The coefficients in (2.1), (2.2) are matrices $W(t)\in L(\mathbb{R}^m,\mathbb{R}^m)$, $R(t)\in L(\mathbb{R}^l,\mathbb{R}^l)$, $S(t)\in L(\mathbb{R}^l,\mathbb{R}^m)$, $A(t)\in L(\mathbb{R}^n,\mathbb{R}^k)$, $B(t)\in L(\mathbb{R}^m,\mathbb{R}^n)$, $C(t)\in L(\mathbb{R}^m,\mathbb{R}^k)$, $D(t)\in L(\mathbb{R}^l,\mathbb{R}^k)$, $t\in[0,T]$, which depend continuously on t, and $V\in L(\mathbb{R}^m,\mathbb{R}^m)$.

The value $z_0\in \mathrm{im}(A(0)B(0))$ is given. The leading term of the DAE (2.2) is assumed to be properly stated in the sense that the decomposition

$$\ker A(t)\oplus \mathrm{im}\, B(t) = \mathbb{R}^n, \quad t\in[0,T], \tag{2.4}$$

holds true, and both subspaces forming this direct sum have constant dimensions and are spanned by continuously differentiable on $[0,T]$ functions (cf. [4]).

We use the symbols $\mathcal{C}$ and $\mathcal{C}^1$ for continuous and continuously differentiable function spaces, respectively (functions defined on $[0,T]$, with values in $\mathbb{R}^l,\mathbb{R}^m,\mathbb{R}^k$, or $\mathbb{R}^n$ as given by the context), and

$$\mathcal{C}^1_B := \{x\in\mathcal{C} : Bx\in\mathcal{C}^1\}, \ \ \mathcal{C}^1_{A^*} := \{\psi\in\mathcal{C} : A^*\psi\in\mathcal{C}^1\}.$$

The coefficients determining the cost (2.1) satisfy the following standard assumptions: $W(t), R(t)$, and V are symmetric, $R(t)$ is positive definite, and $\left[\begin{smallmatrix} W(t) & S(t)\\ S(t)^* & R(t)\end{smallmatrix}\right]$ is positive semidefinite, $t\in[0,T]$.

A pair $(u,x)\in\mathcal{C}\times\mathcal{C}^1_B$ satisfying the IVP (2.2), (2.3) is said to be *admissible*.

Let $K(t)\in L(\mathbb{R}^n,\mathbb{R}^n)$ denote the projector that realizes decomposition (2.4), $\ker K(t) = \ker A(t)$, $\mathrm{im} K(t) = \mathrm{im} B(t)$, $t\in[0,T]$. Since these subspaces are continuously differentiable, so is the projector function $K:[0,T]\to L(\mathbb{R}^n,\mathbb{R}^n)$.

In addition to $K(t)$ we introduce $Q(t)\in L(\mathbb{R}^m,\mathbb{R}^m)$, $Q_*(t)\in L(\mathbb{R}^k,\mathbb{R}^k)$, which are the orthoprojectors onto $\ker(A(t)B(t))$ and $\ker(B(t)^*A(t)^*) = \mathrm{im}(A(t)B(t))^\perp$, respectively; furthermore, $P(t) := I - Q(t), P_*(t) := I - Q_*(t)$, $t\in[0,T]$. The projector functions Q, P, Q_*, and P_* are continuous.

It is natural to assume that $V = VP(T)$ (see, e.g., [13]).

Having the projectors K, P, and P_*, we introduce the generalized inverses B^- of B and A^{*-} of A^* by

$$\begin{aligned} B^-BB^- &= B^-, \quad & BB^-B &= B, \quad & BB^- &= K, \quad & B^-B &= P,\\ A^{*-}A^*A^{*-} &= A^{*-}, \quad & A^*A^{*-}A^* &= A^*, \quad & A^*A^{*-} &= K^*, \quad & A^{*-}A^* &= P_*. \end{aligned} \tag{2.5}$$

Notice that B^- and A^{*-} are uniquely determined by (2.5) and continuous on $[0,T]$. It holds further that

$$B^-K = B^-, \quad A = AK, \quad A^* = K^*A^*, \quad B^{-*} = K^*B^{-*}. \tag{2.6}$$

Next we consider the terminal value problem

$$B^*(A^*YB^-)'B = -Y^*C - C^*Y + (S + Y^*D)R^{-1}(S^* + D^*Y) - W, \tag{2.7}$$

$$A(T)^*Y(T)B(T)^- = B(T)^{-*}VB(T)^-. \tag{2.8}$$

Equation (2.7) generalizes the (well-known for $A = I$, $B = I$) Riccati differential equation and may be understood as a Riccati DAE.

LEMMA 2.1. *If $Y : [0,T] \to L(\mathbb{R}^m, \mathbb{R}^k)$ is continuous with a continuously differentiable part A^*YB^-, and if it satisfies the terminal value problem* (2.7), (2.8), *then the symmetry relation*

$$A^*YB^- = B^{-*}Y^*A \tag{2.9}$$

becomes true.

Proof. Multiplying (2.7) by B^{-*} from the left, and by B^- from the right, leads to

$$K^*(A^*YB^-)'K = B^{-*}\{-Y^*C - C^*Y + (S + Y^*D)R^{-1}(S^* + D^*Y) - W\}B^- =: \mathfrak{A},$$

where $\mathfrak{A} = \mathfrak{A}^*$, and, further (cf. (2.6)),

$$(A^*YB^-)' = \mathfrak{A} + K^{*'}A^*YB^- + A^*YB^-K'.$$

It becomes clear that $U := A^*YB^-$ satisfies the ODE $U' = \mathfrak{A} + K^{*'}U + UK'$ as well as the condition $U(T) = B(T)^{-*}VB(T)^-$. Obviously, U^* is a further solution of the same final value problem; i.e., $U = U^*$ must be true. □

Remark 2.2. If Y solves (2.7), (2.8) and if, additionally, the condition $A^*YQ = 0$ is given, then it follows that

$$B^*A^*Y = Y^*AB \tag{2.10}$$

must hold. Conversely, relation (2.10) implies $A^*YQ = 0$.

Remark 2.3. If one has, instead of the continuous coefficient B considered here, a B that is continuously differentiable, one can consider

$$(B^*A^*Y)' = B^{*\prime}A^*Y + Y^*AB' - Y^*C - C^*Y + (S + Y^*D)R^{-1}(S^* + D^*Y) - W, \tag{2.11}$$

$$B(T)^*A(T)^*Y(T) = P(T)VP(T) = V \tag{2.12}$$

instead of (2.7), (2.8). All solutions of (2.11), (2.12) have the symmetry property (2.10). At the same time they are solutions of (2.7), (2.8) and satisfy the additional condition $A^*YQ = 0$. Observe that (2.11), (2.12) coincide with (1.13). At first glance this shows that, considering the Riccati DAE (2.7), we may expect positive solvability results as in [12] for (1.13).

Remark 2.4. Equation (2.11) was first considered in [12]. Special cases (resp., slight modifications of (2.11)) were discussed in [19] (where A or B is absent) and in [15], [16] (where A is absent, B is constant, and $S = 0$).

THEOREM 2.5. *Let Y be a solution of the terminal value problem* (2.7), (2.8), *and let the condition $A^*YQ = 0$ be fulfilled. Let $x_* \in \mathcal{C}_B^1$ be a solution of the IVP*

$$A(Bx)' = Cx - DR^{-1}(S^* + D^*Y)x, \quad A(0)B(0)x(0) = z_0, \tag{2.13}$$

and let

$$u_* := -R^{-1}(S^* + D^*Y)x_*. \tag{2.14}$$

Then it holds for each admissible pair $(u, x) \in \mathcal{C} \times \mathcal{C}_B^1$ that

$$J(u, x) \geq J(u_*, x_*) = \frac{1}{2}\langle z_0, A(0)^{*-}B(0)^{-*}Y(0)^* z_0\rangle;$$

i.e., (u_*, x_*) is an optimal pair and (2.14) *describes the optimal feedback.*

Proof. It holds that $A^*Y = A^*YP = A^*YB^-B$, and that $B^{-*}Y^*AB = A^*Y$. Given an admissible pair (u, x), we derive

$$\begin{aligned}
\frac{d}{dt}\langle Bx, A^*Yx\rangle &= \langle (Bx)', A^*Yx\rangle + \langle Bx, (A^*YB^-Bx)'\rangle \\
&= \langle (Bx)', A^*Yx\rangle + \langle Bx, (A^*YB^-)'Bx\rangle + \langle Bx, A^*YB^-(Bx)'\rangle \\
&= \langle (Bx)', A^*Yx\rangle + \langle Bx, (A^*YB^-)'Bx\rangle + \langle A^*Yx, (Bx)'\rangle \\
&= 2\langle (Bx)', A^*Yx\rangle + \langle x, B^*(A^*YB^-)'Bx\rangle \\
&= 2\langle A(Bx)', Yx\rangle + \langle x, B^*(A^*YB^-)'Bx\rangle.
\end{aligned}$$

Taking into account (2.2) and (2.7) we obtain the expression

$$\begin{aligned}
\frac{d}{dt}\langle Bx, A^*Yx\rangle = &-\{\langle Wx, x\rangle + 2\langle Su, x\rangle + \langle Ru, u\rangle\} \\
&+ \langle R(u + R^{-1}(S^*x + D^*Yx)), u + R^{-1}(S^*x + D^*Yx)\rangle.
\end{aligned}$$

By this we find

$$J(u, x) = \frac{1}{2}\langle x(T), Vx(T)\rangle - \frac{1}{2}\int_0^T \frac{d}{dt}\langle B(t)x(t), A(t)^*Y(t)x(t)\rangle dt + \mathfrak{B}(u, x),$$

$$\begin{aligned}
\mathfrak{B}(u, x) = \frac{1}{2}\int_0^T \langle R(t)(u(t) + R(t)^{-1}(S(t)^* + D(t)^*Y(t))x(t)), u(t) \\
+R(t)^{-1}(S(t)^* + D(t)^*Y(t))x(t)\rangle dt.
\end{aligned}$$

From the positive definiteness of $R(t)$ it follows that $\mathfrak{B}(u, x) \geq 0$.

Notice that $\mathfrak{B}(u_*, x_*) = 0$.

Compute further

$$\begin{aligned}
J(u, x) = &\frac{1}{2}\langle x(T), Vx(T)\rangle - \frac{1}{2}\langle B(T)x(T), A(T)^*Y(T)x(T)\rangle \\
&+\frac{1}{2}\langle B(0)x(0), A(0)^*Y(0)x(0)\rangle + \mathfrak{B}(u, x).
\end{aligned}$$

Using the conditions (2.3) and (2.8) as well as the relations $V = VP(T)$, $A^*Y = A^*YB^-B$, and (2.10) we arrive at

$$J(u,x) = \frac{1}{2}\langle z_0, A(0)^{*-}B(0)^{-*}Y(0)^*z_0\rangle + \mathfrak{B}(u,x).$$

Since the first term is independent of the admissible pair (u,x), we conclude that

$$J(u,x) \geq \frac{1}{2}\langle z_0, A(0)^{*-}B(0)^{-*}Y(0)^*z_0\rangle = J(u_*,x_*). \qquad \square$$

The linear-quadratic optimal control problem (2.1)–(2.3) is closely related to the boundary value problem (BVP)

$$\begin{bmatrix} A & 0 \\ 0 & -B^* \end{bmatrix} \frac{d}{dt}\left(\begin{bmatrix} B & 0 \\ 0 & A^* \end{bmatrix}\begin{bmatrix} x \\ \psi \end{bmatrix}\right) = \begin{bmatrix} C - DR^{-1}S^* & -DR^{-1}D^* \\ W - SR^{-1}S^* & C^* - SR^{-1}D^* \end{bmatrix}\begin{bmatrix} x \\ \psi \end{bmatrix}, \tag{2.15}$$

$$A(0)B(0)x(0) = z_0, \tag{2.16}$$

$$B(T)^*A(T)^*\psi(T) = Vx(T). \tag{2.17}$$

If this BVP has a solution pair x_*, ψ_*, then $u_* := -R^{-1}(S^*x_* + D^*\psi_*)$ is an optimal control. This can be realized by slightly modifying Proposition 3.2 in [7] or Lemma 2.2 in [13] . Conversely, if u_*, x_* is an optimal pair, and if the composed matrix function $[AB - CQ, D]$ has on $[0,T]$ full row rank, then there exists an adjoint function ψ_* such that x_*, ψ_* solve the BVP (2.15)–(2.17) (see [2]). If A and B are nonsingular, then the full rank condition is always given. For singular A and B, if the full rank condition fails to be valid, then it may happen (see [2]) that there is an optimal pair u_*, x_*, but an adjoint function to solve the BVP does not exist. Assuming the rank condition to be satisfied, we can use the BVP (2.15)–(2.17) as a sufficient and necessary optimality condition. For a further discussion of recent developments concerning extremal conditions for optimization problems involving linear and nonlinear DAEs we refer to [2].

In the case when $A = B = I$, system (2.15) is nothing else than the Hamiltonian ODE associated with the standard linear-quadratic optimal control problem (1.1)–(1.3). For singular A and B, (2.15) is a DAE with a properly stated leading term. We adopt the notion *Hamiltonian system* for this DAE. This is justified, since under certain conditions (cf. Remark 6.4) the dynamic part inherent in (2.15) actually shows a Hamiltonian flow (see [3]).

While, e.g., in [5], [8] the Riccati-type DAEs are constructed to solve the Hamiltonian system, here a direct optimality proof is applied to Theorem 2.5 and, at the same time, our new Riccati DAE system is justified. In section 6 we will elucidate relations between solutions of the Riccati DAE and solutions of the corresponding Hamiltonian system.

Remark 2.6. In [13] we dealt with linear-quadratic optimal control problems in a more general Hilbert space setting, where R is not necessarily invertible and the side conditions are given as $(Bx)' = Cx + Du$, $B(0)x(0) = z_0$. Sufficient solvability conditions are derived by investigating the structure as well as the inherent flow of a linear (abstract) descriptor system associated with a sufficient extremal condition.

3. Solvability of the Riccati DAE system. In this section we consider solutions of the system

$$B^*(A^*YB^-)'B = -Y^*C - C^*Y + (S + Y^*D)R^{-1}(S^* + D^*Y) - W, \tag{3.1}$$

$$P_*YQ = 0, \tag{3.2}$$

which satisfy the terminal condition

$$A(T)^*Y(T)B(T)^- = \widetilde{V} := B(T)^{-*}VB(T)^-. \tag{3.3}$$

Each solution Y that must be continuous with a continuously differentiable part A^*YB^- can be decomposed as

$$\begin{aligned} Y &= P_*YP + Q_*YP + Q_*YQ \\ &= A^{*-}A^*YB^-B + Q_*YP + Q_*YQ. \end{aligned}$$

We are going to show that the components

$$U := A^*YB^- \in \mathcal{C}^1, \quad \mathcal{V} := Q_*YP, \quad Z := Q_*YQ = YQ \in \mathcal{C} \tag{3.4}$$

satisfy a standard Riccati differential equation, a linear equation, and an algebraic Riccati equation, respectively.

Multiplying (3.1) by Q from the left and right, then by Q from the left and P from the right, and also by B^{-*} from the left and B^- from the right, we obtain the system

$$0 = -(YQ)^*CQ - QC^*YQ + (QS + (YQ)^*D)R^{-1}(S^*Q + D^*YQ) - QWQ, \tag{3.5}$$

$$0 = -(YQ)^*CP - QC^*YP + (QS + (YQ)^*D)R^{-1}(S^*P + D^*YP) - QWP, \tag{3.6}$$

$$\begin{aligned} K^*(A^*YB^-)'K &= -(YB^-)^*CB^- - B^{-*}C^*YB^- \\ &\quad + (B^{-*}S + (YB^-)^*D)R^{-1}(S^*B^- + D^*YB^-) - B^{-*}WB^-. \end{aligned} \tag{3.7}$$

Since multiplication of (3.1) by P from the left and Q from the right yields (3.6) once more, we know (3.1) to be equivalent to (3.5)–(3.7). Obviously, the component $Z = Q_*YQ = YQ$ satisfies (cf. (3.5)) the algebraic Riccati equation

$$0 = -Z^*Q_*CQ - QC^*Q_*Z + (QS + Z^*Q_*D)R^{-1}(S^*Q + D^*Q_*Z) - QWQ \tag{3.8}$$

and the trivial conditions $P_*Z = 0,\ ZP = 0$.

Next, from (3.6) we obtain a linear relation for the components Z, U, and $\mathcal{V}$, namely,

$$MQ_*\mathcal{V} + MP_*A^{*-}UB = -Z^*Q_*CP + (QS + Z^*Q_*D)R^{-1}S^*P - QWP,$$

where

$$M := QC^* - (QS + Z^*Q_*D)R^{-1}D^*, \quad M = QM. \tag{3.9}$$

Notice that, if the conditions

$$\mathrm{im}MQ_* = \mathrm{im}Q, \quad \ker M \cap \mathrm{im}Q_* = 0 \tag{3.10}$$

are fulfilled, we also have $\ker MQ_* = \ker Q_*$; further

$$(MQ_*)^+ MQ_* = Q_*, \quad MQ_*(MQ_*)^+ = Q, \tag{3.11}$$

and the resulting linear equation

$$MQ_*\mathcal{V} = -Z^*Q_*CP + (QS + Z^*Q_*D)R^{-1}S^*P - QWP - MP_*A^{*-}UB \tag{3.12}$$

determines $\mathcal{V}$ uniquely, depending on Z and U. Let us then write

$$\mathcal{V} = C_1 + C_2A^{*-}UB, \tag{3.13}$$

with

$$C_1 := (MQ_*)^+\{-Z^*Q_*CP + (QS + Z^*Q_*D)R^{-1}S^*P - QWP\},$$
$$C_2 := -(MQ_*)^+MP_*.$$

Notice that $(MQ_*)^+$ is continuous. It holds that $C_1 = Q_*C_1 = C_1P$, $C_2Q_*C_2 = C_2P_*$.

Finally, we turn to (3.7). Since K is continuously differentiable and $UK = U$, $K^*U = U$ hold true, we may write

$$K^*(A^*YB^-)'K = K^*U'K = U' - K^{*\prime}U - UK'.$$

Recall that U is symmetric due to Lemma 2.1. Using (3.13) we derive

$$\begin{aligned} YP &= Q_*YP + P_*YP = \mathcal{V} + A^{*-}UB \\ &= C_1 + C_2A^{*-}UB + A^{*-}UB, \end{aligned}$$

that is,

$$YP = C_1 + C_3A^{*-}UB, \quad C_3 := C_2 + P_*. \tag{3.14}$$

Thus we obtain, from (3.7), the following differential equation for U:

$$\begin{aligned} U' = {} & K^{*\prime}U + U^*K' - B^{-*}WB^- - B^{-*}(C_1 + C_3A^{*-}UB)^*CB^- \\ & - B^{-*}C^*(C_1 + C_3A^{*-}UB)B^- \\ & + B^{-*}(S + (C_1 + C_3A^{*-}UB)^*D)R^{-1}(S^* + D^*(C_1 + C_3A^{*-}UB))B^-, \end{aligned}$$

that is, considering that U is symmetric,

$$U' = -\widetilde{W} - \widetilde{C}^*U - U\widetilde{C} + U\widetilde{D}R^{-1}\widetilde{D}^*U, \tag{3.15}$$

where

$$\widetilde{C}^* := -K^{*\prime} + B^{-*}C^*C_3A^{*-} - B^{-*}(S + C_1^*D)R^{-1}D^*C_3A^{*-},$$
$$\widetilde{D}^* := D^*C_3A^{*-},$$
$$\begin{aligned} \widetilde{W} := {} & B^{-*}\{PWP + PC_1^*CP + PC^*C_1P \\ & -P(S + C_1^*D)R^{-1}(S^* + D^*C_1)P\}B^- = \widetilde{W}^*. \end{aligned}$$

LEMMA 3.1. *Let condition* (3.10) *be given, and additionally,*

$$\mathrm{im}Z = \mathrm{im}Q_*, \quad \ker Z = \ker Q. \tag{3.16}$$

Then, (3.15) *represents a standard Riccati differential equation with a symmetric, positive semidefinite coefficient* $\widetilde{W}$.

Proof. Condition (3.16) leads to $ZZ^+ = Q_*$, $Z^+Z = Q$, and Z^+ is continuous.

By construction of C_2, C_1 it holds that

$$MQ_*C_2 = -QMP_* = -MP_*,$$

$$MP_*A^{*-}UB = -MQ_*C_2A^{*-}UB = -MQ_*(\mathcal{V} - C_1) = MQ_*C_1 - MQ_*\mathcal{V}.$$

Taking this into account, from (3.12) we obtain the relation

$$0 = -QWP - Z^*Q_*CP + (QS + Z^*Q_*D)R^{-1}S^*P - MQ_*C_1. \tag{3.17}$$

Next we turn to

$$MQ_* = QC^*Q_* - (QS + Z^*Q_*D)R^{-1}D^*Q_*.$$

From (3.8) we derive the expression

$$\begin{aligned}(QS + Z^*Q_*D)R^{-1}D^*Q_* = {} & QWQZ^+ + Z^*Q_*CQZ^+ + QC^*Q_* \\ & -(QS + Z^*Q_*D)R^{-1}S^*QZ^+\end{aligned}$$

and put it into the formula for MQ_*, that is,

$$MQ_* = -QWQZ^+ - Z^*Q_*CQZ^+ + (QS + Z^*Q_*D)R^{-1}S^*QZ^+.$$

By this, (3.17) becomes

$$\begin{aligned}0 = {} & -QWP - Z^*Q_*CP + (QS + Z^*Q_*D)R^{-1}S^*P \\ & + QWQZ^+C_1 + Z^*Q_*CQZ^+C_1 - (QS + Z^*Q_*D)R^{-1}S^*QZ^+C_1,\end{aligned}$$

and hence, by multiplication from the left by $C_1^*Z^{+*}$,

$$\begin{aligned}0 = {} & -C_1^*Z^{+*}QWP - C_1^*Q_*CP + C_1^*Z^{+*}(QS + Z^*Q_*D)R^{-1}S^*(P - QZ^+C_1) \\ & + C_1^*Z^{+*}QWQZ^+C_1 + C_1^*Q_*CQZ^+C_1.\end{aligned}$$

This yields the expressions

$$\begin{aligned}C_1^*CP = C_1^*Q_*CP = {} & -C_1^*Z^{+*}QWP + C_1^*Q_*CQZ^+C_1 \\ & + C_1^*Z^{+*}QWQZ^+C_1 + C_1^*Z^{+*}(QS + Z^*Q_*D)R^{-1}S^*(P - QZ^+C_1),\end{aligned}$$

and, using properties of C_1,

$$\begin{aligned}
B^*\widetilde{W}B &= PWP + PC_1^*CP + PC^*C_1P - P(S + C_1^*D)R^{-1}(S^* + D^*C_1)P \\
&= PWP + C_1^*Q_*CP + PC^*Q_*C_1 - (PS + C_1^*D)R^{-1}(S^*P + D^*C_1) \\
&= PWP - PSR^{-1}S^*P - PSR^{-1}D^*C_1 - C_1^*DR^{-1}S^*P - C_1^*DR^{-1}D^*C_1 \\
&\quad - C_1^*Z^{+*}QWP + C_1^*Q_*CQZ^+C_1 + C_1^*Z^{+*}QWQZ^+C_1 \\
&\quad + C_1^*Z^{+*}QSR^{-1}S^*P - C_1^*Z^{+*}QSR^{-1}S^*QZ^+C_1 \\
&\quad + C_1^*Q_*DR^{-1}S^*P - C_1^*Q_*DR^{-1}S^*QZ^+C_1 \\
&\quad - PWQZ^+C_1 + C_1^*Z^{+*}QC^*Q_*C_1 + C_1^*Z^{+*}QWQZ^+C_1 \\
&\quad + PSR^{-1}S^*QZ^+C_1 - C_1^*Z^{+*}QSR^{-1}S^*QZ^+C_1 \\
&\quad + PSR^{-1}D^*Q_*C_1 - C_1^*Z^{+*}QSR^{-1}D^*Q_*C_1 \\
&= (P - C_1^*Z^{+*}Q)(W - SR^{-1}S^*)(P - QZ^+C_1) + \mathfrak{B}, \\
\mathfrak{B} &:= - C_1^*DR^{-1}D^*C_1 + C_1^*Q_*CQZ^+C_1 + C_1^*Z^{+*}QWQZ^+C_1 \\
&\quad - C_1^*Q_*DR^{-1}S^*QZ^+C_1 + C_1^*Z^{+*}QC^*Q_*C_1 \\
&\quad - C_1^*Z^{+*}QSR^{-1}S^*QZ^+C_1 - C_1^*Z^{+*}QSR^{-1}D^*Q_*C_1.
\end{aligned}$$

Taking into account that (cf. (3.8))

$$\begin{aligned}
&C_1^*Z^{+*}QWQZ^+C_1 + C_1^*Q_*CQZ^+C_1 + C_1^*Z^{+*}QC^*Q_*C_1 \\
&\qquad = C_1^*Z^{+*}(QS + Z^*Q_*D)R^{-1}(S^*Q + D^*Q_*Z)Z^+C_1
\end{aligned}$$

we find

$$\begin{aligned}
\mathfrak{B} &:= - C_1^*DR^{-1}D^*C_1 - C_1^*Q_*DR^{-1}S^*QZ^+C_1 - C_1^*Z^{+*}QSR^{-1}S^*QZ^+C_1 \\
&\quad - C_1^*Z^{+*}QSR^{-1}D^*Q_*C_1 \\
&\quad + C_1^*Z^{+*}QSR^{-1}S^*QZ^+C_1 + C_1^*Z^{+*}QSR^{-1}D^*Q_*C_1 \\
&\quad + C_1^*Q_*DR^{-1}S^*QZ^+C_1 + C_1^*Q_*DR^{-1}D^*Q_*C_1 = 0.
\end{aligned}$$

It results that

$$\widetilde{W} = B^{-*}(P - C_1^*Z^{+*}Q)(W - SR^{-1}S^*)(P - QZ^+C_1)B^-. \tag{3.18}$$

For $t \in [0,T]$ and all $x \in \mathbb{R}^m$ it holds that

$$\begin{aligned}
&\langle (W(t) - S(t)R(t)^{-1}S(t)^*)x, x\rangle \\
&\qquad = \left\langle \begin{bmatrix} W(t) & S(t) \\ S(t)^* & R(t) \end{bmatrix} \begin{bmatrix} x \\ -R(t)^{-1}S(t)^*x \end{bmatrix}, \begin{bmatrix} x \\ -R(t)^{-1}S(t)^*x \end{bmatrix} \right\rangle \geq 0,
\end{aligned}$$

i.e., $W(t) - S(t)R(t)^{-1}S(t)^*$ is positive semidefinite, and so is $\widetilde{W}(t)$. □

The following assertion reflects what we have derived.

THEOREM 3.2. *If Y is a solution of the Riccati-type terminal value problem* (3.1), (3.2), (3.3), *and if the conditions* (3.10) *and* (3.16) *are fulfilled, then the component $Z = Q_*YQ$ is a solution of the algebraic Riccati equation* (3.8), *$U = A^*YB^-$ is a solution of the standard Riccati differential equation* (3.15), *and $\mathcal{V} = Q_*YP$ satisfies* (3.12).

Conversely, considering now the following decoupled system for the unknown functions $Z, U, \mathcal{V}$ to be given (cf. (3.8), (3.2), (3.15), (2.8), (3.12)) as

$$0 = -Z^*Q_*CQ - QC^*Q_*Z + (QS + Z^*Q_*D)R^{-1}(S^*Q + D^*Q_*Z) - QWQ, \tag{3.19}$$

$$P_*Z = 0, \tag{3.20}$$

$$ZP = 0, \tag{3.21}$$

$$U' = -\widetilde{W} - \widetilde{C}^*U - U^*\widetilde{C} + U^*\widetilde{D}R^{-1}\widetilde{D}^*U, \tag{3.22}$$

$$U(T) = \widetilde{V} := B(T)^{-*}VB(T)^-, \tag{3.23}$$

$$MQ_*\mathcal{V} = -MP_*A^{*-}UB - QWP - Z^*Q_*CP + (QS + Z^*Q_*D)R^{-1}S^*P, \tag{3.24}$$

we may try to compose a solution Y of the original Riccati system (3.1)–(3.3) from the solutions $Z, U, \mathcal{V}$. Let us recall that the coefficients $\widetilde{C}, \widetilde{D}$, and M as defined above depend on Z.

If Z is a solution of the algebraic equation (3.19), then $Z + P_*\widetilde{Z}$, where $\widetilde{Z}$ is an arbitrary $k \times m$ matrix function, is also a solution of (3.19). By means of (3.20), the arbitrary solution part belonging to $\mathrm{im}P_*$ is fixed as zero.

By multiplication of (3.19) from both sides by Q we realize that, if Z solves (3.19), then ZQ also does. By means of condition (3.21) we pick up solutions with $Z = ZQ$. From (3.20), (3.21) we have $Z = Q_*ZQ$.

Obviously, (3.19) itself is symmetric, but Z is not so necessarily. Notice that Z has k rows and m columns. If $m = k$ and $Q_* = Q$ (i.e., $\ker AB = \ker(AB)^*$), then Z can be expected to be symmetric.

What we need is a continuous solution Z that satisfies the conditions

$$\mathrm{im}Z = \mathrm{im}Q_*, \quad \ker Z = \ker Q, \tag{3.25}$$

$$\mathrm{im}MQ_* = \mathrm{im}Q, \quad \ker MQ_* = \ker Q_*, \tag{3.26}$$

with $M = QC^* - (QS + Z^*Q_*D)R^{-1}D^*$.

These requirements ensure that the coefficients $\widetilde{W}$, $\widetilde{C}$, and $\widetilde{D}$ in (3.22) are well defined and continuous. Additionally, $\widetilde{W}$ is symmetric and positive semidefinite. It turns out that (3.22) is a standard Riccati differential equation, and the solution U of the terminal value problem (3.22), (3.23) is symmetric, $U = U^*$.

LEMMA 3.3. *We are given a continuous solution Z of* (3.19)–(3.21) *such that the conditions* (3.25), (3.26) *are fulfilled. Then, for the unique solution U of the resulting standard Riccati differential equation* (3.22), *which satisfies the terminal condition* (3.23), *the relations*

$$U = U^*, \quad U = UK, \quad U = K^*UK \tag{3.27}$$

hold true.

Proof. Let U be a solution of (3.22), (3.23). It remains to verify that $U = K^*UK$.

Inspecting the coefficients we find that $\widetilde{W}(I-K) = 0$, $\widetilde{D} = K\widetilde{D}$, $\widetilde{C} = -K' + K\widetilde{C}K$ must hold. Multiplying (3.22) by $(I-K)$ from the right-hand side, we derive

$$U'(I-K) = -\widetilde{C}^*U(I-K) - U^*(-K' + K\widetilde{C}K)(I-K) + U^*K\widetilde{D}R^{-1}\widetilde{D}^*U(I-K),$$

and hence, denoting $U(I-K) =: \widetilde{U}$, $UK =: U_K$ and taking into account that $U = U^*$,

$$\widetilde{U}' - U(I-K)' = -\widetilde{C}^*\widetilde{U} + UK'(I-K) + U_K\widetilde{D}R^{-1}\widetilde{D}^*\widetilde{U},$$

i.e.,

$$\begin{aligned}\widetilde{U}' &= U(I-K)' - UK(I-K)' + (U_K\widetilde{D}R^{-1}\widetilde{D}^* - \widetilde{C}^*)\widetilde{U}\\ &= \widetilde{U}(I-K)' + F\widetilde{U},\\ F &:= U_K\widetilde{D}R^{-1}\widetilde{D}^* - \widetilde{C}^*.\end{aligned}$$

It becomes clear that the function $\widetilde{U} = U(I-K)$ is the solution of the homogeneous linear terminal value problem $\widetilde{U}' = -\widetilde{U}K' + F\widetilde{U}$, $\widetilde{U}(T) = 0$, but then $\widetilde{U}$ vanishes identically. $\widetilde{U} = 0$ means $U = UK$; further, $U = U^* = K^*U = K^*UK$. ∎

Having the matrix functions U and Z, we compose

$$\mathcal{V} := (MQ_*)^+\{-MP_*A^{*-}UB + (QS + Z^*Q_*D)R^{-1}S^*P - QWP - Z^*Q_*CP\} \tag{3.28}$$

to satisfy (3.24) and, finally,

$$Y := A^{*-}UB + Z + \mathcal{V}. \tag{3.29}$$

Under the assumptions of Lemma 3.3, both $\mathcal{V}$ and Y are continuous. It holds that

$$Q_*YP = Q_*\mathcal{V}P = \mathcal{V}, \quad Q_*YQ = Q_*ZQ = Z, \quad A^*YB^- = K^*UK = U. \tag{3.30}$$

The component A^*YB^- of Y is continuously differentiable and symmetric. Straightforward calculations in the direction opposite to that which we realized provided system (3.19)–(3.24) will show Y to be a solution of our system (3.1)–(3.3). By this, the following assertion providing the solution Y for Theorem 2.5 is proved.

THEOREM 3.4. *Let the algebraic Riccati system* (3.19)–(3.21) *have a continuous solution Z that satisfies the conditions* (3.25) *and* (3.26).

Then, the original Riccati DAE system (3.1)–(3.3) *has a continuous solution Y whose component A^*YB^- is continuously differentiableand symmetric. Additionally, it holds that $A^*YQ = 0$.*

Remark 3.5. For special solvability assertions concerning algebraic Riccati equations as well as standard Riccati differential equations, we refer to [1].

Remark 3.6. As far as the practical potential of the new Riccati-type terminal value problem (3.1)–(3.3) is concerned, we believe that Theorem 3.2 and Lemma 3.1 offer good chances for effective use. The inherent dynamic part within the Riccati DAE system (3.1), (3.2) is just the standard Riccati matrix differential equation (3.15) that has a positive semidefinite coefficient $\widetilde{W}$. We expect this strong structural knowledge to be very helpful in view of applications and further research.

Remark 3.7. What concerns the numerical treatment of the terminal value problem (3.1)–(3.3) we recall that, in this work, is that the weight R is positive definite.

If R becomes singular, additional difficulties will arise. Further, we stress once more that the dynamic part contained in the Riccati DAE system (3.1), (3.2) is the standard Riccati matrix differential equation (3.15). It seems to be possible to figure out so-called *numerically qualified* versions (see, e.g., [11]) of the Riccati DAE system (in vectorized form). For this, following along the lines of [8] and [10] (resp., [11]), further careful investigations are to be carried out. To speculate upon this might lead to numerically qualified index-one DAEs. Since for those DAEs, discretization (by stiffly accurate Runge–Kutta methods and backward differentiation formulas) and theoretical structural decoupling commute, the integration should be as safe as for standard Riccati ODEs. Due to the index-one property and stability preservation (see [11]), it seems that difficulties as reported, for instance, in the earlier work [6], will be avoided. This is a topic of further research.

4. Solvability of the closed loop problem. To confirm the existence of an optimal control u_* with the minimal cost $J(u_*, x_*)$ from Theorem 2.5, in addition to the existence of a Riccati DAE solution Y, one necessarily needs to confirm the existence of a solution of the resulting closed loop DAE, that is (cf. (2.13)),

$$A(Bx)' = Cx - DR^{-1}(S^* + D^*Y)x, \tag{4.1}$$

which satisfies the initial condition

$$A(0)B(0)x(0) = z_0, \tag{4.2}$$

where $z_0 \in \operatorname{im}(A(0)B(0))$ is fixed but chosen arbitrarily.

Clearly, if A and B are nonsingular, then the IVP (4.1), (4.2) always has a uniquely determined solution for each arbitrary z_0. In the case of singular A and B the situation is different, and so for time-invariant descriptor systems (see, e.g., [5]) one takes care to obtain a closed loop system that has no so-called *impulsive behavior* for any z_0. Within the scope of DAE theory, this means that one should have closed loop systems (4.1) that are regular with tractability index one.

Below we shall provide conditions ensuring the index-one property for the DAE (4.1). To this end, we recall some basic information on the tractability index.

The tractability index generalizes the Kronecker index of matrix pencils to time-varying DAEs. The basic tools in this concept are special decoupling projectors computed from the coefficients of the given DAE and certain characteristic subspaces. Any regular linear DAE with a properly stated leading term (see [22]) can be decoupled into characteristic parts analogously to the decoupling of a regular matrix pencil into dynamic, nondynamic, and impulsive parts (see [23]). Since no so-called derivative arrays are used, the concept applies to continuous coefficient equations.

The tractability index is defined for linear DAEs with a time-varying constant-rank matrix E(t) in front of the derivative (cf. (1.6)), e.g., as in [21], and for DAEs with a properly stated leading term as in [4], [22]. A brief description is given in [3, pp. 293–296]. Notice that, for nonlinear DAEs, the tractability index works with linearizations (see, e.g., [24]).

Consider the DAE

$$A(t)(B(t)x(t))' = H(t)x(t) + q(t),\ t \in [0, T], \tag{4.3}$$

with k equations and the unknown function $x(.)$ with values in $\mathbb{R}^m$. Let (4.3) have a properly stated leading term as described in section 2. Introduce $G_0(t) := A(t)B(t)$, the nullspace $N_0(t) := \ker G_0(t)$, and the subspace $S_0(t) := \{z \in \mathbb{R}^m : H(t)z \in$

$\mathrm{im}G_0(t)\}$. Let $Q_0(t) := Q(t)$ be the orthoprojector onto $\ker G_0(t)$. Further, denote $G_1(t) := G_0(t) - H(t)Q_0(t)$, $N_1(t) := \ker G_1(t)$, and $S_1(t) := \{z \in \mathbb{R}^m : H(t)z \in \mathrm{im}G_1(t)\}$, $r_0 := \mathrm{rankG_0(t)}$, $\nu_0(t) := \dim(\mathrm{N_0(t)} \cap \mathrm{S_0(t)})$. By construction, $P_0(t)$ has constant rank r_0, and $Q_0(t)$ has rank $m - r_0$.

In this paper, we deal with DAEs up to index two only, and we quote just this definition from [4]. Note that a regular DAE with tractability index μ also has perturbation index μ.

DEFINITION 4.1. *Let the subspaces BN_1 and BS_1 be spanned by continuously differentiable basis functions. The DAE* (4.3) *is said to be regular with tractability index one, if $m = k$ and, for $t \in [0,T]$, it holds that $N_0(t) \cap S_0(t) = 0$. The DAE is regular with tractability index two if $m = k$, and if the last intersection has a constant positive dimension on $[0,T]$, but the intersection $N_1(t) \cap S_1(t)$ is trivial for all $t \in [0,T]$.*

It turns out (see [4]) that a regular DAE (4.3) with tractability index one has the solutions

$$x = (I + Q_0 G_1^{-1} H)B^- u + Q_0 G_1^{-1} q,$$

where $u = Bx$ is a solution of the explicit ODE (the so-called inherent explicit ODE)

$$u' = K'u + BG_1^{-1}HB^- u + BG_1^{-1}q,$$

the coefficients of which are uniquely determined by the coefficients A, B, H. This corresponds to the decoupling of the DAE (4.3) into two portions by using the decomposition $I = P_0 + Q_0$ and premultiplication by G_1^{-1}. The P_0-portion leads to the inherent ODE, which has dimension r_0, and the Q_0-portion is the algebraic constraint or nondynamic part with dimension $m - r_0$. With $Bx = BB^- u = u$, we realize that any IVP for (4.3) with continuous $q(.)$, and the initial condition

$$A(0)B(0)x(0) = z_0,\ z_0 \in \mathrm{im(A(0)B(0))},$$

has exactly one solution belonging to the function space $\mathcal{C}_B^1$.

A regular DAE with tractability index two is different. It decouples into three parts: the inherent explicit ODE that has the lower dimension $r_0 - \nu_0$, the algebraic part with dimension $m - r_0$, and an extra part containing a differentiation (an impulsive part in descriptor systems) which is associated with the intersection $N_0 \cap S_0$ and has dimension ν_0. By means of the further projectors Q_1 onto N_1 along S_1, $P_1 := I - Q_1$ we describe the initial conditions appropriate for unique solvability as [4]

$$A(0)B(0)P_1(0)x(0) = z_0,\ z_0 \in \mathrm{im(A(0)B(0)P_1(0))}.$$

IVPs with z_0 not belonging to $\mathrm{im(A(0)B(0)P_1(0))}$, in particular, those with $q = 0$ or smooth q, are no longer solvable in $\mathcal{C}_B^1$.

Let us now turn back to the closed loop DAE (4.1).

THEOREM 4.2. *Let the conditions of Theorem* 3.4 *be given, $m = k$, and Y be a solution of the Riccati DAE system* (3.1)–(3.3). *Then the DAE* (4.1) *is regular with tractability index one, and there is exactly one solution $x_* \in \mathcal{C}_B^1$ of the IVP* (4.1), (4.2).

Proof. As it is shown, e.g., in [4], the IVP-solvability is a consequence of the index-one property. Notice that a linear DAE with a properly stated leading term is

regular with index one if its adjoint equation is, and vice versa (see, e.g., [4]). The adjoint equation to (4.1) reads

$$-B^*(A^*\lambda)' = C^*\lambda - (Y^*D + S)R^{-1}D^*\lambda. \tag{4.4}$$

The DAE (4.4) is regular with index one if the subspaces $\ker B^*A^* = \mathrm{im}Q_*$ and $\ker Q\{C^* - (Y^*D + S)R^{-1}D^*\} =: S_*$ intersect trivially (see, e.g., [4]). Because of $QY^* = (YQ)^* = (ZQ)^* = QZ^*$ we have $S_* = \ker\{QC^* - (QZ^*D + QS)R^{-1}D^*\} = \ker M$. This means the DAE (4.4) is regular with index one if $\ker M$ and $\mathrm{im}Q_*$ intersect trivially, but this in turn is a consequence of condition (3.26). □

THEOREM 4.3. *Let the conditions of Theorem* 3.4 *be given, $m > k$, and Y be a solution of the Riccati DAE system* (3.1)–(3.3). *Then there are solutions $x_* \in \mathcal{C}_B^1$ of the IVP* (4.1), (4.2).

Proof. Compute $G_1 := AB - \{C - DR^{-1}(S^* + D^*Y)\}Q$ and ask whether this matrix function has full row rank k. Obviously, this is in fact the case if $Q_*\{CQ - DR^{-1}(S^*Q + D^*ZQ)\} = Q_*M^* = (MQ_*)^*$ has the same range as Q_*, i.e., if $\mathrm{im}(MQ_*)^* = \mathrm{im}Q_*$. However, this is ensured by (3.26).

Denote $F := C - DR^{-1}(S^* + D^*Y)$.

In [7, Proof of Proposition 3.2], a coordinate transform $x = H\bar{x}$ is applied to the DAE $A(Bx)' = Fx$ with full row rank $G_1 = AB - FQ$ such that the transformed variable has the structure

$$\bar{x} = \begin{pmatrix} z \\ v \end{pmatrix} \begin{matrix} \}k \\ \}m-k \end{matrix}$$

and the transformed IVP is of the form

$$A(\widetilde{B}z)' = \widetilde{F}_1 z + \widetilde{F}_2 v, \quad A(0)\widetilde{B}(0)z(0) = z_0, \tag{4.5}$$

while (4.5), with any given v, represents a regular index-one DAE for z. □

Remark 4.4. By fixing v in (4.5), the resulting IVP for z is uniquely solvable. How to choose the mentioned transformation H in practice is discussed in [7].

5. A case study. Here we deal with the very special case of $k = m = 2$, $n = 1$, $l = 1$, $T = 1$,

$$J(u,x) = \frac{1}{2}\int_0^1 (\alpha x_1(t)^2 + \beta x_2(t)^2 + u(t)^2)dt, \tag{5.1}$$

where $\alpha \geq 0$, $\beta \geq 0$, $W = \left(\begin{smallmatrix} \alpha & 0 \\ 0 & \beta \end{smallmatrix}\right)$, $R = 1$, $V = 0$, $S = 0$, and the DAE describing the side condition is

$$\begin{aligned} x_1'(t) &= c_{12}(t)x_2(t), \\ 0 &= c_{21}(t)x_1(t) + c_{22}(t)x_2(t) + u(t), \end{aligned} \tag{5.2}$$

i.e.,

$$A = \begin{bmatrix} 1 \\ 0 \end{bmatrix},\ B = [1\ \ 0],\ B^- = \begin{bmatrix} 1 \\ 0 \end{bmatrix},\ K = 1,\ D = \begin{bmatrix} 0 \\ 1 \end{bmatrix},\ C = \begin{bmatrix} 0 & c_{12} \\ c_{21} & c_{22} \end{bmatrix}.$$

The initial condition for (5.2) reads

$$x_1(0) = x_{10}. \tag{5.3}$$

We have taken this problem from [14] and will discuss the same three cases as considered there. In the first two cases, optimal controls exist, and we obtain them via our Riccati DAE system, while the Riccati DAE system used in [14] has no solutions. In the third case, if $x_{10} \neq 0$, there is no optimal control, which is reflected by the failure of our conditions (3.25) and (3.26). Notice that just in this case the Riccati DAE in [14] may have solutions. We should like also to point out that this little academic problem (namely, special cases and infinite-horizon modifications) was already used earlier in the literature for illustrative purposes (see, e.g., [5]).

Consider the Riccati DAE system (3.1)–(3.3) for the 2×2 matrix function $Y = \left[\begin{smallmatrix} Y_{11} & Y_{12} \\ Y_{21} & Y_{22} \end{smallmatrix}\right]$. We describe (3.1) by means of the following three equations (cf. (3.5), (3.6), (3.7)), taking into account that we have here $Q = Q_* = \left[\begin{smallmatrix} 0 & 0 \\ 0 & 1 \end{smallmatrix}\right]$, $P = P_* = \left[\begin{smallmatrix} 1 & 0 \\ 0 & 0 \end{smallmatrix}\right]$, and dropping the equations "$0 = 0$,"

$$0 = -\beta - (Y_{12}c_{12} + Y_{22}c_{22}) - (c_{12}Y_{12} + c_{22}Y_{22}) + Y_{22}^2, \tag{5.4}$$

$$0 = -c_{21}Y_{22} - (c_{12}Y_{11} + c_{22}Y_{21}) + Y_{22}Y_{21}, \tag{5.5}$$

$$Y_{11}' = -\alpha - c_{21}Y_{21} - c_{21}Y_{21} + Y_{21}^2. \tag{5.6}$$

The terminal value condition (3.3) is

$$Y_{11}(1) = 0, \tag{5.7}$$

and condition (3.2) here means that

$$Y_{12} = 0. \tag{5.8}$$

Applying (5.8), (5.4) simplifies to

$$0 = -\beta + (Y_{22} - c_{22})^2 - c_{22}^2. \tag{5.9}$$

This algebraic equation has the solutions

$$Y_{22} = c_{22} \pm \sqrt{\beta + c_{22}^2}, \tag{5.10}$$

and the resulting matrix functions $Z = Q_*YQ$ and MQ_* (cf. (3.9)) are

$$Z = \begin{bmatrix} 0 & 0 \\ 0 & Y_{22} \end{bmatrix}, \quad MQ_* = \begin{bmatrix} 0 & 0 \\ 0 & c_{22} - Y_{22} \end{bmatrix}.$$

In this case the conditions (3.25) and (3.26) are equivalent to the conditions that

$$Y_{22}(t) \quad \text{has no zeros} \tag{5.11}$$

and

$$Y_{22}(t) - c_{22}(t) = \pm\sqrt{\beta + c_{22}(t)^2} \quad \text{has no zeros, respectively.} \tag{5.12}$$

Case I. c_{12} and c_{21} vanish identically, and $\beta > 0$.

Here, both Y_{22} and $Y_{22} - c_{22}$ do not have zeros; i.e., the conditions (3.25) and (3.26) are fulfilled. Equation (5.5) is simply $0 = (Y_{22} - c_{22})Y_{21}$, which leads to $Y_{21} = 0$. Equation (5.6) yields $Y_{11}' = -\alpha$. Hence, in this case

$$Y(t) = \begin{bmatrix} -\alpha(t-1) & 0 \\ 0 & c_{22}(t) \pm \sqrt{\beta + c_{22}(t)^2} \end{bmatrix}$$

solves the system. The feedback optimal control is given by $u = -(c_{22} \pm \sqrt{\beta + c_{22}^2})x_2$. The optimal trajectory, i.e., the solution of the IVP (4.1), (4.2) (cf. (2.13)) is $x_*(t) \equiv \binom{x_{10}}{0}$ the optimal control is $u_* = 0$, and the optimal cost is $J(u_*, x_*) = \frac{1}{2}\alpha x_{10}^2$.

Case II. c_{22} vanishes identically, c_{12} and c_{21} have no zeros, and $\beta > 0$. Again, both $Y_{22} = \pm\sqrt{\beta}$ and $Y_{22} - c_{22} = Y_{22}$ have no zeros, and the conditions (3.25) and (3.26) are fulfilled. This time, (5.5) leads to

$$Y_{21} = c_{21} \pm \frac{1}{\sqrt{\beta}} c_{12} Y_{11}. \tag{5.13}$$

From (5.6) and (5.13) we derive the ODE

$$Y_{11}' = -\alpha - 2c_{21}\left(c_{21} \pm \frac{1}{\sqrt{\beta}} c_{12} Y_{11}\right) + \left(c_{21} \pm \frac{1}{\sqrt{\beta}} c_{12} Y_{11}\right)^2.$$

For example, for $c_{12} = c_{21} = 1,\ x_{10} = 1$, the result is that

$$Y_{11}' = -(\alpha + 1) + \frac{1}{\sqrt{\beta}} Y_{11}^2,$$

$$Y_{11}(t) = \beta\gamma \frac{1 - e^{2\gamma(t-1)}}{1 + e^{2\gamma(t-1)}} \qquad \text{with } \gamma = \sqrt{\frac{1+\alpha}{\beta}}.$$

Then, $u = (\mp\frac{1}{\sqrt{\beta}} Y_{11} - 1)x_1 \mp \sqrt{\beta} x_2$ is an optimal feedback control. The DAE (4.1) is of the form

$$x_1' = x_2, \ \ 0 = \frac{1}{\sqrt{\beta}} Y_{11} x_1 + \sqrt{\beta} x_2,$$

and the optimal pair (u_*, x_*) consists of

$$u_*(t) = -x_{*1}(t), \ \ x_{*1}(t) = \frac{e^{\gamma t} + e^{\gamma(2-t)}}{1 + e^{2\gamma}}, \ \ x_{*2}(t) = -\frac{1}{\beta} Y_{11}(t) x_{*1}(t).$$

The minimal cost is

$$J(u_*, x_*) = \frac{\beta\gamma}{2} \cdot \frac{1 - e^{-2\gamma}}{1 + e^{-2\gamma}}.$$

Case III. $\beta = 0,\ c_{22}$ vanishes identically, and c_{12}, c_{21} have no zeros. Here, (5.9) implies $Y_{22} = 0$, and hence, $Z = 0,\ MQ_* = 0$, and the conditions (3.25) and (3.26) fail to be valid. Equation (5.5) simplifies to $c_{12} Y_{11} = 0$, and hence $Y_{11} = 0$ must be true. By (5.6) we find $Y_{21} = c_{21} \pm \sqrt{\alpha + c_{21}^2}$. Therefore, the matrix function

$$Y = \begin{bmatrix} 0 & 0 \\ c_{21} \pm \sqrt{\alpha + c_{21}^2} & 0 \end{bmatrix}$$

solves the system (3.1)–(3.3); however, the conditions (3.25) and (3.26) no longer hold. The resulting closed loop DAE (4.1) is now $x_1' = c_{12} x_2,\ 0 = \sqrt{\alpha + c_{21}^2}\, x_1$, and it has only the trivial solution. Consequently, for $x_{10} \neq 0$, there is no solution of the IVP (4.1), (4.2). If $x_{10} = 0$, then the trivial pair $u_* = 0,\ x_* = 0$ is optimal in accordance with Theorem 2.5. If $x_{10} \neq 0$, then the linear-quadratic optimal control problem has no solution at all.

The Hamiltonian system (2.15) corresponding to the special problem (5.1)–(5.3) is the following:

$$\begin{aligned} x_1' &= c_{12}x_2, \\ 0 &= c_{21}x_1 + c_{22}x_2 - \psi_2, \\ -\psi_1' &= \alpha x_1 + c_{21}\psi_2, \\ 0 &= \beta x_2 + c_{12}\psi_1 + c_{22}\psi_2. \end{aligned} \tag{5.14}$$

For this system, the initial and terminal conditions

$$x_1(0) = x_{10}, \quad \psi_1(1) = 0 \tag{5.15}$$

have to be taken into account. This linear DAE with respect to x, ψ is regular with index one exactly if $\beta + c_{22}^2 \neq 0$. This index-one condition is valid in Cases I and II.

In Case III, the BVP (5.14), (5.15) has no solution for $x_{10} \neq 0$. For $x_{10} = 0$ it has the trivial solution. It may be checked that this DAE has index two.

Notice that, for the solvability of the corresponding Riccati DAE (1.10) treated in [14], it is necessary that $\beta = 0$ be given; i.e., unfortunately, this Riccati DAE is no longer solvable in the unproblematic cases I and II. In Case III the terminal value problem for the Riccati DAE (1.10) may or may not have solutions. From this point of view, the Riccati DAEs (1.7) or (1.10) seem not to be appropriate tools for constructing optimal feedback solutions, whereas the Riccati DAE (1.15) and the versions in [15], [16], [17], [12] are useful for this purpose.

6. Riccati equations and Hamiltonian systems.

THEOREM 6.1. *Given a solution Y of* (2.7), (2.8) *with $A^*YQ = 0$, if the continuous matrix function $X : [0,T] \to L(\mathbb{R}^p, \mathbb{R}^m)$, with a continuously differentiable part BX, satisfies the equation*

$$A(BX)' = (C - DR^{-1}S^* - DR^{-1}D^*Y)X, \tag{6.1}$$

then the pair $X, \Psi := YX$ forms a solution of the Hamiltonian system

$$A(BX)' = (C - DR^{-1}S^*)X - DR^{-1}D^*\Psi, \tag{6.2}$$

$$-B^*(A^*\Psi)' = (W - SR^{-1}S^*)X + (C^* - SR^{-1}D^*)\Psi. \tag{6.3}$$

Ψ is continuous with $A^*\Psi$ being continuously differentiable.

Proof. Equation (6.2) is a trivial consequence of (6.1).

Due to $A^*\Psi = A^*YX = A^*YB^-BX$, $A^*\Psi$ is continuously differentiable. We derive

$$\begin{aligned} B^*(A^*\Psi)' &= B^*(A^*YB^-)'BX + B^*A^*YB^-(BX)' \\ &= B^*(A^*YB^-)'BX + Y^*A(BX)' \\ &= -(W - SR^{-1}S^*)X - (C^* - SR^{-1}D^*)\Psi, \end{aligned}$$

and we are done. ∎

The above pair X, Ψ combines p columns of solutions of the differential-algebraic Hamiltonian system (cf. (2.15))

$$\begin{bmatrix} A & 0 \\ 0 & -B^* \end{bmatrix} \frac{d}{dt} \left(\begin{bmatrix} B & 0 \\ 0 & A^* \end{bmatrix} \begin{bmatrix} x \\ \psi \end{bmatrix} \right) = \begin{bmatrix} C - DR^{-1}S^* & -DR^{-1}D^* \\ W - SR^{-1}S^* & C^* - SR^{-1}D^* \end{bmatrix} \begin{bmatrix} x \\ \psi \end{bmatrix}. \tag{6.4}$$

If one tries to solve the system (6.2), (6.3), one is confronted by the index of the DAE (6.4). Equation (6.4) has a properly stated leading term since (2.2) has one. Equation (6.4) is a square system having $m+k$ equations and $m+k$ unknown functions, respectively.

THEOREM 6.2. *If A and B remain nonsingular,* (6.4) *represents an implicit regular ODE (regular DAE with tractability index zero). Otherwise, for the DAE* (6.4) *to be regular with tractability index one, it is necessary and sufficient that the following two conditions are satisfied:*

$$[AB - CQ,\ D] \quad \textit{has full row rank } k, \tag{6.5}$$

$$\operatorname{im}[Q(C^* - SR^{-1}D^*)Q_*,\ Q(W - SR^{-1}S^*)Q] = \operatorname{im} Q. \tag{6.6}$$

Proof. In the case of nonsingular A and B, the assertion is obvious. Let A, B be singular. In [3], the pair of conditions

$$[AB - CQ,\ D] \quad \text{has full row rank } k, \tag{6.7}$$

and

$$\begin{bmatrix} B^*A^* - C^*Q_* & WQ & S \\ -D^*Q_* & S^*Q & R \end{bmatrix} \quad \text{has full row rank } m + l \tag{6.8}$$

was shown to be necessary and sufficient for the DAE

$$\begin{bmatrix} A & 0 \\ 0 & -B^* \\ 0 & 0 \end{bmatrix} \frac{d}{dt} \left(\begin{bmatrix} B & 0 & 0 \\ 0 & A^* & 0 \end{bmatrix} \begin{bmatrix} x \\ \psi \\ u \end{bmatrix} \right) = \begin{bmatrix} C & 0 & D \\ W & C^* & S \\ S^* & D^* & R \end{bmatrix} \begin{bmatrix} x \\ \psi \\ u \end{bmatrix} \tag{6.9}$$

to be regular with tractability index one. Clearly, (6.9) is regular with index one if (6.4) is, and vice versa. Hence, the above two conditions are valid for (6.4), too. The condition (6.7) coincides with (6.5). Taking into account the invertibility of R, the second condition (6.8) is equivalent to the injectivity of

$$\begin{bmatrix} AB \\ Q_*(C - DR^{-1}S^*) \\ Q(W - SR^{-1}S^*) \end{bmatrix},$$

but this is equivalent to (6.6). (Notice that in [3] slightly more general problems with R positive semidefinite are considered.) □

Remark 6.3. In [5], descriptor systems (1.6) in an *SVD coordinate system* play a special role, and, in particular, the invertibility of a certain matrix $\bar{R}$ (cf. [5]) is a basic property assumed to be given in all four versions of the Riccati differential equations studied in [BeLa, section IV]. From the viewpoint of DAE theory, for those very special systems (6.9), the invertibility of $\bar{R}$ exactly means regularity with tractability index one (cf. [3]).

Remark 6.4. Recall from [3] that, if the system (6.9) is regular with tractability index one, and, additionally, $\ker B^* = 0$, then the so-called inherent regular ODEs of (6.9), and of (6.2), (6.3), actually have a Hamiltonian structure—a property that should be useful concerning the solvability of BVPs for the Hamiltonian system (6.2), (6.3). However, notice that in general it may happen that the so-called Hamiltonian system (6.2), (6.3) may lose the inherent Hamiltonian structure (cf. [3]).

We end up with an assertion saying that if the Hamiltonian system (6.2), (6.3) somehow has good solvability, then the Riccati DAE system (3.1), (3.2) is solvable at the same time.

THEOREM 6.5. *Let $X(t) \in L(\mathbb{R}^m, \mathbb{R}^m), \Psi(t) \in L(\mathbb{R}^m, \mathbb{R}^k)$ be continuous on [0,T], and such that their m columns belong to $\mathcal{C}_B^1$ and $\mathcal{C}_{A^*}^1$, respectively, and*

$$A(BX)' = (C - DR^{-1}S^*)X - DR^{-1}D^*\Psi, \tag{6.10}$$

$$-B^*(A^*\Psi)' = (W - SR^{-1}S^*)X + (C^* - SR^{-1}D^*)\Psi \tag{6.11}$$

is satisfied.

Let X be nonsingular and let $X^{-1}B^-$ belong to $\mathcal{C}^1$. Let $Y := \Psi X^{-1}$ be such that

$$P_*YQ = 0, \quad A^*YB^- = B^{-*}Y^*A.$$

Then, Y is continuous with a continuously differentiable part A^*YB^- and satisfies the Riccati DAE system (3.1), (3.2).

Proof. Here condition (3.2) is given, and $A^*YB^- = A^*YXX^{-1}B^- = A^*\Psi X^{-1}B^-$ belongs to $\mathcal{C}^1$. Derive from (6.11) that

$$B^*(A^*YX)'X^{-1} = -(W - SR^{-1}S^*) - (C^* - SR^{-1}D^*)Y.$$

By means of $B^*(A^*YX)'X^{-1} = B^*(A^*YB^-BX)'X^{-1} = B^*(A^*YB^-)'B + B^*A^*YB^-(BX)'X^{-1} = B^*(A^*YB^-)'B + Y^*A(BX)'X^{-1}$ and taking into account (6.10), (6.11), we obtain (3.1). ∎

If X, Ψ in Theorem 6.5 are chosen to meet the terminal conditions $B(T)^*A(T)^*\Psi(T) = V$, $A(T)B(T)X(T) = A(T)B(T)$, then it follows that $A(T)^*Y(T)B(T)^- = B(T)^{-*}VB(T)^-$; that is, the terminal condition (3.3) is satisfied.

7. Final remark. We have shown that optimal feedback controls of linear-quadratic optimal control problems with constraints described by general linear DAEs with variable coefficients can be obtained by suitably formulating a Riccati DAE system, similarly to the classical example in which the constraints are described by explicit ODEs. Compared to earlier papers and some less suitable Riccati DAEs, we could do without several restrictive assumptions.

Furthermore, we would like to stress that it is not necessary and probably not even reasonable to transform the DAE describing the constraints (descriptor system) or the DAE describing the Hamiltonian system with great expense into a special canonical form.

What is on the agenda is the development of feasible solution methods for the Riccati DAE (3.1), (3.2).

PASSIVITY AND PASSIFICATION FOR NETWORKED CONTROL SYSTEMS*

HUIJUN GAO†, TONGWEN CHEN‡, AND TIANYOU CHAI§

Abstract. This paper investigates the problems of passivity analysis and passification for network-based linear control systems. A new sampled-data model is first formulated based on the updating instants of the ZOH (zeroth order hold), where the physical plant and the controller are, respectively, in continuous time and discrete time. In this model, network-induced delays, data packet dropouts, and signal measurement quantization have been taken into account. The measurement quantizer is assumed to be logarithmic, and the network-induced delays are assumed to have both a lower bound and an upper bound, which is more general than those assumptions used in the literature. The key idea is to transform the sampled-data model into a linear system with two successive delay components in the state. Then, by using a Lyapunov–Krasovskii approach plus the free weighting matrix technique, a passivity performance condition is formulated in the form of linear matrix inequalities (LMIs). Based on this condition, two procedures are proposed for designing passification controllers, which guarantee that the closed-loop networked control system (NCS) is passive. Finally, two illustrative examples are presented: one shows the advantage of introducing the lower bound of transmission delays and shows how much the quantization behavior affects the passivity performance; the other illustrates the applicability and effectiveness of the proposed passification results.

Key words. networked control systems, passivity and passification, quantization, sampled-data systems

1. Introduction.

It is well known that in many practical systems, the physical plant, controller, sensor, and actuator are difficult to locate in the same place, and thus signals are required to be transmitted from one place to another. In modern industrial systems, these components are often connected over network media (typically digital band-limited serial communication channels), giving rise to the so-called networked control systems (NCSs). Compared with traditional feedback control systems, where these components are usually connected via point-to-point cables, the introduction of communication network media brings great advantages, such as low cost, reduced weight and power requirements, simple installation and maintenance, and high reliability [21]. Therefore, NCSs have received more and more attention and have become more and more popular in many practical applications in recent years. Modeling, analysis, and synthesis of network-based feedback systems with limited

communication capability has emerged as a topic of significant interest in the control community, a topic which is highlighted in the recent special issue edited by Antsaklis and Baillieul [2]. From among the reported results on NCSs, we mention a few: the stability issue is investigated in [29, 36, 48], stabilizing controllers are designed in [43, 44, 47, 49], performance preserved control is studied in [23, 28, 33, 45], and moving horizon control is proposed in [17].

What makes an NCS distinct from traditional feedback control systems? To answer this question, we need to look at a few phenomena that typically exist for a network-based control system. Probably the most significant are the network-induced delays, which are usually caused by the limited bit rate of the communication channels, by a node waiting to send out a packet via a busy channel, or by signal processing and propagation. The existence of time delays generally brings negative effects on the stability and performance of NCSs. The time delays in a typical NCS usually take the forms of input delay and output delay, which are essentially different from the state-delayed models, for which a great number of results have been reported recently [18, 19]. The second interesting problem in an NCS is the packet dropout (or data missing [37, 38]) phenomenon, which is usually caused by unavoidable errors or losses in the transmitted packet. Though many NCSs employ automatic repeat request mechanisms, packet dropout phenomenon is still unavoidable. Moreover, packet dropouts may occur if one packet sampled at the sensor node reaches the destination later than its successors. In this situation, it is natural to use the most updated packet by dropping out the old ones, giving rise to packet dropout phenomenon. Another important issue in NCSs is the quantization effect. In NCSs, the measurement and command signals are usually quantized before being communicated, and the number of quantization levels is closely related to the information flow between the components of the control system and thus to the capacity required to transmit the information. The classical control theory, which is based on the standard assumption that data transmission required by the system can be performed with infinite precision, may not be valid in the presence of signal quantization or capacity-limited feedback, and therefore there is a need for developing tools for analysis and design of quantized feedback systems. Many important results on quantized control have been reported; see, for instance, [3, 6, 11, 12, 21, 22, 24, 25, 32, 34] and the references therein.

On the other hand, the notion of passivity plays an important role in the analysis and design of linear and nonlinear systems. In the first place, many systems need to be passive in order to attenuate noises effectively. In the second place, the robustness measure (such as robust stability or robust performance) of a system often reduces to a subsystem or a modified system that is passive. Passivity analysis is a major tool for studying stability of uncertain or nonlinear systems, especially for high-order systems, and thus the passivity analysis approach has been used in control problems for a long time to deal with robust stability problems for complex uncertain systems (see [5, 8, 27, 30, 35, 40] and the references therein). Apart from its direct applications, the notion of passivity is closely related to bounded realness, which is an equally important notion in control. In fact, it is well known that there is a one-to-one relationship between bounded realness and passivity [1]. Consequently, bounded realness analysis can be converted into passivity analysis and vice versa. Very recently, the passivity-based control has been investigated for a few classes of complex systems, including time-delay systems [31, 42], two-dimensional systems [41], fuzzy systems [7], and signal processing systems [39]. To the best of our knowledge, however, the problems of passivity analysis and passification for NCSs have not been investigated and still

remain challenging, which motivates the present study.

In this paper, we investigate the problems of passivity analysis and passification for network-based linear control systems. A new sampled-data model is first formulated based on the updating instants of the ZOH (zeroth order hold) (instead of the sampling instants), where the physical plant and the controller are, respectively, in continuous time and discrete time. In this model, network-induced delays, data packet dropouts, and signal measurement quantization have been taken into account. The measurement quantizer is assumed to be logarithmic, and the network-induced delays are assumed to have both a lower bound and an upper bound, which is more general than those assumptions used in the literature. The key idea is to transform the sampled-data model into a linear system with two successive delay components in the state. Then, by using a Lyapunov–Krasovskii approach plus the free weighting matrix technique, a passivity performance condition is formulated in the form of linear matrix inequalities (LMIs). Based on this condition, two procedures are proposed for designing passification controllers, which guarantee that the closed-loop NCS is passive. Finally, two illustrative examples are presented: one shows the advantage of introducing the lower bound of transmission delays, and how much the quantization behavior affects the passivity performance; the other illustrates the applicability and effectiveness of the proposed passification results.

The remainder of this paper is organized as follows. The problems of passivity analysis and passification for network-based linear control systems are formulated in section 2. Sections 3 and 4 present the main results on passivity analysis and passification, respectively. Section 5 gives two illustrative examples, and we conclude the paper in section 6.

Notation. The notation used throughout the paper is fairly standard. The superscript T stands for matrix transposition, $\mathbb{R}^n$ denotes the n-dimensional Euclidean space, and $P > 0$ (≥ 0) means that P is real symmetric and positive definite (semidefinite). In symmetric block matrices or complex matrix expressions, we use an asterisk ($*$) to represent a term that is induced by symmetry, and diag$\{\ldots\}$ stands for a block-diagonal matrix. Matrices, if their dimensions are not explicitly stated, are assumed to be compatible with algebraic operations.

2. Problem formulation. Consider a typical NCS, shown in Figure 1. Suppose the physical plant is given by the following linear system:

$$\begin{aligned} \dot{x}(t) &= Ax(t) + Bu(t), \\ z(t) &= Cx(t) + Du(t). \end{aligned} \tag{1}$$

Here $x(t) \in \mathbb{R}^n$ is the state vector; $u(t) \in \mathbb{R}^p$ is the input; $z(t) \in \mathbb{R}^q$ is the output; and A, B, C, D are system matrices with appropriate dimensions.

In Figure 1, it is assumed that the sampler is clock-driven, while the quantizer, controller, and actuator are event-driven. The sampling period is assumed to be h, where h is a positive real constant, and we denote the *sampling instant* of the sampler as s_k, $k = 1, \ldots, \infty$. In addition, it is assumed that the state variable $x(t)$ is online measurable, and the measurements of $x(t)$ are first quantized via a quantizer and then transmitted with a single packet. The quantizer is denoted as $f(\cdot) = \left[\begin{array}{cccc} f_1(\cdot) & f_2(\cdot) & \cdots & f_n(\cdot) \end{array}\right]^T$, which is assumed to be symmetric, that is, $f_j(-v) = -f_j(v)$, $j = 1, \ldots, n$. In this paper, we are interested in the logarithmic static and time-invariant quantizer. For each $f_j(\cdot)$, the set of quantized levels is

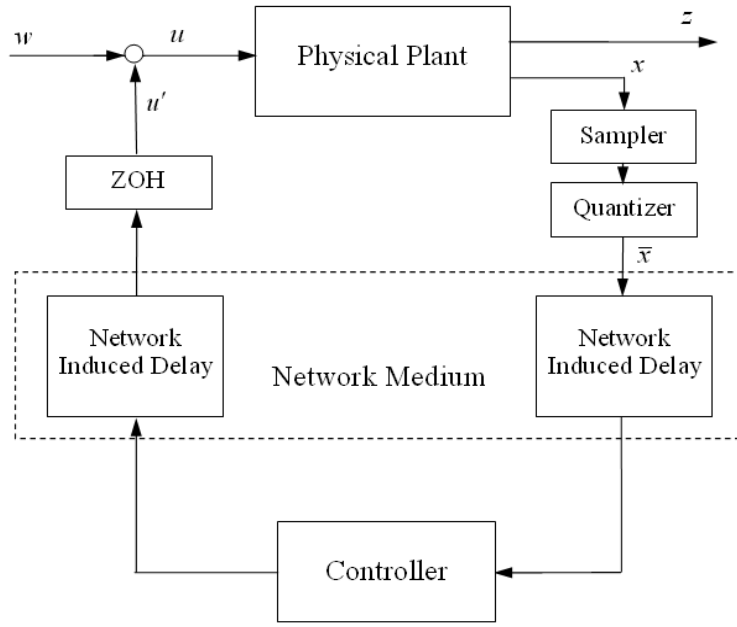

FIG. 1. *An NCS.*

described by

$$\mathcal{U}_j = \left\{ \pm u_i^{(j)}, \quad i = 0, \pm 1, \pm 2, \ldots \right\} \cup \{0\}. \tag{2}$$

According to [10, 13], a quantizer is called *logarithmic* if the set of quantized levels is characterized by

$$\mathcal{U}_j = \left\{ \pm u_i^{(j)},\ u_i^{(j)} = \rho_j^i u_0^{(j)},\ i = \pm 1, \pm 2, \ldots \right\} \cup \left\{ \pm u_0^{(j)} \right\} \cup \{0\}, \quad 0 < \rho_j < 1, \quad u_0^{(j)} > 0. \tag{3}$$

Each of the quantization levels $u_i^{(j)}$ corresponds to a segment such that the quantizer maps the whole segment to this quantization level. In addition, these segments form a partition of $\mathbb{R}$; that is, they are disjoint and their union equals $\mathbb{R}$. For the logarithmic quantizer, the associated quantizer $f_j(\cdot)$ is defined as follows:

$$f_j(v) = \begin{cases} u_i^{(j)} & \text{if } \frac{1}{1+\sigma_j} u_i^{(j)} < v \le \frac{1}{1-\sigma_j} u_i^{(j)}, \quad v > 0, \\ 0 & \text{if } v = 0, \\ -f_j(-v) & \text{if } v < 0, \end{cases} \tag{4}$$

where

$$\sigma_j = \frac{1-\rho_j}{1+\rho_j}. \tag{5}$$

Then, at the sampling instant s_k, we have

$$\bar{x}(s_k) = f(x(s_k)) = \left[\begin{array}{cccc} f_1(x_1(s_k)) & f_2(x_2(s_k)) & \cdots & f_n(x_n(s_k)) \end{array} \right]^T.$$

Now denote the *updating instant* of the ZOH as t_k, $k = 1, \ldots, \infty$, and suppose that the updating signal (the successfully transmitted signal from the sampler to the controller and to the ZOH) at the instant t_k has experienced signal transmission delays η_k ($\eta_k = \tau_k + d_k$, where τ_k is the delay from the quantizer to the controller and d_k is the delay from the controller to the ZOH. It is assumed that there is no delay between the sensor and quantizer). Therefore, the state-feedback controller takes the following form:

$$u'(t_k) = Kf(x(t_k - \eta_k)), \tag{6}$$

where K is the state-feedback control gain. Thus, considering the behavior of the ZOH, we have

$$u(t) = Kf(x(t_k - \eta_k)) + w(t), \quad t_k \le t < t_{k+1}, \tag{7}$$

with t_{k+1} being the next updating instant of the ZOH after t_k, and $w(t) \in \mathbb{R}^p$ being the external input.

A natural assumption on the network-induced delays η_k can be made as follows:

$$\eta_m \le \eta_k \le \eta_M, \tag{8}$$

where η_m and η_M denote the minimum and the maximum delays, respectively. In addition, at the updating instant t_k the number of accumulated data packet dropouts since the last updating instant t_{k-1} is denoted as δ_k. We assume that the maximum number of data packet dropouts is $\bar{\delta}$, that is,

$$\delta_k \le \bar{\delta}. \tag{9}$$

Then, it can be seen from (8) and (9) that

$$t_{k+1} - t_k = (\delta_k + 1)h + \eta_{k+1} - \eta_k. \tag{10}$$

Remark 1. It is worth noting that the assumption on the network-induced delays η_k made in (8) is more general than those assumptions in [43, 44, 45]. The main difference lies in the lower bound we introduced. By assuming $\eta_m = 0$, we see that (8) is the same as those assumptions in [43, 44, 45]. The introduction of the lower bound η_m will be shown later, via a numerical example, and will be advantageous for reducing conservativeness.

Therefore, from (1)–(7) we obtain the following closed-loop system:

$$\begin{aligned} \dot{x}(t) &= Ax(t) + BKf(x(t_k - \eta_k)) + Bw(t), \\ z(t) &= Cx(t) + DKf(x(t_k - \eta_k)) + Dw(t), \\ & t_k \le t < t_{k+1}. \end{aligned} \tag{11}$$

Remark 2. It is important to note that in (7), t_k refers to the *updating instant* of the ZOH. While in [43], the controller is expressed as

$$u(t) = F\bar{x}(t_k), \quad t_k \le t < t_{k+1}, \tag{12}$$

with t_k standing for the *sampling instant*. It should be noted that when the controller and actuator are event-driven, we cannot use the sampling instant to model the behavior of the ZOH. The reason is that the signal transmission delays may not

necessarily be integer multiples of the sampling period, and thus the ZOH may be updated between sampling instants. By using the updating instant in this paper, we do not need to synchronize the ZOH and the sampler, and thus the networked control model formulated here is essentially different from that in [43] and is more general, though they appear to be similar.

Before proceeding further, we introduce the following definition [26].

DEFINITION 1. *The closed-loop NCS in* (11) *is said to be passive if there exists a scalar* $\gamma > 0$ *such that*

$$2\int_0^T w^T(t)z(t)dt \geq -\gamma \int_0^T w^T(t)w(t)dt \tag{13}$$

for all $T > 0$ *under zero initial conditions.*

Then, the problems to be addressed in this paper are expressed as follows.

PROBLEM 1 (passivity analysis). *Consider the NCS in Figure* 1. *Given the system matrices* A, B, C, D *in* (1) *and the controller gain matrix* K *in* (6), *determine under what condition the closed-loop networked control system in* (11) *is passive in the sense of Definition* 1.

PROBLEM 2 (passification). *Consider the NCS in Figure* 1. *Given the system matrices* A, B, C, D *in* (1), *determine the controller gain matrix* K *in* (6) *such that the closed-loop NCS in* (11) *is passive in the sense of Definition* 1.

3. Passivity analysis. This section is concerned with the problem of passivity analysis. More specifically, assuming that the matrices A, B, C, D in (1) and the controller gain matrix K in (6) are known, we shall study the conditions under which the closed-loop NCS in (11) is passive in the sense of Definition 1. The following theorem shows that the closed-loop passivity can be guaranteed if there exist some matrices satisfying certain LMIs. This theorem will play an instrumental role in the problem of passification for NCSs (the proof is given in the appendix).

THEOREM 1. *Consider the NCS in Figure* 1. *Given the matrices* A, B, C, D, *the controller gain matrix* K, *and a positive constant* γ, *the closed-loop system in* (11) *is passive in the sense of Definition* 1 *if there exist matrices* $P > 0$; $Q > 0$; $M_i > 0$, $i = 1, 2$; U_i, V_i, $i = 1, \ldots, 4$; *and a diagonal matrix* $R > 0$ *satisfying*

$$\begin{bmatrix}
\Gamma_{11} & \Gamma_{12} & \Gamma_{13} & \Gamma_{14} & U_1 & V_1 & A^TM_1 & A^TM_2 & PBK \\
* & \Gamma_{22} & \Gamma_{23} & \Gamma_{24} & U_2 & V_2 & 0 & 0 & 0 \\

&\Gamma_{34} = -V_4^T - K^TD^T, && \Gamma_{44} = -\gamma I - D - D^T, \\
&\kappa = \eta_M - \eta_m + \left(\bar{\delta} + 1\right)h, && \Lambda = \operatorname{diag}\{\sigma_1, \ldots, \sigma_n\}.
\end{aligned} \tag{15}$$

Theorem 1 deserves some remarks.

Remark 3. The basic idea behind Theorem 1 is to transform the sampled-data system in (11) into the state-delay system in (40). The passivity of the transformed time-delay system is then analyzed by defining a new Lyapunov–Krasovskii functional plus free weighting matrix techniques. The most significant feature is that no model transformation has been performed to the delay system in (40), which is essentially different from the results obtained in [43] based on a descriptor model transformation. This helps us avoid using a bounding technique for seeking upper bounds of the inner product between two vectors. Similar ideas appear in [19, 20], whose techniques have been shown to be potentially less conservative than those using model transformation methods.

Remark 4. It is worth noting that if the closed-loop NCS in (11) is passive according to Theorem 1, the asymptotic stability of (11) with $w(t) = 0$ is also guaranteed. This is shown as follows: First, define the Lyapunov–Krasovskii functional in (44). Then, by following along lines similar to the proof Theorem 1, we see that the time derivative of $V(t)$ along the solution of (41) with $w(t) = 0$ is given by

$$\begin{aligned}\dot{V}(t) &\le \bar{\zeta}^T(t)\left(\bar{\Gamma} + \eta_m \bar{U} M_1^{-1} \bar{U}^T + \kappa \bar{V} M_2^{-1} \bar{V}^T\right)\bar{\zeta}(t) \\ &- \int_{t-\eta_m}^{t} \left[\bar{\zeta}^T(t)\bar{U} + \dot{x}^T(\alpha) M_1\right] M_1^{-1} \left[\bar{U}^T \bar{\zeta}(t) + M_1 \dot{x}(\alpha)\right] d\alpha \\ &- \int_{t-\eta_m-\eta(t)}^{t-\eta_m} \left[\bar{\zeta}^T(t)\bar{V} + \dot{x}^T(\alpha) M_2\right] M_2^{-1} \left[\bar{V}^T \bar{\zeta}(t) + M_2 \dot{x}(\alpha)\right] d\alpha,\end{aligned}$$

where

$$\bar{\zeta}(t) = \begin{bmatrix} x(t) \\ x(t-\eta_m) \\ x(t-\eta_m-\eta(t)) \end{bmatrix}, \quad \bar{U} = \begin{bmatrix} U_1 \\ U_2 \\ U_3 \end{bmatrix},$$
$$\bar{V} = \begin{bmatrix} V_1 \\ V_2 \\ V_3 \end{bmatrix}, \quad \bar{\Gamma} = \begin{bmatrix} \bar{\Gamma}_{11} & \Gamma_{12} & \bar{\Gamma}_{13} \\ * & \Gamma_{22} & \Gamma_{23} \\ * & * & \bar{\Gamma}_{33} \end{bmatrix}.$$

By following along lines similar to the proof of Theorem 1, we see that (14) guarantees $\bar{\Gamma} + \eta_m \bar{U} M_1^{-1} \bar{U}^T + \kappa \bar{V} M_2^{-1} \bar{V}^T < 0$, and the asymptotic stability is established.

Remark 5. If there is no quantizer in the NCS shown in Figure 1, then (40) in the above proof reads

$$\begin{aligned}\dot{x}(t) &= Ax(t) + BKx(t-\eta_m-\eta(t)) + Bw(t), \\ z(t) &= Cx(t) + DKx(t-\eta_m-\eta(t)) + Dw(t).\end{aligned} \tag{16}$$

Then, we have the following corollary, which can be proved by following arguments similar to the proof of Theorem 1.

COROLLARY 1. *Consider the NCS in Figure* 1*, but without the quantizer. Given the matrices* A, B, C, D*, the controller gain matrix* K *and a positive constant* γ*, the closed-loop system in* (16) *is passive in the sense of Definition* 1 *if there exist matrices*

$P > 0$; $Q > 0$; $M_i > 0$, $i = 1, 2$; U_i, V_i, $i = 1, \ldots, 4$, *satisfying*

$$\begin{bmatrix} \Gamma_{11} & \Gamma_{12} & \Gamma_{13} & \Gamma_{14} & U_1 & V_1 & A^T M_1 & A^T M_2 \\ * & \Gamma_{22} & \Gamma_{23} & \Gamma_{24} & U_2 & V_2 & 0 & 0 \\ * & * & \Gamma_{33} & \Gamma_{34} & U_3 & V_3 & K^T B^T M_1 & K^T B^T M_2 \\ * & * & * & \Gamma_{44} & U_4 & V_4 & B^T M_1 & B^T M_2 \\ * & * & * & * & -\eta_m^{-1} M_1 & 0 & 0 & 0 \\ * & * & * & * & * & -\kappa^{-1} M_2 & 0 & 0 \\ * & * & * & * & * & * & -\eta_m^{-1} M_1 & 0 \\ * & * & * & * & * & * & * & -\kappa^{-1} M_2 \end{bmatrix} < 0,$$

where Γ_{ij} *is given in* (15).

Remark 6. It is worth noting that in the proof of Theorem 1, the transformed system in (40) contains two successive delay components η_m and $\eta(t)$, where η_m is a constant delay, and $\eta(t)$ is a nondifferentiable time-varying delay with bound κ. If the lower bound of the network-induced delays is assumed to be zero, that is, $\eta_m = 0$, (40) takes the following form:

$$\begin{aligned} \dot{x}(t) &= Ax(t) + BKf(x(t - \eta(t))) + Bw(t), \\ z(t) &= Cx(t) + DKf(x(t - \eta(t))) + Bw(t), \end{aligned} \tag{17}$$

with

$$0 \le \eta(t) \le \bar{\kappa}, \tag{18}$$

where

$$\bar{\kappa} = \eta_M + \left(\bar{\delta} + 1\right) h. \tag{19}$$

Compared with (39), the upper bound of $\eta(t)$ in (18) is increased by η_m. In other words, without taking the lower bound of the transmission delays into consideration, η_m will be treated as a nondifferentiable time-varying delay instead of a constant one when it is nonzero. Therefore, the introduction of the lower bound η_m will naturally reduce conservativeness, which will be showed via a numerical example later. However, the existing results on NCSs, such as [43, 44, 45], did not offer to take the lower bound η_m into consideration. The following corollary gives a passivity analysis result for the case when $\eta_m = 0$.

COROLLARY 2. *Consider the NCS in Figure* 1*, and suppose the network-induced delays satisfy* $0 \le \eta_k \le \eta_M$*. Given the matrices* A, B, C, D*, the controller gain matrix* K *and a positive constant* γ*, the closed-loop system in* (17) *is passive in the sense of Definition* 1 *if there exist matrices* $P > 0$; $M > 0$; U_i, $i = 1, 2, 3$; *and a diagonal matrix* $R > 0$ *satisfying*

$$\begin{bmatrix} \Pi_{11} & \Pi_{12} & \Pi_{13} & U_1 & A^T M & PBK \\ * & \Pi_{22} + \Lambda^2 R & \Pi_{23} & U_2 & K^T B^T M & 0 \\ * & * & \Pi_{33} & U_3 & B^T M & -DK \\ * & * & * & -\bar{\kappa}^{-1} M & 0 & 0 \\ * & * & * & * & -\bar{\kappa}^{-1} M & MBK \\ * & * & * & * & * & -R \end{bmatrix} < 0, \tag{20}$$

where $\bar{\kappa}$ *is as given in* (19)*,* Λ *is as given in* (15)*, and*

$$\begin{aligned} \Pi_{11} &= PA + A^T P + U_1 + U_1^T, & \Pi_{12} &= PBK - U_1 + U_2^T, \\ \Pi_{22} &= -U_2 - U_2^T, & \Pi_{13} &= PB - C^T + U_3^T, \\ \Pi_{23} &= -K^T D^T - U_3^T, & \Pi_{33} &= -D^T - D - \gamma I. \end{aligned}$$

Proof. The proof follows along lines similar to the proof of Theorem 1 and thus is outlined briefly. First, by considering the quantization behavior, the closed-loop NCS in (17) can be transformed into

$$\begin{aligned} \dot{x}(t) &= Ax(t) + BK(I + \Lambda(t))(x(t - \eta(t))) + Bw(t), \\ z(t) &= Cx(t) + DK(I + \Lambda(t))(x(t - \eta(t))) + Dw(t) \end{aligned} \tag{21}$$

with $\Lambda(t)$ as given in (42). Define the following Lyapunov–Krasovskii functional:

$$V(t) = x^T(t)Px(t) + \int_{-\bar{\kappa}}^{0} \int_{t+\beta}^{t} \dot{x}^T(\alpha) M \dot{x}(\alpha) d\alpha d\beta, \tag{22}$$

where $P > 0$ and $M > 0$ are matrices to be determined. Then, the corollary can be proved by following along lines similar to the proof of Theorem 1. □

4. Passification. This section is devoted to solving the problem of passification for NCSs.

PROPOSITION 1. *Consider the NCS in Figure* 1. *Given a positive constant* γ, *there exists a state-feedback controller in the form of* (6) *such that the closed-loop system in* (11) *is passive in the sense of Definition* 1 *if there exist matrices* $\bar{P} > 0$; $\bar{Q} > 0$; $\bar{M}_i > 0$, $i = 1, 2$; $\bar{U}_i$, $\bar{V}_i$, $i = 1, \ldots, 4$; $\bar{K}$; *and a diagonal matrix* $\bar{R} > 0$ *satisfying*

(23)

$$\begin{bmatrix} \Omega_{11} & \Omega_{12} & \Omega_{13} & \Omega_{14} & \bar{U}_1 & \bar{V}_1 & \bar{P}A^T & \bar{P}A^T & B\bar{K} & 0 \\ * & \Omega_{22} & \Omega_{23} & \Omega_{24} & \bar{U}_2 & \bar{V}_2 & 0 & 0 & 0 & 0 \\ * & * & \Omega_{33} & \Omega_{34} & \bar{U}_3 & \bar{V}_3 & \bar{K}^T B^T & \bar{K}^T B^T & 0 & \bar{P} \\ * & * & * & \Omega_{44} & \bar{U}_4 & \bar{V}_4 & B^T & B^T & -D\bar{K} & 0 \\ * & * & * & * & -\eta_m^{-1} \bar{P} \bar{M}_1^{-1} \bar{P} & 0 & 0 & 0 & 0 & 0 \\ * & * & * & * & * & -\kappa^{-1} \bar{P} \bar{M}_2^{-1} \bar{P} & 0 & 0 & 0 & 0 \\ * & * & * & * & * & * & -\eta_m^{-1} \bar{M}_1 & 0 & B\bar{K} & 0 \\ * & * & * & * & * & * & * & -\kappa^{-1} \bar{M}_2 & B\bar{K} & 0 \\ * & * & * & * & * & * & * & * & -\bar{P}\bar{R}^{-1}\bar{P} & 0 \\ * & * & * & * & * & * & * & * & * & -\Lambda^{-2}\bar{R} \end{bmatrix} < 0,$$

where κ *and* Λ *are given in* (15) *and*

$$\begin{aligned} \Omega_{11} &= A\bar{P} + \bar{P}A^T + \bar{Q} + \bar{U}_1 + \bar{U}_1^T, & \Omega_{12} &= -\bar{U}_1 + \bar{U}_2^T + \bar{V}_1, \\ \Omega_{22} &= -\bar{Q} - \bar{U}_2 - \bar{U}_2^T + \bar{V}_2 + \bar{V}_2^T, & \Omega_{13} &= \bar{U}_3^T - \bar{V}_1 + B\bar{K}, \\ \Omega_{23} &= -\bar{U}_3^T - \bar{V}_2 + \bar{V}_3^T, & \Omega_{33} &= -\bar{V}_3 - \bar{V}_3^T, \\ \Omega_{14} &= B + \bar{U}_4^T - \bar{P}C^T, & \Omega_{24} &= -\bar{U}_4^T + \bar{V}_4^T, \\ \Omega_{34} &= -\bar{V}_4^T - \bar{K}^T D^T, & \Omega_{44} &= -\gamma I - D - D^T. \end{aligned} \tag{24}$$

Moreover, if the above condition is feasible, the gain matrix of a desired controller in the form of (6) *is given by*

$$K = \bar{K}\bar{P}^{-1}. \tag{25}$$

Proof. From Theorem 1, we know that there exists a state-feedback controller in the form of (6) such that the closed-loop NCS in (11) is passive in the sense of Definition 1 if there exist matrices $P > 0$; $Q > 0$; $M_i > 0$, $i = 1, 2$; U_i, V_i, $i = 1, \ldots, 4$; and a diagonal matrix $R > 0$ satisfying (14). Performing a congruence

transformation to (14) by diag $\{P^{-1}, P^{-1}, P^{-1}, I, P^{-1}, P^{-1}, M_1^{-1}, M_2^{-1}, P^{-1}\}$, and a Schur complement operation to the term $\Lambda^2 P^{-1} R P^{-1}$ in the (3,3) block, together with the change of matrix variables defined by

$$\bar{P} = P^{-1}, \quad \bar{M}_i = M_i^{-1}, \quad \bar{R} = R^{-1}, \quad \bar{K} = KP^{-1}, \quad \bar{Q} = P^{-1}QP^{-1},$$

$$\bar{U} = \begin{bmatrix} \bar{U}_1 \\ \bar{U}_2 \\ \bar{U}_3 \\ \bar{U}_4 \end{bmatrix} = \begin{bmatrix} P^{-1} & 0 & 0 & 0 \\ * & P^{-1} & 0 & 0 \\ * & * & P^{-1} & 0 \\ * & * & * & I \end{bmatrix} \begin{bmatrix} U_1 \\ U_2 \\ U_3 \\ U_4 \end{bmatrix} P^{-1},$$

$$\bar{V} = \begin{bmatrix} \bar{V}_1 \\ \bar{V}_2 \\ \bar{V}_3 \\ \bar{V}_4 \end{bmatrix} = \begin{bmatrix} P^{-1} & 0 & 0 & 0 \\ * & P^{-1} & 0 & 0 \\ * & * & P^{-1} & 0 \\ * & * & * & I \end{bmatrix} \begin{bmatrix} V_1 \\ V_2 \\ V_3 \\ V_4 \end{bmatrix} P^{-1},$$

we obtain (23), and the proposition is proved. □

The condition in Proposition 1 still cannot be implemented by using standard numerical software due to the existence of the terms $\bar{P}\bar{M}_i^{-1}\bar{P}$ and $\bar{P}\bar{R}^{-1}\bar{P}$. By noticing $\bar{M}_i > 0$ and $\bar{R} > 0$, we have

$$\left(\bar{M}_i - \bar{P}\right) \bar{M}_i^{-1} \left(\bar{M}_i - \bar{P}\right) \geq 0, \quad \left(\bar{R} - \bar{P}\right) \bar{R}^{-1} \left(\bar{R} - \bar{P}\right) \geq 0,$$

which is equivalent to

$$-\bar{P}\bar{M}_i^{-1}\bar{P} \leq \bar{M}_i - 2\bar{P}, \quad -\bar{P}\bar{R}^{-1}\bar{P} \leq \bar{R} - 2\bar{P}. \tag{26}$$

By combining (23) and (26), we readily obtain the following theorem.

THEOREM 2. *Consider the NCS in Figure* 1. *Given a positive constant* γ, *there exists a state-feedback controller in the form of* (6) *such that the closed-loop system in* (11) *is passive in the sense of Definition* 1 *if there exist matrices* $\bar{P} > 0$; $\bar{Q} > 0$; $\bar{M}_i > 0$, $i = 1, 2$; $\bar{U}_i$, $\bar{V}_i$, $i = 1, \ldots, 4$; $\bar{K}$; *and a diagonal matrix* $\bar{R} > 0$ *satisfying*

(27)

$$\begin{bmatrix} \Omega_{11} & \Omega_{12} & \Omega_{13} & \Omega_{14} & \bar{U}_1 & \bar{V}_1 & \bar{P}A^T & \bar{P}A^T & B\bar{K} & 0 \\ * & \Omega_{22} & \Omega_{23} & \Omega_{24} & \bar{U}_2 & \bar{V}_2 & 0 & 0 & 0 & 0 \\ * & * & \Omega_{33} & \Omega_{34} & \bar{U}_3 & \bar{V}_3 & \bar{K}^T B^T & \bar{K}^T B^T & 0 & \bar{P} \\ * & * & * & \Omega_{44} & \bar{U}_4 & \bar{V}_4 & B^T & B^T & -D\bar{K} & 0 \\ * & * & * & * & \eta_m^{-1}\left(\bar{M}_1 - 2\bar{P}\right) & 0 & 0 & 0 & 0 & 0 \\ * & * & * & * & * & \kappa^{-1}\left(\bar{M}_2 - 2\bar{P}\right) & 0 & 0 & 0 & 0 \\ * & * & * & * & * & * & -\eta_m^{-1}\bar{M}_1 & 0 & B\bar{K} & 0 \\ * & * & * & * & * & * & * & -\kappa^{-1}\bar{M}_2 & B\bar{K} & 0 \\ * & * & * & * & * & * & * & * & \bar{R} - 2\bar{P} & 0 \\ * & * & * & * & * & * & * & * & * & -\Lambda^{-2}\bar{R} \end{bmatrix} < 0,$$

where Ω_{ii} *is as given in* (24). *Moreover, if the above condition is feasible, the gain matrix of a desired controller in the form of* (6) *is given by* (25).

Remark 7. Note that (27) is an LMI not only over the matrix variables, but also over the scalar γ. This implies that the scalar γ can be included as an optimization variable to obtain a reduction of the passivity performance bound. Then, the minimum (in terms of the feasibility of (27)) passivity performance bound with admissible controllers can be readily found by solving the following convex optimization problem using the LMI toolbox in MATLAB:

$$\begin{aligned} &\text{Minimize } \gamma \text{ subject to (27) over } \bar{P} > 0;\ \bar{Q} > 0;\ \bar{M}_i > 0,\ i = 1, 2; \\ &\bar{U}_i,\ \bar{V}_i,\ i = 1, \ldots, 4;\ \bar{K};\ \text{and diagonal } \bar{R} > 0. \end{aligned}$$

Theorem 2 presents an LMI condition for the existence of desired state-feedback controllers based on the inequalities in (26). In the following, we present another approach to solving the condition in Proposition 1.

Now introduce additional matrix variables $\bar{N}_i > 0$ and $\bar{S} > 0$, and replace (23) with

$$\begin{bmatrix} \Omega_{11} & \Omega_{12}\Omega_{13} & \Omega_{14} & \bar{U}_1 & \bar{V}_1 & \bar{P}A^T & \bar{P}A^T & B\bar{K} & 0 \\ * & \Omega_{22}\Omega_{23} & \Omega_{24} & \bar{U}_2 & \bar{V}_2 & 0 & 0 & 0 & 0 \\ * & * \ \Omega_{33} & \Omega_{34} & \bar{U}_3 & \bar{V}_3 & \bar{K}^T B^T & \bar{K}^T B^T & 0 & \bar{P} \\ * & * & * & \Omega_{44} & \bar{U}_4 & \bar{V}_4 & B^T & B^T & -D\bar{K} & 0 \\ * & * & * & * & -\eta_m^{-1}\bar{N}_1 & 0 & 0 & 0 & 0 & 0 \\ * & * & * & * & * & -\kappa^{-1}\bar{N}_2 & 0 & 0 & 0 & 0 \\ * & * & * & * & * & * & -\eta_m^{-1}\bar{M}_1 & 0 & B\bar{K} & 0 \\ * & * & * & * & * & * & * & -\kappa^{-1}\bar{M}_2 & B\bar{K} & 0 \\ * & * & * & * & * & * & * & * & -\bar{S} & 0 \\ * & * & * & * & * & * & * & * & * & -\Lambda^{-2}\bar{R} \end{bmatrix} < 0, \tag{28}$$

$$\bar{N}_i - \bar{P}\bar{M}_i^{-1}\bar{P} \le 0, \quad i = 1, 2, \tag{29}$$

$$\bar{S} - \bar{P}\bar{R}^{-1}\bar{P} \le 0. \tag{30}$$

By the Schur complement, (29) and (30) are equivalent to

$$\begin{bmatrix} -\bar{N}_i^{-1} & \bar{P}^{-1} \\ * & -\bar{M}_i^{-1} \end{bmatrix} \le 0, \quad i = 1, 2, \tag{31}$$

$$\begin{bmatrix} -\bar{S}^{-1} & \bar{P}^{-1} \\ * & -\bar{R}^{-1} \end{bmatrix} \le 0. \tag{32}$$

Then, we readily obtain the following theorem.

THEOREM 3. *Consider the NCS in Figure* 1. *Given a positive constant* γ, *there exists a state-feedback controller in the form of* (6) *such that the closed-loop system in* (11) *is passive in the sense of Definition* 1 *if there exist matrices* $\bar{P} > 0$; $P > 0$; $\bar{S} > 0$; $S > 0$; $\bar{Q} > 0$; $\bar{N}_i > 0$; $N_i > 0$; $\bar{M}_i > 0$; $M_i > 0$, $i = 1, 2$; $\bar{U}_i$, $\bar{V}_i$, $i = 1, \ldots, 4$; $\bar{K}$; *and diagonal matrices* $\bar{R} > 0$, $R > 0$ *satisfying* (28) *and*

$$\begin{bmatrix} -S & P \\ * & -R \end{bmatrix} \le 0, \quad \begin{bmatrix} -N_i & P \\ * & -M_i \end{bmatrix} \le 0, \quad i = 1, 2, \tag{33}$$

$$\bar{P}P = I, \quad \bar{R}R = I, \quad \bar{M}_i M_i = I, \quad \bar{N}_i N_i = I, \quad i = 1, 2. \tag{34}$$

Moreover, if the above condition is feasible, the gain matrix of a desired controller in the form of (6) *is given by* (25).

The condition presented in Theorem 3 is equivalent to that in Proposition 1. It is noted that this condition is not a convex set due to the matrix equality constraints in (34). Several approaches have been proposed to solve such nonconvex feasibility problems, among which the cone complementarity linearization (CCL) method [9] is the most commonly used (for instance, the CCL algorithm has been used for solving the controller design problems as well as model reduction problems [15, 16, 46]). The basic idea in CCL algorithm is that if the LMI $\left[\begin{smallmatrix} P & I \\ I & L \end{smallmatrix}\right] \ge 0$ is feasible in the $n \times n$ matrix variables $L > 0$ and $P > 0$, then $\mathrm{tr}(PL) \ge n$, and $\mathrm{tr}(PL) = n$ if and only if $PL = I$.

Now using a cone complementarity approach [9], we suggest the following nonlinear minimization problem involving LMI conditions instead of the original nonconvex feasibility problem formulated in Theorem 3.

PROBLEM PCD (PASSIFICATION CONTROLLER DESIGN).

$$\min \ \operatorname{tr}\left(\bar{P}P + \bar{R}R + \sum_{i=1}^{2}\left(\bar{M}_i M_i + \bar{N}_i N_i\right)\right) \ \textit{subject to (28), (33) and}$$

$$\begin{bmatrix} \bar{P} & I \\ I & P \end{bmatrix} \geq 0, \quad \begin{bmatrix} \bar{R} & I \\ I & R \end{bmatrix} \geq 0, \quad \begin{bmatrix} \bar{M}_i & I \\ I & M_i \end{bmatrix} \geq 0, \quad \begin{bmatrix} \bar{N}_i & I \\ I & N_i \end{bmatrix} \geq 0, \quad i = 1, 2.$$

According to [9], if the solution of the above minimization problem is $6n$, that is,

$$\min \ \operatorname{tr}\left(\bar{P}P + \bar{R}R + \sum_{i=1}^{2}\left(\bar{M}_i M_i + \bar{N}_i N_i\right)\right) = 6n,$$

then the conditions in Theorem 3 are solvable. Algorithm 1 in [9] can be easily adapted to solve Problem PCD.

5. Illustrative example. In this section, two examples are provided to illustrate the results developed above. We first use a numerical example to show the advantage of introducing the lower bound of transmission delays, and to show how much the quantization behavior affects the passivity performance. The second example shows the applicability of the passification results.

Example 1. Suppose the system of matrices A, B, C, D in (1) and the controller gain K in (6) are given by

$$A = \begin{bmatrix} 0 & 1 \\ -1 & -2 \end{bmatrix}, \quad B = \begin{bmatrix} 0 \\ 1 \end{bmatrix}, \quad C = \begin{bmatrix} 1 & 0 \end{bmatrix}, \quad D = 0.3, \quad K = \begin{bmatrix} -1 & 1 \end{bmatrix}.$$

The parameters for the quantizer $f(\cdot)$ are given by $\rho_1 = 0.8$ and $\rho_2 = 0.9$; thus according to (4) we have $\sigma_1 = 0.1111$ and $\sigma_2 = 0.0526$. It is assumed that the network-induced delays η_k satisfy $\eta_m \leq \eta_k \leq 0.4$ s, the maximum number of data packet dropouts is 2, and the sampling period is 10 ms. Our purpose is to determine the minimum guaranteed passivity performances for different values of the lower delay bound η_m.

When we do not consider the lower bound of the network-induced delays, that is, $\eta_m = 0$, by using Corollary 2 and Theorem 1 (assuming η_m is sufficiently small), the minimum guaranteed passivity performance obtained is $\gamma_{\min} = 5.4425$. However, if we assume $\eta_m = 0.1$ s, the minimum guaranteed passivity performance obtained is $\gamma_{\min} = 0.9578$. A more detailed comparison for different values of η_m is provided in Table 1, which shows that considering the lower bound of the signal transmission delay gives rise to less conservative results.

TABLE 1
Comparison for different values of η_m.

η_m (s)	0	0.05	0.1	0.15	0.2
Guaranteed passivity performance $\gamma_{\min}$	5.4425	1.7528	0.9578	0.6019	0.3958

The second task in this example is to show how much the quantization behavior affects the guaranteed passivity performance. Now we assume $\eta_m = 0.15$, and other parameters, except that related to the quantizer $f(\cdot)$, are the same as above. When $\rho_1 = 0.8$ and $\rho_2 = 0.9$ (corresponding to $\sigma_1 = 0.1111$ and $\sigma_2 = 0.0526$), by Theorem 1, the minimum guaranteed passivity performance obtained is $\gamma_{\min} = 0.6019$. When

$\rho_1 = 0.7$ and $\rho_2 = 0.8$ (corresponding to $\sigma_1 = 0.1765$ and $\sigma_2 = 0.1111$), the minimum guaranteed passivity performance obtained is $\gamma_{\min} = 2.8398$. This shows that for a coarser quantizer (corresponding to smaller ρ_j or larger σ_j), the obtained minimum guaranteed passivity performance is usually larger. A more detailed comparison for different values of ρ_j is provided in Table 2. To facilitate the presentation, we assume $\rho_1 = \rho_2 = \rho$ (corresponding to $\sigma_1 = \sigma_2 = \sigma$) in the comparison.

TABLE 2
Comparison for different quantizer parameters.

ρ	0.9	0.85	0.8	0.75
σ	0.0526	0.0811	0.1111	0.1429
Guaranteed passivity performance $\gamma_{\min}$	0.3704	0.6652	1.2815	3.3814

Example 2. Suppose the physical plant in Figure 1 is a satellite system, which appears in [4, 14]. The satellite system consists of two rigid bodies joined by a flexible link. This link is modeled as a spring with torque constant k and viscous damping f. Denoting the yaw angles for the two bodies (the main body and the instrumentation module) by θ_1 and θ_2, the control torque by $u(t)$, and the moments of inertia of the two bodies by J_1 and J_2, we see that the dynamic equations are given by

$$J_1\ddot{\theta}_1(t) + f(\dot{\theta}_1(t) - \dot{\theta}_2(t)) + k((\theta_1(t) - \theta_2(t))) = u(t),$$
$$J_2\ddot{\theta}_2(t) + f(\dot{\theta}_1(t) - \dot{\theta}_2(t)) + k((\theta_1(t) - \theta_2(t))) = 0.$$

Assume the output is the angular positions $\theta_2(t)$. Thus, the state-space representation of the above equation is given by

$$\begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & J_1 & 0 \\ 0 & 0 & 0 & J_2 \end{bmatrix} \begin{bmatrix} \dot{\theta}_1(t) \\ \dot{\theta}_2(t) \\ \ddot{\theta}_1(t) \\ \ddot{\theta}_2(t) \end{bmatrix} = \begin{bmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ -k & k & -f & f \\ k & -k & f & -f \end{bmatrix} \begin{bmatrix} \theta_1(t) \\ \theta_2(t) \\ \dot{\theta}_1(t) \\ \dot{\theta}_2(t) \end{bmatrix} + \begin{bmatrix} 0 \\ 0 \\ 1 \\ 0 \end{bmatrix} u(t),$$

$$y(t) = \begin{bmatrix} 0 & 1 & 0 & 0 \end{bmatrix} \begin{bmatrix} \theta_1(t) \\ \theta_2(t) \\ \dot{\theta}_1(t) \\ \dot{\theta}_2(t) \end{bmatrix}. \tag{35}$$

Here we choose $J_1 = J_2 = 1$, $k = 0.09$, and $f = 0.04$ (the values of k and f are chosen within their respective ranges). Then, the corresponding matrices described in section 2 are given by

$$A = \begin{bmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ -0.3 & 0.3 & -0.004 & 0.004 \\ 0.3 & -0.3 & 0.004 & -0.004 \end{bmatrix}, \quad B = \begin{bmatrix} 0 \\ 0 \\ 1 \\ 0 \end{bmatrix},$$
$$C = \begin{bmatrix} 0 & 1 & 0 & 0 \end{bmatrix}, \quad D = 0.$$

It is assumed that the sampling period $h = 10$ ms; the network-induced delay bound in (8) are given by $\eta_m = 10$ ms and $\eta_M = 20$ ms; and the maximum number of data packet dropouts $\bar{\delta} = 2$. In addition, the parameters for the quantizer $f(\cdot)$ are assumed to be $\rho_1 = \rho_2 = \rho_3 = \rho_4 = 0.9$.

The eigenvalues of A are $-0.04 + 0.4224j$, $-0.0400 - 0.4224j$, 0, 0, and thus the above system is not stable. Our purpose is to design a state-feedback controller in

the form of (6) such that the closed-loop system is passive in the sense of Definition 1. By using Theorem 2 (minimizing γ in (27)), we obtain the following matrices (for space consideration we do not list all the obtained matrices here):

$$\bar{P} = \begin{bmatrix} 3.8994 & 0.4268 & -0.4130 & -0.4647 \\ 0.4268 & 0.7929 & 0.5678 & -0.2679 \\ -0.4130 & 0.5678 & 2.0103 & -0.2784 \\ -0.4647 & -0.2679 & -0.2784 & 0.1820 \end{bmatrix},$$
$$\bar{K} = \begin{bmatrix} -1.4010 & -0.0335 & -1.9367 & 0.0873 \end{bmatrix},$$
$$\bar{R} = \operatorname{diag}\{0.0874,\ 0.2912,\ 0.0598,\ 0.0052\}.$$

Thus, according to (25), the gain matrix for the state-feedback controller in (6) is given by

$$K = \begin{bmatrix} -1.2647 & 0.2377 & -2.0589 & -5.5490 \end{bmatrix},$$

and the obtained minimum guaranteed passivity performance in terms of the feasibility of (27) is $\gamma^* = 1.1736$.

We first show that the closed-loop system is asymptotically stable. The initial condition is assumed to be

$$\begin{bmatrix} -0.5 & 0.2 & 0.3 & -0.3 \end{bmatrix}^T.$$

The state responses are depicted in Figure 2, from which we can see that all four states converge to zero. In the simulation, the network-induced delays and the data packet dropouts are generated randomly (meanly distributed within their ranges) according to the above assumption and are shown in Figures 3 and 4. The computed control inputs arriving at the ZOH are shown in Figure 5 (with zoomed area given in Figure 6), where we can see the discontinuous holding behavior of the control inputs.

Now, we will show the passivity of the closed-loop system. To this end, let us assume zero initial conditions and select a set of input signals as follows:

$$w(t) = \begin{cases} \sin t, & 5 \le t \le 15\text{s}, \\ 0 & \text{otherwise}. \end{cases} \tag{36}$$

Figures 7 and 8 depict the state responses and the control input, respectively. Now denote

$$L(t) \triangleq 2\int_0^t w^T(s)z(s)ds, \quad R(t) \triangleq -\gamma\int_0^t w^T(s)w(s)ds,$$

which correspond to the left-hand and right-hand sides of (13), respectively. $L(t)$ and $R(t)$ are depicted in Figure 9, which shows that $L(t) \ge R(t)$ for all $t \ge 0$, and thus (13) is guaranteed and the effectiveness of the passification design is clear.

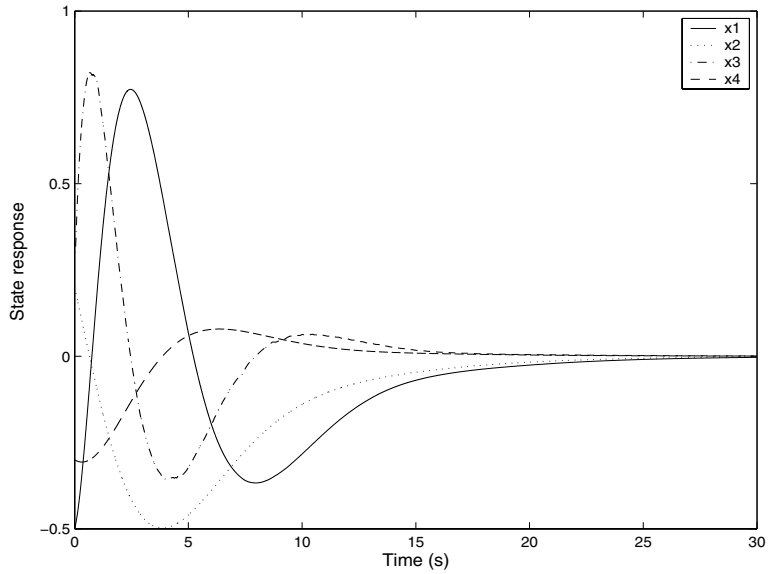

FIG. 2. *State response.*

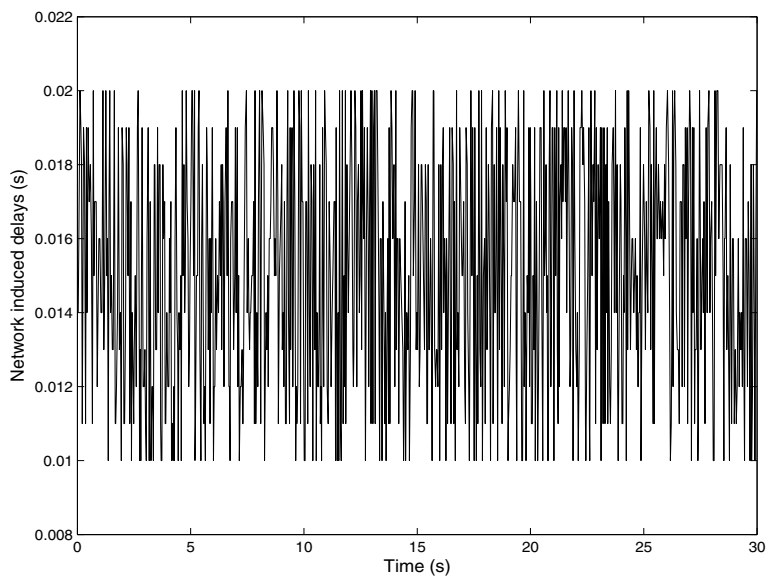

FIG. 3. *Networked-induced delays.*

6. Conclusions. The problems of passivity analysis and passification for network-based linear control systems have been investigated. The physical plant is in continuous time, and the controller is in discrete time. The problems are solved by using a sampled-data approach, which has taken the network-induced delays, data packet dropouts, and measurement quantization into consideration. The measurement quantizer is assumed to be logarithmic, and the network-induced delays are assumed to have both a lower bound and an upper bound, which is more general than those assumptions used in the literature. A new model based on the updating instants of the

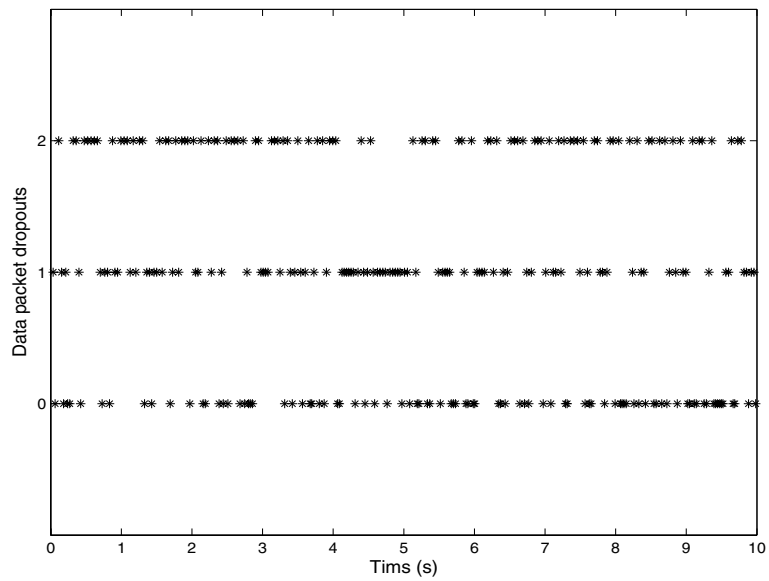

FIG. 4. *Data packet dropouts.*

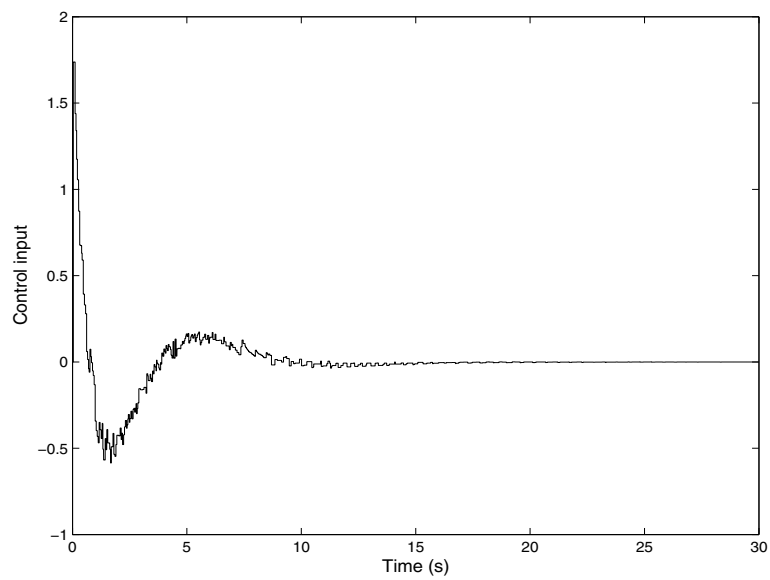

FIG. 5. *Control input.*

ZOH (instead of the sampling instants) has been formulated, and a passivity analysis performance condition has been proposed in the form of an LMI. Based on this condition, a controller design procedure has been developed, which guarantees that the closed-loop NCS is passive. The results developed here can be further extended to linear systems with parameter uncertainties, represented in either norm-bounded or polytopic frameworks. Two illustrative examples have been provided to show the usefulness and effectiveness of the proposed theoretical results. It is worth noting that in this paper, only one side of the quantization effect (from sampler to controller) has

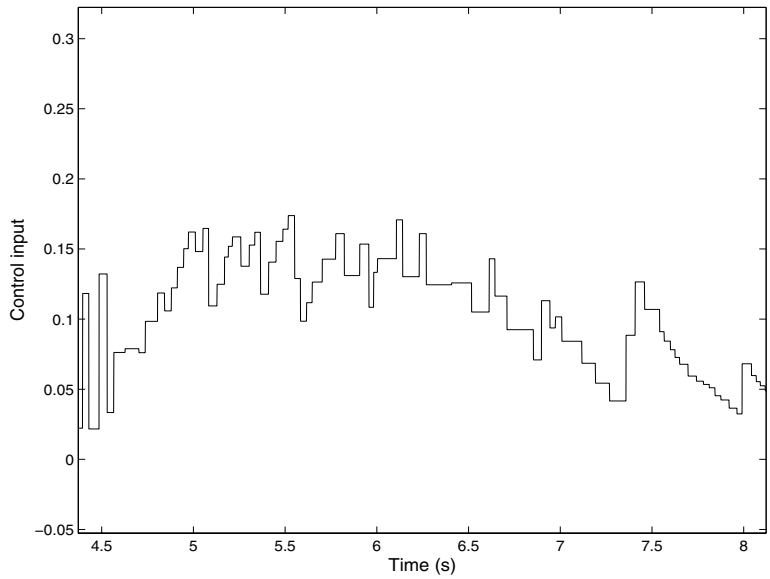

FIG. 6. *Zoomed area of control input.*

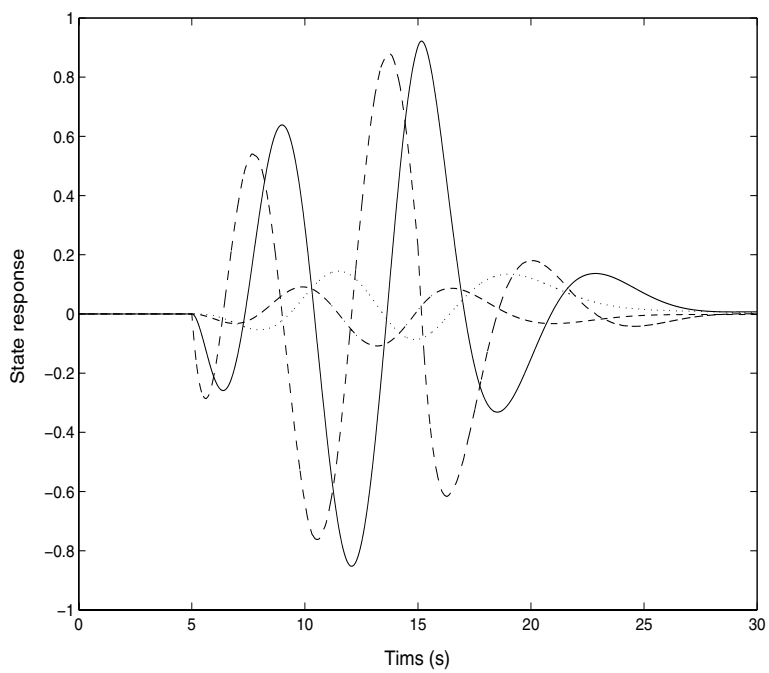

FIG. 7. *State response under* (36).

been taken into consideration. A more challenging problem is to consider the case where quantization effects appear in both sides (from sampler to controller and from controller to ZOH). Moreover, future research effort could be directed towards solving the passification problem via output-feedback controllers, which is useful when the state variables are not measurable.

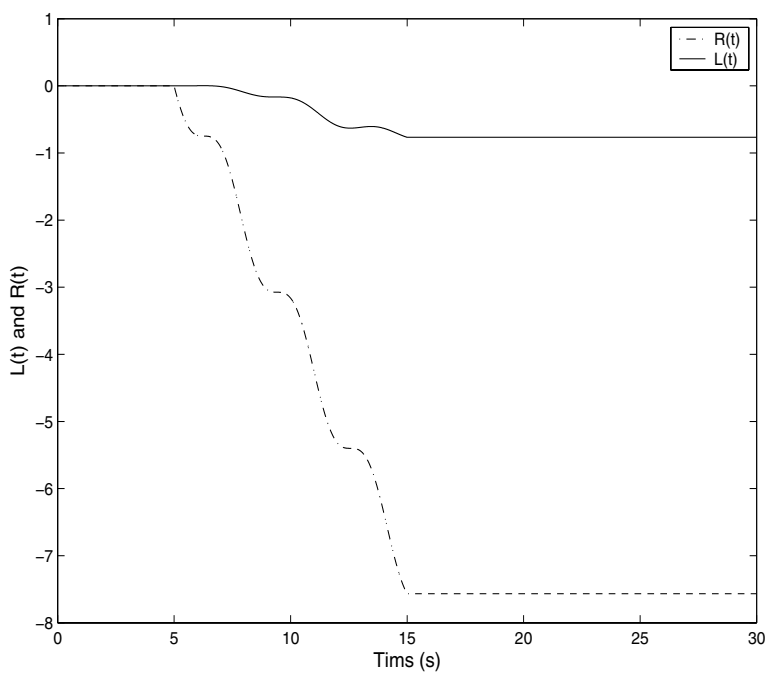

FIG. 9. *Calculation of* $L(t)$ *and* $R(t)$.

Appendix A. Proof of Theorem 1. First, let us represent $t_k - \eta_k$ in (11) as

$$t_k - \eta_k = t - \eta_m - \eta(t), \tag{37}$$

where

$$\eta(t) = t - t_k + (\eta_k - \eta_m). \tag{38}$$

Then, from (10) we have

$$0 \le \eta(t) \le \kappa, \tag{39}$$

where κ is as given in (15). By substituting (37) into (11), we obtain

$$\begin{aligned} \dot{x}(t) &= Ax(t) + BKf(x(t - \eta_m - \eta(t))) + Bw(t), \\ z(t) &= Cx(t) + DKf(x(t - \eta_m - \eta(t))) + Dw(t). \end{aligned} \tag{40}$$

In addition, considering the quantization behavior shown in (2)–(5), and according to [10, 13], (40) can be expressed as

$$\begin{aligned} \dot{x}(t) &= Ax(t) + BK(I + \Lambda(t))(x(t - \eta_m - \eta(t))) + Bw(t), \\ z(t) &= Cx(t) + DK(I + \Lambda(t))(x(t - \eta_m - \eta(t))) + Dw(t), \end{aligned} \tag{41}$$

where

$$\Lambda(t) = \operatorname{diag}\{\Lambda_1(t), \Lambda_2(t), \ldots, \Lambda_n(t)\}, \tag{42}$$

with

$$\Lambda_j(t) \in [-\sigma_j, \sigma_j], \quad j = 1, \ldots, n. \tag{43}$$

Choose the following Lyapunov–Krasovskii functional:

$$\begin{aligned} V(t) &= x^T(t)Px(t) + \int_{t-\eta_m}^{t} x^T(\alpha)Qx(\alpha)\,d\alpha \\ &\quad + \int_{-\eta_m}^{0}\int_{t+\beta}^{t} \dot{x}^T(\alpha)M_1\dot{x}(\alpha)d\alpha d\beta + \int_{-\eta_m-\kappa}^{-\eta_m}\int_{t+\beta}^{t} \dot{x}^T(\alpha)M_2\dot{x}(\alpha)d\alpha d\beta, \end{aligned} \tag{44}$$

where $P > 0$, $Q > 0$, $M_i > 0$ are matrices to be determined. Then, along the solution of system (41), the time derivative of $V(t)$ is given by

$$\begin{aligned} \dot{V}(t) &= 2x^T(t)P\dot{x}(t) + x^T(t)Qx(t) - x^T(t - \eta_m)Qx(t - \eta_m) \\ &\quad + \eta_m\dot{x}^T(t)M_1\dot{x}(t) - \int_{t-\eta_m}^{t} \dot{x}^T(\alpha)M_1\dot{x}(\alpha)d\alpha \\ &\quad + \kappa\dot{x}^T(t)M_2\dot{x}(t) - \int_{t-\eta_m-\kappa}^{t-\eta_m} \dot{x}^T(\alpha)M_2\dot{x}(\alpha)\,d\alpha \\ &\le 2x^T(t)P\dot{x}(t) + x^T(t)Qx(t) - x^T(t - \eta_m)Qx(t - \eta_m) \\ &\quad + \dot{x}^T(t)\Psi\dot{x}(t) - \int_{t-\eta_m}^{t} \dot{x}^T(\alpha)M_1\dot{x}(\alpha)d\alpha - \int_{t-\eta_m-\eta(t)}^{t-\eta_m} \dot{x}^T(\alpha)M_2\dot{x}(\alpha)\,d\alpha, \end{aligned} \tag{45}$$

where $\Psi = \eta_m M_1 + \kappa M_2$. By the Newton–Leibniz formula, we have

$$\int_{t-\eta_m}^{t} \dot{x}(\alpha)\, d\alpha = x(t) - x(t-\eta_m), \tag{46}$$

$$\int_{t-\eta_m-\eta(t)}^{t-\eta_m} \dot{x}(\alpha) d\alpha = x(t-\eta_m) - x(t-\eta_m-\eta(t)). \tag{47}$$

Then, for any matrices

$$U = \begin{bmatrix} U_1^T & U_2^T & U_3^T & U_4^T \end{bmatrix}^T \quad \text{and} \quad V = \begin{bmatrix} V_1^T & V_2^T & V_3^T & V_4^T \end{bmatrix}^T,$$

we have

$$2\zeta^T(t) U \left[x(t) - x(t-\eta_m) - \int_{t-\eta_m}^{t} \dot{x}(\alpha)\, d\alpha \right] = 0, \tag{48}$$

$$2\zeta^T(t) U \left[x(t-\eta_m) - x(t-\eta_m-\eta(t)) - \int_{t-\eta_m-\eta(t)}^{t-\eta_m} \dot{x}(\alpha) d\alpha \right] = 0, \tag{49}$$

where

$$\zeta(t) = \begin{bmatrix} x^T(t) & x^T(t-\eta_m) & x^T(t-\eta_m-\eta(t)) & w^T(t) \end{bmatrix}^T.$$

Then, from (41), (45), (48), (49), we obtain

(50)

$$\begin{aligned}
&\dot{V}(t) - 2w^T(t)z(t) - \gamma w^T(t)w(t) \\
&\quad \le 2x^T(t)P\dot{x}(t) + x^T(t) Q x(t) - x^T(t-\eta_m) Q x(t-\eta_m) \\
&\qquad + \dot{x}^T(t)\Psi\dot{x}(t) - \int_{t-\eta_m}^{t} \dot{x}^T(\alpha) M_1 \dot{x}(\alpha) d\alpha - \int_{t-\eta_m-\eta(t)}^{t-\eta_m} \dot{x}^T(\alpha) M_2 \dot{x}(\alpha)\, d\alpha \\
&\qquad - 2w^T(t)z(t) - \gamma w^T(t)w(t) + 2\zeta^T(t) U \left[x(t) - x(t-\eta_m) - \int_{t-\eta_m}^{t} \dot{x}(\alpha)\, d\alpha \right] \\
&\qquad + 2\zeta^T(t) V \left[x(t-\eta_m) - x(t-\eta_m-\eta(t)) - \int_{t-\eta_m-\eta(t)}^{t-\eta_m} \dot{x}(\alpha) d\alpha \right] \\
&\quad \le \zeta^T(t) \left(\Gamma + \eta_m U M_1^{-1} U^T + \kappa V M_2^{-1} V^T \right) \zeta(t) \\
&\qquad - \int_{t-\eta_m}^{t} \left[\zeta^T(t) U + \dot{x}^T(\alpha) M_1 \right] M_1^{-1} \left[U^T \zeta(t) + M_1 \dot{x}(\alpha) \right] d\alpha \\
&\qquad - \int_{t-\eta_m-\eta(t)}^{t-\eta_m} \left[\zeta^T(t) V + \dot{x}^T(\alpha) M_2 \right] M_2^{-1} \left[V^T \zeta(t) + M_2 \dot{x}(\alpha) \right] d\alpha,
\end{aligned}$$

where

$$\Gamma = \begin{bmatrix} \bar{\Gamma}_{11} & \Gamma_{12} & \bar{\Gamma}_{13} & \bar{\Gamma}_{14} \\ * & \Gamma_{22} & \Gamma_{23} & \Gamma_{24} \\ * & * & \bar{\Gamma}_{33} & \bar{\Gamma}_{34} \\ * & * & * & \bar{\Gamma}_{44} \end{bmatrix},$$

$$\begin{aligned}
&\bar{\Gamma}_{11} = \Gamma_{11} + A^T \Psi A, \quad \bar{\Gamma}_{14} = \Gamma_{14} + A^T \Psi B, \\
&\bar{\Gamma}_{13} = \Gamma_{13} + PBK\Lambda(t) + A^T \Psi BK(I + \Lambda(t)), \\
&\bar{\Gamma}_{33} = \Gamma_{33} + (I + \Lambda(t)) K^T B^T \Psi BK(I + \Lambda(t)), \\
&\bar{\Gamma}_{34} = \Gamma_{34} + (I + \Lambda(t)) K^T B^T \Psi B - \Lambda(t) K^T D^T, \\
&\bar{\Gamma}_{44} = \Gamma_{44} + B^T \Psi B.
\end{aligned}$$

In the following, we will show that (14) guarantees that $\dot{V}(t) - 2w^T(t)z(t) - \gamma w^T(t)w(t) \leq 0$. Notice that $M_1 > 0$ and $M_2 > 0$; then we have

$$\begin{aligned}
&\left[\zeta^T(t) U + \dot{x}^T(\alpha) M_1\right] M_1^{-1} \left[U^T \zeta(t) + M_1 \dot{x}(\alpha)\right] \geq 0, \\
&\left[\zeta^T(t) V + \dot{x}^T(\alpha) M_2\right] M_2^{-1} \left[V^T \zeta(t) + M_2 \dot{x}(\alpha)\right] \geq 0.
\end{aligned}$$

Therefore, from (51) we know that $\dot{V}(t) - 2w^T(t)z(t) - \gamma w^T(t)w(t) \leq 0$ if

$$\Gamma + \eta_m U M_1^{-1} U^T + \kappa V M_2^{-1} V^T < 0,$$

which, by the Schur complement, is equivalent to

(51)

$$\begin{bmatrix}
\Gamma_{11} & \Gamma_{12}\tilde{\Gamma}_{13} & \Gamma_{14} & U_1 & V_1 & A^T M_1 & A^T M_2 \\
* & \Gamma_{22}\Gamma_{23} & \Gamma_{24} & U_2 & V_2 & 0 & 0 \\
* & * \ \Gamma_{33} & \tilde{\Gamma}_{34} & U_3 & V_3 & (I + \Lambda(t)) K^T B^T M_1 & (I + \Lambda(t)) K^T B^T M_2 \\
* & * \ * & \Gamma_{44} & U_4 & V_4 & B^T M_1 & B^T M_2 \\
* & * \ * & * & -\eta_m^{-1} M_1 & 0 & 0 & 0 \\
* & * \ * & * & * & -\kappa^{-1} M_2 & 0 & 0 \\
* & * \ * & * & * & * & -\eta_m^{-1} M_1 & 0 \\
* & * \ * & * & * & * & * & -\kappa^{-1} M_2
\end{bmatrix} < 0,$$

where $\tilde{\Gamma}_{13} = \Gamma_{13} + PBK\Lambda(t)$ and $\tilde{\Gamma}_{34} = \Gamma_{34} - \Lambda(t) K^T D^T$. Rewrite (51) in the form of

$$\Sigma_1 + \Sigma_3 \Sigma_2 + \Sigma_2^T \Sigma_3^T < 0 \tag{52}$$

with

$$\Sigma_1 = \begin{bmatrix} \Gamma_{11} & \Gamma_{12} & \Gamma_{13} & \Gamma_{14} & U_1 & V_1 & A^T M_1 & A^T M_2 \\ * & \Gamma_{22} & \Gamma_{23} & \Gamma_{24} & U_2 & V_2 & 0 & 0 \\ * & * & \Gamma_{33} & \Gamma_{34} & U_3 & V_3 & K^T B^T M_1 & K^T B^T M_2 \\ * & * & * & \Gamma_{44} & U_4 & V_4 & B^T M_1 & B^T M_2 \\ * & * & * & * & -\eta_m^{-1} M_1 & 0 & 0 & 0 \\ * & * & * & * & * & -\kappa^{-1} M_2 & 0 & 0 \\ * & * & * & * & * & * & -\eta_m^{-1} M_1 & 0 \\ * & * & * & * & * & * & * & -\kappa^{-1} M_2 \end{bmatrix},$$

$$\Sigma_2 = \begin{bmatrix} 0 & 0 & \Lambda(t) & 0 & 0 & 0 & 0 & 0 \end{bmatrix},$$

$$\Sigma_3 = \begin{bmatrix} K^T B^T P & 0 & 0 & -K^T D^T & 0 & 0 & K^T B^T M_1 & K^T B^T M_2 \end{bmatrix}^T.$$

It is noted that for some matrix $R > 0$ we have

$$\left(\Sigma_3 R^{-\frac{1}{2}} + \Sigma_2^T R^{\frac{1}{2}}\right)\left(\Sigma_3 R^{-\frac{1}{2}} + \Sigma_2^T R^{\frac{1}{2}}\right)^T \geq 0,$$

which gives rise to $\Sigma_3\Sigma_2 + \Sigma_2^T\Sigma_3^T \leq \Sigma_3 R^{-1}\Sigma_3^T + \Sigma_2^T R\Sigma_2$. Therefore, (52) holds if for some matrix $R > 0$,

$$\Sigma_1 + \Sigma_3 R^{-1}\Sigma_3^T + \Sigma_2^T R\Sigma_2 < 0. \tag{53}$$

Note that R is required to be diagonal positive definite. Then, by using a Schur complement operation and by considering (43), (14) guarantees (51), and thus we have $\dot{V}(t) - 2w^T(t)z(t) - \gamma w^T(t)w(t) \leq 0$. Integrating both sides with respect to t over the time period $[0, T]$, we have

$$V(T) - V(0) - 2\int_0^T w^T(t)z(t)dt - \gamma\int_0^T w^T(t)w(t)dt \leq 0. \tag{54}$$

Under the zero initial conditions, we have $V(0) = 0$ and $V(T) \geq 0$; thus (54) guarantees (13), and the proof is completed. □

AN ANALOGUE OF SHANNON INFORMATION THEORY FOR DETECTION AND STABILIZATION VIA NOISY DISCRETE COMMUNICATION CHANNELS*

ALEXEY S. MATVEEV† AND ANDREY V. SAVKIN‡

Abstract. The paper addresses both detection and stabilization problems involving communication errors and capacity constraints. Discrete-time partially observed linear systems are studied. Unlike the classic theory, the sensor signals are transmitted to the estimator/controller over a noisy digital communication link modeled as a stochastic stationary discrete memoryless channel. It is shown that for noise-free plants, the Shannon capacity of the channel constitutes the border separating the cases where stabilization and reliable detection (asymptotic state estimation) with arbitrarily large probability are and are not possible, respectively.

Key words. control over communications channels, communication constraints, Shannon information theory, stabilization, networked control systems

1. Introduction.

The standard assumption in the classical control theory is that data transmission required by the algorithm can be performed with infinite precision. However, due to the growth in communication technology, it is becoming more common to employ digital finite capacity networks for the exchange of information between plant components. Examples concern complex dynamical processes such as advanced aircraft, spacecraft, automotive, industrial and defense systems, arrays of microactuators, and power control in mobile communication. Bandwidth communication constraints are often major obstacles to control system design by means of the classical theory. For instance, as was shown in [58], the design of control systems for platoons of underwater vehicles strongly highlights the need for control strategies that explicitly address the bandwidth limitation on communication between vehicles, which is severely restricted underwater. All these emerging applications motivate the development of a new chapter of control theory that deals with networked systems and combines the control and communication issues, taking into account all the limitations on communication between sensors, controllers, and actuators.

Recently there was a good deal of research activity in this field; e.g., see [2, 5, 7, 12, 13, 19, 20, 21, 22, 23, 24, 26, 27, 29, 30, 31, 32, 34, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 47, 50, 51, 52, 53, 57, 59, 60, 61, 62, 63] and the references therein. In particular, optimization problems for perfect (memoryless and noise-free) finite alphabet channels and noisy Gaussian channels with power constraints were studied in [61, 62, 63]; such problems for discrete perfect channels were also examined in [5, 36, 52]. The related problem of the design of optimal sequential quantization schemes for uncontrolled Markov processes was addressed in [6, 62]. Various schemes for stabilization

and observation of unstable linear plants via limited capacity channels were proposed and analyzed in, e.g., [2, 3, 7, 12, 19, 23, 29, 30, 31, 41, 44, 45, 47, 57, 59, 60, 62]. The smallest data rate above which stabilization/observation of a linear plant is possible was derived in [2, 19, 41, 43, 44, 45, 60, 62] in various settings, including both stochastic [41, 43, 44, 45] and deterministic [2, 19, 52, 60, 62] ones. The focus in these works was on the channel quantization effects and perfect finite alphabet channels. This is a natural necessary step in developing the theory. At the same time, this is in contrast with the classic communication theory, where limited capacity channels are modeled in terms of not only quantization effects but also channel errors and time delays. Moreover, many of the major results in this theory are grown on the ground of noisy channel models. So incorporating noisy discrete channels into control problem models seems to be an unavoidable step in the synthesis of the control and communication theories.

To our knowledge, observability/stabilizability of unstable linear plants over noisy discrete channels was addressed in [24, 29, 30, 31, 50, 51, 57, 59]. In [24, 50, 51, 57], the focus was on scalar linear systems with additive disturbances and mth moment observability/stabilizability. It was shown in [50, 51] that, in general, the Shannon concept of capacity cannot serve as the proper figure-of-merit for erroneous channels in control feedback loops. Both sufficient and necessary criteria for observability/stabilizability were given in [50, 51] in terms of a new parametric notion of the channel capacity (called anytime capacity) introduced in [50]. An encoder-decoder pair for estimating the state of a scalar noisy linear system via a noisy binary symmetric channel was proposed in [24]. It was shown by simulation that the estimation error is bounded. Another such pair was constructed in [57] for such a channel with a perfect feedback link. Conditions ensuring that the mathematical expectation of the estimation error is bounded were obtained. In [67], the focus is on stabilizability by means of memoryless controllers in the case where the channels transmitting both observations and controls are noisy and discrete, and the plant is scalar, linear, and stochastic. The works [29, 30, 31] deal with the moment stabilizability of uncertain linear systems with additive disturbances over truncation channels. Such a channel transmits binary code words by dropping a random number of concluding bits. This generalization of the classic erasure channel is motivated by certain wireless communication applications in [29]. Constructive conditions for the robust moment stabilizability are obtained, and a stabilizing controller of a limited computation complexity is explicitly constructed.

It should be remarked that the moment observability/stability formally permits the error at a given time to be large and ensures only that large errors occur with a small probability. Modulo the strong law of large numbers, this guarantees only that along almost any trajectory, the frequency of large errors is small. The natural stronger control objective is to exclude large errors altogether. For stochastic models, this takes the form of almost sure observability/stabilizability. Such an observability/stabilizability via noisy communication links was addressed in [34, 35, 59] for noise-free linear time-invariant (LTI) plants. A necessary condition was established for general erroneous channels in [59]. This condition is that the Shannon capacity $\mathfrak{c}$ of the channel [56] is greater than or equal to the sum η of the logarithms of the absolute values of the system unstable eigenvalues. The sufficiency of this condition (with the strict inequality sign) was justified for only a particular channel model, i.e., the erasure channel with a perfect feedback. Such a channel either transmits the message correctly or loses it. In the latter case, the transmitter becomes aware of the failure via the feedback communication link. It was shown that whenever $\mathfrak{c} > \eta$ and there are no plant disturbances, the system is almost surely asymptotically observable

and stabilizable over the erasure channel. A similar stabilizability result is obtained in [27] under a stronger assumption about the erasure channel.[1]

This paper considers observability/stabilizability almost surely and with as large a probability as desired for general noisy *discrete memoryless channels* (DMC). We study how both quantization effects and channel errors limit the capability for reliable detection or stabilization. In doing so, we look for criteria that are "almost" exhaustive: they are necessary and "almost" sufficient. Furthermore, we examine both cases where the feedback communication link is and is not available, respectively. The objective is to provide a theoretical benchmark by discovering the role of the fundamental concept introduced by Shannon: the capacity of the erroneous channel [54].

We show that for general DMC, this capacity $\mathfrak{c}$ constitutes the border between the cases, where the noiseless LTI partially observed plant is and is not, respectively, almost surely asymptotically observable/stabilizable. More precisely, for such an observability/stabilizability to hold, the inequality $\mathfrak{c} \geq \eta$ is necessary and $\mathfrak{c} > \eta$ is sufficient. (We recall that η is the sum of the logarithms of the absolute values of the system unstable eigenvalues.) In its necessity part, this fact was previously established in [59] for more general (not necessarily discrete and memoryless) channels. We supplement this result from [59] by showing that the inequality $\mathfrak{c} \geq \eta$ remains necessary not only for almost sure but also certain weaker forms of observability/stabilizability. For example, it holds whenever some observer/controller keeps the time-average estimation/stabilization error bounded with a nonzero probability. We also specify the necessity of the above bound $\mathfrak{c}$ by showing that whenever it is trespassed $\eta > \mathfrak{c}$, any estimation/stabilization algorithm almost surely exponentially diverges. The sufficiency part of our result deals with arbitrary DMC and thus extends the corresponding results from [27, 59], which concern only the erasure channels. This part of our work can be viewed as completing the research [59] in the important case of DMC. We also show that the inequality $\mathfrak{c} > \eta$ is sufficient irrespective of availability of the feedback communication link.

More specifically, we show that in the absence of such a link, the estimation error can be made decaying to zero with as large a probability as desired by a proper design of the observer. However, this is achieved at the expense of using code words whose lengths grow as the estimation process progresses. It should be stressed that despite this, the observer produces an asymptotically exact state estimate online. In other words, the estimate of the state at time t is generated at time t, i.e., with no delay. At the same time, the increasing code word lengths require that the memory used by the estimator should increase accordingly.[2] This disadvantage can be discarded if a perfect feedback communication link is available: the result of any transmission across the (feedforward) channel becomes known to the transmitter by the time of the next transmission. This makes it possible to establish a complete synchronization of the encoder and decoder, within which the encoder duplicates the state estimate generated by the decoder. Our main result concerning the detection problem asserts that whenever $\mathfrak{c} > \eta$, the above feedback enables one to design an observer on the basis of fixed length code words for which the estimation error decays to zero almost surely.

A realistic converging observer is explicitly constructed. However, the scheme for the transmission of information across the channel is not described in detail. The point is that the observer employs block codes transmitting data at a given rate below

[1] This is the assumption on p. 736 about the uniform convergence of the average dropout rate to the limit, which makes the model from [27] a particular case of that from [37].

[2] The same feature is characteristic of the anytime coding-decoding schemes considered in [50, 51].

the channel capacity $\mathfrak{c}$ with a given probability of error. Classic information theory guarantees the existence of such a code. Moreover, the invention of such codes is the standard long-standing task in information sciences. It is supposed that a relevant solution should be employed to construct the observer. Thus it is shown that whenever the observability condition $\mathfrak{c} > \eta$ is satisfied and a perfect feedback link is available, almost sure detection can be ensured by a realistic observer with bounded (as time progresses) algebraic complexity and memory consumption per step, which is based on classic block coding-decoding schemes of communication.

Our results on stabilizability are similar to those concerning observability. However, there is a strong distinction. Specifically, we show that unlike detection, stabilization needs far less feedback communication. As a preliminary fact, we first show that to make the stabilization error decaying to zero almost surely by using fixed length code words, a feedback communication of arbitrarily small rate is sufficient. Second, we demonstrate that in fact such a communication requires no special means (such as a special feedback link), since it can be implemented by means of control. This can be arranged thanks to the fact that, on the one hand, the decoder-controller influences the motion of the system and, on the other hand, the sensor observes this motion and feeds the coder by the observation. So the controller is able to encode a message by imparting the motion a certain specific feature. The coder can receive the message by observing the motion and detecting this feature.

Apparently, control should be employed for information transmission with caution, since this potentially contradicts the main control objective [59]. For example, the best result of stabilization would be to keep the state exactly at the required position. However, the information transmission along the above lines requires us to deviate the state from this position. Thus a certain trade-off between the major control objective and communicating information by means of control should be established. Our first stabilization result serves this trade-off by showing that as little information as desired may be transmitted by means of control to achieve stability.

The focus on noise-free plants is motivated by the objective of the paper: to highlight the role of the Shannon (ordinary) capacity. The point is that in the presence of additive bounded disturbances, the border between the cases where the plant can and cannot, respectively, be observed/stabilized with an almost sure bounded error is constituted not by the ordinary $\mathfrak{c}$ but the zero error capacity $\mathfrak{c}_0$ of the channel, another fundamental characteristic introduced by Shannon [55]. In particular, if $\mathfrak{c}_0 < \eta$, the system affected by uniformly and arbitrarily small external disturbances can never be observed/stabilized: the error is unbounded almost surely, irrespective of which causal algorithm of observation/stabilization is employed. These facts were established for erasure infinite alphabet channels in [32] and general DMC in [39]. A result similar in spirit is obtained in [30, 31] for truncation channels and noise-free LTI plants. It is shown that for such a plant to be uniformly stabilizable (i.e., with an error uniformly bounded over the initial states from the unit ball) over such a channel, it is necessary that a certain number $r_{\min}$ of bits is not lost under any circumstances (i.e., with probability 1), and this number $r_{\min}$ exceeds the above quantity η. Since $r_{\min}$ equals the zero-error capacity of the channel at hand, this claim is in harmony with the results of [39]. It should be remarked that $\mathfrak{c}_0 \le \mathfrak{c}$, in general, and $0 = \mathfrak{c}_0 < \mathfrak{c}$ for many particular communication channels [25, 65]. It follows that an asymptotically unstable ($\eta > 0$) plant can never be observed/stabilized with an almost sure bounded error over such channels in the presence of disturbances, whereas almost sure observation/stabilization is possible, provided the disturbance is zero and $\eta < \mathfrak{c}$. A problem of stabilization via noisy channels in probability was considered for linear

plants with bounded disturbances in [38, 51], and necessary and sufficient conditions were presented. Furthermore, detailed discussions of these topics can be found in the research monograph [33].

The observers/controllers considered in this paper employ quantizers with adjusted sensitivity [7, 62] in the multirate fashion [47]. Such a quantizer can be viewed as a cascade of a multiplier by an adjustable factor and an analog-to-digital converter. To be transmitted across the channel, the outputs of this converter are encoded by means of low-error block codes. This is in the vein of the classic source-channel separation principle [4, 17, 18]. (For the state estimation problem, a similar approach was earlier considered in [50] in the form of the following separation of the source and channel. At first, a coder-decoder pair is designed under the assumption that the channel is perfect. Then another coder-decoder pair is constructed to carry the outputs of the first coder reliably across the channel.) For the stabilization problem, the above scheme is considered in connection with a limited communication feedback of arbitrarily small capacity. This feedback is used to put the values of only one scalar variable computed by both the coder and decoder in harmony. This variable is the above adjustable factor. The synchronization is delayed and, as a result, not complete: the values become coherent only if the current feedforward transmission across the channel is errorless. However, we show that this is enough to make the stabilization error almost surely decaying to zero.

The view of the control loop as a link transmitting information is not new. A posteriori, this means that the control loop does transmit information, though its contents may not be clearly specified a priori [11]. The "constructive" part of the same view is the idea that the control signals can be employed as carriers of a priori prespecified information from the decoder-controller to the coder. For various settings, various schemes of such a transmission were considered in, e.g., [34, 38, 51, 59].

The paper is organized as follows. Sections 2 and 3 contain the statements of the detection and stabilization problems. The main results are formulated in section 5, which is prefaced by the list of basic notations and assumptions in section 4. The necessary conditions for observability and stabilizability are justified in sections 6 and 7, respectively. Sections 8 and 9 are focused on the respective sufficient conditions. There also is an appendix containing the proof of a technical result.

2. Detection problem. We consider unstable discrete-time invariant linear plants of the form

$$x(t+1) = Ax(t); \qquad x(0) = x_0, \qquad y(t) = Cx(t). \tag{2.1}$$

Here $x \in \mathbb{R}^n$ is the state and $y \in \mathbb{R}^{n_y}$ is the measured output. The instability means that there is an eigenvalue λ of the matrix A with $|\lambda| \geq 1$. The initial state x_0 is a random vector. The objective is to estimate the current state on the basis of the prior measurements.

We consider the case where this estimate is required at a remote location. The only way to communicate information from the sensor to this location is via a given random noisy discrete channel. So to be transmitted, measurements must first be translated into a sequence of symbols e from the finite *input alphabet* $\mathcal{E}$ of the channel. This is done by a special system's component, referred to as the *coder*. Its outputs e are then transmitted over the channel and transformed by some sort of random disturbance or noise into a sequence of channel's outputs s from a finite *output alphabet* $\mathcal{S}$. By employing the prior outputs s, the *decoder(-estimator)* produces an estimate $\widehat{x}$ of the current state x. In this situation illustrated in Figure 1, the *observer* is

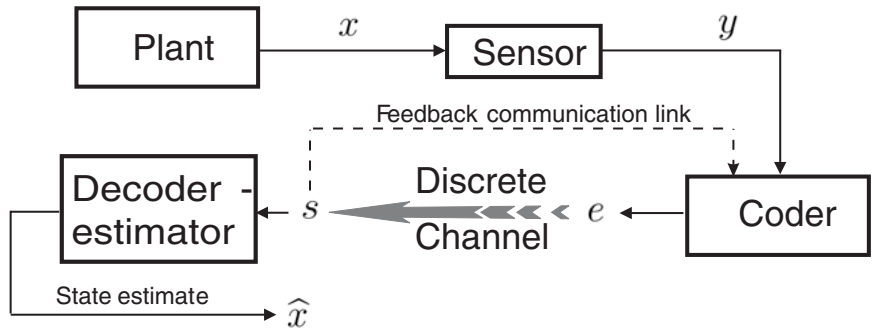

FIG. 1. *Estimation via a limited capacity communication channel.*

constituted by the coder-decoder pair.

The decoder is defined by an equation of the form

$$\widehat{x}(t) = \mathfrak{X}\left[t, s(0), s(1), \ldots, s(t)\right]. \tag{2.2}$$

We consider two classes of coders, each giving rise to a particular problem setup. The first class is related to feedback communication channels [55]: the transmission result $s(t)$ becomes known at the coder site by time $t+1$ of the next transmission. The second class corresponds to the channels with no feedback. The coders from these classes are said to be *with* and *without a feedback* and are given by the following equations, respectively:

$$e(t) = \mathfrak{E}[t, y(0), \ldots, y(t), s(0), \ldots, s(t-1)] \in \mathcal{E}, \tag{2.3}$$

$$e(t) = \mathfrak{E}[t, y(0), \ldots, y(t)] \in \mathcal{E}. \tag{2.4}$$

The communication feedback enables the coder (2.3) to be aware of the actions of the decoder via duplicating the computations in accordance with (2.2). This gives the coder the ground to try to compensate for the previous channel errors. However, it should be noted that this feedback does not increase the rate at which the information can be transmitted across the channel with as small a probability of error as desired [10, 54]. At the same time, it may increase the rate at which information can be transmitted with the zero probability of error [55]. The feedback may also increase the reliability function [68] and simplify coding and decoding operations [65]. For further discussion of this issue and a detailed survey, we refer the reader to [65]. The role of communication feedback in control and state estimation was discussed in [59, 60, 62, 63, 66].

The information received by the decoder is limited to a finite number of bits at any time. So the decoder is hardly able to restore the state with the infinite exactness $\widehat{x}(t) = x(t)$ for a finite time. In this paper, we pursue a more realistic objective of detecting the unstable modes of the system and accept that an observer succeeds if

$$|x(t) - \widehat{x}(t)| \to 0 \quad \text{as} \quad t \to \infty. \tag{2.5}$$

DEFINITION 2.1. *The coder-decoder pair is said to* detect *or* track *the state whenever* (2.5) *is true and to* keep the estimation error (or time-average error) bounded *if the following much weaker properties hold, respectively:*

$$\overline{\lim_{t\to\infty}} |x(t) - \widehat{x}(t)| < \infty, \qquad \overline{\lim_{t\to\infty}} \frac{1}{t} \sum_{\theta=0}^{t-1} |x(\theta) - \widehat{x}(\theta)| < \infty. \tag{2.6}$$

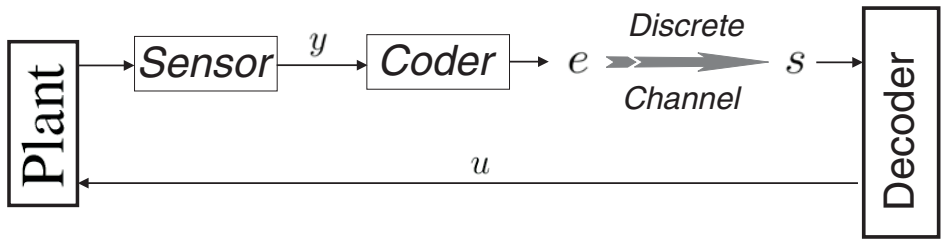

FIG. 2. *Stabilization via a limited capacity communication channel.*

The main question to be discussed is *how low the data rate of the channel can be made before the construction of a coder-decoder pair detecting the state becomes impossible.* In this paper, we focus on the cases where "detecting" means either "detecting with arbitrarily large probability" $p < 1$ or "detecting almost surely."

3. Stabilization problem. Now we consider the controlled version of the unstable plant (2.1):

$$x(t+1) = Ax(t) + Bu(t), \qquad x(0) = x_0, \qquad y(t) = Cx(t), \tag{3.1}$$

where $u \in \mathbb{R}^{n_u}$ is the control. The objective is to construct a controller that asymptotically stabilizes the system: $x(t) \to 0$ and $u(t) \to 0$ as $t \to \infty$.

We examine a remote control setup. Based on the prior observations, the *coder* emits a message $e \in \mathcal{E}$ into the channel. This message may be corrupted during the transmission $e \xrightarrow{\text{channel noise}} s \in \mathcal{S}$. Proceeding from the messages s received over the channel up to the current time t, the *decoder(-controller)* selects a control $u(t)$:

$$u(t) = \mathfrak{U}\left[t, s(0), s(1), \dots, s(t)\right]. \tag{3.2}$$

In this situation, depicted in Figure 2, the controller is assembled of the coder and decoder.

We still consider two classes of coders given by (2.3) and (2.4), respectively. The first of them is associated with the case where there is a perfect feedback in communication between the coder and decoder (see Figure 3). The second class deals with the situation where no such a feedback is available.

DEFINITION 3.1. *A coder-decoder pair is said to* stabilize *the system if*

$$|x(t)| \to 0 \quad \text{and} \quad |u(t)| \to 0 \quad \text{as} \quad t \to \infty \tag{3.3}$$

and to keep the stabilization error (or time-average error) bounded *if the much weaker properties hold, respectively:*

$$\overline{\lim_{t\to\infty}} |x(t)| < \infty, \qquad \overline{\lim_{t\to\infty}} \frac{1}{t} \sum_{\theta=0}^{t-1} |x(\theta)| < \infty. \tag{3.4}$$

What is the bound on the data rate of the channel above which there exists a stabilizing coder-decoder pair? Here "stabilizing" means either "stabilizing almost surely" or "stabilizing with as large a probability as desired."

4. Notations and assumptions. The symbols $\boldsymbol{P}$ and $\boldsymbol{E}$ stand for probability and expectation, respectively. For a random variable $A \in \mathcal{A} = \{a\}$, the conditional

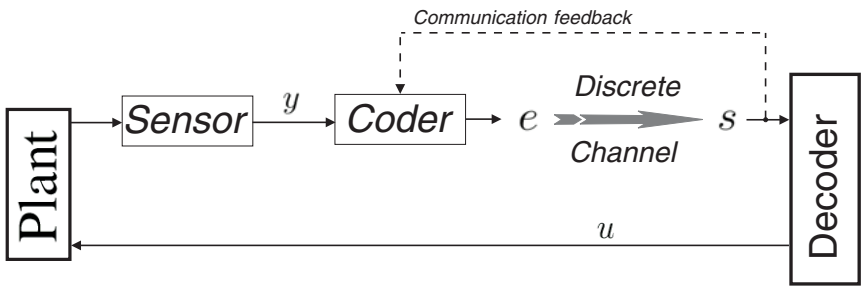

FIG. 3. *Stabilization under a communication feedback.*

probability given $A = a$ is denoted by $\boldsymbol{P}(\cdot|A = a)$ or $\boldsymbol{P}(\cdot|a)$, and $\boldsymbol{P}(a) := \boldsymbol{P}(A = a)$. For two such variables A and $B \in \mathcal{B} = \{b\}$, the symbol $I(A, B)$ stands for the *mutual information*:

$$I(A,B) = \int \boldsymbol{P}(da,db) \log_2 \frac{\boldsymbol{P}(da,db)}{\boldsymbol{P}(da) \otimes \boldsymbol{P}(db)} = \boldsymbol{E} \log_2 \frac{\boldsymbol{P}(da,db)}{\boldsymbol{P}(da) \otimes \boldsymbol{P}(db)} \tag{4.1}$$

if the joint distribution $\boldsymbol{P}(da, db)$ of A and B has the density $\frac{\boldsymbol{P}(da,db)}{\boldsymbol{P}(da)\otimes\boldsymbol{P}(db)}$ with respect to the probability measure $\boldsymbol{P}(da) \otimes \boldsymbol{P}(db)$, and $I(A, B) = \infty$ otherwise [48]. (Here and throughout, $\log_2 0 := -\infty$, $\pm\infty \cdot 0 := 0$.) If the sets $\mathcal{A}, \mathcal{B}$ are finite, then

$$I(A,B) = H(B) - H(B|A) = H(A) - H(A|B) = \sum_{a\in\mathcal{A}, b\in\mathcal{B}} \boldsymbol{P}(a,b) \log_2 \frac{\boldsymbol{P}(a,b)}{\boldsymbol{P}(a)\boldsymbol{P}(b)},$$

where the symbols $H(B), H_a(B) = H_{A=a}(B)$, and $H(B|A)$ denote the *entropy*, the *conditional entropy* given $A = a$, and the *averaged conditional entropy*, respectively, i.e.,

$$H(B) := -\sum_{b\in\mathcal{B}} \boldsymbol{P}(b) \log_2 \boldsymbol{P}(b), \qquad H_a(B) = -\sum_{b\in\mathcal{B}} \boldsymbol{P}(b|a) \log_2 \boldsymbol{P}(b|a), \tag{4.2}$$

$$H(B|A) = \boldsymbol{E} H_A(B) = \sum_{a\in\mathcal{A}} \boldsymbol{P}(a) H_a(B).$$

The probability density of a random vector $V \in \mathbb{R}^s$ is denoted by $p_V(\cdot)$ and that given $A = a$ by $p_V(\cdot|A = a) = p_V(\cdot|a)$. The *differential entropy* of V is the quantity

$$h(V) := -\boldsymbol{E} \log_2 p_V(V) = -\int_{\mathbb{R}^s} p_V(v) \log_2 p_V(v)\, dv. \tag{4.3}$$

This entropy can be viewed as a measure of information required to describe the random vector to a particular accuracy. Approximately $h(V) + sb + \log_2 \mathbf{mes}\, B_0^1$ bits suffice to describe $V \in \mathbb{R}^s$ to b-bit accuracy. (Here B_0^1 is the unit ball in $\mathbb{R}^s$ and **mes** is the Lebesgue measure.) The differential entropy can take negative and infinite values. The symbol $h_{B=b}(V)$ stands for the conditional differential entropy given $B = b$.

The following assumptions are adopted throughout the paper.

Assumption 4.1. The coder sends signals to the decoder over a given stationary discrete noisy memoryless channel [14, 18]. In other words, given a current channel input $e(t)$, the current output $s(t)$ is statistically independent of all other inputs and outputs $e(j), s(j)$, $j \neq t$, and the conditional probability $W(s|e) := \boldsymbol{P}[s(t) = s|e(t) = e]$, $s \in \mathcal{S}$, $e \in \mathcal{E}$, does not depend on time t.

Note that this model incorporates the effect of message loss by including a special "void" symbol $\emptyset$ in the output alphabet $\mathcal{S}$. Then $s(t) = \emptyset$ means that the message $e(t)$ is lost by the channel.

Assumption 4.2. The plant does not affect the operation of the channel: given an input $e(t)$, the output $s(t)$ is statistically independent of the initial state x_0.

Assumption 4.3. The initial state x_0 has a probability density $p_0(x)$.

Assumption 4.4. The pair (A, C) is detectable.

When dealing with the stabilization problem, we impose one more assumption.

Assumption 4.5. The pair (A, B) is stabilizable.

To state the results of the paper, we need the notion of the Shannon *capacity* of the stationary discrete memoryless channel. This is the maximum mutual information between the input and output of the channel [14]:

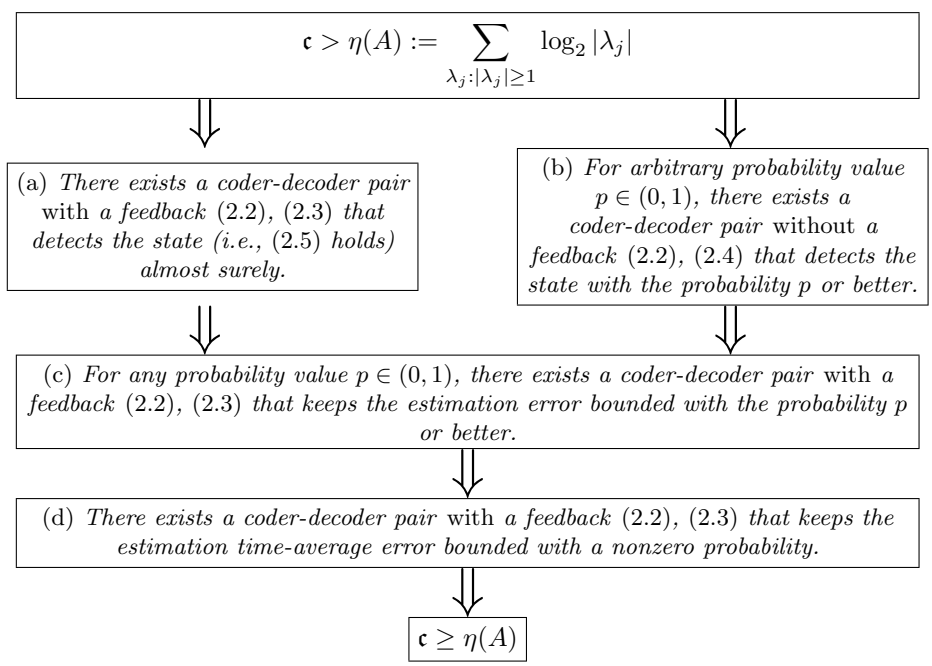
$$\mathfrak{c} = \max_{\boldsymbol{P}_E} I(e, s). \tag{4.4}$$

Here the maximum is over all probability distributions $\boldsymbol{P}_E$ on the input channel alphabet $\mathcal{E} = \{e\}$. Whereas $\boldsymbol{P}_E$ is interpreted as the probability distribution of e, the joint distribution of the channel input e and output s is taken to be that of (e, s) when s results from sending e over the channel: $\boldsymbol{P}_{E,S}(e, s) := W(s|e)\boldsymbol{P}_E(e)$.

5. The domains of observability and stabilizability are determined by the Shannon channel capacity.

5.1. Detection problem.

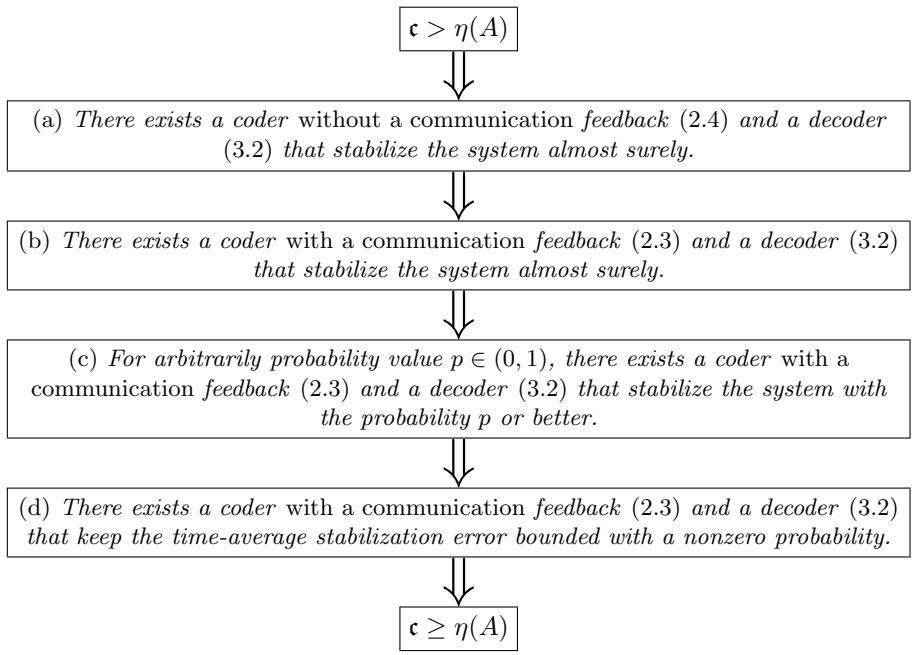
THEOREM 5.1. *Suppose that Assumptions* 4.1–4.4 *hold. Denote by* $\lambda_1, \dots, \lambda_n$ *the eigenvalues of the system* (2.1) *repeating in accordance with their algebraic multiplicities and by* $\mathfrak{c}$ *the capacity* (4.4) *of the communication channel. Then the following implications are true:*



The proof of this theorem will be given in sections 6 and 8. The explicit constructions of tracking coder-decoder pairs will be presented in subsections 8.3 and 8.5.

5.2. Stabilization problem. Similar results are valid for the stabilization problem.

THEOREM 5.2. *Suppose that Assumptions* 4.1–4.5 *hold, and adopt the notations* $\mathfrak{c}$ *and* $\eta(A)$ *from Theorem* 5.1. *Then the following implications are true:*



The proof of this theorem will be given in sections 7 and 9. The explicit construction of a stabilizing coder-decoder pair will be offered in subsections 9.1 and 9.2.

5.3. Comments. The implications (a) $\Rightarrow$ $\mathfrak{c} \geq \eta(A)$ and (b) $\Rightarrow$ $\mathfrak{c} \geq \eta(A)$ contained in Theorems 5.1 and 5.2, respectively, were proved in [59] for general noisy channels (not necessarily discrete and memoryless). The implications $\mathfrak{c} > \eta(A) \Rightarrow$ (a) and $\mathfrak{c} > \eta(A) \Rightarrow$ (b) from Theorems 5.1 and 5.2, respectively, were justified in [59] for a particular DMC: the erasure channel with arbitrary finite alphabet. The implications (a) $\vee$ (b) $\Rightarrow$ (c) $\Rightarrow$ (d) from Theorem 5.1 and (a) $\Rightarrow$ (b) $\Rightarrow$ (c) $\Rightarrow$ (d) from Theorem 5.2 are evident. They are mentioned to stress that the claims (a), (b), (c), and (d) are included in the chains of implications with approximately identical extreme terms. Thus these statements are "almost equivalent," and the inequality $\mathfrak{c} > \eta(A)$ is sufficient and "almost necessary" for the systems (2.1) and (3.1) to be detectable and stabilizable, respectively, via the noisy communication channel.

In spirit, Theorem 5.1 resembles the celebrated Shannon channel coding theorem [14, 18, 54]. Indeed, the latter states that whenever the source produces information at the rate $R < \mathfrak{c}$ bits per unit time, the success, i.e., errorless transmission, can be ensured with as large a probability as desired. If, conversely, $R > \mathfrak{c}$, this is impossible. Here the means to ensure success are the rules to encode and decode information before and after transmission, respectively. Theorem 5.1 asserts just the same, provided the "success" is understood as asymptotic tracking (2.5) of the state, the "means" are the coder and decoder-estimator, and R is replaced by $\eta(A)$. This analogy is enhanced by the similarity between the quantities R and $\eta(A)$. Each of them can be interpreted as the unit-time increment of the number of bits required to describe the entity that the receiver wants to know.

Indeed, in the case of the Shannon theorem, this entity is abstract information generated by a source at the rate R, and the interpretation is apparent. In the case considered in this paper, this entity is the "unstable" part x_+ of the state x (since asymptotic tracking (2.5) does not concern the "stable" x_- one).

Explanation 5.1. Here and throughout the paper, $x_\pm \in L_\pm$, where L_+ and L_- are the invariant subspaces of A related to the unstable $\{\lambda_j : |\lambda_j| \geq 1\}$ and stable $\{\lambda_j : |\lambda_j| < 1\}$ parts of its spectrum, and $A_\pm$ denotes the operator A acting on its invariant subspace $L_\pm$.

With regard to the relation $x_+(t+1) = A_+ x_+(t)$, simple calculus (see, e.g., [45] or (6.6)) shows that the entropy (4.3) of $x_+(t)$ evolves as follows:

$$h[x_+(t+1)] = h[x_+(t)] + \log_2 |\det A_+|,$$

where det is the determinant. Thus the number of bits required to describe $x_+(t)$ to any given accuracy b increases by $\log_2 |\det A_+|$ per unit time. It remains to note that $\log_2 |\det A_+| = \eta(A)$.

The above remark on the similarity between the channel coding theorem and Theorem 5.1 clearly extends on Theorem 5.2. Another point of similarity between Theorem 5.2 and the classic information theory concerns the communication feedback. Whereas the classic theory states that this feedback does not increase the rate at which data can be reliably transmitted across the noisy channel [10, 54], Theorem 5.2 shows that the feedback does not visibly extend the class of stabilizable noise-free plants.

Equations (2.2)–(2.4), (3.2) impose no restrictions on the memories of the coder and decoder. At the same time, the observer reliably tracking the state in the presence of the communication feedback and the stabilizing controller that will be explicitly constructed further consume limited (as time progresses) memories.

In the case of the perfect channel ($\mathcal{E} = \mathcal{S}$ and $W(e|e) = 1$), Theorems 5.1 and 5.2 come to results from [41, 42, 43, 44, 45, 47, 53, 60, 62], and the strict inequality $\mathfrak{c} > \eta(A)$ is necessary for the existence of both the tracking observer and the stabilizing controller.

5.4. Complements to the necessary conditions. The last implication (d) $\Rightarrow$ $\mathfrak{c} \geq \eta(A)$ from both Theorems 5.1 and 5.2 can be complemented and enhanced by the following facts.

PROPOSITION 5.3. *Suppose that* $\mathfrak{c} < \eta(A)$. *Then the state can never be observed and the plant can never be stabilized with a bounded error:*

$$\left.\begin{array}{r} \overline{\lim_{t\to\infty}}\, |x(t) - \widehat{x}(t)| = \infty \\ \overline{\lim_{t\to\infty}}\, |x(t)| = \infty \end{array}\right\} \quad \text{a.s. for the plant } \left\{\begin{array}{l}(2.1)\\(3.1)\end{array}\right\}, \text{ any coder,} \tag{5.1}$$

$$\text{and } \left\{\begin{array}{l}\text{decoder-estimator}\\ \text{decoder-controller}\end{array}\right. .$$

This divergence is as fast as exponential. Specifically, pick $\alpha > 1$ *so that* $\log_2 \alpha < \frac{\eta(A)-\mathfrak{c}}{\dim x}$. *Then*

$$\left.\begin{array}{r} \overline{\lim_{t\to\infty}}\, \alpha^{-t}|x(t) - \widehat{x}(t)| = \infty \\ \overline{\lim_{t\to\infty}}\, \alpha^{-t}|x(t)| = \infty \end{array}\right\} \quad \text{a.s. for the plant } \left\{\begin{array}{l}(2.1)\\(3.1)\end{array}\right\}, \text{ any coder,} \tag{5.2}$$

$$\text{and } \left\{\begin{array}{l}\text{decoder-estimator}\\ \text{decoder-controller}\end{array}\right. .$$

REMARK 5.1. *Proposition* 5.3 *entails that* (d) $\Rightarrow \mathfrak{c} \geq \eta(A)$ *in the context of both Theorems* 5.1 *and* 5.2.

Indeed, consider the context of Theorem 5.1 for the definiteness. Suppose that $\mathfrak{c} < \eta(A)$. Then by (5.2), there exist random times $0 < \tau_1 < \tau_2 < \cdots$ such that almost surely $|x(\tau_i) - \widehat{x}(\tau_i)| \geq \alpha^{\tau_i}$ for all i. Then

$$\frac{1}{\tau_i + 1} \sum_{\theta=0}^{\tau_i} |x(\theta) - \widehat{x}(\theta)| \geq \frac{|x(\tau_i) - \widehat{x}(\tau_i)|}{\tau_i + 1} \geq \frac{\alpha^{\tau_i}}{\tau_i + 1} \to \infty \quad \text{as} \quad i \to \infty \quad \text{a.s.}$$

in violation of (d). Hence (d) $\Rightarrow \mathfrak{c} \geq \eta(A)$.

The probability of large observation and stabilization errors is estimated in the following proposition.

PROPOSITION 5.4. *Suppose that the system has no stable modes,* $\eta(A) > \mathfrak{c}$*, and the initial state* x_0 *is almost surely bounded and has a finite differential entropy. Then*

$$\left.\begin{array}{r} \varlimsup\limits_{t\to\infty} \boldsymbol{P}\Big[|x(t) - \widehat{x}(t)| \geq b(t)\Big] \\ \varlimsup\limits_{t\to\infty} \boldsymbol{P}\Big[|x(t)| \geq b(t)\Big] \end{array}\right\} \geq 1 - \frac{\mathfrak{c}}{\eta(A)} \text{ for the plant } \left\{\begin{array}{l} (2.1) \\ (3.1) \end{array}\right\}, \text{ any coder,}$$

$$\text{and } \left\{\begin{array}{l} \text{decoder-estimator} \\ \text{decoder-controller} \end{array}\right. .$$

Here $b(t) > 0$, $t = 0, 1, \ldots$, *is any sequence such that* $\frac{\log_2 b(t)}{t} \to 0$ *as* $t \to \infty$.

REMARK 5.2. *This proposition implies that* $\mathfrak{c} \geq \eta(A)$ *whenever there exist a coder and decoder that keep the mathematical expectation of the error* $\epsilon(t)$ *(or at least the time average* $\frac{1}{t}\sum_{\theta=0}^{t-1} \boldsymbol{E}\epsilon(\theta)$*) bounded.*

The proofs of Propositions 5.3 and 5.4 will be given in sections 6 and 7 (where the detection and stabilization problems will be addressed, respectively).

6. Proofs of Propositions 5.3 and 5.4 for the state estimation problem and the (d) $\Rightarrow \mathfrak{c} \geq \eta(A)$ part of Theorem 5.1. In this section, the focus is on the proof of Proposition 5.3. Proposition 5.4 will be justified within this proof, whereas the above part of Theorem 5.1 follows from Proposition 5.3 by Remark 5.1.

We start with a simple observation. So far as the asymptotic tracking does not concern the stable modes, it seems more or less clear that the proof can be confined to systems with only unstable ones. This is ensured by the following lemma, which employs the notations from Explanation 5.1.

LEMMA 6.1. *Suppose that some coder-decoder pair keeps the estimation error bounded with the probability better than* p *for the primal system* (2.1)*. Then such a pair can also be constructed for the system*

$$x_+(t+1) = A_+ x_+(t), \quad x_+(t) \in L_+, \quad x_+(0) = x_0^+, \quad y(t) = C x_+(t) \tag{6.1}$$

with some initial random vector x_0^+ *that satisfies Assumptions* 4.2 *and* 4.3*, is almost surely bounded, and has a finite entropy.*

It should be remarked that generally speaking, the system (6.1) is considered on a new underlying probability space. However, Assumptions 4.1–4.4 are still true and the channel parameters $W(s|e)$ remain unchanged.

It is easy to see that equations (6.1) describe the processes in the primal system (2.1) starting at $x(0) = x_0^+ \in L_+$. A certain technical nontriviality of Lemma 6.1 comes from the fact that due to Assumption 4.3, the probability to start at $x(0) \in L_+$

is zero (if $L_+ \neq \mathbb{R}^n$). At the same time, the assumptions of the lemma allow the initial coder-decoder pair to produce asymptotically infinite estimation errors not only with zero but a positive probability. To keep the estimation error bounded for the processes (6.1), this pair should be modified in general.

The proof of Lemma 6.1 is placed in the appendix.

To prove Proposition 5.3, we also need the concept of the joint entropy of a vector and a discrete quantity [48]. Let a random vector $V \in \mathbb{R}^s$ have a probability density and a random quantity B take values in a finite set $\mathcal{B}$ with elements b. We denote by $|M|$ the size of the set M, and by db the counting measure, i.e., the function $\mathcal{B}' \mapsto |\mathcal{B}'|$ of the set $\mathcal{B}' \subset \mathcal{B}$. The random quantity B has a probability density $p_B(b) := \boldsymbol{P}(B = b)$ with respect to the measure db, and the definition of the entropy $H(B)$ from (4.2) takes the form similar to (4.3): $H(B) = -\int_{\mathcal{B}} p_B(b) \log_2 p_B(b)\, db$. The joint entropy of $(V, B) \in \mathbb{R}^s \times \mathcal{B}$ is introduced by continuing this analogy. We note that (V, B) has a probability density $p_{V,B}(v, b) := p_V(v|B = b)\boldsymbol{P}(B = b)$ with respect to the measure $dx \otimes db$, and we set

$$H(V, B) := -\boldsymbol{E} \log_2 p_{V,B}(V, B) = -\int_{\mathbb{R}^s \times \mathcal{B}} p_{V,B}(v, b) \log_2 p_{V,B}(v, b)\, dvdb.$$

This entropy inherits many properties of (4.2) and (4.3). Now we list some of them. In doing so, we assume that B_i are random quantities taking finitely many values, either $\widehat{V} := V$ or $\widehat{V} := (V, B_1)$, Ψ is a deterministic function, and $h(V) \in \mathbb{R}$. The conditional entropy $H_{B=b}(\widehat{V}) = H_b(\widehat{V}) =: \mathfrak{H}(b)$ is the entropy of $\widehat{V}$ with respect to the probability given $B = b$, and $H(\widehat{V}|B) = \boldsymbol{E}\mathfrak{H}(B)$ is the averaged conditional entropy. (If $\widehat{V} = V$, we use h instead of H here.) The following properties hold:

$$h(V) \in \mathbb{R} \Rightarrow -\infty < H(\widehat{V}|B) \leq H(\widehat{V}) < +\infty, \qquad I(V, B) = h(V) - h(V|B), \tag{6.2}$$

$$H(V, B_1|B) = h(V|B_1, B) + H(B_1|B) \geq h(V|B), \tag{6.3}$$

$$h(V) \overset{[9]}{\leq} \frac{s}{2} \log_2\Bigl(2\pi e \boldsymbol{E}|V|^2\Bigr), \qquad h(V|B) = h(V - \Psi(B)|B). \tag{6.4}$$

The next preliminary fact is an estimate of uncertainty about the current state $x(t)$ given the output of the decoder. Further, the symbols S and E stand for sequences $\{s(t)\}_{t=0}^{\infty}$ and $\{e(t)\}_{t=0}^{\infty}$. Whenever $0 \leq m_- \leq m_+$, we put $S_{m_-}^{m_+} := \{s(j)\}_{j=m_-}^{m_+}$ and define $E_{m_-}^{m_+}$ similarly.

LEMMA 6.2. *Suppose that* $\det A \neq 0$, $h(x_0) \in \mathbb{R}$, *and* $\mathfrak{c}$ *is the capacity* (4.4) *of the channel. Then for any coder-decoder pair with a feedback* (2.2), (2.3), *the entropy* $h\bigl[x(t)|S_0^t\bigr]$ *is finite and*

$$h\bigl[x(t)|S_0^t\bigr] \geq h\bigl[x_0\bigr] + t\bigl(\log_2 |\det A| - \mathfrak{c}\bigr) - \mathfrak{c}. \tag{6.5}$$

Proof. Note first that by (2.1), the probability densities of $x(t)$ given S_0^θ evolve as follows: $p_j(x) = |\det A|^{-j} \times p_0(A^{-j}x)$, where $p_j(\cdot) := p_{x(j)}(\cdot|S_0^\theta)$ for all j and θ is a fixed time. By (4.3), this implies

$$h\bigl[x(t)\bigl|S_0^\theta\bigr] = h\bigl[x_0\bigl|S_0^\theta\bigr] + t \log_2 |\det A|. \tag{6.6}$$

By the standard arguments [10, 17, 48, 54], $I\bigl[x_0, S_0^t\bigr] \leq \mathfrak{c}(t + 1)$. It remains to note that $I\bigl[x_0, S_0^t\bigr] = h[x_0] - h\bigl[x_0\bigl|S_0^t\bigr]$ and to employ (6.6) with $\theta := t$.

LEMMA 6.3. *Suppose that* $|\det A| > 1$, $h(x_0) \in \mathbb{R}$, *and* $|x_0| < b_0$ *almost surely. Then, for any coder-decoder pair,*

$$\boldsymbol{P}\Big[|x(t) - \widehat{x}(t)| \le b\Big] \le \frac{\mathfrak{c}}{\log_2 |\det A|} + \frac{1}{t} \times \frac{1 - h(x_0) + \mathfrak{c} + \frac{n}{2}\log_2\big(2\pi e \max\{b^2, b_0^2\}\big)}{\log_2 |\det A|} \qquad \forall b > 0, t \ge 1. \tag{6.7}$$

A similar inequality can be obtained from Lemma 3.2 in [59].

REMARK 6.1. *Lemma* 6.3 *evidently justifies Proposition* 5.4 *for the detection problem.*

Proof of Lemma 6.3. Pick t and denote by $\mathfrak{B}$ the random event $\{|x(t) - \widehat{x}(t)| \le b\}$ and by $\mathcal{I}$ its indicator: $\mathcal{I} = 1$ if $\mathfrak{B}$ holds and $\mathcal{I} = 0$ otherwise. We also put $\eta := \log_2 |\det A|$ and $p := \boldsymbol{P}\big[\mathfrak{B}\big]$. Then

$$H\big[x(t), \mathcal{I}\big|S_0^t\big] \overset{(6.3)}{\ge} h\big[x(t)\big|S_0^t\big] \overset{(6.5)}{\ge} h[x_0] - \mathfrak{c} + t\big[\eta - \mathfrak{c}\big]. \tag{6.8}$$

The random variable $\mathcal{I}$ takes only two values. So its entropy (given any event) does not exceed 1. Hence

$$H\big[x(t), \mathcal{I}\big|S_0^t\big] \overset{(6.3)}{=\!=} h\big[x(t)\big|\mathcal{I}, S_0^t\big] + H\big[\mathcal{I}\big|S_0^t\big] \le 1 + \sum_{\sigma=0,1} \boldsymbol{P}(\mathcal{I} = \sigma) h_{\mathcal{I}=\sigma}\big[x(t)\big|S_0^t\big].$$

Repeating the arguments underlying (6.6) shows that $h_{\mathcal{I}=0}\big[x(t)\big|S_0^t\big] = h_{\mathcal{I}=0}\big[x_0\big|S_0^t\big] + t\eta$. Hence

$$\begin{aligned} H\big[x(t), \mathcal{I}\big|S_0^t\big] &\le 1 + (1-p) h_{\mathcal{I}=0}\big[x_0\big|S_0^t\big] + (1-p)t\eta + p h_{\mathcal{I}=1}\big[x(t)\big|S_0^t\big] \\ &\overset{(6.2)}{\le} 1 + (1-p) h_{\mathcal{I}=0}\big[x_0\big] + (1-p)t\eta + p h_{\mathcal{I}=1}\big[x(t)\big|S_0^t\big]. \end{aligned}$$

Here $|x_0| \le b_0$ almost surely, and so $h_{\mathcal{I}=0}[x_0] \overset{(6.4)}{\le} \frac{n}{2}\log_2[2\pi e \boldsymbol{E}(|x_0|^2|\mathcal{J} = 0)] \le \frac{n}{2}\log_2[2\pi e b_0^2]$. Furthermore,

$$\begin{aligned} h_{\mathcal{I}=1}\big[x(t)\big|S_0^t\big] &\overset{(2.2),(6.4)}{=\!=} h_{\mathcal{I}=1}\big[x(t) - \widehat{x}(t)\big|S_0^t\big] \overset{(6.2)}{\le} h_{\mathcal{I}=1}\big[x(t) - \widehat{x}(t)\big] \\ &\overset{(6.4)}{\le} \frac{n}{2}\log_2\Big[2\pi e \boldsymbol{E}\big(\underbrace{|x(t) - \widehat{x}(t)|^2}_{\le b^2 \text{ whenever } \mathfrak{B} \text{ holds}} \big|\mathfrak{B}\big)\Big] \le \frac{n}{2}\log_2\Big[2\pi e b^2\Big]. \end{aligned}$$

Thus we see that

$$\begin{aligned} H\big[x(t), \mathcal{I}\big|S_0^t\big] &\le 1 + (1-p)t\eta + \frac{n}{2}\big[(1-p)\log_2\big(2\pi e b_0^2\big) + p\log_2\big(2\pi e b^2\big)\big] \\ &\le 1 + (1-p)t\eta + \frac{n}{2}\log_2\big(2\pi e \max\{b_0^2, b^2\}\big). \end{aligned}$$

By combining this with (6.8), we get the following formula, which clearly implies (6.7):

$$t\Big\{\big[1 - (1-p)\big]\eta - \mathfrak{c}\Big\} \le 1 + \frac{n}{2}\log_2\big(2\pi e \max\{b_0^2, b^2\}\big) - h(x_0) + \mathfrak{c}\,. \qquad \square$$

Proof of Proposition 5.3 *for the state estimation problem.* Evidently, it suffices to consider the system with the full observation $y = x$, $C = I$ in (2.1). Suppose that

(5.1) fails to be true for the detection problem; i.e., there exists a coder-decoder pair that keeps the estimation error bounded with a positive probability. By Lemma 6.1, such a pair also exists for the auxiliary system (6.1). Since $\eta(A) = \eta(A_+)$, this system can be put in place of (2.1) in the proof. In other words, one can assume in the proof that $h(x_0) \in \mathbb{R}$, $|x_0| \le b_0 < \infty$ almost surely, and the system (2.1) at hand has no stable modes, and so $\eta(A) = \log_2 |\det A|$.

By sacrificing a small probability, the error boundedness can be made uniform: there exist $b > 0$ such that

$$\boldsymbol{P}\Big[\big|x(t) - \widehat{x}(t)\big| \le b \ \forall t\Big] > 0. \tag{6.9}$$

At the same time, Lemma 6.3 ensures that for any $\rho > \frac{\mathfrak{c}}{\eta(A)}$, there exists a nonrandom time $\tau_1 > 0$ such that

$$\boldsymbol{P}\Big[\big|x(t) - \widehat{x}(t)\big| \le b\Big] \le \rho \qquad \forall t \ge \tau_1.$$

Since $\eta(A) > \mathfrak{c}$ by the hypotheses of Proposition 5.3, one may pick $\rho < 1$ here.

Now we consider the tail of the process $x(t), \widehat{x}(t), e(t), s(t)$, $t \ge \tau_1 + 1$, in the conditional probability space given that $|x(\tau_1) - \widehat{x}(\tau_1)| \le b$ and $S_0^{\tau_1} = \boldsymbol{S}$. Here we employ an $\boldsymbol{S} \in \mathcal{S}^{\tau_1+1}$ such that

$$\boldsymbol{P}\big[\mathfrak{B}^1_{\boldsymbol{S}}\big] > 0, \qquad \text{where} \quad \mathfrak{B}^1_{\boldsymbol{S}} := \big\{|x(\tau_1) - \widehat{x}(\tau_1)| \le b \wedge S_0^{\tau_1} = \boldsymbol{S}\big\}.$$

The initial state $x(\tau_1+1) = A^{\tau_1+1}x_0$ of this tail is almost surely bounded and $h(x_0) \in \mathbb{R} \overset{(6.2),(6.6)}{\Longrightarrow} h\big[x(\tau_1+1)|\mathfrak{B}^1_{\boldsymbol{S}}\big] \in \mathbb{R}$. At the same time, the above conditioning does not alter the channel (considered for $t > \tau_1$) due to Assumptions 4.1 and 4.2. The signals $\widehat{x}(t), e(t), s(t)$, $t \ge \tau_1 + 1$, are still generated by (2.2) and (2.3) (or (2.4)), where $\boldsymbol{S}$ and $A^{-\tau_1-1}x(\tau_1+1), A^{-\tau_1}x(\tau_1+1), \dots, A^{-1}x(\tau_1+1)$ are substituted for $s(0), \dots, s(\tau_1)$ and $y(0), \dots, y(\tau_1)$, respectively. Thus Lemma 6.3 can be applied once more. It follows that $\boldsymbol{P}[|x(t) - \widehat{x}(t)|\mathfrak{B}^1_{\boldsymbol{S}}| \le b] \le \rho$ for all $t \ge \tau_2(\boldsymbol{S})$. For $\tau_2 := \max_{\boldsymbol{S}} \tau_2(\boldsymbol{S})$, we have

$$\begin{aligned}\boldsymbol{P}\Big[\big|x(\tau_2) - \widehat{x}(\tau_2)\big| \le b\Big|\big|x(\tau_1) - \widehat{x}(\tau_1)\big| \le b\Big] &= \sum_{\boldsymbol{S}} \boldsymbol{P}\Big[S^{\tau_1} = \boldsymbol{S}\Big|\big|x(\tau_1) - \widehat{x}(\tau_1)\big| \le b\Big] \\ &\times \boldsymbol{P}\Big[\big|x(\tau_2) - \widehat{x}(\tau_2)\big| \le b\Big|\mathfrak{B}^1_{\boldsymbol{S}}\Big] \le \rho \sum_{\boldsymbol{S}} \boldsymbol{P}\Big[S^{\tau_1} = \boldsymbol{S}\Big|\big|x(\tau_1) - \widehat{x}(\tau_1)\big| \le b\Big] = \rho.\end{aligned}$$

Now we repeat the above arguments with respect to the tail on $t > \tau_2$ and conditioning given that $|x(\tau_1) - \widehat{x}(\tau_1)| \le b, |x(\tau_2) - \widehat{x}(\tau_2)| \le b$, $S_0^{\tau_2} = \boldsymbol{S}$. By continuing likewise, we get a sequence $0 < \tau_1 < \tau_2 < \cdots$ such that

$$\begin{aligned}p_{i+1|1,\dots,i} &:= \boldsymbol{P}\Big[\big|x(\tau_{i+1}) - \widehat{x}(\tau_{i+1})\big| \le b\Big|\big|x(\tau_1) - \widehat{x}(\tau_1)\big| \le b, \dots, \big|x(\tau_i) - \widehat{x}(\tau_i)\big| \le b\Big] \\ &\le \rho \qquad \forall i.\end{aligned}$$

Hence

$$\begin{aligned}\boldsymbol{P}\Big[\big|x(t) - \widehat{x}(t)\big| \le b \ \forall t\Big] &\le \boldsymbol{P}\Big[\big|x(\tau_i) - \widehat{x}(\tau_i)\big| \le b \ \forall i\Big] \\ &= \lim_{k\to\infty} \boldsymbol{P}\Big[\big|x(\tau_i) - \widehat{x}(\tau_i)\big| \le b \ \forall i = 1, \dots, k\Big] \\ &= \lim_{k\to\infty} \boldsymbol{P}\Big[\big|x(\tau_1) - \widehat{x}(\tau_1)\big| \le b\Big] \times \prod_{i=2}^{k} p_{i|1,\dots,i-1} \le \lim_{k\to\infty} \prod_{i=1}^{k} \rho \overset{\rho<1}{=\!=} 0\end{aligned}$$

in violation of (6.9). The contradiction obtained proves (5.1) for the detection problem.

To prove (5.2), we apply (5.1) to the process $x_*(t) := \alpha^{-t}x(t)$, $\widehat{x}_*(t) := \alpha^{-t}\widehat{x}(t)$, $e(t)$, $s(t)$. This is possible, since it is generated by (2.1), (2.2), and (2.3) (or (2.4)), where $A := \alpha^{-1}A$, $\mathfrak{X}_*[t,\cdot] := \alpha^{-t}\mathfrak{X}[t,\cdot]$, and $[y(0),\dots,y(t)]$ is replaced by $x_*(0)$, $\alpha x_*(1),\dots,\alpha^t x_*(t)$. The condition $\eta(\alpha^{-1}A) > \mathfrak{c}$ holds, since

$$\eta(\alpha^{-1}A) = \sum_{\lambda_j} \max\{\log_2(\alpha^{-1}|\lambda_j|),0\} = \sum_{\lambda_j}\big[\max\{\log_2|\lambda_j|,\log_2\alpha\} - \log_2\alpha\big]$$
$$\geq \sum_{\lambda_j} \max\{\log_2|\lambda_j|,0\} - n\log_2\alpha = \eta(A) - n\log_2\alpha > \mathfrak{c},$$

where $n = \dim x$ and the last inequality follows from the assumption $\log_2\alpha < \frac{\eta(A)-\mathfrak{c}}{n}$ of Proposition 5.3. □

Proof of the (d) $\Rightarrow \mathfrak{c} \geq \eta(A)$ *part of Theorem* 5.1. As was pointed out, this part of Theorem 5.1 follows from Proposition 5.3 by Remark 5.1.

7. Proofs of Propositions 5.3 and 5.4 for the stabilization problem and the (d) $\Rightarrow \mathfrak{c} \geq \eta(A)$ part of Theorem 5.2. These proofs result from the arguments from the previous section, along with the following simple observation, which is close to similar facts from [50, 59, 60, 62].

LEMMA 7.1. *Consider a coder* (2.3) *and decoder* (3.2). *Then there exist other coders and decoder-estimator*

$$e(t) = \mathfrak{E}_{un}[t, y_{un}(0),\dots,y_{un}(t), s(0),\dots,s(t-1)], \qquad \widehat{x}_{un}(t) = \mathfrak{X}\,[t, s(0), s(1),\dots,s(t)]$$

that generate an estimate $\widehat{x}_{un}(t)$ *of the state of the uncontrolled system* (2.1)

$$x_{un}(t+1) = Ax_{un}(t), \qquad x_{un}(0) = x_0, \qquad y_{un}(t) = Cx_{un}(t)$$

and produce the estimation error identical to the stabilization error of the original coder-decoder pair:

$$|x_{un}(t) - \widehat{x}_{un}(t)| = |x(t)|. \tag{7.1}$$

Proof. Let the new decoder generate the estimate via the recursion

$$\widehat{x}_{\rm un}(t+1) = A\widehat{x}_{\rm un}(t) - Bu(t), \quad u(t) := \mathfrak{U}\,[t, s(0), s(1),\dots,s(t)]\,, \quad \widehat{x}_{\rm un}(0) = 0,$$

where $\mathfrak{U}(\cdot)$ is taken from (3.2), and let the new coder be defined by the formula

$$e(t) := \mathfrak{E}[t, y_{\rm un}(0) - C\widehat{x}_{\rm un}(0),\dots,y_{\rm un}(t) - C\widehat{x}_{\rm un}(t), s(0),\dots,s(t-1)],$$

where $\mathfrak{E}(\cdot)$ is taken from (2.3). This formula presupposes that the coder also computes the estimate $\widehat{x}_{\rm un}(t)$.

Now we consider the process $\{x(t),u(t)\}_{t=0}^{\infty}$ generated in the system (3.1) by the original coder and decoder. Arguing by induction on t, it is easy to see that, first, both coder-decoder pairs give rise to common sequences $\{e(t)\},\{s(t)\},\{u(t)\}$, and, second, $y(t) = y_{\rm un}(t) - C\widehat{x}_{\rm un}(t)$ and (7.1) does hold. □

Modulo Lemma 7.1, Propositions 5.3 and 5.4 for the stabilization problem are immediate from the same propositions concerning the detection problem, whereas the (d) $\Rightarrow \mathfrak{c} \geq \eta(A)$ part of Theorem 5.2 follows from the matching part of Theorem 5.1.

8. Proof of Theorem 5.1. The necessity part of this theorem was justified in section 6. In this section, the focus is on proving that the inequality $\mathfrak{c} > \eta(A)$ is sufficient for almost sure observability.

From now until subsection 8.6, we consider the plants (2.1) with no stable modes. In this case, $\eta(A) = \log_2 |\det A|$. We start with some preliminaries.

8.1. Error exponents for discrete memoryless channels. We shall use the convenient notations $\lesssim$ and $\approx$ for inequality and equality up to a polynomial factor. In other words, $\varphi(m) \lesssim \psi(m) \Leftrightarrow \varphi(m) \le \psi(m)g(m)$ for all $m = 1, 2, \dots$, where $g(m)$ is a polynomial in m, and $\varphi(m) \approx \psi(m) \Leftrightarrow \varphi(m) \lesssim \psi(m)$ & $\psi(m) \lesssim \varphi(m)$. When $\varphi(m)$ and $\psi(m)$ depend on some other variables, the polynomial is assumed to be independent of them. The symbols $\mathcal{E}^m = \{\boldsymbol{e}\}$ and $\mathcal{S}^m = \{\boldsymbol{s}\}$ stand for the sets of all m-words over the input and output channel alphabets, respectively: $\boldsymbol{e} = (e_0, \dots, e_{m-1})$, $\boldsymbol{s} = (s_0, \dots, s_{m-1})$. The following result is straightforward from Lemma IV.1 and Theorem IV.1 in [8] (see also [14, 16]). We recall that $\mathfrak{c}$ is the capacity (4.4) of the channel.

THEOREM 8.1. *For any $0 < R < \mathfrak{c}$ and $m = 1, 2, \dots$, there exist $N \approx 2^{mR}$ input code words $\boldsymbol{e}^{[1]}, \dots, \boldsymbol{e}^{[N]} \in \mathcal{E}^m$ and a decoding rule $\mathfrak{D}_m : \mathcal{S}^m \to \{1, 2, \dots, N\}$ such that the maximum probability of error obeys the bound*

$$\max_{i=1,\dots,N} f_i \lesssim 2^{-mF(R,W)}. \tag{8.1}$$

Here $F(R, W) > 0$ does not depend on m (but depends on the rate R and the channel W) and

$$f_i = \boldsymbol{P}\Big[\mathfrak{D}_m(\boldsymbol{s}) \ne i \Big| \boldsymbol{e}^{[i]}\Big] := \sum_{\boldsymbol{s}:\mathfrak{D}_m(\boldsymbol{s})\ne i} \prod_{j=0}^{m-1} W(s_j|e_j^{[i]}), \qquad \boldsymbol{e}^{[i]} = (e_0^{[i]}, \dots, e_{m-1}^{[i]}),$$

is the probability of incorrect decoding, provided that the code word $\boldsymbol{e}^{[i]}$ was sent over the channel.

8.2. Contracted quantizers and detection in the case of errorless transmission. The facts presented in this subsection are mainly based on the ideas and results from [7, 40, 42, 53, 60, 62].

An N-level *quantizer* $\mathfrak{Q}$ in $\mathbb{R}^n$ is a partition of the unit ball B_0^1 with respect to some norm $|\cdot|$ in $\mathbb{R}^n$ into N disjoint sets $Q_1, \dots, Q_N \subset \mathbb{R}^n$, each equipped with a point $q_i \in Q_i$ called the *centroid* of Q_i. Such a quantizer associates any vector $x \in Q_i$ with its *quantized value* q_i and any vector outside B_0^1 with an alarm symbol ✠.

DEFINITION 8.2. *The quantizer $\mathfrak{Q}$ is said to be* m-contracted *($m = 1, 2, \dots$) for the system* (2.1) *if*

$$A^m (Q_i - q_i) \subset \rho_{\mathfrak{Q}} B_0^1 \qquad \forall i = 1, \dots, N, \tag{8.2}$$

where $\rho_{\mathfrak{Q}} \in (0, 1)$ is called the contraction rate.

The role of such quantizers in the solution of the estimation problem is revealed by the following lemma.

LEMMA 8.3. *Suppose that the following statements hold:*

(i) *at a time instant $t = t_*$, an estimate $\widehat{x}(t)$ and its exactness $\delta = \delta(t) \ge |\widehat{x}(t) - x(t)|$ are known at both the coder and decoder sites;*

(ii) *an N-level m-contracted quantizer is given;*

(iii) *there exist ways to both encode N distinct messages for transmission over the channel within the subsequent time interval of duration m and decode the received data by time $t_* + m$ so that the overall transmission is errorless.*

Then the estimate $\widehat{x}(t)$ for $t = t_*, \dots, t_* + m$ can be constructed so that

$$\begin{aligned} &|\widehat{x}(t) - x(t)| \le \rho_{\mathfrak{Q}}\delta \quad \text{for } t = t_* + m \\ \text{and} \quad &|\widehat{x}(t) - x(t)| \le \|A\|^{t-t_*}\delta \quad \text{for} \quad t = t_*, \dots, t_* + m - 1. \end{aligned} \tag{8.3}$$

Proof. We apply the quantizer to the scaled error $\delta^{-1}[x(t) - \widehat{x}(t)]$ and, by employing (iii), make the decoder aware of the corresponding quantized value q_i by time $t_* + m$. The estimate is defined by

$$\widehat{x}(t) := A^{t-t_*}\widehat{x}(t_*) \text{ for } t = t_*, \dots, t_* + m - 1 \quad \text{and} \quad \widehat{x}(t_* + m) := A^m[\widehat{x}(t_*) + \delta q_i].$$

Then for $t = t_*, \dots, t_* + m - 1$, it follows from (2.1) that

$$|\widehat{x}(t) - x(t)| = |A^{t-t_*}\widehat{x}(t_*) - A^{t-t_*}x(t_*)| \le \|A\|^{t-t_*}|\widehat{x}(t_*) - x(t_*)| \le \|A\|^{t-t_*}\delta;$$

i.e. the second relation from (8.3) holds. Furthermore,

$$\begin{aligned} |\widehat{x}(t_* + m) - x(t_* + m)| &= \left|A^m[\widehat{x}(t_*) + \delta q_i] - A^m x(t_*)\right| \\ &= \delta\Big|A^m\Big\{\underbrace{\delta^{-1}[x(t_*) - \widehat{x}(t_*)]}_{\in Q_i} - q_i\Big\}\Big| \overset{(8.2)}{\le} \rho_{\mathfrak{Q}}\delta. \end{aligned}$$

□

A coder-decoder pair tracking the state in the case of errorless transmission. Let (iii) be true at any time $t = t_*$. Then the scheme from the above proof can be successively repeated. In doing so, we put $\delta(t_* + m) := \rho_{\mathfrak{Q}}\delta(t_*)$ in accordance with (8.3). (We assume that computations of $\widehat{x}(t)$ and $\delta(t)$ are performed by both the decoder and the coder. So (i) holds for $t = t_* + m$ whenever it is true for $t = t_*$.) This ensures tracking, since (8.3) $\Rightarrow$ (2.5).

This conclusion tacitly assumes that (i) does hold for some t_*. To ensure this, suppose that (iii) is true not only at any time but also with an increased number of messages $N := N + 1$. (One message is reserved to carry the alarm signal ✠.) Let the coder and decoder be given common initial estimate $\widehat{x}(0)$ and its exactness $\delta(0)$. Whenever $\Delta(t_*) := |x(t_*) - \widehat{x}(t_*)| \le \delta(t_*)$, the above algorithm is applied. Otherwise, the signal ✠ is sent over the channel. On its decoding at time $t_* + m$, the value of δ is increased, $\delta(t_* + m) := \gamma\delta(t_*)$, where $\gamma > 1$ is a given coefficient. In this case, the estimate is defined by $\widehat{x}(t+1) := A\widehat{x}(t)$ for $t = t_* + m - 1$. Then we put $t_* := t_* + m$ and repeat the described operations. Note that

$$\begin{aligned} \Delta(t_*) > \delta(t_*) \Rightarrow \Delta(t_* + m) &= |A^m[\widehat{x}(t_*) - x(t_*)]| \\ &\le \|A\|^m\Delta(t_*) \quad \text{and} \quad \delta(\mathrm{t}_* + \mathrm{m}) = \gamma\delta(\mathrm{t}_*). \end{aligned}$$

So until (i) holds, the error $\Delta(jm)$ increases no faster than $\|A\|^{jm}$, whereas $\delta(jm) = \gamma^j\delta(0)$. Now pick $\gamma > \|A\|^m$. Then necessarily $\Delta(jm) \le \delta(jm)$ for large j; i.e., (i) does hold sooner or later.

Thus a contracted quantizer is a gate to an observer successfully tracking the state.

A problem with the construction of such an observer along the above lines is that assumptions (ii) and (iii) imply converse requirements to the parameters N and m.

Indeed, (iii) presupposes that the number N cannot be large given m. (In the case of the perfect channel, $N \le |\mathcal{E}|^m$.) On contrary, (ii) means that the number N of quantizer levels must be large enough: $N > 2^{m\eta(A)}$. (Indeed, let **mes** denote the Lebesgue measure. Then (8.2) implies $|\det A|^m \,\mathbf{mes}\,(Q_i) \le \rho_{\mathfrak{Q}}^n \,\mathbf{mes}\, B_0^1$. Summing over i gives $|\det A|^m \,\mathbf{mes}\, B_0^1 \le N\rho_{\mathfrak{Q}}^n \,\mathbf{mes}\, B_0^1 \Rightarrow N > 2^{m\eta(A)}$.)

To look for a trade-off between the above converse requirements, it is important to know whether the bound $N > 2^{m\eta(A)}$ is tight. In other words, is it sufficient for the existence of a contracted quantizer? The next theorem shows that the answer is in a sense affirmative.

THEOREM 8.4. *For any square matrix A with no stable modes and $m = 1, 2, \dots$, there exists an m-contracted quantizer with $N \approx 2^{m\eta(A)}$ levels.*

Sketch of proof. We restrict ourselves to only a sketch, since the claim can be derived from the arguments scattered over [7, 40, 42, 53, 60, 62]. Note first that whenever the statement is true for two matrices A_1 and A_2, it is also true for the block matrix $\left(\begin{smallmatrix} A_1 & 0 \\ 0 & A_2 \end{smallmatrix}\right)$. By employing the canonical Jordan form of A as in [60, 62], this reduces the proof to the case where the matrix is a real Jordan block. Let s denote its size, λ its eigenvalue, and $\omega := |\lambda|$. As follows from, e.g., [64, Lemma 3.1, p. 64], $\Xi(m) := \omega^{-m} g(m)^{-1} A^m \to 0$ as $m \to \infty$ for some polynomial $g(\cdot)$. So $\|\Xi(m)\| < \rho < 1$ for $m \approx \infty$. Here $\|\cdot\|$ is the operator norm associated with the norm $|z| := \max_i |z_i|$ in $\mathbb{R}^s = \{z = (z_1, \dots, z_s)\}$. Multiplying the polynomial $g(m)$ by a sufficiently large scalar factor makes the inequality $\|\Xi(m)\| < \rho$ true for all m. Now consider the uniform quantizer $\mathfrak{Q}$ partitioning the unit ball B_0^1 into $N := k^s$ balls Q_i of radius $\frac{1}{k}$. Here $k := \lceil \omega^m g(m) \rceil$ and $\lceil d \rceil$ is the minimum integer exceeding d. The centroid q_i is the center of the ball Q_i. Then $\|\Xi(m)\| < \rho \Rightarrow \Xi(m)[Q_i - q_i] \subset \rho[Q_i - q_i] = \frac{\rho}{k} B_0^1 \Rightarrow A^m[Q_i - q_i] \subset \rho \frac{\omega^m g(m)}{k} B_0^1 \subset \rho B_0^1$. Thus the quantizer is m-contracted. It remains to note that $N = k^s \approx \omega^{sm} = |\det A|^m = 2^{m\eta(A)}$. □

The contraction rate ρ of the proposed quantizer does not depend on m. However, this rate can be made geometrically decreasing in m, provided the number of levels N is slightly increased.

LEMMA 8.5. *Suppose that a square matrix A with no stable modes and $\eta > \eta(A)$ are given. Then for any $m = 1, 2, \dots$, there exists an m-contracted quantizer with the contraction rate $\varkappa^{2m}$ and $N \lesssim 2^{m\eta}$ levels, where $\varkappa = \varkappa_{\eta,A} \in (0, 1)$ does not depend on m.*

Sketch of proof. In the above sketched proof of Theorem 8.4, one must alter the choice of k by $k := \lceil \alpha^m \omega^m g(m) \rceil$. Here $\alpha > 1$ is a parameter to be adjusted. This evidently provides the rate of contraction $\rho_{\mathfrak{Q}} \le \rho\alpha^{-m} \le \alpha^{-m}$ and gives rise to a quantizer with $N \approx \alpha^{sm}\omega^{sm} = 2^{m[\eta(A) + s \log_2 \alpha]}$ levels. Then the statement of the lemma results from properly adjusting the value of $\alpha > 1$. □

8.3. A coder-decoder pair without a feedback for a noisy channel. In this subsection, we assume that $\mathfrak{c} > \eta(A)$. The observer to be constructed resembles that from the previous subsection. The difference is that now employed are code words and quantizers with increasing length m_i and number of levels, respectively. So the observer operation is composed of time cycles $[\tau_i : \tau_{i+1}]$ of increasing durations $\tau_{i+1} - \tau_i = m_i$.

To construct an observer, we pick

1. two numbers η and R such that $\eta(A) < \eta < R < \mathfrak{c}$; and then for any $m = 1, 2, \dots$, we choose
2. a set $\mathfrak{E}^{[m]} \subset \mathcal{E}^m$ of $N = N'_m \approx 2^{mR}$ input code words, each of length m, and a decoding rule $\mathfrak{D}_m$ with the properties described in Theorem 8.1; and

3. an m-contracted quantizer $\mathfrak{Q}_m$ described in Lemma 8.5.

REMARK 8.1. *The quantizer outputs including the alarm signal* ✠ *can be encoded by the code words from the set* $\boldsymbol{\mathcal{E}}^{[m]}$*, provided that* m *is large enough.*

Indeed, let N''_m denote the number of the quantizer levels. Then

$$N'_m \approx 2^{mR} \quad \text{and} \quad \mathrm{N}''_{\mathrm{m}} \lesssim 2^{\mathrm{m}\eta} \quad \text{and} \quad \eta < \mathrm{R} \Rightarrow \mathrm{N}''_{\mathrm{m}} + 1 \le \mathrm{N}''_{\mathrm{m}} \qquad \forall \mathrm{m} \ge \mathrm{m}_*,$$

where m_* is large enough.

Finally, we pick $\gamma > \|A\|$ and consider the sequence of integers

$$m_i := i + m_0, \qquad i = 0, 1, \dots, \tag{8.4}$$

where $m_0 \ge n, m_*$ is an integer parameter of the observer.

Operation of the observer. Both the coder and the decoder compute their own estimates $\widehat{x}_c(t)$, $\widehat{x}_d(t)$ and bounds for the estimate exactness $\delta_c(t)$, $\delta_d(t)$, respectively. Initially, they are given common and arbitrarily chosen values of $\widehat{x}_c(0) = \widehat{x}_d(0) = \widehat{x}_0$ and $\delta_c(0) = \delta_d(0) = \delta_0 > 0$. (The inequality $\delta_0 \ge |\widehat{x}_0 - x(0)|$ may be violated.)

At any time t, both the coder and the decoder compute the next estimates and the bounds by the formulas

(8.5)
$$\widehat{x}_c(t{+}1) := A\widehat{x}_c(t), \qquad \widehat{x}_d(t{+}1) := A\widehat{x}_d(t), \qquad \delta_c(t{+}1) := \delta_c(t), \qquad \delta_d(t{+}1) := \delta_d(t).$$

However, at times $t = \tau_i$, where

$$\tau_i := m_0 + \dots + m_{i-1} = i \cdot m_0 + \frac{i(i-1)}{2}, \tag{8.6}$$

they preface these computations by the following operations.

The coder (at times $t = \tau_i$, $i = 1, 2, \dots$) does the following:

c.1. proceeding from the previous measurements calculates the current state $x(\tau_i)$;

c.2. employs the quantizer $\mathfrak{Q}_{m_i}$ and computes the quantized value $q_c(\tau_i)$ of the current scaled estimation error

$$\varepsilon(\tau_i) := \big[\delta_c(\tau_i)\big]^{-1}\big[x(\tau_i) - \widehat{x}_c(\tau_i)\big] \tag{8.7}$$

(we recall that the quantized value of any vector outside the unit ball is the alarm symbol $q_c(\tau_i) = ✠$);

c.3. encodes the quantized value $q_c(\tau_i)$ by means of the code book $\boldsymbol{\mathcal{E}}^{[m_i]}$, and thus obtained code word of length m_i is transmitted over the channel during the next operation cycle $[\tau_i : \tau_{i+1})$;

c.4. corrects the estimate and then the exactness bound

(8.8)
$$\widehat{x}_c(\tau_i) := \widehat{x}_c(\tau_i) + \delta_c(\tau_i)\, \overset{\star}{q}_c\,(\tau_i), \quad \delta_c(\tau_i) := \delta_c(\tau_i) \times \Big(\langle q_c(\tau_i)\rangle_{\varkappa,\gamma}\Big)^{m_i}, \quad \text{where}$$
$$\overset{\star}{q} := \begin{cases} q & \text{if } q \ne ✠, \\ 0 & \text{otherwise,} \end{cases} \qquad \langle q\rangle_{\varkappa,\gamma} := \begin{cases} \varkappa & \text{if } q \ne ✠, \\ \gamma & \text{otherwise,} \end{cases}$$

and $\varkappa \in (0, 1)$ is the parameter from Lemma 8.5.

Only after this does the coder perform the computations in accordance with (8.5). Note that step c.1 is possible, since the system (2.1) (with no stable modes) is observable thanks to Assumption 4.4.

The decoder (at times $t = \tau_i, i = 2, 3, \dots$) does the following:

d.1. applies the decoding rule $\mathfrak{D}_{m_{i-1}}$ to the data received within the previous operation cycle $[\tau_{i-1} : \tau_i)$ and thus computes the decoded value $q_d(\tau_i)$ of the quantized and scaled estimation error $q_c(\tau_{i-1})$ (this value may be incorrect due to transmission errors);

d.2. corrects successively the estimate and the exactness bound (8.9)

$$\widehat{x}_d(\tau_i) := \widehat{x}_d(\tau_i) + \delta_d(\tau_i) A^{m_{i-1}} \overset{\star}{q}_d(\tau_i), \quad \delta_d(\tau_i) := \delta_d(\tau_i) \times \Big(\langle q_d(\tau_i) \rangle_{\varkappa,\gamma} \Big)^{m_{i-1}}.$$

Only after this does it perform the computations from (8.5).

The coder can alter instantaneous multiplication of $\delta_c(\tau_i)$ by $\varkappa^{m_i}$ or γ^{m_i} at the time τ_i with keeping $\delta_c(t)$ constant during the next operation cycle $[\tau_i : \tau_{i+1})$ by multiplying by $\varkappa$ or γ, respectively, at each step of this cycle. Likewise, computing the large power $A^{m_{i-1}}$ employed in (8.9) can be distributed over the cycle $[\tau_{i-1} : \tau_i]$. This hint cannot be directly applied to computing $\delta_d(t)$, since the decoder becomes aware of the multiplier ($\varkappa$ or γ) only at the end of the current cycle $[\tau_{i-1} : \tau_i]$. However, one can perform both the computations and then choose the correct quantity ($\delta_d(\tau_{i-1})\varkappa^{m_{i-1}}$ or $\delta_d(\tau_{i-1})\gamma^{m_{i-1}}$) at the end τ_i of the cycle.

8.4. Tracking with arbitrarily large probability. Now we show that the coder-decoder pair constructed in the previous subsection tracks the state (2.5) with as large a probability as desired. More precisely, it does so, provided the parameter m_0 from (8.4) is chosen properly. (This choice depends on the desired probability.)

The values of the quantities $\widehat{x}_d, \widehat{x}_c, \delta_c, \delta_d$ before and after the update at time τ_i are marked by $^-$ and $^+$, respectively . We start with the following key fact.

LEMMA 8.6. *In any event where the decoder always decodes the data correctly* $q_d(\tau_i) = q_c(\tau_{i-1})$ *for all* $i \geq 2$*, the coder-decoder pair ensures asymptotic tracking* (2.5). *Furthermore,*

$$\big| x(\tau_i) - \widehat{x}_c^-(\tau_i) \big| \leq k \varkappa^{\tau_i}, \qquad i = 1, 2, \ldots, \tag{8.10}$$

where the constant k *does not depend on* i *(but may depend on the event).*

Proof. We start with showing that there exists an index $i = 1, 2, \ldots$ for which

$$|\varepsilon(\tau_i)| \leq 1, \tag{8.11}$$

where the scaled error $\varepsilon(\tau_i)$ is defined in (8.7). Indeed, otherwise, $q_c(\tau_i) = \maltese$, $\delta_c^-(\tau_{i+1}) = \delta_c^-(\tau_i)\gamma^{m_i}$ for all $i \geq 1$ and $\widehat{x}_c(t+1) = A\widehat{x}_c(t)$ for all t. So for $i \geq 2$, we have

$$\begin{aligned} |\varepsilon(\tau_i)| &= \Big[\gamma^{\sum_{j=1}^{i-1} m_j} \delta_0 \Big]^{-1} \Big| A^{\tau_i} \big[x_0 - \widehat{x}_0 \big] \Big| \overset{(8.6)}{=\!=} \frac{\gamma^{m_0}}{\delta_0} \gamma^{-\tau_i} \Big| A^{\tau_i} \big[x_0 - \widehat{x}_0 \big] \Big| \\ &\leq \left(\frac{\|A\|}{\gamma} \right)^{\tau_i} \gamma^{m_0} \frac{|x_0 - \widehat{x}_0|}{\delta_0} \xrightarrow{\gamma > \|A\|} 0 \end{aligned}$$

as $i \to \infty$ in violation of the hypothesis $\varepsilon(\tau_i) > 1$ for all i. Thus (8.11) does hold for some i.

Now consider an index i such that (8.11) holds. Then (8.11) is still true for

$i := i+1$. Indeed,

$$|\varepsilon(\tau_{i+1})| \overset{(8.7)}{=\!=} \big[\delta_c^-(\tau_{i+1})\big]^{-1}\big|x(\tau_{i+1}) - \widehat{x}_c^-(\tau_{i+1})\big| \overset{(2.1),(8.6),(8.8)}{=\!=\!=} \varkappa^{-m_i}\big[\delta_c^-(\tau_i)\big]^{-1} \times \Big|A^{m_i}x(\tau_i) - A^{m_i}\big[\widehat{x}_c^-(\tau_i) + \delta_c^-(\tau_i)q_c(\tau_i)\big]\Big| = \varkappa^{-m_i}\Big|A^{m_i}\Big\{\underbrace{\delta_c^-(\tau_i)\big]^{-1}\big[x(\tau_i) - \widehat{x}_c^-(\tau_i)\big]}_{v} - q_c(\tau_i)\Big\}\Big|.$$

Here $q_c(\tau_i)$ is the quantized value of the vector v, and an m_i-contracted quantizer with the contraction rate $\rho_{\mathfrak{Q}} = \varkappa^{2m_i}$ is applied. So (8.2) yields

$$|\varepsilon(\tau_{i+1})| \le \varkappa^{m_i} < 1; \tag{8.12}$$

i.e., (8.11) does hold for $i := i+1$.

It follows that (8.11) is true for all $i \ge \overline{i}$, where $\overline{i}$ is large enough. Hence (8.8) yields

$$\delta_c^-(\tau_i) = \delta_c^-(\tau_{\overline{i}})\varkappa^{\sum_{j=\overline{i}}^{i-1} m_j}.$$

We proceed by taking into account (8.7) and (8.11):

$$\big|x(\tau_i) - \widehat{x}_c^-(\tau_i)\big| \le \delta_c^-(\tau_i) = \overline{\delta}\varkappa^{\sum_{j=0}^{i-1} m_j} \overset{(8.6)}{=\!=} \overline{\delta}\varkappa^{\tau_i}, \qquad \text{where} \quad \overline{\delta} := \delta_c(\tau_{\overline{i}})\varkappa^{-\sum_{j=0}^{\overline{i}-1} m_j}.$$

This evidently implies (8.10) and shows that the coder tracks the state. As for the decoder, note that

$$\widehat{x}_d^+(\tau_i) = \widehat{x}_c^-(\tau_i), \qquad i = 1, 2, \dots . \tag{8.13}$$

Indeed, for $i = 1$, this relation is evident. Suppose that this relation is true for some $i \ge 1$. Due to the absence of transmission errors, $\delta_d^{\pm}(\tau_j) = \delta_c^{\pm}(\tau_{j-1})$, $j = 2, 3, \dots$. So

$$\widehat{x}_d^+(\tau_{i+1}) \overset{(8.9)}{=\!=} \widehat{x}_d^-(\tau_{i+1}) + \delta_d^-(\tau_{i+1})A^{m_i} \overset{\star}{q}_d(\tau_{i+1}) \overset{(8.5)}{=\!=} A^{m_i}\widehat{x}_d^+(\tau_i) + \delta_c^-(\tau_i)A^{m_i} \overset{\star}{q}_c(\tau_i) \overset{(8.13)}{=\!=} A^{m_i}\Big[\widehat{x}_c^-(\tau_i) + \delta_c^-(\tau_i) \overset{\star}{q}_c(\tau_i)\Big] \overset{(8.8)}{=\!=} A^{m_i}\widehat{x}_c^+(\tau_i) \overset{(8.5)}{=\!=} \widehat{x}_c^-(\tau_{i+1});$$

i.e., (8.13) holds for $i := i+1$. Thus this relation is true for all $i \ge 1$.

Whenever $\tau_i < t \le \tau_{i+1}$, we have by (8.5)

$$\big|x(t) - \widehat{x}_d(t)\big| = \Big|A^{t-\tau_i}\big[x(\tau_i) - \widehat{x}_d^+(\tau_i)\big]\Big| \overset{(8.13)}{\le} \|A\|^{t-\tau_i}\big|x(\tau_i) - \widehat{x}_c^-(\tau_i)\big|, \tag{8.14}$$

$$\max_{\tau_i < t \le \tau_{i+1}} \big|x(t) - \widehat{x}_d(t)\big| \overset{(8.10)}{\le} k\|A\|^{m_i}\varkappa^{\tau_i} = k2^{m_i \log_2 \|A\| + \log_2 \varkappa \tau_i} \overset{(8.4),(8.6)}{=\!=\!=} k2^{(i+m_0)\log_2 \|A\| + \left[i\cdot m_0 + \frac{i(i-1)}{2}\right]\log_2 \varkappa}.$$

So far as $\log_2 \varkappa < 0$, this maximum converges to 0 as $i \to \infty$; i.e., (2.5) does hold with $\widehat{x}(t) := \widehat{x}_d(t)$. □

Now we show that the assumption of Lemma 8.6 holds with large probability, provided that the parameter m_0 in (8.4) is chosen large.

LEMMA 8.7. *The probability* $\boldsymbol{p}_{err}$ *that the decoder decodes at least one message incorrectly does not exceed*

$$\boldsymbol{p}_{err} \le K_{R,W,F} 2^{-m_0 F}.$$

Here the constant $K_{R,W,F}$ *does not depend on* m_0*, and the inequality holds with any* $F \in (0, F(R,W))$*, where* $F(R,W)$ *is taken from* (8.1).

Proof. Denote by $\boldsymbol{e}(i)$ and $\boldsymbol{s}(i)$ the messages of length m_{i-1} formed by the coder at time τ_{i-1} and received by the decoder at time τ_i, respectively. For simplicity of notation, we assume that the map $\mathfrak{D}_m$ from Theorem 8.1 takes values in the set $\mathcal{E}^{[m]}$ of input code words. The symbol $\boldsymbol{p}_{\rm err}(i)$ stands for the probability that the decoding of $\boldsymbol{s}(i)$ is wrong: $\boldsymbol{p}_{\rm err}(i) = \boldsymbol{P}\{\mathfrak{D}_{m_j}[\boldsymbol{s}(j)] \ne \boldsymbol{e}(j)\}$. Since the estimate (8.1) implies $\max_i f_i \le c_{R,W,F} q^{-mF}$, we have

$$\begin{aligned}
\boldsymbol{p}_{\rm err}(i) &= \sum_{\boldsymbol{e}\in\mathcal{E}^{[m_{i-1}]}} \boldsymbol{P}\big[\boldsymbol{e}(i)=\boldsymbol{e}\big]\boldsymbol{P}\Big\{\mathfrak{D}_{m_{i-1}}[\boldsymbol{s}(i)] \ne \boldsymbol{e}(i)\Big|\boldsymbol{e}(i)=\boldsymbol{e}\Big\} \\
&\le c_{R,W,F} \sum_{\boldsymbol{e}\in\mathcal{E}^{[m_{i-1}]}} \boldsymbol{P}\big[\boldsymbol{e}(i)=\boldsymbol{e}\big] 2^{-m_{i-1}F} \overset{(8.4)}{=\!=} c_{R,W,F} 2^{-(i-1+m_0)F}; \\
\boldsymbol{p}_{\rm err} &\le \sum_{i=1}^{\infty} \boldsymbol{p}_{\rm err}(i+1) \le c_{R,W,F} \sum_{i=1}^{\infty} 2^{-(i+m_0)F} = \frac{c_{R,W,F}}{2^F-1} 2^{-m_0 F}. \qquad \square
\end{aligned}$$

As was shown in [50], the probability of error cannot be made small when stationary fixed length block coding-decoding schemes are employed.

By combining Lemmas 8.6 and 8.7, we arrive at the following conclusion.

COROLLARY 8.8. *Suppose that the system* (2.1) *has no stable modes and* $\eta(A) < \mathfrak{c}$*. Then statement* (b) *from Theorem* 5.1 *holds.*

8.5. Tracking almost surely by means of fixed length code words. The observer from the previous subsection employs code words whose lengths increase as the estimation process progresses. So the memories of the coder and decoder should increase accordingly.[3] In this subsection, we show that almost sure asymptotic state tracking can be achieved on the basis of fixed length code words whenever a communication feedback is available. In doing so, we still consider the system (2.1) with no stable modes. Extensions on systems with both stable and unstable modes will be given in subsection 8.6.

The almost sure tracking coder-decoder pair is that from subsection 8.3 modified as follows:

(i) The operation cycles are of equal and fixed duration m_0, i.e., (8.4) and (8.6) are replaced by $m_i = m_0$ and $\tau_i := i m_0$, respectively.

(ii) Instead of forming its own sequences of state estimates $\{\widehat{x}_c(t)\}$ and exactness bounds $\{\delta_c(t)\}$, the coder duplicates those generated by the decoder.

To accomplish (ii), the coder must be aware of the results $\boldsymbol{s}(i)$ of the transmissions across the channel. This becomes possible thanks to the communication feedback. Specifically, now the coder operates as follows.

At times $t = \tau_i$, $i = 1, 2, \dots$, the *coder* prefaces (8.5) by the following actions:

- It carries out step c.1 of the previous coder (see subsection 8.3). Then it in fact duplicates steps d.1 and d.2 of the decoder, i.e., for $t = \tau_i$, $i = 2, 3, \dots$.

[3] The same feature is characteristic of the anytime coding-decoding schemes considered in [50].

- The coder applies the decoding rule $\mathfrak{D}_{m_0}$ to the data received by the decoder within the previous operation cycle $[\tau_{i-1} : \tau_i)$ and thus gets $q_d(\tau_i)$.
- It corrects $\widehat{x}_c(\tau_i)$ and $\delta_c(\tau_i)$ in accordance with the formulas (8.15)

$$\widehat{x}_c(\tau_i) := \widehat{x}_c(\tau_i) + \delta_c(\tau_i) A^{m_0} \overset{\star}{q}_d(\tau_i), \qquad \delta_c(\tau_i) := \delta_c(\tau_i) \left(\langle q_d(\tau_i) \rangle_{\varkappa,\gamma} \right)^{m_0}.$$

- After this steps c.2 and c.3 of the previous coder are performed if $i = 1, 2, \ldots$.

For technical convenience, we put $q_c(\tau_0) := q_d(\tau_1) := ✠$ and suppose that at times $t = \tau_0, \tau_1$ the coder and decoder act accordingly. By comparing (8.9) and (8.15), we see that $\widehat{x}_c^{\pm}(\tau_i) = \widehat{x}_d^{\pm}(\tau_i)$ and $\delta_c^{\pm}(\tau_i) = \delta_d^{\pm}(\tau_i)$.

The main result of this subsection is as follows.

PROPOSITION 8.9. *Suppose that Assumptions* 4.1–4.4 *hold, the system* (2.1) *has no stable modes, and* $\mathfrak{c} > \eta(A)$*, where* $\mathfrak{c}$ *and* $\eta(A)$ *are taken from Theorem* 5.1*. Then the modified coder-decoder pair detects the state (i.e.,* (2.5) *holds) almost surely, provided the duration of the operation cycle is large enough:* $m_0 \geq M(A, B, \varkappa, \gamma, W, R)$.

An explicit formula for $M(A, B, \varkappa, \gamma, W, R)$ can be derived from the proof of this proposition.

COROLLARY 8.10. *Suppose that the system* (2.1) *has no stable modes and* $\eta(A) < \mathfrak{c}$*. Then statement* (a) *from Theorem* 5.1 *holds.*

In the remainder of the subsection, we prove Proposition 8.9; so its hypotheses are assumed to hold. At first, we informally discuss the idea of the proof. The operation cycle $[\tau_{i-1} : \tau_i)$ is said to be *regular* if during it a message different from the alarm one is correctly transmitted from the coder to the decoder $q_d(\tau_i) = q_c(\tau_{i-1}) \neq ✠$ and $\delta_d^+(\tau_{i-1})$ is a true bound for the estimation error: $\delta_d^+(\tau_{i-1}) \geq |x(\tau_{i-1}) - \widehat{x}_d^+(\tau_{i-1})|$. Then the update (8.9) at time $t = \tau_i$ improves the error bound via multiplying by $\varkappa^{m_0} < 1$, while keeping it correct for the updated estimate, which can be proved similarly to (8.12). However, a cycle is not necessarily regular. First, the initial bound δ_0 may be incorrect. This is a weak reason, since the algorithm would make the bound correct for a finite time in the absence of decoding errors at step d.1 (see the proof of Lemma 8.6). Second, the cycle may be irregular due to such errors. Any of them may make not only the current cycle irregular but also launch a whole "tail" of irregular cycles even if the messages transmitted across the channel during the subsequent cycles were decoded correctly. This holds if the transmission error makes the upper bound δ incorrect. During this tail, the error bound would increase via multiplying by $\gamma^{m_0} > 1$ in order to become correct once more. So any error has an aftereffect, which evidently remains true in the real circumstances where the subsequent cycles are not necessarily "errorless." A priori, it is not even clear that the chain of consecutive irregular cycles will be terminated and a regular one will occur.

The proof is based on the fact that the probability of the decoding errors can be made as small as desired by properly picking m_0. By the strong law of large numbers, this entails that the average frequency of the decoding errors is small almost surely. In other words, the errors are rarely encountered. The next step is to evaluate the duration of the aftereffect of each such error and to show that the average frequency ω_{irr} of the irregular cycles does not exceed the average frequency of the above errors multiplied by a fixed factor. So ω_{irr} is also small. Hence not only do regular cycles follow any irregular one but also the average frequency of regular cycles $\omega_{reg} \gg \omega_{irr}$. By taking into account that at any irregular cycle the bound δ_d is increased at most by multiplying by γ^{m_0}, we conclude that (approximately) $\delta_d^-(\tau_i) \leq \delta_0 \varkappa^{im_0\omega_{reg}} \gamma^{im_0\omega_{irr}} \to 0$ as $i \to \infty$. This convergence is extended on the estimation error on the ground that

$\delta_d^-(\tau_i)$ is the correct bound for this error for most of the i's.

To carry out the first step of this plan, we need the following variant of the strong law of large numbers [28, sect. 32, p. 53] (see also [46, 49]).

THEOREM 8.11. *Suppose that $\mathcal{F}_i$ is a flow of nondecreasing σ-algebras in a probability space, the random variable ξ_i is $\mathcal{F}_i$-measurable, and $b_i \uparrow \infty$, $b_i > 0$, $i = 1, 2, \ldots$. Suppose also that $\boldsymbol{E}\big|\xi_i - \boldsymbol{E}(\xi_i|\mathcal{F}_{i-1})\big| < \infty$ and*

$$\sum_{i=1}^{\infty} \frac{1}{b_i^2} \boldsymbol{E}\Big\{ \big[\xi_i - \boldsymbol{E}(\xi_i|\mathcal{F}_{i-1})\big]^2 \Big\} < \infty. \tag{8.16}$$

Then with probability 1,

$$\frac{1}{b_r} \sum_{i=1}^{r} \big[\xi_i - \boldsymbol{E}(\xi_i|\mathcal{F}_{i-1})\big] \to 0 \quad \text{as} \quad r \to \infty. \tag{8.17}$$

Now we consider the stochastic process generated by the coder-decoder pair from Proposition 8.9. The symbols $\boldsymbol{e}(i)$ and $\boldsymbol{s}(i)$ stand for the messages formed by the coder at time τ_{i-1} and received by the decoder at time τ_i, respectively. We also introduce the error indicator function:

$$I^{\mathrm{err}}(i) := 1 \quad \text{if} \quad \mathfrak{D}_{m_0}[\boldsymbol{s}(i)] \neq \boldsymbol{e}(i),\ i \geq 2, \qquad \text{and} \quad I^{\mathrm{err}}(i) := 0 \quad \text{otherwise.} \tag{8.18}$$

LEMMA 8.12. *We pick $0 < F < F(R, W)$, where $F(R, W)$ is taken from* (8.1). *Then the following relation holds almost surely, provided that m_0 is sufficiently large:*

$$\overline{\lim_{r \to \infty}} \frac{1}{r} \sum_{i=1}^{r} I^{err}(i) \leq 2^{-Fm_0}. \tag{8.19}$$

Proof. We are going to apply Theorem 8.11 to $\xi_i := I^{\mathrm{err}}(i)$ and $b(i) := i$. The σ-algebra $\mathcal{F}_i$ is taken to be that generated by the random quantities $x_0, \boldsymbol{s}(0), \ldots, \boldsymbol{s}(i)$. Due to the construction of the coder, $\boldsymbol{e}(i) = \mathfrak{E}_*[i, x_0, \boldsymbol{s}(0), \ldots, \boldsymbol{s}(i-1)]$, where $\mathfrak{E}_*(\cdot)$ is a deterministic function. It follows that $I^{\mathrm{err}}(i)$ is $\mathcal{F}_i$-measurable. Furthermore, $0 \leq I^{\mathrm{err}}(i) \leq 1 \Rightarrow 0 \leq \boldsymbol{E}[I^{\mathrm{err}}(i)|\mathcal{F}_{i-1}] \leq 1$ almost surely, which implies (8.16). So by Theorem 8.11,

$$\frac{1}{r} \sum_{i=1}^{r} \Big\{ I^{\mathrm{err}}(i) - \boldsymbol{E}[I^{\mathrm{err}}(i)|\mathcal{F}_{i-1}] \Big\} = 0 \quad \text{a.s.} \tag{8.20}$$

Now we are going to estimate $\boldsymbol{E}[I^{\mathrm{err}}(i)|\mathcal{F}_{i-1}]$. By invoking Assumptions 4.1, 4.2, and that $\boldsymbol{e}(i) = \mathfrak{E}_*[i, x_0, \boldsymbol{s}(0), \ldots, \boldsymbol{s}(i-1)]$, we get

$$\begin{aligned}
\boldsymbol{E}[I^{\mathrm{err}}(i)|\mathcal{F}_{i-1}] &= \boldsymbol{E}\Big\{ I^{\mathrm{err}}(i) \big| x_0, \boldsymbol{s}(0), \ldots, \boldsymbol{s}(i-1), \boldsymbol{e}(i) \Big\} \\
&= \boldsymbol{P}\big[\mathfrak{D}_{m_0}[\boldsymbol{s}(i)] \neq \boldsymbol{e}(i) \big| x_0, \boldsymbol{s}(0), \ldots, \boldsymbol{s}(i-1), \boldsymbol{e}(i) \big] \\
&= \sum_{\boldsymbol{\epsilon}} \boldsymbol{P}\big[\mathfrak{D}_{m_0}[\boldsymbol{s}(i)] \neq \boldsymbol{\epsilon} \big| \boldsymbol{e}(i) = \boldsymbol{\epsilon} \big] I_{\boldsymbol{e}(i) = \boldsymbol{\epsilon}} \overset{(8.1)}{\lesssim} 2^{-m_0 F(R,W)}.
\end{aligned}$$

Since $F < F(R, W)$, this implies

$$\boldsymbol{E}[I^{\mathrm{err}}(i)|\mathcal{F}_{i-1}] \leq 2^{-Fm_0} \qquad \forall i \qquad \text{for} \quad m_0 \approx \infty. \tag{8.21}$$

So by invoking (8.20), we see that almost surely

$$\begin{aligned}\overline{\lim_{r\to\infty}}\,\frac{1}{r}\sum_{i=1}^{r} I^{\rm err}(i) \;&=\; \overline{\lim_{r\to\infty}}\,\frac{1}{r}\sum_{i=1}^{r} \boldsymbol{E}[I^{\rm err}(i)|\mathcal{F}_{i-1}]\\ &\quad+\lim_{r\to\infty}\frac{1}{r}\sum_{i=1}^{r}\Big\{I^{\rm err}(i)-\boldsymbol{E}[I^{\rm err}(i)|\mathcal{F}_{i-1}]\Big\}\le 2^{-Fm_0}. \qquad \square\end{aligned}$$

Now we start to analyze the influence of the channel noise on the estimation errors. To this end, introduce the indicator functions of the following events:

$$\begin{array}{ccc} I_0(i) & \longleftrightarrow & q_d(\tau_i)=q_c(\tau_{i-1})\neq \text{✠},\\ I_{\text{✠}}(i) & \longleftrightarrow & q_d(\tau_i)=q_c(\tau_{i-1})=\text{✠},\\ I^{\rm err}_{\rm c\text{✠}}(i) & \longleftrightarrow & q_d(\tau_i)\neq q_c(\tau_{i-1})=\text{✠},\\ I^{\rm err}_{\rm d\text{✠}}(i) & \longleftrightarrow & \text{✠}=q_d(\tau_i)\neq q_c(\tau_{i-1}),\\ I^{\rm err}_{0}(i) & \longleftrightarrow & \text{✠}\neq q_d(\tau_i)\neq q_c(\tau_{i-1})\neq\text{✠}.\end{array} \tag{8.22}$$

Note that $I^{\rm err}_{\rm c\text{✠}}(i)+I^{\rm err}_{\rm d\text{✠}}(i)+I^{\rm err}_{0}(i)=I^{\rm err}(i)$ and $I_0(i)+I_{\text{✠}}(i)=1-I^{\rm err}(i)$. We first study the evolution of

$$\delta_i:=\delta_c^+(\tau_i)\quad\text{and}\quad z_i:=|\widehat{x}_c^+(\tau_i)-x(\tau_i)|. \tag{8.23}$$

Lemma 8.13. *The following relations hold for any $i\ge 1$:*

$$\delta_i=\delta_{i-1}\Big\{\varkappa^{m_0}\big[I_0(i)+I_0^{err}(i)+I_{c\text{✠}}^{err}(i)\big]+\gamma^{m_0}\big[I_{\text{✠}}(i)+I_{d\text{✠}}^{err}(i)\big]\Big\}, \tag{8.24}$$

$$\begin{aligned} z_i &\le z_{i-1}\|A\|^{m_0}\big[I_{\text{✠}}(i)+I_{d\text{✠}}^{err}(i)\big]\\ &\quad+\delta_{i-1}\varkappa^{2m_0}I_0(i)+\|A\|^{m_0}(z_{i-1}+\delta_{i-1})\big[I_0^{err}(i)+I_{c\text{✠}}^{err}(i)\big].\end{aligned} \tag{8.25}$$

Here $\varkappa\in(0,1)$ is taken from Lemma 8.5, and $\gamma>\|A\|$ is the parameter of the estimator.

Proof. To prove (8.24), we note that

$$\delta_i\overset{(8.23)}{=\!=}\delta_c^+(\tau_i)\overset{(8.15)}{=\!=}\delta_c^-(\tau_i)\left(\langle q_d(\tau_i)\rangle_{\varkappa,\gamma}\right)^{m_0}\overset{(8.23)}{=\!=}\delta_{i-1}\left(\langle q_d(\tau_i)\rangle_{\varkappa,\gamma}\right)^{m_0}.$$

So (8.24) is immediate from (8.22) and the definition of $\langle\cdot\rangle_{\varkappa,\gamma}$ from (8.8). To justify (8.25), we observe that

$$\begin{aligned} z_i &\overset{(8.23)}{=\!=} |\widehat{x}_c^+(\tau_i)-x(\tau_i)|\overset{(8.15)}{=\!=}|\widehat{x}_c^-(\tau_i)+\delta_c^-(\tau_i)A^{m_0}\overset{\star}{q}_d(\tau_i)-x(\tau_i)|\\ &\overset{(2.1),(8.5)}{=\!=\!=} \Big|A^{m_0}\Big[\widehat{x}_c^+(\tau_{i-1})+\delta_c^+(\tau_{i-1})\overset{\star}{q}_d(\tau_i)-x(\tau_{i-1})\Big]\Big|\\ &\overset{(8.23)}{=\!=} \Big|A^{m_0}\Big[\widehat{x}_c^+(\tau_{i-1})-x(\tau_{i-1})+\delta_{i-1}\overset{\star}{q}_d(\tau_i)\Big]\Big|.\end{aligned}$$

If $I_{\text{✠}}(i)+I^{\rm err}_{\rm d\text{✠}}(i)=1$, then $q_d(\tau_i)=\text{✠}$ and $\overset{\star}{q}_d(\tau_i)=0$ by (8.8). So $z_i\le\|A\|^{m_0}|\widehat{x}_c^+(\tau_{i-1})-x(\tau_{i-1})|\overset{(8.23)}{=\!=}\|A\|^{m_0}z_{i-1}$. If $I_0(i)=1$, then $\text{✠}\neq q_c(\tau_{i-1})=q_d(\tau_i)=\overset{\star}{q}_d(\tau_i)$. So $z_i=\delta_{i-1}\,|A^{m_0}\,[\varepsilon(\tau_{i-1})-q_c(\tau_{i-1})]|$ due to (8.7), where $q_c(\tau_{i-1})$ is the quantized value of $\varepsilon(\tau_{i-1})$. Hence by invoking (8.2), where $\rho_{\mathfrak{Q}}=\varkappa^{2m_0}$ thanks to Lemma 8.5, we get $z_i\le\varkappa^{2m_0}\delta_{i-1}$. Finally, suppose that $I_0^{\rm err}(i)+I^{\rm err}_{\rm c\text{✠}}(i)=1$. Then $|\overset{\star}{q}_d(\tau_i)|\le 1$, and

so $z_i \le \|A\|^{m_0}\,(|\widehat{x}_c^+(\tau_{i-1}) - x(\tau_{i-1})| + \delta_{i-1}) \overset{(8.23)}{=\!=} \|A\|^{m_0}\,(z_{i-1} + \delta_{i-1})$. Summarizing, we arrive at (8.25). □

Lemma 8.13 entails an important conclusion about the evolution of the ratio $\xi_i := z_i/\delta_i$, which determines whether the alarm symbol ✠ is sent over the channel:

$$q_c(\tau_i) = \text{✠} \Leftrightarrow \xi_i = z_i/\delta_i > 1. \tag{8.26}$$

Corollary 8.14. *For $i \ge 1$, the following inequality holds:*

$$\xi_i \le \left\{ \begin{array}{ll} \rho\xi_{i-1} & \text{if} \quad \xi_{i-1} > 1 \\ \varkappa^{m_0} & \text{if} \quad \xi_{i-1} \le 1 \end{array} \right\} \big[1 - I^{err}(i)\big] + b/2\big[\xi_{i-1} + 1\big] I^{err}(i), \tag{8.27}$$

where $I^{err}(i)$ is the error indicator function (8.18)*, and*

$$\rho := \left(\frac{\|A\|}{\gamma}\right)^{m_0}, \qquad b := 2\left(\frac{\|A\|}{\varkappa}\right)^{m_0}. \tag{8.28}$$

The proof of this claim is by merely checking (8.27) on the basis of (8.24) and (8.25).

Now we are going to study how often the alarm symbol ✠ is sent or, in other words, the frequency of the event $\xi_i > 1$. The following lemma reveals a relationship between this event and the channel errors.

Lemma 8.15. *Whenever $\xi_i > 1$ for $i = \bar{i} + 1, \dots, \bar{i} + r$, the number l of channel errors within the interval $[\bar{i} + 1 : \bar{i} + r]$ obeys the lower bound*

$$l := \big|j = \bar{i} + 1, \dots, \bar{i} + r : I^{err}(j) = 1\big| \ge r\frac{\log_2[\rho^{-1}]}{\log_2 b + \log_2[\rho^{-1}]} - \frac{\log_2 \max\{\xi_{\bar{i}}, \frac{\xi_{\bar{i}}+1}{2}\}}{\log_2 b + \log_2[\rho^{-1}]}. \tag{8.29}$$

Proof. If $\xi_{\bar{i}} \le 1$ and $I^{\rm err}(\bar{i}+1) = 0$, then (8.27) implies $\xi_{\bar{i}+1} = \varkappa^{m_0} < 1$ in violation of the hypotheses of the lemma. Thus $\xi_{\bar{i}} \le 1 \Rightarrow I^{\rm err}(\bar{i}+1) = 1$. By invoking (8.27) once more, we get, for $i = \bar{i} + 1, \dots, \bar{i} + r$,

$$\begin{aligned} \xi_i &\le \rho\xi_{i-1}[1 - I^{\rm err}(i)] + b\xi_{i-1}I^{\rm err}(i) + \frac{b}{2}[1 - \xi_{i-1}]I^{\rm err}(i) \\ &\le \xi_{i-1}\big\{\rho[1 - I^{\rm err}(i)] + bI^{\rm err}(i)\big\} + \frac{b}{2}\max\{1 - \xi_{i-1}, 0\}I^{\rm err}(i). \end{aligned}$$

The last summand does not vanish only if $i = \bar{i}+1$ and $I^{\rm err}(\bar{i}+1) = 1$. It follows that

$$\begin{aligned} 1 < \xi_{\bar{i}+r} \le \xi_{\bar{i}}\rho^{r-l}b^l + \frac{b}{2}\max\{1 - \xi_{\bar{i}}, 0\}\rho^{r-l}b^{l-1} = \rho^{r-l}b^l \max\left\{\xi_{\bar{i}}, \frac{\xi_{\bar{i}}+1}{2}\right\}, \\ 0 < (l-r)\log_2[\rho^{-1}] + l\log_2 b + \log_2 \max\left\{\xi_{\bar{i}}, \frac{\xi_{\bar{i}}+1}{2}\right\} \;\Big|\; \Rightarrow \text{(8.29)}. \end{aligned}$$ □

Now we are in a position to estimate the frequency of sending the alarm signal ✠.

