for any $\lambda \geq C$ and $s \geq C(T^{2m}+T^m)$.

Thanks to (12), the observability inequality (36) readily follows from (37).

As in the proof of Lemma 7, we first deal with the heat equation satisfied by φ and we try to obtain an independent Carleman inequality, viewing $(P_1^*(t,x;D)\psi)\theta_1$ as a right-hand side. More precisely, we consider the heat equation satisfied by $P_2^*\varphi$:

$$(P_2^*\varphi)_t + \Delta(P_2^*\varphi) + cP_2^*\varphi + E\cdot\nabla(P_2^*\varphi) = \Delta((P_1^*(t,x;D)\psi)\theta_1) \ \text{ in } Q.$$

To $P_2^*\varphi$ (as solution of the previous heat equation), we apply Lemma 6 and we obtain

$$\begin{aligned} I_w(P_2^*\varphi) \le \Bigg(& s^3\lambda^4 \iint_{\omega_0\times(0,T)} e^{-2s\alpha_m}\xi_m^3 |P_2^*\varphi|^2 \,dx\,dt \\ & + s\lambda \iint_\Sigma e^{-2s\alpha_m^*}\xi_m^* \left(\left|\frac{\partial P_2^*\varphi}{\partial n}\right|^2 + \left|\frac{\partial}{\partial n}(P_1^*(t,x;D)\psi)\right|^2 \right) dx\,dt \\ & + s^2\lambda^2 \iint_Q e^{-2s\alpha_m}\xi_m^2 (|\Delta\psi|^2 + |\nabla\psi|^2 + |\psi|^2)\,dx\,dt \Bigg), \end{aligned} \tag{38}$$

for any $\lambda \ge C$ and $s \ge C(T^{2m} + T^{2m-1})$.

Next, we estimate the boundary term in the right-hand side of (38). To this end, we define $\varphi^* = \eta(t)\varphi$, with $\eta(t)$ given by (28). This function fulfills the following system:

$$\begin{cases} \varphi_t^* + \Delta\varphi^* + c\varphi^* + E\cdot\nabla\varphi^* = \eta(t)(P_1^*(t,x;D)\psi)\theta_1 + \eta_t\varphi & \text{in } \Omega, \\ \varphi^* = 0 & \text{on } \partial\Omega, \\ \varphi^*|_{t=T} = 0 & \text{in } \Omega. \end{cases} \tag{39}$$

Assuming that the right-hand side of (39) belongs to $L^2(0,T;H^2(\Omega))$, we have $\varphi^* \in L^2(0,T;(H^4\cap H_0^1)(\Omega)) \cap H^1(0,T;H^2(\Omega))$ (see, for instance, [16]) and

$$\begin{aligned} & \|\varphi^*\|^2_{L^2(0,T;H^4(\Omega))} + \|\varphi_t^*\|^2_{L^2(0,T;H^2(\Omega))} \\ & \qquad \le C(I_w(P_2^*\varphi) + \|\eta(t)(P_1^*(t,x;D)\psi)\theta_1\|_{L^2(0,T;H^2(\Omega))}). \end{aligned} \tag{40}$$

Here we have used (12).

With the same argument as in the previous section, we get

$$\begin{aligned} & s^{(3/2)-3/(2m)}\lambda^3 \int_0^T e^{-2s\alpha_m^*}(\xi_m^*)^{(3/2)-3/(2m)} \left\| \frac{\partial P_2^*\varphi}{\partial n}\right\|^2_{L^2(\Sigma)} dt \\ & \qquad \le C(I_w(P_2^*\varphi) + \|\eta(t)(P_1^*(t,x;D)\psi)\theta_1\|_{L^2(0,T;H^2(\Omega))}). \end{aligned} \tag{41}$$

Again, since $m > 3$, this justifies that the second term in the right-hand side of (38) is absorbed.

As a conclusion, we obtain from (38)

$$\begin{aligned} I_w(P_2^*\varphi) \le C\Bigg(& s^3\lambda^4 \iint_{\omega_0\times(0,T)} e^{-2s\alpha_m}\xi_m^3 |P_2^*\varphi|^2 \,dx\,dt \\ & + s^{1-2/m}\lambda^2 \int_0^T e^{-2s\alpha_m^*}(\xi_m^*)^{1-2/m} \|(P_1^*(t,x;D)\psi)\theta_1\|^2_{H^2(\Omega)}\,dt \\ & + s^2\lambda^2 \iint_Q e^{-2s\alpha_m}\xi_m^2 (|\Delta\psi|^2 + |\nabla\psi|^2 + |\psi|^2)\,dx\,dt \Bigg), \end{aligned} \tag{42}$$

for any $\lambda \geq C$ and $s \geq C(T^{2m} + T^m)$.

Now we deal with the equation satisfied by ψ. Thus, we apply the classical Carleman inequality for the heat equation with right-hand side in $L^2(Q)$. Let us define

$$I_0(\psi) = s^6\lambda^8 \iint_Q e^{-2s\alpha_m}\xi_m^6|\psi|^2\,dx\,dt + s^4\lambda^6 \iint_Q e^{-2s\alpha_m}\xi_m^4|\nabla\psi|^2\,dx\,dt + s^2\lambda^4 \iint_Q e^{-2s\alpha_m}\xi_m^2|\Delta\psi|^2\,dx\,dt.$$

Then we have

$$I_0(\psi) \leq C\bigg(s^6\lambda^8 \iint_{\omega_0\times(0,T)} e^{-2s\alpha_m}\xi_m^6|\psi|^2\,dx\,dt + s^3\lambda^4 \iint_Q e^{-2s\alpha_m}\xi_m^3|P_2^*\varphi|^2\,dx\,dt\bigg),$$

for $\lambda \geq C$ and $s \geq C(T^{2m} + T^{2m-1})$. Combining this with (42), we obtain

$$\begin{aligned} I_0(\psi) + I_w(P_2^*\varphi) \leq C\bigg(&s^3\lambda^4 \iint_{\omega_0\times(0,T)} e^{-2s\alpha_m}\xi_m^3|P_2^*\varphi|^2\,dx\,dt \\ &+ s^{1-2/m}\lambda^2 \int_0^T e^{-2s\alpha_m^*}(\xi_m^*)^{1-2/m}\|\psi\|^2_{H^3(\Omega)}\,dt \\ &+ s^6\lambda^8 \iint_{\omega_0\times(0,T)} e^{-2s\alpha_m}\xi_m^6|\psi|^2\,dx\,dt\bigg), \end{aligned} \tag{43}$$

for $\lambda \geq C$ and $s \geq C(T^{2m} + T^m)$.

Let us now introduce the function $\widehat{\psi} = \rho_0(t)\psi$, with

$$\rho_0(t) = s^{1/2}\lambda e^{-s\alpha_m^*}(\xi_m^*)^{1/2}.$$

Then $\widehat{\psi}$ satisfies

$$\begin{cases} \widehat{\psi}_t + \Delta\widehat{\psi} + h\widehat{\psi} + K\cdot\nabla\widehat{\psi} = \rho_0(t)(P_2^*\varphi)\theta_2 + \rho_{0,t}\psi & \text{in } \Omega, \\ \widehat{\psi} = 0 & \text{on } \partial\Omega, \\ \widehat{\psi}|_{t=T} = 0 & \text{in } \Omega. \end{cases} \tag{44}$$

Since the right-hand side belongs to $L^2(0,T;H^1(\Omega))$, we deduce that $\widehat{\psi} \in L^2(0,T;H^3(\Omega))$ and

$$\begin{aligned} \|\widehat{\psi}\|^2_{L^2(0,T;H^3(\Omega))} \leq C\bigg(&s\lambda^2 \iint_Q e^{-2s\alpha_m}\xi_m(|\nabla(P_2^*\varphi)|^2 + |P_2^*\varphi|^2)\,dx\,dt \\ &+ T^2s^3\lambda^2 \iint_Q e^{-2s\alpha_m^*}(\xi_m^*)^{3+2/m}|\nabla\psi|^2\,dx\,dt\bigg) \\ &\leq C(I_0(\psi) + I_w(P_2^*\varphi)). \end{aligned} \tag{45}$$

Observe that in inequality (45) we did not use all the information we had about φ, because in the argument of estimating the normal derivative of $P_2^*\varphi$, we obtained

good estimates for $\|\varphi\|^2_{L^2(0,T;H^3(\Omega))}$ with the power $s^{2-1/m}$. We chose not to profit from this for the sake of simplicity.

In particular, from (45) we deduce that the second term in the right-hand side of (43) is absorbed.

For the moment, we have

$$
\begin{aligned}
&I_0(\psi) + I_w(P_2^*\varphi) + \|\widehat{\psi}\|^2_{L^2(0,T;H^3(\Omega))} \\
&\qquad \le C\left(s^3\lambda^4 \iint_{\omega_0\times(0,T)} e^{-2s\alpha_m}\xi_m^3 |P_2^*\varphi|^2 \,dx\,dt \right. \\
&\qquad\qquad \left. + s^6\lambda^8 \iint_{\omega_0\times(0,T)} e^{-2s\alpha_m}\xi_m^6 |\psi|^2 \,dx\,dt \right),
\end{aligned} \tag{46}
$$

for $\lambda \ge C$ and $s \ge C(T^{2m} + T^m)$.

We will finally estimate the local term concerning $P_2^*\varphi$. From the equation satisfied by ψ, we have

$$
P_2^*\varphi = \psi_t + \Delta\psi + h\psi + K\cdot\nabla\psi \ \text{ in } \omega_0\times(0,T)
$$

(recall that supp $\theta_2 \subset \overline{\omega}_2$ and $\omega_0 \subset \omega_2$). This gives

$$
\begin{aligned}
&s^3\lambda^4 \iint_{\omega_0\times(0,T)} e^{-2s\alpha_m}\xi_m^3 |P_2^*\varphi|^2 \,dx\,dt \\
&= s^3\lambda^4 \iint_{\omega_0\times(0,T)} e^{-2s\alpha_m}\xi_m^3 (P_2^*\varphi)(\psi_t + \Delta\psi + h\psi + K\cdot\nabla\psi)\,dx\,dt.
\end{aligned}
$$

As in the previous section, with the help of a cut-off function $\theta_0 \in C_c^2(\omega)$ with $\theta_0 \equiv 1$ in ω_0, we can integrate by parts with respect to both time and space, and we find

$$
\begin{aligned}
&s^3\lambda^4 \iint_{\omega_0\times(0,T)} e^{-2s\alpha_m}\xi_m^3 |P_2^*\varphi|^2 \,dx\,dt \le \varepsilon(I_w(\Delta\varphi) + I_0(\psi)) \\
&+ C(1+T^2)s^6\lambda^6 \iint_{\omega\times(0,T)} f(\theta_0) e^{-4s\alpha_m + 2s\alpha_m^*}\xi_m^6 (|\psi|^2 + |\nabla\psi|^2)\,dx\,dt,
\end{aligned}
$$

for some $f(\theta_0) \in C_c^1(\omega)$. Observe that in order to estimate the first term

$$
\iint_{\omega\times(0,T)} e^{-2s\alpha_m}\xi_m^3\theta_0\, P_2^*\varphi\, \psi_t \,dx\,dt,
$$

we have integrated in time and used (40) for the integral

$$
\iint_{\omega\times(0,T)} e^{-2s\alpha_m}\xi_m^3\theta_0\, P_2^*\varphi_t\, \psi \,dx\,dt.
$$

We integrate by parts again and obtain

$$
\begin{aligned}
&s^3\lambda^4 \iint_{\omega_0\times(0,T)} e^{-2s\alpha_m}\xi_m^3 |P_2^*\varphi|^2 \,dx\,dt \\
&\qquad \le \varepsilon\left(I_w(P_2^*\varphi) + I_0(\psi) + s^2\lambda^4 \iint_Q e^{-2s\alpha_m}\xi_m^2 |\Delta\psi|^2 \,dx\,dt \right) \\
&\qquad + C(1+T^2)s^{10}\lambda^8 \iint_{\omega\times(0,T)} e^{-6s\alpha_m + 4s\alpha_m^*}\xi_m^{10} |\psi|^2 \,dx\,dt.
\end{aligned}
$$

From this and (46), we deduce the desired Carleman inequality (37). This finishes the proof of Theorem 3. □

EXPLICIT SOLUTION TO AN OPTIMAL SWITCHING PROBLEM IN THE TWO-REGIME CASE*

VATHANA LY VATH† AND HUYÊN PHAM†

Abstract. This paper considers the problem of determining the optimal sequence of stopping times for a diffusion process subject to regime switching decisions. This is motivated in the economics literature by the investment problem under uncertainty for a multi-activity firm involving opening and closing decisions. We use a viscosity solutions approach combined with the smooth-fit property, and explicitly solve the problem in the two-regime case when the state process is of geometric Brownian nature. The results of our analysis take several qualitatively different forms, depending on model parameter values.

Key words. optimal switching, system of variational inequalities, viscosity solutions, smooth-fit principle

1. Introduction.

The theory of optimal stopping and its generalization, thoroughly studied in the 1970s, has received a renewed interest with a variety of applications in economics and finance. These applications include asset pricing (American options, swing options), firm investment, and real options. We refer to [4] for a classical and well-documented reference on the subject.

In this paper, we consider the optimal switching problem for a one-dimensional stochastic process X. The diffusion process X may take a finite number of regimes that are switched at stopping time decisions. For example, in the firm's investment problem under uncertainty, a company (oil tanker, electricity station, etc.) manages several production activities operating in different modes or regimes representing a number of different economic outlooks (e.g., state of economic growth, open or closed production activity). The process X is the price of input or output goods of the firm and its dynamics may differ according to the regimes. The firm's project yields a running payoff that depends on the commodity price X and on the regime choice. The transition from one regime to another is realized sequentially at time decisions and incurs certain fixed costs. The problem is to find the switching strategy that maximizes the expected value of profits resulting from the project.

Optimal switching problems were studied by several authors; see [1] or [10]. These control problems lead, via the dynamic programming principle, to a system of variational inequalities. Applications to option pricing, real options, and investment under uncertainty were considered in [2], [5], and [7]. In this last paper, the drift and volatility of the state process depend on an uncontrolled finite-state Markov chain, and the author provides an explicit solution to the optimal stopping problem with applications to Russian options. In [2], an explicit solution is found for a resource extraction problem with two regimes (open or closed field), a linear profit function, and a price process following a geometric Brownian motion. In [5], a similar model is solved with a general profit function in one regime and equal to zero in the other. In

†Laboratoire de Probabilités et Modèles Aléatoires, CNRS, UMR 7599, Université Paris 7, 75251 Paris, Cedex 05, France (lyvath@math.jussieu.fr, pham@math.jussieu.fr).

both models [2], [5], there is no switching in the diffusion process: changes of regimes affect only the payoff functions. Their method of resolution is to construct a solution to the dynamic programming system by guessing a priori the form of the strategy, and then validate a posteriori the optimality of their candidate by a verification argument. Our model combines regime switchings on both the diffusion process and the general profit functions. We use a viscosity solutions approach for determining the solution to the system of variational inequalities. In particular, we derive directly the smooth-fit property of the value functions and the structure of the switching regions. Explicit solutions are provided in the following cases:

- the drift and volatility terms of the diffusion take two different regime values, and the profit functions are identical of power type;
- there is no switching on the diffusion process, and the two different profit functions satisfy a general condition, including typically power functions.

We also consider the cases for which both switching costs are positive, and for which one of the two is negative. This last case is interesting in applications where a firm chooses between an open or closed activity, and may regain a fraction of its opening costs when it decides to close. The results of our analysis take several qualitatively different forms, depending on model parameter values, essentially the payoff functions and the switching costs.

The paper is organized as follows. We formulate in section 2 the optimal switching problem. In section 3, we state the system of variational inequalities satisfied by the value functions in the viscosity sense. The smooth-fit property for this problem, proved in [9], plays an important role in our subsequent analysis. We also state some useful properties on the switching regions. In section 4, we explicitly solve the problem in the two-regime case when the state process is of geometric Brownian nature.

2. Formulation of the optimal switching problem. We consider a stochastic system that can operate in d modes or regimes. The regimes can be switched at a sequence of stopping times decided by the operator (individual, firm, etc.). The indicator of the regimes is modeled by a cadlag process I_t valued in $\mathbb{I}_d = \{1, \dots, d\}$. The stochastic system X (commodity price, salary, etc.) is valued in $\mathbb{R}_+^* = (0, \infty)$ and satisfies the SDE.

$$dX_t = b_{I_t} X_t dt + \sigma_{I_t} X_t dW_t, \tag{2.1}$$

where W is a standard Brownian motion on a filtered probability space $(\Omega, \mathcal{F}, \mathbb{F} = (\mathcal{F}_t)_{t \geq 0}, P)$ satisfying the usual conditions. $b_i \in \mathbb{R}$ and $\sigma_i > 0$ are the drift and volatility, respectively, of the system X once in regime $I_t = i$ at time t.

A strategy decision for the operator is an impulse control α consisting of a double sequence $\tau_1, \dots, \tau_n, \dots, \kappa_1, \dots, \kappa_n, \dots$, $n \in \mathbb{N}^* = \mathbb{N} \setminus \{0\}$, where τ_n are stopping times, $\tau_n < \tau_{n+1}$ and $\tau_n \to \infty$ a.s., representing the switching regimes time decisions, and κ_n are $\mathcal{F}_{\tau_n}$-measurable valued in $\mathbb{I}_d$ representing the new value of the regime at time $t = \tau_n$. We denote by $\mathcal{A}$ the set of all such impulse controls. Now, for any initial condition $(x, i) \in (0, \infty) \times \mathbb{I}_d$, and any control $\alpha = (\tau_n, \kappa_n)_{n \geq 1} \in \mathcal{A}$, there exists a unique strong solution valued in $(0, \infty) \times \mathbb{I}_d$ to the controlled stochastic system:

$$X_0 = x, \quad I_{0^-} = i, \tag{2.2}$$

$$dX_t = b_{\kappa_n} X_t dt + \sigma_{\kappa_n} X_t dW_t, \quad I_t = \kappa_n, \quad \tau_n \leq t < \tau_{n+1}, \quad n \geq 0. \tag{2.3}$$

Here, we set $\tau_0 = 0$ and $\kappa_0 = i$. We denote by $(X^{x,i}, I^i)$ this solution (as usual, we omit the dependence in α for notational simplicity). We notice that $X^{x,i}$ is a continuous process and I^i is a cadlag process, possibly with a jump at time 0 if $\tau_1 = 0$, and so $I_0 = \kappa_1$.

We are given a running profit function $f : \mathbb{R}_+ \times \mathbb{I}_d \to \mathbb{R}$ and we set $f_i(.) = f(., i)$ for $i \in \mathbb{I}_d$. We assume that for each $i \in \mathbb{I}_d$, the function f_i is nonnegative and is Hölder continuous on $\mathbb{R}_+$: there exists $\gamma_i \in (0, 1]$ such that (s.t.)

$$|f_i(x) - f_i(\hat{x})| \leq C|x - \hat{x}|^{\gamma_i} \quad \forall x, \hat{x} \in \mathbb{R}_+, \tag{2.4}$$

for some positive constant C. Without loss of generality (see Remark 2.1), we may assume that $f_i(0) = 0$. We also assume that for all $i \in \mathbb{I}_d$, the conjugate of f_i is finite on $(0, \infty)$:

$$\tilde{f}_i(y) := \sup_{x \geq 0} \big[f_i(x) - xy \big] \ < \ \infty \quad \forall y > 0. \tag{2.5}$$

The cost for switching from regime i to j is a constant equal to g_{ij}, with the convention $g_{ii} = 0$, and we assume the triangular condition

$$g_{ik} < g_{ij} + g_{jk}, \quad j \neq i, k. \tag{2.6}$$

This last condition means that it is less expensive to switch directly in one step from regime i to k than in two steps via an intermediate regime j. Notice that a switching cost g_{ij} may be negative, and condition (2.6) for $i = k$ prevents arbitrage by switching back and forth, i.e.,

$$g_{ij} + g_{ji} > 0, \quad i \neq j \in \mathbb{I}_d. \tag{2.7}$$

The expected total profit of running the system when the initial state is (x, i) and when using the impulse control $\alpha = (\tau_n, \kappa_n)_{n \geq 1} \in \mathcal{A}$ is

$$J_i(x, \alpha) = E \left[\int_0^\infty e^{-rt} f(X_t^{x,i}, I_t^i) dt - \sum_{n=1}^\infty e^{-r\tau_n} g_{\kappa_{n-1}, \kappa_n} \right].$$

Here $r > 0$ is a positive discount factor, and we use the convention that $e^{-r\tau_n(\omega)} = 0$ when $\tau_n(\omega) = \infty$. We also make the standing assumption

$$r > b := \max_{i \in \mathbb{I}_d} b_i. \tag{2.8}$$

The objective is to maximize this expected total profit over all strategies α. Accordingly, we define the value functions

$$v_i(x) = \sup_{\alpha \in \mathcal{A}} J_i(x, \alpha), \quad x \in \mathbb{R}_+^*, \ i \in \mathbb{I}_d. \tag{2.9}$$

We shall see in the next section that under (2.5) and (2.8), the expectation defining $J_i(x)$ is well defined and the value function v_i is finite.

Remark 2.1. The initial values $f_i(0)$ of the running profit functions received by the firm manager (the controller) before any decisions occur are considered to be included in the switching costs during changing of the regime. This means that

w.l.o.g. we may assume that $f_i(0) = 0$. Indeed, for any profit function f_i, and by setting $\tilde{f}_i = f_i - f_i(0)$, we have for all $x > 0$, $\alpha \in \mathcal{A}$,

$$\begin{aligned}
J_i(x,\alpha) &= E\left[\sum_{n=1}^{\infty}\int_{\tau_{n-1}}^{\tau_n} e^{-rt} f(X_t^{x,i},\kappa_{n-1})dt - \sum_{n=1}^{\infty} e^{-r\tau_n} g_{\kappa_{n-1},\kappa_n}\right] \\
&= E\left[\sum_{n=1}^{\infty}\int_{\tau_{n-1}}^{\tau_n} e^{-rt}\left(\tilde{f}(X_t^{x,i},\kappa_{n-1}) + f_{\kappa_{n-1}}(0)\right)dt \; - \sum_{n=1}^{\infty} e^{-r\tau_n} g_{\kappa_{n-1},\kappa_n}\right] \\
&= E\left[\sum_{n=1}^{\infty}\int_{\tau_{n-1}}^{\tau_n} e^{-rt}\tilde{f}(X_t^{x,i},\kappa_{n-1})dt + \frac{f_{\kappa_0}(0)}{r}\right. \\
&\qquad\qquad \left. - \sum_{n=1}^{\infty} e^{-r\tau_n}\left(g_{\kappa_{n-1},\kappa_n} + \frac{f_{\kappa_n}(0) - f_{\kappa_{n-1}}(0)}{r}\right)\right] \\
&= \frac{f_i(0)}{r} + E\left[\int_0^{\infty} e^{-rt}\tilde{f}(X_t^{x,i},I_t^i)dt - \sum_{n=1}^{\infty} e^{-r\tau_n}\tilde{g}_{\kappa_{n-1},\kappa_n}\right],
\end{aligned}$$

with modified switching costs that take into account the possibly different initial values of the profit functions,

$$\tilde{g}_{ij} = g_{ij} + \frac{f_j(0) - f_i(0)}{r},$$

and that are assumed to satisfy the triangle inequality $\tilde{g}_{ik} < \tilde{g}_{ij} + \tilde{g}_{jk}$, $j \neq i,k$.

3. System of variational inequalities, switching regions, and viscosity solutions. We first state the linear growth property and the boundary condition on the value functions.

LEMMA 3.1. *We have for all $i \in \mathbb{I}_d$,*

$$\max_{j\in\mathbb{I}_d}[-g_{ij}] \; \leq v_i(x) \leq \; \frac{xy}{r-b} \; + \; \max_{j\in\mathbb{I}_d}\frac{\tilde{f}_j(y)}{r} + \max_{j\in\mathbb{I}_d}[-g_{ij}] \; \forall x > 0 \; \forall y > 0. \tag{3.1}$$

In particular, we have $v_i(0^+) = \max_{j\in\mathbb{I}_d}[-g_{ij}]$.

Proof. By considering the particular strategy $\tilde{\alpha} = (\tilde{\tau}_n, \tilde{\kappa}_n)$ of immediately switching from the initial state (x,i) to state (x,j), $j \in \mathbb{I}_d$ (eventually equal to i), at cost g_{ij} and then doing nothing, i.e., $\tilde{\tau}_1 = 0$, $\tilde{\kappa}_1 = j$, $\tilde{\tau}_n = \infty$, $\tilde{\kappa}_n = j$ for all $n \geq 2$, we have

$$J_i(x,\tilde{\alpha}) = E\left[\int_0^{\infty} e^{-rt} f_j(\tilde{X}_t^{x,j})dt - g_{ij}\right],$$

where $\tilde{X}^{x,j}$ denotes the geometric Brownian in regime j starting from x at time 0. Since f_j is nonnegative, and by the arbitrariness of j, we get the lower bound in (3.1).

Given an initial state $(X_0, I_{0^-}) = (x,i)$ and an arbitrary impulse control $\alpha = (\tau_n,\kappa_n)$, we get from the dynamics (2.2)–(2.3) the following explicit expression of $X^{x,i}$:

$$\begin{aligned}
X_t^{x,i} \; &= \; xY_t(i) \\
&:= x\left(\prod_{l=0}^{n-1} e^{b_{\kappa_l}(\tau_{l+1}-\tau_l)} Z^{\kappa_l}_{\tau_l,\tau_{l+1}}\right) e^{b_{\kappa_n}(t-\tau_n)} Z^{\kappa_n}_{\tau_n,t}, \quad \tau_n \leq t < \tau_{n+1}, \quad n \in \mathbb{N},
\end{aligned} \tag{3.2}$$

where

$$Z^j_{s,t} = \exp\left(\sigma_j(W_t - W_s) - \frac{\sigma_j^2}{2}(t-s)\right), \quad 0 \le s \le t, \quad j \in \mathbb{I}_d. \tag{3.3}$$

Here, we used the conventions that $\tau_0 = 0$, $\kappa_0 = i$, and that the product term from l to $n-1$ in (3.2) is equal to 1 when $n = 1$. We then deduce the inequality $X^{x,i}_t \le xe^{bt}M_t$ for all t, where

$$M_t = \left(\prod_{l=0}^{n-1} Z^{\kappa_l}_{\tau_l,\tau_{l+1}}\right) Z^{\kappa_n}_{\tau_n,t}, \quad \tau_n \le t < \tau_{n+1}, \quad n \in \mathbb{N}. \tag{3.4}$$

Now, we notice that (M_t) is a martingale obtained by continuously patching the martingales $(Z^{\kappa_{n-1}}_{\tau_{n-1},t})$ and $(Z^{\kappa_n}_{\tau_n,t})$ at the stopping times τ_n, $n \ge 1$. In particular, we have $E[M_t] = M_0 = 1$ for all t.

We set $\tilde{f}(y) = \max_{j\in\mathbb{I}_d} \tilde{f}_i(y)$, $y > 0$, and we notice by definition of $\tilde{f}_i$ in (2.5) that $f(X^{x,i}_t, I^i_t) \le yX^{x,i}_t + \tilde{f}(y)$ for all t, y. Moreover, we show by induction on N that for all $N \ge 1$, $\tau_1 \le \cdots \le \tau_N$, $\kappa_0 = i$, $\kappa_n \in \mathbb{I}_d$, $n = 1, \dots, N$,

$$-\sum_{n=1}^{N} e^{-r\tau_n} g_{\kappa_{n-1},\kappa_n} \le \max_{j\in\mathbb{I}_d}[-g_{ij}] \quad \text{a.s.}$$

Indeed, the above assertion is obviously true for $N = 1$. Suppose now it holds true at step N. Then, at step $N+1$, we distinguish two cases:

- If $g_{\kappa_N,\kappa_{N+1}} \ge 0$, then we have $-\sum_{n=1}^{N+1} e^{-r\tau_n} g_{\kappa_{n-1},\kappa_n} \le -\sum_{n=1}^{N} e^{-r\tau_n} g_{\kappa_{n-1},\kappa_n}$ and we conclude by the induction hypothesis at step N.
- If $g_{\kappa_N,\kappa_{N+1}} < 0$, then by (2.6), and since $\tau_N \le \tau_{N+1}$, we have $-e^{-r\tau_N} g_{\kappa_{N-1},\kappa_N} - e^{-r\tau_{N+1}} g_{\kappa_N,\kappa_{N+1}} \le e^{-r\tau_N} g_{\kappa_{N-1},\kappa_{N+1}}$, and so $-\sum_{n=1}^{N+1} e^{-r\tau_n} g_{\kappa_{n-1},\kappa_n} \le -\sum_{n=1}^{N} e^{-r\tau_n} g_{\tilde{\kappa}_{n-1},\tilde{\kappa}_n}$, with $\tilde{\kappa}_n = \kappa_n$ for $n = 1, \dots, N-1$, $\tilde{\kappa}_N = \kappa_{N+1}$.

We then conclude by the induction hypothesis at step N.

It follows that

$$\begin{aligned} J_i(x,\alpha) &\le E\left[\int_0^\infty e^{-rt}\left(yxe^{bt}M_t + \tilde{f}(y)\right)dt + \max_{j\in\mathbb{I}_d}[-g_{ij}]\right] \\ &= \int_0^\infty e^{-(r-b)t} yxE[M_t]dt + \int_0^\infty e^{-rt}\tilde{f}(y)dt + \max_{j\in\mathbb{I}_d}[-g_{ij}] \\ &= \frac{xy}{r-b} + \frac{\tilde{f}(y)}{r} + \max_{j\in\mathbb{I}_d}[-g_{ij}]. \end{aligned}$$

From the arbitrariness of α, this shows the upper bound for v_i.

By sending x to zero and then y to infinity into the r.h.s. of (3.1), and recalling that $\tilde{f}_i(\infty) = f_i(0) = 0$ for $i \in \mathbb{I}_d$, we conclude that v_i goes to $\max_{j\in\mathbb{I}_d}[-g_{ij}]$ when x tends to zero. □

We next show the Hölder continuity of the value functions.

LEMMA 3.2. *For all $i \in \mathbb{I}_d$, v_i is Hölder continuous on $(0,\infty)$:*

$$|v_i(x) - v_i(\hat{x})| \le C|x - \hat{x}|^\gamma \quad \forall x, \hat{x} \in (0,\infty) \ \text{ with } \ |x - \hat{x}| \le 1,$$

for some positive constant C, and where $\gamma = \min_{i\in\mathbb{I}_d} \gamma_i$ of condition (2.4).

Proof. By definition (2.9) of v_i and under condition (2.4), we have for all $x, \hat{x} \in (0,\infty)$, with $|x-\hat{x}| \leq 1$,

$$
\begin{aligned}
|v_i(x) - v_i(\hat{x})| &\leq \sup_{\alpha\in\mathcal{A}} |J_i(x,\alpha) - J_i(\hat{x},\alpha)| \\
&\leq \sup_{\alpha\in\mathcal{A}} E\left[\int_0^\infty e^{-rt}\left|f(X_t^{x,i},I_t^i) - f(X_t^{\hat{x},i},I_t^i)\right| dt\right] \\
&\leq C \sup_{\alpha\in\mathcal{A}} E\left[\int_0^\infty e^{-rt}\left|X_t^{x,i} - X_t^{\hat{x},i}\right|^{\gamma_{I_t^i}} dt\right] \\
&= C \sup_{\alpha\in\mathcal{A}} \int_0^\infty E\left[e^{-rt}|x-\hat{x}|^{\gamma_{I_t^i}} |Y_t(i)|^{\gamma_{I_t^i}} dt\right] \\
&\leq C|x-\hat{x}|^\gamma \sup_{\alpha\in\mathcal{A}} \int_0^\infty e^{-(r-b)t} E|M_t|^{\gamma_{I_t^i}} dt \qquad (3.5)
\end{aligned}
$$

by (3.2) and (3.4). For any $\alpha = (\tau_n,\kappa_n)_n \in \mathcal{A}$, by the independence of $(Z^{\kappa_n}_{\tau_n,\tau_{n+1}})_n$ in (3.3), and since

$$
E\left[\left|Z^{\kappa_n}_{\tau_n,\tau_{n+1}}\right|^{\gamma_{\kappa_n}} \middle| \mathcal{F}_{\tau_n}\right] = E\left[\exp\left(\gamma_{\kappa_n}(\gamma_{\kappa_n}-1)\frac{\sigma^2_{\kappa_n}}{2}(\tau_{n+1}-\tau_n)\right)\middle|\mathcal{F}_{\tau_n}\right] \leq 1 \quad \text{a.s.},
$$

we clearly see that $E|M_t|^{\gamma_{I_t^i}} \leq 1$ for all $t \geq 0$. We thus conclude with (3.5). □

The dynamic programming principle combined with the notion of viscosity solutions is known to be a general and powerful tool for characterizing the value function of a stochastic control problem via a PDE representation; see [6]. We recall the definition of viscosity solutions for a PDE in the form

$$
H(x,v,D_xv,D^2_{xx}v) = 0, \quad x \in \mathcal{O}, \qquad (3.6)
$$

where $\mathcal{O}$ is an open subset in $\mathbb{R}^n$ and H is a continuous function and nonincreasing in its last argument (with respect to the order of symmetric matrices).

DEFINITION 3.3. *Let v be a continuous function on $\mathcal{O}$. We say that v is a viscosity solution to* (3.6) *on $\mathcal{O}$ if it is*

(i) *a viscosity supersolution to* (3.6) *on $\mathcal{O}$: For any $\bar{x} \in \mathcal{O}$ and any C^2 function φ in a neighborhood of $\bar{x}$ s.t. $\bar{x}$ is a local minimum of $v-\varphi$, we have*

$$
H(\bar{x}, v(\bar{x}), D_x\varphi(\bar{x}), D^2_{xx}\varphi(\bar{x})) \geq 0;
$$

and

(ii) *a viscosity subsolution to* (3.6) *on $\mathcal{O}$: For any $\bar{x} \in \mathcal{O}$ and any C^2 function φ in a neighborhood of $\bar{x}$ s.t. $\bar{x}$ is a local maximum of $v-\varphi$, we have*

$$
H(\bar{x}, v(\bar{x}), D_x\varphi(\bar{x}), D^2_{xx}\varphi(\bar{x})) \leq 0.
$$

Remark 3.1. 1. By misuse of notation, we shall say that v is a viscosity supersolution (resp., subsolution) to (3.6) by writing

$$
H(x,v,D_xv,D^2_{xx}v) \geq (\text{resp.}, \leq)\ 0, \quad x \in \mathcal{O}, \qquad (3.7)
$$

2. We recall that if v is a smooth C^2 function on $\mathcal{O}$, supersolution (resp., subsolution) in the classical sense to (3.7), then v is a viscosity supersolution (resp., subsolution) to (3.7).

3. There is an equivalent formulation of viscosity solutions, which is useful for proving uniqueness results (see [3]).

(i) A continuous function v on $\mathcal{O}$ is a viscosity supersolution to (3.6) if

$$H(x, v(x), p, M) \geq 0 \quad \forall x \in \mathcal{O},\ \forall (p, M) \in J^{2,-}v(x).$$

(ii) A continuous function v on $\mathcal{O}$ is a viscosity subsolution to (3.6) if

$$H(x, v(x), p, M) \leq 0 \quad \forall x \in \mathcal{O},\ \forall (p, M) \in J^{2,+}v(x).$$

Here $J^{2,+}v(x)$ is the second order superjet defined by

$$J^{2,+}v(x) = \left\{ (p, M) \in \mathbb{R}^n \times S^n : \right.$$

$$\left. \limsup_{\substack{x' \to x \\ x \in \mathcal{O}}} \frac{v(x') - v(x) - p.(x' - x) - \frac{1}{2}(x' - x).M(x' - x)}{|x' - x|^2} \ \leq\ 0 \right\},$$

S^n is the set of symmetric $n \times n$ matrices, and $J^{2,-}v(x) = -J^{2,+}(-v)(x)$.

In what follows, we shall denote by $\mathcal{L}_i$ the second order operator associated with the diffusion X when we are in regime i: for any C^2 function φ on $(0, \infty)$,

$$\mathcal{L}_i \varphi = \frac{1}{2}\sigma_i^2 x^2 \varphi'' + b_i x \varphi'.$$

We then have the following PDE characterization of the value functions v_i by means of viscosity solutions.

THEOREM 3.4. *The value functions v_i, $i \in \mathbb{I}_d$, are the unique viscosity solutions, with linear growth conditions on $(0, \infty)$ and boundary conditions $v_i(0^+) = \max_{j \in \mathbb{I}_d}[-g_{ij}]$, to the system of variational inequalities:*

$$\min \left\{ rv_i - \mathcal{L}_i v_i - f_i\ ,\ v_i - \max_{j \neq i}(v_j - g_{ij}) \right\} = 0, \quad x \in (0, \infty), \quad i \in \mathbb{I}_d. \tag{3.8}$$

This means we have the following properties.

(1) *Viscosity property. For each $i \in \mathbb{I}_d$, v_i is a viscosity solution to*

$$\min \left\{ rv_i - \mathcal{L}_i v_i - f_i\ ,\ v_i - \max_{j \neq i}(v_j - g_{ij}) \right\} = 0, \quad x \in (0, \infty). \tag{3.9}$$

(2) *Uniqueness property. If w_i, $i \in \mathbb{I}_d$, are viscosity solutions, with linear growth conditions on $(0, \infty)$ and boundary conditions $w_i(0^+) = \max_{j \in \mathbb{I}_d}[-g_{ij}]$, to the system of variational inequalities* (3.8)*, then $v_i = w_i$ on $(0, \infty)$.*

Proof. (1) The viscosity property follows from the dynamic programming principle and is proved in [9].

(2) Uniqueness results for switching problems have been proved in [10] in the finite horizon case under different conditions. For sake of completeness, we provide in the appendix a proof of the comparison principle in our infinite horizon context, which implies the uniqueness result. □

Remark 3.2. For fixed $i \in \mathbb{I}_d$, we also have uniqueness of viscosity solutions to (3.9) in the class of continuous functions with linear growth conditions on $(0, \infty)$ and

given boundary conditions on 0. In the next section, we shall use either uniqueness of viscosity solutions to the system (3.8) or for fixed i to (3.9), for the identification of an explicit solution in the two-regime case $d = 2$.

We shall also combine the uniqueness result for the viscosity solutions with the smooth-fit property on the value functions that we state below.

For any regime $i \in \mathbb{I}_d$, we introduce the switching region

$$\mathcal{S}_i = \left\{ x \in (0,\infty) : v_i(x) = \max_{j \neq i} (v_j - g_{ij})(x) \right\}.$$

$\mathcal{S}_i$ is a closed subset of $(0,\infty)$ and corresponds to the region where it is optimal for the operator to change regime. The complement set $\mathcal{C}_i$ of $\mathcal{S}_i$ in $(0,\infty)$ is the so-called continuation region:

$$\mathcal{C}_i = \left\{ x \in (0,\infty) : v_i(x) > \max_{j \neq i} (v_j - g_{ij})(x) \right\},$$

where the operator remains in regime i. In this open domain, the value function v_i is smooth C^2 on $\mathcal{C}_i$ and satisfies, in a classical sense,

$$r v_i(x) - \mathcal{L}_i v_i(x) - f_i(x) = 0, \quad x \in \mathcal{C}_i.$$

As a consequence of the condition (2.6), we have the following elementary partition property of the switching regions (see Lemma 4.2 in [9]):

$$\mathcal{S}_i = \cup_{j \neq i} \mathcal{S}_{ij}, \quad i \in \mathbb{I}_d,$$

where

$$\mathcal{S}_{ij} = \{ x \in \mathcal{C}_j : v_i(x) = (v_j - g_{ij})(x) \}.$$

$\mathcal{S}_{ij}$ represents the region where it is optimal to switch from regime i to regime j and to remain for a moment, i.e., without changing instantaneously from regime j to another regime. The following lemma gives some partial information about the structure of the switching regions.

LEMMA 3.5. *For all $i \neq j$ in $\mathbb{I}_d$, we have*

$$\mathcal{S}_{ij} \subset Q_{ij} := \{ x \in \mathcal{C}_j : (\mathcal{L}_j - \mathcal{L}_i) v_j(x) + (f_j - f_i)(x) - r g_{ij} \geq 0 \}.$$

Proof. Let $x \in \mathcal{S}_{ij}$. By setting $\varphi_j = v_j - g_{ij}$, this means that x is a minimum of $v_i - \varphi_j$ with $v_i(x) = \varphi_j(x)$. Moreover, since x lies in the open set $\mathcal{C}_j$ where v_j is smooth, we have that φ_j is C^2 in a neighborhood of x. By the supersolution viscosity property of v_i to the PDE (3.8), this yields

$$r\varphi_j(x) - \mathcal{L}_i \varphi_j(x) - f_i(x) \geq 0. \tag{3.10}$$

Now recall that for $x \in \mathcal{C}_j$, we have

$$r v_j(x) - \mathcal{L}_j v_j(x) - f_j(x) = 0,$$

so that by substituting into (3.10), we obtain

$$(\mathcal{L}_j - \mathcal{L}_i) v_j(x) + (f_j - f_i)(x) - r g_{ij} \geq 0,$$

which is the required result. □

We quote the smooth-fit property on the value functions, proved in [9].

THEOREM 3.6. *For all $i \in \mathbb{I}_d$, the value function v_i is continuously differentiable on $(0,\infty)$.*

Remark 3.3. In a given regime i, the variational inequality satisfied by the value function v_i is a free-boundary problem as in the optimal stopping problem, which divides the state space into the switching region (stopping region in the pure optimal stopping problem) and the continuation region. The main difficulty with regard to optimal stopping problems for proving the smooth-fit property through the boundaries of the switching regions, is that the switching region for the value function v_i depends also on the other value functions v_j. The method in [9] uses viscosity solutions arguments, and the condition of one-dimensional state space is critical for proving the smooth-fit property. The crucial conditions in this paper require that the diffusion coefficient in any regime of the system X be strictly positive on the interior of the state space, which is the case here since $\sigma_i > 0$ for all $i \in \mathbb{I}_d$, and a triangular condition (2.6) on the switching costs. Under these conditions, on a point x of the switching region $\mathcal{S}_i$ for regime i, there exists some $j \neq i$ s.t. $x \in \mathcal{S}_{ij}$, i.e., $v_i(x) = v_j(x) - g_{ij}$, and the C^1 property of the value functions is written as $v_i'(x) = v_j'(x)$ since g_{ij} is constant.

The next result provides suitable conditions for determining a viscosity solution to the variational inequality type arising in our switching problem.

LEMMA 3.7. *Fix $i \in \mathbb{I}_d$. Let $\mathcal{C}$ be an open set in $(0,\infty)$, $\mathcal{S} = (0,\infty)\setminus\mathcal{C}$ assumed to be the union of a finite number of closed intervals in $(0,\infty)$, and w, h two continuous functions on $(0,\infty)$, with $w = h$ on $\mathcal{S}$ such that*

$$w \text{ is } C^1 \text{ on } \partial\mathcal{S}, \tag{3.11}$$

$$w \geq h \text{ on } \mathcal{C}, \tag{3.12}$$

w is C^2 on $\mathcal{C}$, solution to

$$rw - \mathcal{L}_i w - f_i = 0 \quad \text{on } \mathcal{C}, \tag{3.13}$$

and w is a viscosity supersolution to

$$rw - \mathcal{L}_i w - f_i \geq 0 \quad \text{on } \operatorname{int}(\mathcal{S}). \tag{3.14}$$

Here $\operatorname{int}(\mathcal{S})$ is the interior of $\mathcal{S}$ and $\partial\mathcal{S} = \mathcal{S} \setminus \operatorname{int}(\mathcal{S})$ its boundary. Then, w is a viscosity solution to

$$\min\{rw - \mathcal{L}_i w - f_i, w - h\} = 0 \quad \text{on } (0,\infty). \tag{3.15}$$

Proof. Take some $\bar{x} \in (0,\infty)$ and distinguish the following cases:

• $\bar{x} \in \mathcal{C}$. Since $w = v$ is C^2 on $\mathcal{C}$ and satisfies $rw(\bar{x}) - \mathcal{L}_i w(\bar{x}) - f_i(\bar{x}) = 0$ by (3.13), and recalling $w(\bar{x}) \geq h(\bar{x})$ by (3.12), we obtain the classical solution property, and so a fortiori the viscosity solution property (3.15) of w at $\bar{x}$.

• $\bar{x} \in \mathcal{S}$. Then $w(\bar{x}) = h(\bar{x})$ and the viscosity subsolution property is trivial at $\bar{x}$. It remains to show the viscosity supersolution property at $\bar{x}$. If $\bar{x} \in \operatorname{int}(\mathcal{S})$, this follows directly from (3.14). Suppose now $\bar{x} \in \partial\mathcal{S}$, and to fix the idea, we consider that $\bar{x}$ is on the left-boundary of $\mathcal{S}$ so that from the assumption on the form of $\mathcal{S}$, there exists $\varepsilon > 0$ s.t. $(\bar{x} - \varepsilon, \bar{x}) \subset \mathcal{C}$ on which w is smooth C^2 (the same argument holds true when $\bar{x}$ is on the right-boundary of $\mathcal{S}$). Take some smooth C^2 function φ

s.t. $\bar{x}$ is a local minimum of $w-\varphi$. Since w is C^1 by (3.11), we have $\varphi'(\bar{x}) = w'(\bar{x})$. We may also assume w.l.o.g. (by taking ε small enough) that $(w-\varphi)(\bar{x}) \leq (w-\varphi)(x)$ for $x \in (\bar{x}-\varepsilon, \bar{x})$. Moreover, by Taylor's formula, we have

$$w(\bar{x}-\eta) \;=\; w(\bar{x}) - \eta \int_0^1 w'(\bar{x}-t\eta)dt, \varphi(\bar{x}-\eta) \;=\; \varphi(\bar{x}) - \eta \int_0^1 \varphi'(\bar{x}-t\eta)dt,$$

so that

$$\int_0^1 \varphi'(\bar{x}-t\eta) - w'(\bar{x}-t\eta)\, dt \geq 0 \quad \forall\, 0 < \eta < \varepsilon.$$

Since $\varphi'(\bar{x}) = w'(\bar{x})$, this last inequality is written as

$$\int_0^1 \frac{\varphi'(\bar{x}-t\eta) - \varphi'(\bar{x})}{\eta} - \frac{w'(\bar{x}-t\eta) - w'(\bar{x})}{\eta}\, dt \geq 0 \quad \forall\, 0 < \eta < \varepsilon. \tag{3.16}$$

Now, from (3.13), we have $rw(x) - \mathcal{L}_i w(x) - f_i(x) = 0$ for $x \in (\bar{x}-\varepsilon, \bar{x})$. By sending x towards $\bar{x}$ into this last equality, this shows that $w''(\bar{x}^-) = \lim_{x \nearrow \bar{x}} w''(x)$ exists, and

$$rw(\bar{x}) - b_i \bar{x} w'(\bar{x}) - \frac{1}{2}\sigma_i^2 \bar{x}^2 w''(\bar{x}^-) - f_i(\bar{x}) = 0. \tag{3.17}$$

Moreover, by sending η to zero into (3.16), we obtain

$$\int_0^1 t\big[-\varphi''(\bar{x}) + w''(\bar{x}^-)\big]dt \geq 0,$$

and so $\varphi''(\bar{x}) \leq w''(\bar{x}^-)$. By substituting into (3.17), and recalling that $w'(\bar{x}) = \varphi'(\bar{x})$, we then obtain

$$rw(\bar{x}) - \mathcal{L}_i \varphi(\bar{x}) - f_i(\bar{x}) \geq 0,$$

which is the required supersolution inequality and ends the proof. □

Remark 3.4. Since $w = h$ on $\mathcal{S}$, relation (3.14) means equivalently that h is a viscosity supersolution to

$$rh - \mathcal{L}_i h - f_i \geq 0 \quad \text{on } \operatorname{int}(\mathcal{S}). \tag{3.18}$$

Practically, Lemma 3.7 shall be used as follows in the next section: We consider two C^1 functions v and h on $(0,\infty)$ s.t.

$$\begin{aligned} v(x) \;=\; h(x),\; v'(x) = h'(x), \quad x \;\in \partial\mathcal{S}, \\ v \geq h \quad \text{on } \mathcal{C}, \end{aligned}$$

v is C^2 on $\mathcal{C}$, solution to

$$rv - \mathcal{L}_i v - f_i = 0 \quad \text{on } \mathcal{C},$$

and h is a viscosity supersolution to (3.18). Then, the function w defined on $(0,\infty)$ by

$$w(x) = \begin{cases} v(x), & x \in \mathcal{C}, \\ h(x), & x \in \mathcal{S} \end{cases}$$

satisfies the conditions of Lemma 3.7 and is a viscosity solution to (3.15). This lemma combined with uniqueness viscosity solution results may be viewed as an alternative to the classical verification approach in the identification of the value function. Moreover, with our viscosity solutions approach, we shall see in section 4.2 that Lemma 3.5 and the smooth-fit property of the value functions in Theorem 3.6 provide a direct derivation for the structure of the switching regions, and thus of the solution to our problem.

4. Explicit solution in the two-regime case. In this section, we consider the case where $d = 2$. In this two-regime case, we know from Theorem 3.4 that the value functions v_i, $i = 1, 2$, are the unique continuous viscosity solutions, with linear growth conditions on $(0, \infty)$, and boundary conditions $v_i(0^+) = (-g_{ij})_+ := \max(-g_{ij}, 0)$, $j \neq i$, to the system

$$\min\{rv_1 - \mathcal{L}_1 v_1 - f_1, v_1 - (v_2 - g_{12})\} = 0, \tag{4.1}$$

$$\min\{rv_2 - \mathcal{L}_2 v_2 - f_2, v_2 - (v_1 - g_{21})\} = 0. \tag{4.2}$$

Moreover, the switching regions are

$$\mathcal{S}_i \;=\; \mathcal{S}_{ij} = \{x > 0 : v_i(x) = v_j(x) - g_{ij}\}, \quad i, j = 1, 2,\ i \neq j.$$

We set

$$\underline{x}_i^* \;=\; \inf \mathcal{S}_i \;\in\; [0, \infty] \bar{x}_i^* \;=\; \sup \mathcal{S}_i \;\in\; [0, \infty],$$

with the usual convention that $\inf \emptyset = \infty$.

Let us also introduce some other notation. We consider the second order ODE for $i = 1, 2$:

$$rv - \mathcal{L}_i v - f_i = 0, \tag{4.3}$$

whose general solution (without second member f_i) is given by

$$v(x) = Ax^{m_i^+} + Bx^{m_i^-},$$

for some constants A, B, and where

$$m_i^- = -\frac{b_i}{\sigma_i^2} + \frac{1}{2} - \sqrt{\left(-\frac{b_i}{\sigma_i^2} + \frac{1}{2}\right)^2 + \frac{2r}{\sigma_i^2}} \;<\; 0,$$

$$m_i^+ = -\frac{b_i}{\sigma_i^2} + \frac{1}{2} + \sqrt{\left(-\frac{b_i}{\sigma_i^2} + \frac{1}{2}\right)^2 + \frac{2r}{\sigma_i^2}} \;>\; 1.$$

We also denote

$$\hat{V}_i(x) = E\left[\int_0^\infty e^{-rt} f_i(\hat{X}_t^{x,i}) dt\right],$$

with $\hat{X}^{x,i}$ the solution to the SDE $d\hat{X}_t = b_i \hat{X}_t dt + \sigma_i \hat{X}_t dW_t$, $\hat{X}_0 = x$. Actually, $\hat{V}_i$ is a particular solution to ODE (4.3), with boundary condition $\hat{V}_i(0^+) = f_i(0) = 0$. It corresponds to the reward function associated with the no switching strategy from initial state (x, i), and so $\hat{V}_i \leq v_i$.

Remark 4.1. If $g_{ij} > 0$, then from (2.7), we have $v_i(0^+) = 0 > (-g_{ji})_+ - g_{ij} = v_j(0^+) - g_{ij}$. Therefore, by continuity of the value functions on $(0,\infty)$, we get $\underline{x}_i^* > 0$.

We now give the explicit solution to our problem in the following two situations:

• The diffusion operators are different and the running profit functions are identical.

• The diffusion operators are identical and the running profit functions are different.

We also consider the cases for which both switching costs are positive, and for which one of the two is negative, the other being then positive according to (2.7). This last case is interesting in applications where a firm chooses between an open or closed activity, and may regain a fraction of its opening costs when it decides to close.

4.1. Identical profit functions with different diffusion operators. In this subsection, we suppose that the running functions are identical in the form

$$f_1(x) \;=\; f_2(x) = x^\gamma, \quad 0 < \gamma < 1, \tag{4.4}$$

and the diffusion operators are different. A straightforward calculation shows that under (4.4), we have

$$\hat{V}_i(x) = K_i x^\gamma \quad \text{with} \;\; K_i \;=\; \frac{1}{r - b_i\gamma + \frac{1}{2}\sigma_i^2\gamma(1-\gamma)} \;>\; 0, \;\; i = 1,2.$$

We show that the structure of the switching regions depends actually only on the sign of $K_2 - K_1$, and of the sign of the switching costs g_{12} and g_{21}. More precisely, we have the following explicit result.

THEOREM 4.1. *Let i, $j = 1,2$, $i \neq j$.*

(1) *If $K_i = K_j$, then*

$$v_i(x) = \hat{V}_i(x) + (-g_{ij})_+, \qquad x \in (0,\infty),$$
$$\mathcal{S}_i = \begin{cases} \emptyset & \text{if } \; g_{ij} > 0, \\ (0,\infty) & \text{if } \; g_{ij} \leq 0. \end{cases}$$

It is always optimal to switch from regime i to j if the corresponding switching cost is nonpositive, and never optimal to switch otherwise.

(2) *If $K_j > K_i$, then we have the following situations depending on the switching costs:*

(a) $g_{ij} \leq 0$: *We have $\mathcal{S}_i = (0,\infty)$, $\mathcal{S}_j = \emptyset$, and*

$$v_i \;=\; \hat{V}_j - g_{ij}, v_j \;=\; \hat{V}_j.$$

(b) $g_{ij} > 0$:

• *If $g_{ji} \geq 0$, then $\mathcal{S}_i = [\underline{x}_i^*, \infty)$ with $\underline{x}_i^* \in (0,\infty)$, $\mathcal{S}_j = \emptyset$, and*

$$v_i(x) = \begin{cases} Ax^{m_i^+} + \hat{V}_i(x), & x < \underline{x}_i^*, \\ v_j(x) - g_{ij}, & x \geq \underline{x}_i^*, \end{cases} \tag{4.5}$$

$$v_j(x) = \hat{V}_j(x), \quad x \in (0,\infty), \tag{4.6}$$

where the constants A and $\underline{x}_i^*$ are determined by the continuity and smooth-fit conditions of v_i at $\underline{x}_i^*$, and explicitly given by

$$\underline{x}_i^* = \left(\frac{m_i^+}{m_i^+ - \gamma}\frac{g_{ij}}{K_j - K_i}\right)^{\frac{1}{\gamma}}, \tag{4.7}$$

$$A = (K_j - K_i)\frac{\gamma}{m_i^+}(\underline{x}_i^*)^{\gamma - m_i^+}. \tag{4.8}$$

When we are in regime i, it is optimal to switch to regime j whenever the state process X exceeds the threshold $\underline{x}_i^*$, while when we are in regime j, it is optimal to never switch.

- *If $g_{ji} < 0$, then $\mathcal{S}_i = [\underline{x}_i^*, \infty)$ with $\underline{x}_i^* \in (0, \infty)$, $\mathcal{S}_j = (0, \bar{x}_j^*]$, and*

$$v_i(x) = \begin{cases} Ax^{m_i^+} + \hat{V}_i(x), & x < \underline{x}_i^*, \\ v_j(x) - g_{ij}, & x \geq \underline{x}_i^*, \end{cases} \tag{4.9}$$

$$v_j(x) = \begin{cases} v_i(x) - g_{ji}, & x \leq \bar{x}_j^*, \\ Bx^{m_j^-} + \hat{V}_j(x), & x > \bar{x}_i^*, \end{cases} \tag{4.10}$$

where the constants A, B and $\bar{x}_j^* < \underline{x}_i^*$ are determined by the continuity and smooth-fit conditions of v_i and v_j at $\underline{x}_i^*$ and $\bar{x}_j^*$, and explicitly given by

$$\begin{aligned} \overline{x}_j &= \left[\frac{-m_j^-(g_{ji} + g_{ij} y^{m_i^+})}{(K_i - K_j)(\gamma - m_j^-)(1 - y^{m_i^+ - \gamma})} \right]^{\frac{1}{\gamma}}, \\ \underline{x}_i &= \frac{\overline{x}_j}{y}, \\ B &= \frac{(K_i - K_j)(m_i^+ - \gamma)\underline{x}_i^{\gamma - m_j^-} + m_i^+ g_{ij} \underline{x}_i^{-m_j}}{m_i^+ - m_j^-}, \\ A &= B\underline{x}_i^{m_j^- - m_i^+} - (K_i - K_j)\underline{x}_i^{\gamma - m_i^+} - g_{ij}\underline{x}_i^{-m_i^+}, \end{aligned}$$

with y solution in

$$\left(0, \left(-\frac{g_{ji}}{g_{ij}}\right)^{\frac{1}{m_i^+}}\right)$$

to the equation

$$\begin{aligned} &m_i^+(\gamma - m_j^-)\left(1 - y^{m_i^+ - \gamma}\right)\left(g_{ij} y^{m_j^-} + g_{ji}\right) \\ &\quad + m_j^-(m_i^+ - \gamma)\left(1 - y^{m_j^- - \gamma}\right)\left(g_{ij} y^{m_i^+} + g_{ji}\right) = 0. \end{aligned}$$

When we are in regime i, it is optimal to switch to regime j whenever the state process X exceeds the threshold $\underline{x}_i^*$, while when we are in regime j, it is optimal to switch to regime i for values of the state process X under the threshold $\bar{x}_j^*$.

Economic interpretation. In the particular case where $\sigma_1 = \sigma_2$, we have that $K_2 - K_1 > 0$ means that regime 2 provides a higher expected return b_2 than b_1 of regime 1 for the same volatility coefficient σ_i. Moreover, if the switching cost g_{21} from regime 2 to regime 1 is nonnegative, it is intuitively clear that it is in our best interest to always stay in regime 2, which is formalized by the property that $\mathcal{S}_2 = \emptyset$. However, if one receives some gain compensation to switch from regime 2 to regime 1, i.e., the corresponding cost g_{21} is negative, then it is in our best interest to change regime for small values of the current state. This is formalized by the property that $\mathcal{S}_2 = (0, \bar{x}_2^*]$. On the other hand, in regime 1, our best interest is to switch to regime 2, for all current

FIG. 1.

values of the state if the corresponding switching cost g_{12} is nonpositive, or from a certain threshold $\underline{x}_1^*$ if the switching cost g_{12} is positive. A similar interpretation holds when $b_1 = b_2$, and $K_2 - K_1 > 0$, i.e., $\sigma_2 < \sigma_1$. Theorem 4.1 extends these results for general coefficients b_i and σ_i, and shows that the critical parameter value determining the form of the optimal strategy is given by the sign of $K_2 - K_1$ and the switching costs. The different optimal strategy structures are depicted in Figure 1.

Proof of Theorem 4.1.

(1) If $K_i = K_j$, then $\hat{V}_i = \hat{V}_j$. We consider the smooth functions $w_i = \hat{V}_i + (-g_{ij})_+$ for $i, j = 1, 2$ and $j \neq i$. Since $\hat{V}_i$ are solutions to (4.3), we see that w_i satisfy

$$rw_i - \mathcal{L}w_i - f_i = r(-g_{ij})_+, \tag{4.11}$$

$$w_i - (w_j - g_{ij}) = g_{ij} + (-g_{ij})_+ - (-g_{ji})_+. \tag{4.12}$$

Notice that the l.h.s. of (4.11) and (4.12) are both nonnegative by (2.7). Moreover,

if $g_{ij} > 0$, then the l.h.s. of (4.11) is zero, and if $g_{ij} \leq 0$, then $g_{ji} > 0$ and the l.h.s. of (4.12) is zero. Therefore, w_i, $i = 1, 2$ is solution to the system

$$\min\{rw_i - \mathcal{L}_i w_i - f_i, w_i - (w_j - g_{ij})\} = 0.$$

Since $\hat{V}_i(0^+) = 0$, we have $w_i(0^+) = (-g_{ij})_+$. Moreover, w_i like $\hat{V}_i$ satisfies a linear growth condition. Therefore, from the uniqueness solutions to the PDE system (4.1)–(4.2), we deduce that $v_i = w_i$. As observed above, if $g_{ij} \leq 0$, then the l.h.s. of (4.12) is zero, and so $\mathcal{S}_i = (0, \infty)$. Finally, if $g_{ij} > 0$, then the l.h.s. of (4.12) is positive, and so $\mathcal{S}_i = \emptyset$.

(2) We now suppose w.l.o.g. that $K_2 > K_1$.

(a) Consider first the case where $g_{12} \leq 0$, and so $g_{21} > 0$. We set $w_1 = \hat{V}_2 - g_{12}$ and $w_2 = \hat{V}_2$. Then, by construction, we have $w_1 = w_2 - g_{12}$ on $(0, \infty)$, and by definition of $\hat{V}_1$ and $\hat{V}_2$:

$$rw_1(x) - \mathcal{L}_1 w_1(x) - f_1(x) = \frac{K_2 - K_1}{K_1} x^\gamma - rg_{12} \ > \ 0 \quad \forall\, x > 0.$$

On the other hand, we also have $rw_2 - \mathcal{L}_2 w_2 - f_2 = 0$ on $(0, \infty)$, and $w_2 \geq w_1 - g_{21}$ since $g_{12} + g_{21} \geq 0$. Hence, w_1 and w_2 are smooth (hence, viscosity) solutions to the system (4.1)–(4.2), with linear growth conditions and boundary conditions $w_1(0^+) = V_1(0^+) - g_{12} = (-g_{12})_+$, $w_2(0^+) = \hat{V}_2(0^+) = 0 = (-g_{21})_+$. By the uniqueness result of Theorem 3.4, we deduce that $v_1 = w_1$, $v_2 = w_2$, and thus $\mathcal{S}_1 = (0, \infty)$, $\mathcal{S}_2 = \emptyset$.

(b) Consider now the case where $g_{12} > 0$. We already know from Remark 4.1 that $\underline{x}_1^* > 0$, and we claim that $\underline{x}_1^* < \infty$. Otherwise, v_1 should be equal to $\hat{V}_1$. Since $v_1 \geq v_2 - g_{12} \geq \hat{V}_2 - g_{12}$, this would imply $(\hat{V}_2 - \hat{V}_1)(x) = (K_2 - K_1)x^\gamma \leq g_{12}$ for all $x > 0$, an obvious contradiction. By definition of $\underline{x}_1^*$, we have $(0, \underline{x}_1^*) \subset \mathcal{C}_1$. We shall prove actually the equality $(0, \underline{x}_1^*) = \mathcal{C}_1$, i.e., $\mathcal{S}_1 = [\underline{x}_1^*, \infty)$. On the other hand, the form of $\mathcal{S}_2$ will depend on the sign of g_{21}.

Case: $g_{21} \geq 0$.

We shall prove that $\mathcal{C}_2 = (0, \infty)$, i.e., $\mathcal{S}_2 = \emptyset$. To this end, let us consider the function

$$w_1(x) = \begin{cases} Ax^{m_1^+} + \hat{V}_1(x), & 0 < x < x_1, \\ \hat{V}_2(x) - g_{12}, & x \geq x_1, \end{cases}$$

where the positive constants A and x_1 satisfy

$$Ax_1^{m_1^+} + \hat{V}_1(x_1) = \hat{V}_2(x_1) - g_{12}, \tag{4.13}$$

$$Am_1^+ x_1^{m_1^+ - 1} + \hat{V}_1'(x_1) = \hat{V}_2'(x_1), \tag{4.14}$$

and are explicitly determined by

$$(K_2 - K_1)x_1^\gamma = \frac{m_1^+}{m_1^+ - \gamma} g_{12}, \tag{4.15}$$

$$A = (K_2 - K_1)\frac{\gamma}{m_1^+} x_1^{\gamma - m_1^+}. \tag{4.16}$$

Notice that by construction, w_1 is C^2 on $(0, x_1) \cup (x_1, \infty)$, and C^1 on x_1.

By using Lemma 3.7, we now show that w_1 is a viscosity solution to

$$\min\left\{rw_1 - \mathcal{L}_1 w_1 - f_1, w_1 - (\hat{V}_2 - g_{12})\right\} = 0 \quad \text{on } (0, \infty). \tag{4.17}$$

We first check that

$$w_1(x) \geq \hat{V}_2(x) - g_{12} \quad \forall\, 0 < x < x_1, \tag{4.18}$$

i.e.,

$$G(x) \;:=\; Ax^{m_1^+} + \hat{V}_1(x) - \hat{V}_2(x) + g_{12} \geq 0 \quad \forall\, 0 < x < x_1.$$

Since $A > 0$, $0 < \gamma < 1 < m_1^+$, $K_2 - K_1 > 0$, a direct derivation shows that the second derivative of G is positive, i.e., G is strictly convex. By (4.14), we have $G'(x_1) = 0$, and so G' is negative, i.e., G is strictly decreasing on $(0, x_1)$. Now, by (4.13), we have $G(x_1) = 0$, and thus G is positive on $(0, x_1)$, which proves (4.18).

By definition of w_1 on $(0, x_1)$, we have in the classical sense

$$rw_1 - \mathcal{L}_1 w_1 - f_1 = 0 \quad \text{on } (0, x_1). \tag{4.19}$$

We now check that

$$rw_1 - \mathcal{L}_1 w_1 - f_1 \geq 0 \quad \text{on } (x_1, \infty) \tag{4.20}$$

holds true in the classical sense, and so a fortiori in the viscosity sense. By definition of w_1 on (x_1, ∞), and K_1, we have for all $x > x_1$,

$$rw_1(x) - \mathcal{L}_1 w_1(x) - f_1(x) = \frac{K_2 - K_1}{K_1} x^\gamma - rg_{12} \quad \forall x > x_1,$$

so that (4.20) is satisfied iff $\frac{K_2 - K_1}{K_1} x_1^\gamma - rg_{12} \geq 0$, or equivalently by (4.15),

$$\frac{m_1^+}{m_1^+ - \gamma} \geq rK_1 \;=\; \frac{r}{r - b_1\gamma + \frac{1}{2}\sigma_1^2\gamma(1-\gamma)}. \tag{4.21}$$

Now, since $\gamma < 1 < m_1^+$, and by definition of m_1^+, we have

$$\frac{1}{2}\sigma_1^2 m_1^+(\gamma - 1) < \frac{1}{2}\sigma_1^2 m_1^+(m_1^+ - 1) \;=\; r - b_1 m_1^+,$$

which proves (4.21) and thus (4.20).

Relations (4.13)–(4.14) and (4.18)–(4.20) mean that the conditions of Lemma 3.7 are satisfied with $\mathcal{C} = (0, x_1)$, $h = \hat{V}_2 - g_{12}$, and we thus get the required assertion (4.17).

On the other hand, we check that

$$\hat{V}_2(x) \geq w_1(x) - g_{21} \quad \forall x > 0, \tag{4.22}$$

which amounts to showing

$$H(x) \;:=\; Ax^{m_1^+} + \hat{V}_1(x) - \hat{V}_2(x) - g_{21} \leq 0 \quad \forall\, 0 < x < x_1.$$

Since $A > 0$, $0 < \gamma < 1 < m_1^+$, $K_2 - K_1 > 0$, a direct derivation shows that the second derivative of H is positive, i.e., H is strictly convex. By (4.14), we have $H'(x_1) = 0$ and so H' is negative, i.e., H is strictly decreasing on $(0, x_1)$. Now, we have $H(0) = -g_{21} \leq 0$ and thus H is negative on $(0, x_1)$, which proves (4.22). Recalling that $\hat{V}_2$ is

a solution to $r\hat{V}_2 - \mathcal{L}_2\hat{V}_2 - f_2 = 0$ on $(0,\infty)$, we deduce that, obviously from (4.22), $\hat{V}_2$ is a classical, hence a viscosity, solution to

$$\min\left\{r\hat{V}_2 - \mathcal{L}_2\hat{V}_2 - f_2, \hat{V}_2 - (w_1 - g_{21})\right\} = 0 \quad \text{on } (0,\infty). \tag{4.23}$$

Since $w_1(0^+) = 0 = (-g_{12})_+$, $\hat{V}_2(0^+) = 0 = (-g_{21})_+$, and w_1, $\hat{V}_2$ satisfy a linear growth condition, we deduce from (4.17), (4.23), and uniqueness to the PDE system (4.1)–(4.2) that

$$v_1 = w_1, v_2 = \hat{V}_2 \quad \text{on } (0,\infty).$$

This proves $\underline{x}_1^* = x_1$, $\mathcal{S}_1 = [x_1,\infty)$, and $\mathcal{S}_2 = \emptyset$.

Case: $g_{21} < 0$.

We shall prove that $\mathcal{S}_2 = (0,\bar{x}_2^*]$. To this end, let us consider the functions

$$w_1(x) = \begin{cases} Ax^{m_1^+} + \hat{V}_1(x), & x < \underline{x}_1, \\ w_2(x) - g_{12}, & x \geq \underline{x}_1, \end{cases}$$

$$w_2(x) = \begin{cases} w_1(x) - g_{21}, & x \leq \bar{x}_2, \\ Bx^{m_2^-} + \hat{V}_2(x), & x > \bar{x}_2, \end{cases}$$

where the positive constants A, B, $\underline{x}_1 > \bar{x}_2$, are the solution to

$$A\underline{x}_1^{m_1^+} + \hat{V}_1(\underline{x}_1) = w_2(\underline{x}_1) - g_{12} = B\underline{x}_1^{m_2^-} + \hat{V}_2(\underline{x}_1) - g_{12}, \tag{4.24}$$

$$Am_1^+\underline{x}_1^{m_1^+-1} + \hat{V}_1'(\underline{x}_1) = w_2'(\underline{x}_1) = Bm_2^-\underline{x}_1^{m_2^--1} + \hat{V}_2'(\underline{x}_1), \tag{4.25}$$

$$A\bar{x}_2^{m_1^+} + \hat{V}_1(\bar{x}_2) - g_{21} = w_1(\bar{x}_2) - g_{21} = B\bar{x}_2^{m_2^-} + \hat{V}_2(\bar{x}_2), \tag{4.26}$$

$$Am_1^+\bar{x}_2^{m_1^+-1} + \hat{V}_1'(\bar{x}_2) = w_1'(\bar{x}_2) = Bm_2^-\bar{x}_2^{m_2^--1} + \hat{V}_2'(\bar{x}_2), \tag{4.27}$$

exist and are explicitly determined after some calculations by

$$\overline{x}_2 = \left[\frac{-m_2^-(g_{21} + g_{12}y^{m_1^+})}{(K_1 - K_2)(\gamma - m_2^-)(1 - y^{m_1^+-\gamma})}\right]^{\frac{1}{\gamma}}, \tag{4.28}$$

$$\underline{x}_1 = \frac{\overline{x}_2}{y}, \tag{4.29}$$

$$B = \frac{(K_1 - K_2)(m_1^+ - \gamma)\underline{x}_1^{\gamma - m_2^-} + m_1^+ g_{12}\underline{x}_1^{-m_2}}{m_1^+ - m_2^-}, \tag{4.30}$$

$$A = B\underline{x}_1^{m_2^- - m_1^+} - (K_1 - K_2)\underline{x}_1^{\gamma - m_1^+} - g_{12}\underline{x}_1^{-m_1^+}, \tag{4.31}$$

with y a solution in

$$\left(0, \left(-\frac{g_{21}}{g_{12}}\right)^{\frac{1}{m_1^+}}\right)$$

to the equation

$$\begin{aligned} &m_1^+(\gamma - m_2^-)\left(1 - y^{m_1^+-\gamma}\right)\left(g_{12}y^{m_2^-} + g_{21}\right) \\ &\quad + m_2^-(m_1^+ - \gamma)\left(1 - y^{m_2^--\gamma}\right)\left(g_{12}y^{m_1^+} + g_{21}\right) = 0. \end{aligned} \tag{4.32}$$

Using (2.7), we have $y < \big(-\frac{g_{21}}{g_{12}}\big)^{\frac{1}{m_1^+}} < 1$. As such, $0 < \bar{x}_2 < \underline{x}_1$. Furthermore, by using (4.29), and (4.32) satisfied by y, we may easily check that A and B are positive constants.

Notice that by construction, w_1 (resp., w_2) is C^2 on $(0, \underline{x}_1) \cup (\underline{x}_1, \infty)$ (resp., $(0, \bar{x}_2) \cup (\bar{x}_2, \infty)$) and C^1 at $\underline{x}_1$ (resp., $\bar{x}_2$).

By using Lemma 3.7, we now show that w_i, $i = 1, 2$, is a viscosity solution to the system

$$\min\{rw_i - \mathcal{L}_i w_i - f_i, w_i - (w_j - g_{ij})\} = 0 \quad \text{on } (0, \infty),\ i, j = 1, 2,\ j \neq i. \tag{4.33}$$

Since the proof is similar for both w_i, $i = 1, 2$, we prove the result only for w_1. We first check that

$$w_1 \geq w_2 - g_{12} \quad \forall\, 0 < x < \underline{x}_1. \tag{4.34}$$

From the definition of w_1 and w_2 and using the fact that $g_{12} + g_{21} > 0$, it is straightforward to see that

$$w_1 \geq w_2 - g_{12} \quad \forall\, 0 < x \leq \overline{x}_2. \tag{4.35}$$

Now, we need to prove that

$$G(x) := Ax^{m_1^+} + \hat{V}_1(x) - Bx^{m_2^-} - \hat{V}_2(x) + g_{12} \geq 0 \quad \forall\, \overline{x}_2 < x < \underline{x}_1. \tag{4.36}$$

We have $G(\bar{x}_2) = g_{12} + g_{21} > 0$ and $G(\underline{x}_1) = 0$. Suppose that there exists some $x_0 \in (\bar{x}_2, \underline{x}_1)$ such that $G(x_0) = 0$. We then deduce that there exists $x_3 \in (\bar{x}_0, \underline{x}_1)$ such that $G'(x_3) = 0$. As such, the equation $G'(x) = 0$ admits at least three solutions in $[\bar{x}_2, \underline{x}_1]$: $\{\bar{x}_2, x_3, \underline{x}_1\}$. However, a straightforward study of the function G shows that G' can take the value zero at most at two points in $(0, \infty)$. This leads to a contradiction, proving therefore (4.36).

By definition of w_1, we have in the classical sense

$$rw_1 - \mathcal{L}_1 w_1 - f = 0 \quad \text{on } (0, \underline{x}_1). \tag{4.37}$$

We now check that

$$rw_1 - \mathcal{L}_1 w_1 - f \geq 0 \quad \text{on } (\underline{x}_1, \infty) \tag{4.38}$$

holds true in the classical sense, and so a fortiori in the viscosity sense. By definition of w_1 on (x_1, ∞), and K_1, we have for all $x > \underline{x}_1$,

$$H(x) := rw_1(x) - \mathcal{L}_1 w_1(x) - f(x) = \frac{K_2 - K_1}{K_1} x^\gamma + m_2^- LBx^{m_2^-} - rg_{12} \quad \forall x > \underline{x}_1, \tag{4.39}$$

where $L = \frac{1}{2}(\sigma_2^2 - \sigma_1^2)(m_2^- - 1) + b_2 - b_1$.

We distinguish two cases:

• First, if $L \geq 0$, the function H would be nondecreasing on $(0, \infty)$ with $\lim_{x \to 0^+} H(x) = -\infty$ and $\lim_{x \to \infty} H(x) = +\infty$. As such, it suffices to show that $H(\underline{x}_1) \geq 0$. From (4.24)–(4.25), we have

$$H(\underline{x}_1) = (K_2 - K_1)\left[\frac{m_1^+ - m_2^-}{K_1} - (m_1^+ - \gamma) m_2^- L\right] - rg_{12} + m_1^+ m_2^- g_{12} L.$$

Using relations (4.21), (4.24), (4.25), (4.29), and the definition of m_1^+ and m_2^-, we then obtain

$$H(\underline{x}_1) = \frac{m_1^+(m_1^+ - m_2^-)}{K_1(m_1^+ - \gamma)} - r \geq \frac{m_1^+}{K_1(m_1^+ - \gamma)} - r \geq 0.$$

- Second, if $L < 0$, it suffices to show that

$$\frac{K_2 - K_1}{K_1} x^\gamma - r g_{12} \geq 0 \quad \forall\, x > \underline{x}_1,$$

which is rather straightforward from (4.21) and (4.29).

Relations (4.34), (4.37), (4.38), and the regularity of w_i, $i = 1, 2$, as constructed, mean that the conditions of Lemma 3.7 are satisfied and we thus get the required assertion (4.33).

Since $w_1(0^+) = 0 = (-g_{12})_+$, $w_2(0^+) = -g_{21} = (-g_{21})_+$, and w_1, $\hat{V}_2$ satisfy a linear growth condition, we deduce from (4.33) and uniqueness to the PDE system (4.1)–(4.2) that

$$v_1 = w_1, v_2 = w_2 \quad \text{on } (0, \infty).$$

This proves $\underline{x}_1^* = \underline{x}_1$, $\mathcal{S}_1 = [x_1, \infty)$ and $\bar{x}_2^* = \bar{x}_2$, $\mathcal{S}_2 = (0, \bar{x}_2]$.

4.2. Identical diffusion operators with different profit functions. In this subsection, we suppose that $\mathcal{L}_1 = \mathcal{L}_2 = \mathcal{L}$, i.e., $b_1 = b_2 = b$, $\sigma_1 = \sigma_2 = \sigma > 0$. We then set $m^+ = m_1^+ = m_2^+$, $m^- = m_1^- = m_2^-$, and $\hat{X}^x = \hat{X}^{x,1} = \hat{X}^{x,2}$. Notice that in this case, the set Q_{ij}, $i, j = 1, 2$, $i \neq j$, introduced in Lemma 3.5, satisfies

$$\begin{aligned} Q_{ij} &= \{x \in \mathcal{C}_j : (f_j - f_i)(x) - r g_{ij} \geq 0\} \\ &\subset \hat{Q}_{ij} := \{x > 0 : (f_j - f_i)(x) - r g_{ij} \geq 0\}. \end{aligned} \tag{4.40}$$

Once we are given the profit functions f_i, f_j, the set $\hat{Q}_{ij}$ can be explicitly computed. Moreover, we prove in the next key lemma that the structure of $\hat{Q}_{ij}$, when it is connected, determines the same structure for the switching region $\mathcal{S}_i$.

LEMMA 4.2. *Let $i, j = 1, 2$, $i \neq j$.*

(1) *Assume that*

$$\sup_{x>0} (\hat{V}_j - \hat{V}_i)(x) > g_{ij}. \tag{4.41}$$

(a) *If there exists $0 < \underline{x}_{ij} < \infty$ such that*

$$\hat{Q}_{ij} = [\underline{x}_{ij}, \infty), \tag{4.42}$$

then $0 < \underline{x}_i^* < \infty$ and

$$\mathcal{S}_i = [\underline{x}_i^*, \infty).$$

(b) *If $g_{ij} \leq 0$ and there exists $0 < \bar{x}_{ij} < \infty$ such that*

$$\hat{Q}_{ij} = (0, \bar{x}_{ij}], \tag{4.43}$$

then $0 < \bar{x}_i^* < \infty$ and

$$\mathcal{S}_i = (0, \bar{x}_i^*].$$

(2) *If there exist* $0 < \underline{x}_{ij} < \bar{x}_{ij} < \infty$ *such that*

$$\hat{Q}_{ij} = [\underline{x}_{ij}, \bar{x}_{ij}], \tag{4.44}$$

then $0 < \underline{x}_i^* < \bar{x}_i^* < \infty$ *and*

$$\mathcal{S}_i = [\underline{x}_i^*, \bar{x}_i^*].$$

(3) *If* $g_{ij} \leq 0$ *and* $\hat{Q}_{ij} = (0, \infty)$*, then* $\mathcal{S}_i = (0, \infty)$ *and* $\mathcal{S}_j = \emptyset$.

Proof. (1a) Consider the case of condition (4.42). Since $\mathcal{S}_i \subset \hat{Q}_{ij}$ by Lemma 3.5, this implies $\underline{x}_i^* := \inf \mathcal{S}_i \geq \underline{x}_{ij} > 0$. We now claim that $\underline{x}_i^* < \infty$. On the contrary, the switching region $\mathcal{S}_i$ would be empty, and so v_i would satisfy on $(0, \infty)$

$$rv_i - \mathcal{L}v_i - f_i = 0 \quad \text{on } (0, \infty).$$

Then, v_i would be in the form

$$v_i(x) = Ax^{m^+} + Bx^{m^-} + \hat{V}_i(x), \quad x > 0.$$

Since $0 \leq v_i(0^+) < \infty$ and v_i is a nonnegative function satisfying a linear growth condition, and using the fact that $m^- < 0$ and $m^+ > 1$, we deduce that v_i should be equal to $\hat{V}_i$. Now, since we have $v_i \geq v_j - g_{ij} \geq \hat{V}_j - g_{ij}$, this would imply

$$\hat{V}_j(x) - \hat{V}_i(x) \leq g_{ij} \quad \forall x > 0.$$

This contradicts condition (4.41), and so $0 < \underline{x}_i^* < \infty$.

By definition of $\underline{x}_i^*$, we already know that $(0, \underline{x}_i^*) \subset \mathcal{C}_i$. We prove actually the equality, i.e., $\mathcal{S}_i = [\underline{x}_i^*, \infty)$ or $v_i(x) = v_j(x) - g_{ij}$ for all $x \geq \underline{x}_i^*$. Consider the function

$$w_i(x) = \begin{cases} v_i(x), & 0 < x < \underline{x}_i^*, \\ v_j(x) - g_{ij}, & x \geq \underline{x}_i^*. \end{cases}$$

We now check that w_i is a viscosity solution of

$$\min\{rw_i - \mathcal{L}w_i - f_i \,,\; w_i - (v_j - g_{ij})\} = 0 \quad \text{on } (0, \infty). \tag{4.45}$$

From Theorem 3.6, the function w_i is C^1 on $(0, \infty)$ and in particular at $\underline{x}_i^*$, where $w_i'(\underline{x}_i^*) = v_i'(\underline{x}_i^*) = v_j'(\underline{x}_i^*)$. We also know that $w_i = v_i$ is C^2 on $(0, \underline{x}_i^*) \subset \mathcal{C}_i$, and satisfies $rw_i - \mathcal{L}w_i - f_i = 0$, $w_i \geq (v_j - g_{ij})$ on $(0, \underline{x}_i^*)$. Hence, from Lemma 3.7, we need only check the viscosity supersolution property of w_i to

$$rw_i - \mathcal{L}w_i - f_i \geq 0 \quad \text{on } (\underline{x}_i^*, \infty). \tag{4.46}$$

For this, take some point $\bar{x} > \underline{x}_i^*$ and some smooth test function φ s.t. $\bar{x}$ is a local minimum of $w_i - \varphi$. Then, $\bar{x}$ is a local minimum of $v_j - (\varphi + g_{ij})$, and by the viscosity solution property of v_j to its Bellman PDE, we have

$$rv_j(\bar{x}) - \mathcal{L}\varphi(\bar{x}) - f_j(\bar{x}) \geq 0.$$

Now, since $\underline{x}_i^* \geq \underline{x}_{ij}$, we have $\bar{x} > \underline{x}_{ij}$ and so by (4.42), $\bar{x} \in \hat{Q}_{ij}$. Hence,

$$(f_j - f_i)(\bar{x}) - rg_{ij} \geq 0.$$

By adding the two previous inequalities, we also obtain the required supersolution inequality:

$$rw_i(\bar{x}) - \mathcal{L}\varphi(\bar{x}) - f_i(\bar{x}) \geq 0,$$

and so (4.45) is proved.

Since $w_i(0^+) = v_i(0^+)$ and w_i satisfies a linear growth condition, and from uniqueness of the viscosity solution to PDE (4.45), we deduce that w_i is equal to v_i. In particular, we have $v_i(x) = v_j(x) - g_{ij}$ for $x \geq \underline{x}_i^*$, which shows that $\mathcal{S}_i = [\underline{x}_i^*, \infty)$.

(1b) The case of condition (4.43) is dealt with by same arguments as above: we first observe that $0 < \bar{x}_i^* := \sup \mathcal{S}_i < \infty$ under (4.41), and then show with Lemma 3.7 that the function

$$w_i(x) = \begin{cases} v_j(x) - g_{ij}, & 0 < x < \bar{x}_i^*, \\ v_i(x), & x \geq \bar{x}_i^*, \end{cases}$$

is a viscosity solution to

$$\min\{rw_i - \mathcal{L}w_i - f_i \ , \ w_i - (v_j - g_{ij})\} = 0 \quad \text{on} \quad (0, \infty).$$

Then, under the condition that $g_{ij} \leq 0$, we see that $g_{ji} > 0$ by (2.7), and so $v_i(0^+) = -g_{ij} = (-g_{ji})_+ - g_{ij} = v_j(0^+) - g_{ij} = w_i(0^+)$. From uniqueness of the viscosity solution to PDE (4.45), we conclude that $v_i = w_i$, and so $\mathcal{S}_i = (0, \bar{x}_i^*]$.

(2) By Lemma 3.5 and (4.40), condition (4.44) implies $0 < \underline{x}_{ij} \leq \underline{x}_i^* \leq \bar{x}_i^* \leq \bar{x}_{ij} < \infty$. We claim that $\underline{x}_i^* < \bar{x}_i^*$. Otherwise, $\mathcal{S}_i = \{\bar{x}_i^*\}$ and v_i would satisfy $rv_i - \mathcal{L}v_i - f_i = 0$ on $(0, \bar{x}_i^*) \cup (\bar{x}_i^*, \infty)$. By continuity and the smooth-fit condition of v_i at $\bar{x}_i^*$, this implies that v_i satisfies actually

$$rv_i - \mathcal{L}v_i - f_i = 0, \quad x \in (0, \infty),$$

and so is in the form

$$v_i(x) = Ax^{m^+} + Bx^{m^-} + \hat{V}_i(x), \quad x \in (0, \infty).$$

Since $0 \leq v_i(0^+) < \infty$ and v_i is a nonnegative function satisfying a linear growth condition, this implies $A = B = 0$. Therefore, v_i is equal to $\hat{V}_i$, which also means that $\mathcal{S}_i = \emptyset$, a contradiction.

We now prove that $\mathcal{S}_i = [\underline{x}_i^*, \bar{x}_i^*]$. Let us consider the function

$$w_i(x) = \begin{cases} v_i(x), & x \in (0, \underline{x}_i^*) \cup (\bar{x}_i^*, \infty), \\ v_j(x) - g_{ij}, & x \in [\underline{x}_i^*, \bar{x}_i^*], \end{cases}$$

which is C^1 on $(0, \infty)$ and in particular on $\underline{x}_i^*$ and $\bar{x}_i^*$ from Theorem 3.6. Hence, by similar arguments as in case (1), using Lemma 3.7, we then show that w_i is a viscosity solution of

$$\min\{rw_i - \mathcal{L}w_i - f_i \ , \ w_i - (v_j - g_{ij})\} = 0. \tag{4.47}$$

Since $w_i(0^+) = v_i(0^+)$ and w_i satisfies a linear growth condition, and from uniqueness of the viscosity solution to PDE (4.47), we deduce that w_i is equal to v_i. In particular, we have $v_i(x) = v_j(x) - g_{ij}$ for $x \in [\underline{x}_i^*, \bar{x}_i^*]$, which shows that $\mathcal{S}_i = [\underline{x}_i^*, \bar{x}_i^*]$.

(3) Suppose that $g_{ij} \leq 0$ and $\hat{Q}_{ij} = (0,\infty)$. We shall prove that $\mathcal{S}_i = (0,\infty)$ and $\mathcal{S}_j = \emptyset$. To this end, we consider the smooth functions $w_i = \hat{V}_j - g_{ij}$ and $w_j = \hat{V}_j$. Then, recalling the ODE satisfied by $\hat{V}_j$, and inequality (2.7), we get

$$rw_j - \mathcal{L}w_j - f_j \;=\; 0, w_j - (w_i - g_{ji}) \;=\; g_{ij} + g_{ji} \;\geq\; 0.$$

Therefore w_j is a smooth (and so a viscosity) solution to

$$\min\big[rw_j - \mathcal{L}w_j - f_j, w_j - (w_i - g_{ji})\big] = 0 \qquad \text{on } \; (0,\infty).$$

On the other hand, by definition of $\hat{Q}_{ij}$, which is assumed equal to $(0,\infty)$, we have

$$\begin{aligned} rw_i(x) - \mathcal{L}w_i(x) - f_i(x) &= r\hat{V}_j(x) - \mathcal{L}\hat{V}_j(x) - f_j(x) + f_j(x) - f_i(x) - rg_{ij} \\ &= f_j(x) - f_i(x) - rg_{ij} \;\geq\; 0 \quad \forall x > 0. \end{aligned}$$

Moreover, by construction we have $w_i = w_j - g_{ij}$. Therefore w_i is a smooth (and so a viscosity) solution to

$$\min\big[rw_i - \mathcal{L}w_i - f_i, w_i - (w_j - g_{ij})\big] = 0 \qquad \text{on } \; (0,\infty).$$

Notice also that $g_{ji} > 0$ by (2.7) and since $g_{ij} \leq 0$. Hence, $w_i(0^+) = -g_{ij} = (-g_{ij})_+ = v_i(0^+)$, $w_j(0^+) = 0 = (-g_{ji})_+ = v_j(0^+)$. From the uniqueness result of Theorem 3.4, we deduce that $v_i = w_i$, $v_j = w_j$, which proves that $\mathcal{S}_i = (0,\infty)$, $\mathcal{S}_j = \emptyset$. □

We shall now provide explicit solutions to the switching problem under general assumptions on the running profit functions, which include several interesting cases for applications:

(**HF**) There exists $\hat{x} \in \mathbb{R}_+$ s.t. the function $F := f_2 - f_1$
is decreasing on $(0,\hat{x})$, increasing on $[\hat{x},\infty)$,
and $F(\infty) := \lim_{x\to\infty} F(x) > 0, \quad g_{12} \;>\; 0.$

Under **(HF)**, there exists some $\bar{x} \in \mathbb{R}_+$ ($\bar{x} > \hat{x}$ if $\hat{x} > 0$ and $\bar{x} = 0$ if $\hat{x} = 0$) from which F is positive: $F(x) > 0$ for $x > \bar{x}$. Economically speaking, condition **(HF)** means that the profit in regime 2 is "better" than the profit in regime 1 from a certain level $\bar{x}$, and the improvement then becomes better and better. Moreover, since profit in regime 2 is better than in regime 1, it is natural to assume that the corresponding switching cost g_{12} from regime 1 to 2 should be positive. However, we shall consider both cases, where g_{21} is positive and nonpositive. Notice that $F(\hat{x}) < 0$ if $\hat{x} > 0$, $F(\hat{x}) = 0$ if $\hat{x} = 0$, and we do not assume necessarily $F(\infty) = \infty$.

Example 4.1. A typical example of different running profit functions satisfying **(HF)** is given by

$$f_i(x) = k_i x^{\gamma_i}, \;\; i = 1,2, \quad \text{with } 0 < \gamma_1 < \gamma_2 < 1, \;\; k_1 \in \mathbb{R}_+, \; k_2 > 0. \tag{4.48}$$

In this case, $\hat{x} = \big(\frac{k_1\gamma_1}{k_2\gamma_2}\big)^{\frac{1}{\gamma_2-\gamma_1}}$, and $\lim_{x\to\infty} F(x) = \infty$.

Another example of profit functions of interest in applications is the case when the profit function in regime 1 is $f_1 = 0$, and the other f_2 is increasing. In this case, assumption **(HF)** is satisfied with $\hat{x} = 0$.

The next proposition states the form of the switching regions in regimes 1 and 2, depending on the parameter values.

PROPOSITION 4.3. *Assume that* **(HF)** *holds.*

(1)
  (i) *If* $rg_{12} \geq F(\infty)$, *then* $\underline{x}_1^* = \infty$, *i.e.,* $\mathcal{S}_1 = \emptyset$.
  (ii) *If* $rg_{12} < F(\infty)$, *then* $\underline{x}_1^* \in (0,\infty)$ *and* $\mathcal{S}_1 = [\underline{x}_1^*, \infty)$.

(2)
  (i) *If* $rg_{21} \geq -F(\hat{x})$, *then* $\mathcal{S}_2 = \emptyset$.
  (ii) *If* $0 < rg_{21} < -F(\hat{x})$, *then* $0 < \underline{x}_2^* < \bar{x}_2^* < \underline{x}_1^*$, *and* $\mathcal{S}_2 = [\underline{x}_2^*, \bar{x}_2^*]$.
  (iii) *If* $g_{21} \leq 0$ *and* $-F(\infty) < rg_{21} < -F(\hat{x})$, *then* $0 = \underline{x}_2^* < \bar{x}_2^* < \underline{x}_1^*$, *and* $\mathcal{S}_2 = (0, \bar{x}_2^*]$.
  (iv) *If* $rg_{21} \leq -F(\infty)$, *then* $\mathcal{S}_2 = (0,\infty)$.

Proof. (1) From Lemma 3.5, we have

$$\hat{Q}_{12} = \{x > 0 : F(x) \geq rg_{12}\}. \tag{4.49}$$

Since $g_{12} > 0$, and $f_i(0) = 0$, we have $F(0) = 0 < rg_{12}$. Under **(HF)**, we then distinguish the two following cases:

(i) If $rg_{12} \geq F(\infty)$, then $\hat{Q}_{12} = \emptyset$, and so by Lemma 3.5 and (4.40), $\mathcal{S}_1 = \emptyset$.

(ii) If $rg_{12} < F(\infty)$, then there exists $\hat{x}_{12} \in (0,\infty)$ such that

$$\hat{Q}_{12} = [\underline{x}_{12}, \infty). \tag{4.50}$$

Moreover, since

$$(\hat{V}_2 - \hat{V}_1)(x) = E\left[\int_0^\infty e^{-rt} F(\hat{X}_t^x) dt\right] \quad \forall x > 0,$$

and F is lower bounded, we obtain by Fatou's lemma:

$$\liminf_{x\to\infty} (\hat{V}_2 - \hat{V}_1)(x) \geq E\left[\int_0^\infty e^{-rt} F(\infty) dt\right] = \frac{F(\infty)}{r} > g_{12}.$$

Hence, conditions (4.41)–(4.42) with $i = 1$, $j = 2$, are satisfied, and we obtain the first assertion by Lemma 4.2(1).

(2) From Lemma 3.5, we have

$$\hat{Q}_{21} = \{x > 0 : -F(x) \geq rg_{21}\}. \tag{4.51}$$

Under **(HF)**, we distinguish the following cases:

(i1) If $rg_{21} > -F(\hat{x})$, then $\hat{Q}_{21} = \emptyset$, and so $\mathcal{S}_2 = \emptyset$.

(i2) If $rg_{21} = -F(\hat{x})$, then either $\hat{x} = 0$ and so $\mathcal{S}_2 = \hat{Q}_{21} = \emptyset$, or $\hat{x} > 0$ and so $\hat{Q}_{21} = \{\hat{x}\}$, $\mathcal{S}_2 \subset \{\hat{x}\}$. In this last case, v_2 satisfies $rv_2 - \mathcal{L}v_2 - f_2 = 0$ on $(0,\hat{x}) \cup (\hat{x},\infty)$. By continuity and the smooth-fit condition of v_2 at $\hat{x}$, this implies that v_2 satisfies actually

$$rv_2 - \mathcal{L}v_2 - f_2 = 0, \quad x \in (0,\infty),$$

and so is in the form

$$v_2(x) = Ax^{m^+} + Bx^{m^-} + \hat{V}_2(x), \quad x \in (0,\infty).$$

Recalling that $0 \leq v_2(0^+) < \infty$ and v_2 is a nonnegative function satisfying a linear growth condition, this implies $A = B = 0$. Therefore, v_2 is equal to $\hat{V}_2$, which also means that $\mathcal{S}_2 = \emptyset$.

If $rg_{21} < -F(\hat{x})$, we need to distinguish three subcases depending on g_{21}:

- If $g_{21} > 0$, then there exist $0 < \underline{x}_{21} < \hat{x} < \bar{x}_{21} < \infty$ such that

$$\hat{Q}_{21} = [\underline{x}_{21}, \bar{x}_{21}]. \tag{4.52}$$

  We then conclude with Lemma 4.2(2) for $i = 2$, $j = 1$.
- If $g_{21} \leq 0$ with $rg_{21} > -F(\infty)$, then there exists $\bar{x}_{21} < \infty$ s.t.

$$\hat{Q}_{21} = (0, \bar{x}_{21}].$$

  Moreover, we clearly have $\sup_{x>0}(\hat{V}_1 - \hat{V}_2)(x) > (\hat{V}_1 - \hat{V}_2)(0) = 0 \geq g_{21}$. Hence, conditions (4.41) and (4.43) with $i = 2$, $j = 1$, are satisfied, and we deduce from Lemma 4.2(1) that $\mathcal{S}_2 = (0, \bar{x}_2^*]$ with $0 < \bar{x}_2^* < \infty$.
- If $rg_{21} \leq -F(\infty)$, then $\hat{Q}_{21} = (0, \infty)$, and we deduce from Lemma 4.2(3) for $i = 2$, $j = 1$, that $\mathcal{S}_2 = (0, \infty)$.

Finally, in the two above subcases when $\mathcal{S}_2 = [\underline{x}_2^*, \bar{x}_2^*]$ or $(0, \bar{x}_2^*]$, we notice that $\bar{x}_2^* < \underline{x}_1^*$ since $\mathcal{S}_2 \subset \mathcal{C}_1 = (0, \infty) \setminus \mathcal{S}_1$, which is equal, from (1), either to $(0, \infty)$ when $\underline{x}_1^* = \infty$ or to $(0, \underline{x}_1^*)$. □

Remark 4.2. In our viscosity solutions approach, the structure of the switching regions is derived from the smooth-fit property of the value functions, uniqueness result for viscosity solutions, and Lemma 3.5. This contrasts with the classical verification approach, where the structure of switching regions should be guessed ad hoc and checked a posteriori by a verification argument.

Economic interpretation. The previous proposition shows that, under **(HF)**, the switching region in regime 1 has two forms depending on the size of its corresponding positive switching cost: If g_{12} is larger than the "maximum net" profit $F(\infty)$ that one can expect by changing regime (case 1(i), which may occur only if $F(\infty) < \infty$), then one has no interest in switching regime, and one always stays in regime 1, i.e., $\mathcal{C}_1 = (0, \infty)$. However, if this switching cost is smaller than $F(\infty)$ (case 1(ii), which always holds true when $F(\infty) = \infty$), then there is some positive threshold from which it is optimal to change regime.

The structure of the switching region in regime 2 exhibits several different forms depending on the sign and size of its corresponding switching cost g_{21} with respect to the values $-F(\infty) < 0$ and $-F(\hat{x}) \geq 0$. If g_{21} is nonnegative larger than $-F(\hat{x})$ (case 2(i)), then one has no interest in switching regime, and one always stays in regime 2, i.e., $\mathcal{C}_2 = (0, \infty)$. If g_{21} is positive, but not too large (case 2(ii)), then there exists some bounded closed interval, which is not a neighborhood of zero, where it is optimal to change regime. Finally, when the switching cost g_{21} is negative, it is optimal to switch to regime 1 at least for small values of the state. Actually, if the negative cost g_{21} is larger than $-F(\infty)$ (case 2(iii), which always holds true for negative cost when $F(\infty) = \infty$), then the switching region is a bounded neighborhood of 0. Moreover, if the cost is negative large enough (case 2(iv), which may occur only if $F(\infty) < \infty$), then it is optimal to change regime for every value of the state.

By combining the different cases for regimes 1 and 2, and observing that case 2(iv) is not compatible with case 1(ii) by (2.7), we then have a priori seven different forms for both switching regions. These forms reduce actually to three when $F(\infty) = \infty$. The various structures of the switching regions are depicted in Figure 2.

Finally, we complete results of Proposition 4.3 by providing the explicit solutions for the value functions and the corresponding boundaries of the switching regions in the seven different cases depending on the model parameter values.

THEOREM 4.4. *Assume that* **(HF)** *holds.*

FIG. 2.

(1) *If* $rg_{12} < F(\infty)$ *and* $rg_{21} \geq -F(\hat{x})$, *then*

$$v_1(x) = \begin{cases} Ax^{m^+} + \hat{V}_1(x), & x < \underline{x}_1^*, \\ v_2(x) - g_{12}, & x \geq \underline{x}_1^*, \end{cases}$$
$$v_2(x) = \hat{V}_2(x),$$

where the constants A and $\underline{x}_1^*$ are determined by the continuity and smooth-fit conditions of v_1 at $\underline{x}_1^*$:

$$A(\underline{x}_1^*)^{m^+} + \hat{V}_1(\underline{x}_1^*) = \hat{V}_2(\underline{x}_1^*) - g_{12},$$
$$Am^+(\underline{x}_1^*)^{m^+-1} + \hat{V}_1'(\underline{x}_1^*) = \hat{V}_2'(\underline{x}_1^*).$$

In regime 1, it is optimal to switch to regime 2 whenever the state process X exceeds the threshold $\underline{x}_1^*$, while when we are in regime 2, it is optimal to never switch.

(2) *If $rg_{12} < F(\infty)$ and $0 < rg_{21} < -F(\hat{x})$, then*

$$v_1(x) = \begin{cases} A_1 x^{m^+} + \hat{V}_1(x), & x < \underline{x}_1^*, \\ v_2(x) - g_{12}, & x \geq \underline{x}_1^*, \end{cases} \tag{4.53}$$

$$v_2(x) = \begin{cases} A_2 x^{m^+} + \hat{V}_2(x), & x < \underline{x}_2^*, \\ v_1(x) - g_{21}, & \underline{x}_2^* \leq x \leq \bar{x}_2^*, \\ B_2 x^{m^-} + \hat{V}_2(x), & x > \bar{x}_2^*, \end{cases} \tag{4.54}$$

where the constants A_1 and $\underline{x}_1^*$ are determined by the continuity and smooth-fit conditions of v_1 at $\underline{x}_1^*$, and the constants A_2, B_2, $\underline{x}_2^*$, $\bar{x}_2^*$ are determined by the continuity and smooth-fit conditions of v_2 at $\underline{x}_2^*$ and $\bar{x}_2^*$:

$$A_1(\underline{x}_1^*)^{m^+} + \hat{V}_1(\underline{x}_1^*) = B_2(\underline{x}_1^*)^{m^-} + \hat{V}_2(\underline{x}_1^*) - g_{12}, \tag{4.55}$$
$$A_1 m^+(\underline{x}_1^*)^{m^+-1} + \hat{V}_1'(\underline{x}_1^*) = B_2 m^-(\underline{x}_1^*)^{m^--1} + \hat{V}_2'(\underline{x}_1^*), \tag{4.56}$$
$$A_2(\underline{x}_2^*)^{m^+} + \hat{V}_2(\underline{x}_2^*) = A_1(\underline{x}_2^*)^{m^+} + \hat{V}_1(\underline{x}_2^*) - g_{21}, \tag{4.57}$$
$$A_2 m^+(\underline{x}_2^*)^{m^+-1} + \hat{V}_2'(\underline{x}_2^*) = A_1 m^+(\underline{x}_2^*)^{m^+-1} + \hat{V}_1'(\underline{x}_2^*), \tag{4.58}$$
$$A_1(\bar{x}_2^*)^{m^+} + \hat{V}_1(\bar{x}_2^*) - g_{21} = B_2(\bar{x}_2^*)^{m^-} + \hat{V}_2(\bar{x}_2^*), \tag{4.59}$$
$$A_1 m^+(\bar{x}_2^*)^{m^+-1} + \hat{V}_1'(\bar{x}_2^*) = B_2 m^-(\bar{x}_2^*)^{m^--1} + \hat{V}_2'(\bar{x}_2^*). \tag{4.60}$$

In regime 1, it is optimal to switch to regime 2 whenever the state process X exceeds the threshold $\underline{x}_1^*$, while when we are in regime 2, it is optimal to switch to regime 1 whenever the state process lies between $\underline{x}_2^*$ and $\bar{x}_2^*$.

(3) *If $rg_{12} < F(\infty)$ and $g_{21} \leq 0$ with $-F(\infty) < rg_{21} < -F(\hat{x})$, then*

$$v_1(x) = \begin{cases} Ax^{m^+} + \hat{V}_1(x), & x < \underline{x}_1^*, \\ v_2(x) - g_{12}, & x \geq \underline{x}_1^*, \end{cases}$$

$$v_2(x) = \begin{cases} v_1(x) - g_{21}, & 0 < x \leq \bar{x}_2^*, \\ Bx^{m^-} + \hat{V}_2(x), & x > \bar{x}_2^*, \end{cases}$$

where the constants A and $\underline{x}_1^*$ are determined by the continuity and smooth-fit conditions of v_1 at $\underline{x}_1^*$, and the constants B and $\bar{x}_2^*$ are determined by the continuity and smooth-fit conditions of v_2 at $\bar{x}_2^*$:

$$A(\underline{x}_1^*)^{m^+} + \hat{V}_1(\underline{x}_1^*) = B(\underline{x}_1^*)^{m^-} + \hat{V}_2(\underline{x}_1^*) - g_{12},$$
$$Am^+(\underline{x}_1^*)^{m^+-1} + \hat{V}_1'(\underline{x}_1^*) = Bm^-(\underline{x}_1^*)^{m^--1} + \hat{V}_2'(\underline{x}_1^*),$$
$$A(\bar{x}_2^*)^{m^+} + \hat{V}_1(\bar{x}_2^*) - g_{21} = B(\bar{x}_2^*)^{m^-} + \hat{V}_2(\bar{x}_2^*),$$
$$Am^+(\bar{x}_2^*)^{m^+-1} + \hat{V}_1'(\bar{x}_2^*) = Bm^-(\bar{x}_2^*)^{m^--1} + \hat{V}_2'(\bar{x}_2^*).$$

(4) *If* $rg_{12} \geq F(\infty)$ *and* $rg_{21} \geq -F(\hat{x})$, *then* $v_1 = \hat{V}_1$, $v_2 = \hat{V}_2$. *It is optimal to never switch in both regimes* 1 *and* 2.

(5) *If* $rg_{12} \geq F(\infty)$ *and* $0 < rg_{21} < -F(\hat{x})$, *then*

$$v_1(x) = \hat{V}_1(x),$$
$$v_2(x) = \begin{cases} Ax^{m^+} + \hat{V}_2(x), & x < \underline{x}_2^*, \\ v_1(x) - g_{21}, & \underline{x}_2^* \leq x \leq \bar{x}_2^*, \\ Bx^{m^-} + \hat{V}_2(x), & x > \bar{x}_2^*, \end{cases}$$

where the constants A, B, $\underline{x}_2^*$, $\bar{x}_2^*$ *are determined by the continuity and smooth-fit conditions of* v_2 *at* $\underline{x}_2^*$ *and* $\bar{x}_2^*$:

$$\begin{aligned} A(\underline{x}_2^*)^{m^+} + \hat{V}_2(\underline{x}_2^*) &= \hat{V}_1(\underline{x}_2^*) - g_{21}, \\ Am^+(\underline{x}_2^*)^{m^+-1} + \hat{V}_2'(\underline{x}_2^*) &= \hat{V}_1'(\underline{x}_2^*), \\ \hat{V}_1(\bar{x}_2^*) - g_{21} &= B(\bar{x}_2^*)^{m^-} + \hat{V}_2(\bar{x}_2^*), \\ \hat{V}_1'(\bar{x}_2^*) &= Bm^-(\bar{x}_2^*)^{m^--1} + \hat{V}_2'(\bar{x}_2^*). \end{aligned}$$

In regime 1, *it is optimal to never switch, while when we are in regime* 2, *it is optimal to switch to regime* 1 *whenever the state process lies between* $\underline{x}_2^*$ *and* $\bar{x}_2^*$.

(6) *If* $rg_{12} \geq F(\infty)$ *and* $g_{21} \leq 0$ *with* $-F(\infty) < rg_{21} < -F(\hat{x})$, *then*

$$v_1(x) = \hat{V}_1(x),$$
$$v_2(x) = \begin{cases} v_1(x) - g_{21}, & 0 < x \leq \bar{x}_2^*, \\ Bx^{m^-} + \hat{V}_2(x), & x > \bar{x}_2^*, \end{cases}$$

where the constants B *and* $\bar{x}_2^*$ *are determined by the continuity and smooth-fit conditions of* v_2 *at* $\bar{x}_2^*$:

$$\begin{aligned} \hat{V}_1(\bar{x}_2^*) - g_{21} &= B(\bar{x}_2^*)^{m^-} + \hat{V}_2(\bar{x}_2^*), \\ \hat{V}_1'(\bar{x}_2^*) &= Bm^-(\bar{x}_2^*)^{m^--1} + \hat{V}_2'(\bar{x}_2^*). \end{aligned}$$

In regime 1, *it is optimal to never switch, while when we are in regime* 2, *it is optimal to switch to regime* 1 *whenever the state process lies below* $\bar{x}_2^*$.

(7) *If* $rg_{12} \geq F(\infty)$ *and* $rg_{21} \leq -F(\infty)$, *then* $v_1 = \hat{V}_1$ *and* $v_2 = v_1 - g_{12}$. *In regime* 1, *it is optimal to never switch, while when we are in regime* 2, *it is always optimal to switch to regime* 1.

Proof. We prove the result only for case (2) since the other cases are dealt with similarly and are even simpler. Case (2) corresponds to the combination of cases 1(ii) and 2(ii) in Proposition 4.3. We then have $\mathcal{S}_1 = [\underline{x}_1^*, \infty)$, which means that $v_1 = v_2 - g_{12}$ on $[\underline{x}_1^*, \infty)$ and v_1 is a solution to $rv_1 - \mathcal{L}v_1 - f_1 = 0$ on $(0, \underline{x}_1^*)$. Since $0 \leq v_1(0^+) < \infty$, v_1 should have the form expressed in (4.53). Moreover, $\mathcal{S}_2 = [\underline{x}_2^*, \bar{x}_2^*]$, which means that $v_2 = v_1 - g_{21}$ on $[\underline{x}_2^*, \bar{x}_2^*]$, and v_2 satisfies $rv_2 - \mathcal{L}v_2 - f_2 = 0$ on $\mathcal{C}_2 = (0, \underline{x}_2^*) \cup (\bar{x}_2^*, \infty)$. Recalling again that $0 \leq v_2(0^+) < \infty$ and v_2 satisfies a linear growth condition, we deduce that v_2 has the form expressed in (4.54). Finally, the constants A_1, $\underline{x}_1^*$, which completely characterize v_1, and the constants A_2, B_2, $\underline{x}_2^*$, $\bar{x}_2^*$, which completely characterize v_2, are determined by the six relations (4.55)–(4.60) resulting from the continuity and smooth-fit conditions of v_1 at $\underline{x}_1^*$ and v_2 at $\underline{x}_2^*$ and $\bar{x}_2^*$, and from recalling that $\bar{x}_2^* < \underline{x}_1^*$. ∎

Remark 4.3. In the classical approach, for instance in case (2), we construct a priori a candidate solution in the form (4.53)–(4.54) and we have to check the existence of a sextuple solution to (4.55)–(4.60), which may be somewhat tedious! Here, by the viscosity solutions approach, and since we already state the smooth-fit C^1 property of the value functions, we know a priori the existence of a sextuple solution to (4.55)–(4.60).

Appendix A. Proof of comparison principle. In this section, we prove a comparison principle for the system of variational inequalities (3.8). The comparison result in [10] for switching problems in a finite horizon does not apply in our context. Inspired by [8], we first produce some suitable perturbation of a viscosity supersolution to deal with the switching obstacle, and then follow the general viscosity solution technique; see, e.g., [3].