Corollary 8.16. *For the indicator function $I_{\xi>1}(i) \longleftrightarrow \xi_i > 1$, the following relation holds almost surely:*

$$\varlimsup_{r\to\infty} \frac{1}{r}\sum_{i=1}^{r} I_{\xi>1}(i-1) \le \beta := \mu^{-1} \varlimsup_{r\to\infty} \frac{1}{r}\sum_{i=1}^{r} I^{err}(i), \qquad \text{where} \quad \mu := \frac{\log_2[\rho^{-1}]}{\log_2 b + \log_2[\rho^{-1}]}. \tag{8.30}$$

Proof. If $\beta \ge 1$, the claim is obvious. Suppose that $\beta < 1$. Then $\xi_i \le 1$ for some $i = i^*$. Indeed, otherwise, Lemma 8.15 with $\bar{i} := 0$ and arbitrary r yields

$$\varlimsup_{r\to\infty} \frac{1}{r}\sum_{i=1}^{r} I^{\mathrm{err}}(i) \ge \mu + \varlimsup_{r\to\infty} -\frac{1}{r}\frac{\log_2 \max\{\xi_0, \frac{\xi_0+1}{2}\}}{\log_2 b + \log_2[\rho^{-1}]} = \mu,$$

which implies $\beta \ge 1$ in violation of the hypothesis. For $r > i^*$, the set $\{i^* \le i \le r : I_{\xi>1}(i) = 1\}$ disintegrates into several intervals of durations $r_1, \dots, r_s$, respectively, not containing i^* and separated by intervals where $\xi_i \le 1$. Now we apply Lemma 8.15 to the jth interval, picking $\bar{i}$ to be the integer preceding its left end. Then $\xi_{\bar{i}} \le 1$, the second ratio in (8.29) is nonpositive, and so the number l_j of errors contained by the interval at hand is no less than $r_j\mu$. Hence

$$\begin{aligned}\varlimsup_{r\to\infty} \frac{1}{r}\sum_{i=1}^{r} I^{\mathrm{err}}(i) &\ge \varlimsup_{r\to\infty} \frac{1}{r}\sum_{i=j}^{s} l_j \ge \mu \varlimsup_{r\to\infty} \frac{1}{r}\sum_{i=j}^{s} r_j \\ &= \mu \varlimsup_{r\to\infty} \frac{1}{r}\sum_{i=i^*}^{r} I_{\xi>1}(i) = \mu \varlimsup_{r\to\infty} \frac{1}{r}\sum_{i=1}^{r} I_{\xi>1}(i-1) \;\Big|\; \Rightarrow \text{ (8.30).} \qquad \square\end{aligned}$$

Corollary 8.17. *The indicator function $I(i) \longleftrightarrow I^{err}(i) = 1 \vee I_{\xi>1}(i-1) = 1$ almost surely obeys the inequality*

$$\begin{aligned}(8.31)\quad \varlimsup_{r\to\infty} \frac{1}{r}\sum_{i=1}^{r} I(i) &\le \left\{2 + \frac{\log_2 b}{\log_2[\rho^{-1}]}\right\} \\ &\times \varlimsup_{r\to\infty} \frac{1}{r}\sum_{i=1}^{r} I^{err}(i) \overset{(8.19)}{\le} \overline{p} := 2^{-Fm_0}\left\{2 + \frac{\log_2 b}{\log_2[\rho^{-1}]}\right\}.\end{aligned}$$

Indeed, this is immediate from Corollary 8.16 and the apparent inequality $I(i) \le I^{\mathrm{err}}(i) + I_{\xi>1}(i-1)$.

Observation 8.1. It is easy to see that the first inequality in (8.31) is a direct consequence of (8.27). In other words, it holds for any nonnegative solution ξ_i of the recursive inequalities (8.27) with $i = 1, 2, \dots$, where $\{I^{\mathrm{err}}(i)\}$ is an arbitrary sequence of reals $I^{\mathrm{err}}(i) = 0, 1$ and $\rho, \varkappa \in (0,1)$, $b > 1$ are arbitrary numbers.

Lemma 8.18. *The coder-decoder pair considered in Proposition* 8.9 *tracks the state almost surely if*

(8.32)

$$\omega := \log_2[\varkappa^{-1}] - \overline{p}\big\{\log_2\gamma + \log_2[\varkappa^{-1}]\big\} > 0 \quad \text{and} \quad \chi := \omega(1-\overline{p}) - \overline{p}\log_2\|A\| > 0.$$

Proof. The symbol c (with a possible index) will be used to denote random constants independent of i and r. For any $\alpha > 0$, (8.31) implies $S(r) := \sum_{i=1}^{r} I(i) \le r(\overline{p} + \alpha)$ for $r \approx \infty$. Since $\varkappa < 1 < \gamma$, (8.22) and (8.24) yield

$$\begin{aligned}\delta_i &\le \delta_{i-1}\Big\{\varkappa^{m_0}[1 - I(i)] + \gamma^{m_0} I(i)\Big\} \qquad \forall i \ge 1 \;\Rightarrow\; \delta_r \\ &\le \delta_0 \varkappa^{rm_0} \prod_{i=1}^{r}\left(\frac{\gamma}{\varkappa}\right)^{m_0 I(i)} = \delta_0 \varkappa^{rm_0}\left(\frac{\gamma}{\varkappa}\right)^{m_0 S(r)} \\ &\overset{r\approx\infty}{\le} \delta_0 \varkappa^{rm_0}\left(\frac{\gamma}{\varkappa}\right)^{rm_0(\overline{p}+\alpha)} = \delta_0 2^{-rm_0\omega_\alpha}, \\ &\qquad \text{where } \omega_\alpha := \log_2[\varkappa^{-1}] - [\overline{p}+\alpha]\big\{\log_2\gamma + \log_2[\varkappa^{-1}]\big\} \xrightarrow{\alpha\to 0} \omega > 0.\end{aligned}$$

Thus for $\alpha \approx 0$, we have $\omega_\alpha > 0$ and

$$\delta_i \le c' 2^{-im_0\omega_\alpha} \to 0 \quad \text{as} \quad i \to \infty. \tag{8.33}$$

Now we note that due to (8.25),

$$z_i \le \delta_{i-1}\varkappa^{2m_0}\big[1 - I(i)\big] + \|A\|^{m_0}(z_{i-1} + \delta_{i-1})I(i) \le \|A\|^{m_0} z_{i-1} I(i) + c2^{-im_0\omega_\alpha},$$

$$z_r \le z_0 \prod_{i=1}^{r}\Big[\|A\|^{m_0} I(i)\Big] + c\sum_{i=1}^{r} 2^{-im_0\omega_\alpha} \prod_{j=i+1}^{r}\Big[\|A\|^{m_0} I(j)\Big].$$

The first relation from (8.32) implies $\overline{p} < 1$. So $\{i \ge 1 : I(i) = 1\} \ne \{i = 1, 2, \dots\}$ due to (8.31). It follows that for $r \approx \infty$, the first summand vanishes and

$$z_r \le c \sum_{i=r-l}^{r} 2^{-im_0\omega_\alpha} \|A\|^{m_0(r-i)},$$

where $\{r-l+1, \dots, r\}$ is the largest subinterval of the set $\mathfrak{I}_r := \{1 \le i \le r : I(i) = 1\}$ containing r. (If $r \notin \mathfrak{I}_r$, then $l := 0$.) We proceed by taking into account the inequality $l \le \sum_{i=1}^{r} I(i) = S(r) \le r(\overline{p} + \alpha)$ for all $r \approx \infty$:

$$\begin{aligned} z_r &\le c2^{-rm_0\omega_\alpha} \sum_{i=r-l}^{r} 2^{(r-i)m_0\omega_\alpha} \|A\|^{m_0(r-i)} = c2^{-rm_0\omega_\alpha} \sum_{i=0}^{l} \big(2^{\omega_\alpha}\|A\|\big)^{m_0 i} \\ &\le c\frac{2^{-rm_0\omega_\alpha}\big(2^{\omega_\alpha}\|A\|\big)^{m_0 l}}{1 - \big(2^{\omega_\alpha}\|A\|\big)^{-m_0}} \\ &\overset{r\approx\infty}{\le} c\frac{2^{-rm_0\omega_\alpha}\big(2^{\omega_\alpha}\|A\|\big)^{m_0 r(\overline{p}+\alpha)}}{1 - \big(2^{\omega_\alpha}\|A\|\big)^{-m_0}} = \frac{c}{1 - \big(2^{\omega_\alpha}\|A\|\big)^{-m_0}} 2^{-rm_0\chi_\alpha}, \end{aligned}$$

where $\chi_\alpha := \omega_\alpha[1 - (\overline{p} + \alpha)] - (\overline{p} + \alpha)\log_2\|A\| \xrightarrow[\alpha\to 0]{(8.32)} \chi > 0$.

Thus $\chi_\alpha > 0$ for $\alpha \approx 0$. So $z_r \overset{(8.23)}{=\!=} |\widehat{x}_c^+(\tau_r) - x(\tau_r)| \to 0$ as $r \to \infty$. Here $\widehat{x}_c^+(\tau_r) = \widehat{x}_d^+(\tau_r)$ thanks to (8.9) and (8.15). It remains to note that for $\tau_r < t \le \tau_{r+1} = \tau_i + m_0$,

$$|\widehat{x}_d(t) - x(t)| \overset{(2.1),(8.5)}{=\!=} \big|A^{t-\tau_r}[\widehat{x}_d^+(\tau_r) - x(\tau_r)]\big| \le \|A\|^{m_0}|\widehat{x}_d^+(\tau_r) - x(\tau_r)| \xrightarrow{t\to\infty} 0,$$

since $r \to \infty$ as $t \to \infty$. □

Proof of Proposition 8.9. By Lemma 8.18, it suffices to show that (8.32) does hold whenever m_0 is large enough. In turn, this is true if $\overline{p} \to 0$ as $m_0 \to \infty$. The required property is established as follows:

$$\overline{p} \overset{(8.31)}{=\!=} 2^{-Fm_0}\left\{2 + \frac{\log_2 b}{\log_2[\rho^{-1}]}\right\} \overset{(8.28)}{=\!=} 2^{-Fm_0}\left\{2 + \frac{1 + m_0[\log_2\|A\| + \log_2\varkappa^{-1}]}{m_0\log_2\gamma - \log_2\|A\|}\right\} \to 0$$

as $m_0 \to \infty$. □

8.6. Completing the proof of Theorem 5.1. The implication $\mathfrak{c} > \eta(A) \Rightarrow$ (a) and (b) has already been justified for systems with no stable modes. Now we consider the general case. Suppose that $\mathfrak{c} > \eta(A)$. Since $\eta(A) = \eta(A_+)$, claims (a) and (b)

are true for the system (6.1) with $x_0^+ := \pi_+ x_0$ by Corollary 8.8 and Proposition 8.9. We apply the corresponding coder-decoder pair to the primal system (2.1). In doing so, we also alter the coder's step c.1, where it identifies the current state $x_+(\tau_i)$ of (6.1). Formerly this was done on the basis of the past measurements from (6.1). Now we employ the observations from (2.1). Then thanks to Assumption 4.4, it is possible to compute $\pi_+ x(\tau_i)$, provided $m_0 \geq n$ in (8.4). Here π_+ is the projector onto L_+ parallel to L_-, and the notations $L_\pm$ were introduced in Explanation 5.1. Since evidently $x_+(t) := \pi_+ x(t)$, this does not alter the operation of the observer. It remains to note that so far as $x_-(t) := x(t) - x_+(t) \to 0$ as $t \to \infty$, this observer tracks that state of (2.1)

$$|x(t) - \widehat{x}_+(t)| = |x_-(t) + x_+(t) - \widehat{x}_+(t)| \leq |x_-(t)| + |x_+(t) - \widehat{x}_+(t)| \to 0$$

whenever it detects the state of (6.1): $|x_+(t) - \widehat{x}_+(t)| \to 0$.

The implications (a) $\vee$ (b) $\Rightarrow$ (c) $\Rightarrow$ (d) are apparent, whereas (d) $\Rightarrow \mathfrak{c} \geq \eta(A)$ was justified in section 6.

9. Proof of Theorem 5.2. The necessity part of this theorem was justified in section 7. In this section, the focus is on proving that the inequality $\mathfrak{c} > \eta(A)$ is sufficient for almost sure stabilizability.

The section is organized as follows. Subsection 9.1 describes a stabilizing coder-decoder pair. Its convergence is proved in subsection 9.3. In subsection 9.2, we show in which way communication feedback required for the almost sure stabilization can be arranged by means of control. In these subsections, we consider the plant (3.1) with no stable modes. In subsection 9.4, all arguments are consolidated, and the proof of Theorem 5.2 is completed.

9.1. Coder-decoder pair stabilizing the plant almost surely by means of fixed length code words. We present it assuming that the stabilizability condition $\mathfrak{c} > \eta(A)$ holds and the plant (3.1) has no stable modes. Then

$$\eta(A) = \log_2 |\det A|, \tag{9.1}$$

and the system is controllable and observable thanks to Assumptions 4.4 and 4.5. In the general case, a stabilizing controller can be obtained by applying that presented below to the unstable part of the system (see subsection 9.4).

Though a stabilizing controller can be constructed along the lines of subsection 8.3, we omit this and focus on stabilization by means of fixed length code words. In doing so, we show that much less communication feedback is required for stabilization than for detection. In fact, a feedback with arbitrarily small rate is sufficient.

As in subsection 8.3, we start with introducing basic components of which the coder and decoder will be assembled. To this end, we first pick two numbers η and R such that

$$\eta(A) < \eta < R < \mathfrak{c}. \tag{9.2}$$

Then for any $m = 1, 2, \ldots$, we choose

- a set $\boldsymbol{\mathcal{E}}^{[m]} \subset \mathcal{E}^m$ of $N = N'_m \approx 2^{mR}$ input code words $\mathfrak{D}_m$ with the properties described in Theorem 8.1,
- an m-contracted quantizer $\mathfrak{Q}_m$ described in Lemma 8.5.

We recall that such a quantizer partitions the unit ball B_0^1 with respect to some norm $|\cdot|$ in $\mathbb{R}^n$ into a collection of disjoint sets $Q_1, \ldots, Q_N$, each equipped with a

centroid $q_i \in Q_i$, and associates any vector $x \in Q_i$ with its quantized value q_i and any vector outside the ball B_0^1 with an alarm symbol ✠. Furthermore,

$$A^m (Q_i - q_i) \subset \rho_m B_0^1 \qquad \forall i = 1, \dots, N, \qquad \text{where} \quad \rho_m := \varkappa^{2m}. \tag{9.3}$$

Deadbeat stabilizer. We also pick a *deadbeat stabilizer*, i.e., a linear transformation of an initial state

$$x(0) = x \xrightarrow{\mathfrak{S}} [u(0), u(1), \dots, u(n-1), 0, 0, \dots] \tag{9.4}$$

into a sequence of controls driving the state to zero: $x(n) = 0$. Since the system (3.1) is controllable, such a stabilizer exists [1, p. 253]. We also define $\mathfrak{S}(✠) := \overline{\boldsymbol{u}}_✠$ by picking an *alarm control sequence* $\overline{\boldsymbol{u}}_✠ = [u_0, \dots, u_{s-1}, 0, 0, \dots]$, which drives the system from $x(0) = 0$ to $x(s) = 0$. This sequence will be specified further, and its role will be explained in subsection 9.2. The number $L(\mathfrak{S}) := \max\{n, s\}$ is called the *length* of the stabilizer.

Operation cycles and parameters. The controller operation consists of time cycles $[\tau_i : \tau_{i+1}]$,

$$\tau_i := i m_0, \tag{9.5}$$

of equal duration m_0. A fixed and independent of the cycle sequence of operations is executed within any cycle. The integer parameter m_0 of the controller, along with one more parameter γ, is chosen so that

$$m_0 \geq n + L(\mathfrak{S}), \qquad \gamma > \|A\|, \tag{9.6}$$

and for all $m \geq m_0$, the outputs of the quantizer $\mathfrak{Q}_m$ including the alarm signal ✠, can be encoded by the code words from the set $\boldsymbol{\mathcal{E}}^{[m]}$. (This is possible by Remark 8.1.) Encoding will be carried out at the beginning τ_i of each operation cycle, and then the code word thus obtained will be transmitted to the decoder during this cycle.

We also suppose that a limited feedback communication is available.

Assumption 9.1. By the end τ_{i+1} of the current operation cycle, the coder almost surely becomes aware whether or not the message received by the decoder at the beginning τ_i of this cycle was the alarm one ✠.

Thus the required feedback concerns only one message ✠ and has the size of one bit per operation cycle. By increasing the cycle duration m_0, the average amount of information transmitted across the feedback link can be made arbitrarily small. Assumption 9.1 may also be true due not to the feedback link but the fact that the alarm signal is transmitted over an especially reliable subchannel.

Remark 9.1. *In subsection* 9.2*, we shall show that Assumption* 9.1 *can always be ensured by means of control via a special choice of the alarm control sequence.*

A stabilizing *coder-decoder pair* operates as follows. Both coder and decoder compute controls $u_c(t)$, $u_d(t)$ and upper bounds for the state norm $\delta_c(t)$, $\delta_d(t)$, respectively. Actually acting upon the plant is the control $u_d(t)$. The initial bound is common: $\delta_c(0) = \delta_d(0) = \delta_0$. (The inequality $\delta_0 \geq |x(0)|$ may be violated.) Within any operation cycle $[\tau_i : \tau_{i+1})$, the coder successively sends over the channel the symbols of the code word of length m_0 formed at time τ_i, and the decoder carries out the control program $u_d(\tau_i), u_d(\tau_i + 1), \dots, u_d(\tau_{i+1} - 1)$ generated at time τ_i. These actions are prefaced at times $t = \tau_i$ by the following operations.

The coder (at times $t = \tau_i$, $i = 1, 2, \dots$) does the following:

c.1. proceeding from the previous measurements calculates the current state $x(\tau_i)$;
c.2. computes the prognosis of the state at time $t = \tau_{i+1}$:

$$\widehat{x}_c(t) := A^{m_0} x(\tau_i) + \sum_{j=\tau_i}^{t-1} A^{t-1-j} B u_c(j); \tag{9.7}$$

c.3. if $i = 3, 4, \dots$ corrects the state norm upper bound:

$$\delta_c(\tau_i) := \delta_c(\tau_i) \frac{\langle q_d(\tau_{i-1})\rangle_{\varkappa,\gamma}^{m_0}}{\langle q_c(\tau_{i-2})\rangle_{\varkappa,\gamma}^{m_0}} \tag{9.8}$$

$$= \delta_c(\tau_i) \times \begin{cases} \left(\frac{\gamma}{\varkappa}\right)^{m_0} & \text{if } q_d(\tau_{i-1}) = \maltese \text{ and } q_c(\tau_{i-2}) \neq \maltese, \\ \left(\frac{\varkappa}{\gamma}\right)^{m_0} & \text{if } q_d(\tau_{i-1}) \neq \maltese \text{ and } q_c(\tau_{i-2}) = \maltese, \\ 1 & \text{if } \begin{array}{c} q_d(\tau_{i-1}) = \maltese \text{ and } q_c(\tau_{i-2}) = \maltese \\ \text{or} \\ q_d(\tau_{i-1}) \neq \maltese \text{ and } q_c(\tau_{i-2}) \neq \maltese; \end{array} \end{cases}$$

here $\varkappa$ and γ are taken from (9.3) and (9.6), respectively, and

$$\langle q\rangle_{\varkappa,\gamma} := \begin{cases} \varkappa & \text{if } q \neq \maltese, \\ \gamma & \text{otherwise;} \end{cases} \tag{9.9}$$

c.4. employs the quantizer $\mathfrak{Q}_{m_0}$ and computes the quantized value $q_c(\tau_i)$ of the scaled state at time τ_{i+1}:

$$\varepsilon(\tau_i) := \big[\delta_c(\tau_i)\big]^{-1} \widehat{x}_c(\tau_{i+1}), \qquad q_c(\tau_i) := \mathfrak{Q}_{m_0}\big[\varepsilon(\tau_i)\big]; \tag{9.10}$$

c.5. encodes this quantized value $q_c(\tau_i)$ by means of the code book $\mathfrak{E}^{[m_0]}$ and thus obtains the code word to be transmitted over the channel during the next operation cycle $[\tau_i : \tau_{i+1})$;
c.6. computes the control program $\overline{\boldsymbol{u}}_{i+1}^c = \big[u_c(\tau_{i+1}), \dots, u_c(\tau_{i+2} - 1)\big]$ for not the next but the overtaking operation cycle $[\tau_{i+1}, \tau_{i+2} - 1)$ and then corrects the state upper bound:

$$\overline{\boldsymbol{u}}_{i+1}^c := \delta_c(\tau_i) \mathfrak{S}\big[q_c(\tau_i)\big], \qquad \delta_c(\tau_i) := \delta_c(\tau_i) \times \langle q_c(\tau_i)\rangle_{\varkappa,\gamma}^{m_0}, \tag{9.11}$$

where $\langle q\rangle_{\varkappa,\gamma}$ is given by (9.9) and $\mathfrak{S}$ is the deadbeat stabilizer.

The decoder (at the times $t = \tau_i$, $i = 2, 3, \dots$) does the following:
d.1. applies the decoding rule $\mathfrak{D}_{m_0}$ to the data received within the previous operation cycle $[\tau_{i-1} : \tau_i]$ and thus acquires the decoded value $q_d(\tau_i)$ of $q_c(\tau_{i-1})$ (which may be incorrect due to the channel errors);
d.2. computes the control program $\overline{\boldsymbol{u}}_i^d = \big[u_d(\tau_i), \dots, u_d(\tau_{i+1} - 1)\big]$ for the next operation cycle $[\tau_i : \tau_{i+1})$ and corrects the state upper bound:

$$\overline{\boldsymbol{u}}_i^d := \delta_d(\tau_i) \mathfrak{S}\big[q_d(\tau_i)\big], \qquad \delta_d(\tau_i) := \delta_d(\tau_i) \times \langle q_d(\tau_i)\rangle_{\varkappa,\gamma}^{m_0}. \tag{9.12}$$

For the definiteness, the initial control programs $\overline{\boldsymbol{u}}_0^c, \overline{\boldsymbol{u}}_0^d, \overline{\boldsymbol{u}}_1^c, \overline{\boldsymbol{u}}_1^d$ are taken to be the alarm ones.

Note that step c.1 is possible. Indeed, due to (9.4), (9.5), (9.12), and the first relation from (9.6), the dynamics of the closed-loop system (3.1) is free, $u(t) = 0$, for at least n time steps before τ_i. Since the system (3.1) is observable, this makes

it possible to identify the state $x(\tau_i)$ proceeding from the measurements even if the coder is unaware of the entire sequence of controls u_d actually acting upon the plant.

Step c.3 is possible by Assumption 9.1. The role of this step is to make the bounds δ_c and δ_d identical whenever the transmission across the channel is errorless. To specify this claim, we mark the values of δ_c and δ_d after and just before the updates in accordance with (9.11), (9.12) with the $^+$ and $^-$ indices, respectively. So the value $\delta_c^-(\tau_i)$ is taken after the correction (9.8). For consistency, we also assume that $q_c(\tau_0) := q_d(\tau_1) := \maltese$.

LEMMA 9.1. *Step* c.3 *ensures that whenever the current transmission is errorless, the next state norm upper bounds used by the coder and decoder, respectively, are identical:*

$$q_c(\tau_{i-1}) = q_d(\tau_i) \quad \Longrightarrow \quad \delta_c^-(\tau_i) = \delta_d^-(\tau_{i+1}), \qquad i = 1, 2, \dots. \tag{9.13}$$

Proof. It suffices to show that for $i = 1, 2, \dots$

$$\delta_c^-(\tau_i) = \delta_d^-(\tau_{i+1}) \left[\frac{\langle q_c(\tau_{i-1}) \rangle_{\varkappa,\gamma}}{\langle q_d(\tau_i) \rangle_{\varkappa,\gamma}} \right]^{m_0}. \tag{9.14}$$

The proof will be by induction on i. For $i = 1$, the claim is evident. Suppose that (9.14) holds for some $i \geq 1$. Then

$$\begin{aligned} \delta_c^-(\tau_{i+1}) \overset{(9.8)}{=\!=} \delta_c^+(\tau_i) \frac{\langle q_d(\tau_i) \rangle_{\varkappa,\gamma}^{m_0}}{\langle q_c(\tau_{i-1}) \rangle_{\varkappa,\gamma}^{m_0}} &\overset{(9.11)}{=\!=} \delta_c^-(\tau_i) \langle q_c(\tau_i) \rangle_{\varkappa,\gamma}^{m_0} \frac{\langle q_d(\tau_i) \rangle_{\varkappa,\gamma}^{m_0}}{\langle q_c(\tau_{i-1}) \rangle_{\varkappa,\gamma}^{m_0}} \\ &\overset{(9.14)}{=\!=} \delta_d^-(\tau_{i+1}) \langle q_c(\tau_i) \rangle_{\varkappa,\gamma}^{m_0} \\ &\overset{(9.12)}{=\!=} \delta_d^-(\tau_{i+2}) \frac{\langle q_c(\tau_i) \rangle_{\varkappa,\gamma}^{m_0}}{\langle q_d(\tau_{i+1}) \rangle_{\varkappa,\gamma}^{m_0}}; \end{aligned}$$

i.e., (9.14) with $i := i + 1$ does hold. □

The main property of the proposed coder-decoder pair is given by the following proposition.

PROPOSITION 9.2. *Suppose that Assumptions* 4.1–4.5*, Assumption* 9.1*, and relations* (9.6) *hold,* $\mathfrak{c} < \eta(A)$*, and the system* (3.1) *has no stable modes. Then the coder-decoder pair introduced in this subsection stabilizes the system almost surely if* m_0 *is large enough:* $m_0 \geq M(A, B, \varkappa, \gamma, W, R)$.

An explicit expression for the bound $M(A, B, \varkappa, \gamma, W, R)$ can be derived from the proof of this proposition, which is given in subsection 9.3. The proof resembles that of Proposition 8.9. However, there are important differences. They mainly proceed from the fact that now the coder and decoder are not completely synchronized via the communication feedback, contrary to the situation from Proposition 8.9. More precisely, the coder and decoder from Proposition 8.9 produce common error upper bounds δ_c, δ_d and state estimates $\widehat{x}_c, \widehat{x}_d$. Now only the bounds δ_c, δ_d are synchronized in a weaker sense: they are not always common but only when the previous transmission across the "feedforward" channel is errorless (see Lemma 9.1). At the same time, the feedback link is not used to put the controls produced by the coder in harmony with those generated by the decoder. In fact, the goal of the proof is to demonstrate that being properly adjusted to the current circumstances, the arguments from the proof of Proposition 8.9 (see subsection 8.5) are not destroyed by this difference.

We also stress that Proposition 9.2 holds for any choice of the alarm control sequence.

9.2. Communication feedback by means of control. Now we show that no special means are required to ensure Assumption 9.1. The point is that the decoder may notify the coder about receiving the alarm signal by means of the alarm control sequence. The idea is roughly as follows. Whenever $q_d(\tau_i) \neq \maltese$, the control program $\overline{\boldsymbol{u}}_i^d = [u_d(\tau_i), \dots, u_d(\tau_{i+1}-1)]$ acting upon the plant is a linear function of the quantized state thanks to (9.12). Since the latter is n-dimensional, this program lies in a certain n-dimensional linear space. During the time interval $[\tau_i : \tau_{i+1}-1]$, the coder observes the sequence of measurements $\overline{\boldsymbol{y}}_i := [y(\tau_i), \dots, y(\tau_{i+1}-1)]$, which is a linear transformation of both this program and the n-dimensional initial state $x(\tau_i)$. So the sequence lies in a $2n$-dimensional linear subspace $\mathfrak{L}$. However, the space of all observation sequences $\overline{\boldsymbol{y}}_i$ may be of larger dimension for large $m_0 = \tau_{i+1} - \tau_i$. This makes it possible to pick the alarm control sequence so that it generates the sequence of observations not in $\mathfrak{L}$. Then the coder may recognize the event $q_d(\tau_i) = \maltese$ by checking the relation $\overline{\boldsymbol{y}}_i \notin \mathfrak{L}$.

To be specific, now we consider a particular example of this scheme.

Alarm control sequence $\overline{\boldsymbol{u}}_{\maltese}$. We first pick a control u_* and a sequence $\overline{\boldsymbol{u}}_- := [u_0^-, \dots, u_{n-1}^-]$ such that $Bu_* \neq 0$ and the sequence $\overline{\boldsymbol{u}}_-$ drives the system from the state $x(0) = A^n B u_*$ to $x(n) = 0$. Then we put

$$\overline{\boldsymbol{u}}_{\maltese} := \big[\underbrace{0, \dots, 0}_{2n}, u_*, \underbrace{0, \dots, 0}_{n}, u_0^-, \dots, u_{n-1}^-\big]. \tag{9.15}$$

It is easy to see that this sequence drives the system from $x(0) = 0$ to $x(4n+1) = 0$, as required. To recognize the event $q_d(\tau_i) = \maltese$ by the end of the current operation cycle $[\tau_i : \tau_{i+1}]$, the coder prefaces step c.3 with the following two steps and then proceeds by executing steps c.3–c.6:

c.3$^{\maltese}$1 proceeding from the previous measurements, the coder computes the states $x(\tau_i + 2n)$ and $x(\tau_i + 3n + 1)$;

c.3$^{\maltese}$2 the coder decides that $q_d(\tau_i) = \maltese$ if and only if $x(\tau_i{+}3n{+}1) \neq A^{n+1} x(\tau_i{+}2n)$.

Step c.3$^{\maltese}$1 is possible, since the dynamics of the system is free, $u(t) = 0$, for at least n time steps before times $\tau_i + 2n$ and $\tau_i + 3n + 1$. So the coder can identify the required states on the basis of the measurements.

Steps c.3$^{\maltese}$1 and c.3$^{\maltese}$2 ensure correct recognition of the event $q_d(\tau_i) = \maltese$. Indeed, it suffices to note that $x(\tau_i + 3n + 1) - A^{n+1} x(\tau_i + 2n)$ amounts to $\delta_d(\tau_i) A^n B u_* \neq 0$ if $q_d(\tau_i) = \maltese$, and 0 otherwise.

9.3. Proof of Proposition 9.2. The assumptions of this proposition are supposed to hold throughout the subsection. To start with, we rewrite the state prognosis (9.7) in a more convenient form.

LEMMA 9.3. *The state prognosis* (9.7) *is given by the formula*

$$\widehat{x}_c(\tau_{i+1}) = \delta_c^-(\tau_{i-1}) A^{m_0} \big[\varepsilon(\tau_{i-1}) - \overset{\star}{q}_c(\tau_{i-1})\big] + A^{m_0} \sum_{j=\tau_{i-1}}^{\tau_i - 1} A^{\tau_i - 1 - j} B \big[u_d(j) - u_c(j)\big]. \tag{9.16}$$

Here $\overset{\star}{q} := 0$ *if* $q = \maltese$ *and* $\overset{\star}{q} := q$ *otherwise,* $q_c(\tau_0) := \maltese$*, and* $\varepsilon(\tau_{i-1})$ *is defined by* (9.10)*, where* $\delta_c(\tau_i) = \delta_c^-(\tau_i)$.

Proof. Suppose first that $q_c(\tau_{i-1}) \neq \maltese$. Due to the first formula from (9.11) with $i := i - 1$ and the definition of the deadbeat stabilizer, the sequence of controls $u_c(\tau_i), \dots, u_c(\tau_{i+1} - 1)$ drives the system from the state $\delta_c^-(\tau_{i-1}) q_c(\tau_{i-1})$ at time τ_i

to the state 0 at time $\tau_i + n$. Since $u_c(t) = 0$ for $t = \tau_i + n, \dots, \tau_{i+1} - 1$, the state 0 is kept until time $\tau_{i+1} = \tau_i + m_0$. Hence

$$\delta_c^-(\tau_{i-1})A^{m_0}\overset{\star}{q}_c(\tau_{i-1}) + \sum_{j=\tau_i}^{\tau_{i+1}-1} A^{\tau_{i+1}-1-j}Bu_c(j) = 0. \tag{9.17}$$

This is still true if $q_c(\tau_{i-1}) = \maltese$. Indeed, then $\overset{\star}{q}_c(\tau_{i-1}) = 0$ and $u_c(j), \tau_i \le j \le \tau_{i+1}-1$ is the alarm control sequence, which drives the system from the state $x(\tau_i) = 0$ to $x(\tau_{i+1}) = 0$. Subtracting (9.7) and (9.17) yields

$$\begin{aligned}\widehat{x}_c(\tau_{i+1}) &= A^{m_0}\big[x(\tau_i) - \delta_c^-(\tau_{i-1})\overset{\star}{q}_c(\tau_{i-1})\big] \\ &= \delta_c^-(\tau_{i-1})A^{m_0}\big[\delta_c^-(\tau_{i-1})^{-1}\widehat{x}_c(\tau_i) - \overset{\star}{q}_c(\tau_{i-1})\big] + A^{m_0}\big[x(\tau_i) - \widehat{x}_c(\tau_i)\big].\end{aligned}$$

Here by (9.7) with $i := i - 1$ and (3.1),

$$\widehat{x}_c(\tau_i) = A^{m_0}x(\tau_{i-1}) + \sum_{j=\tau_{i-1}}^{\tau_i-1} A^{\tau_i-1-j}Bu_c(j),$$

$$x(\tau_i) = A^{m_0}x(\tau_{i-1}) + \sum_{j=\tau_{i-1}}^{\tau_i-1} A^{\tau_i-1-j}Bu_d(j).$$

As a result, we arrive at (9.16) by taking into account (9.10). □

Now we consider the stochastic process generated by the coder and decoder. The symbols $\boldsymbol{e}(i)$ and $\boldsymbol{s}(i)$ stand for the messages formed by the coder at time τ_{i-1} and received by the decoder at time τ_i, respectively. We also introduce the error indicator function

$$I^{\mathrm{err}}(i) := 1 \quad \text{if} \quad \mathfrak{D}_{m_0}[\boldsymbol{s}(i)] \ne \boldsymbol{e}(i), \quad i \ge 2, \qquad \text{and} \quad I^{\mathrm{err}}(i) := 0 \quad \text{otherwise},$$

and pick $0 < F < F(R, W)$, where $F(R, W)$ is taken from (8.1). By retracing the arguments from the proof of Lemma 8.12, it is easy to see that the following relation holds almost surely for all sufficiently large m_0:

$$\varlimsup_{r\to\infty} \frac{1}{r}\sum_{i=1}^{r} I^{\mathrm{err}}(i) \le 2^{-Fm_0}. \tag{9.18}$$

Corollary 9.4. *For the indicator function* $\widehat{I}^{err}(i) \leftrightarrow I^{err}(i) = 1 \vee I^{err}(i-1) = 1 \vee I^{err}(i-2) = 1$, *we have*

$$\varlimsup_{r\to\infty} \frac{1}{r}\sum_{i=1}^{r} \widehat{I}^{err}(i) \le 3 \cdot 2^{-Fm_0}. \tag{9.19}$$

Indeed, this is immediate from (9.18) and the inequality $\widehat{I}^{\mathrm{err}}(i) \le I^{\mathrm{err}}(i) + I^{\mathrm{err}}(i-1) + I^{\mathrm{err}}(i-2)$.

Now we start to analyze the influence of the channel errors on the evolution of the closed-loop system. To this end, we introduce the following linear operators by employing the deadbeat stabilizer (9.4) and its length $L(\mathfrak{S})$:

$$\mathfrak{C}[u_0, \dots, u_{L(\mathfrak{S})-1}] := \sum_{j=0}^{L(\mathfrak{S})-1} A^{-1-j}Bu_j, \tag{9.20}$$

$$x \in \mathbb{R}^n \xrightarrow{\mathfrak{S}} \big[u(0), \dots, u(n-1), 0, 0, \dots\big] \xrightarrow{\mathfrak{C}} \mathfrak{B}(x).$$

We also put $\tau_{-1} := -1$, $q_c(\tau_l) := q_d(\tau_j) := \maltese$, $l = -1, 0$, $j = 0, 1$, and for $i \geq 0$, we consider the indicator functions (8.22). We first study the evolution of

$$\delta_i := \delta_c^-(\tau_i) \quad \text{and} \quad z_i := |\widehat{x}_c(\tau_{i+1})|. \tag{9.21}$$

LEMMA 9.5. *The following relations hold for $j \geq 1$ and $i \geq 2$:*

$$\begin{aligned}
\delta_j &= \delta_{j-1}\Big\{\varkappa^{m_0}\big[I_0(j) + I_0^{err}(j) + I_{d\maltese}^{err}(j)\big] + \gamma^{m_0}\big[I_\maltese(j) + I_{c\maltese}^{err}(j)\big]\Big\} \\
&\quad \times \left\{\left(\frac{\gamma}{\varkappa}\right)^{m_0} I_{d\maltese}^{err}(j-1) + \left(\frac{\varkappa}{\gamma}\right)^{m_0} I_{c\maltese}^{err}(j-1) + [1 - I_{d\maltese}^{err}(j-1) \right. \\
&\quad \left. - I_{c\maltese}^{err}(j-1)]\right\}, \qquad (9.22) \\
z_i &\leq z_{i-1}\|A\|^{m_0}\big[I_\maltese(i) + I_{c\maltese}^{err}(i)\big] \\
&\quad + \delta_{i-1}\varkappa^{2m_0}\big[I_0(i) + I_0^{err}(i) + I_{d\maltese}^{err}(i)\big] + \delta_{i-2}d(m_0)\widehat{I}^{err}(i). \qquad (9.23)
\end{aligned}$$

Here $\varkappa \in (0,1)$, $\gamma > \|A\|$, and $\widehat{I}^{err}(i)$ are taken from (9.3), (9.6), *and Corollary* 9.4, *respectively, and*

$$d(m) := \|A\|^{2m}\left[1 + \left(\frac{\gamma}{\varkappa}\right)^m\right]\max\big\{\|\mathfrak{B}\|, |\mathfrak{C}\overline{\boldsymbol{u}}_\maltese|\big\}, \tag{9.24}$$

where $\overline{\boldsymbol{u}}_\maltese$ is the alarm control sequence.

Proof. We start with proving (9.22):

$$\delta_j \overset{(9.21)}{=\!=} \delta_c^-(\tau_j) \overset{(9.8)}{=\!=} \delta_c^+(\tau_{j-1})\frac{\langle q_d(\tau_{j-1})\rangle_{\varkappa,\gamma}^{m_0}}{\langle q_c(\tau_{j-2})\rangle_{\varkappa,\gamma}^{m_0}} \overset{(9.11),(9.21)}{=\!=\!=} \delta_{j-1}\langle q_c(\tau_{j-1})\rangle_{\varkappa,\gamma}^{m_0}\frac{\langle q_d(\tau_{j-1})\rangle_{\varkappa,\gamma}^{m_0}}{\langle q_c(\tau_{j-2})\rangle_{\varkappa,\gamma}^{m_0}}.$$

It remains to note that due to (9.9) and (8.22), the second multiplier and the ratio in the last expression equal the first and second expressions in the curly brackets $\{\ \}$ from (9.22), respectively. To justify (9.23), we denote by s' and s'' the first and second summands from (9.16), respectively. Since in (9.16), $q_c(\tau_{i-1})$ is the quantized value of $\varepsilon(\tau_{i-1})$ by means of the quantizer $\mathfrak{Q}_{m_0}$, relation (9.3) yields

$$\begin{aligned}
|s'| &\leq \delta_{i-1} \times \left\{\begin{array}{lll} \varkappa^{2m_0} & \text{if} & q_c(\tau_{i-1}) \neq \maltese \\ \|A\|^{m_0}|\varepsilon(\tau_{i-1})| & \text{if} & q_c(\tau_{i-1}) = \maltese \end{array}\right\} \\
&\overset{(8.22)}{=\!=} \delta_{i-1}\varkappa^{2m_0}\big[I_0(i) + I_0^{\mathrm{err}}(i) + I_{\mathrm{d}\maltese}^{\mathrm{err}}(i)\big] + \delta_c^-(\tau_{i-1})|\varepsilon(\tau_{i-1})|\|A\|^{m_0}\big[I_\maltese(i) + I_{\mathrm{c}\maltese}^{\mathrm{err}}(i)\big].
\end{aligned}$$

Here $\delta_c^-(\tau_{i-1})|\varepsilon(\tau_{i-1})| = |\widehat{x}_c(\tau_i)| = z_{i-1}$ by (9.10) and (9.21). As a result, we see that $|s'|$ does not exceed the sum of the first two summands from (9.23).

The second summand s'' from (9.16) can be rewritten in the following form due to (9.11), (9.12), and (9.20):

$$\begin{aligned}
s'' &= A^{2m_0}\Big\{\delta_d^-(\tau_{i-1})\beta\big[q_d(\tau_{i-1})\big] - \delta_c^-(\tau_{i-2})\beta\big[q_c(\tau_{i-2})\big]\Big\}, \quad \text{where} \\
\beta(q) &:= \left\{\begin{array}{ll} \mathfrak{B}(q) & \text{if } q \neq \maltese, \\ \mathfrak{C}\overline{\boldsymbol{u}}_\maltese & \text{otherwise,} \end{array}\right. \\
s'' &\overset{(9.14),(9.21)}{=\!=\!=} \delta_{i-2}A^{2m_0}\left\{\frac{\langle q_d(\tau_{i-2})\rangle_{\varkappa,\gamma}^{m_0}}{\langle q_c(\tau_{i-3})\rangle_{\varkappa,\gamma}^{m_0}}\beta\big[q_d(\tau_{i-1})\big] - \beta\big[q_c(\tau_{i-2})\big]\right\}.
\end{aligned}$$

Whenever $\widehat{I}^{\rm err}(i)=0$, we have $q_d(\tau_{i-1})=q_c(\tau_{i-2})$, $q_d(\tau_{i-2})=q_c(\tau_{i-3})$, and so the last expression in the brackets $\{\}$ vanishes. In any case, $|\beta(q)|\le\max\{\|\mathfrak{B}\|,|\mathfrak{C}\overline{\boldsymbol{u}}_{\maltese}|\}$ for $q:=q_d(\tau_{i-1}),q_c(\tau_{i-2})$, since $q\neq\maltese\Rightarrow|q|\le1\Rightarrow|\beta(q)|\le\|\mathfrak{B}\|$. At the same time, $\frac{\langle q_d(\tau_{i-2})\rangle_{\varkappa,\gamma}}{\langle q_c(\tau_{i-3})\rangle_{\varkappa,\gamma}}\le\gamma/\varkappa$ due to (9.8). As a result, we see that $|s''|$ does not exceed the last summand from (9.23), which completes the proof. □

Now we focus on the evolution of the ratio $\xi_i:=z_i/\delta_i$ determining whether $\maltese$ is sent over the channel.

LEMMA 9.6. *For $i\ge2$, inequality* (8.27) *holds with $I^{err}(i):=\widehat{I}^{err}(i)$, where the indicator function $\widehat{I}^{err}(i)$ was introduced in Corollary* 9.4*, and*

$$\rho:=\left(\frac{\|A\|}{\gamma}\right)^{m_0},\qquad b:=2\left(\frac{\gamma}{\varkappa^2}\right)^{2m_0}\bigl[1+d(m_0)\bigr]. \tag{9.25}$$

Proof. Thanks to (9.22), (9.23), and (9.25)

$$\begin{aligned}\xi_i\ \le\ &\Bigl\{\xi_{i-1}\rho\bigl[I_{\maltese}(i)+I^{\rm err}_{{\rm c}\maltese}(i)\bigr]+\varkappa^{m_0}\bigl[I_0(i)+I^{\rm err}_0(i)+I^{\rm err}_{{\rm d}\maltese}(i)\bigr]\Bigr\}\\ &\times\ \underbrace{\left\{\left(\frac{\varkappa}{\gamma}\right)^{m_0}I^{\rm err}_{{\rm d}\maltese}(i-1)+\left(\frac{\gamma}{\varkappa}\right)^{m_0}I^{\rm err}_{{\rm c}\maltese}(i-1)+[1-I^{\rm err}_{{\rm d}\maltese}(i-1)-I^{\rm err}_{{\rm c}\maltese}(i-1)]\right\}}_{\lambda}\\ &+\frac{\delta_{i-2}}{\delta_i}d(m_0)\widehat{I}^{\rm err}(i).\end{aligned}$$

By (9.22), $\frac{\delta_{j-1}}{\delta_j}\le\gamma^{m_0}\varkappa^{-2m_0}\Rightarrow\frac{\delta_{i-2}}{\delta_i}\le\gamma^{2m_0}\varkappa^{-4m_0}$. Due to the definition of $\widehat{I}^{\rm err}(i)$ from Corollary 9.4,

$$\lambda\le\left(\frac{\gamma}{\varkappa}\right)^{m_0}\widehat{I}^{\rm err}(i)+1-\widehat{I}^{\rm err}(i),\qquad I(i)[1-\widehat{I}^{\rm err}(i)]=0,$$

for $I:=I^{\rm err}_0,I^{\rm err}_{{\rm d}\maltese},I^{\rm err}_{{\rm c}\maltese}$. Hence

$$\begin{aligned}\xi_i&\le\Bigl[\xi_{i-1}\rho I_{\maltese}(i)+\varkappa^{m_0}I_0(i)\Bigr]\Bigl[1-\widehat{I}^{\rm err}(i)\Bigr]\\ &\quad+\Bigl[\xi_{i-1}\rho\bigl\{I_{\maltese}(i)+I^{\rm err}_{{\rm c}\maltese}(i)\bigr\}+\varkappa^{m_0}\bigl\{I^{\rm err}_0(i)+I^{\rm err}_{{\rm d}\maltese}(i)+I_0(i)\bigr\}\Bigr]\\ &\quad\times\left(\frac{\gamma}{\varkappa}\right)^{m_0}\widehat{I}^{\rm err}(i)+\gamma^{2m_0}\varkappa^{-4m_0}d(m_0)\widehat{I}^{\rm err}(i)\\ &\le\Bigl[\xi_{i-1}\rho I_{\maltese}(i)+\varkappa^{m_0}I_0(i)\Bigr]\Bigl[1-\widehat{I}^{\rm err}(i)\Bigr]\\ &\quad+\Bigl\{\bigl[\xi_{i-1}\rho+\varkappa^{m_0}\bigr]\times\left(\frac{\gamma}{\varkappa}\right)^{m_0}+\gamma^{2m_0}\varkappa^{-4m_0}d(m_0)\Bigr\}\widehat{I}^{\rm err}(i).\end{aligned}$$

Here $\rho<1$ by (9.6) and (9.25), and $\varkappa<1$. So the factor multiplying $\widehat{I}^{\rm err}(i)$ in the last summand does not exceed

$$(\xi_{i-1}+1)\left(\frac{\gamma}{\varkappa}\right)^{m_0}+\left(\frac{\gamma}{\varkappa^2}\right)^{2m_0}d(m_0)\le\left(\frac{\gamma}{\varkappa^2}\right)^{2m_0}[1+d(m_0)](\xi_{i-1}+1)\overset{(9.25)}{=\!=}b/2(\xi_{i-1}+1).$$

Summarizing, we arrive at (8.27) with $I^{\rm err}(i):=\widehat{I}^{\rm err}(i)$. □

COROLLARY 9.7. *The indicator function $I(i)\longleftrightarrow\widehat{I}^{err}(i)=1\vee I_{\xi>1}(i-1)=1$ almost surely obeys the inequality*

$$\varlimsup_{r\to\infty}\frac{1}{r}\sum_{i=1}^{r}I(i)\le\overline{p}:=3\cdot2^{-Fm_0}\left\{2+\frac{\log b}{\log[\rho^{-1}]}\right\}. \tag{9.26}$$

Indeed, thanks to Lemma 9.6 and Observation 8.1,

$$\varlimsup_{r\to\infty}\frac{1}{r}\sum_{i=1}^{r}I(i)\le\left\{2+\frac{\log b}{\log[\rho^{-1}]}\right\}\times\varlimsup_{r\to\infty}\frac{1}{r}\sum_{i=1}^{r}\widehat{I}^{\rm err}(i)\overset{(9.19)}{\Longrightarrow}(9.26).$$

LEMMA 9.8. *Under the assumptions of Proposition* 9.2*, the coder and decoder stabilize the system almost surely if*

(9.27)
$$\omega:=\log_2[\varkappa^{-1}]-2\overline{p}\big\{\log_2\gamma+\log_2[\varkappa^{-1}]\big\}>0\quad\text{and}\quad\chi:=\omega(1-\overline{p})-\overline{p}\log_2\|A\|>0.$$

Proof. The symbol c (with a possible index) will be used to denote random constants independent of i and r. For any $\alpha>0$, (9.26) implies $S(r):=\sum_{i=1}^{r}I(i)\le r(\overline{p}+\alpha)$ for $r\approx\infty$. Since $\varkappa<1<\gamma$, (8.22) and (9.22) yield

$$\begin{aligned}\delta_i&\le\delta_{i-1}\left\{\varkappa^{m_0}[1-I(i)]+\left(\frac{\gamma^2}{\varkappa}\right)^{m_0}I(i)\right\}\quad\forall i\ge1\Rightarrow\delta_r\\&\le\delta_0\varkappa^{rm_0}\prod_{i=1}^{r}\left(\frac{\gamma}{\varkappa}\right)^{2m_0I(i)}=\delta_0\varkappa^{rm_0}\left(\frac{\gamma}{\varkappa}\right)^{2m_0S(r)}\\&\overset{r\approx\infty}{\le}\delta_0\varkappa^{rm_0}\Big(\frac{\gamma}{\varkappa}\Big)^{2rm_0(\overline{p}+\alpha)}=\delta_02^{-rm_0\omega_\alpha},\\&\qquad\text{where }\omega_\alpha:=\log_2[\varkappa^{-1}]-2[\overline{p}+\alpha]\big\{\log_2\gamma+\log_2[\varkappa^{-1}]\big\}\xrightarrow{\alpha\to0}\omega>0.\end{aligned}$$

Thus for $\alpha\approx0$, we have $\omega_\alpha>0$ and

$$\delta_i\le c'2^{-im_0\omega_\alpha}\to0\quad\text{as}\quad i\to\infty.\tag{9.28}$$

This, along with (9.11), (9.12), (9.14), and (9.21), implies

$$u_c(t)\to0,\quad u(t)=u_d(t)\to0\qquad\text{as}\quad t\to\infty.\tag{9.29}$$

In particular, the second relation from (3.3) holds. To prove the first one, we note that due to (9.23) and (9.28)

$$\begin{aligned}z_i\le z_{i-1}\|A\|^{m_0}I(i)+c''[\delta_{i-1}+\delta_{i-2}]\le z_{i-1}\|A\|^{m_0}I(i)+c2^{-im_0\omega_\alpha}\qquad\forall i\ge2;\\z_r\le z_1\prod_{i=2}^{r}\Big[\|A\|^{m_0}I(i)\Big]+c\sum_{i=2}^{r}2^{-im_0\omega_\alpha}\prod_{j=i+1}^{r}\Big[\|A\|^{m_0}I(j)\Big].\end{aligned}$$

The first relation from (9.27) implies $\overline{p}<1$. So $\{i\ge2:I(i)=1\}\ne\{i=2,3,\dots\}$ due to (9.26). It follows that for $r\approx\infty$, the first summand vanishes and

$$z_r\le c\sum_{i=r-l}^{r}2^{-im_0\omega_\alpha}\|A\|^{m_0(r-i)},$$

where $\{r-l+1,\dots,r\}$ is the largest subinterval of the set $\mathfrak{I}_r:=\{2\le i\le r:I(i)=1\}$ containing r. (If $r\notin\mathfrak{I}_r$, then $l:=0$.) We proceed by taking into account the inequality

$l \le \sum_{i=1}^{r} I(i) = S(r) \le r(\overline{p}+\alpha)$ for all $r \approx \infty$:

$$\begin{aligned} z_r &\le c2^{-rm_0\omega_\alpha} \sum_{i=r-l}^{r} 2^{(r-i)m_0\omega_\alpha} \|A\|^{m_0(r-i)} = c2^{-rm_0\omega_\alpha} \sum_{i=0}^{l} \bigl(2^{\omega_\alpha}\|A\|\bigr)^{m_0 i} \\ &\le c\frac{2^{-rm_0\omega_\alpha}\bigl(2^{\omega_\alpha}\|A\|\bigr)^{m_0 l}}{1-\bigl(2^{\omega_\alpha}\|A\|\bigr)^{-m_0}} \\ &\overset{r\approx\infty}{\le} c\frac{2^{-rm_0\omega_\alpha}\bigl(2^{\omega_\alpha}\|A\|\bigr)^{m_0 r(\overline{p}+\alpha)}}{1-\bigl(2^{\omega_\alpha}\|A\|\bigr)^{-m_0}} = \frac{c}{1-\bigl(2^{\omega_\alpha}\|A\|\bigr)^{-m_0}} 2^{-rm_0\chi_\alpha}, \\ &\qquad \text{where} \quad \chi_\alpha := \omega_\alpha[1-(\overline{p}+\alpha)] - (\overline{p}+\alpha)\log_2\|A\| \xrightarrow[\alpha\to 0]{(9.27)} \chi > 0. \end{aligned}$$

Thus $\chi_\alpha > 0$ for $\alpha \approx 0$. So $z_r \overset{(9.21)}{=\!=} |\widehat{x}_c(\tau_{r+1})| \to 0$ as $r \to \infty$. This and (9.7), (9.29) yield $A^{m_0}x(\tau_r) \to 0$ as $r \to \infty$. Since the matrix A has no stable modes, the matrix A^{-m_0} is well defined, and so $x(\tau_r) \to 0$ as $r \to \infty$. To obtain the first relation from (3.3), it remains to note that for $\tau_r \le t < \tau_{r+1} = \tau_i + m_0$,

$$|x(t)| = \left| A^{t-\tau_r}x(\tau_r) + \sum_{j=\tau_r}^{t-j} A^{t-1-j}Bu_d(j) \right| \le \|A\|^{m_0} \left(|x(\tau_r)| + \|B\| \sum_{j=\tau_i}^{\tau_{i+1}-1} |u_d(j)| \right)$$

and to invoke (9.29). □

Completing the proof of Proposition 9.2. By Lemma 9.8, it suffices to show that (9.27) holds whenever m_0 is large enough. Owing to (9.24) and (9.25),

$$\begin{aligned} \frac{1}{m_0}\log_2[1+d(m_0)] &= \frac{1}{m_0}\Bigl(\log_2 d(m_0) + \log_2[1+d(m_0)^{-1}]\Bigr) \\ &= 2\log_2\|A\| + \log_2\gamma + \log_2\varkappa^{-1} + \frac{1}{m_0}\log_2\left[1+\left(\frac{\varkappa}{\gamma}\right)^{m_0}\right] \\ &\quad + \frac{1}{m_0}\log_2\max\{\|\mathfrak{B}\|, |\mathfrak{C}\overline{u}_{\mathfrak{A}}|\} + \frac{1}{m_0}\log_2[1+d(m_0)^{-1}] \\ &\xrightarrow{m_0\to\infty} \Delta_\infty := 2\log_2\|A\| + \log_2\gamma + \log_2\varkappa^{-1}, \\ \frac{\log_2 b}{\log_2[\rho^{-1}]} &= \frac{1+2m_0[\log_2\gamma + 2\log_2\varkappa^{-1}] + \log_2[1+d(m_0)]}{m_0[\log_2\gamma - \log_2\|A\|]} \\ &\xrightarrow{m_0\to\infty} \frac{2[\log_2\gamma + 2\log_2\varkappa^{-1}] + \Delta_\infty}{\log_2\gamma - \log_2\|A\|}. \end{aligned}$$

This and (9.26) yield $\overline{p} \to 0$ as $m_0 \to \infty$, and we see that (9.27) does hold for $m_0 \approx \infty$. □

9.4. Completing the proof of Theorem 5.2. The arguments from subsection 9.2 and Proposition 9.2 ensure that $\mathfrak{c} > \eta(A) \Rightarrow$ (a) for systems with no stable modes. Now we consider the general case. Suppose that $\mathfrak{c} > \eta(A)$ and invoke the notations from Explanation 5.1. Since $\eta(A) = \eta(A_+)$, claim (a) is true for the system

$$x_+(t+1) = A_+x_+(t) + \pi_+Bu(t), \qquad x_+(0) := \pi_+x_0, \qquad y_+(t) = Cx_+(t), \tag{9.30}$$

where π_+ and π_- are the projectors onto L_+ parallel to L_- and vice versa, respectively. While picking the parameter m_0 in (9.6) and the alarm control sequence (9.15) for

the coder and decoder stabilizing the system (9.30), we employ the dimension n of the state of the original system. Now we apply this coder and this decoder to the primal system (3.1). In doing so, we alter the coder's steps c.1 and c.3✠1, where it identifies the state $x_+(\tau)$ for $\tau = \tau_i, \tau_i + 2n, \tau_i + 3n + 1$. Formerly this was done on the basis of the past measurements from (9.30). Now we employ the observations from (3.1). Then thanks to Assumption 4.4, it is possible to compute $\pi_+ x(\tau) = x_+(\tau)$ because the dynamics of the system (3.1) is free, $u(t) = 0$, at least n time steps before τ. It follows that

$$|\pi_+ x(t)| \to 0 \quad \text{and} \quad |u(t)| \to 0 \qquad \text{as} \quad t \to \infty \qquad \text{a.s.} \tag{9.31}$$

So to complete the proof, it suffices to show that $x_-(t) := \pi_- x(t) \to 0$ whenever (9.31) holds. To this end, we note that

$$x_-(t+1) = A_- x_-(t) + \pi_- B u(t), \qquad \|A_-^m\| \le c\rho^m, \qquad m = 0, 1, 2, \dots,$$

for some $\rho \in (0, 1)$. Hence for any given t_* and $t > t_*$, we have

$$\begin{aligned}
|x_-(t)| &= \Big| A_-^t x_-(0) + \sum_{j=0}^{t-1} A_-^{t-1-j} \pi_- B u(j) \Big| \\
&\le c\rho^t |x_-(0)| + c\|B\|\|\pi_-\| \Big[\sum_{j=0}^{t_*} \rho^{t-1-j} |u(j)| + \sum_{j=t_*}^{t-1} \rho^{t-1-j} |u(j)| \Big], \\
\varlimsup_{t\to\infty} |x_-(t)| &= c\|B\|\|\pi_-\| \varlimsup_{t\to\infty} \sum_{j=t_*}^{t-1} \rho^{t-1-j} |u(j)| \\
&\le \frac{c\|B\|\|\pi_-\|}{1-\rho} \sup_{t \ge t_*} |u(t)| \to 0 \quad \text{as} \quad t_* \to \infty,
\end{aligned}$$

where the last relation follows from (9.31). Thus (a) does hold.

The implications (a) $\Rightarrow$ (b) $\Rightarrow$ (c) $\Rightarrow$ (d) are apparent, whereas (d) $\Rightarrow \mathfrak{c} \ge \eta(A)$ holds due to Remark 5.1.

Appendix: Proof of Lemma 6.1. The proof is prefaced by two technical facts.

LEMMA A.1. *Suppose that Assumptions* 4.1 *and* 4.2 *hold and a decoder* (2.2) *and a feedback coder* (2.3) *are taken. Then the joint distribution of the variables* x_0, $E_0^t = \{e_j\}_{j=0}^t$, $S_0^t = \{s_j\}_{j=0}^t$ *is given by*

$$\boldsymbol{P}[dx, dS_0^t, dE_0^t] = \prod_{j=0}^{t} W(s_j|e_j) \delta\Big[e_j, \mathfrak{E}_x\big(j, x, S_0^{j-1}\big)\Big] ds_j de_j \boldsymbol{P}_0(dx), \quad \text{where} \tag{A.1}$$

$$\mathfrak{E}_x[t, x_0, S_0^{t-1}] := \mathfrak{E}[t, Cx_0, \dots, CA^t x_0, S_0^{t-1}] \overset{(2.1),(2.3)}{=\!=} e(t). \tag{A.2}$$

Here $\boldsymbol{P}_0(dx)$ *is the probability distribution of* x_0, *and* $\delta(e, e') := 1$ *if* $e = e'$ *and* $\delta(e, e') := 0$ *otherwise.*

Proof. The proof will be by induction on t. For $t = 0$,

$$\begin{aligned}
\boldsymbol{P}[dx, dS_0^t, dE_0^t] &= \boldsymbol{P}[dx, ds_0, de_0] \\
&= \boldsymbol{P}[dx, ds_0|e_0] \boldsymbol{P}(de_0) \overset{\text{Assumptions 4.1, 4.2}}{=\!=\!=} \boldsymbol{P}[dx|e_0] \boldsymbol{P}[ds_0|e_0] \boldsymbol{P}(de_0) \\
\overset{\text{Assumption 4.1,}}{=\!=\!=} W(s_0|e_0) \boldsymbol{P}[dx, de_0] ds_0 &\overset{(A.2)}{=\!=} W(s_0|e_0) \delta\big[e_0, \mathfrak{E}_x(0, x)\big] ds_0 de_0 \boldsymbol{P}_0(dx);
\end{aligned}$$

i.e., (A.1) does hold for $t = 0$. Suppose that it holds for some $t = 0, 1, \dots$. Then

$$\begin{aligned}\boldsymbol{P}\big[dx, dS_0^{t+1}, dE_0^{t+1}\big] &= \boldsymbol{P}\big[dx, dS_0^t, ds_{t+1}, dE_0^t, de_{t+1}\big]\\ &= \boldsymbol{P}\big[dx, dS_0^t, ds_{t+1}, dE_0^t|e_{t+1}\big]\boldsymbol{P}\big[de_{t+1}\big]\\ \overset{\text{Assumptions 4.1, 4.2}}{=\!=\!=} &\ \boldsymbol{P}\big[dx, dS_0^t, dE_0^t|e_{t+1}\big]\boldsymbol{P}\big[ds_{t+1}|e_{t+1}\big]\boldsymbol{P}\big[de_{t+1}\big]\\ = &\ W(s_{t+1}|e_{t+1})\boldsymbol{P}\big[dx, dS_0^t, dE_0^t, de_{t+1}\big]ds_{t+1}\\ \overset{\text{(A.2)}}{=\!=} &\ W(s_{t+1}|e_{t+1})\delta\big[e_{t+1}, \mathfrak{E}_x(t+1, x, S_0^t)\big]\boldsymbol{P}\big[dx, dS_0^t, dE_0^t,\big]ds_{t+1}de_{t+1}.\end{aligned}$$

This and the induction hypothesis show that (A.1) does hold for $t = t + 1$. □

Corollary A.2. *Given a coder and decoder-estimator, we denote by* $\mathfrak{B}$ *the random event of keeping the error bounded* (2.6)*. The conditional probability of this event given* $x(0) = x$ *can be chosen so that it does not depend on the distribution of the initial state* $x(0)$*, provided Assumption* 4.2 *holds. This is true irrespective of whether or not this distribution has a probability density.*

Indeed, thanks to Lemma A.1, the conditional distribution

$$\begin{aligned}\boldsymbol{P}\big[dS_0^t|x(0) = x\big] &= \sum_{E_0^t}\prod_{j=0}^{t} ds_j W(s_j|e_j)\delta\big[e_j, \mathfrak{E}_x(j, x, S_0^{j-1})\big]\\ &= \prod_{j=0}^{t} ds_j W\big[s_j|\mathfrak{E}_x(j, x, S_0^{j-1})\big]\end{aligned}$$

does not depend on the distribution of the initial state. It remains to note that

$$\boldsymbol{P}(\mathfrak{B}|x) = \lim_{k\to\infty}\lim_{l\to\infty}\int_{\left\{S_0^l:|A^t x - \mathfrak{X}(t,S_0^t)|<k\ \forall t=0,\dots,l\right\}}\boldsymbol{P}\big[dS_0^l|x(0) = x\big].$$

Proof of Lemma 6.1. Consider a coder (2.3) and decoder (2.2) that keep the estimation error bounded with the probability better than p for the primal system (2.1). By invoking the notation $p_0(\cdot)$ from Assumption 4.3 and putting $Q_{>p} := \{x \in \mathbb{R}^n : \boldsymbol{P}(\mathfrak{B}|x) > p\}$, we get

$$\begin{aligned}p < \boldsymbol{P}(\mathfrak{B}) &= \int_{\mathbb{R}^n}\boldsymbol{P}(\mathfrak{B}|x)p_0(x)\,dx \Rightarrow \int_{Q_{>p}} p_0(x)\,dx\\ &= \boldsymbol{P}(x_0 \in Q_{>p}) > 0 \Rightarrow \exists c > 0 : \boldsymbol{P}(x_0 \in Q) > 0,\end{aligned}$$

where $Q := \{x \in Q_{>p} : p_0(x) \le c\}$. Then there exists a compact subset $\overset{\circ}{Q} \subset Q$ such that $\boldsymbol{P}[x_0 \in \overset{\circ}{Q}] = \int_{\overset{\circ}{Q}} p_0(x)\,dx > 0$ [15, sect. 134Fb]. Now we pass to the probability space related to the probability given $x_0 \in \overset{\circ}{Q}$. This evidently keeps Assumptions 4.1–4.3 true and the channel parameters $W(s|e)$ unchanged. We assume that all random variables inherit their initial notations. Note also that in the new probability space, the initial vector x_0 is almost surely bounded and has a bounded density. Hence $h(x_0) \in \mathbb{R}$.

Now we introduce the projector π_+ onto L_+ parallel to L_- and the compact set $Q_+ := \pi_+\overset{\circ}{Q} \subset L_+$, and we define the initial vector in (6.1) to be $x_0^+ := \pi_+ x_0$. This vector evidently has a bounded probability density,

$$x_0^+ \in Q_+ \quad \text{a.s.}, \tag{A.3}$$

and so the second moment of x_0 is finite. It follows that $h(x_0^+) \in \mathbb{R}$.

The multivalued function $x_+ \in Q_+ \mapsto \mathfrak{V}(x_+) := \{x_- \in L_- : x_+ + x_- \in \overset{\circ}{Q}\}$ has a closed graph $\overset{\circ}{Q}$ and so is upper-hemicontinuous. Thus there exists a single-valued measurable selector $x_+ \in Q_+ \mapsto \chi_-(x_+) \in \mathfrak{V}(x_+)$. By extending it as a measurable function on L_+ and putting $\chi(x_+) := x_+ + \chi_-(x_+)$, we get

$$x_+ \in Q_+ \Rightarrow \chi(x_+) \in \overset{\circ}{Q} \subset Q \Rightarrow \boldsymbol{P}\big[\mathfrak{B}|\chi(x_+)\big] > p. \tag{A.4}$$

Now we are in a position to transform the original coder-decoder pair (2.3), (2.2) serving the primal system into that keeping the estimation error bounded for the auxiliary system (6.1). We note first that the system (6.1) is observable thanks to Assumption 4.4. So for any $t \geq n-1$, there exists a *dead-beat observer*, i.e., a linear transformation $y(0), \dots, y(t) \overset{\mathfrak{S}_t}{\mapsto} x_+(0)$, where $y(i)$ are taken from (6.1). We define a new coder and decoder as follows. For $t = 0, \dots, n-1$, they in fact do nothing. However, for the sake of definiteness, we pick $e_* \in \mathcal{E}$ and put $\mathfrak{E}_+[t, y(0), \dots, y(t), S_0^{t-1}] := e_*$, $\mathfrak{X}_+[t, S_0^t] := 0$. For $t \geq n$, the new coder and decoder act as follows:

$$\begin{aligned} \omega &= \big[y(0), \dots, y(t), S_0^{t-1}\big] \overset{\mathfrak{S}_t}{\mapsto} x_+(0), S_0^{t-1} \mapsto \mathfrak{E}_+[t, \omega] \\ &:= \mathfrak{E}\big\{t-n, C\chi[x_+(0)], \dots, CA^{t-n}\chi[x_+(0)], S_n^{t-1}\big\}, \\ \widehat{x}_+(t) &:= \mathfrak{X}_+\big[t, S_0^t\big] := \pi_+ A^n \mathfrak{X}\big[t-n, S_n^t\big]. \end{aligned}$$

Now consider the process $\xi(t) = [x(t), y(t), e(t), s(t), \widehat{x}(t)]$, $t = 0, 1, \dots$, generated by the original coder-decoder pair in the system (2.1) when started with the initial random state $\chi[x_0^+]$. It is easy to see that $\pi_+ x(t)$, $C\pi_+ x(t)$, $e(t-n)$, $s(t-n)$, $\pi_+ A^n \widehat{x}(t-n)$ is a process generated by the new coder and decoder in the auxiliary system (6.1). Here $\widehat{x}(t) := 0$, $e(t) := e_*$ for $t < 0$, and $s(-n), \dots, s(-1)$ are mutually independent and independent of $\xi(t)$, $t = 0, 1, \dots$ random quantities, each with the distribution $W(s|e_*)$. Hence for $t \geq n$,

$$\begin{aligned} |x_+(t) - \widehat{x}_+(t)| &= |\pi_+ x(t) - \pi_+ A^n \widehat{x}(t-n)| \leq \|\pi_+\| |x(t) - A^n \widehat{x}(t-n)| \\ &= \|\pi_+\| |A^n x(t-n) - A^n \widehat{x}(t-n)| \leq \|\pi_+\| \|A^n\| |x(t-n) - \widehat{x}(t-n)|. \end{aligned}$$

So for the new coder-decoder pair and the system (6.1), the probability of keeping the estimation error bounded is no less than that for the process $\xi(t)$, $t = 0, 1, \dots$. It remains to note that the latter amounts to $\boldsymbol{EP}[\mathfrak{B}|\chi(x_0^+)]$ and is greater than p by (A.3) and (A.4).

OPTIMAL VORTEX REDUCTION FOR INSTATIONARY FLOWS BASED ON TRANSLATION INVARIANT COST FUNCTIONALS*

K. KUNISCH† AND B. VEXLER‡

Abstract. We consider the problem of an appropriate choice of a cost functional for vortex reduction for unsteady flows described by the Navier–Stokes equations. This choice is directly related to a physically correct definition of a vortex. Therefore, we discuss different possibilities for the cost functional and analyze the resulting optimal control problems. Moreover, we present an efficient numerical realization of this concept based on space-time finite element discretization and demonstrate its behavior in some numerical experiments. It is demonstrated that the choice of cost functionals has a significant effect on the reduction of vortices.

Key words. optimal control, vortex reduction, Navier–Stokes equations

1. Introduction.

This work focuses on the choice of proper cost functionals in optimal control formulations for vortex reduction in incompressible fluids. The formalization of vorticity is still a major challenge and a subject of intense research within fluid mechanics research itself. In the context of optimal control the quantification must satisfy the additional requirement that it allows the description of vorticity as a scalar-valued functional in terms of observables of the fluid. Moreover, the mathematical properties of the functional have significant consequences for mathematical programming considerations and for the numerical realization of the resulting optimization problems.

Let us first summarize some of the cost functionals that were already used in the optimal control literature to formulate vortex reduction problems. We denote by $y(t,x)$ the velocity vector and by $p(t,x)$ the pressure of an incompressible fluid which extends over the time horizon $[0,T]$ and the spatial domain Ω. Further, let $\tilde{\Omega}$ be the subset of Ω over which vortex reduction is desired.

An intensively studied cost functional in the context of optimal control of vortex reduction is given by

$$\int_0^T \int_{\tilde{\Omega}} |\operatorname{curl} y(t,x)|^2 \, dx \, dt; \tag{1.1}$$

see, e.g., [AT, G]. One of the objections against this functional is that it is not Galilean invariant; i.e., it is not invariant under transformations of the form $\mathcal{Q}x + d\,t$ of the flow field y, where $\mathcal{Q}$ is a time-independent matrix and d is a constant vector. Another frequently used functional is of the form

$$\int_0^T \int_{\tilde{\Omega}} |y(t,x) - y_{des}(t,x)|^2 \, dx \, dt, \tag{1.2}$$

where y_{des} stands for a given desired flow field which contains some of the expected features of the controlled flow field without the undesired vortices. Typically y_{des} is chosen as the solution to the Stokes problem on the same flow geometry and with the same boundary conditions as those which are involved for the characterization of y. This functional is referred to as a tracking-type functional. Just like the functional in (1.1), the tracking-type functional is not Galilean invariant. From the mathematical programming point of view the functionals in (1.1), (1.2) behave quite differently, however. To explain this fact let us consider the following prototype boundary optimal control problem:

$$\begin{cases} \min J(y) + G(u) \\ \text{subject to} \\ y_t - \nu\Delta y + y \cdot \nabla y + \nabla p = f \text{ in } (0,T] \times \Omega, \\ -\text{div } y = 0 \text{ in } (0,T] \times \Omega, \\ y(0,\cdot) = y_0 \text{ on } \Omega, \\ y = u \text{ on } (0,T] \times \Gamma_c,\ y = 0 \text{ on } (0,T] \times (\partial\Omega \setminus \Gamma_c), \end{cases} \tag{1.3}$$

where $\nu > 0$, f and y_0 are given, and u denotes the control variable acting on $(0,T]\times\Gamma_c$ and satisfying $\int_{\Gamma_c} u(t)\, n\, dx = 0$, with n denoting the outer normal to $\partial\Omega$. Further J and G are real-valued functionals penalizing vorticity and control-action, respectively, with J as in (1.1) or (1.2), and $G(u) = \frac{1}{2}|u|^2$, where $|\cdot|$ denotes an appropriate norm on the control space. If u is an optimal solution to (1.3), then u, together with the associated velocity y and pressure p, satisfies the primal equations, which are the equations in (1.3), the adjoint equation

$$\begin{cases} -\lambda_t - \nu\Delta\lambda + (\nabla y)^t\lambda - (y \cdot \nabla)\lambda + \nabla\pi = J'(y) \text{ in } (0,T] \times \Omega, \\ -\text{div } \lambda = 0 \text{ in } (0,T] \times \Omega, \\ \lambda(T,\cdot) = 0 \text{ on } \Omega, \\ \lambda = 0 \text{ on } (0,T] \times \partial\Omega, \end{cases} \tag{1.4}$$

with adjoint velocity λ and adjoint pressure π, and satisfies as well the so-called optimality condition formally given by

$$\nu\frac{\partial\lambda}{\partial n} + G'(u) - \pi n = 0 \text{ on } \Gamma_c. \tag{1.5}$$

We refer to [FGH] and [HK], for example, for rigorous frameworks for boundary control of the Navier–Stokes equations. Note that the adjoint equations related to (1.1) and (1.2) differ significantly with respect to the regularity of the right-hand sides: in the former case the right-hand side involves second order derivatives of the velocity field, whereas for the tracking-type cost functional only y without derivatives appears in (1.4). Moreover, in the case when the residue between y_{des} and y at the optimal control is sufficiently small, a second order optimality condition for (1.3) with J as in (1.2) holds [HK]. It appears to be difficult to obtain conditions which

lend themselves to an intuitive interpretation and which imply second order sufficient optimality for optimal control problems involving (1.1). For second order sufficient optimality conditions related to optimal control of the Navier–Stokes equations, we also refer to [TW].

To discuss candidates for Galilean invariant measures we decompose the velocity gradient tensor ∇y as

$$\nabla y = S + \Omega,$$

where $S = \frac{1}{2}(\nabla y + (\nabla y)^t)$ is the rate of strain tensor and $\Omega = \frac{1}{2}(\nabla y - (\nabla y)^t)$ is the vorticity tensor. The fact that Ω is used for both the spatial domain and the antisymmetric part of ∇y should not create confusion. We use this notation for both since they are quite standard in the literature.

The Δ-criterion (see [CPC] and [BMC]) is based on a local phase plane analysis of

$$\dot{\xi} = A\,\xi \tag{1.6}$$

with $A = \nabla y(t, x)$. For two-dimensional systems the geometry of the trajectories in terms of the eigenvalues of A can be found in many textbooks. For the case when A is a 3×3 matrix, a detailed analysis is given in [CPC], for example. In particular, if

$$\Delta = \frac{1}{2}\left(\frac{Q}{3}\right)^3 + \left(\frac{\det \nabla y}{2}\right)^2 > 0, \tag{1.7}$$

where

$$Q = \frac{1}{2}(|\Omega|^2 - |S|^2), \tag{1.8}$$

then the characteristic equation associated with A has one real and two complex eigenvalues. Thus, the regions in $(0, T) \times \Omega$, where Δ is positive, are candidates for local instantaneous stirring. In (1.8) we denote $|\Omega|^2 = \sum_{i,j} \Omega_{ij}^2$ and similarly for $|S|$. For incompressible fluids we have

$$Q = -\frac{1}{2}\mathrm{trace}(A^2).$$

The research in [JH] contains an interesting discussion of some of the shortcomings of earlier characterizations of vortices, including (1.7), and it proposes to define vortices as regions where the second eigenvalue of the symmetric matrix $S^2 + \Omega^2$ satisfies

$$\lambda_2(S^2 + \Omega^2) < 0.$$

Under appropriate conditions this criterion guarantees an instantaneous local pressure minimum in a two-dimensional plane in a three-dimensional flow.

In the case when spatial domain Ω is two-dimensional, it can be easily verified by direct computation that the following criteria are equivalent:

(i) The smaller eigenvalue of $S^2 - \Omega^2$ is negative;
(ii) ∇y has complex eigenvalues;
(iii) $Q > 0$;
(iv) $\det \nabla y > 0$.

These considerations suggest the use of

$$\int_0^T \int_{\tilde{\Omega}} \max(0, \det \nabla y(t,x))\, dx\, dt \tag{1.9}$$

as a cost functional in vortex-reduction formulations. Note that due to the max-operation the cost functional in (1.9) is nondifferentiable and therefore, for numerical optimization routines, regularization of the max-operator may be necessary. This cost functional was used for optimal vortex reduction in a driven-cavity problem in [HKSV].

Let us return to the cost functional (1.1) involving the curl-operator and note that it can be equivalently expressed as

$$\int_0^T \int_{\tilde{\Omega}} |\Omega(t,x)|^2\, dx\, dt.$$

Vorticity, together with thresholding, has been widely used for representing vortices; see [JH] and the references given there. However, it is now well accepted as an inadequate vorticity measure, for example, in the context of boundary layers. In particular, it was shown in [Lu] that maxima and minima of $|\Omega|$ in planar wall-bounded flows occur only at the wall.

A well-known Galilean invariant measure defines the vorticity region as the domain where the vorticity tensor dominates the rate of strain tensor, i.e.,

$$Q = \frac{1}{2}(|\Omega|^2 - |S|^2) = -\frac{1}{2}(\lambda_1 + \lambda_2 + \lambda_3) > 0,$$

where λ_i are the eigenvalues of $S^2 + \Omega^2$.

This criterion was originally proposed in [O] and [W] for two-dimensional domains and investigated in [HWM] for three-dimesional domains. It is referred to as the Okubo–Weiss criterion, or Q-criterion, and readily lends itself to being used in a cost functional of the form

$$\int_0^T \int_{\tilde{\Omega}} \max(0, |\Omega(t,x)|^2 - |S(t,x)|^2)\, dx\, dt.$$

As mentioned above, the Okubo–Weiss criterion coincides with the $\det \nabla y > 0$ criterion in two dimensions.

Galilean invariant vortex criteria allow a classification which is invariant under frame changes that move at a constant speed relative to each other. In a variety of different theoretical and example-driven approaches (see, e.g., [H1], [H2], [LHK], [LKH], [TK]), it was established that Galilean invariance is not sufficient for reliable vortex identification. Rather, criteria must be invariant also under coordinate transformations of the form $\mathcal{Q}(t)x + d(t)$, where $\mathcal{Q}$ is a time-dependent orthogonal matrix and d a time-dependent velocity vector. Such transformations are called *objective* in continuum mechanics and, in particular, they allow time-dependent rotations. An alternative way to point out the deficiencies of Galilean invariant criteria is based on taking the point of view of tracer dynamics. The gradient of the tracer q satisfies

$$\frac{D\nabla q}{Dt} = -(\nabla y)^t \nabla q,$$

where $\frac{D}{Dt}$ is the material derivative and $(\nabla y)^t$ denotes the transpose of the velocity gradient tensor. Studies have shown that the acceleration gradient tensor or second

derivatives of the pressure must be considered as well; see [LKH, LHK] and the references given there. In [LKH] an objective criterion is obtained in two dimensions which defines a rotation dominated region by means of

$$|r(y,p)| > 1, \tag{1.10}$$

where

$$r(y,p) = \frac{\omega}{\sigma} - \frac{\sigma_s(p_{x_1x_1} - p_{x_2x_2}) - 2\sigma_n p_{x_1x_2}}{\sigma^{\frac{3}{2}}}, \tag{1.11}$$

and $\omega = (y_2)_{x_1} - (y_1)_{x_2}$, $\sigma_s = (y_2)_{x_1} + (y_1)_{x_2}$, $\sigma_n = (y_1)_{x_1} - (y_2)_{x_2}$, $\sigma = (\sigma_s^2 + \sigma_n^2)^{1/2}$. It can readily be used for vortex-reduction by introducing the cost functional

$$\int_0^T \int_{\tilde{\Omega}} \max(r(t,x)^2 - 1, 0)\, dx\, dt, \tag{1.12}$$

for example.

In [TK] the Okubo–Weiss criterion is reconsidered through study of the stability of fluid particles in the eigenbasis of the rate of strain tensor S. This results in the modified criterion

$$Q_s = \frac{1}{2}(|\Omega - \Omega_S|^2 - |S|^2) > 0, \tag{1.13}$$

where Ω_S is the matrix containing the time derivatives of the unit eigenvectors of S in the Lagrangian frame. This criterion is well defined and objective regardless of the spatial dimension; however, as noted in [TK], the physical principles used in deriving (1.13) are restricted to two dimensions. In the appendix of [TK] it is verified that in two dimensions the criteria (1.10) and (1.13) coincide.

An interesting new vorticity criterion [H1, H2] again departs from a stability consideration of $\xi = 0$ in (1.7). It utilizes the Lyapunov functional

$$V(t,\xi) = \frac{1}{2}\frac{d}{dt}|\xi|^2 = \xi^t S(t, x(t))\xi.$$

By incompressibility of the velocity field, it can be argued that $Z = Z(t) = \{\xi : V(t,\xi) = 0\}$ defines a cone in $\mathbb{R}^3(\mathbb{R}^2)$ separating regions with different qualitative properties of the flow of (1.6) depending on the signs of the real eigenvalues of $\nabla y(t, x(t))$. To analyze the qualitative behavior of the flow, the strain acceleration tensor $M = S_t + (\nabla S)y + S\nabla y + (\nabla y)^t S$ is defined and its restriction M_Z to Z is considered. The elliptic region is defined as the set in (t,x) space, where M_Z is indefinite or $S(t,x)$ vanishes on Z. A vortex is a bounded connected set of fluid trajectories that remain in the elliptic region. This is an objective criterion valid for two and three dimensions. It appears that further considerations are necessary regarding how to design a practical cost functional based on this vortex definition which can be used in optimal control formulations.

In this paper we shall show the practical efficiency of the objective functional (1.12) for vortex reduction. We shall further conduct a comparison among the four functionals (1.1), (1.2), (1.9), and (1.12). Optimal control problems based on these four functionals can give surprisingly different results. A comparison among different cost functionals is, at first, impeded by the following difficulty: As indicated in the prototype problem (1.3), usually a term $G(u)$ representing control costs is utilized.

Mathematically it guarantees a priori bounds on minimizing sequences for (1.3) and, subsequently, existence of a minimizer for the optimal control problem (1.3). The optimal solution depends on G and therefore, if J is taken as one of the four functionals (1.1), (1.2), (1.9), (1.12), the question must be addressed of how to eliminate the effect of the control-cost term on the solutions of these optimal control problems. Here we take the approach of eliminating G altogether. As a consequence, we have to consider atypical existence problems for optimal control problems with the Navier–Stokes equations as constraints. In fact, there are no obvious a priori bounds for the control. We can only hope for a priori bounds for y due to J. Assuming that such bounds can be obtained it is, however, unfeasible to assume that boundedness of y implies boundedness of u for most practical norms for y and u, where y and u are linked through the Navier–Stokes equations. For this reason we consider finite dimensional control spaces only. This still leaves us with interesting existence problems for optimal control problems without control costs in the functional to be minimized.

We should also note the fact that some arbitrariness remains due to the fact that vorticity criteria of the type $c(t,x) > 0$ pointwise in the space-time cylinder must be converted to scalar-valued functionals; compare (1.10) and (1.12), for example.

Let us briefly outline the following sections. Section 2 is devoted to existence results for optimal control problems with the Navier–Stokes equations as constraints. Specifically we also consider the situation without control costs, where a priori bounds on the controls can result only from the differential equation which appears as a constraint. In section 3 we discuss optimality systems for the optimal control problems under consideration. Section 4 is devoted to algorithmic aspects concerning the optimization algorithm and the space-time finite element discretization. Numerical examples for a channel flow with an obstacle are given in section 5. In section 6 (appendix) the proofs for the theorems and propositions of sections 2 and 3 are provided.

2. Optimal control problem. In this section we formulate optimal control problems for vortex reduction and discuss the existence of solutions in some prototypical cases. In order to compare different vortex descriptions leading to different cost functionals, we choose a formulation where the control variable does not explicitly enter the cost functional; i.e., we consider optimal control problems without control costs. In general, existence of a solution for such problems cannot be guaranteed. Therefore we restrict ourselves to the consideration of finite dimensional control spaces. Even then, due to nonlinearity of the state equation and possible nonconvexity of the cost functional, existence of optimal controls does not follow from standard arguments. These arguments can be employed if the cost functional is radially unbounded with respect to the control, but this is not the case in our work; see, e.g., [AT, Li]. In practice, as well, the control variables are often restricted to a finite dimensional setting.

Throughout this section we consider the optimal control problem of vortex reduction on the spacial domain $\Omega \subset \mathbb{R}^2$, with boundary $\partial\Omega$ of C^1-class, in the time interval $I = (0,T)$. The space-time cylinder is denoted by $Q = (0,T) \times \Omega$.

In order to formulate the optimal control problem we introduce the following spaces:

$$\mathcal{V} = \left\{ v \in H^1(\Omega)^2 \,:\, \operatorname{div} v = 0 \right\}, \quad \mathcal{V}_0 = \left\{ v \in H_0^1(\Omega)^2 \,:\, \operatorname{div} v = 0 \right\},$$

$$\mathcal{H} = \left\{ v \in L^2(\Omega)^2 \,:\, \operatorname{div} v = 0 \right\}, \quad H = \left\{ v \in H_0^1(\Omega)^2 \,:\, \operatorname{div} v = 0 \right\}^{-_{L^2(\Omega)^2}},$$

where $-_{L^2(\Omega)^2}$ denotes the closure in $L^2(\Omega)^2$, and $\mathcal{V}^*$ is the dual space to $\mathcal{V}$. These

spaces build a Gelfand triple $\mathcal{V} \hookrightarrow \mathcal{H} \hookrightarrow \mathcal{V}^*$; i.e., the imbeddings $\mathcal{V} \hookrightarrow \mathcal{H}$ and $\mathcal{H} \hookrightarrow \mathcal{V}^*$ are continuous and $\mathcal{V}$ is dense in $\mathcal{H}$.

For an arbitrary space Y we use the abbreviations $L^p(Y) = L^p(0,T;Y)$, for $1 \le p < \infty$, and $C(Y) = C([0,T];Y)$. We further set

$$W = \left\{ w \in L^2(\mathcal{V}) \,:\, w_t \in L^2(\mathcal{V}_0^*) \right\}, \quad W_0 = W \cap L^2(\mathcal{V}_0), \tag{2.1}$$

$$L^2(\Omega)/\mathbb{R} = \left\{ v \in L^2(\Omega) \,:\, \int_\Omega v \, dx = 0 \right\}.$$

The space W_Σ of admissible functions appearing in the Dirichlet boundary conditions is chosen as

$$W_\Sigma = \{ \hat{g} = \tau g \,:\, g \in W \},$$

where $\tau : W \to L^2(H^{1/2}(\partial\Omega)^2)$ is the trace operator onto the lateral boundary $(0,T) \times \partial\Omega$ of the cylinder Q; see [HK].

As motivated in the introduction, we choose a finite dimensional control space $U \cong \mathbb{R}^n$ $(n \in \mathbb{N})$ and consider a control operator $\hat{B} \in \mathcal{L}(U, W_\Sigma)$. Then $\hat{B}$ can be expressed as

$$\hat{B}u = \sum_{i=1}^{n} u_i \hat{\psi}_i, \quad \hat{\psi}_i = \tau\psi_i, \quad \text{with } \psi_i \in W .$$

Throughout we assume the operator $\hat{B}$ to be injective, i.e., the functions $\{\hat{\psi}_i\}$ are linearly independent, and that

$$\psi_i(0) \in H, \quad i = 1, 2, \dots, n.$$

The latter condition implies that $\psi_i(0) \cdot n = 0$ on $\partial\Omega$ and also will be required for the initial condition y_0 below. Our results can easily be generalized to just requiring the compatibility condition

$$\left((\hat{B}u)(0) - y_0|_{\partial\Omega} \right) \cdot n = 0 .$$

For later use, we introduce a prolongation operator $B \in \mathcal{L}(U, W)$ of the control operator $\hat{B}$ with the property

$$\tau(Bu) = \hat{B}u \quad \text{for all } u \in U .$$

This prolongation may be defined by $Bu = \sum_i u_i \psi_i$ or as in Lemma 6.2, but each prolongation satisfying the above condition is admissible.

The state equation for the velocity field $y = y(t,x)$ and pressure $p = p(t,x)$ is formulated as follows:

$$\begin{cases} y_t - \nu\Delta y + y \cdot \nabla y + \nabla p = f \text{ in } (0,T] \times \Omega, \\ -\operatorname{div} y = 0 \text{ in } (0,T] \times \Omega, \\ y(0,\cdot) = y_0 \text{ on } \Omega, \\ y = \hat{B}u \text{ on } (0,T] \times \partial\Omega. \end{cases} \tag{2.2}$$

The data are assumed to satisfy $\nu > 0$, $f \in L^2(H^{-1}(\Omega)^2)$, and $y_0 \in H$, where $H^{-1}(\Omega)$ is the dual space of $H_0^1(\Omega)$. The state equation (2.2) is understood in the distributional sense, allowing for a variational formulation for the velocity component y. The introduction of the pressure component and its regularity is discussed below in Proposition 2.1.

To introduce the weak formulation for the velocity component we define a semilinear form $\bar{a}\colon W \times W_0 \to \mathbb{R}$ by

$$\bar{a}(y,\psi) = \int_0^T \{(y_t,\psi) + \nu(\nabla y, \nabla\psi) + (y\nabla y,\psi) - (f,\psi)\}\, dt + (y(0) - y_0, \psi(0)).$$

The velocity component y is called the variational solution of (2.2) if $y \in W$ satisfies

$$y \in Bu + W_0 \ :\ \bar{a}(y)(\psi) = 0 \quad \text{for all } \psi \in L^2(\mathcal{V}_0). \tag{2.3}$$

For the state equation formulated in this setting we have the following existence result.

PROPOSITION 2.1. *For every $u \in U$ there exists a unique variational solution $y \in W$ of the state equation* (2.3) *defining a continuous solution operator $S\colon U \to W$. Moreover, there exists a distribution p fulfilling* (2.2) *such that $p = \partial_t P$ with some $P \in C(L^2(\Omega)/\mathbb{R})$. The mapping $u \mapsto P$ is continuous from U to $C(L^2(\Omega)/\mathbb{R})$.*

The proof of this proposition is given in section 6 (appendix), where it is shown that the pair (y, P) satisfies

$$y(t) - y(0) - \nu\int_0^t \Delta y(s)\, ds + \int_0^t (y(s)\cdot\nabla)y(s)\, ds + \nabla P(t) = \int_0^t f(s)\, ds$$

in $C(H^{-1}(\Omega)^2)$.

The space of all pairs $x = (y,p)$ satisfying $y \in W$ and $p = \partial_t P$ (as distribution) with some $P \in C(L^2(\Omega)/\mathbb{R})$ is denoted by X, i.e.,

$$X = \left\{(y,p) \ :\ y \in W \text{ and } p = \partial_t P,\ P \in C(L^2(\Omega)/\mathbb{R})\right\}.$$

In the following proposition a regularity result for the solution $x = (y,p)$ of (2.2) is given. It will be shown that x lies in the space

$$\mathcal{X} = L^2(H^2(\Omega)^2) \cap H^1(L^2(\Omega)^2) \times L^2(H^1(\Omega)),$$

provided that additional assumptions are satisfied. This regularity in particular allows us to interpret the pressure component p as an almost everywhere defined function rather than as only a distribution.

PROPOSITION 2.2. *If $\partial\Omega$ is of C^2-class, $f \in L^2(L^2(\Omega)^2)$, $y_0 \in \mathcal{V}_0$, $\psi_i \in W \cap L^2(H^2(\Omega)^2) \cap H^1(L^2(\Omega)^2)$, and $\psi_i(0) \in \mathcal{V}_0$, then $x \in \mathcal{X}$.*

The proof of this proposition is given in section 6 (appendix).

Under the assumptions of Proposition 2.2 a variational formulation incorporating the pressure component can be stated. To this end we introduce the space $\mathcal{X}_0$ by

$$\mathcal{X}_0 = \{(y,p) \in \mathcal{X} \ :\ \tau y = 0\}$$

and define for $x = (y, p) \in \mathcal{X}$ and $\zeta = (\psi, \xi) \in \mathcal{X}_0$ the semilinear form $a\colon \mathcal{X} \times \mathcal{X}_0 \to \mathbb{R}$ by

$$a(x)(\zeta) = \int_0^T \{(y_t, \psi) + \nu(\nabla y, \nabla \psi) + (y \nabla y, \psi) - (p, \operatorname{div} \psi) - (f, \psi) + (\operatorname{div} y, \xi)\}\, dt + (y(0) - y_0, \psi(0)).$$

We introduce a prolongation $\mathcal{B} \in \mathcal{L}(U, \mathcal{X})$ by $\mathcal{B}u = (Bu, 0)$ and state the corresponding variational formulation as follows:

$$x \in \mathcal{B}u + \mathcal{X}_0 \ : \ a(x, \zeta) = 0 \quad \text{for all } \zeta \in \mathcal{X}_0\,. \tag{2.4}$$

Under the assumptions of Proposition 2.2 the solution x satisfies the variational problem (2.4).

We are now prepared to introduce the optimization problems which will further be investigated. In the following section we shall derive optimality systems under the mild regularity requirements of Proposition 2.1 as well as under the stronger ones of Proposition 2.2. The corresponding variational formulations are given in (2.3) and (2.4), respectively.

The optimization problems are of the form

$$\text{minimize } J(x) \ \text{ subject to (2.2)}, \quad x \in X,\ u \in U, \tag{2.5}$$

where $J\colon X \to \mathbb{R}$ and the solutions to (2.2) are understood in the sense of Proposition 2.1.

We stress that due to the absence of a control cost term, one cannot use standard techniques to ensure the existence of a solution of (2.5). In the following, we first provide the existence of solutions for two choices of the functional J:

$$J_1(y) = \int_0^T \int_\Omega |y(t, x) - y_{des}(t, x)|^2\, dx\, dt, \tag{2.6}$$

$$J_2(y) = \int_0^T \int_\Omega |\operatorname{curl} y(t, x)|^2\, dx\, dt, \tag{2.7}$$

where $y_{des} \in L^2(L^2(\Omega))$ is a given desired velocity field.

THEOREM 2.3. *There exists a solution for the optimal control problem* (2.5) *for both choices of the cost functional $J = J_1$ and $J = J_2$.*

The proof of this theorem is given in section 6 (appendix).

As discussed in the previous section, the cost functionals J_1 and J_2 defined in (2.6) and (2.7) are not based on Galilean invariant or objective vortex definitions. Therefore we additionally consider the functional obtained from the Q-criterion:

$$J_3(y) = \int_0^T \int_\Omega g_3(\det \nabla y)\, dx\, dt, \tag{2.8}$$

which is Galilean invariant, and the functional based on the vortex criterion from [LKH]:

$$J_4(y, p) = \int_0^T \int_\Omega g_4(r(y, p))\, dx\, dt, \tag{2.9}$$

which is even objective. Here, $r(y,p)$ is defined as in (1.11) and the functions $g_3, g_4 \in C^2(\mathbb{R})$ are chosen as follows:

$$g_3(t) = \begin{cases} 0, & t \le 0, \\ l(t), & t > 0, \end{cases} \qquad g_4(t) = \begin{cases} l(-t-1), & t < -1, \\ 0, & -1 \le t \le 1\,, \\ l(t-1), & t > 1, \end{cases} \qquad l(t) = \frac{t^3}{t^2+1}.$$

The techniques presented in section 6 for ensuring the existence of optimal solutions for optimal control problem (2.5) with $J = J_1$ and $J = J_2$ (without the control cost term) cannot be directly applied for the cost functionals J_3 and J_4. For J_3 we obtain the following result.

THEOREM 2.4. *The optimal control problem* (2.5) *with* $J = J_3$ *and additional control constraints* $u_a \le u \le u_b$ *(*$u_a, u_b \in U$*) possesses an optimal solution.*

The proof of this theorem is given in section 6 (appendix).

Remark 2.1. The discussion of the case $J = J_4$ requires more regularity of the state variable for this cost functional to be well defined. For the required regularity, including $p \in L^2(0,T;H^2(\Omega))$, strong compatibility assumptions on the data are necessary; see, e.g., [T]. A detailed analysis for existence and optimality conditions is not within the scope of this paper.

3. Optimality system. In this section we discuss necessary optimality conditions for (2.5). The derivation is rigorous for J_1, J_2, J_3, but only formal for J_4.

In order to set up the optimality system, we introduce the adjoint equation for $z = (\lambda, \pi)$:

$$\begin{cases} -\lambda_t - \nu\Delta\lambda + (\nabla y)^t\lambda - (y\cdot\nabla)\lambda + \nabla\pi = J_y'(y,p) \text{ in } (0,T]\times\Omega, \\ -\text{div } \lambda = J_p'(y,p) \text{ in } (0,T]\times\Omega, \\ \lambda(T,\cdot) = 0 \text{ on } \Omega, \\ \lambda = 0 \text{ on } (0,T]\times\partial\Omega\,. \end{cases} \tag{3.1}$$

This equation is understood in the distributional sense, allowing for a variational formulation for the velocity component λ. The adjoint pressure π is introduced in Theorem 3.1 similarly to how the primal pressure p was introduced in Proposition 2.1.

We note that for $J = J_1, J_2, J_3$ the term J_p' vanishes and the adjoint velocity field λ is divergence-free. This is not the case for the choice $J = J_4$. For J_4, moreover, regularity beyond $x \in X$ is required to make $J_{4,y}'$ rigorous; see Remark 2.1 above. In fact, the derivatives $J_{4,y}'$ and $J_{4,p}'$ are given by

$$J_{4,y}'(x)(\delta y) = \int_0^T \int_\Omega g_4'(r(y,p))r_y'(y,p)(\delta y)\,dx\,dt,$$

$$J_{4,p}'(x)(\delta y) = \int_0^T \int_\Omega g_4'(r(y,p))r_p'(y,p)(\delta p)\,dx\,dt,$$

where $r_y'(y,p)(\delta y)$ and $r_p'(y,p)(\delta p)$ are directional derivatives of $r(y,p)$ defined in (1.11).

The following theorem ensures the existence of the solution for this adjoint equation for the choices $J = J_1, J_2, J_3$, where the velocity component λ of the adjoint state z is given in the following variational sense:

$$\lambda \in L^2(\mathcal{V}_0) \,:\, \bar{a}'(y)(\psi,\lambda) = J'(y)(\psi) \quad \text{for all } \psi \in W_0\,. \tag{3.2}$$

THEOREM 3.1. *The functionals $J = J_1, J_2, J_3$ are Gateaux differentiable on $L^2(H^1(\Omega)^2)$, and for every $x = (y, p) \in X$ there exists a unique distributional solution $z = (\lambda, \pi)$ of the adjoint equation* (3.1) *with $\lambda \in L^2(\mathcal{V}_0)$, $\lambda_t \in L^{4/3}(\mathcal{V}_0^*)$, and $\pi = \partial_t \Pi$ with $\Pi \in C(L^2(\Omega)/\mathbb{R})$. If, in addition, the assumptions of Proposition* 2.2 *are fulfilled, then $z \in \mathcal{X}_0$.*

The proof is given in section 6 (appendix). It implies that the solution of Theorem 3.1 satisfies

$$\lambda(t) - \nu \int_t^T \Delta\lambda \, ds + \int_t^T \big((\nabla y)^t \lambda - (y \cdot \nabla)\lambda\big) \, ds + \nabla\Pi(t) = \int_t^T J_y'(y) \, ds.$$

The existence of the adjoint state allows the formulation of first order optimality conditions for the problem (2.5). Due to the fact that the functionals J_i $(i = 1, 2, 3)$ do not depend on p, we can formulate the optimality system using only the velocity components y of x and λ of z, respectively:

$$y \in Bu + W_0 : \bar{a}(y)(\psi) = 0 \quad \text{for all } \psi \in L^2(\mathcal{V}_0), \tag{3.3}$$

$$\lambda \in L^2(\mathcal{V}_0) : \bar{a}'(y)(\psi, \lambda) = J'(y)(\psi) \quad \text{for all } \psi \in W_0, \tag{3.4}$$

$$u \in U_{ad} : J'(y)(B(v-u)) - \bar{a}'(y)(B(v-u), \lambda) \geq 0 \quad \text{for all } v \in U_{ad}, \tag{3.5}$$

where $U_{ad} = U$ in the case when $J = J_1$ or $J = J_2$, and $U_{ad} = \{u \in U : u_a \leq u \leq u_b\}$ in the case when $J = J_3$.

THEOREM 3.2. *Let $(u, x) \in U \times X$ be a local solution of the optimal control problem* (2.5) *for the choices $J = J_1, J_2, J_3$. Then the triple (u, x, z) fulfills the optimality system* (3.3)–(3.5)*, where $z = (\lambda, \pi)$ is the adjoint state. In the case when $U = U_{ad}$ the inequality* (3.5) *can be replaced by an equality.*

The proof is given in section 6 (appendix).

If the assumptions of Proposition 2.2 are fulfilled, then we have $x, z \in \mathcal{X}$. In this case the optimality system can be equivalently rewritten using the semilinear form $a(\cdot)(\cdot)$ involving pressure components:

$$x \in \mathcal{B}u + \mathcal{X}_0 : a(x)(\zeta) = 0 \quad \text{for all } \zeta \in \mathcal{X}_0, \tag{3.6}$$

$$z = (\lambda, \pi) \in \mathcal{X}_0 : a'(x)(\zeta, z) = J'(x)(\zeta) \quad \text{for all } \zeta \in \mathcal{X}_0, \tag{3.7}$$

$$u \in U_{ad} : J'(x)(\mathcal{B}(v-u)) - a'(x)(\mathcal{B}(v-u), z) \geq 0 \quad \text{for all } v \in U_{ad}\,. \tag{3.8}$$

Moreover, integration by parts, Green's formula, and the fact that $Bv \in W$ for all $v \in U$ imply that

$$J'(x)(\mathcal{B}(v-u)) - a'(x)(\mathcal{B}(v-u), z) = \int_0^T \int_{\partial\Omega} (\nu \nabla\lambda \cdot n) \cdot \hat{B}(v-u) \, ds \, dt\,. \tag{3.9}$$

Here, the trace $\nu\nabla\lambda \cdot n$ in (3.9) can be understood in a usual $L^2(L^2(\partial\Omega))$ sense.

Remark 3.1. On the discrete level the equality (3.9) does not hold anymore due to the lack of the appropriate formulas for integration by parts of the discretized solutions. As suggested in [V], we use the integrated residual (3.8) of the adjoint equation on the discrete level, which allows a higher order of convergence, with respect to the maximal cell-size h, than the discretization based on the boundary integral of the flux $\nu\nabla\lambda\cdot n$. A similar technique for the approximation of boundary integrals using a representation as volume integrals in the context of finite element discretization is discussed, e.g., in [GLLS].

4. Algorithmic aspects. In this section we describe a solution algorithm for optimal control problems of vortex reduction. The problem is reformulated as an unconstrained optimization problem by eliminating the state equation. Based on this formulation we describe the Newton method for solving this problem on the continuous level. Subsequently the optimization problem is discretized by space-time finite element methods. This allows a natural translation of the optimality conditions from the continuous to the discrete level due to the fact that the approaches *optimize-then-discretize* and *discretize-then-optimize* coincide for Galerkin-type discretizations. For more details of the finite element discretization of nonstationary optimal control problems we refer to [BMV].

4.1. Optimization algorithm. Before describing the discretization, we discuss the solution algorithm based on Newton's method on the continuous level. Since a finite element discretization is used, the continuous algorithm can then be simply translated into a discrete one by projection. Throughout this section, we require the assumptions of Proposition 2.2, which ensures the existence of a solution operator $S\colon U \to \mathcal{X}$ for the state equation in formulation (2.4) such that

$$S(u) \in \mathcal{B}u + \mathcal{X}_0 \,:\, a(S(u))(\zeta) = 0 \quad \text{for all } \zeta \in \mathcal{X}_0 \quad \text{for all } u \in U.$$

This gives rise to the introduction of a reduced cost functional $j\colon U \to \mathbb{R}$ by

$$j(u) = J(S(u)), \tag{4.1}$$

and allows us to reformulate the optimization problem (2.5) as an unconstrained problem

$$\text{minimize } j(u), \quad u \in U. \tag{4.2}$$

For J_3 and J_4 we should, in principle, replace U by U_{ad}. Since, for the numerical examples we consider, the inequality constraints did not become active, we do not consider U_{ad} here.

For the application of Newton's method to this optimization problem, we have to compute the derivatives of the reduced cost functional j. This is addressed in the following proposition.

PROPOSITION 4.1. *Let j be the reduced cost functional defined in* (4.1). *Its derivatives can be expressed as follows:*

(a) *For an arbitrary direction $\delta u \in U$ we have*

$$j'(u)(\delta u) = J'(x)(\mathcal{B}\delta u) - a'(x)(\mathcal{B}\delta u, z),$$

where $x = S(u)$ is the solution of the state equation (2.4) *and $z \in \mathcal{X}_0$ is the solution of the adjoint equation* (3.7).

(b) *For arbitrary directions $\delta u, \tau u \in U$ we have*

$$j''(u)(\delta u, \tau u) = J''(x)(\delta x, \mathcal{B}\tau u) - a''(x)(\delta x, \mathcal{B}\tau u, z) - a'(x)(\mathcal{B}\tau u, \delta z),$$

where $z \in X_0$ is the solution of the adjoint equation (3.7), *$\delta x \in \mathcal{X}$ is determined by the tangent equation*

$$\delta x \in \mathcal{B}\delta u + \mathcal{X}_0 \,:\, a'(x)(\delta x, \zeta) = 0 \quad \textit{for all } \zeta \in \mathcal{X}_0, \tag{4.3}$$

and $\delta z \in \mathcal{X}_0$ is the solution of the dual Hessian equation

$$\delta z \in \mathcal{X}_0 \,:\, a'(x)(\zeta, \delta z) = J''(x)(\delta x, \zeta) - a''(x)(\delta x, \zeta, z) \quad \textit{for all } \zeta \in \mathcal{X}_0. \tag{4.4}$$

The proof is similar to [HK] and [BMV].

In the following we describe the solution of the optimization problem (4.2) by Newton's method on the continuous level. Starting with an initial guess $u^0 \in U$, the next iterate u^{n+1} is computed by an update step

$$u^{n+1} = u^n + \delta u^n,$$

where δu^n solves

$$j''(u^n)(\delta u^n, v) = -j'(u^n)(v) \quad \text{for all } v \in U. \tag{4.5}$$

To solve (4.5) we use the conjugate gradient (cg) method, which requires only the evaluation of the right-hand side and of matrix-vector products. Thus we have to evaluate $j'(u^n)(v)$ and $j''(u^n)(\delta u^n, v)$ for fixed v. This can be done efficiently based on Proposition 4.1. Note that the second derivative $a''(x)$ involved in the representation of $j''(u)$ does not depend on the state x due to the quadratic structure of the Navier–Stokes equations.

Remark 4.1. For one step of the cg method, we have to solve one tangent equation (4.3) and one dual-Hessian equation (4.4). In some cases, if the dimension of U is small, it might be more efficient to build up the Hessian $\nabla^2 j(u^n)$; see [BMV] for a detailed discussion and a comparison.

4.2. Finite element discretization. In order to apply Newton's method described before, we consider a space-time finite element discretization of the optimal control problem under consideration. For the time discretization we use the dG (discontinuous Galerkin) or the cG (continuous Galerkin) method; see, e.g., [EJT].

For the time grid

$$0 = t_0 < \cdots < t_l < \cdots < t_M = T, \quad k_l = t_l - t_{l-1},$$

and a space mesh $\mathcal{T}_h$ consisting of quadrilaterals, we consider a space of spatially continuous and cellwise bilinear (biquadratic) and discontinuous in time piecewise polynomial functions of order r, X_{hk}^r. A similar space with continuous and piecewise polynomial functions in time of order s is denoted by Y_{hk}^s. The Galerkin method using X_{kh}^r as the trial and the test spaces leads to dG discretization. If the continuous in time space Y_{hk}^s is used as a trial space, this results in a cG discretization. For the detailed description of discrete equations to be solved within one step of the Newton method we refer to [BMV]. In our practical realization we use the dG(0) method, which results in a variant of the backward Euler and the cG(1) method, which is very similar to the Crank–Nicolson method. We emphasize that the space-time finite element discretization leads to the exact representation of the first and second derivatives of the discrete reduced cost functional, which is important for the convergence of the optimization algorithms. The derivation of these representations follows along the same lines as in the continuous case; cf. Proposition 4.1. The first directional derivatives of the reduced cost functional are given by

$$j'_{kh}(u)(\delta u) = J'(x_{kh})(B_h \delta u) - a'_k(x)(B_h \delta u, z_{kh}),$$

where x_{kh} and z_{kh} are the solutions of the discretized state and adjoint equations, respectively, and $a_k(\cdot,\cdot)(\cdot)$ is the discrete analogue of the semilinear form $a(\cdot,\cdot)(\cdot)$. The operator B_h is the extension of the control operator $\hat{B}$ in the discrete state space, with the property that $(B_h \delta u)(t, x_i) = 0$ for all interior nodes x_i of the mesh

$\mathcal{T}_h$. This choice leads to the fact that the integration in the above representation is done only over the cells adjacent to the boundary. We refer to [KV] for a more detailed discussion of this construction.

Remark 4.2. The use of (at least) quadratic elements for the pressure is essential for the practical realization for $J = J_4$. This is due to the fact that the second derivatives of the pressure are involved in the definition of J_4 and they must be accurately approximated by the numerical scheme in order to reliably compare the results of the four cost functionals.

Remark 4.3. The solution of the underlying state equation is required in the whole time interval for the computation of the dual, tangent, and dual-Hessian equations. If all data are stored, the storage grows linearly with respect to the number of time intervals in the time grid and also linearly with respect to the number of degrees of freedom in the space discretization. This makes the optimization procedure prohibitive for fine discretizations. This difficulty can be overcome by using storage reduction techniques known as "check-pointing" or "windowing"; see, e.g., [Gr], [BGL], and [BMV] for an application to optimization problems governed by parabolic equations.

Remark 4.4. For the examples that will be presented in the following section we use isoparametric biquadratic finite elements for the space discretization of both pressure and velocities. We add further terms to the semilinear form a in order to obtain a stable formulation with respect to both the pressure-velocity coupling and convection dominated flows. This type of stabilization technique is based on local projections of the pressure gradients (LPS method) first introduced in [BB]. In the context of optimal control problems this type of stabilization is analyzed in [RV, BV].

5. Numerical examples. In this section we discuss some numerical examples illustrating the effect of different choices of the cost functional in the context of optimal vortex reduction. For these examples we chose the dG(0) method for time and biquadratic elements for space discretization, as described in the previous section. In the context of the optimization, we use trust region techniques for globalization of the convergence; see, e.g., [NW]. The use of such techniques in the examples described below is necessary, particularly for the optimization of the cost functional J_4.

We use two different configurations, both based on the computational domain Ω; see Figure 5.1.

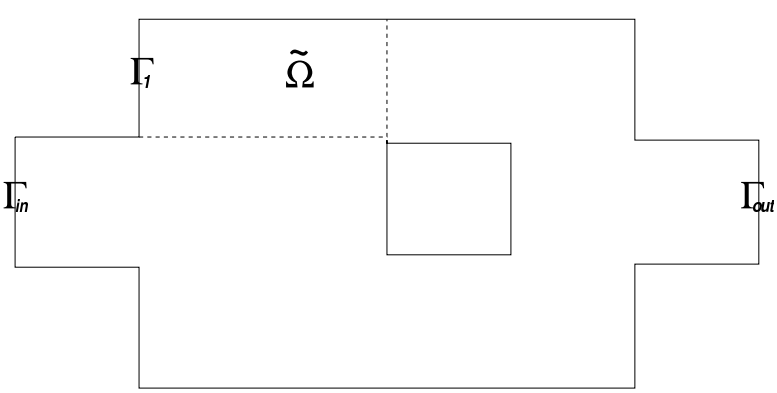

FIG. 5.1. *Computational domain.*

In both configurations we start with the following uncontrolled situation: We have constant parabolic inflow on Γ_{in}, "no-slip" boundary conditions on $\partial\Omega \setminus (\Gamma_{in} \cup \Gamma_{out})$, and "do nothing" boundary conditions on Γ_{out} (see [HRT]), i.e.,

$$\nu \nabla y \cdot n - p \cdot n = 0 \text{ on } \Gamma_{out}.$$

The flow with Reynolds number $Re \approx 10^3$ is considered on the time horizon $(0, T)$ with $T = 3$. The initial velocity field y_0 is chosen as the solution of the nonstationary Stokes equation on the same configuration after several time steps.

The solution of the uncontrolled state equation for $t = 2.4$ is shown in Figure 5.2. In this figure we observe two primary "vortex regions."

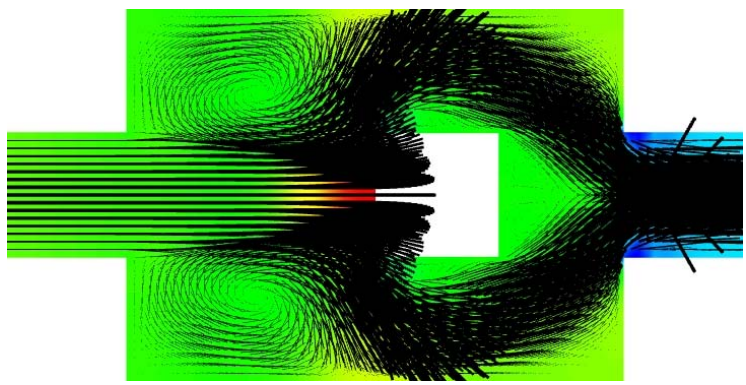

FIG. 5.2. *Uncontrolled flow, $t = 2.4$.*

In our first test we consider Dirichlet control on the part of boundary Γ_1 given as follows: $y = u\hat{y}_1$ on Γ_1, with a parabolic profile $\hat{y}_1$. The control space U is one-dimensional here, i.e., $U = \mathbb{R}$. In the following, we study the dependency of four different cost functionals J_1, J_2, J_3, and J_4 on $u \in [-8; 8]$ with observation region $\widetilde{\Omega}$ (see Figure 5.1) and the whole Ω (see Figures 5.3–5.6).

Figure 5.9 We conclude that for the present situation the vortex reduction with the help of these four cost functions leads to very different results. The reduced cost functional seems to be convex for J_1 and J_3 and to have several local extrema for the functional J_4. In our second configuration we compare the optimal solutions in more detail.

For the second configuration we set the following Dirichlet boundary conditions:

$$\begin{aligned} y &= 0 \qquad \text{on } \partial\Omega \setminus (\Gamma_{in} \cup \Gamma_{out}), \\ y &= g(u)\, \hat{y}_{in} \text{ on } \Gamma_{in}, \end{aligned}$$

where $\hat{y}_{in}$ is a fixed parabolic profile and

$$g(u)(t) = (c_0/T) + \sum_{k=1}^{n} \big(u_{2k-1} \sin(2\pi kt/T) + u_{2k} \cos(2\pi kt/T)\big).$$

The control variable u is searched for in the space $U = \mathbb{R}^{2n}$. For this setting we have for all $u \in U$

$$\int_0^T \int_{\Gamma_{in}} y \cdot n \, ds \, dt = c_0 \int_{\Gamma_{in}} \hat{y}_{in} \cdot n \, ds$$

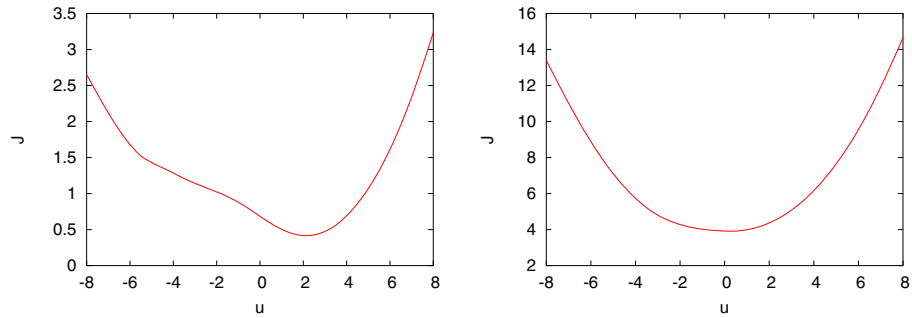

FIG. 5.3. *Cost functional* J_1 *(tracking) for* $u \in [-8, 8]$*, observation domain* $\widetilde{\Omega}$ *(left) and* Ω *(right).*

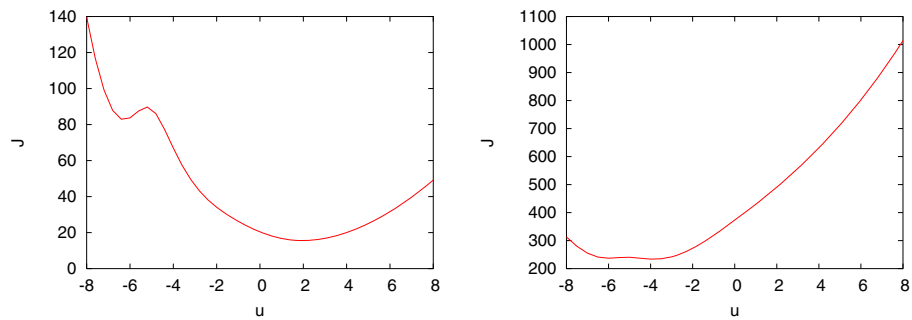

FIG. 5.4. *Cost functional* J_2 (curl) *for* $u \in [-8, 8]$*, observation domain* $\widetilde{\Omega}$ *(left) and* Ω *(right).*

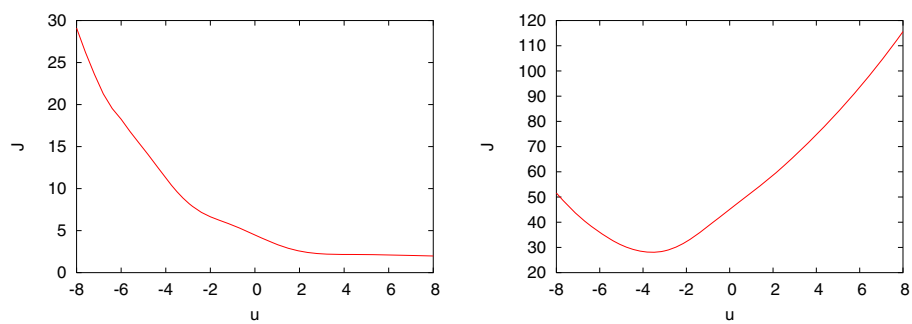

FIG. 5.5. *Cost functional* J_3 (det) *for* $u \in [-8, 8]$*, observation domain* $\widetilde{\Omega}$ *(left) and* Ω *(right).*

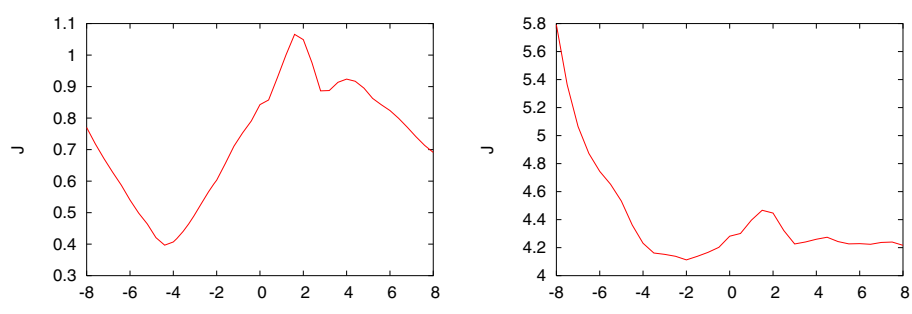

FIG. 5.6. *Cost functional* J_4 *(LKH) for* $u \in [-8, 8]$*, observation domain* $\widetilde{\Omega}$ *(left) and* Ω *(right).*

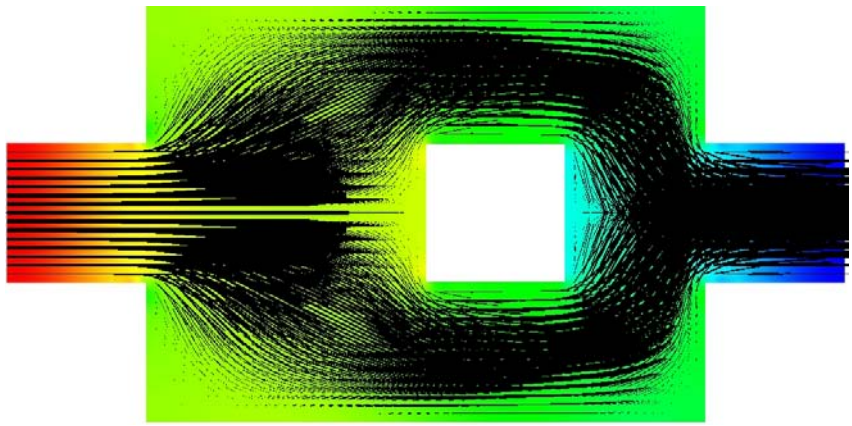

FIG. 5.7. *Stokes flow, used as the desired state for the tracking-type functional.*

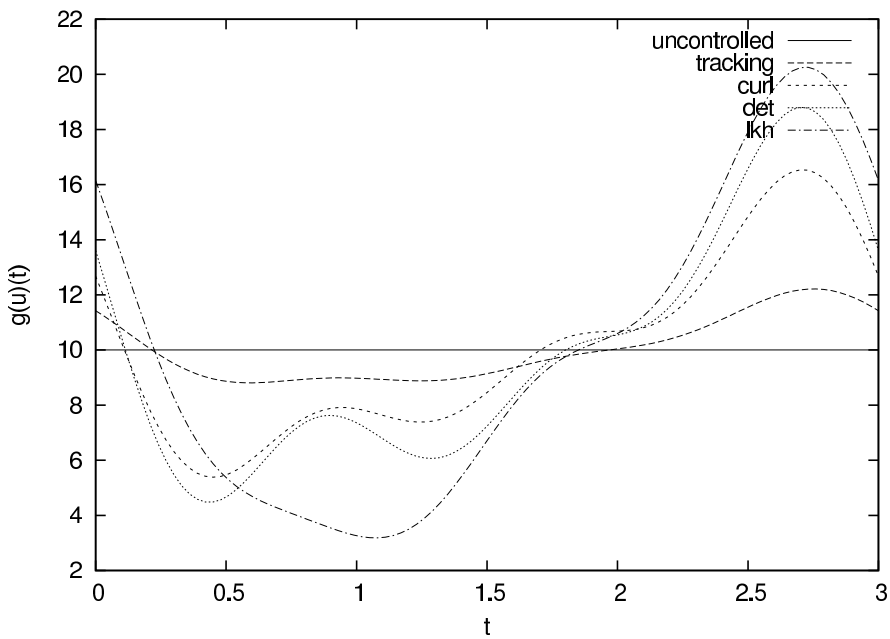

FIG. 5.8. *Optimal controls $g(u)(t)$ for four different cost functionals.*

independently of u. This condition has the following physical interpretation: The total flux through the inflow boundary in the time horizon $(0, T)$ does not depend on the control action. Thus we aim for the vortex reduction under the constraint that the total flux remains unchanged.

In Figures 5.8 and 5.9 we collect the results for the four cost functionals in the specified configuration. For the tracking-type functional we use the solution of the Stokes equation (see Figure 5.7) as the desired state y_{des}. In Figure 5.8 we show the optimal trajectories $g(u)(t)$ of the controls for the four cost functionals under consideration. In Figure 5.9 we collect the solutions of the state equation for the optimal control u with respect to the four different cost functionals J_1, J_2, J_3, J_4. It can be noted that from the point of view of graphical vortex representation there is a significant reduction of "vorticity" as we move from J_1 to J_4.

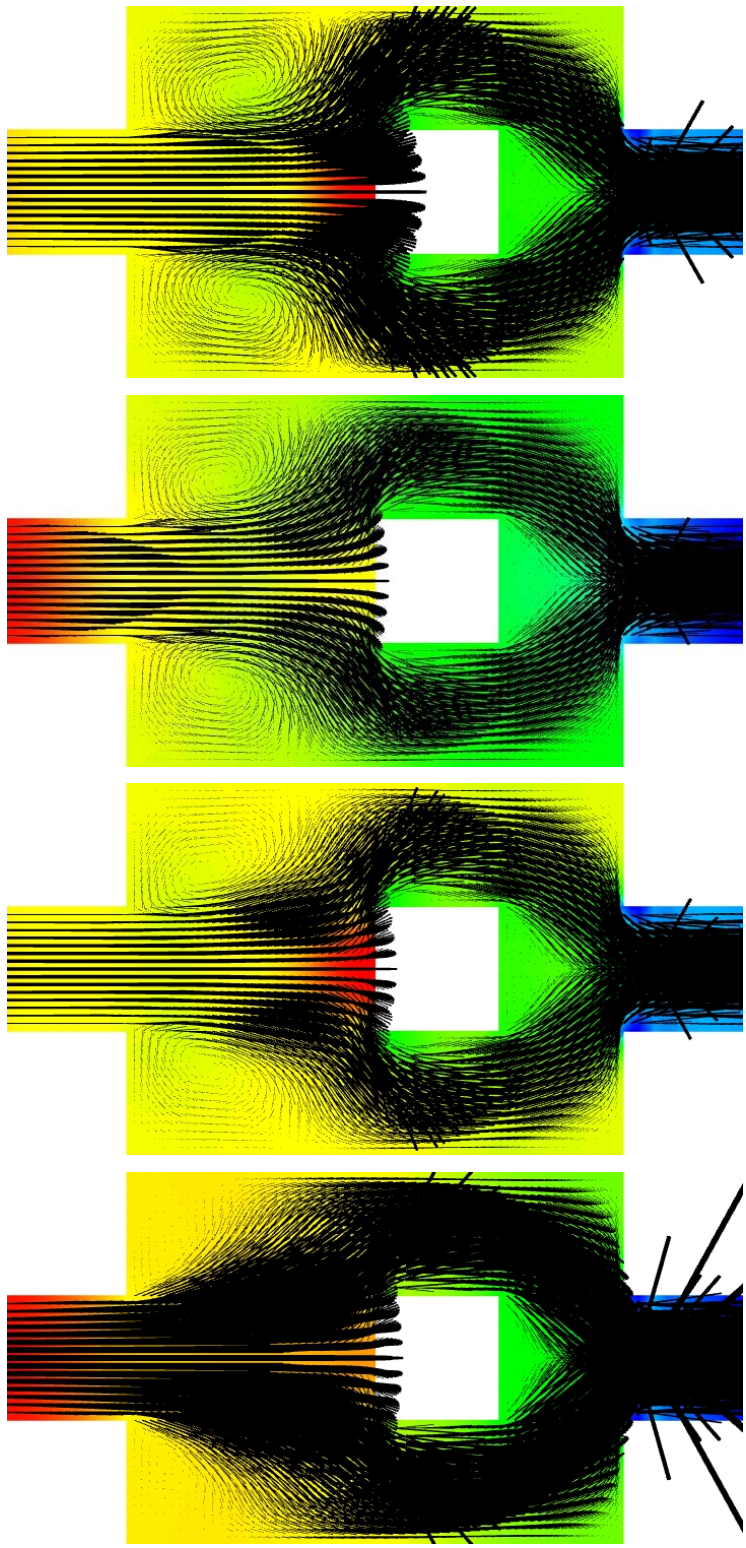

FIG. 5.9. *Optimal flow with respect to four different cost functionals (from top to bottom):* J_1 *(tracking),* J_2 (curl), J_3 (det), J_4 *(LKH).*

TABLE 5.1
Values of the four cost functionals for no control (u^0) and optimal control u^I, u^{II}, u^{III}, and u^{IV}.

	J_1	J_2	J_3	J_4
u^0	0.29608	5.60368	1.76442	0.525471
u^I	**0.14346**	3.72201	0.77298	0.350834
u^{II}	0.17125	**3.52171**	0.65593	0.390835
u^{III}	0.35245	3.79186	**0.46048**	0.422569
u^{IV}	0.18587	4.41063	0.93945	**0.181102**

In the first configuration, we have observed that the cost functionals J_2, J_3, J_4 may have local minima. Although it is impossible to check numerically, if the computed local minimum is a global one, we can provide the following results confirming our belief that we have found global minima. We denote by u^I, u^{II}, u^{III}, and u^{IV} the optimal solutions for the optimal control problems with the functionals J_1, J_2, J_3, and J_4, respectively. Moreover, we denote by $u^0 = 0$ the control which corresponds to the uncontrolled situation. In Table 5.1 we present the values of the four cost functionals J_1, J_2, J_3, and J_4 for these controls. As expected the smallest value in the first column corresponds to the optimal solution with the cost functional J_1, i.e., u^I, etc.

6. Appendix.

Proof of Proposition 2.1. We abbreviate $\|\cdot\| = \|\cdot\|_{L^2(\Omega)^2}$, $(\cdot,\cdot) = (\cdot,\cdot)_{L^2(L^2(\Omega))}$, and $\langle\cdot,\cdot\rangle = \langle\cdot,\cdot\rangle_{L^2(\mathcal{V}_0^*),L^2(\mathcal{V}_0)}$. We shall use the trilinear form

$$c(u,v,w) = \sum_{i,j=1}^{2} \int_\Omega u_j \frac{\partial u_i}{\partial x_j} w_i dx \quad \text{for } u,v,w \in H^1(\Omega)^2,$$

and the following properties of c:

(i) $c(u,v,w) = -c(u,w,v)$ for all $u \in \mathcal{V}_0$, $v,w \in H^1(\Omega)^2$;
(ii) $c(u,v,w) = -c(u,w,v)$ for all $u \in \mathcal{V}$, $v \in H^1(\Omega)^2$, $w \in H_0^1(\Omega)^2$;
(iii) $|c(u,v,w)| \le \sqrt{2}\|u\|^{1/2}\|\nabla u\|^{1/2}\,\|\nabla v\|\,\|w\|^{1/2}\,\|\nabla w\|^{1/2}$ for all $u,v,w \in H^1(\Omega)$;

see, e.g., [T].

First, we recall that $H_0^1(\Omega)^2$ can be expressed as

$$H_0^1(\Omega)^2 = \mathcal{V}_0 \oplus \mathcal{V}_0^\perp\,,$$

where

$$\mathcal{V}_0^\perp = \left\{(-\Delta_0)^{-1}\nabla q \;:\; q \in L^2(\Omega)/\mathbb{R}\right\},$$

and Δ_0 denotes the Laplacian with homogeneous Dirichlet boundary conditions; see [GR]. The forcing function $f \in L^2(H^{-1}(\Omega)^2)$ can therefore be decomposed as $f = (f_1, f_2) \in L^2(\mathcal{V}_0^*) \times L^2((\mathcal{V}_0^\perp)^*)$, and there exists $q_f \in L^2(L^2(\Omega)/\mathbb{R})$ such that

$$f_2(v) = \langle \nabla q_f, v\rangle_{L^2(H^{-1}(\Omega)^2),L^2(H_0^1(\Omega)^2)} \quad \text{for all } v \in L^2(\mathcal{V}_0^\perp)\,.$$

We abbreviate $\hat{g} = \hat{B}u$ and note that $\hat{g}(0) \in H$ since $\psi_i(0) \in H$ for $i = 1,\dots,n$. The results in [HK], specifically Theorems 1.1 and 2.1, imply the existence of a unique velocity component $y \in W$ of (2.2) in the form

$$y = y_L + y_N,$$

where

$$\text{(6.1)}\qquad \begin{cases} \langle y_{L,t}, v\rangle + \nu\,(\nabla y_L, \nabla v) = \langle f_1, v\rangle \quad \text{for all } v \in L^2(\mathcal{V}_0)\,, \\ \tau y_L = \hat{g} \text{ in } W_\Sigma\,, \\ y_L(0) = y_0 \text{ in } H, \end{cases}$$

and

$$\text{(6.2)}\qquad \begin{cases} \langle y_{N,t}, v\rangle + \nu\,(\nabla y_N, \nabla v) + \displaystyle\int_0^T c(y_N + y_L, y_N + y_L, v)dt = 0 \\ \qquad\qquad \text{for all } v \in L^2(\mathcal{V}_0), \\ \tau y_N = 0 \text{ in } W_\Sigma\,, \\ y_N(0,\cdot) = 0 \text{ in } H. \end{cases}$$

Moreover, there exists a constant K_1, and a continuous function $K_2 : \mathbb{R}^3 \to \mathbb{R}^+$, both independent of y_0, f_1, and $\hat{g}$, such that

$$\text{(6.3)}\qquad \|y_L\|_{L^2(\mathcal{V})} + \|y_{L,t}\|_{L^2(\mathcal{V}_0^*)} + \|y_L\|_{C(\mathcal{H})} \le K_1 \left(\|y_0\|_H + \|f_1\|_{L^2(\mathcal{V}_0^*)} + \|\hat{g}\|_{W_\Sigma}\right)$$

and

$$\text{(6.4)}\qquad \|y\|_{L^2(\mathcal{V})} + \|y_t\|_{L^2(\mathcal{V}_0^*)} + \|y\|_{C(\mathcal{H})} \le K_2 \left(\|y_0\|_H, \|f_1\|_{L^2(\mathcal{V}_0^*)}, \|\hat{g}\|_{W_\Sigma}\right).$$

The results in [HK] are for $f = 0$ but can easily be extended to an arbitrary $f \in L^2(H^{-1}(\Omega)^2)$.

To argue continuity of $\hat{g} \mapsto y(\hat{g})$ from W_Σ to W, let $\hat{g}_n \to \hat{g}$ in W_Σ. Then $\{\hat{g}_n\}_{n=1}^\infty$ is bounded in W_Σ, and by (6.2) there exists a constant K_3 such that

$$\text{(6.5)}\qquad \|y(\hat{g}_n)\|_W + \|y(\hat{g}_n)\|_{C(\mathcal{H})} \le K_3 \quad \text{for all } n = 1, 2, \ldots,$$

and this estimate holds for $y(\hat{g}_n)$ replaced by $y = y(\hat{g})$ as well. Let us henceforth denote $y^n = y(\hat{g}_n)$ with decomposition according to (6.1) and (6.2) as $y^n = y_L^n + y_N^n$. Further we write $y = y_L + y_N$ for $y = y(\hat{g})$. From (6.3) we have

$$\text{(6.6)}\qquad \|y_L^n - y_L\|_{L^2(\mathcal{V})} + \|y_{L,t}^n - y_{L,t}\|_{L^2(\mathcal{V}_0^*)} + \|y_L^n - y_L\|_{C(\mathcal{H})} \le K_1 \|\hat{g}^n - \hat{g}\|_{W_\Sigma}.$$

For $y_N^n - y_N$ we have the equation

$$\text{(6.7)}\qquad \begin{cases} \langle y_{N,t}^n - y_{N,t}, v\rangle + \nu\,(\nabla(y_N^n - y_N), \nabla v) \\ \quad + \displaystyle\int_0^T \left(c(y_N^n + y_L^n, y_N^n + y_L^n, v) - c(y_N + y_L, y_N + y_L, v)\right) dt = 0 \text{ for all } v \in L^2(\mathcal{V}_0)\,, \\ \tau(y_N^n - y_N) = 0\,, \\ y_N^n(0) - y_N(0) = 0. \end{cases}$$

Abbreviating $w = y_N^n - y_N \in W_0$ and setting $v = w\chi_{(0,t)}$, where $\chi_{(0,t)} : (0,T) \to \mathbb{R}$ denotes the characteristic function of $(0,t)$ for $t > 0$, using $w(0) = 0$ we find

$$\int_0^t \Big(\frac{1}{2}\frac{d}{ds}\|w(s)\|^2 + \nu\,\|\nabla w\|^2 + c(y_N^n + y_L^n, y_N^n - y_N, w) + c(y_N^n + y_L^n, y_L^n - y_L, w) \\ + c(y_N^n - y_N, y_N + y_L, w) + c(y_L^n - y_L, y_N + y_L, w) \Big)\, ds = 0\,.$$

By (ii) this implies that

$$\int_0^t \Big(\frac{1}{2}\frac{d}{ds}\|w(s)\|^2 + \nu\,\|\nabla w\|^2 + c(y^n, y_L^n - y_L, w) + c(w, y, w) + c(y_L^n - y_L, y, w) \Big)\, ds = 0,$$

and hence by (i),

$$\frac{1}{2}\|w(t)\|^2 + \nu \int_0^t \|\nabla w\|^2 \le \int_0^t \big(|c(y^n, w, y_L^n - y_L)| + |c(w, y, w)| + |c(y_L^n - y_L, w, y)| \big)\, ds.$$

By (iii), (6.5), and (6.6) there exists a constant K_4 independent of n such that

$$\begin{aligned} &\frac{1}{2}\|w(t)\|^2 + \nu \int_0^t \|\nabla w(s)\|^2\, ds \\ &\le \sqrt{2} \int_0^t \Big(\|\nabla w(s)\|\, \|\nabla(y_L^n(s) - y_L(s))\|^{\frac{1}{2}}\, \|y_L^n(s) - y_L(s)\|^{\frac{1}{2}} \big(\|y_n(s)\|^{\frac{1}{2}}\, \|\nabla y_n(s)\|^{\frac{1}{2}} \\ &\qquad + \|y(s)\|^{\frac{1}{2}}\, \|\nabla y(s)\|^{\frac{1}{2}} \big) + \|\nabla w(s)\|\, \|w(s)\|\, \|\nabla y(s)\| \Big) ds \\ &\le K_4 \int_0^t \Big(\|\nabla w(s)\|\, \|\nabla(y_L^n(s) - y_L(s))\|^{\frac{1}{2}} \big(\|\nabla y_n(s)\|^{\frac{1}{2}} + \|\nabla y(s)\|^{\frac{1}{2}} \big) \\ &\qquad + \|\nabla w(s)\|\, \|w(s)\|\, \|\nabla y(s)\| \Big)\, ds\,. \end{aligned}$$

Using Young's inequality and absorbing terms we obtain

(6.8)
$$\begin{aligned} \|w(t)\|^2 + \nu \int_0^t \|\nabla w(s)\|^2 &\le \frac{4K_4^2}{\nu} \int_0^t \|\nabla(y_L^n(s) - y_L(s))\| \big(\|\nabla y^n(s)\| + \|\nabla y(s)\| \big)\, ds \\ &\quad + \frac{2K_4^2}{\nu} \int_0^t \|w(s)\|^2\, \|\nabla y(s)\|^2 ds \le \frac{8K_4^2 K_3}{\nu}\, \|y_L^n - y_L\|_{L^2(\mathcal{V})} \\ &\quad + \frac{2K_4^2}{\nu} \int_0^t \|w(s)\|^2\, \|\nabla y(s)\|^2 ds\,. \end{aligned}$$

By Gronwall's inequality we have with $K_5 = \frac{8K_4^2 K_3}{\nu}$

$$\|w(t)\|^2 \le K_5\, \exp\left(\frac{2K_4^2}{\nu}\, \|y\|_{L^2(\mathcal{V})}^2 \right) \|y_L^n - y_L\|_{L^2(\mathcal{V})}. \tag{6.9}$$

By (6.6) the right-hand side of (6.9) converges to 0 as $n \to \infty$ and from (6.8) we deduce that $w = y_N^n - y_N \to 0$ in W_0 as $n \to \infty$. Together with (6.6) this implies that $y^n \to y$ in W which establishes the desired continuity of $g \mapsto y(g)$ from W_Σ to W. Consequently $u \to y(\hat{B}u)$ is continuous from U to W as well.

So far we worked in solenoidal spaces. To introduce the pressure component we first set

$$Y(t) = \int_0^t y(s)\,ds, \quad \hat{b}(t) = y_0 - y(t) - \int_0^t \big((y(s)\cdot\nabla)y(s) - f_1(s)\big)\,ds\,.$$

We have, using (iii), that $Y \in H^1(H^1(\Omega)^2) \hookrightarrow C(H^1(\Omega)^2)$ and $\hat{b} \in C(H^{-1}(\Omega)^2)$, and

$$\nu(\nabla Y(t), \nabla v) - \langle \hat{b}(t), v\rangle_{H^{-1}(\Omega)^2, H_0^1(\Omega)^2} = 0 \quad \text{for all } v \in \mathcal{V}_0 \text{ and each } t \in (0,T)\,.$$

Then by de Rham's theorem there exists a unique $\hat{P}(t) \in L^2(\Omega)/\mathbb{R}$ such that

$$\nu(\nabla Y(t), \nabla v) - \langle \nabla \hat{P}(t) - \hat{b}(t), v\rangle_{H^{-1}(\Omega)^2, H_0^1(\Omega)^2} = 0$$

$$\text{for all } v \in H_0^1(\Omega)^2 \text{ and each } t \in (0,T);$$

see, e.g., [DL, T]. Since the gradient operator is an isomorphism from $L^2(\Omega)/\mathbb{R}$ into $H^{-1}(\Omega)^2$ and $\hat{b}(t) + \nu\Delta Y(t) \in H^{-1}(\Omega)^2$ we conclude that $\hat{P} \in C(L^2(\Omega)/\mathbb{R})$.

Now we insert the f_2 component of f and define

$$b(t) = y_0 - y(t) - \int_0^t \big((y(s)\cdot\nabla)y(s) - f(s)\big)\,ds \quad \text{and} \quad P(t) = \hat{P}(t) + q_f(t)\,.$$

Then $P \in C(L^2(\Omega/\mathbb{R}))$ and

$$\nu(\nabla Y(t), \nabla v) - \langle \nabla P(t) - b(t), v\rangle_{H^{-1}(\Omega)^2, H_0^1(\Omega)^2} = 0$$

$$\text{for all } v \in H_0^1(\Omega)^2 \text{ and each } t \in (0,T),$$

which is equivalent to the following equality in $H^{-1}(\Omega)^2$:

$$y(t) - y(0) - \nu\int_0^t \Delta y(s)\,ds + \int_0^t (y(s)\cdot\nabla)y(s)\,ds + \nabla P(t) = \int_0^t f(s)\,ds\,. \tag{6.10}$$

This allows us to introduce pressure p as the (distributional) derivative $p = \partial_t P$.

To argue continuity of $\hat{g} \mapsto P(\hat{g})$ from W_Σ to $C(L^2(\Omega/\mathbb{R}))$, we again consider a sequence $\hat{g}^n \to \hat{g}$, $P^n = P(\hat{g}^n)$, $y^n = y(\hat{g}^n)$, and $P = P(\hat{g})$, $y = y(\hat{g})$. For a constant K_6 independent of t and n we have from (6.10)

$$\|\nabla P^n(t) - \nabla P(t)\| \le K_6\Big(\|y^n - y\|_{C(\mathcal{H})} + \|y^n - y\|_{L^2(\mathcal{V})} + \sup_{\|v\|_{L^2(H_0^1(\Omega)^2)}=1} \int_0^T |c(y^n(t), y^n(t), v(t)) - c(y(t), y(t), v(t))|\,dt\Big)\,.$$

For the last term we have, using (ii) and (iii) and the fact that the sequence $\{\|y^n\|_{L^2(\mathcal{H})}\}$ is bounded, for a constant K_7 independent of n,

$$\begin{aligned}
&\int_0^T |c(y^n(t), y^n(t), v(t)) - c(y(t), y(t), v(t))|\, dt \\
&\qquad \le \int_0^T \left(|c(y(t), v(t), y(t) - y^n(t))| + |c(y(t) - y^n(t), v, y^n(t))| \right) dt \\
&\qquad \le K_7 \int_0^T \|\nabla(y(t) - y^n(t))\|^{\frac{1}{2}} \|\nabla v(t)\| \left(\|\nabla y(t)\|^{\frac{1}{2}} + \|\nabla y^n(t)\|^{\frac{1}{2}} \right) dt \\
&\qquad \le \sqrt{2}\, K_7 \left(\int_0^T \|\nabla(y(t) - y^n(t))\| \left(\|\nabla y(t)\| + \|\nabla y^n(t)\| \right) dt \right)^{\frac{1}{2}} \\
&\qquad \le \sqrt{2}\, K_7 \|y - y^n\|^{\frac{1}{2}}_{L^2(\mathcal{V})} \left(\|y\|^{\frac{1}{2}}_{L^2(\mathcal{V})} + \|y^n\|^{\frac{1}{2}}_{L^2(\mathcal{V})} \right) \to 0 \text{ for } n \to \infty .
\end{aligned}$$

This proves that $\nabla P^n(t) \to \nabla P(t)$ in $H^{-1}(\Omega)^2$ uniformly in $t \in [0, T]$, and therefore $P^n \to P$ in $C(L^2(\Omega)/\mathbb{R})$. □

Proof of Proposition 2.2. We recall the following two additional properties of $c(\cdot, \cdot, \cdot)$.

(iv) For all $u \in H^1(\Omega)^2, v \in H^2(\Omega)^2, w \in L^2(\Omega)^2$ there holds

$$|c(u, v, w)| \le c_4 \|u\|^{\frac{1}{2}} \|u\|^{\frac{1}{2}}_{H^1(\Omega)^2} \|v\|^{\frac{1}{2}}_{H^1(\Omega)^2} \|v\|^{\frac{1}{2}}_{H^2(\Omega)^2} \|w\|.$$

(v) For all $u \in H^2(\Omega)^2, v \in H^1(\Omega)^2, w \in L^2(\Omega)^2$,

$$|c(u, v, w)| \le c_5 \|u\|^{\frac{1}{2}} \|u\|^{\frac{1}{2}}_{H^2(\Omega)^2} \|v\|_{H^1(\Omega)^2} \|w\|;$$

see, e.g., [T].

We recall the decomposition

$$L^2(\Omega)^2 = H \oplus H^\perp, \quad H^\perp = \{\nabla q \ : \ q \in H^1(\Omega)\};$$

see, e.g., [GR]. The forcing function $f \in L^2(L^2(\Omega)^2)$ can therefore be decomposed as $f = (f_1, f_2) \in L^2(H) \times L^2(H^\perp)$.

We consider the decomposition $y = y_L + y_N$, where y_L fulfills (6.1) and y_N fulfills (6.2), respectively. Due to the fact that $\psi_i(0) \in V_0$ and $\psi_i \in W \cap L^2(H^2(\Omega)^2) \cap H^1(L^2(\Omega)^2)$ for all i, we have

$$\hat{g} = \tau g, \quad \text{with } g \in W \cap L^2(H^2(\Omega)^2) \cap H^1(L^2(\Omega)^2), \quad g(0) \in \mathcal{V} .$$

We consider $w = y_L - g$ fulfilling

$$\begin{cases}
\langle w_t, v \rangle + \nu\, (\nabla w, \nabla v) = \langle f_1, v \rangle + \langle g_t, v \rangle + \nu\, (\nabla g, \nabla v) \quad \text{for all } v \in L^2(\mathcal{V}_0)\,, \\
\tau w = 0 \text{ in } W_\Sigma\,, \\
w(0) = y_0 - g(0) \text{ in } H\,.
\end{cases}$$

Using the regularity of g we obtain that

$$\langle f_1, v \rangle + \langle g_t, v \rangle + \nu\, (\nabla g, \nabla v)$$

is a linear continuous functional on $L^2(L^2(\Omega)^2)$ and $w(0) \in \mathcal{V}_0$. Therefore using a regularity result for Stokes equations with homogeneous Dirichlet boundary conditions (see, e.g., [DL]), we conclude $w \in L^2(H^2(\Omega)^2) \cap H^1(L^2(\Omega)^2) \cap C(H^1(\Omega)^2)$, $y_L \in L^2(H^2(\Omega)^2) \cap H^1(L^2(\Omega)^2) \cap C(H^1(\Omega)^2)$, and

$$\|y_L\|_{L^2(H^2(\Omega)^2)} + \|y_L\|_{H^1(L^2(\Omega)^2)} + \|y_L\|_{C(H^1(\Omega)^2)} \le C_1\big(\|f_1\|_{L^2(L^2(\Omega)^2)} + \|g\|_{H^1(L^2(\Omega)^2)} + \|g\|_{L^2(H^2(\Omega)^2)}\big), \tag{6.11}$$

with a constant C_1 dependent on f and g. To argue the corresponding result for y_N, we derive an a priori estimate for y_N in $L^2(H^2(\Omega)^2) \cap H^1(L^2(\Omega)^2) \cap C(H^1(\Omega)^2)$ using the fact that y_L satisfies (6.11). Then, the existence of a solution with asserted regularity can be obtained using a standard Galerkin procedure; see, e.g., [T].

We use $v = \chi_{(0,t)}\,\Delta y_N$ as a test function in (6.2), where $\chi_{(0,t)}$ is the characteristic function of $(0,t)$, for $t > 0$, and obtain

$$\begin{aligned}\frac{1}{2}\|\nabla y_N(t)\|^2 + \nu \int_0^t \|\Delta y_N(s)\|^2\,ds \\ \le \int_0^t \big(\,|c(y_N(s), y_N(s), \Delta y_N(s))| + |c(y(s), y_L(s), \Delta y_N(s))| \\ + |c(y_L(s), y_N(s), \Delta y_N(s))|\,\big)\,ds.\end{aligned}$$

For the first term we obtain, using (ii) and (iv),

$$\begin{aligned}\int_0^t |c(y_N(s), y_N(s), \Delta y_N(s))|\,ds &\le c_4 \int_0^t \|y_N(s)\|^{\frac{1}{2}}\,\|\nabla y_N(s)\|\,\|\Delta y_N(s)\|^{\frac{3}{2}}\,ds \\ &\le \frac{27c_4^4}{4\nu^3}\int_0^t \|y_N(s)\|^2\,\|\nabla y_N(s)\|^4\,ds + \frac{\nu}{4}\int_0^t \|\Delta y_N(s)\|^2\,ds \\ &\le C_2 \int_0^t \|\nabla y_N(s)\|^2\,\|\nabla y_N(s)\|^2\,ds + \frac{\nu}{4}\int_0^t \|\Delta y_N(s)\|^2\,ds\end{aligned}$$

for a constant C_2, where we used the fact that $\|y_N\|_{C(H)}$ is bounded according to (6.4). For the second and third terms we have, using (iv), (v), and (6.11),

$$\begin{aligned}\int_0^t \big(|c(y(s), y_L(s), \Delta y_N(s))| + |c(y_L(s), y_N(s), \Delta y_N(s))|\big)\,ds \\ \le C_3 \int_0^t \Big(\|y(s)\|^{\frac{1}{2}}\,\|y(s)\|_{\mathcal{V}}^{\frac{1}{2}}\,\|y_L(s)\|_{\mathcal{V}}^{\frac{1}{2}} + \|y_L(s)\|^{\frac{1}{2}}\|\nabla y_N(s)\|\Big) \\ \times \|y_L(s)\|_{H^2(\Omega)^2}^{\frac{1}{2}}\|\Delta y_N(s)\|\,ds \le C_4 \int_0^t \|y(s)\|_{\mathcal{V}}\|y_L(s)\|_{H^2(\Omega)^2}ds \\ + C_4 \int_0^t \|y_L(s)\|_{H^2(\Omega)^2}\|\nabla y_N(s)\|^2 ds + \frac{\nu}{4}\int_0^t \|\Delta y_N(s)\|^2 ds,\end{aligned}$$

with some constants C_3, C_4. Absorbing terms we obtain

$$\|\nabla y_N(t)\|^2 + \nu \int_0^t \|\Delta y_N(s)\|^2 \, ds \le 2C_4 \|y\|_{L^2(V)} \, \|y_L\|_{L^2(H^2(\Omega)^2)} + \int_0^t \big(2C_2 \|\nabla y_N(s)\|^2 + 2C_4 \|y_L\|_{L^2(H^2(\Omega)^2)}\big) \|\nabla y_N(s)\|^2 \, ds \,.$$

Using Gronwall's inequality we first infer that y_N is bounded in $C(H^1(\Omega)^2) \cap L^2(H^2(\Omega)^2)$. The boundedness of $y_{N,t}$ in $L^2(L^2(\Omega)^2)$ is then obtained using (6.2). Using arguments similar to those for the introduction of the pressure in the proof of Proposition 2.1, we obtain $p \in L^2(H^1(\Omega))$. In fact $\nabla \colon H^1(\Omega)/\mathbb{R} \to H^\perp$ is a homeomorphism,

$$t \mapsto y_t - \nu \Delta y + (y \cdot \nabla) y - f_1 \in L^2(L^2(\Omega)),$$

and

$$\big(y_t(t) - \nu \Delta y(t) + (y\cdot) y(t) - f_1(t), v\big) = 0 \quad \text{for all } v \in H \text{ and a.e. } t \in (0,T).$$

Hence, there is $p_1 \in L^2(H^1(\Omega)/\mathbb{R})$ fulfilling the following equality in $L^2(\Omega)^2$:

$$y_t(t) - \nu \Delta y(t) + (y\cdot) y(t) + \nabla p_1 = f_1 \,.$$

The second component of the pressure is given through the definition of $H^\perp$, i.e., $p = p_1 + p_2$, $\nabla p_2 = f_2$. This completes the proof. ∎

In order to prove Theorem 2.3, we start with a regularity result for the Stokes equation that we need in what follows.

LEMMA 6.1. *Let $(v, s) \in X$ be the solution of the Stokes equation:*

$$\begin{cases} v_t - \nu \Delta v + \nabla s = f \ \textit{in}\ (0,T] \times \Omega, \\ -\operatorname{div} v = 0 \ \textit{in}\ (0,T] \times \Omega, \\ v(0,\cdot) = 0 \ \textit{on}\ \Omega, \\ v = 0 \ \textit{on}\ (0,T] \times \partial\Omega, \end{cases} \tag{6.12}$$

with $f \in L^q(Q)$, $q > d+2$. Then the following estimate holds:

$$\|\nabla v\|_{L^\infty(Q)} + \|v(T)\|_{L^2(\Omega)} \le c \, \|f\|_{L^q(Q)}$$

with a constant c independent of $f \in L^q(Q)$.

Proof. For the proof we introduce the Sobolev space $W_q^{k,l}(Q)$ consisting of functions whose derivatives of order $\le k$ with respect to x and of order $\le l$ with respect to t are in $L^q(Q)$. From [S2] we have the following result:

$$\|v\|_{W_q^{2,1}(Q)} \le c \, \|f\|_{L^q(Q)};$$

see also [DL]. Using an embedding theorem from [S1] we obtain for $q > d+2$,

$$\|\nabla v\|_{L^\infty(Q)} \le c \, \|v\|_{W_q^{2,1}(Q)}.$$

Moreover, the following estimate is well known (see, e.g., [DL]):

$$\|v(T)\|_{L^2(\Omega)} \le c \, \|v\|_W \le c \, \|v\|_{W_2^{2,1}(Q)}.$$

This completes the proof. ∎

In the following, we formulate two core lemmas for functionals J_1 and J_2 that will be used for proving the existence of solutions to (2.5).

LEMMA 6.2. *For a sequence $\{u_k\} \subset U$, let $(y_k, p_k) \in X$ denote the solutions of the state equation (2.2), and assume that $J_1(y_k) \leq C$ for a constant $C > 0$. Then the sequence $\{u_k\}$ is bounded in U.*

Proof. We introduce prolongation $\psi_i \in W$ of the functions $\hat{\psi}_i \in W_\Sigma$, which define $\hat{B}$, by means of the Stokes equations:

$$\begin{cases} (\psi_i)_t - \nu\Delta\psi_i + \nabla\zeta_i = 0 \text{ in } (0,T] \times \Omega, \\ -\text{div } \psi_i = 0 \text{ in } (0,T] \times \Omega, \\ \psi_i(0,\cdot) = 0 \text{ on } \Omega, \\ \psi_i = \hat{\psi}_i \text{ on } (0,T] \times \partial\Omega. \end{cases} \tag{6.13}$$

This allows us to define a prolongation $B\colon U \to W$ of the control operator $\hat{B}$ by means of

$$Bu = \sum_{i=1}^{n} u_i \psi_i$$

and the corresponding operator for the pressure $R\colon U \to L^2(L^2(\Omega)/\mathbb{R})$ by

$$Ru = \sum_{i=1}^{n} u_i \zeta_i.$$

Note that the family $\{\psi_i\}$ is linearly independent in W. Next, we set

$$z_k = y_k - Bu_k, \quad r_k = p_k - Ru_k.$$

These variables satisfy the following equations:

$$\begin{cases} (z_k)_t - \nu\Delta z_k + \nabla r_k = f - y_k \cdot \nabla y_k \text{ in } (0,T] \times \Omega, \\ -\text{div } z_k = 0 \text{ in } (0,T] \times \Omega, \\ z_k(0,\cdot) = y_0 \text{ on } \Omega, \\ z_k = 0 \text{ on } (0,T] \times \partial\Omega. \end{cases} \tag{6.14}$$

We proceed by showing that $\{z_k\}$ is bounded in $L^{q'}(Q)$, where

$$\frac{1}{q'} + \frac{1}{q} = 1, \quad q > d + 2.$$

For this purpose we consider the following "dual" equation for an arbitrary function $\xi \in L^q(Q)$: Find $(v, s) \in X$ such that

$$\begin{cases} -v_t - \nu\Delta v - \nabla s = \xi \text{ in } (0,T] \times \Omega, \\ -\text{div } v = 0 \text{ in } [0,T) \times \Omega, \\ v(T,\cdot) = 0 \text{ on } \Omega, \\ v = 0 \text{ on } [0,T) \times \partial\Omega. \end{cases} \tag{6.15}$$

From Lemma 6.1 we obtain

$$\|\nabla v\|_{L^\infty(Q)} + \|v(0)\|_{L^2(\Omega)} \le c\,\|\xi\|_{L^q(Q)}\,. \tag{6.16}$$

Using (6.14) for z_k and (6.15) for v we obtain

$$\begin{aligned}\int_0^T (z_k,\xi)\,dt &= \int_0^T \{(-v_t,z_k) + \nu(\nabla v,\nabla z_k)\}\,dt \\ &= \int_0^T \{(v,(z_k)_t) + \nu(\nabla v,\nabla z_k)\}\,dt + (v(0),z_k(0)) - (v(T),z_k(T)) \\ &= \int_0^T (f,v)\,dt - \int_0^T (y_k\cdot\nabla y_k,v)\,dt + (v(0),y_0).\end{aligned}$$

For the second term in the last expression we have

$$\Big|-\int_0^T (y_k\cdot\nabla y_k,v)\,dt\Big| = \Big|\int_0^T (y_k\cdot\nabla v,y_k)\Big| \le \|\nabla v\|_{L^\infty(Q)}\,\|y_k\|^2_{L^2(Q)}.$$

Using (6.16) we obtain

$$\Big|\int_0^T (z_k,\xi)\,dt\Big| \le c\left(\|f\|_{L^2(V^*)} + \|y_k\|^2_{L^2(Q)} + \|y_0\|_{L^2(\Omega)}\right)\|\xi\|_{L^q(Q)}\,.$$

Due to the fact that $J_1(y_k)$ is bounded, we have

$$\|z_k\|_{L^{q'}(Q)} = \sup_{\xi\in L^q(Q)} \frac{\int_0^T (z_k,\xi)\,dt}{\|\xi\|_{L^q(Q)}} \le C,$$

with a generic positive constant C. Due to $1 < q' < 2$, this implies that

$$\|Bu_k\|_{L^{q'}(Q)} \le \|z_k\|_{L^{q'}(Q)} + \|y_k\|_{L^{q'}(Q)} \le C + \|y_k\|_{L^2(Q)} \le C.$$

Since B is an injective mapping to $L^{q'}(Q)$, it follows that $\{u_k\}$ is bounded in U. This completes the proof. ∎

LEMMA 6.3. *For a sequence $\{u_k\}\subset U$, let $(y_k,p_k)\in X$ denote the solutions of the state equation* (2.2)*, and assume that $J_2(y_k)\le C$, with a constant $C\in\mathbb{R}_+$. Then the sequence $\{u_k\}$ is bounded in U.*

The proof uses the same techniques as those for Lemma 6.2.

Using Proposition 2.1, Lemma 6.2, and Lemma 6.3 we are now able to prove Theorem 2.3.

Proof of Theorem 2.3. Let $\mathcal{A}\subset X\times U$ be a set of admissible pairs:

$$\mathcal{A} = \{((y,p),u)\in X\times U\,:\,(y,p)\in X \text{ fulfills the state equation (2.2)}\}\,.$$

From Proposition 2.1 we have that $\mathcal{A}$ is not empty, and due to boundedness from below the functionals J_1 and J_2, we obtain in both cases the existence of a nonnegative real number J^* with

$$J^* = \inf_{((y,p),u)\in\mathcal{A}} J(y)$$

and a sequence $\{((y_k, p_k), u_k)\} \subset \mathcal{A}$ with

$$\lim_{k\to\infty} J(y_k) = J^*.$$

Therefore $J(y_k)$ is bounded, and using Lemma 6.2 (respectively, Lemma 6.3) we obtain that $\{u_k\}$ is bounded as well. Choosing a subsequence u_{k_l} we have

$$u_{k_l} \to u^* \in U.$$

We set $(y^*, p^*) = S(u^*)$, and due to Proposition 2.1 we obtain

$$J^* = \lim_{l\to\infty} J(y_{k_l}) = J(y^*).$$

This completes the proof. □

Proof of Theorem 2.4. The functional J_3 is well defined and continuous on $L^2(\mathcal{V})$. The reduced cost functional $j_3 \colon U \to \mathbb{R}$ is defined as $j_3(u) = J_3(S(u))$, where S is the (continuous) solution operator of the state equation (2.2); see Proposition 2.1. Thus, j_3 is continuous as well.

Let $\{u_n\} \subset U$ be a minimizing sequence, i.e.,

$$J^* = \inf_{u\in U,\ u_a\le u\le u_b} j_3(u), \quad j_3(u_n) \to J^*.$$

Due to the facts that $\{u_n\}$ is bounded and U is finite dimensional, there exists a subsequence converging to $u^* \in U$. Continuity of j_3 completes the proof. □

Proof of Theorem 3.1. The functionals $J_i \colon L^2(H^1(\Omega)^2) \to \mathbb{R}$ $(i = 1, 2, 3)$ are continuous. Moreover, for any $y \in L^2(H^1(\Omega)^2)$ and $\psi \in L^2(H^1(\Omega)^2)$, there exist the directional derivatives $J_i'(y)(\psi)$ given by

$$J_1'(y)(\psi) = 2\int_0^T \int_\Omega (y - y_{des})\psi \, dx \, dt,$$

$$J_2'(y)(\psi) = 2\int_0^T \int_\Omega \operatorname{curl} y \cdot \operatorname{curl} \psi \, dx \, dt,$$

$$J_3'(y)(\psi) = \int_0^T \int_\Omega g_3'(\det(\nabla y)) \cdot \left(y^1_{x_1}\psi^2_{x_2} + \psi^1_{x_1}y^2_{x_2} - y^2_{x_1}\psi^1_{x_2} - \psi^2_{x_1}y^1_{x_2}\right) dx \, dt.$$

Due to the fact that $g_3'(t) \in [0, 3]$ for all $t \in \mathbb{R}$, we obtain that $g_3'(\det(\nabla y)) \in L^\infty(Q)$ and that

$$J_i'(y) \in L^2(H^{-1}(\Omega)^2), \qquad i = 1, 2, 3.$$

The existence of the adjoint velocity $\lambda \in L^2(\mathcal{V}_0)$ with $\lambda_t \in L^{4/3}(\mathcal{V}_0^*)$ follows, e.g., from [HK]. The introduction of dual pressure π can be done as in the proof of Proposition 2.1. Under the assumptions from Proposition 2.2 additional regularity $z \in \mathcal{X}_0$ can be argued as in [HK]. □

Proof of Theorem 3.2. The reduced cost functional $j \colon U \to \mathbb{R}$ is defined as $j(u) = J(S(u))$, where $S : U \to W$ is the (continuous) solution operator for the velocity component of the state equation (2.2); see Proposition 2.1. The solution operator S is directionally differentiable, and the directional derivative $\delta y = S'(u)(\delta u)$ fulfills the following linearized equation (see, e.g., [HK]):

$$\delta y \in B\delta u + W_0 \ : \ \bar{a}'(y)(\delta y, \psi) = 0 \quad \text{for all } \psi \in L^2(\mathcal{V}_0).$$

In the proof of Theorem 3.1 it is shown that the functionals $J = J_1, J_2$, and J_3 are directionally differentiable. Therefore, the reduced cost functional j is directionally differentiable too. A necessary optimality condition for the reduced cost functional is given by

$$j'(u)(\delta u - u) \geq 0 \quad \text{for all } \delta u \in U_{ad}.$$

To complete the proof it remains to show the representation of the directional derivative of j. For this purpose we recall the definition of the adjoint equation, and using the fact that $\delta y - B\delta u \in W_0$ we find

$$\begin{aligned} j'(u)(\delta u) &= J'(y)(\delta y) = J'(y)(\delta y - B\delta u) + J'(y)(B\delta u) \\ &= \bar{a}'(y)(\delta y - B\delta u, \lambda) + J'(y)(B\delta u) \\ &= -\bar{a}'(y)(B\delta u, \lambda) + J'(y)(B\delta u). \qquad \square \end{aligned}$$

WELL-POSEDNESS OF THE SHOOTING ALGORITHM FOR STATE CONSTRAINED OPTIMAL CONTROL PROBLEMS WITH A SINGLE CONSTRAINT AND CONTROL*

J. FRÉDÉRIC BONNANS† AND AUDREY HERMANT†

Abstract. This paper deals with the shooting algorithm for optimal control problems with a scalar control and a regular scalar state constraint. Additional conditions are displayed, under which the so-called alternative formulation is equivalent to Pontryagin's minimum principle. The shooting algorithm appears to be well-posed (invertible Jacobian) iff (i) the no-gap second-order sufficient optimality condition holds, and (ii) when the constraint is of order $q \geq 3$, there is no boundary arc. Stability and sensitivity results without strict complementarity at touch points are derived using Robinson's strong regularity theory, under a minimal second-order sufficient condition. The directional derivatives of the control and state are obtained as solutions of a linear quadratic problem.

Key words. optimal control, Pontryagin's principle, state constraints, junction conditions, shooting algorithm, no-gap second-order optimality conditions, strong regularity, sensitivity analysis, directional derivatives

1. Introduction.

For optimal control problems satisfying the strengthened Legendre–Clebsch condition, Pontryagin's principle allows us to express the control as a function of the state and the costate. For unconstrained problems, the resulting two-point boundary value problem reduces to a finite-dimensional "shooting" equation whose unknown is the initial costate (see, e.g., [29]). The extension to control constrained problems is relatively easy, assuming nontangentiality conditions when a constraint becomes active or inactive. This approach allows us to compute accurate solutions at low cost, once the *structure* of active constraints is known, and reasonable initial values of unknowns can be guessed. For state constrained optimal control problems, a reformulation of the optimality conditions is needed, and the shooting equations take into account only some of the optimality conditions. Therefore, checking that the shooting equations are well-posed under minimal hypotheses becomes challenging.

An alternative formulation, suitable for the shooting algorithm in the presence of state constraints, was first introduced by Bryson, Denham, and Dreyfus [8] (see also [9]) in a heuristic manner. Some additional conditions (necessary for optimality) were missing, as shown in Jacobson, Lele, and Speyer [18], where the first results on the regularity of the multiplier and on junction conditions are stated. A significant clarification of their work can be found in the unpublished paper by Maurer [25], where the link between the results of [18] and the alternative formulation of [8, 9] is established. Numerous different versions of Pontryagin's principle with state constraints were given in the literature; see the survey by Hartl, Sethi, and Vickson [16].

Stability results for *first*-order state constraints and directional differentiability of

solutions in L^2 were first obtained by Malanowski [21] using an infinite-dimensional implicit function theorem and differentiation of the projection on a convex set [15]. The (strong) second-order sufficient condition used in the analysis was later weakened by Malanowski [22], taking into account the strictly active constraints. These results require *no assumptions on the structure* of the trajectory. However, no extensions of this method for higher-order state constraints are known. Dontchev and Hager [12] derived, still for first-order constraints, L^∞ stability results under an additional assumption on the structure of the contact set. Malanowski and Maurer obtain sensitivity results in [23] (first order) and [24] (higher order), when there are finitely many nontangential junction points and strict complementarity holds, by application of the implicit function theorem to the shooting mapping. They obtain derivatives as the solution of an equality constrained linear quadratic problem, but when the order of the constraint is $q \geq 2$, the data of the latter depend on the (precomputed) variation of entry times. Numerical applications of the shooting algorithm to state constrained problems in the aerospace field are presented, e.g., in [10, 3] and in [26], where the role of additional conditions appears crucial to eliminate nonoptimal solutions; numerical examples of sensitivity analysis are given in [2]. Discretization errors are studied in, e.g., [13].

This paper handles the case of a scalar control and a regular scalar state constraint, for which regularity and junction conditions results are known. We assume that the Hamiltonian is uniformly strongly convex w.r.t. the control variable, that there are finitely many nontangential junction times, and that strict complementarity on boundary arcs holds.

We express the additional conditions under which the alternative formulation is equivalent to Pontryagin's principle. When strict complementarity holds at touch points as well, we prove that the shooting algorithm is well-posed (invertible Jacobian) iff (i) the no-gap second-order sufficient condition in [5] holds, and (ii) when the constraint is of order $q \geq 3$, there is no boundary arc. Then stability and sensitivity results, removing the strict complementarity hypothesis at touch points, are derived, applying Robinson's strong regularity theory [28] to the shooting mapping. We give a necessary and sufficient second-order condition characterizing the strong regularity property. The directional derivatives of the control and state are obtained as solutions of an inequality constrained linear quadratic problem, independent of the variations of junction times.

The paper is organized as follow. In section 2, we give the characterization of Pontryagin extremals as solutions of the shooting equations under some minimal additional conditions. Then, in section 3, we give the characterization of the well-posedness of the shooting algorithm and its relation to the no-gap second-order optimality conditions obtained in [5, 6]. Finally, in section 4, we give stability and sensitivity analysis results.

The results of sections 2 and 3 of this paper are extended to the case of vector-valued state constraints and control in the report [4]. The main difficulty is the extension of the junction conditions result of Jacobson, Lele, and Speyer [18] (Proposition 2.5 below). The latter plays a crucial role in the proof of the *necessity* of the condition claimed in this paper as necessary and sufficient for the well-posedness of the shooting algorithm (see Theorem 3.3).

2. Junction conditions. The section is organized as follows. After introducing notation, definitions, assumptions, and basic results needed in the paper, we recall in subsection 2.1 an alternative formulation for optimality conditions (Definition 2.7),

which is useful for the shooting algorithm. This is one of the various formulations existing in the literature (see, e.g., the survey [16]). Therefore, one of the main concerns of this paper is to investigate, in subsection 2.2, the equivalence with Pontryagin's minimum principle (Proposition 2.10). Finally, in subsection 2.3, we formulate the shooting algorithm and show that some of the additional conditions are automatically satisfied by a solution of the shooting equations (Proposition 2.15).

Denote by $L^\infty(0,T)$ the Banach space of measurable and essentially bounded functions and by $W^{1,\infty}(0,T)$ the Sobolev space of functions having a weak derivative in $L^\infty(0,T)$. Let the control and state spaces be, respectively, $\mathcal{U} := L^\infty(0,T)$ and $\mathcal{Y} := W^{1,\infty}(0,T;\mathbb{R}^n)$. We consider the following optimal control problem with a scalar state constraint and a scalar control:

$$(\mathcal{P}) \qquad \min_{(u,y)\in\mathcal{U}\times\mathcal{Y}} \int_0^T \ell(u(t),y(t))\mathrm{d}t + \phi(y(T)) \tag{2.1}$$

$$\text{subject to} \qquad \dot{y}(t) = f(u(t),y(t)) \quad \text{a.e. } t\in[0,T]; \quad y(0)=y_0, \tag{2.2}$$

$$g(y(t)) \le 0 \qquad \text{for all } t\in[0,T]. \tag{2.3}$$

The data of the problem are the distributed cost $\ell : \mathbb{R}\times\mathbb{R}^n \to \mathbb{R}$, final cost $\phi : \mathbb{R}^n \to \mathbb{R}$, dynamics $f : \mathbb{R}\times\mathbb{R}^n \to \mathbb{R}^n$, state constraint $g : \mathbb{R}^n \to \mathbb{R}$, final time $T > 0$, and initial condition $y_0 \in \mathbb{R}^n$.

We assume throughout the paper that the following hold:

(A0) The mappings ℓ, ϕ, f, and g are k-times continuously differentiable (C^k) with $k \ge 2$ and have locally Lipschitz continuous second-order derivatives when $k = 2$. The dynamics f is Lipschitz continuous.

(A1) The initial condition satisfies $g(y_0) < 0$.

The space of row vectors is denoted by $\mathbb{R}^{n*}$. The space of continuous functions over $[0,T]$ is denoted by $C[0,T]$. The dual space of Radon measures, denoted by $\mathcal{M}[0,T]$, is identified with the space of functions of bounded variation $BV(0,T)$ vanishing at zero. The transposition operator in $\mathbb{R}^n$ is denoted by a star *. Fréchet derivatives of f, ℓ, etc., w.r.t. arguments $u\in\mathbb{R}$, $y\in\mathbb{R}^n$, are denoted by a subscript, for instance $f_u(u,y) = D_u f(u,y)$, $f_{uu}(u,y) = D^2_{uu} f(u,y)$. One exception to this rule, which should not be a source of confusion, is that we denote by y_u the (unique) solution in $\mathcal{W}$ of the state equation (2.2) associated with the control $u\in\mathcal{U}$. Total derivation w.r.t. time is denoted by a dot, i.e., $\dot{y}(t) = \frac{\mathrm{d}y(t)}{\mathrm{d}t}$.

A *trajectory* is an element (u,y) of $\mathcal{U}\times\mathcal{Y}$ satisfying the state equation (2.2). A trajectory (u,y) is said to be *feasible* if it satisfies the state constraint (2.3). Define the classical (resp., generalized) *Hamiltonian* functions of $(\mathcal{P})$, $H : \mathbb{R}\times\mathbb{R}^n\times\mathbb{R}^{n*} \to \mathbb{R}$ (resp., $\mathcal{H} : \mathbb{R}\times\mathbb{R}\times\mathbb{R}^n\times\mathbb{R}^{n*} \to \mathbb{R}$) by

$$H(u,y,p) := \ell(u,y) + pf(u,y); \quad \mathcal{H}(p_0,u,y,p) := p_0\ell(u,y) + pf(u,y). \tag{2.4}$$

First-order necessary optimality conditions for $(\mathcal{P})$ are given by *Pontryagin's minimum principle*.

Definition 2.1. *A trajectory (u,y) is a* Pontryagin extremal *if there exists $p_0\in\mathbb{R}^+$, $p\in BV([0,T];\mathbb{R}^{n*})$, and $\eta\in\mathcal{M}[0,T]$, with $(p_0,\mathrm{d}\eta)\neq 0$, such that*

$$\dot{y}(t) = \mathcal{H}_p(p_0,u(t),y(t),p(t)) \quad \text{a.e. } t\in[0,T]; \quad y(0)=y_0, \tag{2.5}$$

$$-\mathrm{d}p(t) = \mathcal{H}_y(p_0,u(t),y(t),p(t))\mathrm{d}t + g_y(y(t))\mathrm{d}\eta(t) \quad \text{in } \mathcal{M}([0,T];\mathbb{R}^{n*}), \tag{2.6}$$

$$p(T) = p_0\phi_y(y(T)), \tag{2.7}$$

$$u(t) \in \operatorname{argmin}_{w\in\mathbb{R}} \mathcal{H}(p_0,w,y(t),p(t)) \quad \text{a.e. } t\in[0,T], \tag{2.8}$$

$$g(y(t)) \le 0 \text{ for all } t \in [0,T]; \quad \mathrm{d}\eta \ge 0; \quad \int_0^T g(y(t))\mathrm{d}\eta(t) = 0. \tag{2.9}$$

By $\mathrm{d}\eta \ge 0$, we mean that $\int_0^T \varphi(t)\mathrm{d}\eta(t) \ge 0$ for all nonnegative continuous functions $\varphi \in C[0,T]$, or equivalently, that η is nondecreasing. The costate equation (2.6) with final condition (2.7) is equivalent to

$$p(t) = \int_t^T \mathcal{H}_y(p_0, u(s), y(s), p(s))\mathrm{d}s + \int_t^T g_y(y(s))\mathrm{d}\eta(s) + p_0\phi_y(y(T)).$$

The next theorem is well known (see [11, 14] for nondifferentiable versions).

THEOREM 2.2. *A trajectory (u,y) solution of $(\mathcal{P})$ is a Pontryagin extremal.*

A trajectory $(\bar u, \bar y)$ is a *local solution* of $(\mathcal{P})$ if it minimizes (2.1) subject to (2.2)–(2.3) and $\|u - \bar u\|_\infty \le \rho$ for some $\rho > 0$. We say that $(u,y) \in \mathcal{U} \times \mathcal{Y}$ is a *stationary point* of $(\mathcal{P})$ if there exists a nonzero $(p_0, p, \eta) \in \mathbb{R}^+ \times BV(0,T;\mathbb{R}^{n*}) \times \mathcal{M}(0,T)$ such that (2.5)–(2.7), (2.9) are satisfied and

$$\mathcal{H}_u(p_0, u(t), y(t), p(t)) = 0 \qquad \text{for a.a. } t \in [0,T].$$

It is well known that a local solution of $(\mathcal{P})$ is a stationary point. Obviously a Pontryagin extremal is a stationary point, but the converse is in general false. An exception is when the (generalized) Hamiltonian is convex w.r.t. the control variable along the trajectory (see also our assumption (A2) below). Whenever this holds, definitions of both Pontryagin extremals and stationary points are equivalent.

Definitions. A *boundary* (resp., *interior*) *arc* is a maximal interval of positive measure $\mathcal{I} \subset [0,T]$ such that $g(y(t)) = 0$ (resp., $g(y(t)) < 0$) for all $t \in \mathcal{I}$. If $[\tau_{en}, \tau_{ex}]$ is a boundary arc, τ_{en} and τ_{ex} are called an *entry* and an *exit* point, respectively. Entry and exit points are said to be *regular* if they are endpoints of an interior arc. A *touch* point τ in $(0,T)$ is an isolated contact point (an endpoint of two interior arcs). Entry, exit, and touch points are called *junction points* (or *times*). We say that the junctions are regular when the entry/exit points are regular.

The first-order time derivative of the state constraint along a trajectory (u,y), i.e., $g^{(1)}(u,y) = \frac{\mathrm{d}}{\mathrm{d}t} g(y(t)) = g_y(y) f(u,y)$, is denoted by $g^{(1)}(y)$ if the function $\mathbb{R}\times\mathbb{R}^n \to \mathbb{R}$, $(u,y) \mapsto g_y(y)f(u,y)$ does not depend on u (that is, the function $(u,y) \mapsto g_u^{(1)}(u,y)$ is identically zero). If f and g are C^q, we may define similarly $g^{(2)}, \dots, g^{(q)}$ if $g_u^{(j)} \equiv 0$ for all $j = 1, \dots, q-1$, and we have $g^{(j)}(u,y) = g_y^{(j-1)}(y) f(u,y)$ for $j = 1, \dots, q$.

Let $q \ge 1$ be the smallest number of time derivations of the state constraint so that a dependence w.r.t. u appears, i.e., $g_u^{(q)} \not\equiv 0$. If q is finite, we say that q is the *order* of the state constraint (see, e.g., [8]). A state constraint of order q is said to be *regular* along the trajectory (u,y) if the condition below holds:

$$\exists\, \gamma > 0, \quad |g_u^{(q)}(\hat u, y(t))| \ge \gamma \quad \text{for all } t \in [0,T] \text{ and all } \hat u \in \mathbb{R}. \tag{2.10}$$

Note that the set of generalized multipliers (p_0, p, η) is a cone. When $p_0 = 0$, we say that the multiplier is singular; otherwise it is regular. Dividing then (p,η) by p_0, we obtain the qualified version of Pontryagin's principle, substituting the generalized Hamiltonian with the classical Hamiltonian. It is easily seen that a Pontryagin extremal satisfying (2.10) (and (A1)) has no singular multiplier, and that the multiplier (p,η) in the qualified version of Pontryagin's principle ($p_0 = 1$) is unique. The same is true for a stationary solution.

Being of bounded variation, p has at most countably many discontinuity times and has everywhere on $[0,T]$ left and right limits, denoted by $p(t^\pm) = \lim_{t'\to t^\pm} p(t')$. The jump at $\tau \in (0,T)$ is denoted by $[p(\tau)] = p(\tau^+) - p(\tau^-)$. Similar observations hold for η.

Assumptions. We say that (u,y) is a *regular Pontryagin extremal* if it satisfies Definition 2.1 with $p_0 = 1$, with costate p and multiplier η, and if assumptions (A2)–(A4) below are satisfied.

(A2) The Hamiltonian is strongly convex w.r.t. the control variable, uniformly w.r.t. $t \in [0,T]$:

$$\exists\, \alpha > 0, \quad H_{uu}(\hat u, y(t), p(t^\pm)) \geq \alpha \quad \text{for all } t \in [0,T] \text{ and all } \hat u \in \mathbb{R}. \tag{2.11}$$

(A3) The data of the problem are C^{2q}, i.e., $k \geq 2q$ in (A0), and the state constraint is of order q and regular, i.e., (2.10) holds.

(A4) The trajectory (u,y) has a *finite set of junction times* that will be denoted by $\mathcal{T} =: \mathcal{T}_{en} \cup \mathcal{T}_{ex} \cup \mathcal{T}_{to}$, with $\mathcal{T}_{en}$, $\mathcal{T}_{ex}$, and $\mathcal{T}_{to}$ the *disjoint* (and possibly empty) subsets of, respectively, entry, exit, and touch points, and we assume that $g(y(T)) < 0$.

Hypothesis (A4) implies that all entry and exit points are regular. In what follows, we denote by $\mathcal{I}_b$ the union of boundary arcs, i.e., $\mathcal{I}_b := \cup_{i=1}^{N_b} [\tau_{en}^i, \tau_{ex}^i]$ for $\mathcal{T}_{en} := \{\tau_{en}^1 < \cdots < \tau_{en}^{N_b}\}$ and $\mathcal{T}_{ex} := \{\tau_{ex}^1 < \cdots < \tau_{ex}^{N_b}\}$.

Remark 2.3. Throughout the paper, (A3) can be weakened, replacing (2.10) by

$$\exists\, \gamma, \varepsilon > 0, \quad |g_u^{(q)}(\hat u, y(t))| \geq \gamma \quad \text{for all } t,\ \operatorname{dist}(t, \mathcal{I}_b \cup \mathcal{T}_{to}) < \varepsilon, \text{ and all } \hat u \in \mathbb{R}. \tag{2.12}$$

Notation. Given a finite subset $\mathcal{S}$ of $(0,T)$, we denote by $PC^k_{\mathcal{S}}[0,T]$ the set of functions over $[0,T]$ that are of class C^k outside $\mathcal{S}$ (PC stands for piecewise continuous) and have, as well as their first k derivatives, a left and right limit over $\mathcal{S}$ and a right (resp., left) limit at 0 (resp., T).

Let φ be a real-valued function over $[0,T]$. Assuming w.l.o.g. the elements of $\mathcal{S}$ in increasing order, we may define $\varphi(\mathcal{S}) := (\varphi(\tau))_{\tau\in\mathcal{S}} \in \mathbb{R}^{\operatorname{Card}\mathcal{S}}$. We adopt a similar convention for vectors, $\nu_{\mathcal{S}} := (\nu_\tau)_{\tau\in\mathcal{S}} \in \mathbb{R}^{\operatorname{Card}\mathcal{S}}$, and will also use the following notation:

$$\nu_{\mathcal{S}}^{1:q} := \begin{pmatrix} \nu_{\mathcal{S}}^1 \\ \vdots \\ \nu_{\mathcal{S}}^q \end{pmatrix} \in \mathbb{R}^{q\operatorname{Card}\mathcal{S}};\ g^{(0:q-1)}(y(\mathcal{S})) := \begin{pmatrix} g(y(\mathcal{S})) \\ \vdots \\ g^{(q-1)}(y(\mathcal{S})) \end{pmatrix} \in \mathbb{R}^{q\operatorname{Card}\mathcal{S}}.$$

2.1. Alternative formulation of optimality conditions. Under assumption (A4) we have a finite number of arcs and we can show, with regularity assumptions (A2)–(A3), that the multiplier η is differentiable on the interior of each arc [18, 25]. An analysis of the optimality system on interiors of arcs shows then that a regular Pontryagin extremal satisfies the conditions stated in Proposition 2.4 below. An analysis at junction times leads afterwards to the junction conditions given in Proposition 2.5.

Proposition 2.4. *Let (u,y) be a regular Pontryagin extremal satisfying* (A2)–(A4). *Then we have $u \in PC^q_{\mathcal{T}}[0,T]$, $y \in PC^{q+1}_{\mathcal{T}}([0,T];\mathbb{R}^n)$ and there exists $p \in PC^1_{\mathcal{T}}([0,T];\mathbb{R}^{n*})$, $\eta_0 \in PC^0_{\mathcal{T}}[0,T]$, and jump parameters $\nu_{\mathcal{T}}$, such that the following optimality system is satisfied:*

$$\dot y(t) = H_p(u(t),y(t),p(t)) = f(u(t),y(t)) \text{ on } [0,T]; \qquad y(0) = y_0, \tag{2.13}$$

$$-\dot p(t) = H_y(u(t),y(t),p(t)) + g_y(y(t))\eta_0(t) \text{ on } [0,T]\setminus\mathcal{T}, \tag{2.14}$$

$$p(T) = \phi_y(y(T)), \tag{2.15}$$

$$0 = H_u(u(t), y(t), p(t)) \quad \text{on } [0,T] \setminus \mathcal{T}, \tag{2.16}$$

$$g(y(t)) = 0 \ \text{ on } \mathcal{I}_b; \quad \eta_0(t) = 0 \ \text{ on } [0,T] \setminus \mathcal{I}_b, \tag{2.17}$$

$$g(y(t)) < 0 \ \text{ on } [0,T] \setminus (\mathcal{I}_b \cup \mathcal{T}_{to}); \quad \eta_0(t) \geq 0 \ \text{ on } \operatorname{int} \mathcal{I}_b, \tag{2.18}$$

$$g(y(\tau)) = 0 \quad \text{for all } \tau \in \mathcal{T}_{to}, \tag{2.19}$$

$$[p(\tau)] = -\nu_\tau g_y(y(\tau)); \ \nu_\tau \geq 0 \text{ for all } \tau \in \mathcal{T}. \tag{2.20}$$

We denote by $\operatorname{int} \mathcal{I}_b$ the interior of $\mathcal{I}_b$. A touch point $\tau \in \mathcal{T}_{to}$ is said to be *essential* if $\nu_\tau > 0$ in (2.20); otherwise it is nonessential. We denote by $\mathcal{T}_{to}^{ess}$ the set of essential touch points. Hypotheses (A2)–(A4) also imply the continuity of the control variable and of some of its time derivatives at junction points. The next proposition is due to Jacobson, Lele, and Speyer [18].

PROPOSITION 2.5. *Let (u,y) be a regular Pontryagin extremal satisfying* (A2)–(A4). *Then*

(i) *for all entry or exit points $\tau \in \mathcal{T}_{en} \cup \mathcal{T}_{ex}$,*

(a) *if q is* odd, *u and its $q-1$ first derivatives are continuous at τ, $\nu_\tau = 0$ and p is continuous at τ;*

(b) *if q is* even, *u and its $q-2$ first derivatives are continuous at τ.*

(ii) *for all touch points $\tau \in \mathcal{T}_{to}$,*

(a) *u and its $q-2$ first derivatives are continuous at τ;*

(b) *if τ is nonessential (i.e., $\nu_\tau = 0$), u and its q first derivatives and p are continuous at τ;*

(c) *if $q = 1$, then τ is a nonessential touch point.*

REMARK 2.6. If (u,y) satisfies (A2)–(A4) and (2.13)–(2.20), the multiplier $\eta \in \mathcal{M}[0,T]$ such that (u,y) satisfies Definition 2.1 is given by

$$\mathrm{d}\eta(t) \ = \ \sum_{\tau \in \mathcal{T}} \nu_\tau \delta_\tau + \eta_0(t)\mathrm{d}t, \tag{2.21}$$

where δ_τ denotes the Dirac measure at time τ, $\nu_\tau = [\eta(\tau)]$ is the nonnegative jump at $\tau \in \mathcal{T}$, and the density $\eta_0 \in PC^0_{\mathcal{T}}[0,T]$ equals $\frac{\mathrm{d}\eta}{\mathrm{d}t}$ on $[0,T] \setminus \mathcal{T}$.

We now present the alternative formulation that will be used in the shooting algorithm. First introduced heuristically in [8], it is based on the use of the mixed explicit constraint $g^{(q)}(u(t), y(t)) = 0$ on boundary arcs. Let the *augmented Hamiltonian* $\tilde{H} : \mathbb{R} \times \mathbb{R}^n \times \mathbb{R}^{n*} \times \mathbb{R} \to \mathbb{R}$ be defined by

$$\tilde{H}(u, y, p_q, \eta_q) = H(u, y, p_q) + \eta_q g^{(q)}(u, y), \tag{2.22}$$

where q denotes the order of the state constraint and H is the classical Hamiltonian (2.4).

DEFINITION 2.7. *We say that a trajectory (u,y) in $PC^q_{\mathcal{T}}[0,T] \times PC^{q+1}_{\mathcal{T}}([0,T];\mathbb{R}^n)$ satisfying* (A3)–(A4) *is a solution of the* alternative formulation *if there exist $p_q \in PC^{q+1}_{\mathcal{T}}([0,T];\mathbb{R}^{n*})$, $\eta_q \in PC^q_{\mathcal{T}}[0,T]$, alternative jump parameters $\nu^j_{\mathcal{T}_{en}}$, $j = 1, \ldots, q$, and $\nu_{\mathcal{T}_{to}}$ such that the following relations are satisfied (we omit dependence in time):*

$$\dot{y} = \tilde{H}_p(u, y, p_q, \eta_q) = f(u,y) \quad \text{on } [0,T]; \quad y(0) = y_0, \tag{2.23}$$

$$-\dot{p}_q = \tilde{H}_y(u, y, p_q, \eta_q) = H_y(u, y, p_q) + \eta_q g^{(q)}_y(u,y) \quad \text{on } [0,T] \setminus \mathcal{T}, \tag{2.24}$$

$$p_q(T) = \phi_y(y(T)), \tag{2.25}$$

$$0 = \tilde{H}_u(u, y, p_q, \eta_q) = H_u(u, y, p_q) + \eta_q g^{(q)}_u(u,y) \quad \text{on } [0,T] \setminus \mathcal{T}, \tag{2.26}$$

$$g^{(j)}(y(\tau)) = 0 \qquad \text{for } j = 0, 1, \ldots, q-1; \quad \tau \in \mathcal{T}_{en}, \tag{2.27}$$

$$g^{(q)}(u, y) = 0 \qquad \text{on } \mathcal{I}_b, \tag{2.28}$$

$$g(y(\tau)) = 0 \qquad \text{for all } \tau \in \mathcal{T}_{to}, \tag{2.29}$$

$$\eta_q(t) = 0 \qquad \text{on } [0,T] \setminus \mathcal{I}_b, \tag{2.30}$$

$$[p_q(\tau)] = -\sum_{j=1}^{q} \nu_\tau^j g_y^{(j-1)}(y(\tau)) \qquad \text{for all } \tau \in \mathcal{T}_{en}, \tag{2.31}$$

$$[p_q(\tau)] = 0 \qquad \text{for all } \tau \in \mathcal{T}_{ex}, \tag{2.32}$$

$$[p_q(\tau)] = -\nu_\tau g_y(y(\tau)) \qquad \text{for all } \tau \in \mathcal{T}_{to}. \tag{2.33}$$

In the heuristic formulation of [8], (2.23)–(2.33) are interpreted as necessary optimality conditions for the problem of minimizing (2.1) subject to (2.2) and *equality constraints* (2.27)–(2.29) for a *fixed* set of junction times $\mathcal{T}$. Alternative jump parameters $\nu_{\tau_{en}}^{1:q}$ appearing in (2.31) are seen as multipliers associated with the q interior point constraints in (2.27) at a regular entry time τ_{en}.

The assumption equivalent to (A2) for the alternative formulation is the following; see Remark 2.11(ii):

(A2$_q$) $\exists\, \alpha > 0,\ \tilde{H}_{uu}(\hat{u}, y(t), p_q(t^\pm), \eta_q(t^\pm)) \geq \alpha$ for all $t \in [0,T]$ and all $\hat{u} \in \mathbb{R}$.

In what follows, we will write (A2)–(A4) (resp., (A2$_q$)–(A4)) to denote the assumptions (A2) (resp., (A2$_q$)), (A3), and (A4).

2.2. Additional conditions. Relations (2.23)–(2.33) due to [8] are necessary, but not sufficient, conditions for regular Pontryagin extremals. This was underlined in [18], where some additional necessary conditions were provided that allowed the authors to show that a trajectory (with a fourth-order state constraint) was not a Pontryagin extremal. We state in Proposition 2.10 the characterization of regular Pontryagin extremals based on the alternative formulation. We need some preliminary lemmas.

LEMMA 2.8. *Let (u, y) be a trajectory, and let $(p_q, \eta_q) \in PC^1_{\mathcal{T}}([0,T]; \mathbb{R}^{n*}) \times PC^0_{\mathcal{T}}[0,T]$ satisfying* (A2$_q$)–(A4) *and* (2.23)–(2.24), (2.26), (2.28). *Then (u, y, p_q, η_q) belongs to the set $PC^q_{\mathcal{T}}[0,T] \times PC^{q+1}_{\mathcal{T}}([0,T]; \mathbb{R}^n) \times PC^{q+1}_{\mathcal{T}}([0,T]; \mathbb{R}^{n*}) \times PC^q_{\mathcal{T}}[0,T]$.*

Proof. By the implicit function theorem, applied to (2.26) on interior arcs, and to (2.26) and (2.28) on boundary arcs, the algebraic variables (u, η_q) can be expressed, on the interior of each arc, as C^q functions of (y, p_q). The result follows. □

LEMMA 2.9. *If constraint regularity* (A3) *holds along a trajectory (u, y), and if $u \in PC^q_{\mathcal{T}}[0,T]$, then, for all $t \in [0,T]$, vectors $(g_y(y(t)), \ldots, g_y^{(q-1)}(y(t)))$ are linearly independent (and hence, $q \leq n$).*

Proof. Since $u \in PC^q_{\mathcal{T}}[0,T]$, the mappings $(A_l)_{0 \leq l \leq q} : [0,T] \setminus \mathcal{T} \to \mathbb{R}^n$ defined inductively by

$$\begin{cases} A_0(t) := f_u(u(t), y(t)), \\ A_l(t) := f_y(u(t), y(t)) A_{l-1}(t) - \dot{A}_{l-1}(t), \qquad l = 1, \ldots, q, \end{cases} \tag{2.34}$$

are well defined, and $A_l \in PC^{q-l}_{\mathcal{T}}([0,T]; \mathbb{R}^n)$ for $l = 0, \ldots, q$. It has been shown in [25] that the following relations hold for all $t \in [0,T]$:

$$\begin{cases} g_y^{(j)}(y(t)) A_l(t^\pm) = 0 \qquad \text{for } j = 0, \ldots, q-2; \qquad l = 0, \ldots, q-2-j, \\ g_u^{(q)}(u(t^\pm), y(t)) = g_y^{(q-l-1)}(y(t)) A_l(t^\pm) \qquad \text{for } l = 0, \ldots, q-1, \end{cases} \tag{2.35}$$

where $t^\pm$ denotes, on both sides of the equality, either t^- or t^+. Denote by C the $n \times q$ matrix $(g_y(y(t))^*, \dots, g_y^{(q-1)}(y(t))^*)$. The above relations imply that the $q \times q$ matrix $D := C^\top(A_{q-1}(t^\pm), \dots, A_0(t^\pm))$ is lower triangular with nonzero diagonal elements equal to $g_u^{(q)}(u(t^\pm), y(t))$ and hence has rank q. Therefore C has rank at least q. The conclusion follows. □

PROPOSITION 2.10. *Let (u, y) be a trajectory satisfying* (A2$_q$)–(A4) *and the alternative formulation* (2.23)–(2.33). *Define the functions η_j, $0 \le j \le q-1$, the costate p, and the jump parameters $\nu_{\mathcal{T}_{en}}$ and $\nu_{\mathcal{T}_{ex}}$ by*

$$\eta_j(t) = (-1)^{q-j} \frac{\mathrm{d}^{q-j}}{\mathrm{d}t^{q-j}} \eta_q(t) \qquad \text{for } j = 0, \dots, q-1; \qquad t \in [0,T] \setminus \mathcal{T}, \tag{2.36}$$

$$p(t) = p_q(t) + \sum_{j=1}^{q} \eta_j(t) g_y^{(j-1)}(y(t)), \qquad t \in [0,T] \setminus \mathcal{T}, \tag{2.37}$$

$$\nu_{\tau_{en}} = \nu^1_{\tau_{en}} - \eta_1(\tau_{en}^+) \text{ for all } \tau_{en} \in \mathcal{T}_{en}; \qquad \nu_{\tau_{ex}} = \eta_1(\tau_{ex}^-) \text{ for all } \tau_{ex} \in \mathcal{T}_{ex}. \tag{2.38}$$

Then (u, y) is a regular Pontryagin extremal that satisfies (2.13)–(2.20) *iff all the following additional conditions are satisfied:*

$$g(y(t)) < 0 \qquad \text{on } [0,T] \setminus (\mathcal{I}_b \cup \mathcal{T}_{to}), \tag{2.39}$$

$$\eta_0(t) = (-1)^q \frac{\mathrm{d}^q}{\mathrm{d}t^q} \eta_q(t) \ge 0 \qquad \text{on } \operatorname{int} \mathcal{I}_b. \tag{2.40}$$

At all entry times τ_{en},

$$\begin{cases} \nu^1_{\tau_{en}} = \eta_1(\tau_{en}^+) & \text{if } q \text{ is odd;} \\ \nu^1_{\tau_{en}} \ge \eta_1(\tau_{en}^+) & \text{if } q \text{ is even;} \end{cases} \qquad \nu^j_{\tau_{en}} = \eta_j(\tau_{en}^+); \qquad j = 2, \dots, q. \tag{2.41}$$

At all exit times τ_{ex},

$$\begin{cases} \eta_1(\tau_{ex}^-) = 0 & \text{if } q \text{ is odd;} \\ \eta_1(\tau_{ex}^-) \ge 0 & \text{if } q \text{ is even;} \end{cases} \qquad \eta_j(\tau_{ex}^-) = 0; \qquad j = 2, \dots, q. \tag{2.42}$$

At all touch times τ_{to},

$$\nu_{\tau_{to}} \ge 0. \tag{2.43}$$

REMARK 2.11.

(i) If (u, y) is a regular Pontryagin extremal solution of (2.13)–(2.20), the functions η_j, $1 \le j \le q$, costate p_q, and alternative jump parameters $\nu^{1:q}_{\mathcal{T}_{en}}$, such that (u, y) satisfies the alternative formulation (2.23)–(2.33) and additional conditions (2.39)–(2.43), can be recovered from p, η_0, and $\nu_{\mathcal{T}}$ as follows. The functions η_j are given by (2.36) by successive integrations of η_0 over boundary arcs, with integration constants determined by the exit time conditions (2.38) for $j = 1$ and (2.42) for $j = 2, \dots, q$. Costate p_q follows then from (2.37), and jump parameters at entry times $\nu^j_{\tau_{en}}$ are given by (2.38) for $j = 1$ and (2.41) for $j = 2, \dots, q$. Jump parameters $\nu_{\mathcal{T}_{to}}$ associated with touch points are the same in both formulations.

(ii) Assumptions (A2) and (A2$_q$) are equivalent, when (2.36)–(2.37) hold, since the constraints are of order q, and hence we have

$$\tilde{H}_{uu}(u,y,p_q,\eta_q) = H_{uu}(u,y,p) - \sum_{j=1}^{q} \eta_j(t) g_y^{(j-1)}(y) f_{uu}(u,y) + \eta_q g_{uu}^{(q)}(u,y)$$
$$= H_{uu}(u,y,p) - \sum_{j=1}^{q-1} \eta_j(t) g_{uu}^{(j)}(y)(u,y) \;=\; H_{uu}(u,y,p).$$

Proof of Proposition 2.10. Since η_q is piecewise C^q by Lemma 2.8, the functions η_j, $0 \le j \le q-1$, are well defined. We show the equivalence between (2.13)–(2.20) and (2.23)–(2.33) augmented with (2.39)–(2.43).

Equivalence between state equations (2.13) and (2.23); final costate conditions (2.15) and (2.25); state constraint equations (2.17) and (2.27), (2.28), (2.30) on boundary arcs; and (2.19) and (2.29) at touch points is obvious. Equivalence between costate equations (2.14) and (2.24), and between control equations (2.16) and (2.26), follows from calculation, using the relations between the functions η_j, p, and p_q and the fact that the state constraint is of order q (see, e.g., [25]).

Additional conditions are necessary to ensure equivalence between complementarity and junction conditions. Obviously, (2.39)–(2.40) are equivalent to (2.18); as well, (2.33) and (2.43) are equivalent to (2.20) for touch points. It remains to check that (2.20) is also equivalent to (2.31)–(2.32) and (2.41)–(2.42) at entry/exit points. Let $\tau_{en} \in \mathcal{T}_{en}$. Expressing $[p_q(\tau_{en})]$, using on the one hand the relationship (2.37) between p and p_q, as well as (2.20), and using on the other hand jump condition (2.31), we obtain

$$[p_q(\tau_{en})] = -\nu_{\tau_{en}} g_y(y(\tau_{en})) - \sum_{j=1}^{q} \eta_j(\tau_{en}^+) g_y^{(j-1)}(y(\tau_{en})), \tag{2.44}$$

$$[p_q(\tau_{en})] = -\sum_{j=1}^{q} \nu_{\tau_{en}}^j g_y^{(j-1)}(y(\tau_{en})). \tag{2.45}$$

By Lemma 2.9 at $t = \tau_{en}$, the right-hand sides of (2.44) and (2.45) are equal iff the coefficients of $g_y^{(j-1)}(y(\tau_{en}))$ for $j = 1, \dots, q$ are equal. Eliminating $\nu_{\tau_{en}}$, which must be nonnegative (and equals zero for odd-order state constraints by Proposition 2.5(i)), we deduce (2.41). Proceeding similarly at exit points, (2.42) follows. ∎

Remark 2.12. Proposition 2.10 slightly improves section 5 of [25], in the sense that we give the complete set of additional conditions for which equivalence between regular Pontryagin extremals and the alternative formulation holds.

Remark 2.13. The sign condition of $\eta_q^{(q)}$ on boundary arcs (2.40) and exit point conditions (2.42) implies that the necessary condition

$$(-1)^{q-j} \frac{\mathrm{d}^{q-j}}{\mathrm{d}t^{q-j}} \eta_q(t) = \eta_j(t) \ge 0 \;\text{ on } \mathcal{I}_b \qquad \text{for } j = 1, \dots, q \tag{2.46}$$

holds as a consequence of (2.40) and (2.42). It is easily seen by induction, since $\dot{\eta}_j = -\eta_{j-1} \le 0$ on $\mathcal{I}_b$ and $\eta_j(\tau_{ex}^-) \ge 0$ for all $\tau_{ex} \in \mathcal{T}_{ex}$. By (2.41), we deduce also that $\nu_{\tau_{en}}^j \ge 0$ for all $\tau \in \mathcal{T}_{en}$ and $j = 1, \dots, q$.

2.3. The shooting algorithm. The shooting algorithm extracts from the necessary optimality conditions a finite-dimensional set of equations (the shooting equations). If its Jacobian is invertible, we obtain a locally convergent algorithm by solving the shooting equations using, say, Newton's method.

In the unconstrained case, the initial value of the costate p_0 is mapped into the final condition (2.25). To handle alternative formulation of Definition 2.7, jump parameters and junction times are introduced as *shooting parameters*. A given set of shooting parameters determines a unique trajectory and multipliers (u, y, p_q, η_q) solution of the coupled state–costate system (2.23)–(2.24) with initial condition $p_q(0) = p_0$; algebraic equations (2.26), (2.28), and (2.30) that give u and η_q as implicit functions of (y, p_q) by (A2)–(A3); and jump conditions (2.31)–(2.33).

We use the shooting formulation of Malanowski and Maurer [23, 24]. Jump parameters $\nu_{\tau_{en}}^{1:q}$ at an entry time τ_{en} are associated with the q interior points conditions (2.27). Necessary optimality conditions for entry and exit points τ_{en} and τ_{ex} and touch points τ_{to} (when $q \geq 2$) are as follows:

$$g^{(q)}(u(\tau_{en}^-), y(\tau_{en})) = 0; \qquad g^{(q)}(u(\tau_{ex}^+), y(\tau_{ex})) = 0, \tag{2.47}$$

$$g^{(1)}(y(\tau_{to})) = 0. \tag{2.48}$$

By Proposition 2.5, the control is continuous along a regular Pontryagin extremal so that (2.47) is a necessary optimality condition for entry/exit times. For a first-order state constraint, we assume in what follows that $\mathcal{T}_{to} = \emptyset$ (see Remark 2.19 below). Since a touch point τ_{to} is a local maximum of $g(y)$ when $q \geq 2$, (2.48) is a necessary optimality condition. Therefore, (2.48) together with the interior point constraint (2.29) provide two conditions associated with τ_{to} and its jump parameter $\nu_{\tau_{to}}$ for each $\tau_{to} \in \mathcal{T}_{to}$.

DEFINITION 2.14. *A trajectory* (u, y) *is a* shooting extremal *if it satisfies both the alternative formulation (Definition* 2.7*) and conditions* (2.47)–(2.48).

Let us show how (2.47) relates to the additional conditions of Proposition 2.10.

PROPOSITION 2.15. *Let* (u, y) *be a trajectory solution of the alternative formulation* (2.23)–(2.33) *and satisfying* (A2$_q$)–(A4). *Then the following two conditions are equivalent:*

(i) *The control* u *is continuous at entry/exit times* τ_{en}, τ_{ex} *(i.e.,* (2.47) *holds).*

(ii) *Those additional conditions in* (2.41)–(2.42) *involving* η_q *are satisfied, i.e.,*

$$\eta_q(\tau_{en}^+) - \nu_{\tau_{en}}^q = 0; \qquad \eta_q(\tau_{ex}^-) = 0. \tag{2.49}$$

Proof. Let $\tau_{en} \in \mathcal{T}_{en}$. By (A3), the function $\hat{u} \mapsto g^{(q)}(\hat{u}, y(\tau_{en}))$ is one-to-one. Since $g^{(q)}(u(\tau_{en}^+), y(\tau_{en})) = 0$, we have that $g^{(q)}(u(\tau_{en}^-), y(\tau_{en})) = 0$ iff the control is continuous at time τ_{en}; the same type of argument holds for exit points. It follows that (2.47) is equivalent to the continuity of the control at entry/exit points.

By (2.26), we have

$$\tilde{H}_u(u(\tau_{en}^-), y(\tau_{en}), p_q(\tau_{en}^-), 0) \;=\; 0 \;=\; \tilde{H}_u(u(\tau_{en}^+), y(\tau_{en}), p_q(\tau_{en}^+), \eta_q(\tau_{en}^+)).$$

We abbreviate $u(\tau_{en}^-)$ to u^- and so on. Using the jump condition of the costate (2.31), it follows that

$$\tilde{H}_u(u^+, y, p_q^+, \eta_q^+) = H_u(u^+, y, p_q^-) - \sum_{j=1}^{q} \nu_{\tau_{en}}^j g_y^{(j-1)}(y) f_u(u^+, y) + \eta_q^+ g_u^{(q)}(u^+, y).$$

The state constraint being of order q, we have $g_y^{(j-1)}(y) f_u(u, y) = g_u^{(j)}(y) = 0$ for $j = 1, \ldots, q-1$, and hence, we obtain

$$0 \;=\; H_u(u^+, y, p_q^-) + (\eta_q^+ - \nu_{\tau_{en}}^q) g_u^{(q)}(u^+, y).$$

Since $g_u^{(q)}(u^+, y) \neq 0$ by (A3), it follows that $H_u(u^+, y, p_q^-) = 0$ iff $\eta_q^+ = \nu_{\tau_{en}}^q$. Since by (A2$_q$) $H_u(u^+, y, p_q^-) = 0$ iff $u^+ = u^-$, we deduce that u is continuous at time τ_{en} iff $\eta_q^+ = \nu_{\tau_{en}}^q$. Similar arguments hold for exit points. The conclusion follows. ∎

REMARK 2.16. We can also check that if (u, y) is a shooting extremal satisfying (A2$_q$)–(A4), then u is continuous at touch points $\tau \in \mathcal{T}_{to}$ if $q \geq 2$. Indeed, (2.26), (2.30), and (2.33) lead to

$$H_u(u^-, y, p_q^-) = 0 = H_u(u^+, y, p_q^+) = H_u(u^+, y, p_q^-) - \nu_\tau g_y(y) f_u(y, u^+).$$

Since $g_y f_u = g_u^{(1)} \equiv 0$, and $H_u(\cdot, y, p_q^-)$ is one-to-one by (A2$_q$), we obtain $u^+ = u^-$.

It follows that if (u, y) is a shooting extremal satisfying (A2$_q$)–(A4), then u is continuous on $[0, T]$, provided that we still assume that $\mathcal{T}_{to} = \emptyset$ if $q = 1$ (see Remark 2.19).

The *structure* of a feasible trajectory is defined as the (finite) *number* of boundary arcs and touch points of the trajectory, and the *order* in which they occur w.r.t. time. Assuming the structure of the optimal trajectory is known, we define the shooting mapping as follows. Denote by N_b and N_{to} the number of boundary arcs and touch points of the trajectory, respectively. The space of shooting parameters is

$$\Theta := \mathbb{R}^n \times \mathbb{R}^{qN_b} \times \mathbb{R}^{N_{to}} \times \mathbb{R}^{N_b} \times \mathbb{R}^{N_b} \times \mathbb{R}^{N_{to}}.$$

With the above notation, and for a given order of boundary arcs and touch points, the shooting mapping $\mathcal{F}$ is defined, over a neighborhood in Θ of shooting parameters associated with a regular Pontryagin extremal, into Θ, by

$$\theta = \begin{pmatrix} p_0^* \\ \nu_{\mathcal{T}_{en}}^{1:q} \\ \nu_{\mathcal{T}_{to}} \\ \mathcal{T}_{en} \\ \mathcal{T}_{ex} \\ \mathcal{T}_{to} \end{pmatrix} \mapsto \begin{pmatrix} p_q(T)^* - \phi_y(y(T))^* \\ g^{(0:q-1)}(y(\mathcal{T}_{en})) \\ g(y(\mathcal{T}_{to})) \\ g^{(q)}(u(\mathcal{T}_{en}^-), y(\mathcal{T}_{en})) \\ g^{(q)}(u(\mathcal{T}_{ex}^+), y(\mathcal{T}_{ex})) \\ g^{(1)}(y(\mathcal{T}_{to})) \end{pmatrix}. \tag{2.50}$$

By construction, a zero of the shooting mapping $\mathcal{F}$ provides a trajectory (u, y) that is a shooting extremal. In view of Propositions 2.10 and 2.15, the following holds.

COROLLARY 2.17. *A shooting extremal satisfying* (A2$_q$)–(A4) *is a regular Pontryagin extremal iff it satisfies the following* minimal additional conditions: (2.39) *on interior arcs,* (2.40) *on boundary arcs,* (2.43) *at touch points, and for all entry points* $\tau_{en} \in \mathcal{T}_{en}$ *and exit points* $\tau_{ex} \in \mathcal{T}_{ex}$,

$$\text{if } q \geq 2 \text{ is even; } \nu_{\tau_{en}}^1 - (-1)^{q-1}\eta_q^{(q-1)}(\tau_{en}^+) \geq 0; \ (-1)^{q-1}\eta_q^{(q-1)}(\tau_{ex}^-) \geq 0; \tag{2.51}$$

$$\begin{cases} \text{if } q \geq 3 \text{ is odd, } j = 1, \ldots, q-1, \text{ and if } q \geq 4 \text{ is even, } j = 2, \ldots, q-1; \\ \nu_{\tau_{en}}^j - (-1)^{q-j}\eta_q^{(q-j)}(\tau_{en}^+) = 0; \quad (-1)^{q-j}\eta_q^{(q-j)}(\tau_{ex}^-) = 0. \end{cases} \tag{2.52}$$

Note that (2.51)–(2.52) is only a reformulation of (2.41)–(2.42), from which we removed the condition corresponding to $j = q$, namely (2.49), since the latter is automatically satisfied by Proposition 2.15. Consequently, when $q = 1$, there remain no additional conditions at entry/exit points for shooting extremals.

REMARK 2.18. It follows that for first- and second-order state constraints, and for constraints of order $q > 2$ having no boundary arcs (see Remark 4.11 concerning existence of boundary arcs for state constraints of order $q \geq 3$), the additional

conditions reduce to the *inequalities* (2.39), (2.40), (2.43), and (2.51) when $q = 2$ at entry/exit points.

REMARK 2.19. For a first-order state constraint, jump parameters $\nu_{\mathcal{T}_{to}}$ associated with touch points are equal to zero along a regular Pontryagin extremal by Proposition 2.5. For this reason, we assume in this paper that $\mathcal{T}_{to} = \emptyset$ if $q = 1$.

REMARK 2.20. The nonlocal hypotheses (A2) (or (A2$_q$)) as well as (2.10) (or (2.12)) are essential in order to prove that the control is continuous. Some of our results remain valid, substituting everywhere *stationary point* for *(regular) Pontryagin extremal*, when the assumptions (A2) and (2.10) in (A3) are replaced by the weaker assumptions that u is continuous over $[0, T]$ and that there exists $\alpha, \gamma > 0$ such that

$$H_{uu}(u(t), y(t), p(t)) \geq \alpha \quad \text{and} \quad |g_u^{(q)}(u(t), y(t))| \geq \gamma \quad \text{for all } t \in [0, T]. \tag{2.53}$$

This holds in particular for Propositions 2.4, 2.5, 2.10, 2.15, Remark 2.16, and Corollary 2.17. The same remark applies for the other results of this paper, i.e., Theorems 3.2, 3.3, 4.3; Corollary 4.10; and Lemmas A.1 and A.2 in the appendix.

3. Well-posedness of the shooting algorithm. We say that the shooting algorithm is locally *well-posed* if the Jacobian of the shooting mapping (2.50) is invertible at some local solution of $(\mathcal{P})$. This allows us to apply locally a Newton method in order to find a shooting extremal; the additional conditions for a Pontryagin extremal have to be checked afterwards.

Let us first give some definitions. Given $u \in \mathcal{U}$, recall that we denote by y_u the (unique) solution in $\mathcal{Y}$ of the state equation (2.2). This well-defined mapping is of class C^k under assumption (A0). Let the cost function be

$$J(u) = \int_0^T \ell(u(t), y_u(t))\mathrm{d}t + \phi(y_u(T)). \tag{3.1}$$

We say that a feasible trajectory $(u, y = y_u)$ is a local solution of $(\mathcal{P})$ satisfying the *quadratic growth condition* if there exists $c, r > 0$ such that

$$J(\tilde{u}) \geq J(u) + c\,\|\tilde{u} - u\|_2^2 \qquad \text{for all } \tilde{u} \in B_\infty(u, r); \quad g(y_{\tilde{u}}(t)) \leq 0 \text{ on } [0, T], \tag{3.2}$$

where B_∞ denotes the open ball in $L^\infty(0, T)$ with center u and radius r. This condition involves two norms, $L^\infty(0, T)$ for the neighborhood and $L^2(0, T)$ for the growth condition.

Let (u, y) be a regular Pontryagin extremal. We make the following strict complementarity assumption (compare to (2.40), (2.51), and (2.43), where large inequalities are replaced by strict inequalities):

(A5) (i) For all boundary arcs $[\tau_{en}, \tau_{ex}]$,

$$(-1)^q \frac{\mathrm{d}^q}{\mathrm{d}t^q}\eta_q(t) > 0 \qquad \text{a.e. on } (\tau_{en}, \tau_{ex}). \tag{3.3}$$

$$\text{If } q \text{ is } \textit{odd}, \qquad \frac{\mathrm{d}^q}{\mathrm{d}t^q}\eta_q(\tau_{en}^+) < 0; \quad \frac{\mathrm{d}^q}{\mathrm{d}t^q}\eta_q(\tau_{ex}^-) < 0. \tag{3.4}$$

$$\text{If } q \text{ is } \textit{even}, \quad \nu^1_{\tau_{en}} + \frac{\mathrm{d}^{q-1}}{\mathrm{d}t^{q-1}}\eta_q(\tau_{en}^+) > 0; \quad \frac{\mathrm{d}^{q-1}}{\mathrm{d}t^{q-1}}\eta_q(\tau_{ex}^-) < 0. \tag{3.5}$$

(ii) For all touch points $\tau_{to} \in \mathcal{T}_{to}$,

$$\nu_{\tau_{to}} > 0. \tag{3.6}$$

Recall that $(-1)^q \frac{\mathrm{d}^q}{\mathrm{d}t^q}\eta_q(t)$ equals η_0, the density of η (see Proposition 2.10). Let $\hat{q} := 2q-1$ if q is *odd* and $\hat{q} := 2q-2$ if q is *even*. By Proposition 2.5, $\hat{q}+1$ is the smallest possible order for which the corresponding time derivative of $g(y(t))$ may be discontinuous at an entry/exit point. Note that $\hat{q} = q$ for $q = 1, 2$.

LEMMA 3.1. *Let (u, y) be a regular Pontryagin extremal satisfying* (A2)–(A4). *For odd (resp., even) q, assumption* (3.4) *(resp.,* (3.5)*) holds iff the following nontangentiality condition at order $\hat{q}+1$ holds: For all entry times $\tau_{en} \in \mathcal{T}_{en}$ and all exit times $\tau_{ex} \in \mathcal{T}_{ex}$,*

$$(-1)^{\hat{q}+1}\frac{\mathrm{d}^{\hat{q}+1}}{\mathrm{d}t^{\hat{q}+1}}g(y(t))|_{t=\tau_{en}^-} < 0; \quad \frac{\mathrm{d}^{\hat{q}+1}}{\mathrm{d}t^{\hat{q}+1}}g(y(t))|_{t=\tau_{ex}^+} < 0. \tag{3.7}$$

Proof. By Proposition 2.10 (see (2.38)), (3.5) is equivalent (when q is even) to the strict positivity of $\nu_\tau > 0$ at entry/exit points $\tau \in \mathcal{T}_{en} \cup \mathcal{T}_{ex}$. The conclusion is then a consequence of Proposition 2.10 and of Lemma A.2, whose (technical) proof is given in the appendix. ∎

Assumption (A5)(ii) implies that if $q = 1$, then $\mathcal{T}_{to} = \emptyset$ by Proposition 2.5(ii). When $q \geq 2$, we assume that all touch points of (u, y) are *reducible* in the following sense:

(A6) For all touch points $\tau_{to} \in \mathcal{T}_{to}$,

$$\frac{\mathrm{d}^2}{\mathrm{d}t^2}g(y(t))|_{t=\tau_{to}} < 0. \tag{3.8}$$

This makes sense, since when $q \geq 2$, we have $\frac{\mathrm{d}^2}{\mathrm{d}t^2}g(y(t)) = g^{(2)}(u, y)$ and u is continuous by Proposition 2.5.

3.1. Statement of main results. Define the quadratic cost function

$$\begin{aligned}\mathcal{J}_q(v, z) \;:=\; & \int_0^T \tilde{H}_{(u,y),(u,y)}(u, y, p_q, \eta_q)((v, z), (v, z))\mathrm{d}t \\ & + \; z(T)^* \phi_{yy}(y(T))z(T) \; + \sum_{\tau\in\mathcal{T}_{en}} \sum_{j=1}^{q} \nu_\tau^j z(\tau)^* g_{yy}^{(j-1)}(y(\tau))z(\tau) \\ & + \sum_{\tau\in\mathcal{T}_{to}} \nu_\tau \left(z(\tau)^* g_{yy}(y(\tau))z(\tau) \; - \; \frac{(g_y^{(1)}(y(\tau))z(\tau))^2}{\frac{\mathrm{d}}{\mathrm{d}t}g^{(1)}(y(t))|_{t=\tau}} \right),\end{aligned} \tag{3.9}$$

where $\tilde{H}$ is the augmented Hamiltonian (2.22) and the set of constraints

$$\dot{z} = f_y(u, y)z + f_u(u, y)v \qquad \text{on } [0, T]; \qquad z(0) = 0, \tag{3.10}$$

$$g_y^{(j)}(y(\tau))z(\tau) = 0 \qquad \text{for } j = 0, \ldots, q-1; \quad \tau \in \mathcal{T}_{en}, \tag{3.11}$$

$$g_{(u,y)}^{(q)}(u(t), y(t))(v(t), z(t)) = 0, \qquad t \in \mathcal{I}_b, \tag{3.12}$$

$$g_y(y(\tau))z(\tau) = 0, \qquad \tau \in \mathcal{T}_{to}. \tag{3.13}$$

Since the state equation and constraints are linear, the cost function is quadratic, and all have bounded coefficients, we may take as linearized control and state spaces $\mathcal{V} := L^2(0, T)$ and $\mathcal{Z} := H^1(0, T; \mathbb{R}^n)$, where $H^1(0, T)$ is the Sobolev space of functions in $L^2(0, T)$ with a weak derivative in $L^2(0, T)$. Let the linear quadratic problem (PQ_q) be defined by

$$(\mathrm{PQ}_q) \qquad \min_{(v,z)\in\mathcal{V}\times\mathcal{Z}} \; \frac{1}{2}\mathcal{J}_q(v, z) \qquad \text{subject to (3.10)–(3.13).} \tag{3.14}$$

Consider the following second-order conditions:

$$(v,z)=0 \text{ is a solution of } (\mathrm{PQ}_q). \tag{3.15}$$

$$(v,z)=0 \text{ is the } \textit{unique} \text{ solution of } (\mathrm{PQ}_q). \tag{3.16}$$

THEOREM 3.2 (no-gap second-order optimality conditions). (i) *Let* (u,y) *be a local solution of* $(\mathcal{P})$ *satisfying* (A2)–(A6). *Then its associated multipliers in the alternative formulation are such that the second-order necessary condition* (3.15) *holds.*

(ii) *Let* (u,y) *be a Pontryagin extremal satisfying* (A2)–(A6). *Then the second-order sufficient condition* (3.16) *holds iff* (u,y) *is a local solution of* $(\mathcal{P})$ *satisfying the quadratic growth condition* (3.2).

THEOREM 3.3 (well-posedness of the shooting algorithm). *Let* (u,y) *be a local solution of* $(\mathcal{P})$ *satisfying* (A2)–(A6). *Then the shooting algorithm is locally well-posed (invertible Jacobian) iff the following two conditions hold:* (i) *If* $q\geq 3$, *the trajectory* (u,y) *does not have boundary arcs.* (ii) *The second-order sufficient condition* (3.16) *holds.*

In general, even for unconstrained problems, the invertibility of the Jacobian of the shooting mapping at a Pontryagin extremal does not imply that the second-order sufficient condition (3.16) holds. We comment on the ill-posedness of the shooting algorithm along boundary arc of order $q\geq 3$ in Remark 4.11.

Combining Theorems 3.2(ii) and 3.3, we obtain that if (u,y) is a local solution of $(\mathcal{P})$ satisfying (A2)–(A6) and condition (i) of Theorem 3.3, then the shooting algorithm is well-posed iff (u,y) satisfies the quadratic growth condition.

3.2. Proof of the no-gap second-order optimality conditions (Theorem 3.2). We use the no-gap second-order optimality conditions established in [6, 5]. Let (u,y) be a regular Pontryagin extremal, with the multiplier $\eta\in\mathcal{M}[0,T]$ given by (2.21). Consider the quadratic cost function

$$\begin{aligned}\mathcal{J}(v,z) \;:=\; & \int_0^T H_{(u,y),(u,y)}(u,y,p)((v,z),(v,z))\mathrm{d}t + z(T)^*\phi_{yy}(y(T))z(T)\\ & + \int_0^T (z^* g_{yy}(y)z)\,\mathrm{d}\eta \;-\; \sum_{\tau\in\mathcal{T}_{to}} \nu_\tau \frac{(g_y^{(1)}(y(\tau))z(\tau))^2}{\frac{\mathrm{d}}{\mathrm{d}t}g^{(1)}(y(t))|_{t=\tau}},\end{aligned} \tag{3.17}$$

where H is the classical Hamiltonian (2.4), and consider the constraint

$$g_y(y(t))z(t)=0 \quad \text{on } \mathcal{I}_b\cup\mathcal{T}_{to}. \tag{3.18}$$

The quadratic problem used in the formulation of the second-order optimality condition in [5] is the following:

$$(\mathrm{PQ}) \qquad \min_{(v,z)\in\mathcal{V}\times\mathcal{Z}} \ \frac{1}{2}\mathcal{J}(v,z) \qquad \text{subject to (3.10) and (3.18).} \tag{3.19}$$

THEOREM 3.4. (i) *If* (u,y) *is a local solution of* $(\mathcal{P})$ *such that* (A2)–(A6) *hold, then* $(v,z)=0$ *is solution of problem* (3.19).

(ii) *If* (u,y) *is a Pontryagin extremal such that* (A2)–(A6) *hold, it is a local solution of* $(\mathcal{P})$ *satisfying the quadratic growth condition* (3.2) *iff problem* (3.19) *has zero for a unique solution.*

Proof. See Corollary 15 and Theorems 18 and 27 in [5], or Theorem 0.1 in [6]. For the sake of completeness, let us recall the main ideas. The proof of the second-order

necessary condition is based on the computation of the curvature term obtained by Kawasaki [19, 20] in an abstract optimization framework. With the junction conditions results of Proposition 2.5 and (A5)(i), we can show that boundary arcs have no zero contribution to the curvature term. For the second-order sufficient condition, a reduction method is used around the finitely many reducible touch points. In fact, the proof of the sufficient condition is very similar to the proof of Lemma 4.9 in the stability analysis below. □

We establish the link between Theorem 3.4 and the second-order conditions (3.15)–(3.16) derived from the alternative formulation. In the end of this section we often omit the time argument when there is no ambiguity. The proof of the next lemma is easy and therefore omitted.

LEMMA 3.5. *Assume that the state constraint is of order q. Then for every trajectory (u, y) and every linearized trajectory $(v, z) \in \mathcal{V} \times \mathcal{Z}$ satisfying* (3.10)*, the following holds:*

$$\frac{\mathrm{d}^j}{\mathrm{d}t^j} g_y(y(t))z(t) = g_y^{(j)}(u, y)z, \qquad j = 1, \dots, q-1, \tag{3.20}$$

$$\frac{\mathrm{d}^q}{\mathrm{d}t^q} g_y(y(t))z(t) = g_y^{(q)}(u, y)z + g_u^{(q)}(u, y)v. \tag{3.21}$$

LEMMA 3.6. *Let (u, y) be a regular Pontryagin extremal satisfying* (A2)–(A4)*, with classical and alternative multipliers (p, η) and $(p_q, \eta_q, \nu^{1:q}_{\mathcal{T}_{en}}, \nu_{\mathcal{T}_{to}})$, respectively, related to each other by* (2.36)–(2.38), (2.41)*, and* (2.21)*. Then the quadratic cost functions $\mathcal{J}$ and $\mathcal{J}_q$, defined, respectively, in* (3.17) *and* (3.9)*, are equal to each other over the space of linearized trajectories $(v, z) \in \mathcal{V} \times \mathcal{Z}$ satisfying* (3.10)*.*

Proof. Let $(v, z) \in \mathcal{V} \times \mathcal{Z}$ satisfy (3.10) and set $\Delta_{PQ} := \mathcal{J}(v, z) - \mathcal{J}_q(v, z)$. Using (2.21), it is easily seen that the terms corresponding to the touch points and to the final time vanish, and hence we get

$$\begin{aligned}\Delta_{PQ} = &\int_0^T (p - p_q) D^2 f(u, y)((v, z), (v, z))\mathrm{d}t + \int_0^T g_{yy}(y)(z, z)\eta_0(t)\mathrm{d}t \\ &- \int_0^T D^2 g^{(q)}(u, y)((v, z), (v, z))\eta_q(t)\mathrm{d}t + \sum_{\tau \in \mathcal{T}_{ex}} \nu_\tau g_{yy}(y)(z, z)(\tau) \\ &+ \sum_{\tau \in \mathcal{T}_{en}} \left(\nu_\tau g_{yy}(y)(z, z)(\tau) \ - \sum_{j=1}^{q} \nu_\tau^j g_{yy}^{(j-1)}(y)(z, z)(\tau) \right).\end{aligned}$$

In what follows we abbreviate the notation $((v, z), (v, z))$ as $((v, z))^2$. Relations (2.36)–(2.37) between p and p_q lead to

$$\begin{aligned}\Delta_{PQ} = &\sum_{j=1}^{q} \int_0^T g_y^{(j-1)}(y) D^2 f(u, y)((v, z))^2 \eta_j(t)\mathrm{d}t + \int_0^T g_{yy}(y)(z, z)\eta_0(t)\mathrm{d}t \\ &- \int_0^T D^2 g^{(q)}(u, y)((v, z))^2 \eta_q(t)\mathrm{d}t + \sum_{\tau \in \mathcal{T}_{ex}} \nu_\tau g_{yy}(y)(z, z)(\tau) \\ &+ \sum_{\tau \in \mathcal{T}_{en}} \left(\nu_\tau g_{yy}(y)(z, z)(\tau) \ - \sum_{j=1}^{q} \nu_\tau^j g_{yy}^{(j-1)}(y)(z, z)(\tau) \right).\end{aligned} \tag{3.22}$$

The constraint being of order q, we have $g^{(j)}(u,y) = g_y^{(j-1)}(y)f(u,y)$ for $j = 0$ to $q-1$. It follows that

$$D^2g^{(j)}(u,y)((v,z))^2 = g_{yyy}^{(j-1)}(f(u,y),z,z) + 2g_{yy}^{(j-1)}(z,Df(u,y)(v,z)) + g_y^{(j-1)}D^2f(u,y)((v,z))^2. \tag{3.23}$$

In addition, by the linearized state equation (3.10), we have, for all $j = 1,\dots,q$,

$$\frac{\mathrm{d}}{\mathrm{d}t}\left[g_{yy}^{(j-1)}(y(t))(z(t),z(t))\right] = g_{yyy}^{(j-1)}(y)(f(u,y),z,z) + 2g_{yy}^{(j-1)}(y)(z,Df(u,y)(v,z)),$$

which gives, by (3.23), for $j = 1,\dots,q$,

$$\frac{\mathrm{d}}{\mathrm{d}t}\left[g_{yy}^{(j-1)}(y(t))(z(t),z(t))\right] = D^2g^{(j)}(u,y)((v,z))^2 - g_y^{(j-1)}(y)D^2f(u,y)((v,z))^2. \tag{3.24}$$

Since $g_u^{(j-1)}(u,y) \equiv 0$ for $j = 1,\dots,q$, we have $g_{yy}^{(j-1)}(y)(z,z) = D^2g^{(j-1)}(u,y)((v,z))^2$ for $j = 1,\dots,q$. Multiplying (3.24) by η_j, integrating over $[0,T]$, and integrating by parts on the left-hand side (recall that $\dot\eta_j = -\eta_{j-1}$), we obtain, for $j = 1,\dots,q$,

$$\begin{aligned}\int_0^T D^2g^{(j-1)}(u,y)((v,z))^2\eta_{j-1}(t)\mathrm{d}t &+ \sum_{\tau\in\tau_{ex}} g_{yy}^{(j-1)}(y)(z,z)\eta_j(\tau^-) \\ &- \sum_{\tau\in\tau_{en}} g_{yy}^{(j-1)}(y)(z,z)\eta_j(\tau^+) \\ = \int_0^T D^2g^{(j)}(u,y)((v,z))^2\eta_j(t)\mathrm{d}t &- \int_0^T g_y^{(j-1)}D^2f(u,y)((v,z))^2\eta_j(t)\mathrm{d}t.\end{aligned}$$

Adding the above equalities for $j = 1,\dots,q$, we get, after simplification by the terms $\int_0^T D^2g^{(j)}(u,y)((v,z))^2\eta_j$ for $j = 1,\dots,q-1$, that

$$\begin{aligned}\int_0^T g_{yy}(y)(z,z)\eta_0(t)\mathrm{d}t &+ \sum_{j=1}^q \sum_{\tau\in\tau_{ex}} g_{yy}^{(j-1)}(y)(z,z)\eta_j(\tau^-) \\ &- \sum_{j=1}^q \sum_{\tau\in\tau_{en}} g_{yy}^{(j-1)}(y)(z,z)\eta_j(\tau^+) \\ = \int_0^T D^2g^{(q)}(u,y)((v,z))^2\eta_q(t)\mathrm{d}t &- \sum_{j=1}^q \int_0^T g_y^{(j-1)}D^2f(u,y)((v,z))^2\eta_j(t)\mathrm{d}t.\end{aligned}$$

Substituting into (3.22) gives

$$\begin{aligned}\Delta_{PQ} = &\sum_{\tau\in\tau_{ex}} \left(\nu_\tau g_{yy}(y)(z,z)(\tau) - \sum_{j=1}^q g_{yy}^{(j-1)}(y)(z,z)\eta_j(\tau^-)\right) \\ &+ \sum_{\tau\in\tau_{en}} \left(\nu_\tau g_{yy}(y)(z,z)(\tau) + \sum_{j=1}^q \left(\eta_j(\tau^+) - \nu_\tau^j\right) g_{yy}^{(j-1)}(y)(z,z)(\tau)\right).\end{aligned}$$

Using (2.38) and additional conditions at entry and exit points (2.41)–(2.42), we obtain that $\Delta_{PQ} = 0$. Thus, the cost functions of the two quadratic problems coincide on the feasible set. ∎

Proof of Theorem 3.2. The state constraint being of order q, it follows from (3.20)–(3.21) that (3.11)–(3.13) and (3.18) are equivalent. By Lemma 3.6, problems (PQ_q) and (3.19) have the same feasible set and the same cost function on that feasible set, and hence they also have the same value and the same set of optimal solutions. The conclusion follows then from Theorem 3.4. ∎

3.3. Proof of the well-posedness (Theorem 3.3). We give a sequence of lemmas; some of them will also be used in section 4.

We denote, e.g., by $g_y^{(j)}(y(\mathcal{T}_{en}))z(\mathcal{T}_{en})$, $g_{(u,y)}^{(q)}(u(\mathcal{T}_{en}),y(\mathcal{T}_{en}))(v(\mathcal{T}_{en}^-),z(\mathcal{T}_{en}))$, the vectors in $\mathbb{R}^{N_b}$ of components $g_y^{(j)}(y(\tau))z(\tau)$, $g_{(u,y)}^{(q)}(u(\tau),y(\tau))(v(\tau^-),z(\tau))$, respectively, for $\tau\in\mathcal{T}_{en}$. By $g_y^{(0:q-1)}(y(\mathcal{T}_{en}))z(\mathcal{T}_{en})$ we denote the vector in $\mathbb{R}^{qN_b}$ of component $g_y^{(j)}(y(\tau))z(\tau)$, $0\le j\le q-1$, $\tau\in\mathcal{T}_{en}$.

LEMMA 3.7. *Let (u,y) be a shooting extremal satisfying* (A2$_q$)–(A4)*, with the set of shooting parameters $\theta_0=(p_0^*,\nu_{\mathcal{T}_{en}}^{1:q},\nu_{\mathcal{T}_{to}},\mathcal{T}_{en},\mathcal{T}_{ex},\mathcal{T}_{to})\in\Theta$, such that $\mathcal{F}(\theta_0)=0$ with the shooting mapping $\mathcal{F}$ defined in* (2.50)*. Then $\mathcal{F}$ is of class C^1 on a neighborhood Θ_0 of θ_0, and at the direction*

$$\omega:=(\pi_0^*,\gamma_{\mathcal{T}_{en}}^{1:q},\gamma_{\mathcal{T}_{to}},\sigma_{\mathcal{T}_{en}},\sigma_{\mathcal{T}_{ex}},\sigma_{\mathcal{T}_{to}})\in\Theta, \tag{3.25}$$

the vector $\mathcal{M}:=D\mathcal{F}(\theta_0)\omega$ can be split into $\mathcal{M}=(\mathcal{M}_{\mathcal{Q}}^*,\mathcal{M}_{\mathcal{T}}^*)^*$ given by

$$\mathcal{M}_{\mathcal{Q}}:=\begin{pmatrix}\pi(T)^*-\phi_{yy}(y(T))z(T)\\ g_y^{(0:q-1)}(y(\mathcal{T}_{en}))z(\mathcal{T}_{en})\\ g_y(y(\mathcal{T}_{to}))z(\mathcal{T}_{to})\end{pmatrix}, \tag{3.26}$$

$$\mathcal{M}_{\mathcal{T}}:=\begin{pmatrix}g_{(u,y)}^{(q)}(u(\mathcal{T}_{en}),y(\mathcal{T}_{en}))(v(\mathcal{T}_{en}^-),z(\mathcal{T}_{en}))+\sigma_{\mathcal{T}_{en}}\dfrac{\mathrm{d}}{\mathrm{d}t}g^{(q)}(u,y)|_{t=\mathcal{T}_{en}^-}\\ g_{(u,y)}^{(q)}(u(\mathcal{T}_{ex}),y(\mathcal{T}_{ex}))(v(\mathcal{T}_{ex}^+),z(\mathcal{T}_{ex}))+\sigma_{\mathcal{T}_{ex}}\dfrac{\mathrm{d}}{\mathrm{d}t}g^{(q)}(u,y)|_{t=\mathcal{T}_{ex}^+}\\ g_y^{(1)}(y(\mathcal{T}_{to}))z(\mathcal{T}_{to})+\sigma_{\mathcal{T}_{to}}\dfrac{\mathrm{d}}{\mathrm{d}t}g^{(1)}(y)|_{t=\mathcal{T}_{to}}\end{pmatrix}, \tag{3.27}$$

where (v,z,π,ζ), the linearized control, state, costate, and state constraint multipliers, are the solutions of (omitting arguments (u,y,p_q,η_q) and t)

$$\dot z=f_yz+f_uv \qquad \text{on } [0,T];\qquad z(0)=0, \tag{3.28}$$

$$-\dot\pi=\tilde H_{yy}z+\tilde H_{yu}v+\pi f_y+\zeta g_y^{(q)} \quad \text{on } [0,T]\setminus\mathcal{T}, \tag{3.29}$$

$$0=\tilde H_{uy}z+\tilde H_{uu}v+\pi f_u+\zeta g_u^{(q)} \quad \text{a.e. on } [0,T], \tag{3.30}$$

$$0=g_y^{(q)}z+g_u^{(q)}v \qquad \text{a.e. on } \mathcal{I}_b, \tag{3.31}$$

$$0=\zeta \qquad \text{on } [0,T]\setminus\mathcal{I}_b, \tag{3.32}$$

with initial conditions of π given by $\pi(0)=\pi_0$ and jump conditions of π given by

$$\begin{aligned}[\pi(\tau)] \;=\; &-\sum_{j=1}^{q}\nu_\tau^j z(\tau)^*g_{yy}^{(j-1)}(y(\tau))-\sum_{j=1}^{q}\gamma_\tau^j g_y^{(j-1)}(y(\tau))\\ &-\sigma_\tau\sum_{j=1}^{q-1}\nu_\tau^j g_y^{(j)}(y(\tau));\qquad \tau\in\mathcal{T}_{en},\end{aligned} \tag{3.33}$$

$$[\pi(\tau)] \;=\; 0;\qquad \tau\in\mathcal{T}_{ex}, \tag{3.34}$$

$$[\pi(\tau)] \;=\; -\nu_\tau z(\tau)^*g_{yy}(y(\tau))-\gamma_\tau g_y(y(\tau))-\sigma_\tau\nu_\tau g_y^{(1)}(y(\tau));\quad \tau\in\mathcal{T}_{to}. \tag{3.35}$$

Proof. We detail only how we obtain the jump conditions of the linearized costate π at entry times; the other equations are obvious. In view of (2.31), it is easy to check that the jump of π at $\tau \in \mathcal{T}_{en}$ is given by

$$[\pi(\tau)] = -\sum_{j=1}^{q} \nu_\tau^j z(\tau)^* g_{yy}^{(j-1)}(y(\tau)) - \sum_{j=1}^{q} \gamma_\tau^j g_y^{(j-1)}(y(\tau)) + \sigma_\tau \Delta_\tau,$$

where the vector of sensitivity coefficients Δ_τ on junction time is given by

$$\Delta_\tau = -\sum_{j=1}^{q} \nu_\tau^j g_{yy}^{(j-1)}(y(\tau)) f(u(\tau^-), y(\tau)) + [\tilde{H}_y(u(\tau), y(\tau), p_q(\tau), \eta_q(\tau))].$$

By continuity of u at junction times (Proposition 2.15) and by (2.31) we have (omitting argument τ and setting $\eta_q^+ = \eta_q(\tau^+)$)

$$\Delta_\tau = -\sum_{j=1}^{q} \nu_\tau^j g_{yy}^{(j-1)}(y) f(u,y) - \sum_{j=1}^{q} \nu_\tau^j g_y^{(j-1)}(y) f_y(u,y) + \eta_q^+ g_y^{(q)}(u,y).$$

Since $g_y^{(j)}(u,y) = g_{yy}^{(j-1)}(y) f(u,y) + g_y^{(j-1)}(y) f_y(u,y)$ for $j = 1, \dots, q$, and since by Proposition 2.15 we have $\eta_q(\tau^+) = \nu_\tau^q$, we obtain (3.33). □

We recall that a continuous quadratic form defined over a Hilbert space is a *Legendre form* (see, e.g., [17, 7]) if it is weakly lower semicontinuous and satisfies the following property: For all weakly convergent subsequences $(v_n) \subset L^2(0,T)$, $v_n \rightharpoonup v$, we have that $v_n \to v$ strongly if $Q(v_n) \to Q(v)$.

LEMMA 3.8. *Let (u,y) be a shooting extremal satisfying* (A2$_q$)–(A4). *For all $v \in \mathcal{V}$, define z_v as the (unique) solution in $\mathcal{Z}$ of the linearized state equation* (3.10), *and define the operator $\mathcal{A} : \mathcal{V} \to W := L^2(\mathcal{I}_b) \times \mathbb{R}^{qN_b} \times \mathbb{R}^{N_{to}}$ by*

$$\mathcal{A}v = \begin{pmatrix} (g_y^{(q)}(u(\cdot), y(\cdot)) z_v(\cdot) + g_u^{(q)}(u(\cdot), y(\cdot)) v(\cdot))|_{\mathcal{I}_b} \\ g_y^{(0:q-1)}(y(\mathcal{T}_{en})) z_v(\mathcal{T}_{en}) \\ g_y(y(\mathcal{T}_{to})) z_v(\mathcal{T}_{to}) \end{pmatrix}. \tag{3.36}$$

Then (i) *the continuous linear operator $\mathcal{A}$ is onto, and* (ii) *if in addition the second-order sufficient condition* (3.16) *holds, then there exists $\alpha > 0$ such that*

$$Q(v) := \mathcal{J}_q(v, z_v) \geq \alpha \|v\|_2^2, \quad \text{for all } v \in \operatorname{Ker} \mathcal{A}. \tag{3.37}$$

By $\varphi|_{\mathcal{I}_b}$, we denote the restriction to $\mathcal{I}_b$ of function φ defined over $[0,T]$.

Proof. The continuity of $\mathcal{A}$ follows from that of $\mathcal{V} \to \mathcal{Z}$, $v \mapsto z_v$. By (2.10) and Lemma 3.5, the range of the mapping $\mathcal{V} \to \mathcal{Z}$, $v \mapsto g_y(y(\cdot)) z_v(\cdot)$ is the subspace denoted by H_0^q of functions $\varphi \in H^q(0,T) = W^{q,2}(0,T)$ satisfying $\varphi^{(j)}(0) = 0$ for all $j = 0, \dots, q-1$. Point (i) follows since, by (A4), for all $(\psi(\cdot), b_{\mathcal{T}_{en}}^{1:q}, b_{\mathcal{T}_{to}}) \in W$, there exists $\varphi \in H_0^q$ such that $\varphi^{(q)}(t) = \psi(t)$ a.e. on $\mathcal{I}_b$, $\varphi^{(j-1)}(\mathcal{T}_{en}) = b_{\mathcal{T}_{en}}^j$, $j = 1, \dots, q$, and $\varphi(\mathcal{T}_{to}) = b_{\mathcal{T}_{to}}$.

By (A2$_q$), we can show that $Q(v)$ is a Legendre form over $L^2(0,T)$ (the proof is similar to that of Lemma 21 in [5]). By (3.16), we have $Q(v) > 0$ for all $v \in \operatorname{Ker} \mathcal{A} \backslash \{0\}$, which implies (3.37) by Lemma B.1. □

PROPOSITION 3.9. *Let (u,y) be a shooting extremal satisfying* (A2$_q$)–(A4) *and denote by $\theta_0 \in \Theta$ its set of shooting parameters. Assume that* (i) *the second-order*

sufficient condition (3.16) *is satisfied, and* (ii) *the following holds at junction times:*

$$\frac{\mathrm{d}}{\mathrm{d}t}g^{(q)}(u,y)|_{t=\tau^-} \neq 0 \text{ for all } \tau \in \mathcal{T}_{en}; \quad \frac{\mathrm{d}}{\mathrm{d}t}g^{(q)}(u,y)|_{t=\tau^+} \neq 0 \text{ for all } \tau \in \mathcal{T}_{ex}, \tag{3.38}$$

$$\frac{\mathrm{d}}{\mathrm{d}t}g^{(1)}(y)|_{t=\tau} \neq 0 \quad \text{for all } \tau \in \mathcal{T}_{to}. \tag{3.39}$$

Then the Jacobian $D\mathcal{F}(\theta_0)$ *of the shooting mapping is invertible, and for all* $\delta = (a_T, b^{1:q}_{\mathcal{T}_{en}}, b_{\mathcal{T}_{to}}, c_{\mathcal{T}_{en}}, c_{\mathcal{T}_{ex}}, c_{\mathcal{T}_{to}}) \in \Theta$, *the (unique) solution* $\omega \in \Theta$ *of* $D\mathcal{F}(\theta_0)\omega = \delta$, *with* ω *given by* (3.25), *is as follows. With the notation of Lemma* 3.8, *denote by* (v_δ, w_δ) *with* $w_\delta = (\zeta_\delta, \lambda^{1:q}_{\delta,\mathcal{T}_{en}}, \lambda_{\delta,\mathcal{T}_{to}})$ *the unique solution in* $L^2(0,T) \times W$ *of the first-order optimality system of the problem*

$$(\mathcal{P}^\delta) \qquad \min_{v\in\mathcal{V}} \quad \frac{1}{2}\mathcal{J}_q(v, z_v) \; + \; a_T^* z_v(T) \; + \; \sum_{\tau\in\mathcal{T}_{to}} c_\tau \nu_\tau \frac{g_y^{(1)}(y(\tau))z_v(\tau)}{\frac{\mathrm{d}}{\mathrm{d}t}g^{(1)}(y)|_{t=\tau}}, \tag{3.40}$$
$$\text{subject to} \qquad \mathcal{A}v = (0_{L_2(\mathcal{I}_b)}, b^{1:q}_{\mathcal{T}_{en}}, b_{\mathcal{T}_{to}})^*.$$

Then $\pi_0 = \pi_\delta(0)$, *where* π_δ *is the solution on* $[0,T]\backslash\mathcal{T}$ *of* (3.29) *with* $(v_\delta, \zeta_\delta, z_\delta := z_{v_\delta})$, *with final and jump conditions of* π_δ *being given by*

$$\pi_\delta(T) = z_\delta(T)^* \phi_{yy}(y(T)) + a_T^*, \tag{3.41}$$

$$-[\pi_\delta(\tau)] = \sum_{j=1}^{q} \nu_\tau^j z_\delta(\tau)^* g_{yy}^{(j-1)}(y(\tau)) + \sum_{j=1}^{q} \lambda^j_{\delta,\tau} g_y^{(j-1)}(y(\tau)), \quad \tau \in \mathcal{T}_{en}, \tag{3.42}$$

$$-[\pi_\delta(\tau)] = 0, \quad \tau \in \mathcal{T}_{ex}, \tag{3.43}$$

$$-[\pi_\delta(\tau)] = \nu_\tau z_\delta(\tau)^* g_{yy}(y(\tau)) \; + \; \lambda_{\delta,\tau} g_y(y(\tau))$$
$$- \nu_\tau z_\delta(\tau)^* \frac{g_y^{(1)}(y(\tau))^* g_y^{(1)}(y(\tau))}{\frac{\mathrm{d}}{\mathrm{d}t}g^{(1)}(y)|_{t=\tau}} + c_\tau \nu_\tau \frac{g_y^{(1)}(y(\tau))}{\frac{\mathrm{d}}{\mathrm{d}t}g^{(1)}(y)|_{t=\tau}}, \quad \tau \in \mathcal{T}_{to}, \tag{3.44}$$

and we have $\gamma_{\mathcal{T}_{to}} = \lambda_{\delta,\mathcal{T}_{to}}$,

$$\sigma_\tau = \frac{c_\tau - g_y^{(1)}(y(\tau))z_\delta(\tau)}{\frac{\mathrm{d}}{\mathrm{d}t}g^{(1)}(y)|_{t=\tau}}, \quad \tau \in \mathcal{T}_{to}, \tag{3.45}$$

$$\sigma_\tau = \frac{c_\tau - g^{(q)}_{(u,y)}(u(\tau), y(\tau))(v_\delta(\tau^+), z_\delta(\tau))}{\frac{\mathrm{d}}{\mathrm{d}t}g^{(q)}(u,y)|_{t=\tau^+}}, \quad \tau \in \mathcal{T}_{ex}, \tag{3.46}$$

$$\sigma_\tau = \frac{c_\tau - g^{(q)}_{(u,y)}(u(\tau), y(\tau))(v_\delta(\tau^-), z_\delta(\tau))}{\frac{\mathrm{d}}{\mathrm{d}t}g^{(q)}(u,y)|_{t=\tau^-}}, \quad \tau \in \mathcal{T}_{en}, \tag{3.47}$$

$$\gamma^1_\tau = \lambda^1_{\delta,\tau}, \quad \gamma^j_\tau \; = \; \lambda^j_{\delta,\tau} - \nu^{j-1}_\tau \sigma_\tau, \quad j = 2, \ldots, q, \quad \tau \in \mathcal{T}_{en}. \tag{3.48}$$

Note that $(v_\delta, \zeta_\delta, z_\delta, \pi_\delta)$ satisfies (3.28)–(3.32). It follows by $(\mathrm{A2}_q)$ and (2.10) that $v_\delta, \zeta_\delta \in PC^q_{\mathcal{T}}[0,T]$, and hence v_δ has limits when $t \to \tau^-$ and $t \to \tau^+$ for τ in, respectively, $\mathcal{T}_{en}$ and $\mathcal{T}_{ex}$, so (3.46)–(3.47) make sense.

REMARK 3.10. Note that (3.38) is equivalent to the discontinuity of $\dot{u}$ at entry/exit points and that, when $q = 1, 2$, (3.7) implies (3.38) since $\hat{q} = q$.

REMARK 3.11. The above proposition is an explicit elimination property, valid for any order $q \geq 1$, that enables us to express the solution ω of $D\mathcal{F}(\theta_0)\omega = \delta$ as a function of the optimal solution and multipliers of the quadratic problem $(\mathcal{P}^\delta)$, *independent*

of the variations of junction times. In the case $q = 1$, the term in the factor of the variation of entry time σ_τ in (3.33) is zero so that Lemma 3.9 is nothing but the block decoupling property of the Jacobian already established in [23]. In the case $q \geq 2$, our result differs from the one in [24] since its authors use a quadratic problem depending on the variation of the entry point, leading to an additional assumption, (A.11).

Proof. Let $\delta \in \Theta$. By (i) and Lemma 3.8, Lemma B.2 (with $r = 0$) implies that the first-order optimality system of $(\mathcal{P}^\delta)$ has a unique solution and multipliers. One can easily check that (3.28)–(3.32) and (3.42)–(3.44), together with (3.41) and

$$g_y^{(0:q-1)}(y(\mathcal{T}_{en}))z_\delta(\mathcal{T}_{en}) = b^{1:q}_{\mathcal{T}_{en}}, \qquad g_y(y(\mathcal{T}_{to}))z_\delta(\mathcal{T}_{to}) = b_{\mathcal{T}_{to}}, \tag{3.49}$$

constitute the first-order optimality system of $(\mathcal{P}_\delta)$, with $\lambda^{1:q}_{\delta,\mathcal{T}_{en}}$ and $\lambda_{\delta,\mathcal{T}_{to}}$ the multipliers associated with (3.49), and thus have a unique solution $(v_\delta, z_\delta, \pi_\delta, \zeta_\delta, \lambda^{1:q}_{\delta,\mathcal{T}_{en}}, \lambda_{\delta,\mathcal{T}_{to}})$.

By (ii), define now $\sigma_\mathcal{T}$ by (3.45)–(3.47), and let $\gamma^{1:q}_{\mathcal{T}_{en}}$ and $\gamma_{\mathcal{T}_{to}}$ be related to $\lambda^{1:q}_{\delta,\mathcal{T}_{en}}$ and $\lambda_{\delta,\mathcal{T}_{to}}$ by the invertible relations (3.48) and $\gamma_{\mathcal{T}_{to}} = \lambda_{\delta,\mathcal{T}_{to}}$. Using (3.45) and (3.48) in, respectively, (3.44) and (3.42), it follows that the system of equations (3.28)–(3.32), (3.33)–(3.35), (3.41), (3.49), and (3.45)–(3.47) has a unique solution $(v_\delta, z_\delta, \pi_\delta, \zeta_\delta, \gamma^{1:q}_{\mathcal{T}_{en}}, \gamma_{\mathcal{T}_{to}}, \sigma_\mathcal{T})$. With Lemma 3.7, this implies that $D\mathcal{F}(\theta_0)\omega = \delta$ iff $\pi_0 = \pi_\delta(0)$, and the remaining variables of ω are determined by (3.45)–(3.48). Lipschitz continuity of ω w.r.t. δ is obtained as an easy consequence of Lemma B.2 and the above relations. ∎

Proof of Theorem 3.3. The proof is organized as follows. We first show the sufficiency of the conditions (i) and (ii) for the well-posedness of the shooting algorithm, which is an easy consequence of the above lemmas. After that we show that (i), and then (ii), is also necessary.

Since (A5)(i) implies, by Lemma 3.1, that (3.7) holds, (3.38) is satisfied when $q = 1, 2$ (see Remark 3.10) or trivially when the trajectory (u, y) has no boundary arc, i.e., $\mathcal{T}_{en} = \mathcal{T}_{ex} = \emptyset$. With (A6) and the second-order sufficient condition (3.16), the invertibility of the Jacobian of the shooting mapping follows from Proposition 3.9.

Let us now show the converse. Assume first that (i) does not hold; i.e., $q \geq 3$ and (u, y) has a boundary arc. By Proposition 2.5(i), $\dot{u}$ is continuous at junction times τ_{en} and τ_{ex}. Therefore, the function $\frac{\mathrm{d}}{\mathrm{d}t} g^{(q)}(u(t), y(t))$ depending on $(y, u, \dot{u})$ is also continuous at entry and exit times and vanishes on the boundary arc, so that (3.38) *does not hold* at any of the regular entry/exit times. Then it is easily seen by Lemma 3.7 that we can find some nonzero $\tilde{\omega} \in \Theta$ such that $D\mathcal{F}(\theta_0)\tilde{\omega} = 0$. Indeed, take, e.g., $\tilde{\sigma}_\tau \neq 0$ for $\tau \in \mathcal{T}_{ex}$, and all other components of $\tilde{\omega}$ equal to zero. It follows that the Jacobian of the shooting mapping is singular.

Assume now that (i) is satisfied but (ii) is not. Since (u, y) is a local solution of $(\mathcal{P})$, by Theorem 3.2 the *second-order necessary condition* (3.15) is satisfied. This says that $(v, z) = 0$ is a solution of problem (PQ_q); therefore the value of (PQ_q) is zero, the infimum is attained, and solutions of this problem do exist. If $(v, z) = 0$ is not the unique solution, that is, if the second-order sufficient condition (3.16) does not hold, this means that there exists another optimal solution $(\tilde{v}_0, \tilde{z}_0) \neq 0$ of (PQ_q), and hence a nonzero solution of its first-order optimality conditions (3.10)–(3.13), (3.28)–(3.32), with final and jump conditions of the associated costate $\tilde{\pi}_0$ given by (3.41)–(3.44) with $a_T = 0$ and $c_{\mathcal{T}_{to}} = 0$, and multipliers $(\tilde{\lambda}^{1:q}_{\mathcal{T}_{en}}, \tilde{\lambda}_{\mathcal{T}_{to}})$ associated, respectively, with (3.11) and (3.13).

Setting $\tilde{\pi}_0 := \tilde{\pi}_0(0)$, we claim that $(\tilde{\pi}_0, \tilde{\lambda}^{1:q}_{\mathcal{T}_{en}}, \tilde{\lambda}_{\mathcal{T}_{to}}) \neq 0$. Indeed, suppose that all of them were zero. Eliminating v by (3.30) as a linear function of (z, π), and integrating

from $(z(0), \pi(0)) = 0$ over the first arc the linear differential equations (3.28)–(3.29), we would have $(z, \pi, v, \zeta) = 0$, until the first junction time. If all the jump parameters $\tilde{\lambda}^j_{\mathcal{T}_{en}}$ and $\tilde{\lambda}_{\mathcal{T}_{to}}$ are equal to zero, and (v, ζ) is given by (3.30)–(3.31) on boundary arcs, we obtain $(\tilde{z}_0, \tilde{\pi}_0, \tilde{v}_0, \tilde{\zeta}_0) = 0$ over $[0, T]$, which leads to a contradiction.

Now let $\tilde{\gamma}_{\mathcal{T}_{to}} = \tilde{\lambda}_{\mathcal{T}_{to}}$ and $(\tilde{\sigma}_{\mathcal{T}}, \tilde{\gamma}^{1:q}_{\mathcal{T}_{en}})$ be solution of (3.45)–(3.48) with $c_{\mathcal{T}} = 0$. We have $\tilde{\omega} := (\tilde{\pi}_0, \tilde{\gamma}^{1:q}_{\mathcal{T}_{en}}, \tilde{\gamma}_{\mathcal{T}_{to}}, \tilde{\sigma}_{\mathcal{T}_{en}}, \tilde{\sigma}_{\mathcal{T}_{ex}}, \tilde{\sigma}_{\mathcal{T}_{to}}) \neq 0$, and by Lemma 3.7, $D\mathcal{F}(\theta_0)\tilde{\omega} = 0$. Therefore, the Jacobian of the shooting mapping is singular, which achieves the proof. ∎

4. Sensitivity analysis without strict complementarity at touch points. In this section, we show how to conduct a sensitivity analysis, removing the strict complementarity hypothesis for touch points.

Let us first note that our framework allows us to deal with nonautonomous problems (i.e., when the data f, ℓ, g depend on t) as well, by introducing an additional state variable equal to the time, provided that the data are sufficiently smooth w.r.t. t. When the original problem (2.1)–(2.3) is autonomous, we still can add the time as a state variable. This transformation affects neither the assumptions nor the first- and second-order optimality conditions in sections 2 and 3 and the condition (ii) of Theorem 4.3. Therefore, we will assume w.l.o.g. throughout this section that the problem $(\mathcal{P})$ is written such that the last component of the state variable y_n satisfies

$$\dot{y}_n(t) = 1 \qquad \text{for all } t \in [0, T]; \qquad y_n(0) = 0$$

(i.e., $y_n(t) = t$, for all t). The reason for doing so is to consider in our stability analysis a wide class of perturbations, including nonautonomous perturbations (and possibly a nonautonomous original problem). Allowing nonautonomous perturbations is indeed needed to obtain the equivalence in Theorem 4.3, even when the original problem is autonomous. We shall not repeat this assumption, which intervenes only in the proof of (i) ⇒ (ii) in Theorem 4.3.

Let M_0 be an open subset of a Banach space M (the perturbation space). Consider, for $\mu \in M_0$, the family of perturbed optimal control problems,

$$(\mathcal{P}^\mu) \qquad \min_{(u,y)\in\mathcal{U}\times\mathcal{Y}} \quad \int_0^T \tilde{\ell}(u(t), y(t), \mu)\mathrm{d}t + \tilde{\phi}(y(T), \mu) \quad \text{subject to}$$
$$\dot{y} = \tilde{f}(u(t), y(t), \mu), \quad \text{a.e. } t \in [0, T]; \quad y(0) = \tilde{y}_0(\mu),$$
$$\tilde{g}(y(t), \mu) \leq 0 \quad \text{for all } t \in [0, T],$$

where $\tilde{\ell} : \mathbb{R} \times \mathbb{R}^n \times M_0 \to \mathbb{R}$, $\tilde{\phi} : \mathbb{R}^n \times M_0 \to \mathbb{R}$, $\tilde{f} : \mathbb{R} \times \mathbb{R}^n \times M_0 \to \mathbb{R}^n$, $\tilde{g} : \mathbb{R}^n \times M_0 \to \mathbb{R}$, and $\tilde{y}_0 : M_0 \to \mathbb{R}^n$ are at least C^2 mappings. We denote $y^\mu_0 := \tilde{y}_0(\mu)$, $\ell^\mu(u, y) := \tilde{\ell}(u, y, \mu)$, etc., and identify $(\ell^\mu, \phi^\mu, f^\mu, g^\mu, y^\mu_0)$ with problem $(\mathcal{P}^\mu)$.

We say that $(\mathcal{P}^\mu)$ is a *q-stable extension* of $(\mathcal{P})$ if (i) there exists $\mu_0 \in M_0$ such that $(\mathcal{P}^{\mu_0}) = (\mathcal{P})$ (i.e., $\ell^{\mu_0} \equiv \ell$, etc.); (ii) the mappings $\tilde{\ell}, \tilde{\phi}, \tilde{f}, \tilde{g}$ are C^{2q}, where q is the order of the state constraint of problem $(\mathcal{P})$; (iii) the state constraints are of order q for all $\mu \in M_0$; and (iv) the mappings f^μ are Lipschitz continuous over $\mathbb{R} \times \mathbb{R}^n$, uniformly over $\mu \in M_0$.

For each $\mu \in M_0$, problem $(\mathcal{P}^\mu)$ satisfies (A0); taking if necessary a smaller neighborhood of μ_0, we may assume that (A1) holds as well. Given $(\mu, u, v) \in M_0 \times \mathcal{U} \times \mathcal{V}$, denote by $(y^\mu_u, z^\mu_{u,v}) \in \mathcal{Y} \times \mathcal{Z}$ the state and linearized state solutions of

$$\dot{y}^\mu_u = f^\mu(u, y^\mu_u); \quad y^\mu_u(0) = y^\mu_0, \tag{4.1}$$
$$\dot{z}^\mu_{u,v} = f^\mu_y(u, y^\mu_u) z^\mu_{u,v} + f^\mu_u(u, y^\mu_u) v; \quad z^\mu_{u,v}(0) = 0, \tag{4.2}$$

and let $J^\mu(u) := \int_0^T \ell^\mu(u(t), y_u^\mu(t))\mathrm{d}t + \phi^\mu(y_u^\mu(T))$.

In what follows, $(\bar u, \bar y)$ denotes a Pontryagin extremal of $(\mathcal{P}) \equiv (\mathcal{P}^{\mu_0})$, with associated multipliers $(\bar p, \bar\eta)$. We denote by $\theta_0 \in \Theta$ the vector of shooting parameters associated with $(\bar u, \bar y)$.

We say that a feasible trajectory (u, y) for $(\mathcal{P}^\mu)$ has a *neighboring structure* to that of $(\bar u, \bar y)$ if the structure of (u, y) (number and order of boundary arcs and touch points) differs from that of $(\bar u, \bar y)$ only by possibly removing some nonessential touch points. With a trajectory (u, y) having a neighboring structure to that of $(\bar u, \bar y)$ is naturally associated a set of shooting parameters $\hat\theta$, but the latter may have a lower dimension than θ_0 if (u, y) has (strictly) fewer touch points than $(\bar u, \bar y)$. We can show (and this is precisely the idea of reduction methods; see further) that when $\|u - \bar u\|_\infty$ and $\|\mu - \mu_0\|$ are small enough and $q \geq 2$, for every touch point τ_{to} of $(\bar u, \bar y)$ satisfying (3.8), the function $g^\mu(y(\cdot))$ reaches its maximum over a small neighborhood of τ_{to} at a unique time denoted τ'_{to}. Then adding to $\hat\theta$ this time τ'_{to} and a zero jump parameter, and doing so for each touch point of $(\bar u, \bar y)$ that is inactive for (u, y), we obtain an *augmented* vector of shooting parameters θ having the same dimension as θ_0. Therefore the following definition makes sense.

Definition 4.1. *We say that the* uniform second-order quadratic growth *condition holds if, for every q-stable extension $(\mathcal{P}^\mu)$ there exist $c > 0$ and open neighborhoods $V_\mu \times V_u \times V_\theta$ of $(\mu_0, \bar u, \theta_0)$ in $M_0 \times \mathcal{U} \times \Theta$, such that for all $\mu \in V_\mu$, there exists a unique stationary point $(u^\mu, y^\mu := y^\mu_{u^\mu}) \in V_u \times \mathcal{Y}$ of $(\mathcal{P}^\mu)$ having a neighboring structure to that of $(\bar u, \bar y)$ with its augmented shooting parameters in V_θ, and that point satisfies*

$$J^\mu(u) \geq J^\mu(u^\mu) + c\|u - u^\mu\|_2^2, \qquad \text{for all } u \in V_u, \quad g^\mu(y_u^\mu) \leq 0 \text{ on } [0, T]. \tag{4.3}$$

As a consequence of the definition of the uniform growth condition, we have $\bar u = u^{\mu_0}$ and $\bar y = y^{\mu_0}$.

Note that in the uniform growth condition (4.3), the neighborhood (in L^∞) on which u^μ satisfies the quadratic growth condition is independent of μ. Our definition of uniform quadratic growth is different from the one in [7, section 5.1], since the latter implies the local uniqueness of solutions of the first-order optimality system (stationary points). Here, since our stability analysis is based on the shooting formulation, we can argue only the uniqueness of the stationary point among the feasible trajectories that have their structure and shooting parameters "in the neighborhood" of those of $(\bar u, \bar y)$. The uniqueness of the stationary point, in a certain sense, is needed to prove the implication (i) $\Rightarrow$ (ii) in Theorem 4.3 below.

We will use the assumption below, which is a modification of (A5).

(A5′) (i) If $q \leq 2$, the following strengthening of (3.3)–(3.4) holds:

$$\exists \beta > 0 \qquad (-1)^q \frac{\mathrm{d}^q}{\mathrm{d}t^q} \bar\eta_q(t) \geq \beta \qquad \text{for all } t \in \operatorname{int} \mathcal{I}_b; \tag{4.4}$$

if $q = 2$, (3.5) holds; if $q > 2$, the trajectory $(\bar u, \bar y)$ has no boundary arc.

(ii) If $q = 1$, $(\bar u, \bar y)$ has no (nonessential) touch points.

Assumption (A5′)(i) is a strengthening of (A5)(i). It requires, in addition to (A5)(i), *uniform* strict complementarity on boundary arcs, which is stronger than (3.3) (and implies (3.4)), and that $(\bar u, \bar y)$ have no boundary arc if $q \geq 3$. Assumption (A5′)(ii) is weaker than (A5)(ii) since it allows nonessential touch points for constraints of order $q \geq 2$ only.

Define the set of increasing times in $(0,T)$ of cardinal N as

$$IT_N := \{\tau \in \mathbb{R}^N;\ 0 < \tau_1 < \cdots < \tau_N < T\}. \tag{4.5}$$

Set $\tau_0 := 0$ and $\tau_{N+1} := T$. Given $\mathcal{S} \subset IT_N$, we have a natural isomorphism between $PC^k_{\mathcal{S}}[0,T]$ and $C^k([0,1];\mathbb{R}^{N+1})$, defined by

$$\left\{\begin{array}{ll} \hat\varphi_i(s) = & \varphi(\tau_i + (\tau_{i+1}-\tau_i)s) \quad \text{for all } \ s \in (0,1), \\ \hat\varphi_i(0) = & \varphi(\tau_i^+),\ \hat\varphi_i(1) = \varphi(\tau_{i+1}^-), \end{array}\right. \qquad i = 0,\dots,N. \tag{4.6}$$

We may therefore identify the set $PC^k_N[0,T] := \cup\{PC^k_{\mathcal{S}}[0,T]; \mathcal{S} \in IT_N\}$ of all possible N-piecewise k-times continuously differentiable functions, with $C^k([0,1];\mathbb{R}^{N+1}) \times IT_N$. The corresponding notion of convergence follows: A sequence $\varphi^n \in PC^k_{\mathcal{S}^n}[0,T]$ converges to $\varphi \in PC^k_{\mathcal{S}}[0,T]$ if $\mathcal{S}^n \to \mathcal{S}$ in $\mathbb{R}^N$ and $\hat\varphi^n \to \hat\varphi$ in $C^k([0,1];\mathbb{R}^{N+1})$. Similarly, a mapping defined over an open subset W of a Banach space, $W \to PC^k_N$, $w \mapsto \varphi^w \in PC^k_{\mathcal{S}^w}$ is of class C^k if the mapping $W \to C^k([0,1];\mathbb{R}^{N+1}) \times \mathbb{R}^N$, $w \mapsto (\hat\varphi^w, \mathcal{S}_w)$ is C^k. We denote by $PC^{k,r}_N[0,T] = PC^k_N[0,T] \cap C^r[0,T]$ the subset of $PC^k_N[0,T]$ of functions having continuous derivatives on $[0,T]$ until order $r \geq 0$. The next lemma is elementary and will be used at the end of this section.

LEMMA 4.2. *Let W be an open subset of a Banach space, and $W \to PC^{1,0}_N$, $w \mapsto \varphi^w \in PC^{1,0}_{\mathcal{S}^w}$ a C^1 mapping. Then the mapping $w \mapsto \varphi^w$ is C^1 in $L^r(0,T)$ for all $1 \leq r < \infty$. More precisely, for $w \in W$, let $\mathcal{S}^w := \{\tau_1^w < \cdots < \tau_N^w\}$ and denote by $(\hat\xi^w, \sigma^w)$ the directional derivative in $C^1([0,1];\mathbb{R}^{N+1}) \times IT_N$ of the mapping $w \mapsto (\hat\varphi^w, \tau^w)$ at point w in direction $\delta w \in W$. Then the directional derivative $\tilde\xi^w$ in $L^r(0,T)$ is given by*

$$\tilde\xi^w(t) = \hat\xi_i^w\left(\frac{t-\tau_i^w}{\tau_{i+1}^w - \tau_i^w}\right) - \dot\varphi^w(t)\left(\sigma_i^w + \frac{t-\tau_i^w}{\tau_{i+1}^w-\tau_i^w}(\sigma_{i+1}^w - \sigma_i^w)\right) \text{ on } (\tau_i^w, \tau_{i+1}^w).$$

By Proposition 2.5, a regular Pontryagin extremal and its multipliers $(u^\mu, y^\mu, p^\mu, \eta^\mu)$ satisfying (A2)–(A4) belong to the product space

$$\mathcal{X}_{\mathcal{S}} := PC^{q,0}_{\mathcal{S}}[0,T] \times PC^{q+1,1}_{\mathcal{S}}([0,T];\mathbb{R}^n) \times PC^1_{\mathcal{S}}([0,T];\mathbb{R}^{n*}) \times PC^1_{\mathcal{S}}[0,T], \tag{4.7}$$

with here $\mathcal{S} = \mathcal{T}$, which is the finite set of its junction times assumed to be of cardinal N. So let us define the union $\mathcal{X}_N$ of all such spaces, and define as well some other sets needed later:

$$\begin{aligned} &\mathcal{X}_N := \cup\{\mathcal{X}_{\mathcal{S}};\ \mathcal{S} \in IT_N\}, \\ &\mathcal{X}^q_{\mathcal{S}} := PC^q_{\mathcal{S}}[0,T] \times PC^{q+1,0}_{\mathcal{S}}([0,T];\mathbb{R}^n) \times PC^{q+1}_{\mathcal{S}}([0,T];\mathbb{R}^{n*}) \times PC^q_{\mathcal{S}}[0,T], \\ &\mathcal{X}^1_{\mathcal{S}} := PC^q_{\mathcal{S}}[0,T] \times PC^{q+1,0}_{\mathcal{S}}([0,T];\mathbb{R}^n) \times PC^1_{\mathcal{S}}([0,T];\mathbb{R}^{n*}) \times PC^1_{\mathcal{S}}[0,T], \\ &\mathcal{X}^q_N := \cup\{\mathcal{X}^q_{\mathcal{S}};\ \mathcal{S} \in IT_N\}, \qquad \mathcal{X}^1_N := \cup\{\mathcal{X}^1_{\mathcal{S}};\ \mathcal{S} \in IT_N\}. \end{aligned}$$

The main result of this section is the next theorem, which gives stability results for the optimal control problem $(\mathcal{P})$ without assuming strict complementarity at the touch points. Therefore we cannot directly apply the implicit function theorem as it was done in [23, 24] and our section 3.

THEOREM 4.3. *Let $(\bar u, \bar y)$ be a Pontryagin extremal of $(\mathcal{P})$ satisfying* (A2)–(A4), (A5′) and (A6). *Then the following statements are equivalent:*

(i) *The uniform second-order quadratic growth condition (Definition* 4.1*) holds. Denote by $u^\mu \in V_u$ the solution of* (4.3) *for $\mu \in V_\mu$, and set $y^\mu := y^\mu_{u^\mu}$. With (u^μ, y^μ)*

are associated a unique costate p^μ *and state constraint multiplier* η^μ*, and the mapping* $\mu \mapsto (u^\mu, y^\mu, p^\mu, \eta^\mu) \in \mathcal{X}_N$ *is Lipschitz continuous over* V_μ.

(ii) *The following strong second-order sufficient condition holds:*

$$\begin{aligned} &\mathcal{J}(v,z) > 0 \text{ for all } (v,z) \in \mathcal{V} \times \mathcal{Z} \setminus \{0\} \text{ satisfying (3.10) and} \\ &g_y(\bar{y}(t))z(t) = 0 \quad \text{for all } t \in \mathcal{I}_b \cup \mathcal{T}_{to}^{ess}. \end{aligned} \tag{4.8}$$

REMARK 4.4. Note that condition (ii) is stronger than the following second-order characterization of quadratic growth (3.2) (see [5]):

$$\begin{aligned} &\mathcal{J}(v,z) > 0 \text{ for all } (v,z) \in \mathcal{V} \times \mathcal{Z} \setminus \{0\} \text{ satisfying (3.10), (4.8), and} \\ &g_y(\bar{y}(\tau))z(\tau) \le 0 \quad \text{for all } \tau \in \mathcal{T}_{to} \setminus \mathcal{T}_{to}^{ess}. \end{aligned}$$

We need the following notation. Denote by $\mathcal{T}_{to}^{nes} := \mathcal{T}_{to} \setminus \mathcal{T}_{to}^{ess}$ the subset of *nonessential touch points* of the trajectory $(\bar{u}, \bar{y})$. For μ close to μ_0, let $\mathcal{F}(\cdot, \mu)$ be the shooting mapping (2.50) for problem $(\mathcal{P}^\mu)$, with the *same structure* as the trajectory $(\bar{u}, \bar{y})$, i.e., the same number of boundary arcs and touch points and the same order of their occurrence w.r.t. time. Thus nonessential touch points are present in the shooting mapping and may be active or inactive for the perturbed problem. Let $\bar{N} := n + (q+2)N_b + 2N_{to}$ denote the dimension of the shooting mapping, with $N_b = \operatorname{Card} \mathcal{T}_{en} = \operatorname{Card} \mathcal{T}_{ex}$ and $N_{to} = \operatorname{Card} \mathcal{T}_{to}$, and denote by N_0 the cardinal of $\mathcal{T}_{to}^{nes}$, the set of nonessential touch points. Split $\mathcal{F}$ into two components such that $\mathcal{F}(\cdot, \mu) = (\Phi(\cdot, \mu)^*, \Psi(\cdot, \mu)^*)^*$ and Ψ corresponds to the component $g^\mu(y(\mathcal{T}_{to}^{nes})) \in \mathbb{R}^{N_0}$. We consider the following problem for μ close to μ_0: Find

$$\theta = (p_0^{\mu *}, \nu_{\mathcal{T}_{en}}^{\mu,1:q}, \nu_{\mathcal{T}_{to}^{ess}}^{\mu}, \nu_{\mathcal{T}_{to}^{nes}}^{\mu}, \mathcal{T}_{en}^{\mu}, \mathcal{T}_{ex}^{\mu}, \mathcal{T}_{to}^{\mu,ess}, \mathcal{T}_{to}^{\mu,nes}) \in \Theta \tag{4.9}$$

such that

$$\Phi(\theta, \mu) = 0; \quad \Psi(\theta, \mu) \in \mathbb{R}_-^{N_0} \cap (\nu_{\mathcal{T}_{to}^{nes}}^{\mu})^\perp; \quad \nu_{\mathcal{T}_{to}^{nes}}^{\mu} \in \mathbb{R}_+^{N_0}. \tag{4.10}$$

In (4.10), we express the complementarity condition for nonessential touch points only. The complementarity condition at essential touch points and boundary arcs, where strict complementarity is satisfied, will hold by continuity, since we perform a local analysis (see further Lemmas 4.6–4.7).

The point θ_0, solution of (4.10) for $\mu = \mu_0$, is said to be *strongly regular* (see Robinson [28]) if there exists a neighborhood $V_\theta' \times V_\delta$ in $\mathbb{R}^{\bar{N}} \times \mathbb{R}^{\bar{N}}$ of $(\theta_0, 0)$ such that for all $\delta \in V_\delta$, $\delta = (\delta_1, \delta_2) \in \mathbb{R}^{\bar{N}-N_0} \times \mathbb{R}^{N_0}$, there exists a unique solution θ in V_θ' of

$$\begin{aligned} &D_\theta \Phi(\theta_0, \mu_0)(\theta - \theta_0) - \delta_1 = 0, \\ &D_\theta \Psi(\theta_0, \mu_0)(\theta - \theta_0) - \delta_2 \in \mathbb{R}_-^{N_0} \cap \nu_{\mathcal{T}_{to}^{nes}}^{\perp}; \quad \nu_{\mathcal{T}_{to}^{nes}} \in \mathbb{R}_+^{N_0}, \end{aligned} \tag{4.11}$$

and the mapping $\Xi : \delta \mapsto \theta(\delta)$ is Lipschitz continuous over V_δ. If θ_0 is strongly regular, then by [28], there exists a neighborhood $V_\theta \times V_\mu$ of (θ_0, μ_0) such that for each $\mu \in V_\mu$, (4.10) has in V_θ a unique solution θ^μ and there exists $\kappa > 0$ such that for all $\mu, \mu' \in V_\mu$,

$$|\theta^\mu - \theta^{\mu'}| \le \kappa \|\mu - \mu'\|. \tag{4.12}$$

In addition, the following expansion of θ^μ holds (see [7, eq. (5.41), p. 413]):

$$\theta^\mu = \Xi(-D_\mu \mathcal{F}(\theta_0, \mu_0)(\mu - \mu_0)) + o(\|\mu - \mu_0\|). \tag{4.13}$$

4.1. Stability analysis (proof of Theorem 4.3). The first step in the proof of (ii) ⇒ (i) in Theorem 4.3 is to show that (ii) implies the strong regularity property (Lemma 4.5). The existence of a (locally unique) shooting extremal (u^μ, y^μ) for problem $(\mathcal{P}^\mu)$ having its shooting parameters in the neighborhood of those of $(\bar u, \bar y)$ follows (Lemma 4.6). The next step is to check the additional conditions of Corollary 2.17, implying that (u^μ, y^μ) is a stationary point (Lemma 4.7). We end the proof by checking that u^μ satisfies the uniform quadratic growth condition (4.3) (Lemmas 4.8–4.9).

LEMMA 4.5. *Under the assumptions of Theorem* 4.3*, condition* (ii) *of Theorem* 4.3 *implies that* θ_0 *is a strongly regular solution of* (4.10) *for* $\mu = \mu_0$.

Proof. The proof is somewhat similar to that of Proposition 3.9. Let $\delta = (\delta_1, \delta_2) \in \mathbb{R}^{\bar N - N_0} \times \mathbb{R}^{N_0}$ with

$$\delta_1 = (a_T, b^{1:q}_{\mathcal{T}_{en}}, b_{\mathcal{T}^{ess}_{to}}, c_{\mathcal{T}_{en}}, c_{\mathcal{T}_{ex}}, c_{\mathcal{T}^{ess}_{to}}, c_{\mathcal{T}^{nes}_{to}}); \quad \delta_2 = b_{\mathcal{T}^{nes}_{to}}.$$

Let us show that there exists a unique $\omega \in \Theta$,

$$\omega = (\pi^*_0, \gamma^{1:q}_{\mathcal{T}_{en}}, \gamma_{\mathcal{T}^{ess}_{to}}, \gamma_{\mathcal{T}^{nes}_{to}}, \sigma_{\mathcal{T}_{en}}, \sigma_{\mathcal{T}_{ex}}, \sigma_{\mathcal{T}^{ess}_{to}}, \sigma_{\mathcal{T}^{nes}_{to}}),$$

solution of the following relation, equivalent to (4.11) with $\omega = \theta - \theta_0$:

$$\begin{aligned} &D_\theta \Phi(\theta_0, \mu_0)\omega - \delta_1 = 0, \\ &D_\theta \Psi(\theta_0, \mu_0)\omega - \delta_2 \in \mathbb{R}^{N_0}_- \cap \gamma^\perp_{\mathcal{T}^{nes}_{to}}; \quad \gamma_{\mathcal{T}^{nes}_{to}} \in \mathbb{R}^{N_0}_+. \end{aligned} \tag{4.14}$$

Consider the following linear quadratic optimal control problem:

$$\begin{aligned} (\mathcal{P}^\delta) \qquad \min_{v \in \mathcal{V}} \quad & \frac{1}{2}\mathcal{J}_q(v, z_v) \;+\; a_T^* z_v(T) \;+\; \sum_{\tau \in \mathcal{T}_{to}} c_\tau \nu_\tau \frac{g_y^{(1)}(y(\tau)) z_v(\tau)}{\frac{\mathrm{d}}{\mathrm{d}t} g^{(1)}(y)|_{t=\tau}} \\ \text{subject to} \quad & Av \;=\; (0_{L_2(\mathcal{I}_b)}, b^{1:q}_{\mathcal{T}_{en}}, b_{\mathcal{T}^{ess}_{to}})^*; \; Bv \;\le\; b_{\mathcal{T}^{nes}_{to}}, \end{aligned} \tag{4.15}$$

where $\mathcal{J}_q(v, z_v)$ is defined by (3.9) and the linear operators A, B are defined by

$$\begin{aligned} Av \;&:=\; \begin{pmatrix} (g_y^{(q)}(u(\cdot), y(\cdot)) z_v(\cdot) + g_u^{(q)}(u(\cdot), y(\cdot)) v(\cdot))|_{\mathcal{I}_b} \\ g_y^{(0:q-1)}(y(\mathcal{T}_{en})) z_v(\mathcal{T}_{en}) \\ g_y(y(\mathcal{T}^{ess}_{to})) z_v(\mathcal{T}^{ess}_{to}) \end{pmatrix}, \\ Bv \;&:=\; g_y(y(\mathcal{T}^{nes}_{to})) z_v(\mathcal{T}^{nes}_{to}). \end{aligned} \tag{4.16}$$

Being equal to $\mathcal{A}$ defined in (3.36), the operator (A, B) is onto by Lemma 3.8. By Lemma B.1, the Legendre form $\bar Q(v) := \mathcal{J}_q(v, z_v)$ is coercive over $\operatorname{Ker} A$. It follows from Lemma B.2 that the first-order optimality system of problem $(\mathcal{P}^\delta)$ has a unique solution $v_\delta \in \mathcal{V}$, with a unique associated Lagrange multiplier $(\zeta_\delta, \lambda^{1:q}_{\delta, \mathcal{T}_{en}}, \lambda_{\delta, \mathcal{T}^{ess}_{to}}, \lambda_{\delta, \mathcal{T}^{nes}_{to}})$ in $L^2(\mathcal{I}_b) \times \mathbb{R}^{qN_b} \times \mathbb{R}^{N_{to} - N_0} \times \mathbb{R}^{N_0}$, and the mapping $\delta \mapsto (v_\delta, \zeta_\delta, \lambda^{1:q}_{\delta, \mathcal{T}_{en}}, \lambda_{\delta, \mathcal{T}^{ess}_{to}}, \lambda_{\delta, \mathcal{T}^{nes}_{to}})$ is Lipschitz continuous. Now, defining as in Proposition 3.9 $\sigma_{\mathcal{T}}$ by (3.45)–(3.47) and defining $\gamma^{1:q}_{\mathcal{T}_{en}}$, $\gamma_{\mathcal{T}^{ess}_{to}}$, $\gamma_{\mathcal{T}^{nes}_{to}}$ by the invertible relations (3.48), $\gamma_{\mathcal{T}^{ess}_{to}} = \lambda_{\delta, \mathcal{T}^{ess}_{to}}$ and $\gamma_{\mathcal{T}^{nes}_{to}} = \lambda_{\delta, \mathcal{T}^{nes}_{to}}$, this implies that the system of equations (3.28)–(3.32), (3.33)–(3.35), (3.41), (3.45)–(3.47), together with the constraints and complementarity conditions of $(\mathcal{P}^\delta)$

$$\begin{gathered} g_y^{(0:q-1)}(y(\mathcal{T}_{en})) z_\delta(\mathcal{T}_{en}) = b^{1:q}_{\mathcal{T}_{en}}, \qquad g_y(y(\mathcal{T}^{ess}_{to})) z_\delta(\mathcal{T}^{ess}_{to}) = b_{\mathcal{T}^{ess}_{to}}, \\ g_y(y(\mathcal{T}^{nes}_{to})) z_\delta(\mathcal{T}^{nes}_{to}) \le b_{\mathcal{T}^{nes}_{to}}, \quad \gamma_{\mathcal{T}^{nes}_{to}} \ge 0, \quad (g_y(y(\mathcal{T}^{nes}_{to})) z_\delta(\mathcal{T}^{nes}_{to}) - b_{\mathcal{T}^{nes}_{to}}) \perp \gamma_{\mathcal{T}^{nes}_{to}}, \end{gathered}$$

has a unique solution $(v_\delta, z_\delta, \pi_\delta, \zeta_\delta, \gamma^{1:q}_{\mathcal{T}_{en}}, \gamma_{\mathcal{T}^{ess}_{to}}, \gamma_{\mathcal{T}^{nes}_{to}}, \sigma_{\mathcal{T}})$. Thus by Lemma 3.7, we obtain that ω is a solution of (4.14) iff $\pi_0 = \pi_\delta(0)$ and the other variables of ω are given as above. The existence and uniqueness of ω follows, and it is not difficult to check the Lipschitz continuity of ω w.r.t. δ. □

By strong regularity, there exist neighborhoods V_μ and V_θ of μ_0 and θ_0 such that, for all $\mu \in V_\mu$, there exists in V_θ a unique solution θ^μ of (4.10):

$$\theta^\mu = (p_0^{\mu *}, \nu^{\mu,1:q}_{\mathcal{T}_{en}}, \nu^{\mu}_{\mathcal{T}^{ess}_{to}}, \nu^{\mu}_{\mathcal{T}^{nes}_{to}}, \mathcal{T}^{\mu}_{en}, \mathcal{T}^{\mu}_{ex}, \mathcal{T}^{\mu,ess}_{to}, \mathcal{T}^{\mu,nes}_{to}) \in V_\theta \subset \mathbb{R}^{\bar{N}}.$$

Denote the associated trajectory and multipliers by $(u^\mu, y^\mu, p^\mu_q, \eta^\mu_q) \in \mathcal{X}^q_N$. Recall that $\Psi(\theta^\mu, \mu) = g^\mu(y^\mu(\mathcal{T}^{\mu,nes}_{to}))$ and set

$$\mathcal{T}^\mu_{to} := \mathcal{T}^{\mu,ess}_{to} \cup \{\tau \in \mathcal{T}^{\mu,nes}_{to} \ ; \ g^\mu(y^\mu(\tau)) = 0\}.$$

By the definition of (4.10), we have $g^\mu(y^\mu(\tau)) < 0$ and $\nu^\mu_\tau = 0$ if $\tau \notin \mathcal{T}^\mu_{to}$. Hence $(u^\mu, y^\mu, p^\mu_q, \eta^\mu_q)$ is a shooting extremal for $(\mathcal{P}^\mu)$, with jump parameters $(\nu^{\mu,1:q}_{\mathcal{T}_{en}}, \nu^{\mu}_{\mathcal{T}^\mu_{to}})$ and junction times $(\mathcal{T}^\mu_{en}, \mathcal{T}^\mu_{ex}, \mathcal{T}^\mu_{to})$.

In order to show now that the mapping $\mu \mapsto (u^\mu, y^\mu, p^\mu, \eta^\mu)$ is Lipschitz continous, where (p^μ, η^μ) is given by (2.36)–(2.38) and (2.21), consider the mapping

$$V_\mu \times V_\theta \to \mathcal{X}^q_N, \qquad (\mu, \theta) \mapsto (u^{\mu,\theta}, y^{\mu,\theta}, p^{\mu,\theta}_q, \eta^{\mu,\theta}_q), \tag{4.17}$$

where $(u^{\mu,\theta}, y^{\mu,\theta}, p^{\mu,\theta}_q, \eta^{\mu,\theta}_q)$ is the solution of (2.23)–(2.24), (2.26), (2.28), (2.30), and (2.31)–(2.33) for $(\mathcal{P}^\mu)$, with initial value of the costate, jump parameters and junction times given by argument θ. By the Cauchy–Lipschitz theorem, this mapping is well defined and of class C^q on neighborhoods $V_\mu \times V_\theta$ of (μ_0, θ_0). Therefore the mapping

$$V_\mu \times V_\theta \to \mathcal{X}^1_N, \qquad (\mu, \theta) \mapsto (u^{\mu,\theta}, y^{\mu,\theta}, p^{\mu,\theta}, \eta^{\mu,\theta}), \tag{4.18}$$

where $\eta^{\mu,\theta}_j$, $0 \le j \le q-1$, $p^{\mu,\theta}$, and $\eta^{\mu,\theta}$ are defined by (2.36)–(2.38) and (2.21), is of class C^1.

LEMMA 4.6. *Under assumptions and condition* (ii) *of Theorem* 4.3*, there exists a neighborhood V_μ of μ_0 such that the mapping $V_\mu \to \mathcal{X}_N$, $\mu \mapsto (u^\mu, y^\mu, p^\mu, \eta^\mu)$, is well defined and Lipschitz continuous on V_μ.*

Proof. Since strong regularity holds by Lemma 4.5, the mapping $\mu \mapsto \theta^\mu$ solution of (4.10) is well defined on a neighborhood of μ and Lipschitz continuous by (4.12). By continuity of the mappings (4.18) and $\mu \mapsto \theta^\mu$, the mapping $\mu \mapsto (u^\mu, y^\mu, p^\mu, \eta^\mu)$ is continuous $V_\mu \to \mathcal{X}^1_N$. Let us show now that u^μ is continuous. By (A2)–(A3), reducing V_μ if necessary, we have $H^\mu_{uu}(\hat{u}, y^\mu(t), p^\mu(t^\pm)) \ge \alpha/2$ and $|(g^\mu)^{(q)}_u(\hat{u}, y^\mu(t))| \ge \gamma/2$ for all t and all $\hat{u}$ in the segment $[u^\mu(t^-), u^\mu(t^+)] := \{\sigma u^\mu(t^+) + (1-\sigma)(u(t^-)),\ \sigma \in [0,1]\}$. By arguments similar to those used in the proof of Proposition 2.15(i) and in Remark 2.16, this is enough to show that u^μ is continuous, and hence, $(u^\mu, y^\mu) \in PC^{q,0}_{\mathcal{T}^\mu}[0,T] \times PC^{q+1,1}_{\mathcal{T}^\mu}([0,T]; \mathbb{R}^n)$. Reducing V^μ if necessary, by composition of $\mu \mapsto \theta^\mu$ with the C^1 mapping (4.18), we deduce that the mapping $\mu \mapsto (u^\mu, y^\mu, p^\mu, \eta^\mu) \in \mathcal{X}_N$ is Lipschitz continuous on a neighborhood of μ. □

LEMMA 4.7. *Under assumptions and condition* (ii) *of Theorem* 4.3*, the shooting extremal (u^μ, y^μ) is a stationary point for problem $(\mathcal{P}^\mu)$.*

Proof. By Corollary 2.17 and Remark 2.20, we need to check (2.39), (2.40), (2.43), and also, when $q = 2$, (2.51). By (A5′) and Lemma 4.6, (2.40) follows from (4.4). If $q = 2$, (2.51) follows from (3.5). By continuity of jumps at essential touch points

and the definition of (4.10), we obtain (2.43). It remains to prove (2.39). Near an entry/exit point τ^μ (when $q = 1$ or 2) this is a consequence of hypothesis (3.7) and continuity w.r.t. μ of $u(\tau^{\mu\pm})$. Similarly, near touch points, this follows from the reducibility hypothesis (3.8). Finally, outside a small neighborhood of contact points, we obtain that $g^\mu(y^\mu) < 0$ by a standard compactness argument. ∎

The next two lemmas extend those in [5, section 4] to the setting of perturbed optimal control problems. In what follows we denote by $\mathrm{supp}(\mathrm{d}\eta)$ the support of the measure η in $\mathcal{M}[0,T]$.

LEMMA 4.8. *Assume that the assumptions and condition* (ii) *of Theorem* 4.3 *hold. Let* $(\mathcal{P}^\mu)$ *be a q-stable extension, and* $\mu_n \to \mu_0$ *with its associated shooting extremal* (u_n, y_n) *and multipliers* (p_n, η_n). *For* $v \in \mathcal{V}$, *define* $Q^n(v) := \mathcal{J}^{\mu_n}(v, z^{\mu_n}_{u_n,v})$, *where* $\mathcal{J}^{\mu_n}(\cdot,\cdot)$ *is given by* (3.17) *for* $(\mathcal{P}^{\mu_n})$ *and* $z^{\mu_n}_{u_n,v}$ *is defined by* (4.2). *Define similarly* $\bar{Q}(v) := \mathcal{J}^{\mu_0}(v, z^{\mu_0}_{\bar{u},v})$. *Let* $v_n \rightharpoonup \bar{v} \in L^2$. *Then it holds that*

$$\bar{Q}(\bar{v}) \;\le\; \liminf Q^n(v_n) \quad \textit{and} \quad v_n \to \bar{v} \textit{ strongly if } Q^n(v_n) \to \bar{Q}(\bar{v}). \tag{4.19}$$

Set $z_n := z^{\mu_n}_{u_n,v_n}$, *and assume in addition that* $g^{\mu_n}_y(y_n(t))z_n(t) \le r_n$, *where* $\|r_n\|_\infty \to 0$ *for all* $t \in \mathrm{supp}(\mathrm{d}\eta_n)$ *and all* n. *Let* $\bar{z} := z^{\mu_0}_{\bar{u},\bar{v}}$. *Then*

$$g_y(\bar{y}(t))\bar{z}(t) \;\le\; 0 \quad \textit{on } \mathrm{supp}(\mathrm{d}\bar{\eta}). \tag{4.20}$$

Proof. Since by Lemma 4.6, (u_n, y_n) converges uniformly to $(\bar{u}, \bar{y})$, and $v_n \rightharpoonup v$, we have that (z_n) converges weakly in H^1 to $\bar{z}$ and hence uniformly. Relation (4.20) follows from the convergence of η_n in PC^1_N, strict complementarity (4.4), and uniform convergence of $g^{\mu_n}_y(y_n)z_n$. Let us now show (4.19).

Set $Q^0_n(v_n) := \int_0^T v_n^* H^{\mu_n}_{uu}(u_n, y_n, p_n)v_n \mathrm{d}t$. By Lemma 4.6, uniform convergence of z_n, and convergence in $\mathcal{X}_N$ of $H^{\mu_n}_{uy}(u_n, y_n, p_n)$ and $H^{\mu_n}_{yy}(u_n, y_n, p_n)$, it follows easily that $Q_n(v_n) - Q^0_n(v_n) \to \bar{Q}(\bar{v}) - \bar{Q}^0(\bar{v})$. Writing $Q^0_n(v_n) = \bar{Q}^0(v_n) + \epsilon_n$ with $\epsilon_n = \int_0^T v_n^*(H^{\mu_n}_{uu}(u_n, y_n, p_n) - H_{uu}(\bar{u}, \bar{y}, \bar{p}))v_n \mathrm{d}t$, by continuity of $H^{\mu_n}_{uu}$ at junction times (Lemma A.1 and Remark 2.20), Lemma 4.6 implies that $H^{\mu_n}_{uu}(u_n, y_n, p_n) \to H_{uu}(\bar{u}, \bar{y}, \bar{p})$ uniformly, and hence, $\epsilon_n \to 0$. Since by (A2), $\bar{Q}^0 : v \mapsto \int_0^T v^* H_{uu}(\bar{u}, \bar{y}, \bar{p})v$ is a Legendre form, (4.19) follows. ∎

We recall the reduction approach of [5, section 5.2]. When $q \ge 2$, with all touch points of the trajectory $(\bar{u}, \bar{y})$ being reducible by (A6), let $\varepsilon, \delta > 0$ and V_μ be small enough so that, for all $\|u - \bar{u}\|_\infty \le \delta$, all $\mu \in V_\mu$, and all $\tau_{to} \in \mathcal{T}_{to}$, the function $g^\mu(y^\mu_u)$ attains its maximum over $[\tau_{to} - \varepsilon, \tau_{to} + \varepsilon]$ at a unique point $\tau^\mu_u \in (\tau_{to} - \varepsilon, \tau_{to} + \varepsilon)$. Set $\bar{I}_{to} := \cup_{\tau_{to} \in \mathcal{T}_{to}}(\tau_{to} - \varepsilon, \tau_{to} + \varepsilon)$ and $\bar{I}_b := [0,T] \setminus \bar{I}_{to}$. When $q = 1$, set $\bar{I}_b := [0,T]$ and $\bar{I}_{to} := \emptyset$. Then the following *reduced problem* is well defined and locally equivalent to $(\mathcal{P}^\mu)$:

$$(\mathcal{P}^\mu_{red}) \qquad \min_{u \in B_\infty(\bar{u},\delta)} J^\mu(u) \qquad \text{subject to}$$

$$\mathcal{G}^\mu(u) := \begin{pmatrix} g(y_u)|_{\bar{I}_b} \\ g^\mu(y^\mu_u(\tau^{\mu,1}_u)) \\ \vdots \\ g^\mu(y^\mu_u(\tau^{\mu,N_{to}}_u)) \end{pmatrix} \in \mathcal{K} := C_-[\bar{I}_b] \times \mathbb{R}^{N_{to}}_-. \tag{4.21}$$

The Lagrangian $\mathcal{L}^\mu$ of the reduced problem (4.21) is given, for $u \in B_\infty(\bar{u}, \delta)$ and a multiplier $\lambda = (\eta_b, \nu) \in \mathcal{M}_+[\bar{I}_b] \times \mathbb{R}^{N_{to}}_+$, by

$$\mathcal{L}^\mu(u, \lambda) = J^\mu(u) + \int_{\bar{I}_b} g^\mu(y^\mu_u(t))\mathrm{d}\eta_b(t) + \sum_{i=1}^{N_{to}} \nu_i g^\mu(y^\mu_u(\tau^{\mu,i}_u)). \tag{4.22}$$

Multipliers η^μ and $\lambda^\mu = (\eta_b^\mu, \nu^\mu)$ associated with u^μ in, respectively, problem $(\mathcal{P}^\mu)$ and its reduced form $(\mathcal{P}^\mu_{red})$, are related by

$$\mathrm{d}\eta^\mu(t) = \mathrm{d}\eta_b^\mu(t) \text{ on } \bar{I}_b; \qquad \mathrm{d}\eta^\mu(t) = \sum_{i=1}^{N_{to}} \nu^\mu_{\tau_i} \delta_{\tau_u^{\mu,i}}(t) \text{ on } \bar{I}_{to}. \tag{4.23}$$

In addition, we can show that the reduced Lagrangian (4.22) is twice Fréchet differentiable at u^μ, and its second-order derivative satisfies, for $v \in \mathcal{V}$,

$$D^2_{uu}\mathcal{L}^\mu(u^\mu, \lambda^\mu)(v, v) = \mathcal{J}^\mu(v, z^\mu_{u,v}), \tag{4.24}$$

with $\mathcal{J}^\mu$ given by (3.17), and that the remainder $r(v)$ in the second-order expansion

$$\mathcal{L}^\mu(u^\mu + v, \lambda^\mu) = \mathcal{L}^\mu(u^\mu, \lambda^\mu) + D_u\mathcal{L}^\mu(u^\mu, \lambda^\mu)v + \tfrac{1}{2}D^2_{uu}\mathcal{L}^\mu(u^\mu, \lambda^\mu)(v, v) + r(v)$$

satisfies

$$r(v)/\|v\|_2^2 \;\to\; 0 \;\text{ when }\; \|v\|_\infty \;\to\; 0. \tag{4.25}$$

In what follows, $T_{\mathcal{K}}(x)$ and $N_{\mathcal{K}}(x)$ denote, respectively, the tangent and normal cones to $\mathcal{K}$ at point $x \in \mathcal{K}$ (in the sense of convex analysis).

LEMMA 4.9. *Under assumptions and condition* (ii) *of Theorem* 4.3*, there exists an open neighborhood V_μ of μ_0 such that the shooting extremal (u^μ, y^μ) associated with $(\mathcal{P}^\mu)$ for $\mu \in V_\mu$ satisfies the uniform quadratic growth condition, and hence, is a local solution of $(\mathcal{P}^\mu)$.*

Proof. If the conclusion does not hold, then there exists a q-stable extension $(\mathcal{P}^\mu)$, a sequence $\mu_n \to \mu_0$, with associated shooting extremal and multipliers (u_n, y_n, p_n, η_n) converging to $(\bar{u}, \bar{y}, \bar{p}, \bar{\eta})$ in $\mathcal{X}_N$ by Lemma 4.6 (which implies in particular $u_n \to \bar{u}$ in L^∞), and a point $\tilde{u}_n \in \mathcal{U}$ feasible for (P^{μ_n}), $\tilde{u}_n \neq u_n$, $\tilde{u}_n \to \bar{u}$ in L^∞, satisfying for all n,

$$J^{\mu_n}(\tilde{u}_n) \le J^{\mu_n}(u_n) + o(\|\tilde{u}_n - u_n\|_2^2). \tag{4.26}$$

Since $\lambda_n \in N_{\mathcal{K}}(\mathcal{G}^{\mu_n}(u_n))$, we have (for the appropriate duality products)

$$\langle \lambda_n, \mathcal{G}^{\mu_n}(\tilde{u}_n) - \mathcal{G}^{\mu_n}(u_n) \rangle \;\le\; 0,$$

and thus

$$\mathcal{L}^{\mu_n}(\tilde{u}_n, \lambda_n) - \mathcal{L}^{\mu_n}(u_n, \lambda_n) \;\le\; o(\|\tilde{u}_n - u_n\|_2^2). \tag{4.27}$$

Let $0 < \varepsilon_n := \|\tilde{u}_n - u_n\|_2 \to 0$ and $v_n := \varepsilon_n^{-1}(\tilde{u}_n - u_n)$. Since $\|v_n\|_2 = 1$ for all n, taking a subsequence if necessary, we may assume that $v_n \rightharpoonup \bar{v} \in \mathcal{V}$. With the notation of Lemma 4.8, we deduce from this lemma that (4.19) holds. Combining $D_u\mathcal{L}^{\mu_n}(u_n, \lambda_n) = 0$ and (4.24) with (4.27) and (4.25), we get

$$Q^n(v_n) = D_{uu}\mathcal{L}^{\mu_n}(u_n, \lambda_n)(v_n, v_n) \;\le\; o(1), \tag{4.28}$$

and thus $\bar{Q}(\bar{v}) \le 0$ by (4.19). Now

$$\mathcal{K} \ni \mathcal{G}^{\mu_n}(\tilde{u}_n) = \mathcal{G}^{\mu_n}(u_n) + \varepsilon_n D\mathcal{G}^{\mu_n}(u_n)v_n + \varepsilon_n r_n,$$

where $\|r_n\|_\infty = o(1)$, and therefore $D\mathcal{G}^{\mu_n}(u_n)v_n + r_n \in T_{\mathcal{K}}(\mathcal{G}^{\mu_n}(u_n))$, implying $g_y^{\mu_n}(y_n)z_n + r_n \le 0$ on $\mathrm{supp}(\mathrm{d}\eta_n)$. Thus (4.20) is satisfied by Lemma 4.8. Also, by (4.26), $DJ^{\mu_n}(u_n)v_n \le o(1)$, and hence,

$$\langle \eta_n, g_y^{\mu_n}(y_n)z_n\rangle = \langle \lambda_n, D\mathcal{G}^{\mu_n}(u_n)v_n\rangle \ge o(1).$$

Passing to the limit, we obtain $\langle \bar\eta, g_y(\bar y)\bar z\rangle \ge 0$. By (4.20) and $\mathrm{d}\bar\eta \ge 0$, we deduce that $g_y(\bar y)\bar z \in \mathrm{supp}(\mathrm{d}\bar\eta)^\perp$; thus $\bar v$ and its associated linearized state $\bar z$ satisfy (3.10) and (4.8). Therefore condition (ii) and $\bar Q(\bar v) \le 0$ imply $\bar v = 0$. Since by (4.28), $\limsup Q^n(v_n) \le 0$, it follows from (4.19) that $Q^n(v_n) \to 0 = \bar Q(\bar v)$, and hence, $v_n \to \bar v = 0$, contradicting $\|v_n\|_2 = 1$ for all n. ∎

Proof of Theorem 4.3. (ii) ⇒ (i) is a consequence of Lemmas 4.5–4.9. Let us show (i) ⇒ (ii). Let ρ be a C^∞ function over $\mathbb{R}$ such that $\mathrm{supp}(\rho) \subset [-1,1]$ and ρ is positive over $(-1,1)$. The function ψ^μ defined by $\psi^\mu(s) := \sum_{\tau\in\mathcal{T}_{to}^{nes}} \mu^{4q+2}\rho(\frac{s-\tau}{\mu})$ for $\mu \ne 0$, and $\psi^0(s) = 0$, for all $s \in [0,T]$, is of class C^{2q} w.r.t. its arguments s and μ and has support in $\cup_{\tau\in\mathcal{T}_{to}^{nes}}[\tau - |\mu|, \tau + |\mu|]$ for $\mu \ne 0$. Consider the perturbed constraint mapping $g^\mu(y) := g(y) - \psi^\mu(y_n)$ (recall that we assume that $(\mathcal{P})$ is written such that $y_n(t) = t$). Observe that $g^0 = g$ and g^μ is of order q for all μ; therefore $(\mathcal{P}^\mu) \equiv (\ell, \phi, f, g^\mu, y_0)$ is a q-stable extension of $(\mathcal{P}^0) = (\mathcal{P})$ with $\mu_0 = 0$. In addition, $g^\mu(y) = g(y)$ for all y such that $y_n \notin \cup_{\tau\in\mathcal{T}_{to}^{nes}}(\tau - |\mu|, \tau + |\mu|)$, and $g^\mu(\bar y(t)) < 0$ on $(\tau - |\mu|, \tau + |\mu|)$ for all $\tau \in \mathcal{T}_{to}^{nes}$. Since the touch points are isolated, we have for $|\mu| > 0$ small enough $g^\mu(\bar y) = g(\bar y)$ on $\mathcal{I}_b \cup \mathcal{T}_{to}^{ess} = \mathrm{supp}(\mathrm{d}\bar\eta)$, and it is easy to see that $(\bar u, \bar y)$ is a stationary point for $(\mathcal{P}^\mu)$, with the same Lagrange multiplier $\bar\eta$ and the same costate $\bar p$. In addition, the stationary point $(\bar u, \bar y)$ for $(\mathcal{P}^\mu)$ has a neighboring structure to that of $(\bar u, \bar y)$ for $(\mathcal{P}^0)$ (all nonessential touch points are removed). Therefore, by (i) and Definition 4.1, for $|\mu|$ small enough, $(\bar u, \bar y)$ satisfies the uniform quadratic growth condition (4.3) for $(\mathcal{P}^\mu)$. Since assumptions (A2)–(A6) are satisfied for $(\mathcal{P}^\mu)$, it follows from Theorem 3.4(ii) that the sufficient condition (ii) holds, which achieves the proof. ∎

4.2. Sensitivity analysis. If strong regularity holds, the mapping $\Xi : V_\delta \to V_\theta$, $\delta \mapsto \theta(\delta)$ is given by $\Xi(\delta) = \theta_0 + \omega(\delta)$, where $\omega(\delta)$ is the solution of (4.14). It follows then from (4.13) that

$$\theta^\mu = \theta_0 + \omega(-D_\mu\mathcal{F}(\theta_0,\mu_0)(\mu - \mu_0)) + o(\|\mu - \mu_0\|).$$

Since the mapping $\mathbb{R}^{\bar N} \to \Theta$, $\delta \mapsto \omega(\delta)$ is positively homogeneous of degree one, the mapping $\mu \mapsto \theta^\mu$ is Fréchet directionally differentiable. The directional derivatives in direction d are obtained by substituting $-D_\mu\mathcal{F}(\theta_0,\mu_0)d$ for δ in (4.14). Therefore,

$$\theta^{\mu_0+d} = \theta_0 + \omega_d + o(\|d\|), \tag{4.29}$$

where $\omega_d = (\pi^*_{d,0}, \gamma^{1:q}_{d,\mathcal{T}_{en}}, \gamma_{d,\mathcal{T}_{to}}, \sigma_{d,\mathcal{T}_{en}}, \sigma_{d,\mathcal{T}_{ex}}, \sigma_{d,\mathcal{T}_{to}})$ is as follows. Denote by (v_d, z_d) and $(\zeta_d, \pi_d, \lambda^{1:q}_{d,\mathcal{T}_{en}}, \lambda_{d,\mathcal{T}_{to}})$ the (unique) optimal solution and multipliers of the quadra-

tic problem below:

$$
\begin{aligned}
(\mathcal{P}_d)\quad \min_{(v,z)\in\mathcal{V}\times\mathcal{Z}}\ & \frac{1}{2}\int_0^T D^2_{(u,y,\mu),(u,y,\mu)}\tilde{H}(\bar{u},\bar{y},\bar{p}_q,\bar{\eta}_q,\mu_0)((v,z,d),(v,z,d))\mathrm{d}t\\
&+\frac{1}{2}D^2\tilde{\phi}(\bar{y}(T),\mu_0)((z(T),d),(z(T),d))\\
&+\frac{1}{2}\sum_{\tau\in\mathcal{T}_{en}}\sum_{j=1}^{q}\nu_\tau^j D^2\tilde{g}^{(j-1)}(\bar{y}(\tau),\mu_0)((z(\tau),d),(z(\tau),d))\\
&+\frac{1}{2}\sum_{\tau\in\mathcal{T}_{to}}\nu_\tau\left(D^2\tilde{g}(\bar{y}(\tau),\mu_0)((z(\tau),d),(z(\tau),d))-\frac{(D\tilde{g}^{(1)}(\bar{y}(\tau),\mu_0)(z(\tau),d))^2}{\frac{\mathrm{d}}{\mathrm{d}t}\tilde{g}^{(1)}(\bar{y}(t),\mu_0)|_{t=\tau}}\right)\\
\text{subject to}\quad & \begin{cases}
\dot{z}(t)=D\tilde{f}(\bar{u},\bar{y},\mu_0)(v,z,d) & \text{on } [0,T],\quad z(0)=D\tilde{y}_0(\mu_0)d,\\
D\tilde{g}^{(0:q-1)}(\bar{y}(\tau),\mu_0)(z(\tau),d)=0, & \tau\in\mathcal{T}_{en},\\
D\tilde{g}(\bar{y}(\tau),\mu_0)(z(\tau),d)=0, & \tau\in\mathcal{T}_{to}^{ess},\\
D\tilde{g}(\bar{y}(\tau),\mu_0)(z(\tau),d)\le 0, & \tau\in\mathcal{T}_{to}^{nes},\\
D\tilde{g}^{(q)}(\bar{u},\bar{y},\mu_0)(v,z,d)=0 & \text{on } \mathcal{I}_b.
\end{cases}
\end{aligned}
$$

Then ω_d is given by $\pi_{d,0}=\pi_q(0)$, $\gamma_{d,\mathcal{T}_{to}}=\lambda_{d,\mathcal{T}_{to}}$,

$$\sigma_{d,\tau}=-\frac{D\tilde{g}^{(1)}(\bar{y}(\tau),\mu_0)(z_d(\tau),d)}{\frac{\mathrm{d}}{\mathrm{d}t}\tilde{g}^{(1)}(\bar{y},\mu_0)|_{t=\tau}},\ \tau\in\mathcal{T}_{to}, \tag{4.30}$$

$$\sigma_{d,\tau}=-\frac{D\tilde{g}^{(q)}(\bar{u}(\tau),\bar{y}(\tau),\mu_0)(v_d(\tau^+),z_d(\tau),d)}{\frac{\mathrm{d}}{\mathrm{d}t}\tilde{g}^{(q)}(\bar{u},\bar{y},\mu_0)|_{t=\tau^+}},\ \tau\in\mathcal{T}_{ex}, \tag{4.31}$$

$$\sigma_{d,\tau}=-\frac{D\tilde{g}^{(q)}(\bar{u}(\tau),\bar{y}(\tau),\mu_0)(v_d(\tau^-),z_d(\tau),d)}{\frac{\mathrm{d}}{\mathrm{d}t}\tilde{g}^{(q)}(\bar{u},\bar{y},\mu_0)|_{t=\tau^-}},\ \tau\in\mathcal{T}_{en}, \tag{4.32}$$

$$\gamma_{d,\tau}^1=\lambda_{d,\tau}^1,\quad \gamma_{d,\tau}^j\ =\ \lambda_{d,\tau}^j-\nu_\tau^{j-1}\sigma_{d,\tau},\quad j=2,\dots,q,\ \tau\in\mathcal{T}_{en}. \tag{4.33}$$

Once we have the expressions for the directional derivatives of the shooting parameters, by composition with the Fréchet derivatives of the C^1 mapping (4.18) in direction (d,ω_d), we obtain the expressions of the directional derivatives, in $\mathcal{X}_N$, of the mapping $\mu\mapsto(u^\mu,y^\mu,p^\mu,\eta^\mu)$. By Lemma 4.2, we then easily obtain the expression of the directional derivatives of the control and state in $L^r(0,T)\times W^{1,r}(0,T;\mathbb{R}^n)$ for all $1\le r<\infty$.

COROLLARY 4.10. *If either point* (i) *or* (ii) *of Theorem* 4.3 *is satisfied, then there exists a neighborhood V_μ of μ such that the mapping $V_\mu\to\mathcal{X}_N$, $\mu\mapsto(u^\mu,y^\mu,p^\mu,\eta^\mu)$, is Fréchet directionally differentiable on V_μ. In addition, the directional derivative in $L^r(0,T)\times W^{1,r}(0,T;\mathbb{R}^n)$, $1\le r<\infty$, of the mapping $\mu\mapsto(u^\mu,y^\mu)$ at point μ_0 in direction d, is the optimal solution (v_d,z_d) of problem $(\mathcal{P}_d)$.*

We end the paper with a remark related to the ill-posedness of the shooting algorithm for a state constraint of order $q\ge 3$ when boundary arcs are present (see Theorem 3.3).

REMARK 4.11 (existence of regular boundary arcs for constraints of order $q\ge 3$). Contrary to some conjectures in the literature, regular boundary arcs *can occur* for state constraints of *all* orders. Take, for example, the problem

$$
\begin{aligned}
(P_q)\qquad & \min_{(u,y)\in L^\infty(0,T)\times W^{q,\infty}(0,T)}\int_0^T\left(y(t)+\frac{u^2(t)}{2}\right)\mathrm{d}t\\
\text{subject to}\quad & y^{(q)}(t)=u(t);\ y(0)=y_1^0;\ \dot{y}(0)=y_2^0;\dots;\ y^{(q-1)}(0)=y_q^0;\\
& y(t)\ge 0,\quad t\in[0,T].
\end{aligned}
$$

It is easy to check that, for $\tau \in (0,T)$, y defined by $y(t) = 0$ on $[\tau, T]$ and

$$y(t) = \begin{cases} \dfrac{(t-\tau)^{2q}}{(2q)!} & \text{if } q \text{ is odd} \\ -\dfrac{(t-\tau)^{2q}}{(2q)!} - \nu\dfrac{(t-\tau)^{2q-1}}{(2q-1)!} & \text{if } q \text{ is even} \end{cases} \quad \text{on } [0,\tau],$$

is, for $\nu > \tau/2q$ if q is even and for *appropriate initial conditions* when $q \geq 3$, a solution that satisfies all necessary optimality conditions, and hence, by convexity of the problem, an optimal solution with a regular entry point τ. Strict complementarity holds since $\eta_0(t) = 1$ on $(\tau, T]$.

Robbins in [27] studies this example when $q = 3$ for generic initial conditions and shows that the optimal trajectory has a boundary arc, whose entry point is not regular, being the limit of an infinite number of touch points, with a geometric decreasing of the length of the interior arcs. Regular boundary arcs correspond to the case when the multiplier of the geometric sequence is equal to zero for a specific subset of initial conditions. Therefore, we see in that example, though satisfying all regularity assumptions (A0)–(A3), that the *structure of boundary arcs* is *not stable* under perturbations of the initial condition when $q \geq 3$, which illustrates why the shooting algorithm should be ill-posed in that case.

Appendix A. The next two lemmas follow immediately from the junction conditions established in [18, 25].

LEMMA A.1. *Let (u,y) be a regular Pontryagin extremal satisfying* (A2)–(A4). *Then the function $t \mapsto H_{uu}(u(t), y(t), p(t))$ is continuous on $[0,T]$.*

Proof. Let $\tau \in \mathcal{T}$. Since u is continuous by Proposition 2.5, we have

$$[H_{uu}(u(\tau), y(\tau), p(\tau))] = [p(\tau)] f_{uu}(u(\tau), y(\tau)) = -\nu_\tau g^{(1)}_{uu}(u(\tau), y(\tau)) = 0,$$

since either $\nu_\tau = 0$ when $q = 1$ by Proposition 2.5, or $g^{(1)}_u \equiv 0$ when $q > 1$. ∎

LEMMA A.2. *Let (u,y) be a regular Pontryagin extremal, satisfying* (A2)–(A4), *and let $\tau \in \mathcal{T}_{en} \cup \mathcal{T}_{ex}$ be an entry/exit time. The following conditions are equivalent:*

(i) (3.7) *holds at τ;*

(ii) *if q is* odd, $\lim_{t \to \tau;\, t \in \mathcal{I}_b} \eta_0(t) > 0$; *if q is* even, $\nu_\tau > 0$.

Proof. Define the mappings $(A_l)_{0 \leq l \leq q} : [0,T] \setminus \mathcal{T} \to \mathbb{R}^n$ by (2.34) and $(a_l)_{0 \leq l \leq q} : [0,T] \setminus \mathcal{T} \to \mathbb{R}$ by

$$a_0(t) = \ell_u(u(t), y(t)); \quad a_l(t) = \ell_y(u(t), y(t)) A_{l-1}(t) - \dot{a}_{l-1}(t), \quad l = 1, \ldots, q.$$

Then it can be seen by (2.35) (see [25]) that for all $t \in [0,T] \setminus \mathcal{T}$, we have

$$0 = \frac{\mathrm{d}^j}{\mathrm{d}t^j} H_u(u(t), y(t), p(t)) = (-1)^j (a_j(t) + p(t) A_j(t)); \qquad j = 0, \ldots, q-1, \tag{A.1}$$

$$0 = \frac{\mathrm{d}^q}{\mathrm{d}t^q} H_u(u(t), y(t), p(t)) = (-1)^q \left(a_q(t) + p(t) A_q(t) + \frac{\mathrm{d}\eta}{\mathrm{d}t} g^{(q)}_u(u(t), y(t)) \right). \tag{A.2}$$

Since the derivatives of the control are continuous until order $q-2$, the functions a_j and A_j are continuous for $j = 0, \ldots, q-2$, and it is then easily seen, since u is continuous, that the jumps of A_{q-1} and a_{q-1} at $\tau \in \mathcal{T}$, when q is even, are given, respectively, by

$$[A_{q-1}(\tau)] = (-1)^{q-1} f_{uu}(u(\tau), y(\tau)) [u^{(q-1)}(\tau)],$$
$$[a_{q-1}(\tau)] = (-1)^{q-1} \ell_{uu}(u(\tau), y(\tau)) [u^{(q-1)}(\tau)].$$

Taking the jump in (A.1) at τ for $j = q-1$ then yields

$$0 \;=\; (-1)^{q-1} H_{uu}(u(\tau), y(\tau), p(\tau^+))[u^{(q-1)}(\tau)] - \nu_\tau g_y(y(\tau)) A_{q-1}(\tau^-).$$

By (2.35), we have $g_y(y(\tau))A_{q-1}(\tau^\pm) = g_u^{(q)}(u(\tau), y(\tau))$, so we obtain, when q is even,

$$\nu_\tau = (-1)^{q-1} \frac{H_{uu}(u(\tau), y(\tau), p(\tau^+))[u^{(q-1)}(\tau)]}{g_u^{(q)}(u(\tau), y(\tau))}. \tag{A.3}$$

It follows that $\nu_\tau > 0$ iff $u^{(q-1)}$ is discontinuous at τ, which is equivalent to saying that (3.7) holds (when q is even). When q is odd, $u^{(q-1)}$, a_{q-1}, and A_{q-1} are continuous (and $\nu_\tau = 0$). Taking the jump in (A.2), we obtain

$$0 = (-1)^q H_{uu}(u(\tau), y(\tau), p(\tau))[u^{(q)}(\tau)] + [\eta_0(\tau)]\, g_u^{(q)}(u(\tau), y(\tau)).$$

Consequently, we have $\eta_0(\tau^\pm) > 0$ at an entry/exit point, where $\tau^\pm$ stands for τ^+ if $\tau \in \mathcal{T}_{en}$ and τ^- if $\tau \in \mathcal{T}_{ex}$ iff $u^{(q)}$ is discontinuous at τ, and hence iff (3.7) holds. ∎

Appendix B. The next two lemmas recall classical results. For the second one see related results by Aubin [1].

LEMMA B.1. *Let X be a Hilbert space and Q a Legendre form over X. Let A be a continuous linear operator over X. The following assertions are equivalent:*

(i) *$Q(v) > 0$, for all $v \in \operatorname{Ker} A \setminus \{0\}$.*

(ii) *There exists $\alpha > 0$ such that $Q(v) \geq \alpha \|v\|_2^2$ for all $v \in \operatorname{Ker} A$.*

LEMMA B.2. *Let X be a Hilbert space and Y a Banach space, $H : X \to X^* \equiv X$ a self-adjoint continuous linear operator, and $A : X \to Y$ and $B : X \to \mathbb{R}^r$, $r \in \mathbb{N}$, continuous linear operators. Assume that*

$$\text{(i)} \quad \exists \alpha > 0, \quad \langle Hx, x\rangle \geq \alpha \|x\|^2 \quad \textit{for all } x \in \operatorname{Ker} A.$$
$$\text{(ii)} \quad \textit{The operator } (A, B) : X \to Y \times \mathbb{R}^r \textit{ is onto.}$$

Then, for all $(x^*, y, \delta) \in X^* \times Y \times \mathbb{R}^r$, there exists a unique $(x, y^*, \nu) \in X \times Y^* \times \mathbb{R}^{r*}$, solution of

$$\left\{ \begin{array}{l} Hx + A^* y^* + B^* \nu \;=\; x^*, \\ Ax \;=\; y, \\ Bx \;\leq\; \delta, \quad \nu \geq 0, \quad \nu(Bx - \delta) = 0, \end{array} \right. \tag{B.1}$$

and the mapping $(x^*, y, \delta) \mapsto (x, y^*, \nu)$, where (x, y^*, ν) is solution of (B.1)*, is Lipschitz continuous.*

ON FEEDBACK CLASSIFICATION OF CONTROL-AFFINE SYSTEMS WITH ONE- AND TWO-DIMENSIONAL INPUTS*

ANDREI AGRACHEV† AND IGOR ZELENKO†

Abstract. The paper is devoted to the local classification of generic germs of control-affine systems on an n-dimensional manifold with scalar input for any $n \geq 4$ or with two inputs for $n = 4$ and $n = 5$, up to state-feedback transformations, preserving the affine structure (in the C^∞ category for $n = 4$ and the C^ω category for $n \geq 5$). First, using the Poincaré series of moduli numbers, we introduce the intrinsic numbers of functional moduli of each prescribed number of variables on which a classification problem depends. In order to classify generic germs of affine systems with scalar input we associate with such a system the canonical frame by normalizing some structural functions in a commutative relation of the vector fields, which define our control system. Then, using this canonical frame, we introduce the canonical coordinates and find a complete system of state-feedback invariants of the system. It also automatically gives the local in state-input space classification of generic germs of nonaffine n-dimensional control systems with scalar input for $n \geq 3$ (in the C^∞ category for $n = 3$ and in the C^ω category for $n \geq 4$). Further, we show how the problem of feedback equivalence of generic germs of affine systems with two-dimensional input in state space of dimensions 4 and 5 can be reduced to the same problem for affine systems with scalar input. In order to make this reduction we distinguish the subsystem of our control system, consisting of the directions of all extremals in dimension 4 and all abnormal extremals in dimension 5 of the time optimal problem, defined by the original control system. In each classification problem under consideration we find the intrinsic numbers of functional moduli of each prescribed number of variables according to its Poincaré series.

Key words. state-feedback equivalence, control-affine systems, Poincaré series, extremals

1. Introduction.

For the convenience of presentation, all objects are C^∞ unless otherwise noted, although all constructions and some statements remain valid in an obvious way also in the C^k category for an appropriate finite k. On the other hand, some of the statements are known to be true only in the real analytic category, which will be indicated explicitly.

Let M be an n-dimensional manifold, and let $f_0, f_1, \dots, f_r$ be vector fields on M, $r < n$. Consider the following control-affine system with r inputs on M:

$$\dot{q} = f_0(q) + \sum_{k=1}^{r} u_k f_k(q), \quad q \in M, \quad u_1, \dots, u_r \in \mathbb{R}. \tag{1.1}$$

We say that a system of type (1.1) is an (r, n) control-affine system. Fix a point $q_0 \in M$. Throughout the paper we will assume that at the point q_0

$$\dim \operatorname{span}\big(f_0(q_0), f_1(q_0), \dots, f_r(q_0)\big) = r + 1. \tag{1.2}$$

Consider the group FB_{q_0} of state-feedback transformations that preserve an affine structure and the point q_0, i.e., transformations of the type

$$\begin{cases} q = \Phi(\tilde{q}), \\ u = \mathcal{B}(\tilde{q})\tilde{u} + \mathcal{A}(\tilde{q}), \\ q_0 = \Phi(q_0), \end{cases} \qquad u = \begin{pmatrix} u_1 \\ \vdots \\ u_r \end{pmatrix}, \tag{1.3}$$

where Φ is a diffeomorphism in a neighborhood of q_0, $\mathcal{A}(q) \in \mathbb{R}^r$, $\mathcal{B}(q)$ is an $(r \times r)$-matrix, and $\det \mathcal{B}(q_0) \neq 0$. This group of transformations acts naturally on the set of germs at q_0 of systems of type (1.1) and defines an equivalence relation, called the *state-feedback equivalence*.[1] The state-feedback equivalence can be described in more geometric terms: any control-affine system on M defines the affine subbundle of the tangent bundle TM of M. Two germs of control-affine systems are state-feedback equivalent if and only if the corresponding germs of affine subbundles belong to the same orbit w.r.t. the natural action of the group of germs of diffeomorphisms of M on the set of germs of affine subbundles of TM. Thus, the problem of state-feedback equivalence of control-affine systems is a particular case of the classical equivalence problem of geometric structures on manifolds.

In the case of corank 1 control-affine systems, i.e., when $r = n - 1$, all generic germs of control-affine systems are state-feedback equivalent to each other. Indeed, under assumption (1.2) there is the natural one-to-one correspondence between the set of control-affine systems, up to feedback transformations, and the set of differential 1-forms on the ambient manifold: To any affine system (1.1) one can assign a unique differential 1-form ω such that $\omega(f_i) = 0$ for $i = 1, \dots, n-1$ and $\omega(f_0) = 1$. Thus, the state-feedback classification of corank 1 control-affine systems satisfying (1.2) is equivalent to the well-known classification of differential 1-forms w.r.t. the action of the group of diffeomorphisms (see, for example, [19, section 3 and Appendix C]). In particular, all germs of (1.1) such that the underlying vector distribution $\operatorname{span}(f_1, \dots, f_{n-1})$ is contact for odd n or quasi-contact for even n (which is a generic assumption) are state-feedback equivalent to the control-affine system, corresponding to the classical Darboux model (note also that in [19] normal forms for codimension 1 singularities are given, too).

Now suppose that $r < n-1$. Let us roughly estimate the "number of parameters" in the considered equivalence problem. The set of r-dimensional affine subspaces in $\mathbb{R}^n$ forms an $(r+1)(n-r)$-dimensional manifold. Therefore, if the coordinates on M are fixed, then the control system of type (1.1) can be defined by $(r+1)(n-r)$ functions of n variables. The group of the coordinate changes on M is parameterized by n functions of n variables. Thus, by a coordinate change one can "normalize," in general, only n functions among those $(r+1)(n-r)$ functions defining our control system. Thus we may expect that the set of orbits of generic germs of systems (1.1) at $q_0 \in M$ w.r.t. the action of the group of transformations of type (1.3) can be parameterized by $(r+1)(n-r) - n = r(n-r-1)$ arbitrary germs of functions of n variables and a number of germs of functions, depending on less than n variables (see the next section for the discussion about the number of these additional functional invariants).

According to the last estimate, for $r < n-1$ generic germs of (r, n) control-affine systems have functional invariants (see also [8, Proposition 3.12]). How does one construct such invariants and, more generally, a complete system of such invariants? These and related questions were the subject of intensive study in the last two decades, and numerous important contributions were made by different authors. Classical methods of differential geometry such as the Cartan method of equivalence (see, for example, [7], [18], [14]) were used, and new methods coming from Pontryagin's maximum principle, such as the theory of Jacobi curves of extremals [1], [2], [3], [4], [16] and the method of critical Hamiltonians [9], were developed. Different criteria

[1] Some authors refer to the transformations (1.3) and the corresponding equivalence by the name "feedback," while in the case $\Phi = \mathrm{Id}$ they use the term "pure feedback."

for the state-feedback equivalence in terms of the associated system of extremals were given as well [6], [10]. Also the important case of the so-called equilibrium point, i.e., when $f_0(q_0) \in \operatorname{span}\big(f_1(q_0), \dots, f_r(q_0)\big)$, was intensively studied for corank 1 control-affine systems, using singularity theory (see, for example, [11], [15], and [20]), and for control-affine systems with scalar input, using the formal approach similar to the classical Poincaré–Dulac procedure [12], [13], [17].

However, as far as we know, except for the case $r = n - 1$, the set of orbits of generic germs of (r, n) control-affine systems w.r.t. the action of the group of state-feedback transformations was parameterized by certain tuples of invariants only in the case $r = 1$, $n = 3$, i.e., in the case of the smallest dimensions, when functional parameters appear [2, section 3, Proposition 3.2]. In particular, it was shown there that in this case this set of orbits can be parameterized by one arbitrary function of three variables, two arbitrary functions of two variables, and the discrete invariant from the set $\{-1, 1\}$.

Remark 1. Actually, in Proposition 3.2 of [2] the two functions of two variables satisfy certain conditions on coordinate subspaces of some special coordinates, which are canonical up to some reflections, but instead of these functions one can take their appropriate partial derivatives, which are already arbitrary. The functions of the parameterization are state-feedback invariants up to some reflections in the coordinates. □

In the present paper we make a classification of generic germs of systems of type (1.1), up to state-feedback equivalence, in the following cases:

1. $r = 1$, $n = 4$;
2. $r = 1$, $n \geq 5$ in the real analytic category;
3. $r = 2$, $n = 4$;
4. $r = 2$, $n = 5$ in the real analytic category.

In general, statements of the kind "the classification problem depends on the tuple of functional invariants, consisting of certain number of functions of each number of variables" need to be clarified: These numbers could be changed rather arbitrarily by mixing, combining, or separating the formal Taylor series of these functional invariants without losing any information (at least if we work in the category of formal Taylor series or in the real analytic category). In [5, section 1] the author proposed using the so-called *Poincaré series of the moduli numbers of the classification problem* in order to determine intrinsically the number of functions of each prescribed number of variables on which some classification problem depends. In section 2 below, using the Poincaré series, we give a canonical selection of these numbers. Throughout this section we demonstrate all our notions and constructions on the problem of classification of germs of Riemannian metrics on a two-dimensional manifold. The way in which the canonical parameterization is obtained indicates the presence of an interesting algebraic structure on the set of all tuples of fundamental invariants parameterizing a given classification problem. For the moment, this algebraic structure remains hidden and needs further research.

In the case of scalar input, our method of the classification is similar to the procedure used in [2] for the case $n = 3$ and is described in section 3. It basically consists of the following two steps: first, for any control system, satisfying some genericity assumptions, we construct the canonical frame by normalizing some structural functions in certain commutative relations of the vector fields, which define our control-affine systems; then, using this canonical frame, we introduce the canonical coordinates and find the complete system of state-feedback invariants of the system.

In addition, to any control system

$$\dot{y} = \mathcal{F}(y, v), \quad y \in S, \quad v \in V, \tag{1.4}$$

on an m-dimensional manifold S (the state space) with one-dimensional control space V one can assign the following control-affine system on the $(m+1)$-dimensional state-space $S \times V$:

$$\begin{cases} \dot{y} = \mathcal{F}(y, v), \\ \dot{v} = u, \end{cases} \tag{1.5}$$

where $v \in \mathbb{R}$ (here we look on v as on a new state variable, u is the new control, $f_0 = (\mathcal{F}(y, v), 0)^T$, and $f_1 = (0, 1)^T$ in the notation of (1.1)). It turns out that having the local classification of generic germs of $(m + 1)$-dimensional control-affine systems with scalar input, one also gets the local in state-input space classification of generic germs of nonaffine m-dimensional control system with scalar input (see Remark 6).

Further, in section 4, we show that the problem of state-feedback classification of the control-affine systems with two-dimensional input in dimensions 4 and 5 can be reduced to the previous problem for the control-affine systems with scalar input in the same dimensions. In order to make this reduction, we distinguish the subsystem, consisting of the directions of all extremals in dimension 4 and all abnormal extremals in dimension 5 of the time optimal problem, defined by the original control system.

In each classification problem under consideration we find the intrinsic numbers of functional moduli of each prescribed number of variables according to its Poincaré series.

Finally note that the previously mentioned papers [12], [17] were devoted to the classification of control-affine systems with scalar control in a neighborhood of an equilibrium point. Here we classify the control-affine systems with scalar control near a nonequilibrium point. In general the feedback invariants, constructed here for generic germs, could also be used for the problem with equilibrium points by passing to the limit. The relation of the invariants obtained in this way with the invariants obtained in [12], [17] is the subject of further study.

2. Poincaré series and the intrinsic number of functional invariants. We start with some terminology. Let M be a smooth manifold. Fix a point $q_0 \in M$. Consider a set $\mathcal{O}$ of germs at q_0 of smooth objects on M (for example, Riemannian metrics, vector distributions, control-affine systems) such that the group of local diffeomorphisms Diff_{q_0}, preserving the point q_0, acts naturally on it. This action defines the equivalence relation on $\mathcal{O}$.

Denote by $J^k(\mathcal{O})$ the space of all k-jets at q_0 of objects from the set $\mathcal{O}$. We say that the set $\widetilde{\mathcal{O}} \subset \mathcal{O}$ is *a generic subset* of $\mathcal{O}$ if there exists an integer $k \geq 0$ and a Zariski open set U in $J^k(\mathcal{O})$ such that

$$\widetilde{\mathcal{O}} = \{\mathfrak{b} \in \mathcal{O} : k\text{-jet of } \mathfrak{b} \text{ belongs to } U\}.$$

By "classification problem on $\mathcal{O}$" we mean the problem of finding a system of fundamental invariants for objects from some generic subset of $\mathcal{O}$ such that two generic objects are equivalent if and only if they have the same systems of fundamental invariants.

Let $\widetilde{\mathcal{O}}$ be a generic subset of $\mathcal{O}$, which is invariant w.r.t. the action of the group Diff_{q_0}.

DEFINITION 1. *A mapping F from the set $\widetilde{\mathcal{O}}$ to the set $C_0^\infty(\mathbb{R}^l,\mathbb{R})$ of germs at 0 of smooth functions in $\mathbb{R}^l$, which is invariant w.r.t. the action of the group Diff_{q_0} on $\widetilde{\mathcal{O}}$, is called a functional invariant of l variables of a generic subset of objects from $\mathcal{O}$ (or, for short, the functional invariant of $\mathcal{O}$).*

When the object $\mathfrak{b}\in\widetilde{\mathcal{O}}$ is fixed, we will mean by the functional invariant also the value of the mapping F at $\mathfrak{b}$. We will denote this germ of function by the same letter F.

Let $\mathrm{Orb}(\widetilde{\mathcal{O}})$ be the set of orbits of $\widetilde{\mathcal{O}}$ w.r.t. the action of Diff_{q_0}. Then any functional invariant $F:\widetilde{\mathcal{O}}\mapsto C_0^\infty(\mathbb{R}^l,\mathbb{R})$ induces the mapping $\widehat{F}:\mathrm{Orb}(\widetilde{\mathcal{O}})\mapsto C_0^\infty(\mathbb{R}^l,\mathbb{R})$ in the obvious way.

DEFINITION 2. *Let $\{F_i\}_{i=1}^s$ be the tuple of functional invariants of $\mathcal{O}$ defined on $\widetilde{\mathcal{O}}$, where each F_i is a functional invariant of l_i variables. We say that the tuple $\{F_i\}_{i=1}^s$ defines a parameterization of the classification problem on $\mathcal{O}$ if the mapping*

$$(\widehat{F}_1,\dots,\widehat{F}_s):\mathrm{Orb}(\widetilde{\mathcal{O}})\mapsto C_0^\infty(\mathbb{R}^{l_1},\mathbb{R})\times\dots\times C_0^\infty(\mathbb{R}^{l_s},\mathbb{R})$$

is injective and has an open image in $C_0^\infty(\mathbb{R}^{l_1},\mathbb{R})\times\dots\times C_0^\infty(\mathbb{R}^{l_s},\mathbb{R})$.

Example 1. Let $\mathcal{O}_1$ be a set of germs of Riemannian metrics at a point q_0 on an oriented two-dimensional manifold M. Given a germ of metric G, let K_G be its Gaussian curvature. Let $\widetilde{\mathcal{O}}_1$ be the set of all germs G of Riemannian metrics at q_0 such that $dK_G(q_0)\neq 0$. Obviously, $\widetilde{\mathcal{O}}_1$ is a generic subset of $\mathcal{O}_1$. For any $G\in\mathcal{O}_1$ consider the geodesic polar coordinates (r,φ) centered at q_0 and in accordance with the orientation such that the vector $\mathrm{grad}\,K_G(q_0)$ is in the direction of the ray $\{\varphi=0\}$. We will call these coordinates *the canonical polar coordinates of* G. The corresponding Cartesian coordinates (x_1,x_2) will be called *the canonical coordinates of the metric* G *at* q_0. Then the mapping $\mathfrak{K}:\widetilde{\mathcal{O}}_1\mapsto C_0^\infty(\mathbb{R}^2,\mathbb{R})$ such that

$$\mathfrak{K}(G)=K_G(x_1,x_2) \tag{2.1}$$

is a functional invariant of two variables of $\mathcal{O}_1$.

Now let us construct the parameterization of the classification problem on $\mathcal{O}_1$. By construction the image of $\mathfrak{K}$ lies in the set

$$\mathcal{N}=\{f\in C_0^\infty(\mathbb{R}^2,\mathbb{R}):f_{x_2}(0,0)=0,\ f_{x_1}(0,0)>0\}.$$

Actually, $\mathfrak{K}$ defines the one-to-one correspondence between the set $\mathrm{Orb}\big(\widetilde{\mathcal{O}}_1\big)$ of orbits of $\widetilde{\mathcal{O}}_1$ w.r.t. the action of Diff_{q_0} and the set $\mathcal{N}$. Indeed, for any $f\in\mathcal{N}$ take the metric G, which can be written in some polar coordinates centered at q_0 in the following way:

$$G=dr^2+\big(B(r,\varphi)\big)^2d\varphi^2, \tag{2.2}$$

where

$$\begin{cases}\dfrac{\partial^2}{\partial r^2}B+f(r\cos\varphi,r\sin\varphi)B=0,\\[2mm] B(0,\phi)=0,\quad \dfrac{\partial}{\partial r}B(0,\phi)=1.\end{cases} \tag{2.3}$$

Then $\mathfrak{K}(G)=f$, and any germ of metric $\overline{G}$ at q_0 such that $\mathfrak{K}(\overline{G})=f$ is isometric to G.

However, $\mathfrak{K}$ does not define the parameterization of the considered classification problem in the sense of Definition 2, because the set $\mathcal{N}$ is not an open subset of $C_0^\infty(\mathbb{R}^2,\mathbb{R})$. But instead of $\mathfrak{K}$ we can consider the following two functional invariants of one variable and one functional invariant of two variables:

$$\mathfrak{K}_1(G)=K_G(x_1,0),\quad \mathfrak{K}_2(G)=\frac{\partial^2}{\partial x_2^2}K_G(0,x_2),\quad \mathfrak{K}_3(G)=\frac{\partial^2}{\partial x_1\partial x_2}K_G(x_1,x_2), \tag{2.4}$$

where (x_1,x_2) are the canonical coordinates of the metric G at q_0. The image of the mapping $(\mathfrak{K}_1,\mathfrak{K}_2,\mathfrak{K}_3)$ is open in $C_0^\infty(\mathbb{R},\mathbb{R})\times C_0^\infty(\mathbb{R},\mathbb{R})\times C_0^\infty(\mathbb{R}^2,\mathbb{R})$; namely, it is equal to

$$\mathcal{N}_1=\{f_1(x_1),f_2(x_2),f_3(x_1,x_2)\in C_0^\infty(\mathbb{R},\mathbb{R})\times C_0^\infty(\mathbb{R},\mathbb{R})\times C_0^\infty(\mathbb{R}^2,\mathbb{R}) : f_1'(0)>0\}.$$

In addition, the original functional invariant $\mathfrak{K}$ can be uniquely recovered from the tuple $(\mathfrak{K}_1,\mathfrak{K}_2,\mathfrak{K}_3)$. Thus, the tuple $(\mathfrak{K}_1,\mathfrak{K}_2,\mathfrak{K}_3)$ defines the one-to-one correspondence between the set $\mathrm{Orb}(\widetilde{\mathcal{O}}_1)$ and the set $\mathcal{N}_1$. Hence this tuple defines the parameterization of the considered classification problem in the sense of Definition 2. □

Now let us describe the Poincaré series of the moduli numbers of the classification problem. The action of the group Diff_{q_0} induces the action $\mathcal{A}_k$ of some finite dimensional Lie group G_k on the space $J^k(\mathcal{O})$ for any integer $k\geq 0$. Thus, $\mathcal{A}_k$ is a mapping from $G_k\times J^k(\mathcal{O})$ to $J^k(\mathcal{O})$. Given any $\mathfrak{b}\in J^k(\mathcal{O})$, let $\mathcal{A}_k^{\mathfrak{b}}$ be the mapping from G_k to $J^k(\mathcal{O})$ such that $\mathcal{A}_k^{\mathfrak{b}}(\cdot)=\mathcal{A}_k(\cdot,\mathfrak{b})$. Let e_k be the identity of the group G_k. Set

$$m(k)=\dim J^k(\mathcal{O})-\max_{b\in J^k(\mathcal{O})}\operatorname{rank} d\mathcal{A}_k^{\mathfrak{b}}(e_k)=\min_{b\in J^k(\mathcal{O})}\operatorname{corank} d\mathcal{A}_k^{\mathfrak{b}}(e_k) \tag{2.5}$$

(here $\operatorname{rank} d\mathcal{A}_k^{\mathfrak{b}}(e_k)$ and $\operatorname{corank} d\mathcal{A}_k^{\mathfrak{b}}(e_k)$ are the rank and the corank of the differential of $\mathcal{A}_k^{\mathfrak{b}}$ at e_k, respectively). Roughly speaking, $m(k)$ is the dimension of the space of orbits w.r.t. the last action $\mathcal{A}_k$. The number $m(k)$ is called the *moduli number of the k-jets. The Poincaré series of the moduli numbers of the classification problem* (or, for short, *the Poincaré series of the classification problem*) is by definition the following function:

$$M(t)=\sum_{k=0}^{\infty}m(k)t^k. \tag{2.6}$$

Remark 2. Since the integer-valued function $\mathfrak{b}\mapsto\operatorname{rank} d\mathcal{A}_k^{\mathfrak{b}}(e_k)$ takes its maximal value at a Zariski open set, in (2.5) we can replace $\mathcal{O}$ by any of its generic subsets $\widetilde{\mathcal{O}}$. □

The Poincaré series could be useful in evaluating the number of the functional invariants of the given number of variables, on which the given classification problem depends, because of the following well-known fact: If one denotes by $j_l(k)$ the dimension of the space $J^k(\mathbb{R}^l,\mathbb{R})$ of k-jets of functions of l-variables, then the corresponding Poincaré series of numbers $j_l(k)$ satisfies

$$\sum_{k=0}^{\infty}j_l(k)t^k=\frac{1}{(1-t)^{l+1}} \tag{2.7}$$

(here one uses that $j_l(k)=\frac{(l+k)!}{l!k!}$). So if, for example, the Poincaré series of some classification problem is equal to

$$M(t) = t^w \sum_{i=1}^{n} \frac{p_i}{(1-t)^{i+1}}, \tag{2.8}$$

where all p_i are nonnegative integers, then it is natural to conclude that this problem depends on the tuple, consisting of p_i functional invariants of i variables for each $1 \le i \le n$, while the parameter w (i.e., the order of zero of the Poincaré series $M(t)$ at $t = 0$) is equal to the minimal $k \ge 0$ such that the action of the group G_k on the space of $J^k(\mathcal{O})$ has a nondiscrete set of orbits.

Until now nothing was known about the form of the functions $M(t)$ for general classification problems. For example, the following open question is stated in [5]: Is it true that the Poincaré series of moduli numbers are rational functions in most classification problems? In the next sections we will show by direct computations that in all classification cases 1–4 listed in the introduction it is true and, moreover, the function $M(t)$ has a unique pole at $t = 1$. On the other hand, in all considered cases (except the cases $r = 1$, $n = 3$ or 5) the Poincaré series has no representation of type (2.8) with nonnegative p_i. Below we give an algorithm to extract the number of functional invariants from Poincaré series also in these cases.

From now on we will suppose that the Poincaré series $M(t)$ of the classification problem is a rational function with a unique pole at $t = 1$. Let w_0 be the order of zero of the function $M(t)$ at $t = 0$.

LEMMA 1. *For any integers $w \ge w_0$ and l there exist a unique polynomial $R(t)$ with*

$$\deg R(t) < w - w_0 \tag{2.9}$$

and a unique rational function $Q(t)$ with the unique pole at $t = 1$ such that

$$M(t) = \frac{t^{w_0} R(t)}{(1-t)^{l+1}} + t^w Q(t). \tag{2.10}$$

Proof. Let us fix $l \in \mathbb{Z}$ and prove the existence of a representation of type (2.10) for any $w \ge w_0$ by induction in w.

If $w = w_0$, then from the condition (2.9) it follows that $R(t) \equiv 0$. Then by definition of order of zero the function $Q(t) = \frac{1}{t^{w_0}} M(t)$ is rational with the unique pole at $t = 1$, which implies (2.10).

Now suppose that a representation of type (2.10) exists for some $w = \bar{w}$, $\bar{w} \ge w_0$, and prove its existence for $w = \bar{w} + 1$. For this let $Q(t)$ and $R(t)$ be as in the representation (2.10) for $w = \bar{w}$. Let

$$Q_1(t) = \frac{1}{t}\left(Q(t) - \frac{Q(0)}{(1-t)^{l+1}}\right). \tag{2.11}$$

Then by construction Q_1 is also the rational function with the unique pole at $t = 1$. Expressing $Q(t)$ from (2.11) and substituting it into (2.10), one has

$$M(t) = \frac{t^{w_0}\big(R(t) + Q(0)t^{\bar{w}-w_0}\big)}{(1-t)^{l+1}} + t^{\bar{w}+1} Q_1(t). \tag{2.12}$$

Since $\deg\big(R(t)+Q(0)t^{\bar{w}-w_0}\big) < \bar{w}-w_0+1$, it implies the existence of a representation (2.10) also for $w = \bar{w}+1$. This completes the proof by induction of the existence part of the lemma.

Now let us prove the uniqueness part. If there exists another representation of $M(t)$ of type (2.10) with a polynomial $\bar{R}(t)$, $\deg \bar{R}(t) < w - w_0$, and a rational function $\bar{Q}(t)$ instead of $R(t)$ and $Q(t)$, then we have the following identity:

$$\bar{R}(t) - R(t) = t^{w-w_0}(1-t)^{l+1}\big(Q(t) - \bar{Q}(t)\big).$$

It implies that the polynomial $\bar{R}(t) - R(t)$ has zero of order not less than $w - w_0$. On the other hand, by assumptions $\deg\big(R(t) - \bar{R}(t)\big) < w - w_0$, which implies that $R(t) \equiv \bar{R}(t)$ and then also $Q(t) \equiv \bar{Q}(t)$. □

We will call the representation (2.10) (with $R(t)$ satisfying (2.9)) the (w,l)-*representation of the function* $M(t)$. Let N be the order of pole of $(1-t)M(t)$ at $t = 1$.

Definition 3. *The* (w,l)*-representation* (2.10) *of* $M(t)$ *with* $R(t)$ *and* $Q(t)$ *satisfying*

$$R(t) = \sum_{i=0}^{w-w_0-1} r_i t^i, \quad Q(t) = \sum_{j=l_1}^{N} \frac{q_j}{(1-t)^{j+1}}, \quad q_{l_1} \neq 0 \tag{2.13}$$

is called nice if $1 \le l \le N$, $l_1 \ge l$, *and all coefficients* r_i, q_j *in* (2.13) *are nonnegative integers.*

Of course, in general a rational function $M(t) = \frac{t^{w_0} Z(t)}{(1-t)^{N+1}}$, where $Z(t)$ is a polynomial (even with integer coefficients), may not have any nice (w,l)-representation. But if the function $M(t)$ is the Poincaré series of a classification problem, which can be parameterized by functional invariants in some reasonable way, then $M(t)$ has at least one nice representation.

To be more precise and to explain why the nice representation of the Poincaré series is interesting, let us introduce additional terminology. Let F be a functional invariant of l variables of a generic subset $\widetilde{\mathcal{O}}$ of objects from $\mathcal{O}$. Denote by Π_k the natural projection from the set $\widetilde{\mathcal{O}}$ to the space $J^k(\widetilde{\mathcal{O}})$. Let $(x_1, \dots, x_l)$ be the standard coordinates in $\mathbb{R}^l$. As before, let $C_0^\infty(\mathbb{R}^l, \mathbb{R})$ be the set of germs at 0 of smooth functions in $\mathbb{R}^l$ and let $J^k(\mathbb{R}^l, \mathbb{R})$ be the space of k-jets of germs of these functions at 0. Denote also by π_k^l the natural projection from $C_0^\infty(\mathbb{R}^l, \mathbb{R})$ to $J^k(\mathbb{R}^l, \mathbb{R})$.

Definition 4. *The weight of the functional invariant* F *of* l *variables, defined on a generic subset* $\widetilde{\mathcal{O}} \subset \mathcal{O}$, *is the minimal nonnegative integer* w *with the following property: For any integer* $k \ge w$ *there exists a mapping* $\mathfrak{F}_k : J^k(\widetilde{\mathcal{O}}) \mapsto J^{k-w}(\mathbb{R}^l, \mathbb{R})$ *such that the diagram*

$$\begin{array}{ccc} \widetilde{\mathcal{O}} & \xrightarrow{\quad F \quad} & C_0^\infty(\mathbb{R}^l, \mathbb{R}) \\ {\scriptstyle \Pi_k}\downarrow & & \downarrow{\scriptstyle \pi^l_{k-w}} \\ J^k(\widetilde{\mathcal{O}}) & \xrightarrow[\quad \mathfrak{F}_k \quad]{} & J^{k-w}(\mathbb{R}^l, \mathbb{R}) \end{array} \tag{2.14}$$

is commutative. If such w *does not exist, we will say that* F *has an infinite weight.*

Suppose that the tuple $\{F_i\}_{i=1}^s$ defines a parameterization of the classification problem on $\mathcal{O}$ such that each F_i is a functional invariant of $l_i \ge 0$ variables and the finite weight ν_i, $\nu_i \le \nu_{i+1}$. Let $\widetilde{\mathcal{O}}$ be the common domain of definition of all invariants F_i, $1 \le i \le s$. For any $k \ge 0$ set $\mu_k = \max\{i \in \{1, \dots, s\} : \nu_i \le k\}$. For a given functional invariant F_i and any $k \ge \nu_i$ denote by $\mathfrak{F}_{i,k} : J^k(\widetilde{\mathcal{O}}) \mapsto J^{k-\nu_i}(\mathbb{R}^{l_i}, \mathbb{R})$ the corresponding mapping in the commutative diagram (2.14) for F_i. Let $\mathrm{Orb}\big(J^k(\widetilde{\mathcal{O}})\big)$

be the set of orbits of $J^k(\widetilde{\mathcal{O}})$ w.r.t. the action $\mathcal{A}_k$ of the group G_k (recall that $\mathcal{A}_k$ is the action on $J^k(\mathcal{O})$ induced by the action of the group Diff_{q_0} on $\mathcal{O}$). Then the mapping $\mathfrak{F}_{i,k} : J^k(\widetilde{\mathcal{O}}) \mapsto J^{k-\nu_i}(\mathbb{R}^{l_i}, \mathbb{R})$ induces the mapping $\widehat{\mathfrak{F}}_{i,k} : \mathrm{Orb}\big(J^k(\widetilde{\mathcal{O}})\big) \mapsto J^{k-\nu_i}(\mathbb{R}^{l_i}, \mathbb{R})$ in the obvious way. Also let $\mathcal{U}_i$ be the image of $\widetilde{\mathcal{O}}$ under F_i. From Definition 2 it follows that the set $\mathcal{U}_i$ is an open subset of $C_0^\infty(\mathbb{R}^{l_i}, \mathbb{R})$. Then, according to the definition of the weight, for any $k \geq 0$ the mapping

$$(\widehat{\mathfrak{F}}_{1,k}, \dots, \widehat{\mathfrak{F}}_{\mu_k,k}) : \mathrm{Orb}\big(J^k(\widetilde{\mathcal{O}})\big) \mapsto J^{k-\nu_1}(\mathbb{R}^{l_1}, \mathbb{R}) \times \cdots \times J^{k-\nu_{\mu_k}}(\mathbb{R}^{l_{\mu_k}}, \mathbb{R}) \tag{2.15}$$

is well defined and has an open image equal to $\pi^{l_1}_{k-\nu_1}(\mathcal{U}_1) \times \cdots \times \pi^{l_{m_k}}_{k-\nu_{\mu_k}}(\mathcal{U}_{\mu_k})$.

Definition 5. *The parameterization, defined by the tuple $\{F_i\}_{i=1}^s$ as above, is called regular if for any $k \geq 0$ the mappings* (2.15) *are injective. We also say that a classification problem is regular if it can be parameterized by a regular parameterization.*

Suppose that w_1 and w_2 are, respectively, the minimal and maximal weights of functional invariants, defining some regular reparameterization, while n_1 and n_2 are, respectively, the minimal and maximal number of variables of these invariants. Then to such regular parameterization one can assign an $(n_2-n_1+1)\times(w_2-w_1+1)$ matrix P such that its (i,j)-entry p_{ij} is equal to the number of the functional invariants of $i+n_1-1$ variables and weight $j+w_1-1$ in this parameterization. Directly from the definitions of regular parameterization, formula (2.7), and Remark 2 it follows that the Poincaré series of the classification problem, admitting such regular parameterization, satisfies

$$M(t) = \frac{t^{w_1-1}}{(1-t)^{n_1}} \sum_{j=1}^{w_2-w_1+1} t^j \left(\sum_{i=1}^{n_2-n_1+1} \frac{p_{ij}}{(1-t)^{i+1}} \right). \tag{2.16}$$

Note that $w_1 = w_0$ and $n_2 = N$, where as before w_0 is the order of zero of $M(t)$ at $t = 0$ and N is the order of pole of $(1-t)M(t)$ at $t = 1$, but all other parameters appearing in (2.16) cannot be uniquely recovered from the Poincaré series $M(t)$. In the considered situation we will say that the classification problem admits *a regular (w_2, n_1)-parameterization with parameterization matrix P.*

The continuation of Example 1. Consider again the situation described in Example 1. From the normal form (2.2)–(2.3) it follows easily that the functional invariant $\mathfrak{K}$, defined by (2.1), has weight 2, while invariants $\mathfrak{K}_1$, $\mathfrak{K}_2$, and $\mathfrak{K}_3$, defined by (2.4), have weights 2, 4, and 4, respectively. Moreover, the tuple of invariants $(\mathfrak{K}_1, \mathfrak{K}_2, \mathfrak{K}_3)$ defines the regular $(4,1)$-parameterization with parameterization matrix

$$P = \begin{pmatrix} 1 & 0 & 1 \\ 0 & 0 & 1 \end{pmatrix}. \tag{2.17}$$

The Poincaré series of the considered classification problem satisfies

$$M(t) = \frac{t^2}{(1-t)^2} + t^4 \left(\frac{1}{(1-t)^3} + \frac{1}{(1-t)^2} \right). \qquad \square \tag{2.18}$$

Given some regular (w_2, n_1)-parameterization of the classification problem, one can easily build a new regular (w_2, n_1)-parameterization with another parameterization matrix. Indeed, take some functional invariant F of the weight j_0, depending on i_0 variables, say $x_1, x_2, \dots, x_{i_0}$, where $2 \leq i_0 \leq n_2 - n_1 + 1$ and $1 \leq j_0 \leq w_2 - w_1$. Let $G(x_1, \dots, x_{i_0})$ be the function such that

$$F(x_1,\dots,x_{i_0}) = F(x_1,\dots,x_{i_0-1},0) + x_{i_0}G(x_1,\dots,x_{i_0}). \tag{2.19}$$

Then we can obtain the new parameterization of the classification problem by replacing the functional invariant $F(x_1,\dots,x_{i_0})$ by two functional invariants $F(x_1,\dots,x_{i_0-1},0)$ and $G(x_1,\dots,x_{i_0})$. Obviously, the first invariant has weight j_0 and depends on i_0-1 variables, while the second one has weight j_0+1 and depends on i_0 invariants. The matrix of the new parameterization is obtained from the original one by decreasing the (i_0,j_0)-entry by 1 and increasing both the (i_0-1,j_0)-entry and the (i_0,j_0+1)-entry by 1. Such transformation on the set of $(N-n_1+1)\times(w_2-w_0+1)$ matrices will be called *an elementary transformation*. Conversely, given two functional invariants G_1 and G_2 such that G_1 depends on i_0-1 variables, say $x_1,\dots,x_{i_0-1}$, and has the weight j_0, while G_2 depends on i_0 variables, say $x_1,\dots,x_{i_0}$, and has the weight j_0+1 (here again $2\le i_0\le n_2-n_1+1$ and $1\le j_0\le w_2-w_1$), one can build the new parameterization by replacing the invariants G_1 and G_2 by one invariant $G_1+x_{i_0}G_2$, which depends on i_0 variables and has the weight j_0. Of course, in this case the matrix of the new parameterization is obtained from the original one by the transformation, which is inverse to the elementary one.

Now for convenience denote

$$K_1 = N-n_1+1, \quad K_2 = w_2-w_0+1. \tag{2.20}$$

Note that among all matrices, which can be obtained from the given $K_1\times K_2$ matrix P with integer entries by a composition of a finite number of elementary transformations and their inverses, there exists a unique matrix, denoted by $\mathrm{Norm}(P)$, such that all its entries, except those lying on the first row and the last column, are equal to zero. To prove the existence of $\mathrm{Norm}(P)$ one can vanish the entries of the matrix P by a composition of elementary transformations and their inverses step by step, starting from the entry in the lower left corner, going along the first column from the bottom to the top until the entry on the second row, then passing to the bottom of the second column, going along it from the bottom to the top until the entry on the second row, and so on until the column before the last one. The uniqueness follows from the fact that if we put the entries of the matrix $\mathrm{Norm}(P)$ instead of the entries of P into the representation (2.16), then we obtain the (w_2,n_1)-representation of the Poincaré function $M(t)$. This representation is unique according to Lemma 1, and the matrix $\mathrm{Norm}(P)$ is obviously uniquely recovered from it. Also it is not difficult to express all nontrivial entries of $\mathrm{Norm}(P)$ by the entries of P:

(2.21a)
$$(\mathrm{Norm}(P))_{1j} = p_{1j} + \sum_{l=0}^{j-1}\sum_{k=1}^{K_1-1}\binom{k+l-1}{l}p_{k+1,j-l}, \qquad 1\le j\le K_2-1,$$

(2.21b)
$$(\mathrm{Norm}(P))_{i,K_2} = p_{i,K_2} + \sum_{l=0}^{K_1-i+1}\sum_{k=1}^{K_2-1}\binom{K_2-k+l-1}{l}p_{i+l,k}, \qquad 2\le i\le K_1,$$

(2.21c)
$$(\mathrm{Norm}(P))_{1,K_2} = p_{1,K_2}.$$

The last relation can be proved, for example, using the procedure of passing from P to $\mathrm{Norm}(P)$, described above, and the following well-known combinatorial identity:

$$\sum_{i=1}^{n}\binom{i+k-1}{k} = \binom{n+k}{k+1}.$$

If the matrix P has only nonnegative integer entries, then the matrix $\mathrm{Norm}(P)$ is obtained from P by a finite composition of elementary transformations (without using their inverses) and also has only nonnegative integer entries (which follows also from relations (2.21)). Moreover, if we put the entries of the matrix $\mathrm{Norm}(P)$ instead of the entries of P into the representation (2.16), then we obtain the nice (w_2, n_1)-representation of the Poincaré function $M(t)$ of our classification problem. We also say that this nice representation *corresponds to the matrix* $\mathrm{Norm}(P)$. We can summarize all of the above in the following proposition.

PROPOSITION 1. *If the classification problem admits a regular (w_2, n_1)-parameterization with parameterization matrix P, then it admits a regular (w_2, n_1)-parameterization with parameterization matrix $\mathrm{Norm}(P)$, and its Poincaré series has the nice (w_2, n_1)-representation, which corresponds to the matrix $\mathrm{Norm}(P)$.*

The last proposition indicates that the nice representations of the Poincaré series (if they exist) may be used in the definition of the intrinsic number of functional invariants of each number of variables and weight, on which the given classification problem depends. Suppose that the Poincaré series $M(t)$ has the nice representation for some (w, l). Thus, the set

$$\mathrm{NS}\big(M(t)\big) \stackrel{def}{=} \{(w,l) : \text{the } (w,l)\text{-representation of } M(t) \text{ is nice}\} \tag{2.22}$$

is not empty. The natural question is what pair to choose from $\mathrm{NS}\big(M(t)\big)$. To answer this question we propose to introduce the order $\prec$ on the set of ordered pairs (w, l) in the following way: $(w, l) \prec (\bar{w}, \bar{l})$ if and only if $w < \bar{w}$ or $w = \bar{w}$, but $l > \bar{l}$. By Definition 3,

$$\mathrm{NS}\big(M(t)\big) \subset \{(w,l) : w \geq w_0,\, l \leq N\}, \tag{2.23}$$

which implies immediately that the set $\mathrm{NS}\big(M(t)\big)$ contains the minimal element w.r.t. the introduced order $\prec$. This minimal element will be called *the characteristic pair of the classification problem*. Denote it by $(\bar{w}, \bar{l})$. Let $\mathcal{C}$ be the $(N - \bar{l} + 1) \times (\bar{w} - w_0 + 1)$ matrix such that the $(\bar{w}, \bar{l})$-representation of $M(t)$ corresponds to the matrix $\mathcal{C}$.

DEFINITION 6. *The (i, j)-entry of the matrix $\mathcal{C}$ is called the intrinsic number of the functional invariants of $i+\bar{l}-1$ variables and the weight $j+w_0-1$ of the considered classification problem. The matrix $\mathcal{C}$ is called the characteristic matrix of the classification problem. Any regular $(\bar{w}, \bar{l})$-parameterization of the problem (if it exists) with the parameterization matrix $\mathcal{C}$ is called the characteristic regular parameterization.*

In general, it is better to have a parameterization consisting of invariants which have minimal possible weight and depend on the maximal possible number of variables. Our definition of characteristic parameterization is in accordance with this goal. Actually the maximal weight of invariants appearing in a characteristic regular parameterization is not greater than the maximal weight of invariants appearing in any other regular parameterization. Besides, the minimal number of variables in invariants of a characteristic regular parameterization is not less than the minimal number of variables in invariants of any other regular parameterization having the same maximal weight of invariants as a characteristic one.

One can improve the formula (2.23) for the localization of the set $\mathrm{NS}\big(M(t)\big)$. Indeed, let d be the degree of the rational function $M(t)$ at infinity. Namely, if $M(t) = \frac{Q_1(t)}{Q_2(t)}$, where $Q_1(t)$ and $Q_2(t)$ are polynomials, then $d = \deg Q_1(t) - \deg Q_2(t)$. Then

$$\mathrm{NS}\big(M(t)\big) \subset \{(w,l) : w \geq w_0,\ 1 \leq l \leq \min(w-d-1, N)\}. \tag{2.24}$$

To prove (2.24) we actually have to prove that if the pair $(w,l) \in \mathrm{NS}\big(M(t)\big)$, then $l \leq w-d-1$. Indeed, from (2.10) and (2.13) it follows that $d = \max(w-l_1-1,\ w_0+\deg R-l_1-1)$. But first, since $l_1 > l$, we have $w-l_1-1 \leq w-l-1$, and second, since $\deg R < w-w_0$, we have $w_0+\deg R-l_1-1 < w-l-1$. Therefore $d \leq w-l-1$. □

From (2.24) it follows also that

$$\mathrm{NS}\big(M(t)\big) \subset \{(w,l) : w \geq \max(w_0, d+2)\}. \tag{2.25}$$

The relations (2.24) and (2.25) may be useful in searching for the characteristic pair of the classification problem.

Conclusion about Example 1. The representation (2.18) of the Poincaré series of the classification problem considered in Example 1 is its nice $(4,1)$-representation. Let us show that $(4,1)$ is the characteristic pair of the considered classification problem. Indeed, from (2.18) in the considered case $w_0 = 2$, $N = 2$, and $d = 2$. Hence from (2.25) it follows that

$$\mathrm{NS}\big(M(t)\big) \subset \{(w,l) : w \geq 4\}. \tag{2.26}$$

Further, using (2.24), one has $\mathrm{NS}\big(M(t)\big) \cap \{(w,l) : w = 4\} = \{(4,1)\}$, which together with (2.26) implies that $(4,1)$ is the minimal element of $\mathrm{NS}\big(M(t)\big)$. In other words, $(4,1)$ is the characteristic pair of our classification problem. Also, it implies that the characteristic matrix $\mathcal{C}$ of the problem is equal to the matrix P from (2.17) (note that in this case $\mathrm{Norm}(P) = P$). Thus, *the characteristic parameterization of a set of germs of Riemannian metrics on an oriented two-dimensional Riemannian manifold consists of one functional invariant of one variable and the weight* 2*, one functional invariant of one variable and the weight* 4*, and one functional invariant of two variables and the weight* 4.

Another useful property of the set $\mathrm{NS}\big(M(t)\big)$ can be formulated as follows.

Lemma 2. *Assume that the function $M(t)$ has the nice (w,l)-representation* (2.10)*, the functions $R(t)$, $Q(t)$, and the number l_1 are as in* (2.13)*, and $l_1 = l$ (or, equivalently, $q_l > 0$); then $(w-1,\ l-1) \notin \mathrm{NS}\big(M(t)\big)$.*

Proof. Let $S(t)$ be the polynomial such that $M(t) = \frac{S(t)}{(1-t)^{N+1}}$. Then, using the assumption $l = l_1$, it is easy to get

$$\deg S(t) = w + N - l. \tag{2.27}$$

Moreover, directly from (2.10) and (2.13) one can obtain that

$$\frac{d^{w+N-l}S}{d\,t^{w+N-l}} = (-1)^{N-l}(w+N-l)!\,q_l. \tag{2.28}$$

On the other hand, if the $(w-1,\ l-1)$-representation of $M(t)$ has the form

$$M(t) = \frac{t^{w_0}\sum_{i=0}^{w-w_0-2}\bar{r}_i t^i}{(1-t)^l} + t^{w-1}\sum_{j=l_2}^{N}\frac{\bar{q}_j}{(1-t)^{j+1}}, \quad \bar{q}_{l_2} \neq 0, \tag{2.29}$$

then $\deg S(t) = \max(w-1+N-l_2,\ w+N-l-1)$. Comparing this with (2.27) one gets easily that $l_2 = l-1$. But then by analogy with (2.28) (applied for the

$(w-1,\, l-1)$-representation instead of the (w,l)-representation), one has

$$\frac{d^{w+N-l}S}{d\,t^{w+N-l}} = (-1)^{N-l+1}(w+N-l)!\,\bar{q}_{l-1}. \tag{2.30}$$

Comparing (2.28) and (2.30), we obtain that $\bar{q}_{l-1} = -q_l$. Hence $\bar{q}_{l-1} < 0$, and the $(w-1,\, l-1)$-representation (2.29) is not nice. □

As a direct consequence of Proposition 1, the previous lemma, and the relation (2.21c) one has the following corollary.

COROLLARY 1. *If the classification problem with the Poincaré series $M(t)$ admits the regular (w,l)-parameterization with the parameterization matrix P such that the entry in the upper right corner of P is positive (i.e., in the previous notation $p_{1,w-w_0+1} > 0$), then $(w-1,\, l-1) \notin \mathrm{NS}\big(M(t)\big)$.*

In what follows we will show that all of the classification problems 1–4 listed in the introduction are regular. For each of these problems we will describe explicitly some of its regular (w,l)-parameterization such that (w,l) is the characteristic pair of the problem and find its characteristic matrix, which also enables us to obtain the characteristic parameterization.

Remark 3. In the classification problem of Example 1 and, as we will see later, in all of the classification problems 1–4 listed in the introduction, one can assign to any generic object the canonical coordinates. This allows us to construct functional invariants in the sense of Definition 1 from the invariants defined on the ambient manifold (in the same manner as in Example 1 where we constructed the functional invariant $\mathfrak{K}$ from the Gaussian curvature). Sometimes (as in the case of $(1,3)$ control-affine systems and in the case of Riemannian metrics on a nonoriented two-dimensional manifold) the canonical coordinates (even for generic objects) are defined up to some discrete group of transformations (in the mentioned cases a group of reflections). Such classification problems can be treated in a similar way after slight modifications of definitions of the functional invariants, the parameterization, the weight, and the regular parameterization.

Indeed, a discrete group Γ on $\mathbb{R}^l$ induces the action $\mathfrak{S}$ on $C_0^\infty(\mathbb{R}^l,\mathbb{R})$ in the obvious way. By the functional quasi invariant we mean the mapping from the generic subset $\widetilde{\mathcal{O}}$ of the set of considered objects to the set of orbits w.r.t. the action $\mathfrak{S}$ on $C_0^\infty(\mathbb{R}^l,\mathbb{R})$ such that this mapping is invariant w.r.t. the action of the group Diff_{q_0} on $\widetilde{\mathcal{O}}$. The notions of the weight of the functional quasi invariants, the parameterization, and the regular parameterization by functional quasi invariants can be defined in the natural way. Besides, in parameterizations we can admit invariants taking their values in some discrete set (or, for short, discrete invariants) and define the regular parameterization by functional (quasi) invariants and discrete invariants in the natural way. Permission of the functional quasi invariant and the discrete invariants does not affect the formula (2.16) for the Poincaré series in terms of the parameterization matrix containing the information about the number of functional (quasi) invariants of the given number of variables and weight in the parameterization. Thus, also the characteristic pair, the characteristic matrix, and the characteristic regular parameterization can be defined in this case, too. In the case of Riemannian metrics on the nonoriented manifolds the canonical coordinates are defined up to the reflection $(x_1,x_2) \mapsto (x_1,-x_2)$, the characteristic pair and the characteristic matrix are as in the oriented case, and the characteristic parameterization is defined by formula (2.4), where we take into account both canonical coordinates (x_1,x_2) and $(x_1,-x_2)$.

Further, according to Proposition 3.2 of [2] (see also Remark 1 and the paragraph before it in the introduction), the state-feedback classification problem for the $(1,3)$

control-affine system admits regular $(2,2)$-parameterization by one discrete invariant taking values in $\{-1,1\}$ and the functional quasi invariants with the 2×2 parameterization matrix $P=\left(\begin{smallmatrix}2&0\\0&1\end{smallmatrix}\right)$. Besides, $w_0=1$ and $N=3$. By the inverse to the elementary transformation one can transform P into the matrix $\widetilde{P}=\left(\begin{smallmatrix}1&0\\1&0\end{smallmatrix}\right)$. The Poincaré series $M(t)$ of the problem satisfies

$$M(t)=t\left(\frac{1}{(1-t)^3}+\frac{1}{(1-t)^4}\right).$$

It is not difficult to see that by erasing the last column of the matrix $\widetilde{P}$ one obtains the characteristic matrix $\mathcal{C}=(1,1)^T$ of the considered classification problem and the characteristic pair is equal to $(1,2)$. Thus, *the characteristic regular parameterization of the state-feedback classification problem for the* $(1,3)$ *control-affine system consists of one functional quasi invariant of three variables and the weight* 1*, one functional quasi invariant of two variables and the weight* 1*, and the discrete invariant from the set* $\{-1,1\}$. This parameterization is obtained from the original one by a rearrangement of the invariants, which corresponds to the inverse to elementary transformation, transforming the matrix P into the matrix $\widetilde{P}$ (such rearrangements were described in the paragraph after the formula (2.19)). □

3. Classification of $(1,n)$ control-affine systems for $n\geq 4$. For $r=1$ the system (1.1) has the form

$$\dot{q}=f_0(q)+u\,f_1(q),\quad q\in M,\quad u\in\mathbb{R}. \tag{3.1}$$

Our genericity assumptions are

$$\dim\operatorname{span}(f_0,f_1,[f_1,f_0],\dots,(\operatorname{ad}f_1)^{n-2}f_0)=n, \tag{3.2}$$

$$\dim\operatorname{span}\big(f_1,\big[f_0,[f_0,f_1]\big],[f_1,f_0],\dots,(\operatorname{ad}f_1)^{n-2}f_0\big)=n, \tag{3.3}$$

and for $n\geq 5$ also

$$\dim\operatorname{span}\big(f_0,f_1,\big[f_0,[f_0,f_1]\big],[f_1,f_0],\dots,(\operatorname{ad}f_1)^{n-3}f_0\big)=n. \tag{3.4}$$

The group of feedback transformations

$$u=\beta(q)\tilde{u}+\alpha(q),\quad \alpha(q),\beta(q)\in\mathbb{R},\quad \beta(q)\neq 0 \tag{3.5}$$

acts naturally on the set of pairs of vector fields (f_0,f_1). The orbit w.r.t. this action is

$$\mathcal{O}_{(f_0,f_1)}=\{(f_0+\alpha f_1,\beta f_1):\alpha,\beta:M\mapsto\mathbb{R}\text{ are functions, }\beta\neq 0\}. \tag{3.6}$$

The first observation is given by the following proposition.

PROPOSITION 2. *If the pair* (f_0,f_1) *satisfies conditions* (3.2) *and* (3.3)*, then there exists a unique pair* $(F_0,F_1)\in\mathcal{O}_{(f_0,f_1)}$ *such that*

$$\big[F_0,[F_0,F_1]\big]=F_0+I_1F_1+I_2[F_1,F_0]+\sum_{k=3}^{n-2}I_k(\operatorname{ad}F_1)^kF_0. \tag{3.7}$$

Proof. By assumption (3.2) the vector fields $f_0, f_1, [f_1, f_0], \dots, (\operatorname{ad} f_1)^{n-2} f_0$ constitute the frame on M. Therefore there are functions E, N, $J_1, \dots, J_{n-2}$ such that

$$\big[f_0, [f_0, f_1]\big] = Ef_0 + J_1 f_1 + J_2[f_1, f_0] + Z\big[f_1, [f_1, f_0]\big] + \sum_{k=3}^{n-2} J_k (\operatorname{ad} f_1)^k f_0. \tag{3.8}$$

Take some pair $(\tilde f_0, \tilde f_1) \in \mathcal{O}_{(f_0, f_1)}$; then

$$\tilde f_0 = f_0 + \alpha f_1, \quad \tilde f_1 = \beta f_1. \tag{3.9}$$

Suppose that

$$\big[\tilde f_0, [\tilde f_0, \tilde f_1]\big] = \widetilde{E} \tilde f_0 + \widetilde{J}_1 \tilde f_1 + \widetilde{J}_2[\tilde f_1, \tilde f_0] + \widetilde{Z}\big[\tilde f_1, [\tilde f_1, \tilde f_0]\big] + \sum_{k=3}^{n-2} J_k (\operatorname{ad} \tilde f_1)^k \tilde f_0. \tag{3.10}$$

First note that

$$\widetilde{E} = \beta E. \tag{3.11}$$

It follows immediately from (3.9) and the following relations:

$$\big[\tilde f_0, [\tilde f_0, \tilde f_1]\big] \equiv \beta \big[f_0, [f_0, f_1]\big] - \alpha\beta \big[f_1, [f_1, f_0]\big] \bmod \operatorname{span}(f_1, [f_0, f_1]), \tag{3.12}$$

$$(\operatorname{ad} f_1)^k f_0 \in \operatorname{span}\big(\tilde f_1, \dots, (\operatorname{ad} \tilde f_1)^k \tilde f_0\big), \quad k \in \mathbb{N}. \tag{3.13}$$

From assumption (3.3) it follows that $E \neq 0$. Therefore, taking $\beta = \frac{1}{E}$, we have

$$\widetilde{E} = 1. \tag{3.14}$$

Let us denote by $\overline{\mathcal{O}}_{(f_0, f_1)}$ the set of all pairs $(\tilde f_0, \tilde f_1)$ satisfying (3.14). We can assume from the beginning that the original pair (f_0, f_1) belongs to $\overline{\mathcal{O}}_{(f_0, f_1)}$; i.e., $E = 1$ (we make this assumption just to avoid extra notation). If $(\tilde f_0, \tilde f_1) \in \overline{\mathcal{O}}_{(f_0, f_1)}$, then also $\widetilde{E} = 1$. Hence $\beta = 1$ or, equivalently, $f_1 = \tilde f_1$. In other words, condition (3.14) normalizes the vector field f_1 or the direction defining the straight line in the set of admissible velocities of the system (3.1) at any point.

Further, from (3.9), taking into account that $\beta = 1$, it follows easily that

$$(\operatorname{ad} f_1)^k f_0 \equiv (\operatorname{ad} \tilde f_1)^k \tilde f_0 \bmod \operatorname{span}(f_1), \quad k \in \mathbb{N}.$$

This and relation (3.12) imply that

$$\widetilde{Z} = Z - \alpha. \tag{3.15}$$

Setting $\alpha = Z$, we make $\widetilde{Z} = 0$, which normalizes the drift $\tilde f_0$. Thus, we have proved that there is a unique $(\tilde f_0, \tilde f_1) \in \mathcal{O}_{(f_0, f_1)}$ such that $\widetilde{E} = 1$ and $\widetilde{Z} = 0$, which completes the proof of the proposition. □

Remark 4. The mappings $I_1, \dots, I_{n-2}$ from M to $\mathbb{R}$, defined by identity (3.7), are state-feedback invariants of the control system (3.1). □

The vector field F_0 and the pair of vector fields (F_0, F_1) from Proposition 2 are called *the canonical drift* and *the canonical pair* of the system (3.1), respectively.

Remark 5. Actually, in the case $n = 4$, the vector $F_0(q)$ is the velocity of the unique abnormal extremal starting at q of the time optimal problem defined by system (3.1). □

Now fix some point $q_0 \in M$. Denote by e^{tf} the flow generated by the vector field f and by $q \circ e^{tf}$ the image of the point q w.r.t. this flow. Let $\Phi_n : \mathbb{R}^n \mapsto M$ be the following mapping:

$$\Phi_4(x_1, x_2, x_3, x_4) = q_0 \circ e^{x_4 \left[F_1,[F_1,F_0]\right]} \circ e^{x_3[F_1,F_0]} \circ e^{x_2 F_1} \circ e^{x_1 F_0}, \tag{3.16}$$

$$\begin{aligned}\Phi_n(x_1, \dots, x_n) = q_0 \circ e^{x_n (\operatorname{ad} F_1)^{n-3} F_0} \circ \dots \circ e^{x_5 \left[F_1,[F_1,F_0]\right]} \\ \circ e^{x_4 \left[F_0,[F_0,F_1]\right]} \circ e^{x_3[F_1,F_0]} \circ e^{x_2 F_0} \circ e^{x_1 F_1}, \quad n \geq 5.\end{aligned} \tag{3.17}$$

From assumption (3.2) in the case $n = 4$ or assumption (3.4) in the case $n \geq 5$ it follows that $\Phi_n'(0)$ is bijective. Hence Φ_n^{-1} defines *the canonical coordinates in a neighborhood of* q_0 (or, for short, *the canonical coordinates at* q_0). Denote

$$\mathcal{I}_k = I_k \circ \Phi_n, \quad k = 1, \dots, n-2. \tag{3.18}$$

Assigning to any generic germ at q_0 of control-affine systems (3.1) the function $\mathcal{I}_k$, we obtain the functional invariant of n variables of this set of objects in the sense of Definition 1 for any $1 \leq k \leq n-2$.

Now let us consider the cases $n = 4$ and $n \geq 5$ separately.

(a) *The case* $n = 4$. By (3.16) and (3.7), in the canonical coordinates the vector fields F_0 and F_1 have the form

$$F_0 = \frac{\partial}{\partial x_1}, \quad F_1 = \sum_{k=1}^{4} a_k \frac{\partial}{\partial x_k}, \tag{3.19}$$

where the components of F_1 satisfy the following second order linear ordinary differential equations w.r.t. the variable x_1:

$$\frac{\partial^2 a_k}{\partial x_1^2} + \mathcal{I}_2 \frac{\partial a_k}{\partial x_1} - \mathcal{I}_1 a_k - \delta_{1,k} = 0, \quad k = 1, 2, 3, 4, \tag{3.20}$$

with the following restrictions on the initial conditions for any $k = 1, 2, 3, 4$:

$$a_k(0, x_2, x_3, x_4) \equiv \delta_{2k}, \tag{3.21a}$$

$$\frac{\partial a_k}{\partial x_1}(0, 0, x_3, x_4) \equiv -\delta_{3k}, \tag{3.21b}$$

$$\frac{\partial^2 a_k}{\partial x_1 \partial x_2}(0, 0, 0, x_4) \equiv -\delta_{4k}, \tag{3.21c}$$

where δ_{ij} is the Kronecker symbol. Let for any $k = 1, 2, 3, 4$

$$\beta_k(x_2, x_3, x_4) \stackrel{def}{=} \frac{\partial^3 a_k}{\partial x_1 \partial x_2^2}(0, x_2, x_3, x_4), \tag{3.22a}$$

$$\psi_k(x_3, x_4) \stackrel{def}{=} \frac{\partial^3 a_k}{\partial x_1 \partial x_2 \partial x_3}(0, 0, x_3, x_4). \tag{3.22b}$$

Thus, with any germ at q_0 of a four-dimensional affine system (3.1) satisfying genericity assumptions (3.2) and (3.3), one can associate the ordered tuple

$$(\mathcal{I}_1, \mathcal{I}_2, \beta_1, \beta_2, \beta_3, \beta_4, \psi_1, \psi_2, \psi_3, \psi_4) \tag{3.23}$$

of state-feedback functional invariants, consisting of two germs $\mathcal{I}_1$ and $\mathcal{I}_2$ of functions of four variables at 0, four germs $\beta_1, \beta_2, \beta_3, \beta_4$ of functions of three variables at 0, and four germs $\psi_1, \psi_2, \psi_3, \psi_4$ of functions of three variables at 0. We call it *the tuple of the primary invariants of the* $(1,4)$ *control-affine system* (3.1) *at the point* q_0. Note that by (3.22) the functional invariants β_k and ψ_k have the weight 3 for any $1 \le k \le 4$, while by (3.20) and (3.21) the functional invariants $\mathcal{I}_1$ and $\mathcal{I}_2$ have the weight 2.

Further, fixing β_k and ψ_k and using (3.21b) and (3.21c), we can find $\frac{\partial a_k}{\partial x_1}(0, x_2, x_3, x_4)$ for any $1 \le k \le 4$ by the appropriate integrations (see (3.31) below). If in turn we fix also $\mathcal{I}_1$ and $\mathcal{I}_2$, then from the knowledge of $\frac{\partial a_k}{\partial x_1}(0, x_2, x_3, x_4)$, condition (3.21a), and differential equation (3.20), we can recover the functions $a_k(x_1, x_2, x_3, x_4)$ and therefore our control-affine system itself, just using the standard existence and uniqueness results from the theory of ordinary differential equations. We summarize all of the above in the following theorem.

THEOREM 1. *Given two arbitrary germs* $\mathcal{I}_1$ *and* $\mathcal{I}_2$ *of functions of four variables at* 0*, four arbitrary germs* $\beta_1, \beta_2, \beta_3, \beta_4$ *of functions of three variables at* 0*, and four arbitrary germs* $\psi_1, \psi_2, \psi_3, \psi_4$ *of functions of two variables at* 0*, there exists a unique, up to state-feedback transformation of type* (1.3)*, four-dimensional control-affine system with scalar input, satisfying genericity assumptions* (3.2) *and* (3.3)*, such that the tuple* $(\mathcal{I}_1, \mathcal{I}_2, \beta_1, \beta_2, \beta_3, \beta_4, \psi_1, \psi_2, \psi_3, \psi_4)$ *is its tuple of the primary invariants at the given point* q_0*. In other words, the tuples of the primary invariants give the regular* $(3,2)$*-parameterization of the considered classification problem with the following* 3×2 *parameterization matrix* P*:*

$$P = \begin{pmatrix} 0 & 4 \\ 0 & 4 \\ 2 & 0 \end{pmatrix}. \tag{3.24}$$

The Poincaré series $M(t)$ *of the considered classification problem satisfies*

$$M(t) = \frac{2t^2}{(1-t)^5} + t^3 \left(\frac{4}{(1-t)^4} + \frac{4}{(1-t)^3} \right). \tag{3.25}$$

It turns out that $(3,2)$ is the characteristic pair of the considered classification problem. Indeed, as before let w_0 be the order of zero of $M(t)$ at $t = 0$, N be the order of pole of $(1-t)M(t)$ at $t = 1$, and d be the degree of $M(t)$ (at infinity). Then from (3.25) it follows that $w_0 = 2$, $N = 4$, and $d = 0$. Hence from (2.23) (or (2.25)) it follows that

$$\mathrm{NS}\big(M(t)\big) \subset \{(w,l) : w \ge 2\}. \tag{3.26}$$

Further, using (2.24), one has

(3.27)

$$\mathrm{NS}\big(M(t)\big) \cap \{(w,l) : w = 2\} \subset \{(2,1)\}, \quad \mathrm{NS}\big(M(t)\big) \cap \{(w,l) : w = 3\} \subset \{(3,1), (3,2)\}.$$

But by the previous theorem our classification problem admits $(3,2)$-parameterization such that its parameterization matrix has a positive entry in the upper right corner.

Therefore from Corollary 1 it follows that $(2,1) \notin \mathrm{NS}\big(M(t)\big)$. Since $(3,2) \prec (3,1)$ we can conclude from (3.26) and (3.27) that $(3,2)$ is the minimal element of $\mathrm{NS}\big(M(t)\big)$. In other words, $(3,2)$ is the characteristic pair of our classification problem. Also, it implies that the characteristic matrix $\mathcal{C}$ of the problem is equal to $\mathrm{Norm}(P)$, which can be found easily by the series of elementary transformations. Namely,

$$\mathcal{C} = \mathrm{Norm}(P) = \begin{pmatrix} 2 & 4 \\ 0 & 6 \\ 0 & 2 \end{pmatrix}. \tag{3.28}$$

Conclusion 1. *The characteristic parameterization of* $(1,4)$ *control-affine systems, up to state-feedback transformations, consists of two functional invariants of four variables and the weight* 3*, six functional invariants of three variables and the weight* 3*, two functional invariants of two variables and the weight* 2*, and four functional invariants of two variables and the weight* 3*.*

In order to obtain a characteristic parameterization from the parameterization by the tuple of the primary invariants one can implement some series of rearrangement of the primary invariants according to the series of elementary transformations from the matrix P to $\mathrm{Norm}(P)$, as described in the previous section (see, for example, formula (2.19) and the paragraph that follows it).

We finish the treatment of the case of $(1,4)$-affine control systems by writing the local normal form of such systems, up to state-feedback transformation, in terms of the tuple of their primary invariants: Let N be the solution of the following nonhomogeneous second order linear ordinary differential equation w.r.t. the variable x_1 with prescribed initial values:

$$\begin{cases} \dfrac{\partial^2 N}{\partial x_1^2} + \mathcal{I}_2 \dfrac{\partial N}{\partial x_1} - \mathcal{I}_1 N - 1 = 0; \\ N(0, x_2, x_3, x_4) \equiv 0, \quad \dfrac{\partial N}{\partial x_1}(x_1, x_2, x_3, x_4)\Big|_{x_1=0} \equiv 0. \end{cases} \tag{3.29}$$

Then let the functions ρ_1, ρ_2 be the solution of the following homogeneous second order linear ordinary differential equations w.r.t. the variable x_1 with prescribed initial values:

$$\begin{cases} \dfrac{\partial^2 \rho_i}{\partial x_1^2} + \mathcal{I}_2 \dfrac{\partial \rho_i}{\partial x_1} - \mathcal{I}_1 \rho_i = 0, \quad i = 1, 2; \\ \begin{pmatrix} \rho_1(0, x_2, x_3, x_4) & \rho_1(0, x_2, x_3, x_4) \\ \frac{\partial}{\partial x_1}\rho_1(0, x_2, x_3, x_4) & \frac{\partial}{\partial x_1}\rho_2(0, x_2, x_3, x_4) \end{pmatrix} \equiv \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}. \end{cases} \tag{3.30}$$

Let also

$$B_k(x_2, x_3, x_4) = -\delta_{3k} + x_2 \left(-\delta_{4k} + \int_0^{x_3} \psi_k(y, x_4)\, dy \right) + \int_0^{x_2} (x_2 - y) \beta_k(y, x_3, x_4)\, dy \tag{3.31}$$

for $1 \le k \le 4$ (actually $B_k(x_2, x_3, x_4) = \frac{\partial a_k}{\partial x_1}(0, x_2, x_3, x_4)$, where the functions a_k are as in (3.19)). Then the generic germs at q_0 of four-dimensional control-affine system (3.1) with the tuple of the primary invariants $(\mathcal{I}_1, \mathcal{I}_2, \beta_1, \beta_2, \beta_3, \beta_4, \psi_1, \psi_2, \psi_3, \psi_4)$ has the following form in the canonical coordinates (x_1, x_2, x_3, x_4), up to a feedback transformation:

$$\begin{cases} \dot{x}_1 = 1 + (N + B_1\rho_2)u, \\ \dot{x}_2 = (\rho_1 + B_2\rho_2)u, \\ \dot{x}_i = B_i\rho_2 u, \quad i = 3, 4, \end{cases} \tag{3.32}$$

where $u \in \mathbb{R}$.

(b) *The case* $n \geq 5$. By (3.17) and (3.7), in the canonical coordinates the vector fields F_0 and F_1 have the form

$$F_0 = \sum_{k=1}^{n} a_k \frac{\partial}{\partial x_k}, \quad F_1 = \frac{\partial}{\partial x_1}, \tag{3.33}$$

where the components a_k of F_0 satisfy the system of partial differential equations

(3.34)

$$\mathcal{I}_{n-2}\frac{\partial^{n-2}a_k}{\partial x_1^{n-2}} + \sum_{j=3}^{n-3}\mathcal{I}_j\frac{\partial^j a_k}{\partial x_1^j} + \sum_{l=1}^{n}\left(a_l\frac{\partial^2 a_k}{\partial x_1^2} - \frac{\partial a_l}{\partial x_1}\frac{\partial a_k}{\partial x_l}\right) + \mathcal{I}_2\frac{\partial a_k}{\partial x_1} + a_k + \mathcal{I}_1\delta_{1,k} = 0,$$

$k = 1, \ldots, n,$

with the following restrictions on the boundary conditions for any $1 \leq k \leq n$:

$$a_k(0, x_2, \ldots, x_n) \equiv \delta_{2k}, \tag{3.35a}$$

$$\frac{\partial a_k}{\partial x_1}(0, 0, x_3 \ldots, x_n) \equiv \delta_{3k}, \tag{3.35b}$$

$$\frac{\partial^2 a_k}{\partial x_1 \partial x_2}(0, 0, 0, x_4, \ldots, x_n) \equiv -\delta_{4k}, \tag{3.35c}$$

$$\frac{\partial^j a_k}{\partial x_1^j}(0, \ldots, 0, x_{j+1}, \ldots, x_n) \equiv \delta_{j+3,k}, \quad 2 \leq j \leq n-3, \tag{3.35d}$$

where δ_{ij} is the Kronecker symbol. Note also that the genericity assumption (3.4) implies that

$$\mathcal{I}_{n-2} \neq 0. \tag{3.36}$$

Let us introduce the following functions for any $1 \leq k \leq n$:

(3.37a)

$$\beta_k(x_2, \ldots, x_n) \stackrel{def}{=} \frac{\partial^3 a_k}{\partial x_1 \partial x_2^2}(0, x_2, \ldots, x_n),$$

(3.37b)

$$\psi_k(x_3, \ldots, x_n) \stackrel{def}{=} \frac{\partial^3 a_k}{\partial x_1 \partial x_2 \partial x_3}(0, 0, x_3, \ldots, x_n),$$

(3.37c)

$$\phi_{kjl}(x_l, \ldots, x_n) \stackrel{def}{=} \frac{\partial^{j+1} a_k}{\partial x_1^j \partial x_l} a_k(0, \ldots, 0, x_l, \ldots x_n), \quad 2 \leq j \leq n-3, \quad 2 \leq l \leq j+2.$$

Thus, with any germ at q_0 of an n-dimensional affine system (3.1), satisfying genericity assumptions (3.2) and (3.3), one can associate the ordered tuple

$$\Big(\{\mathcal{I}_s(x_1, \ldots, x_n)\}_{s=1}^{n-2}, \{\beta_k(x_2, \ldots, x_n)\}_{k=1}^{n}, \{\psi_k(x_3, \ldots, x_n)\}_{k=1}^{n}, \\ \{\phi_{kjl}(x_l, \ldots, x_n) : 1 \leq k \leq n, 2 \leq j \leq n-3, 2 \leq l \leq j+2\}\Big) \tag{3.38}$$

of state-feedback invariants. We call it *the tuple of the primary invariants of the* $(1,n)$*-affine control system* (3.1) *with* $n>4$ *at the point* q_0. Note that by (3.22) for any $1\le k\le n$ the functional invariants β_k and ψ_k have the weight 3, and the functional invariants ϕ_{kjl} have the weight $j+1$, while by (3.20) and (3.21) for any $1\le s\le n-2$ the functional invariants $\mathcal{I}_s$ have the weight $n-2$.

Further, fixing β_k and ψ_k and using (3.35b) and (3.35c), one finds $\frac{\partial a_k}{\partial x_1}(0,x_2,\dots,x_n)$ for any $1\le k\le n$ by the appropriate integrations. Similarly, fixing $\{\phi_{kjl}\}_{l=2}^{j+2}$ for given j, $2\le j\le n-3$, and using (3.35d), one can find $\frac{\partial^j a_k}{\partial x_1^j}(0,x_2,\dots,x_n)$ for any $1\le k\le n$ by the appropriate integrations. Finally, if we suppose that all functions β_k, ψ_k, and ϕ_{kjl} are real analytic and fix also real analytic $\{\mathcal{I}_s\}_{s=1}^{n-2}$, then from the knowledge of $\frac{\partial^j a_k}{\partial x_1^j}(0,x_2,\dots,x_n)$ for all $1\le j\le n-3$, condition (3.35a), and differential equation (3.34), we can recover the functions $a_k(x_1,\dots,x_n)$ and therefore our affine control system itself, just by using the classical Cauchy–Kowalewsky theorem for system (3.34). We summarize all of the above in the following theorem.

THEOREM 2. *If* $n\ge 5$*, then given an arbitrary tuple* (3.38) *of germs of real analytic functions, there exists a unique, up to state-feedback real analytic transformation of type* (1.3)*,* n*-dimensional real analytic control-affine system with scalar input, satisfying genericity assumptions* (3.2)*,* (3.3)*, and* (3.4)*, such that the tuple* (3.38) *is its tuple of the primary invariants at the given point* q_0*. In other words, the tuples of the primary invariants give the regular* $(n-2,2)$*-parameterization of the considered classification problem in the real analytic category with the* $(n-1)\times(n-4)$*-parameterization matrix* P *such that for* $n=5$

$$P=(5,10,10,3)^T, \tag{3.39}$$

and for $n>5$

$$P=\begin{pmatrix} 0 & \dots\dots\dots & 0 & n\\ \vdots & & \iddots\ \iddots & \vdots\\ \vdots & \iddots\ \iddots & & \vdots\\ \vdots & \iddots\ \iddots & & \vdots\\ 0 & n & \dots\dots\dots & n\\ n & n & \dots\dots\dots & n\\ 2n & n & \dots\dots\dots & n\\ 2n & n & \dots\dots\dots & n\\ 0 & \dots\dots\dots & 0 & n-2 \end{pmatrix} \tag{3.40}$$

(in the matrix P *all entries in the triangle with vertices in the* $(1,1)$*-entry, the* $(1,n-5)$*-entry, and the* $(n-5,1)$*-entry are equal to* 0*, while all entries in the triangle with vertices in the* $(1,n-4)$*-entry, the* $(n-4,1)$*-entry, and the* $(n-4,\,n-4)$*-entry are equal to* n*). The Poincaré series* $M(t)$ *of the considered classification problem satisfies*

$$\begin{aligned} M(t)&=nt^3\left(\frac{2}{(1-t)^n}+\frac{2}{(1-t)^{n-1}}+\frac{1}{(1-t)^{n-2}}\right)\\ &\quad+n\sum_{i=4}^{n-2}t^i\sum_{j=n-i}^{n-1}\frac{1}{(1-t)^{j+1}}+\frac{(n-2)t^{n-2}}{(1-t)^{n+1}}. \end{aligned} \tag{3.41}$$

It turns out that $(n-2,2)$ is the characteristic pair of the considered classification problem. Indeed, as before let w_0 be the order of zero of $M(t)$ at $t=0$, let N be the order of pole of $(1-t)M(t)$ at $t=1$, and let d be the degree of $M(t)$ (at infinity). Then from (3.25) it follows that $w_0=3$, $N=n$, and $d=n-5$. Hence from (2.25) it follows that

$$\mathrm{NS}\big(M(t)\big) \subset \{(w,l) : w \geq n-3\}. \tag{3.42}$$

Further, using (2.24), one has

$$\begin{aligned} &\mathrm{NS}\big(M(t)\big) \cap \{(w,l) : w = n-3\} \subset \{(n-3,1)\},\\ &\mathrm{NS}\big(M(t)\big) \cap \{(w,l) : w = n-2\} \subset \{(n-2,1),(n-2,2)\}. \end{aligned} \tag{3.43}$$

But by the previous theorem our classification problem admits $(n-2,2)$-parameterization such that its parameterization metric has a positive entry in the upper right corner. Therefore from Corollary 1 it follows that $(n-3,1) \notin \mathrm{NS}\big(M(t)\big)$. Since $(n-2,2) \prec (n-2,1)$, we can conclude from (3.42) and (3.43) that $(n-2,2)$ is the minimal element of $\mathrm{NS}\big(M(t)\big)$. In other words, $(n-2,2)$ is the characteristic pair of our classification problem. Also, it implies that the characteristic matrix $\mathcal{C}$ of the problem is equal to $\mathrm{Norm}(P)$, where P is as in Theorem 2. If $n=5$, then obviously $\mathcal{C}=\mathrm{Norm}(P)=P$. For $n>5$ one can calculate all nontrivial entries of $\mathrm{Norm}(P)$, using identities (2.21). This gives all nontrivial entries of the characteristic matrix $\mathcal{C}$:

(3.44)

$$\begin{aligned} &\mathcal{C}_{n-1,n-4} = n-2,\\ &\mathcal{C}_{n-2,n-4} = n(n-3),\\ &\mathcal{C}_{i,n-4} = n\left(1+\sum_{l=1}^{n-3-i}\tbinom{i+2l-3}{l}+\tbinom{2n-9-i}{n-3-i}+2\tbinom{2n-8-i}{n-2-i}+\tbinom{2n-7-i}{n-7-i}\right), \quad 2\leq i\leq n-3,\\ &\mathcal{C}_{1,n-4} = n,\\ &\mathcal{C}_{1j} = n\left(\tbinom{n-4+j}{j-1}+2\tbinom{n-5+j}{j-1}+2\tbinom{n-6+j}{j-1}+\tbinom{n-7+j}{j-1}-1-\sum_{l=1}^{j-1}\tbinom{n+2l-7-j}{l}\right),\\ &\quad 1\leq j\leq n-5. \end{aligned}$$

Recall that $\mathcal{C}_{ij}$ is the intrinsic number of the functional invariants of $i+1$ variables and the weight $j+2$. In order to obtain a characteristic parameterization from the parameterization by the tuple of the primary invariants, one can implement some series of rearrangement of the primary invariants according to the series of elementary transformations from the matrix P to $\mathrm{Norm}(P)$, as described in the previous section (see, for example, the formula (2.19) and the paragraph that follows it).

Remark 6. Two control systems $\dot{y}=\mathcal{F}(y,v)$ and $\dot{\tilde{y}}=\widetilde{\mathcal{F}}(\tilde{y},\tilde{v})$, with m-dimensional state-space S and one-dimensional control space V, are called *locally in state-input space state-feedback equivalent at the point* $(y_0,v_0)\in S\times V$ if there exists the state-feedback transformation

$$\begin{cases} \tilde{y}=\Phi_1(y),\\ \tilde{v}=\Phi_2(y,v),\\ y_0=\Phi_1(y_0), \quad v_0=\Phi_2(y_0,v_0) \end{cases}$$

such that in a neighborhood of (y_0, v_0) in $S \times V$ the following identity holds:

$$\widetilde{\mathcal{F}}\big(\Phi_1(y), \Phi_2(y,v)\big) = d\Phi_1 \mathcal{F}(y,v).$$

The affine $(1, m+1)$ control system (1.5) will be called *the affine extension* of the control system (1.4). It is not difficult to show that two control systems with scalar input are locally in state-input space state-feedback equivalent at some point $(y_0, v_0) \in S \times V$ if and only if their affine extensions are locally equivalent w.r.t. the state-feedback transformations of type (1.3) at the same point. Note also that the affine extensions of generic m-dimensional control systems with scalar input are generic in the set of all $(1, m+1)$-affine systems. Using this fact and Theorems 1 and 2, one obtains the local in state-input space state-feedback classification of generic germs of nonaffine m-dimensional control systems with scalar inputs, and $m \geq 3$ by the tuples of the primary invariants of their affine extensions (in the C^∞ category for $m = 3$ and the C^ω category for $m \geq 4$). Obviously, the Poincaré series, the characteristic pair, and the characteristic matrix of the local in state-input space state-feedback classification problem for m-dimensional control systems with scalar input are exactly the same as in the case of the state-feedback classification problem of $(1, m+1)$ control-affine systems. Besides, since in our method of normalization of $(1, n)$ control-affine systems with $n \geq 5$ we rectify the vector field f_1, in the case $m \geq 4$ the generic germ at (y_0, v_0) of an m-dimensional real analytic control system with the prescribed tuple (3.38) of the primary invariants of its affine extension has the following normal form w.r.t. the local in state-input space state-feedback equivalence:

$$\dot{\xi}_s = f_s(\xi_1, \dots, \xi_m, \nu), \quad 1 \leq s \leq m,$$

such that $f_s(x_2, x_3, \dots, x_{m+1}, x_1) = a_{s+1}(x_1, \dots, x_{m+1})$, where the tuple $\{a_k\}_{k=1}^{m+1}$ is the solution of the system of partial differential equations (3.34) with boundary conditions, which can be expressed by the primary invariants β_k, ψ_k, and ϕ_{kjl}, using (3.37) (the point (y_0, v_0) corresponds to the origin of the coordinates $(\xi_1, \dots, \xi_m, \nu)$ in the state-input space).

4. Reduction of control-affine systems with two-dimensional input to the scalar input case in dimensions 4 and 5. For $r = 2$ the system (1.1) has the following form:

$$\dot{q} = f_0(q) + u_1 f_1(q) + u_2 f_2(q), \quad q \in M, \quad u_1, u_2 \in \mathbb{R}. \tag{4.1}$$

Our aim is to assign to the system (4.1) in a canonical way an affine subsystem with scalar input.[2] It turns out that in the case $n = 4$ the original system can be recovered from it uniquely up to a feedback transformation, while in the case $n = 5$ such unique recovering is possible after introducing an additional invariant function of n variables (which is natural in view of the estimates for the number of functional parameters given in the introduction).

4.1. Preliminaries. Let us look on (4.1) as on the time optimal control problem and find its extremals. First we introduce some notation. Let T^*M be the cotangent bundle of M with canonical symplectic form σ. Denote by h_i, $0 \leq i \leq 2$, the following functions on T^*M:

$$h_i(\lambda) = p \cdot f_i(q), \quad \lambda = (p, q), \quad q \in M, \quad p \in T_q^* M. \tag{4.2}$$

[2]The meaning of the word "subsystem" is that at any point q the set of its admissible velocities is a subset of the set of the admissible velocities of the original system at q.

For a given function $G : T^*M \mapsto \mathbb{R}$ denote by $\vec{G}$ the corresponding Hamiltonian vector field defined by the relation $\sigma(\vec{G}, \cdot) = -d\,G(\cdot)$. For a given vector distribution D on M (i.e., a subbundle of the tangent bundle), define the lth power D^l by the recursive relation

$$D^l = D^{l-1} + [D, D^{l-1}], \quad D^1 = D,$$

and denote by $(D^l)^\perp \subset T^*M$ the annihilator of D^l, namely,

$$(D^l)^\perp = \{(p, q) \in T^*M : p \cdot v = 0 \ \forall v \in D^l(q)\}.$$

In the introduced notation the Hamiltonian of Pontryagin's maximum principle for the time optimal problem (4.1) can be written as follows:

$$H(\lambda, u_1, u_2) = h_0(\lambda) + u_1 h_1(\lambda) + u_2 h_2(\lambda), \quad \lambda \in T^*M, \quad u_1, u_2 \in \mathbb{R}. \tag{4.3}$$

Let $\gamma(\cdot)$ be an extremal of (4.1) with extremal control functions $\bar{u}_1(t)$ and $\bar{u}_2(t)$. Then

$$\dot{\gamma}(t) = \vec{h}_0\big(\gamma(t)\big) + \bar{u}_1(t)\vec{h}_1\big(\gamma(t)\big) + \bar{u}_2(t)\vec{h}_2\big(\gamma(t)\big), \tag{4.4}$$

and from the maximality condition for H it follows that

$$\gamma(\cdot) \subset \{\lambda \in T^*M : h_1(\lambda) = h_2(\lambda) = 0\}. \tag{4.5}$$

If we denote $D_2 = \operatorname{span}(f_1, f_2)$, then (4.5) is equivalent to $\gamma(\cdot) \subset (D_2)^\perp$. Combining (4.4) and (4.5), we obtain

$$d_{\gamma(t)} h_i\big(\dot{\gamma}(t)\big) = 0, \quad i = 1, 2. \tag{4.6}$$

Then from (4.4) and (4.6) it follows that

$$\begin{aligned} &\{h_0, h_1\}\big(\gamma(t)\big) + \bar{u}_2(t)\{h_2, h_1\}\big(\gamma(t)\big) = 0, \\ &\{h_0, h_2\}\big(\gamma(t)\big) + \bar{u}_1(t)\{h_1, h_2\}\big(\gamma(t)\big) = 0 \end{aligned} \tag{4.7}$$

(here $\{h_i, h_j\}$ are Poisson brackets of the Hamiltonians h_i and h_j: $\{h_i, h_j\} = dh_j(\vec{h}_i)$). Now suppose that

$$\dim D_2^2 = 3. \tag{4.8}$$

Then relations (4.7) imply that the extremals of (4.1), lying in $(D_2)^\perp \backslash (D_2^2)^\perp$, are exactly the integral curves of the vector field

$$\vec{X} = \vec{h}_0 + \frac{\{h_0, h_2\}}{\{h_2, h_1\}}\vec{h}_1 + \frac{\{h_1, h_0\}}{\{h_2, h_1\}}\vec{h}_2 \tag{4.9}$$

(which is the Hamiltonian vector field, corresponding to the Hamiltonian $X = h_0 + \frac{\{h_0,h_2\}}{\{h_2,h_1\}}h_1 + \frac{\{h_1,h_0\}}{\{h_2,h_1\}}h_2$). Denote by V the affine subbundle of TM, defined by system (4.1), and let $V(q)$ be the set of all admissible velocities of the system (4.1) at the point q,

$$V(q) = \{f_0(q) + u_1 f_1(q) + u_2 f_2(q) : u_1, u_2 \in \mathbb{R}\}.$$

Let $\pi : T^*M \mapsto M$ be the canonical projection. The set

$$\operatorname{Ext}(q) = \{\pi_* \vec{X}(\lambda) : \lambda \in T_q^*M \cap (D_2)^\perp \backslash (D_2^2)^\perp\}, \quad q \in M, \tag{4.10}$$

is the subset of $V(q)$, consisting of the velocities of all extremal trajectories starting at q and having a lift in $(D_2)^\perp \backslash (D_2^2)^\perp$.

Among all extremals on $(D_2)^\perp \backslash (D_2^2)^\perp$, one can distinguish so-called abnormal extremals, i.e., the extremals lying on the zero level set of the Hamiltonian X. Denote $D_3 = \operatorname{span}(f_0, f_1, f_2)$ and suppose that

$$\dim(D_2^2 + D_3) = 4. \tag{4.11}$$

The set

$$\operatorname{Abn}(q) = \{\pi_* \vec{X}(\lambda) : \lambda \in T_q^* M \cap (D_3)^\perp \backslash (D_2^2)^\perp\}, \quad q \in M, \tag{4.12}$$

is the subset of $\operatorname{Ext}(q)$, consisting of the velocities of all abnormal extremal trajectories starting at q and having a lift in $(D_2)^\perp \backslash (D_2^2)^\perp$. One can show that for generic germs of affine systems of type (4.1), $\operatorname{Ext}(q) = V(q)$ in the case $n \geq 5$ and $\operatorname{Abn}(q) = V(q)$ in the case $n \geq 6$. But in the cases $n = 4$ and $n = 5$ either $\operatorname{Ext}(q)$ or $\operatorname{Abn}(q)$ (or both of them) defines the proper subsystem of the original system (4.1). Moreover, it turns out that these subsystems are affine with scalar input, so one can apply the theory of the previous section. Now let us consider the cases $n = 4$ and $n = 5$ separately.

4.2. The case $n = 4$. Let

$$[V, D_2](q) = \{[X, Y](q) : X \in V,\ Y \in D_2, \text{ are vector fields}\}.$$

It is not difficult to show that $[V, D_2](q)$ is a linear space and

$$[V, D_2](q) = \operatorname{span}\big(f_1(q), f_2(q), [f_1, f_2](q), [f_0, f_1](q), [f_0, f_2](q)\big). \tag{4.13}$$

The crucial observation is formulated in the following proposition.

PROPOSITION 3. *The set* $\operatorname{Ext}(q)$ *is an affine line, provided that* (4.8) *holds and*

$$\dim [V, D_2](q) = 4. \tag{4.14}$$

Proof. Take some vector field f_3 such that the tuple (f_0, f_1, f_2, f_3) constitutes the frame on M. Denote by c_{ji}^k the structural functions of this frame, i.e., the functions satisfying

$$[f_i, f_j] = \sum_{k=0}^{3} c_{ji}^k f_k. \tag{4.15}$$

Using the well-known property of the Poisson brackets,

$$\{h_i, h_j\}(p, q) = p \cdot [f_i, f_j](q), \quad q \in M, \quad p \in T_q^* M, \tag{4.16}$$

and (4.9), one can easily obtain that

$$\operatorname{Ext}(q) = \Pi(q) \cap V(q), \tag{4.17}$$

where

$$\begin{aligned} \Pi(q) = \big\{ &\big(c_{12}^0(q)\nu + c_{12}^3(q)\mu\big) f_0(q) + \big(c_{20}^0(q)\nu + c_{20}^3(q)\mu\big) f_1(q) \\ &+ \big(c_{01}^0(q)\nu + c_{01}^3(q)\mu\big) f_2(q) : \mu, \nu \in \mathbb{R}\big\}. \end{aligned} \tag{4.18}$$

From assumption (4.14) and identity (4.13) it follows that $\Pi(q)$ is a plane. Assumption (4.8) implies that the plane $\Pi(q)$ is not parallel to the plane $V(q)$. Note also that both $\Pi(q)$ and $V(q)$ belong to $D_3(q)$. Hence by (4.17) it follows that the set $\mathrm{Ext}(q)$ is an affine line. □

Consider the control system such that $\mathrm{Ext}(q)$ is its set of admissible velocities at q. By Proposition 3 it is an affine system with scalar input. We call this system *the reduction of the four-dimensional control-affine system* (4.1). The following proposition gives another characterization of the reduction of the system (4.1).

PROPOSITION 4. *Assume that the four-dimensional control-affine system* (4.1) *satisfies the conditions* (4.8) *and* (4.14). *Then the subsystem*

$$\dot{q} = g_0 + ug_1 \tag{4.19}$$

of (4.1) *is its reduction if and only if*

$$[g_0, g_1] \in D_2. \tag{4.20}$$

Proof. By definition, the system (4.19) is the reduction of (4.1) if and only if

$$\mathrm{Ext}(q) = \{g_0(q) + tg_1(q) : t \in \mathbb{R}\}. \tag{4.21}$$

On the other hand, one can take from the beginning $f_0 = g_0$ and $f_1 = g_1$. Then comparing (4.21) with (4.17) and (4.18), we obtain that the system (4.19) is the reduction of (4.1) if and only if $c_{01}^0 = c_{01}^3 = 0$, which is equivalent to $[g_0, g_1] \in \mathrm{span}(g_1, f_2) = D_2$. □

COROLLARY 2. *Assume that a four-dimensional affine control system* (4.19) *satisfies*

$$\dim \mathrm{span}\big(g_1, [g_1, g_0], \big[g_1, [g_1, g_0]\big], \big[g_0, [g_1, g_0]\big]\big) = 4. \tag{4.22}$$

Then any four-dimensional control-affine system with two-dimensional input, having the system (4.19) *as its reduction, is feedback equivalent to the system*

$$\dot{q} = g_0 + u_1 g_1 + u_2 [g_0, g_1], \quad u_1, u_2 \in \mathbb{R}. \tag{4.23}$$

Proof. First, by assumption (4.22) and relation (4.13), the system (4.23) satisfies conditions (4.8) and (4.14) (where f_0, f_1, and f_2 are replaced by g_0, g_1, and $[g_0, g_1]$). Hence, by Proposition 3 the system (4.23) admits the reduction, and by Proposition 4 this reduction is the system (4.19). On the other hand, suppose that some system (4.1) has the reduction (4.19). Then from the previous proposition $[g_0, g_1] \in \mathrm{span}(g_1, f_2)$. According to (4.22), g_1 and $[g_0, g_1]$ are linearly independent. Hence the system (4.1) is feedback equivalent to (4.23). □

According to the previous proposition, a generic germ of a four-dimensional control-affine system with two-dimensional input can be uniquely—up to a feedback transformation—recovered from its reduction. Suppose that the reduction (4.19) of the system (4.1) satisfies (4.22) and

$$\dim \mathrm{span}\big(g_0, g_1, [g_1, g_0], \big[g_1, [g_1, g_0]\big]\big) = 4. \tag{4.24}$$

Then we can apply to the system (4.19) all constructions of section 2. In particular, one can construct the tuple of the primary invariants of (4.19) at a given point, which are also feedback invariants of the original system (4.1). Note that the set of germs of systems of type (4.1) having the reductions, which satisfies conditions (4.22) and

(4.24), is generic. Combining Theorem 1, Corollary 2, and normal form (3.32), we obtain the following classification of generic germs of systems of type (4.1) in terms of the tuple of the primary invariants of their reductions as follows.

THEOREM 3. *Given two arbitrary germs $\mathcal{I}_1$ and $\mathcal{I}_2$ of functions of four variables at 0, four arbitrary germs $\beta_1, \beta_2, \beta_3, \beta_4$ of functions of three variables at 0, and four arbitrary germs $\psi_1, \psi_2, \psi_3, \psi_4$ of functions of two variables at 0, there exists a unique, up to state-feedback transformation of type* (1.3)*, four-dimensional control-affine system with two-dimensional input such that its reduction satisfies genericity assumptions* (4.22) *and* (4.24) *and $(\mathcal{I}_1, \mathcal{I}_2, \beta_1, \beta_2, \beta_3, \beta_4, \psi_1, \psi_2, \psi_3, \psi_4)$ is the tuple of the primary invariants of the reduction at the given point q_0. This control system is state-feedback equivalent to the following system:*

$$\begin{cases} \dot{x}_1 = 1 + (N + B_1\rho_2)u_1 + \left(\dfrac{\partial N}{\partial x_1} + \beta_1 \dfrac{\partial \rho_2}{\partial x_1}\right) u_2, \\ \dot{x}_2 = (\rho_1 + B_2\rho_2)u_1 + \left(\dfrac{\partial \rho_1}{\partial x_1} + B_2 \dfrac{\partial \rho_2}{\partial x_1}\right) u_2, \qquad u_1, u_2 \in \mathbb{R}, \\ \dot{x}_i = B_i\rho_2 u_1 + \beta_i \dfrac{\partial \rho_2}{\partial x_1} u_2, \quad i = 3, 4, \end{cases} \tag{4.25}$$

where N is the solution of (3.29)*, ρ_i, $i = 1, 2$, are the solutions of* (3.30)*, and B_k, $1 \le k \le 4$, are as in* (3.31)*. The Poincaré series, the characteristic pair, and the characteristic matrix of the classification problem are exactly the same as in the case of* $(1, 4)$ *control-affine systems.*

Remark 7. It is easy to show that in the case $n = 4$ the set $\mathrm{Abn}(q)$ consists of one vector provided that (4.11) holds. Besides, if the system (4.19) is the reduction of the system (4.1) and it satisfies (4.22) and (4.24), then $\mathrm{Abn}(q)$ is exactly its canonical drift. □

Remark 8. Actually, there is another intrinsic way to assign to the system (4.1), satisfying (4.11), an affine subsystem with scalar input: As a drift one can take again $\mathrm{Abn}(q)$. It remains to define canonically the direction of the affine line of the reduction. For this note first that the distribution D_2 satisfies (4.8) because of assumption (4.11). Therefore through any point of M the unique (unparameterized) abnormal extremal trajectory of the rank 2 distribution D_2 passes: The line subdistribution L of D_2, tangent to the abnormal extremal trajectories at any point, is characterized by the relation $[L, D^2] \subseteq D^2$. The direction of the affine line of the reduction can be taken parallel to L. The direction of L is different in general from the direction of the affine line in the first reduction. But this new reduction is worse than the previous one, because the original system (4.1) is not uniquely recovered from it: If $(\bar{g}_0, \bar{g}_1)$ is the canonical pair of the new reduction (by construction and the previous remark $g_0 = \mathrm{Abn}$), then the field f_2 can be taken in the form $f_2 = \alpha\bar{g}_0 + [\bar{g}_1, \bar{g}_0]$, where the function α satisfies some second order ordinary differential equation along each integral curve of $\bar{g}_1$. Note that the direction $\bar{g}_1$ depends on the second jet of the original system (4.1), while the direction of the affine line in the first reduction depends only on the first jet. This could be the reason for the loss of some information about the original system during the reduction described in the present remark. □

4.3. The case $n = 5$. In this case by analogy with Proposition 3 we have the following proposition.

PROPOSITION 5. *The set* $\mathrm{Abn}(q)$ *is an affine line, provided that* (4.11) *holds and*

$$\dim D_3^2 = 5. \tag{4.26}$$

Proof. Take some vector fields f_3 and f_4 such that the tuple $(f_0, f_1, f_2, f_3, f_4)$ constitutes the frame on M. By analogy with (4.15), let c_{ji}^k, $0 \le i, j, k \le 4$, be the structural functions of this frame. From (4.9) and (4.12), using (4.16) and the fact that $h_0 = 0$ on $(D_3)^\perp$, one can easily obtain that

$$\mathrm{Abn}(q) = \Pi_1(q) \cap V(q), \tag{4.27}$$

where

$$\begin{aligned}\Pi_1(q) = \big\{ &\big(c_{12}^3(q)\nu + c_{12}^4(q)\mu\big) f_0(q) + \big(c_{20}^3(q)\nu + c_{20}^4(q)\mu\big) f_1(q) \\ &+ \big(c_{01}^3(q)\nu + c_{01}^4(q)\mu\big) f_2(q) : \mu, \nu \in \mathbb{R}\big\}.\end{aligned} \tag{4.28}$$

From assumption (4.26) and identity (4.13) it follows that $\Pi_1(q)$ is a plane. Assumption (4.11) implies that the plane $\Pi_1(q)$ is not parallel to the plane $V(q)$. Note also that both $\Pi_1(q)$ and $V(q)$ belong to $D_3(q)$. Hence by (4.27) the set $\mathrm{Abn}(q)$ is an affine line. □

Consider the control system such that $\mathrm{Abn}(q)$ is its set of admissible velocities at q. By Proposition 5 it is an affine system with scalar input. We call this system *the reduction of the five-dimensional control-affine system* (4.1). The following proposition gives another characterization of the reduction of the system (4.1).

PROPOSITION 6. *Assume that the five-dimensional control-affine system* (4.1) *satisfies the conditions* (4.26) *and* (4.11). *Then the subsystem*

$$\dot q = g_0 + u g_1 \tag{4.29}$$

of (4.1) *is its reduction if and only if*

$$[g_0, g_1] \in D_3. \tag{4.30}$$

Proof. By definition, the system (4.19) is the reduction of (4.1) if and only if

$$\mathrm{Abn}(q) = \{g_0(q) + t g_1(q) : t \in \mathbb{R}\}. \tag{4.31}$$

On the other hand, one can take from the beginning $f_0 = g_0$ and $f_1 = g_1$. Then comparing (4.31) with (4.27) and (4.28), we obtain that the system (4.29) is the reduction of (4.1) if and only if $c_{01}^3 = c_{01}^4 = 0$, which is equivalent to $[g_0, g_1] \in \mathrm{span}(g_0, g_1, f_2) = D_3$. □

COROLLARY 3. *Assume that a five-dimensional affine control system* (4.19) *satisfies*

$$\dim \mathrm{span}\big(g_0, g_1, [g_1, g_0], \big[g_1, [g_1, g_0]\big], \big[g_0, [g_1, g_0]\big]\big) = 5. \tag{4.32}$$

Then a five-dimensional control-affine system with two-dimensional input has the system (4.19) *as its reduction if and only if it is feedback equivalent to the system*

$$\dot q = g_0 + u_1 g_1 + u_2(\alpha g_0 + [g_0, g_1]), \quad u_1, u_2 \in \mathbb{R}, \tag{4.33}$$

where α is some function.

Proof. First by assumption (4.32) the system (4.33) satisfies conditions (4.26) and (4.11). Hence, by Proposition 5 the system (4.33) admits the reduction, and by Proposition 6 this reduction is the system (4.19). On the other hand, suppose that some system (4.1) has the reduction (4.19). Then from the previous proposition

$[g_0, g_1] \in \operatorname{span}(g_0, g_1, f_2)$. According to (4.22), g_0, g_1, and $[g_0, g_1]$ are linearly independent. Hence, $f_2 = \xi_0 g_0 + \xi_1 g_1 + \xi_2 [g_0, g_1]$, where $\xi_2 \neq 0$. Hence by a feedback transformation we can replace f_2 with $\alpha g_0 + [g_0, g_1]$. □

Thus, in contrast to the case $n = 4$, five-dimensional control-affine systems with two-dimensional input cannot be recovered from their reduction only. Suppose that the system (4.1) has the reduction (4.29) satisfying condition (4.32) and also

$$\dim \operatorname{span}\big(g_0, g_1, [g_1, g_0], \big[g_1, [g_1, g_0]\big], \big[g_1, \big[g_1, [g_1, g_0]\big]\big]\big) = 5, \tag{4.34}$$

$$\dim \operatorname{span}\big(g_1, \big[g_0, [g_0, g_1]\big], [g_1, g_0], \big[g_1, [g_1, g_0]\big], \big[g_1, \big[g_1, [g_1, g_0]\big]\big]\big) = 5. \tag{4.35}$$

Then we can apply to the system (4.29) all constructions of section 2. In particular, let (G_0, G_1) be the canonical pair of the system (4.29). As before, let V be the affine subbundle of TM, defined by system (4.1). Then by the same arguments, as in the proof of Corollary 3, there exists a unique vector field $G_2 \in V$ such that

$$G_2 = RG_0 + [G_0, G_1]. \tag{4.36}$$

By construction, the function R is a feedback invariant of system (4.1). Moreover, the system (4.1) can be uniquely—up to a feedback transformation—recovered from its reduction and the function R.

Fix some point q_0 in M. Let Φ_5 be as in (3.17). Denote

$$\mathcal{R} = R \circ \Phi_5. \tag{4.37}$$

Note that $\mathcal{R}$ is the germ of a function of five variables at 0. We call it *the recovering invariant of* (4.1) *at the point* q_0. By construction, it is an invariant of the weight 0. Note that the set of germs of systems of type (4.1) having the reductions, which satisfies conditions (4.32), (4.34), and (4.35), is generic. Using Theorem 2 in the case $n = 5$ and the definition of the recovering invariant, we obtain the following classification of generic real analytic germs of systems of type (4.1) in terms of the tuple of the primary invariants of their reductions and their recovering invariant.

THEOREM 4. *Given four germs $\mathcal{I}_1$, $\mathcal{I}_2$, $\mathcal{I}_3$, and $\mathcal{R}$ of real analytic functions of five variables at 0 such that $\mathcal{I}_3(0) \neq 0$, 10 germs $\{\beta_k\}_{k=1}^5$ and $\{\phi_{k22}\}_{k=1}^5$ of real analytic functions of four variables at 0, 10 germs $\{\psi_k\}_{k=1}^5$ and $\{\phi_{k23}\}_{k=1}^5$ of real analytic functions of three variables at 0, and five germs $\{\phi_{k24}\}_{k=1}^5$ of real analytic functions of two variables at 0, there exists a unique, up to state-feedback real analytic transformation of type* (1.3)*, five-dimensional real analytic control-affine system with two inputs such that first, its reduction satisfies genericity assumptions* (4.32), (4.34), (4.35)*, second,* $\big(\{\mathcal{I}_j\}_{j=1}^3, \{\beta_k\}_{k=1}^5, \{\psi_k\}_{k=1}^5, \{\phi_{k2l} : 1 \leq k \leq 5,\ 2 \leq l \leq 4\}\big)$ *is its tuple of the primary invariants, and finally, $\mathcal{R}$ is its recovering invariant at the given point q_0. In other words, the tuples of the primary invariants give the regular* $(3, 2)$*-parameterization of the considered classification problem in the real analytic category with the following* (4×4)*-parameterization matrix P:*

$$P = \begin{pmatrix} 0 & 0 & 0 & 5 \\ 0 & 0 & 0 & 10 \\ 0 & 0 & 0 & 10 \\ 1 & 0 & 0 & 3 \end{pmatrix}. \tag{4.38}$$

The Poincaré series $M(t)$ of the considered classification problem satisfies

$$M(t) = \frac{1}{(1-t)^6} + t^3 \left(\frac{5}{(1-t)^3} + \frac{10}{(1-t)^4} + \frac{10}{(1-t)^5} + \frac{3}{(1-t)^6} \right). \tag{4.39}$$

By the same arguments, as in the case of the $(1,n)$-affine control system with $n \geq 5$, treated in section 3, one can show that $(3,2)$ is the characteristic pair of the considered classification problem (just use formulas (2.24), (2.25), and Corollary 1). The characteristic matrix $\mathcal{C}$ of the problem is equal to $\mathrm{Norm}(P)$, which can be found easily by the series of elementary transformations. Namely,

$$\mathcal{C} = \mathrm{Norm}(P) = \begin{pmatrix} 1 & 3 & 6 & 5 \\ 0 & 0 & 0 & 16 \\ 0 & 0 & 0 & 13 \\ 0 & 0 & 0 & 4 \end{pmatrix}. \tag{4.40}$$

Conclusion 2. *The characteristic parameterization of* $(2,5)$ *control-affine systems, up to state-feedback transformations, consists of four functional invariants of five variables and the weight* 3*,* 13 *functional invariants of four variables and the weight* 3*,* 16 *functional invariants of three variables and the weight* 3*, one functional invariant of two variables and the weight* 0*, three functional invariants of two variables and the weight* 1*, six functional invariants of two variables and the weight* 2*, and five functional invariants of two variables and the weight* 3*.*

In order to obtain a characteristic parameterization from the parameterization by the tuple of the primary invariants and the recovering invariant, one can implement some series of rearrangement of the primary invariants according to the series of elementary transformations from the matrix P to $\mathrm{Norm}(P)$, as described in the previous section (see, for example, formula (2.19) and the paragraph that follows it).

OPTIMAL TERMINAL WEALTH UNDER PARTIAL INFORMATION: BOTH THE DRIFT AND THE VOLATILITY DRIVEN BY A DISCRETE-TIME MARKOV CHAIN*

MICHAEL TAKSAR† AND XUDONG ZENG†

Abstract. We consider a multistock market model. The stock price process satisfies a stochastic differential equation where both the drift and the volatility are driven by a discrete-time Markov chain of finite states. Not only the underlying Brownian motion but also the Markov chain in the stochastic differential equation are assumed to be unobservable. Investors can observe the stock price process only. The main result of this paper is that we derive the approximation of the optimal trading strategy and the corresponding optimal expected utility function from the terminal wealth for the CRRA utility function.

Key words. partial information, optimal terminal wealth, CRRA utility, dynamic programming

1. Introduction. In this paper, we consider a model of an incomplete market in which stocks are driven by an m-dimensional geometric Brownian motion the same as in the Black–Scholes model. However, the drift and the diffusion coefficients of this process depend on a discrete-time Markov chain whose states are not observable. Moreover, we do not observe the driving diffusion process—rather only the values of the price process.

There are quite a few papers devoted to studies of the problem of maximizing the expected utility function from the terminal wealth under partial information. Pham and Quenez [15] considered a stochastic volatility model. They solved the portfolio optimization problem under partial information by stochastic filtering techniques and adapting martingale duality methods. For more literature on partial information and stochastic volatility problems, we refer the reader to Lakner [12], [13], Frey [8], Runggaldier [16], Frey and Runggaldier [9], Cvitanić, Lipster, and Rozovskii [1], Elliott and Rishel [6], Elliott [7], and Henderson and Hobson [10].

Sass and Haussman [18] considered a multistock market model in continuous–time. The drift is a continuous–time, finite state Markov chain, and the volatility matrix is constant and nonsingular. They used Malliavin calculus and hidden Markov chain theory to derive an explicit expression for the optimal portfolio selection. However, their method cannot be extended to the case in which the volatility is driven by a Markov chain, because the EM algorithm they used to estimate the drift does not work for the volatility due to the fact that the measures involved in their method are not equivalent if the volatility is driven by a Markov chain.

In this paper, we consider a discrete-time multistock market model where both the drift and the volatility are driven by a Markov chain. In our paper, we use the method of estimating volatility studied by Elliott [4], Elliott, Hunter, and Jamieson

[5], developed for the discrete-time setting. The algorithm enables us to estimate the states of the Markov chain and its transition matrix. We solve the problem of optimizing the expected utility from the terminal wealth problem, and using dynamic programming we construct the optimal strategy in terms of the filter of the price process.

The rest of this paper is structured as follows. In section 2, we present the discrete-time model from the general continuous model and describe the relationship between the two models. We prove some preliminary results, which will be used in subsequent calculation. In section 3, we introduce some definitions and state the optimization problem. Section 4 is devoted to an important lemma related to an approximation of the optimal trading strategy for the CRRA utility function. In section 5 we show the results of simulation to illustrate our results.

2. Models and preliminary results.

2.1. Regime switching model: Continuous time. Consider the m-dimensional stock price process whose dynamics is given by a geometric Brownian motion equation:

$$dS(t) = \mathrm{diag}(S_t)(\mu(Y(t))dt + \hat{\sigma}(Y(t))dW(t)), \quad 0 \le t \le T. \tag{2.1}$$

Here $S_t = (S_t^{(1)}, S_t^{(2)}, \ldots, S_t^{(m)})'$, and the column vector W_t is an m-dimensional standard Brownian motion. $Y(t)$ is a finite state, homogeneous Markov chain with a generator $Q = (q_{ij})_{d\times d}$, independent of $W(t)$. The distribution of $Y(0)$ is known. $Y(t)$ has a state space $\mathcal{M} = \{e_1, \ldots, e_d\}$, where $e_i, i = 1, 2, \ldots, d$, is the unit vector in $\mathcal{R}^d$.

$$Y(t) \in \mathcal{M} := \{e_1, \ldots, e_d\}.$$

There are different values for the drift and different matrices for the volatility corresponding to states of the Markov chain $Y(t)$. Thus $\mu(\cdot)$ (resp., $\sigma(\cdot)$) is a mapping of $\mathcal{M}$ (resp., $\mathcal{N} := \{B := (b_{i,j})_{1\le i,j\le m}$ is invertible $|b_{i,j} \in \mathcal{R}^+\}$) into R^m (resp., into $R^{m\times m}$).

Suppose r is a constant interest rate. Then (2.1) may be written as follows.

$$d\ \log(e^{-rt}S(t)) = (\mu(Y(t)) - r1_m - \mathrm{diag}(\hat{\sigma}_{n-1}\hat{\sigma}'_{n-1}))dt + \hat{\sigma}(Y(t))dW(t), \tag{2.2}$$

where $0 \le t \le T, 1_m = (1, 1, \ldots, 1)' \in \mathcal{R}^{m\times 1}$, where we use the following convention:

$$\log((x_1, x_2, \ldots, x_n)') = (\log(x_1), \ldots, \log(x_n))'.$$

2.2. Regime switching model: Discrete time. In this paper, we will consider a discrete approximation to the continuous-time model (2.1).

Let $\Delta t = \frac{T}{N}$, $Y_n = Y(n\Delta t)$,

$$\mu_n = \mu(Y(n\Delta t)), \hat{\sigma}_n = \hat{\sigma}(Y(n\Delta t)), S_n = S(n\Delta t),$$

where $n = 0, 1, \ldots, N$. Then (2.2) becomes

$$\begin{aligned} &\log(S_n e^{-r\Delta t}) - \log(S_{n-1}) \\ &= (\mu_{n-1} - r1_m - \mathrm{diag}(\hat{\sigma}_{n-1}\hat{\sigma}'_{n-1})/2)\Delta t + \hat{\sigma}_{n-1}(W_n - W_{n-1}) \\ &:= y_n \end{aligned} \tag{2.3}$$

for $n = 1, 2, 3, \ldots, N$.

Let

$$\begin{cases} g_n : & = (\mu_n - r1_m - \operatorname{diag}(\hat{\sigma}_n \hat{\sigma}_n')/2)\Delta t \\ & = (\mu(Y_n) - r - \operatorname{diag}(\hat{\sigma}(Y_n)\hat{\sigma}(Y_n)')/2)\Delta t, \\ \sigma_n : & = \hat{\sigma}_n \sqrt{\Delta t} = \hat{\sigma}(Y_n)\sqrt{\Delta t}. \end{cases} \tag{2.4}$$

Then

$$y_n = g_{n-1} + \sigma_{n-1} Z_n, \quad n = 1, 2, \ldots, N, \tag{2.5}$$

where $Z_n = (W_n - W_{n-1})/\sqrt{\Delta t}, n = 1, 2, \ldots, N$, is a sequence of standard normal independently and identically distributed random variables.

Note that g_n and σ_n are functions of Y_n and can be written as $G(Y_n)$ and $H(Y_n)$, respectively, which obviously satisfy

$$\begin{array}{l} \frac{G(e_i)}{\Delta t} = \mu(e_i) - r1_m - \operatorname{diag}(\hat{\sigma}(e_i)\hat{\sigma}(e_i)')/2, \\ \frac{H(e_i)}{\sqrt{\Delta t}} = \hat{\sigma}(e_i). \end{array} \tag{2.6}$$

In this paper, we assume only the price of stock S_n or y_n can be observed. Denote the filtration generated by S_n by $\{\mathcal{F}_n\}$. We will study an optimization of the utility function of the terminal wealth in the discrete-time model (2.5).

2.3. Preliminary results. We present some preliminary results which will be used in the proofs in what follows.

By the definition of y_n (2.3), we know that for each $i = 1, 2, \ldots, m$,

$$S_n^{(i)} = S_{n-1}^{(i)} e^{y_n^{(i)}} e^{r\Delta t}.$$

For $k = 1, 2, \ldots, d$, denote

$$b_k := G(e_k) \in \mathcal{R}^{m\times 1}, f_k := H(e_k) \in \mathcal{R}^{m\times m}.$$

Let $b_k(i)$ stand for the ith component of b_k, and let $f_k(i)$ stands for the ith row of f_k. Then we have the following lemma.

LEMMA 2.1.

$$Pr(y_n^{(i)} \le t|\mathcal{F}_{n-1}) = \sum_{k=1}^{d} Pr(Y_{n-1} = e_k|\mathcal{F}_{n-1}) \int_{-\infty}^{t-b_k(i)} \phi_{ik}(x)dx,$$

where $\phi_{ik}(x) = \frac{1}{\sqrt{2\pi(f_k(i)\cdot f_k(i)')}} e^{-\frac{x^2}{2f_k(i)\cdot f_k(i)'}}$, $i = 1, 2, \ldots, m$.

Proof.

$$\begin{aligned} Pr(y_n^{(i)} \le t|\mathcal{F}_{n-1}) &= Pr(g_{n-1}^{(i)} + \sigma_{n-1}^{(i)} Z_n \le t|\mathcal{F}_{n-1}) \\ &= \sum_{k=1}^{d} Pr(b_k(i) + f_k(i)Z_n \le t, Y_{n-1} = e_k|\mathcal{F}_{n-1}) \\ &= \sum_{k=1}^{d} Pr(b_k(i) + f_k(i)Z_n \le t) Pr(Y_{n-1} = e_k|\mathcal{F}_{n-1}) \\ &= \sum_{k=1}^{d} Pr(Y_{n-1} = e_k|\mathcal{F}_{n-1}) \int_{-\infty}^{t-b_k(i)} \phi_{ik}(x)dx. \end{aligned}$$

□

Remark 1. Similarly, for the multidimensional case, $x \in R^{m\times 1}$, we have

$$\begin{aligned} &Pr(y_n \le x|\mathcal{F}_{n-1}) \\ &= \textstyle\sum_{k=1}^{d} Pr(Y_{n-1} = e_k|\mathcal{F}_{n-1}) \int_{-\infty}^{x_1-b_k(1)} \dots \int_{-\infty}^{x_m-b_k(m)} \phi_k(z)dz, \end{aligned} \tag{2.7}$$

where $\phi_k(x) = (2\pi|f_k f_k'|)^{\frac{-1}{2}} e^{-x'(f_k f_k')^{-1}x/2}, x \in R^{m\times 1}$.

LEMMA 2.2. *We have a recursive filter:*

$$Pr(Y_n = e_k|\mathcal{F}_n) = \frac{\sum_{i=1}^{d} Pr(Y_{n-1} = e_i|\mathcal{F}_{n-1})\phi_i(y_n - b_i)p_{ki}}{\sum_{i=1}^{d} Pr(Y_{n-1} = e_i|\mathcal{F}_{n-1})\phi_i(y_n - b_i)}, \tag{2.8}$$

where p_{ki} is the (k,i) entry of the transition matrix P.

Proof. This is Theorem 3.1 of Elliott [4]. □

In what follows, we will use the notation $E_n[\zeta] := E[\zeta|\mathcal{F}_n]$.

LEMMA 2.3. *$\alpha < 1$. For $i = 1, 2, \dots m$, we have*

(i) $|E_{n-1}[e^{y_n^{(i)}} - 1]| = O(\Delta t)$, (ii) $|E_{n-1}[(e^{y_n^{(i)}} - 1)^2]| = O(\Delta t)$,
(iii) $|E_{n-1}[(e^{y_n^{(i)}} - 1)^3]| = O(\Delta t)^2$, (iv) $|E_{n-1}[(1 - e^{-y_n^{(i)}})^3]| = O(\Delta t)^2$,
(v) $|E_{n-1}[e^{\alpha y_n^{(i)}}(1 - e^{-y_n^{(i)}})^3]| = O(\Delta t)^2$.

Proof. The proof of this lemma is in Appendix A. □

Remark 2. Using Lemmas 2.1 and 2.3, we have for $m = 1$ (i.e., when there is only one stock in the model)

$$\begin{aligned} &\tfrac{E_{n-1}[\Delta S_n]}{E_{n-1}[(\Delta S_n)^2]} \\ &= \frac{\sum_{k=1}^{d} Pr(Y_{n-1}=e_k|\mathcal{F}_{n-1})e^{(f_k^2/2+b_k)}-1}{e^{r\Delta t}S_{n-1}(\sum_{k=1}^{d} Pr(Y_{n-1}=e_k|\mathcal{F}_{n-1})e^{(2f_k^2+2b_k)}-2\sum_{k=1}^{d} Pr(Y_{n-1}=e_k|\mathcal{F}_{n-1})e^{(f_k^2/2+b_k)}+1)} \\ &= \frac{\sum_{k=1}^{d} Pr(Y_{n-1}=e_k|\mathcal{F}_{n-1})b_k}{e^{r\Delta t}S_{n-1}\sum_{k=1}^{d} Pr(Y_{n-1}=e_k|\mathcal{F}_{n-1})f_k^2} + O(\Delta t). \end{aligned} \tag{2.9}$$

When $d = 1$, denote the unique state of μ_n by μ and the unique state of $\hat{\sigma}_n$ by σ. Then (2.9) is reduced to

$$\begin{aligned} \tfrac{(E_{n-1}[\Delta S_n])}{E_{n-1}[(\Delta S_n)^2]} &= \tfrac{1}{e^{r\Delta t}S_{n-1}} \tfrac{e^{\sigma^2/2+g}-1}{e^{2\sigma^2+2g}-2e^{\sigma^2/2+g}+1} \\ &= \tfrac{1}{e^{r\Delta t}S_{n-1}} \tfrac{\mu-r}{\sigma^2} + O(\Delta t). \end{aligned} \tag{2.10}$$

3. Definition and optimization problem.

3.1. Wealth process and admissible strategies. In this section we describe a discrete-time optimization model which approximates the original continuous-time model presented at the beginning of this paper.

DEFINITION 3.1. *$h_{n-1} \in \mathcal{F}_{n-1}, n = 1, \dots, N$, are column vectors $\in R^{m\times 1}$. A wealth process $\{X_n^{h_{n-1}}\}_{n=1,2,\dots,N}, X_0 = x_0$ is defined as*

$$X_n^{h_{n-1}} = X_{n-1}^{h_{n-2}} e^{r\Delta t}\left(1 - \sum_{i=1}^{m} h_{n-1}^{(i)}\right) + X_{n-1}^{h_{n-2}} \sum_{i=1}^{m} h_{n-1}^{(i)} \frac{S_n^{(i)}}{S_{n-1}^{(i)}} + o(\sqrt{\Delta t}),$$

where $h_{n-1}^{(i)}$ or $S_{n-1}^{(i)}$ denotes the ith component of the vector h_{n-1} or S_{n-1}.

Using the notation defined in section 1, the wealth process has a simpler expression:

$$X_n^{h_{n-1}} = X_{n-1}^{h_{n-2}} e^{r\Delta t}(1 + h_{n-1} \cdot (e^{y_n} - 1)),$$

where "·" stands for the inner product in R^m. Generally, we have

$$X_n^{h_{n-1}} = X_0 e^{rn\Delta t}(1 + h_0 \cdot (e^{y_1} - 1)) \dots (1 + h_{n-1} \cdot (e^{y_n} - 1)), \quad n = 1, \dots, N.$$

DEFINITION 3.2. *A vector sequence* $h = \{h_i\}_{i=0}^{N-1}$ *is an* admissible *strategy if* $Pr(X_n^{h_{n-1}} > 0$ *for all* $n = 1, 2, \dots, N) = 1$.

We use $\mathcal{H}$ to denote the set of all admissible strategies.

Remark 3. If h is admissible, then

$$Pr(X_n^{h_{n-1}} > 0 | X_{n-1}^{h_{n-2}} > 0) = \frac{Pr(X_n^{h_{n-1}} > 0, X_{n-1}^{h_{n-2}} > 0)}{Pr(X_{n-1}^{h_{n-2}} > 0)} = 1.$$

Then we have

$$Pr(X_{n-1}^{h_{n-2}} e^{r\Delta t}(1 + h_{n-1} \cdot (e^{y_n} - 1)) > 0 | X_{n-1}^{h_{n-2}} > 0) = 1.$$

So if h is admissible, then

$$Pr(1 + h_{n-1} \cdot (e^{y_n} - 1) > 0) = 1. \tag{3.1}$$

By (2.5), we have $y_n^{(i)} \in (-\infty, \infty), e^{y_n^{(i)}} - 1 \in (-1, \infty)$. Hence the equality (3.1) implies

$$\|h_{n-1}\|_1 \le 1, \quad 1 \ge h_{n-1}^{(i)} \ge 0, \tag{3.2}$$

for each $i \in \{1, 2, \dots, m\}$.

The inequalities above imply no stock shorting as well as no money borrowing in our model. Rogers also mentioned such a restriction on the portfolio in his h-investor model (see [17]).

3.2. HARA utility functions.

DEFINITION 3.3. *A function* $u : (x_u, \infty) \to \mathcal{R}, x_u \in \mathcal{R}$, *is called a* utility function *if* u *is strictly increasing, strictly concave, and twice continuously differentiable on* (x_u, ∞) *and satisfies* $\lim_{x\to\infty} u'(x) = 0$ *and* $\lim_{x\to x_u^+} u'(x) = \infty$.

Next we define the coefficient of absolute risk aversion,

$$R_a(x) = -\frac{u''(x)}{u'(x)}.$$

DEFINITION 3.4. *If* $R_a^{-1}(x)$ *is a linear function, i.e.,* $R_a^{-1}(x) = a + bx$, *then we say that* $u(x)$ *is of the hyperbolic absolute risk aversion (HARA) class.*

It should be mentioned that the solution to the differential equation

$$\frac{1}{a + bx} = -\frac{u''(x)}{u'(x)}$$

is a power, logarithmic, or exponential function, i.e.,

$$u(x) = \begin{cases} \frac{c}{b-1}(a + bx)^{1-\frac{1}{b}} + d, x > \frac{-a}{b} & \text{if } b > 0, b \ne 1, \\ c\ \ln(a + x) + e,\ x > -a & \text{if } b = 1, \\ \frac{-f}{a} e^{-x/a} + g, x \in \mathcal{R} & \text{if } b = 0, \end{cases}$$

where c, d, e, f, g are some constants.

Hence, a HARA utility function is thirdly continuously differentiable and

$$\frac{u'''(x)}{u''(x)} = -\frac{1+b}{a+bx}.$$

The most popular HARA utility functions are

- constant relative risk aversion (CRRA): $u(x) = x^\beta/\beta$, where $\beta < 1$, and
- constant absolute risk aversion (CARA): $u(x) = -e^{-\beta x}/\beta$, where $\beta > 0$.

3.3. Optimization problem. Let $u(x)$ be a utility function, and $\{X_n^h\}$ be the wealth process. The objective is to calculate

$$(*) \qquad V^* = \sup_{h\in\mathcal{H}}\{E[u(X_N^h)]\}$$

and find an admissible trading strategy h^* s.t. $E[u(X_N^{h^*})] = V^*$.

4. Dynamic programming. Define

$$(4.1) \qquad U_n(x) = \sup_{h\in\mathcal{H}} E[u(X_N^h)|\mathcal{F}_n],\ n = 0, 1, \ldots, N.$$

From this definition, $U_0 = V^*$, as defined in the optimization problem of section 3.3. The dynamic programming equation for the sequence $u_0, u_1, \ldots, u_N$ is

$$(4.2) \qquad \begin{cases} U_n(x) = \sup_{h_n} E[U_{n+1}(xe^{r\Delta t} + xe^{r\Delta t}h_n \cdot (e^{y_{n+1}} - 1))|\mathcal{F}_n], \\ U_N(x) = u(x). \end{cases}$$

In what follows we derive a numerical scheme for the solution of these dynamic programming equations and approximations for the optimal strategies for the original optimization problem.

For each $\eta_n \in \mathcal{F}_n, n = 0, 2, \ldots, N-1$, define

$$A_{n-1,\eta_n} = E_{n-1}\left[\eta_n \begin{pmatrix} (e^{y_n^{(1)}} - 1)^2 & . & . & (e^{y_n^{(m)}} - 1)(e^{y_n^{(1)}} - 1) \\ (e^{y_n^{(2)}} - 1)(e^{y_n^{(1)}} - 1) & . & . & (e^{y_n^{(m)}} - 1)(e^{y_n^{(2)}} - 1) \\ . & . & . & . \\ (e^{y_n^{(m)}} - 1)(e^{y_n^{(1)}} - 1) & . & . & (e^{y_n^{(m)}} - 1)^2 \end{pmatrix}\right].$$

PROPOSITION 4.1. *Let* $u(x) = x^\alpha/\alpha, 0 \neq \alpha < 1$. *Let*

$$\lambda_N := 1,\ \eta_n := E_n[\textstyle\prod_{k=n}^N \lambda_k],$$
$$\lambda_{n-1} := (1 + \tfrac{1}{1-\alpha}(e^{y_n} - 1)' A_{n-1,\eta_n}^{-1} E_{n-1}[(e^{y_n} - 1)\eta_n])^\alpha,$$

$n = 1, \ldots, N$. *Then the following hold:*

(i) $\eta_n \in \mathcal{F}_n$ *is bounded.*

(ii) A_{n-1,η_n} *is invertible and there exists a constant* C *s.t.* $\Delta t\|A_{n-1,\eta_n}^{-1}\| < C$ *for all* $n = 1, 2, \ldots, N$.

(iii) $\|E_{n-1}[\eta_n(e^{y_n} - 1)]\| = o(\sqrt{\Delta t})$.

The proof of this proposition follows from Theorem B.3 (iii), (ii) and Theorem B.4.

For each $\eta_n \in \mathcal{F}_n, n = 0, 2, \ldots, N-1$, define

$$W_n(x_n, h_n) := E[\eta_{n+1} u(x_n^{h_n}) | \mathcal{F}_n] \tag{4.3}$$
$$= E[\eta_{n+1} u(x_n e^{r\Delta t} + x_n e^{r\Delta t} h_n \cdot (e^{y_{n+1}} - 1)) | \mathcal{F}_n],$$

$$V_n(x_n, h_n) \tag{4.4}$$
$$:= E\Big[\eta_{n+1}(u(x_n e^{r\Delta t}) + u'(x_n e^{r\Delta t}) x_n e^{r\Delta t} h_n \cdot (e^{y_{n+1}} - 1)$$
$$+ \frac{1}{2} u''(x_n e^{r\Delta t})(x_n e^{r\Delta t} h_n \cdot (e^{y_{n+1}} - 1))^2) | \mathcal{F}_n\Big].$$

Assume for any $x_{n-1} \geq 0$ that there exist $h_{n-1}^*, h_{n-1}^{**} \in [0,1]^m \subset \mathcal{R}^m$ s.t.

$$W_{n-1}(x_{n-1}, h_{n-1}^*) = \sup_{h_{n-1}} W_{n-1}(x_{n-1}, h_{n-1}) \tag{4.5}$$

and

$$V_{n-1}(x_{n-1}, h_{n-1}^{**}) = \sup_{h_{n-1}} V_{n-1}(x_{n-1}, h_{n-1}). \tag{4.6}$$

We use h_n^{**} defined in (4.6) to approximate h_n^* defined in (4.5).

As is seen from (4.4), (4.5) V_n is obtained from W_n by taking a Taylor expansion up to the second term. Thus the function V_n approximates W_n when Δt is small (and as a result y_n is close to 0).

LEMMA 4.2. *Let $u(x) = x^\alpha/\alpha, 0 \neq \alpha < 1$. Let η_n be defined as in Proposition 4.1. Then*

$$|W_{n-1}(x_{n-1}, h_{n-1}^{**}) - W_{n-1}(x_{n-1}, h_{n-1}^*)| = x^\alpha o(\Delta t), \tag{4.7}$$

where

$$h_{n-1}^{**} = \frac{1}{1-\alpha} A_{n-1,\eta_n}^{-1} \cdot E_{n-1}[\eta_n (e^{y_n} - 1)]. \tag{4.8}$$

The proof of this lemma is in Appendix B.

Remark 4. Using the same route we can prove that Lemma 4.2 holds for any η_n satisfying the three conditions in Proposition 4.1.

Remark 5. The motivation to define W_n and V_n can be seen as follows. Let $n = N-1$. Then in (4.2) we have

$$U_{N-1}(x) = \sup_{h_{N-1}} E[u(xe^{r\Delta t} + xe^{r\Delta t} h_{N-1} \cdot (e^{y_N} - 1)) | \mathcal{F}_{N-1}].$$

Clearly, $U_{N-1}(x_{N-1})$ coincides with $W_{N-1}(x_{N-1}, h_{N-1}^*)$ defined by (4.4), (4.5) with $\eta_N = 1$. Below, we write $\mathcal{E}_{n-1}(x_{n-1}) := W_{n-1}(x_{n-1}, h_{n-1}^*) - W_{n-1}(x_{n-1}, h_{n-1}^{**})$ for convenience.

In other words,

$$\begin{aligned} &U_{N-1}(x_{N-1}) = W_{N-1}(x_{N-1}, h_{N-1}^*) = W_{N-1}(x_{N-1}, h_{N-1}^{**}) + \mathcal{E}_{N-1} \\ &\approx W_{N-1}(x_{N-1}, h_{N-1}^{**}) = E_{N-1}[u(x_{N-1} e^{r\Delta t}(1 + h_{N-1}^{**} \cdot (e^{y_N} - 1)))], \end{aligned} \tag{4.9}$$

since $\mathcal{E}_{N-1}$ is small by Lemma 4.2.

As a result, one can find an approximation for the optimal strategy in a recursive way. Moreover, the expected utility of the terminal wealth associated with $h^{**} = \{h_k^{**}\}_{k=0}^{N-1}$ is an approximation for the value function V^* in the optimization problem. The next two theorems show that in a limit as Δt tends to zero the value of V^{**} converges to that of V^*. Thus h_n^{**} can serve as an approximation for the optimal strategy.

Hence Lemma 4.2 shows that the difference between the wealth associated with optimal portfolio h^* and the portfolio h^{**} is small when Δt is small.

THEOREM 4.3. *Let* $u(x) = \frac{x^\alpha}{\alpha}, 0 \neq \alpha < 1$. *Define*

$$\begin{aligned} &\lambda_N := 1, \eta_N = 1, \\ &h_{n-1}^{**} = \tfrac{1}{1-\alpha} A_{n-1,\eta_n}^{-1} \cdot E_{n-1}[(e^{y_n} - 1)\eta_n], \\ &\lambda_{n-1} := e^{r\Delta t\alpha}(1 + \tfrac{1}{1-\alpha} h_{n-1}^{**} \cdot (e^{y_n} - 1))^\alpha, \\ &\eta_n := E_n[\textstyle\prod_{i=n}^N \lambda_i], 1 \le n \le N. \end{aligned} \tag{4.10}$$

Then

$$|U_n^{**}(x_n) - U_n(x_n)| = u(x_n)o(1), \tag{4.11}$$

where

$$\begin{aligned} &U_n^{**}(x_n) := E_n[u(x_{n,N}^{**})], \\ &x_{n,k}^{**} := x_n e^{(k-n)r\Delta t} \cdot \textstyle\prod_{i=n}^{k-1}(1 + h_i^{**} \cdot (e^{y_{i+1}} - 1)). \end{aligned} \tag{4.12}$$

Proof. Define the following sequences:

$$\begin{aligned} &U_N^{**} := u(x), \\ &U_k^{**}(x_k) := W_k(x_k, h_k^{**}), \\ &U_k^*(x_k) := W_k(x_k, h_k^*). \end{aligned}$$

From the definition of η_n and (4.4), (4.8), we verify that

$$U_k^{**}(x_k) = u(x_k)\eta_k, \tag{4.13}$$

and using (4.13) above we can write

$$\begin{aligned} &U_k^*(x_k) = W_k(x_k, h_k^*) \\ &= \sup_{h_k} E_k[\eta_{k+1} u(x_k e^{r\Delta t}(1 + h_k \cdot (e^{y_{k+1}} - 1)))] \\ &= \sup_{h_k} E_k[U_{k+1}^{**}(x_k e^{r\Delta t}(1 + h_k \cdot (e^{y_{k+1}} - 1)))]. \end{aligned} \tag{4.14}$$

First, we prove that

$$|U_{N-1}^{**}(x_{N-1}) - U_{N-1}(x_{N-1})| \le u(x_{N-1})o(\Delta t).$$

Really $U_{N-1}^{**}(x_{N-1}) = u(x_{N-1})\eta_{N-1}$, and

$$\begin{aligned} &U_{N-1}^*(x_{N-1}) = \sup_{h_{N-1}} E_{N-1}[U_N^{**}(x_{N-1}e^{r\Delta t}(1 + h_{N-1} \cdot (e^{y_N} - 1)))] \\ &= \sup_{h_{N-1}} E_{N-1}[u(x_{N-1}e^{r\Delta t}(1 + h_{N-1} \cdot (e^{y_N} - 1)))] = U_{N-1}(x_{N-1}). \end{aligned}$$

Therefore,

$$\begin{aligned} |U_{N-1}^{**}(x_{N-1}) - U_{N-1}(x_{N-1})| &= |W_{N-1}(x_{N-1}, h_{N-1}^{**}) - U_{N-1}^*(x_{N-1})| \\ &= |W_{N-1}(x_{N-1}, h_{N-1}^{**}) - W_{N-1}(x_{N-1}, h_{N-1}^*)| \le u(x_{N-1})o(\Delta t). \end{aligned}$$

The last inequality is due to Lemma 4.2.

Let $C_1 = 1$. Suppose for $n \le N$ we have

$$|U_n^{**}(x_n) - U_n(x_n)| = C_{N-n} u(x_n) o(\Delta t), \tag{4.15}$$

where $\{C_k\}_{k=2}^N$ is a bounded sequence to be determined later. Then

$$\begin{aligned}
|U_{n-1}^{**} - U_{n-1}| &= |W_{n-1}(x_{n-1}, h_{n-1}^{**}) - U_{n-1}| \\
&\le |W_{n-1}(x_{n-1}, h_{n-1}^{**}) - W_{n-1}(x_{n-1}, h_{n-1}^{*})| \\
&\quad + |W_{n-1}(x_{n-1}, h_{n-1}^{*}) - U_{n-1}| \\
&\le o(\Delta t) u(x_{n-1}) + | \sup_{h_{n-1}} E_{n-1}[U_n^{**}(x_{n-1} e^{r\Delta t}(1 + h_{n-1} \cdot (e^{y_n} - 1)))] \\
&\quad - \sup_{h_{n-1}} E_{n-1}[U_n(x_{n-1} e^{r\Delta t}(1 + h_{n-1} \cdot (e^{y_n} - 1)))]|.
\end{aligned}$$

Then, using (4.14), (4.15), and Lemma 4.2, we get

$$\begin{aligned}
&|U_{n-1}^{**} - U_{n-1}| \\
&\le o(\Delta t) u(x_{n-1}) + \sup_{h_{n-1}} E_{n-1}[|U_n^{**}(\gamma) - U_n(\gamma)|]|_{\gamma = x_{n-1} e^{r\Delta t}(1 + h_{n-1} \cdot (e^{y_n} - 1))} \\
&\le o(\Delta t) u(x_{n-1}) + \sup_{h_{n-1}} E_{n-1}[u(x_{n-1} e^{r\Delta t}(1 + h_{n-1} \cdot (e^{y_n} - 1))) C_{N-n} o(\Delta t)]
\end{aligned}$$

for all sufficiently small Δt (so as $o(\Delta t) < 1$).

Applying Remark 4 with $\eta_n = 1$, we have

$$\begin{aligned}
&\sup_{h_{n-1}} E_{n-1}[u(x_{n-1} e^{r\Delta t}(1 + h_{n-1} \cdot (e^{y_n} - 1)))] \\
&\le E_{n-1}[u(x_{n-1} e^{r\Delta t}(1 + h_{n-1}^{**} \cdot (e^{y_n} - 1)))] + o(\Delta t) u(x_{n-1}) \\
&= (\nu_{n-1} + o(\Delta t)) u(x_{n-1}),
\end{aligned}$$

where $\nu_{n-1} := e^{r\alpha\Delta t} E_{n-1}[(1 + h_{n-1}^{**} \cdot (e^{y_n} - 1))^{\alpha}]$. Therefore,

$$|U_{n-1}^{**} - U_{n-1}| \le (1 + C_{N-n}(\nu_{n-1} + o(\Delta t))) o(\Delta t) u(x_{n-1}).$$

Define $C_n = 1 + C_{N-n}(\nu_{N-n} + o(\Delta t))$, $C_1 = 1$. Then

$$|U_{n-1}^{**} - U_{n-1}| \le C_{N-n+1} o(\Delta t) u(x_{n-1}).$$

Continuing this process we get

$$|U_0^{**} - U_0| \le C_N u(x_0) o(\Delta t).$$

To complete the proof, we have to prove $C_N o(\Delta t) = o(1)$. In fact, ν_{N-k} has the limit 1 as $\Delta t \to 0$ by virtue of Theorem B.3. Moreover, there exists a constant $D_2 > 0$ s.t.

$$\lim_{\Delta t \to 0} \frac{1}{\Delta t} |\nu_{N-k} - 1| < D_2$$

for all $k = 1, \dots, N$. From the definition of C_k and the properties of ν_k for $k \ge 2$, we have

$$C_k \le 1 + C_{k-1}(1 + (D_2 + 1)\Delta t) \le \cdots \le (k-2) + \frac{1}{(D_2+1)\Delta t}((1 + (D_2+1)\Delta t)^k - 1).$$

Then $C_N\Delta t$ converges to a constant as $\Delta t \to 0$. Consequently $C_N o(\Delta t) \to 0$ as $\Delta t \to 0$. Hence we have proved that U_0^{**} has the same limit as U_0 (the optimal expected utility of the terminal wealth), as $\Delta t \to 0$, i.e.,

$$|U_0^{**} - U_0|u(x_0) = o(1).$$

By the definition of U_n^{**}, it is easy to see that

$$\begin{aligned}
&U_n^{**}(x_n) := W_n(x_n, h_n^{**}) = E_n[\eta_{n+1}u(x_n e^{r\Delta t}(1 + h_n^{**} \cdot (e^{y_{n+1}} - 1)))] \\
&= E_n[W_{n+1}(x_n e^{r\Delta t}(1 + h_n^{**} \cdot (e^{y_{n+1}} - 1)), h_{n+1}^{**})] \\
&= E_n[\eta_{n+2}u(x)|_{x=x_{n+1}e^{r\Delta t}(1+h_n^{**}(e^{y_{n+1}}-1))}] \\
&= E_n[W_{N-1}(x_{n,N-1}^{**}, h_{N-1}^{**})] = E_n[u(x_{n,N}^{**})],
\end{aligned}$$

where $x_{n,k}^{**} = x_n e^{(k-n)r\Delta t} \cdot \prod_{i=n}^{k-1}(1 + h_i^{**} \cdot (e^{y_{i+1}} - 1))$. □

The case of a logarithmic utility function can be treated as the same way as the power utility function. The same results hold, although with a higher rate of convergence.

LEMMA 4.4. *Let $u(x) = \log(x)$, and choose $\eta_n = 1, n = 1, 2, \ldots, N$. Then we have*

$$|W_{n-1}(x_{n-1}, h_{n-1}^{**}) - W_{n-1}(x_{n-1}, h_{n-1}^{*})| = O(\Delta t)^2,$$

where

$$h_{n-1}^{**} = A_{n-1,1}^{-1} \cdot E_{n-1}[e^{y_n} - 1]. \tag{4.16}$$

The proof is the same as that of Lemma 4.2. Moreover when we repeat the proof, we see that the resulting convergence rate is $O(\Delta t)^2$, which is higher than $O(\Delta t)$ obtained in the case of the power utility function.

THEOREM 4.5. *Let $u(x) = \log(x)$, and choose $\eta_n = 1, n = 1, 2, \ldots, N$. Then*

$$|U_n(x_n) - U_n^{**}(x_n)| = O(\Delta t),$$

where

$$\begin{aligned}
&U_n^{**}(x_n) := E_n[u(x_{n,N}^{**})], \\
&x_{n,k}^{**} := x_n e^{(k-n)r\Delta t} \cdot \textstyle\prod_{i=n}^{k-1}(1 + h_i^{**} \cdot (e^{y_{i+1}} - 1)),
\end{aligned}$$

and h_i^{**} is defined by (4.16).

Proof. This is the special case of Lemma 4.2 with $\alpha = 0$. However, the condition $\alpha = 0$ enables us to obtain a higher convergence rate of $O(\Delta t)$. □

Remark 6. There are particular cases depending on the structure of the transition matrix P, when we have the convergence rate $O(\Delta t)$ as above even for the power utility function. One of those cases is when the transition matrix has identical columns. We also have another case in Appendix D, Theorem B.5 (ii), when the convergence rate is of a higher rate of $O(\Delta t)$.

Remark 7. Let $u(x) = \frac{1}{\gamma}e^{-x\gamma}$. Define

$$\begin{aligned}
&\eta_N := 1, \\
&\eta_{n-1} := e^{-\gamma h_{n-1}^{**}(e^{y_n}-1)}, \\
&h_{n-1}^{**} = A_{n-1,\eta_n}^{-1} \cdot E_{n-1}[(e^{y_n} - 1)\eta_n](\tfrac{1}{\gamma x_{n-1}}e^{-r(N-n)\Delta t}), \\
&U_{n-1}^{**} = u(x_{n-1}e^{r(N-n+1)\Delta t}\textstyle\prod_{k=n-1}^{N-1}(1 + h_i^{**} \cdot (e^{y_{i+1}} - 1))), \quad n = N, \ldots, 1.
\end{aligned}$$

Then

$$|U_0(x_0) - U_0^{**}(x_0)| = o(1).$$

The proof follows the same route as that of Theorem 4.3.

Remark 8. From the definition (4.10) of η_n, we can see that η_n is the expected utility under strategy h^{**}, given $\mathcal{F}_n$, and given $x_n = 1$. That is,

$$\eta_n = E[u(X_N^{h^{**}})|\mathcal{F}_n, x_n = 1].$$

5. Simulations. Generally, as a result it is not easy to compute the approximate optimal strategy $\{h_n^{**}\}_{n=0}^{N-1}$ in (4.8) in the case of a power utility function. However, we can get an estimation using a simplified strategy:

$$\bar{h}_n^{**} := -\frac{1}{1-\alpha} A_{n-1,1}^{-1} \cdot E_{n-1}[(e^{y_n} - 1)], \quad n = 0, 1, \ldots, N-1.$$

From the definition of V^*, we see that the expected utility $E[u(x_N^{\bar{h}^{**}})]$ associated with $\bar{h}^{**}$ is a lower bound for V^*.

There are cases, however, where (4.8) is relatively easy to evaluate. For example, if the transition matrix has identical columns, then the conditional probability $Pr(Y_n = e_k|\mathcal{F}_n), n \geq 1$, would be a constant regardless of n, k. Thus η_n is a constant, and it can be excluded from the expression for h_{n-1}^{**} (4.8). Therefore, the strategy h^{**} is the same as $\bar{h}^{**}$.

We apply the results of section 2 to obtain an applicable representation of the strategy for the case of $m = 1$,

$$\bar{h}_{n-1}^{**} \overset{m=1}{=} \frac{\sum_{k=1}^{d} Pr(Y_{n-1} = e_k|\mathcal{F}_{n-1})(\mu(e_k) - r)}{(1-\alpha)\sum_{k=1}^{d} Pr(Y_{n-1} = e_k|\mathcal{F}_{n-1})\hat{\sigma}(e_k)^2} + O(\Delta t), n = 1, 2, \ldots, N. \tag{5.1}$$

The simulations in this section deal with (5.1). We use Lemma 2.2 to calculate $Pr(Y_n = e_k|\mathcal{F}_n)$ recursively.

Comparing the strategies (5.1) with Merton strategies, we can see that in our case the constant drift or the constant volatility in the expression for Merton strategies is replaced by linear combinations of the drifts or of the volatilities corresponding to different states of the Markov chain. The weights of the linear combinations are probabilities that the Markov chain is in those states. We divide the time interval [0,T] into N parts and assume the transition of the Markov chain occurs only at those points of time. Hence we have the Merton model on each interval. The consequence is that we might obtain a solution directly like (5.1) in the case of the logarithmic utility function. However, it is not true for the power or the exponential utility functions.

To illustrate this point, let us assume that the transition matrix does not have identical columns. Then in (4.8) we cannot choose $\eta_n = 1$ as in the case of a logarithmic utility function, nor can we simplify the expression by canceling η_n as in the case when all the columns of the transition matrix are identical. A representation as simple as (5.1) cannot not be obtained. We have to employ the Monte Carlo method to calculate the portfolio (4.8). However, we may use (5.1) to get a lower bound for V^*.

In our simulations, W_0 stands for the initial wealth. The default value of W_0 is 1. P denotes the transition matrix. The interest rate r is equal to 0.06. The time horizon T is 1, and it is divided into $N = 1000$ parts, i.e., $\Delta t = 10^{-3}$.

We compare our optimal strategy with the Merton strategy. Since the Markov chain has several states, we use the Merton strategy, replacing the drift and volatility in it with those obtained from taking the average of the drift and volatility, respectively, over different states of the Markov chain. The resulting Merton's strategy is

$$h_{n-1} = \frac{\bar{\mu} - r}{(1-\alpha)\bar{\sigma}^2}, \quad n = 1, \ldots, N, \tag{5.2}$$

where $\bar{\mu} = \sum_i \mu(e_i)/d, \bar{\sigma} = \sum_i \hat{\sigma}(e_i)/d$. One may think of using $\sum_i \sigma(e_i)^2/d$ instead of $\bar{\sigma}^2$ in the formula. However, our simulation shows that it does not provide a better result.

We also compare our optimal strategy with the buy-and-hold strategy, which is denoted as "b/h." The buy-and-hold strategy means to buy the stock using all cash available at the beginning and then hold the stock until the end. We generate the wealth process 1000 times and calculate the average of the utilities from the terminal wealth.

Table 1 lists the result for a Markov chain which has a transition matrix with identical columns. For the power utility function, we can obtain that our optimal strategy is a constant 0.1133 while the Merton strategy is also a constant 0.3636 different from ours as seen from (5.1). Table 1 shows that our optimal strategy on average gives better utilities with smaller standard deviations for both the logarithm and the power law utility functions. The last line of Table 1 shows the number of simulations in which our optimal strategy generates a better utility than the Merton strategy or the b/h strategy. Note that in the case of the power utility function, even though our optimal strategy generates only 487 better than the Merton strategy among 1000 simulations, the average (-0.2748) is still significantly higher than the one (-0.2974) generated by the Merton strategy, and the standard deviation (0.0380) is also significantly less than 0.1348.

In Table 2, we use the same parameters except the transition matrix is replaced by a matrix with nonidentical columns. In this case for the power utility function, the Merton strategy is still a constant ($h = 0.3636$). However, our optimal strategy h^{**} varies from 0.1294 to 0.3324 with a mean 0.1450, while it is a constant 0.1133 in the previous case. The result are similar to those of Table 1, though.

The average utility may vary slightly if more wealth processes are generated in the simulation. However, we always find that our optimal strategy generates on average the best utilities. The results in Table 3 for 5000 and 10000 simulations show that although the utilities vary slightly, our optimal strategy still has the best performance among the three strategies.

For one more example, we choose the same parameters as in Example 1 of Sass and Haussmann [18]. The results for this example are listed in Table 4. Table 5 is a copy of Table 2 of Sass and Haussmann [18]. One can see that our optimal strategy generates the average utilities (0.3969 for the logarithm, and -0.1128 for the power) very close to theirs (0.399 for the logarithm, and -0.121 for the power). It is not surprising because our model can be viewed as an extension of theirs in an approximate sense. Therefore, similar results are expected when the same parameters are employed.

Finally, we provide standard deviations in Tables 1 and 2. One can see that the standard deviation associated with the optimal strategy is always the smallest one.

Appendix A. Proof of Lemma 2.3.

Proof. For $k = 1, 2, \ldots, d$, denote

$$b_k := g_{n-1}|_{Y_{n-1}=e_k} \in \mathcal{R}^{m\times 1}, f_k := \sigma_{n-1}|_{Y_{n-1}=e_k} \in \mathcal{R}^{m\times m}.$$

(i) Using Lemma 2.1, we have

$$\begin{aligned}
&|E[y_n^{(i)} - 1|\mathcal{F}_{n-1}]| \\
&= \left| \int e^{y_n^{(i)}} \sum_{k=1}^{d} Pr(Y_{n-1} = e_k|\mathcal{F}_{n-1}) \phi_{ik}(y_n^{(i)} - b_k(i)) dy_n^{(i)} - 1 \right| \\
&= \left| \sum_{k=1}^{d} Pr(Y_{n-1} = e_k|\mathcal{F}_{n-1}) e^{f_k(i) f_k(i)'/2 + b_k(i)} - 1 \right| \\
&\leq \max_k \{|e^{f_k(i) f_k(i)'/2 + b_k(i)} - 1|\}.
\end{aligned}$$

By virtue of (2.6) the right-hand side of the above expression is of the order Δt. Therefore, there exists a constant $C_1 > 0$ s.t.

$$|E_{n-1}[e^{y_n^{(i)}} - 1]| \leq C_1 \Delta t.$$

(ii) Similarly,

$$\begin{aligned}
&E_{n-1}[(e^{y_n(i)} - 1)^2] \\
&= \sum_{k=1}^{d} Pr(Y_{n-1} = e_k|\mathcal{F}_{n-1}) e^{2 f_k(i) f_k(i)' + 2 b_k(i)} \\
&- 2 \sum_{k=1}^{d} Pr(Y_{n-1} = e_k|\mathcal{F}_{n-1}) e^{f_k(i) f_k(i)'/2 + b_k(i)} + 1 \\
&= \sum_{k=1}^{d} Pr(Y_{n-1} = e_k|\mathcal{F}_{n-1}) (e^{2 f_k(i) f_k(i)' + 2 b_k(i)} - 2 e^{f_k(i) f_k(i)'/2 + b_k(i)} + 1).
\end{aligned}$$

TABLE 3

TABLE 4
$\mu = [0.8, -0.4]', \hat{\sigma} = [0.2, 0.2]', Q = [-30, 24; 30, -24], P = e^{Q/250}, \Delta t = 1/250$. 500 *simulations.*

u(x)	*log(x)*			$-x^{-5}/5$		
Strategy	*opt*	*Merton*	*b/h*	*opt*	*Merton*	*b/h*
av. u(x)	0.3969	0.1125	0.1205	−0.1128	− 0.1525	− 0.2180
med u(x)	0.2965	0.1033	0.1186	−0.0902	− 0.1218	− 0.1105
opt better		319	313		338	288

Note that we assumed $f_k(i,j)$ to be positive for any k, i, j, and

$$e^{2f_k(i)f_k(i)'+2b_k(i)} - 2e^{f_k(i)f_k(i)'/2+b_k(i)} + 1 = f_k(i)f_k(i)' + O(\Delta t^2).$$

Therefore, using (2.6) once more we conclude that there exist constants $C_2 > 0, C_3 > 0$ s.t.

$$C_2\Delta t < E_{n-1}[(e^{y_n^{(i)}} - 1)^2] \le C_3\Delta t.$$

(iii) Again, we have

$$\begin{aligned}
&|E_{n-1}[(e^{y_n^{(i)}} - 1)^3]| \\
&= \left|\sum_{k=1}^{d} Pr(Y_{n-1} = e_k|\mathcal{F}_{n-1})(e^{9f_{ik}^2/2+3b_{k(i)}} - 3e^{2f_{ik}^2+2b_k(i)} + 3e^{f_{ik}^2/2+b_k(i)} - 1)\right| \\
&\le \max_k\{|e^{9f_{ik}^2/2+3b_{k(i)}} - 3e^{2f_{ik}^2+2b_k(i)} + 3e^{f_{ik}^2/2+b_k(i)} - 1|\} = O((\Delta t)^2).
\end{aligned}$$

Therefore,

$$|E[(e^{y_n^{(i)}} - 1)^3]|\mathcal{F}_{n-1}]| = O((\Delta t)^2).$$

(iv) Similarly,

$$\begin{aligned}
&|E[(1 - e^{-y_n^{(i)}})^3|\mathcal{F}_{n-1}]| \\
&\le \sum_{k=1}^{d} Pr(Y_{n-1} = e_k|\mathcal{F}_{n-1})|(-e^{9f_{ik}^2/2-3b_k(i)} + 3e^{2f_{ik}^2-2b_k(i)} - 3e^{f_{ik}^2/2-b_k(i)} + 1)| \\
&\le \max_k| - e^{9f_{ik}^2/2-3b_k(i)} + 3e^{2f_{ik}^2-2b_k(i)} - 3e^{f_{ik}^2/2-b_k(i)} + 1| \\
&= O(\Delta t)^2.
\end{aligned}$$

(v) Similarly, we have

$$E[e^{y_n\alpha}(1 - e^{-y_n})^3|\mathcal{F}_{n-1}] = O(\Delta t)^2. \qquad \square$$

Appendix B. Proof of Lemma 4.2.

Proof. Using the definition (4.5), we have the first order condition:

$$\begin{aligned}
0 &= \left(\frac{\partial W_{n-1}}{\partial h_{n-1}}\right)|_{h_{n-1}=h^*_{n-1}} = \left(\frac{\partial W_{n-1}(x_{n-1},h_{n-1})}{\partial h_{n-1}}\right)|_{h_{n-1}=h^*_{n-1}} \\
&= E[\eta_n u'(x_{n-1}e^{r\Delta t} + x_{n-1}e^{r\Delta t}h^*_{n-1}\cdot(e^{y_n}-1))(e^{y_n}-1)x_{n-1}e^{r\Delta t}|\mathcal{F}_{n-1}] \\
&= E_{n-1}[\eta_n(e^{y_n}-1)]u'(x_{n-1}e^{r\Delta t})x_{n-1}e^{r\Delta t} + (x_{n-1}e^{r\Delta t})^2 E_{n-1}[\eta_n(h^*_{n-1} \\
&\quad \cdot (e^{y_n}-1))(e^{y_n}-1)u''(x_{n-1}e^{r\Delta t}) \\
&\quad + x^3_{n-1}e^{3r\Delta t}E_{n-1}[\eta_n(h^*_{n-1}\cdot(e^{y_n}-1))^2(e^{y_n}-1)u'''(\xi)]/2,
\end{aligned}$$

where $\xi = x_{n-1}e^{r\Delta t}(1+t\cdot(e^{y_n}-1))$ for some $t\in[0,1]^m \subset \mathcal{R}^{m\times 1}$. Solving h^*_{n-1} from the equations above, we obtain

(B.1)

$$\begin{aligned}
h^*_{n-1} = &- A^{-1}_{n-1,\eta_n}\cdot E_{n-1}[\eta_n(e^{y_n}-1)]\frac{u'(x_{n-1}e^{r\Delta t})}{u''(x_{n-1}e^{r\Delta t})x_{n-1}e^{r\Delta t}} \\
&- A^{-1}_{n-1,\eta_n}\cdot E_{n-1}[\eta_n(h^*_{n-1}\cdot(e^{y_n}-1))^2(e^{y_n}-1)u'''(\xi)]\frac{x_{n-1}e^{2r\Delta t}}{2u''(x_{n-1}e^{r\Delta t})},
\end{aligned}$$

where A_{n-1,η_n} is defined right before Proposition 4.1.

At the same time, according to the first order condition for the function V_{n-1}, we have

(B.2)
$$\begin{aligned}
h^{**}_{n-1} &= -A^{-1}_{n-1,\eta_n}\cdot E_{n-1}[\eta_n(e^{y_n}-1)]\frac{u'(x_{n-1}e^{r\Delta t})}{u''(x_{n-1}e^{r\Delta t})x_{n-1}e^{r\Delta t}} \\
&= \frac{1}{1-\alpha}A^{-1}_{n-1,\eta_n}\cdot E_{n-1}[\eta_n(e^{y_n}-1)].
\end{aligned}$$

Therefore, using (B.1) and (B.2), we have

$$\|h^*_{n-1}-h^{**}_{n-1}\|_1 = \left\|A^{-1}_{n-1,\eta_n}\cdot E_{n-1}[\eta_n(e^{y_n}-1)(h^*_{n-1}\cdot(e^{y_n}-1))^2u'''(\xi)]\frac{x_{n-1}e^{r\Delta t}}{2u''(x_{n-1}e^{r\Delta t})}\right\|_1.$$

Since each entry of A_{n-1,η_n} is of the order $O(\Delta t)$, it is easy to show that every entry of A^{-1}_{n-1,η_n} is of the order of $1/O(\Delta t)$. By Theorem B.2, we have

$$\|E_{n-1}[\eta_n(e^{y_n}-1)(h^*_{n-1}\cdot(e^{y_n}-1))^2u'''(\xi)]\| = u'''(x_{n-1}e^{r\Delta t})o(\Delta t)^{3/2}.$$

Therefore,

$$\begin{aligned}
\|h^*_{n-1}-h^{**}_{n-1}\|_1 &= \|A^{-1}_{n-1,\eta_n}\|_\infty u'''(x_{n-1}e^{r\Delta t})o(\Delta t^{3/2})\left|\frac{x_{n-1}e^{r\Delta t}}{u''(x_{n-1}e^{r\Delta t})}\right| \\
&= \frac{x_{n-1}u'''(x_{n-1}e^{r\Delta t})}{u''(x_{n-1}e^{r\Delta t})}\cdot o\Delta t^{1/2} = o(\Delta t)^{1/2}.
\end{aligned}$$

On the other hand,

$$\begin{aligned}&|W_{n-1}(x_{n-1},h^{**}_{n-1})-W_{n-1}(x_{n-1},h^{*}_{n-1})|\\&=\|E_{n-1}[\eta_n u'(\zeta)(e^{y_n}-1)]\|_1\|h^{*}_{n-1}-h^{**}_{n-1}\|_1 x_{n-1}e^{r\Delta t}\\&=x_{n-1}o(\Delta t^{1/2})\|E_{n-1}[\eta_n(e^{y_n}-1)u'(\zeta)]\|_1,\end{aligned}$$

where $\zeta = x_{n-1}e^{r\Delta t}(1+s\cdot(e^{y_n}-1))$ for some s between h^{*}_{n-1} and h^{**}_{n-1}.

Note that since we assume $h^{*}_{n-1}, h^{**}_{n-1}\in[0,1]^m$, then $s\in[0,1]^m$. By the assumption (i), η_n is bounded, and we can apply the dominated convergence theorem to obtain

$$\begin{aligned}&\lim_{\Delta t\to 0}\|E_{n-1}[\eta_n(e^{y_n}-1)((1+s\cdot(e^{y_n}-1))^{\alpha-1}-1)]\|_1\frac{1}{\Delta t}\\&\le E_{n-1}\left[\lim_{\Delta t\to 0}\left\|\frac{\eta_n(e^{y_n}-1)}{\sqrt{\Delta t}}\right\|_1\ \lim_{\Delta t\to 0}\left|\frac{1}{\sqrt{\Delta t}}((1+s(e^{y_n}-1))^{\alpha-1}-1)\right|\right]\\&<\text{Constant}.\end{aligned}$$

Therefore,

$$\|E_{n-1}[\eta_n(e^{y_n}-1)((1+s\cdot(e^{y_n}-1))^{\alpha-1}-1)]\|_1 = O(\Delta t). \tag{B.3}$$

To complete our proof, we apply (B.3) and Theorem B.4 to obtain

$$\begin{aligned}&\|E_{n-1}[\eta_n(e^{y_n}-1)u'(\zeta)]\|_1\\&\le\|E_{n-1}[\eta_n(e^{y_n}-1)(u'(\zeta)-x_{n-1}^{\alpha-1}e^{(\alpha-1)r\Delta t})]\|_1+\|E_{n-1}[\eta_n(e^{y_n}-1)x_{n-1}^{\alpha-1}e^{(\alpha-1)r\Delta t}]\|_1\\&=x_{n-1}^{\alpha-1}e^{(\alpha-1)r\Delta t}E_{n-1}[\eta_n(e^{y_n}-1)((1+s(e^{y_n}-1))^{\alpha-1}-1)]+x_{n-1}^{\alpha-1}o(\Delta t^{1/2})\\&=x_{n-1}^{\alpha-1}o(\Delta t^{1/2}).\end{aligned}$$

As a result we have proved

$$|W_{n-1}(x_{n-1},h^{**}_{n-1})-W_{n-1}(x_{n-1},h^{*}_{n-1})| = x_{n-1}^{\alpha}o(\Delta t). \qquad \square$$

PROPOSITION B.1. *If $\xi=(1+s\cdot(e^y-1))^{\alpha-3}, \alpha<1, s\in[0,1]^m, \sum_{i=1}^m s_i\le 1$, $y=g\Delta t+\sigma\sqrt{\Delta t}Z, \sigma>0, Z=(Z_1,\dots,Z_m)'\in\mathcal{R}^m, Z_i\sim N(0,1)$, then there exists a constant C s.t. $|\xi-1|\le C(1+\|Z\|_1)e^{\|Z\|_1}\sqrt{\Delta t}$.*

Proof. First, we suppose $\sum_{i=1}^m s_i<1$. It is easy to see that

$$(1+s\cdot(e^y-1))^{\alpha-3}<\left(1-\sum_{i=1}^m s_i\right)^{\alpha-3}.$$

Then for small Δt, we have

$$\begin{aligned}&\frac{1}{\sqrt{\Delta t}}|(1+s\cdot(e^y-1))^{\alpha-3}-1|\\&=(3-\alpha)(1+s\cdot(e^{g\tau-\sigma\sqrt{\tau}Z}-1))^{\alpha-4}(s\cdot(\operatorname{diag}(2g^{(i)}\sqrt{\tau}+\sigma^{(i)}Z)e^{g\tau+\sigma\sqrt{\tau}Z}))|\\&\le C\left(1-\sum_i^m s_i\right)^{\alpha-4}\sum_{i=1}^m(2|g^{(i)}\tau|+\sigma^{(i)}|Z|)e^{g^{(i)}\tau+\sigma^{(i)}\sqrt{\tau}Z}\\&\le C(1+\|Z\|_1)e^{\|Z\|_1},\end{aligned}$$

where $\tau \in [0, \sqrt{\Delta t}]$. Therefore $|(1 + s \cdot (e^y - 1))^{\alpha-3} - 1| \le C(1 + \|Z\|_1)e^{\|Z\|_1}\sqrt{\Delta t}$.

In case $\sum_{i=1}^m s_i = 1$, we observe

$$\begin{aligned}(1 + s \cdot (e^y - 1))^{\alpha-3} &= \left(1 + \sum_{i=2}^m s_i(e^{y^{(i)}-y^{(1)}} - 1)\right)^{\alpha-3} e^{y^{(1)}(\alpha-3)} \\ &< \left(1 - \sum_{i=2}^m s_i\right)^{\alpha-3} e^{y^{(1)}(\alpha-3)}.\end{aligned}$$

We still can prove the proposition as above. □

THEOREM B.2. *$u(x) = x^\alpha/\alpha, \alpha < 1$. If $\alpha = 0$, define $u(x) = \log(x)$. $\xi = xe^{r\Delta t}(1 + s \cdot (e^{y_n} - 1))$ for some $s \in (0,1)^m \subset \mathcal{R}^m$. y_n is defined by (2.5). $h_{n-1} \in (0,1)^m \subset \mathcal{R}^m$ satisfies the constraints (3.2). $\eta_n \in \mathcal{F}_n$ is bounded by a constant δ. Then*

$$\|E_{n-1}[\eta_n(e^{y_n} - 1)(h_{n-1} \cdot (e^{y_n} - 1))^2 u'''(\xi)]\|_1 = u'''(x_{n-1})o(\Delta t^{3/2}).$$

Proof. Write $G_i = e^{y(i)} - 1, h_{n-1} = (h_{n-1}(1), \ldots, h_{n-1}(m)) \in R^M$. We have

$$\begin{aligned}&\|E_{n-1}[\eta_n(e^y - 1)(h_{n-1} \cdot (e^y - 1))^2 u'''(\xi)]\|_1 \\ &\le m \max_i \left| E_{n-1}\left[\eta_n \sum_{j,k} h_{n-1}(j)G_j h_{n-1}(k)G_k G_i u'''(\xi)\right]\right| \\ &\le m^3 \max_{i,j,k} |E_{n-1}[\eta_n h_{n-1}(j)G_j h_{n-1}(k)G_k G_i u'''(\xi)]| \\ &\le m^3 \max_{i,j,k} |E_{n-1}[\eta_n G_j G_k G_i u'''(\xi)]|.\end{aligned}$$

Recall (3.2); that is, $\|h\|_1 \le 1$ and $1 \ge h(i) \ge 0$ for $i = 1, \ldots, m$.

$$\begin{aligned}&|E_{n-1}[\eta_n G_j G_k G_i u'''(\xi)]| \\ &\le |E_{n-1}[\eta_n G_j G_k G_i (u'''(\xi) - u'''(x_{n-1}))]| + u'''(x_{n-1})|E_{n-1}[\eta_n G_j G_k G_i]| \\ &\le |E_{n-1}[\eta_n G_j G_k G_i (u'''(\xi) - u'''(x_{n-1}))]| + |E_{n-1}[\eta_n G_j G_k G_i]|u'''(x_{n-1}).\end{aligned} \tag{B.4}$$

The second term is $u'''(x_{n-1})o(\Delta t^{3/2})$ according to Theorem B.4.

Now consider the first term. We have

$$\begin{aligned}|u'''(\xi) - u'''(x_{n-1})| &= (\alpha - 1)(\alpha - 2)|((1 + s \cdot (e^{y_n} - 1))^{\alpha-3} - 1)x_{n-1}^{\alpha-3}| \\ &= u'''(x_{n-1})|(1 + s \cdot (e^{y_n} - 1))^{\alpha-3} - 1|.\end{aligned}$$

By Proposition B.1, we know

$$\lim_{\Delta t \to 0} \frac{1}{\sqrt{\Delta t}} |(1 + s \cdot (e^{y_n} - 1))^{\alpha-3} - 1| = \text{Constant, a.s.}$$

Proposition B.1 also guarantees that the dominated convergence theorem works. Hence we have

$$\begin{aligned}&\lim_{\Delta t \to 0} \frac{1}{u'''(x_{n-1})\Delta t^2} |E_{n-1}[\eta_n G_i G_j G_k (u'''(\xi) - u'''(x_{n-1}))]| \\ &\le \delta\ E_{n-1}\left[\lim_{\Delta t \to 0} \frac{|G_i G_j G_k|}{\Delta t^{3/2}} \frac{|u'''(\xi) - u'''(x_{n-1})|}{\sqrt{\Delta t} u'''(x_{n-1})}\right] = 0.\end{aligned}$$

So the first term of (B.4) is of order $O(\Delta t^2)$. Therefore,

$$\begin{aligned}&\|E_{n-1}[\eta_n(e^y-1)(h_{n-1}\cdot(e^y-1))^2u'''(\xi)]\|_1\\ &\le m^3\max_{i,j,k}|E_{n-1}[\eta_nG_jG_kG_iu'''(\xi)]| = u'''(x_{n-1})o(\Delta t)^{3/2}\\ &= u'''(x_{n-1})(O(\Delta t^2)+o(\Delta t^{3/2})) = u'''(x_{n-1})o(\Delta t^{3/2}).\end{aligned}$$

□

Define

$$\lambda_N := 1, \eta_n := E_n\left[\prod_{k=n}^{N}\lambda_k\right],$$

$$h_{n-1}^{**} = \frac{1}{1-\alpha}A_{n-1,\lambda_n}^{-1}E_{n-1}[(e^{y_n}-1)\eta_n],$$

$$\lambda_{n-1} := (1+h_{n-1}^{**}\cdot(e^{y_n}-1))^\alpha = \left(1+\frac{1}{1-\alpha}(e^{y_n}-1)'A_{n-1,\lambda_n}^{-1}E_{n-1}[(e^{y_n}-1)\eta_n]\right)^\alpha,$$

$$A_{n-1,\eta_n} := E_{n-1}\left[\eta_n\begin{pmatrix}(e^{y_n^{(1)}}-1)^2 & . & . & (e^{y_n^{(m)}}-1)(e^{y_n^{(1)}}-1)\\ (e^{y_n^{(2)}}-1)(e^{y_n^{(1)}}-1) & . & . & (e^{y_n^{(m)}}-1)(e^{y_n^{(2)}}-1)\\ . & . & . & .\\ (e^{y_n^{(m)}}-1)(e^{y_n^{(1)}}-1) & . & . & (e^{y_n^{(m)}}-1)^2\end{pmatrix}\right]$$

for $i = 1,\dots,N$.