THEOREM A.1. *Suppose u_i, $i \in \mathbb{I}_d$, are continuous viscosity subsolutions to the system of variational inequalities* (3.8) *on $(0,\infty)$, and w_i, $i \in \mathbb{I}_d$, are continuous viscosity supersolutions to the system of variational inequalities* (3.8) *on $(0,\infty)$, satisfying the boundary conditions $u_i(0^+) \le w_i(0^+)$, $i \in I_d$, and the linear growth condition*

$$|u_i(x)| + |w_i(x)| \le C_1 + C_2 x \quad \forall x \in (0,\infty),\ i \in \mathbb{I}_d, \tag{A.1}$$

for some positive constants C_1 and C_2. Then,

$$u_i \le w_i \quad \text{on } (0,\infty)\ \ \forall i \in \mathbb{I}_d.$$

Proof. Step 1. Let u_i and w_i, $i \in \mathbb{I}_d$, as in Theorem A.1. We first construct strict supersolutions to the system (3.8) with suitable perturbations of w_i, $i \in \mathbb{I}_d$. We set

$$h(x) = C_1' + C_2' x^p, \quad x > 0,$$

where C_1', $C_2' > 0$, and $p > 1$ are positive constants to be determined later. We then define for all $\lambda \in (0,1)$ the continuous functions on $(0,\infty)$ by

$$w_i^\lambda = (1-\lambda) w_i + \lambda(h + \alpha_i), \quad i \in \mathbb{I}_d,$$

where $\alpha_i = \min_{j \ne i} g_{ji}$. We then see that for all $\lambda \in (0,1)$, $i \in \mathbb{I}_d$,

$$\begin{aligned} w_i^\lambda - \max_{j \ne i}(w_j^\lambda - g_{ij}) &= \lambda\alpha_i + (1-\lambda)w_i - \max_{j \ne i}[(1-\lambda)(w_j - g_{ij}) + \lambda\alpha_j - \lambda g_{ij}] \\ &\ge (1-\lambda)[w_i - \max_{j \ne i}(w_j - g_{ij})] + \lambda\left(\alpha_i + \min_{j \ne i}(g_{ij} - \alpha_j)\right) \\ &\ge \lambda \min_{i \in \mathbb{I}_d}\left(\alpha_i + \min_{j \ne i}(g_{ij} - \alpha_j)\right) \\ &\ge \lambda \underline{\nu}, \end{aligned} \tag{A.2}$$

where $\underline{\nu} := \min_{i \in \mathbb{I}_d}[\alpha_i + \min_{j \ne i}(g_{ij} - \alpha_j)]$ is a constant independent of i. We now check that $\underline{\nu} > 0$, i.e., $\nu_i := \alpha_i + \min_{j \ne i}(g_{ij} - \alpha_j) > 0$, $\forall i \in \mathbb{I}_d$. Indeed, fix $i \in \mathbb{I}_d$, and let $k \in \mathbb{I}_d$ such that $\min_{j \ne i}(g_{ij} - \alpha_j) = g_{ik} - \alpha_k$ and set $\underline{i}$ such that $\alpha_i = \min_{j \ne i} g_{ji} = g_{\underline{i}i}$. We then have

$$\nu_i = g_{\underline{i}i} + g_{ik} - \min_{j \ne k} g_{jk} \ > \ g_{\underline{i}k} - \min_{j \ne k} g_{jk} \ \ge \ 0$$

by (2.6) and thus $\underline{\nu} > 0$.

By definition of the Fenchel–Legendre function in (2.5), and by setting $\tilde{f}(1) = \max_{i\in\mathbb{I}_d} \tilde{f}_i(1)$, we have for all $i \in \mathbb{I}_d$,

$$f_i(x) \le \tilde{f}(1) + x \ \le \tilde{f}(1) + 1 + x^p \quad \forall x > 0.$$

Moreover, recalling that $r > b := \max_i b_i$, we can choose $p > 1$ s.t.

$$\rho \ := \ r - pb - \frac{1}{2}\sigma^2 p(p-1) > 0,$$

where we set $\sigma := \max_i \sigma_i > 0$. By choosing

$$C_1' \ \ge \ \frac{2 + \tilde{f}(1)}{r} - \min_i \alpha_i, C_2' \ \ge \ \frac{1}{\rho},$$

we then have for all $i \in \mathbb{I}_d$,

$$\begin{aligned} rh(x) - \mathcal{L}_i h(x) - f_i(x) &= rC_1' + C_2' x^p \left[r - pb_i - \frac{1}{2}\sigma_i^2 p(p-1) \right] - f_i(x) \\ &\ge rC_1' + \rho C_2' x^p - f_i(x) \\ &\ge 1 \quad \forall x > 0. \end{aligned} \tag{A.3}$$

From (A.2) and (A.3), we then deduce that for all $i \in \mathbb{I}_d$, $\lambda \in (0,1)$, w_i^λ is a supersolution to

$$\min\left\{ rw_i^\lambda - \mathcal{L}_i w_i^\lambda - f_i, w_i^\lambda - \max_{j\neq i}(w_j^\lambda - g_{ij}) \right\} \ge \lambda\delta \quad \text{on } (0,\infty), \tag{A.4}$$

where $\delta = \underline{\nu} \wedge 1 > 0$.

Step 2. In order to prove the comparison principle, it suffices to show that for all $\lambda \in (0,1)$,

$$\max_{j\in\mathbb{I}_d} \sup_{(0,+\infty)} (u_j - w_j^\lambda) \le 0$$

since the required result is obtained by letting λ go to 0. We argue by contradiction and suppose that there exist some $\lambda \in (0,1)$ and $i \in \mathbb{I}_d$ s.t.

$$\theta \ := \ \max_{j\in\mathbb{I}_d} \sup_{(0,+\infty)} (u_j - w_j^\lambda) = \sup_{(0,+\infty)} (u_i - w_i^\lambda) \ > \ 0. \tag{A.5}$$

From the linear growth condition (A.1), and since $p > 1$, we observe that $u_i(x) - w_i^\lambda(x)$ goes to $-\infty$ when x goes to infinity. By choosing also $C_1' \ge \max_i w_i(0^+)$, we then have $u_i(0^+) - w_i^\lambda(0^+) = u_i(0^+) - w_i(0^+) + \lambda(w_i(0^+) - C_1') \le 0$. Hence, by continuity of the functions u_i and w_i^λ, there exists $x_0 \in (0,\infty)$ s.t.

$$\theta = u_i(x_0) - w_i^\lambda(x_0).$$

For any $\varepsilon > 0$, we consider the functions

$$\begin{aligned} \Phi_\varepsilon(x,y) &= u_i(x) - w_i^\lambda(y) - \phi_\varepsilon(x,y), \\ \phi_\varepsilon(x,y) &= \frac{1}{4}|x - x_0|^4 + \frac{1}{2\varepsilon}|x - y|^2 \end{aligned}$$

for all $x, y \in (0,\infty)$. By standard arguments in the comparison principle, the function Φ_ε attains a maximum in $(x_\varepsilon, y_\varepsilon) \in (0,\infty)^2$, which converges (up to a subsequence) to (x_0, x_0) when ε goes to zero. Moreover,

$$\lim_{\varepsilon\to 0} \frac{|x_\varepsilon - y_\varepsilon|^2}{\varepsilon} = 0. \tag{A.6}$$

Applying Theorem 3.2 in [3], we get the existence of M_ε, $N_\varepsilon \in \mathbb{R}$ such that

$$\begin{aligned}(p_\varepsilon, M_\varepsilon) &\in J^{2,+}u_i(x_\varepsilon),\\ (q_\varepsilon, N_\varepsilon) &\in J^{2,-}w_i^\lambda(y_\varepsilon),\end{aligned}$$

where

$$\begin{aligned}p_\varepsilon &= D_x\phi_\varepsilon(x_\varepsilon, y_\varepsilon) = \frac{1}{\varepsilon}(x_\varepsilon - y_\varepsilon) + (x_\varepsilon - x_{_0})^3,\\ q_\varepsilon &= -D_y\phi_\varepsilon(x_\varepsilon, y_\varepsilon) = \frac{1}{\varepsilon}(x_\varepsilon - y_\varepsilon),\end{aligned}$$

and

$$\begin{pmatrix} M_\varepsilon & 0\\ 0 & -N_\varepsilon\end{pmatrix} \;\le\; D^2\phi_\varepsilon(x_\varepsilon, y_\varepsilon) + \varepsilon\left(D^2\phi_\varepsilon(x_\varepsilon, y_\varepsilon)\right)^2 \tag{A.7}$$

with

$$D^2\phi_\varepsilon(x_\varepsilon, y_\varepsilon) = \begin{pmatrix} 3(x_\varepsilon - x_{_0})^2 + \frac{1}{\varepsilon} & -\frac{1}{\varepsilon}\\ -\frac{1}{\varepsilon} & \frac{1}{\varepsilon}\end{pmatrix}.$$

By writing the viscosity subsolution property (3.9) of u_i and the viscosity strict supersolution property (A.4) of w_i^λ, we have the following inequalities:

$$\begin{aligned}\min\Bigg\{ru_i(x_\varepsilon) - \left(\frac{1}{\varepsilon}(x_\varepsilon - y_\varepsilon) + (x_\varepsilon - x_{_0})^3\right) b_i x_\varepsilon - \frac{1}{2}\sigma_i^2 x_\varepsilon^2 M_\varepsilon - f_i(x_\varepsilon),\\ u_i(x_\varepsilon) - \max_{j\neq i}(u_j - g_{ij})(x_\varepsilon)\Bigg\} \;\le\; 0,\end{aligned} \tag{A.8}$$

$$\begin{aligned}\min\Bigg\{rw_i^\lambda(y_\varepsilon) - \frac{1}{\varepsilon}(x_\varepsilon - y_\varepsilon)b_i y_\varepsilon - \frac{1}{2}\sigma_i^2 y_\varepsilon^2 N_\varepsilon - f_i(y_\varepsilon),\\ w_i^\lambda(y_\varepsilon) - \max_{j\neq i}(w_j^\lambda - g_{ij})(y_\varepsilon)\Bigg\} \;\ge\; \lambda\delta.\end{aligned} \tag{A.9}$$

We then distinguish the following two cases:

(1) $u_i(x_\varepsilon) - \max_{j\neq i}(u_j - g_{ij})(x_\varepsilon) \le 0$ in (A.8).

By sending $\varepsilon \to 0$, this implies

$$u_i(x_0) - \max_{j\neq i}(u_j - g_{ij})(x_0) \le 0. \tag{A.10}$$

On the other hand, we have by (A.9):

$$w_i^\lambda(y_\varepsilon) - \max_{j\neq i}(w_j^\lambda - g_{ij})(y_\varepsilon) \ge \lambda\delta,$$

so that by sending ε to zero,

$$w_i^\lambda(x_0) - \max_{j\neq i}(w_j^\lambda - g_{ij})(x_0) \geq \lambda\delta. \tag{A.11}$$

Combining (A.10) and (A.11), we obtain

$$\begin{aligned}\theta \;=\; u_i(x_0) - w_i^\lambda(x_0) &\leq -\lambda\delta + \max_{j\neq i}(u_j - g_{ij})(x_0) - \max_{j\neq i}(w_j^\lambda - g_{ij})(x_0)\\ &\leq -\lambda\delta + \max_{j\neq i}(u_j - w_j^\lambda)(x_0)\\ &\leq -\lambda\delta + \theta,\end{aligned}$$

which is a contradiction.

(2) $ru_i(x_\varepsilon) - \left(\frac{1}{\varepsilon}(x_\varepsilon - y_\varepsilon) + (x_\varepsilon - x_0)^3\right) b_i x_\varepsilon - \frac{1}{2}\sigma_i^2 x_\varepsilon^2 M_\varepsilon - f_i(x_\varepsilon) \leq 0$ in (A.8). Since by (A.9), we also have

$$rw_i^\lambda(y_\varepsilon) - \frac{1}{\varepsilon}(x_\varepsilon - y_\varepsilon)b_i y_\varepsilon - \frac{1}{2}\sigma_i^2 y_\varepsilon^2 N_\varepsilon - f_i(y_\varepsilon) \geq \lambda\delta,$$

this yields, by combining the above two inequalities,

$$\begin{aligned}ru_i(x_\varepsilon) - rw_i^\lambda(y_\varepsilon) - \frac{1}{\varepsilon}b_i(x_\varepsilon - y_\varepsilon)^2 - (x_\varepsilon - x_0)^3 b_i x_\varepsilon\\ +\frac{1}{2}\sigma_i^2 y_\varepsilon^2 N_\varepsilon - \frac{1}{2}\sigma_i^2 x_\varepsilon^2 M_\varepsilon + f_i(y_\varepsilon) - f_i(x_\varepsilon) \leq -\lambda\delta.\end{aligned} \tag{A.12}$$

Now, from (A.7), we have

$$\frac{1}{2}\sigma_i^2 x_\varepsilon^2 M_\varepsilon - \frac{1}{2}\sigma_i^2 y_\varepsilon^2 N_\varepsilon \leq \frac{3}{2\varepsilon}\sigma_i^2(x_\varepsilon - y_\varepsilon)^2 + \frac{3}{2}\sigma_i^2 x_\varepsilon^2(x_\varepsilon - x_0)^2\left(3\varepsilon(x_\varepsilon - x_0)^2 + 2\right),$$

so that by plugging into (A.12), we have

$$\begin{aligned}r\left(u_i(x_\varepsilon) - w_i^\lambda(y_\varepsilon)\right) \leq \frac{1}{\varepsilon}b_i(x_\varepsilon - y_\varepsilon)^2 + (x_\varepsilon - x_0)^3 b_i x_\varepsilon + \frac{3}{2\varepsilon}\sigma_i^2(x_\varepsilon - y_\varepsilon)^2\\ + \frac{3}{2}\sigma_i^2 x_\varepsilon^2(x_\varepsilon - x_0)^2\left(3\varepsilon(x_\varepsilon - x_0)^2 + 2\right) + f_i(y_\varepsilon) - f_i(x_\varepsilon) - \lambda\delta.\end{aligned}$$

By sending ε to zero, and using (A.6), continuity of f_i, we obtain the required contradiction that $r\theta \leq -\lambda\delta < 0$. This ends the proof of Theorem A.1. □

THE RELAXED STOCHASTIC MAXIMUM PRINCIPLE IN SINGULAR OPTIMAL CONTROL OF DIFFUSIONS*

SEID BAHLALI†, BOUALEM DJEHICHE‡, AND BRAHIM MEZERDI†

Abstract. This paper studies optimal control of systems driven by stochastic differential equations, where the control variable has two components, the first being absolutely continuous and the second singular. Our main result is a stochastic maximum principle for relaxed controls, where the first part of the control is a measure valued process. To achieve this result, we establish first order optimality necessary conditions for strict controls by using strong perturbation on the absolutely continuous component of the control and a convex perturbation on the singular one. The proof of the main result is based on the strict maximum principle, Ekeland's variational principle, and some stability properties of the trajectories and adjoint processes with respect to the control variable.

Key words. singular control, maximum principle, adjoint process, variational inequality, relaxed control, variational principle

1. Introduction.

We consider in this paper mixed, relaxed-singular stochastic control problems of systems governed by stochastic differential equations (SDEs), where the control variable has two components, the first being measure valued and the second singular. More precisely the system under consideration evolves according to the SDE

$$\begin{cases} dx_t^q = \int_{A_1} b\left(t, x_t^q, a\right) q_t\left(da\right) dt + \sigma\left(t, x_t^q\right) dB_t + G_t d\xi_t, \\ x^q(0) = x_0, \end{cases}$$

where b, σ, and G are given deterministic functions, x_0 is the initial state, and $B = (B_t)_{t\geq 0}$ is a standard Brownian motion, defined on a probability space $(\Omega, \mathcal{F}, P)$, equipped with a filtration $(\mathcal{F}_t)_{t\geq 0}$ satisfying the usual conditions. The control variable is a suitable process (q, ξ), where $q : \Omega \times [0,T] \longrightarrow P(A_1)$, $\xi : \Omega \times [0,T] \longrightarrow A_2 = ([0,\infty))^m$ are $\mathcal{F} \otimes B[0,T]$ measurable, $(\mathcal{F}_t)$ adapted, and ξ is an increasing process (componentwise), continuous on the left with limits on the right such that $\xi_0 = 0$.

The expected cost to be minimized over the class of admissible controls has the form

$$J(q,\xi) = E\left[g\left(x_T^q\right) + \int_0^T \int_{A_1} h\left(t, x_t^q, a\right) q_t(da) + \int_0^T k_t d\xi_t\right].$$

A control process that solves this problem is called optimal.

Singular control problems have been studied by many authors including Beněs, Shepp, and Witsenhausen [3], Chow, Menaldi, and Robin [6], Karatzas and Shreve

[13], Davis and Norman [7], and Haussmann and Suo [10, 11, 12]. See [10] for a complete list of references on the subject. The approaches used in these papers are mainly based on dynamic programming. It was shown in particular that the value function is a solution of a variational inequality, and the optimal state is a reflected diffusion at the free boundary. Note that in [10], the authors apply the compactification method to show existence of an optimal relaxed singular control.

The second major method for solving control problems is to derive necessary conditions satisfied by some optimal control, known as the stochastic maximum principle. The first version of the stochastic maximum principle that covers singular control problems was obtained by Cadenillas and Haussmann [5] for linear systems. Second order necessary conditions for optimality for nonlinear SDEs with a controlled diffusion matrix were obtained by Bahlali and Mezerdi [2], extending the Peng maximum principle [17] to singular control problems. A first order weak maximum principle has been derived by Bahlali and Chala [1] in which convex perturbations are used for both absolutely continuous and singular components.

Our main goal in this paper is to establish a maximum principle for relaxed-singular controls, where the first part of the control is a measure valued process. This leads to necessary conditions of optimality satisfied by an optimal control, which exists under general conditions on the coefficients (see [10]). To achieve this program, we first prove a first order stochastic maximum principle for strict controls by using spike variation of the absolutely continuous part of the control and a convex perturbation of the singular part. Then by applying Ekeland's variational principle, we are able to prove necessary conditions for near optimality, satisfied by a sequence of strict controls converging in some sense to the relaxed optimal control, by the so-called chattering lemma. The relaxed maximum principle is then derived by using some stability properties of the trajectories and the adjoint processes with respect to the control variable. Our result generalizes the classical relaxed maximum principle proved in Mezerdi and Bahlali [16], to relaxed-singular control problems. However, we note that our maximum principle does not cover the work of Cadenillas and Haussmann [5]. The systems considered in [5] are linear but with random coefficients. In addition, the control variable in [5] is allowed to enter into the diffusion coefficient.

The plan of the rest of the paper is as follows. In section 2, we formulate the control problem and describe the assumptions of the model. In section 3, we derive the maximum principle for strict controls. The last section is devoted to the maximum principle for relaxed controls, which is the main result of this paper.

2. Assumptions. Let T be a fixed strictly positive real number and $(\Omega, \mathcal{F}, \mathcal{F}_t, P)$ be a filtered probability space satisfying the usual conditions, on which a d-dimensional Brownian motion $B = (B_t)_t$ is defined. We assume that $(\mathcal{F}_t)_t$ is the natural filtration of (B_t) augmented by P-null sets of $\mathcal{F}$.

Consider the following sets. A_1 is a nonempty subset of R^k and $A_2 = ([0,\infty))^m$.

DEFINITION 2.1. *An admissible strict control is a pair* (u,ξ) *of* $(A_1 \times A_2)$*-valued, measurable,* $\mathcal{F}_t$*-adapted processes, such that*

(i) ξ *is of bounded variation, nondecreasing left-continuous with right limits and* $\xi_0 = 0$.

(ii)

$$E\left[\sup_{t\in[0,T]} |u_t|^2 + |\xi_T|^2\right] < \infty.$$

We denote by $\mathcal{U} = \mathcal{U}_1 \times \mathcal{U}_2$ *the set of admissible strict controls.*

For any $(u,\xi)\in\mathcal{U}$, we consider the SDE

$$\left\{\begin{array}{l} dx_t = b\left(t,x_t,u_t\right)dt + \sigma\left(t,x_t\right)dB_t + G_t d\xi_t, \\ x\left(0\right) = x_0, \end{array}\right. \tag{2.1}$$

where

$$\begin{array}{l} b : [0,T]\times\mathbb{R}^n\times A_1 \longrightarrow \mathbb{R}^n, \\ \sigma : [0,T]\times\mathbb{R}^n \longrightarrow \mathcal{M}_{n\times d}\left(\mathbb{R}\right), \\ G : [0,T] \longrightarrow \mathcal{M}_{n\times m}\left(\mathbb{R}\right). \end{array}$$

The expected cost is given by

$$J\left(u,\xi\right) = E\left[g\left(x_T\right) + \int_0^T h\left(t,x_t,u_t\right)dt + \int_0^T k_t d\xi_t\right], \tag{2.2}$$

where

$$\begin{array}{l} g : \mathbb{R}^n \longrightarrow \mathbb{R}, \\ h : [0,T]\times\mathbb{R}^n\times A_1 \longrightarrow \mathbb{R}, \\ k : [0,T] \longrightarrow \left([0,\infty)\right)^m. \end{array}$$

The strict optimal control problem is to minimize the functional $J\left(.\right)$ over $\mathcal{U}$. A control that solves this problem is called optimal.

The following assumptions will be in force throughout this paper:

$$\begin{array}{c} b,\sigma,g,h \text{ are continuously differentiable with respect to } x. \text{ They and all their} \\ \text{derivatives, } b_x,\sigma_x,g_x,,h_x, \text{are continuous in } (x,u). \\ \text{The derivatives } \sigma_x, g_x \text{ are bounded and } b_x, h_x \text{ are bounded uniformly in } u. \\ b,\sigma \text{ are bounded by } C\left(1+|x|+|u|\right). \\ G \text{ and } k \text{ are continuous and } G \text{ is bounded.} \end{array} \tag{2.3}$$

Under the above hypothesis, (2.1) has a unique strong solution and the cost is well defined from $\mathcal{U}$ into $\mathbb{R}$.

We need the following matrix notation. We denote by $\mathcal{M}_{n\times d}\left(\mathbb{R}\right)$ the space of $n\times d$ real matrices and by $\mathcal{M}^d_{n\times n}\left(\mathbb{R}\right)$ the linear space of vectors $M=\left(M_1,\ldots,M_d\right)$, where $M_i\in\mathcal{M}_{n\times n}\left(\mathbb{R}\right)$.

For any $M,N\in\mathcal{M}^d_{n\times n}\left(\mathbb{R}\right)$, $L,Q\in\mathcal{M}_{n\times d}\left(\mathbb{R}\right)$, $x,y\in\mathbb{R}^n$, and $z\in\mathbb{R}^d$, we use the following notations:

$xy=\sum_{i=1}^n x_i y_i\in\mathbb{R}$ is the product scalar in $\mathbb{R}^n$;

$LQ=\sum_{i=1}^d L_i Q_i\in\mathbb{R}$, where L_i and Q_i are the ith columns of L and Q;

$ML=\sum_{i=1}^d M_i L_i\in\mathbb{R}^n$;

$Mxz=\sum_{i=1}^d \left(M_i x\right) z_i\in\mathbb{R}^n$;

$MN=\sum_{i=1}^d M_i N_i\in\mathcal{M}_{n\times n}\left(\mathbb{R}\right)$;

$$MLN = \sum_{i=1}^{d} M_i L N_i \in \mathcal{M}_{n\times n}(\mathbb{R});$$
$$MLz = \sum_{i=1}^{d} M_i L z_i \in \mathcal{M}_{n\times n}(\mathbb{R}).$$

We denote by L^* the transpose of the matrix L and $M^* = (M_1^*, \dots, M_d^*)$.

3. The maximum principle for strict controls. Facing a control problem, one may ask for necessary conditions satisfied by some optimal control. Throughout this section, let us suppose that $(u,\xi) \in \mathcal{U}$ is an optimal strict control and denote by (x_t) the corresponding optimal trajectory, i.e., the solution of (2.1) controlled by (u,ξ). The strict maximum principle will be proved in two steps. First we define a family of perturbed controls $\left(u^\theta,\xi\right)$, where u^θ is a spike variation of the absolutely continuous part u on a small time interval. The first variational inequality is derived from the fact that

$$J\left(u^\theta,\xi\right) - J(u,\xi) \geq 0.$$

The second step is to introduce another family of perturbed controls $\left(u,\xi^\theta\right)$, where ξ^θ is a convex perturbation of ξ. The second variational inequality is then obtained from the inequality

$$J\left(u,\xi^\theta\right) - J(u,\xi) \geq 0.$$

3.1. The first variational inequality. To obtain the first variational inequality in the stochastic maximum principle, we define the strong perturbation of the absolutely continuous part of the control, sometimes called the spike variation,

$$\left(u_t^\theta,\xi_t\right) = \begin{cases} (v,\xi_t) & \text{if } t \in [\tau,\tau+\theta], \\ (u_t,\xi_t) & \text{otherwise,} \end{cases} \tag{3.1}$$

where $0 \leq \tau < T$ is fixed, $\theta > 0$ is sufficiently small, and v is an arbitrary A_1-valued, F_τ-measurable random variable such that $E[|v|^2] < +\infty$. Note that the singular part is not affected by the perturbation.

If $x_t^{\left(u^\theta,\xi\right)}$ denotes the trajectory associated with $\left(u^\theta,\xi\right)$, then

$$\begin{aligned} x_t^{\left(u^\theta,\xi\right)} &= x_t, \quad t \leq \tau, \\ dx_t^{\left(u^\theta,\xi\right)} &= b\left(t, x_t^{\left(u^\theta,\xi\right)}, v\right)dt + \sigma\left(t, x_t^{\left(u^\theta,\xi\right)}\right)dB_t + G_t d\xi_t, \quad \tau < t < \tau+\theta, \\ dx_t^{\left(u^\theta,\xi\right)} &= b\left(t, x_t^{\left(u^\theta,\xi\right)}, u_t\right)dt + \sigma\left(t, x_t^{\left(u^\theta,\xi\right)}\right)dB_t + G_t d\xi_t, \quad \tau+\theta < t < T. \end{aligned}$$

It is easy to check by standard arguments that

$$E\left(\sup_{t\in[0,T]}\left|x_t^{\left(u^\theta,\xi\right)} - x_t\right|^2\right) \longrightarrow 0 \text{ as } \theta \longrightarrow 0. \tag{3.2}$$

Since (u,ξ) is optimal, then

$$J(u,\xi) \leq J\left(u^\theta,\xi\right) = J(u,\xi) + \theta\left.\frac{dJ\left(u^\theta,\xi\right)}{d\theta}\right|_{\theta=0} + o(\theta)$$

if the indicated derivative exists. Thus a necessary condition for optimality is that

$$\left.\frac{dJ\left(u^{\theta},\xi\right)}{d\theta}\right|_{\theta=0}\geq 0.$$

The rest of this subsection is devoted to the computation of this derivative.

Note that since $b(t,x,u)$ and $h(t,x,u)$ are sufficiently integrable, then the following property holds:

$$\frac{1}{\theta}\int_{t}^{t+\theta}E\left[\left|f(s,x_{s},u_{s})-f(t,x_{t},u_{t})\right|^{2}\right]\longrightarrow 0\ as\ \theta\longrightarrow 0,\ dt-a.e, \tag{3.3}$$

where f stands for b or h.

Choose τ such that (3.3) holds. We define y as the solution of the linear SDE

$$\begin{cases} dy_{t}=b_{x}\left(s,x_{s},u_{s}\right)y_{s}ds+\sigma_{x}\left(s,x_{s}\right)y_{s}dB_{s},\ \tau\leq s\leq T,\\ y_{\tau}=b\left(\tau,x_{\tau},v\right)-b\left(\tau,x_{\tau},u_{\tau}\right)\end{cases} \tag{3.4}$$

and define ς by

$$\begin{cases} d\varsigma_{t}=h_{x}\left(s,x_{s},u_{s}\right)y_{s}ds,\ \tau\leq s\leq T,\\ \varsigma_{\tau}=h\left(\tau,x_{\tau},v\right)-h\left(\tau,x_{\tau},u_{\tau}\right).\end{cases}$$

Lemma 3.1.

$$\lim_{\theta\to 0}E\left[\left|\frac{x_{T}^{\left(u^{\theta},\xi\right)}-x_{T}}{\theta}-y_{T}\right|^{2}\right]=0, \tag{3.5a}$$

$$\lim_{\theta\to 0}E\left[\left|\frac{1}{\theta}\int_{\tau}^{T}\left(h\left(t,x_{t},u_{t}^{\theta}\right)-h\left(t,x_{t},u_{t}\right)\right)dt-\varsigma_{T}\right|^{2}\right]=0. \tag{3.5b}$$

Proof. Since $x_{T}^{\left(u^{\theta},\xi\right)}-x_{T}$ does not depend on the singular part, the proof follows that of [4, Lemma 2.2]. □

Corollary 3.2.

$$\left.\frac{dJ\left(u^{\theta},\xi\right)}{d\theta}\right|_{\theta=0}=E\left[g_{x}\left(x_{T}\right).y_{T}+\varsigma_{T}\right]. \tag{3.6}$$

Proof. See [4, Corollary 2.1]. □

Let us introduce the adjoint process and the first variational inequality from (3.6). We proceed as in Bensoussan [4].

Let $\Phi(t,\tau)$ be the solution of the linear equation

$$\begin{cases} d\Phi(t,\tau)=b_{x}(t,x_{t},u_{t})\Phi(t,\tau)dt+\sigma_{x}(t,x_{t})\Phi(t,\tau)dB_{t},\ t>\tau,\\ \Phi(\tau,\tau)=I_{d}.\end{cases} \tag{3.7}$$

This equation is linear with bounded coefficients. Hence it admits a unique strong solution which is invertible, and its inverse Ψ_{t} is the unique solution of

$$\begin{cases} d\Psi_{t}=\left[\sigma_{x}(t,x_{t})\Psi_{t}\sigma_{x}^{*}(t,x_{t})-\Psi_{t}b_{x}\left(t,x_{t},u_{t}\right)\right]dt-\Psi_{t}\sigma_{x}\left(t,x_{t}\right)dB_{t},\ t>\tau,\\ \Psi(\tau,\tau)=I_{d}.\end{cases} \tag{3.8}$$

Moreover $\Phi(t,\tau)$ satisfies a semigroup property; that is, if $t > s > r$, then $\Phi(t,r) = \Phi(t,s).\Phi(s,r)$, which implies in particular that $\Phi(t,\tau) = \Phi(t)\Psi(\tau)$, where $\Phi(t) = \Phi(t,0)$ and $\Psi(t) = \Psi(t,0)$.

By the uniqueness property, it is easy to check that

$$y(t) = \Phi(t,\tau)\left(b\left(\tau, x_\tau, v\right) - b\left(\tau, x_\tau, u_\tau\right)\right).$$

Then replacing $y(t)$ with its value in (3.4), it holds that

$$\begin{aligned}\left.\frac{dJ\left(u^\theta,\xi\right)}{d\theta}\right|_{\theta=0} &= E\left(g_x\left(x_T\right).\Phi(T,\tau)\left(b\left(\tau,x_\tau,v\right) - b\left(\tau,x_\tau,u_\tau\right)\right)\right)\\ &\quad + E\left(h\left(\tau,x_\tau,v\right) - h\left(\tau,x_\tau,u_\tau\right)\right)\\ &\quad + E\left(\int_\tau^T h_x\left(s,x_s,u_s\right)\Phi(s,\tau)\left(b\left(\tau,x_\tau,v\right) - b\left(\tau,x_\tau,u_\tau\right)\right)ds\right).\end{aligned}$$

Now if we define the adjoint process by

$$p_t = E\left[\Psi_t^*\Phi_T^* g_x(x_T) + \Psi_t^*\int_t^T \Phi_s^* h_x\left(s,x_s,u_s\right)ds/\ \mathcal{F}_t\right], \tag{3.9}$$

it follows that

$$\left.\frac{dJ\left(u^\theta,\xi\right)}{d\theta}\right|_{\theta=0} = E\left[p_t.\left(b\left(\tau,x_\tau,v\right) - b\left(\tau,x_\tau,u_\tau\right)\right) + \left(h\left(\tau,x_\tau,v\right) - h\left(\tau,x_\tau,u_\tau\right)\right)\right].$$

If we define the Hamiltonian H from $[0,T]\times\mathbb{R}^n\times A_1\times\mathbb{R}^n$ into $\mathbb{R}$ by

$$H\left(t,x,v,p\right) = h\left(t,x,v\right) + p.b\left(t,x,v\right),$$

then we get from the optimality of (u,ξ) the first variational inequality

$$0 \le E\left[H\left(\tau,x_\tau,v,p_\tau\right) - H\left(\tau,x_\tau,u_\tau,p_\tau\right)\right], d\tau - a.e. \tag{3.10}$$

3.2. The second variational inequality. To obtain the second variational inequality of the stochastic maximum principle, we introduce the convex perturbation

$$\left(u_t,\xi_t^\theta\right) = \left(u_t,\xi_t + \theta\left(\eta_t - \xi_t\right)\right), \tag{3.11}$$

where $\theta > 0$ and η is an arbitrary element of $\mathcal{U}_2$. Note that the first part of the control is not affected by the perturbation. Since (u,ξ) is an optimal control, we'll derive the second variational inequality from the fact that

$$0 \le J\left(u,\xi^\theta\right) - J\left(u,\xi\right). \tag{3.12}$$

LEMMA 3.3. *Let $x_t^{\left(u,\xi^\theta\right)}$ be the trajectory associated with $\left(u,\xi^\theta\right)$. Then the following estimation holds:*

$$\lim_{\theta\to 0} E\left[\sup_{t\in[0,T]}\left|x_t^{\left(u,\xi^\theta\right)} - x_t\right|^2\right] = 0. \tag{3.13}$$

Proof. From assumption (2.3) and by using the Burkholder–Davis–Gundy inequality for the martingale part, we get

$$E\left[\sup_{t\in[0,T]}\left|x_t^{(u,\xi^\theta)}-x_t\right|^2\right]\le 6KE\int_0^t\sup_{\alpha\in[0,s]}\left|x_\alpha^{(u,\xi^\theta)}-x_\alpha\right|^2 ds+3M\theta^2E\left|\eta_T-\xi_T\right|^2.$$

From Definition 2.1 and using Gronwall's inequality, the result follows immediately by letting θ go to zero. □

LEMMA 3.4. *Under assumption* (2.3)*, the following estimation holds:*

$$\lim_{\theta\to 0}E\left[\left|\frac{x_t^{(u,\xi^\theta)}-x_t}{\theta}-z_t\right|^2\right]=0, \tag{3.14}$$

where z is the solution of the integral equation

$$z_t=\int_0^t b_x\left(s,x_s,u_s\right)z_s ds+\int_0^t\sigma_x\left(s,x_s\right)z_s dB_s+\int_0^t G_s d\left(\eta-\xi\right)_s.$$

Proof. From Definition 2.1 and assumption (2.3), it is easy to verify by Gronwall's inequality that

$$E\left[\sup_{t\in[0,T]}|z_t|^2\right]<\infty. \tag{3.15}$$

Let

$$\gamma_t^\theta=\frac{x_t^{(u,\xi^\theta)}-x_t^{(u,\xi)}}{\theta}-z_t.$$

It is easy to see that

$$\begin{aligned}E\left|\gamma_t^\theta\right|^2\le{}&3\int_0^t E\left|\int_0^1 b_x\left(s,x_s^{(u,\xi^\theta)}+\lambda\left[x_s^{(u,\xi^\theta)}-x_s\right],u_s\right)\gamma_t^\theta d\lambda\right|^2 dt\\&+3\int_0^t E\left|\int_0^1\sigma_x\left(s,x_s^{(u,\xi^\theta)}+\lambda\left[x_s^{(u,\xi^\theta)}-x_s\right]\right)\gamma_t^\theta d\lambda\right|^2 ds+3E\left|\rho_t^\theta\right|^2,\end{aligned}$$

where ρ_t^θ is given by

$$\begin{aligned}\rho_t^\theta={}&\int_0^t\int_0^1 z_s\left[b_x\left(s,x_s^{(u,\xi^\theta)}+\lambda\left[x_s^{(u,\xi^\theta)}-x_s\right],u_s\right)-b_x\left(s,x_s,u_s\right)\right]d\lambda ds\\&+\int_0^t\int_0^1 z_s\left[\sigma_x\left(s,x_s^{(u,\xi^\theta)}+\lambda\left[x_s^{(u,\xi^\theta)}-x_s\right]\right)-\sigma_x\left(s,x_s\right)\right]d\lambda dB_s.\end{aligned}$$

Since b_x,σ_x are bounded, it holds that

$$E\left|\gamma_t^\theta\right|^2\le 6C\int_0^t E\left|\gamma_s^\theta\right|^2 dt+3E\left|\rho_t^\theta\right|^2.$$

By using (3.13) and (3.15), the dominated convergence theorem, we obtain

$$\lim_{\theta\to 0}E\left|\rho_t^\theta\right|^2=0.$$

We conclude by applying Gronwall's lemma and letting θ go to zero. □

LEMMA 3.5. *The following inequality holds:*

$$0 \leq E\left[g_x\left(x_T\right) z_T\right] + E\int_0^T h_x\left(t, x_t, u_t\right) z_t dt + E\int_0^T k_t d\left(\eta - \xi\right)_t. \tag{3.16}$$

Proof. From (3.12), we have

$$\begin{aligned}
0 \leq\ & \frac{1}{\theta} E\left[g\left(x_T^{(u,\xi^\theta)}\right) - g\left(x_T\right)\right] + \frac{1}{\theta} E\int_0^T \left(h\left(t, x_t^{(u,\xi^\theta)}, u_t\right) - h\left(t, x_t, u_t\right)\right) dt \\
& + E\int_0^T k_t d\left(\eta_t - \xi_t\right) \\
=\ & E\int_0^1 \left(\frac{x_T^{(u,\xi^\theta)} - x_t}{\theta}\right) g_x\left(x_t + \lambda\left(x_T^{(u,\xi^\theta)} - x_t\right)\right) d\lambda \\
& + E\int_0^T \int_0^1 \left(\frac{x_T^{(u,\xi^\theta)} - x_t}{\theta}\right) h_x\left(t, x_t + \lambda\left(x_T^{(u,\xi^\theta)} - x_t\right), u_t\right) d\lambda dt \\
& + E\int_0^T k_t d\left(\eta - \xi\right)_t.
\end{aligned}$$

Since the derivatives g_x and h_x are continuous and bounded, by letting θ go to 0, we see that the result follows from (3.13) and (3.14). □

By the same method as in the last section, we are able to derive the second variational inequality from (3.16). If $\Phi(t,s)$ denotes the solution of (3.7), it is easy to check that z_t is given explicitly by

$$z_t = \int_0^t \Phi(t,s).G_s d\left(\eta - \xi\right)_s.$$

Replacing z_t with its value, we obtain the second variational inequality

$$0 \leq E\int_0^T \left(k_t + G_t^* p_t\right) d\left(\eta - \xi\right)_t, \tag{3.17}$$

where p_t is the adjoint process defined in the last subsection by (3.9).

3.3. The adjoint equation and the stochastic maximum principle. Applying Itô's formula to p_t given by (3.9), it is easy to see that p_t satisfies the linear backward SDE

$$\begin{cases} -dp_t = \left[h_x\left(t, x_t, u_t\right) + b_x^*\left(t, x_t, u_t\right) p_t + \sigma_x^*\left(t, x_t\right) K_t\right] dt - K_t dB_t, \\ p_T = g_x(x_T), \end{cases} \tag{3.18}$$

where K_t is given by

$$K_t = \Psi_t^* Q_t - \sigma_x^*\left(t, x_t\right) p_t; \quad K_t \in L^2\left(\left[0,T\right]; \mathbb{R}^{n\times d}\right), \tag{3.19}$$

and Q_t is given by the Itô representation of Brownian martingales

$$\begin{aligned}
\int_0^t Q_s dB_s = & E\left[\Phi_T^* g_x(x_T) + \int_0^T \Phi_t^* h_x(t, x_t, u_t) dt \ / \ \mathcal{F}_t\right] \\
& - E\left[\Phi_T^* g_x(x_T) + \int_0^T \Phi_t^* h_x(t, x_t, u_t) dt\right].
\end{aligned} \tag{3.20}$$

The stochastic maximum principle in its integral form is given by the following theorem.

THEOREM 3.6 (the strict stochastic maximum principle in integral form). *Let (u,ξ) be a strict optimal control minimizing the cost J over $\mathcal{U}$, and let x be the corresponding optimal trajectory. Then there exists a unique pair of adapted processes*

$$(p,K)\in L^2\left([0,T];\mathbb{R}^n\right)\times L^2\left([0,T];\mathbb{R}^{n\times d}\right),$$

which is the solution of the backward SDE (3.18) *such that for all $a\in A_1$ and $\eta\in\mathcal{U}_2$,*

$$H\left(t,x_t,u_t,p_t\right)\leq H\left(t,x_t,a,p_t\right),\ P-a.s,\ dt-a.e, \tag{3.21}$$

$$0\leq E\int_0^T\left(k_t+G_t^*p_t\right)d\left(\eta-\xi\right)_t. \tag{3.22}$$

Proof. From (3.10) we have

$$0\leq E\left[H\left(t,x_t,v,p_t\right)-H\left(t,x_t,u_t,p_t\right)\right],\quad dt-pp,$$

for every bounded A_1-valued, $\mathcal{F}_t$-measurable random variable v such that $E\left|v\right|^2<+\infty$.
Let $a\in A_1$ be a deterministic element and F be an arbitrary element of the σ-algebra $\mathcal{F}_t$, and set

$$w_t=a1_F+u_t1_{\Omega-F}.$$

It is obvious that w is an admissible control. Applying (3.10) with w we get

$$E\left[1_F\left(H\left(t,x_t,a,p_t\right)-H\left(t,x_t,u_t,p_t\right)\right)\right]\geq 0\quad\forall F\in\mathcal{F}_t,$$

which implies that $E\left[\left(H\left(t,x_t,a,p_t\right)-H\left(t,x_t,u_t,p_t\right)\right)/\mathcal{F}_t\right]\geq 0$.

The quantity inside the conditional expectation is $\mathcal{F}_t$-measurable, and thus the result follows immediately.

The second variational inequality (3.22) is proved in subsection 3.2. □

THEOREM 3.7 (the strict stochastic maximum principle). *Let (u,ξ) be an optimal control minimizing the cost J over $\mathcal{U}$, and let x be the corresponding optimal trajectory. Then there exists a unique pair of adapted processes*

$$(p,K)\in L^2\left([0,T];\mathbb{R}^n\right)\times L^2\left([0,T];\mathbb{R}^{n\times d}\right),$$

which is the solution of the backward SDE (3.18), *such that*

$$H\left(t,x_t,u_t,p_t\right)=\min_{a\in A_1}H\left(t,x_t,a,p_t\right),\ dt-a.e,\ P-a.s, \tag{3.23}$$

$$P\left\{\forall t\in[0,T],\ \forall i\ ;\ k_i\left(t\right)+G_i^*\left(t\right)p_t\geq 0\right\}=1, \tag{3.24}$$

$$P\left\{\sum_{i=1}^m\mathbf{1}_{\{k_i(t)+G_i^*(t)p_t\geq 0\}}d\xi_t^i=0\right\}=1. \tag{3.25}$$

Proof. To prove (3.24) and (3.25) we follow [5, Theorem 4.2]. Since (u, ξ) is optimal, the inequality

$$E \int_0^T (k_t + G_t^* p_t)\, d\,(\eta - \xi)_t \geq 0$$

holds for every $\eta \in \mathcal{U}_2$. In particular, let $\eta \in \mathcal{U}_2$ be defined by

$$d\eta_t^i = \begin{cases} 0 & \text{if } k_i(t) + G_i^*(t)\, p_t > 0, \\ d\xi_t^i & \text{otherwise.} \end{cases}$$

Then

$$\begin{aligned} E \int_0^T & (k_t + G_t^* p_t)\, d\,(\eta - \xi)_t \\ &= E\left[\sum_{i=1}^m \int_0^T (k_i(t) + G_i^*(t)\, p_t)\, 1_{\{k_i(t)+G_i^*(t)p_t>0\}} d\left(-\xi_t^i\right)\right] \\ &\geq 0, \end{aligned}$$

which implies that

$$E\left[\sum_{i=1}^m \int_0^T (k_i(t) + G_i^*(t)\, p_t)\, 1_{\{k_i(t)+G_i^*(t)p_t>0\}} d\xi_t^i\right] = 0,$$

and relation (3.25) follows immediately.

Let us prove (3.24). For each $i \in \{1, 2, \ldots, m\}$, let

$$A_t^i = \{\omega \in \Omega : k_i(t) + G_i^*(t)\, p_t < 0\},$$

$$A^i = \{(t, \omega) \in [0, T] \times \Omega : k_i(t) + G_i^*(t)\, p_t < 0\},$$

and define

$$\eta_t^i = \xi_t^i + \int_0^t 1_{A^i}(s, \omega) ds.$$

It is easy to see that $\eta_t = (\eta_t^1, \eta_t^2, \ldots, \eta_t^m)$ is in $\mathcal{U}_2$. Moreover

$$E \int_0^T (k_t + G_t^* p_t)\, d\,(\eta - \xi)_t = E\left[\sum_{i=1}^m \int_0^T (k_i(t) + G_i^*(t)\, p_t)\, 1_{A^i} dt\right] < 0,$$

which contradicts (3.22), unless for every $i \in \{1, 2, \ldots, m\}$, $dt \otimes P(A^i) = 0$. This proves the desired result since k, G, and p are continuous. □

4. The relaxed model. The strict control problem, as defined in section 3, may fail to have an optimal solution. The reason is that the set $\mathcal{U}$ of strict controls is too narrow and should be embedded into a wider class with a richer topological structure for which the control problem becomes solvable (see [10]). Our main goal in this section is to establish a maximum principle for relaxed-singular controls. This leads to necessary conditions satisfied by an optimal relaxed-singular control, which exists under general assumptions on the coefficients.

Let us begin by a deterministic example which shows that even in simple cases, existence of a strict optimal control is not ensured. The problem is to minimize the cost function

$$J(u) = \int_0^T x^u(t)^2 dt,$$

over the set U_{ad} of open loop controls, i.e., measurable functions $u : [0,T] \longrightarrow \{-1,1\}$. Let $x^u(t)$ denote the solution of

$$dx_t^u = u\, dt, \qquad x(0) = 0.$$

It is clear that $\inf_{u\in\mathcal{U}} J(u) = 0$. Indeed, consider the sequence of controls

$$u_n(t) = (-1)^k \quad \text{if} \quad \frac{k}{n} \le t \le \frac{k+1}{n}, \qquad 0 \le k \le n-1.$$

Clearly $|x^{u_n}(t)| \le \frac{1}{n}$ and $|J(u_n)| \le \frac{T}{n^2}$, which implies that $\inf_{u\in\mathcal{U}} J(u) = 0$. There is, however, no control u such that $J(u) = 0$. If this were the case, then for every t, $x^u(t) = 0$. This in turn would imply that $u_t = 0$, which is impossible. The problem is that the sequence (u_n) has no limit in the space of strict controls. This limit, if it exists, will be the natural candidate for optimality. If we identify $u_n(t)$ with the Dirac measure $\delta_{u_n(t)}(da)$ and set $q_n(dt,du) = \delta_{u_n(t)}(du)dt$, we get a measure on $[0,1]\times A_1$. Then $(q_n(dt,du))_n$ converges weakly to $\frac{1}{2}dt\cdot[\delta_{-1}+\delta_1](da)$.

The idea of relaxed control is to replace the absolutely continuous part of the control (u_t) with a $P(A_1)$-valued process (q_t), where $P(A_1)$ denotes the space of probability measures equipped with the topology of weak convergence.

DEFINITION 4.1. *A relaxed-singular control is a pair (q,η) of processes such that*

(i) *q is a $P(A_1)$–valued process, progressively measurable with respect to $(\mathcal{F}_t)$ and such that for each t, $1_{(0,t]}.q$ is $\mathcal{F}_t$ measurable.*

(ii) $\eta \in \mathcal{U}_2$.

We denote by $\mathcal{R} = \mathcal{R}_1 \times \mathcal{U}_2$ the set of relaxed-singular controls.

For any $(q,\eta) \in \mathcal{R}$, we consider the relaxed SDE

$$\begin{cases} dx_t^q = \int_{A_1} b\,(t, x_t^q, a)\, q_t\,(da)\, dt + \sigma\,(t, x_t^q)\, dB_t + G_t d\eta_t, \\ x^q(0) = x_0. \end{cases} \tag{4.1}$$

The expected cost associated with a relaxed control (q,η) is defined as

$$J(q,\eta) = E\left[g\,(x_T^q) + \int_0^T \int_{A_1} h\,(t, x_t^q, a)\, q_t(da) + \int_0^T k_t d\eta_t \right]. \tag{4.2}$$

The set $\mathcal{U}_1$ is embedded into the set $\mathcal{R}_1$ of $P(A_1)$-valued processes by the mapping

$$\Psi : u \in \mathcal{U}_1 \longmapsto \Psi\,(u)_t\,(da) = \delta_{u(t)}(da) \in \mathcal{R}_1,$$

where δ_u denotes the Dirac measure at a single point u.

Throughout this section we suppose that

$$b \text{ and } h \text{ are bounded,} \tag{4.3}$$

$$A_1 \text{ is compact.} \tag{4.4}$$

Using the compactification method, Haussmann and Suo [10] proved that the relaxed-singular control problem admits an optimal solution. See also [9] for a complete study of relaxed controls for classical control problems.

4.1. Approximation of trajectories. The next lemma, known as the chattering lemma, tells us that any relaxed control is a weak limit of a sequence of strict controls. This lemma was first proved for deterministic measures and then extended to random measures in [9].

LEMMA 4.2 (chattering lemma). *Let (q_t) be a predictable process with values in the space of probability measures on A_1. Then there exists a sequence of predictable processes (u^n) with values in A_1 such that the sequence of random measures $\left(\delta_{u_t^n}(da)\,dt\right)$ converges weakly to $q_t(da)\,dt$, $P-a.s.$*

The next lemma gives the stability of the controlled SDE with respect to the control variable.

LEMMA 4.3. *Let $(q,\eta)\in\mathcal{R}$ be a relaxed control, and let x^q be the corresponding trajectory. Then there exists a sequence $(v^n,\eta)_n\subset\mathcal{U}$ such that*

$$\lim_{n\to\infty} E\left[\sup_{t\in[0,T]}|x_t^n-x_t^q|^2\right]=0, \tag{4.5}$$

$$\lim_{n\to\infty} J(v^n,\eta)=J(q,\eta), \tag{4.6}$$

where x^n denotes the solution of (2.1) associated with (v^n,η).

Proof. (i) Applying the Burkholder–Davis–Gundy inequality for the martingale part, we get

$$\begin{aligned}E\left[\sup_{t\in[0,T]}|x_t^n-x_t^q|^2\right]&\le\alpha_t^n+3\int_0^t E\left|b(s,x_s^n,v_s^n)-b(s,x_s^q,v_s^n)\right|^2ds\\&\quad+3\int_0^t E\left|\sigma(s,x_s^n)-\sigma\left(s,x_s^q\right)\right|^2ds,\end{aligned}$$

where $q_s^n(da)=\delta_{v_s^n}(da)$ and α_t^n is given by

$$\alpha_t^n=4E\left|\int_0^t\int_{A_1}b(s,x_s^q,a)q_s^n(da)ds-\int_0^t\int_{A_1}b(s,x_s^q,a)q_s(da)ds\right|^2.$$

Since the coefficients b and σ are Lipshitz in the state variable x, then

$$E\left(\sup_{t\in[0,T]}|x_t^q-x_t^n|^2\right)\le\alpha_t^n+6M\int_0^t E\left(\sup_{t\in[0,T]}|x_s^n-x_s^q|^2\right)ds,$$

b is bounded and continuous, and then from Lemma 4.2 and using the dominated convergence theorem, we obtain

$$\lim_{n\to\infty}\alpha_t^n=0.$$

The result follows from Gronwall's lemma.

(ii) On the other hand, since g and h are Lipshitz continuous in x, by using the Cauchy–Schwarz inequality, we get

$$\begin{aligned}|J(q^n,\eta)-J(q,\eta)|&\le C\left(E\left|x_T^n-x_T^q\right|^2\right)^{1/2}+C\int_0^T\left(E\left|x_t^n-x_t^q\right|^2\right)^{1/2}ds\\&\quad+\left(E\left|\int_0^T\int_{A_1}h(t,x_t^q,v_t^n)dt-\int_0^T\int_{A_1}h(t,x_t^q,a)q_t\left(da\right)dt\right|^2\right)^{1/2}.\end{aligned}$$

From (4.5), the first and second terms in the right-hand side converge to zero. Since h is continuous and bounded, by using the dominated convergence theorem, we have that the third term in the right-hand side tends to zero. □

Remark. As a consequence, it is easy to see that the strict and relaxed optimal control problems have the same value function.

4.2. Maximum principle for near optimal controls. In this section we establish necessary conditions of near optimality satisfied by a sequence of nearly optimal strict controls. This result is based on Ekeland's variational principle, which is given by the following.

LEMMA 4.4 (Ekeland [8]). *Let (E,d) be a complete metric space and $f : E \longrightarrow \overline{\mathbb{R}}$ be lower semicontinuous and bounded from below. Given $\varepsilon > 0$, suppose $u^\varepsilon \in E$ satisfies $f(u^\varepsilon) \leq \inf(f) + \varepsilon$. Then for any $\lambda > 0$, there exists $v \in E$ such that*

1. $f(v) \leq f(u^\varepsilon)$.
2. $d(u^\varepsilon, v) \leq \lambda$.
3. $f(v) < f(w) + \frac{\varepsilon}{\lambda} d(v,w)$ *for all* $w \neq v$.

To apply Ekeland's variational principle, we have to endow the set $\mathcal{U}$ of strict controls with an appropriate metric. For any $(u,\xi),(v,\eta) \in \mathcal{U}$, we set

$$
\begin{aligned}
d_1(u,v) &= P \otimes dt\left\{(\omega,t) \in \Omega \times [0,T],\ u(t,\omega) \neq v(t,\omega)\right\},\\
d_2(\xi,\eta) &= E\left(\sup_{t\in[0,T]} |\xi_t - \eta_t|^2\right)^{1/2},\\
d[(u,\xi),(v,\eta)] &= d_1(u,v) + d_2(\xi,\eta),
\end{aligned}
$$

where $P \otimes dt$ is the product measure of P with the Lebesgue measure dt.

Let us summarize some of the properties satisfied by d.

LEMMA 4.5.

1. *$(\mathcal{U},d)$ is a complete metric space.*
2. *The cost functional J is continuous from $\mathcal{U}$ into $\mathbb{R}$.*

Proof. 1. It is clear that $(\mathcal{U}_2,d_2)$ is a complete metric space. Moreover, it was shown in [15] that $(\mathcal{U}_1,d_1)$ is a complete metric space. Hence $(\mathcal{U},d)$ is a complete metric space as a product of two complete metric spaces.

Item 2 is proved as in [15]. □

Now let $(\mu,\xi) \in \mathcal{R}$ be an optimal relaxed control and denote by x^μ the trajectory of the system controlled by (μ,ξ). From Lemmas 4.2 and 4.3, there exists a sequence $(u^n)_n$ of strict controls such that

$$
\begin{aligned}
dt\mu_t^n(da) = dt\delta_{u_t^n}(da) &\underset{n\longrightarrow\infty}{\longrightarrow} dt\mu_t(da) \text{ weakly}, \quad P-a.s,\\
E\left[\sup_{t\in[0,T]} |x_t^n - x_t^\mu|^2\right] &\underset{n\longrightarrow\infty}{\longrightarrow} 0,
\end{aligned}
$$

where x_t^n is the solution of (4.1) corresponding to the control μ^n.

According to the optimality of (μ,ξ) and (4.6), there exists a sequence (ε_n) of positive real numbers with $\lim_{n\to\infty} \varepsilon_n = 0$ such that

$$
J(u^n,\xi) = J(\mu^n,\xi) \leq J(\mu,\xi) + \varepsilon_n.
$$

A suitable version of Lemma 4.4 implies that, given any $\varepsilon_n > 0$, there exists

$(u^n, \xi) \in \mathcal{U}$ such that

$$J(u^n, \xi) \leq \inf_{(v,\eta)\in\mathcal{U}} J(v, \eta) + \varepsilon_n,$$

$$J(u^n, \xi) \leq J(v, \eta) + \varepsilon_n d[(u^n, \xi); (v, \eta)] \quad \forall (v, \eta) \in \mathcal{U}. \tag{4.7}$$

Let us define the two perturbations

$$\left(u_t^{n,\theta}, \xi_t\right) = \begin{cases} (v, \xi_t) & \text{if } t \in [\tau, \tau + \theta], \\ (u_t^n, \xi_t) & \text{otherwise,} \end{cases} \tag{4.8}$$

$$\left(u_t^n, \xi_t^\theta\right) = (u_t^n, \xi_t + \theta(\eta_t - \xi_t)). \tag{4.9}$$

From (4.7) we have

$$0 \leq J\left(u_t^{n,\theta}, \xi_t\right) - J(u^n, \xi) + \varepsilon_n d\left[(u^n, \xi); \left(u^{n,\theta}, \xi\right)\right],$$

$$0 \leq J\left(u_t^n, \xi_t^\theta\right) - J(u^n, \xi) + \varepsilon_n d\left[(u^n, \xi); \left(u^n, \xi^\theta\right)\right].$$

From the definition of the metric d, we obtain

$$0 \leq J\left(u_t^{n,\theta}, \xi_t\right) - J(u^n, \xi) + \varepsilon_n d_1\left(u^n, u^{n,\theta}\right),$$

$$0 \leq J\left(u_t^n, \xi_t^\theta\right) - J(u^n, \xi) + \varepsilon_n d_2\left(\xi, \xi^\theta\right).$$

Using the definitions of d_1 and d_2, it holds that

$$0 \leq J\left(u_t^{n,\theta}, \xi_t\right) - J(u^n, \xi) + \varepsilon_n M_1 \theta, \tag{4.10}$$

$$0 \leq J\left(u_t^n, \xi_t^\theta\right) - J(u^n, \xi) + \varepsilon_n M_2 \theta, \tag{4.11}$$

where M_i is a positive constant.

From these above inequalities, we shall establish necessary conditions for near optimality.

THEOREM 4.6 (the near maximum principle in integral form). *For each $\varepsilon_n > 0$, there exists $(u^n, \xi) \in \mathcal{U}$ such that there exists a unique pair of adapted processes*

$$(p^n, K^n) \in L^2([0, T]; \mathbb{R}^n) \times L^2\left([0, T]; \mathbb{R}^{n\times d}\right),$$

which is the solution of the backward SDE

$$\begin{cases} -dp_t^n = [h_x(t, x_t^n, u_t^n) + b_x^*(t, x_t^n, u_t^n) p_t^n + \sigma_x^*(t, x_t^n) K_t^n] dt - K_t^n dB_t, \\ p_T^n = g_x(x_T^n), \end{cases} \tag{4.12}$$

such that for all $(v, \eta) \in \mathcal{U}$,

$$0 \leq E[H(t, x_t^n, v, p_t^n) - H(t, x_t^n, u_t^n, p_t^n)] + M_1 \varepsilon_n, \tag{4.13}$$

$$0 \leq E \int_0^T (k_t + G_t^* p_t^n) d(\eta - \xi)_t + M_2 \varepsilon_n, \tag{4.14}$$

where M_i is a positive constant.

Proof. From inequalities (4.10) and (4.11), respectively, we use the same method as in subsection 3.3 to obtain, respectively, (4.13) and (4.14). ∎

4.3. The relaxed stochastic maximum principle.

THEOREM 4.7 (the relaxed maximum principle in integral form). *Let (μ, ξ) be an optimal relaxed control minimizing the cost J over $\mathcal{R}$, and let x_t^μ be the corresponding optimal trajectory. Then there exists a unique pair of adapted processes*

$$(p^\mu, K^\mu) \in L^2\left([0,T];\mathbb{R}^n\right) \times L^2\left([0,T];\mathbb{R}^{n\times d}\right),$$

which is the solution of the backward SDE

$$\left\{\begin{array}{ll} -dp_t^\mu & = \left[\int_{A_1} h_x\left(t, x_t^\mu, a\right)\mu_t\left(da\right) + \int_{A_1} b_x^*\left(t, x_t^\mu, a\right)\mu_t\left(da\right)p_t^\mu\right]dt \\ & \quad + \sigma_x^*\left(t, x_t^\mu\right)K_t^\mu dt - K_t^\mu dB_t, \\ p_T^\mu & = g_x(x_T^\mu), \end{array}\right. \tag{4.15}$$

such that for all $(v,\eta) \in \mathcal{U}_1 \times \mathcal{U}_2$, we have

$$0 \le E\left[H\left(t, x_t^\mu, v, p_t^\mu\right) - H\left(t, x_t^\mu, \mu_t, p_t^\mu\right)\right], \tag{4.16}$$

$$0 \le E\int_0^T G_t^* p_t^\mu d\left(\eta - \xi\right)_t, \tag{4.17}$$

where $H\left(t, x_t^\mu, \mu_t, p_t^\mu\right) = \int_{A_1} H\left(t, x_t^\mu, a, p_t^\mu\right)\mu_t\left(da\right)$.

To prove Theorem 4.7, we need the following lemma.

LEMMA 4.8. *Let (p^n, K^n) and (p^μ, K^μ), respectively, be the solutions of* (4.12) *and* (4.15). *Then we have*

$$\lim_{n\longrightarrow\infty}\left(E\left[\sup_{t\in[0,T]}\left|p_t^n - p_t^\mu\right|^2\right] + E\int_0^T \left|K_t^n - K_t^\mu\right|^2 ds\right) = 0. \tag{4.18}$$

Proof. For simplicity of notation we set

$$\begin{aligned} b_t^\mu &= \int_{A_1} b_x^*\left(t, x_t^\mu, a\right)\mu_t(da),\ b_t^n = \int_{A_1} b_x^*\left(t, x_t^n, a\right)\mu_t^n(da), \\ \sigma_t^\mu &= \sigma_x^*\left(t, x_t^\mu\right),\ \sigma_t^n = \sigma_x^*\left(t, x_t^n\right), \\ h_t^\mu &= \int_{A_1} h_x\left(t, x_t^\mu, a\right)\mu_t(da),\ h_t^n = \int_{A_1} h_x\left(t, x_t^n, a\right)\mu_t^n(da), \\ \mu_t^n(da) &= \delta_{u_t^n}(da). \end{aligned}$$

Since b_x, σ_x, and h_x are continuous and bounded, by using Lemmas 4.2 and 4.3 and the dominated convergence theorem, we get

$$\lim_{n\longrightarrow\infty} E\left|b_t^n - b_t^\mu\right|^2 = \lim_{n\longrightarrow\infty} E\left|\sigma_t^n - \sigma_t^\mu\right|^2 = \lim_{n\longrightarrow\infty} E\left|h_t^n - h_t^\mu\right|^2 = 0. \tag{4.19}$$

Applying Itô's formula to $(p_t^n - p_t^\mu)^2$, it follows that

$$\begin{aligned} E\left|p_t^n - p_t^\mu\right|^2 + \int_t^T E\left|K_s^n - K_s^\mu\right|^2 ds &= E\left|g_x(x_T^n) - g_x(x_T^\mu)\right|^2 \\ &\quad + 2\int_t^T E\left|\left(p_s^\mu - p_s^n\right)\left(F_s^n - F_s^\mu\right)\right| ds, \end{aligned}$$

where F_t^μ and F_t^n are given by

$$\begin{aligned} F_t^\mu &= b_t^\mu p_t^\mu + \sigma_t^\mu K_t^\mu + h_t^\mu, \\ F_t^n &= b_t^n p_t^n + \sigma_t^n Q_t^n + h_t^n. \end{aligned}$$

Using Young's inequality $|c_1c_2| \leq \frac{\varepsilon}{2}|c_1|^2 + \frac{1}{2\varepsilon}|c_2|^2$, we obtain

$$\begin{aligned} E|p_t^n - p_t^\mu|^2 + \int_t^T E|K_t^n - K_s^\mu|^2\,dt &\leq E|g_x(x_T^n) - g_x(x_T^\mu)|^2 + \frac{1}{\varepsilon}\int_t^T E|p_s^\mu - p_s^n|^2\,ds \\ &\quad + \varepsilon\int_t^T E|F_s^n - F_s^\mu|^2\,ds \\ &\leq \left(\frac{1}{\varepsilon} + 6M\varepsilon\right)\int_t^T E|p_s^\mu - p_s^n|^2\,ds \\ &\quad + 6M\varepsilon\int_t^T E|K_s^n - K_s^\mu|^2\,ds + \varepsilon\xi_t^n, \end{aligned}$$

where ξ_t^n is given by

$$\begin{aligned} \xi_t^n = \frac{1}{\varepsilon}\left(E|g_x(x_T^n) - g_x(x_T^\mu)|^2\right) + 6E\int_t^T |(b_s^n - b_s^\mu)\,p_s^n|^2\,ds \\ + 6E\int_t^T |(\sigma_s^n - \sigma_s^\mu)\,K_s^n|^2\,ds + 3E\int_t^T |h_s^n - h_s^\mu|^2\,ds. \end{aligned} \tag{4.20}$$

Choose $\varepsilon = \frac{1}{12M}$. It follows that

$$E|p_t^n - p_t^\mu|^2 + \frac{1}{2}\int_t^T E|K_s^n - K_s^\mu|^2\,ds \leq C\int_t^T E|p_s^\mu - p_s^n|^2\,ds + C\xi_t^n,$$

with $C = \max\left\{\frac{1}{12M}, 12M + \frac{1}{2}\right\}$.
Hence

$$E|p_t^n - p_t^\mu|^2 \leq C\int_t^T E|p_s^\mu - p_s^n|^2\,ds + C\xi_t^n, \tag{4.21}$$

$$\int_t^T E|K_s^n - K_s^\mu|^2\,ds \leq 2C\int_t^T E|p_s^\mu - p_s^n|^2\,ds + 2C\xi_t^n. \tag{4.22}$$

Let us prove that $\lim_{n\longrightarrow\infty}\xi_t^n = 0$.
Since b_x is bounded, we have

$$|(b_s^n - b_s^\mu)\,p_s^n| \leq 2M|p_s^n|. \tag{4.23}$$

Then by the Cauchy–Schwarz inequality we get

$$\begin{aligned} E\int_t^T |(b_s^n - b_s^\mu)\,p_s^n|\,ds &\leq \int_t^T \left(E|b_s^n - b_s^\mu|^2\right)^{1/2}\left(E|p_s^n|^2\right)^{1/2}ds \\ &\leq c\int_t^T \left(E|b_s^n - b_s^\mu|^2\right)^{1/2}ds. \end{aligned}$$

Now from (4.19), we have

$$\lim_{n\longrightarrow\infty} E\int_t^T |(b_s^n - b_s^\mu)\,p_s^n|\,ds = 0, \tag{4.24}$$

and from (4.23), (4.24), and the dominated convergence theorem, we obtain

$$\lim_{n\longrightarrow\infty} E\int_t^T |(b_s^n - b_s^\mu)\,p_s^n|^2\,ds = 0. \tag{4.25}$$

Using the same arguments, it follows that

$$\lim_{n\longrightarrow\infty} E\int_t^T \left|\left(\sigma_s^n-\sigma_s^\mu\right)K_s^n\right|^2 ds=0. \tag{4.26}$$

Now since g_x is continuous and bounded,

$$\lim_{n\longrightarrow\infty} E\left|g_x(x_T^n)-g_x(x_T^\mu)\right|^2=0. \tag{4.27}$$

Now it is easy to see that by using the above results, $\lim_{n\longrightarrow\infty}\xi_t^n=0$.

The desired result follows from Gronwall's inequality. □

Proof of Theorem 4.6. Let (μ,ξ) be an optimal relaxed control. From Theorem 4.6, there exists a sequence $(u^n,\xi)_n$ in $\mathcal{U}$ such that for all $(v,\eta)\in\mathcal{U}$, the variational equations (4.13) and (4.14) hold. The result follows immediately by letting n go to infinity in (4.13) and (4.14) and using Lemma 4.8. □

THEOREM 4.9 (the relaxed maximum principle). *Let (μ,ξ) be an optimal relaxed control minimizing the functional cost J over $\mathcal{R}$ and let x_t^μ be the trajectory of the system controlled by (μ,ξ). Then there exists a unique pair of adapted processes*

$$\left(p^\mu,K^\mu\right)\in L^2\left([0,T];\mathbb{R}^n\right)\times L^2\left([0,T];\mathbb{R}^{n\times d}\right),$$

which is the solution of the backward SDE (4.15)*, such that*

$$H\left(t,x_t^\mu,\mu_t,p_t^\mu\right)=\min_{a\in A_1} H\left(t,x_t^\mu,a,p_t^\mu\right);\ dt-a.e\ ,\ P-a.s, \tag{4.28}$$

$$P\left\{\forall t\in[0,T]\ ,\ \forall i\ ;\ k_i\left(t\right)+G_i^*\left(t\right).p_t^\mu\geq 0\right\}=1, \tag{4.29}$$

$$P\left\{\sum_{i=1}^m \mathbf{1}_{\{k_i(t)+G_i^*(t).p_t^\mu\geq 0\}}d\xi_t^i=0\right\}=1. \tag{4.30}$$

Proof. From (4.16), we immediately deduce (4.28) by applying the same arguments as in the proof of Theorem 3.6. Using (4.17), we see that assertions (4.29) and (4.30) are proved exactly as in Theorem 3.7. □

Remarks. (1) If $G=k=0$, we recover the relaxed stochastic maximum principle for classical controls (see Mezerdi and Bahlali [16]).

(2) If $\mu_t(da)=\delta_{u(t)}(da)$, we recover the strict maximum principle (Theorem 3.7).

(3) If $\mu_t(da)=\delta_{u(t)}(da)$ and $G=k=0$, we obtain Kushner's stochastic maximum principle [14].

COROLLARY 4.10. *Under the same conditions as in Theorem* 4.9*, we have*

$$H\left(t,x_t^\mu,\mu_t,p_t^\mu\right)=\min_{q\in P(A_1)} H\left(t,x_t^\mu,q,p_t^\mu\right);\ dt-a.e,\ P-a.s, \tag{4.31}$$

$$P\left\{\forall t\in[0,T]\ ,\ \forall i\ ;\ k_i\left(t\right)+G_i^*\left(t\right).p_t^\mu\geq 0\right\}=1,$$

$$P\left\{\sum_{i=1}^m \mathbf{1}_{\{k_i(t)+G_i^*(t).p_t^\mu\geq 0\}}d\xi_t^i=0\right\}=1.$$

Proof. Equation (4.31) is proved as in [16, Corollary 4.2]. □

Acknowledgments. The authors would like to thank the referees for valuable suggestions that improved the manuscript.

STABILIZING FEEDBACK CONTROLS FOR QUANTUM SYSTEMS*

MAZYAR MIRRAHIMI† AND RAMON VAN HANDEL‡

Abstract. No quantum measurement can give full information on the state of a quantum system; hence any quantum feedback control problem is necessarily one with partial observations and can generally be converted into a completely observed control problem for an appropriate quantum filter as in classical stochastic control theory. Here we study the properties of controlled quantum filtering equations as classical stochastic differential equations. We then develop methods, using a combination of geometric control and classical probabilistic techniques, for global feedback stabilization of a class of quantum filters around a particular eigenstate of the measurement operator.

Key words. quantum feedback control, quantum filtering equations, stochastic stabilization

1. Introduction.

Though they are both probabilistic theories, probability theory and quantum mechanics have historically developed along very different lines. Nonetheless, the two theories are remarkably close, and indeed a rigorous development of quantum probability [27, 9] contains classical probability theory as a special case. The embedding of classical into quantum probability has a natural interpretation that is central to the idea of a quantum measurement: any set of *commuting* quantum observables can be represented as random variables on some probability space, and, conversely, any set of random variables can be encoded as commuting observables in a quantum model. The quantum probability model then describes the statistics of any set of measurements that we are allowed to make, whereas the sets of random variables obtained from commuting observables describe measurements that can be performed in a single realization of an experiment. As we are not allowed to make noncommuting observations in a single realization, any quantum measurement yields even in principle only partial information about the system.

The situation in quantum feedback control [18, 19] is thus very close to classical stochastic control with partial observations [7]. A typical quantum control scenario, representative of experiments in quantum optics, is shown in Figure 1.1. We wish to control the state of a cloud of atoms; e.g., we could be interested in controlling their collective angular momentum. To observe the atoms, we scatter a laser probe field off the atoms and measure the scattered light using a homodyne detector (a cavity can be used to increase the interaction strength between the light and the atoms). The observation process is fed into a controller which can feed back a control signal to the atoms through some actuator, e.g., a time-varying magnetic field. The entire setup can be described by a Schrödinger equation for the atoms and the probe field, which takes the form of a "quantum stochastic differential equation" in a Markovian limit. The controller, however, has access only to the observations of the probe. The

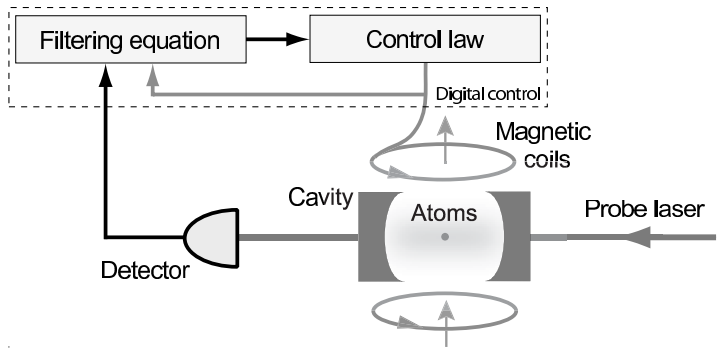

FIG. 1.1. *A typical feedback control scenario in quantum optics. A probe laser scatters off a cloud of atoms in an optical cavity and is ultimately detected. The detected signal is processed by a controller which feeds back to the system through a time-varying magnetic field.*

laser probe itself contributes quantum fluctuations to the observations; hence the observation process can be considered as a noisy observation of an atomic variable.

As in classical stochastic control we can use the properties of the conditional expectation to convert the output feedback control problem into one with complete observations. The conditional expectation $\pi_t(X)$ of an observable X given the observations $\{Y_s : 0 \le s \le t\}$ is the least mean square estimate of X_t (the observable X at time t) given $Y_{s\le t}$. One can obtain a quantum filtering equation [6, 9] that propagates $\pi_t(X)$ or, alternatively, the conditional density matrix ρ_t defined by the relation $\pi_t(X) = \mathrm{Tr}[\rho_t X]$. This is the quantum counterpart of the classical Kushner–Stratonovich equation and plays an equivalent role in quantum stochastic control. In particular, as $\mathbb{E}X_t = \mathbb{E}\pi_t(X)$ we can control the expectations of observables by designing a state feedback control law based on the filter.

Note that as the observation process $Y_{s\le t}$ is measured in a single experimental realization, it is equivalent to a classical stochastic process (i.e., the observables Y_t commute with each other at different times). But as the filter depends only on the observations, it is thus equivalent to a classical stochastic equation; in fact, the filter can be expressed as a classical (Itô) stochastic differential equation for the conditional density matrix ρ_t. Hence ultimately any quantum control problem of this form is reduced to a classical stochastic control problem for the filter.

In this paper we consider a class of quantum control problems of the following form. Rather than specifying a cost function to minimize, as in optimal control theory, we desire to asymptotically prepare a particular quantum state ρ_f in the sense that $\mathbb{E}X_t \to \mathrm{Tr}[\rho_f X]$ as $t \to \infty$ for all X (for a deterministic version, see, e.g., [30]). As $\mathbb{E}X_t = \mathbb{E}\pi_t(X)$, this comes down to finding a feedback control that will ensure the convergence $\rho_t \to \rho_f$ of the conditional density ρ_t. In addition to this convergence, we will show that our controllers also render the filter stochastically stable around the target state, which suggests some degree of robustness to perturbations. (This statement should be interpreted with care, however. See the remark after Proposition 3.4; we will not dwell on this issue.) In section 4 we will discuss the preparation of states in a cloud of atoms where the z-component of the angular momentum has zero variance, whereas in section 5 we will discuss the preparation of correlated states of two spins. Despite their relatively simple description, the creation of such states is not simple. Quantum feedback control may provide a desirable method for reliably preparing such states in practice (though other issues, e.g., the reduction of quan-

tum filters [17] for efficient real-time implementation, must be resolved before such schemes can be realized experimentally; see [15] for a state-of-the-art experimental demonstration of a related quantum control scenario).

Other work. Though we have attempted to indicate the origin of the control problems studied here, a detailed review of the physical and mathematical considerations behind our models is beyond the scope of this paper; nor can we do justice to the full history of the subject, or to results which do not relate directly to the control problems studied in this paper. In these respects we restrict ourselves to providing here a brief historical overview. In the remainder of the paper we will consider the quantum filtering equation as our starting point and concern ourselves exclusively with the associated classical stochastic control problem. For further details on the physical and mathematical basis for our models we refer the reader to the references below.

The theory of quantum nonlinear filtering was developed by Belavkin [6, 5]. The models used in the theory are based on the Hudson–Parthasarathy quantum stochastic calculus [21] and the theory of continuous quantum measurements as in the work of Barchielli and Lupieri [2]; a discrete-time version of the theory that did not require these tools can be found in Belavkin's earlier paper [4]. The potential for feedback control was already realized at that time; [4] develops discrete-time optimal controls for the models considered there, and a continuous-time version was sketched in [5]. We refer the reader to [8] and [14] for recent developments in quantum optimal feedback control, and to [9] for an accessible introduction to quantum probability and filtering. The control problems studied in this paper are not of the optimal control type; they have their origins in [33, 18]. See also [19] for further references.

In the physics literature the theory was independently developed by Carmichael [10] based on earlier work by Davies [11]. The connection to classical filtering theory (as in [6, 5]) was realized only much later; see, e.g., [12]. Wiseman [35] realized that Carmichael's work could be used to describe feedback in the quantum setting, but the controllers used in his work were of a restricted and somewhat unrealistic form: direct (unfiltered) linear feedback of white noise photocurrents with a deterministic gain. We do not consider this type of system here (see [36] for some remarks).

Structure of the paper. In section 2 we first introduce some tools from stochastic stability theory and stochastic analysis that we will use in our proofs. In section 3 we introduce the quantum filtering equation and study issues such as existence and uniqueness of solutions, continuity of the paths, etc. Though some of these issues have been considered in the literature in the absence of control (but in a more general setting; see, e.g., [3] and the references therein), to our knowledge such results are not available in the controlled case. In section 4 we pose the problem of stabilizing an angular momentum eigenstate and prove global stability under a particular control law. It is our expectation that the methods of section 4 are sufficiently flexible to be applied to a wide class of quantum state preparation scenarios. As an example, we use in section 5 the techniques developed in section 4 to stabilize particular entangled states of two spins. Additional results and numerical simulations will appear in [29].

2. Geometric tools for stochastic processes. In this section we briefly review two methods that will allow us to apply geometric control techniques to stochastic systems. The first is a stochastic version of the classical Lyapunov and LaSalle invariance theorems. The second, a support theorem for stochastic differential equations, will allow us to infer properties of stochastic sample paths through the study of a related deterministic system. We refer the reader to the references for proofs of the theorems.

2.1. Lyapunov and LaSalle invariance theorems. The Lyapunov stability theory and LaSalle's invariance theorem are important tools in the analysis of and control design for deterministic systems. Similarly, their stochastic counterparts will play an essential role in what follows. The subject of stochastic stability was studied extensively by Has'minskiĭ [20] and by Kushner [24]. We will cite a small selection of the results that will be needed in the following: a Lyapunov (local) stability theorem for Markov processes and the LaSalle invariance theorem of Kushner [24, 25, 26].

DEFINITION 2.1. *Let x_t^z be a diffusion process on the metric state space X, started at $x_0 = z$, and let $\tilde{z}$ denote an equilibrium position of the diffusion, i.e., $x_t^{\tilde{z}} = \tilde{z}$. Then*

1. *the equilibrium $\tilde{z}$ is said to be* stable in probability *if*

$$\lim_{z\to\tilde{z}} \mathbb{P}\left(\sup_{0\le t<\infty} \|x_t^z - \tilde{z}\| \ge \varepsilon\right) = 0 \qquad \forall \varepsilon > 0, \tag{2.1}$$

2. *the equilibrium $\tilde{z}$ is* globally stable *if it is stable in probability and additionally*

$$\mathbb{P}\left(\lim_{t\to\infty} x_t^z = \tilde{z}\right) = 1 \qquad \forall z \in X. \tag{2.2}$$

In the theorems below we will make the following assumptions.

1. The state space X is a complete separable metric space, and x_t^z is a homogeneous strong Markov process on X with continuous sample paths.
2. $V(\cdot)$ is a nonnegative real-valued continuous function on X.
3. For $\lambda > 0$, let $Q_\lambda = \{x \in X : V(x) < \lambda\}$ and assume Q_λ is nonempty. Let $\tau_\lambda = \inf\{t : x_t^z \notin Q_\lambda\}$ and define the stopped process $\tilde{x}_t^z = x_{t\wedge\tau_\lambda}^z$.
4. $\mathscr{A}_\lambda$ is the weak infinitesimal operator of $\tilde{x}_t$, and V is in the domain of $\mathscr{A}_\lambda$.

The following theorems can be found in Kushner [24, 25, 26].

THEOREM 2.2 (local stability). *Let $\mathscr{A}_\lambda V \le 0$ in Q_λ. Then the following hold:*

1. *$\lim_{t\to\infty} V(\tilde{x}_t^z)$ exists a.s., so $V(x_t^z)$ converges for a.e. path remaining in Q_λ.*
2. *$\mathbb{P}\text{-}\lim_{t\to\infty} \mathscr{A}_\lambda V(\tilde{x}_t^z) = 0$, so $\mathscr{A}_\lambda V(x_t^z) \to 0$ in probability as $t \to \infty$ for almost all paths which never leave Q_λ.*
3. *For $z \in Q_\lambda$ and $\alpha \le \lambda$ we have the uniform estimate*

$$\mathbb{P}\left(\sup_{0\le t<\infty} V(x_t^z) \ge \alpha\right) = \mathbb{P}\left(\sup_{0\le t<\infty} V(\tilde{x}_t^z) \ge \alpha\right) \le \frac{V(z)}{\alpha}. \tag{2.3}$$

4. *If $V(\tilde{z}) = 0$ and $V(x) \ne 0$ for $x \ne \tilde{z}$, then $\tilde{z}$ is stable in probability.*

The following theorem is a stochastic version of the LaSalle invariance theorem. Recall that a diffusion x_t^z is said to be Feller continuous if for fixed t, $\mathbb{E}G(x_t^z)$ is continuous in z for any bounded continuous G.

THEOREM 2.3 (invariance). *Let $\mathscr{A}_\lambda V \le 0$ in Q_λ. Suppose Q_λ has compact closure, $\tilde{x}_t^z$ is Feller continuous, and that $\mathbb{P}(\|\tilde{x}_t^z - z\| > \varepsilon) \to 0$ as $t \to 0$ for any $\varepsilon > 0$, uniformly for $z \in Q_\lambda$. Then $\tilde{x}_t^z$ converges in probability to the largest invariant set contained in $C_\lambda = \{x \in Q_\lambda : \mathscr{A}_\lambda V(x) = 0\}$. Hence x_t^z converges in probability to the largest invariant set contained in C_λ for almost all paths which never leave Q_λ.*

2.2. The support theorem. In the nonlinear control of deterministic systems an important role is played by the application of geometric methods, e.g., Lie algebra techniques, to the vector fields generating the control system. Such methods usually cannot be directly applied to stochastic systems, however, as the processes involved are not (sufficiently) differentiable. The support theorem for stochastic differential equations, in its original form due to Stroock and Varadhan [34], connects events of

probability one for a stochastic differential equation to the solution properties of an associated deterministic system. One can then apply classical techniques to the latter and invoke the support theorem to apply the results to the stochastic system; see, e.g., [22] for the application of Lie algebraic methods to stochastic systems.

We quote the following form of the theorem [23, 22].

THEOREM 2.4. *Let M be a connected, paracompact C^∞-manifold and let X_k, $k = 0, \dots, n$, be C^∞ vector fields on M such that all linear sums of X_k are complete. Let $X_k = \sum_l X_k^l(x)\partial_l$ in local coordinates and consider the Stratonovich equation*

$$dx_t = X_0(x_t)\,dt + \sum_{k=1}^{n} X_k(x_t) \circ dW_t^k, \qquad x_0 = x. \tag{2.4}$$

Consider in addition the associated deterministic control system

$$\frac{d}{dt}x_t^u = X_0(x_t^u) + \sum_{k=1}^{n} X_k(x_t^u)u^k(t), \qquad x_0^u = x, \tag{2.5}$$

with $u^k \in \mathscr{U}$, the set of all piecewise constant functions from $\mathbb{R}_+$ to $\mathbb{R}$. Then

$$\mathscr{S}_x = \overline{\{x_\cdot^u : u \in \mathscr{U}^n\}} \subset \mathscr{W}_x, \tag{2.6}$$

where $\mathscr{W}_x$ is the set of all continuous paths from $\mathbb{R}_+$ to M starting at x, equipped with the topology of uniform convergence on compact sets, and $\mathscr{S}_x$ is the smallest closed subset of $\mathscr{W}_x$ such that $\mathbb{P}(\{\omega \in \Omega : x_\cdot(\omega) \in \mathscr{S}_x\}) = 1$.

3. Solution properties of quantum filters. The purpose of this section is to introduce the dynamical equations for a general quantum system with feedback and to establish their basic solution properties.

We will consider quantum systems with finite dimension $1 < N < \infty$. The state space of such a system is given by the set of density matrices

$$\mathcal{S} = \{\rho \in \mathbb{C}^{N\times N} : \rho = \rho^*,\ \operatorname{Tr}\rho = 1,\ \rho \geq 0\}, \tag{3.1}$$

where ρ^* denotes Hermitian conjugation. In noncommutative probability the space $\mathcal{P}$ is the analogue of the set of probability measures of an N-state random variable. Finite-dimensional quantum systems are ubiquitous in contemporary quantum physics; a system with dimension $N = 2^n$, for example, can represent the collective state of n qubits in the setting of quantum computing, and $N = 2J + 1$ represents a system with fixed angular momentum J. The following lemma describes the structure of $\mathcal{S}$.

LEMMA 3.1. *$\mathcal{S}$ is the convex hull of $\{\rho \in \mathbb{C}^{N\times N} : \rho = vv^*,\ v \in \mathbb{C}^N,\ v^*v = 1\}$.*

Proof. The statement is easily verified by diagonalizing the elements of $\mathcal{P}$. ∎

We now consider continuous measurement of such a system, e.g., by weakly coupling it to an optical probe field and performing a diffusive observation of the field. When the state of the system is conditioned on the observation process, we obtain the following matrix-valued Itô equation for the conditional density, which is a quantum analogue of the Kushner–Stratonovich equation of nonlinear filtering [6, 9, 18]:

$$\begin{aligned} d\rho_t = {} & -i(H_t\rho_t - \rho_t H_t)\,dt + (c\rho_t c^* - \tfrac{1}{2}(c^*c\rho_t + \rho_t c^*c))\,dt \\ & + \sqrt{\eta}\,(c\rho_t + \rho_t c^* - \operatorname{Tr}[(c + c^*)\rho_t]\rho_t)\,dW_t. \end{aligned} \tag{3.2}$$

Here we have introduced the following quantities:

- The Wiener process W_t is the innovation $dW_t = dy_t - \sqrt{\eta}\,\mathrm{Tr}[(c+c^*)\rho_t]dt$. Here y_t, a continuous semimartingale with quadratic variation $\langle y, y\rangle_t = t$, is the observation process obtained from the system.
- $H_t = H_t^*$ is a Hamiltonian matrix which describes the action of external forces on the system. We will consider H_t of the form $H_t = F + u_t G$ with $F = F^*$, $G = G^*$, and the (real) scalar control input u_t.
- u_t is a bounded real càdlàg process that is adapted to $\mathcal{F}_t^y = \sigma(y_s, 0 \le s \le t)$, the filtration generated by the observations up to time t.
- c is a matrix which determines the coupling to the external (readout) field.
- $0 < \eta \le 1$ is the detector efficiency.

Let us begin by studying a different form of (3.2). Consider the linear Itô equation

$$d\tilde\rho_t = -i(H_t\tilde\rho_t - \tilde\rho_t H_t)\,dt + (c\tilde\rho_t c^* - \tfrac{1}{2}(c^*c\tilde\rho_t + \tilde\rho_t c^* c))\,dt + \sqrt{\eta}\,(c\tilde\rho_t + \tilde\rho_t c^*)\,dy_t, \tag{3.3}$$

which is the quantum analogue of the Zakai equation. As it obeys a global (random) Lipschitz condition, this equation has a unique strong solution [32, pp. 249–253].

LEMMA 3.2. *The set of nonnegative nonzero matrices is a.s. invariant for* (3.3).

Proof. We begin by expanding $\tilde\rho_0$ into its eigenstates, i.e., $\tilde\rho_0 = \sum_i \lambda_i v_0^i v_0^{i*}$ with $v_0^i \in \mathbb{C}^N$ being the ith eigenvector and λ_i the ith eigenvalue. As $\tilde\rho_0$ is nonnegative, all the λ_i are nonnegative. Now consider the set of equations

$$d\rho_t^i = -i(H_t\rho_t^i - \rho_t^i H_t)\,dt + (c\rho_t^i c^* - \tfrac{1}{2}(c^*c\rho_t^i + \rho_t^i c^*c))\,dt + (c\rho_t^i + \rho_t^i c^*)\,dW_t' \tag{3.4}$$

with $\rho_0^i = v_0^i v_0^{i*}$. Here we have extended our probability space to admit a Wiener process $\hat W_t$ that is independent of y_t, and $W_t' = \sqrt{\eta}\,y_t + \sqrt{1-\eta}\,\hat W_t$. The process $\tilde\rho_t$ is then equivalent in law to $\mathbb{E}[\rho_t'|\mathcal{F}_t^y]$, where $\rho_t' = \sum_i \lambda_i \rho_t^i$.

Now note that the solution of the set of equations

$$dv_t^i = -iH_t v_t^i\,dt - \tfrac{1}{2}c^*c\,v_t^i\,dt + c\,v_t^i\,dW_t', \qquad v_t^i \in \mathbb{C}^N, \tag{3.5}$$

satisfies $\rho_t^i = v_t^i v_t^{i*}$, as is readily verified by Itô's rule. By [32, pp. 326], we have that $v_t^i = U_t v_0^i$, where the random matrix U_t is a.s. invertible for all t. Hence a.s. $v_t^i \neq 0$ for any finite time unless $v_0^i = 0$. Thus clearly ρ_t' is a.s. a nonnegative nonzero matrix for all t, and the result follows. □

PROPOSITION 3.3. *Equation* (3.2) *has a unique strong solution* $\rho_t = \tilde\rho_t/\mathrm{Tr}\,\tilde\rho_t$ *in* $\mathcal{S}$.

Clearly this must be satisfied if (3.2) is to propagate a density.

Proof. As the set of nonnegative nonzero matrices is invariant for $\tilde\rho_t$, this implies in particular that $\mathrm{Tr}\,\tilde\rho_t > 0$ for all t a.s. Thus the result follows simply from application of Itô's rule to (3.3) and from the fact that if $M = \sum_i \lambda_i v_i$ is a nonnegative nonzero matrix, then $M/\mathrm{Tr}\,M = \sum_i (\lambda_i/\sum_j \lambda_j) v_i \in \mathcal{S}$. □

PROPOSITION 3.4. *The following uniform estimate holds for* (3.2):

$$\mathbb{P}\left(\sup_{0\le\delta\le\Delta} \|\rho_{t+\delta} - \rho_t\| > \varepsilon\right) \le C\Delta(1+\Delta) \qquad \forall \varepsilon > 0, \tag{3.6}$$

where $0 < C < \infty$ *depends only on* ε *and* $\|\cdot\|$ *is the Frobenius norm. Hence the solution of* (3.2) *is stochastically continuous uniformly in* t *and* ρ_0.

Proof. Write $\rho_t = \rho_0 + \Phi_t + \Xi_t$, where

$$\Phi_t = \int_0^t \left[-i(H_s\rho_s - \rho_s H_s) + (c\rho_s c^* - \tfrac{1}{2}(c^*c\rho_s + \rho_s c^*c))\right] ds, \tag{3.7}$$

$$\Xi_t = \int_0^t \sqrt{\eta}\,(c\rho_s + \rho_s c^* - \mathrm{Tr}[(c+c^*)\rho_s]\rho_s)\,dW_s. \tag{3.8}$$

For Ξ_t we have the estimate [1, pp. 81]

$$\mathbb{E}\left(\sup_{0\le\delta\le\Delta}\|\Xi_{t+\delta}-\Xi_t\|^2\right) \le 4\eta\int_t^{t+\Delta}\mathbb{E}\|c\rho_s+\rho_s c^*-\mathrm{Tr}[(c+c^*)\rho_s]\rho_s\|^2\,ds. \tag{3.9}$$

As the integrand is bounded clearly, this expression is bounded by $C_1\Delta$ for some positive constant $C_1<\infty$. For Φ_t we can write

$$\mathbb{E}\left(\sup_{0\le\delta\le\Delta}\|\Phi_{t+\delta}-\Phi_t\|^2\right) \le \mathbb{E}\left[\sup_{0\le\delta\le\Delta}\int_t^{t+\delta}\|G_s\|\,ds\right]^2 = \mathbb{E}\left[\int_t^{t+\Delta}\|G_s\|\,ds\right]^2, \tag{3.10}$$

where G_s denotes the integrand of (3.7). As $\|G_s\|$ is bounded, we can estimate this expression by $C_2\Delta^2$ with $C_2<\infty$. Using $\|A+B\|^2\le 2(\|A\|^2+\|B\|^2)$, we can write

$$\sup_{0\le\delta\le\Delta}\|\rho_{t+\delta}-\rho_t\|^2 \le 2\left(\sup_{0\le\delta\le\Delta}\|\Phi_{t+\delta}-\Phi_t\|^2+\sup_{0\le\delta\le\Delta}\|\Xi_{t+\delta}-\Xi_t\|^2\right). \tag{3.11}$$

Finally, Chebyshev's inequality gives

$$\mathbb{P}\left(\sup_{0\le\delta\le\Delta}\|\rho_{t+\delta}-\rho_t\|>\varepsilon\right) \le \frac{1}{\varepsilon^2}\mathbb{E}\left(\sup_{0\le\delta\le\Delta}\|\rho_{t+\delta}-\rho_t\|^2\right) \le \frac{2C_1\Delta+2C_2\Delta^2}{\varepsilon^2}, \tag{3.12}$$

from which the result follows. □

Remark. The statistics of the observation process y_t should, of course, depend both on the control u_t that is applied to the system and on the initial state ρ_0. We will always assume that the filter initial state ρ_0 matches the state in which the system is initially prepared (i.e., we do not consider "wrongly initialized" filters) and that the same control u_t is applied to the system and to the filter (see Figure 1.1). Quantum filtering theory then guarantees that the innovation W_t is a Wiener process. To simplify our proofs, we make from this point on the following choice: for all initial states and control policies, the corresponding observation processes are defined in such a way that they give rise to the same innovation process W_t.[1]

We now specialize to the following case:

- $u_t = u(\rho_t)$ with $u \in C^1(\mathcal{S},\mathbb{R})$.

In this simple feedback case we can prove several important properties of the solutions. First, however, we must show existence and uniqueness for the filtering equation with feedback: it is not a priori obvious that the feedback $u_t = u(\rho_t)$ results in a well-defined càdlàg control.

[1] This is contrary to the usual stochastic control setup: there the system and observation noises are fixed Wiener processes, and every initial state and control policy gives rise to a different innovation (Wiener) process. However, in the quantum case the system and observation noises do not even commute with the observations process, and thus we cannot use them to fix the innovations. In fact, the observation process y_t that emerges from the quantum probability model is defined only in a "weak" sense as a *-isomorphism between an algebra of observables and a set of random variables on $(\Omega,\mathcal{F},\mathbb{P})$ [9]. Hence we might as well choose the isomorphism for each initial state and control in such a way that all observations $y_t[\rho_0,u_t]$ give rise to the fixed innovations process W_t, regardless of ρ_0,u_t. Note that the only results that depend on the precise choice of $y_t[\rho_0,u_t]$ on $(\Omega,\mathcal{F},\mathbb{P})$ are joint statistics of the filter sample paths for different initial states or controls. However, such results are physically meaningless as the corresponding quantum models generally do not commute.

PROPOSITION 3.5. *Equation* (3.2) *with* $u_t = u(\rho_t)$, $u \in C^1$, *and* $\rho_0 = \rho \in \mathcal{S}$ *has a unique strong solution* $\rho_t \equiv \varphi_t(\rho, u)$ *in* $\mathcal{S}$, *and* u_t *is a continuous bounded control.*

Proof. As $\mathcal{S}$ is compact, we can find an open set $\mathcal{T} \subset \mathbb{C}^{N\times N}$ such that $\mathcal{S}$ is strictly contained in $\mathcal{T}$. Let $C(\rho) : \mathbb{C}^{N\times N} \to [0,1]$ be a smooth function with compact support such that $C(\rho) = 1$ for $\rho \in \mathcal{T}$, and let $U(\rho)$ be a $C^1(\mathbb{C}^{N\times N}, \mathbb{R})$ function such that $U(\rho) = u(\rho)$ for $\rho \in \mathcal{S}$. Then the equation

$$\begin{aligned} d\bar\rho_t = -iC(\bar\rho_t)[F + U(\bar\rho_t)G, \bar\rho_t]\,dt + C(\bar\rho_t)(c\bar\rho_t c^* - \tfrac{1}{2}(c^*c\bar\rho_t + \bar\rho_t c^*c))\,dt \\ + C(\bar\rho_t)\sqrt{\eta}\,(c\bar\rho_t + \bar\rho_t c^* - \mathrm{Tr}[(c+c^*)\bar\rho_t]\bar\rho_t)\,dW_t, \end{aligned}$$

where $[A, B] = AB - BA$, has global Lipschitz coefficients and hence has a unique strong solution in $\mathbb{C}^{N\times N}$ and a.s. continuous adapted sample paths [32]. Moreover, $\bar\rho_t$ must be bounded as $C(\rho)$ has compact support. Hence $U_t = U(\bar\rho_t)$ is an a.s. continuous, bounded adapted process.

Now consider the solution ρ_t of (3.2) with $u_t = U(\bar\rho_t)$ and $\rho_0 = \bar\rho_0 \in \mathcal{S}$. As both ρ_t and $\bar\rho_t$ have a unique solution, the solutions must coincide up to the first exit time from $\mathcal{T}$. But we have already established that ρ_t remains in $\mathcal{S}$ for all $t > 0$, so $\bar\rho_t$ can certainly never exit $\mathcal{T}$. Hence $\bar\rho_t = \rho_t$ for all $t > 0$, and the result follows. ∎

In the following, we will denote by $\varphi_t(\rho, u)$ the solution of (3.2) at time t with the control $u_t = u(\rho_t)$ and initial condition $\rho_0 = \rho \in \mathcal{S}$.

PROPOSITION 3.6. *If* $V(\rho)$ *is continuous, then* $\mathbb{E}V(\varphi_t(\rho, u))$ *is continuous in* ρ; *i.e., the diffusion* (3.2) *is Feller continuous.*

Proof. Let $\{\rho^n \in \mathcal{S}\}$ be a sequence of points converging to $\rho^\infty \in \mathcal{S}$. Let us write $\rho_t^n = \varphi_t(\rho^n, u)$ and $\rho_t^\infty = \varphi_t(\rho^\infty, u)$. First, we will show that

$$\mathbb{E}\|\rho_t^n - \rho_t^\infty\|^2 \to 0 \quad \text{as} \quad n \to \infty, \tag{3.13}$$

where $\|\cdot\|$ is the Frobenius norm ($\|A\|^2 = (A, A)$ with the inner product $(A, B) = \mathrm{Tr}\,(A^*B)$). We will write $\delta_t^n = \rho_t^n - \rho_t^\infty$. Using Itô's rule we obtain

$$\begin{aligned} \mathbb{E}\|\delta_t^n\|^2 = \|\delta_0^n\|^2 &+ \int_0^t \eta\mathbb{E}\mathrm{Tr}\left((c\delta_s^n + \delta_s^n c^* - \mathrm{Tr}[(c+c^*)\rho_s^n]\rho_s^n + \mathrm{Tr}[(c+c^*)\rho_s^\infty]\rho_s^\infty)^2\right) ds \\ &+ \int_0^t 2\,\mathbb{E}\left[\mathrm{Tr}\left((i[\rho_s^n, H(\rho_s^n)] - i[\rho_s^\infty, H(\rho_s^\infty)])\delta_s^n\right) + \mathrm{Tr}\left(c\delta_s^n c^*\delta_s^n - c^*c(\delta_s^n)^2\right)\right] ds, \end{aligned} \tag{3.14}$$

where $[A, B] = AB - BA$. Let us estimate each of these terms. We have

$$\begin{aligned} \mathrm{Tr}\left(c^*c(\delta_t^n)^2\right) &= \|c\delta_t^n\|^2 \le C_1\|\delta_t^n\|^2, \\ \mathrm{Tr}\,(c\delta_t^n c^*\delta_t^n) &= (\delta_t^n c, c\delta_t^n) \le \|\delta_t^n c\|\ \|c\delta_t^n\| \le C_2\|\delta_t^n\|^2, \end{aligned} \tag{3.15}$$

where we have used the Cauchy–Schwarz inequality and the fact that all the operators are bounded. Next we tackle

$$\mathrm{Tr}\left((i[\rho_t^n, H(\rho_t^n)] - i[\rho_t^\infty, H(\rho_t^\infty)])\delta_t^n\right) \le \|i[\rho_t^n, H(\rho_t^n)] - i[\rho_t^\infty, H(\rho_t^\infty)]\|\ \|\delta_t^n\|. \tag{3.16}$$

Now note that $S(\rho) = i[\rho, H(\rho)] = i[\rho, F + u(\rho)G]$ is C^1 in the matrix elements of ρ, and that its derivatives are bounded as $\mathcal{S}$ is compact. Hence $S(\rho)$ is Lipschitz continuous, and we have

$$\|S(\rho_t^n) - S(\rho_t^\infty)\| \le C_3\|\rho_t^n - \rho_t^\infty\| = C_3\|\delta_t^n\|, \tag{3.17}$$

which implies

$$\mathrm{Tr}\left((i[\rho_t^n, H(\rho_t^n)] - i[\rho_t^\infty, H(\rho_t^\infty)])\delta_t^n\right) \le C_3\|\delta_t^n\|^2. \tag{3.18}$$

Finally, we have $\|c\delta_t^n + \delta_t^n c^*\| \le C_4\|\delta_t^n\|$ due to boundedness of multiplication with c, and a Lipschitz argument similar to the one above can be applied to $S'(\rho) = \mathrm{Tr}[(c+c^*)\rho]\rho$, giving

$$\|\mathrm{Tr}[(c+c^*)\rho_t^n]\rho_t^n - \mathrm{Tr}[(c+c^*)\rho_t^\infty]\rho_t^\infty\| \le C_5\|\delta_t^n\|. \tag{3.19}$$

We can now use $\|A+B\|^2 \le \|A\|^2 + 2\|A\|\,\|B\| + \|B\|^2$ to estimate the last term in (3.14) by $C_6\|\delta_t^n\|^2$. Putting all these together, we obtain

$$\mathbb{E}\|\delta_t^n\|^2 \le \|\delta_0^n\|^2 + C\int_0^t \mathbb{E}\|\delta_s^n\|^2 ds, \tag{3.20}$$

and thus by Gronwall's lemma

$$\mathbb{E}\|\delta_t^n\|^2 \le e^{Ct}\|\delta_0^n\|^2 = e^{Ct}\|\rho^n - \rho^\infty\|^2. \tag{3.21}$$

As t is fixed, (3.13) follows.

We have now proved that $\rho_t^n \to \rho_t^\infty$ in mean square as $n \to \infty$, which implies convergence in probability. But then for any continuous V, $V(\rho_t^n) \to V(\rho_t^\infty)$ in probability [16, pp. 60]. As $\mathcal{S}$ is compact, V is bounded, and we have

$$\mathbb{E}V(\rho_t^\infty) = \mathbb{E}[\mathbb{P}\text{-}\lim_{n\to\infty} V(\rho_t^n)] = \lim_{n\to\infty} \mathbb{E}V(\rho_t^n) \tag{3.22}$$

by dominated convergence [16, pp. 72]. But as this holds for any convergent sequence ρ^n, the result follows. ∎

PROPOSITION 3.7. *$\varphi_t(\rho, u)$ is a strong Markov process in $\mathcal{S}$.*

Proof. The proof of the Markov property in [31, pp. 109–110] carries over to our case. But then the strong Markov property follows from Feller continuity [24]. ∎

PROPOSITION 3.8. *Let τ be the first exit time of ρ_t from an open set $Q \subset \mathcal{S}$ and consider the stopped process $\rho_t^Q = \varphi_{t\wedge\tau}(\rho, u)$. Then ρ_t^Q is also a strong Markov process in $\mathcal{S}$. Furthermore, for V s.t. $\mathscr{A}V$ exists and is continuous, where $\mathscr{A}$ is the weak infinitesimal operator associated to $\varphi_t(\rho, u)$, we have $\mathscr{A}_Q V(x) = \mathscr{A}V(x)$ if $x \in Q$ and $\mathscr{A}_Q V(x) = 0$ if $x \ne Q$ for the weak infinitesimal operator $\mathscr{A}_Q$ associated to ρ_t^Q.*

Proof. This follows from [24, pp. 11–12] and Proposition 3.4. ∎

4. Angular momentum systems. In this section we consider a quantum system with fixed angular momentum J ($2J \in \mathbb{N}$), e.g., an atomic ensemble, which is detected through a dispersive optical probe [19]. After conditioning, such systems are described by an equation of the form (3.2), where

- the Hilbert space dimension $N = 2J+1$;
- $c = \beta F_z$, $F = 0$, and $G = \gamma F_y$ with $\beta, \gamma > 0$.

Here F_y and F_z are the (self-adjoint) angular momentum operators defined as follows. Let $\{\psi_k : k = 0, \dots, 2J\}$ be the standard basis in $\mathbb{C}^N$; i.e., ψ_i is the vector with a single nonzero element $\psi_i^i = 1$. Then [28]

$$\begin{aligned} F_y\psi_k &= ic_{k-J}\psi_{k+1} - ic_{J-k}\psi_{k-1}, \\ F_z\psi_k &= (k-J)\psi_k \end{aligned} \tag{4.1}$$

with $c_m = \frac{1}{2}\sqrt{(J-m)(J+m+1)}$. Without loss of generality we will choose $\beta = \gamma = 1$, as we can always rescale time and u_t to obtain any β, γ.

Let us begin by studying the dynamical behavior of the resulting equation,

$$d\rho_t = -iu_t[F_y, \rho_t]\,dt - \tfrac{1}{2}[F_z,[F_z,\rho_t]]\,dt + \sqrt{\eta}\,(F_z\rho_t + \rho_t F_z - 2\,\mathrm{Tr}[F_z\rho_t]\rho_t)\,dW_t \tag{4.2}$$

without feedback $u_t = 0$.

Proposition 4.1 (quantum state reduction). *For any $\rho_0 \in \mathcal{S}$, the solution ρ_t of (4.2) with $u_t = 0$ converges a.s. as $t \to \infty$ to one of $\psi_m\psi_m^*$.*

Proof. We will apply Theorem 2.2 with $Q_\lambda = \mathcal{S}$. Consider the Lyapunov function $v(\rho) = \mathrm{Tr}[F_z^2\rho] - (\mathrm{Tr}[F_z\rho])^2$. One easily calculates $\mathscr{A}v(\rho) = -4\eta\, v(\rho)^2 \le 0$, and hence

$$\mathbb{E}v(\rho_t) = v(\rho_0) - 4\eta\int_0^t \mathbb{E}v(\rho_s)^2\,ds \tag{4.3}$$

by using Itô's rule. Note that $v(\rho) \ge 0$, so

$$4\eta\int_0^t \mathbb{E}v(\rho_s)^2\,ds = v(\rho_0) - \mathbb{E}v(\rho_t) \le v(\rho_0) < \infty. \tag{4.4}$$

Thus we have by monotone convergence

$$\mathbb{E}\int_0^\infty v(\rho_s)^2\,ds < \infty \quad\Longrightarrow\quad \int_0^\infty v(\rho_s)^2\,ds < \infty \quad \text{a.s.} \tag{4.5}$$

By Theorem 2.2 the limit of $v(\rho_t)$ as $t \to \infty$ exists a.s., and hence (4.5) implies that $v(\rho_t) \to 0$ a.s. But the only states ρ that satisfy $v(\rho) = 0$ are $\rho = \psi_m\psi_m^*$. ∎

The main goal of this section is to provide a feedback control law that globally stabilizes (4.2) around the equilibrium solution ($\rho_t \equiv \rho_f, u \equiv 0$), where we select a target state $\rho_f = v_f v_f^*$ from one of $v_f = \psi_m$.

Stabilization of quantum state reduction for low-dimensional angular momentum systems has been studied in [18]. It is shown that the main challenge in such a stabilization problem is due to the geometric symmetry hidden in the state space of the system. Many natural feedback laws fail to stabilize the closed-loop system around the equilibrium point ρ_f because of this symmetry: the ω-limit set contains points other than ρ_f. The approach of [18] uses computer searches to find continuous control laws that break this symmetry and globally stabilize the desired state. Unfortunately, the method is computationally involved and can be applied only to low-dimensional systems. Additionally, it is difficult to prove stability in this way for arbitrary parameter values, as the method is not analytical.

Here we present a different approach which avoids the unwanted limit points by changing the feedback law around them. The approach is entirely analytical and globally stabilizes the desired target state for any dimension N and $0 < \eta \le 1$. The main result of this section can be stated as the following theorem.

Theorem 4.2. *Consider the system (4.2) evolving in the set $\mathcal{S}$. Let $\rho_f = v_f v_f^*$, where v_f is one of ψ_m, and let $\gamma > 0$. Consider the following control law:*

1. *$u_t = -\mathrm{Tr}\,(i[F_y,\rho_t]\rho_f)$ if $\mathrm{Tr}\,(\rho_t\rho_f) \ge \gamma$.*
2. *$u_t = 1$ if $\mathrm{Tr}\,(\rho_t\rho_f) \le \gamma/2$.*
3. *If $\rho_t \in \mathcal{B} = \{\rho : \gamma/2 < \mathrm{Tr}\,(\rho\rho_f) < \gamma\}$, then $u_t = -\mathrm{Tr}\,(i[F_y,\rho_t]\rho_f)$ if ρ_t last entered $\mathcal{B}$ through the boundary $\mathrm{Tr}\,(\rho\rho_f) = \gamma$, and $u_t = 1$ otherwise.*

Then there exists $\gamma > 0$ *s.t.* u_t *globally stabilizes* (4.2) *around* ρ_f *and* $\mathbb{E}\rho_t \to \rho_f$ *as* $t \to \infty$.

Throughout the proofs we use the "natural" distance function

$$V(\rho) = 1 - \mathrm{Tr}\,(\rho\rho_f) : \mathcal{S} \to [0,1]$$

from the state ρ to the target state ρ_f. For future reference, let us define for each $\alpha \in [0,1]$ the level set $\mathcal{S}_\alpha$ to be

$$\mathcal{S}_\alpha = \{\rho \in \mathcal{S} : V(\rho) = \alpha\}.$$

Furthermore, we define the following sets:

$$\begin{aligned}
\mathcal{S}_{>\alpha} &= \{\rho \in \mathcal{S} : \alpha < V(\rho) \le 1\},\\
\mathcal{S}_{\ge\alpha} &= \{\rho \in \mathcal{S} : \alpha \le V(\rho) \le 1\},\\
\mathcal{S}_{<\alpha} &= \{\rho \in \mathcal{S} : 0 \le V(\rho) < \alpha\},\\
\mathcal{S}_{\le\alpha} &= \{\rho \in \mathcal{S} : 0 \le V(\rho) \le \alpha\}.
\end{aligned}$$

The proof of Theorem 4.2 proceeds in four steps.

1. In the first step we show that when the initial state lies in the set $\mathcal{S}_1$, the constant control field $u = 1$ ensures the exit of the trajectories (at least) in expectation from the level set $\mathcal{S}_1$.
2. In the second step we use the result of step 1 to show that there exists a $\gamma > 0$ such that whenever the initial state lies inside the set $\mathcal{S}_{>1-\gamma}$ and the control field is taken to be $u = 1$, the expectation value of the first exit time from this set takes a finite value. Thus if we start the controlled system in the set $\mathcal{S}_{>1-\gamma}$, it will exit this set in finite time with probability one.
3. In the third step we show that whenever the initial state lies inside the set $\mathcal{S}_{\le 1-\gamma}$ and the control is given by the feedback law $u(t) = -\mathrm{Tr}\,(i[F_y, \rho_t]\rho_f)$, the sample paths never exit the set $\mathcal{S}_{<1-\gamma/2}$ with a probability uniformly larger than a strictly positive value. We also show that almost all paths that never leave $\mathcal{S}_{<1-\gamma/2}$ converge to the equilibrium point ρ_f.
4. In the final step, we prove that there is a unique solution ρ_t under the control u_t by piecing together the solutions with fixed controls $u = 1$ and $u = -\mathrm{Tr}\,(i[F_y, \rho_t]\rho_f)$. Combining the results of the second and third steps, we show that the resulting trajectories of the system eventually converge toward the equilibrium state ρ_f with probability one.