THEOREM B.3. *Let $u(x) = \frac{x^\alpha}{\alpha}, \alpha < 1$. Assume that $h_{n-1}^{**}, n = 1,2,\dots,N$, defined above are admissible; then we have the following:*

(i) *For all n, there exist positive constants $D > \frac{1}{\Delta t}$ s.t.*

$$\frac{|E_n[\lambda_n]-1|}{\Delta t} < D.$$

(ii) *For all n, $\Delta t\|A_{n-1,\eta_n}^{-1}\|_\infty \le C_2$, where C_2 is a constant.*

(iii) *For all n,*

$$(1-D\Delta t)^{N-n} \le \eta_n \le (1+D\Delta t)^{N-n}.$$

Proof. We prove the theorem for the case $m = 1$. It becomes much more complex if $m > 1$; the idea of the proof is the same though.

Directly, we have

$$\begin{aligned}\lim_{\Delta t\to 0}\frac{|E_n[\lambda_n]-1|}{\Delta t} &= \lim_{\Delta t\to 0}\left|E_n\left[\frac{1}{\Delta t}|(1+(h_n^{**})'(e^{y_{n+1}}-1))^\alpha-1\right]\right|\\ &= \lim_{\Delta t\to 0}\frac{1}{\Delta t}|E_n[\alpha(h_n^{**})'(e^{y_{n+1}}-1)]+O(\Delta t)|\\ &= \lim_{\Delta t\to 0}\left|\alpha(h_n^{**})'E_n\left[\frac{\alpha(e^{y_{n+1}}-1)}{\Delta t}\right]\right|+C_0\\ &\le \lim_{\Delta t\to 0}\left\|E_n\left[\frac{\alpha(e^{y_{n+1}}-1)}{\Delta t}\right]\right\|_1+C_0 = D.\end{aligned}$$

In the last inequality above, we use the assumption that h^{**} are admissible (and therefore bounded). (We may get the same conclusion by applying Proposition B.1.)

Therefore, λ_n satisfies (i).

To prove (iii), note that λ_n is $\mathcal{F}_{n+1}$ measurable, and so

$$\begin{aligned}\eta_n &= E_n[\lambda_n\eta_{n+1}] = E_n[\lambda_n\lambda_{n+1}\dots\lambda_{N-2}E_N[\lambda_{N-1}]]\\ &\le E_n[\lambda_n\dots\lambda_{N-2}](1+D\Delta t)\\ &\le \cdots \le (1+D\Delta t)^{N-n}.\end{aligned}$$

Similarly, we obtain $\eta_n > (1-D\Delta t)^{N-n}$. So we proved (iii). Applying (iii), we can know that each of the diagonal elements of A_{n-1,η_n} is of order $O(\Delta t)$, while nondiagonal elements are of order $O(\Delta t)^2$. Hence, $\|A_{n-1,\eta_n}\|_\infty$ are of order $1/O(\Delta t)$. □

THEOREM B.4. *η_n defined in* (4.10) *or in Proposition* 4.1 *satisfies*

$$E_{n-1}[\eta_n(e^{y_n}-1)] = o(\sqrt{\Delta t})$$

and

$$E_{n-1}[\eta_n(e^{y_n}-1)^3] = o(\Delta t^{3/2}).$$

Proof. Write $t=(n-1)\Delta t$. Fix t; then

$$E_{n-1}[\eta_n(e^{y_n}-1)^3] = E[\eta_n(e^{y_n}-1)^3|\mathcal{F}_t].$$

By Theorem B.3 (iii), η_n is bounded, so there exists an upper limit as $\Delta t\to 0$. Denote the limit by $\bar\eta_t$. Then

$$\begin{aligned}&\bar{\lim}_{\Delta t\to 0}\frac{1}{\sqrt{\Delta t}}E_{n-1}[\eta_n(e^{y_n}-1)]\\ &= \bar{\lim}_{\Delta t\to 0}\frac{1}{\sqrt{\Delta t}}E_{n-1}[(\eta_n-\bar\eta_t)(e^{y_n}-1)] + E_{n-1}[\bar\eta_t(e^{y_n}-1)]\\ &= E_{n-1}\left[\bar{\lim}_{\Delta t\to 0}(\eta_n-\bar\eta_t)\frac{1}{\sqrt{\Delta t}}(e^{y_n}-1)\right] + \bar\eta_t E_{n-1}\left[\frac{1}{\sqrt{\Delta t}}(e^{y_n}-1)\right]\\ &= 0.\end{aligned}$$

In the last step, we use the fact

$$\frac{e^{y_n^{(i)}}-1}{\sqrt{\Delta t}} \le Ce^{\|Z\|_1}(1+\|Z\|_1)$$

for each $i=1,2,\dots,m$, so that the dominated convergence theorem can be applied.

Therefore, we proved the first equality. Similarly, we can prove the second one. □

THEOREM B.5. *For either of the two following cases:*

(i) *the transition matrix P has identical columns;*

(ii) *all $b_i = (\mu(e_i) - r1_m - \operatorname{diag}(\hat\sigma(e_i)\hat\sigma(e_i)')/2)\Delta t$, $i=1,\dots,d$, are the same,*

we have

$$\begin{aligned}E_{n-1}[\eta_n(e^{y_n}-1)] &= O(\Delta t),\\ E_{n-1}[\eta_n(e^{y_n}-1)^3] &= O(\Delta t)^2.\end{aligned}$$

Proof. Again, we suppose $m=1$ (there is only one stock).

Note that by the definition, η_n is the expected utility of terminal wealth given $x_n=1$ and $\mathcal{F}_n$, while the wealth process is associated with the strategy $\{h_n^{**}\}$.

Intuitively, the expected utility of the terminal wealth should depend only on the initial wealth and the initial state of the Markov chain. Since the initial wealth is given as 1, η_n should be a functional of $E_n[Y_n]$—the expected state of Markov chain Y_n at time $n * \Delta t$. To see this point, one may use the definition of η_n, λ_n and Lemma 2.2 to calculate η_n directly. For example,

$$\begin{aligned}\eta_{N-1} &= E_{N-1}[\lambda_{N-1}] \\ &= E_{N-1}[(1 + h_{N-1}^{**}{}'(e^{y_N} - 1))^{\alpha}] \\ &\overset{(2.1)}{=} \int_{\mathcal{R}} (1 + h_{N-1}^{**}{}'(e^{y_N} - 1))^{\alpha} \sum_{k=1}^{d} Pr(Y_{N-1} = e_k | \mathcal{F}_{N-1}) \phi_k(y_N - b_k) dy_N.\end{aligned}$$

We can see that η_{N-1} is a function of $E_{N-1}[Y_{N-1}]$. Recursively, we may conclude that each η_n is a function of $E_n[Y_n]$.

Recalling $E_n[Y_n] \in [0,1]^d \subset R^d$, we can rewrite (2.2) in a vector form,

$$H(y_n) := E_n[Y_n] = \frac{P\Phi(y_n)E_{n-1}[Y_{n-1}]}{\|\Phi(y_n)E_{n-1}[Y_{n-1}]\|_1},$$

where

$$\begin{aligned}\Phi(y_n) &= \operatorname{diag}\{(2\pi f_i^2)^{-\frac{1}{2}} e^{-\frac{(y_n - b_i)^2}{f_i^2}}, i = 1, \ldots, d\}, \\ f_i &= \mu(e_i)\sqrt{\Delta t}, b_i = (\mu(e_i) - r - \hat{\sigma}(e_i)^2/2)\Delta t.\end{aligned}$$

Using the density function of y_n in Lemma 2.1, we have

$$\begin{aligned}&E_{n-1}[\eta_n(H(y_n))y_n] \\ &= \int_{\mathcal{R}} \eta_n(H(y_n))\ y_n\ \sum_{k=1}^{d} Pr(Y_{n-1} = e_k | \mathcal{F}_{n-1}) \phi_k(y_n - b_k) dy_n \\ &= \sum_{k=1}^{d} Pr(Y_{n-1} = e_k | \mathcal{F}_{n-1}) \int_{\mathcal{R}} \eta_n(H(b_k + f_k Z_n)) \\ &\quad \cdot (b_k + f_k Z_n)\ \phi_k(b_k + f_k Z_n - b_k) d(f_k Z_n)\ \text{(change variable)}.\end{aligned}$$

Note $b_i/\Delta t = \text{Constant}$, $f_i/\sqrt{\Delta t} = \text{Constant}$ for $i = 1, \ldots, d$. Therefore, we have

$$\begin{aligned}&E_{n-1}[\eta_n(H(y_n))] \\ &= \sum_{k=1}^{d} Pr(Y_{n-1} = e_k | \mathcal{F}_{n-1}) f_k^2 \int_{\mathcal{R}} \eta_n(H(b_k + f_k Z_n))\ Z_n\ \phi_k(f_k Z_n) dZ_n + O(\Delta t) \\ &= \sum_{k=1}^{d} Pr(Y_{n-1} = e_k | \mathcal{F}_{n-1}) \int_{\mathcal{R}} \eta_n(H(b_k + f_k Z_n))\ Z_n\ \frac{f_k}{\sqrt{2\pi}} e^{-Z_n^2/2} dZ_n + O(\Delta t).\end{aligned}$$

One can see that if $H(b_k + f_k Z_n)$ is an even function of Z_n, then

$$\int_{\mathcal{R}} \eta_n(H(b_k + f_k Z_n))\ Z_n\ \frac{f_k}{\sqrt{2\pi}} e^{-Z_n^2/2} dZ_n = 0;$$

therefore,

$$E_{n-1}[\eta_n(H(y_n))] = O(\Delta t). \tag{B.5}$$

For the case (i) given in the condition of the theorem, one can easily check that the value of H depends only on P—the transition matrix. In fact, H equals one column of P which is constant, so the theorem is true for this case.

For the case (ii), we can see that $H(b_k + f_k Z_n)$ is even by applying the condition $b_k = b_j, k \neq j$, in the definition of $H(y_n)$.

Therefore,

$$E_{n-1}[\eta_n y_n] = O(\Delta t),$$

and

$$E_{n-1}[\eta_n(e^{y_n} - 1)] = E_{n-1}[\eta_n y_n] + O(\Delta t) = O(\Delta t).$$

Similarly, we can prove

$$E_{n-1}[\eta_n(e^{y_n} - 1)^3] = O(\Delta t)^2. \qquad \square$$

A SMALL-GAIN THEOREM FOR A WIDE CLASS OF FEEDBACK SYSTEMS WITH CONTROL APPLICATIONS*

IASSON KARAFYLLIS† AND ZHONG-PING JIANG‡

Abstract. A small-gain theorem, which can be applied to a wide class of systems that includes systems satisfying the weak semigroup property, is presented in the present work. The result generalizes all existing results in the literature and exploits notions of weighted, uniform, and nonuniform input-to-output stability properties. Applications to partial state feedback stabilization problems with sampled-data feedback applied with zero order hold and positive sampling rate are also presented.

Key words. input-to-output stability, control systems, small-gain theorem

1. Introduction.

A common feature of stability analysis for complex interconnected systems is the application of small-gain results. Small-gain theorems for continuous-time finite-dimensional systems expressed in terms of "nonlinear gain functions" have a long history (see [14, 32, 51, 52] and the references therein). A nonlinear small-gain result was presented in [14], which allowed numerous applications to feedback stabilization problems. The methodology presented in [14] was followed by many researchers (see [15, 16, 22, 24, 47, 50]). A common characteristic of current research on nonlinear small-gain results in mathematical systems theory is the use of the notion of uniform input-to-state stability (ISS), introduced by Sontag in [44] for systems described by ordinary differential equations, or the notion of uniform input-to-output stability (IOS), introduced by Sontag and Wang in [46] (also see [14]) and extended in [10]. Small-gain theorems for discrete-time systems can be found in [17, 18, 19].

Extensions of small-gain results were presented recently in the literature. In [12, 13] less conservative small-gain conditions were presented for finite-dimensional systems. In [2, 3] matrix gain functions were used for the study of large scale finite-dimensional systems. A nonuniform in time small-gain theorem for continuous-time finite-dimensional systems was presented in [22]. Moreover, in [24, 47] small-gain results for wide classes of systems were provided. The classes of systems considered in [24, 47] satisfy the classical semigroup property (see [24, 25, 26, 45]). Small-gain results for hybrid systems satisfying the classical semigroup property were recently presented in [30].

An important feature of certain hybrid systems is that they do not satisfy the classical semigroup property: For example, the solution $x(t)$ of a system Σ with initial condition $x(t_0) = x_0$ does not coincide (in general) for $t \geq t_1 > t_0$ with the solution $\tilde{x}(t)$ of Σ with initial condition $\tilde{x}(t_1) = x(t_1)$. Such systems arise when sampled-data feedback laws are applied to finite-dimensional control systems or when numerical

discretization schemes are applied for the numerical solution of a system of ordinary differential equations. However, from a mathematical point of view, these structures cannot be considered as "systems" in the sense given in [20, 24, 45]. This feature has important consequences, since the researcher cannot use the tools developed for systems theory and mathematical control theory. In [25, 26] the notion of a system was relaxed so that the semigroup property does not hold in a strict sense. Moreover, the modification introduced allows the results obtained in [24] to hold. Thus we are in a position to develop a complete stability theory, which covers the systems that satisfy the so-called "weak semigroup property."

The purpose of the present work is to present a small-gain result (Theorem 3.1 and Corollary 3.4), which

- ∗ can be applied to a very general class of systems (including systems that do not satisfy the classical semigroup property),
- ∗ unifies all existing results, which make use of uniform or nonuniform and weighted notions of ISS or IOS,
- ∗ can be used directly for the solution of sampled-data feedback stabilization problems or problems of numerical stability of discretization schemes, and
- ∗ can be applied to uncertain time-varying systems with vanishing or nonvanishing perturbations.

We believe that the main result of the present work is a valuable tool for establishing stability and will be used frequently in future research. However, we would like to emphasize the theoretical significance of our main result: It is a method for establishing qualitative properties expressed in a very general framework that unifies works from various fields as well as different stability notions. The results presented in the paper can be extended without much difficulty to the case of local stability notions.

The contents of this paper are presented as follows. In section 2 we provide the definitions of the notions used and several examples of systems that have the "boundedness-implies-continuation" (BIC) property. In section 3 the main result is stated and proved. In section 4, it is shown how the main result of the present work can be applied to an ISS stabilization problem of a certain class of systems with partial-state sampled-data feedback. It should be emphasized that sampled-data control systems cannot be handled with small-gain results that have appeared so far in the literature, since sampled-data control systems do not satisfy the classical semigroup property. Finally, section 5 contains the conclusions of the paper. The proofs of some basic results are given in the appendix.

Notations. Throughout this paper we adopt the following notations:

- ∗ We denote by K^+ the class of positive, continuous functions defined on $\Re^+$. We say that a function $\rho : \Re^+ \to \Re^+$ is of class $\mathcal{N}$, if ρ is continuous, nondecreasing, with $\rho(0) = 0$. By K we denote the set of positive definite, increasing and continuous functions. We say that a positive definite, increasing and continuous function $\rho : \Re^+ \to \Re^+$ is of class K_∞ if $\lim_{s\to+\infty} \rho(s) = +\infty$. By KL we denote the set of all continuous functions $\sigma = \sigma(s,t) : \Re^+ \times \Re^+ \to \Re^+$ with the properties: (i) for each $t \geq 0$ the mapping $\sigma(\cdot\,, t)$ is of class K; (ii) for each $s \geq 0$, the mapping $\sigma(s, \cdot\,)$ is nonincreasing with $\lim_{t\to+\infty} \sigma(s,t) = 0$.
- ∗ By $\|\ \|_{\mathcal{X}}$, we denote the norm of the normed linear space $\mathcal{X}$. By $|\ |$ we denote the Euclidean norm of $\Re^n$. Let $U \subseteq \mathcal{X}$, with $0 \in U$. By $B_U[0,r] := \{\, u \in U\ ;\ \|u\|_{\mathcal{X}} \leq r \,\}$ we denote the intersection of $U \subseteq \mathcal{X}$ with the closed sphere of radius $r \geq 0$, centered at $0 \in U$.

∗ Let a set U be a subset of a normed linear space $\mathcal{U}$, with $0 \in U$. By $\mathcal{M}(U)$ we denote the set of all locally bounded functions $u : \Re^+ \to U$. By u_0 we denote the identically zero input, i.e., the input that satisfies $u_0(t) = 0 \in U$ for all $t \geq 0$. If $U \subseteq \Re^n$, then $L^\infty_{loc}(\Re^+; U)$ denotes the space of measurable, locally bounded functions $u : \Re^+ \to U$.

The following convention will be adopted throughout the paper: The Cartesian product of two normed linear spaces $C := \mathcal{X} \times \mathcal{Y}$ will be considered to be endowed with the norm $\|(x, y)\|_C := \sqrt{\|x\|^2_{\mathcal{X}} + \|y\|^2_{\mathcal{Y}}}$, unless stated otherwise. Furthermore, our results can be extended to the case of measurable and locally essentially bounded inputs (where the "sup" operator is to be understood as "essential supermum").

2. Input-to-output stability in a system-theoretic framework. In this section we first give the notion of a control system with outputs. We emphasize that we consider control systems which do not necessarily satisfy the classical semigroup property (see [20, 24, 45]).

DEFINITION 2.1. *A control system* $\Sigma := (\mathcal{X}, \mathcal{Y}, M_U, M_D, \phi, \pi, H)$ *with outputs consists of*

(i) *a set* U *(control set) which is a subset of a normed linear space* $\mathcal{U}$*, with* $0 \in U$*, and a set* $M_U \subseteq \mathcal{M}(U)$ *(allowable control inputs) which contains at least the identically zero input* u_0*,*

(ii) *a set* D *(disturbance set) and a set* $M_D \subseteq \mathcal{M}(D)$*, which is called the "set of allowable disturbances,"*

(iii) *a pair of normed linear spaces* $\mathcal{X}, \mathcal{Y}$ *called the "state space" and the "output space," respectively,*

(iv) *a continuous map* $H : \Re^+ \times \mathcal{X} \times U \to \mathcal{Y}$ *that maps bounded sets of* $\Re^+ \times \mathcal{X} \times U$ *into bounded sets of* $\mathcal{Y}$*, called the "output map,"*

(v) *a set-valued map* $\Re^+ \times \mathcal{X} \times M_U \times M_D \ni (t_0, x_0, u, d) \to \pi(t_0, x_0, u, d) \subseteq [t_0, +\infty)$*, with* $t_0 \in \pi(t_0, x_0, u, d)$ *for all* $(t_0, x_0, u, d) \in \Re^+ \times \mathcal{X} \times M_U \times M_D$*, called the set of "sampling times," and*

(vi) *the map* $\phi : A_\phi \to \mathcal{X}$*, where* $A_\phi \subseteq \Re^+ \times \Re^+ \times \mathcal{X} \times M_U \times M_D$*, called the "transition map," which has the following properties:*

(1) *Existence: For each* $(t_0, x_0, u, d) \in \Re^+ \times \mathcal{X} \times M_U \times M_D$*, there exists* $t > t_0$ *such that* $[t_0, t] \times \{(t_0, x_0, u, d)\} \subseteq A_\phi$*.*

(2) *Identity property: For each* $(t_0, x_0, u, d) \in \Re^+ \times \mathcal{X} \times M_U \times M_D$*, it holds that* $\phi(t_0, t_0, x_0, u, d) = x_0$*.*

(3) *Causality: For each* $(t, t_0, x_0, u, d) \in A_\phi$*, with* $t > t_0$*, and for each* $(\tilde{u}, \tilde{d}) \in M_U \times M_D$*, with* $(\tilde{u}(\tau), \tilde{d}(\tau)) = (u(\tau), d(\tau))$ *for all* $\tau \in [t_0, t]$*, it holds that* $(t, t_0, x_0, \tilde{u}, \tilde{d}) \in A_\phi$*, with* $\phi(t, t_0, x_0, u, d) = \phi(t, t_0, x_0, \tilde{u}, \tilde{d})$*.*

(4) *Weak semigroup property: There exists a constant* $r > 0$ *such that for each* $t \geq t_0$ *with* $(t, t_0, x_0, u, d) \in A_\phi$*:*

(a) $(\tau, t_0, x_0, u, d) \in A_\phi$ *for all* $\tau \in [t_0, t]$*;*

(b) $\phi(t, \tau, \phi(\tau, t_0, x_0, u, d), u, d) = \phi(t, t_0, x_0, u, d)$ *for all* $\tau \in [t_0, t] \cap \pi(t_0, x_0, u, d)$*;*

(c) *if* $(t+r, t_0, x_0, u, d) \in A_\phi$*, then it holds that* $\pi(t_0, x_0, u, d) \cap [t, t+r] \neq \emptyset$*;*

(d) *for all* $\tau \in \pi(t_0, x_0, u, d)$*, with* $(\tau, t_0, x_0, u, d) \in A_\phi$*, we have* $\pi(\tau, \phi(\tau, t_0, x_0, u, d), u, d) = \pi(t_0, x_0, u, d) \cap [\tau, +\infty)$*.*

In order to develop stability notions for a control system with outputs we need to clarify the notions of an equilibrium point as well as certain other important notions

and classes of systems that characterize the dynamic behavior of the system (see [24, 25]).

DEFINITION 2.2. *Let $T > 0$. A control system $\Sigma := (\mathcal{X}, \mathcal{Y}, M_U, M_D, \phi, \pi, H)$ with outputs is called T-periodic, if:*

(a) *$H(t+T, x, u) = H(t, x, u)$ for all $(t, x, u) \in \Re^+ \times \mathcal{X} \times U$,*

(b) *for every $(u, d) \in M_U \times M_D$ and integer k there exist inputs $P_{kT}u \in M_U$, $P_{kT}d \in M_D$, with $(P_{kT}u)(t) = u(t + kT)$ and $(P_{kT}d)(t) = d(t + kT)$, for all $t + kT \geq 0$,*

(c) *for each $(t, t_0, x_0, u, d) \in A_\phi$, with $t \geq t_0$, and for each integer k, with $t_0 - kT \geq 0$ it follows that $(t - kT, t_0 - kT, x_0, P_{kT}u, P_{kT}d) \in A_\phi$ and $\pi(t_0 - kT, x_0, P_{kT}u, P_{kT}d) = \cup_{\tau \in \pi(t_0, x_0, u, d)}\{\tau - kT\}$, with $\phi(t, t_0, x_0, u, d) = \phi(t - kT, t_0 - kT, x_0, P_{kT}u, P_{kT}d)$.*

DEFINITION 2.3. *A control system $\Sigma := (\mathcal{X}, \mathcal{Y}, M_U, M_D, \phi, \pi, H)$ with outputs is called time-invariant or autonomous, if it is T-periodic for all $T > 0$.*

DEFINITION 2.4. *Consider a control system $\Sigma := (\mathcal{X}, \mathcal{Y}, M_U, M_D, \phi, \pi, H)$ with outputs. We say that system Σ*

(i) *has the BIC property if for each $(t_0, x_0, u, d) \in \Re^+ \times \mathcal{X} \times M_U \times M_D$, there exists a maximal existence time, i.e., there exists $t_{\max} := t_{\max}(t_0, x_0, u, d) \in (t_0, +\infty]$, such that $A_\phi = \cup_{(t_0, x_0, u, d) \in \Re^+ \times \mathcal{X} \times M_U \times M_D}[t_0, t_{\max}) \times \{(t_0, x_0, u, d)\}$. In addition, if $t_{\max} < +\infty$, then for every $M > 0$ there exists $t \in [t_0, t_{\max})$, with $\|\phi(t, t_0, x_0, u, d)\|_{\mathcal{X}} > M$; and*

(ii) *is robustly forward complete (RFC) from the input $u \in M_U$ if it has the BIC property and for every $r \geq 0, T \geq 0$, it holds that*

$$\sup\{\|\phi(t_0 + s, t_0, x_0, u, d)\|_{\mathcal{X}}; \\ u \in \mathcal{M}(B_U[0, r]) \cap M_U, s \in [0, T], \|x_0\|_{\mathcal{X}} \leq r, t_0 \in [0, T], d \in M_D\} < +\infty.$$

DEFINITION 2.5. *Consider a control system $\Sigma := (\mathcal{X}, \mathcal{Y}, M_U, M_D, \phi, \pi, H)$, and suppose that $H(t, 0, 0) = 0$ for all $t \geq 0$. We say that $0 \in \mathcal{X}$ is a robust equilibrium point from the input $u \in M_U$ for Σ if*

(i) *for every $(t, t_0, d) \in \Re^+ \times \Re^+ \times M_D$, with $t \geq t_0$, it holds that $\phi(t, t_0, 0, u_0, d) = 0$; and*

(ii) *for every $\varepsilon > 0$, $T, h \in \Re^+$ there exists $\delta := \delta(\varepsilon, T, h) > 0$ such that for all $(t_0, x, u) \in [0, T] \times \mathcal{X} \times M_U$, $\tau \in [t_0, t_0 + h]$, with $\|x\|_{\mathcal{X}} + \sup_{t \geq 0}\|u(t)\|_{\mathcal{U}} < \delta$, it holds that $(\tau, t_0, x, u, d) \in A_\phi$ for all $d \in M_D$ and*

$$\sup\{\|\phi(\tau, t_0, x, u, d)\|_{\mathcal{X}}; d \in M_D, \tau \in [t_0, t_0 + h], t_0 \in [0, T]\} < \varepsilon.$$

Remark 2.6. Consider a control system $\Sigma := (\mathcal{X}, \mathcal{Y}, M_U, M_D, \phi, \pi, H)$ with the BIC property. It follows that Σ satisfies the (classical) semigroup property (see [24, 45]) if the weak semigroup property holds with $\pi(t_0, x_0, u, d) = [t_0, t_{\max})$, where $t_{\max} \in (t_0, +\infty]$ is the maximal existence time of the transition map for Σ that corresponds to $(t_0, x_0, u, d) \in \Re^+ \times \mathcal{X} \times M_U \times M_D$, i.e.,

"for each $t \in [t_0, t_{\max})$ it holds that
$\phi(t, \tau, \phi(\tau, t_0, x_0, u, d), u, d) = \phi(t, t_0, x_0, u, d)$ for all $\tau \in [t_0, t]$"
(classical semigroup property).

The following example shows the difference between the classical semigroup property and the weak semigroup property for simple systems.

Example 2.7. Consider the following system:

$$\begin{array}{l} \dot{x}(t) = -x(\tau_i)\,,\ t \in [\tau_i, \tau_{i+1}), \\ \tau_{i+1} = \tau_i + 1, \\ x(t) \in \Re, \end{array} \tag{2.1}$$

with initial condition $x(t_0) = x_0 \in \Re$ and $\tau_0 = t_0 \geq 0$. Such systems will be characterized as hybrid systems with a sampling partition generated by the system (see Example 2.11), and they satisfy the BIC property. In this case we can determine analytically the transition map for all $t \geq t_0$ (u, d in this example are irrelevant):

$$\phi(t, t_0, x_0) = \begin{cases} (1 - t + t_0)x_0 & \text{for } t \in [t_0, t_0 + 1), \\ 0 & \text{for } t \geq t_0 + 1. \end{cases}$$

It is clear that the state space is $\Re$ and that the classical semigroup property does not hold for this system. On the other hand, the weak semigroup property holds for this system with $\pi(t_0, x_0) = \{t_0, t_0 + 1, t_0 + 2, \ldots\}$. Notice that the set of sampling times (the sampling partition) $\pi(t_0, x_0) = \{t_0, t_0 + 1, t_0 + 2, \ldots\}$ is generated by the system itself and depends on the initial condition. Furthermore, according to Definition 2.3, system (2.1) is autonomous.

Next, consider the following system:

$$\begin{array}{l} \dot{x}(t) = -x(\tau_i)\,,\ t \in [\tau_i, \tau_{i+1}), \\ x(t) \in \Re\,,\ \pi = \{\tau_i\}_{i=0}^{\infty} = \{0, 1, 2, \ldots\}. \end{array} \tag{2.2}$$

Such systems will be characterized as hybrid systems with impulses at fixed times (see Example 2.12), and they satisfy the BIC property. Notice that if the initial time t_0 is not a member of the partition $\pi = \{\tau_i\}_{i=0}^{\infty} = \{0, 1, 2, \ldots\}$, then it is not possible to determine the solution of (2.2) based only on the initial condition $x(t_0) = x_0 \in \Re$ and the transition map is not well-defined. In order to be able to determine the solution of (2.2), we need to know $x(t_0), x([t_0]) = x_0 = (x_{1,0}, x_{2,0}) \in \Re^2$ (where $[t_0]$ denotes the integer part of t_0). Indeed, we have

$$x(t) = \begin{cases} x_{1,0} - (t - t_0)x_{2,0}, & t_0 \leq t < [t_0] + 1, \\ (2 - t + [t_0])\,(x_{1,0} - ([t_0] + 1 - t_0)x_{2,0})\,, & [t_0] + 1 \leq t < [t_0] + 2, \text{ if } t_0 \notin \pi, \\ 0, & t \geq [t_0] + 2, \end{cases}$$

$$x(t) = \begin{cases} (1 - t + t_0)x_{1,0} & \text{for } t \in [t_0, t_0 + 1), \\ 0 & \text{for } t \geq t_0 + 1, \end{cases} \quad \text{if } t_0 \in \pi.$$

In this case the state space is $\Re^2$, and the state of (2.2) at time $t \geq t_0$ is $\phi(t, t_0, x_0) = (x(t), x([t])) \in \Re^2$. Furthermore, notice that the classical semigroup property holds and that the partition $\pi = \{\tau_i\}_{i=0}^{\infty} = \{0, 1, 2, \ldots\}$ is fixed and does not depend on the initial condition. Finally, according to Definitions 2.2 and 2.3, system (2.2) is T-periodic, with $T = 1$, but it is not autonomous.

It should be emphasized that there are systems which do not satisfy the weak semigroup property (e.g., systems described by integrodifferential equations studied in [29], such as $\dot{x}(t) = -x(t) + \int_{t_0}^{t} \sin(tx(s))\, ds$, $x(t) \in \Re$, with initial condition $x(t_0) = x_0 \in \Re$). However, many classes of systems used in physics and engineering satisfy the weak semigroup property and the BIC property and have a robust equilibrium point. The following examples provide classes of control systems which satisfy the weak semigroup property and the BIC property and possess a robust equilibrium point.

The examples help the reader to understand that the notions defined by Definitions 2.4–2.5 are typical for a wide class of systems under minimal assumptions.

Example 2.8 (finite-dimensional control systems described by ordinary differential equations (ODEs)). Consider the class of systems described by ODEs of the form

$$\begin{aligned} &\dot{x}(t) = f(t, x(t), u(t), d(t)), \\ &Y(t) = H(t, x(t), u(t)), \\ &x(t) \in \Re^n\,,\ u(t) \in U\,,\ d(t) \in D\,,\ t \geq t_0, \end{aligned} \tag{2.3}$$

where $U \subseteq \Re^m$, $D \subseteq \Re^l$, with $0 \in U$, and $f : \Re^+ \times \Re^n \times U \times D \to \Re^n$, $H : \Re^+ \times \Re^n \times U \to \Re^k$ are two locally bounded mappings, with $H(t, 0, 0) = 0$, $f(t, 0, 0, d) = 0$ for all $(t, d) \in \Re^+ \times D$, that satisfy the following hypotheses.

(A1) The mapping $(x, u, d) \to f(t, x, u, d)$ is continuous for each fixed $t \geq 0$, measurable with respect to $t \geq 0$ for each fixed $(x, u, d) \in \Re^n \times U \times D$ and such that for every pair of bounded sets $I \subseteq \Re^+$, $S \subset \Re^n \times U$, there exists a constant $L \geq 0$ such that

$$\begin{aligned} &(x - y)'\,(f(t, x, u, d) - f(t, y, u, d)) \leq L\,|x - y|^2 \\ &\forall t \in I\,,\ \forall (x, u, y, u) \in S \times S\,,\ \forall d \in D. \end{aligned}$$

(A2) The mapping $H : \Re^+ \times \Re^n \times U \to \Re^k$ is continuous.

(A3) There exist functions $\gamma \in K^+$, $a \in K_\infty$ such that $|f(t, x, u, d)| \leq \gamma(t)a(|x| + |u|)$ for all $(t, x, u, d) \in \Re^+ \times \Re^n \times U \times D$.

The theory of ordinary differential equations guarantees that, under hypotheses (A1)–(A3), for each $(t_0, x_0) \in \Re^+ \times \Re^n$ and for each pair of measurable and locally bounded inputs $(u, d) \in \mathcal{M}(U) \times \mathcal{M}(D)$, there exists a unique absolutely continuous mapping $x(t)$ that satisfies a.e. the differential equation (2.3) with initial condition $x(t_0) = x_0 \in \Re^n$. Moreover, certain results from the theory of ordinary differential equations guarantee that (2.3) is a control system $\Sigma := (\Re^n, \Re^k, M_U, M_D, \phi, \pi, H)$ with outputs that satisfies the BIC property with M_U, M_D the sets of all measurable and locally bounded mappings $u : \Re^+ \to U$, $d : \Re^+ \to D$, respectively. Furthermore, the classical semigroup property is satisfied for this system; i.e., we have $\pi(t_0, x_0, u, d) = [t_0, t_{\max})$, where $t_{\max} > t_0$ is the maximal existence time of the solution. Finally, hypotheses (A1)–(A3) guarantee that $0 \in \Re^n$ is a robust equilibrium point from the input $u \in M_U$ for Σ.

The following example presents a class of neutral functional equations described by continuous-time difference equations. Such systems were recently studied in [26, 42]. The importance of functional difference equations in applications is explained in [42].

Example 2.9 (control systems described by functional difference equations (FDEs)). Consider the class of systems described by FDEs of the form

$$\begin{aligned} &x(t) = f(t, T_{r-\tau(t)}(t - \tau(t))x, u(t), d(t)), \\ &Y(t) = H(t, T_r(t)x, u(t)), \\ &x(t) \in \Re^n\,,\ Y(t) \in Y\,,\ u(t) \in U\,,\ d(t) \in D\,,\ t \geq t_0, \end{aligned} \tag{2.4}$$

where $r > 0$ is a constant, $\tau : \Re^+ \to (0, +\infty)$ is a positive continuous function, with $\sup_{t \geq 0} \tau(t) \leq r$, $D \subset \Re^l$, $U \subseteq \Re^m$, with $0 \in U$, are nonempty sets, $T_{r-\tau(t)}(t - \tau(t))x := x(t - \tau(t) + \theta); \theta \in [-r + \tau(t), 0]$, $T_r(t)x := x(t + \theta); \theta \in [-r, 0]$ and H, $f : \Omega \times U \times D \to \Re^n$, where $\Omega = \cup_{t \geq 0}\{t\} \times \mathcal{F}_t$ and $\mathcal{F}_t$ denotes the set of bounded functions $x : [-r + \tau(t), 0] \to \Re^n$, are locally bounded mappings which satisfy the following hypotheses.

(R1) There exist functions $\gamma \in K^+$, $a \in K_\infty$ such that $|f(t, T_{r-\tau(t)}(-\tau(t))x, u, d)| \leq \gamma(t)a(\sup_{\theta\in[-r,-\tau(t)]} |x(\theta)| + |u|)$ for all $(t, x, u, d) \in \Re^+ \times \mathcal{X} \times U \times D$, where $\mathcal{X}$ is the normed linear space of the bounded functions $x : [-r, 0] \to \Re^n$, with $\|x\|_{\mathcal{X}} := \sup_{\theta\in[-r,0]} |x(\theta)|$.

(R2) The output map $H : \Re^+ \times \mathcal{X} \times U \to \mathcal{Y}$, where $\mathcal{Y}$ is a normed linear space, is a continuous mapping that maps bounded sets of $\Re^+ \times \mathcal{X} \times U$ into bounded sets of $\mathcal{Y}$ with $H(t, 0, 0) = 0$ for all $t \geq 0$.

It should be clear that, under the hypotheses stated above, for each $(t_0, x_0) \in \Re^+ \times \mathcal{X}$ and for each pair of locally bounded functions $u : \Re^+ \to U$, $d : \Re^+ \to D$, there exists a unique locally bounded mapping $x(t)$ that satisfies the difference equations (2.4) with initial condition $x(t_0+\theta) = x_0(\theta); \theta \in [-r, 0]$. Consequently, (2.4) describes a control system $\Sigma := (\mathcal{X}, \mathcal{Y}, M_U M_D, \phi, \pi, H)$, with outputs and evolution map ϕ defined by $\phi(t, t_0, x_0, u, d) = x(t + \theta); \theta \in [-r, 0]$, where $\mathcal{U} := \Re^m$, M_U the set of all locally bounded functions $u : \Re^+ \to U$ and M_D the set of all functions $d : \Re^+ \to D$.

Systems described by functional difference evolution equations of the form (2.4) are considered in [6, 26, 42]. Working exactly in the same way as in [26], it can be shown that system (2.4) is RFC from the input $u \in M_U$ and that $0 \in \mathcal{X}$ is a robust equilibrium point from the input $u \in M_U$ for system (2.4).

Notice that a major advantage of allowing the output to take values in abstract normed linear spaces is that we are in a position to consider:

- outputs with no delays, e.g., $Y(t) = h(t, x(t), u(t))$, with $\mathcal{Y} = \Re^k$,
- outputs with discrete or distributed delay, e.g., $Y(t) = h(t, x(t), x(t-r), u(t))$ or $Y(t) = \sup_{\theta\in[t-r,t]} h(t, \theta, x(\theta), u(t))$, with $\mathcal{Y} = \Re^k$, and
- functional outputs with memory, e.g., $Y(t) = h(t, \theta, x(t + \theta)); \theta \in [-r, 0]$ or the identity output $Y(t) = T_r(t)x = x(t + \theta); \theta \in [-r, 0]$, with $\mathcal{Y} = \mathcal{X}$.

Finally, notice that the classical semigroup property is satisfied for this system; i.e., we have $\pi(t_0, x_0, u, d) = [t_0, +\infty)$.

The following example is an immediate consequence of Theorems 2.2 and 3.2 in [6], concerning continuous dependence on initial conditions and continuation of solutions of retarded functional differential equations, respectively.

Example 2.10 (control systems described by retarded functional differential equations (RFDEs)). Consider the class of systems described by RFDEs of the form

$$\begin{aligned} &\dot{x}(t) = f(t, T_r(t)x, u(t), d(t)), \\ &Y(t) = H(t, T_r(t)x, u(t)), \\ &x(t) \in \Re^n\,,\ u(t) \in U\,,\ d(t) \in D\,,\ t \geq t_0, \end{aligned} \tag{2.5}$$

where $T_r(t)x := x(t+\theta); \theta \in [-r, 0]$, $D \subseteq \Re^l$ is a nonempty set, $U \subseteq \Re^m$ is a nonempty set, with $0 \in U$, $f : \Re^+ \times C^0([-r, 0]; \Re^n) \times U \times D \to \Re^n$, $H : \Re^+ \times C^0([-r, 0]; \Re^n) \times U \to \mathcal{Y}$ ($\mathcal{Y}$ is a normed linear space) are locally bounded mappings, with $f(t, 0, 0, d) = 0$, $H(t, 0, 0) = 0$ for all $(t, d) \in \Re^+ \times D$, that satisfy the following hypotheses.

(S1) The mapping $(x, u, d) \to f(t, x, u, d)$ is continuous for each fixed $t \geq 0$ and such that, for every bounded $I \subseteq \Re^+$ and for every bounded $S \subset C^0([-r, 0]; \Re^n) \times U$, there exists a constant $L \geq 0$ such that

$$\begin{aligned} &(x(0) - y(0))' \left(f(t, x, u, d) - f(t, y, u, d)\right) \leq L \max_{\tau\in[-r,0]} |x(\tau) - y(\tau)|^2 \\ &\forall t \in I, \forall (x, u, y, u) \in S \times S, \forall d \in D. \end{aligned}$$

(S2) There exist functions $\gamma \in K^+$, $a \in K_\infty$ such that $|f(t, x, u, d)| \leq \gamma(t)a(\|x\|_r + |u|)$ for all $(t, x, u, d) \in \Re^+ \times C^0([-r, 0]; \Re^n) \times U \times D$, where $\|x\|_r$ denotes the sup-norm of the space $C^0([-r, 0]; \Re^n)$, i.e., $\|x\|_r := \max_{\theta\in[-r,0]} |x(\theta)|$.

(S3) There exists a countable set $A \subset \Re^+$, which is either finite or $A = \{t_k; k = 1, \dots, \infty\}$, with $t_{k+1} > t_k > 0$ for all $k = 1, 2, \dots$ and $\lim t_k = +\infty$, such that the mapping $(t, x, u, d) \in (\Re^+ \backslash A) \times C^0([-r, 0]; \Re^n) \times U \times D \to f(t, x, u, d)$ is continuous. Moreover, for each fixed $(t_0, x, u, d) \in \Re^+ \times C^0([-r, 0]; \Re^n) \times U \times D$, we have $\lim_{t \to t_0^+} f(t, x, u, d) = f(t_0, x, u, d)$.

(S4) The mapping $H : \Re^+ \times C^0([-r, 0]; \Re^n) \times U \to \mathcal{Y}$ is a continuous mapping that maps bounded sets of $\Re^+ \times C^0([-r, 0]; \Re^n) \times U$ into bounded sets of $\mathcal{Y}$.

The theory of retarded functional differential equations guarantees that under hypotheses (S1)–(S4), for each $(t_0, x_0) \in \Re^+ \times C^0([-r, 0]; \Re^n)$ and for each pair of measurable and locally bounded inputs $(u, d) \in \mathcal{M}(U) \times \mathcal{M}(D)$, there exists a unique absolutely continuous mapping $x(t)$ that satisfies a.e. the differential equation (2.5) with initial condition $x(t_0) = x_0 \in C^0([-r, 0]; \Re^n)$. Moreover, certain results from the theory of retarded functional differential equations (Theorems 2.2 and 3.2 in [6]) guarantee that (2.5) is a control system $\Sigma := (C^0([-r, 0]; \Re^n), \mathcal{Y}, M_U, M_D, \phi, \pi, H)$ with outputs that satisfies the BIC property with M_U, M_D the sets of all measurable and locally bounded mappings $u : \Re^+ \to U$, $d : \Re^+ \to D$, respectively. Furthermore, the classical semigroup property is satisfied for this system; i.e., we have $\pi(t_0, x_0, u, d) = [t_0, t_{\max})$, where $t_{\max} > t_0$ is the maximal existence time of the solution. Finally, hypotheses (S1)–(S4) guarantee that $0 \in C^0([-r, 0]; \Re^n)$ is a robust equilibrium point from the input $u \in M_U$ for Σ. Again notice that a major advantage of allowing the output to take values in abstract normed linear spaces is that we are in a position to consider various output cases (see previous example).

The following example presents an important class of systems that does not satisfy the classical semigroup property.

Example 2.11 (hybrid systems with sampling partition generated by the system). Consider the class of systems described by impulsive differential equations of the form

$$\begin{aligned} &\dot{x}(t) = f(t, \tau_i, x(t), x(\tau_i), u(t), u(\tau_i), d(t), d(\tau_i)), \quad t \in [\tau_i, \tau_{i+1}), \\ &\tau_0 = t_0,\ \tau_{i+1} = \tau_i + h(\tau_i, x(\tau_i), u(\tau_i), d(\tau_i))\,,\ i = 0, 1, \dots, \\ &x(\tau_{i+1}) = R\left(\tau_i, \lim_{t \to \tau_{i+1}^-} x(t), x(\tau_i), u(\tau_{i+1}), u(\tau_i), d(\tau_{i+1}), d(\tau_i)\right), \\ &Y(t) = H(t, x(t), u(t)), \end{aligned} \tag{2.6}$$

where $D \subseteq \Re^l$, $U \subseteq \Re^m$ is a closed set, with $0 \in U$, $h : \Re^+ \times \Re^n \times U \times D \to (0, r]$ is a positive function which is bounded by a certain constant $r > 0$, $f : \Re^+ \times \Re^+ \times \Re^n \times \Re^n \times U \times U \times D \times D \to \Re^n$, $H : \Re^+ \times \Re^n \times U \to \Re^p$, and $R : \Re^+ \times \Re^n \times \Re^n \times U \times U \times D \times D \to \Re^n$ is a triplet of vector fields that satisfy the following hypotheses.

(P1) $f(t, \tau, x, x_0, u, u_0, d, d_0)$ is measurable with respect to $t \geq 0$, continuous with respect to $(x, d, u) \in \Re^n \times D \times U$, and such that for every bounded $S \subset \Re^+ \times \Re^+ \times \Re^n \times \Re^n \times U \times U$ there exists a constant $L \geq 0$ such that

$$\begin{aligned} &(x - y)' \left(f(t, \tau, x, x_0, u, u_0, d, d_0) - f(t, \tau, y, x_0, u, u_0, d, d_0)\right) \leq L\, |x - y|^2 \\ &\forall (t, \tau, x, x_0, u, u_0, d, d_0) \in S \times D \times D\ ,\ \forall (t, \tau, y, x_0, u, u_0, d, d_0) \in S \times D \times D. \end{aligned}$$

(P2) There exist functions $\gamma \in K^+$, $a \in K_\infty$ such that

$$\begin{aligned} &|f(t, \tau, x, x_0, u, u_0, d, d_0)| \leq \gamma(t)\, a\left(|x| + |x_0| + |u| + |u_0|\right) \\ &\qquad \forall (\tau, u, u_0, d, d_0, x, x_0) \in \Re^+ \times U \times U \times D \times D \times \Re^n \times \Re^n, \quad \forall t \geq \tau, \\ &|R(t, x, x_0, u, u_0, d, d_0)| \leq \gamma(t)\, a\left(|x| + |x_0| + |u| + |u_0|\right) \\ &\qquad \forall (t, u, u_0, d, d_0, x, x_0) \in \Re^+ \times U \times U \times D \times D \times \Re^n \times \Re^n. \end{aligned}$$

(P3) $H : \Re^+ \times \Re^n \times U \to \Re^p$ is a continuous map, with $H(t,0,0) = 0$ for all $t \geq 0$.

(P4) There exist a positive, continuous, and bounded function $h_l : \Re^+ \times \Re^n \times U \to (0, r]$ and a partition $\pi = \{T_i\}_{i=0}^{\infty}$ of $\Re^+$, i.e., an increasing sequence of times with $T_0 = 0$ and $T_i \to +\infty$, such that

$$h(t,x,u,d) \geq \min\{p_\pi(t) - t\,,\, h_l(t,x,u)\} \quad \forall (t,x,u,d) \in \Re^+ \times \Re^n \times U \times D,$$

where $p_\pi(t) := \min\{T \in \pi; t < T\}$.

Hybrid systems of the form (2.6) under hypotheses (P1)–(P4) are considered in [25, 26], where it is shown that, for each $(t_0, x_0) \in \Re^+ \times \Re^n$ and for each pair of measurable and locally bounded inputs $u : \Re^+ \to U$ and $d : \Re^+ \to D$, there exists a unique piecewise absolutely continuous function $t \to x(t) \in \Re^n$ with initial condition $x(t_0) = x_0$, which is produced by the following algorithm:

Step i:

1. Given τ_i and $x(\tau_i)$, calculate τ_{i+1} using the equation $\tau_{i+1} = \tau_i + h(\tau_i, x(\tau_i), u(\tau_i), d(\tau_i))$.
2. Compute the state trajectory $x(t)$, $t \in [\tau_i, \tau_{i+1})$, as the solution of the differential equation $\dot{x}(t) = f(t, \tau_i, x(t), x(\tau_i), u(t), u(\tau_i), d(t), d(\tau_i))$.
3. Calculate $x(\tau_{i+1})$ using the equation $x(\tau_{i+1}) = R(\tau_i, \lim_{t \to \tau_{i+1}^-} x(t), x(\tau_i), u(\tau_{i+1}), u(\tau_i), d(\tau_{i+1}), d(\tau_i))$.
4. Compute the output trajectory $Y(t)$, $t \in [\tau_i, \tau_{i+1}]$, using the equation $Y(t) = H(t, x(t), u(t))$.

For $i = 0$ we take $\tau_0 = t_0$ and $x(\tau_0) = x_0$ (initial condition).

In [25] it is shown that system (2.6) under hypotheses (P1)–(P4) is a control system $\Sigma := (\mathcal{X}, \mathcal{Y}, M_U, M_D, \phi, \pi, H)$ with outputs with the BIC property for which $0 \in \Re^n$ is a robust equilibrium point from the input $u \in M_U$. Particularly, we have $\mathcal{X} = \Re^n$, $\mathcal{Y} = \Re^p$, $\mathcal{U} = \Re^m$, and M_U, M_D the sets of measurable and locally bounded inputs $u : \Re^+ \to U$ and $d : \Re^+ \to D$, respectively. The set $\pi(t_0, x_0, u, d) \subseteq [t_0, +\infty)$ involved in the weak semigroup property consists of the sequence $\pi = \{\tau_0, \tau_1, \ldots\}$ generated by the recursive relation $\tau_{i+1} = \tau_i + h(\tau_i, x(\tau_i), u(\tau_i), d(\tau_i))$, $i = 0, 1, \ldots$, with $\tau_0 = t_0$. Notice that the control system (2.6) fails to satisfy the classical semigroup property.

If $h(\tau+T, x, u, d) = h(\tau, x, u, d)$, $f(t+T, \tau+T, x, x_0, u, u_0, d, d_0) = f(t, \tau, x, x_0, u, u_0, d, d_0)$, $R(\tau+T, x, x_0, u, u_0, d, d_0) = R(\tau, x, x_0, u, u_0, d, d_0)$, and $H(t+T, x, u) = H(t, x, u)$ for certain $T > 0$ and for $(t, \tau, u, u_0, d, d_0, x, x_0) \in \Re^+ \times \Re^+ \times U \times U \times D \times D \times \Re^n \times \Re^n$, with $t \geq \tau$, then system (2.6) is *T-periodic*. Moreover, if $h(\tau, x, u, d) = h(x, u, d)$, $f(t, \tau, x, x_0, u, u_0, d, d_0) = f(t-\tau, x, x_0, u, u_0, d, d_0)$, $R(\tau, x, x_0, u, u_0, d, d_0) = R(x, x_0, u, u_0, d, d_0)$, and $H(t, x, u) = H(x, u)$ for $(t, \tau, u, u_0, d, d_0, x, x_0) \in \Re^+ \times \Re^+ \times U \times U \times D \times D \times \Re^n \times \Re^n$, with $t \geq \tau$, then system (2.6) is autonomous.

Systems of the form (2.6) under hypotheses (P1)–(P4) arise frequently in certain applications in mathematical control theory and numerical analysis. Specifically, they arise when

(i) a (not necessarily continuous) sampled-data feedback law (with a possibly variable sampling rate) is applied to a finite-dimensional control system. For example, state-dependent sampling rates were related in [4] with the classical work on discontinuous stabilizability in [1], while feedback stabilization problems with zero order hold and a constant positive sampling rate were considered in [33, 34, 35, 36, 37, 38, 40] and time-varying sampling rates were considered in [8, 9],

(ii) a synchronous controller switching strategy is applied to a finite-dimensional control system (see [31, 43]), and

(iii) a numerical discretization method (with possibly variable integration step sizes) is applied in order to obtain the numerical solution of a given system of ordinary differential equations; see [5, 48] for the case of constant integration step sizes and [23, 25] for the case of variable integration step sizes.

For a unified description of the above problems, see [25, 26].

In contrast with the previous example, it should be noted that hybrid systems with impulses at fixed times satisfy the classical semigroup property. The following example illustrates this case.

Example 2.12 (hybrid systems with impulses at fixed times). Consider the class of systems described by impulsive differential equations of the form

$$\begin{aligned} &\dot{x}(t) = f\left(t, d(t), d\left(\tau_i\right), x(t), x\left(\tau_i\right), u(t), u\left(\tau_i\right)\right), \qquad \tau_i \le t < \tau_{i+1}, \\ &x(\tau_{i+1}) = R\left(\tau_i, \lim_{t \to \tau_{i+1}^-} x(t), x(\tau_i), u(\tau_{i+1}), u(\tau_i), d(\tau_{i+1}), d(\tau_i)\right), \\ &Y(t) = H(t, x(t), u(t)), \\ &x(t) \in \Re^n \ , \ Y(t) \in \Re^k \ , \ u(t) \in V \subseteq \Re^m \ , \ t \ge 0 \ , \ d(t) \in D, \end{aligned} \tag{2.7}$$

where $D \subseteq \Re^l$, $V \subseteq \Re^m$ is a closed set, with $0 \in V$, $\pi = \{\tau_i\}_{i=0}^{\infty}$ is a partition of $\Re^+$with diameter $r > 0$, i.e., an increasing sequence of times with $\tau_0 = 0$, $\sup\{\tau_{i+1} - \tau_i; i = 0, 1, 2, \ldots\} = r$, and $\tau_i \to +\infty$, $d(t)$ represents the disturbance vector or the vector of time-varying uncertainties taking values in the set $D \subset \Re^l$, $Y(t)$ represents the output of the system, and $u(t) \in V$ represents the input vector. A wide class of systems described by impulsive differential equations with impulses at fixed times, as well as hybrid systems of the form:

$$\begin{aligned} &\dot{x}(t) = f(t, x(t), u(t), w(i)), \qquad \tau_i \le t < \tau_{i+1}, \\ &w(i) = g(i, x(\tau_i), u(\tau_i)), \end{aligned} \tag{2.8}$$

where $\pi = \{\tau_i\}_{i=0}^{\infty}$ is a partition of $\Re^+$ of diameter $r > 0$, can be represented by the time-varying case (2.7). Fundamental properties of the solutions of systems of the form (2.8) are studied in [28, 29].

Consider system (2.7) under the following assumptions.

(Q1) $\pi = \{\tau_i\}_{i=0}^{\infty}$ is a partition of $\Re^+$ with finite diameter $r > 0$, i.e., an increasing sequence of times with $\tau_0 = 0$, $\sup\{\tau_{i+1} - \tau_i; i = 0, 1, 2, \ldots\} = r$, and $\tau_i \to +\infty$.

(Q2) $H : \Re^+ \times \Re^n \times V \to \Re^k$ is continuous, with $H(t, 0, 0) = 0$, for all $t \ge 0$.

(Q3) $f(t, d, d_0, x, x_0, u, u_0)$ is measurable with respect to $t \ge 0$, continuous with respect to $(x, d, u) \in \Re^n \times D \times V$, and such that, for every compact $S \subset \Re^n \times \Re^n \times V \times V$ and for every compact $I \subset \Re^+$, there exists a constant $L \ge 0$ such that

$$\begin{aligned} &(x - y)' \left(f(t, d, d_0, x, x_0, u, u_0) - f(t, d, d_0, y, x_0, u, u_0)\right) \le L \left|x - y\right|^2 \\ &\forall t \in I \ , \ \forall (d, d_0) \in D \times D \ , \ \forall (x, x_0, u, u_0) \in S \ , \ \forall (y, x_0, u, u_0) \in S. \end{aligned}$$

(Q4) There exist functions $\gamma \in K^+$, $a \in K_\infty$ such that $|f(t, d, d_0, x, x_0, u, u_0)| \le \gamma(t) a(|x_0| + |x| + |u| + |u_0|)$, $|R(t, x, x_0, u, u_0, d, d_0)| \le \gamma(t) a(|x| + |x_0| + |u| + |u_0|)$ for all $(t, d, d_0, x, x_0, u, u_0) \in \Re^+ \times D \times D \times \Re^n \times \Re^n \times V \times V$.

Systems of the form (2.7) with $R(t, x, x_0, u, u_0, d, d_0) \equiv x$ (impulse free case) were considered in [27]. Special classes of impulsive systems of the form (2.7) were studied in [7]. Using the method of steps on consecutive intervals, it is clear that system (2.7)

under hypotheses (Q1)–(Q4) defines a control system $\Sigma := (\mathcal{X}, \mathcal{Y}, M_U, M_D, \phi, \pi, H)$ with outputs and the BIC property, with state space $\mathcal{X} = \Re^n \times \Re^n$, output space $\mathcal{Y} = \Re^k$, the set of structured uncertainties M_D being the set of mappings $t \in \Re^+ \to d(t) = \{\tilde{d}(t+\theta); \theta \in [-r, 0]\}$, where $\tilde{d} : \Re \to D$ is any measurable and locally bounded function, input space $\mathcal{U}$ the normed linear space of measurable and bounded functions on $[-r, 0]$ taking values in $\Re^m$ endowed with the sup-norm, $U \subseteq \mathcal{U}$ the set of measurable and bounded functions on $[-r, 0]$ taking values in $V \subseteq \Re^m$, and the set of external inputs M_U being the set of mappings $t \in \Re^+ \to u(t) = \{\tilde{u}(t+\theta); \theta \in [-r, 0]\} \in U$, where $\tilde{u} : \Re \to \Re^m$ is a measurable and locally bounded function. The reader may be surprised by the complicated definition of M_D and M_U, but it should be emphasized that this definition guarantees that the causality property of the control system (2.7) holds. Notice that the classical semigroup property is satisfied for this system; i.e., we have $\pi(t_0, x_0, u, d) = [t_0, t_{\max})$, where $t_{\max} > t_0$ is the maximal existence time of the solution. However, notice that if the vector fields f and R are independent of $d(\tau_i), x(\tau_i), u(\tau_i)$ (this is the case studied in [7]), then system (2.7) under hypotheses (Q1)–(Q4) defines a control system $\Sigma := (\mathcal{X}, \mathcal{Y}, M_U, M_D, \phi, \pi, H)$ with outputs and the BIC property, with state space $\mathcal{X} = \Re^n$, output space $\mathcal{Y} = \Re^k$, the set of structured uncertainties M_D being the set of measurable and locally bounded functions $d : \Re \to D$, input space $\mathcal{U} = \Re^m$, and M_U being the set of measurable and locally bounded functions $u : \Re \to U$.

Let $q_\pi(t) = \max\{\tau_i; \tau_i \in \pi, \tau_i \leq t\}$. For all $(t_0, x_0, x_1, d, u) \in \Re^+ \times \Re^n \times \Re^n \times M_D \times M_U$, we denote by $x(t) = \phi(t, t_0, x_0, x_1; d, u) \in \Re^n$ the solution of (2.7) at time $t \geq t_0$ with initial condition $x(t_0) = x_0$ and the additional condition $x(q_\pi(t_0)) = x_1$, which holds only for the case $t_0 \notin \pi$, corresponding to inputs $(d, u) \in M_D \times M_U$ (this solution is unique by virtue of property (Q3)). Notice that the actual state of system (2.7) at time $t \geq t_0$ is given by $\tilde{\phi}(t, t_0, x_0, x_1; d, u) = (\phi(t, t_0, x_0, x_1; d, u), \phi(q_\pi(t), t_0, x_0, x_1; d, u)) \in \Re^n \times \Re^n$.

Hypotheses (Q3)–(Q4) can be used in order to show that $0 \in \Re^n \times \Re^n$ is a robust equilibrium point from the input $u \in M_U$, exactly in the same way with the proof of the analogous result in [27]. Notice that if $f(t+T, x, x_0, u, u_0, d, d_0) = f(t, x, x_0, u, u_0, d, d_0)$, $R(t+T, x, x_0, u, u_0, d, d_0) = R(t, x, x_0, u, u_0, d, d_0)$, $H(t+T, x, u) = H(t, x, u)$, and $\pi = \{iT\}_{i=0}^{\infty}$ for certain $T > 0$ and for all $(t, u, u_0, d, d_0, x, x_0) \in \Re^+ \times V \times V \times D \times D \times \Re^n \times \Re^n$, then system (2.7) is *T-periodic*. Moreover, it should be noted that system (2.7) fails to be autonomous for every possible selection of the sets D, V, vector fields f, R, H, and partition π.

For control systems with the BIC property the following lemma provides a useful characterization of the RFC property. Its proof is provided in the appendix.

LEMMA 2.13. *System $\Sigma := (\mathcal{X}, \mathcal{Y}, M_U, M_D, \phi, \pi, H)$ is RFC from the input $u \in M_U$ if and only if for every $\beta \in K^+$ there exist functions $\mu, c \in K^+, a, p \in K_\infty$ (depending only on $\beta \in K^+$) such that the following estimate holds for all $(t_0, x_0, d, u) \in \Re^+ \times \mathcal{X} \times M_D \times M_U$:*

$$\begin{aligned} &\beta(t)\, \|\phi(t, t_0, x_0, u, d)\|_{\mathcal{X}} \\ &\quad \leq \max\left\{ \mu(t - t_0)\,,\ c(t_0)\,,\ a\left(\|x_0\|_{\mathcal{X}}\right),\ \sup_{t_0 \leq \tau \leq t} p\left(\|u(\tau)\|_{\mathcal{U}}\right) \right\} \quad \forall t \geq t_0. \end{aligned} \tag{2.9}$$

Next we present the IOS property for the class of systems described by Definition 2.1.

DEFINITION 2.14. *Consider a control system $\Sigma := (\mathcal{X}, \mathcal{Y}, M_U, M_D, \phi, \pi, H)$ with outputs and the BIC property and for which $0 \in \mathcal{X}$ is a robust equilibrium point from the input $u \in M_U$. Suppose that Σ is RFC from the input $u \in M_U$.*

- *If there exist functions $\sigma \in KL$, β, $\delta \in K^+$, $\gamma \in \mathcal{N}$ such that the following estimate holds for all $u \in M_U$, $(t_0, x_0, d) \in \Re^+ \times X \times M_D$, and $t \geq t_0$:*

$$\begin{aligned} &\|H(t, \phi(t, t_0, x_0, u, d), u(t))\|_{\mathcal{Y}} \\ &\quad \leq \sigma\left(\beta(t_0)\|x_0\|_{\mathcal{X}}, t - t_0\right) + \sup_{t_0 \leq \tau \leq t} \gamma\left(\delta(\tau)\|u(\tau)\|_{\mathcal{U}}\right), \end{aligned} \tag{2.10}$$

  then we say that Σ satisfies the weighted input-to-output stability (WIOS) property from the input $u \in M_U$, with gain $\gamma \in \mathcal{N}$ and weight $\delta \in K^+$. Moreover, if $\beta(t) \equiv 1$, then we say that Σ satisfies the uniform weighted input-to-output stability (UWIOS) property from the input $u \in M_U$, with gain $\gamma \in \mathcal{N}$ and weight $\delta \in K^+$.
- *If there exist functions $\sigma \in KL$, $\beta \in K^+$, $\gamma \in \mathcal{N}$ such that the following estimate holds for all $u \in M_U$, $(t_0, x_0, d) \in \Re^+ \times \mathcal{X} \times M_D$, and $t \geq t_0$:*

$$\|H(t, \phi(t, t_0, x_0, u, d), u(t))\|_{\mathcal{Y}} \leq \sigma\left(\beta(t_0)\|x_0\|_{\mathcal{X}}, t - t_0\right) + \sup_{t_0 \leq \tau \leq t} \gamma\left(\|u(\tau)\|_{\mathcal{U}}\right), \tag{2.11}$$

  then we say that Σ satisfies the IOS property from the input $u \in M_U$, with gain $\gamma \in \mathcal{N}$. Moreover, if $\beta(t) \equiv 1$, then we say that Σ satisfies the uniform input-to-output stability (UIOS) property from the input $u \in M_U$, with gain $\gamma \in \mathcal{N}$.

Finally, for the special case of the identity output mapping, i.e., $H(t, x, u) := x$, the (uniform) (weighted) input-to-output stability property from the input $u \in M_U$ is called the (uniform) (weighted) input-to-state stability ((U)(W)ISS) property from the input $u \in M_U$.

Remark 2.15. Using the inequalities $\max\{a, b\} \leq a + b \leq \max\left\{a + \rho(a), b + \rho^{-1}(b)\right\}$ (which hold for all $\rho \in K_\infty$ and $a, b \geq 0$), it should be clear that the WIOS property for $\Sigma := (\mathcal{X}, \mathcal{Y}, M_U, M_D, \phi, \pi, H)$ can be defined by using an estimate of the form

$$\begin{aligned} &\|H(t, \phi(t, t_0, x_0, u, d), u(t))\|_{\mathcal{Y}} \\ &\quad \leq \max\left\{\sigma\left(\beta(t_0)\|x_0\|_{\mathcal{X}}, t - t_0\right), \sup_{t_0 \leq \tau \leq t} \gamma\left(\delta(\tau)\|u(\tau)\|_{\mathcal{U}}\right)\right\} \end{aligned} \tag{2.10$'$}$$

instead of (2.10). Similarly, the IOS property for $\Sigma := (\mathcal{X}, \mathcal{Y}, M_U, M_D, \phi, \pi, H)$ can be defined by using an estimate of the form

$$\|H(t, \phi(t, t_0, x_0, u, d), u(t))\|_{\mathcal{Y}} \leq \max\left\{\sigma\left(\beta(t_0)\|x_0\|_{\mathcal{X}}, t - t_0\right), \sup_{t_0 \leq \tau \leq t} \gamma\left(\|u(\tau)\|_{\mathcal{U}}\right)\right\} \tag{2.11$'$}$$

instead of (2.11).

The following lemmas provide $\varepsilon - \delta$ characterizations of the WIOS and UWIOS properties, which are going to be used in the following section of the paper. Their proofs are provided in the appendix.

LEMMA 2.16. *Consider a control system $\Sigma := (\mathcal{X}, \mathcal{Y}, M_U, M_D, \phi, \pi, H)$ with outputs and the BIC property and for which $0 \in \mathcal{X}$ is a robust equilibrium point from the input $u \in M_U$. Suppose that Σ is RFC from the input $u \in M_U$. Furthermore, suppose that there exist functions $V : \Re^+ \times \mathcal{X} \times U \to \Re^+$, with $V(t, 0, 0) = 0$, for all $t \geq 0$, $\gamma \in \mathcal{N}$, and $\delta \in K^+$ such that the following properties hold:*

P1. *For every $s \geq 0$, $T \geq 0$, it holds that*

$$\sup\left\{V(t,\phi(t,t_0,x_0,u,d),u(t)) - \sup_{t_0\leq\tau\leq t}\gamma\left(\delta(\tau)\left\|u(\tau)\right\|_{\mathcal{U}}\right);\right.$$
$$\left. t\geq t_0, \left\|x_0\right\|_{\mathcal{X}} \leq s, t_0 \in [0,T], d\in M_D, u\in M_U\right\} < +\infty.$$

P2. *For every $\varepsilon > 0$ and $T \geq 0$, there exists a $\rho := \rho(\varepsilon, T) > 0$ such that*

$$\sup\left\{V(t,\phi(t,t_0,x_0,u,d),u(t)) - \sup_{t_0\leq\tau\leq t}\gamma\left(\delta(\tau)\left\|u(\tau)\right\|_{\mathcal{U}}\right);\right.$$
$$\left. t\geq t_0, \left\|x_0\right\|_{\mathcal{X}} \leq \rho, t_0 \in [0,T], d\in M_D, u\in M_U\right\} \leq \varepsilon.$$

P3. *For every $\varepsilon > 0$, $T \geq 0$, and $R \geq 0$, there exists a $\tau := \tau(\varepsilon, T, R) \geq 0$ such that*

$$\sup\left\{V(t,\phi(t,t_0,x_0,u,d),u(t)) - \sup_{t_0\leq\tau\leq t}\gamma\left(\delta(\tau)\left\|u(\tau)\right\|_{\mathcal{U}}\right);\right.$$
$$\left. t\geq t_0+\tau, \left\|x_0\right\|_{\mathcal{X}} \leq R, t_0 \in [0,T], d\in M_D, u\in M_U\right\} \leq \varepsilon.$$

Then there exist functions $\sigma \in KL$ and $\beta \in K^+$ such that the following estimate holds for all $u \in M_U$, $(t_0, x_0, d) \in \Re^+ \times \mathcal{X} \times M_D$, and $t \geq t_0$:

$$V(t,\phi(t,t_0,x_0,u,d),u(t)) \leq \sigma\left(\beta(t_0)\left\|x_0\right\|_{\mathcal{X}}, t-t_0\right) + \sup_{t_0\leq\tau\leq t}\gamma\left(\delta(\tau)\left\|u(\tau)\right\|_{\mathcal{U}}\right). \tag{2.12}$$

Moreover, if there exists $a \in \mathcal{N}$ such that $\left\|H(t,x,u)\right\|_{\mathcal{Y}} \leq a(V(t,x,u))$ for all $(t,x,u) \in \Re^+ \times \mathcal{X} \times U$, then for every $\rho \in K_\infty$, Σ satisfies the WIOS property from the input $u \in M_U$, with gain $\tilde{\gamma} \in \mathcal{N}$ and weight $\delta \in K^+$, where $\tilde{\gamma}(s) := a\left(\gamma(s) + \rho\left(\gamma(s)\right)\right)$.

LEMMA 2.17. *Consider a control system $\Sigma := (\mathcal{X}, \mathcal{Y}, M_U, M_D, \phi, \pi, H)$ with outputs and the BIC property and for which $0 \in \mathcal{X}$ is a robust equilibrium point from the input $u \in M_U$. Suppose that Σ is RFC from the input $u \in M_U$. Furthermore, suppose that there exist functions $V : \Re^+ \times \mathcal{X} \times U \to \Re^+$, with $V(t,0,0) = 0$, for all $t \geq 0$, $\gamma \in \mathcal{N}$, and $\delta \in K^+$ such that the following properties hold:*

P1. *For every $s \geq 0$, it holds that*

$$\sup\left\{V(t,\phi(t,t_0,x_0,u,d),u(t)) - \sup_{t_0\leq\tau\leq t}\gamma\left(\delta(\tau)\left\|u(\tau)\right\|_{\mathcal{U}}\right);\right.$$
$$\left. t\geq t_0, \left\|x_0\right\|_{\mathcal{X}} \leq s, t_0 \geq 0, d\in M_D, u\in M_U\right\} < +\infty.$$

P2. *For every $\varepsilon > 0$, there exists a $\rho := \rho(\varepsilon) > 0$ such that*

$$\sup\left\{V(t,\phi(t,t_0,x_0,u,d),u(t)) - \sup_{t_0\leq\tau\leq t}\gamma\left(\delta(\tau)\left\|u(\tau)\right\|_{\mathcal{U}}\right);\right.$$
$$\left. t\geq t_0, \left\|x_0\right\|_{\mathcal{X}} \leq \rho, t_0 \geq 0, d\in M_D, u\in M_U\right\} \leq \varepsilon.$$

P3. *For every $\varepsilon > 0$ and $R \geq 0$, there exists a $\tau := \tau(\varepsilon, R) \geq 0$ such that*

$$\sup\left\{V(t,\phi(t,t_0,x_0,u,d),u(t)) - \sup_{t_0\leq\tau\leq t}\gamma\left(\delta(\tau)\left\|u(\tau)\right\|_{\mathcal{U}}\right);\right.$$
$$\left. t\geq t_0+\tau, \left\|x_0\right\|_{\mathcal{X}} \leq R, t_0 \geq 0, d\in M_D, u\in M_U\right\} \leq \varepsilon.$$

Then there exists a function $\sigma \in KL$ such that estimate (2.12) *holds for all $u \in M_U$, $(t_0, x_0, d) \in \Re^+ \times \mathcal{X} \times M_D$, and $t \geq t_0$, with $\beta(t) \equiv 1$. Moreover, if there exists $a \in \mathcal{N}$ such that $\|H(t,x,u)\|_{\mathcal{Y}} \leq a(V(t,x,u))$ for all $(t,x,u) \in \Re^+ \times \mathcal{X} \times U$, then for every $\rho \in K_\infty$, Σ satisfies the UWIOS property from the input $u \in M_U$, with gain $\tilde{\gamma} \in \mathcal{N}$ and weight $\delta \in K^+$, where $\tilde{\gamma}(s) := a\left(\gamma(s) + \rho\left(\gamma(s)\right)\right)$.*

Remark 2.18. Notice that Lemmas 2.16 and 2.17 can be very useful for the demonstration of the (U)WIOS property, because in practice we show properties (P1)–(P3) for some Lyapunov functional V and not necessarily for the norm of the output map. Moreover, notice that it is not required that V is continuous. If $V : \Re^+ \times \mathcal{X} \times U \to \Re^+$ is a continuous functional that maps bounded sets of $\Re^+ \times \mathcal{X} \times U$ into bounded sets of $\Re^+$, then Lemmas 2.16 and 2.17 guarantee that Σ satisfies the WIOS and the UWIOS properties with V as output, respectively, from the input $u \in M_U$, with gain $\gamma \in \mathcal{N}$ and weight $\delta \in K^+$.

Finally, we end this section with some useful observations for *T-periodic* control systems. It turns out that periodicity guarantees uniformity with respect to the initial times. The following lemmas should be compared with Lemma 1.1, p. 131 in [6]. Their proofs are provided in the appendix.

LEMMA 2.19. *Suppose that $\Sigma := (\mathcal{X}, \mathcal{Y}, M_U, M_D, \phi, \pi, H)$ is T-periodic. If Σ satisfies the WIOS property from the input $u \in M_U$, then Σ satisfies the UWIOS property from the input $u \in M_U$.*

LEMMA 2.20. *Suppose that $\Sigma := (\mathcal{X}, \mathcal{Y}, M_U, M_D, \phi, \pi, H)$ is T-periodic. If Σ satisfies the IOS property from the input $u \in M_U$, then Σ satisfies the UIOS property from the input $u \in M_U$.*

3. A small-gain theorem for a wide class of systems. The main result of the present work is stated next.

THEOREM 3.1. *Consider the system $\Sigma := (\mathcal{X}, \mathcal{Y}, M_U, M_D, \phi, \pi, H)$ with the BIC property for which $0 \in \mathcal{X}$ is a robust equilibrium point from the input $u \in M_U$, and suppose that there exist maps $V_1 : \Re^+ \times \mathcal{X} \times U \to \Re^+$, $V_2 : \Re^+ \times \mathcal{X} \times U \to \Re^+$, with $V_i(t,0,0) = 0$ for all $t \geq 0$ $(i = 1, 2)$ such that the following hypotheses hold.*

(H1) *There exist functions $\sigma_1 \in KL$, β_1, μ_1, c_1, δ_1, δ_1^u, $q_1^u \in K^+$, γ_1, γ_1^u, a_1, p_1, $p_1^u \in \mathcal{N}$, $L_1 : \Re^+ \times \mathcal{X} \to \Re^+$, with $L_i(t,0) = 0$ for all $t \geq 0$, such that for every $(t_0, x_0, u, d) \in \Re^+ \times \mathcal{X} \times M_U \times M_D$ the mapping $t \to V_1(t, \phi(t, t_0, x_0, u, d), u(t))$ is locally bounded on $[t_0, t_{\max})$, and the following estimates hold for all $t \in [t_0, t_{\max})$:*

$$V_1(t, \phi(t, t_0, x_0, u, d), u(t)) \leq \sigma_1\left(\beta_1(t_0) L_1(t_0, x_0), t - t_0\right) + \sup_{t_0 \leq \tau \leq t} \gamma_1\left(\delta_1(\tau) V_2(\tau)\right) + \sup_{t_0 \leq \tau \leq t} \gamma_1^u\left(\delta_1^u(\tau) \|u(\tau)\|_{\mathcal{U}}\right), \tag{3.1}$$

$$\beta_1(t) L_1(t, \phi(t, t_0, x_0, u, d)) \leq \max\left\{\mu_1(t - t_0), c_1(t_0), a_1\left(\|x_0\|_{\mathcal{X}}\right), \sup_{t_0 \leq \tau \leq t} p_1\left(V_2(\tau)\right), \sup_{t_0 \leq \tau \leq t} p_1^u\left(q_1^u(\tau) \|u(\tau)\|_{\mathcal{U}}\right)\right\}, \tag{3.2}$$

where $V_2(t) = V_2\left(t, \phi(t, t_0, x_0, u, d), u(t)\right)$ and $t_{\max}$ is the maximal existence time of the transition map of Σ.

(H2) *There exist functions $\sigma_2 \in KL$, β_2, μ_2, c_2, δ_2, δ_2^u, $q_2^u \in K^+$, γ_2, γ_2^u, a_2, p_2, $p_2^u \in \mathcal{N}$, $L_2 : \Re^+ \times \mathcal{X} \to \Re^+$, with $L_2(t,0) = 0$ for all $t \geq 0$, such that for every $(t_0, x_0, u, d) \in \Re^+ \times \mathcal{X} \times M_U \times M_D$ the mapping $t \to V_2(t, \phi(t, t_0, x_0, u, d), u(t))$ is*

locally bounded on $[t_0, t_{\max})$*, and the following estimates hold for all* $t \in [t_0, t_{\max})$*:*

$$V_2(t, \phi(t, t_0, x_0, u, d), u(t)) \le \sigma_2\left(\beta_2(t_0) L_2(t_0, x_0), t - t_0\right) + \sup_{t_0 \le \tau \le t} \gamma_2\left(\delta_2(\tau) V_1(\tau)\right) + \sup_{t_0 \le \tau \le t} \gamma_2^u\left(\delta_2^u(\tau) \left\|u(\tau)\right\|_{\mathcal{U}}\right), \tag{3.3}$$

$$\beta_2(t) L_2(t, \phi(t, t_0, x_0, u, d)) \le \max\left\{\mu_2(t - t_0), c_2(t_0), a_2\left(\left\|x_0\right\|_{\mathcal{X}}\right), \sup_{t_0 \le \tau \le t} p_2\left(V_1(\tau)\right), \sup_{t_0 \le \tau \le t} p_2^u\left(q_2^u(\tau) \left\|u(\tau)\right\|_{\mathcal{U}}\right)\right\}, \tag{3.4}$$

where $V_1(t) = V_1\left(t, \phi(t, t_0, x_0, u, d), u(t)\right)$ *and* $t_{\max}$ *is the maximal existence time of the transition map of* Σ*.*

(H3) *There exist a function* $\rho \in K_\infty$ *and a constant* $M > 0$ *such that*

$$\delta_1(t) \le M \quad \forall t \ge 0, \tag{3.5}$$

$$g_1\left(\delta_1(t) g_2\left(\delta_2(\tau) s\right)\right) \le s \quad \forall t, s \ge 0 \text{ and } \tau \in [0, t], \tag{3.6}$$

where $g_i(s) := \gamma_i(s) + \rho\left(\gamma_i(s)\right)$*,* $i = 1, 2$*.*

(H4) *There exists a function* $a \in \mathcal{N}$ *such that the following inequality holds for all* $(t, x, u) \in \Re^+ \times \mathcal{X} \times U$*:*

$$\left\|H(t, x, u)\right\|_{\mathcal{Y}} \le a\left(V_1(t, x, u) + \gamma_1\left(\delta_1(t) V_2(t, x, u)\right)\right). \tag{3.7}$$

(H5) *There exist functions* $b \in \mathcal{N}$*,* $\mu \in K^+$ *such that the following inequalities hold for all* $(t, x) \in \Re^+ \times \mathcal{X}$*:*

$$\mu(t) \left\|x\right\|_{\mathcal{X}} \le b\left(L_1(t, x) + L_2(t, x)\right); \quad \max\left(L_1(t, x), L_2(t, x)\right) \le b\left(\left\|x\right\|_{\mathcal{X}}\right). \tag{3.8}$$

Then there exists a function $\gamma \in \mathcal{N}$ *such that system* Σ *satisfies the WIOS property from the input* $u \in M_U$*, with gain* $\gamma \in \mathcal{N}$ *and weight* $\delta \in K^+$*, where*

$$\delta(t) := \max\{\delta_1^u(t), \delta_2^u(t), q_1^u(t), q_2^u(t)\}. \tag{3.9}$$

Moreover, if $\beta_1, \beta_2, c_1, c_2, \delta_2 \in K^+$ *are bounded, then system* Σ *satisfies the UWIOS property from the input* $u \in M_U$*, with gain* $\gamma \in \mathcal{N}$ *and weight* $\delta \in K^+$*.*

Remark 3.2.

(a) It should be clear that Theorem 3.1 takes into account all possible cases (weights, nonuniformity with respect to initial times) and thus is applicable to a very wide class of systems.

(b) When $\gamma_1 \in \mathcal{N}$ (or $\gamma_2 \in \mathcal{N}$) is identically zero, it follows that (3.6) is automatically satisfied. This is the case of systems in cascade (see [14]). On the other hand, if $\gamma_i(s) = K_i s$ for certain constants $K_i \ge 0$ $(i = 1, 2)$, then inequality (3.6) is satisfied if $K_1 K_2 \sup_{t \ge 0}\left(\delta_1(t) \max_{\tau \in [0,t]} \delta_2(\tau)\right) < 1$. Moreover, if $\gamma_i(s) = K_i s$ for certain constants $K_i \ge 0$ $(i = 1, 2)$ and $\delta_1(t) \equiv \delta_2(t) \equiv 1$, then hypothesis (H3) is satisfied if $K_1 K_2 < 1$. This is the case of the classical small-gain theorem.

(c) If, instead of hypothesis (H4), there exists a function $a \in \mathcal{N}$ such that $\left\|H(t, x, u)\right\|_{\mathcal{Y}} \le a\left(V_2(t, x, u) + \gamma_2\left(\delta_2(t) V_1(t, x, u)\right)\right)$ holds for all $(t, x, u) \in \Re^+ \times \mathcal{X} \times U$, then indices 1 and 2 must be changed in hypothesis (H3). Furthermore, in this case system Σ satisfies the UWIOS property from the input $u \in M_U$, with gain $\gamma \in \mathcal{N}$ and weight $\delta \in K^+$, if functions $\beta_1, \beta_2, c_1, c_2, \delta_1 \in K^+$ are bounded.

(d) In previous nonlinear small-gain theorems (e.g., [14]), the functions $L_1 : \Re^+ \times \mathcal{X} \to \Re^+$ and $L_2 : \Re^+ \times \mathcal{X} \to \Re^+$ take the form $L_1(t,x) = x_1$ and $L_2(t,x) = x_2$, respectively, where $x = (x_1, x_2)$. It follows that hypothesis (H5) automatically holds with $b(s) := s$ and $\mu(t) \equiv 1$. This is the case in Corollary 3.4 below.

(e) Hypothesis (H4) in conjunction with (3.5) guarantees that: (i) if the mappings $t \to V_1(t, \phi(t, t_0, x_0, u, d), u(t))$, $t \to V_2(t, \phi(t, t_0, x_0, u, d), u(t))$ are bounded, then the mapping $t \to \|H(t, \phi(t, t_0, x_0, u, d), u(t))\|_{\mathcal{Y}}$ is bounded as well, and (ii) if $V_1(t, \phi(t, t_0, x_0, u, d), u(t)) \to 0$, $V_2(t, \phi(t, t_0, x_0, u, d), u(t)) \to 0$, then $\|H(t, \phi(t, t_0, x_0, u, d), u(t))\|_{\mathcal{Y}} \to 0$. In other words, hypothesis (H4) guarantees that the behavior of the output of system $\Sigma := (\mathcal{X}, \mathcal{Y}, M_U, M_D, \phi, \pi, H)$ can be determined by studying the behavior of the functionals $V_1 : \Re^+ \times \mathcal{X} \times U \to \Re^+, V_2 : \Re^+ \times \mathcal{X} \times U \to \Re^+$.

Since small-gain results are frequently applied to feedback interconnections of control systems, we need to clarify the notion of the feedback interconnection of two control systems. However, the fact that we do not require the classical semigroup property for each of the interconnected subsystems creates technical difficulties: For example, the determination of the set of sampling times for the composite system is not trivial. In order to guarantee the existence of a set of sampling times for the composite system, we assume that the sampling times of the composite system are the common sampling times of the interconnected subsystems. The details are given in the following definition.

DEFINITION 3.3. *Consider a pair of control systems* $\Sigma_1 = (\mathcal{X}_1, \mathcal{Y}_1, M_{S_2 \times U}, M_D, \tilde{\phi}_1, \pi_1, H_1)$, $\Sigma_2 = (\mathcal{X}_2, \mathcal{Y}_2, M_{S_1 \times U}, M_D, \tilde{\phi}_2, \pi_2, H_2)$ *with outputs* $H_1 : \Re^+ \times \mathcal{X}_1 \times \mathcal{Y}_2 \times U \to S_1 \subseteq Y_1, H_2 : \Re^+ \times \mathcal{X}_2 \times \mathcal{Y}_1 \times U \to S_2 \subseteq \mathcal{Y}_2$ *and the BIC property and for which* $0 \in \mathcal{X}_i$, $i = 1, 2$, *are robust equilibrium points from the inputs* $(v_2, u) \in M_{S_2 \times U}, (v_1, u) \in M_{S_1 \times U}$, *respectively. Suppose that there exists a* unique *pair of a map* $\phi = (\phi_1, \phi_2) : A_\phi \to \mathcal{X}$ *and a set-valued map* $\Re^+ \times \mathcal{X} \times M_U \times M_D \ni (t_0, x_0, u, d) \to \pi(t_0, x_0, u, d) \subseteq [t_0, +\infty)$, *where* $A_\phi \subseteq \Re^+ \times \Re^+ \times \mathcal{X} \times M_U \times M_D$, $\mathcal{X} = \mathcal{X}_1 \times \mathcal{X}_2$, *such that for every* $(t, t_0, x_0, u, d) \in A_\phi$, *with* $t \geq t_0$, $x_0 = (x_{1,0}, x_{2,0}) \in \mathcal{X}_1 \times \mathcal{X}_2$, *it holds that:*

> *"there exists a pair of external inputs* $v_i \subseteq \mathcal{M}(S_i), i = 1, 2$, *with* $v_1(\tau) = H_1(\tau, \phi_1(\tau, t_0, x_0, u, d), v_2(\tau), u(\tau)), v_2(\tau) = H_2(\tau, \phi_2(\tau, t_0, x_0, u, d), v_1(\tau), u(\tau))$ *for all* $\tau \in [t_0, t], (v_i, u) \in M_{S_i \times U}, i = 1, 2, \pi(t_0, x_0, u, d) = \pi_1(t_0, x_{1,0}, (v_2, u), d) \cap \pi_2(t_0, x_{2,0}, (v_1, u), d)$, *and* $\phi_1(\tau, t_0, x_0, u, d) = \tilde{\phi}_1(\tau, t_0, x_{1,0}, (v_2, u), d), \phi_2(\tau, t_0, x_0, u, d) = \tilde{\phi}_2(\tau, t_0, x_{2,0}, (v_1, u), d)$ *for all* $\tau \in [t_0, t]$*."*

Moreover, let $\mathcal{Y}$ *be a normed linear space and* $H : \Re^+ \times \mathcal{X} \times U \to \mathcal{Y}$ *a continuous map that maps bounded sets of* $\Re^+ \times \mathcal{X} \times U$ *into bounded sets of* $\mathcal{Y}$, *with* $H(t, 0, 0) = 0$ *for all* $t \geq 0$, *and suppose that* $\Sigma := (\mathcal{X}, \mathcal{Y}, M_U, M_D, \phi, \pi, H)$ *is a control system with outputs and the BIC property, for which* $0 \in \mathcal{X}$ *is a robust equilibrium point from the input* $u \in M_U$. *Then system* Σ *is said to be the* feedback connection *or the* interconnection *of systems* Σ_1 *and* Σ_2.

It should be emphasized that the feedback interconnection of two systems may create a system which has different qualitative properties from each of the interconnected subsystems. For example, if we interconnect a subsystem described by RFDEs (see Example 2.10) with a hybrid subsystem with impulses at fixed times (see Example 2.12), then the overall system will be a system with both "memory" and impulses (discontinuous systems described by RFDEs—see [49]).

We are now in a position to state our main result for feedback interconnections of control systems. It is a direct consequence of Theorem 3.1, and its proof is omitted.

COROLLARY 3.4. *Suppose that* $\Sigma := (\mathcal{X}, \mathcal{Y}, M_U, M_D, \phi, \pi, H)$ *is the feedback connection of systems* $\Sigma_1 = (\mathcal{X}_1, \mathcal{Y}_1, M_{S_2\times U}, M_D, \tilde{\phi}_1, \pi_1, H_1)$ *and* $\Sigma_2 = (\mathcal{X}_2, \mathcal{Y}_2, M_{S_1\times U}, M_D, \tilde{\phi}_2, \pi_2, H_2)$ *with outputs* $H_1 : \Re^+ \times \mathcal{X}_1 \times \mathcal{Y}_2 \times U \to S_1 \subseteq \mathcal{Y}_1, H_2 : \Re^+ \times \mathcal{X}_2 \times \mathcal{Y}_1 \times U \to S_2 \subseteq \mathcal{Y}_2$. *We assume the following.*

(H1′) *Subsystem* Σ_1 *satisfies the WIOS property from the inputs* $v_2 \in \mathcal{M}(S_2)$ *and* $u \in M_U$. *Particularly, there exist functions* $\sigma_1 \in KL$, $\beta_1, \mu_1, c_1, \delta_1, \delta_1^u, q_1^u \in K^+, \gamma_1, \gamma_1^u, a_1, p_1, p_1^u \in \mathcal{N}$ *such that the following estimate holds for all* $(t_0, x_1, (v_2, u_0), d) \in \Re^+ \times \mathcal{X}_1 \times M_{S_2\times U} \times M_D$ *and* $t \geq t_0$:

$$\begin{aligned}\left\|H_1(t, \tilde{\phi}_1(t, t_0, x_1, (v_2, u), d), v_2(t), u(t))\right\|_{\mathcal{Y}_1} &\leq \sigma_1\left(\beta_1(t_0)\left\|x_1\right\|_{\mathcal{X}_1}, t - t_0\right) \\ &+ \sup_{t_0\leq\tau\leq t} \gamma_1\left(\delta_1(\tau)\left\|v_2(\tau)\right\|_{\mathcal{Y}_2}\right) + \sup_{t_0\leq\tau\leq t} \gamma_1^u\left(\delta_1^u(\tau)\left\|u(\tau)\right\|_{\mathcal{U}}\right),\end{aligned} \tag{3.10}$$

$$\begin{aligned}\beta_1(t)\left\|\tilde{\phi}_1(t, t_0, x_1, (v_2, u), d)\right\|_{\mathcal{X}_1} \leq \max\Bigg\{&\mu_1(t - t_0), c_1(t_0), a_1\left(\left\|x_1\right\|_{\mathcal{X}_1}\right), \\ &\sup_{t_0\leq\tau\leq t} p_1\left(\left\|v_2(\tau)\right\|_{\mathcal{Y}_2}\right), \sup_{t_0\leq\tau\leq t} p_1^u\left(q_1^u(\tau)\left\|u(\tau)\right\|_{\mathcal{U}}\right)\Bigg\}.\end{aligned} \tag{3.11}$$

(H2′) *Subsystem* Σ_2 *satisfies the WIOS property from the inputs* $v_1 \in \mathcal{M}(S_1)$ *and* $u \in M_U$. *Particularly, there exist functions* $\sigma_2 \in KL, \beta_2, \mu_2, c_2, \delta_2, \delta_2^u, q_2^u \in K^+, \gamma_2, \gamma_2^u, a_2, p_2, p_2^u \in \mathcal{N}$ *such that the following estimate holds for all* $(t_0, x_2, (v_1, u_0), d) \in \Re^+ \times \mathcal{X}_2 \times M_{S_1\times U} \times M_D$ *and* $t \geq t_0$:

$$\begin{aligned}&\left\|H_2(t, \tilde{\phi}_2(t, t_0, x_2, (v_1, u), d), v_1(t), u(t))\right\|_{\mathcal{Y}_2} \\ &\leq \sigma_2\left(\beta_2(t_0)\left\|x_2\right\|_{\mathcal{X}_2}, t - t_0\right) + \sup_{t_0\leq\tau\leq t} \gamma_2\left(\delta_2(\tau)\left\|v_1(\tau)\right\|_{\mathcal{Y}_1}\right) + \sup_{t_0\leq\tau\leq t} \gamma_2^u\left(\delta_2^u(\tau)\left\|u(\tau)\right\|_{\mathcal{U}}\right),\end{aligned} \tag{3.12}$$

$$\begin{aligned}\beta_2(t)\left\|\tilde{\phi}_2(t, t_0, x_2, (v_1, u), d)\right\|_{\mathcal{X}_2} \leq \max\Bigg\{&\mu_2(t - t_0), c_2(t_0), a_2\left(\left\|x_2\right\|_{X_2}\right), \\ &\sup_{t_0\leq\tau\leq t} p_2\left(\left\|v_1(\tau)\right\|_{\mathcal{Y}_1}\right), \sup_{t_0\leq\tau\leq t} p_2^u\left(q_2^u(\tau)\left\|u(\tau)\right\|_{\mathcal{U}}\right)\Bigg\}.\end{aligned} \tag{3.13}$$

Moreover, assume that hypothesis (H3) *of Theorem* 3.1 *holds and there exists a function* $a \in \mathcal{N}$ *such that the following inequality holds for all* $(t, x, u, Y_1, Y_2) \in \Re^+ \times \mathcal{X} \times U \times \mathcal{Y}_1 \times \mathcal{Y}_2$, *with* $x = (x_1, x_2) \in \mathcal{X}_1 \times \mathcal{X}_2, Y_1 = H_1(t, x_1, Y_2, u), Y_2 = H_2(t, x_2, Y_1, u)$:

$$\left\|H(t, x, u)\right\|_{\mathcal{Y}} \leq a\left(\left\|Y_1\right\|_{\mathcal{Y}_1} + \gamma_1\left(\delta_1(t)\left\|Y_2\right\|_{\mathcal{Y}_2}\right)\right). \tag{3.14}$$

Then there exists a function $\gamma \in \mathcal{N}$ *such that system* Σ *satisfies the WIOS property from the input* $u \in M_U$, *with gain* $\gamma \in \mathcal{N}$ *and weight* $\delta \in K^+$, *where* $\delta \in K^+$ *is defined by* (3.9). *Moreover, if* $\beta_1, \beta_2, c_1, c_2, \delta_2 \in K^+$ *are bounded, then system* Σ *satisfies the UWIOS property from the input* $u \in M_U$, *with gain* $\gamma \in \mathcal{N}$ *and weight* $\delta \in K^+$.

Remark 3.5.

(a) When $\delta_1(t) \equiv \delta_2(t) \equiv 1$, $H_1 : \Re^+ \times \mathcal{X}_1 \times U \to S_1 \subseteq \mathcal{Y}_1$, and $\gamma_1 \in K_\infty$, then the result of Corollary 3.4 guarantees the WIOS property from the input $u \in M_U$ for the output $H(t, x, u) := (H_1(t, x_1, u), H_2(t, x_2, H_1(t, x_1, u), u))$, i.e., for the output that combines the outputs of each individual subsystem. Moreover, if in addition the functions $\delta_i^u(t)$, $q_i^u(t)$ $(i = 1, 2)$ are bounded, then the result of Corollary 3.4 guarantees the IOS from the input $u \in M_U$ for the output $H(t, x, u) := (H_1(t, x_1, u), H_2(t, x_2, H_1(t, x_1, u), u))$. Finally,

if in addition the functions $\beta_1, \beta_2, c_1, c_2, \delta_2 \in K^+$ are bounded, then the result of Corollary 3.4 guarantees the UIOS from the input $u \in M_U$ for the output $H(t,x,u) := (H_1(t,x_1,u), H_2(t,x_2,H_1(t,x_1,u),u))$. This particular case coincides with the prior result of the nonlinear ISS small-gain theorem presented in [14] for control systems described by ODEs.

(b) Conditions (3.11) and (3.13) hold automatically, when each one of the subsystems Σ_1 and Σ_2 satisfy the WISS property.

(c) If, instead of hypothesis (3.14), there exists a function $a \in \mathcal{N}$ such that $\|H(t,x,u)\|_{\mathcal{Y}} \leq a\left(\|Y_2\|_{\mathcal{Y}_2} + \gamma_2\left(\delta_2(t)\|Y_1\|_{\mathcal{Y}_1}\right)\right)$ holds for all $(t,x,u,Y_1,Y_2) \in \Re^+ \times \mathcal{X} \times U \times \mathcal{Y}_1 \times \mathcal{Y}_2$, with $x = (x_1,x_2) \in \mathcal{X}_1 \times \mathcal{X}_2$, $Y_1 = H_1(t,x_1,Y_2,u)$, $Y_2 = H_2(t,x_2,Y_1,u)$, then indices 1 and 2 must be changed in hypothesis (H3). Furthermore, in this case system Σ satisfies the UWIOS property from the input $u \in M_U$, with gain $\gamma \in \mathcal{N}$ and weight $\delta \in K^+$, if functions $\beta_1, \beta_2, c_1, c_2, \delta_1 \in K^+$ are bounded.

Proof of Theorem 3.1. The proof consists of three steps:

Step 1. We show that Σ is RFC from the input $u \in M_U$.

Step 2. Let $\tilde{\varphi}(s) := s + \frac{1}{2}\rho(s)$, where $\rho \in K_\infty$ is the function involved in hypothesis (H3). We show that properties P1 and P2 of Lemma 2.16 hold for system Σ with $V = V_1$ or $V = \tilde{\varphi}\left(\gamma_1\left(\delta_1(t)V_2\right)\right)$, for appropriate $\tilde{\gamma} \in \mathcal{N}$ and $\delta \in K^+$ as defined by (3.9). Moreover, if $\beta_1, \beta_2 \in K^+$ are bounded, we show that properties P1 and P2 of Lemma 2.17 hold for system Σ with $V = V_1$ or $V = \tilde{\varphi}\left(\gamma_1\left(\delta_1(t)V_2\right)\right)$, for appropriate $\tilde{\gamma} \in \mathcal{N}$ and $\delta \in K^+$ as defined by (3.9).

Step 3. We show that property P3 of Lemma 2.16 holds for system Σ with $V = V_1$ or $V = \tilde{\varphi}\left(\gamma_1\left(\delta_1(t)V_2\right)\right)$, for appropriate $\tilde{\gamma} \in \mathcal{N}$ and $\delta \in K^+$ as defined by (3.9). Moreover, if $\beta_1, \beta_2, c_1, c_2, \delta_2 \in K^+$ are bounded, we show that property P3 of Lemma 2.17 holds for system Σ with $V = V_1$ or $V = \tilde{\varphi}\left(\gamma_1\left(\delta_1(t)V_2\right)\right)$, for appropriate $\tilde{\gamma} \in \mathcal{N}$ and $\delta \in K^+$ as defined by (3.9).

It then follows from Lemma 2.16 that there exist functions $\sigma \in KL$ and $\beta \in K^+$ such that the following estimate holds for all $u \in M_U$, $(t_0,x_0,d) \in \Re^+ \times \mathcal{X} \times M_D$, and $t \geq t_0$:

$$V_1(t,\phi(t,t_0,x_0,u,d),u(t)) \leq \sigma\left(\beta(t_0)\|x_0\|_{\mathcal{X}}, t-t_0\right) + \sup_{t_0 \leq \tau \leq t} \gamma\left(\delta(\tau)\|u(\tau)\|_{\mathcal{U}}\right), \tag{3.15a}$$

$$\begin{aligned} &\tilde{\varphi}\left(\gamma_1\left(\delta_1(t)V_2(t,\phi(t,t_0,x_0,u,d),u(t))\right)\right) \\ &\quad \leq \sigma\left(\beta(t_0)\|x_0\|_{\mathcal{X}}, t-t_0\right) + \sup_{t_0 \leq \tau \leq t} \gamma\left(\delta(\tau)\|u(\tau)\|_{\mathcal{U}}\right). \end{aligned} \tag{3.15b}$$

Moreover, if $\beta_1, \beta_2, c_1, c_2, \delta_2 \in K^+$ are bounded, it follows from Lemma 2.17 that estimates (3.15a)–(3.15b) hold with $\beta(t) \equiv 1$.

Thus, using (3.7) and the fact that $\tilde{\varphi}(s) \geq s$ for all $s \geq 0$, we conclude that Σ satisfies the WIOS property from the input $u \in M_U$, with gain $\gamma(s) := a\left(4\tilde{\gamma}(s)\right) \in \mathcal{N}$ and weight $\delta \in K^+$. Moreover, if $\beta_1, \beta_2, c_1, c_2, \delta_2 \in K^+$ are bounded, we conclude that Σ satisfies the UWIOS property from the input $u \in M_U$, with gain $\gamma(s) := a\left(4\tilde{\gamma}(s)\right) \in \mathcal{N}$ and weight $\delta \in K^+$.

Step 1. Let arbitrary $(t,t_0,x_0,u,d) \in A_\phi$, with $t \geq t_0$, $x_0 \in \mathcal{X}$, and let $t_{\max} \in (t_0, +\infty]$ the maximal existence time of the transition map ϕ of $\Sigma := (\mathcal{X}, \mathcal{Y}, M_U, M_D, \phi, \pi, H)$ that corresponds to $(t_0,x_0,u,d) \in \Re^+ \times \mathcal{X} \times M_U \times M_D$. Notice that, by virtue of the BIC property, if $t_{\max} < +\infty$, then for every $M > 0$ there exists $t \in [t_0, t_{\max})$, with $\|\phi(t,t_0,x_0,u,d)\|_{\mathcal{X}} > M$. We define $V_1(\tau) = V_1(\tau,\phi(\tau,t_0,x_0,u,d),u(\tau))$, $L_1(\tau) = L_1(\tau,\phi(\tau,t_0,x_0,u,d))$ and $V_2(\tau) = V_2(\tau,\phi(\tau,t_0,x_0,u,d),u(\tau))$, $L_2(\tau) = L_2(\tau,\phi(\tau,t_0,x_0,u,d))$ for all $\tau \in [t_0,t]$.

The previous definitions in conjunction with (3.1), (3.2), (3.3), (3.4) imply the following inequalities for all $t \in [t_0, t_{\max})$:

$$V_1(t) \leq \sigma_1\left(\beta_1(t_0)L_1(t_0), t-t_0\right) + \sup_{t_0\leq\tau\leq t} \gamma_1\left(\delta_1(\tau)V_2(\tau)\right) + \sup_{t_0\leq\tau\leq t} \gamma_1^u\left(\delta_1^u(\tau)\left\|u(\tau)\right\|_{\mathcal{U}}\right), \tag{3.16}$$

$$\begin{aligned}\beta_1(t)L_1(t) \leq \max\Bigg\{&\mu_1(t-t_0), c_1(t_0), a_1\left(\left\|x_0\right\|_{\mathcal{X}}\right), \sup_{t_0\leq\tau\leq t} p_1\left(V_2(\tau)\right), \\ &\sup_{t_0\leq\tau\leq t} p_1^u\left(q_1^u(\tau)\left\|u(\tau)\right\|_{\mathcal{U}}\right)\Bigg\},\end{aligned} \tag{3.17}$$

$$\begin{aligned}V_2(t) \leq{}& \sigma_2\left(\beta_2(t_0)L_2(t_0), t-t_0\right) + \sup_{t_0\leq\tau\leq t} \gamma_2\left(\delta_2(\tau)V_1(\tau)\right) \\ &+ \sup_{t_0\leq\tau\leq t} \gamma_2^u\left(\delta_2^u(\tau)\left\|u(\tau)\right\|_{\mathcal{U}}\right),\end{aligned} \tag{3.18}$$

$$\begin{aligned}\beta_2(t)L_2(t) \leq \max\Bigg\{&\mu_2(t-t_0), c_2(t_0), a_2\left(\left\|x_0\right\|_{\mathcal{X}}\right), \sup_{t_0\leq\tau\leq t} p_2\left(V_1(\tau)\right), \\ &\sup_{t_0\leq\tau\leq t} p_2^u\left(q_2^u(\tau)\left\|u(\tau)\right\|_{\mathcal{U}}\right)\Bigg\}.\end{aligned} \tag{3.19}$$

Let $\rho \in K_\infty$ the function involved in hypothesis (H3), and define $\kappa(s) := s + \rho^{-1}(s)$, $\varphi(s) := s + \rho(s)$. Using the inequality $r + s \leq \max\{\kappa(r); \varphi(s)\}$ (which holds for all $r, s \geq 0$) as well as the equality $g_2(s) = \varphi\left(\gamma_2(s)\right)$, we obtain from (3.18) for all $t \in [t_0, t_{\max})$:

$$\begin{aligned}V_2(t) \leq \max\Bigg\{&\kappa\left(\sigma_2\left(\beta_2(t_0)L_2(t_0), t-t_0\right) + \sup_{t_0\leq\tau\leq t} \gamma_2^u\left(\delta_2^u(\tau)\left\|u(\tau)\right\|_{\mathcal{U}}\right)\right); \\ &\sup_{t_0\leq\tau\leq t} g_2\left(\delta_2(\tau)V_1(\tau)\right)\Bigg\}.\end{aligned} \tag{3.20}$$

Notice that inequality (3.6) implies that $\gamma_1\left(\delta_1(t)g_2\left(\delta_2(\tau)s\right)\right) \leq \varphi^{-1}(s)\ \forall t, s \geq 0$ and $\tau \in [0, t]$. Thus (3.20) in conjunction with (3.5) and the previous observation implies the following estimate which holds for all $t \in [t_0, t_{\max})$:

$$\begin{aligned}\gamma_1\left(\delta_1(t)V_2(t)\right) \leq \max\Bigg\{&\gamma_1\Bigg(M\kappa\Bigg(\sigma_2\left(\beta_2(t_0)L_2(t_0), t-t_0\right) \\ &+ \sup_{t_0\leq\tau\leq t} \gamma_2^u\left(\delta_2^u(\tau)\left\|u(\tau)\right\|_{\mathcal{U}}\right)\Bigg)\Bigg); \varphi^{-1}\left(\sup_{t_0\leq\tau\leq t} V_1(\tau)\right)\Bigg\}.\end{aligned} \tag{3.21}$$

Combining estimate (3.16) with (3.21), we obtain

$$\begin{aligned}\sup_{t_0\leq\tau\leq t} V_1(\tau) \leq{}& \sigma_1\left(\beta_1(t_0)L_1(t_0), 0\right) + \sup_{t_0\leq\tau\leq t} \gamma_1^u\left(\delta_1^u(\tau)\left\|u(\tau)\right\|_{\mathcal{U}}\right) \\ &+ \max\Bigg\{\gamma_1\Bigg(M\kappa\Bigg(\sigma_2\left(\beta_2(t_0)L_2(t_0), 0\right) + \sup_{t_0\leq\tau\leq t} \gamma_2^u\left(\delta_2^u(\tau)\left\|u(\tau)\right\|_{\mathcal{U}}\right)\Bigg)\Bigg); \\ &\varphi^{-1}\left(\sup_{t_0\leq\tau\leq t} V_1(\tau)\right)\Bigg\}.\end{aligned} \tag{3.22}$$

Distinguishing the cases $\gamma_1(M\kappa(\sigma_2(\beta_2(t_0)L_2(t_0), 0) + \sup_{t_0\leq\tau\leq t} \gamma_2^u(\delta_2^u(\tau)\|u(\tau)\|_{\mathcal{U}}))) \geq \varphi^{-1}(\sup_{t_0\leq\tau\leq t} V_1(\tau))$, $\gamma_1(M\kappa(\sigma_2(\beta_2(t_0)L_2(t_0), 0) + \sup_{t_0\leq\tau\leq t} \gamma_2^u(\delta_2^u(\tau)\|u(\tau)\|_{\mathcal{U}}))) \leq \varphi^{-1}(\sup_{t_0\leq\tau\leq t} V_1(\tau))$, using the identity $s - \varphi^{-1}(s) = \kappa^{-1}(s)$ and the fact that $\kappa(s) \geq$

s in conjunction with (3.22) and (3.8) (which implies $L_i(t_0) \leq b\left(\|x_0\|_{\mathcal{X}}\right)$, $i = 1, 2$) gives the following estimate which holds for all $t \in [t_0, t_{\max})$:

$$\sup_{t_0 \leq \tau \leq t} V_1(\tau) \leq \max\left\{\kappa\left(\sigma_1\left(\beta_1(t_0) b\left(\|x_0\|_{\mathcal{X}}\right), 0\right) + \sup_{t_0 \leq \tau \leq t} \gamma_1^u\left(\delta_1^u(\tau)\|u(\tau)\|_{\mathcal{U}}\right)\right); W\right\} \tag{3.23a}$$

where

$$\begin{aligned} W := {} & \sigma_1\left(\beta_1(t_0) b\left(\|x_0\|_{\mathcal{X}}\right), 0\right) + \sup_{t_0 \leq \tau \leq t} \gamma_1^u\left(\delta_1^u(\tau)\|u(\tau)\|_{\mathcal{U}}\right) \\ & + \gamma_1\left(M\kappa\left(\sigma_2\left(\beta_2(t_0) b\left(\|x_0\|_{\mathcal{X}}\right), 0\right) + \sup_{t_0 \leq \tau \leq t} \gamma_2^u\left(\delta_2^u(\tau)\|u(\tau)\|_{\mathcal{U}}\right)\right)\right) \end{aligned} \tag{3.23b}$$

We show next that Σ is RFC from the input $u \in M_U$ by contradiction. Suppose that $t_{\max} < +\infty$. Then by virtue of the BIC property for every $M > 0$ there exists $t \in [t_0, t_{\max})$ with $\|\phi(t, t_0, x_0, u, d)\|_{\mathcal{X}} > M$. On the other hand, estimate (3.23a) in conjunction with the hypothesis $t_{\max} < +\infty$ shows that there exists $M_1 \geq 0$ such that $\sup_{t_0 \leq \tau < t_{\max}} V_1(\tau) \leq M_1$. The fact that $V_1(t)$ is bounded in conjunction with estimates (3.18) and (3.19) implies that there exist constants $M_2, M_3 \geq 0$ such that $\sup_{t_0 \leq \tau < t_{\max}} V_2(\tau) \leq M_2$ and $\sup_{t_0 \leq \tau < t_{\max}} L_2(\tau) \leq M_3$. Finally, the fact that $V_2(t)$ is bounded in conjunction with estimate (3.17) implies that there exists a constant $M_4 \geq 0$ such that $\sup_{t_0 \leq \tau < t_{\max}} L_1(\tau) \leq M_4$. It follows from (3.8) and inequality $\mu(t)\|\phi(t, t_0, x_0, u, d)\|_{\mathcal{X}} \leq b\left(L_1(t) + L_2(t)\right)$ that the transition map of Σ, i.e., $\phi(t, t_0, x_0, u, d)$, is bounded on $[t_0, t_{\max})$, and this contradicts the requirement that for every $M > 0$ there exists $t \in [t_0, t_{\max})$ with $\|\phi(t, t_0, x_0, u, d)\|_{\mathcal{X}} > M$. Hence, we must have $t_{\max} = +\infty$.

Let arbitrary $R \geq 0, T \geq 0$. For every $u \in M(B_U[0, R]) \cap \mathcal{M}_U, s \in [0, T], \|x_0\|_{\mathcal{X}} \leq R, t_0 \in [0, T], d \in M_D$ estimate (3.23a) shows that there exists $M_1(T, R) \geq 0$ such that $V_1(t_0 + s) \leq M_1(T, R)$ for all $s \in [0, T]$. The previous observation in conjunction with estimates (3.18), (3.19), and (3.8) (which gives $L_i(t_0) \leq b\left(\|x_0\|_X\right)$, $i = 1, 2$) implies that there exist $M_2(T, R), M_3(T, R) \geq 0$ such that for every $u \in \mathcal{M}(B_U[0, R]) \cap M_U, s \in [0, T], \|x_0\|_{\mathcal{X}} \leq R, t_0 \in [0, T], d \in M_D$ we have $V_2(t_0 + s) \leq M_2(T, R)$ and $L_2(t_0 + s) \leq M_3(T, R)$ for all $s \in [0, T]$. Finally, inequality $V_2(t_0 + s) \leq M_2(T, R)$ in conjunction with estimate (3.17) implies that there exists a constant $M_4(T, R) \geq 0$ such that for every $u \in \mathcal{M}(B_U[0, R]) \cap M_U, s \in [0, T], \|x_0\|_{\mathcal{X}} \leq R, t_0 \in [0, T], d \in M_D$ we have $L_1(t_0 + s) \leq M_4(T, R)$ for all $s \in [0, T]$. It follows from (3.8) and inequality $\mu(t)\|\phi(t, t_0, x_0, u, d)\|_{\mathcal{X}} \leq b\left(L_1(t) + L_2(t)\right)$ that for every $u \in \mathcal{M}(B_U[0, R]) \cap M_U, s \in [0, T], \|x_0\|_{\mathcal{X}} \leq R, t_0 \in [0, T], d \in M_D$ the transition map of Σ, i.e., $\phi(t, t_0, x_0, u, d)$, satisfies $\|\phi(t, t_0, x_0, u, d)\|_{\mathcal{X}} \leq \frac{b(M_3(T,R) + M_4(T,R))}{\min\{\mu(t): t \in [0, 2T]\}} < +\infty$, and this according to Definition 2.2 implies that Σ is RFC from the input $u \in M_U$.

Step 2. Using (3.23a) in conjunction with the inequality $q(r + s) \leq q\left(\kappa(r)\right) + q\left(\varphi(s)\right)$ (which holds for all $r, s \geq 0$ and $q \in \mathcal{N}$) gives the following estimate, which holds for all $t \geq t_0$:

$$\begin{aligned} V_1(t) \leq {} & \kappa\left(\kappa\left(\sigma_1\left(\beta_1(t_0) b\left(\|x_0\|_{\mathcal{X}}\right), 0\right)\right)\right) + \gamma_1\left(M\kappa\left(\kappa\left(\sigma_2\left(\beta_2(t_0) b\left(\|x_0\|_{\mathcal{X}}\right), 0\right)\right)\right)\right) \\ & + \sup_{t_0 \leq \tau \leq t} \kappa\left(\varphi\left(\gamma_1^u\left(\delta_1^u(\tau)\|u(\tau)\|_{\mathcal{U}}\right)\right)\right) + \sup_{t_0 \leq \tau \leq t} \gamma_1\left(M\kappa\left(\varphi\left(\gamma_2^u\left(\delta_2^u(\tau)\|u(\tau)\|_{\mathcal{U}}\right)\right)\right)\right). \end{aligned} \tag{3.24}$$

Moreover, combining estimates (3.21) and (3.23a) and using the equalities $\varphi^{-1}\left(\kappa(s)\right) = \rho(s)$ and $\varphi(s) := s + \rho\left(s\right)$ as well as the inequalities $\varphi^{-1}(s) \leq s$ and (3.8) (which gives

$L_i(t_0) \leq b(\|x_0\|_{\mathcal{X}})$, $i = 1, 2)$ gives the following estimate, which holds for all $t \geq t_0$:

$$\begin{aligned}\gamma_1(\delta_1(t)V_2(t)) \leq \gamma_1\left(M\kappa\left(\sigma_2(\beta_2(t_0)b(\|x_0\|_{\mathcal{X}}),0) + \sup_{t_0\leq\tau\leq t}\gamma_2^u(\delta_2^u(\tau)\|u(\tau)\|_{\mathcal{U}})\right)\right)\\ + \varphi\left(\sigma_1(\beta_1(t_0)b(\|x_0\|_{\mathcal{X}}),0) + \sup_{t_0\leq\tau\leq t}\gamma_1^u(\delta_1^u(\tau)\|u(\tau)\|_{\mathcal{U}})\right).\end{aligned} \tag{3.25}$$

Using (3.25) in conjunction with the inequality $q(r+s) \leq q(\kappa(r)) + q(\varphi(s))$ (which holds for all $r, s \geq 0$ and $q \in \mathcal{N}$) gives the following estimate, which holds for all $t \geq t_0$:

$$\begin{aligned}\gamma_1(\delta_1(t)V_2(t)) \leq \gamma_1(&M\kappa(\kappa(\sigma_2(\beta_2(t_0)b(\|x_0\|_{\mathcal{X}}),0))))\\ &+ \sup_{t_0\leq\tau\leq t}\gamma_1(M\kappa(\varphi(\gamma_2^u(\delta_2^u(\tau)\|u(\tau)\|_{\mathcal{U}}))))\\ &+ \varphi(\kappa(\sigma_1(\beta_1(t_0)b(\|x_0\|_{\mathcal{X}}),0)))\\ &+ \sup_{t_0\leq\tau\leq t}\varphi(\varphi(\gamma_1^u(\delta_1^u(\tau)\|u(\tau)\|_{\mathcal{U}}))).\end{aligned} \tag{3.26}$$

Let $\tilde{\varphi}(s) := s + \frac{1}{2}\rho(s)$. Using (3.26) in conjunction with the inequality $q(r+s) \leq q(\kappa(r)) + q(\varphi(s))$ (which holds for all $r, s \geq 0$ and $q \in \mathcal{N}$), we obtain the following estimate, which holds for all $t \geq t_0$:

$$\begin{aligned}\tilde{\varphi}(\gamma_1(\delta_1(t)V_2(t))) \leq \tilde{\varphi}(&\kappa(\gamma_1(M\kappa(\kappa(\sigma_2(\beta_2(t_0)b(\|x_0\|_{\mathcal{X}}),0))))\\ &+ \varphi(\kappa(\sigma_1(\beta_1(t_0)b(\|x_0\|_{\mathcal{X}}),0)))))\\ &+ \sup_{t_0\leq\tau\leq t}\tilde{\varphi}(\varphi(\varphi(\gamma_1^u(\delta_1^u(\tau)\|u(\tau)\|_{\mathcal{U}}))))\\ &+ \gamma_1(M\kappa(\varphi(\gamma_2^u(\delta_2^u(\tau)\|u(\tau)\|_{\mathcal{U}})))))).\end{aligned} \tag{3.27}$$

Estimates (3.24), (3.27) show that properties P1 and P2 of Lemma 2.16 hold for system Σ with $V = V_1$ or $V = \tilde{\varphi}(\gamma_1(\delta_1(t)V_2))$, for appropriate $\tilde{\gamma} \in \mathcal{N}$ and $\delta \in K^+$ as defined by (3.9). Moreover, if $\beta_1, \beta_2 \in K^+$ are bounded, then estimates (3.24), (3.27) show that properties P1 and P2 of Lemma 2.17 hold for system Σ with $V = V_1$ or $V = \tilde{\varphi}(\gamma_1(\delta_1(t)V_2))$, for appropriate $\tilde{\gamma} \in \mathcal{N}$ and $\delta \in K^+$ as defined by (3.9). Particularly, $\tilde{\gamma} \in \mathcal{N}$ satisfies

$$\begin{aligned}&\tilde{\gamma}(s) \geq \tilde{\varphi}(\varphi(\varphi(\gamma_1^u(s))) + \gamma_1(M\kappa(\varphi(\gamma_2^u(s))))))\\ &\text{and } \tilde{\gamma}(s) \geq \kappa(\varphi(\gamma_1^u(s))) + \gamma_1(M\kappa(\varphi(\gamma_2^u(s)))) \text{ for all } s \geq 0.\end{aligned} \tag{3.28}$$

Step 3. Let $\tilde{\varphi}(s) := s + \frac{1}{2}\rho(s)$, $\tilde{\kappa}(s) := s + \rho^{-1}(2s)$. Exploiting estimates (3.16), (3.21) in conjunction with the inequality $r + s \leq \max\{\tilde{\kappa}(r); \tilde{\varphi}(s)\}$ (which holds for all $r, s \geq 0$), we obtain:

$$\begin{aligned}V_1(t) \leq \max\Bigg\{&\tilde{\kappa}\left(\sigma_1(\beta_1(t_0)L_1(t_0), t-t_0) + \sup_{t_0\leq\tau\leq t}\gamma_1^u(\delta_1^u(\tau)\|u(\tau)\|_{\mathcal{U}})\right);\\ &\sup_{t_0\leq\tau\leq t}\tilde{\varphi}(\gamma_1(\delta_1(\tau)V_2(\tau)))\Bigg\},\end{aligned} \tag{3.29}$$

$$\begin{aligned}\tilde{\varphi}(\gamma_1(\delta_1(t)V_2(t))) \leq \max\Bigg\{&\tilde{\varphi}\Bigg(\gamma_1(M\kappa(\sigma_2(\beta_2(t_0)L_2(t_0), t-t_0)\\ &+ \sup_{t_0\leq\tau\leq t}\gamma_2^u(\delta_2^u(\tau)\|u(\tau)\|_{\mathcal{U}})))); \tilde{\varphi}\left(\varphi^{-1}\left(\sup_{t_0\leq\tau\leq t}V_1(\tau)\right)\right)\Bigg\}.\end{aligned} \tag{3.30}$$

Let arbitrary $\xi \in \pi(t_0, x_0, u, d)$ and $t \geq \xi$. Estimates (3.29), (3.30) in conjunction with estimates (3.17), (3.19) and the weak semigroup property imply

$$V_1(t) \leq \max \left\{ \begin{array}{l} \tilde{\kappa}\left(\kappa\left(\sigma_1\left(a_1\left(\|x_0\|_{\mathcal{X}}\right) + c_1(t_0) + \mu_1(\xi - t_0), t - \xi\right)\right)\right), \\ \sup\limits_{t_0 \leq \tau \leq \xi} \tilde{\kappa}\left(\kappa\left(\sigma_1\left(p_1^u\left(q_1^u(\tau)\|u(\tau)\|_{\mathcal{U}}\right), 0\right)\right)\right), \sup\limits_{t_0 \leq \tau \leq \xi} \tilde{\kappa}\left(\kappa\left(\sigma_1\left(p_1\left(V_2(\tau)\right), t - \xi\right)\right)\right) \\ \sup\limits_{\xi \leq \tau \leq t} \tilde{\varphi}\left(\gamma_1\left(\delta_1(\tau) V_2(\tau)\right)\right), \sup\limits_{\xi \leq \tau \leq t} \tilde{\kappa}\left(\varphi\left(\gamma_1^u\left(\delta_1^u(\tau)\|u(\tau)\|_{\mathcal{U}}\right)\right)\right) \end{array} \right\},$$

(3.31)

$$\tilde{\varphi}\left(\gamma_1\left(\delta_1(t) V_2(t)\right)\right) \leq \max \left\{ \begin{array}{l} \tilde{\varphi}\left(\gamma_1\left(M\kappa\left(\kappa\left(\sigma_2\left(a_2\left(\|x_0\|_{\mathcal{X}}\right) + c_2(t_0) + \mu_2(\xi - t_0), t - \xi\right)\right)\right)\right)\right), \\ \sup\limits_{\xi \leq \tau \leq t} \tilde{\varphi}\left(\gamma_1\left(M\kappa\left(\varphi\left(\gamma_2^u\left(\delta_2^u(\tau)\|u(\tau)\|_{\mathcal{U}}\right)\right)\right)\right)\right), \\ \sup\limits_{t_0 \leq \tau \leq \xi} \tilde{\varphi}\left(\gamma_1\left(M\kappa\left(\kappa\left(\sigma_2\left(p_2^u\left(q_2^u(\tau)\|u(\tau)\|_{\mathcal{U}}\right), 0\right)\right)\right)\right)\right), \\ \tilde{\varphi}\left(\varphi^{-1}\left(\sup\limits_{\xi \leq \tau \leq t} V_1(\tau)\right)\right), \sup\limits_{t_0 \leq \tau \leq \xi} \tilde{\varphi}\left(\gamma_1\left(M\kappa\left(\kappa\left(\sigma_2\left(p_2\left(V_1(\tau)\right), t - \xi\right)\right)\right)\right)\right) \end{array} \right\}.$$

(3.32)

Estimate (3.32) combined with estimate (3.24) gives

$$\tilde{\varphi}\left(\gamma_1\left(\delta_1(t) V_2(t)\right)\right) \leq \max \left\{ \begin{array}{l} \tilde{\varphi}\left(\gamma_1\left(M\kappa\left(\kappa\left(\sigma_2\left(a_2\left(\|x_0\|_{\mathcal{X}}\right) + c_2(t_0) + \mu_2(\xi - t_0) \right.\right.\right.\right.\right. \\ \qquad \left.\left.\left.\left.\left. + p_2(\kappa(A)), t - \xi\right)\right)\right)\right)\right), \\ \sup\limits_{\xi \leq \tau \leq t} \tilde{\varphi}\left(\gamma_1\left(M\kappa\left(\varphi\left(\gamma_2^u\left(\delta_2^u(\tau)\|u(\tau)\|_{\mathcal{U}}\right)\right)\right)\right)\right), \\ \sup\limits_{t_0 \leq \tau \leq \xi} \tilde{\varphi}\left(\gamma_1\left(M\kappa\left(\kappa\left(\sigma_2\left(p_2^u\left(q_2^u(\tau)\|u(\tau)\|_{\mathcal{U}}\right), 0\right)\right)\right)\right)\right), \\ \tilde{\varphi}\left(\varphi^{-1}\left(\sup\limits_{\xi \leq \tau \leq t} V_1(\tau)\right)\right), \\ \sup\limits_{t_0 \leq \tau \leq t} \tilde{\varphi}\left(\gamma_1\left(M\kappa\left(\kappa\left(\sigma_2\left(p_2\left(\varphi\left(B\right)\right), 0\right)\right)\right)\right)\right) \end{array} \right\},$$

(3.33)

where

$$\begin{aligned} A &= \kappa\left(\kappa\left(\sigma_1\left(\beta_1(t_0) b\left(\|x_0\|_{\mathcal{X}}\right), 0\right)\right)\right) + \gamma_1\left(M\kappa\left(\kappa\left(\sigma_2\left(\beta_2(t_0) b\left(\|x_0\|_{\mathcal{X}}\right), 0\right)\right)\right)\right), \\ B &= \kappa\left(\varphi\left(\gamma_1^u\left(\delta_1^u(\tau)\|u(\tau)\|_{\mathcal{U}}\right)\right)\right) + \gamma_1\left(M\kappa\left(\varphi\left(\gamma_2^u\left(\delta_2^u(\tau)\|u(\tau)\|_{\mathcal{U}}\right)\right)\right)\right). \end{aligned}$$

Similarly, estimate (3.18) combined with estimate (3.24) and inequality (3.8) (which implies $L_i(t_0) \leq b\left(\|x_0\|_{\mathcal{X}}\right)$, $i = 1, 2$) gives

$$\begin{aligned} V_2(t) &\leq \sigma_2\left(\beta_2(t_0) b\left(\|x_0\|_{\mathcal{X}}\right), 0\right) + \sup_{t_0 \leq \tau \leq t} \gamma_2^u\left(\delta_2^u(\tau)\|u(\tau)\|_{\mathcal{U}}\right) \\ &+ \gamma_2\left(\tilde{\delta}_2(t)\kappa\left(\kappa\left(\kappa\left(\sigma_1\left(\beta_1(t_0) b\left(\|x_0\|_{\mathcal{X}}\right), 0\right)\right)\right) + \gamma_1\left(M\kappa\left(\kappa\left(\sigma_2\left(\beta_2(t_0) b\left(\|x_0\|_{\mathcal{X}}\right), 0\right)\right)\right)\right)\right)\right) \\ &+ \sup_{t_0 \leq \tau \leq t} \gamma_2\left(\tilde{\delta}_2(t)\varphi\left(\kappa\left(\varphi\left(\gamma_1^u\left(\delta_1^u(\tau)\|u(\tau)\|_{\mathcal{U}}\right)\right)\right) + \gamma_1\left(M\kappa\left(\varphi\left(\gamma_2^u\left(\delta_2^u(\tau)\|u(\tau)\|_{\mathcal{U}}\right)\right)\right)\right)\right)\right), \end{aligned}$$

(3.34)

where

$$\tilde{\delta}_2(t) := \max_{0 \leq \tau \leq t} \delta_2(\tau).$$

Consequently, by combining estimates (3.31) and (3.34) we obtain

$$V_1(t) \leq \max \left\{ \begin{array}{l} \tilde{\kappa}\left(\kappa\left(\sigma_1\left(a_1\left(\|x_0\|_{\mathcal{X}}\right) + c_1(t_0) + \mu_1(\xi - t_0), t - \xi\right)\right)\right), \tilde{\kappa}\left(\kappa\left(\sigma_1\left(p_1\left(\kappa(C)\right), t - \xi\right)\right)\right), \\ \sup\limits_{t_0 \leq \tau \leq \xi} \tilde{\kappa}\left(\kappa\left(\sigma_1\left(p_1^u\left(q_1^u(\tau)\|u(\tau)\|_{\mathcal{U}}\right), 0\right)\right)\right), \sup\limits_{t_0 \leq \tau \leq t} \tilde{\kappa}\left(\kappa\left(\sigma_1\left(p_1\left(\varphi(D)\right), 0\right)\right)\right), \\ \sup\limits_{\xi \leq \tau \leq t} \tilde{\varphi}\left(\gamma_1\left(\delta_1(\tau) V_2(\tau)\right)\right), \sup\limits_{\xi \leq \tau \leq t} \tilde{\kappa}\left(\varphi\left(\gamma_1^u\left(\delta_1^u(\tau)\|u(\tau)\|_{\mathcal{U}}\right)\right)\right), \tilde{\kappa}\left(\kappa\left(\sigma_1\left(p_1\left(E\right), t - \xi\right)\right)\right) \end{array} \right\},$$

(3.35)

where

$$C := \sigma_2\left(\beta_2(t_0) b\left(\|x_0\|_{\mathcal{X}}\right), 0\right) + \gamma_2\Big(\tilde{\delta}_2(\xi)\kappa\left(\kappa\left(\kappa\left(\sigma_1\left(\beta_1(t_0) b\left(\|x_0\|_{\mathcal{X}}\right), 0\right)\right)\right)\right.$$
$$\left. + \gamma_1\ \left(M\kappa\left(\kappa\left(\sigma_2\left(\beta_2(t_0) b\left(\|x_0\|_{\mathcal{X}}\right), 0\right)\right)\right)\right)\right),$$

$$D := \gamma_2^u\left(\delta_2^u(\tau)\|u(\tau)\|_{\mathcal{U}}\right) + \gamma_2\left(\varphi\left(\frac{1}{2}\varphi^2\left(\kappa\left(\varphi\left(\gamma_1^u\left(\delta_1^u(\tau)\|u(\tau)\|_{\mathcal{U}}\right)\right)\right)\right)\right.\right.$$
$$\left.\left. + \gamma_1\ \left(M\kappa\left(\varphi\left(\gamma_2^u\left(\delta_2^u(\tau)\|u(\tau)\|_{\mathcal{U}}\right)\right)\right)\right)\right)\right),$$

$$E := \gamma_2\left(\kappa\left(\frac{1}{2}\tilde{\delta}_2^2(\xi)\right)\right).$$

From (3.33) and (3.35) we conclude that there exist functions $S_1, S_2 \in KL$, continuous functions $M_1, M_2 : (\Re^+)^3 \to \Re^+$, and $\tilde{\gamma} \in \mathcal{N}$ such that the following estimates hold for all $\xi \in \pi(t_0, x_0, u, d)$ and $t \geq \xi$:

$$\tilde{\varphi}\left(\gamma_1\left(\delta_1(t)V_2(t)\right)\right) \leq \max\left\{\begin{array}{l} S_2\left(M_2\left(t_0, \xi - t_0, \|x_0\|_{\mathcal{X}}\right), t - \xi\right), \\ \tilde{\varphi}\left(\varphi^{-1}\left(\sup\limits_{\xi\leq\tau\leq t} V_1(\tau)\right)\right), \sup\limits_{t_0\leq\tau\leq t}\tilde{\gamma}\left(\delta(\tau)\|u(\tau)\|_{\mathcal{U}}\right) \end{array}\right\},$$

(3.36)

$$V_1(t) \leq \max\left\{\begin{array}{l} S_1\left(M_1\left(t_0, \xi - t_0, \|x_0\|_{\mathcal{X}}\right), t - \xi\right), \\ \sup\limits_{\xi\leq\tau\leq t}\tilde{\varphi}\left(\gamma_1\left(\delta_1(\tau)V_2(\tau)\right)\right), \sup\limits_{t_0\leq\tau\leq t}\tilde{\gamma}\left(\delta(\tau)\|u(\tau)\|_{\mathcal{U}}\right) \end{array}\right\}, \quad (3.37)$$

where $\delta \in K^+$ is defined by (3.9). Notice that if $\beta_1, \beta_2, c_1, c_2, \delta_2 \in K^+$ are bounded, then the functions $M_1, M_2 : (\Re^+)^3 \to \Re^+$ are independent of $t_0 \in \Re^+$ (but still depend on $\xi - t_0$). Moreover, the function $\tilde{\gamma} \in \mathcal{N}$ in addition to (3.28) satisfies for all $s \geq 0$:

$$\tilde{\gamma}(s) \geq \max\left\{\tilde{\kappa}\left(\kappa\left(\sigma_1\left(p_1^u(s), 0\right)\right)\right), \tilde{\kappa}\left(\kappa\left(\sigma_1\left(p_1\left(\varphi(D(s))\right), 0\right)\right)\right), \tilde{\kappa}\left(\varphi\left(\gamma_1^u(s)\right)\right)\right\}, \quad (3.38a)$$

$$\tilde{\gamma}(s) \geq \max\left\{\tilde{\varphi}\left(\gamma_1\left(M\kappa\left(\varphi\left(\gamma_2^u(s)\right)\right)\right)\right), \tilde{\varphi}\left(\gamma_1\left(M\kappa\left(\kappa\left(\sigma_2\left(p_2^u(s), 0\right)\right)\right)\right)\right),\right.$$
$$\left.\tilde{\varphi}\left(\gamma_1\left(M\kappa\left(\kappa\left(\sigma_2\left(p_2\left(\varphi\left(B(s)\right)\right), 0\right)\right)\right)\right)\right)\right\}, \quad (3.38b)$$

where $D(s) := \gamma_2^u(s) + \gamma_2\left(\varphi\left(\frac{1}{2}\varphi^2\left(\kappa\left(\varphi\left(\gamma_1^u(s)\right)\right) + \gamma_1\left(M\kappa\left(\varphi\left(\gamma_2^u(s)\right)\right)\right)\right)\right)\right)$ and $B(s) := \kappa\left(\varphi\left(\gamma_1^u(s)\right)\right) + \gamma_1\left(M\kappa\left(\varphi\left(\gamma_2^u(s)\right)\right)\right)$ are functions of class $\mathcal{N}$.

We define:

$$a_1(h, T, R) := \sup\left\{V_1(t_0 + h) - \sup_{t_0\leq\tau\leq t_0+h}\tilde{\gamma}\left(\delta(\tau)\|u(\tau)\|_{\mathcal{U}}\right);\right.$$
$$\left.\|x_0\|_{\mathcal{X}} \leq R, t_0 \in [0, T], d \in M_D, u \in M_U\right\}, \quad (3.39)$$

$$a_2(h, T, R) := \sup\left\{\tilde{\varphi}\left(\gamma_1\left(\delta_1(t_0 + h)V_2(t_0 + h)\right)\right) - \sup_{t_0\leq\tau\leq t_0+h}\tilde{\gamma}\left(\delta(\tau)\|u(\tau)\|_{\mathcal{U}}\right);\right.$$
$$\left.\|x_0\|_{\mathcal{X}} \leq R, t_0 \in [0, T], d \in M_D, u \in M_U\right\}, \quad (3.40)$$

$$l_1 := \limsup_{h\to+\infty} a_1(h, T, R), \quad l_2 := \limsup_{h\to+\infty} a_2(h, T, R). \quad (3.41)$$

By virtue of (3.24) and (3.27), the limits defined in (3.41) exist and are finite. Definition (3.41) implies that, for every $\varepsilon > 0$, $T \geq 0$, and $R \geq 0$, there exists a $\tau := \tau(\varepsilon, T, R) \geq 0$ such that

$$a_1(h, T, R) \leq l_1 + \varepsilon, \quad a_2(h, T, R) \leq l_2 + \varepsilon \quad \forall h \geq \tau. \quad (3.42)$$

By virtue of the weak semigroup property for system Σ, there exists a constant $r > 0$ such that for each $(t_0, x_0, u, d) \in \Re^+ \times \mathcal{X} \times M_U \times M_D$ we have $\pi(t_0, x_0, u, d) \cap [t_0 + \tau, t_0 + \tau + r] \neq \emptyset$. Let $\xi \in \pi(t_0, x_0, u, d) \cap [t_0 + \tau, t_0 + \tau + r]$. Estimates (3.36), (3.37) in conjunction with definitions (3.39), (3.40) and inequalities (3.42) give

$$V_1(t) - \sup_{t_0 \leq \tau \leq t} \tilde{\gamma}\left(\delta(\tau)\left\|u(\tau)\right\|_{\mathcal{U}}\right) \leq \max\left\{S_1\left(M_1\left(t_0, \xi - t_0, \left\|x_0\right\|_{\mathcal{X}}\right), t - \xi\right); l_2 + \varepsilon\right\}, \tag{3.43}$$

$$\begin{aligned}&\tilde{\varphi}\left(\gamma_1\left(\delta_1(t)V_2(t)\right)\right) - \sup_{t_0 \leq \tau \leq t} \tilde{\gamma}\left(\delta(\tau)\left\|u(\tau)\right\|_{\mathcal{U}}\right)\\ &\leq \max\left\{\begin{array}{l} S_2\left(M_2\left(t_0, \xi - t_0, \left\|x_0\right\|_{\mathcal{X}}\right), t - \xi\right),\\ \tilde{\varphi}\left(\varphi^{-1}\left(l_1 + \varepsilon + \sup\limits_{t_0 \leq \tau \leq t} \tilde{\gamma}\left(\delta(\tau)\left\|u(\tau)\right\|_{\mathcal{U}}\right)\right)\right) - \sup\limits_{t_0 \leq \tau \leq t} \tilde{\gamma}\left(\delta(\tau)\left\|u(\tau)\right\|_{\mathcal{U}}\right)\end{array}\right\}.\end{aligned} \tag{3.44}$$

Using the identity $\tilde{\varphi}\left(\varphi^{-1}(s)\right) = s - \frac{1}{2}\rho\left(\varphi^{-1}(s)\right)$ and inequality (3.44), we get

$$\begin{aligned}&\tilde{\varphi}\left(\gamma_1\left(\delta_1(t)V_2(t)\right)\right) - \sup_{t_0 \leq \tau \leq t} \tilde{\gamma}\left(\delta(\tau)\left\|u(\tau)\right\|_{\mathcal{U}}\right)\\ &\qquad \leq \max\left\{S_2\left(M_2\left(t_0, \xi - t_0, \left\|x_0\right\|_{\mathcal{X}}\right), t - \xi\right); l_1 + \varepsilon - \frac{1}{2}\rho\left(\varphi^{-1}\left(l_1\right)\right)\right\}.\end{aligned} \tag{3.45}$$

The properties of the KL functions in conjunction with estimates (3.43), (3.45), the fact that $\xi \in [t_0 + \tau, t_0 + \tau + r]$, and definitions (3.39), (3.40), (3.41) give for all $\varepsilon > 0$:

$$l_1 \leq l_2 + \varepsilon; \quad l_2 \leq l_1 + \varepsilon - \frac{1}{2}\rho\left(\varphi^{-1}\left(l_1\right)\right).$$

From the first inequality we obtain $l_1 \leq l_2$. The second inequality implies $\rho(\varphi^{-1}(l_1)) \leq 2\varepsilon$ for all $\varepsilon > 0$, which directly gives $l_1 = l_2 = 0$.

Definitions (3.39), (3.40), and (3.41) imply that P3 of Lemma 2.16 holds for system Σ with $V = V_1$ or $V = \tilde{\varphi}\left(\gamma_1\left(\delta_1(t)V_2\right)\right)$, for appropriate $\tilde{\gamma} \in \mathcal{N}$ (which satisfies (3.28) and (3.39)) and $\delta \in K^+$ as defined by (3.9).

Notice that if $\beta_1, \beta_2, c_1, c_2, \delta_2 \in K^+$ are bounded, then definitions (3.39), (3.40) are modified as follows:

$$\begin{aligned}a_1(h, R) := \sup\Big\{&V_1(t_0 + h) - \sup_{t_0 \leq \tau \leq t_0 + h} \tilde{\gamma}\left(\delta(\tau)\left\|u(\tau)\right\|_{\mathcal{U}}\right);\\ &\left\|x_0\right\|_{\mathcal{X}} \leq R, t_0 \geq 0, d \in M_D, u \in M_U\Big\},\end{aligned} \tag{3.46}$$

$$\begin{aligned}a_2(h, R) := \sup\Big\{&\varphi\left(\gamma_1\left(\delta_1(t_0 + h)V_2(t_0 + h)\right)\right) - \sup_{t_0 \leq \tau \leq t_0 + h} \tilde{\gamma}\left(\delta(\tau)\left\|u(\tau)\right\|_{\mathcal{U}}\right);\\ &\left\|x_0\right\|_X \leq R, t_0 \geq 0, d \in M_D, u \in M_U\Big\}.\end{aligned} \tag{3.47}$$

Similar arguments as above show that property P3 of Lemma 2.17 holds for system Σ with $V = V_1$ or $V = \tilde{\varphi}\left(\gamma_1\left(\delta_1(t)V_2\right)\right)$, for appropriate $\tilde{\gamma} \in \mathcal{N}$ (which satisfies (3.28) and (3.38)) and $\delta \in K^+$ as defined by (3.9). The proof is complete. □

Remark 3.6. If the functions $\gamma_1^u, p_1^u, \gamma_2^u, p_2^u \in \mathcal{N}$ are all identically zero, then it follows that the gain function $\gamma \in \mathcal{N}$ is identically zero. Indeed, the reader should notice that $\gamma \in \mathcal{N}$ may be selected as $\gamma(s) := a\left(4\tilde{\gamma}(s)\right) \in \mathcal{N}$, where $a \in \mathcal{N}$ is the function involved in hypothesis (H4) and $\tilde{\gamma} \in \mathcal{N}$ is the function that satisfies (3.28), (3.38a)–(3.38b). Moreover, notice that for the input free case Theorem 3.1 and Corollary 3.4 imply (uniform) robust global asymptotic output stability (RGAOS)

for the corresponding system. The following example shows the applicability of this particular remark to systems with impulses at fixed times.

Example 3.7. Consider the following system:

$$\begin{aligned} \dot{z}(t) &= Az(t) + g(x(t)), \\ \dot{x}(t) &= f(x(t)), t \notin \pi, \end{aligned} \tag{3.48a}$$

$$x(\tau_i) = h\left(\lim_{t \to \tau_i^-} x(t)\right), \tag{3.48b}$$

$$z(t) \in \Re^k, x(t) \in \Re^n,$$

where $A \in \Re^{k \times k}$ is a Hurwitz matrix, $\pi = \{\tau_i\}_{i=0}^{\infty}$ is a partition of $\Re^+$ with diameter $r > 0$, $f : \Re^n \to \Re^n$, $g : \Re^n \to \Re^k$, $h : \Re^n \to \Re^n$ are continuous vector fields, $f(x)$ being locally Lipschitz with respect to $x \in \Re^n$, with $f(0) = 0$, $g(0) = 0$, $h(0) = 0$. Notice that subsystem (3.48a) is a system described by ODEs which satisfies hypotheses (A1)–(A3) of Example 2.8. Hence, subsystem (3.48a) satisfies the BIC property, and $0 \in \Re^k$ is a robust equilibrium point from the input x. Moreover, subsystem (3.48b) is a hybrid system with impulses at fixed times, which satisfies hypotheses (Q1)–(Q4) of Example 2.12. Hence, subsystem (3.48b) satisfies the BIC property, and $0 \in \Re^n$ is a robust equilibrium point (from the zero input). We remark that both subsystems (3.48a)–(3.48b) satisfy the classical semigroup property, and consequently the composite system (3.48) can be regarded as the feedback interconnection of subsystems (3.48a)–(3.48b).

Since $A \in \Re^{k \times k}$ is Hurwitz, it follows that subsystem (3.48a) satisfies the UISS property from the input x. Moreover, if there exists a C^1 positive definite and radially unbounded function $V : \Re^n \to \Re^+$ and constants $c_1, c_2 \in \Re$, with $c_2 \neq 0$, $\mu, \lambda > 0$, such that

$$\nabla V(x) f(x) \leq -c_1 V(x) \quad \forall x \in \Re^n, \tag{3.49a}$$

$$V(h(x)) \leq \exp(-c_2) V(x) \quad \forall x \in \Re^n, \tag{3.49b}$$

$$-c_2 card\,(\pi \cap [s, s+t)) \leq \mu + (c_1 - \lambda) t \forall s, t \in \Re^+. \tag{3.49c}$$

where $card(S)$ denotes the cardinal number of the set S, then Theorem 1 in [7] implies that $0 \in \Re^n$ is uniformly globally asymptotically stable for subsystem (3.48b). Taking into account Remarks 3.2(b) and 3.6, we conclude that $0 \in \Re^k \times \Re^n$ is uniformly globally asymptotically stable for the composite system (3.48) under the hypotheses stated above.

4. Application to partial-state sampled-data control. In this section we present applications of the small-gain results (Theorem 3.1 and Corollary 3.4) to partial-state sampled-data control problems. It should be emphasized that sampled-data control systems cannot be handled with small-gain results that have appeared so far in the literature, since sampled-data control systems do not satisfy the classical semigroup property (see Example 2.11).

Consider the following control system described by ODEs:

$$\begin{aligned} \dot{z} &= f(t, d, z, x, u), \\ & z \in \Re^k\,,\ d \in D\,,\ u \in U\,,\ t \geq 0, \end{aligned} \tag{4.1a}$$

$$\begin{aligned} \dot{x} &= Ax + Bv + Bg(t, d, z, u), \\ & x \in \Re^n\,,\ v \in \Re\,,\ d \in D\,,\ u \in U\,,\ t \geq 0, \end{aligned} \tag{4.1b}$$

where (A, B) is a controllable pair of matrices, $D \subset \Re^l$ is a compact set, $U \subseteq \Re^p$ is nonempty, with $0 \in U$, and the mappings $f : \Re^+ \times D \times \Re^k \times \Re^n \times U \to \Re^k$, $g : \Re^+ \times D \times \Re^k \times U \to \Re$ are continuous, locally Lipschitz in (z, x), uniformly in $d \in D$, with $f(t, d, 0, 0, 0) = 0$, $g(t, d, 0, 0) = 0$ for all $(t, d) \in \Re^+ \times D$. The problem we consider is the (W)ISS stabilization problem for (4.1) with sampled-data feedback applied with zero order hold and depending only on $x \in \Re^n$; i.e., we want to find a function $k : \Re^n \to \Re$ with $k(0) = 0$ and a constant $r > 0$ such that system (4.1a) with

$$\begin{aligned} &\dot{x}(t) = Ax(t) + Bk(x(\tau_i)) + Bg(t, d(t), z(t), u(t)), t \in [\tau_i, \tau_{i+1}), \\ &\tau_{i+1} = \tau_i + \exp(-w(\tau_i))\, r, \quad w(t) \in \Re^+ \end{aligned} \tag{4.2}$$

satisfies the WISS property from the inputs (u, w). Notice that the input w has been introduced in order to quantify the uncertainty in sampling times; i.e., we have to guarantee stability properties for the closed-loop system (4.1a)–(4.2) for all sampling schedules of diameter less than or equal to $r > 0$. To this purpose we make the following assumptions.

(A1) System (4.1a) satisfies the WISS property from the inputs x and u. Specifically, there exist functions $\sigma \in KL$, $\beta, \delta_1^u \in K^+$, γ_1, $\gamma_1^u \in \mathcal{N}$ such that for all $(t_0, z_0, d, x, u) \in \Re^+ \times \Re^k \times \mathcal{L}^\infty_{loc}(\Re^+; D) \times \mathcal{L}^\infty_{loc}(\Re^+; \Re^n) \times \mathcal{L}^\infty_{loc}(\Re^+; U)$ the solution of (4.1) with initial condition $z(t_0) = z_0$ corresponding to inputs $(d, x, u) \in \mathcal{L}^\infty_{loc}(\Re^+; D) \times \mathcal{L}^\infty_{loc}(\Re^+; \Re^n) \times \mathcal{L}^\infty_{loc}(\Re^+; U)$ satisfies the following estimate for all $t \geq t_0$:

$$|z(t)| \leq \sigma\left(\beta(t_0)\,|z_0|, t - t_0\right) + \sup_{t_0 \leq \tau \leq t} \gamma_1\left(|x(\tau)|\right) + \sup_{t_0 \leq \tau \leq t} \gamma_1^u\left(\delta_1^u(\tau)\,|u(\tau)|\right). \tag{4.3}$$

(A2) There exist functions $\delta_2^u \in K^+$, γ_2, $\gamma_2^u \in \mathcal{N}$ such that the following inequality holds for all $(t, z, d, u) \in \Re^+ \times \Re^k \times D \times U$:

$$|g(t, d, z, u)| \leq \gamma_2(|z|) + \gamma_2^u\left(\delta_2^u(t)\,|u|\right). \tag{4.4}$$

(A3) There exist a function $\rho \in K_\infty$and a constant $R \geq 1$ such that

$$\gamma_1\left(R^{-1}\gamma_2(s) + \rho\left(R^{-1}\gamma_2(s)\right)\right) + \rho\left(\gamma_1\left(R^{-1}\gamma_2(s) + \rho\left(R^{-1}\gamma_2(s)\right)\right)\right) \leq s \ \forall s \geq 0. \tag{4.5}$$

For example, hypothesis (A3) holds if $\gamma_i(s) = K_i s$, where $K_i \geq 0$ $(i = 1, 2)$, i.e., if the gain functions are linear.

Next we show that the problem of WISS stabilization problem for (4.1) with sampled-data feedback applied with zero order hold and depending only on $x \in \Re^n$ is solvable under hypotheses (A1)–(A3) by linear feedback. The proof of this result will be made by making use of Corollary 3.4.

Notice that since (A, B) is a controllable pair of matrices, it follows that for every $\mu > 0$, $R \geq 1$ there exist a symmetric positive definite matrix $P \in \Re^{n \times n}$, a vector $k \in \Re^n$, and constants $Q_1, Q_2 > 0$ such that the following inequalities hold for all $(x, u) \in \Re^n \times \Re$:

$$\begin{aligned} Q_1\,|x|^2 \leq x'Px \leq Q_2\,|x|^2, \\ 2x'P(A + Bk')x + 2x'PBu \leq -4\mu x'Px + \frac{Q_1}{4\mu R^2}u^2. \end{aligned} \tag{4.6}$$

Next we show the following claim.

Claim. *For every $\mu > 0$, $R \geq 1$ there exists a vector $k \in \Re^n$ and constants $M, r > 0$ such that for all $(t_0, x_0, d, z, u, w) \in \Re^+ \times \Re^n \times \mathcal{L}^\infty_{loc}(\Re^+; D) \times \mathcal{L}^\infty_{loc}(\Re^+; \Re^k) \times$*

$\mathcal{L}^\infty_{loc}(\Re^+;U)\times\mathcal{L}^\infty_{loc}(\Re^+;\Re^+)$ *the solution of the hybrid system*

$$\begin{aligned}\dot{x}(t) &= Ax(t)+Bk'x(\tau_i)+Bg(t,d(t),z(t),u(t)), t\in[\tau_i,\tau_{i+1}),\\ \tau_{i+1} &= \tau_i+\exp\left(-w(\tau_i)\right)r, \quad w(t)\in\Re^+,\end{aligned} \tag{4.7}$$

with initial condition $x(t_0)=x_0$ *corresponding to inputs* $(d,z,u,w)\in\mathcal{L}^\infty_{loc}(\Re^+;D)\times\mathcal{L}^\infty_{loc}(\Re^+;\Re^k)\times\mathcal{L}^\infty_{loc}(\Re^+;U)\times\mathcal{L}^\infty_{loc}(\Re^+;\Re^+)$*, satisfies the following estimate for all* $t\geq t_0$*:*

$$|x(t)|\leq M\exp\left(-\mu(t-t_0)\right)|x_0|+\sup_{t_0\leq\tau\leq t}R^{-1}\gamma_2\left(|z(\tau)|\right)+\sup_{t_0\leq\tau\leq t}R^{-1}\gamma_2^u\left(\delta_2^u(\tau)\,|u(\tau)|\right), \tag{4.8}$$

where $\delta_2^u\in K^+$*,* γ_2*,* $\gamma_2^u\in\mathcal{N}$ *are the functions involved in* (4.4).

Proof of Claim. Let arbitrary $\mu>0, R>1$. Since (A,B) is a controllable pair of matrices, it follows that there exists a symmetric positive definite matrix $P\in\Re^{n\times n}$, a vector $k\in\Re^n$, and constants $Q_1,Q_2>0$ such that inequalities (4.6) hold for all $(x,u)\in\Re^n\times\Re$. Let arbitrary $(t_0,x_0,d,z,u,w)\in\Re^+\times\Re^n\times\mathcal{L}^\infty_{loc}(\Re^+;D)\times\mathcal{L}^\infty_{loc}(\Re^+;\Re^k)\times\mathcal{L}^\infty_{loc}(\Re^+;U)\times\mathcal{L}^\infty_{loc}(\Re^+;\Re^+)$, and consider the solution $x(t)$ of (4.7) with initial condition $x(t_0)=x_0$ corresponding to inputs $(d,z,u,w)\in\mathcal{L}^\infty_{loc}(\Re^+;D)\times\mathcal{L}^\infty_{loc}(\Re^+;\Re^k)\times\mathcal{L}^\infty_{loc}(\Re^+;U)\times\mathcal{L}^\infty_{loc}(\Re^+;\Re^+)$ (the solution exists for all $t\geq t_0$). Finally, consider the function $V(t):=x'(t)Px(t)$, which is absolutely continuous on $[t_0,+\infty)$. By virtue of (4.6) the derivative of $V(t)$ satisfies a.e. on the interval $[\tau_i,\tau_{i+1})$:

$$\dot{V}(t)\leq-4\mu V(t)+2x'PBk'(x(\tau_i)-x(t))+\frac{Q_1}{4\mu R^2}\left|g(t,d(t),z(t),u(t))\right|^2. \tag{4.9}$$

Let $r>0$ be a constant that satisfies

$$\begin{gathered}r\leq\frac{2\mu}{M\,|Bk'|\,|A+Bk'|\,(2\,|A+Bk'|+|B|)+2\mu\,|A|+2\mu\,|A+Bk'|};\\ r\leq\frac{1}{4\mu R^2M\,|B|\,|Bk'|+|A|+|A+Bk'|},\end{gathered} \tag{4.10}$$

where $M:=\frac{Q_2}{Q_1}\geq1$.

It follows from (4.7) that $|x(t)-x(\tau_i)|\leq r|A|\sup_{\tau_i\leq s\leq t}|x(s)-x(\tau_i)|+r|A+Bk'||x(\tau_i)|+r|B|\sup_{\tau_i\leq s\leq t}|g(s,d(s),z(s),u(s))|$, which directly implies $|x(t)-x(\tau_i)|\leq\frac{r|A+Bk'|}{1-r|A}|x(\tau_i)|+\frac{r|B|}{1-r|A|}\sup_{\tau_i\leq s\leq t}|g(s,d(s),z(s),u(s))|$, for all $t\in[\tau_i,\tau_{i+1})$. Moreover, the previous inequality in conjunction with the triangle inequality $|x(\tau_i)|\leq|x(t)-x(\tau_i)|+|x(t)|$ implies the estimate $|x(t)-x(\tau_i)|\leq\frac{r|A+Bk'|}{1-r|A|-r|A+Bk'|}|x(t)|+\frac{r|B|}{1-r|A|-r|A+Bk'|}\sup_{\tau_i\leq s\leq t}|g(s,d(s),z(s),u(s))|$ for all $t\in[\tau_i,\tau_{i+1})$. Using the previous inequality in conjunction with (4.9) and completing the squares, we obtain for almost all $t\in[\tau_i,\tau_{i+1})$:

$$\begin{aligned}\dot{V}(t)\leq&-\left(4\mu-\frac{rM\,|Bk'|\;|A+Bk'|\;(2\,|A+Bk'|+|B|)}{1-r\,(|A|+|A+Bk'|)}\right)V(t)\\ &+\left(\frac{Q_1}{4\mu\,R^2}+\frac{r\,|B|\;Q_2\,|Bk'|}{1-r\,(|A|+|A+Bk'|)}\right)\sup_{\tau_i\leq s\leq t}|g(s,d(s),z(s),u(s))|^2.\end{aligned} \tag{4.11}$$

It follows from inequalities (4.10), (4.11) that the following estimate holds for the derivative of $V(t)$ a.e. on the interval $[\tau_i,\tau_{i+1})$:

$$\dot{V}(t)\leq-2\mu V(t)+\frac{Q_1}{2\mu R^2}\sup_{t_0\leq s\leq t}|g(s,d(s),z(s),u(s))|^2. \tag{4.12}$$

Notice that, since estimate (4.12) does not depend on the particular interval $[\tau_i, \tau_{i+1})$, we may conclude that estimate (4.12) holds a.e. for $t \geq t_0$. Estimate (4.12) implies directly that $V(t) \leq \exp(-2\mu(t-t_0))V(t_0) + \frac{Q_1}{R^2}\sup_{t_0\leq s\leq t}|g(s,d(s),z(s),u(s))|^2$ for all $t \geq t_0$. Finally, estimate (4.8) is an immediate consequence of the previous inequality, definitions $V(t) := x'(t)Px(t)$ and $M := \frac{Q_2}{Q_1} \geq 1$, as well as inequalities (4.4) and (4.6). The proof of the claim is complete. □

By making use of Corollary 3.4 and specifically Remark 3.5(b), we may conclude that the closed-loop system (4.1a) with (4.7) satisfies the WISS property from the inputs u and w, when $R > 1$ is chosen to be greater than or equal to the constant involved in hypothesis (A3). Moreover, the gain function for the input w is identically zero. Furthermore, if the functions $\delta_1^u, \delta_2^u \in K^+$ are bounded, then the closed-loop system (4.1a) with (4.7) satisfies the ISS property from the inputs u and w. Finally, if in addition $\beta \in K^+$ is bounded, then the closed-loop system (4.1a) with (4.7) satisfies the UISS property from the inputs u and w.

Example 4.1. The following planar system described by ODEs:

$$\begin{aligned} &\dot{z} = -z^3 + zx, \\ &\dot{x} = d(t)z^2 + u + v, \\ &(z,x)' \in \Re^2, u, v \in \Re \end{aligned} \tag{4.13}$$

is studied in [11], where it is shown that if $d(t) \equiv d$ with $|d| < \frac{1}{2}$, then the feedback law $v(t) = -x(t)$ guarantees the UISS property for the closed-loop system from the input $u \in \Re$. The proof of this fact is made by using a slightly modified version of the small-gain theorem presented in [14]. Here we study the possibility of robustly globally stabilizing the origin for system (4.13), using the following feedback law with zero order hold and a positive sampling rate:

$$\begin{aligned} &v(t) = -x(\tau_i), t \in [\tau_i, \tau_{i+1}), \\ &\tau_{i+1} = \tau_i + \exp(-w(\tau_i))r, w(t) \in \Re^+ \end{aligned} \tag{4.14}$$

for time-varying disturbances $d(t) \in D := [-\delta, \delta]$, with $\delta \in (0,1)$.

First notice that system (4.13) is a system of the form (4.1) with $f(t,d,z,x,u) = -z^3 + zx$, $g(t,d,z,u) = dz^2 + u$, $B = [1]$, $A = [0]$. Moreover, hypothesis (A2) holds with $\gamma_2(s) = \delta s^2$, $\gamma_2^u(s) := s$, and $\delta_2^u(t) \equiv 1$.

Working exactly as in [11] it may be shown that for every $\varepsilon \in (0,1)$ the subsystem Σ_1:

$$\dot{z} = -z^3 + zx \tag{4.15}$$

satisfies the UISS property from the input x with gain function $\gamma_1(s) := \sqrt{\frac{s}{1-\varepsilon}}$. Thus the subsystem Σ_1 satisfies hypothesis (A1) with $\gamma_1(s) := \sqrt{\frac{s}{1-\varepsilon}}$, $\beta(t) \equiv 1$, $\gamma_2^u(s) := s$, and appropriate $\sigma \in KL$.

For every $\delta \in (0,1)$ there exist $\varepsilon \in (0,1)$ and $L > 0$ such that

$$(1+L)\sqrt{\frac{(1+L)\delta}{1-\varepsilon}} \leq 1. \tag{4.16}$$

Selecting $\rho(s) := Ls$, with $L > 0$, we conclude from (4.16) that (4.5) holds with $R = 1$. Finally, since (4.6) holds with $Q_1 = Q_2 = 1$, $P = [1]$, $\mu = \frac{1}{4}$, and $k = -1$, we conclude that (4.13) with (4.14) satisfies the UISS property from the inputs u and w. Moreover, the gain function for the input w is identically zero. The maximum allowable sampling period (r) may be determined by inequalities (4.10), which give $r = 1/7$.

5. Conclusions. A small-gain theorem, which can be applied to a wide class of systems that includes systems that satisfy the weak semigroup property, is presented in the present work. The result generalizes all existing results in the literature and exploits notions of weighted, uniform, and nonuniform IOS property. Moreover, the small-gain theorem of the present work is a method for establishing qualitative properties expressed in a very general framework unifying works from various fields as well as different stability notions. The results presented in the paper can be extended without much difficulty to the case of local stability notions.

Applications to partial-state feedback stabilization problems with sampled-data feedback applied with zero order hold and a positive sampling rate are also presented. It should be emphasized that sampled-data control systems cannot be handled with small-gain results that have appeared so far in the literature, since sampled-data control systems do not satisfy the classical semigroup property. The results are illustrated by examples which show the usefulness of the main result for the stability analysis of interconnected systems. Other promising applications of the new generalized small-gain theorem include the popular topics of hybrid systems and networked control systems. Some initial, interesting results can be found in [30, 39, 41].

Appendix A.

Proof of Lemma 2.13. Lemma 3.5 in [24] guarantees that the control system $\Sigma := (\mathcal{X}, \mathcal{Y}, M_U, M_D, \phi, \pi, H)$ which has the BIC property is RFC from the input $u \in \mathcal{M}(U)$ if and only if there exist functions $q \in K^+$, $a \in K_\infty$ and a constant $R \geq 0$ such that the following estimate holds for all $(t_0, x_0, d, u) \in \Re^+ \times \mathcal{X} \times M_D \times M_U$ and $t \geq t_0$:

$$\|\phi(t, t_0, x_0, u, d)\|_{\mathcal{X}} \leq q(t) a \left(R + \|x_0\|_{\mathcal{X}} + \sup_{t_0 \leq \tau \leq t} \|u(\tau)\|_{\mathcal{U}} \right). \tag{A.1}$$

It should be emphasized that all results in [24] were proved under the assumption of the classical semigroup property for the control system. However, the proof of Lemma 3.5 does not depend on the semigroup property and consequently may be repeated as it stands for a system which satisfies the weak semigroup property. Let $\beta \in K^+$ arbitrary. Using (A.1) we obtain

$$\begin{aligned}
&\beta(t) \|\phi(t, t_0, x_0, u, d)\|_{\mathcal{X}} \\
&\quad \leq \frac{1}{2} q^2(t) \beta^2(t) + \frac{1}{2} \max \left\{ a^2(3R); a^2\left(3 \|x_0\|_{\mathcal{X}}\right); \sup_{t_0 \leq \tau \leq t} a^2\left(3 \|u(\tau)\|_{\mathcal{U}}\right) \right\} \\
&\quad \leq \max \left\{ q^2(t)\beta^2(t)\,;\, a^2(3R)\,;\, a^2\left(3 \|x_0\|_{\mathcal{X}}\right)\,;\, \sup_{t_0 \leq \tau \leq t} a^2\left(3 \|u(\tau)\|_{\mathcal{U}}\right) \right\} \\
&\quad \leq \max \left\{ \gamma(t)\,;\, a^2\left(3 \|x_0\|_{\mathcal{X}}\right)\,;\, \sup_{t_0 \leq \tau \leq t} a^2\left(3 \|u(\tau)\|_{\mathcal{U}}\right) \right\},
\end{aligned} \tag{A.2}$$

where $\gamma(t) = q^2(t)\beta^2(t) + a^2(3R)$. Define

$$a(T, s) := \max \{ \gamma(t_0 + h) - \gamma(t_0) : h \in [0, s], t_0 \in [0, T] \}. \tag{A.3}$$

Clearly, definition (A.3) implies that, for each fixed $s \geq 0$, $a(\cdot, s)$ is nondecreasing and, for each fixed $T \geq 0$, $a(T, \cdot)$ is nondecreasing. Furthermore, continuity of γ guarantees that, for every $T \geq 0, \lim_{s \to 0^+} a(T, s) = a(T, 0) = 0$. It turns out from Lemma 2.3 in [21] that there exist functions $\zeta \in K_\infty$ and $\kappa \in K^+$ such that

$$a(T, s) \leq \zeta(\kappa(T)s) \quad \forall (T, s) \in \left(\Re^+\right)^2. \tag{A.4}$$

Combining definition (A.3) with inequality (A.4), we conclude that, for all $t_0 \geq 0$ and $t \geq t_0$, it holds that

$$\begin{aligned}\gamma(t) &\leq \gamma(t_0) + \zeta\left(\kappa(t_0)\,(t-t_0)\right) \leq \gamma(t_0) + \zeta\left(\tfrac{1}{2}\kappa^2(t_0) + \tfrac{1}{2}\,(t-t_0)^2\right)\\ &\leq \gamma(t_0) + \zeta\left(\kappa^2(t_0)\right) + \zeta\left((t-t_0)^2\right) \leq \max\left\{2\gamma(t_0) + 2\zeta\left(\kappa^2(t_0)\right); 2\zeta\left((t-t_0)^2\right)\right\}.\end{aligned}$$

The above inequality in conjunction with (A.2) implies that (2.9) holds for all $(t_0, x_0, d, u) \in \Re^+ \times \mathcal{X} \times M_D \times M_U$ and $t \geq t_0$ with $\mu(t) := 2\zeta\left(t^2+1\right)$, $c(t) := 2\gamma(t) + 2\zeta\left(\kappa^2(t)\right)$, $a(s) := a^2(3s)$, and $p(s) := a^2(3s)$. The proof is complete. □

Proof of Lemma 2.16. As in the proof of Proposition 2.2 in [21], let $T, h \geq 0$, $s \geq 0$, and define

$$\begin{aligned}a(T,s) := \sup\Big\{ & V(t, \phi(t, t_0, x_0, u, d), u(t)) - \sup_{t_0 \leq \tau \leq t} \gamma\left(\delta(\tau)\,\|u(\tau)\|_{\mathcal{U}}\right);\\ & \|x_0\|_{\mathcal{X}} \leq s, t \geq t_0 \in [0,T], d \in M_D, u \in M_U\Big\},\end{aligned} \tag{A.5}$$

$$\begin{aligned}M(h,T,s) := \sup\Big\{ & V(t_0+h, \phi(t_0+h, t_0, x_0, u, d), u(t)) - \sup_{t_0 \leq \tau \leq t_0+h} \gamma\left(\delta(\tau)\,\|u(\tau)\|_{\mathcal{U}}\right);\\ & \|x_0\|_X \leq s, t_0 \in [0,T], d \in M_D, u \in M_U\Big\}.\end{aligned} \tag{A.6}$$

First notice that by virtue of property P1 it holds that $a(T,s) < +\infty$ for all $T \geq 0$, $s \geq 0$. Moreover, notice that, since $0 \in \mathcal{X}$ is a robust equilibrium point from the input $u \in M_U$ and $V(t,0,0) = 0$ for all $t \geq 0$, we have $a(T,s) \geq 0$ for all $T \geq 0$, $s \geq 0$. Furthermore, notice that M is well-defined, since by definitions (A.5), (A.6) the following inequality is satisfied for all $T, h \geq 0$ and $s \geq 0$:

$$0 \leq M(h,T,s) \leq a(T,s). \tag{A.7}$$

Clearly, definition (A.5) implies that, for each fixed $s \geq 0$, $a(\cdot, s)$ is nondecreasing and, for each fixed $T \geq 0$, $a(T,\cdot)$ is nondecreasing. Furthermore, property P2 asserts that, for every $T \geq 0$, $\lim_{s \to 0^+} a(T,s) = 0$. Hence, the inequality $a(T,0) \geq 0$ for all $T \geq 0$, in conjunction with $\lim_{s\to 0^+} a(T,s) = 0$ and the fact that $a(T,\cdot)$ is nondecreasing, implies $a(\cdot,0) = 0$. It turns out from Lemma 2.3 in [21] that there exist functions $\zeta \in K_\infty$ and $q \in K^+$ such that

$$a(T,s) \leq \zeta(q(T)s) \quad \forall (T,s) \in \left(\Re^+\right)^2. \tag{A.8}$$

Without loss of generality we may assume that $q \in K^+$ is nondecreasing. Moreover, property P3 guarantees that, for every $\varepsilon > 0$, $T \geq 0$, and $R \geq 0$, there exists a $\tau = \tau(\varepsilon, T, R) \geq 0$ such that

$$M(h,T,s) \leq \varepsilon \;\forall\; h \geq \tau(\varepsilon,T,R) \text{ and } 0 \leq s \leq R. \tag{A.9}$$

Let

$$g(s) := \sqrt{s} + s^2, \tag{A.10}$$

and let p be a nondecreasing function of class K^+, with $p(0) = 1$ and

$$\lim_{t \to +\infty} p(t) = +\infty. \tag{A.11}$$

Define

$$\mu(h) := \sup\left\{\frac{M(h,T,s)}{p(T)g\left(\zeta\left(q(T)s\right)\right)};\quad T\geq 0, s>0\right\}. \tag{A.12}$$

Obviously, by virtue of (A.7), (A.8), and (A.10) the function $\mu : \Re^+ \to \Re^+$ is well-defined and satisfies $\mu(\cdot)\leq 1$. We show that $\lim_{h\to+\infty}\mu(h)=0$; equivalently, we establish that for any given $\varepsilon>0$ there exists a $\delta=\delta(\varepsilon)\geq 0$ such that

$$\mu\left(h\right)\leq\varepsilon \text{ for } h\geq\delta\left(\varepsilon\right). \tag{A.13}$$

Notice first that for any given $\varepsilon>0$ there exist constants $a:=a(\varepsilon)$ and $b:=b(\varepsilon)$, with $0<a<b$, such that

$$x\notin(a,b)\Rightarrow\frac{x}{\sqrt{x}+x^2}\leq\varepsilon. \tag{A.14}$$

We next recall (A.11), which asserts that, for the above ε for which (A.14) holds, there exists a $c:=c(\varepsilon)\geq 0$ such that $p(T)\geq\frac{1}{\varepsilon}$ for all $T\geq c$. This by virtue of (A.7), (A.8), (A.10), and (A.14) yields

$$\frac{M(h,T,s)}{p(T)g(\zeta(q(T)s))}\leq\varepsilon\quad\forall h\geq 0,\ \text{when } T\geq c \text{ or } \zeta(q(T)s)\notin(a,b). \tag{A.15}$$

Hence, in order to establish (A.13), it remains to consider the case:

$$a\leq\zeta(q(T)s)\leq b \text{ and } 0\leq T\leq c. \tag{A.16}$$

Since, for each fixed $(h,s)\in\left(\Re^+\right)^2$, the mappings $M(h,\cdot,s)$, $M(h,s,\cdot)$, $q(\cdot)$, and $p(\cdot)$ are nondecreasing, we have that

$$\frac{M(h,T,s)}{p(T)g\left(\zeta\left(q(T)s\right)\right)}\leq\frac{M\left(h,c,\frac{\zeta^{-1}(b)}{q(0)}\right)}{g\left(a\right)}, \tag{A.17}$$

provided that (A.16) holds. By using (A.9) and (A.17) with

$$\varepsilon:=\varepsilon g(a), T:=c, R:=\frac{\zeta^{-1}(b)}{q(0)},$$

it follows

$$M\left(h,c,\frac{\zeta^{-1}(b)}{q(0)}\right)\leq\varepsilon g\left(a\right)\ \text{ for } h\geq\delta\left(\varepsilon\right):=\tau\left(\varepsilon\, g(a),c,\frac{\zeta^{-1}(b)}{q(0)}\right). \tag{A.18}$$

By taking into account (A.15), (A.16), (A.17), (A.18), and definition (A.12) of $\mu\left(\cdot\right)$, it follows that (A.13) holds with $\delta=\delta\left(\varepsilon\right)$ as selected in (A.18). Since $\varepsilon>0$ was arbitrary we conclude that $\lim_{h\to+\infty}\mu(h)=0$. Consequently, there exists a continuous strictly decreasing function $\bar{\mu}:\Re^+\to(0,+\infty)$ such that $\bar{\mu}(h)\geq\mu(h)$ for all $h\geq 0$ and $\lim_{h\to+\infty}\bar{\mu}(h)=0$. Thus, by recalling definition (A12) we obtain

$$M(h,T,s)\leq\bar{\mu}(h)\theta(T,s)\quad\forall(T,s)\in\left(\Re^+\right)^2,\quad\forall h\geq 0, \tag{A.19}$$

where $\theta(T,s):=p(T)g(\zeta(q(T)s))$. Clearly, θ satisfies all hypotheses of Lemma 2.3 in [21], and therefore there exist $\zeta_2\in K_\infty$ and $\beta\in K^+$ such that

$$\theta(T,s)\leq\zeta_2(\beta(T)s)\quad\forall(T,s)\in\left(\Re^+\right)^2. \tag{A.20}$$

Thus definition (A.6) implies that the following estimate holds for all $u \in M_U$, $(t_0, x_0, d) \in \Re^+ \times \mathcal{X} \times M_D$, and $t \geq t_0$:

$$V(t, \phi(t, t_0, x_0, u, d), u(t)) \leq \bar{\mu}(t - t_0)\zeta_2\left(\beta(t_0)\left\|x_0\right\|_X\right) + \sup_{t_0 \leq \tau \leq t} \gamma\left(\delta(\tau)\left\|u(\tau)\right\|_{\mathcal{U}}\right). \tag{A.21}$$

Estimate (A.21) implies (2.12) with $\sigma(s,t) := \bar{\mu}(t)\zeta_2(s)$. □

Proof of Lemma 2.17. As in the proof of Lemma 2.16, let $h \geq 0$, $s \geq 0$, and define

$$a(s) := \sup\left\{V(t, \phi(t, t_0, x_0, u, d), u(t)) - \sup_{t_0 \leq \tau \leq t} \gamma\left(\delta(\tau)\left\|u(\tau)\right\|_{\mathcal{U}}\right); \right. \\ \left. \left\|x_0\right\|_{\mathcal{X}} \leq s, t \geq t_0 \geq 0, d \in M_D, u \in M_U\right\}, \tag{A.22}$$

$$M(h,s) := \sup\left\{V(t_0 + h, \phi(t_0 + h, t_0, x_0, u, d), u(t)) - \sup_{t_0 \leq \tau \leq t_0 + h} \gamma\left(\delta(\tau)\left\|u(\tau)\right\|_{\mathcal{U}}\right); \right. \\ \left. \left\|x_0\right\|_{\mathcal{X}} \leq s, t_0 \geq 0, d \in M_D, u \in M_U\right\}. \tag{A.23}$$

First notice that by virtue of property P1 it holds that $a(s) < +\infty$ for all $s \geq 0$. Moreover, notice that, since $0 \in \mathcal{X}$ is a robust equilibrium point from the input $u \in M_U$ and $V(t, 0, 0) = 0$ for all $t \geq 0$, we have $a(s) \geq 0$ for all $s \geq 0$. Furthermore, notice that M is well-defined, since by definitions (A.22), (A.23) the following inequality is satisfied for all $h \geq 0$ and $s \geq 0$:

$$0 \leq M(h,s) \leq a(s). \tag{A.24}$$

Clearly, definition (A.22) implies that $a(\cdot)$ is nondecreasing. Furthermore, property P2 asserts that $\lim_{s \to 0^+} a(s) = 0$. Hence, the inequality $a(0) \geq 0$, in conjunction with $\lim_{s \to 0^+} a(s) = 0$ and the fact that $a(\cdot)$ is nondecreasing, implies $a(0) = 0$. It turns out that a can be bounded from above by the K_∞ function $\tilde{a}$ defined by $\tilde{a}(s) := s + \frac{1}{s}\int_s^{2s} a(w)dw$ for $s > 0$ and $\tilde{a}(0) = 0$. Define

$$\mu(h) := \sup\left\{\frac{M(h,s)}{g\left(\tilde{a}\left(s\right)\right)}; s > 0\right\}, \tag{A.25}$$

where g is defined by (A.10). Working exactly as in the proof of Lemma 2.16 we can show that the function $\mu : \Re^+ \to \Re^+$ is well-defined and satisfies $\mu(\cdot) \leq 1$, $\lim_{h \to +\infty} \mu(h) = 0$. Consequently, there exists a continuous strictly decreasing function $\bar{\mu} : \Re^+ \to (0, +\infty)$ such that $\bar{\mu}(h) \geq \mu(h)$ for all $h \geq 0$ and $\lim_{h \to +\infty} \bar{\mu}(h) = 0$. Thus, by recalling definition (A.25) we obtain

$$M(h,s) \leq \bar{\mu}(h) g(\tilde{a}(s)) \quad \forall h, s \geq 0. \tag{A.26}$$

Hence definition (A.23) implies that the following estimate holds for all $u \in M_U$, $(t_0, x_0, d) \in \Re^+ \times \mathcal{X} \times M_D$, and $t \geq t_0$:

$$V(t, \phi(t, t_0, x_0, u, d), u(t)) \leq \bar{\mu}(t - t_0) g\left(\tilde{a}(\left\|x_0\right\|_X)\right) + \sup_{t_0 \leq \tau \leq t} \gamma\left(\delta(\tau)\left\|u(\tau)\right\|_{\mathcal{U}}\right). \tag{A.27}$$

Estimate (A.27) implies (2.12) with $\beta(t) \equiv 1$ and $\sigma(s,t) := \bar{\mu}(t) g(\tilde{a}(s))$. □

Proof of Lemmas 2.19–2.20. The proof is based on the following observation: If $\Sigma := (\mathcal{X}, \mathcal{Y}, M_U, M_D, \phi, \pi, H)$ is *T-periodic*, then for all $(t_0, x_0, u, d) \in \Re^+ \times$

$\mathcal{X} \times M_U \times M_D$ it holds that $\phi(t, t_0, x_0, u, d) = \phi(t - kT, t_0 - kT, x_0, P_{kT}u, P_{kT}d)$ and $H(t, \phi(t, t_0, x_0, u, d), u(t)) = H(t - kT, \phi(t - kT, t_0 - kT, x_0, P_{kT}u, P_{kT}d), (P_{kT}u)(t - kT))$, where $k := [t_0/T]$ denotes the integer part of t_0/T and the inputs $P_{kT}u \in M_U, P_{kT}d \in M_D$ are defined in Definition 2.2.

Since $\Sigma := (\mathcal{X}, \mathcal{Y}, M_U, M_D, \phi, \pi, H)$ satisfies the WIOS property from the input $u \in M_U$, there exist functions $\sigma \in KL, \beta, \delta \in K^+, \gamma \in \mathcal{N}$ such that (2.10) holds for all $(t_0, x_0, u, d) \in \Re^+ \times \mathcal{X} \times M_U \times M_D$ and $t \geq t_0$. Consequently, it follows that the following estimate holds for all $(t_0, x_0, u, d) \in \Re^+ \times \mathcal{X} \times M_U \times M_D$ and $t \geq t_0$:

$$\begin{aligned}&\|H(t, \phi(t, t_0, x_0, u, d), u(t))\|_{\mathcal{Y}} \\ &\quad \leq \sigma\left(\beta\left(t_0 - kT\right)\|x_0\|_{\mathcal{X}}, t - t_0\right) + \sup_{\tau \in [t_0 - kT, t - kT]} \gamma\left(\delta(\tau)\left\|\left(P_{kT}u\right)(\tau)\right\|_{\mathcal{U}}\right).\end{aligned}$$

Setting $\tau = s - kT$ and since $0 \leq t_0 - \left[\frac{t_0}{T}\right] T < T$ for all $t_0 \geq 0$, we obtain

$$\begin{aligned}&\|H(t, \phi(t, t_0, x_0, u, d), u(t))\|_{\mathcal{Y}} \\ &\quad \leq \tilde{\sigma}\left(\|x_0\|_{\mathcal{X}}, t - t_0\right) + \sup_{s \in [t_0, t]} \gamma\left(\delta(s - kT)\left\|\left(P_{kT}u\right)(s - kT)\right\|_{\mathcal{U}}\right),\end{aligned} \tag{A.28}$$

where $\tilde{\sigma}(s, t) := \sigma(rs, t)$ and $r := \max\{\beta(t); 0 \leq t \leq T\}$. Estimate (A.28) and the identity $\left(P_{kT}u\right)(s - kT) = u(s)$ for all $s \geq 0$ imply that the following estimate holds for all $(t_0, x_0, u, d) \in \Re^+ \times \mathcal{X} \times M_U \times M_D$ and $t \geq t_0$:

$$\|H(t, \phi(t, t_0, x_0, u, d), u(t))\|_{\mathcal{Y}} \leq \tilde{\sigma}\left(\|x_0\|_{\mathcal{X}}, t - t_0\right) + \sup_{s \in [t_0, t]} \gamma\left(\tilde{\delta}(s)\|u(s)\|_{\mathcal{U}}\right), \tag{A.29}$$

where $\tilde{\delta}(t) := \max\{\delta(s); s \in [0, t]\}$.

In the case that $\Sigma := (\mathcal{X}, \mathcal{Y}, M_U, M_D, \phi, \pi, H)$ satisfies the IOS property from the input $u \in M_U$, then all arguments above may be repeated with $\delta(t) \equiv 1$. Thus we conclude that (A.29) holds for all $(t_0, x_0, u, d) \in \Re^+ \times X \times M_U \times M_D$ and $t \geq t_0$ with $\tilde{\delta}(t) \equiv 1$. The proof is complete. ∎

BILATERAL OBSTACLE CONTROL PROBLEM OF PARABOLIC VARIATIONAL INEQUALITIES*

QIHONG CHEN†, DELIN CHU‡, AND ROGER C. E. TAN‡

Abstract. In this paper, the optimality system as well as the existence theorem for an obstacle optimal control problem are established, in which the governing system is a parabolic bilateral variational inequality and the input control is the pair of upper and lower obstacles.

Key words. bilateral obstacle control problem, parabolic variational inequality, optimality system, monotonicity inequality

1. Introduction.

Throughout this paper, the following notation is used:

- $\Omega \subset \mathcal{R}^n$ is a bounded domain with a $C^{1,1}$ boundary $\partial\Omega$;
- $Q = \Omega \times (0,T)$, $\Sigma = \partial\Omega \times (0,T)$, $\partial_p Q = \Sigma \bigcup \bar{\Omega} \times \{0\}$;
- $L^2(0,T;H_0^1(\Omega)) = \{z\colon (0,T) \to H_0^1(\Omega) |\ \int_0^T \|z(\cdot,t)\|^2_{H_0^1(\Omega)} dt < \infty\}$;
- $W = \{y \in L^2(0,T;H_0^1(\Omega)) |\ y_t \in L^2(0,T;H^{-1}(\Omega)\}$;
- $W_p^{2,1}(Q) = \{z \in L^p(Q) |\ z_t, z_x, z_{xx} \in L^p(Q)\}$;
- $\dot{W}_p^{2,1}(Q) = \{z \in W_p^{2,1}(Q) |\ z|_{\partial_p Q} = 0\}$.

This paper deals with an optimal obstacle control problem in which the state y is governed by a semilinear parabolic bilateral variational inequality

$$\begin{cases} y \in W_2^{2,1}(Q) \cap L^2(0,T;H_0^1(\Omega)), \quad y|_{t=0} = y_0 & \text{in } \Omega, \\ \varphi \le y \le \psi & \text{in } Q, \\ (y_t - \Delta y - f(x,t,y))(y-\varphi) \le 0 & \text{in } Q, \\ (y_t - \Delta y - f(x,t,y))(y-\psi) \le 0 & \text{in } Q, \end{cases} \tag{1.1}$$

and the input control (φ, ψ) is a pair of upper and lower obstacles.

We assume that

(i)

$$y_0 \in C_0^\alpha(\bar{\Omega}) \cap W^{2-\frac{1}{p},p}(\Omega)$$

for some $\alpha \in (0,1)$ and any $p > 1$.

(ii) the function $f\colon \Omega \times [0,T] \times \mathcal{R} \to \mathcal{R}$ has the following properties:

- $f(\cdot,\cdot,y)$ is measurable on $\Omega \times [0,T]$;
- $f(x,t,\cdot)$ is a decreasing function in $C^1(\mathcal{R})$, so it is monotone;

- $f(x,t,\cdot)$ is a Lipschitz function, and thus, there exists a constant $K>0$, such that

$$|f(x,t,y_1)-f(x,t,y_2)| \le K\ |y_1-y_2| \quad \forall\ (x,t)\in\Omega\times[0,T];\ y_1,\ y_2\in\mathcal{R}; \tag{1.2}$$

-

$$|f(x,t,0)|\le K \qquad \forall\ (x,t)\in\Omega\times[0,T]. \tag{1.3}$$

Denote

$$\mathcal{U}=\{(\varphi,\psi)\in W_p^{2,1}(Q)\times W_p^{2,1}(Q)|\varphi\le\psi \text{ in } Q,\ \varphi=0=\psi \text{ on } \Sigma,\ \varphi|_{t=0}\le y_0\le\psi|_{t=0} \text{ in } \Omega\}.$$

For any given $(\varphi,\psi)\in\mathcal{U}$, the bilateral variational inequality (1.1) is uniquely solvable (see Proposition 2.4 below). We will denote by $y=\mathcal{S}(\varphi,\psi)$ the unique solution of (1.1) corresponding to (φ,ψ).

We shall take the pair of upper and lower obstacles (φ,ψ) as the control so that the corresponding state y becomes close to a desired target profile $z_d\in L^2(Q)$. This leads to the following problem.

Problem (C). *Find a control pair* $(\bar\varphi,\bar\psi)\in\mathcal{U}$ *such that*

$$J(\bar\varphi,\bar\psi)=\inf_{(\varphi,\psi)\in\mathcal{U}} J(\varphi,\psi),$$

where the objective functional $J(\varphi,\psi)$ *is defined by*

$$J(\varphi,\psi)=\int_Q\left\{\frac{1}{2}(\mathcal{S}(\varphi,\psi)-z_d)^2+\frac{1}{p}[|\varphi_t|^p+|\Delta\varphi|^p+|\psi_t|^p+|\Delta\psi|^p]\right\}dxdt. \tag{1.4}$$

The variational inequalities and related optimal control problems have been studied extensively; see, e.g., [1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 17, 18, 20, 21, 22, 23, 24, 27, 29] and the references therein. When the governing system is an obstacle variational inequality and the obstacle is considered as the control, the resulting problem is referred to as an optimal obstacle control problem. This type of problem usually appears in shape optimization (cf. [26]). It may concern, for example, the design of the shape for a string in the one-dimensional obstacle problem, or the optimal shape for a dam, in which case the obstacle gives the form to be designed such that the pressure of the fluid inside the dam is close to a desired value.

The motivations of our present work are as follows:

(a) In Problem (C), the state system is a parabolic bilateral variational inequality, which has played an important role in the following recent research on mathematical finance: (1) the pricing model for American contingent claims (cf. [28]) is formulated as a parabolic variational inequality with the obstacle being the "payoff" function, and in that particular case, controlling the obstacle is equivalent to the design of the "payoff"; (2) in [11] the optimal investment problem with finite-horizon and transaction costs for a constant relative risk aversion investor is linked with a parabolic bilateral problem involving two free boundaries which correspond to the optimal buying and selling boundaries, respectively; and (3) in [12] the pricing model of a callable convertible security is formulated as a parabolic bilateral variational inequality in order

to study the optimal policies of the holder's conversion and issuer's calling for the callable American warrants and callable convertible bonds. It should be acknowledged that there is a nontrivial gap between the results of the present paper and that of the problem arising from mathematical finance, since Black–Scholes with American options has singular coefficients and an unbounded domain. However, in practical computation, we always truncate the unbounded domain, then solve the related partial differential equations on a bounded domain. In fact, if information on the interface between buy and sell regions is available, then this can be used as a sophisticated way of "cutting off" the domain; on this point we refer the reader to [30]. We also note that there may be other discussions of this point, e.g., in the stochastic community. Thus, it is possible, in some sense, to apply our results to mathematical finance. This is a research topic worthy of further study.

(b) The existence and uniqueness as well as characterizations of the optimal pair for an optimal obstacle control problem of an elliptic variational inequality have been given in [1]. The optimal obstacle control problem for more general systems has also been studied in [2, 3, 6, 8, 9, 10, 21, 22]. A problem, which is similar to Problem (C) with $p = 2$, has been considered in [2]. However, it seems that the method used in [2] cannot be applied to Problem (C) with $p > 2$ in the sense that when $p > 2$ a nonlinear leading differential operator, which lacks weak continuity, appears in the approximate optimality system (3.4) in section 3, but this operator is linear in the case $p = 2$.

(c) In general, when the penalty on control is stronger, the proof of the existence of optimal control becomes easier, whereas the derivation of necessary conditions will become harder, since the corresponding duality relation has to be established in a bigger space. Moreover, when the state equation is a variational inequality, one has to prove the convergence of the approximate adjoint equation, which is difficult due to the fact that the approximate adjoint equation is defined in a very weak sense, and then some measure term will occur in the limit. As far as the optimality system is concerned, it is incomplete as long as the measure which intervenes in the adjoint equation has not been precisely described. Hence, Problem (C) with $p > 2$ is much more difficult than its version with $p = 2$ in the sense that it is hard to derive the desired optimality system.

(d) Generally the existing results for elliptic variational inequalities cannot be extended to Problem (C) for parabolic variational inequalities in a trivial manner. In addition, some existing ideas, for example, the idea in [6], cannot be used to solve Problem (C) with $p > 2$ because of the difficulties described below. Furthermore, it is not clear if some existing results for the optimal control of elliptic variational inequalities are still true for the case of parabolic variational inequality; for instance, it is interesting to investigate whether the optimality conditions in [17] and [23] can still be true for Problem (C).

In this paper, we mainly aim at establishing an optimality system for Problem (C). Our approach is based on the penalty method and Barbu's treatment (cf. [4, 5]) as a penalty parameter approaching zero. In order to derive a more complete optimality system for Problem (C) than the one presented in [2] for a similar problem with $p = 2$, we adopt the $W_p^{2,1}$ framework which, however, causes some further difficulties due to the lack of weak continuity of the leading differential operator in the approximate optimality systems. We have overcome the encountered difficulties by

making full use of the special structure of the approximate optimality systems, including the monotonicity of the leading differential operator. We will prove that for most optimality conditions in [17, Theorem 5.1] and [23, Theorem 3.2], we can find their counterparts in our parabolic bilateral obstacle control problem.

Our approach can also be applied to more general cases; for instance, the Laplacian in (1.1) may be replaced by a general second order uniform elliptic operator with smooth coefficients.

2. State analysis. This section is devoted to some necessary preliminaries for the developments in the next sections.

2.1. Weak formulation. Given $(\varphi, \psi) \in \mathcal{U}$, define

$$\mathbf{K}(\varphi, \psi) = \{w \in W \,|\, \varphi \le w \le \psi \text{ a.e. in } Q \text{ and } w|_{t=0} = y_0 \text{ a.e. in } \Omega\}.$$

Clearly, $\mathbf{K}(\varphi, \psi)$ is a nonempty convex and closed subset of W.

LEMMA 2.1. *Let $y \in W_2^{2,1}(Q) \cap L^2(0,T; H_0^1(\Omega))$. Then $y = \mathcal{S}(\varphi, \psi)$ if and only if*

(2.1)
$$\begin{cases} y \in \mathbf{K}(\varphi, \psi), \\ \int_Q [y_t(w-y) + \nabla y \cdot \nabla(w-y)]dxdt \ge \int_Q f(x,t,y)(w-y)dxdt \quad \forall w \in \mathbf{K}(\varphi, \psi). \end{cases}$$

Proof. If y solves (1.1), then

$$y \in \mathbf{K}(\varphi, \psi),$$

and, for any $w \in \mathbf{K}(\varphi, \psi)$, $(w-y)^+$ (resp., $(w-y)^-$) can differ from 0 only when $y - \psi < 0$ (resp., $y - \varphi > 0$) and therefore $y_t - \Delta y - f \ge 0$ (resp., $y_t - \Delta y - f \le 0$). Thus, by the divergence theorem, the following inequality holds:

$$\begin{aligned} &\int_Q [y_t(w-y) + \nabla y \cdot \nabla(w-y) - f(x,t,y)(w-y)dxdt \\ &\quad = \int_Q (y_t - \Delta y - f)(w-y)dxdt \\ &\quad = \int_Q (y_t - \Delta y - f)(w-y)^+ dxdt - \int_Q (y_t - \Delta y - f)(w-y)^- dxdt \\ &\quad \ge 0 \qquad \forall w \in \mathbf{K}(\varphi, \psi). \end{aligned} \tag{2.2}$$

On the other hand, any $y \in W_2^{2,1}(Q) \cap L^2(0,T; H_0^1(\Omega))$ satisfying (2.1) must be a solution of (1.1). In fact, for any fixed $D \subset Q$ and any sequence $\{\chi_n\}$ of functions in $C_c^\infty(Q)$ satisfying $0 \le \chi_n \le 1$ and $\chi_n \to \chi_D$ (characteristic function of D) a.e. in Q, we can insert $w = y + \chi_n(\varphi - y)$ and $w = y + \chi_n(\psi - y)$ into (2.2), and then get

$$\int_Q (y_t - \Delta y - f)\chi_n(\varphi - y)dxdt \ge 0, \quad \int_Q (y_t - \Delta y - f)\chi_n(\psi - y)dxdt \ge 0. \tag{2.3}$$

So, by letting $n \to \infty$ in (2.3) we obtain that

$$\int_D (y_t - \Delta y - f)(\varphi - y)dxdt \ge 0 \quad \text{and} \quad \int_D (y_t - \Delta y - f)(\psi - y)dxdt \ge 0.$$

Hence the last two inequalities in (1.1) follow directly from the arbitrariness of D. ∎

Clearly, (2.1) is a weak formulation of the bilateral variational problem (1.1).

2.2. Approximation to the state. The objective functional $J(\varphi,\psi)$ defined by (1.4) is not smooth, which will cause difficulties for deriving an optimal system for Problem (C), so we approximate it by a smooth functional. For this purpose, we define

$$\beta(s)=\begin{cases}0, & 0\le s<+\infty,\\ -s^2, & -\frac{1}{2}\le s<0,\\ s+\frac{1}{4}, & -\infty<s<-\frac{1}{2},\end{cases}$$

$$\gamma(s)=\begin{cases}0, & -\infty<s<0,\\ s^2, & 0\le s<\frac{1}{2},\\ s-\frac{1}{4}, & \frac{1}{2}\le s<+\infty\end{cases}$$

and introduce a family of approximations to the state equation (2.1):

$$\begin{cases} y_t^\epsilon-\Delta y^\epsilon+\frac{1}{\epsilon}[\beta(y^\epsilon-\varphi)+\gamma(y^\epsilon-\psi)]=f(x,t,y^\epsilon) & \text{in } Q,\\ y^\epsilon|_\Sigma=0,\ y^\epsilon|_{t=0}=y_0.\end{cases}\tag{2.4}$$

For any given $(\varphi,\psi)\in\mathcal{U}$ and $\epsilon>0$, (2.4) is uniquely solvable in W. This unique solution is denoted by $y^\epsilon=\mathcal{S}^\epsilon(\varphi,\psi)$.

We consider the $W_p^{2,1}$-estimation and the convergence for approximate state y^ϵ in the following lemmas.

LEMMA 2.2. *For any $(\varphi,\psi)\in\mathcal{U}$ and $\epsilon>0$, the following inequality always holds:*

$$\|y^\epsilon\|_{W_p^{2,1}(Q)}\le C\left(1+\|\varphi\|_{W_p^{2,1}(Q)}+\|\psi\|_{W_p^{2,1}(Q)}\right),\tag{2.5}$$

where C is a constant independent of $\epsilon>0$ and $(\varphi,\psi)\in\mathcal{U}$.

Proof. To obtain (2.5), it suffices to prove the two estimates

$$\|\beta(y^\epsilon-\varphi)\|_{L^p(Q)}\le\epsilon C\left(1+\|\varphi\|_{W_p^{2,1}(Q)}\right),\tag{2.6}$$

$$\|\gamma(y^\epsilon-\psi)\|_{L^p(Q)}\le\epsilon C\left(1+\|\psi\|_{W_p^{2,1}(Q)}\right),\tag{2.7}$$

since (2.5) follows immediately from (2.6)–(2.7) and the standard parabolic L^P-estimate (cf. [19]).

Define, for $s\in\mathcal{R}$, $B(s)=|\beta(s)|^{p-2}\beta(s)$ and $\Gamma(s)=|\gamma(s)|^{p-2}\gamma(s)$. Then we have

$$B(s)\le 0\quad\text{and}\quad\Gamma(s)\ge 0\qquad\forall s\in\mathcal{R},\tag{2.8}$$

$$B(s)=0\ \forall s\ge 0\quad\text{and}\quad\Gamma(s)=0\ \forall s\le 0,\tag{2.9}$$

$$B'(s)=(p-1)|\beta(s)|^{p-2}\beta'(s)\ge 0\quad\text{and}\quad\Gamma'(s)=(p-1)|\gamma(s)|^{p-2}\gamma'(s)\ge 0.\tag{2.10}$$

Let

$$\Phi(s)=\int_0^s B(\tau)d\tau.$$

By (2.8)–(2.10), we further have

$$\Phi(s) \geq 0, \quad \Phi'(s) = B(s) \leq 0 \quad \text{in } \mathcal{R}; \quad \Phi(s) = 0 \quad \text{in } \mathcal{R}^+.$$

Thus, we easily get

$$\begin{aligned} &\int_Q [(y^\epsilon - \varphi)_t B(y^\epsilon - \varphi) + \nabla(y^\epsilon - \varphi) \cdot \nabla B(y^\epsilon - \varphi)] dxdt \\ &\quad = \int_\Omega \Phi(y^\epsilon - \varphi)|_{t=T} dx + \int_Q B'(y^\epsilon - \varphi)|\nabla(y^\epsilon - \varphi)|^2 dxdt \\ &\quad \geq 0. \end{aligned} \tag{2.11}$$

Under assumption (ii) of the introduction, f is decreasing in y, so using (2.8)–(2.9) we have that

$$\int_Q f(x,t,y^\epsilon) B(y^\epsilon - \varphi) dxdt \leq \int_Q f(x,t,\varphi) B(y^\epsilon - \varphi) dxdt. \tag{2.12}$$

Note that (2.9) implies

$$B(y^\epsilon - \varphi)\gamma(y^\epsilon - \psi) = 0 \qquad \text{a.e. in } Q,$$

so we can multiply (2.4) by $\epsilon B(y^\epsilon - \varphi)$, integrate it over Q, and then get

$$\begin{aligned} &\epsilon \int_Q [y_t^\epsilon B(y^\epsilon - \varphi) + \nabla y^\epsilon \cdot \nabla B(y^\epsilon - \varphi)] dxdt + \int_Q |\beta(y^\epsilon - \varphi)|^p dxdt \\ &\qquad = \epsilon \int_Q f(x,t,y^\epsilon) B(y^\epsilon - \varphi) dxdt. \end{aligned} \tag{2.13}$$

Furthermore, from (2.13) using (2.11)–(2.12) and Hölder's inequality we can deduce that

$$\begin{aligned} &\|\beta(y^\epsilon - \varphi)\|^p_{L^p(Q)} \\ &\quad \leq \epsilon \int_Q \{f(x,t,\varphi) B(y^\epsilon - \varphi) - [\varphi_t B(y^\epsilon - \varphi) + \nabla\varphi \cdot \nabla B(y^\epsilon - \varphi)]\} dxdt \\ &\quad = \epsilon \int_Q [f(x,t,\varphi) - \varphi_t + \Delta\varphi] B(y^\epsilon - \varphi) dxdt \\ &\quad \leq \epsilon [\|f(\cdot,\cdot,\varphi(\cdot,\cdot))\|_{L^p(Q)} + \|\varphi\|_{W^{2,1}_p(Q)}] \, \|\beta(y^\epsilon - \varphi)\|^{p-1}_{L^p(Q)}. \end{aligned}$$

Finally, because (1.2) and (1.3) hold, we get

$$|f(x,t,\varphi(x,t))| \leq |f(x,t,0)| + |f(x,t,\varphi(x,t)) - f(x,t,0)| \leq K[1 + |\varphi(x,t)|] \tag{2.14}$$

and then

$$\|f(\cdot,\cdot,\varphi(\cdot,\cdot))\|_{L^p(Q)} \leq C \left(1 + \|\varphi\|_{W^{2,1}_p(Q)}\right) \tag{2.15}$$

with C being independent of $\epsilon > 0$ and φ. Thus, (2.6) follows.

The inequality (2.7) can be obtained similarly. □

LEMMA 2.3. *Given a sequence of obstacle pairs* $(\varphi^\epsilon, \psi^\epsilon) \in \mathcal{U}$, *let* $y^\epsilon = \mathcal{S}^\epsilon(\varphi^\epsilon, \psi^\epsilon)$. *If the sequence* $\{(\varphi^\epsilon, \psi^\epsilon)\}$ *is bounded in* $W_p^{2,1}(Q) \times W_p^{2,1}(Q)$ *with* $p > (n+2)/2$, *then for some subsequences (still denoted by themselves), as* $\epsilon \to 0^+$,

$$\left.\begin{array}{l} \varphi^\epsilon \to \varphi \\ \psi^\epsilon \to \psi \\ y^\epsilon \to y \end{array}\right\} \text{weakly in } W_p^{2,1}(Q) \text{ and strongly in } C^{\theta,\theta/2}(\bar{Q}) \cap L^2(0,T;H_0^1(\Omega))$$

for some $\theta \in (0,1)$, *where* $(\varphi, \psi) \in \mathcal{U}$ *and* $y = \mathcal{S}(\varphi, \psi)$.

Proof. First, by Simon's compactness lemma (cf. [25]), we know that, if $p > (n+2)/2$, any bounded subset of $W_p^{2,1}(Q)$ is relatively compact in $C^{\theta,\theta/2}(\bar{Q}) \cap L^2(0,T;H_0^1(\Omega))$ for some $\theta \in (0,1)$. Thus, we can extract a subsequence (still denoted by itself) by virtue of (2.5) such that

$$\left.\begin{array}{l} \varphi^\epsilon \to \varphi \\ \psi^\epsilon \to \psi \\ y^\epsilon \to y \end{array}\right\} \text{weakly in } W_p^{2,1}(Q) \text{ and strongly in } C^{\theta,\theta/2}(\bar{Q}) \cap L^2(0,T;H_0^1(\Omega)).$$

Obviously, $(\varphi, \psi) \in \mathcal{U}$.

Next, by using (2.6), (2.7), the strong convergence of $(\varphi^\epsilon, \psi^\epsilon, y^\epsilon)$ to (φ, ψ, y) in $C^{\theta,\theta/2}(\bar{Q})$, and the definition of $\beta(\cdot)$ and $\gamma(\cdot)$, we also have (as $\epsilon \to 0^+$)

$$\beta(y^\epsilon - \varphi^\epsilon) + \gamma(y^\epsilon - \psi^\epsilon) \to 0 \quad \text{in } L^p(Q),$$

$$\beta(y - \varphi) + \gamma(y - \psi) = 0 \qquad \text{a.e. in } Q,$$

and

$$\varphi(x,t) \le y(x,t) \le \psi(x,t) \qquad \text{a.e. in } Q.$$

Clearly, $y|_{t=0} = y_0$. Hence, $y \in \mathbf{K}(\varphi, \psi)$.

For any $w \in \mathbf{K}(\varphi, \psi)$, let $w^\epsilon = \sup(\varphi^\epsilon, \inf(\psi^\epsilon, w))$. Since $\beta(y^\epsilon - \varphi^\epsilon)$ can differ from 0 only when $y^\epsilon < \varphi^\epsilon \le w^\epsilon$, and $\gamma(y^\epsilon - \psi^\epsilon)$ can differ from 0 only when $y^\epsilon > \psi^\epsilon \ge w^\epsilon$, we deduce from (2.4) that

$$\begin{aligned} &\int_Q [y_t^\epsilon(w^\epsilon - y^\epsilon) + \nabla y^\epsilon \cdot \nabla(w^\epsilon - y^\epsilon)]dxdt \\ &= -\frac{1}{\epsilon}\int_Q [\beta(y^\epsilon - \varphi^\epsilon) + \gamma(y^\epsilon - \psi^\epsilon)](w^\epsilon - y^\epsilon)dxdt + \int_Q f(x,t,y^\epsilon)(w^\epsilon - y^\epsilon)dxdt \\ &\ge \int_Q f(x,t,y^\epsilon)(w^\epsilon - y^\epsilon)dxdt. \end{aligned}$$

Then letting $\epsilon \to 0^+$ in the above inequality, we obtain that $y = \lim_{\epsilon \to 0^+} y^\epsilon$ satisfies (2.1). Hence, $y = \mathcal{S}(\varphi, \psi)$. ∎

2.3. Unique solvability of the state system. As claimed in the introduction, the state system (1.1) is uniquely solvable, and we prove this point in this subsection.

PROPOSITION 2.4. *For any given* $(\varphi, \psi) \in \mathcal{U}$, *the state system* (1.1) *is uniquely solvable. Moreover, let* $y = \mathcal{S}(\varphi, \psi)$; *then*

$$\|y\|_{W_p^{2,1}(Q)} \le C\left(1 + \|\varphi\|_{W_p^{2,1}(Q)} + \|\psi\|_{W_p^{2,1}(Q)}\right), \tag{2.16}$$

where C is a constant independent of $(\varphi, \psi) \in \mathcal{U}$.

Proof. Choose $(\varphi^\epsilon, \psi^\epsilon) \equiv (\varphi, \psi)$ and let $y^\epsilon = \mathcal{S}^\epsilon(\varphi, \psi)$; then Lemma 2.3 gives

$$y^\epsilon \to y = \mathcal{S}(\varphi, \psi),$$

and thus (2.16) follows from Lemma 2.2.

To prove the uniqueness, let y_i $(i = 1, 2)$ be two weak solutions of the state system (1.1). Taking y_2 (resp., y_1) as a test function, substituting it into inequality (2.1) of y_1 (resp., y_2), and then adding, we get

$$\frac{1}{2}\int_\Omega (y_1 - y_2)^2|_{t=T} dx + \int_Q |\nabla(y_1 - y_2)|^2 dxdt \le \int_Q [f(x,t,y_1) - f(x,t,y_2)](y_1 - y_2) dxdt.$$

By assumption (ii) of the introduction, the integral on the right-hand side is nonpositive, so we can assert that

$$\|y_1 - y_2\|_{L^2(0,T;H_0^1(\Omega))} = 0,$$

i.e.,

$$y_1(x,t) = y_2(x,t) \qquad \text{a.e. in } Q. \qquad \square$$

3. Main results. In this section we establish our main results, which are the existence and the optimality system for Problem (C).

In our cost functional (1.4), there appears the Laplacian together with the t-derivative of the control (obstacle), which provides a certain compactness of the control. As a direct result, the existence of the optimal control is almost routine. Consequently, the following existence theorem for Problem (C) can be obtained by some standard ideas with some suitable variational inequality techniques.

THEOREM 3.1. *Problem* (C) *has at least one pair of optimal obstacles* $(\bar\varphi, \bar\psi) \in \mathcal{U}$.

Let $(\bar\varphi, \bar\psi)$ be an optimal pair for Problem (C) and let $\bar y = \mathcal{S}(\bar\varphi, \bar\psi)$. We first introduce a family of approximate control problems.

PROBLEM (C^ϵ). *Find a pair* $(\varphi^\epsilon, \psi^\epsilon) \in \mathcal{U}$ *such that*

$$J^\epsilon(\varphi^\epsilon, \psi^\epsilon) = \inf_{(\varphi,\psi)\in\mathcal{U}} J^\epsilon(\varphi, \psi),$$

where

$$J^\epsilon(\varphi,\psi) = \int_Q \Big\{ \frac{1}{2}(y^\epsilon - z_d)^2 + \frac{1}{p}[|\varphi_t|^p + |\Delta\varphi|^p + |\psi_t|^p + |\Delta\psi|^p + |\varphi - \bar\varphi|^p + |\psi - \bar\psi|^p] \Big\} dxdt$$

with $y^\epsilon = \mathcal{S}^\epsilon(\varphi, \psi)$ *being the approximate state solving* (2.4).

As an analogy to Problem (C), we have the following.

PROPOSITION 3.2. *There exists an optimal control pair* $(\varphi^\epsilon, \psi^\epsilon) \in \mathcal{U}$ *for Problem* (C^ϵ).

Before deriving the optimality system for Problem (C^ϵ) *we need a support result on the Gâteaux-differentiability of the approximate state operator* $\mathcal{S}^\epsilon$.

LEMMA 3.3. *For any fixed* $\epsilon > 0$, *the solution mapping* $\mathcal{S}^\epsilon : (\varphi, \psi) \mapsto y^\epsilon$ *of* (2.4) *is differentiable in the following sense:*

Given $(\varphi,\psi)\in\mathcal{U}$, *for any* $(u,\,v)\in\mathcal{U}$,

$$\frac{\mathcal{S}^\epsilon(\varphi+\delta(u-\varphi),\psi+\delta(v-\psi))-\mathcal{S}^\epsilon(\varphi,\psi)}{\delta}\to\xi^\epsilon \qquad \textit{weakly in } W$$

as $\delta\to 0^+$, *where* ξ^ϵ *satisfies*

$$\text{(3.1)}\qquad \begin{cases} \xi^\epsilon_t-\Delta\xi^\epsilon+\{\frac{1}{\epsilon}[\beta'(y^\epsilon-\varphi)+\gamma'(y^\epsilon-\psi)]-f_y(x,t,y^\epsilon)\}\xi^\epsilon \\ \qquad\qquad =\frac{1}{\epsilon}[\beta'(y^\epsilon-\varphi)(u-\varphi)+\gamma'(y^\epsilon-\psi)(v-\psi)] \qquad \textit{in } Q,\\ \xi^\epsilon|_{\partial_pQ}=0. \end{cases}$$

Proof. The proof is standard and tedious. We omit it here. □

PROPOSITION 3.4. *Assume* $(\varphi^\epsilon,\psi^\epsilon)$ *is an optimal solution to Problem* (C^ϵ) *and* $y^\epsilon=\mathcal{S}^\epsilon(\varphi^\epsilon,\psi^\epsilon)$. *Then, there exists* $p^\epsilon\in L^2(0,T;H_0^1(\Omega))$ *such that the following optimality system is satisfied:*

$$\text{(3.2)}\qquad \begin{cases} y^\epsilon_t-\Delta y^\epsilon+\frac{1}{\epsilon}[\beta(y^\epsilon-\varphi^\epsilon)+\gamma(y^\epsilon-\psi^\epsilon)]=f(x,t,y^\epsilon) \qquad \textit{in } Q,\\ y^\epsilon|_\Sigma=0,\ y^\epsilon|_{t=0}=y_0, \end{cases}$$

(3.3)

$$\begin{cases} -p^\epsilon_t-\Delta p^\epsilon+\{\frac{1}{\epsilon}[\beta'(y^\epsilon-\varphi^\epsilon)+\gamma'(y^\epsilon-\psi^\epsilon)]-f_y(x,t,y^\epsilon)\}p^\epsilon=y^\epsilon-z_d \quad \textit{in } Q,\\ p^\epsilon|_\Sigma=0,\\ p^\epsilon|_{t=T}=0, \end{cases}$$

and

(3.4)

$$\begin{aligned}\int_Q\Bigg\{&\left[\frac{1}{\epsilon}\beta'(y^\epsilon-\varphi^\epsilon)p^\epsilon+|\varphi^\epsilon-\bar\varphi|^{p-2}(\varphi^\epsilon-\bar\varphi)\right](\varphi-\varphi^\epsilon)\\ &+\left[\frac{1}{\epsilon}\gamma'(y^\epsilon-\psi^\epsilon)p^\epsilon+\ |\psi^\epsilon-\bar\psi|^{p-2}(\psi^\epsilon-\bar\psi)\right](\psi-\psi^\epsilon)\\ &+[|\varphi^\epsilon_t|^{p-2}\varphi^\epsilon_t(\varphi-\varphi^\epsilon)_t+|\Delta\varphi^\epsilon|^{p-2}\Delta\varphi^\epsilon\Delta(\varphi-\varphi^\epsilon)]\\ &+[|\psi^\epsilon_t|^{p-2}\psi^\epsilon_t(\psi-\psi^\epsilon)_t+|\Delta\psi^\epsilon|^{p-2}\Delta\psi^\epsilon\Delta(\psi-\psi^\epsilon)]\Bigg\}dxdt\ge 0\end{aligned}$$

$$\forall(\varphi,\psi)\in\mathcal{U}.$$

Proof. Let $(\varphi^\epsilon,\psi^\epsilon)\in\mathcal{U}$ be an optimal control pair for Problem (C^ϵ) and let $y^\epsilon=\mathcal{S}^\epsilon(\varphi^\epsilon,\psi^\epsilon)$. For any given $(\varphi,\psi)\in\mathcal{U}$, as $(\varphi^\epsilon,\psi^\epsilon)$ is optimal to Problem (C^ϵ), we have

$$\begin{aligned} 0 &\le \liminf_{\delta\to 0}\ \delta^{-1}[J^\epsilon(\varphi^\epsilon+\delta(\varphi-\varphi^\epsilon),\psi^\epsilon+\delta(\psi-\psi^\epsilon))-J^\epsilon(\varphi^\epsilon,\psi^\epsilon)]\\ &= \int_Q\{(y^\epsilon-z_d)\xi^\epsilon+[|\varphi^\epsilon_t|^{p-2}\varphi^\epsilon_t(\varphi-\varphi^\epsilon)_t+|\Delta\varphi^\epsilon|^{p-2}\Delta\varphi^\epsilon\Delta(\varphi-\varphi^\epsilon)]\\ &\qquad+[|\psi^\epsilon_t|^{p-2}\psi^\epsilon_t(\psi-\psi^\epsilon)_t+|\Delta\psi^\epsilon|^{p-2}\Delta\psi^\epsilon\Delta(\psi-\psi^\epsilon)]\\ &\qquad+[|\varphi^\epsilon-\bar\varphi|^{p-2}(\varphi^\epsilon-\bar\varphi)(\varphi-\varphi^\epsilon)+|\psi^\epsilon-\bar\psi|^{p-2}(\psi^\epsilon-\bar\psi)(\psi-\psi^\epsilon)]\}dxdt,\end{aligned}$$

where ξ^ϵ satisfies

$$\text{(3.5)}\qquad \begin{cases} \xi^\epsilon_t-\Delta\xi^\epsilon+\{\frac{1}{\epsilon}[\beta'(y^\epsilon-\varphi^\epsilon)+\gamma'(y^\epsilon-\psi^\epsilon)]-f_y(x,t,y^\epsilon)\}\xi^\epsilon\\ \qquad\qquad =\frac{1}{\epsilon}[\beta'(y^\epsilon-\varphi^\epsilon)(\varphi-\varphi^\epsilon)+\gamma'(y^\epsilon-\psi^\epsilon)(\psi-\psi^\epsilon)] \qquad \text{in } Q,\\ \xi^\epsilon|_{\partial_pQ}=0. \end{cases}$$

Let $p^\epsilon \in W$ be the unique solution of linear equation (3.3). Then, using (3.3) and (3.5) we get that

$$\int_Q (y^\epsilon - z_d)\xi^\epsilon dxdt = \int_Q \tfrac{1}{\epsilon} p^\epsilon [\beta'(y^\epsilon - \varphi^\epsilon)(\varphi - \varphi^\epsilon) + \gamma'(y^\epsilon - \psi^\epsilon)(\psi - \psi^\epsilon)]dxdt.$$

So (3.4) follows. □

With respect to the approximate optimality condition (3.4), we give the following remarks, which are crucial in deriving the optimality system for the original Problem (C).

Remark 1. Using the so-called monotonicity inequality (cf. [16]),

$$(|a|^{p-2}a - |b|^{p-2}b)(a-b) \geq 0 \qquad (a, b \in \mathcal{R}),$$

we can deduce from (3.4) that

$$\begin{aligned}(3.6)\qquad \int_Q \Big\{ & \left[\frac{1}{\epsilon}\beta'(y^\epsilon - \varphi^\epsilon)p^\epsilon + |\varphi^\epsilon - \bar\varphi|^{p-2}(\varphi^\epsilon - \bar\varphi)\right](\varphi - \varphi^\epsilon) \\ & + \left[\frac{1}{\epsilon}\gamma'(y^\epsilon - \psi^\epsilon)p^\epsilon + |\psi^\epsilon - \bar\psi|^{p-2}(\psi^\epsilon - \bar\psi)\right](\psi - \psi^\epsilon) \\ & + [|\varphi_t|^{p-2}\varphi_t(\varphi - \varphi^\epsilon)_t + |\Delta\varphi|^{p-2}\Delta\varphi\Delta(\varphi - \varphi^\epsilon)] \\ & + [|\psi_t|^{p-2}\psi_t(\psi - \psi^\epsilon)_t + |\Delta\psi|^{p-2}\Delta\psi\Delta(\psi - \psi^\epsilon)]\Big\}dxdt \geq 0 \\ & \forall (\varphi, \psi) \in \mathcal{U}.\end{aligned}$$

Remark 2. For any $w \in \dot W_p^{2,1}(Q)$, by inserting $\varphi = \varphi^\epsilon + w$ and $\psi = \psi^\epsilon + w$ into inequality (3.4), we get

$$\begin{aligned}(3.7)\qquad \int_Q \Big\{ & \left[\frac{1}{\epsilon}(\beta'(y^\epsilon - \varphi^\epsilon) + \gamma'(y^\epsilon - \psi^\epsilon))p^\epsilon + |\varphi^\epsilon - \bar\varphi|^{p-2}(\varphi^\epsilon - \bar\varphi) + |\psi^\epsilon - \bar\psi|^{p-2}(\psi^\epsilon - \bar\psi)\right] w \\ & + [|\varphi_t^\epsilon|^{p-2}\varphi_t^\epsilon + |\psi_t^\epsilon|^{p-2}\psi_t^\epsilon]w_t \\ & + [|\Delta\varphi^\epsilon|^{p-2}\Delta\varphi^\epsilon + |\Delta\psi^\epsilon|^{p-2}\Delta\psi^\epsilon]\Delta w\Big\}dxdt = 0 \\ & \forall w \in \dot W_p^{2,1}(Q).\end{aligned}$$

The equality in (3.7), instead of the inequality, is due to the arbitrariness of w.

The relationship between Problems (C) and (C$^\epsilon$) is revealed in the following proposition.

PROPOSITION 3.5. *Let $(\varphi^\epsilon, \psi^\epsilon) \in \mathcal{U}$ be an optimal control pair for Problem* (C$^\epsilon$) *and let $y^\epsilon = \mathcal{S}^\epsilon(\varphi^\epsilon, \psi^\epsilon)$. Then, for $p > (n+2)/2$,*

$$\left.\begin{array}{l}\varphi^\epsilon \to \bar\varphi \\ \psi^\epsilon \to \bar\psi \\ y^\epsilon \to \bar y\end{array}\right\} \text{ weakly in } W_p^{2,1}(Q) \text{ and strongly in } C^{\theta,\theta/2}(\bar Q) \cap L^2(0,T;H_0^1(\Omega)),$$

and

$$\lim_{\epsilon \to 0^+} J^\epsilon(\varphi^\epsilon, \psi^\epsilon) = J(\bar\varphi, \bar\psi),$$

where $\theta \in (0,1)$ and $(\bar{\varphi}, \bar{\psi}) \in \mathcal{U}$ is the optimal control pair for Problem (C) *given at the beginning of this subsection and $\bar{y} = \mathcal{S}(\bar{\varphi}, \bar{\psi})$ is the corresponding optimal state.*

Proof. First, Lemma 2.2 yields

$$J^\epsilon(\varphi^\epsilon, \psi^\epsilon) \le J^\epsilon(\bar{\varphi}, \bar{\psi}) \le C\left(1 + \|\bar{\varphi}\|_{W_p^{2,1}(Q)} + \|\bar{\psi}\|_{W_p^{2,1}(Q)}\right).$$

So, $(\varphi^\epsilon, \psi^\epsilon)$ is bounded in $W_p^{2,1}(Q) \times W_p^{2,1}(Q)$, due to the form of the functional J^ϵ.

Then, by Lemma 2.3, for some subsequences (still denoted by themselves) and some $\theta \in (0,1)$,

$$\left.\begin{array}{l} \varphi^\epsilon \to \varphi^* \\ \psi^\epsilon \to \psi^* \\ y^\epsilon \to y^* \end{array}\right\} \text{ weakly in } W_p^{2,1}(Q) \text{ and strongly in } C^{\theta,\theta/2}(\bar{Q}) \cap L^2(0,T; H_0^1(\Omega)),$$

where $(\varphi^*, \psi^*) \in \mathcal{U}$ and $y^* = \mathcal{S}(\varphi^*, \psi^*)$.

Next, from the weak lower semicontinuity of the L^p-norm, we have

(3.8)

$$\begin{aligned} &J(\varphi^*, \psi^*) \\ &\le J(\varphi^*, \psi^*) + \frac{1}{p}\int_Q \left\{|\varphi^* - \bar{\varphi}|^p + |\psi^* - \bar{\psi}|^p\right\} dxdt \\ &= \int_Q \left\{\frac{1}{2}(y^* - z_d)^2 + \frac{1}{p}[|\varphi_t^*|^p + |\Delta\varphi^*|^p + |\psi_t^*|^p + |\Delta\psi^*|^p + |\varphi^* - \bar{\varphi}|^p \right. \\ &\qquad \left. + |\psi^* - \bar{\psi}|^p]\right\} dxdt \\ &\le \liminf_{\epsilon\to 0} J^\epsilon(\varphi^\epsilon, \psi^\epsilon) \\ &\le \limsup_{\epsilon\to 0} J^\epsilon(\varphi^\epsilon, \psi^\epsilon) \\ &\le \lim_{\epsilon\to 0} J^\epsilon(\bar{\varphi}, \bar{\psi}) \\ &= J(\bar{\varphi}, \bar{\psi}). \end{aligned}$$

On the other hand, $(\bar{\varphi}, \bar{\psi})$ is optimal to Problem (C), and then $J(\bar{\varphi}, \bar{\psi}) \le J(\varphi^*, \psi^*)$. Thus, all the equalities in (3.9) must hold. This means that

$$\int_Q \left\{|\varphi^* - \bar{\varphi}|^p + |\psi^* - \bar{\psi}^p\right\} dxdt = 0;$$

i.e., $\varphi^* = \bar{\varphi}$ and $\psi^* = \bar{\psi}$. By the unique solvability of the state variational inequality (1.1), we get $y^* = \bar{y}$. In addition, we see that

$$\lim_{\epsilon\to 0^+} J^\epsilon(\varphi^\epsilon, \psi^\epsilon) = J(\bar{\varphi}, \bar{\psi}).$$

Finally, the uniqueness of limit point implies the convergence of the whole sequence of $(\varphi^\epsilon, \psi^\epsilon)$ and the whole sequence of y^ϵ as well. The proof is completed. ∎

We are now ready to present the optimality system for Problem (C).

THEOREM 3.6. *Let $(\bar{\varphi}, \bar{\psi})$ be an optimal control pair for Problem* (C) *and let $\bar{y} = \mathcal{S}(\bar{\varphi}, \bar{\psi})$. Then for $p > (n+2)/2$, there exist $\bar{p} \in L^2(0,T; H_0^1(\Omega))$ and $\bar{\mu} \in \mathcal{M}_0(\bar{Q})$*

satisfying[1]

$$\begin{cases} -\bar{p}_t - \Delta\bar{p} - f_y(x,t,\bar{y})\bar{p} = \bar{y} - z_d - \bar{\mu} & \text{in } Q, \\ \bar{p}|_\Sigma = 0, \\ \bar{p}|_{t=T} = 0, \end{cases} \tag{3.9}$$

with

$$\operatorname{supp}\bar{\mu} \subset \{(x,t) \in Q | \quad \bar{y}(x,t) = \bar{\varphi}(x,t) \quad \text{or} \quad \bar{y}(x,t) = \bar{\psi}(x,t)\}; \tag{3.10}$$

$$\begin{aligned} \operatorname{supp}[\bar{y}_t - \Delta\bar{y} - f(x,t,\bar{y})] \subset \{(x,t) \in Q | \quad & \bar{y}(x,t) = \bar{\varphi}(x,t) \quad \text{or} \\ & \bar{y}(x,t) = \bar{\psi}(x,t)\} \end{aligned} \tag{3.11}$$

such that

$$\int_Q [(|\bar{\varphi}_t|^{p-2}\bar{\varphi}_t + |\bar{\psi}_t|^{p-2}\bar{\psi}_t)w_t + (|\Delta\bar{\varphi}|^{p-2}\Delta\bar{\varphi} + |\Delta\bar{\psi}|^{p-2}\Delta\bar{\psi})\Delta w]dxdt + \langle\bar{\mu}, w\rangle = 0 \tag{3.12}$$

$$\forall w \in \dot{W}_p^{2,1}(Q)$$

and

$$\int_Q [\bar{y}_t - \Delta\bar{y} - f(x,t,\bar{y})]\bar{p}dxdt = 0. \tag{3.13}$$

Moreover,

$$-\bar{y}_t + \Delta\bar{y} + f(x,t,\bar{y}) = \bar{\lambda}_\varphi + \bar{\lambda}_\psi$$

with

$$\langle\bar{\lambda}_\varphi, \bar{y} - \bar{\varphi}\rangle = 0; \qquad \langle\bar{\lambda}_\psi, \bar{y} - \bar{\psi}\rangle = 0; \tag{3.14}$$

$$\operatorname{supp}\bar{\lambda}_\varphi \subset \{(x,t) \in Q | \, \bar{y}(x,t) = \bar{\varphi}(x,t)\}; \ \operatorname{supp}\bar{\lambda}_\psi \subset \{(x,t) \in Q | \, \bar{y}(x,t) = \bar{\psi}(x,t)\}; \tag{3.15}$$

and

$$\bar{\mu} = \bar{\mu}_\varphi + \bar{\mu}_\psi$$

with

$$\langle\bar{\mu}_\varphi, \bar{y} - \bar{\varphi}\rangle = 0; \qquad \langle\bar{\mu}_\psi, \bar{y} - \bar{\psi}\rangle = 0; \tag{3.16}$$

[1] According to [2], the function $\bar{p} \in L^2(0,T; H_0^1(\Omega))$ solves (3.9) in the sense that

$$\int_Q [\bar{p}\chi_t + \nabla\bar{p}\cdot\nabla\chi - f_y(x,t,\bar{y})\bar{p}\chi - (\bar{y} - z_d)\chi]\,dxdt + \langle\bar{\mu},\chi\rangle = 0 \quad \forall\chi \in \dot{W}_p^{2,1}(Q),$$

or equivalently,

$$\int_Q [\bar{p}\chi_t + \nabla\bar{p}\cdot\nabla\chi - f_y(x,t,\bar{y})\bar{p}\chi]\,dxdt = \int_Q (\bar{y} - z_d)\chi\,dxdt - \langle\bar{\mu},\chi\rangle \quad \forall\chi \in \dot{W}_p^{2,1}(Q).$$

(3.17)
$$\operatorname{supp}\bar{\mu}_\varphi \subset \{(x,t)\in Q|\, \bar{y}(x,t) = \bar{\varphi}(x,t)\};\ \operatorname{supp}\bar{\mu}_\psi \subset \{(x,t)\in Q|\, \bar{y}(x,t) = \bar{\psi}(x,t)\}.$$

Remark. In the above optimality system, (3.9) and (3.13) are referred to as the adjoint equation and the optimality condition, respectively. The condition (3.10) is understood as the following: For any $\eta \in C_0(\bar{Q}) = \{\eta \in C(\bar{Q})|\, \eta|_\Sigma = 0\}$ with $\operatorname{supp}\eta \subset Q' = \{(x,t)\in Q|\, \bar{\varphi}(x,t) < \bar{y}(x,t) < \bar{\psi}(x,t)\}$,

$$\langle \bar{\mu},\, \eta\rangle_{\mathcal{M}_0(\bar{Q}),\, C_0(\bar{Q})} = 0,$$

where $\mathcal{M}_0(\bar{Q}) = C_0(\bar{Q})^*$ is the set of all regular signed measures on $\bar{Q}$ with the support contained in $Q \cup (\Omega \times \{0,T\})$.

Proof. Let $(\bar{y},\bar{\varphi},\bar{\psi})$ be an optimal triple to Problem (C). Consider the approximate Problem (C^ϵ) related to $(\bar{y},\bar{\varphi},\bar{\psi})$. Let $(y^\epsilon,\varphi^\epsilon,\psi^\epsilon)$ be any optimal triple to Problem (C^ϵ). Then, by Proposition 3.4, (3.4) holds (furthermore, (3.6) and (3.7) also hold) for some $p^\epsilon \in L^2(0,T;H_0^1(\Omega))$ which satisfies (3.3). Note that by $\beta' \geq 0$, $\gamma' \geq 0$, and $f_y \leq 0$ (cf. assumption (ii) of the introduction), one can easily get the following estimate from (3.3):

$$\|p^\epsilon\|_{L^2(0,T;H_0^1(\Omega))} \leq C,$$

where C is independent of ϵ. This implies that for some subsequence,

$$p^\epsilon \rightharpoonup \bar{p} \qquad \text{weakly in } L^2(0,T;H_0^1(\Omega)). \tag{3.18}$$

Denote

$$\mu_\varphi^\epsilon = \frac{1}{\epsilon}\beta'(y^\epsilon-\varphi^\epsilon)p^\epsilon,\quad \mu_\psi^\epsilon = \frac{1}{\epsilon}\gamma'(y^\epsilon-\psi^\epsilon)p^\epsilon,\quad \mu^\epsilon = \mu_\varphi^\epsilon + \mu_\psi^\epsilon,$$

and let $S_\delta(\cdot)\in C^1(\mathcal{R})$ be a family of smooth approximations to the sign function and satisfy the following:

$$S_\delta'(r) \geq 0 \qquad \forall r\in\mathcal{R}$$

and

$$S_\delta(r) = \begin{cases} 1 & \text{if} \quad r>\delta,\\ 0 & \text{if} \quad r=0,\\ -1 & \text{if} \quad r<-\delta. \end{cases}$$

Then we can multiply (3.3) by $S_\delta(p^\epsilon)$ and integrate it over Q. As a result, we get

$$\int_Q \mu^\epsilon S_\delta(p^\epsilon)dxdt \leq C.$$

Moreover, by letting $\delta\to 0^+$ we have that

$$\|\mu^\epsilon\|_{L^1(Q)}\,(=\|\mu_\varphi^\epsilon\|_{L^1(Q)} + \|\mu_\psi^\epsilon\|_{L^1(Q)}) \leq C.$$

Thus, after extracting some subsequence if necessary, we can let

$$\left.\begin{array}{c} \mu_\varphi^\epsilon \rightharpoonup \bar{\mu}_\varphi \\ \mu_\psi^\epsilon \rightharpoonup \bar{\mu}_\psi \\ \mu^\epsilon \rightharpoonup \bar{\mu} \end{array}\right\} \text{weakly}^\star \text{ in } \mathcal{M}_0(\bar{Q}), \tag{3.19}$$

where $\bar{\mu} = \bar{\mu}_\varphi + \bar{\mu}_\psi$.

Multiplying (3.3) by any test function χ in $\dot{W}_p^{2,1}(Q)$, integrating it over Q, and then letting $\epsilon \to 0^+$, we get

$$\int_Q [\bar{p}\chi_t + \nabla\bar{p}\cdot\nabla\chi - f_y(x,t,\bar{y})\bar{p}\chi - (\bar{y}-z_d)\chi]\,dxdt + \langle\bar{\mu},\chi\rangle = 0 \quad \forall\chi \in \dot{W}_p^{2,1}(Q),$$

which shows that $\bar{p}$ solves (3.9).

Furthermore, by passing to the limit in (3.6) we have that

$$\begin{aligned}\langle\bar{\mu}_\varphi,\varphi-\bar{\varphi}\rangle &+ \langle\bar{\mu}_\psi,\psi-\bar{\psi}\rangle \\ &+\int_Q [|\varphi_t|^{p-2}\varphi_t(\varphi-\bar{\varphi})_t + |\Delta\varphi|^{p-2}\Delta\varphi\Delta(\varphi-\bar{\varphi}) \\ &\quad + |\psi_t|^{p-2}\psi_t(\psi-\bar{\psi})_t + |\Delta\psi|^{p-2}\Delta\psi\Delta(\psi-\bar{\psi})]dxdt \geq 0 \qquad \forall(\varphi,\psi)\in\mathcal{U}\end{aligned}$$

and consequently, by inserting $\varphi = \varphi^\epsilon + w$ and $\psi = \psi^\epsilon + w$ into the above inequality, we have that

(3.20)

$$\begin{aligned}&\langle\bar{\mu},w\rangle + \int_Q [|(\bar{\varphi}+w)_t|^{p-2}(\bar{\varphi}+w)_t + |(\bar{\psi}+w)_t|^{p-2}(\bar{\psi}+w)_t]w_t dxdt \\ &+\int_Q [|\Delta(\bar{\varphi}+w)|^{p-2}\Delta(\bar{\varphi}+w) + |\Delta(\bar{\psi}+w)|^{p-2}\Delta(\bar{\psi}+w)]\Delta w dxdt \geq 0 \ \forall w \in \dot{W}_p^{2,1}(Q).\end{aligned}$$

Note that for $p' = p/(p-1)$,

$$\||\varphi_t^\epsilon|^{p-2}\varphi_t^\epsilon + |\psi_t^\epsilon|^{p-2}\psi_t^\epsilon\|_{p'} \leq \|\varphi_t^\epsilon\|_p^{p-1} + \|\psi_t^\epsilon\|_p^{p-1} \leq C,$$

$$\||\Delta\varphi^\epsilon|^{p-2}\Delta\varphi^\epsilon + |\Delta\psi^\epsilon|^{p-2}\Delta\psi^\epsilon\|_{p'} \leq \|\Delta\varphi^\epsilon\|_p^{p-1} + \|\Delta\psi^\epsilon\|_p^{p-1} \leq C,$$

we may assume for some subsequence that

$$|\varphi_t^\epsilon|^{p-2}\varphi_t^\epsilon + |\psi_t^\epsilon|^{p-2}\psi_t^\epsilon \rightharpoonup F \quad \text{weakly in } L^{p'}(Q),$$

$$|\Delta\varphi^\epsilon|^{p-2}\Delta\varphi^\epsilon + |\Delta\psi^\epsilon|^{p-2}\Delta\psi^\epsilon \rightharpoonup G \quad \text{weakly in } L^{p'}(Q).$$

Taking the limit in (3.7), we obtain

$$\langle\bar{\mu},w\rangle + \int_Q (Fw_t + G\Delta w)dxdt = 0 \qquad \forall w \in \dot{W}_p^{2,1}(Q). \tag{3.21}$$

Now, to prove (3.13), we need only verify that

(3.22)

$$\begin{aligned}&\int_Q (F\chi_t + G\Delta\chi)dxdt \\ &= \int_Q [(|\bar{\varphi}_t|^{p-2}\bar{\varphi}_t + |\bar{\psi}_t|^{p-2}\bar{\psi}_t)\chi_t + (|\Delta\bar{\varphi}|^{p-2}\Delta\bar{\varphi} + |\Delta\bar{\psi}|^{p-2}\Delta\bar{\psi})\Delta\chi]dxdt \\ &\forall\chi \in \dot{W}_p^{2,1}(Q).\end{aligned}$$

In fact, by combining (3.21) and (3.21) we have that

(3.23)
$$\begin{aligned}&\int_Q (Fw_t + G\Delta w)dxdt\\ &\quad\le \int_Q [|(\bar\varphi + w)_t|^{p-2}(\bar\varphi + w)_t + |(\bar\psi + w)_t|^{p-2}(\bar\psi + w)_t]w_t dxdt\\ &\quad+\int_Q [|\Delta(\bar\varphi + w)|^{p-2}\Delta(\bar\varphi + w) + |\Delta(\bar\psi + w)|^{p-2}\Delta(\bar\psi + w)]\Delta w dxdt\\ &\quad\forall w\ \in \dot W_p^{2,1}(Q).\end{aligned}$$

For any given $\chi \in \dot W_p^{2,1}(Q)$, take $w = \kappa\chi$ ($\kappa \neq 0$) in (3.24), then divide it by κ. Finally, by letting $\kappa \to 0^+$ and $\kappa \to 0^-$, respectively, we get

$$\begin{aligned}&\int_Q (F\chi_t + G\Delta\chi)dxdt\\ &\quad\le \int_Q [(|\bar\varphi_t|^{p-2}\bar\varphi_t + |\bar\psi_t|^{p-2}\bar\psi_t)\chi_t + (|\Delta\bar\varphi|^{p-2}\Delta\bar\varphi + |\Delta\bar\psi|^{p-2}\Delta\bar\psi)\Delta\chi]dxdt\end{aligned}$$

and

$$\begin{aligned}&\int_Q (F\chi_t + G\Delta\chi)dxdt\\ &\quad\ge \int_Q [(|\bar\varphi_t|^{p-2}\bar\varphi_t + |\bar\psi_t|^{p-2}\bar\psi_t)\chi_t + (|\Delta\bar\varphi|^{p-2}\Delta\bar\varphi + |\Delta\bar\psi|^{p-2}\Delta\bar\psi)\Delta\chi]dxdt,\end{aligned}$$

respectively. Thus, (3.23) follows.

Denote

$$\lambda_\varphi^\epsilon = \frac{1}{\epsilon}\beta(y^\epsilon - \varphi^\epsilon), \quad \lambda_\psi^\epsilon = \frac{1}{\epsilon}\gamma(y^\epsilon - \psi^\epsilon), \quad \lambda^\epsilon = \lambda_\varphi^\epsilon + \lambda_\psi^\epsilon.$$

Recalling approximate equation (2.4), estimates (2.5)–(2.6), and Lemma 2.3, we know that

(3.24)
$$\left.\begin{array}{l}\lambda_\varphi^\epsilon \rightharpoonup \bar\lambda_\varphi\\ \lambda_\psi^\epsilon \rightharpoonup \bar\lambda_\psi\end{array}\right\} \quad \text{weakly in } L^p(Q),$$

$$\lambda^\epsilon = -y_t^\epsilon + \Delta y^\epsilon + f(x,t,y^\epsilon) \rightharpoonup -\bar y_t + \Delta\bar y + f(x,t,\bar y) \equiv \bar\lambda,$$

where $\bar\lambda = \bar\lambda_\varphi + \bar\lambda_\psi$.

Now, (3.13) is equivalent to

(3.25)
$$\int_Q \bar\lambda\,\bar p\,dxdt = 0,$$

which can be proved by the following steps:

(1) Prove

(3.26)
$$\langle\mu_\varphi^\epsilon,\, y^\epsilon - \varphi^\epsilon\rangle \to 0; \qquad \langle\mu_\psi^\epsilon,\, y^\epsilon - \psi^\epsilon\rangle \to 0$$

(which implies (3.16)).

As $\mu_\varphi^\epsilon = \frac{1}{\epsilon}\beta'(y^\epsilon - \varphi^\epsilon)p^\epsilon$ is different from zero only when $y^\epsilon - \varphi^\epsilon < 0$, we have

$$\langle \mu_\varphi^\epsilon,\, (y^\epsilon - \varphi^\epsilon)^+ \rangle = 0 \qquad \forall \epsilon > 0.$$

In addition, by (3.19) and Lemma 2.3, we have that

$$\langle \mu_\varphi^\epsilon,\, (y^\epsilon - \varphi^\epsilon)^- \rangle \to \langle \bar{\mu}_\varphi,\, (\bar{y} - \bar{\varphi})^- \rangle = \langle \bar{\mu}_\varphi,\, 0 \rangle = 0.$$

Hence,

$$\langle \bar{\mu}_\varphi, \bar{y} - \bar{\varphi} \rangle = \lim_{\epsilon \to 0^+} \langle \mu_\varphi^\epsilon,\, y^\epsilon - \varphi^\epsilon \rangle = 0.$$

The other assertion in (3.26) can be obtained similarly.

(2) Prove

$$\int_Q \lambda^\epsilon\, p^\epsilon\, dxdt \to 0. \tag{3.27}$$

By direct computation, we have

$$\int_Q \lambda_\psi^\epsilon\, p^\epsilon\, dxdt = \frac{1}{\epsilon}\int_Q \left[\left(y^\epsilon - \psi^\epsilon - \frac{1}{4} \right) \chi_{\{y^\epsilon - \psi^\epsilon \geq \frac{1}{2}\}} + (y^\epsilon - \psi^\epsilon)^2 \chi_{\{0 < y^\epsilon - \psi^\epsilon < \frac{1}{2}\}} \right] p^\epsilon\, dxdt$$

and

$$\langle \mu_\psi^\epsilon,\, y^\epsilon - \psi^\epsilon \rangle = \frac{1}{\epsilon}\int_Q [(y^\epsilon - \psi^\epsilon)\chi_{\{y^\epsilon - \psi^\epsilon \geq \frac{1}{2}\}} + 2(y^\epsilon - \psi^\epsilon)^2 \chi_{\{0 < y^\epsilon - \psi^\epsilon < \frac{1}{2}\}}]\, p^\epsilon\, dxdt.$$

Then

$$2\int_Q \lambda_\psi^\epsilon\, p^\epsilon\, dxdt - \langle \mu_\psi^\epsilon,\, y^\epsilon - \psi^\epsilon \rangle = \frac{1}{\epsilon}\int_Q \left(y^\epsilon - \psi^\epsilon - \frac{1}{2} \right) \chi_{\{y^\epsilon - \psi^\epsilon \geq \frac{1}{2}\}}\, p^\epsilon\, dxdt.$$

Noting the fact that

$$\frac{1}{4} \leq \left| y^\epsilon - \psi^\epsilon - \frac{1}{4} \right| \qquad \text{in } \left\{ y^\epsilon - \psi^\epsilon \geq \frac{1}{2} \right\},$$

we get by using (2.7) that

$$\frac{1}{4^p}\text{meas}\left\{ y^\epsilon - \psi^\epsilon \geq \frac{1}{2} \right\} \leq \int_Q \left| y^\epsilon - \psi^\epsilon - \frac{1}{4} \right|^p \chi_{\{y^\epsilon - \psi^\epsilon \geq \frac{1}{2}\}}\, dxdt \leq \|\gamma(y^\epsilon - \psi^\epsilon)\|_{L^p(Q)}^p \to 0.$$

Applying Hölder's inequality, we obtain

$$\begin{aligned}
&\left| 2\int_Q \lambda_\psi^\epsilon\, p^\epsilon\, dxdt - \langle \mu_\psi^\epsilon,\, y^\epsilon - \psi^\epsilon \rangle \right| \\
&\quad \leq \frac{1}{\epsilon}\left\| \left(y^\epsilon - \psi^\epsilon - \frac{1}{2} \right) \chi_{\{y^\epsilon - \psi^\epsilon \geq \frac{1}{2}\}} \right\|_{L^p(Q)} \|p^\epsilon \chi_{\{y^\epsilon - \psi^\epsilon \geq \frac{1}{2}\}}\|_{L^{p'}(Q)} \\
&\quad \leq \frac{2}{\epsilon}\left\| \left(y^\epsilon - \psi^\epsilon - \frac{1}{4} \right) \chi_{\{y^\epsilon - \psi^\epsilon \geq \frac{1}{2}\}} \right\|_{L^p(Q)} \|p^\epsilon\|_{L^2(Q)} \|\chi_{\{y^\epsilon - \psi^\epsilon \geq \frac{1}{2}\}}\|_{L^{\frac{2p'}{2-p'}}(Q)} \\
&\quad \leq \frac{2}{\epsilon}\|\gamma(y^\epsilon - \psi^\epsilon)\|_{L^p(Q)}\, \|p^\epsilon\|_{L^2(Q)}\, \left(\text{meas}\left\{ y^\epsilon - \psi^\epsilon \geq \frac{1}{2} \right\} \right)^{\frac{2-p'}{2p'}} \\
&\quad = 2\|\lambda_\psi^\epsilon\|_{L^p(Q)}\, \|p^\epsilon\|_{L^2(Q)}\, \left(\text{meas}\left\{ y^\epsilon - \psi^\epsilon \geq \frac{1}{2} \right\} \right)^{\frac{2-p'}{2p'}} \\
&\quad \to 0,
\end{aligned}$$

which, in view of (3.26), leads to

$$\int_Q \lambda_\psi^\epsilon \, p^\epsilon \, dxdt \to 0.$$

Similarly, we can prove that

$$\int_Q \lambda_\varphi^\epsilon \, p^\epsilon \, dxdt \to 0,$$

and hence (3.27) follows.

(3) Prove

$$\int_Q (\bar{\lambda} - \lambda^\epsilon) \, p^\epsilon \, dxdt \to 0. \tag{3.28}$$

Lemma 2.3 gives

$$y^\epsilon \to \bar{y} \qquad \text{strongly in } C_0(\bar{Q}),$$

and thus

$$\langle \mu^\epsilon, \, \bar{y} - y^\epsilon \rangle \to 0;$$

$$\|f(x,t,\bar{y}) - f(x,t,y^\epsilon)\|_{L^\infty(Q)} \to 0.$$

Then, it is not hard to get

$$\begin{aligned}
&\int_Q (\bar{\lambda} - \lambda^\epsilon) \, p^\epsilon \, dxdt \\
&\quad = \int_Q [-(\bar{y} - y^\epsilon)_t + \Delta(\bar{y} - y^\epsilon) + (f(x,t,\bar{y}) - f(x,t,y^\epsilon))] \, p^\epsilon \, dxdt \\
&\quad = \int_Q [(p_t^\epsilon + \Delta p^\epsilon)(\bar{y} - y^\epsilon) + (f(x,t,\bar{y}) - f(x,t,y^\epsilon))p^\epsilon] \, dxdt \\
&\quad = \int_Q [(\mu^\epsilon - f_y(x,t,y^\epsilon)p^\epsilon - (y^\epsilon - z_d))(\bar{y} - y^\epsilon) + (f(x,t,\bar{y}) - f(x,t,y^\epsilon))p^\epsilon] \, dxdt \\
&\quad \to 0.
\end{aligned}$$

By the weak convergency of p^ϵ to $\bar{p}$ in $L^2(Q)$,

$$\int_Q \bar{\lambda} \, \bar{p} \, dxdt = \lim_{\epsilon \to 0^+} \int_Q \bar{\lambda} \, p^\epsilon \, dxdt.$$

Thus, (3.27) combined with (3.28) implies (3.25). (Note that, since both $\{\lambda^\epsilon\}$ and $\{p^\epsilon\}$ are only weakly convergent, (3.27) does not suffice to imply (3.25) without (3.28).)

It remains to prove (3.10) and (3.11). As $p > (n+2)/2$, the $W_p^{2,1}$-bounded subset is relatively compact in $C^{\theta,\theta/2}(\bar{Q})$ for some $\theta \in (0,1)$. So, for any $\eta \in C_0(\bar{Q})$ with $\operatorname{supp} \eta \subset Q'$, the uniform convergence of the approximate optimal control and state (cf. Proposition 3.5), together with the compactness of $\operatorname{supp} \eta$, ensures that, for some $\epsilon_0 > 0$,

$$\varphi^\epsilon(x,t) < y^\epsilon(x,t) < \psi^\epsilon(x,t) \qquad \forall (x,t) \in \operatorname{supp} \eta, \quad 0 < \epsilon < \epsilon_0,$$

which yields

$$\begin{aligned}\langle \bar{\mu},\, \eta\rangle_{\mathcal{M}_0(\bar{Q}),\, C_0(\bar{Q})} &= \lim_{\epsilon\to 0}\int_Q \mu^\epsilon \eta\, dxdt \\ &= \lim_{\epsilon\to 0}\int_{\operatorname{supp}\eta} \frac{1}{\epsilon}[\beta'(y^\epsilon-\varphi^\epsilon)+\gamma'(y^\epsilon-\psi^\epsilon)]p^\epsilon\eta\, dxdt \\ &= 0.\end{aligned}$$

Thus (3.10) holds. Replacing μ^ϵ and $\bar{\mu}$ by λ^ϵ and $\bar{\lambda}$, respectively, (3.11) follows.

Alternatively, we can first prove (3.18) which also leads to (3.10).

In a similar way, (3.14) and (3.15) can be obtained.

The proof is completed. □

In Theorem 3.6, it is assumed that $p > (n+2)/2$, which excludes the case $p = 2$ when $n \geq 2$. Hence, before closing this section, we consider the case $p = 2$.

When $p = 2$, the objective functional $J(\varphi, \psi)$ and Problem (C) are reduced to

$$J_2(\varphi,\psi) \equiv \frac{1}{2}\int_Q \left\{[\mathcal{S}(\varphi,\psi)-z_d]^2 + |\varphi_t|^2 + |\Delta\varphi|^2 + |\psi_t|^2 + |\Delta\psi|^2\right\} dxdt$$

and the following.

PROBLEM (C_2). *Find a control pair* $(\bar{\varphi}, \bar{\psi}) \in \mathcal{U}_2$ *such that*

$$J_2(\bar{\varphi},\bar{\psi}) = \inf_{(\varphi,\psi)\in\mathcal{U}_2} J_2(\varphi,\psi),$$

respectively, where

$$\begin{aligned}\mathcal{U}_2 = \{(\varphi,\psi) \in W_2^{2,1}(Q)\times W_2^{2,1}(Q) | \varphi \leq \psi \text{ in } Q,\\ \varphi = 0 = \psi \quad \text{on } \Sigma,\ \varphi|_{t=0} \leq y_0 \leq \psi|_{t=0} \text{ in } \Omega\}.\end{aligned}$$

Accordingly, the approximate optimal control problem is to minimize the following approximate functional:

$$J_2^\epsilon(\varphi,\psi) \equiv \frac{1}{2}\int_Q [(y^\epsilon - z_d)^2 + |\varphi_t|^2 + |\Delta\varphi|^2 + |\psi_t|^2 + |\Delta\psi|^2 + |\varphi-\bar{\varphi}|^2 + |\psi-\bar{\psi}|^2] dxdt,$$

where $y^\epsilon = \mathcal{S}^\epsilon(\varphi,\psi)$ is the approximate state solving (2.4) and $(\bar{\varphi},\bar{\psi})$ is an optimal control pair of Problem (C_2).

The following result is an analogy to Proposition 3.5.

PROPOSITION 3.7. *Let* $(\bar{\varphi},\bar{\psi},\bar{y})$ *be an optimal triple for Problem* (C_2), *let* $(\varphi^\epsilon,\psi^\epsilon) \in \mathcal{U}_2$ *be approximate optimal control pairs, and let* $y^\epsilon = \mathcal{S}^\epsilon(\varphi^\epsilon,\psi^\epsilon)$. *Then*

$$\left.\begin{array}{l}\varphi^\epsilon \to \bar{\varphi}\\ \psi^\epsilon \to \bar{\psi}\\ y^\epsilon \to \bar{y}\end{array}\right\} \text{ weakly in } W_2^{2,1}(Q) \text{ and strongly in } L^2(0,T;H_0^1(\Omega)).$$

By taking limits in the corresponding approximate optimality condition, which can be obtained easily, owing to the quadratic cost functional and smooth state equation, we arrive at the following result for Problem (C_2).

THEOREM 3.8. *Let* $(\bar{\varphi},\bar{\psi})$ *be an optimal control pair for Problem* (C_2) *and let* $\bar{y} = \mathcal{S}(\bar{\varphi},\bar{\psi})$. *Then there exist* $\bar{p} \in L^2(0,T;H_0^1(\Omega))$ *and* $\bar{\mu} \in \mathcal{M}_0(\bar{Q})$ *such that* $\bar{p}$ *solves the following equation:*

$$\left\{\begin{array}{ll}-\bar{p}_t - \Delta\bar{p} - f_y(x,t,\bar{y})\bar{p} = \bar{y} - z_d - \bar{\mu} & \text{in } Q,\\ \bar{p}|_\Sigma = 0,\\ \bar{p}|_{t=T} = 0,\end{array}\right.$$

and furthermore,

$$\int_Q [(\bar{\varphi}_t + \bar{\psi}_t)w_t + (\Delta\bar{\varphi} + \Delta\bar{\psi})\Delta w]dxdt + \langle \bar{\mu}, w\rangle = 0 \qquad \forall\ w\ \in\ \dot{W}_2^{2,1}(Q).$$

In the present situation with $p = 2$, although the state analysis in section 2 is still valid for the set of approximate optimal controls and states, the compactness in Hölder spaces $C^{\theta,\theta/2}(\bar{Q})$ with $\theta \in (0,1)$ would not be expected to remain valid, since a bounded subset in $W_2^{2,1}(Q)$ is not necessarily compact in $C^{\theta,\theta/2}(\bar{Q})$ for any $\theta \in (0,1)$ when $n \geq 2$. As a result, if $p = 2$, the conditions (3.10), (3.11), *and* (3.13)–(3.17) *in Theorem* 3.6 *cannot be expected to remain valid; however, the results and analysis for the related Problem* (C_2) *and Theorem* 3.8 *would still be useful.*

Acknowledgments. We would like to thank the anonymous referees, the editor, and the associate editor for their valuable comments and constructive criticism, which helped us to improve the paper substantially.

DIET SELECTION AS A DIFFERENTIAL FORAGING GAME*

FRÉDÉRIC HAMELIN†, PIERRE BERNHARD†, A. J. SHAIJU‡, AND ÉRIC WAJNBERG§

Abstract. An important issue addressed by behavioral ecology is that of the evolutionary relevance of foraging strategies adopted by animals in quest of a patchily distributed resource, both in terms of diet selection and patch-leaving decisions under competition. We revisit the classical model of diet selection concerning an isolated—not subject to competition—forager; it yields a zero-one rule, i.e., a type of resource should be always accepted, or always rejected, that appears to be more the exception than the rule, as partial preferences are commonly observed in many species. Thus arises the question of the rule's robustness where there is an uncertainty on the time available to a forager to enjoy a patch, due to the possible occurrence of a perturbating event. We mean any event that would affect its gain with respect to what it would obtain by enjoying alone the patch as long as it wants. For instance, the sudden presence of a predator could force it to flee the patch or the arrival of a conspecific would deprive it of some good resources. By taking into account the potentially imminent arrival of a conspecific—but also any event that would suddenly shorten patch exploitation—we show that the classical policy of diet selection no longer holds, as it changes the qualitative aspect of the optimal foraging strategies. Qualitatively, the optimal strategy is close to, but less greedy than, the evolutionarily stable strategy that concerns foragers actually competing for resources. It consists in accepting only the most profitable resource until it is depleted down to a given level, after which time both resources are accepted. The underlying mathematical technique involves the solution of nonzero-sum differential games and synthesis techniques.

Key words. differential games, evolutionarily stable strategies, optimal foraging theory, behavioral ecology

1. Introduction.

"Nothing in biology makes sense except in the light of evolution."[1] In this respect, behavioral ecology [18] interprets an animal's behavior through an evolutionary approach, via estimating its capacity to get through the natural selection process and thus maximize Darwinian *fitness* [22]—a notion analogous to that of "utility" in economics. Typically, in foraging theory [33], or the art of gathering resources in the environment, fitness is related to the amount of resource gathered. In many cases, the resource is patchily distributed and the utility function on each patch is strictly increasing, concave, and bounded with respect to time. As the *intake-rate* decreases with the quantity of resource available on the patch, it is likely advantageous for an animal to leave a patch not yet exhausted in order to find a new one, in spite of an uncertain *travel time*. Charnov's marginal value theorem [6] reveals that the optimal giving-up time is when the intake-rate is equal to the optimal long-term

[1] Theodosius Dobzhansky, geneticist, 1900–1975.

mean rate γ^* which, if achieved, gives the best fitness a forager can expect in its environment.

This famous theoretical model was originally designed for lone foragers in quest of a singular patchily distributed resource. In parallel, another branch of the theory grew by focusing on the optimal diet selection [5, 17, 31] when the environment offers a plural resource which varies both in profitability and abundance but spatially is regularly and homogeneously distributed. The authors of [23] have merged these two theories.

Naturally, the question arises of whether this theory holds for foragers competing for a common patchily distributed resource, i.e., whether this is an evolutionarily stable strategy [20]; for instance, it might have implications in terms of population dynamics [34, 37].

Concerning the singular resource case, Charnov's patch-leaving rule remains qualitatively unchanged under scramble competition, i.e., when the only competition between foragers is in sharing a common resource [32, 8]; γ^* is clearly affected by the number of potential competitors, but the patch-leaving rule is unchanged. However, if there is *interference*, i.e., a decline in intake-rate due to competition, the game results in a *war of attrition* [32, 9] or random patch-leaving strategies.

In the present paper, our aim is to determine the evolutionarily stable strategy that noninterfering foragers competing for a plural and depleting resource should adopt, both in terms of diet selection and patch-leaving decision [3, 33].

The remainder of the paper is organized as follows. In section 2, we reformulate the optimal diet selection policy for a lone forager free to leave the current patch of resources at any time. On our way, we solve the optimal diet selection problem for a single forager with a fixed end time; this is done in Appendix A. In section 3, we investigate the foraging game involving several foragers arriving simultaneously on a patch containing two distinct types of resources. Section 4 focuses on an asynchronous two-forager game, where the interarrival time is assumed deterministic. Finally, the game considered in section 5 lets the possible arrival of an opponent be a Poisson variable.[2]

2. Foraging alone. It is well known [5, 16] that a lone forager should accept a unit of resource i if its energy value e_i is worth the time required to retrieve it, i.e., the *handling-time* h_i. Indeed, Charnov's marginal value theorem [6, 22] prohibits the intake-rate from falling below a critical threshold γ^*. Hence the rule is to accept this resource if and only if $\gamma^* \leq e_i/h_i$. However, let us recall this result in order to introduce our modeling and solution approaches—the latter is close to that of [26]. We shall define *profitability* of resource i as the ratio e_i/h_i. We shall also let $\delta_i := e_i - \gamma^* h_i$.

Let x be the state vector containing the ratios $x_i \in [0,1]$ of each type of resource available in the patch. Let u be the control vector containing the controls $u_i \in [0,1]$ deciding the acceptance rate[3] of each type of resource available in the patch. Let $\dot{x} := \mathrm{d}x/\mathrm{d}t$, where t stands for the *residence time*.

Proceeding as in [14, 8] and most of the literature, an assumption of random

[2]A particular case of that game is that of a single player with an exponential random end time, such as the possible occurrence of a predator.

[3]Or equivalently the probability to accept a given type of resource when encountered.

probing on a patch yields the following dynamics:

$$(2.1)\quad \forall i \in \{1,\dots,N\}\,,\quad q\dot{x}_i = -\frac{u_i x_i}{\alpha + \sum_{j=1}^N u_j x_j h_j}\,,\quad x_i(0) = x_i^0\,,\quad \sum_{i=1}^N x_i^0 = 1\,,$$

where α is the time required to probe an area of the patch that could contain a unit of resource and q is the quality of the patch or the quantity of resources it initially contains.

Following [22], we want to maximize the criterion

$$(2.2)\qquad J = \int_0^{t^*} L(x,u)\mathrm{d}t \quad \text{with} \quad L(x,u) = -\sum_{j=1}^N e_j q\dot{x}_j - \gamma^*\,,$$

where t^* is a free final time.

We claim the following result.

THEOREM 2.1. *The optimal policy in the problem stated by* (2.1) *and* (2.2) *is given by*

- $\forall t \in [0,t^*]$, *take* $u_i = \begin{cases} 1 \text{ if } \gamma^* < e_i/h_i, \\ \text{arbitrary in } [0,1] \text{ if } \gamma^* = e_i/h_i, \\ 0 \text{ if } \gamma^* > e_i/h_i \end{cases}$
- *and leave as soon as* $\sum_{j=1}^N u_j x_j (e_j - \gamma^* h_j) - \gamma^* \alpha \le 0$.

Proof. Let s be such that $\mathrm{d}t = qD\mathrm{d}s$ with $D := \alpha + \sum_{j=1}^N h_j u_j x_j$. Let $\mathring{x} := \mathrm{d}x/\mathrm{d}s$ and $f(x,u) := \mathring{x}$. The dynamics become

$$\mathring{x_i} = -u_i x_i\,,\quad x_i(0) = x_i^0\,.$$

Our criterion can now be expressed as follows: Let

$$\mathcal{J} := J/q = \int_0^{s^*} \mathcal{L}(x,u)\mathrm{d}s \quad \text{with} \quad \mathcal{L}(x,u) = \sum_{j=1}^N u_j x_j e_j - \gamma^* D\,.$$

It directly yields that the optimal end time is such that $\mathcal{L}$ is zero on the optimal trajectories, since $\partial\mathcal{J}/\partial s^* = \mathcal{L}(x(s^*), u(s^*)) = 0$; this corresponds to Charnov's patch-leaving rule. Hence the claim of the theorem.

Let λ be the adjoint vector. It yields the Hamiltonian

$$\mathcal{H} = \mathcal{L}(x,u) + \langle \lambda, f(x,u)\rangle = \sum_{j=1}^N (\delta_j - \lambda_j) u_j x_j - \alpha\gamma^*\,.$$

According to Pontryagin's maximum principle [30], if a policy $u^*(s)$ generating a trajectory $x^*(s)$ is optimal, then there exists an adjoint trajectory $\lambda(s)$ such that

$$\begin{cases} \mathring{\lambda} = -\nabla_x \mathcal{H}(\lambda, u^*, x^*), \\ \lambda(s^*) = 0, \\ \mathcal{H}(s^*) = 0. \\ \quad \forall s \in [0,s^*], \text{ where } u^*(\cdot) \text{ is continuous}, \\ \quad \mathcal{H}(\lambda(s), u^*(s), x^*(s)) = \max_{u\in[0,1]^n} \mathcal{H}(\lambda(s), u, x^*(s)). \end{cases}$$

The last condition above translates into the switch-functions

$$\sigma_i := \partial\mathcal{H}/\partial u_i = (\delta_i - \lambda_i)x_i$$

and the *bang-bang* optimal policy

$$u_i^* = \begin{cases} 1 \text{ if } \sigma_i > 0, \\ 0 \text{ if } \sigma_i < 0. \end{cases}$$

The singular case $\sigma_i = 0$ allows the focal forager to either accept or reject the less profitable resource indifferently.

We also have

$$\mathring{\lambda}_i = -\partial\mathcal{H}/\partial x_i = -(\delta_i - \lambda_i)u_i\,, \quad \lambda_i(s^*) = 0\,.$$

It yields $\mathring{\sigma}_i = 0$. Hence the sign of σ_i never changes, and therefore the optimal policy is

$$\forall t \in [0, t^*]\,, \quad u_i = \begin{cases} 1 \text{ if } \gamma^* < e_i/h_i, \\ 0 \text{ if } \gamma^* > e_i/h_i. \end{cases}$$

As already mentioned in [23], the reason the author of [26] found another result is that he—consciously—considered, as a constraint, an arbitrarily predetermined residence time.[4] It has to be noticed that in this simple model, *partial preferences* [21] should occur only in the nongeneric case $\gamma^* = e_i/h_i$. □

Given the optimal policy as a function of γ^*, it is possible to compute both γ^* and the corresponding optimal diet, as done in [23], where the authors provide an algorithm that converges to the solution.

3. The synchronous foraging game. The authors of [15] argue that when "a large number" of foragers is competing for a plural and depleting resource, they should maximize their intake-rate. Thus the evolutionarily stable policy consists of being *selective* first and, after a while, being *opportunistic*.[5] The results of both [26, 35] are in agreement with [15], except that the authors of [26, 35] found "earlier" switch-times for a relatively low number of competitors. However, both approaches point to a convergence of the switch-time towards the intake-rate maximizing switch-time as the number of foragers increases.

Our aim now is to determine the evolutionarily stable policy via an approach similar to that of [26], except that we do not set any arbitrarily predetermined residence time or final patch state.

Following section 2, we now restrict the resource range to those resources which would be included in the diet of a lone forager: $\forall i \in \{1, 2\}\,, \delta_i \geq 0$—the resource types rejected by a lone forager should a fortiori be rejected under competition. We shall also let $\zeta := e_1h_2 - e_2h_1 \geq 0$ as $e_2/h_2 \leq e_1/h_1$ by hypothesis.

Proceeding as in [26], we look for the optimal policy against a strategy assumed commonly adopted by the opponents. If it leads to the latter, this is indeed an evolutionarily stable strategy—as this is a strict and symmetric Nash equilibrium [13, 9]. However, to be consistent, we need to assume a state feedback strategy for the opponents. Hence we must use a regular synthesis technique in order to recover

[4] This issue is addressed in Appendix A.

[5] The author of [10] also mentioned this "expanding-specialist" strategy under competition.

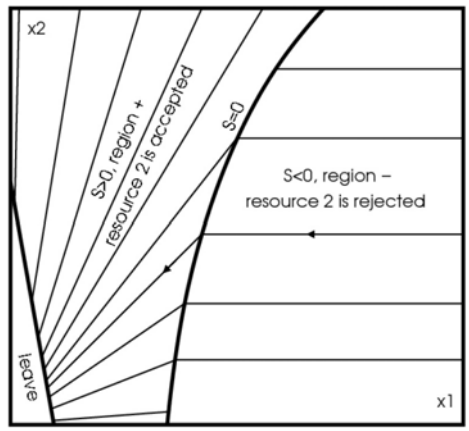

FIG. 3.1. *The Nash-optimal fields of trajectories in the state-space* (x_1, x_2).

the costate vector as a function of the current state and to construct a switch-manifold in the state space. This, in turn, induces discontinuities in the adjoint variables of the focal player and other difficulties that we must take into account. Throughout our reasoning, we shall refer to Figure 3.1, which represents the state-space (x_1, x_2).

Let n be the number of foragers on the patch. Let u be the decision variable of the focal forager, i.e., the acceptance rate of resource 2—as resource 1, the most profitable one, should, of course, always be accepted. Similarly, let v be the decision variable of its opponents.

Let $D(u) := \alpha + h_1 x_1 + u h_2 x_2$. The dynamics are now

$$\left\{ \begin{array}{ll} q\dot{x}_1 = -x_1/D(u) - (n-1)x_1/D(v)\,, & x_1(0) = x_1^0, \\ q\dot{x}_2 = -ux_2/D(u) - v(n-1)x_2/D(v)\,, & x_2(0) = x_2^0. \end{array} \right. \tag{3.1}$$

The criterion of the focal forager is

$$J = \int_0^{t^*} L(x,u)\mathrm{d}t \quad \text{with} \quad L(x,u) = e_1 x_1/D(u) + u e_2 x_2/D(u) - \gamma^*, \tag{3.2}$$

where t^* is a free final time.

We claim the following result (see Figure 3.1).

THEOREM 3.1. *The unique pure symmetric state feedback Nash equilibrium in the game stated by* (3.1) *and* (3.2) *corresponds to*

- *take* $\left\{ \begin{array}{l} u = 0 \text{ as long as } S(x) \le 0, \\ u = 1 \text{ as soon as } S(x) > 0, \end{array} \right.$ *where* $S(x)$ *is given by* (3.9)
- *and leave as soon as* $\delta_1 x_1 + \delta_2 x_2 - \gamma^* \alpha \le 0$.

Proof. Let s be such that $\mathrm{d}t =: qD(u)\mathrm{d}s$. Let $\mathring{x} := \mathrm{d}x/\mathrm{d}s$ and $f(x,u) := \mathring{x}$. The dynamics become

$$\left\{ \begin{array}{ll} \mathring{x}_1 = -x_1(1 + (n-1)D(u)/D(v))\,, & x_1(0) = x_1^0, \\ \mathring{x}_2 = -x_2(u + v(n-1)D(u)/D(v))\,, & x_2(0) = x_2^0. \end{array} \right.$$

Our criterion can now be expressed as follows: Let

$$\mathcal{J} := J/q = \int_0^{s^*} \mathcal{L}(x,u)\mathrm{d}s \quad \text{with} \quad \mathcal{L}(x,u) = e_1 x_1 + u e_2 x_2 - \gamma^* D(u)\,.$$

Clearly, $\partial\mathcal{J}/\partial s^* = \mathcal{L}(x(s^*), u(s^*)) = 0$. It directly yields that the optimal end time is such that $\mathcal{L}$—which does not depend on s—is zero on the optimal trajectories; this corresponds to Charnov's patch-leaving rule. The oblique line sloping to the left in Figure 3.1 represents this terminal manifold.

Let λ be the adjoint vector associated with the focal forager. It yields the Hamiltonian

$$\begin{aligned}\mathcal{H} = {} & e_1x_1 + ue_2x_2 - \gamma^* D(u) - \lambda_1 x_1(1 + (n-1)D(u)/D(v)) \\ & -\lambda_2 x_2(u + v(n-1)D(u)/D(v))\,.\end{aligned}$$

According to Pontryagin's maximum principle,[6] the optimal policy is thus bang-bang, according to the switch-function

$$\sigma = [\delta_2 - \lambda_1(n-1)h_2x_1/D(v) - \lambda_2(1 + v(n-1)h_2x_2/D(v))]x_2\,.$$

We have

$$\begin{aligned}\mathring{\lambda}_1 &= \lambda_1[(1 + (n-1)D(u)/D(v)) + (n-1)h_1x_1(1/D(v) - D(u)/D(v)^2)] \\ &\quad + \lambda_2 v(n-1)h_1x_2(1/D(v) - D(u)/D(v)^2) - \delta_1\,, \quad \lambda_1(s^*) = 0, \\ \mathring{\lambda}_2 &= \lambda_2[(u + v(n-1)D(u)/D(v)) + v(n-1)h_2x_2(u/D(v) - vD(u)/D(v)^2)] \\ &\quad + \lambda_1(n-1)h_2x_1(u/D(v) - vD(u)/D(v)^2) - u\delta_2\,, \quad \lambda_2(s^*) = 0\,.\end{aligned}$$

Clearly, $u^*(s^*) = 1$ as $\sigma(s^*) = \delta_2x_2 \geq 0$ by hypothesis.

Proceeding as in [26], we first assume that the opponents are opportunists. The optimal strategy is then given via integrating backward the above differential equations, with $v = 1$. As long—as from the end time—σ remains positive, being opportunistic is optimal. Thus if it remains so backward up to time zero, being opportunistic the whole time spent on the patch is the evolutionarily stable strategy. Otherwise, i.e., if the sign of σ changes in backward time, being selective is, at least locally, optimal before the switch-point. Thanks to the assumed symmetry among foragers, if such a switch-point appears, then it prevails for any competitor on the patch. Therefore, we shall assume in a second time that $v = 0$ from this possible switch-point down to $s = 0$. However, a prerequisite for reiterating a similar process backward in time is that being selective is optimal against selective opponents.

Let $(\hat{s}, \hat{x})$ be either the first—in backward time—switch-point, if there is one, or $(0, x(0))$ otherwise; i.e., beyond this point, being opportunistic remains optimal up to the end time. Let the superscript + denote the region of the state-space beyond the last switch-point; thus we postulate that in region + the Nash-optimal strategies are $u = v = 1$. For instance, let $D^+ := D(1) = \alpha + h_1x_1 + h_2x_2$. We have $\forall s \in (\hat{s}, s^*)$, $\forall i \in \{1, 2\}$,

$$\mathring{x}_i = -nx_i\,, \quad x_i(s^*) =: x_i^* \quad \text{and} \quad \mathring{\lambda}_i^+ = n\lambda_i^+ - \delta_i\,, \quad \lambda_i^+(s^*) = 0\,.$$

We also have

$$\sigma^+ = [\delta_2 - \lambda_1^+(n-1)h_2x_1/D^+ - \lambda_2^+\left(1 + (n-1)h_2x_2/D^+\right)]x_2 \tag{3.3}$$

and $\mathcal{H}^+ = e_1x_1 + e_2x_2 - \gamma^*D^+ - \lambda_1^+x_1n - \lambda_2^+x_2n$. It yields $\forall s \in (\hat{s}, s^*)$, $\forall i \in \{1, 2\}$,

$$x_i(s) = x_i^*\mathrm{e}^{n(s^*-s)} \quad \text{and} \quad \lambda_i^+(s) = \delta_i(1 - \mathrm{e}^{-n(s^*-s)})/n\,. \tag{3.4}$$

[6] As long as the opponent uses a Lipschitz continuous (here, constant) strategy w.r.t. x.

As a consequence

$$\lambda_1^+(s) = \delta_1(1 - x_1^*/x_1)/n \geq 0\,. \tag{3.5}$$

Moreover, one can notice from (3.4) that $\forall s \in (\hat{s}, s^*)$, $x_1^*/x_1 = x_2^*/x_2$ or, equivalently, that x_1/x_2 is invariant over $[\hat{s}, s^*]$—this results from our assumption of homogeneous probing on the patch, and that is why in Figure 3.1 the field of optimal trajectories is a radial one. Furthermore, as the Hamiltonian remains constant all along the optimal trajectory, it remains equal to zero here and this yields $\forall s \in (\hat{s}, s^*)$, $\forall i \in \{1, 2\}$,

$$x_i^*/x_i = \frac{\gamma^*\alpha}{x_1\delta_1 + x_2\delta_2}\,. \tag{3.6}$$

Hence the claim of the theorem.

The switch-function can also be rewritten as follows:

$$\sigma^+ = \left[(e_2 - \lambda_2^+)(\alpha + h_1x_1) - (e_1 - \lambda_1^+)h_2x_1\right] x_2/D^+\,.$$

Let us now assume that there is a switch-point by definition such that $\sigma^+(\hat{s}) = 0$. Our aim now is to verify that switching—in backward time—u to zero remains optimal if v switches to zero simultaneously at time $\hat{s}$. Let the superscript $-$ denote the region of the state-space where we conjecture that the Nash-optimal strategies are $u = v = 0$. For instance, let $D^- := D(0) = \alpha + h_1x_1$. We have

$$\sigma^-(\hat{s}) = [\delta_2 - \lambda_1^-(\hat{s})(n-1)h_2\hat{x}_1/D^-(\hat{s}) - \lambda_2^-(\hat{s})]\hat{x}_2\,.$$

One also has $\mathcal{H}^-(\hat{s}) = e_1\hat{x}_1 - \gamma^*D^-(\hat{s}) - \lambda_1^-(\hat{s})\hat{x}_1n$.

Notice that the time instant $\hat{s}$ depends on the trajectory considered, and thus $x(\hat{s})$ describes a switch-manifold $S(x) = 0$—the curve in Figure 3.1. Therefore, $\lambda_1^-(\hat{s})$ and $\lambda_2^-(\hat{s})$ must satisfy the system of equations below—the difference of the adjoint vectors is a normal to the manifold (see, e.g., [1]):

$$\begin{pmatrix} \lambda_1^-(\hat{s}) \\ \lambda_2^-(\hat{s}) \\ -\mathcal{H}^-(\hat{s}) \end{pmatrix} = \begin{pmatrix} \lambda_1^+(\hat{s}) \\ \lambda_2^+(\hat{s}) \\ -\mathcal{H}^+(\hat{s}) \end{pmatrix} + \kappa \begin{pmatrix} \partial S(\hat{s})/\partial x_1 \\ \partial S(\hat{s})/\partial x_2 \\ \partial S(\hat{s})/\partial s \end{pmatrix}, \tag{3.7}$$

where κ is a scalar that remains to be determined and S is any function that characterizes the manifold $\sigma^+ = 0$ in the plane (x_1, x_2). Indeed, (3.5) and (3.6) clearly show that σ^+ can be expressed as a function of x_1 and x_2 alone, and not s. Hence $\partial S/\partial s = 0$. Therefore, $\mathcal{H}^-(\hat{s}) = \mathcal{H}^+(\hat{s}) = 0$ and it yields $\lambda_1^-(\hat{s}) = [e_1\hat{x}_1 - \gamma^*D^-]/\hat{x}_1n$; thus $\lambda_1^-(\hat{s}) - \lambda_1^+(\hat{s}) = (\delta_1x_1^* - \gamma^*\alpha)/(\hat{x}_1n) \leq 0$ as $\mathcal{L}(s^*) = \delta_1x_1^* + \delta_2x_2^* - \gamma^*\alpha = 0$.

Moreover, using $\mathcal{H}^-(\hat{s}) = 0$, we can rewrite $\sigma^-(\hat{s})$ as follows:

$$\sigma^-(\hat{s}) = \left[(e_2 - \lambda_2^-(\hat{s}))(\alpha + h_1\hat{x}_1) - (e_1 - \lambda_1^-(\hat{s}))h_2\hat{x}_1\right] x_2/D^-(\hat{s})\,.$$

Using the fact that $\sigma^+(\hat{s}) = 0$ yields

$$\sigma^-(\hat{s}) = \kappa\left(\frac{\partial S(\hat{s})}{\partial x_1}h_2\hat{x}_1 - \frac{\partial S(\hat{s})}{\partial x_2}(\alpha + h_1\hat{x}_1)\right)\hat{x}_2/D^-(\hat{s}),$$

and we have

$$\sigma^-(\hat{s}) = [\lambda_1^-(\hat{s}) - \lambda_1^+(\hat{s})]\left(h_2\hat{x}_1 - (\alpha + h_1\hat{x}_1)\frac{\partial S(\hat{s})}{\partial x_2}\Big/\frac{\partial S(\hat{s})}{\partial x_1}\right)\hat{x}_2/D^-(\hat{s})\,. \tag{3.8}$$

Describing the switch manifold via an implicit function $\hat{x}_1 = \xi(\hat{x}_2)$, equation (3.8) also reads

$$\sigma^-(\hat{s}) = [\lambda_1^-(\hat{s}) - \lambda_1^+(\hat{s})] \left(h_2\hat{x}_1 + (\alpha + h_1\hat{x}_1)\frac{\mathrm{d}\xi(\hat{x}_2)}{\mathrm{d}x_2} \right) x_2/D^-(\hat{s})\,.$$

Choose $S(x_1, x_2) := n(x_1\delta_1 + x_2\delta_2)D^+\sigma^+/x_2$, and S can be expressed as follows:

(3.9)

$$\left| \begin{array}{l} S(x_1,x_2) = a(x_2)x_1^2 + b(x_2)x_1 + c(x_2) \text{ or } S(x_1,x_2) = d(x_1)x_2 + e(x_1), \text{ where} \\ \\ \left| \begin{array}{ll} a := -(n-1)\delta_1\zeta \le 0, & \left| \begin{array}{l} b := -fx_2 - g + h \text{ with} \\ f := -\delta_2 a/\delta_1 \ge 0, \\ g := \zeta\gamma^*\alpha \ge 0, \\ h := \alpha\delta_1(e_2 n - \delta_2) \ge 0. \end{array} \right. \\ c := x_2\delta_2 h/\delta_1 + \delta_2\gamma^*\alpha^2 \ge 0, & \\ d := -fx_1 + \delta_2 h/\delta_1 = \delta_2(ax_1 + h)/\delta_1, & \\ e := -ax_1^2 + (g+h)x_1 + \delta_2\gamma\alpha^2, & \end{array} \right. \end{array} \right.$$

Hence $\xi(x_2) = \left(-b - \sqrt{b^2 - 4ac}\right)/2a$ and one has

$$\frac{\mathrm{d}\xi(x_2)}{\mathrm{d}x_2} = -\frac{d}{2a\xi(x_2) + b} = \frac{\delta_2}{\delta_1}\frac{a\xi(x_2) + h}{2a\xi(x_2) + b} = -\frac{\delta_2}{2\delta_1}\left(1 + \frac{b - 2h}{\sqrt{b^2 - 4ac}}\right)\,.$$

As $b - 2h \le 0$, it yields

$$\frac{\mathrm{d}\xi(x_2)}{\mathrm{d}x_2} = -\frac{\delta_2}{2\delta_1}\left(1 - \sqrt{\frac{(b-2h)^2}{b^2 - 4ac}}\right) = -\frac{\delta_2}{2\delta_1}\left(1 - \sqrt{1 + \frac{\iota}{b^2 - 4ac}}\right) \ge 0$$

as $\iota = 4[ac - h(b-h)] = 4n\zeta{\gamma^*}^2\alpha^2\delta_1 h_2 \ge 0$. Hence $\forall x_2\,,\ \mathrm{d}\xi(x_2)/\mathrm{d}x_2 \ge 0$, which justifies the orientation of the curve in Figure 3.1. As a consequence, $\sigma^-(\hat{s}) \le 0$.

As long as u remains equal to zero while going backward in time from $\hat{s}$, one has

$$\left\{ \begin{array}{ll} \mathring{\hat{x}}_1 = -nx_1\,, & x_1(\hat{s}) =: \hat{x}_1, \\ \mathring{\hat{x}}_2 = 0\,, & x_2(\hat{s}) =: \hat{x}_2, \end{array} \right.$$

and $\sigma^- = \left[(e_2 - \lambda_2^-)(\alpha + h_1x_1) - (e_1 - \lambda_1^-)h_2x_1\right] x_2/D^-$, with

$$\left\{ \begin{array}{ll} \mathring{\lambda}_1^- = n\lambda_1^- - \delta_1\,, & \lambda_1^-(\hat{s}) = [e_1\hat{x}_1 - \gamma^* D^-(\hat{s})]/\hat{x}_1 n, \\ \mathring{\lambda}_2^- = 0\,, & \lambda_2^-(\hat{s}) = \cdot \end{array} \right.$$

Thus, still going backward in time from $\hat{s}$ with $u = v = 0$, one has

$$\left\{ \begin{array}{l} x_1(s) = \hat{x}_1 \mathrm{e}^{n(\hat{s}-s)}, \\ x_2(s) = \hat{x}_2 \end{array} \right. \quad \text{and} \quad \left\{ \begin{array}{l} \lambda_1^-(s) = (e_1x_1 - \gamma^* D^-)/x_1 n, \\ \lambda_2^-(s) = \lambda_2^-(\hat{s}). \end{array} \right.$$

Introducing $y(x_1) := e_1h_2(n-1)x_1/[n(\alpha + h_1x_1)]$ yields $\sigma^- - \sigma^-(\hat{s}) = y(\hat{x}_1) - y(x_1)$. It is easy to see that $y(x_1)$ is increasing. Thus $\forall s \in [0, \hat{s}]\,,\ \sigma^- \le 0$. Hence there is at most one switch-point.

Finally, it is also necessary to check that if the focal forager does not switch to the generalist strategy upon reaching the switch manifold the state nevertheless crosses the said manifold and enters the region where the optimal behavior for all players is to be opportunistic. This is the so-called "permeability condition" [1].[7]

[7]Yet, this is a nonzero sum game, and one cannot conclude as in [1] that the adjoint variables are continuous.

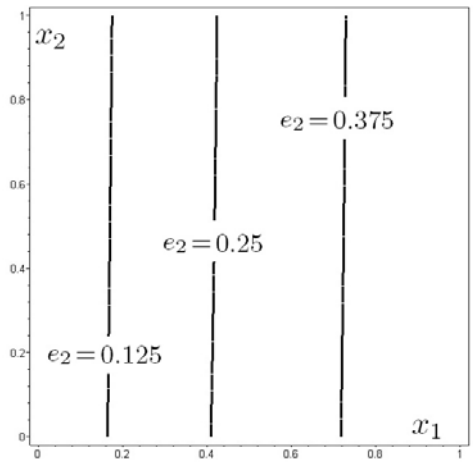

FIG. 3.2. *The switch-manifolds associated with several values of e_2 in the state-space (x_1, x_2). We took $n = 2$, $e_1 = 1$, $\alpha = 1$, $h_1 = h_2 = 1$, $\gamma^* = 0.1$, and from the left to the right, $e_2 = \{0.125, 0.25, 0.375\}$.*

To that aim, let $\nu = (-1, \mathrm{d}\xi/\mathrm{d}x_2)$ be a normal vector of the switch-manifold which points in the same direction as the outgoing trajectories. We have

$$\langle \nu, f(x, 1, 1) \rangle = \left(x_1 - x_2 \frac{\mathrm{d}\xi}{\mathrm{d}x_2} \right) > 0 \,.$$

We calculate

$$\langle \nu, f(x, 0, 1) \rangle = x_1 + (n-1) \frac{\alpha + h_1 x_1}{\alpha + h_1 x_1 + h_2 x_2} \left(x_1 - x_2 \frac{\mathrm{d}\xi}{\mathrm{d}x_2} \right) ,$$

which, taking the previous inequality into account, is clearly positive. Hence the permeability condition is satisfied.

Therefore, the evolutionarily stable strategy is indeed either opportunistic during the whole time spent on the patch, or it is selective first and, after a while, is opportunistic. □

Our aim now is to characterize this possible switch-point. Clearly, $\hat{x}_2 = 1 - x_1^0$ and thus $\hat{x}_1 = \xi(1 - x_1^0)$.

Figure 3.2 shows the switch-manifolds associated with several values of e_2 in the state-space (x_1, x_2). Interestingly, we see that the threshold $\hat{x}_1$ is almost independent from x_2. In other words, the curve in Figure 3.1 seems to be qualitatively very close to a straight line of constant x_1.

Figure 3.3 shows the mapping $n \mapsto \hat{x}_1$. Interestingly, the greater the number of foragers on the patch, the closer the evolutionarily stable strategy becomes to the intake-rate maximization.

3.1. Partial conclusion. Our results are in agreement with those of [26], obtained via a similar approach, although the author of [26] ignored the discontinuities on the adjoint variables; see (3.7). Our innovation lies in the fact that we do not consider any arbitrarily predetermined residence time or final patch state. It allows us to analyze the sensitivity of the switch-point to the initial conditions, and our

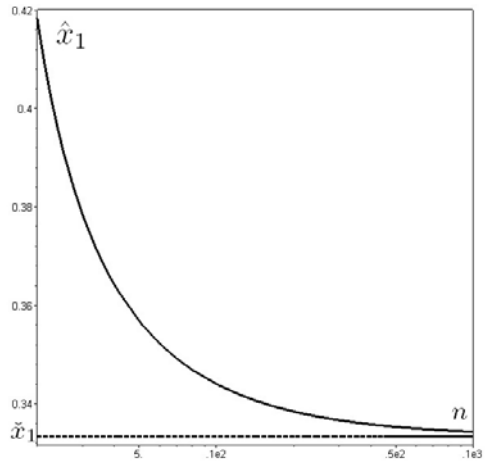

FIG. 3.3. *The mapping $n \mapsto \hat{x}_1$. We took $e_2 = 0.25$, $x_1^0 = 0.5$, $n \in [2, 100]$ and left the others parameters unchanged. The horizontal axis has a logarithmic scale. The dashed line represent the threshold $\check{x}_1$ that corresponds to intake-rate maximization; indeed, intake-rate maximization is selective, while x_1 remains larger than a given threshold $\check{x}_1 := e_2\alpha/\zeta$, independent of x_2.*

model reveals[8] that it seems almost independent from them. Qualitatively, the evolutionarily stable strategy is then close to intake-rate maximization, a policy that is selective until the best resource is depleted down to an optimal threshold—whatever the abundance of the less profitable resource. However, the intake-rate maximization threshold remains a lower bound; for instance, the larger the number of foragers on the patch, the closer the evolutionarily stable strategy to intake-rate maximization. Moreover, these results are also in agreement with those of [15, 35] obtained by quite different approaches.

As the diet selection policy of an isolated—not subject to competition—forager is really different from the evolutionarily stable strategy relevant in a situation of actual competition, the question that arises then is, What should a lone forager entering a patch do if the probability of facing a situation of competition is nonzero?

4. An asynchronous but deterministic foraging game. As a preliminary approach, this section focuses on an asynchronous two-forager game, where the arrival time t_a of the second one is assumed deterministic—this might be relevant in a case of group foraging with "information sharing" [7], assuming that the first forager on a patch has some time to take advantage of its discovery.

Once the second forager arrives, the evolutionarily stable policy depends only on the current patch-state x and is detailed in section 3. It thus remains to determine the optimal strategy before the intruder's arrival.

We claim the following result (see Figure 4.1).

THEOREM 4.1. *In the deterministic arrival time problem, the optimal strategy of the first forager before the arrival of the second one is as follows:*

- *Any admissible policy that leads to $S(x) = 0$ at $t = t_a$, provided that it is feasible; if so, there exists an infinite number of optimal trajectories.*

[8] Compared to [26], as the author of [35] also observed that the switch-point is "nearly independent of... the ratio of the prey types... initially present on the patch."

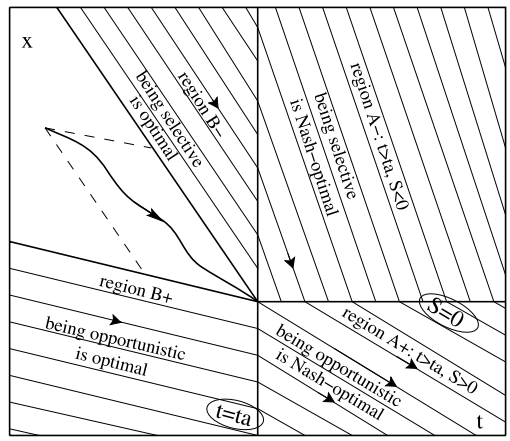

FIG. 4.1. *This graph represents the optimal fields of trajectories in the state-space* (t, x). *The regions* B *(before the opponent's arrival) and* A *(after) correspond, respectively, to* $t < t_a$ *and* $t \geq t_a$, *or equivalently, to* $n = 1$ *and* $n = 2$. *The signs* $-$ *and* $+$ *denote, respectively, that being strictly selective or strictly opportunistic is the (Nash) optimal policy in the region considered. In the latter case, optimal trajectories are, symbolically, linearly plotted. The vertical line represents the manifold* $t = t_a$. *The horizontal one in region* A *represents the switch-manifold given by* $S(x) = 0$. *The curvilinear trajectory starting in the region (not cross-hatched by "linear" trajectories) reflects the fact that any trajectory that remains in this region is optimal.*

- *Otherwise, take* $u = 0$, *respectively,* $u = 1$, *all along the trajectory if this leads to* $S(x) < 0$, *respectively,* $S(x) > 0$, *at time* $t = t_a$.

Proof. As we now need to consider the variable t explicitly, we let it be a state variable; thus the dynamics are extended as follows:

$$\begin{cases} \mathring{x}_1 = -x_1[1 + (n-1)D(u)/D(v)], & x_1(0) = x_1^0, \\ \mathring{x}_2 = -x_2[u + v(n-1)D(u)/D(v)], & x_2(0) = x_2^0 = 1 - x_1^0, \\ \mathring{t} = D(u), & t(0) = 0. \end{cases}$$

From now on, we shall refer to Figure 4.1 to support our reasoning; we stress that this is a symbolic sketch. In region A, the Nash-optimal fields of trajectories are perfectly known, thanks to section 3; i.e., the evolutionarily stable strategy depends only on the sign of $S(x)$.

It remains to determine the optimal fields of trajectories in region B.

For ease of notation, we let μ and H be, respectively, the adjoint vector and the Hamiltonian associated with the trajectories evolving in region B—the part of the game during which the forager is still alone. Connecting μ to λ is a matter of transversality conditions relative to the manifold $t = t_a$—or possibly only to its intersection with the switch-manifold given by $S(x) = 0$. The plane $t = t_a$, parallel to the x subspace, is consequently transparent for this patch-state variable. Thus the only possible discontinuity concerning the adjoint vector is on the costate variables associated with t, say, μ_3 and λ_3—except on the intersection of the two manifolds. Thus, apart from this particular 1-D curve, we have the following relation:

$$\begin{pmatrix} \mu_1(s_a) \\ \mu_2(s_a) \\ \mu_3(s_a) \\ -\mathsf{H}(s_a) \end{pmatrix} = \begin{pmatrix} \lambda_1(s_a) \\ \lambda_2(s_a) \\ \lambda_3(s_a) = 0 \\ -\mathcal{H}(s_a) = 0 \end{pmatrix} + \nu \begin{pmatrix} 0 \\ 0 \\ 1 \\ 0 \end{pmatrix},$$

where ν is a scalar that remains to be determined and s_a is such that $t(s_a) = t_a$. To be exhaustive, we show that the transversality condition associated with the curve given by the intersection of the two manifolds is the following, although we will not need it:

$$\begin{pmatrix} \mu_1(s_a) \\ \mu_2(s_a) \\ \mu_3(s_a) \\ -\mathsf{H}(s_a) \end{pmatrix} = \begin{pmatrix} \lambda_1(s_a) \\ \lambda_2(s_a) \\ \lambda_3(s_a) \\ -\mathcal{H}(s_a) \end{pmatrix} + \tilde{\kappa} \begin{pmatrix} \partial S(s_a)/\partial x_1 \\ \partial S(s_a)/\partial x_2 \\ \partial S(s_a)/\partial t = 0 \\ \partial S(s_a)/\partial s = 0 \end{pmatrix} + \tilde{\nu} \begin{pmatrix} 0 \\ 0 \\ 1 \\ 0 \end{pmatrix}.$$

As, in region B, $n = 1$, one has $\mathsf{H} = \mathcal{L} - \mu_1 x_1 - \mu_2 u x_2 + \mu_3 D(u)$.

Let $\varsigma = \partial \mathsf{H}/\partial u = (\delta_2 - \mu_2 + h_2\mu_3)x_2$. The fact that $\mathsf{H}(s_a) = \mathcal{H}(s_a) = 0$ yields

$$\mu_3(s_a) = \nu = -\frac{\mu_1 x_1(s_a) + \mu_2 u x_2(s_a)}{\alpha + h_1 x_1(s_a) + h_2 x_2(s_a)}.$$

Thus $\varsigma(s_a) = \sigma(s_a)$: the discontinuity on the costate variable associated with t precisely maintains the continuity of the switch-function. Moreover, one has

$$\begin{cases} \mathring{\mu}_1 = -\partial \mathsf{H}/\partial x_1 = \delta_1 - \mu_1 + h_1\mu_3\,, & \mu_1(s_a) = \lambda_1(s_a), \\ \mathring{\mu}_2 = -\partial \mathsf{H}/\partial x_2 = -u(\delta_2 - \mu_2 + h_2\mu_3)\,, & \mu_2(s_a) = \lambda_2(s_a), \\ \mathring{\mu}_3 = -\partial \mathsf{H}/\partial t = 0\,, & \mu_3(s_a) = \nu, \end{cases}$$

and it yields $\mathring{\varsigma} = 0$. We now investigate the possible geometry of the trajectory fields, referring the reader to the four sketches of Figure A.2. As it is clear that being opportunistic does not deplete the best resource as much as being selective during the same time, the fourth quadrant represents an impossible scenario. If being selective until the intruder's arrival yields $S(x(s_a)) < 0$ (second quadrant), then this is optimal. In a similar fashion, if being opportunistic yields $S(x(s_a)) > 0$ (first quadrant), then this is optimal. Otherwise (third quadrant), the optimal policy is such that $S(x(s_a)) = 0$. Moreover, as $\mathrm{d}\xi/\mathrm{d}x_2 \geq 0$, the scenario of the third quadrant, now considering the dashed line as the switch-manifold, cannot happen. Hence there is no state prior to t_a through which trajectories of the two extremal fields can pass. On the contrary, there is indeed a gap—a region uncovered by our extremal fields—between regions + and − in region B of Figure 4.1.

Appendix A provides a relation giving the time spent to move from a point of the state-space (x_1, x_2) to another—as it does not depend on the trajectory followed—via the same dynamics if taken with $n = 1$. It thus yields the locus of all points attainable in a time t_a from a given point (x_1^0, x_2^0)—the manifold represented by the dot-dashed line in the third quadrant of Figure 4.2 contains the said locus. More precisely, this manifold corresponds to the application

$$x_1 \mapsto x_2^0 - [t_a - \alpha \ln(x_1^0/x_1) - (x_1^0 - x_1)h_1]/h_2\,,$$

clearly monotonously decreasing. Hence for each initial condition, there is a unique point $(\hat{x}_1, \hat{x}_2)$ such that $S(\hat{x}_1, \hat{x}_2) = 0$ at time t_a—this is the intersection of the two manifolds. Therefore, any trajectory that remains in the gap has to reach this unique point, and therefore yields the same overall payoff. Further, since optimal trajectories cannot penetrate any of the two extremal fields, any trajectory remaining in the gap and reaching the switch-manifold at $t = t_a$ is optimal. □

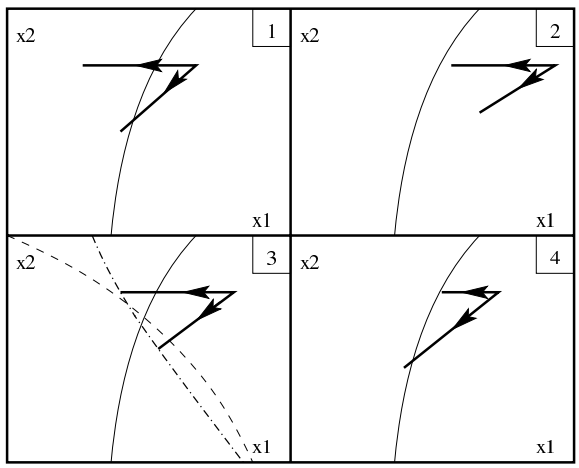

FIG. 4.2. *Each quadrant represents a state-space* (x_1, x_2). *The thick arrows are possible trajectories. The solid curves represent the switch-manifold* $S(x) = 0$. *The time horizon is the same for both trajectories plotted: "being selective" and "being opportunistic."*

5. An asynchronous stochastic foraging game. It remains to show how to forage optimally under the risk of competition, i.e., if the intruder's arrival is no longer deterministic.

As in the last section, once the possible intruder arrives, the optimal policy depends only on the current patch-state x and is as detailed in section 3. Therefore, the optimal total future reward $V_2(x)$ is known. It thus remains to determine the optimal strategy before a possible intruder's arrival.

Notice that taking $V_2 = 0$ addresses the question of the optimal diet selection when the end time is random; for instance, the sudden arrival of a predator could cause the forager to flee from the patch.

Let this possible perturbation be a Poisson variable of intensity π.

We still let the time have a cost—in terms of missed opportunities—of γ^* per unit, and thus the forager is nevertheless incited to leave the patch in order to avoid wasting its time.

Let t^* be the time the forager would remain on the patch if not interrupted and ϵ be the random event time, exponentially distributed with mean $1/\pi$.

Our dynamics are

$$\left\{ \begin{array}{ll} q\dot{x}_1 = -x_1/D(u)\,, & x_1(0) = x_1^0, \\ q\dot{x}_2 = -ux_2/D(u)\,, & x_2(0) = x_2^0. \end{array} \right. \tag{5.1}$$

Let our criterion be

$$G = \mathbb{E}\, J \quad \text{with} \quad J = \int_0^{\epsilon \wedge t^*} L(x,u)\mathrm{d}t + \left\{ \begin{array}{l} V_2(x(\epsilon \wedge t^*)) \text{ if } \epsilon < t^*, \\ 0 \text{ otherwise,} \end{array} \right. \tag{5.2}$$

and $L(x,u) = e_1 x_1/D(u) + u e_2 x_2/D(u) - \gamma^*$.

We claim the following result.

THEOREM 5.1. *The optimal policy in the stochastic arrival time problem stated by* (5.1) *and* (5.2) *is bang-bang with a single switch from* $u = 0$ *to* $u = 1$ *occurring before reaching the manifold* $S(x) = 0$. *The leaving policy is unchanged from Theorem* 3.1.

Proof. Using the fact that $P(\epsilon > t^*) = \mathrm{e}^{-\pi t^*}$, we have

$$\begin{aligned} G &= \mathbb{E}_{\epsilon<t^*}\left[\int_0^{\epsilon} L(x,u)\mathrm{d}t + V_2(x)\right] + \mathrm{e}^{-\pi t^*}\int_0^{t^*} L(x,u)\mathrm{d}t \\ &= \int_0^{t^*}\left[\left(\int_0^{\epsilon} L(x,u)\mathrm{d}t\right) + V_2(x)\right]\pi\mathrm{e}^{-\pi\epsilon}\mathrm{d}\epsilon + \mathrm{e}^{-\pi t^*}\int_0^{t^*} L(x,u)\mathrm{d}t\,, \\ &= \int_0^{t^*} L(x,u)\left(\int_t^{t^*}\pi\mathrm{e}^{-\pi\epsilon}\mathrm{d}\epsilon\right)\mathrm{d}t + \int_0^{t^*} V_2(x)\pi\mathrm{e}^{-\pi\epsilon}\mathrm{d}\epsilon + \mathrm{e}^{-\pi t^*}\int_0^{t^*} L(x,u)\mathrm{d}t\,, \\ &= \int_0^{t^*}\big[L(x,u) + \pi V_2(x)\big]\mathrm{e}^{-\pi t}\mathrm{d}t\,. \end{aligned}$$

Having in mind these equivalent dynamics $f(x,u)$,

$$\begin{cases} \mathring{x}_1 = -x_1\,, & x_1(0) = x_1^0, \\ \mathring{x}_2 = -ux_2\,, & x_2(0) = x_2^0, \end{cases}$$

our criterion can also be expressed as follows:

$$G = q\int_0^{s^*}\mathcal{L}(x,u)\mathrm{e}^{-\pi t(s)}\mathrm{d}s\,, \quad \mathcal{L}(x,u) = \delta_1 x_1 + u\delta_2 x_2 - \gamma^*\alpha + \pi V_2(x)D(u)\,,$$

with $t(s) := \alpha s + h_1(x_1^0 - x_1) + h_2(x_2^0 - x_2)$—see Appendix A—and $t(s^*) := t^*$.

However, let us consider an equivalent criterion:

$$\mathcal{G} = \mathrm{e}^{\pi\left(h_1x_1^0 + h_2x_2^0\right)}G/q = \int_0^{s^*}\mathcal{L}(x,u)\mathrm{e}^{-\pi(\alpha s - h_1x_1 - h_2x_2)}\mathrm{d}s\,.$$

Our stochastic end time optimization problem is thus equivalent to the above deterministic one. Formulated in such a fashion, it directly yields that the end time is such that $\mathcal{L}$ is zero. As V_2 is zero beyond the manifold $\delta_1x_1 + \delta_2x_2 - \gamma^*\alpha = 0$, the latter is the terminal manifold corresponding to this problem. Therefore, we introduce the *value function* V, or the optimal total future reward, which is the solution of the following Hamilton–Jacobi–Bellman equation:

$$\begin{cases} \forall x\,,\ V(x,s^*) = 0 \quad \text{and} \quad \forall(x, s < s^*)\,, \\ -\partial V(x,s)/\partial s = \max_u\left[\langle\nabla_x V(x,s), f(x,u)\rangle + \mathcal{L}(x,u)\mathrm{e}^{-\pi(\alpha s - h_1x_1 - h_2x_2)}\right]. \end{cases}$$

Let $V(x,s) =: \mathrm{e}^{-\pi(\alpha s - h_1x_1 - h_2x_2)}\mathcal{V}(x)\ \forall i \in \{1,2\}$, $\mu_i := \partial\mathcal{V}/\partial x_i$, and $\mathsf{V}(x) := \mathcal{V}(x) - V_2(x)$; V is thus the solution of the following stationary Hamilton–Jacobi–Bellman equation:

$$\begin{cases} \forall(x|\mathcal{L}\le 0)\,,\ \mathsf{V}(x) = 0, \quad \text{and} \quad \forall(x|\mathcal{L} > 0)\,, \\ \alpha\pi\mathsf{V}(x) = \max_u\left[x_1(\delta_1 - \pi h_1\mathsf{V}(x) - \mu_1) + ux_2(\delta_2 - \pi h_2\mathsf{V}(x) - \mu_2) - \gamma^*\alpha\right]. \end{cases}$$

Let us notice that $\mathcal{V}(x)$ is indeed the optimal value of our payoff $\mathcal{G}$. Hence $\mathsf{V}(x)$ is nonnegative.

As it is clear that the optimal control is bang-bang, let us introduce the switch-function $\sigma = \delta_2 - \pi h_2\mathsf{V}(x) - \mu_2$. We conjecture that there is at most one switch. Let the superscript + denote the region of the state-space beyond the switch-point, where we postulate that the optimal strategy is $u = 1$. For instance, let $D^+ := D(1) = \alpha + h_1x_1 + h_2x_2$.

We have $\forall i \in \{1,2\}\,,\ \mu_i^+(s^*) = 0$. It yields $\sigma^+(s^*) = \delta_2 \geq 0$ by hypothesis. Thus at the end time, the optimal policy is to be opportunistic, i.e., to take both resources.

The Hamilton–Jacobi–Bellman equation states that $\forall (x|\mathcal{L} > 0)$ in region $+$,

$$\pi D^+ \mathsf{V}^+(x) = x_1(\delta_1 - \mu_1^+) + x_2(\delta_2 - \mu_2^+) - \gamma^*\alpha\,.$$

Let $\forall i \in \{1,2\}\,,\ \nu_i := \partial \mathsf{V}/\partial x_i = \mu_i - \lambda_i$, as $\lambda_i = \partial V_2/\partial x_i$.

According to the classical theory of characteristics [4], $\forall i \in \{1,2\}$,

$$\mathring{\mu}_i^+ = \pi D^+ \nu_i^+ - (\delta_i - \pi h_i \mathsf{V}^+(x) - \mu_i^+)\,, \quad \mu_i^+(\hat{s}) = \hat{\mu}_i\,.$$

We thus have $\mathring{\sigma}^+ = \pi h_2(x_1\nu_1^+ + x_2\nu_2^+) - \mathring{\mu}_2^+ = \pi h_2 x_1 \nu_1^+ - \pi D^- \nu_2^+ + \sigma^+$.

Our aim is now to show that, if σ^+ becomes zero while going backward in time, switching u to zero remains optimal down to the initial time. Let the superscript $-$ denote the region of the state-space where we conjecture that the optimal strategy is $u = 0$. For instance, let $D^- := D(0) = \alpha + h_1 x_1$.

In the latter region, the Hamilton–Jacobi–Bellman equation states that $\forall x$,

$$\pi D^- \mathsf{V}^-(x) = x_1(\delta_1 - \mu_1^-) - \gamma^*\alpha\,. \tag{5.3}$$

Via a similar calculation of the characteristics:

$$\begin{cases} \mathring{\mu}_1^- = \pi D^- \nu_1^- - (\delta_1 - \pi h_1 \mathsf{V}^-(x) - \mu_1)\,, & \mu_1^-(\hat{s}) = \hat{\mu}_1, \\ \mathring{\mu}_2^- = \pi D^- \nu_2^-\,, & \mu_2^-(\hat{s}) = \hat{\mu}_2, \end{cases}$$

where $\hat{s}$ is the time at which the switch-manifold is reached.

We thus have $\mathring{\sigma}^- := \pi h_2 x_1 \nu_1^- - \mathring{\mu}_2^- = \pi h_2 x_1 \nu_1^- - \pi D^- \nu_2^-$. Hence on the switch-manifold, $\mathring{\sigma}^-(\hat{s}) = \mathring{\sigma}^+(\hat{s}) \geq 0$.

Using (5.3), we have

$$\begin{aligned} \mathring{\mu}_1 &= \pi D^- \nu_1^- - (\alpha\pi \mathsf{V}^-(x) + \gamma^*\alpha)/x_1 \\ &= \pi D^- \mu_1^- - \left[(\alpha\pi \mathsf{V}^-(x) + \gamma^*\alpha)/x_1 + \pi D^- \lambda_1\right]\,. \end{aligned}$$

Let $\Theta(x) := [(\alpha\pi \mathsf{V}^-(x) + \gamma^*\alpha)/x_1 + \pi D^- \lambda_1] \geq 0$,

$$\chi(s,\hat{s}) := \exp\left(\pi \int_{\hat{s}}^{s} D^- \mathrm{d}\ell\right) = \mathrm{e}^{\pi[t(s) - t(\hat{s})]}\,,$$

and

$$\phi(s,\hat{s}) := \alpha\pi \int_s^{\hat{s}} \Theta(x)\chi(s,\ell)\mathrm{d}\ell \geq 0\,,$$

as it is clear from section 3 that $\forall x,\ \lambda_1(x) \geq 0$.

We have $\forall s \in [0,\hat{s}]$,

$$\begin{cases} \mu_1^-(s) = \hat{\mu}_1\chi(s,\hat{s}) + \phi(s,\hat{s}), \\ \mu_2^-(s) = \hat{\mu}_2\chi(s,\hat{s}). \end{cases}$$

Let $\psi(x_1) := \pi h_2 x_1 \hat{\mu}_1^- - \pi D^- \hat{\mu}_2^- = \pi(h_2\hat{\mu}_1 - h_1\hat{\mu}_2)x_1 - \pi\alpha\hat{\mu}_2$, which yields

$$\mathring{\sigma}^- = \psi(x_1)\chi(s,\hat{s}) + \phi(s,\hat{s})\pi h_2 x_1\,.$$

As $\psi(\hat{x}_1) = \mathring{\sigma}^-(\hat{s}) \geq 0$, $(h_2\hat{\mu}_1 - h_1\hat{\mu}_2)$ is clearly positive. Thus $\psi(x_1)$ is increasing in x_1. Therefore $\mathring{\sigma}^-$ remains positive in region $-$. As an expected consequence, the trajectory generated by taking $u = 0$ backward from the switch-manifold implies that σ^- remains negative down to the initial time. Hence the optimal strategy is indeed at most one-switch bang-bang. □

5.1. A digression on the random end time problem. In this subsection, our aim is to numerically characterize the switch-manifold for a random end time problem, i.e., taking $\forall x\,,\ V_2(x) = 0$.

Integrating forward the trajectory field where $u = 1$ yields

$$\mathcal{V}^+(x) = \Delta B_1(\beta) - \gamma^* \alpha B_0(\beta)\,,$$

with $\Delta := \delta_1 x_1 + \delta_2 x_2$, $\beta := \pi(h_1 x_1 + h_2 x_2)$, and the function B_n is defined as follows, with $n \in \mathbb{N}$:

$$B_n(\beta) := \int_0^{s^*} \mathrm{e}^{-(n+\pi\alpha)s - \beta(1-\mathrm{e}^{-s})} \mathrm{d}s\,.$$

Integrating by parts easily yields

$$\left| \begin{array}{l} B_1(\beta) = (1 - z_0(\beta) - \pi\alpha B_0(\beta))/b, \\ B_2(\beta) = (1 - z_1(\beta) - (1+\pi\alpha)B_1(\beta))/\beta \end{array} \right.$$

with $z_n(\beta) := \mathrm{e}^{-(n+\pi\alpha)s^* - \beta(1-\mathrm{e}^{-s^*})}$.

Using either the explicit form of s^*[9] or the remark that it maximizes $\mathcal{G}$ and the envelope lemma, we have that

$$\forall i \in \{1,2\}\,, \quad \mu_i^+ = \delta_i B_1(\beta) - \Delta\pi h_i (B_1(\beta) - B_2(\beta)) + \gamma^* \alpha \pi h_i (B_0(\beta) - B_1(\beta))\,.$$

As $\sigma^+ := \delta_2 - \pi h_2 \mathcal{V}^+ - \mu_2^+$, we have that

$$\begin{aligned} \sigma^+ &= \delta_2 - \delta_2 B_1(\beta) - \Delta\pi h_2 B_2(\beta) + \gamma^* \alpha \pi h_2 B_1(\beta) \\ &= (\delta_2 - \Delta\pi h_2 (1 - z_1(\beta))/\beta) - (\delta_2 - (1+\pi\alpha)\Delta\pi h_2/\beta - \gamma^* \alpha \pi h_2) B_1(\beta)\,. \end{aligned}$$

The switch-manifold is thus given by $\sigma^+(x) = 0$. Figure 5.1 shows the switch-manifolds associated with various values of π.

5.2. Implications for the original problem. It is clear that the switch-manifold corresponding to the original problem is bounded by that of the synchronous foraging game characterized in section 3, as it corresponds to being disturbed by a conspecific with a probability of one. Besides the latter point, it is likely that qualitatively, the optimal policy remains equivalent to the random end time problem, i.e., switching at a given x_1, depending on the intensity of the Poisson process.

6. Conclusion. Our aim was to determine the evolutionarily stable strategy [20] that foragers competing for a plural and depleting resource should adopt, both in terms of diet selection and patch-leaving decision [3, 33].

First, we reformulated the optimal diet selection policy [23] for a lone forager, in a similar fashion to [26], except that we allow for a free patch-leaving time. On our way, we solved the optimal diet selection problem for a single forager with an end time either fixed or possibly random.

Next, we investigated the foraging game involving several foragers arriving simultaneously at a patch containing two distinct types of resources. The resulting differential game involves discontinuous state feedback strategies constructed via a classical synthesis technique, and hence requires for its solution a careful analysis of

[9] As s^* is the time to leave the patch as a function of the current state, we have $s^* = -\ln(\gamma^*\alpha/\Delta)$; see (3.6) and the dynamics taken with $u = 1$.

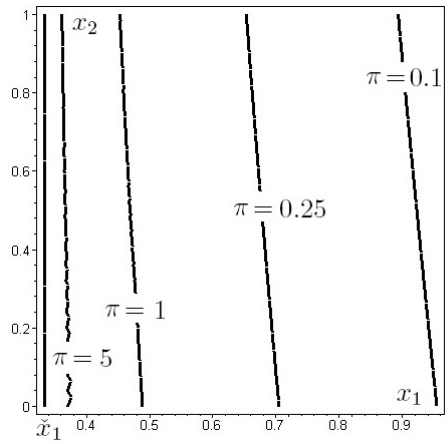

FIG. 5.1. *The switch-manifolds in the state-space* (x_1, x_2) *associated with several values of* π*; from right to left,* $\pi = \{0.1, 0.25, 1, 5\}$*, with* $\alpha = 1$*,* $h_1 = 1$*,* $h_2 = 1$*,* $e_1 = 1$*,* $e_2 = 0.25$*, and* $\gamma^* = 0.1$*. The left bound corresponds to the intake rate maximization switch-manifold, i.e.,* $\check{x}_1 = e_2\alpha/\zeta$*.*

the induced discontinuities of the adjoint variables. The end result is a one-switch bang-bang evolutionarily stable strategy. This is in agreement with [15, 26, 35] and is more precise in several respects.

As there is a qualitative gap between the optimal behavior of an isolated forager and that of competing foragers, the question which thus arose was that of the optimal strategy of a single forager subject to a potentially imminent competition.

As a preliminary approach, we solved an asynchronous two-forager game, where the interarrival time was assumed deterministic. Partial preferences arose in several fashions.

Finally, we no longer considered a deterministic interarrival time but let the probability that an opponent enters the game follow a Poisson distribution. We showed that the optimal policy belongs to a qualitative continuum which fills[10] the gap that separates the two extremal policies found previously.

Thus, although the classical diet selection policy states that a lone forager should take both resources indiscriminately during the whole time spent on the patch (see section 2), we showed that it suffices to add some stochasticity in the model to predict a qualitatively different behavior. Indeed, under the risk of viewing a predator (or a conspecific) shortening its time spent (alone) on the patch, a lone forager should be selective for a while, at least if the probability of being disturbed is nonnegligible.

7. Discussion and prospects. Our results are based on the assumption that foragers are identical in terms of their ability to find and consume resources and of the relative values they attribute to resources with respect to both other resources and their environment. The game is symmetric in this sense. In recent years, however, foraging theory has looked more at the effect of the foragers' state; see [16]. Thus arises the question of the robustness of our results when considering relevant differences in forager state such as

- competitive ability, which may be correlated to the size of the animal [25, 24];
- level of satiation or body reserves and their effect on the relative values of food

[10] By playing on the intensity of the Poisson variable.

resources compared to other resources or opportunities in the environment, such as finding a mate;
- time away from the nest and its effect on the "cost of the time";
- life expectancy of the animal [36], i.e., a time horizon.

In this sense the game would no longer be symmetric. Moreover, the question of the information on the opponent state would also arise. Yet, we conjecture that, of course, the foragers would probably not switch or leave simultaneously, but a qualitatively similar behavior would persist; i.e., switching from being selective to opportunistic and leaving according to their own Charnov's rule.

Also, in our model, foragers' ability to gather resources is not affected by the presence of conspecifics; the present paper ignores interference (i.e., contacts or fights) that could occur among them. As in the single resource case, as long as there is no interference, the evolutionarily stable strategy is pure, in particular in terms of the patch-leaving policy. We conjecture that including interference in the model would result in a war of attrition, or random patch-leaving times, but would not qualitatively affect the resource acceptance policy. More accurately, we conjecture that a war of attrition occurs after foragers have switched from a selective diet to an opportunistic one. Yet, this makes sense to us as long as interference intensity does not depend on the resource acceptance policy. If it does, i.e., if interference is greater when both foragers focus on the best quality resource, the question is open (see [25, 24] for experimental evidence of a competition avoidance behavior).

Last, but not least, the question arises of the relevance of this model with respect to real life. A field study in the Negev Desert, Israel [12] was conducted on Nubian ibex *Capra ibex nubiana*, wild social goats that actually compete for resources. Interestingly, an indirect observation based on "giving-up densities" [2] tends to show that Nubian ibex "forage selectively on plants of higher quality until a certain threshold density, switching later to a more opportunistic foraging." Also, such an interpretation may hold with respect to similar observations made on kangaroo rats *Dipodomys merriami* foraging on the same patch during a study done in Arizona [3]. As pointed out by [11], diet selection dynamics are rarely directly observed.[11] Nevertheless, the authors of [27] observed, through laboratory experiments with the cichlid fish *Haplochromis piceatus* (a predator accustomed to foraging in group), a switch in their resource acceptance policy, regardless of whether they were foraging alone or by pair. However, the switch-point occurred at a higher density of the preferred resource when foraging by pair than when foraging alone [35]. In light of the present model, an inverse ranking of the switch-points would have been expected; i.e., if uncertainty with respect to the time available to exploit resources—possibly before the expected arrival of a competitor—makes a single forager focus on the best resources first, such a selectivity is expected to be exacerbated, or at least unaffected, under competition. Our simple model is therefore falsifiable and seems to be so in this species. Moreover, white king pigeons, which also forage in a group under natural conditions, have been shown [29, 28] to be more "choosy" alone than in the presence of a competitor. More accurately, the authors actually observed that pigeons switch "earlier" under competition. It may be that interference occurring when focusing on the preferred resource qualitatively changes the resource acceptance policy. Further theoretical investigations are thus needed to better understand how competition affects the dynamics of diet selection.

[11] Yet, this article refers to other (of a physiological nature) dynamics, ignoring resource depletion and competition.

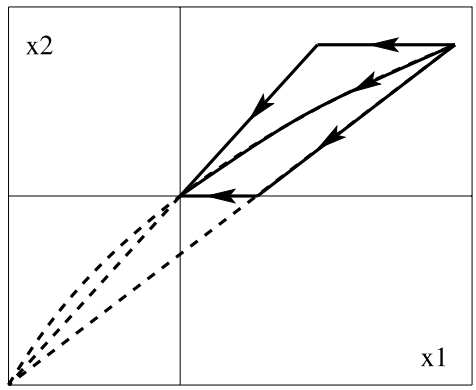

FIG. A.1. *Three of the optimal trajectories in the state-space* (x_1, x_2)*: "accepting the less profitable resource with a constant optimal acceptance rate"; "switching from selective to opportunistic"; and vice versa. The intersection of the vertical and horizontal lines represents the point* $(\hat{x}_1, \hat{x}_2)$*.*

Appendix A. Optimal diet selection with a fixed end time. In the body of the paper, we allow the forager a free patch-leaving time, given that the time itself has a cost of γ^* per unit. This appendix is a digression on the optimal diet selection problem under a fixed residence time constraint, as already addressed by some authors; see [26, 19], where the example of an intertidal forager is mentioned. Our patch dynamics are closer to that of [26],[12] whose author argues that there is a partial preference region in the state-space; our aim is to prove this statement.

Although the question addressed is not the same, our basic model remains that detailed in the body of the paper. As we consider a lone forager in an environment that offers two types of resources, the notations we shall use are those introduced in section 3. For instance, we assume that resource 1 is more profitable than resource 2, i.e., $e_1/h_1 \geq e_2/h_2$.

We claim the following result (see Figure A.1).

THEOREM A.1. *In the fixed end time problem, the optimal strategy is as follows: Let* $\hat{x}_1 = e_2\alpha/\zeta$*.*

- *Any admissible strategy that leads to* $x_1(T) = \hat{x}_1$*, provided that it is feasible. If so, there exists an infinite number of optimal trajectories, all of them reaching the same point* $(\hat{x}_1, \hat{x}_2)$*;* $\hat{x}_2$ *is given by* (A.1)*.*
- *Otherwise, take* $u = 0$*, respectively,* $u = 1$*, all along the trajectory if this leads to* $x_1(T) > e_2\alpha/\zeta$*, respectively,* $x_1(T) < e_2\alpha/\zeta$*.*

Proof. As we need to consider the variable t explicitly, we let it be a state variable. We thus have the following dynamics $f(x, u)$:

$$\begin{cases} \mathring{x}_1 = -x_1\,, & x_1(0) = x_1^0, \\ \mathring{x}_2 = -ux_2\,, & x_2(0) = x_2^0 = 1 - x_1^0, \\ \mathring{t} = D(u)\,, & t(0) = 0. \end{cases}$$

Our criterion is

$$\mathcal{J} = \mathcal{K}(x(T)), \quad \text{where} \quad \mathcal{K}(x) := e_1(x_1^0 - x_1) + e_2(x_2^0 - x_2)$$

[12]The dynamics of [19] are, then, really stochastic, as they allow for "a run of back luck" that leads the forager to "become more selective as the time left in the patch runs out."

and T is a fixed final time.

Let S be the final s, i.e., $t(S) = T$. Let λ be the adjoint vector. It yields the Hamiltonian

$$\mathcal{H} = \langle \lambda, f(x,u) \rangle = -\lambda_1 x_1 - \lambda_2 u x_2 + \lambda_3 D(u)\,.$$

According to Pontryagin's maximum principle, if a policy $u^*(s)$ generating a trajectory $x^*(s)$ is optimal, then there exists an adjoint trajectory $\lambda(s)$ such that

$$\left\{ \begin{array}{l} \mathring{\lambda} = -\nabla_x \mathcal{H}(\lambda, u^*, x^*), \\ \lambda(s^*) = \nabla_x \mathcal{K}(x^*) + \mathsf{v}, \\ \mathcal{H}(s^*) = 0 \\ \left| \begin{array}{l} \forall s \in [0, s^*], \text{ where } u^*(\cdot) \text{ is continuous}, \\ \mathcal{H}(\lambda(s), u^*(s), x^*(s)) = \max_{u \in [0,1]} \mathcal{H}(\lambda(s), u, x^*(s)), \end{array} \right. \end{array} \right.$$

where v is a vector normal to the target manifold. As the latter is the plane $t = T$, the only nonzero component of v is that in t, say, ν. We have

$$\left\{ \begin{array}{ll} \mathring{\lambda}_1 = -\partial\mathcal{H}/\partial x_1 = \lambda_1 - \lambda_3 h_1\,, & \lambda_1(S) = \partial\mathcal{K}/\partial x_1 = -e_1, \\ \mathring{\lambda}_2 = -\partial\mathcal{H}/\partial x_2 = u(\lambda_2 - \lambda_3 h_2)\,, & \lambda_2(S) = \partial\mathcal{K}/\partial x_2 = -e_2, \\ \mathring{\lambda}_3 = -\partial\mathcal{H}/\partial t = 0\,, & \lambda_3(S) = \partial\mathcal{K}/\partial t + \nu = \nu. \end{array} \right.$$

The last condition above translates into the switch-function

$$\sigma = \partial\mathcal{H}/\partial u = x_2(\lambda_3 h_2 - \lambda_2)\,.$$

As S is free, the final value of the Hamiltonian is zero. It yields

$$\forall s, \quad \lambda_3(s) = \nu = -\frac{e_1 x_1(S) + u e_2 x_2(S)}{\alpha + h_1 x_1(S) + h_2 x_2(S)}\,.$$

Thus

$$\sigma(S) = x_2(S)\left(\frac{e_2\alpha + x_1(S)(e_2 h_1 - e_1 h_2)}{\alpha + h_1 x_1(S) + h_2 x_2(S)}\right)\,.$$

It is easy to show that $\forall s,\ \mathring{\sigma} = 0$. Let $\hat{x}_1 = e_2\alpha/\zeta$. Hence

$$\left\{ \begin{array}{ll} \text{if } x_1(S) > \hat{x}_1, & \text{then } \forall s, \sigma < 0 \Rightarrow u^* = 0; \\ \text{if } x_1(S) = \hat{x}_1, & \text{then } \forall s, \sigma = 0 \Rightarrow u^* \in [0,1]; \\ \text{if } x_1(S) < \hat{x}_1, & \text{then } \forall s, \sigma > 0 \Rightarrow u^* = 1. \end{array} \right.$$

We now investigate the possible geometry of the trajectory fields, referring the reader to the four sketches of Figure A.2. Therefore, if being opportunistic yields a ratio of the best resource that remains lower than $\hat{x}_1$ (first quadrant), then this is optimal. In a similar fashion, if being selective yields a ratio of the best resource that remains greater than $\hat{x}_1$ (second quadrant), then this is optimal. Otherwise (third quadrant), the optimal policy is such that the ratio of best resources equals $\hat{x}_1$ at the end time. As it is clear that being opportunistic does not deplete the best resource as much as being selective during the same time, the fourth quadrant represents an impossible scenario.

However, Pontryagin's maximum principle provides only necessary conditions; it does not prove that *any* policy that leads to $x_1(S) = \hat{x}_1$ is optimal.

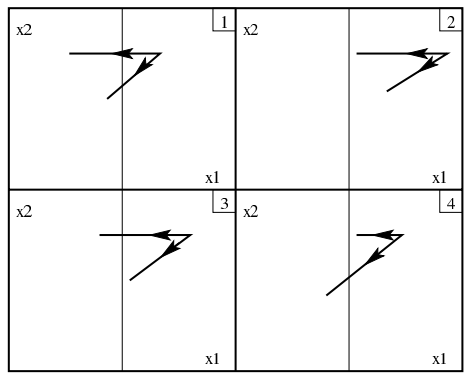

FIG. A.2. *Each quadrant represents a state-space* (x_1, x_2). *Vertical lines indicate the manifold* $x_1 = \hat{x}_1$. *The temporal horizon is the same for both trajectories plotted: "being selective" and "being opportunistic."*

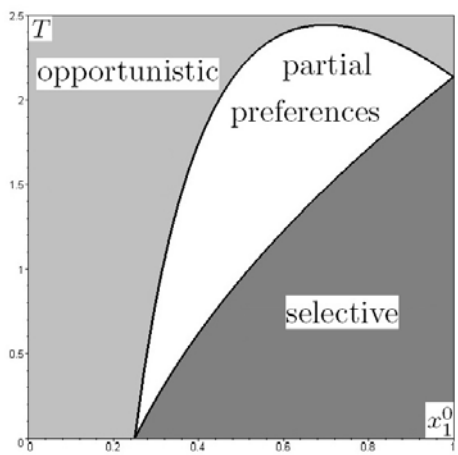

FIG. A.3. *The differing regions in the parameter space* (x_1^0, T). *We took* $\alpha = 1$, $e_1 = 1$, $e_2 = 1$, $h_1 = 1$, *and* $h_2 = 5$.

It is easy to see that

$$\forall u, s, \quad t(s) = \alpha s + [x_1^0 - x_1(s)]h_1 + [x_2^0 - x_2(s)]h_2 \,,$$

and that $S = \ln(x_1^0/\hat{x}_1)$. Hence there is a unique $x_2(S)$ such that $x_1(S) = \hat{x}_1$; i.e., $x_2(S) =: \hat{x}_2$ is such that

$$T = \alpha \ln(x_1^0/\hat{x}_1) + [x_1^0 - \hat{x}_1]h_1 + [x_2^0 - \hat{x}_2]h_2 \,. \tag{A.1}$$

However, it does not mean that the optimal trajectory is unique, as the time needed to move from a point (x_1, x_2) to another does not depend on the path followed. Therefore, any strategy that leads to $x_1(S) = \hat{x}_1$ is indeed optimal. For instance, Figure A.1 represents some possible optimal trajectories in the state-space (x_2, x_1). □

Figure A.3 shows the differing regions in the parameter space (x_1^0, T) that correspond to each policy: being selective, being opportunistic, and having "partial

preferences." The manifold separating the selective region and the partial preferences is given by the application

$$x_1^0 \mapsto \alpha \ln(x_1^0/\hat{x}_1) + [x_1^0 - \hat{x}_1]h_1 \,,$$

as $x_2^0 = \hat{x}_2$ on this boundary, and the other boundary (separating the partial preferences region from the opportunistic one) is given by

$$x_1^0 \mapsto \alpha \ln(x_1^0/\hat{x}_1) + (x_1^0 - \hat{x}_1)[h_1 + h_2 x_2^0/x_1^0],$$

as $x_1^0/x_2^0 = \hat{x}_1/\hat{x}_2$ on this boundary.

SINGULAR PERTURBATIONS IN ERGODIC CONTROL OF DIFFUSIONS*

VIVEK S. BORKAR† AND VLADIMIR GAITSGORY‡

Abstract. Ergodic control of a nondegenerate diffusion with two time-scales is studied in the limiting case as the time-scale separation increases to infinity. It is shown that the limit problem is another ergodic control problem for the slow time-scale component alone, with its dynamics averaged over the (controlled) invariant probability measures for the fast component. These measures in turn can be treated as the "effective control variable."

Key words. controlled diffusions, two time-scales, singular perturbations, ergodic control, invariant probability measures

1. Introduction.

In this paper, we consider a long run average (ergodic) problem of optimal control of nonlinear singularly perturbed (SP) stochastic differential equations (SDEs), in which the singular perturbations parameter $\epsilon > 0$ is introduced in such a way that the state variables are decomposed into a group of slow variables that change their values with rates of the order $O(1)$, and a group of fast variables that change their values with rates of the order $O(\frac{1}{\epsilon})$.

Singularly perturbed problems of control and optimization have been studied intensively in both deterministic and stochastic settings (see the classic texts [7], [23], [25], [31] and the most recent publications [1], [2], [3], [4], [5], [6], [12], [14], [15], [16], [17], [18], [20], [21], [22], [26], [30], [32], [33]). Problems of optimal control of SP SDEs have been studied in [1], [7], [12], [21], [25], where earlier references can also be found.

In [12], in particular, it has been established in a very general setup that, for the problem of optimal control of SP SDEs considered on a finite time interval, the limiting problem (obtained when the singular perturbation parameter tends to zero) is an averaged problem, in which the slow dynamics is controlled by stationary marginal distributions of the fast dynamics, obtained with the slow state variables kept "frozen" (note that a deterministic counterpart of this result has been obtained in [17]).

In this article, we continue the line of research started in [12] by establishing the validity of a similar limit behavior for long run average problems of optimal control of SP SDEs (referred to in what follows as SP ergodic control problems). Note that in our study we restrict ourselves to the case of nondegenerate diffusions, and thus our results complement earlier results obtained in the purely deterministic setting in [18]. Our analysis is largely based on the stability and control theory for nondegenerate diffusions established in [8], [9], and [11].

The paper is organized as follows. We introduce the singularly perturbed ergodic control problem in the next section. Our objective will be to relate this problem to the ergodic control problem for the "averaged" system obtained in the $\epsilon \to 0$ limit, i.e., to prove that the latter (lower dimensional) problem is a valid approximation to the above problem for small ϵ. The exact definition of the averaged problem is deferred until after the appropriate terminology has been introduced. A key assumption here is a condition on the running cost (see (4) below) which penalizes large excursions of the state process.

Section 3 recalls some known facts about ergodic control, notably the basic existence result (Theorem 3.1 below). This is stated in both the "almost sure" and the "expectation" form. It uses a characterization of limit points of the joint empirical process for state and control processes. This in turn shows that with probability one, none of these limit points can improve over the best attainable cost over the so-called Markov controls that depend only on the present state.

Section 4 is devoted to some preliminaries, in particular the definition of the averaged control problem. It then gives an important characterization of the set of the so-called "ergodic occupation measures," which have the property that the cost under stable Markov controls can be expressed as an average of the running cost function w.r.t. these. This result plays an important role throughout, as it helps us characterize limits of sequences of ergodic occupation measures and invariant measures. Section 4 also specializes the result concerning existence of optimal controls from section 3 to the present scenario.

Section 5 shows that the optimal cost for the averaged problem serves in general as an asymptotic lower bound for the optimal cost for the original problem in the $\epsilon \downarrow 0$ limit (Corollary 5.1). This argument is based on the tightness of the optimal ergodic occupation measures as ϵ is reduced to zero, implying their relative compactness in Prohorov topology. Section 6 shows that in the special case of the control entering the drift in an affine manner and the running cost strictly convex in the control, it is in fact the exact limit (Theorem 6.1). This crucially uses the fact that under these conditions, the expression being minimized over the control parameter in the associated Hamilton–Jacobi–Bellman equation is strictly convex, and therefore the minimizer is unique and continuously varying with ϵ. This result is extended to a more general case in section 7 under some technical assumptions (Theorem 7.1). These assumptions basically allow us, given an optimal control for the averaged problem, to approximate the optimal process at process level (i.e., in law) by the ϵ-indexed processes we start with, along with the associated control processes.

Section 8 discusses the "stable case," where a blanket stability condition is imposed on the controlled diffusion instead of the aforementioned condition on the running cost. This is sketched in the barest outline, as most of the details will be repetitive. Section 9 concludes with some discussion, which includes some directions for future research. The main tools used throughout are relative compactness in Prohorov topology and, in some cases, in the total variation norm, of the invariant distributions/ergodic occupation measures as the case may be, when appropriate parameters are varied.

2. The control problem. Let $\epsilon > 0$. We consider the coupled pair of SDEs in $\mathcal{R}^d \times \mathcal{R}^s$ given by

$$dz^\epsilon(t) = h(z^\epsilon(t), x^\epsilon(t), u(t))dt + \gamma(z^\epsilon(t))dB(t), \tag{1}$$

$$dx^\epsilon(t) = \frac{1}{\epsilon} m(z^\epsilon(t), x^\epsilon(t), u(t))dt + \frac{1}{\sqrt{\epsilon}} \sigma(z^\epsilon(t), x^\epsilon(t))dW(t). \tag{2}$$

Here

- for a prescribed compact metric action space A, $h : \mathcal{R}^d \times \mathcal{R}^s \times A \to \mathcal{R}^d$, $\gamma : \mathcal{R}^d \to \mathcal{R}^{d\times d}$, $m : \mathcal{R}^d \times \mathcal{R}^s \times A \to \mathcal{R}^s$, $\sigma : \mathcal{R}^d \times \mathcal{R}^s \to \mathcal{R}^{s\times s}$ are Lipschitz in the first and second (if any) arguments uniformly w.r.t. the third (if any);
- the least eigenvalues of $\gamma(z)\gamma(z)^T$, $\sigma(z,x)\sigma(z,x)^T$ are uniformly bounded away from zero (nondegeneracy assumption);
- the initial values are fixed: $(z^\epsilon(0), x^\epsilon(0)) = (z_0, x_0)$;
- $B(\cdot), W(\cdot)$ are, resp., d- and s-dimensional independent standard Brownian motions;
- $u(\cdot)$ is an A-valued control process with measurable paths satisfying the following *nonanticipativity* condition: for $t \geq s$, $(B(t) - B(s), W(t) - W(s))$ is independent of $\mathcal{F}_s \stackrel{def}{=}$ the completion of

$$\cap_{s'>s}\sigma(z^\epsilon(y), x^\epsilon(y), u(y), y \leq s').$$

We call such $u(\cdot)$ an *admissible control*.

We shall impose further restrictions on A, h, m later. The ergodic control problem is to minimize over all admissible $u(\cdot)$ the "ergodic cost"

$$\lim_{t\uparrow\infty} \frac{1}{t} \int_0^t E[k(z^\epsilon(s), x^\epsilon(s), u(s))]ds. \tag{3}$$

Here $k : \mathcal{R}^d \times \mathcal{R}^s \times A \to \mathcal{R}^+$ is a continuous map satisfying

$$\lim_{||(z,x)||\to\infty} \inf_u k(z,x,u) = \infty. \tag{4}$$

We shall discuss a possible relaxation of this condition later. We also assume the following:

(†) There exists an $\infty > M^* > 0$ such that for each $\epsilon \in (0,1)$, the cost for at least one admissible $u(\cdot)$ is $\leq M^*$.

We shall work with the *weak formulation* of the above control problem and assume that $u(\cdot)$ is a *relaxed* control. That is, for some compact metric space A', $A = \mathcal{P}(A') \stackrel{def}{=}$ the space of probability measures on A' with the Prohorov topology. Moreover, all functions above of the form $f(\ldots, u(t))$ (specifically, k and the components of h, m) are of the form $\int f'(\ldots, y)u(t, dy)$ for an f' satisfying the same conditions as f, except that the factor A of its domain is replaced by A'. This relaxation, originally introduced by L. C. Young in deterministic control, is a true relaxation in this context, in the sense that the infima of the cost over relaxed and original setup coincide. See [9, Chapter I] for more on this. As above, $\mathcal{P}(Z)$ for a Polish space Z will denote the Polish space of probability measures on Z with the Prohorov topology [10, Chapter 2].

Furthermore, we assume that the following "stochastic Liapunov" condition holds: Define $\mathcal{L} : C^2(\mathcal{R}^s)(\stackrel{def}{=}$ the space of twice continuously differentiable functions $\mathcal{R}^s \to \mathcal{R}) \to C_b(\mathcal{R}^d \times \mathcal{R}^s \times A')$ by

$$\mathcal{L}f(z,x,u) \stackrel{def}{=} \frac{1}{2} tr\left(\sigma(z,x)\sigma^T(z,x)\nabla^2 f(x)\right) + \langle \nabla f(x), m'(z,x,u)\rangle \tag{5}$$

$\forall\ f \in C^2(\mathcal{R}^s)$. Then there exists a $V \in C^2(\mathcal{R}^s)$, $g \in C(\mathcal{R}^d \times \mathcal{R}^s)$ such that $\lim_{||x||\to\infty} V(x) = \infty$, $\lim_{||x||\to\infty} g(z,x) = \infty$ uniformly in z belonging to any compact subset of $\mathcal{R}^d$, and

$$\mathcal{L}V(z,x,u) \leq -g(z,x). \tag{6}$$

3. Ergodic control. We now recall from [9, Chapter VI] some facts about ergodic control applicable to the above framework. For this purpose, we introduce the notion of a Markov control as a $u(\cdot)$ of the form $u(t) = v(z^\epsilon(t), x^\epsilon(t))\ \forall t$ for a measurable $v : \mathcal{R}^d \times \mathcal{R}^s \to A$. By a standard abuse of terminology, we identify this $u(\cdot)$ with the map v. Note that under a Markov control, $(z^\epsilon(\cdot), x^\epsilon(\cdot))$ will be a time-homogeneous Markov process. In turn, v will be said to be a stable Markov control if the resulting Markov diffusion is positive recurrent and thus has a unique invariant probability measure $\zeta_v(dzdx)$. Furthermore, (3) will then equal $\int k'(z,x,u)v(du|z,x)\zeta_v(dzdx)$. We call $\Phi_v(dzdxdu) \stackrel{def}{=} \zeta_v(dzdx)v(du|z,x)$ the *ergodic occupation measure* associated with v and denote by $\mathcal{G}$ the set of all ergodic occupation measures Φ_v as v varies over all stable Markov controls. This has another characterization as follows: Let

$$\begin{aligned}&\hat{\mathcal{L}}f(z,x,u)\\ &\stackrel{def}{=} \frac{1}{2}tr\left(\gamma(z)\gamma^T(z)\nabla_z^2 f(z,x)\right) + \langle \nabla_z f(z,x), h'(z,x,u)\rangle\\ &\qquad + \frac{1}{2\epsilon}tr\left(\sigma(z,x)\sigma^T(z,x)\nabla_x^2 f(z,x)\right) + \frac{1}{\epsilon}\langle \nabla_x f(z,x), m'(z,x,u)\rangle,\end{aligned}$$

where ∇_y, ∇_y^2 denote, resp., the gradient and the Hessian in the variable y. Also let $C_0^2(\mathcal{R}^{d+s}) \stackrel{def}{=}$ the space of twice continuously differentiable functions $\mathcal{R}^{d+s} \to \mathcal{R}$ that vanish at infinity, along with their first and second order partial derivatives.

We recall now Lemma 1.1 from [9, p. 144] (see [8] for a more general result).

LEMMA 3.1. $\mathcal{G} = \{\Phi \in \mathcal{P}(\mathcal{R}^{d+s} \times A') : \int \hat{\mathcal{L}} f d\Phi = 0\ \forall f \in C_0^2(\mathcal{R}^{d+s})\}$.

Proof. Let $\Phi(dzdxdu) = \zeta(dzdx)v(du|z,x) \in \mathcal{G}$ and denote by $\hat{\mathcal{L}}_v$ the extended generator of the diffusion controlled by the Markov control v, i.e., $\hat{\mathcal{L}}_v f \stackrel{def}{=} \int \hat{\mathcal{L}} f(z,x,u)v(du|z,x)$. The corresponding diffusion is a time-homogeneous Markov process with a transition semigroup $T_t, t \geq 0$, of positive operators on the Banach space $\mathcal{B}$ of bounded measurable functions $\mathcal{R}^{d+s} \to \mathcal{R}$ (with essential supremum norm) and with (operator) norm 1. Its infinitesimal generator $\mathcal{L}'_v$ is an extension to $\mathcal{D}(\mathcal{L}'_v)$ of $\hat{\mathcal{L}}_v : C_0^2(\mathcal{R}^{d+s}) \subset \mathcal{B} \to \mathcal{B}$. Thus, in particular,

$$\frac{d}{dt}T_t f = \hat{\mathcal{L}}_v T_t f = T_t \hat{\mathcal{L}}_v f, \quad f \in C_0^2(\mathcal{R}^{d+s}). \tag{7}$$

Also, ζ is invariant under $\{T_t\}$:

$$\int f d\zeta = \int T_t f d\zeta \quad \forall t \geq 0, \quad f \in C_b(\mathcal{R}^{d+s}). \tag{8}$$

Then for $t > s$, $f \in C_0^2(\mathcal{R}^{d+s})$,

$$T_t f = T_s f + \int_s^t T_y \hat{\mathcal{L}}_v f dy.$$

Integrating w.r.t. ζ and using (8), we get

$$\int f d\zeta = \int f d\zeta + \int_s^t \int \hat{\mathcal{L}}_v f d\zeta dy, \qquad t > s.$$

It follows that $\zeta(dzdx)v(du|z,x) = \Phi(dzdxdu)$ satisfies

$$\int \hat{\mathcal{L}} f d\Phi \quad \left(= \int \hat{\mathcal{L}}_v f d\zeta\right) = 0, \quad f \in C_0^2(\mathcal{R}^{d+s}). \tag{9}$$

Conversely, let $\Phi(dzdxdu) = \zeta(dzdx)v(du|z,x)$ satisfy (9). Then $\zeta(t) \equiv \zeta \ \forall t \geq 0$ satisfies the forward equation

$$\int f d\zeta(t) = \int f d\zeta(0) + \int_0^t \int \hat{\mathcal{L}}_v f d\zeta(s) ds. \tag{10}$$

From (7) and (10), direct calculation shows that $\frac{d}{ds}\int T_{t-s} f d\zeta(s) = 0$. Integrating this from 0 to t, we have $\int f d\zeta(t) = \int T_t f d\zeta(0)$. Since $\zeta(t) = \zeta(0) = \zeta$, this implies that ζ is stationary under v. In particular, in view of our nondegeneracy assumption, the resulting Markov diffusion process is ergodic. That is, $\Phi \in \mathcal{G}$. □

Define the empirical measures $\nu_t, t > 0$, and the average empirical measures $\bar{\nu}_t, t > 0$, by

$$\int f d\nu_t \stackrel{def}{=} \frac{1}{t}\int_0^t f(z^\epsilon(s), x^\epsilon(s), u(s)) ds,$$

$$\int f d\bar{\nu}_t \stackrel{def}{=} \frac{1}{t}\int_0^t E[f(z^\epsilon(s), x^\epsilon(s), u(s))] ds$$

for $f \in C_b(\mathcal{R}^{d+s} \times A')$. Let $\mathcal{R}^*$ denote the one point compactification of $\mathcal{R}^d \times \mathcal{R}^s$ with ∞ the point at infinity. Finally, let

$\mathcal{G}^* \stackrel{def}{=} \{\Phi \in \mathcal{P}(R^* \times A') :$ there exist some $0 \leq a \leq 1, \phi \in \mathcal{G},$ and $\phi' \in \mathcal{P}(\{\infty\} \times A')$ such that$\Phi(B \times B') = a\phi((B \times B') \cap (\mathcal{R}^{d+s} \times A')) + (1-a)\phi'((B \times B') \cap (\{\infty\} \times A')) \ \forall$ B Borel in $\mathcal{R}^*$, B' Borel in $A'\}$.

The following is adapted from [9, Chapter VI].

LEMMA 3.2. *As $t \uparrow \infty$, $\bar{\nu}_t \to \mathcal{G}^*$ and $\nu_t \to \mathcal{G}^*$ a.s. in $\mathcal{P}(R^* \times A')$.*

Proof. Consider $f \in C_0^2(\mathcal{R}^{d+s})$. Then

$$\frac{E[f(z^\epsilon(t), x^\epsilon(t))]}{t} - \frac{E[f(z^\epsilon(0), x^\epsilon(0))]}{t} = \frac{1}{t}\int_0^t E[\hat{\mathcal{L}} f(z^\epsilon(s), x^\epsilon(s), u(s))] ds$$

$$= \int \hat{\mathcal{L}} f d\bar{\nu}_t.$$

Let ν be a limit point of $\bar{\nu}_t$ in $\mathcal{P}(\mathcal{R}^* \times A')$ as $t \to \infty$. It can then be written as $a\nu_1 + (1-a)\nu_2$, where $\nu_1 \in \mathcal{P}(\mathcal{R}^{d+s} \times A')$, $\nu_2 \in \mathcal{P}(\infty \times A')$, and $a \in [0,1]$. Letting $t \to \infty$ in the above equation along an appropriate subsequence, it follows that $\int \hat{\mathcal{L}} f d\nu_1 = 0$ when $a > 0$. When $a = 0$, this may be imposed without any loss of generality. By Lemma 3.1, it then follows that $\nu_1 \in \mathcal{G}$. For the second claim, one similarly has

$$\frac{f(z^\epsilon(t), x^\epsilon(t))}{t} - \frac{f(z^\epsilon(0), x^\epsilon(0))}{t}$$

$$= \frac{1}{t}\int_0^t \hat{\mathcal{L}} f(z^\epsilon(s), x^\epsilon(s), u(s)) ds$$

$$= \frac{1}{t}\int_0^t \langle \nabla f(z^\epsilon(s), x^\epsilon(s)), (\gamma(z^\epsilon(s)) dB(s), \frac{1}{\sqrt{\epsilon}}\sigma(z^\epsilon(s), x^\epsilon(s)) dW(s))\rangle$$

$$= \int \hat{\mathcal{L}} f d\nu_t + \frac{M(t)}{t},$$

where $M(t)$ is a continuous square-integrable martingale with quadratic variation $\langle M\rangle(t)$ which is $O(t)$. Since $M(t)/\langle M\rangle(t) \to 0$ a.s. on $\{\langle M\rangle(t) \uparrow \infty\}$ (see, e.g., [28]), it follows that

$$\frac{M(t)}{t} = \frac{M(t)}{\langle M\rangle(t)} \frac{\langle M\rangle(t)}{t} \to 0$$

a.s., whence the second claim follows by arguments similar to those used for proving the first. □

The following consequence thereof follows easily.

THEOREM 3.1. *There exists a stable optimal Markov control v_ϵ^* such that if Φ_ϵ^* is the corresponding ergodic occupation measure, then under any admissible $u(\cdot)$,*

$$\liminf_{t\uparrow\infty} \frac{1}{t} \int_0^t k(z^\epsilon(s), x^\epsilon(s), u(s))ds \geq \int k' d\Phi_\epsilon^* \quad a.s.,$$

$$\liminf_{t\uparrow\infty} \frac{1}{t} \int_0^t E[k(z^\epsilon(s), x^\epsilon(s), u(s))]ds \geq \int k' d\Phi_\epsilon^*.$$

Proof. From Lemma 3.2 and (4), it follows that the left-hand side in both cases is ("a.s." in the former case) at least as much as $\inf_{\Phi\in\mathcal{G}} \int k' d\Phi$. By (4), it also follows that the set $\{\Phi \in \mathcal{G} : \int k' d\Phi \leq c\}$ is compact for any $c > 0$. Since $\Phi \to \int k' d\Phi$ is lower semicontinuous on $\mathcal{G}$, it follows that the infimum is attained at some $\Phi_\epsilon^* \in \mathcal{G}$. The claim follows. □

Remark. One can in fact show that the v_ϵ^* can be taken to be *precise*, i.e., $v_\epsilon^*(z, x)$ is a Dirac measure $\forall\ z, x$. This is because the extreme points of $\mathcal{G}$ correspond to precise controls, as proved in [13].

4. The averaged system. Setting $\tau = \frac{t}{\epsilon}$, $\bar{x}(\tau) = x^\epsilon(\epsilon\tau)$, $\bar{z}(\tau) = z^\epsilon(\epsilon\tau)$, $\bar{u}(\tau) = u(\epsilon\tau)$, $\bar{W}(\tau) = \frac{1}{\sqrt{\epsilon}} W(\epsilon\tau)$, (2) becomes

$$d\bar{x}(\tau) = m(\bar{z}(\tau), \bar{x}(\tau), \bar{u}(\tau))d\tau + \sigma(\bar{z}(\tau), \bar{x}(\tau))d\bar{W}(\tau),$$

which does not depend on ϵ explicitly. To this we associate the *associated system*

$$d\bar{x}(\tau) = m(\bar{z}, \bar{x}(\tau), \bar{u}(\tau))d\tau + \sigma(\bar{z}, \bar{x}(\tau))d\bar{W}(\tau), \tag{11}$$

where $\bar{z}$ is fixed, $\bar{W}(\cdot)$ is a standard Brownian motion independent of $\bar{x}(0)$, and admissibility of $\bar{u}(\cdot)$ is defined by the following: For $t > s$, $\bar{W}(t) - \bar{W}(s)$ is independent of $\Xi_s \stackrel{def}{=}$ the completion of $\cap_{s'>s}\sigma(\bar{x}(\tau), \bar{u}(\tau), \bar{W}(\tau), \tau \leq s')$.

Remark. Equation (11) above is the relaxed control form of the associated system. One also has the prerelaxation form

$$d\bar{x}(\tau) = m'(\bar{z}, \bar{x}(\tau), \bar{u}'(\tau))d\tau + \sigma(\bar{z}, \bar{x}(\tau))d\bar{W}(\tau), \tag{12}$$

which we shall have occasion to use later.

Let $D_z \stackrel{def}{=} \{\mu \in \mathcal{P}(\mathcal{R}^s \times A') : \int \mathcal{L}f(z, x, u)\mu(dxdu) = 0\ \forall\ f \in C_0^2(\mathcal{R}^s)\}$, where $\mathcal{L}$ is as in (5). The next lemma in particular characterizes this as the set of ergodic occupation measures for the associated system.

LEMMA 4.1. *D_z = the set of $\mu(dxdu)$ of the form $\mu(dxdu) = \eta(dx)v(du|x)$, where η is the unique stationary distribution for the time-homogeneous Markov diffusion $X(\cdot)$ given by (11) when $u(\cdot) = v(X(\cdot)) \stackrel{def}{=} v(du|X(\cdot))$. The set valued map $z \to D_z$*

is convex compact valued and continuous. Furthermore, for compact $B \subset \mathcal{R}^d$, $\cup_{z\in B} D_z$ *is compact.*

Proof. The first claim follows exactly as in Lemma 3.1. That D_z is convex closed for each z is easily verified from the definition. Thus we need to verify its relative compactness in $\mathcal{P}(\mathcal{R}^s \times A')$. Since A' is compact, it suffices to verify the relative compactness of the corresponding marginals $\eta(dx)$ in $\mathcal{P}(\mathcal{R}^s)$. Under our assumption (6), this is proved in [11]. (The key step is to prove that $\int g d\eta$ is uniformly bounded over all such η, from which the claim is immediate in view of the condition $\lim_{\|(z,x)\|\to\infty} g(z,x) = \infty$, and the Chebyshev inequality.) Next, let $z_n \to z_\infty$ and $\mu_n \in D_{z_n}\ \forall\ n, 1 \le n < \infty$. Then

(i) $\{\mu_n\}$ are tight by arguments similar to those used in [11] (see above), and

(ii) any limit point μ thereof is in D_{z_∞}—this is easily verified from the definition of D_z. Thus $z \to D_z$ is upper semicontinuous.

Now fix a $\mu(dxdu) = \eta_{z_\infty}(dx)v(du|x) \in D_{z_\infty}$. Under $z = z_n$, the stationary Markov control $v(du|x)$ leads to a unique stationary distribution $\eta_{z_n}(dx), 1 \le n \le \infty$. By our nondegeneracy assumption, the transition probabilities for $t > 0$ of the corresponding time-homogeneous Markov processes have densities w.r.t. the Lebesgue measure. Therefore so do the corresponding invariant probability measures $\{\eta_{z_n}\}$. Let $\{\chi_{z_n}(\cdot)\}$ denote these densities. We claim that they are pointwise bounded and equicontinuous. If pointwise boundedness does not hold, $\chi_{z_n}(x^*) \uparrow \infty$ for some x^*. But $\{\chi_{z_n}\}$ satisfy $(\mathcal{L}_v^{z_n})^*\chi_{z_n} \equiv 0$, where

$$\mathcal{L}_v^z \stackrel{def}{=} \frac{1}{2} tr\left(\sigma(z,x)\sigma^T(z,x)\nabla_x^2\right) + \langle m(z,x,v(x)), \nabla_x\rangle,$$

and $(\mathcal{L}_v^z)^*$ denotes its formal adjoint given by

$$(\mathcal{L}_v^z)^* f \stackrel{def}{=} \frac{1}{2}\sum_{i,j,k} \frac{\partial^2}{\partial x_i \partial x_j}\left(\sigma_{ik}(z,x)\sigma_{jk}(z,x)f(x)\right) - \sum_i \frac{\partial}{\partial x_i}\left(m_i(z,x,v(x))f\right).$$

By Harnack's inequality (see Theorem 8.20 on page 199 of [19]), the ratio of the maximum to the minimum of $\chi_{z_n}(\cdot)$ on any compact set must remain bounded uniformly in n. Thus $\chi_{z_n}(\cdot) \uparrow \infty$ uniformly on compacts, which contradicts the fact that they are probability densities. Hence they are pointwise bounded. By [19, Theorem 8.24, p. 202], they satisfy a uniform Hölder continuity condition on compacts, which gives equicontinuity. In particular, $\chi_{z_n}(\cdot)$ are uniformly continuous on compacts. The equation

$$\int \mathcal{L}_v^{z_n} f(x)\eta_{z_n}(dx) = 0\ \forall\ f \in C_0^2(\mathcal{R}^s) \tag{13}$$

characterizes $\eta_{z_n}(dx)$ and therefore $\chi_{z_n}(\cdot)$. Let η^* denote a limit point of $\eta_{z_n}(dx)$ in $\mathcal{P}(\mathcal{R}^s)$ as $n \uparrow \infty$. By the Arzela–Ascoli theorem, we may drop to a subsequence if necessary and suppose that $\chi_{z_n}(\cdot) \to \chi^*(\cdot)$ in $C(\mathcal{R}^s)$. Then for compactly supported $f \in C(\mathcal{R}^s)$,

$$\int f(x)\chi_{z_n}(x)dx \to \int f(x)\chi^*(x)dx,$$

implying that $\eta^*(dx) = \chi^*(x)dx$. By Scheffe's theorem (see Borkar [10, p. 26]), we have $\eta_{z_n}(dx) \to \eta^*$ in total variation. Hence we can let $n \to \infty$ in (13) to obtain

$$\int \mathcal{L}_v^{z_\infty} f d\eta^* = 0\ \forall\ f \in C_0^2(\mathcal{R}^s),$$

implying $\eta^*(dx) = \eta_{z_\infty}(dx)$. Thus the lower semicontinuity of $z \to D_z$ follows. Together, upper and lower semicontinuity imply continuity of this set-valued map. Compactness of $\cup_{z\in B} D_z$ is proved by an argument similar to the one used for proving upper semicontinuity. □

In particular, it follows that $\{(z,\mu) : z \in \mathcal{R}^s, \mu \in D_z\}$ is closed and $\{(z,\mu) : z \in B, \mu \in D_z\}$ is compact for compact $B \subset \mathcal{R}^s$. Define

$$\bar{h}(z,\mu) \stackrel{def}{=} \int h'(z,x,u)\mu(dxdu),$$

$$\bar{k}(z,\mu) \stackrel{def}{=} \int k'(z,x,u)\mu(dxdu).$$

The *averaged system* is defined by

$$dz(t) = \bar{h}(z(t),\mu(t))dt + \gamma(z(t))dB'(t), \tag{14}$$

$$\mu(t) \in D_{z(t)} \quad \forall\, t. \tag{15}$$

Here $z(0) = z_0$ (the same as in (1)), $B'(\cdot)$ is a standard Brownian motion in $\mathcal{R}^d$, and $\mu(\cdot)$ satisfies (15) and the following nonanticipativity condition: For $t \geq s \geq 0$, $B'(t) - B'(s)$ is independent of the completion of $\cap_{s'>s}\sigma(z(y), B'(y), \mu(y), y \leq s')$. We may view $\mu(\cdot)$ as the "effective control process" for the averaged system. The objective for the averaged control problem is to minimize

$$\limsup_{t\uparrow\infty} \frac{1}{t} E\left[\int_0^t \bar{k}(z(s),\mu(s))\right] ds$$

over all admissible $\mu(\cdot)$. By analogy with section 2, we call $\mu(\cdot)$ a Markov control if $\mu(t) = q(z(t)) \stackrel{def}{=} q(dxdu|z(t))\ \forall t$, identified with the measurable map q. Call it a stable Markov control if, in addition, the resulting time-homogeneous Markov process $z(\cdot)$ is positive recurrent. In the latter case, $z(\cdot)$ will have a unique invariant probability distribution $\varphi_q(dz)$ and the corresponding ergodic occupation measure $\Gamma(dzdxdu) \stackrel{def}{=} \varphi_q(dz)q(dxdu|z)$. Let $\mathcal{Q}$ denote the set of such Γ. Then as before, one has the following characterization: Define $\tilde{\mathcal{L}} : C_0^2(\mathcal{R}^d) \to C_b(\mathcal{R}^d \times \mathcal{P}(\mathcal{R}^s \times A'))$ by

$$\tilde{\mathcal{L}}f(z,\mu) = \frac{1}{2} tr\left(\gamma(z)\gamma^T(z)\nabla^2 f(z)\right) + \langle \nabla f(z), \bar{h}(z,\mu)\rangle.$$

Lemma 4.2.

$$\mathcal{Q} = \Bigg\{ \xi = q(dxdu|z)\phi(dz) \in \mathcal{P}(\mathcal{R}^d \times \mathcal{R}^s \times A') : q(\cdot|z) \in D_z\ \forall z,$$

$$\int \tilde{\mathcal{L}}f(z, q(dxdu|z))\phi(dz) = 0\ \forall\ f \in C_0^2(\mathcal{R}^d) \Bigg\}.$$

This again follows exactly as in Lemma 3.1. We have then the following counterpart of Theorem 3.1, proved analogously.

Theorem 4.1. *There exists a stable optimal Markov control q^* for the averaged system such that if $\Gamma^*(dzdxdu) = q^*(dxdu|z)\varphi^*(dz)$ is the corresponding ergodic*

occupation measure, then for any admissible $\mu(\cdot)$ as above,

$$\liminf_{t\uparrow\infty} \frac{1}{t}\int_0^t \bar{k}(z(s),\mu(s))ds \geq \int k'd\Gamma^* \ \ a.s.,$$

$$\liminf_{t\uparrow\infty} \frac{1}{t}\int_0^t E[\bar{k}(z(s),\mu(s))]ds \geq \int k'd\Gamma^*.$$

Let $\mathcal{Q}_{opt}$ denote the set of optimal ergodic occupation measures, i.e.,

$$\text{Argmin}\left\{\int k'd\xi : \xi \in \mathcal{Q}\right\}. \tag{16}$$

Also, write

$$q^*(dxdu|z) = v^*(du|z,x)\eta^*(dx|z). \tag{17}$$

5. A lower bound. We now consider the $\epsilon \downarrow 0$ limit. Let Φ^*_ϵ be as in Theorem 3.1 above. Then by (†), it follows that $\sup \int k d\Phi^*_\epsilon < \infty$. In turn, by (4) and the Chebyshev inequality, it then follows that $\{\Phi^*_\epsilon, \epsilon \in (0,1)\}$ is tight. Let Φ^*_0 be a limit point thereof in $\mathcal{P}(\mathcal{R}^{d+s}\times A')$.

THEOREM 5.1. $\Phi^*_0 \in \mathcal{Q}$.

Proof. Disintegrate Φ^*_0 as

$$\begin{aligned}\Phi^*_0(dzdxdu) &= \varphi(dz)\mu(dxdu|z)\\ &= \varphi(dz)\eta(dx|z)v(du|z,x).\end{aligned}$$

(In particular, $\mu(dxdu|z) = \eta(dx|z)v(du|z,x)$.) Let $f_1 \in C^2_0(\mathcal{R}^d), f_2 \in C^2_0(\mathcal{R}^s)$. Let $\epsilon \downarrow 0$ in the equation $\epsilon\int \hat{\mathcal{L}}(f_1 f_2)d\Phi^*_\epsilon = 0$ to obtain

$$\int f_1(z)\int \mathcal{L}f_2(z,x,u)\mu(dxdu|z)\varphi(dz) = 0. \tag{18}$$

Then as (18) holds $\forall\ f_1 \in C^2_0(\mathcal{R}^d)$, we conclude that for φ-a.s. z,

$$\int \mathcal{L}f_2(z,x,u)d\mu(dxdu|z) = 0,$$

implying that $\mu(dxdu|z) \in D_z$. The qualification "φ-a.s." may be dropped by choosing a suitable version. Now for $h \in C^2_0(\mathcal{R}^d)$ (i.e., h is a function of $z \in \mathcal{R}^d$ alone), let $\epsilon \downarrow 0$ in $\int \hat{\mathcal{L}}h d\Phi^*_\epsilon = 0$ to obtain

$$\int \hat{\mathcal{L}}h d\Phi^*_0 = \int \tilde{\mathcal{L}}h(z,\mu(\cdot|z))\varphi(dz) = 0. \tag{19}$$

By Lemma 4.2, (19) implies that φ is the unique stationary distribution under μ for the averaged system. It follows that $\Phi^*_0 \in \mathcal{Q}$. ∎

COROLLARY 5.1. $\liminf_{\epsilon\downarrow 0}\int k'd\Phi^*_\epsilon \geq \int \bar{k}d\Gamma^*$.

This shows that the optimal ergodic cost for the averaged problem provides an asymptotic lower bound (as $\epsilon \downarrow 0$) for the optimal ergodic cost of the original problem. To show that it is in fact a valid approximation, we must replace the "lim inf" by "lim" in the above and replace the inequality by an equality. We shall do so under additional assumptions in the following sections.

6. Main results—the affine case. Assume the following:

(*) A' is a compact subset of $\mathcal{R}^m$ for some $m \geq 1$, and for each z, x, $h'(z,x,\cdot)$, $m'(z,x,\cdot)$ are componentwise affine, and $k'(z,x,\cdot)$ is strictly convex.

(**) $||h'(z,x,u)|| = o(k'(z,x,u))$ as $||(z,x)|| \uparrow \infty$ and

$$\sup_u |k'(z,x,u)|^{1+a} \leq Kg(z,x)$$

for some $K, a > 0$, and g as in (6).

The next lemma, which uses only (*) and (**), shows in particular that v^* in (17) is unique. Thus we can state our third assumption as follows:

(***) $v^*(z,x) \stackrel{def}{=} v^*(du|z,x)$ in (17) is a stable Markov control for (1), (2) for sufficiently small $\epsilon > 0$ (say, $\epsilon < \epsilon_0$) and the corresponding stationary distributions, denoted $\zeta^\epsilon(dzdx), 0 < \epsilon < \epsilon_0$, are tight.

A stochastic Liapunov condition along the lines of (6) can be given to ensure this.

LEMMA 6.1. *$v^*(du|z,x)$ in (17) is unique (that is, $\mathcal{Q}_{opt}$ is a singleton: $\mathcal{Q}_{opt} = \{\Gamma^*\}$) and continuous in z, x.*

Proof. By [9, Theorem 3.3, p. 163], a necessary and sufficient condition for the optimality of q^* is that $q^*(z)$ minimize the function

$$\mu \to \bar{k}(z,\mu) + \langle \nabla\Psi(z), \bar{h}(z,\mu)\rangle \tag{20}$$

over D_z for a.e. z, where $\Psi \in C^2(\mathcal{R}^d)$ is the value function for the ergodic control problem for the averaged system.[1] We may drop the qualification "for a.e. z" by taking an appropriate version. Now for fixed z, consider the ergodic control problem for the associated system (12) with cost

$$\limsup_{t\uparrow\infty} \frac{1}{t} \int_0^t E[\ell_z(\bar{x}(s), a(t))]ds,$$

where $\ell_z \in C(\mathcal{R}^s \times A')$ is defined by

$$\ell_z(x,a) \stackrel{def}{=} k'(z,x,a) + \langle \nabla\Psi(z), h'(z,x,a)\rangle.$$

Since D_z is precisely the set of ergodic occupation measures for the associated system, q^* is the optimal ergodic occupation measure for the above problem. By (**), [9, Theorem 3.3, p. 163] can be applied again to this new control problem in order to conclude as above that $v^*(du|z,x)$ minimizes

$$\kappa \to \int (\ell_z(x,\cdot) + \langle \nabla\tilde{\Psi}_z(x), m'(z,x,\cdot)\rangle) d\kappa,$$

where $\tilde{\Psi}_z \in C^2(\mathcal{R}^s)$ is the value function for this new ergodic control problem. (Note that for each z, the cost function ℓ_z satisfies a condition akin to (4) because of the first half of (**), and thus the above remarks apply.) By [9, Theorem 2.1, p. 183], it follows

[1] [9] proves the existence of a C^2 value function and the associated "verification theorem" for non-degenerate diffusions with bounded coefficients and the so-called "near-monotone" cost for the case when the control space is state-independent. The latter would correspond to D_z being independent of z in the present setup. Condition (4) is a special case of near-monotonicity. The modifications required to handle the more general Lipschitz coefficients and state-dependent control space needed here are minor in view of the continuity of the set-valued map $z \to D_z$ already established. The details, though routine, would be a significant digression and are therefore omitted.

that the map $(z,x) \to \nabla\tilde{\Psi}_z(x)$ is continuous. By (*), the above minimum is attained at a unique point. It is easy to see then that this point will depend continuously on z,x. That is, $(z,x) \to v^*(z,x)$ is continuous. □

Remark. Note that $v^*(z,x)$ will in fact be Dirac $\forall\ z,x$. Also note that the assumption of affine dependence of k', m' on u is crucial in proving the strict convexity claims above: The sum of a strictly convex function and an affine function is strictly convex. Weakening it to convexity would not do because we do not have control on the signs of the components of $\nabla\Psi, \nabla\tilde{\Psi}$.

Recall the measures q^*, Γ^* from Theorem 4.1.

COROLLARY 6.1. *q^*, Γ^* are unique.*

Proof. Recall that $q^*(dxdu|z) = \eta^*(dx|z)v^*(du|z,x)$, where $\eta^*(dx|z)$ is the unique stationary distribution for the associated system under $v^*(du|z,x)$. Uniqueness of q^* follows. In turn, $\Gamma^*(dzdxdu) = q^*(dxdu|z)\varphi^*(dz)$, where φ^* is the unique stationary distribution of the averaged system under $q^*(dxdu|z)$. Thus Γ^* is unique. □

Let

$$\tilde{\Phi}_\epsilon(dzdxdu) \stackrel{def}{=} \zeta^\epsilon(dzdx)v^*(du|z,x), \qquad \epsilon \in (0,\epsilon_0),$$

and let v^* be as in (17).

THEOREM 6.1. $\lim_{\epsilon\downarrow 0}\tilde{\Phi}_\epsilon = \Gamma^*$, *the convergence being in* $\mathcal{P}(\mathcal{R}^d \times \mathcal{R}^s \times A')$. *Also*

$$\lim_{\epsilon\downarrow 0}\int k'd\tilde{\Phi}_\epsilon = \int k'd\Gamma^* \tag{21}$$

and

$$\lim_{\epsilon\downarrow 0}\int k'd\Phi^*_\epsilon = \int k'd\Gamma^*. \tag{22}$$

Proof. In view of Theorem 5.1, (21) implies (22). Below, we will prove the convergence of $\tilde{\Phi}_\epsilon$ to Γ^* and then show the validity of (21).

Let $\zeta^\epsilon(dzdx) \to \hat{\zeta}(dzdx) = \hat{\varphi}(dz)\hat{\eta}(dx|z)$ along a subsequence as $\epsilon \downarrow 0$. In view of the continuity of $v^*(du|\cdot,\cdot)$, we may pass to the limit along this subsequence in

$$\epsilon\int \hat{\mathcal{L}}f(z,x,u)v^*(du|z,x)\zeta^\epsilon(dzdx) = 0,\ f \in C_0^2(\mathcal{R}^{d+s})$$

to obtain

$$\int \hat{\mathcal{L}}f(z,x,u)v^*(du|z,x)\hat{\zeta}(dzdx) = 0,\ f \in C_0^2(\mathcal{R}^{d+s}).$$

Argue as in Theorem 5.1 to conclude that $\hat{\eta}(dx|z)$ is in fact the unique stationary distribution for the associated system controlled by $v^*(du|z,x)$ (i.e., $\hat{\eta}(dx|z) = \eta^*(dx|z)$) for $\hat{\varphi}$-a.s. z. The latter qualification may be dropped by choosing an appropriate version. Recall that $q^*(dxdu|z) = \eta^*(dx|z)v^*(du|z,x)\ \forall\ z$. Let $\epsilon \downarrow 0$ in

$$\int \hat{\mathcal{L}}f(z,x,u)v^*(du|z,x)\zeta^\epsilon(dzdx) = 0$$

for $f \in C_0^2(\mathcal{R}^d)$ (i.e., f is a C^2 function of the z variable alone). An argument similar to the above then yields

$$\int \tilde{\mathcal{L}}f(z,q^*(\cdot|z))\hat{\varphi}(dz) = 0,\ f \in C_0^2(\mathcal{R}^d).$$

Thus $\hat{\varphi}(dz)$ is the unique stationary distribution for the averaged system controlled by the stable Markov control q^*, i.e., $\hat{\varphi} = \varphi^*$. Then

$$v^*(du|z,x)\hat{\zeta}(dzdx) = \Gamma^*(dzdxdu).$$

That is, $\tilde{\Phi}_\epsilon \to \Gamma^*$. By (6) and Theorem 8.3 of [11], $\int g d\Phi$ is uniformly bounded as Φ varies over $\mathcal{Q}$. By the second half of (**) and [10, Theorem 1.3.10, p. 10], it then follows that k' is uniformly integrable over $\mathcal{Q}$. Hence (21) holds. □

7. Main results—the general case. Now we drop (*). Define $v^*_\delta(du|z,x), \delta > 0$ small (say, $\delta \in (0, \delta_0]$), by

$$\int f v^*_\delta(du|z,x) \stackrel{def}{=} \int\int f v^*(du|z',x')\pi_\delta(z-z', x-x')dz'dx', \ f \in C(A'),$$

where $\{\pi_\delta : \mathcal{R}^{d+s} \to \mathcal{R}, \delta \in (0,\delta_0]\}$ are smooth approximations to the Dirac measure, i.e., compactly supported C^∞ probability density functions such that $\pi_\delta(z,x)dzdx \to \delta_{(0,0)}$ in $\mathcal{P}(\mathcal{R}^{d+s})$ as $\delta \downarrow 0$. In the following, $v^*_0(du|z,x) \stackrel{def}{=} v^*(du|z,x)$ and all quantities with subscript $\delta = 0$ correspond to it. Replace (***) by (A1), (A2) below.

(A1) $v^*_\delta(z,x) \stackrel{def}{=} v^*_\delta(du|z,x)$ is a stable Markov control for (1), (2) for $\delta \in [0,\delta_0], \epsilon \in (0,\epsilon_0)$. Furthermore, there exists a $\hat{g} \in C(\mathcal{R}^{d+s})$ satisfying

$$\sup_u |k'(z,x,u)|^{1+a} \le K\hat{g}(z,x) \tag{23}$$

such that the stationary distributions of (1), (2) corresponding to $\{v^*_\delta\}$, denoted by $\zeta^\epsilon_\delta(dzdx), 0 < \epsilon < \epsilon_0$, satisfy

$$\sup_{0<\epsilon<\epsilon_0} \int \hat{g}(z,x)\zeta^\epsilon_\delta(dzdx) < \infty \tag{24}$$

for each $\delta \in [0,\delta_0]$.

Once again in view of our nondegeneracy assumption, the transition probabilities for $t > 0$ of the time-homogeneous Markov process described by (11) under Markov control $v^*_\delta, \delta \in [0,\delta_0]$, have densities w.r.t. the Lebesgue measure. Therefore so do the corresponding invariant probability measures $\hat{\eta}_\delta(dx|z)$. Let $\chi_\delta(x|z)$ denote this density. Let $\bar{\mu}_\delta(dxdu|z) \stackrel{def}{=} \hat{\eta}_\delta(dx|z)v^*_\delta(du|z,x)$ and $\bar{\varphi}_\delta$ be the unique stationary distribution for (14) under the Markov control $\bar{\mu}_\delta$. Let $\zeta^0_\delta(dzdx) \stackrel{def}{=} \hat{\eta}_\delta(dx|z)\bar{\varphi}_\delta(dz)$ and $\Phi^0_\delta(dzdxdu) \stackrel{def}{=} \zeta^0_\delta(dzdx)v^*_\delta(du|z,x)$ for δ as above. Note that $\Phi^0_0 \in \mathcal{Q}_{opt}$. We also assume the following.

(A2) $\bar{\mu}_\delta(dxdu|z)$ is a stable Markov control for (14) for $\delta \in [0,\delta_0]$, and for $\hat{g}$ as above,

$$\sup_{\delta\in[0,\delta_0]} \int \hat{g}(z,x)\zeta^0_\delta(dzdx) < \infty. \tag{25}$$

LEMMA 7.1. *As $(\delta_n, z_n) \to (\delta, z)$ in $[0,\delta^*] \times \mathcal{R}^d$, $\hat{\eta}_{\delta_n}(dx|z_n) \to \hat{\eta}_\delta(dx|z)$ in total variation.*

Proof. This follows by an argument based on the Harnack inequality, as in the proof of Lemma 4.1, using the fact that $\chi_\delta(\cdot|z)$ will be equicontinuous and pointwise bounded. □

LEMMA 7.2. $\int k' d\Phi_\delta^0 \to \int k' d\Phi_0^0$ *as* $\delta \downarrow 0$.

Proof. By (4), (23), (25), and the Chebyshev inequality, $\zeta_\delta^0, \delta \in [0, \delta_0]$, and therefore $\bar{\varphi}_\delta, \delta \in [0, \delta_0]$, are tight. Let $\bar{\varphi}$ be any limit point of $\bar{\varphi}_\delta$ as $\delta \downarrow 0$. Since $\bar{\varphi}_\delta$ is characterized by

$$\int \tilde{\mathcal{L}} f(z, \bar{\mu}_\delta(\cdot|z)) \bar{\varphi}_\delta(dz) = 0, \ f \in C^2(\mathcal{R}^s), \tag{26}$$

an argument based on the Harnack inequality analogous to that of Lemma 4.1 implies that this convergence is in fact in total variation. Now for $f \in C_b(\mathcal{R}^d \times \mathcal{R}^s \times A')$,

$$\int f(z, x, u) v_\delta^*(du|z, x) \to \int f(z, x, u) v_0^*(du|z, x)$$

a.e. along a subsequence $\delta = \delta_m \downarrow 0$. (This convergence is in $L^1_{loc}(\mathcal{R}^{d+s})$ by [27, Theorem 2.16, p. 64] and therefore a.e. along a subsequence.) Hence by Lemma 7.1, along this subsequence,

$$\int\int f(z, x, u) v_\delta^*(du|z, x) \hat{\eta}_\delta(dx|z) \to \int\int f(z, x, u) v_0^*(du|z, x) \hat{\eta}_0(dx|z)$$

a.e., which in turn leads to

$$\begin{aligned} &\int\int\int f(z, x, u) v_\delta^*(du|z, x) \hat{\eta}_\delta(dx|z) \bar{\varphi}_\delta(dz) \\ &\quad \to \int\int\int f(z, x, u) v_0^*(du|z, x) \hat{\eta}_0(dx|z) \bar{\varphi}(dz). \end{aligned}$$

In particular, letting $\delta \downarrow 0$ along an appropriate subsequence in (26), we have

$$\int \tilde{\mathcal{L}} f(z, \bar{\mu}_0(\cdot|z)) \bar{\varphi}(dz) = 0, \ f \in C^2(\mathcal{R}^s), \tag{27}$$

i.e., $\bar{\varphi} = \bar{\varphi}_0$. Thus $\Phi_\delta^0 = \mu_\delta(dxdu|z)\bar{\varphi}_\delta(dz) \to \Phi_0^0 = \mu_0(dxdu|z)\bar{\varphi}_0(dz)$ as $\delta \downarrow 0$. Equations (23) and (25) and [10, Theorem 1.3.4, p. 10] ensure uniform integrability of k' under these, which in turn implies the claim. □

Going back to (1), (2), let $u(\cdot) = v_\delta^*(z^\epsilon(\cdot), x^\epsilon(\cdot))$ and let $\Phi_\delta^\epsilon \in \mathcal{P}(\mathcal{R}^d \times \mathcal{R}^s \times A')$ be the corresponding ergodic occupation measure for $\delta > 0$.

LEMMA 7.3. $\int k' d\Phi_\delta^\epsilon \to \int k' d\Phi_\delta^0$ *as* $\epsilon \downarrow 0$.

The proof follows along similar lines, using (24) in place of (25), and is omitted.

THEOREM 7.1. $\lim_{\epsilon \downarrow 0} \int k' d\Phi_\epsilon^* = \int k' d\Phi_0^*$.

Proof. Fix $\alpha > 0$ and take $\delta > 0$ small enough such that

$$\left| \int k' d\Phi_\delta^0 - \int k' d\Phi_0^0 \right| < \frac{\alpha}{2}.$$

Then pick $\epsilon > 0$ small enough so that

$$\left| \int k' d\Phi_\delta^\epsilon - \int k' d\Phi_\delta^0 \right| < \frac{\alpha}{2}.$$

Thus

$$\begin{aligned} \limsup_{\epsilon \downarrow 0} \int k' d\Phi_\epsilon^* &\le \limsup_{\epsilon \downarrow 0} \int k' d\Phi_\delta^\epsilon \\ &\le \int k' d\Phi_0^0 + \alpha. \end{aligned}$$

Since $\alpha > 0$ is arbitrary, the claim follows in view of Corollary 5.1. □

We conclude this section by pointing out a routine extension of the condition (4): It can be replaced by the weaker requirement

$$\lim_{||z||\to\infty} \inf_{x,u} k(z,x,u) > \beta^* \stackrel{def}{=} \sup_{0\le\epsilon<\epsilon_0} \beta^\epsilon \tag{28}$$

for some $\epsilon_0 > 0$, where $\beta^\epsilon, \epsilon > 0$, is the optimal cost for the ergodic control problem ($\epsilon = 0$ corresponds to the same for the averaged problem). This follows exactly along the lines of [9, Chapter VI]. The important thing to note is that the above condition suffices to ensure tightness of Q. Since in particular this presupposes that β^ϵ are uniformly bounded for $\epsilon \in (0, \epsilon_0)$, we may replace the "$\sup_{0\le\epsilon<\epsilon_0} \beta^\epsilon$" above by "$\sup_{0<\epsilon<\epsilon_0} \beta^\epsilon$" in view of Theorem 5.1.

8. The stable case. We briefly indicate the corresponding developments when a blanket stability condition is available. We do not assume (4) or its generalization (28), but require that k' be bounded from below. Suppose for $\epsilon \in (0, \epsilon_0)$ there exist $\Delta_\epsilon, a_\epsilon > 0, B \subset \mathcal{R}^{d+s}$ bounded and $V_\epsilon^{(i)} \in C^2(\mathcal{R}^{d+s}), i = 1, 2$, such that $V_\epsilon^{(i)} \ge 0, \lim_{||(z,x)||\to\infty} V_\epsilon^{(i)}(z,x) = \infty$ for $i = 1, 2$, and,

$$\hat{\mathcal{L}} V_\epsilon^{(1)}(z,x,u) \le -\Delta_\epsilon, \tag{29}$$

$$\hat{\mathcal{L}} V_\epsilon^{(2)}(z,x,u) \le -a_\epsilon V_\epsilon^{(1)}(z,x) \tag{30}$$

for $(z,x) \notin B$. Let $\tau \stackrel{def}{=} \inf\{t \ge 0 : (z^\epsilon(t), x^\epsilon(t)) \in B\}$ and $\bar{\tau}_N \stackrel{def}{=} \inf\{t \ge 0 : ||(z^\epsilon(t), x^\epsilon(t))|| > N\}, N \ge 1$. Then $\bar{\tau}_N \uparrow \infty$ a.s., and for $(z_0, x_0) \notin B$, the Ito–Dynkin formula and (29) lead to

$$E[V_\epsilon^{(1)}(z^\epsilon(\tau \wedge \bar{\tau}_N), x^\epsilon(\tau \wedge \bar{\tau}_N))] - V_\epsilon^{(1)}(z_0, x_0) \le -\Delta_\epsilon E[\tau \wedge \bar{\tau}_N].$$

Letting $N \uparrow \infty$ and rearranging terms, we have

$$E[\tau] \le \frac{V_\epsilon^{(1)}(z_0, x_0)}{\Delta_\epsilon}.$$

Similarly from (30) we get

$$E\left[\int_0^{\tau\wedge\bar{\tau}_N} V_\epsilon^{(1)}(z^\epsilon(t), x^\epsilon(t))dt\right] \le \frac{V_\epsilon^{(2)}(z_0, x_0)}{a_\epsilon},$$

and therefore

$$\begin{aligned}
&\frac{1}{2}E[(\tau \wedge \bar{\tau}_N)^2] \\
&= E\left[\int_0^{\tau\wedge\bar{\tau}_N} (\tau \wedge \bar{\tau}_N - t)dt\right] \\
&= E\left[\int_0^{\tau\wedge\bar{\tau}_N} E[\tau \wedge \bar{\tau}_N - t|\mathcal{F}_t]dt\right] \\
&\le \frac{1}{\Delta_\epsilon} E\left[\int_0^{\tau\wedge\bar{\tau}_N} V_\epsilon^{(1)}(z^\epsilon(t), x^\epsilon(t))dt\right] \\
&\le \frac{1}{a_\epsilon \Delta_\epsilon} V^{(2)}(z_0, x_0).
\end{aligned}$$

Letting $N \uparrow \infty$,

$$E[\tau^2] \leq \frac{2}{a_\epsilon \Delta_\epsilon} V^{(2)}(z_0, x_0).$$

In view of this, one can argue as in [9, Chapter VI] to conclude Theorem 3.1. The key step is that the above inequality ensures that $\{\nu_t\}$ remain a.s. tight (so do $\{\bar{\nu}_t\}$), and thus Lemma 3.2 can be strengthened to the claim

$$\nu_t \to \mathcal{G} \text{ a.s.}, \qquad \bar{\nu}_t \to \mathcal{G}.$$

Furthermore, $\mathcal{G}$ can be shown to be compact. This allows one to conclude Theorem 3.1 without the need to use (4). Conditions similar to (29), (30) imposed on (14) ensure Theorem 4.1. Next, for obtaining the counterparts of the results of section 6 above for the affine case, assume the additional conditions stipulated in [9, section VI.4] to ensure the existence of C^2 value functions for the two ergodic control problems featured in the proof of Lemma 6.1. The rest remains as before. We omit the details, as they are straightforward adaptations of the foregoing.

9. Some future directions. We conclude by pointing out some further possibilities. We have not allowed σ to depend on the control variable u, or γ to depend on either u or x. This is because such a dependence would lead to a diffusion matrix which is measurable but not necessarily continuous under a Markov control (for the averaged system in the latter case). Even in the nondegenerate case, only the existence of weak solutions is known for this level of generality, not their uniqueness [24], [29]. It may be possible to work with a "set of all weak solutions" in place of the unique weak solution and extend the foregoing. In the degenerate case, even with the existing form of (1), (2), there are problems. The results of [8] extend the characterization of ergodic occupation measures from Lemma 3.1, which allows us to prove Theorem 5.1 under suitable hypotheses. But Theorem 6.1 is a more difficult proposition due to a lack of ergodicity and other problems.

EXACT CONTROLLABILITY FOR MULTIDIMENSIONAL SEMILINEAR HYPERBOLIC EQUATIONS*

XIAOYU FU†, JIONGMIN YONG‡, AND XU ZHANG§

Abstract. In this paper, we obtain a global exact controllability result for a class of multidimensional semilinear hyperbolic equations with a superlinear nonlinearity and variable coefficients. For this purpose, we establish an observability estimate for the linear hyperbolic equation with an unbounded potential, in which the crucial observability constant is estimated explicitly by a function of the norm of the potential. Such an estimate is obtained by a combination of a pointwise estimate and a global Carleman estimate for the hyperbolic differential operators and analysis on the regularity of the optimal solution to an auxiliary optimal control problem.

Key words. exact controllability, semilinear hyperbolic equation, superlinear growth, observability inequality, global Carleman estimate

1. Introduction.

Given $T > 0$ and a bounded domain Ω of $\mathbb{R}^n$ ($n \in \mathbb{N}$) with C^2 boundary Γ, put $Q = (0,T)\times\Omega$ and $\Sigma = (0,T)\times\Gamma$. Let ω be a proper open nonempty subset of Ω and denote by χ_ω the characteristic function of ω. For any set $M \subset \mathbb{R}^n$ and $\delta > 0$, we define $\mathcal{O}_\delta(M) = \big\{x \in \mathbb{R}^n \,\big|\, |x - x'| < \delta \text{ for some } x' \in M\big\}$. Also, we denote $\sum_{i,j=1}^n$ and $\sum_{i=1}^n$ simply by $\sum_{i,j}$ and $\sum_i$, respectively. For simplicity, we will use the notation $y_i = y_{x_i}$, where x_i is the ith coordinate of a generic point $x = (x_1, \dots, x_n)$ in $\mathbb{R}^n$. In a similar manner, we use the notation w_i, v_i, etc. for the partial derivatives of w and v with respect to x_i. On the other hand, for any domain M in $\mathbb{R}^n$ (even without any regularity condition on its boundary ∂M), we refer to [1, Chap. 3] for the definition and basic properties of the Sobolev spaces $H_0^1(M)$, $H^{-1}(M)$, etc. (Hence, $H_0^1(Q)$ and $H^{-1}(Q)$ are particularly well defined in [1, Chap. 3].)

Let $a^{ij}(\cdot) \in C^1(\overline{\Omega})$ be fixed, satisfying

$$a^{ij}(x) = a^{ji}(x) \quad \forall\, x \in \overline{\Omega}, \qquad i,j = 1,2,\dots,n, \tag{1.1}$$

and for some constant $\beta > 0$,

$$\sum_{i,j} a^{ij}(x)\xi^i\xi^j \geq \beta|\xi|^2 \quad \forall\, (x,\xi) \in \overline{\Omega}\times\mathbb{R}^n, \tag{1.2}$$

where $\xi = (\xi^1, \dots, \xi^n)$. In what follows, put $A \stackrel{\triangle}{=} (a^{ij})_{n\times n}$. We define a differential

operator $\mathcal{P}$ by

$$\mathcal{P}y \triangleq y_{tt} - \sum_{i,j} \left(a^{ij}(x)y_i\right)_j . \tag{1.3}$$

Next, we fix a function $f(\cdot) \in C^1(\mathbb{R})$, satisfying the following condition:

$$\overline{\lim_{s\to\infty}} \frac{f(s)}{s \ln^{1/2} |s|} = 0. \tag{1.4}$$

Note that $f(\cdot)$ in the above can have a superlinear growth. We consider the following controlled semilinear hyperbolic equation with an internal local controller acting on ω:

$$\begin{cases} \mathcal{P}y = f(y) + \chi_\omega(x)\gamma(t,x) & \text{in } Q, \\ y = 0 & \text{on } \Sigma, \\ y(0) = y_0, \quad y_t(0) = y_1 & \text{in } \Omega. \end{cases} \tag{1.5}$$

In (1.5), $(y(t,\cdot), y_t(t,\cdot))$ is the *state*, and $\gamma(t,\cdot)$ is the *control* which acts on the system through the subset ω of Ω. In what follows, we choose the *state space* and the *control space* of system (1.5) to be $H_0^1(\Omega) \times L^2(\Omega)$ and $L^2((0,T)\times\omega)$, respectively. We point out that some other choices of spaces are possible. But our choice is natural in the context of the hyperbolic equations. The space $H_0^1(\Omega) \times L^2(\Omega)$ is often referred to as the *finite energy space*. For any $(y_0, y_1) \in H_0^1(\Omega) \times L^2(\Omega)$ and $\gamma \in L^2((0,T)\times\Omega)$, using the method in [4] one can prove the global existence of a unique weak solution $y \in C([0,T]; H_0^1(\Omega)) \cap C^1([0,T]; L^2(\Omega))$ for (1.5) under assumption (1.1)–(1.2), and under (1.4) with $f(\cdot) \in C^1(\mathbb{R})$.

The main purpose of this paper is to study the global exact controllability of (1.5), by which we mean the following: For any given $(y_0, y_1), (z_0, z_1) \in H_0^1(\Omega) \times L^2(\Omega)$, find a control $\gamma \in L^2((0,T)\times\omega)$ such that the corresponding weak solution y of (1.5) satisfies

$$y(T) = z_0, \quad y_t(T) = z_1 \qquad \text{in } \Omega. \tag{1.6}$$

Due to the finite propagation speed of solutions to hyperbolic equations, the "waiting time" T has to be large enough. The estimate of T is also a part of the problem.

The problem of exact controllability for linear hyperbolic equations (for example, $f(\cdot)$ is a linear function, or simply, $f(\cdot) \equiv 0$ in (1.5)) has been studied by many authors. We mention here some standard references, for example, [2, 29, 33].

The study of exact controllability problems for nonlinear hyperbolic equations began in the 1960s. Early works, including [5, 6, 10] and so on, were mainly devoted to the local controllability problem, by which we mean that the controllability property was proved under some smallness assumptions on the initial data and/or the final target. In [43], further local results were proved for the exact controllability of some semilinear wave equations in the form of (1.5) with $A = I$, the identity matrix, and under a very general assumption on the nonlinearity $f(\cdot)$ (which allows $f(\cdot)$ to be local Lipschitz continuous). We refer to [27] and the references cited therein for some recent local controllability results of certain quasi-linear hyperbolic systems.

A global boundary exact controllability result for semilinear wave equations, corresponding to (1.5), in the state spaces $H_0^r(\Omega) \times H^{r-1}(\Omega)$ $(r \in (0,1/2) \cup (1/2,1))$ or $H_{00}^{1/2}(\Omega) \times (H_{00}^{1/2}(\Omega))'$, with Dirichlet boundary control, was given in [44] under the

assumption that $A = I$ and that the nonlinearity $f(\cdot)$ is globally Lipschitz continuous, i.e., $f'(\cdot) \in L^\infty(\mathbb{R})$. In [23], this controllability result was improved to include the critical points $r = 0$ and 1, and also extended to the abstract setting. Recent progress in this respect can be found in [36] and [37]. In the case that $f(\cdot)$ is sublinear, we refer to [34] for the global exact controllability of (1.5).

As for the case that $f(\cdot)$ grows superlinearly at infinity, very little is known for the global exact controllability of the semilinear hyperbolic equation (1.5) except for the one space dimension, i.e., $n = 1$. We refer to [3, 9, 30, 45] for related one-dimensional results. To our best knowledge, in the superlinear setting, [26] is the only paper that discussed the global exact controllability for multidimensional system (1.5) (we refer to [42] for an updated survey on this problem). By assuming that $A = I$ and $\omega = \mathcal{O}_\delta(\Gamma) \cap \Omega$ for some $\delta > 0$, [26] shows that system (1.5) with $f(\cdot)$ satisfying (1.4) is exactly controllable. In this paper, based on a method which is different from [26], we shall consider a more general case by using a smaller controller $\omega = \mathcal{O}_\delta(\Gamma_+) \cap \Omega$ (see (2.5) for Γ_+) and allowing the coefficients matrix A to be nonconstant one. We refer the reader to Condition 2.1 and the subsequent remarks, and especially Proposition 2.1, for assumptions on matrix A.

In order to obtain the exact controllability of (1.5), one needs to consider, by the well-known duality argument (see [29], [28, Lemma 2.4, p. 282], and [39, Theorem 3.2, p. 19], for example), the following dual system of the linearized system of (1.5):

$$\left\{\begin{array}{ll} \mathcal{P}w = qw & \text{in } Q, \\ w = 0 & \text{on } \Sigma, \\ (w(0), w_t(0)) = & (w_0, w_1) \in L^2(\Omega) \times H^{-1}(\Omega), \end{array}\right. \tag{1.7}$$

with a potential q in some space (larger than $L^\infty(Q)$, in general). It follows from the standard perturbation theorem in the semigroup theory [31] that for a suitable q, say $q \in L^\infty(0, T; L^n(\Omega))$, (1.7) is well-posed in $L^2(\Omega) \times H^{-1}(\Omega)$.

Similar to [45] and [26], the above controllability problem may be reduced to an explicit observability estimate for system (1.7). Namely, we expect to find a constant $\mathcal{C}(q) > 0$ such that all weak solutions w of (1.7) satisfy

$$|(w_0, w_1)|_{L^2(\Omega)\times H^{-1}(\Omega)} \leq \mathcal{C}(q)|w|_{L^2((0,T)\times\omega)} \ \forall\ (w_0, w_1) \in L^2(\Omega) \times H^{-1}(\Omega). \tag{1.8}$$

The explicit estimate of $\mathcal{C}(q)$ in terms of a suitable norm of the potential q is an indispensable part of the problem, which is actually the key novelty in this paper. Similar problems for $A = I$ and bounded potentials q were considered in [36, 37]. However, in the present case we cannot assume that q in (1.7) is bounded since we do not assume that the nonlinearity $f(\cdot)$ in (1.5) is globally Lipschitz continuous. To overcome this difficulty, we need, among other things, to combine some ideas found in [18] and [37].

It is well known that the Carleman estimate is one of the major tools used in the study of unique continuation, observability, and controllability problems for various kinds of partial differential equations (PDEs). However, the "concrete" Carleman estimate for these problems is actually quite different! Indeed, in principle, among these problems unique continuation is the "easiest," and one may develop an abstract theory for the unique continuation property (usually, of local nature) for very general partial differential operators, based on a pseudoconvexity condition, the Carleman estimate, and by means of the microlocal analysis technique [16, 17, 35]. Observability is, however, a quantitative version of the global unique continuation, which is much

more difficult to establish than the classical (qualitative) unique continuation. For example, the unique continuation for the parabolic equations was known for a very long time, but the observability for the same equation was not established until the 1990s by means of a new Carleman estimate [11, 14]. Also, for the hyperbolic equations, the work of [20, 21] applied Carleman estimates for the proofs of the observability results. On the other hand, there are many equations (say, the hyperbolic-parabolic coupled systems in [32]), for which one can easily establish its unique continuation, but its observability is completely unknown for multidimensions (the analysis for the one-dimensional problem [41] is highly nontrivial, and some atypical phenomenon occurs). Finally, as for controllability problems, as mentioned before the classical duality argument reduces the problem to obtaining a suitable observability estimate. However, for the global controllability problems for semilinear PDEs with superlinear growing nonlinearity, the key point is the explicit estimate of the observability constant by a suitable function of the norm of the potential. For this purpose, one has to proceed more carefully than one would for the usual observability when using the Carleman estimate. Note also that the approach developed in this article seems to be virtually complete. Our key estimate on the observability constant $\mathcal{C}(q)$ is presented in (2.12) of Theorem 2.3. As suggested by [8, Theorem 1.2], it may well be that (2.12) is sharp (see also our Remark 2.1). In this respect, it is worth mentioning that one can also adopt the method developed in [20, 21, 22] to establish an explicit observability estimate for some special case of system (1.7) (i.e., $A = aI$ with a suitable positive function a), as done in [36]. However, it seems that the estimate obtained in this way is far from sharp. Indeed, the estimate on the observability constant $\mathcal{C}(q)$ obtained in [36] (for bounded potential q) reads as $C\exp(\exp(\exp(Cr_0)))$ with $r_0 = |q|_{L^\infty(Q)}$, which is much weaker than that in (2.12). It would be quite interesting to check whether the method in [20, 21, 22] can be adopted to derive the same estimate as that of (2.12) in Theorem 2.3. But this remains to be done.

The rest of this paper is organized as follows. In section 2, we shall state the main results. Some preliminary results are collected in section 3. In section 4, we derive an estimate for second order differential operators with symmetric coefficients that is of independent interest. This estimate will play a key role when we establish in section 5 a global Carleman estimate for the hyperbolic differential operators in $H_0^1(Q)$. The latter estimate, in turn, is one of the crucial preliminary results we derive in section 7, i.e., a similar global Carleman estimate for the hyperbolic differential operators in a larger space $L^2(Q)$. Another crucial preliminary we study, in section 6, is an auxiliary optimal control problem, where the key point is to obtain some regularity of the optimal solution. In sections 8–9, we will prove our main results. Finally, Appendices A, B, and C are devoted to proving some technical results that are used throughout the paper.

2. Statement of the main results. To begin, we introduce the following condition.

CONDITION 2.1. *There exists a function $d(\cdot) \in C^2(\overline{\Omega})$ satisfying the following:* (i) *For some constant $\mu_0 > 0$, it holds that*

$$\sum_{i,j}\left\{\sum_{i',j'}\left[2a^{ij'}(a^{i'j}d_{i'})_{j'} - a^{ij}_{j'}a^{i'j'}d_{i'}\right]\right\}\xi^i\xi^j \geq \mu_0\sum_{i,j}a^{ij}\xi^i\xi^j \quad \forall\,(x,\xi^1,\dots,\xi^n) \in \overline{\Omega}\times\mathbb{R}^n. \tag{2.1}$$

(ii) *There is no critical point of function* $d(\cdot)$ *in* $\overline{\Omega}$, *i.e.,*

$$\min_{x\in\overline{\Omega}} |\nabla d(x)| > 0. \tag{2.2}$$

Let us make some remarks on the above condition.

First, Condition 2.1 is really a restriction on the coefficient matrix A and the domain Ω. Indeed, as we shall see later, Condition 2.1 at least leads to the exact controllability of system (1.5) with $f(\cdot) \equiv 0$ and $\omega = \mathcal{O}_\delta(\Gamma)\bigcap\Omega$ for any given $\delta > 0$ and sufficiently large "waiting time" $T > 0$, while it is shown in [2] that, in order for the latter to hold, (T, Ω, ω) has to satisfy a geometric optics condition which is characterized by the null bicharacteristic of operator $\mathcal{P}$. But, for any $T > 0$, this condition may fail to be true for some $\mathcal{P}$ (with special coefficients) and some (Ω, ω) (see [2]). This condition is crucial in what follows, where we derive a Carleman estimate for the hyperbolic operators (see (11.4)). Nevertheless, to the best of our knowledge, there is no universal tractable Carleman estimates in the literature for general hyperbolic operators. We shall give below some tractable examples. However, a detailed analysis of Condition 2.1 is beyond the scope of this paper and will be presented elsewhere.

Second, by (1.1)–(1.2), one can check that (2.1) is equivalent to the uniform positivity of the following (symmetric) matrix:

$$\begin{aligned}\mathcal{A} &\triangleq \left(\sum_{i',j'}\left(a^{ij'}a^{i'j}d_{i'j'} + \frac{(a^{ij'}a_{j'}^{i'j} + a^{jj'}a_{j'}^{i'i} - a_{j'}^{ij}a^{i'j'})d_{i'}}{2}\right)\right)_{1\le i,j\le n} \\ &\equiv A\mathcal{H}_d A + \frac{1}{2}\left(\sum_{i',j'}(a^{ij'}a_{j'}^{i'j} + a^{jj'}a_{j'}^{i'i} - a_{j'}^{ij}a^{i'j'})d_{i'}\right)_{1\le i,j\le n},\end{aligned} \tag{2.3}$$

where $\mathcal{H}_d$ is the Hessian matrix of $d(\cdot)$. Hence, if A is a constant matrix, then $\mathcal{A} = A\mathcal{H}_d A$, and (2.1) is reduced to the (uniformly) strict convexity of $d(x)$. A little further, for any uniformly strict convex function $d(\cdot) \in C^2(\overline{\Omega})$, one can show that the matrix $A\mathcal{H}_d A$ is uniformly positive definite. Therefore, if

$$\max_{1\le i,j,k\le n} \sup_{x\in\overline{\Omega}} |a_k^{ij}(x)| \text{ is small enough,} \tag{2.4}$$

one concludes that $\mathcal{A}$ is uniformly positive definite. Consequently, if in addition, $d(\cdot)$ satisfies (2.2), then Condition 2.1 holds for $d(\cdot)$.

Third, the above remark, especially (2.4), does not mean that Condition 2.1 can hold only for coefficient matrices A which are close to constant matrices. To illustrate this, let us state the following proposition, whose proof is presented in Appendix A.

PROPOSITION 2.1. *Let* $n = 2$, *and let* $A = \operatorname{diag}[a^1, a^2]$ *with* $a^1 \in C^2(\overline{\Omega})$ *and* $a^2 \in C^1(\overline{\Omega})$ *being uniformly positive functions. Assume further that*

(i) $a^1(x_1, x_2) \equiv a^1(x_1)$, *i.e., it is independent of* x_2;

(ii) $a_1^1 a_1^2 \ge 0$ *in* Ω; *and*

(iii) *there is at most one point* $x_1^0 \in G \triangleq \overline{\{x_1 \in \mathbb{R} \big| (x_1, x_2) \in \Omega \text{ for some } x_2 \in \mathbb{R}\}}$ *so that* $a_1^1(x_1^0) = 0$. *Moreover, if such an* x_1^0 *exists, it satisfies* $a_{11}^1(x_1^0) < 0$. *Then Condition* 2.1 *holds.*

We emphasize that in the above, the derivatives $a_1^1(\cdot)$, $a_1^2(\cdot)$, and $a_2^2(\cdot)$ are not necessarily small. Therefore, the matrix A is not necessarily close to a constant matrix.

As a more concrete case, let us look at the following situation: Let $a(x_1) \in C^2(G)$ be a uniformly positive and strictly concave function. One may check that if $a^1(x_1, x_2) \equiv a^2(x_1, x_2) \equiv a(x_1)$, then a^1 and a^2 satisfy the conditions in Proposition 2.1. What is more interesting is that for this nonidentity matrix $A = aI$, if a_1, the derivative of a with respect to x_1, changes sign, then one may further check that it does not satisfy the geometric condition introduced in [22, Theorem 2.2.4] (which, in our notation, reads $\frac{1}{2} - (x - x_0) \cdot \nabla a \geq 0$ in $\overline{\Omega}$, for some $x_0 \in \mathbb{R}^n$) unless the length of G, or the positive part of a_1 in G (i.e., $\max_{x \in G} a_1^+(x)$), or the negative part of a_1 in G (i.e., $\max_{x \in G} a_1^-(x)$), is assumed to be sufficiently small. Hence, we have found a class of explicit and nontrivial examples satisfying our Condition 2.1. Also, we indicate that it is possible to construct nontrivial examples of nondiagonal coefficient matrices that satisfy Condition 2.1.

For the function $d(\cdot)$ satisfying Condition 2.1, we introduce the following set:

$$\Gamma_+ \triangleq \left\{ x \in \Gamma \;\middle|\; \sum_{i,j} a^{ij} \nu_i d_j > 0 \right\}, \tag{2.5}$$

where $\nu = \nu(x) = (\nu_1, \nu_2, \ldots, \nu_n)$ is the unit outward normal vector of Ω at $x \in \Gamma$.

Note that for the case $A = I$, by choosing $d(x) = |x - x_0|^2$ with any given $x_0 \in \mathbb{R}^n \setminus \overline{\Omega}$, we have Condition 2.1 with $\mu_0 = 4$, and (2.1) holds with an equality. In this case,

$$\Gamma_+ = \Big\{ x \in \Gamma \;\Big|\; (x - x_0) \cdot \nu(x) > 0 \Big\},$$

which coincides with the usual star-shaped part of the whole boundary of Ω [29].

On the other hand, it is easy to check that, if $d(\cdot) \in C^2(\overline{\Omega})$ satisfies (2.1), then for any given constants $a \geq 1$ and $b \in \mathbb{R}$, the function

$$\hat{d} = \hat{d}(x) \triangleq a d(x) + b \tag{2.6}$$

(scaling and translating $d(x)$) still satisfies Condition 2.1 with μ_0 replaced by $a\mu_0$; meanwhile, the scaling and translating $d(x)$ do not change the set Γ_+. Hence, by scaling and translating $d(x)$, if necessary, we may assume without loss of generality that

$$\begin{cases} \text{(2.1) holds with } \mu_0 \geq 4, \\ \dfrac{1}{4} \displaystyle\sum_{i,j} a^{ij}(x) d_i(x) d_j(x) \geq \max_{x \in \overline{\Omega}} d(x) \geq \min_{x \in \overline{\Omega}} d(x) > 0 \qquad \forall\, x \in \overline{\Omega}. \end{cases} \tag{2.7}$$

In what follows, we let

$$R_1 \triangleq \max_{x \in \overline{\Omega}} \sqrt{d(x)}, \qquad T_* \triangleq 2 \inf \Big\{ R_1 \;\Big|\; d(\cdot) \text{ satisfies (2.7)} \Big\}. \tag{2.8}$$

Concerning the controller ω in (1.5), we need the following assumption.

CONDITION 2.2. *There is a constant $\delta > 0$ such that*

$$\omega = \mathcal{O}_\delta(\Gamma_+) \bigcap \Omega. \tag{2.9}$$

Note that condition (2.9) can be replaced by

$$\omega \supseteq \overline{\Gamma}_+, \tag{2.10}$$

which looks much weaker. In fact, when (2.10) holds, one can find a $\delta > 0$ such that

$$\omega \supseteq \mathcal{O}_\delta(\Gamma_+) \bigcap \Omega. \tag{2.11}$$

It is not hard to see that if we can prove the controllability for (1.5) with a smaller controller ω satisfying (2.9), then we can do so for a larger controller ω satisfying (2.11) (in particular, we can choose ω to be $\mathcal{O}_\delta(\Gamma) \bigcap \Omega$, a neighborhood of the whole boundary Γ). We assume an equality in (2.9) only for simplicity of presentation.

The main controllability result in this paper is stated as follows.

THEOREM 2.2. *Let $a^{ij}(\cdot) \in C^1(\overline{\Omega})$ satisfy* (1.1)–(1.2)*, and let $f(\cdot) \in C^1(\mathbb{R})$ satisfy* (1.4)*. Let Conditions* 2.1–2.2 *hold. Then for any $T > T_*$, system* (1.5) *is exactly controllable in $H_0^1(\Omega) \times L^2(\Omega)$ at time T by using some control $\gamma \in L^2((0,T) \times \omega)$.*

In what follows, we will use C to denote a generic positive constant which may vary from line to line (unless otherwise stated). As we mentioned before, the proof of Theorem 2.2 can be reduced to the following observability estimate result for system (1.7).

THEOREM 2.3. *Let $a^{ij}(\cdot) \in C^1(\overline{\Omega})$ satisfy* (1.1)–(1.2)*, $q \in L^\infty(0,T; L^n(\Omega))$, and Conditions* 2.1–2.2 *hold. Then for any $T > T_*$, all weak solutions w of system* (1.7) *satisfy estimate* (1.8) *with an observability constant $\mathcal{C}(q) > 0$ of the form*

$$\mathcal{C}(q) = C \exp(Cr^2), \tag{2.12}$$

where

$$r = |q|_{L^\infty(0,T;L^n(\Omega))}. \tag{2.13}$$

Several remarks are in order.

Remark 2.1. By adopting the approach developed in this paper, Theorem 2.3 is strengthened in [8] as follows (see [8, Theorem 2.2]): Replace the assumption on q by $q \in L^\infty(0,T; L^s(\Omega))$ for any fixed $s \in [n, \infty]$ and let the other assumptions in Theorem 2.3 remain unchanged. Then for any $T > T_*$, all weak solutions w of system (1.7) satisfy estimate (1.8) with an observability constant $\mathcal{C}(q) > 0$ of the form

$$\mathcal{C}(q) = C \exp\left(C|q|^{\frac{1}{3/2-n/s}}_{L^\infty(0,T;L^s(\Omega))} \right). \tag{2.14}$$

On the other hand, it is shown in [8, Theorem 1.2] that the exponent $2/3$ in the estimate $|q|^{2/3}_{L^\infty(0,T;L^\infty(\Omega))}$ (in (2.14) for the special case $s = \infty$) is sharp. Although the problem of the optimality of the exponent $\frac{1}{3/2-n/s}$ in $|q|^{\frac{1}{3/2-n/s}}_{L^\infty(0,T;L^s(\Omega))}$ is unsolved when $s \in [n, \infty)$, [8, Theorem 1.2] does support the idea that the exponent 2 of the estimate r^2 in (2.12) might be sharp.

Remark 2.2. The "minimal" waiting time T_* in Theorems 2.2–2.3 is explicitly constructed (by (2.8)) but not sharp. The sharp T_*, as suggested by the special case $A = I$ considered in [36, 37], should be given as follows:

$$T_* \triangleq 2 \inf \Bigg\{ R_1 \;\Big|\; d(x) \text{ satisfies (2.1) with } \mu_0 \geq 4 \text{ and } \frac{1}{4} \sum_{i,j} a^{ij}(x) d_i(x) d_j(x) \geq d(x) \geq \min_{x \in \overline{\Omega}} d(x) > 0 \quad \forall\, x \in \overline{\Omega} \Bigg\},$$

i.e., one replaces the term $\max_{x\in\overline{\Omega}} d(x)$ in (2.7) by $d(x)$. Unfortunately, we are unable to obtain such a sharp waiting time at this moment. One will see that the inequality involving $\sum_{i,j} a^{ij}(x)d_i(x)d_j(x)$ and $\max_{x\in\overline{\Omega}} d(x)$ in (2.7) plays a key role in (11.7).

Remark 2.3. Condition (1.4) on the nonlinearity $f(\cdot)$ in Theorem 2.2 is not sharp. As suggested in [45] for the one-dimensional problem, it is reasonable to expect that (1.4) may be relaxed to the following:

$$\overline{\lim_{s\to\infty}} \frac{f(s)}{s\ln^2|s|} = 0.$$

But this remains unsolved for the time being.

Remark 2.4. Theorems 2.2–2.3 cover the main results in [26] except the minimal waiting time T_*.

Remark 2.5. Theorems 2.2 can be extended to the case when the nonlinearity $f(y)$ in (1.5) is replaced by $f(t,x,y)$, under suitable growth conditions on (t,x,y). However, it seems to us that in the case when nonlinearity is $f(y,y_t,\nabla y)$, the technique developed in this paper is not enough, and one might have to employ the Nash–Moser–Hörmander iteration method [15] to overcome the difficulty due to the "loss of derivatives." The detailed study of this problem will be presented elsewhere. Note, however, that for purely PDE problems (existence and uniqueness of solutions, etc.) of the hyperbolic equations, the treatment on the nonlinearity $f(y,y_t,\nabla y)$ is almost the same as the simpler one, $f(y)$. This means that for the controllability problem of nonlinear systems, there exist some extra difficulties.

3. Some preliminaries. Let us consider the following linear inhomogeneous hyperbolic equation:

$$\begin{cases} \mathcal{P}z = f & \text{in } Q,\\ z = 0 & \text{on } \Sigma. \end{cases} \tag{3.1}$$

In what follows, we call $z\in L^2(Q)$ a weak solution to (3.1) if

$$(z,\mathcal{P}\eta)_{L^2(Q)} = \int_0^T \langle\, f(t,\cdot),\eta(t,\cdot)\,\rangle_{H^{-1}(\Omega),H_0^1(\Omega)}dt \quad \forall\ \eta\in C_0^2((0,T);H^2(\Omega)\cap H_0^1(\Omega)).$$

Note that in (3.1), no initial conditions are specified. Similarly to [40, Lemma 5.1], one can prove the following regularity result for system (3.1).

LEMMA 3.1. *Let $0<t_1<t_2<T$, $f\in L^1(0,T;H^{-1}(\Omega))$, and $g\in L^2((t_1,t_2)\times\Omega)$ be given. Assume that $z\in L^2(Q)$ is a weak solution to* (3.1)*, and $z=g$ in $(t_1,t_2)\times\Omega$. Then $z\in C([0,T];L^2(\Omega))\cap C^1([0,T];H^{-1}(\Omega))$, and there exists a constant $C>0$, depending only on T, t_1, t_2, Ω, and a^{ij}, such that*

$$|z|_{C([0,T];L^2(\Omega))\cap C^1([0,T];H^{-1}(\Omega))} \le C\Big[|f|_{L^1(0,T;H^{-1}(\Omega))} + |g|_{L^2((t_1,t_2)\times\Omega)}\Big]. \tag{3.2}$$

From the above, we see that g plays the role of initial value for the weak solution z. Next, similarly to [36, Lemma 3.3] we have the following result.

LEMMA 3.2. *Let $a^{ij}\in C^1(\overline{\Omega})$ satisfy* (1.1)*, and let $g\triangleq(g^1,\dots,g^n):\mathbb{R}_t\times\mathbb{R}_x^n\to$*

$\mathbb{R}^n$ *be a vector field of class* C^1. *Then for any* $z \in C^2(\mathbb{R}_t \times \mathbb{R}^n_x)$, *we have*

$$\begin{aligned}
&-\sum_j \left[2(g\cdot\nabla z)\sum_i a^{ij} z_i + g^j \left(z_t^2 - \sum_{i,k} a^{ik} z_i z_k \right) \right]_j \\
&= 2\left[(\mathcal{P}z) g\cdot\nabla z - (z_t g\cdot\nabla z)_t + z_t g_t\cdot\nabla z - \sum_{i,j,k} a^{ij} z_i z_k \frac{\partial g^k}{\partial x_j} \right] \\
&\quad - (\nabla\cdot g) z_t^2 + \sum_{i,j} z_i z_j \nabla\cdot(a^{ij} g).
\end{aligned} \tag{3.3}$$

Next, we denote the energy of system (1.7) by

$$E(t) \triangleq \frac{1}{2}\Big[|w_t(t,\cdot)|^2_{H^{-1}(\Omega)} + |w(t,\cdot)|^2_{L^2(\Omega)} \Big]. \tag{3.4}$$

Using the usual energy method, one obtains the following result.

LEMMA 3.3. *Let* $T > 0$, $q \in L^\infty(0,T;L^n(\Omega))$, $w_0 \in L^2(\Omega)$, *and* $w_1 \in H^{-1}(\Omega)$. *Then the weak solution* $w(\cdot) \in C([0,T];L^2(\Omega)) \cap C^1([0,T];H^{-1}(\Omega))$ *of* (1.7) *satisfies (recall* (2.13) *for* r*)*

$$E(t) \le CE(s)e^{Cr} \qquad \forall\, t,s \in [0,T]. \tag{3.5}$$

Further, proceeding as in [36, Lemma 3.4], we conclude the following.

LEMMA 3.4. *Let* $0 \le S_1 < S_2 < T_2 < T_1 \le T$ *and* $q \in L^\infty(0,T;L^n(\Omega))$. *Then the weak solution* $w(\cdot) \in C([0,T];L^2(\Omega)) \cap C^1([0,T];H^{-1}(\Omega))$ *of* (1.7) *satisfies*

$$\int_{S_2}^{T_2} E(t)dt \le C(1+r)\int_{S_1}^{T_1} |w(t,\cdot)|^2_{L^2(\Omega)} dt. \tag{3.6}$$

Finally, the following proposition will be useful.

PROPOSITION 3.5. *For any* $h > 0$, $m = 2,3,\ldots$, *and* $q_m^i, w_m^i \in \mathbb{C}$ $(i = 0,1,\ldots,m)$ *with* $q_m^0 = q_m^m = 0$, *one has*

$$\begin{aligned}
-\sum_{i=1}^{m-1} q_m^i \frac{(w_m^{i+1} - 2w_m^i + w_m^{i-1})}{h^2} &= \sum_{i=0}^{m-1} \frac{(q_m^{i+1} - q_m^i)}{h} \frac{(w_m^{i+1} - w_m^i)}{h} \\
&= \sum_{i=1}^{m} \frac{(q_m^i - q_m^{i-1})}{h} \frac{(w_m^i - w_m^{i-1})}{h}.
\end{aligned} \tag{3.7}$$

Proof.

$$\begin{aligned}
-\sum_{i=1}^{m-1} q_m^i \frac{(w_m^{i+1} - 2w_m^i + w_m^{i-1})}{h^2} &= -\sum_{i=1}^{m-1} q_m^i \frac{(w_m^{i+1} - w_m^i)}{h^2} + \sum_{i=1}^{m-1} q_m^i \frac{(w_m^i - w_m^{i-1})}{h^2} \\
&= \sum_{i=1}^{m-1} \frac{(q_m^{i+1} - q_m^i)}{h} \frac{(w_m^{i+1} - w_m^i)}{h} - \sum_{i=1}^{m-1} \frac{q_m^{i+1}}{h} \frac{(w_m^{i+1} - w_m^i)}{h} + \sum_{i=0}^{m-2} \frac{q_m^{i+1}}{h} \frac{(w_m^{i+1} - w_m^i)}{h} \\
&= \sum_{i=1}^{m-1} \frac{(q_m^{i+1} - q_m^i)}{h} \frac{(w_m^{i+1} - w_m^i)}{h} + \frac{q_m^1}{h} \frac{(w_m^1 - w_m^0)}{h} \\
&= \sum_{i=0}^{m-1} \frac{(q_m^{i+1} - q_m^i)}{h} \frac{(w_m^{i+1} - w_m^i)}{h},
\end{aligned}$$

which gives the desired equality. ∎

4. Second order differential operators with symmetric coefficients. In this section, we consider second order differential operators with symmetric coefficients. Our hyperbolic differential operator $\mathcal{P}$ is of such a type. We will establish a pointwise equality and a couple of inequalities for such differential operators, which will play important roles. First, we have the following identity.

THEOREM 4.1. *Let* $m \in \mathbb{N}$,

$$b^{ij} = b^{ji} \in C^1(\mathbb{R}^m), \qquad i,j = 1,2,\dots,m, \tag{4.1}$$

and $u,\ \ell,\ \Psi \in C^2(\mathbb{R}^m)$. *Set* $\theta = e^{\ell}$ *and* $v = \theta u$. *Then*

$$\begin{aligned}
&\theta^2 \left| \sum_{i,j} (b^{ij} u_i)_j \right|^2 + 2 \sum_j \left\{ 2 \sum_{i,i',j'} b^{ij} b^{i'j'} \ell_{i'} v_i v_{j'} - \sum_{i,i',j'} b^{ij} b^{i'j'} \ell_i v_{i'} v_{j'} \right. \\
&\qquad \left. + \Psi \sum_i b^{ij} v_i v - \sum_i b^{ij} \left[(\Lambda + \Psi)\ell_i + \frac{\Psi_i}{2} \right] v^2 \right\}_j \\
&= 2 \sum_{i,j} \left\{ \sum_{i',j'} \left[2 b^{ij'} \left(b^{i'j} \ell_{i'} \right)_{j'} - \left(b^{ij} b^{i'j'} \ell_{i'} \right)_{j'} \right] + \Psi b^{ij} \right\} v_i v_j + B v^2 \\
&\qquad + \left| \sum_{i,j} (b^{ij} v_i)_j - \Lambda v \right|^2 + 4 \left| \sum_{i,j} b^{ij} \ell_i v_j \right|^2,
\end{aligned} \tag{4.2}$$

where

$$\begin{cases}
\Lambda \triangleq - \displaystyle\sum_{i,j} (b^{ij} \ell_i \ell_j - b^{ij}_j \ell_i - b^{ij} \ell_{ij}) - \Psi, \\
B \triangleq 2 \left[\Lambda \Psi - \displaystyle\sum_{i,j} \left((\Lambda + \Psi) b^{ij} \ell_i \right)_j \right] + \Psi^2 - \displaystyle\sum_{i,j} (b^{ij} \Psi_j)_i.
\end{cases} \tag{4.3}$$

We see that only the symmetry condition (4.1) is assumed in the above. Hence, Theorem 4.1 is applicable to hyperbolic and ultrahyperbolic operators.

Theorem 4.1 looks similar to [25, Lemma 1, p. 124](which is devoted to a similar problem for a class of ultrahyperbolic operators). The main difference is that we leave the function v on the right-hand side of (4.2) without returning to u, unlike the result of [25] mentioned above, which has only the variable u on both sides. Our result greatly simplifies the computation. Also, a similar idea played a key role in establishing the observability estimate for the wave equations with Neumann boundary conditions in [24] (which should be compared with [19]). We refer the reader to [12, 13] for further application of Theorem 4.1 and its generalization, and to [7] for related work.

Proof of Theorem 4.1. The proof is divided into several steps.

Step 1. Recalling $\theta = e^{\ell}$ and $v = \theta u$, one has $u_i = \theta^{-1}(v_i - \ell_i v)$ $(i = 1,2,\dots,m)$. By the symmetry condition (4.1), it is easy to see that

$$\sum_{i,j} b^{ij} (\ell_i v_j + \ell_j v_i) = 2 \sum_{i,j} b^{ij} \ell_i v_j.$$

Thus, we obtain

$$
\begin{aligned}
(4.4)\qquad \sum_{i,j}(b^{ij}u_i)_j &= \sum_{i,j}[\theta^{-1}b^{ij}(v_i-\ell_i v)]_j \\
&= \theta^{-1}\sum_{i,j}[b^{ij}(v_i-\ell_i v)]_j - \theta^{-1}\sum_{i,j} b^{ij}(v_i-\ell_i v)\ell_j \\
&= \theta^{-1}\sum_{i,j}\Big[(b^{ij}v_i)_j - b^{ij}(\ell_i v_j+\ell_j v_i) + (b^{ij}\ell_i\ell_j - b^{ij}_j\ell_i - b^{ij}\ell_{ij})v\Big] \\
&= \theta^{-1}\sum_{i,j}\Big[(b^{ij}v_i)_j - 2b^{ij}\ell_i v_j + (b^{ij}\ell_i\ell_j - b^{ij}_j\ell_i - b^{ij}\ell_{ij})v\Big] \\
&\equiv -\theta^{-1}(I_1+I_2+I_3),
\end{aligned}
$$

where

$$
(4.5)\qquad \begin{cases}
I_1 \triangleq -\displaystyle\sum_{i,j}\Big[(b^{ij}v_i)_j + (b^{ij}\ell_i\ell_j - b^{ij}_j\ell_i - b^{ij}\ell_{ij})v\Big] - \Psi v \\
\qquad\ = -\displaystyle\sum_{i,j}(b^{ij}v_i)_j + \Lambda v, \\
I_2 \triangleq 2\displaystyle\sum_{i,j} b^{ij}\ell_i v_j, \qquad I_3 \triangleq \Psi v.
\end{cases}
$$

Then, by (4.4) and (4.5), we get

$$
(4.6)\qquad \theta^2\Big|\sum_{i,j}(b^{ij}u_i)_j\Big|^2 = |I_1|^2+|I_2|^2+|I_3|^2+2(I_1I_2+I_2I_3+I_1I_3).
$$

Step 2. Let us compute I_1I_2. Using (4.1) again, and noting

$$
\sum_{i,j,i',j'}\Big(b^{ij}b^{i'j'}\ell_{i'}v_iv_j\Big)_{j'} = \sum_{i,j,i',j'}\Big(b^{ij}b^{i'j'}\ell_i v_{i'}v_{j'}\Big)_j,
$$

we get

$$
\begin{aligned}
&2\sum_{i,j,i',j'} b^{ij}b^{i'j'}\ell_{i'}v_iv_{jj'} \\
&= \sum_{i,j,i',j'} b^{ij}b^{i'j'}\ell_{i'}(v_iv_{jj'}+v_jv_{ij'}) = \sum_{i,j,i',j'} b^{ij}b^{i'j'}\ell_{i'}(v_iv_j)_{j'} \\
&= \sum_{i,j,i',j'}\Big(b^{ij}b^{i'j'}\ell_{i'}v_iv_j\Big)_{j'} - \sum_{i,j,i',j'}\Big(b^{ij}b^{i'j'}\ell_{i'}\Big)_{j'}v_iv_j \\
&= \sum_{i,j,i',j'}\Big(b^{ij}b^{i'j'}\ell_i v_{i'}v_{j'}\Big)_j - \sum_{i,j,i',j'}\Big(b^{ij}b^{i'j'}\ell_{i'}\Big)_{j'}v_iv_j.
\end{aligned}
\qquad (4.7)
$$

Hence, by (4.5) and (4.7), and noting

$$
\sum_{i,j,i',j'} b^{ij}\Big(b^{i'j'}\ell_{i'}\Big)_j v_iv_{j'} = \sum_{i,j,i',j'} b^{ij'}\Big(b^{i'j}\ell_{i'}\Big)_{j'}v_iv_j,
$$

we get

$$
\begin{aligned}
I_1I_2 &= 2\sum_{i,j} b^{ij}\ell_i v_j\Big[-\sum_{i,j}(b^{ij}v_i)_j+\Lambda v\Big]\\
&= -2\sum_{i,j,i',j'}(b^{ij}b^{i'j'}\ell_{i'}v_iv_{j'})_j+2\sum_{i,j,i',j'}b^{ij}(b^{i'j'}\ell_{i'})_jv_iv_{j'}\\
&\quad +2\sum_{i,j,i',j'}b^{ij}b^{i'j'}\ell_{i'}v_iv_{j'j}+\Lambda\sum_{i,j}b^{ij}\ell_i(v^2)_j \qquad (4.8)\\
&= -\sum_j\Big(2\sum_{i,i',j'}b^{ij}b^{i'j'}\ell_{i'}v_iv_{j'}-\sum_{i,i',j'}b^{ij}b^{i'j'}\ell_iv_{i'}v_{j'}-\Lambda\sum_i b^{ij}\ell_iv^2\Big)_j\\
&\quad +\sum_{i,j,i',j'}\Big[2b^{ij'}(b^{i'j}\ell_{i'})_{j'}-(b^{ij}b^{i'j'}\ell_{i'})_{j'}\Big]v_iv_j-\sum_{i,j}(\Lambda b^{ij}\ell_i)_jv^2.
\end{aligned}
$$

Step 3. Let us compute I_2I_3 and I_1I_3. By (4.5), we see that

$$
\begin{aligned}
I_2I_3 &= 2\Psi v\sum_{i,j}b^{ij}\ell_iv_j=\Psi\sum_{i,j}b^{ij}\ell_i(v^2)_j\\
&= \sum_{i,j}\Big(\Psi b^{ij}\ell_iv^2\Big)_j-\sum_{i,j}\Big(\Psi b^{ij}\ell_i\Big)_jv^2. \qquad (4.9)
\end{aligned}
$$

Similarly, by (4.5), we get

$$
\begin{aligned}
2I_1I_3 &= 2\Psi v\Big[-\sum_{i,j}(b^{ij}v_i)_j+\Lambda v\Big]\\
&= -2\sum_{i,j}\Big(\Psi b^{ij}vv_i\Big)_j+2\Psi\sum_{i,j}b^{ij}v_iv_j+\sum_{i,j}b^{ij}\Psi_j(v^2)_i+2\Lambda\Psi v^2\\
&= -\sum_{i,j}\Big(2\Psi b^{ij}vv_i-b^{ij}\Psi_iv^2\Big)_j+2\Psi\sum_{i,j}b^{ij}v_iv_j+\Big[-\sum_{i,j}(b^{ij}\Psi_j)_i+2\Lambda\Psi\Big]v^2. \qquad (4.10)
\end{aligned}
$$

Step 4. Finally, combining (4.6), (4.8), (4.9), and (4.10), we immediately conclude with the desired equality (4.2). This completes the proof of Theorem 4.1. ∎

As a consequence of Theorem 4.1, we have the following.

COROLLARY 4.2. *Let $a^{ij}\in C^1(\overline{\Omega})$ satisfy* (1.1)*, and let $u,\ell,\Psi\in C^2(\mathbb{R}^{1+n})$. Let $\theta=e^\ell$ and $v=\theta u$. Then*

$$
\begin{aligned}
&\theta^2|\mathcal{P}u|^2 \qquad (4.11)\\
&+2\Big[\ell_t\Big(v_t^2+\sum_{i,j}a^{ij}v_iv_j\Big)-2\sum_{i,j}a^{ij}\ell_iv_jv_t-\Psi vv_t+\Big((\Lambda+\Psi)\ell_t+\frac{\Psi_t}{2}\Big)v^2\Big]_t\\
&+2\sum_j\Big\{2\sum_{i,i',j'}a^{ij}a^{i'j'}\ell_{i'}v_iv_{j'}-\sum_{i,i',j'}a^{ij}a^{i'j'}\ell_iv_{i'}v_{j'}+\Psi v\sum_i a^{ij}v_i\\
&-2\ell_tv_t\sum_i a^{ij}v_i+\sum_i a^{ij}\ell_iv_t^2-\sum_i a^{ij}\Big[(\Lambda+\Psi)\ell_i+\frac{\Psi_i}{2}\Big]v^2\Big\}_j\\
&\geq 2\Big(\ell_{tt}+\sum_{i,j}(a^{ij}\ell_i)_j-\Psi\Big)v_t^2-8\sum_{i,j}a^{ij}\ell_{jt}v_iv_t\\
&+2\sum_{i,j}\Big\{a^{ij}\ell_{tt}+\sum_{i',j'}\Big[2a^{ij'}(a^{i'j}\ell_{i'})_{j'}-(a^{ij}a^{i'j'}\ell_{i'})_{j'}\Big]+\Psi a^{ij}\Big\}v_iv_j+Bv^2,
\end{aligned}
$$

where

$$\begin{cases} \Lambda = (\ell_t^2 - \ell_{tt}) - \sum_{i,j}(a^{ij}\ell_i\ell_j - a^{ij}_j\ell_i - a^{ij}\ell_{ij}) - \Psi, \\ B = 2\left[\Lambda\Psi + \Big((\Lambda+\Psi)\ell_t\Big)_t - \sum_{i,j}\Big((\Lambda+\Psi)a^{ij}\ell_i\Big)_j\right] \\ \qquad + \Psi^2 + \Psi_{tt} - \sum_{i,j}(a^{ij}\Psi_j)_i. \end{cases} \tag{4.12}$$

In particular, if

$$\begin{cases} \phi = \phi(t,x) \triangleq d(x) - c(t-T/2)^2, \\ \Psi \triangleq \lambda\left[\sum_{i,j}(a^{ij}d_i)_j - 2c - 1 + k\right], \\ \ell \triangleq \lambda\phi, \quad v \triangleq \theta u, \quad \theta \triangleq e^{\ell}, \end{cases} \tag{4.13}$$

with $\lambda, T > 0$, $c \in (0,1)$, *and* $k \in \mathbb{R}$, *then*

$$\begin{aligned} &\text{(left-hand side of (4.11))} \geq 2\lambda(1-k)v_t^2 \\ &+ 2\lambda\sum_{i,j}\left\{(k-1-4c)a^{ij} + \sum_{i',j'}\Big[2a^{ij'}(a^{i'j}d_{i'})_{j'} - a^{ij}_{j'}a^{i'j'}d_{i'}\Big]\right\}v_iv_j + Bv^2, \end{aligned} \tag{4.14}$$

where

$$\begin{cases} \Lambda = \lambda^2\left[4c^2(t-T/2)^2 - \sum_{i,j}a^{ij}d_id_j\right] + \lambda(4c+1-k), \\ B = 2\lambda^3\Big[(4c+1-k)\sum_{i,j}a^{ij}d_id_j + \sum_{i,j}a^{ij}d_i\left(\sum_{i',j'}a^{i'j'}d_{i'}d_{j'}\right)_j \\ \qquad -4(8c+1-k)c^2(t-T/2)^2\Big] + O(\lambda^2). \end{cases} \tag{4.15}$$

Proof. Using Theorem 4.1 with $m = 1+n$, and

$$(b^{ij})_{m\times m} = \begin{pmatrix} -1 & 0 \\ 0 & A \end{pmatrix},$$

by a direct calculation, we obtain (4.11). The inequality occurs because we have dropped the last two nonnegative terms (see (4.2)). Next, by the choice of (4.13), we can obtain (4.14). ∎

5. Global Carleman estimate for the hyperbolic operators in $H_0^1(Q)$. Recall (2.8) for the definitions of R_1 and T_*. Let $T > T_*$ be given. We may assume that

$$T > 2R_1. \tag{5.1}$$

By (5.1), one may choose a constant $c \in (0,1)$ so that

$$\left(\frac{2R_1}{T}\right)^2 < c < \frac{2R_1}{T}. \tag{5.2}$$

Henceforth, we choose $\phi(t,x)$ as in (4.13) with T and c satisfying, respectively, (5.1) and (5.2).

Remark 5.1. The function ϕ constructed above, together with Condition 2.1, will play a similar role in establishing the Carleman estimate for the hyperbolic operators to that of the function ψ in [18, Condition 1.1], both of which are pseudoconvex in the sense of [17, Definition 28.3.1]. We refer to the classical monographs [16, 17] for more extensive treatment of the Carleman estimate for general partial differential operators, based on pseudoconvex assumptions. Note, however, that our more concrete and explicit choice of ϕ has the following advantages:

(1) It avoids the complicated verification of the pseudoconvex assumption, say, Condition 1.1 in [18]. Indeed, we need only check the "convexity" condition (2.1) and the nonvanishing condition (2.2) (see Proposition 2.1 for an example).
(2) Our ϕ is more natural. In this respect, we note that the time variable t and spatial variables x are separate, which matches the very fact that for the principal operator $\mathcal{P}$, the time derivative ∂_{tt} and the spatial derivatives $-\sum_{i,j}\partial_j(a^{ij}(x)\partial_i)$ have a similar separation property.
(3) The explicit form of $\phi(\cdot)$ or $d(\cdot)$ is useful in the definition of the "controlled/observed" subboundary Γ_+ in (2.5). Also, it plays a key role by scaling and translating $d(x)$ as in (2.6) to achieve (2.7).
(4) What is more important, as mentioned before, is that with our assumption of Condition 2.1, we can give an explicit formula for the waiting time T_*, but this seems to be impossible in the setting of [18] and in that of [16, 17]. Meanwhile, as we shall see later (in the proof of Theorem 2.3), the explicit form of $\phi(\cdot)$ will play a crucial role in deducing the key estimate (2.12) on the observability constant $\mathcal{C}(q)$.

The following Carleman estimate will play a crucial role in section 7.

THEOREM 5.1. *Let $a^{ij} \in C^1(\overline{\Omega})$ satisfy* (1.1)–(1.2)*, and let Conditions* 2.1–2.2 *hold. Then there exists a $\lambda_0 > 1$ such that for all $\lambda \geq \lambda_0$ and all $u \in H_0^1(Q)$ with $\mathcal{P}u \in L^2(Q)$, it holds that*

$$\begin{aligned} &\lambda \int_Q (\lambda^2 u^2 + u_t^2 + |\nabla u|^2) e^{2\lambda\phi} dxdt \\ &\leq C\left[|e^{\lambda\phi}\mathcal{P}u|^2_{L^2(Q)} + \lambda^2 \int_0^T \int_\omega (\lambda^2 u^2 + u_t^2) e^{2\lambda\phi} dxdt\right]. \end{aligned} \tag{5.3}$$

For the reader's convenience, in Appendix B we will give a proof of Theorem 5.1 which is close to the spirit of [24].

Remark 5.2. In the above theorem, the main element, which enables one to integrate over the entire cylinder Q instead of the "conventional" case of its subdomain

bounded by a level surface of the function ϕ, is that $u(0,x)=u(T,x)=0$ in Ω. From the proof of Theorem 5.1, one can see that this point is achieved via (11.10). In the cases $A=I$, and more generally $A=a(x)I$, with a quite restrictive positive function $a(x)$, inequality (11.10) actually follows from [22, equation (2.2.51)] if we introduce (in this paper) a new variable $\tau=t-T/2$ instead of the time variable t.

6. An auxiliary optimal control problem. In this section, we will present an auxiliary optimal control problem which will be useful later. Although some ideas are taken from [18, pp. 190–199], our presentation seems to be easier to understand.

Throughout this section, we fix ϕ as in (4.13), a parameter $\lambda>0$, and a function $u\in C([0,T];L^2(\Omega))$ satisfying $u(0,x)=u(T,x)=0$ for $x\in\Omega$. For any $K>1$, we choose a function $\varrho\equiv\varrho^K(x)\in C^2(\overline{\Omega})$ with $\min_{x\in\overline{\Omega}}\varrho(x)=1$ so that (recall Condition 2.2 for ω)

$$\varrho(x)=\begin{cases}1 & \text{for } x\in\omega,\\ K & \text{for } \operatorname{dist}(x,\omega)\geq\frac{1}{\ln K}.\end{cases}\tag{6.1}$$

Next, fix any integer $m\geq 3$. Let $h=\frac{T}{m}$. Define

$$u_m^i\equiv u_m^i(x)=u(ih,x),\quad \phi_m^i\equiv\phi_m^i(x)=\phi(ih,x),\qquad i=0,1,\dots,m.\tag{6.2}$$

Let $\{(z_m^i,r_{1m}^i,r_{2m}^i,r_m^i)\}_{i=0}^m\in(H_0^1(\Omega)\times(L^2(\Omega))^3)^{m+1}$ satisfy the following system:

$$\begin{cases}\dfrac{z_m^{i+1}-2z_m^i+z_m^{i-1}}{h^2}-\displaystyle\sum_{j_1,j_2=1}^n\partial_{x_{j_2}}(a^{j_1j_2}\partial_{x_{j_1}}z_m^i)\\ \qquad=\dfrac{r_{1m}^{i+1}-r_{1m}^i}{h}+r_{2m}^i+\lambda u_m^i e^{2\lambda\phi_m^i}+r_m^i,\quad(1\leq i\leq m-1) & \text{in }\Omega,\\ z_m^i=0,\qquad(0\leq i\leq m) & \text{on }\Gamma,\\ z_m^0=z_m^m=r_{2m}^0=r_{2m}^m=r_m^0=r_m^m=0,\quad r_{1m}^0=r_{1m}^1 & \text{in }\Omega.\end{cases}\tag{6.3}$$

Note that we do not assume r_{1m}^0 and r_{1m}^m vanish; instead we assume $r_{1m}^0=r_{1m}^1$. In system (6.3), $(r_{1m}^i,r_{2m}^i,r_m^i)\in(L^2(\Omega))^3$ $(i=0,1,\dots,m)$ can be regarded as controls. The set of *admissible sequences* for (6.3) is defined as

$$\mathcal{A}_{ad}\stackrel{\triangle}{=}\Big\{\{(z_m^i,r_{1m}^i,r_{2m}^i,r_m^i)\}_{i=0}^m\in(H_0^1(\Omega)\times(L^2(\Omega))^3)^{m+1}\;\Big|\;\{(z_m^i,r_{1m}^i,r_{2m}^i,r_m^i)\}_{i=0}^m\text{ satisfy (6.3)}\Big\}.$$

Since $\{(0,0,0,-\lambda u_m^i e^{2\lambda\phi_m^i})\}_{i=0}^m\in\mathcal{A}_{ad}$, one sees that $\mathcal{A}_{ad}\neq\emptyset$.

Next, let us introduce the cost functional

$$\begin{aligned}&J(\{(z_m^i,r_{1m}^i,r_{2m}^i,r_m^i)\}_{i=0}^m)\\ &=\frac{h}{2}\int_\Omega\varrho\frac{|r_{1m}^m|^2}{\lambda^2}e^{-2\lambda\phi_m^m}dx\\ &\quad+\frac{h}{2}\sum_{i=1}^{m-1}\left[\int_\Omega|z_m^i|^2e^{-2\lambda\phi_m^i}dx+\int_\Omega\varrho\left(\frac{|r_{1m}^i|^2}{\lambda^2}+\frac{|r_{2m}^i|^2}{\lambda^4}\right)e^{-2\lambda\phi_m^i}dx+K\int_\Omega|r_m^i|^2dx\right].\end{aligned}\tag{6.4}$$

We pose the following *optimal control problem*: Find a $\{(\hat{z}_m^i, \hat{r}_{1m}^i, \hat{r}_{2m}^i, \hat{r}_m^i)\}_{i=0}^m \in \mathcal{A}_{ad}$ such that

$$\begin{aligned} &J(\{(\hat{z}_m^i, \hat{r}_{1m}^i, \hat{r}_{2m}^i, \hat{r}_m^i)\}_{i=0}^m) \\ &= \min_{\{(z_m^i, r_{1m}^i, r_{2m}^i, r_m^i)\}_{i=0}^m \in \mathcal{A}_{ad}} J(\{(z_m^i, r_{1m}^i, r_{2m}^i, r_m^i)\}_{i=0}^m). \end{aligned} \tag{6.5}$$

Note that for any $\{(z_m^i, r_{1m}^i, r_{2m}^i, r_m^i)\}_{i=0}^m \in \mathcal{A}_{ad}$, by standard regularity results of elliptic equations, one has that $z_m^i \in H^2(\Omega) \cap H_0^1(\Omega)$. The following technical result will play a crucial role in section 7.

PROPOSITION 6.1. *For any $K > 1$ and $m \geq 3$, problem* (6.5) *admits a unique solution $\{(\hat{z}_m^i, \hat{r}_{1m}^i, \hat{r}_{2m}^i, \hat{r}_m^i)\}_{i=0}^m \in \mathcal{A}_{ad}$ (which depends on K). Furthermore, for*

$$p_m^i \equiv p_m^i(x) \triangleq K\hat{r}_m^i(x), \qquad 0 \leq i \leq m, \tag{6.6}$$

one has

$$\hat{z}_m^0 = \hat{z}_m^m = p_m^0 = p_m^m = 0 \text{ in } \Omega, \hat{z}_m^i, p_m^i \in H^2(\Omega) \cap H_0^1(\Omega) \text{ for } 1 \leq i \leq m-1, \tag{6.7}$$

and the following optimality conditions hold:

$$\begin{cases} \dfrac{p_m^i - p_m^{i-1}}{h} + \varrho \dfrac{\hat{r}_{1m}^i}{\lambda^2} e^{-2\lambda\phi_m^i} = 0 & \text{in } \Omega, \\ p_m^i - \varrho \dfrac{\hat{r}_{2m}^i}{\lambda^4} e^{-2\lambda\phi_m^i} = 0 & \text{in } \Omega, \end{cases} \qquad 1 \leq i \leq m, \tag{6.8}$$

$$\begin{cases} \dfrac{p_m^{i+1} - 2p_m^i + p_m^{i-1}}{h^2} - \displaystyle\sum_{j_1, j_2 = 1}^n \partial_{x_{j_2}} (a^{j_1 j_2} \partial_{x_{j_1}} p_m^i) + \hat{z}_m^i e^{-2\lambda\phi_m^i} = 0 & \text{in } \Omega, \\ p_m^i = 0 & \text{on } \Gamma, \\ & 1 \leq i \leq m-1. \end{cases} \tag{6.9}$$

Moreover, there is a constant $C = C(K, \lambda) > 0$, independent of m, such that

$$h \sum_{i=1}^{m-1} \int_\Omega \left[|\hat{z}_m^i|^2 + |\hat{r}_{1m}^i|^2 + |\hat{r}_{2m}^i|^2 + K|\hat{r}_m^i|^2 \right] dx + h \int_\Omega |\hat{r}_{1m}^m|^2 dx \leq C, \tag{6.10}$$

and

$$\begin{aligned} h \sum_{i=0}^{m-1} \int_\Omega \Bigg[&\frac{(\hat{z}_m^{i+1} - \hat{z}_m^i)^2}{h^2} + \frac{(\hat{r}_{1m}^{i+1} - \hat{r}_{1m}^i)^2}{h^2} + \frac{(\hat{r}_{2m}^{i+1} - \hat{r}_{2m}^i)^2}{h^2} \\ &+ K \frac{(\hat{r}_m^{i+1} - \hat{r}_m^i)^2}{h^2} \Bigg] dx \leq C. \end{aligned} \tag{6.11}$$

We refer to Appendix C for a proof of this proposition.

7. Global Carleman estimate for hyperbolic operators in $L^2(Q)$. In order to prove Theorem 2.3, we need the following result.

THEOREM 7.1. *Let $a^{ij} \in C^1(\overline{\Omega})$ satisfy (1.1)–(1.2). Let Conditions 2.1–2.2 hold. Then for any $\lambda \geq \lambda_0 \geq 1$, and any $u \in C([0,T];L^2(\Omega))$ satisfying $u(0,x) = u(T,x) = 0$ for $x \in \Omega$, $\mathcal{P}u \in H^{-1}(Q)$, and*

$$(7.1) \quad (u, \mathcal{P}\eta)_{L^2(Q)} = \langle \mathcal{P}u, \eta \rangle_{H^{-1}(Q),H_0^1(Q)} \quad \forall\, \eta \in H_0^1(Q) \text{ with } \mathcal{P}\eta \in L^2(Q),$$

it holds that

$$(7.2) \qquad \lambda \int_Q u^2 e^{2\lambda\phi} dxdt \leq C \left(|e^{\lambda\phi}\mathcal{P}u|^2_{H^{-1}(Q)} + \lambda^2 \int_0^T \int_\omega u^2 e^{2\lambda\phi} dxdt \right),$$

where ϕ is the same as in Theorem 5.1.

Proof. The proof is close to that of [18, Theorem 1.1]. However, for the reader's convenience, we give the details here.

The main idea is to apply (7.1) to some special η with $\mathcal{P}\eta = \cdots + \lambda u e^{2\lambda\phi}$, which yields the desired term $\lambda \int_Q u^2 e^{2\lambda\phi} dxdt$ and reduces the estimate to that for $|\eta|_{H_0^1(Q)}$. We shall employ Proposition 6.1 to provide the desired η. The proof is divided into several steps.

Step 1. First, recall the functions $\{(\hat{z}^i_m, \hat{r}^i_{1m}, \hat{r}^i_{2m}, \hat{r}^i_m)\}_{i=0}^m$ in Proposition 6.1. We define

$$\begin{aligned}
\tilde{z}^m(t,x) &= \frac{1}{h} \sum_{i=0}^{m-1} \Big[(t-ih)\hat{z}^{i+1}_m(x) - \Big(t-(i+1)h\Big)\hat{z}^i_m(x) \Big] \chi_{(ih,(i+1)h]}(t), \\
\tilde{r}^m_1(t,x) &= \hat{r}^0_{1m}(x)\chi_{\{0\}}(t) \\
&\quad + \frac{1}{h} \sum_{i=0}^{m-1} \Big[(t-ih)\hat{r}^{i+1}_{1m}(x) - \Big(t-(i+1)h\Big)\hat{r}^i_{1m}(x) \Big] \chi_{(ih,(i+1)h]}(t), \\
\tilde{r}^m_2(t,x) &= \frac{1}{h} \sum_{i=0}^{m-1} \Big[(t-ih)\hat{r}^{i+1}_{2m}(x) - \Big(t-(i+1)h\Big)\hat{r}^i_{2m}(x) \Big] \chi_{(ih,(i+1)h]}(t), \\
\tilde{r}^m(t,x) &= \frac{1}{h} \sum_{i=0}^{m-1} \Big[(t-ih)\hat{r}^{i+1}_{m}(x) - \Big(t-(i+1)h\Big)\hat{r}^i_{m}(x) \Big] \chi_{(ih,(i+1)h]}(t).
\end{aligned}$$

By (6.10)–(6.11), one can find a subsequence of $(\tilde{z}^m, \tilde{r}^m_1, \tilde{r}^m_2, \tilde{r}^m)$, which converges weakly to some $(\tilde{z}, \tilde{r}_1, \tilde{r}_2, \tilde{r}) \in (H^1(0,T;L^2(\Omega)))^4$, as $m \to \infty$.

For any constant $K > 1$, put

$$\tilde{p} \triangleq K\tilde{r}.$$

In what follows, we shall choose K to be sufficiently large (see (7.19)). By (6.3), (6.8)–(6.11), and noting Lemma 3.1, we see that

$$\tilde{z},\ \tilde{p} \in C([0,T];H_0^1(\Omega)) \cap C^1([0,T];L^2(\Omega))$$

and

$$
\begin{cases}
\mathcal{P}\tilde{z} = \tilde{r}_{1,t} + \tilde{r}_2 + \lambda u e^{2\lambda\phi} + \tilde{r} & \text{in } Q,\\
\mathcal{P}\tilde{p} + \tilde{z}e^{-2\lambda\phi} = 0 & \text{in } Q,\\
\tilde{p} = \tilde{z} = 0 & \text{on } \Sigma,\\
\tilde{p}(0) = \tilde{p}(T) = \tilde{z}(0) = \tilde{z}(T) = 0 & \text{in } \Omega,\\
\tilde{p}_t + \varrho\dfrac{\tilde{r}_1}{\lambda^2}e^{-2\lambda\phi} = 0 & \text{in } Q,\\
\tilde{p} - \varrho\dfrac{\tilde{r}_2}{\lambda^4}e^{-2\lambda\phi} = 0 & \text{in } Q.
\end{cases}
\tag{7.3}
$$

Step 2. Applying Theorem 5.1 to $\tilde{p}$ in (7.3), one gets

$$
\begin{aligned}
&\lambda\int_Q (\lambda^2\tilde{p}^2 + \tilde{p}_t^2 + |\nabla\tilde{p}|^2)e^{2\lambda\phi}dxdt\\
&\le C\left[\int_Q \tilde{z}^2 e^{-2\lambda\phi}dxdt + \lambda^2\int_0^T\int_\omega (\lambda^2\tilde{p}^2 + \tilde{p}_t^2)e^{2\lambda\phi}dxdt\right]\\
&\le C\left[\int_Q \tilde{z}^2 e^{-2\lambda\phi}dxdt + \int_0^T\int_\omega \left(\frac{\tilde{r}_1^2}{\lambda^2} + \frac{\tilde{r}_2^2}{\lambda^4}\right)e^{-2\lambda\phi}dxdt\right].
\end{aligned}
\tag{7.4}
$$

Here and henceforth, C is a constant, independent of K and λ.

By (7.3) again, one finds that $\tilde{p}_t$ satisfies

$$
\begin{cases}
\mathcal{P}\tilde{p}_t + (\tilde{z}e^{-2\lambda\phi})_t = 0 & \text{in } Q,\\
\tilde{p}_t = 0 & \text{on } \Sigma,\\
\tilde{p}_{tt} + \dfrac{\varrho}{\lambda}\Big(\dfrac{\tilde{r}_{1,t}}{\lambda} - 2\phi_t\tilde{r}_1\Big)e^{-2\lambda\phi} = 0 & \text{in } Q,\\
\tilde{p}_t - \dfrac{\varrho}{\lambda^2}\Big(\dfrac{\tilde{r}_{2,t}}{\lambda^2} - \dfrac{2}{\lambda}\phi_t\tilde{r}_2\Big)e^{-2\lambda\phi} = 0 & \text{in } Q.
\end{cases}
\tag{7.5}
$$

Applying Theorem 5.1 to $\tilde{p}_t$ and noting (7.5), we obtain

$$
\begin{aligned}
&\lambda\int_Q \Big(\lambda^2\tilde{p}_t^2 + \tilde{p}_{tt}^2 + |\nabla\tilde{p}_t|^2\Big)e^{2\lambda\phi}dxdt\\
&\le C\left[|e^{\lambda\phi}(e^{-2\lambda\phi}\tilde{z})_t|^2_{L^2(Q)} + \lambda^2\int_0^T\int_\omega \left(\lambda^2\tilde{p}_t^2 + \tilde{p}_{tt}^2\right)e^{2\lambda\phi}dxdt\right]\\
&\le C\left[\int_Q (\tilde{z}_t^2 + \lambda^2\tilde{z}^2)e^{-2\lambda\phi}dxdt + \int_0^T\int_\omega \left(\frac{\tilde{r}_{1,t}^2}{\lambda^2} + \frac{\tilde{r}_{2,t}^2}{\lambda^4} + \tilde{r}_1^2 + \frac{\tilde{r}_2^2}{\lambda^2}\right)e^{-2\lambda\phi}dxdt\right].
\end{aligned}
\tag{7.6}
$$

Step 3. From (7.3), and noting that

$$
-\int_Q (\tilde{r}_{1,t}+\tilde{r}_2)\tilde{p}dxdt = \int_Q \Big(\tilde{r}_1\tilde{p}_t - \tilde{r}_2\tilde{p}\Big)dxdt = -\int_Q \varrho\left(\frac{\tilde{r}_1^2}{\lambda^2} + \frac{\tilde{r}_2^2}{\lambda^4}\right)e^{-2\lambda\phi}dxdt,
\tag{7.7}
$$

and recalling $\tilde{p} = K\tilde{r}$, we get

$$\begin{aligned} 0 &= (\mathcal{P}\tilde{z} - \tilde{r}_{1,t} - \tilde{r}_2 - \lambda u e^{2\lambda\phi} - \tilde{r}, \tilde{p})_{L^2(Q)} \\ &= -\int_Q \tilde{z}^2 e^{-2\lambda\phi} dxdt - \int_Q \varrho \left(\frac{\tilde{r}_1^2}{\lambda^2} + \frac{\tilde{r}_2^2}{\lambda^4} \right) e^{-2\lambda\phi} dxdt \\ &\quad - \lambda \int_Q u\tilde{p} e^{2\lambda\phi} dxdt - K \int_Q \tilde{r}^2 dxdt. \end{aligned} \tag{7.8}$$

Hence

$$\begin{aligned} &\int_Q \tilde{z}^2 e^{-2\lambda\phi} dxdt + \int_Q \varrho \left(\frac{\tilde{r}_1^2}{\lambda^2} + \frac{\tilde{r}_2^2}{\lambda^4} \right) e^{-2\lambda\phi} dxdt + K \int_Q \tilde{r}^2 dxdt \\ &= -\lambda \int_Q u\tilde{p} e^{2\lambda\phi} dxdt. \end{aligned} \tag{7.9}$$

Combining (7.4) and (7.9), we arrive at

$$\begin{aligned} &\int_Q \tilde{z}^2 e^{-2\lambda\phi} dxdt + \int_Q \varrho \left(\frac{\tilde{r}_1^2}{\lambda^2} + \frac{\tilde{r}_2^2}{\lambda^4} \right) e^{-2\lambda\phi} dxdt + K \int_Q \tilde{r}^2 dxdt \\ &\leq \frac{C}{\lambda} \int_Q u^2 e^{2\lambda\phi} dxdt. \end{aligned} \tag{7.10}$$

Step 4. Using (7.3) and (7.5) again, and noting $\tilde{p}_{tt}(0) = \tilde{p}_{tt}(T) = 0$ in Ω, we get

$$\begin{aligned} 0 &= (\mathcal{P}\tilde{z} - \tilde{r}_{1,t} - \tilde{r}_2 - \lambda u e^{2\lambda\phi} - \tilde{r}, \tilde{p}_{tt})_{L^2(Q)} \\ &= -\int_Q \tilde{z}(e^{-2\lambda\phi}\tilde{z})_{tt} dxdt - \int_Q (\tilde{r}_{1,t} + \tilde{r}_2)\tilde{p}_{tt} dxdt \\ &\quad - \lambda \int_Q u\tilde{p}_{tt} e^{2\lambda\phi} dxdt - \int_Q \tilde{r}\tilde{p}_{tt} dxdt. \end{aligned} \tag{7.11}$$

Note

$$\begin{aligned} -\int_Q \tilde{z}(e^{-2\lambda\phi}\tilde{z})_{tt} dxdt &= \int_Q \left(\tilde{z}_t^2 e^{-2\lambda\phi} - \frac{\tilde{z}^2}{2}(e^{-2\lambda\phi})_{tt} \right) dxdt \\ &= \int_Q (\tilde{z}_t^2 + \lambda\phi_{tt}\tilde{z}^2 - 2\lambda^2\phi_t^2\tilde{z}^2) e^{-2\lambda\phi} dxdt. \end{aligned} \tag{7.12}$$

Further, in view of the third and fourth equalities in (7.5), one has

$$\begin{aligned} &-\int_Q (\tilde{r}_{1,t} + \tilde{r}_2)\tilde{p}_{tt} dxdt = -\int_Q (\tilde{r}_{1,t}\tilde{p}_{tt} - \tilde{r}_{2,t}\tilde{p}_t) dxdt \\ &= \int_Q \tilde{r}_{1,t} \frac{\varrho}{\lambda} \left(\frac{\tilde{r}_{1,t}}{\lambda} - 2\phi_t \tilde{r}_1 \right) e^{-2\lambda\phi} dxdt + \int_Q \tilde{r}_{2,t} \frac{\varrho}{\lambda^2} \left(\frac{\tilde{r}_{2,t}}{\lambda^2} - \frac{2}{\lambda}\phi_t \tilde{r}_2 \right) e^{-2\lambda\phi} dxdt \\ &= \int_Q \varrho \left(\frac{\tilde{r}_{1,t}^2}{\lambda^2} + \frac{\tilde{r}_{2,t}^2}{\lambda^4} - \frac{2}{\lambda}\phi_t \tilde{r}_1 \tilde{r}_{1,t} - \frac{2}{\lambda^3}\phi_t \tilde{r}_2 \tilde{r}_{2,t} \right) e^{-2\lambda\phi} dxdt. \end{aligned} \tag{7.13}$$

Moreover, by $\tilde{p} \triangleq K\tilde{r}$ and integration by parts, one gets

$$-\int_Q \tilde{r}\tilde{p}_{tt}dxdt = K\int_Q \tilde{r}_t^2 dxdt. \tag{7.14}$$

Combining (7.11)–(7.14), we end up with

$$\begin{aligned}&\int_Q \varrho\left(\frac{\tilde{r}_{1,t}^2}{\lambda^2}+\frac{\tilde{r}_{2,t}^2}{\lambda^4}-\frac{2}{\lambda}\phi_t\tilde{r}_1\tilde{r}_{1,t}-\frac{2}{\lambda^3}\phi_t\tilde{r}_2\tilde{r}_{2,t}\right)e^{-2\lambda\phi}dxdt+K\int_Q \tilde{r}_t^2dxdt\\ &+\int_Q(\tilde{z}_t^2+\lambda\phi_{tt}\tilde{z}^2-2\lambda^2\phi_t^2\tilde{z}^2)e^{-2\lambda\phi}dxdt=\lambda\int_Q u\tilde{p}_{tt}e^{2\lambda\phi}dxdt.\end{aligned} \tag{7.15}$$

Now, by (7.15)$+C\lambda^2\cdot$(7.10) (with a sufficiently large $C>0$), using the Cauchy–Schwarz inequality and noting (7.6), we obtain

$$\begin{aligned}&\int_Q\left(\tilde{z}_t^2+\lambda^2\tilde{z}^2\right)e^{-2\lambda\phi}dxdt+\int_Q\varrho\left(\frac{\tilde{r}_{1,t}^2}{\lambda^2}+\frac{\tilde{r}_{2,t}^2}{\lambda^4}+\tilde{r}_1^2+\frac{\tilde{r}_2^2}{\lambda^2}\right)e^{-2\lambda\phi}dxdt\\ &\le C\lambda\int_Q u^2e^{2\lambda\phi}dxdt.\end{aligned} \tag{7.16}$$

Step 5. By (7.3), we have

$$\begin{aligned}&(\tilde{r}_{1,t}+\tilde{r}_2+\lambda ue^{2\lambda\phi}+\tilde{r},\tilde{z}e^{-2\lambda\phi})_{L^2(Q)}=(\mathcal{P}\tilde{z},\tilde{z}e^{-2\lambda\phi})_{L^2(Q)}\\ &=-\int_Q\tilde{z}_t(\tilde{z}e^{-2\lambda\phi})_tdxdt+\sum_{i,j}\int_Q a^{ij}\tilde{z}_i(\tilde{z}e^{-2\lambda\phi})_jdxdt\\ &=-\int_Q(\tilde{z}_t^2+\lambda\phi_{tt}\tilde{z}^2-2\lambda^2\phi_t^2\tilde{z}^2)e^{-2\lambda\phi}dxdt+\sum_{i,j}\int_Q a^{ij}\tilde{z}_i\tilde{z}_je^{-2\lambda\phi}dxdt\\ &\quad-2\lambda\sum_{i,j}\int_Q a^{ij}\tilde{z}_i\tilde{z}\phi_je^{-2\lambda\phi}dxdt.\end{aligned} \tag{7.17}$$

This, combined with (1.2), yields (recall $\lambda\ge\lambda_0>1$)

$$\begin{aligned}&\int_Q|\nabla\tilde{z}|^2e^{-2\lambda\phi}dxdt\\ &\le C\int_Q\left[|\tilde{r}_{1,t}+\tilde{r}_2+\tilde{r}||\tilde{z}|e^{-2\lambda\phi}+\lambda|u\tilde{z}|+(\tilde{z}_t^2+\lambda^2\tilde{z}^2)e^{-2\lambda\phi}\right]dxdt\\ &\le C\int_Q\left[u^2e^{2\lambda\phi}+\left(\frac{\tilde{r}_{1,t}^2}{\lambda^2}+\frac{\tilde{r}_2^2}{\lambda^2}+\tilde{r}^2+\tilde{z}_t^2+\lambda^2\tilde{z}^2\right)e^{-2\lambda\phi}\right]dxdt.\end{aligned} \tag{7.18}$$

Combining (7.10), (7.16), and (7.18); choosing the constant K in (7.10) so that

$$K\ge Ce^{2\lambda\max_{(t,x)\in Q}|\phi|} \tag{7.19}$$

(to absorb the term $C\int_Q\tilde{r}^2e^{-2\lambda\phi}dxdt$ in the right-hand side of (7.18)); and noting that $\varrho(x)\ge1$ in Ω, we deduce that

$$\begin{aligned}&\int_Q(|\nabla\tilde{z}|^2+\tilde{z}_t^2+\lambda^2\tilde{z}^2)e^{-2\lambda\phi}dxdt+\int_Q\varrho\left(\frac{\tilde{r}_{1,t}^2}{\lambda^2}+\frac{\tilde{r}_{2,t}^2}{\lambda^4}+\tilde{r}_1^2+\frac{\tilde{r}_2^2}{\lambda^2}\right)e^{-2\lambda\phi}dxdt\\ &\le C\lambda\int_Q u^2e^{2\lambda\phi}dxdt.\end{aligned} \tag{7.20}$$

Step 6. Recall that $(\tilde{z}, \tilde{r}_1, \tilde{r}_2, \tilde{r})$ depend on K. We now fix λ and let $K \to \infty$. By (7.10) and (7.20), we conclude that there exists a subsequence of $(\tilde{z}, \tilde{r}_1, \tilde{r}_2, \tilde{r})$ which converges weakly to some $(\check{z}, \check{r}_1, \check{r}_2, 0)$ in $H_0^1(Q) \times (H^1(0,T;L^2(\Omega)))^2 \times L^2(Q)$, with $\operatorname{supp} \check{r}_i \subset \overline{(0,T) \times \omega}$ $(i = 1, 2)$ since $\varrho(x) \equiv \varrho^K(x) \to \infty$ for any $x \notin \omega$, as $K \to \infty$. By (7.3), we deduce that $(\check{z}, \check{r}_1, \check{r}_2)$ satisfies

$$\begin{cases} \mathcal{P}\check{z} = \check{r}_{1,t} + \check{r}_2 + \lambda u e^{2\lambda\phi} & \text{in } Q, \\ \check{z} = 0 & \text{on } \partial Q. \end{cases} \tag{7.21}$$

Using (7.20) again, we find

$$|\check{z}e^{-\lambda\phi}|^2_{H_0^1(Q)} + \frac{1}{\lambda^2}\int_0^T \int_\omega (\check{r}_{1,t}^2 + \check{r}_2^2) e^{-2\lambda\phi} dxdt \le C\lambda \int_Q u^2 e^{2\lambda\phi} dxdt. \tag{7.22}$$

Now, by (7.1) with η replaced by the above $\check{z}$, one gets

$$\Big(u, \check{r}_{1,t} + \check{r}_2 + \lambda u e^{2\lambda\phi}\Big)_{L^2(Q)} = \langle\, \mathcal{P}u, \check{z}\,\rangle_{H^{-1}(Q), H_0^1(Q)}.$$

Hence, noting $\operatorname{supp} \check{r}_i \subset \overline{(0,T) \times \omega}$ $(i = 1, 2)$, we conclude that for any $\varepsilon > 0$, it holds that

$$\begin{aligned} \lambda \int_Q u^2 e^{2\lambda\phi} dxdt &= \langle\, \mathcal{P}u, \check{z}\,\rangle_{H^{-1}(Q), H_0^1(Q)} - (u, \check{r}_{1,t} + \check{r}_2)_{L^2((0,T)\times\omega)} \\ &\le C\Bigg\{ \frac{1}{\varepsilon}\left[|e^{\lambda\phi}\mathcal{P}u|^2_{H^{-1}(Q)} + \lambda^2 \int_0^T \int_\omega u^2 e^{2\lambda\phi} dxdt \right] \\ &\quad + \varepsilon \left[|\check{z}e^{-\lambda\phi}|^2_{H_0^1(Q)} + \frac{1}{\lambda^2}\int_0^T \int_\omega (\check{r}_{1,t}^2 + \check{r}_2^2) e^{-2\lambda\phi} dxdt \right] \Bigg\}. \end{aligned} \tag{7.23}$$

Finally, choosing ε in (7.23) sufficiently small and noting (7.22), we arrive at the desired estimate (7.2). This completes the proof of Theorem 7.1. ∎

8. Proof of Theorem 2.3. The main idea is to use the Carleman estimate in Theorem 7.1. Note, however, that our w satisfying (1.7) does not necessarily vanish at $t = 0, T$. Therefore we need to introduce a suitable cutoff function. To this end, set

$$\begin{cases} T_i \triangleq T/2 - \varepsilon_i T, \quad T_i' \triangleq T/2 + \varepsilon_i T, \\ R_0 \triangleq \min\limits_{x \in \overline{\Omega}} \sqrt{d(x)}\ (> 0), \end{cases} \tag{8.1}$$

where $i = 0, 1$; $0 < \varepsilon_0 < \varepsilon_1 < 1/2$ will be given below.

From (5.2) and (4.13), it is easy to see that

$$\phi(0,x) = \phi(T,x) < R_1^2 - cT^2/4 < 0 \qquad \forall\, x \in \Omega. \tag{8.2}$$

Therefore there exists an $\varepsilon_1 \in (0, 1/2)$ close to $1/2$ such that

$$\phi(t,x) \le R_1^2/2 - cT^2/8 < 0 \qquad \forall\, (t,x) \in \Big((0,T_1) \bigcup (T_1', T)\Big) \times \Omega \tag{8.3}$$

with T_1 and T_1' given by (8.1). Further, by (4.13), we see that

$$\phi(T/2,x)=d(x)\geq R_0^2 \qquad \forall\, x\in\Omega.$$

Hence, one can find an $\varepsilon_0\in(0,1/2)$, close to 0, such that

$$\phi(t,x)\geq R_0^2/2 \qquad \forall\,(t,x)\in(T_0,T_0')\times\Omega, \tag{8.4}$$

with T_0 and T_0' given by (8.1). We now choose a nonnegative function $\xi\in C_0^\infty(0,T)$ so that

$$\xi(t)\equiv 1 \quad \text{in } (T_1,T_1'). \tag{8.5}$$

Clearly, ξw vanishes at $t=0,T$. Hence, by Theorem 7.1, for any $\lambda\geq\lambda_0$, we have

$$\lambda\int_Q(\xi w)^2e^{2\lambda\phi}dxdt\leq C\left(|e^{\lambda\phi}\mathcal{P}(\xi w)|^2_{H^{-1}(Q)}+\lambda^2\int_0^T\int_\omega w^2e^{2\lambda\phi}dxdt\right). \tag{8.6}$$

By (1.7), we have

$$\begin{aligned}
&|e^{\lambda\phi}\mathcal{P}(\xi w)|_{H^{-1}(Q)}=|e^{\lambda\phi}(\xi\mathcal{P}w+2\xi_tw_t+w\xi_{tt}|_{H^{-1}(Q)}\\
&=|e^{\lambda\phi}(\xi qw+2\xi_tw_t+w\xi_{tt})|_{H^{-1}(Q)}\\
&=\sup_{|f|_{H_0^1(Q)}=1}\langle\, e^{\lambda\phi}(\xi qw+2\xi_tw_t+w\xi_{tt}),f\,\rangle_{H^{-1}(Q),H_0^1(Q)}\\
&\leq\sup_{|f|_{H_0^1(Q)}=1}\int_Q e^{\lambda\phi}\xi qwf\,dxdt\\
&\quad+\sup_{|f|_{H_0^1(Q)}=1}\langle\, e^{\lambda\phi}(2\xi_tw_t+w\xi_{tt}),f\,\rangle_{H^{-1}(Q),H_0^1(Q)}.
\end{aligned} \tag{8.7}$$

Using the Sobolev embedding theorem and the Hölder inequality, and recalling $r\stackrel{\triangle}{=}|q|_{L^\infty(0,T;L^n(\Omega))}$, we get

$$\sup_{|f|_{H_0^1(Q)}=1}\int_Q e^{\lambda\phi}\xi qwf\,dxdt\leq Cr|e^{\lambda\phi}w|_{L^2(Q)}. \tag{8.8}$$

On the other hand, by (8.3) and (8.5), we have

$$\begin{aligned}
&\sup_{|f|_{H_0^1(Q)}=1}\langle\, e^{\lambda\phi}(2\xi_tw_t+w\xi_{tt}),f\,\rangle_{H^{-1}(Q),H_0^1(Q)}\\
&=\sup_{|f|_{H_0^1(Q)}=1}\int_Q e^{\lambda\phi}w(-\xi_{tt}f-2\xi_tf_t-2\lambda\phi_t\xi_tf)dxdt\\
&\leq Ce^{(R_1^2/2-cT^2/8)\lambda}(1+\lambda)(|w|_{L^2((0,T_1)\times\Omega)}+|w|_{L^2((T_1',T)\times\Omega)}).
\end{aligned} \tag{8.9}$$

Further, by (8.3) and (8.5), we have

$$\begin{aligned}
&\int_Q (\xi w)^2 e^{2\lambda\phi} dxdt = \int_Q w^2 e^{2\lambda\phi} dxdt - \int_Q (1-\xi^2) w^2 e^{2\lambda\phi} dxdt \\
&= \int_Q w^2 e^{2\lambda\phi} dxdt - \int_0^{T_1} \int_\Omega (1-\xi^2) w^2 e^{2\lambda\phi} dxdt \\
&\qquad\qquad - \int_{T_1'}^{T} \int_\Omega (1-\xi^2) w^2 e^{2\lambda\phi} dxdt \\
&\geq \int_Q w^2 e^{2\lambda\phi} dxdt - Ce^{(R_1^2 - cT^2/4)\lambda} (|w|^2_{L^2((0,T_1)\times\Omega)} + |w|^2_{L^2((T_1',T)\times\Omega)}).
\end{aligned} \tag{8.10}$$

Combining (8.6)–(8.10), we arrive at

$$\begin{aligned}
&\lambda \int_Q w^2 e^{2\lambda\phi} dxdt \\
&\leq C_1 \bigg[r^2 \int_Q w^2 e^{2\lambda\phi} dxdt + \lambda^2 \int_0^T \int_\omega w^2 e^{2\lambda\phi} dxdt \\
&\qquad + e^{(R_1^2 - cT^2/4)\lambda} (1+\lambda^2) (|w|^2_{L^2((0,T_1)\times\Omega)} + |w|^2_{L^2((T_1',T)\times\Omega)}) \bigg],
\end{aligned} \tag{8.11}$$

for a constant $C_1 > 0$, independent of λ and r. Since $R_1^2 - cT^2/4 < 0$, one may find a $\lambda_1 \geq \lambda_0$ such that $e^{(R_1^2 - cT^2/4)\lambda}(1+\lambda^2) < 1$ for all $\lambda \geq \lambda_1$. Now, taking

$$\lambda \geq 2C_1(\lambda_1 + r^2), \tag{8.12}$$

it follows from (8.11) that

$$\begin{aligned}
&\lambda \int_Q w^2 e^{2\lambda\phi} dxdt \\
&\leq C \left(\lambda^2 \int_0^T \int_\omega w^2 e^{2\lambda\phi} dxdt + |w|^2_{L^2((0,T_1)\times\Omega)} + |w|^2_{L^2((T_1',T)\times\Omega)} \right).
\end{aligned} \tag{8.13}$$

From (8.4), we see that

$$\int_Q w^2 e^{2\lambda\phi} dxdt \geq e^{R_0^2\lambda} \int_{T_0}^{T_0'} \int_\Omega w^2 dxdt. \tag{8.14}$$

For any $S_0 \in (T_0, T/2)$ and $S_0' \in (T/2, T_0')$, by Lemma 3.4, we obtain (recall (3.4) for $E(t)$)

$$\int_{S_0}^{S_0'} E(t) dt \leq C(1+r) \int_{T_0}^{T_0'} \int_\Omega w^2 dxdt. \tag{8.15}$$

On the other hand, by Lemma 3.3, we have

$$|w|^2_{L^2((0,T_1)\times\Omega)} + |w|^2_{L^2((T_1',T)\times\Omega)} \leq CE(0)e^{Cr} \tag{8.16}$$

and

$$\int_{S_0}^{S_0'} E(t)dt \geq CE(0)e^{Cr}. \tag{8.17}$$

Combining (8.13)–(8.17), we end up with

$$\Big(C_2\lambda e^{R_0^2\lambda+C_2r} - C_3(1+r)e^{C_3r}\Big)E(0) \leq C\lambda^2(1+r)e^{C\lambda}\int_0^T\int_\omega w^2dxdt, \tag{8.18}$$

for two constants $C_2 > 0$ and $C_3 > 0$, independent of λ and r. We now choose λ so that

$$C_2\lambda \geq C_3(1+r), \qquad R_0^2\lambda + C_2r \geq C_3r. \tag{8.19}$$

Then, from (8.18), we obtain

$$E(0) \leq \mathcal{C}(q)|w|^2_{L^2((0,T)\times\omega)}. \tag{8.20}$$

Finally, noting (8.12) and (8.19), we conclude (2.12). This completes the proof of Theorem 2.3. □

9. Proof of Theorem 2.2. The proof is very close to that of [26, Theorem 3.1] and [38, Theorem 2.1]. However, for the reader's convenience, we give some details here.

Define a function $h(\cdot) \in C(\mathbb{R})$ by

$$h(s) \stackrel{\triangle}{=} \begin{cases} [f(s)-f(0)]/s & \text{if } s \neq 0, \\ f'(0) & \text{if } s = 0. \end{cases} \tag{9.1}$$

Let the initial and final data $(y_0, y_1), (z_0, z_1) \in H_0^1(\Omega) \times L^2(\Omega)$ be given. For any given $z(\cdot) \in L^\infty(0,T; L^2(\Omega))$, we look for a control $\gamma = \gamma(z(\cdot)) \in L^2((0,T)\times\omega)$ such that the solution $y = y(\cdot; z(\cdot))$ of

$$\begin{cases} \mathcal{P}y = h(z(\cdot))y + f(0) + \chi_\omega(x)\gamma(t,x) & \text{in } Q, \\ y = 0 & \text{on } \Sigma, \\ y(0) = y_0, \quad y_t(0) = y_1 & \text{in } \Omega \end{cases} \tag{9.2}$$

satisfies

$$y(T) = z_0, \quad y_t(T) = z_1 \qquad \text{in } \Omega. \tag{9.3}$$

For this purpose, we use the classical duality argument [29, 28, 39]. First, we solve

$$\begin{cases} \mathcal{P}v = h(z(\cdot))v + f(0) & \text{in } Q, \\ v = 0 & \text{on } \Sigma, \\ v(T) = z_0, \quad v_t(T) = z_1 & \text{in } \Omega, \end{cases} \tag{9.4}$$

which admits a unique weak solution $v = v(\cdot; z(\cdot)) \in C([0,T]; H_0^1(\Omega)) \cap C^1([0,T]; L^2(\Omega))$. Next, put $X \stackrel{\triangle}{=} L^2(\Omega) \times H^{-1}(\Omega)$. For any $(w_0, w_1) \in X$, we solve

$$\begin{cases} \mathcal{P}w = h(z(\cdot))w & \text{in } Q, \\ w = 0 & \text{on } \Sigma, \\ w(0) = w_0, \quad w_t(0) = w_1 & \text{in } \Omega \end{cases} \tag{9.5}$$

and

$$\begin{cases} \mathcal{P}\eta = h(z(\cdot))\eta + \chi_\omega(x)w(t,x) & \text{in } Q, \\ \eta = 0 & \text{on } \Sigma, \\ \eta(T) = \eta_t(T) = 0 & \text{in } \Omega. \end{cases} \tag{9.6}$$

Now, we define a linear and continuous operator $\Lambda : X \to X'$, the dual space of X, by

$$\Lambda(w_0, w_1) \stackrel{\triangle}{=} (-\eta_t(0), \eta(0)), \tag{9.7}$$

where $\eta \in C([0,T]; H_0^1(\Omega)) \cap C^1([0,T]; L^2(\Omega))$ is the weak solution of (9.6).

Let us show the existence of some $(w_0, w_1) \in X$ such that

$$\Lambda(w_0, w_1) = (-y_1 + v_t(0), y_0 - v(0)). \tag{9.8}$$

For this purpose, we observe that, by multiplying the first equation in (9.6) by w; integrating it in Q; using integration by parts; and noting (9.5), $\eta(T) = \eta_t(T) = 0$ in Ω, and (9.7), it follows that

$$\langle\, \Lambda(w_0, w_1), (w_0, w_1)\, \rangle_{X',X} = \int_0^T \int_\omega w^2 dxdt. \tag{9.9}$$

However, by Theorem 2.3 and (9.9), we have

$$\langle\, \Lambda(w_0, w_1), (w_0, w_1)\, \rangle_{X',X} \geq \frac{1}{\mathcal{C}(h(z(\cdot)))} |(w_0, w_1)|_X^2 \qquad \forall\, (w_0, w_1) \in X, \tag{9.10}$$

where $\mathcal{C}(\cdot)$ is the constant given in (2.12). By the Lax–Milgram theorem, (9.8) admits a unique solution $(w_0, w_1) \in X$. It is easy to check that

$$\gamma = w \tag{9.11}$$

is the desired control such that the weak solution $y \equiv v + \eta$ of (9.2) satisfies (9.3).

Further, proceeding as in the proof of [38, Theorem 2.1], by (9.10) we end up with

$$\begin{aligned} &|w|_{C([0,T];L^2(\Omega))} \\ &\leq \mathcal{C}(h(z(\cdot)))(|f(0)| + |(y_0, y_1)|_{H_0^1(\Omega)\times L^2(\Omega)} + |(z_0, z_1)|_{H_0^1(\Omega)\times L^2(\Omega)}). \end{aligned} \tag{9.12}$$

Next, similarly to the proof of [26, Theorem 3.1] by applying the classical energy method to (9.2), noting (9.11)–(9.12), and recalling assumption (1.4), one concludes that there is a constant $C > 0$ such that, for any $\varepsilon \in (0, 4]$, it holds that

$$\begin{aligned} &|y|_{C([0,T];H_0^1(\Omega))\cap C^1([0,T];L^2(\Omega))} \\ &\leq C[|f(0)| + |(y_0, y_1)|_{H_0^1(\Omega)\times L^2(\Omega)} \\ &\qquad + |(z_0, z_1)|_{H_0^1(\Omega)\times L^2(\Omega)}]\Big(1 + |z|^{4/(1+\varepsilon)}_{L^\infty(0,T;L^2(\Omega))}\Big). \end{aligned} \tag{9.13}$$

Consequently if we take $\varepsilon = 4$ in (9.13), the desired exact controllability result follows from the fixed point technique. This completes the proof of Theorem 2.2. ∎

10. Appendix A. Proof of Proposition 2.1. Consider first the case when $A = \operatorname{diag}[a^1, \dots, a^n]$ with $a^i \in C^1(\overline{\Omega})$ $(i = 1, \dots, n)$. In this case, the matrix $\mathcal{A}$ (defined in (2.3)) reads

$$\mathcal{A} = \left(a^i a^j d_{ij} + \frac{a^i a^j_i d_j + a^j a^i_j d_i}{2} \right)_{1 \le i,j \le n} - \frac{1}{2} \operatorname{diag} \left[\sum_k a^k a^1_k d_k, \dots, \sum_k a^k a^n_k d_k \right].$$

In particular, when $n = 2$ and a^1 is independent of x_2 (hence $a^1_2 \equiv 0$), the above $\mathcal{A}$ is specialized as

$$\begin{aligned} \mathcal{A} &= \begin{pmatrix} (a^1)^2 d_{11} + \frac{a^1 a^1_1 d_1 - a^2 a^1_2 d_2}{2} & a^1 a^2 d_{12} + \frac{a^1 a^2_1 d_2 + a^2 a^1_2 d_1}{2} \\ a^1 a^2 d_{12} + \frac{a^1 a^2_1 d_2 + a^2 a^1_2 d_1}{2} & (a^2)^2 d_{22} + \frac{a^2 a^2_2 d_2 - a^1 a^2_1 d_1}{2} \end{pmatrix} \\ &= \begin{pmatrix} (a^1)^2 d_{11} + \frac{a^1 a^1_1 d_1}{2} & a^1 a^2 d_{12} + \frac{a^1 a^2_1 d_2}{2} \\ a^1 a^2 d_{12} + \frac{a^1 a^2_1 d_2}{2} & (a^2)^2 d_{22} + \frac{a^2 a^2_2 d_2 - a^1 a^2_1 d_1}{2} \end{pmatrix} \\ &\equiv \begin{pmatrix} \hat{a}^{11} & \hat{a}^{12} \\ \hat{a}^{12} & \hat{a}^{22} \end{pmatrix}. \end{aligned} \tag{10.1}$$

Put $L = 2\operatorname{diam}\Omega$. For any parameters $\tau > 0$ and $\mu > 0$, we now choose d to be of the form

$$d(x_1, x_2) = e^{-\tau a^1(x_1)} + e^{-\mu(L + x_2)}.$$

Then,

$$\begin{aligned} &d_1 = -\tau a^1_1 e^{-\tau a^1}, \quad d_{11} = \tau(\tau |a^1_1|^2 - a^1_{11}) e^{-\tau a^1}, \\ &d_{12} = 0, \quad d_2 = -\mu e^{-\mu(L + x_2)}, \quad d_{22} = \mu^2 e^{-\mu(L + x_2)}. \end{aligned} \tag{10.2}$$

We consider only the case when there is an $x_0 \in G$ such that $a^1_1(x^0_1) = 0$, $a^1_{11}(x^0_1) < 0$, $|a^1_1| \neq 0$ in $G \setminus \{x^0_1\}$ (the case when $a^1_1(x_1) \neq 0$ for any $x_1 \in G$ is easier to analyze). By (10.1), (10.2), and noting that a^1 is uniformly positive in $\overline{\Omega}$, one may choose a sufficiently large τ such that

$$\begin{aligned} \hat{a}^{11} &= (a^1)^2 d_{11} + \frac{a^1 a^1_1 d_1}{2} \\ &= \tau \left[\left(\tau (a^1)^2 - \frac{a^1}{2} \right) |a^1_1|^2 - a^1_{11} (a^1)^2 \right] e^{-\tau a^1} > 0 \end{aligned} \tag{10.3}$$

uniformly in $\overline{\Omega}$.

Further, by (10.1) and (10.2), by noting that $a^1_1 a^2_1 \ge 0$, and by noting that a^2 is uniformly positive in $\overline{\Omega}$, one may choose a sufficiently large μ such that

$$\begin{aligned} \hat{a}^{22} &= (a^2)^2 d_{22} + \frac{a^2 a^2_2 d_2 - a^1 a^2_1 d_1}{2} \\ &= \left[(a^2)^2 \mu^2 - \frac{a^2 a^2_2 \mu}{2} \right] e^{-\mu(L + x_2)} + \frac{a^1 a^1_1 a^2_1 \tau}{2} e^{-\tau a^1} > 0 \end{aligned} \tag{10.4}$$

uniformly in $\overline{\Omega}$.

Further, we have

$$\hat{a}^{12} = a^1 a^2 d_{12} + \frac{a^1 a_1^2 d_2}{2} = -\frac{a^1 a_1^2 \mu}{2} e^{-\mu(L+x_2)}.$$

Now, fixing the parameter τ, it is easy to see that

$$\hat{a}^{11}\hat{a}^{22} - (\hat{a}^{12})^2 > 0 \qquad \text{uniformly in } \overline{\Omega}, \tag{10.5}$$

provided that μ is large enough (because $(\hat{a}^{12})^2$ is an infinitesimal of higher order, compared to $\hat{a}^{11}\hat{a}^{12}$, with respect to large μ). By (10.3)–(10.5), we deduce that the matrix $\mathcal{A}$ in (10.1) is uniformly positive definite in $\overline{\Omega}$.

It is clear that $\min_{x\in\overline{\Omega}} |\nabla d(x)| > 0$. Therefore, Condition 2.1 holds for the above constructed function d. □

11. Appendix B. Proof of Theorem 5.1. The proof is long and we divide it into several steps.

Step 1. Applying Corollary 4.2 to our present u and d, we conclude that for any constants $\lambda > 0$ and $k \in (0,1)$, it holds that

$$\begin{aligned}
&\theta^2|\mathcal{P}u|^2 + M_t \\
&\quad + 2\sum_j \left\{ 2\sum_{i,i',j'} a^{ij}a^{i'j'}\ell_{i'}v_i v_{j'} - \sum_{i,i',j'} a^{ij}a^{i'j'}\ell_i v_{i'}v_{j'} + \Psi v \sum_i a^{ij}v_i \right. \\
&\qquad \left. -2\ell_t v_t \sum_i a^{ij}v_i + \sum_i a^{ij}\ell_i v_t^2 - \sum_i a^{ij}\left[(\Lambda+\Psi)\ell_i + \frac{\Psi_i}{2}\right]v^2 \right\}_j \\
&\quad \geq 2\lambda(1-k)v_t^2 + Bv^2 \\
&\quad + 2\lambda\sum_{i,j}\left\{ (k-1-4c)a^{ij} + \sum_{i',j'}\left[2a^{ij'}(a^{i'j}d_{i'})_{j'} - a^{ij}_{j'}a^{i'j'}d_{i'}\right]\right\} v_i v_j,
\end{aligned} \tag{11.1}$$

where

$$\left\{\begin{array}{l}
M \triangleq 2\left[\ell_t\left(v_t^2 + \sum_{i,j} a^{ij}v_i v_j\right) - 2\sum_{i,j} a^{ij}\ell_i v_j v_t \right. \\
\qquad\qquad \left. -\Psi v v_t + \left((\Lambda+\Psi)\ell_t + \frac{\Psi_t}{2}\right)v^2\right], \\
\Psi \triangleq \lambda\left[\sum_{i,j}(a^{ij}d_i)_j - 2c - 1 + k\right], \quad \ell \triangleq \lambda\phi, \quad v \triangleq \theta u, \quad \theta \triangleq e^{\ell}, \\
\Lambda = \lambda^2\left[4c^2(t-T/2)^2 - \sum_{i,j} a^{ij}d_i d_j\right] + \lambda(4c+1-k), \\
B = 2\lambda^3\left[(4c+1-k)\sum_{i',j'} a^{i'j'}d_{i'}d_{j'} + \sum_{i,j} a^{ij}d_i\left(\sum_{i',j'} a^{i'j'}d_{i'}d_{j'}\right)_j \right. \\
\qquad\qquad \left. -4(8c+1-k)c^2(t-T/2)^2\right] + O(\lambda^2).
\end{array}\right. \tag{11.2}$$

Next, fix a k with $4c-3<k<1$. Hence

$$1-k>0. \tag{11.3}$$

On the other hand, by Condition 2.1 and noting (2.1) with $\mu_0 \geq 4$, we get

$$\begin{aligned}
&\sum_{i,j}\left\{(k-1-4c)a^{ij}+\sum_{i',j'}\left[2a^{ij'}(a^{i'j}d_{i'})_{j'}-a^{ij}_{j'}a^{i'j'}d_{i'}\right]\right\}v_iv_j\\
&\geq (k-4c-1+\mu_0)\sum_{i,j}a^{ij}v_iv_j\\
&=\mu\sum_{i,j}a^{ij}v_iv_j \quad \forall\, x\in\Omega,
\end{aligned} \tag{11.4}$$

where

$$\mu=\mu_0-1+k-4c\geq 3+k-4c>0. \tag{11.5}$$

Recalling that d satisfies (2.1), and noting $a^{i'j'}=a^{j'i'}$, we find

$$\begin{aligned}
\mu_0\sum_{i,j}a^{ij}d_id_j &\leq \sum_{i,j,i',j'}\left[2a^{ij'}(a^{i'j}d_{i'})_{j'}-a^{ij}_{j'}a^{i'j'}d_{i'}\right]d_id_j\\
&=\sum_{i,j,i',j'}\left[2a^{ij'}a^{i'j}_{j'}d_{i'}d_id_j+2a^{ij'}a^{i'j}d_{i'j'}d_id_j-a^{ij}_{j'}a^{i'j'}d_{i'}d_id_j\right]\\
&=\sum_{i,j,i',j'}\left[a^{ij'}a^{i'j}_{j'}d_{i'}d_id_j+2a^{ij'}a^{i'j}d_{i'j'}d_id_j\right]\\
&=\sum_{i,j,i',j'}\left[a^{ij}a^{i'j'}_{j}d_{i'}d_id_{j'}+2a^{ij}a^{i'j'}d_{i'j}d_id_{j'}\right]\\
&=\sum_{i,j,i',j'}\left[a^{ij}a^{i'j'}_{j}d_{i'}d_id_{j'}+a^{ij}a^{i'j'}d_{i'j}d_id_{j'}+a^{ij}a^{j'i'}d_{j'j}d_id_{i'}\right]\\
&=\sum_{i,j}a^{ij}d_i\left(\sum_{i',j'}a^{i'j'}d_{i'}d_{j'}\right)_j.
\end{aligned} \tag{11.6}$$

Hence, recalling, respectively, (2.8) and (11.2) for R_1 and B, by (11.6) and using the third inequality in (2.7), and noting that A is positive definite and $4c+1-k+\mu_0>8c+1-k$, we arrive at

$$\begin{aligned}
B&\geq 2\lambda^3\left\{(4c+1-k+\mu_0)\sum_{i,j}a^{ij}d_id_j-4(8c+1-k)c^2(t-T/2)^2\right\}+O(\lambda^2)\\
&\geq 2\lambda^3(8c+1-k)\left[\sum_{i,j}a^{ij}d_id_j-4c^2(t-T/2)^2\right]+O(\lambda^2)\\
&\geq 16c(4R_1^2-c^2T^2)\lambda^3+O(\lambda^2).
\end{aligned} \tag{11.7}$$

Note that, by (5.2), the constant $16c(4R_1^2 - c^2T^2)$ in (11.7) is positive. Hence, by choosing a suitable $\lambda_0 > 1$, for any $\lambda \geq \lambda_0$, we have

$$B \geq 8c(4R_1^2 - c^2T^2)\lambda^3. \tag{11.8}$$

Step 2. Integrating (11.1) on Q, using integration by parts, recalling (11.3)–(11.5) and (11.8), and noting that $v_i = \frac{\partial v}{\partial \nu}\nu_i$ on Σ (which follows from $v|_\Sigma = 0$), we arrive at (recall (11.2) for $M = M(t,x)$)

$$\begin{aligned}
&\lambda \int_Q \left(\lambda^2 v^2 + v_t^2 + \sum_{i,j} a^{ij} v_i v_j \right) dxdt \\
&\leq C \Bigg[\int_Q \theta^2 |\mathcal{P}u|^2 dxdt + \int_\Omega M(T,x)dx - \int_\Omega M(0,x)dx \\
&\qquad + \lambda \int_\Sigma \left(\sum_{i,j} a^{ij}\nu_i\nu_j \right) \left(\sum_{i',j'} a^{i'j'} d_{i'}\nu_{j'} \right) \Big| \frac{\partial v}{\partial \nu} \Big|^2 dxdt \Bigg] \qquad \forall\, \lambda \geq \lambda_0.
\end{aligned} \tag{11.9}$$

By (4.13) and (11.2), and noting that $u(0,x) = u(T,x) \equiv 0$, we get

$$\begin{aligned}
&M(0,x) = 2\ell_t(0,x)[\theta(0,x)u_t(0,x)]^2 = 2cT\lambda[\theta(0,x)u_t(0,x)]^2 > 0, \\
&M(T,x) = 2\ell_t(T,x)[\theta(T,x)u_t(T,x)]^2 = -2cT\lambda[\theta(T,x)u_t(T,x)]^2 < 0.
\end{aligned} \tag{11.10}$$

Combining (11.9) and (11.10), and noting the definition of Γ_+ in (2.5), we obtain

$$\begin{aligned}
&\lambda \int_Q \left(\lambda^2 v^2 + v_t^2 + \sum_{i,j} a^{ij} v_i v_j \right) dxdt \\
&\leq C \Bigg[\int_Q \theta^2 |\mathcal{P}u|^2 dxdt \\
&\qquad + \lambda \int_0^T \int_{\Gamma_+} \left(\sum_{i,j} a^{ij}\nu_i\nu_j \right) \left(\sum_{i',j'} a^{i'j'} d_{i'}\nu_{j'} \right) \Big| \frac{\partial v}{\partial \nu} \Big|^2 dxdt \Bigg].
\end{aligned} \tag{11.11}$$

Recalling $u = \theta^{-1}v$ and $\theta = e^\ell$, noting (4.13) and (11.11), and noting (1.2) and $u|_\Sigma = 0$, we get

$$\begin{aligned}
&\lambda \int_Q \theta^2 (\lambda^2 u^2 + u_t^2 + |\nabla u|^2) dxdt \\
&\leq C \left(\int_Q \theta^2 |\mathcal{P}u|^2 dxdt + \lambda \int_0^T \int_{\Gamma_+} \theta^2 \Big| \frac{\partial u}{\partial \nu} \Big|^2 dxdt \right).
\end{aligned} \tag{11.12}$$

Step 3. Let us estimate

$$\int_0^T \int_{\Gamma_+} \theta^2 \Big| \frac{\partial u}{\partial \nu} \Big|^2 dxdt.$$

We choose a $g_0 \in C^1(\overline{\Omega}; \mathbb{R}^n)$ such that $g_0 = \nu$ on Γ, and a $\rho \in C^2(\overline{\Omega}; [0,1])$ such that (recall Condition 2.2 for δ)

$$\begin{cases} \rho(x) \equiv 1, & x \in \mathcal{O}_{\delta/3}(\Gamma_+) \cap \Omega, \\ \rho(x) \equiv 0, & x \in \Omega \setminus \mathcal{O}_{\delta/2}(\Gamma_+). \end{cases} \tag{11.13}$$

Put

$$g = g_0 \rho \theta^2. \tag{11.14}$$

Integrating (3.3) (in Lemma 3.2) in Q, with g defined by (11.14) and z replaced by u; using integration by parts; and noting (11.13), $u_i = \frac{\partial u}{\partial \nu}\nu_i$ on Σ (which follows from $u|_\Sigma = 0$), and $u(0,x) = u(T,x) \equiv 0$, we get

$$\begin{aligned}
&\int_\Sigma \left(\sum_{i,j} a^{ij}\nu_i\nu_j \right) \rho\theta^2 \Big| \frac{\partial u}{\partial \nu} \Big|^2 dxdt \\
&= \int_Q \sum_j \left[2(g\cdot\nabla u) \sum_i a^{ij} u_i + g^j \left(u_t^2 - \sum_{i,k} a^{ik} u_i u_k \right) \right]_j dxdt \\
&= -\int_Q \left\{ 2 \left[(\mathcal{P}u) g\cdot\nabla u - (u_t g\cdot\nabla u)_t + u_t g_t \cdot \nabla u - \sum_{i,j,k} a^{ij} u_i u_k \frac{\partial g^k}{\partial x_j} \right] \right. \\
&\qquad \left. -(\nabla\cdot g)\left(u_t^2 - \sum_{i,j} a^{ij} u_i u_j \right) \right\} dxdt \qquad (11.15) \\
&= -\int_Q \left\{ 2 \left[(\mathcal{P}u) g\cdot\nabla u + u_t g\cdot\nabla u + u_t g_t \cdot \nabla u - \sum_{i,j,k} a^{ij} u_i u_k \frac{\partial g^k}{\partial x_j} \right] \right. \\
&\qquad \left. -(\nabla\cdot g)\left(u_t^2 - \sum_{i,j} a^{ij} u_i u_j \right) \right\} dxdt \\
&\le C \left[\frac{1}{\lambda} |\theta \mathcal{P}u|^2_{L^2(Q)} + \lambda \int_0^T \int_{\mathcal{O}_{\delta/2}(\Gamma_+)\cap\Omega} \theta^2 (u_t^2 + |\nabla u|^2) dxdt \right].
\end{aligned}$$

Step 4. Let us estimate

$$\int_0^T \int_{\mathcal{O}_{\delta/2}(\Gamma_+)\cap\Omega} \theta^2 |\nabla u|^2 dxdt.$$

Put

$$\eta = \eta(t,x) \triangleq \rho_1^2 \theta^2, \tag{11.16}$$

where $\rho_1 \in C^2(\overline{\Omega}; [0,1])$ satisfies

$$\begin{cases} \rho_1(x) \equiv 1, & x \in \mathcal{O}_{\delta/2}(\Gamma_+) \cap \Omega, \\ \rho_1(x) \equiv 0, & x \in \Omega \setminus \omega. \end{cases} \tag{11.17}$$

By (1.3), we obtain

$$\begin{aligned}
\int_Q \eta u \mathcal{P} u dxdt &= \int_Q \eta u \left(u_{tt} - \sum_{i,j} (a^{ij} u_i)_j \right) dxdt \\
&= -\int_Q \Big[u_t (\eta_t u + \eta u_t) \Big] dxdt + \int_Q \eta \sum_{i,j} a^{ij} u_i u_j dxdt + \int_Q u \sum_{i,j} a^{ij} u_i \eta_j dxdt.
\end{aligned} \tag{11.18}$$

Hence, by (1.2) and (11.16)–(11.18), we find

$$\begin{aligned}&\int_0^T\int_{\mathcal{O}_{\delta/2}(\Gamma_+)\cap\Omega}\theta^2|\nabla u|^2dxdt\\&\le C\left[\frac{1}{\lambda^2}|\theta\mathcal{P}u|^2_{L^2(Q)}+\int_0^T\int_\omega\theta^2(\lambda^2u^2+u_t^2)dxdt\right].\end{aligned}\tag{11.19}$$

Finally, combining (11.12), (11.15), and (11.19), and noting (11.13), we get the desired estimate (5.3). □

12. Appendix C. Proof of Proposition 6.1. We borrow some ideas from [18]. The proof is split into several steps.

Step 1. Let $\{\{(z_m^{i,j},r_{1m}^{i,j},r_{2m}^{i,j},r_m^{i,j})\}_{i=0}^m\}_{j=1}^\infty\subset\mathcal{A}_{ad}$ be a minimizing sequence of $J(\cdot)$. Because of the coercivity of the cost functional and noting that $z_m^{i,j}$ solves an elliptic equation, it can be shown that $\{\{(z_m^{i,j},r_{1m}^{i,j},r_{2m}^{i,j},r_m^{i,j})\}_{i=0}^m\}_{j=1}^\infty$ is bounded in $\mathcal{A}_{ad}$. Therefore, there exists a subsequence of $\{\{(z_m^{i,j},r_{1m}^{i,j},r_{2m}^{i,j},r_m^{i,j})\}_{i=0}^m\}_{j=1}^\infty$ converging weakly in $(H_0^1(\Omega)\times(L^2(\Omega))^3)^{m+1}$ to some $\{(\hat z_m^i,\hat r_{1m}^i,\hat r_{2m}^i,\hat r_m^i)\}_{i=0}^m\in\mathcal{A}_{ad}$. Since the function J is strictly convex, this element is the unique solution of (6.5). By (6.6) and the definition of $\mathcal{A}_{ad}$, it is obvious that $\hat z_m^0=\hat z_m^m=p_m^0=p_m^m=0$ in Ω.