Step 1. Let us take a fixed time $T > 0$ and define the nonnegative function

$$\chi(\rho) = \min_{t\in[0,T]} \mathbb{E}V(\varphi_t(\rho, 1)), \qquad \rho \in \mathcal{S}.$$

Recall that $\varphi_t(\rho, 1)$ denotes the solution of (4.2) at time t with the control $u_t = 1$ and initial condition $\rho_0 = \rho$. The goal of the first step is to show the following result.

LEMMA 4.3. $\chi(\rho) < 1$ *for all* $\rho \in \mathcal{S}_1$.

To prove this statement we will first show the following deterministic result.

LEMMA 4.4. *Consider the deterministic differential equation*

$$\frac{d}{dt}v_t = (-iF_y - F_z^2 + CF_z)v_t, \qquad v_0 \in \mathbb{C}^N \setminus \{0\}. \tag{4.6}$$

For sufficiently large $C \gg 1$, v_t *exits the set* $\{v : v^*v_f = 0\}$ *in the interval* $[0,T]$*; i.e., there exists* $t \in [0,T]$ *such that* $v_t^*v_f \neq 0$.

Proof. The matrices F_z and F_y are of the form

$$F_z = \begin{pmatrix} * & & & & 0 \\ & * & & & \\ & & \ddots & & \\ & & & * & \\ 0 & & & & * \end{pmatrix}, \qquad F_y = \begin{pmatrix} 0 & * & & & 0 \\ * & 0 & * & & \\ & \ddots & \ddots & \ddots & \\ & & * & 0 & * \\ 0 & & & * & 0 \end{pmatrix},$$

where F_z has no repeated diagonal entries (F_z has a nondegenerate spectrum) and the starred elements directly above and below the diagonal of F_y are all nonzero.

Now choose a constant κ so that the matrix

$$A = -iF_y - F_z^2 + \kappa F_z$$

admits distinct eigenvalues. This is always possible by choosing sufficiently large κ, as F_z has nondegenerate eigenvalues and the eigenvalues of A depend continuously[2] on κ. For $k \in \{1, \dots, N\}$ define the matrices A_{k-1} and $\tilde{A}_{k+1}$ to be

$$A_{k-1} = [A_{ij}]_{1 \le i,j \le k-1}, \qquad \tilde{A}_{k+1} = [A_{ij}]_{k+1 \le i,j \le N}.$$

The fact that the matrices $[(F_z)_{ij}]_{1 \le i,j \le k-1}$ and $[(F_z)_{ij}]_{k+1 \le i,j \le N}$ have different eigenvalues then implies that for sufficiently large κ the matrices A_{k-1} and $\tilde{A}_{k+1}$ have disjoint spectra as well.

Suppose that the solution of

$$\dot{v} = Av, \qquad v|_{t=0} = v_0,$$

never leaves the set $\{v : v^* v_f = 0\}$ in the interval $t \in [0, T]$. Then in particular

$$\frac{d^n}{dt^n} v^* v_f|_{t=0} = (A^n v_0)^* v_f = 0, \qquad n = 0, 1, \dots .$$

The matrix A is diagonalizable as it has distinct eigenvalues; i.e., $A = PDP^{-1}$ where D is a diagonal matrix. Thus

$$(D^n \tilde{v}_0)^* \tilde{v}_f = 0, \qquad n = 0, 1, \dots, \tag{4.7}$$

where $\tilde{v}_0 = P^{-1} v_0$ and $\tilde{v}_f = P^* v_f$. Equation (4.7) implies that $M \tilde{v}_0 = 0$, where

$$M = \begin{pmatrix} (\tilde{v}_f)_1^* & \dots & (\tilde{v}_f)_N^* \\ (\tilde{v}_f)_1^* D_{11} & \dots & (\tilde{v}_f)_N^* D_{NN} \\ (\tilde{v}_f)_1^* D_{11}^2 & \dots & (\tilde{v}_f)_N^* D_{NN}^2 \\ \vdots & \vdots & \vdots \\ (\tilde{v}_f)_1^* D_{11}^{N-1} & \dots & (\tilde{v}_f)_N^* D_{NN}^{N-1} \end{pmatrix}.$$

The determinant of this Vandermonde matrix is

$$\det M = (\tilde{v}_f)_1^* \cdots (\tilde{v}_f)_N^* \prod_{i>j} (D_{ii} - D_{jj}).$$

[2]Note that the coefficients of the characteristic polynomial of A are continuous functions of κ, and the roots of a polynomial depend continuously on the polynomial coefficients.

As the matrix A has distinct eigenvalues, all the entries $D_{11}, D_{22}, \dots, D_{NN}$ are different. Thus if we can show that all the entries of the vector $\tilde{v}_f$ are nonzero, then the matrix M must be invertible. But then $M\tilde{v}_0 = 0$ implies that $\tilde{v}_0 = 0$, and hence $v_0 = 0$ is the only initial state for which the dynamics does not leave the set $\{v : v^* v_f = 0\}$ in the interval $t \in [0, T]$, proving our assertion.

Let us thus show that in fact all elements of $\tilde{v}_f$ are nonzero. Note that

$$(\tilde{v}_f)_k = (P^* v_f)_k = P^*_{fk},$$

and hence it suffices to show that the eigenvectors of the matrix A have only nonzero elements. Suppose that an eigenvector Ξ of A admits a zero entry, i.e.,

$$A\Xi = \lambda\Xi, \qquad \Xi_k = 0 \text{ for some } k \in \{1, \dots, N\}.$$

Defining $\chi_{k-1} = [\Xi_j]_{j=1,\dots,k-1}$ and $\tilde{\chi}_{k+1} = [\Xi_j]_{j=k+1,\dots,N}$, a straightforward computation shows that due to the structure of the matrix A

$$A_{k-1}\chi_{k-1} = \lambda\chi_{k-1} \quad \text{and} \quad \tilde{A}_{k+1}\tilde{\chi}_{k+1} = \lambda\tilde{\chi}_{k+1}.$$

But by the discussion above, A_{k-1} and $\tilde{A}_{k+1}$ have disjoint spectra, so Ξ can be an eigenvector only if either $\chi_{k-1} = 0$ or $\tilde{\chi}_{k+1} = 0$.

Let us consider the case where $\chi_{k-1} = 0$; the treatment of the second case follows an identical argument. Let $j > k$ be the first nonzero entry of Ξ, i.e.,

$$\Xi_1 = \Xi_2 = \cdots = \Xi_{j-1} = 0 \quad \text{and} \quad \Xi_j \neq 0. \tag{4.8}$$

As $A\Xi = \lambda\Xi$, we have that

$$0 = \lambda\Xi_{j-1} = A_{j-1,j-2}\Xi_{j-2} + A_{j-1,j-1}\Xi_{j-1} + A_{j-1,j}\Xi_j = A_{j-1,j}\Xi_j = -i(F_y)_{j-1,j}\Xi_j.$$

As $(F_y)_{j-1,j} \neq 0$, this relation ensures that $\Xi_j = 0$. But this is in contradiction with (4.8) and thus Ξ cannot admit any zero entry. This completes the proof. ∎

Proof of Lemma 4.3. We begin by restating the problem as in the proof of Lemma 3.2. We can write $\varphi_t(\rho, 1) = \tilde{\rho}_t / \operatorname{Tr} \tilde{\rho}_t$ with $\tilde{\rho}_t = \sum_i \lambda_i \mathbb{E}[v_t^i v_t^{i*} | \mathcal{F}_t^y]$, where λ_i are convex weights and v_t^i are given by the equations

$$dv_t^i = -iF_y v_t^i \, dt - \tfrac{1}{2} F_z^2 v_t^i \, dt + F_z v_t^i \, dW_t', \qquad v_0^i \in \mathbb{C}^N \setminus \{0\}. \tag{4.9}$$

Note that $\mathbb{E}\operatorname{Tr}[\varphi_t(\rho, 1)\rho_f] = 0$ if and only if $\mathbb{E}\operatorname{Tr}[\tilde{\rho}_t \rho_f] = \sum_i \lambda_i \mathbb{E}[v_t^{i*} \rho_f v_t^i] = 0$. But as $v_t^{i*} \rho_f v_t^i \geq 0$, we obtain $\mathbb{E}V(\varphi_t(\rho, 1)) = 1$ if and only if $v_t^{i*} v_f = 0$ a.s. for all i.

To prove the assertion of the lemma, it suffices to show that there exists a $t \in [0, T]$ such that $\mathbb{E}V(\varphi_t(\rho, 1)) < 1$. Thus it is sufficient to prove that

$$\exists t \in [0, T] \quad \text{s.t.} \quad \mathbb{P}(v_t^* v_f \neq 0) > 0, \tag{4.10}$$

where v_t is the solution of an equation of the form (4.9). To this end we will use the support theorem, Theorem 2.4, together with Lemma 4.4.

To apply the support theorem we must first take care of two preliminary issues. First, the support theorem in the form of Theorem 2.4 must be applied to stochastic differential equations with a Wiener process as the driving noise, whereas the noise W_t' of (4.9) is a Wiener process with (bounded) drift:

$$dW_t' = \sqrt{\eta}\, dy_t + \sqrt{1-\eta}\, d\hat{W}_t = 2\eta \operatorname{Tr}[F_z \rho_t] dt + \sqrt{\eta}\, dW_t + \sqrt{1-\eta}\, d\hat{W}_t. \tag{4.11}$$

Using Girsanov's theorem, however, we can find a new measure $\mathbb{Q}$ that is equivalent to $\mathbb{P}$, such that W'_t is a Wiener process under $\mathbb{Q}$ on the interval $[0,T]$. But as the two measures are equivalent,

$$\exists t \in [0,T] \quad \text{s.t.} \quad \mathbb{Q}(v_t^* v_f \neq 0) > 0 \tag{4.12}$$

implies (4.10). Second, the support theorem refers to an equation in the Stratonovich form; however, we can easily find the Stratonovich form

$$dv_t = -iF_y v_t\,dt - F_z^2 v_t\,dt + F_z v_t \circ dW'_t \tag{4.13}$$

which is equivalent to (4.9). It is easily verified that this linear equation satisfies all the requirements of the support theorem.

To proceed, let us suppose that (4.12) does not hold true. Then

$$\mathbb{Q}(v_t^* v_f = 0) = 1 \qquad \forall t \in [0,T]. \tag{4.14}$$

Recall the following sets: $\mathscr{W}_{v_0}$ is the set of continuous paths starting at v_0, and $\mathscr{S}_{v_0}$ is the smallest closed subset of $\mathscr{W}_{v_0}$ such that $\mathbb{Q}(\{\omega \in \Omega : v_\cdot(\omega) \in \mathscr{S}_{v_0}\}) = 1$. Now denote by $\mathscr{T}_{v_0,t}$ the subset of $\mathscr{W}_{v_0}$ such that $v_t^* v_f = 0$, and note that $\mathscr{T}_{v_0,t}$ is closed in the compact uniform topology for any t. Then (4.14) would imply that $\mathscr{S}_{v_0} \subset \mathscr{T}_{v_0,t}$ for all $t \in [0,T]$. But by the support theorem the solutions of (4.6) are elements of $\mathscr{S}_{v_0}$, and by Lemma 4.4 there exist a time $t \in [0,T]$ and a constant C such that the solution of (4.6) is not an element of $\mathscr{T}_{v_0,t}$. Hence we have a contradiction, and the assertion is proved. □

Step 2. We begin by extending the result of Lemma 4.3 to hold uniformly in a neighborhood of the level set $\mathcal{S}_1$.

LEMMA 4.5. *There exists* $\gamma > 0$ *such that* $\chi(\rho) < 1-\gamma$ *for all* $\rho \in \mathcal{S}_{\geq 1-\gamma}$.

Proof. Suppose that for every $\xi > 0$ there exists a matrix $\rho_\xi \in \mathcal{S}_{>1-\xi}$ such that

$$1 - \xi < \chi(\rho_\xi) \leq 1.$$

By extracting a subsequence $\xi_n \searrow 0$ and using the compactness of $\mathcal{S}$, we can assume that $\rho_{\xi_n} \to \rho_\infty \in \mathcal{S}_1$ and that $\chi(\rho_{\xi_n}) \to 1$. But by Lemma 4.3 $\chi(\rho_\infty) = 1 - \epsilon < 1$. Now choose $s \in [0,T]$ such that

$$\mathbb{E}V(\varphi_s(\rho_\infty, 1)) = 1 - \epsilon.$$

Using Feller continuity, Proposition 3.6, we can now write

$$1 = \lim_{n\to\infty} \chi(\rho_{\xi_n}) \leq \lim_{n\to\infty} \mathbb{E}V(\varphi_s(\rho_{\xi_n}, 1)) = \mathbb{E}V(\varphi_s(\rho_\infty, 1)) = 1 - \epsilon < 1,$$

which is a contradiction. Hence there exists $\xi > 0$ such that $\chi(\rho) \leq 1 - \xi$ for all $\rho \in \mathcal{S}_{>1-\xi}$. The result follows by choosing $\gamma = \xi/2$. □

The following lemma is the main result of Step 2.

LEMMA 4.6. *Let* $\tau_\rho(\mathcal{S}_{>1-\gamma})$ *be the first exit time of* $\varphi_t(\rho, 1)$ *from* $\mathcal{S}_{>1-\gamma}$. *Then*

$$\sup_{\rho \in \mathcal{S}_{>1-\gamma}} \mathbb{E}\tau_\rho(\mathcal{S}_{>1-\gamma}) < \infty.$$

Proof. The following result can be found in Dynkin [13, Lemma 4.3, pp. 111]:

$$\mathbb{E}\tau_\rho(\mathcal{S}_{>1-\gamma}) \leq \frac{T}{1 - \sup_{\zeta \in \mathcal{S}} \mathbb{P}\{\tau_\zeta(\mathcal{S}_{>1-\gamma}) > T\}}.$$

We will show that

$$\sup_{\zeta\in\mathcal{S}} \mathbb{P}\{\tau_\zeta(\mathcal{S}_{>1-\gamma}) > T\} < 1. \tag{4.15}$$

This holds trivially for $\zeta \in \mathcal{S}_{\leq 1-\gamma}$, as then $\tau_\zeta(\mathcal{S}_{>1-\gamma}) = 0$. Let us thus suppose that

$$\forall \epsilon > 0 \quad \exists \zeta_\epsilon \in \mathcal{S}_{>1-\gamma} \quad \text{such that} \quad \mathbb{P}\{\tau_{\zeta_\epsilon}(\mathcal{S}_{>1-\gamma}) > T\} > 1-\epsilon.$$

Then for all $s \in [0,T]$, we have that

$$\mathbb{E}V(\varphi_s(\zeta_\epsilon, 1)) > (1-\epsilon) \inf_{\rho\in\mathcal{S}_{>1-\gamma}} V(\rho) = (1-\epsilon)(1-\gamma).$$

By compactness there exist a sequence $\epsilon_n \searrow 0$ and $\zeta_\infty \in \mathcal{S}_{\geq 1-\gamma}$ such that $\zeta_{\epsilon_n} \to \zeta_\infty$ as $n \to \infty$. Thus by Proposition 3.6

$$\mathbb{E}V(\varphi_s(\zeta_\infty, 1)) > 1-\gamma \quad \forall s \in [0,T].$$

But this is in contradiction with the result of Lemma 4.5. Hence there exists an $\epsilon > 0$ such that $\sup_{\zeta\in\mathcal{S}} \mathbb{P}\{\tau_\zeta(\mathcal{S}_{>1-\gamma}) > T\} = 1-\epsilon$, and we obtain

$$\mathbb{E}(\tau_\rho(\mathcal{S}_{>1-\gamma})) \leq \frac{T}{1-(1-\epsilon)} = \frac{T}{\epsilon} < \infty$$

uniformly in ρ. This completes the proof. □

Step 3. In this step we deal with the situation where the initial state lies inside the set $\mathcal{S}_{\leq 1-\gamma}$. We will denote by $u_1(\rho) = -\mathrm{Tr}\,(i[F_y,\rho]\rho_f)$ and by $\varphi_t(\rho,u_1)$ the solution of (4.2) with $\rho_0 = \rho$ and with $u_t = u_1(\rho_t)$. Denote by $\mathscr{A}$ the weak infinitesimal operator of $\varphi_t(\rho,u_1)$. We will apply the stochastic Lyapunov theorems with $Q_\lambda = \mathcal{S}$.

We begin by showing that there is a nonzero probability $p > 0$ that whenever the initial state lies inside $\mathcal{S}_{\leq 1-\gamma}$ the trajectories of the system never exit the set $\mathcal{S}_{<1-\gamma/2}$.

LEMMA 4.7. *For all* $\rho \in \mathcal{S}_{\leq 1-\gamma}$

$$\mathbb{P}\left[\sup_{0\leq t<\infty} V(\varphi_t(\rho,u_1)) \geq 1-\gamma/2\right] \leq 1-p = \frac{1-\gamma}{1-\gamma/2} < 1.$$

Proof. This follows from Theorem 2.2 and $\mathscr{A}V(\rho) = -u_1(\rho)^2 \leq 0$. □

We now restrict ourselves to the paths that never leave $\mathcal{S}_{<1-\gamma/2}$. We will first show that these paths converge toward ρ_f in probability. We then extend this result to prove almost sure convergence.

LEMMA 4.8. *The sample paths of* $\varphi_t(\rho,u_1)$ *that never exit the set* $\mathcal{S}_{<1-\gamma/2}$ *converge in probability to* ρ_f *as* $t \to \infty$.

Proof. Consider the Lyapunov function

$$\mathcal{V}(\rho) = 1 - \mathrm{Tr}\,(\rho\rho_f)^2.$$

It is easily verified that $\mathcal{V}(\rho) \geq 0$ for all $\rho \in \mathcal{S}$ and that $\mathcal{V}(\rho) = 0$ if and only if $\rho = \rho_f$. A straightforward computation gives

$$\mathscr{A}\mathcal{V}(\rho) = -2u_1(\rho)^2\,\mathrm{Tr}\,(\rho\rho_f) - 4\eta\,(\lambda_f - \mathrm{Tr}\,(\rho F_z))^2\,\mathrm{Tr}\,(\rho\rho_f)^2 \leq 0,$$

where λ_f is the eigenvalue of F_z associated to v_f. Now note that all the conditions of Theorem 2.3 are satisfied by virtue of Propositions 3.6 and 3.4. Hence $\varphi_t(\rho,u_1)$

converges in probability to the largest invariant set contained in $\mathcal{C} = \{\rho \in \mathcal{S} : \mathscr{A}\mathcal{V}(\rho) = 0\}$.

In order to satisfy the condition $\mathscr{A}\mathcal{V}(\rho) = 0$, we must have $u_1(\rho)^2 \operatorname{Tr}(\rho\rho_f) = 0$ as well as $(\lambda_f - \operatorname{Tr}(\rho F_z))^2 \operatorname{Tr}(\rho\rho_f)^2 = 0$. The latter implies that

$$\text{either} \quad \operatorname{Tr}(\rho\rho_f) = 0 \qquad \text{or} \quad \operatorname{Tr}(\rho F_z) = \lambda_f.$$

Let us investigate the largest invariant set contained in $\mathcal{C}' = \{\rho \in \mathcal{S} : \operatorname{Tr}(\rho F_z) = \lambda_f\}$. Clearly this invariant set can contain only $\rho \in \mathcal{C}'$ for which $\operatorname{Tr}(\varphi_t(\rho, u_1)F_z)$ is constant. Using Itô's rule we obtain

$$d\operatorname{Tr}(\rho_t F_z) = -iu_1(\rho_t)\operatorname{Tr}([F_y, \rho_t]F_z)\, dt + 2\sqrt{\eta}\,(\operatorname{Tr}(F_z^2\rho_t) - \operatorname{Tr}(F_z\rho_t)^2)\, dW_t.$$

Hence in order for $\operatorname{Tr}(\varphi_t(\rho, u_1)F_z)$ to be constant, we must at least have

$$\operatorname{Tr}(F_z^2\rho) - \operatorname{Tr}(F_z\rho)^2 = 0.$$

But as in the proof of Proposition 4.1, this implies that $\rho = \psi_m\psi_m^*$ for some m, and thus the only possibilities are $V(\rho) = 0$ (for $\rho = v_f v_f^*$) or $V(\rho) = 1$.

From the discussion above it is evident that the largest invariant set contained in $\mathcal{C}$ must be contained inside the set $\{\rho_f\} \cup \mathcal{S}_1$. But then the paths that never exit $\mathcal{S}_{<1-\gamma/2}$ must converge in probability to ρ_f. Thus the assertion is proved. □

LEMMA 4.9. *$\varphi_t(\rho, u_1)$ converges to ρ_f as $t \to \infty$ for almost all paths that never exit the set $\mathcal{S}_{<1-\gamma/2}$.*

Proof. Define the event $P^\rho_{<1-\gamma/2} = \{\omega \in \Omega : \varphi_t(\rho, u_1)$ never exits $\mathcal{S}_{<1-\gamma/2}\}$. Then Lemma 4.8 implies that

$$\lim_{t\to\infty} \mathbb{P}\left(\|\varphi_t(\rho, u_1) - \rho_f\| > \varepsilon \;\middle|\; P^\rho_{<1-\gamma/2}\right) = 0 \qquad \forall \varepsilon > 0.$$

By continuity of V, this also implies

$$\lim_{t\to\infty} \mathbb{P}\left(V(\varphi_t(\rho, u_1)) > \varepsilon \;\middle|\; P^\rho_{<1-\gamma/2}\right) = 0 \qquad \forall \varepsilon > 0.$$

As $V(\rho) \le 1$, we have

$$\begin{aligned}\mathbb{E}\left(V(\varphi_t(\rho, u_1)) \;\middle|\; P^\rho_{<1-\gamma/2}\right) &\le \mathbb{P}\left(V(\varphi_t(\rho, u_1)) > \varepsilon \;\middle|\; P^\rho_{<1-\gamma/2}\right) \\ &\quad + \varepsilon\left[1 - \mathbb{P}\left(V(\varphi_t(\rho, u_1)) > \varepsilon \;\middle|\; P^\rho_{<1-\gamma/2}\right)\right].\end{aligned}$$

Thus

$$\limsup_{t\to\infty} \mathbb{E}\left(V(\varphi_t(\rho, u_1)) \;\middle|\; P^\rho_{<1-\gamma/2}\right) \le \varepsilon \qquad \forall \varepsilon > 0,$$

which implies

$$\lim_{t\to\infty} \mathbb{E}\left(V(\varphi_t(\rho, u_1)) \;\middle|\; P^\rho_{<1-\gamma/2}\right) = 0.$$

But we know by Theorem 2.2 that $V(\varphi_t(\rho, u_1))$ converges a.s. As V is bounded, we obtain by dominated convergence

$$\mathbb{E}\left(\lim_{t\to\infty} V(\varphi_t(\rho, u_1)) \;\middle|\; P^\rho_{<1-\gamma/2}\right) = 0,$$

from which the result follows immediately. □

Step 4. It remains to combine the results of Steps 2 and 3 to prove existence, uniqueness, and global stability of the solution ρ_t. We will denote by u the control law of Theorem 4.2 and by $\varphi_t(\rho, u)$ the associated solution. Note that $\varphi_t(\rho, u)$ is not a Markov process, as the control u depends on the past history of the solution. We will construct $\varphi_t(\rho, u)$ by pasting together the strong Markov processes $\varphi_t(\rho, 1)$ and $\varphi_t(\rho, u_1)$ at the times where the control switches.

LEMMA 4.10. *There is a unique solution $\varphi_t(\rho, u)$ for all $t \in \mathbb{R}_+$. Moreover, for almost every sample path of $\varphi_t(\rho, u)$ there exists a time $T < \infty$ after which the path never exits the set $\mathcal{S}_{<1-\gamma/2}$ and the active control law is u_1.*

Proof. Fix the initial state ρ. We begin by constructing a solution $\varphi_{t\wedge n}(\rho, u)$ up to (at most) an integer time $n \in \mathbb{N}$. To this end, define the predictable stopping time

$$\tau_1^n = \inf\{t \geq 0 : \varphi_t(\rho, 1) \in \mathcal{S}_{\leq 1-\gamma}\} \wedge n.$$

Then we can define $\rho_{\tau_1^n} = \varphi_{\tau_1^n}(\rho, 1)$ and $\varphi_{t\wedge n}(\rho, u) = \varphi_t(\rho, 1)$ for $t < \tau_1^n$. In the following, we will need the two-parameter solution $\varphi_{s,t}(\rho, u')$ of the filtering equation under the simple control u', given the initial state ρ at time s. Define

$$\sigma_1^n = \inf\{t \geq \tau_1^n : \varphi_{\tau_1^n,t}(\rho_{\tau_1^n}, u_1) \in \mathcal{S}_{\geq 1-\gamma/2}\} \wedge n.$$

We can extend our solution by

$$\varphi_{t\wedge n}(\rho, u) = \chi_{t<\tau_1^n}\varphi_t(\rho, 1) + \chi_{\tau_1^n \leq t<\sigma_1^n}\varphi_{\tau_1^n,t}(\rho_{\tau_1^n}, u_1), \qquad t < \sigma_1^n,$$

where χ_A is the indicator function on the set A. To extend the solution further, we continue again with the control law $u = 1$. Recursively, we define an entire sequence of predictable stopping times

$$\sigma_k^n = \inf\{t \geq \tau_k^n : \varphi_{\tau_k^n,t}(\rho_{\tau_k^n}, u_1) \in \mathcal{S}_{\geq 1-\gamma/2}\} \wedge n,$$

$$\tau_k^n = \inf\{t \geq \sigma_{k-1}^n : \varphi_{\sigma_{k-1}^n,t}(\rho_{\sigma_{k-1}^n}, 1) \in \mathcal{S}_{\leq 1-\gamma}\} \wedge n,$$

where

$$\rho_{\sigma_k^n} = \varphi_{\tau_k^n,\sigma_k^n}(\rho_{\tau_k^n}, u_1), \qquad \rho_{\tau_k^n} = \varphi_{\sigma_{k-1}^n,\tau_k^n}(\rho_{\sigma_{k-1}^n}, 1).$$

We can use these times to construct the solution

$$\varphi_{t\wedge n}(\rho, u) = \chi_{t<\tau_1^n}\varphi_t(\rho, 1) + \sum_{k=1}^{\infty}\Big[\chi_{\tau_k^n \leq t<\sigma_k^n}\varphi_{\tau_k^n,t}(\rho_{\tau_k^n}, u_1) + \chi_{\sigma_k^n \leq t<\tau_{k+1}^n}\varphi_{\sigma_k^n,t}(\rho_{\sigma_k^n}, 1)\Big]$$

for all times $t < \Sigma^n = \lim_{k\to\infty}\sigma_k^n \leq n$ (the limit exists, as σ_k is a nondecreasing sequence of stopping times.) Moreover, the solution is a.s. unique, as the segments between each two stopping times are a.s. uniquely defined.

Now note that as anticipated by the notation, it is not difficult to verify that $\varphi_{t\wedge(n+1)}(\rho, u) = \varphi_{t\wedge n}(\rho, u)$ a.s. for $t < \Sigma^n$, and, moreover, $\Sigma^n = \Sigma \wedge n$, $\tau_k^n = \tau_k \wedge n$, $\sigma_k^n = \sigma_k \wedge n$, where $\Sigma = \lim_{t\to\infty}\Sigma^n$, etc. Hence we can let $n \to \infty$ to obtain the unique solution $\varphi_t(\rho, u)$ defined up to the accumulation time Σ, where τ_k, σ_k are the consecutive times at which the control switches. It remains to prove that the solution exists for all time, i.e., that $\Sigma = \infty$ a.s. In particular, this uniquely defines a càdlàg

control u_t, so that by uniqueness $\varphi_t(\rho,u)$ must coincide with the solution of (3.2) with the control u_t. Below we will prove that a.s., only finitely many σ_k are finite. This is sufficient to prove not only existence but also the second statement of the lemma.

To proceed, we use the fact that the strong Markov property holds on each segment between consecutive switching times $\tau_n \le t < \sigma_n$ and $\sigma_n \le t < \tau_{n+1}$. Thus

$$\begin{aligned}\mathbb{P}(\sigma_n < \infty \text{ and } \tau_n < \infty)\\ = \int \chi_{\tau_n<\infty}(\tilde\omega)\,\mathbb{P}(\varphi_t(\rho_{\tau_n}(\tilde\omega),u_1) \text{ exits } \mathcal{S}_{<1-\gamma/2} \text{ in finite time})\,\mathbb{P}(d\tilde\omega),\end{aligned}$$

which implies

$$\begin{aligned}\mathbb{P}(\sigma_n < \infty \,|\, \tau_n < \infty)\\ = \int \mathbb{P}(\varphi_t(\rho_{\tau_n}(\tilde\omega),u_1) \text{ exits } \mathcal{S}_{<1-\gamma/2} \text{ in finite time})\,\mathbb{P}(d\tilde\omega \,|\, \tau_n < \infty).\end{aligned}$$

But $\rho_{\tau_n} \in \mathcal{S}_{\le 1-\gamma}$ on a set Ω_{τ_n} with $\mathbb{P}(\Omega_{\tau_n} \,|\, \tau_n < \infty) = 1$. Hence by Lemma 4.7

$$\mathbb{P}(\sigma_n < \infty \,|\, \tau_n < \infty) \le 1 - p.$$

Through a similar argument, and using Lemma 4.6, we obtain

$$\mathbb{P}(\tau_n < \infty \,|\, \sigma_{n-1} < \infty) = 1.$$

But note that by construction

$$\mathbb{P}(\tau_n < \infty \,|\, \sigma_n < \infty) = \mathbb{P}(\sigma_{n-1} < \infty \,|\, \tau_n < \infty) = 1.$$

Hence we obtain

$$\begin{aligned}\frac{\mathbb{P}(\sigma_n < \infty)}{\mathbb{P}(\sigma_{n-1} < \infty)} &= \frac{\mathbb{P}(\tau_n < \infty \,|\, \sigma_n < \infty)\mathbb{P}(\sigma_n < \infty)}{\mathbb{P}(\tau_n < \infty)}\,\frac{\mathbb{P}(\sigma_{n-1} < \infty \,|\, \tau_n < \infty)\mathbb{P}(\tau_n < \infty)}{\mathbb{P}(\sigma_{n-1} < \infty)}\\ &= \mathbb{P}(\sigma_n < \infty \,|\, \tau_n < \infty)\,\mathbb{P}(\tau_n < \infty \,|\, \sigma_{n-1} < \infty) \le 1 - p.\end{aligned}$$

But $\mathbb{P}(\sigma_1 < \infty) = \mathbb{P}(\sigma_1 < \infty \,|\, \tau_1 < \infty) \le 1 - p$ as $\tau_1 < \infty$ a.s. Hence

$$\mathbb{P}(\sigma_n < \infty) \le (1-p)^n,$$

and thus

$$\sum_{n=1}^{\infty} \mathbb{P}(\sigma_n < \infty) \le \sum_{n=1}^{\infty} (1-p)^n = \frac{1-p}{p} < \infty.$$

By the Borel–Cantelli lemma, we conclude that

$$\mathbb{P}(\sigma_n < \infty \text{ for infinitely many } n) = 0.$$

Hence $\Sigma = \infty$ a.s., and for almost every sample path, there exists an integer $N < \infty$ such that $\sigma_n = \infty$ (and hence also $\tau_{n+1} = \infty$) for all $n \ge N$, and such that $\sigma_n < \infty$ (and hence also $\tau_{n+1} < \infty$) for all $n < N$, which implies the assertion. □

Finally, we can now put together all the ingredients and complete the proof of Theorem 4.2.

Proof of Theorem 4.2. We must check three things: that the target state ρ_f is (locally) stable in probability; that almost all sample paths are attracted to the target state as $t \to \infty$; and that this is also true in expectation. Existence and uniqueness of the solution follows from Lemma 4.10.

(i) To study local stability, we can restrict ourselves to the stopped process

$$\varphi_{t\wedge\tilde{\tau}}(\rho,u) = \varphi_{t\wedge\tilde{\tau}}(\rho,u_1), \quad \tilde{\tau} = \inf\{t : \varphi_t(\rho,u) \notin \mathcal{S}_{<1-\gamma/2}\}.$$

Denote by $\tilde{\mathscr{A}}$ the weak infinitesimal operator of $\varphi_{t\wedge\tilde{\tau}}(\rho,u_1)$, and note that Proposition 3.8 allows us to calculate $\tilde{\mathscr{A}}V$ from (4.2) in the usual way. In particular, we find $\tilde{\mathscr{A}}V(\rho) = -u_1(\rho)^2 \le 0$ for $\rho \in \mathcal{S}_{<1-\gamma/2}$. Hence we can apply Theorem 2.2 with $Q_\lambda = \mathcal{S}_{<1-\gamma/2}$ to conclude stability in probability.

(ii) From Lemmas 4.9 and 4.10, it follows that $\varphi_t(\rho,u) \to \rho_f$ a.s. as $t \to \infty$.

(iii) We have shown that

$$\mathbb{E}\left[\lim_{t\to\infty} V(\varphi_t(\rho,u))\right] = V(\rho_f) = 0.$$

But as V is uniformly bounded, we obtain by dominated convergence

$$V\left(\lim_{t\to\infty} \mathbb{E}\varphi_t(\rho,u)\right) = \lim_{t\to\infty} \mathbb{E}\left[V(\varphi_t(\rho,u))\right] = 0,$$

where we have used that V is linear and continuous. Hence $\mathbb{E}\varphi_t(\rho,u) \to \rho_f$. ∎

5. Two-qubit systems. The methods employed in the previous section can be extended to other quantum feedback control problems. As an example, we treat the case of two qubits in a symmetric dispersive interaction with an optical probe field. Qubits, i.e., two-level quantum systems (having a Hilbert space of dimension two), and in particular correlated (entangled) states of multiple such qubits, play an important role in quantum information processing. Here we investigate the stabilization of two such states in the two-qubit system.

We begin by defining the Pauli matrices

$$\sigma_x = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \qquad \sigma_y = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}, \qquad \sigma_z = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix},$$

and we define the basis $\psi_\uparrow = (1\ 0)^*$ and $\psi_\downarrow = (0\ 1)^*$ in $\mathbb{C}^2$. A system of two qubits lives on the four-dimensional space $\mathbb{C}^2 \otimes \mathbb{C}^2$ with the standard basis $\{\psi_{\uparrow\uparrow} = \psi_\uparrow \otimes \psi_\uparrow$, $\psi_{\uparrow\downarrow} = \psi_\uparrow \otimes \psi_\downarrow$, $\psi_{\downarrow\uparrow} = \psi_\downarrow \otimes \psi_\uparrow$, $\psi_{\downarrow\downarrow} = \psi_\downarrow \otimes \psi_\downarrow\}$. We denote by $\sigma^1_{x,y,z} = \sigma_{x,y,z} \otimes \mathbb{1}$ and $\sigma^2_{x,y,z} = \mathbb{1} \otimes \sigma_{x,y,z}$ the Pauli matrices on the first and second qubit, respectively, and by $F_{x,y,z} = \sigma^1_{x,y,z} + \sigma^2_{x,y,z}$ the (unnormalized) collective angular momentum operators.

The quantum filtering equation for the two-qubit system is given by an equation of the form (3.2):

$$\begin{aligned} d\rho_t = {} & -iu_1(t)[\sigma^1_y, \rho_t]\,dt - iu_2(t)[\sigma^2_y, \rho_t]\,dt \\ & - \tfrac{1}{2}[F_z,[F_z,\rho_t]]\,dt + \sqrt{\eta}\,(F_z\rho_t + \rho_t F_z - 2\,\mathrm{Tr}\,(F_z\rho_t)\,\rho_t)\,dW_t, \end{aligned} \tag{5.1}$$

where u_1 and u_2 are two independent controls acting as local magnetic fields in the y-direction on each of the qubits. The main goal of this section is to stabilize this system around two interesting target states,

$$\rho_s = \frac{1}{2}(\psi_{\uparrow\downarrow} + \psi_{\downarrow\uparrow})(\psi_{\uparrow\downarrow} + \psi_{\downarrow\uparrow})^*, \qquad \rho_a = \frac{1}{2}(\psi_{\uparrow\downarrow} - \psi_{\downarrow\uparrow})(\psi_{\uparrow\downarrow} - \psi_{\downarrow\uparrow})^*.$$

Here ρ_s is a symmetric and ρ_a is an antisymmetric qubit state.

THEOREM 5.1. *Consider the following control law:*

1. $u_1(t) = 1 - \mathrm{Tr}\left(i[\sigma_y^1, \rho_t]\rho_a\right)$, $u_2(t) = 1 - \mathrm{Tr}\left(i[\sigma_y^2, \rho_t]\rho_a\right)$ *if* $\mathrm{Tr}\,(\rho\rho_a) \geq \gamma$;
2. $u_1(t) = 1$, $u_2(t) = 0$ *if* $\mathrm{Tr}\,(\rho\rho_a) \leq \gamma/2$;
3. *if* $\rho_t \in \mathcal{B}_a = \{\rho : \gamma/2 < \mathrm{Tr}\,(\rho\rho_a) < \gamma\}$, *then take* $u_1(t) = 1 - \mathrm{Tr}\left(i[\sigma_y^1, \rho_t]\rho_a\right)$, $u_2(t) = 1 - \mathrm{Tr}\left(i[\sigma_y^2, \rho_t]\rho_a\right)$ *if* ρ_t *last entered the set* $\mathcal{B}_a$ *through the boundary* $\mathrm{Tr}\,(\rho\rho_a) = \gamma$, *and* $u_1(t) = 1$, $u_2(t) = 0$ *otherwise.*

Then there exists $\gamma > 0$ *s.t.* (5.1) *is globally stable around* ρ_a *and* $\mathbb{E}\rho_t \to \rho_a$ *as* $t \to \infty$. *Similarly, consider the following control law:*

1. $u_1(t) = 1 - \mathrm{Tr}\left(i[\sigma_y^1, \rho_t]\rho_s\right)$, $u_2(t) = -1 - \mathrm{Tr}\left(i[\sigma_y^2, \rho_t]\rho_s\right)$ *if* $\mathrm{Tr}\,(\rho\rho_s) \geq \gamma$;
2. $u_1(t) = 1$, $u_2(t) = 0$ *if* $\mathrm{Tr}\,(\rho\rho_s) \leq \gamma/2$;
3. *if* $\rho_t \in \mathcal{B}_s = \{\rho : \gamma/2 < \mathrm{Tr}\,(\rho\rho_s) < \gamma\}$, *then take* $u_1(t) = 1 - \mathrm{Tr}\left(i[\sigma_y^1, \rho_t]\rho_s\right)$, $u_2(t) = -1 - \mathrm{Tr}\left(i[\sigma_y^2, \rho_t]\rho_s\right)$ *if* ρ_t *last entered the set* $\mathcal{B}_s$ *through the boundary* $\mathrm{Tr}\,(\rho\rho_s) = \gamma$, *and* $u_1(t) = 1$, $u_2(t) = 0$ *otherwise.*

This stabilizes the system around the symmetric state ρ_s.

We will prove the result for the antisymmetric case; the proof for the symmetric case may be done exactly in the same manner. We proceed in the same way as in the proof of Theorem 4.2.

Step 1. The proof of Lemma 4.3 carries over directly to the two-qubit case. The proof of Lemma 4.4 also carries over after minor modifications; in particular, in the two-qubit case we can explicitly compute that

$$A = -i\sigma_y^1 - F_z^2 + 2F_z = \begin{pmatrix} 0 & -1 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & -1 \\ 0 & 0 & 1 & -8 \end{pmatrix}$$

admits the diagonalization $A = PDP^{-1}$ with

$$P = \begin{pmatrix} 1 & 1 & 0 & 0 \\ -i & i & 0 & 0 \\ 0 & 0 & 1 & 1 \\ 0 & 0 & .1270 & 7.8730 \end{pmatrix}, \qquad D = \begin{pmatrix} i & 0 & 0 & 0 \\ 0 & -i & 0 & 0 \\ 0 & 0 & -.1270 & 0 \\ 0 & 0 & 0 & -7.8730 \end{pmatrix}.$$

Hence the matrix A has a nondegenerate spectrum, and, moreover,

$$\tilde{v}_a = \tfrac{1}{\sqrt{2}}\, P^*(\psi_{\uparrow\downarrow} - \psi_{\downarrow\uparrow}) = \tfrac{1}{\sqrt{2}}\,(i \;\; -i \;\; -1 \;\; -1)^*$$

has only nonzero entries. The remainder of the proof is identical to that of Lemma 4.3.

Step 2. The proofs of Lemmas 4.5 and 4.6 carry over directly.

Step 3. The proofs of Lemmas 4.7 and 4.9 carry over directly. The following replaces Lemma 4.8. We denote by $U_1(\rho) = 1 - \mathrm{Tr}\left(i[\sigma_y^1, \rho]\rho_a\right)$, by $U_2(\rho) = 1 - \mathrm{Tr}\left(i[\sigma_y^2, \rho]\rho_a\right)$, and by $\varphi_t(\rho, U_1, U_2)$ the associated solution of (5.1).

LEMMA 5.2. *The sample paths of* $\varphi_t(\rho, U_1, U_2)$ *that never exit the set* $\mathcal{S}_{<1-\gamma/2}$ *converge in probability to* ρ_a *as* $t \to \infty$.

Proof. Consider the Lyapunov function

$$\mathcal{V}(\rho) = 1 - \mathrm{Tr}\,(\rho\rho_a)^2\,.$$

It is easily verified that $\mathcal{V}(\rho) \geq 0$ for all $\rho \in \mathcal{S}$ and that $\mathcal{V}(\rho) = 0$ if and only if $\rho = \rho_a$. A straightforward computation gives

$$\mathscr{A}\mathcal{V}(\rho) = -2\left[(U_1(\rho) - 1)^2 + (U_2(\rho) - 1)^2\right]\mathrm{Tr}\,(\rho\rho_a) - 4\eta\,\mathrm{Tr}\,(\rho F_z)^2\;\mathrm{Tr}\,(\rho\rho_a)^2 \leq 0,$$

where $\mathscr{A}$ is the weak infinitesimal operator associated to $\varphi_t(\rho, U_1, U_2)$ (here we have used $[F_y, \rho_a] = 0$ in calculating this expression). Now note that all the conditions of Theorem 2.3 are satisfied by virtue of Propositions 3.6 and 3.4. Hence $\varphi_t(\rho, U_1, U_2)$ converges in probability to the largest invariant set contained in $\mathcal{C} = \{\rho \in \mathcal{S} : \mathscr{A}\mathcal{V}(\rho) = 0\}$.

In order to satisfy the condition $\mathscr{A}\mathcal{V}(\rho) = 0$ we must have at least

$$\text{either} \quad \operatorname{Tr}(\rho\rho_a) = 0 \qquad \text{or} \quad \operatorname{Tr}(\rho F_z) = 0.$$

Let us investigate the largest invariant set contained in $\mathcal{C}' = \{\rho \in \mathcal{S} : \operatorname{Tr}(\rho F_z) = 0\}$. Clearly this invariant set can contain only $\rho \in \mathcal{C}'$ for which $\operatorname{Tr}(\varphi_t(\rho, U_1, U_2)F_z)$ is constant. Using Itô's rule we obtain

$$d\operatorname{Tr}(\rho_t F_z) = -\sum_{j=1}^{2} U_j(\rho_t) \operatorname{Tr}\left(i[\sigma_y^j, \rho_t]F_z\right) dt + 2\sqrt{\eta}\left(\operatorname{Tr}\left(F_z^2\rho_t\right) - \operatorname{Tr}(F_z\rho_t)^2\right) dW_t.$$

Hence in order for $\operatorname{Tr}(\varphi_t(\rho, U_1, U_2)F_z)$ to be constant, we must at least have

$$\operatorname{Tr}\left(F_z^2\rho\right) - \operatorname{Tr}(F_z\rho)^2 = 0,$$

which implies that ρ must be an eigenstate of F_z. The latter can take only one of the following forms: either $\rho = \psi_{\uparrow\uparrow}\psi_{\uparrow\uparrow}^*$ or $\rho = \psi_{\downarrow\downarrow}\psi_{\downarrow\downarrow}^*$, or ρ is any state of the form

$$\rho = \alpha\psi_{\uparrow\downarrow}\psi_{\uparrow\downarrow}^* + \beta\psi_{\uparrow\downarrow}\psi_{\downarrow\uparrow}^* + \beta^*\psi_{\downarrow\uparrow}\psi_{\uparrow\downarrow}^* + (1-\alpha)\psi_{\downarrow\uparrow}\psi_{\downarrow\uparrow}^*. \tag{5.2}$$

Let us investigate in particular the latter case. Note that any density matrix of the form (5.2) satisfies $F_z\rho = \rho F_z = 0$. Suppose that (5.1) with $u_1 = U_1$, $u_2 = U_2$ leaves the set (5.2) invariant; then the solution at time t of

$$\frac{d}{dt}\rho_t = -i[F_y, \rho_t] \tag{5.3}$$

must coincide with $\varphi_t(\rho, U_1, U_2)$ when ρ is of the form (5.2), and in particular (5.3) must leave the set (5.2) invariant (here we have used that $U_1(\rho) = U_2(\rho) = 1$ for ρ of the form (5.2)). We claim that this is only the case if $\rho = \rho_a$, which implies that of all states of the form (5.2) only ρ_a is in fact invariant. To see this, note that by Lemma 3.1 we can write any ρ of the form (5.2) as a convex combination $\sum_i \lambda_i \psi^i\psi^{i*}$ of unit vectors $\psi^i \in \operatorname{span}\{\psi_{\uparrow\downarrow}, \psi_{\downarrow\uparrow}\}$. Thus the solution of (5.3) at time t is given by $\sum_i \lambda_i \psi_t^i\psi_t^{i*}$ with

$$\frac{d}{dt}\psi_t^i = -iF_y\psi_t^i, \qquad \psi_0^i = \psi^i.$$

But $F_y\psi^i \notin \operatorname{span}\{\psi_{\uparrow\downarrow}, \psi_{\downarrow\uparrow}\}$ unless $\psi^i \propto \psi_{\uparrow\downarrow} - \psi_{\downarrow\uparrow}$, which implies the assertion.

From the discussion above it is evident that the largest invariant set contained in $\mathcal{C}$ must be contained inside the set $\{\rho_a\} \cup \mathcal{S}_1$. But then the paths that never exit $\mathcal{S}_{<1-\gamma/2}$ must converge in probability to ρ_a. Thus the lemma is proved. □

Step 4. The remainder of the proof of Theorem 5.1 carries over directly.

Acknowledgments. The authors thank Hideo Mabuchi and Houman Owhadi for helpful discussions.

ON THE NEW BARRIER FUNCTION AND SPECIALIZED ALGORITHMS FOR A CLASS OF SEMIDEFINITE PROGRAMS*

CHUNG-YAO KAO† AND ALEXANDRE MEGRETSKI‡

Abstract. Semidefinite programs (SDPs) arising from the Kalman–Yakubovich–Popov (KYP) lemma are frequently encountered in systems robustness analysis, filter design, and other control/signal processing related applications. These programs possess a special structure that can be exploited to construct specialized algorithms that substantially outperform general-purpose SDP solvers. In this paper, a new interior path-following algorithm that utilizes this structure is proposed. The main idea behind the algorithm is a new barrier function for these specially structured SDPs. Convergence of the new algorithm is shown and a measure of the accuracy of suboptimal solutions produced by the algorithm is provided. The algorithm is tested in numerical experiments and the results indicate that the new algorithm is indeed favorable against general-purpose SDP solvers in many circumstances.

Key words. interior point method, barrier function, semidefinite program, KYP lemma, robustness analysis

1. Introduction.

Consider a semidefinite problem (SDP) of the form

$$\begin{aligned} &\inf_{\lambda,P} \ c'\lambda \quad \text{subject to} \\ &\mathcal{F}(P,\lambda) := \begin{bmatrix} PA + A'P & PB \\ B'P & 0 \end{bmatrix} + M_0 + \sum_{i=1}^{n} \lambda_i M_i > 0, \end{aligned} \tag{1.1}$$

where the variables to be optimized are the vector $\lambda \in \mathbf{R}^n$ and the matrix P. The real matrices A and B are of dimensions $m \times m$ and $m \times p$, respectively. The matrix A is assumed to be Hurwitz; i.e., the real part of each eigenvalue of A is strictly negative. The matrices P and M_i, $i = 0, 1, \ldots, n$ are symmetric. The inequality sign in (1.1) denotes matrix inequality; i.e., $X > 0$ means $v'Xv > 0$ for all nonzero v.

The SDP (1.1) is referred to as the KYP–SDP for its tight connection to the Kalman–Yakubovich–Popov lemma [21, 33]. The KYP–SDP frequently appears in control and signal processing related applications. A partial list includes systems robustness analysis [5, 18, 23, 31, 32], filter design [1], and linear control system synthesis [3, 9]. We note that in (1.1), the number of decision variables in P is proportional to the square of the dimension of the matrix A, while the matrices A and B usually correspond to the state space realization of the linear time-invariant (LTI) part of the system to be analyzed or designed. Hence, in practical applications where the LTI systems under consideration have state spaces of large dimension,

the number of decision variables in P is often order-of-magnitude larger than the number of decision variables in λ. In these cases, the matrix variable P becomes the major computational burden in solving SDP (1.1). It is often observed that when the dimension of A is of several hundred, SDP (1.1) becomes difficult or even impossible to solve using a general-purpose SDP solver. It is not unusual in control system applications to encounter complex dynamical systems having many states. Typical examples of such systems are aircraft autopilots, electrical power grids, large-scale networked control systems, and vibration controllers for flexible structures. Hence, it is of practical importance to develop more efficient and specialized solvers to solve SDPs in the form of (1.1).

To improve the efficiency of the conventional SDP approach, some specialized algorithms have been proposed recently [7, 8, 25, 28, 29, 30]. These algorithms are based on the primal-dual interior point algorithms for solving standard SDPs. Efficiency is achieved by exploring and exploiting the special structure of (1.1). In [25, 29], it is reported that such specialized algorithms are able to solve KYP–SDPs with tens of thousands of decision variables at a reasonable speed, while general-purpose SDP solvers either fail to solve the problem due to lack of sufficient computer memory or become extremely slow, occupying most of the computational capacity of the computer for days.

On the other hand, since computing the matrix variable P constitutes the main computational burden when solving a KYP–SDP, another approach for improving computational efficiency is to avoid this matrix variable. According to the KYP lemma, the SDP (1.1) can be equivalently formulated as the following SDP:

$$\begin{aligned} &\inf_{\lambda} \ c'\lambda \quad \text{subject to} \\ &\begin{bmatrix} (j\omega I - A)^{-1} \\ B \end{bmatrix}^* \left(M_0 + \sum_{i=1}^{n} \lambda_i M_i \right) \begin{bmatrix} (j\omega I - A)^{-1} \\ B \end{bmatrix} > 0 \quad \forall\, \omega \in [0, \infty], \end{aligned} \tag{1.2}$$

where the feasible set is defined by an infinite number of linear matrix inequalities. Furthermore, the KYP lemma also gives rise to a computationally efficient algorithm for checking the feasibility of a given λ. Based on these observations, several cutting plane algorithms were proposed to solve KYP–SDP (1.1) [14, 15, 20]. These algorithms appear to work well, especially when the size of A is large and the number of decision variables in λ is relatively small. However, a common disadvantage of cutting plane and similar methods is that they generally require many iterations to converge to a suboptimal solution of good accuracy, and the number of iterations grows rapidly as the number of decision variables increases. Furthermore, it is commonly known that when attempting to find a very accurate suboptimal solution using such algorithms one often encounters numerical difficulty.

In light of the disadvantage of the cutting plane algorithm, we propose a new interior point algorithm for solving KYP–SDP (1.1). The main idea behind the algorithm is a new barrier function defined on the feasible set of the equivalent SDP (1.2). The barrier function is efficiently computable: the main computation for obtaining the barrier function's first and second derivatives is to solve Lyapunov equations, for which efficient computational routines are widely available. Based on the new barrier function, a path-following algorithm for solving KYP–SDP (1.2) is developed. Results of several numerical experiments indicate that the proposed path-following algorithm is able to solve the KYP–SDP in a much more efficient fashion. Regarding the issue of computational complexity, it can be shown that the proposed barrier

function is self-concordant. However, the self-concordant coefficient appears to be dependent on the problem data, and the exact dependency is yet to be discovered. Hence, Nesterov and Nemirovskii's theorem regarding polynomial-time complexity of the path-following methods [19] is not applicable to the algorithm proposed in this paper, and its worst-case complexity is still to be determined.

The main contribution of this paper is twofold. On the technical side, while the path-following algorithm described in this paper is rather standard and well known, the barrier function on which the algorithm is based has not been considered previously for KYP–SDP (1.1). We show how to evaluate the function and calculate the gradient and the Hessian at any given point in an efficient fashion. On the practical side, the proposed algorithm is implemented, tested in a number of numerical experiments, and compared against SeDuMi [24], a popular general-purpose SDP solver. The results show that the proposed algorithm is indeed favorable in many circumstances.

The paper is organized as follows. In the rest of this section, notations and terminology used throughout the paper are defined. In section 2, the semi-infinite optimization problem equivalent to KYP–SDP (1.1) is formally defined and its dual problem is stated. Section 3 contains the main technical results of the paper, where the new barrier function is described. Furthermore, how to efficiently evaluate the function and compute its gradient and Hessian are shown. In sections 4 and 5 the central path of the semi-infinite optimization problem and the path-following algorithm based on the new barrier function are discussed. Convergence of the algorithm is shown, and a measure of the accuracy of the suboptimal solution produced by the algorithm is provided. In section 6, we explain why the proposed algorithm is more efficient than the general-purpose SDP solvers from the point of view of computational complexity. Numerical experiments are conducted for testing the efficiency of the proposed algorithm. The results and a comparison against the general-purpose SDP solver SeDuMi are presented in section 7. Concluding remarks are drawn in section 8.

Notations and terminology. Given a function $F(\lambda) : \mathbf{R}^n \to \mathbf{R}$, the notations $\nabla F(\lambda)$ and $\nabla^2 F(\lambda)$ are used to denote the *gradient vector* and the *Hessian matrix* of $F(\lambda)$ (the *gradient* and the *Hessian* for short), respectively. The partial derivative of $F(\lambda)$ with respect to the ith component of λ is denoted by $\partial_i F(\lambda)$. The second partial derivative of $F(\lambda)$ with respect to the ith and jth components of λ is denoted by $\partial^2_{ij} F(\lambda)$. If $F(\lambda)$ is at least k times differentiable, then the notation

$$\nabla^k F(\lambda)[h_1, \ldots, h_k]$$

denotes the value of the kth differential of F taken at λ along the collection of directions $h_1, \ldots, h_k$, where $h_i \in \mathbf{R}^n$.

We use I_n to denote the $n \times n$ *identity* matrix. Sometimes the subscript n is dropped when the dimension of I_n is obvious from the context. Given a matrix M, the transposition and the conjugate transposition are denoted by M' and M^*, respectively. We call a matrix M *symmetric* if $M = M'$, and *Hermitian* if $M = M^*$. As mentioned before, the notation $M > 0$ is used to denote positive definiteness. The positive semidefiniteness, negative definiteness, and negative semidefiniteness are denoted using $\geq$, $<$, and $\leq$, respectively. A matrix M is called *Hurwitz* if all its eigenvalues have strictly negative real part. The notation $\mathbf{tr}(M)$ denotes the trace of M. The *Frobenius norm* of a square matrix M is defined as $\|M\|_F := \sqrt{\mathbf{tr}(M'M)}$.

Let $M_1, \ldots, M_n$ be square matrices. Then $M = \mathrm{diag}(M_1, \ldots, M_n)$ (sometimes abbreviated as $M = \mathrm{diag}_i(M_i)$) defines the block diagonal matrix

$$M = \begin{bmatrix} M_1 & & \\ & \ddots & \\ & & M_n \end{bmatrix}.$$

2. The semi-infinite optimization problem and its dual problem. Consider the KYP–SDP (1.1) and its equivalent semi-infinite optimization problem (1.2). To simplify the notation, let $\mathbf{H}_i(\omega, \lambda)$, $i = 0, \ldots, n$, be

$$\mathbf{H}_i(\omega) = \begin{bmatrix} (j\omega I_m - A)^{-1}B \\ I_p \end{bmatrix}^* M_i \begin{bmatrix} (j\omega I_m - A)^{-1}B \\ I_p \end{bmatrix}.$$

For the development in the sequential sections, let M_i be further partitioned into

$$\begin{bmatrix} Q_i & S_i \\ S_i' & R_i \end{bmatrix}, \tag{2.1}$$

where Q_i and R_i are $m \times m$ and $p \times p$ symmetric matrices, respectively. Also let us define $Q(\lambda)$, $F(\lambda)$, and $R(\lambda)$ to be

$$Q_0 + \sum_{i=1}^{n} \lambda_i Q_i, \quad S_0 + \sum_{i=1}^{n} \lambda_i S_i, \quad R_0 + \sum_{i=1}^{n} \lambda_i R_i. \tag{2.2}$$

Finally, define $\mathbf{H}(\omega, \lambda)$ to be $\mathbf{H}_0(\omega) + \sum_{i=1}^{n} \lambda_i \mathbf{H}_i(\omega)$, and the semi-infinite optimization problem (1.2) can be stated as

$$\inf_{\lambda} \; c'\lambda \quad \text{subject to} \quad \mathbf{H}(\omega, \lambda) > 0 \;\; \forall\, \omega \in [0, \infty]. \tag{2.3}$$

The feasible set of problem (2.3) is denoted as Ω, i.e.,

$$\Omega := \{\lambda \mid \mathbf{H}(\omega, \lambda) > 0 \;\forall\, \omega \in [0, \infty]\}. \tag{2.4}$$

Without loss of generality, matrices M_i are assumed to be linearly independent, which ensures that none of the decision variables is redundant. Furthermore, we also assume that Ω is bounded and nonempty.

Note that the constraint in (2.3) and (2.4) should be understood as: there exist an $\varepsilon > 0$ such that $\mathbf{H}(\omega, \lambda) \geq \varepsilon I_p$ for all $\omega \in [0, \infty)$. Hence, by definition, $R(\lambda_F)$ is (strictly) positive definite for any $\lambda_F \in \Omega$.

The semi-infinite optimization problem (2.3) and the KYP–SDP (1.1) are equivalent in the sense that for any pair (λ_F, P_F) that is feasible to (1.1), λ_F is a feasible solution of (2.3). On the other hand, given any feasible solution λ_F of (2.3), there exists a matrix P_F such that (λ_F, P_F) is feasible to (1.1).

The Lagrange dual problem associated with problem (2.3) is given as

$$\begin{aligned} &\sup_{Z(\omega)} \; -\langle \mathbf{H}_0(\omega), Z(\omega) \rangle \quad \text{subject to} \\ &\langle \mathbf{H}_i(\omega), Z(\omega) \rangle = c_i, \;\; i = 1, \ldots, n, \quad \text{and} \quad Z(\omega) \in \mathcal{P}_{NBV}^{m \times m}, \end{aligned} \tag{2.5}$$

where $\langle \mathbf{H}_i(\omega), Z(\omega) \rangle$ is defined by the Stieltjes integral

$$\int_{-\infty}^{\infty} \mathbf{tr}(\mathbf{H}_i(\omega) dZ(\omega)) := 2 \lim_{N \to \infty} \sum_{k=1}^{N} \mathbf{tr}(\mathbf{H}_i(\omega_{k-1})(Z(\omega_k) - Z(\omega_{k-1}))),$$

where $0 = \omega_0 \le \omega_1 \le \cdots \le \omega_N = \infty$ is a partition of $[0, \infty]$ which satisfies

$$\max_{k \in \{1,\ldots,N-1\}} |\omega_k - \omega_{k-1}| \to 0 \quad \text{and} \quad \omega_{N-1} \to \infty \quad \text{as} \quad N \to \infty.$$

$\mathcal{P}_{NBV}^{m\times m}$ is the positive cone defined as

$$\mathcal{P}_{NBV}^{m\times m} := \{Z(\omega) \in \mathcal{S}_{NBV}^{m\times m} \mid Z(\omega_1) \ge Z(\omega_2) \ \forall\ \omega_1 \ge \omega_2 > 0\},$$

where $\mathcal{S}_{NBV}^{m\times m}$ denotes the space of normalized bounded variation functions which map $\mathbf{R} \cup \{\infty\}$ to the space of $m \times m$ complex-valued Hermitian matrices. Readers are referred to [17] for the properties of $\mathcal{S}_{NBV}^{m\times m}$ and $\mathcal{P}_{NBV}^{m\times m}$.

Given any pair of primal-dual feasible solution $(\lambda, Z(\omega))$, we have

$$c'\lambda + \langle \mathbf{H}_0(\omega), Z(\omega)\rangle = \langle \mathbf{H}(\omega, \lambda), Z(\omega)\rangle \ge 0.$$

The last inequality follows $\mathbf{H}(\omega, \lambda) > 0$ for all $\omega \in [0, \infty]$ and $Z(\omega) \in \mathcal{P}_{NBV}^{m\times m}$. Hence, the weak duality theorem holds. The strong duality theorem, which states that the primal and the dual optimization problems have the same optimal objectives, holds under standard regularity assumption. See [10, 11] for details.

3. The barrier function for the semi-infinite optimization problem. Consider the following function from Ω to $\mathbf{R}$:

$$\mathcal{B}(\lambda) = \log \mathcal{G}(\lambda), \tag{3.1}$$

where

$$\mathcal{G}(\lambda) := \frac{1}{\pi} \int_{-\infty}^{\infty} \mathbf{tr}(\mathbf{H}(\omega, \lambda)^{-1}) \frac{d\omega}{1+\omega^2}. \tag{3.2}$$

It is obvious that $\mathcal{B}(\lambda)$ is smooth on Ω. The ith element of the gradient and the (i, j) entry of the Hessian of $\mathcal{B}(\lambda)$ are given as follows:

$$\partial_i \mathcal{B}(\lambda) = \mathcal{G}(\lambda)^{-1} \partial_i \mathcal{G}(\lambda), \tag{3.3}$$

$$\partial_{ij}^2 \mathcal{B}(\lambda) = \mathcal{G}(\lambda)^{-1} \partial_{ij}^2 \mathcal{G}(\lambda) - \mathcal{G}^{-2}(\lambda) \partial_i \mathcal{G}(\lambda) \partial_j \mathcal{G}(\lambda)', \tag{3.4}$$

where

$$\partial_i \mathcal{G}(\lambda) = -\frac{1}{\pi} \int_{-\infty}^{\infty} \mathbf{tr}(\mathbf{H}(\omega, \lambda)^{-1} \mathbf{H}_i(\omega) \mathbf{H}(\omega, \lambda)^{-1}) \frac{d\omega}{1+\omega^2}, \tag{3.5}$$

$$\begin{aligned} \partial_{ij}^2 \mathcal{G}(\lambda) = {} & \frac{1}{\pi} \int_{-\infty}^{\infty} \mathbf{tr}(\mathbf{H}(\omega, \lambda)^{-1} \mathbf{H}_i(\lambda) \mathbf{H}(\omega, \lambda)^{-1} \mathbf{H}_j(\omega) \mathbf{H}(\omega, \lambda)^{-1}) \frac{d\omega}{1+\omega^2} \\ & + \frac{1}{\pi} \int_{-\infty}^{\infty} \mathbf{tr}(\mathbf{H}(\omega, \lambda)^{-1} \mathbf{H}_j(\lambda) \mathbf{H}(\omega, \lambda)^{-1} \mathbf{H}_i(\omega) \mathbf{H}(\omega, \lambda)^{-1}) \frac{d\omega}{1+\omega^2}. \end{aligned} \tag{3.6}$$

The following proposition shows that $\mathcal{B}(\lambda)$ is also a convex function.

PROPOSITION 3.1. *$\mathcal{B}(\lambda)$ is a convex function.*

Proof. We show that the Hessian of $\mathcal{B}(\lambda)$ is strictly positive definite on Ω. It can be easily verified that

$$\nabla^2 \mathcal{B}(\lambda) = \mathcal{G}^{-1}(\lambda) \nabla^2 \mathcal{G}(\lambda) - \nabla \mathcal{G}(\lambda) \mathcal{G}^{-2}(\lambda) \nabla \mathcal{G}(\lambda)'.$$

Since $\mathcal{G}(\lambda) > 0$ for any $\lambda \in \Omega$, therefore, given any $\lambda \in \Omega$, $\nabla^2\mathcal{B}(\lambda) > 0$ if and only if

$$\nabla^2\mathcal{G}(\lambda) - \nabla\mathcal{G}(\lambda)\mathcal{G}^{-1}(\lambda)\nabla\mathcal{G}(\lambda)' > 0.$$

To prove $\nabla^2\mathcal{G}(\lambda) - \nabla\mathcal{G}(\lambda)\mathcal{G}^{-1}(\lambda)\nabla\mathcal{G}(\lambda)' > 0$, it is sufficient to show that

$$\begin{bmatrix} \nabla^2\mathcal{G}(\lambda) & \nabla\mathcal{G}(\lambda) \\ \nabla\mathcal{G}(\lambda)' & \mathcal{G}(\lambda) \end{bmatrix} > 0. \tag{3.7}$$

Matrix inequality (3.7) holds if $\nabla^2\mathcal{G}(\lambda)[h,h] + 2\nabla\mathcal{G}(\lambda)[h] + \mathcal{G}(\lambda) > 0$ for all nonzero h in $\mathbf{R}^n$. Let $\mathcal{A} = \sum_i^n h_i\mathbf{H}_i(\omega)$. By (3.5) and (3.6), we have

$$\begin{aligned}
&\nabla^2\mathcal{G}(\lambda)[h,h] + 2\nabla\mathcal{G}(\lambda)[h] + \mathcal{G}(\lambda) = \sum_{i,j} h_ih_j\partial^2_{ij}\mathcal{G}(\lambda) + 2\sum_i h_i\partial_i\mathcal{G}(\lambda) + \mathcal{G}(\lambda) \\
&= \frac{1}{\pi}\int_{-\infty}^{\infty} \mathbf{tr}(2\mathbf{H}^{-1}\mathcal{A}\mathbf{H}^{-1}\mathcal{A}\mathbf{H}^{-1} - 2\mathbf{H}^{-1}\mathcal{A}\mathbf{H}^{-1} + \mathbf{H}^{-1})\frac{d\omega}{1+\omega^2} \\
&= \frac{1}{\pi}\int_{-\infty}^{\infty} (2\|\mathbf{H}^{-\frac{1}{2}}\mathcal{A}\mathbf{H}^{-1} - 0.5\mathbf{H}^{\frac{1}{2}}\|_F^2 + 0.5\|\mathbf{H}^{-\frac{1}{2}}\|_F^2)\frac{d\omega}{1+\omega^2}.
\end{aligned}$$

Hence, for any $\lambda \in \Omega$, $\nabla^2\mathcal{G}(\lambda)[h,h] + 2\nabla\mathcal{G}(\lambda)[h] + \mathcal{G}(\lambda) > 0$ for all $h \neq 0$. This in turn implies that $\nabla^2\mathcal{B}(\lambda) > 0$ for all $\lambda \in \Omega$, and thus $\mathcal{B}(\lambda)$ is a convex function. ∎

Although the integral over an infinite horizon makes it seemingly difficult to evaluate $\mathcal{B}(\lambda)$ for any given λ, the evaluation can be performed by using a rather efficient computational procedure. The main computation for evaluating $\mathcal{B}(\lambda)$ is to solve one Riccati equation and one Lyapunov equation. Furthermore, it can also be shown that the value of $\mathcal{B}(\lambda)$ approaches infinity as λ approaches the boundary of Ω. This property, together with smoothness and convexity, makes $\mathcal{B}(\lambda)$ a natural barrier for Ω.

Given $\lambda_F \in \Omega$, the following factorization formulas for $\mathbf{H}(\omega, \lambda_F)$ lead to an efficient computational procedure for evaluating $\mathcal{B}(\lambda_F)$.

PROPOSITION 3.2. *Suppose that $A \in \mathbf{R}^{m\times m}$ is a Hurwitz matrix. Given $\lambda_F \in \Omega$, the following factorization formulas hold for $\mathbf{H}(\omega, \lambda_F)$:*

(1) *$\mathbf{H}(\omega, \lambda_F)^{-1}$ can be factorized as $D_H + G_H(j\omega) + G_H(j\omega)^*$, where*

$$G_H(s) = C_H(sI - A_H)^{-1}B_H, \tag{3.8}$$

$$A_H = A - BR_F^{-1}(PB + S_F)', \tag{3.9}$$

$$B_H = BR_F^{-1} - Y(PB + S_F)R_F^{-1}, \tag{3.10}$$

$$C_H = -R_F^{-1}(PB + S_F)', \tag{3.11}$$

$$D_H = R_F^{-1}, \tag{3.12}$$

and P, Y satisfy the following Riccati and Lyapunov equations, respectively:

$$PA + A'P + Q_F - (PB + S_F)R_F^{-1}(PB + S_F)' = 0, \tag{3.13}$$

$$A_HY + YA_H' + BR_F^{-1}B' = 0. \tag{3.14}$$

Matrices Q_F, S_F, and R_F are equal to $Q(\lambda_F)$, $S(\lambda_F)$, and $R(\lambda_F)$, respectively. Furthermore, matrix A_H is also a Hurwitz matrix and the dimension of A_H is the same as that of A.

(2) $\mathbf{H}(\omega,\lambda_F)^{-1}$ *can be factorized as* $\Psi(j\omega)\Psi(j\omega)^*$, *where*

$$\Psi(s) = R_F^{-\frac{1}{2}} + C_H(sI - A_H)^{-1}BR_F^{-\frac{1}{2}}. \tag{3.15}$$

Proof. See Appendix A. ∎

The next proposition offers an algebraic form (as opposed to the integral form) for $\mathcal{G}(\lambda)$. Hence, computation of $\mathcal{G}(\lambda)$ and $\mathcal{B}(\lambda)$ can be performed without numerically integrating $\frac{1}{1+\omega^2}\mathbf{tr}(\mathbf{H}(\omega,\lambda)^{-1})$ over an infinite horizon.

PROPOSITION 3.3. *Let* $\lambda_F \in \Omega$. *Then* $\mathcal{G}(\lambda_F) = \mathbf{tr}(D_H) + 2\mathbf{tr}(C_H(I - A_H)^{-1}B_H)$, *where* A_H, B_H, C_H, D_H *are defined as in* (3.9)–(3.12).

Proof. First, notice that the orders of the trace operator and the integral operator can be exchanged; therefore, by the first factorization formula given in Proposition 3.2, we have

$$\begin{aligned}\mathcal{G}(\lambda_F) &= \mathbf{tr}\left(\frac{1}{\pi}\int_{-\infty}^{\infty}(D_H + G_H(j\omega) + G_H(j\omega)^*)\frac{d\omega}{1+\omega^2}\right)\\ &= \mathbf{tr}(D_H) + \mathbf{tr}\left(\frac{1}{\pi}\int_{-\infty}^{\infty}(G_H(j\omega) + G_H(j\omega)^*)\frac{d\omega}{1+\omega^2}\right).\end{aligned}$$

Now, if we treat $G_H(j\omega)$ as the Fourier transform of the stable causal system $G_H(s)$ and let $g(t)$ be the impulse response of $G_H(s)$, by the Plancherel theorem,

$$\frac{1}{\pi}\int_{-\infty}^{\infty} G_H(j\omega)\frac{1}{1+\omega^2}\,d\omega = \frac{1}{2\pi}\int_{-\infty}^{\infty} G_H(j\omega)\frac{2}{1+\omega^2}\,d\omega = g(t) * e^{-|t|}\Big|_{t=0},$$

where $*$ denotes the convolution operator. Since $G_H(s)$ is stable and causal, we have

$$g(t) * e^{-|t|}\Big|_{t=0} = \int_0^{\infty} g(\tau)e^{-\tau}d\tau = G_H(1) = C_H(I - A_H)^{-1}B_H.$$

Similarly, we have

$$\frac{1}{\pi}\int_{-\infty}^{\infty} G_H(j\omega)^*\frac{1}{1+\omega^2}d\omega = C_H(I - A_H)^{-1}B_H.$$

This concludes the proof. ∎

Therefore, the computation of $\mathcal{G}(\lambda)$ mainly involves solving Riccati equation (3.13) and Lyapunov equation (3.14). Solving Riccati equations and Lyapunov equations has been well studied. Efficient computational routines for solving such equations are widely available.

The following proposition shows that $\mathcal{B}(\lambda)$ approaches infinity as λ approaches the boundary of Ω.

PROPOSITION 3.4. *The value of the barrier function* $\mathcal{B}(\lambda)$ *is unbounded on the boundary of* Ω.

Proof. Let λ_b belong to the boundary Ω; i.e., $\mathbf{H}(\omega,\lambda_b)$ is only semipositive definite. Suppose that $\mathbf{H}(\omega,\lambda_b)$ is singular at the set $\Gamma = \{\pm\omega_i,\ i = 1,\dots,l\}$. It can then be shown (Chapter 13.4 of [33]) that

(1) matrix $R_b := R(\lambda_b)$ is singular if $\infty \in \Gamma$.

(2) the corresponding A_H has pure imaginary eigenvalues $j\omega_i$, $\omega_i \in \Gamma$, $\omega_i \neq \pm\infty$.

If R_b is singular, unboundedness of $\mathcal{G}(\lambda_b)$ and $\mathcal{B}(\lambda_b)$ immediately follows (3.12). If R_b is not singular, then $\mathbf{H}(\omega,\lambda_b)$ can be factorized as $\Psi(j\omega)\Psi(j\omega)^*$, where $\Psi(s)$ is defined as in (3.15). Note that

$$\frac{1}{\pi}\int_{-\infty}^{\infty}\mathbf{tr}(\mathbf{H}(\omega,\lambda_b)^{-1})\frac{d\omega}{1+\omega^2} = 2\left(\frac{1}{2\pi}\int_{-\infty}^{\infty}\mathbf{tr}(\widetilde{\Psi}(j\omega)\widetilde{\Psi}(j\omega)^*)d\omega\right), \tag{3.16}$$

where $\widetilde{\Psi}(s) = \frac{1}{s+1}\Psi(s)$. The integral in the parentheses gives the $\mathcal{H}_2$-norm of $\widetilde{\Psi}(s)$. Since A_H has eigenvalues on the imaginary axis, $\widetilde{\Psi}(s)$ is not a stable transfer matrix. Therefore, its $\mathcal{H}_2$-norm is unbounded, which in turn implies that $\mathcal{G}(\lambda_b)$ is unbounded, and thus so is $\mathcal{B}(\lambda_b)$. This concludes the proof. ∎

3.1. Gradients and Hessians of $\mathcal{B}(\lambda)$. Proposition 3.3 gives the following equivalent expression for $\mathcal{G}(\lambda)$:

$$\mathcal{G}(\lambda) = \mathbf{tr}(D_H(\lambda) + 2C_H(\lambda)(I - A_H(\lambda))^{-1}B_H(\lambda)), \tag{3.17}$$

where $A_H(\lambda)$, $B_H(\lambda)$, $C_H(\lambda)$, and $D_H(\lambda)$ are defined as in (3.8)–(3.14) with Q_F, S_F, and R_F replaced by $Q(\lambda)$, $F(\lambda)$, and $R(\lambda)$. Differentiating (3.17) with respect to λ_i, we obtain the following expressions for the ith component of the gradient of $\mathcal{G}(\lambda)$:

$$\begin{aligned}\partial_i\mathcal{G}(\lambda) &= \mathbf{tr}(\partial_i D_H + 2(\partial_i C_H)(I - A_H)^{-1}B_H - 2C_H(I - A_H)^{-1}(\partial_i A_H)(I - A_H)^{-1}B_H \\ &\qquad + 2C_H(I - A_H)^{-1}(\partial_i B_H)) \\ &= \mathbf{tr}(\partial_i D_H + 2(I + C_H(I - A_H)^{-1}B)((\partial_i C_H)(I - A_H)^{-1}B_H) \\ &\qquad + 2C_H(I - A_H)^{-1}(\partial_i B_H)),\end{aligned} \tag{3.18}$$

where the second equality is obtained by noting that $\partial_i A_H = B(\partial_i C_H)$. It can be easily verified that the partial derivatives of B_H, C_H, and D_H with respect to λ_1 have the following expressions:

$$\partial_i B_H = (\partial_i Y)C_H' + Y(\partial_i C_H)', \tag{3.19}$$

$$\partial_i C_H = R^{-1}R_i R^{-1}(PB + F)' - R^{-1}((\partial_i P)B + F_i)', \tag{3.20}$$

$$\partial_i D_H = -R^{-1}R_i R^{-1}, \tag{3.21}$$

and the partial derivatives of P and Y with respect to λ_i satisfy the following equations:

$$(\partial_i P)A_H + A_H'(\partial_i P) + (Q_i + F_i C_H + C_H' F_i' + C_H' R_i C_H) = 0, \tag{3.22}$$

$$A_H(\partial_i Y) + (\partial_i Y)A_H' + (B(\partial_i C_H)Y + Y(\partial_i C_H)'B' - BR^{-1}R_i R^{-1}B') = 0. \tag{3.23}$$

For a given point $\lambda \in \Omega$, computation of $\partial_i\mathcal{B}(\lambda)$ can be performed as follows: First, notice that for a fixed λ, (3.22) is a Lyapunov equation with respect to $\partial_i P$. Thus, the value of $\partial_i P$ can be obtained by solving the Lyapunov equation. Then the values of $\partial_i D_H$ and $\partial_i C_H$ can be computed according to expressions (3.21) and (3.20), respectively. As soon as the value of $\partial_i C_H$ is available, one can solve another Lyapunov equation in the form of (3.23) to obtain the value of $\partial_i Y$, and then $\partial_i B_H$ can be computed using expression (3.19). Finally, $\partial_i\mathcal{G}(\lambda)$ can be evaluated using (3.18) and $\partial_i\mathcal{B}(\lambda)$ evaluated using (3.3).

If we further differentiate (3.18) with respect to λ_j, we obtain an expression for $\partial_{ij}\mathcal{G}(\lambda)$:

$$\begin{aligned}\partial_{ij}\mathcal{G}(\lambda) &= \mathbf{tr}(\partial_{ij}^2 D_H) \\ &\qquad + 2\mathbf{tr}(C_H(I - A_H)^{-1}(\partial_{ij}^2 B_H) + (I + C_H(I - A_H)^{-1}B)T_1),\end{aligned} \tag{3.24}$$

where

$$T_1 = (\partial^2_{ij} C_H)(I - A_H)^{-1} B_H + (\partial_i C_H)(I - A_H)^{-1}(\partial_j B_H + B(\partial_j C_H)$$
$$\times \quad (I - A_H)^{-1} B_H) + (\partial_j C_H)(I - A_H)^{-1}(\partial_i B_H) + B(\partial_i C_H) \tag{3.25}$$
$$\times \quad (I - A_H)^{-1} B_H),$$

$$\partial^2_{ij} B_H = (\partial^2_{ij} Y) C'_H + Y(\partial^2_{ij} C_H)' + (\partial_i Y)(\partial_j C_H)' + (\partial_j Y)(\partial_i C_H)', \tag{3.26}$$

$$\partial^2_{ij} C_H = -R^{-1}(R_j(\partial_i C_H) + R_i(\partial_j C_H) + B'(\partial^2_{ij} P)'), \tag{3.27}$$

$$\partial^2_{ij} D_H = R^{-1} R_i R^{-1} R_j R^{-1} + R^{-1} R_j R^{-1} R_i R^{-1}. \tag{3.28}$$

$\partial^2_{ij} P$ and $\partial^2_{ij} Y$ satisfy the following Lyapunov equations:

$$(\partial^2_{ij} P) A_H + A'_H(\partial^2_{ij} P) + (T_2 + T'_2) = 0, \tag{3.29}$$

$$(\partial^2_{ij} Y) A_H + A'_H(\partial^2_{ij} Y) + (T_3 + T'_3) = 0, \tag{3.30}$$

where T_2 and T_3 denote the following expressions:

$$T_2 = ((\partial_i P) B + C_H R_i + F_i)(\partial_j C_H), \tag{3.31}$$

$$T_3 = B((\partial_i C_H)(\partial_j Y) + (\partial_j C_H)(\partial_i Y) + (\partial^2_{ij} C_H) Y) + B R^{-1} R_i R^{-1} R_j R^{-1} B'. \tag{3.32}$$

For a given $\lambda \in \Omega$, the computational procedure of evaluating $\partial^2_{ij} \mathcal{B}(\lambda)$ is similar to that of computing $\partial_i \mathcal{B}(\lambda)$. Assume that the values of the first partial derivatives of B_H, C_H, D_H, P, and Y are available. Then, T_2 can be evaluated, and Lyapunov equation (3.29) can be solved for the value of $\partial^2_{ij} P$. As soon as the value of $\partial^2_{ij} P$ is available, one can evaluate $\partial^2_{ij} C_H$ and $\partial^2_{ij} D_H$ using expressions (3.27) and (3.28). Once the value of $\partial^2_{ij} C_H$ is obtained, Lyapunov equation (3.30) can be solved for the value of $\partial^2_{ij} Y$, which in turn is used to obtain the value of $\partial^2_{ij} B_H$ using (3.26). Finally, $\partial^2_{ij} \mathcal{G}(\lambda)$ can be computed according to expression (3.24) and $\partial^2_{ij} \mathcal{B}(\lambda)$ computed by (3.4).

The computational complexity of evaluating the barrier function and its derivatives can be estimated as follows: The computation mainly involves solving one Riccati equation of the form (3.13), solving $\mathbf{O}(n^2)$ Lyapunov equations of the form (3.14), inverting matrices of sizes $m \times m$ and $p \times p$, and multiplying matrices of sizes $m \times m$, $m \times p$, $p \times m$, and $p \times p$. The computational complexity of solving (3.13) is $\mathbf{O}(m^3)$. Complexity of solving (3.14) is also $\mathbf{O}(m^3)$, or $\mathbf{O}(m^2)$ if diagonalization of the A_H matrix is permissible. The complexity of inverting an $m \times m$ matrix is $\mathbf{O}(m^3)$, as is the complexity of multiplying two $m \times m$ matrices. Therefore, the complexity of the algorithm for evaluating the barrier function and its derivatives is estimated to be $\mathbf{O}(n^2(m^3 + p^3))$.

4. The central path. In this section we describe the central path of the primal optimization problem (2.3) and give some of its properties. Let $t \geq 1$ and define

$$\varphi_t(\lambda) = tc'\lambda + \mathcal{B}(\lambda).$$

For any fixed t, consider the minimization problem

$$\inf \ \varphi_t(\lambda) \quad \text{subject to } \lambda \in \Omega. \tag{4.1}$$

Problem (4.1) is often referred to as *centering*, and the minimizer $\lambda^\star(t)$ is called the center of (4.1). Note that $\varphi_t(\lambda)$ is a convex function, which becomes unbounded at

the boundary of Ω. Under the assumption imposed on $\mathbf{H}(\omega, \lambda)$, problem (4.1) has a unique minimizer, which is strictly inside Ω. The curve $\lambda^\star(t)$, parameterized by $t \geq 1$, is referred to as the *primal central path*.

The minimizer $\lambda^\star(t)$ of (4.1) is characterized by the optimality condition $\nabla\varphi_t(\lambda) = 0$. Using expression (3.5), we have

$$tc_i = \left(\int_{-\infty}^{\infty} \mathbf{tr}(\mathbf{H}(\omega,\lambda^\star)^{-1})\frac{d\omega}{1+\omega^2}\right)^{-1} \int_{-\infty}^{\infty} \mathbf{tr}(\mathbf{H}(\omega,\lambda^\star)^{-1}\mathbf{H}_i(\omega)\mathbf{H}(\omega,\lambda^\star)^{-1})\frac{d\omega}{1+\omega^2}$$

for $i = 1, \ldots, n$. Hence, the matrix function $Z^\star(\omega, t)$, which satisfies

$$\frac{dZ^\star(\omega,t)}{d\omega} = \frac{1}{t}\left(\int_{-\infty}^{\infty} \mathbf{tr}(\mathbf{H}(\omega,\lambda^\star(t))^{-1})\frac{d\omega}{1+\omega^2}\right)^{-1} \frac{1}{1+\omega^2}\mathbf{H}^{-2}(\omega,\lambda^\star(t)), \tag{4.2}$$

is strictly dual feasible. Therefore, the primal-dual duality gap associated with $\lambda^\star(t)$ and $Z^\star(\omega, t)$ can be found as follows:

$$\begin{aligned} c'\lambda^\star(t) + \langle \mathbf{H}_0(\omega), Z^\star(\omega,t)\rangle &= \left\langle \sum_{k=1}^{n} \mathbf{H}_i(\omega)\lambda_i^\star(t), Z^\star(\omega,t)\right\rangle + \langle \mathbf{H}_0(\omega), Z^\star(\omega,t)\rangle \\ &= \langle \mathbf{H}(\omega,\lambda^\star), Z(\omega,t)\rangle = \frac{1}{t}. \end{aligned} \tag{4.3}$$

This implies that the central path converges to the solution of the semi-infinite optimization (2.3) as t approaches infinity.

Newton's method for centering. Consider the minimization problem (4.1). We employ Newton's method with line search to solve this problem.

Newton's method for minimizing $\boldsymbol{\varphi_t(\lambda)}$.
Start at a strictly feasible point λ_0. Select tolerance ϵ and set $n = 0$.
Repeat
(a) Compute the Newton descent direction $\delta\lambda_n = -(\nabla^2\varphi_t(\lambda_n))^{-1}\nabla\varphi_t(\lambda_n)$.
(b) Compute $\rho = (\nabla\varphi_t(\lambda_n)'(\nabla^2\varphi_t(\lambda_n))^{-1}\nabla\varphi_t(\lambda_n))^{\frac{1}{2}}$.
(c) Line minimization: compute $\alpha^\star = \operatorname{argmin}\ \varphi_t(\lambda_n + \alpha\cdot\delta\lambda_n)$.
(d) Update $\lambda_{n+1} := \lambda_n + \alpha^\star\delta\lambda_n$ and $n := n + 1$.
(e) If $\rho < \epsilon$, then stop the loop and return λ_n.
End

The quantity ρ is called the Newton decrement, which is used to measure the closeness to the central path for a strictly feasible λ.

It is well known that Newton's method converges quadratically asymptotically. The global convergence of Newton's method was analyzed by Nesterov and Nemirovskii. In [19] they show that if the function to be minimized has a certain property called *self-concordance*, Newton's method converges in polynomial time. The bound on the number of iterations before the algorithm terminated is also explicitly given.

Let $X \subset \mathbf{R}^n$ be a convex open set. A smooth convex function $F : X \to \mathbf{R}$ is called self-concordant with the parameter value a (or *a-self-concordant* for short) if there exists a constant a such that the following inequality holds for all $x \in X$ and for all $h \in \mathbf{R}^n$:

$$|\nabla^3 F(x)[h,h,h]| \leq 2a^{\frac{-1}{2}}(\nabla^2 F(x)[h,h])^{\frac{3}{2}}.$$

$F(x)$ is called strongly a-self-concordant if $F(x) \to \infty$ as x approaches the boundary of X. Nesterov and Nemirovskii gave a complete characterization of the speed

of convergence of Newton's method applied to minimize a strongly self-concordant function. Readers interested in this result are referred to Chapter 2 of [19]. Since any linear function is trivially self-concordant, $\varphi_t(\lambda)$ is self-concordant if $\mathcal{B}(\lambda)$ is. It can be shown that the barrier function $\mathcal{B}(\lambda)$ is indeed self-concordant.

THEOREM 4.1. *For a given $\mathcal{B}(\lambda)$, there exists a constant a such that*

$$|\nabla^3\mathcal{B}(\lambda)[h,h,h]| \leq a(\nabla^2\mathcal{B}(\lambda)[h,h])^{\frac{3}{2}} \quad \forall\ h \in \mathbf{R}^n \tag{4.4}$$

holds for all $\lambda \in \Omega$.

Proof. See Appendix B. □

The proof of Theorem 4.1 is based on asymptotic analysis. Basically, what is shown is that the ratio

$$\frac{|\nabla^3\mathcal{B}(\lambda)[h,h,h]|}{(\nabla^2\mathcal{B}(\lambda)[h,h])^{\frac{3}{2}}}$$

does not become unbounded as λ approaches the boundary of Ω. However, neither the value nor an upper bound of a is obtained in our proof. Since such information is essential for applying Nesterov and Nemirovskii's results to construct polynomial-time algorithms, the complexity of minimizing $\varphi_t(\lambda)$ is yet to be determined. Note that Theorem 4.1 plays no important role in our algorithm and is not claimed to be a major contribution of this paper.

5. Path-following algorithms. Path-following algorithms can be dated back to Fiacco and McCormick's work in [6], where the path-following algorithm was called the sequential unconstrained minimization method. Worst-case convergence analysis was first attempted by Renegar, who proved the polynomial complexity of a path-following algorithm for linear programming [22]. In the case of general nonlinear convex optimization problems, convergence analysis was studied by Nesterov and Nemirovskii [19]. They proved worst-case polynomial complexity for the case when the barriers used in the path-following algorithms are self-concordant. Interested readers are referred to [19] for an historical overview.

Barrier functions $\mathcal{B}(\lambda)$ are used to construct path-following algorithms for solving the semi-infinite optimization problem (2.3). The algorithms we consider here are standard, which follows the basic principles described below:

Given: $\lambda_0 \in \Omega$.
Initialization: Select $\mu > 1$ and $\epsilon > 0$. Let $t = 1$.
Repeat
(1) Centering: starting from λ_0, find an approximate solution $\lambda^\star(t)$ to the problem

$$\min_{\lambda}\ \varphi_t(\lambda),$$

where $tc'\lambda + \mathcal{B}(\lambda)$, using Newton's method.
(2) Update λ_0: set $\lambda_0 := \lambda^\star(t)$.
(3) Update t: set $t := \mu t$.
Until $(c'(\lambda^\star(t) - \lambda_{opt}) \leq \epsilon)$.

Here λ_{opt} denotes the optimal solution of (2.3). The initial feasible point λ_0 can be found (or determined not to exist) using the so-called big-M method [4]. The path-following algorithm for the big-M method is essentially the same as the algorithm described above. Note that, should the problem be feasible, the big-M method will produce a feasible solution λ_0, which is sufficiently centered. The algorithm terminates

when a certificate that proves $c'(\lambda^\star(t) - \lambda_{opt}) \leq \epsilon$ is obtained. How to obtain such a certificate is discussed in the next section.

The centering step is often referred to as the *inner loop*, and the loop that involves increasing t by a factor μ and finding $\lambda^\star(\mu t)$ from $\lambda^\star(t)$ is called the *outer loop*. While the inner loop is to find feasible solutions that are close to the central path, the outer loop serves to bring $\lambda^\star(t)$ toward the optimal solution λ_{opt}.

The selection of μ involves a certain trade-off. A large μ incurs a large increase on t per outer iteration, and hence less outer steps are required for approximate central solutions to converge to the optimal one. However, a large μ also implies that $\lambda^\star(\mu t)$ is sufficiently far away from $\lambda^\star(t)$, and hence more steps in the inner loop are required for centralization.

There are various strategies for selecting the factor μ. The strategy ultimately dictates the overall complexity of the path-following algorithm. In [19], variants in selecting μ are discussed and the complexity of the corresponding path-following algorithms is given under the assumption that the barrier functions used in the algorithms are self-concordant. Since the complexity of minimizing $\varphi_t(\lambda)$ by Newton's method is yet to be determined, we will not pursue the issue of how to select μ from the theoretical prospect in this paper. Instead, we test different values of μ in numerical experiments, results of which are reported in section 7.

Stopping criterion. The weak and strong duality theorems imply that given any pair of primal and dual feasible solutions $(\lambda,\, Z(\omega))$, the inequality

$$c'\lambda - c'\lambda_{opt} \leq c'\lambda + \langle \mathbf{H}_0(\omega), Z(\omega)\rangle$$

holds, where λ_{opt} is the optimal solution of (2.3). Furthermore, from (4.3) we see that when a centralized feasible solution $\lambda^\star(t)$ is found, a dual solution $Z^\star(\omega, t)$ is immediately given, as in (4.2), which allows us to conclude that $c'\lambda^\star(t) - c'\lambda_{opt} \leq 1/t$.

Practically, a feasible solution on the central path never could be obtained exactly, and an approximation only up to a certain degree of accuracy can be found. Hence, the form (4.2) for obtaining a dual feasible solution is not directly useful in practice, and so seems the bound (4.3). However, when a feasible solution is sufficiently close to the central path, a dual feasible solution can be constructed according to the following proposition.

PROPOSITION 5.1. *Given $\lambda_F \in \Omega$, let $\mathbf{H}_F(\omega)$ and v_N denote $\mathbf{H}(\omega, \lambda_F)$ and the Newton descent direction at λ_F; i.e.,*

$$v_N = -(\nabla^2\varphi_t(\lambda_F))^{-1}\nabla\varphi_t(\lambda_F).$$

Furthermore, let $\kappa = 1 - \mathcal{G}(\lambda_F)^{-1}\nabla\mathcal{G}(\lambda_F)'v_N$ and consider $Z(\omega, t)$, which satisfies

$$\begin{aligned}\frac{dZ(\omega,t)}{d\omega} = \frac{1}{t\pi}\mathcal{G}(\lambda_F)^{-1}\frac{1}{1+\omega^2}\Bigg(&\kappa\mathbf{H}_F(\omega)^{-2} - \mathbf{H}_F(\omega)^{-2}\left(\sum_{j=1}^{n} v_{N,j}\mathbf{H}_j(\omega)\right)\\ &\times\, \mathbf{H}_F(\omega)^{-1} - \mathbf{H}_F(\omega)^{-1}\left(\sum_{j=1}^{n} v_{N,j}\mathbf{H}_j(\omega)\right)\mathbf{H}_F(\omega)^{-2}\Bigg).\end{aligned} \tag{5.1}$$

Then $Z(\omega, t)$ satisfies $\langle \mathbf{H}_i(\omega), Z(\omega, t)\rangle = c_i$. Moreover, if

$$\frac{\kappa}{2}\mathbf{H}_F(\omega) \geq \sum_{i=1}^{n} v_{N,i}\mathbf{H}_i(\omega) \quad \forall\ \omega \in [0, \infty], \tag{5.2}$$

then $Z(\omega,t)$ *is dual feasible and* $c'\lambda_F + \langle \mathbf{H}_0(\omega), Z(\omega,t)\rangle$ *is equal to* $(1+\mathcal{G}(\lambda_F)^{-1}\nabla\mathcal{G}(\lambda_F)'v_N)/t$.

Proof. The following equation can be easily verified:

$$\nabla^2\mathcal{G}(\lambda_F)v_N + \kappa\nabla\mathcal{G}(\lambda_F) = -\mathcal{G}(\lambda_F)tc,$$

which implies

$$\begin{aligned}-\mathcal{G}(\lambda_F)tc_i = {}& \frac{1}{\pi}\int_{-\infty}^{\infty}\mathbf{tr}\left(\mathbf{H}_F(\omega)^{-1}\left(\sum_{j=1}^{n}v_{N,j}\mathbf{H}_j(\omega)\right)\mathbf{H}_F(\omega)^{-1}\mathbf{H}_i(\omega)\mathbf{H}_F(\omega)^{-1}\right)\frac{d\omega}{1+\omega^2}\\ &+\frac{1}{\pi}\int_{-\infty}^{\infty}\mathbf{tr}\left(\mathbf{H}_F(\omega)^{-1}\mathbf{H}_i(\omega)\mathbf{H}_F(\omega)^{-1}\left(\sum_{j=1}^{n}v_{N,j}\mathbf{H}_j(\omega)\right)\mathbf{H}_F(\omega)^{-1}\right)\frac{d\omega}{1+\omega^2}\\ &-\frac{\kappa}{\pi}\int_{-\infty}^{\infty}\mathbf{tr}(\mathbf{H}_F(\omega)^{-1}\mathbf{H}_i(\omega)\mathbf{H}_F(\omega)^{-1})\frac{d\omega}{1+\omega^2}.\end{aligned}$$

Hence,

$$\begin{aligned}c_i = {}& \int_{-\infty}^{\infty}\mathbf{tr}\left(\mathbf{H}_i(\omega)\frac{-1}{t\pi}\mathcal{G}(\lambda_F)^{-1}\mathbf{H}_F(\omega)^{-2}\left(\sum_{j=1}^{n}v_{N,j}\mathbf{H}_j(\omega)\right)\mathbf{H}_F(\omega)^{-1}\right)\frac{d\omega}{1+\omega^2}\\ &+\int_{-\infty}^{\infty}\mathbf{tr}\left(\mathbf{H}_i(\omega)\frac{-1}{t\pi}\mathcal{G}(\lambda_F)^{-1}\mathbf{H}_F(\omega)^{-1}\left(\sum_{j=1}^{n}v_{N,j}\mathbf{H}_j(\omega)\right)\mathbf{H}_F(\omega)^{-2}\right)\frac{d\omega}{1+\omega^2}\\ &+\int_{-\infty}^{\infty}\mathbf{tr}\left(\mathbf{H}_i(\omega)\frac{\kappa}{t\pi}\mathcal{G}(\lambda_F)^{-1}\mathbf{H}_F(\omega)^{-2}\right)\frac{d\omega}{1+\omega^2}.\end{aligned}$$

This shows that $Z(\omega,t)$ as defined in (5.1) satisfies $\langle \mathbf{H}_i(\omega), Z(\omega,t)\rangle = c_i$. Furthermore, if (5.2) holds, then

$$\kappa\mathbf{H}_F(\omega)^2 - \mathbf{H}_F(\omega)\left(\sum_{j=1}^{n}v_{N,j}\mathbf{H}_j(\omega)\right) - \left(\sum_{j=1}^{n}v_{N,j}\mathbf{H}_j(\omega)\right)\mathbf{H}_F(\omega) \geq 0 \quad \forall\ \omega\in[0,\infty],$$

which in turn implies that

$$\frac{dZ(\omega,t)}{d\omega} \geq 0 \quad \forall\ \omega\in[0,\infty]$$

and that $Z(\omega,t)\in\mathcal{P}_{NBV}^{m\times m}$. Hence, $Z(\omega,t)$ is dual feasible.

To see $c'\lambda_F + \langle \mathbf{H}_0(\omega), Z(\omega,t)\rangle = (1+\mathcal{G}(\lambda_F)^{-1}\nabla\mathcal{G}(\lambda_F)'v_N)/t$, note that $c'\lambda_F + \langle \mathbf{H}_0(\omega), Z(\omega,t)\rangle = \langle \mathbf{H}_F(\omega), Z(\omega,t)\rangle$, and therefore

$$\begin{aligned}c'\lambda_F + \langle \mathbf{H}_0(\omega), Z(\omega,t)\rangle = {}& \frac{1}{t\pi}\mathcal{G}(\lambda_F)^{-1}\int_{-\infty}^{\infty}\kappa\cdot\mathbf{tr}(\mathbf{H}_F(\omega)^{-1})\frac{d\omega}{1+\omega^2} - 2\frac{1}{t\pi}\mathcal{G}(\lambda_F)^{-1}\\ &\times\int_{-\infty}^{\infty}\mathbf{tr}\left(\mathbf{H}_F(\omega)^{-1}\left(\sum_{j=1}^{n}v_{N,j}\mathbf{H}_j(\omega)\right)\mathbf{H}_F(\omega)^{-1}\right)\frac{d\omega}{1+\omega^2}\\ ={}& \frac{1}{t}(\kappa + 2\mathcal{G}(\lambda_F)^{-1}\nabla\mathcal{G}(\lambda_F)'v_N)\\ ={}& \frac{1}{t}(1+\mathcal{G}(\lambda_F)^{-1}\nabla\mathcal{G}(\lambda_F)'v_N).\end{aligned}$$

This concludes the proof. □

Note that if λ_F is on the central path, i.e., λ_F minimizes $\varphi_t(\lambda)$, then $v_N \equiv 0$, $\kappa = 1$, and expression (5.1) reduces to expression (4.2) with inequality (5.2) trivially satisfied. Hence, as λ_F is sufficiently close to the central path, a dual feasible solution can be obtained as the form of (5.1), which serves as a certificate for proving $c'\lambda - c'\lambda_{opt} \leq (1 + \mathcal{G}(\lambda_F)^{-1}\nabla\mathcal{G}(\lambda_F)'v_N)/t$.

Although a prescribed measure of the "closeness" of λ_F to the central path can be derived and described in terms of the $\mathcal{H}_\infty$ norms of $\mathbf{H}_i(\omega)$ and $\mathbf{H}_F(\omega)$, the length of λ_F and v_N, and the value of $\mathcal{G}(\lambda_F)$, such a measure may be too conservative for all practical purposes. In practice, it may be more favorable to verify inequality (5.2) numerically as the algorithm proceeds, because checking (5.2) can be done rather efficiently by computing the eigenvalues of a certain Hamiltonian matrix of size $2n \times 2n$. See Chapter 13.4 of [33] for details.

6. Remarks on computational complexity. In this section, we comment on the computational complexities of solving (2.3) using the proposed interior path-following algorithm, and solving (1.1) using general-purpose SDP solvers. Arguments are given to explain why the proposed algorithm may outperform a general-purpose SDP solver, which solves (1.1) without exploiting the special structure of the problem. We recall that the dimension of matrix A is $m \times m$, the dimension of matrix B is $m \times p$, and the number of the decision variables is n.

Problem (1.1) has a well-known, strongly self-concordant barrier $-\log\det(\mathcal{F}(P, \lambda))$. The primal-dual interior-point algorithm for solving (1.1) can be proved to converge in $\mathbf{O}(\sqrt{m+p}\log\frac{m+p}{\varepsilon})$ Newton steps [19, 26]. In each Newton step, without utilizing the special structure of the problem, the computational complexity of evaluating the gradient is estimated to be $\mathbf{O}((m+p)^3(\frac{m^2}{2}+n))$. This involves matrix inversion of an $(m+p)\times(m+p)$ matrix, and $\mathbf{O}(\frac{m^2}{2}+n)$ matrix multiplications, where the multiplicands and multipliers are all $(m+p)\times(m+p)$. The complexity for evaluating the Hessian is $\mathbf{O}((m+p)^2(\frac{m^2}{2}+n)^2)$. The calculation involves $\mathbf{O}((\frac{m^2}{2}+n)^2)$ vector multiplications, where the dimension of the vectors is $(m+p)^2$. Finally, calculating the Newton descent direction requires inversion of an $(\frac{m^2+m}{2}+n)\times(\frac{m^2+m}{2}+n)$ matrix, which has complexity $\mathbf{O}((\frac{m^2}{2}+n)^3)$. Therefore, the overall complexity is $\mathbf{O}(\sqrt{m+p}\log\frac{m+p}{\varepsilon})\cdot(\mathbf{O}((m+p)^3(\frac{m^2}{2}+n))+\mathbf{O}((m+p)^2(\frac{m^2}{2}+n)^2)+\mathbf{O}((\frac{m^2}{2}+n)^3))$.

For the interior path-following algorithm proposed in this paper, the total number of Newton steps required for the algorithms to converge is yet to be determined. However, the complexity of each Newton step of the algorithm can be estimated as follows: In each Newton step, the algorithm involves evaluating the gradient, evaluating the Hessian, calculating the Newton descent direction, and performing a line search to find a new point, which requires $\mathbf{O}(1)$ evaluations of the barrier function. The overall complexity of evaluating the barrier function, its gradient, and Hessian is $\mathbf{O}(n^2(m+p)^3)$ as discussed at the end of section 3.1. The complexity of calculating the Newton descent direction is $\mathbf{O}(n^3)$. Therefore, the estimated complexity of each Newton step is roughly $\mathbf{O}(n^2(m+p)^3)+\mathbf{O}(n^3)$.

Suppose that m and p are of the same order, and $n \ll m$. Then each Newton step of a general-purpose SDP solver solving (1.1) requires $\mathbf{O}(m^6)$ arithmetic operations, while each Newton step of the interior path-following algorithm proposed in section 4 requires only $\mathbf{O}(n^2m^3)$. This is why the algorithms proposed in this paper are more efficient. Furthermore, we expect that when the ratio m/n is large enough, the algorithm proposed in section 4 will perform significantly better than the con-

ventional method. The argument here is based on the assumption that the number of iterations which the proposed path-following algorithm requires to solve (2.3) is roughly the same as the number of iterations which a general-purpose SDP solver requires to solve (1.1). According to the numerical experiments demonstrated in the next section, this assumption seems to hold in practice. As we will see, results of the numerical experiments agree with the arguments presented above.

7. Numerical experiments. Consider the standard block diagram for robustness analysis in Figure 7.1. The nominal system G is LTI and has a state space representation

$$\begin{aligned}\dot{x} &= Ax + B_1 w_1 + B_2 w_2,\\ z_1 &= C_1 x + D_{11} w_1 + D_{22} w_2,\\ z_2 &= C_2 x + D_{21} w_1 + D_{22} w_2,\end{aligned}$$

where A is an $m \times m$ Hurwitz matrix, and w_1, w_2, z_1, z_2 are vector-valued signals. Each of them has n components. The uncertainty Δ corresponds to a diagonal, gain bounded, linear time-varying operator. That is, if z_{2i} and w_{2i} denote the ith components of signals z_2 and w_2, respectively, then $z_{2i} = \delta_i(t) w_{2i}$, where $|\delta_i(t)| \le 1$ for all t. We note that the uncertain system described above captures a large class of practical problems [2].

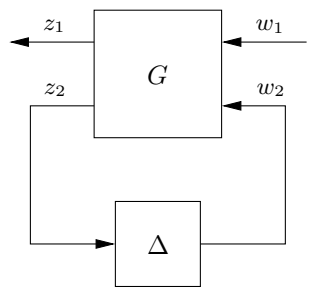

FIG. 7.1. *Standard block diagram for robustness analysis.*

In the experiments, we would like to compute an upper bound of the $\mathbf{L}_2$-gain of the system in Figure 7.1. By the standard integral quadratic constraint (IQC) analysis, an upper bound of the $\mathbf{L}_2$-gain can be found by solving

$$\begin{aligned}&\inf_{\lambda} && \lambda_{n+1}\\ &\text{subject to} && H(\omega,\lambda) > 0 \quad \forall\, \omega \in [0,\infty],\\ &&& \lambda_i > 0, \quad i = 1,\dots,n+1,\end{aligned} \tag{7.1}$$

where

$$H(\omega,\lambda) := \begin{bmatrix} G_{11}(j\omega) & G_{12}(j\omega)\\ G_{21}(j\omega) & G_{22}(j\omega)\\ I & 0\\ 0 & I \end{bmatrix}^* \begin{bmatrix} -I & 0 & 0 & 0\\ 0 & -\Lambda & 0 & 0\\ 0 & 0 & \lambda_{n+1} I & 0\\ 0 & 0 & 0 & \Lambda \end{bmatrix} \begin{bmatrix} G_{11}(j\omega) & G_{12}(j\omega)\\ G_{21}(j\omega) & G_{22}(j\omega)\\ I & 0\\ 0 & I \end{bmatrix},$$

$G_{rs}(j\omega) = C_r(j\omega I - A)^{-1} B_s + D_{rs}$, and $\Lambda = \operatorname{diag}(\lambda_1,\dots,\lambda_n)$. The equivalent KYP–

SDP of problem (7.1) can be expressed as

$$\begin{aligned} &\inf_{P,\lambda} && \lambda_{n+1} \\ &\text{subject to} && \mathcal{F}(P,\lambda) > 0, \\ &&& P = P', \quad \lambda_i > 0, \quad i = 1, \ldots, n+1, \end{aligned} \tag{7.2}$$

where P is a matrix variable and

$$\mathcal{F}(P,\lambda) := \begin{bmatrix} PA + A'P & PB \\ B'P & 0 \end{bmatrix} + \begin{bmatrix} C & D \\ 0 & I \end{bmatrix}' \begin{bmatrix} M_1 & 0 \\ 0 & M_2 \end{bmatrix} \begin{bmatrix} C & D \\ 0 & I \end{bmatrix}.$$

Matrices B, C, D, M_1, and M_2 are defined as follows:

$$B = \begin{bmatrix} B_1 & B_2 \end{bmatrix}, C = \begin{bmatrix} C_1 \\ C_2 \end{bmatrix}, D = \begin{bmatrix} D_{11} & D_{12} \\ D_{21} & D_{22} \end{bmatrix}, M_1 = \begin{bmatrix} -I & 0 \\ 0 & -\Lambda \end{bmatrix}, M_2 = \begin{bmatrix} \lambda_{n+1} I & 0 \\ 0 & \Lambda \end{bmatrix}.$$

Comparison with a general-purpose solver. Let $n = 10$ and $m = 10, 20, \ldots, 120$. For each pair of (n, m), 15 problems of the form (7.2) are randomly generated using an algorithm which is virtually identical to that given in Example 3 of [8], except for some minor numerical values. The algorithm is included in Appendix C for interested readers.

These problems are solved using the proposed specialized interior path-following algorithm (SIPA), and the general-purpose SDP solver SeDuMi (version 1.0.5) [24] via the YALMIP interface [16]. The experiments were performed on a 3.2 GHz Pentium IV PC with 2 GB of memory. The solvers were executed on MATLAB platform version 7.0.4.

Figure 7.2 shows the CPU times (in seconds) that SIPA and SeDuMi spent solving the randomly generated L_2-gain minimization problems. Times that SIPA spent are represented by circles, while times that SeDuMi spent are represented by triangles. The solvers stop when either infeasibility is proved or a feasible solution which achieves accuracy no worse than 10^{-4} (proved by a solution of the dual problem) is obtained. We observe that SIPA starts to outperform SeDuMi when the dimension of matrix A (indicated by the number m) reaches 60×60. Significantly better performance of SIPA is observed when m reaches 80 and, when m is equal to 110, SIPA is order-of-magnitude faster than SeDuMi. When m is equal to 120, SeDuMi encounters an out-of-memory problem, while it took only 6 to 12 minutes for SIPA to solve each of the 15 problems. The average CPU times in seconds that the two solvers spent are shown in Table 7.1. Table 7.2 shows the average CPU times per iteration (in seconds) that SIPA and SeDuMi spent solving the randomly generated L_2-gain minimization problems. We can see that, for SeDuMi, the per-iteration CPU time grows much faster, which conforms to the analysis given in section 6.

We note that SIPA is only crudely implemented in MATLAB language. Its custom-made codes are not optimized in any way and its efficiency can be further improved. Hence, the SIPA algorithm potentially could perform faster than it does now.

Comparison with a specialized solver. In this section, comparison is made with a specialized KYP–SDP solver, KYPD [25, 27, 28, 29]. KYPD is a collection of MATLAB functions which implement the dual method described in [25, 28, 29]. The main idea behind KYPD is to reformulate the KYP–SDP into its dual formulation. The dual problem is then solved using any general-purpose SDP solver. KYPD

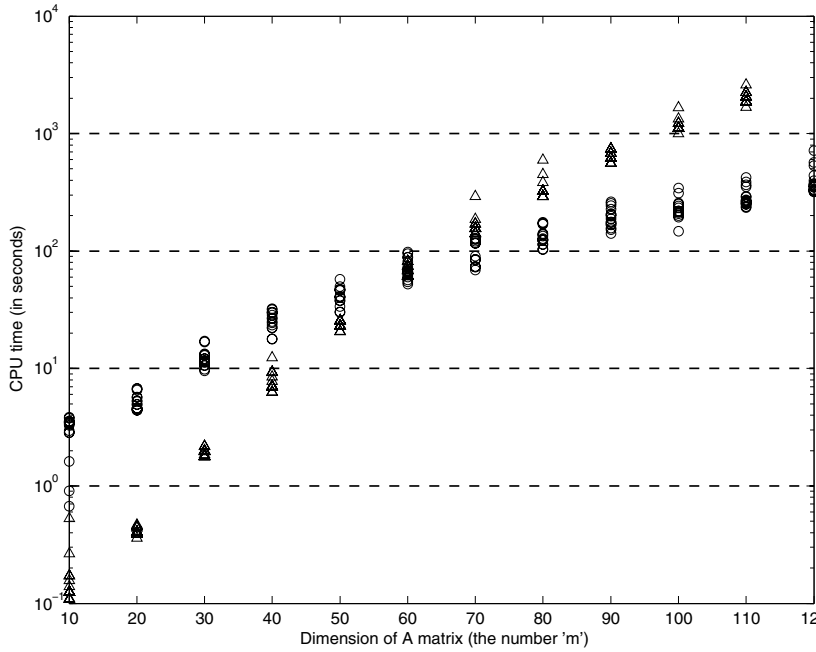

FIG. 7.2. *Comparison of SIPA and SeDuMi. Times that SIPA spent are represented by circles, while times that SeDuMi spent are represented by triangles.*

uses YALMIP to interface with MATLAB. KYPD comes with no SDP solver; the underlying SDP solver we used with KYPD was SeDuMi.