Step 2. Fix any $\delta_{0m}^i\in H^2(\Omega)\cap H_0^1(\Omega)$, $\delta_{1m}^i\in L^2(\Omega)$, and $\delta_{2m}^i\in L^2(\Omega)$ $(i=0,1,2,\dots,m)$ with $\delta_{0m}^0=\delta_{0m}^m=\delta_{2m}^0=\delta_{2m}^m\equiv0$ and $\delta_{1m}^0=\delta_{1m}^1$ in Ω. For $(\lambda_0,\lambda_1,\lambda_2)\in\mathbb{R}^3$, put

$$\begin{cases}r_m^i\triangleq\dfrac{\hat z_m^{i+1}-2\hat z_m^i+\hat z_m^{i-1}}{h^2}+\dfrac{\delta_{0m}^{i+1}-2\delta_{0m}^i+\delta_{0m}^{i-1}}{h^2}\lambda_0\\\qquad\quad-\displaystyle\sum_{j_1,j_2=1}^n\partial_{x_{j_2}}\Big(a^{j_1j_2}\partial_{x_{j_1}}(\hat z_m^i+\lambda_0\delta_{0m}^i)\Big)\\\qquad\quad-\dfrac{\hat r_{1m}^{i+1}-\hat r_{1m}^i}{h}-\dfrac{\delta_{1m}^{i+1}-\delta_{1m}^i}{h}\lambda_1-\hat r_{2m}^i-\lambda_2\delta_{2m}^i-\lambda u_m^ie^{2\lambda\phi_m^i},\quad1\le i\le m-1;\\r_m^0=r_m^m=0.\end{cases}$$

Then $\{(\hat z_m^i+\lambda_0\delta_{0m}^i,\hat r_{1m}^i+\lambda_1\delta_{1m}^i,\hat r_{2m}^i+\lambda_2\delta_{2m}^i,r_m^i)\}_{i=0}^m\in\mathcal{A}_{ad}$. Define a function in $\mathbb{R}^3$ by

$$g(\lambda_0,\lambda_1,\lambda_2)=J\big(\{(\hat z_m^i+\lambda_0\delta_{0m}^i,\hat r_{1m}^i+\lambda_1\delta_{1m}^i,\hat r_{2m}^i+\lambda_2\delta_{2m}^i,r_m^i)\}_{i=0}^m\big).$$

Obviously g has a minimum at $(0,0,0)$. Hence, $\nabla g(0,0,0)=0$. By $\frac{\partial g(0,0,0)}{\partial\lambda_1}=\frac{\partial g(0,0,0)}{\partial\lambda_2}=0$, and noting that $\{(\hat z_m^i,\hat r_{1m}^i,\hat r_{2m}^i,\hat r_m^i)\}_{i=0}^m$ satisfy the first equation in (6.3), one gets

$$\begin{aligned}&-K\sum_{i=1}^{m-1}\int_\Omega\hat r_m^i\frac{\delta_{1m}^{i+1}-\delta_{1m}^i}{h}dx+\sum_{i=1}^m\int_\Omega\varrho\frac{\hat r_{1m}^i\delta_{1m}^i}{\lambda^2}e^{-2\lambda\phi_m^i}dx=0,\\&-K\sum_{i=1}^{m-1}\int_\Omega\hat r_m^i\delta_{2m}^idx+\sum_{i=1}^{m-1}\int_\Omega\varrho\frac{\hat r_{2m}^i\delta_{2m}^i}{\lambda^4}e^{-2\lambda\phi_m^i}dx=0,\end{aligned}$$

which, combined with (6.6) and $p_m^0 = p_m^m = \hat{r}_{2m}^m = 0$ in Ω, gives (6.8). From $\frac{\partial g(0,0,0)}{\partial \lambda_0} = 0$, we obtain

$$\sum_{i=1}^{m-1} \int_\Omega \left\{ K\hat{r}_m^i \left[\frac{\delta_{0m}^{i+1} - 2\delta_{0m}^i + \delta_{0m}^{i-1}}{h^2} - \sum_{j_1,j_2=1}^{n} \partial_{x_{j_2}} (a^{j_1 j_2} \partial_{x_{j_1}} \delta_{0m}^i) \right] + \hat{z}_m^i \delta_{0m}^i e^{-2\lambda\phi_m^i} \right\} dx = 0, \tag{12.1}$$

which, combined with $p_m^0 = p_m^m = \delta_{0m}^0 = \delta_{0m}^m = 0$ in Ω, implies that $p_m^i = K\hat{r}_m^i$ is a weak solution of (6.9). By means of the regularity theory for elliptic equations of second order, one sees that $\hat{z}_m^i,\ p_m^i \in H^2(\Omega) \cap H_0^1(\Omega)$ for $1 \le i \le m-1$.

Step 3. Recalling that $\{(\hat{z}_m^i, \hat{r}_{1m}^i, \hat{r}_{2m}^i, \hat{r}_m^i)\}_{i=0}^m$ satisfy (6.3), and noting (6.7)–(6.9) and $p_m^i = K\hat{r}_m^i$, one gets

$$\begin{aligned}
0 &= \sum_{i=1}^{m-1} \int_\Omega \left(\frac{\hat{z}_m^{i+1} - 2\hat{z}_m^i + \hat{z}_m^{i-1}}{h^2} - \sum_{j_1,j_2=1}^{n} \partial_{x_{j_2}} (a^{j_1 j_2} \partial_{x_{j_1}} \hat{z}_m^i) \right. \\
&\qquad \left. - \frac{\hat{r}_{1m}^{i+1} - \hat{r}_{1m}^i}{h} - \hat{r}_{2m}^i - \lambda u_m^i e^{2\lambda\phi_m^i} - \hat{r}_m^i \right) p_m^i dx \\
&= \sum_{i=1}^{m-1} \int_\Omega \left(\frac{p_m^{i+1} - 2p_m^i + p_m^{i-1}}{h^2} - \sum_{j_1,j_2=1}^{n} \partial_{x_{j_2}} (a^{j_1 j_2} \partial_{x_{j_1}} p_m^i) \right) \hat{z}_m^i dx \\
&\quad + \sum_{i=1}^{m} \int_\Omega \frac{p_m^i - p_m^{i-1}}{h} \hat{r}_{1m}^i dx - \sum_{i=1}^{m-1} \int_\Omega \left(\hat{r}_{2m}^i + \lambda u_m^i e^{2\lambda\phi_m^i} + \hat{r}_m^i \right) p_m^i dx \\
&= -\sum_{i=1}^{m-1} \left[\int_\Omega |\hat{z}_m^i|^2 e^{-2\lambda\phi_m^i} dx + \int_\Omega \varrho \left(\frac{|\hat{r}_{1m}^i|^2}{\lambda^2} + \frac{|\hat{r}_{2m}^i|^2}{\lambda^4} \right) e^{-2\lambda\phi_m^i} dx \right. \\
&\qquad \left. + K \int_\Omega |\hat{r}_m^i|^2 dx \right] - \int_\Omega \varrho \frac{|\hat{r}_{1m}^m|^2}{\lambda^2} e^{-2\lambda\phi_m^m} dx - \lambda \sum_{i=1}^{m-1} \int_\Omega u_m^i e^{2\lambda\phi_m^i} p_m^i dx.
\end{aligned} \tag{12.2}$$

Using the Hölder inequality, by (12.2) and (6.8) we conclude that there is a constant $C = C(K, \lambda) > 0$, independent of m, such that

$$\begin{aligned}
&\sum_{i=1}^{m-1} \left[\int_\Omega |\hat{z}_m^i|^2 e^{-2\lambda\phi_m^i} dx + \int_\Omega \varrho \left(\frac{|\hat{r}_{1m}^i|^2}{\lambda^2} + \frac{|\hat{r}_{2m}^i|^2}{\lambda^4} \right) e^{-2\lambda\phi_m^i} dx + K \int_\Omega |\hat{r}_m^i|^2 dx \right] \\
&\qquad + \int_\Omega \varrho \frac{|\hat{r}_{1m}^m|^2}{\lambda^2} e^{-2\lambda\phi_m^m} dx \\
&\le C \sum_{i=1}^{m-1} \int_\Omega |u_m^i|^2 e^{2\lambda\phi_m^i} dx.
\end{aligned}$$

This yields (6.10).

Step 4. Noting that (6.9) holds for $i = 1, 2, \ldots, m-1$, and that $p_m^0 = \hat{z}_m^0 = p_m^m = \hat{z}_m^m = 0$, one gets

$$
\begin{aligned}
&\frac{p_m^3-4p_m^2+5p_m^1}{h^4}-\sum_{j_1,j_2=1}^{n}\partial_{x_{j_2}}\left(a^{j_1j_2}\partial_{x_{j_1}}\frac{(p_m^2-2p_m^1-p_m^0)}{h^2}\right)\\
&\quad+\frac{\hat z_m^2e^{-2\lambda\phi_m^2}-2\hat z_m^1e^{-2\lambda\phi_m^1}+\hat z_m^0e^{-2\lambda\phi_m^0}}{h^2}=0 \qquad \text{in } \Omega,\\
&\frac{5p_m^{m-1}-4p_m^{m-2}+p_m^{m-3}}{h^4}-\sum_{j_1,j_2=1}^{n}\partial_{x_{j_2}}\left(a^{j_1j_2}\partial_{x_{j_1}}\frac{(p_m^m-2p_m^{m-1}+p_m^{m-2})}{h^2}\right)\\
&\quad+\frac{\hat z_m^me^{-2\lambda\phi_m^m}-2\hat z_m^{m-1}e^{-2\lambda\phi_m^{m-1}}+\hat z_m^{m-2}e^{-2\lambda\phi_m^{m-2}}}{h^2}=0 \qquad \text{in } \Omega,
\end{aligned}
\tag{12.3}
$$

and for $i=2,\dots,m-2$,

$$
\begin{aligned}
&\frac{p_m^{i+2}-4p_m^{i+1}+6p_m^i-4p_m^{i-1}+p_m^{i-2}}{h^4}\\
&\quad-\sum_{j_1,j_2=1}^{n}\partial_{x_{j_2}}\left(a^{j_1j_2}\partial_{x_{j_1}}\frac{(p_m^{i+1}-2p_m^i+p_m^{i-1})}{h^2}\right)\\
&\quad+\frac{\hat z_m^{i+1}e^{-2\lambda\phi_m^{i+1}}-2\hat z_m^ie^{-2\lambda\phi_m^i}+\hat z_m^{i-1}e^{-2\lambda\phi_m^{i-1}}}{h^2}=0 \qquad \text{in } \Omega.
\end{aligned}
\tag{12.4}
$$

By (6.3), we find

$$
\begin{aligned}
0=\sum_{i=1}^{m-1}\int_\Omega\Bigg(&\frac{\hat z_m^{i+1}-2\hat z_m^i+\hat z_m^{i-1}}{h^2}-\sum_{j_1,j_2=1}^{n}\partial_{x_{j_2}}(a^{j_1j_2}\partial_{x_{j_1}}\hat z_m^i)\\
&-\frac{\hat r_{1m}^{i+1}-\hat r_{1m}^i}{h}-\hat r_{2m}^i-\lambda u_m^ie^{2\lambda\phi_m^i}-\hat r_m^i\Bigg)\frac{(p_m^{i+1}-2p_m^i+p_m^{i-1})}{h^2}dx.
\end{aligned}
\tag{12.5}
$$

Noting $\hat z_m^0=\hat z_m^m=p_m^0=p_m^m=0$ again, and using (12.3)–(12.4), we arrive at

$$
\begin{aligned}
&\sum_{i=1}^{m-1}\int_\Omega\frac{(\hat z_m^{i+1}-2\hat z_m^i+\hat z_m^{i-1})}{h^2}\frac{(p_m^{i+1}-2p_m^i+p_m^{i-1})}{h^2}dx\\
&=\sum_{i=2}^{m-1}\int_\Omega\hat z_m^i\frac{(p_m^i-2p_m^{i-1}+p_m^{i-2})}{h^4}dx-2\sum_{i=1}^{m-1}\int_\Omega\hat z_m^i\frac{(p_m^{i+1}-2p_m^i+p_m^{i-1})}{h^4}dx\\
&\quad+\sum_{i=1}^{m-2}\int_\Omega\hat z_m^i\frac{(p_m^{i+2}-2p_m^{i+1}+p_m^i)}{h^4}dx\\
&=\int_\Omega\hat z_m^1\frac{(p_m^3-4p_m^2+5p_m^1)}{h^4}dx+\int_\Omega\hat z_m^{m-1}\frac{(5p_m^{m-1}-4p_m^{m-2}+p_m^{m-3})}{h^4}dx\\
&\quad+\sum_{i=2}^{m-2}\int_\Omega\hat z_m^i\frac{(p_m^{i+2}-4p_m^{i+1}+6p_m^i-4p_m^{i-1}+p_m^{i-2})}{h^4}dx\\
&=\sum_{i=1}^{m-1}\int_\Omega\hat z_m^i\Bigg\{\sum_{j_1,j_2=1}^{n}\partial_{x_{j_2}}\left[a^{j_1j_2}\partial_{x_{j_1}}\frac{(p_m^{i+1}-2p_m^i+p_m^{i-1})}{h^2}\right]\\
&\qquad\qquad-\frac{\hat z_m^{i+1}e^{-2\lambda\phi_m^{i+1}}-2\hat z_m^ie^{-2\lambda\phi_m^i}+\hat z_m^{i-1}e^{-2\lambda\phi_m^{i-1}}}{h^2}\Bigg\}dx.
\end{aligned}
\tag{12.6}
$$

Next, noting $z_m^i|_\Gamma = p_m^i|_\Gamma = 0$, for $0 \le i \le m$, one has

$$\begin{aligned}(12.7)\quad &\sum_{i=1}^{m-1}\int_\Omega \left(\sum_{j_1,j_2=1}^{n} \partial_{x_{j_2}}(a^{j_1j_2}\partial_{x_{j_1}}\hat z_m^i)\right)\frac{(p_m^{i+1}-2p_m^i+p_m^{i-1})}{h^2}dx\\ &=\sum_{i=1}^{m-1}\int_\Omega \hat z_m^i \sum_{j_1,j_2=1}^{n}\partial_{x_{j_2}}\left(a^{j_1j_2}\partial_{x_{j_1}}\frac{(p_m^{i+1}-2p_m^i+p_m^{i-1})}{h^2}\right)dx.\end{aligned}$$

Combining (12.5)–(12.7), we obtain

$$\begin{aligned}(12.8)\quad 0=&-\sum_{i=1}^{m-1}\int_\Omega\left[\hat z_m^i\frac{(\hat z_m^{i+1}e^{-2\lambda\phi_m^{i+1}}-2\hat z_m^i e^{-2\lambda\phi_m^i}+\hat z_m^{i-1}e^{-2\lambda\phi_m^{i-1}})}{h^2}\right.\\ &\left.+\left(\frac{\hat r_{1m}^{i+1}-\hat r_{1m}^i}{h}+\hat r_{2m}^i+\lambda u_m^i e^{2\lambda\phi_m^i}+\hat r_m^i\right)\frac{(p_m^{i+1}-2p_m^i+p_m^{i-1})}{h^2}\right]dx.\end{aligned}$$

By Proposition 3.5 and noting $p_m^i = K\hat r_m^i$, one has

$$\begin{aligned}(12.9)\quad &-\sum_{i=1}^{m-1}\int_\Omega\left[\hat z_m^i\frac{(\hat z_m^{i+1}e^{-2\lambda\phi_m^{i+1}}-2\hat z_m^i e^{-2\lambda\phi_m^i}+\hat z_m^{i-1}e^{-2\lambda\phi_m^{i-1}})}{h^2}\right.\\ &\qquad\left.+\hat r_m^i\frac{(p_m^{i+1}-2p_m^i+p_m^{i-1})}{h^2}\right]dx\\ &=\sum_{i=0}^{m-1}\int_\Omega\left[\frac{(\hat z_m^{i+1}-\hat z_m^i)}{h}\frac{(\hat z_m^{i+1}e^{-2\lambda\phi_m^{i+1}}-\hat z_m^i e^{-2\lambda\phi_m^i})}{h}+K\frac{(\hat r_m^{i+1}-\hat r_m^i)^2}{h^2}\right]dx\\ &=\sum_{i=0}^{m-1}\int_\Omega\left[\frac{(\hat z_m^{i+1}-\hat z_m^i)^2}{h^2}e^{-2\lambda\phi_m^i}+\frac{(\hat z_m^{i+1}-\hat z_m^i)}{h}\frac{(e^{-2\lambda\phi_m^{i+1}}-e^{-2\lambda\phi_m^i})}{h}\hat z_m^{i+1}\right.\\ &\qquad\left.+K\frac{(\hat r_m^{i+1}-\hat r_m^i)^2}{h^2}\right]dx.\end{aligned}$$

Further, by (6.8), and using Proposition 3.5 again, we find

$$\begin{aligned}(12.10)\quad &-\sum_{i=1}^{m-1}\int_\Omega\left(\frac{\hat r_{1m}^{i+1}-\hat r_{1m}^i}{h}+\hat r_{2m}^i+\lambda u_m^i e^{2\lambda\phi_m^i}\right)\frac{(p_m^{i+1}-2p_m^i+p_m^{i-1})}{h^2}dx\\ &=-\sum_{i=1}^{m-1}\int_\Omega\left(\frac{\hat r_{1m}^{i+1}-\hat r_{1m}^i}{h}+\lambda u_m^i e^{2\lambda\phi_m^i}\right)\frac{1}{h}\left(\frac{p_m^{i+1}-p_m^i}{h}-\frac{p_m^i-p_m^{i-1}}{h}\right)dx\\ &\quad+\sum_{i=0}^{m-1}\int_\Omega\frac{(\hat r_{2m}^{i+1}-\hat r_{2m}^i)}{h}\frac{(p_m^{i+1}-p_m^i)}{h}dx\\ &=\sum_{i=1}^{m-1}\int_\Omega\frac{\varrho}{\lambda^2}\left(\frac{\hat r_{1m}^{i+1}-\hat r_{1m}^i}{h}+\lambda u_m^i e^{2\lambda\phi_m^i}\right)\frac{(\hat r_{1m}^{i+1}e^{-2\lambda\phi_m^{i+1}}-\hat r_{1m}^i e^{-2\lambda\phi_m^i})}{h}dx\\ &\quad+\sum_{i=0}^{m-1}\int_\Omega\frac{\varrho}{\lambda^4}\frac{(\hat r_{2m}^{i+1}-\hat r_{2m}^i)}{h}\frac{(\hat r_{2m}^{i+1}e^{-2\lambda\phi_m^{i+1}}-\hat r_{2m}^i e^{-2\lambda\phi_m^i})}{h}dx\\ &=\sum_{i=1}^{m-1}\int_\Omega\frac{\varrho}{\lambda^2}\left[\frac{(\hat r_{1m}^{i+1}-\hat r_{1m}^i)^2}{h^2}e^{-2\lambda\phi_m^i}\right.\\ &\qquad\left.+\frac{(\hat r_{1m}^{i+1}-\hat r_{1m}^i)}{h}\frac{(e^{-2\lambda\phi_m^{i+1}}-e^{-2\lambda\phi_m^i})}{h}\hat r_{1m}^{i+1}\right]dx\end{aligned}$$

$$+\lambda\sum_{i=1}^{m-1}\int_\Omega \frac{\varrho}{\lambda^2}u_m^i\left[\frac{(\hat r_{1m}^{i+1}-\hat r_{1m}^i)}{h}e^{-2\lambda\phi_m^i}+\frac{(e^{-2\lambda\phi_m^{i+1}}-e^{-2\lambda\phi_m^i})}{h}\hat r_{1m}^{i+1}\right]dx$$
$$+\sum_{i=0}^{m-1}\int_\Omega \frac{\varrho}{\lambda^4}\left[\frac{(\hat r_{2m}^{i+1}-\hat r_{2m}^i)^2}{h^2}e^{-2\lambda\phi_m^i}\right.$$
$$\left.+\frac{(\hat r_{2m}^{i+1}-\hat r_{2m}^i)}{h}\frac{(e^{-2\lambda\phi_m^{i+1}}-e^{-2\lambda\phi_m^i})}{h}\hat r_{2m}^{i+1}\right]dx.$$

Combining (12.8)–(12.10), and noting that $\hat r_{1m}^1=\hat r_{1m}^0$, $u_m^0=0$, we end up with

$$\begin{aligned}
&\sum_{i=0}^{m-1}\int_\Omega\left[\frac{(\hat z_m^{i+1}-\hat z_m^i)^2}{h^2}e^{-2\lambda\phi_m^i}+\frac{\varrho}{\lambda^2}\frac{(\hat r_{1m}^{i+1}-\hat r_{1m}^i)^2}{h^2}e^{-2\lambda\phi_m^i}\right.\\
&\qquad\left.+\frac{\varrho}{\lambda^4}\frac{(\hat r_{2m}^{i+1}-\hat r_{2m}^i)^2}{h^2}e^{-2\lambda\phi_m^i}+K\frac{(\hat r_m^{i+1}-\hat r_m^i)^2}{h^2}\right]dx\\
&=-\sum_{i=0}^{m-1}\int_\Omega\frac{(\hat z_m^{i+1}-\hat z_m^i)}{h}\frac{(e^{-2\lambda\phi_m^{i+1}}-e^{-2\lambda\phi_m^i})}{h}\hat z_m^{i+1}dx\\
&\quad-\sum_{i=1}^{m-1}\int_\Omega\frac{\varrho}{\lambda^2}\frac{(\hat r_{1m}^{i+1}-\hat r_{1m}^i)}{h}\frac{(e^{-2\lambda\phi_m^{i+1}}-e^{-2\lambda\phi_m^i})}{h}\hat r_{1m}^{i+1}dx\\
&\quad-\lambda\sum_{i=1}^{m-1}\int_\Omega\frac{\varrho}{\lambda^2}u_m^i\left[\frac{(\hat r_{1m}^{i+1}-\hat r_{1m}^i)}{h}e^{-2\lambda\phi_m^i}+\frac{(e^{-2\lambda\phi_m^{i+1}}-e^{-2\lambda\phi_m^i})}{h}\hat r_{1m}^{i+1}\right]dx\\
&\quad-\sum_{i=0}^{m-1}\int_\Omega\frac{\varrho}{\lambda^4}\frac{(\hat r_{2m}^{i+1}-\hat r_{2m}^i)}{h}\frac{(e^{-2\lambda\phi_m^{i+1}}-e^{-2\lambda\phi_m^i})}{h}\hat r_{2m}^{i+1}dx.
\end{aligned}\tag{12.11}$$

Using the Hölder inequality and noting that ϕ is a smooth function, from (12.11) we conclude that there is a positive constant $C=C(K,\lambda)$, independent of m, such that

$$\begin{aligned}
&\sum_{i=0}^{m-1}\int_\Omega\left[\frac{(\hat z_m^{i+1}-\hat z_m^i)^2}{h^2}e^{-2\lambda\phi_m^i}+\frac{\varrho}{\lambda^2}\frac{(\hat r_{1m}^{i+1}-\hat r_{1m}^i)^2}{h^2}e^{-2\lambda\phi_m^i}\right.\\
&\qquad\left.+\frac{\varrho}{\lambda^4}\frac{(\hat r_{2m}^{i+1}-\hat r_{2m}^i)^2}{h^2}e^{-2\lambda\phi_m^i}+K\frac{(\hat r_m^{i+1}-\hat r_m^i)^2}{h^2}\right]dx\\
&\le C\left[\sum_{i=1}^{m-1}\int_\Omega\Big(|\hat z_m^i|^2+|\hat r_{1m}^i|^2+|\hat r_{2m}^i|^2+K|\hat r_m^i|^2+|u_m^i|^2\Big)dx\right.\\
&\qquad\left.+\int_\Omega|\hat r_{1m}^m|^2dx\right].
\end{aligned}\tag{12.12}$$

Finally, combining (12.12) and (6.10), and recalling that $u\in C([0,T];L^2(\Omega))$, we establish the desired estimate (6.11). This completes the proof of Proposition 6.1. □

CONVERGENCE IN NONLINEAR FILTERING FOR STOCHASTIC DELAY SYSTEMS*

ANTONELLA CALZOLARI†, PATRICK FLORCHINGER‡, AND GIOVANNA NAPPO§

Abstract. We study an approximation scheme for a nonlinear filtering problem when the state process $\boldsymbol{X}$ is the solution of a stochastic delay diffusion equation and the observation process is a noisy function of $X(s)$ for $s \in [t-\tau, t]$, where τ is a constant. The approximating state is the piecewise linear Euler–Maruyama scheme, and the observation process is a noisy function of the approximating state. The rate of convergence of this scheme is computed.

Key words. conditional laws, strong approximation, stochastic delay differential equations, rate of convergence

1. Introduction.

Stochastic diffusion processes with delay have been used as models in many applications: in population dynamics (see Goel, Maitra, and Montroll [16]), in respiratory systems (see Longtin et al. [30]), in eye movement control (see Vasilakos and Beuter [42]), in postural control (see Peterka [37]), and in transmission delays for neural networks and/or ensemble of coupled neural oscillators (see Niebur, Schuster, and Kammen [35]).

In most of the literature the stochastic process is assumed to be completely observable. However, this cannot always be the case, since measurement errors may occur. This difficulty can be overcome by modelling this situation as a nonlinear filtering problem.

The aim of stochastic nonlinear filtering is to compute the conditional law at time t of a state process, which cannot be directly observed, given an observation process up to time t. This task can be achieved only in a few specific cases, and therefore the problem of the approximation of the conditional law naturally arises.

A classical model of partially observed system extensively studied in the last few years arises when both the state and the observation processes are diffusion processes.

For this model, under suitable hypotheses on the coefficients, the filtering equations have been established by Kushner [23], Duncan [10], Mortensen [34], and Zakai [43] and have been studied since then by many authors (see, for example, Pardoux [36] or Kallianpur [18] and the references therein). Different approximation schemes for the filter have been studied in various frameworks by many authors (see, for example, Kushner [24], Le Gland [28], or Del Moral [9] and the references therein).

In this paper we are interested in nonlinear filtering of partially observed delay systems of the following form.

The state process $\boldsymbol{X} = \big(X(t)\big)_{t\in[-\tau,T]}$ satisfies the stochastic delay differential equation on the probability space $(\Omega, \mathcal{F}, (\mathcal{F}_t)_{t\in[0,T]}, P)$

$$\begin{cases} X(t) = \eta(t), & -\tau \le t \le 0, \\ X(t) = \eta(0) + \displaystyle\int_0^t a(u, \Pi_u X)du + \int_0^t b(u, \Pi_u X)d\tilde{W}_u, & 0 \le t \le T, \end{cases} \tag{1.1}$$

where τ is a positive constant, $\big(\Pi_t X\big)_{t\in[0,T]}$ is a $C([-\tau,0],\mathbb{R})$-valued random process defined by

$$\Pi_t X(s) = X(t+s), \qquad -\tau \le s \le 0,$$

$\tilde{\boldsymbol{W}} = \big(\tilde{W}(t)\big)_{t\in[0,T]}$ is a standard Brownian motion, and $\boldsymbol{\eta} = \big(\eta(s)\big)_{s\in[-\tau,0]}$ is a $C([-\tau,0],\mathbb{R})$-valued random variable.

The observation process $\boldsymbol{Y} = \big(Y(t)\big)_{t\in[0,T]}$ is given by

$$Y(t) = \int_0^t h(u, \Pi_u X)du + W(t), \qquad 0 \le t \le T, \tag{1.2}$$

where $\boldsymbol{W} = \big(W(t)\big)_{t\in[0,T]}$ is a standard Brownian motion, independent of $\tilde{\boldsymbol{W}}$, and $h : [0,T] \times C([-\tau,0],\mathbb{R}) \to \mathbb{R}$ is a Borel measurable function.

As an example the functions $a(t,\theta)$, $b(t,\theta)$, and $h(t,\theta)$ for $\theta \in C([-\tau,0],\mathbb{R})$ can be taken of the form

$$g\left(t, \max_{u\in[\tau_{i-1},\tau_i]} \theta(u);\, i = 1,\dots,r\right), \tag{1.3}$$

where $-\tau = \tau_0 < \tau_1 < \cdots < \tau_r = 0$, or

$$g\left(t, \int_{-\tau}^0 \psi_i(u,\theta(u))\gamma_i(du);\, i = 1,\dots,r\right), \tag{1.4}$$

where γ_i are finite measures on $[-\tau,0]$, and g and ψ_i are continuous functions.

By taking in (1.4) $\psi_i(u,x) = x$ for all i, and $\gamma_i(ds)$ in the set $\{e^{\lambda s}ds, \delta_{-\tau}(ds), \delta_0(ds)\}$, we recover the stochastic delay differential equation considered in a control framework by Larssen and Risebro [27] and by Elsanousi and Larssen [11]

$$\begin{aligned} dX(t) = {} & g_a\left(t, X(t),\, X(t-\tau),\, \int_{t-\tau}^t e^{\lambda(u-t)}X(u)\,du,\, w(t)\right)dt \\ & + g_b\left(t, X(t),\, X(t-\tau),\, \int_{t-\tau}^t e^{\lambda(u-t)}X(u)\,du,\, w(t)\right)d\widetilde{W}_t, \end{aligned}$$

where $w(t)$ is the control.

Moreover, when the function $g_a(t,x_1,x_2,x_3,w)$, as well as $g_b(t,x_1,x_2,x_3,w)$, depends only on (x_1,x_2), we recover the fixed time delay model

$$dX(t) = g_a\big(X(t),\, X(t-\tau)\big)dt + g_b\big(X(t),\, X(t-\tau)\big)d\widetilde{W}_t, \tag{1.5}$$

which is studied in Frank [14], and in particular, for $g_a(x_1,x_2) = \big(H - K\log(x_2)\big)\,x_1$ and $g_b(x_1,x_2) = x_1$, we recover the stochastic Gompertz model with delay; see Goel,

Maitra, and Montroll [16] and Frank and Beek [15]. The stochastic Gompertz model without delay has been used in population growth (see Ricciardi [40]) or in biomedical sciences (see Ferrante et al. [12]).

At first the aim was to obtain a computable approximation for $E\big[\varphi\big(X(t)\big)/\mathcal{F}_t^Y\big]$ for all functions φ belonging to a determining class, i.e., the best estimate of $\varphi\big(X(t)\big)$ given the σ-algebra of the observations up to time t, $\mathcal{F}_t^Y = \sigma\{Y(s),\ s \le t\}$. In fact, since $\Pi_t X(0) = X(t)$, we shall give a computable approximation for the filter π_t associated with the delay system $\big(\Pi_t X, Y(t)\big)_{t\in[0,T]}$, defined for any measurable and bounded functions ϕ mapping $C([-\tau,0],\mathbb{R})$ into $\mathbb{R}$ by

$$\pi_t(\phi) = E[\phi(\Pi_t X)|\mathcal{F}_t^Y]. \tag{1.6}$$

In our paper the state is approximated by the piecewise linear Euler–Maruyama scheme (see (2.7) and (2.10)), while the observation is approximated by a diffusion (see (2.8)), which can be considered as a continuous Euler–Maruyama scheme (see Remark 2.1 for the peculiarities due to the delay). The filter process of this approximating system is the first approximation scheme of $\boldsymbol{\pi} = (\pi_t)_{t\in[0,T]}$ we consider (see (2.14)). This approximation scheme has a drawback: it depends on the approximating observation process, which is not the actual observation process $\boldsymbol{Y}$. Instead, the other approximation scheme we consider depends on the actual observation process (see (2.15)).

As the time step converges to zero, the two approximating filters converge in probability to $\boldsymbol{\pi}$ as measure-valued processes (see Theorem 2.2).

To our knowledge there are only three papers dealing with nonlinear filtering for delay systems: Kwong and Willsky [26], Chang [8], and Kallianpur and Mandal [20].

In [26] Kwong and Willsky give a characterization of the optimal filter when dealing with nonlinear delay systems with Gaussian noises, i.e., with b depending only on time. A Fujisaki–Kallianpur–Kunita equation for the filter is deduced from a representation result which characterizes conditional moment functionals of nonlinear delay systems. However, the uniqueness of the solution of this equation is not guaranteed.

In [8] Chang gives a computable approximation for the optimal filter when dealing with one-dimensional nonlinear delay filtering systems with $b = 1$. The original model is approximated by a discrete-time model obtained by applying an Euler discretization scheme. An optimal filter for the approximate system is obtained by an explicit procedure, and the weak convergence of the approximating process and the approximating filter to the original ones is verified.

In [20] Kallianpur and Mandal study a nonlinear filtering problem where the state process is solution of the stochastic delay differential equation (1.1), in the homogeneous case, and the observation process is given by (1.2). By using some extensions of results obtained by Mohammed [32] for stochastic delay differential equations, they prove that the signal process is the unique solution to an appropriate martingale problem. By taking this fact into account the authors prove that the optimal filter corresponding to the nonlinear filtering problem solves a Zakai-type equation. The uniqueness for the solution of the Zakai equation is deduced from the results of Bhatt, Kallianpur, and Karandikar [2], and a Fujisaki–Kallianpur–Kunita equation for the filter is deduced from the Zakai equation by usual arguments in nonlinear filtering theory.

In addition to the previous references we also quote the paper [3] by Bhatt, Kallianpur, and Karandikar, which is the starting point in some of our analysis, and Bhatt and Karandikar [4]. Though none of these papers is explicitly connected with

filtering models involving delays, the results achieved by these authors can be used in the delay context.

This paper is divided into six sections and is organized as follows. In section 2, we introduce the approximation scheme for the system we are dealing with in this paper and state the main results. The first result concerns the convergence of the approximation schemes for the filter, while the second result deals with the rate of convergence w.r.t. the bounded Lipschitz metric. In section 3, we prove the convergence for the filter by making use of a convergence result deduced from the papers by Bhatt, Kallianpur, and Karandikar [3] and Bhatt and Karandikar [4]. In section 4, we compute an upper bound for the rate of convergence w.r.t. the bounded Lipschitz metric for our approximation scheme by combining filter approximation techniques similar to those in Calzolari, Florchinger, and Nappo [7] with a convergence result for the approximation of stochastic delay differential equations. In section 5, we give the proofs of some technical results that we use in sections 3 and 4. Moreover we recall a result on the expectation of the modulus of continuity for diffusion due to Słomiński [41], which we use in the proof of the approximation result for stochastic delay differential equations. In section 6, we conclude by giving a comparison between our result and the one by Chang [8], and we discuss briefly some works on approximation for stochastic delay differential equations, in particular the one by Mao and Sabanis [31].

2. Approximation scheme and main results. For the partially observed delay system (1.1) and (1.2) stated above we assume the following standing hypotheses:

(A1) η is a $\mathcal{F}_0$-measurable $C([-\tau,0],\mathbb{R})$-valued random variable, with

$$E\left(\|\Pi_0 X\|^{2k}\right) = E\left(\sup_{s\in[-\tau,0]}|\eta(s)|^{2k}\right) < \infty, \qquad k=1,2.$$

(A2) The functionals $a(t,\theta)$ and $b(t,\theta)$ on $[0,T]\times C([-\tau,0],\mathbb{R})$ are jointly globally continuous, Hölder in time, and Lipschitz in space, i.e.,

$$|a(t,\theta)-a(t',\bar\theta)|^2 + |b(t,\theta)-b(t',\bar\theta)|^2 \le K\left(|t-t'|^{2\alpha} + \|\theta-\bar\theta\|^2\right), \qquad \alpha>0, \tag{2.1}$$

and satisfy the growth condition

$$|a(t,\theta)|^2 + |b(t,\theta)|^2 \le K\left(1+\|\theta\|^2\right) \tag{2.2}$$

for some constant $K>0$.

(A3) $h:[0,T]\times C([-\tau,0],\mathbb{R})\to\mathbb{R}$ is jointly continuous and sublinear, i.e.,

$$|h(t,\theta)|^2 \le K(1+\|\theta\|^2).$$

Conditions (A1) and (A2), with $t'=t$ in (2.1), assure the existence and the uniqueness of the solution of (1.1) together with

$$E\left[\sup_{u\in[0,T]}\|\Pi_u X\|^{2k}\right] < \infty, \qquad k=1,2 \tag{2.3}$$

(see [32, Theorem II.2.1 and Lemma III.1.2] and [33, Theorem I.2]). Note that, under condition (A2), with $t'=t$ in (2.1), the existence and the uniqueness of the solution of (1.1) follow without condition (A1) (see Kallianpur and Mandal [20]). The latter

condition is used to obtain (2.3), which together with the sublinearity of h implies that

$$\int_0^T E[|h(u,\Pi_u X)|^{2k}]du < \infty, \qquad k=1,2.$$

The above condition, for $k=1$, together with the independence of the noises, is a classical assumption in nonlinear filtering theory which guarantees that the filter π_t can be represented via a Kallianpur–Striebel formula

$$\pi_t(\phi) = \frac{\sigma_t(\phi)}{\sigma_t(\mathbf{1})},$$

with

$$\sigma_t(\phi) = E^0\left[\phi(\Pi_t X)\exp\left\{\int_0^t h(s,\Pi_s X)dY_s - \frac{1}{2}\int_0^t |h(s,\Pi_s X)|^2\,ds\right\}\Big|\mathcal{F}_t^Y\right], \tag{2.4}$$

where E^0 denotes the expectation w.r.t. the reference probability measure P^0, defined by the Radon–Nikodym derivative

$$\frac{dP^0}{dP} = \exp\left\{-\int_0^T h(s,\Pi_s X)dY_s + \frac{1}{2}\int_0^T |h(s,\Pi_s X)|^2\,ds\right\}. \tag{2.5}$$

The independence of $\boldsymbol{X}$ and $\boldsymbol{W}$ under P implies the independence of $\boldsymbol{X}$ and $\boldsymbol{Y}$ under P^0; furthermore the law of $\boldsymbol{X}$ is the same under P and P^0 (see, e.g., Bhatt, Kallianpur, and Karandikar [3] and Kallianpur and Mandal [20]). This fact will play a fundamental role in the proof of our approximation results. In particular it implies that there exists a deterministic functional, with values in $\mathcal{P}(C([-\tau,0],\mathbb{R}))$, the metric space of probability measures on $C([-\tau,0],\mathbb{R})$, endowed with the Prohorov metric,

$$\begin{aligned} U:\ [0,T]\times C([0,T],\mathbb{R}) &\to \mathcal{P}(C([-\tau,0],\mathbb{R})),\\ (t,\boldsymbol{y}) &\mapsto U\big(t,\boldsymbol{y}\big)\end{aligned}$$

with the property $U\big(t,\boldsymbol{y}\big) = U\big(t,y(\cdot\wedge t)\big)$, and such that

$$\pi_t = U\big(t,\boldsymbol{Y}\big). \tag{2.6}$$

We recall that the paths $t\mapsto U(t,\boldsymbol{y})$ are right continuous with left limits, i.e., belong to the Skorohod space $D_{\mathcal{P}(C([-\tau,0],\mathbb{R}))}([0,T])$ of *càdlàg* functions with values in $\mathcal{P}(C([-\tau,0],\mathbb{R}))$, and therefore the same property holds for $t\mapsto\pi_t$.

In this paper we consider the following approximation scheme.

The approximation $\boldsymbol{X^n} = \big(X^n(t)\big)_{t\in[-\tau,T]}$ of the state process $\boldsymbol{X} = \big(X(t)\big)_{t\in[-\tau,T]}$ is the piecewise linear Euler–Maruyama scheme, that is, the linear interpolation of the Euler discretization scheme with step $\delta=\delta_n = T/n$, with $\tau = m\delta$ (as in Chang [8], for the sake of simplicity, we assume that T/τ is rational):[1]

$$\begin{cases} X^n(\ell\delta) = \eta(\ell\delta), & -m\le\ell\le 0,\\ X^n((\ell+1)\delta) = X^n(\ell\delta) + a(\ell\delta,\Pi_{\ell\delta}X^n)\delta & \\ \qquad\qquad + b(\ell\delta,\Pi_{\ell\delta}X^n)\big[\tilde W((\ell+1)\delta) - \tilde W(\ell\delta)\big], & 0\le\ell\le n-1. \end{cases} \tag{2.7}$$

[1] It is clear that, assuming $T=\frac{p}{q}\tau$, we first fix $m=kq$ a multiple of q and then set $\delta=\tau/m$, so that $T=kp\delta$ and $n=kp$. Or better, we first fix m, then set $\delta=\tau/m$, and finally take the interval $[-\tau,\lfloor T/\delta\rfloor\delta]$, instead of $[-\tau,T]$, so that $n=n(m)$.

With this approximation for the state process $\boldsymbol{X}$, we can consider the piecewise-constant $C([-\tau,0],\mathbb{R})$-valued process $\big(\Pi_{\lfloor t/\delta\rfloor\cdot\delta}X^n\big)_{t\in[0,T]}$ as an approximation of the $C([-\tau,0],\mathbb{R})$-valued process $\big(\Pi_tX\big)_{t\in[0,T]}$.

For the approximation of the observation process, we define $\boldsymbol{Y^n}=\big(Y^n(t)\big)_{t\in[0,T]}$ by

$$Y^n(t)=\int_0^t h(\lfloor s/\delta\rfloor\cdot\delta,\Pi_{\lfloor s/\delta\rfloor\cdot\delta}X^n)ds+W(t),\qquad 0\le t\le T, \tag{2.8}$$

where $\lfloor x\rfloor$ is the integer part of x.

Remark 2.1. *Note that, unlike in the finite-dimensional Euler scheme, the interpolation has to be performed at every step in order to evaluate $\Pi_{\ell\delta}X^n$. Nevertheless it is clear that*

$$\big\{\big(X^n(\ell\delta),X^n((\ell-1)\delta),\dots,X^n((\ell-m)\delta)\big)\big\}_{0\le\ell\le n} \tag{2.9}$$

is an $(m+1)$-dimensional Markov chain, and for $t\in[\ell\delta,(\ell+1)\delta]$, $0\le\ell\le n-1$,

$$\begin{aligned}X^n(t)&=X^n(\ell\delta)+a(\ell\delta,\Pi_{\ell\delta}X^n)(t-\ell\delta)\\&\quad+b(\ell\delta,\Pi_{\ell\delta}X^n)\big[\tilde W((\ell+1)\delta)-\tilde W(\ell\delta)\big](t-\ell\delta)/\delta,\end{aligned} \tag{2.10}$$

with $X^n(0)=\eta(0)$, and

$$Y^n(t)=Y^n(\ell\delta)+h(\ell\delta,\Pi_{\ell\delta}X^n)(t-\ell\delta)+\big[W(t)-W(\ell\delta)\big], \tag{2.11}$$

with $Y^n(0)=0$.

When the state is given by fixed time delay model (1.5)*, the linear interpolation, in the above discrete Euler–Maruyama scheme, is not needed in order to compute the sequence $\{X^n(\ell\delta)\}_{0\le\ell\le n}$. Indeed in this case*

$$\begin{aligned}X^n((\ell+1)\delta)&=X^n(\ell\delta)+g_a\big(\ell\delta,X^n(\ell\delta),X^n((\ell-m)\delta)\big)\delta\\&\quad+g_b\big(\ell\delta,X^n(\ell\delta),X^n((\ell-m)\delta)\big)\big[\tilde W((\ell+1)\delta)-\tilde W(\ell\delta)\big],\end{aligned}$$

with $X^n(0)=\eta(0)$, and therefore the computation of the discrete Markov chain (2.9) *is much simpler.*

The process $\boldsymbol{X^n}$ is neither adapted nor Markov, and therefore one cannot use the results of [2] to characterize the filter as the unique solution of the Zakai equation. Nevertheless the signal noise $\boldsymbol{W}$ is independent of $\boldsymbol{X^n}$, and the same holds for the approximated state process $\big(\Pi_{\lfloor t/\delta\rfloor\cdot\delta}X^n\big)_{t\in[0,T]}$, which is an adapted process; therefore one can compute the filter π_t^n associated with the approximating delay system $\big(\Pi_{\lfloor t/\delta\rfloor\cdot\delta}X^n,Y^n(t)\big)_{t\in[0,T]}$ by means of the classical Kallianpur–Striebel formula (see, e.g., [19] and [3]). The filter π_t^n is then given by

$$\pi_t^n(\phi)=\frac{\sigma_t^n(\phi)}{\sigma_t^n(\mathbf{1})}=\frac{E^{0,n}\big[\phi(\Pi_{\lfloor t/\delta\rfloor\cdot\delta}X^n)\mathcal{L}_t^n|\mathcal{F}_t^{Y^n}\big]}{E^{0,n}\big[\mathcal{L}_t^n|\mathcal{F}_t^{Y^n}\big]}, \tag{2.12}$$

where $E^{0,n}$ denotes the expectation w.r.t. the reference probability measure $P^{0,n}$, defined by the Radon–Nikodym derivative

$$\frac{dP^{0,n}}{dP}=\big(\mathcal{L}_T^n\big)^{-1},$$

with

(2.13)
$$\mathcal{L}_t^n = \exp\left\{\int_0^t h(\lfloor s/\delta\rfloor\cdot\delta, \Pi_{\lfloor s/\delta\rfloor\cdot\delta}X^n)dY_s^n - \frac{1}{2}\int_0^t |h(\lfloor s/\delta\rfloor\cdot\delta, \Pi_{\lfloor s/\delta\rfloor\cdot\delta}X^n)|^2\,ds\right\},$$

which is well defined thanks to the sublinearity of h and (A1).

Taking into account that $s \mapsto h(\lfloor s/\delta\rfloor\cdot\delta, \Pi_{\lfloor s/\delta\rfloor\cdot\delta}X^n)$ is piecewise constant, we have that

$$\mathcal{L}_t^n = L_t^n(X^n(\cdot), Y_0^n, Y_\delta^n, \dots, Y_{\lfloor t/\delta\rfloor}^n, Y_t^n),$$

where, for $0 \le \ell \le n$,

$$\log L_{\ell\delta}^n(x(\cdot), y_0, y_1, \dots, y_\ell) = \sum_{k=0}^{\ell-1} h(k\delta, \Pi_{k\delta}x(\cdot))(y_{k+1} - y_k) - \frac{1}{2}\sum_{k=0}^{\ell-1} |h(k\delta, \Pi_{k\delta}x(\cdot))|^2\delta,$$

and, for $t \in (\ell\delta, (\ell+1)\delta)$, $0 \le \ell \le n-1$,

$$\begin{aligned}\log L_t^n(x(\cdot), y_0, y_1, \dots, y_\ell, y) &= \log L_{\ell\delta}^n(x(\cdot), y_0, y_1, \dots, y_\ell)\\ &\quad + h(\lfloor t/\delta\rfloor\cdot\delta, \Pi_{\lfloor t/\delta\rfloor\cdot\delta}x(\cdot))(y - y_\ell) - \frac{1}{2}|h(\lfloor t/\delta\rfloor\cdot\delta, \Pi_{\lfloor t/\delta\rfloor\cdot\delta}x(\cdot))|^2(t - \ell\delta).\end{aligned}$$

Moreover, under $P^{0,n}$, the processes $\boldsymbol{X^n}$ and $\boldsymbol{Y^n}$ are independent and the law of the approximated state process is invariant under P and $P^{0,n}$, and hence, for $t \in [\ell\delta, (\ell+1)\delta)$, $0 \le \ell \le n-1$,

$$\sigma_t^n(\phi) = E\left[\phi(\Pi_{\lfloor t/\delta\rfloor\cdot\delta}X^n)L_t^n(X^n(\cdot), y_0, y_1, \dots, y_\ell, y)\right]\Big|_{y_0=Y_0^n, y_1=Y_\delta^n, \dots, y_\ell=Y_{\ell\delta}^n, y=Y_t^n}.$$

Therefore, by taking the above equality into account, one can explicitly obtain a deterministic functional

$$\begin{aligned}U^n :\ [0,T]\times C([0,T],\mathbb{R}) &\to \mathcal{P}(C([-\tau,0],\mathbb{R}))\\ (t, \boldsymbol{y}) &\mapsto U^n\big(t, \boldsymbol{y}\big),\end{aligned}$$

with the property that $U^n\big(t, \boldsymbol{y}\big)$ depends only on $\big(y(k\delta)\big)_{0\le k\le\lfloor\frac{t}{\delta}\rfloor}$ and $y(t)$, such that

$$\pi_t^n = U^n\big(t, \boldsymbol{Y^n}\big). \tag{2.14}$$

So the filter π_t^n defined above depends explicitly on the approximated observation process $\boldsymbol{Y^n}$, which, however, is not directly observable. To overcome this difficulty we also consider the following approximation $\tilde{\pi}_t^n$ for the filter:

$$\tilde{\pi}_t^n = U^n\big(t, \boldsymbol{Y}\big) = \frac{\tilde{\sigma}_t^n}{\tilde{\sigma}_t^n(\mathbf{1})}, \tag{2.15}$$

where

(2.16)
$$\tilde{\sigma}_t^n(\phi) = E\left[\phi(\Pi_{\lfloor t/\delta\rfloor\cdot\delta}X^n)L_t^n(X^n(\cdot), y_0, y_1, \dots, y_\ell, y)\right]\Big|_{y_0=Y_0, y_1=Y_\delta, \dots, y_\ell=Y_{\ell\delta}, y=Y_t}.$$

Then the following convergence result, which will be proved in the following section, holds.

THEOREM 2.2. *Let* $\boldsymbol{\pi} = (\pi_t; t \geq 0)$, $\boldsymbol{\pi^n} = (\pi_t^n; t \geq 0)$, *and* $\tilde{\boldsymbol{\pi}}^{\boldsymbol{n}} = (\tilde{\pi}_t^n; t \geq 0)$ *be the càdlàg probability measure-valued processes defined by* (1.6), (2.12), *and* (2.15), *respectively. Then the following hold:*

1. *The sequence of filters* $\boldsymbol{\pi^n}$ *converges in probability (and therefore weakly) to the original filter* $\boldsymbol{\pi}$ *in* $D_{\mathcal{P}(C([-\tau,0],\mathbb{R}))}([0,T])$.

2. *The sequence of measure-valued processes* $\tilde{\boldsymbol{\pi}}^{\boldsymbol{n}}$ *converges in probability to the original filter* $\boldsymbol{\pi}$.

3. *The sequence* $\max_{k=1,\dots,n} d(\tilde{\pi}_{k\delta}^n, \pi_{k\delta})$, *where* d *denotes the Prohorov metric, converges in probability to zero.*

From the practical point of view, the interest of this method relies on the fact that $\sigma_t(\phi)$ in (2.4) cannot usually be computed explicitly, or with a Monte Carlo method, while $\tilde{\sigma}_t^n(\phi)$ in (2.16) can always be computed by means of a Monte Carlo method. In addition, under further hypotheses on a, b, and h, the following result concerning the rate of convergence w.r.t. the bounded Lipschitz metric of our approximation scheme will be proved in section 4. For the ease of the reader we recall that, for any metric space S, and for given probability measures ν_1 and ν_2 on S,

$$d_{BL}(\nu_1, \nu_2) = \sup \left\{ \frac{|\nu_1(\varphi) - \nu_2(\varphi)|}{\|\varphi\| \vee L_\varphi}; \varphi \text{ bounded and Lipschitz} \right\},$$

where $\|\varphi\|$ denotes the sup-norm, and L_φ is the Lipschitz constant of φ.

THEOREM 2.3. *Assume further that the functions* a *and* b *are bounded,* $1/2 \leq \alpha \leq 1$ *in* (2.1), *the function* h *is jointly globally Lipschitz, and there exists a constant* C_η *such that the modulus of continuity of the initial condition* η *satisfies*

$$E\big[\omega_\eta^2\big(\delta; [-\tau, 0]\big)\big] \leq C_\eta\, \delta\, \log\big(\tfrac{1}{\delta}\big). \tag{2.17}$$

Then there exists a constant C *such that*

$$E\big[d_{BL}(\pi_t, \tilde{\pi}_t^n)\big] \leq C\big(\tfrac{\log n}{n}\big)^{\frac{1}{2}}, \tag{2.18}$$

where d_{BL} *is the bounded Lipschitz metric on the space* $\mathcal{P}(C([-\tau, 0], \mathbb{R}))$.

REMARK 2.4. *As will be shown in the example at the end of section* 4, *by considering the case where* $\eta = 0$, $a = 0$, $b = 1$, *and* $h = 0$, *the upper bound for the rate of convergence given by* (2.18) *appears to be the best we can obtain in our context.*

Furthermore, as is clear from the proof (see (5.13)*), if* $E\big[\omega_\eta^2\big(\delta; [-\tau, 0]\big)\big]$ *converges to zero with an order of convergence lower than* $O\big(\delta \log\big(\frac{1}{\delta}\big)\big)$, *then*

$$E\big[d_{BL}(\pi_t, \tilde{\pi}_t^n)\big] \leq C\,\big(E\big[\omega_\eta^2\big(\delta; [-\tau, 0]\big)\big]\big)^{\frac{1}{2}}$$

for a suitable constant C.

Finally, as will be clear from the proof, condition (A1) *for* $k = 2$ *is not necessary (see Proposition* 4.2*).*

To conclude this section, note that in order to evaluate π_t^n and $\tilde{\pi}_t^n$ we need to compute

(a) the transition probability of the $(m+1)$-dimensional Markov chain

$$\big(X^n(\ell\delta), X^n((\ell-1)\delta), \dots, X^n((\ell-m)\delta)\big),$$

(b) the explicit expression of L_t^n.

Consequently we need the explicit expression of $a(\ell\delta, \Pi_{\ell\delta} X^n)$, $b(\ell\delta, \Pi_{\ell\delta} X^n)$, and $h(\ell\delta, \Pi_{\ell\delta} X^n)$.

When the functionals a, b, and h are taken to be of the form (1.4), with $r = 1$, we need to evaluate expressions such as

$$g\left(\ell\delta, \int_{-\tau}^{0} \psi(u, \Pi_{\ell\delta} X^n(u))\, \gamma(du)\right),$$

where

$$\int_{-\tau}^{0} \psi(u, \Pi_{\ell\delta} X^n(u))\gamma(du) = \int_{-\tau}^{0} \psi(u, X^n(\ell\delta + u))\, \gamma(du)$$
$$= \sum_{k=-m}^{-1} \int_{k\delta}^{(k+1)\delta} \psi\big(u, X^n((\ell+k)\delta) + \tfrac{u - k\delta}{\delta}\big[X^n((\ell+k+1)\delta) - X^n((\ell+k)\delta)\big]\big)\, \gamma(du).$$

3. The convergence result. This section is dedicated to the proof of Theorem 2.2. With this aim, we will make use of a result deduced from the papers by Bhatt, Kallianpur, and Karandikar [3] and Bhatt and Karandikar [4] in the following context.

Consider a signal process $\boldsymbol{\mathcal{X}} = (\mathcal{X}_t)_{t\in[0,T]}$, with values in a complete separable metric space (S, d_S), defined on $(\Omega, \mathcal{F}, P)$, with *càdlàg* paths and being continuous in probability, and the observation process $\boldsymbol{Y} = (Y(t))_{t\in[0,T]}$ given by

$$Y(t) = \int_0^t \boldsymbol{h}(\mathcal{X}_s) ds + W(t), \tag{3.1}$$

where $\boldsymbol{W} = (W(t))_{t\in[0,T]}$ is a standard Brownian motion, defined on $(\Omega, \mathcal{F}, P)$, independent of $\boldsymbol{\mathcal{X}}$, and $\boldsymbol{h}$ is a measurable function on S with values in $\mathbb{R}^k$, such that

$$P\left(\int_0^T |\boldsymbol{h}(\mathcal{X}_s)|^2\, ds < \infty\right) = 1.$$

The approximation signal processes $\boldsymbol{\mathcal{X}^n} = (\mathcal{X}_t^n)_{t\in[0,T]}$ are defined on $(\Omega, \mathcal{F}, P)$ and take values in S as well. The approximation observation processes $\boldsymbol{Y^n} = (Y^n(t))_{t\in[0,T]}$ are defined by

$$Y^n(t) = \int_0^t \boldsymbol{h}^n(\mathcal{X}_s^n) ds + W(t), \tag{3.2}$$

where $\boldsymbol{W}$ is independent of $\boldsymbol{\mathcal{X}^n}$, and $\boldsymbol{h}^n$ are measurable functions on S with values in $\mathbb{R}^k$, such that

$$P\left(\int_0^T |\boldsymbol{h}^n(\mathcal{X}_s^n)|^2\, ds < \infty\right) = 1.$$

Then the following result is an easy consequence of [3] and Remark 7.4 in [4].

THEOREM 3.1. *Assume that*

(B1) $\boldsymbol{h}^n$ *converges to* $\boldsymbol{h}$ *uniformly on compact sets;*

(B2) $\boldsymbol{h}$ *is continuous;*

(B3) $\boldsymbol{\mathcal{X}^n}$ *converges in* P*-probability (and therefore weakly) to* $\boldsymbol{\mathcal{X}}$ *in* $D_S([0,T])$*;*

(B4) $\lim_{n\to\infty} E(\int_0^T |\boldsymbol{h}^n(\mathcal{X}_s^n) - \boldsymbol{h}(\mathcal{X}_s)|^2\, ds) = 0.$

Then the filters of the system $(\boldsymbol{\mathcal{X}^n}, \boldsymbol{Y^n})$ *converge in probability (and therefore weakly) to the filter of the system* $(\boldsymbol{\mathcal{X}}, \boldsymbol{Y})$ *as processes with values in* $D_{\mathcal{P}(S)}([0,T])$*, where* $\mathcal{P}(S)$ *is the metric space of probability measures on* S*, endowed with the Prohorov metric.*

Note that the above conditions (B1)–(B4) are only sufficient conditions and that in [3] weaker conditions and different frameworks can be found.

In order to be in the framework described above, we take $S = [0,T] \times C([-\tau, 0], \mathbb{R})$, endowed with the distance

$$\|(t,\theta) - (t',\theta')\|_S = |t - t'| + \|\theta - \theta'\|,$$

and we consider the limit model $\big(\mathcal{X}_t, Y(t)\big)_{t\in[0,T]}$, where

$$\mathcal{X}_t = (t, \Pi_t X),$$

and $Y(t)$ is given by (1.2), and the approximating model $\big(\mathcal{X}^n_t, Y^n(t)\big)_{t\in[0,T]}$, where

$$\mathcal{X}^n_t = (\delta \cdot \lfloor t/\delta \rfloor, \Pi_{\delta\cdot\lfloor t/\delta\rfloor} X^n), \tag{3.3}$$

and $Y^n(t)$ is given by (2.11).

Then with this choice, the processes $\big(\mathcal{X}_t\big)_{t\in[0,T]}$ and $\big(\mathcal{X}^n_t\big)_{t\in[0,T]}$ have paths in $D_S([0,T])$, and conditions (B1) and (B2) are obviously satisfied with $\boldsymbol{h}^n = \boldsymbol{h} = h$.

Condition (B3), which asserts that $\boldsymbol{\mathcal{X}^n} = \big((\delta\cdot\lfloor t/\delta\rfloor, \Pi_{\delta\cdot\lfloor t/\delta\rfloor} X^n)\big)_{t\in[0,T]}$ converges in probability to $\boldsymbol{\mathcal{X}} = \big((t, \Pi_t X)\big)_{t\in[0,T]}$ in $D_S([0,T]) = D_{[0,T]\times C([-\tau,0],\mathbb{R})}([0,T])$, is also satisfied thanks to the following proposition, which will be proved in section 5.

PROPOSITION 3.2. *Assume that conditions* (A1)*, for* $k = 1$*, and* (A2) *are satisfied. Then*

$$\lim_{n\to\infty} E\left[\sup_{t\in[0,T]} \big\|(\delta\cdot\lfloor t/\delta\rfloor, \Pi_{\delta\cdot\lfloor t/\delta\rfloor} X^n) - (t, \Pi_t X)\big\|^2_S\right] = 0. \tag{3.4}$$

In our approximation scheme, since the function h appears in the definitions of both $Y(t)$ and $Y^n(t)$, condition (B4) reads

$$\lim_{n\to\infty} \int_0^T E\Big(|h(\delta\cdot\lfloor s/\delta\rfloor, \Pi_{\delta\cdot\lfloor s/\delta\rfloor} X^n) - h(s, \Pi_s X)|^2\Big) ds = 0. \tag{3.5}$$

When the observation function h is jointly globally Lipschitz, then condition (3.5) immediately follows by Proposition 3.2. Furthermore, condition (A1) is used for $k = 1$, in the proof of Proposition 3.2, and, for $k = 2$, to obtain (3.5) in the general case considered in (A3). In this general case, since h is jointly continuous and the convergence condition (3.4) holds, the sequence $|h(\delta\cdot\lfloor s/\delta\rfloor, \Pi_{\delta\cdot\lfloor s/\delta\rfloor} X^n) - h(s, \Pi_s X)|^2$ in (3.5) converges to zero in probability. Moreover a uniform integrability condition holds by property (2.3), for $k = 2$, and by

$$\sup_{s\in[0,T]} \sup_n E\left[|h(\delta\cdot\lfloor s/\delta\rfloor, \Pi_{\delta\cdot\lfloor s/\delta\rfloor} X^n)|^4\right] \le \sup_n E\left[C'\left(1 + \sup_{t\in[-\tau,T]} |X^n(t)|^4\right)\right] < \infty.$$

The above inequalities are immediate, thanks to the sublinear growth conditions in (A3) and Lemma 3.3, which will be proved in section 5. Then the dominated convergence theorem implies (3.5).

LEMMA 3.3. *Assume that conditions* (A1) *and* (A2) *are satisfied; then, for* $k = 1, 2$,

$$\sup_n E\left[\sup_{t\in[0,T]} \|\Pi_t X^n\|^{2k}\right] = \sup_n E\left[\sup_{u\in[-\tau,T]} |X^n(u)|^{2k}\right] < \infty.$$

Therefore, since all the conditions in Theorem 3.1 hold, the filters of the systems $(\boldsymbol{\mathcal{X}^n}, \boldsymbol{Y^n})$ converge in probability to the filter of the system $(\boldsymbol{\mathcal{X}}, \boldsymbol{Y})$ as random processes with values in $D_{\mathcal{P}(S)}([0,T])$, and this implies the convergence of $\boldsymbol{\pi^n}$ to $\boldsymbol{\pi}$ as random processes with values in $D_{\mathcal{P}(C([-\tau,0],\mathbb{R}))}([0,T])$.

To prove the second assertion of Theorem 2.2, we make use, as in section 2, of a representation result for the filters $(\boldsymbol{\mathcal{X}^n}, \boldsymbol{Y^n})$ and $(\boldsymbol{\mathcal{X}}, \boldsymbol{Y})$ in the state space S.

In this setting there exist functionals

$$V^n,\, V:\ [0,T] \times D_{\mathbb{R}^k}([0,T]) \mapsto \mathcal{P}(S), \tag{3.6}$$

with the properties $V^n\big(t, \boldsymbol{y}\big) = V^n\big(t, y(\cdot \wedge t)\big)$ and $V\big(t, \boldsymbol{y}\big) = V\big(t, y(\cdot \wedge t)\big)$, such that the filters of $(\boldsymbol{\mathcal{X}^n}, \boldsymbol{Y^n})$ and $(\boldsymbol{\mathcal{X}}, \boldsymbol{Y})$ are given by $V^n(t, \boldsymbol{Y^n})$ and $V(t, \boldsymbol{Y})$, respectively. This fact is true under very general conditions (see, for instance, Kurtz and Ocone [22]). Note that if one uses the general representation result, then one could only say that the functionals V^n and V are defined almost surely w.r.t. $P_{\boldsymbol{Y^n}}$, the law of $\boldsymbol{Y^n}$, and w.r.t. $P_{\boldsymbol{Y}}$, the law of $\boldsymbol{Y}$, respectively. Therefore, the approximation $V^n(t, \boldsymbol{Y})$ of the $(\boldsymbol{\mathcal{X}}, \boldsymbol{Y})$-filter (as the one provided in (2.15)) could be not well defined. However, in this case $P_{\boldsymbol{Y^n}}$ and $P_{\boldsymbol{Y}}$ are equivalent, and this problem does not occur.

In our delay case, $S = [0,T] \times C([-\tau, 0], \mathbb{R})$ and the functional V^n can be computed starting from the Kallianpur–Striebel formula with the Radon–Nikodym derivative $\mathcal{L}_t^n$ defined by (2.13). This fact implies also that, for any $(t, \boldsymbol{y})$ in $[0,T] \times C([0,T], \mathbb{R})$, the projection on the space $C([-\tau, 0], \mathbb{R})$ of the probability measure $V^n(t, \boldsymbol{y})$ coincides with $U^n(t, \boldsymbol{y})$, defined in section 2.

Moreover in [3] (see Theorem 3.3(a)), as a step in the proof of a weak convergence result, the authors prove that for any Wiener process $\boldsymbol{B} = (B(t))_{t\in[0,T]}$, the $\mathcal{P}(S)$-valued processes $(V^n(t, \boldsymbol{B}))_{t\in[0,T]}$ converge in probability to the $\mathcal{P}(S)$-valued process $(V(t, \boldsymbol{B}))_{t\in[0,T]}$. This amounts to saying that if P^0 is the reference probability measure defined by the Radon–Nikodym derivative

$$\frac{dP^0}{dP} = \exp\left\{-\int_0^T \boldsymbol{h}(\mathcal{X}_s) dY_s + \frac{1}{2}\int_0^T |\boldsymbol{h}(\mathcal{X}_s)|^2\, ds\right\}, \tag{3.7}$$

i.e., the measure under which the process $\boldsymbol{Y}$ is a Wiener process, independent of the state process $\boldsymbol{\mathcal{X}}$, then the $\mathcal{P}(S)$-valued processes $(V^n(t, \boldsymbol{Y}))_{t\in[0,T]}$ converge in P^0-probability to the $\mathcal{P}(S)$-valued process $(V(t, \boldsymbol{Y}))_{t\in[0,T]}$. In addition, since the measure P is also absolutely continuous w.r.t. P^0, the convergence also holds in P-probability. This implies that

$$\tilde{\boldsymbol{\pi}}^{\boldsymbol{n}} \text{ converges in } P\text{-probability to } \boldsymbol{\pi},$$

which is the second assertion in Theorem 2.2.

Since the filter $\boldsymbol{\pi}$ is continuous in time, the last statement of the theorem is an immediate consequence of the convergence in probability of $\tilde{\boldsymbol{\pi}}^{\boldsymbol{n}}$ to $\boldsymbol{\pi}$.

4. Rate of convergence. The aim of this section is to compute an upper bound for the rate of convergence of our scheme under the further hypotheses that h is jointly globally Lipschitz, that a and b are bounded, and that $1/2 \leq \alpha \leq 1$ in (2.1), i.e., to prove Theorem 2.3.

Let $(\boldsymbol{\mathcal{X}}, \boldsymbol{\mathcal{X}^n}, \boldsymbol{Y}, \boldsymbol{Y^n})$ be the stochastic processes introduced at the beginning of section 3, with values in a complete separable metric space (S, d_S), and let P^n be the probability measure defined by

$$\frac{dP^n}{dP^0} = \exp\left\{ \int_0^T \boldsymbol{h}^n(\mathcal{X}_s^n) dY_s - \frac{1}{2} \int_0^T |\boldsymbol{h}^n(\mathcal{X}_s^n)|^2 \, ds \right\}, \tag{4.1}$$

where P^0 is the reference probability measure on $(\Omega, \mathcal{F})$ defined in (3.7).

Then the law of $(\boldsymbol{\mathcal{X}^n}, \boldsymbol{Y})$ under P^n is the same as the law of $(\boldsymbol{\mathcal{X}^n}, \boldsymbol{Y^n})$ under P, so that the processes $(\boldsymbol{\mathcal{X}}, \boldsymbol{\mathcal{X}^n}, \boldsymbol{Y})$ and the probabilities P^0, P, and P^n satisfy conditions (a), ($\mathrm{a_n}$), (b1), and (b2) of Calzolari, Florchinger, and Nappo [7], apart from the fact that we are in a complete separable metric space (S, d_S). Therefore, with slight modifications in the proof of (32) in Theorem 2.3 of [7], we get

$$\begin{aligned} &E\big[d_{BL}^S\big(V(t,\boldsymbol{Y}), V^n(t,\boldsymbol{Y})\big)\big] \\ &\leq 2\, E^0\Big[\big|(dP^n/dP^0)|_{\widetilde{\mathcal{F}}_t} - (dP/dP^0)|_{\widetilde{\mathcal{F}}_t}\big|\Big] + E\big[d_S\big(\mathcal{X}_t, \mathcal{X}_t^n\big)\big], \end{aligned} \tag{4.2}$$

where V and V^n are the functionals defined as in (3.6), d_{BL}^S is the bounded Lipschitz metric on $\mathcal{P}(S)$, and $\widetilde{\mathcal{F}}_t = \mathcal{F}_t^{\mathcal{X}, \mathcal{X}^n, Y}$.

The above inequality is the starting point of the proof of Theorem 2.3, and, as a consequence, we need the estimates for the quantities in the right-hand side of (4.2) stated in the following proposition.

PROPOSITION 4.1. *For all $t \leq T$, we have*

$$\begin{aligned} &E^0\Big[\big|(dP^n/dP^0)|_{\widetilde{\mathcal{F}}_t} - (dP/dP^0)|_{\widetilde{\mathcal{F}}_t}\big|\Big] \\ &\leq 2\left(E\left[\int_0^t \big[\boldsymbol{h}^n(\mathcal{X}_s^n) - \boldsymbol{h}(\mathcal{X}_s)\big]^2 \, ds \right] \right)^{\frac{1}{2}} + E\left[\int_0^t \big[\boldsymbol{h}^n(\mathcal{X}_s^n) - \boldsymbol{h}(\mathcal{X}_s)\big]^2 \, ds \right]. \end{aligned} \tag{4.3}$$

In the particular case when $\boldsymbol{h}^n = \boldsymbol{h}$ and $\boldsymbol{h}$ is a globally Lipschitz function, then, for all $t \leq T$, we have, for a suitable constant $K(T)$,

$$\begin{aligned} &E^0\Big[\big|(dP^n/dP^0)|_{\widetilde{\mathcal{F}}_t} - (dP/dP^0)|_{\widetilde{\mathcal{F}}_t}\big|\Big] \\ &\leq 2\, K(T) \left\{ \sup_{s\in[0,T]} \big(E\big[d_S^2(\mathcal{X}_s^n, \mathcal{X}_s)\big]\big)^{\frac{1}{2}} + \sup_{s\in[0,T]} E\big[d_S^2(\mathcal{X}_s^n, \mathcal{X}_s)\big] \right\}. \end{aligned} \tag{4.4}$$

Proof. Define Λ_t and Λ_t^n by

$$\Lambda_t = \int_0^t \boldsymbol{h}(\mathcal{X}_s) dY_s - \frac{1}{2} \int_0^t |\boldsymbol{h}(\mathcal{X}_s)|^2 \, ds \tag{4.5}$$

and

$$\Lambda_t^n = \int_0^t \boldsymbol{h}^n(\mathcal{X}_s^n) dY_s - \frac{1}{2} \int_0^t |\boldsymbol{h}^n(\mathcal{X}_s^n)|^2 \, ds. \tag{4.6}$$

Then, using the fact that $|e^a - e^b| \le e^a\,|a-b| + e^b\,|a-b|$, we have

$$\begin{aligned} E^0\Big[\big|(dP^n/dP^0)|_{\widetilde{\mathcal{F}}_t} - (dP/dP^0)|_{\widetilde{\mathcal{F}}_t}\big|\Big] &= E^0\Big[\big|e^{\Lambda_t^n} - e^{\Lambda_t}\big|\Big] \\ &\le E^0\Big[e^{\Lambda_t^n}\big|\Lambda_t^n - \Lambda_t\big|\Big] + E^0\Big[e^{\Lambda_t}\big|\Lambda_t^n - \Lambda_t\big|\Big] \\ &= E^n\Big[\big|\Lambda_t^n - \Lambda_t\big|\Big] + E\Big[\big|\Lambda_t^n - \Lambda_t\big|\Big], \end{aligned}$$

where E^n is the expectation w.r.t. P^n.

An easy calculation gives

$$\begin{aligned} \Lambda_t^n - \Lambda_t &= \int_0^t \big[\boldsymbol{h}^n(\mathcal{X}_s^n) - \boldsymbol{h}(\mathcal{X}_s)\big]\,dY_s - \frac{1}{2}\int_0^t \big[|\boldsymbol{h}^n(\mathcal{X}_s^n)|^2 - |\boldsymbol{h}(\mathcal{X}_s)|^2\big]\,ds \\ &= \int_0^t \big[\boldsymbol{h}^n(\mathcal{X}_s^n) - \boldsymbol{h}(\mathcal{X}_s)\big]\big(dY_s - \boldsymbol{h}^n(\mathcal{X}_s^n)ds\big) + \frac{1}{2}\int_0^t \big[\boldsymbol{h}^n(\mathcal{X}_s^n) - \boldsymbol{h}(\mathcal{X}_s)\big]^2\,ds \\ &= \int_0^t \big[\boldsymbol{h}^n(\mathcal{X}_s^n) - \boldsymbol{h}(\mathcal{X}_s)\big]\big(dY_s - \boldsymbol{h}(\mathcal{X}_s)ds\big) + \frac{1}{2}\int_0^t \big[\boldsymbol{h}^n(\mathcal{X}_s^n) - \boldsymbol{h}(\mathcal{X}_s)\big]^2\,ds. \end{aligned}$$

Therefore we have

$$\begin{aligned} &E^0\Big[\big|(dP^n/dP^0)|_{\widetilde{\mathcal{F}}_t} - (dP/dP^0)|_{\widetilde{\mathcal{F}}_t}\big|\Big] \le E^n\Big[\big|\Lambda_t^n - \Lambda_t\big|\Big] + E\Big[\big|\Lambda_t^n - \Lambda_t\big|\Big] \\ &\le E^n\left[\left|\int_0^t \big[\boldsymbol{h}^n(\mathcal{X}_s^n) - \boldsymbol{h}(\mathcal{X}_s)\big]\big(dY_s - \boldsymbol{h}^n(\mathcal{X}_s^n)ds\big)\right|\right] \\ &+ \frac{1}{2}E^n\left[\int_0^t \big[\boldsymbol{h}^n(\mathcal{X}_s^n) - \boldsymbol{h}(\mathcal{X}_s)\big]^2\,ds\right] \\ &+ E\left[\left|\int_0^t \big[\boldsymbol{h}^n(\mathcal{X}_s^n) - \boldsymbol{h}(\mathcal{X}_s)\big]\big(dY_s - \boldsymbol{h}(\mathcal{X}_s)ds\big)\right|\right] + \frac{1}{2}E\left[\int_0^t \big[\boldsymbol{h}^n(\mathcal{X}_s^n) - \boldsymbol{h}(\mathcal{X}_s)\big]^2\,ds\right]. \end{aligned}$$

By recalling that

$$Y_t - \int_0^t \boldsymbol{h}^n(\mathcal{X}_s^n)ds \quad \text{and} \quad Y_t - \int_0^t \boldsymbol{h}(\mathcal{X}_s)ds$$

are Wiener processes under P^n and P, respectively, we get, by Cauchy–Schwarz inequality and the isometry of stochastic integrals,

$$\begin{aligned} &E^0\Big[\big|(dP^n/dP^0)|_{\widetilde{\mathcal{F}}_t} - (dP/dP^0)|_{\widetilde{\mathcal{F}}_t}\big|\Big] \\ &\le \left(E^n\left[\int_0^t \big[\boldsymbol{h}^n(\mathcal{X}_s^n) - \boldsymbol{h}(\mathcal{X}_s)\big]^2\,ds\right]\right)^{\frac{1}{2}} + \frac{1}{2}E^n\left[\int_0^t \big[\boldsymbol{h}^n(\mathcal{X}_s^n) - \boldsymbol{h}(\mathcal{X}_s)\big]^2\,ds\right] \\ &+ \left(E\left[\int_0^t \big[\boldsymbol{h}^n(\mathcal{X}_s^n) - \boldsymbol{h}(\mathcal{X}_s)\big]^2\,ds\right]\right)^{\frac{1}{2}} + \frac{1}{2}E\left[\int_0^t \big[\boldsymbol{h}^n(\mathcal{X}_s^n) - \boldsymbol{h}(\mathcal{X}_s)\big]^2\,ds\right]. \end{aligned}$$

As the joint laws of $\boldsymbol{\mathcal{X}}$ and $\boldsymbol{\mathcal{X}^n}$ under P^n and P coincide (with the joint law under P^0), the final upper bound is

$$\begin{aligned} &E^0\Big[\big|(dP^n/dP^0)|_{\widetilde{\mathcal{F}}_t} - (dP/dP^0)|_{\widetilde{\mathcal{F}}_t}\big|\Big] \\ &\le 2\left(E\left[\int_0^T \big[\boldsymbol{h}^n(\mathcal{X}_s^n) - \boldsymbol{h}(\mathcal{X}_s)\big]^2\,ds\right]\right)^{\frac{1}{2}} + E\left[\int_0^T \big[\boldsymbol{h}^n(\mathcal{X}_s^n) - \boldsymbol{h}(\mathcal{X}_s)\big]^2\,ds\right], \end{aligned}$$

which is inequality (4.3), and it immediately implies inequality (4.4). □

As in the previous section, we take $S = [0,T] \times C([-\tau,0],\mathbb{R})$, $\mathcal{X}_t = (t, \Pi_t X)$, $\mathcal{X}^n_t = (\delta \cdot \lfloor t/\delta \rfloor, \Pi_{\delta\cdot\lfloor t/\delta\rfloor} X^n)$, and $\boldsymbol{h}^n = \boldsymbol{h} = h$. Therefore (4.2) implies that

$$E\big[d_{BL}(\pi_t, \tilde{\pi}^n_t)\big] \le 2E^0\Big[\big|(dP^n/dP^0)|_{\tilde{\mathcal{F}}_t} - (dP/dP^0)|_{\tilde{\mathcal{F}}_t}\big|\Big] + E\big[\|\mathcal{X}_t - \mathcal{X}^n_t\|_S\big], \tag{4.7}$$

and, when h is a jointly globally Lipschitz function, inequality (4.4) holds. Finally the result of Theorem 2.3 is a direct consequence of the following improvement of the result of Proposition 3.2.

PROPOSITION 4.2. *Assume that conditions* (A1), *for* $k = 1$, *and* (A2), *with* $1/2 \le \alpha \le 1$, *are satisfied, and furthermore assume that the initial condition* η *satisfies* (2.17) *and that the functions* a *and* b *are bounded. Then there exists a constant* C_X *such that*

$$E\left[\sup_{t\in[0,T]} \big\|(\delta\cdot\lfloor t/\delta\rfloor, \Pi_{\delta\cdot\lfloor t/\delta\rfloor} X^n) - (t, \Pi_t X)\big\|^2_S\right] \le C_X \,\frac{\log n}{n}. \tag{4.8}$$

The proof of this result will be given in section 5.

REMARK 4.3. *Obviously, from* (4.8) *there exists a constant* $C'_X \le C_X$ *such that*

$$\sup_{t\in[0,T]} E\left[\big\|(\delta\cdot\lfloor t/\delta\rfloor, \Pi_{\delta\cdot\lfloor t/\delta\rfloor} X^n) - (t, \Pi_t X)\big\|^2_S\right] \le C'_X \,\frac{\log n}{n}, \tag{4.9}$$

and, by (4.4), *the above inequality is a sufficient condition to get the upper bound* (2.18) *in Theorem* 2.3. *From the following example it appears that the rate of convergence cannot be improved either in the right-hand side of the previous inequality or in* (2.18).

Example. Take $\eta = 0$, $a = 0$, $b = 1$, and $h = 0$. In this case $X = \tilde{W}$ and $X^n = \tilde{W}^n$, where $\tilde{W}^n$ is the piecewise linear interpolation of $\tilde{W}$. Moreover π_t and $\tilde{\pi}^n_t$ coincide with the laws of $\Pi_t\tilde{W}$ and $\Pi_{\delta\cdot\lfloor t/\delta\rfloor}\tilde{W}^n$, respectively, and therefore

$$\begin{aligned} E\big[d_{BL}(\pi_t, \tilde{\pi}^n_t)\big] &= d_{BL}(\pi_t, \tilde{\pi}^n_t) \\ &\le E\left[\big\|\Pi_{\delta\cdot\lfloor t/\delta\rfloor}\tilde{W}^n - \Pi_t\tilde{W})\big\|\right] \le \left(E\left[\big\|\Pi_{\delta\cdot\lfloor t/\delta\rfloor}\tilde{W}^n - \Pi_t\tilde{W})\big\|^2\right]\right)^{\frac{1}{2}}, \end{aligned}$$

where the first inequality follows by standard coupling techniques.

Furthermore,

$$E\left[\big\|\Pi_{\delta\cdot\lfloor t/\delta\rfloor}\tilde{W}^n - \Pi_t\tilde{W})\big\|^2\right] = O(\tfrac{\log n}{n})$$

for any $t \in [0,T]$ and uniformly in $[0,T]$. This fact can be shown by using the results established by Pickands in [38] (see also Fischer and Nappo [13]). This result could be expected thanks to Lévy's modulus of continuity, which implies that there exists a finite random variable M such that

$$\sup_{\substack{s,t\in[0,1]\\ |s-t|\le\delta,}} |\tilde{W}_s - \tilde{W}_t| \le M\sqrt{\delta\,\log(1/\delta)}$$

holds almost surely (see the paper by Pinsky [39] for a simple proof).

5. Technical results. This section is devoted to the proofs of Lemma 3.3, Proposition 3.2, and Proposition 4.2. In order to prove these results we introduce, as a technical tool,

• the operator P^δ, which gives the linear interpolation of a function $\big(x(s)\big)_{s\in[-\tau,T]}$, with step δ, so that $\big(P^\delta x(s)\big)_{s\in[-\tau,T]}$ is the linear interpolation of $(\ell\delta, x(\ell\delta))$ for $\ell = -m,\dots,n$,

and, as another approximation for the state,

• the continuous Euler–Maruyama scheme, i.e., the diffusion processes $\boldsymbol{Z^n} = \big(Z^n(t)\big)_{t\in[0,T]}$, where

$$\text{(5.1)}\qquad \begin{cases} Z^n(t) := \eta(t), & -\tau \le t \le 0,\\ Z^n(t) := \eta(0) + \displaystyle\int_0^t a(\delta\cdot\lfloor s/\delta\rfloor, \Pi_{\delta\cdot\lfloor s/\delta\rfloor}X^n)ds & \\ \qquad\qquad + \displaystyle\int_0^t b(\delta\cdot\lfloor s/\delta\rfloor, \Pi_{\delta\cdot\lfloor s/\delta\rfloor}X^n)d\tilde W_s, & 0\le t\le T, \end{cases}$$

which can be considered as intermediate approximation processes for the state $\boldsymbol{X}$.

The processes $\boldsymbol{Z^n}$ have the property that

$$\text{(5.2)}\qquad P^\delta Z^n(s) = X^n(s) \qquad \text{for } s\in[-\tau,0]\cup[0,T],$$

since

$$Z^n(\ell\delta) = X^n(\ell\delta) \qquad \text{for } \ell\ge -m.$$

Indeed $Z^n(\ell\delta) = X^n(\ell\delta) = \eta(\ell\delta)$ for $-m\le\ell\le 0$. The case $\ell\ge 0$ follows by observing that for $t\in[\ell\delta,(\ell+1)\delta]$

$$\begin{aligned} Z^n(t) &= Z^n(\ell\delta) + \int_{\ell\delta}^t a(\ell\delta,\Pi_{\ell\delta}X^n)ds + \int_{\ell\delta}^t b(\ell\delta,\Pi_{\ell\delta}X^n)d\tilde W_s\\ &= Z^n(\ell\delta) + a(\ell\delta,\Pi_{\ell\delta}X^n)(t-\ell\delta) + b(\ell\delta,\Pi_{\ell\delta}X^n)[\tilde W(t)-\tilde W(\ell\delta)], \end{aligned}$$

so that

$$Z^n((\ell+1)\delta) = Z^n(\ell\delta) + a(\ell\delta,\Pi_{\ell\delta}X^n)\delta + b(\ell\delta,\Pi_{\ell\delta}X^n)[\tilde W((\ell+1)\delta)-\tilde W(\ell\delta)],$$

and finally comparing the above recursive formula with the definition of $X^n((\ell+1)\delta)$ in (2.7).

We are now able to prove Lemma 3.3.

Proof of Lemma 3.3. First, observe that by (5.2)

$$\sup_{t\in[-\tau,T]}|X^n(t)| \le \max\left(\|\eta\|, \sup_{t\in[0,T]}|Z^n(t)|\right),$$

and set

$$\text{(5.3)}\qquad M_t^n := \int_0^t b_n(u)d\tilde W_u, \quad \text{where } b_n(u) := b(\delta\cdot\lfloor u/\delta\rfloor, \Pi_{\delta\cdot\lfloor u/\delta\rfloor}X^n).$$

For any $\ell \in \{1,2\}$ take $\alpha = 2\ell$ and $\beta = 2\ell/(2\ell-1)$, so that $(1/\alpha)+(1/\beta)=1$. Then for any stopping time σ, there exists a suitable constant C_ℓ such that

$$\begin{aligned}
&\sup_{u\in[-\tau,t\wedge\sigma]} |X^n(u)|^{2\ell} \\
&\le C_\ell \left\{ \|\eta\|^{2\ell} + \left[\int_0^t \sup_{u\in[0,s\wedge\sigma]} |a(\delta\cdot\lfloor u/\delta\rfloor, \Pi_{\delta\cdot\lfloor u/\delta\rfloor} X^n)| ds \right]^{2\ell} + \sup_{s\in[0,t\wedge\sigma]} |M_s^n|^{2\ell} \right\} \\
&\le C_\ell \left\{ \|\eta\|^{2\ell} + t^{\frac{2\ell}{\beta}} \left[\int_0^t \sup_{u\in[0,s\wedge\sigma]} |a(\delta\cdot\lfloor u/\delta\rfloor, \Pi_{\delta\cdot\lfloor u/\delta\rfloor} X^n)|^\alpha ds \right]^{\frac{2\ell}{\alpha}} + \sup_{s\in[0,t\wedge\sigma]} |M_s^n|^{2\ell} \right\} \\
&\le C_\ell \left\{ \|\eta\|^{2\ell} + t^{2\ell-1} \int_0^t \ell K^\ell \left[1 + \sup_{u\in[-\tau,s\wedge\sigma]} |X^n(u)|^{2\ell} \right] ds + \sup_{s\in[0,t]} |M_{s\wedge\sigma}^n|^{2\ell} \right\}.
\end{aligned}$$

If $M_{t\wedge\sigma}^n$ is a martingale, setting

$$\phi_{\sigma,\ell}^n(t) := E\left[\sup_{u\in[-\tau,t\wedge\sigma]} |X^n(u)|^{2\ell} \right]$$

and applying Doob's inequality for $p = 2\ell$ to $M_{t\wedge\sigma}^n$ yields

$$\phi_{\sigma,\ell}^n(t) \le C'_\ell \left\{ 1 + \|\eta\|^{2\ell} + \int_0^t \phi_{\sigma,\ell}^n(s) ds + E\left[|M_{t\wedge\sigma}^n|^{2\ell} \right] \right\}, \tag{5.4}$$

for all $t\in[0,T]$, for a suitable constant $C'_\ell = C'_\ell(T)$.

Taking $\sigma = \sigma_N^n := \inf\{s>0;\, \sup_{u\in[-\tau,s]} |X^n(u)| \ge N\}$, we have

$$\int_0^T E[\mathbf{1}_{s\le\sigma_N^n} b_n^{2\ell}(s)] ds < \infty, \tag{5.5}$$

and $M_{t\wedge\sigma}^n = M_{t\wedge\sigma_N^n}^n$ is a martingale. Indeed by the sublinearity condition (2.2) on b we have

$$\int_0^t E[\mathbf{1}_{s\le\sigma_N^n} b_n^{2\ell}(s)] ds \le \int_0^t E\left[\ell K^\ell \left(1 + \sup_{u\in[-\tau,s\wedge\sigma_N^n]} |X^n(u)|^{2\ell} \right) \right] ds, \tag{5.6}$$

which is finite since $\sup_{u\in[-\tau,s\wedge\sigma_N^n]} |X^n(u)| \le N$. Then

$$E[|M_{t\wedge\sigma_N^n}^n|^2] = E\left[\left(\int_0^t \mathbf{1}_{s\le\sigma_N^n} b_n(s) d\tilde{W}_s \right)^2 \right] = \int_0^t E[\mathbf{1}_{s\le\sigma_N^n} b_n^2(s)] ds$$

and (see, e.g., Lemma 4.12, page 125, in Liptser and Shiryayev [29])

$$E[|M_{t\wedge\sigma}^n|^4] = E\left[\left(\int_0^t \mathbf{1}_{s\le\sigma_N^n} b_n(s) d\tilde{W}_s \right)^4 \right] \le 6^2 t \int_0^t E[\mathbf{1}_{s\le\sigma_N^n} b_n^4(s)] ds.$$

Then, taking into account (5.4) and (5.6) and invoking Gronwall's inequality, we get a bound for $\phi_{\sigma,\ell}^n(T) = \phi_{\sigma_N^n,\ell}^n(T)$, uniform in n and N. Therefore, applying Fatou's lemma and making use of the fact that $\sigma_N^n \to \infty$ as $N\to\infty$, we get the results. □

REMARK 5.1. *Note that with the same technique one could prove that under the same assumptions of Lemma* 3.3

$$\sup_n E\left[\sup_{t\in[0,T]}\|\Pi_t Z^n\|^{2\ell}\right]=\sup_n E\left[\sup_{u\in[-\tau,T]}|Z^n(u)|^{2\ell}\right]<\infty \qquad \textit{for } \ell=1,2.$$

In order to prove Proposition 3.2 we need some intermediate results, stated in the following lemmas, which will be proved at the end of this section.

The first lemma concerns the behavior of the modulus of continuity.

LEMMA 5.2. *Denoting by*

$$\omega_x(\delta;[-\tau,T]):=\sup_{\substack{s,t\in[-\tau,T]\\ |s-t|\le\delta,}}|x(s)-x(t)|$$

the modulus of continuity of the function $\big(x(s)\big)_{s\in[-\tau,T]}$, *we have*

$$\sup_{t\in[0,T]}\|\Pi_{\delta\cdot\lfloor t/\delta\rfloor}P^\delta x-\Pi_t x\|\le 2\,\omega_x(\delta;[-\tau,T]), \tag{5.7}$$

and, for $\delta=\delta_n$,

$$\lim_{n\to\infty}E\left[\omega_X^2(\delta,[-\tau,T])\right]=0 \tag{5.8}$$

and

$$\lim_{n\to\infty}E\left[\sup_{t\in[0,T]}\|\Pi_{\delta\cdot\lfloor t/\delta\rfloor}P^\delta X-\Pi_t X\|^2\right]=0. \tag{5.9}$$

The second lemma concerns the convergence of the approximation $\boldsymbol{Z^n}$.

LEMMA 5.3. *Under the hypotheses of Proposition* 3.2

$$\lim_{n\to\infty}E\left[\sup_{t\in[0,T]}\|\Pi_t Z^n-\Pi_t X\|^2\right]=0.$$

With the above results the proof of Proposition 3.2 is straightforward.

Proof of Proposition 3.2. First, we note that

$$\left\|\left(\delta\cdot\lfloor t/\delta\rfloor,\Pi_{\delta\cdot\lfloor t/\delta\rfloor}X^n\right)-\left(t,\Pi_t X\right)\right\|_S^2\le 2\,\delta^2+2\,\left\|\Pi_{\delta\cdot\lfloor t/\delta\rfloor}X^n-\Pi_t X\right\|^2. \tag{5.10}$$

Then, by adding and subtracting $\Pi_{\delta\cdot\lfloor t/\delta\rfloor}P^\delta X$ in the second term on the right-hand side of the above expression, it yields

$$\left\|\Pi_{\delta\cdot\lfloor t/\delta\rfloor}X^n-\Pi_t X\right\|^2\le 2\left\|\Pi_{\delta\cdot\lfloor t/\delta\rfloor}X^n-\Pi_{\delta\cdot\lfloor t/\delta\rfloor}P^\delta X\right\|^2+2\left\|\Pi_{\delta\cdot\lfloor t/\delta\rfloor}P^\delta X-\Pi_t X\right\|^2. \tag{5.11}$$

Then, taking into account (5.9) and that

$$\begin{aligned}&\sup_{t\in[0,T]}\|\Pi_t X^n-\Pi_t P^\delta X\|=\sup_{k:k\delta\in[-\tau,T]}|X^n(k\delta)-X(k\delta)|\\ &=\sup_{k:k\delta\in[-\tau,T]}|Z^n(k\delta)-X(k\delta)|\le\sup_{t\in[-\tau,T]}|Z^n(t)-X(t)|=\sup_{t\in[0,T]}\|\Pi_t Z^n-\Pi_t X\|,\end{aligned}$$

the result follows by Lemma 5.3. □

Proof of Lemma 5.2. Noticing that $\Pi_{\delta\cdot\lfloor t/\delta\rfloor}P^\delta x = P^\delta \Pi_{\delta\cdot\lfloor t/\delta\rfloor}x$, we have

$$\begin{aligned}\|\Pi_{\delta\cdot\lfloor u/\delta\rfloor}P^\delta x - \Pi_u x\| &\le \|\Pi_{\delta\cdot\lfloor u/\delta\rfloor}P^\delta x - \Pi_{\delta\cdot\lfloor u/\delta\rfloor}x\| + \|\Pi_{\delta\cdot\lfloor u/\delta\rfloor}x - \Pi_u x\| \\ &= \|P^\delta \Pi_{\delta\cdot\lfloor u/\delta\rfloor}x - \Pi_{\delta\cdot\lfloor u/\delta\rfloor}x\| + \|\Pi_{\delta\cdot\lfloor u/\delta\rfloor}x - \Pi_u x\|.\end{aligned}$$

Furthermore, since

$$P^\delta\theta(v) = \lambda(v)\,\theta(\delta\cdot\lfloor v/\delta\rfloor + \delta) + (1-\lambda(v))\,\theta(\delta\cdot\lfloor v/\delta\rfloor)$$

with $\lambda(v) = v/\delta - \lfloor v/\delta\rfloor$, and since $\theta(v) = \lambda(v)\,\theta(v) + (1-\lambda(v))\,\theta(v)$, we deduce that

$$\|\Pi_{\delta\cdot\lfloor u/\delta\rfloor}P^\delta x - \Pi_u x\| \le 2\sup_{\substack{s,t\in[0,T]\\ |s-t|\le\delta,}}\|\Pi_s x - \Pi_t x\| = 2\sup_{\substack{s,t\in[-\tau,T]\\ |s-t|\le\delta,}}|x(s)-x(t)|,$$

which is the first assertion (5.7) of the lemma.

Equality (5.8) follows by the dominated convergence theorem: indeed

$$\omega_x(\delta;[-\tau,T]) \le 2\sup_{t\in[-\tau,T]}|x(t)|,$$

the integrability condition (2.3) for $k=1$ holds, and, finally, the modulus of continuity $\omega_X(\delta,[-\tau,T])$ converges to zero as $\delta=\delta_n$ converges to zero, as the paths of X are continuous.

The last assertion (5.9) is an interesting observation which is a straightforward consequence of (5.7) and (5.8). □

Proof of Lemma 5.3. Noticing that $P^\delta Z^n(s) = X^n(s)$, for $s\in[-\tau,0]\cup[0,T]$, then we can rewrite (5.1) as

$$Z^n(t) = \eta(0) + \int_0^t a(\delta\cdot\lfloor s/\delta\rfloor, \Pi_{\delta\cdot\lfloor s/\delta\rfloor}P^\delta Z^n)ds + \int_0^t b(\delta\cdot\lfloor s/\delta\rfloor, \Pi_{\delta\cdot\lfloor s/\delta\rfloor}P^\delta Z^n)d\tilde{W}_s.$$

Therefore, taking into account that $Z^n(t) = X(t) = \eta(t)$ for $t\in[-\tau,0]$,

$$\begin{aligned}&\sup_{s\in[-\tau,t]}|Z^n(s)-X(s)|^2 \\ &\le 2\left(\int_0^t |a(\delta\cdot\lfloor u/\delta\rfloor, \Pi_{\delta\cdot\lfloor u/\delta\rfloor}P^\delta Z^n) - a(u,\Pi_u X)|du\right)^2 \\ &+ 2\sup_{s\in[0,t]}\left(\int_0^s \left[b(\delta\cdot\lfloor u/\delta\rfloor, \Pi_{\delta\cdot\lfloor u/\delta\rfloor}P^\delta Z^n) - b(u,\Pi_u X)\right]d\tilde{W}_u\right)^2 \\ &\le 2t\int_0^t |a(\delta\cdot\lfloor u/\delta\rfloor, \Pi_{\delta\cdot\lfloor u/\delta\rfloor}P^\delta Z^n) - a(u,\Pi_u X)|^2du \\ &+ 2\sup_{s\in[0,t]}\left(\int_0^s \left[b(\delta\cdot\lfloor u/\delta\rfloor, \Pi_{\delta\cdot\lfloor u/\delta\rfloor}P^\delta Z^n) - b(u,\Pi_u X)\right]d\tilde{W}_u\right)^2.\end{aligned}$$

By Lemma 3.3, Remark 5.1, and the sublinearity of b,

$$\int_0^s \left[b(\delta\cdot\lfloor u/\delta\rfloor, \Pi_{\delta\cdot\lfloor u/\delta\rfloor}P^\delta Z^n) - b(u,\Pi_u X)\right]d\tilde{W}_u$$

is a martingale.

Then taking the expectations we can apply Doob's inequality, and we get for $t \in [0,T]$

$$
\begin{aligned}
&E\left[\sup_{u\in[0,t]} \|\Pi_u Z^n - \Pi_u X\|^2\right] = E\left[\sup_{s\in[-\tau,t]} |Z^n(s) - X(s)|^2\right] \\
&\le 2t \int_0^t E\left[\left|a(\delta\cdot\lfloor u/\delta\rfloor, \Pi_{\delta\cdot\lfloor u/\delta\rfloor} P^\delta Z^n) - a(u,\Pi_u X)\right|^2\right] du \\
&+ 8\int_0^t E\left[\left|b(\delta\cdot\lfloor u/\delta\rfloor, \Pi_{\delta\cdot\lfloor u/\delta\rfloor} P^\delta Z^n) - b(u,\Pi_u X)\right|^2\right] du \\
&\le \max(2T,8)\int_0^t KE\left[\sup_{u\in[0,s]} \|\Pi_{\delta\cdot\lfloor u/\delta\rfloor} P^\delta Z^n - \Pi_u X\|^2 + \delta^{2\alpha}\right] ds \\
&\le C(T)\int_0^t E\left[\sup_{u\in[0,s]} \Big(\|\Pi_{\delta\cdot\lfloor u/\delta\rfloor} P^\delta Z^n - \Pi_{\delta\cdot\lfloor u/\delta\rfloor} P^\delta X\|^2 \right. \\
&\qquad\qquad \left. + \|\Pi_{\delta\cdot\lfloor u/\delta\rfloor} P^\delta X - \Pi_u X\|^2\Big) + \delta^{2\alpha}\right] ds \\
&\le C(T)\int_0^t E\left[\sup_{u\in[0,s]} \|\Pi_u Z^n - \Pi_u X\|^2 + 4\omega_X^2(\delta;[-\tau,T]) + \delta^{2\alpha}\right] ds,
\end{aligned}
$$

where we have used (5.7).

Then Gronwall's inequality gives the upper bound

$$
E\left[\sup_{u\in[0,T]} \|\Pi_u Z^n - \Pi_u X\|^2\right] \le C_1(T)\left(E\left[\omega_X^2(\delta;[-\tau,T])\right] + \delta^{2\alpha}\right) \tag{5.12}
$$

and the proof is accomplished, since $\delta = \delta_n$ and (according to (5.8)) $E\left[\omega_X^2(\delta;[-\tau,T])\right]$ go to zero as n goes to infinity. □

We conclude this section with the proof of Proposition 4.2.

Proof of Proposition 4.2. First, we note that the inequalities in the proof of Proposition 3.2 together with (5.7) imply

$$
\begin{aligned}
&\left\|(\delta\cdot\lfloor t/\delta\rfloor, \Pi_{\delta\cdot\lfloor t/\delta\rfloor} X^n) - (t,\Pi_t X)\right\|_S^2 \\
&\le 4\left(\delta^2 + \sup_{t\in[0,T]} \|\Pi_t Z^n - \Pi_t X\|^2 + \omega_X^2(\delta;[-\tau,T])\right).
\end{aligned}
$$

Then by (5.12) we get

$$
E\left[\left\|(\delta\cdot\lfloor t/\delta\rfloor, \Pi_{\delta\cdot\lfloor t/\delta\rfloor} X^n) - (t,\Pi_t X)\right\|_S^2\right] \le C_2(T)\left(\delta^{2\alpha} + E\left[\omega_X^2(\delta;[-\tau,T])\right]\right).
$$

The thesis follows by observing that

$$
\omega_X(\delta;[-\tau,T]) \le \omega_\eta(\delta;[-\tau,0]) + \omega_X(\delta;[0,T]) \tag{5.13}
$$

and taking into account the result of Lemma A.4 of Słomiński [41], which is recalled in what follows for the ease of the reader. □

LEMMA 5.4 (Lemma A.4 of Słomiński [41]). *Let H, G be two adapted processes with values in $\mathbb{R}^d \otimes \mathbb{R}^d$ and $\mathbb{R}^d$, respectively, such that $\|H_t\|_{\mathbb{R}^d\otimes\mathbb{R}^d}$, $|G_t| \le L < \infty$,*

for some constant $L > 0$, and let $Y_t = \int_0^t H_s\, dW_s + \int_0^t G_s\, ds$, $t \in \mathbb{R}^+$. Then for every $p \in \mathbb{N}$

$$E\left[\omega_Y^{2p}(\tfrac{1}{n};[0,T])\right] = O\left(\left(\tfrac{\log n}{n}\right)^p\right). \tag{5.14}$$

REMARK 5.5. *We observe that the thesis holds for any real $p > 0$, as can be seen following the lines in the proof by Słomiński.*

6. Conclusion. As already recalled in the introduction, Chang in [8] gives a computable approximation for the optimal filter associated with the partially observable delay system (1.1) and (1.2), with $b(t,\theta) = 1$. The state process is approximated by the linear interpolation of $X^n(\ell\delta)$ as in (2.7) and the approximation for the observation process is the linear interpolation of $Y^n(\ell\delta)$ defined by (2.8), while our approximation of the observation process is a continuous time diffusion. However, the two approximation processes coincide at times $\ell\delta$.

The author proves weak convergence of the filters under the assumption that there exists a strictly positive constant k such that

$$E[\exp\{k\|\eta\|^2\}] < \infty,$$

and for any partition $-\tau \le \tau_0 < \cdots < \tau_n = 0$ the $(n+1)$-dimensional random vector $(\eta(\tau_i);\ 0 \le i \le n)$ has a density w.r.t. the Lebesgue measure in $\mathbb{R}^{n+1}$. There are other minor differences between our assumptions and the one by Chang, about the diffusion coefficients, which allow us to consider coefficients of the form (1.4) but not of the form (1.3).

Other weak approximation schemes, such as those recently used by Kushner in a stochastic control framework (see Kushner [25]), could also be used to get weak convergence of the filters. Nevertheless it seems difficult to compute the rate of convergence with these methods. For this reason we were interested in strong approximation schemes.

The problem of strong approximation for stochastic delay differential equations has been the subject of research for many authors in the last years. There is quite a substantial amount of work in this field, and in the following we mention only some of them. Küchler and Platen [21] have proposed a Taylor approximation scheme, besides the Euler scheme, and have proved the strong convergence of their scheme (see also Baker and Buckwar [1] and Buckwar [6]). Hu, Mohammed, and Yan [17] have studied strong convergence of Milstein schemes for stochastic delay differential equations with tame coefficient functions g_a and g_b as in (1.4), with $\gamma_i = \delta_{s_i}$, for $s_i \in [-\tau, 0]$. Though these schemes have better performances than Euler schemes, the authors do not deal with convergence of the expectation of the uniform norm on $[-\tau, T]$, which we need in order to get our first result. In [31] Mao and Sabanis have investigated the uniform norm for the continuous Euler–Maruyama scheme instead of the piecewise linear Euler–Maruyama scheme, in the framework of a variable delay, namely, when in (1.5) the term $X(t-\tau)$ is replaced by $X(\delta(t))$, where $\delta(t)$ is a Lipschitz function with $-\tau \le \delta(t) \le t$, and when g_a and g_b are locally Lipschitz functions. Moreover Mao and Sabanis get, under suitable assumptions, a rate of convergence of order less than or equal to $\sqrt{1/n}$. In our setting, and with our techniques, we cannot get a rate of convergence of order $\sqrt{1/n}$, as one can see from the example at the end of section 4, where the simple case of a Wiener process with redundant observation is considered. Note that in this example the Wiener process coincides with its continuous Euler–Maruyama approximation scheme, and hence the two filters also coincide, while this

does not happen with the piecewise linear Euler–Maruyama scheme. Nevertheless in the latter case the filters coincide with the expectations, and a rate of convergence of order $\sqrt{1/n}$ is achieved when restricting to functions $\phi(\theta)$ depending on a fixed number of times $s_i \in [-\tau, 0]$.

Finally, note that the boundedness condition on a in Proposition 4.2 (and as a consequence in Theorem 2.3) is not necessary, since

$$\left| \int_t^{t'} a(u, \Pi_u X) du \right| \leq |t' - t| \, K^{1/2} \left(1 + \sup_{u \in [0,T]} \|\Pi_u X\|^2 \right)^{1/2},$$

while the boundedness condition on b is fundamental to use Lemma 5.4. However, one expects that this condition can be dropped, since a rate of convergence of order $(\log n/n)^{1/2}$ holds for the piecewise linear approximation of solutions of ordinary stochastic differential equations (see Bouleau and Lépingle [5]). This fact is under investigation.

Note added in proof. As conjectured above, the results of Theorem 2.3 are still valid without the boundedness condition on the coefficients a and b: indeed one can use a generalization of Słomiński's lemma (see [13]).

DUAL NONLINEAR FILTERS AND ENTROPY PRODUCTION*

NIGEL J. NEWTON†

Abstract. This paper makes connections between nonlinear filtering and the entropic properties of Markov processes. It starts by developing information flow models for continuous-time, discrete-state filtering problems, identifying rates of information *supply* and *dissipation*. Time reversal yields a *dual* filtering problem in which these flows are interchanged. The dual problem comprises a diffusion signal with nonlinear dynamics, and observations of the point process variety, but yields a finite-dimensional nonlinear filter. The paper goes on to define an entropic time derivative for a general class of Markov processes and relates the entropic derivatives of the signal and filter to the rates of information supply and dissipation. This leads to the definition of a *rate of interactive entropy production*, which measures the time asymmetry of the interaction between the signal and filter. This asymmetry is of the same nature as that occurring in the theory of nonequilibrium statistical mechanics based on stochastic dynamics. In this context, the interaction between the signal and filter is *nondissipative*—a property intimately connected with the existence of a dual problem.

Key words. dual filters, entropic derivative, finite-dimensional nonlinear filters, information theory, nonequilibrium statistical mechanics, statistical filtering

1. Introduction.

This paper investigates the information-theoretic properties of nonlinear filters for discrete-state Markov processes. It builds on results appearing in [19], concerning linear Gaussian problems. Starting from conventional definitions of signal, X, and observation, Y, it defines information *supply*, *storage*, and *dissipation* processes that quantify the information value of the observation history, $(Y_s,\ s \le t)$, in the context of estimators of the entire signal process, X, its present and future, $(X_s,\ s \ge t)$, and its past, $(X_s,\ s < t)$, respectively. The filter state variable, Z_t, is thought of as *storing* that part of the information in the observation history useful for estimating the present and future values of the signal. As time progresses, information *flows* from the observation process into the filter state and is later dissipated. Rates of information supply and dissipation are identified.

The signal and filter processes have the following key properties: (i) they are *jointly* Markov; (ii) they are *marginally* Markov; (iii) the future of the signal is X_t-conditionally independent of the past of both processes; (iv) the past of the filter is Z_t-conditionally independent of the future of both processes. Property (iii) states that the evolution of the signal is not influenced by the filter process, and so the flow of information between the processes is strictly one-way, from signal to filter. Properties (i)–(iv) are retained if time is reversed and the signal and filter processes are interchanged. The processes thus obtained can be thought of as the signal and

filter of a *dual* problem. Like the original, this has information supply, storage, and dissipation processes, and these are simply related to those of the original. The dual problem has an $\mathbb{R}^n$-valued signal with nonlinear dynamics and a point process observation with signal dependent switching rates. Normally such a problem would require an infinite-dimensional filter [6], but because of the special relation between the signal and observation here, the filter is not only of finite dimension but even evolves on a finite space.

One of the motivations for studying such issues is their connection with statistical mechanics. In a modern theory of nonequilibrium statistical mechanics, based on stochastic dynamics (see, for example, [3], [11], [13], and [15]), invariant distributions of time-homogeneous Markov processes are used to model *stationary states* of statistical mechanical systems. The latter come in two varieties called *equilibrium* and *nonequilibrium* states. Nonequilibrium states are time-invariant states in which there is a nonzero flow of some physical quantity (often energy). In this paper we define an entropic time derivative for a general class of continuous-time Markov processes. This is defined either in or out of an invariant distribution and is also defined for time-inhomogeneous processes. For time-homogeneous processes admitting invariant distributions, it coincides with the *rate of entropy production*, as defined in [13] (although it is defined in a totally different way). Because our filtering problems have properties (i) and (ii) above, we can identify three entropic time derivatives: one for the signal, X, one for the filter, Z, and one for the joint process, (X, Z). Subtracting the first two from the third, we obtain a *rate of interactive entropy production* that characterizes the interaction between the signal and filter. (In fact, it is not quite that easy because of degeneracy issues.)

The statistical mechanical properties of Kalman–Bucy filters are developed in some detail in [18], and the interactive statistical mechanics of linear and nonlinear filters are investigated in [20]. In the analogies developed in those papers, the signal-filter pair describes a nondissipative system that makes statistical mechanical sense in reverse time. This property is intimately connected with the existence of a dual filtering problem. It is also connected with an information theoretic optimality of Bayesian estimation, investigated in its abstract form in [17].

The paper is structured as follows. Section 2 introduces the signal and filter models and evaluates the information theoretic quantities of interest. Section 3 derives the dual system and relates its information flows to those of the original. Section 4 defines entropic time derivatives for Markov processes and, in particular, a rate of interactive entropy production for the system comprising the signal and filter. Finally, a simple illustrative example is developed in section 5.

2. Information flow in Markov chain filters. This section investigates the information flows occurring between a discrete-state signal and its nonlinear filter based on observations of the "signal-plus-white-noise" variety. In the model we consider, both processes evolve over the finite time interval $[-T, T]$, and the observation comprises *initial* and *running* parts. This enables the study of transient effects since it permits the signal and filter to be initialized in any consistent state (including their joint invariant distribution, where one exists). By "consistent state" we mean that the average value of the filter variable (whose range is the space of probability measures on that of the signal) should equal the marginal distribution of the signal. The use of a *symmetric* time interval simplifies the discussion of the dual filter in section 3. All random quantities are defined on the complete probability space $(\Omega, \mathcal{F}, \mathbb{P})$.

The signal, X, is a measurable Markov process taking values in the finite set

$\mathbf{X} = \{1, 2, \ldots, n\}$, and having finite rate matrix A, so that

$$\mathbb{P}(X_{t+\epsilon} = i \mid X_t = j) = (I_n + A\epsilon)_{i,j} + o(\epsilon),$$

where I_n is the $n \times n$ matrix identity. Let $\mathcal{P}(\mathbf{X})$ be the set of probability measures on $\mathbf{X}$. We identify elements $Q \in \mathcal{P}(\mathbf{X})$ by the associated probability mass function in vector form:

$$c(Q) := \mathrm{vec}_i\{Q(\{i\})\}.$$

We shall be particularly interested in the convex subset of $\mathcal{P}(\mathbf{X})$ corresponding to probability mass functions that belong to the following set:

$$\mathbb{S}^{n-1} := \{z \in \mathbb{R}^n : z_i \in (0,1) \text{ for all } i;\ \Sigma_i z_i = 1\}.$$

We assume that the initial value of the signal, X_{-T}, has distribution $\theta \in \mathbb{S}^{n-1}$; the prior distribution of X_t, $p_X(t)$ $(= \exp(A(t+T))\theta)$, is then also in $\mathbb{S}^{n-1}$ for all t.

The initial observation is a random variable, ψ, taking values in a Borel space $(M, \mathcal{M}, \mu)$; it is X_{-T}-conditionally independent of X with X_{-T}-conditional density (with respect to μ) $q : \mathbf{X} \times M \to \mathbb{R}^+$. We assume that

$$\mathbf{E} \log(q(i,\psi)/q(j,\psi)) < \infty \quad \text{for all } i, j; \tag{2.1}$$

this ensures (among other properties) that the posterior distribution of X_{-T} is also in $\mathbb{S}^{n-1}$. The *running* observation takes the form

$$Y_t^r = \int_{-T}^t g(X_s)\, ds + W_t \quad \text{for } t \in [-T, T], \tag{2.2}$$

where $g : \mathbf{X} \to \mathbb{R}^d$, and W is a d-vector *shifted* Brownian motion, independent of (X, ψ); i.e., $(W_t = B_{T+t},\ t \in [-T, T])$, where B is a d-vector standard Brownian motion independent of (X, ψ). The *full* observation is then the $M \times \mathbb{R}^d$-valued process $Y = ((\psi, Y_t^r),\ t \in [-T, T])$.

Remark 2.1. *Multidimensional* running observations are included in this study since they play an essential role in section 4, where a relaxation argument is used to define interactive entropy production. Whatever the dimension of Y^r in the filtering problem of interest, a "relaxed" version, in which the dimension of the running observation is at least $n - 1$, is used in that context.

Throughout the paper, $\mathcal{F}_{s,t}^{\xi}$ will be used to signify the σ-field generated by a process ξ over the time interval $[s, t]$, where $-T \le s \le t \le T$:

$$\mathcal{F}_{s,t}^{\xi} := \sigma(\xi_r,\ r \in [s, t]). \tag{2.3}$$

Thus $(\mathcal{F}_{-T,t}^{Y},\ t \in [-T, T])$ is the filtration generated by the observations process.

Wonham's filter [21] is a recursive formula for calculating a continuous process $(Z_t \in \mathbb{R}^n,\ t \in [-T, T])$ with the property that Z_t is the $\mathcal{F}_{-T,t}^{Y}$-conditional distribution of X_t for all t. The initial value, Z_{-T}, is found from the initial prior, θ, the likelihood function, $q(\,\cdot\,, \psi)$, and Bayes's formula; subsequent values of Z are found from the following Itô equation, which has a strong solution (see [21] or [14]):

$$\begin{aligned} Z_t &= Z_{-T} + \int_{-T}^t (AZ_s - \sigma(Z_s)\bar{g}(Z_s))\, ds + \int_{-T}^t \sigma(Z_s)\, dY_s^r \\ &= Z_{-T} + \int_{-T}^t AZ_s\, ds + \int_{-T}^t \sigma(Z_s)\, d\nu_s. \end{aligned} \tag{2.4}$$

Here, $\bar{g} \in C_b^2(\mathbb{R}^n;\mathbb{R}^d)$, $\sigma \in C_b^2(\mathbb{R}^n;\mathbb{R}^{n\times d})$, and, for all $z \in \mathbb{S}^{n-1}$,

$$\begin{aligned} \bar{g}(z) &:= \Sigma_i g(i) z_i, \\ \sigma(z) &:= \mathrm{mat}_{i,l}\{(g(i) - \bar{g}(z))_l z_i\}, \end{aligned} \tag{2.5}$$

and ν is the innovations process,

$$\nu_t := Y_t^r - \int_{-T}^t \bar{g}(Z_s)\, ds. \tag{2.6}$$

Remark 2.2. The process Z remains in $\mathbb{S}^{n-1}$. (See Proposition 2.1.) The extension of the domains of definition of $\bar{g}$ and σ to the whole of $\mathbb{R}^n$ is purely a matter of convenience. It enables the use of standard results from the theory of stochastic differential equations in $\mathbb{R}^n$.

Remark 2.3. Unlike the problem addressed in this paper, the filtering problem in [21] (and most papers on nonlinear filtering) does not involve an initial observation. However, the extension of the results of that paper to the problem addressed here is straightforward. Since (2.4) has a strong solution, and Z_{-T} is X_{-T}-conditionally independent of X, the filtering problem can be thought of as a *family* of problems parametrized by the values of Z_{-T}, each problem having no initial observation. The "parameter" Z_{-T} is then the *prior* distribution for the initial signal value in the corresponding filtering problem. The family of distributions of the signal (respectively, observation, filter) processes of these problems is a regular Z_{-T}-conditional distribution for the signal (respectively, observation, filter) of this paper.

In order to derive some useful properties of X and Z, we introduce a measure transformation of the type first proposed by Duncan in [7]. Let $\mathbb{P}^M$ be the measure on $\mathcal{F}$, whose Radon–Nikodym derivative with respect to $\mathbb{P}$ is L_T, where

$$\begin{aligned} L_t = \frac{\chi(X_{-T})'\theta}{\chi(X_{-T})'Z_{-T}} \exp\Bigg(&- \int_{-T}^t (g(X_s) - \bar{g}(Z_s))'\, dW_s \\ &- \frac{1}{2}\int_{-T}^t |g(X_s) - \bar{g}(Z_s)|^2\, ds \Bigg) \quad \text{for } t \in [-T,T]. \end{aligned} \tag{2.7}$$

Here, and in what follows, $|\cdot|$ is the Euclidean norm in $\mathbb{R}^d$, and $\chi : \mathbf{X} \to \{0,1\}^n$ is the "occupancy" map

$$\chi(i) = \mathrm{vec}_j\{\mathbf{1}_{\{i\}}(j)\}, \tag{2.8}$$

where $\mathbf{1}_B$ is the indicator function of a set B.

PROPOSITION 2.1. (i) *The processes X, Z, and (X,Z) are Markov and have infinitesimal generators $\mathcal{L}^X$, $\mathcal{L}^Z$, and $\mathcal{L}^{X,Z}$, respectively, defined, for appropriate functions f, as follows:*

$$\begin{aligned} (\mathcal{L}^X f)(i) &= \sum_j A_{j,i}(f(j) - f(i)), \\ (\mathcal{L}^Z f)(z) &= \sum_j (Az)_j \frac{\partial f}{\partial z_j}(z) + \frac{1}{2}\sum_{j,k} (\sigma\sigma')(z)_{j,k} \frac{\partial^2 f}{\partial z_j \partial z_k}(z), \\ (\mathcal{L}^{X,Z} f)(i,z) &= \sum_j b(i,z)_j \frac{\partial f}{\partial z_j}(i,z) + \frac{1}{2}\sum_{j,k} (\sigma\sigma')(z)_{j,k} \frac{\partial^2 f}{\partial z_j \partial z_k}(i,z) \\ &\quad + \sum_j A_{j,i}(f(j,z) - f(i,z)), \end{aligned} \tag{2.9}$$

where, for each $i \in \mathbf{X}$, $b(i, \cdot) \in C_b^2(\mathbb{R}^n; \mathbb{R}^n)$ *and, for* $i \in \mathbf{X}$ *and* $z \in \mathbb{S}^{n-1}$,

$$b(i, z) := Az + \sigma(z)(g(i) - \bar{g}(z)). \tag{2.10}$$

(ii) *For each* $t \in [-T, T]$, $\mathcal{F}^X_{-T,T}$ *and* $\mathcal{F}^Y_{-T,t}$ *are* $\mathcal{F}^Z_{-T,t}$*-conditionally independent.*

(iii) *For each* $t \in [-T, T]$, $\mathcal{F}^{X,Z}_{-T,t}$ *and* $\mathcal{F}^X_{t,T}$ *are* X_t*-conditionally independent.*

(iv) *For each* $t \in [-T, T]$, $\mathcal{F}^Z_{-T,t}$ *and* $\mathcal{F}^{X,Z}_{t,T}$ *are* Z_t*-conditionally independent.*

(v) $\mathbb{P}(Z_t \in \mathbb{S}^{n-1} \text{ for all } t \in [-T, T]) = 1$, *and* $\sup_{i \in \mathbf{X},\, t \in [-T,T]} \mathbf{E} \log(Z^{-1}_{t,i}) < \infty$.

(vi) $\mathbb{P}^M$ *is a probability measure;* $\mathbb{P}$ *and* $\mathbb{P}^M$ *are mutually absolutely continuous.*

(vii) *Under* $\mathbb{P}^M$, $(L_t^{-1}, \mathcal{F}^{X,Z}_{-T,t})$ *is a martingale.*

(viii) *Under* $\mathbb{P}^M$, X *and* (Y, Z) *are independent processes but retain the marginal distributions they have under* $\mathbb{P}$.

Proof. See Appendix A. □

We define information *supply*, *storage*, and *dissipation* processes as follows: for each $t \in [-T, T]$,

$$\begin{aligned} S(t) &:= I(X\,;\,(Y_s,\, s \in [-T, t])), \\ C(t) &:= I((X_s,\, s \in [t, T])\,;\,(Y_s,\, s \in [-T, t])), \\ D(t) &:= S(t) - C(t), \end{aligned} \tag{2.11}$$

where, for random variables Θ and Φ taking values in measurable spaces and having joint and marginal distributions $\mathbb{P}_{\Theta,\Phi}$, $\mathbb{P}_\Theta$, and $\mathbb{P}_\Phi$, $I(\Theta\,;\,\Phi)$ is the *mutual information*:

$$I(\Theta\,;\,\Phi) := \begin{cases} \displaystyle\int \log\left(\frac{d\,\mathbb{P}_{\Theta,\Phi}}{d(\mathbb{P}_\Theta \otimes \mathbb{P}_\Phi)}\right) d\,\mathbb{P}_{\Theta,\Phi} & \text{if the integral exists,} \\ +\infty & \text{otherwise.} \end{cases} \tag{2.12}$$

Remark 2.4. Where one of the random quantities in $I(\,\cdot\,;\,\cdot\,)$ is a *stochastic process*, as is the case in (2.11), it is regarded as being a random variable taking values in a product space. Thus, if $(\eta_t,\ t \in [-T, T])$ is a stochastic process taking values in the space E, then η is regarded as being a random variable that takes values in the measurable space $(E^{[-T,T]}, \mathcal{B}_E^{[-T,T]})$, where $E^{[-T,T]}$ is the space of all maps $f : [-T, T] \to E$ and $\mathcal{B}_E^{[-T,T]}$ is the σ-field generated by the cylinder sets in $E^{[-T,T]}$. Thus, for example, the joint distribution $P_{X,Y}$ is a probability measure on $\mathcal{B}_{\mathbf{X}}^{[-T,T]} \times \mathcal{M} \times \mathcal{B}_{\mathbb{R}^d}^{[-T,T]}$. $S(t)$, $C(t)$, and $D(t)$ are insensitive to any choices we make about the nature of the sample paths of X, Y^r, and Z but depend only on their finite-dimensional distributions.

The reader should think of $S(t)$ (respectively, $C(t)$) as being the information about X (respectively, $(X_s,\, s \in [t, T])$) made available to the filter by the observations $(Y_s,\, s \in [-T, t])$. It follows from parts (ii), (iii), (vii), and (viii) of Proposition 2.1 and elementary manipulations of Radon–Nikodym derivatives that

$$\begin{aligned} S(t) &= I(X\,;\,(Z_s,\, s \in [-T, t])) \\ &= I((X_s,\, s \in [-T, t])\,;\,(Z_s,\, s \in [-T, t])) \\ &= \mathbf{E} \log(L_t^{-1}) \\ &= \mathbf{E} \sum_i \log\left(\frac{Z_{-T,i}}{\theta_i}\right) Z_{-T,i} + \frac{1}{2}\mathbf{E}\int_{-T}^{t} |g(X_s) - \bar{g}(Z_s)|^2\, ds. \end{aligned} \tag{2.13}$$

Similarly, it follows from parts (ii), (iii), and (iv) of Proposition 2.1 that

$$\begin{aligned} C(t) &= I((X_s,\, s\in[t,T])\,;\,(Z_s,\, s\in[-T,t])) \\ &= I(X_t\,;\,(Z_s,\, s\in[-T,t])) \\ &= I(X_t\,;\,Z_t) \\ &= \mathbf{E}\sum_i \log\left(\frac{Z_{t,i}}{p_X(t)_i}\right) Z_{t,i}. \end{aligned} \tag{2.14}$$

Itô's rule can be used to obtain a stochastic integral representation for the integrand here, and this shows that the storage $C(t)$ changes with rate

$$\dot{C}(t) = \mathbf{E}\sum_{i,j} \log\left(\frac{Z_{t,i}}{p_X(t)_i}\right) A_{i,j} Z_{t,j} + \frac{1}{2}\mathbf{E}\left|g(X_t) - \bar{g}(Z_t)\right|^2. \tag{2.15}$$

Thus the information dissipation, $D(t)$, takes the form

$$D(t) = -\mathbf{E}\int_{-T}^{t} \sum_{i,j} \log\left(\frac{Z_{s,i}}{p_X(s)_i}\right) A_{i,j} Z_{s,j}\, ds. \tag{2.16}$$

It follows from elementary properties of mutual information that both S and C take only nonnegative values. That the same is true of D follows from (2.18). Furthermore, $\dot{S}(t)$ is clearly nonnegative for all t, and since $\dot{D}(t) = \mathbf{E}f(Z_t) - f(\mathbf{E}Z_t)$, where f is the convex function $f(z) = -\sum_{i,j}\log(z_i)A_{i,j}z_j$, the same is true of $\dot{D}(t)$.

The connection between quantities equivalent to $S(t)$ and $D(t)$ for diffusion filters was investigated in [16]. It was shown there that the rate of change of $D(t)$ is essentially a Fisher information quantity. This is also the case for the discrete-state signal of this paper; in fact

$$\dot{D}(t) = -\mathbf{E}\left(\mathcal{L}^X \log\left(\frac{Z_{t,i}}{p_X(t)_i}\right)\right)(X_t), \tag{2.17}$$

and so $\dot{D}(t)$ is associated with the randomization of X as described by its infinitesimal generator, $\mathcal{L}^X$. The dissipation also has the following interpretation. Consider the problem of estimating $(X_s,\, s\in[t,T])$ given the "initial" observation $(Y_s,\, s\in[-T,t])$ and the running observation $(Y^r_s - Y^r_t,\, s\in[t,T])$. It follows from its definition that $C(t)$ is the initial information supply in this problem. Furthermore, arguments similar to those used to derive (2.13) show that the rate of information supply for this problem at time $s\in[t,T]$ is $\dot{S}(s)$. Thus, for any $t\in[-T,T]$,

$$\begin{aligned} I((X_s,\, s\in[t,T])\,;\,Y) &= C(t) + \frac{1}{2}\mathbf{E}\int_t^T \left|g(X_s) - \bar{g}(Z_s)\right|^2 ds \\ &= S(T) - D(t). \end{aligned} \tag{2.18}$$

So $D(t)$ is that part of the information on X, derived from Y, that is of no use in estimating the values of X at and beyond time t. It is shown in section 3 that $D(t)$ is itself an (average) mutual information.

3. The dual filter. This section explores the time-reversed dynamics of the joint process (X,Z) under both $\mathbb{P}$ and $\mathbb{P}^M$, and shows that they are the dynamics of a dual system, in which Z is a signal process and X its filter.

Let $(\tilde{Z}_t\in\mathbb{R}^{n-1},\, t\in[-T,T])$ be the following parametrization of the filter:

$$\tilde{Z}_t := \Gamma Z_t = [I_{n-1}\ 0]\, Z_t \quad \text{for all } t\in[-T,T]. \tag{3.1}$$

We assume the following:

(H1) $\tilde{Z}_{-T}$ has a square-integrable density with respect to Lebesgue measure.

The following technical lemma prepares the way for time reversal.

LEMMA 3.1. *Suppose that* (H1) *holds; then, for almost every* t*, the distribution of* $\tilde{Z}_t$ *has a density,* $p_{\tilde{Z}}(\,\cdot\,,t)$.

Proof. $\tilde{Z}$ is the unique solution on $(\Omega,\mathcal{F},\mathbb{P},Z_{-T},\nu)$ of the following equation:

$$\tilde{Z}_t = \Gamma Z_{-T} + \int_{-T}^{t} \Gamma A\tilde{\gamma}(\tilde{Z}_s)\,ds + \int_{-T}^{t} \Gamma\sigma\circ\tilde{\gamma}(\tilde{Z}_s)\,d\nu_s, \tag{3.2}$$

where $\tilde{\gamma}\in C_b^2(\mathbb{R}^{n-1};\mathbb{R}^n)$ and $\tilde{\gamma}(\Gamma z)=z$ for all $z\in\mathbb{S}^{n-1}$. The statement of the lemma follows from (H1), the Lipschitz continuity and boundedness of $A\tilde{\gamma}$ and $\sigma\circ\tilde{\gamma}$, the boundedness of the first two derivatives of $\sigma\circ\tilde{\gamma}$, and Theorem 3.1 in [12]. □

For each $t\in[-T,T]$ and each $z\in\mathbb{R}^n$, let

$$\begin{aligned} X_t^* &:= Z_{-t},\\ Z_t^* &:= X_{-t},\\ \bar{b}(z,t) &:= -Az + \operatorname{vec}_i\left\{\sum_j \frac{\partial(\sigma\sigma')_{i,j}}{\partial z_j}\right\}(z) + (\sigma\sigma')(z)\Gamma'\frac{(\nabla_{\tilde{z}}p_{\tilde{Z}})(\Gamma z,-t)}{p_{\tilde{Z}}(\Gamma z,-t)}, \end{aligned} \tag{3.3}$$

where $\bar{b}$ is taken to be zero at any (z,t) for which $p_{\tilde{Z}}(\Gamma z,-t)$ is zero, and $\nabla_{\tilde{z}}p_{\tilde{Z}}$ is the gradient of $p_{\tilde{Z}}$ with respect to its first argument; the latter is understood in the sense of distributions if $p_{\tilde{Z}}(\,\cdot\,,t)$ is not differentiable. For each $t\in[-T,T]$ and $z\in\mathbb{S}^{n-1}$, let $\bar{A}(t)$ and $\breve{A}(z)$ be $n\times n$ Markov rate matrices defined as follows:

$$\begin{aligned} \bar{A}(t)_{i,j} &= A_{j,i}\frac{p_X(-t)_i}{p_X(-t)_j} \quad\text{and}\quad \breve{A}(z)_{i,j} = A_{j,i}\frac{z_i}{z_j} \quad \text{if } j\neq i,\\ \bar{A}(t)_{i,i} &= -\sum_{j\neq i}\bar{A}(t)_{j,i} \quad\text{and}\quad \breve{A}(z)_{i,i} = -\sum_{j\neq i}\breve{A}(z)_{j,i}. \end{aligned} \tag{3.4}$$

THEOREM 3.2. *The processes* X^**,* Z^**, and* (X^*,Z^*) *are Markov and have infinitesimal generators* $\mathcal{L}_t^{X^*}$*,* $\mathcal{L}_t^{Z^*}$*, and* $\mathcal{L}_t^{X^*,Z^*}$*, respectively, defined, for appropriate functions* f*, as follows:*

$$\begin{aligned} (\mathcal{L}_t^{X^*}f)(z) &= \sum_j \bar{b}(z,t)_j\frac{\partial f}{\partial z_j}(z) + \frac{1}{2}\sum_{j,k}(\sigma\sigma')(z)_{j,k}\frac{\partial^2 f}{\partial z_j\partial z_k}(z),\\ (\mathcal{L}_t^{Z^*}f)(i) &= \sum_j \bar{A}(t)_{j,i}(f(j)-f(i)),\\ (\mathcal{L}_t^{X^*,Z^*}f)(z,i) &= \sum_j \bar{b}(z,t)_j\frac{\partial f}{\partial z_j}(z,i) + \frac{1}{2}\sum_{j,k}(\sigma\sigma')(z)_{j,k}\frac{\partial^2 f}{\partial z_j\partial z_k}(z,i)\\ &\quad + \sum_j \breve{A}(z)_{j,i}(f(z,j)-f(z,i)). \end{aligned} \tag{3.5}$$

Proof. See Appendix B. □

We can regard X^* and Z^* as being the signal and filter processes of a dual problem. The dual signal X^* is a Markov process in its own right, evolving on the state space $\mathbb{S}^{n-1}$ and having the infinitesimal generator $\mathcal{L}_t^{X^*}$. The $\mathbf{X}$-valued process Z^* is a filter for this dual signal in the sense that Z_t^* is a sufficient statistic for estimating

the future of X^* from the past of Z^*, as is shown by the following argument. For any bounded, measurable $f : \mathbb{S}^{n-1} \to \mathbb{R}$ and any $B \in \mathcal{F}^X_{t,T}$,

$$\begin{aligned}\int_B \mathbf{E}\left(f(Z_t) \,|\, \mathcal{F}^X_{t,T}\right) d\,\mathbb{P} &= \int_B f(Z_t)\, d\,\mathbb{P} \\ &= \int \mathbf{E}(\mathbf{1}_B f(Z_t) \,|\, X_t)\, d\,\mathbb{P} \\ &= \int \mathbf{E}(\mathbf{1}_B \,|\, X_t)\mathbf{E}(f(Z_t) \,|\, X_t)\, d\,\mathbb{P} \\ &= \int_B \mathbf{E}(f(Z_t) \,|\, X_t)\, d\,\mathbb{P},\end{aligned}$$

where the third step follows from part (iii) of Proposition 2.1. Thus

$$\mathbf{E}\left(f(X^*_t) \,|\, \mathcal{F}^{Z^*}_{-T,t}\right) = \mathbf{E}\left(f(X^*_t) \,|\, Z^*_t\right) \quad \text{a.s.}$$

A straightforward application of Bayes's formula shows that the Z^*_t-conditional distribution of X^*_t has the form

$$\begin{aligned}P_{X^*|Z^*}(B, i, t) &= \mathbb{P}(Z_{-t} \in B \mid X_{-t} = i) \\ &= \frac{\mathbf{E}Z_{-t,i}\mathbf{1}_B(Z_{-t})}{\mathbb{P}(X_{-t} = i)} \\ &= \int_{\Gamma B} \frac{\tilde{\gamma}(\tilde{z})_i p_{\tilde{Z}}(\tilde{z}, -t)}{p_X(-t)_i}\, d\tilde{z}.\end{aligned} \tag{3.6}$$

Clearly we could also regard Z^* as being the dual observation process. However, there are other possibilities. Any dual observation process $(Y^*_t,\ t \in [-T, T])$ must satisfy the following two conditions:

(O1) $\mathcal{F}^{Y^*}_{-T,t} \supseteq \mathcal{F}^{Z^*}_{-T,t}$ for all $t \in [-T, T]$;

(O2) X^* and $\mathcal{F}^{Y^*}_{-T,t}$ are $\mathcal{F}^{Z^*}_{-T,t}$-conditionally independent for all $t \in [-T, T]$.

The first of these requires that the dual filter should be derivable from the dual observations; the second requires that any randomness in Y^* that is not in Z^* should bear no additional information about X^*.

Remark 3.1. The observation process of the original filtering problem in section 2 obviously satisfies the equivalent of (O1); that it also satisfies the equivalent of (O2) is demonstrated in part (ii) of Proposition 2.1.

The following two examples of dual observation processes satisfy (O1) and (O2). For ease of construction, we (temporarily) assume that Z^* has right-continuous paths with left limits.

Example 3.1. Let $(Y^*_t,\ t \in [-T, T])$ be the n-vector process whose ith component is defined as follows:

$$Y^*_{t,i} = \mathbf{1}_{\{i\}}(Z^*_{-T}) + \sum_{s \in (-T,t]} \left(1 - \mathbf{1}_{\{i\}}(Z^*_{s-})\right)\left(\chi(Z^*_s) - \chi(Z^*_{s-})\right)_i. \tag{3.7}$$

Y^* is a vector of counting processes; its ith component increments by one whenever Z^* jumps into state i. Conditions (O1) and (O2) are trivially satisfied for this Y^* since $\mathcal{F}^{Y^*}_{-T,t} = \mathcal{F}^{Z^*}_{-T,t}$ for all t. Note, however, that $\mathcal{F}^{Y^*}_{t,t}$ is not in general the same as $\mathcal{F}^{Z^*}_{t,t}$, and so there is some work for the filter to do; in fact $Z^*_t = \chi^{-1}(Y^*_{-T})$ if no component of Y^* jumps during the interval $(-T, t]$; otherwise

$$Z^*_t = \arg\max_i \left\{\max\{s \in (-T, t] : (Y^*_{s,i} - Y^*_{s-,i}) = 1\}\right\}.$$

The observation process here generates the same filtration as does the filter process, a property that is not as unnatural as it may seem at first sight. In fact it is shared by the original filtering problem of section 2 in the special case that there is no initial observation, the dimension of the running observation d is one, and $g(i) \neq g(j)$ for at least one pair $i, j \in \mathbf{X}$.

Example 3.2. Let $(B_k \in \{0,1\},\ k = 0,1,\ldots)$ be a sequence of independent Bernoulli random variables, independent of (X^*, Z^*), with $\mathbb{P}(B_k = 0) = \mathbb{P}(B_k = 1) = 0.5$. Let

$$Y_t^* = 2Z_t^* + \sum_{k=0}^{N_t} B_k,$$

where $N_t = \#\{s \in (-T,t] : Z_s^* - Z_{s-}^* \neq 0\}$. The observation filtration here, $\mathcal{F}_{-T,t}^{Y^*}$, is strictly larger than that generated by the filter process. However, condition (O2) is satisfied since the source of the additional randomness, (B_k), is independent of (X^*, Z^*). Condition (O1) is satisfied since

$$\begin{aligned} Z_{-T}^* &= [0.5Y_{-T}^*], \\ Z_t^* - Z_{t-}^* &= \left[0.5(Y_t^* - Y_{t-}^*)\right] \quad \text{for } t \in (-T,T], \end{aligned}$$

where, for $u \in \mathbb{R}$, $[u]$ is the largest integer less than or equal to u. The additional randomness in the observations here may appear, at first sight, to be rather superficial. However, this is because the observation process is expressed in terms of the *filter* process, rather than the signal. Of course, having constructed the observation in this way we could express it purely in terms of X^* by integrating out Z^* according to its X^*-conditional distribution.

The dual filter is a very particular example of a *finite-dimensional* nonlinear filter. The dual signal is a multidimensional diffusion process with nonlinear dynamics, and the components of the dual observation process are Markov-modulated point processes. In general, problems of this nature lead to infinite-dimensional nonlinear filters. Here, because of the special connection between the prior distribution and dynamics of X^*, and the observation mechanism, the nonlinear filter is not only finite dimensional but even evolves on a finite space.

In analogy with the definitions of $S(t)$, $C(t)$, and $D(t)$ in section 2, we can identify the information supply, storage, and dissipation of the dual filter as follows:

$$\begin{aligned} S^*(t) &:= I(X^*\,;\,(Y_s^*,\ s \in [-T,t])), \\ C^*(t) &:= I((X_s^*,\ s \in [t,T])\,;\,(Y_s^*,\ s \in [-T,t])), \\ D^*(t) &:= S^*(t) - C^*(t). \end{aligned} \tag{3.8}$$

The dual supply, like $S(t)$, could be found by a measure transformation technique involving an integral formula for the dual martingale

$$L_t^* = \mathbf{E}\left(L_T \,|\, \mathcal{F}_{-T,t}^{X^*,Z^*}\right), \tag{3.9}$$

where L is as defined in (2.7). However, there is an easier way of finding S^*. It follows from (O2), part (ii) of Proposition 2.1, and (2.18) that

$$\begin{aligned} S^*(t) &= I((X_s,\ s \in [-t,T])\,;\,Z) \\ &= S(T) - D(-t). \end{aligned} \tag{3.10}$$

Furthermore, as in (2.14), it follows from (O2) that

$$\begin{aligned} C^*(t) &= I((X_s,\, s\in[-t,T])\,;\,(Z_s,\, s\in[-T,-t])) \\ &= C(-t), \end{aligned} \tag{3.11}$$

and so

$$D^*(t) = S(T) - S(-t). \tag{3.12}$$

This shows that the time-reversed information flows for the original problem can be interpreted as the forward-time information flows for the dual problem, with information supply and dissipation swapping roles.

Like $\dot{D}$ in (2.17), $\dot{D}^*$ is associated with the randomization of the dual signal, as described by its infinitesimal generator, $\mathcal{L}^{X^*}$. In fact

$$\dot{D}^*(t) = -\mathbf{E}\left(\mathcal{L}^{X^*}\log\left(\frac{\chi(Z^*_t)'z}{\chi(Z^*_t)'p_X(-t)}\right)\right)(X^*_t). \tag{3.13}$$

It may seem, at first sight, that $\dot{S}^*(-t)$ should equal $\dot{S}(t)$ since both concern the supply of information between X and Z over the short time interval $[t,t+\delta t]$. That this is not so is because S and S^* are *cumulative* information quantities with derivatives that represent the flow rate of *new* information. What constitutes new information between X and Z depends on the time direction over which it is being accumulated. Over the time interval $[t,t+\delta t]$ an amount $S(t+\delta t)-S(t)\approx\dot{S}(t)\delta t$ of new information is supplied in the original problem. Because this is new, it relates to a dependency between $X_{t+\delta t}$ and $Z_{t+\delta t}$ that is not present between $(X_s,\, s\in[-T,t])$ and $(Z_s,\, s\in[-T,t])$. It is present in $C(t+\delta t)$ $(=C^*(-t-\delta t))$, and therefore useful to the dual filter at time $-t-\delta t$, but not present in $C(t)$ $(=C^*(-t))$, and therefore no longer useful to the dual filter at time $-t$. For this reason the dual filter dissipates it and $\dot{D}^*(-t)=\dot{S}(t)$.

4. Entropic derivatives. This section further investigates the interaction between the components of the joint process (X,Z). Parts (iii) and (iv) of Proposition 2.1 show that, in forward time, the evolution of X at time t is influenced only by the first component of (X_t,Z_t) and that, in reverse time, the evolution of Z is influenced only by the second component. These properties result in unidirectional flows of entropy between the two components. Let $S_X(t)$, $S_Z(t)$, and $S_{X,Z}(t)$ be the entropies of X_t, Z_t, and (X_t,Z_t), respectively:

$$\begin{aligned} S_X(t) &:= -\mathbf{E}\log\left(\chi(X_t)'p_X(t)\right), \\ S_Z(t) &:= -\mathbf{E}\log\left(p_{\tilde{Z}}(\Gamma Z_t,t)\right), \\ S_{X,Z}(t) &:= -\mathbf{E}\log\left(\chi(X_t)'Z_t p_{\tilde{Z}}(\Gamma Z_t,t)\right). \end{aligned} \tag{4.1}$$

(S_Z is defined in terms of a *uniform* measure on $\mathbb{S}^{n-1}$, whose total mass is $\int_{\Gamma\mathbb{S}^{n-1}} d\tilde{z}$.)

As t increases, $S_X(t)$ can increase, decrease, or remain constant according to the distribution $p_X(t)$. Whichever of these happens, X_t acquires "new" entropy from the random switching and loses "old" entropy as it "forgets its past." If X has an invariant distribution, then these two effects are balanced in that distribution. The same is true of $S_Z(t)$, except that part of the "new" entropy acquired by Z_t comes from X_t, (the remainder having its origin in the observation noise). This intuition can be made precise from a consideration of the *side* entropies:

$$S_{X|Z}(t) := S_X(t) - I(X_t\,;\,Z_t) \quad\text{and}\quad S_{Z|X}(t) := S_Z(t) - I(X_t\,;\,Z_t).$$

The common term here $I(X_t\,;\,Z_t)$ $(= C(t))$ is a *shared* component of the joint entropy $S_{X,Z}(t)$. In fact

$$S_{X,Z}(t) = S_{X|Z}(t) + C(t) + S_{Z|X}(t). \tag{4.2}$$

The sum of the first two components on the right-hand side of (4.2) is the signal entropy $S_X(t)$. Its rate of change would not be altered if we were to "turn off" the observation mechanism at time t (which could be achieved by setting the observation function, g, to zero); however, such action would reduce the rate of change of C by the amount $\dot{S}(t)$. From this we can deduce that there is a *flow* of entropy from the first component to the second component on the right-hand side of (4.2) of rate $\dot{S}(t)$. (The term "flow" is justified because the entropy changes in question are conservative.) This flow is strictly one way because of the optimality of the filter, which never discards any information that is relevant to the present and future of the signal.

Similarly, the sum of the second and third components on the right-hand side of (4.2) is the entropy of the dual signal $S_{X^*}(-t)$ $(= S_Z(t))$. Its rate of change would not be affected if we were to "turn off" the dual observation mechanism at (reverse) time $-t$ (which could be achieved by replacing $\breve{A}(X^*_{-t})$ by $\bar{A}(-t)$). However, a simple rearrangement of (2.17) shows that

$$\dot{S}^*(-t) = \mathbf{E} \sum_{i,j:\, A_{i,j}>0} \log\left(\frac{\breve{A}(X^*_{-t})_{i,j}}{\bar{A}(-t)_{i,j}}\right) A_{j,i} X^*_{-t,i}, \tag{4.3}$$

which in turn shows that this action would reduce the rate of change of C^* by the amount $\dot{S}^*(-t)$. From this we can deduce that, in forward time, there is a flow of entropy from the second component to the third component on the right-hand side of (4.2) of rate $\dot{S}^*(-t)$ $(= \dot{D}(t))$. Once again, this is conservative and strictly one way. Of course, these entropy flows are the *information* flows of sections 2 and 3.

In the theory of nonequilibrium statistical mechanics based on stochastic dynamics (see, for example, [3], [11], [13], and [15]), invariant distributions of Markov processes are used to model *stationary states* of statistical mechanical systems. The latter come in two varieties called *equilibrium* and *nonequilibrium* states. Nonequilibrium states represent time-invariant states in which there is a nonzero flow of some physical quantity (often energy). For example, if the two ends of a cylinder of gas are held at different fixed temperatures, a stationary nonequilibrium state is eventually set up in the gas in which energy flows from the hotter end to the cooler end. The state is *stationary* in the sense that the temperature profile along the cylinder does not change with time; it is *nonequilibrium* in the sense that there is a nonzero flow of energy through the system in the state. One of the fundamental features of thermodynamics is that energy flow down a temperature gradient is accompanied by entropy increase.

The joint process (X, Z) of this paper is Markov, and so it can be associated with an abstract statistical mechanical system. This analogy is developed in [18] and [20], where it is shown that the signal-filter pair models a nondissipative system lying on the boundary between systems that do and do not satisfy the second law of thermodynamics. In the analogy, the unidirectional flow of entropy identified above is accompanied by a unidirectional flow of energy that is not driven by temperature gradients. This does not cause entropy increase, and so it makes statistical mechanical sense in reverse time—a property connected with the existence of a dual system.

In what follows, we define an *entropic time derivative* for Markov processes and explore its connections with the information flows of sections 2 and 3. In [13], a

rate of entropy flow is identified for stationary nonequilibrium states of certain time-homogeneous Markov processes. This involves large-time limits of the forward and backward dynamics of the process in its stationary state. A *rate of entropy production* for nonstationary states is then defined in terms of this quantity and the rate of change of entropy of the state (cf. $\dot{S}_X(t)$ above). Despite the name, a positive rate of entropy production does not always imply that the physical system modelled causes entropy increase, merely that its dynamics reveal the direction of time. The rate of entropy production of [13] subsumes entropy changes and (conservative) entropy flows. The entropic time derivative defined below coincides with the rate of entropy production of [13] when the process in question is time-homogeneous and admits an invariant distribution. However, since it involves small-time limits, it is inherently dynamical in nature and is equally applicable to time-inhomogeneous processes such as the dual signal process of section 3. We call the entropic time derivative a "rate of entropy production" because of this connection with statistical mechanics.

Let $(\eta_t,\ t \in [a,b])$ be a Markov process defined on a complete probability space and taking values in a Borel space $(E,\mathcal{E})$. For any $t \in (a,b)$, let $\bar{\epsilon} := \min\{t-a,\, b-t\}$, and let $G := (\mathcal{G}_\epsilon \subseteq \mathcal{B}_E^{[0,\epsilon]},\ 0 < \epsilon < \bar{\epsilon})$ be a family of σ-fields parametrized by ϵ. For each ϵ, $\mathcal{G}_\epsilon$ is a sub-σ-field of $\mathcal{B}_E^{[0,\epsilon]}$ (the σ-field on $E^{[0,\epsilon]}$, generated by the cylinder sets). Let $\Pi^\eta_{t,t+\epsilon}$ and $\Pi^\eta_{t,t-\epsilon}$ be the distributions of the processes $(\eta_{t+s},\ s \in [0,\epsilon])$ and $(\eta_{t-s},\ s \in [0,\epsilon])$, respectively, on the common space $(E^{[0,\epsilon]}, \mathcal{B}_E^{[0,\epsilon]})$. Let $\Pi^{\eta,G}_{t,t+\epsilon}$ and $\Pi^{\eta,G}_{t,t-\epsilon}$ be the restrictions of $\Pi^\eta_{t,t+\epsilon}$ and $\Pi^\eta_{t,t-\epsilon}$ to $\mathcal{G}_\epsilon$. For probability measures $\mathbb{P}_a$ and $\mathbb{P}_b$ on a measurable space $(N,\mathcal{N})$, let $h(\mathbb{P}_a|\mathbb{P}_b)$ be the *relative entropy*:

$$h(\mathbb{P}_a|\mathbb{P}_b) := \begin{cases} \displaystyle\int \log\left(\frac{d\,\mathbb{P}_a}{d\,\mathbb{P}_b}\right) d\,\mathbb{P}_a & \text{if } \mathbb{P}_a \ll \mathbb{P}_b \text{ and the integral exists,} \\ +\infty & \text{otherwise.} \end{cases} \tag{4.4}$$

Definition 4.1. (i) *The rate of entropy production (entropic time derivative) of the process η at time t* with respect to the family G *is*

$$R_{\eta,G}(t) := \limsup_{\epsilon \downarrow 0} \epsilon^{-1} \mathbf{E} h\left(\Pi^{\eta,G}_{t,t+\epsilon} \,|\, \Pi^{\eta,G}_{t,t-\epsilon}\right). \tag{4.5}$$

(ii) *The* path *rate of entropy production of the process η at time t is its rate of entropy production with respect to the family $\{\mathcal{G}_\epsilon = \mathcal{B}_E^{[0,\epsilon]},\ 0 < \epsilon < \bar{\epsilon}\}$.*

(iii) *The* point *rate of entropy production of the process η at time t is its rate of entropy production with respect to the family $\{\mathcal{G}_\epsilon = (\phi_0, \phi_\epsilon)^{-1}(\mathcal{E}^2),\ 0 < \epsilon < \bar{\epsilon}\}$, where ϕ is the coordinate function on $E^{[0,\epsilon]}$.*

Remark 4.1. $R_{\eta,G}$ depends only on the finite-dimensional distributions of η, and is not influenced by the choice of *versions* of η, for the same reason that this is true of S, C, and D. (See Remark 2.4.)

Remark 4.2. The initial-time marginals of $\Pi^\eta_{t,t+\epsilon}$ and $\Pi^\eta_{t,t-\epsilon}$ are the same (they are both the distribution of η_t). So, if the paths of η take values in a Polish space (for example the Skorohod space $D([0,\infty);E)$, where E is a Polish space), then the relative entropy in part (ii) (respectively, part (iii)) can also be thought of as that between regular conditional forward and backward path (respectively, point) *transition* measures.

$R_{\eta,G}(t)$ is a measure of the *time asymmetry* of the process η at time t. Consider a game in which one player secretly takes a segment of the sample path of η between

times $t-\epsilon$ and $t+\epsilon$, tosses a coin, reversing the time direction of the segment if "heads" occurs, and then shows the segment to the second player, asking whether or not it has been reversed. $R_{\eta,G}(t)$ is a measure of how easily the second player, knowing only the forward and backward generators of the process, could answer correctly. It follows from the convexity of the function $x \mapsto x \log x$ and Jensen's inequality that if families G_1 and G_2 are such that $\mathcal{G}_{1,\epsilon} \subseteq \mathcal{G}_{2,\epsilon}$ for all ϵ, then $R_{\eta,G_1}(t) \leq R_{\eta,G_2}(t)$, and so the measures of time asymmetry, $R_{\eta,G}$, become sharper as the families of σ-fields, G, become richer. The sharpest measure is the *path* rate of entropy production.

We do not dwell here on the properties of $R_{\eta,G}$ in the general case but proceed to investigate it in the context of the filtering problems of sections 2 and 3. Since the information quantities $S(t)$, $D(t)$, $S^*(t)$, and $D^*(t)$ are defined in terms of path measures, and since we aim to connect rates of entropy production with these information quantities, we shall concentrate on *path* rates of entropy production and omit the subscript G from R_η. We shall make use of the following conditions; these are *not* all required in the main result of this section (Proposition 4.4).

(H2) $A_{i,j} > 0$ for any $i, j \in \mathbf{X}$ for which $A_{j,i} > 0$.

(H3) $d = n-1$, and $\operatorname{rank}\{\sigma(z)\} = n-1$ for all $z \in \mathbb{S}^{n-1}$.

(H4) $\max_{i,j} \mathbf{E}(q(i,\psi)/q(j,\psi))^2 < \infty$, where ψ is the initial observation and q is the likelihood function of (2.1).

(H5) For a specified $t \in (-T,T)$, there is an $\epsilon > 0$ such that $p_{\tilde{Z}}(\tilde{z},s)$ is differentiable with respect to $\tilde{z}$ for all $s \in [t-\epsilon, t]$, and $\mathbf{E}\,|\sigma(Z_{t+r})'\Gamma'(\nabla_{\tilde{z}} \log p_{\tilde{Z}})(\Gamma Z_{t+r}, t-|r|)|^2$ is bounded and continuous as a function of r on the interval $r \in (-\epsilon, \epsilon)$.

PROPOSITION 4.2. (i) *Let R_X and R_{Z^*} be the path rates of entropy production of the signal process, X, and its time reversal, Z^*. Then, for each $t \in (-T,T)$,*

(4.6)
$$R_X(t) = R_{Z^*}(-t) = \begin{cases} \displaystyle\sum_{i,j:\, A_{i,j}>0} \log\left(\frac{A_{i,j}}{\bar{A}(-t)_{i,j}}\right) A_{i,j} p_X(t)_j & \text{if (H2) is satisfied,} \\ +\infty & \text{otherwise.} \end{cases}$$

(ii) *Let R_Z and R_{X^*} be the path rates of entropy production of the filter process, Z, and its time reversal, X^*. If* (H1), (H3), *and* (H4) *are satisfied, then, for each $t \in (-T,T)$ for which* (H5) *is satisfied,*

$$R_Z(t) = R_{X^*}(-t) = \frac{1}{2}\mathbf{E}\left|(\Gamma\sigma(Z_t))^{-1}\Gamma(AZ_t - \bar{b}(Z_t,-t))\right|^2 < \infty. \tag{4.7}$$

(iii) *Let $R_{X,Z}$ and R_{X^*,Z^*} be the path rates of entropy production of the joint process, (X,Z), and its time reversal, (Z^*,X^*). If* (H1)–(H4) *are satisfied, then, for each $t \in (-T,T)$ for which* (H5) *is satisfied,*

$$\begin{aligned} R_{X,Z}(t) = R_{X^*,Z^*}(-t) = {} & \frac{1}{2}\mathbf{E}\left|(\Gamma\sigma(Z_t))^{-1}\Gamma(b(X_t,Z_t) - \bar{b}(Z_t,-t))\right|^2 \\ & + \mathbf{E}\sum_{i,j:\, A_{i,j}>0} \log\left(\frac{A_{i,j}}{\breve{A}(Z_t)_{i,j}}\right) A_{i,j} Z_{t,j} < \infty. \end{aligned} \tag{4.8}$$

Proof. See Appendix C. □

Remark 4.3. Parts (ii) and (iii) of Proposition 4.2 are not in their ripest form, in that condition (H5) is not easy to verify. It would clearly be preferable to replace it by explicit conditions on the parameters n, A, d, g, etc. The main difficulty with

such a result is that of establishing suitable regularity properties for $p_{\tilde{Z}}$—the forward equation for $p_{\tilde{Z}}$ is not uniformly parabolic, and this is a condition in many results concerning explicit bounds on solutions and their derivatives. (See, for example, [10].) Where explicit bounds are available, for example in [1], they are not sufficiently tight for the purposes of establishing (H5). However, (H5) is only marginally stronger than the finiteness of the right-hand sides in (4.7) and (4.8). The term in (H5) also occurs in the Itô expansion of $\log(p_{\tilde{Z}}(\Gamma Z_t, t))$, and so (H5) is connected with the finiteness of the rate of change of entropy of the filter, $\dot{S}_Z(t)$. For example, if (X_t, Z_t) is in an invariant distribution with twice differentiable $\tilde{Z}_t$-marginal density $p_{\tilde{Z},SS}$ and $S_{Z,SS} > -\infty$, then a comparison of the terms in $\log(M_1(x))$ of Appendix C with those of the Itô expansion of $\log(p_{\tilde{Z},SS}(\Gamma Z_t))$ shows that (H5) is satisfied, and

$$\frac{1}{2}\mathbf{E}\left|\sigma(Z_t)'\Gamma'(\nabla_{\tilde{z}}\log p_{\tilde{Z},SS})(\Gamma Z_t)\right|^2 = -\operatorname{tr}(A) + \frac{1}{2}\sum_{i,j}\mathbf{E}\frac{\partial^2(\sigma\sigma')_{i,j}}{\partial z_i \partial z_j}(Z_t).$$

Remark 4.4. When regarded as an equation on $\Gamma B_m \times (-T, T)$, where $B_m = \{z \in \mathbb{S}^{n-1} : z_i > m^{-1} \text{ for all } i\}$, the forward equation for $p_{\tilde{Z}}$ *is* uniformly parabolic; this observation can be used as the basis for a definition of a *local* path rate of entropy production for Z and (X, Z) with respect to the sequence of sets (B_m). This is the lim sup, over m, of the path rate of entropy production of the processes Z and (X, Z), *stopped* at the exit time of the forward and backward processes $(Z_{t+s},\ s \in [0, \epsilon])$ and $(X^*_{-t+s},\ s \in [0, \epsilon])$ from B_m. Condition (H5) is easily verified for these stopped processes, and Z, X^*, (X, Z), and (X^*, Z^*) can be shown to have local path rates of entropy production equal to the derivatives of Proposition 4.2 under mild, explicit conditions. However, unlike R_η of Definition 4.1, this local rate depends on the choice of a specific version of Z. We do not pursue it further in this paper.

Remark 4.5. If (H3) is not satisfied, then, except in special cases, R_Z, R_{X^*}, $R_{X,Z}$, and R_{X^*,Z^*} are all infinite. This is because the components of the vector fields $\Gamma A Z_t$ and $\Gamma\bar{b}(Z_t, -t)$ in the kernel of $\Gamma\sigma(Z_t)\sigma(Z_t)'\Gamma'$ can differ, resulting in the mutual singularity of $\Pi^Z_{t,t+\epsilon}$ and $\Pi^Z_{t,t-\epsilon}$.

Remark 4.6. Proposition 4.2 shows that (at least for the processes of this paper under (H1)–(H5)) the path rate of entropy production is *time symmetric*—the rates for the forward and time-reversed processes are identical, even though $h(\Pi^\eta_{t,t+\epsilon} \,|\, \Pi^\eta_{t,t-\epsilon}) \neq h(\Pi^\eta_{t,t-\epsilon} \,|\, \Pi^\eta_{t,t+\epsilon})$ in general. This is because the negation caused by the inversion of the Radon–Nikodym derivative in $h(\Pi^\eta_{t,t+\epsilon} \,|\, \Pi^\eta_{t,t-\epsilon})$ is countered, in the limit of small ϵ, by the change of integrating measure.

The fact that X and Z are both marginally and jointly Markov can be used to isolate a component of their joint path rate of entropy production that is purely associated with their *interaction*. If conditions (H1)–(H4) are satisfied, and (H5) is satisfied for a given t, then an *interactive* path rate of entropy production can be defined by simple subtraction. A straightforward calculation then shows that

$$R_I(t) := R_{X,Z}(t) - R_X(t) - R_Z(t) = \dot{S}(t) + \dot{D}(t). \tag{4.9}$$

Clearly, the interactive path rate of the dual problem at time $-t$ also takes this value. Thus the time asymmetry of the *interaction* between the signal and filter processes, as measured by the path rate of entropy production, is entirely associated with the flow of information between the processes. The reason for this property becomes apparent when the Radon–Nikodym derivative $d\Pi^{X,Z}_{t,t+\epsilon}/d\Pi^{X,Z}_{t,t-\epsilon}$ is factorized in terms of the likelihood functions of the original and dual filters. (See (C.3), (C.6), (C.7), and

(C.8) in Appendix C.) It is closely related to the time symmetry property discussed in Remark 4.6. Since R_I is purely associated with the conservative flows of information, $\dot{S}$ and $\dot{D}$, it could also be called a rate of interactive entropy *flow*.

The sum of the supply and dissipation rates, $\dot{S}(t) + \dot{D}(t)$, is finite under much weaker conditions than (H1)–(H5), and so it is natural to ask whether one can define a rate of interactive entropy production for filtering problems not satisfying these conditions. In fact this can be done via a relaxation argument.

Let $(\Phi^k := (\Omega^k, \mathcal{F}^k, \mathbb{P}^k, X^k, \psi^k, Y^{k,r}, Z^k),\ k \in \mathbb{N})$ be a sequence of filtering problems similar to that of section 2. More precisely, for each k, let X^k be an $\mathbf{X}$-valued Markov process with initial distribution $\theta^k \in \mathbb{S}^{n-1}$ and rate matrix A^k; let ψ^k $(\in M^k)$ be an initial observation that is X^k_{-T}-conditionally independent of X^k; and let $Y^{k,r}$ be an $\mathbb{R}^m$-valued running observation process of the form

$$Y^{k,r}_t = \int_{-T}^{t} g^k(X_s)\, ds + W^k_t \quad \text{for } t \in [-T, T], \tag{4.10}$$

where $m \geq \max\{d, n-1\}$, $g^k : \mathbf{X} \to \mathbb{R}^m$, and W^k is an m-vector shifted Brownian motion, independent of (X^k, ψ^k). Suppose, further, that the following hold:

(A1) for each k, Φ^k satisfies (2.1) and (H1)–(H4);

(A2) $A^k \to A$;

(A3) $(X^k_{-T}, Z^k_{-T}) \Rightarrow (X_{-T}, Z_{-T})$ and $\mathbf{E}^k \log(Z^k_{-T,i}) \to \mathbf{E} \log(Z_{-T,i})$ for all i;

(A4) for each $i \in \mathbf{X}$, $g^k(i) \to g^0(i)$, where g^0 is the $\mathbb{R}^m$-valued function on $\mathbf{X}$ whose first d components are those of g and whose remaining components are zero.

Example 4.1. For each k, let $\zeta^k : \Omega^k \to \mathbb{S}^{n-1}$ and $\eta^k : \Omega^k \to \mathbb{R}^n$ be independent, ζ^k having the same distribution as Z_{-T} and η^k having the standard n-variate Gaussian distribution. Let

$$\begin{aligned}
A^k &:= A + k^{-1}(J_n J_n' - nI_n),\\
g^k_l &:= g_l \qquad\qquad \text{for } l = 1, 2, \ldots, d,\\
&\quad\ k^{-1}\mathbf{1}_{\{l-d\}} \qquad \text{for } l = d+1, d+2, \ldots, d+n-1,\\
\psi^{k,1} &:= (kn)^{-1} J_n + (1 - k^{-1})\zeta^k,\\
\psi^{k,2} &:= \chi(X^k_{-T}) + k\eta^k,
\end{aligned} \tag{4.11}$$

where J_n is the n-vector whose entries are all 1, $\mathbf{1}$ is the indicator function, X^k_{-T} has $\psi^{k,1}$-conditional distribution $\psi^{k,1}$, and X^k is X^k_{-T}-conditionally independent of (ζ^k, η^k) with rate matrix A^k. Let the running observation be as in (4.10), and let the initial observation be ψ^k $(:= (\psi^{k,1}, \psi^{k,2}))$. Then (Φ^k) satisfies (A1)–(A4). (It can also be shown by means of a number of theorems in [10] that $\tilde{Z}_t$ has a strictly positive differentiable density for all $t \in (-T, T]$, and so Φ^k satisfies at least part of (H5).)

Definition 4.3. *The* path rate of interactive entropy production *of the process* (X, Z) *at time* t *is*

$$\begin{aligned}
R_I(t) := \limsup_{k\uparrow\infty} \limsup_{\epsilon\downarrow 0} \epsilon^{-1} \mathbf{E}^k \Bigg(& h\left(\Pi^{X,Z,k}_{t,t+\epsilon} \,|\, \Pi^{X,Z,k}_{t,t-\epsilon}\right) - h\left(\Pi^{X,k}_{t,t+\epsilon} \,|\, \Pi^{X,k}_{t,t-\epsilon}\right)\\
& - h\left(\Pi^{Z,k}_{t,t+\epsilon} \,|\, \Pi^{Z,k}_{t,t-\epsilon}\right)\Bigg),
\end{aligned} \tag{4.12}$$

where $\infty - \infty$ *is taken to be* $+\infty$, (Φ^k) *is a sequence of filtering problems satisfying* (A1)–(A4), *and* $\Pi^{X,Z,k}_{t,t+\epsilon}$ *is the equivalent of* $\Pi^{X,Z}_{t,t+\epsilon}$ *for the filtering problem* Φ^k, *etc.*

The following proposition justifies Definition 4.3, and shows that it is consistent, in the sense that the limits in (4.12) do not depend on the specific sequence satisfying (A1)–(A4). It also evaluates R_I.

PROPOSITION 4.4. *Let* (Φ^k) *be a sequence of filtering problems satisfying* (A1)–(A4).

(i) *The processes* $((X^k, Z^k), k = 1, 2, \ldots)$, *considered as random variables in the product space* $\mathbf{X}^{[-T,T]} \times C([-T, T]; \mathbb{S}^{n-1})$, *converge weakly as* $k \uparrow \infty$ *to* (X, Z).

(ii) *For each* $t \in (-T, T)$, *the forward and backward generators of the processes* (X^k, Z^k) *at time* t *converge to those of* (X, Z) *in the following sense. For any* $f, h : \mathbf{X} \times \mathbb{R}^n \to \mathbb{R}$ *such that* $f(i, \cdot), h(i, \cdot) \in C^2(\mathbb{R}^n; \mathbb{R})$ *for all* i,

$$\begin{aligned} &\lim_{k\uparrow\infty} \lim_{\epsilon\downarrow 0} \epsilon^{-1} \mathbf{E}^k \left(f(X^k_{t\pm\epsilon}, Z^k_{t\pm\epsilon}) - f(X^k_t, Z^k_t) \right) h(X^k_t, Z^k_t) \\ &\qquad = \lim_{\epsilon\downarrow 0} \epsilon^{-1} \mathbf{E} \left(f(X_{t\pm\epsilon}, Z_{t\pm\epsilon}) - f(X_t, Z_t) \right) h(X_t, Z_t). \end{aligned} \tag{4.13}$$

(iii) *For each* $t \in (-T, T)$, *for which the filtering problems in the sequence* (Φ^k) *satisfy* (H5),

$$R_I(t) = \dot{S}(t) + \dot{D}(t). \tag{4.14}$$

Proof. See Appendix D. □

Remark 4.7. If (H1)–(H5) are satisfied by the original filtering problem, then the problems in the sequence (Φ^k) can all be chosen to be the same as the original, which shows that Definition 4.3 is consistent with that in (4.9).

5. A simple example. The ideas of sections 2 to 4 are illustrated here through a simple example in which $n = 2$ and the signal process X has the following symmetrical rate matrix for some positive constant λ:

$$A = \begin{bmatrix} -\lambda & \lambda \\ \lambda & -\lambda \end{bmatrix}.$$

The filtering problem will be investigated in its invariant distribution, and so the initial distribution of X is chosen to be $\theta = [0.5\ 0.5]'$.

The running observation has dimension $d = 1$, and $g(i) = \alpha u(i)$, where α is a constant and $u(i) := 2i - 3$. In order to exploit the symmetry of the example, we will represent the signal value by the $\{-1, +1\}$-valued statistic $u(X_t)$, and the filter value, Z_t, by the $(-1, 1)$-valued conditional mean of $u(X_t)$,

$$\mu_t := Z_{t,2} - Z_{t,1}.$$

The filter formulae of (2.4) now take the form

$$\begin{aligned} d\mu_t &= \left(-2\lambda\mu_t - \alpha^2(1 - \mu_t^2)\mu_t \right) dt + \alpha(1 - \mu_t^2)\, dY^r_t \\ &= -2\lambda\mu_t\, dt + \alpha(1 - \mu_t^2)\, d\nu_t. \end{aligned} \tag{5.1}$$

μ has the following invariant density (for an appropriate normalizing constant K):

$$p_{\mu,SS}(x) = \frac{K}{(1 - x^2)^2} \exp\left(\frac{-2\lambda x^2}{\alpha^2(1 - x^2)} \right). \tag{5.2}$$

In order to initialize the filter in this distribution, we choose an initial observation $\psi : \Omega \to (-1, 1)$ with the following X_{-T}-conditional density:

$$p_{\psi|X_{-T}}(x, i) = (1 + u(i)x) p_{\mu,SS}(x).$$

With this initial observation, $\mu_{-T} = \psi$.

The storage, $C(t)$, and the supply and dissipation rates, $\dot{S}(t)$ and $\dot{D}(t)$, can now be evaluated from (2.14), (2.13), and (2.16):

$$\begin{aligned} C(t) &= \frac{1}{2}\int_{-1}^{1}\left(\log(1-x^2) + x\log\left(\frac{1+x}{1-x}\right)\right)p_{\mu,SS}(x)\,dx, \\ \dot{S}(t) &= \frac{1}{2}\alpha^2\int_{-1}^{1}(1-x^2)p_{\mu,SS}(x)\,dx, \\ \dot{D}(t) &= \lambda\int_{-1}^{1}x\log\left(\frac{1+x}{1-x}\right)p_{\mu,SS}(x)\,dx. \end{aligned} \tag{5.3}$$

(Since the signal and filter are initialized in their joint invariant distribution, these quantities do not depend on t, and $\dot{S} = \dot{D}$.) One can easily define "disintegrated," μ_t-conditional information quantities by removing the averaging operation in (5.3). This reveals that the disintegrated supply rate is proportional to the power signal-to-noise ratio, α^2; it is largest when μ_t is close to zero and decreases to zero as μ_t approaches ± 1. Similarly, the disintegrated dissipation rate is proportional to the signal switching rate, λ; it is large when μ_t approaches ± 1 and zero when μ_t is zero. The disintegrated storage is zero when $\mu_t = 0$ and equal to the self information of X_t (1 bit) if $\mu_t = \pm 1$.

It is clear that (H1)–(H5) are all satisfied for this example. Time reversing the pair (X, μ), we obtain the dual system. The dual signal X^* takes values in the interval $(-1, 1)$ and evolves according to the following equation:

$$dX_t^* = -2\lambda X_t^*\,dt + \alpha(1 - X_t^*)^2\,dV_t^*, \tag{5.4}$$

where $((V_t^*, \mathcal{F}_{-T,t}^{X^*,Z^*}),\ t \in [-T,T])$ is a scalar shifted Brownian motion; it has initial distribution $p_{\mu,SS}$. The dual observation is the counting process Y^* of (3.7) in Example 3.1. The dual filter is a two-state Markov process with initial X^*-conditional distribution

$$P(Z_{-T}^* = i \mid X_{-T}^*) = (1 + u(i)X_{-T}^*)/2 \quad \text{for } i = 1, 2$$

and X^*-conditional rate matrix at time t

$$\breve{A}(X_t^*) = \lambda\begin{bmatrix} -(1+X_t^*)/(1-X_t^*) & (1-X_t^*)/(1+X_t^*) \\ (1+X_t^*)/(1-X_t^*) & -(1-X_t^*)/(1+X_t^*) \end{bmatrix}.$$

The observation-conditional distribution of X_t^* is as follows:

$$P(X_t^* \in B \mid Y_s^*,\ s \in [-T,t]) = \int_B (1 + u(Z_t^*)x)p_{\mu,SS}(x)\,dx.$$

The disintegrated dual information supply rate is the same as the disintegrated primal dissipation rate, and so it is large when the switching rate scaling factor λ is large. Thus a high switching rate for Y^* is associated with a high information supply rate. Similarly, the disintegrated dual dissipation rate is the same as the disintegrated primal supply rate, and so it is large when the dual signal noise factor, α^2, is large. We can also "disintegrate" the dual supply and dissipation rates with respect to X_t^* to obtain Z_t^*-conditional rates. However, because of the symmetry of the simple problem considered here, these are equal to $\dot{S}^*$ and $\dot{D}^*$ for both values of Z_t^*.

Both processes X and μ are *self-adjoint*, in that their dynamics are the same in both time directions. This results in their (marginal) path rates of entropy production, R_X and R_μ, being zero. Of course the dynamics of their *interaction* are not time symmetric, and

$$R_I = R_{X,\mu} = \dot{S} + \dot{D} = 2\dot{S}. \tag{5.5}$$

6. Conclusions. This paper has developed dual nonlinear filtering problems and defined and related information flows for them. It has defined an entropic time derivative for a general class of Markov processes and connected the entropic derivatives of the signal and filter processes with these information flows. In the special case of time-homogeneous processes admitting invariant distributions, the entropic time derivative coincides with the "rate of entropy production" of [13]. This connection enables the construction of statistical mechanical analogies for the signal and filter (reported in [18] and [20]) in which the signal and filter interact in a nondissipative way. The existence of dual filtering problems is thus connected with the second law of thermodynamics.

The derivation of dual filters by the techniques of this paper is not restricted to systems with discrete-state signals. The same approach can be taken with filters for diffusion processes and leads to systems in which the optimal filter for an *infinite-dimensional* signal is of *finite* dimension. A notable exception to this is the linear Gaussian case in which the signal and filter are both of finite dimension. The signal and Kalman–Bucy filter equations are *self-dual* in a certain sense. (See [19].) Other special cases are the finite-dimensional filters of Beneš [2].

Appendix A. Proof of Proposition 2.1. It follows from the boundedness of $g - \bar{g}$ and the Novikov criterion (e.g., Theorem 6.1 in [14]) that, under $\mathbb{P}$, $(L_t, \mathcal{F}^{X,Y}_{-T,t})$ is a martingale, and so $\mathbb{P}^M(\Omega) = \mathbf{E}L_T = \mathbf{E}L_{-T} = 1$, which shows that $\mathbb{P}^M$ is a probability measure. By the same argument $(L_t^{-1}, \mathcal{F}^{X,Y}_{-T,t})$ is a martingale under $\mathbb{P}^M$, and this proves part (vi).

For any $\epsilon > 0$, let

$$\begin{aligned}\tau_\epsilon &:= \inf\{t \in [-T,T] : Z_{t,i} \le \epsilon \text{ for any } i \in \mathbf{X}\} \wedge T,\\ \xi^\epsilon_t &:= Z_{t\wedge\tau_\epsilon};\end{aligned}$$

then, from Itô's rule applied to the second equation in (2.4),

$$\begin{aligned}\log(\xi^\epsilon_{T,i}) &= \log(\xi^\epsilon_{-T,i}) + \int_{-T}^{\tau_\epsilon}\left((\xi^\epsilon_{t,i})^{-1}(A\xi^\epsilon_t)_i - \frac{1}{2}(\xi^\epsilon_{t,i})^{-2}(\sigma\sigma'(\xi^\epsilon_t))_{i,i}\right)dt\\ &\quad + \int_{-T}^{\tau_\epsilon}(\xi^\epsilon_{t,i})^{-1}\left(\sigma(\xi^\epsilon_t)\,d\nu_t\right)_i\\ &\ge \log(\xi^\epsilon_{-T,i}) + \int_{-T}^{\tau_\epsilon}\left(A_{i,i} - \frac{1}{2}|g(i) - \bar{g}(Z_t)|^2\right)ds + \int_{-T}^{\tau_\epsilon}(g(i) - \bar{g}(Z_t))'\,d\nu_t\\ &\ge \zeta(\omega) > -\infty \quad \text{a.s.},\end{aligned}$$

where ζ does not depend on ϵ or i. Thus, if $\epsilon < \exp(\zeta(\omega))$, then $\tau_\epsilon(\omega) = T$. This, and the fact that $\mathbb{P}(\Sigma_i Z_{t,i} = 1 \text{ for all } t) = 1$ (which follows immediately from (2.4)), proves part (v).

For any Borel measurable $x : [-T,T] \to \mathbf{X}$ and any $t \in [-T,T]$, let

$$M(x)_t := Z_t - Z_{-T} - \int_{-T}^{t}(AZ_s + \sigma(Z_s)(g(x_s) - \bar{g}(Z_s)))\,ds;$$

then $(M(x)_t, \mathcal{F}^Z_{-T,t})$ and $(M(X)_t, \mathcal{F}^{X,Z}_{-T,t})$ are both continuous semimartingales with the same quadratic covariation:

$$\begin{aligned}[M(x)_i, M(x)_j]_t &= [M(X)_i, M(X)_j]_t \\ &= \int_{-T}^t (\sigma\sigma')(Z_s)_{i,j}\, ds \\ &= \int_{-T}^t Z_{s,i} Z_{s,j} (g(i) - \bar{g}(Z_s))'(g(j) - \bar{g}(Z_s))\, ds.\end{aligned}$$

Let

$$K(x)_t := \frac{\chi(x_{-T})'\theta}{\chi(x_{-T})' Z_{-T}} \exp\left(\int_{-T}^t (\chi(x_s)' Z_s)^{-1} \chi(x_s)'\, dM(x)_s \right. \\ \left. - \frac{1}{2} \int_{-T}^t |g(x_s) - \bar{g}(Z_s)|^2\, ds \right).$$

(The stochastic integral here is well defined in the L^2 sense because of part (v).) Then $L_t^{-1} = K(X)_t$, which shows that L is adapted to $(\mathcal{F}^{X,Z}_{-T,t})$. This, together with the fact that $(L_t^{-1}, \mathcal{F}^{X,Y}_{-T,t})$ is a martingale under $\mathbb{P}^M$, proves part (vii).

The abstract Bayes formula of nonlinear filtering (e.g., Theorem 7.23 in [14]) states that, for any $B \in \mathcal{B}^X_{-T,T}$,

$$\mathbb{P}\left(X \in B \mid \mathcal{F}^Y_{-T,t}\right) = \int_B K(x)_t\, P_X(dx), \tag{A.1}$$

where P_X is the distribution of X considered as a random variable taking values in $(\mathbf{X}^{[-T,T]}, \mathcal{B}^X_{-T,T})$. (In fact, Theorem 7.23 of [14] does not treat filtering problems having initial observations. However, its extension to the filtering problem of this paper is straightforward. See Remark 2.3.) Part (viii) follows from the fact that

$$\frac{d\,\mathbb{P}}{d\,\mathbb{P}^M} = K(X)_T = \frac{dP_{X,Y}}{d(P_X \otimes P_Y)}(X, Y),$$

where P_Y is the distribution of Y considered as a random variable taking values in $(M \times C([-T,T]; \mathbb{R}^d), \mathcal{M} \times \mathcal{B}^d_{-T,T})$, and $P_{X,Y}$ is the joint distribution of X and Y. (See Theorem 7.23 in [14].)

The signal and filter processes X and Z are Markov, X by definition, and Z since it is a solution of the second equation in (2.4), in which the process ν is a multivariate Brownian motion. (See, again, Theorem 7.23 in [14].) That their infinitesimal generators are as stated in (2.9) follows from Itô's rule. For any $B \in \mathcal{F}^{X,Z}_{-T,t}$ and any $C \in \mathcal{F}^{X,Z}_{t,T}$,

$$\begin{aligned}\int_B \mathbb{P}\left(C \mid \mathcal{F}^{X,Z}_{-T,t}\right) d\,\mathbb{P} &= \int_B \mathbf{E}^M\left(\mathbf{1}_C L_T^{-1} \mid \mathcal{F}^{X,Z}_{-T,t}\right) d\,\mathbb{P}^M \\ &= \int_B \mathbf{E}^M\left(\mathbf{1}_C L_T^{-1} L_t \mid \mathcal{F}^{X,Z}_{-T,t}\right) L_t^{-1}\, d\,\mathbb{P}^M \\ &= \int_B \mathbf{E}^M\left(\mathbf{1}_C L_T^{-1} L_t \mid X_t, Z_t\right) d\,\mathbb{P},\end{aligned} \tag{A.2}$$

where we have used part (vii), the fact that (X, Z) is Markov under $\mathbb{P}^M$, and the fact that $L_T^{-1} L_t = K(X)_T K(X)_t^{-1}$, which is $\mathcal{F}^{X,Z}_{-T,t}$-measurable, in the third step.

From this it follows that $\mathbb{P}(C \,|\, \mathcal{F}^{X,Z}_{-T,t})$ is (X_t, Z_t)-measurable, which shows that (X, Z) is Markov under $\mathbb{P}$. Once again, Itô's rule shows that $\mathcal{L}^J$ is its generator, and this proves part (i).

Part (ii) follows directly from (A.1), since $K(x)_t$ is $\mathcal{F}^Z_{-T,t}$-measurable. For any $B \in \mathcal{F}^{X,Z}_{-T,t}$ and any $C \in \mathcal{F}^X_{t,T}$,

$$\begin{aligned}\int_B \mathbb{P}\left(C \,|\, \mathcal{F}^{X,Z}_{-T,t}\right) d\,\mathbb{P} &= \int_B \mathbb{P}^M\left(C \,|\, \mathcal{F}^{X,Z}_{-T,t}\right) L_t^{-1}\, d\,\mathbb{P}^M \\ &= \int_B \mathbb{P}^M(C \,|\, X_t)\, d\,\mathbb{P}.\end{aligned}$$

Thus $\mathbb{P}(C \,|\, \mathcal{F}^{X,Z}_{-T,t})$ is X_t-measurable, and this proves part (iii). Finally, let $B \in \mathcal{F}^Z_{-T,t}$, $i \in \mathbf{X}$, and $C \in \mathcal{B}^n$; then

$$\begin{aligned}\int \mathbb{P}(B \,|\, X_t, Z_t)\mathbf{1}_{\{i\}\times C}(X_t, Z_t)\, d\,\mathbb{P} &= \int_B \mathbf{E}(\mathbf{1}_{\{i\}\times C}(X_t, Z_t) \,|\, \mathcal{F}^Z_{-T,t})\, d\,\mathbb{P} \\ &= \int_B Z_{t,i}\mathbf{1}_C(Z_t)\, d\,\mathbb{P} \\ &= \int \mathbb{P}(B \,|\, Z_t)\mathbf{1}_{\{i\}\times C}(X_t, Z_t)\, d\,\mathbb{P}.\end{aligned}$$

This shows that $\mathbb{P}(B \,|\, X_t, Z_t)$ is Z_t-measurable, and this, together with part (i), proves part (iv).

Appendix B. Proof of Theorem 3.2. Under the measure $\mathbb{P}^M$ (as introduced before Proposition 2.1), X^* and Z^* are independent Markov processes with the same marginal distributions they have under $\mathbb{P}$, and so, in order to prove the statement of the theorem concerning the marginal processes X^* and Z^*, it suffices to show that the following hold:

(a) $(\Omega, \mathcal{F}, \mathbb{P}^M, X^*)$ solves the martingale problem associated with $\mathcal{L}^{X^*}_t$;

(b) $(\Omega, \mathcal{F}, \mathbb{P}^M, Z^*)$ solves the martingale problem associated with $\mathcal{L}^{Z^*}_t$.

By (a), we mean that for all $f \in C^2_b(\mathbb{R}^n; \mathbb{R})$, all $h \in C_b(\mathbb{R}^n; \mathbb{R})$, and all $s \le t$,

$$\mathbf{E}\left(\left(f(X^*_t) - f(X^*_s) - \int_s^t (\mathcal{L}^{X^*}_r f)(X^*_r)\, dr\right) h(X^*_s)\right) = 0.$$

(Since ΓX^*_r has a density, this formulation of the martingale problem admits the case that $\nabla_{\tilde{z}} p_{\tilde{Z}}(\,\cdot\,, t)$ is defined only in the sense of distributions.) Statement (a) follows from an application of Theorems 2.1 and 3.1 in [12] to the process $\tilde{Z}$ of (3.1). To prove (b), we proceed as follows.

For any $f : \mathbf{X} \to \mathbb{R}$, any $i \in \mathbf{X}$, and any $s \le t$, let

$$\begin{aligned}\pi(i, t) &:= \sum_j f(j) \exp(A(t-s))_{i,j} p_X(s)_j, \\ \phi(i, t) &:= \pi(i, -t)/p_X(-t)_i.\end{aligned}$$

Then $\mathbf{E}(f(X_s) \mid X_t = i) = \phi(i, -t)$, and

$$\begin{aligned}\frac{\partial \phi}{\partial t}(i, t) &= -(p_X(-t)_i)^{-1} \frac{\partial \pi}{\partial t}(i, -t) + (p_X(-t)_i)^{-2} \pi(i, -t) \frac{\partial (p_X)_i}{\partial t}(-t), \\ &= -\sum_j \bar{A}(t)_{j,i}(\phi(j, t) - \phi(i, t)),\end{aligned}$$

and so Z^* is a Markov jump process on $\mathbf{X}$ with time-dependent rate matrix $\bar{A}$, and this proves (b).

In order to prove the statement of the theorem concerning the joint process (X^*, Z^*), it now suffices to establish that, under $\mathbb{P}$, Z^* is X^*-conditionally Markov with rate matrix $\breve{A}$ of (3.4). For some $t \in [-T, T]$, let $B \in \mathcal{F}^X_{t,T}$, $C \in \mathcal{F}^{X,Z}_{-T,t}$, and $D \in \mathcal{F}^Z_{t,T}$; then

$$\begin{aligned}
\int_{C\cap D} \mathbb{P}(B \mid \mathcal{F}^X_{-T,t} \vee \mathcal{F}^Z_{-T,T})\, d\mathbb{P} &= \int_C \mathbb{P}(B \cap D \mid \mathcal{F}^{X,Z}_{-T,t})\, d\mathbb{P} \\
&= \int_C \mathbb{P}(B \cap D \mid X_t, Z_t)\, d\mathbb{P} \\
&= \int_C \mathbf{E}\left(\mathbb{P}(B \mid X_t, \mathcal{F}^Z_{t,T})\mathbf{1}_D \mid X_t, Z_t\right) d\mathbb{P} \\
&= \int_C \mathbf{E}\left(\mathbb{P}(B \mid X_t, \mathcal{F}^Z_{t,T})\mathbf{1}_D \mid \mathcal{F}^{X,Z}_{-T,t}\right) d\mathbb{P} \\
&= \int_{C\cap D} \mathbb{P}(B \mid X_t, \mathcal{F}^Z_{t,T})\, d\mathbb{P},
\end{aligned}$$

where we have used the joint Markov property in the second and fourth steps. Since $(C \cap D)$ forms a Dynkin π-system that generates $\mathcal{F}^X_{-T,t} \vee \mathcal{F}^Z_{-T,T}$, the first and last integrands are equal a.s., and X is Z-conditionally Markov, so that Z^* is X^*-conditionally Markov.

For any $f : \mathbf{X} \to \mathbb{R}$, any $j \in \mathbf{X}$, and any $s \le t$, let

$$\begin{aligned}
\alpha^{s,j}_t &= \mathrm{vec}_i \left\{\mathbb{P}(X_t = i \mid X_s = j,\, \mathcal{F}^Y_{-T,t})\right\}, \\
\beta^s_t &= \mathrm{vec}_i \left\{\mathbb{P}(X_s = i \mid \mathcal{F}^Y_{-T,t})\right\}, \\
\Phi(i, -t) &= \mathbf{E}(f(X_s) \mid X_t = i,\, Z) \\
&= \sum_j f(j)\alpha^{s,j}_{t,i}\beta^s_{t,j}Z^{-1}_{t,i}.
\end{aligned}$$

Then it follows from Theorems 9.3 and 9.4 in [14], and Itô's rule, that

$$\frac{\partial}{\partial t}\alpha^{s,j}_{t,i}\beta^s_{t,j}Z^{-1}_{t,i} = \beta^s_{t,j}Z^{-2}_{t,i}(Z_{t,i}(A\alpha^{s,j}_t)_i - \alpha^{s,j}_{t,i}(AZ_t)_i),$$

and so

$$\begin{aligned}
\left(\frac{\partial \Phi}{\partial t}\right)(i, -t) &= \sum_{j,k} f(j)\beta^s_{t,j}Z^{-2}_{t,i}\left(Z_{t,i}A_{i,k}\alpha^{s,j}_{t,k} - \alpha^{s,j}_{t,i}A_{i,k}Z_{t,k}\right) \\
&= -\sum_k A_{i,k}\frac{Z_{t,k}}{Z_{t,i}}\sum_i f(j)\beta^s_{t,j}\left(\frac{\alpha^{s,j}_{t,i}}{Z_{t,i}} - \frac{\alpha^{s,j}_{t,k}}{Z_{t,k}}\right) \\
&= -\sum_k \breve{A}(Z_t)_{k,i}\left(\Phi(k, -t) - \Phi(i, -t)\right).
\end{aligned}$$

Appendix C. Proof of Proposition 4.2. We prove part (iii) only. Parts (i) and (ii) follow from similar (but simpler) arguments. Throughout the proof, X^t, Z^t, X^{*t}, and Z^{*t} will be used as shorthand for the processes $(X_{t+s},\ s \in [0, \epsilon])$, $(Z_{t+s},\ s \in [0, \epsilon])$, $(X^*_{-t+s},\ s \in [0, \epsilon])$, and $(Z^*_{-t+s},\ s \in [0, \epsilon])$. The proof involves the

construction of Radon–Nikodym derivatives between various regular X_t-, Z_t-, and (X_t, Z_t)-conditional distributions of these processes. We shall, therefore, use versions of X^t and Z^{*t} whose sample paths belong to the space, $D([0,\epsilon];\mathbf{X})$, of right-continuous functions having left limits. When equipped with the Skorohod metric corresponding to the Krönecker metric on $\mathbf{X}$ ($r(i,j) = 1$ if $i \neq j$), this is a Polish space. (See, for example, [4], [8], and [9].) Of course, the sample paths of Z^t and X^{*t} belong to the space $C([0,\epsilon];\overline{\mathbb{S}^{n-1}})$, where $\overline{\mathbb{S}^{n-1}}$ is the closure of $\mathbb{S}^{n-1}$ in $\mathbb{R}^n$; this becomes a Polish space when "metrized" by the supremum norm. For a process $(\eta_s, s \in [0,\epsilon])$ having sample paths in a Polish space, $\Pi^{\eta}_{\epsilon|0}(\,\cdot\,,\theta)$ will signify a regular $(\eta_0 = \theta)$-conditional distribution of η.

Let $G_{i,t} := g(i) - \bar{g}(Z_t)$; then it follows from Itô's rule that

$$dZ^{-1}_{t,i} = \left(|G_{i,t}|^2 - A_{i,i}\right) Z^{-1}_{t,i}\,dt - Z^{-1}_{t,i} G'_{i,t}\,d\nu_t - Z^{-2}_{t,i} \sum_{j\neq i} A_{i,j} Z_{t,j}\,dt.$$

Let $(\Theta_t,\ t \in [-T,T])$ be defined by the following equation:

$$\Theta_t = Z^{-1}_{-T,i} + \int_{-T}^{t} \left(|G_{i,s}|^2 - A_{i,i}\right)\Theta_s\,ds - \int_{-T}^{t} \Theta_s G'_{i,s}\,d\nu_s;$$

then

$$\begin{aligned}\Theta_t - Z^{-1}_{t,i} &= \int_{-T}^{t} \exp\left(\int_s^t \left(\left(\frac{1}{2}|G_{i,r}|^2 - A_{i,i}\right)dr - G'_{i,r}\,d\nu_r\right)\right) Z^{-2}_{s,i} \sum_{j\neq i} A_{i,j} Z_{s,j}\,ds \\ &\geq 0,\end{aligned}$$

and so $0 < Z^{-1}_{t,i} < \Theta_t$ for all t. It now follows from (H4) and a standard result on the moments of solutions of Itô equations (see, for example, Theorem 4.6 in [14]) that

$$\sup_{t\in[-T,T]} \mathbf{E} Z^{-2}_{t,i} \leq \sup_{t\in[-T,T]} \mathbf{E}\Theta^2_t < \infty. \tag{C.1}$$

Let $F : D([0,\epsilon];\mathbf{X}) \times \mathbb{S}^{n-1} \times C([0,\epsilon];\mathbb{R}^{n-1}) \to C([0,\epsilon];\mathbb{S}^{n-1})$ be the strong solution of the following equation (which is parametrized by $x \in D([0,\epsilon];\mathbf{X})$):

$$\rho_s = \rho_0 + \int_0^s b(x_r,\rho_r)\,dr + \int_0^s \sigma(\rho_r)\,dB_r \quad \text{for } s \in [0,\epsilon],$$

so that $Z^t = F(X^t, Z_t, W)$. For $x \in D([0,\epsilon];\mathbf{X})$ and $z_0 \in \mathbb{S}^{n-1}$, let $\Pi^{Z^t|X^t}_{\epsilon|0}(\,\cdot\,,x,z_0)$ be the distribution of $F(x,z_0,W)$. (This is a regular $(X^t = x,\ Z_t = z_0)$-conditional distribution for Z^t.)

For $x \in D([0,\epsilon];\mathbf{X})$, $z \in C([0,\epsilon];\mathbb{S}^{n-1})$, and $s \in [0,\epsilon]$, let

$$\begin{aligned}\alpha(x,z)_s &:= (\Gamma\sigma(z_s))^{-1}\Gamma(b(x_s,z_s) - \bar{b}(z_s,s-t)), \\ V^*_s &:= \int_0^s (\Gamma\sigma(X^{*t}_r))^{-1}\Gamma\left(dX^{*t}_r - \bar{b}(X^{*t}_r, r-t)dr\right), \\ \bar{V}(x)_s &:= -\int_0^s \alpha(x,X^{*t})_r\,dr + V^*_s, \\ M_1(x) &:= \exp\left(\int_0^\epsilon \alpha(x,X^{*t})'_s\,d\bar{V}(x)_s + \frac{1}{2}\int_0^\epsilon \left|\alpha(x,X^{*t})_s\right|^2 ds\right).\end{aligned}$$

It follows from (C.1) and (H5) that, for ϵ sufficiently small, the ordinary integral in the expression for M_1 has finite expected value. Furthermore, $X^{*t} = F(x, Z_t, \bar{V}(x))$, and so $(\alpha(x, X^{*t})_s,\ s \in [0,\epsilon])$ is adapted to $(\mathcal{F}^Z_{t,t} \vee \mathcal{F}^{\bar{V}(x)}_{0,s},\ s \in [0,\epsilon])$. Now $(V^*_s, \mathcal{F}^{X^{*t}}_{0,s},\ s \in [0,\epsilon])$ is a standard $(n-1)$-vector Brownian motion, and so it follows from Theorem 7.6 in [14] that $\bar{V}(x)$ has a regular $(Z_t = z_0)$-conditional distribution, $\mu_{\bar{V}(x)}(\,\cdot\,, z_0)$, that is absolutely continuous with respect to the Wiener measure, μ_W, and

$$\frac{d\mu_{\bar{V}(x)}(\,\cdot\,, Z_t)}{d\mu_W}(\bar{V}(x)) = M_1(x)^{-1} \quad \text{a.s.} \tag{C.2}$$

Now $F(x, z_0, V^*)$ has the distribution $\Pi^{Z^t|X^t}_{\epsilon|0}(\,\cdot\,, x, z_0)$, and so it follows from (C.1) and (H5) that, for almost all z_0 $(\Pi^Z_{t,t})$,

$$\mathbf{E}\int_0^\epsilon |\alpha(x, F(x, z_0, V^*))_s|^2\, ds < \infty$$

and from Theorem 7.7 in [14] that $\mu_W \ll \mu_{\bar{V}(x)}(\,\cdot\,, z_0)$ for almost all z_0 $(\Pi^Z_{t,t})$. Thus the measure on $\mathcal{F}$, defined by $d\,\mathbb{P}_1(x) = M_1(x) d\,\mathbb{P}$, is a probability measure under which $(\bar{V}(x)_s, \mathcal{F}^{X^{*t}}_{0,s},\ s \in [0,\epsilon])$ is an $(n-1)$-vector standard Brownian motion and X^{*t} has the Z_t-conditional distribution $\Pi^{Z^t|X^t}_{\epsilon|0}(\,\cdot\,, x, Z_t)$. So

$$\frac{d\Pi^{Z^t|X^t}_{\epsilon|0}(\,\cdot\,, x, Z_t)}{d\Pi^{X^{*t}}_{\epsilon|0}(\,\cdot\,, Z_t)}(X^{*t}) = M_1(x) \quad \text{a.s.} \tag{C.3}$$

We now apply a similar procedure to the jump processes X^t and Z^{*t}. For each $z \in C([0,\epsilon]; \mathbb{S}^{n-1})$ and $s \in (0,\epsilon]$, let

$$\begin{aligned}
\lambda_s &:= -\chi(X^t_{s-})' A \chi(X^t_{s-}),\\
\breve{\lambda}(z)_s &:= -\chi(X^t_{s-})' \breve{A}(z_s) \chi(X^t_{s-}),\\
\Phi_s &:= \begin{cases} \mathrm{vec}_i\left\{\lambda_s^{-1}(1 - \mathbf{1}_{\{i\}}(X^t_{s-}))\chi(i)' A \chi(X^t_{s-})\right\} & \text{if } \lambda_s > 0,\\ 0 & \text{otherwise,}\end{cases}\\
\breve{\Phi}(z)_s &:= \begin{cases} \mathrm{vec}_i\left\{\breve{\lambda}(z)_s^{-1}(1 - \mathbf{1}_{\{i\}}(X^t_{s-}))\chi(i)' \breve{A}(z_s) \chi(X^t_{s-})\right\} & \text{if } \breve{\lambda}(z)_s > 0,\\ 0 & \text{otherwise,}\end{cases}\\
\beta(z)_s &:= \mathrm{vec}_i\left\{\log\left(\frac{\lambda_s \Phi_{s,i}}{\breve{\lambda}(z)_s \breve{\Phi}(z)_{s,i}}\right)\right\} \quad \text{(where } 0/0 \text{ is taken to be 1)},\\
N_s &:= \mathrm{vec}_i\left\{\int_{(0,s]} (1 - \mathbf{1}_{\{i\}}(X^t_{r-}))\, d\mathbf{1}_{\{i\}}(X^t_r)\right\},\\
M_2(z) &:= \exp\left(-\int_{(0,\epsilon]} \beta(z)'_s\, dN_s + \int_0^\epsilon (\lambda_s - \breve{\lambda}(z)_s)\, ds\right).
\end{aligned}$$

In the terminology of Chapter VIII in [5], X^t is a $\mathbf{X}$-marked point process with local characteristics $(\lambda_s, \Phi_s, \mathcal{F}^{X^t}_{0,s-},\ s \in [0,\epsilon])$. Since z is continuous and $[0,\epsilon]$ is compact, there exists a $\delta > 0$ such that $\inf_{s,i}\{z_{s,i}\} > \delta$, and so

$$\sup_{s\in[0,\epsilon]} \breve{\lambda}(z)_s < \infty \quad \text{a.s.}, \tag{C.4}$$

$$\sup_{s\in[0,\epsilon]} |\beta(z)_s| \le n \sup_{s\in[0,\epsilon];\, i,j:\, A_{i,j}>0} \left| \log\left(\frac{A_{i,j}}{\breve{A}(z_s)_{i,j}} \right) \right| < \infty \quad \text{a.s.}, \tag{C.5}$$

and, for any $K < \infty$,

$$\mathbf{E} \exp\left(K \Sigma_i N_{\epsilon,i}\right) \le \sum_{k=0}^{\infty} \exp(Kk) \frac{(\Lambda\epsilon)^k}{k!} \exp(-\Lambda\epsilon) < \infty,$$

where $\Lambda := \max_i(-A_{i,i})$. It therefore follows from Theorem T11 in Chapter VIII of [5] that $\mathbf{E}M_2(z) = 1$ for all z, and from Theorem T10 of the same reference that the measure defined on $\mathcal{F}$ by $d\,\mathbb{P}_2(z) = M_2(z) d\,\mathbb{P}$ is a probability measure, under which X^t is an $\mathbf{X}$-marked point process with local characteristics $(\breve{\lambda}(z)_s, \breve{\Phi}(z)_s, \mathcal{F}^{X^t}_{0,s-},\, s \in [0,\epsilon])$. Under $\mathbb{P}_2(z)$, the regular $(X_t = i)$-conditional distribution of X^t is the same as the regular $(X^{*t} = z,\, X_t = i)$-conditional distribution of Z^{*t} under $\mathbb{P}$, $\Pi^{Z^{*t}|X^{*t}}_{\epsilon|0}(\,\cdot\,, z, i)$. The latter is therefore absolutely continuous with respect to $\Pi^{X^t}_{\epsilon|0}(\,\cdot\,, i)$, and

$$\frac{d\Pi^{Z^{*t}|X^{*t}}_{\epsilon|0}(\,\cdot\,, z, X_t)}{d\Pi^{X^t}_{\epsilon|0}(\,\cdot\,, X_t)}(X^t) = M_2(z) \quad \text{a.s.} \tag{C.6}$$

It now easily follows from (C.3) and (C.6) that

$$R_{X,Z}(t) = \limsup_{\epsilon\downarrow 0} \epsilon^{-1} \mathbf{E}\left(\mathbf{E}_1(x) \log(M_1(x))|_{x=X^t} - \log(M_2(Z^t)) \right) \tag{C.7}$$

and

$$R_{X^*,Z^*}(-t) = \limsup_{\epsilon\downarrow 0} \epsilon^{-1} \mathbf{E}\left(\mathbf{E}_2(z) \log(M_2(z))|_{z=X^{*t}} - \log(M_1(Z^{*t})) \right). \tag{C.8}$$

Now (C.1), (C.4), and (C.5) show that, for each $z \in C([0,\epsilon]; \mathbb{S}^{n-1})$ and each $i \in \mathbf{X}$,

$$\mathbf{E} \int_0^\epsilon \beta(Z^t)^2_{s,i} \lambda_s \Phi_{s,i}\, ds < \infty \quad \text{and} \quad \mathbf{E}_2(z) \int_0^\epsilon \beta(z)^2_{s,i} \breve{\lambda}(z)_s \breve{\Phi}(z)_{s,i}\, ds < \infty,$$

and so, from a standard result in the L_2 theory of stochastic integration,

$$\begin{aligned} \mathbf{E} \int_{(0,\epsilon]} \beta(Z^t)'_s \left(dN_s - \lambda_s \Phi_s\, ds \right) &= \mathbf{E}_2(z) \int_{(0,\epsilon]} \beta(z)'_s \left(dN_s - \breve{\lambda}(z)_s \breve{\Phi}(z)_s\, ds \right) \\ &= 0. \end{aligned} \tag{C.9}$$

A simple calculation shows that $\mathbf{E}_2(z)(\breve{\lambda}(z) - \lambda) \equiv \mathbf{E}(\breve{\lambda}(Z^t) - \lambda) \equiv 0$, and this, together with (C.9) and (C.1), shows that

$$\begin{aligned} \lim_{\epsilon\downarrow 0} \epsilon^{-1} \mathbf{E}\mathbf{E}_2(z) \log(M_2(z))|_{z=X^{*t}} &= -\lim_{\epsilon\downarrow 0} \epsilon^{-1} \mathbf{E} \log(M_2(Z^t)) \\ &= \mathbf{E} \sum_{i,j:\, A_{i,j}>0} \log\left(\frac{A_{i,j}}{\breve{A}(Z_t)_{i,j}} \right) A_{i,j} Z_{t,j}. \end{aligned} \tag{C.10}$$

Similarly, it follows from (H5) and (C.1) that

$$\begin{aligned}\lim_{\epsilon\downarrow 0}\epsilon^{-1}\mathbf{E}\mathbf{E}_1(x)\log(M_1(x))|_{x=X^t} &= -\lim_{\epsilon\downarrow 0}\epsilon^{-1}\mathbf{E}\log(M_1(Z^{*t}))\\ &= \frac{1}{2}\mathbf{E}\left|(\Gamma\sigma(Z_t))^{-1}\Gamma(b(X_t,Z_t)-\bar{b}(Z_t,-t))\right|^2.\end{aligned}\tag{C.11}$$

Equations (C.7), (C.8), (C.10), and (C.11) now prove part (iii).

Appendix D. Proof of Proposition 4.4. As in the proof of Proposition 4.2, we use versions of the jump processes X^k and X whose sample paths belong to the Skorohod space $D([-T,T];\mathbf{X})$. Throughout the proof the superscript 0 will be used to indicate a parameter or process of the original (unrelaxed) filtering problem.

For each $k=0,1,2,\ldots$, let $(T^k(t),\ t\in[-T,T])$ be the transition semigroup of the process $((X_t^k,Z_{-T}^k),\ t\in[-T,T])$, so that $(T^k(t)f)(i,z)=\Sigma_j\exp(A^kt)_{j,i}f(j,z)$. The T^k are all Feller semigroups, and $T^k(t)f\to T^0(t)f$ for all $t\in[-T,T]$ and $f\in C(\mathbf{X}\times\mathbb{S}^{n-1};\mathbb{R})$. It thus follows from Theorem 2.5 (p. 167) in [9] that $(X^k,Z_{-T}^k)\Rightarrow(X^0,Z_{-T}^0)$, and from the Skorohod representation theorem that there exists a sequence $((\hat{X}^k,\hat{Z}_{-T}^k),\ k=0,1,2,\ldots)$, defined on a common probability space $(\hat{\Omega},\hat{\mathcal{F}},\hat{\mathbb{P}})$, such that $(\hat{X}^k,\hat{Z}_{-T}^k)$ has the same distribution as (X^k,Z_{-T}^k) for all k, and

$$(\hat{X}^k,\hat{Z}_{-T}^k)\to(\hat{X}^0,\hat{Z}_{-T}^0)\quad\text{pointwise on }\hat{\Omega}.\tag{D.1}$$

Let W^1 be the m-vector shifted Brownian motion of the relaxed problem Φ^1, and, for each k, let $(\hat{Z}_t^k,\ t\in[-T,T])$ be the solution on Ω^1 of the following equation (which is parametrized by $\hat{\omega}$):

$$\hat{Z}_t^k=\hat{Z}_{-T}^k+\int_{-T}^t b^k(\hat{X}_s^k,\hat{Z}_s^k)\,ds+\int_{-T}^t\sigma^k(\hat{Z}_s^k)\,dW_s^1,$$

where b^k and σ^k are the equivalents of b and σ, as defined in (2.5) and (2.10), for the problem Φ^k. (Note that $b^0=b$, and σ^0 is defined in terms of g^0 of (A4).) Jensen's inequality shows that

$$\begin{aligned}\left|\hat{Z}_t^k-\hat{Z}_t^0\right|^2\le 3\left|\hat{Z}_{-T}^k-\hat{Z}_{-T}^0\right|^2+6T\int_{-T}^t\left|b^k(\hat{X}_s^k,\hat{Z}_s^k)-b^0(\hat{X}_s^0,\hat{Z}_s^0)\right|^2ds\\ +3\left|\int_{-T}^t\left(\sigma^k(\hat{Z}_s^k)-\sigma^0(\hat{Z}_s^0)\right)dW_s^1\right|^2,\end{aligned}$$

and Doob's submartingale inequality shows that

$$\mathbf{E}^1\sup_{s\in[-T,t]}\left|\int_{-T}^s\left(\sigma^k(\hat{Z}_r^k)-\sigma^0(\hat{Z}_r^0)\right)dW_r^1\right|^2\le 4\mathbf{E}^1\int_{-T}^t\left\|\sigma^k(\hat{Z}_s^k)-\sigma^0(\hat{Z}_s^0)\right\|^2ds.$$

Now $b^k(i,\cdot)$ and σ^k are Lipschitz continuous on $\mathbb{S}^{n-1}$, uniformly in (i,k), and so, for some $K<\infty$ not depending on k,

$$\mathbf{E}^1\sup_{s\in[-T,t]}\left|\hat{Z}_s^k-\hat{Z}_s^0\right|^2\le R^k+\int_{-T}^t K\mathbf{E}^1\sup_{-T\le r\le s}\left|\hat{Z}_r^k-\hat{Z}_r^0\right|^2dr,$$

where

$$
\begin{aligned}
R^k := 3\left|\hat{Z}^k_{-T} - \hat{Z}^0_{-T}\right|^2 &+ 18T\int_{-T}^{T}\mathbf{E}^1\left|b^k(\hat{X}^k_t,\hat{Z}^k_t) - b^k(\hat{X}^0_t,\hat{Z}^0_t)\right|^2 dt \\
&+ 18T\int_{-T}^{T}\mathbf{E}^1\left|b^k(\hat{X}^0_t,\hat{Z}^0_t) - b^0(\hat{X}^0_t,\hat{Z}^0_t)\right|^2 dt \\
&+ 24T\int_{-T}^{T}\mathbf{E}^1\left\|\sigma^k(\hat{Z}^0_t) - \sigma^0(\hat{Z}^0_t)\right\|^2 dt.
\end{aligned}
\tag{D.2}
$$

Gronwall's lemma now shows that

$$
\mathbf{E}^1\sup_{t\in[-T,T]}\left|\hat{Z}^k_t - \hat{Z}^0_t\right|^2 \le \exp(2KT)R^k. \tag{D.3}
$$

Let $N(\hat{\omega})$ be the number of jumps made by $\hat{X}^0(\hat{\omega})$ in the time interval $[-T,T]$, and suppose that k is sufficiently large that $\|\hat{X}^k(\hat{\omega}) - \hat{X}^0(\hat{\omega})\|_D < \epsilon < 1$, where $\|\cdot\|_D$ is the Skorohod norm; then the Lebesgue measure of the subset of $[-T,T]$ on which $\hat{X}^k(\hat{\omega})$ and $\hat{X}^0(\hat{\omega})$ differ is upper bounded by $N(\hat{\omega})\epsilon$. Thus, since b^k is bounded on $\mathbf{X}\times\mathbb{S}^{n-1}$, uniformly in k, the first integral in (D.2) converges to zero. Since $(b^k,\sigma^k)\to(b^0,\sigma^0)$ uniformly on $\mathbf{X}\times\mathbb{S}^{n-1}$, the second and third integrals in (D.2) also converge to zero. It thus follows from (D.3) that

$$
\mathbf{E}^1\|\hat{Z}^k - \hat{Z}^0\|^2_C \to 0 \quad \text{for all } \hat{\omega}\in\hat{\Omega}, \tag{D.4}
$$

where $\|\cdot\|_C$ is the supremum norm on $C([-T,T];\overline{\mathbb{S}^{n-1}})$. Equations (D.1) and (D.4) now readily show that $(\hat{X}^k,\hat{Z}^k)\to(\hat{X}^0,\hat{Z}^0)$ in probability $(\hat{\mathbb{P}}\otimes\mathbb{P}^1)$, and this proves part (i).

Let f and h be as in part (ii) of the proposition. Then

$$
\begin{aligned}
&\lim_{\epsilon\downarrow 0}\epsilon^{-1}\mathbf{E}\left(f(X_{t-\epsilon},Z_{t-\epsilon}) - f(X_t,Z_t)\right)h(X_t,Z_t) \\
&\quad= \lim_{\epsilon\downarrow 0}\epsilon^{-1}\mathbf{E}\int_{t-\epsilon}^{t}\left(f(X_{t-\epsilon},Z_{t-\epsilon})(\mathcal{L}^{X,Z}h)(X_s,Z_s) - (\mathcal{L}^{X,Z}fh)(X_s,Z_s)\right)ds \\
&\quad\to \mathbf{E}\left(f\mathcal{L}^{X,Z}h - \mathcal{L}^{X,Z}fh\right)(X_t,Z_t),
\end{aligned}
$$

where $\mathcal{L}^{X,Z}$ is the differential generator of (X,Z), defined in (2.9). A similar expression holds with X and Z replaced by X^k and Z^k and $\mathcal{L}^{X,Z}$ replaced by the differential generator of (X^k,Z^k), $\mathcal{L}^{X,Z,k}$. Equation (4.13) with $\pm = -$ now follows from part (i) and the fact that the functions $f\mathcal{L}^{X,Z,k}h - \mathcal{L}^{X,Z,k}fh$ are continuous and converge to $f\mathcal{L}^{X,Z}h - \mathcal{L}^{X,Z}(fh)$ uniformly on $\mathbf{X}\times\mathbb{S}^{n-1}$. Equation (4.13) with $\pm = +$ follows from a similar argument.

The inner lim sup on the right-hand side of (4.12) is the rate of interactive entropy production of the relaxed problem Φ^k, which, according to (4.9), (2.13), and (2.16), takes the value

$$
\dot{S}^k(t) + \dot{D}^k(t) = \frac{1}{2}\mathbf{E}^k\left|g^k(X^k_t) - \bar{g}^k(Z^k_t)\right|^2 - \mathbf{E}^k\sum_{i,j}\log\left(\frac{Z^k_{t,i}}{p^k_X(t)_i}\right)A^k_{i,j}Z^k_{t,j}.
$$

Part (iii) now follows from part (i) and (A3).

Acknowledgments. The author would like to thank Professor Sanjoy Mitter of the Laboratory for Information and Decision Systems (LIDS) at MIT for suggesting this subject area as one fruitful for research, for providing encouragement and support during a number of visits made by the author to LIDS, and for the many engaging and productive discussions that took place during those visits. He would also like to thank one of the anonymous referees for detailed comments that have led to a substantial improvement in the presentation of this material.

OPTIMAL DESIGN OF THIN PLATES BY A DIMENSION REDUCTION FOR LINEAR CONSTRAINED PROBLEMS*

GUY BOUCHITTÉ† AND ILARIA FRAGALÀ‡

Abstract. The goal of this paper is to give a rigorous justification for the Hessian-constrained problems introduced in [G. Bouchitté and I. Fragalà, *Arch. Ration. Mech. Anal.*, 184 (2007), pp. 257–284] and to show how they are linked to the optimal design of thin plates. To that aim, we study the asymptotic behavior of a sequence of optimal elastic compliance problems in the double limit when both the maximal height of the design region and the total volume of the material tend to zero. In the vanishing volume limit, a sequence of linear constrained first order vector problems is obtained, which in turn—in the vanishing thickness limit—produces a new linear constrained problem where both first and second order gradients appear. When the load is orthogonal to the plate, only the Hessian constraint is active, and we recover as a particular case the optimization problem studied in [G. Bouchitté and I. Fragalà, *Arch. Ration. Mech. Anal.*, 184 (2007), pp. 257–284] (see also [T. Lewinski and J. J. Telega, *Arch. Mech. (Arch. Mech. Stos.)*, 53 (2001), pp. 457–485]).

1. Introduction.

Let Ω be an open bounded connected subset of $\mathbb{R}^2$ with a smooth boundary. In [14] we considered the following *mass optimization problem*, which consists in finding the optimal distribution of a given amount of plate-like material in the design region $\overline{\Omega}$ in order to minimize the work made on it by a given system of forces:

$$\mathcal{I} = \inf\big\{\mathcal{C}^{\rm pl}(\mu, j, f) \ : \ \mu \in \mathcal{P}(\overline{\Omega})\big\} \ . \tag{1.1}$$

Here measures μ in the space $\mathcal{P}(\overline{\Omega})$ of probabilities on $\overline{\Omega}$ represent the admissible designs, which are allowed to be diffused as well as concentrated on low-dimensional sets. The cost $\mathcal{C}^{\rm pl}(\mu, j, f)$ that we want to minimize is the *plate compliance*: for any $\mu \in \mathcal{P}(\overline{\Omega})$, for a given stored energy density $j : \mathbb{R}^{2\times 2}_{\rm sym} \to \mathbb{R}$, and for a given real measure $f \in \mathcal{M}(\overline{\Omega}; \mathbb{R})$, it is obtained as

$$\mathcal{C}^{\rm pl}(\mu, j, f) := -\inf\left\{\int j(\nabla^2 u)\, d\mu - \langle f, u\rangle_{\mathbb{R}^2} \ : \ u \in \mathcal{C}^\infty(\mathbb{R}^2; \mathbb{R})\right\} \ . \tag{1.2}$$

In particular, in [14] we established the equality

$$\mathcal{I} = \mathcal{S}^2/2 \ , \tag{1.3}$$

where $\mathcal{S}$ is computed through the following *linear constrained problem*:

$$\mathcal{S} = \sup\Big\{\langle f, u\rangle_{\mathbb{R}^2} \ : \ u \in \mathcal{C}^\infty(\mathbb{R}^2; \mathbb{R}) \text{ such that } \rho(\nabla^2 u) \le 1 \text{ on } \Omega\Big\} \tag{1.4}$$

(ρ being related to j by $j(z) = (1/2)\rho^2(z)$). Moreover, we proved that problems (1.1) and (1.4) share the same optimality conditions, which can be explicitly determined.

The goal of this paper is to give a rigorous justification for problems of kind (1.1) or (1.4) and to show how they are linked to the optimal design of thin plates. In fact in [14] these problems were introduced just *formally*, as the second order analogues of their corresponding first order problems. When the design region is a subset of $\mathbb{R}^3$ of the form $Q = \overline{\Omega} \times [-h, h] \subset \mathbb{R}^2 \times \mathbb{R}$, the *elastic compliance* of a mass distribution $\mu \in \mathcal{P}(Q)$ for a given density $j : \mathbb{R}^{3\times 3}_{\rm sym} \to \mathbb{R}$ and a given measure load $F \in \mathcal{M}(Q; \mathbb{R}^3)$ is given by

$$\mathcal{C}^{\rm el}(\mu, j, F) := -\inf\left\{ \int j(e(U))\, d\mu - \langle F, U\rangle_{\mathbb{R}^3} \ : \ U \in \mathcal{C}^\infty(\mathbb{R}^3; \mathbb{R}^3) \right\} , \tag{1.5}$$

where $e(U)$ denotes the symmetric gradient of U. Then the first order three-dimensional (3D) versions of (1.1) and (1.4) read, respectively,

$$\inf\{\mathcal{C}^{\rm el}(\mu, j, F) \ : \ \mu \in \mathcal{P}(Q)\}, \tag{1.6}$$

$$\sup\Big\{ \langle F, U\rangle_{\mathbb{R}^3} \ : \ U \in \mathcal{C}^\infty(\mathbb{R}^3; \mathbb{R}^3) \text{ such that } \rho(e(U)) \le 1 \text{ on } Q \Big\} . \tag{1.7}$$

These problems were studied in detail in [11]; in particular, it turns out that they are related to each other by the condition analogous to (1.3). From a mechanical point of view, they are perfectly justified: when one tries to optimize the compliance of an elastic material under a given load, in the limit of *vanishing volume* microstructures appear—meaning that the material tends to occupy low-dimensional networks—and the limit problem is of type (1.6). This is true both in the case of real materials, due to a common-use result in shape optimization, and in the case of so-called fictitious materials; see section 3.1 for more details.

We now ask,

Do problems of type (1.1) *(or equivalently* (1.4)*) admit any mechanical justification?*

Before explaining the approach we adopt in order to answer this question, let us mention that, prior to [14], problems of type (1.4) had already made their first appearance in the extensive literature on thin plates. Indeed, in the paper [26] by Lewinski and Telega, problems of type (1.4) are obtained in the vanishing volume limit starting from a two-dimensional (2D) compliance model for a plate with *constant* thickness. In the present paper, problems of type (1.1) are obtained through a new, different approach, which in particular enlightens their link with problems of type (1.6). Actually we perform a 3D–2D reduction dimension analysis for problems (1.6): we multiply the maximal height h by an infinitesimal parameter δ, and we take the design region of the form $Q_\delta = \overline{\Omega} \times [-h\delta, h\delta] \subset \mathbb{R}^2 \times \mathbb{R}$. In order to pass to the limit as $\delta \to 0$, a quite natural idea—formerly unexplored to our knowledge—is to start with the 3D vanishing volume model given by (1.7), with Q replaced by Q_δ. One might expect that such suprema remain finite as $\delta \to 0$ and that the convex set of constraints appearing in the limit problem, which is nothing more than the Kuratowski limit of the sets

$$K_\delta := \Big\{ U \in \mathcal{C}^\infty(\mathbb{R}^3; \mathbb{R}^3) \text{ such that } \rho(e(U)) \le 1 \text{ on } \Omega \times (-\delta h, \delta h) \Big\} ,$$

is given by functions whose first order gradient satisfies some suitable relation. Actually, facts come up to these expectations only in the scalar case, namely, when

functions U in K_δ take real values (see Remark 3.8). In spite of this, in the vector case when functions U in K_δ take values in $\mathbb{R}^3$, the situation is dramatically different. First, if the vertical component of the force is of order 1, the suprema in (1.7) blow up to infinity (like δ^{-1}). Then we need to rescale the third component of the force by a factor δ. After such scaling, another crucial difference with respect to the scalar case shows up when studying the Kuratowski limit of K_δ: indeed, due to the role played by a specific strain-displacement relation (of Kirchoff–Love type), two independent constraints appear, each one involving both first and second order derivatives. This analytical fact has an immediate mechanical counterpart: when the load is suitably scaled, a bending effect coupled with membrane energy appears in the limit problem, which can be written as

$$(\mathcal{P}) \qquad \sup\Big\{ \langle \overline{F}, v\rangle_{\mathbb{R}^2} \ : \ v \in \mathcal{C}^\infty(\mathbb{R}^2;\mathbb{R}^3) \text{ such that } \ \overline{\rho}(e(v_1,v_2) \pm h\nabla^2 v_3) \le 1 \text{ on } \Omega \Big\}$$

for a suitably averaged system of forces $\overline{F}$ and a suitably modified function $\overline{\rho}$ (see Theorem 3.3).

Problem $(\mathcal{P})$ reduces to a problem of type (1.4) in the particular case when the unique nonzero component of the load is the vertical one, because in such a case the double constraint imposed on fields v simplifies into one inequality for the Hessian matrix of their third component v_3.

This amounts to saying—see Corollary 3.6—that problems of type (1.1) are recovered as 3D–2D limits of problems of type (1.6) when the load is a vertical one. In particular, for such a kind of load, the optimality conditions found in [14] can be fruitfully employed in order to determine explicit solutions to problem $(\mathcal{P})$. For arbitrary loads, the optimality system has to be suitably generalized in order to cover the case of mixed regimes; see Proposition 3.10 and the examples in section 4.

To conclude this introduction, let us mention that problems of type (1.1) possibly admit further justifications coming from the same background. More precisely, consider a sequence of classical 3D-elasticity problems, where both the maximal height of the design and the total volume of the material are multiplied by infinitesimal parameters, say δ and ε, respectively. The asymptotics of such problems as $\varepsilon, \delta \to 0$ can be studied by adopting one of the two following "strategies (A) or (B)" (notice indeed that δ cannot go to zero for fixed ε). The first possible approach, which we call strategy (A), consists in passing to the limit first in ε—which as already mentioned yields problems of type (1.7)—and then in δ, ending up with problems of type $(\mathcal{P})$ (or (1.1)).

But it is tempting to also look at different ways of performing the double limit in δ and ε. One might follow the alternative strategy (B) of passing to the limit *contemporarily* in ε and δ, keeping the quotient $\eta := \delta/\varepsilon$ fixed, and eventually letting η tend to $+\infty$.

The interest in this alternative strategy (B) is twofold: investigating the commutativity of the double limit process, and linking our approach with the classical thin plates model widely studied in the literature, where a cubic dependence on the profile of the plate appears (without any attempt of being complete, let us refer the reader to [1, 5, 6, 7, 8, 9, 16, 18, 20, 22, 25, 27, 28]).

Here we limit ourselves to address strategy (B) as an interesting open field. We do not accomplish the outcoming results, which are postponed to a forthcoming work.

The paper is organized as follows. In section 2 we fix some notation and the setting of the problem; then we state our main results in section 3. Section 4 is

entirely devoted to exemplifying the application of the results obtained in section 3. Proofs are collected in section 5.

2. Preliminaries and setting of the problem. Let us take a design region in $\mathbb{R}^3$ of the form $Q = \overline{\Omega} \times [-h, h]$, where Ω is an open bounded connected subset of $\mathbb{R}^2$ and h is fixed in $\mathbb{R}^+$; the spatial variable in Q will be denoted by (x', x_3).

Consider a given amount m of elastic material placed in a subset A of the design region: thus A is subject to the constraints

$$A \subseteq Q = \overline{\Omega} \times [-h, h] \ , \qquad \mathrm{vol}(A) = m \ .$$

If the stored energy density is represented by a given integrand $j : \mathbb{R}^{3\times 3}_{\mathrm{sym}} \to \mathbb{R}$ and the material is subject to a given system of forces $F = (F_1, F_2, F_3) \in \mathcal{M}(Q; \mathbb{R}^3)$, the resulting elastic compliance is given by

$$\mathcal{C}^{\mathrm{el}}\big(A, j, F\big) := -\inf \left\{ \int_A j(e(U))\, dx - \langle F, U\rangle_{\mathbb{R}^3} \ : \ U \in \mathcal{C}^\infty(\mathbb{R}^3; \mathbb{R}^3) \right\}$$

(here and in the following, $e(U)$ denotes the symmetric part of the gradient of U).

We assume that j is convex, 2-homogeneous, and coercive, so that it can be written as

$$j(z) = \frac{1}{2}\rho^2(z) \ , \qquad \text{with } \inf_{z\neq 0} \frac{\rho(z)}{|z|} > 0 \ . \tag{2.1}$$

The typical choice of j is the usual quadratic elastic potential of the kind

$$j(z) = \frac{\lambda}{2}(\mathrm{tr}(z))^2 + \mu |z|^2 \ . \tag{2.2}$$

Moreover, for the compliance to be finite, we ask that the system of forces is *balanced*, namely,

$$\langle F, U\rangle_{\mathbb{R}^3} = 0 \qquad \text{whenever } e(U) = 0 \, , \tag{2.3}$$

and also that it belongs to the Sobolev space $H^{-1}(Q; \mathbb{R}^3)$.

We want to now consider the problem of optimizing the compliance when both the maximal height of the design and the total volume of the material become very small. In this situation the maximal height and the total volume will be multiplied by two positive vanishing parameters, say δ and ε, respectively:

$$A \subseteq Q_\delta = \overline{\Omega} \times [-\delta h, \delta h] \ , \qquad \mathrm{vol}(A) = \varepsilon m \ . \tag{2.4}$$

The same optimization problem can also be considered for "fictitious materials," that is, when the set A is replaced by a density θ satisfying

$$\theta \in L^\infty(\mathbb{R}^3; [0, 1]) \ , \qquad \mathrm{spt}(\theta) \subseteq Q_\delta \ , \qquad \int \theta\, dx = \varepsilon m \ , \tag{2.5}$$

and the definition of compliance is extended by setting

$$\mathcal{C}^{\mathrm{el}}\big(\theta, j, F\big) := -\inf \left\{ \int j(e(U))\, \theta\, dx - \langle F, U\rangle_{\mathbb{R}^3} \ : \ U \in \mathcal{C}^\infty(\mathbb{R}^3; \mathbb{R}^3) \right\} \ . \tag{2.6}$$

So we focus attention on the two variational problems

$$\inf\Big\{\mathcal{C}^{\rm el}\big(A,j,F\big)\ :\ A \text{ satisfying (2.4)}\Big\}\,, \tag{2.7}$$

$$\inf\Big\{\mathcal{C}^{\rm el}\big(\theta,j,F\big)\ :\ \theta \text{ satisfying (2.5)}\Big\}\,. \tag{2.8}$$

As announced in the introduction, in this paper we study the asymptotics of the above infima as $\varepsilon,\delta\to 0$ through strategy (A), which seems to be the simpler way leading from the infima in (2.7) or (2.8) to a problem of kind (1.1). Recall that this strategy consists in the following two steps:

- *Step* 1. Keeping δ fixed, let ε tend to zero (so that the quotient $\eta := \delta/\varepsilon$ tends to $+\infty$).
- *Step* 2. Let δ tend to zero.

The first crucial remark is that the infima in (2.7) or (2.8) blow up at each of the two steps. More precisely, if δ is fixed and ε tends to zero, the infima are of order ε^{-1}. Indeed, via the change of variables $V = U/\varepsilon$, it is easy to obtain the identity

$$\mathcal{C}^{\rm el}\left(\frac{\theta}{\varepsilon},j,F\right) = \varepsilon\mathcal{C}^{\rm el}\big(\theta,j,F\big)\ ,$$

whose left-hand side has a finite infimum for θ satisfying (2.5). Therefore, we are led to rescale the system of forces into $\sqrt{\varepsilon}F$; this will ensure that the infimum of the compliance remains finite as ε tends to zero in view of the identity

$$\mathcal{C}^{\rm el}\big(\theta,j,\sqrt{\varepsilon}F\big) = \varepsilon\mathcal{C}^{\rm el}\big(\theta,j,F\big)\ .$$

In turn, the infima obtained through the first step of strategy (A) blow up again when performing the second step, that is, when δ also tends to zero. Thus, we need to rescale the system of forces also with respect to δ. It will be more clear later on (see the proof of Theorem 3.3) that the right scaling of the load in order to keep finite the suprema in (3.3) as $\delta\to 0$ is the following one: set $Q_\delta := \overline{\Omega}\times[-\delta h,\delta h]$, and change F into the element $F^\delta\in H^{-1}(Q_\delta;\mathbb{R}^3)$ which acts on any test function $\varphi\in\mathcal{C}^\infty(\mathbb{R}^3;\mathbb{R}^3)$ as

$$\langle F^\delta,\varphi\rangle_{\mathbb{R}^3} := \sum_{i=1}^{2}\langle F_i(x),\varphi_i(x',\delta x_3)\rangle_{\mathbb{R}^3} + \delta\langle F_3(x),\varphi_3(x',\delta x_3)\rangle_{\mathbb{R}^3}\ .$$

We stress that, in the above definition, the vertical component F_3 is multiplied by δ, as is usual when dealing with plates in a flexion regime.

Summarizing, our rescaled optimization problems read

$$\mathcal{I}_{\varepsilon,\delta} := \inf\Big\{\mathcal{C}^{\rm el}\big(A,j,\sqrt{\varepsilon}F^\delta\big)\ :\ A \text{ satisfying (2.4)}\Big\}\ , \tag{2.9}$$

$$\widetilde{\mathcal{I}}_{\varepsilon,\delta} := \inf\Big\{\mathcal{C}^{\rm el}\big(\theta,j,\sqrt{\varepsilon}F^\delta\big)\ :\ \theta \text{ satisfying (2.5)}\Big\}\ . \tag{2.10}$$

Notice that, for each fixed (ε,δ), $\mathcal{I}_{\varepsilon,\delta}$ and $\widetilde{\mathcal{I}}_{\varepsilon,\delta}$ should remain finite because $\sqrt{\varepsilon}F^\delta$ is still balanced; that is, it fulfills (2.3). Further, in view of the heuristic considerations above, we expect that $\mathcal{I}_{\varepsilon,\delta}$ and $\widetilde{\mathcal{I}}_{\varepsilon,\delta}$ admit finite limits as ε and δ tend to zero. In the remainder of the paper our goal is to identify such limits.

For simplicity of notation, in what follows we take the volume parameter m appearing in (2.4) and (2.5) equal to 1 (this is not restrictive up to a multiplicative factor).

3. Main results. The two steps of strategy (A) are carried out, respectively, in subsections 3.1 and 3.2 below, and the optimality conditions for the limit problem follow in subsection 3.3. All the statements (except the one of Proposition 3.2) will be proved in section 5.

3.1. Vanishing volume limit (fixed thickness). When one performs the limit as $\varepsilon \to 0$ of $\mathcal{I}_{\varepsilon,\delta}$ or of $\widetilde{\mathcal{I}}_{\varepsilon,\delta}$, one obtains a pretty tractable limit infimum problem over the space $\mathcal{P}(Q_\delta)$ of probabilities on Q_δ. The functional to be minimized is of the kind $\mu \mapsto \mathcal{C}^{\rm el}\big(\mu, \mathcal{J}, F^\delta\big)$, where for a given integrand $\mathcal{J}$ we have set

$$\mathcal{C}^{\rm el}\big(\mu, \mathcal{J}, F^\delta\big) := -\inf\left\{ \int \mathcal{J}(e(U))\, d\mu - \langle F^\delta, U\rangle_{\mathbb{R}^3} \ : \ U \in \mathcal{C}^\infty(\mathbb{R}^3, \mathbb{R}^3) \right\} .$$

The only difference between the real and the fictitious case lies in the determination of the integrand $\mathcal{J}$: in the fictitious case one can simply take $\mathcal{J} = j$, while in the real case one has to take $\mathcal{J} = j_0$, with j_0 being deduced from j through a suitable formula. This is stated more precisely in the next two propositions.

Proposition 3.1 (fictitious materials). *There holds*

$$\lim_{\varepsilon\to 0} \widetilde{\mathcal{I}}_{\varepsilon,\delta} = \widetilde{\mathcal{I}}_\delta := \inf\Big\{ \mathcal{C}^{\rm el}\big(\mu, j, F^\delta\big) \ : \ \mu \in \mathcal{P}(Q_\delta) \Big\} .$$

Proposition 3.2 (real materials). *Assume that j is taken of the form* (2.2). *Then there holds*

$$\lim_{\varepsilon\to 0} \mathcal{I}_{\varepsilon,\delta} = \mathcal{I}_\delta := \inf\Big\{ \mathcal{C}^{\rm el}\big(\mu, j_0, F^\delta\big) \ : \ \mu \in \mathcal{P}(Q_\delta) \Big\} ,$$

where $j_0 : \mathbb{R}^{3\times 3}_{\rm sym} \to \mathbb{R}$ denotes the following modified integrand:

$$j_0(z) = \frac{1}{2}\rho_0(z)^2 := \sup\big\{ z\cdot z^* - j^*(z^*) \ : z \in \mathbb{R}^{3\times 3}_{\rm sym} \ , \ \det(z^*) = 0 \big\} . \tag{3.1}$$

Proposition 3.2 is actually a reformulation of the results in [2, 4] (to which we refer for a proof), where the effective stress potential—the Fenchel conjugate $j_0^*(z^*)$ of $j_0(z)$—is characterized explicitly in terms of the eigenvalues of the symmetric tensor z^*. Formula (3.1) is a concise way to recover directly the related effective strain potential j_0; we refer the reader to [3] for some explicit computations in case j is given by (2.2). We believe that Proposition 3.2 remains true even for nonquadratic strain potentials; see [10].

3.2. Vanishing thickness limit. The kind of mass optimization problem given by Propositions 3.1 and 3.2 has been widely studied in [11], where it is proved in particular that

$$\widetilde{\mathcal{I}}_\delta = \widetilde{\mathcal{S}}_\delta^2/2 \ , \qquad \mathcal{I}_\delta = \mathcal{S}_\delta^2/2 \ , \tag{3.2}$$

where $\widetilde{\mathcal{S}}_\delta, \mathcal{S}_\delta$ are given by the following linear constraint problems:

$$\begin{aligned} \widetilde{\mathcal{S}}_\delta &:= \sup\Big\{ \langle F^\delta, U\rangle_{\mathbb{R}^3} \ : \ U \in \mathcal{C}^\infty(\mathbb{R}^3;\mathbb{R}^3) \ \text{ such that } \ \rho(e(U)) \le 1 \text{ on } Q_\delta \Big\} , \\ \mathcal{S}_\delta &:= \sup\Big\{ \langle F^\delta, U\rangle_{\mathbb{R}^3} \ : \ U \in \mathcal{C}^\infty(\mathbb{R}^3;\mathbb{R}^3) \ \text{ such that } \ \rho_0(e(U)) \le 1 \text{ on } Q_\delta \Big\} . \end{aligned} \tag{3.3}$$

Thanks to the crucial equalities (3.2), this second step in strategy (A) is reduced to determining the limit of the sequences $\widetilde{\mathcal{S}}_\delta$ and $\mathcal{S}_\delta$ in (3.3) as $\delta \to 0$. In other words,

our goal is reached if we are able to perform the 3D–2D reduction dimension analysis for such sequences of linear constrained problems.

In order to state our main theorem, we need to introduce an effective system of forces $\overline{F} \in \mathcal{M}(\overline{\Omega};\mathbb{R}^3)$ and an effective integrand $\overline{j} : \mathbb{R}^{2\times 2}_{\rm sym} \to \mathbb{R}$.

For any $\lambda \in \mathcal{M}(Q;\mathbb{R})$, we denote by $[\lambda] \in \mathcal{M}(\overline{\Omega},\mathbb{R})$ the marginal measure defined by the equality

$$\langle [\lambda], \varphi\rangle_{\mathbb{R}^2} := \langle \lambda, \varphi\rangle_{\mathbb{R}^3} \qquad \forall \varphi \in \mathcal{C}^\infty(\mathbb{R}^2;\mathbb{R}) \ ; \tag{3.4}$$

then we define the effective system of forces $\overline{F} = (\overline{F}_1, \overline{F}_2, \overline{F}_3) \in \mathcal{M}(\overline{\Omega};\mathbb{R}^3)$ componentwise by

$$\overline{F}_i := [F_i], \qquad i = 1,2, \qquad \text{and} \qquad \overline{F}_3 := \left[F_3 + x_3 \sum_{i=1}^{2} \frac{\partial F_i}{\partial x_i} \right] \ . \tag{3.5}$$

The effective density $\overline{j} : \mathbb{R}^{2\times 2}_{\rm sym} \to \mathbb{R}$ is obtained from j through the following formula:

$$\overline{j}(z) = \frac{1}{2}\overline{\rho}(z)^2 := \inf \left\{ j\left(z + \sum_{i=1}^{3} \xi_i (e_i \otimes e_3)^* \right) \ : \ \xi_i \in \mathbb{R} \right\} \ . \tag{3.6}$$

THEOREM 3.3. *The limit as $\delta \to 0$ of both the sequences $\{\widetilde{\mathcal{S}}_\delta\}$ and $\{\mathcal{S}_\delta\}$ defined by* (3.3) *is given by*

$$\mathcal{S}_0 := \sup\Big\{ \langle \overline{F}, v\rangle_{\mathbb{R}^2} \ : \ v \in \mathcal{C}^\infty(\mathbb{R}^2;\mathbb{R}^3) \ , \ \overline{\rho}(e(v_1,v_2) \pm h\nabla^2 v_3) \le 1 \text{ on } \Omega \Big\} \ , \tag{3.7}$$

where $\overline{F}$ and $\overline{\rho}$ are given by (3.5) *and* (3.6)*, respectively.*

It is worth noticing that, once Theorem 3.3 is proved for one among the two sequences $\{\widetilde{\mathcal{S}}_\delta\}$ and $\{\mathcal{S}_\delta\}$, the statement for the other one follows immediately from the following algebraic lemma.

LEMMA 3.4. *There holds*

$$\overline{j}(z) = \overline{j_0}(z) \qquad \forall\, z \in \mathbb{R}^{2\times 2}_{\rm sym} \ .$$

Another remark about Theorem 3.3 is that, in general, the limit problem given by (3.7) cannot be "decoupled" into two separate problems, respectively, of first order in (v_1, v_2) and of second order in v_3. Nevertheless, there are special cases when it simplifies into one of them.

COROLLARY 3.5.

(i) *If $\overline{F}_1 = \overline{F}_2 = 0$, then*

$$\mathcal{S}_0 = \sup\Big\{ \langle \overline{F}_3, v_3\rangle_{\mathbb{R}^2} \ : \ v_3 \in \mathcal{C}^\infty(\mathbb{R}^2;\mathbb{R}) \text{ such that } \ \overline{\rho}(\nabla^2 v_3) \le 1/h \text{ on } \Omega \Big\} \ .$$

(ii) *If $\overline{F}_3 = 0$, then*

$$\mathcal{S}_0 = \sup\Bigg\{ \sum_{i=1}^{2} \langle \overline{F}_i, v_i\rangle_{\mathbb{R}^2} \ : \ (v_1,v_2) \in \mathcal{C}^\infty(\mathbb{R}^2;\mathbb{R}^2) \text{ such that } \overline{\rho}(e(v_1,v_2)) \le 1 \text{ on } \Omega \Bigg\} \ .$$

When $\overline{F}_1 = \overline{F}_2 = 0$, combining case (i) of the above corollary with our results in [14], we are finally able to prove that the infima in (2.10) converge to a limit problem of type (1.1).

COROLLARY 3.6. *Let $\mathcal{I}_{\varepsilon,\delta}$ and $\widetilde{\mathcal{I}}_{\varepsilon,\delta}$ be defined, respectively, by* (2.9) *and* (2.10). *If $\overline{F}_1 = \overline{F}_2 = 0$, there holds*

$$\lim_{\delta\to 0}\lim_{\varepsilon\to 0}\mathcal{I}_{\varepsilon,\delta} = \lim_{\delta\to 0}\lim_{\varepsilon\to 0}\widetilde{\mathcal{I}}_{\varepsilon,\delta} = h^{-2}\inf\left\{\mathcal{C}^{\rm pl}\big(\mu,\overline{j},\overline{F}_3\big)\ :\ \mu\in\mathcal{P}(\overline{\Omega})\right\}, \tag{3.8}$$

where the plate compliance $\mathcal{C}^{\rm pl}\big(\mu,\overline{j},\overline{F}_3\big)$ is defined according to (1.2).

Remark 3.7. Let us emphasize that the assumption $F\in H^{-1}(Q;\mathbb{R}^3)$ stated in section 2 is not needed for the well-posedness of the variational problems in (3.7) or (3.8). For instance, it is enough to ask that F is a measure with finite variation. In particular, pointwise applied forces are allowed in our limit problem.

Remark 3.8. The scalar analogue of Theorem 3.3 is simpler, and it can be easily obtained with the same proof. For any $f\in\mathcal{M}(Q;\mathbb{R})$ (with $f\in H^{-1}(Q;\mathbb{R})$ and $\int_Q f = 0$) and any convex, 1-homogeneous, coercive function $\rho:\mathbb{R}^3\to\mathbb{R}$, it can be stated as follows: the limit as $\delta\to 0$ of

$$s_\delta := \sup\Big\{\langle f^\delta, u\rangle_{\mathbb{R}^3}\ :\ u\in\mathcal{C}^\infty(\mathbb{R}^3;\mathbb{R})\ \text{ such that }\ \rho(\nabla u)\le 1 \text{ on } Q_\delta\Big\}$$

is given by

$$s_0 := \sup\Big\{\langle [f], v\rangle_{\mathbb{R}^2}\ :\ v\in\mathcal{C}^\infty(\mathbb{R}^2;\mathbb{R}) \text{ such that }\ \overline{\rho}(\nabla v)\le 1 \text{ on } \Omega\Big\}.$$

Here $f^\delta\in\mathcal{M}(Q;\mathbb{R})$ is the measure which acts on any test function $\varphi\in\mathcal{C}^\infty(\mathbb{R}^3,\mathbb{R})$ as $\langle f^\delta,\varphi\rangle_{\mathbb{R}^3} := \langle f, \varphi(x',\delta x_3)\rangle_{\mathbb{R}^3}$, while $[f]\in\mathcal{M}(\overline{\Omega};\mathbb{R})$ is defined according to (3.4), and $\overline{\rho}:\mathbb{R}^2\to\mathbb{R}$ is given by $\overline{\rho}(z) := \inf\big\{\rho(z+\xi e_3)\ :\ \xi\in\mathbb{R}\big\}$.