The same sets of problems were solved by KYPD/SeDuMi. The solver is set to terminate when either a feasible solution which achieves accuracy no worse than 10^{-4} is found or infeasibility is proved. Performances of KYPD and SIPA are shown in Figure 7.3. The average CPU times which the two solvers spent are given in Table 7.3, while the average per-iteration CPU times are shown in Table 7.4.

We observed that when m is between 20 and 50, SIPA and KYPD have rather similar performances. Noticeably better performance of SIPA is observed when m reaches 70. When m reaches 90, SIPA is about 2.5 times faster than KYPD on

TABLE 7.1

Comparison of SIPA and SeDuMi. Shown above are the average CPU times (in seconds) that SIPA and SeDuMi spent solving the randomly generated L_2-gain minimization problems.

	$m = 30$	40	50	60	70	80	90	100	110	120
SIPA	12.3	25.9	41.8	71.8	99.1	133	195	232	293	407

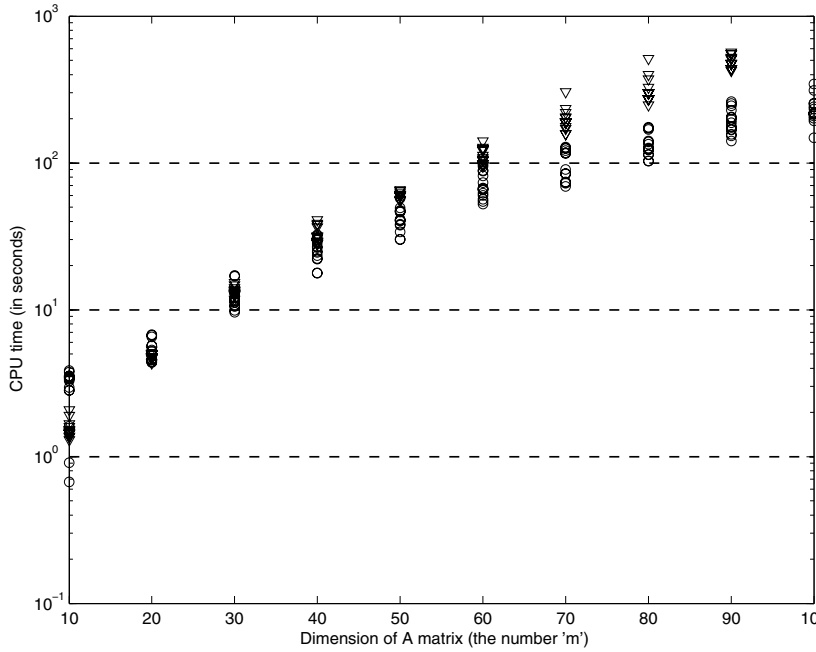

FIG. 7.3. *Comparison of SIPA and KYPD. Times that SIPA spent are represented by circles, while times that KYPD spent are represented by triangles.*

average. Also notice that, according to these tests, the average performance of KYPD is no better than the general-purpose solver SeDuMi when $m \leq 70$. KYPD began to outperform SeDuMi when m reaches 80. Another interesting observation is the memory usage of the three solvers. Under the current implementation, the memory required by SeDuMi and KYPD grows very fast with respect to m, the dimension of the A matrix. Given the same memory space (2 GB), KYPD was able to solve problems with A matrices up to 90×90, while SeDuMi holds up to 110×110. In contrast, SIPA appears to be the most efficient in this regard. The memory space which SIPA requires for all problems is below 400 MB.

Remark. To explain why KYPD broke down at $m = 100$, we note that the value of p (the number of columns of the B matrix) is 20 in all tests. When $m = 100$, the dual

formulation of the KYP–SDP involves a 120×120 positive-definite symmetric matrix variable Z which must satisfy certain equality constraints. The KYPD reduces the number of the variables in the dual formulation by calculating a set of bases for Z and by representing Z using those bases. When $m = 100$ and $p = 20$, the number of bases is equal to 2210. It was this huge amount of data—more than two thousand 120×120 matrices—which somehow ate up all the memory resource. As far as we can see, the program broke when YALMIP was processing the data for SeDuMi. We believe that the dual method described in [25, 28, 29] is computationally efficient, especially when p is very small; however, care is required for memory resource management when it comes to implementation.

Remark. By these test results, the authors by no means wish to claim that the proposed SIPA algorithm is superior to KYPD or any other specialized algorithms for KYP–SDP in that regard. The main purpose of this paper, as well as of the selected numerical experiments, is to demonstrate that there is much to gain in computational speed by taking into account the special structure of the KYP–SDP. As much as we agree that a careful comparison among the existing specialized algorithms for KYP–SDP is necessary and important, we believe such a comparison (in terms of computational speed, numerical stability, and required computational resources) must be done by testing the algorithms on a wider range of problems, which is beyond the scope of this paper.

The selection of μ. Recall that in section 5 we refer to the factor by which the weighting coefficient t is increased per outer iteration as μ. Here we present results of numerical experiments which show how the value of μ affects the speed of centralization and overall convergence.

Four randomly generated L_2-gain minimizations were solved using the SIPA algorithm with different values of μ. For different values of μ, the algorithm starts at the same feasible point in each test. In each outer iteration, centralization is considered completed when both of the following conditions are satisfied: (1) a primal feasible solution λ_F is found such that the number $\mathcal{G}(\lambda_F)^{-1}\nabla\mathcal{G}(\lambda_F)'v_N$ is less than 0.05 in absolute value, where v_N is the Newton descent direction at λ_F; (2) the solution λ_F and the corresponding Newton descent direction v_N allow a dual solution to be constructed using formula (5.1).

The results of the tests are shown in Table 7.5. Under each value of μ, the columns "Cen'l" show the average number of Newton steps per outer iteration; namely, these are the average numbers of Newton steps executed for computing a new primal feasible solution, which satisfies the above-mentioned conditions after the weighting coefficient t is increased by a factor of μ. The columns "Tot'l" show the numbers of total Newton steps executed for obtaining a feasible solution of desired accuracy. The observation here is consistent with what is commonly known for the path-following algorithm: the larger the μ is, the smaller the number of outer iterations is required for computing a solution with a prespecified accuracy. On the other hand, the larger the μ is, the larger the number of Newton steps is required for recentering. Hence, the selection of μ involves the trade-off between the number of total outer iterations and the number of Newton steps required for centralization. For the numerical experiments presented here, the most suitable value of μ is apparently between 50 and 100.

8. Concluding remarks. In this paper, a new interior-point method is proposed to efficiently solve the KYP–SDP. The main idea this paper proposes is *not* to solve the original KYP–SDP but to solve an equivalent semi-infinite optimization problem. The main technical contribution of this paper is to give a new bar-

TABLE 7.5
The effect of different values of μ on centralization and overall convergence.

μ	2		10		50		100		300	
	Cen'l	Tot'l	Cen'l	Tot'l	Cen'l	Tot'l	Cen'l	Tot'l	Cen'l	Tot'l

rier function for the semi-infinite optimization problem, which allows the standard path-following algorithm to be applied to solve the problem. Numerical experiments show that the proposed path-following method can solve the semi-infinite optimization problem much faster than a general-purpose SDP solver solves the corresponding KYP–SDP. The computational savings are mainly due to the fact that computing a Newton descent direction in the proposed path-following algorithm can be performed much more efficiently than in the algorithms used to solve the corresponding KYP–SDP.

Another natural candidate for the barrier function is the "inverse" barrier; i.e., the function $\mathcal{G}(\lambda)$ itself. We have also investigated this option [12, 13]. The reasons that we consider $\mathcal{G}(\lambda)$ less preferable are

- that function $\mathcal{G}(\lambda)$ is not self-concordant [12], and
- more important, that the primal central path associated with $\mathcal{G}(\lambda)$ does not give a good characterization of convergence.

To be more specific on the second point, we let $\lambda^\star(t)$ be at the primal central path associated with $\mathcal{G}(\lambda)$ and let $Z^\star(\omega, t)$ be the corresponding dual feasible solution which satisfies

$$\frac{dZ^\star(\omega,t)}{d\omega} = \frac{1}{\pi t}\frac{1}{1+\omega^2}\mathbf{H}^{-2}(\omega,\lambda^\star(t)).$$

It can be easily verified that the duality gap $c'\lambda^\star(t) + \langle \mathbf{H}_0(\omega), Z^\star(\omega,t)\rangle$ is equal to $\mathcal{G}(\lambda^\star(t))/t$. Since $\mathcal{G}(\lambda)$ approaches infinity as λ approaches the boundary of the feasible set, the quantity $\mathcal{G}(\lambda^\star(t))/t$ does not give a useful measure of the optimality of $\lambda^\star(t)$. Although this may not imply that $\mathcal{G}(\lambda)$ is inferior to $\log \mathcal{G}(\lambda)$ in practice, we prefer the latter because it offers a better measure of global convergence with respect to t.

Appendix A. Proof of Proposition 3.2. Throughout this section, the notation

$$G := \left[\begin{array}{c|c} A & B \\ \hline C & D \end{array}\right]$$

is used to denote a rational transfer matrix $G(s) = C(sI - A)^{-1}B + D$. Note that $G^{-1}(s)$ exists if and only if D is invertible. In such cases,

$$G^{-1} = \left[\begin{array}{c|c} A - BD^{-1}C & BD^{-1} \\ \hline -D^{-1}C & D^{-1} \end{array}\right].$$

Furthermore, given two rational transfer matrices of compatible dimensions

$$G_1 := \left[\begin{array}{c|c} A_1 & B_1 \\ \hline C_1 & D_1 \end{array}\right], \quad G_2 := \left[\begin{array}{c|c} A_2 & B_2 \\ \hline C_2 & D_2 \end{array}\right],$$

the following formulas hold:

$$G_1+G_2=\left[\begin{array}{cc|c} A_1 & 0 & B_1 \\ 0 & A_2 & B_2 \\ \hline C_1 & C_2 & D_1+D_2 \end{array}\right], \quad G_1G_2=\left[\begin{array}{cc|c} A_1 & B_1C_2 & B_1D_2 \\ 0 & A_2 & B_2 \\ \hline C_1 & D_1C_2 & D_1D_2 \end{array}\right].$$

Now consider Proposition 3.2. Given $\lambda_F \in \Omega$, $\mathbf{H}(\omega,\lambda_F)$ is a matrix function on ω which has the form

$$\begin{bmatrix} (j\omega I-A)^{-1} \\ B \end{bmatrix}^* \begin{bmatrix} Q_F & S_F \\ S_F' & R_F \end{bmatrix} \begin{bmatrix} (j\omega I-A)^{-1} \\ B \end{bmatrix}.$$

Hence, $\mathbf{H}(\omega,\lambda_F)$ can also be expressed as $\Phi(j\omega)$, where $\Phi(s)$ is the rational transfer matrix

$$\Phi := \left[\begin{array}{cc|c} A & 0 & B \\ Q_F & -A' & S_F \\ \hline S_F' & -B' & R_F \end{array}\right].$$

Let P be a solution of the Riccati equation (3.13), and observe that

$$\begin{bmatrix} I & 0 \\ P & I \end{bmatrix} \begin{bmatrix} A & 0 \\ Q_F & -A' \end{bmatrix} \begin{bmatrix} I & 0 \\ P & I \end{bmatrix}^{-1} = \begin{bmatrix} A & 0 \\ (PB+S_F)R_F^{-1}(PB+S_F)' & -A' \end{bmatrix},$$

$$\begin{bmatrix} I & 0 \\ P & I \end{bmatrix} \begin{bmatrix} B \\ S_F \end{bmatrix} = \begin{bmatrix} B \\ PB+S_F \end{bmatrix}, \quad \begin{bmatrix} S_F' & -B' \end{bmatrix} \begin{bmatrix} I & 0 \\ P & I \end{bmatrix}^{-1} = \begin{bmatrix} (PB+S_F)' & -B' \end{bmatrix}.$$

Therefore, the rational transfer matrix $\Phi(s)$ can also be expressed as

$$\left[\begin{array}{cc|c} A & 0 & B \\ (PB+S_F)R_F^{-1}(PB+S_F)' & -A' & PB+S_F \\ \hline (PB+S_F)' & -B' & R_F \end{array}\right],$$

which in turn can be factorized as $\Phi^{\frac{1}{2}}(-s)'\Phi^{\frac{1}{2}}(s)$, where

$$\Phi^{\frac{1}{2}}(s) := \left[\begin{array}{c|c} A & B \\ \hline (R_F^{-\frac{1}{2}})'(PB+S_F)' & R_F^{\frac{1}{2}} \end{array}\right].$$

Now, it can be readily verified that $\mathbf{H}(\omega,\lambda_F)^{-1}$ is equal to $\Phi(j\omega)^{-1}$, which in turn is equal to $\Psi(j\omega)\Psi(j\omega)^*$, where

$$\Psi(s)=\Phi^{-\frac{1}{2}}(s)=\left[\begin{array}{c|c} A-BR_F^{-1}(PB+S_F)' & BR_F^{-\frac{1}{2}} \\ \hline -R_F^{-1}(PB+S_F)' & R_F^{-\frac{1}{2}} \end{array}\right]=\left[\begin{array}{c|c} A_H & BR_F^{-\frac{1}{2}} \\ \hline C_H & R_F^{-\frac{1}{2}} \end{array}\right].$$

This proves the second factorization. To prove the first factorization, we will show that

$$D_H+G_H(-s)'+G_H(s)=\Psi(s)\Psi(-s)'.$$

Note that

$$\Psi(s)\Psi(-s)'=\left[\begin{array}{cc|c} A_H & -BR_F^{-1}B' & BR_F^{-1} \\ 0 & -A_H' & C_H' \\ \hline C_H & -R_F^{-1}B' & R_F^{-1} \end{array}\right].$$

Let Y be a solution of the Lyapunov equation (3.14). We see

$$\begin{bmatrix} I & Y \\ 0 & I \end{bmatrix} \begin{bmatrix} A_H & -BR_F^{-1}B' \\ 0 & -A_H' \end{bmatrix} \begin{bmatrix} I & Y \\ 0 & I \end{bmatrix}^{-1} = \begin{bmatrix} A_H & 0 \\ 0 & -A_H' \end{bmatrix},$$
$$\begin{bmatrix} I & Y \\ 0 & I \end{bmatrix} \begin{bmatrix} BR_F^{-1} \\ C_H' \end{bmatrix} = \begin{bmatrix} BR_F^{-1} + YC_H' \\ C_H' \end{bmatrix} = \begin{bmatrix} B_H \\ C_H' \end{bmatrix},$$
$$\begin{bmatrix} C_H & -R_F^{-1}B' \end{bmatrix} \begin{bmatrix} I & Y \\ 0 & I \end{bmatrix}^{-1} = \begin{bmatrix} C_H & -C_HY - R_F^{-1}B' \end{bmatrix} = \begin{bmatrix} C_H & -B_H' \end{bmatrix}.$$

Therefore

$$\Psi(s)\Psi(-s)' = \left[\begin{array}{cc|c} A_H & 0 & B_H \\ 0 & -A_H' & C_H' \\ \hline C_H & -B_H' & R_F^{-1} \end{array}\right] = D_H + G_H(s) + G_H(s)'.$$

Finally, existence of a solution P for (3.13) such that $A_H := A - BR_F^{-1}(PB + S_F)'$ is Hurwitz is guaranteed as long as $\lambda_F \in \Omega$. Proof of this is established by results in Chapters 13.2–13.4 of [33]. Existence of a solution Y for (3.14) is guaranteed because A_H has no eigenvalue on the imaginary axis.

Appendix B. Proof of Theorem 4.1. The following two lemmas will be used in the proof.

LEMMA B.1. *Let ω_0 be a real number and $\beta \geq 2$ be a positive even integer. Let*

$$G(t,\omega) = \frac{r_0(t) + r_1(t)(\omega-\omega_0)^\beta + \cdots + r_{n-1}(t)(\omega-\omega_0)^{\beta(n-1)}}{(p(t) + (\omega-\omega_0)^\beta q(t))^n}, \tag{B.1}$$

where $p(t)$, $q(t)$, $r_i(t)$, $i = 0, \ldots, n-1$, are polynomial functions in t. Consider the integral

$$F(t) := \int_{\omega_0-\epsilon}^{\omega_0+\epsilon} G(t,\omega)d\omega, \tag{B.2}$$

where ϵ is a positive number. $F(t)$ can be expressed as

$$F(t) = \sum_{i=0}^{n-1} c_i(t;\epsilon) \cdot r_i(t)p(t)^{i+\frac{1}{\beta}-n} q(t)^{-(i+\frac{1}{\beta})}, \tag{B.3}$$

where each $c_i(t;\epsilon)$ is positive and bounded for all t and ϵ.

Proof. Fix t and let

$$\omega = \omega_0 + \left(\frac{p(t)}{q(t)}\right)^{\frac{1}{\beta}} \widetilde{\omega}.$$

We have

$$\begin{aligned} \int_{\omega_0-\epsilon}^{\omega_0+\epsilon} \frac{r_i(t)(\omega-\omega_0)^{\beta\cdot i}}{(p(t)+(\omega-\omega_0)^\beta q(t))^n}\, d\omega &= \int_{-\eta}^{\eta} \frac{r_i(t)p(t)^{i+\frac{1}{\beta}} q(t)^{-(i+\frac{1}{\beta})} \widetilde{\omega}^{\beta i}}{p(t)^n(1+\widetilde{\omega}^\beta)^n}\, d\widetilde{\omega} \\ &= r_i(t)p(t)^{i+\frac{1}{\beta}-n} q(t)^{-(i+\frac{1}{\beta})} \int_{-\eta}^{\eta} \frac{\widetilde{\omega}^{\beta i}}{(1+\widetilde{\omega}^\beta)^n}\, d\widetilde{\omega}, \end{aligned}$$

where $\eta = \epsilon \left(\frac{p(t)}{q(t)}\right)^{-\frac{1}{\beta}}$. Now we define

$$c_i(t;\epsilon) := \int_{-\eta}^{\eta} \frac{\widetilde{\omega}^{\beta i}}{(1+\widetilde{\omega}^{\beta})^n}\, d\widetilde{\omega}, \tag{B.4}$$

and we reach the expression of $F(t)$. Finally, to see that $c_i(t;\epsilon)$ is bounded, note that the following inequalities hold for all $i = 0, \ldots, n-1$:

$$\int_{-\eta}^{\eta} \frac{\widetilde{\omega}^{\beta i}}{(1+\widetilde{\omega}^{\beta})^n}\, d\widetilde{\omega} \le \int_{-\infty}^{\infty} \frac{\widetilde{\omega}^{\beta i}}{(1+\widetilde{\omega}^{\beta})^n}\, d\widetilde{\omega} \le \int_{-\infty}^{\infty} \frac{1}{(1+\widetilde{\omega}^{\beta})^{n-i}}\, d\widetilde{\omega} = \text{constant}.$$

This concludes the proof. ∎

LEMMA B.2. *Let $\alpha \ge 1$ be an integer and $\beta \ge 2$ be an even integer. Let*

$$G(t,\omega) = \frac{r(t)}{t^{\alpha}p(t) + (\omega-\omega_0)^{\beta}q(t)}, \quad F(t) = \int_{\omega_0-\epsilon}^{\omega_0+\epsilon} G(t,\omega)\, d\omega,$$

where ϵ is a given positive number. Functions $p(t)$, $q(t)$, $r(t)$ are polynomials in t which satisfy $r(0) \neq 0$, $p(0) \neq 0$, and $q(0) \neq 0$. Then

$$F(t) = t^{-n}s_0(t), \quad \dot{F}(t) = t^{-n-1}s_1(t), \tag{B.5}$$

$$\ddot{F}(t) = t^{-n-2}s_2(t), \quad \dddot{F}(t) = t^{-n-3}s_3(t), \tag{B.6}$$

where $n = \alpha - \frac{\alpha}{\beta}$, and each $s_i(t)$ satisfies $s_i(0) \neq 0$ and $s_i(0) < \infty$.

Proof. Notice that $G(t)$ is in the form of (B.1). The corresponding $r_0(t)$, $p(t)$, $q(t)$, and n are $r(t)$, $t^{\alpha}p(t)$, $q(t)$, and 1, respectively. Therefore, by Lemma B.1, we have

$$F(t) = c_0(t;\epsilon)r(t)(t^{\alpha}p(t))^{\frac{1}{\beta}-1}q(t)^{-\frac{1}{\beta}} = t^{-\alpha+\frac{\alpha}{\beta}}c(t)r(t)p(t)^{\frac{1}{\beta}-1}q(t)^{-\frac{1}{\beta}},$$

which is exactly of the form described in (B.5) with $s_0(t) = c_0(t;\epsilon)r(t)p(t)^{\frac{1}{\beta}-1}q(t)^{-\frac{1}{\beta}}$. Note that $c_0(t;\epsilon)$ is of the form (B.4). Since $p(0) \neq 0$, $c_0(0;\epsilon)$ is strictly positive and bounded. This, together with $q(0) \neq 0$ and $r(0) \neq 0$, implies that $s_0(0) \neq 0$ and is bounded.

Now, consider the derivatives of $F(t)$. We have

$$\dot{F}(t) = \int_{\omega_0-\epsilon}^{\omega_0+\epsilon} \dot{G}(t,\omega)\, d\omega, \quad \ddot{F}(t) = \int_{\omega_0-\epsilon}^{\omega_0+\epsilon} \ddot{G}(t,\omega)\, d\omega, \quad \dddot{F}(t) = \int_{\omega_0-\epsilon}^{\omega_0+\epsilon} \dddot{G}(t,\omega)\, d\omega,$$

where

$$\dot{G}(t,\omega) = \frac{d_{10}(t) + d_{11}(t)(\omega-\omega_0)^{\beta}}{(t^{\alpha}p(t) + (\omega-\omega_0)^{\beta}q(t))^2},$$

$$\ddot{G}(t,\omega) = \frac{d_{20}(t) + d_{21}(t)(\omega-\omega_0)^{\beta} + d_{22}(t)(\omega-\omega_0)^{2\beta}}{(t^{\alpha}p(t) + (\omega-\omega_0)^{\beta}q(t))^3},$$

$$\dddot{G}(t,\omega) = \frac{d_{30}(t) + d_{31}(t)(\omega-\omega_0)^{\beta} + d_{32}(t)(\omega-\omega_0)^{2\beta} + d_{33}(t)(\omega-\omega_0)^{3\beta}}{(t^{\alpha}p(t) + (\omega-\omega_0)^{\beta}q(t))^4},$$

and $d_{ij}(t)$ are polynomial functions in t. We note that

$$d_{10}(t) = \dot{r}t^{\alpha}p - r(\alpha t^{\alpha-1}p + t^{\alpha}\dot{p}) = -\alpha t^{\alpha-1}rp + \mathbf{P}(t^{\alpha}),$$

$$d_{20}(t) = \dot{d}_{10}t^{\alpha}p - 2d_{10}(\alpha t^{\alpha-1}p + t^{\alpha}\dot{p}) = \alpha(\alpha+1)t^{2\alpha-2}rp^2 + \mathbf{P}(t^{2\alpha-1}),$$

$$d_{30}(t) = \dot{d}_{20}t^{\alpha}p - 3d_{20}(\alpha t^{\alpha-1}p + t^{\alpha}\dot{p}) = -\alpha(\alpha+1)(\alpha+2)t^{3\alpha-3}rp^3 + \mathbf{P}(t^{3\alpha-2}).$$

Here we use $\mathbf{P}(t^k)$ to denote any polynomial in t, where each term has at least power k. Furthermore,

$$d_{11}(t) = \dot{r}q - r\dot{q} = \mathbf{P}(t^{\gamma_1}),$$

$$d_{21}(t) = t^\alpha \dot{d}_{11}p + \dot{d}_{10}q - 2(d_{11}(\alpha t^{\alpha-1}p + t^\alpha \dot{p}) + d_{10}\dot{q}) = \begin{cases} \mathbf{P}(t^{\alpha-2}) & \text{if } \alpha \geq 2, \\ \mathbf{P}(t^0) & \text{if } \alpha = 1, \end{cases}$$

$$d_{22}(t) = \dot{d}_{11}q - 2d_{11}\dot{q} = \mathbf{P}(t^{\gamma_2}),$$

$$d_{31}(t) = t^\alpha \dot{d}_{21}p + \dot{d}_{20}q - 3(d_{21}(\alpha t^{\alpha-1}p + t^\alpha \dot{p}) + d_{20}\dot{q}) = \begin{cases} \mathbf{P}(t^{2\alpha-3}) & \text{if } \alpha \geq 2, \\ \mathbf{P}(t^0) & \text{if } \alpha = 1, \end{cases}$$

$$d_{32}(t) = t^\alpha \dot{d}_{22}p + \dot{d}_{21}q - 3(d_{22}(\alpha t^{\alpha-1}p + t^\alpha \dot{p}) + d_{21}\dot{q}) = \begin{cases} \mathbf{P}(t^{\alpha-3}) & \text{if } \alpha \geq 3, \\ \mathbf{P}(t^0) & \text{if } \alpha = 2, 1, \end{cases}$$

$$d_{33}(t) = \dot{d}_{22}q - 3d_{22}\dot{q} = \mathbf{P}(t^{\gamma_3}),$$

where γ_i are some nonnegative integers. By Lemma B.1,

$$\dot{F}(t) = c_0(t;\epsilon)d_{10}(t)t^{-2\alpha+\frac{\alpha}{\beta}}p(t)^{\frac{1}{\beta}-2}q(t)^{-\frac{1}{\beta}} + c_1(t;\epsilon)d_{11}(t)t^{-\alpha+\frac{\alpha}{\beta}}p(t)^{\frac{1}{\beta}-1}q(t)^{-(\frac{1}{\beta}+1)}.$$

Substituting $d_{10}(t)$ and $d_{11}(t)$ in the above expression, we obtain

$$\begin{aligned} \dot{F}(t) &= t^{-2\alpha+\frac{\alpha}{\beta}}(-\alpha t^{\alpha-1}r(t)p(t) + \mathbf{P}(t^\alpha))c_0(t;\epsilon)p(t)^{\frac{1}{\beta}-2}q(t)^{-\frac{1}{\beta}} \\ &\quad + t^{-\alpha+\frac{\alpha}{\beta}}\mathbf{P}(t^{\gamma_1})c_1(t;\epsilon)p(t)^{\frac{1}{\beta}-1}q(t)^{-(\frac{1}{\beta}+1)} \\ &= t^{-n-1}(-\alpha c_0(t;\epsilon)r(t)p(t)^{\frac{1}{\beta}-1}q(t)^{-\frac{1}{\beta}} + \mathbf{P}(t)c_0(t;\epsilon)p(t)^{\frac{1}{\beta}-2}q(t)^{-\frac{1}{\beta}} \\ &\qquad + \mathbf{P}(t^{\gamma_1+1})c_1(t;\epsilon)p(t)^{\frac{1}{\beta}-1}q(t)^{-(\frac{1}{\beta}+1)}) \\ &= t^{-n-1}s_1(t). \end{aligned}$$

Note that $s_1(0) = -\alpha c_0(0;\epsilon)r(0)^2p(0)^{\frac{1}{\beta}-1}q(0)^{-\frac{1}{\beta}} = -\alpha s_0(0)$. Hence, $s_1(0) \neq 0$ and is bounded above. This concludes that $\dot{F}(t)$ is of the form described in (B.5). A similar derivation leads to the forms described in (B.6) for $\ddot{F}(t)$ and $\dddot{F}(t)$, where $s_2(t)$ and $s_3(t)$ satisfy $s_2(0) \neq 0$ and $s_3(0) \neq 0$, and where both are bounded above. ∎

Proof of Theorem 4.1. We are now ready to prove Theorem 4.1. Recall that

$$\mathcal{B}(\lambda) = \log(\mathcal{G}(\lambda)) \quad \text{and} \quad \mathcal{G}(\lambda) = \left(\frac{1}{\pi}\int_{-\infty}^{\infty} \mathbf{tr}(\mathbf{H}(\omega,\lambda)^{-1})\frac{d\omega}{1+\omega^2}\right).$$

Given any $\lambda \in \Omega$ and any $h \in \mathbf{R}^n$, let T be the bounded open interval $\{t : \lambda + th \in \Omega\}$. Now, define $F(t) : T \to \mathbf{R} := \mathcal{G}(\lambda + th)$ and $E(t) : T \to \mathbf{R} := \mathcal{B}(\lambda + th) = \log(F(t))$. Let $\gamma(t) := \dddot{E}(t)^2/\ddot{E}(t)^3$. The idea is to show that the supremum of $\gamma(t)$ over T is bounded from above. Since $\gamma(t)$ is a continuous function, this property would imply that $\gamma(t)$ is finite as t approaches the boundary of T, which in turn implies that (4.4) holds.

Note that one may express $\mathbf{tr}(\mathbf{H}(\omega,\lambda+th)^{-1})/(\pi(1+\omega^2))$ as $r(\omega,t)/s(\omega,t)$, where $r(\omega,t)$ and $s(\omega,t)$ are polynomials in ω and t. Without loss of generality, let us assume that 0 is a boundary point of T and $\mathbf{H}(\omega,\lambda+th)$ is singular at $\omega = \omega_1,\ldots,\omega_n$ at $t = 0$, where each $\omega_i < \infty$. In the case when $\mathbf{H}(\omega,\lambda+th)$ has singularity at infinity, $\mathbf{tr}(\mathbf{H}(\omega,\lambda+th)^{-1})/(\pi(1+\omega^2))$ can be expressed as $r(\omega,t)/s(\omega,t) + 1/(t^\nu \cdot \pi(1+\omega^2))$, and the analysis is completely analogous to what is presented below.

Under these assumptions, we have the following expression for $s(\omega,t)$:

$$s(\omega,t) = t^{\alpha}p(\omega,t) + q(\omega,t)\Pi_{i=1}^{n}(\omega-\omega_i)^{\beta_i},$$

where α is an integer greater than or equal to 1 and each β_i is an even integer greater than or equal to 2. Furthermore, $r(\omega,t)$, $p(\omega,t)$, and $q(\omega,t)$ satisfy $r(\omega_i,0)\neq 0$, $p(\omega_i,0)\neq 0$, and $q(\omega_i,0)\neq 0$ for $i=1,\ldots,n$. Let

$$G_i(\omega,t) = \frac{r_i(t)}{t^{\alpha}p_i(t) + q_i(t)(\omega-\omega_i)^{\beta_i}},$$

where $r_i(t) := r(\omega_i,t)$, $p_i(t) := p(\omega_i,t)$, and $q_i(t) := q(\omega_i,t)$. Let ϵ be a small positive number and $\Sigma = \bigcup_{k=1}^{n}[\omega_k-\epsilon,\ \omega_k+\epsilon]$. Note that when ϵ is sufficiently small, $r(\omega,t)/s(\omega,t) \approx G_i(\omega,t)$ for $\omega\in[\omega_i-\epsilon,\omega_i+\epsilon]$. Therefore, the following hold:

$$F(t) = \sum_{i=1}^{n}\int_{\omega_i-\epsilon}^{\omega_i+\epsilon}\frac{r(\omega,t)}{s(\omega,t)}d\omega + \int_{[-\infty,\ \infty]\setminus\Sigma}\frac{r(\omega,t)}{s(\omega,t)}d\omega \tag{B.7}$$

$$\approx \sum_{i=1}^{n}\int_{\omega_i-\epsilon}^{\omega_i+\epsilon} G_i(\omega,t)d\omega + M(t), \tag{B.8}$$

where $M(t)\leq\mathcal{M}<\infty$ for all $t\in T$. To see this, we note that $s(\omega,t)$ is bounded away from 0 for all $t\in T$ and for all $\omega\in[-\infty,\ \infty]\setminus\Sigma$; therefore, the second integral in (B.7) is bounded above for all $t\in T$.

Now consider the kth derivative of $F(t)$. We have

$$\begin{aligned}\frac{d^k}{dt^k}F(t) &= \sum_{i=1}^{n}\int_{\omega_i-\epsilon}^{\omega_i+\epsilon}\frac{d^k}{dt^k}\left(\frac{r(\omega,t)}{s(\omega,t)}\right)d\omega + \int_{[-\infty,\ \infty]\setminus\Sigma}\frac{d^k}{dt^k}\left(\frac{r(\omega,t)}{s(\omega,t)}\right)d\omega\\ &= \sum_{i=1}^{n}\int_{\omega_i-\epsilon}^{\omega_i+\epsilon}\frac{\bar{r}_k(\omega,t)}{s(\omega,t)^k}d\omega + \int_{[-\infty,\ \infty]\setminus\Sigma}\frac{\bar{r}_k(\omega,t)}{s(\omega,t)^k}d\omega,\end{aligned}$$

where $\bar{r}_k(\omega,t)$ is a polynomial in ω and t. Similarly, since $s(\omega,t)^k$ is bounded away from 0 for all $t\in T$ and for all $\omega\in[-\infty,\ \infty]\setminus\Sigma$, and for any $\bar{t}\in T$,

$$\frac{d^k}{dt^k}\left(\frac{r(\omega,\bar{t})}{s(\omega,\bar{t})}\right) \approx \frac{d^k}{dt^k}G_i(\omega,\bar{t}) \quad \text{for } \omega\in[\omega_i-\epsilon,\omega_i+\epsilon],$$

we conclude that

$$\frac{d^k}{dt^k}F(t) \approx \sum_{i=1}^{n}\int_{\omega_i-\epsilon}^{\omega_i+\epsilon}\frac{d^k}{dt^k}G_i(\omega,t)d\omega + M_k(t), \tag{B.9}$$

where $M_k(t)\leq\mathcal{M}_k<\infty$ for all $t\in T$. Now, let

$$F_i(t) = \int_{\omega_i-\epsilon}^{\omega_i+\epsilon} G_i(\omega,t)d\omega, \quad i=1,\ldots,n.$$

By virtue of Lemma B.2, we have $F_i(t) = t^{-m_i}s_{i0}(t)$, $\dot{F}_i(t) = t^{-m_i-1}s_{i1}(t)$, $\ddot{F}_i(t) = t^{-m_i-2}s_{i2}(t)$, $\dddot{F}_i(t) = t^{-m_i-3}s_{i3}(t)$, where $m_i = \alpha - \frac{\alpha}{\beta_k}$, and each $s_{ij}(t)$, $j=0,\ldots,3$,

satisfies that $s_{ij}(0) \neq 0$ and is bounded above. Without loss of generality, let us assume $m_1 \geq m_2 \geq \cdots \geq m_n$. Then (B.8) and (B.9) imply that

$$F(t) \approx t^{-m_1} s_0(t), \quad \dot{F}(t) \approx t^{-m_1-1} s_1(t), \tag{B.10}$$

$$\ddot{F}(t) \approx t^{-m_1-2} s_2(t), \quad \dddot{F}(t) \approx t^{-m_1-3} s_3(t). \tag{B.11}$$

Again, in (B.10) and (B.11), each $s_i(t)$, $i = 0, \ldots, 3$, satisfies that $s_i(0) \neq 0$ and is bounded above. Now, consider $E(t) = \log F(t)$. It can be readily verified that

$$\gamma(t) := \frac{\dddot{E}(t)^2}{\ddot{E}(t)^3} = \frac{(F(t)^2 \dddot{F}(t) - 3F(t)\dot{F}(t)\ddot{F}(t) + 2\dot{F}(t)^3)^2}{(F(t)\ddot{F}(t) - \dot{F}(t)^2)^3}. \tag{B.12}$$

Substituting (B.10) and (B.11) in (B.12), we obtain

$$\gamma(t) \approx \frac{t^{-6m_1-6}(s_0(t)^2 s_3(t) - 3s_0(t)s_1(t)s_2(t) + 2s_1(t)^3)^2}{t^{-6m_1-6}(s_0(t)s_2(t) - s_1(t)^2)^3}.$$

Therefore, as $t \to 0$, we have

$$\gamma(0) \approx \frac{(s_0(0)^2 s_3(0) - 3s_0(0)s_1(0)s_2(0) + 2s_1(0)^3)^2}{(s_0(0)s_2(0) - s_1(0)^2)^3},$$

which is a finite number. This shows that the supremum of $\dddot{E}(t)^2/\ddot{E}(t)^3$ over T is bounded, which in turn implies that $\mathcal{B}(\lambda)$ satisfies (4.4).

Appendix C. The algorithm for generating the random systems in section 7. The random systems in section 7 were generated using an algorithm which is virtually identical to that given in Example 3 of [8]. The algorithm works as follows. Let ν_{ij}, $i = 1, \ldots, 10$, $j = 1, \ldots, l$, be drawn from a uniform distribution on $[-\nu_l^0, -\nu_l^0 + 1]$, where ν_l^0, $l = 1, \ldots, 12$, have the following numerical values, respectively: 4.8, 3.0, 2.5, 2.1, 2.0, 1.95, 1.85, 1.85, 1.84, 1.83, 1.82, 1.81. Define $\bar{A}_i = \operatorname{diag}_j(\nu_{ij}) + A_0$, where A_0 is an $l \times l$ matrix of zeros, except for the first superdiagonal, which has all elements equal to 1. Then let $\bar{A} = \operatorname{diag}_i(\bar{A}_i)$. For $\bar{B}$, we first define $\bar{B}_i \in \mathbf{R}^{l \times 1}$ to be $\begin{bmatrix} 0 & 0 & \cdots & 1 \end{bmatrix}'$ and let $\bar{B}_t = \operatorname{diag}_i(\bar{B}_i)$. Finally, define $\bar{B} = \begin{bmatrix} B_t & 2B_t \end{bmatrix}$. For $\bar{C}$, the construction is similar: first we introduce $\bar{C}_i = \begin{bmatrix} 1 & 0 & \cdots & 0 \end{bmatrix} \in \mathbf{R}^{1 \times l}$ and let $\bar{C}_t = \operatorname{diag}_i(\bar{C}_i)$. Finally, let $\bar{C} = [\bar{C}_t \quad 2\bar{C}_t]$. The dimensions of $\bar{A}$, $\bar{B}$, and $\bar{C}$ are $m \times m$, $m \times p$, and $p \times m$, where $m = 10l$ and $p = 20$. By changing l, we vary the dimensions of the systems from 10 to 120. In order to couple all inputs with all outputs, random unitary transformations are introduced. For this, we produce two matrices $\Upsilon_m \in \mathbf{R}^{m \times m}$ and $\Upsilon_p \in \mathbf{R}^{p \times p}$, whose entries are drawn from a uniform distribution on $[0, 1]$. Let the singular value decompositions of Υ_m and Υ_p be $U_m \Sigma_m V_m'$ and $U_p \Sigma_p V_p'$, respectively. Finally, we define $A = U_m' \bar{A} U_m$, $B = U_m' \bar{B} V_p$, and $C = U_p' \bar{C} U_m$. The random systems in section 7 are realized by the pair of matrices $(A, B, C, 0_{p \times p})$.

THE FAST FOURIER TRANSFORM*

ULRICH OBERST†

Abstract. Fast Fourier transforms (FFTs) are fast algorithms, i.e., of low complexity, for the computation of the discrete Fourier transform (DFT) on a finite abelian group. They are among the most important algorithms in applied and engineering mathematics and in computer science, in particular for one- and multidimensional systems theory and signal processing. We give a relatively short survey of the FFT for arbitrary finite abelian groups, cyclic or not, with complete and partially novel proofs, the main distinction being explicit induction formulas for the FFT in all cases which generalize the original FFT-algorithm due to Cooley and Tukey and, much earlier, to Gauß. We believe that our approach has didactic advantages over the usual ones. We also present the application of the FFT to fast convolution algorithms, and the so-called number theoretic transforms over finite coefficient rings. We do not treat those algorithms which decrease the multiplicative complexity at the expense of many more rational linear combinations, which in this context are considered costless, nor do we discuss the DFT for nonabelian finite groups.

Key words. fast Fourier transform, discrete Fourier transform, fast convolution

DOI. 10.1137/060658242

1. Introduction.

Fast Fourier transforms (FFTs) are fast algorithms, i.e., of low complexity, for the computation of the *discrete Fourier transform* (DFT) on a finite abelian group which, in turn, is a special case of the Fourier transform on a locally compact abelian group. The FFTs are among the most important algorithms in applied and engineering mathematics and in computer science, in particular for *one- and multidimensional systems theory and signal processing*, as evidenced by references [4], [11], [14], [17], [21], [24], [25], [31], [32], [37]. Various textbooks on the FFT are mentioned at the end of this introduction.

The present article gives a relatively *short* survey of the FFT for arbitrary finite abelian groups, cyclic or not, with complete and partially novel proofs which in our opinion have didactic advantages over the usual ones. The main distinction consists in *explicit induction formulas* for the FFT, proven and announced in 1988 [27], [28], for all possible cases which generalize the FFT-algorithm on the group $\mathbb{Z}/\mathbb{Z}2^r$ due to Cooley and Tukey [16] and, much earlier, to Gauß. We also treat the applications of the FFT to fast convolution algorithms. We do not discuss the algorithms with fewer *essential multiplications* at the expense of many more rational linear combinations, i.e., those with low *multiplicative complexity*, for instance, those of Winograd [40]. Nor do we treat the FFT for *noncommutative* finite groups [5], [12].

An algorithm is called *fast* if it has *low complexity*, where the complexity is the number of elementary computation steps necessary to execute it. In this paper and in most computer processors such a step is of the form $ax + y$ with numbers a, x, y; i.e., it consists of one multiplication together with one addition.

The following *motivational* remarks taken from [6] and [22] on the Fourier theory for general locally compact abelian groups or *harmonic analysis* will not be used in

any way in the rest of this article. For the group $G = \mathbb{R}^r$ the *Fourier transform* of a function $a \in \mathrm{L}^1(\mathbb{R}^r)$ is the bounded, continuous function

$$\widehat{a}(y) := \int_{\mathbb{R}^r} a(x) \exp(-2\pi i x \bullet y) dx,\ y \in \mathbb{R}^r,\ \text{where } x \bullet y := x_1 y_1 + \cdots + x_r y_r$$

is the standard scalar product. Under suitable assumptions, for instance, if $\widehat{a}$ is absolutely integrable, too [20, p. 164], the *Fourier inversion formula*

$$a(x) = \int_{\mathbb{R}^r} \widehat{a}(y) \exp(+2\pi i x \bullet y) dy$$

holds almost everywhere. For fixed y the map $x \mapsto \langle x, y\rangle := \exp(-2\pi i x \bullet y)$ is a character on $\mathbb{R}^r$, i.e., a continuous group homomorphism from $\mathbb{R}^r$ into the circle group $\mathrm{S}^1 := \{z \in \mathbb{C};\ |\ z\ | = 1\}$. Let $\mathrm{Gr}_{\mathrm{cont}}(\mathbb{R}^r, \mathrm{S}^1)$ denote the multiplicative group of all characters with the multiplication of functions. Then, more precisely, the continuous, symmetric, bimultiplicative form $\langle -, -\rangle$ is nondegenerate, i.e., induces the (topological) isomorphism

$$\mathbb{R}^r \cong \mathrm{Gr}_{\mathrm{cont}}(\mathbb{R}^r, \mathrm{S}^1),\ y \mapsto \langle -, y\rangle,$$

and the Fourier inversion has the form

$$\widehat{a}(y) := \int_{\mathbb{R}^r} a(x)\langle x, y\rangle dx,$$
$$a(x) := \int_{\mathbb{R}^r} \widehat{a}(y)\langle -x, y\rangle dy,\ \langle -x, y\rangle = \langle x, y\rangle^{-1} = \overline{\langle x, y\rangle}.$$

In general, the character group $\widehat{G} := \mathrm{Gr}_{\mathrm{cont}}(G, \mathrm{S}^1)$ of a locally compact abelian group G is not isomorphic to G, for instance, $\widehat{\mathbb{Z}^r} \cong (\mathrm{S}^1)^r$, but the form $\langle -, -\rangle : G \times \widehat{G} \to \mathrm{S}^1,\ \langle g, \widehat{g}\rangle := \widehat{g}(g)$, is nondegenerate in the sense that the map $G \to \mathrm{Gr}_{\mathrm{cont}}(\widehat{G}, \mathrm{S}^1),\ g \mapsto \langle g, -\rangle$, is a (topological) isomorphism and the Fourier inversion has the form

$$\widehat{a}(\widehat{g}) := \int_G a(g)\langle g, \widehat{g}\rangle dg,\ a \in \mathrm{L}^1(G),$$
$$a(g) := \int_{\widehat{G}} \widehat{a}(\widehat{g})\langle -g, \widehat{g}\rangle d\widehat{g},\ \langle -g, \widehat{g}\rangle = \langle g, \widehat{g}\rangle^{-1} = \overline{\langle g, \widehat{g}\rangle},$$

where dg, respectively, $d\widehat{g}$, are the suitably normalized *Haar measures* on G, respectively, $\widehat{G}$.

We specialize the preceding considerations to the simple case of a finite abelian group G of exponent $d > 0$, i.e., satisfying $dG = 0$. In various ways one can choose a group $\widehat{G} \cong G$, for instance, $\widehat{G} = G$, and a biadditive form

$$\bullet : G \times \widehat{G} \to \mathbb{Z}/\mathbb{Z}d \text{ such that}$$
$$\widehat{G} \cong \mathrm{Hom}(G, \mathbb{Z}/\mathbb{Z}d),\ \widehat{g} \mapsto (-) \bullet \widehat{g},\ \text{and } G \cong \mathrm{Hom}(\widehat{G}, \mathbb{Z}/\mathbb{Z}d),\ g \mapsto g \bullet (-),$$

are isomorphisms, the latter signifying that the form $\bullet$ is *nondegenerate*. In the engineering literature the groups G and $\widehat{G}$ are called the *time*, respectively, the *frequency* domain, in the standard one-dimensional case of time signals. We choose a primitive dth root of one in $\mathbb{C}$, for instance, $\zeta := \exp(-\frac{2\pi i}{d})$; hence

$$\mathbb{Z}/\mathbb{Z}d \cong \mu := \langle\zeta\rangle = \{1, \zeta, \cdots, \zeta^{d-1}\} \subseteq \mathrm{S}^1, \overline{k} \mapsto \zeta^{\overline{k}} := \zeta^k.$$

The nondegenerate form $\bullet$ thus induces the nondegenerate bimultiplicative form

$$\langle -, -\rangle : G \times \widehat{G} \to \mu,\ \langle g, \widehat{g}\rangle := \zeta^{g \bullet \widehat{g}},\ \text{such that}$$
$$\widehat{G} \cong \mathrm{Gr}(G, \mu),\ \widehat{g} \mapsto \langle -, \widehat{g}\rangle,\ \text{and } G \cong \mathrm{Gr}(\widehat{G}, \mu),\ g \mapsto \langle g, -\rangle.$$

Here $\mathrm{Gr}(G,\mu)$ denotes the *multiplicative* abelian group of homomorphisms from the *additive* abelian group G into the *multiplicative* abelian group μ. The canonical group isomorphisms

$$\widehat{G} \cong \mathrm{Hom}(G, \mathbb{Z}/\mathbb{Z}d) \cong \mathrm{Gr}(G,\mu) = \mathrm{Gr}(G, \mathrm{S}^1)$$

hold. In this article we use the chosen group $\widehat{G}$ instead of the isomorphic *character group* $\mathrm{Gr}(G,\mu)$ for the development of the theory. The standard choices for the one-dimensional DFT are

$$d > 0,\ G := \widehat{G} = \mathbb{Z}/\mathbb{Z}d,\ \overline{k} \bullet \overline{l} = \overline{kl},\ \langle \overline{k}, \overline{l} \rangle = \exp\left(-2\pi i \tfrac{kl}{d}\right).$$

It is a well-known and simple, but for this paper essential, observation that the contravariant *duality functor* $G \mapsto \widehat{G} \cong \mathrm{Gr}(G,\mu)$ is exact on finite abelian groups of exponent d. The Haar integral on $\mathbb{C}^G$ which is unique up to a multiplicative positive constant is the map $\mathbb{C}^G \to \mathbb{C},\ a \mapsto \sum_{g\in G} a(g)$. Therefore we define two DFTs

$$\mathrm{Four}_G : \mathbb{C}^G \to \mathbb{C}^{\widehat{G}},\ a \mapsto \widehat{a},\ \widehat{a}(\widehat{g}) := \textstyle\sum_{g\in G} a(g)\langle g, \widehat{g}\rangle,\ \text{and}$$
$$\mathrm{Four}_{\widehat{G}} : \mathbb{C}^{\widehat{G}} \to \mathbb{C}^G,\ b \mapsto \widehat{b},\ \widehat{b}(g) := \textstyle\sum_{\widehat{g}\in\widehat{G}} b(\widehat{g})\langle g, \widehat{g}\rangle.$$

The map $\mathrm{Four}_{\widehat{G}}$ is sometimes called the *inverse discrete Fourier transform* (IDFT). The Fourier inversion formula has the form

$$N^{-1}\widehat{\widehat{a}}(-g) = a(g),\ \text{where } a \in \mathbb{C}^G,\ N := \mathrm{ord}(G).$$

The form $\langle -, - \rangle$ and the Fourier transform can also be defined if $\mathbb{C}$ is replaced by an arbitrary commutative ring K and if ζ is a primitive dth root of one in K, and we will do this in these notes. However, the Fourier inversion holds under additional assumptions on ζ only [26], [15], [18]. Interesting cases concern finite factor rings $K = \mathbb{Z}/\mathbb{Z}M$ of $\mathbb{Z}$, where the corresponding DFT is also called a *number theoretic transform* (NTT), or rings of algebraic integers. In our opinion the change of the coefficient ring does not justify a change of the terminology, so we will always talk of the DFT.

Any filtration or increasing sequence of subgroups $0 = G_0 \subseteq G_1 \subseteq \cdots \subseteq G_r = G$ of G gives rise to an FFT-algorithm for the computation of Four_G. That nontrivial subgroups H of G and their factor groups G/H are significant for the construction of an FFT for Four_G has been one of the basic observations in this field since [16], and the book [5], for instance, stresses this point of view. For groups of prime order there are no FFTs *in this sense*, and different algorithms have been designed, the first one by Rader [33]. Our description of the recursive FFT-algorithms gives simple explicit recursion formulas and makes essential use of the exactness of the duality functor. For the important case of cyclic groups similar formulas are contained in [8, pp. 188–191].

The central and novel sections of this survey paper are those on the FFT. The sections on duality theory, the DFT, and the complexity of linear maps contain necessary preliminaries and are simple adaptions from the literature. The two short sections on fast convolution algorithms derived from the FFT and on NTTs are included for completeness' sake and are also simple variants of the literature [26].

Since the FFT is so important in engineering applications there are very many papers and books on this subject, too numerous to be available to and be read and known by the author. Therefore the list of references at the end of this survey paper

contains only books and papers which are actually mentioned in the text, and omission of an article is no comment whatsoever on its historical or practical significance. Standard textbooks on the FFT are those of Brigham [8], Nussbaumer [26], and Beth [5] (in German), newer books are those of Clausen and Baum [12], Chu and George [13], and Garg [18]. Besides the signal processing and systems textbooks quoted above, the book [8] and especially that of Briggs and Henson [7] give surveys of the many mathematical and technical applications of the DFT and thus of the FFT from an engineering point of view, for instance, to the computation of Fourier integrals and coefficients, to trigonometric interpolation, and to digital filtering.

We discuss briefly the literature on the construction of FFT and convolution algorithms which minimize the *multiplicative complexity* according to Winograd and which are otherwise not treated in the present paper. The seminal papers in this direction are those of Winograd, Auslander, and Tolimieri and their coworkers [39], [40], [2], [1], [35]. In [29], [38], and the book [30], which unfortunately has not yet appeared, we constructed the *optimal* fast Fourier and Hartley, respectively, Gelfand, transforms on arbitrary finite abelian groups, respectively, finite-dimensional, commutative, semisimple $\mathbb{Q}$-algebras, i.e., algorithms for these transformations of *minimal multiplicative complexity*, and computed the exact value of the latter with the help of [3]. The recent paper [36] emphasizes the renewed interest in such algorithms.

The present paper presupposes the algebraic knowledge of a mathematics student at the end of the second university year. Some results are recalled under the heading *Reminder*.

2. Duality.

Reminder 1 (see [23, p. 46]). Let $G = (G, +)$ be a finite abelian group, written additively. Then there are numbers $d_1 > 0, \cdots, d_r > 0$ and an isomorphism

$$G \cong \mathbb{Z}/\mathbb{Z}d_1 \times \cdots \times \mathbb{Z}/\mathbb{Z}d_r. \tag{1}$$

The least common multiple

$$\exp(G) := \operatorname{lcm}(d_1, \cdots, d_r) \text{ with } \mathbb{Z}\exp(G) = \{k \in \mathbb{Z};\ kG = 0\} \tag{2}$$

is called *the exponent* of G. If, in addition, d_ϱ divides $d_{\varrho+1}$ for all $\varrho = 1, \cdots, r-1$, then the d_ϱ are unique and are called the *invariant factors* of G and $\exp(G) = d_r$. If d is a multiple of $\exp(G)$ or, in other words, if $dG = 0$, we say that G is a *group of exponent* d.

If G and H are additively written abelian groups, the group of all additive or $\mathbb{Z}$-linear homomorphisms from G to H is denoted by $\operatorname{Hom}(G, H) = \operatorname{Hom}_{\mathbb{Z}}(G, H)$ as usual.

If $r > 0$ and K is a field, the map

$$\bullet : K^r \times K^r \to K,\ x \bullet y := x_1y_1 + \cdots + x_ry_r \text{ for } x = (x_1, \cdots, x_r),$$

is a nondegenerate symmetric bilinear form; i.e., the induced map

$$K^r \to \operatorname{Hom}_K(K^r, K),\ y \mapsto (-) \bullet y = y \bullet (-),$$

is a K-isomorphism.

The following symmetric bilinear form is the analogue of the preceding one for finite abelian groups.

THEOREM 2 (nondegenerate bilinear form). *Let*

$$G = \mathbb{Z}/\mathbb{Z}d_1 \times \cdots \times \mathbb{Z}/\mathbb{Z}d_r \ni g = (\overline{g_1}, \cdots, \overline{g_r}),\ g_\varrho \in \mathbb{Z},$$

be the finite abelian group of exponent $d > 0$, i.e., $dG = 0$. Then the map

$$\bullet : G \times G \to \mathbb{Z}/\mathbb{Z}d,\ g \bullet h := \overline{\textstyle\sum_{\varrho=1}^{r} g_\varrho h_\varrho \frac{d}{d_\varrho}}, \tag{3}$$

is well defined and is a nondegenerate, symmetric $\mathbb{Z}$-bilinear form; i.e., the following hold.

(1) *The definition is independent of the representatives g_ϱ, h_ϱ.*

(2) *$g \bullet h = h \bullet g$, $g \bullet (h + h') = g \bullet h + g \bullet h'$ for all g, h, h' in G.*

(3) *$G \cong \mathrm{Hom}(G, \mathbb{Z}/\mathbb{Z}d)$, $h \mapsto (-) \bullet h$.*

Proof. (1) *The map is well defined*: Let $g = (\overline{g_1}, \cdots, \overline{g_r}) = (\overline{g'_1}, \cdots, \overline{g'_r})$; hence $g'_\varrho = g_\varrho + k_\varrho d_\varrho$, $k_\varrho \in \mathbb{Z}$, for $\varrho = 1, \ldots, r$. But then

$$\textstyle\sum_{\varrho=1}^{r} g'_\varrho h_\varrho \frac{d}{d_\varrho} = \sum_{\varrho=1}^{r} g_\varrho h_\varrho \frac{d}{d_\varrho} + \sum_{\varrho=1}^{r} g_\varrho h_\varrho k_\varrho d \in \sum_{\varrho=1}^{r} g_\varrho h_\varrho \frac{d}{d_\varrho} + \mathbb{Z}d, \text{ and hence}$$
$$\overline{\textstyle\sum_{\varrho=1}^{r} g'_\varrho h_\varrho \frac{d}{d_\varrho}} = \overline{\textstyle\sum_{\varrho=1}^{r} g_\varrho h_\varrho \frac{d}{d_\varrho}} = g \bullet h.$$

The independence of the representatives h_ϱ is shown in the same fashion.

(2) The symmetry and bilinearity follow trivially from the definition.

(3) It remains to show that $G \to \mathrm{Hom}(G, \mathbb{Z}/\mathbb{Z}d),\ h \bullet (-) = (-) \bullet h$, is an isomorphism.

(i) *Monomorphism*: Assume that $(-) \bullet h = 0$. For $\varrho = 1, \ldots, r$ let $\delta_\varrho := (0, \cdots, 0, \underset{\varrho}{\overline{1}}, 0, \cdots, 0)$ denote the analogue of the standard basis such that $(\overline{g_1}, \cdots, \overline{g_r}) = \sum_{\varrho=1}^{r} g_\varrho \delta_\varrho$ for all $g \in G$. Then

$$0 = \delta_\varrho \bullet h = \overline{h_\varrho \tfrac{d}{d_\varrho}} \in \mathbb{Z}/\mathbb{Z}d;\ \text{hence for } \varrho = 1, \ldots, r$$
$$d \mid h_\varrho \tfrac{d}{d_\varrho} \text{ or } d_\varrho \mid h_\varrho \text{ and } \overline{h_\varrho} = 0 \text{ in } \mathbb{Z}/\mathbb{Z}d_\varrho,\ \text{i.e., } h = 0.$$

(ii) *Epimorphism*: Let $\varphi : G \to \mathbb{Z}/\mathbb{Z}d$ be any homomorphism. The equation

$$d_\varrho \delta_\varrho = 0 \text{ implies } d_\varrho \varphi(\delta_\varrho) = 0 \text{ in } \mathbb{Z}/\mathbb{Z}d;\ \text{hence } \varphi(\delta_\varrho) = \overline{h_\varrho \tfrac{d}{d_\varrho}} = \delta_\varrho \bullet h,\ h_\varrho \in \mathbb{Z},$$
$$\text{and for } g \in G :\ \varphi(g) = \varphi(\textstyle\sum_{\varrho=1}^{r} g_\varrho \delta_\varrho) = \sum_{\varrho=1}^{r} g_\varrho \varphi(\delta_\varrho)$$
$$= \textstyle\sum_{\varrho=1}^{r} g_\varrho \delta_\varrho \bullet h = (\sum_{\varrho=1}^{r} g_\varrho \delta_\varrho) \bullet h = g \bullet h \text{ and } \varphi = (-) \bullet h. \qquad \square$$

COROLLARY 3. *With the data of the preceding theorem, let G_1 and G_2 be two groups which are isomorphic to G and let $\varphi_i : G_i \cong G$, $i = 1, 2$, be two isomorphisms. Then*

$$\bullet : G_1 \times G_2 \to \mathbb{Z}/\mathbb{Z}d,\ g_1 \bullet g_2 := \varphi_1(g_1) \bullet \varphi_2(g_2), \tag{4}$$

is a nondegenerate bilinear form; i.e., the maps

$$G_1 \to \mathrm{Hom}(G_2, \mathbb{Z}/\mathbb{Z}d),\ g_1 \mapsto g_1 \bullet (-), \quad \text{and} \quad G_2 \to \mathrm{Hom}(G_1, \mathbb{Z}/\mathbb{Z}d),\ g_2 \mapsto (-) \bullet g_2,$$

are isomorphisms.

The proof is obvious. The corollary implies that the following assumptions can be realized in various ways.

Assumption 4. Let $d > 0$. In what follows we consider finite abelian groups G with $dG = 0$. For each such G we choose a group $\widehat{G}$ and a nondegenerate bilinear form $\bullet : G \times \widehat{G} \to \mathbb{Z}/\mathbb{Z}d$, hence the *canonical* isomorphisms

(5)
$$\text{can} : G \cong \text{Hom}(\widehat{G}, \mathbb{Z}/\mathbb{Z}d),\ g \mapsto g \bullet (-),\ \text{and}\ \text{can} : \widehat{G} \cong \text{Hom}(G, \mathbb{Z}/\mathbb{Z}d),\ \widehat{g} \mapsto (-) \bullet \widehat{g}.$$

For the groups $G = \mathbb{Z}/\mathbb{Z}d_1 \times \cdots \times \mathbb{Z}/\mathbb{Z}d_r$ the canonical choices are $\widehat{G} = G$ and the symmetric form of (3). In the context of the FFT the groups G (resp., $\widehat{G}$) are often called the *time domain* (resp., the *frequency domain*), and therefore it is advantageous to make a notational distinction between G and $\widehat{G}$ even if $G = \widehat{G}$.

If G is any finite abelian group, the theory applies for $d = \exp(G)$.

Reminder 5 (see [23, pp. 76,77]). $\text{Hom}(G, H)$ is an *additive functor* in its two variables G and H. In particular, a homomorphism $\varphi : G_1 \to G_2$ of abelian groups induces the homomorphism

$$\text{Hom}(\varphi, \mathbb{Z}/\mathbb{Z}d) : \text{Hom}(G_2, \mathbb{Z}/\mathbb{Z}d) \to \text{Hom}(G_1, \mathbb{Z}/\mathbb{Z}d),\ \chi_2 \mapsto \chi_2\varphi,$$

in the reverse direction. This assignment satisfies the relations

$$\text{Hom}(\text{id}_G, \mathbb{Z}/\mathbb{Z}d) = \text{id}_{\text{Hom}(G,\mathbb{Z}/\mathbb{Z}d)},$$
$$\text{Hom}(\varphi_1, \mathbb{Z}/\mathbb{Z}d)\,\text{Hom}(\varphi_2, \mathbb{Z}/\mathbb{Z}d) = \text{Hom}(\varphi_2\varphi_1, \mathbb{Z}/\mathbb{Z}d) \text{ for } G_1 \xrightarrow{\varphi_1} G_2 \xrightarrow{\varphi_2} G_3,$$
$$\text{Hom}(\varphi^{-1}, \mathbb{Z}/\mathbb{Z}d) = \text{Hom}(\varphi, \mathbb{Z}/\mathbb{Z}d)^{-1} \text{ if } \varphi : G_1 \cong G_2.$$

Corollary 6. *For each finite abelian group G of exponent $d > 0$ there is a* noncanonical *isomorphism $G \cong \widehat{G}$.*

Proof. Choose an isomorphism $\varphi : H = \mathbb{Z}/\mathbb{Z}d_1 \times \cdots \times \mathbb{Z}/\mathbb{Z}d_r \to G$ and on H the bilinear form from (3) which induces the isomorphism $H \cong \text{Hom}(H, \mathbb{Z}/\mathbb{Z}d)$. Then

$$\widehat{G} \cong \text{Hom}(G, \mathbb{Z}/\mathbb{Z}d) \overset{\text{Hom}(\varphi,\mathbb{Z}/\mathbb{Z}d)}{\cong} \text{Hom}(H, \mathbb{Z}/\mathbb{Z}d) \cong H \cong G. \qquad \square$$

Remark 7. If K is a field, V a finite-dimensional K-vector space, and $V^\star := \text{Hom}_K(V, K)$ its dual space, the canonical Gelfand map

$$\text{Gelf} : V \to V^{\star\star},\ v \mapsto \text{Gelf}(v),\ \text{Gelf}(v)(v^\star) := v^\star(v),$$

is a K-isomorphism. The following result is the analogue for finite abelian groups.

Theorem 8. *There is the unique* canonical Gelfand *isomorphism*

$$\text{Gelf}_G : G \cong \widehat{\widehat{G}} \text{ with } g \bullet \widehat{g} = \widehat{g} \bullet \text{Gelf}_G(g) \text{ for all } g \in G,\ \widehat{g} \in \widehat{G}. \tag{6}$$

Proof.

$$G \cong \text{Hom}(\widehat{G}, \mathbb{Z}/\mathbb{Z}d) \cong \widehat{\widehat{G}},\ g \to g \bullet (-) = (-) \bullet \text{Gelf}_G(g) \leftarrow \text{Gelf}_G(g). \qquad \square$$

Lemma and Definition 9. 1. *For each homomorphism $\varphi : G_1 \to G_2$ there is a unique homomorphism*

$$\varphi^\star : \widehat{G_2} \to \widehat{G_1} \text{ such that } \varphi(g_1) \bullet \widehat{g_2} = g_1 \bullet \varphi^\star(\widehat{g_2}) \text{ for all } g_1 \in G_1,\ \widehat{g_2} \in \widehat{G_2}. \tag{7}$$

The map $\varphi^\star$ is called the adjoint *of φ.*

2. *The relations $\text{id}_G^\star = \text{id}_{\widehat{G}}$ and $\varphi_1^\star\varphi_2^\star = (\varphi_2\varphi_1)^\star$ for $G_1 \xrightarrow{\varphi_1} G_2 \xrightarrow{\varphi_2} G_3$ hold.*

Hence the assignment $G \mapsto \widehat{G},\ \varphi \mapsto \varphi^\star$, *is a contravariant functor on finite abelian groups of exponent* $d > 0$ *and is called the* duality functor *in this article. Observe that* $\widehat{G} \cong \mathrm{Hom}(G, \mathbb{Z}/\mathbb{Z}d)$ *can be chosen in various ways.*

Proof. 1. There is a unique homomorphism $\varphi^\star$ such that the following diagram with vertical isomorphisms is commutative:

$$\begin{array}{ccc} \widehat{G_2} & \xrightarrow{\varphi^\star} & \widehat{G_1} \\ \downarrow \mathrm{can}_2 & & \downarrow \mathrm{can}_1 \\ \mathrm{Hom}(G_2, \mathbb{Z}/\mathbb{Z}d) & \xrightarrow{\mathrm{Hom}(\varphi, \mathbb{Z}/\mathbb{Z}d)} & \mathrm{Hom}(G_1, \mathbb{Z}/\mathbb{Z}d) \\ \widehat{g_2} & \mapsto & \varphi^\star(\widehat{g_2}) \\ \downarrow & & \downarrow \\ \chi_2 := (-) \bullet \widehat{g_2} & \mapsto & \chi_2\varphi = \varphi(-) \bullet \widehat{g_2} = (-) \bullet \varphi^\star(\widehat{g_2}) \end{array} \tag{8}$$

viz., $\varphi^\star := \mathrm{can}_1^{-1} \circ \mathrm{Hom}(\varphi, \mathbb{Z}/\mathbb{Z}d) \circ \mathrm{can}_2$. The commutativity signifies that

$$\varphi(g_1) \bullet \widehat{g_2} = g_1 \bullet \varphi^\star(\widehat{g_2}) \text{ for all } g_1 \in G_1,\ \widehat{g_2} \in \widehat{G_2}.$$

2. The relations follow from the commutative diagram (8) and Reminder 5. □

LEMMA 10. *The Gelfand map is a natural transformation; i.e., for* $\varphi : G_1 \to G_2$ *the following diagram is commutative:*

$$\begin{array}{ccc} G_1 & \xrightarrow{\varphi} & G_2 \\ \downarrow \mathrm{Gelf}_1 & & \downarrow \mathrm{Gelf}_2 \\ \widehat{\widehat{G_1}} & \xrightarrow{\varphi^{\star\star}} & \widehat{\widehat{G_2}} \end{array} . \tag{9}$$

Proof. For all $g_1 \in G_1$ and $\widehat{g_2} \in \widehat{G_2}$ we have

$$\begin{gathered} \widehat{g_2} \bullet \mathrm{Gelf}_2(\varphi(g_1)) = \varphi(g_1) \bullet \widehat{g_2} = g_1 \bullet \varphi^\star(\widehat{g_2}) \\ = \varphi^\star(\widehat{g_2}) \bullet \mathrm{Gelf}_1(g_1) = \widehat{g_2} \bullet \varphi^{\star\star}(\mathrm{Gelf}_1(g_1)); \text{ hence} \\ \mathrm{Gelf}_2(\varphi(g_1)) = \varphi^{\star\star}(\mathrm{Gelf}_1(g_1)). \end{gathered}$$ □

Reminder 11 (exactness [25, pp. 16, 77]). 1. Consider a sequence of abelian groups and homomorphisms

$$G_1 \xrightarrow{\varphi_1} G_2 \xrightarrow{\varphi_2} G_3. \tag{10}$$

The sequence is called a *complex* if $\varphi_2\varphi_1 = 0$ or $\mathrm{im}(\varphi_1) \subseteq \ker(\varphi_2)$.

2. The sequence (10) is called *exact* if $\mathrm{im}(\varphi_1) = \ker(\varphi_2)$.

3. A possibly infinite sequence

$$G_* :\ \cdots \to G_{i+1} \xrightarrow{d_{i+1}} G_i \xrightarrow{d_i} G_{i-1} \to \cdots, i \in \mathbb{Z}, \tag{11}$$

is called a *complex* (resp., *exact*) if and only if all three member subsequences have this property, i.e. $B_i := \mathrm{im}(d_{i+1}) \subseteq Z_i := \ker(d_i)$ (resp., $B_i = Z_i$) for all i. The groups $H_i(G_*) := Z_i/B_i$ are called the *homology groups* of the complex and are all zero if and only if G_* is exact.

4. For a sequence

$$0 \longrightarrow G_1 \xrightarrow{\varphi_1} G_2 \xrightarrow{\varphi_2} G_3 \tag{12}$$

the following properties are equivalent.

(a) The sequence is exact.
(b) $\ker(\varphi_1) = 0$, i.e., φ_1 is a monomorphism, and $\operatorname{im}(\varphi_1) = \ker(\varphi_2)$.
(c) The map φ_1 induces an isomorphism $\varphi_{1,\mathrm{ind}} : G_1 \cong \ker(\varphi_2)$.

5. For a sequence

$$G_1 \xrightarrow{\varphi_1} G_2 \xrightarrow{\varphi_2} G_3 \longrightarrow 0 \tag{13}$$

and the *cokernel* $\operatorname{cok}(\varphi_1) := G_2/\operatorname{im}(\varphi_1)$ the following properties are equivalent.
(a) The sequence is exact.
(b) $\operatorname{im}(\varphi_2) = G_3$, i.e., φ_2 is an epimorphism, and $\operatorname{im}(\varphi_1) = \ker(\varphi_2)$.
(c) The map φ_2 induces the isomorphism $\varphi_{2,\mathrm{ind}} : \operatorname{cok}(\varphi_1) \cong G_3$, $\overline{g_2} \mapsto \varphi_2(g_2)$.

6. The Hom-functor is left exact. Moreover, the sequence (13) is exact if and only if for all abelian groups X the derived sequence

$$\operatorname{Hom}(G_1, X) \xleftarrow{\operatorname{Hom}(\varphi_1, X)} \operatorname{Hom}(G_2, X) \xleftarrow{\operatorname{Hom}(\varphi_2, X)} \operatorname{Hom}(G_3, X) \longleftarrow 0 \tag{14}$$

is exact.

The next *duality theorem* states that the duality functor $G \mapsto \widehat{G}$ preserves and reflects exactness.

THEOREM 12 (duality theorem). *A sequence*

$$G_1 \xrightarrow{\varphi_1} G_2 \xrightarrow{\varphi_2} G_3 \tag{15}$$

of finite abelian groups G of exponent d ($dG = 0$) is exact if and only if its dual sequence

$$\widehat{G_1} \xleftarrow{\varphi_1^\star} \widehat{G_2} \xleftarrow{\varphi_2^\star} \widehat{G_3} \tag{16}$$

has this property.

Proof. $\Rightarrow$: 1. Assume first that the sequence

$$G_1 \xrightarrow{\varphi_1} G_2 \xrightarrow{\varphi_2} G_3 \longrightarrow 0 \tag{17}$$

is exact, i.e., φ_2 is surjective. Lemma 9 implies the commutative diagram

$$\begin{array}{ccccccc}
\widehat{G_1} & \xleftarrow{\varphi_1^\star} & \widehat{G_2} & \xleftarrow{\varphi_2^\star} & \widehat{G_3} & \leftarrow & 0 \\
\downarrow \mathrm{can}_1 & & \downarrow \mathrm{can}_2 & & \downarrow \mathrm{can}_3 & & \\
\operatorname{Hom}(G_1, \mathbb{Z}/\mathbb{Z}d) & \xleftarrow{\operatorname{Hom}(\varphi_1, \mathbb{Z}/\mathbb{Z}d)} & \operatorname{Hom}(G_2, \mathbb{Z}/\mathbb{Z}d) & \xleftarrow{\operatorname{Hom}(\varphi_2, \mathbb{Z}/\mathbb{Z}d)} & \operatorname{Hom}(G_3, \mathbb{Z}/\mathbb{Z}d) & \leftarrow & 0
\end{array}$$

with vertical isomorphisms whose lower row is exact according to part 6 of Reminder 11. The commutativity then implies that also the upper row is exact.

2. We prove that $\varphi^\star$ is an epimorphism if $\varphi : G_1 \to G_2$ is a monomorphism.

The sequence

$$0 \leftarrow C := \operatorname{cok}(\varphi^\star) \xleftarrow{\mathrm{can}} \widehat{G_1} \xleftarrow{\varphi^\star} \widehat{G_2}$$

is exact. Part 1 of this proof and Lemma 10 imply the commutative diagram

$$\begin{array}{ccccccc}
 & & & & G_1 & \xrightarrow{\varphi} & G_2 \\
 & & & & \downarrow \mathrm{Gelf}_1 & & \downarrow \mathrm{Gelf}_2 \\
0 & \to & \widehat{C} & \xrightarrow{\mathrm{can}^\star} & \widehat{\widehat{G_1}} & \xrightarrow{\varphi^{\star\star}} & \widehat{\widehat{G_2}}
\end{array}$$

with exact row and vertical isomorphisms. Since φ is a monomorphism, so is $\varphi^{\star\star}$, and hence $\widehat{C} = 0$. Since C and $\widehat{C}$ are isomorphic, we obtain $C = \operatorname{cok}(\varphi^\star) = 0$ or that $\varphi^\star$ is surjective.

3. The exact sequence (15) gives rise to the commutative diagram

$$\begin{array}{ccccccc} G_1 & \xrightarrow{\varphi_1} & G_2 & \xrightarrow{\text{can}} & C := \operatorname{cok}(\varphi_1) & \longrightarrow & 0 \\ & & \downarrow \varphi_2 & & \downarrow \psi & & \\ & & G_3 & = & G_3 & & \end{array},$$

where $\psi(\overline{g_2}) = \varphi_2(g_2)$. Since $C = G_2/\operatorname{im}(\varphi_1) = G_2/\ker(\varphi_2)$, the homomorphism theorem implies that ψ is a monomorphism. Dual to the preceding one is the commutative diagram

$$\begin{array}{ccccccc} \widehat{G_1} & \xleftarrow{\varphi_1^\star} & \widehat{G_2} & \xleftarrow{\text{can}^\star} & \widehat{C} & \longleftarrow & 0 \\ & & \uparrow \varphi_2^\star & & \uparrow \psi^\star & & \\ & & \widehat{G_3} & = & \widehat{G_3} & & \end{array}.$$

Its first row is exact, and $\psi^\star$ is an epimorphism according to parts 1 and 2 of the proof. Since $\varphi_2^\star = \text{can}^\star\, \psi^\star$, we conclude that $\operatorname{im}(\varphi_2^\star) = \operatorname{im}(\text{can}^\star) = \ker(\varphi_1^\star)$ and thus the exactness of (16).

$\Leftarrow$: Assume that (16) is exact. There results the diagram

$$\begin{array}{ccccc} G_1 & \xrightarrow{\varphi_1} & G_2 & \xrightarrow{\varphi_2} & G_3 \\ \downarrow \text{Gelf}_1 & & \downarrow \text{Gelf}_2 & & \downarrow \text{Gelf}_3 \\ \widehat{\widehat{G_1}} & \xrightarrow{\varphi_1^{\star\star}} & \widehat{\widehat{G_2}} & \xrightarrow{\varphi_2^{\star\star}} & \widehat{\widehat{G_3}} \end{array}.$$

The exactness of (16) and the proof "$\Rightarrow$" imply the exactness of its lower row, and Lemma 10 implies its commutativity. Since the Gelfand maps are isomorphisms, the wanted exactness of the upper row follows. □

3. The discrete Fourier transform. In this section we define and investigate the DFT for K-valued functions on a *finite* abelian group where K denotes a suitable coefficient field or even ring.

Assumption 13. The assumptions of section 2 remain in force, in particular $d > 0$. We consider finite additively written abelian groups G of exponent d ($dG = 0$) and the nondegenerate bilinear forms $\bullet : G \times \widehat{G} \to \mathbb{Z}/\mathbb{Z}d$. Let K be a commutative *coefficient* ring. Then K^G is the K-module of functions from G to K with its argumentwise addition and scalar multiplication. The standard case for the FFT will be the coefficient field $\mathbb{C}$ of complex numbers. However, since we are also going to discuss the so-called arithmetic transforms with a finite coefficient ring or field, we consider the more general situation from Assumption 13. Let $\mathrm{U}(K)$ denote the group of units or invertible elements of K. For the definition of the DFT on K^G we also need an analogue of the circle group $S^1 = \{z \in \mathbb{C};\ |\ z\ | = 1\} \subset \mathrm{U}(\mathbb{C})$ in the standard case of complex Fourier transforms. Therefore we make the following additional assumption for the ring K.

Assumption 14. Let $\zeta \in \mathrm{U}(K)$ be a *primitive dth root of one* in K, i.e.,

$$\zeta^d = 1,\ \mu := \langle\zeta\rangle = \{1, \zeta, \cdots, \zeta^{d-1}\} \subseteq \mathrm{U}(K),\ \operatorname{ord}(\zeta) = \operatorname{ord}(\mu) = d.$$

Examples 15.

(1) Let

$$K := \mathbb{C},\ \zeta := \exp\left(-\tfrac{2\pi i}{d}\right).\ \text{Then}\ \mu := \langle\zeta\rangle = \{\eta \in \mathbb{C};\ \eta^d = 1\}$$

is the group of *all* dth roots of one in $\mathbb{C}$ and consists of the vertices of the regular d-gon. These data are those of the standard complex DFT.

(2) Let $d := 2,\ K := \mathbb{R},\ \zeta := -1$. These data are used for the discrete *Walsh–Fourier* transform.

(3) Let $K := \mathbb{C} \times \mathbb{C},\ \zeta := (\zeta_1, \zeta_2) := (\exp(-\frac{2\pi i}{d}), 1)$. This is a primitive dth root of one, but it does not generate the finite group of all dth roots of one which consists of the elements (ζ_1^m, ζ_1^n).

(4) Let K be a finite field of characteristic p and dimension $[K : \mathbb{Z}/\mathbb{Z}p] = n$, hence with $q := p^n$ elements. The group $\mathrm{U}(K) = K \setminus \{0\}$ is cyclic and hence generated by a primitive root of order $d := q-1$. For instance, $\mathrm{U}(\mathbb{Z}/\mathbb{Z}7) = \langle\overline{3}\rangle$, whereas $\mathrm{ord}(\overline{2}) = 3$.

If G_1 and G_2 are arbitrary abelian groups and one of them is multiplicatively written, we denote the group of all homomorphisms from G_1 to G_2 by $\mathrm{Gr}(G_1, G_2)$ instead of $\mathrm{Hom}(G_1, G_2)$.

LEMMA 16. *Consider the situation of Example* 15(1) *and a finite abelian group* G *with* $dG = 0$. *Then* $\mathrm{Gr}(G, \mu) = \mathrm{Gr}(G, S^1)$ *is the group of all* complex characters *on* G.

Proof. Let $\chi : G \to S^1$ be any character, i.e., homomorphism. The relations $dg = 0$ for $g \in G$ imply $\chi(g)^d = 1$ and hence $\chi(g) \in \mu$ since μ is the group of *all* roots of 1. □

This result suggests that we consider the group $\mathrm{Gr}(G, \mu)$ as a suitable analogue of the character group for general coefficient rings, and we will do this; i.e, we call this group the *character group* of G. Notice that, in general, this group depends on the choice of ζ in contrast to the complex case.

COROLLARY AND DEFINITION 17. *The maps*

$$\begin{gathered}\mathbb{Z}/\mathbb{Z}d \cong \mu = \langle\zeta\rangle,\ \overline{k} \mapsto \zeta^{\overline{k}} := \zeta^k,\ \textit{hence also}\\ \mathrm{Hom}(G, \mathbb{Z}/\mathbb{Z}d) \cong \mathrm{Gr}(G, \mu),\ \varphi \mapsto \chi,\ \chi(g) = \zeta^{\varphi(g)},\end{gathered} \tag{18}$$

are isomorphisms. For each group G *(finite abelian,* $dG = 0$*) the nondegenerate bilinear form* $\bullet : G \times \widehat{G} \to \mathbb{Z}/\mathbb{Z}d$ *induces the nondegenerate bimultiplicative form*

$$\langle -, - \rangle : G \times \widehat{G} \to \mu = \langle\zeta\rangle,\ \langle g, \widehat{g}\rangle := \zeta^{g \bullet \widehat{g}};\ \textit{i.e.,} \tag{19}$$

(1) *for all* $g_1, g_2 \in G$ *and* $\widehat{g_1}, \widehat{g_2} \in \widehat{G}$

$$\langle g_1, \widehat{g_1} + \widehat{g_2}\rangle = \langle g, \widehat{g_1}\rangle\langle g, \widehat{g_2}\rangle,\ \langle g_1 + g_2, \widehat{g}\rangle = \langle g_1, \widehat{g}\rangle\langle g_2, \widehat{g}\rangle,$$

(2)

$$G \cong \mathrm{Gr}(\widehat{G}, \mu),\ g \mapsto \langle g, -\rangle,\ \widehat{G} \cong \mathrm{Gr}(G, \mu),\ \widehat{g} \mapsto \langle -, \widehat{g}\rangle.$$

The proof of this corollary is obvious since it consists in just replacing the additive group $\mathbb{Z}/\mathbb{Z}d$ by the multiplicative group $\mu = \langle\zeta\rangle$.

Reminder 18. The K-module K^G of all functions $a = (a(g))_{g \in G} : G \to K$ has the standard basis $\delta_h := (\delta_{h,g})_{g \in G},\ h \in G$, and the basis representation is

$$a = (a(g))_{g \in G} = \textstyle\sum_{g \in G} a(g)\delta_g.$$

We also consider the function module $K^{\widehat{G}}$ with the corresponding structure.

LEMMA AND DEFINITION 19 (DFT). *The data are as introduced above. The map*

$$\mathrm{Four}_G : K^G \to K^{\widehat{G}},\ a \mapsto \widehat{a},\ \widehat{a}(\widehat{g}) := \textstyle\sum_{g\in G} a(g)\langle g, \widehat{g}\rangle,$$

is K-linear and is called the discrete Fourier transform (DFT). *The function $\widehat{a} \in K^{\widehat{G}}$ is also called the Fourier transform of a. The analogous map*

$$\mathrm{Four}_{\widehat{G}} : K^{\widehat{G}} \to K^G,\ b \mapsto \widehat{b},\ \widehat{b}(g) := \textstyle\sum_{\widehat{g}\in\widehat{G}} b(\widehat{g})\langle g, \widehat{g}\rangle,$$

is called the Fourier transform *on $K^{\widehat{G}}$ or* inverse discrete Fourier transform (IDFT). *Notice that* $\mathrm{Four}_{\widehat{G}}$ *maps into K^G and not into $K^{\widehat{\widehat{G}}}$.*

The Fourier transform depends on the choice of the nondegenerate form $\bullet$ and of the primitive dth root ζ.

Examples 20. (1) Let $d := n > 0$, $K := \mathbb{C}$, $\zeta := \exp(-\frac{2\pi i}{n})$, and $G := \mathbb{Z}_n := \mathbb{Z}/\mathbb{Z}n = \widehat{G}$ with $\overline{k} \bullet \overline{l} := \overline{kl} \in \mathbb{Z}_n$ and hence $\langle \widehat{k}, \widehat{l}\rangle = \zeta^{kl} = \exp(-2\pi i \frac{kl}{n})$.

We identify

$$G = \mathbb{Z}_n = \{\overline{0}, \cdots, \overline{n-1}\} = \{0, \cdots, n-1\},$$
$$\mathbb{C}^G = \mathbb{C}^{\widehat{G}} = \mathbb{C}^{\mathbb{Z}_n} = \mathbb{C}^n \ni a = (a(\overline{k}))_{\overline{k}\in\mathbb{Z}_n}$$
$$= (a(\overline{0}), \cdots, a(\overline{n-1}) = (a(0), \cdots, a(n-1)), \text{ and hence}$$
$$\mathrm{Four}_G = \mathrm{Four}_{\widehat{G}} : \mathbb{C}^n \to \mathbb{C}^n.$$

The Fourier transform of $a = (a(0), \cdots, a(n-1))$ is

$$\widehat{a} = (\widehat{a}(0), \cdots, \widehat{a}(n-1)),$$
$$\widehat{a}(l) = \textstyle\sum_{\overline{k}\in\mathbb{Z}_n} a(k)\langle \overline{k}, \overline{l}\rangle = \sum_{k=0}^{n-1} a(k)\zeta^{kl} = \sum_{k=0}^{n-1} a(k)\exp\left(-2\pi i \frac{kl}{n}\right).$$

(2) Let $d := 2$, $K := \mathbb{R}$, $\zeta := -1$, and let $G = \mathbb{Z}_2^r \ni g = (g_1, \cdots, g_r)$ be the finite-dimensional $\mathbb{Z}_2$-vector space which is the typical finite group of exponent 2. We choose

$$\widehat{G} := G,\ g \bullet h := g_1h_1 + \cdots + g_rh_r, \text{ and hence } \langle g, h\rangle = (-1)^{g\bullet h}.$$

The *Fourier transform* $\widehat{a}$ of $a \in \mathbb{R}^G$ is given by $\widehat{a}(h) = \sum_{g\in G} a(g)(-1)^{g\bullet h}$. One also talks about the *Walsh–Fourier transform* in this case.

LEMMA 21. *For each $g \in G$ the Fourier transform of*

$$\delta_g \in K^G \text{ is } \widehat{\delta_g} = \langle g, -\rangle \in \mathrm{Gr}(\widehat{G}, \mu) \subset K^{\widehat{G}}.$$

Proof. $\widehat{\delta_g}(\widehat{g}) = \sum_{h\in G} \delta_g(h)\langle h, \widehat{g}\rangle = \langle g, \widehat{g}\rangle$. □

The K-module K^G admits two structures as commutative K-algebras which are both significant for the DFT.

LEMMA AND DEFINITION 22. *With the argumentwise multiplication*

$$(a_1a_2)(g) := a_1(g)a_2(g),\ a_1, a_2 \in K^G,\ g \in G, \tag{20}$$

the K-module K^G is a commutative K-algebra whose identity 1_{K^G} is the constant function with value 1. *The standard basis consists of complete orthogonal idempotents, i.e.,*

$$\textstyle\sum_{g\in G} \delta_g = 1,\ \delta_g\delta_h = \delta_{g,h}\delta_g.$$

The proof is obvious.

LEMMA AND DEFINITION 23. *With the* convolution *multiplication*

$$(a_1 * a_2)(g) := \sum_{g_1+g_2=g} a_1(g_1)a_2(g_2) = \sum_{h\in G} a_1(g-h)a_2(h) = \sum_{h\in G} a_1(h)a_2(g-h) \tag{21}$$

the K-module K^G is a commutative K-algebra with the identity δ_0. One writes $K[G] := (K^G, *)$ and calls this algebra the group algebra *of G with coefficients in K. The map*

$$\delta : G \to U(K[G]),\ g \mapsto \delta_g, \tag{22}$$

is a group monomorphism, i.e., injective with

$$\delta_0 = 1,\ \delta_{g_1+g_2} = \delta_{g_1} * \delta_{g_2},\ \text{hence } \delta_g^{-1} = \delta_{-g}.$$

The proof is analogous to that for the polynomial algebra $K[X] := K[\mathbb{N}]$ and is omitted.

The map $\delta : G \to U(K[G])$ has the following *universal property*. For two K-algebras A and B let $\mathrm{Al}_K(A, B)$ denote the set of K-algebra homomorphisms from A to B.

THEOREM 24 (universal property). *For each K-algebra B the map*

$$\mathrm{Al}_K(K[G], B) \to \mathrm{Gr}(G, \mathrm{U}(B)),\ \varphi \mapsto \chi := \varphi \circ \delta, \tag{23}$$

is bijective. The inverse map is given by

$$\chi \mapsto \varphi,\ \varphi(a) = \sum_{g\in G} a(g)\chi(g),\ a \in K^G.$$

Proof. The map is injective since $\chi := \varphi \circ \delta,\ \chi(g) = \varphi(\delta_g)$, implies

$$\varphi(a) = \varphi\left(\sum_{g\in G} a(g)\delta_g\right) = \sum_{g\in G} a(g)\varphi(\delta_g) = \sum_{g\in G} a(g)\chi(g). \tag{24}$$

Let, conversely, χ be given and define φ via the K-linear map (24), in particular,

$$\varphi(\delta_g) = \chi(g) \text{ and } \varphi(1_{K[G]}) = \varphi(\delta_0) = \chi(0) = 1_B.$$

Then

$$\varphi(\delta_{g_1} * \delta_{g_2}) = \varphi(\delta_{g_1+g_2}) = \chi(g_1+g_2) = \chi(g_1)\chi(g_2) = \varphi(\delta_{g_1})\varphi(\delta_{g_2}).$$

Therefore φ is multiplicative on the standard basis and therefore a K-algebra homomorphism by bilinear extension. □

COROLLARY 25. *For $B := K$ there results the bijection*

$$\mathrm{Al}_K(K[G], K) \cong \mathrm{Gr}(G, \mathrm{U}(K)),\ \varphi \mapsto \varphi \circ \delta.$$

In particular, for every $\widehat{g} \in \widehat{G}$, the group homomorphism $\langle -, \widehat{g}\rangle : G \to \mu \subseteq \mathrm{U}(K)$ induces the K-algebra homomorphism

$$K[G] = (K^G, *) \to K,\ a \mapsto \sum_{g\in G} a(g)\langle g, \widehat{g}\rangle = \widehat{a}(\widehat{g}).$$

THEOREM 26 (convolution theorem). *The K-linear Fourier transform* $\mathrm{Four}_G : K[G] \to K^{\widehat{G}}$ *is an algebra homomorphism, i.e.,*

$$\widehat{\delta_0} = \langle 0, - \rangle = 1_{K^{\widehat{G}}},\ \widehat{a_1 * a_2}(\widehat{g}) = \widehat{a_1}(\widehat{g})\widehat{a_2}(\widehat{g}).$$

Proof. Since $K^{\widehat{G}}$ is supplied with the argumentwise multiplication, the theorem is a direct consequence of Corollary 25. □

COROLLARY AND DEFINITION 27 (antipode). *The group automorphism $g \mapsto -g$ of G induces the algebra automorphism*

$$\mathrm{S}_G : K^G \cong K^G,\ \delta_g \mapsto \delta_{-g},\ \mathrm{S}_G(a)(g) = a(-g),$$

with respect to both multiplications on K^G. This map is called the antipode *on K^G and is an involution, i.e., $\mathrm{S}_G^2 = \mathrm{id}_{K^G}$ or $\mathrm{S}_G^{-1} = \mathrm{S}_G$. We likewise define $\mathrm{S}_{\widehat{G}}$ on $K^{\widehat{G}}$.*

Proof. For the convolution multiplication this follows from the universal property of $K[G]$, and for the argumentwise multiplication directly from the definition. □

LEMMA 28. *The antipode commutes with the Fourier transform, i.e., the diagram*

$$\begin{array}{ccc} K^G & \xrightarrow{\mathrm{Four}_G} & K^{\widehat{G}} \\ \downarrow\ \mathrm{S}_G & & \downarrow\ \mathrm{S}_{\widehat{G}} \\ K^G & \xrightarrow{\mathrm{Four}_G} & K^{\widehat{G}} \end{array} \quad \textit{is commmutative or } \mathrm{Four}_G\,\mathrm{S}_G = \mathrm{S}_{\widehat{G}}\,\mathrm{Four}_G\,.$$

Proof. The following sequence of equations is valid:

$$\mathrm{Four}_G\,\mathrm{S}_G(\delta_g) = \mathrm{Four}_G(\delta_{-g}) = \langle -g, - \rangle = \mathrm{S}_{\widehat{G}}(\langle g, - \rangle) = \mathrm{S}_{\widehat{G}}\,\mathrm{Four}_G(\delta_g). \qquad \square$$

For the proof of the *Fourier inversion theorem* we need an additional assumption on the root ζ.

Assumption 29 (see [15, Satz 2.8]). For the data of Assumption 14 we assume in what follows that d is invertible in K and that for each divisor $m > 1$ of d and the root $\eta := \zeta^{\frac{d}{m}}$ of order $\mathrm{ord}(\eta) = m$ the relation

$$1 + \eta + \cdots + \eta^{m-1} = 0$$

holds. In Theorem 80 we will give several equivalent conditions for this assumption as in [15, Satz 2.8].

Recall that all considered groups G are finite abelian of exponent d ($dG = 0$). Let $N := \mathrm{ord}(G)$ denote the order of G.

COROLLARY 30. *The preceding Assumption* 29 *is satisfied if K is a field.*

Proof. The second property follows from the relation

$$0 = \eta^m - 1 = (\eta - 1)(\eta^{m-1} + \cdots + \eta + 1)$$

since $\mathrm{ord}(\eta) = m \neq 1$; hence $\eta \neq 1$. Assume that the characteristic p of K divides d or $d = 0$ in K. Then p is prime and

$$d = pk \ \Rightarrow\ 0 = \zeta^d - 1 = (\zeta^k)^p - 1^p = (\zeta^k - 1)^p \ \Rightarrow\ \zeta^k = 1 \ \Rightarrow\ \mathrm{ord}(\zeta) \leq k < d,$$

a contradiction to $\mathrm{ord}(\zeta) = d$. □

COROLLARY 31. *Under Assumption* 29 *the order $N := \mathrm{ord}(G)$ of G is also invertible in K.*

Proof. If $G \cong \mathbb{Z}/\mathbb{Z}d_1 \times \cdots \times \mathbb{Z}/\mathbb{Z}d_r$ with $d_\varrho \mid d$, then $N = d_1 * \cdots * d_r$ divides d^r and therefore is invertible like d. ∎

LEMMA 32. *Under Assumption* 29 *any character* $\chi \in Gr(G, \mu)$ *of the group* G *satisfies the relation*

$$\textstyle\sum_{g\in G} \chi(g) = N\delta_{1,\chi} = \begin{cases} N & \text{if } \chi = 1, \\ 0 & \text{if } \chi \neq 1. \end{cases}$$

Here $1 : G \to \mu,\ g \mapsto 1$, *denotes the trivial character which is the neutral element of the character group.*

Proof. The assertion is obvious for $\chi = 1$. Assume therefore that $\chi \neq 1$ and that the image $\mathrm{im}(\chi)$ has the order $m \neq 1$. Then $\mathrm{im}(\chi)$ is the unique subgroup of order m of the cyclic group $\mu = \langle\zeta\rangle$ and is generated by $\eta := \zeta^{\frac{d}{m}}$; hence $\mathrm{im}(\chi) = \langle\eta\rangle = \{1, \eta, \cdots, \eta^{m-1}\}$. Let $\eta = \chi(g)$. The isomorphism

$$G/\ker(\chi) \cong \mathrm{im}(\chi) = \langle\eta\rangle, \overline{ig} \mapsto \chi(ig) = \chi(g)^i = \eta^i,$$

implies that every element $h \in G$ has a unique representation

$$h = ig + k, 0 \leq i \leq m-1, k \in \ker(\chi).$$

We infer

$$\begin{aligned} \textstyle\sum_{h\in G} \chi(h) &= \textstyle\sum \{\chi(ig+k); 0 \leq i \leq m-1, k \in \ker(\chi)\} \\ &= \textstyle\sum_{i,k} \chi(g)^i = \sum_k \left(\sum_{i=0}^{m-1} \eta^i\right) = 0, \end{aligned}$$

where $\sum_{i=0}^{m-1} \eta^i = 0$ according to Assumption 29. ∎

THEOREM 33. *The following equations hold for* $a \in K^G,\ b \in K^{\widehat{G}},\ g \in G,\ \widehat{g} \in \widehat{G}$:

$$\begin{aligned} Na(0) = \textstyle\sum_{\widehat{g}\in\widehat{G}} \widehat{a}(\widehat{g}),\ Nb(0) = \textstyle\sum_{g\in G} \widehat{b}(g), \\ N\delta_{0,g} = \textstyle\sum_{\widehat{g}\in\widehat{G}} \langle g, \widehat{g}\rangle,\ N\delta_{0,\widehat{g}} = \textstyle\sum_{g\in G} \langle g, \widehat{g}\rangle. \end{aligned}$$

Proof. Since $\widehat{\delta_g} = \langle g, -\rangle$ and $\widehat{\delta_{\widehat{g}}} = \langle -, \widehat{g}\rangle$, only the first equation has to be shown. With $\chi := \langle g, -\rangle : \widehat{G} \to \mu$ Lemma 32 implies $\sum_{\widehat{g}\in\widehat{G}} \langle g, \widehat{g}\rangle = N\delta_{0,g}$; hence

$$\begin{aligned} \textstyle\sum_{\widehat{g}\in\widehat{G}} \widehat{a}(\widehat{g}) = \textstyle\sum_{\widehat{g}\in\widehat{G}, g\in G} a(g)\langle g, \widehat{g}\rangle \\ = \textstyle\sum_g a(g) \sum_{\widehat{g}} \langle g, \widehat{g}\rangle = \sum_g a(g) N\delta_{0,g} = Na(0). \end{aligned}$$ ∎

THEOREM 34 (Fourier inversion theorem). *Under Assumption* 29 *the Fourier transform* Four_G *is an isomorphism and*

$$\begin{aligned} \mathrm{Four}_{\widehat{G}} \circ \mathrm{Four}_G = N\,\mathrm{S}_G \ \textit{ or } \ \mathrm{Four}_G^{-1} = N^{-1}\,\mathrm{S}_G\,\mathrm{Four}_{\widehat{G}} = N^{-1}\,\mathrm{Four}_{\widehat{G}}\,\mathrm{S}_{\widehat{G}} \ \textit{ or} \\ \widehat{\widehat{a}}(g) = Na(-g) \ \textit{or}\ \widehat{\widehat{a}} = N\,\mathrm{S}_G(a). \end{aligned}$$

Proof. All assertions follow from the last equation which has to be shown for the standard basis vectors only, from the invertibility of N and of the antipode and the same properties for $\mathrm{Four}_{\widehat{G}}$ instead of Four_G. But for $g, h \in G$

$$\begin{aligned} \widehat{\widehat{\delta_h}}(g) = \widehat{\langle h, -\rangle}(g) = \textstyle\sum_{\widehat{g}\in\widehat{G}} \langle h, \widehat{g}\rangle\langle g, \widehat{g}\rangle = \sum_{\widehat{g}\in\widehat{G}} \langle g+h, \widehat{g}\rangle \\ = N\delta_{0,g+h} = N\delta_{-h}(g) = N\,\mathrm{S}_G(\delta_h)(g);\ \text{hence } \widehat{\widehat{\delta_h}} = N\,\mathrm{S}_G(\delta_h). \end{aligned}$$ ∎

Example 35. In the situation of Example 20(1), with $d = N = n$ the Fourier inversion has the form

$$a \leftrightarrow \widehat{a},\ \widehat{a}(l) = \textstyle\sum_{k=0}^{n-1} a(k) \exp\left(-2\pi i \frac{kl}{n}\right),\ a(k) = n^{-1} \sum_{l=0}^{n-1} \widehat{a}(l) \exp\left(+2\pi i \frac{kl}{n}\right).$$

THEOREM 36 (product theorem). *The map* $N^{-1} \operatorname{Four}_G : K^G \to K[\widehat{G}]$ *is an algebra isomorphism; i.e.,*

$$N^{-1}\widehat{a_1 a_2} = N^{-1}\widehat{a_1} * N^{-1}\widehat{a_2} \text{ or } \widehat{a_1 a_2} = N^{-1}\widehat{a_1} * \widehat{a_2} \text{ and } N^{-1}\widehat{1} = \delta_0 \text{ or } \widehat{1} = N\delta_0.$$

Proof. The Fourier inversion theorem (Theorem 34) and Lemma 28 imply that $N^{-1} \operatorname{S}_G \operatorname{Four}_{\widehat{G}} : K^{\widehat{G}} \to K[G]$ and $\operatorname{S}_G : K[G] \to K[G]$ are algebra isomorphisms. The same follows for $N^{-1} \operatorname{Four}_{\widehat{G}}$ and then also for $N^{-1} \operatorname{Four}_G$. □

The action of the group G on itself by translation induces an action on K^G by K-algebra automorphisms, viz.,

$$\circ : G \times K^G, (g, a) \mapsto g \circ a := \delta_g * a, \quad (g \circ a)(h) = a(h - g). \tag{25}$$

Similarly $\widehat{G}$ acts on $K^{\widehat{G}}$.

THEOREM 37 (shift theorem). *For* $a \in K^G$, $g \in G$, *and* $\widehat{g} \in \widehat{G}$ *the following relations hold:*

$$\operatorname{Four}_G(g \circ a) = \langle g, - \rangle \widehat{a}, \quad \operatorname{Four}_G(\langle -, \widehat{g} \rangle a) = (-\widehat{g}) \circ \widehat{a}. \tag{26}$$

Proof. The first equation follows from the convolution theorem since

$$\widehat{g \circ a} = \widehat{\delta_g * a} = \widehat{\delta}_g \widehat{a} = \langle g, - \rangle \widehat{a},$$

and the second from

$$\begin{aligned} &\operatorname{Four}_G(\langle -, \widehat{g}_1 \rangle a)(\widehat{g}_2) = \textstyle\sum_{g \in G} \langle g, \widehat{g}_1 \rangle a(g) \langle g, \widehat{g}_2 \rangle \\ &= \textstyle\sum_{g \in G} a(g) \langle g, \widehat{g}_1 + \widehat{g}_2 \rangle = \widehat{a}(\widehat{g}_1 + \widehat{g}_2) = ((-\widehat{g}_1) \circ \widehat{a})(\widehat{g}_2). \end{aligned}$$ □

COROLLARY AND DEFINITION 38 (correlation). *The* correlation function $a \circ b \in K^G$ *of two functions* $a, b \in K^G$ *is defined as*

$$\begin{aligned} a \circ b &:= (\operatorname{S}_G a) * b, \text{ i.e. }, \\ (a \circ b)(h) &:= \textstyle\sum_{g \in G} (\operatorname{S}_G a)(g) b(h - g) \\ &= \textstyle\sum_{g \in G} a(-g) b(h - g) = \sum_{g \in G} a(g) b(h + g). \end{aligned}$$

Then

$$b \circ a = \operatorname{S}_G(a \circ b) \text{ and } \operatorname{Four}_G(a \circ b) = (\operatorname{S}_{\widehat{G}} \widehat{a}) \widehat{b}.$$

Proof. Since S_G is an involution and an algebra homomorphism, we infer

$$S_G(a \circ b) = S_G^2 a * S_G b = S_G b * a = b \circ a.$$

The second equation follows from the convolution theorem and from $\operatorname{S}_{\widehat{G}} \operatorname{Four}_G = \operatorname{Four}_G \operatorname{S}_G$. □

For the coefficient field $K := \mathbb{C}$ the preceding considerations can be slightly changed. For a function $a \in \mathbb{C}^G$ we define the complex conjugate function $\overline{a} \in$

$\mathbb{C}^G$ as $\overline{a}(g) := \overline{a(g)}$ and likewise for $a \in \mathbb{C}^{\widehat{G}}$. On $\mathbb{C}^G$ and likewise on $\mathbb{C}^{\widehat{G}}$ we define the standard hermitian inner product

(27)
$$(a_1, a_2) := \sum_{g\in G} \overline{a_1(g)}a_2(g) = \sum_{g\in G}(S\overline{a_1})(-g)a_2(g) = (S\overline{a_1} * a_2)(0) = (\overline{a_1} \circ a_2)(0),$$

where S denotes either S_G or $S_{\widehat{G}}$.

LEMMA 39. *$\widehat{\overline{a}} = \overline{S\widehat{a}}$, and hence $S\widehat{\overline{a}} = \overline{\widehat{a}}$.*

Proof.

$$\widehat{\overline{a}}(\widehat{g}) = \sum_g \overline{a(g)}\langle g, \widehat{g}\rangle = \overline{\sum_g a(g)\langle g, -\widehat{g}\rangle} = \overline{S\widehat{a}(\widehat{g})}. \qquad \square$$

THEOREM 40 (Plancherel). *For $a_1, a_2 \in \mathbb{C}^G$: $N(a_1, a_2) = (\widehat{a_1}, \widehat{a_2})$.*

Proof. Using (27), Theorem 33, Corollary 38, and finally the preceding lemma, we get

$$N(a_1, a_2) = N(\overline{a_1} \circ a_2)(0) = \sum_{\widehat{g}\in\widehat{G}} \widehat{\overline{a_1} \circ a_2}(\widehat{g})$$
$$= \sum_{\widehat{g}\in\widehat{G}}((S\widehat{\overline{a_1}})\widehat{a_2})(\widehat{g}) = \sum_{\widehat{g}\in\widehat{G}}(\widehat{\overline{a_1}}\widehat{a_2})(\widehat{g}) = (\widehat{a_1}, \widehat{a_2}). \qquad \square$$

COROLLARY 41 (orthogonality relations). *For two characters $a_i := \langle -, \widehat{g_i}\rangle$, $\widehat{g_1}$, $\widehat{g_2} \in \widehat{G}$, on G one obtains the orthogonality relation*

$$(a_1, a_2) = N(\delta_{\widehat{g_1}}, \delta_{\widehat{g_2}}) = N\delta_{\widehat{g_1},\widehat{g_2}}.$$

Hence the characters $\langle -, \widehat{g}\rangle$ are an orthogonal basis of $\mathbb{C}^G$.

Proof. This follows from the preceding theorem and $\widehat{\delta_{\widehat{g_i}}} = \langle -, \widehat{g_i}\rangle$ with the roles of G and $\widehat{G}$ interchanged. $\square$

4. Linear complexity. The FFT is a *fast* algorithm for the computation of the DFT. An algorithm is called fast if it has low complexity. In this section we define the *linear complexity* [9, Chap. 13] of matrices and in particular of the DFT to make this terminology precise. See [34] or the book [9] for a comprehensive treatment of *algebraic complexity theory*.

Let K again denote a commutative ring and I, J finite sets, for instance, G and $\widehat{G}$ in the preceding section. We consider the free column module $K^J := K^{J\times 1}$ with the column vectors $\xi = (\xi_j)_{j\in J}$, the free row module $K^{1\times J}$ with the row vectors $x = (x_j)_{j\in J}$ and the standard basis δ_j, $j \in J$, and the free module $K^{I\times J}$ of $I \times J$ matrices with coefficients in K. We identify

(28)
$$K^{I\times J} = \mathrm{Hom}_K(K^J, K^I),\ A = (\xi \mapsto A\xi),\ \text{in particular,}$$
$$K^{1\times J} = \mathrm{Hom}_K(K^J, K),\ x = (\xi \mapsto x\xi = \textstyle\sum_{j\in J} x_j\xi_j).$$

The following considerations will be applied mainly to the Fourier transform $\mathrm{Four}_G \in K^{\widehat{G}\times G} = \mathrm{hom}_K(K^G, K^{\widehat{G}})$. In the complexity theoretic arguments below we will mostly assume $A \in K^{m\times n}$.

Motivation 42. For $A \in K^{I\times J}$ the complexity or cost of an algorithm for the computation of $A\xi$ for arbitrary ξ will be the number of necessary *elementary computation steps* whose cost is defined to be 1. Such a step could be an addition or a multiplication, but we will use steps of the form $(x, y) \mapsto ax + y$ of one multiplication and one addition for numbers a, x, y in K as realized in many standard computer processors. If, more generally, $a \in K$ is a constant and $v, w \in K^{1\times J}$, $\xi \in K^J$ are vectors,

then $(av+w)\xi = a(v\xi)+(w\xi)$; i.e., the result is obtained from the numbers $v\xi$ and $w\xi$ with one elementary computation step. This motivates the following definitions of an algorithm and its complexity.

DEFINITION 43. *Let I, J be finite sets and let $A \in K^{I\times J}$. A* sequential algorithm *of* complexity *or* cost *$M \geq 0$ for A or, in more detail, for the computation of $A\xi$ for all $\xi \in K^J$ is a sequence $v_1, \cdots, v_M$ of row vectors in $K^{1\times J}$ with the following properties.*

(1) *Each row A_{i-}, $i \in I$, belongs to $V := \{\delta_j;\ j \in J\} \cup \{0\} \cup \{v_1, \cdots, v_M\}$.*
(2) *For each $k = 1, \ldots, M$ the vector v_k is given in the form $v_k = av + w$, where $a \in K$ and $v, w \in \{\delta_j;\ j \in J\} \cup \{0\} \cup \{v_1, \cdots, v_{k-1}\}$.*

The data a, v, w depend on k, but do not get an index for notational simplicity. The algorithm to compute $A\xi$ for arbitrary ξ computes the list of M values $v_1\xi, \cdots, v_M\xi$ with M elementary computation steps $v_k\xi = a(v\xi)+(w\xi)$ for values $v\xi$ and $w\xi$ computed earlier, and the $(A\xi)_i = A_{i-}\xi$, $i \in I$, are among these by condition (1) of Definition 43. In contrast, the computation of $0\xi = 0$ and $\delta_j\xi = \xi_j$ is costless. This signifies that the access time to the components of ξ on a real computer is neglected.

LEMMA 44. *For the computation of $A \in K^{m\times n}$ there is an algorithm of complexity $\leq mn$.*

Proof. The algorithm is the standard one for the matrix-vector product and is given by the sequence of vectors

$$\begin{array}{ccccccc}
v_{1,1} := A_{11}\delta_1 & \cdots & v_{1,j} = A_{1j}\delta_j + v_{1,j-1} & \cdots & v_{1,n} = A_{1-} = A_{1n}\delta_n + v_{1,n-1} \\
\cdots & \cdots & \cdots & \cdots & \cdots \\
v_{i,1} := A_{i1}\delta_1 & \cdots & v_{i,j} = A_{ij}\delta_j + v_{i,j-1} & \cdots & v_{i,n} = A_{i-} = A_{in}\delta_n + v_{i,n-1} \\
\cdots & \cdots & \cdots & \cdots & \cdots \\
v_{m,1} := A_{m1}\delta_1 & \cdots & v_{m,j} = A_{mj}\delta_j + v_{m,j-1} & \cdots & v_{m,n} = A_{m-} = A_{mn}\delta_n + v_{m,n-1}.
\end{array}$$ ∎

If in the preceding proof $A_{ij} = 0$ and hence $v_{i,j} = v_{i,j-1}$, one of these vectors can be omitted and hence the following corollary holds.

COROLLARY 45. *If N is the number of nonzero components of a matrix $A \in K^{m\times n}$, then there is an algorithm for A of complexity N.*

DEFINITION AND COROLLARY 46. *The* linear complexity *$\mu(A)$ of a matrix $A \in K^{I\times J}$ is the minimal complexity of an algorithm for A. Then*

(1) *$\mu(A) \leq N$, where N is the number of nonzero components of A;*
(2) *$\mu(A) = 0$ if and only if each row of A is either zero or a standard basis vector;*
(3) *$\mu(1, a_2, \cdots, a_n) \leq n-1$ for $a_2, \cdots, a_n \in K$.*

More generally, if ${}_KW$ and ${}_KV$ are free K-modules of finite dimension $n := [W : K]$ (resp., $m := [V : K]$), if $\underline{w} = (w_1, \cdots, w_n)$ (resp., $\underline{v} = (v_1, \cdots, v_m)$) are fixed chosen bases of these modules, and if $f : W \to V$, $f(\underline{w}) = \underline{v}A$, is a linear map with the matrix A with respect to the chosen bases*, then we define the complexity*

$$\mu(f) := \mu_{\underline{w},\underline{v}}(f) := \mu(A)$$

as that of the matrix A. Of course, basis transformations of V do not have complexity zero in general.

Proof. Concerning the last item the $1 \times n$ matrix $A := (1, a_2, \cdots, a_n)$ admits the algorithm $v_2 := \delta_1 + a_2\delta_2, \cdots, v_n := A$ since the computation of $1\xi_1 = \xi_1$ is of complexity zero. ∎

COROLLARY 47. *If Assumption 29 holds and G is a group of order N, the complexity of the Fourier transform $\mathrm{Four}_G = (\langle g, \widehat{g}\rangle)_{\widehat{g}\in\widehat{G}, g\in G} \in K^{\widehat{G}\times G}$ is at most $N(N-1)$.*

Proof. This follows like item 3 of Corollary 46 since for the column index $g := 0$ and any row index $\widehat{g}$ the entry of Four_G is $\langle 0, \widehat{g}\rangle = 1$. □

Definition and Corollary 48. *If $\alpha : I \to J$ is any map between finite index sets, the map*

$$K^\alpha : K^J \to K^I,\ \xi = (\xi_j)_{j\in J} \mapsto \xi \circ \alpha = (\xi_{\alpha(i)})_{i\in I}$$

is called an index transformation *and is of complexity zero.*

Proof. The computation of $K^\alpha(\xi)_i = \xi_{\alpha(i)}$ just reads off one component of ξ, and these operations are costless. □

The following theorem is decisive for the computation of an upper bound of the FFT.