3.3. Dual problem and optimality conditions. For the practice computation of $\mathcal{S}_0$, one needs to determine optimality conditions for the infimum problem $(\mathcal{P})$ which defines $\mathcal{S}_0$. Such optimality conditions are obtained in [14], by exploiting the results of [15], in the special situation of Corollary 3.5(i). Let us see how they look in the more general situation of Theorem 3.3. As a preliminary step, we begin by writing the dual problem of $(\mathcal{P})$ (intended in the usual sense of convex analysis; see, e.g., [19]). We denote by $\rho^o:\mathbb{R}^{2\times 2}\to\mathbb{R}$ the *polar function of* ρ, that is,

$$\rho^o(\xi) := \sup\{\xi\cdot z\ :\ \rho(z)\le 1\},$$

where $\xi\cdot z$ indicates the Euclidean scalar product. Then, for λ in the space $\mathcal{M} = \mathcal{M}(\overline{\Omega};\mathbb{R}^{2\times 2}_{\rm sym})$ of $\mathbb{R}^{2\times 2}_{\rm sym}$-valued measures supported on $\overline{\Omega}$ with finite total variation, we use the notation $\int\rho^o(\lambda)$ in the usual sense of convex 1-homogeneous functionals on measures (see, for instance, [21]).

LEMMA 3.9. *The dual problem $(\mathcal{P}^*)$ of $(\mathcal{P})$ is given by*

$$\min\Big\{\int\overline{\rho}^o(\lambda^+)+\int\overline{\rho}^o(\lambda^-)\ :\ \lambda^\pm\in\mathcal{M}\ ,\ -\operatorname{div}(\lambda^+-\lambda^-) = (\overline{F}_1,\overline{F}_2)\ ,\\ h\operatorname{div}^2(\lambda^+-\lambda^-) = \overline{F}_3\Big\}\ ,$$

where the operators div *and* div^2 *are intended in distributional sense.*

PROPOSITION 3.10. *Let v be admissible for $(\mathcal{P})$ and $\lambda^{\pm}$ be admissible for $(\mathcal{P})^*$. They are optimal for the respective problems if and only if the following two equations are satisfied:*

$$\overline{\rho}^o(\lambda^+) = \big\langle \lambda^+,\, e(v_1,v_2) + h\nabla^2 v_3 \big\rangle_{\mathbb{R}^2}\,, \quad \overline{\rho}^o(\lambda^-) = \big\langle \lambda^-,\, e(v_1,v_2) - h\nabla^2 v_3 \big\rangle_{\mathbb{R}^2}\,. \tag{3.9}$$

The application of Proposition 3.10 is exemplified in two concrete cases in section 4.

Remark 3.11. In Lemma 3.9 and Proposition 3.10, the measures $\lambda^{\pm}$ play the role of Lagrange multipliers for the constraint $\overline{\rho}(e(v_1,v_2) \pm h\nabla^2 v_3) \le 1$ in (3.7). From the mechanical point of view, they can be interpreted as follows: for each $\delta > 0$, let σ_δ be the stress tensor in the 3D elastic problem, which after rescaling and change of variables is supported on an optimal structure located in the reference set $Q = \overline{\Omega} \times [-h,h]$. When $\delta \to 0$, σ_δ as a tensor measure concentrates on the top-bottom region $\overline{\Omega} \times \{x_3 = \pm h\}$ and produces $\lambda^{\pm}$ as limit in-plane stress tensors.

Remark 3.12. The optimality condition (3.9) can be extended to the case where v is not smooth by using suitable notions of tangential (first and second order) gradient with respect to measures for which we refer the reader to [12, 15]. Such optimal v are in fact limits of maximizing sequences for $(\mathcal{P})$ and satisfy $v_1, v_2 \in W^{1,q}(\Omega)$ for all $q < +\infty$ and $v_3 \in W^{2,\infty}(\Omega)$.

4. Examples. In the examples we are going to discuss, the systems of loads are discrete (see Remark 3.7). Moreover, they lie in a plane, so that the corresponding optimal structures are supported in that plane. As a consequence, we take a planar design region Q of the form $\overline{\Omega} \times [-h,h]$, with Ω being an open bounded interval of the real line. Thus throughout this section the spatial variable $x' \in \overline{\Omega}$ will become x_1, and the role of the "vertical variable" x_3 will be played by x_2. Clearly, the limit problem will simply reduce to a one-dimensional problem.

We take as a function ρ in (3.3) the Euclidean norm on $\mathbb{R}^{2\times 2}_{\rm sym}$. In this case it is easy to check, by using Lemma 3.4, that the corresponding functions $\overline{\rho}$ and $\overline{\rho_0}$ will simply be equal to the Euclidean norm on $\mathbb{R}$.

Example 4.1 (pure flexion regime). For fixed nonnegative parameters l and h_0, let the points O, A, B have coordinates

$$O := \big(0,0\big)\,, \qquad A := \big(l,0\big)\,, \qquad B := \big(0,h_0\big)\,,$$

and let us consider the following system of forces:

$$F_1 := \delta_O - \delta_B\,, \qquad F_2 = \frac{h_0}{l}(\delta_B - \delta_A)\,.$$

This system of forces is supported on the design region $Q = \overline{\Omega} \times [-h,h]$, provided Ω is an interval containing both O and A, and $h \ge h_0$ (see Figure 4.1). Moreover, it is immediate to check that this system is balanced. Then we can apply Theorem 3.3 to compute $\mathcal{S}_0$, namely the limit as $\delta \to 0$ of the suprema $\mathcal{S}_\delta$ or $\widetilde{\mathcal{S}}_\delta$ in (3.3). The effective system of forces on the x_1-axis is easily obtained:

$$\overline{F}_1 := 0\,, \qquad \overline{F}_2 = \frac{h_0}{l}(\delta_O - \delta_A) - h_0\delta'_O\,.$$

Then according to (3.7) $\mathcal{S}_0$ can be expressed as

$$\sup\left\{ \frac{h_0}{l}\big(v_2(O) - v_2(A)\big) + h_0 v_2'(O) \;:\; v_2 \in \mathcal{C}^\infty(\mathbb{R};\mathbb{R}) \text{ such that } |(v_2)''| \le \frac{1}{h} \text{ on } \Omega \right\}\,.$$

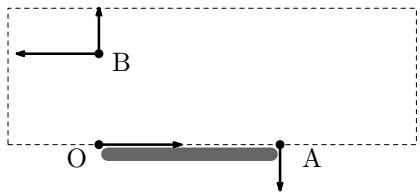

FIG. 4.1. *Loads yielding a pure flexion regime in the whole of* $\overline{OA}$.

In order to compute the explicit value of $\mathcal{S}_0$, we apply Proposition 3.10. Given $v = (v_1, v_2) \in \mathcal{C}^\infty(\mathbb{R}; \mathbb{R}^2)$ and $\lambda^\pm \in \mathcal{M}(\overline{\Omega}; \mathbb{R})$, they are solutions to problem $(\mathcal{P})$ and its dual $(\mathcal{P}^*)$ if the following system is satisfied:

$$\begin{cases} (\lambda^+ + \lambda^-)' = 0\,, \\ h(\lambda^+ - \lambda^-)'' = \dfrac{h_0}{l}(\delta_O - \delta_A) - h_0\delta'_O\,, \\ |(v_2)''| \le \dfrac{1}{h}\,, \\ |\lambda^\pm| = \langle \lambda^\pm, \pm h(v_2)'' \rangle_{\mathbb{R}}\ , \end{cases}$$

where the first two equations select admissible $\lambda^\pm$ in problem $(\mathcal{P})^*$ (see Lemma 3.9), the third equation selects admissible v in problem $(\mathcal{P})$, and the last couple of equations corresponds to the optimality conditions (3.9).

Solutions $\lambda^\pm$ to the first two equations are determined by

$$\lambda^+ = -\lambda^- = \frac{1}{2}\frac{h_0}{hl}(x_1 - l)\chi_{\overline{OA}}(x_1)\mathcal{L}^1 \llcorner \overline{OA}\ ,$$

and the remaining conditions are satisfied if we take

$$v_2(x_1) = -\frac{x_1^2}{2h}\ .$$

Thus we find for the value of the energy

$$\mathcal{S}_0 = \frac{lh_0}{2h}\ .$$

Remark 4.2. (i) Exactly the same result above holds if, in the system of forces, the point A is replaced by any other point of the type (l, h_1), with $|h_1| \le h$ (or even more generally if δ_A is replaced by any probability on the segment $l \times [-h, h]$).

(ii) Exactly the same result above holds if, with the same system of forces, the design region is changed into $\overline{\Omega} \times [0, h]$.

(iii) Note that $\mathcal{S}_0$ is infinitesimal as $h \to +\infty$, as always happens in a pure flexion regime (see Corollary 3.5(i)).

(iv) The role of $\lambda^\pm$ in the reconstruction of 3D-optimal structures will be investigated more deeply in a subsequent work. In the above example we guess that, for any $\delta > 0$, optimal structures are given by two horizontal bars at heights 0 and h, connected by some diagonal bars of vanishing mass.

Example 4.3 (mixed regime). For fixed nonnegative parameters l, h_0, α, let the points O, A, B, C have coordinates

$$O := (0,0)\ , \qquad A := \left(-\frac{l}{2}, 0\right)\ , \qquad B := \left(\frac{l}{2}, 0\right)\ , \qquad C := (0, h_0)\ ,$$

and let us consider the axially symmetric system of forces:

$$F_1 := \alpha(\delta_B - \delta_A)\ , \qquad F_2 = \delta_C - \frac{1}{2}(\delta_A + \delta_B)\ .$$

This system of forces is balanced and is supported on the design region $Q = \overline{\Omega} \times [-h, h]$, provided the interval Ω contains both A and B, and $h \geq h_0$. The effective system of forces is given on the x_1-axis by

$$\overline{F}_1 := \alpha\big(\delta_B - \delta_A\big)\ , \qquad \overline{F}_2 = \delta_O - \frac{1}{2}\big(\delta_A + \delta_B\big)\ .$$

Then according to (3.7) the limit $\mathcal{S}_0$ of the suprema $\mathcal{S}_\delta$ or $\widetilde{\mathcal{S}}_\delta$ in (3.3) can be expressed as

$$\sup\Big\{\alpha\big[v_1(B) - v_1(A)\big] + v_2(O) - \frac{1}{2}\big[v_2(A) + v_2(B)\big]\ :\ v \in \mathcal{C}^\infty(\mathbb{R};\mathbb{R}^2) \text{ such that } |(v_1)' \pm h(v_2)''| \leq 1 \text{ on } \Omega\Big\}\ .$$

Let us compute the explicit value of $\mathcal{S}_0$ in terms of the involved parameters.

By Proposition 3.10, given $v = (v_1, v_2) \in \mathcal{C}^\infty(\mathbb{R}^2;\mathbb{R}^2)$ and $\lambda^\pm \in \mathcal{M}(\overline{\Omega};\mathbb{R})$, they are solutions to problem $(\mathcal{P})$ and its dual $(\mathcal{P}^*)$ if the following system is satisfied:

$$\begin{cases} -(\lambda^+ + \lambda^-)' = \alpha\big(\delta_A - \delta_B\big)\,, \\ h(\lambda^+ - \lambda^-)'' = \delta_O - \dfrac{1}{2}\big(\delta_A + \delta_B\big)\,, \\ |(v_1)' \pm h(v_2)''| \leq 1\,, \\ |\lambda^\pm| = \langle \lambda^\pm, (v_1)' \pm h(v_2)''\rangle_{\mathbb{R}}\ . \end{cases}$$

Solutions $\lambda^\pm$ to the first two equations are determined by

$$\lambda^+ + \lambda^- = \alpha\mathcal{L}^1 \llcorner \overline{AB}\ , \qquad \lambda^+ - \lambda^- = \frac{1}{2h}\left(|x_1| - \frac{l}{2}\right)\mathcal{L}^1 \llcorner \overline{AB}\ , \tag{4.1}$$

and the remaining conditions are satisfied, provided

$$(v_1)' \pm h(v_2)'' = \operatorname{sign}(\lambda^\pm)\ , \tag{4.2}$$

where $\operatorname{sign}(\lambda^\pm)$ denotes the sign of (the densities of) $\lambda^\pm$.

From (4.1), we see in particular that λ^- remains always nonnegative, whereas for λ^+ two cases may occur:

case (1): if $h \geq l/(4\alpha)$, then λ^+ remains nonnegative;

case (2): if $h < l/(4\alpha)$, then

$$\begin{cases} \lambda^+ \geq 0 & \text{if } |x_1| \geq (l/2) - 2h\alpha\,, \\ \lambda^+ < 0 & \text{if } |x_1| < (l/2) - 2h\alpha\ . \end{cases}$$

Accordingly, solutions to (4.2) and the value of $\mathcal{S}_0$ can be easily computed:

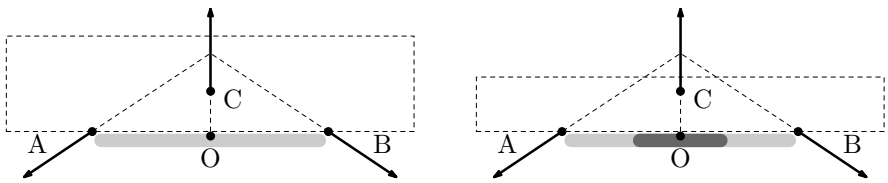

FIG. 4.2. *Loads yielding a membrane/flexion regime in the clear/dark part of* $\overline{AB}$.

case (1): we have $(v_1)' = 1$, $(v_2)'' = 0$ (see the left side of Figure 4.2), and

$$\mathcal{S}_0 = \int \lambda^+ + \int \lambda^- = \alpha l \ ;$$

case (2): we have (see the right side of Figure 4.2)

$$\begin{cases} (v_1)' = 1 \text{ and } (v_2)'' = 0 & \text{if } |x_1| \geq (l/2) - 2h\alpha \,, \\ (v_1)' = 0 \text{ and } (v_2)'' = 1/h & \text{if } |x_1| < (l/2) - 2h\alpha \ , \end{cases}$$

and

$$\mathcal{S}_0 = \int |\lambda^+| + \int \lambda^- = 2h\big[\alpha^2 + l^2/(16h^2)\big] \ .$$

Summing up, we have obtained

$$\mathcal{S}_0 = \begin{cases} \alpha l & \text{if } h \geq l/(4\alpha) \,, \\ 2h\big[\alpha^2 + l^2/(16h^2)\big] & \text{if } h < l/(4\alpha) \ . \end{cases}$$

Remark 4.4. (i) The value found above for $\mathcal{S}_0$ is always independent of the parameter h_0.

(ii) The critical height $h_c := l/(4\alpha)$ is the second coordinate of the intersection point between the straight lines $A + t(-\alpha, -1/2)$ and $B + t(\alpha, -1/2)$ (namely the point where the two forces $(-\alpha, -1/2)\delta_A$ and $(\alpha, -1/2)\delta_B$ concur). If $h \geq h_c$, then the value of $\mathcal{S}_0$ is independent of h. In spite of this, if $h < h_c$, then the dependence of $\mathcal{S}_0$ on h tells that optimal structures for $\mathcal{S}_\delta$ or $\widetilde{\mathcal{S}}_\delta$ do "touch" the bottom of the design region (independently of the choice of h_0).

5. Proofs of the results in section 3.

Proof of Proposition 3.1. Let δ be fixed. We introduce, for every ε, the functional J_ε and the function φ_ε defined, respectively, on $\mathcal{M}(Q_\delta; \mathbb{R}^+)$ and on $\mathbb{R}$ by

$$J_\varepsilon(\mu) := \begin{cases} \mathcal{C}^{\rm el}\big(\mu, j, F^\delta\big) & \text{if } \mu = \theta\, dx \ , \ \theta \in L^\infty(\mathbb{R}^3; [0, \varepsilon^{-1}]) \ , \ \mathrm{spt}(\theta) \subseteq Q_\delta \,, \\ +\infty & \text{otherwise,} \end{cases}$$

$$\varphi_\varepsilon(t) := \begin{cases} \inf\left\{ J_\varepsilon(\mu) \ : \ \mu \in \mathcal{M}(Q_\delta; \mathbb{R}^+) \ , \ \displaystyle\int d\mu = t \right\} & \text{if } 0 < t \leq \varepsilon^{-1} |Q_\delta| \,, \\ +\infty & \text{otherwise.} \end{cases}$$

It is easy to check that J_ε and φ_ε are convex and decrease as ε goes down to zero. In particular, the limit $\varphi_0(t) = \lim_{\varepsilon \to 0} \varphi_\varepsilon(t)$ exists and is convex as a function of t. We claim that, for every $t > 0$, there holds

$$\varphi_0(t) = \frac{(\widetilde{\mathcal{S}}_\delta)^2}{2\, t} \,. \tag{5.1}$$

Recalling (3.2), the proposition will follow by taking $t = 1$, since by (2.10) and (2.6)

$$\widetilde{\mathcal{I}}_{\varepsilon,\delta} = \inf\left\{\mathcal{C}^{\rm el}\left(\frac{\theta}{\varepsilon}, j, F^\delta\right) \ : \ \theta \text{ satisfying (2.5)}\right\} \ = \ \varphi_\varepsilon(1) \ .$$

For proving (5.1), we are going to identify the Fenchel conjugate of φ_0 through the formula

$$\varphi_0^* = \Big(\inf_\varepsilon \varphi_\varepsilon\Big)^* = \sup_\varepsilon \varphi_\varepsilon^* \ . \tag{5.2}$$

To compute φ_ε^*, we begin by noticing that for every $k \in \mathbb{R}$, φ_ε^* computed at $-k$ coincides with the Fenchel conjugate of J_ε computed at the constant function identically equal to $-k$. Indeed,

$$\varphi_\varepsilon^*(-k) = \sup\left\{-\int k\, d\mu - J_\varepsilon(\mu) \ : \ \mu \in \mathcal{M}(Q_\delta;\mathbb{R}^+) \ , \ \int d\mu = t\right\} = J_\varepsilon^*(-k) \ . \tag{5.3}$$

Let us compute $J_\varepsilon^*(-k)$. By definition we have

$$J_\varepsilon^*(-k) = \sup_\mu \inf_U \left\{\int j\big(e(U) - k\big)\ d\mu - \langle F^\delta, U\rangle_{\mathbb{R}^3}\right\} \ ,$$

where the infimum in U is taken over $\mathcal{C}^\infty(\mathbb{R}^3;\mathbb{R}^3)$, while the supremum in μ is taken over the class of measures of the form $\mu = \theta\, dx$ with $\theta \in L^\infty(\mathbb{R}^3;[0,\varepsilon^{-1}])$ and $\mathrm{spt}(\theta) \subseteq Q_\delta$. Since the latter class is compact and since the dependence with respect to (μ, U) is convex-concave, we may exchange the supremum and the infimum (see, e.g., [14, Proposition 2.2]) so that

$$\begin{aligned} J_\varepsilon^*(-k) \ &= \inf_U \left\{-\langle F^\delta, U\rangle_{\mathbb{R}^3} + \sup_\mu \int \big(j(e(U)) - k\big)\ d\mu\right\} \\ &= \inf_U \left\{-\langle F^\delta, U\rangle_{\mathbb{R}^3} + \varepsilon^{-1}\int_{Q_\delta} \big(j(e(U)) - k\big)^+\ dx\right\} \ . \end{aligned}$$

Then, in order to compute the limit as $\varepsilon \to 0$ of $J_\varepsilon^*(-k)$ (which is also their supremum), we are led to consider the functionals G_ε defined on $H^1(\mathbb{R}^3;\mathbb{R}^3)$ by

$$G_\varepsilon(U) := \begin{cases} -\langle F^\delta, U\rangle_{\mathbb{R}^3} + \varepsilon^{-1}\displaystyle\int_{Q_\delta} \big(j(e(U)) - k\big)^+\ dx & \text{if } U \in \mathcal{C}^\infty(\mathbb{R}^3;\mathbb{R}^3)\,, \\ +\infty & \text{otherwise.} \end{cases}$$

It is easy to check that, since $F^\delta \in H^{-1}(Q_\delta;\mathbb{R}^3)$, the functionals G_ε are lower semicontinuous with respect to the weak topology on $H^1(\mathbb{R}^3;\mathbb{R}^3)$. Therefore, since the sequence G_ε is monotone increasing in ε, its Γ-limit with respect to the weak convergence on coincides with the functional G_0 defined by

$$G_0(U) := \begin{cases} -\langle F^\delta, U\rangle_{\mathbb{R}^3} & \text{if } U \in H^1(\mathbb{R}^3;\mathbb{R}^3) \text{ such that } j(e(U)) \le k \text{ a.e. on } Q_\delta\,, \\ +\infty & \text{otherwise} \end{cases}$$

(in particular, $G_0 \equiv +\infty$ for $k < 0$). Moreover, by using the coercivity of j and the Korn inequality, one can easily check that any sequence $\{U^\varepsilon\}$ with $\sup_\varepsilon G_\varepsilon(U^\varepsilon) < +\infty$ is weakly precompact in $H^1(\mathbb{R}^3;\mathbb{R}^3)$ (up to subtracting a rigid displacement, which

is not restrictive thanks to (2.3)). This compactness property, combined with the Γ-convergence of G_ε to G_0, ensures that the infima of G_ε converge to the infimum of G_0. Therefore

$$\begin{aligned}
&-\lim_\varepsilon J_\varepsilon^*(-k)\\
&= -\inf\Big\{-\langle F^\delta, U\rangle_{\mathbb{R}^3} \ : \ U\in H^1(\mathbb{R}^3;\mathbb{R}^3) \text{ such that } j(e(U))\le k \text{ a.e. on } Q_\delta\Big\}\\
&= \sup\Big\{\langle F^\delta, U\rangle_{\mathbb{R}^3} \ : \ U\in \mathcal{C}^\infty(\mathbb{R}^3;\mathbb{R}^3) \text{ such that } j(e(U))\le k \text{ on } Q_\delta\Big\}\ .
\end{aligned}$$

Recalling the definition of $\widetilde{\mathcal{S}}_\delta$ in (3.3) and by the 2-homogeneity of j (see (2.1)), we deduce after an easy computation that

$$-\lim_\varepsilon J_\varepsilon^*(-k) = \sqrt{2k}\,\widetilde{\mathcal{S}}_\delta \qquad \text{for } k\ge 0$$

(and $-\infty$ otherwise). By (5.2) and (5.3), then we arrive at $\varphi_0^*(-k) = -\sqrt{2k}\,\widetilde{\mathcal{S}}_\delta$ for $k\ge 0$ (and $+\infty$ otherwise). Passing to the biconjugate, we infer that, for any $t>0$,

$$\varphi_0^{**}(t) = \sup_{k\ge 0}\Big\{-kt-\varphi_0^*(-k)\Big\} = \sup_{k\ge 0}\Big\{-kt+\sqrt{2k}\,\widetilde{\mathcal{S}}_\delta\Big\} = \frac{1}{2}\frac{(\widetilde{\mathcal{S}}_\delta)^2}{t}\ .$$

Finally, to deduce (5.1), it remains to check that φ_0^{**} coincides with φ_0. This is a consequence of the fact that φ_0 is convex continuous on $\mathbb{R}^+$. Indeed, let μ_0 be the uniform probability density on Q_δ. As F^δ belongs to $H^{-1}(Q_\delta;\mathbb{R}^3)$, we have that $k(\delta) := \mathcal{C}^{\rm el}(\mu_0, j, F^\delta) < +\infty$. Then, for every $t>0$, the measure $t\mu_0$ is admissible for $\varphi_\varepsilon(t)$ whenever $\varepsilon\le t^{-1}|Q_\delta|$. Thus

$$\varphi_0(t) \ \le\ \varphi_\varepsilon(t) \ \le\ \mathcal{C}^{\rm el}(t\mu_0, j, F^\delta) \ =\ \frac{k(\delta)}{t}\ ,$$

where the last equality is obtained performing the rescaling $V=tU$ on the competing strain displacements. The continuity of the convex function φ_0 on $(0,+\infty)$ follows from the latter upper bound, and the proof of Proposition 3.1 is concluded. □

Proof of Theorem 3.3. In view of Lemma 3.4, it is enough to prove that one among the sequences $\widetilde{\mathcal{S}}_\delta$ and $\mathcal{S}_\delta$, say $\widetilde{\mathcal{S}}_\delta$, converges to $\mathcal{S}_0$.

Let us begin by writing $\widetilde{\mathcal{S}}_\delta$ in a more convenient way. We set

$$U(x) = \Big(u_1\big(x',\delta^{-1}x_3\big),\ u_2\big(x',\delta^{-1}x_3\big),\ \delta^{-1}u_3\big(x',\delta^{-1}x_3\big)\Big)\ ,$$

so that

$$e(U)(x) = e_\delta(u)\big(x',\delta^{-1}x_3\big) := \begin{bmatrix} e_{\alpha\beta}(u) & \delta^{-1}e_{\alpha 3}(u)\\ \delta^{-1}e_{\alpha 3}(u) & \delta^{-2}e_{33}(u)\end{bmatrix}(x',\delta^{-1}x_3)\ , \tag{5.4}$$

where the indices α and β take values in $\{1,2\}$. Hence

$$\begin{aligned}
\widetilde{\mathcal{S}}_\delta &= \sup\Big\{\langle F,u\rangle_{\mathbb{R}^3} \ : \ u\in\mathcal{C}^\infty(\mathbb{R}^3;\mathbb{R}^3) \text{ such that } \rho(e_\delta(u)(x',\delta^{-1}x_3))\le 1 \text{ on } Q_\delta\Big\}\\
&= \sup\Big\{\langle F,u\rangle_{\mathbb{R}^3} \ : \ u\in\mathcal{C}^\infty(\mathbb{R}^3;\mathbb{R}^3) \text{ such that } \rho(e_\delta(u))\le 1 \text{ on } Q\Big\}\\
&= \sup\Big\{\langle F,u\rangle_{\mathbb{R}^3} \ : \ u\in K_\delta\Big\}\ ,
\end{aligned}$$

where K_δ denotes the convex set

$$K_\delta := \Big\{ u \in \mathcal{C}^\infty(\mathbb{R}^3;\mathbb{R}^3) \ : \ \rho(e_\delta(u)) \le 1 \text{ on } Q \Big\} \ .$$

As a preliminary remark, we notice that the following compactness property holds: if we take a sequence $\{u^\delta\}$ such that $u^\delta \in K_\delta$, then up to subsequences and up to a rigid motion, it converges uniformly on Q. Indeed, by (2.1) we have that $e_\delta(u^\delta)$ is uniformly bounded in $L^\infty(Q)$; hence, up to subtracting a rigid displacement (which is not restrictive thanks to (2.3)), by the Korn inequality $\{u^\delta\}$ is equibounded in $W^{1,p}(Q;\mathbb{R}^3)$ for every $p \in (1,+\infty)$.

In view of this remark, we are reduced to identifying the Kuratowski limit (if any) of the sequence $\{K_\delta\}$ with respect to the uniform convergence on the compact Q. Indeed, if $\overline{K}$ denotes such a Kuratowski limit, since the linear form $u \mapsto \langle F, u\rangle$ is continuous with respect to the uniform convergence, we will have that

$$\lim_{\delta\to 0} \widetilde{\mathcal{S}}_\delta \ = \ \sup\Big\{ \langle F, u\rangle_{\mathbb{R}^3} \ : \ u \in \overline{K} \Big\} \ . \tag{5.5}$$

We claim that the set $\overline{K}$ can be characterized as follows:

$$\overline{K} = \Big\{ u \in L^\infty(Q;\mathbb{R}^3) \ : \ e(u) \in L^\infty(Q;\mathbb{R}^{3\times 3}_{\rm sym}) \ , \ \overline{\rho}(e_{\alpha\beta}(u)) \le 1 \ , \ e_{i3}(u) = 0 \text{ a.e. on } Q \Big\} \ . \tag{5.6}$$

Let us first show how Theorem 3.3 follows from (5.6) and then give the proof of (5.6).

As a slight variant of Theorem 3.1 in [13], it is easy to check that the right-hand side of (5.6) is the closure in the uniform norm of the set of Kirchoff–Love displacements

$$K = \Big\{ u \in \mathcal{C}^\infty(\mathbb{R}^3;\mathbb{R}^3) \ : \ \overline{\rho}(e_{\alpha\beta}(u)) \le 1 \ , \ e_{i3}(u) = 0 \text{ on } Q \Big\} \ .$$

As is well known, any function $u \in K$ may be written under the form

$$u_i(x) = v_i(x') - \frac{\partial v_3}{\partial x_i}(x') x_3 \qquad \text{for } i = 1,2 \ , \qquad u_3(x) = v_3(x') \ .$$

In terms of the function v, the matrix $e_{\alpha\beta}(u)$ is given by

$$e_{\alpha\beta}(u) = e(v_1, v_2) - x_3 \nabla^2 v_3 \ , \tag{5.7}$$

and hence v must satisfy the inequality

$$\overline{\rho}\big(e(v_1,v_2) - x_3\nabla^2 v_3\big) \le 1 \qquad \forall\, (x', x_3) \in \Omega \times \big(-h, h\big) \ ,$$

which by convexity is equivalent to

$$\overline{\rho}\big(e(v_1,v_2) \pm h\nabla^2 v_3\big) \le 1 \qquad \text{on } \Omega \ . \tag{5.8}$$

On the other hand, we have

$$\langle F, u\rangle_{\mathbb{R}^3} = \sum_{i=1}^3 \langle F_i, v_i\rangle_{\mathbb{R}^3} + \sum_{i=1}^2 \left\langle x_3 \frac{\partial F_i}{\partial x_i}, v_3 \right\rangle_{\mathbb{R}^3} = \langle \overline{F}, v\rangle_{\mathbb{R}^2} \ . \tag{5.9}$$

By (5.5), (5.8), (5.9) and recalling the definition of $\mathcal{S}_0$ in (3.7), we conclude that

$$\lim_{\delta\to 0} \widetilde{\mathcal{S}}_\delta \ = \ \sup\Big\{ \langle F, u\rangle_{\mathbb{R}^3} \ : \ u \in K \Big\} = \mathcal{S}_0 \ .$$

It remains to establish (5.6). Such an equality holds, provided one has

(i) $u^\delta \in K_\delta$, $u^\delta \to u$ uniformly on $Q \implies u \in \overline{K}$,

(ii) $u \in K \implies \exists u^\delta \in K_\delta$ such that $u^\delta \to u$ uniformly on Q.

Proof of (i). Let $u^\delta \in K_\delta$ such that $u^\delta \to u$ uniformly on Q. As already noticed above in this proof, such a sequence $\{u^\delta\}$ is weakly precompact in $W^{1,p}(Q;\mathbb{R}^3)$ for every $p \in (1,+\infty)$, which ensures that u belongs $W^{1,p}(Q;\mathbb{R}^3)$ for every such p. Possibly passing to a subsequence, we may assume that $\{e_\delta(u^\delta)\}$ converges weakly in $L^p(Q;\mathbb{R}^{3\times 3}_{\rm sym})$ to some matrix valued function $M(x)$ which is of the form

$$M = \begin{bmatrix} e_{\alpha\beta}(u) & \xi_{\alpha 3} \\ \xi_{\alpha 3} & \xi_{33} \end{bmatrix} .$$

By the convexity of ρ, one has

$$\|\rho(M)\|_{L^\infty(Q)} \le \liminf_\delta \|\rho(e_\delta(u^\delta))\|_{L^\infty(Q)} \le 1 .$$

Thus, by the definition (3.6) of $\overline{\rho}$, it follows that

$$\|\overline{\rho}(e_{\alpha\beta}(u))\|_{L^\infty(Q)} \le \|\rho(M)\|_{L^\infty(Q)} \le 1 .$$

On the other hand, it is clear that, for $i = 1,2,3$, $e_{i3}(u^\delta)$ does converge strongly to 0 in $L^p(Q)$ and therefore $e_{i3}(u) = 0$. Summarizing we have proved that u belongs to $\overline{K}$.

Proof of (ii). Let $u \in K$. We search for $u^\delta \in K_\delta$ such that $u^\delta \to u$ uniformly on Q. To this end, it not restrictive to assume that the *strict* inequality $\overline{\rho}(e_{\alpha\beta}(u)) < 1$ holds on Q (indeed, for any $u \in K$ the function $\tilde{u} := (1-\delta)u$ satisfies $e_{i3}\tilde{u} = 0$ and $\overline{\rho}(e_{\alpha\beta}\tilde{u}) < 1$). Let $\xi^i = \xi^i(x', x_3)$ be arbitrary smooth functions, and let Φ_i denote their primitives with respect to the x_3 variable:

$$\Phi_i(x', x_3) := \int_0^{x_3} \xi_i(x', s)\, ds .$$

We define the sequence $\{u^\delta\}$ componentwise by

$$u_1^\delta = u_1 + \delta\Phi_1 , \qquad u_2^\delta = u_2 + \delta\Phi_2 , \qquad u_3^\delta = u_3 + \delta^2\Phi_3 .$$

Clearly $\{u^\delta\}$ converges uniformly to u, and, according to definition (5.4), an immediate calculation gives

$$e_\delta(u^\delta) = e_{\alpha\beta}(u) + \sum_{i=1}^{2} \Big(\xi_i + \delta\frac{\partial\Phi_3}{\partial x_i}\Big)(e_i \otimes e_3)^* + \xi_3(e_3 \otimes e_3) ,$$

so that

$$\rho(e_\delta(u^\delta)) \le \rho\left(e_{\alpha\beta}(u) + \sum_{i=1}^{3} \xi^i (e_i \otimes e_3)^*\right) + o(1) .$$

The proof of (ii) is concluded by the arbitrariness of the functions ξ_i. □

Proof of Lemma 3.4. For any given integrand $g : \mathbb{R}^{2\times 2}_{\rm sym} \to \mathbb{R}$, if $\overline{g}$ is defined according to (3.6), one can easily check that the Fenchel conjugates of g and $\overline{g}$ are related by the identity

$$(\overline{g})^*(z^*) = g^*(z^*|0) \qquad \forall\, z^* \in \mathbb{R}^{2\times 2}_{\rm sym} ,$$

where $(z^*|0)$ denotes the 3×3 matrix obtained by adding to z^* a null third line and third column.

Applying this to the convex integrands j and j_0 yields, for every $z\in\mathbb{R}^{2\times 2}_{\rm sym}$,

$$\begin{aligned}\overline{j_0}(z) &= \sup\big\{z\cdot z^* - (j_0)^*(z^*|0)\ :\ z^*\in\mathbb{R}^{2\times 2}_{\rm sym}\big\}\,,\\ \overline{j}(z) &= \sup\big\{z\cdot z^* - j^*(z^*|0)\ :\ z^*\in\mathbb{R}^{2\times 2}_{\rm sym}\big\}\ .\end{aligned}$$

Then the lemma is proved if we can show that

$$(j_0)^*(z^*|0) = j^*(z^*|0)\qquad \forall\, z^*\in\mathbb{R}^{2\times 2}_{\rm sym}\ .$$

Actually, this equality is satisfied since j_0^* and j^* turn out to coincide more generally on the class of degenerated tensors (see [10, Lemma 3.1]). Indeed, the inequality $j_0^*(\tau)\geq j^*(\tau)$ holds for all $\tau\in\mathbb{R}^{3\times 3}_{\rm sym}$ because by definition j_0 satisfies the inequality $j_0\leq j$. On the other hand, let $\tau\in\mathbb{R}^{3\times 3}_{\rm sym}$ be a degenerated tensor. By definition of j_0, for all $z\in\mathbb{R}^{3\times 3}_{\rm sym}$ there holds

$$z\cdot\tau - j_0(z)\leq j^*(\tau)\ ,$$

so that the inequality $j_0^*(\tau)\leq j^*(\tau)$ follows by passing to the supremum over z in the left-hand side. □

Proof of Corollary 3.5. In case (i) it is immediate that

$$\mathcal{S}_0\geq \sup\Big\{\langle\overline{F}_3,v_3\rangle_{\mathbb{R}^2}\ :\ v_3\in\mathcal{C}^\infty(\mathbb{R}^2;\mathbb{R}) \text{ such that } \ \overline{\rho}(\nabla^2 v_3)\leq 1/h \text{ on } \Omega\Big\}\ .$$

The converse inequality is obtained by noticing that, since $\overline{\rho}$ is even and subadditive, the constraint $\overline{\rho}\big(e(v_1,v_2)\pm h\nabla^2 v_3\big)\leq 1$ implies $\overline{\rho}\big(\nabla^2 v_3\big)\leq 1/h$. The proof in case (ii) is analogous. □

Proof of Corollary 3.6. In view of Lemma 3.4, it is enough to prove the statement for one among the sequences $\widetilde{\mathcal{I}}_{\varepsilon,\delta}$ and $\mathcal{I}_{\varepsilon,\delta}$, say $\widetilde{\mathcal{I}}_{\varepsilon,\delta}$.

First, we recall that there holds $\lim_\varepsilon \widetilde{\mathcal{I}}_{\varepsilon,\delta}=\widetilde{\mathcal{I}}_\delta$ (see Proposition 3.1) and that $\widetilde{\mathcal{I}}_\delta=\widetilde{\mathcal{S}}_\delta^2/2$ [11, Theorem 2.3]. Then Theorem 3.3 gives $\lim_\delta\widetilde{\mathcal{S}}_\delta=\mathcal{S}_0$. Finally, we apply Corollary 3.5(i) and [14, Theorem 2.4] to conclude that $\mathcal{S}_0^2/2=h^{-2}\inf\big\{\mathcal{C}^{\rm pl}\big(\mu,\overline{j},\overline{F}_3\big)\ :\ \mu\in\mathcal{P}(\overline{\Omega})\big\}$. □

Proof of Lemma 3.9. Let us rewrite $(\mathcal{P})$ as

$$(\mathcal{P})\qquad -\inf\Big\{-\langle\overline{F},v\rangle_{\mathbb{R}^2}+\chi_{\mathcal{K}}(A^+v)+\chi_{\mathcal{K}}(A^-v)\ :\ v\in\mathcal{C}^\infty(\mathbb{R}^2;\mathbb{R}^3)\Big\}\ ,$$

where $\chi_{\mathcal{K}}$ is the characteristic function of the set

$$\mathcal{K}=\Big\{M\in\mathcal{C}_0(\Omega;\mathbb{R}^{2\times 2}_{\rm sym})\ :\ \overline{\rho}(M)\leq 1\Big\}\ ,$$

and $A:\mathcal{C}_0(\Omega;\mathbb{R}^3)\ni v\mapsto(A^+v,A^-v)\in[\mathcal{C}_0(\Omega;\mathbb{R}^{2\times 2}_{\rm sym})]^2$ is the linear operator densely defined by $A^\pm v:=e(v_1,v_2)\pm h\nabla^2 v_3$ for all smooth functions v.

By standard duality theory (see, for instance, [19]), there holds

$(\mathcal{P}^*)$

$$\min\Big\{\int\overline{\rho}^o(\lambda^+)+\int\overline{\rho}^o(\lambda^-)\ :\ (\lambda^+,\lambda^-)\in[\mathcal{M}(\overline{\Omega};\mathbb{R}^{2\times 2}_{\rm sym})]^2\ ,\ A^*(\lambda^+,\lambda^-)=\overline{F}\Big\}\ ,$$

where $A^* : [\mathcal{M}(\overline{\Omega};\mathbb{R}^{2\times 2}_{\rm sym})]^2 \to \mathcal{M}(\overline{\Omega};\mathbb{R}^3)$ is the adjoint operator of A. It is determined by the following identity (valid for every smooth v):

$$\begin{aligned}\langle A^*(\lambda^+,\lambda^-),v\rangle_{\mathbb{R}^2} &= \langle(\lambda^+,\lambda^-),(A^+v,A^-v)\rangle_{\mathbb{R}^2}\\ &= \langle\lambda^+,e(v_1,v_2)+h\nabla^2 v_3\rangle_{\mathbb{R}^2}+\langle\lambda^-,e(v_1,v_2)-h\nabla^2 v_3\rangle_{\mathbb{R}^2}\\ &= -\langle\operatorname{div}(\lambda^++\lambda^-),(v_1,v_2)\rangle_{\mathbb{R}^2}+\langle h\operatorname{div}^2(\lambda^+-\lambda^-),v_3\rangle_{\mathbb{R}^2}\ .\end{aligned}$$

Therefore, when rewritten componentwise, the constraint $A^*(\lambda^+,\lambda^-)=\overline{F}$ is equivalent to the system of two conditions: $-\operatorname{div}(\lambda^+ + \lambda^-) = (\overline{F}_1,\overline{F}_2)$ and $h\operatorname{div}^2(\lambda^+ - \lambda^-) = \overline{F}_3$. □

Proof of Proposition 3.10. Let v and $\lambda^\pm$ be optimal, respectively, for problems $(\mathcal{P})$ and $(\mathcal{P})^*$. By Lemma 3.9 there holds

$$\int \overline{\rho}^o(\lambda^+) + \int \overline{\rho}^o(\lambda^-) = \langle\overline{F},v\rangle\ . \tag{5.10}$$

On the other hand, if the operator $Av = (A^+v, A^-v)$ is defined as in the proof of Lemma 3.9, we have

$$\overline{\rho}^o(\lambda^\pm) \geq \overline{\rho}^o(\lambda^\pm)\,\overline{\rho}(A^\pm v) \geq \langle\lambda^\pm, A^\pm v\rangle_{\mathbb{R}^2}\ , \tag{5.11}$$

which implies

$$\int \overline{\rho}^o(\lambda^+) + \int \overline{\rho}^o(\lambda^-) \geq \langle(\lambda^+,\lambda^-),Av\rangle_{\mathbb{R}^2} = \langle A^*(\lambda^+,\lambda^-),v\rangle_{\mathbb{R}^2} = \langle\overline{F},v\rangle_{\mathbb{R}^2}\ . \tag{5.12}$$

Combining (5.10) and (5.12), we deduce that the inequalities in (5.11) must turn into equalities, so that the optimality conditions (3.9) hold.

Conversely, any v and $\lambda^\pm$ which are admissible, respectively, for problems $(\mathcal{P})$ and $(\mathcal{P})^*$ satisfy

$$\langle\overline{F},v\rangle_{\mathbb{R}^2} \leq \mathcal{S}_0 \leq \int \overline{\rho}^o(\lambda^+) + \int \overline{\rho}^o(\lambda^-)\ . \tag{5.13}$$

If equations (3.9) hold, we have

$$\langle\overline{F},v\rangle_{\mathbb{R}^2} = \langle A^*(\lambda^+,\lambda^-),v\rangle_{\mathbb{R}^2} = \langle(\lambda^+,\lambda^-),Av\rangle_{\mathbb{R}^2} = \int \overline{\rho}^o(\lambda^+) + \int \overline{\rho}^o(\lambda^-)\ ,$$

and hence the inequalities in (5.13) must turn into equalities, which means that v and $\lambda^\pm$ are optimal. □

Acknowledgments. We are very grateful to Pierre Seppecher for having suggested to us the choice of Example 4.1 and to one of the referees for having drawn the paper [26] to our attention. The second author thanks the University of Toulon for the kind hospitality.

ASYMPTOTIC CONVERGENCE ANALYSIS OF A NEW CLASS OF PROXIMAL POINT METHODS*

WILLIAM W. HAGER† AND HONGCHAO ZHANG‡

Abstract. Finite dimensional local convergence results for self-adaptive proximal point methods and nonlinear functions with multiple minimizers are generalized and extended to a Hilbert space setting. The principle assumption is a local error bound condition which relates the growth in the function to the distance to the set of minimizers. A local convergence result is established for almost exact iterates. Less restrictive acceptance criteria for the proximal iterates are also analyzed. These criteria are expressed in terms of a subdifferential of the proximal function and either a subdifferential of the original function or an iteration difference. If the proximal regularization parameter $\mu(\mathbf{x})$ is sufficiently small and bounded away from zero and f is sufficiently smooth, then there is local linear convergence to the set of minimizers. For a locally convex function, a convergence result similar to that for almost exact iterates is established. For a locally convex solution set and smooth functions, it is shown that if the proximal regularization parameter has the form $\mu(\mathbf{x}) = \beta\|f'[\mathbf{x}]\|^\eta$, where $\eta \in (0,2)$, then the convergence is at least superlinear if $\eta \in (0,1)$ and at least quadratic if $\eta \in [1,2)$.

Key words. proximal point, degenerate optimization, multiple minima, self-adaptive method

1. Introduction.

In this paper, we consider an optimization problem:

$$\min\{f(\mathbf{x}) : \mathbf{x} \in \mathcal{H}\}, \tag{1.1}$$

where $\mathcal{H}$ is a real Hilbert space with inner product $\langle\cdot,\cdot\rangle$ and $f : \mathcal{H} \mapsto \mathcal{R}$. It is assumed that the set of minimizers for (1.1), denoted $\mathbf{X}$, is nonempty and closed. We establish new convergence rate results for proximal point methods for solving (1.1).

Literature connected with the analysis and development of proximal point methods includes [1, 2, 3, 4, 6, 8, 9, 10, 11, 12, 15, 16, 18, 19, 20, 21, 24, 25, 26, 27]. In the proximal point method, iterates $\mathbf{x}_k$, $k \geq 1$, are generated by the following rule:

$$\mathbf{x}_{k+1} \in \arg\ \min\{F_k(\mathbf{x}) : \mathbf{x} \in \mathcal{H}\}, \tag{1.2}$$

where

$$F_k(\mathbf{x}) = f(\mathbf{x}) + \frac{1}{2}\mu_k\|\mathbf{x} - \mathbf{x}_k\|^2.$$

Here $\mathbf{x}_0 \in \mathcal{H}$ is an initial guess for a minimizer, the parameters μ_k, $k \geq 0$, are positive scalars, and $\|\cdot\| = \langle\cdot,\cdot\rangle^{1/2}$ is the usual Hilbert space norm. When f is twice continuously differentiable, the eigenvalues of the second derivative operator F_k'' are bounded from below by μ_k at a local minimizer; consequently, the regularization term $\mu_k\|\mathbf{x} - \mathbf{x}_k\|^2$ improves the conditioning of (1.1).

In [21] Rockafellar shows that if f is convex, then the proximal point method converges linearly when μ_k is bounded away from zero and superlinearly when μ_k tends to zero. For these convergence results, $\mathbf{X}$ is a singleton. Luque [14] studied the case when $\mathbf{X}$ may contain more than one element. By assuming some growth properties for the (multivalued) inverse of the derivative, results analogous to those of Rockafellar were obtained. Kaplan and Tichatschke [11] consider the case where f is convex, μ_k is constant, and $\mathbf{X}$ may contain more than one element. A linear convergence result for the iterates is established under a growth condition for the function which is similar to the growth condition used in our paper (see Assumption 14.4 and Theorem 14.5 in [11]).

In another research direction, Combettes and Pennanen [2], Iusem, Pennanen, and Svaiter [10], and Pennanen [19] replace the monotonicity assumptions appearing in earlier work by a weaker hypomonotonicity condition for the inverse of the derivative, that is, the inverse of the derivative is monotone when a multiple of the identity is added. Additional assumptions, however, enter into the analysis which imply the solution set $\mathbf{X}$ is a singleton.

In [7] we present a new class of self-adaptive proximal point methods for finite dimensional optimization problems. Our analysis employs the following local error bound condition at $\hat{\mathbf{x}} \in \mathbf{X}$: There exist positive constants α and ρ such that

$$f(\mathbf{x}) - f^* \geq \alpha D(\mathbf{x}, \mathbf{X})^2 \quad \text{whenever } \|\mathbf{x} - \hat{\mathbf{x}}\| \leq \rho, \tag{1.3}$$

where f^* is the minimum value in (1.1) and

$$D(\mathbf{x}, \mathbf{X}) = \inf_{\mathbf{y} \in \mathbf{X}} \|\mathbf{x} - \mathbf{y}\|.$$

In other words, $D(\mathbf{x}, \mathbf{X})$ measures the distance to the solution set $\mathbf{X}$. If (1.3) is satisfied, then we say that f provides a local error bound at $\hat{\mathbf{x}} \in \mathbf{X}$. For an exact proximal iterate $\mathbf{x}_{k+1}$ satisfying (1.2), we show in [7] that for any starting guess $\mathbf{x}_0$ in a neighborhood of the solution set, the iterates converge to a solution $\mathbf{x}^*$ of (1.1) and the following estimate holds:

$$D(\mathbf{x}_{k+1}, \mathbf{X}) \leq C\mu_k D(\mathbf{x}_k, \mathbf{X}), \tag{1.4}$$

where $C = 2/(2\alpha - \mu_k)$.

In a Hilbert space setting, the exact proximal iterate (1.2) may not exist. In this paper, we establish a similar convergence result using the following acceptance criterion: $\mathbf{x}_{k+1}$ is acceptable when

$$\begin{aligned} F_k(\mathbf{x}_{k+1}) &\leq \inf_{\mathbf{x} \in \mathbf{X}} \left\{ F_k(\mathbf{x}) + \frac{\mu_k^2}{2} \|\mathbf{x} - \mathbf{x}_k\|^2 \right\} \\ &= \inf_{\mathbf{x} \in \mathbf{X}} \left\{ f(\mathbf{x}) + \left(\frac{\mu_k + \mu_k^2}{2} \right) \|\mathbf{x} - \mathbf{x}_k\|^2 \right\}. \end{aligned} \tag{C0}$$

In section 3 we show that there always exists an iterate satisfying (C0), and a convergence result of the form (1.4) holds.

Although (C0) leads to an elegant convergence theory, which can be applied to any function whose set of minimizers is nonempty and closed, the acceptance criterion is not easily implemented since it is expressed in terms of the solution set (which we are trying to compute). Consequently, we now introduce implementable acceptance criteria which are expressed in terms of the (basic) subdifferential of f (see [17, p. 82]

and [22]) denoted $\partial f(\mathbf{x})$. If f is Fréchet differentiable, then $\partial f(\mathbf{x}) = f'[\mathbf{x}]$. If f is convex, then $\partial f(\mathbf{x})$ is the usual subdifferential of convex analysis. The acceptance criteria for (1.2) are

(C1) $F_k(\mathbf{x}_{k+1}) \leq f(\mathbf{x}_k)$ and $\|\partial F_k(\mathbf{x}_{k+1})\|_{\inf} \leq \mu_k \|\partial f(\mathbf{x}_k)\|_{\inf}$, and

(C2) $F_k(\mathbf{x}_{k+1}) \leq f(\mathbf{x}_k)$ and $\|\partial F_k(\mathbf{x}_{k+1})\|_{\inf} \leq \theta\mu_k \|\mathbf{x}_{k+1} - \mathbf{x}_k\|$.

Here θ is a positive constant smaller than $1/\sqrt{2}$, and $\|\cdot\|_{\inf}$ denotes the distance to the origin; that is, for any set $\mathcal{S} \subset \mathcal{H}$,

$$\|\mathcal{S}\|_{\inf} = \inf_{s \in \mathcal{S}} \|\mathbf{s}\|.$$

If $\mathcal{S} = \emptyset$, then we set $\|\mathcal{S}\|_{\inf} = \infty$.

In [14] and [21], the authors considered the acceptance condition

$$\|\partial F_k(\mathbf{x}_{k+1})\| \leq \epsilon_k \mu_k \|\mathbf{x}_{k+1} - \mathbf{x}_k\|,$$

where $\sum_k \epsilon_k < \infty$. Our criterion (C2) corresponds to the case $\sum_k \epsilon_k = \infty$. In [14] and [21], the authors consider convex functionals, while here we obtain local convergence rates for general nonlinear functionals. Note that our acceptance criteria employ a subdifferential rather than the derivative used in our earlier work.

Slightly different versions of the proximal point method for maximal monotone operators are developed by Solodov and Svaiter in the series of papers [24, 25, 26]. They develop both a hybrid proximal point algorithm where an approximate proximal step is followed by a projection and a hybrid extragradient version in which the original operator is replaced by an ϵ enlargement. In order to compare their analysis to the results in our paper, we focus on the special case where the operator is the subdifferential of a convex function f. In each iteration of the Solodov/Svaiter scheme, they first compute an approximate proximal iterate $\mathbf{y}_k$ satisfying a relaxed version of (C2); they then update the iterate along the negative gradient:

$$\mathbf{x}_{k+1} = \mathbf{x}_k - s_k \mathbf{g}_k, \tag{1.5}$$

where $\mathbf{g}_k \in \partial f(\mathbf{y}_k)$, s_k is the scalar stepsize, and $\theta < 1$. In [24], $s_k = 1/\mu_k$ (the reciprocal of the proximal regularization parameter), while in [25], s_k is chosen so that $\mathbf{x}_{k+1}$ is the projection of $\mathbf{x}_k$ onto the half-space

$$\{\mathbf{x} \in \mathcal{H} : \langle \mathbf{g}_k, \mathbf{x} - \mathbf{y}_k \rangle \geq 0\}.$$

Since the Solodov/Svaiter update (1.5) amounts to an extragradient step, their convergence theory for fixed θ (see [26, Thm. 8]) yields linear convergence, even when μ_k tends to 0, unless the accuracy criterion (C2) for the approximate proximal iterate $\mathbf{y}_k$ is strengthened. Ways to improve the accuracy of $\mathbf{y}_k$ so as to obtain superlinear convergence with the Solodov/Svaiter hybrid schemes are the following: (a) Replace θ by θ_k in (C2) and let θ_k tend to 0 (see [26, Rem. 9]). (b) In the case $\mathcal{H} = \mathbb{R}^n$, compute $\mathbf{y}_k$ by a Newton iteration applied to the proximal problem (1.2), with μ_k on the order of $\|\nabla f(\mathbf{x}_k)\|^{1/2}$ (see [26, sect. 5.2]).

In this paper, we obtain superlinear convergence with (C2) by letting μ_k approach 0, and we analyze how the convergence speed depends on the decay rate of μ_k. We consider both a convex cost function analogous to the maximal monotone operator in [24, 25, 26] and the more general case where the solution set $\mathbf{X}$ is locally convex and f is sufficiently smooth. We allow multiple solutions satisfying the local error bound condition (1.3), while in [24, 25, 26] the solution set is unique since the inverse operator is required to be Lipschitz continuous at zero [26, eq. (28)].

We will show that for either (C1) or (C2), for μ_k sufficiently small, and for either f locally convex or $\mathbf{X}$ locally convex and f sufficiently smooth, an estimate of the form (1.4) holds. For μ_k sufficiently small and bounded away from zero, and for smooth functions, there is at least local linear convergence to the set of minimizers. For $\mathbf{X}$ locally convex and f sufficiently smooth, and for $\mu_k = \beta\|f'[\mathbf{x}_k]\|^\eta$, where $\eta \in (0,2)$, the convergence is superlinear when $\eta \in (0,1)$ and at least quadratic when $\eta \in [1,2)$.

Our paper is organized as follows: In section 2 we establish the equivalence, when f is twice continuously differentiable, of our local error bound condition and a gradient-based local error bound condition used in [5, 13, 14, 28, 29, 30]. Note, though, that our local error bound condition can be applied even when f has no derivative. In section 3 we analyze proximal iterates which satisfy (C0). Section 4 studies the criteria (C1) and (C2).

1.1. Notation. Throughout this paper, we use the following notation. If $A : \mathcal{H} \mapsto \mathcal{H}$ is a bounded linear operator, then $\|A\|$ is the operator norm induced by the Hilbert space norm $\|\cdot\|$. The empty set is denoted $\emptyset$. The complement of a set $\mathcal{S} \subset \mathcal{H}$ is denoted $\mathcal{S}^c$. If $\mathbf{x}$ and $\mathbf{y} \in \mathcal{H}$, then $[\mathbf{x},\mathbf{y}]$ is the line segment connecting $\mathbf{x}$ and $\mathbf{y}$. $\mathcal{B}_\rho(\mathbf{x})$ is the ball with center $\mathbf{x}$ and radius ρ. $f'[\mathbf{x}]$ and $f''[\mathbf{x}]$ are the first- and second-order Fréchet derivatives of f at $\mathbf{x}$ when they exist. The derivatives are operators defined on either $\mathcal{H}$ or $\mathcal{H} \times \mathcal{H}$. We also view $f'[\mathbf{x}]$ as an element of $\mathcal{H}$ and write $f'[\mathbf{x}](\mathbf{y}) = \langle f'[\mathbf{x}], \mathbf{y}\rangle$. Similarly, we view $f''[\mathbf{x}]$ as a bounded linear map from $\mathcal{H}$ to itself and write

$$f''[\mathbf{x}](\mathbf{y},\mathbf{z}) = \langle f''[\mathbf{x}]\mathbf{y}, \mathbf{z}\rangle.$$

2. Local error bound based on derivative. In this paper, we utilize the local error bound condition (1.3) based on function value. Earlier work [5, 13, 14, 28, 29, 30] has exploited a local error bound condition based on the derivative. Namely, f' provides a local error bound at $\hat{\mathbf{x}} \in \mathbf{X}$ if there exist positive constants α and ρ such that

$$\|f'[\mathbf{x}]\| \geq \alpha D(\mathbf{x}, \mathbf{X}) \quad \text{whenever } \|\mathbf{x} - \hat{\mathbf{x}}\| \leq \rho. \tag{2.1}$$

We now show that when f is smooth enough, these two conditions are equivalent.

LEMMA 2.1. *If f is twice continuously Fréchet differentiable in a neighborhood of $\hat{\mathbf{x}} \in \mathbf{X}$, then f provides a local error bound at $\hat{\mathbf{x}}$ in the sense of* (1.3) *if and only if f' provides a local error bound at $\hat{\mathbf{x}}$ in the sense of* (2.1).

Proof. Suppose f provides a local error bound at $\hat{\mathbf{x}} \in \mathbf{X}$ with positive scalars α and ρ satisfying (1.3). Choose ρ smaller, if necessary, so that f is twice continuously Fréchet differentiable in $\mathcal{B}_\rho(\hat{\mathbf{x}})$ and

$$\|f''[\mathbf{x}] - f''[\mathbf{y}]\| \leq \alpha/3 \quad \text{for all } \mathbf{x},\mathbf{y} \in \mathcal{B}_\rho(\hat{\mathbf{x}}). \tag{2.2}$$

Define $r = \rho/2$. Given $\mathbf{x} \in \mathcal{B}_r(\hat{\mathbf{x}})$, let $\bar{\mathbf{x}}$ be any element of $\mathbf{X} \cap \mathcal{B}_r(\mathbf{x})$. Since $\mathbf{x} \in \mathcal{B}_r(\hat{\mathbf{x}})$, we have $\hat{\mathbf{x}} \in \mathbf{X} \cap \mathcal{B}_r(\mathbf{x})$, which shows that $\mathbf{X} \cap \mathcal{B}_r(\mathbf{x})$ is nonempty. The triangle inequality implies that

$$\|\bar{\mathbf{x}} - \hat{\mathbf{x}}\| \leq \|\bar{\mathbf{x}} - \mathbf{x}\| + \|\mathbf{x} - \hat{\mathbf{x}}\| \leq 2r = \rho. \tag{2.3}$$

Since both $\mathbf{x}$ and $\bar{\mathbf{x}} \in \mathcal{B}_\rho(\hat{\mathbf{x}})$, f is twice continuously Fréchet differentiable in $\mathcal{B}_\rho(\hat{\mathbf{x}})$, and $f'[\bar{\mathbf{x}}] = \mathbf{0}$, we have

$$f(\mathbf{x}) - f^* = f(\mathbf{x}) - f(\bar{\mathbf{x}}) = \frac{1}{2}\langle \mathbf{x} - \bar{\mathbf{x}}, f''[\bar{\mathbf{x}}](\mathbf{x} - \bar{\mathbf{x}})\rangle + R_2(\mathbf{x}, \bar{\mathbf{x}}), \tag{2.4}$$

where R_2 is the remainder term. The bound (2.2) gives

$$|R_2(\mathbf{x}, \bar{\mathbf{x}})| \leq \frac{\alpha}{3}\|\mathbf{x} - \bar{\mathbf{x}}\|^2$$

whenever $\mathbf{x}$ and $\bar{\mathbf{x}} \in \mathcal{B}_\rho(\hat{\mathbf{x}})$. In this case, (2.4) and the local error bound condition (1.3) give

$$\alpha D(\mathbf{x}, \mathbf{X})^2 \leq f(\mathbf{x}) - f^* \leq \frac{1}{2}\|\mathbf{x} - \bar{\mathbf{x}}\|\|f''[\bar{\mathbf{x}}](\mathbf{x} - \bar{\mathbf{x}})\| + \frac{\alpha}{3}\|\mathbf{x} - \bar{\mathbf{x}}\|^2. \tag{2.5}$$

Again, since f is twice continuously Fréchet differentiable in $\mathcal{B}_\rho(\hat{\mathbf{x}})$ and $f'[\bar{\mathbf{x}}] = \mathbf{0}$, we have

$$f'[\mathbf{x}] = f'[\mathbf{x}] - f'[\bar{\mathbf{x}}] = f''[\bar{\mathbf{x}}](\mathbf{x} - \bar{\mathbf{x}}) + \mathbf{R}_1(\mathbf{x}, \bar{\mathbf{x}}), \tag{2.6}$$

where $\mathbf{R}_1$ is the remainder term. The bound (2.2) gives

$$\|R_1(\mathbf{x}, \bar{\mathbf{x}})\| \leq \frac{\alpha}{3}\|\mathbf{x} - \bar{\mathbf{x}}\| \tag{2.7}$$

whenever $\mathbf{x}$ and $\bar{\mathbf{x}} \in \mathcal{B}_\rho(\hat{\mathbf{x}})$. Combining (2.5)–(2.7) yields

$$\alpha D(\mathbf{x}, \mathbf{X})^2 \leq \frac{1}{2}\left(\|\mathbf{x} - \bar{\mathbf{x}}\|\|f'[\mathbf{x}]\| + \alpha\|\mathbf{x} - \bar{\mathbf{x}}\|^2\right). \tag{2.8}$$

Since $\mathbf{X} \cap \mathcal{B}_r(\mathbf{x})$ is nonempty, we have

$$D(\mathbf{x}, \mathbf{X}) = \inf_{\bar{\mathbf{x}} \in \mathbf{X}} \|\mathbf{x} - \bar{\mathbf{x}}\| = \inf\{\|\mathbf{x} - \bar{\mathbf{x}}\| : \bar{\mathbf{x}} \in \mathbf{X} \cap \mathcal{B}_r(\mathbf{x})\}.$$

Minimizing the right-hand side of (2.8) over $\bar{\mathbf{x}} \in \mathbf{X} \cap \mathcal{B}_r(\mathbf{x})$ gives

$$\alpha D(\mathbf{x}, \mathbf{X})^2 \leq \frac{1}{2}\left(D(\mathbf{x}, \mathbf{X})\|f'[\mathbf{x}]\| + \alpha D(\mathbf{x}, \mathbf{X})^2\right).$$

Rearranging this yields

$$\|f'[\mathbf{x}]\| \geq \alpha D(\mathbf{x}, \mathbf{X}).$$

Hence, $\partial f = f'$ provides a local error bound at $\hat{\mathbf{x}}$ with constants α and r.

Conversely, suppose f' provides a local error bound at $\hat{\mathbf{x}} \in \mathbf{X}$ with positive scalars α and ρ satisfying (2.1). Let ρ be as in the first half of the proof. Choose ρ smaller, if necessary, so that

$$\|f''[\mathbf{x}] - f''[\mathbf{y}]\| \leq \frac{7\alpha^2}{18(\lambda + 1)} \quad \text{for all } \mathbf{x}, \mathbf{y} \in \mathcal{B}_\rho(\hat{\mathbf{x}}), \tag{2.9}$$

where

$$\lambda = \sup\{\|f''[\mathbf{x}]\| : \mathbf{x} \in \mathcal{B}_\rho(\hat{\mathbf{x}})\}. \tag{2.10}$$

Let $r = \rho/2$, let $\mathbf{x} \in \mathcal{B}_r(\hat{\mathbf{x}})$, and let $\bar{\mathbf{x}} \in \mathbf{X} \cap \mathcal{B}_r(\hat{\mathbf{x}})$.

Since f achieves a minimum at $\bar{\mathbf{x}} \in \mathbf{X}$, $f''[\bar{\mathbf{x}}]$ is positive. Thus, there exists a unique, positive self-adjoint bounded linear operator B, the square root of $f''[\bar{\mathbf{x}}]$,

satisfying $f''[\bar{\mathbf{x}}] = B^2$ [23, Thm. 13.31]. By (2.6), (2.7), and the local error bound condition (2.1), we have

$$\begin{aligned}\alpha D(\mathbf{x},\mathbf{X}) &\le \|f'[\mathbf{x}]\| \\ &\le \|f''[\bar{\mathbf{x}}](\mathbf{x}-\bar{\mathbf{x}})\| + \frac{\alpha}{3}\|\mathbf{x}-\bar{\mathbf{x}}\| \\ &= \|B^2(\mathbf{x}-\bar{\mathbf{x}})\| + \frac{\alpha}{3}\|\mathbf{x}-\bar{\mathbf{x}}\| \\ &\le \|B\|\|B(\mathbf{x}-\bar{\mathbf{x}})\| + \frac{\alpha}{3}\|\mathbf{x}-\bar{\mathbf{x}}\|.\end{aligned}$$

Squaring both sides yields

$$\begin{aligned}\alpha^2 D(\mathbf{x},\mathbf{X})^2 &\le 2\|B\|^2\|B(\mathbf{x}-\bar{\mathbf{x}})\|^2 + \frac{2\alpha^2}{9}\|\mathbf{x}-\bar{\mathbf{x}}\|^2 \\ &= 2\langle \mathbf{x}-\bar{\mathbf{x}}, f''[\bar{\mathbf{x}}](\mathbf{x}-\bar{\mathbf{x}})\rangle\|f''[\bar{\mathbf{x}}]\| + \frac{2\alpha^2}{9}\|\mathbf{x}-\bar{\mathbf{x}}\|^2 \\ &\le 2\langle \mathbf{x}-\bar{\mathbf{x}}, f''[\bar{\mathbf{x}}](\mathbf{x}-\bar{\mathbf{x}})\rangle\lambda + \frac{2\alpha^2}{9}\|\mathbf{x}-\bar{\mathbf{x}}\|^2,\end{aligned}$$

where λ is defined in (2.10). It follows that

$$\langle \mathbf{x}-\bar{\mathbf{x}}, f''[\bar{\mathbf{x}}](\mathbf{x}-\bar{\mathbf{x}})\rangle \ge \frac{\alpha^2[9D(\mathbf{x},\mathbf{X})^2 - 2\|\mathbf{x}-\bar{\mathbf{x}}\|^2]}{18(\lambda+1)}.$$

(1 is added to the denominator to allow for the possibility that $\lambda = 0$.) Using this in (2.4) yields

$$\begin{aligned}f(\mathbf{x}) - f^* &= \frac{1}{2}\langle(\mathbf{x}-\bar{\mathbf{x}}), f''[\bar{\mathbf{x}}](\mathbf{x}-\bar{\mathbf{x}})\rangle + R_2(\mathbf{x},\bar{\mathbf{x}}) \\ &\ge \frac{\alpha^2[9D(\mathbf{x},\mathbf{X})^2 - 2\|\mathbf{x}-\bar{\mathbf{x}}\|^2]}{18(\lambda+1)} + R_2(\mathbf{x},\bar{\mathbf{x}}).\end{aligned} \tag{2.11}$$

By the choice of ρ in (2.9), we have

$$|R_2(\mathbf{x},\bar{\mathbf{x}})| \le \frac{\beta}{2}\|\mathbf{x}-\bar{\mathbf{x}}\|^2, \quad \beta = \frac{7\alpha^2}{18(\lambda+1)},$$

whenever $\mathbf{x}$ and $\bar{\mathbf{x}} \in \mathcal{B}_\rho(\hat{\mathbf{x}})$. By (2.11),

$$f(\mathbf{x}) - f^* \ge \frac{\alpha^2[9D(\mathbf{x},\mathbf{X})^2 - 2\|\mathbf{x}-\bar{\mathbf{x}}\|^2]}{18(\lambda+1)} - \frac{\beta}{2}\|\mathbf{x}-\bar{\mathbf{x}}\|^2.$$

Minimizing $\|\mathbf{x}-\bar{\mathbf{x}}\|$ over $\bar{\mathbf{x}} \in \mathbf{X} \cap \mathcal{B}_r(\mathbf{x})$ gives

$$f(\mathbf{x}) - f^* \ge \left(\frac{\beta}{2}\right) D(\mathbf{x},\mathbf{X})^2,$$

which completes the proof. ∎

3. Convergence analysis for almost exact minimization. We first show that (C0) can always be satisfied.

LEMMA 3.1. *If $\mu_k > 0$, then there exists $\mathbf{x}_{k+1} \in \mathcal{H}$ satisfying* (C0)*; moreover, for any $\mathbf{x}_{k+1}$ satisfying* (C0)*, we have*

$$\|\mathbf{x}_{k+1} - \mathbf{x}_k\| \le \sqrt{1+\mu_k}\, D(\mathbf{x}_k,\mathbf{X}). \tag{3.1}$$

Proof. If $\mathbf{x}_k \in \mathbf{X}$, then the lemma holds trivially since $\mathbf{x}_{k+1} = \mathbf{x}_k$. Hence, assume that $D(\mathbf{x}_k, \mathbf{X}) > 0$. Since $\mu_k > 0$, we have

$$\begin{aligned}\inf_{\mathbf{x}\in\mathbf{X}} \left\{ F_k(\mathbf{x}) + \frac{\mu_k^2}{2}\|\mathbf{x} - \mathbf{x}_k\|^2 \right\} &= f^* + \left(\frac{\mu_k + \mu_k^2}{2}\right) \inf_{\mathbf{x}\in\mathbf{X}} \{\|\mathbf{x} - \mathbf{x}_k\|\} \\ &= f^* + \left(\frac{\mu_k + \mu_k^2}{2}\right) D(\mathbf{x}_k, \mathbf{X}) \\ &> f^* + \frac{\mu_k}{2} D(\mathbf{x}_k, \mathbf{X}) \\ &= \inf_{\mathbf{x}\in\mathbf{X}} F_k(\mathbf{x}) \geq \inf_{\mathbf{x}\in\mathcal{H}} F_k(\mathbf{x}).\end{aligned}$$

Since one of these inequalities is strict, there exists $\mathbf{x}_{k+1} \in \mathcal{H}$ satisfying (C0). Moreover, for all $\mathbf{x} \in \mathbf{X}$, (C0) yields

$$\begin{aligned}F_k(\mathbf{x}_{k+1}) = f(\mathbf{x}_{k+1}) + \frac{\mu_k}{2}\|\mathbf{x}_{k+1} - \mathbf{x}_k\|^2 &\leq F_k(\mathbf{x}) + \frac{\mu_k^2}{2}\|\mathbf{x} - \mathbf{x}_k\|^2 \\ &= f^* + \frac{\mu_k + \mu_k^2}{2}\|\mathbf{x} - \mathbf{x}_k\|^2.\end{aligned}$$

Since $f^* \leq f(\mathbf{x}_{k+1})$, we conclude that

$$\|\mathbf{x}_{k+1} - \mathbf{x}_k\| \leq \sqrt{1 + \mu_k}\|\mathbf{x} - \mathbf{x}_k\| \tag{3.2}$$

for all $\mathbf{x} \in \mathbf{X}$. Taking the infimum over $\mathbf{x} \in \mathbf{X}$ gives (3.1). ∎

Iterates which satisfy the criterion (C0) are now analyzed.

THEOREM 3.2. *Assume the following conditions are satisfied:*

(E0) *f provides a local error bound at $\hat{\mathbf{x}} \in \mathbf{X}$ with positive scalars α and ρ satisfying* (1.3).

(E1) *$\beta > 0$ is small enough that the following inequalities hold:*

$$\frac{\beta + 2\beta^2}{2} \leq \frac{\alpha}{3} \quad \textit{and} \quad \gamma := \frac{\beta\sqrt{3(1+\beta)(3+4\alpha)}}{2\alpha} < 1.$$

(E2) $\mu_k \in (0, \beta]$.

(E3) $\mathbf{x}_0$ *is close enough to* $\hat{\mathbf{x}}$ *that*

$$\|\mathbf{x}_0 - \hat{\mathbf{x}}\|\left(1 + \frac{\sqrt{1+\beta}}{1-\gamma}\right) \leq \rho.$$

Then any proximal iterates $\{\mathbf{x}_k\}$ satisfying (C0) *have the property that $\mathbf{x}_k \in \mathcal{B}_\rho(\hat{\mathbf{x}})$ for each k, and they approach a minimizer $\mathbf{x}^* \in \mathbf{X}$; moreover, for each k, we have*

$$\|\mathbf{x}_k - \mathbf{x}^*\| \leq c_1\gamma^k D(\mathbf{x}_0, \mathbf{X}) \quad \textit{and} \quad D(\mathbf{x}_{k+1}, \mathbf{X}) \leq c_2\mu_k D(\mathbf{x}_k, \mathbf{X}), \tag{3.3}$$

where

$$c_1 = \frac{\sqrt{1+\beta}}{1-\gamma} \quad \textit{and} \quad c_2 = \gamma/\beta. \tag{3.4}$$

Proof. For $j = 0$, (E3) implies that

$$\|\mathbf{x}_j - \hat{\mathbf{x}}\| \leq \rho \quad \text{and} \quad D(\mathbf{x}_j, \mathbf{X}) \leq \gamma^j D(\mathbf{x}_0, \mathbf{X}). \tag{3.5}$$

Proceeding by induction, suppose that (3.5) holds for all $j \in [0,k]$ and for some $k \geq 0$. We show that (3.5) also holds for $j = k+1$. By the triangle inequality, Lemma 3.1, (E2), and the induction hypothesis, it follows that

$$\begin{aligned}\|\mathbf{x}_{k+1} - \mathbf{x}_0\| &\leq \sum_{j=0}^{k} \|\mathbf{x}_{j+1} - \mathbf{x}_j\| \leq \sum_{j=0}^{k} \sqrt{1+\mu_j} D(\mathbf{x}_j, \mathbf{X}) \\ &\leq \sqrt{1+\beta} \sum_{j=0}^{k} \gamma^j D(\mathbf{x}_0, \mathbf{X}) \leq \frac{\sqrt{1+\beta}}{1-\gamma} D(\mathbf{x}_0, \mathbf{X}) \leq \frac{\sqrt{1+\beta}}{1-\gamma} \|\mathbf{x}_0 - \hat{\mathbf{x}}\|.\end{aligned}$$

Again, by the triangle inequality and (E3),

$$\|\mathbf{x}_{k+1} - \hat{\mathbf{x}}\| \leq \|\mathbf{x}_{k+1} - \mathbf{x}_0\| + \|\mathbf{x}_0 - \hat{\mathbf{x}}\| \leq \left(1 + \frac{\sqrt{1+\beta}}{1-\gamma}\right) \|\mathbf{x}_0 - \hat{\mathbf{x}}\| \leq \rho. \tag{3.6}$$

For any $\mathbf{x} \in \mathcal{H}$, observe that

$$\begin{aligned}&\|\mathbf{x} - \mathbf{x}_k\|^2 - \|\mathbf{x}_{k+1} - \mathbf{x}_k\|^2 \\ &\quad = \langle \mathbf{x} + \mathbf{x}_{k+1} - 2\mathbf{x}_k, \mathbf{x} - \mathbf{x}_{k+1} \rangle \\ &\quad \leq (\|\mathbf{x} - \mathbf{x}_{k+1}\| + 2\|\mathbf{x}_{k+1} - \mathbf{x}_k\|) \|\mathbf{x} - \mathbf{x}_{k+1}\|. \qquad (3.7)\end{aligned}$$

Rearranging (C0) and utilizing (3.7) gives, for all $\mathbf{x} \in \mathbf{X}$,

$$\begin{aligned}&f(\mathbf{x}_{k+1}) - f^* \\ &\quad \leq \frac{\mu_k}{2}(\|\mathbf{x} - \mathbf{x}_k\|^2 - \|\mathbf{x}_{k+1} - \mathbf{x}_k\|^2) + \frac{\mu_k^2}{2}\|\mathbf{x} - \mathbf{x}_k\|^2 \\ &\quad \leq \frac{\mu_k}{2}(\|\mathbf{x} - \mathbf{x}_{k+1}\| + 2\|\mathbf{x}_{k+1} - \mathbf{x}_k\|)\|\mathbf{x} - \mathbf{x}_{k+1}\| + \frac{\mu_k^2}{2}\|\mathbf{x} - \mathbf{x}_k\|^2 \\ &\quad \leq \frac{\mu_k}{2}(\|\mathbf{x} - \mathbf{x}_{k+1}\| + 2\|\mathbf{x}_{k+1} - \mathbf{x}_k\|)\|\mathbf{x} - \mathbf{x}_{k+1}\| + \frac{\mu_k^2}{2}(\|\mathbf{x} - \mathbf{x}_{k+1}\| + \|\mathbf{x}_{k+1} - \mathbf{x}_k\|)^2 \\ &\quad \leq \frac{\mu_k}{2}\|\mathbf{x} - \mathbf{x}_{k+1}\|^2 + \mu_k\|\mathbf{x}_{k+1} - \mathbf{x}_k\|\|\mathbf{x} - \mathbf{x}_{k+1}\| \\ &\qquad\quad + \mu_k^2(\|\mathbf{x} - \mathbf{x}_{k+1}\|^2 + \|\mathbf{x}_{k+1} - \mathbf{x}_k\|^2).\end{aligned}$$

Utilizing the inequalities

$$\mu_k\|\mathbf{x}_{k+1} - \mathbf{x}_k\|\|\mathbf{x} - \mathbf{x}_{k+1}\| \leq \frac{\alpha}{3}\|\mathbf{x} - \mathbf{x}_{k+1}\|^2 + \frac{3\mu_k^2}{4\alpha}\|\mathbf{x}_{k+1} - \mathbf{x}_k\|^2$$

and $\mu_k \leq \beta$, we obtain

$$f(\mathbf{x}_{k+1}) - f^* \leq \left(\frac{\beta + 2\beta^2}{2} + \frac{\alpha}{3}\right)\|\mathbf{x} - \mathbf{x}_{k+1}\|^2 + \left(\frac{3+4\alpha}{4\alpha}\right)\mu_k^2\|\mathbf{x}_{k+1} - \mathbf{x}_k\|^2. \tag{3.8}$$

Taking the infimum over $\mathbf{x} \in \mathbf{X}$ on the right-hand side of (3.8) gives

$$f(\mathbf{x}_{k+1}) - f^* \leq \left(\frac{\beta + 2\beta^2}{2} + \frac{\alpha}{3}\right)D(\mathbf{x}_{k+1}, \mathbf{X})^2 + \left(\frac{3+4\alpha}{4\alpha}\right)\mu_k^2\|\mathbf{x}_{k+1} - \mathbf{x}_k\|^2. \tag{3.9}$$

By (3.6), $\mathbf{x}_{k+1} \in \mathcal{B}_\rho(\hat{\mathbf{x}})$. Since f provides a local error bound at $\hat{\mathbf{x}}$,

$$\alpha D(\mathbf{x}_{k+1}, \mathbf{X})^2 \leq f(\mathbf{x}_{k+1}) - f^*. \tag{3.10}$$

Combining this with (3.9) gives

$$\left(\frac{2\alpha}{3} - \frac{\beta + 2\beta^2}{2}\right) D(\mathbf{x}_{k+1}, \mathbf{X})^2 \le \left(\frac{3+4\alpha}{4\alpha}\right) \mu_k^2 \|\mathbf{x}_{k+1} - \mathbf{x}_k\|^2. \tag{3.11}$$

By (E1), the coefficient of D in (3.11) is bounded from below by $\alpha/3$. Hence, (3.11), Lemma 3.1, and (3.5), with $j = k$, yield

$$\begin{aligned} D(\mathbf{x}_{k+1}, \mathbf{X}) &\le \mu_k \frac{\sqrt{3(3+4\alpha)}}{2\alpha} \|\mathbf{x}_{k+1} - \mathbf{x}_k\| \\ &\le \mu_k \sqrt{1+\mu_k} \frac{\sqrt{3(3+4\alpha)}}{2\alpha} D(\mathbf{x}_k, \mathbf{X}) \\ &\le \mu_k \frac{\sqrt{3(1+\beta)(3+4\alpha)}}{2\alpha} D(\mathbf{x}_k, \mathbf{X}) \qquad (3.12) \\ &\le \gamma D(\mathbf{x}_k, \mathbf{X}) \le \gamma^{k+1} D(\mathbf{x}_0, \mathbf{X}). \qquad (3.13) \end{aligned}$$

Relations (3.6) and (3.13) complete the proof of the induction step. Relations (3.12) and (3.13) give the estimate (3.3).

By Lemma 3.1 and (3.5), the proximal iterates $\mathbf{x}_k$ form a Cauchy sequence in $\mathcal{H}$, which has a limit denoted $\mathbf{x}^*$. By (3.5), Lemma 3.1, and the bound $\mu_k \le \beta$, we have

$$\begin{aligned} \|\mathbf{x}_k - \mathbf{x}^*\| &\le \sum_{j=k}^{\infty} \|\mathbf{x}_{j+1} - \mathbf{x}_j\| \le \sum_{j=k}^{\infty} \sqrt{1+\mu_k} D(\mathbf{x}_j, \mathbf{X}) \\ &\le \sqrt{1+\beta} \sum_{j=k}^{\infty} \gamma^j D(\mathbf{x}_0, \mathbf{X}) = \gamma^j \frac{\sqrt{1+\beta}}{1-\gamma} D(\mathbf{x}_0, \mathbf{X}). \qquad (3.14) \end{aligned}$$

By (3.5) and (3.14), for any $k \ge 0$ we have

$$D(\mathbf{x}^*, \mathbf{X}) \le D(\mathbf{x}_k, \mathbf{X}) + \|\mathbf{x}_k - \mathbf{x}^*\| \le \left(\gamma^k + \gamma^k \frac{\sqrt{1+\beta}}{1-\gamma}\right) D(\mathbf{x}_0, \mathbf{X}).$$

Thus $D(\mathbf{x}^*, \mathbf{X}) = 0$. Since $\mathbf{X}$ is closed, the limit $\mathbf{x}^* \in \mathbf{X}$. ∎

We now give a choice for μ_k which leads to a quadratic convergence rate for the proximal point iteration.

COROLLARY 3.3. *Assume that conditions* (E0), (E1), *and* (E3) *of Theorem* 3.2 *are satisfied. In addition, let* $e : \mathcal{H} \mapsto \mathbb{R}$ *be any nonnegative function with the property that*

$$e(\mathbf{x}) \le \beta \quad \text{and} \quad e(\mathbf{x}) \le L D(\mathbf{x}, \mathbf{X}) \tag{3.15}$$

for all $\mathbf{x} \in \mathcal{B}_\rho(\hat{\mathbf{x}})$ *and for some* $L \in \mathbb{R}$. *Then for the choice* $\mu_k = e(\mathbf{x}_k)$, *any proximal iterates* $\{\mathbf{x}_k\}$ *satisfying* (C0) *have the property that* $\mathbf{x}_k \in \mathcal{B}_\rho(\hat{\mathbf{x}})$ *for each* k, *the iterates approach a minimizer* $\mathbf{x}^* \in \mathbf{X}$, *and for each* k, *we have*

$$D(\mathbf{x}_{k+1}, \mathbf{X}) \le c_2 L D(\mathbf{x}_k, \mathbf{X})^2, \tag{3.16}$$

where c_2 *is given in* (3.4).

Proof. This follows directly from the proof of Theorem 3.2; simply append the condition $\mu_j \le \beta$ for each $j \in [0, k]$ to the induction hypothesis (3.5):

$$\|\mathbf{x}_j - \hat{\mathbf{x}}\| \le \rho, \quad D(\mathbf{x}_j, \mathbf{X}) \le \gamma^j D(\mathbf{x}_0, \mathbf{X}), \quad \text{and} \quad \mu_j \le \beta. \tag{3.17}$$

Since $\mathbf{x}_0 \in \mathcal{B}_\rho(\hat{\mathbf{x}})$, (3.15) implies that $\mu_0 = e(\mathbf{x}_0) \le \beta$. Hence, (3.17) is satisfied for $j = 0$. In the proof of Theorem 3.2, we show that if $\mu_j \le \beta$ for $j \in [0, k]$, then the first two conditions in (3.17) hold for $j = k+1$. In (3.6), we show that $\mathbf{x}_{k+1} \in \mathcal{B}_\rho(\hat{\mathbf{x}})$. Consequently, $\mu_{k+1} = e(\mathbf{x}_{k+1}) \le \beta$, and (3.17) holds for $j = k+1$. Replacing μ_k by $e(\mathbf{x}_k) \le LD(\mathbf{x}_k, \mathbf{X})$ in (3.3) gives (3.16). □

If f is Lipschitz continuously differentiable, then the function $e(\mathbf{x}) = \|f'[\mathbf{x}]\|$ satisfies the hypotheses of Corollary 3.3 when ρ is sufficiently small since $f'[\bar{\mathbf{x}}] = \mathbf{0}$ for all $\bar{\mathbf{x}} \in \mathbf{X}$.

4. Convergence analysis for approximate minimization. We now analyze the situation where the proximal point iteration (1.2) need only satisfy (C1) or (C2). The following property of a convex function is used in the analysis.

PROPOSITION 4.1. *If $\mathbf{x}^*$ is a local minimizer of F_k and f is convex in $\mathcal{B}_\rho(\mathbf{x}^*)$ for some $\rho > 0$, then*

$$F_k(\mathbf{x}) \le F_k(\mathbf{x}^*) + \frac{\|\partial F_k(\mathbf{x})\|_{\inf}^2}{\mu_k} \tag{4.1}$$

for all $\mathbf{x} \in \mathcal{B}_\rho(\mathbf{x}^*)$.

Proof. If $\partial F_k(\mathbf{x})$ is empty, then $\|\partial F_k(\mathbf{x})\|_{\inf} = \infty$, and there is nothing to prove. Hence, we assume that $\partial F_k(\mathbf{x}) \ne \emptyset$. Since f is convex in $\mathcal{B}_\rho(\mathbf{x}^*)$, we have

$$F_k(\mathbf{x}^*) \ge F_k(\mathbf{x}) + \langle \mathbf{y}, \mathbf{x}^* - \mathbf{x} \rangle \quad \text{for all } \mathbf{y} \in \partial F_k(\mathbf{x}). \tag{4.2}$$

For a convex functional, the subdifferentials satisfy the monotonicity condition [17, Thm. 3.56]

$$\langle \bar{\mathbf{y}} - \mathbf{y}^*, \mathbf{x} - \mathbf{x}^* \rangle \ge 0 \quad \text{for all } \bar{\mathbf{y}} \in \partial f(\mathbf{x}) \quad \text{and} \quad \mathbf{y}^* \in \partial f(\mathbf{x}^*). \tag{4.3}$$

Given $\bar{\mathbf{y}} \in \partial f(\mathbf{x})$, define

$$\mathbf{y} = \bar{\mathbf{y}} + \mu_k(\mathbf{x} - \mathbf{x}_k) \in \partial F_k(\mathbf{x}). \tag{4.4}$$

Since $\mathbf{x}^*$ is a local minimizer of F_k, $\mathbf{0} \in \partial F_k(\mathbf{x}^*)$, or equivalently, there exists $\mathbf{y}^* \in \partial f(\mathbf{x}^*)$ such that

$$\mathbf{0} = \mathbf{y}^* + \mu_k(\mathbf{x}^* - \mathbf{x}_k). \tag{4.5}$$

By (4.3), (4.4), and (4.5), we have

$$\begin{aligned} \langle \mathbf{y}, (\mathbf{x} - \mathbf{x}^*) \rangle &= \langle \bar{\mathbf{y}} + \mu_k(\mathbf{x} - \mathbf{x}_k) - (\mathbf{y}^* + \mu_k(\mathbf{x}^* - \mathbf{x}_k)), \mathbf{x} - \mathbf{x}^* \rangle \\ &= \langle \bar{\mathbf{y}} - \mathbf{y}^*, \mathbf{x} - \mathbf{x}^* \rangle + \mu_k \|\mathbf{x} - \mathbf{x}^*\|^2 \\ &\ge \mu_k \|\mathbf{x} - \mathbf{x}^*\|^2 \end{aligned} \tag{4.6}$$

for any $\mathbf{y} \in \partial F_k(\mathbf{x})$. The Schwarz inequality yields

$$\|\mathbf{x} - \mathbf{x}^*\| \le \frac{\|\mathbf{y}\|}{\mu_k}. \tag{4.7}$$

Thus, it follows from (4.2) and (4.7) that for any $\mathbf{y} \in \partial F_k(\mathbf{x})$,

$$F_k(\mathbf{x}) \le F_k(\mathbf{x}^*) + \frac{\|\mathbf{y}\|^2}{\mu_k}.$$

Minimizing over $\mathbf{y} \in \partial F_k(\mathbf{x})$ gives (4.1). □

In our first convergence result, we focus on the case where f is convex over the level set defined by the starting guess. We also employ a subdifferential generalization of the gradient-based local error bound condition (2.1): For some $\hat{\mathbf{x}} \in \mathbf{X}$, there exist positive constant α and ρ such that

$$\|\partial f(\mathbf{x})\|_{\inf} \geq \alpha D(\mathbf{x}, \mathbf{X}) \quad \text{whenever } \|\mathbf{x} - \hat{\mathbf{x}}\| \leq \rho. \tag{4.8}$$

If (4.8) is satisfied, then we say that ∂f provides a local error bound at $\hat{\mathbf{x}} \in \mathbf{X}$.

THEOREM 4.2. *Assume that the following conditions are satisfied:*

(A0) *∂f provides a local error bound at $\hat{\mathbf{x}} \in \mathbf{X}$ with positive scalars α and ρ satisfying* (4.8).

(A1) *If $\mathcal{L}$ is the level set $\{\mathbf{x} \in \mathcal{H} : f(\mathbf{x}) \leq f(\mathbf{x}_0)\}$, then f is convex and lower semicontinuous on $\mathcal{L}$, and there exists a constant L such that $\|\partial f(\mathbf{x})\|_{\inf} \leq LD(\mathbf{x}, \mathbf{X})$ for all $\mathbf{x} \in \mathcal{L}$.*

(A2) *Define the parameters*

$$\Lambda = L + \tau \quad \text{and} \quad \tau^2 = 1 + 2L^2 \quad \text{if acceptance criterion (C1) is used,}$$

while

$$\Lambda = \tau(1 + \theta) \quad \text{and} \quad \tau^2 = \frac{1}{1 - 2\theta^2} \quad \text{if acceptance criterion (C2) is used.}$$

$\beta > 0$ is small enough that the following inequality holds:

$$\gamma := \frac{\beta\Lambda}{\alpha} < 1. \tag{4.9}$$

(A3) *$\mu_k \in (0, \beta]$ and $\theta < 1/\sqrt{2}$.*

(A4) *$\mathbf{x}_0$ is close enough to $\hat{\mathbf{x}}$ that*

$$\|\mathbf{x}_0 - \hat{\mathbf{x}}\| \left(1 + \frac{\tau}{1 - \gamma}\right) \leq \rho.$$

If the approximate proximal iterates $\mathbf{x}_k$ satisfy either (C1) *or* (C2)*, then the iterates are all contained in $\mathcal{B}_\rho(\hat{\mathbf{x}})$, and they approach a minimizer $\mathbf{x}^* \in \mathbf{X}$; moreover, for each k, we have*

$$\|\mathbf{x}_k - \mathbf{x}^*\| \leq c_1 \gamma^k D(\mathbf{x}_0, \mathbf{X}) \quad \text{and} \quad D(\mathbf{x}_{k+1}, \mathbf{X}) \leq c_2 \mu_k D(\mathbf{x}_k, \mathbf{X}), \tag{4.10}$$

where

$$c_1 = \frac{\tau}{1 - \gamma} \quad \text{and} \quad c_2 = \gamma/\beta.$$

Proof. For $j = 0$, we have

$$\|\mathbf{x}_j - \hat{\mathbf{x}}\| \leq \rho, \quad \mathbf{x}_j \in \mathcal{L}, \quad \text{and} \quad D(\mathbf{x}_j, \mathbf{X}) \leq \gamma^j D(\mathbf{x}_0, \mathbf{X}). \tag{4.11}$$

Proceeding by induction, suppose that (4.11) holds for all $j \in [0, k]$ and for some $k \geq 0$. We show that (4.11) also holds for $j = k + 1$.

Due to the convexity and lower semicontinuity of f on $\mathcal{L}$, this level set is closed and convex. Suppose $j \in [0, k]$. By (C1) or (C2), we have

$$f(\mathbf{x}_{j+1}) \leq F_j(\mathbf{x}_{j+1}) \leq f(\mathbf{x}_j). \tag{4.12}$$

We conclude that $f(\mathbf{x}_j) \le f(\mathbf{x}_0)$ for each j. Since $F_j(\mathbf{x}_j) = f(\mathbf{x}_j) \le f(\mathbf{x}_0)$, minimizing F_j over $\mathcal{H}$ is equivalent to minimizing F_j over $\mathcal{L}$. Since F_j is strongly convex and lower semicontinuous on $\mathcal{L}$, F_j is weakly lower semicontinuous on $\mathcal{L}$, and there exists an exact proximal point iterate $\mathbf{x}_j^*$ defined by

$$\mathbf{x}_j^* \in \arg\ \min \{F_j(\mathbf{x}) : \mathbf{x} \in \mathcal{H}\}.$$

Moreover, $f(\mathbf{x}_j^*) \le f(\mathbf{x}_j) \le f(\mathbf{x}_0)$. Combining this with (4.12), both $\mathbf{x}_{j+1}$ and $\mathbf{x}_j^*$ lie in $\mathcal{L}$. By (A2) and Proposition 4.1, we have

$$\begin{aligned} F_j(\mathbf{x}_{j+1}) &= F_j(\mathbf{x}_j^*) + (F_j(\mathbf{x}_{j+1}) - F_j(\mathbf{x}_j^*)) \\ &\le F_j(\mathbf{x}_j^*) + \frac{\|\partial F_j(\mathbf{x}_{j+1})\|_{\inf}^2}{\mu_j} \\ &\le f^* + \frac{\mu_j}{2} D(\mathbf{x}_j, \mathbf{X})^2 + \frac{\|\partial F_j(\mathbf{x}_{j+1})\|_{\inf}^2}{\mu_j}. \end{aligned}$$

Since $f^* \le f(\mathbf{x}_{j+1})$, it follows that

$$\frac{\mu_j}{2}\|\mathbf{x}_{j+1} - \mathbf{x}_j\|^2 \le \frac{\mu_j}{2} D(\mathbf{x}_j, \mathbf{X})^2 + \frac{\|\partial F_j(\mathbf{x}_{j+1})\|_{\inf}^2}{\mu_j}. \tag{4.13}$$

By (C1) and (A1),

$$\|\partial F_j(\mathbf{x}_{j+1})\|_{\inf} \le \mu_j \|\partial f(\mathbf{x}_j)\|_{\inf} \le \mu_j L D(\mathbf{x}_j, \mathbf{X}). \tag{4.14}$$

Combining this with (4.13), we have

$$\|\mathbf{x}_{j+1} - \mathbf{x}_j\|^2 \le (1 + 2L^2) D(\mathbf{x}_j, \mathbf{X})^2. \tag{4.15}$$

Similarly, if criterion (C2) is used, then $\|\partial F_j(\mathbf{x}_{j+1})\|_{\inf} \le \theta\mu_j \|\mathbf{x}_{j+1} - \mathbf{x}_j\|$, and by (4.13), we have

$$\|\mathbf{x}_{j+1} - \mathbf{x}_j\|^2 \le \frac{1}{1 - 2\theta^2} D(\mathbf{x}_j, \mathbf{X})^2. \tag{4.16}$$

Together, (4.15) and (4.16) yield

$$\|\mathbf{x}_{j+1} - \mathbf{x}_j\| \le \tau D(\mathbf{x}_j, \mathbf{X}), \tag{4.17}$$

where τ is defined in (A2); this holds for any $j \in [0, k]$.

By (4.11), we have

$$\begin{aligned} \|\mathbf{x}_{k+1} - \mathbf{x}_0\| &\le \sum_{j=0}^{k} \|\mathbf{x}_{j+1} - \mathbf{x}_j\| \le \sum_{j=0}^{k} \tau D(\mathbf{x}_j, \mathbf{X}) \\ &\le \tau \sum_{j=0}^{k} \gamma^j D(\mathbf{x}_0, \mathbf{X}) \le \frac{\tau}{1-\gamma} D(\mathbf{x}_0, \mathbf{X}) \le \frac{\tau}{1-\gamma} \|\mathbf{x}_0 - \hat{\mathbf{x}}\|. \end{aligned}$$

Again, by the triangle inequality and (A4),

$$\|\mathbf{x}_{k+1} - \hat{\mathbf{x}}\| \le \|\mathbf{x}_{k+1} - \mathbf{x}_0\| + \|\mathbf{x}_0 - \hat{\mathbf{x}}\| \le \left(1 + \frac{\tau}{1-\gamma}\right) \|\mathbf{x}_0 - \hat{\mathbf{x}}\| \le \rho.$$

Hence, $\mathbf{x}_{k+1} \in \mathcal{B}_\rho(\hat{\mathbf{x}})$, which establishes the first relation in (4.11).

By (A0), we have

$$\alpha D(\mathbf{x}_{k+1}, \mathbf{X}) \le \|\partial f(\mathbf{x}_{k+1})\|_{\inf} \le \|\partial F_k(\mathbf{x}_{k+1})\|_{\inf} + \mu_k \|\mathbf{x}_{k+1} - \mathbf{x}_k\|. \tag{4.18}$$

If (C1) is used, then $\|\partial F_k(\mathbf{x}_{k+1})\|_{\inf} \le \mu_k \|\partial f(\mathbf{x}_k)\|_{\inf}$; hence, (A1) and (4.18) imply that

$$\begin{aligned} \alpha D(\mathbf{x}_{k+1}, \mathbf{X}) &\le \mu_k(\|\partial f(\mathbf{x}_k)\|_{\inf} + \|\mathbf{x}_{k+1} - \mathbf{x}_k\|) \\ &\le \mu_k(L D(\mathbf{x}_k, \mathbf{X}) + \|\mathbf{x}_{k+1} - \mathbf{x}_k\|). \end{aligned} \tag{4.19}$$

If (C2) is used, then $\|\partial F_k(\mathbf{x}_{k+1})\|_{\inf} \le \theta \mu_k \|\mathbf{x}_{k+1} - \mathbf{x}_k\|$, and by (4.18), we have

$$\alpha D(\mathbf{x}_{k+1}, \mathbf{X}) \le \mu_k(1+\theta)\|\mathbf{x}_{k+1} - \mathbf{x}_k\|. \tag{4.20}$$

Inserting the bound (4.17) into (4.19) or (4.20) yields the second half of (4.10). By the second half of (4.10) and (A3), we have

$$D(\mathbf{x}_{k+1}, \mathbf{X}) \le \left(\frac{\Lambda \mu_k}{\alpha}\right) D(\mathbf{x}_k, \mathbf{X}) \le \gamma D(\mathbf{x}_k, \mathbf{X}) \le \gamma^{k+1} D(\mathbf{x}_0, \mathbf{X}).$$

This establishes the last relation in (4.11) for $j = k+1$, and the proof of the induction step is complete. The proof that the $\mathbf{x}_k$ form a Cauchy sequence converging to a limit $\mathbf{x}^* \in \mathbf{X}$ and the first part of (4.10) are exactly as in Theorem 3.2. □

Suppose that $\mathbf{x}^*$ is a local minimizer of F_k, f is convex in $\mathcal{B}_\rho(\mathbf{x}^*)$ for some $\rho > 0$, and the following inequality holds:

$$f(\mathbf{x}_1) \ge f(\mathbf{x}_2) + \frac{1}{2}\langle \mathbf{y}_1 + \mathbf{y}_2, \mathbf{x}_1 - \mathbf{x}_2 \rangle \tag{4.21}$$

whenever $\mathbf{y_i} \in \partial f(\mathbf{x}_i)$, $i = 1, 2$. For example, when f is a quadratic, (4.21) is satisfied with equality. When (4.21) holds, Proposition 4.1 can be strengthened to

$$F_k(\mathbf{x}) \le F_k(\mathbf{x}^*) + \frac{\|\partial F_k(\mathbf{x})\|_{\inf}^2}{2\mu_k} \tag{4.22}$$

for all $\mathbf{x} \in \mathcal{B}_\rho(\mathbf{x}^*)$. In Theorem 4.2, we require that $\theta < 1/\sqrt{2}$ in (A3); this requirement arises at inequality (4.16) since we need to ensure that $1 - 2\theta^2 > 0$. If f satisfies (4.21), then by exploiting the stronger inequality (4.22), the restriction on θ for stopping criterion (C2) can be relaxed to $\theta < 1$.

We now relax the convexity requirement for f while strengthening the smoothness condition. We require only that $\mathbf{X}$ is locally convex, while f is locally, twice continuously differentiable. If the set $\mathcal{B}_\rho(\hat{\mathbf{x}}) \cap \mathbf{X}$ is convex for some $\rho > 0$, then the projection $\bar{\mathbf{x}}$ of $\mathbf{x}$ onto $\mathcal{B}_\rho(\hat{\mathbf{x}}) \cap \mathbf{X}$ exists. For $\mathbf{x} \in \mathcal{B}_{\rho/2}(\hat{\mathbf{x}})$, it follows that $\|\mathbf{x} - \mathbf{y}\| \ge \rho/2$ when $\mathbf{y} \in \mathcal{B}_\rho(\hat{\mathbf{x}})^c$, where c denotes complement. Hence, the distance from $\mathbf{x} \in \mathcal{B}_{\rho/2}(\hat{\mathbf{x}})$ to $\mathbf{X}$ is the same as the distance from $\mathbf{x}$ to $\mathbf{X} \cap \mathcal{B}_\rho(\hat{\mathbf{x}})$:

$$\|\mathbf{x} - \bar{\mathbf{x}}\| = \min\{\|\mathbf{x} - \mathbf{y}\| : \mathbf{y} \in \mathcal{B}_\rho(\hat{\mathbf{x}}) \cap \mathbf{X}\} = \min\ \{\|\mathbf{x} - \mathbf{y}\| : \mathbf{y} \in \mathbf{X}\} = D(\mathbf{x}, \mathbf{X}).$$

The following lemma plays the role of Proposition 4.1 when we remove the convexity requirement for f.

LEMMA 4.3. *Suppose f provides a local error bound at $\hat{\mathbf{x}} \in \mathbf{X}$ with positive scalars α and ρ satisfying* (1.3), *$\mathbf{X} \cap B_\rho(\hat{\mathbf{x}})$ is convex, and f is twice Lipschitz continuously*

Fréchet differentiable on $\mathcal{B}_\rho(\hat{\mathbf{x}})$. *If* $\mu_k = \beta\|f'[\mathbf{x}_k]\|^\eta$, *where* $\eta \geq 0$ *and* $\beta > 0$, *then there exist* $r \in (0, \rho/2]$ *and positive constants* C_1 *and* C_2 *with the following property: For each* $\mathbf{x}_k \in \mathcal{B}_r(\hat{\mathbf{x}})$, *we have*

$$F_k(\mathbf{x}) - F_k(\bar{\mathbf{x}}) \leq \frac{C_1}{\mu_k}\|F_k'(\mathbf{x})\|^2 \tag{4.23}$$

whenever $\mathbf{x} \in \mathcal{B}_r(\hat{\mathbf{x}})$ *and* $\|\mathbf{x} - \bar{\mathbf{x}}\| \leq C_2\|\mathbf{x}_k - \bar{\mathbf{x}}_k\|^\eta$.

Proof. If $\mathbf{x}_k = \bar{\mathbf{x}}_k$, then (4.23) is trivial. Hence, we assume that $\mathbf{x}_k \neq \bar{\mathbf{x}}_k$. By Lemma 2.1, f' provides a local error bound with constants α and $r \in (0, \rho/2]$. Hence, for any $\mathbf{x}_k \in \mathcal{B}_r(\hat{\mathbf{x}})$, we have

$$\alpha\|\mathbf{x}_k - \bar{\mathbf{x}}_k\| = \alpha D(\mathbf{x}_k, \mathbf{X}) \leq \|f'[\mathbf{x}_k]\|.$$

Raising this inequality to the η power and utilizing the definition of μ_k gives

$$\mu_k \geq \beta\alpha^\eta\|\mathbf{x}_k - \bar{\mathbf{x}}_k\|^\eta. \tag{4.24}$$

By the second-order necessary optimality condition, the second derivative operator $f''[\mathbf{x}]$ is positive for any $\mathbf{x} \in \mathbf{X}$. Hence, given any $\mathbf{x} \in \mathcal{B}_r(\hat{\mathbf{x}})$ and $\mathbf{y} \in \mathcal{H}$, we deduce from (4.24) that

$$\begin{aligned}\langle \mathbf{y}, F_k''(\mathbf{x})\mathbf{y}\rangle &= \langle \mathbf{y}, (f''[\bar{\mathbf{x}}] + \mu_k\mathbf{I} + f''[\mathbf{x}] - f''[\bar{\mathbf{x}}])\mathbf{y}\rangle \\ &\geq \mu_k\|\mathbf{y}\|^2 + \langle \mathbf{y}, (f''[\mathbf{x}] - f''[\bar{\mathbf{x}}])\mathbf{y}\rangle \\ &\geq \Big(\beta\alpha^\eta\|\mathbf{x}_k - \bar{\mathbf{x}}_k\|^\eta - L_2\|\mathbf{x} - \bar{\mathbf{x}}\|\Big)\|\mathbf{y}\|^2,\end{aligned}$$

where L_2 is a Lipschitz constant for f'' on $\mathcal{B}_\rho(\hat{\mathbf{x}})$. Hence, if $\mathbf{x} \in \mathcal{B}_r(\hat{\mathbf{x}})$ satisfies

$$\|\mathbf{x} - \bar{\mathbf{x}}\| \leq C_2\|\mathbf{x}_k - \bar{\mathbf{x}}_k\|^\eta, \quad C_2 = \frac{\beta\alpha^\eta}{2L_2}, \tag{4.25}$$

then we have

$$\langle \mathbf{y}, F_k''(\mathbf{x})\mathbf{y}\rangle \geq \frac{\beta\alpha^\eta}{2}\|\mathbf{x}_k - \bar{\mathbf{x}}_k\|^\eta\|\mathbf{y}\|^2. \tag{4.26}$$

Let $\mathcal{A}$ be the collection of $\mathbf{x} \in \mathcal{B}_r(\hat{\mathbf{x}})$ which satisfies (4.25):

$$\mathcal{A} = \{\mathbf{x} \in \mathcal{B}_r(\hat{\mathbf{x}}) : \|\mathbf{x} - \bar{\mathbf{x}}\| \leq C_2\|\mathbf{x}_k - \bar{\mathbf{x}}_k\|^\eta\}.$$

We now show that $\mathcal{A}$ is closed and convex. Since $r \leq \rho/2$, it follows from the discussion preceding the lemma that for each $\mathbf{y}$ and $\mathbf{z} \in \mathcal{B}_r(\hat{\mathbf{x}})$, the projections $\bar{\mathbf{y}}$ and $\bar{\mathbf{z}}$ onto $\mathbf{X}$ exist in $\mathcal{B}_\rho(\hat{\mathbf{x}})$. By the convexity of $\mathcal{B}_\rho(\hat{\mathbf{x}}) \cap \mathbf{X}$, the line segment $[\bar{\mathbf{y}}, \bar{\mathbf{z}}]$ is contained in $\mathcal{B}_\rho(\hat{\mathbf{x}}) \cap \mathbf{X}$. Thus, if $\mathbf{y}$ and $\mathbf{z} \in \mathcal{A}$, then each $\mathbf{x} \in [\mathbf{y}, \mathbf{z}]$ lies in $\mathcal{A}$. $\mathcal{A}$ is closed since the projection onto a convex set is Lipschitz continuous.

By (4.26), F_k is strongly convex over the closed, convex set $\mathcal{A}$. Consequently, there exists a unique minimizer $\mathbf{x}_k^*$:

$$\mathbf{x}_k^* = \arg\min\{F_k(\mathbf{x}) : \mathbf{x} \in \mathcal{A}\}. \tag{4.27}$$

Given $\mathbf{x} \in \mathcal{A}$ and $t \in [0, 1]$, we define $\mathbf{x}(t) = \mathbf{x}_k^* + t(\mathbf{x} - \mathbf{x}_k^*)$. Since $\mathcal{A}$ is convex and both $\mathbf{x}$ and $\mathbf{x}_k^* \in \mathcal{A}$, it follows that $\mathbf{x}(t) \in \mathcal{A}$ for all $t \in [0, 1]$. Since $\mathbf{x}(0) = \mathbf{x}_k^*$

achieves the minimum in (4.27), we have $F_k(\mathbf{x}_k^*) \le F_k(\mathbf{x}(t))$ for all $t \in [0,1]$. Thus for $\phi(t) := F_k(\mathbf{x}(t))$, we have $\phi'(0) \ge 0$, and by (4.26),

$$\begin{aligned}\|F_k'(\mathbf{x})\|\|\mathbf{x}-\mathbf{x}_k^*\| &\ge F_k'(\mathbf{x})(\mathbf{x}-\mathbf{x}_k^*) = \phi'(1) \ge \phi'(1)-\phi'(0) = \phi''(s)\\ &= \langle F_k''(\mathbf{x}(s))(\mathbf{x}-\mathbf{x}_k^*), \mathbf{x}-\mathbf{x}_k^*\rangle\\ &\ge \frac{\beta\alpha^\eta}{2}\|\mathbf{x}_k-\bar{\mathbf{x}}_k\|^\eta\|\mathbf{x}-\mathbf{x}_k^*\|^2\end{aligned}$$

for some $s \in [0,1]$. Hence, we have

$$\|\mathbf{x}-\mathbf{x}_k^*\| \le \frac{2}{\beta\alpha^\eta\|\mathbf{x}_k-\bar{\mathbf{x}}_k\|^\eta}\|F_k'(\mathbf{x})\|. \tag{4.28}$$

By (4.26), $F_k(\mathbf{x}(t))$ is convex as a function of $t \in [0,1]$. This implies that $\phi'(t)$ is an increasing function of $t \in [0,1]$. We combine this observation with (4.27) and (4.28) to obtain

$$\begin{aligned}F_k(\mathbf{x}) - F_k(\bar{\mathbf{x}}_k) &\le F_k(\mathbf{x}) - F_k(\mathbf{x}_k^*)\\ &= F_k(\mathbf{x}(1)) - F_k(\mathbf{x}(0))\\ &= \int_0^1 \phi'(t)dt \le \phi'(1) = F_k'(\mathbf{x})(\mathbf{x}-\mathbf{x}_k^*)\\ &\le \frac{2}{\beta\alpha^\eta\|\mathbf{x}_k-\bar{\mathbf{x}}_k\|^\eta}\|F_k'(\mathbf{x})\|^2 \qquad (4.29)\end{aligned}$$

whenever $\mathbf{x} \in \mathcal{A}$ and $\mathbf{x}_k \in \mathcal{B}_r(\hat{\mathbf{x}})$.

If L_1 is a Lipschitz constant for f' over $\mathcal{B}_\rho(\hat{\mathbf{x}})$, then we have

$$\|f'[\mathbf{x}_k]\| = \|f'[\mathbf{x}_k] - f'[\bar{\mathbf{x}}_k]\| \le L_1\|\mathbf{x}_k - \bar{\mathbf{x}}_k\|$$

whenever $\mathbf{x}_k \in \mathcal{B}_r(\hat{\mathbf{x}})$. By the definition of μ_k, it follows that

$$\|\mathbf{x}_k - \bar{\mathbf{x}}_k\|^\eta \ge \mu_k/(\beta L_1^\eta).$$

Combining this with (4.29) gives (4.23) with $C_1 = 2L_1^\eta/\alpha^\eta$. □

THEOREM 4.4. *Assume that the following conditions are satisfied:*

(B0) *f provides a local error bound at $\hat{\mathbf{x}} \in \mathbf{X}$ with positive scalars α and ρ satisfying* (1.3).

(B1) *The set $\mathcal{B}_\rho(\hat{\mathbf{x}}) \cap \mathbf{X}$ is convex.*

(B2) *f is twice Lipschitz continuously Fréchet differentiable in $\mathcal{B}_\rho(\hat{\mathbf{x}})$.*

(B3) *The proximal iterates $\mathbf{x}_k$ satisfy either* (C1) *or* (C2) *with $\mu_k = \beta\|f'[\mathbf{x}_k]\|^\eta$, where $\eta \in (0,2)$ and β is positive. If* (C2) *is used, then θ is small enough that $2C_1\theta^2 < 1$, where C_1 is the constant in* (4.23).

Then for ϵ sufficiently small and for each $\mathbf{x}_0 \in \mathcal{B}_\epsilon(\hat{\mathbf{x}})$, the proximal iterates $\mathbf{x}_k$ are all contained in $\mathcal{B}_\rho(\hat{\mathbf{x}})$, and they approach a minimizer $\mathbf{x}^* \in \mathbf{X}$; moreover, for each k, we have

$$\begin{aligned}&\|\mathbf{x}_k - \mathbf{x}^*\| \le c_1\gamma^k D(\mathbf{x}_0, \mathbf{X}) \quad \textit{and}\\ &D(\mathbf{x}_{k+1}, \mathbf{X}) \le c_2\mu_k D(\mathbf{x}_k, \mathbf{X}) \le \beta c_2 L_1^\eta D(\mathbf{x}_k, \mathbf{X})^{1+\eta}, \qquad (4.30)\end{aligned}$$

where $\gamma < 1$, c_1, and c_2 are constants independent of k.

Proof. We start by explaining how to choose ϵ so that the theorem holds. Define the parameters

$$\Lambda = L_1 + \tau \quad \text{and} \quad \tau^2 = 1 + 2C_1L_1^2 \quad \text{if acceptance criterion (C1) is used,}$$

while

$$\Lambda = \tau(1+\theta) \quad \text{and} \quad \tau^2 = \frac{1}{1-2C_1\theta^2} \quad \text{if acceptance criterion (C2) is used,}$$

where C_1 is the constant in (4.23) and L_1 is a Lipschitz constant for f' over $\mathcal{B}_\rho(\hat{\mathbf{x}})$. Notice that the hypotheses of the theorem are satisfied if ρ is decreased. Choose ρ small enough that

$$\gamma := \sup_{\mathbf{x}\in\mathcal{B}_\rho(\hat{\mathbf{x}})} \frac{\beta\|f'[\mathbf{x}]\|^\eta\Lambda}{\alpha} < 1. \tag{4.31}$$

By Lemma 2.1, we can choose ρ smaller, if necessary, so that f' provides a local error bound with constants α and $\rho/2$. By Lemma 4.3, we can choose ρ smaller, if necessary, so that (4.23) holds whenever $\mathbf{x} \in \mathcal{B}_\rho(\hat{\mathbf{x}})$ and $\|\mathbf{x}-\bar{\mathbf{x}}\| \le C_2\|\mathbf{x}_k - \bar{\mathbf{x}}_k\|^\eta$. Choose $\epsilon > 0$ small enough that

$$\left(\epsilon + \frac{E\epsilon^{1-\eta/2}}{1-\gamma^{1-\eta/2}}\right) \le \frac{\rho}{2}, \quad \text{where} \quad E = \sqrt{\frac{L_1}{2\beta\alpha^\eta}}, \tag{4.32}$$

and

$$\epsilon(L_1 + E\epsilon^{-\eta/2})\left(\frac{\beta L_1^\eta}{\alpha}\right) \le C_2 \quad \text{if stopping criterion (C1) is used,} \tag{4.33}$$

$$E\epsilon^{1-\eta/2}(1+\theta)\left(\frac{\beta L_1^\eta}{\alpha}\right) \le C_2 \quad \text{if stopping criterion (C2) is used.} \tag{4.34}$$

Since $\eta \in (0,2)$, (4.33) and (4.34) are satisfied for ϵ sufficiently small.

We now prove the theorem. Again, let $\bar{\mathbf{x}}$ be the projection of $\mathbf{x}$ onto $\mathbf{X}$. For $j = 0$, we have

$$\|\mathbf{x}_j - \hat{\mathbf{x}}\| \le \rho/2 \quad \text{and} \quad \|\mathbf{x}_j - \bar{\mathbf{x}}_j\| \le \gamma^j\|\mathbf{x}_0 - \bar{\mathbf{x}}_0\| \tag{4.35}$$

since $\mathbf{x}_0 \in \mathcal{B}_\epsilon(\hat{\mathbf{x}}) \subset \mathcal{B}_{\rho/2}(\hat{\mathbf{x}})$. Proceeding by induction, suppose that (4.35) holds for all $j \in [0,k]$ and for some $k \ge 0$.

For any $j \in [0,k]$, the condition $F_j(\mathbf{x}_{j+1}) \le f(\mathbf{x}_j)$ in (C1) or (C2) implies that

$$\mu_j\|\mathbf{x}_{j+1} - \mathbf{x}_j\|^2 \le f(\mathbf{x}_j) - f(\mathbf{x}_{j+1}) \le f(\mathbf{x}_j) - f(\bar{\mathbf{x}}_j). \tag{4.36}$$

By the induction hypothesis, $\mathbf{x}_j \in \mathcal{B}_{\rho/2}(\hat{\mathbf{x}})$, and by the triangle inequality, we have

$$\|\bar{\mathbf{x}}_j - \hat{\mathbf{x}}\| \le \|\bar{\mathbf{x}}_j - \mathbf{x}_j\| + \|\mathbf{x}_j - \hat{\mathbf{x}}\| \le \|\bar{\mathbf{x}}_0 - \mathbf{x}_0\| + \frac{\rho}{2} \le \rho. \tag{4.37}$$

Hence, $\bar{\mathbf{x}}_j \in \mathcal{B}_\rho(\hat{\mathbf{x}})$. We expand f in (4.36) in a Taylor series around $\bar{\mathbf{x}}_j$ and use the fact that $f'[\bar{\mathbf{x}}_j] = \mathbf{0}$ to obtain

$$\mu_j\|\mathbf{x}_{j+1} - \mathbf{x}_j\|^2 \le \frac{L_1}{2}\|\mathbf{x}_j - \bar{\mathbf{x}}_j\|^2, \tag{4.38}$$

where L_1 is a Lipschitz constant for f'. Since f' provides a local error bound with constants α and $\rho/2$ and $\mathbf{x}_j \in \mathcal{B}_{\rho/2}(\hat{\mathbf{x}})$, it follows that

$$\mu_j = \beta \|f'[\mathbf{x}_j]\|^\eta \geq \beta\alpha^\eta \|\mathbf{x}_j - \bar{\mathbf{x}}_j\|^\eta.$$

Combining this with (4.38) gives

$$\|\mathbf{x}_{j+1} - \mathbf{x}_j\| \leq E\|\mathbf{x}_j - \bar{\mathbf{x}}_j\|^{1-\eta/2} \tag{4.39}$$

for $j \in [0, k]$, where E is defined in (4.32). By the triangle inequality, (4.32), (4.35), and (4.39), we have

$$\begin{aligned}
\|\mathbf{x}_{k+1} - \hat{\mathbf{x}}\| &\leq \|\mathbf{x}_0 - \hat{\mathbf{x}}\| + \sum_{j=0}^{k} \|\mathbf{x}_{j+1} - \mathbf{x}_j\| \\
&\leq \|\mathbf{x}_0 - \hat{\mathbf{x}}\| + E\sum_{j=0}^{k} \|\mathbf{x}_j - \bar{\mathbf{x}}_j\|^{1-\eta/2} \\
&\leq \|\mathbf{x}_0 - \hat{\mathbf{x}}\| + E\|\mathbf{x}_0 - \hat{\mathbf{x}}\|^{1-\eta/2} \sum_{j=0}^{k} (\gamma^{1-\eta/2})^j \\
&\leq \|\mathbf{x}_0 - \hat{\mathbf{x}}\| + \frac{E\|\mathbf{x}_0 - \hat{\mathbf{x}}\|^{1-\eta/2}}{1 - \gamma^{1-\eta/2}} \\
&\leq \epsilon + \frac{E\epsilon^{1-\eta/2}}{1 - \gamma^{1-\eta/2}} \leq \rho/2.
\end{aligned}$$

This establishes the first half of (4.35) for $j = k + 1$.

To establish the second half of (4.35), we will apply Lemma 4.3 to $\mathbf{x} = \mathbf{x}_{k+1}$. Since $\mathbf{x}_{k+1} \in \mathcal{B}_{\rho/2}(\hat{\mathbf{x}})$, we need only show that $\mathbf{x} = \mathbf{x}_{k+1}$ satisfies the qualification $\|\mathbf{x} - \bar{\mathbf{x}}\| \leq C_2\|\mathbf{x}_k - \bar{\mathbf{x}}_k\|^\eta$ for (4.23). Since $\|\mathbf{x}_{k+1} - \hat{\mathbf{x}}\| \leq \rho/2$ and since f' provides a local error bound at $\hat{\mathbf{x}}$ with constants α and $\rho/2$,

$$\alpha\|\mathbf{x}_{k+1} - \bar{\mathbf{x}}_{k+1}\| \leq \|f'[\mathbf{x}_{k+1}]\| \leq \|F_k'(\mathbf{x}_{k+1})\| + \mu_k\|\mathbf{x}_{k+1} - \mathbf{x}_k\|. \tag{4.40}$$

Since f' is Lipschitz continuous over $\mathcal{B}_\rho(\hat{\mathbf{x}})$, it follows from (4.39), (4.40), and the definition of μ_k that for stopping criterion (C1),

$$\begin{aligned}
\|\mathbf{x}_{k+1} - \bar{\mathbf{x}}_{k+1}\| &\leq \frac{\mu_k}{\alpha}(\|\nabla f(\mathbf{x}_k)\| + \|\mathbf{x}_{k+1} - \mathbf{x}_k\|) \\
&\leq \left(\frac{\beta L_1^\eta}{\alpha}(L_1\|\mathbf{x}_k - \bar{\mathbf{x}}_k\| + \|\mathbf{x}_{k+1} - \mathbf{x}_k\|)\right)\|\mathbf{x}_k - \bar{\mathbf{x}}_k\|^\eta \\
&\leq \left(\frac{\beta L_1^\eta}{\alpha}(L_1\|\mathbf{x}_0 - \bar{\mathbf{x}}_0\| + E\|\mathbf{x}_k - \bar{\mathbf{x}}_k\|^{1-\eta/2})\right)\|\mathbf{x}_k - \bar{\mathbf{x}}_k\|^\eta \\
&\leq \left(\frac{\beta L_1^\eta}{\alpha}(L_1\|\mathbf{x}_0 - \hat{\mathbf{x}}\| + E\|\mathbf{x}_0 - \hat{\mathbf{x}}\|^{1-\eta/2})\right)\|\mathbf{x}_k - \bar{\mathbf{x}}_k\|^\eta \\
&\leq C_2\|\mathbf{x}_k - \bar{\mathbf{x}}_k\|^\eta. \qquad (4.41)
\end{aligned}$$

The first inequality is due to (4.40) and (C1); the second inequality is based on the definition of μ_k and the Lipschitz continuity of f'; the third inequality utilizes the induction hypothesis (4.35), the bound (4.39) for $j = k$, and the fact that $\mathbf{x}_k$ and

$\bar{\mathbf{x}}_k \in \mathcal{B}_\rho(\hat{\mathbf{x}})$ (see (4.37)); and the fourth inequality is a consequence of the induction hypothesis and the fact that ϵ satisfies (4.33).

If stopping criterion (C2) is used, then in the same fashion, (4.34) gives

$$\begin{aligned}\|\mathbf{x}_{k+1}-\bar{\mathbf{x}}_{k+1}\| &\le \frac{\mu_k}{\alpha}(1+\theta)\|\mathbf{x}_{k+1}-\mathbf{x}_k\| \\ &\le \left(\frac{\beta L_1^\eta}{\alpha}(1+\theta)\|\mathbf{x}_{k+1}-\mathbf{x}_k\|\right)\|\mathbf{x}_k-\bar{\mathbf{x}}_k\|^\eta \\ &\le \left(\frac{\beta L_1^\eta}{\alpha}(1+\theta)E\|\mathbf{x}_k-\bar{\mathbf{x}}_k\|^{1-\eta/2}\right)\|\mathbf{x}_k-\bar{\mathbf{x}}_k\|^\eta \\ &\le \left(\frac{\beta L_1^\eta}{\alpha}(1+\theta)E\|\mathbf{x}_0-\hat{\mathbf{x}}\|^{1-\eta/2}\right)\|\mathbf{x}_k-\bar{\mathbf{x}}_k\|^\eta \\ &\le C_2\|\mathbf{x}_k-\bar{\mathbf{x}}_k\|^\eta. \qquad (4.42)\end{aligned}$$

Thus, if either stopping criterion (C1) or (C2) is used, then $\mathbf{x}=\mathbf{x}_{k+1}$ satisfies the qualifications of Lemma 4.3.

We now give another bound for the change $\|\mathbf{x}_{k+1}-\mathbf{x}_k\|$. Lemma 4.3 yields

$$F_k(\mathbf{x}_{k+1}) \le F_k(\bar{\mathbf{x}}_k) + \frac{C_1}{\mu_k}\|F_k'(\mathbf{x}_{k+1})\|^2. \qquad (4.43)$$

Since $f(\bar{\mathbf{x}}_k) \le f(\mathbf{x}_{k+1})$, we conclude that

$$\frac{\mu_k}{2}\|\mathbf{x}_{k+1}-\mathbf{x}_k\|^2 \le \frac{\mu_k}{2}\|\bar{\mathbf{x}}_k-\mathbf{x}_k\|^2 + \frac{C_1}{\mu_k}\|F_k'(\mathbf{x}_{k+1})\|^2. \qquad (4.44)$$

If (C1) is used, then we have

$$\begin{aligned}\|\mathbf{x}_{k+1}-\mathbf{x}_k\|^2 &\le \|\bar{\mathbf{x}}_k-\mathbf{x}_k\|^2 + 2C_1\|f'[\mathbf{x}_k]\|^2 \\ &\le \|\bar{\mathbf{x}}_k-\mathbf{x}_k\|^2 + 2C_1L_1^2\|\bar{\mathbf{x}}_k-\mathbf{x}_k\|^2.\end{aligned}$$

If (C2) is used, then (4.44) gives

$$\|\mathbf{x}_{k+1}-\mathbf{x}_k\|^2 \le \frac{1}{1-2C_1\theta^2}\|\mathbf{x}_k-\bar{\mathbf{x}}_k\|^2.$$

In either case,

$$\|\mathbf{x}_{k+1}-\mathbf{x}_k\| \le \tau\|\mathbf{x}_k-\bar{\mathbf{x}}_k\|, \qquad (4.45)$$

where τ is defined at the start of the proof.

If (C1) is used, then

$$\|F_k'(\mathbf{x}_{k+1})\| \le \mu_k\|f'[\mathbf{x}_k]\| = \mu_k\|f'[\mathbf{x}_k]-f'[\bar{\mathbf{x}}_k]\| \le \mu_k L_1\|\mathbf{x}_k-\bar{\mathbf{x}}_k\|.$$

By (4.40) and (4.45), we have

$$\|\mathbf{x}_{k+1}-\bar{\mathbf{x}}_{k+1}\| \le \frac{\mu_k}{\alpha}(L_1+\tau)\|\mathbf{x}_k-\bar{\mathbf{x}}_k\|. \qquad (4.46)$$

If (C2) is used, then $\|F_k'(\mathbf{x}_{k+1})\| \le \theta\mu_k\|\mathbf{x}_{k+1}-\mathbf{x}_k\|$, and by (4.40) and (4.45), we have

$$\|\mathbf{x}_{k+1}-\bar{\mathbf{x}}_{k+1}\| \le \frac{\tau\mu_k(1+\theta)}{\alpha}\|\mathbf{x}_k-\bar{\mathbf{x}}_k\|. \qquad (4.47)$$

In either case, since $\mathbf{x}_k \in \mathcal{B}_{\rho/2}(\hat{\mathbf{x}})$, it follows from the definition of γ and μ_k that

$$\|\mathbf{x}_{k+1} - \bar{\mathbf{x}}_{k+1}\| \leq \gamma \|\mathbf{x}_k - \bar{\mathbf{x}}_k\|.$$

This establishes the second half of (4.35) for $j = k+1$. Hence, the proof of the induction step is complete. The proof that the $\mathbf{x}_k$ form a Cauchy sequence converging to a limit $\mathbf{x}^* \in \mathbf{X}$ is exactly as in Theorem 3.2. The first half of (4.30) follows from (4.46) and (4.47). In the second half of (4.30), we replace μ_k by $\beta \|f'[\mathbf{x}_k]\|^\eta$ and exploit the Lipschitz continuity of f'. □

Remark. During the proof of Theorem 4.4, in (4.41) and (4.42), we show that each iterate $\mathbf{x}_{k+1}$ lies in the region where F_k is convex (4.26).

When $\eta = 0$, we can drop the requirement of Theorem 4.4 that $\mathbf{X}$ is locally convex. This convexity requirement arose since we use Lemma 4.3, which assumes that $\mathbf{X}$ is locally convex. We now show that Lemma 4.3 can be established without local convexity when μ_k is bounded away from 0.

LEMMA 4.5. *Let $\beta > 0$ and suppose that $\mu_k \geq \beta$ for each k. Given $\hat{\mathbf{x}} \in \mathbf{X}$ and $\delta \in (0,1)$, suppose f is twice Lipschitz continuously Fréchet differentiable on $\mathcal{B}_\rho(\hat{\mathbf{x}})$, let L_2 be a Lipschitz constant for f'' on $\mathcal{B}_\rho(\hat{\mathbf{x}})$, and let $r = \min\{\rho, \delta\beta/L_2\}$. Then we have*

$$F_k(\mathbf{x}) - F_k^* \leq \left(\frac{1}{(1-\delta)\mu_k}\right) \|F_k'(\mathbf{x})\|^2 \tag{4.48}$$

for all $\mathbf{x} \in \mathcal{B}_r(\hat{\mathbf{x}})$, where

$$F_k^* = \min_{\mathbf{x} \in \mathcal{B}_r(\hat{\mathbf{x}})} F_k(\mathbf{x}).$$

Proof. Suppose $\mathbf{x} \in \mathcal{B}_r(\hat{\mathbf{x}})$. We start with the identity

$$\langle F_k''[\mathbf{x}]\mathbf{y}, \mathbf{y}\rangle = \langle F_k''[\hat{\mathbf{x}}]\mathbf{y}, \mathbf{y}\rangle + \langle (F_k''[\mathbf{x}] - F_k''[\hat{\mathbf{x}}])\mathbf{y}, \mathbf{y}\rangle.$$

By the second-order optimality condition, $f''[\hat{\mathbf{x}}]$ is positive. Consequently, we have

$$\langle F_k''[\hat{\mathbf{x}}]\mathbf{y}, \mathbf{y}\rangle \geq \mu_k \|\mathbf{y}\|^2.$$

Since $F_k''[\mathbf{x}] - F_k''[\hat{\mathbf{x}}] = f''[\mathbf{x}] - f''[\hat{\mathbf{x}}]$, it follows from the Lipschitz continuity of f'' that

$$\langle (F_k''[\mathbf{x}] - F_k''[\hat{\mathbf{x}}])\mathbf{y}, \mathbf{y}\rangle \leq L_2 \|\mathbf{x} - \hat{\mathbf{x}}\| \, \|\mathbf{y}\|^2 \leq \delta\beta \|\mathbf{y}\|^2 \leq \delta\mu_k \|\mathbf{y}\|^2$$

since $r \leq \delta\beta/L_2$. Hence, if $\mathbf{x} \in \mathcal{B}_r(\hat{\mathbf{x}})$, we have

$$\langle F_k''[\mathbf{x}]\mathbf{y}, \mathbf{y}\rangle \geq (1-\delta)\mu_k \|\mathbf{y}\|^2. \tag{4.49}$$

By (4.49), F_k is convex on $\mathcal{B}_r(\hat{\mathbf{x}})$. Consequently, the minimizer $\mathbf{x}_k^*$ over $\mathcal{B}_r(\hat{\mathbf{x}})$ exists:

$$\mathbf{x}_k^* = \arg\min\{F_k(\mathbf{x}) : \mathbf{x} \in \mathcal{B}_r(\hat{\mathbf{x}})\}.$$

Since $\mathcal{B}_r(\hat{\mathbf{x}})$ is a convex set, the first-order optimality condition

$$\langle F_k'[\mathbf{x}_k^*], \mathbf{x} - \mathbf{x}_k^*\rangle \geq 0$$

holds for all $\mathbf{x} \in \mathcal{B}_r(\hat{\mathbf{x}})$. It follows that

$$\langle F_k'[\mathbf{x}], \mathbf{x} - \mathbf{x}_k^* \rangle \geq \langle F_k'[\mathbf{x}] - F_k'[\mathbf{x}_k^*], \mathbf{x} - \mathbf{x}_k^* \rangle.$$

We utilize the strong convexity property (4.49) to obtain

$$\langle F_k'[\mathbf{x}], \mathbf{x} - \mathbf{x}_k^* \rangle \geq (1-\delta)\mu_k \|\mathbf{x} - \mathbf{x}_k^*\|^2,$$

which gives

$$\|\mathbf{x} - \mathbf{x}_k^*\| \leq \frac{1}{(1-\delta)\mu_k} \|F_k'[\mathbf{x}]\|. \tag{4.50}$$

The convexity of F_k on $\mathcal{B}_r(\hat{\mathbf{x}})$ implies that

$$F_k(\mathbf{x}^*) \geq F_k(\mathbf{x}) + F_k'[\mathbf{x}](\mathbf{x}_k^* - \mathbf{x}).$$

Combining this with (4.50) completes the proof. ∎

Theorem 4.4 holds with the following modifications: (i) The assumption (B0) that $\mathcal{B}_\rho(\hat{\mathbf{x}}) \cap \mathbf{X}$ is convex is dropped; and (ii) $\mu_k \in [\beta_0, \beta_1]$, where β_1 is chosen small enough that the constant $\gamma = \beta_2 \Lambda/\alpha$ is less than 1. For completeness, we state the modified result.

THEOREM 4.6. *Assume that the following conditions are satisfied:*

(b0) *f provides a local error bound at $\hat{\mathbf{x}} \in \mathbf{X}$ with positive scalars α and ρ satisfying* (1.3).

(b1) *f is twice Lipschitz continuously Fréchet differentiable in $\mathcal{B}_\rho(\hat{\mathbf{x}})$.*

(b2) *The proximal iterates $\mathbf{x}_k$ satisfy either* (C1) *or* (C2) *with $\mu_k \in [\beta_0, \beta_1]$, where $\beta_0 > 0$. If* (C2) *is used, then $\theta < 1/\sqrt{2}$. $\delta \in (0,1)$ is chosen small enough that $\theta^2 < (1-\delta)/2$.*

(b3) *Define the parameters*

$$\Lambda = L_1 + \tau \quad \text{and} \quad \tau^2 = 1 + 2L_1^2/(1-\delta) \quad \text{if acceptance criterion (C1) is used,}$$

while

$$\Lambda = \tau(1+\theta) \quad \text{and} \quad \tau^2 = \frac{1}{1 - 2\theta^2/(1-\delta)} \quad \text{if acceptance criterion (C2) is used,}$$

where L_1 is a Lipschitz constant for f' over $\mathcal{B}_\rho(\hat{\mathbf{x}})$. β_1 is small enough that

$$\gamma := \frac{\beta_1 \Lambda}{\alpha} < 1.$$

Then for ϵ sufficiently small and for each $\mathbf{x}_0 \in \mathcal{B}_\epsilon(\hat{\mathbf{x}})$, the proximal iterates $\mathbf{x}_k$ are all contained in $\mathcal{B}_\rho(\hat{\mathbf{x}})$, and they approach a minimizer $\mathbf{x}^* \in \mathbf{X}$; moreover, for each k, we have

$$\|\mathbf{x}_k - \mathbf{x}^*\| \leq c_1 \gamma^k D(\mathbf{x}_0, \mathbf{X}),$$

where c_1 is a constant independent of k.

The proof of Theorem 4.6 is the same as the proof of Theorem 4.4, except that we use Lemma 4.5 instead of Lemma 4.3 and we replace expressions like $\|\mathbf{x} - \bar{\mathbf{x}}\|$ by $D(\mathbf{x}, \mathbf{X})$.

5. Final discussion. The local convergence results obtained in [7] for a new class of self-adaptive proximal point methods have been extended from a finite dimensional setting to a Hilbert space setting. In particular the local convergence estimates obtained for exact iterates in [7] are now established for approximate iterates satisfying (C0). Our analysis, which permits multiple minimizers, employs a local error bound condition (1.3) relating the growth in f to the distance from the set of minimizers. The gradient-based acceptance criteria in [7] have been replaced by subdifferential-based criteria (C1) and (C2). The local convergence results for the subdifferential-based stopping criteria are similar to the convergence results for iterates satisfying (C0). Three types of assumptions were considered in our analysis connected with (C1) and (C2): (a) f is convex and lower semicontinuous on a level set; (b) the set $\mathbf{X} \cap \mathcal{B}_\rho(\hat{\mathbf{x}})$ is convex for some $\rho > 0$, and f is twice continuously differentiable on $\mathcal{B}_\rho(\hat{\mathbf{x}})$; and (c) $\mu_k \in [\beta_0, \beta_1]$, with β_1 sufficiently small, $\beta_0 > 0$, and f twice continuously differentiable on $\mathcal{B}_\rho(\hat{\mathbf{x}})$. The conditions (b) and (c) are weaker than the local convexity requirement for f in [7].

The analysis in this paper has focused on local convergence. Global convergence issues are studied in section 6 of [7], where we also present computational results which show that for a class of ill-conditioned nonlinear optimization problem, a proximal point approach could reduce the computing time.

OPTIMAL ENERGY CONTROL IN FINITE TIME BY VARYING THE LENGTH OF THE STRING*

MARTIN GUGAT†

Abstract. We consider a finite string where, at both end points, a homogeneous Dirichlet boundary condition holds. One boundary point is fixed, and the other is moving; hence the length of the string is changing in time. The string is controlled through the movement of this boundary point. We consider movements of the boundary that are Lipschitz continuous. Only movements for which at the given finite terminal time the string has the same length as at the beginning are admissible. Moreover, we impose an upper bound for the Lipschitz constant of the movement that is smaller than the speed of wave propagation. We consider the optimal control problem to find an admissible movement for which at the given terminal time the energy of the string is minimal. We give a sufficient condition for the existence and uniqueness of an optimal movement and construct an optimal control movement.

1. Introduction.

We consider a string of finite length that is governed by the wave equation with homogeneous Dirichlet boundary conditions. The left boundary point is fixed, and the other boundary point of the string is moving. This system has already been studied in [3].

The boundary control of the wave equation has been studied by many authors (see, e.g., [16], [13], [11], [12], [1], [20], [8], and the references therein). In most studies both boundary points of the string are fixed, and the string is controlled through prescribed function values at the fixed boundary points.

In contrast to this approach, in this paper we control the system through the movement of the boundary point, that is, through the length of the string as a function of time. For the case of dimensions greater than one, this corresponds to the control of the shape as a function of time. Thus our problem is a one-dimensional (1-d) case for optimal shape control of a hyperbolic partial differential equation. The monograph [5] gives an overview about problems where moving boundaries play an essential role. Controllability of the wave equation with point control where the point is moving in the system's fixed spatial domain is studied in [9]. Observability and stabilizability of this system are considered in [10]. A problem with moving control of the heat equation is studied in [4].

The well-posedness of the wave equation in a noncylindrical, time periodical domain in $R \times R^N$ has been studied in [17]. Distributed control of the wave equation in a domain with a moving boundary has been studied in [2] for dimensions unequal to two. For these dimensions, a contraction of the domain always leads to nondecreasing energy, and an expansion always leads to nonincreasing energy (see Theorem 2.1 in [2]).

†Lehrstuhl für angewandte Mathematik AM2, Martensstr. 3, 91058 Erlangen, Germany (gugat@am.uni-erlangen.de).

The situation in dimension two is completely different. For certain expansions, the energy is nonincreasing, but also, if the interval is contracting sufficiently fast, a decay of the energy can be achieved. In [18], [19] the stabilization of the wave equation through the movement of the boundary is studied in dimension two. A movement is constructed that assures exponential decay of the energy.

In this paper, we study the 1-d-case. In [6] the stability of the string with varying length has been studied, and it has been shown that the energy cannot become arbitrarily small unless it is zero from the start. This follows from inequality (5.10), where a lower bound for the energy at time t is given that depends on the initial state. A sufficient condition for exponential growth of the energy is given in [7]. Interestingly, this situation of exponential energy growth could have applications in photon creation from the vacuum; see [14].

We consider the following optimal boundary movement control problem: Let at time $t = 0$ the length L of the string and an initial state be given. Let a terminal time T and a positive real number D that is strictly less than the speed of wave propagation be given. We admit movements of the right boundary point of the string that are given by a Lipschitz continuous function with a Lipschitz constant that is less than or equal to the number D. Moreover, we assume that at the terminal time T the string has the same length as at the beginning. For the set of Lipschitz continuous functions on the time interval $[0, T]$, we use the notation

$$Lip = \{\phi \,|\, \phi : [0,T] \to (0,\infty) \text{ such that } \phi \text{ is Lipschitz continuous } \}.$$

We consider the boundary movements in the admissible set

$$\Phi = \{\phi \in Lip \text{ with Lipschitz constant } \leq D \text{ and } \phi(0) = L,\ \phi(T) = L\}\,. \tag{1.1}$$

Our problem is to find an admissible boundary movement for which the energy of the string at the terminal time T is miminal. We present an explicit formula for optimal movements that solve this optimal control problem.

This paper has the following structure: In section 2, we define the problem of energy minimizing boundary movement control for a vibrating string with homogeneous Dirichlet boundary conditions at both ends. We assume that at the terminal time the string has the same length as at the beginning. As a control constraint, we prescribe an upper bound for the Lipschitz constants of the admissible boundary movements.

Section 3 contains our main results. In Theorem 3.2, we present an optimal boundary movement that depends on the initial state in a robust way. The energy decay that can be achieved depends on the initial state. For certain initial states, it is not possible to achieve an energy decay by boundary movement control. Theorem 3.1 contains sufficient conditions for the existence and uniqueness of optimal controls.

The proof of the main result uses the solution of the initial-boundary-value problem for a given boundary movement that is given in section 4. The construction is based upon the method of characteristics. It is necessary to make sure that the Lipschitz constants of the admissible boundary movements are strictly less than the speed of wave propagation, because, otherwise, the solution of the corresponding initial boundary value problem is, in general, not well-defined. The reason is that the information travels on the characteristic curves, and, if the length of the string increases too fast, it may happen that there exist points that are not reached by characteristic curves of both families.

In section 5, we introduce a set of functions that depend in a bijective way on the boundary movements (see Lemma 5.1). These functions are the unknowns in our

transformed optimization problem. To obtain the transformed problem, we write our objective function, that is, the energy of the string at time T in terms of the new unknowns. The solution of the transformed problem is given in Lemma 5.6.

2. The problem. Let the wave speed $c > 0$ be given. At the initial time $t = 0$, the string has the length $L > 0$. Define the control time $T = 2L/c$. Let $p \in [1, \infty)$ be given. Now we define the set B of admissible initial states. In the definition of the set B and in what follows, we use generalized derivatives. Let

$$B = \{(y_0, y_1) : \ y_0' \in L^p(0, L), \ y_1 \in L^p(0, L), \ y_0(0) = y_0(L) = 0\}. \tag{2.1}$$

Let a real number $D \in (0, c)$ be given. Define the set Φ of admissible boundary motions as in (1.1). Let $(y_0, y_1) \in B$ be given. We consider the problem

$$P: \qquad \text{Find } \ \phi \in \Phi \text{ such that}$$

$$W(T) = \int_0^L \left| v_x(x,T) + \frac{1}{c} v_t(x,T) \right|^p + \left| v_x(x,T) - \frac{1}{c} v_t(x,T) \right|^p \, dx$$

is minimized, where $v(x,t)$ is the solution of the initial boundary value problem

$$v(x,0) = y_0(x), \ v_t(x,0) = y_1(x), \ x \in (0, L), \tag{2.2}$$

$$v(0,t) = 0, \ v(\phi(t), t) = 0, \ t \in (0, T), \tag{2.3}$$

$$v_{tt}(x,t) = c^2 v_{xx}(x,t), \ (x,t) \in \Omega = \{(x,t) : \ t \in (0,T), \ x \in (0, \ \phi(t))\}. \tag{2.4}$$

For $p = 2$, we have

$$W(T) = 2 \int_0^L \left(v_x(x,T)^2 + \frac{1}{c^2} v_t(x,T)^2 \right) dx;$$

hence, $W(T)$ is equivalent to the classical energy. In the general case, we further refer to $W(T)$ as a generalized energy function. For any $t \in (0,T)$, the definition of $W(t)$ is given in (5.8), where the integration interval is $(0, \phi(t))$. If both boundary points are fixed (that is, $\phi(t) \equiv L$), the generalized energy defined in (5.8) is conserved; see Remark 5.1.

3. Main result: Energy minimizing movement.

THEOREM 3.1 (existence and uniqueness of the solution of problem P). *There exists a movement $\phi \in \Phi$ that solves problem P.*

Let $p \in (1, \infty)$ and $(y_0, y_1) \in B$ be given. Define the L^p-function A as

$$A(x) = \begin{cases} y_0'(-x) & -(1/c) y_1(-x) \quad \text{if } x \in [-L, 0), \\ y_0'(x) & +(1/c) y_1(x) \quad \text{if } x \in [0, L]. \end{cases} \tag{3.1}$$

Define the set $M_z = \{x \in [-L, L] : A(x) = 0\}$. If the set M_z has measure zero, the solution of P is uniquely determined.

For a point z on the real axis define the projection on the interval $[\frac{c-D}{c+D}, \ \frac{c+D}{c-D}]$ in the usual way as

$$\Pi_{[\frac{c-D}{c+D}, \ \frac{c+D}{c-D}]}(z) = \max\{(c-D)/(c+D), \min\{(c+D)/(c-D), \ z\}\}.$$

Define $W(0)$ as follows:

$$W(0) = \int_0^L \left| y_0'(x) + \frac{1}{c} y_1(x) \right|^p + \left| y_0'(x) - \frac{1}{c} y_1(x) \right|^p \, dx.$$

THEOREM 3.2 (solution of problem P). *For $p = 1$, for all $\phi \in \Phi$ we have $W(T) = W(0)$.*

Let $p \in (1, \infty)$ and an initial state $(y_0, y_1) \in B$ be given. Define the L^p-function A as in (3.1). *If $\int_{-L}^{L} |A(y)| \, dy > 0$, there exists a real number $\lambda > 0$ such that the moment equation*

$$\int_{-L}^{L} \Pi_{[\frac{c-D}{c+D}, \, \frac{c+D}{c-D}]}(\lambda \, |A(y)| \,) \, dy = 2L \tag{3.2}$$

holds. With this choice of λ, define the function $h : [-L, L] \to [L, 3L]$ by

$$h(x) = L + \int_{-L}^{x} \Pi_{[\frac{c-D}{c+D}, \, \frac{c+D}{c-D}]}(\lambda \, |A(y)| \,) \, dy$$

and the functions $H_1 : [-L, L] \to (0, \infty)$ and $H_2 : [-L, L] \to [0, 2L]$ by

$$H_1(x) = \frac{h(x) - x}{2}, \; H_2(x) = \frac{h(x) + x}{2}.$$

Then an optimal control movement that is a solution of problem P is given by the function $\phi \in \Phi$ defined by

$$\phi(t) = H_1(H_2^{-1}(ct)), \; t \in (0, T), \tag{3.3}$$

that yields the minimal value for

$$W(T) = \int_{-L}^{L} \frac{|A(s)|^p}{h'(s)^{p-1}} \, ds. \tag{3.4}$$

If $\int_{-L}^{L} |A(y)| \, dy = 0$, we have $W(T) = 0$ for all $\phi \in \Phi$.

The proofs of Theorems 3.1 and 3.2 will be given in section 5.4. They are based upon an explicit representation of the solution of the initial-boundary-value problem (2.2), (2.3), (2.4) for a given boundary motion. This representation of the solution is given in section 4.2. It is used to transform the optimal control problem to a convex optimization problem in a function space that we can solve. The transformed set of admissible functions is defined in section 5.1 by positive pointwise bounds for the function values and a moment equation that prescribes the integral of the admissible functions. For the solution of the transformed problem, the convexity of the transformed objective function on the transformed set of admissible functions is essential.

Remark 3.1. The (non)movement $\phi(t) = L$, $t \in [0, T]$ is admissible. For this movement, the energy is conserved for all p (see Remark 5.1). Therefore the optimal control movement does *not* lead to energy increase.

Remark 3.2. Assume that there exists a real constant $r > 0$ such that $|A(x)| = r$ for all $x \in [-L, L]$. Then for the minimal value of $W(T)$ we have $W(T) = W(0)$. This follows from Theorem 3.2, since to satisfy the moment equation (3.2), the number λ has to be chosen such that $\Pi_{[\frac{c-D}{c+D}, \, \frac{c+D}{c-D}]}(\lambda \, |A(y)| \,) = 1$. This yields $h(x) = x + 2L$,

$H_1(x) = L$, $\phi(t) = L$; hence, in this case it is optimal not to move the boundary point, and thus the energy is conserved.

Example 3.1. Assume that $c = 1$ and $D \in [1/2, 1)$. Then $(c + D)/(c - D) \geq 3$. Let $\gamma > 0$ be given. Assume that

$$\gamma\, y_0(x) = \begin{cases} \frac{1}{3}x, & x \in [0, L/2], \\ (L/6) - (4/3)(x - (L/2)), & x \in (L/2, (5L/6)], \\ -(5L/18) + (5/3)(x - (5L/6)), & x \in (5L/6), L], \end{cases}$$

$$\gamma\, y_1(x) = \begin{cases} 0, & x \in [0, L/2], \\ -5/3, & x \in (L/2, (5L/6)], \\ 4/3, & x \in (5L/6, L]. \end{cases}$$

Then we have

$$\gamma\, A(x) = \begin{cases} \frac{1}{3}, & x \in [-L, L/2], \\ -3, & x \in (L/2, (5L/6)], \\ 3, & x \in ((5L/6), L]. \end{cases}$$

Equation (3.2) holds with $\lambda = \gamma$. For the function h defined in Theorem 3.2 we have

$$h(t) = \begin{cases} \frac{4}{3}L + \frac{1}{3}t, & t \in [-L, L/2], \\ 3t, & t \in (L/2, L]. \end{cases}$$

This yields the optimal movement

$$\phi(t) = \frac{L}{2} + \frac{1}{2}|t - L|,\ t \in [0, 2L].$$

For the energy we have

$$W(0) = \frac{1}{\gamma^p}\,\frac{1}{2}\left(3^p + \frac{1}{3^{p-1}}\right)L,\ W(T) = \frac{1}{\gamma^p}\,2L.$$

This yields the ratio

$$\frac{W(T)}{W(0)} = \frac{4}{3^p + \frac{1}{3^{p-1}}};$$

thus, for $p = 2$ we have $W(T)/W(0) = 3/7$. Hence the optimal movement absorbs more than half of the initial energy. Since the set M_z has measure zero, Theorem 3.1 implies that the solution ϕ of P is uniquely determined.

Example 3.2. Let $y_0(x) = |x - (L/2)| - (L/2)$, $y_1(x) = 0$, $x \in [0, L]$. We have $|A| = 1$ almost everywhere; thus, the set M_z has measure zero. Theorem 3.1 implies the existence of a solution of P. Since M_z has measure zero, Theorem 3.1 implies that the solution of P is unique. Theorem 3.2 implies that the unique optimal movement is the nonmovement $\phi(t) = L$, $t \in [0, 2L]$ that corresponds to the function $h(x) = 2L + x$. Remark 5.1 implies that $W(T)/W(0) = 1$, so by boundary movement an energy decrease cannot be achieved. Since the solution of P is unique, this implies that for every other admissible boundary movement an energy growth is produced at the terminal time.

Example 3.3. Assume that $2L < D < c$ and $(y_0, y_1) \in B$ are such that for some $\lambda > 0$ we have

$$\lambda |A(x)| = \frac{2c}{\sqrt{c^2(1-T)^2 + 4c(L+x)}} - 1.$$

Then M_z has measure zero; thus, Theorem 3.1 implies that P has a unique solution. For all $x \in [-L, L]$: $\lambda|A(x)| \in [(c-D)/(c+D),\ (c+D)/(c-D)]$, and (3.2) holds. We have $h(x) = -x + \sqrt{c^2(1-T)^2 + 4c(L+x)} - c(1-T)$, and the optimal movement is given by $\phi(x) = L + cx(T-x)$.

Example 3.4. Assume that $L(c+D) \le 2c$. Let $\gamma = 2c/(L(c-D))$. Then $\gamma \ge (c+D)/(c-D)$. Let $y_1(x) = 0$ and

$$y_0(x) = \begin{cases} \gamma x, & x \in [0, \frac{1}{2\gamma}], \\ 1 - \gamma x, & x \in (\frac{1}{2\gamma}, \frac{1}{\gamma}], \\ 0, & x > \frac{1}{\gamma}. \end{cases}$$

With $\lambda = 1$, (3.2) holds. Theorem 3.2 implies that an optimal movement is given by the function ϕ corresponding to

$$h'(t) = \begin{cases} \frac{c+D}{c-D}, & t \in [-\frac{1}{\gamma}, \frac{1}{\gamma}], \\ \frac{c-D}{c+D}, & t \notin [-\frac{1}{\gamma}, \frac{1}{\gamma}]. \end{cases}$$

For the energy, this yields

$$\frac{W(T)}{W(0)} = \left(\frac{c-D}{c+D}\right)^{p-1}.$$

For the corresponding optimal movement we have $\phi'(H_2(x)/c) = cH_1'(x)/H_2'(x)$, and thus $\phi'(H_2(x)/c) = D$, if $x \in [-1/\gamma, 1/\gamma]$ and $\phi'(H_2(x)/c) = -D$ otherwise. Hence

$$\phi'(t) = \begin{cases} D, & t \in [\frac{H_2(-1/\gamma)}{c},\ \frac{H_2(1/\gamma)}{c}] = [\frac{L}{2c},\ \frac{L}{c}\left(\frac{3}{2} + \frac{D}{c}\right)], \\ -D, & \text{otherwise.} \end{cases}$$

Example 3.5. Assume that $\varepsilon \in (0, 2D/(c+D))$ and $|A(x)| = 1 + \varepsilon \sin(x)$. Then M_z has measure zero; thus, P has a unique solution. Equation (3.2) holds with $\lambda = 1$, $H_1(x) = L + \varepsilon[\cos(L) - \cos(x)]/2$, $H_2(x) = H_1(x) + x$. For the graph of ϕ, by (3.3) we obtain the curve $G = \{(t, \phi(t)) : t \in [0, T]\} = \{(H_2(x)/c,\ H_1(x)), x \in [-L, L]\}$.

4. Transformation of the problem. For a given boundary movement ϕ from the set Φ defined in (1.1), we want to find a representation of the solution of the initial-boundary-value problem (2.2), (2.3), (2.4) with one moving boundary point in terms of traveling waves; that is, we want to derive d'Alembert's solution for our problem. In particular, we have to show that such a solution exists.

4.1. Wave propagation auxiliary functions. In this section we define some auxiliary functions that we need to derive d'Alembert's solution for our problem. Let $\phi \in \Phi$ be given. Since ϕ is Lipschitz, ϕ is absolutely continuous. For $t \in [0, T]$, define

$$\psi_1(t) = \phi(t) - ct,\ \psi_2(t) = \phi(t) + ct. \tag{4.1}$$

Then $\psi_1'(t) = \phi'(t) - c$. The definition of the set Φ implies the inequality

$$-D \le \phi'(t) \le D$$

and thus $\psi_1'(t) \leq D - c < 0$; hence, ψ_1 is strictly decreasing on $[0,T]$ and thus invertible. We have $\psi_1(0) = L$ and $\psi_1(T) = -L$; therefore, $\psi_1^{-1}(s)$ is defined for $s \in [-L, L]$.

We have $\psi_2'(t) = \phi'(t) + c \geq -D + c > 0$; hence, ψ_2 is strictly increasing on $[0,T]$ and thus invertible. We have $\psi_2(0) = L$ and $\psi_2(T) = 3L$; therefore, $\psi_2^{-1}(s)$ is defined for $s \in [L, 3L]$.

Since $\phi(t) \geq 0$, for all $t \in [0,T]$ we have

$$-\psi_1(t) = ct - \phi(t) < ct + \phi(t) = \psi_2(t). \tag{4.2}$$

For $x \in [-L, L]$ define

$$h(x) = \psi_2(\psi_1^{-1}(-x)). \tag{4.3}$$

Then h is strictly increasing and

$$h'(x) = -\frac{\psi_2'(\psi_1^{-1}(-x))}{\psi_1'(\psi_1^{-1}(-x))} > 0. \tag{4.4}$$

On account of (4.2) for all $x \in [-L, L]$ we have

$$x = -\psi_1(\psi_1^{-1}(-x)) < \psi_2(\psi_1^{-1}(-x)) = h(x).$$

For the inverse of h we have

$$h^{-1}(x) = -\psi_1(\psi_2^{-1}(x)). \tag{4.5}$$

We have

$$h^{-1}(L) = -L,\ h^{-1}(3L) = L. \tag{4.6}$$

Note that

$$L = \psi_2(0) < h(0) = \psi_2(\psi_1^{-1}(0)), \tag{4.7}$$

since

$$0 < \psi_1^{-1}(0),$$

which is true on account of

$$L = \psi_1(0) > 0.$$

Let $t_1 = \psi_1^{-1}(0)$. Then $\phi(t_1) - ct_1 = 0$, and thus $\phi(t_1) = ct_1$. Therefore

$$\psi_2(t_1) = \phi(t_1) + ct_1 = 2ct_1.$$

Hence

$$h(0) = \psi_2(\psi_1^{-1}(0)) = \psi_2(t_1) = 2ct_1 = 2c\psi_1^{-1}(0).$$

In fact, t_1 is the time that a characteristic curve starting at time zero at the left end point of the string needs to reach the moving end of the string.

Later in Lemma 5.1 we will show that there is a bijection between the maps h as defined in (4.3) and the corresponding maps ϕ, which allows one to transform our optimal control problem to an optimization problem in terms of the function h.

4.2. Solution of the initial-boundary-value problem. In this section, we give a representation of the solution of the initial-boundary-value problem for a given fixed boundary movement $\phi \in \Phi$.

THEOREM 4.1. *Let $\phi \in \Phi$ and $(y_0, y_1) \in B$ be given. With h^{-1} as in* (4.5)*, define the functions*

$$\alpha(x) = \begin{cases} -y_0(-x) + (1/c) \int_0^{-x} y_1(s)\,ds, & x \in (-L, 0), \\ y_0(x) + (1/c) \int_0^{x} y_1(s)\,ds, & x \in [0, L), \\ -y_0(-h^{-1}(x)) + (1/c) \int_0^{-h^{-1}(x)} y_1(s)\,ds, & x \in [L, h(0)), \\ y_0(h^{-1}(x)) + (1/c) \int_0^{h^{-1}(x)} y_1(s)\,ds, & x \in [h(0), 3L) \end{cases} \tag{4.8}$$

and

$$v(x,t) = [\alpha(x+ct) - \alpha(-x+ct)]/2, \quad (x,t) \in \Omega. \tag{4.9}$$

We have $\alpha' \in L^p(-L, 3L)$. The function v is continuous on Ω and v_t, $v_x \in L^1(\Omega)$.

Define the family of test functions $\mathcal{T}$ as

$\mathcal{T} = \{\varphi \in C^2(\Omega)$: There exists a set $Q = [x_1, x_2] \times [t_1, t_2] \subset \Omega$ such that the support of φ is contained in the interior of $Q\}$.

The function v satisfies the wave equation (2.4) *in the following weak sense:*

$$\int_\Omega v_t(x,t)\varphi_t(x,t)\,d(x,t) = c^2 \int_\Omega v_x(x,t)\varphi_x(x,t)\,d(x,t) \text{ for all } \varphi \in \mathcal{T}. \tag{4.10}$$

The function v satisfies (2.2) *and* (2.3)*. In this sense, v is the solution of the initial-boundary-value problem* (2.2)*,* (2.3)*,* (2.4)*.*

Proof. Since $y_0' \in L^p(0, L)$, the Sobolev imbedding theorem implies that y_0 is continuous. Moreover, y_1 is in $L^p(0, L)$, and thus α is well-defined. Now we discuss the regularity of α. On the intervals $(-L, 0)$, $[0, L)$, $[L, h(0))$, and $[h(0), 3L)$ the function α is continuous. Due to the definition of the set B we have

$$\lim_{x\to 0-} \alpha(x) = -y_0(0) = 0 = y_0(0) = \lim_{x\to 0+} \alpha(x),$$

$$\lim_{x\to L-} \alpha(x) = y_0(L) + \frac{1}{c}\int_0^L y_1(s)\,ds = -y_0(L) + \frac{1}{c}\int_0^L y_1(s)\,ds = \lim_{x\to L+} \alpha(x),$$

$$\lim_{x\to h(0)-} \alpha(x) = -y_0(0) = y_0(0) = \lim_{x\to h(0)+} \alpha(x),$$

and hence α is continuous on the interval $(-L, 3L)$. The derivative α' in the sense of distributions exists on the intervals $(-L, 0)$, $(0, L)$, $(L, h(0))$, and $(h(0), 3L)$ as a L^p-function. Since α is continuous, this implies that α is absolutely continuous on $(-L, 3L)$. Hence $\alpha' \in L^1(-L, 3L)$, and the L^p regularity on the subintervals $(-L, 0)$, $(0, L)$, $(L, h(0))$, and $(h(0), 3L)$ implies that $\alpha' \in L^p(-L, 3L)$. The continuity of v follows from the continuity of α. For $t = 0$ and $x \in (0, L)$ we have

$$v(x, 0) = [\alpha(x) - \alpha(-x)]/2 = y_0(x).$$

For $(x, t) \in \Omega$ almost everywhere, we have

$$v_t(x,t) = c[\alpha'(x+ct) - \alpha'(-x+ct)]/2. \tag{4.11}$$

Thus the definition of α implies the equation $v_t(x,0) = y_1(x)$. Hence the initial conditions (2.2) are valid.

For $(x,t) \in \Omega$ almost everywhere, we have

$$v_x(x,t) = [\alpha'(x+ct) + \alpha'(-x+ct)]/2. \tag{4.12}$$

By Tonelli's theorem (see, e.g., [15]), (4.12) implies $v_x \in L^1(\Omega)$, and (4.11) implies $v_t \in L^1(\Omega)$.

For all $\varphi \in \mathcal{T}$, integration by parts, (4.12) and (4.11) yield

$$\begin{aligned}
\int_\Omega v_x(x,t)\varphi_x(x,t)\,d(x,t) &= \int_{x_1}^{x_2}\int_{t_1}^{t_2} \varphi_x(x,t)[\alpha'(x+ct) + \alpha'(-x+ct)]/2\,dt\,dx \\
&= -\int_{x_1}^{x_2}\int_{t_1}^{t_2} \varphi_{xt}(x,t)[\alpha(x+ct) + \alpha(-x+ct)]/(2\,c)\,dt\,dx \\
&= -\int_{t_1}^{t_2}\int_{x_1}^{x_2} \varphi_{tx}(x,t)[\alpha(x+ct) + \alpha(-x+ct)]/(2\,c)\,dx\,dt \\
&= \int_{t_1}^{t_2}\int_{x_1}^{x_2} \varphi_t(x,t)[\alpha'(x+ct) - \alpha'(-x+ct)]/(2\,c)\,dx\,dt \\
&= \int_\Omega \varphi_t(x,t)\,v_t(x,t)/c^2\,d(x,t),
\end{aligned}$$

and hence (4.10) holds.

For $x = 0$ we have $v(0,t) = [\alpha(ct) - \alpha(ct)]/2 = 0$; hence, at $x = 0$ the boundary condition $v(0,t) = 0$ holds for all $t \in (0,T)$.

We have $v(\phi(t),t) = [\alpha(\phi(t)+ct) - \alpha(-\phi(t)+ct)]/2 = [\alpha(\psi_2(t)) - \alpha(-\psi_1(t))]/2$. The definition of the set Φ implies that, on the interval $[0,T]$, h is strictly increasing and invertible (see section 4.1). By (4.6), for all $s \in [L,3L] = [\psi_2(0), \psi_2(T)]$ we have $h^{-1}(s) \in [-L,L]$. Hence the definition of α implies the equation

$$\alpha(h^{-1}(s)) = \begin{cases} -y_0(-h^{-1}(s)) + (1/c)\int_0^{-h^{-1}(s)} y_1(t)\,dt, & h^{-1}(s) \in (-L,0), \\ y_0(h^{-1}(s)) + (1/c)\int_0^{h^{-1}(s)} y_1(t)\,dt, & h^{-1}(s) \in [0,L). \end{cases} \tag{4.13}$$

On the other hand, for $s \in (L, h(0))$ the definition of α implies that $\alpha(s) = -y_0(-h^{-1}(s)) + (1/c)\int_0^{-h^{-1}(s)} y_1(t)\,dt$, and we have $h^{-1}(s) \in (h^{-1}(L),\, 0) = (-L, 0)$. Thus (4.13) implies that $\alpha(h^{-1}(s)) = \alpha(s)$ for $s \in (L, h(0))$.

For $s \in (h(0), 3L)$, the definition of α yields $\alpha(s) = y_0(h^{-1}(s)) + \frac{1}{c}\int_0^{h^{-1}(s)} y_1(t)\,dt$, and we have $h^{-1}(s) \in (0,\, h^{-1}(3L)) = (0,\, L)$. Thus also in this case (4.13) implies that $\alpha(h^{-1}(s)) = \alpha(s)$.

Hence for all $s \in (L, 3L)$ the following equation holds:

$$\alpha(h^{-1}(s)) = \alpha(s). \tag{4.14}$$

Thus for all $t \in (0,T)$ we have

$$\alpha(\psi_2(t)) = \alpha(h^{-1}(\psi_2(t)) = \alpha(-\psi_1(\psi_2^{-1}(\psi_2(t)))) = \alpha(-\psi_1(t)).$$

Therefore, the boundary condition $v(\phi(t),t) = 0$ holds for all $t \in (0,T)$. ∎

The following lemma contains regularity conditions for the initial state and the boundary movement ϕ that guarantee the existence of a solution of the initial-boundary-value problem (2.2), (2.3), (2.4) that satisfies the wave equation pointwise almost everywhere.

LEMMA 4.2. *If $y_0 \in C^2[0,L]$, $y_1 \in C^1[0,L]$, $y_0(0) = 0$, $y_0(L) = y_0'(L) = 0$, $y_1(0) = 0 = y_1(L)$, and $\phi \in \Phi \cap C^2[0,T]$, then α defined by* (4.8) *is in $C^1(-L,3L)$, α' is absolutely continuous, $\alpha'' \in L^\infty(-L,3L)$, and v defined by* (4.9) *satisfies the wave equation* (2.4) *in the following weak sense:*

$$\int_\Omega v_{tt}(x,t)\varphi(x,t)\,d(x,t) = c^2 \int_\Omega v_{xx}(x,t)\varphi(x,t)\,d(x,t) \text{ for all } \varphi \in \mathcal{T}. \tag{4.15}$$

Moreover, v satisfies (2.4) *pointwise almost everywhere in Ω.*

Proof. Since $\phi \in C^2[0,T]$, definition (4.1) implies that ψ_1 and ψ_2 are in $C^2[0,T]$. Moreover, ψ_1^{-1} and ψ_2^{-1} are in $C^2[0,T]$. Hence the definition (4.3) of h implies that h is in $C^2[-L,L]$, and (4.5) implies that h^{-1} is also two times continuously differentiable.

In the proof of Theorem 4.1, we have seen that α is absolutely continuous. Since $y_0 \in C^2[0,L]$ and $y_1 \in C^1[0,L]$, the definition (4.8) of α implies that on the intervals $(-L,0)$, $(0,L)$, $(L,h(0))$, and $(h(0),3L)$ the function α is two times continuously differentiable. Due to the conditions $y_0(0) = 0$, $y_0(L) = y_0'(L) = 0$, $y_1(0) = 0 = y_1(L)$ in the end point of these intervals, we have the one-sided derivatives

$$\begin{aligned}
\alpha_-'(0) &= y_0'(0) - (1/c)y_1(0) = y_0'(0) = y_0'(0) + (1/c)y_1(0) = \alpha_+'(0),\\
\alpha_-'(L) &= y_0'(L) + (1/c)y_1(L) = 0 = y_0'(L)\ (h^{-1})'(L) - (1/c)y_1(L)\ (h^{-1})'(L)\\
&= y_0'(-h^{-1}(L))\ (h^{-1})'(L) - (1/c)y_1(-h^{-1}(L))\ (h^{-1})'(L)\\
&= \alpha_+'(L),\\
\alpha_-'(h(0)) &= y_0'(0)\ (h^{-1})'(h(0)) - (1/c)y_1(0)\ (h^{-1})'(h(0)) = y_0'(0)\ (h^{-1})'(h(0))\\
&= y_0'(0)\ (h^{-1})'(h(0)) + (1/c)y_1(0)\ (h^{-1})'(h(0)) = \alpha_+'(h(0)).
\end{aligned}$$

Since the one-sided derivatives are equal, α' is continuous, and hence $\alpha \in C^1(-L,3L)$. Since α'' exists on the intervals $(-L,0)$, $(0,L)$, $(L,h(0))$, and $(h(0),3L)$ as a bounded continuous function, this implies that α' is absolutely continuous on $(-L,3L)$ and $\alpha'' \in L^\infty(-L,3L)$. For (x,t) in Ω almost everywhere we have

$$\begin{aligned}
v_{tt}(x,t) &= c^2[\alpha''(x+ct) - \alpha''(-x+ct)]/2,\\
v_{xx}(x,t) &= [\alpha''(x+ct) - \alpha''(-x+ct)]/2,
\end{aligned}$$

and hence (2.4) holds almost everywhere in Ω. For all $\varphi \in \mathcal{T}$, integration by parts yields

$$\int_\Omega \varphi_t(x,t)\,v_t(x,t)/c^2\,d(x,t) = -\int_\Omega \varphi(x,t)\,v_{tt}(x,t)/c^2\,d(x,t)$$

and

$$\int_\Omega \varphi_x(x,t)\,v_x(x,t)\,d(x,t) = -\int_\Omega \varphi(x,t)\,v_{xx}(x,t)\,d(x,t).$$

Hence (4.10) implies that (4.15) holds. ∎

Remark 4.1. For x in the interval $(0,L)$ we have

$$\alpha'(x)^2 + \alpha'(-x)^2 = \frac{[\alpha'(x) + \alpha'(-x)]^2}{2} + \frac{[\alpha'(x) - \alpha'(-x)]^2}{2} = 2\,y_0'(x)^2 + \frac{2}{c^2}y_1(x)^2.$$

5. Solution of the optimal shape control problem.

5.1. The transformed set of admissible controls. Definition (4.3) states how h can be obtained from a given movement ϕ. The following lemma shows that, if h is known, the corresponding movement ϕ is uniquely determined and can be computed.

LEMMA 5.1. *Let $\phi \in \Phi$ be given. Define the function h by* (4.3). *For $x \in [-L, L]$, define*

$$H_1(x) = \frac{h(x) - x}{2},\ H_2(x) = \frac{h(x) + x}{2}. \tag{5.1}$$

Then for all $t \in [0, T]$, we have

$$\phi(t) = H_1(H_2^{-1}(ct)). \tag{5.2}$$

Proof. In section 4.1, we have seen that h is strictly increasing, and hence H_2 is strictly increasing. Since $h(-L) = L$, we have $H_2(-L) = 0$. Since $h(L) = 3L$, $H_2(L) = 2L$. Thus the assertion (5.2) is equivalent to the statement that for all $x \in [-L, L]$ we have

$$\phi\left(\frac{H_2(x)}{c}\right) = H_1(x).$$

From (4.1), we have for all $t \in [0, T]$ the equation $\psi_1(t) + 2ct = \psi_2(t)$. For $t = \psi_1^{-1}(x)$ with $x \in [-L, L]$, this yields

$$x + 2c\psi_1^{-1}(x) = \psi_2(\psi_1^{-1}(x)),$$

and by (4.3) this implies

$$h(x) = \psi_2(\psi_1^{-1}(-x)) = 2c\psi_1^{-1}(-x) - x.$$

Therefore, the following equation holds: $H_2(x) = [h(x) + x]/2 = c\psi_1^{-1}(-x)$. This implies the equation

$$\psi_1\left(\frac{H_2(x)}{c}\right) = \psi_1(\psi_1^{-1}(-x)) = -x = \phi\left(\frac{H_2(x)}{c}\right) - H_2(x),$$

where we have again used the definition of ψ_1. Hence

$$\phi\left(\frac{H_2(x)}{c}\right) = H_2(x) - x = H_1(x),$$

where the last equation follows from definition (5.1). ∎

Define the set H of functions defined on the interval $[-L, L]$ as follows:

$$H = \{h : h(x) = \psi_2(\psi_1^{-1}(-x)),\ x \in [-L, L], \text{ with } \psi_1, \psi_2 \text{ as in (4.1) for some } \phi \in \Phi\ \}.$$

LEMMA 5.2. *Define the map $\theta : \Phi \to H$ by $\theta(\phi) = h$, where $h(x) = \psi_2(\psi_1^{-1}(-x))$, $x \in [-L, L]$ with ψ_1, ψ_2 as in* (4.1). *Then θ is bijective.*

Proof. First we show that θ is injective. Let ϕ_1, $\phi_2 \in \Phi$ be given such that $h_1 = \theta(\phi_1) = \theta(\phi_2) = h_2$. Lemma 5.1 implies that, with

$$H_1^i(x) = \frac{h_i(x) - x}{2},\ H_2^i(x) = \frac{h_i(x) + x}{2},\ i \in \{1, 2\},$$

we have

$$\phi_i(t) = H_1^i((H_2^i)^{-1}(ct)),\ i \in \{1, 2\}.$$

Since $h_1 = h_2$, we have $H_1^1 = H_1^2$ and $H_2^1 = H_2^2$, and thus $\phi_1(t) = \phi_2(t)$. Therefore θ is injective. The definition of the set H implies that $H = \theta(\Phi)$, and thus θ is surjective. □

Later we will need the following result in a proof.

LEMMA 5.3. *Let $I = [\frac{c-D}{c+D},\ \frac{c+D}{c-D}]$. The following equation holds:*

$$c \max_{z \in I} \left\{ \frac{z-1}{z+1},\ \frac{1-z}{1+z} \right\} = D. \tag{5.3}$$

Proof. For $z \in I$, let $\eta_1(z) = (z-1)/(z+1)$. Since $\eta_1'(z) > 0$, for all $z \in I$ we have $\eta_1(z) \le \eta_1(\frac{c+D}{c-D}) = D/c$.

For $z \in I$, let $\eta_2(z) = (1-z)/(1+z)$. Since $\eta_2'(z) < 0$, for all $z \in I$ we have $\eta_2(z) \le \eta_2(\frac{c-D}{c+D}) = D/c$. □

LEMMA 5.4. *Define the set*

(5.4)

$$M = \left\{ h | h : [-L, L] \to [L, 3L] \text{ such that } h(x) = L + \int_{-L}^{x} f(s)\, ds \text{ with } f \in F \right\},$$

where the set F is defined as

$$F = \left\{ f | f : [-L, L] \to \left[\frac{c-D}{c+D},\ \frac{c+D}{c-D} \right] \text{ such that } f \text{ is Lebesgue integrable and } \int_{-L}^{L} f(x)\, dx = 2L \right\}.$$

Then $M = H$.

Proof. First we show that $H \subset M$. Let $h \in H = \theta(\Phi)$, $h(x) = \psi_2(\psi_1^{-1}(-x))$, $x \in [-L, L]$. Since ψ_2 is Lipschitz continuous with Lipschitz constant $c + D$, for all $x_1,\ x_2 \in [-L, L]$ we have

$$|h(x_1) - h(x_2)| = |\psi_2(\psi_1^{-1}(-x_1)) - \psi_2(\psi_1^{-1}(-x_2))| \le (c+D)|\psi_1^{-1}(-x_1) - \psi_1^{-1}(-x_2)|.$$

For ψ_1 and $t_1,\ t_2 \in [0, T]$ we have the inequality

$$|\psi_1(t_1) - \psi_1(t_2)| = |\phi(t_1) - \phi(t_2) - c(t_1 - t_2)| \ge c|t_1 - t_2| - |\phi(t_1) - \phi(t_2)| \ge (c-D)|t_1 - t_2|.$$

With $t_1 = \psi_1^{-1}(-x_1)$, $t_2 = \psi_1^{-1}(-x_2)$, this yields

$$|\psi_1^{-1}(-x_1) - \psi_1^{-1}(-x_2)| \le \frac{1}{c-D}|x_1 - x_2|.$$

This implies the inequality

$$|h(x_1) - h(x_2)| \le \frac{c+D}{c-D}\,|x_1 - x_2|,$$

and thus h is Lipschitz continuous with Lipschitz constant $\frac{c+D}{c-D}$. Since h is Lipschitz, h is absolutely continuous, and, for the derivative, we have the inequality $|h'(x)| \le (c+D)/(c-D)$ almost everywhere.

For all t_1, $t_2 \in [0,T]$, we have

$$|\psi_2(t_1) - \psi_2(t_2)| \geq (c-D)|t_1 - t_2|,\ |\psi_1(t_1) - \psi_1(t_2)| \leq (c+D)|t_1 - t_2|.$$

With $t_1 = \psi_1^{-1}(-x_1)$, $t_2 = \psi_1^{-1}(-x_2)$, this yields

$$|x_1 - x_2| \leq (c+D)|\psi_1^{-1}(-x_1) - \psi_1^{-1}(-x_2)|.$$

Hence

$$|h(x_1) - h(x_2)| \geq (c-D)|\psi_1^{-1}(-x_1) - \psi_1^{-1}(-x_2)| \geq \frac{c-D}{c+D}|x_1 - x_2|.$$

This implies that $|h'(x)| \geq (c-D)/(c+D)$ almost everywhere. In section 4.1, we have shown that h is strictly increasing. Hence we have the inequality

$$\frac{c-D}{c+D} \leq h'(x) \leq \frac{c+D}{c-D}. \tag{5.5}$$

We can write

$$h(x) = h(-L) + \int_{-L}^{x} h'(s)\,ds = L + \int_{-L}^{x} h'(s)\,ds.$$

Since $h(L) = L + \int_{-L}^{L} h'(s)\,ds = 3L$, we have $\int_{-L}^{L} h'(s)\,ds = 2L$. So we have shown $h' \in F$, which implies $h \in M$, and thus $H \subset M$.

Now we show that $M \subset H$. Let $m \in M$ be given, $m(x) = L + \int_{-L}^{x} f(s)\,ds$, with $f \in F$ and $x \in [-L,L]$. Then m is strictly increasing. For $x \in [-L,L]$, define $H_1(x) = [m(x) - x]/2$, $H_2(x) = [m(x) + x]/2$. Then H_2 is strictly increasing, and $\{H_2(x) :\ x \in [-L,L)\} = [H_2(-L),\ H_2(L)] = [\frac{m(-L)-L}{2},\ \frac{m(L)+L}{2}] = [0,2L]$. For $t \in [0,T]$, we have $ct \in [0,2L] = H_2[-L,L]$. Hence $H_2^{-1}(ct)$ is well-defined and in $[-L,L]$. So we can define

$$\phi(t) = H_1(H_2^{-1}(ct)). \tag{5.6}$$

Since $H_2(-L) = 0$ and $H_2(L) = 2L$ we have

$$\phi(0) = H_1(H_2^{-1}(0)) = H_1(-L) = L,$$
$$\phi(T) = H_1(H_2^{-1}(2L)) = H_1(L) = L.$$

Our assumptions imply that H_1 is Lipschitz continuous with Lipschitz constant $c/(c-D)$ and H_2^{-1} is Lipschitz continuous with Lipschitz constant $(c+D)/c$. Hence ϕ is Lipschitz continuous and thus absolutely continuous. Since $\phi(H_2(x)/c) = H_1(x)$, the chain rule implies that for the derivative we have the equation $\phi'(H_2(x)/c) = cH_1'(x)/H_2'(x)$, which implies the inequality

$$\left|\phi'\left(\frac{H_2(x)}{c}\right)\right| = c\,\frac{|H_1'(x)|}{H_2'(x)} = c\frac{|f(x)-1|}{f(x)+1} \leq c\max\left\{\frac{f(x)-1}{f(x)+1},\ \frac{1-f(x)}{1+f(x)}\right\} \leq D,$$

where the last inequality follows from Lemma 5.3 since $f \in F$. Hence $\phi \in \Phi$. Therefore we can compute $\theta(\phi)$.

For $x \in [-L,L]$, we have $H_2(x)/c \in [0,2L/c] = [0,T]$, and the definition of ϕ implies the equation $\phi(H_2(x)/c) = H_1(x) = [m(x) - x]/2$, and hence

$$\psi_2\left(\frac{H_2(x)}{c}\right) = \phi\left(\frac{H_2(x)}{c}\right) + H_2(x) = \frac{m(x)-x}{2} + \frac{m(x)+x}{2} = m(x).$$

Moreover, we have

$$-\psi_1\left(\frac{H_2(x)}{c}\right) = H_2(x) - \phi\left(\frac{H_2(x)}{c}\right) = H_2(x) - H_1(x) = \frac{m(x)+x}{2} - \frac{m(x)-x}{2} = x.$$

This implies the equation $\psi_1^{-1}(-x) = H_2(x)/c$. Hence $\theta(\phi)(x) = \psi_2(\psi_1^{-1}(-x)) = \psi_2(H_2(x)/c) = m(x)$. So we have shown that $\theta(\phi) = m$. Hence $m \in \theta(\Phi) = H$. Since $m \in M$ was arbitrary, this yields $M \subset H$. Since we have already shown the inclusion $H \subset M$, this yields the equation $H = M$. Moreover, this implies the equation

$$\phi = \theta^{-1}(m). \qquad \square \tag{5.7}$$

We see that the mapping θ defined in Lemma 5.2 is a bijection between the admissible motions $\phi \in \Phi$ and the functions $h \in M$. Moreover, for all $m \in M$, (5.7) implies that $\phi = \theta^{-1}(m)$ is given by (5.6).

5.2. The objective function: Computation of the energy. Let $t \in [0,T]$ be given. Define the integrals

$$I_1(t) = \int_0^{\phi(t)} \left| v_x(x,t) + \frac{1}{c} v_t(x,t) \right|^p \, dx, \; I_2(t) = \int_0^{\phi(t)} \left| v_x(x,t) - \frac{1}{c} v_t(x,t) \right|^p \, dx$$

and the generalized energy by

$$W(t) = I_1(t) + I_2(t). \tag{5.8}$$

Equation (4.9) implies that

$$I_1(t) = \int_{ct}^{\psi_2(t)} |\alpha'(x)|^p \, dx, \; I_2(t) = \int_{-\psi_1(t)}^{ct} |\alpha'(x)|^p \, dx.$$

Thus for all $t \in [0,T]$, we have

$$W(t) = \int_{-\psi_1(t)}^{ct} |\alpha'(x)|^p \, dx + \int_{ct}^{\psi_2(t)} |\alpha'(x)|^p \, dx = \int_{-\psi_1(t)}^{\psi_2(t)} |\alpha'(x)|^p \, dx.$$

For our terminal time T this implies that

$$W(T) = \int_L^{3L} |\alpha'(x)|^p \, dx = \int_{h^{-1}(L)}^{h^{-1}(3L)} |\alpha'(h(s))|^p \, h'(s) \, ds = \int_{-L}^{L} |\alpha'(h(s))|^p \, h'(s) \, ds.$$

By (4.14), for all $u \in [L,3L]$ we have $h^{-1}(u) \in [-L,L]$ and $\alpha(h^{-1}(u)) = \alpha(u)$. Thus for all $s \in [-L,L]$ we have $\alpha(s) = \alpha(h(s))$ and thus

$$\alpha'(s) = \alpha'(h(s)) \, h'(s).$$

This yields the equation

$$W(T) = \int_{-L}^{L} \frac{|\alpha'(x)|^p}{h'(x)^{p-1}} \, dx. \tag{5.9}$$

We see that W as a function of t on the interval $[0,T]$ is absolutely continuous and the derivative is given by the L^1 function

$$\begin{aligned} W'(t) &= |\alpha'(\psi_2(t))|^p\,\psi_2'(t) + |\alpha'(-\psi_1(t))|^p\,\psi_1'(t) \\ &= |\alpha'(\psi_2(t))|^p\,\psi_2'(t) + |\alpha'(h(-\psi_1(t)))|^p\,[h'(-\psi_1(t))]^p\,\psi_1'(t) \\ &= |\alpha'(\psi_2(t))|^p\,\psi_2'(t) + |\alpha'(\psi_2(t))|^p\left[-\frac{\psi_2'(t)}{\psi_1'(t)}\right]^p\psi_1'(t) \\ &= |\alpha'(\psi_2(t))|^p\,\psi_2'(t)\frac{|\psi_1'(t)|^{p-1} - |\psi_2'(t)|^{p-1}}{|\psi_1'(t)|^{p-1}}. \end{aligned}$$

Here we have used (4.4) to evaluate $h'(-\psi_1(t))$. Since $|\phi'(t)| < c$, this implies that the sign of $W'(t)$ is equal to the sign of

$$|\psi_1'(t)|^{p-1} - |\psi_2'(t)|^{p-1} = (c - \phi'(t))^{p-1} - (c + \phi'(t))^{p-1}.$$

If, for almost all $t \in (0,t_1)$, $\phi'(t) > 0$, this implies that $W'(t) < 0$ on $(0,t_1)$, and thus $W(0) > W(t_1)$. This means that an expansion causes a decrease in energy.

On the other hand, if, for almost all $t \in (0,t_1)$, $\phi'(t) < 0$, we have $W'(t) > 0$ on $(0,t_1)$, and therefore $W(0) < W(t_1)$. Thus a contraction causes an increase in energy.

This means that the results given in Theorem 2.1 in [2] for the case $p = 2$ and dimension unequal to two are also valid for $p \neq 2$, $p \in (1,\infty)$ in the 1-d case.

Remark 5.1 (conservation of the energy for $\phi(t) \equiv L$). Let $\phi(t) \equiv L$. Then for all $t \in (0,T)$, $\phi'(t) = 0$; hence, $W'(t) = 0$ and therefore $W(t) = W(0)$; that is, in the case of two fixed boundary points the generalized energy $W(t)$ is conserved.

Remark 5.2 (conservation of the energy for $p = 1$). For $p = 1$ we have for all $\phi \in \Phi$ and for $t \in (0,T)$

$$W'(t) = |\alpha'(\psi_2(t))|\,\psi_2'(t)\frac{|\psi_1'(t)|^{1-1} - |\psi_2'(t)|^{1-1}}{|\psi_1'(t)|^{1-1}} = 0,$$

and thus the integral

$$W(t) = \int_{-L}^{L} |\alpha'(x)|\,dx = W(T)$$

is conserved for the limit case $p = 1$ regardless of ϕ. In other words, for $p = 1$ the control problem P is meaningless.

Remark 5.3 (sharp lower bounds for the energy). Let q be such that $\frac{1}{p} + \frac{1}{q} = 1$. Hölder's inequality implies that

$$\begin{aligned} \int_{-L}^{L} |\alpha'(x)|\,dx = \int_{-\psi_1(t)}^{\psi_2(t)} |\alpha'(x)|\,dx &\le \left(\int_{-\psi_1(t)}^{\psi_2(t)} |\alpha'(x)|^p\,dx\right)^{1/p}\left(\int_{-\psi_1(t)}^{\psi_2(t)} 1^q\,dx\right)^{1/q} \\ &= (2\,\phi(t))^{1-1/p} W(t)^{1/p}. \end{aligned}$$

Thus for all $t > 0$ we have the following lower bound for the energy:

$$W(t) \ge \frac{1}{(2\,\phi(t))^{p-1}}\left(\int_{-L}^{L} |\alpha'(x)|\,dx\right)^p. \tag{5.10}$$

Assume now that $\alpha(x)$ is such that there exists a real number r such that for all $x \in [-\psi_1(t), \psi_2(t)]$ we have $|\alpha'(x)| = r$. Such a situation occurs in Example 3.2 with $r = 1$. Then $\int_{-L}^{L} |\alpha'(x)|\,dx = \int_{-\psi_1(t)}^{\psi_2(t)} |\alpha'(x)|\,dx = 2\phi(t)\,r$ and

$$W(t) = 2\phi(t)\,r^p = \frac{1}{(2\,\phi(t))^{p-1}} \left(\int_{-L}^{L} |\alpha'(x)|\,dx \right)^p,$$

which shows that the lower bound (5.10) is sharp.

Equation (5.9) yields a lower bound for the energy $W(T)$ at the terminal time T. With (5.5), (5.9) implies the inequality

$$W(T) \geq \left(\frac{c-D}{c+D} \right)^{p-1} \int_{-L}^{L} |\alpha'(x)|^p = \left(\frac{c-D}{c+D} \right)^{p-1} W(0).$$

This lower bound is attained in Example 3.4.

5.3. The transformed optimization problem. Later in this section, we will need the following result in a proof.

LEMMA 5.5. *Assume that $p \in (1, \infty)$. Let $r \geq 0$ be given. For $z \in (0, [c+D]/[c-D]]$, define the function $\tau(z) = r/z^{p-1}$, and let $\kappa = \frac{1}{2}\,(p-1)p(c-D)^{p+1}/(c+D)^{p+1} > 0$. Then for all z_1, $z_2 \in (0, [c+D]/[c-D]]$, the following inequality holds:*

$$\tau(z_2) - \tau(z_1) \geq r(1-p)\frac{1}{z_1^p}(z_2 - z_1) + r\kappa(z_2 - z_1)^2.$$

Proof. We have $\tau'(z) = r(1-p)/z^p$ and $\tau''(z) = r(p-1)p/z^{p+1}$. We consider the Taylor expansion for τ which yields the existence of a point μ between z_1 and z_2 such that

$$\begin{aligned} \tau(z_2) &= \tau(z_1) + \tau'(z_1)(z_2 - z_1) + \frac{\tau''(\mu)}{2}(z_2 - z_1)^2 \\ &\geq \tau(z_1) + \tau'(z_1)(z_2 - z_1) + \frac{1}{2} r(p-1)p(z_2 - z_1)^2 / \max\{z_1, z_2\}^{p+1} \\ &\geq \tau(z_1) + \tau'(z_1)(z_2 - z_1) + r\,\kappa\,(z_2 - z_1)^2, \end{aligned}$$

and the assertion follows. ∎

Now we come to the transformed optimization problem. Let the set F be defined as in Lemma 5.4. For $f \in F$, define

$$J(f) = \int_{-L}^{L} \frac{|\alpha'(x)|^p}{f(x)^{p-1}}\,dx.$$

In Theorem 4.1, we have seen that $\alpha' \in L^p(-L, L)$. Due to the bounds for f in the definition of the set F, this implies that the number $J(f)$ is well-defined. Lemma 5.4 states that $M = H$. Due to (5.9), for all $h \in M$, we have $W(T) = J(h')$. Hence the definition (5.4) of the set M and the bijection θ between the sets Φ and M given in Lemma 5.2 imply that our problem P is equivalent to the problem

$$Q: \qquad \text{Find } f \in F \text{ such that } J(f) \text{ is minimized.} \tag{5.11}$$

Problem Q is a convex optimization problem. The necessary optimality conditions lead us to the following solution of problem Q.

LEMMA 5.6. *Let $p \in (1,\infty)$, and let α be defined as in* (4.8). *For $\lambda > 0$, define the function f on the interval $[-L,L]$ by*

$$f(x) = \begin{cases} \frac{c-D}{c+D} & \text{if} \quad x \in [-L,L] \quad \text{and} \quad \lambda|\alpha'(x)| \le \frac{c-D}{c+D}, \\ \lambda|\alpha'(x)| & \text{if} \quad x \in [-L,L] \quad \text{and} \quad \lambda|\alpha'(x)| \in (\frac{c-D}{c+D},\ \frac{c+D}{c-D}), \\ \frac{c+D}{c-D} & \text{if} \quad x \in [-L,L] \quad \text{and} \quad \lambda|\alpha'(x)| \ge \frac{c+D}{c-D}. \end{cases}$$

If $\int_L^L |\alpha'(y)|\,dy > 0$, there exists a real number $\lambda > 0$ such that

$$\int_{-L}^{L} f(x)\,dx = 2L, \tag{5.12}$$

and, with this choice of λ, we have $f \in F$, and f is a solution of problem Q.

Define the set $M_z = \{x \in [-L,L] : \alpha'(x) = 0\}$. If M_z has measure zero, the solution of Q is uniquely determined.

If $\int_L^L |\alpha'(y)|\,dy = 0$, we have $J(f) = 0$ for all $f \in F$.

Proof. **A special case.** For the special case that $\int_L^L |\alpha'(y)|\,dy > 0$ and for

$$\lambda = \frac{2L}{\int_{-L}^{L} |\alpha'(x)|\,dx},$$

we have $\lambda|\alpha'(x)| \in [\frac{c-D}{c+D},\ \frac{c+D}{c-D}]$ for all $x \in [-L,L]$, and we give a proof for the optimality of f that is based upon Hölder's inequality. We have

$$J(f) = \frac{1}{\lambda^{p-1}} \int_{-L}^{L} \frac{|\alpha'(x)|^p}{|\alpha'(x)|^{p-1}}\,dx = \frac{(\int_{-L}^{L} |\alpha'(x)|\,dx)^p}{(2L)^{p-1}}.$$

Let q be such that $(1/p) + (1/q) = 1$, and let $g \in F$. Then we have

$$\begin{aligned} \int_{-L}^{L} |\alpha'(x)|\,dx &= \int_{-L}^{L} \frac{|\alpha'(x)|}{g(x)^{1/q}}\, g(x)^{1/q}\,dx \\ &\le \left(\int_{-L}^{L} \frac{|\alpha'(x)|^p}{g(x)^{p/q}}\,dx\right)^{1/p} \left(\int_{-L}^{L} g(x)\,dx\right)^{1/q} \\ &\le \left(\int_{-L}^{L} \frac{|\alpha'(x)|^p}{g(x)^{p-1}}\,dx\right)^{1/p} (2L)^{1/q} \\ &= J(g)^{1/p}(2L)^{1/q}. \end{aligned}$$

This implies the desired inequality

$$J(g) \ge \frac{(\int_{-L}^{L} |\alpha'(x)|\,dx)^p}{(2L)^{p/q}} = \frac{(\int_{-L}^{L} |\alpha'(x)|\,dx)^p}{(2L)^{p-1}} = J(f).$$

The general case. For the general case where $\int_L^L |\alpha'(y)|\,dy > 0$, we give a proof that is based upon the convexity of the objective function. Assume that f is given as defined in Lemma 5.6 and that (5.12) holds. Then $f \in F$. Let $g \in F$ be given. Define

the difference function $\Delta = g - f$. Then $\int_{-L}^{L} \Delta(x)\,dx = 0$. Define the sets

$$M_{\leq} = \left\{ x \in [-L, L] :\ |\alpha'(x)| \leq \frac{c-D}{c+D}\ \frac{1}{\lambda} \right\},$$
$$M_0 = \left\{ x \in [-L, L] :\ |\alpha'(x)| \in \left(\frac{c-D}{c+D}\ \frac{1}{\lambda},\ \frac{c+D}{c-D}\ \frac{1}{\lambda} \right) \right\},$$
$$M_{\geq} = \left\{ x \in [-L, L] :\ |\alpha'(x)| \geq \frac{c+D}{c-D}\ \frac{1}{\lambda} \right\}.$$

For all $x \in M_{\leq}$, we have $\Delta(x) = g(x) - \frac{c-D}{c+D} \geq 0$. Hence due to the definition of f the following inequality holds:

$$\int_{M_{\leq}} \frac{|\alpha'(x)|^p}{f(x)^p}\ \Delta(x)\,dx = \left(\frac{c+D}{c-D} \right)^p \int_{M_{\leq}} |\alpha'(x)|^p\ \Delta(x)\,dx$$
$$\leq \left(\frac{c+D}{c-D} \right)^p \left(\frac{c-D}{c+D} \right)^p \frac{1}{\lambda^p} \int_{M_{\leq}} \Delta(x)\,dx = \frac{1}{\lambda^p} \int_{M_{\leq}} \Delta(x)\,dx.$$

For all $x \in M_{\geq}$, we have $\Delta(x) = g(x) - \frac{c+D}{c-D} \leq 0$. Hence due to the definition of f the following inequality holds:

$$\int_{M_{\geq}} \frac{|\alpha'(x)|^p}{f(x)^p}\ \Delta(x)\,dx = \left(\frac{c-D}{c+D} \right)^p \int_{M_{\geq}} |\alpha'(x)|^p\ \Delta(x)\,dx$$
$$\leq \left(\frac{c-D}{c+D} \right)^p \left(\frac{c+D}{c-D} \right)^p \frac{1}{\lambda^p} \int_{M_{\geq}} \Delta(x)\,dx = \frac{1}{\lambda^p} \int_{M_{\geq}} \Delta(x)\,dx.$$

Moreover, the definition of f implies the equation

$$\int_{M_0} \frac{|\alpha'(x)|^p}{f(x)^p}\ \Delta(x)\,dx = \int_{M_0} \frac{|\alpha'(x)|^p}{\lambda^p\,|\alpha'(x)|^p}\ \Delta(x)\,dx = \frac{1}{\lambda^p} \int_{M_0} \Delta(x)\,dx.$$

We have $f(x),\ g(x) \in [\frac{c-D}{c+D},\ \frac{c+D}{c-D}]$ almost everywhere on the interval $[-L, L]$. Hence, for our objective function, the application of Lemma 5.5 pointwise for all $x \in [-L, L]$ with $r = |\alpha'(x)|^p$ and $z_2 = g(x)$, $z_1 = f(x)$ yields

$$\begin{aligned} J(g) - J(f) &= \int_{-L}^{L} \frac{|\alpha'(x)|^p}{g(x)^{p-1}} - \frac{|\alpha'(x)|^p}{f(x)^{p-1}}\,dx \\ &\geq \int_{-L}^{L} (1-p) \frac{|\alpha'(x)|^p}{f(x)^p}\ \Delta(x)\,dx + \int_{-L}^{L} |\alpha'(x)|^p\,\kappa\,\Delta(x)^2\,dx \\ &= (1-p) \int_{M_{\leq}} \frac{|\alpha'(x)|^p}{f(x)^p}\ \Delta(x)\,dx + (1-p) \int_{M_0} \frac{|\alpha'(x)|^p}{f(x)^p}\ \Delta(x)\,dx \\ &\quad + (1-p) \int_{M_{\geq}} \frac{|\alpha'(x)|^p}{f(x)^p}\ \Delta(x)\,dx + \kappa \int_{-L}^{L} |\alpha'(x)|^p\,\Delta(x)^2\,dx. \end{aligned}$$

Since $(1-p) < 0$, with the inequalities for the integrals on $M_{\leq}$, $M_{\geq}$, and M_0 derived

above, this implies the inequality

$$\begin{aligned} J(g) - J(f) &\geq (1-p)\int_{M_{\leq}} \frac{1}{\lambda^p}\,\Delta(x)\,dx + (1-p)\int_{M_0} \frac{1}{\lambda^p}\,\Delta(x)\,dx \\ &\quad + (1-p)\int_{M_{\geq}} \frac{1}{\lambda^p}\,\Delta(x)\,dx + \kappa\int_{-L}^{L} |\alpha'(x)|^p\,\Delta(x)^2\,dx \\ &= \frac{1-p}{\lambda^p}\int_{-L}^{L} \Delta(x)\,dx + \kappa\int_{-L}^{L} |\alpha'(x)|^p\,\Delta(x)^2\,dx \\ &= \kappa\int_{-L}^{L} |\alpha'(x)|^p\,\Delta(x)^2\,dx \geq 0. \end{aligned}$$

Thus $J(g) \geq J(f)$. Hence f is a solution of the optimization problem Q.

Define the set $M_1 = \{x \in [-L, L] :\ \Delta(x) \neq 0\}$. If M_z has measure zero and M_1 has strictly positive measure, that is, $g \neq f$, we have the inequality

$$J(g) - J(f) \geq \kappa\int_{-L}^{L} |\alpha'(x)|^p\,\Delta(x)^2\,dx > 0.$$

Hence in this case, the solution of Q is uniquely determined.

Define the function U on the interval $(0, \infty)$ by the equation

$$U(\lambda) = \int_{-L}^{L} \Pi_{[\frac{c-D}{c+D},\ \frac{c+D}{c-D}]}(\lambda\,|\alpha'(y)|\,)\,dy,\ \lambda \in (0, \infty).$$

For all z_1, $z_2 \in (0, \infty)$, we have the inequality

$$\left|\Pi_{[\frac{c-D}{c+D},\ \frac{c+D}{c-D}]}(z_1) - \Pi_{[\frac{c-D}{c+D},\ \frac{c+D}{c-D}]}(z_2)\right| \leq |z_1 - z_2|.$$

Hence for all λ_1, $\lambda_2 \in (0, \infty)$ we have

$$\begin{aligned} |U(\lambda_1) - U(\lambda_2)| &\leq \int_{-L}^{L} \left|\Pi_{[\frac{c-D}{c+D},\ \frac{c+D}{c-D}]}(\lambda_1\,|\alpha'(y)|) - \Pi_{[\frac{c-D}{c+D},\ \frac{c+D}{c-D}]}(\lambda_2|\alpha'(y)|)\right|\,dy \\ &\leq \int_{-L}^{L} |\ \lambda_1\,|\alpha'(y)| - \lambda_2|\alpha'(y)|\ |\,dy \\ &= |\lambda_1 - \lambda_2|\int_{-L}^{L} |\alpha'(y)|\,dy. \end{aligned}$$

Thus U is Lipschitz continuous. We have $\lim_{\lambda\to 0} U(\lambda) = 2L\frac{c-D}{c+D} < 2L$.

Since $\int_{L}^{L} |\alpha'(y)|\,dy > 0$ we have $\lim_{\lambda\to\infty} U(\lambda) = 2L\frac{c+D}{c-D} > 2L$. Hence there exists a number $\lambda > 0$ such that $U(\lambda) = 2L$, which means that (5.12) is valid.

The case where $\int_{L}^{L} |\alpha'(y)|\,dy = 0$ is trivial. □

5.4. Proofs of the main results.

Proof of Theorem 3.1. For $p = 1$, $W(0) = W(T)$ for all $\phi \in \Phi$ (see Remark 5.2), so $\phi(t) = L \in \Phi$ is a solution of P.

Assume that $p > 1$. Due to (5.9) and the transformation of the set of admissible controls described in section 5.1, problem P is equivalent to the problem

$$P_1 : \text{Find } h \in H \text{ such that } J(h') = \int_{-L}^{L} \frac{|\alpha'(x)|^p}{h'(x)^{p-1}}\,dx \text{ is minimized.}$$

For all $h \in H$, we have $h'(x) \in F$, and, for all $f \in F$, we have $h(x) = -L + \int_{-L}^{x} f(x)\,ds \in H$. Moreover, $J(h') = J(f)$. Due to the representation (5.4) of the set H, this implies that P_1 is equivalent to Q.

Lemma 5.6 implies the existence of a solution of Q, which yields in turn the existence of a solution of P.

By Theorem 4.1, we have $\alpha' \in L^p(-L, 3L)$, and, due to the compatibility conditions $y_0(0) = y_0(L) = 0$ in the definition of the set B, the definition of the function α implies that, for all $x \in [-L, L]$, we have $\alpha'(x) = A(x)$.

Hence the definition of the set M_z in Theorem 3.1 is equivalent to the definition in Lemma 5.6. If the set M_z has measure zero, Lemma 5.6 implies the uniqueness of the solution of Q. We have seen that each function $f \in F$ corresponds to an admissible function $\phi \in \Phi$ with $J(f) = W(T)$. This implies the uniqueness of the solution of P. □

Proof of Theorem 3.2. If $\int_{L}^{L} |A(y)|\,dy > 0$, Lemma 5.6 implies the existence of a number $\lambda > 0$ such that (5.12) holds. If (5.12) holds for $\lambda > 0$, then (3.2) is valid with this value of λ, and, for the function f defined in Lemma 5.6, we have

$$f(x) = \Pi_{[\frac{c-D}{c+D},\ \frac{c+D}{c-D}]}(\lambda\,|A(x)|\,).$$

For the function h defined in Theorem 3.2, we have $h(x) = -L + \int_{-L}^{x} f(x)\,ds$. Since f solves Q, h solves problem P_1 defined above. In Lemma 5.2, we have shown that the solution ϕ of P can then be obtained by $\phi = \theta^{-1}(h)$. Equations (5.7) and (5.6) show that ϕ is given by (3.3). Equation (5.9) yields the minimal value of $W(T)$ and the result for the case $\int_{L}^{L} |A(y)|\,dy = 0$. □

6. Conclusion. We study a system that is controlled through the movement of the boundary and where the boundary movements are described by Lipschitz continuous functions. To obtain a well-posed problem, we require that the Lipschitz constants for the admissible controls are less than or equal to a given number D that is strictly less than the speed of wave propagation. We give a representation of a boundary movement that generates a maximal decrease of the energy in the given finite time interval. In particular, we give sufficient conditions for the existence and uniqueness of an optimal movement. Due to the nature of our system it is impossible to drive the energy arbitrarily close to zero unless it is zero from the start. For some initial states, it is even impossible to achieve any energy decrease by boundary movement control. The optimal energy decrease depends on the initial state. Depending on the initial state a considerable reduction of the energy can be achieved.

CONSTRAINED DIRICHLET BOUNDARY CONTROL IN L^2 FOR A CLASS OF EVOLUTION EQUATIONS*

K. KUNISCH† AND B. VEXLER‡

Abstract. Optimal Dirichlet boundary control based on the very weak solution of a parabolic state equation is analyzed. This approach allows us to consider the boundary controls in L^2, which has advantages over approaches which consider control in Sobolev spaces involving (fractional) derivatives. Pointwise constraints on the boundary are incorporated by the primal-dual active set strategy. Its global and local superlinear convergences are shown. A discretization based on space-time finite elements is proposed and numerical examples are included.

Key words. Dirichlet boundary control, inequality constraints, parabolic equations, very weak solution

1. Introduction.

In this work we focus on the Dirichlet boundary optimal control problem with pointwise constraints on the boundary, formally given by

$$\begin{cases} \min & J(y,u) \\ \text{subject to} & \partial_t y - \kappa\Delta y + b\cdot\nabla y = f \quad \text{in } Q, \\ & y = u, \quad u \le \psi \quad \text{on } \Sigma, \\ & y(0) = y_0 \quad \text{in } \Omega, \end{cases} \tag{1.1}$$

where $Q = (0,T]\times\Omega$, $\Sigma = (0,T]\times\partial\Omega$, and κ, b, f, y_0, ψ, and $T > 0$ are fixed. We propose and analyze a function space formulation which is amenable to efficient numerical realizations. To incorporate the constraints numerically the primal-dual active set (PDAS) strategy is used and its convergence is investigated. We also propose a space-time Galerkin approximation and provide numerical examples.

The specific difficulties involved in Dirichlet control problems result from the fact that they are not of variational type. In the literature several treatments of Dirichlet boundary control problems can be found, where the function space for the controls is H^s with $s \ge \frac{1}{2}$. As a consequence, the numerical realization by finite elements or finite differences is more involved than if the control space were L^2. Our approach will be based on the concept of very weak solutions to the state equation. This allows the use of L^2 as the control space.

Let us briefly describe possible approaches to treating Dirichlet boundary optimal control problems. While in our work we shall treat the time-dependent case, it will be convenient for the present purpose to restrict our attention to a tracking-type optimal

control problem with the most simple stationary elliptic equation as constraint:

$$
(1.2)\qquad \begin{cases} \min & \frac{1}{2}|y-z|^2_{L^2(\Omega)} + \frac{\beta}{2}|u|^2_{L^2(\partial\Omega)} \\ \text{over} & (y,u) \in L^2(\Omega)\times L^2(\partial\Omega) \\ \text{subject to} & -(y,\Delta v)_{L^2(\Omega)} = -(u, \frac{\partial}{\partial n} v)_{L^2(\partial\Omega)} \quad \text{for all } v \in H^2(\Omega)\cap H^1_0(\Omega) \\ \text{and} & u \le \psi \quad \text{on } \partial\Omega, \end{cases}
$$

where $z \in L^2(\Omega)$ and $\partial\Omega$ denotes the boundary of the domain Ω. The variational equation in (1.2) is the very weak form of

$$
\begin{cases} -\Delta y = 0 \quad \text{in } \Omega, \\ y = u \quad \text{on } \partial\Omega; \end{cases}
$$

see [36]. In our work we shall use the analogue of (1.2). If the state variable y is considered in $H^1(\Omega)$, then a proper formulation is given by

$$
(1.3)\qquad \begin{cases} \min & \frac{1}{2}|y-z|^2_{L^2(\Omega)} + \frac{\beta}{2}|u|^2_{H^{\frac{1}{2}}(\partial\Omega)} \\ \text{over} & (y,u) \in H^1(\Omega)\times H^{\frac{1}{2}}(\partial\Omega) \\ \text{subject to} & (\nabla y, \nabla v)_{L^2(\Omega)} = 0 \quad \text{for all } v \in H^1_0(\Omega) \text{ and } y = u \text{ on } \partial\Omega \\ \text{and} & u \le \psi \quad \text{on } \partial\Omega. \end{cases}
$$

For both formulations (1.2) and (1.3) it is classical to argue existence of a unique solution; see, e.g., [36]. Numerically realizing the $H^{1/2}$-norm in (1.3) is more involved than realizing the L^2-norm in (1.2). To avoid difficulties with implementing the $H^{1/2}$-norm it was replaced in several publications by the H^1-norm. As a consequence the Laplace–Beltrami operator appears in the optimality condition. This formulation, properly modified for the specific application and without control constraints, was used in the context of optimal boundary control of the Navier–Stokes equations and the Boussinesq equations; see, e.g., [23, 24, 33]. For a numerical wavelet–based realization of H^s-norms in the context of Dirichlet control of elliptic equations, we refer to [30].

A third alternative is given by

$$
(1.4)\qquad \begin{cases} \min & \frac{1}{2}|y-z|^2_{H^1(\Omega)} + \frac{\beta}{2}|u|^2_{L^2(\partial\Omega)} \\ \text{over} & (y,u) \in H^1(\Omega)\times H^{1/2}(\partial\Omega) \\ \text{subject to} & (\nabla y, \nabla v)_{(\Omega)} = 0 \quad \text{for all } v \in H^1_0(\Omega) \text{ and } y = u \quad \text{on } \partial\Omega \\ \text{and} & u \le \psi \quad \text{on } \partial\Omega. \end{cases}
$$

Again existence can be argued by standard arguments, but for (1.4), differently from (1.2) and (1.3), the essential term for obtaining coercivity is the H^1-norm of the tracking functional. Just like (1.2) this formulation also avoids having to deal with fractional order Sobolev spaces. It was used in the context of boundary control of the stationary Navier–Stokes equations in [15], for example. In the adjoint equation, however, a Laplacian now appears in the source term acting on the defect $y - z$.

Besides the difficulties already mentioned with (1.3) and (1.4) there is yet another, possibly more essential, reason to favor the formulation in (1.2). For (1.2) the Lagrange multiplier associated to the constraint $u \le \psi$ is an L^2-function, whereas

it is only a measure for the formulations in (1.3) and (1.4). As a consequence the complementarity conditions related to the inequality constraint can be expressed in a pointwise a.e. manner by the common pointwise complementarity functions like the max or the Fischer–Burmeister functions only for formulation (1.2). Such a pointwise formulation is a basis for efficient optimization algorithms such as the PDAS strategy or the semismooth Newton method.

Let us also recall the possibility of approximating Dirichlet boundary control problems by regularization based on Robin boundary controls of the form $\delta \frac{\partial y}{\partial n} + y = u$ for $\delta \to 0^+$. This results in the variational formulation

$$
\left\{
\begin{array}{ll}
\text{min} & \frac{1}{2}|y-z|^2_{L^2(\Omega)} + \frac{\beta}{2}\,|u|^2_{L^2(\partial\Omega)} \\
\text{over} & (y,u) \in H^1(\Omega) \times L^2(\partial\Omega) \\
\text{subject to} & (\nabla y, \nabla v)_{L^2(\Omega)} = \frac{1}{\delta}(y-u,v)_{L^2(\partial\Omega)} \quad \text{for all } v \in H^1(\Omega) \\
\text{and} & u \le \psi \quad \text{on } \partial\Omega.
\end{array}
\right. \tag{1.5}
$$

The choice of δ remains a delicate matter. This approach was used for stationary and nonstationary problems in [6] and [2], respectively. In [5] a numerical approach to Dirichlet boundary control based on a discretization using the Nitsche method was proposed.

We next point out some additional features of this paper. As already mentioned, the pointwise inequality constraint $u \le \psi$ will be treated by the PDAS algorithm. Its global, as well as local, superlinear convergence will be analyzed. Here it is essential that the Lagrange multiplier is an L^2-function and that the resulting complementarity condition involving the max operation is Newton differentiable. This is the case for (1.2), whereas this is not true for the other two formulations. Newton differentiability will be shown for (1.2) for time-dependent problems in the present paper. For stationary problems it easily follows as well.

Discretization of infinite-dimensional problems will be carried out by a space-time finite element method. This approach guarantees that the algorithm is invariant with respect to the ordering of discretization of the problem and gradient computations.

In spite of the fact that we use the very weak solution concept as our functional analytic setting for Dirichlet boundary control, the numerical discretization is based on standard space-time Galerkin finite-dimensional spaces. This will be justified by the fact that the solutions of the optimal control problems are more regular than those required by (1.2).

In our numerical implementation we use piecewise (bi)linear elements for spatial discretization of the primal and adjoint states as well as for the controls. This may appear to be incompatible at first, since the optimality condition involves $\frac{\partial p}{\partial n}$ and u in an additive manner, where p denotes the adjoint state. However, we replace $\frac{\partial p}{\partial n}$ by a variational expression in such a way that the resulting discretization is well balanced.

In section 2 we gather well-posedness results and a priori estimates for a class of evolution equations with Dirichlet boundary conditions in L^2. We include a convection term, due to future interest in considering similar problems for the Boussinesq systems, with specific nonconvex cost functionals, motivated by fluid mechanics considerations. In this case the convection coefficient is the velocity field of the fluid. Section 3 is devoted to the statements and analysis of the optimal control problems under consideration. In particular, we describe regularity properties of the optimal solutions. These are not only of interest in their own right, but are essential for superlinear convergence of the PDAS strategy, as explained in section 4. Section 5 contains a

description of the finite element discretization, and section 6 is devoted to selected numerical examples.

2. On the state equation. In this section we provide the necessary existence and a priori estimates for very weak solutions to

$$\begin{cases} \partial_t y - \kappa\Delta y + b\cdot\nabla y = f \quad \text{in } Q,\\ y = u \quad \text{on } \Sigma,\\ y(0) = y_0 \quad \text{in } \Omega, \end{cases} \tag{2.1}$$

where $Q = (0,T]\times\Omega$, $\Sigma = (0,T]\times\partial\Omega$, and Ω is a bounded domain in $\mathbb{R}^n$, $n\geq 2$, with C^2 boundary $\partial\Omega$. This boundary regularity of Ω guarantees that the Laplacian with homogeneous Dirichlet boundary conditions, denoted by Δ_0, is an isomorphism form $H^2(\Omega)\cap H_0^1(\Omega)$ to $L^2(\Omega)$. We shall denote the adjoint of Δ_0, mapping from $L^2(\Omega)$ to $H^{-2}(\Omega) = (H^2(\Omega)\cap H_0^1(\Omega))^*$ by Δ_0 as well. For any Banach space Y, we use the abbreviations $L^2(Y) = L^2(0,T;Y)$, $H^s(Y) = H^s(0,T;Y)$, $s\in[0,\infty)$, and $C(Y) = C([0,T];Y)$.

Further $\kappa>0$, $y_0\in H^{-1}(\Omega)$, $f\in L^2(H^{-2}(\Omega))$, $u\in L^2(\Sigma)$ and $b\in\mathbb{L}^\infty(Q)$, div b $\in L^\infty(L^{\hat n}(\Omega))$, where $\hat n = \max(n,3)$, and $\mathbb{L}^\infty(Q) = \bigotimes_{i=1}^n L^\infty(Q)$. At times we shall simply write $L^p(Q)$ for $\mathbb{L}^p(Q)$.

The very weak form of (2.1) that we shall utilize is given by

$$\begin{cases} \langle\partial_t y(t), v\rangle - \kappa(y(t),\Delta v) - (y(t), \operatorname{div}(b(t))\, v) - (y(t), b(t)\nabla v)\\ \qquad = \langle f(t), v\rangle - \kappa(u(t), \frac{\partial}{\partial n} v)_{\partial\Omega} \quad \text{for all } v\in H^2(\Omega)\cap H_0^1(\Omega)\\ \qquad\qquad\qquad\qquad\qquad\qquad \text{and a.e. } t\in(0,T),\\ y(0) = y_0, \end{cases} \tag{2.2}$$

where $\langle\cdot,\cdot\rangle = \langle\cdot,\cdot\rangle_{H^{-2}(\Omega),H^2(\Omega)\cap H_0^1(\Omega)}$ and denotes the canonical duality pairing, and $(\cdot,\cdot)$ and $(\cdot,\cdot)_{\partial\Omega}$ stand for the inner products in $L^2(\Omega)$ and $L^2(\partial\Omega)$, respectively. The last equality in (2.2) is understood in $H^{-1}(\Omega)$. The existence and uniqueness of a very weak solution in the space $L^2(Q)\cap H^1(H^{-2}(\Omega))\cap C(H^{-1}(\Omega))$ is shown in the following theorem.

THEOREM 2.1. *For every $\kappa>0$, $b\in L^\infty(Q)$, with* div $b\in L^\infty(L^{\hat n}(\Omega))$, $y_0\in H^{-1}(\Omega)$, $f\in L^2(H^{-2}(\Omega))$, *and* $u\in L^2(\Sigma)$, *there exists a unique very weak solution* $y\in L^2(Q)\cap H^1(H^{-2}(\Omega))\cap C(H^{-1}(\Omega))$ *satisfying*

$$|y|_{L^2(Q)\cap H^1(H^{-2}(\Omega))\cap C(H^{-1}(\Omega))} \leq C(|y_0|_{H^{-1}(\Omega)} + |f|_{L^2(H^{-2}(\Omega))} + |u|_{L^2(\Sigma)}), \tag{2.3}$$

where C depends continuously on $\kappa>0$, $|b|_{L^\infty(Q)}$, and $|\operatorname{div} b|_{L^\infty(L^{\hat n}(\Omega))}$, *and is independent of $f\in L^2(H^{-2}(\Omega))$, $u\in L^2(\Sigma)$, and $y_0\in H^{-1}(\Omega)$.*

Proof. Let us first assume existence of y with the claimed regularity and verify the a priori estimate (2.3). Throughout, k will denote a generic embedding constant. Let us introduce the transformed state-variable $\hat y(t) = y(t)e^{-ct}$, $c\geq 0$, and note that if y is a very weak solution of (2.1), then $\hat y\in L^2(Q)\cap H^1(H^{-2}(\Omega))$ is a very weak solution of

$$\begin{cases} \partial_t\hat y + c\hat y - \kappa\Delta\hat y + b\cdot\nabla\hat y = \hat f \quad \text{in } Q,\\ \hat y = \hat u \quad \text{on } \Sigma,\\ \hat y(0) = y_0 \quad \text{in } \Omega, \end{cases}$$

where $\hat f = f e^{-ct}$, $\hat u = u e^{-ct}$. The constant c will be fixed below. We further introduce $\omega = (-\Delta_0)^{-1}\,\hat y \in L^2(H^2(\Omega)\cap H_0^1(\Omega))\cap H^1(L^2(\Omega))$ and note that ω satisfies for all $v \in H^2(\Omega)\cap H_0^1(\Omega)$

$$\begin{aligned}\langle(-\Delta_0)\,\partial_t\omega(t),\,v\rangle + \kappa(\Delta_0\,\omega(t),\,\Delta v) + c(-\Delta_0\,\omega(t),\,v)\\ + (\Delta_0\,\omega(t),\,\operatorname{div} b(t)\,v) + (\Delta_0\,\omega(t),\,b(t)\nabla v) = \langle\hat f(t),\,v\rangle - \kappa\left(\hat u(t),\,\frac{\partial}{\partial n}\,v\right)_{\partial\Omega}\end{aligned}$$

for all $t\in(0,T)$. Setting $v=\omega(t)$ and integrating over $(0,t)$, we find

$$\begin{aligned}\frac12|\nabla\omega(t)|^2 - \frac12|\nabla\omega(0)|^2 + \kappa\int_0^t|\Delta_0\;\omega(s)|^2\,ds + c\int_0^t|\nabla\omega(s)|^2\,ds\\ + \int_0^t(\Delta_0\,\omega(s),\,\operatorname{div} b(s)\,\omega(s))\,ds + \int_0^t(\Delta_0\,\omega(s),\,b(s)\nabla\omega(s))\,ds\\ = \int_0^t\langle\hat f(s),\omega(s)\rangle\,ds - \kappa\int_0^t\left(\hat u(s),\frac{\partial}{\partial n}w(s)\right)_{\partial\Omega},\end{aligned}$$

and consequently using $\|\frac{\partial}{\partial n}w(s)\|_{L^2(\partial\Omega)}\le k\,\|\Delta_0 w(s)\|_{L^2(\Omega)}$ we obtain

$$\begin{aligned}&\frac12|\nabla\omega(t)|^2\,ds + \kappa\int_0^t|\Delta_0\,\omega(s)|^2ds + c\int_0^t|\nabla\omega(s)|^2\,ds\\ &\le \frac12|\nabla\omega(0)|^2 + \frac{\kappa}{8}\int_0^t|\Delta_0\,\omega(s)|^2\,ds + \frac{2k}{\kappa}\,|\operatorname{div} b|^2_{L^\infty(L^{\hat n}(\Omega)}\int_0^t|\nabla\omega(s)|^2\,ds\\ &\quad+\frac{\kappa}{8}\int_0^t|\Delta_0\,\omega(s)|^2 + \frac{2|b|^2_{L^\infty(Q)}}{\kappa}\int_0^t|\nabla\omega(s)|^2\,ds + \frac{2k^2}{\kappa}\int_0^t|\hat f(s)|^2_{H^{-2}} + \frac{\kappa}{8}\int_0^t|\Delta_0\,\omega|^2\,ds\\ &\quad+2\kappa^2\int_0^t|\hat u(s)|^2_{L^2(\partial\Omega)}\,ds + \frac{\kappa}{8}\int_0^t|\Delta_0\,\omega(s)|^2\,ds\\ &\le \frac12|\nabla\omega(0)|^2 + \frac{4\kappa}{8}\int_0^t|\Delta_0\,\omega(s)|^2\,ds + \left(\frac{2k}{\kappa}\,|\operatorname{div} b|^2_{L^\infty(L^{\hat n}(\Omega))} + \frac{2|b|^2_{L^\infty(Q)}}{\kappa}\right)\int_0^t|\nabla\omega(s)|^2\,ds\\ &\quad+\frac{2k^2}{\kappa}\int_0^t|\hat f(s)|^2_{H^{-2}(\Omega)}\,ds + 2k^2\int_0^t|\hat u(s)|^2_{L^2(\partial\Omega)}\,ds\,.\end{aligned}$$

If we choose c such that

$$\frac{2k}{\kappa}\,|\operatorname{div} b|^2_{L^\infty(L^{\hat n}(\Omega))} + \frac{2\,|b|^2_{L^\infty(Q)}}{\kappa} \le \frac{c}{2}\,, \tag{2.4}$$

then

$$\begin{aligned}\frac12\,|\nabla\omega(t)|^2 + \frac{k}{2}\int_0^t|\Delta_0\,\omega(s)|^2\,ds + \frac{c}{2}\int_0^t|\nabla\omega(s)|^2\,ds\\ \le \frac12\,|\nabla\omega(0)|^2 + \frac{2k^2}{\kappa}\int_0^t|\hat f(s)|^2_{H^{-2}(\Omega)}\,ds + 2k^2\int_0^t|\hat u(s)|^2_{L^2(\partial\Omega)}\,ds\,.\end{aligned} \tag{2.5}$$

From (2.5) we deduce the existence of a constant C with the specified properties such that for all $t\in[0,T]$

$$|\hat y(t)|_{H^{-1}(\Omega)} + \int_0^t|\hat y(s)|^2_{L^2(\Omega)}\,ds \le C(|y_0|_{H^{-1}(\Omega)} + |f|_{L^2(H^{-2}(\Omega))} + |u|_{L^2(\Sigma)})\,,$$

and, since $\hat{y}(t) = y(t)e^{-ct}$, we find for a possibly modified C:

$$|y(t)|_{H^{-1}(\Omega)} + \int_0^t |y(s)|^2_{L^2(\Omega)} ds \le C(|y_0|_{H^{-1}(\Omega)} + |f|_{L^2(H^{-2}(\Omega))} + |u|_{L^2(\Sigma)}) . \tag{2.6}$$

Finally using (2.2) we obtain

$$\begin{aligned}\int_0^T |\partial_t y(t)|^2_{H^{-2}(\Omega)}\, dt &= \int_0^T \sup_{\substack{v\in H^2(\Omega)\cap H^1_0(\Omega),\\ |\Delta_0 v|\le 1}} \langle \partial_t y(t), v\rangle^2\, dt \\ &\le \kappa^2 \int_0^T |y(t)|^2\, dt + \int_0^T (y(t), \operatorname{div} b\, v)^2_{L^2(\Omega)}\, dt \\ &\quad + |b|^2_{L^\infty(Q)} \int_0^T |y(t)|^2\, dt + |f|^2_{L^2(H^{-2}(\Omega))} + k\,|u|^2_{L^2(\Sigma)} .\end{aligned}$$

For the second term on the right-hand side we estimate for $n > 4$

$$\begin{aligned}\int_0^T (y(t), \operatorname{div} b\, v)^2_{L^2(\Omega)}\, dt &\le \int_0^T |y(t)|^2_{L^2(\Omega)}\, |\operatorname{div} b|^2_{L^{2p}(\Omega)}\, |v|^2_{L^{2q}(\Omega)}\, dt \\ &\le k \int_0^T |y(t)|^2_{L^2(\Omega)}\, |\operatorname{div} b|^2_{L^{\hat{n}}(\Omega)}\, dt ,\end{aligned}$$

where $q = \frac{n}{n-4}$, $p = \frac{n}{4}$, and we used that $H^2(\Omega) \hookrightarrow L^{\frac{2n}{n-4}}(\Omega)$ and $\hat{n} > 2p = \frac{n}{2}$. The same estimate for dimensions $n = 2, 3, 4$ follows quite easily.

We obtain

$$\begin{aligned}&\int_0^T |\partial_t y|^2_{H^{-2}(\Omega)}\, dt \\ &\quad \le (\kappa^2 + k\,|\operatorname{div} b|_{L^\infty(L^{\hat{n}}(\Omega))} + |b|_{L^\infty(Q)}) \int_0^T |y(t)|^2\, dt + |f|^2_{L^2(H^{-2}(\Omega))} + k\,|u|^2_{L^2(\Sigma)} .\end{aligned}$$

Together with (2.6) this gives the desired estimate (2.3), which in particular also implies the uniqueness of the very weak solution to (2.1). Existence follows, for example, by combining this a priori estimate with a Galerkin procedure; see, e.g., [14, Chapter 18]. Alternatively analytic semigroup theory as in [32] can be used, noting that $-\kappa\Delta - b\cdot\nabla + cI$ generates an analytic semigroup in $L^2(\Omega)$. □

From the proof it follows that the solution y to (2.2) also satisfies the variational equation in Q given by

$$\begin{aligned}&\int_0^T \big(\langle \partial_t y(t), v(t)\rangle - \kappa(y(t), \Delta v(t)) - (y(t), \operatorname{div}(b(t))v(t)\,) - (y(t), b(t)\nabla v(t))\big)\, dt \\ &= \int_0^T \langle f(t), v(t)\rangle dt - \kappa \int_0^T \left(u(t), \frac{\partial}{\partial n} v(t)\right)_{L^2(\Omega)} dt \quad \text{for all } v \in L^2(H^2(\Omega)\cap H^1_0(\Omega)).\end{aligned} \tag{2.7}$$

The following result will allow us to consider cost functionals with pointwise-in-time evaluation of the trajectory.

COROLLARY 2.2. *If, in addition to the assumptions of Theorem* 2.1, $y_0 \in L^2(\Omega), f \in L^2(Q)$, *and* $u \in L^\infty(L^2(\partial\Omega))$, *then the very weak solution satisfies* $y \in$

$L^\infty(L^2(\Omega))$ and $y(\bar t)$ is a well-defined element in $L^2(\Omega)$ for every fixed $\bar t \in (0,T]$. Moreover, there exists a constant C independent of y_0, f, and u, such that for the corresponding solution $y = y(u)$ we have

$$|y(\bar t)|_{L^2(\Omega)} \le C(|y_0|_{L^2(\Omega)} + |f|_{L^2(Q)} + |u|_{L^\infty(L^2(\partial\Omega))}). \tag{2.8}$$

Proof. Fix $\kappa > 0$ and $b \in L^\infty(Q)$ with $\operatorname{div} b \in L^\infty(L^{\hat n}(\Omega))$. Without loss of generality we can assume that $A = -\kappa\Delta - b\cdot\nabla$ is uniformly elliptic. If not, we add a multiple c of the identity operator and accordingly multiply the constant C by the factor e^{cT}. Then A generates an analytic semigroup in $L^2(\Omega)$. For the equation with $u = 0$, estimate (2.8) follows by standard semigroup arguments. Using the superposition principle for (2.1) it therefore suffices to consider the case $y_0 = 0$, $f = 0$, and $u \in L^\infty(L^2(\partial\Omega))$. From [32] (see also [2]), we have the existence of $C > 0$ such that

$$|y|_{L^\infty(L^2(\Omega))} \le C|u|_{L^\infty(L^2(\partial\Omega))}\,. \tag{2.9}$$

From Theorem 2.1 we deduce $y \in C(H^{-1}(\Omega))$ and therefore

$$y(\bar t) = \lim_{\varepsilon\to 0} \frac{1}{\varepsilon}\int_{-\varepsilon}^{0} y(\bar t + \tau)\,d\tau, \tag{2.10}$$

where the integral and the equality are interpreted in $H^{-1}(\Omega)$. Denoting

$$g_\varepsilon = \frac{1}{\varepsilon}\int_{-\varepsilon}^{0} y(\bar t + \tau)\,d\tau\,,$$

we obtain using (2.9) that

$$|g_\varepsilon|_{L^2(\Omega)} \le C|u|_{L^\infty(L^2(\partial\Omega))}.$$

Therefore, there is a subsequence converging weakly in $L^2(\Omega)$ to $\tilde g$ with

$$|\tilde g|_{L^2(\Omega)} \le C|u|_{L^\infty(L^2(\partial\Omega))}.$$

Using (2.10) we obtain that $y(\bar t) = \tilde g$. The desired conclusion follows. ∎

3. The optimal control problems and regularity of optimal controls. We consider the following two optimal control problems:

$$\text{(P1)}\qquad \begin{cases} \min & J(y,u) = G(y) + \frac{\beta}{2}\,|u|^2_{L^2(\Sigma)} \\ \text{over} & (y,u) \in L^2(Q)\times L^2(\Sigma) \\ \text{subject to} & (2.1) \text{ and } \ u \le \psi \text{ on } \ \Sigma, \end{cases}$$

where $\beta > 0$, $\psi \in L^2(\Sigma)$, and $G : L^2(Q) \to \mathbb{R}$ is bounded below, C^1, and weakly lower semicontinuous. The second problem under consideration is

$$\text{(P2)}\qquad \begin{cases} \min & J(y,u) = G\,(y(T)) + \frac{\beta}{2}\,|u|^2_{L^2(\Sigma)} \\ \text{over} & (y,u) \in L^2(Q)\times L^2_{T_1}(\Sigma) \\ \text{subject to} & (2.1), \quad \varphi \le u \le \psi \text{ on } \ \Sigma, \end{cases}$$

where $\beta > 0$, $\varphi, \psi \in L^\infty(L^2(\partial\Omega))$, $\varphi(x) < \psi(x)$ a.e. on Σ, and $G : L^2(\Omega) \to \mathbb{R}$ is bounded below, weakly lower semicontinuous, and C^1. Here

$$L^2_{T_1}(\Sigma) = \{u \in L^2(\Sigma) : u(t,x) = 0 \quad \text{for } t \in (T_1, T)\},$$

with $T_1 \in [0,T]$. For (P2) we require that $\varphi \le 0 \le \psi$ a.e. on (T_1, T). In section 3.2 we shall require that $T_1 < T$. The practical interpretation of setting $u = 0$ in a neighborhood of T is that the controller and the observer are not acting simultaneously. This choice will be important for obtaining better regularity results for $y(T)$.

We refer to (y,u) as a solution of (2.1) if that equation is satisfied in the very weak sense (2.2). Throughout this section the regularity assumptions of Theorem 2.1 for b are supposed to hold, and

$$f \in L^2(Q), \quad y_0 \in L^2(\Omega).$$

Then we have the following result.

PROPOSITION 3.1. *There exist solutions* $(y^*, u^*) = (y(u^*), u^*)$ *to* (P1) *as well as* (P2)*, which are unique if* G *is convex.*

This follows from weak sequential limit arguments (see, e.g., [36]) utilizing Theorem 2.1, respectively, Corollary 2.2. For (P1) a lower bound $\varphi \le u$ can be added and treated as we do for (P2). In (P2) the simultaneous use of upper and lower bounds for the control is essential to guarantee the $L^\infty(L^2(\partial\Omega))$ bound for the controls, which is required by Corollary 2.2.

The above theorem is valid for all $T_1 \le T$. If one additionally assumes that $T_1 < T$, then the condition $\varphi, \psi \in L^\infty(L^2(\partial\Omega))$ can be weakened to $\varphi, \psi \in L^2(\Sigma)$, and the statement of the theorem follows from additional regularity of $y(T)$ in this case.

3.1. Problem (P1). To argue the existence of Lagrange multipliers for the inequality constraint in (P1), we introduce

$$\begin{aligned} e = (e_1, e_2) : (L^2(Q) \cap H^1(H^{-2})) \times L^2(\Sigma) &\to L^2(H^{-2}(\Omega)) \times H^{-1}(\Omega)\,, \\ g : L^2(\Sigma) &\to L^2(\Sigma) \end{aligned}$$

by

$$\begin{aligned} \langle e_1(y,u), v\rangle &= \int_0^T \left(\langle \partial_t y - f, v\rangle - (y \operatorname{div} b, v) - \kappa(y, \Delta v) - (y, b\cdot\nabla v) + \kappa \left(u, \frac{\partial}{\partial n} v \right)_{\partial\Omega} \right) dt\,, \\ e_2(y,u) &= y(0) - y_0\,, \\ g(u) &= u - \psi \end{aligned}$$

for arbitrary $v \in L^2(H^2(\Omega) \cap H^1_0(\Omega))$. Recall that $L^2(Q) \cap H^1(H^{-2}) \subset C(H^{-1}(\Omega))$, so that e_2 is well defined. The linearizations e' of e and g' of g are obtained from e and g by deleting the affine terms y_0, f, and ψ, respectively. We introduce the Lagrangian

$$\mathcal{L}(y,u,p,p_0,\lambda) = G(y) + \frac{\beta}{2}|u|^2_{L^2(\Sigma)} + \langle (p,p_0), e(y,u)\rangle + (\lambda, g(u)).$$

From Theorem 2.1 it follows that (e', g') is surjective, and hence there exists a Lagrange multiplier $(p, p_0, \lambda) \in L^2(H^2(\Omega) \cap H^1_0(\Omega)) \times H^1_0(\Omega) \times L^2(\Sigma)$ associated to the constraints (e, g); see, e.g., [37]. It follows that the optimality system satisfied

by an optimal pair (y^*, u^*) is obtained by setting $\nabla_{y,u,p,p_0}\mathcal{L}(y,u,p,p_0,\lambda) = 0$, and $\lambda \geq 0$, $g(u) \leq 0$, $\lambda\, g(u) = 0$. Consequently the optimality system for (P1) is given by

$$\begin{cases} \partial_t y - \kappa\Delta y + b\cdot\nabla y = f \quad \text{in } Q, \\ y = u \text{ on } \Sigma,\ y(0) = y_0 \quad \text{in } \Omega, \\ -\partial_t p - \kappa\Delta p - \operatorname{div} b\, p - b\cdot\nabla p = -G'(y) \quad \text{in } Q, \\ p = 0 \text{ on } \Sigma, \quad p(T) = 0 \quad \text{in } \Omega, \\ \kappa\frac{\partial p}{\partial n} + \beta u + \lambda = 0 \quad \text{on } \Sigma, \\ \lambda = \max(0, \lambda + c(u-\psi)) \quad \text{on } \Sigma \end{cases} \tag{3.1}$$

for any $c > 0$. Moreover, $p(0) = p_0$. Note that the last equation in (3.1) is equivalent to $\lambda \geq 0$, $u \leq \psi$, and $\lambda(u-\psi) = 0$. The equations in the last two lines of (3.1) are equivalent to

$$u = \min\left(\psi, -\frac{\kappa}{\beta}\frac{\partial p}{\partial n}\right).$$

The equations in the first two lines of (3.1) are understood in the sense of very weak solutions. The time derivative in $\partial_t p$ must first be interpreted in variational form, but from the third equation in (3.1) it immediately follows that $p \in L^2(H^2(\Omega)\cap H_0^1(\Omega))\cap H^1(L^2(\Omega))$. This is consistent with the regularity results for parabolic equations, since $G'(y) \in L^2(Q)$; see, e.g., [31, p. 342]. If G is convex, then (3.1) is a necessary and sufficient optimal condition for (P1).

We now turn to regularity properties of the optimal solution on Σ. This result is essential for superlinear convergence of the PDAS method; see section 4. Henceforth let (y,u,p,λ) denote a solution to (3.1). The active and inactive sets at a solution are denoted by

$$\mathcal{A} = \{\,(t,x)\in\Sigma\,:\,u(t,x) = \psi\,\}, \quad \mathcal{I} = \{\,(t,x)\in\Sigma\,:\,u(t,x) < \psi\,\}.$$

THEOREM 3.2. *On the inactive set $\mathcal{I}$ we have for the optimal solution $u|\mathcal{I} \in L^{q_n}(\mathcal{I})$ with*

$$q_n = \begin{cases} \frac{2(n+1)}{n} & \text{if } n \geq 3, \\ 3-\varepsilon & \text{if } n = 2. \end{cases} \tag{3.2}$$

On the active set the regularity of u is determined by ψ. Moreover,

$$\frac{\partial p}{\partial n} \in L^{q_n}(\Sigma) \quad \text{and} \quad \left\|\frac{\partial p}{\partial n}\right\|_{L^{q_n}(\Sigma)} \leq C\,\|p\|_{L^2(H^2(\Omega))\cap H^1(L^2(\Omega))}$$

with an embedding constant C.

Proof. As already noted, $p \in L^2(H^2(\Omega))\cap H^1(L^2(\Omega))$. This implies that

$$\frac{\partial p}{\partial n} \in L^2(H^{\frac12}(\partial\Omega))\cap H^{\frac14}(L^2(\partial\Omega));$$

see [21], or [31, Chapter II and p. 342]. Since $H^{\frac14}(L^2(\partial\Omega)) \hookrightarrow L^4(L^2(\partial\Omega))$ (see [1]), we find

$$\frac{\partial p}{\partial n} \in L^2(H^{\frac12}(\partial\Omega))\cap L^4(L^2(\partial\Omega)), \tag{3.3}$$

and hence interpolation [42, Chapter 1] implies that

$$\frac{\partial p}{\partial n} \in L^{r_s}([H^{\frac{1}{2}}(\partial\Omega), L^2(\partial\Omega)]_s), \quad \text{where } \frac{1}{r_s} = \frac{1-s}{2} + \frac{s}{4}.$$

For $n \geq 3$ we use the fact that for $H^{\frac{1}{2}}(\partial\Omega) \hookrightarrow L^{\frac{2n-2}{n-2}}(\partial\Omega)$, and we obtain

$$[H^{\frac{1}{2}}(\partial\Omega), L^2(\partial\Omega)]_s \hookrightarrow L^{q_s}(\partial\Omega), \quad \text{where } \frac{1}{q_s} = \frac{(1-s)(n-2)}{2n-2} + \frac{s}{2}.$$

Next we choose s such that $r_s = q_s$, i.e.,

$$r_s = \frac{8}{4-2s} = \frac{2n-2}{n+s-2} = q_s.$$

This implies that $s = \frac{2}{n+1}$ and hence $q_s = \frac{2(n+1)}{n}$. Consequently for $n \geq 3$ we obtain $\frac{\partial p}{\partial n} \in L^{\frac{2(n+1)}{n}}(\Sigma)$.

For $n = 2$ we have that $H^{\frac{1}{2}}(\partial\Omega) \hookrightarrow L^r(\partial\Omega)$ for all $r < \infty$. Using similar arguments to those before, we deduce that $\frac{\partial p}{\partial n} \in L^{3-\frac{1}{r-1}}(\Sigma)$.

From (3.1) we have that $\frac{\partial p}{\partial n} = -\beta u$ on $\mathcal{I}$, and the asserted regularity of u follows. The desired estimate for $\|\frac{\partial p}{\partial n}\|_{L^{q_n}(\Sigma)}$ holds due to the continuity of all embeddings involved. ∎

Our next objective is to show that for the optimal solution u the corresponding very weak solution y to the state equation is in fact a variational solution in the sense that $y \in L^2(H^1(\Omega)) \cap H^1(H^{-1}(\Omega))$, $y = u$ a.e. on Σ, and

$$\int_Q \partial_t y\, v\, dxdt = \int_Q (-\kappa \nabla y\, \nabla v - b \cdot \nabla y\, v + fv) dxdt$$

for all $v \in L^2(H^2(\Omega) \cap H_0^1(\Omega))$. This is important for numerical realizations which are conveniently based on this formulation. We shall require the following lemma, which uses the notion of uniform 1-smooth regularity property of the boundary, for which we refer to [1].

LEMMA 3.3. *Let D be a domain in $\mathbb{R}^n$, having the uniform 1-smooth regularity property and a bounded boundary, and let $s \in [0,1]$.*

(a) *If $v \in H^s(D)$, then $\max(0,v) \in H^s(D)$ and*

$$|\max(0,v)|_{H^s(D)} \leq |v|_{H^s(D)}.$$

(b) *If $v \in H^s(0,T;L^2(D))$, then $\max(0,v) \in H^s(0,T;L^2(D))$ and*

$$|\max(0,v)|_{H^s(0,T;L^2(D))} \leq |v|_{H^s(0,T;L^2(D))}.$$

Proof. (a) For $s = 0$ the claim is trivial and for $s = 1$ it is well known; see [42]. Thus let us consider the case $0 < s < 1$. Under the stated regularity properties for ∂D, the interpolation norm on $H^s(D)$ is equivalent to the intrinsic $H^s(D)$-norm on D given by

$$|v|^2_{L^2(D)} + \int_D \int_D \frac{|v(x) - v(y)|^2}{|x-y|^{n+2s}}\, dxdy; \tag{3.4}$$

see [1]. Let $S_i \subset D \times D$ be given by

$$S_1 = \{(x,y) : v(x) \geq 0,\, v(y) \geq 0\},\ S_2 = \{(x,y) : v(x) \geq 0,\, v(y) < 0\},$$
$$S_3 = \{(x,y) : v(x) < 0,\, v(y) \geq 0\},\ S_4 = \{(x,y) : v(x) < 0,\, v(y) < 0\}.$$

Then with $v^+ = \max(0, v)$

$$\int_D \int_D \frac{|v^+(x) - v^+(y)|^2}{|x-y|^{n+2s}}\, dxdy \le \int_{s_1 \cup s_2 \cup s_3} \int_{s_1 \cup s_2 \cup s_3} \frac{|v(x) - v(y)|^2}{|x-y|^{n+2s}}\, dxdy \le \int_D \int_D \frac{|v(x) - v(y)|^2}{|x-y|^{n+2s}}\, dxdy,$$

and (a) follows. Turning to (b), from [29, Theorem 1.7], it is known that for $s \in (0,1)$ up to equivalence of norms we have

$$|v|^2_{H^s(L^2(D))} = |v|^2_{L^2(L^2(D))} + 2\int_0^T \int_0^{T-t} t^{-1-2s} \, |v(\tau) - v(t+\tau)|^2_{L^2(D)} d\tau dt.$$

Setting $t + \tau = r$ the last term can equivalently be expressed as

$$\int_0^T \int_\tau^T |r-\tau|^{-1-2s} \, |v(\tau) - v(r)|^2 \, dr d\tau,$$

and using the symmetry of this expression with respect to s and τ, we find

$$|v|^2_{H^s(L^2(D))} = |v|^2_{L^2(L^2(D))} + \int_0^T \int_0^T \frac{|v(\tau) - v(r)|^2_{L^2(D)}}{|\tau - r|^{1+2s}}\, dr d\tau,$$

which is analogous to (3.4). The integral term can be expressed as

$$\int_0^T \int_0^T \int_\Omega \frac{|v(\tau, x) - v(r, x)|^2}{|\tau - r|^{1+2s}}\, dx\, dr\, d\tau,$$

and hence the proof can be completed as in (a). ∎

THEOREM 3.4. *Let (y, u) denote a solution to* (P1) *and assume that $\psi \in L^2(H^{\frac{1}{2}}(\partial\Omega)) \cap H^{\frac{1}{4}}(L^2(\partial\Omega))$. Then y is a variational solution of the state equation with*

$$u \in L^2(H^{\frac{1}{2}}(\partial\Omega)) \cap H^{\frac{1}{4}}(L^2(\partial\Omega)) \quad \text{and} \quad y \in L^2(H^1(\Omega)) \cap H^{\frac{1}{2}}(L^2(\Omega)) \cap H^1(H^{-1}(\Omega)).$$

If, moreover, $G'(y) \in L^2(H^1(\Omega)) \cap H^{\frac{1}{2}}(L^2(\Omega))$, $y_0 \in H^{\frac{1}{2}-\epsilon}(\Omega)$, and $\psi \in L^2(H^1(\partial\Omega)) \cap H^{\frac{1}{2}}(L^2(\partial\Omega))$, then

$$u \in L^2(H^1(\partial\Omega)) \cap H^{\frac{1}{2}}(L^2(\partial\Omega)) \quad \text{and} \quad y \in L^2(H^{\frac{3}{2}-\epsilon}(\Omega)) \cap H^{\frac{3-2\epsilon}{4}}(L^2(\Omega))$$

for every $\epsilon \in (0, \frac{1}{2}]$. In addition $u = 0$ on $\mathcal{I} \cap (\{T\} \times \partial\Omega)$.

Proof. From the proof of Theorem 3.2 we have that

$$\frac{\partial p}{\partial n} \in L^2(H^{\frac{1}{2}}(\partial\Omega)) \cap H^{\frac{1}{4}}(L^2(\partial\Omega)).$$

From (3.1) with $\beta = c$ we deduce that $u = \min(0, -\frac{1}{\beta}\frac{\partial p}{\partial n} - \psi) + \psi$, and hence Lemma 3.3 implies that $u \in L^2(H^{\frac{1}{2}}(\partial\Omega)) \cap H^{\frac{1}{4}}(L^2(\partial\Omega))$. By regularity results for parabolic equations based on interpolation theory [35, p. 78] (with $s = -\frac{1}{2}$), we obtain that $y \in L^2(H^1(\Omega)) \cap H^{\frac{1}{2}}(L^2(\Omega))$. Therefore

$$\int_0^T \langle \partial_t y, v\rangle \, dt = \int_Q (-\kappa \nabla y \, \nabla v - b \cdot \nabla y \, v + f v) dx dt$$

for all $v \in L^2(H^2(\Omega) \cap H_0^1(\Omega))$. Since the right-hand side can uniquely be extended to a continuous functional on $L^2(H_0^1(\Omega))$, it follows that $\partial_t y \in L^2(H^{-1}(\Omega))$. From (2.7), moreover, $y = u$ in $L^2(H^{\frac{1}{2}}(\partial\Omega))$. We conclude that y is a variational solution to (2.2).