Theorem 49. *If $A \in K^{m\times n}$ and $B \in K^{n\times p}$, then $\mu(AB) \le \mu(A) + \mu(B)$.*

Proof. Let $v_1, \cdots, v_M$ (resp., $w_1, \cdots, w_N$) be algorithms for A (resp., B) of minimal complexity $M := \mu(A)$ and $N := \mu(B)$. We are going to show that $w_1, \cdots, w_N, v_1B, \cdots, v_MB$ is an algorithm for AB; hence $\mu(AB) \le M + N = \mu(A) + \mu(B)$. Let

$$\begin{aligned} V_A &:= \{\delta_i;\ i = 1, \ldots, n\} \cup \{0\} \cup \{v_1, \cdots, v_M\},\\ V_B &:= \{\delta_j;\ j = 1, \ldots, p\} \cup \{0\} \cup \{w_1, \cdots, w_N\},\\ V_{AB} &:= \{\delta_j;\ j = 1, \ldots, p\} \cup \{0\} \cup \{w_1, \cdots, w_N, v_1B, \cdots, v_MB\}. \end{aligned}$$

By definition $V_B \subseteq V_{AB}$. We have to show that V_{AB} satisfies properties (1) and (2) from Definition 43.

(1) We use $A_{i-} \in V_A,\ B_{j-} \in V_B$ and show that $(AB)_{i-} = A_{i-}B \in V_{AB}$.

Case 1. $A_{i-} = 0 \ \Rightarrow\ A_{i-}B = 0 \in V_{AB}$.

Case 2. $A_{i-} = \delta_k \ \Rightarrow\ A_{i-}B = \delta_k B = B_{k-} \in V_B \subseteq V_{AB}$.

Case 3. $A_{i-} = v_k \ \Rightarrow\ A_{i-}B = v_kB \in V_{AB}$.

(2) We have to show that each vector x in $\{w_1, \cdots, v_MB\}$ is obtained from vectors in V_{AB} preceding x by an elementary computation step. For the vectors $w_l \in V_B$ this is obvious. Therefore consider a vector $x = v_kB \in V_{AB}$, where $v_k = au_1 + u_2$ with $a \in K$ and vectors $u_1, u_2 \in V_A$ preceding v_k. Then $x = v_kB = a(u_1B) + (u_2B)$, and we have to show that u_1B and u_2B precede x in V_{AB}.

Case 1. $u_j = 0 \ \Rightarrow\ u_jB = 0 \in V_{AB}$ preceding x.

Case 2. $u_j =$ standard basis vector $\ \Rightarrow\ u_jB =$ row of $B \ \Rightarrow\ u_jB \in V_B \subseteq V_{AB}$ preceding $x = v_kB$.

Case 3. $u_j = v_l,\ l < k \ \Rightarrow\ u_jB = v_lB \in V_{AB}$ preceding $x = v_kB$.

Hence V_{AB} has the properties of an algorithm. □

Corollary 50. *The complexity of block matrices satisfies*

$$\mu\left(\begin{pmatrix} A & 0\\ 0 & B\end{pmatrix}\right) \le \mu(A) + \mu(B),\ A, B \in K^{\bullet\times\bullet} \text{ of arbitrary size.}$$

Proof. Theorem 49, $\left(\begin{smallmatrix} A & 0 \\ 0 & B \end{smallmatrix}\right) = \left(\begin{smallmatrix} A & 0 \\ 0 & \mathrm{id} \end{smallmatrix}\right)\left(\begin{smallmatrix} \mathrm{id} & 0 \\ 0 & B \end{smallmatrix}\right)$, and the trivial relation $\mu\left(\begin{smallmatrix} A & 0 \\ 0 & \mathrm{id} \end{smallmatrix}\right) = \mu(A)$ yield the result. □

Remark 51 (multiplicative complexity). Let $(X - x_1) * \cdots * (X - x_n) \in \mathbb{Q}[X] \subset \mathbb{C}[X]$ be a rational polynomial with n distinct rational roots $x_i,\ i = 1, \ldots, n$. Then Lagrange interpolation or the Chinese remainder theorem implies the canonical $\mathbb{C}$-isomorphism

$$\varphi : \mathbb{C}[X]_{<n} \cong \mathbb{C}^n,\ f \mapsto (f(x_1), \cdots, f(x_n)),$$

where $\mathbb{C}[X]_{\langle n}$ is the space of polynomials of degree less than n. The domain (resp., the codomain) of φ has the basis $1, \cdots, X^{n-1}$ (resp., the standard basis $\delta_1, \cdots, \delta_n$). For fixed j and $f = a_{n-1}X^{n-1} + \cdots + a_0 \in \mathbb{C}[X]$ euclidean division furnishes

$$f = g(X - x_j) + f(x_j),\ g := b_{n-2}X^{n-2} + \cdots + b_0 \text{ with}$$
$$b_{n-2} = a_{n-1},\ b_{i-1} = a_i + x_j b_i,\ i = n-2, \ldots, 1,\ f(x_j) = a_0 + x_j b_0.$$

This shows that $f(x_j)$ can be computed from f with $n-1$ elementary computation steps and hence $\mu(\varphi) \leq n(n-1)$. Observe, however, that the necessary multiplications have the rational factor x_j. In the multiplicative complexity theory due to Winograd [40] which is, for instance, also used in [26] or [18], these rational multiplications—at least if the x_j are small integers—and rational linear combinations are considered costless, and therefore the complexity of φ is considered to be zero. This is not justified for those computers where the elementary computation step consists of one multiplication and one addition. The same cautionary remarks apply to almost all fast algorithms which use the Chinese remainder theorem and which are not discussed in this paper.

5. The fast Fourier transform (FFT). This is the central section of this article. Assumptions 14 and 29 are in force; in particular all groups are finite abelian of exponent $d > 0$.

Reminder 52. If $\varphi : G \to H$ is a group epimorphism of additive groups, a map $\sigma : H \to G$ is called a *section* of φ if $\varphi\sigma = \mathrm{id}_H$. Then σ is injective, and the elements $\sigma(h),\ h \in H$, are a system of representatives of $G/\ker(\varphi)$; i.e., the map

$$H \times \ker(\varphi) \to G,\ (h, k) \mapsto \sigma(h) + k, \tag{29}$$

is bijective. The map (29) is an isomorphism, and especially $G = \sigma(H) \oplus \ker(\varphi)$ if and only if σ is a monomorphism, but, in general, these properties do *not* hold.

We construct the FFT algorithm by means of a given *filtration* or sequence of subgroups

$$G_0 = 0 \subseteq G_1 \subseteq \cdots \subseteq G_r = G. \tag{30}$$

A filtration (30) gives rise to the commutative exact diagrams (with exact rows and

columns) for $i = 1, \dots, r$:

$$
\begin{array}{ccccccccc}
 & & & & & & 0 & & \\
 & & & & & & \downarrow & & \\
 & & 0 & & & & G_i/G_{i-1} & & \\
 & & \downarrow & & & & \downarrow{\scriptstyle \gamma_i:=\text{inj}} & & \\
0 & \longrightarrow & G_{i-1} & \xrightarrow{\alpha_{i-1}:=\text{inj}} & G & \xrightarrow{\lambda_{i-1}:=\text{can}} & G/G_{i-1} & \longrightarrow & 0 \\
 & & \downarrow{\scriptstyle \beta_i:=\text{inj}} & & \| & & \downarrow{\scriptstyle \nu_i:=\text{can}} & & \\
0 & \longrightarrow & G_i & \xrightarrow{\alpha_i:=\text{inj}} & G & \xrightarrow{\lambda_i:=\text{can}} & G/G_i & \longrightarrow & 0 \\
 & & \downarrow{\scriptstyle \mu_i:=\text{can}} & & & & \downarrow & & \\
 & & G_i/G_{i-1} & & & & 0 & & \\
 & & \downarrow & & & & & & \\
 & & 0 & & & & & &
\end{array}
\tag{31}
$$

where inj (resp., can) are the canonical injections (resp., surjections). Moreover, λ_0 and α_r are isomorphisms, and the compatibility relations $\lambda_{i-1}\alpha_i = \gamma_i\mu_i$ hold. For more flexibility we now make the following, slightly more general assumption.

Assumption 53. Assume that Assumptions 14 and 29 are satisfied and that commutative exact diagrams (32) are given for $i = 1, \dots, r$:

$$
\begin{array}{ccccccccc}
 & & & & & & 0 & & \\
 & & & & & & \downarrow & & \\
 & & 0 & & & & K_i & & \\
 & & \downarrow & & & & \downarrow{\scriptstyle \gamma_i} & & \\
0 & \longrightarrow & G_{i-1} & \xrightarrow{\alpha_{i-1}} & G & \xrightarrow{\lambda_{i-1}} & H_{i-1} & \longrightarrow & 0 \\
 & & \downarrow{\scriptstyle \beta_i} & & \| & & \downarrow{\scriptstyle \nu_i} & & \\
0 & \longrightarrow & G_i & \xrightarrow{\alpha_i} & G & \xrightarrow{\lambda_i} & H_i & \longrightarrow & 0 \\
 & & \downarrow{\scriptstyle \mu_i} & & & & \downarrow & & \\
 & & K_i & & & & 0 & & \\
 & & \downarrow & & & & & & \\
 & & 0 & & & & & &
\end{array}
\tag{32}
$$

such that the following additional properties hold:

(1) G_0 and H_r are zero or λ_0 and α_r are isomorphisms.

(2) The compatibility relations $\lambda_{i-1}\alpha_i = \gamma_i\mu_i$, $i = 1, \dots, r$, hold.

(3) Sections $\sigma_i : K_i \to G_i$, $i = 1, \dots, r$, with $\mu_i\sigma_i = \mathrm{id}_{K_i}$ and $\sigma_i(0) = 0$ are chosen arbitrarily.

These diagrams, in turn, induce the filtration $0 \subseteq \alpha_1(G_1) \subseteq \cdots \subseteq \alpha_r(G_r) = G$ and the isomorphisms

$$G/\alpha_i(G_i) \cong H_i, \bar{g} \mapsto \lambda_i(g),$$
$$G_i/\beta_i(G_{i-1}) \cong \alpha_i(G_i)/\alpha_{i-1}(G_{i-1}) \cong K_i, \overline{g_i} \mapsto \overline{\alpha_i(g_i)} \mapsto \mu_i(g_i).$$

In the situation of the preceding assumption we define

$$N := \operatorname{ord}(G) \text{ and } e_\varrho := \operatorname{ord}(K_\varrho); \text{ hence } N = e_1 * \cdots * e_r. \tag{33}$$

Recall that every group admits a Jordan–Hölder series, i.e., a filtration (30) or diagrams (31) or (32) with the property that the factors $K_\varrho \cong G_\varrho/G_{\varrho-1}$ are simple or have prime order e_ϱ, and that these prime numbers are uniquely determined by G.

Application of the duality functor $G \mapsto \widehat{G}$ to the preceding diagram yields further commutative exact diagrams.

COROLLARY 54. *Under Assumption* 53 *the following diagrams are commutative and exact:*

$$\begin{array}{ccccccccc}
 & & & & 0 & & & & \\
 & & & & \downarrow & & & & \\
 & & 0 & & \widehat{K_j} & & & & \\
 & & \downarrow & & \downarrow{\scriptstyle \mu_j^\star} & & & & \\
0 & \longrightarrow & \widehat{H_j} & \xrightarrow{\lambda_j^\star} & \widehat{G} & \xrightarrow{\alpha_j^\star} & \widehat{G_j} & \longrightarrow & 0 \\
 & & \downarrow{\scriptstyle \nu_j^\star} & & \| & & \downarrow{\scriptstyle \beta_j^\star} & & \\
0 & \longrightarrow & \widehat{H_{j-1}} & \xrightarrow{\lambda_{j-1}^\star} & \widehat{G} & \xrightarrow{\alpha_{j-1}^\star} & \widehat{G_{j-1}} & \longrightarrow & 0 \\
 & & \downarrow{\scriptstyle \gamma_j^\star} & & & & \downarrow & & \\
 & & \widehat{K_j} & & & & 0 & & \\
 & & \downarrow & & & & & & \\
 & & 0 & & & & & &
\end{array} \tag{34}$$

for $j = r, r-1, \ldots, 1$. *Furthermore, they have the additional properties that*

1. $\lambda_0^\star$ *and* $\alpha_r^\star$ *are isomorphisms,*
2. $\alpha_j^\star \lambda_{j-1}^\star = \mu_j^\star \gamma_j^\star$, *and*
3. *sections* $\widehat{\sigma}_j : \widehat{K_j} \to \widehat{H_{j-1}}$ *with* $\gamma_j^\star \widehat{\sigma}_j = \mathrm{id}_{\widehat{K_j}}$ *and* $\widehat{\sigma}_j(0) = 0$ *are chosen arbitrarily.*

Thus, up to the reverse numbering, the diagrams from (34) satisfy the same properties as the diagrams (32) of Assumption 53, and the same arguments apply to both of them.

LEMMA 55. *Under Assumption* 53 *the map*

$$\operatorname{ind} : \textstyle\prod_{i=1}^r K_i \to G,\ k = (k_i)_{i=1,\ldots,r} \mapsto \operatorname{ind}(k) := \sum_{i=1}^r \alpha_i \sigma_i(k_i),$$

is bijective; i.e., every $g \in G$ *admits a unique representation* $g = \sum_{i=1}^r \alpha_i \sigma_i(k_i)$ *with* $k_i \in K_i$.

Proof. By induction on $i = 0, \dots, r$ we show that $g = \alpha_i(g_i) \in \alpha_i(G_i), g_i \in G_i$, admits a unique representation

$$g = \sum_{j=0}^{i} \alpha_j \sigma_j(k_j), k_j \in K_j.$$

The assertion is trivial for $i = 0$ and $\alpha_0(G_0) = 0$. For $i > 0$ the exact sequence

$$0 \to G_{i-1} \xrightarrow{\beta_i} G_i \underset{\sigma_i}{\overset{\mu_i}{\rightleftarrows}} K_i \to 0$$

with the section σ_i of μ_i and (29) imply the unique representation

$$g_i = \beta_i(g_{i-1}) + \sigma_i(k_i), g_{i-1} \in G_{i-1}, k_i \in K_i,$$

and

$$g = \alpha_i(g_i) = \alpha_i\beta_i(g_{i-1}) + \alpha_i\sigma_i(k_i) = \alpha_{i-1}(g_{i-1}) + \alpha_i\sigma_i(k_i).$$

By induction there are unique $k_j \in K_j,\ j = 0, \dots, i-1$, with

$$\alpha_{i-1}(g_{i-1}) = \sum_{j=0}^{i-1} \alpha_j\sigma_j(k_j);\ \text{hence } g = \alpha_i(g_i) = \sum_{j=0}^{i} \alpha_j\sigma_j(k_j). \qquad \square$$

Application of Lemma 55 to diagram (34) yields the corollary.

COROLLARY 56. *Under Assumption* 53 *every* $\widehat{g} \in \widehat{G}$ *has a unique representation*

$$\widehat{g} = \sum_{j=1}^{r} \lambda_{j-1}^{\star}\widehat{\sigma}_j(\widehat{k}_j), \widehat{k}_j \in \widehat{K_j},$$

or, in other terms, the map

$$\widehat{\mathrm{ind}} : \textstyle\prod_{j=1}^{r} \widehat{K_j} \to \widehat{G}, \widehat{k} = (\widehat{k}_j)_{j=1,\dots,r} \mapsto \widehat{\mathrm{ind}}(\widehat{k}) := \sum_{j=1}^{r} \lambda_{j-1}^{\star}\widehat{\sigma}_j(\widehat{k}_j),$$

is bijective.

COROLLARY AND DEFINITION 57 (index transformations). *The maps*

$$\mathrm{Ind} := K^{\mathrm{ind}} : K^G \to K^{\prod_{i=1}^{r} K_i}, a \mapsto a_0 := a \circ \mathrm{ind},$$
$$a_0(k_1, \cdots, k_r) = a\left(\textstyle\sum_{i=1}^{r} \alpha_i\sigma_i(k_i)\right), k_i \in K_i,$$

and

$$\widehat{\mathrm{Ind}} := K^{\widehat{\mathrm{ind}}} : K^{\widehat{G}} \to K^{\prod_{j=1}^{r} \widehat{K_j}}, b \mapsto b_r := b \circ \widehat{\mathrm{ind}},$$
$$b_r(\widehat{k}_1, \cdots, \widehat{k}_r) = b\left(\textstyle\sum_{j=1}^{r} \lambda_{j-1}^{\star}\widehat{\sigma}_j(\widehat{k}_j)\right)$$

are K*-isomorphisms and* index transformations *according to Definition and Corollary* 48, *and hence are of complexity zero.*

The following easy considerations are central for the fast computation of the Fourier transform $\widehat{a}$ of a function $a \in K^G$ given by $\widehat{a}(\widehat{g}) = \sum_{g \in G} a(g)\langle g, \widehat{g}\rangle$. According to Lemmas 55 and 56 we write g and $\widehat{g}$ as

$$g = \mathrm{ind}(k) = \textstyle\sum_{i=1}^{r} \alpha_i\sigma_i(k_i), k = (k_i)_{i=1,\dots,r} \in \prod_{i=1}^{r} K_i,$$
$$\widehat{g} = \widehat{\mathrm{ind}}(\widehat{k}) = \textstyle\sum_{j=1}^{r} \lambda_{j-1}^{\star}\widehat{\sigma}_j(\widehat{k}_j), \widehat{k} = (\widehat{k}_j)_{j=1,\dots,r} \in \prod_{j=1}^{r} \widehat{K_j},$$

and compute the bimultiplicative form $\langle g, \widehat{g}\rangle$ as

$$\begin{aligned}\langle g, \widehat{g}\rangle &= \Big\langle \textstyle\sum_{i=1}^r \alpha_i\sigma_i(k_i), \sum_{j=1}^r \lambda_{j-1}^\star \widehat{\sigma}_j(\widehat{k}_j)\Big\rangle = \prod_{i,j=1}^r \mathrm{fact}_{ij}(k,\widehat{k}), \text{ where}\\ \mathrm{fact}_{ij}(k,\widehat{k}) &:= \langle \alpha_i\sigma_i(k_i), \lambda_{j-1}^\star\widehat{\sigma}_j(\widehat{k}_j)\rangle = \langle \lambda_{j-1}\alpha_i\sigma_i(k_i), \widehat{\sigma}_j(\widehat{k}_j)\rangle.\end{aligned} \tag{35}$$

For $j > i$ the commutativity of the diagram (32) furnishes

$$\begin{aligned}\lambda_{j-1}\circ\alpha_i = \nu_{j-1}\circ\cdots\circ\nu_{i+1}\circ\lambda_i\circ\alpha_i = 0 \text{ since}\\ \lambda_i\circ\alpha_i = 0;\ \text{hence}\ \mathrm{fact}_{i,j}(k,\widehat{k}) = \langle 0, \widehat{\sigma}_j(\widehat{k}_j)\rangle = 1.\end{aligned}$$

For $j = i$ we use the compatibility condition (2) from Assumption 53 and infer

$$\begin{aligned}\mathrm{fact}_{ii}(k,\widehat{k}) &= \langle \lambda_{i-1}\alpha_i\sigma_i(k_i), \widehat{\sigma}_i(\widehat{k}_i)\rangle = \langle \gamma_i\mu_i\sigma_i(k_i), \widehat{\sigma}_i(\widehat{k}_i)\rangle\\ &= \langle \mu_i\sigma_i(k_i), \gamma_i^\star\widehat{\sigma}_i(\widehat{k}_i)\rangle = \langle k_i, \widehat{k}_i\rangle.\end{aligned}$$

Thus

$$\mathrm{fact}_{ij}(k,\widehat{k}) = \langle \alpha_i\sigma_i(k_i), \lambda_{j-1}^\star\widehat{\sigma}_j(\widehat{k}_j)\rangle = \begin{cases}\langle k_i, \widehat{k}_i\rangle & \text{if } i = j,\\ 1 & \text{if } i < j.\end{cases} \tag{36}$$

From (35) and (36) we infer

$$\begin{aligned}\langle g, \widehat{g}\rangle &= \textstyle\prod_{j\le i} \mathrm{fact}_{ij}(k,\widehat{k}) = \prod_{i=1}^r\prod_{j=1}^i \mathrm{fact}_{ij}(k,\widehat{k})\\ &= \textstyle\prod_{i=1}^r \varphi_i(k_i;\widehat{k}_1,\cdots,\widehat{k}_i), \text{ where } \varphi_i : K_i\times\widehat{K_1}\times\cdots\times\widehat{K_i}\to K,\\ \varphi_i(k_i;\widehat{k}_1,\cdots,\widehat{k}_i) &:= \textstyle\prod_{j=1}^i \mathrm{fact}_{ij}(k,\widehat{k}) = \Big\langle \alpha_i\sigma_i(k_i), \sum_{j=1}^i \lambda_{j-1}^\star\widehat{\sigma}_j(\widehat{k}_j)\Big\rangle.\end{aligned} \tag{37}$$

The decisive property of the functions φ_i is that they depend on the first i components $\widehat{k}_1,\cdots,\widehat{k}_i$ of $\widehat{k}$ only. In the same fashion (35) and (36) give rise to the representation

$$\begin{aligned}\langle g, \widehat{g}\rangle &= \textstyle\prod_{j=1}^r\prod_{i=j}^r \mathrm{fact}_{ij}(k,\widehat{k}) = \prod_{j=1}^r \widehat{\varphi}_j(k_j,\cdots,k_r;\widehat{k}_j) \qquad \text{with}\\ &\widehat{\varphi}_j : K_j\times\cdots\times K_r\times\widehat{K_j}\to K,\\ \widehat{\varphi}_j(k_j,\cdots,k_r;\widehat{k}_j) &:= \textstyle\prod_{i=j}^r \mathrm{fact}_{ij}(k,\widehat{k}) = \Big\langle \sum_{i=j}^r \alpha_i\sigma_i(k_i), \lambda_{j-1}^\star\widehat{\sigma}_j(\widehat{k}_j)\Big\rangle.\end{aligned} \tag{38}$$

For fixed $\widehat{g} = \widehat{\mathrm{ind}}(\widehat{k}) \in \widehat{G}$ Lemma 55 and (37) imply

$$\begin{aligned}\widehat{a}(\widehat{g}) &= \textstyle\sum_{g\in G} a(g)\langle g, \widehat{g}\rangle = \sum_{k\in\prod_{i=1}^r K_i} a(\mathrm{ind}(k))\langle \mathrm{ind}(k), \widehat{\mathrm{ind}}(\widehat{k})\rangle\\ &= \textstyle\sum_{k_1\in K_1,\cdots,k_r\in K_r} a_0(k_1,\cdots,k_r)\prod_{i=1}^r \varphi_i(k_i;\widehat{k}_1,\cdots,\widehat{k}_i),\end{aligned} \tag{39}$$

where $a_0 = a\circ\mathrm{ind} = \mathrm{Ind}(a)$ according to Corollary 57. This formula for $\widehat{a}(\widehat{g})$ suggests that we define, for $\varrho = 1,\dots,r$, intermediate functions

$$\begin{aligned}a_\varrho &: \widehat{K_1}\times\cdots\times\widehat{K_\varrho}\times K_{\varrho+1}\times\cdots\times K_r\to K,\\ &a_\varrho(\widehat{k}_1,\cdots,\widehat{k}_\varrho,k_{\varrho+1},\cdots,k_r)\\ &:= \textstyle\sum_{k_1\in K_1,\cdots,k_\varrho\in K_\varrho} a_0(k_1,\cdots,k_r)\prod_{i=1}^\varrho \varphi_i(k_i;\widehat{k}_1,\cdots,\widehat{k}_i).\end{aligned} \tag{40}$$

By definition and according to (39), we have

$$a_0(k_1,\cdots,k_r) = a(\mathrm{ind}(k)) \text{ and } a_r(\widehat{k}_1,\cdots,\widehat{k}_r) = \widehat{a}(\widehat{\mathrm{ind}}(\widehat{k})).$$

The next theorem is the most important result of this paper. Its main idea, viz., the recursive computation of the DFT, is due to Cooley and Tukey [16] who developed the algorithm for the group $G = \mathbb{Z}/\mathbb{Z}2^r$ on the basis of the filtration

$$G_0 := 0 \subset G_1 := \mathbb{Z}2^{r-1}/\mathbb{Z}2^r \subset \cdots \subset G_i := \mathbb{Z}2^{r-i}/\mathbb{Z}2^r \subset \cdots \subset G_r = G.$$

Later it turned out that the same idea had been used before, in particular, by Gauss. See the introduction of [8] for a short historical survey. The "decimation in time" and "decimation in frequency" terminology used below comes from the application of the DFT to the computation of one-dimensional Fourier integrals or series where $\mathbb{R}$ or $\mathbb{Z}$ are interpreted as time or frequency models, and has been adapted from [8, pp. 188–191].

THEOREM 58 (Cooley–Tukey FFT or decimation in time). *The following recursive algorithm computes the Fourier transform $\widehat{a} \in K^{\widehat{G}}$ of a function $a \in K^G$. By induction on $\varrho = 0, \ldots, r$ define functions*

$$\begin{gathered}
a_\varrho : \widehat{K_1} \times \cdots \times \widehat{K_\varrho} \times K_{\varrho+1} \times \cdots \times K_r \to K \qquad \textit{by} \\
a_0(k_1, \cdots, k_r) := a\left(\textstyle\sum_{i=1}^r \alpha_i \sigma_i(k_i)\right) \ \textit{and for } 1 \le \varrho \le r \\
a_\varrho(\widehat{k}_1, \cdots, \widehat{k}_\varrho, k_{\varrho+1}, \cdots, k_r) \\
:= \textstyle\sum_{k_\varrho \in K_\varrho} a_{\varrho-1}(\widehat{k}_1, \cdots, \widehat{k}_{\varrho-1}, k_\varrho, k_{\varrho+1}, \cdots, k_r)\varphi_\varrho(k_\varrho; \widehat{k}_1, \cdots, \widehat{k}_\varrho), \qquad \textit{where} \\
\varphi_\varrho(k_\varrho; \widehat{k}_1, \cdots, \widehat{k}_\varrho) = \left\langle \alpha_\varrho \sigma_\varrho(k_\varrho), \textstyle\sum_{j=1}^\varrho \lambda_{j-1}^\star \widehat{\sigma}_j(\widehat{k}_j) \right\rangle .
\end{gathered}$$

Then

$$\widehat{a}(\widehat{g}) = a_r(\widehat{k}_1, \cdots, \widehat{k}_r) \textit{ for } \widehat{g} = \widehat{\mathrm{ind}}(\widehat{k}) = \sum_{j=1}^r \lambda_{j-1}^\star \widehat{\sigma}_j(\widehat{k}_j) \in \widehat{G}, \widehat{k}_j \in \widehat{K_j}.$$

Proof. It remains to show that the functions a_ϱ defined in (40) satisfy these recursive relations. But for $\varrho > 0$

$$\begin{gathered}
a_\varrho(\widehat{k}_1, \cdots, \widehat{k}_\varrho, k_{\varrho+1}, \cdots, k_r) \\
= \textstyle\sum_{k_1, \cdots, k_\varrho} a_0(k_1, \cdots, k_r) \prod_{i=1}^\varrho \varphi_i(k_i; \widehat{k}_1, \cdots, \widehat{k}_i) \\
= \textstyle\sum_{k_\varrho \in K_\varrho} \varphi_\varrho(k_\varrho; \widehat{k}_1, \cdots, \widehat{k}_\varrho) \sum_{k_1, \cdots, k_{\varrho-1}} a_0(k_1, \cdots, k_r) \prod_{i=1}^{\varrho-1} \varphi_i(k_i; \widehat{k}_1, \cdots, \widehat{k}_i) \\
= \textstyle\sum_{k_\varrho \in K_\varrho} \varphi_\varrho(k_\varrho; \widehat{k}_1, \cdots, \widehat{k}_\varrho) a_{\varrho-1}(\widehat{k}_1, \cdots, \widehat{k}_{\varrho-1}, k_\varrho, \cdots, k_r). \qquad \square
\end{gathered}$$

The induction formula of the preceding theorem can be given another traditional form. From the definition of φ_ϱ in (37) and from (36) we infer

$$\begin{aligned}
\varphi_\varrho(k_\varrho; \widehat{k}_1, \cdots, \widehat{k}_\varrho) &= \left\langle \alpha_\varrho \sigma_\varrho(k_\varrho), \textstyle\sum_{j=1}^\varrho \lambda_{j-1}^\star \widehat{\sigma}_j(\widehat{k}_j) \right\rangle \\
&= \langle k_\varrho, \widehat{k}_\varrho \rangle \left\langle \alpha_\varrho \sigma_\varrho(k_\varrho), \textstyle\sum_{j=1}^{\varrho-1} \lambda_{j-1}^\star \widehat{\sigma}_j(\widehat{k}_j) \right\rangle
\end{aligned}$$

or

$$\begin{gathered}
\varphi_\varrho(k_\varrho; \widehat{k}_1, \cdots, \widehat{k}_\varrho) = \langle k_\varrho, \widehat{k}_\varrho \rangle \tau_\varrho(k_\varrho; \widehat{k}_1, \cdots, \widehat{k}_{\varrho-1}) \text{ with} \\
\tau_\varrho(k_\varrho; \widehat{k}_1, \cdots, \widehat{k}_{\varrho-1}) := \left\langle \alpha_\varrho \sigma_\varrho(k_\varrho), \textstyle\sum_{j=1}^{\varrho-1} \lambda_{j-1}^\star \widehat{\sigma}_j(\widehat{k}_j) \right\rangle .
\end{gathered} \tag{41}$$

The elements τ_ϱ are roots of unity and hence nonzero and are usually called the *twiddle factors* [8, p. 191], [5, p. 121]. With their help we define, for $\varrho = 1, \dots, r$, the isomorphisms

$$
\begin{aligned}
T_\varrho &: K^{\widehat{K_1}\times\cdots\times\widehat{K_{\varrho-1}}\times K_\varrho\times\cdots\times K_r} \to K^{\widehat{K_1}\times\cdots\times\widehat{K_\varrho}\times K_{\varrho+1}\times\cdots\times K_r},\\
&T_\varrho(c)(\widehat{k}_1, \cdots, \widehat{k}_\varrho, k_{\varrho+1}, \cdots, k_r)\\
&:= \textstyle\sum_{k_\varrho\in K_\varrho} c(\widehat{k}_1, \cdots, \widehat{k}_{\varrho-1}, k_\varrho, \cdots, k_r)\varphi_\varrho(k_\varrho; \widehat{k}_1, \cdots, \widehat{k}_\varrho)\\
&= \mathrm{Four}_{K_\varrho}[c(\widehat{k}_1, \cdots, \widehat{k}_{\varrho-1}, -, k_{\varrho+1}, \cdots, k_r)\tau_\varrho(-; \widehat{k}_1, \cdots, \widehat{k}_{\varrho-1})](\widehat{k}_\varrho).
\end{aligned}
\tag{42}
$$

Here the argument of $\mathrm{Four}_{K_\varrho}$ is a function in K^{K_ϱ} which depends on the parameters $\widehat{k}_1, \cdots, \widehat{k}_{\varrho-1}, k_{\varrho+1}, \cdots, k_r$. The map T_ϱ is an isomorphism since the multiplication with τ_ϱ and the Fourier transform $\mathrm{Four}_{K_\varrho}$ are bijective.

THEOREM 59. *In the situation of Theorem* 58 *the induction formula computing* a_ϱ *from* $a_{\varrho-1}$ *can be expressed as* $a_\varrho = T_\varrho(a_{\varrho-1})$, $\varrho = 1, \dots, r$; *hence*

$$\mathrm{Four}_G = \widehat{\mathrm{Ind}}^{-1} \circ T_r \circ \cdots \circ T_1 \circ \mathrm{Ind} : K^G \to K^{\widehat{G}}.$$

With $e_\varrho := \mathrm{ord}(K_\varrho)$ *and* $N := e_1 * \cdots * e_r = \mathrm{ord}(G)$ *the complexity satisfies*

$$\mu(\mathrm{Four}_G) \le N(e_1 + \cdots + e_r - r).$$

Proof. The first assertion is obvious. Concerning the complexity recall the condition $\sigma_\varrho(0) = 0$ from Assumption 53 and

$$\varphi_\varrho(k_\varrho; \widehat{k}_1, \cdots, \widehat{k}_\varrho) = \left\langle \alpha_\varrho\sigma_\varrho(k_\varrho), \textstyle\sum_{j=1}^{\varrho} \lambda_{j-1}^\star \widehat{\sigma}_j(\widehat{k}_j) \right\rangle; \text{ hence } \varphi_\varrho(0; \widehat{k}_1, \cdots, \widehat{k}_\varrho) = 1.$$

From this and (42) we infer $\mu(T_\varrho) \le N(e_\varrho - 1)$ as in the proof of part 3 of Corollary 46. Since index transformations are costless according to Definition and Corollary 48, we conclude by means of Theorem 49 that

$$\mu(\mathrm{Four}_G) \le \textstyle\sum_\varrho \mu(T_\varrho) \le N(e_1 - 1 + \cdots + e_r - 1) = N(e_1 + \cdots + e_r - r). \qquad \square$$

Remark 60 (butterfly diagrams). In the literature special cases of the induction formula of Theorem 58 are often represented by means of a directed graph or so-called butterfly diagram. Such a graph can be introduced in general; it is, however, useless for the actual execution of the fast algorithm. Its graphical representation in the plane is also of no practical significance and, moreover, is complicated except in the simplest cases such as $G = \mathbb{Z}/\mathbb{Z}8$ where it is usually shown. Indeed, consider the graph $\Gamma := (V, E)$ with vertex (resp., edge) sets V (resp., E), where

$$V := \biguplus_{\varrho=0}^r V_\varrho, V_\varrho := \widehat{K_1} \times \cdots \times \widehat{K_\varrho} \times K_{\varrho+1} \times \cdots \times K_r,\ E \subset V \times V,$$

with edges from $(\widehat{k}_1, \cdots, \widehat{k}_{\varrho-1}, k_\varrho, \cdots, k_r)$ to $(\widehat{k}_1, \cdots, \widehat{k}_\varrho, k_{\varrho+1}, \cdots, k_r)$ or from $V_{\varrho-1}$ to V_ϱ only. For $w = (\widehat{k}_1, \cdots, \widehat{k}_\varrho, k_{\varrho+1}, \cdots, k_r) \in V_\varrho$, $\varrho \ge 1$, there results the bijection

$$
\begin{aligned}
K_\varrho &\cong \{(v, w); (v, w) \text{ is an edge of } \Gamma \text{ with endpoint } w\},\\
k_\varrho &\mapsto (v, w), v := (\widehat{k}_1, \cdots, \widehat{k}_{\varrho-1}, k_\varrho, \cdots, k_r) \in V_{\varrho-1}.
\end{aligned}
$$

With the abbreviation $a(v) := a_{\varrho-1}(\widehat{k}_1, \cdots, \widehat{k}_{\varrho-1}, k_\varrho, \cdots, k_r)$ the recursion formula of Theorem 58 has the form

$$a(w) = \sum a(v)\varphi_\varrho(k_\varrho; \widehat{k}_1, \cdots, \widehat{k}_\varrho),$$

where $v = (\widehat{k}_1, \cdots, \widehat{k}_{\varrho-1}, k_\varrho, \cdots, k_r)$ runs over all sources of edges with sink w.

The next theorem on the "decimation in frequency" FFT computes $\mathrm{Four}_{\widehat{G}} : K^{\widehat{G}} \to K^G$ and is proved in the same fashion as Theorem 58 on the basis of (38) instead of (37). For the choice $\widehat{G} = G$ it yields a second fast algorithm for the computation of Four_G (compare [8, p. 192]).

THEOREM 61 (Sande–Tukey FFT or decimation in frequency). *Using data from Assumption* 53 *and Corollary* 54, *the following algorithm computes the Fourier transform* $\widehat{b} \in K^G$ *of a function* $b \in K^{\widehat{G}}$. *By recursion from* $\varrho = r$ *to* 0 *define functions*

$$b_\varrho : \widehat{K_1} \times \cdots \times \widehat{K_\varrho} \times K_{\varrho+1} \times \cdots \times K_r \to K, \varrho = r, \ldots, 0,$$
$$b_r(\widehat{k}_1, \cdots, \widehat{k}_r) := b\left(\textstyle\sum_{j=1}^r \lambda_{j-1}^\star \widehat{\sigma}_j(\widehat{k}_j)\right), \widehat{k}_j \in \widehat{K}_j, \text{ and for } r \geq \varrho > 0$$
$$b_{\varrho-1}(\widehat{k}_1, \cdots, \widehat{k}_{\varrho-1}, k_\varrho, \cdots, k_r)$$
$$:= \textstyle\sum_{\widehat{k}_\varrho \in \widehat{K}_\varrho} b_\varrho(\widehat{k}_1, \cdots, \widehat{k}_\varrho, k_{\varrho+1}, \cdots, k_r)\widehat{\varphi}_\varrho(k_\varrho, \cdots, k_r; \widehat{k}_\varrho).$$

Then

$$\widehat{b}(g) = \textstyle\sum_{\widehat{g} \in \widehat{G}} b(\widehat{g})\langle g, \widehat{g}\rangle = b_0(k_1, \cdots, k_r) \text{ for } g = \sum_{i=1}^r \alpha_i\sigma_i(k_i) \in G, k_i \in K_i.$$

Proof. According to (38) we have

$$\widehat{b}(g) = \textstyle\sum_{\widehat{k} \in \prod_{j=1}^r \widehat{K_j}} b(\widehat{\mathrm{ind}}(\widehat{k}))\langle \mathrm{ind}\, k, \widehat{\mathrm{ind}}(\widehat{k})\rangle$$
$$= \textstyle\sum_{\widehat{k}_1 \in \widehat{K_1}, \cdots, \widehat{k}_r \in \widehat{K_r}} b_r(\widehat{k}_1, \cdots, \widehat{k}_r) \prod_{j=1}^r \widehat{\varphi}_j(k_j, \cdots, k_r; \widehat{k}_j).$$

In analogy to (40) we define functions $b_\varrho, r \geq \varrho \geq 0$, by

$$b_r(\widehat{k}_1, \cdots, \widehat{k}_r) := b(\widehat{\mathrm{ind}}(\widehat{k})) \text{ and for } \varrho < r \text{ by}$$
$$b_\varrho(\widehat{k}_1, \cdots, \widehat{k}_\varrho, k_{\varrho+1}, \cdots, k_r)$$
$$= \textstyle\sum_{\widehat{k}_{\varrho+1} \in \widehat{K}_{\varrho+1}, \cdots, \widehat{k}_r \in \widehat{K}_r} b_r(\widehat{k}_1, \cdots, \widehat{k}_r) \prod_{j=\varrho+1}^r \widehat{\varphi}_j(k_j, \cdots, k_r; \widehat{k}_j),$$

and show that they satisfy the recursive relations from which the theorem follows directly. But, indeed,

$$b_{\varrho-1}(\widehat{k}_1, \cdots, \widehat{k}_{\varrho-1}, k_\varrho, \cdots, k_r)$$
$$= \textstyle\sum_{\widehat{k}_\varrho \in \widehat{K}_\varrho} \widehat{\varphi}_\varrho(k_\varrho, \cdots, k_r; \widehat{k}_\varrho) \sum_{\widehat{k}_{\varrho+1} \in \widehat{K}_{\varrho+1}, \cdots, \widehat{k}_r \in \widehat{K}_r} b_r(\widehat{k}_1, \cdots, \widehat{k}_r)$$
$$* \textstyle\prod_{j=\varrho+1}^r \widehat{\varphi}_j(k_j, \cdots, k_r; \widehat{k}_j)$$
$$= \textstyle\sum_{\widehat{k}_\varrho \in \widehat{K}_\varrho} \widehat{\varphi}_\varrho(k_\varrho, \cdots, k_r; \widehat{k}_\varrho) b_\varrho(\widehat{k}_1, \cdots, \widehat{k}_\varrho, k_{\varrho+1}, \cdots, k_r). \qquad \square$$

In analogy to (41) and (42) we also obtain, for $\varrho = r, \ldots, 1$,

$$\widehat{\varphi}_\varrho(k_\varrho, \cdots, k_r; \widehat{k}_\varrho) = \langle k_\varrho, \widehat{k}_\varrho\rangle \widehat{\tau}_\varrho(k_{\varrho+1}, \cdots, k_r; \widehat{k}_\varrho),$$
$$\widehat{\tau}_\varrho(k_{\varrho+1}, \cdots, k_r; \widehat{k}_\varrho) := \left\langle \textstyle\sum_{i=\varrho+1}^r \alpha_i\sigma_i(k_i), \lambda_{\varrho-1}^\star \widehat{\sigma}_\varrho(\widehat{k}_\varrho)\right\rangle, \tag{43}$$

and define the isomorphism

$$\begin{gathered}\widehat{T}_\varrho : K^{\widehat{K_1}\times\cdots\times\widehat{K_\varrho}\times K_{\varrho+1}\times\cdots\times K_r} \cong K^{\widehat{K_1}\times\cdots\times\widehat{K_{\varrho-1}}\times K_\varrho\times\cdots\times K_r},\\ \widehat{T}_\varrho(c) := \mathrm{Four}_{\widehat{K_\varrho}}[c(\widehat{k}_1,\cdots,\widehat{k}_{\varrho-1},-,k_{\varrho+1},\cdots,k_r)\widehat{\tau}_\varrho(k_{\varrho+1},\cdots,k_r;-)].\end{gathered} \tag{44}$$

THEOREM 62. *In the situation of Theorem* 61 *and with the isomorphisms* $\widehat{T}_\varrho$ *from* (44) *and* $\mathrm{Ind}, \widehat{\mathrm{Ind}}$ *from Corollary* 57*, we have*

$$\begin{gathered}\mathrm{Four}_{\widehat{G}} = \mathrm{Ind}^{-1}\circ\widehat{T}_1\circ\cdots\circ\widehat{T}_r\circ\widehat{\mathrm{Ind}} \text{ and}\\ \mu(\mathrm{Four}_{\widehat{G}}) \le N(e_1+\cdots+e_r-r),\end{gathered}$$

where $e_\varrho := \mathrm{ord}(K_\varrho)$ *and* $N := e_1 * \cdots * e_r = \mathrm{ord}(G)$.

Theorems 59 and 62 signify that the FFT-algorithms in Theorems 58 and 61 are *fast*, i.e., of relatively *low complexity* $N(e_1+\cdots+e_r-r)$ instead of the $N(N-1)$ of the direct computation of Four_G. Recall that the algorithms and their complexity depend on the diagrams from Assumption 53.

The best FFT-algorithms according to the preceding theorems are obtained when the diagrams from Assumption 53 are constructed by means of a Jordan–Hölder series of G (see the explanation after (33)). Then $N = e_1 * \cdots * e_r$ is the prime factor decomposition of G.

For the next theorem we introduce a logarithm type arithmetic function Λ. Let $\mathbb{N} := \{0,1,\cdots\}$ denote the additive monoid of natural numbers and $\mathbb{N}_{>0} := \{1,2,\cdots\}$ the multiplicative monoid of positive numbers. Every $N \in \mathbb{N}_{>0}$ admits the unique prime factor decomposition

$$N = \textstyle\prod_{p\in\mathcal{P}} p^{\mathrm{ord}_p(N)},\ \mathrm{ord}_p(N) = 0 \text{ for almost all } p,$$

where $\mathcal{P} = \{2,3,5,\cdots\}$ is the set of prime numbers. The standard isomorphism

$$\mathbb{N}_{>0} \cong \mathbb{N}^{(\mathcal{P})} := \{\nu \in \mathbb{N}^{\mathcal{P}};\ \nu(p) = 0 \text{ for almost all } p \in \mathcal{P}\},\ N \mapsto (\mathrm{ord}_p(N))_{p\in\mathcal{P}},$$

follows and induces the composed epimorphism

$$\Lambda : \mathbb{N}_{>0} \cong \mathbb{N}^{(\mathcal{P})} \to \mathbb{N},\ N \mapsto (\mathrm{ord}_p(N))_{p\in\mathcal{P}} \mapsto \Lambda(N) := \textstyle\sum_{p\in\mathcal{P}}(p-1)\,\mathrm{ord}_p(N); \tag{45}$$

hence $\Lambda(1) = 0,$ and $\Lambda(M*N) = \Lambda(M) + \Lambda(N)$. The obvious inequality

$$\begin{gathered}1+(p-1)m < (1+p-1)^m = p^m \text{ for } m \ge 2 \text{ implies } \Lambda(N) \le N-1 \text{ and}\\ \Lambda(N) = N-1 \ \Leftrightarrow\ N = 1 \text{ or } N \text{ is prime.}\end{gathered}$$

THEOREM 63. *Let* G *be an abelian group of exponent* d *and order* N*. Then*

$$\mu(\mathrm{Four}_G) \le N\Lambda(N) \le N(N-1).$$

The equality $N(N-1) = N\Lambda(N)$ *holds if and only if* G *is simple or zero.*

Proof. Choose a Jordan–Hölder series of G, the corresponding diagrams (31) as those in (32), and the FFT-algorithms derived from these diagrams. Then the numbers e_ϱ are exactly the prime factors of $N = e_1 * \cdots * e_r$ and

$$\begin{gathered}\Lambda(e_\varrho) = e_\varrho - 1,\ \Lambda(N) = \Lambda(e_1 * \cdots * e_r) = \textstyle\sum_\varrho \Lambda(e_\varrho) = \sum_\varrho (e_\varrho - 1);\ \text{hence}\\ \mu(\mathrm{Four}_G) \le N(e_1 - 1 + \cdots + e_r - 1) = N\Lambda(N). \qquad \square\end{gathered}$$

Examples 64. Let G be a group of order N.

(1) The first standard case was that of Cooley and Tukey [16]:

$$N = 2^r,\ \Lambda(N) = (2-1) * r = r,\ \mu(\mathrm{Four}_G) \leq 2^r * r = N \log_2(N).$$

(2)

$$N = 675 = 3^3 * 5^2,\ \Lambda(N) = (3-1) * 3 + (5-1) * 2 = 14 \text{ and}$$
$$N\Lambda(N) = 675 * 14 = 9450 < N(N-1) = 454950.$$

(3) $G := \mathbb{Z}/\mathbb{Z}2^{10} \times \mathbb{Z}/\mathbb{Z}2^{10},\ N = 2^{20}$. This group can be considered as a lattice with approximately one million points and may, for instance, be used for digital image processing. The direct computation of Four_G has complexity $N(N-1) \sim 2^{40}$, whereas that of the FFT is $20 * 2^{20} = 1,25 * 2^{24}$. The improvement of the complexity is dramatic.

6. The FFT in the standard cases. Assumption 29 remains in force. In this section we derive the standard special cases of the FFT and start with that of a cyclic group $G = \mathbb{Z}/\mathbb{Z}n$ of exponent $d > 0$, i.e., with $n \mid d$. As usual in the engineering literature we often identify

$$\mathbb{Z}/\mathbb{Z}n = \{0, 1, \cdots, n-1\},\ k = \overline{k},\ 0 \leq k \leq n-1, \tag{46}$$

and emphasize that the necessary care has to be taken in context with this identification. For $G = \mathbb{Z}/\mathbb{Z}n$ we choose

$$\widehat{G} := G = \mathbb{Z}/\mathbb{Z}n, \langle \overline{k}, \overline{l} \rangle := \zeta^{kld/n},\ \overline{k}, \overline{l} \in \mathbb{Z}/\mathbb{Z}n, \tag{47}$$

according to Theorem 2. A factorization $n = n_1 n_2$ of n gives rise to the exact sequence with a natural section $\sigma : \mathbb{Z}/\mathbb{Z}n_2 \to \mathbb{Z}/\mathbb{Z}n$:

(48)

$$\begin{array}{ccccccccc} 0 & \longrightarrow & \mathbb{Z}/\mathbb{Z}n_1 & \xrightarrow{\text{inj}} & \mathbb{Z}/\mathbb{Z}n & \xrightarrow{\text{can}} & \mathbb{Z}/\mathbb{Z}n_2 & \longrightarrow & 0 \\ & & \| & & \| & & \| & & \\ & & \{0, \cdots, n_1 - 1\} & & \{0, \cdots, n-1\} & & \{0, \cdots, n_2 - 1\}, & & \end{array}$$

where $\mathrm{inj}(\overline{k_1}) := \overline{k_1 n_2},\ \mathrm{can}(\overline{k}) := \overline{k},\ \sigma(\overline{k_2}) := \overline{k_2}$ if $0 \leq k_2 \leq n_2 - 1$. For $\overline{k} \in \mathbb{Z}/\mathbb{Z}n$ and $\overline{k_2} \in \mathbb{Z}/\mathbb{Z}n_2$ the equations

$$\langle \mathrm{can}(\overline{k}), \overline{k_2} \rangle_{\mathbb{Z}/\mathbb{Z}n_2} = \zeta^{kk_2 d/n_2} = \zeta^{k(k_2 n_1)d/n} = \langle \overline{k}, \mathrm{inj}(\overline{k_2}) \rangle_{\mathbb{Z}/\mathbb{Z}n}$$

prove $\mathrm{can}^\star(\overline{k_2}) = \mathrm{inj}(\overline{k_2})$; hence

$$\begin{gathered} (\mathrm{can} : \mathbb{Z}/\mathbb{Z}n \to \mathbb{Z}/\mathbb{Z}n_2)^\star = \mathrm{inj} : \mathbb{Z}/\mathbb{Z}n_2 \to \mathbb{Z}/\mathbb{Z}n \text{ and} \\ (\mathrm{inj} : \mathbb{Z}/\mathbb{Z}n_1 \to \mathbb{Z}/\mathbb{Z}n)^\star = \mathrm{can} : \mathbb{Z}/\mathbb{Z}n \to \mathbb{Z}/\mathbb{Z}n_1, \end{gathered} \tag{49}$$

the second equality following from the first by means of $\mathrm{inj}^\star = (\mathrm{can}^\star)^\star = \mathrm{can}$. Now assume that a factorization of d is given from which we derive the following data:

$$\begin{gathered} d = e_1 * \cdots * e_r,\ d_1(i) := e_1 * \cdots * e_i,\ i = 0, \ldots, r; \text{ hence} \\ d_1(0) = 1,\ d_1(i) = d_1(i-1) * e_i, \\ d_2(j) := d/d_1(j) = e_{j+1} * \cdots * e_r,\ j = r, \ldots, 0, \\ d_2(r) = 1,\ d_2(j-1) = d_2(j) * e_j. \end{gathered} \tag{50}$$

From (50) and by means of (48) we construct commutative exact diagrams of the type (53):

$$
\begin{array}{ccccccccc}
 & & & & 0 & & & & \\
 & & & & \downarrow & & & & \\
 & & 0 & & \mathbb{Z}/\mathbb{Z}e_i & & & & \\
 & & \downarrow & & \downarrow{\scriptstyle \gamma_i=\mathrm{inj}} & & & & \\
0 & \longrightarrow & \mathbb{Z}/\mathbb{Z}d_1(i-1) & \xrightarrow{\alpha_{i-1}=\mathrm{inj}} & \mathbb{Z}/\mathbb{Z}d & \xrightarrow{\lambda_{i-1}=\mathrm{can}} & \mathbb{Z}/\mathbb{Z}d_2(i-1) & \longrightarrow & 0 \\
 & & \downarrow{\scriptstyle \beta_i=\mathrm{inj}} & & \| & & \downarrow{\scriptstyle \nu_i=\mathrm{can}} & & \\
0 & \longrightarrow & \mathbb{Z}/\mathbb{Z}d_1(i) & \xrightarrow{\alpha_i=\mathrm{inj}} & \mathbb{Z}/\mathbb{Z}d & \xrightarrow{\lambda_i=\mathrm{can}} & \mathbb{Z}/\mathbb{Z}d_2(i) & \longrightarrow & 0 \\
 & & \downarrow{\scriptstyle \mu_i=\mathrm{can}} & & & & \downarrow & & \\
 & & \mathbb{Z}/\mathbb{Z}e_i & & & & 0 & & \\
 & & \downarrow & & & & & & \\
 & & 0 & & & & & &
\end{array}
\tag{51}
$$

with the natural sections σ from (48) in $\mathbb{Z}/\mathbb{Z}d_1(i) \underset{\sigma_i=\sigma}{\overset{\mu_i=\mathrm{can}}{\rightleftarrows}} \mathbb{Z}/\mathbb{Z}e_i$. Application of the exact duality functor $H \mapsto \widehat{H} = H$ to the cyclic groups of the preceding diagram and the identities (49) yield the dual commutative exact diagrams of the type (34):

$$
\begin{array}{ccccccccc}
 & & & & 0 & & & & \\
 & & & & \downarrow & & & & \\
 & & 0 & & \mathbb{Z}/\mathbb{Z}e_j & & & & \\
 & & \downarrow & & \downarrow{\scriptstyle \mu_j^\star=\mathrm{inj}} & & & & \\
0 & \longrightarrow & \mathbb{Z}/\mathbb{Z}d_2(j) & \xrightarrow{\lambda_j^\star=\mathrm{inj}} & \mathbb{Z}/\mathbb{Z}d & \xrightarrow{\alpha_j^\star=\mathrm{can}} & \mathbb{Z}/\mathbb{Z}d_1(j) & \longrightarrow & 0 \\
 & & \downarrow{\scriptstyle \nu_j^\star=\mathrm{inj}} & & \| & & \downarrow{\scriptstyle \beta_j^\star=\mathrm{can}} & & \\
0 & \longrightarrow & \mathbb{Z}/\mathbb{Z}d_2(j-1) & \xrightarrow{\lambda_{j-1}^\star=\mathrm{inj}} & \mathbb{Z}/\mathbb{Z}d & \xrightarrow{\alpha_{j-1}^\star=\mathrm{can}} & \mathbb{Z}/\mathbb{Z}d_1(j-1) & \longrightarrow & 0 \\
 & & \downarrow{\scriptstyle \gamma_j^\star=\mathrm{can}} & & & & \downarrow & & \\
 & & \mathbb{Z}/\mathbb{Z}e_j & & & & 0 & & \\
 & & \downarrow & & & & & & \\
 & & 0 & & & & & &
\end{array}
\tag{52}
$$

with the natural sections $\widehat{\sigma}$ from (48) in $\mathbb{Z}/\mathbb{Z}d_2(j-1) \underset{\widehat{\sigma}_j=\sigma}{\overset{\gamma_j^\star=\mathrm{can}}{\rightleftarrows}} \mathbb{Z}/\mathbb{Z}e_j$. According to Lemma 55 the diagram (51) gives rise to the index bijection

$$\begin{gathered}\operatorname{ind} : \prod_{i=1}^{r} \mathbb{Z}/\mathbb{Z}e_i = \prod_{i=1}^{r} \{0, \cdots, e_i - 1\} \cong \mathbb{Z}/\mathbb{Z}d = \{0, \cdots, d-1\}, \\ \operatorname{ind}(k_1, \cdots, k_r) = \sum_{i=1}^{r} \alpha_i \sigma_i(k_i) = \sum_{i=1}^{r} k_i d/d_1(i) \\ = \sum_{i=1}^{r} k_i d_2(i) = \sum_{i=1}^{r} k_i * e_{i+1} * \cdots * e_r. \end{gathered} \tag{53}$$

Likewise, the diagram (52) induces the bijection

$$\begin{gathered}\widehat{\operatorname{ind}} : \prod_{j=1}^{r} \mathbb{Z}/\mathbb{Z}e_j = \prod_{j=1}^{r} \{0, \cdots, e_j - 1\} \cong \mathbb{Z}/\mathbb{Z}d = \{0, \cdots, d-1\}, \\ \widehat{\operatorname{ind}}(\widehat{k}_1, \cdots, \widehat{k}_r) = \sum_{j=1}^{r} \lambda_{j-1}^{\star} \widehat{\sigma}_j(\widehat{k}_j) = \sum_{j=1}^{r} \widehat{k}_j d/d_2(j-1) \\ = \sum_{j=1}^{r} \widehat{k}_j * e_1 * \cdots * e_{j-1}. \end{gathered} \tag{54}$$

Corollary 65. *The unique representation*

$$n = \sum_{i=1}^{r} k_i * e_{i+1} * \cdots * e_r,\ 0 \le n < d,\ 0 \le k_i < e_i,\ i = 1, \ldots, r,$$

according to (53) *is obtained by recursion with respect to* i *as*

$$n_r := n,\ n_i := n_{i-1} * e_i + k_i,\ 0 \le k_i < e_i,\ i = r, \ldots, 1.$$

Likewise, the unique representation

$$n = \sum_{j=1}^{r} \widehat{k}_j * e_1 * \cdots * e_{j-1},\ 0 \le n < d,\ 0 \le \widehat{k}_j < e_j,\ j = 1, \ldots, r,$$

according to (54) *is obtained by induction with respect to* j *as*

$$\widehat{n}_0 := n,\ \widehat{n}_{j-1} = \widehat{n}_j * e_j + \widehat{k}_j,\ 0 \le \widehat{k}_j < e_j,\ j = 1, \ldots, r.$$

Proof. The proof is the same as that of the q-adic representation of a natural number for $q > 1$. For instance,

$$\begin{gathered} d > n =: n_r := n_{r-1} * e_r + k_r,\ 0 \le k_r < e_r,\ n_{r-1} \le \tfrac{n}{e_r} < \tfrac{d}{e_r} = e_1 * \cdots * e_{r-1}, \\ d > n =: \widehat{n}_0 = \widehat{n}_1 * e_1 + \widehat{k}_1,\ 0 \le \widehat{k}_1 < e_1,\ \widehat{n}_1 < e_2 * \cdots * e_r. \end{gathered}$$

□

For vectors $(k_i; \widehat{k}_1, \cdots, \widehat{k}_i)$ with components $k_i,\ \widehat{k}_i \in \mathbb{Z}/\mathbb{Z}e_i = \{0, \cdots, e_i - 1\}$ the function φ_i according to (37) is defined by

$$\begin{gathered}\varphi_i(k_i; \widehat{k}_1, \cdots, \widehat{k}_i) = \left\langle \alpha_i \sigma_i(k_i), \sum_{j=1}^{i} \lambda_{j-1}^{\star} \widehat{\sigma}_j(\widehat{k}_j) \right\rangle \\ = \left\langle k_i d/d_1(i), \sum_{j=1}^{i} \widehat{k}_j d/d_2(j-1) \right\rangle = \zeta^{\varepsilon_i(k_i; \widehat{k}_1, \cdots, \widehat{k}_i)}, \text{ where} \\ \varepsilon_i(k_i; \widehat{k}_1, \cdots, \widehat{k}_i) := k_i * e_{i+1} * \cdots * e_r * \sum_{j=1}^{i} \widehat{k}_j * e_1 * \cdots * e_{j-1},\ 0 \le k_i,\ \widehat{k}_i < e_i. \end{gathered} \tag{55}$$

Similarly the function $\widehat{\varphi}_j$ from (38) has the form

$$\begin{gathered}\widehat{\varphi}_j(k_j, \cdots, k_r; \widehat{k}_j) = \zeta^{\widehat{\varepsilon}_j(k_j, \cdots, k_r; \widehat{k}_j)},\ j = 1, \cdots, r, \text{ where} \\ \widehat{\varepsilon}_j(k_j, \cdots, k_r; \widehat{k}_j) := \widehat{k}_j * e_1 * \cdots * e_{j-1} * \sum_{i=j}^{r} k_i * e_{i+1} * \cdots * e_r,\ 0 \le k_i,\ \widehat{k}_i < e_i. \end{gathered} \tag{56}$$

Theorem 58 applied to the preceding situation now implies the following theorem.

Theorem 66 (FFT for cyclic groups [8, pp. 188–191]). *Consider a number* $d > 0$ *with a factorization* $d = e_1 * \cdots * e_r$*, the cyclic group* $G := \mathbb{Z}/\mathbb{Z}d$*, and the associated DFT*

$$\begin{gathered}\operatorname{Four}_{\mathbb{Z}/\mathbb{Z}d} : K^{\mathbb{Z}/\mathbb{Z}d} = K^{\{0, \cdots, d-1\}} = K^d \to K^d,\ a \mapsto \widehat{a}, \\ \widehat{a}(l) := \sum_{k=0}^{d-1} a(k) \zeta^{kl},\ 0 \le l < d. \end{gathered}$$

1. *The following "decimation in time" algorithm computes* $\widehat{a}$ *from* a *with complexity* $d(e_1+\cdots+e_r-r)$. *Inductively define functions*

$$a_\varrho : \prod_{i=1}^{r}\{0,\cdots,e_i-1\} \to K \text{ for } \varrho = 0,\dots,r \text{ by}$$
$$a_0(k_1,\cdots,k_r) := a\left(\textstyle\sum_{i=1}^{r} k_i * e_{i+1} * \cdots * e_r\right),$$
$$a_\varrho(\widehat{k}_1,\cdots,\widehat{k}_\varrho,k_{\varrho+1},\cdots,k_r) := \textstyle\sum_{k_\varrho=0}^{e_\varrho-1} a_{\varrho-1}(\widehat{k}_1,\cdots,\widehat{k}_{\varrho-1},k_\varrho,\cdots,k_r)\zeta^{\varepsilon_\varrho(k_\varrho;\widehat{k}_1,\cdots,\widehat{k}_\varrho)}$$

with ε_ϱ *from* (55). *Then*

$$\widehat{a}(l) = a_r(\widehat{k}_1,\cdots,\widehat{k}_r) \text{ for } l = \textstyle\sum_{j=1}^{r}\widehat{k}_j * e_1 * \cdots * e_{j-1},\ 0 \le l < d, 0 \le \widehat{k}_j < e_j.$$

2. *The following "decimation in frequency" algorithm also computes* $\widehat{a}$ *with complexity* $d(e_1+\cdots+e_r-r)$. *Recursively define functions*

$$b_\varrho : \prod_{\varrho=1}^{r}\{0,\cdots,e_\varrho-1\} \to K \text{ for } \varrho = r,\dots,0 \text{ by}$$
$$b_r(\widehat{k}_1,\cdots,\widehat{k}_r) := a\left(\textstyle\sum_{j=1}^{r}\widehat{k}_j * e_1 * \cdots * e_{j-1}\right),$$
$$b_{\varrho-1}(\widehat{k}_1,\cdots,\widehat{k}_{\varrho-1},k_\varrho,\cdots,k_r) = \textstyle\sum_{\widehat{k}_\varrho=0}^{e_\varrho-1} b_\varrho(\widehat{k}_1,\cdots,\widehat{k}_\varrho,k_{\varrho+1},\cdots,k_r)\zeta^{\widehat{\varepsilon}_\varrho(k_\varrho,\cdots,k_r;\widehat{k}_\varrho)}$$

with $\widehat{\varepsilon}_\varrho$ *from* (56). *Then*

$$\widehat{a}(k) = b_0(k_1,\cdots,k_r) \text{ for } k = \textstyle\sum_{i=1}^{r} k_i * e_{i+1} * \cdots * e_r, 0 \le k < d, 0 \le k_i < e_i.$$

Example 67. In the situation of the preceding theorem we choose

$$K := \mathbb{C},\ d = 6 = 2*3,\ G := \mathbb{Z}/\mathbb{Z}6 = \{0,\cdots,5\},$$
$$\zeta := \exp(2\pi i/6) = 1/2 + i\sqrt{3}/2,\ \zeta^6 = 1,$$
$$\widehat{a}(l) = \textstyle\sum_{k=0}^{5} a(k)\zeta^{kl},\ 0 \le k,l \le 5.$$

The FFT-algorithm of the preceding theorem computes $\widehat{a}$ from $a = (a(0),\cdots,a(5))$ with $6*(2+3-2) = 18$ elementary computation steps. The root ζ satisfies the cyclotomic equation $\phi_6(\zeta) = \zeta^2-\zeta+1 = 0$ or $\zeta^2 = \zeta-1$, hence the group table

k	0	1	2	3	4	5
ζ^k	1	ζ	$\zeta-1$	-1	$-\zeta$	$-\zeta+1$

The index functions are

$$\mathrm{ind}(k_1,k_2) = k_1 * e_2 + k_2 = 3k_1 + k_2 \text{ and}$$
$$\widehat{\mathrm{ind}}(\widehat{k}_1,\widehat{k}_2) = \widehat{k}_1 + \widehat{k}_2 * e_1 = \widehat{k}_1 + 2\widehat{k}_2, \quad 0 \le k_1,\widehat{k}_1 \le 1,\ 0 \le k_2,\widehat{k}_2 \le 2.$$

The values of ind and $\widehat{\mathrm{ind}}$ are given in the following table:

(k_1,k_2)	$(0,0)$	$(0,1)$	$(0,2)$	$(1,0)$	$(1,1)$	$(1,2)$
$\mathrm{ind}(k_1,k_2)$	0	1	2	3	4	5
$\widehat{\mathrm{ind}}(k_1,k_2)$	0	2	4	1	3	5

The value table of $a_0 := a \circ \mathrm{ind}$ is

(k_1,k_2)	$(0,0)$	$(0,1)$	$(0,2)$	$(1,0)$	$(1,1)$	$(1,2)$
$a_0(k_1,k_2)$	$a(0)$	$a(1)$	$a(2)$	$a(3)$	$a(4)$	$a(5)$

For the computation of a_1 we need the exponent ε_1, where

$$\varepsilon_1(k_1;\widehat{k}_1) = k_1 * \widehat{k}_1 * e_2 = 3k_1\widehat{k}_1,\ \varepsilon_1(0;\widehat{k}_1) = 0,\ \varepsilon_1(1;\widehat{k}_1) = 3\widehat{k}_1,$$
$$a_1(\widehat{k}_1,k_2) = a_0(0,k_2) + a_0(1,k_2)\zeta^{3\widehat{k}_1}.$$

In detail we get

$$\begin{array}{lllllllll}
a_1(0,0) & = & a_0(0,0) & + & a_0(1,0) & = & a(0) & + & a(3),\\
a_1(0,1) & = & a_0(0,1) & + & a_0(1,1) & = & a(1) & + & a(4),\\
a_1(0,2) & = & a_0(0,2) & + & a_0(1,2) & = & a(2) & + & a(5),\\
a_1(1,0) & = & a_0(0,0) & + & a_0(1,0)\zeta^3 & = & a(0) & - & a(3),\\
a_1(1,1) & = & a_0(0,1) & - & a_0(1,1)\zeta^3 & = & a(1) & - & a(4),\\
a_1(1,2) & = & a(0,2) & - & a_0(1,2)\zeta^3 & = & a(2) & - & a(5).
\end{array}$$

For the computation of a_2 we need ε_2, where

$$\varepsilon_2(k_2;\widehat{k}_1;\widehat{k}_2) = k_2(\widehat{k}_1 + 2\widehat{k}_2),$$
$$a_2(\widehat{k}_1,\widehat{k}_2) = a_1(\widehat{k}_1,0) + a_1(\widehat{k}_1,1)\zeta^{\widehat{k}_1+2\widehat{k}_2} + a_1(\widehat{k}_1,2)\zeta^{2(\widehat{k}_1+2\widehat{k}_2)}.$$

In detail, we obtain

$$\begin{aligned}
\widehat{a}(0) = a_2(0,0) &= a_1(0,0) + a_1(0,1) + a_1(0,2)\\
&= a(0) + a(3) + a(1) + a(4) + a(2) + a(5) = \textstyle\sum_{i=0}^{5} a(i)\zeta^{i*0},\\
\widehat{a}(2) = a_2(0,1) &= a_1(0,0) + a_1(0,1)\zeta^2 + a_1(0,2)\zeta^4\\
&= a(0) + a(3) + (a(1) + a(4))\zeta^2 + (a(2) + a(5))(-\zeta)\\
&= a(0) + a(1)\zeta^2 + a(2)(-\zeta) + a(3) + a(4)\zeta^2 + a(5)(-\zeta)\\
&= \textstyle\sum_{i=0}^{5} a(i)\zeta^{i*2},\\
\widehat{a}(4) = a_2(0,2) &= a_1(0,0) + a_1(0,1)\zeta^4 + a_1(0,2)\zeta^8\\
&= (a(0) + a(3)) + (a(1) + a(4))(-\zeta) + (a(2) + a(5))\zeta^2\\
&= a(0) + a(1)(-\zeta) + a(2)\zeta^2 + a(3) + a(4)(-\zeta) + a(5)\zeta^2\\
&= \textstyle\sum_{i=0}^{5} a(i)\zeta^{i*4},\\
\widehat{a}(1) = a_2(1,0) &= a_1(1,0) + a_1(1,1)\zeta^1 + a_1(1,2)\zeta^2\\
&= (a(0) - a(3)) + (a(1) - a(4))\zeta + (a(2) - a(5))\zeta^2\\
&= a(0) + a(1)\zeta + a(2)\zeta^2 + a(3)(-1) + a(4)(-\zeta) + a(5)(-\zeta^2)\\
&= \textstyle\sum_{i=0}^{5} a(i)\zeta^{i*1},\\
\widehat{a}(3) = a_2(1,1) &= a_1(1,0) + a_1(1,1)\zeta^3 + a_1(1,2)\zeta^6\\
&= (a(0) - a(3)) + (a(1) - a(4))(-1) + (a(2) - a(5))\\
&= a(0) + a(1)(-1) + a(2) + a(3)(-1) + a(4) + a(5)(-1)\\
&= \textstyle\sum_{i=0}^{5} a(i)\zeta^{i*3},\\
\widehat{a}(5) = a_2(1,2) &= a_1(1,0) + a_1(1,1)\zeta^5 + a_1(1,2)\zeta^{10}\\
&= (a(0) - a(3)) + (a(1) - a(4))(-\zeta^2) + (a(2) - a(5))(-\zeta)\\
&= a(0) + a(1)(-\zeta^2) + a(2)(-\zeta) + a(3)(-1) + a(4)\zeta^2 + a(5)\zeta\\
&= \textstyle\sum_{i=0}^{5} a(i)\zeta^{i*5}.
\end{aligned}$$

In the following corollary we assume that d in Theorem 66 is a power of a number q; i.e.,

$$d = q^r,\ q > 1,\ r > 1,\ e_1 = \cdots = e_r = q,\ d_1(i) = q^i,\ d_2(i) = q^{r-i}. \tag{57}$$

The associated index functions according to (53) and (54) are

$$\begin{gathered}\operatorname{ind}(k_1,\cdots,k_r)=\textstyle\sum_{i=1}^r k_i q^{r-i}=\sum_{j=1}^r k_{r+1-j}q^{j-1},\ 0\le k_i<q,\\ \widehat{\operatorname{ind}}(\widehat{k}_1,\cdots,\widehat{k}_r)=\textstyle\sum_{j=1}^r \widehat{k}_j q^{j-1},\ 0\le \widehat{k}_j<q,\end{gathered}\tag{58}$$

and they give the q-adic representation of a natural number. The map

$$\begin{gathered}\widehat{\operatorname{ind}}^{-1}\circ\operatorname{ind}=\operatorname{ind}^{-1}\circ\widehat{\operatorname{ind}}:\{0,\cdots,q-1\}^r\to\{0,\cdots,q-1\}^r,\\ (k_1,\cdots,k_r)\mapsto(k_r,\cdots,k_1),\end{gathered}\tag{59}$$

is usually called the *bit reversal map* for an obvious reason. The functions ε_i and $\widehat{\varepsilon}_j$ from (55) and (56) are

(60)
$$\varepsilon_i(k_i;\widehat{k}_1,\cdots,\widehat{k}_i)=\textstyle\sum_{j=1}^i k_i\widehat{k}_j q^{j-1+r-i},\quad \widehat{\varepsilon}_j(k_j,\cdots,k_r;\widehat{k}_j)=\sum_{i=j}^r k_i\widehat{k}_j q^{j-1+r-i}.$$

Corollary 68. *Consider natural numbers $q>1$, $r>1$, and $d:=q^r$, the cyclic group $G:=\mathbb{Z}/\mathbb{Z}q^r$, and the DFT*

$$\operatorname{Four}_{\mathbb{Z}/\mathbb{Z}q^r}K^G=K^{q^r}\to K^{q^r},\ a\mapsto\widehat{a},\ \widehat{a}(l):=\textstyle\sum_{k=0}^{q^r-1}a(k)\zeta^{kl},\ 0\le l<q^r.$$

1. *The following "decimation in time" algorithm computes $\widehat{a}$ from a with complexity $q^r(q-1)r$. Inductively define functions*

$$\begin{gathered}a_\varrho:\{0,\cdots,q-1\}^r\to K\ \text{for}\ \varrho=0,\dots,r\ \text{by}\\ a_0(k_1,\cdots,k_r):=a\left(\textstyle\sum_{i=1}^r k_i q^{r-i}\right),\\ a_\varrho(\widehat{k}_1,\cdots,\widehat{k}_\varrho,k_{\varrho+1},\cdots,k_r):=\textstyle\sum_{k_\varrho=0}^{q-1}a_{\varrho-1}(\widehat{k}_1,\cdots,\widehat{k}_{\varrho-1},k_\varrho,\cdots,k_r)\zeta^{\varepsilon_\varrho(k_\varrho;\widehat{k}_1,\cdots,\widehat{k}_\varrho)}\end{gathered}$$

with ε_ϱ from (60). *Then*

$$\widehat{a}(l)=a_r(\widehat{k}_1,\cdots,\widehat{k}_r)\ \text{for}\ l=\textstyle\sum_{j=1}^r\widehat{k}_j q^{j-1},\ 0\le l<q^r,\ 0\le\widehat{k}_j<q.$$

2. *The following "decimation in frequency" algorithm also computes $\widehat{a}$ with complexity $q^r(q-1)r$. Recursively define functions*

$$\begin{gathered}b_\varrho:\{0,\cdots,q-1\}^r\to K\ \text{for}\ \varrho=r,\dots,0\ \text{by}\\ b_r(\widehat{k}_1,\cdots,\widehat{k}_r):=a\left(\textstyle\sum_{j=1}^r\widehat{k}_j q^{j-1}\right),\\ b_{\varrho-1}(\widehat{k}_1,\cdots,\widehat{k}_{\varrho-1},k_\varrho,\cdots,k_r)=\textstyle\sum_{\widehat{k}_\varrho=0}^{q-1}b_\varrho(\widehat{k}_1,\cdots,\widehat{k}_\varrho,k_{\varrho+1},\cdots,k_r)\zeta^{\widehat{\varepsilon}_\varrho(k_\varrho,\cdots,k_r;\widehat{k}_\varrho)}\end{gathered}$$

with $\widehat{\varepsilon}_\varrho$ from (60). *Then*

$$\widehat{a}(k)=b_0(k_1,\cdots,k_r)\ \text{for}\ k=\textstyle\sum_{i=1}^r k_i q^{r-i},\ 0\le k<q^r,\ 0\le k_i<q.$$

Corollary 69 (see [16]). *In the situation of Corollary* 68 *assume that $q=2$ and $G=\mathbb{Z}/\mathbb{Z}2^r$. The FFT-algorithms reduce to the following algorithms. The functions $a,\widehat{a}$ and a_ϱ,b_ϱ belong to K^{2^r} (resp., $K^{\{0,1\}^r}$).*

1. *The following "decimation in time" algorithm computes $\widehat{a}$ from a with complexity $r*2^r$. Inductively define functions*

$$\begin{gathered}a_\varrho:\{0,1\}^r\to K\ \text{for}\ \varrho=0,\dots,r\ \text{by}\\ a_0(k_1,\cdots,k_r):=a\left(\textstyle\sum_{i=1}^r k_i 2^{r-i}\right),\\ a_\varrho(\widehat{k}_1,\cdots,\widehat{k}_\varrho,k_{\varrho+1},\cdots,k_r)\\ :=a_{\varrho-1}(\widehat{k}_1,\cdots,\widehat{k}_{\varrho-1},0,k_{\varrho+1},\cdots,k_r)+a_{\varrho-1}(\widehat{k}_1,\cdots,\widehat{k}_{\varrho-1},1,k_{\varrho+1},\cdots,k_r)\zeta^{\varepsilon_\varrho(1;\widehat{k}_1,\cdots,\widehat{k}_\varrho)}\end{gathered}$$

with $\varepsilon_\varrho(1;\widehat{k}_1,\cdots,\widehat{k}_\varrho) := \sum_{j=1}^{\varrho}\widehat{k}_j 2^{j-1+r-\varrho}$. *Then*

$$\widehat{a}(l) = a_r(\widehat{k}_1,\cdots,\widehat{k}_r) \text{ for } l = \textstyle\sum_{j=1}^{r}\widehat{k}_j 2^{j-1},\ 0 \le l < 2^r, 0 \le \widehat{k}_j \le 1.$$

2. *The following "decimation in frequency" algorithm also computes* $\widehat{a}$ *with complexity* $r * 2^r$. *Recursively define functions*

$$b_\varrho : \{0,1\}^r \to K \text{ for } \varrho = r,\dots,0 \text{ by}$$
$$b_r(\widehat{k}_1,\cdots,\widehat{k}_r) := a\left(\textstyle\sum_{j=1}^{r}\widehat{k}_j 2^{j-1}\right),$$
$$b_{\varrho-1}(\widehat{k}_1,\cdots,\widehat{k}_{\varrho-1},k_\varrho,\cdots,k_r)$$
$$= b_\varrho(\widehat{k}_1,\cdots,\widehat{k}_{\varrho-1},0,k_{\varrho+1},\cdots,k_r) + b_\varrho(\widehat{k}_1,\cdots,\widehat{k}_{\varrho-1},1,k_{\varrho+1},\cdots,k_r)\zeta^{\widehat{\varepsilon}_\varrho(k_\varrho,\cdots,k_r;1)}$$

with $\widehat{\varepsilon}_\varrho(k_\varrho,\cdots,k_r;1) := \sum_{i=\varrho}^{r} k_i 2^{\varrho-1+r-i}$. *Then*

$$\widehat{a}(k) = b_0(k_1,\cdots,k_r) \text{ for } k = \sum_{i=1}^{r} k_i 2^{r-i},\ 0 \le k < 2^r,\ 0 \le k_i \le 1.$$

Observe that the computation of $a_\varrho(\widehat{k}_1,\cdots,\widehat{k}_\varrho,k_{\varrho+1},\cdots,k_r)$ *(resp., of* $b_{\varrho-1}(\widehat{k}_1,\cdots,\widehat{k}_{\varrho-1},k_\varrho,\cdots,k_r)$*) from* $a_{\varrho-1}$ *(resp.,* b_ϱ*) requires just one elementary computation step* $\alpha+\lambda\beta$.

For the next application of Theorem 58 we assume that a direct decomposition of the group G, i.e., an isomorphism

$$\varphi : \textstyle\prod_{i=1}^{r} K_i \cong G, \tag{61}$$

is given. For every subset I of $\{1,\cdots,r\}$ we define

$$G(I) := \textstyle\prod_{i\in I} K_i, \text{ especially } G_i := G(\{1,\cdots,i\}), H_i := G(\{i+1,\cdots,r\}). \tag{62}$$

For $J \subseteq I$ there results the exact sequence

$$0 \to G(J) \xrightarrow{\text{inj}} G(I) \xrightarrow{\text{proj}} G(I\setminus J) \to 0,$$
$$\text{inj}((l_j)_{j\in J}) := (k_i)_{i\in I}, \text{ where } k_i := \begin{cases} l_i & \text{if } i \in J,\\ 0 & \text{if } i \in I\setminus J,\end{cases} \tag{63}$$
$$\text{proj}((k_i)_{i\in I}) := (k_i)_{i\in I\setminus J},$$

where, moreover, inj : $G(I\setminus J) \to G(I)$ is a *homomorphic* section of the canonical projection proj. The groups $\widehat{K_i}$ and the forms $\langle -,-\rangle_{K_i}$ being given arbitrarily, we now choose

$$\widehat{G(I)} := \textstyle\prod_{i\in I}\widehat{K_i}, \quad \langle (k_i)_{i\in I}, (\widehat{k}_i)_{i\in I}\rangle := \prod_{i\in I}\langle k_i,\widehat{k}_i\rangle_{K_i}. \tag{64}$$

It is then easily seen that

$$(\text{inj} : G(J) \to G(I))^\star = \text{proj} : \widehat{G(I)} \to \widehat{G(J)},$$
$$(\text{proj} : G(I) \to G(J))^\star = \text{inj} : \widehat{G(J)} \to \widehat{G(I)}. \tag{65}$$

The isomorphism φ from (61) and the exact sequences (63) and (65) now imply the exact sequences

$$
\begin{aligned}
0 \to G_i &\xrightarrow{\varphi\circ\mathrm{inj}} G \xrightarrow{\mathrm{proj}\circ\varphi^{-1}} H_i \to 0,\\
0 \to \widehat{H_i} &\xrightarrow{(\varphi^\star)^{-1}\circ\mathrm{inj}} \widehat{G} \xrightarrow{\mathrm{proj}\circ\varphi^\star} \widehat{G_i} \to 0.
\end{aligned} \tag{66}
$$

Finally we use these data to construct the diagrams (32) and (34) in the form

$$
\begin{array}{ccccccccc}
 & & & & & & 0 & & \\
 & & & & & & \downarrow & & \\
 & & 0 & & & & K_i & & \\
 & & \downarrow & & & & \downarrow{\scriptstyle \gamma_i:=\mathrm{inj}} & & \\
0 & \longrightarrow & G_{i-1} & \xrightarrow{\alpha_{i-1}:=\varphi\circ\mathrm{inj}} & G & \xrightarrow{\lambda_{i-1}:=\mathrm{proj}\circ\varphi^{-1}} & H_{i-1} & \longrightarrow & 0 \\
 & & \downarrow{\scriptstyle \beta_i:=\mathrm{inj}} & & \| & & \downarrow{\scriptstyle \nu_i:=\mathrm{proj}} & & \\
0 & \longrightarrow & G_i & \xrightarrow{\alpha_i:=\varphi\circ\mathrm{inj}} & G & \xrightarrow{\lambda_i:=\mathrm{proj}\circ\varphi^{-1}} & H_i & \longrightarrow & 0 \\
 & & \downarrow{\scriptstyle \mu_i:=\mathrm{proj}} & & & & \downarrow & & \\
 & & K_i & & & & 0 & & \\
 & & \downarrow & & & & & & \\
 & & 0 & & & & & &
\end{array} \tag{67}
$$

$$
\begin{array}{ccccccccc}
 & & & & & & 0 & & \\
 & & & & & & \downarrow & & \\
 & & 0 & & & & \widehat{K_j} & & \\
 & & \downarrow & & & & \downarrow{\scriptstyle \mu_j^\star:=\mathrm{inj}} & & \\
0 & \longrightarrow & \widehat{H_j} & \xrightarrow{\lambda_j^\star:=(\varphi^\star)^{-1}\circ\mathrm{inj}} & \widehat{G} & \xrightarrow{\alpha_j^\star:=\mathrm{proj}\circ\varphi^\star} & \widehat{G_j} & \longrightarrow & 0 \\
 & & \downarrow{\scriptstyle \nu_j^\star:=\mathrm{inj}} & & \| & & \downarrow{\scriptstyle \beta_j^\star:=\mathrm{proj}} & & \\
0 & \longrightarrow & \widehat{H_{j-1}} & \xrightarrow{\lambda_{j-1}^\star:=(\varphi^\star)^{-1}\circ\mathrm{inj}} & \widehat{G} & \xrightarrow{\alpha_{j-1}^\star:=\mathrm{proj}\circ\varphi^\star} & \widehat{G_{j-1}} & \longrightarrow & 0 \\
 & & \downarrow{\scriptstyle \gamma_j^\star:=\mathrm{proj}} & & & & \downarrow & & \\
 & & \widehat{K_j} & & & & 0 & & \\
 & & \downarrow & & & & & & \\
 & & 0 & & & & & &
\end{array} \tag{68}
$$

with the canonical homomorphic sections

$$
\sigma_i := \mathrm{inj} : K_i \to G_i = \textstyle\prod_{k=1}^{i} K_k \text{ and } \widehat{\sigma}_j := \mathrm{inj} : \widehat{K_j} \to \widehat{H_{j-1}} = \textstyle\prod_{k=j}^{r} \widehat{K_k}. \tag{69}
$$

These diagrams induce the index transformations ind and $\widehat{\text{ind}}$ from Corollaries 55 and 56; indeed

$$\begin{aligned}\text{ind}((k_i)_{i=1,\cdots,r}) &= \textstyle\sum_{i=1}^r \alpha_i\sigma_i(k_i) = \varphi\left(\sum_{i=1}^r \text{inj}\circ\text{inj}(k_i)\right)\\ &= \varphi\left(\textstyle\sum_{i=1}^r (0,\cdots,0,k_i,0,\cdots,0)\right) = \varphi((k_i)_{i=1,\cdots,r}),\end{aligned}$$

and hence

$$\text{ind} = \varphi : \textstyle\prod_{i=1}^r K_i \cong G \text{ and likewise } \widehat{\text{ind}} = (\varphi^\star)^{-1} : \prod_{j=1}^r \widehat{K_j} \cong \widehat{G}. \tag{70}$$

Also, with the notation from (35), we have

$$\begin{aligned}\text{fact}_{ij}(k,\widehat{k}) &= \langle \alpha_i\sigma_i(k_i), \lambda_{j-1}^\star \widehat{\sigma}_j(\widehat{k}_j)\rangle\\ &= \langle \varphi\,\text{inj}(k_i), (\varphi^\star)^{-1}\,\text{inj}(\widehat{k}_j)\rangle = \langle \varphi^{-1}\varphi\,\text{inj}(k_i), \text{inj}(\widehat{k}_j)\rangle\\ = \langle (0,\cdots,0,k_i,0,\cdots,0), (0,\cdots,0,\widehat{k}_j,0,\cdots,0)\rangle &= \begin{cases}\langle k_i,\widehat{k}_i\rangle & \text{if } i=j,\\ 1 & \text{if } i\neq j,\end{cases} \text{ and hence}\\ \varphi_\varrho(k_\varrho;\widehat{k}_1,\cdots,\widehat{k}_\varrho) &= \langle k_\varrho,\widehat{k}_\varrho\rangle,\ \varrho=1,\cdots,r.\end{aligned}$$

Theorem 58 now implies the following theorem.

THEOREM 70. *Assume that a group isomorphism $\varphi : \prod_{i=1}^r K_i \cong G$ is given. Then the following recursive algorithm computes the Fourier transform $\widehat{a} \in K^{\widehat{G}}$ of a function $a \in K^G$ with complexity $N(e_1+\cdots+e_r-r)$, where $N := \text{ord}(G)$ and $e_i := \text{ord}(K_i)$. Inductively define functions*

$$\begin{aligned}&a_\varrho : \widehat{K_1}\times\cdots\times\widehat{K_\varrho}\times K_{\varrho+1}\times\cdots\times K_r \to K \ \text{ for } \varrho=0,\dots,r \text{ by } a_0 := a\circ\varphi \text{ and}\\ &a_\varrho(\widehat{k}_1,\cdots,\widehat{k}_\varrho,k_{\varrho+1},\cdots,k_r) := \textstyle\sum_{k_\varrho\in K_\varrho} a_{\varrho-1}(\widehat{k}_1,\cdots,\widehat{k}_{\varrho-1},k_\varrho,\cdots,k_r)\langle k_\varrho,\widehat{k}_\varrho\rangle \text{ or}\\ &a_\varrho(\widehat{k}_1,\cdots,\widehat{k}_{\varrho-1},-,k_{\varrho+1},\cdots,k_r) := \text{Four}_{K_\varrho}\left(a_{\varrho-1}(\widehat{k}_1,\cdots,\widehat{k}_{\varrho-1},-,k_{\varrho+1},\cdots,k_r)\right).\\ &\text{Then } \widehat{a} = a_r\circ\varphi^\star.\end{aligned}$$

If, in particular, $G := \prod_{i=1}^r K_i$ and $\varphi = \text{id}$, then $a_0 = a$ and $\widehat{a} = a_r$.

Example 71 (Walsh–Fourier FFT). We apply the preceding theorem to $d := 2$, the group

$$G := \widehat{G} := (\mathbb{Z}/\mathbb{Z}2)^r = \{0,1\}^r \ni k = (k_1,\cdots,k_r),\ 0\le k_i\le 1,$$

of exponent 2 with the form $k\bullet l := \sum_{i=1}^r k_i l_i \in \mathbb{Z}/\mathbb{Z}2$, and a ring K in which 2 is invertible so that Assumption 29 is satisfied for $\zeta := -1$. The Walsh–Fourier DFT is given by

$$\text{Four}_G : K^G \cong K^G,\ \text{Four}_G(a)(\widehat{k}) := \widehat{a}(\widehat{k}_1,\cdots,\widehat{k}_r) = \textstyle\sum_{k\in G} a(k)(-1)^{k\bullet\widehat{k}}$$

and inductively computed with complexity $r*2^r$ by means of the algorithm

$$\begin{aligned}&a_0 := a \text{ and for } 1\le\varrho\le r\\ &a_\varrho(\widehat{k}_1,\cdots,\widehat{k}_\varrho,k_{\varrho+1},\cdots,k_r)\\ &:= a_{\varrho-1}(\widehat{k}_1,\cdots,\widehat{k}_{\varrho-1},0,k_{\varrho+1},\cdots,k_r) + a_{\varrho-1}(\widehat{k}_1,\cdots,\widehat{k}_{\varrho-1},1,k_{\varrho+1},\cdots,k_r)(-1)^{\widehat{k}_\varrho},\\ &\widehat{a} = a_r.\end{aligned}$$

The next example contains the prime factor algorithm according to Good.

Example 72 (the Good FFT or the prime factor algorithm [19]). In the situation of Theorem 66 assume that the numbers e_i are relatively prime. The euclidean algorithm and the Chinese remainder theorem yield representations

$$1 = r_i * e_i + s_i * d/e_i = a_i + b_i, \quad b_i := s_i * d/e_i,$$

and the group isomorphism

$$\Delta : G := \mathbb{Z}/\mathbb{Z}d \cong \prod_{i=1}^r K_i := \prod_{i=1}^r \mathbb{Z}/\mathbb{Z}e_i,\ \bar{l} \mapsto (\bar{l}, \cdots, \bar{l}).$$

The inverse map of Δ is

$$\varphi := \Delta^{-1} : \prod_{i=1}^r \mathbb{Z}/\mathbb{Z}e_i \cong \mathbb{Z}/\mathbb{Z}d,\ \varphi(\overline{k_1}, \cdots, \overline{k_r}) = \overline{\textstyle\sum_{i=1}^r k_i b_i}.$$

For the application of Theorem 70 we compute $\varphi^\star$. The equations

$$\langle \varphi(\overline{k_1}, \cdots, \overline{k_r}), \bar{l}\rangle = \zeta^{\sum_{i=1}^r k_i b_i l}$$
$$= \zeta^{\sum_{i=1}^r k_i (s_i l) d/e_i} = \prod_{i=1}^r \langle \overline{k_i}, \overline{s_i l}\rangle_{K_i} = \langle \overline{k}, (\overline{s_1 l}, \cdots, \overline{s_r l})\rangle$$

imply

$$\varphi^\star(\bar{l}) = (\overline{s_1 l}, \cdots, \overline{s_r l}) = (\overline{s_1}, \cdots, \overline{s_r})\Delta(\bar{l}) \in \prod_{i=1}^r \mathbb{Z}/\mathbb{Z}e_i.$$

Application of Theorem 70 to the preceding data now shows that the following algorithm computes $\widehat{a} \in K^G$ from $a \in K^G$ with complexity $d(e_1 + \cdots + e_r - r)$. Inductively define functions

$$a_\varrho : \prod_{i=1}^r \{0, \cdots, e_i - 1\} \to K \text{ for } \varrho = 0, \ldots, r \text{ by}$$
$$a_0(k_1, \cdots, k_r) := a\left(\overline{\textstyle\sum_{i=1}^r k_i b_i}\right),$$
$$a_\varrho(\widehat{k}_1, \cdots, \widehat{k}_\varrho, k_{\varrho+1}, \cdots, k_r) := \textstyle\sum_{k_\varrho=0}^{e_\varrho - 1} a_{\varrho-1}(\widehat{k}_1, \cdots, \widehat{k}_{\varrho-1}, k_\varrho, \cdots, k_r)\zeta^{k_\varrho \widehat{k}_\varrho d/e_\varrho}.$$ Then
$$\overline{a}(\bar{l}) = a_r(\overline{s_1 l}, \cdots, \overline{s_r l}), \quad \bar{l} \in \mathbb{Z}/\mathbb{Z}d.$$

Consider, in particular, the case of Example 67, i.e., $d = 6 = e_1 e_2 = 2 * 3$. Then

$$1 = (-1) * 2 + 1 * 6/2 = 2 * 6/3 + (-1) * 3;\ \text{hence } s_1 = 1,\ b_1 = 3,\ s_2 = 2,\ b_2 = 4.$$

The maps

$$\varphi,\ (\varphi^\star)^{-1} : \mathbb{Z}/\mathbb{Z}2 \times \mathbb{Z}/\mathbb{Z}3 = \{0,1\} \times \{0,1,2\} \to \mathbb{Z}/\mathbb{Z}6 = \{0,1,2,3,4,5\}$$

have the value table

(k_1, k_2)	$(0,0)$	$(0,1)$	$(0,2)$	$(1,0)$	$(1,1)$	$(1,2)$
$\varphi(k_1, k_2)$	0	4	2	3	1	5
$(\varphi^\star)^{-1}(k_1, k_2)$	0	2	4	3	5	1

Since the maps φ and $(\varphi^\star)^{-1}$ differ from the index maps ind and $\widehat{\text{ind}}$ from Example 67, the FFT-algorithms from Theorem 66 and Example 72 applied to the same case $d = e_1 * \cdots * e_r$ with relatively prime e_i differ, too.

7. Fast convolution. The assumptions of section 3 are in force; in particular, the Fourier transform is invertible.

The FFT also induces a fast convolution algorithm for the group algebra $K[G]$ and the polynomial algebra $K[z_1, \cdots, z_r]$. Let, more generally, A be a commmutative K-algebra with a fixed chosen basis of length N, for instance, $K[G]$ with the standard basis. The multiplication $A \times A \to A$ is K-bilinear, but not linear, and therefore requires the notion of a *bilinear or multiplicative* complexity. Several papers and books treat this type of complexity and construct fast algorithms of small multiplicative complexity [40], [3], [1], [34], [9, Def. 14.7], [30], [18]. In the present paper we do not treat these algorithms and use only the complexity of linear maps as introduced in section 4. For fixed $a \in A$ the map $A \to A,\ b \mapsto ab$, is K-linear and therefore its linear complexity (with respect to the chosen basis),

$$\mu_A(a) := \mu(A \to A,\ b \mapsto ab) \le N^2 \text{ and then } \mu_{\lin}(A) := \max_{b \in A} \mu_A(b) \le N^2, \tag{71}$$

is defined according to Definition 46. It is obvious that K^G with the argumentwise multiplication and the standard basis has the complexity

$$\mu_{\lin}(K^G) \le N := \ord(G) \tag{72}$$

since the corresponding matrices are diagonal matrices with at most N nonzero entries.

THEOREM 73 (fast convolution). *The data are as in Theorem* 63. *Let $a \in K[G]$ be an arbitrarily chosen but fixed function and consider the linear map $f : K[G] \to K[G],\ b \mapsto a * b$. Then f is the composition of the maps*

$$f : K[G] \xrightarrow{\Four_G} K^{\widehat{G}} \xrightarrow{\widehat{a}\cdot(-)} K^{\widehat{G}} \xrightarrow{N^{-1}\Four_{\widehat{G}}} K^G \xrightarrow{S_G} K^G,$$

and hence its complexity satisfies

$$\mu_{K[G]}(a) := \mu(f) \le N(1 + 2\Lambda(N)) \text{ and thus also } \mu_{\lin}(K[G]) \le N(1 + 2\Lambda(N)).$$

Proof. Let $c := a * b$; hence $\widehat{c} := \widehat{a}\widehat{b}$ by the convolution theorem. The Fourier inversion theorem implies

$$f(b) = c = S_G(N^{-1}\Four_{\widehat{G}})(\widehat{c}) = S_G(N^{-1}\Four_{\widehat{G}})(\widehat{a}\widehat{b}),$$

and f is indeed the asserted composition. According to Theorem 49 its complexity is at most the sum of the complexities of its factors. The two Fourier transforms have complexity at most $N\Lambda(N)$ according to Theorem 63 and the argumentwise multiplication with $\widehat{a}$ at most N. The complexity of the antipode is zero since it is an index transformation; see Definition and Corollary 48. The algorithm for $\Four_{\widehat{G}}$ from Theorem 61 can be adapted to the computation of $N^{-1}\Four_{\widehat{G}}$ by replacing

$$\widehat{\varphi}_r(k_r, \widehat{k}_r) = \fact_{rr}(k_r, \widehat{k}_r) = \langle k_r, \widehat{k}_r \rangle$$

in the recursion step $c_r \mapsto c_{r-1}$ by $N^{-1}\langle k_r, \widehat{k}_r \rangle$. This implies that also $N^{-1}\Four_{\widehat{G}}$ has complexity at most $N\Lambda(N)$, and therefore the complexity of $b \mapsto a * b$ and of $K[G]$ is indeed at most $N(1 + 2\Lambda(N))$. □

ALGORITHM 74 (fast convolution). *The fast algorithm for the convolution $a * b$ in the group algebra $K[G]$ consists of the following steps:*

1. *Precompute the Fourier transform $\widehat{a} \in K^{\widehat{G}}$. This computation and its complexity are not counted because $\widehat{a}$ is assumed known when f is applied.*

2. *Compute* $\widehat{b}$ *with the decimation in time FFT according to Theorems* 58 *and* 63 *with complexity* $N\Lambda(N)$.
3. *Compute* $\widehat{c} := \widehat{a}\widehat{b},\ (\widehat{a}\widehat{b})(\widehat{g}) = \widehat{a}(\widehat{g})\widehat{b}(\widehat{g})$ *with complexity at most* N.
4. *Compute* $N^{-1}\widehat{\widehat{c}}$ *with the slight modification of the decimation in frequency FFT from Theorem* 61 *with complexity* $N\Lambda(N)$ *and then apply the antipode to the result to obtain* $c = a * b$.

It suffices to compute $b_r(\widehat{k})$ *only in the first FFT-algorithm (see Theorem* 58*) and to start the second FFT-algorithm with* $c_r(\widehat{k}) = a_r(\widehat{k})b_r(\widehat{k})$*; i.e., the computation of the elements* $\widehat{g} = \widehat{\mathrm{ind}}(\widehat{k}) = \sum_{j=1}^{r} \lambda_{j-1}^{\star}\widehat{\sigma}_j(\widehat{k}_j)$ *is superfluous.*

Remark 75. If in the preceding algorithm for $a * b$ the complexity of computing $\widehat{a}$ is also counted, then the total complexity of the algorithm is $N(1 + 3\Lambda(N))$. Recall, however, that in this article we gave only a formal definition for the complexity of a linear, but not of a bilinear, map such as $a * b$ with variable a and b. Our complexity counts *all* necessary elementary computation steps for the computation of $c = a*b$ and not only the *essential* multiplications which enter into the *multiplicative complexity.*

The fast convolution also induces a fast algorithm for the multiplication of multivariate polynomials in $K[z] = K[z_1, \cdots, z_r]$. For this purpose we consider the case

$$\begin{gathered} G = \widehat{G} = \mathbb{Z}/\mathbb{Z}d_1 \times \cdots \times \mathbb{Z}/\mathbb{Z}d_r \\ \underset{\text{ident.}}{=} I(d) := \{0, \cdots, d_1 - 1\} \times \cdots \times \{0, \cdots, d_r - 1\} \ni \mu = (\mu_1, \cdots, \mu_r), \\ \mu \bullet \nu := \overline{\textstyle\sum_{i=1}^{r} \mu_i \nu_i \frac{d}{d_i}} \in \mathbb{Z}/\mathbb{Z}d,\ \langle \mu, \nu \rangle = \zeta^{\mu \bullet \nu}. \end{gathered} \tag{73}$$

The group algebra $K[G]$ has the K-basis $\delta_\mu,\ \mu \in G$. With

$$x := (x_1, \cdots, x_r),\ x_i := \delta_{(0,\cdots,0,1,0,\cdots,0)},\ 1 \text{ at the } i\text{th place},\ i = 1, \ldots, r, \text{ we get}$$
$$\delta_\mu = x^\mu \text{ and } x_i^{d_i} - 1 = 0.$$

Lemma and Definition 76. *The substitution homomorphism* $K[z] \to K[G]$, $z_i \mapsto x_i$, *induces an isomorphism*

$$K[z]/\langle z_1^{d_1} - 1, \cdots, z_r^{d_r} - 1\rangle \cong K[G],\ \overline{z^\mu} \mapsto \delta_\mu = x^\mu,\ \overline{f} \mapsto f(x). \tag{74}$$

In what follows we therefore identify *these two algebras, i.e., for*

$$f = \textstyle\sum_{\mu \in \mathbb{N}^r} f_\mu z^\mu \in K[z] :\ \overline{f} = f(x) = \sum_{\mu \in \mathbb{N}^r} f_\mu x^\mu = \sum_{\mu \in \mathbb{N}^r} f_\mu \delta_\mu.$$

In particular, we get the K*-linear isomorphism*

$$\begin{aligned} K[z]_{I(d)} &:= \{f \in K[z];\ \textit{for all } i = 1, \ldots, r :\ \deg_{z_i}(f) \le d_i - 1\} \\ &= \oplus_{\mu \in I(d)} K z^\mu \cong K[G],\ z^\mu \mapsto \delta_\mu = x^\mu. \end{aligned}$$

In other words, one can reproduce f *from* $f(x)$ *if the degree bounds* $\deg_{z_i}(f) \le d_i - 1$ *are observed.*

Proof. Induction by means of the canonical isomorphism

$$\begin{aligned} &K[z]/\langle z_1^{d_1} - 1, \cdots, z_r^{d_r} - 1\rangle \\ &\cong (K[z_1, \cdots, z_{r-1}]/\langle z_1^{d_1} - 1, \cdots, z_{r-1}^{d_{r-1}} - 1\rangle)[z_r]/\langle z_r^{d_r} - 1\rangle \end{aligned}$$

shows that this algebra has the K-basis $\overline{z^\mu},\ \mu \in I(d)$. The induced homomorphism (74) maps this K-basis onto the basis $x^\mu,\ \mu \in I(d) \underset{\text{ident.}}{=} G$ of $K[G]$, and is thus an isomorphism. □

Now let m, n, d be vectors in $\mathbb{N}^r$ with the property

$$m_i + n_i \le d_i + 1,\ i = 1, \dots, r, \text{ such that } K[z]_{I(m)} \times K[z]_{I(n)} \xrightarrow{\text{mult}} K[z]_{I(d)} \tag{75}$$

is well defined.

COROLLARY 77 (fast multiplication of polynomials). *The multiplication*

$$\begin{gathered} K[z]_{I(m)} \times K[z]_{I(n)} \xrightarrow{\text{mult}} K[z]_{I(d)},\ (P, Q) \mapsto PQ, \\ P = \textstyle\sum_{\mu \in I(m)} a_\mu z^\mu,\ Q = \sum_{\nu \in I(n)} b_\nu z^\nu, \\ PQ = \textstyle\sum_{\lambda \in I(d)} \sum_{\mu,\nu,\ \mu+\nu=\lambda} \{a_\mu b_\nu,\ \mu_j \le m_j - 1,\ \nu_j \le n_j - 1\} z^\lambda \end{gathered} \tag{76}$$

equals the composition of the maps

$$K[z]_{I(m)} \times K[z]_{I(n)} \xrightarrow{\text{inj} \times \text{inj}} K[z]_{I(d)} \times K[z]_{I(d)} \cong K[G] \times K[G] \xrightarrow{*} K[G] \cong K[z]_{I(d)}. \tag{77}$$

If the product PQ is computed according to the algorithm in (76)*, the complexity is*

$$\textstyle\prod_{i=1}^r m_i n_i.$$

If, on the other hand, (77) *is used with the fast convolution algorithm, Algorithm* 74*, then the algorithm has the complexity*

$$N(1 + 3\Lambda(N)),\ \textit{where } N = \operatorname{ord}(G) := d_1 * \cdots * d_r.$$

Note that this algorithm depends on the choice of $d_1, \cdots, d_r$.

Proof. The proof is obvious since in (77) all maps except the convolution have complexity zero. See Remark 75 for the applied complexity notion. □

In applications of the preceding algorithm (77) the degrees m_j and n_j are given in general, whereas the numbers $d_j > m_j + n_j - 2$ may be suitably chosen. We illustrate the case

$$r = 1, \quad m_1 = n_1 = m, \quad 2 * (m - 1) < d = N.$$

Examples 78.

(1) The standard choice is

$$\begin{gathered} N = 2^e, e \ge 2,\ \Lambda(2^e) = e, m \le 2^{e-1};\ \text{hence} \\ N(1 + 3\Lambda(N)) = 2^e(1 + 3e).\ \text{But} \\ 2^{e-2} \le 1 + 3e \text{ for } 2 \le e \le 6;\ \text{hence} \\ m^2 \le 2^{2(e-1)} \le 2^e(1 + 3e) = N(1 + 3\Lambda(N)) \text{ for } N = 2^e, 2 \le e \le 6. \end{gathered}$$

This signifies that for the convolution of polynomials of degree at most 31 the direct computation of complexity $m^2 = 1024$ is faster than the algorithm of (77) with $N = 2^6$ and complexity $2^6 * (1 + 3 * 6) = 1216$.

(2)

$$\begin{gathered} m := 36, N_1 := 72 = 2^3 * 3^2 < N_2 = 128 = 2^7, \\ \Lambda(N_1) = 3 * 1 + 2 * 2 = 7 = \Lambda(N_2).\ \text{Again} \\ m^2 = 1296 < N_1(1 + 3\Lambda(N_1)) = 1584 < N_2(1 + 3\Lambda(N_2) = 2816. \end{gathered}$$

Also in this case the direct computation of the product is better than the two algorithms (77) for N_1 (resp., N_2).

(3)

$$m := 70, N_1 = 144 = 2^4 * 3^2, N_2 := 2^8,$$
$$\Lambda(N_1) = 4 + 2 * 2 = 8 = \Lambda(N_2). \text{ Then}$$
$$N_1(1 + 3\Lambda(N_1)) = 3600 < m^2 = 4900 < N_2(1 + 3\Lambda(N_2)) = 6400.$$

The algorithm for N_1 is faster than the direct computation, while that for the smallest power-of-two, 2^8, which exceeds $2 * 69$ is slower. This example shows that the standard choice of the power-of-two Cooley–Tukey FFT may not work at all or may give bad results for the fast multiplication of polynomials.

(4) This example is a multivariate one with

$$r > 1, \text{ but } m_1 = \cdots = m_r = n_1 = \cdots = n_r = 2.$$

The polynomials P and Q are of degree at most one in each indeterminate z_i or contain only square-free monomials. The direct computation of PQ has the total complexity $\prod_{j=1}^{r} m_j n_j = 4^r$. The optimal choice for the d_j is

$$d_1 = \cdots = d_r = 3; \text{ hence } N = 3^r, \ \Lambda(N) = 2r.$$

The algorithm (77) for these data has the complexity

$$N(1 + 3\Lambda(N)) = 3^r(1 + 6r) < 4^r \text{ for } r \geq 16.$$

The best applicable power-of-two FFT is that with $d_1 = \cdots = d_r = 4$ and the ensuing multiplication complexity $4^r(1 + 6r)$ which is much slower than the direct multiplication.

8. Number theoretic transforms (NTT). The following considerations give interesting examples of the DFT with coefficient rings instead of fields. They are simple variants or special cases of those in [26, Chap. 8], [15], [18, Chap. 7], where also the technical significance of these transforms is discussed. We adapt our notation to that of [26] and consider $N > 0$, a commutative ring K, and a primitive Nth root of one $\zeta \in K$. Consider the groups

$$G := \widehat{G} := \mathbb{Z}/\mathbb{Z}N \underset{\text{ident.}}{=} \{0, \cdots, N-1\} \text{ with } \overline{k} \bullet \overline{l} := \overline{kl} \in \mathbb{Z}/\mathbb{Z}N, \ \langle \overline{k}, \overline{l} \rangle := \zeta^{kl},$$
$$\mu := \langle \zeta \rangle = \{\eta_0, \cdots, \eta_i := \zeta^i, \cdots, \eta_{N-1} := \zeta^{N-1}\}.$$

The Fourier transform $\text{Four} := \text{Four}_G$ on G is given as (see Example 20)

$$a, \ \widehat{a} := \text{Four}_{\mathbb{Z}/\mathbb{Z}N}(a) \in K^N, \ \widehat{a}(l) = \sum_{k=0}^{N-1} \zeta^{lk} a(k), \text{ or}$$
$$\begin{pmatrix} \widehat{a}(0) \\ \widehat{a}(1) \\ \cdots \\ \widehat{a}(N-1) \end{pmatrix} = \begin{pmatrix} 1 & 1 & \cdots & 1 \\ \eta_0 & \eta_1 & \cdots & \eta_{N-1} \\ \cdots & \cdots & \cdots & \cdots \\ \eta_0^{N-1} & \eta_1^{N-1} & \cdots & \eta_{N-1}^{N-1} \end{pmatrix} \begin{pmatrix} a(0) \\ a(1) \\ \cdots \\ a(N-1) \end{pmatrix}.$$

The determinant of this Vandermonde matrix is

$$\det := \prod_{0 \leq i < j \leq N-1} (\eta_j - \eta_i) = \prod_{0 \leq i < j \leq N-1} \zeta^i (\zeta^{j-i} - 1), \tag{78}$$

whose factors are the units ζ^i and the $\eta - 1, \ 1 \neq \eta \in \mu$.

Reminder 79 (see [23, pp. 203–207]). Let $z := \exp(\frac{2\pi i}{N})$ denote a complex primitive Nth root of one and $\nu := \langle z \rangle$ the cyclic group of all complex Nth roots of one. If $d \geq 1$ is a divisor of N, the set $\nu_d := \{z^{\frac{N}{d}k}; 1 \leq k \leq d-1, \gcd(k,d) = 1\}$ consists exactly of the $\varphi(d) := \mathrm{ord}(\mathrm{U}(\mathbb{Z}/\mathbb{Z}d))$ primitive dth roots of one, and the dth *cyclotomic polynomial* $\Phi_d := \prod_{x \in \nu_d}(X - x)$ is the (irreducible) minimal polynomial of all its roots in $\mathbb{Q}[X]$ and has coefficients in $\mathbb{Z}$, the latter property being derived from the obvious product representation

$$X^N - 1 = \prod_{x \in \nu}(X - x) = \prod_{d|N} \prod_{x \in \nu_d}(X - x) = \prod_{d|N} \Phi_d. \tag{79}$$

Since $\Phi_d \in \mathbb{Z}[X]$ the value $\Phi_d(x)$ is defined for every element x of any ring.

THEOREM 80 (see [26, Thms. 8.3, 8.4], [15, Satz 2.8]). *The following assertions are equivalent.*

(1) *Assumption* 29 *is satisfied, and hence the Fourier inversion theorem, Theorem* 34*, holds for all finite abelian groups of exponent* N*, i.e.,* (i) $N \in \mathrm{U}(K)$ *and* (ii)

$$\textit{for all } d > 1,\ d \mid N,\ \eta := \zeta^{\frac{N}{d}}: \quad 1 + \eta + \cdots + \eta^{d-1} = 0.$$

(2) *The Fourier transform* $\mathrm{Four}_{\mathbb{Z}/\mathbb{Z}N}$ *is an isomorphism.*

(3) *For all* $\eta \neq 1$ *in* $\mu = \langle \zeta \rangle$ *the element* $\eta - 1$ *is a unit in* K*.*

(4) (i) $N \in \mathrm{U}(K)$*.* (ii) $\Phi_N(\zeta) = 0$*.*

Proof. (1) $\Rightarrow$ (2): This is a special case.

(2) $\Leftrightarrow$ (3): The Fourier transform is an isomorphism if and only if its (Vandermonde) determinant (78) is a unit, and this is the case if and only if all factors $\eta - 1$, $1 \neq \eta \in \mu$, of this determinant are units, the ζ^i being units by assumption.

(3) $\Rightarrow$ (1): As just shown, $\mathrm{Four}_{\mathbb{Z}/\mathbb{Z}N}$ is an isomorphism. Let $d > 1$ be a divisor of N and let $\eta := \zeta^{\frac{N}{d}}$ be the root of order $\mathrm{ord}(\eta) = d$; hence

$$0 = \eta^d - 1 = (\eta - 1)(\eta^{d-1} + \cdots + 1).$$

But

$$\frac{N}{d} < N,\ \mathrm{ord}(\zeta) = N \ \Rightarrow\ \eta \neq 1 \underset{(3)}{\Rightarrow} \eta - 1 \in \mathrm{U}(K) \ \Rightarrow\ \eta^{d-1} + \cdots + 1 = 0,$$

and this is the second condition of Assumption 29. The proof of Theorem 34 then implies that $\mathrm{Four}^2_{\mathbb{Z}/\mathbb{Z}N} = NS_{\mathbb{Z}/\mathbb{Z}N}$. Since $\mathrm{Four}_{\mathbb{Z}/\mathbb{Z}N}$ and $S_{\mathbb{Z}/\mathbb{Z}N}$ are isomorphisms, N is invertible in K.

(1), (2), (3) $\Rightarrow$ (4): Equation (79) implies

$$0 = \zeta^N - 1 = \Phi_N(\zeta) \prod_{d|N,\ 1 \leq d < N} \Phi_d(\zeta).$$

But $\Phi_d \mid X^d - 1$ and condition (3) imply that

$$\text{for all } d \text{ with } d \mid N,\ 1 \leq d < N : \Phi_d(\zeta) \in \mathrm{U}(K);$$

hence $\Phi_N(\zeta) = 0$.

(4) $\Rightarrow$ (1): Let $1 < d$ be a divisor of N and let

$$Y := X^{\frac{N}{d}};\ \text{hence } X^N - 1 = Y^d - 1 = (Y - 1)(Y^{d-1} + \cdots + 1).$$

The polynomial Φ_N is irreducible in $\mathbb{Z}[X]$ and divides X^N-1, but not $X^{\frac{N}{d}}-1$ since $d>1$; hence Φ_N divides $Y^{d-1}+\cdots+1$. But then

$$\Phi_N(\zeta)=0,\ \eta:=Y(\zeta)=\zeta^{\frac{N}{d}},\ \text{and thus } \eta^{d-1}+\cdots+1=0.$$

This is exactly the second condition of Assumption 29. □

Reminder 81 (see [23, Exercise 7, p. 73]). Let

$$p=\text{odd prime},\ m\geq 1,\ K:=\mathbb{Z}/\mathbb{Z}p^m,\ \text{can}:K\to\mathbb{Z}/\mathbb{Z}p,\ \overline{k}\mapsto\overline{k}.\ \text{The group}$$
$$\mathrm{U}(K)=\{\eta=\overline{k}\in K;\ \gcd(p,k)=1 \text{ or } \text{can}(\eta)\neq 0 \text{ or } \text{can}(\eta)\in\mathrm{U}(\mathbb{Z}/\mathbb{Z}p)\}$$

is cyclic of order $\varphi(p^m)=p^{m-1}(p-1)$. More precisely, one obtains an exact sequence

$$1\to\langle 1+\overline{p}\rangle\xrightarrow{\subseteq}\mathrm{U}(K)\underset{\sigma}{\overset{\text{can}}{\rightleftarrows}}\mathrm{U}(\mathbb{Z}/\mathbb{Z}p)\to 1,$$

where $\langle 1+\overline{p}\rangle$ is cyclic of order p^{m-1} and where σ is the unique section of can which satisfies the condition $\sigma(\lambda^p)=\sigma(\lambda)^p$; indeed, σ is the well-defined map

$$\sigma:\mathrm{U}(\mathbb{Z}/\mathbb{Z}p)\to U(K),\ \overline{k}\mapsto\overline{k^{p^{m-1}}},$$

which is a monomorphism and induces the isomorphism

$$\mathrm{U}(\mathbb{Z}/\mathbb{Z}p)\times\langle 1+\overline{p}\rangle\cong\mathrm{U}(K),\ (\lambda,\eta)\mapsto\sigma(\lambda)\eta.$$

Since $\mathrm{U}(\mathbb{Z}/\mathbb{Z}p)$ is cyclic of order $p-1$ and $\gcd(p^{m-1},p-1)=1$, the Chinese remainder theorem implies that $\mathrm{U}(K)$ is cyclic, too, and is generated by $\sigma(\lambda)(1+\overline{p})$, where λ is a primitive $(p-1)$st root of one in $\mathbb{Z}/\mathbb{Z}p$. If $p=2$ and $m\geq 3$, the group $\mathrm{U}(\mathbb{Z}/\mathbb{Z}2^m)$ is not cyclic and is uninteresting for the DFT as will be shown instantly.

LEMMA 82. *Let p be prime, $m\geq 1$, $K:=\mathbb{Z}/\mathbb{Z}p^m$, and $\zeta\in K$ a primitive Nth root of one which satisfies the equivalent conditions of Theorem* 80. *Then N divides $p-1$. In particular, if $p=2$, then $N=1$ and $\zeta=1$, and therefore the case $p=2$ is uninteresting within the context of the DFT.*

Proof. Assume $p-1<N$. By Theorem 80, $\zeta^{p-1}-1$ is a unit in K and hence so is $\text{can}(\zeta^{p-1}-1)=\text{can}(\zeta)^{p-1}-1=0$ in $\mathbb{Z}/\mathbb{Z}p$, which is a contradiction. On the other hand, N divides the order $\varphi(p^m)=p^{m-1}(p-1)$ of $\mathrm{U}(K)$, and thus N is a divisor of $p-1$. □

THEOREM 83 (see [26, Thm. 8.6], [15, Satz 2.2]). *Let $M>2$ be an odd number, $M=p_1^{m_1}*\cdots*p_s^{m_s}$ its prime factor decomposition, $K=\mathbb{Z}/\mathbb{Z}M$, and $N>0$. Then K contains an Nth root of one satisfying the equivalent conditions of Theorem* 80 *if and only if N divides* $\gcd(p_1-1,\cdots,p_s-1)$.

Proof. The Chinese remainder theorem furnishes the isomorphism

$$\Delta:K=\mathbb{Z}/\mathbb{Z}M\cong K_1\times\cdots\times K_s:=\mathbb{Z}/\mathbb{Z}p_1^{m_1}\times\cdots\times\mathbb{Z}/\mathbb{Z}p_s^{m_s},\ \overline{k}\mapsto\Delta(\overline{k})=(\overline{k},\cdots,\overline{k}).$$

Assume $\zeta\in K$ satisfies the assumptions of Theorem 80 and let

$$\Delta(\zeta)=(\zeta_1,\cdots,\zeta_s);\ \text{hence } N=\text{ord}(\zeta)=\text{lcm}(N_1,\cdots,N_s),\ N_i:=\text{ord}(\zeta_i),\ \text{and}$$
$$\Delta(\zeta^m-1)=(\zeta_1^m-1,\cdots,\zeta_s^m-1).$$

The latter element is a unit if $m:=N_i<N$, but $\zeta_i^{N_i}-1=0$; hence $N=N_1=\cdots=N_s$ and $N\mid p_i-1,\ i=1,\ldots,s$, by Lemma 82.

If, conversely, for all i the number N divides p_{i-1}, λ_i is a generator of $\mathrm{U}(\mathbb{Z}/\mathbb{Z}p_i)$ and $\sigma_i : \mathrm{U}(\mathbb{Z}/\mathbb{Z}p_i) \to \mathrm{U}(\mathrm{K}_i)$ is the section according to Reminder 81, then

$$\zeta := \Delta^{-1}\left(\sigma_1\left(\lambda_1^{\frac{p_1-1}{N}}\right), \cdots, \sigma_s\left(\lambda_1^{\frac{p_s-1}{N}}\right)\right)$$

is the asserted root of one. □

We refer the reader to [26] and [18] for the discussion of special cases of the preceding theorem, in particular, those of *Mersenne and Fermat number transforms* with $M = 2^n - 1$ (resp., $M = 2^n + 1$).

Acknowledgment. I thank the two referees for their careful reading of the article, their positive opinion, and their suggestions. These have been incorporated into the revised version to the best of my abilities. One of the referees is obviously an aesthete.

PERFORMANCE BOUNDS IN L_p-NORM FOR APPROXIMATE VALUE ITERATION*

RÉMI MUNOS†

Abstract. *Approximate value iteration* (AVI) is a method for solving large Markov decision problems by approximating the optimal value function with a sequence of value function representations V_n processed according to the iterations $V_{n+1} = \mathcal{A}\mathcal{T}V_n$, where $\mathcal{T}$ is the so-called *Bellman operator* and $\mathcal{A}$ an *approximation operator*, which may be implemented by a *supervised learning* (SL) algorithm. Usual bounds on the asymptotic performance of AVI are established in terms of the L_∞-norm approximation errors induced by the SL algorithm. However, most widely used SL algorithms (such as least squares regression) return a function (the best fit) that minimizes an empirical approximation error in L_p-norm ($p \geq 1$). In this paper, we extend the performance bounds of AVI to weighted L_p-norms, which enables us to directly relate the performance of AVI to the approximation power of the SL algorithm, hence assuring the tightness and practical relevance of these bounds. The main result is a performance bound of the resulting policies expressed in terms of the L_p-norm errors introduced by the successive approximations. The new bound takes into account a concentration coefficient that estimates how much the discounted future-state distributions starting from a probability measure used to assess the performance of AVI can possibly differ from the distribution used in the regression operation. We illustrate the tightness of the bounds on an optimal replacement problem.

1. Introduction.

We consider the problem of solving large state-space *Markov decision processes* (MDPs) [29] in an infinite time horizon, discounted reward setting.

The *value iteration* algorithm is a method for computing the optimal value function V^* by processing a sequence of value function representations V_n according to the iterations $V_{n+1} = \mathcal{T}V_n$, where $\mathcal{T}$ is the so-called *Bellman operator*. Due to a contraction property—in L_∞-norm—of the Bellman operator, the iterates V_n converge to V^* as $n \to \infty$. However, this method is intractable when the number of states is so large that an exact representation of the values is impossible. We therefore need to represent the functions with a moderate number of coefficients and use methods for finding an approximate solution.

A very popular algorithm is the *approximate value iteration* (AVI) algorithm. It has long been implemented in many different settings in dynamic programming (DP) [32, 5] with online variants in the field of reinforcement learning (RL) [7, 33]. It is defined by a sequence of value function representations V_n that are processed recursively by means of the iterations

$$V_{n+1} = \mathcal{A}\mathcal{T}V_n, \tag{1.1}$$

where $\mathcal{T}$ is the *Bellman operator* and $\mathcal{A}$ an *approximation operator*, which may be sampling-based implemented by a *supervised learning* (SL) algorithm (see, e.g., [15]).

†SequeL team, INRIA Futurs, Université de Lille, 59653 Villeneuve d'Ascq, France (remi.munos@inria.fr).

Since we will make use of different norms, let us now recall their definition: Let $u \in \mathbb{R}^N$. Its supremum (L_∞) norm is defined by $||u||_\infty := \sup_{1\leq x\leq N} |u(x)|$. Now, for μ being a probability measure on $\{1,\ldots,N\}$, the weighted L_p-(semi)norm (for $p \geq 1$)—denoted by $L_{p,\mu}$—of u is $||u||_{p,\mu} := \left[\sum_{1\leq x\leq N} \mu(x)|u(x)|^p\right]^{1/p}$. In addition, we denote by $||\cdot||_p$ the unweighted L_p-norm (i.e., when μ is uniform).

A typical implementation of AVI is *fitted value iteration*, which, given a function space $\mathcal{F}$, computes at each iteration a new value representation $V_{n+1} \in \mathcal{F}$ by projecting onto $\mathcal{F}$ the Bellman image of the current estimate V_n. For illustration, a sampling-based version of this algorithm could be defined as follows: At stage n, we draw a set of independent states $\{x_k \sim \mu\}_{1\leq k\leq K}$, where μ is some probability measure on the state space, compute the Bellman values $\{v_k := \mathcal{T}V_n(x_k)\}_{1\leq k\leq K}$ for the current approximation V_n at those states, then make a call to an SL algorithm with the data $\{(x_k, v_k)\}_{1\leq k\leq K}$ ($\{x_k\}$ being the input and $\{v_k\}$ the desired output). The SL algorithm would return a function V_{n+1} (the best fit) that minimizes some empirical loss

$$V_{n+1} := \arg\min_{g\in\mathcal{F}} \frac{1}{K} \sum_{1\leq k\leq K} l(g(x_k) - v_k),$$

where the *loss function* l is usually a square or an absolute function (or variants, such as the ϵ-insensitive loss used in support vectors [36]).

This is a sampling-based version of the minimization problem in a weighted (by μ) absolute or quadratic norm ($L_{p,\mu}$-norm with $p = 1$ or 2, respectively)

$$\arg\min_{g\in\mathcal{F}} ||g - \mathcal{T}V_n||_{p,\mu}.$$

The field of *statistical learning* analyses the difference between the minimized empirical loss $\frac{1}{K}\sum_{1\leq k\leq K} l(V_{n+1}(x_k) - v_k)$ and the corresponding $L_{p,\mu}$-norm approximation error $||V_{n+1} - \mathcal{T}V_n||_{p,\mu}$ in terms of the number of samples K and a capacity measure of the function space $\mathcal{F}$ (such as the *covering number* or the *Vapnik–Chervonenkis (VC) dimension* [28, 36] of $\mathcal{F}$).

It is therefore natural to search for bounds on the performance of AVI that rely on weighted L_p-norms ($p \geq 1$) of the approximation errors $||V_{n+1} - \mathcal{T}V_n||_{p,\mu}$.

Unfortunately, the main field of investigation so far in approximate DP makes use of the supremum norm [4, 5, 6, 29, 7, 16, 13]. For example, the asymptotic performance of the policies deduced by the AVI algorithm may be bounded in terms of the L_∞-norm of the approximation errors $||V_{n+1} - \mathcal{T}V_n||_\infty$ (see section 2). However, this bound is not very useful since this uniform approximation error is difficult to control in general and is not very practical because most currently known SL algorithms solve an empirical minimization problem in L_p-norm (like least squares regression, neural networks, support vector, and kernel regression). Since most approximation operators provide good approximations in L_p-norm but a poor performance with respect to (w.r.t.) the L_∞-norm, it would be relevant to measure the algorithm performance w.r.t. the former norm.

The purpose of this paper is to extend error bounds for AVI to L_p-norms. The performance of AVI can therefore be directly related to the approximation power of the SL algorithm.

To begin with, let us mention that of course norms are equivalent (in the case of finite-dimensional spaces) since $||\cdot||_p \leq ||\cdot||_\infty \leq N^{1/p}||\cdot||_p$ (with $p \geq 1$ and N being the number of states); thus the usual L_∞ bound for AVI (detailed in section 2) may

also be used to derive an L_p-norm bound. However, because of the $N^{1/p}$ factor, this yields a very loose bound for large scale problems.

The bounds derived here (see Theorem 5.2 in section 5) depend on a new concentration (or stability) measure of the MDP: The *concentration coefficient* $C(\nu, \mu)$ measures how much the discounted average future-state distribution starting from some distribution ν used to assess the performance of AVI (through the weighting of the L_p-norm of the algorithm's performance) can possibly diverge from the distribution μ used in the regression step (by the SL algorithm). This concentration coefficient is defined as an upper bound, taken for any nonstationary policy, of the derivative of the discounted future-state distribution (starting from ν and following a policy) w.r.t. the regression distribution μ.

This coefficient is related to the so-called *top-Lyapunov exponent*, which is commonly used to analyze the stability of stochastic processes. Further discussion about this concept in continuous spaces (where this coefficient is defined in terms of the Radon–Nikodým derivative of the related probability measures) can be found in [27].

A sufficient condition for the concentration coefficient to be small is when the MDP is "smooth" (i.e., when the transition probabilities are strongly stochastic, e.g., close to uniform distribution). Actually, we derive another bound, this time on the L_∞ performance of the AVI algorithm (but still in terms of the L_p approximation errors) using another concentration coefficient $C(\mu)$ that relates the immediate transition probabilities of the MDP to the regression distribution μ. For a uniform μ, a smooth MDP will define a small $C(\mu)$ value, and our bound will be sharp. However, for an MDP with deterministic transitions, the coefficient $C(\mu)$ could depend heavily on the number of states N, making our new bounds no more informative than a usual L_∞-norm bound. This is illustrated in the *chain walk* MDP (for which $C(\mu) = N$) described in subsection 5.5. However, even for deterministic MDPs, the concentration coefficient $C(\nu, \mu)$ may be small, and independent of N, as illustrated in the same example. For such cases, the new L_p bound is arbitrarily better than the usual L_∞ one.

The main intuition underlying this extension of usual L_∞ bounds to L_p-norms is actually simple (see the first paragraph of section 5) and is a consequence of the componentwise bounds obtained in section 4.

To the best of our knowledge, this weighted L_p-norm analysis of AVI is new. Previous L_p analyses in *approximate dynamic programming* (ADP) include *temporal difference learning* (for the evaluation of a fixed policy) with linear approximation [35] and *approximate policy iteration* [26] (and [1] in the continuous space, sampling-based case). Let us mention that there is an important body of literature in the domain of weighted L_∞-norm analysis of ADP [7, 17], especially for the linear programming approach [10]. Let us also remark that there exists an important related field concerned with stability, ergodicity, and convergence properties of future state distributions w.r.t. the invariant probability measure (in Markov chains [19] or MDPs [18, 25]). This is not the direction followed in this paper since we are interested in the discounted reward case (with a fixed discount factor) and not the average reward case.

The paper is organized as follows: In section 2, we recall some approximation results in L_∞-norm. Section 3 is a rough survey of approximation operators and SL algorithms. The main tool used in this paper is the derivation of the componentwise bounds for AVI, detailed in section 4. The performance bounds in L_p-norms are stated in section 5, and the main result of this paper is given in Theorem 5.2. A subsection

provides some intuition on these results in case the AVI algorithm would converge, which leads to bounds expressed in terms of the L_p Bellman residual. Section 6 details practical implementations of AVI (a sampling-based method using state-action value function approximation). The case of a continuous measurable state space is treated in section 7, and a numerical experiment on an optimal replacement problem is detailed.

Preliminaries. We now describe the framework of MDPs in the infinite-time horizon, discounted reward setting, considered here.

Let X be the state space, assumed to be finite with N states, and let A be a finite action space. The results given in this paper extend to infinite state spaces (either countable spaces or continuous spaces, the latter case being illustrated in section 7). Let $p(x,a,y)$ be the probability that the next state is y given that the current state is x and the action a. Let $r(x,a,y)$ be the (deterministic) reward received when a transition $(x,a) \to y$ occurs.

We call a *(Markov* or *stationary) policy* π a mapping from X to A. We denote by P^π the $N \times N$ matrix with elements $P^\pi(x,y) := p(x,\pi(x),y)$ and by r^π the N-vector with components $r^\pi(x) := \sum_y p(x,\pi(x),y) r(x,\pi(x),y)$.

For a given policy π, the *value function* V^π (considered as a vector with N components) is defined as the expected sum of discounted rewards:

$$V^\pi(x) := \mathbb{E}\Big[\sum_{t=0}^{\infty} \gamma^t\, r(x_t,a_t,x_{t+1}) | x_0 = x, a_t = \pi(x_t)\Big],$$

where $\gamma \in [0,1)$ is the *discount factor*. It is well known that V^π is the fixed-point of the operator $\mathcal{T}^\pi : \mathbb{R}^N \to \mathbb{R}^N$ defined, for any vector $W \in \mathbb{R}^N$, by $\mathcal{T}^\pi W := r^\pi + \gamma P^\pi W$.

The *optimal value function* $V^* := \sup_\pi V^\pi$ is the fixed-point of the Bellman operator $\mathcal{T}$ defined, for any $W \in \mathbb{R}^N$, $x \in X$, by

$$\mathcal{T}W(x) = \max_{a \in A} \sum_{y \in X} p(x,a,y)[r(x,a,y) + \gamma W(y)].$$

We say that a policy π is *greedy w.r.t.* $W \in \mathbb{R}^N$ if for all $x \in X$,

$$\pi(x) \in \arg\max_{a \in A} \sum_{y \in X} p(x,a,y)[r(x,a,y) + \gamma W(y)].$$

The goal is to find an optimal policy π^*, which is such that for all $x \in X$, $V^{\pi^*}(x) = \max_\pi V^\pi(x)$. It is easy to see that a policy greedy w.r.t. V^* is optimal. Since $\mathcal{A}$ is finite, such an optimal policy always exits.

2. Approximation results in L_∞-norm. Consider the *AVI algorithm* defined by (1.1) and define

$$\varepsilon_n := \mathcal{T}V_n - V_{n+1} \in \mathbb{R}^N \tag{2.1}$$

as the *approximation error* at stage n. In general, AVI does not converge, but nevertheless its asymptotic behavior may be analyzed. If the approximation errors are uniformly bounded $||\varepsilon_n||_\infty \le \varepsilon$, then a bound on the difference between the asymptotic performance of policies π_n greedy w.r.t. V_n and the optimal policy is (see, e.g., [7])

$$\limsup_{n \to \infty} ||V^* - V^{\pi_n}||_\infty \le \frac{2\gamma}{(1-\gamma)^2}\varepsilon. \tag{2.2}$$

Since the proof is very simple, it is recalled here.

Proof. From the triangle inequality, the γ-contraction of the Bellman operators $\mathcal{T}$ and $\mathcal{T}^{\pi_n}$, and the fact that π_n is greedy w.r.t. V_n (i.e., $\mathcal{T}^{\pi_n} V_n = \mathcal{T} V_n$), we have

$$\begin{aligned} ||V^* - V^{\pi_n}||_\infty &\leq ||\mathcal{T}V^* - \mathcal{T}^{\pi_n} V_n||_\infty + ||\mathcal{T}^{\pi_n} V_n - \mathcal{T}^{\pi_n} V^{\pi_n}||_\infty \\ &\leq \gamma ||V^* - V_n||_\infty + \gamma(||V_n - V^*||_\infty + ||V^* - V^{\pi_n}||_\infty), \end{aligned}$$

and thus

$$||V^* - V^{\pi_n}||_\infty \leq \frac{2\gamma}{1-\gamma} ||V^* - V_n||_\infty. \tag{2.3}$$

Moreover, $||V^* - V_{n+1}||_\infty \leq ||\mathcal{T}V^* - \mathcal{T}V_n||_\infty + ||\mathcal{T}V_n - V_{n+1}||_\infty \leq \gamma ||V^* - V_n||_\infty + \varepsilon$. Now, taking the upper limit yields $\limsup_{n\to\infty} ||V^* - V_n||_\infty \leq \varepsilon/(1-\gamma)$, which combined with (2.3) yields (2.2). □

This L_∞ bound is expressed in terms of the uniform approximation error over all states, which is difficult to guarantee, especially for large state-space problems. Moreover, it is not very useful in practice since most current approximation operators and supervised learning methods perform a minimization problem in L_1- or L_2-norm (although some exceptions of L_∞ function approximation in the framework of DP exist; see, e.g., [12, 14]).

3. Approximation operators and supervised learning algorithms. In this section we present an overview of the problem of function approximation in the context of *statistical learning* (see, e.g., [36, 15]). To illustrate, an example of a supervised learning (SL) algorithm would take as input some data $\{(x_k, v_k)\}_{1\leq k\leq K}$, where the states $\{x_k \in X\}$ are drawn according to some distribution μ on X, and the values $\{v_k \in \mathbb{R}\}$ are unbiased estimates of some (unknown) random function with mean $f(x_k)$. This SL algorithm would return a function (called the *best fit*) that minimizes (within a given class of functions $\mathcal{F}$) the empirical loss, solving

$$\inf_{g\in\mathcal{F}} \frac{1}{K} \sum_{k=1}^{K} l(v_k - g(x_k)),$$

where the loss function l is usually an absolute or a quadratic function (or variants, such as the *ϵ-insensitive loss function* used in support vectors or *Huber loss function* used for robust regression [36]).

If the unknown function is deterministic (i.e., $v_k = f(x_k)$), $\mathcal{A}$ may be considered as an approximation operator that returns a compact representation $g \in \mathcal{F}$ of an unknown function f by minimizing some empirical L_p-norm ($p = 1$ or 2) based on the data. This is a sampling-based version of a minimization problem in weighted norm $L_{p,\mu}$. Statistical learning theory establishes bounds on the error between the minimized empirical loss $\frac{1}{K}\sum_{k=1}^{K} l(f(x_k) - g(x_k))$ and the $L_{p,\mu}$-norm difference $||f - g||_{p,\mu}$ in terms of the number of samples K and the capacity (or complexity) measure of the function space $\mathcal{F}$, characterized, e.g., by the *covering number* or the *VC dimension* [28, 36] of $\mathcal{F}$.

The projection onto the span of a fixed family of functions (often called *features*) is called *linear approximation* and include *splines*, *radial basis, and Fourier* or *wavelet decomposition*. It is often the case that a better approximation is reached when choosing the features according to f (i.e., *feature selection*). This *nonlinear approximation*

is particularly efficient when f has piecewise regularities (e.g., in the adaptive wavelet basis [24] such functions are compactly represented with few nonzero coefficients). Greedy algorithms for selecting the best features among a given dictionary of functions include the *matching pursuit* and variants [9]. Approximation theory studies the approximation error in terms of the smoothness of f [11].

In statistical learning, SL algorithms include *neural network*, *locally weighted learning* and *kernel regression* [2], *support vectors*, and *reproducing kernels* [37, 36].

Hence, given the fact that we may always bound the empirical minimized error using statistical learning tools, in what follows, we will establish our bounds using the $L_{p,\mu}$-norm of the approximation errors. An extension of these results to sampling-based AVI is described in [27] and a policy iteration algorithm with Bellman residual minimization using a single sample-path is described in [1].

4. Componentwise performance bounds. In this section, we formulate componentwise performance bounds, from which L_p bounds will be derived in the next section. The L_∞ bound previously stated (2.2) is also an immediate consequence of a componentwise bound.

4.1. Performance bound for AVI. A componentwise bound on the asymptotic performance of the policies π_n greedy w.r.t. V_n is provided now.

LEMMA 4.1. *Consider the AVI algorithm defined by* (1.1) *and write* $\varepsilon_n = \mathcal{T}V_n - V_{n+1} \in \mathbb{R}^N$ *to denote the approximation error at stage* n. *Let* π_n *be a greedy policy w.r.t.* V_n. *We have*

$$\limsup_{n\to\infty} V^* - V^{\pi_n} \le \limsup_{n\to\infty} (I - \gamma P^{\pi_n})^{-1} \times \left(\sum_{k=0}^{n-1} \gamma^{n-k} \left[(P^{\pi^*})^{n-k} + P^{\pi_n} P^{\pi_{n-1}} \dots P^{\pi_{k+2}} P^{\pi_{k+1}} \right] |\varepsilon_k| \right), \tag{4.1}$$

where $|\varepsilon_k|$ *denotes the vector of absolute values of* ε_k.

In order to prove this lemma, we first need the following preliminary result.

LEMMA 4.2. *Let* A *be an invertible matrix such that all the elements of its inverse are positive. Then the solutions to the inequality* $Au \le b$ *are also solutions to* $u \le A^{-1}b$.

Proof of Lemma 4.2. Let u be a solution to $Au \le b$. This means that there exists a vector c with positive components such that $Au = b - c$; thus $u = A^{-1}b - A^{-1}c$. Since all components of $A^{-1}c$ are positive, we deduce that $u \le A^{-1}b$. □

Proof of Lemma 4.1. From the definitions of $\mathcal{T}$ and $\mathcal{T}^\pi$ we have componentwise $\mathcal{T}V_k \ge \mathcal{T}^{\pi^*}V_k$ and $\mathcal{T}V^* \ge \mathcal{T}^{\pi_k}V^*$, and thus

$$V^* - V_{k+1} = \mathcal{T}^{\pi^*}V^* - \mathcal{T}^{\pi^*}V_k + \mathcal{T}^{\pi^*}V_k - \mathcal{T}V_k + \varepsilon_k \le \gamma P^{\pi^*}(V^* - V_k) + \varepsilon_k,$$

$$V^* - V_{k+1} = \mathcal{T}V^* - \mathcal{T}^{\pi_k}V^* + \mathcal{T}^{\pi_k}V^* - \mathcal{T}V_k + \varepsilon_k \ge \gamma P^{\pi_k}(V^* - V_k) + \varepsilon_k,$$

where in the second line we used the definition of π_k as a greedy policy w.r.t. V_k, i.e., $\mathcal{T}^{\pi_k}V_k = \mathcal{T}V_k$. We deduce by induction

$$V^* - V_n \le \sum_{k=0}^{n-1} \gamma^{n-k-1}(P^{\pi^*})^{n-k-1}\varepsilon_k + \gamma^n (P^{\pi^*})^n (V^* - V_0), \tag{4.2}$$

$$V^* - V_n \ge \sum_{k=0}^{n-1} \gamma^{n-k-1}(P^{\pi_{n-1}} P^{\pi_{n-2}} \dots P^{\pi_{k+1}})\varepsilon_k + \gamma^n (P^{\pi_n} P^{\pi_{n-1}} \dots P^{\pi_1})(V^* - V_0). \tag{4.3}$$

Now, using again the definition of π_n and the fact that $\mathcal{T}V_n \geq \mathcal{T}^{\pi^*}V_n$, we have

$$\begin{aligned} V^* - V^{\pi_n} &= \mathcal{T}^{\pi^*}V^* - \mathcal{T}^{\pi^*}V_n + \mathcal{T}^{\pi^*}V_n - \mathcal{T}V_n + \mathcal{T}V_n - \mathcal{T}^{\pi_n}V^{\pi_n} \\ &\leq \mathcal{T}^{\pi^*}V^* - \mathcal{T}^{\pi^*}V_n + \mathcal{T}V_n - \mathcal{T}^{\pi_n}V^{\pi_n} \\ &= \gamma P^{\pi^*}(V^* - V_n) + \gamma P^{\pi_n}(V_n - V^{\pi_n}) \\ &= \gamma P^{\pi^*}(V^* - V_n) + \gamma P^{\pi_n}(V_n - V^* + V^* - V^{\pi_n}). \end{aligned}$$

Thus $(I - \gamma P^{\pi_n})(V^* - V^{\pi_n}) \leq \gamma(P^{\pi^*} - P^{\pi_n})(V^* - V_n)$. Now, since $(I - \gamma P^{\pi_n})$ is invertible and its inverse $\sum_{k\geq 0}(\gamma P^{\pi_n})^k$ has positive elements, we use Lemma 4.2 to deduce that

$$V^* - V^{\pi_n} \leq \gamma(I - \gamma P^{\pi_n})^{-1}(P^{\pi^*} - P^{\pi_n})(V^* - V_n).$$

This, combined with (4.2) and (4.3), and after taking the absolute value (note that the vector $V^* - V^{\pi_n}$ is nonnegative), yields

$$\begin{aligned} V^* - V^{\pi_n} \leq (I - \gamma P^{\pi_n})^{-1} \Bigg\{ &\sum_{k=0}^{n-1} \gamma^{n-k} \left[(P^{\pi^*})^{n-k} + (P^{\pi_n} P^{\pi_{n-1}} \dots P^{\pi_{k+1}}) \right] |\varepsilon_k| \\ &+ \gamma^{n+1} \left[(P^{\pi^*})^{n+1} + (P^{\pi_n} P^{\pi_n} P^{\pi_{n-1}} \dots P^{\pi_1}) \right] |V^* - V_0| \Bigg\}. \end{aligned}$$

We deduce (4.1) by taking the upper limit. ∎

4.2. Performance bound based on the Bellman residual. In this section, we derive a componentwise performance bound of a policy π greedy w.r.t. some function $V \in \mathbb{R}^N$ in terms of the Bellman residual of V. This result extends the L_∞ bound (see a proof in [38]):

$$||V^* - V^\pi||_\infty \leq \frac{2}{1-\gamma} ||\mathcal{T}V - V||_\infty. \tag{4.4}$$

The componentwise counterpart of this bound is stated now.

LEMMA 4.3. *Let $V \in \mathbb{R}^N$ and let π be a policy greedy w.r.t. V. Then*

$$V^* - V^\pi \leq \left[(I - \gamma P^{\pi^*})^{-1} + (I - \gamma P^\pi)^{-1} \right] |\mathcal{T}V - V|. \tag{4.5}$$

We immediately notice that (4.4) is a direct consequence of this result, since for any stochastic matrix P, $||(I - \gamma P)^{-1}||_\infty = 1/(1-\gamma)$.

Proof of Lemma 4.3. We use the fact that $\mathcal{T}V \geq \mathcal{T}^{\pi^*}V$ and the definition of π (i.e., $\mathcal{T}V = \mathcal{T}^\pi V$) to derive

$$\begin{aligned} V^* - V^\pi &= \mathcal{T}^{\pi^*}V^* - \mathcal{T}^{\pi^*}V + \mathcal{T}^{\pi^*}V - \mathcal{T}V + \mathcal{T}V - \mathcal{T}^\pi V^\pi \\ &\leq \gamma P^{\pi^*}(V^* - V^\pi + V^\pi - V) + \gamma P^\pi(V - V^\pi); \end{aligned}$$

hence $(I - \gamma P^{\pi^*})(V^* - V^\pi) \leq \gamma(P^{\pi^*} - P^\pi)(V^\pi - V)$. Again, since $(I - \gamma P^{\pi^*})$ is invertible and its inverse has positive elements, from Lemma 4.2, we deduce

$$V^* - V^\pi \leq \gamma(I - \gamma P^{\pi^*})^{-1}(P^{\pi^*} - P^\pi)(V^\pi - V).$$

Moreover,

$$\begin{aligned}(I-\gamma P^\pi)(V^\pi - V) &= V^\pi - V - \gamma P^\pi V^\pi + \gamma P^\pi V \\ &= r^\pi + \gamma P^\pi V - (r^\pi + \gamma P^\pi V^\pi) + V^\pi - V \\ &= \mathcal{T}^\pi V - \mathcal{T}^\pi V^\pi + V^\pi - V = \mathcal{T}V - V,\end{aligned}$$

and thus

$$\begin{aligned}V^* - V^\pi &\le \gamma(I-\gamma P^{\pi^*})^{-1}(P^{\pi^*} - P^\pi)(I-\gamma P^\pi)^{-1}(\mathcal{T}V - V) \\ &= (I-\gamma P^{\pi^*})^{-1}\Big[(I-\gamma P^\pi) - (I-\gamma P^{\pi^*})\Big](I-\gamma P^\pi)^{-1}(\mathcal{T}V - V) \\ &= \Big[(I-\gamma P^{\pi^*})^{-1} - (I-\gamma P^\pi)^{-1}\Big](\mathcal{T}V - V) \\ &\le \Big[(I-\gamma P^{\pi^*})^{-1} + (I-\gamma P^\pi)^{-1}\Big]|\mathcal{T}V - V|. \qquad \square\end{aligned}$$

5. Approximation results in L_p-norms. In this section, we generalize the previously mentioned L_∞ bounds to L_p-norms. The main intuition behind this extension is simple and relies on the componentwise results described in the previous section.

Indeed, assume that there exist two vectors u and v with positive components, such that componentwise $u \le Qv$, where Q is a stochastic matrix. Of course, we may deduce that $||u||_\infty \le ||v||_\infty$, but in addition, if ν and μ are probability measures on X such that componentwise $\nu Q \le C\mu$, where $C \ge 1$ is a constant (and using usual matrix notation with the probability measures being considered as row vectors), then we deduce that

$$||u||_{p,\nu} \le C^{1/p}||v||_{p,\mu}.$$

Indeed we have

$$\begin{aligned}||u||_{p,\nu}^p = \sum_{x\in X}\nu(x)|u(x)|^p &\le \sum_{x\in X}\nu(x)\Big[\sum_{y\in X}Q(x,y)v(y)\Big]^p \\ &\le \sum_{x\in X}\nu(x)\sum_{y\in X}Q(x,y)v(y)^p \\ &\le C\sum_{y\in X}\mu(y)|v(y)|^p = C||v||_{p,\mu}^p,\end{aligned}$$

using Jensen's inequality.

For example, if the Markov chain induced by Q has an invariant probability measure ν, then we have $||u||_{p,\nu} \le ||v||_{p,\nu}$ (i.e., the constant $C = 1$). This is the main tool used in [35] to derive an L_p-norm bound for temporal difference learning with linear function approximation, where only one policy is considered.

Now, in an MDP, there are several policies, and thus several stochastic matrices to be considered in order to relate $||u||_{p,\nu}$ to $||v||_{p,\mu}$. The next subsection defines the *concentration coefficients* $C_1(\nu,\mu)$, $C_2(\nu,\mu)$, and $C(\mu)$ that generalize the constant C used here for the case when several policies are considered.

A simple case for which the above idea may apply is the case of Bellman residual bounds: Choose $u = V^* - V^\pi$ and $v = \frac{2}{1-\gamma}|\mathcal{T}V - V|$, and notice that the L_∞ bound (4.4) is a consequence of (4.5). The above idea will yield an L_p-norm performance bound (this will be done in subsection 5.3).

This same idea also holds for deriving performance bounds for AVI. We notice that the L_∞ bound (2.2) may be deduced from the componentwise bounds (4.1), and extension to L_p-norms is possible with an adequate constant, to be defined now.

5.1. Definition of the concentration coefficients. We now define the concentration coefficients $C(\mu)$, $C_1(\nu, \mu)$, and $C_2(\nu, \mu)$, which depend on the MDP, under which the distributions ν and μ may be related. Let ν and μ be two probability measures on X.

DEFINITION 5.1. *We call* $C(\mu) \in \mathbb{R}^+ \cup \{+\infty\}$ *the* transition probabilities concentration coefficient*, defined by*

$$C(\mu) = \max_{x,y \in X,\, a \in A} \frac{p(x,a,y)}{\mu(y)}$$

(with the convention that $0/0 = 0$*, and we set* $C(\mu) = \infty$ *if* $\mu(y) = 0$ *and* $p(x,a,y) > 0$ *for some* x, y, a*). Now, let* $\pi_1, \pi_2, \ldots$ *denote any sequence of policies. For every integer* $m \geq 1$*, we define* $c(m) \in \mathbb{R}^+ \cup \{+\infty\}$ *by*

$$c(m) = \max_{\pi_1,\ldots,\pi_m,\, y \in X} \frac{(\nu P^{\pi_1} P^{\pi_2} \ldots P^{\pi_m})(y)}{\mu(y)} \tag{5.1}$$

(with the same convention as above) and write $c(0) = 1$*. Note that these constants depend on* ν *and* μ*.*

We define $C_1(\nu, \mu)$ *and* $C_2(\nu, \mu) \in \mathbb{R}^+ \cup \{+\infty\}$*, the* first *and* second order discounted future state distribution concentration coefficients*, by*

$$C_1(\nu, \mu) := (1-\gamma) \sum_{m \geq 0} \gamma^m c(m), \tag{5.2}$$

$$C_2(\nu, \mu) := (1-\gamma)^2 \sum_{m \geq 1} m \gamma^{m-1} c(m). \tag{5.3}$$

Note that since these coefficients will appear in our bounds we are interested in the cases of finite values, for which it is sufficient that the distribution μ be strictly positive.

The transition probability concentration coefficient $C(\mu)$ was introduced in [26] to derive performance bounds for approximate policy iteration. $C(\mu)$ provides information about the relative smoothness of the immediate transition probabilities w.r.t. μ, whereas $C_1(\nu, \mu)$ and $C_2(\nu, \mu)$ give information about the worst discounted average future state distribution when starting from ν and following any policy. Informally, the future state transition is a probability measure over the state space induced by the state visitation frequency of the Markov chain resulting from the MDP when following a policy.

The coefficients $c(m)$ measure how much the future state distributions $\nu P^{\pi_1} \ldots P^{\pi_m}$ may possibly differ from the distribution μ. The definition of $C_1(\nu, \mu)$ and $C_2(\nu, \mu)$ introduces an exponential discounting (first order discounting weight of γ^m for $C_1(\nu, \mu)$, and second order discounting weight of $(m+1)\gamma^m$ for $C_2(\nu, \mu)$, where m is the horizon time). The discounting makes these coefficients small for a reasonably

large class of MDPs. For any sequence of policies $\pi_1, \ldots, \pi_m$, the (first and second order) discounted future state distributions starting from ν and using this sequence of policies (i.e., $\{x_i \sim p(x_{i-1}, \pi_i(x_{i-1}), \cdot)\}_{1 \le i \le m}$) is bounded by these coefficients ($C_1(\nu,\mu)$ and $C_2(\nu,\mu)$) times μ: for all x_0, y in X,

$$(1-\gamma) \sum_{m \ge 0} \gamma^m \Pr\big(x_m = y \big| x_0 \sim \nu, \pi_1, \ldots, \pi_m\big) \le C_1(\nu,\mu)\mu(y),$$

$$(1-\gamma)^2 \sum_{m \ge 1} m\gamma^{m-1} \Pr\big(x_m = y \big| x_0 \sim \nu, \pi_1, \ldots, \pi_m\big) \le C_2(\nu,\mu)\mu(y).$$

These coefficients are related to the so-called *top-Lyapunov exponent* Γ, which play a fundamental role in the stability analysis of stochastic processes. It turns out that the stability of a stochastic system, as related to the top-Lyapunov condition $\Gamma \le 0$ [8], is equivalent to the finiteness of the concentration coefficients. Hence, a small value of these coefficients can be interpreted as a stability condition too. Further discussion about this concept can be found in the report [27].

5.2. L_p-norm performance bounds for AVI. The next result establishes performance bounds for AVI in terms of the $L_{p,\mu}$-norm of the approximation errors $\varepsilon_n = V_{n+1} - \mathcal{T}V_n$.

THEOREM 5.2. *Let μ and ν be two probability measures on X. Consider the AVI algorithm defined by* (1.1)*, write π_n to denote a policy greedy w.r.t. V_n, and let $\varepsilon_n = V_{n+1} - \mathcal{T}V_n \in \mathbb{R}^N$ be the approximation error. Let $\varepsilon > 0$ and assume that $\mathcal{A}$ returns ε-approximations V_{n+1} in the $L_{p,\mu}$-norm ($p \ge 1$) of $\mathcal{T}V_n$, i.e., $||\varepsilon_n||_{p,\mu} \le \varepsilon$ for $n \ge 0$. Then*

$$\limsup_{n\to\infty} ||V^* - V^{\pi_n}||_\infty \le \frac{2\gamma}{(1-\gamma)^2} \big[C(\mu)\big]^{1/p} \varepsilon, \tag{5.4}$$

$$\limsup_{n\to\infty} ||V^* - V^{\pi_n}||_{p,\nu} \le \frac{2\gamma}{(1-\gamma)^2} \big[C_2(\nu,\mu)\big]^{1/p} \varepsilon. \tag{5.5}$$

Notice that the left-hand side (l.h.s.) of the first result (5.4) evaluates the performance in terms of a L_∞-norm, whereas the l.h.s. of the second result (5.5) makes use of an L_p-norm (although the right-hand side (r.h.s.) of both results is expressed in the L_p-norm). The first result does not depend on the distribution ν and may directly be compared to the L_∞ bound (2.2). Actually (5.4) directly implies (2.2) when $p \to \infty$ (for any strictly positive measure μ).

Proof of Theorem 5.2. First, notice that the coefficient $C(\mu)$ is always larger than $C_2(\nu,\mu)$ for any distribution ν. Indeed, for all $m \ge 1$, $c(m) \le C(\mu)$. Thus $C_2(\nu,\mu) \le (1-\gamma)^2 \sum_{m\ge1} m\gamma^{m-1} C(\mu) = C(\mu)$. Thus, if the bound (5.5) holds for any ν, choosing ν to be a Dirac at each state implies that (5.4) also holds. Therefore, we only need to prove (5.5). We may rewrite (4.4) as

$$V^* - V^{\pi_n} \le \frac{2\gamma(1-\gamma^{n+1})}{(1-\gamma)^2} \left[\sum_{k=0}^{n-1} \alpha_k A_k |\varepsilon_k| + \alpha_n A_n |V^* - V_0| \right],$$

with the positive coefficients $\{\alpha_k\}_{0 \le k \le n}$,

$$\alpha_k := \frac{(1-\gamma)\gamma^{n-k-1}}{1-\gamma^{n+1}} \quad \text{for } 0 \le k < n,$$

$$\alpha_n := \frac{(1-\gamma)\gamma^n}{1-\gamma^{n+1}}$$

(we notice that the sum $\sum_{k=0}^{n} \alpha_k = 1$), and the stochastic matrices $\{A_k\}_{0 \le k \le n}$,

$$A_k := \frac{1-\gamma}{2}(I - \gamma P^{\pi_n})^{-1}\left[(P^{\pi^*})^{n-k} + (P^{\pi_n} P^{\pi_{n-1}} \dots P^{\pi_{k+1}})\right] \quad \text{for } 0 \le k < n,$$

$$A_n := \frac{1-\gamma}{2}(I - \gamma P^{\pi_n})^{-1}\left[(P^{\pi^*})^{n+1} + (P^{\pi_n} P^{\pi_n} \dots P^{\pi_1})\right].$$

Since the two sides of this componentwise bound are positive, we may take the $L_{p,\nu}$-norm of those two vectors:

$$\begin{aligned} &||V^* - V^{\pi_n}||_{p,\nu}^p \\ &\quad \le \left[\frac{2\gamma(1-\gamma^{n+1})}{(1-\gamma)^2}\right]^p \sum_{x \in X} \nu(x) \left[\sum_{k=0}^{n-1} \alpha_k A_k |\varepsilon_k| + \alpha_n A_n |V^* - V_0|\right]^p (x) \\ &\quad \le \left[\frac{2\gamma(1-\gamma^{n+1})}{(1-\gamma)^2}\right]^p \sum_{x \in X} \nu(x) \left[\sum_{k=0}^{n-1} \alpha_k A_k |\varepsilon_k|^p + \alpha_n A_n |V^* - V_0|^p\right](x), \end{aligned} \tag{5.6}$$

using two times Jensen's inequality (since the coefficients $\{\alpha_k\}_{0 \le k \le n}$ sum to 1 and the matrix A_k are stochastic) (i.e., convexity of $x \to |x|^p$). The second term in the brackets disappears when taking the upper limit. Now, from the definition of the coefficients $c(m)$, $\nu A_k \le (1-\gamma) \sum_{m \ge 0} \gamma^m c(m+n-k)\mu$; thus the first term in (5.6) satisfies

$$\begin{aligned} \sum_x \nu(x) \sum_{k=0}^{n-1} \alpha_k A_k |\varepsilon_k|^p(x) &\le \sum_{k=0}^{n-1} \alpha_k (1-\gamma) \sum_{m \ge 0} \gamma^m c(m+n-k) ||\varepsilon_k||_{p,\mu}^p \\ &\le \frac{(1-\gamma)^2}{1-\gamma^{n+1}} \sum_{m \ge 0} \sum_{k=0}^{n-1} \gamma^{m+n-k-1} c(m+n-k) \varepsilon^p \\ &\le \frac{1}{1-\gamma^{n+1}} C_2(\nu, \mu) \varepsilon^p, \end{aligned}$$

where we replaced α_k by their values, and used the fact that $||\varepsilon_k||_{p,\mu} \le \varepsilon$. By taking the upper limit in (5.6), we deduce (5.5). □

What if AVI converges? We know that there is no guarantee that AVI converges. However, experimentally, we observe that in some cases convergence occurs. It is interesting to notice that in such cases, better bounds may be derived (in any norm) whenever $\gamma > 1/2$. Indeed, convergence of AVI would mean that there exists $V \in \mathbb{R}^N$ such that $\lim_{n \to \infty} V_n = V$. Thus, by taking the limit in (1.1), we deduce that V is a fixed-point of the operator $\mathcal{A}\mathcal{T}$, i.e., $V = \mathcal{A}\mathcal{T}V$, and the approximation error (2.1) tends to the residual $\mathcal{T}V - V$ of V.

We deduce that the asymptotic performance of AVI is the performance of a policy π greedy w.r.t. V, and thus may be expressed in terms of the residual $\mathcal{T}V - V$. Hence, the bounds based on the Bellman residual (the L_∞-norm bound (4.4) or the componentwise bound (4.5)), which yields a coefficient $2/(1-\gamma)$ instead of $2\gamma/(1-\gamma)^2$ (for AVI bounds), provides a better bound whenever $\gamma > 1/2$. The next subsection provides an extension of Bellman residual bounds to L_p-norms.

5.3. L_p-norm bounds based on the Bellman residual. Here, we relate the performance of a policy π greedy w.r.t. V (where $V \in \mathbb{R}^N$) in terms of the $L_{p,\mu}$-norm of its residual $\mathcal{T}V - V$.

THEOREM 5.3. *Let V be a vector of size N and π a policy greedy w.r.t. V. Let μ and ν be two probability measures on X. Then*

$$||V^* - V^\pi||_\infty \leq \frac{2}{(1-\gamma)}\big[C(\mu)\big]^{1/p}||\mathcal{T}V - V||_{p,\mu}, \tag{5.7}$$

$$||V^* - V^\pi||_{p,\nu} \leq \frac{2}{(1-\gamma)}\big[C_1(\nu,\mu)\big]^{1/p}||\mathcal{T}V - V||_{p,\mu}. \tag{5.8}$$

Here also the first result (5.7) provides an L_∞-norm bound on the performance, which may directly be compared to the L_∞ bound (4.4) (letting $p \to \infty$), whereas an L_p-norm performance bound is stated in the second result (5.8).

Proof of Theorem 5.3. We may rewrite (4.5) as

$$V^* - V^\pi \leq \frac{2}{1-\gamma} A|\mathcal{T}V - V|,$$

where A is the stochastic matrix

$$A = \frac{1-\gamma}{2}\Big[(I - \gamma P^{\pi^*})^{-1} + (I - \gamma P^\pi)^{-1}\Big].$$

Using the idea described in the introduction of this section, we have

$$\begin{aligned} ||V^* - V^\pi||_{p,\nu}^p &\leq \Big[\frac{2}{1-\gamma}\Big]^p \sum_{x\in X} \nu(x)\Big[A|\mathcal{T}V - V|\Big]^p(x) \\ &\leq \Big[\frac{2}{1-\gamma}\Big]^p \sum_{x\in X} \nu(x)\Big[A|\mathcal{T}V - V|^p\Big](x) \end{aligned} \tag{5.9}$$

from Jensen's inequality. Now, from the definition of the coefficients $c(m)$, $\nu A \leq (1-\gamma)\sum_{m\geq 0}\gamma^m c(m)\mu = C_1(\nu,\mu)\mu$, and thus

$$||V^* - V^\pi||_{p,\nu}^p \leq \Big[\frac{2}{1-\gamma}\Big]^p C_1(\nu,\mu)\mu|\mathcal{T}V - V|^p = \Big[\frac{2}{1-\gamma}\Big]^p C_1(\nu,\mu)||\mathcal{T}V - V||_{p,\mu}^p,$$

which proves (5.8). Now, since $C(\mu) \geq C_1(\nu,\mu)$ for any ν, choosing ν to be a Dirac at each state yields (5.7). □

For the purposes of intuition, the components $A(x,y)$ of the matrix A indicate a bound on the contribution of the (absolute value of the) residual at a state y to the performance error at the state x. Indeed,

$$V^*(x) - V^\pi(x) \leq \frac{2}{1-\gamma}\sum_{y\in X} A(x,y)|\mathcal{T}V - V|(y).$$

It is clear from (5.9) that if we chose $\mu = \nu A$, then the L_p bound becomes

$$||V^* - V^\pi||_{p,\nu} \leq \frac{2}{(1-\gamma)}||\mathcal{T}V - V||_{p,\mu}. \tag{5.10}$$

This bound may inspire us for solving a direct Bellman residual minimization problem, in some given function space $\mathcal{F}$,

$$\min_{V \in \mathcal{F}} ||\mathcal{T}V - V||_{p,\mu}^p,$$

where the distribution μ now depends on V, through the policy π greedy w.r.t. V, i.e., $\mu = \nu A = \frac{1-\gamma}{2}\nu[(I - \gamma P^{\pi^*})^{-1} + (I - \gamma P^{\pi})^{-1}]$. We write $\mu = (\mu^\pi + \mu^*)/2$, with $\mu^\pi = (1-\gamma)\nu(I-\gamma P^\pi)^{-1}$ being the discounted future state distribution starting from ν and following policy π, and $\mu^* = (1-\gamma)\nu(I - \gamma P^{\pi^*})^{-1}$, similarly defined from the optimal policy π^*.

Thus the $L_{p,\mu}$-norm of the residual to be minimized is composed of two contributions:

$$||\mathcal{T}V - V||_{p,\mu}^p = \frac{1}{2}\Big(||\mathcal{T}V - V||_{p,\mu^\pi}^p + ||\mathcal{T}V - V||_{p,\mu^*}^p\Big). \tag{5.11}$$

One may consider an iterative optimization method, such as a gradient method, where at each iteration an empirical residual would be computed and minimized. Minimization of the first term in (5.11) is easy to implement by designing a sampling device from μ^π (i.e., start from an initial state $x \sim \nu$ and follow transitions using the current policy π during a horizon time that is a exponential random variable with coefficient γ). The second term is more difficult to deal with because there is no sampling device from μ^* since π^* is unknown; one may consider a somewhat uniform density instead or use a discounted future state distribution using a stochastic policy (where each action has a strict positive probability to be chosen).

5.4. Some intuition about the coefficients $C(\mu)$, $C_1(\nu,\mu)$, and $C_2(\nu,\mu)$. Let us give some more insight about these coefficients in the case of a uniform distribution $\mu = (\frac{1}{N} \dots \frac{1}{N})$. In this case, from its definition, the coefficient $C(\mu)$ is always smaller than the number of states N. $C(\mu)$ equals N if there exists at least a deterministic transition (i.e., for some $x, y \in X$, $a \in A$, we have $p(x,a,y) = 1$). In that case, the L_p (say, for $p = 1$) bound (5.4) would not be better than the L_∞ one (2.2) combined with the simple norm comparison result $||\cdot||_\infty \leq N||\cdot||_1$.

Hence, the L_p bound (5.4) (resp., (5.7)) is more informative than the usual L_∞ one (2.2) (resp., (4.4)) whenever the concentration coefficient $C(\mu)$ is smaller than the number of states. An interesting case for which this happens is when the state space is continuous and the transition kernel admits a density w.r.t. μ, for which case $C(\mu)$ is the upper bound of this density. This continuous space case will be considered in section 7 and illustrated on an optimal replacement problem.

Now, consider the coefficients $C_1(\nu,\mu)$ and $C_2(\nu,\mu)$ when ν and μ are both uniform.

- Their largest possible value is obtained in an MDP where for a specific policy π all states jump to a given state—say state 1—with probability 1. Thus, for any ν, for all m, $\nu(P^\pi)^m = (1\,0 \dots 0) \leq c(m)\mu$ holds with $c(m) = N$ (with equality in state 1), and therefore $C_1(\nu,\mu) = C_2(\nu,\mu) = N$. This is the worst case because the future state distribution accumulates on a single state. In that case, the L_p bound (5.5) (resp., (5.8)) may actually be derived from the L_∞ one (2.2) (resp., (4.4)) since $||\cdot||_p \leq ||\cdot||_\infty$ and $||\cdot||_\infty \leq N^{1/p}||\cdot||_p$.
- Their lowest possible value is obtained in an MDP with uniform transition probabilities $p(x,a,y) = 1/N$ for all $x, y \in X$ and $a \in A$. When ν and μ are both uniform then $c(m) = 1$ and $C_1(\nu,\mu) = C_2(\nu,\mu) = 1$ (this is the lowest

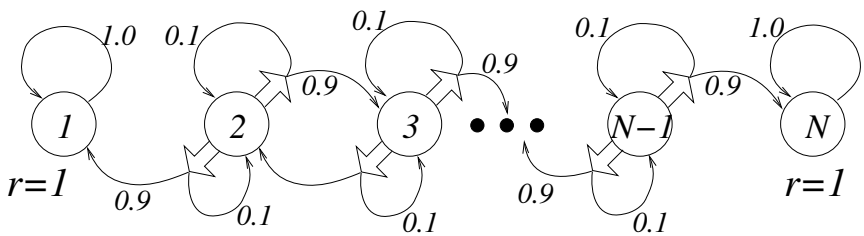

FIG. 5.1. *The chain walk MDP.*

possible value since for a uniform ν and any stochastic matrix P we have $\max_y \sum_x \nu(x)P(x,y) \geq 1/N$).

Notice, however, that any deterministic MDP would not necessarily lead to a high value of the coefficients $C_1(\nu,\mu)$ and $C_2(\nu,\mu)$ (contrarily to the case of $C(\mu)$). Indeed, in an MDP where the policies consist in permutations of the states (for which each state has a unique successor and unique predecessor), then $C(\mu) = N$ (since the transitions are deterministic, as seen previously), but $C_1(\nu,\mu) = C_2(\nu,\mu) = 1$ for uniform distributions ν and μ (since for all $m \geq 0$, $c(m) = 1$). Another example where the discounted future state distribution concentration coefficients is low (and independent of the number of states N) is provided in the chain walk MDP described in the next subsection.

The concentration coefficients $C_1(\nu,\mu)$ and $C_2(\nu,\mu)$ express how the (first and second order) discounted future state distribution, starting from the initial distribution ν, may possibly differ from μ. A low value of these coefficients means that the mass of the discounted future state distribution starting from ν does not accumulate on few specific states for which the distribution μ is low. For the purpose of obtaining low values of these coefficients (thus probably good performance for AVI), it is desirable that μ be somehow uniformly distributed (this condition was already mentioned in [22, 21, 26] to secure the policy improvement steps in approximate policy iteration).

5.5. Illustration on the chain walk MDP. We illustrate the fact that the L_p-norm bound (5.5) given in Theorem 5.2 is tighter than the L_∞-norm (2.2) (combined with the norm comparison $||\cdot||_\infty \leq N^{1/p}||\cdot||_p$) on the *chain walk* MDP defined in [23] (see Figure 5.1). This case provides an example for which the coefficient $C(\mu)$ is high (its value is the number of states N) but $C_1(\nu,\mu)$ and $C_2(\nu,\mu)$ are low (independent of N).

This is a linear chain with N states with two dead-end states: states 1 and N. On each of the interior states $2 \leq x \leq N-1$ there are two possible actions: right or left, which moves the state in the intended direction with probability 0.9, and fails with probability 0.1, leaving the state unchanged. The reward simply depends on the current state and is 1 at boundary states and 0 elsewhere: $r = (1\,0\ldots0\,1)'$.

We consider an approximation of the value function in the two-dimensional function space $\mathcal{F} := \{f_\alpha(x) = \alpha_1 + \alpha_2 x\}_{\alpha\in\mathbb{R}^2}$, where $x \in \{1,\ldots,N\}$ is the state index. Assume that the initial approximation is zero: $V_0 = (0\ldots0)'$. Then $\mathcal{T}V_0 = (1\,0\ldots0\,1)'$. The best fit (in L_∞-norm) of $\mathcal{T}V_0$ in $\mathcal{F}$ is the constant function $V_1 = (\frac{1}{2}\ldots\frac{1}{2})'$, which produces an error $||V_1 - \mathcal{T}V_0||_\infty = \frac{1}{2}$.

Let us choose uniform distributions $\nu = \mu = (\frac{1}{N}\ldots\frac{1}{N})$. In L_1-norm, the best fit of $\mathcal{T}V_0$ in $\mathcal{F}$ is $V_1 = (0\ldots0)'$ (for $N > 4$) and the resulting error is $||V_1 - \mathcal{T}V_0||_1 = \frac{2}{N}$. In L_2-norm the best fit is also constant $V_1 = (\frac{2}{N}\ldots\frac{2}{N})'$ and the error is $||V_1 - \mathcal{T}V_0||_2 = \frac{\sqrt{2N-4}}{N}$.

In these three cases, we observe by induction that the successive approximations V_n are constant; thus $\mathcal{T}V_n = r + \gamma V_n$ and the approximation errors remain the same as in the first iteration: for all $n \geq 0$, $||V_{n+1} - \mathcal{T}V_n||_\infty = \frac{1}{2}$, $||V_{n+1} - \mathcal{T}V_n||_1 = \frac{2}{N}$, and $||V_{n+1} - \mathcal{T}V_n||_2 = \frac{\sqrt{2N-4}}{N}$.

Since V_n is constant, any policy π_n is greedy w.r.t. V_n. Hence for $\pi_n = \pi^*$ the l.h.s. of (2.2) and (5.5) are equal to zero. Now, in order to compare the r.h.s. of these inequalities, let us calculate the coefficients $C(\mu)$ and $C_1(\nu, \mu)$ and $C_2(\nu, \mu)$. Since state 1 jumps to itself with probability 1, we have no better coefficient than $C(\mu) = N$.

Now, the maximum in (5.1) is reached when the mass of the future state distribution is mostly concentrated on one specific state—say state 1—which corresponds to a policy π_{Left} that chooses everywhere action left. We see that for $\nu = \mu$,

$$\nu(P^{\pi_{\text{Left}}})^m(x) \leq \nu(P^{\pi_{\text{Left}}})^m(1) \leq (1 + 0.9m)\mu(x)$$

for all $x \geq 0$, and thus $c(m) \leq 1 + 0.9m$. We deduce that the coefficients $C_1(\nu, \mu) \leq (1-\gamma)\sum_{m\geq 0} \gamma^m(1+0.9m)$ and $C_2(\nu, \mu) \leq (1-\gamma)^2 \sum_{m\geq 1} m\gamma^{m-1}(1+0.9m)$ are upper bounded by a value that is *independent of the number of states* N.

Thus, if we consider the performance of AVI in L_1-norm, the bound (5.5) (for $p = 1$) provides an approximation of order $O(N^{-1})$, whereas the L_1 bound that would be obtained from the usual L_∞ result (2.2) combined with the norm comparison $||\cdot||_\infty \leq N||\cdot||_1$ would provide a $O(1)$ approximation only.

Similarly, the L_2-norm bound is of order $O(N^{-1/2})$, whereas the L_∞-norm bound (2.2) combined with $||\cdot||_\infty \leq N^{1/2}||\cdot||_2$ would only be of order $O(1)$.

Thus, if our supervised learning algorithm returns the best regression function by minimizing an approximation error in L_p-norm (which is usually the case in practice), *the bound* (5.5) *may be arbitrarily more informative than* (2.2) *for large values of* N.

6. Practical algorithms. Practical implementations of AVI depend on the amount of knowledge available on the state dynamics as well as the way the expectation operation (in the Bellman operator) may be processed.

In the case of a *complete model* (when the state transitions $p(x, a, y)$ are perfectly known) and if the expectation operation is computationally tractable, then a possible implementation of AVI has already been described in the introduction: at each stage n, we select a set of states $\{x_k \in X\}_{1\leq k\leq K}$ drawn according to some distribution μ, compute the backed-up values $\{v_k = \mathcal{T}V_n(x_k)\}_{1\leq k\leq K}$, and make a call to an SL algorithm with the data $\{(x_k; v_k)\}_{1\leq k\leq K}$, which returns an ε-approximation V_{n+1} in $L_{p,\mu}$-norm, i.e., $||V_{n+1} - \mathcal{T}V_n||_{p,\mu} \leq \varepsilon$. Of course, we need additional assumptions on the number of samples K and the complexity of the function space $\mathcal{F}$ (in terms of covering number or VC dimension) to guarantee that the empirical loss $\left(\frac{1}{K}\sum_{k=1}^K |V_{n+1}(x_k) - v_k|^p\right)^{1/p}$ is close to the norm of the approximation error $||V_{n+1} - \mathcal{T}V_n||_{p,\mu}$, but such considerations are omitted here, and we direct the interested reader to [36, 15, 30].

However, it is often the case that no explicit representation of the transition probabilities $p(x, a, y)$ is available, but there exists a sampling device that allows us to generate states y according to the distribution $p(x, a, \cdot)$ at any state x and action a of our choice. We call this a *generative model* (see [20] for a survey of several sampling models). One possible way to compute the expectation operation in the Bellman operator is to replace it by an empirical mean using this sampling device. This leads to *sampling-based fitted value iteration*, studied in [34].

Another alternative, closer in spirit to reinforcement learning (RL) [33], consists in introducing the state-action value function, or Q-function, defined for each state-action $(x,a) \in X \times A$ by

$$Q^*(x,a) := \sum_{y \in X} p(x,a,y)\big[r(x,a,y) + \gamma V^*(y)\big].$$

We have the properties that $V^*(x) = \max_{a \in A} Q^*(x,a)$, and Q^* is the fixed-point of the operator $\mathcal{R}$, mapping from the space of functions $X \times A \to \mathbb{R}$ to itself, defined for any $Q : X \times A \to \mathbb{R}$ by

$$\mathcal{R}Q(x,a) := \sum_{y \in X} p(x,a,y)\big[r(x,a,y) + \gamma \max_{b \in A} Q(y,b)\big].$$

An AVI algorithm using this representation would consist in defining successive approximations Q_n (with any initial Q_0) according to the recursion

$$Q_{n+1} = \mathcal{A}\mathcal{R}Q_n, \tag{6.1}$$

where $\mathcal{A}$ is an SL algorithm on $X \times A$. A model-free RL algorithm would collect a number of transitions of the form $\{(x_k,a_k) \stackrel{r_k}{\to} y_k\}_{1 \le k \le K}$, where a_k is an action chosen in state x_k, the next state y_k being generated according to the generative model (i.e., $y_k \sim p(x_k,a_k,\cdot)$), and $r_k = r(x_k,a_k,y_k)$ is the received reward. We then compute the back-up values $v_k = r_k + \gamma \max_{b \in A} Q_n(y_k,b)$ (which provides an unbiased estimate of $\mathcal{R}Q_n(x_k,a_k)$), and make a call to the SL algorithm with the data $\{(x_k,a_k); v_k\}_{1 \le k \le K}$ (the inputs being the couples $\{(x_k,a_k)\}$, and the desired output $\{v_k\}$), which returns the next Q-function Q_{n+1}.

An interesting case is when $\mathcal{A}$ is a linear operator *in the values* $\{v_k\}$ such as in linear approximation, memory-based learning (k-nearest neighbors, locally weighted learning [3, 15]) or support vector regression (in the case of a quadratic loss function). In that case, the approximation $\mathcal{A}$ and expectation $\mathbb{E}$ operators commute and the approximation Q_{n+1} returned by the SL algorithm is therefore an unbiased estimate of $\mathcal{A}\mathcal{R}Q_n$. Thus when K is large, such an iteration acts like a (model-based) AVI iteration, and bounds similar to those of Theorem 5.2 may be derived.

Notice that a policy π'_n derived from the approximate Q-function, $\pi'_n(x) \in \arg\max_{a \in A} Q_n(x,a)$, is different from the policy π_n greedy w.r.t. V_n, defined by $V_n(x) = \max_a Q_n(x,a)$. Indeed, the latter satisfies $\pi_n(x) \in \arg\max_{a \in A} \mathcal{R}Q_n(x,a)$. However, bounds similar to (2.2), (5.4), and (5.5) on the performance of such policies π'_n may be derived analogously. An example of such a bound in L_∞-norm is provided now. Extension to L_p bounds would follow along the same lines as in sections 4 and 5.

The performance $Q^\pi : X \times A \to \mathbb{R}$ of a policy π is defined as follows: $Q^\pi(x,a)$ is the expected sum of rewards when starting from x, choosing action a and using policy π thereafter. Q^π is also the fixed-point of the Bellman operator $\mathcal{R}^\pi$, mapping from the space of functions $X \times A \to \mathbb{R}$ to itself, defined by

$$\mathcal{R}^\pi Q(x,a) := \sum_{y \in X} p(x,a,y)\big[r(x,a,y) + \gamma Q(y,\pi(y))\big].$$

THEOREM 6.1. *Consider the AVI algorithm defined by the Q-function iteration* (6.1). *Let ε be a uniform bound on the L_∞ approximation errors of the Q-functions,*

i.e., $||Q_{n+1} - \mathcal{R}Q_n||_\infty \leq \varepsilon$. *The asymptotic performance of the policy* π'_n *(defined by* $\pi'_n(x) \in \arg\max_{a \in A} Q_n(x,a)$*) satisfies*

$$\limsup_{n \to \infty} ||Q^* - Q^{\pi'_n}||_\infty \leq \frac{2\gamma}{(1-\gamma)^2}\varepsilon.$$

Proof of Theorem 6.1. The proof is similar to that of (2.2); it suffices to replace the V-value by the Q-values, the $\mathcal{T}$ (resp., $\mathcal{T}^\pi$) operator by the $\mathcal{R}$ (resp., Q^π) operators, and notice that $\mathcal{R}^{\pi'_n} Q_n = \mathcal{R}Q_n$. □

7. Numerical experiment in the continuous case. All previous results extend to the case of continuous measurable state spaces. We first redefine the concentration coefficients in this context and illustrate numerically the method on an optimal replacement problem, for which the coefficient $C(\mu)$ is explicitly computed.

Let us write $P(x,a,B)$ the transition probability kernel, where B is any measurable subset of X. For a stationary policy $\pi : X \to A$, we write $P^\pi(x,B) = P(x,\pi(x),B)$, which defines a right linear operator (defined on the space of bounded measurable function V with domain X): $P^\pi V(x) := \int_X V(y) P^\pi(x,dy)$, and a left-linear operator (defined on the space of probability measures μ on X): $\mu P^\pi(B) := \int_X P^\pi(x,B)\mu(dx)$. The product of two kernels P^{π_1} and P^{π_2} is defined by $P^{\pi_1}P^{\pi_2}(x,B) := \int_X P^{\pi_1}(x,dy)P^{\pi_2}(y,B)$.

7.1. Concentration coefficients. With this notation, the concentration coefficients are defined as follows: let ν and μ be two probability distributions on X.

We assume that for all $x \in X$, $a \in A$, $P(x,a,\cdot)$ is absolutely continuous w.r.t. μ and the Radon–Nikodým derivative of $P(x,a,\cdot)$ w.r.t. $\mu(\cdot)$ is bounded uniformly in x and a. Then the transition probabilities concentration coefficient $C(\mu)$ is defined by

$$C(\mu) := \sup_{x \in X, a \in A} \frac{dP(x,a,\cdot)}{d\mu}.$$

Notice that if μ is the Lebesgue measure over X, and if $P(x,a,\cdot)$ admits a uniformly bounded density, then the concentration coefficient $C(\mu)$ is equal to the upper bound of this density. This case is illustrated in the numerical experiment below. The first and second order discounted future state distribution concentration coefficients $C_1(\nu,\mu)$ and $C_2(\nu,\mu)$ are defined similarly to (5.2) and (5.3).

7.2. An optimal replacement problem. This experiment illustrates the respective tightness of the L_∞-, L_1-, and L_2-norm bounds on a continuous space control problem excerpted from [31].

A one-dimensional continuous variable $x_t \in [0, x_{\max}]$ measures the accumulated utilization (such as the odometer reading on a car) of a product. $x_t = 0$ denotes a brand-new product. At each discrete time t, there are two possible decisions: either keep ($a_t = \mathrm{K}$) or replace ($a_t = \mathrm{R}$), in which case an additional cost $C_{replace}$ (of selling the existing product and replacing it for a new one) occurs. The transition densities are exponential with parameter β with a truncated queue. Moreover, if the next state y is larger than the maximal value $x_{\max}$ (e.g., the car breaks down because it is too damaged), then a new state is immediately redrawn and a penalty $C_{dead} > C_{replace}$ occurs. The transition densities are thus defined as follows: defining

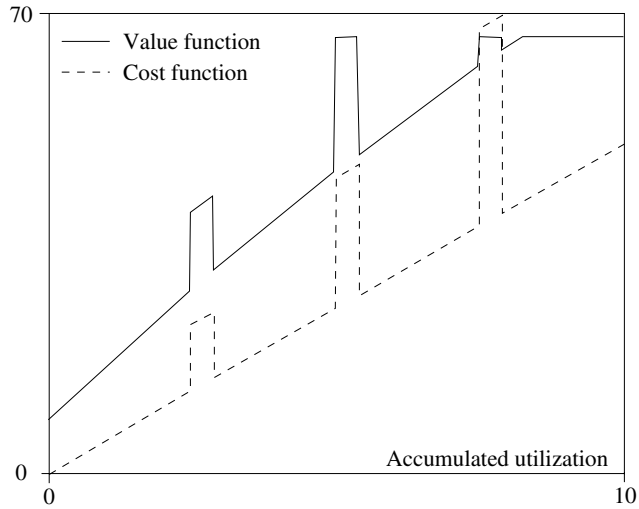

FIG. 7.1. *Cost and value functions.*

$q(x) := \beta e^{-\beta x}/(1 - e^{-\beta x_{\max}})$,

$$p(x, a = \mathrm{R}, y) = \begin{cases} q(y) & \text{if } y \in [0, x_{\max}], \\ 0 & \text{otherwise.} \end{cases}$$

$$p(x, a = \mathrm{K}, y) = \begin{cases} q(y - x) & \text{if } y \in [x, x_{\max}], \\ q(y - x + x_{\max}) & \text{if } y \in [0, x), \\ 0 & \text{otherwise.} \end{cases}$$

The current cost (opposite of a reward) $c(x)$ is the sum of a slowly increasing function (maintenance cost) and a discontinuous punctual cost (e.g., which may represent car insurance fees).

The current cost function and the optimal value function (computed by a discretization on a high resolution grid) are shown in Figure 7.1.

We choose the numerical values $\gamma = 0.6$, $\beta = 0.6$, $C_{replace} = 50$, $C_{dead} = 70$, and $x_{\max} = 10$. We consider a uniform distribution μ on the domain $[0, x_{\max}]$. We choose K points (with $K = 200$ or 2000 points) uniformly located over the domain $\{x_k := kx_{\max}/K\}_{0 \le k < K}$ to perform the L_2 minimization fitting problem at each iteration:

$$V_{n+1} = \arg\min_{f \in \mathcal{F}} \frac{1}{K} \sum_{k=1}^{K} [f(x_k) - \mathcal{T}V_n(x_k)]^2,$$

where $\mathcal{F}$ is the space spanned by a truncated cosine basis (with $M = 20$ or $M = 40$ basis functions):

$$\mathcal{F} := \left\{ f(x) = \sum_{m=1}^{M} \alpha_m \cos\left(m\pi \frac{x}{x_{\max}} \right) \right\}_{\alpha \in \mathbb{R}^M}.$$

We start with initial values $V_0 = 0$. In Figure 7.2 we show the first iteration (for the grid with $K = 200$ points): the backed-up values $\mathcal{T}V_0$ (indicated with crosses), the

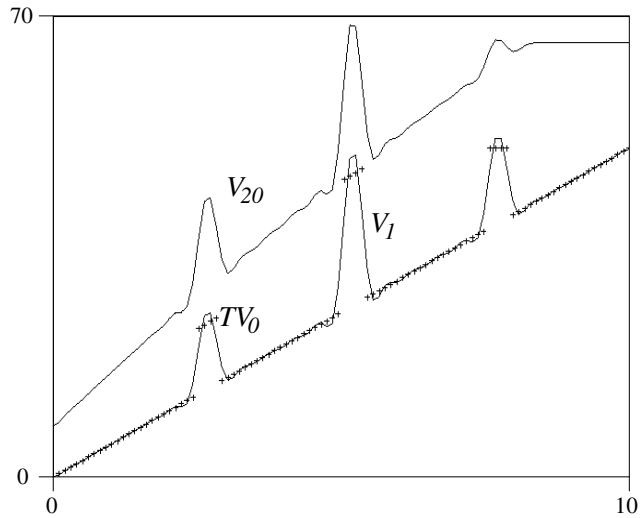

FIG. 7.2. *$\mathcal{T}V_0$ (crosses), V_1, and V_{20}.*

TABLE 7.1
Comparison of the r.h.s. of the L_∞, L_1, and L_2 bounds.

	$\|\|\varepsilon_n\|\|_\infty$	$C(\mu)\|\|\varepsilon_n\|\|_1$	$\sqrt{C(\mu)}\|\|\varepsilon_n\|\|_2$
$K = 200$, $M = 20$	12.4	0.367	1.16
$N = 2000$, $M = 40$	12.4	0.0552	0.897

corresponding approximation V_1 (best fit of $\mathcal{T}V_0$ in the cosine approximation space $\mathcal{F}$). The approximate value function computed after 20 iterations (when there are no significant improvement of the approximations) is also plotted.

The concentration coefficient $C(\mu)$ is the highest peak of the transition density w.r.t. the uniform distribution μ; thus $C(\mu) = q(0)x_{\max} = \beta x_{\max}/(1 - e^{-\beta x_{\max}}) \simeq 6$.

Table 7.1 compares the r.h.s. (up to the constant $2\gamma/(1-\gamma)^2$) of equations (2.2) and (5.4) for $p = 1$ and 2, their l.h.s. being the same since they use the same L_∞-norm. We notice that the L_1 and L_2 bounds (5.4) are much tighter than the L_∞ one (2.2). Moreover we observe that the L_1 and L_2 approximation errors tend to 0 when the number K of sampling points and the number M of basis functions go to infinity, whereas the L_∞ bound does not. Indeed, since the cost function is discontinuous, the L_∞ approximation error (using continuous function approximation such as the cosine basis used here) will never be smaller than half the value of the largest jump, even for large values of K and M. This example illustrates the fact that the L_p bound (5.4) may be arbitrarily tighter than the L_∞ one (2.2).

8. Conclusion. Theorem 5.2 provides a useful tool to bound the performance of AVI from the L_p-norm of the approximation errors, and thus in terms of the approximation power of most SL algorithms. Expressing the performance of AVI in the same norm as the norm used by the supervised learner to solve the regression problem guarantees the tightness and practical application of the bounds.

In order for these bounds to be of any use, we need to estimate an upper bound on the concentration coefficients $C(\mu)$, $C_1(\nu, \mu)$, and $C_2(\nu, \mu)$, which may be difficult

in general. We illustrate the case of low values of $C_1(\nu, \mu)$, and $C_2(\nu, \mu)$ in the chain walk MDP, and the case of a low value of $C(\mu)$ in the optimal replacement problem. Future work would consider defining classes of problems for which these coefficients may be evaluated.

Extension to other loss functions l, such as ϵ-*insensitive* (used in support vectors) or *Huber loss function* (for robust regression) [36], is straightforward (as long as l is an increasing and convex function over $\mathbb{R}^+$). Another possible extension is AVI for Markov games.

Acknowledgments. The author wishes to thank Csaba Szepesvári and the anonymous reviewers who helped significantly improve the clarity of the concepts introduced in the paper.

SIMULATION AND BISIMULATION OF NONLINEAR CONTROL SYSTEMS WITH ADMISSIBLE CLASSES OF INPUTS AND DISTURBANCES*

KEVIN A. GRASSE†

Abstract. Motivated by analogous concepts in theoretical computer science, the concepts of simulation and bisimulation relations have recently been introduced in the study of the geometric theory of nonlinear control systems. Simulation relations generalize such notions as trajectory propagation and trajectory lifting, while bisimulation relations generalize such notions as system equivalence and state-space reduction. This paper explores previously obtained necessary and sufficient conditions for the existence of (bi)simulation relations and determines to what extent those relations can be maintained if inputs and disturbances are restricted to specified "admissible" classes. We show how the results obtained here for general simulation relations extend prior results obtained for trajectory propagation and trajectory lifting. Also addressed briefly are some sufficient conditions for simulation relations to hold semiglobally in time.

Key words. nonlinear control systems, simulation, bisimulation, related systems, trajectory propagation, trajectory lifting, controlled invariance

1. Introduction.

An effective and recurring approach to the problem of classifying nonlinear control systems entails defining a relation (or equivalence relation) between systems that affords the possibility of "complex" systems being related to "simpler" systems. The usage of the terms "complex" and "simpler" is intentionally vague here, but one can think of a system as being "complex" if, for example, its state space has large dimension or if it is highly nonlinear. "Simpler" systems, on the other hand, may evolve on a state space of reduced dimension or be either linear or mildly nonlinear. Through the use of an appropriately defined relation between systems one may hope to infer properties and behaviors of the complex system from those of the simpler system. Motivated by an analogous concept in theoretical computer science, Haghverdi, Tabuada, and Pappas [7] initiated the study of *bisimulation relations* in continuous-time dynamical and control systems. Roughly speaking, a bisimulation relation between two control systems is first and foremost a relation (i.e., a subset of the Cartesian product of their state spaces) but has the additional property that trajectories of the first system can be paired, by way of the relation, with trajectories of the second system and, conversely, trajectories of the second system can be paired, by way of the relation, with trajectories of the first system. (We will present one version of a precise definition of a bisimulation relation in section 2, based on that given in [18], but readers should be aware that there are some variations in the definitions of this notion in the references cited in this paper.) In connection with the aforementioned work [7], Pappas [11] derived detailed results characterizing bisimulation relations induced by linear surjections for discrete and continuous-time linear control systems, while Tabuada and Pappas [14] derived a characterization of bisimulation relations induced by nonlinear submersions for nonlinear continuous-time systems

that are affine in the control. Further progress in bisimulation relations as they apply to continuous-time control systems was made by van der Schaft in [17, 18], where, among other things, he derives an elegant and constructive algorithm for computing the maximal bisimulation relation between two systems.

Bisimulation relations are natural objects in control systems theory in that they nicely generalize such well-studied notions as state-space equivalence (see, e.g., [2]) and state-space reduction (see, e.g., [1]). As pointed out by various authors [5, 11, 18], these relations also have close ties to the fundamental concept of *controlled invariance* in geometric control theory [3, 8, 9]. Bisimulation relations are, by their very nature, "two-way" relations, but one can create an obvious definition of a analogous "one-way" counterpart, which is referred to as a *simulation relation* (see [18, Def. 5.1] or section 2 for the definition). Simulation relations also occur frequently in control systems theory in a variety of contexts. For example, if Φ is a mapping between the state spaces of two systems that propagates trajectories of the "domain system" to the "range system," then the graph of Φ is an example of a simulation relation; in such a case the systems are sometimes called Φ-*related* and the range system is called an *abstraction* of the domain system [12, 13, 15, 4]. Alternatively, the graph of Φ is also a simulation relation (however, in the opposite direction) if we can lift trajectories from the range system to the domain system [5, 16].

This paper refines the aforementioned work on bisimulation relations by paying somewhat closer attention to regularity properties of the controls (or, as we will see shortly, of the input-disturbance pairs) that generate the system's trajectories. Our motivation for this work rests with certain mathematical foundational issues in nonlinear control theory. When one formulates precise mathematical definitions of control systems and the related objects of controls and trajectories (see, for example, the meticulous treatment in the book of Sontag [19]), some care must be exercised to ensure that when a control and initial condition are specified the resulting trajectories exist, are unique, and depend continuously on the data. Put differently, we want our dynamical model to be *well posed*. To this end, limitations are placed on the class of controls that are deemed "admissible," so that the resulting nonautonomous ordinary differential equations meet the usual theoretical criteria for the existence, uniqueness, and continuous dependence of solutions (the so-called C^1 *Carathéodory conditions*). However, at the same time one wants the class of controls to be as large as possible to facilitate proving positive results about controllability, existence of optimal controls, etc. In particular, existence proofs for optimal controls usually require that controls be members of a specified class of (Lebesgue) measurable functions of time (say, an L^2 space). When considerations of (bi)simulation relations are juxtaposed with regularity issues of the underlying controls, one is consequently confronted with the question of the extent to which such relations will persist if one restricts controls to specified admissible classes. It turns out that for linear, time-invariant systems, matters take care of themselves rather nicely (see Remark 3.11). However, one does not have to delve very deeply into classes of nonlinear systems to see that some care is required to be assured that (bi)simulation relations are indeed maintained when controls are restricted to (even rather large) "admissible" classes (see Example 2.7). Previously, the author considered related control-admissibility issues for trajectory propagation [4] and trajectory lifting [5], and this work should be regarded as an extension of these papers. We also acknowledge the substantial influence of the paper of van der Schaft [18] in motivating the results contained herein.

The remainder of this paper is organized as follows. In section 2 we recall the definitions of the basic objects at hand (control systems and controls) and we formulate

the basic definitions of simulation and bisimulation relations with admissible classes of controls. Our definitions closely follow those given by van der Schaft [17, 18], and in particular we adopt his approach of decomposing controls into inputs and disturbances. However, we have phrased our definitions to be inherently *local* in time because of the phenomenon of finite escape time of trajectories of nonlinear systems. Section 3 contains the main results of the paper on necessary and sufficient conditions for (bi)simulation relations with admissible classes of inputs and disturbances. In section 4 the results of section 3 are shown to subsume previously obtained results on trajectory propagation (i.e., Φ-related systems) and trajectory lifting. We also consider two simple cases in which the "local-in-time" nature of (bi)simulation relations can be guaranteed to be global in time; for example, such behavior would certainly be expected of linear systems as we will show.

2. Preliminaries. By the term *differentiable manifold* we will always mean a connected, finite-dimensional, second-countable, Hausdorff, differentiable manifold of class C^k with $k \geq 2$. Given a differentiable manifold M, we use TM to denote the tangent bundle of M, $\pi_M : TM \to M$ its canonical projection onto M, and we recall that TM is a differentiable manifold of class C^{k-1}. If $\Phi : M \to N$ is a C^1 mapping of manifolds, then $d\Phi : TM \to TN$ will denote its differential, while for each $x \in M$ we use $d\Phi_x : T_xM \to T_{\Phi(x)}N$ to denote the corresponding linear mapping on the indicated tangent spaces (that is, fibers of the tangent bundles).

Given C^k differentiable manifolds M and O, and given a separable metric space Λ, we will say that a mapping $\Phi : M \times \Lambda \to O$ is *nicely C^k on M relative to Λ* if for each $\lambda \in \Lambda$ the mapping $x \mapsto \Phi(x, \lambda)$ is C^k and if the partial derivatives of Φ with respect to x up to order k are continuous on $M \times \Lambda$. In particular, a C^1 *control system with state space M and control space Λ* is a mapping $F : M \times \Lambda \to TM$ that is nicely C^1 on M relative to Λ and satisfies $(\pi_M \circ F)(x, \lambda) = x$ for every $(x, \lambda) \in M \times \Lambda$ (for more details, see [4, Def. 2.1] or [6, Def. 2.2]). Control systems will sometimes be informally specified by the notation $\dot{x} = F(x, v(t))$. *Potential controls* for such a system are members of the family $\mathcal{U}^{\Lambda}_{\text{meas}}$ of all Lebesgue-measurable mappings of $\mathbb{R}$ into Λ; that is, $v \in \mathcal{U}^{\Lambda}_{\text{meas}}$ if and only if for every open subset W of Λ the preimage $v^{-1}(W)$ is a Lebesgue-measurable subset of $\mathbb{R}$. Useful subclasses of $\mathcal{U}^{\Lambda}_{\text{meas}}$ are the family $\mathcal{U}^{\Lambda}_{\text{cpt}}$ of all Lebesgue-measurable mappings of $\mathbb{R}$ into Λ that are *essentially compact valued on compact intervals* (see [6, Ex. 2.10(2)]), the family $\mathcal{U}^{\Lambda}_{\text{simp}}$ of all Lebesgue-measurable mappings of $\mathbb{R}$ into Λ that are *simple* (that is, have finite range), and the family $\mathcal{U}^{\Lambda}_{\text{cont}}$ of all continuous mappings of $\mathbb{R}$ into Λ. Obviously, we have $\mathcal{U}^{\Lambda}_{\text{simp}} \subseteq \mathcal{U}^{\Lambda}_{\text{cpt}}$ and $\mathcal{U}^{\Lambda}_{\text{cont}} \subseteq \mathcal{U}^{\Lambda}_{\text{cpt}}$. In the case where Λ is the finite-dimensional Euclidean space $\mathbb{R}^p$, it will also be handy to designate by $L^1_{\text{loc}}(\mathbb{R}, \mathbb{R}^p) \subseteq \mathcal{U}^{\mathbb{R}^p}_{\text{meas}}$ the family of all Lebesgue-measurable mappings of $\mathbb{R}$ into $\mathbb{R}^p$ that are integrable on compact subintervals of $\mathbb{R}$. A potential control $v : \mathbb{R} \to \Lambda$ is called *admissible* for a C^1 control system $F : M \times \Lambda \to TM$ if the mapping $F_v : M \times \mathbb{R} \to TM$ defined by $F_v(x, t) = F(x, v(t))$ is such that its local representation with respect to every coordinate chart of M satisfies C^1 Carathéodory conditions (see [4, Def. 2.6] or [6, Def. 2.8]). We let $\mathcal{U}^{\Lambda}_{\text{meas}}(F)$ denote the subset of $\mathcal{U}^{\Lambda}_{\text{meas}}$ consisting of all admissible controls for the C^1 control system F. In general the family of admissible controls $\mathcal{U}^{\Lambda}_{\text{meas}}(F)$ is strongly dependent on the control system F, but one always has

$$\mathcal{U}^{\Lambda}_{\text{simp}} \subseteq \mathcal{U}^{\Lambda}_{\text{meas}}(F),\ \mathcal{U}^{\Lambda}_{\text{cpt}} \subseteq \mathcal{U}^{\Lambda}_{\text{meas}}(F),\ \mathcal{U}^{\Lambda}_{\text{cont}} \subseteq \mathcal{U}^{\Lambda}_{\text{meas}}(F)$$

for an arbitrary C^1 control system F (see [6, Ex. 2.10(2)]). Standard results from the theory of ordinary differential equations guarantee that for every $x_0 \in M$ and for

every $v \in \mathcal{U}^{\Lambda}_{\text{meas}}(F)$ there exist an open interval $J \subseteq \mathbb{R}$ containing 0 and a unique mapping $\psi : J \to M$ such that $\psi(0) = x_0$, ψ is absolutely continuous on every compact subinterval of J, and

$$\dot{\psi}(t) = F(\psi(t), v(t)) \quad \text{for almost every} \quad t \in J$$

(by "almost every" we mean except on a set of Lebesgue measure zero; henceforth we will use the standard abbreviation a.e.). We call $t \mapsto \psi(t)$ a *trajectory* of F corresponding to the initial condition x_0 and the control v. Often we will use the notation

$$\psi(t) \stackrel{\text{def}}{=} \psi(t, x_0, v)$$

to make explicit the dependence of the trajectory on the initial condition and control, in which case we will refer to the function ψ of time, the initial state, and the control as the *trajectory mapping* of F.

The formal definitions of simulation and bisimulation relations will be cast in the somewhat more general framework of control systems with *inputs*, *disturbances*, and *outputs*. Roughly speaking, we view the control as comprising all external factors that can affect the system, and then partition the control into an input (or *deterministic*) component that we may think of as being within our domain of influence, and a disturbance (or *nondeterministic*) component that we may think of as being outside of our domain of influence. As noted by Pappas and his coauthors (see [7, 11, 14]), the initial introduction of simulation and bisimulation relations in control systems theory was motivated by analogous concepts in theoretical computer science which apply to nondeterministic automata. The presence of the disturbance component in the control systems formulation of these relations allows the evolutionary behavior of the control systems under consideration to mirror the nondeterministic aspect of the transitions allowed in nondeterministic automata. We will comment further on interpretations of the disturbance component in Remark 2.4.

DEFINITION 2.1.

(i) *A* C^1 input-disturbance *(ID) system is a* C^1 *control system* $F : M \times \Lambda \to TM$ *whose control space* Λ *is a Cartesian product* $\Lambda = \Omega \times \Delta$. *We refer to* Ω *as the input space and* Δ *as the disturbance space, and we note that each of* Ω *and* Δ *inherits the structure of a separable metric space from* Λ.

(ii) *A* C^1 input-disturbance-output *(IDO) system is a pair* (F, h), *where* $F : M \times \Omega \times \Delta \to TM$ *is a* C^1 *ID system and* $h : M \times \Omega \to O$ *is a continuous mapping of* $M \times \Omega$ *into a topological space* O; *we call* h *the* output mapping *and* O *the* output space.

(iii) *If* $\mathcal{U} \subseteq \mathcal{U}^{\Omega}_{\text{meas}}$ *and* $\mathcal{D} \subseteq \mathcal{U}^{\Delta}_{\text{meas}}$ *are chosen to satisfy* $\mathcal{U} \times \mathcal{D} \subseteq \mathcal{U}^{\Omega\times\Delta}_{\text{meas}}(F)$, *then we refer to the four-tuple* $(F, h, \mathcal{U}, \mathcal{D})$ *as an* IDO system with admissible inputs $\mathcal{U}$ and admissible disturbances $\mathcal{D}$.

A C^1 IDO system $(F, h, \mathcal{U}, \mathcal{D})$ can also be designated by the more informal notation

$$\begin{aligned} \dot{x} &= F(x, u(t), d(t)), \quad u \in \mathcal{U}, \quad d \in \mathcal{D}, \\ y &= h(x, u(t)), \end{aligned}$$

where $u(\cdot)$ is the input function and $d(\cdot)$ is the disturbance function.

The following definitions of simulation and bisimulation relations between two IDO systems are patterned after the definition of bisimulation given by van der Schaft

in [18, Def. 2.1], but we will be a bit more explicit about the assumed regularity properties of the inputs and disturbances.

DEFINITION 2.2. *Let M and N be differentiable manifolds, let O be a topological space, let Ω, Δ, and E be separable metric spaces, and suppose that we are given a pair of C^1 IDO systems with admissible inputs and admissible disturbances*

$$F : M \times \Omega \times \Delta \to TM, \quad h : M \times \Omega \to O, \quad u \in \mathcal{U}, \quad d \in \mathcal{D}$$

and

$$\widetilde{F} : N \times \Omega \times E \to TN, \quad \tilde{h} : N \times \Omega \to O, \quad u \in \mathcal{U}, \quad e \in \mathcal{E},$$

which have the common input space Ω, common output space O, and common family of admissible inputs $\mathcal{U}$, where

$$\mathcal{U} \subseteq \mathcal{U}_{\text{meas}}^{\Omega}, \quad \mathcal{D} \subseteq \mathcal{U}_{\text{meas}}^{\Delta}, \quad \mathcal{E} \subseteq \mathcal{U}_{\text{meas}}^{E}$$

are such that

$$\mathcal{U} \times \mathcal{D} \subseteq \mathcal{U}_{\text{meas}}^{\Omega \times \Delta}(F), \quad \mathcal{U} \times \mathcal{E} \subseteq \mathcal{U}_{\text{meas}}^{\Omega \times E}(\widetilde{F}).$$

A nonempty subset $\mathcal{R} \subseteq M \times N$ is called a simulation relation of $(F, h, \mathcal{U}, \mathcal{D})$ by $(\widetilde{F}, \tilde{h}, \mathcal{U}, \mathcal{E})$ *if for every $(x_0, z_0) \in \mathcal{R}$, for every $u \in \mathcal{U}$, and for every $d \in \mathcal{D}$ there exist $e \in \mathcal{E}$ and a compact interval I containing 0 in its interior such that for every $t \in I$ both $\psi(t, x_0, u, d)$ and $\tilde{\psi}(t, z_0, u, e)$ are defined (here ψ and $\tilde{\psi}$ are the trajectory mappings of F and $\widetilde{F}$, respectively), and we have*

$$t \in I \;\Rightarrow\; (\psi(t, x_0, u, d), \tilde{\psi}(t, z_0, u, e)) \in \mathcal{R} \tag{2.1}$$

and

$$t \in I \;\Rightarrow\; h(\psi(t, x_0, u, d), u(t)) = \tilde{h}(\tilde{\psi}(t, z_0, u, e), u(t)). \tag{2.2}$$

Remark 2.3. Relations (2.1) and (2.2) are required to hold only on a compact interval containing 0 in its interior because of the possibility of finite escape time for the trajectories of the nonlinear systems under consideration. Naturally, in cases where the systems are *complete* one would like to strengthen these relations to hold for *all* $t \in \mathbb{R}$, a point we will address later (see section 4). We further note that if one chooses to identify inputs and disturbances that agree almost everywhere, then relation (2.2) should be required to hold only for a.e. $t \in I$, but we will not make such identifications in this paper.

Remark 2.4. We offer a few comments on Definition 2.2 as it relates to the presence of the disturbance component.

(i) The concept of simulation relation as defined here (which again we attribute to van der Schaft [18]) guarantees only that the simulating system $(\widetilde{F}, \tilde{h}, \mathcal{U}, \mathcal{E})$ has the capability of mimicking the *class* of all input-output "behaviors" of the simulated system $(F, h, \mathcal{U}, \mathcal{D})$ in the manner dictated by the simulation relation $\mathcal{R}$. However, it does not guarantee that the simulating system can be made to mimic specific individual behaviors of the simulated system because we have no assurance that the disturbance affecting the simulating system is the one whose existence is assured by the definition. Nevertheless, there are useful control problems that can be formulated

with such a nondeterministic interpretation of the disturbances. For example, if one can design a state feedback controller for the simulating system that drives the output to zero (say, as $t \to \infty$) for all disturbances in a specified class, then one can seek conditions under which such a controller will exist for the simulated system.

(ii) Other interpretations of the disturbance component are also possible and of potential utility in the control-systems formulation of simulation relations. For example, it may happen that the disturbance affecting the simulated system is nondeterministic, but is also measurable (the wind velocity affecting the glide path of an aircraft may not be predictable in advance of its occurrence, but it can be measured as it occurs). To force the simulating system to mimic the simulated system, one could try to synthesize a "disturbance" that generates a desired trajectory of the simulating system from the states and common input of both systems, as well as the measured values of the disturbance affecting the simulated system. In this context, the term "disturbance" as applied to the simulating system has a connotation that differs somewhat from a purely random effect, and a certain amount of care must be exercised.

DEFINITION 2.5. *Let* $(F,h,\mathcal{U},\mathcal{D})$ *and* $(\widetilde{F},\tilde{h},\mathcal{U},\mathcal{E})$ *be as Definition* 2.2. *A nonempty subset* $\mathcal{R} \subseteq M \times N$ *is called a* bisimulation relation between $(F,h,\mathcal{U},\mathcal{D})$ and $(\widetilde{F},\tilde{h},\mathcal{U},\mathcal{E})$ *if* $\mathcal{R}$ *is both a simulation relation of* $(F,h,\mathcal{U},\mathcal{D})$ *by* $(\widetilde{F},\tilde{h},\mathcal{U},\mathcal{E})$ *and a simulation relation of* $(\widetilde{F},\tilde{h},\mathcal{U},\mathcal{E})$ *by* $(F,h,\mathcal{U},\mathcal{D})$.

Reference [18] contains a statement of the following proposition, which provides a necessary and sufficient condition for a submanifold of $M \times N$ to be a bisimulation relation between two IDO systems (see, specifically, [18, Prop. 7.1 and Rem. 7.4]; we have altered the notation of [18] to be consistent with the notation used here).

PROPOSITION 2.6. *Let* $\mathcal{R}$ *be a* C^2 *submanifold of* $M \times N$. *Then* $\mathcal{R}$ *is a bisimulation relation between two IDO systems* $(F,h,\mathcal{U},\mathcal{D})$ *and* $(\widetilde{F},\tilde{h},\mathcal{U},\mathcal{E})$ *if and only if for every* $(x,z) \in M \times N$ *and* $\omega \in \Omega$ *the following conditions are met:*

(i) *For every* $\delta \in \Delta$ *there exists* $\varepsilon \in E$ *such that*

$$\big(F(x,\omega,\delta), \widetilde{F}(z,\omega,\varepsilon)\big) \in T_{(x,z)}\mathcal{R}, \tag{2.3}$$

and conversely, for every $\varepsilon \in E$ *there exists* $\delta \in \Delta$ *such that* (2.3) *holds;*

(ii)

$$h(x,\omega) = \tilde{h}(z,\omega). \tag{2.4}$$

Regularity issues of inputs and disturbances are deliberately understated in [18] because most of the presentation therein focuses on linear, time-invariant systems, where such regularity issues are not of critical significance (see Remark 3.11). However, the next example shows that regularity of inputs and disturbances can be a significant factor in nonlinear IDO systems.

Example 2.7. Consider the IDO system with $M = \Delta = O = \mathbb{R}$ given by

$$F(x,\delta) = 1 + x^2\delta, \quad h(x) = x,$$

and consider the IDO system with $N = \mathbb{R}^2$ and $E = O = \mathbb{R}$ given by

$$\widetilde{F}(z_1,z_2,\varepsilon) = (1 + z_1^3\varepsilon, \varepsilon), \quad \tilde{h}(z_1,z_2) = z_1$$

(observe that in both cases the input space Ω is absent). Because these systems are affine in their disturbances, we will use in each case the largest reasonable class of disturbances

$$\mathcal{D} = \mathcal{E} = L^1_{\mathrm{loc}}(\mathbb{R},\mathbb{R}).$$

If we set

$$\mathcal{R} = \{(x, z_1, z_2) \in \mathbb{R}^3 \mid x = z_1\},$$

then $\mathcal{R}$ is a closed vector subspace (and, in particular, a closed submanifold) of $M \times N = \mathbb{R}^3$, and it is easy to check that conditions (2.3) and (2.4) are satisfied. However, we claim that $\mathcal{R}$ cannot be a bisimulation relation as defined in Definition 2.5. To see this, select $(x_0, z_{10}, z_{20}) = (0, 0, 0) \in \mathcal{R}$ and $d \in \mathcal{D},\ d(t) \equiv 1$. It is easily seen that the corresponding state trajectory of F is

$$t \mapsto \psi(t, 0, d) = \tan t \quad (|t| < \pi/2).$$

Suppose that $e \in \mathcal{E}$ and I is a compact interval containing 0 such that relation (2.1) holds. Then the corresponding state trajectory

$$t \mapsto \tilde{\psi}(t, (0,0), e) = \big(\tilde{\psi}_1(t, (0,0), e), \tilde{\psi}_2(t, (0,0), e)\big)$$

of $\widetilde{F}$ must satisfy for a.e. $t \in I$

$$\begin{aligned} & \tan t = \tilde{\psi}_1(t, (0,0), e) \\ \Rightarrow \quad & \frac{d}{dt} \tan t = \frac{d}{dt} \tilde{\psi}_1(t, (0,0), e) = 1 + \tilde{\psi}_1(t, (0,0), e)^3 e(t) \\ \Rightarrow \quad & \sec^2 t = 1 + \tan^2 t = 1 + (\tan^3 t) e(t), \end{aligned}$$

so it must be the case that $e(t) = 1/\tan t$ for a.e. t. It follows that $e(\cdot)$ is not integrable on I. Furthermore, even if we attempted to press ahead with this choice of e, the second component of the trajectory would have to satisfy

$$\frac{d}{dt} \tilde{\psi}_2(t, (0,0), e) = \frac{1}{\tan t},$$

which precludes $t \mapsto \tilde{\psi}_2(t, (0,0), e)$ being absolutely continuous on any compact subinterval of $\mathbb{R}$ containing 0. Roughly speaking, the source of the difficulty is that the disturbance vector fields

$$x \mapsto x^2, \quad (z_1, z_2) \mapsto \begin{bmatrix} z_1^3 \\ 1 \end{bmatrix}$$

are "rank deficient" modulo the tangent space to the purported bisimulation relation $\mathcal{R}$ at the origin (see condition (i) of Proposition 3.6 for a precise statement of the rank condition that is violated here).

3. Main results. Our main result deals with nonlinear IDO systems that are affine in the disturbance, a concept that we define next.

DEFINITION 3.1. *A C^1 IDO system $F : M \times \Omega \times \Delta \to TM$ is said to be* affine in the disturbance *if the disturbance space Δ is a finite-dimensional Euclidean space $\mathbb{R}^p$ and F has the form*

$$F(x, \omega, \delta) = f(x, \omega) + \sum_{i=1}^{p} \delta_i g_i(x) \tag{3.1}$$

for $(x, \omega, \delta) \in M \times \Omega \times \mathbb{R}^p$, where $f : M \times \Omega \to TM$ is a C^1 control system, $g_1, \ldots, g_p$ are C^1 vector fields on M, and $\delta = (\delta_1, \ldots, \delta_p) \in \mathbb{R}^p$.

We will often write (3.1) in the abbreviated form

$$F(x,\omega,\delta) = f(x,\omega) + G(x)\delta, \tag{3.2}$$

where $G(x) = [g_1(x), \ldots, g_p(x)]$.

Remark 3.2. For the disturbance affine ID system F having the form (3.1) or (3.2), it is easy to check that

$$\mathcal{U}^{\Omega}_{\text{meas}}(f) \times L^1_{\text{loc}}(\mathbb{R}, \mathbb{R}^p) \subseteq \mathcal{U}^{\Omega\times\mathbb{R}^p}_{\text{meas}}(F).$$

Notation 3.3. Given finite-dimensional (real) vector spaces $\mathcal{V}$ and $\mathcal{W}$, we will let $\mathcal{L}(\mathcal{V},\mathcal{W})$ denote the family of all linear mappings from $\mathcal{V}$ into $\mathcal{W}$. Given differentiable manifolds M, N and points $x \in M$, $z \in N$, we will make the canonical identification

$$T_{(x,z)}(M \times N) \cong T_xM \times T_zN,$$

and often write tangent vectors $v \in T_{(x,z)}(M \times N)$ in the stacked form

$$v = \begin{bmatrix} \bar{v} \\ \tilde{v} \end{bmatrix}, \quad \text{where } \bar{v} \in T_xM \text{ and } \tilde{v} \in T_zN.$$

Given C^1 vector fields $\tilde{g}_1, \ldots, \tilde{g}_q$ on N and $z \in N$, we set $\widetilde{G}(z) = [\tilde{g}_1(z), \ldots, \tilde{g}_q(z)]$ and use the notation

$$\operatorname{Im} \begin{bmatrix} 0 \\ \widetilde{G}(z) \end{bmatrix}$$

to stand for the vector subspace of the tangent space $T_xM \times T_zN$ spanned by the tangent vectors

$$\begin{bmatrix} 0 \\ \tilde{g}_1(z) \end{bmatrix}, \ldots, \begin{bmatrix} 0 \\ \tilde{g}_q(z) \end{bmatrix}.$$

An analogous interpretation applies to the notation

$$\operatorname{Im} \begin{bmatrix} G(x) \\ 0 \end{bmatrix},$$

where $G(x) = [g_1(x), \ldots, g_p(x)]$ and $g_1, \ldots, g_p$ are C^1 vector fields on M.

The following two lemmas will play a key role in the proof of our main result.

LEMMA 3.4. *Let $\mathcal{V}$ be a finite-dimensional (real) vector space with inner product $\langle\cdot,\cdot\rangle$, let $\mathcal{W} \subseteq \mathcal{V}$ be a vector subspace having codimension $0 < \sigma < \dim \mathcal{V}$, and let $\eta_1, \ldots, \eta_\sigma \in \mathcal{V}$ be a basis for the orthogonal complement $\mathcal{W}^\perp$. If $v_1, \ldots, v_\lambda \in \mathcal{V}$ is a finite collection of vectors, if $\mathcal{Z} = \operatorname{span}\{v_1, \ldots, v_\lambda\}$, and if*

$$\ell = \dim(\mathcal{Z} + \mathcal{W})/\mathcal{W},$$

then the $\sigma \times \lambda$ matrix

$$\big[\langle \eta_i, v_j \rangle\big]_{1\le i\le\sigma, 1\le j\le\lambda}$$

has rank ℓ.

Proof. This is a straightforward exercise in linear algebra. □

LEMMA 3.5. *Let r, p, q be positive integers, let $\mathcal{X}$ be a C^k differentiable manifold of dimension r, and let $\Sigma : \mathcal{X} \to \mathcal{L}(\mathbb{R}^p, \mathbb{R}^q)$ be a C^k mapping such that $\zeta \mapsto \operatorname{rank} \Sigma(\zeta)$ is constant for $\zeta \in \mathcal{X}$. Then there exists a C^k mapping $\Theta : \mathcal{X} \to \mathcal{L}(\mathbb{R}^q, \mathbb{R}^p)$ such that*

$$\zeta \in \mathcal{X} \quad \Rightarrow \quad \Sigma(\zeta)\Theta(\zeta)\Sigma(\zeta) = \Sigma(\zeta).$$

Proof. See the proof of Claim 1 in [3, Thm. 3.11] and [3, Rem. 3.14]. □

In the next proposition we have isolated some of the technical details that are required in the proof of our main result.

PROPOSITION 3.6. *Let*

$$F : M \times \Omega \times \Delta \to TM, \quad \widetilde{F} : N \times \Omega \times \mathbb{R}^q \to TN$$

be two C^1 ID systems that have common input space Ω, and suppose that $\widetilde{F}$ is affine in its disturbance; that is,

$$(z, \omega, \varepsilon) \in N \times \Omega \times \mathbb{R}^q \;\Rightarrow\; \widetilde{F}(z, \omega, \varepsilon) = \tilde{f}(z, \omega) + \widetilde{G}(z)\varepsilon, \tag{3.3}$$

where $\widetilde{G}(z) = [\tilde{g}_1(z), \ldots, \tilde{g}_q(z)]$ and $\tilde{g}_1, \ldots, \tilde{g}_q$ are C^1 vector fields on N. Let $\mathcal{R} \subseteq M \times N$ be a C^2 immersed submanifold of $M \times N$ with the following properties:

(i) *For $(x, z) \in \mathcal{R}$ the vector subspace*

$$\widetilde{\mathcal{V}}_{(x,z)} = T_{(x,z)}\mathcal{R} + \operatorname{Im} \begin{bmatrix} 0 \\ \widetilde{G}(z) \end{bmatrix} \tag{3.4}$$

of $T_{(x,z)}(M \times N)$ has a constant dimension as (x, z) varies over $\mathcal{R}$.

(ii) *For every $(x, z) \in \mathcal{R}$, $\omega \in \Omega$, and $\delta \in \Delta$, there exists $\varepsilon \in \mathbb{R}^q$ such that*

$$\begin{bmatrix} F(x, \omega, \delta) \\ \tilde{f}(z, \omega) + \widetilde{G}(z)\varepsilon \end{bmatrix} \in T_{(x,z)}\mathcal{R}. \tag{3.5}$$

Then there exists a mapping $\Upsilon : \mathcal{R} \times \Omega \times \Delta \to \mathbb{R}^q$ that is nicely C^1 in $(x, z) \in \mathcal{R}$ relative to $(\omega, \delta) \in \Omega \times \Delta$ and satisfies

$$((x, z), \omega, \delta) \in \mathcal{R} \times \Omega \times \Delta \;\Rightarrow\; \begin{bmatrix} F(x, \omega, \delta) \\ \tilde{f}(z, \omega) + \widetilde{G}(z)\Upsilon(x, z, \omega, \delta) \end{bmatrix} \in T_{(x,z)}\mathcal{R}. \tag{3.6}$$

Proof. We will show that the desired mapping Υ exists locally (relative to $\mathcal{R}$) in a neighborhood of an arbitrary point (x_0, z_0) in $\mathcal{R}$, after which we will glue the local versions of Υ together via a partition of unity to obtain the desired globally defined mapping (again, relative to $\mathcal{R}$). Thus we fix a point $(x_0, z_0) \in \mathcal{R}$ and appeal to a standard result in the theory of differentiable manifolds (see, for example, [20, p. 28]) which guarantees the existence of an open neighborhood $\mathcal{S}$ of (x_0, z_0) relative to $\mathcal{R}$ such that $\mathcal{S}$ is a *slice* of a coordinate neighborhood $\mathcal{N}$ of (x_0, z_0) in $M \times N$ (the terminology is as in [20]). We note that $\mathcal{S}$ may not be an open subset of $\mathcal{R}$ in the relative topology that $\mathcal{R}$ inherits from $M \times N$ due to the fact that we are assuming only that $\mathcal{R}$ is an immersed submanifold; in particular, we are not asserting that $\mathcal{S} = \mathcal{R} \cap \mathcal{N}$, but only that $\mathcal{S}$ is a subset of $\mathcal{N}$ on which certain of the coordinate functions on $\mathcal{N}$ are constant. Let $m = \dim M$, $n = \dim N$, and let σ be the codimension of $\mathcal{R}$ in $M \times N$. Since $\mathcal{S}$ is a slice of the coordinate neighborhood $\mathcal{N}$, it is easy to obtain a family of $m + n$ C^1 vector fields defined on $\mathcal{N}$,

$$\xi_1, \ldots, \xi_{m+n-\sigma}, \eta_1, \ldots, \eta_\sigma : \mathcal{N} \to T(M \times N),$$

such that

$$(x,z)\in\mathcal{S}\ \Rightarrow\ T_{(x,z)}\mathcal{S}=T_{(x,z)}\mathcal{R}=\operatorname{span}_{\mathbb{R}}\{\xi_1(x,z),\dots,\xi_{m+n-\sigma}(x,z)\} \tag{3.7}$$

and

$$(x,z)\in\mathcal{S}\ \Rightarrow\ \langle\eta_i(x,z),\xi_j(x,z)\rangle=0\quad(i=1,\dots,\sigma,j=1,\dots,m+n-\sigma), \tag{3.8}$$

where $\langle\cdot,\cdot\rangle$ is any conveniently chosen Riemannian metric on $M\times N$. In particular, for $(x,z)\in\mathcal{S}$ and $v\in T_{(x,z)}(M\times N)$ we have

$$v\in T_{(x,z)}\mathcal{S}=T_{(x,z)}\mathcal{R}\ \Leftrightarrow\ \langle\eta_i(x,z),v\rangle=0\text{ for every }i=1,\dots,\sigma. \tag{3.9}$$

Without loss of generality we may further assume that $\mathcal{N}=U\times V$, where U is a coordinate neighborhood of x_0 in M that is diffeomorphic to $\mathbb{R}^m$ and V is a coordinate neighborhood of z_0 in N that is diffeomorphic to $\mathbb{R}^n$. We can then identify the ID system F with its local representation

$$F:\mathbb{R}^m\times\Omega\times\Delta\to\mathbb{R}^m$$

relative to U. Similarly we can identify the ID system $\widetilde{F}$ with its local representation

$$\widetilde{F}:\mathbb{R}^n\times\Omega\times\mathbb{R}^q\to\mathbb{R}^n,\quad \widetilde{F}(z,\omega,\varepsilon)=\tilde{f}(z,\omega)+\widetilde{G}(z)\varepsilon,$$

relative to V, where $\tilde{f}:\mathbb{R}^n\times\Omega\to\mathbb{R}^n$ is nicely C^1 in $z\in\mathbb{R}^n$ relative to $\omega\in\Omega$ and $\widetilde{G}:\mathbb{R}^n\to\mathcal{L}(\mathbb{R}^q,\mathbb{R}^n)$ is C^1. Moreover, the C^1 vector fields $\xi_1,\dots,\xi_{m+n-\sigma},\eta_1,\dots,\eta_\sigma$ can be identified with their local representations

$$\xi_1,\dots,\xi_{m+n-\sigma},\eta_1,\dots,\eta_\sigma:\mathbb{R}^m\times\mathbb{R}^n\to\mathbb{R}^m\times\mathbb{R}^n.$$

If we identify the slice $\mathcal{S}\subseteq\mathcal{N}$ with its image in $\mathbb{R}^m\times\mathbb{R}^n$ under the coordinate diffeomorphism $\mathcal{N}\cong\mathbb{R}^m\times\mathbb{R}^n$, then $\mathcal{S}$ is an immersed submanifold of $\mathbb{R}^m\times\mathbb{R}^n$ for which (3.7) continues to hold and for which (3.8) can be replaced with

$$(x,z)\in\mathcal{S}\ \Rightarrow\ \eta_i(x,z)^\tau\xi_j(x,z)=0\quad(i=1,\dots,\sigma,j=1,\dots,m+n-\sigma),$$

where the superscript τ denotes the matrix transpose, elements of $\mathbb{R}^m\times\mathbb{R}^n$ are viewed as column vectors, and we select the Riemannian metric induced by the standard inner product on $\mathbb{R}^m\times\mathbb{R}^n$.

Likewise, (3.9) can be replaced with

$$v\in T_{(x,z)}\mathcal{S}\ \Leftrightarrow\ \eta_i(x,z)^\tau v=0\text{ for every }i=1,\dots,\sigma.$$

Next we select columns $\tilde{g}_{j_1},\dots,\tilde{g}_{j_\ell}$ from the $n\times q$-matrix $\widetilde{G}=[\tilde{g}_1,\dots,\tilde{g}_q]$ such that the family of $m+n$-dimensional vectors

$$\xi_1(x,z),\dots,\xi_{m+n-\sigma}(x,z),\begin{bmatrix}0\\ \tilde{g}_{j_1}(z)\end{bmatrix},\dots,\begin{bmatrix}0\\ \tilde{g}_{j_\ell}(z)\end{bmatrix} \tag{3.10}$$

is a basis of the vector space $\widetilde{\mathcal{V}}_{(x_0,z_0)}$ defined in (3.4) when $x=x_0$ and $z=z_0$. By continuity the vector fields (3.10) will be linearly independent in some open neighborhood $\mathcal{S}_0\subseteq\mathcal{S}$ of (x_0,z_0) (open relative to the submanifold topology of $\mathcal{R}$), and since

by assumption the dimension of $\widetilde{\mathcal{V}}_{(x,z)}$ is constant for $(x,z) \in \mathcal{R}$, we infer that the vectors (3.10) will form a basis for $\widetilde{\mathcal{V}}_{(x,z)}$ for every $(x,z) \in \mathcal{S}_0$. Because

$$T_{(x,z)}\mathcal{R} = \operatorname{span}_{\mathbb{R}}\{\xi_1(x,z), \ldots, \xi_{m+n-\sigma}(x,z)\},$$

we see that

$$(x,z) \in \mathcal{S}_0 \;\Rightarrow\; \dim \widetilde{\mathcal{V}}_{(x,z)}/T_{(x,z)}\mathcal{R} = \ell. \tag{3.11}$$

Since the vectors $\eta_1(x,z), \ldots, \eta_\sigma(x,z)$ form a basis for the orthogonal complement of $T_{(x,z)}\mathcal{R}$, if we let $L(x,z)$ denote the $\sigma \times (m+n)$-matrix

$$L(x,z) = \begin{bmatrix} \eta_1(x,z)^\tau \\ \vdots \\ \eta_\sigma(x,z)^\tau \end{bmatrix}, \tag{3.12}$$

then relation (3.11) and Lemma 3.4 imply that

$$(x,z) \in \mathcal{S}_0 \;\Rightarrow\; \operatorname{rank} L(x,z) \begin{bmatrix} 0 \\ \widetilde{G}(z) \end{bmatrix} = \ell. \tag{3.13}$$

It will also be convenient to partition the matrix $L(x,z)$ defined by (3.12) as

$$L(x,z) = \big[\Lambda(x,z), \widetilde{\Lambda}(x,z)\big], \tag{3.14}$$

where $\Lambda(x,z)$ has dimensions $\sigma \times m$, $\widetilde{\Lambda}(x,z)$ has dimensions $\sigma \times n$, and both have entries that are C^1 functions of $(x,z) \in \mathcal{S}_0$. From relation (3.13) and the partitioned form of $L(x,z)$ given by (3.14), we obtain

$$(x,z) \in \mathcal{S}_0 \;\Rightarrow\; \operatorname{rank} \widetilde{\Lambda}(x,z)\widetilde{G}(z) = \ell.$$

Thus by Lemma 3.5 there exists a C^1 mapping $\Theta : \mathcal{S}_0 \to \mathcal{L}(\mathbb{R}^\sigma, \mathbb{R}^q)$ such that

$$(x,z) \in \mathcal{S}_0 \;\Rightarrow\; \widetilde{\Lambda}(x,z)\widetilde{G}(z)\Theta(x,z)\widetilde{\Lambda}(x,z)\widetilde{G}(z) = \widetilde{\Lambda}(x,z)\widetilde{G}(z) \tag{3.15}$$

(for later reference we point out that up to this point in the proof we have not yet invoked assumption (ii)).

With the aid of the mapping Θ just obtained, we will now demonstrate the (local) existence of the desired mapping Υ. For $(x,z) \in \mathcal{S}_0$ and $(\omega,\delta) \in \Omega \times \mathbb{R}^p$ assumption (ii) implies the existence of $\varepsilon \in \mathbb{R}^q$ such that (3.5) is satisfied. Clearly ε depends on the variables (x,z,ω,δ), that is, $\varepsilon = \varepsilon(x,z,\omega,\delta)$, but it is not yet apparent that this dependence has the regularity properties claimed in the statement of the proposition. Because the rows of the matrix L defined by (3.12) span the orthogonal complement of $T_{(x,z)}\mathcal{S}_0 = T_{(x,z)}\mathcal{R}$, we see that

$$\begin{aligned} \mathbb{R}^\sigma \ni 0 &= L(x,z) \begin{bmatrix} F(x,\omega,\delta) \\ \tilde{f}(z,\omega) + \widetilde{G}(z)\varepsilon(x,z,\omega,\delta) \end{bmatrix} \\ &= \big[\Lambda(x,z), \widetilde{\Lambda}(x,z)\big] \begin{bmatrix} F(x,\omega,\delta) \\ \tilde{f}(z,\omega) + \widetilde{G}(z)\varepsilon(x,z,\omega,\delta) \end{bmatrix} \\ &= \Lambda(x,z)F(x,\omega,\delta) + \widetilde{\Lambda}(x,z)\big[\tilde{f}(z,\omega) + \widetilde{G}(z)\varepsilon(x,z,\omega,\delta)\big]. \end{aligned} \tag{3.16}$$

Define a mapping $\Gamma : \mathcal{S}_0 \times \Omega \times \Delta \to \mathbb{R}^\sigma$ by

$$\Gamma(x,z,\omega,\delta) = -\Lambda(x,z)F(x,\omega,\delta) - \widetilde{\Lambda}(x,z)\tilde{f}(z,\omega). \tag{3.17}$$

It is clear that Γ is nicely C^1 in the variables $(x,z) \in \mathcal{S}_0$ relative to $(\omega,\delta) \in \Omega \times \Delta$ and relation (3.16) yields

$$\Gamma(x,z,\omega,\delta) = \widetilde{\Lambda}(x,z)\widetilde{G}(z)\varepsilon(x,z,\omega,\delta), \tag{3.18}$$

so from (3.18) and (3.15) we obtain

$$\begin{aligned} &\widetilde{\Lambda}(x,z)\widetilde{G}(z)\Theta(x,z)\Gamma(x,z,\omega,\delta) \\ &\qquad = \widetilde{\Lambda}(x,z)\widetilde{G}(z)\Theta(x,z)\widetilde{\Lambda}(x,z)\widetilde{G}(z)\varepsilon(x,z,\omega,\delta) \\ &\qquad = \widetilde{\Lambda}(x,z)\widetilde{G}(z)\varepsilon(x,z,\omega,\delta) \\ &\qquad = \Gamma(x,z,\omega,\delta). \end{aligned} \tag{3.19}$$

If we define $\Upsilon : \mathcal{S}_0 \times \Omega \times \Delta \to \mathbb{R}^q$ by

$$\Upsilon(x,z,\omega,\delta) = \Theta(x,z)\Gamma(x,z,\omega,\delta), \tag{3.20}$$

then Υ is nicely C^1 in the variables $(x,z) \in \mathcal{R}$ relative to $(\omega,\delta) \in \Omega \times \Delta$ because Γ has this property and Θ is C^1. Moreover, from (3.19) and (3.17) we obtain

$$\begin{aligned} \widetilde{\Lambda}(x,z)\widetilde{G}(z)\Upsilon(x,z,\omega,\delta) &= \Gamma(x,z,\omega,\delta) \\ &= -\Lambda(x,z)F(x,\omega,\delta) - \widetilde{\Lambda}(x,z)\tilde{f}(z,\omega), \end{aligned}$$

which can be rewritten in the form

$$\begin{aligned} 0 &= \left[\Lambda(x,z), \widetilde{\Lambda}(x,z)\right] \begin{bmatrix} F(x,\omega,\delta) \\ \tilde{f}(z,\omega) + \widetilde{G}(z)\Upsilon(x,z,\omega,\delta) \end{bmatrix} \\ &= L(x,z) \begin{bmatrix} F(x,\omega,\delta) \\ \tilde{f}(z,\omega) + \widetilde{G}(z)\Upsilon(x,z,\omega,\delta) \end{bmatrix}. \end{aligned}$$

Since the rows of the matrix $L(x,z)$ span the orthogonal complement of $T_{(x,z)}\mathcal{R}$, we immediately obtain relation (3.6) for every $((x,z),\omega,\delta) \in \mathcal{S}_0 \times \Omega \times \Delta$. Consequently, the existence of the desired mapping Υ has been established in some neighborhood of an arbitrary point $(x_0,z_0) \in \mathcal{R}$.

To obtain the globally defined version of Υ, we appeal to the local result just obtained and a partition-of-unity argument. By the local result and by the second countability of $\mathcal{R}$ in its submanifold topology, there exist a countable open cover $\{\mathcal{S}_i \mid i \in \mathbb{N}\}$ of $\mathcal{R}$ and mappings

$$\Upsilon_i : \mathcal{S}_i \times \Omega \times \Delta \to \mathbb{R}^q$$

that are nicely C^1 in $(x,z) \in \mathcal{S}_i$ relative to $(\omega,\delta) \in \Omega \times \Delta$ and satisfy (3.6) for $((x,z),\omega,\delta) \in \mathcal{S}_i \times \Omega \times \Delta$. If we select a C^1 partition of unity $\{\psi_i : \mathcal{R} \to \mathbb{R} \mid i \in \mathbb{N}\}$ subordinate to the open cover $\{\mathcal{S}_i \mid i \in \mathbb{N}\}$, then the mapping

$$\Upsilon : \mathcal{R} \times \Omega \times \Delta \to \mathbb{R}^q, \quad \Upsilon((x,z),\omega,\delta) = \sum_{i=1}^{\infty} \psi_i(x,z)\Upsilon_i((x,z),\omega,\delta)$$

is easily seen to satisfy (3.6) everywhere on $\mathcal{R} \times \Omega \times \Delta$ while being nicely C^1 in the variables (x,z) relative to (ω,δ). This completes the proof. □

Remark 3.7.

1. The constant-dimension assumption (i) in Proposition 3.6 is fairly common in results of this type; see, for example, [10, Prop. 11.2].

2. If F is affine in its disturbance variable (say, with $\Delta = \mathbb{R}^p$), then Υ can also be chosen to be affine in the disturbance variable δ in the sense that there exist mappings

$$P : \mathcal{R} \times \Omega \to \mathbb{R}^q, \quad Q : \mathcal{R} \times \Omega \to \mathcal{L}(\mathbb{R}^p, \mathbb{R}^q),$$

both of which are nicely C^1 in (x, z) relative to $\omega \in \Omega$ and for which

$$\Upsilon((x, z), \omega, \delta) = P((x, z), \omega) + Q((x, z), \omega)\delta.$$

This follows directly from the formulas (3.20) and (3.17), which specify Υ locally, and the fact that the affine structure is preserved under the pasting process by which the globally defined version of Υ is obtained.

We are now in a position to prove the main results of this paper.

THEOREM 3.8. *Let (F, h) and $(\widetilde{F}, \tilde{h})$ be two C^1 IDO systems that satisfy the assumptions of Proposition* 3.6 *(in particular, they have common input space Ω, common output space O, and $\widetilde{F}$ is affine in its disturbance of the form* (3.3)*). Let $\mathcal{R} \subseteq M \times N$ be a C^2 immersed submanifold of $M \times N$ for which constant-dimension assumption* (i) *of Proposition* 3.6 *holds, and consider the following "simulation condition":*

(*SC*) *For every $(x, z) \in \mathcal{R}$ and $\omega \in \Omega$ we have $h(x, \omega) = \tilde{h}(z, \omega)$. Furthermore, for every $(x, z) \in \mathcal{R}$, $\omega \in \Omega$, and $\delta \in \Delta$, there exists $\varepsilon \in \mathbb{R}^q$ such that*

$$\begin{bmatrix} F(x, \omega, \delta) \\ \tilde{f}(z, \omega) + \widetilde{G}(z)\varepsilon \end{bmatrix} \in T_{(x,z)}\mathcal{R}. \tag{3.21}$$

Suppose that $\mathcal{U} \subseteq \mathcal{U}^{\Omega}_{\text{meas}}(\tilde{f})$, $\mathcal{D} \subseteq \mathcal{U}^{\Delta}_{\text{meas}}$ are such that $\mathcal{U} \times \mathcal{D} \subseteq \mathcal{U}^{\Omega\times\Delta}_{\text{meas}}(F)$, and let $\mathcal{E} \subseteq L^1_{\text{loc}}(\mathbb{R}, \mathbb{R}^q)$. Then the following statements hold:

1. *If $\mathcal{R}$ is a simulation relation of $(F, h, \mathcal{U}, \mathcal{D})$ by $(\widetilde{F}, \tilde{h}, \mathcal{U}, \mathcal{E})$ and if $\mathcal{U}$ and $\mathcal{D}$ contain all of the constant mappings in their respective ranges, then (SC) holds.*

2. *If (SC) holds, then $\mathcal{R}$ is a simulation relation of $(F, h, \mathcal{U}, \mathcal{D})$ by $(\widetilde{F}, \tilde{h}, \mathcal{U}, L^1_{\text{loc}}(\mathbb{R}, \mathbb{R}^q))$.*

Proof. To prove the first statement we first observe that our assumptions on $\mathcal{U}$ and $\mathcal{E}$ yield

$$\mathcal{U} \times \mathcal{E} \subseteq \mathcal{U}^{\Omega}_{\text{meas}}(\tilde{f}) \times L^1_{\text{loc}}(\mathbb{R}, \mathbb{R}^q) \subseteq \mathcal{U}^{\Omega\times\mathbb{R}^q}_{\text{meas}}(\widetilde{F})$$

by Remark 3.2. Assume that $\mathcal{R}$ is a simulation relation of $(F, h, \mathcal{U}, \mathcal{D})$ by $(\widetilde{F}, \tilde{h}, \mathcal{U}, \mathcal{E})$, and let $(x_0, z_0) \in \mathcal{R}$, $\omega_0 \in \Omega$, and $\delta_0 \in \mathbb{R}^p$ be given. If we let $u : \mathbb{R} \to \Omega$ and $d : \mathbb{R} \to \mathbb{R}^p$ be the constant mappings $u(t) \equiv \omega_0$ and $d(t) \equiv \delta_0$, then by assumption $u \in \mathcal{U}$ and $d \in \mathcal{D}$, so by Definition 2.2 there exist $e \in \mathcal{E}$ and a compact interval I containing 0 in its interior such that (we will use the abbreviated notations $\psi(t) = \psi(t, x_0, u, d)$ and $\tilde{\psi}(t) = \tilde{\psi}(t, z_0, u, e)$ for the trajectories)

$$t \in I \;\Rightarrow\; (\psi(t), \tilde{\psi}(t)) \in \mathcal{R} \tag{3.22}$$

and

$$t \in I \;\Rightarrow\; h(\psi(t), \omega_0) = \tilde{h}(\tilde{\psi}(t), \omega_0).$$

Thus we can set $t = 0$ to obtain $h(x_0, \omega_0) = \tilde{h}(z_0, \omega_0)$. Furthermore, the trajectories are absolutely continuous as functions of t, so we can differentiate (3.22) to obtain

$$\big(\dot{\psi}(t), \dot{\tilde{\psi}}(t)\big) \in T_{(\psi(t),\tilde{\psi}(t))}\mathcal{R} \quad \text{for a.e. } t \in I. \tag{3.23}$$

If the disturbance $t \mapsto e(t)$ is at least continuous, then (3.23) will hold for every $t \in I$ and we can then set $t = 0$ and immediately obtain (3.21) for $x = x_0$, $z = z_0$, $\omega = \omega_0$, $\delta = \delta_0$, and $\varepsilon = e(0)$. However, if e is measurable only as a function of t, then there is no guarantee that $t = 0$ is a Lebesgue point of the mapping $t \mapsto \tilde{\psi}(t)$ and further reasoning is required. The argument of Proposition 3.6 yields an open neighborhood $\mathcal{S}_0$ of (x_0, z_0) in $\mathcal{R}$ and C^1 mapping $L : \mathcal{S}_0 \to \mathcal{L}(\mathbb{R}^{m+n}, \mathbb{R}^\sigma)$ such that for $(x, z) \in \mathcal{S}_0$ we have

$$v \in T_{(x,z)}\mathcal{S}_0 = T_{(x,z)}\mathcal{R} \quad \Leftrightarrow \quad L(x, z)v = 0 \in \mathbb{R}^\sigma \tag{3.24}$$

(as before, σ is the codimension of $\mathcal{R}$ in $M \times N$, and since we are working locally we have passed to local coordinates $M \cong \mathbb{R}^m$, $N \cong \mathbb{R}^n$). If we partition L as in (3.14), then we also obtain a C^1 mapping $\Theta : \mathcal{S}_0 \to \mathcal{L}(\mathbb{R}^\sigma, \mathbb{R}^q)$ satisfying (3.15). Choose $\epsilon > 0$ such that $(-\epsilon, \epsilon) \subseteq I$ and $(\psi(t), \tilde{\psi}(t)) \in \mathcal{S}_0$ for $t \in (-\epsilon, \epsilon)$. Then (3.23) and (3.24) yield

$$\begin{aligned} \mathbb{R}^\sigma \ni 0 &= L(\psi(t), \tilde{\psi}(t)) \begin{bmatrix} F(\psi(t), \omega_0, \delta_0) \\ \tilde{f}(\tilde{\psi}(t), \omega_0) + \widetilde{G}(\tilde{\psi}(t))e(t) \end{bmatrix} \\ &= \Lambda(\psi(t), \tilde{\psi}(t))F(\psi(t), \omega_0, \delta_0) \\ &\qquad + \widetilde{\Lambda}(\psi(t), \tilde{\psi}(t))\big[\tilde{f}(\tilde{\psi}(t), \omega_0) + \widetilde{G}(\tilde{\psi}(t))e(t)\big] \\ &\qquad\qquad \text{for a.e. } t \in (-\epsilon, \epsilon). \end{aligned} \tag{3.25}$$

The argument used in the proof of Proposition 3.6 shows that if $\Upsilon : \mathcal{S}_0 \times \Omega \times \Delta \to \mathbb{R}^q$ is the mapping defined in (3.20), then relation (3.25) will continue to hold with $e(t)$ replaced by $\Upsilon(\psi(t), \tilde{\psi}(t), \omega_0, \delta_0)$. However, $t \mapsto \Upsilon(\psi(t), \tilde{\psi}(t), \omega_0, \delta_0)$ is continuous because Υ, ψ, and $\tilde{\psi}$ are continuous, so we obtain

$$|t| < \epsilon \Rightarrow 0 = L(\psi(t), \tilde{\psi}(t)) \begin{bmatrix} F(\psi(t), \omega_0, \delta_0) \\ \tilde{f}(\tilde{\psi}(t), \omega_0) + \widetilde{G}(\tilde{\psi}(t))\Upsilon(\psi(t), \tilde{\psi}(t), \omega_0, \delta_0) \end{bmatrix}. \tag{3.26}$$

In particular, we can set $t = 0$ in (3.26) and use relation (3.24) to infer that (3.21) holds when the variables x, z, ω, δ, and ε are replaced with $x_0, z_0, \omega_0, \delta_0$, and $\Upsilon(x_0, z_0, \omega_0, \delta_0)$, respectively, and the first statement is proved.

To prove the second statement we assume that (SC) holds and fix $(x_0, z_0) \in \mathcal{R}$, $u \in \mathcal{U}$, and $d \in \mathcal{D}$. The hypotheses of Proposition 3.6 are satisfied, so we infer the existence of a mapping $\Upsilon : \mathcal{R} \times \Omega \times \Delta \to \mathbb{R}^q$ that is nicely C^1 in the variables $(x, z) \in \mathcal{R}$ relative to $(\omega, \delta) \in \Omega \times \Delta$ and for which relation (3.6) holds. It follows that the mapping

$$\mathcal{F} : \mathcal{R} \times \Omega \times \Delta \to T(M \times N)$$

given by

$$\mathcal{F}((x, z), \omega, \delta) = \begin{bmatrix} F(x, \omega, \delta) \\ \tilde{f}(z, \omega) + \widetilde{G}(z)\Upsilon(x, z, \omega, \delta) \end{bmatrix} \tag{3.27}$$

takes values in the tangent bundle $T\mathcal{R}$ of the submanifold $\mathcal{R}$ ($T\mathcal{R}$ is, of course, a subbundle of $T(M \times N)$), and as such defines a C^1 control system on $\mathcal{R}$ with control space $\Omega \times \Delta$. A straightforward (though not completely obvious) check of the construction of Υ in Proposition 3.6 shows that

$$\mathcal{U} \times \mathcal{D} \subseteq \mathcal{U}_{\text{meas}}^{\Omega \times \mathbb{R}^p}(\mathcal{F}),$$

so for the given initial point $(x_0, z_0) \in \mathcal{R}$ and the given controls $u \in \mathcal{U}$, $d \in \mathcal{D}$, the corresponding state trajectory

$$t \mapsto \Psi(t, (x_0, z_0), u, d)$$

of the system $\mathcal{F}$ is defined on a compact interval I containing 0 in its interior and takes values in $\mathcal{R}$. If we define $e : \mathbb{R} \to \mathbb{R}^q$ by

$$e(t) = \begin{cases} \Upsilon(\Psi(t, (x_0, z_0), u, d), u(t), d(t)) & \text{if } t \in I, \\ 0 & \text{otherwise,} \end{cases} \tag{3.28}$$

then the form of Υ derived in Proposition 3.6 and the assumptions imposed on u and d force $e(\cdot)$ to be Lebesgue integrable on $\mathbb{R}$. One can also easily verify that

$$t \in I \;\Rightarrow\; \Psi(t, (x_0, z_0), u, d) = \big(\psi(t, x_0, u, d), \tilde{\psi}(t, z_0, u, e)\big),$$

where ψ and $\tilde{\psi}$ are the trajectory mappings for F and $\widetilde{F}$, respectively, so, in particular,

$$t \in I \;\Rightarrow\; \big(\psi(t, x_0, u, d), \tilde{\psi}(t, z_0, u, e)\big) \in \mathcal{R},$$

and, moreover,

$$t \in I \;\Rightarrow\; h(\psi(t, x_0, u, d), u(t)) = \tilde{h}(\tilde{\psi}(t, z_0, u, e), u(t))$$

by the assumption on h and $\tilde{h}$ in (SC), so the proof is complete. □

Remark 3.9. One can easily prove variations of assertion (2) in Theorem 3.8 to obtain simulation results for other (restricted) classes of inputs and disturbances. For example, a straightforward modification of the proof of Theorem 3.8.2 shows that if $\mathcal{U} \subseteq \mathcal{U}_{\text{cont}}^{\Omega}$ and $\mathcal{D} \subseteq \mathcal{U}_{\text{cont}}^{\Delta}$, then (SC) implies that $\mathcal{R}$ is a simulation relation of $(F, h, \mathcal{U}, \mathcal{D})$ by $(\widetilde{F}, \tilde{h}, \mathcal{U}, \mathcal{U}_{\text{cont}}^{\mathbb{R}^q})$. One simply checks that the requisite disturbance e is synthesized by way of the mapping Υ given by Proposition 3.6, and Υ is continuous (the definition of e in (3.28) needs to be adjusted slightly by extending e from I to $\mathbb{R}$ continuously instead of by zero). Similar results can be obtained for piecewise continuous inputs and disturbance, or (piecewise) differentiable inputs and disturbances if the input and disturbance spaces are assumed to be differentiable manifolds and the control systems are jointly differentiable in their state and control variables.

Two applications of Theorem 3.8 immediately yield the following bisimulation result.

THEOREM 3.10. *Let (F, h) and $(\widetilde{F}, \tilde{h})$ be two C^1 IDO systems that have common input space Ω, common output space O, and are affine in their disturbances (so F has the form (3.2) and $\widetilde{F}$ has the form (3.3)). Let $\mathcal{R} \subseteq M \times N$ be a C^2 immersed submanifold of $M \times N$ for which the following rank condition holds:*

(RC) For $(x, z) \in \mathcal{R}$ the vector subspaces

$$\mathcal{V}_{(x,z)} = T_{(x,z)}\mathcal{R} + \operatorname{Im}\begin{bmatrix} G(x) \\ 0 \end{bmatrix}, \quad \widetilde{\mathcal{V}}_{(x,z)} = T_{(x,z)}\mathcal{R} + \operatorname{Im}\begin{bmatrix} 0 \\ \widetilde{G}(z) \end{bmatrix}$$

of $T_{(x,z)}(M \times N)$ have constant—but possibly unequal—dimensions as (x, z) varies over $\mathcal{R}$ (in particular, these vector spaces need not coincide).

Consider the following "bisimulation condition":

(BC) For every $(x,z)\in\mathcal{R}$ *and* $\omega\in\Omega$ *we have* $h(x,\omega)=\tilde{h}(z,\omega)$. *Furthermore, for every* $(x,z)\in\mathcal{R}$, $\omega\in\Omega$, *and* $\delta\in\mathbb{R}^p$, *there exists* $\varepsilon\in\mathbb{R}^q$ *such that*

$$\begin{bmatrix} f(x,\omega)+G(x)\delta \\ \tilde{f}(z,\omega)+\widetilde{G}(z)\varepsilon \end{bmatrix} \in T_{(x,z)}\mathcal{R}, \tag{3.29}$$

and conversely for every $(x,z)\in\mathcal{R}$, $\omega\in\Omega$, *and* $\varepsilon\in\mathbb{R}^q$, *there exists* $\delta\in\mathbb{R}^p$ *such that* (3.29) *holds.*

Then the following statements hold:

1. *Let* $\mathcal{U}\subseteq\mathcal{U}^{\Omega}_{\mathrm{meas}}(f)\cap\mathcal{U}^{\Omega}_{\mathrm{meas}}(\tilde{f})$, $\mathcal{D}\subseteq L^1_{\mathrm{loc}}(\mathbb{R},\mathbb{R}^p)$, $\mathcal{E}\subseteq L^1_{\mathrm{loc}}(\mathbb{R},\mathbb{R}^q)$ *be specified classes of inputs and disturbances that contain all of the constant mappings of* $\mathbb{R}$ *in their respective ranges. If* $\mathcal{R}$ *is a bisimulation relation between* $(F,h,\mathcal{U},\mathcal{D})$ *and* $(\widetilde{F},\tilde{h},\mathcal{U},\mathcal{E})$, *then* (BC) *holds.*

2. *If* $\mathcal{U}\subseteq\mathcal{U}^{\Omega}_{\mathrm{meas}}(f)\cap\mathcal{U}^{\Omega}_{\mathrm{meas}}(\tilde{f})$ *and if* (BC) *holds, then* $\mathcal{R}$ *is a bisimulation relation between* $(F,h,\mathcal{U},L^1_{\mathrm{loc}}(\mathbb{R},\mathbb{R}^p))$ *and* $(\widetilde{F},\tilde{h},\mathcal{U},L^1_{\mathrm{loc}}(\mathbb{R},\mathbb{R}^q))$.

Remark 3.11. Of some interest is the special case of the previous theorem when the systems F and $\widetilde{F}$ are linear. That is, we suppose that the systems' state, input, and disturbance spaces are Euclidean (say, $M=\mathbb{R}^m$, $N=\mathbb{R}^n$, $\Omega=\mathbb{R}^r$, $\Delta=\mathbb{R}^p$, $E=\mathbb{R}^q$), F and $\widetilde{F}$ have the form

$$F(x,\omega,\delta)=Ax+B\omega+G\delta,\quad (x,\omega,\delta)\in\mathbb{R}^m\times\mathbb{R}^r\times\mathbb{R}^p,$$

and

$$\widetilde{F}(z,\omega,\varepsilon)=\widetilde{A}z+\widetilde{B}\omega+\widetilde{G}\varepsilon,\quad (z,\omega,\varepsilon)\in\mathbb{R}^n\times\mathbb{R}^r\times\mathbb{R}^q$$

for constant matrices A, B, G, $\widetilde{A}$, $\widetilde{B}$, and $\widetilde{G}$ of the appropriate dimensions, and $\mathcal{R}$ is a vector subspace of $M\times N=\mathbb{R}^m\times\mathbb{R}^n$. Then (RC) holds trivially (note that $T_{(x,z)}\mathcal{R}=\mathcal{R}$ in this case), so for any $\mathcal{U}\subseteq L^1_{\mathrm{loc}}(\mathbb{R},\mathbb{R}^r)$, we can infer that $\mathcal{R}$ is a bisimulation relation between $(F,h,\mathcal{U},L^1_{\mathrm{loc}}(\mathbb{R},\mathbb{R}^p))$ and $(\widetilde{F},\tilde{h},\mathcal{U},L^1_{\mathrm{loc}}(\mathbb{R},\mathbb{R}^q))$ if the following bisimulation condition holds:

(BC′) For every $(x,z)\in\mathcal{R}$ and $\omega\in\mathbb{R}^r$ we have $h(x,\omega)=\tilde{h}(z,\omega)$. Furthermore, for every $(x,z)\in\mathcal{R}$, $\omega\in\mathbb{R}^r$, and $\delta\in\mathbb{R}^p$, there exists $\varepsilon\in\mathbb{R}^q$ such that

$$(Ax+B\omega+G\delta,\widetilde{A}z+\widetilde{B}\omega+\widetilde{G}\varepsilon)\in\mathcal{R}, \tag{3.30}$$

and conversely for every $(x,z)\in\mathcal{R}$, $\omega\in\mathbb{R}^r$, and $\varepsilon\in\mathbb{R}^q$, there exists $\delta\in\mathbb{R}^p$ such that (3.30) holds.

4. Discussion and related results. A particularly important example of simulation relations arises from the notion of systems "related" by smooth mappings [4, 12, 13]. Specifically, suppose we are given a pair of C^1 IDO systems

$$F:M\times\Omega\times\Delta\to TM,\quad h:M\times\Omega\to O,\quad u\in\mathcal{U},\quad d\in\mathcal{D}$$

and

$$\widetilde{F}:N\times\Omega\times E\to TN,\quad \tilde{h}:N\times\Omega\to O,\quad u\in\mathcal{U},\quad e\in\mathcal{E},$$

which have the common input space Ω, the common output space O, the common family of admissible inputs $\mathcal{U}$, and admissible families of disturbances $\mathcal{D}$ and $\mathcal{E}$, respectively, and let $\Phi:M\to N$ be a C^2 mapping. We wish to explore conditions

under which these IDO systems are "related" by the mapping Φ according to either of the following definitions (as before, ψ and $\tilde{\psi}$ denote the trajectory mappings of F and $\widetilde{F}$, respectively).

DEFINITION 4.1. *We say that* Φ maps trajectories of $(F, h, \mathcal{U}, \mathcal{D})$ to trajectories of $(\widetilde{F}, \tilde{h}, \mathcal{U}, \mathcal{E})$ while preserving outputs *if for every* $x_0 \in M$, $u \in \mathcal{U}$, *and* $d \in \mathcal{D}$ *there exist* $e \in \mathcal{E}$ *and a compact interval* I *containing* 0 *in its interior such that both of the trajectories* $t \mapsto \psi(t, x_0, u, d)$ *and* $t \mapsto \tilde{\psi}(t, z_0, u, e)$ *(here* $z_0 = \Phi(x_0)$*) are defined for every* $t \in I$ *and satisfy*

$$t \in I \;\Rightarrow\; \Phi\big(\psi(t, x_0, u, d)\big) = \tilde{\psi}(t, z_0, u, e) \tag{4.1}$$

and

$$t \in I \;\Rightarrow\; h(\psi(t, x_0, u, d), u(t)) = \tilde{h}(\tilde{\psi}(t, z_0, u, e), u(t)). \tag{4.2}$$

DEFINITION 4.2. *We say that* Φ lifts trajectories of $(\widetilde{F}, \tilde{h}, \mathcal{U}, \mathcal{E})$ to trajectories of $(F, h, \mathcal{U}, \mathcal{D})$ while preserving outputs *if for every* $z_0 \in N$, $u \in \mathcal{U}$, $e \in \mathcal{E}$, *and* $x_0 \in \Phi^{-1}(z_0)$ *there exist* $d \in \mathcal{D}$ *and a compact interval* I *containing* 0 *in its interior such that both of the trajectories* $t \mapsto \psi(t, x_0, u, d)$ *and* $t \mapsto \tilde{\psi}(t, z_0, u, e)$ *are defined for every* $t \in I$ *and satisfy relations* (4.1) *and* (4.2).

Remark 4.3. We note in passing that one can handle systems without outputs under this framework by simply specifying that the output mappings h and $\tilde{h}$ are constant, since in this case the output relation (4.2) is trivially satisfied.

As one might expect, the notions of mapping and lifting trajectories are subsumed by the notion of simulation of one system by another if we associate to Φ its graph

$$\mathcal{R} = \mathrm{Graph}(\Phi) = \{(x, \Phi(x)) \mid x \in M\}.$$

Observe that $\mathcal{R}$ is first and foremost a relation in $M \times N$, but it is also a C^2 (in this case closed and imbedded) submanifold of $M \times N$ that is C^2 diffeomorphic to M. The tangent spaces to $\mathcal{R}$ are easily described as follows:

$$T_{(x,\Phi(x))}\mathcal{R} = \left\{ \begin{bmatrix} v \\ d\Phi_x(v) \end{bmatrix} \mid v \in T_x M \right\} \quad (x \in M) \tag{4.3}$$

(we use the stacked representation of tangent vectors in $T\mathcal{R} \subseteq T(M \times N)$ introduced in Notation 3.3). Since $z_0 = \Phi(x_0)$ and relation (4.1) are equivalent to $(x_0, z_0) \in \mathcal{R}$ and

$$t \in I \;\Rightarrow\; \big(\psi(t, x_0, u, d), \tilde{\psi}(t, z_0, u, e)\big) \in \mathcal{R},$$

we immediately obtain the following propositions.

PROPOSITION 4.4. *The* C^2 *mapping* $\Phi : M \to N$ *maps trajectories of* $(F, h, \mathcal{U}, \mathcal{D})$ *to trajectories of* $(\widetilde{F}, \tilde{h}, \mathcal{U}, \mathcal{E})$ *while preserving outputs if and only if the relation* $\mathcal{R} = \mathrm{Graph}(\Phi)$ *is a simulation relation of* $(F, h, \mathcal{U}, \mathcal{D})$ *by* $(\widetilde{F}, \tilde{h}, \mathcal{U}, \mathcal{E})$.

PROPOSITION 4.5. *The* C^2 *mapping* $\Phi : M \to N$ *lifts trajectories of* $(\widetilde{F}, \tilde{h}, \mathcal{U}, \mathcal{E})$ *to trajectories of* $(F, h, \mathcal{U}, \mathcal{D})$ *while preserving outputs if and only if the relation* $\mathcal{R} = \mathrm{Graph}(\Phi)$ *is a simulation relation of* $(\widetilde{F}, \tilde{h}, \mathcal{U}, \mathcal{E})$ *by* $(F, h, \mathcal{U}, \mathcal{D})$.

For illustrative purposes, we show how the previous propositions, when combined with the results of section 3, allow us to recover previously obtained results on trajectory propagation and trajectory lifting.

THEOREM 4.6 (see [4, Thm. 3.11]). *Let (F,h) and $(\widetilde{F},\tilde{h})$ be two C^1 IDO systems that satisfy the assumptions of Proposition* 3.6 *(in particular, they have common input space Ω, common output space O, and $\widetilde{F}$ is affine in its disturbance of the form* (3.3)*). Let $\Phi : M \to N$ be a C^2 mapping such that*

(i) $(x,\omega) \in M \times \Omega \;\Rightarrow\; \tilde{h}(\Phi(x),\omega) = h(x,\omega)$*;*

(ii) *for every $(x,\omega) \in M \times \Omega$ we have*

$$\{d\Phi_x F(x,\omega,\delta) \mid \delta \in \Delta\} \subseteq \{\tilde{f}(\Phi(x),\omega) + \widetilde{G}(\Phi(x))\varepsilon \mid \varepsilon \in \mathbb{R}^q\};$$

(iii) *the vector space $\operatorname{Im}\tilde{G}(\Phi(x))$ has constant dimension as x varies over M.*

If $\mathcal{U} \subseteq \mathcal{U}^{\Omega}_{\mathrm{meas}}(\tilde{f})$, $\mathcal{D} \subseteq \mathcal{U}^{\Delta}_{\mathrm{meas}}$, and $\mathcal{U}\times\mathcal{D} \subseteq \mathcal{U}^{\Omega\times\Delta}_{\mathrm{meas}}(F)$, then Φ maps trajectories of $(F,h,\mathcal{U},\mathcal{D})$ to trajectories of $(\widetilde{F},\tilde{h},\mathcal{U},L^1_{\mathrm{loc}}(\mathbb{R},\mathbb{R}^q))$ while preserving outputs.

Proof. If $(x,z) \in \operatorname{Graph}(\Phi)$ and $\omega \in \Omega$, then $z = \Phi(x)$ and assumption (i) yields $h(x,\omega) = \tilde{h}(z,\omega)$. Moreover, for $(x,\omega) \in M \times \Omega$ and $\delta \in \Delta$ assumption (ii) yields a $\varepsilon \in \mathbb{R}^q$ for which

$$d\Phi_x F(x,\omega,\delta) = \tilde{f}(z,\omega) + \widetilde{G}(z)\varepsilon,$$

and this, along with the description of the tangent spaces of $\mathcal{R} = \operatorname{Graph}(\Phi)$ given by (4.3), implies

$$\begin{bmatrix} F(x,\omega,\delta) \\ \tilde{f}(z,\omega) + \widetilde{G}(z)\varepsilon \end{bmatrix} \in T_{(x,z)}\mathcal{R},$$

so we obtain the simulation condition (SC) of Theorem 3.8. For $(x,z) \in \mathcal{R}$ we also have (here I_m denotes the $m \times m$ identity matrix)

$$\begin{aligned}
\widetilde{\mathcal{V}}_{(x,z)} = T_{(x,z)}\mathcal{R} + \operatorname{Im}\begin{bmatrix} 0 \\ \widetilde{G}(z) \end{bmatrix} &= T_{(x,\Phi(x))}\mathcal{R} + \operatorname{Im}\begin{bmatrix} 0 \\ \widetilde{G}(\Phi(x)) \end{bmatrix} \\
&= \left\{ \begin{bmatrix} v \\ d\Phi_x(v) + \widetilde{G}(\Phi(x))\varepsilon \end{bmatrix} \;\middle|\; v \in T_xM,\ \varepsilon \in \mathbb{R}^q \right\} \\
&= \left\{ \begin{bmatrix} I_m & 0 \\ d\Phi_x & \widetilde{G}(\Phi(x)) \end{bmatrix} \begin{bmatrix} v \\ \varepsilon \end{bmatrix} \;\middle|\; v \in T_xM,\ \varepsilon \in \mathbb{R}^q \right\}.
\end{aligned}$$

It follows that

$$\dim \widetilde{\mathcal{V}}_{(x,\Phi(x))} = m + \operatorname{rank}\widetilde{G}(\Phi(x)),$$

from which assumption (iii) implies that $\dim \widetilde{\mathcal{V}}_{(x,z)}$ is constant as (x,z) varies over $\mathcal{R} = \operatorname{Graph}(\Phi)$. Thus we infer from Theorem 3.8.2 that $\mathcal{R}$ is a simulation relation of $(F,h,\mathcal{U},\mathcal{D})$ by $(\widetilde{F},\tilde{h},\mathcal{U},L^1_{\mathrm{loc}}(\mathbb{R},\mathbb{R}^q))$, and the theorem is now a direct consequence of Proposition 4.4. ∎

Remark 4.7. In the literature (see, for example, [4, 12, 13]) the systems F and $\widetilde{F}$ are called Φ-*related* if assumption (ii) of Theorem 4.6 holds. Theorem 4.6 is also closely related to (and generalizes somewhat) a result of Elkin [1, Thm. 2.1].

THEOREM 4.8 (see [5, Thm. 3.2]). *Let*

$$F : M \times \Omega \times \mathbb{R}^p \to TM, \quad h : M \times \Omega \to O$$

and

$$\widetilde{F} : N \times \Omega \times E \to TN, \quad \tilde{h} : N \times \Omega \to O$$

be two C^1 IDO systems that have common input space Ω, common output space O, and suppose that F is affine in its disturbance of the form (3.2). *Let $\Phi : M \to N$ be a C^2 mapping, let $\mathcal{R} = \mathrm{Graph}(\Phi) \subseteq M \times N$, and suppose that the following conditions are met:*

(i) $(x,\omega) \in M \times \Omega \;\Rightarrow\; \tilde{h}(\Phi(x),\omega) = h(x,\omega)$;

(ii) *for every $(z,\omega) \in N \times \Omega$ and for every $x \in \Phi^{-1}(z)$ we have*

$$\{d\Phi_x[f(x,\omega) + G(x)\delta] \mid \delta \in \Delta\} \supseteq \{\widetilde{F}(z,\omega,\varepsilon) \mid \varepsilon \in \mathbb{R}^q\};$$

(iii) *the vector space $\operatorname{Im} d\Phi_x \circ G(x)$ has constant dimension as x varies over M. If $\mathcal{U} \subseteq \mathcal{U}^{\Omega}_{\mathrm{meas}}(f)$ and $\mathcal{E} \subseteq \mathcal{U}^{E}_{\mathrm{meas}}$ are such that $\mathcal{U} \times \mathcal{E} \subseteq \mathcal{U}^{\Omega\times E}_{\mathrm{meas}}(\widetilde{F})$, then Φ lifts trajectories of $(\widetilde{F},\tilde{h},\mathcal{U},\mathcal{E})$ to trajectories of $(F,h,\mathcal{U},L^1_{\mathrm{loc}}(\mathbb{R},\mathbb{R}^p))$ while preserving outputs.*

Proof. As in the proof of the previous theorem, we immediately see that $(x,z) \in \mathcal{R}$ and $\omega \in \Omega \;\Rightarrow\; h(x,\omega) = \tilde{h}(z,\omega)$. Moreover, for $(x,z) \in \mathcal{R} = \mathrm{Graph}(\Phi)$, $\omega \in \Omega$, and $\varepsilon \in E$ we have $x \in \Phi^{-1}(z)$, and assumption (ii) yields $\delta \in \mathbb{R}^p$ such that

$$d\Phi_x[f(x,\omega) + G(x)\delta] = \widetilde{F}(z,\omega,\varepsilon),$$

and this, along with the description of the tangent spaces of $\mathcal{R} = \mathrm{Graph}(\Phi)$ given by (4.3), implies

$$\begin{bmatrix} f(x,\omega) + G(x)\delta \\ \widetilde{F}(z,\omega,\varepsilon) \end{bmatrix} \in T_{(x,z)}\mathcal{R}.$$

Thus we have established the analogue of the simulation condition (SC) in Theorem 3.8 obtained by reversing the roles of F and $\widetilde{F}$. For $(x,z) \in \mathcal{R}$ we also have

$$\begin{aligned}
\mathcal{V}_{(x,z)} = T_{(x,z)}\mathcal{R} + \operatorname{Im}\begin{bmatrix} G(x) \\ 0 \end{bmatrix} &= T_{(x,\Phi(x))}\mathcal{R} + \operatorname{Im}\begin{bmatrix} G(x) \\ 0 \end{bmatrix} \\
&= \left\{ \begin{bmatrix} v + G(x)\delta \\ d\Phi_x(v) \end{bmatrix} \;\middle|\; v \in T_xM,\ \delta \in \mathbb{R}^p \right\} \\
&= \left\{ \begin{bmatrix} I_m & G(x) \\ d\Phi_x & 0 \end{bmatrix} \begin{bmatrix} v \\ \delta \end{bmatrix} \;\middle|\; v \in T_xM,\ \delta \in \mathbb{R}^p \right\}.
\end{aligned}$$

It follows that

$$\begin{aligned}
\dim \mathcal{V}_{(x,z)} &= \operatorname{rank}\begin{bmatrix} I_m & G(x) \\ d\Phi_x & 0 \end{bmatrix} \\
&= \operatorname{rank}\begin{bmatrix} I_m & 0 \\ -d\Phi_x & I_n \end{bmatrix}\begin{bmatrix} I_m & G(x) \\ d\Phi_x & 0 \end{bmatrix} \\
&= \operatorname{rank}\begin{bmatrix} I_m & G(x) \\ 0 & -d\Phi_x G(x) \end{bmatrix},
\end{aligned}$$

where the second equality is due to the fact that we are premultiplying by an invertible matrix. Consequently,

$$\dim \mathcal{V}_{(x,\Phi(x))} = m + \operatorname{rank} d\Phi_x G(\Phi(x)),$$

from which assumption (iii) implies that $\dim \mathcal{V}_{(x,z)}$ is constant as (x,z) varies over $\mathcal{R} = \mathrm{Graph}(\Phi)$. Thus Theorem 3.8.2 implies that $\mathcal{R}$ is a simulation relation of

$(\widetilde{F},\tilde{h},\mathcal{U},\mathcal{E})$ by $(F,h,\mathcal{U},L^1_{\mathrm{loc}}(\mathbb{R},\mathbb{R}^p))$. The theorem is now a direct consequence of Proposition 4.5. □

We conclude by making some remarks concerning finite escape time of trajectories. As pointed out in Remark 2.3, our definition of bisimulation relation (Definition 2.2) is local in time (i.e., holds only on a compact interval containing the initial time 0) because the trajectories of the "simulating system" $\widetilde{F}$ may not be guaranteed to exist for all times for which the corresponding trajectories of the "original system" F are defined. However, it is desirable to identify situations in which the simulating trajectory is guaranteed to exist over any compact interval on which the corresponding trajectory of the original system is defined. Such a situation is addressed by the following definition.

DEFINITION 4.9. *Let $(F,h,\mathcal{U},\mathcal{D})$ and $(\widetilde{F},\tilde{h},\mathcal{U},\mathcal{E})$ be a pair of C^1 IDO systems with admissible inputs and disturbances, and let $\mathcal{R}\subseteq M\times N$ be a simulation relation of $(F,h,\mathcal{U},\mathcal{D})$ by $(\widetilde{F},\tilde{h},\mathcal{U},\mathcal{E})$ as given by Definition* 2.2. *We say that $\mathcal{R}$ is* semiglobal in time *if for every $(x_0,z_0)\in\mathcal{R}$, for every $u\in\mathcal{U}$, for every $d\in\mathcal{D}$, and for every compact interval I containing* 0 *on which the trajectory $t\mapsto\psi(t,x_0,u,d)$ is defined there exists $e\in\mathcal{E}$ such that the trajectory $t\mapsto\tilde{\psi}(t,z_0,u,e)$ is defined for every $t\in I$ and relations* (2.1) *and* (2.2) *hold for every $t\in I$.*

We note in passing that usage the term "semiglobal" instead of "global" is intended to emphasize the fact that we do not require the stronger property that our systems' trajectories be defined for all $t\in\mathbb{R}$. Indeed, the realization of trajectories that are defined for all $t\in\mathbb{R}$ (or all $t\geq 0$) would necessitate further restrictions on the class of systems under consideration and the families of admissible inputs and disturbances (at the very least, local L^1 boundedness would have to be replaced with L^1 boundedness), which we will not pursue here.

As a first step in realizing simulation relations that are semiglobal in time, one could impose the condition of completeness on $\widetilde{F}$. However, it is not obvious that such a condition would, in and of itself, be sufficient to guarantee the desired behavior because additional nonlinearities in the state variables may be introduced by the feedback mapping Υ through which the simulating control e is synthesized. Here we will identify two fairly simple situations in which the simulating trajectory is guaranteed to have the same interval of definition as the original trajectory, but we do not claim that this discussion is a definitive resolution of the matter. Our first result in this direction deals with compact simulation relations.

PROPOSITION 4.10. *Assume that $(F,h,\mathcal{U},\mathcal{D})$ and $(\widetilde{F},\tilde{h},\mathcal{U},\mathcal{E})$ are IDO systems with admissible classes of inputs and disturbances that satisfy the assumptions of Theorem* 3.8 *relative to the C^2 immersed submanifold $\mathcal{R}$ of $M\times N$, assume that condition (SC) holds, and suppose that $\mathcal{E}=L^1_{\mathrm{loc}}(\mathbb{R},\mathbb{R}^q)$. Suppose further that $\mathcal{R}$ is a compact subset of $M\times N$. Then $\mathcal{R}$ is a simulation relation of $(F,h,\mathcal{U},\mathcal{D})$ by $(\widetilde{F},\tilde{h},\mathcal{U},\mathcal{E})$ that is semiglobal in time.*

Proof. Fix $(x_0,z_0)\in\mathcal{R}$, $u\in\mathcal{U}$, $d\in\mathcal{D}$, and let I be any compact subinterval of $\mathbb{R}$ containing 0 on which $\psi(\cdot,x_0,u,d)$ is defined (as before, ψ is the trajectory mapping of F). The proof of Theorem 3.8.2 shows that $\mathcal{F}:\mathcal{R}\times\Omega\times\Delta\to T(M\times N)$ defined by (3.27) is tangent to the submanifold $\mathcal{R}$ and thus defines a C^1 control system on $\mathcal{R}$ with control space $\Omega\times\Delta$. Since $\mathcal{R}$ is compact, standard continuation results in the theory of ordinary differential equations guarantee that the trajectory $t\mapsto\Psi(t,(x_0,z_0),u,d)$ of $\mathcal{F}$ with initial condition (x_0,z_0) corresponding to the input u and disturbance d is defined for all $t\in I$ and takes values in $\mathcal{R}$. As pointed out in the proof of Theorem 3.8, if $\tilde{\psi}$ is the trajectory mapping of $\widetilde{F}$, then $\psi(\cdot,x_0,u,d)$ is the

first component of $\Psi(\cdot,(x_0,z_0),u,d)$ and $\tilde{\psi}(\cdot,z_0,u,e)$ is the second component, where e is defined by (3.28). A routine check of the assumptions in force shows that e is in fact a member of $L^1_{\mathrm{loc}}(\mathbb{R},\mathbb{R}^q)$, so the conclusion follows directly from Theorem 3.8.2. □

To obtain sufficient conditions for noncompact simulation relations that are global or semiglobal in time, one must impose rather special conditions on the systems under consideration. We will be content to present one illustrative result in this direction.

PROPOSITION 4.11. *Suppose that the system state spaces and the input space are Euclidean (i.e., $M=\mathbb{R}^m$, $N=\mathbb{R}^n$, and $\Omega=\mathbb{R}^r$), and let*

$$F:\mathbb{R}^m\times\mathbb{R}^r\times\Delta\to\mathbb{R}^m,\quad h:\mathbb{R}^m\times\mathbb{R}^r\to O$$

and

$$\widetilde{F}:\mathbb{R}^n\times\mathbb{R}^r\times\mathbb{R}^q\to\mathbb{R}^n,\quad \tilde{h}:\mathbb{R}^n\times\mathbb{R}^r\to O$$

be two C^1 IDO systems that have common input space $\mathbb{R}^r$, common output space O, and suppose that $\widetilde{F}$ is linear; that is,

$$(z,\omega,\varepsilon)\in\mathbb{R}^n\times\mathbb{R}^r\times\mathbb{R}^q\ \Rightarrow\ \widetilde{F}(z,\omega,\varepsilon)=\widetilde{A}z+\widetilde{B}\omega+\widetilde{G}\varepsilon$$

for constant matrices $\widetilde{A}$, $\widetilde{B}$, and $\widetilde{G}$ of the appropriate dimensions. Let $\mathcal{R}$ be a vector subspace of $M\times N=\mathbb{R}^m\times\mathbb{R}^n$ for which the following modified simulation condition holds:

(SC′) For every $(x,z)\in\mathcal{R}$ and $\omega\in\mathbb{R}^r$ we have $h(x,\omega)=\tilde{h}(z,\omega)$. Furthermore, for every $(x,z)\in\mathcal{R}$, $\omega\in\mathbb{R}^r$, and $\delta\in\Delta$, there exists $\varepsilon\in\mathbb{R}^q$ such that

$$\begin{bmatrix}F(x,\omega,\delta)\\ \widetilde{A}z+\widetilde{B}\omega+\widetilde{G}\varepsilon\end{bmatrix}\in\mathcal{R}.$$

Further suppose that $\mathcal{U}\subseteq L^1_{\mathrm{loc}}(\mathbb{R},\mathbb{R}^r)$, $\mathcal{D}\subseteq\mathcal{U}^{\Delta}_{\mathrm{meas}}$ are such that $\mathcal{U}\times\mathcal{D}\subseteq\mathcal{U}^{\mathbb{R}^r\times\Delta}_{\mathrm{meas}}(F)$. Then $\mathcal{R}$ is a simulation relation of $(F,h,\mathcal{U},\mathcal{D})$ by $(\widetilde{F},\tilde{h},\mathcal{U},L^1_{\mathrm{loc}}(\mathbb{R},\mathbb{R}^q))$ that is semiglobal in time.

Proof. We first observe that assumption (i) of Proposition 3.6 is trivially satisfied in this case because the vector space

$$\mathcal{V}_{(x,z)}=\mathcal{R}+\operatorname{Im}\begin{bmatrix}0\\ \widetilde{G}\end{bmatrix}$$

is now constant as (x,z) varies over $\mathcal{R}$ (itself a vector space). Letting σ be the codimension of the vector subspace $\mathcal{R}$ in $\mathbb{R}^m\times\mathbb{R}^n$ and letting N be any $\sigma\times(m+n)$ matrix whose rows span the orthogonal complement of $\mathcal{R}$, we see that the matrix functions Λ, $\widetilde{\Lambda}$, and Θ of Proposition 3.6 can be taken to be constant. Thus the mapping Υ given by Proposition 3.6 will have the form (see (3.20) and (3.17))

$$\Upsilon(x,z,\omega,\delta)=\Theta\big[-\Lambda F(x,\omega,\delta)-\widetilde{\Lambda}(\widetilde{A}z+\widetilde{B}\omega)\big].$$

The proof of Proposition 3.6 shows that the control system

$$\mathcal{F}:\mathcal{R}\times\mathbb{R}^r\times\Delta\to\mathbb{R}^m\times\mathbb{R}^n \tag{4.4}$$

given by

$$\mathcal{F}((x,z),\omega,\delta) = \begin{bmatrix} F(x,\omega,\delta) \\ (I_n - \widetilde{G}\Theta\widetilde{\Lambda})(\widetilde{A}z + \widetilde{B}\omega) - \widetilde{G}\Theta\Lambda F(x,\omega,\delta) \end{bmatrix} \tag{4.5}$$

is actually tangent to the subspace $\mathcal{R}$ (i.e., takes values in $\mathcal{R}$), and $\mathcal{R}$ is closed as a subset of $\mathbb{R}^m \times \mathbb{R}^n$, so the trajectories of $\mathcal{F}$ will stay in $\mathcal{R}$ if they are initialized in $\mathcal{R}$. Fix $(x_0, z_0) \in \mathcal{R}$, $u \in \mathcal{U}$, $d \in \mathcal{D}$, and let I be any compact subinterval of $\mathbb{R}$ containing 0 on which $\psi(\cdot, x_0, u, d)$ is defined (as before, ψ is the trajectory mapping of F). Write $\psi(t) = \psi(t, x_0, u, d)$ to lighten the notation and consider the linear, time-varying ordinary differential equation on $\mathbb{R}^n$ given by

$$\dot{z} = (I_n - \widetilde{G}\Theta\widetilde{\Lambda})(\widetilde{A}z + \widetilde{B}u(t)) - \widetilde{G}\Theta\Lambda F(\psi(t), u(t), d(t)). \tag{4.6}$$

Because u is locally integrable on $\mathbb{R}$ and, by our definitions, $t \mapsto F(\psi(t), u(t), d(t))$ is integrable on I, the linearity of (4.6) guarantees that its unique solution, call it $t \mapsto \eta(t)$, for the initial condition $\eta(0) = z_0$ is defined for all $t \in I$. Furthermore, it is clear that the mapping $t \mapsto (\psi(t), \eta(t))$ is a trajectory of the control system $\mathcal{F}$ defined by (4.5) with initial condition (x_0, z_0) corresponding to the input u and the disturbance d. Since $(x_0, z_0) \in \mathcal{R}$ and $\mathcal{F}$ is tangent to $\mathcal{R}$, we infer that

$$t \in I \quad \Rightarrow \quad (\psi(t), \eta(t)) \in \mathcal{R}. \tag{4.7}$$

If we define $e : \mathbb{R} \to \mathbb{R}^q$ by

$$e(t) = \begin{cases} -\Theta\widetilde{\Lambda}\widetilde{A}\eta(t) - \Theta\widetilde{\Lambda}\widetilde{B}u(t) - \Theta\Lambda F(\psi(t), u(t), d(t)) & \text{if } t \in I, \\ 0 & \text{otherwise,} \end{cases}$$

then e is integrable on $\mathbb{R}$ (because it is integrable on I) and we have

$$\dot{\eta}(t) = \widetilde{A}\eta(t) + \widetilde{B}u(t) + \widetilde{G}e(t) \quad \text{for a.e. } t \in I.$$

Consequently we see that $\eta(t) = \tilde{\psi}(t, z_0, u, e)$ for $t \in I$, where $\tilde{\psi}$ is the trajectory mapping of $\widetilde{F}$. When combined with (4.7) and the fact that $\psi(t) = \psi(t, x_0, u, d)$, this immediately yields (2.1). Relation (2.2) now follows from this and the assumption that $h(x, \omega) = \tilde{h}(z, \omega)$ for every $(x, z) \in \mathcal{R}$ and $\omega \in \mathbb{R}^r$, so the proof is complete. ∎

RELATIVELY OPTIMAL CONTROL: A STATIC PIECEWISE-AFFINE SOLUTION*

FRANCO BLANCHINI† AND FELICE ANDREA PELLEGRINO‡

Abstract. A relatively optimal control is a stabilizing controller that, without initialization nor feedforwarding and tracking the optimal trajectory, produces the optimal (constrained) behavior for the nominal initial condition of the plant. In a previous work, for discrete-time linear systems, we presented a linear *dynamic* relatively optimal control. Here we provide a *static* solution, namely a deadbeat piecewise-affine state-feedback controller based on a suitable partition of the state space into polyhedral sets. The vertices of the polyhedra are the states of the optimal trajectory; hence a bound for the complexity of the controller is known in advance. We also show how to obtain a controller that is not deadbeat by removing the zero terminal constraint while guaranteeing stability. Finally, we compare the proposed static compensator with the dynamic one.

Key words. optimal control, linear systems, discrete-time systems, invariance

1. Introduction.

It is known that, unless for very special cases, determining an optimal control in a feedback form under output or input constraints is a computationally hard task. The problem can be addressed in a receding horizon fashion, but in this case an optimization problem must be solved online at each time interval. Explicit (piecewise-affine) solutions exist [1, 2] but are limited to quadratic or 1-norm cost and linear constraints. However, for those systems that are explicitly built to perform specific operation through a specific trajectory with known initial and final states, the request for optimality from *any* initial state can be relaxed, requiring optimality only from a *specific* initial condition. The relatively optimal control (ROC) [5] is defined as *a stabilizing controller that guarantees optimality of the trajectory and constraint satisfaction from a given (or a set of given) initial condition(s) without the involvement of any feedforward action.* In [5] it has been proved that a controller enjoying these properties is linear dynamic and its order is equal to the length of the optimal trajectory minus the order of the plant. In [6] the zero terminal constraint was removed in order to assign a characteristic polynomial to the closed-loop system, and the problem of output feedback was addressed. Here, a *static* ROC is constructed by partitioning the state space into polyhedral sets whose vertices are the states of the optimal trajectory and their opposite.

The main contribution of the paper can be summarized in the following points.

- It is shown that for discrete-time linear systems with convex constraints and cost, it is always possible to construct a static ROC by means of a proper partition of the state space into polyhedral sets (a procedure to construct it is provided).

- If the constraints and/or the cost are not convex, a sufficient condition on the optimal trajectory that guarantees that the static ROC can be constructed is provided.
- The proposed controller is a deadbeat piecewise-affine state-feedback controller. The vertices of each of the polyhedral sets are the states of the optimal trajectory and their opposite. The control at each vertex is the corresponding control of the optimal sequence, while the control at a generic state is given by a convex combination of the controls corresponding to the vertices of the polyhedron to which the state belongs.
- An upper bound on the number of polyhedral sets as a function of the order of the system and the length of the optimal trajectory is provided.
- By removing the zero state terminal constraint and requiring the final state of the optimal trajectory to belong to a controlled invariant set, it is possible to obtain a nondeadbeat controller.
- The proposed static controller is compared with the dynamic one previously introduced.

2. Problem statement. We give the discrete-time reachable system

$$\begin{aligned} x(k+1) &= Ax(k) + Bu(k), \\ y(k) &= Cx(k) + Du(k), \end{aligned} \tag{1}$$

where $x(k) \in \mathbb{R}^n$, $u(k) \in \mathbb{R}^m$, $y(k) \in \mathbb{R}^q$ and A, B, C, D are matrices of appropriate dimensions. For this system we consider the locally bounded convex cost functions of the output

$$g(y), \quad l_i(y), \quad i = 1, 2, \ldots, s \tag{2}$$

(we assume they are 0-symmetric, i.e., $g(y) = g(-y)$ and $l_i(y) = l_i(-y)$) with assigned initial condition

$$\bar{x} \neq 0 \tag{3}$$

and the constraint

$$y(k) \in \mathcal{Y}, \tag{4}$$

where $\mathcal{Y}$ is a convex, closed, and 0-symmetric set. Then we consider the following problem (consistently with [5] and with no loss of generality, we assume $k = 1$ is initial time):

$$J_{opt}(\bar{x}) = \min \sum_{k=1}^{N} g(y(k)) \tag{5}$$

subject to

$$x(k+1) = Ax(k) + Bu(k), \ k = 1, \ldots, N, \tag{6}$$

$$y(k) = Cx(k) + Du(k), \ k = 1, \ldots, N, \tag{7}$$

$$\sum_{k=1}^{N} l_i(y(k)) \leq \mu_i, \quad i = 1, 2, \ldots, s, \tag{8}$$

$$y(k) \in \mathcal{Y}, \quad k = 1, \ldots, N, \tag{9}$$

$$x(1) = \bar{x}, \tag{10}$$

$$x(N+1) = 0, \tag{11}$$

$$N \geq 1 \quad \text{assigned (or free).} \tag{12}$$

In the extremely general formulation of the problem we have considered the option of N free, in order to also consider the special case of minimum-time control. The choice of N depends on the circumstances and has to guarantee the feasibility of the above open-loop optimal control problem. Note that the cost and the constraint achieved, assuming g and l_i only depending on y, are quite general since we can include cost and pointwise or integral constraints depending on both x and u by suitable choices of C and D. Finding an open-loop solution for the above problem is well known as a convex problem [10] which can be solved by means of standard convex programming algorithms. Here we are interested in a feedback static solution; more precisely the problem we consider is the following.

PROBLEM 1. *Find a static state-feedback compensator of the form $u = \Phi(x)$ which is stabilizing and such that for $x(1) = \bar{x}$ the control and state trajectories are the optimal ones.*

Any solution of the above problem will be referred to as a *static relatively optimal controller*. We stress that in the ROC framework, the constraints (8) and (9) represent *design specification "soft" constraints*. Hence their violation implies a performance loss only and is allowed for nonnominal initial conditions. In the following we will construct a solution to Problem 1 in two steps: First, a relatively optimal controller that is only locally stabilizing (being defined in a convex subset of the state space, containing the origin) will be constructed. We will refer to this controller as the *local relatively optimal controller*. Then the local controller will be extended to the whole state space, obtaining a *global relatively optimal controller*.

Remark 2.1. Any initial state $\bar{x}$ for which the problem is feasible (hence the constraints can be satisfied) is suitable as a nominal initial condition; there are no further restrictions.

3. Main results. We now assume that the optimal trajectory starting from the assigned initial condition $\bar{x}$ does exist and has been computed (offline). We consider the following assumption.

ASSUMPTION 1. *The optimal trajectory is such that the residual cost is strictly decreasing, i.e.,*

$$\sum_{k=h}^{N} g(y(k)) < \sum_{k=h+1}^{N} g(y(k)) \quad \forall h = 1, \ldots, N-1.$$

Assumption 1 is absolutely reasonable and avoids trivialities (it is obviously true, for instance, if g is positive definite with respect to y). The way we solve Problem 1 can be explained as follows: Based on points of the optimal trajectory and their opposite (connected by the solid line in Figure 1), we partition the state space into disjoint regions. The convex hull of the points of the optimal trajectory and their opposite (the shaded hexagon in Figure 1) represents a region that can be divided into simplices, in each of which the control is affine. This region includes the nominal initial state $\bar{x}$ (possibly in its interior). The external part is divided into cones, centered in the origin, and "truncated to keep the outer part," in each of which the controller is linear. The control is Lipschitz continuous. To formally state the main result we need to introduce some notations. The inequality $p \leq 0$, if p is a vector, has to be interpreted componentwise. Let us denote by $\bar{1}$ the vector (the dimension depending on the context) having all components equal to 1:

$$\bar{1} = [\ 1 \ \ 1 \ \ \ldots \ \ 1\ ]^T \tag{13}$$

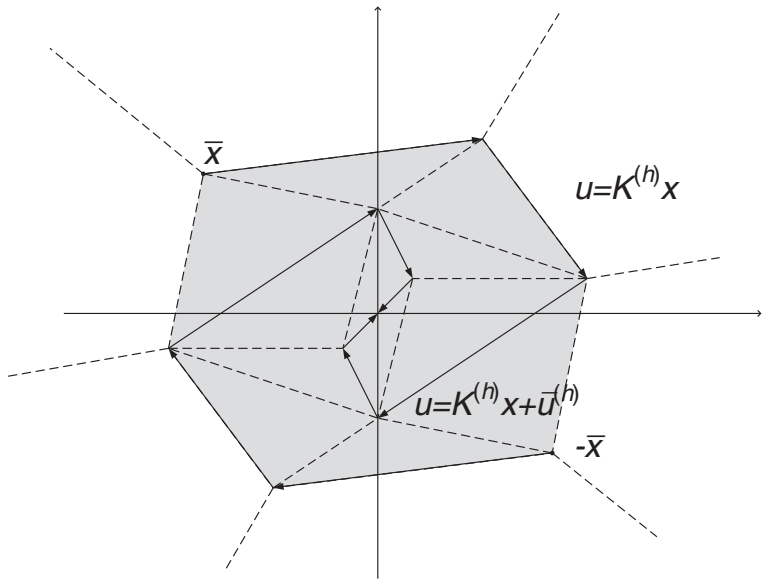

FIG. 1. *The state space partition.*

(note that the expression $\bar{1}^T p$ is the sum of the components of vector p). Given an $n \times (n+1)$ full row rank matrix X, a *simplex* in $\mathbb{R}^n$ is a set of the form

$$\mathcal{S}(X) = \{x = Xp : \quad p \geq 0, \quad \bar{1}^T p = 1\}. \tag{14}$$

Given an $n \times n$ full rank matrix X, a *simplicial cone* in $\mathbb{R}^n$ is a set of the form

$$\mathcal{C}(X) = \{x = Xp : \quad p \geq 0\}. \tag{15}$$

Note that a simplicial cone is always generated by a simplex having the origin among its corners. Together with these standard notations we need to consider the complement (the outer part) of the unit sector in a simplicial cone, which is the closure of the complement in $\mathcal{C}$,

$$\tilde{\mathcal{C}}(X) = \{x = Xp : \quad p \geq 0, \quad \bar{1}^T p \geq 1\}. \tag{16}$$

If $\Phi : \mathbb{R}^n \to \mathbb{R}$ is a function and X is an $n \times m$ matrix, we denote by $\Phi(X)$ the following vector:

$$\Phi(X) = [\ \Phi(x_1) \quad \Phi(x_2) \quad \dots \quad \Phi(x_m)\ ]^T. \tag{17}$$

The next theorem states that there exists a control which is optimal for $x(1) = \bar{x}$ and locally stabilizing.

THEOREM 3.1. *There exists a convex and compact polyhedron $\mathcal{P}$, including the origin in its interior, which is partitioned into simplices $\mathcal{S}^{(h)}$, each generated by an $n \times (n+1)$ matrix $X^{(h)}$ whose columns are vectors properly chosen from among the states of the optimal trajectory and their opposite:*

$$\mathcal{P} = \bigcup \mathcal{S}^{(h)} = \bigcup \mathcal{S}(X^{(h)}) \tag{18}$$

such that each pair of simplices has an intersection with an empty interior,

$$\text{int}\{\mathcal{S}^{(h)} \bigcap \mathcal{S}^{(k)}\} = \emptyset, \quad h \neq k, \tag{19}$$

and such that $\bar{x} \in \mathcal{P}$. *To each simplex* $\mathcal{S}^{(h)}$ *we can associate an* $m \times (n+1)$ *matrix* $U^{(h)}$ *whose columns are vectors properly chosen from among the inputs of the optimal trajectory and their opposite. The piecewise-affine static controller*

$$u = \Phi_{\mathcal{P}}(x) = K^{(h)}x + \bar{u}^{(h)} = U^{(h)} \begin{bmatrix} X^{(h)} \\ \bar{1}^T \end{bmatrix}^{-1} \begin{bmatrix} x \\ 1 \end{bmatrix} \quad \textit{for} \;\; x \in \mathcal{S}^{(h)} \tag{20}$$

is Lipschitz continuous and relatively optimal inside $\mathcal{P}$*; more precisely it is stabilizing with a domain of attraction* $\mathcal{P}$ *and for* $x(1) = \bar{x}$ *produces the optimal trajectory. Moreover, for each* $x(1) \in \mathcal{P}$, *the constraints are satisfied and the transient cost is bounded as*

$$J(x(1)) \leq \max_{i=1,\ldots,n+1} J_{opt}(x_{k_i}), \tag{21}$$

where $x_{k_1}, \; x_{k_2}, \ldots, x_{k_{n+1}}$ *are the vertices of the simplex* $\mathcal{S} \ni x(1)$ *and* $J_{opt}(x_{k_i})$ *is the optimal cost associated with the initial condition* x_{k_i}.

The next theorem states that the same control can be globally extended over $\mathbb{R}^n$.

THEOREM 3.2. *The control* (20) *can be extended onto* $\mathbb{R}^n$ *as follows. The complement of the polytope* $\mathcal{P}$ *can be partitioned into complements of simplices inside a cone*

$$\tilde{\mathcal{C}}^{(h)} = \tilde{\mathcal{C}}(X^{(h)}), \tag{22}$$

each generated by a square invertible matrix $X^{(h)}$, *having intersection with empty interior*

$$\text{int}\{\tilde{\mathcal{C}}^{(h)} \bigcap \tilde{\mathcal{C}}^{(k)}\} = \emptyset, \quad h \neq k, \tag{23}$$

and intersection with empty interior with $\mathcal{P}$,

$$\text{int}\{\tilde{\mathcal{C}}^{(h)} \bigcap \mathcal{P}\} = \emptyset, \tag{24}$$

such that

$$\mathcal{P} \bigcup \left[\bigcup_h \tilde{\mathcal{C}}^{(h)} \right] = \mathbb{R}^n. \tag{25}$$

To each set $\tilde{\mathcal{C}}^{(h)}$ *can be associated an* $m \times n$ *matrix* $U^{(h)}$ *whose columns are vectors properly chosen from among the inputs of the optimal trajectory, obtaining a control*

$$u = \Phi(x) = K^{(h)}x = U^{(h)} \left[X^{(h)} \right]^{-1} x \; . \tag{26}$$

The extended control obtained in this way is globally Lipschitz continuous and relatively optimal.

Theorems 3.1 and 3.2 will be proved constructively in sections 4 and 5, respectively.

4. Construction of a local relatively optimal control. Denote by

$$\bar{x}(1), \dots, \bar{x}(N)$$

the optimal state trajectory from the initial condition $\bar{x} = \bar{x}(1)$, obtained by solving (5)–(12). We introduce the notation (basically inverting time)

$$x_1 = \bar{x}(N), \quad x_2 = \bar{x}(N-1), \dots, \quad x_N = \bar{x}(1), \tag{27}$$

and

$$u_1 = \bar{u}(N), \quad u_2 = \bar{u}(N-1), \dots, \quad u_N = \bar{u}(1), \tag{28}$$

and we coherently assume $x_0 = 0$; hence we have that $x_{i-1} = Ax_i + Bu_i$, $i = 1, \dots, N$. We also denote by x_{-i}, $i = 1, \dots, N$, the opposite of x_i. Then we introduce the following assumption, which simplifies considerably the proof of Theorem 3.1 but is not essential (in fact it can be easily removed as we will show later on).

ASSUMPTION 2. *The matrix $X_n = [x_1\ x_2\ \dots\ x_n]$, formed by the last n states of the optimal trajectory, is invertible.*

Let us consider the polyhedral set

$$\mathcal{P}_n = \{x = X_n p : \|p\|_1 \le 1\}. \tag{29}$$

Such a set is the convex hull of the last n states of the optimal trajectory and their opposite. It contains the origin in its interior and is 0-symmetric. An example for $n = 2$ is shown in Figure 2: $\mathcal{P}_n$ (the darkest area) is the convex hull of the last two states of the optimal trajectory (connected by the solid line) and their opposite (connected by the dashed line). Thanks to Assumption 2 the following lemma holds.

LEMMA 4.1. *The linear control*

$$u(x) = U_n X_n^{-1} x, \tag{30}$$

where $U_n = [u_1\ u_2\ \dots\ u_n]$, renders positively invariant the set $\mathcal{P}_n$ satisfying the constraints for all initial conditions inside the set. In particular, it is deadbeat and steers the state to zero in at most n steps.

Proof. The control law $u(x) = U_n X_n^{-1} x$ is a control-at-the-vertices strategy. All $x \in \mathcal{P}_n$ can be written in a unique way as a linear combination of the columns of X_n, namely, the last n states of the optimal trajectory:

$$x = X_n p. \tag{31}$$

Since X_n is invertible, it follows that

$$p(x) = X_n^{-1} x; \tag{32}$$

hence the control law $u(x) = U_n X_n^{-1} x$ basically computes a control which is a linear combination of the controls at the vertices of $\mathcal{P}_n$ according to the coefficients $p(x)$. Positive invariance is a consequence of the fact that, by construction, the control at each vertex keeps the state inside the set [4]. The satisfaction of the constraints is guaranteed for all initial conditions inside the set because the input and state constraints are convex and 0-symmetric. To prove that the control is deadbeat, note that if at time k we have

$$x(k) = x_n p_n + \dots + x_2 p_2 + x_1 p_1, \tag{33}$$

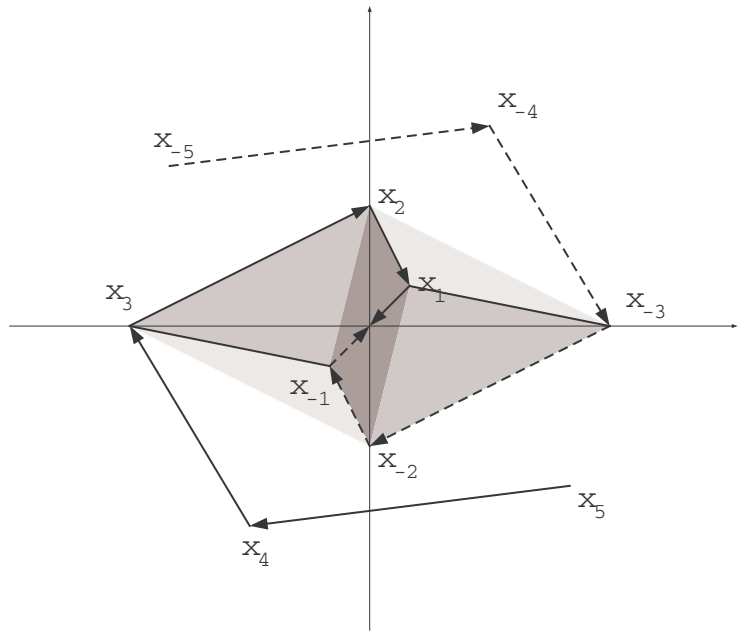

FIG. 2. *Considering x_3 and its opposite x_{-3}, we can construct four simplices starting from $\mathcal{P}_2$ (the darkest area).*

then the computed control will be

$$u(k) = u_n p_n + \cdots + u_2 p_2 + u_1 p_1. \tag{34}$$

Since $x_{i-1} = Ax_i + Bu_i$, we obtain, by linearity,

$$x(k+1) = x_{n-1} p_n + \cdots + x_1 p_2 + 0 p_1, \tag{35}$$

and at the next step we will have, reasoning in the same way,

$$x(k+2) = x_{n-2} p_n + \cdots + x_1 p_3 + 0 p_2 + 0 p_1, \tag{36}$$

and so on; therefore, we immediately verify that after at most n steps the system will reach the origin. □

Remark 4.1. The control law defined above is such that inside $\mathcal{P}_n$, at each step, the state is a convex combination of points with decreasing index and 0.

Note that if the system reaches the state $x_n = \bar{x}(N - n + 1) \in \mathcal{P}_n$, it starts following the last n steps of the optimal trajectory. Note also that $\mathcal{P}_n$ (which will be the first element of a sequence of sets) is affine to a diamond and thus can be partitioned into simplices. The next sets of the sequence are computed as follows.

Consider the state x_{n+1} (corresponding to the state x_3 in the example of Figure 2). Since x_{n+1} and its opposite $x_{-(n+1)}$ are outside $\mathcal{P}_n$ (as will be shown later), they can be connected with a certain number of vertices of $\mathcal{P}_n$ without crossing such a set; thus simplices are formed by some vertices of $\mathcal{P}_n$ and the two points x_{n+1} and $x_{-(n+1)}$ (in the example of Figure 2, such simplices are the triangles (x_3, x_2, x_{-1})

and (x_3, x_{-1}, x_{-2}) and their symmetric). Denoting by $\mathcal{S}^j_{n+1}$, $j = 1, \ldots, m_{n+1}$, the simplices having x_{n+1} as a vertex and by $\mathcal{S}^j_{n+1}$, $j = -m_{n+1}, \ldots, -1$, those having $x_{-(n+1)}$ as a vertex, we can define the set $\mathcal{P}_{n+1}$ as follows:

$$\mathcal{P}_{n+1} = \bigcup_{j=\pm 1,\ldots,\pm m_{n+1}} \mathcal{S}^j_{n+1} \cup \mathcal{P}_n. \tag{37}$$

The procedure goes on exactly in the same manner to generate the sequence of sets $\mathcal{P}_k$, $k = n+1, n+2, \ldots, N$, ordered by inclusion and the corresponding simplicial partition: If we define the set

$$\mathcal{P}_k = \operatorname{conv}\{x_1, x_2, \ldots, x_k, x_{-1}, x_{-2}, \ldots, x_{-k}\}, \quad k < N, \tag{38}$$

we can consider the vector x_{k+1} and form a new simplicial partition for $\mathcal{P}_{k+1}$ by adding new simplices. It is fundamental to note that each new simplicial partition of $\mathcal{P}_{k+1}$ preserves all the simplices forming the simplicial partition for $\mathcal{P}_k$. To prove that the construction is well defined we need the following lemma.

LEMMA 4.2. *The vector x_{k+1} in the construction is outside $\mathcal{P}_k$.*

Proof. Assume by contradiction that $x_{k+1} \in \mathcal{P}_k$. Then x_{k+1} could be written as a convex combination of the vertices of $\mathcal{P}_k$. So if we take x_{k+1} as an initial state, since we considered convex constraints, then x_{k+1} could be driven to zero in a time not exceeding k at a cost not exceeding the maximum cost of all vertices of $\mathcal{P}_k$. This is in contradiction with Assumption 1. □

Therefore the procedure is such that $\{\mathcal{P}_k\}$ is a strictly increasing (in the sense of inclusion) sequence of sets, each of which preserves the simplicial partition of the former. This construction terminates once $\mathcal{P} \doteq \mathcal{P}_N$ is constructed.

Note that the innermost set $\mathcal{P}_n$ can be partitioned into simplices $\mathcal{S}^j_n$, each having the origin as a vertex. The remaining n vertices are any independent subset of $x_{\pm k}$, $k = 1, \ldots, n$, namely, the last n steps of the optimal trajectory and their opposite. It is easy to recognize that in this case the control law (30) takes the form (20), i.e.,

$$u = \Phi(x) = K^j_n x = U^j_n \left[X^j_n\right]^{-1} x\ , \tag{39}$$

where j denotes the simplex, while X^j_n and U^j_n are matrices whose columns are a subset of the states of the optimal trajectory (and their opposite) and the corresponding optimal control values (and their opposite).

The next step is to show how to associate a control with each simplex. With each of the simplices $\mathcal{S}^j_k$,

1. associate a matrix X^j_k whose columns are the vertices (in arbitrary order).
2. associate a matrix U^j_k whose columns are the controls corresponding to the vertices (in the same order as they appear in X^j_k). If the vertex belongs to the optimal trajectory, take the corresponding control; if it belongs to the opposite of the optimal trajectory, take the opposite of the corresponding control.

Now, the control strategy is as follows: Given $x \in \mathcal{P}$, if $x \in \mathcal{S}^j_k$, then

$$\Phi_{\mathcal{P}}(x) = U^j_k p, \tag{40}$$

where $p \geq 0$ is the (unique) vector such that

$$x = X^j_k\ p, \quad \bar{1}^T p = 1. \tag{41}$$

Note that p is such that

$$\begin{bmatrix} X_k^j \\ \bar{1}^T \end{bmatrix} p = \begin{bmatrix} x \\ 1 \end{bmatrix}, \tag{42}$$

so that u is of the form (20).

Remark 4.2. Given a simplex $\mathcal{S}_k^j$, the vector p of (42) is the vector of the barycentric (normalized) coordinates of x with respect to the vertices of the simplex (the columns of X_k^j). Barycentric coordinates, as well as simplicial partitions, are well known in the context of finite element analysis [7].

To show the properties of the control we need to introduce the index $\mathrm{In}(\mathcal{S})$ of a sector $\mathcal{S}$ as the maximum of the absolute values of the indices of its generating vectors. Formally, if $\mathcal{S}$ is generated by corners $x_{k_1}, x_{k_2}, \ldots, x_{k_n}$, then

$$\mathrm{In}(\mathcal{S}) = \max\{|k_1|, |k_2|, \ldots, |k_n|\}. \tag{43}$$

For reasons that will be clear soon, $\mathrm{In}(\mathcal{S})$ will be referred to as the *distance* of $\mathcal{S}$ from 0.

Remark 4.3. The notion of "sector" deserves some comment. Indeed, we now consider possibly degenerate simplices that can have an empty interior formed by some points x_k and with the origin repeatedly considered. For instance, $\mathcal{S}$ could be generated by $[0\ 0\ x_1\ x_2]$, representing a two-dimensional degenerate simplex in the three-dimensional space. Note also that $\mathrm{In}(\mathcal{S}) \leq k$ for all sectors inside $\mathcal{P}_k$.

The next lemma shows that, with the proposed control, if the system state is inside a sector, then it jumps to another one closer to zero.

LEMMA 4.3. *The proposed strategy is such that if $x \in \mathcal{S}$, a sector of $\mathcal{P}_k$, then $Ax + Bu(x) \in \mathcal{S}'$ with*

$$In(\mathcal{S}') < In(\mathcal{S}), \tag{44}$$

as long as $In(\mathcal{S}) \neq 0$, and therefore if $x(1) \in \mathcal{P}_k$, the control steers the system to zero in at most k steps.

Proof. As a first step we note that, according to Lemma 4.1 and Remark 4.1, the jump to sector closer to 0 occurs for all $x \in \mathcal{P}_n$. Now we proceed by induction. Assume that $x \in \mathcal{P}_{n+1}$. If $x \in \mathcal{P}_n$, there is nothing to prove; otherwise x is necessarily in a sector $\mathcal{S}$ generated by x_{n+1} or its opposite $x_{-(n+1)}$ and other vertices of smaller indices

$$x = \sum_{i=1}^{n+1} x_{k_i} p_i, \quad \sum_{i=1}^{n+1} p_i = 1, \quad p_i \geq 0, \tag{45}$$

with $|k_i| \leq n$, $i = 1, 2, \ldots, n$, and $|k_{n+1}| = n + 1$. Then we have, by construction,

$$Ax + B\Phi_{\mathcal{P}}(x) = A\left[\sum_{i=1}^{n+1} x_{k_i} p_i\right] + B\left[\sum_{i=1}^{n+1} u_{k_i} p_i\right] = \sum_{i=1}^{n+1} p_i \underbrace{[Ax_{k_i} + Bu_{k_i}]}_{\in \mathcal{P}_n} \in \mathcal{P}_n. \tag{46}$$

Therefore, necessarily $Ax + B\Phi_{\mathcal{P}}(x)$ is in a sector with index $\mathrm{In} \leq n$. The rest of the proof proceeds in the same way. Any point x in $\mathcal{P}_{k+1}$, if not in $\mathcal{P}_k$, is included in a sector $\mathcal{S}$ with index $\mathrm{In}(\mathcal{S}) = k + 1$ and, by means of the same machinery, we can show that $Ax + B\Phi_{\mathcal{P}}(x) \in \mathcal{S}'$ with $\mathrm{In}(\mathcal{S}') \leq k$. The fact that if $x(1) \in \mathcal{P}_k$, the state converges to 0 in at most k steps is an immediate consequence. ∎

The procedure for partitioning the state space and constructing the region $\mathcal{P}_N \supset \mathcal{P}_n$ and the associated local controller can be summarized as follows.

PROCEDURE 4.1. *We give the system* (1) *and the optimal open-loop trajectory, computed by solving* (5)–(12)*, which satisfies Assumption* 2.

1. *Let the set* $\mathcal{P}_n = \{x : x = X_n p, \|p\|_1 \leq 1\}$*, where* $X_n = [x_1\ x_2\ \dots\ x_n]$*, be the convex hull of the last* n *states of the optimal trajectory and their opposite.*
2. *Let* $U_n = [u_1\ u_2\ \dots\ u_n]$ *be the matrix whose columns are the control vectors corresponding to the last* n *states of the optimal trajectory.*
3. *Take* $i = n + 1$.
4. *Construct the simplices* $\mathcal{S}_i^j,\ j = \pm 1, \dots, \pm m_i$*, by connecting* x_i *and* x_{-i} *to the vertices of* $\mathcal{P}_{i-1}$ *without crossing such a set. This is always possible since* $x_i, x_{-i} \notin \mathcal{P}_{i-1}$.
5. *Let* X_i^j *be the matrix whose columns are the vertices of* $\mathcal{S}_i^j$ *in an arbitrary order and* U_i^j *be the controls corresponding to the vertices in the same order. For vertices belonging to the opposite of the optimal trajectory, take the opposite of the control.*
6. *Let* $\mathcal{P}_i = \bigcup_j \mathcal{S}_i^j \cup \mathcal{P}_{i-1}$.
7. *Increase* i.
8. *If* $i \leq N$*, go back to step* 4.

Note that, by construction, the sets $\mathcal{P}_i$, $i = n, \dots, N$, are convex, 0-symmetric, and such that $\mathcal{P}_i \subset \mathcal{P}_{i+1}$. The set $\mathcal{P}_{i+1} \setminus \mathcal{P}_i$, the difference between $\mathcal{P}_{i+1}$ and $\mathcal{P}_i$, is composed of simplices S_i^j, each of which has all vertices but one (precisely x_{i+1} or $x_{-(i+1)}$) belonging to $\mathcal{P}_i$.

In order to prove Theorem 3.1 we must provide the following lemmas.

LEMMA 4.4. *The proposed control* $\Phi_{\mathcal{P}}(x)$ *is Lipschitz continuous inside* $\mathcal{P} = \mathcal{P}_N$.

Proof. Since the cardinality of the partition is finite, it is sufficient to prove continuity. Inside each of the simplices, the control action (40) is a linear combination of the control at each vertex, with the weights being the components of p. Now, the proof follows immediately from a well-known result of finite element analysis, namely, the fact that using barycentric coordinates as weights in a triangular (or, in general, simplicial) mesh guarantees interelement continuity [7]. ∎

LEMMA 4.5. *For any state* $x(1) = x \in \mathcal{S} \subset \mathcal{P}_N$ *the proposed control* $\Phi_{\mathcal{P}}(x)$ *satisfies the constraints and it ensures a cost* $J(x)$ *bounded as*

$$J(x) \leq \max_{i=1,\dots,n+1} J_{opt}(x_{k_i}), \tag{47}$$

where $\mathcal{S}$ *is generated by the points* $x_{k_1},\ x_{k_2}, \dots, x_{k_{n+1}}$.

Proof. The constraints are convex and 0-symmetric and, by construction, they are satisfied by each of the vertices of the convex set $\mathcal{P}_N$. Hence they are satisfied by any state belonging to $\mathcal{P}_N$. Since $\mathcal{P}_N$ is positively invariant under the control law $\Phi_{\mathcal{P}}(x)$, any trajectory originating in $\mathcal{P}_N$ satisfies the constraints. It follows from Lemmas 4.2 and 4.3 that the cost achieved from a given initial condition x is bounded by the maximum cost achieved from the vertices of the sector $\mathcal{S} \ni x$. Consider the cost function $\hat{g}(x) = g(x, \Phi_{\mathcal{P}}(x))$. Since $\hat{g}(x)$ is convex and 0-symmetric, it is easy to recognize that

$$\hat{g}(x) \leq \hat{g}(x_{In(\mathcal{S}(x))}), \tag{48}$$

where $\mathcal{S}(x)$ denotes the sector $\mathcal{S} \ni x$ and $x_{In(\mathcal{S}(x))}$ belongs to the optimal trajectory. From Lemma 4.2 and from the fact that $\hat{g}(x)$ is convex and 0-symmetric, it follows

that

$$\hat{g}(x_i) \leq \hat{g}(x_j) \tag{49}$$

for $0 < i < j \leq N$. Therefore, the maximum in the right-hand side of (47) is obtained for $k_i = \mathrm{In}(\mathcal{S}(x))$, i.e., it is the (optimal) cost from the vertex $x_{In(\mathcal{S}(x))}$. Let us now compare the cost achieved from x to that achieved from $x_{In(\mathcal{S}(x))}$. We recall that the control law $\Phi_{\mathcal{P}}(x)$ steers the system from $x \in \mathcal{S}(x) \subset \mathcal{P}_N$ to zero in at most $In(\mathcal{S}(x))$ steps. Denoting

$$f(x) = Ax + B\Phi_{\mathcal{P}}(x) \tag{50}$$

and

$$f^i(x) = f(f(\dots f(x)\dots)), \tag{51}$$

we can rewrite (48) as

$$\hat{g}(f^i(x)) \leq \hat{g}(x_{In(\mathcal{S}(f^i(x)))}), \tag{52}$$

for all $i = 0, \dots, \mathrm{In}(\mathcal{S}(x)) - 1$. On the other hand, Lemma 4.3 states that the sequence of indices corresponding to a trajectory originating in $\mathcal{P}_N$ is strictly decreasing. It follows that

$$\mathrm{In}(\mathcal{S}(f^i(x))) \leq \mathrm{In}(\mathcal{S}(x)) - i \tag{53}$$

for all $i = 0, \dots, \mathrm{In}(\mathcal{S}(x)) - 1$. Therefore, from (49) we can write

$$\hat{g}(x_{In(\mathcal{S}(f^i(x)))}) \leq \hat{g}(x_{In(\mathcal{S}(x))-i}) \tag{54}$$

and, by (52),

$$\hat{g}(f^i(x)) \leq \hat{g}(x_{In(\mathcal{S}(x))-i}). \tag{55}$$

Finally, by summing over $i = 0, \dots, \mathrm{In}(\mathcal{S}(x)) - 1$, we obtain

$$J(x) \leq J(x_{In(\mathcal{S}(x))}). \qquad \square \tag{56}$$

Now we show how to remove Assumption 2. If Assumption 2 does not hold, the construction of the regions is basically the same. The only difference is that now we must start the construction from the beginning (i.e., $\mathcal{P}_1$, $\mathcal{P}_2, \dots$) until we construct the region $\mathcal{P}_r$, where $r > n$ is the smallest value for which $[x_1\ x_2\ \dots\ x_r]$ has full rank (and then $\mathcal{P}_r$ is a neighborhood of the origin). In forming the sets $\mathcal{P}_k$, $k < r$, we construct a partition of "degenerate polytopes" in subspaces having the same properties mentioned above. When we add the vertex x_r (and its opposite $-x_r$), we reach full dimension and can construct a (nondegenerate) simplex partition of $\mathcal{P}_r$ in which each simplex has x_r as a vertex. Then the construction proceeds as already mentioned, with the difference that the control is not ultimately linear since, in general, we cannot associate a linear control with $\mathcal{P}_r$. If such an r does not exist (i.e., the whole optimal trajectory belongs to a proper subspace of $\mathbb{R}^n$), we can extend the trajectory backward, i.e., adding points x_{N+1}, x_{N+2} to reach the full rank. Clearly, optimality is ensured only from $\bar{x} = x_N$. Using the same trick of extending the trajectory backward, we can arbitrarily enlarge the domain of attraction.

We are now in the position of proving relative optimality with local stability of the control.

Proof of Theorem 3.1. The constructed simplicial partition and the control are of the form (20), which is Lipschitz as proved in Lemma 4.4. If we assume $x(1) = \bar{x}$, then the trajectory is the optimal constrained one by construction. The fact that the control is stabilizing follows from Lemma 4.3. The satisfaction of the constraints and the cost bound (21) follow easily from Lemma 4.5. □

TABLE 1
Upper bound for the number of simplices given the number N of steps of the optimal trajectory and the order n of the system.

N, n	3	4	8	12	16
4	33	39	-	-	-
8	133	207	1425	-	-
12	297	503	11965	54257	-
16	525	927	47497	592013	$2.1\ 10^6$
20	817	1479	132085	$3.2\ 10^6$	$2.8\ 10^7$

An important question is whether the complexity of the controller (i.e., the number of simplices obtained by partitioning the state space according to Procedure 4.1) is known in advance. For $n = 2$, the number of simplices (triangles) is exactly $4N - k$, where k is the number of the vertices of the convex hull of the optimal trajectory and its opposite [12]. For $n > 2$, since such simplices form a *triangulation* [8] of a point set, their number N_s is bounded according to the expression [13]

$$N_s \leq \begin{pmatrix} 2N + 2 - \left\lceil \frac{n+1}{2} \right\rceil \\ \left\lfloor \frac{n+1}{2} \right\rfloor \end{pmatrix} + \begin{pmatrix} 2N + 1 - \left\lceil \frac{n}{2} \right\rceil \\ \left\lfloor \frac{n}{2} \right\rfloor \end{pmatrix} - (n+1), \tag{57}$$

where $\lfloor x \rfloor$ denotes the maximum integer less than or equal to x, $\lceil x \rceil$ denotes the minimum integer greater than or equal to x, and $\binom{a}{b}$ denotes the binomial coefficient. Table 1 reports such an upper bound for some pairs of N and n. Upper bound (57) resembles that provided in [2], in the context of the explicit linear $1/\infty$-norm regulator for constrained systems, with the substantial difference that *for the static ROC the upper bound does not depend on the number of constraints*, since the controller is computed based on the optimal trajectory only. In other words, the number of constraints does not influence directly the complexity of the controller.

Remark 4.4. As shown above, the convexity of the constraints and the cost guarantees that

$$x_i \notin \mathcal{P}_{i-1} \ \forall i = n+1, \ldots, N. \tag{58}$$

However, as long as condition (58) on the optimal trajectory is satisfied, the ROC can be constructed independently of the convexity of the optimization problem. In other words, a sufficient condition for constructing the static ROC is that each of the points of the optimal trajectory does not belong to the convex hull of the subsequent points and their opposite. Obviously, the satisfaction of the constraints is guaranteed for all the trajectories originating in $\mathcal{P} = \mathcal{P}_N$ only if the constraints are convex and 0-symmetric.

5. Construction of a global controller. For $x \in \mathcal{P} = \mathcal{P}_N$, the controller described above is a solution for Problem 1. However, the control law is not defined for $x \notin \mathcal{P}$. A possible way to extend the control outside $\mathcal{P}$ is to "immerse" $\mathcal{P}$ in

the maximal invariant set $\mathcal{X}_{max}$, namely, the set of all states which can be brought to the origin in finitely many steps without state or input constraint violations (note that $\mathcal{P} \subseteq \mathcal{X}_{max}$). Then, for $x \notin \mathcal{P}$, one can apply the control law derived from $\mathcal{X}_{max}$ (many algorithms have been proposed to find $\mathcal{X}_{max}$ and an associated control law; see, for example, [9]). By definition, the constraints are satisfied and the convergence is guaranteed if and only if $x(1) \in \mathcal{X}_{max}$.

A different strategy can be derived as the *natural extension of the controller computed within* $\mathcal{P}$. In this way we have basically two advantages:

- the obtained controller is globally Lipschitz;
- the state behavior outside the set $\mathcal{P}$ resembles the internal one and therefore the system performs "reasonably well" outside $\mathcal{P}$.

The set $\mathcal{P}$ is a polytope including the origin in its interior. This means that the state space can be partitioned in simplicial cones, each having a center in the origin and generated by n vertices of $\mathcal{P}$. These cones $\mathcal{C}^{(h)}$ have a nonempty interior, have intersections with empty interior, and cover $\mathbb{R}^n$:

$$\text{int}\{\mathcal{C}^{(h)}\} \neq \emptyset, \tag{59}$$

$$\text{int}\{\mathcal{C}^{(h)} \bigcap \mathcal{C}^{(k)}\} = \emptyset, \quad h \neq k, \tag{60}$$

$$\bigcup_h \mathcal{C}^{(h)} = \mathbb{R}^n. \tag{61}$$

For each cone generated by a square matrix $X^{(h)}$, we consider the complement with respect to $\mathcal{P}$,

$$\tilde{\mathcal{C}}^{(h)}; \tag{62}$$

therefore the union of the complements and the simplices forming $\mathcal{P}$ cover $\mathbb{R}^n$. For each cone generated by an invertible $X^{(h)}$ we consider the corresponding input matrix $U^{(h)}$[1] and the control

$$\tilde{\Phi}(x) = U^{(h)}[X^{(h)}]^{-1}x. \tag{63}$$

Such a control is Lipschitz [3].

In principle, continuity is not an issue in discrete-time systems. In practice, it avoids chattering. Thus we state the next lemma.

LEMMA 5.1. *Consider the following extension outside* $\mathcal{P}$ *of the control* $\Phi_{\mathcal{P}}(x)$*:*

$$\Phi(x) \doteq \begin{cases} \Phi_{\mathcal{P}}(x) & \textit{for } x \in \mathcal{P}, \\ \tilde{\Phi}(x) & \textit{for } x \notin \mathcal{P}. \end{cases} \tag{64}$$

Such a control is globally Lipschitz.

Proof. Since the control is piecewise affine and the cardinality of the partition is finite, we need only prove global continuity. Then the Lipschitz constant for each component of Φ is given by the maximum value of the norm of its gradient. Note also that $\Phi_{\mathcal{P}}$ is continuous inside $\mathcal{P}$ and $\tilde{\Phi}$ is continuous outside $\mathcal{P}$. As a consequence, we need only prove that the extended control is continuous in $\partial\mathcal{P}$. Consider $\hat{x} \in (\mathcal{P} \cap \tilde{\mathcal{C}}^{(h)}) \subset \partial\mathcal{P}$. By construction, $\tilde{\mathcal{C}}^{(h)}$ and $\mathcal{P}$ have a facet in common, precisely

[1]The matrix whose columns are the (optimal) control vectors associated with the columns in $X^{(h)}$, elements of the optimal trajectory.

the facet whose vertices are the generator vectors of $\tilde{\mathcal{C}}^{(h)}$. Since $\hat{x}$ lies in the common facet, it can be expressed as a linear combination of those vectors in a unique way. From (40) and (63) it follows that $\Phi_{\mathcal{P}}(\hat{x})$ and $\tilde{\Phi}(\hat{x})$ are the linear combination of the controls associated with the same vectors according to the same coefficients; then $\tilde{\Phi}(\hat{x}) = \Phi_{\mathcal{P}}(\hat{x})$ for all $\hat{x} \in \mathcal{P} \cap \tilde{\mathcal{C}}^{(h)}$, i.e., the extended control is continuous in $\partial\mathcal{P}$. □

Now the problem is to show that the extended control $\Phi(x)$ is globally stabilizing. Then we consider as a candidate Lyapunov function the Minkowski function of $\mathcal{P}$, that is, the norm whose unit ball is $\mathcal{P}$:

$$\Psi(x) = \min\{\lambda \geq 0 : \quad x \in \lambda\mathcal{P}\}. \tag{65}$$

We have the following preliminary lemma.

LEMMA 5.2. *The function $\Psi(x(k))$ is nonincreasing as long as $x(k) \notin \mathcal{P}$.*

Proof. Since $x(k+1) = Ax + B\Phi(x(k))$, we must prove that

$$\Psi(Ax + B\Phi(x)) \leq \Psi(x) \quad \forall x \notin \mathcal{P}. \tag{66}$$

As shown above, the extended control $\Phi(x)$ is globally continuous. Furthermore, it is linear inside each of the $\tilde{\mathcal{C}}^{(h)}$. As a consequence, outside the interior of $\mathcal{P}$, the control can be expressed as

$$\Phi(x) = \Psi(x)\Phi_{\mathcal{P}}(\bar{x}), \quad x \notin \text{int}(\mathcal{P}), \tag{67}$$

where the vector

$$\bar{x} = \frac{x}{\Psi(x)} \tag{68}$$

belongs to the boundary of $\mathcal{P}$. Consider a generic $x \notin \mathcal{P}$ and its "projection" $\bar{x}$ onto $\partial\mathcal{P}$. Since $\Phi_{\mathcal{P}}$ renders invariant the set $\mathcal{P}$, it follows that

$$A\bar{x} + B\Phi_{\mathcal{P}}(\bar{x}) \in \mathcal{P} \tag{69}$$

and, multiplying by $\Psi(x)$,

$$A\Psi(x)\bar{x} + B\Psi(x)\Phi_{\mathcal{P}}(\bar{x}) \in \Psi(x)\mathcal{P}. \tag{70}$$

From (67) and (70) and by substituting $x = \Psi(x)\bar{x}$ we obtain

$$Ax + B\Phi(x) \in \Psi(x)\mathcal{P}, \tag{71}$$

which implies, by the definition of the Minkowski function, that

$$\Psi(Ax + B\Phi(x)) \leq \Psi(x), \quad x \notin \mathcal{P}. \qquad \square \tag{72}$$

Lemma 5.2 proves the boundedness of the state but not convergence to 0. To prove convergence, since the function $\Psi(x)$ is only nonincreasing, we must use a trick. Define

$$x(k+1) = f(x) = Ax + B\Phi(x) \tag{73}$$

and consider the N steps forward system defined as the composition of f:

$$x(k+N) = f^N(x(k)) = f(f(\dots f(x)\dots)) \doteq F(x). \tag{74}$$

By means of this system we can show the following.

LEMMA 5.3. *The function* $\Psi(x(k))$*, as long as* $x(k) \notin int(\mathcal{P})$*, is strictly decreasing along the trajectory of the system* (74)*, precisely*

$$\Delta\Psi(x) \doteq \Psi(F(x)) - \Psi(x) < 0 \quad \forall x \notin \mathrm{int}(\mathcal{P}). \tag{75}$$

Proof. Consider a generic $x \notin \mathrm{int}(\mathcal{P})$ and its projection $\bar{x}$ onto $\partial\mathcal{P}$. As a first step we observe that there exists $1 \le h \le N$ such that

$$\bar{x}, f(\bar{x}), \dots, f^{h-1}(\bar{x}) \in \partial\mathcal{P}, \tag{76}$$

$$f^h(\bar{x}) \in \mathrm{int}(\mathcal{P}). \tag{77}$$

This is an immediate consequence of the fact that the control steers the system to zero in at most N steps starting from any $x \in \mathcal{P}$ and, in particular, from any $\bar{x} \in \partial\mathcal{P}$. By definition, we can express $x \notin \mathrm{int}(\mathcal{P})$ as the product of its projection $\bar{x}$ onto $\partial\mathcal{P}$ and the Minkowski function $\Psi(x)$:

$$x = \bar{x}\Psi(x). \tag{78}$$

By substituting in $f(x)$ we get

$$f(x) = Ax + B\Phi(x) = A\Psi(x)\bar{x} + B\Psi(x)\Phi_{\mathcal{P}}(\bar{x}) = \Psi(x)(A\bar{x} + B\Phi_{\mathcal{P}}(\bar{x})) = \Psi(x)f(\bar{x}), \tag{79}$$

where the last equality holds since $\Phi_{\mathcal{P}}(\bar{x}) = \Phi(\bar{x})\ \forall \bar{x} \in \partial\mathcal{P}$. Similarly it can be shown that $f^i(x) = \Psi(x)f^i(\bar{x})\ \forall i = 2, \dots, N$. Now, by multiplying (76) and (77) by $\Psi(x)$ it follows that

$$x, f(x), \dots, f^{h-1}(x) \in \partial(\Psi(x)\mathcal{P}), \tag{80}$$

$$f^h(x) \in \mathrm{int}(\Psi(x)\mathcal{P}); \tag{81}$$

then we obtain

$$\Psi(f^h(x)) < \Psi(x). \tag{82}$$

Thanks to Lemma 5.2, during the next $N - h$ steps, the state cannot escape from the region $\mathrm{int}(\Psi(x)\mathcal{P})$; hence

$$\Psi(F(x)) = \Psi(f^N(x)) \le \Psi(f^h(x)). \tag{83}$$

Finally, from these and (82) it follows that

$$\Psi(F(x)) < \Psi(x). \qquad \square \tag{84}$$

Now we are in the position of proving global stability.

Proof of Theorem 3.2. The considered control is Lipschitz and piecewise affine. We need to prove global asymptotic stability. To prove this fact we show that for any initial state $x(1) = x^* \notin \mathcal{P}$ there exists a finite M such that $x(M) \in \mathcal{P}$. Once $\mathcal{P}$ is reached, the state converges to zero as already proved.

This requires standard Lyapunov arguments. Indeed, the composed function $F(x)$ and the candidate Lyapunov function $\Psi(x)$ are continuous, and thus the function $\Delta\Psi(x)$ is continuous. Consider the compact set

$$\mathcal{H} = \{x :\ 1 \le \Psi(x) \le \Psi(x^*)\}. \tag{85}$$

In such a set, $\Delta\Psi(x)$ admits a negative maximum $-\mu$ with $\mu > 0$. Then we have

$$\Psi(x(k+N)) - \Psi(x(k)) = \Delta\Psi(x(k)) \leq -\mu. \tag{86}$$

This means that

$$\Psi(x(hN)) \leq \Psi(x^*) - h\mu. \tag{87}$$

But this means that, in finite time, the condition $\Psi(x(k)) < 1$ occurs, and therefore $x(k)$ reaches $\mathcal{P}$. □

Remark 5.1. The constraint (11) may be relaxed as follows:

$$x(N+1) \in \mathcal{X}_{fin}, \tag{88}$$

where $\mathcal{X}_{fin}$ is a 0-symmetric controlled-invariant polyhedron (that is, there exists a local control that renders $\mathcal{X}_{fin}$ positively invariant and such that the constraints are satisfied for all initial conditions inside the set). Then one can construct the ROC by positing $\mathcal{P}_n = \mathcal{X}_{fin}$ and following steps 3–7 of Procedure 4.1. As a result, a dual control strategy may be adopted: Apply the control $\Phi(x)$ for $x(k) \notin \mathcal{X}_{fin}$ and switch to the local control as soon as the condition $x(k) \in \mathcal{X}_{fin}$ is satisfied.

6. Example. Consider the double integrator

$$x(k+1) = \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix} x(k) + \begin{bmatrix} 0 \\ 1 \end{bmatrix} u(k), \tag{89}$$

under the constraints $|x(k)| \leq 5, |u(k)| \leq 3$. Given the initial state $x(1) = [-2 \quad 5]^T$, the horizon $N = 5$, the final state $x(N+1) = 0$, and the cost function $J = \sum_{i=1}^{N} u(k)^2$, the optimal (open-loop) control and trajectory, found by solving a quadratic-programming problem are, respectively,

$$\bar{U} = \begin{bmatrix} -3 & -2.9 & -1.3 & 0.3 & 1.9 \end{bmatrix} \tag{90}$$

and

$$\bar{X} = \begin{bmatrix} -2 & 3 & 5 & 4.1 & 1.9 \\ 5 & 2 & -0.9 & -2.2 & -1.9 \end{bmatrix}. \tag{91}$$

The optimal trajectory is reported in Figure 3. By means of Procedure 4.1, the triangulation reported in Figure 4 is obtained; the number of triangles is 12 (including the four triangles in which the darkest region, i.e., $\mathcal{P}_2$, can be split). The piecewise-affine control law obtained by applying a control-at-the-vertices strategy inside each of the triangles, as stated above, is relatively optimal, and hence is optimal for the nominal initial condition and guarantees convergence and constraint satisfaction for the other initial conditions. In Figure 4, the trajectories from three nonnominal initial conditions are reported. Note that the number of steps required to reach the origin depends on the triangle to which the initial state belongs. Figure 5 shows the effectiveness of the *extended* control, reporting some trajectories starting from outside $\mathcal{P}$; the dash-dotted lines represent the boundaries between the simplicial cones $\mathcal{C}^{(h)}$ in the complement of $\mathcal{P}$.

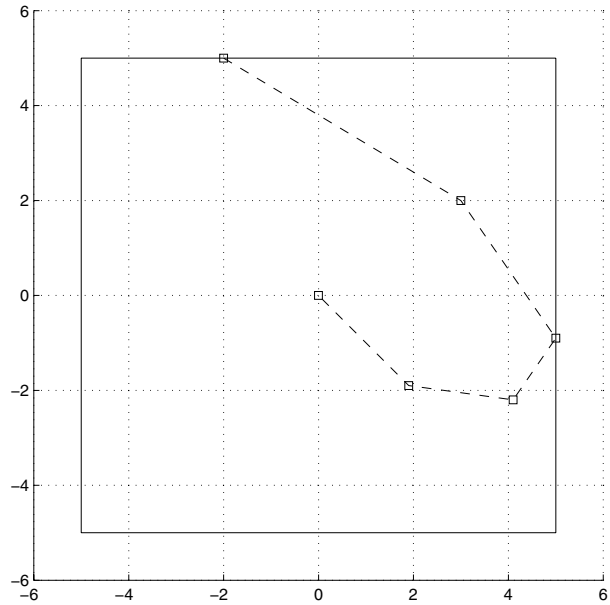

FIG. 3. *The optimal trajectory.*

7. Comparison with the dynamic ROC. Some significant differences between the dynamic ROC [5, 6] and the static one are highlighted in the following points:

1. Since the static ROC is nonlinear, the trajectory originating from $\lambda\bar{x}$ is not proportional, in general, to the one originating from $\bar{x}$ as with the dynamic ROC. However, by construction, opposite initial conditions generate opposite trajectories.
2. The dynamic ROC allows for the optimization from a set of n linearly independent initial conditions, while the static version described in this paper is thought of for a *single initial condition*. Extending the results to more than one initial condition for the static ROC is a matter of further investigation.
3. The dynamic ROC cannot guarantee the satisfaction of the constraints for initial conditions different from the nominal one. Hence it is suitable only in those cases when the constraints are actually *soft* constraints (constraints whose violation causes a performance loss only). On the contrary, by immersing the set $\mathcal{P}$ in the maximal invariant set as outlined in the beginning of section 5, the piecewise-affine solution can deal effectively with *hard* constraints.
4. The dynamic ROC is a linear system of order $N - n$, and hence is of low complexity. By looking at Table 1 it is clear that the complexity of the static ROC is much higher and depends strongly on the dimension of the state space (although the table shows only an upper bound for the number of simplices). As a consequence, the implementation of the static ROC may be difficult for high-order systems. However, almost all the approaches based on partitions of the state space are prone to this problem.

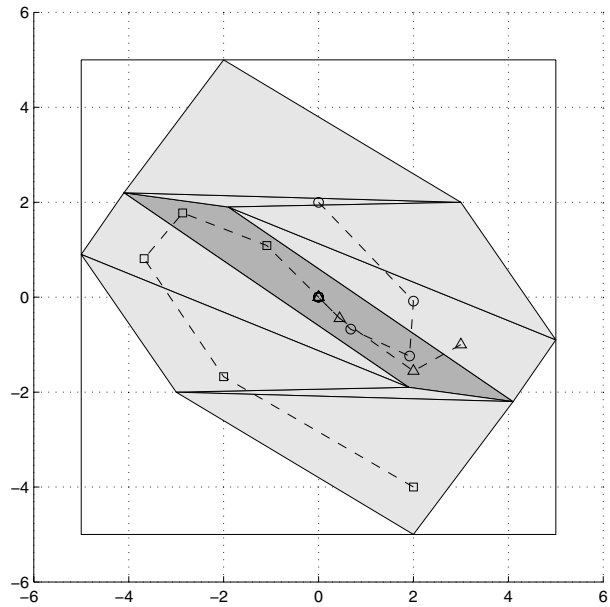

FIG. 4. *The triangulation induced by the optimal trajectory and the trajectories from three nonnominal initial conditions inside* $\mathcal{P}$.

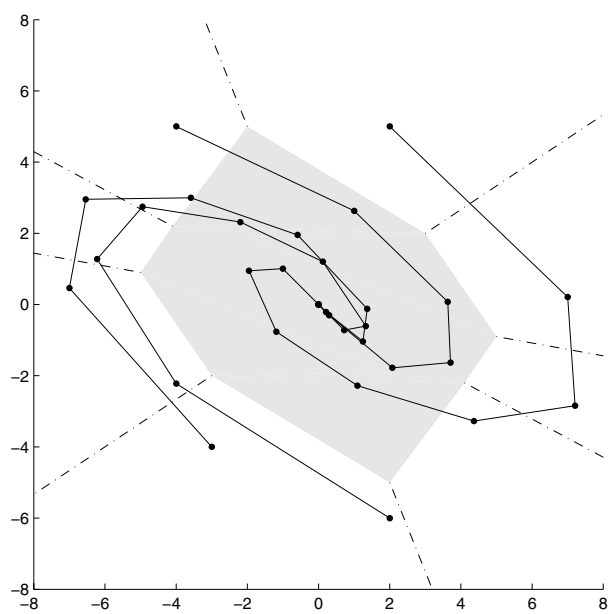

FIG. 5. *Some trajectories starting from outside* $\mathcal{P}$.

8. Conclusions. In this paper, a static version of the relatively optimal control (ROC) [5, 6] is proposed. The proposed controller is a deadbeat piecewise-affine state-feedback controller, based on a triangulation of the points of the optimal trajectory (computed offline). An upper bound on the number of polyhedral sets (whose vertices are the states of the optimal trajectory and their opposite) as a function of the order of the system and the length of the optimal trajectory is provided. The control at each vertex is the corresponding control vector of the optimal sequence, while the control at a generic state is given by a convex combination of the controls corresponding to the vertices of the set to which the state belongs. By removing the zero state terminal constraint and requiring the final state of the optimal trajectory to belong to a controlled invariant set, it is possible to obtain a nondeadbeat controller. The proposed control can deal effectively with hard constraints (a significant advantage with respect to the dynamic one previously introduced). We point out that the 0-symmetry of the constraint set is not necessary for the construction of the ROC, namely, for solving Problem 1; however, it guarantees the additional property that the constraints are satisfied for all initial conditions inside $\mathcal{P}_N$. Further work includes extending the results to more than one initial condition and exploiting the particular structure of the triangulation in order to obtain a tighter bound on the number of simplices.

OPTIMAL CONTROL OF THE STATIONARY NAVIER–STOKES EQUATIONS WITH MIXED CONTROL-STATE CONSTRAINTS*

J. C. DE LOS REYES† AND F. TRÖLTZSCH‡

Abstract. In this paper we consider the distributed optimal control of the Navier–Stokes equations in the presence of pointwise mixed control-state constraints. After deriving a first order necessary condition, the regularity of the mixed constraint multiplier is investigated. Second order sufficient optimality conditions are studied as well. In the last part of the paper, a semismooth Newton method is applied for the numerical solution of the control problem. The convergence of the method is proved and numerical experiments are carried out.

Key words. optimal control, Navier–Stokes equations, mixed control-state constraints, semismooth Newton methods

1. Introduction.

Continuing our efforts in the investigation of optimal control problems governed by the Navier–Stokes equations in the presence of pointwise control and state constraints (cf. [7, 8, 9, 10, 25]), we consider the following mixed control-state constrained problem:

$$\begin{cases} \min\ J(y,u) = \frac{1}{2}\int_\Omega |y - z_d|^2\ dx + \frac{\alpha}{2}\int_\Omega |u|^2\ dx \\ \text{subject to} \\ -\nu\Delta y + (y\cdot\nabla)y + \nabla p = u, \\ \operatorname{div} y = 0, \\ y|_\Gamma = g, \\ a \le \varepsilon u + y \le b \text{ a.e.}, \end{cases} \tag{1.1}$$

where $\alpha > 0$ and $\varepsilon > 0$. Due to the mixed nature of the pointwise constraints, expressed by the last relation of (1.1), the corresponding Lagrange multiplier is expected to be more regular than in the state constrained case (cf. [8]). In fact, such a constraint can be introduced as a way of regularizing the state constrained case, and it is expected that, as ε tends to zero, the solutions converge to the optimal solution of the state constrained problem (see [21]).

Optimal control of partial differential equations in the presence of state constraints is a very challenging research field, mainly due to the difficult structure of the Lagrange multiplier associated to the state constraints (see [2, 3, 4]). In the case of Navier–Stokes control, the problem has been investigated in [8], where the measure structure of the multiplier was studied.

This paper is a contribution to the numerical analysis of optimal control problems of the Navier–Stokes equations with pointwise state constraints.

‡Institut für Mathematik, TU Berlin, Berlin, Germany (troeltzsch@math.tu-berlin.de).

The unconstrained and control constrained optimal control problems of the Navier–Stokes equations have been studied in many papers (see [1, 5, 7, 14, 15, 16, 18, 19, 25, 26]), where optimality conditions and/or numerical methods were discussed. Moreover, we refer the reader to the detailed references in [13].

In contrast to this, only a few papers consider associated problems with state constraints. To our best knowledge, in flow control, only [8, 10, 11, 27] deal with state constraints. In [8] and [11, 27] necessary optimality conditions are derived for the stationary and time dependent problems, respectively. In [10] the numerical solution utilizing a penalized problem together with a semismooth Newton method has been studied.

The novelty of our paper consists of a Lavrentiev-type regularization of the state constraints. Here we follow an approach introduced in [21, 22] to approximate the state constraints by mixed control-state constraints. This approach permits us to work with regular functions rather than with measures, which are unavoidable for pure pointwise state constraints. In this way, we are able to show regularity of Lagrange multipliers and to derive second order sufficient optimality conditions. An additional novelty is the consideration of semismooth Newton methods in this context. We set up a semismooth Newton algorithm for the numerical solution of the control problem and prove local superlinear convergence of the method. All these issues have not yet been considered in the literature.

The outline of the paper is as follows. In section 2, the optimal control problem is stated and existence of a global optimal solution is proved. In section 3, the problem is reformulated as a control constrained optimal control problem and first order necessary optimality conditions are obtained. Sufficient conditions of second order type are the topic of section 4. In section 5, a semismooth Newton algorithm is stated and the superlinear convergence of the method is proved. Reports on numerical experiments are summarized in section 6.

2. Problem statement and existence of solution. Consider a bounded regular domain $\Omega \subset \mathbb{R}^d$, $d \in \{2, 3\}$. Our objective is to characterize and find a solution $(u^*, y^*) \in \mathbf{L}^2(\Omega) \times \mathbf{H}^1(\Omega)$ to the following optimal control problem:

$$\begin{cases} \min\ J(y,u) = \frac{1}{2}\int_\Omega |y - z_d|^2\ dx + \frac{\alpha}{2}\int_\Omega |u|^2\ dx \\ \text{subject to} \\ -\nu\Delta y + (y\cdot\nabla)y + \nabla p = u, \\ \text{div } y = 0, \\ y|_\Gamma = g, \\ a \le \varepsilon u + y \le b \text{ a.e.}, \end{cases} \tag{2.1}$$

where $\alpha > 0$, $\varepsilon > 0$, z_d is the desired state, $a \le b \in \mathbf{L}^2(\Omega)$, and $g \in \mathbf{H}_0^{1/2}(\Gamma)$, with $\mathbf{H}_0^{1/2}(\Gamma) := \{v \in \mathbf{H}^{1/2}(\Gamma) : \int_\Gamma v\cdot\vec{n}\ d\Gamma = 0\}$ are given. The inequalities in the last line of (2.1) have to be understood componentwise. We denote by $(\cdot,\cdot)_X$ the inner product in the Hilbert space X and by $\|\cdot\|_X$ the associated norm. The subindex is suppressed if the L^2-inner product or norm is meant. Hereafter, the bold notation stands for the product of spaces. Additionally, we introduce the solenoidal space $V = \{v \in \mathbf{H}_0^1(\Omega) : \text{div } v = 0\}$, the closed subspace $\mathbf{H} := \{v \in \mathbf{H}^1(\Omega) : \text{div } v = 0\}$, and the trilinear form $c : \mathbf{H}\times\mathbf{H}\times\mathbf{H} \to \mathbb{R}$ defined by

$$c(u,w,v) = ((u\cdot\nabla)w, v). \tag{2.2}$$

Considering a force term $f \in V'$, the weak formulation of the Navier–Stokes equations is then given by

$$\nu(\nabla y, \nabla v) + c(y, y, v) = \langle f, v\rangle_{V',V} \text{ for all } v \in V, \tag{2.3}$$

$$\gamma_0 y = g, \tag{2.4}$$

where $\nabla y = \begin{pmatrix} \partial_1 y_1 & \dots & \partial_d y_1 \\ \vdots & \ddots & \vdots \\ \partial_1 y_d & \dots & \partial_d y_d \end{pmatrix}$, $(\nabla y, \nabla v) := \sum_{i=1}^d \sum_{j=1}^d (\partial_i y_j, \partial_i v_j)_{L^2(\Omega)}$, and $\gamma_0 : \mathbf{H}^1(\Omega) \to \mathbf{H}^{1/2}(\Gamma)$ stands for the trace operator. It is now standard to show existence of a solution for (2.3)–(2.4). Also an appropriate estimate and uniqueness, for ν sufficiently large or f sufficiently small, are obtained. The main results are summarized in the following theorem.

THEOREM 2.1. *Let $\Omega \in \mathbb{R}^d$, $d \in \{2, 3\}$, be a bounded regular domain, and $f \in \mathbf{H}^{-1}(\Omega)$ and $g \in \mathbf{H}_0^{1/2}(\Gamma)$. Then, there exists at least one solution for the nonhomogeneous problem* (2.3)–(2.4) *that satisfies the estimate*

$$\|y - \hat{y}\|_V \le \frac{2}{\nu} \|F\|_{V'}, \tag{2.5}$$

where $\hat{y} \in \mathbf{H}$ is a function such that $\gamma_0 \hat{y} = g$ and $F = f + \nu\Delta\hat{y} - (\hat{y} \cdot \nabla)\hat{y}$. Moreover, if $\|\hat{y}\|_{\mathbf{H}}$ is sufficiently small, such that

$$|c(v, \hat{y}, v)| \le \frac{\nu}{2} \|v\|_V^2 \text{ for all } v \in V$$

and $\nu^2 > 4\mathcal{N}\|F\|_{V'}$, with $\mathcal{N} = \sup_{u,v,w \in V} \frac{|c(u,v,\phi)|}{\|u\|_V \|v\|_V \|w\|_V}$, then the solution is unique.

Proof. For the proof we refer the reader to [23, pp. 178–180]. ∎

Next, we verify the existence of an optimal solution for our control problem. For that purpose let us define the set of admissible solutions

$$\mathcal{T}_{ad} = \{(y, u) \in \mathbf{H} \times \mathbf{L}^2(\Omega) : (y, u) \text{ satisfies the restrictions in (2.1)}\}.$$

THEOREM 2.2. *If $\mathcal{T}_{ad}$ is nonempty, then there exists an optimal solution for* (2.1).

Proof. Assuming that there is at least one feasible pair for our problem, we take a minimizing sequence $\{(y_n, u_n)\}$ in $\mathbf{L}^2(\Omega) \times \mathbf{H}^1(\Omega)$ and, considering the quadratic nature of the cost functional, we get that $\{u_n\}$ is uniformly bounded in $\mathbf{L}^2(\Omega)$.

From estimate (2.5) it follows that the sequence $\{y_n\}$ is also uniformly bounded in $\mathbf{H}^1(\Omega)$. Therefore, we may extract a weakly convergent subsequence, also denoted by $\{(y_n, u_n)\}$, such that $u_n \rightharpoonup u^*$ in $\mathbf{L}^2(\Omega)$ and $y_n \rightharpoonup y^*$ in $\mathbf{H}^1(\Omega)$. Due to the weak sequential continuity of the nonlinear form (cf. [12, p. 286]), it follows that $c(y_n, y_n, v) \to c(y^*, y^*, v)$. Consequently, due also to the linearity and continuity of the other terms involved, the limit (y^*, u^*) satisfies the state equations.

Since the set $C := \{v \in \mathbf{L}^2(\Omega) : a \le v \le b \text{ a.e.}\}$ is closed and convex, it is weakly closed. Hence, from the linearity and continuity of the mapping $(y, u) \to \varepsilon u + y$, it follows that $\varepsilon u^* + y^* \in C$. Taking into consideration that $J(y, u)$ is weakly lower semicontinuous, the result follows in a standard way. ∎

3. First order necessary optimality conditions. Let us consider the set

$$U = \{u \in \mathbf{L}^2(\Omega) : \|u\| < \left(\nu^2 - 4\mathcal{N}\,\|\nu\Delta\hat{y} - (\hat{y}\cdot\nabla)\hat{y}\|_{V'}\right)/(4\mathcal{N}\hat{c})\},$$

where $\hat{c}$ denotes the embedding constant of $\mathbf{L}^2(\Omega)$ into V' and $\hat{y}$ is a suitable velocity profile from Theorem 2.1. According to Theorem 2.1 there exists, for each $u \in U$ on the right-hand side of (2.3), a unique solution of the Navier–Stokes equations. Introducing the control-to-state operator $G : U \to \mathbf{H}$ that assigns to each $u \in U \subset \mathbf{L}^2(\Omega)$ the corresponding Navier–Stokes solution $y(u)$, and using the composite mapping $\mathcal{G} = \mathcal{I} \circ G$, where $\mathcal{I} : \mathbf{H} \to \mathbf{L}^2(\Omega)$ stands for the continuous compact injection, problem (2.1) can be expressed in a reduced form as

$$(\mathcal{P}) \qquad \begin{cases} \min_{u\in U}\ J(u) = \frac{1}{2}\int_\Omega |\mathcal{G}u - z_d|^2\,dx + \frac{\alpha}{2}\int_\Omega |u|^2\,dx \\ \text{subject to} \\ a \le \varepsilon u + \mathcal{G}u \le b \text{ a.e. in } \Omega. \end{cases}$$

Since U is open, we cannot expect in general that $(\mathcal{P})$ admits a global solution. However, in what follows, we concentrate on certain local solutions rather than consider exclusively global ones. Therefore, we are justified to assume $u^* \in U$ below.

In what follows we will frequently utilize the condition

$$\nu > \mathcal{M}(y^*), \tag{3.1}$$

with $\mathcal{M}(y) := \sup_{v\in V} \frac{|c(v,y,v)|}{\|v\|_V^2}$, which is responsible for the ellipticity of the linearized equations (see Lemma 3.1 below). Condition (3.1) is immediately satisfied for all pairs $(y(u), u)$ that fulfill the hypotheses of Theorem 2.1 (see [7, Remark 3.1]). In particular, it holds for all pairs $(y(u), u)$ with $u \in U$.

LEMMA 3.1. *Let $u \in U$ and $y := G(u)$. The control-to-state operator G is twice Fréchet differentiable at u and its derivatives $w := G'(u)h$ and $z := G''(u)[h]^2$ are given by the unique solutions of the systems*

$$\begin{aligned} -\nu\Delta w + (w\cdot\nabla)y + (y\cdot\nabla)w + \nabla\pi &= h, \\ \operatorname{div} w &= 0, \\ w|_\Gamma &= 0 \end{aligned} \tag{3.2}$$

and

$$\begin{aligned} -\nu\Delta z + (z\cdot\nabla)y + (y\cdot\nabla)z + \nabla\varrho &= -2(w\cdot\nabla)w, \\ \operatorname{div} z &= 0, \\ z|_\Gamma &= 0, \end{aligned} \tag{3.3}$$

respectively.

Proof. Let us begin by considering system (3.2). Its variational formulation is given by

$$a_1(w,\phi) := \nu(\nabla w, \nabla\phi) + c(w,y,\phi) + c(y,w,\phi) = (h,\phi)$$

for all $\phi \in V$. Since for all pairs (y,u) with $u \in U$ condition (3.1) holds (see [7, Remark 3.1]), coercivity of $a_1(\cdot,\cdot)$ and, consequently, the existence and uniqueness of the solution w, follow.

Let us denote the increment by $\bar{y} := y_{u+h} - y_u$, where $y_u := G(u)$. Considering that

$$c(y_{u+h}, y_{u+h}, \phi) - c(y_u, y_u, \phi) = c(\bar{y}, \bar{y}, \phi) + c(y_u, \bar{y}, \phi) + c(\bar{y}, y_u, \phi), \tag{3.4}$$

it can be verified that $\bar{y}$ is a solution of

$$\nu(\nabla \bar{y}, \nabla \phi) + c(\bar{y}, \bar{y}, \phi) + c(\bar{y}, y_u, \phi) + c(y_u, \bar{y}, \phi) = (h, \phi) \text{ for all } w \in V. \tag{3.5}$$

Taking $\phi = \bar{y}$ as a test function in (3.5) yields

$$(h, \bar{y}) = \nu \|\bar{y}\|_V^2 + c(\bar{y}, y_u, \bar{y}) \geq \nu \|\bar{y}\|_V^2 - \mathcal{M}(y_u) \|\bar{y}\|_V^2$$

and therefore

$$\|\bar{y}\|_V \leq \kappa \sigma(y) \|h\|, \tag{3.6}$$

where κ denotes the Poincaré inequality constant and $\sigma(y) := \frac{1}{\nu - \mathcal{M}(y)}$. Considering now $\tilde{y} = y_{u+h} - y_u - w$, we obtain the following equation:

$$\begin{aligned} \nu(\nabla \tilde{y}, \nabla \phi) + c(y_{u+h}, y_{u+h}, \phi) - c(y_u, y_u, \phi) \\ - c(w, y_u, \phi) - c(y_u, w, \phi) = 0 \text{ for all } w \in V. \end{aligned} \tag{3.7}$$

Using (3.4) and choosing $\tilde{y}$ as a test function in (3.7) we get that

$$\nu \|\tilde{y}\|_V^2 - c(\tilde{y}, \tilde{y}, y_u) = -c(\bar{y}, \bar{y}, \tilde{y}),$$

which, together with (3.6) and condition (3.1), yields

$$\|\tilde{y}\|_V \leq \mathcal{N} \kappa^2 \sigma^3(y) \|h\|^2. \tag{3.8}$$

Hence, the Fréchet differentiability follows. Moreover, since condition (3.1) holds, existence and uniqueness of solutions for (3.2) are verified. Therefore, the inverse operator exists for all $u \in U$ as a linear continuous operator and, from the implicit function theorem, the operator G is of class C^2 from U to $\mathbf{H}$. Taking the derivative on both sides of (3.2) yields (3.3) (see [6, p. 14]). □

The idea now consists in reformulating problem $(\mathcal{P})$ in a new variable $v := \varepsilon u + \mathcal{G}(u)$ and treating it as a control constrained optimal control problem. In order to express u as a function of v we consider the operator

$$\begin{aligned} F : \mathbf{L}^2(\Omega) \times \mathbf{L}^2(\Omega) &\to \mathbf{L}^2(\Omega), \\ (v, u) &\mapsto \varepsilon u + \mathcal{G}(u) - v \end{aligned}$$

and the solvability of the equation

$$F(v, u) = 0.$$

To justify existence and uniqueness of u for each $v \in \mathbf{L}^2(\Omega)$, we will consider an $\mathbf{L}^2$ neighborhood of the optimal control u^* contained in U. From the implicit function theorem (cf. [28]), since $F(v, u)$ is clearly defined in a neighborhood of u^* and $v^* = \varepsilon u^* + \mathcal{G}(u^*)$, it suffices to verify existence and continuity of the mapping $F_u(v^*, u^*)^{-1}$ from $\mathbf{L}^2(\Omega)$ to $\mathbf{L}^2(\Omega)$.

From the open mapping theorem, existence and continuity of $F_u(v^*, u^*)^{-1}$ hold if the operator $F_u(v^*, u^*) = \varepsilon + \mathcal{G}'(u^*)$ is bijective. Let us therefore consider the equation

$$(\varepsilon + \mathcal{G}'(u^*))h = \varphi, \tag{3.9}$$

with $\varphi \in \mathbf{L}^2(\Omega)$. It is easy to see that $\mathcal{G}'(u^*) = \mathcal{I} \circ G'(u^*)$ is compact due to the embedding $\mathcal{I} : \mathbf{H}^1(\Omega) \to \mathbf{L}^2(\Omega)$. Since $\varepsilon > 0$ and $\nu > \mathcal{M}(y^*)$, it can be verified that $\ker(\varepsilon + \mathcal{G}'(u^*)) = \{0\}$ and consequently ε is not an eigenvalue of $-\mathcal{G}'(u^*)$. Applying Fredholm's alternative, we get the existence of a unique solution $h \in \mathbf{L}^2(\Omega)$ for (3.9) and consequently the existence and continuity of $F_u(v^*, u^*)^{-1}$.

Therefore, there are constants $r, r_0 > 0$ such that for each $v \in \mathbf{L}^2(\Omega)$ with $\|v - v^*\| \le r_0$, there exists a unique $u := K(v)$ with $\|u - u^*\| \le r$ and

$$\varepsilon K(v) + \mathcal{G}(K(v)) = v. \tag{3.10}$$

Moreover, since F is twice continuously Fréchet differentiable, the implicit function theorem (cf. [28]) also implies that K is twice continuously Fréchet differentiable. Let us denote by $K''(v)[\xi, \eta]$ the second derivative of K in directions ξ and η and introduce $K''(v)[\xi]^2 := K''(v)[\xi, \xi]$. Taking the first and second derivatives on both sides of (3.10) in direction ξ yields

$$(\varepsilon + \mathcal{G}'(K(v)))K'(v)\xi = \xi, \tag{3.11}$$

$$(\varepsilon + \mathcal{G}'(K(v)))K''(v)[\xi]^2 = -\mathcal{G}''(K(v))[K'(v)\xi]^2, \tag{3.12}$$

which implies that

$$K'(v) = (\varepsilon + \mathcal{G}'(K(v)))^{-1}$$

and

$$K''(v)[\xi]^2 = -(\varepsilon + \mathcal{G}'(K(v)))^{-1}\mathcal{G}''(K(v))[K'(v)\xi]^2,$$

respectively.

Locally around u^*, our control problem can therefore be equivalently formulated as

$$(\mathcal{P}_r) \qquad \begin{cases} \min\ \mathcal{J}(v) =: J(y(K(v)), K(v)) \\ \text{subject to} \\ a \le v \le b \text{ a.e.}, \\ v \in B_{r_0}(v^*). \end{cases}$$

THEOREM 3.2. *Let u^* be a local optimal solution of $(\mathcal{P})$. Then there exist Lagrange multipliers $\lambda \in V$, $q \in L^2_0(\Omega)$ and μ_a, $\mu_b \in \mathbf{L}^2(\Omega)$ such that*

$$\begin{aligned} -\nu\Delta y^* + (y^* \cdot \nabla)y^* + \nabla p &= u^*, \\ \text{div } y^* &= 0, \\ y^*|_\Gamma &= g, \end{aligned} \tag{3.13}$$

$$-\nu\Delta\lambda - (y^* \cdot \nabla)\lambda + (\nabla y^*)^T\lambda + \nabla q = z_d - y^* + \mu_a - \mu_b,$$

$$\text{div } \lambda^* = 0, \tag{3.14}$$

$$\lambda^*|_\Gamma = 0,$$

$$\lambda - \alpha u^* = \varepsilon(\mu_b - \mu_a), \tag{3.15}$$

$$a \le \varepsilon u + y^* \le b,$$

$$\mu_a,\ \mu_b \ge 0, \tag{3.16}$$

$$(\mu_{a_i}, a_i - \varepsilon u_i^* - y_i^*) = (\mu_{b_i}, b_i - \varepsilon u_i^* - y_i^*) = 0 \text{ for } i = 1, 2$$

hold in the variational sense.

Proof. Since u^* is a locally optimal solution of $(\mathcal{P})$, we get for some $r > 0$

$$J(y^*, u^*) \le J(y(u), u)$$

for all $u \in B_r(u^*)$ with $a \le \varepsilon u + y(u) \le b$. Equivalently, since $u = K(v)$ holds locally,

$$\mathcal{J}(v^*) \le \mathcal{J}(v)$$

for all $v \in B_{r_0}(v^*)$ with $a \le v \le b$ and for an appropriate constant $r_0 > 0$.

Therefore, the following first order necessary condition follows:

$$\mathcal{J}'(v^*)(v - v^*) \ge 0 \text{ for all } a \le v \le b. \tag{3.17}$$

Applying the chain rule, the derivative of $\mathcal{J}(v^*)$ in any direction $\xi \in \mathbf{L}^2(\Omega)$ is given by

$$(\mathcal{J}'(v^*), \xi) = (y^* - z_d, \mathcal{G}'(u^*)K'(v^*)\xi) + \alpha(u^*, K'(v^*)\xi), \tag{3.18}$$

which, by $h := K'(v^*)\xi$, yields

$$(\mathcal{J}'(v^*), \xi) = (y^* - z_d, \mathcal{G}'(u^*)h) + \alpha(u^*, h).$$

Denoting by $\mu \in \mathbf{L}^2(\Omega)$ the Riesz representative of $-\mathcal{J}'(v^*)$ and using explicitly the derivative of K we obtain

$$(\mu, \xi) = (\mu, (\varepsilon + \mathcal{G}'(u^*))h) = \varepsilon(\mu, h) + (\mu, \mathcal{G}'(u^*)h).$$

Therefore, (3.18) is equivalent to

$$(y^* - z_d + \mu, \mathcal{G}'(u^*)h) + (\alpha u^* + \varepsilon\mu, h) = 0. \tag{3.19}$$

We now introduce the adjoint system of equations

$$-\nu\Delta\lambda - (y^* \cdot \nabla)\lambda + (\nabla y^*)^T\lambda + \nabla q = z_d - y^* - \mu,$$

$$\text{div } \lambda^* = 0, \tag{3.20}$$

$$\lambda^*|_\Gamma = 0.$$

Since, by hypothesis $\nu > \mathcal{M}(y^*)$, the ellipticity of the adjoint operator can be easily verified and, therefore, for $z_d - y^* - \mu \in \mathbf{L}^2(\Omega)$, there exists a unique solution $\lambda \in V$ for the adjoint system.

Consequently, (3.19) can be rewritten as

$$\lambda - \alpha u^* = \varepsilon\mu. \tag{3.21}$$

Utilizing the decomposition $\mu = \mu_b - \mu_a$, with

$$\mu_b := \mu_+ = \frac{1}{2}(\mu + |\mu|),$$

$$\mu_a := \mu_- = \frac{1}{2}(-\mu + |\mu|),$$

where $|\mu| = (|\mu_1|, |\mu_2|)^T$, the optimality condition (3.17) can be rewritten as

$$(\mathcal{J}'(v^*), v^*) = \min_{a \le v \le b}(\mu_a - \mu_b, v) = \min_{a \le v \le b}\{(\mu_{a,1}, v_1) - (\mu_{b,1}, v_1) + (\mu_{a,2}, v_2) - (\mu_{b,2}, v_2)\}.$$

By fixing the second component of the new control variable $v_2 = v_2^*$ and considering the mutual disjoint sets $\{x : \mu_{a,1}(x) > 0\}$ and $\{x : \mu_{b,1}(x) > 0\}$, we obtain that

$$(\mathcal{J}'(v^*), v^*) = (\mu_{a,1}, a_1) - (\mu_{b,1}, b_1) + (\mu_{a,2}, v_2^*) - (\mu_{b,2}, v_2^*)$$

and, consequently,

$$(\mu_{a,1}, a_1 - \varepsilon u_1^* - y_1^*) - (\mu_{b,1}, b_1 - \varepsilon u_1^* - y_1^*) = 0.$$

Fixing now the first component of v and proceeding in a similar manner we get that

$$(\mu_{a,2}, a_2 - \varepsilon u_2^* - y_2^*) - (\mu_{b,2}, b_2 - \varepsilon u_2^* - y_2^*) = 0.$$

Taking into account that, by definition, $\mu_a,\ \mu_b \ge 0$ componentwise, the complementarity system (3.16) follows. □

Remark 3.3. Notice that the existence of μ_a, μ_b cannot be deduced in a standard way from Kuhn–Tucker theorems in Banach spaces, since the cone of nonnegative functions in $\mathbf{L}^2(\Omega)$ has an empty interior and we work just in this constraint space.

4. Second order sufficient condition. Next, we turn to second order sufficient optimality conditions for problem $(\mathcal{P})$. Following [22], the idea consists again in utilizing the second order sufficient optimality properties of the pure control constrained problem $(\mathcal{P}_r)$ and translate them to the original setting.

We begin by verifying the relation between the Lagrangian

$$\mathcal{L}(y, u, \lambda) = \frac{1}{2}\|y^* - z_d\|^2 + \frac{\alpha}{2}\|u\|^2 + \nu(\nabla\lambda, \nabla y) + c(y, y, \lambda) - (\lambda, u)$$

and the second derivative of the reduced functional $\mathcal{J}$.

LEMMA 4.1. *The second derivative of the reduced cost functional in direction ξ satisfies*

$$\mathcal{J}''(v^*)[\xi]^2 = \mathcal{L}''(y^*, u^*, \lambda)(w, h)^2, \tag{4.1}$$

where $h = K'(v^*)\xi$ and w is the solution to (3.2) *with h on the right-hand side.*

Proof. Considering the reduced cost functional and differentiating it twice in direction ξ we get

$$\begin{aligned}
&\mathcal{J}''(v^*)[\xi]^2 \\
&\quad = J''(K(v^*))[K'(v^*)\xi]^2 + J'(K(v^*))\ K''(v^*)[\xi]^2 \\
&\quad = \|\mathcal{G}'(K(v^*))K'(v^*)\xi\|^2 + (y(K(v^*)) - z_d, \mathcal{G}''(K(v^*))[K'(v^*)\xi]^2) \\
&\qquad + (y(K(v^*)) - z_d, \mathcal{G}'(K(v^*))K''(v^*)\xi^2) + \alpha\,\|K'(v^*)\xi\|^2 + \alpha(K(v^*), K''(v^*)\xi^2),
\end{aligned}$$

which, by the relations $h = K'(v^*)\xi,\ u^* = K(v^*),\ y^* = y(K(v^*)),\ w = \mathcal{G}'(u^*)h$, and $z = \mathcal{G}''(u^*)[h]^2$, yields

$$\begin{aligned}
(4.2)\quad \mathcal{J}''(v^*)[\xi]^2 &= \|w\|^2 + (y^* - z_d, z) \\
&\quad + (y^* - z_d, \mathcal{G}'(u^*)K''(v)\xi^2) + \alpha\,\|h\|^2 + \alpha(u^*, K''(v^*)\xi^2).
\end{aligned}$$

From the optimality condition (3.19) we get

$$(y^* - z_d, \mathcal{G}'(u^*)K''(v^*)\xi^2) + \alpha(u^*, K''(v^*)\xi^2) = -(\mu, (\varepsilon + \mathcal{G}'(u^*))K''(v^*)\xi^2),$$

which implies that

$$\mathcal{J}''(v^*)[\xi]^2 = \|w\|^2 + \alpha\,\|h\|^2 + (y^* - z_d, z) - (\mu, (\varepsilon + \mathcal{G}'(u^*))K''(v^*)\xi^2).$$

Additionally, by (3.12) we find

$$-(\mu, (\varepsilon + \mathcal{G}'(u^*))K''(v^*)\xi^2) = (\mu, z).$$

From (3.14), using integration by parts and (3.3), we get that

$$\begin{aligned}
(y^* - z_d, z) - (\mu, (\varepsilon + \mathcal{G}'(u^*))K''(v^*)[\xi]^2) &= \nu(\Delta z, \lambda) - c(y^*, z, \lambda) - c(z, y^*, \lambda) \\
&= 2c(w, w, \lambda).
\end{aligned}$$

We thus obtain

$$\mathcal{J}''(v^*)[\xi]^2 = \|w\|^2 + \alpha\,\|h\|^2 + 2((w \cdot \nabla)w, \lambda).$$

On the other hand, computing the first and second derivatives of the Lagrangian yields

$$\begin{aligned}
\mathcal{L}'(y^*, u^*, \lambda)(w, h) &= (y^* - z_d, w) + \alpha(u^*, h) + \nu(\nabla\lambda, \nabla w) \\
&\quad + c(y^*, w, \lambda) + c(w, y^*, \lambda) - (\lambda, h), \\
\mathcal{L}''(y^*, u^*, \lambda)(w, h)^2 &= \|w\|^2 + \alpha\,\|h\|^2 + 2c(w, w, \lambda),
\end{aligned}$$

and consequently

$$(4.3)\qquad \mathcal{J}''(v^*)[\xi]^2 = \mathcal{L}''(y^*, u^*, \lambda)(w, h)^2 = \|w\|^2 + \alpha\,\|h\|^2 + 2c(w, w, \lambda),$$

where w is a solution of (3.2) with h on the right-hand side. ∎

Let us now introduce the set of strongly active constraints

$$\mathcal{A}_{\tau,i} := \{x \in \Omega : |\mu_i(x)| \geq \tau\},\ i = 1, \dots, d,$$

and the critical cone

$$\tilde{C}_\tau = \left\{ \begin{array}{c} \\ v \in \mathbf{L}^2(\Omega) : \\ \\ \end{array} \begin{array}{c} v_i(x) = 0 \text{ if } x \in \mathcal{A}_{\tau,i}, \\ v_i(x) \geq 0 \text{ if } v_i^*(x) = a_i, x \notin \mathcal{A}_{\tau,i}, \\ v_i(x) \leq 0 \text{ if } v_i^*(x) = b_i, x \notin \mathcal{A}_{\tau,i} \end{array} \right\}.$$

For the investigation of optimality for a given stationary pair (y^*, u^*) let us hereafter assume that the following second order condition holds: there exist $\tau > 0$, $\delta > 0$ such that

$$\mathcal{L}''(y^*, u^*, \lambda)(w, h)^2 \geq \delta \|h\|^2 \tag{SSC}$$

for all $(w, h) \in C_\tau$, where C_τ consists of all pairs $(w, h) \in V \times \mathbf{L}^2(\Omega)$ such that $\varepsilon h + w \in \tilde{C}_\tau$ and

$$\begin{aligned} -\nu\Delta w + (w \cdot \nabla)y^* + (y^* \cdot \nabla)w + \nabla\pi &= h, \\ \text{div } w &= 0, \\ w|_\Gamma &= 0. \end{aligned} \tag{4.4}$$

THEOREM 4.2. *If u^* is a stationary point of $(\mathcal{P})$ and* (SSC) *holds for some $\delta > 0$, $\tau > 0$, then there exist constants $\rho > 0$ and $\sigma > 0$ such that*

$$J(y, u) \geq J(y^*, u^*) + \sigma \|u - u^*\| \tag{4.5}$$

for all pairs (y, u) such that $y = G(u), a \leq \varepsilon u + y \leq b$, and $\|u - u^*\| \leq \rho$.

Proof. Utilizing (3.11), (4.1), and (SSC) it follows that

$$\mathcal{J}''(v^*)[\xi]^2 \geq \delta \left\|(\varepsilon + \mathcal{G}'(u^*))^{-1}\xi\right\|^2,$$

which using the continuity of the mapping $(\varepsilon + \mathcal{G}'(u^*))$ yields

$$\mathcal{J}''(v^*)[\xi]^2 \geq \delta \left(\frac{1}{\|\varepsilon + \mathcal{G}'(u^*)\|} \|\xi\|\right)^2 = \delta \|\varepsilon + \mathcal{G}'(u^*)\|^{-2} \|\xi\|^2 = \tilde{\delta} \|\xi\|^2.$$

Using the second order sufficient conditions for the reduced problem (cf. [24, p. 190]), we get the existence of constants $\tilde{\rho} > 0,\ \tilde{\sigma} > 0$ such that

$$\mathcal{J}(v) \geq \mathcal{J}(v^*) + \tilde{\sigma} \|v - v^*\|^2$$

for all $a \leq v \leq b,\ \|v - v^*\| \leq \tilde{\rho}$.

By the implicit function theorem there exist constants $r,\ r_0 > 0$ such that for all $v \in \mathbf{L}^2(\Omega)$ with $\|v - v^*\| \leq r_0$, there is a $u = K(v)$ which satisfies $\|u - u^*\| \leq r$.

Taking $\hat{\rho} = \min(\tilde{\rho}, r_0)$ we have that $\|u - u^*\| \leq r$ and

$$J(u) \geq J(u^*) + \tilde{\sigma} \|v - v^*\|^2 \tag{4.6}$$

$$= J(u^*) + \tilde{\sigma} \|\varepsilon(u - u^*) + \mathcal{G}(u) - \mathcal{G}(u^*)\|^2. \tag{4.7}$$

From the quadratic nature of the Navier–Stokes nonlinear term we obtain, using Taylor expansion, that

$$\mathcal{G}(u) - \mathcal{G}(u^*) = \mathcal{G}'(u^*)(u-u^*) + \frac{1}{2}\mathcal{G}''(u^*)[u-u^*]^2,$$

which, considering (4.7), implies that

$$J(u) \geq J(u^*) + \tilde{\sigma}\left\|(\varepsilon + \mathcal{G}'(u^*))(u-u^*) + \frac{1}{2}\mathcal{G}''(u^*)(u-u^*)^2\right\|^2 \tag{4.8}$$

$$\geq J(u^*) + \tilde{\sigma}\left(\|(\varepsilon + \mathcal{G}'(u^*))(u-u^*)\| - \left\|\frac{1}{2}\mathcal{G}''(u^*)(u-u^*)^2\right\|\right)^2. \tag{4.9}$$

Since the operator $(\varepsilon + \mathcal{G}'(u^*))^{-1}$ is linear and continuous we get that

$$\begin{aligned}\|u-u^*\| &= \left\|(\varepsilon + \mathcal{G}'(u^*))^{-1}(\varepsilon + \mathcal{G}'(u^*))(u-u^*)\right\| \\ &\leq \left\|(\varepsilon + \mathcal{G}'(u^*))^{-1}\right\| \|(\varepsilon + \mathcal{G}'(u^*))(u-u^*)\|,\end{aligned}$$

which implies that

$$\|(\varepsilon + \mathcal{G}'(u^*))(u-u^*)\| \geq \frac{1}{\|(\varepsilon + \mathcal{G}'(u^*))^{-1}\|}\|u-u^*\| = \bar{C}\|u-u^*\|.$$

Additionally, possibly by reducing r,

$$\left\|\frac{1}{2}\mathcal{G}''(u^*)[u-u^*]^2\right\| \leq \frac{\bar{C}}{2}\|u-u^*\|.$$

Therefore, we get that

$$J(u) \geq J(u^*) + \tilde{\sigma}\left(\bar{C}\|u-u^*\| - \frac{\bar{C}}{2}\|u-u^*\|\right)^2 = J(u^*) + \sigma\|u-u^*\|^2$$

with $\sigma := \frac{\tilde{\sigma}\bar{C}^2}{4}$ and, consequently, the local optimality of u^* and the quadratic rate follow. □

Remark 4.3. For the analysis of second order numerical methods, a stronger condition is needed (see [19, 24]): there exist constants $\tau > 0,\ \delta > 0$ such that

$$\mathcal{L}''(y^*, u^*, \lambda)(w,h)^2 \geq \delta\|h\|^2 \tag{$\overline{SSC}$}$$

for all pairs $(w,h) \in V \times \mathbf{L}^2(\Omega)$ that solve (4.4) and satisfy $\varepsilon h_i + w_i = 0$ on $\mathcal{A}_{\tau,i}$ for $i = 1, \ldots, d$.

5. Semismooth Newton method. In this section we propose a semismooth Newton method for the numerical solution of $(\mathcal{P})$. The infinite dimensional method is applied to the optimality system (3.13)–(3.16) and superlinear convergence is proved. Additionally, the close relationship between semismooth Newton and primal-dual active set methods (see [17]) allows a practical formulation of the algorithm in terms of active and inactive sets.

We begin by reformulating the complementarity system (3.16) as the operator equation

$$\mu = \max(0, \mu + c(v-b)) + \min(0, \mu + c(v-a)) \tag{5.1}$$

for all $c > 0$. Equation (5.1) suggests an update strategy based on active and inactive sets information.

DEFINITION 5.1. *Let X and Z be Banach spaces and $D \subset X$ an open subset. The mapping $F : D \to Z$ is called Newton differentiable in the open subset $U \subset D$ if there exists a mapping $\Psi : U \to L(X, Z)$ such that*

$$\lim_{h\to 0} \frac{1}{\|h\|} \|F(x+h) - F(x) - \Psi(x+h)h\| = 0$$

for every $x \in U$.

Since the $\max(0,\cdot)$ and $\min(0,\cdot)$ functions are Newton differentiable (see [7, 17]) from $L^p(\Omega) \to L^q(\Omega)$, with $q < p$, the application of the semismooth Newton method is justified with the special choice $c := \alpha/\varepsilon^2$ (see Theorem 5.5 below). The complete algorithm is defined through the following steps.

ALGORITHM 5.2.

1. *Initialize the variables $u_0 \in \mathbf{L}^2(\Omega)$, $y_0 \in V$, $\mu_0 = 0$, and set $k = 1$.*
2. *Until a stopping criterion is satisfied, set, for $i = 1, \dots, d$,*

$$\mathcal{A}_{b_i}^n = \left\{ x : \mu_i^{n-1} + \frac{\alpha}{\varepsilon^2}\left(\varepsilon u_i^{n-1} + y_i^{n-1} - b_i\right) > 0 \right\},$$

$$\mathcal{A}_{a_i}^n = \left\{ x : \mu_i^{n-1} + \frac{\alpha}{\varepsilon^2}(\varepsilon u_i^{n-1} + y_i^{n-1} - a_i) < 0 \right\},$$

$$\mathcal{I}_i^n = \Omega \backslash (\mathcal{A}_{b_i}^n \cup \mathcal{A}_{a_i}^n),$$

and find the solution (y, p, λ, q) of

(5.2)

$$-\nu\Delta y_i + y_1^{n-1}\partial_1 y_i + y_2^{n-1}\partial_2 y_i + y_1\partial_1 y_i^{n-1} + y_2\partial_2 y_i^{n-1} + \partial_i p = y_1^{n-1}\partial_1 y_i^{n-1} + y_2^{n-1}\partial_2 y_i^{n-1} + \begin{cases} \frac{1}{\varepsilon}(b_i - y_i) & \text{on } \mathcal{A}_{b_i}^n, \\ \frac{\lambda_i}{\alpha} & \text{on } \mathcal{I}_i^n, \\ \frac{1}{\varepsilon}(a_i - y_i) & \text{on } \mathcal{A}_{a_i}^n, \end{cases}$$

$$\operatorname{div} y = 0,$$

$$y|_\Gamma = g,$$

(5.3)

$$-\nu\Delta\lambda_i + \frac{1}{\varepsilon}\lambda_i - y_1\partial_1\lambda_i^{n-1} - y_2\partial_2\lambda_i^{n-1} - y_1^{n-1}\partial_1\lambda_i - y_2^{n-1}\partial_2\lambda_i + \lambda_1\partial_i y_1^{n-1} + \lambda_2\partial_i y_2^{n-1} + \lambda_1^{n-1}\partial_i y_1 + \lambda_2^{n-1}\partial_i y_2 + \partial_i q = z_{d,i} - y_i - y_1^{n-1}\partial_1\lambda_i^{n-1} - y_2^{n-1}\partial_2\lambda_i^{n-1} + \lambda_1^{n-1}\partial_i y_1^{n-1} + \lambda_2^{n-1}\partial_i y_2^{n-1} + \begin{cases} \frac{\alpha}{\varepsilon^2}(b_i - y_i) & \text{on } \mathcal{A}_{b_i}^n, \\ \frac{\lambda_i}{\varepsilon} & \text{on } \mathcal{I}_i^n, \\ \frac{\alpha}{\varepsilon^2}(a_i - y_i) & \text{on } \mathcal{A}_{a_i}^n, \end{cases}$$

$$\operatorname{div} \lambda = 0,$$

$$\lambda|_\Gamma = 0.$$

Set

$$(y^n,p^n,\lambda^n,q^n)=(y,p,\lambda,q),u_i^n=\begin{cases}\frac{1}{\varepsilon}(b_i-y_i^n) & \text{on } \mathcal{A}_{b_i}^n,\\ \frac{\lambda_i^n}{\alpha} & \text{on } \mathcal{I}_i^n,\\ \frac{1}{\varepsilon}(a_i-y_i^n) & \text{on } \mathcal{A}_{a_i}^n,\end{cases}\quad \mu^n=\frac{1}{\varepsilon}(\lambda^n-\alpha u^n),$$

and go to step 2.

Note that the system to be solved in step 2 corresponds to the optimality system of the optimal control problem

(5.4)

$$\begin{cases}\min\limits_{\delta_x\in V\times\tilde{C}^n} \frac{1}{2}\langle\mathcal{L}''(x^{n-1},\lambda^{n-1})\delta_x,\delta_x\rangle+\langle\mathcal{L}'(x^{n-1},\lambda^{n-1}),\delta_x\rangle\\ \qquad +\frac{\alpha}{2\varepsilon^2}\sum\limits_{i=1}^d\int_{\mathcal{A}_{b_i}^n}\left|b_i-y_i^{n-1}-\delta_{y_i}\right|^2dx+\frac{\alpha}{2\varepsilon^2}\sum\limits_{i=1}^d\int_{\mathcal{A}_{a_i}^n}\left|a_i-y_i^{n-1}-\delta_{y_i}\right|^2dx\\ \qquad +\frac{1}{\varepsilon}\sum\limits_{i=1}^d\int_{\mathcal{A}_{b_i}^n}\lambda_i^{n-1}\cdot\delta_{y_i}\,dx+\frac{1}{\varepsilon}\sum\limits_{i=1}^d\int_{\mathcal{A}_{a_i}^n}\lambda_i^{n-1}\cdot\delta_{y_i}\,dx\\ \text{subject to}\\ -\nu\Delta\delta_{y_i}+y_1^{n-1}\partial_1\delta_{y_i}+y_2^{n-1}\partial_2\delta_{y_i}+\delta_{y_1}\partial_1y_i^{n-1}+\delta_{y_2}\partial_2y_i^{n-1}+\partial_ip^n\\ \qquad =\nu\Delta y_i^{n-1}-y_1^{n-1}\partial_1y_i^{n-1}-y_2^{n-1}\partial_2y_i^{n-1}+\begin{cases}\frac{1}{\varepsilon}(b_i-y_i^{n-1}-\delta_{y_i}) & \text{on } \mathcal{A}_{b_i}^n,\\ u_i^{n-1}+\delta_{u_i} & \text{on } \mathcal{I}_i^n,\\ \frac{1}{\varepsilon}(a_i-y_i^{n-1}-\delta_{y_i}) & \text{on } \mathcal{A}_{a_i}^n,\end{cases}\\ \operatorname{div}\delta_y=0,\\ \delta_y|_\Gamma=-y^{n-1}|_\Gamma+g,\end{cases}$$

where $x^n=(y^n,u^n)$, $\delta_x=x^n-x^{n-1}$, and

$$\tilde{C}^n:=\left\{h\in\mathbf{L}^2(\Omega):h_i(x)=0 \text{ for } x\in\mathcal{A}_{b_i}^n\cup\mathcal{A}_{a_i}^n,\ i=1,\dots,d\right\}.$$

Problem (5.4) corresponds to a quadratic control problem with affine constraints. Existence and uniqueness of a solution, as well as existence of Lagrange multipliers, will be verified next.

THEOREM 5.3. *Let $u^*\in U$ be a stationary point of $(\mathcal{P})$ that satisfies the second order condition $(\overline{SSC})$. If $\mathcal{I}_i^n\subset\mathcal{I}_{\tau,i}$, with $\mathcal{I}_{\tau,i}:=\Omega\backslash\mathcal{A}_{\tau,i}$, $i=1,\dots,d$, and $\|y^{n-1}-y^*\|_V$, $\|\lambda^{n-1}-\lambda^*\|_V$ are sufficiently small, then there exists a unique solution for system* (5.2)–(5.3).

Proof. Existence of Lagrange multipliers for (5.4) follows from the satisfaction of the regular point condition (see [20]), which in the present case is fulfilled if there exists a unique weak solution $w\in V$ of

$$\begin{aligned}-\nu\Delta w+(w\cdot\nabla)y^{n-1}+(y^{n-1}\cdot\nabla)w+\nabla\pi&=h,\\ \operatorname{div}w&=0,\\ w|_\Gamma&=0\end{aligned}\tag{5.5}$$

with $\varepsilon h+w\in\tilde{C}^n$. Multiplying both sides of (5.5) by w, existence and uniqueness follow from the Lax–Milgram theorem if the coercivity condition $\nu>\mathcal{M}(y^{n-1})$ holds.

From the definition of $\mathcal{M}(\cdot)$ we get that

$$\begin{aligned}\nu - \mathcal{M}(y^{n-1}) &= \nu - \sup_{w\in V} \frac{|c(w, y^{n-1}, w)|}{\|w\|_V^2} \\ &\geq \nu - \sup_{w\in V} \frac{|c(w, y^{n-1} - y^*, w)|}{\|w\|_V^2} - \mathcal{M}(y^*) \\ &\geq \nu - \mathcal{M}(y^*) - \mathcal{N}\left\|y^{n-1} - y^*\right\|_V.\end{aligned}$$

Choosing $\|y^{n-1} - y^*\|_V \leq \frac{\nu - \mathcal{M}(y^*)}{2\mathcal{N}}$ yields

$$\nu - \mathcal{M}(y^{n-1}) \geq \frac{\nu - \mathcal{M}(y^*)}{2} > 0,$$

and, thus, each solution of (5.4) satisfies the optimality system (5.2)–(5.3).

On the other hand, to see that a solution to (5.2)–(5.3) corresponds to the solution of (5.4) a second order condition has to hold. Denoting by $L(\delta_y, \delta_u)$ the Lagrangian of (5.4), the second order condition can be stated as follows: there exists a constant $\rho > 0$ such that

$$L''(\delta_y, \delta_u)(w, h)^2 \geq \rho \|h\|^2 \tag{5.6}$$

for all $(w, h) \in V \times \mathbf{L}^2(\Omega)$ that solve (5.5) and satisfy $\varepsilon h + w \in \tilde{C}^n$. Taking such a (w, h) arbitrary but fixed, we introduce the decomposition $(w, h) = (\xi, \bar{h}) + (\psi, \underline{h})$ with $\xi \in V$ a weak solution of

$$\begin{aligned}-\nu\Delta\xi + (\xi\cdot\nabla)y^* + (y^*\cdot\nabla)\xi + \nabla\pi_1 &= \bar{h}, \\ \operatorname{div}\xi &= 0, \\ \xi|_\Gamma &= 0,\end{aligned} \tag{5.7}$$

with

$$\bar{h}_i := \begin{cases} -\frac{1}{\varepsilon}\xi_i & \text{on } \mathcal{A}^n_{b_i}, \\ h_i & \text{on } \mathcal{I}^n_i, \\ -\frac{1}{\varepsilon}\xi_i & \text{on } \mathcal{A}^n_{a_i} \end{cases}$$

for $i = 1, \ldots, d$, and $\psi \in V$ a weak solution of

$$\begin{aligned}-\nu\Delta\psi + (\psi\cdot\nabla)y^{n-1} + (y^{n-1}\cdot\nabla)\psi + \nabla\pi_2 \\ = -((y^{n-1} - y^*)\cdot\nabla)\xi - (\xi\cdot\nabla)(y^{n-1} - y^*) + \underline{h}, \\ \operatorname{div}\psi = 0, \\ \psi|_\Gamma = 0\end{aligned} \tag{5.8}$$

with

$$\underline{h}_i = \begin{cases} -\frac{1}{\varepsilon}\psi_i & \text{on } \mathcal{A}^n_{b_i}, \\ 0 & \text{on } \mathcal{I}^n_i, \\ -\frac{1}{\varepsilon}\psi_i & \text{on } \mathcal{A}^n_{a_i} \end{cases}$$

for $i = 1, \dots, d$. We therefore get that $(\xi, \bar{h})$ solves (5.7) and satisfies $\varepsilon\bar{h} + \xi \in \tilde{C}^n$. From (4.3) and using Cauchy–Schwarz we thus obtain

$$L''(\delta_y, \delta_u)(w,h)^2 \geq \|\xi\|^2 + \alpha \left\|\bar{h}\right\|^2 - 2\|\xi\|\,\|\psi\| - 2\alpha \left\|\bar{h}\right\| \|\underline{h}\| + 2c(w, w, \lambda^{n-1}),$$

which implies, using the properties of the trilinear form, that

$$\begin{aligned} L''(\delta_y, \delta_u)(w,h)^2 &\geq \mathcal{L}''(y^*, u^*, \lambda^*)(\xi, \bar{h})^2 - 2\|\xi\|\,\|\psi\| - 2\alpha \left\|\bar{h}\right\| \|\underline{h}\| \\ &\quad - 2\mathcal{N}\|\xi\|_V^2 \left\|\lambda^{n-1} - \lambda^*\right\|_V - 4\mathcal{N}\|\xi\|_V \|\psi\|_V \left\|\lambda^{n-1}\right\|_V - 2\mathcal{N}\|\psi\|_V^2 \left\|\lambda^{n-1}\right\|_V. \end{aligned}$$

From (5.7) and (5.8) it can be verified that the following estimates hold:

$$\|\xi\|_V \leq \kappa\sigma \left\|\bar{h}\right\|, \tag{5.9}$$

$$\|\psi\|_V \leq 4\mathcal{N}\kappa\sigma^2 \left\|y^{n-1} - y^*\right\|_V \left\|\bar{h}\right\|, \tag{5.10}$$

with $\sigma := (\nu - \mathcal{M}(y^*))^{-1}$.

Since by hypothesis u^* satisfies $(\overline{SSC})$ and $\mathcal{I}_i^n \subset \mathcal{I}_{\tau,i}$, it follows that $\varepsilon\bar{h} + \xi = 0$ on $\mathcal{A}_{\tau,i}$ and, using estimates (5.9), (5.10),

$$\begin{aligned} &L''(\delta_y, \delta_u)(w,h)^2 \\ &\quad \geq \delta \left\|\bar{h}\right\|^2 - 8\mathcal{N}\kappa^4\sigma^3 \left\|y^{n-1} - y^*\right\|_V \left\|\bar{h}\right\|^2 - \frac{8}{\varepsilon}\alpha\mathcal{N}\kappa^2\sigma^2 \left\|y^{n-1} - y^*\right\|_V \left\|\bar{h}\right\|^2 \\ &\quad\quad - 2\mathcal{N}\kappa^2\sigma^2 \left\|\lambda^{n-1} - \lambda^*\right\|_V \left\|\bar{h}\right\|^2 - 16\mathcal{N}^2\kappa^2\sigma^3 \left\|\lambda^{n-1}\right\|_V \left\|y^{n-1} - y^*\right\|_V \left\|\bar{h}\right\|^2 \\ &\quad\quad - 32\mathcal{N}^3\kappa^2\sigma^4 \left\|\lambda^{n-1}\right\|_V \left\|y^{n-1} - y^*\right\|_V^2 \left\|\bar{h}\right\|^2. \end{aligned}$$

Choosing $\|y^{n-1} - y^*\|_V$ and $\|\lambda^{n-1} - \lambda^*\|_V$ sufficiently small such that

$$\begin{aligned} \rho := \delta &- 2\mathcal{N}\kappa^2\sigma^2 \left\|\lambda^{n-1} - \lambda^*\right\|_V - 8\mathcal{N}\kappa^2\sigma^2 \left\|y^{n-1} - y^*\right\|_V \big[\kappa^2\sigma + \alpha/\varepsilon \\ &+ 2\mathcal{N}\sigma \left\|\lambda^{n-1}\right\|_V + 4\mathcal{N}^2\sigma^2 \left\|\lambda^{n-1}\right\|_V \left\|y^{n-1} - y^*\right\|_V\big] > 0, \end{aligned}$$

condition (5.6) is satisfied.

Therefore, system (5.2)–(5.3) is uniquely solvable since it corresponds to the solution of a linear quadratic control problem with convex objective. ∎

Remark 5.4. From the definition of the inactive sets, it can be verified that the condition $\mathcal{I}_i^n \subset \mathcal{I}_{\tau,i}$ holds for $\|y^{n-1} - y^*\|_V$ and $\|\lambda^{n-1} - \lambda^*\|_V$ sufficiently small.

By considering the state variable y and the newly defined control variable v, the optimal control problem $(\mathcal{P})$ can locally also be expressed as the following control constrained optimal control problem:

(5.11)
$$\begin{cases} \min\ J(y,v) = \frac{1}{2}\int_\Omega |y - z_d|^2\,dx + \frac{\alpha}{2\varepsilon^2}\int_\Omega |v|^2\,dx - \frac{\alpha}{\varepsilon^2}\int_\Omega v\ y\,dx + \frac{\alpha}{2\varepsilon^2}\int_\Omega |y|^2\,dx \\ \text{subject to} \\ -\nu\Delta y + \frac{1}{\varepsilon}y + (y\cdot\nabla)y + \nabla p = \frac{1}{\varepsilon}v, \\ \operatorname{div} y = 0, \\ y|_\Gamma = g, \\ a \leq v \leq b \text{ a.e.} \end{cases}$$

The presence of the mixed term $\frac{\alpha}{\varepsilon^2}\int_\Omega v\ y\ dx$ in the cost functional is responsible for a different problem structure which does not allow the application of already known results about convergence of the semismooth Newton method for control constrained optimal control problems (see [9, 17]).

In the next theorem sufficient conditions for the local superlinear convergence of the semismooth Newton method are stated.

THEOREM 5.5. *Let $u^* \in U$ be a stationary point of $(\mathcal{P})$ that satisfies $(\overline{SSC})$. If $\|\lambda^*\|_V < \frac{\alpha^{1/2}}{4\varepsilon}(\nu - \mathcal{M}(y^*))(\frac{\varepsilon(\alpha+\varepsilon^2)-\alpha}{\varepsilon^{1/2}(\alpha+\varepsilon^2)^{1/2}+\alpha^{1/2}})$ and $\|y^0 - y^*\|_V$, $\|\lambda^0 - \lambda^*\|_V$ are sufficiently small, then the sequence $\{(y^n, v^n, \lambda^n, \mu^n)\}$ generated by the algorithm converges superlinearly in $\mathbf{H}^1(\Omega)\times\mathbf{L}^2(\Omega)\times V\times\mathbf{L}^2(\Omega)$ to $(y^*, u^*, \lambda^*, \mu^*)$. Moreover, there exists a constant $C > 0$ such that*

$$\begin{aligned}(5.12)\quad &\big\|(v^{n+1}-v^*, y^{n+1}-y^*, \lambda^{n+1}-\lambda^*)\big\|_{\mathbf{L}^2\times V\times V}\\ &\qquad\le C\left(\|y^n-y^*\|_V^2 + \|\lambda^n-\lambda^*\|_V^2\right) + o(\|(y^n-y^*, \lambda^n-\lambda^*)\|_{\mathbf{L}^p\times\mathbf{L}^p}).\end{aligned}$$

Proof. By considering system (3.13)–(3.16) and the system in step 2 of Algorithm 5.2, it can be verified that the increments $\delta_y = y^{n+1}-y^*$, $\delta_\lambda = \lambda^{n+1}-\lambda^*, \delta_u, \delta_\mu$, and δ_ϕ satisfy the system

$$\begin{aligned}(5.13)\quad &\nu(\nabla\delta_y, \nabla\phi) + \frac{1}{\varepsilon}(\delta_y, \phi) + c(y^n, \delta_y, \phi) + c(\delta_y, y^n, \phi)\\ &\qquad = \frac{1}{\varepsilon}(\delta_v, \phi) + (((y^n-y^*)\cdot\nabla)(y^n-y^*), \phi) \text{ for all } \phi\in V,\end{aligned}$$

$$\begin{aligned}(5.14)\quad &\nu(\nabla\delta_\lambda, \nabla\phi) - c(y^n, \delta_\lambda, \phi) - c(\delta_y, \lambda^n, \phi) + c(w, y^n, \delta_\lambda) + c(w, \delta_y, \lambda^n)\\ &\qquad = ((\nabla(y^n-y^*))^T(\lambda^n-\lambda^*) - ((y^n-y^*)\cdot\nabla)(\lambda^n-\lambda^*), \phi) - (\delta_y+\delta_\mu, \phi)\\ &\qquad \text{for all } \phi\in V.\end{aligned}$$

Introducing the auxiliary variable $\varphi := \varepsilon\mu + \frac{\alpha}{\varepsilon}v$ and considering (3.15) and (5.1) together with the semismooth Newton update for u^n and μ^n, we also obtain that

$$(5.15)\qquad \delta_\lambda - \frac{\alpha}{\varepsilon}\delta_v + \frac{\alpha}{\varepsilon}\delta_y = \varepsilon\delta_\mu,$$

$$(5.16)\qquad \delta_\varphi = \varepsilon\delta_\mu + \frac{\alpha}{\varepsilon}\delta_v,$$

$$(5.17)\qquad \delta_\varphi - \frac{\alpha}{\varepsilon}\delta_v = G^n_{\max}(\delta_\varphi) + G^n_{\min}(\delta_\varphi) + R,$$

where

$$G^n_{\max,i}(\phi) = \begin{cases}\phi \text{ on } \mathcal{A}^{n+1}_{b_i},\\ 0 \text{ on } \Omega\backslash\mathcal{A}^{n+1}_{b_i},\end{cases} \quad\text{and}\quad G^n_{\min,i}(\phi) = \begin{cases}\phi \text{ on } \mathcal{A}^{n+1}_{a_i},\\ 0 \text{ on } \Omega\backslash\mathcal{A}^{n+1}_{a_i}\end{cases}$$

and

$$\begin{aligned}R = &\max\left(0, \varphi^* + (\varphi^n-\varphi^*) - \frac{\alpha}{\varepsilon}b\right) - \max\left(0, \varphi^* - \frac{\alpha}{\varepsilon}b\right) - G^n_{\max}(\varphi^n-\varphi^*)\\ &+ \min\left(0, \varphi^* + (\varphi^n-\varphi^*) - \frac{\alpha}{\varepsilon}a\right) - \min\left(0, \varphi^* - \frac{\alpha}{\varepsilon}a\right) - G^n_{\min}(\varphi^n-\varphi^*).\end{aligned}$$

Due to Newton differentiability of the $\max(0,\cdot)$ and $\min(0,\cdot)$ functions (cf. [17]) from $L^p(\Omega) \to L^q(\Omega)$, with $q < p$, we therefore obtain that

$$\|R\|_{\mathbf{L}^2} = o(\|\varphi^n - \varphi^*\|_{\mathbf{L}^p}), \tag{5.18}$$

with $p > 2$.

Multiplying (5.17) by δ_v, we get that

$$-(R, \delta_v) = (G^n_{\max}(\delta_\varphi) + G^n_{\min}(\delta_\varphi), \delta_v) - (\delta_\varphi, \delta_v) + \frac{\alpha}{\varepsilon} \|\delta_v\|^2 . \tag{5.19}$$

Additionally, from the definition of $G^n_{\max}$ and $G^n_{\min}$,

$$(G^n_{\max}(\delta_\varphi) + G^n_{\min}(\delta_\varphi), \delta_v) - (\delta_\varphi, \delta_v) = (\delta_\varphi, \delta_v)_{\mathcal{I}^n}, \tag{5.20}$$

where $(v, w)_{\mathcal{I}^n} := \int_{\mathcal{I}^n} v \cdot w \, dx$.

On the other hand, substituting (5.15) into (5.14) and multiplying by δ_y, we get that

$$\begin{aligned} &\nu(\nabla\delta_\lambda, \nabla\delta_y) + \frac{1}{\varepsilon}(\delta_\lambda, \delta_y) - c(y^n, \delta_\lambda, \delta_y) - c(\delta_y, \lambda^n, \delta_y) \\ &\quad + c(\delta_y, y^n, \delta_\lambda) + c(\delta_y, \delta_y, \lambda^n) = ((\nabla(y^n - y^*))^T(\lambda^n - \lambda^*) \\ &\quad - ((y^n - y^*) \cdot \nabla)(\lambda^n - \lambda^*), \delta_y) - \|\delta_y\|^2 + \frac{\alpha}{\varepsilon^2}(\delta_v, \delta_y) - \frac{\alpha}{\varepsilon^2} \|\delta_y\|^2 , \end{aligned} \tag{5.21}$$

which, utilizing (5.13), multiplied by δ_λ yields

$$\begin{aligned} &\frac{1}{\varepsilon}(\delta_v, \delta_\lambda) + (((y^n - y^*) \cdot \nabla)(y^n - y^*), \delta_\lambda) - c(y^n, \delta_y, \delta_\lambda) - c(\delta_y, y^n, \delta_\lambda) \\ &\quad = ((\nabla(y^n - y^*))^T(\lambda^n - \lambda^*) - ((y^n - y^*) \cdot \nabla)(\lambda^n - \lambda^*), \delta_y) - \frac{\alpha}{\varepsilon^2} \|\delta_y\|^2 \\ &+ \frac{\alpha}{\varepsilon^2}(\delta_v, \delta_y) - \|\delta_y\|^2 + c(y^n, \delta_\lambda, \delta_y) + c(\delta_y, \lambda^n, \delta_y) - c(\delta_y, y^n, \delta_\lambda) - c(\delta_y, \delta_y, \lambda^n). \end{aligned} \tag{5.22}$$

Consequently, utilizing the properties of the trilinear form,

$$\begin{aligned} &\left(\frac{\alpha + \varepsilon^2}{\varepsilon^2}\right) \|\delta_y\|^2 + \frac{1}{\varepsilon}(\delta_v, \delta_\lambda) + \frac{\alpha}{\varepsilon^2}(\delta_v, \delta_y) - 2c(\delta_y, \lambda^n, \delta_y) = ((\nabla(y^n - y^*))^T(\lambda^n - \lambda^*) \\ &\quad - ((y^n - y^*) \cdot \nabla)(\lambda^n - \lambda^*), \delta_y) - (((y^n - y^*) \cdot \nabla)(y^n - y^*), \delta_\lambda) + \frac{2\alpha}{\varepsilon^2}(\delta_v, \delta_y) \end{aligned} \tag{5.23}$$

and therefore

$$\begin{aligned} \frac{1}{\varepsilon}(\delta_v, \delta_\varphi) \le \frac{2\alpha}{\varepsilon^2}(\delta_v, \delta_y) + 2\mathcal{N} \|\lambda^n\|_V \|\delta_y\|_V^2 - \left(\frac{\alpha + \varepsilon^2}{\varepsilon^2}\right) \|\delta_y\|^2 \\ + ((\nabla(y^n - y^*))^T(\lambda^n - \lambda^*) - ((y^n - y^*) \cdot \nabla)(\lambda^n - \lambda^*), \delta_y) \\ - (((y^n - y^*) \cdot \nabla)(y^n - y^*), \delta_\lambda). \end{aligned} \tag{5.24}$$

Let us now consider the increment equation (5.13) and multiply it by δ_y. We get the estimate

$$\nu \|\delta_y\|_V^2 + \frac{1}{\varepsilon}\|\delta_y\|^2 - \mathcal{M}(y^n)\|\delta_y\|_V^2 \le \frac{1}{\varepsilon}(\delta_v,\delta_y) + \mathcal{N}\|y^n - y^*\|_V^2 \|\delta_y\|_V , \tag{5.25}$$

which, by considering a y^* neighborhood such that

$$\nu - \mathcal{M}(y^n) \ge \frac{1}{2}(\nu - \mathcal{M}(y^*)) > 0 \tag{5.26}$$

and the Poincaré inequality, implies that

$$\frac{1}{2}(\nu - \mathcal{M}(y^*))\|\delta_y\|_V^2 + \frac{1}{\varepsilon}\|\delta_y\|^2 \le \frac{1}{\varepsilon}(\delta_v,\delta_y) + \mathcal{N}\|y^n - y^*\|_V^2 \|\delta_y\|_V . \tag{5.27}$$

Consequently, we obtain the estimate

$$\|\delta_y\|_V \le 2\sigma\left(\frac{\kappa}{\varepsilon}\|\delta_v\| + \mathcal{N}\|y^n - y^*\|_V^2\right), \tag{5.28}$$

with $\sigma := (\nu - \mathcal{M}(y^*))^{-1}$.

Using (5.27) in (5.24) and grouping terms yield

$$\begin{aligned}\frac{1}{\varepsilon}(\delta_v,\delta_\varphi) \le{}& \frac{2\alpha + 4\sigma\varepsilon\|\lambda^n\|_V}{\varepsilon^2}(\delta_v,\delta_y) - \left(\frac{\alpha + \varepsilon^2 + 4\sigma\varepsilon\|\lambda^n\|_V}{\varepsilon^2}\right)\|\delta_y\|^2 \\ &+ 4\mathcal{N}\sigma\|\lambda^n\|_V\|y^n - y^*\|_V^2\|\delta_y\|_V - (((y^n - y^*)\cdot\nabla)(y^n - y^*),\delta_\lambda) \\ &+ ((\nabla(y^n - y^*))^T(\lambda^n - \lambda^*) - ((y^n - y^*)\cdot\nabla)(\lambda^n - \lambda^*),\delta_y).\end{aligned} \tag{5.29}$$

Since

$$\begin{aligned}\left\| c\delta_v - \left(\frac{\alpha + \varepsilon^2 + 4\sigma\varepsilon\|\lambda^n\|_V}{\varepsilon^2}\right)^{1/2}\delta_y\right\|^2 ={}& c^2\|\delta_v\|^2 \\ &- \frac{2c}{\varepsilon}\left(\alpha + \varepsilon^2 + 4\sigma\varepsilon\|\lambda^n\|_V\right)^{1/2}(\delta_v,\delta_y) + \left(\frac{\alpha + \varepsilon^2 + 4\sigma\varepsilon\|\lambda^n\|_V}{\varepsilon^2}\right)\|\delta_y\|^2,\end{aligned} \tag{5.30}$$

we obtain, by choosing $c = \frac{\alpha + 2\sigma\varepsilon\|\lambda^n\|_V}{\varepsilon\sqrt{\alpha + \varepsilon^2 + 4\sigma\varepsilon\|\lambda^n\|_V}}$, that

$$\begin{aligned}\frac{1}{\varepsilon}(\delta_v,\delta_\varphi) \le{}& \frac{(\alpha + 2\sigma\varepsilon\|\lambda^n\|_V)^2}{\varepsilon^2(\alpha + \varepsilon^2 + 4\sigma\varepsilon\|\lambda^n\|_V)}\|\delta_v\|^2 + 4\mathcal{N}\sigma\|\lambda^n\|_V\|y^n - y^*\|_V^2\|\delta_y\|_V \\ &+ ((\nabla(y^n - y^*))^T(\lambda^n - \lambda^*) - ((y^n - y^*)\cdot\nabla)(\lambda^n - \lambda^*),\delta_y) - (((y^n - y^*)\cdot\nabla)(y^n - y^*),\delta_\lambda).\end{aligned} \tag{5.31}$$

Consequently, from (5.19)–(5.20) and (5.31) we therefore obtain

$$\begin{aligned}|(R,\delta_v)| \ge{}& \frac{\alpha}{\varepsilon}\|\delta_v\|^2 - \Bigg|\frac{(\alpha + 2\sigma\varepsilon\|\lambda^n\|_V)^2}{\varepsilon^2(\alpha + \varepsilon^2 + 4\sigma\varepsilon\|\lambda^n\|_V)}\|\delta_v\|_{\mathcal{I}^n}^2 \\ &+ ((\nabla(y^n - y^*))^T(\lambda^n - \lambda^*) - ((y^n - y^*)\cdot\nabla)(\lambda^n - \lambda^*),\delta_y)_{\mathcal{I}^n} \\ &- (((y^n - y^*)\cdot\nabla)(y^n - y^*),\delta_\lambda)_{\mathcal{I}^n} + 4\mathcal{N}\sigma\|\lambda^n\|_V\|y^n - y^*\|_V^2\|\delta_y\|_V\Bigg|,\end{aligned}$$

which, by considering a (y^*, λ^*) neighborhood such that

$$\|\lambda^n\|_V \leq 2\,\|\lambda^*\|_V\,, \tag{5.32}$$

implies that

$$\begin{aligned}|(R,\delta_v)| \geq \frac{\alpha}{\varepsilon}\,\|\delta_v\|^2 - \frac{(\alpha+4\sigma\varepsilon\,\|\lambda^*\|_V)^2}{\varepsilon^2(\alpha+\varepsilon^2)}\,\|\delta_v\|^2 \\ - \mathcal{N}\,\|y^n-y^*\|_V^2\,(8\sigma\,\|\lambda^*\|_V\,\|\delta_y\|_V + \|\delta_\lambda\|_V) \\ - 2\mathcal{N}\,\|y^n-y^*\|_V\,\|\lambda^n-\lambda^*\|_V\,\|\delta_y\|_V\,.\end{aligned}$$

Since, by hypothesis, $\|\lambda^*\|_V < \frac{\alpha^{1/2}}{4\varepsilon}(\nu - \mathcal{M}(y^*))\frac{\varepsilon(\alpha+\varepsilon^2)-\alpha}{\varepsilon^{1/2}(\alpha+\varepsilon^2)^{1/2}+\alpha^{1/2}}$, we get that

$$\beta := \frac{\alpha\varepsilon(\alpha+\varepsilon^2) - (\alpha+4\sigma\varepsilon\,\|\lambda^*\|_V)^2}{\varepsilon^2(\alpha+\varepsilon^2)} > 0, \tag{5.33}$$

and therefore

$$\begin{aligned}\beta\,\|\delta_v\|^2 \leq \|R\|\,\|\delta_v\| + \mathcal{N}\,\|y^n-y^*\|_V^2\,(8\sigma\,\|\lambda^*\|_V\,\|\delta_y\|_V + \|\delta_\lambda\|_V) \\ + 2\mathcal{N}\,\|y^n-y^*\|_V\,\|\lambda^n-\lambda^*\|_V\,\|\delta_y\|_V\,.\end{aligned} \tag{5.34}$$

On the other hand, by multiplying (5.14) by δ_λ we get that

$$\begin{aligned}\nu\,\|\delta_\lambda\|_V^2 + \frac{1}{\varepsilon}\,\|\delta_\lambda\|^2 - \mathcal{M}(y^n)\,\|\delta_\lambda\|_V^2 \leq 2\mathcal{N}\,\|\delta_y\|_V\,\|\lambda^n\|_V\,\|\delta_\lambda\|_V \\ + 2\mathcal{N}\,\|y^n-y^*\|_V\,\|\lambda^n-\lambda^*\|_V\,\|\delta_\lambda\|_V + \Big(\frac{\alpha}{\varepsilon^2}+1\Big)\,\|\delta_y\|\,\|\delta_\lambda\| + \frac{\alpha}{\varepsilon^2}\,\|\delta_v\|\,\|\delta_\lambda\|\,,\end{aligned} \tag{5.35}$$

which, considering (5.32) and (5.26), implies that

$$\begin{aligned}\frac{1}{2}(\nu - \mathcal{M}(y^*))\,\|\delta_\lambda\|_V \leq \left(\frac{\kappa^2\alpha}{\varepsilon^2} + \kappa^2 + 4\mathcal{N}\,\|\lambda^*\|_V\right)\left(\frac{\alpha+\varepsilon^2}{\varepsilon^2}\right)\|\delta_y\|_V \\ + \frac{\alpha}{\varepsilon^2}\,\|\delta_v\| + 2\mathcal{N}\,\|\lambda^n-\lambda^*\|_V\,\|y^n-y^*\|_V\,.\end{aligned} \tag{5.36}$$

Therefore, utilizing estimate (5.28), there exists a constant $\bar{C}$ such that

$$\|\delta_\lambda\|_V \leq \bar{C}(\|\delta_v\| + \|\lambda^n-\lambda^*\|_V^2 + \|y^n-y^*\|_V^2). \tag{5.37}$$

From the definition of φ and (5.18) we therefore obtain that

$$\|R\| = o(\|(y^n-y^*,\lambda^n-\lambda^*)\|_{\mathbf{L}^p\times\mathbf{L}^p}),$$

which, considering estimates (5.28) and (5.37) in (5.34), implies the existence of a constant C such that

$$\begin{aligned}\|(\delta_v,\delta_y,\delta_\lambda)\|_{\mathbf{L}^2\times V\times V} \leq C\left(\|y^n-y^*\|_V^2 + \|\lambda^n-\lambda^*\|_V^2\right) \\ + o(\|(y^n-y^*,\lambda^n-\lambda^*)\|_{\mathbf{L}^p\times\mathbf{L}^p}).\end{aligned} \tag{5.38}$$

Consequently, the superlinear convergence is verified. ∎

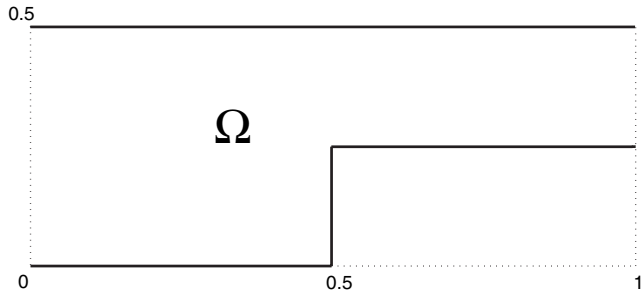

FIG. 6.1. *Forward facing step channel.*

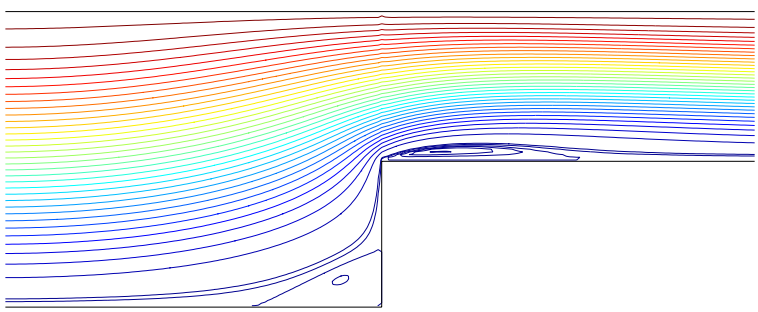

FIG. 6.2. *Streamlines of the uncontrolled state.*

6. Numerical results. For the numerical tests, a "forward facing step channel" was utilized (see Figure 6.1). The fluid flows from left to right with a parabolic inflow condition with the maximum value equal to one and "do nothing" outflow condition. In the remaining boundary parts a homogeneous Dirichlet condition was imposed. The geometry was discretized using a staggered grid and an upwinding finite differences scheme was applied. The behavior of the uncontrolled fluid flow with Reynolds number $Re = 1000$ is depicted in Figure 6.2. Two main recirculation zones, which increase their size together with the Reynolds number, can be clearly identified from the graphics.

The target of our control problem is to properly diminish the recirculations of interest by considering, together with the tracking-type cost functional, adequate pointwise control-state constraints.

For the solution of the optimality system, Algorithm 5.2 was utilized. The semismooth Newton algorithm stops when the $\mathbf{L}^2$-norm of the state increment is lower than 10^{-4}. Unless otherwise specified, the mesh step size $h = 1/240$ was considered. For the solution of the linear systems, MATLAB's exact solver was utilized.

6.1. Example 1. In this first experiment, we consider the elimination of bubbles in the channel by imposing the constraint $y_1 + \varepsilon u_1 \geq -10^{-7}$. For ε sufficiently small, this constraint avoids backward flow in the channel and thus possible recirculations. Additionally, the tracking-type component of the cost functional is responsible for a more linear behavior of the flow field. The remaining parameter data utilized are $h = 1/240$, $Re = 1000$, $\varepsilon = 10^{-4}$, and $\alpha = 0.1$. The semismooth Newton method (SSN) stops after 9 iterations, with the final active set containing 28 grid points. The cost functional takes the final value $J(y^*, u^*) = 0.00445224$ and the nonlinear

TABLE 6.1
Example 1: $h = 1/240$, $tol = 10^{-4}$.

ε	SSN iter.	$J(y^*, u^*)$	$\lvert\mathcal{A}^a \cup \mathcal{A}^b\rvert$
10^{-1}	5	0.00399972	33
10^{-2}	6	0.00410360	42
10^{-3}	8	0.00438273	29
10^{-4}	9	0.00445224	28
10^{-5}	9	0.00445989	32

complementarity function residuum the value 2.2737×10^{-9}. The optimal control field is depicted in Figure 6.3, where the concentration of the control action on the recirculation zones can be observed. The desired recirculation diminishing effect of the control can be visualized from the plot of the reached controlled state streamlines in Figure 6.4. In Table 6.1 the number of SSN iterations, the final cost functional value, and the size of the active set are registered for different ε values. It can be observed that as ε tends to 0, the problem becomes harder to solve and more SSN iterations are required.

Subsequently we consider the limit case where the tracking-type part of the cost functional is dismissed. We aim to find the control of minimum norm that allows the satisfaction of the state constraint $y_1 + \varepsilon u_1 \geq 10^{-7}$ over the domain of interest. As before, the constraint takes care that no important backward flow arises. By considering the constraint on the whole domain, i.e., $\Omega_S = \Omega$, both recirculations before and after the step are diminished (see Figure 6.5). From Figure 6.5 it can also be observed that the behavior of the fluid flow, mainly before the step, is not close

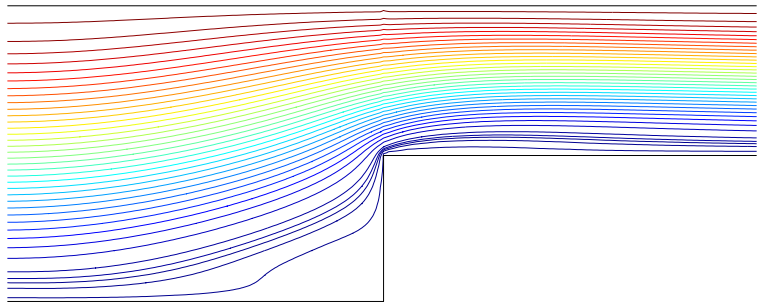

FIG. 6.5. *Example* 1: *Streamlines of the controlled state without tracking component.*

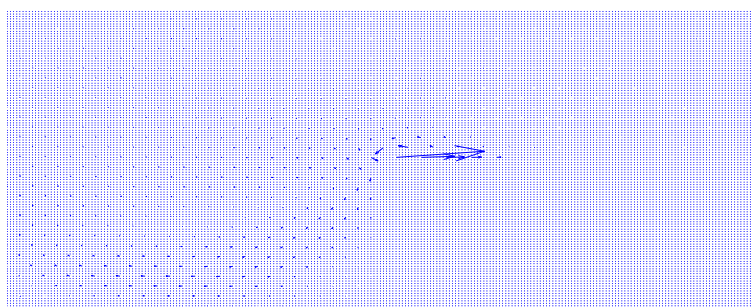

FIG. 6.6. *Example* 1: *Control vector field without tracking component.*

to the Stokes flow, as is the case when the tracking-type component is present. From the control vector plot (see Figure 6.6) it can be observed that the control action in this case is even more concentrated on the recirculations zones. The parameter values for this case are $Re = 1000$, $\varepsilon = 10^{-4}$, and $\alpha = 0.1$. The number of SSN iterations needed is 29 and the cost functional takes the final value 8.99816×10^{-4}.

In many practical cases, the recirculation reduction or elimination on the whole domain is not necessary, if not undesirable. In such cases the state constraint may be imposed in the sectors where the bubble to be diminished is localized. In the case of our geometry the essential recirculation to be diminished is the one after the step. By considering the state constraint on the subdomain $\Omega_S := [0.5, 0.75] \times [0.25, 0.5]$, this elimination is attached with the cost functional value 8.98898×10^{-4} in 6 SSN iterations. The final controlled state is shown in Figure 6.7, where it can be clearly seen that the recirculation after the step is numerically eliminated, although the one before the step becomes bigger than in the uncontrolled case.

6.2. Example 2. As an alternative strategy for the reduction of the recirculation after the step, we consider in this example a state constraint that guarantees a homogeneous outflow velocity. The constraint imposed is $y_1 + \varepsilon u_1 \leq 1.7$ and the remaining parameter values are $Re = 1000$, $\varepsilon = 10^{-3}$, and $\alpha = 0.01$. In this case, the SSN algorithm stops after 15 iterations and the resulting active set contains 2283 grid points. The cost functional takes the final value $J(y^*, u^*) = 0.003470768$. The controlled state is depicted in Figure 6.8, where an important reduction of the recirculations can be visualized.

Since the outgoing velocity is the quantity of interest, it is natural to consider the case where the constraint is imposed only in the last part of the channel. By

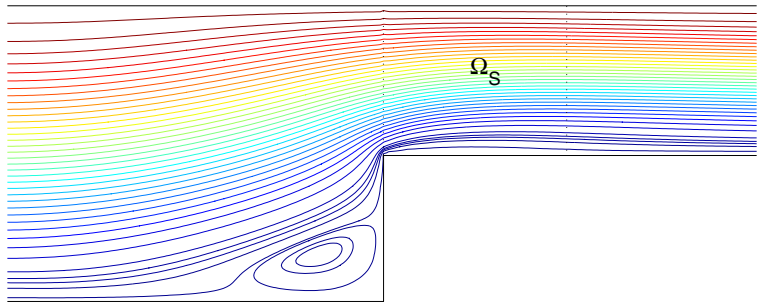

FIG. 6.7. *Example* 1: *Streamlines of the controlled state without tracking component; state constraint subdomain.*

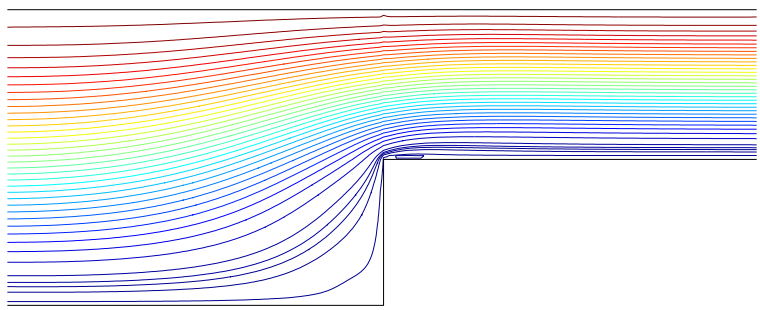

FIG. 6.8. *Example* 2: *Streamlines of the controlled state.*

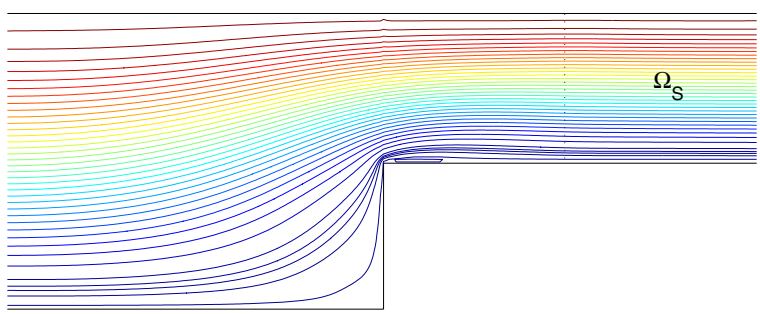

FIG. 6.9. *Example* 2: *Streamlines of the controlled state; state constraint subdomain.*

considering the domain $\Omega_S := [0.5, 0.75] \times [0.25, 0.5]$, the recirculation diminishing effect does also take place (see Figure 6.9), but with a lower final cost functional value $J(y^*, u^*) = 0.0031112131$. The SSN algorithm stops after 10 iterations with a final active set containing 906 active points. The remaining parameter values are the same as in the case $\Omega_S = \Omega$.

Finally, in order to visualize the structure of the control-state constraint multiplier, we modify the Reynolds number to 500 and impose the homogeneous outgoing velocity constraint $y_1 + \varepsilon u_1 \leq 1.7$. The evolution of the multiplier as ε decreases can be observed in Figure 6.10. In Table 6.2 the evolution of the SSN is registered. The algorithm stops after 7 iterations with the final active set containing 2465 grid points. As expected from the theoretical results, local superlinear convergence can be

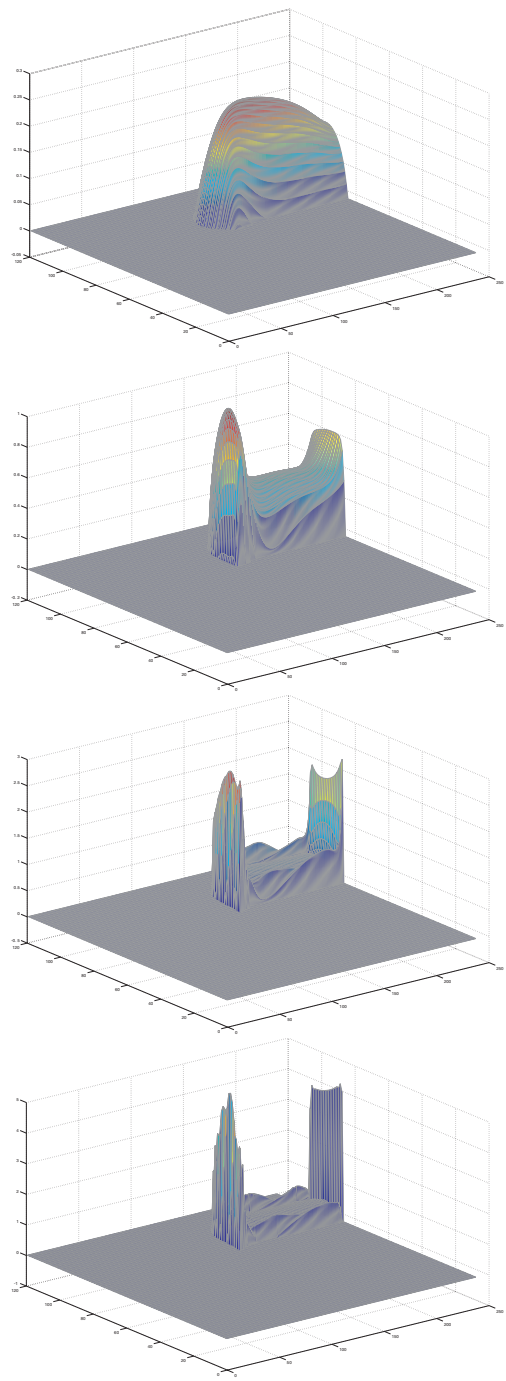

FIG. 6.10. *State constraint multiplier;* $\varepsilon = 10^{-1},\ \varepsilon = 10^{-2},\ \varepsilon = 10^{-3},\ \varepsilon = 10^{-4}$.

TABLE 6.2

A HARMONIC FRAMEWORK FOR CONTROLLABILITY IN LINEAR CONTINUOUS-TIME PERIODIC SYSTEMS*

JUN ZHOU†

Abstract. Controllability of linear continuous-time periodic systems is dealt with via a harmonic analysis approach for the first time in this paper. This approach reveals that controllability of continuous-time periodic systems can be connected to necessary and sufficient conditions expressed explicitly with Fourier coefficients of the system matrices, which can be interpreted in a way similar to what we have seen in linear time-invariant cases. These controllability conditions shed new light upon structural characteristics of continuous-time periodic systems that are hard to know by means of existing time-domain controllability criteria in the literature. Controllability canonical decomposition of linear continuous-time periodic systems is revisited through state coordinate transforms of strong analytic features. The results are heuristic and significant for examining structural characteristics of continuous-time periodic systems and extending controllability-related techniques that are widely employed in linear time-invariant systems to linear continuous-time periodic systems.

1. Introduction.

Controllability is one of the structural characteristics in dynamical systems, and plays an irreplaceable role in analysis techniques and synthesis algorithms in control theory. For example, in linear time-invariant (LTI) control systems, zero/pole structural algebra [30], [32], geometric theory [39], frequency-domain techniques for multivariable control [36], linear matrix inequalities [6], H_2/H_∞ robust performance designs [13], [22], [44], and so on cannot proceed without controllability. This is also the case for engineering applications involving finite-dimensional linear continuous-time periodic (FDLCP) systems [20], [18], [21], [25], among which typical problems include stabilization of helicopter rotors and ships in waves, and reduction of electromechanical oscillations in electricity generators [9], [10], [14], [28], [29]. As a matter of fact, controllability is a prerequisite to many problems involving FDLCP modelings, for instance, in periodic Riccati [1] and Lyapunov differential equations [5]. Unfortunately, however, due to the time-varying feature of FDLCP systems, controllability and its relevant structural properties in FDLCP systems still need further scrutiny, compared with the situation in LTI systems, though various controllability concepts and corresponding criteria are introduced and lasting efforts have been made [1], [7], [11], [15], [17], [33], [34] over the last dozens of years.

Now we simply review results about controllability in FDLCP systems to motivate our study. It is well known that in LTI systems the Gramian, rank, and Popov–Belevitch–Hautus (PBH) criteria [39], [30], [44] are frequently employed for controllability, and have brought fruitful results about the structure characteristics of LTI systems [30], [32]. For instance, the structural decomposition has greatly deepened our understanding about such structural properties as zero/pole cancellation in feedback control, which in turn pave the way for optimal linear quadratic regulation

problems [36], H_2/H_∞ performance designs [13], [44], etc. In contrast, it is relatively hard to tackle controllability in the FDLCP field. There seem to be few controllability criteria for FDLCP systems that possess time-invariant expressions of the system matrices and can be implemented without the state transition matrix knowledge of FDLCP systems. Usually one must face some conservative assumptions about system matrices when utilizing such controllability criteria as that of [33], or one must base controllability testing on the state transition matrix [1], [2], [3], [4], [25], whose computation is itself another thorny and interesting problem in the FDLCP field [24], [26], [35]. In view of this, it would be fair to say that controllability and its corresponding properties in FDLCP systems have not been well addressed for the purpose of carrying over LTI techniques into FDLCP systems through controllability/observability concepts. Thus, it is natural for us to develop controllability criteria which have more explicit expressions with system matrices. Such controllability criteria are the major achievements of this paper.

Although more than a dozen kinds of controllability are described in the literature, three kinds are generally known: K-controllability proposed by Kalman [20], which leads to the Gramian controllability criterion; Kalman–Weiss–Brunovsky (KWB)-controllability [17], which is stated via linear independence of the state transition and input matrices; and H-controllability defined by Hewer [2], [17], which is stated via characteristic-multiplier/
eigenvector relations of the monodromy and input matrices of the FDLCP system concerned. The first two are defined for general dynamical systems, while the third one is introduced specifically for FDLCP systems. It has been claimed in [17] that K-controllability is equivalent to KWB-controllability. It should be noted that some arguments about validity of results in [17] are raised through a counter example in [1]. Equivalence between K-controllability and H-controllability is explicated in [2]. Bearing these in mind, we concentrate our attention in what follows only on K-controllability, and thus all the prefixes will be removed from terminologies pertaining to controllability. As an interesting side note related closely to controllability (and observability), it is worth mentioning that various characterizations of stabilizability and detectability of linear continuous-time periodic systems are given and their equivalences are scrutinized in [4].

The paper is outlined as follows. Section 2 collects preliminaries to FDLCP systems, such as the Floquet theorem, the harmonic Floquet similarity transformation formulas, the controllability definition, and the Gramian criterion and its various interpretations. In section 3, harmonic controllability conditions for FDLCP systems and their implementing algorithms are proved. Controllability of approximate modelings and controllability canonical decomposition via analytic state coordinate transforms are dealt with in section 4. There are numeric examples to illustrate the main results in section 5. Conclusions are summarized in section 6.

2. Preliminaries to FDLCP systems. Section 2.1 collects facts on FDLCP systems. Section 2.2 moves to discussions about exponential operators defined in FDLCP systems. Section 2.3 is devoted to the controllability definition, the Gramian controllability criterion, and its various interpretations. The results of section 2.3 play a key role in developing a harmonic framework for controllability.

To facilitate the statements we list notation used in the paper. $||\cdot||$ is the Euclidean norm and the norm of a matrix induced by it. l_2 is the set of all infinite-dimensional vectors $\underline{x}$ such that $||\underline{x}||_{l_2}^2 = \sum_{k=-\infty}^{+\infty} ||x_k||^2 < \infty$, where x_k is the kth (vector) entry of $\underline{x}$. $L_\infty[0,h]$ is the set of all measurable functions x defined on $[0,h)$ such that

$||x(\cdot)||_\infty = \text{ess sup}_{t\in[0,h)} ||x(t)|| < \infty$. $L_{\rm PCD}[0,h]$ is the set of all piecewise continuous functions that are differentiable almost everywhere in $[0,h)$. $L_{\rm CAC}[0,h]$ denotes the set of all continuous functions whose Fourier series are absolutely convergent. Obviously, $L_{\rm PCD}[0,h] \subset L_\infty[0,h]$ and $L_{\rm CAC}[0,h] \subset L_\infty[0,h]$. $F(t) \in L_\infty[0,h]$ means that $F(\cdot)$ is a matrix function, each element of which is h-periodic and belongs to $L_\infty[0,h]$ when its domain is restricted to $[0,h)$. $\mathcal{C}$ is the set of all complex numbers. $\mathcal{Z}$ is the ring of all integers. $*(l,k)$ denotes an $l\times k$ matrix, the exact evaluation of whose entries is not needed, while $0(l,k)$ is an $l\times k$ zero matrix.

Let $\sum_{\mu=-\infty}^{+\infty} A_\mu e^{j\mu\omega_h t}$ with $\omega_h := 2\pi/h$ be the Fourier series of $A(t) \in L_\infty[0,h]$. The Toeplitz transformation $\mathcal{T}\{A(t)\}$ is a Toeplitz operator [38] (or block Laurent operator [12]) given by

$$\mathcal{T}\{A(t)\} = \begin{bmatrix} \ddots & \vdots & \vdots & \vdots & \iddots \\ \cdots & A_0 & A_{-1} & A_{-2} & \cdots \\ \cdots & A_1 & A_0 & A_{-1} & \cdots \\ \cdots & A_2 & A_1 & A_0 & \cdots \\ \iddots & \vdots & \vdots & \vdots & \ddots \end{bmatrix} =: \underline{A},$$

where $A(t)$ is called the defining function of $\underline{A}$ by the terminology of [12].

2.1. Floquet theorem and its interpretations. Consider the FDLCP system given by

$$\dot{x} = A(t)x + B(t)u, \tag{1}$$

where $A(t)$ and $B(t)$ are h-periodically time-varying $n\times n$ and $n\times m$ matrices, respectively. By the Floquet theorem [10], [16], [23], [24], if the entries of $A(t)$ are piecewise continuous in t, the state transition matrix $\Phi(t,0)$ of (1) can be expressed in a Floquet factorization $\Phi(t,0) = P(t,0)e^{Qt}$, where $P(t,0)$ is absolutely continuous in t and nonsingular and h-periodic in t, and Q is constant but probably complex. Conventionally, $\Phi(h,0)$ is called the monodromy of (1), whose eigenvalues are called characteristic multipliers, while the eigenvalues of Q are called characteristic exponents.

Define the fundamental strip $\mathcal{C}_f$ on the complex place $\mathcal{C}$ as follows:

$$\mathcal{C}_f := \{z \in \mathcal{C} : -\omega_h/2 < \text{Im}(z) \le \omega_h/2\}, \quad \omega_h = 2\pi/h.$$

In a Floquet factorization $\Phi(t,0) = P(t,0)e^{Qt}$, if all characteristic exponents belong to $\mathcal{C}_f$, then $P(t,0)e^{Qt}$ is called a Floquet simplex. Lemma 2.1 claims that Floquet simplices exist in general FDLCP systems. A proof for Lemma 2.1 is given in Appendix A. Floquet simplices play a key role in establishing the main results of this paper.

LEMMA 2.1. *In the* FDLCP *system* (1)*, let the entries of* $A(t)$ *be piecewise continuous in* t*.*

(a) *The state transition matrix* $\Phi(t,0)$ *of* (1) *can always be expressed in a Floquet simplex; that is,* $\Phi(t,0) = P(t,0)e^{Qt}$ *with* $\lambda(Q) \subset \mathcal{C}_f$*;*

(b) *Suppose that* $\Phi(t,0)$ *possesses a Floquet factorization* $\tilde{P}(t,0)e^{\tilde{Q}t}$ *satisfying*

$$\tilde{P}(t,0) = \sum_{|k|\le N_p} \tilde{P}_k e^{jk\omega_h t}, \quad \lambda(\tilde{Q}) \subset \bigcup_{|k|\le N_q} \{\mathcal{C}_f + jk\omega_h\} \tag{2}$$

for some integers $N_p \geq 0$ and $N_q \geq 0$; that is, the Fourier series of $\tilde{P}(t,0)$ contains finitely many harmonic waves, and the eigenvalues of $\tilde{Q}$ belong to a horizontally bounded strip in the complex plane formed along $\mathcal{C}_f$. Then, there exists a Floquet simplex $\Phi(t,0) = P(t,0)e^{Qt}$ such that

$$P(t,0) = \sum_{|k| \leq N_p + N_q} P_k e^{jk\omega_h t}, \quad \lambda(Q) \subset \mathcal{C}_f. \tag{3}$$

Here $\tilde{P}_k$ and P_k denote the Fourier coefficients of $\tilde{P}(t,0)$ and $P(t,0)$, respectively. In the above, $\lambda(\cdot)$ is the set of all the eigenvalues of a matrix $(\cdot)$.

By the first assertion of Lemma 2.1, an interesting point about a Floquet simplex $\Phi(t,0) = P(t,0)e^{Qt}$ is that for any two eigenvalues of Q, $\mathrm{Im}(\lambda_i(Q)) - \mathrm{Im}(\lambda_k(Q)) \neq r\omega_h$ for $i \neq k$, where r is a nonzero integer. This is a key result for establishing the harmonic framework for controllability. The second assertion of Lemma 2.1 plays a role in deriving a numerically implementable controllability criterion from infinite-dimensional harmonic controllability criteria.

Now we recall the harmonic Floquet similarity transformation formula [41], [42], which has an important role in defining exponential operators of the unbounded harmonic state operators [43] in Proposition 2.3 and establishing controllability criteria in Theorems 3.2 and 3.3. In what follows, we write $\underline{B} := \mathcal{T}\{B(t)\}$, $\underline{P} := \mathcal{T}\{P(t,0)\}$, $\underline{\hat{B}} := \mathcal{T}\{P^{-1}(t,0)B(t)\}$, $\underline{Q} := \mathcal{T}\{Q\}$, and

$$\underline{E}(j0) := \mathrm{diag}[\cdots, -j2\omega_h I, -j\omega_h I, 0, j\omega_h I, j2\omega_h I, \cdots],$$

where 0-block is at the center of the infinite-dimensional matrix $\underline{E}(j0)$, which is unbounded on l_2. As an appropriate domain for $\underline{E}(j0)$, we define the set $l_E := \{\underline{x} \in l_2 : \underline{E}(j0)\underline{x} \in l_2\}$. It is shown [41] that l_E is a proper subset of l_2 and dense in l_2.

LEMMA 2.2. *In the* FDLCP *system* (1)*, let $A(t) \in L_{\mathrm{PCD}}[0,h]$ and $\Phi(t,0) = P(t,0)e^{Qt}$ be a Floquet factorization. Then, $\underline{P}$ is invertible both on l_E and l_2, and the inverse of $\underline{P}$ on l_E is that of $\underline{P}$ on l_2 restricted to l_E. Also, l_E is $\underline{P}$-, $\underline{P}^{-1}$-, $\underline{P}^H$-, and $\underline{P}^{-H}$-invariant. The unbounded operators $\underline{P}(\underline{E}(j0) - \underline{Q})\underline{P}^{-1}$ and $\underline{E}(j0) - \underline{A}$ are densely defined on l_2 and coincide on l_E with each other:*

$$\underline{P}(\underline{Q} - \underline{E}(j0))\underline{P}^{-1} = \underline{A} - \underline{E}(j0).$$

Moreover, if $B(t) \in L_{\mathrm{CAC}}[0,h]$, then $\hat{B}(t) = P^{-1}(t,0)B(t) \in L_{\mathrm{CAC}}[0,h]$ and $\underline{\hat{B}} = \underline{P}^{-1}\underline{B}$.

Furthermore, let $\Lambda(\cdot)$ denote the collection of all eigenvalues of an operator $(\cdot)$. Then

$$\Lambda(\underline{A} - \underline{E}(j0)) = \Lambda(\underline{Q} - \underline{E}(j0)) = \{\lambda(Q) + j\mu\omega_h : \mu \in \mathcal{Z}\} =: \Lambda,$$

and for each eigenvalue $\lambda \in \Lambda$ there exists an associated eigenvector of $\underline{A} - \underline{E}(j0)$ (or $\underline{Q} - \underline{E}(j0)$) that belongs to the space l_E.

2.2. Exponential operators defined on $\underline{A} - \underline{E}(j0)$ and $\underline{Q} - \underline{E}(j0)$. For the subsequent arguments, we introduce the following two infinite-dimensional exponential operators about the unbounded operators $\underline{A} - \underline{E}(j0)$ and $\underline{Q} - \underline{E}(j0)$:

$$\begin{cases} \underline{e}(\underline{A} - \underline{E}(j0), t) := \displaystyle\sum_{k=0}^{\infty} \frac{1}{k!}(\underline{A} - \underline{E}(j0))^k t^k, \\ \underline{e}(\underline{Q} - \underline{E}(j0), t) := \displaystyle\sum_{k=0}^{\infty} \frac{1}{k!}(\underline{Q} - \underline{E}(j0))^k t^k. \end{cases} \tag{4}$$

Since $\underline{A}-\underline{E}(j0)$ and $\underline{Q}-\underline{E}(j0)$ are unbounded on the Hilbert space l_2 and their infinite powers are involved in the definition, the domains of $\underline{A}-\underline{E}(j0)$ and $\underline{Q}-\underline{E}(j0)$ must be restricted appropriately in l_E to guarantee that $\underline{e}(\underline{A}-\underline{E}(j0),t)$ and $\underline{e}(\underline{Q}-\underline{E}(j0),t)$ are well defined.

To this end, we denote the eigenspace of an eigenvalue $\lambda_i \in \Lambda$ of $\underline{A}-\underline{E}(j0)$ and $\underline{Q}-\underline{E}(j0)$, respectively, by $\mathcal{N}(\lambda_i\underline{I}+\underline{E}(j0)-\underline{A})$ and $\mathcal{N}(\lambda_i\underline{I}+\underline{E}(j0)-\underline{Q})$, where $\underline{I}=\mathcal{T}\{I\}$. It is not hard to show that for any nonnegative integer k, $(\underline{A}-\underline{E}(j0))^k$ and $(\underline{Q}-\underline{E}(j0))^k$ can be restricted to $\mathcal{N}(\lambda_i\underline{I}+\underline{E}(j0)-\underline{A})$ and $\mathcal{N}(\lambda_i\underline{I}+\underline{E}(j0)-\underline{Q})$, respectively. Simple algebra yields that $\underline{e}(\underline{A}-\underline{E}(j0),t):\mathcal{N}(\lambda_i\underline{I}+\underline{E}(j0)-\underline{A})\to\mathcal{N}(\lambda_i\underline{I}+\underline{E}(j0)-\underline{A})$ and $\underline{e}(\underline{Q}-\underline{E}(j0),t):\mathcal{N}(\lambda_i\underline{I}+\underline{E}(j0)-\underline{Q})\to\mathcal{N}(\lambda_i\underline{I}+\underline{E}(j0)-\underline{Q})$ are bounded for each fixed $\lambda_i\in\Lambda$ and $t\in[0,\infty)$. Based on Lemma 2.2 one can readily assert the results in Proposition 2.3.

PROPOSITION 2.3. *In the* FDLCP *system* (1)*, let* $A(t)\in L_{\mathrm{PCD}}[0,h]$ *and* $\Phi(t,0)=P(t,0)e^{Qt}$ *be a Floquet factorization. Then,* $\mathcal{N}(\lambda_i\underline{I}+\underline{E}(j0)-\underline{A})\subset l_E$ *and* $\mathcal{N}(\lambda_i\underline{I}+\underline{E}(j0)-\underline{Q})\subset l_E$ *satisfying* $\mathcal{N}(\lambda_i\underline{I}+\underline{E}(j0)-\underline{A})=\underline{P}\,\mathcal{N}(\lambda_i\underline{I}+\underline{E}(j0)-\underline{Q})$*. Furthermore, for each fixed* $\lambda_i\in\Lambda$*, it holds on* $\mathcal{N}(\lambda_i\underline{I}+\underline{E}(j0)-\underline{A})$ *that* $\underline{e}(\underline{A}-\underline{E}(j0),t)=\underline{P}\,\underline{e}(\underline{Q}-\underline{E}(j0),t)\underline{P}^{-1}$.

2.3. Controllability and the Gramian criterion. As argued in the introduction, there are many ways to define controllability in general dynamic systems. Here we recall only the controllability definition given by Kalman [20], which has been refined over the years in the FDLCP setting.

DEFINITION 2.4. *Let* J *be a time interval. We call a state* $x(t_0)$ *of a dynamic system considered at time* $t_0\in J$ *controllable if there exist some time* $t_1>t_0$ *and an integrable input* $u(\cdot)$ *defined on* (t_0,t_1) *which transfers the state* $x(t_0)$ *to* $x(t_1)=0$.

If for a fixed time $t_0\in J$ *every state* $x(t_0)$ *is controllable in the above sense, we say that the system is completely controllable at* $t_0\in J$.

If for every $t_0\in J$ *the system is completely controllable, we say that the system is completely controllable over* J. *If* $J=[0,\infty)$*, we say simply that the system is completely controllable.*

If the system (1) is completely controllable, we also say that the pair $(A(\cdot),B(\cdot))$ is completely controllable. Based on the Gramian criterion, it can be proved that controllability of the FDLCP system (1) over $[0,\infty)$ can be reduced to that of the same system over $[0,kh)$, where k is a positive integer defined in Lemma 2.5. Regarding this controllability interval reduction a short but extensive survey can be found in [26]. The results [2], [7], [15] directly related to our later discussions are summarized in Proposition 2.6, which is proved in Appendix B. To claim these results in the current fashion may facilitate the reader's understanding about the subsequent arguments. This is especially true for Lemma 2.5 and Proposition 2.7.

To facilitate our statements in Propositions 2.6 and 2.7, we define

$$W_c[t_0,t_1]:=\int_{t_0}^{t_1}\Phi(t_0,\tau)B(\tau)B^T(\tau)\Phi^T(t_0,\tau)d\tau. \tag{5}$$