If $G'(y) \in L^2(H^1(\Omega)) \cap H^{\frac{1}{2}}(L^2(\Omega))$, then $p \in L^2(H^3(\Omega)) \cap H^{\frac{3}{2}}(L^2(\Omega))$ [35, p. 32] (with $k = 1$). It follows that $\frac{\partial p}{\partial n} \in L^2(H^{\frac{3}{2}}(\partial\Omega)) \cap H^{\frac{3}{4}}(L^2(\partial\Omega))$; see, e.g., [20, p. 9]. Due to the regularity assumption on ψ and Lemma 3.3, we find that $u \in L^2(H^1(\partial\Omega)) \cap H^{\frac{1}{2}}(L^2(\partial\Omega))$. This implies that $y \in L^2(H^{\frac{3}{2}-\epsilon}(\Omega)) \cap H^{\frac{3}{4}-\frac{\epsilon}{2}}(L^2(\Omega))$ for every $\epsilon > 0$ [35, p. 78] (with $s = -\frac{1}{4} - \frac{\epsilon}{2}$). Regularity of p implies that $p(T) \in H^{2-\epsilon}(\Omega)$ and hence $\frac{\partial p}{\partial n}(T) \in H^{\frac{1}{2}-\epsilon}(\partial\Omega)$. Since $p(T) = 0$ on Ω we find that $\frac{\partial p}{\partial n}(T) = 0$ on $\partial\Omega$. Hence from the fifth equation in (3.1) we deduce that $u = 0$ on $\mathcal{I} \cap (\{T\} \times \partial\Omega)$. □

Remark 3.1. For $G(y) = \frac{1}{2}|y - y_d|^2$ the condition $G'(y) \in L^2(H^1(\Omega)) \cap H^{\frac{1}{2}}(L^2(\Omega))$ is satisfied if $y_d \in L^2(H^1(\Omega)) \cap H^{\frac{1}{2}}(L^2(\Omega))$ and $\psi \in L^2(H^{\frac{1}{2}}(\partial\Omega)) \cap H^{\frac{1}{4}}(L^2(\partial\Omega))$.

COROLLARY 3.5 (extra L^p regularity). *By interpolation one can show that if* $u \in L^2(H^1(\partial\Omega)) \cap H^{\frac{1}{2}}(L^2(\partial\Omega))$, *then* $u \in L^{q_\epsilon}(\Sigma)$, *where* $q_\epsilon = \frac{2(n+1)}{n-1} - \epsilon$, *for every* $\epsilon > 0$.

3.2. Problem (P2). We first derive the optimality system for (P2). This requires more care than for (P1) since G in this case is not defined on the space of trajectories $L^2(Q)$.

Let (y, u) denote an optimal solution to (P2). We shall require that $G'(y(T)) \in H_0^1(\Omega)$. This will guarantee the required regularity of the adjoint state. In case $G(y(T)) = \frac{1}{2}|y(T) - z|^2$, this is the case if $y(T) - z \in H_0^1(\Omega)$, i.e., we require regularity of $y(T)$ (and z) beyond that which is guaranteed by Corollary 2.2, as well as boundary conditions for $y(T) - z$. The required regularity of y at T can be achieved by restricting u to be a function of t only in a neighborhood of T. To take into consideration the additional boundary condition, we require that $u = 0$ in a neighborhood of $T = 0$. Then by semigroup theory $y(T) \in H_0^1(\Omega) \cap H^2(\Omega)$ and, if $z \in H_0^1(\Omega)$, we have $y(T) - z \in H_0^1(\Omega)$. Thus for tracking-type functionals the requirement that $G'(y(T)) \in H_0^1(\Omega)$ holds if $u \in L^2_{T_1}(\Sigma)$ and $z \in H_0^1(\Omega)$. This motivates the use of $L^2_{T_1}(\Sigma)$ in (P2).

THEOREM 3.6. *Let* (y, u) *denote a solution to* (P2) *with* $T_1 < T$ *and assume that* $G'(y(T)) \in H_0^1(\Omega)$. *Then there exist* $p \in L^2(H^2(\Omega) \cap H_0^1(\Omega)) \cap H^1(L^2(\Omega))$ *and* $\lambda \in L^2(\Sigma_{T_1})$ *such that for all* $c > 0$

$$
\text{(3.5)} \qquad \begin{cases} \partial_t y - \kappa\Delta y + b \cdot \nabla y = f \quad \text{in } Q, \\ y = u \quad \text{on } \Sigma, \quad y = y_0 \quad \text{in } \Omega, \\ -\partial_t p - \kappa\Delta p - \operatorname{div} b\, p - b \cdot \nabla p = 0 \quad \text{in } Q, \\ p = 0 \quad \text{on } \Sigma, \quad p(T) = -G'(y(T)) \quad \text{in } \Omega, \\ \kappa \frac{\partial p}{\partial n} + \beta u + \lambda = 0 \quad \text{on } \Sigma_{T_1}, \\ \lambda = \max(0, \lambda + c(u - \psi)) + \min(0, \lambda + c(u - \varphi)) \quad \text{on } \Sigma_{T_1} \end{cases}
$$

holds, where $\Sigma_{T_1} = (0, T_1) \times \partial\Omega$.

Proof. From Theorem 2.1 the affine mapping $u \to y(u)$ is continuous from $L^2(\Sigma)$ to $L^2(Q) \cap H^1(H^{-2}(\Omega))$. The linearization $\dot{y}$ at u in direction h satisfies

$$
\text{(3.6)} \quad \langle \partial_t \dot{y}(t),\, v\rangle - \kappa(\dot{y}(t),\, \Delta v) - (\dot{y}(t),\, \operatorname{div}(b(t))v) - (\dot{y}(t),\, b(t)\nabla v) = \kappa \left(h(t), \frac{\partial}{\partial n} v \right)_{\partial\Omega} \quad \text{for all } v \in H^2(\Omega) \cap H_0^1(\Omega) \text{ and a.e. } t \in (0, T).
$$

Moreover, by Corollary 2.2, the affine mapping $u \to y(T;u)$ is continuous from $L^\infty(\Sigma)$ to $L^2(\Omega)$, and hence it is differentiable at u in directions $h \in L^\infty(\Sigma)$. By assumption, $G'(y(T)) \in H_0^1(\Omega))$, and hence the solution to the adjoint equation satisfies $p \in L^2(H^2(\Omega) \cap H_0^1(\Omega)) \cap H^1(L^2(\Omega))$ [31]. Let $j(u) = J(y(u),u)$ denote the reduced cost functional corresponding to (P2). For the derivative at $u \in L^\infty(\Sigma)$ in direction $h \in L^2(\Sigma)$ we obtain by (3.6)

$$\begin{aligned}(j'(u),h)_{L^2(\Sigma)} &= (G'(y(T)),\, \dot y(T))_{L^2(\Omega)} + \beta(u,h)_{L^2(\Sigma)} \\ &= -(p(T),\, \dot y(T))_{L^2(\Omega)} + \beta(u,h)_{L^2(\Sigma)} = -\int_0^T \frac{d}{dt}(p(t),\dot y(t))_{L^2(\Omega)}dt + \beta(u,h)_{L^2(\Sigma)} \\ &= \left(\kappa\frac{\partial p}{\partial n} + \beta u,\, h\right)_{L^2(\Sigma)}.\end{aligned}$$

At the solution we therefore have

$$(j'(u),\, h-u) \geq 0 \quad \text{for all } \ h \in L^2_{T_1}(\Sigma), \ \text{with } \ \varphi \leq h \leq \psi. \tag{3.7}$$

Note that the directions h in (3.7) are in $L^\infty_{T_1}(\Sigma)$ as well. Define

$$\mathcal{A}_\varphi = \{(t,x) \in \Sigma_{T_1} : u = \varphi\}, \quad \mathcal{A}_\psi = \{(t,x) \in \Sigma_{T_1} : u = \psi\}, \quad \mathcal{I} = \Sigma_{T_1} \setminus (\mathcal{A}_\varphi \cup \mathcal{A}_\psi),$$

where $\Sigma_1 = (0,T_1)\times\partial\Omega$. Set $\mathcal{S} = \{(t,x) \in \mathcal{I} : j'(u) \geq 0\}$ and define $\bar h = \varphi\,\chi_{\mathcal{S}} + u\,\chi_{\Sigma\setminus\mathcal{S}}$, which satisfies $\varphi \leq \bar h \leq \psi$ on Σ_{T_1}. By (3.7)

$$0 \leq (j'(u),\, \bar h - u)_{L^2(\Sigma_{T_1})} = (j'(u),\, \varphi - u)_{L^2(\mathcal{S})} \leq 0,$$

and hence $j'(u) = 0$ on $\mathcal{S}$, since $\varphi < u < \psi$ on $\mathcal{S}$. Analogously one shows that $j'(u) = 0$ on $\{(t,x) \in \mathcal{I} : j'(u) \leq 0\}$ and hence $j'(u) = 0$ on $\mathcal{I}$. Next set $\mathcal{S}_\psi = \{(t,x) \in \mathcal{A}_\psi : j'(u) \geq 0\}$, and define $\bar h = \varphi\,\chi_{\mathcal{S}_\psi} + u\,\chi_{\Sigma\,\setminus\,\mathcal{S}_\psi}$. Then by (3.7)

$$0 \leq (j'(u),\, \bar h - u)_{L^2(\Sigma_{T_1})} = (j'(u),\, \varphi - \psi)_{L^2(\Sigma_{T_1})} \leq 0.$$

Since $\varphi < \psi$ a.e. on Σ_{T_1} this implies that $j'(u) = 0$ on $\mathcal{S}_\psi$ and hence $j'(u) \leq 0$ on $\mathcal{A}_\psi$. Analogously one shows that $j'(u) \geq 0$ on $\mathcal{A}_\varphi$.

Setting

$$\lambda = \begin{cases} -\kappa\frac{\partial p}{\partial n} - \beta u & \text{on } \ \Sigma_{T_1} \setminus \mathcal{I}, \\ 0 & \text{on } \ \mathcal{I}, \end{cases}$$

the last two equations of (3.5) follow and the optimality system is verified. □

COROLLARY 3.7. *Under the assumptions of Theorem* 3.4 *we have* $\frac{\partial p}{\partial n} \in L^{q_n}(\Sigma)$ *and* $u|\mathcal{I} \in L^{q_n}(\mathcal{I})$ *with* q_n *defined in* (3.2).

This is a direct consequence of Theorem 3.6, which asserts that $p \in L^2(H^2(\Omega)) \cap H^1(L^2(\Omega))$, and of the proof of Theorem 3.2.

COROLLARY 3.8. *Under the assumptions of Theorem* 3.6 *and if* $\varphi,\psi \in L^2(H^{\frac12}(\partial\Omega)) \cap H^{\frac14}(L^2(\partial\Omega))$, *then* y *is a variational solution of the state equation with*

$$u \in L^2(H^{\frac12}(\partial\Omega)) \cap H^{\frac14}(L^2(\partial\Omega)) \ \ \textit{and} \ \ y \in L^2(H^1(\Omega)) \cap H^{\frac12}(L^2(\Omega)) \cap H^1(H^{-1}(\Omega)).$$

If, moreover, $G'(y(T)) \in H^2(\Omega)\cap H_0^1(\Omega)$, $y_0 \in H^{\frac12-\epsilon}(\Omega)$, *and* $\varphi,\psi \in L^2(H^1(\partial\Omega))\cap H^{\frac12}(L^2(\partial\Omega))$, *then*

$$u \in L^2(H^1(\partial\Omega)) \cap H^{\frac{1-\varepsilon}{2}}(L^2(\partial\Omega)) \ \ \textit{and} \ \ y \in L^2(H^{\frac32-\epsilon}(\Omega)) \cap H^{\frac{3-2\epsilon}{4}}(L^2(\Omega))$$

for every $\epsilon \in (0, \frac{1}{2}]$.

Proof. The proof of the first part is similar to that of Theorem 3.4. By the last two equations of (3.5) we find

$$u = \max\left(\varphi, \min\left(\psi, -\frac{\kappa}{\beta}\frac{\partial p}{\partial n}\right)\right) \quad \text{a.e. on } \Sigma_{T_1}, \tag{3.8}$$

which is equivalent to $u = \max(0, \min(0, -\frac{\kappa}{\beta}\frac{\partial p}{\partial n} - \psi) + \psi - \varphi) + \varphi$. Since $\frac{\partial p}{\partial n} \in L^2(H^{\frac{1}{2}}(\partial\Omega)) \cap H^{\frac{1}{4}}(L^2(\partial\Omega))$ this implies by Lemma 3.3 that

$$u|(0,T_1) \in L^2(0,T_1; H^{\frac{1}{2}}(\partial\Omega)) \cap H^{\frac{1}{4}}(0,T_1; L^2(\partial\Omega)),$$

and by concatenation of functions in $H^{\frac{1}{4}}$ this implies that

$$u \in L^2(0,T; H^{\frac{1}{2}}(\partial\Omega)) \cap H^{\frac{1}{4}}(0,T; L^2(\partial\Omega))$$

(see [29, Proposition 1.13]), and hence $y \in L^2(H^1(\Omega)) \cap H^{\frac{1}{2}}(L^2(\Omega))$. Turning to the second part of the proof, we assume that $G'(y(T)) \in H^2(\Omega) \cap H_0^1(\Omega)$. Then $p \in L^2(H^3(\Omega)) \cap H^{\frac{3}{2}}(L^2(\Omega))$ [35, p. 32], and $\frac{\partial p}{\partial n} \in L^2(H^{\frac{3}{2}}(\partial\Omega)) \cap H^{\frac{3}{4}}(L^2(\partial\Omega))$. By (3.8) and concatenation of H^s-functions with $s \in [0, \frac{1}{2})$, we find that $u \in L^2(H^1(\partial\Omega)) \cap H^{\frac{1-\varepsilon}{2}}(L^2(\partial\Omega))$ for every $\varepsilon \in (0,1)$. This implies that $y \in L^2(H^{\frac{3}{2}-\varepsilon}(\Omega)) \cap H^{\frac{3-2\varepsilon}{4}}(L^2(\Omega))$. ∎

4. The PDAS strategy and its convergence properties. The PDAS strategy has proved to be very efficient for solving constrained optimal control problems [8]. We describe it here for (P1) and defer the necessary modifications for (P2) to Remark 4.3.

In addition to the assumptions on $G : L^2(Q) \to \mathbb{R}$ made in section 3, we assume that G is convex so that all auxiliary optimal control problems that arise in this section have unique solutions.

The PDAS strategy is an iterative algorithm which, based on the current iterate (u_k, λ_k), defines the active set

$$\mathcal{A}_k = \{\, x \in \Omega \,:\, \lambda_k(x) + c(u_k - \psi)(x) > 0 \,\}$$

and the inactive set

$$\mathcal{I}_k = \Omega \setminus \mathcal{A}_k.$$

The subsequent step consists in solving the optimal control problem with equality constraints only:

$$(\mathrm{P_k}) \qquad \begin{cases} \min & J(y,u) = G(y) + \frac{\beta}{2}|u|^2_{L^2(\Sigma)} \\ \text{over} & (y,u) \in L^2(Q) \times L^2(\Sigma) \\ \text{subject to} & (2.1) \ \text{ and } u = \psi \ \text{ on } \mathcal{A}_k. \end{cases}$$

This leads to the following iterative algorithm, in which step (iii) is the necessary and sufficient optimality condition for (P_k).

PDAS ALGORITHM.

(i) Choose $(u_1, \lambda_1) \in L^2(\Sigma) \times L^2(\Sigma),\ c > 0$.

(ii) Define $\mathcal{A}_k = \{\, x \in \Omega \,:\, \lambda_k(x) + c(u_k - \psi)(x) > 0 \,\},\ \mathcal{I}_k = \Omega \setminus \mathcal{A}_k$.

(iii) Solve for $(y_{k+1}, u_{k+1}, p_{k+1}) \in L^2(Q) \cap H^1(H^{-2}(\Omega)) \cap C(H^{-1}(\Omega)) \times L^2(\Sigma) \times L^2(H^2(\Omega) \cap H_0^1(\Omega))$:

$$\text{(4.1)} \qquad \begin{cases} \partial_t y - \kappa \Delta y + b \cdot \nabla y = f \quad \text{in } Q, \\ y = u \quad \text{on } \Sigma, \quad y(0) = y_0 \quad \text{in } \Omega, \\ -\partial_t p - \kappa \Delta p - \operatorname{div} b\, p - b \cdot \nabla p = -G'(y) \quad \text{in } Q, \\ p = 0 \quad \text{on } \Sigma, \quad p(T) = 0 \quad \text{in } \Omega, \\ u = \psi \text{ on } \mathcal{A}_k, \quad \kappa \frac{\partial p}{\partial n} + \beta u = 0 \text{ on } \mathcal{I}_k. \end{cases}$$

(iv) Set

$$\lambda_{k+1} = \begin{cases} 0 & \text{on } \mathcal{I}_k, \\ -\kappa \frac{\partial p_{k+1}}{\partial n} - \beta \psi & \text{on } \mathcal{A}_k. \end{cases}$$

(v) Stop or return to (ii).

Remark 4.1. For practical features of this algorithm, we refer to [8] and [9], for example. Here, we mention only that

1. for $k \geq 2$ the iterates of the algorithm are independent of the choice of c, and
2. if the algorithm finds two successive active sets, for which $\mathcal{A}_k = \mathcal{A}_{k+1}$, then $(y(u_k), u_k)$ is the solution of the problem.

The latter will be used as a stopping criterion for numerical examples in section 6.

Remark 4.2. The equality-constrained optimization problem (P_k) is solved using the Newton method for the reduced cost functional $j(u) = G(y(u)) + \frac{\beta}{2} |u|^2_{L^2(\Sigma)}$. The required first and second derivatives of j are computed using solutions of the adjoint problems; see, e.g., [3]. In section 5 we describe the computation of these derivatives on the discrete level.

For the following result it will be convenient to choose a specific initialization for λ, given by

$$\text{(4.2)} \qquad \begin{cases} \text{choose} & u_1 \in L^2(\Sigma), \\ \text{set} & \lambda_1 = -\kappa \frac{\partial p(u_1)}{\partial n} - \beta u_1, \\ \text{and set} & c = \beta \text{ for the first iteration.} \end{cases}$$

THEOREM 4.1. *If the PDAS algorithm is initialized by* (4.2)*, and if further* $\psi \in L^{\frac{2(n+1)}{n}}(\Sigma)$, $G' : L^2(Q) \to L^2(Q)$ *is locally Lipschitz, and* $|u_1 - u^*|_{L^2(\Sigma)}$ *is sufficiently small, then the iterates* $(y_k, u_k, p_k, \lambda_k)$ *converge superlinearly in* $L^2(Q) \cap H^1(H^{-2}(\Omega)) \cap C(H^{-1}(\Omega)) \times L^2(\Sigma) \times L^2(H^2(\Omega) \cap H_0^1(\Omega)) \times L^2(\Sigma)$ *to* $(y^*, u^*, p^*, \lambda^*)$.

Proof. Let us consider λ in the last equation of (3.1) as a function of u. Then (3.1) can equivalently be expressed as

$$\text{(4.3)} \qquad F(u) = \lambda(u) - \max(0, \lambda(u) + \beta(u - \psi)) = 0, \text{ where } F : L^2(\Sigma) \to L^2(\Sigma).$$

Note that (4.3) is equivalent to

$$\text{(4.4)} \qquad F(u) = \beta u - \beta \psi + \max\left(0, \kappa \frac{\partial p}{\partial n} + \beta \psi\right) = 0,$$

due to the fifth equation in (3.1). By Theorem 3.2 and the assumption that $\psi \in L^{\frac{2(n+1)}{n}}(\Sigma)$ we have that $\kappa\frac{\partial p}{\partial n} + \beta\psi \in L^{q_n}(\Sigma)$ with q_n defined in (3.2). Due to the fact that $q_n > 2$ we obtain that

$$u \to F(u)$$

is Newton differentiable, as introduced in Definition 1 of [25] (see Proposition 4.1 of [25]), with the generalized derivate of F at u in direction $h \in L^2(\Sigma)$ given by

$$G_F(u)h = \beta h + G_{\max}\left(\kappa\frac{\partial p}{\partial n} + \beta\psi\right)\frac{\partial p(h)}{\partial n},$$

where

$$G_{\max}(u)(x) = \begin{cases} 1 & \text{if } u(x) > 0, \\ 0 & \text{if } u(x) \le 0. \end{cases}$$

It was proved in general terms in [25, Theorem 4.1] that $G_F(u)$ has a bounded inverse from $L^2(\Sigma)$ to itself for every $u \in L^2(\Sigma)$. Hence it follows that the semismooth Newton algorithm applied to $F(u) = 0$ is locally superlinearly convergent. The semismooth Newton iteration consists of the iteration

$$\begin{cases} G_F(u_\kappa)\delta u = -F(u_\kappa), \\ u_{k+1} = u_k + \delta u. \end{cases} \tag{4.5}$$

In the following arguments we show that the semismooth Newton iteration and the PDAS strategy coincide. In principle this argument can be extracted from [25], but we believe that it is instructive to carry it out for the present case. A short consideration shows that a semismooth Newton step (4.5) is equivalent to

$$\begin{cases} \partial_t y_{k+1} - \kappa\Delta y_{k+1} + b\cdot\nabla y_{k+1} = f \quad \text{in } Q, \\ y_{k+1} = u_{k+1} \quad \text{on } \Sigma,\ y(0) = y_0 \quad \text{in } \Omega, \\ -\partial_t p_{k+1} - \kappa\Delta p_{k+1} - \operatorname{div} b\, p_{k+1} - b\cdot\nabla p_{k+1} = -G'(y_{k+1}) \quad \text{in } Q, \\ p_{k+1} = 0 \quad \text{on } \Sigma, \quad p_{k+1}(T) = 0 \quad \text{in } \Omega, \\ u_{k+1} = \psi \quad \text{on } \mathcal{A}_k^{SN},\ \kappa\frac{\partial p_{k+1}}{\partial n} + \beta u_{k+1} = 0 \quad \text{on } \mathcal{I}_k^{SN}, \end{cases} \tag{4.6}$$

where

$$\mathcal{A}_k^{SN} = \left\{x : \left(-\kappa\frac{\partial p_k}{\partial n} - \beta\psi\right)(x) > 0\right\}, \qquad \mathcal{I}_k^{SN} = \Omega \setminus \mathcal{A}_k^{SN}.$$

We further set

$$\lambda_{k+1} = \begin{cases} 0 & \text{on } \mathcal{I}_k^{SN}, \\ -\kappa\frac{\partial p_{k+1}}{\partial n} - \beta\psi & \text{on } \mathcal{A}_k^{SN} \end{cases} \tag{4.7}$$

and observe that

$$\lambda_k + \beta(u_k - \psi) = -\kappa\frac{\partial p_{k+1}}{\partial n} - \beta\psi \quad \text{for } k = 2, 3, \dots. \tag{4.8}$$

Note that

$$\lambda_k(u_k - \psi) = 0 \quad \text{for } k = 2, 3, \dots. \tag{4.9}$$

Hence $\lambda_k + \beta(u_k - \psi) > 0$ if and only if $\lambda_k + c(u_k - \psi) > 0$ for any $c > 0$. From (4.8) we have that

$$\mathcal{A}_k = \mathcal{A}_k^{SN} \quad \text{and} \quad \mathcal{I}_k = \mathcal{I}_k^{SN} \quad \text{for } k = 2, 3, \dots.$$

Therefore the PDAS strategy and the semismooth Newton iteration coincide, provided that their initialization phases coincide. For that it suffices to check that $\mathcal{A}_1 = \mathcal{A}_1^{SN}$. This is the case since for λ_1 as in (4.2) we have

$$\lambda_1 + \beta(u_1 - \psi) = -\kappa \frac{\partial p(u_1)}{\partial n} - \beta\psi_1.$$

Superlinear convergence of y_k to y^* in $L^2(Q) \cap H^1(H^{-2}(\Omega)) \cap C(H^{-1}(\Omega))$ follows from Theorem 2.1. Moreover, superlinear convergence of (p_k, λ_k) to (p^*, λ^*) in $L^2(H^2(\Omega) \cap H_0^1(\Omega)) \times L^2(\Sigma)$ is a consequence of (3.1) and (4.1),

$$\lambda^* - \lambda_k = -\beta(u^* - u_k) - \kappa \left(\frac{\partial p^*}{\partial n} - \frac{\partial p_k}{\partial n} \right),$$

and of Theorem 3.1. ∎

In Theorem 4.1 we addressed local convergence of the PDAS algorithm. We now turn to global convergence, i.e., to convergence from arbitrary initializations $(u_1, \lambda_1) \in L^2(\Sigma) \times L^2(\Sigma)$.

THEOREM 4.2. *If β is sufficiently large and $G(y) = \frac{1}{2}|y - z|^2_{L^2(Q)}$ for some $z \in L^2(Q)$, then the iterates $(y_k, u_k, p_k, \lambda_k) \to (y^*, u^*, p^*, \lambda^*)$ in $L^2(Q) \cap H^1(H^{-2}(\Omega)) \cap C(H^{-1}(\Omega)) \times L^2(\Sigma) \times L^2(H^2(\Omega) \cap H_0^1(\Omega)) \times L^2(\Sigma)$.*

Proof. Convergence of $(u_k, \lambda_k) \to (u^*, \lambda^*)$ in $L^2(\Sigma) \times L^2(\Sigma)$ follows from a general result in [27, Theorem 4.1]. It requires that $\beta > \|T\|_{\mathcal{L}(L^2(\Sigma), L^2(Q))}$, where $Tu = y(u)$. Convergence of (y_k, u_k) in the specified norms is a consequence of the governing equations for y_k and p_k. ∎

Remark 4.3. For (P2), under the assumptions of Theorem 3.6, identical assertions to Theorems 4.1 and 4.2 hold. (P2) differs from (P1) in that it involves a terminal observation and bilateral constraints. We again have, provided by Corollary 3.7, the necessary additional regularity $\frac{\partial p}{\partial n} \in L^{q_n}(\Sigma)$. Global convergence and local superlinear convergence for bilaterally constrained problems were treated in [27, Theorems 4.1 and 6.1].

5. Finite element discretization. In this section we discuss the space-time finite element discretization of the optimization problem under consideration. The space discretization of the state equation is based on the usual H^1-conforming finite elements, whereas the time discretization is done by a discontinuous Galerkin method as proposed in [16, 17]. We refer to [3, 38] for a detailed description of the space-time finite element methods for parabolic optimization problems including adaptivity. We emphasize that space-time Galerkin discretizations of optimal control problems allow a natural translation of the optimality system and the optimization algorithms from the continuous to the discrete level: in fact, the approaches "discretize-then-optimize" and "optimize-then-discretize" coincide. We return to this aspect in Remark 6.2 below.

Since the state equation (2.2) is considered in the very weak sense, it may appear at first that its approximation by finite elements based on the standard variational

formulation may not be appropriate. However, such an approach is justified since the optimal state and control which need to be approximated possess the common regularity of a variational solution; see Theorem 3.4. For an interesting discussion of finite element discretizations of equations with rough boundary data, we refer to [7] in the elliptic case and to [19] in the parabolic case. Finite element approximation of Dirichlet optimal control problems governed by elliptic equations are discussed in [11, 43].

For this section it is convenient to introduce the following notation: $V = H^1(\Omega)$, $V_0 = H_0^1(\Omega)$, $H = L^2(\Omega)$, and $X = L^2(0,T;V) \cap H^1(0,T;V^*)$. We introduce a bilinear form $a\colon X \times X \to \mathbb{R}$ corresponding to the standard variational formulation of the state equation:

$$a(y,v) = \int_0^T \{(\partial_t y, v) + \kappa(\nabla y, \nabla v) + (b \cdot \nabla y, v)\}\, dt\,.$$

To define the discretization in time, let us partition the time interval $\bar{I} = [0,T]$ as

$$\bar{I} = \{0\} \cup I_1 \cup I_2 \cup \cdots \cup I_M$$

with subintervals $I_m = (t_{m-1}, t_m]$ of size k_m and time points

$$0 = t_0 < t_1 < \cdots < t_{M-1} < t_M = T.$$

We define the discretization parameter k as a piecewise constant function by setting $k|_{I_m} = k_m$ for $m = 1, \ldots, M$.

By means of the subintervals I_m, we define for $r \in \mathbb{N}_0$ a semidiscrete space X_k^r consisting of discontinuous-in-time piecewise polynomial functions:

$$X_k^r = \{\, v_k \in L^2(I, V_0) : v_k\big|_{I_m} \in \mathcal{P}^r(I_m, V_0) \text{ and } v_k(0) \in H \,\}\,.$$

Here, $\mathcal{P}^r(I_m, V_0)$ denotes the space of polynomials up to order r defined on I_m with values in V_0. For the definition of the discontinuous Galerkin method we introduce the following notation for a function $v_k \in X_k^r$:

$$v_{k,m}^+ := \lim_{t \to 0^+} v_k(t_m + t), \quad v_{k,m}^- := \lim_{t \to 0^+} v_k(t_m - t) = v_k(t_m), \quad [v_k]_m := v_{k,m}^+ - v_{k,m}^-\,.$$

Using this notation we define a discretized version of the bilinear form a:

$$a_k(y_k, v_k) = \sum_{m=1}^{M} \int_{I_m} \{(\partial_t y_k, v_k) + \kappa(\nabla y_k, \nabla v_k) + (b \cdot \nabla y_k, v_k)\}\, dt + \sum_{m=0}^{M-1} ([y_k]_{m-1}, v_{k,m-1}^+) + (y_{k,0}^-, v_{k,0}^-)\,.$$

For the space discretization, we consider two- or three-dimensional shape-regular meshes; see, e.g., [12]. A mesh consists of quadrilateral or hexahedral cells K, which constitute a nonoverlapping cover of the computational domain Ω. The corresponding mesh is denoted by $\mathcal{T}_h = \{K\}$, where we define the discretization parameter h as a cellwise constant function by setting $h\big|_K = h_K$ with the diameter h_K of the cell K.

On the mesh $\mathcal{T}_h$ we construct a conforming finite element space $V_h \subset V$ in a standard way:

$$V_h^s = \{\, v \in V : v\big|_K \in \mathcal{Q}^s(K) \text{ for } K \in \mathcal{T}_h \,\}.$$

Here, $\mathcal{Q}^s(K)$ consists of shape functions obtained via bi- or trilinear transformations of polynomials in $\widehat{\mathcal{Q}^s}(\widehat{K})$ defined on the reference cell $\widehat{K} = (0,1)^n$, where

$$\widehat{\mathcal{Q}^s}(\widehat{K}) = \operatorname{span}\left\{ \prod_{j=1}^{n} x_j^{k_j} :\ k_j \in \mathbb{N}_0,\ k_j \le s \right\}.$$

Remark 5.1. The definition of V_h^s can be extended to the case of triangular meshes in the obvious way.

The discrete space with homogeneous Dirichlet boundary conditions is denoted by $V_{h,0}^s = V_h^s \cap H_0^1(\Omega)$. Moreover, we introduce the space of traces of function in V_h^s:

$$W_h^s = \{\, w_h \in H^{1/2}(\partial\Omega) : w_h = \gamma(v_h), v_h \in V_h^s \,\},$$

where $\gamma\colon H^1(\Omega) \to H^{1/2}(\partial\Omega)$ is the trace operator.

With these preliminaries, we define the discrete spaces for the control and state variables:

$$X_{k,h}^{r,s} = \{\, v_{kh} \in L^2(I, V_{h,0}^s) : v_{kh}\big|_{I_m} \in \mathcal{P}^r(I_m, V_{h,0}^s) \text{ and } v_{kh}(0) \in V_h^s \,\} \subset X_k^r,$$
$$U_{k,h}^{r,s} = \{\, u_{kh} \in L^2(I, W_h^s) : u_{kh}\big|_{I_m} \in \mathcal{P}^r(I_m, W_h^s) \,\}.$$

Remark 5.2. In the above definition of the discrete spaces $X_{k,h}^{r,s}$ and $U_{k,h}^{r,s}$, we assumed that the spatial discretization is fixed for all time intervals. However, in many situations the use of different meshes $\mathcal{T}_h^m$ for each of the subintervals I_m is required for efficient adaptive discretizations. The consideration of such dynamically changing meshes can be included in the above definitions in a natural way [41].

For a function $u_{kh} \in U_{k,h}^{r,s}$ we define an extension $\widehat{u}_{kh} \in X_{k,h}^{r,s}$ such that

$$\gamma(\widehat{u}_{kh}(t,\cdot)) = u_{kh}(t,\cdot) \ \text{ and } \ \widehat{u}_{kh}(t,x_i) = 0 \ \text{ on all interior nodes } x_i \text{ of } \mathcal{T}_h. \tag{5.1}$$

The optimization problem on the discrete level is then formulated as follows:

$$\min J(y_{kh}, u_{kh}), \quad u_{kh} \in U_{k,h}^{r,s} \cap U_{ad} \tag{5.2}$$

subject to

$$y_{kh} \in \widehat{u}_{kh} + X_{k,h}^{r,s}, \quad a_k(y_{kh}, v_{kh}) = \int_0^T (f, v_{kh})\, dt + (y_0, v_{kh,0}^-) \quad \text{for all } v_{kh} \in X_{k,h}^{r,s}. \tag{5.3}$$

The discrete state equation (5.3) defines a discrete solution operator S_{kh} which maps a given discrete control u_{kh} to the (unique) solution of (5.3). As on the continuous level we introduce a discrete reduced cost functional

$$j_{kh}(u_{kh}) = J(S_{kh}(u_{kh}), u_{kh}). \tag{5.4}$$

The discrete optimization problem (5.2)–(5.3) is solved by the PDAS strategy described in the previous section. In each step an equality-constrained optimization

problem is solved by the Newton method for the discrete reduced cost functional j_{kh}; see Remark 4.2. For the realization of the Newton method, we need representations of the first and second directional derivatives of j_{kh}.

PROPOSITION 5.1. *Let the discrete reduced cost functional j_{kh} be defined as in* (5.4). *Then the following hold:*

(a) *The first directional derivative in direction $\delta u_{kh} \in U_{k,h}^{r,s}$ can be expressed as*

$$j'_{kh}(u_{kh})(\delta u_{kh}) = J'_y(y_{kh}, u_{kh})(\widehat{\delta u}_{kh}) - a_k(\widehat{\delta u}_{kh}, p_{kh}) + J'_u(y_{kh}, u_{kh})(\delta u_{kh}), \tag{5.5}$$

where $y_{kh} = S_{kh}(u_{kh})$, the extension $\widehat{\delta u}_{kh}$ is defined in (5.1), *and $p_{kh} \in X_{k,h}^{r,s}$ is the solution of the discrete adjoint equation*

$$a_k(v_{kh}, p_{kh}) = J'_y(y_{kh}, u_{kh})(v_{kh}) \quad \text{for all } v_{kh} \in X_{k,h}^{r,s}. \tag{5.6}$$

(b) *The second derivatives of j_{kh} in directions $\delta u_{kh}, \tau u_{kh} \in U_{k,h}^{r,s}$ can be expressed as*

$$\begin{aligned} j''_{kh}(u_{kh})(\delta u_{kh}, \tau u_{kh}) = J''_{yy}(y_{kh}, u_{kh})(\delta y_{kh}, \widehat{\tau u}_{kh}) - a_k(\widehat{\tau u}_{kh}, \delta p_{kh}) \\ + J''_{uu}(y_{kh}, u_{kh})(\delta u_{kh}, \tau u_{kh}), \end{aligned} \tag{5.7}$$

where δy_{kh} is the solution of the discrete tangent equation

$$\delta y_{kh} \in \widehat{\delta u}_{kh} + X_{k,h}^{r,s} \ : \ a_k(\delta y_{kh}, v_{kh}) = 0 \quad \text{for all } v_{kh} \in X_{k,h}^{r,s}\,, \tag{5.8}$$

$\delta p_{kh} \in X_{k,h}^{r,s}$ is given by

$$a_k(v_{kh}, \delta p_{kh}) = J''_{yy}(y_{kh}, u_{kh})(\delta y_{kh}, v_{kh}) \quad \text{for all } v_{kh} \in X_{k,h}^{r,s}\,, \tag{5.9}$$

and $\widehat{\delta u}_{kh}, \widehat{\tau u}_{kh}$ are the extensions of $\delta u_{kh}, \tau u_{kh}$ defined as in (5.1).

Proof. Using the solution $\delta y_{kh} = S'_{kh}(u_{kh})(\delta u_{kh})$ of the discretized tangent equation (5.8), we obtain

$$j'_{kh}(u_{kh})(\delta u_{kh}) = J'_y(y_{kh}, u_{kh})(\delta y_{kh}) + J'_u(y_{kh}, u_{kh})(\delta u_{kh}).$$

We rewrite the first term using (5.8) and (5.6):

$$\begin{aligned} &J'_y(y_{kh}, u_{kh})(\delta y_{kh}) = J'_y(y_{kh}, u_{kh})(\delta y_{kh} - \widehat{\delta u}_{kh}) + J'_y(y_{kh}, u_{kh})(\widehat{\delta u}_{kh}) \\ &= a_k(\delta y_{kh} - \widehat{\delta u}_{kh}, p_{kh}) + J'_y(y_{kh}, u_{kh})(\widehat{\delta u}_{kh}) = -a_k(\widehat{\delta u}_{kh}, p_{kh}) + J'_y(y_{kh}, u_{kh})(\widehat{\delta u}_{kh}). \end{aligned}$$

This gives the desired representation (5.5). The representation of the second derivatives is obtained in a similar way. ∎

Remark 5.3. On the continuous level, similar representations of the derivatives hold. They can be equivalently expressed using the normal derivatives of the adjoint state on the boundary; see (3.1). A direct discretization of the representation involving normal fluxes is in general not equivalent to (5.5) and would not lead to the exact representation of the derivatives of j_{kh} due to the lack of appropriate formulas for integration by parts of the discretized solutions.

Remark 5.4. In the convection dominated case, i.e., if $|b| \gg \kappa$, the finite element discretization may lead to strongly oscillatory solutions. Several stabilization methods are known to improve the approximation properties of the pure Galerkin discretization and to reduce the oscillatory behavior; see, e.g., [10, 22, 28, 39, 40]. For the stabilized finite elements in the context of stationary optimal control problems, we refer the reader to [13, 4].

6. Numerical examples. In this section we discuss numerical examples illustrating our results and give some details on the numerical realization.

Due to the fact that the trial and the test spaces in the formulation of the discrete state equation (5.3) are discontinuous in time, this formulation results in a time stepping scheme. In our numerical realization we use bilinear finite elements for the space discretization and piecewise constant functions in time resulting in spaces $X_{k,h}^{0,1}$ and $U_{k,h}^{0,1}$. In the following we describe the state equation (5.3), the adjoint equation (5.6), equations (5.8) and (5.9), and the evaluation of the derivatives of the discrete reduced cost functional for this choice of discretization. We define

$$U_m = u_{kh}\big|_{I_m},\ Y_m = y_{kh}\big|_{I_m},\ P_m = p_{kh}\big|_{I_m}, \quad i = 1, \dots, M,$$

$$Y_0 = y_{kh,0}^-,\ P_0 = p_{kh,0}^- .$$

The discrete state equation reads as follows for $Y_0 \in V_h$ and $Y_m \in U_m + V_{h,0}$:

$$(Y_0, \phi) = (y_0, \phi) \quad \text{for all } \phi \in V_h ,$$

$$\begin{aligned}(Y_m, \phi) + k_m\,(\nabla Y_m, \nabla\phi) + k_m\left(\int_{I_m} b(s)\,ds \cdot \nabla Y_m, \phi\right) &= (Y_{m-1}, \phi) \\ + k_m\left(\int_{I_m} f(s)\,ds, \phi\right) \quad &\text{for all } \phi \in V_{h,0},\ m = 1, \dots, M .\end{aligned}$$

Remark 6.1. If the time integrals are approximated by the box rule, then the resulting scheme is equivalent to the implicit Euler method. However, a better approximation of these time integrals leads to a scheme which allows for better error estimates with respect to the required smoothness of the solution and to long time integration ($T \gg 1$); see, e.g., [18]. For the numerical examples which follow, the trapezoidal rule is used, which guarantees this improved convergence behavior.

In order to cover both problem (P1) with a time-distributed cost functional and the problem (P2) with a terminal time functional, we write the cost functional in the form

$$J(y, u) = \int_0^T I(y(s))\,ds + K(y(T)) + \frac{\beta}{2}|u|^2_{L^2(\Sigma)} .$$

The discrete adjoint equation reads as follows for $P_0 \in V_h$ and $P_m \in V_{h,0}$:

$$\begin{aligned}(\phi, P_M) + k_M\,(\nabla\phi, \nabla P_M) + k_M\left(\int_{I_M} b(s)\,ds \cdot \nabla\phi, P_M\right) &= K'(Y_M)(\phi) \\ + k_M\,I'(Y_M)(\phi) \quad &\text{for all } \phi \in V_{h,0},\end{aligned}$$

$$\begin{aligned}(\phi, P_m) + k_m\,(\nabla\phi, \nabla P_m) + k_m\left(\int_{I_m} b(s)\,ds \cdot \nabla\phi, P_m\right) &= (\phi, P_{m+1}) \\ + k_m\,I'(Y_m)(\phi) \quad &\text{for all } \phi \in V_{h,0},\ m = M-1, \dots, 1 ,\end{aligned}$$

$$(\phi, P_0) = (\phi, P_1) \quad \text{for all } \phi \in V_h .$$

Remark 6.2. There are two possible ways to obtain the above equations for P_m, $m = 0, \dots, M$:

- discretization of the continuous adjoint equation with dG(0) in time and with H^1-conforming finite elements in space (optimize-then-discretize approach);
- application of the Lagrange formalism on the discrete level for the optimization problem with the state equation discretized by dG(0) in time and H^1-conforming finite elements in space (discretize-then-optimize approach).

The resulting schemes for P_m coincide independent of the temporal grid. This fact relies on the space-time Galerkin discretization.

For a standard formulation of the implicit Euler scheme, i.e.,

$$\frac{1}{k_m}\,(Y_m - Y_{m-1}, \phi) + (\nabla Y_m, \nabla\phi) + (b(t_m)\nabla Y_m, \phi) = (f(t_m), \phi) \quad \text{for all } \phi \in V_{h,0},$$

the optimize-then-discretize approach leads to the discrete adjoint

$$\frac{1}{k_{m+1}}\,(\phi, P_m - P_{m+1}) + (\nabla\phi, \nabla P_m) + (b(t_m)\nabla\phi, P_m) = (I'(Y_m), \phi) \quad \text{for all } \phi \in V_{h,0},$$

whereas the discretize-then-optimize approach produces

$$\frac{1}{k_m}\,(\phi, P_m) - \frac{1}{k_{m+1}}\,(\phi, P_{m+1}) + (\nabla\phi, \nabla P_m) + (b(t_m)\nabla\phi, P_m) = (I'(Y_m), \phi) \quad \text{for all } \phi \in V_{h,0}.$$

These schemes are different for nonconstant time steps k_m.

For the optimization algorithm we need the evaluation of the derivatives of j_{kh} for basis functions in $U_{k,h}^{0,1}$. We consider the following basis of $U_{k,h}^{0,1}$:

$$w_{i,m}(t,x) = \begin{cases} \phi_i(x), & t \in I_m, \\ 0 & \text{otherwise}, \end{cases} \tag{6.1}$$

where $\phi_i = \gamma(\widehat{\phi}_i)$ and $\widehat{\phi}_i \in V_h$ is a finite element nodal basis function for a boundary node i. We obtain the following corollary from Proposition 5.1.

COROLLARY 6.1. *The following representation holds:*

$$\begin{aligned} j'_{kh}(u_{kh})(w_{i,M}) = {} & \beta(U_M, \phi_i)_{\partial\Omega} + K'(Y_M)(\widehat{\phi}_i) + k_M\, I'(Y_M)(\widehat{\phi}_i) \\ & - (\widehat{\phi}_i, P_M) - k_M\,(\nabla\widehat{\phi}_i, \nabla P_M) - k_M \left(\int_{I_M} b(s)\,ds \cdot \nabla\widehat{\phi}_i, P_M\right), \end{aligned}$$

$$\begin{aligned} j'_{kh}(u_{kh})(w_{i,m}) = {} & \beta(U_m, \phi_i)_{\partial\Omega} + k_m\, I'(Y_m)(\widehat{\phi}_i) + (\widehat{\phi}_i, P_{m+1}) \\ & - (\widehat{\phi}_i, P_m) - k_m\,(\nabla\widehat{\phi}_i, \nabla P_m) - k_m \left(\int_{I_m} b(s)\,ds \cdot \nabla\widehat{\phi}_i, P_m\right), \\ & m = M-1, \ldots, 1\,. \end{aligned}$$

Remark 6.3. Due to the fact that $\widehat{\phi}_i$ has local support, the spatial integration in the representations above is done only over cells adjacent to the boundary.

Next, we describe (5.8) and (5.9) and the evaluation of the second derivatives. We define

$$\delta U_m = \delta u_{kh}\big|_{I_m},\ \delta Y_m = \delta y_{kh}\big|_{I_m},\ \delta P_m = \delta p_{kh}\big|_{I_m}, \quad i = 1, \ldots, M,$$

$$\delta Y_0 = \delta y^-_{kh,0},\ \delta P_0 = \delta p^-_{kh,0}\,.$$

The discrete tangent equation reads as follows for $\delta Y_0 \in V_h$ and $\delta Y_m \in \delta U_m + V_{h,0}$:

$$\delta Y_0 = 0\,,$$

$$(\delta Y_m, \phi) + k_m\,(\nabla \delta Y_m, \nabla \phi) + k_m\,\left(\int_{I_m} b(s)\,ds \cdot \nabla \delta Y_m, \phi\right) = (\delta Y_{m-1}, \phi)$$
$$\text{for all } \phi \in V_h\,,\ m = 1, \dots, M\,.$$

The discrete equation (5.9) reads as follows for $\delta P_0 \in V_h$ and $\delta P_m \in V_{h,0}$:

$$(\phi, \delta P_M) + k_M\,(\nabla \phi, \nabla \delta P_M) + k_M\,\left(\int_{I_M} b(s)\,ds \cdot \nabla \phi, \delta P_M\right) = K''(Y_M)(\delta Y_M, \phi)$$
$$+\ k_M\,I''(Y_M)(\delta Y_M, \phi) \quad \text{for all } \phi \in V_h\,,$$

$$(\phi, \delta P_m) + k_m\,(\nabla \phi, \nabla \delta P_m) + k_m\,\left(\int_{I_m} b(s)\,ds \cdot \nabla \phi, \delta P_m\right) = (\phi, \delta P_{m+1})$$
$$+\ k_m\,I''(Y_m)(\delta Y_m, \phi) \quad \text{for all } \phi \in V_h\,,\ m = M-1, \dots, 1\,,$$

$$(\phi, \delta P_0) = (\phi, \delta P_1) \quad \text{for all } \phi \in V_h\,.$$

Using the basis (6.1) we obtain the following representation of $j''_{kh}(u_{kh})(\delta u_{kh}, w_{i,m})$ as a corollary to Proposition 5.1.

COROLLARY 6.2. *The following representation holds:*

$$j''_{kh}(u_{kh})(\delta u_{kh}, w_{i,M}) = \beta(\delta U_M, \phi_i)_{\partial\Omega} + K''(Y_M)(\delta Y_M, \widehat{\phi}_i) + k_M\,I''(Y_M)(\delta Y_M, \widehat{\phi}_i)$$
$$-\ (\widehat{\phi}_i, \delta P_M) - k_M\,(\nabla \widehat{\phi}_i, \nabla \delta P_M) - k_M\,\left(\int_{I_M} b(s)\,ds \cdot \nabla \widehat{\phi}_i, \delta P_M\right)$$

$$j''_{kh}(u_{kh})(\delta u_{kh}, w_{i,m}) = \beta(\delta U_m, \phi_i)_{\partial\Omega} + k_m\,I''(Y_m)(\delta Y_M, \widehat{\phi}_i) + (\widehat{\phi}_i, \delta P_{m+1})$$
$$-\ (\widehat{\phi}_i, \delta P_m) - k_m\,(\nabla \widehat{\phi}_i, \nabla \delta P_m) - k_m\,\left(\int_{I_m} b(s)\,ds \cdot \nabla \widehat{\phi}_i, \delta P_m\right),$$
$$m = M-1, \dots, 1\,.$$

We close the paper with three numerical examples. The first two examples correspond to problems (P1) and (P2), respectively, and examine the behavior of the PDAS method if the dimension of the discrete problem increases due to the refinement of spatial and time meshes. The third example is devoted to the superlinear convergence of the PDAS method.

Our special interest in considering the behavior of the algorithm as the mesh is refined results from previous experience with constrained optimal control problems with distributed controls. Pointwise control, respectively, state constraints, result in a very different behavior of the algorithm in the sense that it is mesh-independent for the former but strongly mesh-dependent for the latter; see [8] and [26]. Analytically this is reflected in the fact that for the former the Lagrange multipliers are L^2-functions, whereas they are only measures in the case of state constraints. Regularization or nested iteration can be used in the latter case to nearly restore mesh-independence.

For the case of Dirichlet boundary control with pointwise constraints on the controls the practical performance of the algorithm and specifically its behavior with respect to mesh refinement cannot easily be predicted from previous experience. On the one hand, as in the case of distributed control, the associated Lagrange multipliers are L^2-regular and we can prove superlinear convergence. However, at least formally, inequality constraints on the control along the boundary are equivalent to inequality constraints on the state on the boundary, and, second, the extra regularity on the adjoint states and the optimal controls obtained in section 3 is rather less than that in the case of distributed controls.

In section 4, we have shown the superlinear convergence of the PDAS method on the continuous level for Dirichlet optimal control problems. On the discrete level, we typically have finite step convergence (cf. the stopping criterion discussed in Remark 4.1), which is, of course, better than superlinear convergence. In our last numerical example, presented in section 6.3, we observe the behavior of the PDAS method corresponding to superlinear convergence also before the method stops finding the optimal discrete solution.

6.1. Example 1: Time-distributed functional. We consider the following Dirichlet optimal control problem on $\Omega \times (0,T)$ with $\Omega = (0,1)^2 \subset \mathbb{R}^2$ and $T = 1$:

$$\begin{aligned} \min \quad & J(u,y) = \frac{1}{2}\|y - y_d\|^2_{L^2(Q)} + \frac{\beta}{2}\|u\|^2_{L^2(\Sigma)}\,, \\ \text{subject to} \quad & y_t - \kappa\Delta y + b\cdot\nabla u = f \quad \text{in } \Omega\times(0,T), \\ & y = u \qquad\qquad\qquad\quad \text{on } \partial\Omega\times(0,T), \\ & y(0) = y_0 \qquad\qquad\qquad\quad \text{in } \Omega \end{aligned}$$

and control constraints

$$u \geq \phi\,.$$

The data are given as follows:

$$f = 0, \quad \kappa = 1, \quad b(t,x) = 15\,(\sin(2\pi t), \cos(2\pi t)), \quad y_0 = 0, \quad \beta = 10^{-4}\,,$$

$$y_d(t,x) = x_1x_2(\cos(\pi t) - x_1)(\sin(\pi t) - x_2), \quad \phi = -0.25\,.$$

This optimal control problem is discretized by space-time finite elements as described above. The resulting finite-dimensional problem is solved by the PDAS method. In Table 6.1 the number of iterations of the method is shown for a sequence of uniformly refined discretizations. Here, M denotes the number of time-steps and N is the number of nodes in the space discretization. In all cases the algorithm terminated with two consecutive active sets coinciding, so that the exact solution of the discretized problem is found.

We present the results for two choices of initial guesses for the control variable: the same choice for all discretization levels ($u_0 = 1$), and an interpolated solution from the previous discretization level (nested iteration). The goal consists in obtaining practical experience as to which degree the weak additional regularity established in Theorem 3.2 and Corollary 3.7 is sufficient for near mesh-independent behavior. The results indicate that the additional regularity is sufficient for nearly mesh-independent behavior and that nested iterations provide only a relatively moderate improvement. The algorithm was also tested with other initial guesses and led to very similar results.

TABLE 6.1
PDAS method on the sequence of uniformly refined discretizations.

N	M	$\dim X_h = M \cdot N$	$\dim U_h$	PDAS iterations	PDAS nested iterations
25	2	50	32	2	2
81	4	324	128	3	3
289	8	2312	512	4	3
1089	16	17424	2048	4	3
4225	32	135200	8192	5	4
16641	64	1065024	32768	6	4

6.2. Example 2: Terminal functional. In this example we consider a Dirichlet optimal control problem with a terminal cost functional:

$$\begin{aligned} \min \quad & J(u,y) = \frac{1}{2}\|y(T) - y_d^T\|^2_{L^2(\Omega)} + \frac{\beta}{2}\|u\|^2_{L^2(\Sigma)}\,, \\ \text{subject to} \quad & y_t - \kappa\Delta y + b\cdot\nabla u = f \quad \text{in } \Omega\times(0,T), \\ & y = u \quad \text{on } \partial\Omega\times(0,T), \\ & y(0) = y_0 \quad \text{in } \Omega\,, \end{aligned}$$

and control constraints

$$\phi \le u \le \psi, \quad u = 0 \text{ on } \partial\Omega\times(T_1,T).$$

The data are given as follows:

$$f = 0, \quad \kappa = 1, \quad b(t,x) = 15\,(\sin(2\pi t), \cos(2\pi t)), \quad y_0 = 0, \quad \beta = 10^{-4}, \quad T_1 = 0.75\,,$$

$$y_d^T(x) = 3\,\left(x_1x_2 + \sin(12\pi x_1^2(1-x_1)^2)\,\sin(12\pi x_2^2(1-x_2)^2)\right), \quad \phi = -0.1, \quad \psi = 2.5\,.$$

In Table 6.2 we present the corresponding results.

TABLE 6.2

16641	64	1065024	32768	6	5

6.3. Example 3. In this example, we consider the following Dirichlet optimal control problem on $\Omega\times(0,T)$ with $\Omega = (0,1)^2 \subset \mathbb{R}^2$ and $T = 1$:

$$\begin{aligned} \min \quad & J(u,y) = \frac{1}{2}\|y - y_d\|^2_{L^2(Q)} + \frac{\beta}{2}\|u\|^2_{L^2(\Sigma)}\,, \\ \text{subject to} \quad & y_t - \kappa\Delta y + b\cdot\nabla u = f \quad \text{in } \Omega\times(0,T), \\ & y = u \quad \text{on } \partial\Omega\times(0,T), \\ & y(0) = y_0 \quad \text{in } \Omega \end{aligned}$$

and control constraints

$$\phi \le u \le \psi\,.$$

The data are given as follows:

$$f = \begin{cases} 2, & x_1 \le 0.25, \\ -35 & \text{else}, \end{cases} \quad \kappa = 1, \;\; b(t,x) = 10\,(\sin(2\pi t), \cos(2\pi t)), \;\; y_0 = 0, \;\; \beta = 10^{-5}\,,$$

$$y_d(t,x) = \begin{cases} 2 - 2x_1, & x_1 \le 0.5, \\ 2 - 2x_2 & \text{else}, \end{cases} \qquad \phi = -1, \quad \psi = 2\,.$$

For a fixed discretization with $M = 64$ time-steps and $N = 1089$ nodes in the spacial mesh, we consider the iteration error

$$e_i = \|u_{kh}^{(i)} - u_{kh}\|_{L^2(\Sigma)},$$

where $u_{kh}^{(i)}$ is the ith iterate, and u_{kh} is the optimal discrete solution. The results presented in Table 6.3 demonstrate superlinear convergence of the algorithm.

OPTIMAL CONTROL OF SEMILINEAR PARABOLIC EQUATIONS WITH $\mathcal{K}$-APPROXIMATE PERIODIC SOLUTIONS*

LING LEI† AND GENGSHENG WANG‡

Abstract. In this paper, we study some optimal control problems governed by certain semilinear parabolic equations with $\mathcal{K}$-approximate periodic solutions. We first prove the existence and uniqueness theorems for $\mathcal{K}$-approximate periodic solutions of the equations. We then use these results to establish the qualified Pontryagin maximum principle. The existence for such optimal controls is also investigated in the paper.

Key words. $\mathcal{K}$-approximate periodic solution, optimal control, non-well-posed parabolic equation, Pontryagin's maximum principle

1. Introduction.

Let Ω be a bounded domain in $\mathbf{R}^n$, $n \geq 3$, with a C^2-smooth boundary $\partial\Omega$. Write Q and Σ for the sets $\Omega \times (0,T)$ and $\partial\Omega \times (0,T)$, respectively. Denote by χ_ω the characteristic function of ω, where ω is a subdomain of Ω. Consider the following controlled parabolic equation:

$$\begin{cases} y_t(x,t) - \Delta y(x,t) + f(x,t,y(x,t)) = \chi_\omega(x)u(x,t) & \text{in } Q, \\ y(x,t) = 0 & \text{on } \Sigma, \end{cases} \tag{1.1}$$

where $f : \Omega \times (0,T) \times \mathbf{R} \to \mathbf{R}$ is a given function satisfying certain conditions to be specified later and the control function $u(x,t)$ is taken from the space $L^2(Q)$. For simplicity, we shall call the aforementioned function $u(x,t)$ a control. This paper is concerned with the optimal control problem governed by (1.1) with $\mathcal{K}$-approximate periodic solutions.

To start, we recall the concept of $\mathcal{K}$-approximate periodic solutions for a parabolic equation, first considered by the first author in [6], [7]. Let $H = L^2(\Omega)$ and $V = H_0^1(\Omega)$. Write $|\cdot|_2$ and $\|\cdot\|$ for the norms of H and V, respectively. Denote by $\langle\cdot,\cdot\rangle$ the inner product in H. Let A be the linear operator from H to H such that $Ay = -\triangle y$, with $D(A) = H^2(\Omega) \cap H_0^1(\Omega)$. Let $\{X_i(x)\}_{i=1}^\infty$ be a complete set of eigenfunctions of A, which serves as an orthonormal basis of H, and let $\{\lambda_i\}_{i=1}^\infty$, with $0 < \lambda_1 < \lambda_2 \leq \cdots < +\infty$, be the corresponding eigenvalues. For each nonnegative integer $\mathcal{K}$, we denote by $H^{I,\mathcal{K}}$ and $H^{II,\mathcal{K}}$ the subspaces spanned by $\{X_i(x)\}_{i=1}^{\mathcal{K}}$ and $\{X_i(x)\}_{i=\mathcal{K}+1}^\infty$, respectively. Then $H = H^{I,\mathcal{K}} \oplus H^{II,\mathcal{K}}$, and each element $h \in H$ can be written as $h = h^{I,\mathcal{K}} + h^{II,\mathcal{K}}$, where $h^{I,\mathcal{K}} \in H^{I,\mathcal{K}}$ and $h^{II,\mathcal{K}} \in H^{II,\mathcal{K}}$. Moreover, each function $\varphi(x,t) \in L^2(0,T;H)$ can be expressed as $\varphi(x,t) = \varphi^{I,\mathcal{K}}(x,t) + \varphi^{II,\mathcal{K}}(x,t) \equiv \sum_{i=1}^{\mathcal{K}} \varphi_i(t)X_i(x) + \sum_{i=\mathcal{K}+1}^\infty \varphi_i(t)X_i(x)$, where $\varphi_i(t) = \langle\varphi(\cdot,t), X_i(\cdot)\rangle \in L^2(0,T)$. In what follows, we shall omit variables x and t for functions in $L^2(0,T;H)$ and omit x for functions of

x, if there is no risk of causing confusion. Write $Y = \{y \in L^2(0,T;D(A));\ y_t \in L^2(0,T;H)\}$ with norm $\|y\|_Y = \{\|y\|^2_{L^2(0,T;D(A))} + \|y_t\|^2_{L^2(0,T;H)}\}^{\frac{1}{2}}$. Then Y is a Hilbert space. We say that y is a $\mathcal{K}$-approximate periodic solution of (1.1) if $y \in Y$ satisfies (1.1) and $y^{II,\mathcal{K}}(0) = y^{II,\mathcal{K}}(T)$. When $\mathcal{K} = 0$, we will always regard $\sum_{i=1}^{0} = 0$. Hence, a 0-approximate periodic solution of (1.1) is a usual periodic solution.

A $\mathcal{K}$-approximate solution of (1.1) can be explained mathematically as a special type of solution for the equation like periodic solutions, steady state solutions, and others. It can also be viewed as a perturbation of a periodic solution in the low frequency part. In physics and applied sciences, it can be regarded as a solution with a periodic higher frequency part.

In this paper, we shall study the following optimal control problem:

$$(\mathbf{P}_{\mathcal{K},r}):\quad \mathrm{Inf}J(y,u) \equiv \mathrm{Inf}\frac{1}{2}\int_Q (y^2+u^2)dxdt \text{ over all } (y,u) \in Y \times L^2(Q)$$

satisfying (1.1) and the following state constraint:

$$\begin{cases} y^{I,\mathcal{K}}(0) = a^{I,\mathcal{K}},\ \ y^{I,\mathcal{K}}(T) \in B^{I,\mathcal{K}}(0,r), \\ y^{II,\mathcal{K}}(0) = y^{II,\mathcal{K}}(T), \end{cases} \tag{1.2}$$

where $a^{I,\mathcal{K}} \in H^{I,\mathcal{K}}$ is a given element and $B^{I,\mathcal{K}}(0,r)$ denotes the closed ball in $H^{I,\mathcal{K}}$ centered at 0 and of radius $r > 0$. We shall establish the Pontryagin maximum principle and the existence of optimal controls for the problem $(\mathbf{P}_{\mathcal{K},r})$. We define the following certain properties for the function f, which will be used in our later discussions.

Property (A_f). The function $f : \Omega \times (0,T) \times \mathbf{R} \to \mathbf{R}$ is measurable in $(x,t) \in \Omega \times (0,T)$ and continuously differentiable in the third variable. Moreover, there exist positive constants L and α, with $1 < \alpha \le \frac{n}{n-2}$, such that

$$|f(x,t,\xi)| \le L(|\xi|^\alpha + 1)\ \forall\ \xi \in \mathbf{R} \text{ and for almost all } (x,t) \text{ in } Q, \tag{1.3}$$

$$|f'_\xi(x,t,\xi)| \le L(|\xi|^{\alpha-1} + 1)\ \forall\ \xi \in \mathbf{R} \text{ and for almost all } (x,t) \text{ in } Q. \tag{1.4}$$

Property (H_f). The function $f : \Omega \times (0,T) \times \mathbf{R} \to \mathbf{R}$ is measurable in $(x,t) \in \Omega \times (0,T)$ and continuously differentiable in the third variable. Moreover,

(i) there exists a positive constant μ such that

$$f(x,t,\xi)\xi + \lambda_1\xi^2 \ge \mu\xi^2,\ \forall\ \xi \in \mathbf{R},\ \text{a.e. } (x,t) \in Q,$$

where λ_1 is the first eigenvalue of operator A;

(ii) there exist positive constants $\widetilde{L}$ and β with $\beta \le \frac{2}{n}$, such that

$$|f(x,t,\xi)| \le \widetilde{L}|\xi|(1+|\xi|^\beta),\ \forall\ \xi \in \mathbf{R},\ \text{a.e. } (x,t) \in Q.$$

We shall derive the Pontryagin maximum principle and the existence of optimal controls for the problem $(\mathbf{P}_{\mathcal{K},r})$ under property $(\mathbf{A_f})$ and $(\mathbf{H_f})$, respectively. We now are ready to state our main results.

THEOREM 1.1. *Suppose that f satisfies property $(\mathbf{A_f})$. Let $(y^*,u^*) \in Y \times L^2(Q)$ be optimal for problem $(\mathbf{P}_{\mathcal{K},r})$. Then there exist a number μ_0, with $\mu_0 \ne 0$, a function p in the space Y, and an element $a_0^{I,\mathcal{K}}$ in the space $H^{I,\mathcal{K}}$ such that*

$$\begin{cases} \chi_\omega p = \mu_0 u^* & a.e.\ in\ \ Q, \\ p_t + \triangle p - f'_y(x,t,y^*)p = \mu_0 y^* & in\ \ Q, \\ p = 0 & on\ \ \Sigma, \\ p^{I,\mathcal{K}}(T) = -a_0^{I,\mathcal{K}},\ p^{II,\mathcal{K}}(T) = p^{II,\mathcal{K}}(0) & in\ \ \Omega. \end{cases}$$

THEOREM 1.2. *Suppose that f satisfies property $(\mathbf{H_f})$. Then, for each $M > 0$, there exist an integer $\mathcal{K} \equiv \mathcal{K}(M) \geq 0$ and a positive constant $r \equiv r(M)$ such that for each $a^{I,\mathcal{K}} \in H^{I,\mathcal{K}}$, with $(1 + \lambda_{\mathcal{K}})|a^{I,\mathcal{K}}|_2^2 \leq M^2$, where $\lambda_{\mathcal{K}}$ is the $\mathcal{K}$th eigenvalue of the operator A, problem $(\mathbf{P}_{\mathcal{K},r})$ has at least one solution.*

Under the assumption $(\mathbf{A_f})$, the controlled system (1.1) with given initial data $y(x,0) = y_0(x)$ (in $L^2(\Omega)$ or in $H_0^1(\Omega)$) may have no solution or may have many solutions in (0,T) for some control $u \in L^2(Q)$. Thus the corresponding optimal control problem $(\mathbf{P}_{\mathcal{K},r})$ cannot be treated by the traditional methods provided in [1], [2], [4], [8], [9], where one regards the state function y as a well-defined functional of the control u. Hence, our optimal control problem is not well-posed. (See [13]). The non-well-posed optimal control problem was first mentioned in [10], where an example of the optimal control problem governed by a semilinear parabolic equation, admitting no solution for some controls, was studied. In [13], a more general non-well-posed optimal control problem governed by some semilinear parabolic equations involving some kinds of state constraints was further investigated. However, in the aforementioned work, due to the technical difficulties, the control is allowed to be acted only in the whole domain Ω, and the state is viewed as the weak solution of the controlled equation, namely, the solution in the space $Y_1 = \{y \in L^2(0,T;H_0^1(\Omega)); y_t - \triangle y \in L^2(Q)\}$. The novelty of the present work compared with the others dealing with non-well-posed optimal control problems mentioned above is as follows: First, we consider a new type of state constraints—$\mathcal{K}$-approximate periodic state constraints (which include periodic state constraints). Moreover, the controls are applied internally into the equations. Second, we consider the strong solution y of the controlled equation (1.1), namely, $y \in Y$, as the state of the optimal control problem. This, together with the state constraint (1.2) and the growth condition $(\mathbf{A_f})$ on the nonlinear term f in (1.1), motivates us to develop a new method to construct an approximate problem $(\mathbf{P}^{\varepsilon}_{\mathcal{K},r})$ to approach the original problem $(\mathbf{P}_{\mathcal{K},r})$. The approximate problems in the works [10], [13] are to ask the infimum of a penalty functional over the whole product space of the state space with the control space, namely, the space $Y_1 \times L^2(Q)$. This is also a general method to construct an approximate problem when people use a penalization method to derive the Pontryagin maximum principle. However, for the current problem, it is difficult for us to construct a suitable penalty functional such that the corresponding infimum problem over the space $Y \times L^2(Q)$ approximates the original problem well. The difficulty is mainly caused by the state constraint (1.2) and the facts that the state is the strong solution and a weak solution of (1.1) satisfying the $\mathcal{K}$-approximate periodic condition may be not a strong solution due to the growth condition $(\mathbf{A_f})$. In this work, we construct a new type of approximate problem $(\mathbf{P}^{\varepsilon}_{\mathcal{K},r})$ which is to ask the infimum of a penalty functional over a suitable subset of the product space $Y \times L^2(Q)$. This approximate problem approaches the original problem well because of the existence and uniqueness result of $\mathcal{K}_0$-approximate solution for the linearized equation of (1.1) at the optimal state y^* for sufficiently large $\mathcal{K}_0$. (See Theorem 2.1.)

Problem $(\mathbf{P}_{\mathcal{K},r})$ studied here is an optimal control problem without a control constraint if one views χ_ω as a linear bounded operator from the space $L^2(\Omega)$ into itself. But, on the other hand, if we set $V(\omega) = \{v(x,t) \in L^2(Q);\ \text{supp}v(x,t) \subset \overline{\omega} \times [0,T]\}$ and write $v(x,t)$ for the term $\chi_\omega(x)u(x,t)$ on the right-hand side of (1.1), then the problem turns to an optimal control problem with control constraint $v \in V(\omega)$. Both the control constraint and the state constraint may cause difficulties for us to get the Pontryagin maximum principle in a qualified form. In this problem, the state constraint is a special kind of two endpoint state constraint, and the control constraint also has a special form. Thus, the unique continuation property for linear

parabolic equations leads us to the Pontryagin maximum principle in a qualified form. If problem $(\mathbf{P}_{\mathcal{K},r})$ involves another type of control constraints, then how to derive the Pontryagin maximum principle in a qualified form is still open for us due to some technical problems.

We emphasize that, even though the cost functional studied in this paper is a typical quadratic form, our main results (Theorems 1.1 and 1.2) can be extended in an identical way to the case where the cost functional has a more general form than that appearing in [1], [13].

Existence and uniqueness problems for periodic solutions for parabolic equations have been extensively studied in the literature. There have also been many works done, in the past years, on the optimal control problems (including the Pontryagin maximum principle and the existence of the optimal controls) governed by semilinear parabolic equations with state constraints. These constraints include two ending point state constraints in the time variable (see [1], [8], [9], [12], [13], [14], and the references therein), the integral type of state constraints (see [5] and the references therein), and the pointwise state constraints (see [4] and the references therein). One of the most important two endpoint state constraints is the periodic state constraints, i.e., $y(x,0) = y(x,T)$ (see [1], [12], and the references therein). The state constraint considered in this paper has the periodic state constraint as a special case.

The paper is organized as follows. In section 2, we establish the existence and uniqueness of $\mathcal{K}$-approximate periodic solutions in the space Y for certain linear parabolic equations which is important for us to get the Pontryagin maximum of optimal controls for problem $(\mathbf{P}_{\mathcal{K},r})$. We also obtain the existence of $\mathcal{K}$-approximate periodic solutions for certain semilinear parabolic equations which plays a key role in the proof of Theorem 1.2. In section 3, we prove Theorem 1.1 by constructing a suitable approximate problem $(\mathbf{P}^{\varepsilon}_{\mathcal{K},r})$. In the last section, we give the proof of Theorem 1.2.

2. Approximate periodic solution for parabolic equations. In this section, we shall give the existence and uniqueness of $\mathcal{K}$-approximate periodic solutions in space Y for some linear parabolic equations and the existence of $\mathcal{K}$-approximate periodic solutions in Y for some semilinear parabolic equations. In the linear case, our method is basically the same as that used in [6], where the existence and uniqueness of $\mathcal{K}$-approximate periodic solutions in space $V_2(Q) \equiv L^\infty(0,T;H) \cap L^2(0,T;V)$ was established. In the semilinear case, we will apply the fixed point theorem and the existence result obtained in the linear problem.

THEOREM 2.1. *Let M be a positive number. Then there exists a nonnegative integer $\mathcal{K}_0 \equiv \mathcal{K}_0(-\triangle, \Omega, T, M)$ depending only on Ω, T, M, and $(-\Delta)$, where the dependence on the operator $-\Delta$ is only through the eigenvalues of the operator $-\Delta$ such that, for each integer $\mathcal{K}$ with $\mathcal{K} \geq \mathcal{K}_0$, each function e in the space $L^\infty(0,T;L^n(\Omega))$, with $\|e\|_{L^\infty(0,T;L^n(\Omega))} \leq M$, each element $a^{I,\mathcal{K}}$ in the space $H^{I,\mathcal{K}}$, and each function v in the space $L^2(0,T;H)$, the following problem has a unique solution y in the space Y:*

$$\begin{cases} y_t - \triangle y - ey = v & \text{in } Q, \\ y = 0 & \text{on } \Sigma, \\ y^{I,\mathcal{K}}(0) = a^{I,\mathcal{K}},\ y^{II,\mathcal{K}}(0) = y^{II,\mathcal{K}}(T) & \text{in } \Omega. \end{cases} \tag{2.1}$$

Moreover, this solution y satisfies the following estimate:

$$\|y\|_Y^2 \leq C(\lambda_{\mathcal{K}} |a^{I,\mathcal{K}}|_2^2 + \|v\|^2_{L^2(0,T;H)}), \tag{2.2}$$

where $C \equiv C(-\triangle, T, \Omega, M)$ is a positive constant depending only on $-\Delta, T, \Omega$, and M and where $\lambda_{\mathcal{K}}$ is the $\mathcal{K}$th eigenvalue of the operator A.

Proof of Theorem 2.1. By the theory of linear evolution equations (see Corollary 4.3, Chapter 1 of [2]), one can easily get that for each function e in the space $L^\infty(0,T;L^n(\Omega))$, with $\|e\|_{L^\infty(0,T;L^n(\Omega))} \le M$, each element z_0 in the space V, and each function v in the space $L^2(0,T;H)$, the following equation:

$$\begin{cases} z_t - \triangle z - ez = v & \text{in } Q, \\ z = 0 & \text{on } \Sigma, \\ z(0) = z_0 & \text{in } \Omega \end{cases} \tag{2.3}$$

has a unique solution z in the space Y. Moreover, there exists a positive constant C such that

$$\|z\|_Y^2 \le C(\|v\|^2_{L^2(0,T;H)} + \|z_0\|^2). \tag{2.4}$$

Here and in what follows, C stands for a positive constant depending only on $-\triangle, T, \Omega$, and M, which may be different in different contexts. Let e be a function in the space $L^\infty(0,T;L^n(\Omega))$ satisfying $\|e\|_{L^\infty(0,T;L^n(\Omega))} \le M$. Then, for each nonnegative integer $\mathcal{K}$ and for each element $a^{II,\mathcal{K}}$ in the space $H^{II,\mathcal{K}} \cap V$, there exists a unique solution $\widetilde{y}(t) \equiv \widetilde{y}(t; a^{II,\mathcal{K}})$ in the space Y satisfying

$$\begin{cases} \widetilde{y}_t - \triangle \widetilde{y} - e\widetilde{y} = 0 & \text{in } Q, \\ \widetilde{y} = 0 & \text{on } \Sigma, \\ \widetilde{y}^{I,\mathcal{K}}(0) = 0,\ \widetilde{y}^{II,\mathcal{K}}(0) = a^{II,\mathcal{K}} & \text{in } \Omega, \end{cases} \tag{2.5}$$

and

$$\|\widetilde{y}\|_Y^2 \le C\|a^{II,\mathcal{K}}\|^2. \tag{2.6}$$

Since $Y \hookrightarrow C([0,T];V)$ (see Chapter 1 of [11]), we have

$$\|\widetilde{y}\|^2_{C([0,T];V)} \le C\|a^{II,\mathcal{K}}\|^2. \tag{2.7}$$

Multiplying the first equation of (2.5) by $(-\triangle \widetilde{y}^{II,\mathcal{K}}(t))$ and integrating over Ω, we get

$$\frac{1}{2}\frac{d}{dt}\|\widetilde{y}^{II,\mathcal{K}}(t)\|^2 + \lambda_{\mathcal{K}+1}\|\widetilde{y}^{II,\mathcal{K}}(t)\|^2 \le |\langle e\widetilde{y}(t), \triangle \widetilde{y}^{II,\mathcal{K}}(t)\rangle|.$$

By the Hölder inequality and the Sobolev embedding theorem, we obtain

$$\begin{aligned} 2|\langle e\widetilde{y}(t), \triangle \widetilde{y}^{II,\mathcal{K}}(t)\rangle| &\le 2\int_\Omega |e\widetilde{y}(t)\triangle \widetilde{y}^{II,\mathcal{K}}(t)|dx \\ &\le 2\left(\int_\Omega |e(x,t)|^n dx\right)^{\frac{1}{n}} \left(\int_\Omega |\widetilde{y}(x,t)|^{\frac{2n}{n-2}} dx\right)^{\frac{n-2}{2n}} \left(\int_\Omega |\triangle \widetilde{y}^{II,\mathcal{K}}(x,t)|^2 dx\right)^{\frac{1}{2}} \\ &\le 2MC_1\|\widetilde{y}(t)\| \cdot |\triangle \widetilde{y}^{II,\mathcal{K}}(t)|_2 \\ &\le \varepsilon |\triangle \widetilde{y}^{II,\mathcal{K}}(t)|_2^2 + C(\varepsilon, M, C_1)\|\widetilde{y}(t)\|^2 \quad \forall\, \varepsilon > 0, \end{aligned}$$

where C_1 is the constant of the embedding from $H_0^1(\Omega)$ into $L^{\frac{2n}{n-2}}(\Omega)$ and $C(\varepsilon, M, C_1)$ is a positive constant depending only on ε, M, and C_1. Thus, it holds that

$$\frac{d}{dt}(e^{2\lambda_{\mathcal{K}+1}t}\|\widetilde{y}^{II,\mathcal{K}}(t)\|^2) \le (\varepsilon|\triangle \widetilde{y}^{II,\mathcal{K}}(t)|_2^2 + C(\varepsilon, M, C_1)\|\widetilde{y}(t)\|^2)e^{2\lambda_{\mathcal{K}+1}t}.$$

Integrating the above over $(0,T)$ and making use of (2.7), we get

$$e^{2\lambda_{\mathcal{K}+1}T}\|\widetilde{y}^{II,\mathcal{K}}(T)\|^2 \le \|a^{II,\mathcal{K}}\|^2 + \varepsilon\int_0^T e^{2\lambda_{\mathcal{K}+1}t}|\triangle\widetilde{y}^{II,\mathcal{K}}(t)|_2^2 dt + C\cdot C(\varepsilon,M,C_1)\|a^{II,\mathcal{K}}\|^2\int_0^T e^{2\lambda_{\mathcal{K}+1}t}dt,$$

which, together with (2.6), implies

$$\begin{aligned}\|\widetilde{y}^{II,\mathcal{K}}(T)\|^2 &\le e^{-2\lambda_{\mathcal{K}+1}T}\|a^{II,\mathcal{K}}\|^2 + C\cdot C(\varepsilon,M,C_1)\left(\frac{1}{2\lambda_{\mathcal{K}+1}} - \frac{e^{-2\lambda_{\mathcal{K}+1}T}}{2\lambda_{\mathcal{K}+1}}\right)\|a^{II,\mathcal{K}}\|^2\\ &\quad +\varepsilon\int_0^T e^{-2\lambda_{\mathcal{K}+1}(T-t)}|\Delta\widetilde{y}^{II,\mathcal{K}}(t)|_2^2 dt\\ &\le \left\{e^{-2\lambda_{\mathcal{K}+1}T} + C\cdot C(\varepsilon,M,C_1)\left(\frac{1}{2\lambda_{\mathcal{K}+1}} - \frac{e^{-2\lambda_{\mathcal{K}+1}T}}{2\lambda_{\mathcal{K}+1}}\right)\right\}\cdot\|a^{II,\mathcal{K}}\|^2\\ &\quad +\varepsilon\cdot C\|a^{II,\mathcal{K}}\|^2.\end{aligned} \tag{2.8}$$

We now first choose an ε sufficiently small such that $\varepsilon\cdot C < \frac{1}{4}$. Then we fix such an ε and an integer $\mathcal{K}_0 \gg 1$ such that $e^{-2\lambda_{\mathcal{K}_0+1}T} < \frac{1}{4}$ and $C(\varepsilon,M,C_1)\cdot C(\frac{1}{2\lambda_{\mathcal{K}_0+1}} - \frac{e^-2\lambda_{\mathcal{K}_0+1}T}{2\lambda_{\mathcal{K}_0+1}}) < \frac{1}{4}$. (Apparently, the choice of such a $\mathcal{K}_0$ depends only on the operators $-\Delta, M, \Omega$, and T.) Then, for each integer $\mathcal{K}$ with $\mathcal{K}\ge\mathcal{K}_0$, it holds that

$$\|\widetilde{y}^{II,\mathcal{K}}(T)\|^2 \le \frac{3}{4}\|a^{II,\mathcal{K}}\|^2 \text{ for each } a^{II,\mathcal{K}}\in H^{II,\mathcal{K}}\cap V. \tag{2.9}$$

Now, for each integer $\mathcal{K}$ with $\mathcal{K}\ge\mathcal{K}_0$, each element $a^{I,\mathcal{K}}$ in the space $H^{I,\mathcal{K}}$, each function v in the space $L^2(0,T;H)$, and each function e in the space $L^\infty(0,T;L^n(\Omega))$ with the estimate $\|e\|_{L^\infty(0,T;L^n(\Omega))}\le M$, we define a map $J:\ H^{II,\mathcal{K}}\cap V\to H^{II,\mathcal{K}}\cap V$ by setting $J(a^{II,\mathcal{K}}) = y^{II,\mathcal{K}}(T;a^{I,\mathcal{K}}+a^{II,\mathcal{K}})$, where $y(t;a^{I,\mathcal{K}}+a^{II,\mathcal{K}})$ is the unique solution of (2.3) with z_0 being replaced by $(a^{I,\mathcal{K}}+a^{II,\mathcal{K}})$. Then, for any $a_1^{II,\mathcal{K}}$, $a_2^{II,\mathcal{K}}$ in the space $H^{II,\mathcal{K}}\cap V$, we have

$$\begin{aligned}\|J(a_1^{II,\mathcal{K}}) - J(a_2^{II,\mathcal{K}})\|^2 &= \|y^{II,\mathcal{K}}(T;a^{I,\mathcal{K}}+a_1^{II,\mathcal{K}}) - y^{II,\mathcal{K}}(T;a^{I,\mathcal{K}}+a_2^{II,\mathcal{K}})\|^2\\ &= \|\widetilde{y}(T;a_1^{II,\mathcal{K}} - a_2^{II,\mathcal{K}})\|^2,\end{aligned}$$

where $\widetilde{y}(t;a_1^{II,\mathcal{K}} - a_2^{II,\mathcal{K}})$ is the unique solution of (2.5) with $a^{II,\mathcal{K}}$ being replaced by $a_1^{II,\mathcal{K}} - a_2^{II,\mathcal{K}}$. Thus by (2.9), we get

$$\|J(a_1^{II,\mathcal{K}}) - J(a_2^{II,\mathcal{K}})\|^2 \le \frac{3}{4}\|a_1^{II,\mathcal{K}} - a_2^{II,\mathcal{K}}\|^2.$$

Hence, the map J has a unique fixed point $\widetilde{a}^{II,\mathcal{K}}$ in the space $H^{II,\mathcal{K}}\cap V$, and thus $y(t;a^{I,\mathcal{K}}+\widetilde{a}^{II,\mathcal{K}})\in Y$ is the unique solution of (2.1).

Next we shall prove the estimate (2.2). Let $\mathcal{K}$ be an integer, with $\mathcal{K}\ge\mathcal{K}_0$, and let e be a function in the space $L^\infty(0,T;L^n(\Omega))$, with $\|e\|_{L^\infty(0,T;L^n(\Omega))}\le M$. We write y for the unique solution of (2.1) corresponding to $a^{I,\mathcal{K}}\in H^{I,\mathcal{K}}$ and $v\in L^2(0,T;H)$. We can write $y = y_1 + y_2$, where the functions y_1 and y_2 satisfy

$$\begin{cases}(y_1)_t - \triangle y_1 - ey_1 = v & \text{in } Q,\\ y_1 = 0 & \text{on } \Sigma,\\ y_1^{I,\mathcal{K}}(0) = a^{I,\mathcal{K}},\ y_1^{II,\mathcal{K}}(0) = 0 & \text{in } \Omega\end{cases}$$

and

$$\begin{cases} (y_2)_t - \triangle y_2 - e y_2 = 0 & \text{in } Q, \\ y_2 = 0 & \text{on } \Sigma, \\ y_2^{I,\mathcal{K}}(0) = 0,\ y_2^{II,\mathcal{K}}(0) = y^{II,\mathcal{K}}(0) & \text{in } \Omega, \end{cases}$$

respectively. Then by (2.4), we have

$$\|y_1^{II,\mathcal{K}}(T)\|^2 \le \|y_1(T)\|^2 \le C\|y_1\|_Y^2 \le C(\|v\|^2_{L^2(0,T;H)} + \|a^{I,\mathcal{K}}\|^2).$$

It follows from (2.9) that

$$\|y_2^{II,\mathcal{K}}(T)\|^2 \le \frac{3}{4}\|y_2^{II,\mathcal{K}}(0)\|^2 = \frac{3}{4}\|y^{II,\mathcal{K}}(0)\|^2.$$

Thus it holds that

$$\begin{aligned} \|y^{II,\mathcal{K}}(0)\|^2 &= \|y^{II,\mathcal{K}}(T)\|^2 = \|y_1^{II,\mathcal{K}}(T) + y_2^{II,\mathcal{K}}(T)\|^2 \\ &\le C(\varepsilon)\|y_1^{II,\mathcal{K}}(T)\|^2 + (1+\varepsilon)\|y_2^{II,\mathcal{K}}(T)\|^2 \\ &\le C(\varepsilon)\cdot C(\|v\|^2_{L^2(0,T;H)} + \|a^{I,\mathcal{K}}\|^2) + \frac{3}{4}(1+\varepsilon)\|y^{II,\mathcal{K}}(0)\|^2 \ \forall\, \varepsilon > 0, \end{aligned}$$

where $C(\varepsilon)$ is a positive constant depending only on ε. Then by taking ε small enough such that $\frac{3}{4}(1+\varepsilon) < 1$, we get

$$\begin{aligned} \|y^{II,\mathcal{K}}(0)\|^2 &\le C(\|v\|^2_{L^2(0,T;H)} + \|a^{I,\mathcal{K}}\|^2) \\ &\le C(\|v\|^2_{L^2(0,T;H)} + \lambda_{\mathcal{K}}|a^{I,\mathcal{K}}|_2^2), \end{aligned}$$

from which and by (2.4), we obtain

$$\|y\|_Y^2 \le C(\|v\|^2_{L^2(0,T;H)} + \|a^{I,\mathcal{K}}\|^2 + \|y^{II,\mathcal{K}}(0)\|^2) \le C(\|v\|^2_{L^2(0,T;H)} + \lambda_{\mathcal{K}}|a^{I,\mathcal{K}}|_2^2).$$

This completes the proof of Theorem 2.1. □

Next, we shall study the existence of $\mathcal{K}$-approximate periodic solutions for some semilinear parabolic equations. Consider the following semilinear parabolic equation:

$$\begin{cases} y_t - \Delta y + f(x,t,y) = v & \text{in } Q, \\ y = 0 & \text{on } \Sigma, \\ y^{I,\mathcal{K}}(0) = a^{I,\mathcal{K}},\ y^{II,\mathcal{K}}(0) = y^{II,\mathcal{K}}(T) & \text{in } \Omega, \end{cases} \tag{2.10}$$

where $\mathcal{K}$ is a nonnegative integer, $a^{I,\mathcal{K}}$ is an element in the space $H^{I,\mathcal{K}}$, and v is a function in the space $L^2(0,T;H)$.

THEOREM 2.2. *Suppose that* ($\mathbf{H_f}$) *holds. Then, for each positive number M, there exists a nonnegative integer $\mathcal{K} \equiv \mathcal{K}(M)$ such that, for each function v in the space $L^2(0,T;H)$ and each element $a^{I,\mathcal{K}}$ in the space $H^{I,\mathcal{K}}$ satisfying the estimate*

$$\|v\|^2_{L^2(0,T;H)} + (1+\lambda_{\mathcal{K}})|a^{I,\mathcal{K}}|_2^2 \le 2M^2,$$

(2.10) *has at least one solution y in Y satisfying $\|y\|_Y^2 \le C(M)$, where $C(M)$ is a positive constant depending on M.*

Proof of Theorem 2.2. Let ρ be a positive number. We write $\mathcal{A}_\rho$ for the set $\{z \in Y;\ \|z\|_Y \le \rho\}$. It is clear that $\mathcal{A}_\rho$ is a compact and convex subset in $L^2(Q)$. We define a function $g : \Omega \times (0,T) \times \mathbf{R} \to \mathbf{R}$ by setting

$$g(x,t,\xi) = \begin{cases} \frac{f(x,t,\xi)}{\xi}, & \xi \neq 0, \\ \lim_{\xi \to 0} \frac{f(x,t,\xi)}{\xi}, & \xi = 0. \end{cases}$$

Since $Y \hookrightarrow L^\infty(0,T;V) \hookrightarrow L^\infty(0,T;L^{\frac{2n}{n-2}}(\Omega))$, it follows from the assumption $(\mathbf{H_f})$ that, for each element z in the set $\mathcal{A}_\rho$, we have

$$\begin{aligned} \operatorname{esssup}_{0\le t\le T} \int_\Omega |g(x,t,z)|^n dx &\le C \operatorname{esssup}_{0\le t\le T} \int_\Omega (1+|z|^\beta)^n dx \\ &\le C \operatorname{esssup}_{0\le t\le T} \int_\Omega (1+|z|^2) dx \le C(1+\rho^2). \end{aligned}$$

Here and throughout the proof of this theorem, C stands for a positive constant independent of ρ, $\mathcal{K}$, v, and $a^{I,\mathcal{K}}$, which may be different in different contexts. Then by Theorem 2.1, there exists a nonnegative integer $\mathcal{K}_0 \equiv \mathcal{K}_0(\rho, -\Delta, \Omega, T)$ such that, for each integer $\mathcal{K}$ with $\mathcal{K} \ge \mathcal{K}_0$, each element z in the set $\mathcal{A}_\rho$, each function v in the space $L^2(0,T;H)$, and each element $a^{I,\mathcal{K}}$ in the space $H^{I,\mathcal{K}}$, the equation

$$\begin{cases} y_t - \Delta y + g(x,t,z)y = v & \text{in } Q, \\ y = 0 & \text{on } \Sigma, \\ y^{I,\mathcal{K}}(0) = a^{I,\mathcal{K}},\ y^{II,\mathcal{K}}(0) = y^{II,\mathcal{K}}(T) & \text{in } \Omega \end{cases} \tag{2.11}$$

has a unique solution $y \equiv y(t; z, v, a^{I,\mathcal{K}}) \in Y$ satisfying

$$\|y\|_Y^2 \le C(\rho, -\Delta, \Omega, T)(\|v\|^2_{L^2(Q)} + \lambda_{\mathcal{K}} |a^{I,\mathcal{K}}|_2^2).$$

Now we fix such an integer $\mathcal{K}$ and such a pair $(a^{I,\mathcal{K}},\ v)$ in the space $H^{I,\mathcal{K}} \times L^2(Q)$ and then define a map $\Phi \equiv \Phi_{\rho,\mathcal{K},v,a^{I,\mathcal{K}}} : \mathcal{A}_\rho \to L^2(Q)$ by setting $\Phi(z) = y$.

We shall prove that the map Φ has a fixed point, and then (2.10) has a solution in Y. To this end, we first claim that the map Φ is continuous from $\mathcal{A}_\rho$ with the topology induced by the $L^2(Q)$-norm to $L^2(Q)$. Let $\{z_m\}$ be a sequence in the set $\mathcal{A}_\rho$ such that $z_m \to \widetilde{z}$ strongly in $L^2(Q)$ as $m \to \infty$. Then one can easily show that $\widetilde{z} \in \mathcal{A}_\rho$. Write $y_m,\ m = 1, 2, \ldots$, for the solutions of (2.11) with z being replaced by z_m. It suffices to show that $y_m \to \widetilde{y}$ strongly in $L^2(Q)$, as $m \to \infty$, and that $\widetilde{y}$ is the solution of (2.11) with z being replaced by $\widetilde{z}$. Here is the argument: Since $\{y_m\}$ and $\{z_m\}$ are bounded in Y, there exist subsequences $\{y_{m_k}\} \subset \{y_m\}$ and $\{z_{m_k}\} \subset \{z_m\}$ such that, as $m_k \to \infty$,

$$\begin{aligned} y_{m_k} \to \overline{y} \quad & \text{weakly in } Y, \\ & \text{strongly in } L^2(Q), \\ & \text{a.e. in } Q \end{aligned} \tag{2.12}$$

and

$$\begin{aligned} z_{m_k} \to \widetilde{z} \quad & \text{weakly in } Y, \\ & \text{strongly in } L^2(Q), \\ & \text{a.e. in } Q. \end{aligned} \tag{2.13}$$

Moreover,

$$(y_{m_k}(0), y_{m_k}(T)) \to (\overline{y}(0), \overline{y}(T)) \text{ strongly in } H \times H \text{ as } m_k \to \infty. \tag{2.14}$$

(Indeed, by the Ascoli–Arzela theorem, we can choose $\{z_{m_k}\}$ and $\{y_{m_k}\}$ such that $y_{m_k} \to \overline{y}$ and $z_{m_k} \to \widetilde{z}$ strongly in $C([0,T];H)$.) Now, by the continuity of g in the third variable and by (2.12) and (2.13), we obtain

$$g(x,t,z_{m_k}(x,t))y_{m_k}(x,t) \to g(x,t,\widetilde{z}(x,t))\overline{y}(x,t) \text{ a.e. in } L^2(Q) \text{ as } m_k \to \infty.$$

On the other hand, by $(\mathbf{H_f})$ and by making use of the Hölder inequality and the Sobolev embedding theorem, we have

$$\|g(x,t,z_{m_k})y_{m_k}\|^2_{L^2(Q)} \le C\|y_{m_k}\|^2_Y \|z_{m_k}\|^2_Y \le C.$$

Thus it holds that

$$g(x,t,z_{m_k}(x,t))y_{m_k}(x,t) \to g(x,t,\widetilde{z}(x,t))\overline{y}(x,t) \text{ weakly in } L^2(Q) \text{ as } m_k \to \infty.$$

Then by (2.12), (2.13), (2.14), and the above, we can pass to the limit, as $m_k \to \infty$, in the equation satisfied by y_{m_k} and z_{m_k} to get $\widetilde{y} = \overline{y}$. Hence, we have proved that $y_m \to \widetilde{y}$ strongly in $L^2(Q)$, as $m \to \infty$, and therefore Φ is continuous.

Next we claim that, for any z in the set $\mathcal{A}_\rho$, the function $y \equiv \Phi(z)$ satisfies the following estimate:

$$\|y\|^2_Y \le \widetilde{C}(1+\rho^{2\beta})(\|v\|^2_{L^2(Q)} + (1+\lambda_{\mathcal{K}})|a^{I,\mathcal{K}}|^2_2), \tag{2.15}$$

where $\widetilde{C}$ is a positive constant independent of ρ, $\mathcal{K}$, v, and $a^{I,\mathcal{K}}$.

By (i) of $(\mathbf{H_f})$, we obtain

$$g(x,t,\xi) \ge \mu - \lambda_1 \ \ \forall\, \xi \in \mathbf{R} \text{ and for almost all } (x,t) \in Q. \tag{2.16}$$

Multiplying the first equation of (2.11) by y and making use of (2.16), we get

$$\frac{1}{2}\frac{d}{dt}|y(t)|^2_2 + \mu|y(t)|^2_2 \le |\langle v(t), y(t)\rangle| \ \forall\ t \in [0,T],$$

from which it follows that

$$\frac{d}{dt}|y(t)|^2_2 + \mu|y(t)|^2_2 \le \frac{1}{\mu}|v(t)|^2_2 \ \forall\ t \in [0,T].$$

Integrating the above over $(0,T)$, we get

$$e^{\mu T}|y(T)|^2_2 \le \frac{1}{\mu}e^{\mu T}\int_0^T |v(t)|^2_2 dt + |y(0)|^2_2.$$

Hence, it holds that

$$e^{\mu T}|y^{II,\mathcal{K}}(T)|^2_2 \le \frac{1}{\mu}e^{\mu T}\int_0^T |v(t)|^2_2 dt + |y^{II,\mathcal{K}}(0)|^2_2 + |a^{I,\mathcal{K}}|^2_2.$$

Since $y^{II,\mathcal{K}}(0) = y^{II,\mathcal{K}}(T)$, we have

$$\begin{aligned} |y^{II,\mathcal{K}}(0)|^2_2 &\le (e^{\mu T}-1)^{-1}\left(\frac{1}{\mu}e^{\mu T}\int_0^T |v(t)|^2_2 dt\right) + (e^{\mu T}-1)^{-1}|a^{I,\mathcal{K}}|^2_2 \\ &\le C(\|v\|^2_{L^2(Q)} + |a^{I,\mathcal{K}}|^2_2), \end{aligned}$$

from which it follows that

$$|y(0)|_2^2 \le C(\|v\|_{L^2(Q)}^2 + |a^{I,\mathcal{K}}|_2^2).$$

Then by (2.11) and (2.16) and by making use of the standard energy estimate argument for linear parabolic equations, we can easily have

$$\begin{aligned}\|y\|_{V_2(Q)}^2 \equiv \operatorname{esssup}_{0\le t\le T}|y(t)|_2^2 + \int_0^T \|y(t)\|^2 dt &\le C(\|v\|_{L^2(Q)}^2 + |y(0)|_2^2)\\ &\le C(\|v\|_{L^2(Q)}^2 + |a^{I,\mathcal{K}}|_2^2).\end{aligned} \tag{2.17}$$

On the other hand, we let $q = \frac{n+2}{n-2}\cdot\frac{1}{\beta}$. Then $q > \frac{n+2}{2}$ for $0 < \beta \le \frac{2}{n}$. By $(\mathbf{H_f})$ and by making use of the Hölder inequality and the Sobolev embedding theorem $(Y \hookrightarrow L^{\frac{2(n+2)}{n-2}}(Q))$, we get

$$\begin{aligned}\|(g(x,t,z))^2\|_{L^q(Q)} &\le C\left\{\int_Q (|z|^\beta + 1)^{2q} dxdt\right\}^{\frac{1}{q}} \le C\left\{1 + \left(\int_Q |z|^{\frac{2(n+2)}{n-2}} dxdt\right)^{\frac{1}{q}}\right\}\\ &\le C\left(1 + \|z\|^{2\beta}_{L^{\frac{2(n+2)}{n-2}}(Q)}\right) \le C(1 + \|z\|_Y^{2\beta}) \le C(1+\rho^{2\beta}).\end{aligned} \tag{2.18}$$

By (2.17) and (2.18), and by the estimate in [3] (see p. 50 in [3]), we get

$$\begin{aligned}\int_Q (g(x,t,z))^2 y^2 dxdt &\le C\|(g(x,t,z))^2\|_{L^q(Q)} \cdot \|y\|_{V_2(Q)}^2\\ &\le C(1+\rho^{2\beta})(\|v\|_{L^2(Q)}^2 + |a^{I,\mathcal{K}}|_2^2).\end{aligned} \tag{2.19}$$

Now let $F = v - g(x,t,z)y \in L^2(Q)$. Then $y \in Y$ satisfies the following heat equation:

$$\begin{cases} y_t - \Delta y = F & \text{in } Q,\\ y = 0 & \text{on } \Sigma,\\ y^{I,\mathcal{K}}(0) = a^{I,\mathcal{K}},\ y^{II,\mathcal{K}}(0) = y^{II,\mathcal{K}}(T) & \text{in } \Omega. \end{cases} \tag{2.20}$$

Moreover, by (2.19), it is clear that

$$\int_Q (F(x,t))^2 dxdt \le C(1+\rho^{2\beta})(\|v\|_{L^2(Q)}^2 + |a^{I,\mathcal{K}}|_2^2). \tag{2.21}$$

Multiplying the first equation of (2.20) by $t(-\Delta y(t))$, we get

$$\frac{d}{dt}(t\|y(t)\|^2) + t|\Delta y(t)|_2^2 \le \|y(t)\|^2 + t|F(t)|_2^2.$$

Integrating the above over $(0,T)$, by (2.17) and (2.21), we get

$$T\|y(T)\|^2 \le \int_0^T \|y(t)\|^2 dt + T\int_0^T |F(t)|_2^2 dt \le C(1+\rho^{2\beta})(\|v\|_{L^2(Q)}^2 + |a^{I,\mathcal{K}}|_2^2),$$

from which it follows that

$$\|y^{II,\mathcal{K}}(0)\|^2 = \|y^{II,\mathcal{K}}(T)\|^2 \le C(1+\rho^{2\beta})(\|v\|_{L^2(Q)}^2 + |a^{I,\mathcal{K}}|_2^2).$$

Hence,

$$\|y(0)\|^2 = \|y^{I,\mathcal{K}}(0)\|^2 + \|y^{II,\mathcal{K}}(0)\|^2 \le C(1+\rho^{2\beta})(\|v\|^2_{L^2(Q)} + |a^{I,\mathcal{K}}|_2^2) + \|a^{I,\mathcal{K}}\|^2$$
$$\le C(1+\rho^{2\beta})(\|v\|^2_{L^2(Q)} + (1+\lambda_{\mathcal{K}})|a^{I,\mathcal{K}}|_2^2).$$

Then by (2.20) and (2.21) and by making use of the standard energy estimate argument for the heat equation, we can get (2.15) easily.

Notice that $\beta \le \frac{2}{n} < 1$. Thus for a given $M > 0$, we can take a $\rho > 0$ large enough such that $2\widetilde{C}M^2(1+\rho^{2\beta}) \le \rho^2$, where the constant $\widetilde{C}$ is the one appearing in (2.15). Then we fix an integer $\mathcal{K} \equiv \mathcal{K}(\rho)$ such that (2.11) has a unique solution in Y for each triplet $(v, a^{I,\mathcal{K}}, z) \in L^2(Q) \times H^{I,\mathcal{K}} \times \mathcal{A}_\rho$. Hence, it follows from (2.15) that, for any pair $(v, a^{I,\mathcal{K}}) \in L^2(Q) \times H^{I,\mathcal{K}}$ with $\|v\|^2_{L^2(Q)} + (1+\lambda_{\mathcal{K}})|a^{I,\mathcal{K}}|_2^2 \le 2M^2$, the map $\Phi \equiv \Phi_{\rho,\mathcal{K},v,a^{I,\mathcal{K}}}$ satisfies

$$\|\Phi(z)\|_Y^2 \le 2\widetilde{C}M^2(1+\rho^{2\beta}) \le \rho^2 \text{ for any } z \in \mathcal{A}_\rho, \text{ namely, } \Phi(\mathcal{A}_\rho) \subset \mathcal{A}_\rho.$$

Since $\mathcal{A}_\rho$ is convex and compact in $L^2(Q)$ and Φ is continuous, we conclude that Φ has a fixed point $y \in Y$ which is a solution to (2.10). This completes the proof of Theorem 2.2. □

Next, we shall give some examples to show how to estimate the integers $\mathcal{K}_0$ and $\mathcal{K}$ in Theorems 2.1 and 2.2 in certain particular cases.

Example 2.3. Consider the following equation:

$$\text{(2.22)} \quad \begin{cases} y_t(x,t) - \Delta y(x,t) - e(x,t)y(x,t) = v(x,t) & 0 \le x \le 1, 0 \le t \le 1, \\ y(0,t) = y(1,t) = 0 & 0 \le t \le 1. \end{cases}$$

Here $e \in L^\infty((0,1)\times(0,1))$ and $v \in L^2((0,1)\times(0,1))$. Notice that $\{\sqrt{2}\sin(j\pi x)\}_{j=1}^\infty$ forms an orthonormal basis of $L^2(0,1)$. We write $v(x,t) = \sum_{j=1}^\infty v_j(t)\sin(j\pi x)$ and $y(x,t) = \sum_{j=1}^\infty w_j(t)\sin(j\pi x)$. We assume first that $e(x,t) \equiv a$ for all (x,t) in $[0,1]\times[0,1]$, where a is a real number. Then we have

$$w_j'(t) = -(j\pi)^2 w_j(t) + a w_j(t) + v_j(t), \quad j = 1, 2, \dots.$$

Thus, it holds that, for all $j = 1, 2, \dots,$

$$\text{(2.23)} \qquad w_j(1)\exp\{-a + (j\pi)^2\} - w_j(0) = \int_0^1 v_j(t)\exp\{-a + (j\pi)^2\}dt.$$

Now, for a given natural number N, we choose $a = (N\pi)^2$ and choose $v(x,t)$ such that $\int_0^1 v_N(t)dt \ne 0$; then, by (2.23), we see that (2.22) can never have a solution $y(x,t) = \sum_{j=1}^\infty w_j(t)\sin(j\pi x)$ such that $w_N(0) = w_N(1)$. Namely, (2.22) can never have a $\mathcal{K}$-approximate periodic solution with $\mathcal{K} = N-1$. However, in the case that $a = (N\pi)^2$, for each $a^{I,\mathcal{K}} = \sum_{j=1}^N a_j \sin(j\pi x)$, $v \in L^2((0,1)\times(0,1))$, (2.22) does have a unique solution y satisfying $y^{I,\mathcal{K}}(0) = a^{I,\mathcal{K}}$, $y^{II,\mathcal{K}}(0) = y^{II,\mathcal{K}}(1)$. Namely, (2.22) has a unique $\mathcal{K}$-approximate periodic solution y with $\mathcal{K} = N$, which satisfies $y^{I,\mathcal{K}}(0) = a^{I,\mathcal{K}}$. Moreover, we can easily see from (2.23) that, for each real number a, if we take $\mathcal{K}_0$ such that

$$\text{(2.24)} \qquad (\mathcal{K}_0\pi)^2 \ge a,$$

then it holds that, for each integer $\mathcal{K} \ge \mathcal{K}_0$, $v \in L^2((0,1)\times(0,1))$, and $a^{I,\mathcal{K}} = \sum_{j=1}^N a_j \sin(j\pi x)$, (2.22) has a unique solution y satisfying $y^{I,\mathcal{K}}(0) = a^{I,\mathcal{K}}$, $y^{II,\mathcal{K}}(0) =$

$y^{II,\mathcal{K}}(1)$. Thus, the inequality (2.24) gives a way to calculate the integer $\mathcal{K}_0$ in Theorem 2.1 in this case.

Next, we consider (2.22) where e is a function in the subset $\{e \in L^\infty((0,1)\times(0,1)); \|e\|_{L^\infty((0,1)\times(0,1))} \le M\}$ for a fixed positive number M. In this case, the integer $\mathcal{K}_0$ in Theorem 2.1 can be estimated as follows. Notice first that the constant C in the inequality (2.8) can be obtained from the embedding inequalities (2.6) and (2.7). Now in (2.8) we take $\varepsilon = \frac{1}{5C} < \frac{1}{4C}$ and $C(\varepsilon, M) = \frac{M^2}{\varepsilon} = 5CM^2$. Then the integer $\mathcal{K}_0$ can be calculated from the following inequalities:

$$\begin{aligned} &\exp\{-2((\mathcal{K}_0+1)\pi)^2\} < \frac{1}{4}, \\ &\frac{5C^2M^2}{2((\mathcal{K}_0+1)\pi)^2}(1-\exp\{-2((\mathcal{K}_0+1)\pi)^2\}) < \frac{1}{4}. \end{aligned} \tag{2.25}$$

Finally, we consider the following semilinear equation:

$$\begin{cases} y_t(x,t) - \Delta y(x,t) + f(y(x,t)) = v(x,t) & 0 \le x \le 1, 0 \le t \le 1, \\ y(0,t) = y(1,t) = 0 & 0 \le t \le 1. \end{cases} \tag{2.26}$$

Here the function $f : \mathbf{R} \to \mathbf{R}$ is continuously differentiable and has the following properties: $f(0) = 0$, $f(\xi)\xi \ge 0$ for all $\xi \in \mathbf{R}$, and there exists a positive constant C_0 such that $|f'(\xi)| \le C_0$ for all $\xi \in \mathbf{R}$. Then the function $g(\xi)$ defined by

$$g(\xi) = \begin{cases} \frac{f(\xi)}{\xi}, & \xi \ne 0, \\ \lim_{\xi\to 0} \frac{f(\xi)}{\xi}, & \xi = 0 \end{cases}$$

satisfies $|g(\xi)| \le C_0$ for all $\xi \in \mathbf{R}$. Hence, it holds that, for each $z \in \mathbf{Y}$,

$$|g(z(x,t))| \le C_0, \quad \text{a.e. } (x,t) \in (0,1)\times(0,1). \tag{2.27}$$

Then, by Theorem 2.1, we obtain that there exists a nonnegative integer $\mathcal{K}_0 \equiv \mathcal{K}_0(-\triangle, C_0)$ such that for each $\mathcal{K} \ge \mathcal{K}_0$, $z \in \mathbf{Y}$, $v \in L^2((0,1)\times(0,1))$, and $a^{I,\mathcal{K}} \in H^{I,\mathcal{K}}$, the linearized equation

$$\begin{cases} y_t - \Delta y + g(z)y = v & 0 \le x \le 1, 0 \le t \le 1, \\ y(0,t) = y(1,t) = 0 & 0 \le t \le 1, \\ y^{I,\mathcal{K}}(0) = a^{I,\mathcal{K}},\ y^{II,\mathcal{K}}(0) = y^{II,\mathcal{K}}(T) & 0 \le x \le 1 \end{cases}$$

has a unique solution $y \in \mathbf{Y}$ satisfying

$$\|y\|_Y^2 \le C(C_0, -\triangle)(\|v\|^2_{L^2((0,1)\times(0,1))} + \lambda_{\mathcal{K}}|a^{I,\mathcal{K}}|_2^2). \tag{2.28}$$

Moreover, the aforementioned integer $\mathcal{K}_0$ can be estimated by (2.25) with M being replaced by C_0. Notice that, in this case, both the integer $\mathcal{K}_0$ and the constant $C(C_0, -\Delta)$ in (2.28) are independent of ρ, which is the positive number given in the proof of Theorem 2.2. Then, by (2.27) and (2.28), after carefully checking the proof of Theorem 2.2, we can obtain that, in this case, the integer $\mathcal{K}$ in Theorem 2.2 can be taken as the aforementioned integer $\mathcal{K}_0$. Hence, in this case, the integer $\mathcal{K}$ in Theorem 2.2 can be estimated by (2.25).

3. Pontryagin's maximum principle of optimal controls for the problem $(\mathbf{P}_{\mathcal{K},r})$. In this section, we shall prove Theorem 1.1, namely, the Pontryagin maximum principle for the optimal control problem $(\mathbf{P}_{\mathcal{K},r})$. The basic idea to be used here is to construct a well-posed approximate optimization problem to approach the non-well-posed problem $(\mathbf{P}_{\mathcal{K},r})$. This idea has been used in [10], [12], [13]. However, in the current work, the approximation problem is to ask the infimum of a penalty functional over a suitable subset of the space $Y \times L^2(Q)$. Moreover, this construction works well due to Theorem 2.1, namely, the results of existence and uniqueness of $\mathcal{K}$-approximate periodic solutions for the linear parabolic equations. Throughout this section, we assume that $(\mathbf{A_f})$ holds.

3.1. Formulation of an approximate problem. Let $(y^*, u^*) \in Y \times L^2(Q)$ be optimal for problem $(\mathbf{P}_{\mathcal{K},r})$. By the property $(\mathbf{A_f})$ and by making use of the Sobolev embedding theorem and the Hölder inequality, we see that there exists a positive constant C_0 such that the following holds:

$$\|f'_y(x,t,y)\|_{L^\infty(0,T;L^n(\Omega))} \le C_0(1 + \|y\|_Y^{\frac{2}{n-2}}) \ \forall\ y \in Y. \tag{3.1}$$

Set

$$M = C_0(1 + \|y^*\|_Y^{\frac{2}{n-2}}) + 1. \tag{3.2}$$

Then by Theorem 2.1, there exists an integer $\mathcal{K}_0 \equiv \mathcal{K}_0(M, \Omega, -\Delta, T)$, with $\mathcal{K}_0 > \mathcal{K}$, such that for each function e in the space $L^\infty(0,T;L^n(\Omega))$ satisfying the estimate $\|e\|_{L^\infty(0,T;L^n(\Omega))} \le M$, each function g in the space $L^2(Q)$, and each element $b^{I,\mathcal{K}_0}$ in the space $H^{I,\mathcal{K}_0}$, the following equation has a unique solution y in the space Y:

$$\begin{cases} y_t - \Delta y + ey = g & \text{in } Q, \\ y = 0 & \text{on } \Sigma, \\ y^{I,\mathcal{K}_0}(0) = b^{I,\mathcal{K}_0},\ y^{II,\mathcal{K}_0}(0) = y^{II,\mathcal{K}_0}(T) & \text{in } \Omega. \end{cases} \tag{3.3}$$

Write $H^{II,\mathcal{K}} = H^{II,\mathcal{K},1} \oplus H^{II,\mathcal{K},2}$, where $H^{II,\mathcal{K},1} = span\{X_i\}_{i=\mathcal{K}+1}^{\mathcal{K}_0}$, $H^{II,\mathcal{K},2} = span\{X_i\}_{i=\mathcal{K}_0+1}^{\infty} \equiv H^{II,\mathcal{K}_0}$. Then, for each $y(t) = \sum_{i=1}^{\infty} y_i(t)X_i \in L^2(0,T;H)$ and for each $h = \sum_{i=1}^{\infty} h_i X_i \in H$, we have

$$y(t) = y^{I,\mathcal{K}}(t) + y^{II,\mathcal{K},1}(t) + y^{II,\mathcal{K},2}(t) \equiv \sum_{i=1}^{\mathcal{K}} y_i(t)X_i + \sum_{i=\mathcal{K}+1}^{\mathcal{K}_0} y_i(t)X_i + \sum_{i=\mathcal{K}_0+1}^{\infty} y_i(t)X_i$$

and

$$h = h^{I,\mathcal{K}} + h^{II,\mathcal{K},1} + h^{II,\mathcal{K},2} \equiv \sum_{i=1}^{\mathcal{K}} h_i X_i + \sum_{i=\mathcal{K}+1}^{\mathcal{K}_0} h_i X_i + \sum_{i=\mathcal{K}_0+1}^{\infty} h_i X_i.$$

Now, for each $\varepsilon > 0$, we define a functional $J_\varepsilon : Y \times L^2(Q) \to \mathbf{R}$ by setting

$$\begin{aligned} J_\varepsilon(y,u) &= J(y,u) + \frac{n-2}{2n}\int_Q (y - y^*)^{\frac{2n}{n-2}} dxdt + \frac{1}{2}\int_Q (u - u^*)^2 dxdt \\ &\quad + \frac{1}{2\varepsilon}|y^{II,\mathcal{K},1}(T) - y^{II,\mathcal{K},1}(0)|_2^2 + \frac{1}{2\varepsilon}(d_B(y^{I,\mathcal{K}}(T)) + \varepsilon)^2 \\ &\quad + \frac{1}{2\varepsilon}\int_Q (y_t - \Delta y + f(x,t,y) - \chi_\omega u)^2 dxdt, \end{aligned} \tag{3.4}$$

where $d_B(\cdot)$ denotes the distance function of $\cdot$ to the set $B^{I,\mathcal{K}}(0,r)$ in the space $H^{I,\mathcal{K}}$. One can easily check that the functional J_ε is well-defined. Set

$$\widetilde{Y} = \{y \in Y;\ y^{I,\mathcal{K}}(0) = a^{I,\mathcal{K}},\ y^{II,\mathcal{K},2}(0) = y^{II,\mathcal{K},2}(T)\},$$

and consider the following optimization problem:

$$(\mathbf{P}^{\varepsilon}_{\mathcal{K},r}):\ \ \mathrm{Inf} J_\varepsilon(y,u) \text{ over all } (y,u) \in \widetilde{Y} \times L^2(Q).$$

We shall use the well-posed approximate problem $(\mathbf{P}^{\varepsilon}_{\mathcal{K},r})$ to approach the original optimal control problem $(\mathbf{P}_{\mathcal{K},r})$ and finally derive the Pontryagin maximum principle in a qualified form for the problem $(\mathbf{P}_{\mathcal{K},r})$.

3.2. Properties of the approximate problem $(\mathbf{P}^{\varepsilon}_{\mathcal{K},r})$. First of all, we shall derive a prior estimate for the solutions to the following equation, which will be used later:

$$\left\{\begin{array}{ll} y_t - \Delta y = g & \text{in } Q,\\ y = 0 & \text{on } \Sigma,\\ y^{I,\mathcal{K}}(0) = b^{I,\mathcal{K}},\ y^{II,\mathcal{K},1}(0) = y^{II,\mathcal{K},1}(T) + \xi^{II,\mathcal{K},1} & \text{in } \Omega,\\ y^{II,\mathcal{K},2}(0) = y^{II,\mathcal{K},2}(T) & \text{in } \Omega. \end{array}\right. \tag{3.5}$$

LEMMA 3.1. *Let $g \in L^2(Q)$, $b^{I,\mathcal{K}} \in H^{I,\mathcal{K}}$, $\xi^{II,\mathcal{K},1} \in H^{II,\mathcal{K},1}$, and $y \in Y$ satisfy* (3.5). *Then there exists a positive constant $C \equiv C(\Omega, -\Delta, T)$ depending only on T, Ω, and the operator $(-\Delta)$ such that*

$$\|y\|^2_Y \le C(\|g\|^2_{L^2(Q)} + |b^{I,\mathcal{K}}|^2_2 + |\xi^{II,\mathcal{K},1}|^2_2). \tag{3.6}$$

Proof of Lemma 3.1. We write $y(x,t) = \sum_{i=1}^{\infty} y_i(t)X_i$, $g(x,t) = \sum_{i=1}^{\infty} g_i(t)X_i$, $b^{I,\mathcal{K}} = \sum_{i=1}^{\mathcal{K}} b_i X_i, \xi^{II,\mathcal{K},1} = \sum_{i=\mathcal{K}+1}^{\mathcal{K}_0} \xi_i X_i$, where $b_i,\ \xi_i \in \mathbf{R}$. Then it holds that

$$\frac{d}{dt} y_i(t) + \lambda_i y_i(t) = g_i(t),\ i = 1,2,\ldots,$$

from which we get

$$y_i(t) = e^{-\lambda_i t} y_i(0) + \int_0^t e^{-\lambda_i (t-s)} g_i(s) ds,\ i = 1,2,\ldots.$$

Then by (3.5), we have

$$\left\{\begin{array}{ll} y_i(0) = b_i, & i = 1,2,\ldots,\mathcal{K},\\ y_i(0) = \dfrac{1}{1-e^{-\lambda_i T}} \left\{ \displaystyle\int_0^T e^{-\lambda_i (T-s)} g_i(s) ds + \xi_i \right\}, & i = \mathcal{K}+1, \mathcal{K}+2, \ldots, \mathcal{K}_0,\\ y_i(0) = \dfrac{1}{1-e^{-\lambda_i T}} \displaystyle\int_0^T e^{-\lambda_i (T-s)} g_i(s) ds, & i = \mathcal{K}_0+1, \mathcal{K}_0+2, \ldots. \end{array}\right. \tag{3.7}$$

Notice that $0 < \lambda_1 < \lambda_2 \le \cdots \to +\infty$. A simple computation, together with (3.7), then leads us to

$$\begin{aligned} \|y(\cdot,0)\|^2 = \sum_{i=1}^{\infty} \lambda_i y_i^2(0) &\le C \left(\sum_{i=1}^{\mathcal{K}} b_i^2 + \sum_{i=\mathcal{K}+1}^{\mathcal{K}_0} \xi_i^2 + \sum_{i=1}^{\infty} \int_0^T g_i^2(t) dt \right)\\ &= C(|b^{I,\mathcal{K}}|^2_2 + |\xi^{II,\mathcal{K},1}|^2_2 + \|g\|^2_{L^2(Q)}). \end{aligned}$$

Then, by the standard energy estimate for the heat equation, we get (3.6). This completes the proof of Lemma 3.1. □

Remark 3.1. Lemma 3.1 holds for all integers $\mathcal{K}, \mathcal{K}_0$, with $0 \le \mathcal{K} < \mathcal{K}_0$.

LEMMA 3.2. *Problem* $(\mathbf{P}^{\varepsilon}_{\mathcal{K},r})$ *has at least one solution.*

Proof of Lemma 3.2. Set $d = \mathrm{Inf}\{J_\varepsilon(y,u);\ (y,u) \in \widetilde{Y} \times L^2(Q)\}$, and let $\{(y_m, u_m)\}$ be a sequence in the space $\widetilde{Y} \times L^2(Q)$ such that

$$d \le J_\varepsilon(y_m, u_m) \le d + \frac{1}{m}. \tag{3.8}$$

By (3.4) and (3.8), it follows that the sequence $\{u_m\}$ is bounded in $L^2(Q)$, the sequence $\{(y_m)_t - \Delta y_m + f(x,t,y_m) - \chi_\omega u_m\}$ is bounded in $L^2(Q)$, and the sequence $\{y_m\}$ is bounded in $L^{\frac{2n}{n-2}}(Q)$. From the latter and by making use of the assumption $(\mathbf{A_f})$, we see easily that the sequence $\{f(x,t,y_m)\}$ is bounded in $L^2(Q)$. Applying (3.4) and (3.8) again, we obtain also that the sequence $\{y_m^{II,\mathcal{K},1}(T) - y_m^{II,\mathcal{K},1}(0)\}$ is bounded in H. Set $g_m = (y_m)_t - \Delta y_m$ and $\xi_m^{II,\mathcal{K},1} = y_m^{II,\mathcal{K},1}(0) - y_m^{II,\mathcal{K},1}(T)$. Then the sequences $\{g_m\}$ and $\{\xi_m^{II,\mathcal{K},1}\}$ are bounded in the spaces $L^2(Q)$ and H, respectively. Since $\{y_m\} \subset \widetilde{Y}$, we have $y_m^{I,\mathcal{K}}(0) = a^{I,\mathcal{K}}$ and $y_m^{II,\mathcal{K},2}(0) = y_m^{II,\mathcal{K},2}(T)$. Thus we can apply Lemma 3.1 to get

$$\|y_m\|_Y^2 \le C(\|g_m\|^2_{L^2(Q)} + |a^{I,\mathcal{K}}|_2^2 + |\xi_m^{II,\mathcal{K},1}|_2^2).$$

Hence, $\{y_m\}$ is bounded in Y. Then by the Aubin compactness theorem and the Ascoli–Arzela theorem, we can extract a subsequence of $\{y_m\}$, which, for simplicity of notation, is still denoted by itself such that as $m \to \infty$

$$y_m \to \widetilde{y} \quad \text{weakly in } Y, \tag{3.9}$$

$$y_m \to \widetilde{y} \quad \text{strongly in } L^2(0,T;V) \cap C([0,T];H), \tag{3.10}$$

$$y_m \to \widetilde{y} \quad \text{a.e. in } Q. \tag{3.11}$$

In particular, it follows from (3.10) that

$$(y_m^{II,\mathcal{K},1}(T), y_m^{II,\mathcal{K},1}(0)) \to (\widetilde{y}^{II,\mathcal{K},1}(T), \widetilde{y}^{II,\mathcal{K},1}(0)) \text{ strongly in } H \times H \text{ as } m \to \infty \tag{3.12}$$

and

$$d_B(y_m^{I,\mathcal{K}}(T)) \to d_B(\widetilde{y}^{I,\mathcal{K}}(T)) \ \text{ as } m \to \infty. \tag{3.13}$$

On the other hand, since the sequence $\{u_m\}$ is bounded in the space $L^2(Q)$, we can assume, without loss of generality, that

$$u_m \to \widetilde{u} \text{ weakly in } L^2(Q) \ \text{ as } m \to \infty. \tag{3.14}$$

Since $\{y_m\} \subset \widetilde{Y}$, it follows from (3.10) that $\widetilde{y}^{I,\mathcal{K}}(0) = a^{I,\mathcal{K}}$, $\widetilde{y}^{II,\mathcal{K},2}(0) = \widetilde{y}^{II,\mathcal{K},2}(T)$. Hence, $\widetilde{y} \in \widetilde{Y}$.

Now we claim that

$$f(x,t,y_m) \to f(x,t,\widetilde{y}) \text{ weakly in } L^2(Q) \ \text{ as } m \to \infty. \tag{3.15}$$

Indeed, by (3.11) and $(\mathbf{A_f})$, we obtain

$$f(x,t,y_m) \to f(x,t,\widetilde{y}) \ \text{ a.e. in } Q \text{ as } m \to \infty.$$

On the other hand, the sequence $\{f(x,t,y_m)\}$ is bounded in $L^2(Q)$. Then (3.15) follows immediately. Now, by (3.9), (3.14), and (3.15), we see that as $m \to \infty$

$$(y_m)_t - \Delta y_m + f(x,t,y_m) - \chi_\omega u_m \to \widetilde{y}_t - \Delta\widetilde{y} + f(x,t,\widetilde{y}) - \chi_\omega \widetilde{u} \text{ weakly in } L^2(Q). \tag{3.16}$$

Then by (3.9), from which it follows that $y_m \to \widetilde{y}$ weakly in $L^{\frac{2n}{n-2}}(Q)$ as $m \to \infty$, and by (3.12), (3.13), (3.14), (3.16), and (3.4), we can easily get that

$$\underline{\lim}_{m\to\infty} J_\varepsilon(y_m, u_m) \geq J_\varepsilon(\widetilde{y}, \widetilde{u}) \geq d.$$

This together with (3.8) implies $J_\varepsilon(\widetilde{y}, \widetilde{u}) = d$. Since $(\widetilde{y}, \widetilde{u}) \in \widetilde{Y} \times L^2(Q)$, $(\widetilde{y}, \widetilde{u})$ is a solution to problem $(\mathbf{P}^\varepsilon_{\mathcal{K},r})$. This completes the proof of Lemma 3.2. □

LEMMA 3.3. *Let $(y_\varepsilon, u_\varepsilon)$ be optimal for problem $(\mathbf{P}^\varepsilon_{\mathcal{K},r})$. Then when $\varepsilon \to 0^+$, $u_\varepsilon \to u^*$ strongly in $L^2(Q)$, $y_\varepsilon \to y^*$ strongly in Y.*

Proof of Lemma 3.3. It is clear that $y^* \in \widetilde{Y}$. By the optimality of $(y_\varepsilon, u_\varepsilon)$ to problem $(\mathbf{P}^\varepsilon_{\mathcal{K},r})$, it follows that

$$J_\varepsilon(y_\varepsilon, u_\varepsilon) \leq J_\varepsilon(y^*, u^*) = J(y^*, u^*) + \frac{\varepsilon}{2},$$

which implies

$$\overline{\lim_{\varepsilon\to 0^+}} J_\varepsilon(y_\varepsilon, u_\varepsilon) \leq J(y^*, u^*). \tag{3.17}$$

By (3.4) and (3.17), we see that the sequence $\{y_\varepsilon\}$ is bounded in $L^{\frac{2n}{n-2}}(Q)$, the sequence $\{u_\varepsilon\}$ is bounded in $L^2(Q)$, the sequence $\{y_\varepsilon^{II,\mathcal{K},1}(T) - y_\varepsilon^{II,\mathcal{K},1}(0)\}$ is bounded in H, and the sequence $\{(y_\varepsilon)_t - \Delta y_\varepsilon + f(x,t,y_\varepsilon) - \chi_\omega u_\varepsilon\}$ is bounded in $L^2(Q)$. Then, by the same argument as that in the proof of Lemma 3.2, we can extract a generalized subsequence of $\{\varepsilon\}$, which, for simplicity of notation, is still denoted in the same way such that as $\varepsilon \to 0^+$

$$\begin{array}{ll} u_\varepsilon \to \widetilde{u} & \text{weakly in } L^2(Q), \\ y_\varepsilon \to \widetilde{y} & \text{weakly in } Y, \\ & \text{a.e. in } Q, \\ & \text{strongly in } C([0,T];H) \cap L^2(0,T;V), \end{array} \tag{3.18}$$

$$(y_\varepsilon)_t - \Delta y_\varepsilon + f(x,t,y_\varepsilon) - \chi_\omega u_\varepsilon \to \widetilde{y}_t - \Delta\widetilde{y} + f(x,t,\widetilde{y}) - \chi_\omega \widetilde{u} \text{ weakly in } L^2(Q). \tag{3.19}$$

Since $\{y_\varepsilon\} \subset \widetilde{Y}$, it follows from (3.18) that $\widetilde{y} \in \widetilde{Y}$.

Applying (3.4) and (3.17) again, we obtain

$$d_B(y_\varepsilon^{I,\mathcal{K}}(T)) \to 0 \ \text{ as } \varepsilon \to 0^+, \tag{3.20}$$

$$y_\varepsilon^{II,\mathcal{K},1}(T) - y_\varepsilon^{II,\mathcal{K},1}(0) \to 0 \ \text{ strongly in } H^{II,\mathcal{K},1} \ \text{ as } \varepsilon \to 0^+, \tag{3.21}$$

and

$$(y_\varepsilon)_t - \Delta y_\varepsilon + f(x,t,y_\varepsilon) - \chi_\omega u_\varepsilon \to 0 \ \text{ strongly in } L^2(Q) \ \text{ as } \varepsilon \to 0^+. \tag{3.22}$$

By (3.18) and (3.20), we have $\widetilde{y}^{I,\mathcal{K}}(T) \in B^{I,\mathcal{K}}(0,r)$. By (3.18) and (3.21), we obtain $\widetilde{y}^{II,\mathcal{K},1}(T) = \widetilde{y}^{II,\mathcal{K},1}(0)$. Then by (3.19) and (3.22) and noticing that $\widetilde{y} \in \widetilde{Y}$, we see that $(\widetilde{y}, \widetilde{u})$ satisfies the following:

$$\begin{cases} \widetilde{y}_t - \Delta\widetilde{y} + f(x,t,\widetilde{y}) = \chi_\omega \widetilde{u} & \text{in } Q, \\ \widetilde{y} = 0 & \text{on } \Sigma, \\ \widetilde{y}^{I,\mathcal{K}}(0) = a^{I,\mathcal{K}},\ \widetilde{y}^{II,\mathcal{K}}(0) = \widetilde{y}^{II,\mathcal{K}}(T) & \text{in } \Omega, \\ \widetilde{y}^{I,\mathcal{K}}(T) \in B^{I,\mathcal{K}}(0,r). \end{cases}$$

Hence, $(\widetilde{y},\widetilde{u}) \in Y \times L^2(Q)$ is admissible for problem $(\mathbf{P}_{\mathcal{K},r})$, and therefore

$$J(\widetilde{y},\widetilde{u}) \geq J(y^*,u^*). \tag{3.23}$$

On the other hand, it follows, from (3.4) and (3.18), that

$$\varliminf_{\varepsilon\to 0^+} J_\varepsilon(y_\varepsilon,u_\varepsilon) \geq \varliminf_{\varepsilon\to 0^+} J(y_\varepsilon,u_\varepsilon) \geq J(\widetilde{y},\widetilde{u}),$$

which, together with (3.17), (3.18), (3.23), and (3.4), implies that $(\widetilde{y},\widetilde{u}) = (y^*,u^*)$ and that as $\varepsilon \to 0^+$

$$u_\varepsilon \to u^* \ \text{ strongly in } L^2(Q), \tag{3.24}$$

$$\begin{aligned} y_\varepsilon \to y^* \quad & \text{strongly in } L^{\frac{2n}{n-2}}(Q) \cap C([0,T];H) \cap L^2(0,T;V), \\ & \text{weakly in } Y. \end{aligned} \tag{3.25}$$

In particular,

$$(y_\varepsilon(0),y_\varepsilon(T)) \to (y^*(0),y^*(T)) \ \text{ strongly in } H\times H \ \text{ as } \varepsilon\to 0^+. \tag{3.26}$$

Next, we shall prove that $y_\varepsilon \to y^*$ strongly in Y as $\varepsilon \to 0^+$. To this end, we first claim that

$$f(x,t,y_\varepsilon) \to f(x,t,y^*) \ \text{ strongly in } L^2(Q) \ \text{ as } \varepsilon\to 0^+. \tag{3.27}$$

Notice that

$$|f(x,t,y_\varepsilon) - f(x,t,y^*)| = |b_\varepsilon(x,t)| \cdot |y_\varepsilon - y^*|,$$

where $b_\varepsilon(x,t) = \int_0^1 f_y'(x,t,y^* + \theta(y_\varepsilon - y^*))d\theta$. By assumption $(\mathbf{A_f})$, we have $|b_\varepsilon|^2 \leq C(1+|y^*|+|y_\varepsilon|)^{2(\alpha-1)}$ for some positive constant C independent of ε. Then by the Sobolev embedding theorem and the Hölder inequality, we see that the sequence $\{b_\varepsilon^2\}$ is bounded in $L^{\frac{n}{2}}(Q)$. By (3.25) and by making use of Hölder's inequality, we obtain

$$\int_Q |f(x,t,y_\varepsilon) - f(x,t,y^*)|^2 dxdt \leq \left(\int_Q |b_\varepsilon|^n dxdt\right)^{\frac{2}{n}} \left(\int_Q |y_\varepsilon - y^*|^{\frac{2n}{n-2}} dxdt\right)^{\frac{n-2}{n}} \to 0 \quad \text{as } \varepsilon\to 0^+.$$

Thus we have proved (3.27).

Now we set $g_\varepsilon = (y_\varepsilon)_t - \Delta y_\varepsilon + f(x,t,y_\varepsilon) - \chi_\omega u_\varepsilon$. Then it follows immediately from (3.22) that $g_\varepsilon \to 0$ strongly in $L^2(Q)$ as $\varepsilon \to 0^+$. Set $\varphi_\varepsilon = y_\varepsilon - y^*$ and $F_\varepsilon = \chi_\omega(u_\varepsilon - u^*) + f(x,t,y^*) - f(x,t,y_\varepsilon)$. Then by (3.24) and (3.27), $F_\varepsilon \to 0$ strongly in $L^2(Q)$ as $\varepsilon \to 0^+$. Moreover, it holds that

$$\begin{cases} (\varphi_\varepsilon)_t - \Delta\varphi_\varepsilon = F_\varepsilon & \text{in } Q, \\ \varphi_\varepsilon = 0 & \text{on } \Sigma. \end{cases} \tag{3.28}$$

Since $y_\varepsilon \in \widetilde{Y}$, we have

$$\varphi_\varepsilon^{I,\mathcal{K}}(0) = 0, \ \ \varphi_\varepsilon^{II,\mathcal{K},2}(0) = \varphi_\varepsilon^{II,\mathcal{K},2}(T). \tag{3.29}$$

By (3.21), it follows that

$$\varphi_\varepsilon^{II,\mathcal{K},1}(0) - \varphi_\varepsilon^{II,\mathcal{K},1}(T) \equiv \xi_\varepsilon^{II,\mathcal{K},1} \to 0 \ \text{ strongly in } H \ \text{ as } \varepsilon\to 0^+. \tag{3.30}$$

Then by (3.28), (3.29), and (3.30), we can apply Lemma 3.1 to get

$$\|\varphi_\varepsilon\|_Y^2 \le C(\|F_\varepsilon\|_{L^2(Q)}^2 + |\xi_\varepsilon^{II,\mathcal{K},1}|_2^2) \to 0 \ \text{ as } \varepsilon \to 0^+.$$

This completes the proof of Lemma 3.3. □

LEMMA 3.4. *Let $(y_\varepsilon, u_\varepsilon) \in \widetilde{Y} \times L^2(Q)$ be optimal for problem $(\mathbf{P}^\varepsilon_{\mathcal{K},r})$. Then there exists an $\varepsilon_0 > 0$ such that, for any ε with $0 < \varepsilon \le \varepsilon_0$, there exist a pair $(\mu_\varepsilon, a_\varepsilon^{I,\mathcal{K}}) \in \mathbf{R} \times H^{I,\mathcal{K}}$ and a function $p_\varepsilon \in Y$ satisfying*

$$1 \le \mu_\varepsilon^2 + |a_\varepsilon^{I,\mathcal{K}}|_2^2 \le 2, \tag{3.31}$$

$$\mu_\varepsilon(2u_\varepsilon - u^*) = \chi_\omega p_\varepsilon, \ \ a.e.\ in\ Q, \tag{3.32}$$

$$\begin{cases} (p_\varepsilon)_t + \Delta p_\varepsilon - f_y'(x,t,y_\varepsilon)p_\varepsilon = \mu_\varepsilon\{y_\varepsilon + (y_\varepsilon - y^*)^{\frac{n+2}{n-2}}\} & in\ Q, \\ p_\varepsilon = 0 & on\ \Sigma, \\ p_\varepsilon^{I,\mathcal{K}}(T) = -a_\varepsilon^{I,\mathcal{K}}, \ \ p_\varepsilon^{II,\mathcal{K}}(T) = p_\varepsilon^{II,\mathcal{K}}(0) & in\ \Omega. \end{cases} \tag{3.33}$$

Proof of Lemma 3.4. Write Z for the set $\{z \in Y;\ z^{I,\mathcal{K}}(0) = 0,\ z^{II,\mathcal{K},2}(0) = z^{II,\mathcal{K},2}(T)\}$. Let (z, v) be an arbitrary but fixed pair in the set $Z \times L^2(Q)$. Write $y_{\varepsilon,\lambda} = y_\varepsilon + \lambda z$ and $u_{\varepsilon,\lambda} = u_\varepsilon + \lambda v$, $\lambda > 0$. Then it holds that $y_{\varepsilon,\lambda} \in \widetilde{Y}$ and $u_{\varepsilon,\lambda} \in L^2(Q)$. Moreover, we have

$$y_{\varepsilon,\lambda} \to y_\varepsilon \ \text{ strongly in } Y, \ \ u_{\varepsilon,\lambda} \to u_\varepsilon \ \text{ strongly in } L^2(Q) \ \text{ as } \lambda \to 0^+.$$

By the optimality of $(y_\varepsilon, u_\varepsilon)$ for problem $(\mathbf{P}^\varepsilon_{\mathcal{K},r})$, we see that

$$0 \le \frac{J_\varepsilon(y_{\varepsilon,\lambda}, u_{\varepsilon,\lambda}) - J_\varepsilon(y_\varepsilon, u_\varepsilon)}{\lambda}. \tag{3.34}$$

Notice that, as $\lambda \to 0^+$,

$$\frac{\frac{1}{2\varepsilon}\{(\varepsilon + d_B(y_{\varepsilon,\lambda}^{I,\mathcal{K}}(T)))^2 - (\varepsilon + d_B(y_\varepsilon^{I,\mathcal{K}}(T)))^2\}}{\lambda} \to \frac{d_B(y_\varepsilon^{I,\mathcal{K}}(T)) + \varepsilon}{\varepsilon}\langle a_\varepsilon^{I,\mathcal{K}}, z^{I,\mathcal{K}}(T)\rangle, \tag{3.35}$$

where

$$a_\varepsilon^{I,\mathcal{K}} \in \partial d_B(y_\varepsilon^{I,\mathcal{K}}(T)) = \begin{cases} 0 & \text{if } y_\varepsilon^{I,\mathcal{K}}(T) \in \mathrm{Int}(B^{I,\mathcal{K}}(0,r)), \\ \left\{\dfrac{s y_\varepsilon^{I,\mathcal{K}}(T)}{|y_\varepsilon^{I,\mathcal{K}}(T)|_2}\right\}_{1 \ge s \ge 0} & \text{if } y_\varepsilon^{I,\mathcal{K}}(T) \in \partial B^{I,\mathcal{K}}(0,r), \\ \dfrac{y_\varepsilon^{I,\mathcal{K}}(T)}{|y_\varepsilon^{I,\mathcal{K}}(T)|_2} & \text{if } y_\varepsilon^{I,\mathcal{K}}(T) \notin B^{I,\mathcal{K}}(0,r). \end{cases} \tag{3.36}$$

Here $\partial d_B(\cdot)$ denotes the subdifferential of $d_B(\cdot)$. (See [1] or [2].) Now we claim that the following holds:

$$\frac{f(x,t,y_{\varepsilon,\lambda}) - f(x,t,y_\varepsilon)}{\lambda} \to f_y'(y_\varepsilon)z \ \text{ strongly in } L^2(Q) \ \text{ as } \lambda \to 0^+. \tag{3.37}$$

Indeed, we can write

$$\frac{f(x,t,y_{\varepsilon,\lambda}) - f(x,t,y_\varepsilon)}{\lambda} = b_{\varepsilon,\lambda}(x,t)z,$$

where $b_{\varepsilon,\lambda} = \int_0^1 f_y'(x,t,y_\varepsilon + \theta\lambda z)d\theta$. It is clear that

$$\{(b_{\varepsilon,\lambda} - f_y'(x,t,y_\varepsilon))z\}^2 \to 0 \text{ a.e. in } Q \text{ as } \lambda \to 0^+.$$

By the assumption in $(\mathbf{A_f})$, we have

$$\{(b_{\varepsilon,\lambda} - f_y'(x,t,y_\varepsilon))z\}^2 \le C(1 + (|y_\varepsilon| + |z|)^{2(\alpha-1)})z^2$$

for a certain positive constant C independent of ε and λ. Then by the Sobolev embedding theorem and the Hölder inequality, we see that the function $(1 + (|y_\varepsilon| + |z|)^{2(\alpha-1)})z^2$ is in the space $L^1(Q)$. Then we can use the Lebesgue dominated convergence theorem to get (3.37). Thus, it holds that, as $\lambda \to 0^+$,

$$\begin{aligned} &\frac{1}{2\varepsilon\lambda}\int_Q \{|(y_{\varepsilon,\lambda})_t - \Delta y_{\varepsilon,\lambda} + f(x,t,y_{\varepsilon,\lambda}) - \chi_\omega u_{\varepsilon,\lambda}|^2 \\ &\qquad - |(y_\varepsilon)_t - \Delta y_\varepsilon + f(x,t,y_\varepsilon) - \chi_\omega u_\varepsilon|^2\}dxdt \\ &\to \frac{1}{\varepsilon}\int_Q ((y_\varepsilon)_t - \Delta y_\varepsilon + f(x,t,y_\varepsilon) - \chi_\omega u_\varepsilon)(z_t - \Delta z + f_y'(x,t,y_\varepsilon)z - \chi_\omega v)dxdt. \end{aligned} \tag{3.38}$$

Write μ_ε for the term $\frac{\varepsilon}{d_B(y_\varepsilon^{I,\mathcal{K}}(T))+\varepsilon}$. Then by (3.36), the estimate (3.31) follows immediately.

Set

$$p_\varepsilon = \frac{\mu_\varepsilon}{\varepsilon}\{(y_\varepsilon)_t - \Delta y_\varepsilon + f(x,t,y_\varepsilon) - \chi_\omega u_\varepsilon\} \in L^2(Q).$$

Then by (3.35) and (3.38) and after some simple computation, we can pass to the limit, as $\lambda \to 0^+$, in (3.34) to get

$$\begin{aligned} 0 \le \mu_\varepsilon \Big\{ &\int_Q (2u_\varepsilon - u^*)v dxdt + \int_Q (y_\varepsilon + (y_\varepsilon - y^*)^{\frac{n+2}{n-2}})z dxdt \\ &+ \left\langle \frac{y_\varepsilon^{II,\mathcal{K},1}(T) - y_\varepsilon^{II,\mathcal{K},1}(0)}{\varepsilon}, z^{II,\mathcal{K},1}(T) - z^{II,\mathcal{K},1}(0) \right\rangle \Big\} \\ &+ \langle a_\varepsilon^{I,\mathcal{K}}, z^{I,\mathcal{K}}(T)\rangle \\ &+ \int_Q p_\varepsilon(z_t - \Delta z + f_y'(x,t,y_\varepsilon)z - \chi_\omega v)dxdt. \end{aligned} \tag{3.39}$$

Since the pair (z,v) was arbitrarily taken from the set $Z \times L^2(Q)$, the inequality (3.39) holds for any pair (z,v) in the set $Z \times L^2(Q)$.

By taking $z = 0 \in Z$ in (3.39), we get

$$0 \le \mu_\varepsilon \int_Q (2u_\varepsilon - u^*)v dxdt - \int_Q p_\varepsilon \chi_\omega v dxdt \ \ \forall\, v \in L^2(Q),$$

from which (3.32) follows easily.

By taking $v = 0$ in (3.39), we get

$$\begin{aligned} 0 \le \mu_\varepsilon \Big\{ &\int_Q (y_\varepsilon + (y_\varepsilon - y^*)^{\frac{n+2}{n-2}})z dxdt + \left\langle \frac{y_\varepsilon^{II,\mathcal{K},1}(T) - y_\varepsilon^{II,\mathcal{K},1}(0)}{\varepsilon}, \right. \\ &\left. z^{II,\mathcal{K},1}(T) - z^{II,\mathcal{K},1}(0) \right\rangle \Big\} \\ &+ \langle a_\varepsilon^{I,\mathcal{K}}, z^{I,\mathcal{K}}(T)\rangle + \int_Q p_\varepsilon(z_t - \Delta z + f(x,t,y_\varepsilon)z)dxdt \ \ \forall\, z \in Z. \end{aligned} \tag{3.40}$$

On the other hand, it follows from Lemma 3.3 that $y_\varepsilon \to y^*$ strongly in Y as $\varepsilon \to 0^+$. Thus by (3.1) and (3.2), there exists a positive number ε_0 such that, for each number ε with $0 < \varepsilon \le \varepsilon_0$,

$$\|f_y'(x,t,y_\varepsilon)\|_{L^\infty(0,T;L^n(\Omega))} \le M. \tag{3.41}$$

Then, for each number ε with $0 < \varepsilon \le \varepsilon_0$, the following equation has a unique solution $q_\varepsilon \in Y$ (see (3.3) and notice that $H^{II,\mathcal{K}_0} = H^{II,\mathcal{K},2}$):

$$\begin{cases} (q_\varepsilon)_t + \Delta q_\varepsilon - f_y'(x,t,y_\varepsilon)q_\varepsilon = -\mu_\varepsilon(y_\varepsilon + (y_\varepsilon - y^*)^{\frac{n+2}{n-2}}) & \text{in } Q, \\ q_\varepsilon = 0 & \text{on } \Sigma, \\ q_\varepsilon^{I,\mathcal{K}}(T) = a_\varepsilon^{I,\mathcal{K}},\ q_\varepsilon^{II,\mathcal{K},1}(T) = \mu_\varepsilon(\frac{y_\varepsilon^{II,\mathcal{K},1}(T) - y_\varepsilon^{II,\mathcal{K},1}(0)}{\varepsilon}) & \text{in } \Omega, \\ q_\varepsilon^{II,\mathcal{K},2}(T) = q_\varepsilon^{II,\mathcal{K},2}(0) & \text{in } \Omega. \end{cases} \tag{3.42}$$

Multiplying the first equation of (3.42) by $z \in Z$ and integrating over Q, noticing that, for each z in the set Z, $z^{I,\mathcal{K}}(0) = 0,\ z^{II,\mathcal{K},2}(0) = z^{II,\mathcal{K},2}(T)$, we obtain that, for each ε with $0 < \varepsilon \le \varepsilon_0$,

$$\begin{aligned} &\mu_\varepsilon \int_Q (y_\varepsilon + (y_\varepsilon - y^*)^{\frac{n+2}{n-2}}) z dx dt + \left\langle \mu_\varepsilon \frac{y_\varepsilon^{II,\mathcal{K},1}(T) - y_\varepsilon^{II,\mathcal{K},1}(0)}{\varepsilon}, z^{II,\mathcal{K},1}(T) \right\rangle \\ &\quad + \langle z^{I,\mathcal{K}}(T), a_\varepsilon^{I,\mathcal{K}} \rangle \\ &= \langle z^{II,\mathcal{K},1}(0), q_\varepsilon^{II,\mathcal{K},1}(0) \rangle + \int_Q q_\varepsilon (z_t - \Delta z + f_y'(x,t,y_\varepsilon) z) dx dt, \end{aligned}$$

which together with (3.40) implies that, for each number ε with $0 < \varepsilon \le \varepsilon_0$,

$$\begin{aligned} 0 \le &\int_Q (p_\varepsilon + q_\varepsilon)(z_t - \Delta z + f_y'(x,t,y_\varepsilon) z) dx dt \\ &+ \left\langle z^{II,\mathcal{K},1}(0), q_\varepsilon^{II,\mathcal{K},1}(0) - \mu_\varepsilon \left(\frac{y_\varepsilon^{II,\mathcal{K},1}(T) - y_\varepsilon^{II,\mathcal{K},1}(0)}{\varepsilon} \right) \right\rangle \quad \forall\, z \in Z. \end{aligned} \tag{3.43}$$

However, for each function g in the space $L^2(Q)$ and for each number ε with $0 < \varepsilon \le \varepsilon_0$, the following equation has a unique solution $z_g \in Y$ (see (3.3)):

$$\begin{cases} z_t - \Delta z + f_y'(x,t,y_\varepsilon) z = g & \text{in } Q, \\ z = 0 & \text{on } \Sigma, \\ z^{I,\mathcal{K}}(0) = 0,\ z^{II,\mathcal{K},1}(0) = 0,\ z^{II,\mathcal{K},2}(0) = z^{II,\mathcal{K},2}(T) & \text{in } \Omega. \end{cases}$$

It is clear that this solution z_g is in the set Z. Thus, we can take $z = z_g$ in (3.43) to get $0 \le \int_Q (p_\varepsilon + q_\varepsilon) g dx dt$. Since the function g is arbitrary in the space $L^2(Q)$, it holds that, for each number ε with $0 < \varepsilon \le \varepsilon_0$,

$$p_\varepsilon = -q_\varepsilon \ \text{ over } Q. \tag{3.44}$$

Now the inequality (3.43) is simplified as follows:

$$0 \le \left\langle z^{II,\mathcal{K},1}(0), q_\varepsilon^{II,\mathcal{K},1}(0) - \mu_\varepsilon \left(\frac{y_\varepsilon^{II,\mathcal{K},1}(T) - y_\varepsilon^{II,\mathcal{K},1}(0)}{\varepsilon} \right) \right\rangle \quad \forall\, z \in Z. \tag{3.45}$$

Recall that $Z \equiv \{z \in Y;\ z^{I,\mathcal{K}}(0) = 0,\ z^{II,\mathcal{K},2}(0) = z^{II,\mathcal{K},2}(T)\}$. Thus, we can take $z^{II,\mathcal{K},1}(0)$ to be any element in $H^{II,\mathcal{K},1}$ in (3.45), which implies that, for each number ε with $0 < \varepsilon \le \varepsilon_0$,

$$q_\varepsilon^{II,\mathcal{K},1}(0) = \mu_\varepsilon \left(\frac{y_\varepsilon^{II,\mathcal{K},1}(T) - y_\varepsilon^{II,\mathcal{K},1}(0)}{\varepsilon} \right) = q_\varepsilon^{II,\mathcal{K},1}(T).$$

From this and by (3.42) and (3.44), we can easily obtain (3.33). This completes the proof of Lemma 3.4. □

3.3. The proof of Theorem 1.1. Now we are ready to give the proof of Theorem 1.1.

Proof of Theorem 1.1. By (3.31), we can assume, without loss of generality, that as $\varepsilon \to 0^+$

$$\begin{array}{ll} \mu_\varepsilon \to \mu_0 & \text{in } \mathbf{R}, \\ a_\varepsilon^{I,\mathcal{K}} \to a_0^{I,\mathcal{K}} & \text{strongly in } H^{I,\mathcal{K}}. \end{array} \tag{3.46}$$

We next claim that for any ε with $0 < \varepsilon \le \varepsilon_0$, where ε_0 was given in Lemma 3.4, it holds that

$$\|p_\varepsilon\|_Y \le C. \tag{3.47}$$

Here and in what follows, C stands for a positive constant independent of ε, which may be different in different contexts. It should be mentioned that we cannot directly apply Theorem 2.1 to get (3.47). (See Remark 3.2 following the proof of Theorem 1.1.)

By (3.41), the sequence $\{f_y'(x,t,y_\varepsilon)\}_{0<\varepsilon\le\varepsilon_0}$ is bounded in the space $L^\infty(0,T;L^n(\Omega))$. Then, by the observability inequality for linear parabolic equations based on the Carleman inequality for linear parabolic equations (see [14]), we see that, for any ε with $0 < \varepsilon \le \varepsilon_0$,

$$|p_\varepsilon(0)|_2^2 \le C\left(\|\mu_\varepsilon(y_\varepsilon + (y_\varepsilon - y^*)^{\frac{n+2}{n-2}})\|_{L^2(Q)}^2 + \int_0^T\int_\omega p_\varepsilon^2 dxdt\right).$$

Since the sequence $\{y_\varepsilon\}$ is bounded in the space Y, which is continuously embedded into the space $L^{\frac{2(n+2)}{n-2}}(Q)$, it follows that the sequence $\{(y_\varepsilon - y^*)^{\frac{n+2}{n-2}}\}$ is bounded in the space $L^2(Q)$. Hence, it holds that

$$|p_\varepsilon(0)|_2^2 \le C\left(1 + \int_0^T\int_\omega p_\varepsilon^2 dxdt\right).$$

Notice that the sequence $\{u_\varepsilon\}$ is bounded in the space $L^2(Q)$. Then, by (3.31) and (3.32), we get

$$\int_0^T\int_\omega p_\varepsilon^2 dxdt \le C.$$

Thus it holds that $|p_\varepsilon(0)|_2^2 \le C$ for any ε with $0 < \varepsilon \le \varepsilon_0$, from which we see that, for any ε with $0 < \varepsilon \le \varepsilon_0$, the following holds:

$$|p_\varepsilon(T)|_2^2 = |p_\varepsilon^{I,\mathcal{K}}(T)|_2^2 + |p_\varepsilon^{II,\mathcal{K}}(T)|_2^2 = |a_\varepsilon^{I,\mathcal{K}}|_2^2 + |p_\varepsilon^{II,\mathcal{K}}(0)|_2^2 \le C. \tag{3.48}$$

On the other hand, by the Hölder inequality and the Sobolev embedding theorem, we have that, for any ε with $0 < \varepsilon \le \varepsilon_0$,

$$\begin{aligned} \int_0^t\int_\Omega |f_y'(x,\tau,y_\varepsilon)p_\varepsilon^2| dxd\tau &\le \int_0^t\left\{\left(\int_\Omega |f_y'(x,\tau,y_\varepsilon)|^n dx\right)^{\frac{1}{n}}\left(\int_\Omega p_\varepsilon^{\frac{2n}{n-2}}dx\right)^{\frac{n-2}{2n}}\left(\int_\Omega p_\varepsilon^2 dx\right)^{\frac{1}{2}}\right\} d\tau \\ &\le \|f_y'(x,\tau,y_\varepsilon)\|_{L^\infty(0,T;L^n(\Omega))}\int_0^t \|p_\varepsilon(\tau)\||p_\varepsilon(\tau)|_2 d\tau \\ &\le C\int_0^t \|p_\varepsilon(\tau)\||p_\varepsilon(\tau)|_2 d\tau. \end{aligned} \tag{3.49}$$

Then multiplying the first equation of (3.33) by p_ε, integrating over $\Omega \times (0,t)$, and making use of (3.48), (3.49), and Gronwall's inequality, we get that, for any ε with $0 < \varepsilon \le \varepsilon_0$,

$$\|p_\varepsilon\|^2_{C([0,T];H)} + \|p_\varepsilon\|^2_{L^2(0,T;V)} \le C. \tag{3.50}$$

By (3.50) and applying the Hölder inequality and the Sobolev embedding theorem again, we see that, for any ε with $0 < \varepsilon \le \varepsilon_0$, the following holds:

$$\begin{aligned}\int_0^T \int_\Omega f'_y(x,t,y_\varepsilon)^2 p_\varepsilon^2 dxdt &\le \int_0^T \left\{ \left(\int_\Omega |f'_y(x,t,y_\varepsilon)|^{2\cdot\frac{n}{2}} dx \right)^{\frac{2}{n}} \right. \\ &\quad \left. \times \left(\int_\Omega |p_\varepsilon|^{\frac{2n}{n-2}} dx \right)^{\frac{n-2}{2n}} \left(\int_\Omega |p_\varepsilon|^{\frac{2n}{n-2}} dx \right)^{\frac{n-2}{2n}} \right\} \\ &\le \|f'_y(x,t,y_\varepsilon)\|^2_{L^\infty(0,T;L^n(\Omega))} \int_0^T \|p_\varepsilon(t)\|^2 dt \le C.\end{aligned}$$

Now we can use Lemma 3.1 to get that, for any ε with $0 < \varepsilon \le \varepsilon_0$,

$$\|p_\varepsilon\|^2_Y \le C(\|f'_y(x,t,y_\varepsilon)p_\varepsilon\|^2_{L^2(Q)} + \|\mu_\varepsilon(y_\varepsilon + (y_\varepsilon - y^*)^{\frac{n+2}{n-2}})\|^2_{L^2(Q)} + |a_\varepsilon^{I,\mathcal{K}}|_2^2) \le C.$$

This proves (3.47).

Next, by (3.47) and by making use of the Aubin compactness theorem and the Ascoli–Arzela theorem, we can extract a generalized subsequence of $\{\varepsilon\}_{0<\varepsilon\le\varepsilon_0}$, which, for simplicity of notation, is still denoted in the same way, such that as $\varepsilon \to 0^+$

$$\begin{aligned} &p_\varepsilon \to p \quad && \text{weakly in } Y, \\ &&& \text{a.e. in } Q, \\ &&& \text{strongly in } L^2(0,T;V) \cap C([0,T];H). \end{aligned} \tag{3.51}$$

By (3.51) and the assumption in $(\mathbf{A_f})$, and by making use of Lemma 3.3, one can easily get that

$$f'_y(x,t,y_\varepsilon)p_\varepsilon \to f'_y(x,t,y^*)p \ \text{ weakly in } L^2(Q) \ \text{ as } \varepsilon \to 0^+. \tag{3.52}$$

Then by (3.46), (3.51), and (3.52), we can pass to the limit, as $\varepsilon \to 0^+$, in (3.33) to get

$$\begin{cases} p_t + \Delta p - f'_y(x,t,y^*)p = \mu_0 y^* & \text{in } Q, \\ p = 0 & \text{on } \Sigma, \\ p^{I,\mathcal{K}}(T) = -a_0^{I,\mathcal{K}}, \ \ p^{II,\mathcal{K}}(T) = p^{II,\mathcal{K}}(0) & \text{in } \Omega. \end{cases} \tag{3.53}$$

By Lemma 3.3 and by (3.51), we can pass to the limit, as $\varepsilon \to 0^+$, in (3.32) to get

$$\chi_\omega p = \mu_0 u^* \ \text{ a.e. in } Q. \tag{3.54}$$

Next, we prove that $\mu_0 \neq 0$. Notice that the number μ_0 appears only in the case that $\mathcal{K} > 0$. (In the case $\mathcal{K} = 0$, namely, in the periodic case, $H = H^{II,\mathcal{K}}$ and both $a^{I,\mathcal{K}}$ and $B^{I,\mathcal{K}}(0,r)$ do not appear. Hence μ_0 does not appear.) Now we seek a contradiction, supposing that $\mu_0 = 0$. Then, by (3.31), we get $|a_\varepsilon^{I,\mathcal{K}}|_2^2 \ge \delta > 0$ for some $\delta > 0$ independent of ε. Since $H^{I,\mathcal{K}}$ is a finite dimensional space, $a_0^{I,\mathcal{K}} \neq 0$. On the other hand, it follows from (3.54) that

$$p = 0 \ \text{ a.e. in } \omega \times (0,T).$$

Then, by the unique continuation of solutions to the linear parabolic equations based on the Carleman inequality for the linear parabolic equations (see [14]), we get

$$p = 0 \text{ a.e. in } \Omega \times (0,T),$$

which leads us to a contradiction since $p^{I,\mathcal{K}}(T) = -a_0^{I,\mathcal{K}} \neq 0$. Hence we have proved $\mu_0 \neq 0$. The proof of Theorem 1.1 is completed. □

Remark 3.2. The boundedness of $\{p_\varepsilon\}_{\varepsilon_0 \geq \varepsilon > 0}$ in Y cannot be obtained by just making use of Theorem 2.1. In the problem $(\mathbf{P}_{\mathcal{K},r})$, the nonnegative integer $\mathcal{K}$ is arbitrarily given. However, the integer $\mathcal{K}$ in Theorem 2.1 must be sufficiently large.

Remark 3.3. By a very similar method, we can obtain the Pontryagin maximum principle for optimal controls for the problem $(\mathbf{P}_{\mathcal{K},r})$ even if the cost functional $J(y,u)$ has the following more general form:

$$J(y,u) = \int_0^T [g(t,y) + h(u)]dt,$$

where $g : [0,T] \times H \to \mathbf{R}^+$ is measurable in t and locally Lipschitzian in the second variable, $g(\cdot,0) \in L^\infty(0,T)$, and $h : H \to \overline{\mathbf{R}} \equiv (-\infty, +\infty]$ is a lower semicontinuous and convex functional satisfying $h(u) \geq C_1|u|_2^2 + C_2$. Here $C_1 > 0$ and $C_2 \in \mathbf{R}$. In this case, the only modification for the proof that we need is to use suitable smooth functionals g_ε and h_ε to approach g and h, respectively. (The reader is referred to [1], [13] for the construction of such smooth approximations.)

4. The existence of optimal controls for the problem $(\mathbf{P}_{\mathcal{K},r})$. In this section, we shall prove Theorem 1.2; namely, we prove the existence of optimal solutions for the problem $(\mathbf{P}_{\mathcal{K},r})$.

Proof of Theorem 1.2. Let $M > 0$ be given. By Theorem 2.2, there exists an integer $\mathcal{K} \equiv \mathcal{K}(M) \geq 0$ such that, for each $a^{I,\mathcal{K}} \in H^{I,\mathcal{K}}$ with $(1+\lambda_{\mathcal{K}})|a^{I,\mathcal{K}}|_2^2 \leq M^2$, there exists a control $u \in L^2(Q)$ with $\|u\|_{L^2(Q)}^2 \leq M^2$ such that the equation

$$\begin{cases} y_t - \Delta y + f(x,t,y) = \chi_\omega u & \text{in } Q, \\ y = 0 & \text{on } \Sigma, \\ y^{I,\mathcal{K}}(0) = a^{I,\mathcal{K}},\ y^{II,\mathcal{K}}(0) = y^{II,\mathcal{K}}(T) & \text{in } \Omega \end{cases} \tag{4.1}$$

has a solution $y \in Y$ with the estimate:

$$|y(T)|_2^2 \leq C\|y\|_Y^2 \leq C(M),$$

which implies $|y^{I,\mathcal{K}}(T)|_2^2 \leq C(M)$. Here $C(M)$ denotes a positive constant depending on M.

Now we fix an integer $\mathcal{K}$ as above, an element $a^{I,\mathcal{K}} \in H^{I,\mathcal{K}}$ with $(1+\lambda_{\mathcal{K}})|a^{I,\mathcal{K}}|_2^2 \leq M^2$, and fix a number r such that $r \geq C(M)$. Then problem $(\mathbf{P}_{\mathcal{K},r})$ has a nonempty admissible set; namely, there exists at least one pair $(y,u) \in Y \times L^2(Q)$ (4.1) and $y^{I,\mathcal{K}}(T) \in B^{I,\mathcal{K}}(0,r)$.

Set $d = \text{Inf}\{J(y,u);\ (y,u) \in Y \times L^2(Q)$ satisfying (1.1) and (1.2)$\}$, and let $\{(y_m,u_m)\} \subset Y \times L^2(Q)$ be a minimization sequence of problem $(\mathbf{P}_{\mathcal{K},r})$, namely,

$$d \leq \frac{1}{2}\int_Q (y_m^2 + u_m^2)dxdt \leq d + \frac{1}{m},\ m = 1,2,\ldots, \tag{4.2}$$

and (y_m,u_m) satisfies (4.1) and $y_m^{I,\mathcal{K}}(T) \in B^{I,\mathcal{K}}(0,r)$. By (4.2), we see that the sequence $\{u_m\}$ is bounded in the space $L^2(Q)$.

Multiplying the first equation of (4.1), where (y,u) is replaced by (y_m,u_m), by y_m and then integrating over $\Omega\times(0,T)$, by making use of (i) of $(\mathbf{H_f})$ and the property that $y_m^{II,\mathcal{K}}(0)=y_m^{II,\mathcal{K}}(T)$, we can easily derive

$$|y_m(0)|_2^2\le C(\|u_m\|_{L^2(Q)}^2+|a^{I,\mathcal{K}}|_2^2).$$

Here and in what follows, C denotes a positive constant independent of m, which may be different in different contexts. From the above, using (4.1) with (y,u) being replaced by (y_m,u_m) and (i) of $(\mathbf{H_f})$ again, we obtain

$$\|y_m\|_{V_2(Q)}^2\le C(\|u_m\|_{L^2(Q)}^2+|a^{I,\mathcal{K}}|_2^2). \tag{4.3}$$

Then by (ii) of $(\mathbf{H_f})$ and by making use of the Hölder inequality and the Sobolev embedding theorem $(V_2(Q)\hookrightarrow L^{\frac{2(n+2)}{n}}(Q))$, we get

$$\begin{aligned}\int_Q f(x,t,y_m)^2dxdt&\le C\int_Q|y_m|(1+|y_m|^\beta)^2dxdt\\&\le C\left(\|y_m\|_{L^2(Q)}^2+\|y_m\|_{L^{\frac{2(n+2)}{n}}(Q)}^{\frac{2(n+2)}{n}}\right)\\&\le C\left(\|y_m\|_{L^2(Q)}^2+\|y_m\|_{V_2(Q)}^{\frac{2(n+2)}{n}}\right)\le C.\end{aligned} \tag{4.4}$$

Now by Lemma 3.1, where $\xi^{II,\mathcal{K},1}=0$, we conclude that

$$\|y_m\|_Y^2\le C(\|u_m\|_{L^2(Q)}^2+\|f(x,t,y_m)\|_{L^2(Q)}^2+|a^{I,\mathcal{K}}|_2^2)\le C.$$

Hence, we can extract subsequences of $\{y_m\}$ and $\{u_m\}$, which, for simplicity of notation, are still denoted by themselves, such that as $m\to\infty$

$$\begin{aligned}&y_m\to\widetilde{y}\quad&&\text{weakly in } Y,\\&&&\text{strongly in } L^2(0,T;V)\cap C([0,T];H),\\&&&\text{a.e. in } Q,\end{aligned} \tag{4.5}$$

$$u_m\to\widetilde{u}\ \text{ weakly in } L^2(Q). \tag{4.6}$$

Now by $(\mathbf{H_f})$, we obtain

$$f(x,t,y_m)\to f(x,t,\widetilde{y})\quad\text{a.e. in } Q\ \text{ as } m\to\infty,$$

which together with (4.4) implies

$$f(x,t,y_m)\to f(x,t,\widetilde{y})\ \text{ weakly in } L^2(Q)\ \text{ as } m\to\infty. \tag{4.7}$$

Then by (4.5), (4.6), and (4.7), we can pass to the limit, as $m\to\infty$, in (4.1) with (y,u) being replaced by (y_m,u_m) to get that $(\widetilde{y},\widetilde{u})$ satisfies (4.1). Moreover, it follows from (4.5) that

$$y_m^{I,\mathcal{K}}(T)\to\widetilde{y}^{I,\mathcal{K}}(T)\ \text{ strongly in } H \text{ as } m\to\infty.$$

Hence,

$$|\widetilde{y}^{I,\mathcal{K}}(T)|_2^2=\lim_{m\to\infty}|y_m^{I,\mathcal{K}}(T)|_2^2\le r^2.$$

Therefore $(\widetilde{y},\widetilde{u})$ is admissible for the problem $(\mathbf{P}_{\mathcal{K},r})$.

Finally, by passing to the limit, as $m\to\infty$, in (4.2), we get $d=\frac{1}{2}\int_Q(\widetilde{y}^2+\widetilde{u}^2)dxdt$. Hence, $(\widetilde{y},\widetilde{u})$ is an optimal solution for the problem $(\mathbf{P}_{\mathcal{K},r})$. This completes the proof of Theorem 1.2. □

THE DYNAMIC PROGRAMMING EQUATION FOR THE PROBLEM OF OPTIMAL INVESTMENT UNDER CAPITAL GAINS TAXES*

IMEN BEN TAHAR†, H. METE SONER‡, AND NIZAR TOUZI§

Abstract. This paper considers an extension of the Merton optimal investment problem to the case where the risky asset is subject to transaction costs and capital gains taxes. We derive the dynamic programming equation in the sense of constrained viscosity solutions. We next introduce a family of functions $(V_\varepsilon)_{\varepsilon>0}$, which converges to our value function uniformly on compact subsets, and which is characterized as the unique constrained viscosity solution of an approximation of our dynamic programming equation. In particular, this result justifies the numerical results reported in the accompanying paper [I. Ben Tahar, H. M. Soner, and N. Touzi (2005), *Modeling Continuous-Time Financial Markets with Capital Gains Taxes*, preprint, http://www.cmap.polytechnique.fr/∼touzi/bst06.pdf].

Key words. optimal consumption and investment in continuous time, transaction costs, capital gains taxes, viscosity solutions

1. Introduction.

The problem of optimal investment and consumption in financial markets has been introduced by Merton [20, 21]. The explicit solution derived in these papers is widely used among fund managers in practical financial markets. Moreover, this problem became very quickly one of the classical examples of application of the verification theorem in stochastic control theory. Indeed, by direct financial considerations, it is easily seen that the value function of the problem satisfies some homogeneity property, which completely determines its dependence on the wealth state variable. Plugging this information into the corresponding dynamic programming equation (DPE) leads to an ordinary differential equation (ODE) which can be solved explicitly, thus providing a candidate smooth solution to the DPE.

In this paper, we consider the extension of the Merton problem to the case where the risky asset is subject to capital gains taxes. For technical reasons, we also assume that the risky asset is subject to proportional transaction costs. This problem is formulated in the accompanying paper [5]. In contrast with the Merton frictionless model, no explicit solution is available in this context. The main result of [5] is the derivation of an explicit first order expansion of the value function for small tax and interest rate parameters. The numerical results reported in [5] show that the relative error induced by this approximation is of the order of 4%. These numerical results are obtained by comparing the explicit first order expansion to the finite differences approximation of the solution of the corresponding DPE.

The literature on the optimal investment problem under capital gains taxes is not very expanded and is mainly developed in discrete-time binomial models; see

[7, 10, 11, 12, 17, 18, 15, 19].

The main purpose of this paper is to justify the approximation of the value function by means of the finite differences scheme applied to the corresponding DPE. Since our optimal control problem is singular, the DPE takes the form of a variational inequality:

$$\min\left\{-\mathcal{L}v,\ \mathbf{g^b}\cdot Dv,\ \mathbf{g^s}\cdot Dv\right\}\ =\ 0 \text{ on } \bar{\mathcal{S}},\qquad v=0 \text{ on } \partial^z\mathcal{S},$$

where $\mathcal{L}$ is a second order differential operator defined in (2.13) $\mathbf{g^b}, \mathbf{g^s}$ are two vector fields defined in (2.15) corresponding to the purchase and sale decisions, $\mathcal{S}$ is the state space, and $\partial^z\mathcal{S}$ is part of the boundary of $\mathcal{S}$. The main difficulty comes from the fact that the vector field $\mathbf{g^s}$ is not locally Lipschitz. Then the standard techniques to prove a uniqueness result for the above partial differential equation (PDE) fail. We then introduce a convenient locally Lipschitz approximation $\mathbf{g^s_\varepsilon}$ of $\mathbf{g^s}$, and we consider the approximating PDE

$$\min\left\{-\mathcal{L}v,\ \mathbf{g^b}\cdot Dv,\ \mathbf{g^s_\varepsilon}\cdot Dv\right\}\ =\ 0 \text{ on } \bar{\mathcal{S}},\qquad v=0 \text{ on } \partial^z\mathcal{S}.$$

The main result of this paper states that the above approximating PDE has a unique continuous viscosity solution V_ε which converges uniformly on compact subsets towards the value function V of our optimal investment problem under capital gains taxes. Applying the general results of Barles and Souganidis [4], we see that this justifies the convergence of the numerical scheme implemented in the accompanying paper [5] towards this unique solution of the approximating PDE.

The paper is organized as follows. Section 2 provides a quick review of the problem of optimal investment under capital gains taxes. The main approximation result is stated in section 3. In section 4, we prove a comparison result for the approximating PDE, which implies the required uniqueness claim. In section 5 we prove the existence of a solution of the approximating PDE by introducing a family of control problems obtained by modifying conveniently our original problem. Finally, section 6 reports the proof of convergence of V_ε towards V uniformly on compact subsets.

Notation. For a domain $\mathbf{D}$ in $\mathbb{R}^n$, we denote by $\mathrm{USC}(\mathbf{D})$ (resp., $\mathrm{LSC}(\mathbf{D})$) the collection of all upper semicontinuous (resp., lower semicontinuous) functions from $\mathbf{D}$ to $\mathbb{R}$. The set of continuous functions from $\mathbf{D}$ to $\mathbb{R}$ is denoted by $\mathrm{C}^0(\mathbf{D}) := \mathrm{USC}(\mathbf{D}) \cap \mathrm{LSC}(\mathbf{D})$. For a parameter $\delta > 0$, we say that a function $f : \mathbf{D} \longrightarrow \mathbb{R}$ has δ-polynomial growth if

$$\sup_{x\in\mathbf{D}} \frac{|f(x)|}{1+|x|^\delta} < \infty.$$

We finally denote $\mathrm{USC}_\delta(\mathbf{D}) := \{f \in \mathrm{USC}(\mathbf{D}) \ :\ f \text{ has } \delta\text{-polynomial growth}\}$. The sets $\mathrm{LSC}_\delta(\mathbf{D})$ and $\mathrm{C}^0_\delta(\mathbf{D})$ are defined similarly.

2. Optimal investment under capital gains taxes.

2.1. Problem formulation. In this section, we quickly review the formulation of the problem of optimal investment under capital gains taxes. We refer the interested reader to the accompanying paper [5] for more details. The financial market consists of a tax-free bank account with constant interest rate $r > 0$ and a risky asset subject to proportional transaction costs and to capital gains taxes. The price process of the risky asset evolves according to the Black–Scholes model:

$$dP_t\ =\ P_t\left(\rho dt + \sigma dW_t\right), \qquad t \geq 0, \tag{2.1}$$

where $\rho > 0$ is a constant instantaneous return of the asset, and $\sigma > 0$ is a constant volatility parameter. The process $W = \{W_t, t \geq 0\}$ is a standard Brownian motion with values in $\mathbb{R}^1$ defined on an underlying complete probability space $(\Omega, \mathcal{F}, \mathbb{P})$. We shall denote by $\mathbb{F}$ the $\mathbb{P}$-completion of the natural filtration of the Brownian motion.

For technical reasons (see section 4), we assume that the risky asset is also subject to proportional transaction costs defined by the coefficients λ, $\mu \in [0, 1)$, so that the bid and ask prices at time t of the risky asset are given by $(1 - \mu)P_t$ and $(1 + \lambda)P_t$.

A control process is a triple of $\mathbb{F}$-adapted processes $\nu = (C, L, M)$, where

$$C \geq 0 \text{ and } \int_0^T C_t dt < \infty \quad \mathbb{P}\text{-a.s. for all } T > 0\,, \tag{2.2}$$

L and M are nondecreasing right-continuous, $L_{0-} = M_{0-} = 0$, and the jumps of M satisfy

$$\Delta M_t \leq 1 \text{ for } t \geq 0 \quad \mathbb{P}\text{-a.s.} \tag{2.3}$$

Here C_t is the consumption rate at time t, $dL_t \geq 0$ is the amount invested between times t and $t + dt$ to purchase risky assets, and $dM_t \geq 0$ is the *proportion* of risky assets in the portfolio which is sold between times t and $t + dt$. Then, the amount of wealth $Y = \{Y_t, t \geq 0\}$ on the risky asset account is defined by the dynamics

$$dY_t = Y_t \frac{dP_t}{P_t} + dL_t - Y_{t-} dM_t\,, \quad t \geq 0. \tag{2.4}$$

Since $\Delta M_t \leq 1$, the no short-sales constraint $Y \geq 0$ holds. Capital gains are taxed only when the investor sells the risky asset. The amount of capital gains (or losses) is evaluated by comparing the actual price P_t to a tax basis B_t specified by the taxation code. In our framework the tax basis is defined as the weighted average of past purchase prices,

$$B_t := \frac{K_t}{Y_t} P_t \text{ if } Y_t > 0 \text{ and } B_t := P_t \text{ otherwise}, \qquad t \geq 0\,,$$

where

$$dK_t = dL_t - K_{t-} dM_t\,, \qquad t \geq 0. \tag{2.5}$$

The natural initial condition for the process K is zero, as initially there are no prior stocks bought. However, the method of dynamic programming always forces us to consider all possible initial data. Hence we consider the K-equation with general initial data $K_0 = k$. Also a more detailed derivation of this tax basis and its place in actual tax codes is given in subsection 2.2 of the accompanying paper [5].

Finally, we consider a linear taxation rule, with constant tax rate parameter $\alpha \in [0, 1]$, so that the after-tax and after-transaction costs induced by selling the amount $Y_{t-} dM_t$ between times t and $t + dt$ are given by

$$(1 - \mu) Y_{t-} dM_t - \alpha(1 - \mu) \left[Y_{t-} dM_t - \frac{Y_{t-} dM_t}{P_t} B_{t-} \right] = (1 - \mu) \left[(1 - \alpha) Y_{t-} + \alpha K_{t-} \right] dM_t.$$

This justifies the following dynamics for the nonrisky asset component of the wealth process:

$$dX_t = (rX_t - C_t)dt - (1 + \lambda)dL_t + (1 - \mu) \left[(1 - \alpha) Y_{t-} + \alpha K_{t-} \right] dM_t, \quad t \geq 0. \tag{2.6}$$

We denote by $\mathcal{A}$ the set of all control processes and by $S = (X, Y, K)$ the corresponding state process defined by (2.4), (2.5), (2.6). A control process ν is said to be admissible if the no bankruptcy condition

$$Z_t \;:=\; X_t + (1-\mu)\left[(1-\alpha)Y_t + \alpha K_t\right] \;\geq\; 0, \quad t \geq 0, \quad \mathbb{P}\text{-a.s.} \tag{2.7}$$

holds. Here Z_t is the after-tax and after-transaction costs liquidation value of the portfolio at time t. Given an initial condition $S_{0-} = s$, we shall denote by $\mathcal{A}(s)$ the collection of all admissible controls.

The problem of optimal consumption and investment under capital gains taxes is defined by the value function

$$V(s) \;:=\; \sup_{\nu \in \mathcal{A}(s)} \mathbb{E}\left[\int_0^\infty e^{-\beta t} U(C_t)dt\right], \quad \text{where } U(x) \;:=\; \frac{x^p}{p}, \quad x \geq 0, \tag{2.8}$$

and $\beta > 0$, $p \in (0,1)$ are two given constant parameters.

Throughout this paper, we assume that the coefficients of the model satisfy the condition

$$\frac{\beta}{p} - r - \frac{(\delta - r)^2}{2(1-p)\sigma^2} > 0, \tag{2.9}$$

which ensures that the value function of the Merton optimal consumption-investment problem (the case $\lambda = \mu = \alpha = 0$) is finite. In particular, the value function V is finite under condition (2.9).

2.2. The DPE. For an admissible control $\nu \in \mathcal{A}(s)$, the induced state process $S^\nu = (X^\nu, Y^\nu, K^\nu)$ defined by (2.4), (2.5), (2.6) together with some initial data $S_0^\nu = s$ is valued in the state space

$$\bar{\mathcal{S}} := \left\{(x,y,k) \in \mathbb{R} \times \mathbb{R}_+ \times \mathbb{R}_+ \;:\; z = x + (1-\mu)[(1-\alpha)y + \alpha k] \geq 0\right\}. \tag{2.10}$$

We denote by $\mathcal{S} := \mathrm{int}(\bar{\mathcal{S}})$ the interior of $\bar{\mathcal{S}}$, and we decompose the boundary of this state space into $\partial\mathcal{S} = \partial^y\mathcal{S} \cup \partial^k\mathcal{S} \cup \partial^z\mathcal{S}$, where

$$\partial^y\mathcal{S} = \left\{s \in \mathcal{S} \;:\; y = 0\right\}, \; \partial^k\mathcal{S} = \left\{s \in \mathcal{S} \;:\; k = 0\right\}, \text{ and } \partial^z\mathcal{S} = \left\{s \in \mathcal{S} \;:\; z = 0\right\}.$$

Observe that the value function is not known on the entire boundary of the state space $\mathcal{S}$. It is shown in [5] that the only boundary information is

$$V(s) \;=\; 0 \text{ for all } s \in \partial^z\mathcal{S}. \tag{2.11}$$

The main result of this section states that the value function V defined in (2.8) solves the corresponding DPE

$$F(s, v, Dv, D^2v) \;:=\; \min\left\{-\mathcal{L}v,\; \mathbf{g^b}\cdot Dv,\; \mathbf{g^s}\cdot Dv\right\} \;=\; 0 \text{ on } \bar{\mathcal{S}} \setminus \partial^z\mathcal{S}, \tag{2.12}$$

where $\mathcal{L}$ is the second order differential operator

$$\mathcal{L}\varphi\,(s) := -\beta\varphi\,(s) + rx\varphi_x\,(s) + \rho y\varphi_y\,(s) + \frac{1}{2}\sigma^2y^2\varphi_{yy}\,(s) + \tilde{U}\left(\varphi_x\,(s)\right), \tag{2.13}$$

$\tilde{U}$ is the Fenchel dual defined by

$$\tilde{U}(\xi) \;:=\; \sup_{c>0}\left(U(c) - c\xi\right) \;\text{ for all }\; \xi > 0, \tag{2.14}$$

and $\mathbf{g^b}$, $\mathbf{g^s}$ are the vector fields defined by

$$\mathbf{g^b} := \begin{pmatrix} 1+\lambda \\ -1 \\ -1 \end{pmatrix}, \mathbf{g^s}(s) := \begin{pmatrix} -(1-\mu) \\ \frac{1}{1-\alpha} \\ 0 \end{pmatrix} + \begin{pmatrix} 0 \\ \frac{-\alpha}{1-\alpha} \\ 1 \end{pmatrix} \frac{k\,\mathbf{1}_{(y,k)\neq 0}}{(1-\alpha)\,y+\alpha k}. \tag{2.15}$$

The DPE can be written in different forms by taking other vector fields which are parallel to our choices $\mathbf{g^b}, \mathbf{g^s}$. Since our choice for $\mathbf{g^s}$ is discontinuous and this fact is central to many of the technicalities, one may propose to choose a parallel vector field which is continuous. However, in singular stochastic control, if the vector fields appearing in the equation vanish (which is the case here if we choose continuous vector fields), then the first order part of the equation (i.e., the part $\mathbf{g^s} \cdot Dv$ in the above particular case) becomes degenerate. Indeed, this degeneracy is equivalent to the technical difficulties related to the discontinuity of the vector fields. For this reason, it is standard in singular control to choose these vector fields as nondegenerate and close to unit vector fields.

Since we have no knowledge of any a priori regularity of the value function V, we will use the theory of viscosity solutions. This notion allows for a weak formulation of solutions to second order parabolic PDEs and boundary conditions; see [23, 9].

In what follows, we use the following classical notation from viscosity theory. For a locally bounded function $v : \bar{\mathcal{S}} \longrightarrow \mathbb{R}$, we denote the corresponding upper and lower semicontinuous envelopes by

$$v^*(s) := \limsup_{\mathcal{S} \ni s' \to s} v(s') \text{ and } v_*(s) := \liminf_{\mathcal{S} \ni s' \to s} v(s').$$

The notation F_* in the subsequent definition is defined similarly. Observe that $F = F_*$ outside the axis $\{(x,0,0) : x \geq 0\}$.

Definition 2.1. (i) *A locally bounded function v is a constrained viscosity subsolution of* (2.11)–(2.12) *if $v^* \leq 0$ on $\partial^z\mathcal{S}$, and for all $s \in \bar{\mathcal{S}} \setminus \partial^z\mathcal{S}$ and $\varphi \in C^2(\bar{\mathcal{S}})$ with $(v^* - \varphi)(s) = \max_{\bar{\mathcal{S}}}(v^* - \varphi)$ we have $F_*\left(s, v(s), D\varphi(s), D^2\varphi(s)\right) \leq 0$.*

(ii) *A locally bounded function v is a viscosity supersolution of* (2.11)–(2.12) *if $v_* \geq 0$ on $\partial^z\mathcal{S}$, and for all $s \in \mathcal{S}$ and $\varphi \in C^2(\mathcal{S})$ with $(v_* - \varphi)(s) = \min_{\mathcal{S}}(v_* - \varphi)$ we have $F\left(s, v(s), D\varphi(s), D^2\varphi(s)\right) \geq 0$.*

(iii) *A locally bounded function v is a constrained viscosity solution of* (2.11)–(2.12) *if it is a constrained viscosity subsolution and supersolution.*

In the above definition, observe that there is no boundary value assigned to the value function on $\partial^y\mathcal{S} \cup \partial^k\mathcal{S}$. Instead, the subsolution property holds on this boundary. Notice that the supersolution property is satisfied only in the interior of the domain $\mathcal{S}$.

Proposition 2.2. *The value function V is a constrained viscosity solution of* (2.11)–(2.12).

The proof is reported in section 5 for the case $\varepsilon = 0$. In the accompanying paper [5] a numerical scheme based on the finite differences approximation of the DPE (2.11)–(2.12) is implemented. In order for us to justify this algorithm, we need a uniqueness result for this DPE. As it is usually the case for parabolic second order equations, uniqueness follows as a consequence of a comparison result. At this point, a chief difficulty is encountered: the vector field $\mathbf{g^s}$ is not locally Lipschitz on the axis $\{(x,0,0),\ x \geq 0\}$. Because of this problem, the standard techniques for the derivation of a comparison result for the DPE (2.11)–(2.12) fail.

Remark 1. Consider the Lipschitz vector field $\mathbf{G^s} := (-(1-\mu)[(1-\alpha)y+\alpha k], y, k) = [(1-\alpha)y+\alpha k]\mathbf{g^s}$. Then, the supersolutions of (2.11)–(2.12) coincide with those of

$$\min\left\{-\mathcal{L}v,\ \mathbf{g^b}\cdot Dv,\ \mathbf{G^s}\cdot Dv\right\} \geq 0 \text{ on } \bar{\mathcal{S}}\setminus\partial^z\mathcal{S} \text{ and } v=0 \text{ on } \partial^z\mathcal{S}. \tag{2.16}$$

However, these two equations do not have the same set of subsolutions. The reason for this is that the subsolution property must hold also on the boundary $\partial^y\mathcal{S}\cup\partial^k\mathcal{S}$. Since $\mathbf{G^s}(x,0,0)=0$ for every $x\geq 0$, (2.16) provides no information on this axis. Notice, however, that $\lim_{n\to\infty}\mathbf{g^s}(s_n)$ exists for some sequences $s_n\to(x,0,0)$, and might be nonzero, so that (2.12) bears more information on this axis.

This remark justifies that the above mentioned difficulty can be avoided if a priori comparison on the axis $\{(x,0,0)\ :\ x\geq 0\}$ is available.

PROPOSITION 2.3. *Let $\lambda+\mu>0$. Let u be an upper semicontinuous constrained viscosity subsolution of* (2.11)–(2.12) *and v be a lower semicontinuous viscosity supersolution of* (2.11)–(2.12) *with $(u-v)^+\in \mathrm{USC}_p(\bar{\mathcal{S}})$. Assume further that $(u-v)(x,0,0)\leq 0$ for all $x\geq 0$. Then $u\leq v$ on $\bar{\mathcal{S}}$.*

The proof of this comparison result is given at the end of section 4. Unfortunately, this result does not provide uniqueness of a constrained viscosity solution for the DPE (2.11)–(2.12), as we have no a priori comparison of two possible solutions on the axis $\{(x,0,0)\ :\ x\geq 0\}$.

The chief goal of this paper is to obtain an alternative characterization of V by considering a convenient approximating PDE which has a unique solution converging to our value function V. Before turning to this issue, we report the following continuity property from [5] which follows from Proposition 2.3.

PROPOSITION 2.4 (see [5]). *Let $\lambda+\mu>0$. For $s=(x,y,k)\in\bar{\mathcal{S}}$ and $z:=x+(1-\mu)[(1-\alpha)y+\alpha k]$, we have $V(s)=z^p\ \mathcal{V}\left(\frac{y}{z},\frac{k}{z}\right)$, where $\mathcal{V}$ is a Lipschitz-continuous function on $\mathbb{R}^2_+$.*

3. The main results. For every $\varepsilon>0$ and $s=(x,y,k)\in\bar{\mathcal{S}}$, we define

$$f^\varepsilon(s)\ :=\ h\left(\frac{k}{\varepsilon z}\right)^+, \text{ where } z:=x+(1-\mu)\left[(1-\alpha)y+\alpha k\right], \tag{3.1}$$

and h is a nondecreasing $C^2(\mathbb{R}_+)$-function with

$$h=0 \ \text{ on } \ [0,1] \ \text{ and } \ h=1 \ \text{ on } \ [2,\infty).$$

For $\varepsilon=0$, we set $f^0(s)=1$.

We next introduce, for all $\varepsilon\geq 0$, the approximation $\mathbf{g^s_\varepsilon}$ of $\mathbf{g^s}$,

$$\mathbf{g^s_\varepsilon}(s)\ :=\ \mathbf{g^s}\left(x,y,kf^\varepsilon(s)\right) \text{ for } s=(x,y,k)\in\bar{\mathcal{S}}, \tag{3.2}$$

and the corresponding approximation of the DPE (2.11)–(2.12):

$$\min\left\{-\mathcal{L}v,\ \mathbf{g^b}\cdot Dv,\ \mathbf{g^s_\varepsilon}\cdot Dv\right\}=0 \text{ on } \bar{\mathcal{S}}\setminus\partial^z\mathcal{S} \text{ and } v=0 \text{ on } \partial^z\mathcal{S}. \tag{3.3}$$

A constrained viscosity solution of this equation is defined exactly as in Definition 2.1, replacing $\mathbf{g^s}$ by $\mathbf{g^s_\varepsilon}$. For each $\varepsilon>0$ the approximation $\mathbf{g^s_\varepsilon}$ is Lipschitz-continuous on $\bar{\mathcal{S}}\setminus\partial^z\mathcal{S}$, and this property is sufficient to obtain the following comparison result.

THEOREM 3.1. *Let $\lambda+\mu>0$ and $\varepsilon>0$. Let u be an upper semicontinuous constrained viscosity subsolution of* (3.3) *and v be a lower semicontinuous viscosity*

supersolution of (3.3) *with* $(u-v)^+ \in \mathrm{USC}_p(\bar{\mathcal{S}})$. *Assume further that* $u \le v$ *on* $\partial^z\mathcal{S}$. *Then* $u \le v$ *on* $\bar{\mathcal{S}}$.

This result is proved in section 4 and implies, as usual, a uniqueness result for the approximating PDE (3.3) for every $\varepsilon > 0$. We can now state our main DPE characterization of the value function V which justifies the numerical scheme implemented in the accompanying paper [5].

THEOREM 3.2. *For every* $\varepsilon > 0$, *there exists a unique constrained viscosity solution* V_ε *for the nonlinear parabolic PDE* (3.3) *in the class* C^0_p. *Moreover, the family* $(V_\varepsilon)_{\varepsilon>0}$ *is nondecreasing and converges to the value function* V *uniformly on compact subsets of* $\bar{\mathcal{S}}$ *as* $\varepsilon \searrow 0$.

The existence of a solution for the approximating PDE (3.3) is proved in section 5 by conveniently modifying the optimal investment problem under capital gains taxes, and showing that the induced value function V_ε is a constrained viscosity solution of (3.3). Moreover, we will prove in Proposition 6.2 that $0 \le V_\varepsilon \le V$, so that V_ε inherits the p-polynomial growth of V stated in [5]. Together with the comparison result of Theorem (3.1), this shows that V^ε is the unique constrained viscosity solution in C^0_p. The convergence result is proved in section 6.

4. The comparison result. We adapt the standard argument based on the Ishii technique; see Theorem 3.2 and Lemma 3.1 in [9]. The subsequent proof is also inspired from [1]. In comparison to the latter paper, we have the additional difficulty implied by the state constraint $(y,k) \in \mathbb{R}^2_+$. We use the idea of Theorem 7.9 in [9] to account for this avoidance of the continuity assumptions of this theorem. We mention that comparison results for second order PDEs with state constraints have been obtained for specific control problems in [2] and [3] but do not apply to our context. In the subsequent analysis, the key result to avoid the continuity is the observation that

$$\begin{aligned} &\text{for each } s \in \bar{\mathcal{S}} \setminus \partial^z\mathcal{S}, \ \text{ there exists some } \ \zeta_s > 0 \ \text{ such that} \\ &\qquad s - \zeta \mathbf{g^b} \ \in \ \mathcal{S} \ \text{ for every } 0 < \zeta < \zeta_s, \end{aligned} \tag{4.1}$$

together with the following.

LEMMA 4.1. *Let* $v \in \mathrm{LSC}(\bar{\mathcal{S}})$ *be such that* $v(s_0) = \liminf_{\mathcal{S}\ni s\to s_0} v(s)$ *for* $s_0 \in \partial\mathcal{S}$. *Assume that* $\mathbf{g^b}\cdot Dv \ge 0$ *on* $\mathcal{S}$ *in the viscosity sense. Then*

$$\lim_{\ell\searrow 0} v(s - \ell\mathbf{g^b}) \ = \ v(s) \text{ for any } s \in \bar{\mathcal{S}} \setminus \partial^z\mathcal{S}.$$

Proof. Since v is a viscosity supersolution of $\mathbf{g^b}\cdot Dv \ge 0$ on $\mathcal{S}$ and (4.1) holds, we deduce that, for any $s \in \mathcal{S}$, the function $\ell \longmapsto v(s-\ell\mathbf{g^b})$ is well defined and nonincreasing on a neighborhood of 0. In particular, $v(s-\ell\mathbf{g^b}) \le v(s)$ for any $s \in \mathcal{S}$, and $\ell \ge 0$ sufficiently small. For $s_0 \in \partial\mathcal{S}$, it follows from the assumption of the lemma that $v(s_0) = \liminf_{\mathcal{S}\ni s\to s_0} v(s) \ge \liminf_{\mathcal{S}\ni s\to s_0} v(s' - \ell\mathbf{g^b}) \ge v(s_0 - \ell\mathbf{g^b})$. Hence

$$v(s-\ell\mathbf{g^b}) \ \le \ v(s) \text{ for any } s \in \bar{\mathcal{S}} \setminus \partial^z\mathcal{S} \text{ and } \ell \ge 0.$$

This implies that, for any $s \in \bar{\mathcal{S}} \setminus \partial^z\mathcal{S}$,

$$v(s) \ \ge \ \limsup_{\ell\searrow 0} v(s-\ell\mathbf{g^b}) \ \ge \ \liminf_{\ell\searrow 0} v(s-\ell\mathbf{g^b}) \ \ge \ \liminf_{\mathcal{S}\ni s'\to s} v(s') \ \ge \ v(s),$$

completing the proof. □

Another important ingredient of our comparison result is the use of a strict supersolution of the equation

$$\min\{\mathbf{g}^{\mathbf{b}} \cdot Dv,\ \mathbf{g}^{\mathbf{s}}_{\varepsilon} \cdot Dv\} \ = \ 0 \text{ on } \bar{\mathcal{S}} \setminus \partial^z \mathcal{S}. \tag{4.2}$$

This is the only place where the presence of transaction costs is crucial.

LEMMA 4.2. *Let $\lambda + \mu > 0$ and assume that condition (2.9) holds. Then, there exist two positive parameters*

$$0 \ < \ \bar{\eta} \ < \ \frac{\lambda + \mu}{2} \text{ and } \delta \in (p, 1) \text{ with } \frac{\beta}{\delta} - r - \frac{\theta^2}{2(1-\delta)} \ > \ 0$$

such that the function

$$\Phi(s) \ := \ \left(x + (1-\mu)\left[(1-\alpha+\bar{\eta})y + (\alpha+\bar{\eta})k\right]\right)^{\delta} \text{ for } s \ \in \ \bar{\mathcal{S}}$$

is a classical strict supersolution of (4.2).

Proof. We show only that $\mathbf{g}^{\mathbf{s}}_{\varepsilon} \cdot D\Phi > 0$, as the other strict inequalities are easily seen to hold. Setting $\tilde{z} := x + (1-\mu)\left[(1-\alpha+\bar{\eta})y + (\alpha+\bar{\eta})k\right]$, we directly compute that

$$\left(\mathbf{g}^{\mathbf{s}}_{\varepsilon} \cdot D\Phi\right)(s) = \frac{(1-\mu)\bar{\eta}}{1-\alpha}\tilde{z}^{\delta-1}\left[1 + (1-2\alpha)\frac{kf^{\varepsilon}(s)}{(1-\alpha)y + \alpha k f^{\varepsilon}(s)}\right].$$

If $y = k = 0$ or $1 - 2\alpha \geq 0$, the required inequality is trivial. We next assume that $(y,k) \neq 0$ and $1 - 2\alpha < 0$. Then using the fact that $f^{\varepsilon}(s) \leq 1$, it follows that

$$\begin{aligned}\left(\mathbf{g}^{\mathbf{s}}_{\varepsilon} \cdot D\Phi\right)(s) &\geq \frac{(1-\mu)\bar{\eta}}{1-\alpha}\tilde{z}^{\delta-1}\left[1 + (1-2\alpha)\frac{k}{(1-\alpha)y + \alpha k}\right] \\ &= \frac{(1-\mu)\bar{\eta}}{1-\alpha}\tilde{z}^{\delta-1}\frac{(1-\alpha)(y+k)}{(1-\alpha)y + \alpha k} \ > \ 0. \qquad \square\end{aligned}$$

We are now ready for the following proof.

Proof of Theorem 3.1. We start by setting a new notation. We denote by $\tilde{\mathcal{L}}$ the operator

$$\tilde{\mathcal{L}}(s,u,q,Q) \ := \ -\beta u + rxq_1 + \rho y q_2 + \frac{1}{2}\sigma^2 Q_{22}$$

for $s = (x,y,k) \in \bar{\mathcal{S}}$, $u \in \mathbb{R}$, $q = (q_i)_{1 \leq i \leq 3} \in \mathbb{R}^3$, and $Q = (Q_{i,j})_{\substack{1 \leq i \leq 3 \\ 1 \leq j \leq 3}} \in \mathbb{S}(3)$, so that the second order operator $\mathcal{L}$ can be written as

$$\mathcal{L}\varphi(s) \ = \ \tilde{\mathcal{L}}\left(s, \varphi(s), D\varphi(s), D^2\varphi(s)\right) + \tilde{U}(\varphi_x(s)).$$

Let u and v be as in the statement of Theorem 3.1, and let us prove that $u \leq v$ in $\bar{\mathcal{S}}$.

We first observe that we can assume, without loss of generality, that

$$v(s) \ = \ \liminf\{v(s') \ : \ s' \in \mathcal{S} \text{ and } s' \neq s\} \text{ for every } s \in \partial^y \mathcal{S} \cup \partial^k \mathcal{S}. \tag{4.3}$$

Indeed, we may define the function $\underline{v} := v$ on $\mathcal{S} \cup \partial^z \mathcal{S}$ and $\underline{v}(s) := \liminf_{s \neq s' \to s} v(s')$ for $s \in \partial^y \mathcal{S} \cup \partial^k \mathcal{S}$. Then, $\underline{v}$ satisfies the same conditions as v, and if we succeed in proving that $u \leq \underline{v}$, we deduce immediately that $u \leq v$ since the inequality $\underline{v} \leq v$ is trivial.

We now start the proof of the comparison result with the additional condition (4.3). Assume to the contrary that

$$(u-v)(s^*) > 0 \text{ for some } s^* \in \bar{\mathcal{S}}. \tag{4.4}$$

Step 1. Let Φ be the strict supersolution of (4.2) defined in Lemma 4.2, and $\eta > 0$, $\zeta > 0$ be some fixed parameters such that

$$m_0 := (u-v)(s_0) - 2\eta\Phi(s_0) - \zeta|\mathbf{g^b}|^2 = \max_{s\in\bar{\mathcal{S}}} (u - v - 2\eta\Phi) - \zeta|\mathbf{g^b}|^2 > 0 \tag{4.5}$$

by (4.4), where the maximum is attained thanks to the p-polynomial growth condition on $(u-v)^+$ and the fact that $\delta > p$. In particular, it follows from (4.5), together with $\Phi \geq 0$, $u \leq v$ on $\partial^z\mathcal{S}$ and (4.1), that

$$s_0 \in \bar{\mathcal{S}} \setminus \partial^z\mathcal{S} \text{ and } s_0 - \zeta\mathbf{g^b} \in \mathcal{S} \text{ for small } \zeta > 0. \tag{4.6}$$

We next define the mappings on $\bar{\mathcal{S}} \times \bar{\mathcal{S}}$ by

$$\begin{aligned}\Psi_n(s,s') &:= (u-\eta\Phi)(s) - (v+\eta\Phi)(s') - \psi_n(s,s'),\\ \psi_n(s,s') &:= \left|n(s-s') - \zeta\mathbf{g^b}\right|^2 + \zeta|s-s_0|^2 .\end{aligned}$$

Here, $\zeta \in (0,1)$ is some given constant. From the p-polynomial growth condition on $(u-v)^+$ and the fact that $\delta > p$ in the definition of Φ, we see that the upper semicontinuous function Ψ_n attains its maximum at some (s_n, s'_n) in $\bar{\mathcal{S}} \times \bar{\mathcal{S}}$, so that by (4.5),

$$m_n := \Psi_n(s_n, s'_n) = \max_{(s,s')\in\bar{\mathcal{S}}\times\bar{\mathcal{S}}} \Psi_n(s,s') \geq m_0 > 0.$$

By (4.6) and the definition of Ψ_n, we have the inequality $\Psi_n(s_n, s'_n) \geq \Psi_n(s_0, s_0 - \frac{\zeta}{n}\mathbf{g^b})$ which, together with the p-polynomial growth condition on u and v, provides

$$\begin{aligned}\left|n(s_n - s'_n) - \zeta\mathbf{g^b}\right|^2 + \zeta\,|s_n - s_0|^2 &\leq (u-\eta\Phi)(s_n) - (v+\eta\Phi)(s'_n)\\ &\quad -(u-\eta\Phi)(s_0) + (v+\eta\Phi)\left(s_0 - \frac{\zeta}{n}\mathbf{g^b}\right)\\ &\leq \tilde{A}\left(1 + |s_n|^p + |s'_n|^p + \eta|s_n|^\delta + \eta|s'_n|^\delta\right)\end{aligned} \tag{4.7}$$

for some positive constant $\tilde{A}$. We deduce from the last inequality that the sequences $(s_n)_{n\geq 1}$ and $(s'_n)_{n\geq 1}$ are bounded, and we can assume, without loss of generality, that $s_n, s'_n \longrightarrow \hat{s} \in \bar{\mathcal{S}}$ as $n \to \infty$. We now use Lemma 4.1, together with the upper semicontinuity of u and the lower semicontinuity of v, to pass to the limit as $n \to \infty$ in (4.7). This provides

$$\begin{aligned}\limsup_{n\to\infty}\left(\left|n(s_n - s'_n) - \zeta\mathbf{g^b}\right|^2 + \zeta\,|s_n - s_0|^2\right) &\leq (u-\eta\Phi)(\hat{s}) - (v+\eta\Phi)(\hat{s})\\ &\quad - ((u-\eta\Phi)(s_0) - (v-\eta\Phi)(s_0))\\ &\leq 0,\end{aligned}$$

where the last inequality follows from (4.5). Consequently

$$\left|n(s_n - s'_n) - \zeta\mathbf{g^b}\right|^2 \longrightarrow 0 \text{ and } s_n, s'_n \longrightarrow s_0 \text{ as } n \to \infty.$$

In particular, it follows from (4.6) that

$$s'_n \;=\; s_n - \frac{\zeta \mathbf{g^b} + o(1)}{n} \;\in\; \mathcal{S} \text{ and } s_n \;\in\; \bar{\mathcal{S}} \setminus \partial^z \mathcal{S} \text{ for large } n. \tag{4.8}$$

Step 2. For each $n \geq 1$, (s_n, s'_n) is a maximum point of

$$\Psi_n \;:\; (s,s') \longmapsto (u - \eta\Phi)(s) - (v + \eta\Phi)(s') - \psi_n(s,s').$$

Then applying Theorem 3.2 in [9] to the upper semicontinuous functions $u - \eta\Phi$ and to the lower semicontinuous function $v + \eta\Phi$, we deduce that there exist 3×3 symmetric matrices Ξ_n and Υ_n, with $\Xi_n \leq \Upsilon_n$ such that

$$j_n := \big(q_n := D_1\psi(s_n,s'_n) + \eta D\Phi(s_n); Q_n := \Xi_n + \eta D^2\Phi(s_n)\big) \;\in\; \bar{J}^{2,+}_{\bar{\mathcal{S}}\setminus\partial^z\mathcal{S}} u(s_n), \tag{4.9}$$

$$j'_n := \big(q'_n := -D_2\psi(s_n,s'_n) - \eta D\Phi(s'_n); Q'_n := \Upsilon_n - \eta D^2\Phi(s'_n)\big) \;\in\; \bar{J}^{2,-}_{\mathcal{S}} v(s'_n), \tag{4.10}$$

and

$$-\big(2n^2 + ||M_n||\big)\, I \;\leq\; \begin{pmatrix} \Xi_n & 0 \\ 0 & -\Upsilon_n \end{pmatrix} \;\leq\; M_n + \frac{1}{2n^2} M - n^2, \tag{4.11}$$

where

$$M_n \;:=\; D^2\psi(s_n,s'_n) \;=\; 2n^2 \begin{pmatrix} I & -I \\ -I & I \end{pmatrix} + 2\zeta \begin{pmatrix} I & 0 \\ 0 & 0 \end{pmatrix},$$

$$D_1\psi(s,s') = 2n\left(n(s-s') - \zeta\mathbf{g^b}\right) + 2\zeta(s - s_0), \quad -D_2\psi(s,s') = 2n\left(n(s-s') - \zeta\mathbf{g^b}\right).$$

Here the norm of a symmetric matrix M is defined as $\|M\| = \sup\{M\xi\cdot\xi \;:\; |\xi| \leq 1\}$.

By (4.8) and for large $n \geq 1$, the subsolution property of u holds at j_n and the supersolution property of v holds at j'_n, i.e.,

$$\min\Big\{\beta u(s_n) - \tilde{\mathcal{L}}(s_n,q_n,Q_n) - \tilde{U}(q_{n\,1}),\; \mathbf{g^b}\cdot q_n,\; \mathbf{g^s_\varepsilon}(s_n)\cdot q_n\Big\} \leq 0, \tag{4.12}$$

$$\min\Big\{\beta v(s'_n) - \tilde{\mathcal{L}}(s'_n,q'_n,Q'_n) - \tilde{U}(q'_{n\,1}),\; \mathbf{g^b}\cdot q'_n,\; \mathbf{g^s_\varepsilon}(s'_n)\cdot q'_n\Big\} \geq 0. \tag{4.13}$$

Step 3. For each $n \geq 1$,

$$\mathbf{g^b}\cdot q_n - \mathbf{g^b}\cdot q'_n = \eta\mathbf{g^b}\cdot(D\Phi(s_n) + D\Phi(s'_n)) + 2\zeta\mathbf{g^b}\cdot(s_n - s_0).$$

Recall that $s_n, s'_n \longrightarrow s_0 \in \bar{\mathcal{S}} \setminus \partial^z\mathcal{S}$, and $\mathbf{g^b}\cdot\Phi > 0$ on $\bar{\mathcal{S}} \setminus \partial^z\mathcal{S}$; then

$$\lim_{n\to\infty}\big(\mathbf{g^b}\cdot q_n - \mathbf{g^b}\cdot q'_n\big) = 2\eta\mathbf{g^b}\cdot D\Phi(s_0) \;>\; 0. \tag{4.14}$$

We also compute for all $n \geq 1$ that

$$\begin{aligned}\mathbf{g^s_\varepsilon}(s_n)\cdot q_n - \mathbf{g^s_\varepsilon}(s'_n)\cdot q'_n = \eta\left(\mathbf{g^s_\varepsilon}(s_n)\cdot D\Phi(s_n) + \mathbf{g^s_\varepsilon}(s'_n)\cdot D\Phi(s'_n)\right) + 2\zeta\mathbf{g^s_\varepsilon}(s_n)\cdot(s_n - s_0)\\ + \left(\mathbf{g^s_\varepsilon}(s_n) - \mathbf{g^s_\varepsilon}(s'_n)\right)\cdot 2n\left[n(s_n - s'_n) - \zeta\mathbf{g^b}\right].\end{aligned}$$

By the local Lipschitz continuity of the function $\mathbf{g^s_\varepsilon}$ at s_0, there exists some positive constant C_0 such that for large n,

$$\begin{aligned}&|\mathbf{g^s_\varepsilon}(s_n)\cdot q_n - \mathbf{g^s_\varepsilon}(s'_n)\cdot q'_n - \eta\left(\mathbf{g^s_\varepsilon}(s_n)\cdot D\Phi(s_n) + \mathbf{g^s_\varepsilon}(s'_n)\cdot D\Phi(s'_n)\right)|\\ &\quad\leq\; 2\zeta\,|\mathbf{g^s_\varepsilon}(s_n)|\,|s_n - s_0|\,C_0\,|s_n - s'_n|\,2n\left|n(s_n - s'_n) - \zeta\mathbf{g^b}\right|\\ &\quad\leq\; 2\zeta\,|\mathbf{g^s_\varepsilon}(s_n)|\,|s_n - s_0|\,2C_0\left|n(s_n - s'_n) - \zeta\mathbf{g^b}\right|^2 + 2C_0\zeta|\mathbf{g^b}|\left|n(s_n - s'_n) - \zeta\mathbf{g^b}\right|.\end{aligned}$$

Since $s_n \longrightarrow s_0$ and $|n(s_n - s'_n) - \zeta \mathbf{g^b}| \longrightarrow 0$, we get

$$\lim_{n\to\infty} (\mathbf{g}^{\mathbf{s}}_{\varepsilon}(s_n)\cdot q_n - \mathbf{g}^{\mathbf{s}}_{\varepsilon}(s'_n)\cdot q'_n) = 2\eta \mathbf{g}^{\mathbf{s}}_{\varepsilon}\cdot D\Phi(s_0) \ > \ 0. \tag{4.15}$$

We deduce from (4.13), (4.14), and (4.15), together with Lemma 4.2, that for large n,

$$\min\left\{\mathbf{g^b}\cdot q_n,\ \mathbf{g}^{\mathbf{s}}_{\varepsilon}(s_n)\cdot q_n\right\} \geq 2\min\left\{\mathbf{g^b}\cdot D\Phi(s_0),\ \mathbf{g}^{\mathbf{s}}_{\varepsilon}(s_n)\cdot D\Phi(s_0)\right] + o(1) \ > \ 0.$$

Consequently (4.12) implies that for large n,

$$\beta u(s_n) - \tilde{\mathcal{L}}(s_n, q_n, Q_n) - \tilde{U}(q_{n\,1}) \leq 0. \tag{4.16}$$

Step 4. From (4.13) and (4.16), it follows that for large n,

$$\beta u(s_n) - \tilde{\mathcal{L}}(s_n, q_n, Q_n) - \tilde{U}(q_{n\,1}) \leq \ 0 \ \leq \beta v(s'_n) - \tilde{\mathcal{L}}(s'_n, q'_n, Q'_n) - \tilde{U}(q'_{n\,1}).$$

Using the local Lipschitz continuity property of the function $\tilde{U}$, a direct calculation shows that for some positive constant C and for large n,

$$\begin{aligned}
\beta(u(s_n) - v(s'_n)) &\leq \tilde{\mathcal{L}}(s_n, q_n, Q_n) - \tilde{\mathcal{L}}(s'_n, q'_n, Q'_n) + \tilde{U}(q_{n\,1}) - \tilde{U}(q'_{n\,1}) \\
&\leq C\left(|s_n|\zeta|s_n - s_0| + |n(s_n - s'_n) - \zeta\mathbf{g^b}|^2 + |D\Phi(s_n) - D\Phi(s'_n)|\right) \\
&\quad + \frac{\sigma^2}{2}\left(y_n^2(Q_n)_{22} - (y'_n)^2(Q'_n)_{22}\right) \\
&\quad + \eta\left\{\tilde{\mathcal{L}}(s_n, D\Phi(s_n), D^2\Phi(s_n)) + \tilde{\mathcal{L}}(s'_n, D\Phi(s'_n), D^2\Phi(s'_n))\right\}.
\end{aligned}$$

From (4.11), we have that

$$\left(y_n^2(Q_n)_{22} - (y'_n)^2(Q'_n)_{22}\right) \leq 4\zeta y_n(u_n - y'_n) + \frac{\zeta^2}{n^2}y_n.$$

Moreover, the mapping Φ satisfies $\beta\Phi(.) - \tilde{\mathcal{L}}(., D\Phi, D^2\Phi)$ on $\bar{\mathcal{S}} \setminus \partial^z\mathcal{S}$, and hence for some positive constant $\tilde{C}$ and for large n,

$$\begin{aligned}
&\beta[u(s_n) - v(s'_n)] - \eta\Phi(s_n) - \eta\Phi(s'_n) \\
&\quad \leq \tilde{\mathcal{L}}(s_n, q_n, Q_n) - \tilde{\mathcal{L}}(s'_n, q'_n, Q'_n) + \tilde{U}(q_{n\,1}) - \tilde{U}(q'_{n\,1}) \\
&\quad \leq \tilde{C}\left\{\frac{1}{n^2} + |s_n|\zeta|s_n - s_0| + |n(s_n - s'_n) - \zeta\mathbf{g^b}|^2 + |D\Phi(s_n) - D\Phi(s'_n)|\right\},
\end{aligned}$$

where the right-hand side of the inequality goes to zero as $n \to \infty$. This implies

$$\beta[u(s_0) - v(s_0)] - 2\eta\Phi(s_0) = \limsup_{n\to\infty}\ (\beta[u(s_n) - v(s'_n)] - \eta\Phi(s_n) - \eta\Phi(s'_n)) \ \leq \ 0,$$

contradicting (4.5). □

We conclude this section with the following proof.

Proof of Proposition 2.3. We use the same arguments as in the proof of Theorem 3.1, but this time substituting $\mathbf{g^s}$ for $\mathbf{g}^{\mathbf{s}}_{\varepsilon}$. The only difference is the following. The maximizer s_0 in (4.5) is now known to be in $\bar{\mathcal{S}} \setminus (\partial^z\mathcal{S} \cup \{(x, 0, 0) : \ x \geq 0\})$, as it is assumed in the statement of the proposition that $u \leq v$ on $\partial^z\mathcal{S} \cup \{(x, 0, 0) : \ x \geq 0\}$. Then, the sequences $(s_n)_n$ and $(s'_n)_n$, defined in Step 1, are valued in a ball around s_0 which does not intersect the axis $\{(x, 0, 0) : \ x \geq 0\}$. Since $\mathbf{g^s}$ is locally Lipschitz on $\bar{\mathcal{S}} \setminus \{(x, 0, 0) : \ x \geq 0\}$, we just follow along the lines of the previous proof. □

5. An approximating control problem. Let $s = (x, y, k)$ be an initial condition in the state space $\bar{\mathcal{S}}$, and consider a control process $\nu \in \mathcal{A}$, i.e., a triple of $\mathbb{F}$-adapted processes $\nu = (C, L, M)$, with nondecreasing right-continuous processes L, M, $L_{0-} = M_{0-} = 0$ and satisfying conditions (2.2) and (2.3). For every parameter $\varepsilon \geq 0$, we denote by $S^{\varepsilon,s,\nu} = (X^{\varepsilon,s,\nu}, Y^{\varepsilon,s,\nu}, K^{\varepsilon,s,\nu})$ the unique strong solution of

$$dX_t^\varepsilon = (rX_t^\varepsilon - C_t)dt - (1+\lambda)dL_t + (1-\mu)\left[(1-\alpha)Y_{t-}^\varepsilon + \alpha f^\varepsilon(S_{t-}^\varepsilon)K_{t-}^\varepsilon\right] dM_t, \tag{5.1}$$

$$dY_t^\varepsilon = Y_t^\varepsilon\left[\rho dt + \sigma dW_t\right] + dL_t - Y_{t-}^\varepsilon dM_t, \tag{5.2}$$

$$dK_t^\varepsilon = dL_t - f^\varepsilon(S_{t-}^\varepsilon)K_{t-}^\varepsilon dM_t \tag{5.3}$$

with initial condition $S_{0-}^{\varepsilon,s,\nu} = s$. With this definition, observe that the jumps of the state processes $S^{\varepsilon,s,\nu}$ are given by

$$\Delta S_t^{\varepsilon,s,\nu} = -\Delta L_t\, \mathbf{g^b} - \Delta M_t \left[(1-\alpha)Y_{t-}^{\varepsilon,s,\nu} + \alpha f^\varepsilon(S_{t-}^{\varepsilon,s,\nu})K_{t-}^{\varepsilon,s,\nu}\right] \mathbf{g}_\varepsilon^{\mathbf{s}}\left(S_{t-}^{\varepsilon,s,\nu}\right),$$

where the vector fields $\mathbf{g^b}$ and $\mathbf{g}_\varepsilon^{\mathbf{s}}$ are defined as in (2.15) and (3.2).

A control process $\nu = (C, L, M)$ is said to be (s, ε)-admissible if the corresponding state process $S^{\varepsilon,s,\nu}$ is valued in $\bar{\mathcal{S}}$. We shall denote by $\mathcal{A}^\varepsilon(s)$ the collection of all (s, ε)-admissible controls.

For every initial condition $s \in \bar{\mathcal{S}}$, $\varepsilon \geq 0$, and (s, ε)-admissible control $\nu = (C, L, M)$, we introduce the criterion

$$J_T^\varepsilon(s, \nu) := \mathbb{E}\left[\int_0^T e^{-\beta t}U(C_t)dt + e^{-\beta T}U(Z_T^{\varepsilon,s,\nu})\mathbf{1}_{T<\infty}\right], \qquad T \in \mathbb{R}_+ \cup \{\infty\}, \tag{5.4}$$

where U is the power utility function defined in (2.8). The value function V_ε is then defined by

$$V_\varepsilon(s) := \sup_{\nu \in \mathcal{A}^\varepsilon(s)} J_\infty^\varepsilon(s, \nu). \tag{5.5}$$

Remark 2. When $\varepsilon = 0$, the above problem reduces to the optimal investment problem under capital gains taxes reviewed in section 2, in particular $V_0 = V$. For positive ε, the control problem (5.5) can be interpreted as a utility maximization problem with a modified taxation rule. Under this new taxation rule, the tax basis used to evaluate the capital gains is equal to the relative weighted average purchase price as long as the ratio K/Z is larger than 2ε, but it is set to zero when $K/Z < \varepsilon$. Roughly speaking, for $\varepsilon > 0$, the investor pays more taxes than in the original market when the ratio $K/Z < \varepsilon$. Consequently, we expect that V_ε increases towards V as ε goes to zero. This will be proved in Proposition 6.2 below.

The main objective of this section is to prove that the function V_ε is a constrained viscosity solution of the approximating PDE (3.3), thus proving the existence statement in Theorem 3.2. The arguments of this section hold for every $\varepsilon \geq 0$. In particular, the proof of Proposition 2.2 corresponds to the special case $\varepsilon = 0$.

As usual, the key ingredient for deriving the DPE is a dynamic programming principle. We state it here without proof, and we refer the reader to [6, 13, 14].

THEOREM 5.1. *Let $\varepsilon \geq 0$, $s \in \bar{\mathcal{S}}$, and let τ be some $\mathbb{P}$-a.s. finite $\mathbb{F}$-stopping time. Then*

$$V_\varepsilon(s) = \sup_{\nu=(C,L,M)\in\mathcal{A}^\varepsilon(s)} \mathbb{E}\left[\int_0^\tau e^{-\beta t}U(C_t)dt + e^{-\beta\tau}V_\varepsilon\left(S_\tau^{\varepsilon,s,\nu}\right)\right].$$

Before turning to the derivation of the DPE for the problem V_ε, we introduce a notation which will be used frequently in what follows. Let $\varepsilon \geq 0$, $s \in \bar{\mathcal{S}}$, $\nu = (C, L, M) \in \mathcal{A}(s)$, and consider some stopping time τ such that $S^{\varepsilon,s,\nu}_{\tau-} \in \bar{\mathcal{S}}$. Then, it is easy to verify that the strategy $\nu(\tau)$ defined by

$$\nu(\tau)_t \;:=\; \left(\bar{C}, \bar{L}, \bar{M}\right) := \nu_t \mathbf{1}_{[0,\tau[}(t) + (0, L_{\tau-}, M_{\tau-} + (1 - \Delta M_\tau))\, \mathbf{1}_{[\tau,\infty)}(t) \tag{5.6}$$

is in $\mathcal{A}^\varepsilon(s)$, and that

$$\mathbb{E}\left[\int_0^\infty e^{-\beta t} U\left(\bar{C}_t\right) dt\right] = \mathbb{E}\left[\int_0^\tau e^{-\beta t} U\left(\bar{C}_t\right) dt\right]. \tag{5.7}$$

5.1. Supersolution property. In this section, we prove that the value function V_ε is a viscosity supersolution of (3.3) on $\mathcal{S}$ for every $\varepsilon \geq 0$.

Step 1. Fix some $\varepsilon \geq 0$. Recall that $V_\varepsilon \geq 0$ by definition, and in particular $(V_\varepsilon)_*(0) \geq 0$. So it remains to show that, for s_0 in $\mathcal{S}$ and φ in $C^2(\bar{\mathcal{S}})$ such that

$$0 \;=\; \left((V_\varepsilon)_* - \varphi\right)(s_0) = \min_{\mathcal{S}} \left((V_\varepsilon)_* - \varphi\right),$$

the test function φ must satisfy, at the point s_0,

$$\min\left\{-\mathcal{L}\varphi,\ \mathbf{g}^{\mathbf{b}} \cdot D\varphi,\ \mathbf{g}^{\mathbf{s}}_\varepsilon \cdot D\varphi\right\}(s_0) \geq 0.$$

Step 2.1. Let $\eta > 0$ be such that $B(s_0, \eta) \subset \mathcal{S}$, and consider some sequence $(s_n)_{n\geq 1}$ satisfying

$$\begin{aligned} &\text{(i) } B(s_0, \eta) \ni s_n \underset{n\to\infty}{\longrightarrow} s_0, \\ &\text{(ii) } \xi_n \;:=\; V_\varepsilon(s_n) - \varphi(s_n) \;\longrightarrow\; 0 \text{ as } n \to 0. \end{aligned}$$

Fix some (c, ℓ, m) in $(0, \infty)^3$, define the strategy $\nu \in \mathcal{A}$ by

$$\nu_t \;=\; (C_t = c, L_t = \ell\, t, M_t = m\, t),$$

and let $(\tau^n)_{n\geq 0}$ be the stopping times

$$\tau^n \;:=\; \inf\{t \geq 0 \;:\; S^{\varepsilon,s_n,\nu}_t \notin \mathcal{S}\} n \geq 0.$$

Given that for each $n \geq 0$, $s_n \notin \partial^z \mathcal{S}$, and that the strategy ν is continuous, we have

$$\tau^n \;>\; 0 \text{ for all } n \geq 0 \;\text{ and }\; \tau^n \underset{n\to\infty}{\longrightarrow} \tau^0 \quad \mathbb{P}\text{-a.s.} \tag{5.8}$$

Step 2.2. To each $n \geq 1$ we associate the (ε, s_n)-admissible strategy $\nu(\tau^n) = (C^n, L^n, M^n) \in \mathcal{A}^\varepsilon(s_n)$ defined in (5.6). To simplify the notation, we set $S^n := S^{\varepsilon,s_n,\nu(\varepsilon,s_n)}$. For any $\mathbb{P}$-a.s. finite stopping time θ^n, the dynamic programming principle of Theorem 5.1 provides

$$V_\varepsilon(s_n) \geq \mathbb{E}\left[\int_0^{\theta^n \wedge \tau^n/2} e^{-\beta t} U(C^n_t) dt \;+\; e^{-\beta\, \theta^n \wedge \tau^n/2} V_\varepsilon\left(S^n_{\theta^n \wedge \tau^n/2}\right)\right].$$

Notice that $S^n_{\theta^n \wedge \tau^n/2} \in \mathcal{S}$; we then deduce from the inequalities $\varphi \leq (V_\varepsilon)_* \leq V_\varepsilon$ on $\mathcal{S}$ that

$$\xi_n \;+\; \varphi(s_n) \geq \mathbb{E}\left[\int_0^{\theta^n \wedge \tau^n/2} e^{-\beta t} U(C^n_t) dt \;+\; e^{-\beta\theta^n \wedge \tau^n/2} \varphi\left(S^n_{\theta^n \wedge \tau^n/2}\right)\right].$$

By the definition of the strategy $\nu(\tau^n)$, jumps of the process S^n may occur only at the stopping time τ^n, and by definition of the stopping time τ^n, the process $\left\{S_t^n \mathbf{1}_{[0,\tau^n]}(t), t \geq 0\right\}$ is uniformly bounded. Hence, using the Itô formula we get

$$
\begin{aligned}
-\xi_n \leq \mathbb{E}\left[\int_0^{\theta^n \wedge \tau^n/2} e^{-\beta t}\left\{-\mathcal{L}\varphi + \tilde{U}(\varphi_x) - \left(U(C_t^n) - C_t^n \varphi_x\right)\right\}(S_t^n) dt\right] \\
+ \ell\, \mathbb{E}\left[\int_0^{\theta^n \wedge \tau^n/2} e^{-\beta t} \mathbf{g}^{\mathbf{b}} \cdot D\varphi(S_t^n) dt\right] \\
+ m\, \mathbb{E}\left[\int_0^{\theta^n \wedge \tau^n/2} e^{-\beta t}\left[(1-\alpha) Y_t^n + \alpha f^\varepsilon(S_t^n) K_t^n\right]\left(\mathbf{g}_\varepsilon^{\mathbf{s}} \cdot D\varphi\right)(S_t^n) dt\right].
\end{aligned} \tag{5.9}
$$

Step 2.3. Set

$$
\theta_n = \begin{cases} \sqrt{\xi_n} & \text{if } \xi_n > 0, \\ n^{-1} & \text{if } \xi_n = 0. \end{cases}
$$

Since $\theta^n \longrightarrow 0$ and $\tau^n \longrightarrow \tau^0 > 0$ $\mathbb{P}$-a.s. as $n \to \infty$, it follows that for $\mathbb{P}$-a.s., $\theta^n \wedge \tau^n/2 = \theta^n$ for large n. Rewriting (5.9), and taking the limits as $n \to \infty$, we obtain

$$
\begin{aligned}
0 &= \lim_{n\to\infty} -\frac{\xi_n}{\theta_n}, \\
&\leq \liminf_{n\to\infty} \mathbb{E}\left[\frac{1}{\theta_n}\int_0^{\theta^n \wedge \tau^n/2} e^{-\beta t}\left\{-\mathcal{L}\varphi + \tilde{U}(\varphi_x) - \left(U(C_t^n) - C_t^n \varphi_x\right)\right\}(S_t^n) dt\right] \\
&\qquad + \ell\, \mathbb{E}\left[\frac{1}{\theta_n}\int_0^{\theta^n \wedge \tau^n/2} e^{-\beta t} \mathbf{g}^{\mathbf{b}} \cdot D\varphi(S_t^n) dt\right] \\
&\qquad + m\, \mathbb{E}\left[\frac{1}{\theta_n}\int_0^{\theta^n \wedge \tau^n/2} e^{-\beta t}\left[(1-\alpha) Y_t^n + \alpha f^\varepsilon(S_t^n) K_t^n\right]\left(\mathbf{g}_\varepsilon^{\mathbf{s}} \cdot D\varphi\right)(S_t^n) dt\right].
\end{aligned} \tag{5.10}
$$

Since $\varphi \in C^2\left(\bar{\mathcal{S}}\right)$, and the process $\left\{S_t^n \mathbf{1}_{[0,\tau^n/2]}(t), t \geq 0\right\}$ is continuous and uniformly bounded, we get by dominated convergence

$$
\begin{aligned}
&\liminf_{n\to\infty} \mathbb{E}\left[\frac{1}{\theta_n}\int_0^{\theta^n \wedge \tau^n/2} e^{-\beta t}\left\{-\mathcal{L}\varphi + \tilde{U}(\varphi_x) - \left(U(C_t^n) - C_t^n \varphi_x\right)\right\}(S_t^n) dt\right] \\
&\qquad + \ell\, \mathbb{E}\left[\frac{1}{\theta_n}\int_0^{\theta^n \wedge \tau^n/2} e^{-\beta t} \mathbf{g}^{\mathbf{b}} \cdot D\varphi(S_t^n) dt\right] \\
&\qquad + m\, \mathbb{E}\left[\frac{1}{\theta_n}\int_0^{\theta^n \wedge \tau^n/2} e^{-\beta t}\left[(1-\alpha) Y_t^n + \alpha f^\varepsilon(S_t^n) K_t^n\right]\left(\mathbf{g}_\varepsilon^{\mathbf{s}} \cdot D\varphi\right)(S_t^n) dt\right] \\
&\quad = -\mathcal{L}\varphi(s_0) + \tilde{U}(\varphi_x(s_0)) - \left(U(c) - c\,\varphi_x(s_0)\right) \\
&\qquad + \ell\, \mathbf{g}^{\mathbf{b}} \cdot D\varphi(s_0) \;+\; m\; \left[(1-\alpha) y_0 + \alpha f^\varepsilon(s_0) k_0\right] \mathbf{g}_\varepsilon^{\mathbf{s}}(s_0) \cdot D\varphi(s_0).
\end{aligned}
$$

Recall (5.10); then

$$
\begin{aligned}
0 \leq -\mathcal{L}\varphi(s_0) + \tilde{U}(\varphi_x(s_0)) - \left(U(c) - c\,\varphi_x(s_0)\right) \\
+ \ell\, \mathbf{g}^{\mathbf{b}} \cdot D\varphi(s_0) + m\; \left[(1-\alpha) y_0 + \alpha f^\varepsilon(s_0) k_0\right] \mathbf{g}_\varepsilon^{\mathbf{s}}(s_0) \cdot D\varphi(s_0).
\end{aligned} \tag{5.11}
$$

Step 2.4. Observe that $s_0 \in \mathcal{S}$ implies that $[(1-\alpha)y_0 + \alpha f^\varepsilon(s_0)k_0] > 0$. Since $(c,\ell,m) \in (0,\infty)^3$, (5.11) provides

$$0 \le \min\left\{-\mathcal{L}\varphi,\ \mathbf{g^b}\cdot D\varphi,\ \mathbf{g}^{\mathbf{s}}_\varepsilon \cdot D\varphi\right\}(s_0).$$

5.2. Subsolution property. In this section, we prove that the value function V_ε is a constrained viscosity subsolution of (3.3) for every $\varepsilon \ge 0$. In preparation for this proof, we state some intermediate results.

LEMMA 5.2. *Let φ be a mapping in $C^2(\bar{\mathcal{S}})$, and let $s_0 \in \bar{\mathcal{S}}$ such that $\varphi_x(s_0) > 0$. Then there exist $\eta > 0$, $\gamma > 0$, and $c_0 > 0$ such that*

$$\tilde{U}\left(\varphi_x(s)\right) - \left[U(c) - c\varphi_x(s)\right] \ge \gamma\left(c - c_0\right)^+ \text{for all } c \ge 0 \text{ and } s \in B\left(s_0,\eta\right) \cap \bar{\mathcal{S}}.$$

Proof. Since $\varphi_x(s_0) > 0$, we can find some $\eta, \delta > 0$ such that $\varphi_x > \delta$ on $B(s_0,\eta) \cap \bar{\mathcal{S}}$. The mapping $s \longmapsto \mathcal{I}\left(\varphi_x(s)\right) := \left(U'\right)^{-1}\left(\varphi_x(s)\right)$ is then bounded on $B(s_0,\eta) \cap \bar{\mathcal{S}}$, and since U' is a decreasing function, we can find $c_0 > 0$ such that

$$c_0 > \max_{B(s_0,\eta)\cap\bar{\mathcal{S}}} \mathcal{I}\left(\varphi_x\right) \text{ and } \gamma := \min_{B(s_0,\eta)\cap\bar{\mathcal{S}}} \left(\varphi_x - U'\left(c_0\right)\right) > 0.$$

For all $s \in B(s_0,\eta) \cap \bar{\mathcal{S}}$, using the nonnegativity and the convexity of the function $c \in \mathbb{R}_+ \longmapsto \tilde{U}(\varphi_x(s)) - (U(c) - c\,\varphi_x(s))$, we get

$$\begin{aligned}
\tilde{U}(\varphi_x(s)) - (U(c) - c\,\varphi_x(s)) &\ge \tilde{U}(\varphi_x(s)) - (U(c) - c\,\varphi_x(s)) \\
&\quad - \tilde{U}(\varphi_x(s)) + (U(c_0) - c_0\,\varphi_x(s)) \\
&\ge \left(\varphi_x(s) - U'\left(c_0\right)\right)\left(c - c_0\right)^+ \\
&\ge \gamma\ \left(c - c_0\right)^+. \qquad \square
\end{aligned}$$

LEMMA 5.3. *Let $\varphi \in \mathrm{C}^1(\bar{\mathcal{S}})$ and $s_0 \in \bar{\mathcal{S}} \setminus \partial^z\mathcal{S}$. Assume that*

$$\min\left\{\mathbf{g^b}\cdot D\varphi,\ \mathbf{g}^{\mathbf{s}}_\varepsilon \cdot D\varphi\right\}(s_0) > 0.$$

Then, there exist $\eta, \gamma > 0$ such that for $s = (x,y,k) \in B(s_0,\eta) \cap \bar{\mathcal{S}}$ and $s' := s - \ell\mathbf{g^b}\eta - m[(1-\alpha)y + \alpha f^\varepsilon(s)k]\mathbf{g}^{\mathbf{s}}_\varepsilon \in B(s_0,\eta) \cap \bar{\mathcal{S}}$ with $\ell, m \ge 0$,

$$\varphi(s) - \varphi(s') \ge \gamma\ell + \gamma m\ \left[(1-\alpha)y + \alpha f^\varepsilon(s)k\right].$$

Proof. We first observe that $\|\mathbf{g}^{\mathbf{s}}_\varepsilon\|_\infty < \infty$. In view of the definition of $\mathbf{g}^{\mathbf{s}}_\varepsilon$, this follows from

$$0 \le \frac{kf^\varepsilon(s)}{(1-\alpha)y + \alpha k f^\varepsilon(s)} \le \frac{k}{(1-\alpha)y + \alpha k} \le \frac{1}{\alpha},$$

where we used the inequality $f^\varepsilon \le 1$. Set

$$4\gamma := \min\left\{\mathbf{g^b}\cdot D\varphi\,;\, \mathbf{g}^{\mathbf{s}}_\varepsilon \cdot D\varphi\right\}(s_0) > 0.$$

Since $\mathbf{g}^{\mathbf{s}}_\varepsilon$ and $D\varphi$ are continuous on $\bar{\mathcal{S}} \setminus \partial^z\mathcal{S}$, there exists some $\eta > 0$ such that for all $s, s' \in B(s_0,\eta) \cap \bar{\mathcal{S}}$,

$$\begin{aligned}
&\text{(i)} \quad \min\left\{\mathbf{g^b}\cdot D\varphi,\ \mathbf{g}^{\mathbf{s}}_\varepsilon \cdot D\varphi\right\}(s) > 2\gamma, \\
&\text{(ii)} \quad |D\varphi(s) - D\varphi(s')| \le \frac{\gamma}{\|\mathbf{g}^{\mathbf{s}}_\varepsilon\|_\infty}.
\end{aligned}$$

Let s and s' be as in the statement of the lemma. By the mean value theorem, there exists some $s^* \in [s, s'] \subset B(s_0, \eta) \cap \bar{\mathcal{S}}$ such that

$$\begin{aligned}
\varphi(s) - \varphi(s') &= (s - s') \cdot D\varphi(s^*) \\
&= \ell\, \mathbf{g^b} \cdot D\varphi(s^*) + m\left[(1-\alpha)y + \alpha f^\varepsilon(s)k\right] \mathbf{g}^{\mathbf{s}}_\varepsilon(s) \cdot D\varphi(s^*) \\
&= \ell\, \mathbf{g^b} \cdot D\varphi(s^*) + m\left[(1-\alpha)y + \alpha f^\varepsilon(s)k\right] \mathbf{g}^{\mathbf{s}}_\varepsilon(s) \cdot D\varphi(s) \\
&\quad - m\left[(1-\alpha)y + \alpha f^\varepsilon(s)k\right] \mathbf{g}^{\mathbf{s}}_\varepsilon(s) \cdot \left[D\varphi(s) - D\varphi(s^*)\right] \\
&\geq \ell\, \mathbf{g^b} \cdot D\varphi(s^*) + m\left[(1-\alpha)y + \alpha f^\varepsilon(s)k\right] \mathbf{g}^{\mathbf{s}}_\varepsilon(s) \cdot D\varphi(s) \\
&\quad - m\left[(1-\alpha)y + \alpha f^\varepsilon(s)k\right] \|\mathbf{g}^{\mathbf{s}}_\varepsilon\|_\infty |D\varphi(s) - D\varphi(s^*)|. \\
&\geq \ell\, 2\gamma + m\left[(1-\alpha)y + \alpha f^\varepsilon(s)k\right](2\gamma - \gamma) \\
&\geq \gamma\, \ell \,+\, \gamma\, m\left[(1-\alpha)y + \alpha f^\varepsilon(s)k\right]. \qquad \square
\end{aligned}$$

Proof of the subsolution property.

Step 1. For each $\varepsilon \geq 0$, the value function V_ε is bounded from above by V; see Proposition 6.2 below. We also recall from Proposition 4.5 in [5] that for every $s = (x, y, k) \in \bar{\mathcal{S}}$,

$$V(s) \leq V^0(x + (1-\mu)\alpha k, (1-\alpha)y),$$

where the function V^0, defined in [5], is continuous and satisfies

$$V^0(\bar{x}, \bar{y}) \;=\; 0 \text{ for all } (\bar{x}, \bar{y}) \in \mathbb{R}^2 \text{ such that } \bar{x} + (1-\mu)\bar{y} = 0.$$

It then follows that for each $\varepsilon \geq 0$, the lower semicontinuous envelope of V_ε satisfies $(V_\varepsilon)_* \leq 0$ on $\partial^z \mathcal{S}$.

Let $s_0 \in \bar{\mathcal{S}} \setminus \partial^z \mathcal{S}$ and $\varphi \in C^2\left(\bar{\mathcal{S}}\right)$ be such that

$$0 \;=\; (V^*_\varepsilon - \varphi)(s_0) = \max_{\bar{\mathcal{S}}} \left(V^*_\varepsilon - \varphi\right),$$

and assume to the contrary that

$$F_*\left(s_0, \varphi(s_0), D\varphi(s_0), D^2\varphi(s_0)\right) > 0.$$

Observe that the last inequality implies that $\tilde{U}\left(\varphi_x(s_0)\right) < \infty$ and therefore $\varphi_x(s_0) > 0$. Since $\varphi \in C^2(\bar{\mathcal{S}})$, we deduce from Lemmas 5.2 and 5.3 the existence of $\eta, \gamma, c_0 > 0$, with $B(s_0, \eta) \subset \bar{\mathcal{S}} \setminus \partial^z \mathcal{S}$, such that

$$\min\left\{-\mathcal{L}\varphi,\; \mathbf{g^b} \cdot D\varphi,\; \mathbf{g}^{\mathbf{s}}_\varepsilon \cdot D\varphi\right\}(s) \wedge \varphi_x(s) \;>\; 0, \tag{5.12}$$

$$\tilde{U}\left(\varphi_x(s)\right) - \left(U(c) - c\varphi_x(s)\right) \geq \gamma\left(c - c_0\right), \tag{5.13}$$

$$\varphi(s) - \varphi(s') \;\geq\; \gamma l + \gamma m\left[(1-\alpha)y + \alpha f^\varepsilon(s)k\right] \tag{5.14}$$

for all $s \in B(s_0, \eta) \cap \bar{\mathcal{S}}$, and $s' = s - \ell \mathbf{g^b}\eta - m\mathbf{g}^{\mathbf{s}}_\varepsilon \in B(s_0, \eta) \cap \bar{\mathcal{S}}$ for some $\ell, m \geq 0$.

Step 2. Let $\left(s_n = (x_n, y_n, k_n)\right)_{n \geq 1}$ be some sequence such that

$$\begin{aligned}
&\text{(i)} \quad s_n \;\in\; B\left(s_0, \frac{\eta}{2}\right), \\
&\text{(ii)} \quad s_n \underset{n\to\infty}{\longrightarrow} s_0, \\
&\text{(iii)} \quad \xi_n \;:=\; \left|V_\varepsilon(s_n) - V^*_\varepsilon(s_0)\right| \underset{n\to\infty}{\longrightarrow} 0.
\end{aligned}$$

For each $n \geq 1$, there exists a strategy $\nu^n = (C^n, L^n, M^n) \in \mathcal{A}^\varepsilon(s_n)$ such that

$$V_\varepsilon(s_n) \leq \xi_n + \mathbb{E}\left[\int_0^\infty e^{-\beta t} U(C_t^n) dt\right].$$

Set $S^n = (X^n, Y^n, K^n) := S^{\varepsilon, s_n, \nu^n}$ for $n \geq 1$, and fix some finite positive time horizon $T > 0$. By the dynamic programming principle of Theorem 5.1,

$$V_\varepsilon(s_n) \leq \xi_n \; + \; \mathbb{E}\left[\int_0^{T\wedge\theta^n} e^{-\beta t} U(C_t^n) dt\right] \; + \; \mathbb{E}\left[e^{-\beta T\wedge\theta^n} V_\varepsilon\left(S^n_{T\wedge\theta^n}\right)\right],$$

where $\theta^n := \inf\{t \geq 0 \, : \, S_t^n \notin B(s_0, \eta)\}$. Since $V_\varepsilon \leq V_\varepsilon^* \leq \varphi$ on $\bar{\mathcal{S}} \setminus \partial^z \mathcal{S}$, and $\xi_n = |V_\varepsilon(s_n) - V_\varepsilon^*(s_0)| = |V_\varepsilon(s_n) - \varphi(s_0)|$, it follows that for all $n \geq 1$,

$$\varphi(s_0) \; - \; \mathbb{E}\left[e^{-\beta T\wedge\theta^n} \varphi\left(S^n_{T\wedge\theta^n}\right)\right] \leq 2\xi_n \; + \; \mathbb{E}\left[\int_0^{T\wedge\theta^n} e^{-\beta t} U(C_t^n) dt\right].$$

Notice that for all $n \geq 1$, the process $\left\{S_t^n \mathbf{1}_{[0, T\wedge\theta^n)}(t), t \geq 0\right\}$ is uniformly bounded; then the Itô formula provides

$$\begin{aligned}
2\,\xi_n \geq\; & \mathbb{E}\left[\int_0^{T\wedge\theta^n} e^{-\beta t}\left[-\mathcal{L}\varphi + \tilde{U}(\varphi_x) - \left(U(C_t^n) - C_t^n \varphi_x\right)\right](S_t^n) dt\right] \\
& + \mathbb{E}\left[\int_0^{T\wedge\theta^n} e^{-\beta t} \mathbf{g^b} \cdot D\varphi(S_t^n) dL_t^{nc}\right] \\
& + \mathbb{E}\left[\int_0^{T\wedge\theta^n} e^{-\beta t}\left[(1-\alpha) Y_t^n + \alpha f^\varepsilon(S_t^n) K_t^n\right]\left(\mathbf{g}_\varepsilon^{\mathbf{s}} \cdot D\varphi\right)(S_t^n) dM_t^{nc}\right] \\
& + \mathbb{E}\left[\sum_{0\leq t<T\wedge\theta^n} e^{-\beta t}\left(\varphi(S_{t-}^n) \; - \; \varphi(S_t^n)\right)\right],
\end{aligned}$$

where L^{nc} and M^{nc} denote the continuous part of L^n and M^n. Recall that φ satisfies (5.12), (5.13), and (5.14); then it follows from the previous inequality that

$$\begin{aligned}
2\,\xi_n \geq\; & \gamma\, e^{-\beta T}\, \mathbb{E}\left[(T\wedge\theta^n) \; + \; L^{nc}_{T\wedge\theta^n} \; + \; \int_0^{T\wedge\theta^n} \left[(1-\alpha) Y_t^n + \alpha f^\varepsilon\left(S_t^n\right) K_t^n\right] dM_t^{nc}\right] \\
& + \gamma e^{-\beta T}\, \mathbb{E}\left[\sum_{0\leq t<T\wedge\theta^n} \Delta L_t^n + \left[(1-\alpha) Y_{t-}^n + \alpha f^\varepsilon\left(S_{t-}^n\right) K_{t-}^n\right] \Delta M_t^n\right] \\
& + e^{-\beta T} \gamma \mathbb{E}\left[\int_0^{T\wedge\theta^n} \left(C_t^n - c_0\right)^+ dt\right], \\
\geq\; & \mathbb{E}[h^n(T\wedge\theta^n)],
\end{aligned}$$

where

$$\begin{aligned}
h^n(T\wedge\theta^n) = \gamma e^{-\beta T}\Bigg\{ & (T\wedge\theta^n) + L^n_{T\wedge\theta^n} + \int_0^{T\wedge\theta^n} \left[(1-\alpha) Y_{t-}^n + \alpha f^\varepsilon\left(S_{t-}^n\right) K_{t-}^n\right] dM_t^n \\
& + \int_0^{T\wedge\theta^n} \left(C_t^n - c_0\right)^+ dt\Bigg\}.
\end{aligned}$$

Step 3. To obtain a contradiction, we show that for a sufficiently small T, there is some constant m_* such that for large $n \geq 1$, $\mathbb{E}\left[h^n(T \wedge \theta^n)\right] \geq m_*$. The following argument is largely inspired from [22].

Step 3.1. We start by providing estimates for $|X^n - x_0|$, $|Y^n - y_0|$, and $|K^n - k_0|$. Fix some $n \geq 1$, and assume that n is sufficiently large so that $\xi_n \leq \eta/2$ holds. Let Λ be the process defined by: $\Lambda_t := (\rho - \frac{\sigma^2}{2})t + \sigma W_t$, and set

$$\Lambda_t^\star := \left|\rho - \frac{\sigma^2}{2}\right| t + \sigma\left(W_t^\star - W_{\star t}\right), \quad \text{where } W_t^\star := \max_{u\in[0,t]} W_u \text{ and } W_{\star t} := \min_{u\in[0,t]} W_u.$$

Since $d\left[Y_t^n e^{-\Lambda_t}\right] = e^{-\Lambda_t} dL_t^n - e^{-\Lambda_t} Y_{t-}^n dM_t^n$, we deduce by a direct calculation that

$$|Y_t^n - y_0| \leq |y_0 - y_n| + y_n|1 - e^{\Lambda_t}| + e^{\Lambda_t^\star} L_t^n + e^{\Lambda_t^\star} \int_0^t Y_{u-}^n dM_u^n. \tag{5.15}$$

The dynamics of the processes K^n and X^n are such that

$$|K_t^n - k_0| \leq |k_0 - k_n| + L_t^n + \int_0^t f^\varepsilon(S_{u-}^n) K_{u-}^n dM_u^n, \tag{5.16}$$

$$|X_t^n - x_0| \leq |x_n - x_0| + |x_n|\left(e^{rt} - 1\right) + e^{rt}\int_0^t e^{-ru} C_u^n du + e^{rt}(1+\lambda)\int_0^t e^{-ru} dL_u^n$$

$$+ e^{rt}\int_0^t e^{-ru}(1-\mu)\left[(1-\alpha)Y_{u-}^n + \alpha f^\varepsilon(S_{u-}^n) K_{u-}^n\right] dM_u^n. \tag{5.17}$$

Step 3.2. We have $|1 - e^{\Lambda_T}| \leq \max\left[e^{\Lambda_T^\star} - 1; 1 - e^{-\Lambda_T^\star}\right]$. Define the set

$$F_T := \left\{\omega \in \Omega \ : \ \max\left[e^{\Lambda_T^\star} - 1; 1 - e^{-\Lambda_T^\star}\right] \leq \min\left[1, \frac{\eta}{4(y_0+1)}\right]\right\}.$$

We claim that it is possible to choose the parameter $T > 0$ such that

$$\mathbb{P}(F_T) \geq \frac{1}{2}, \quad e^{rT} - 1 \leq \frac{\eta}{4(1+|x_0|)}, \quad \text{and} \quad e^{rT} \leq 2. \tag{5.18}$$

Indeed, Doob's maximal Martingale inequalities provide, for $\delta > 0$,

$$\mathbb{P}\{W_T^\star \geq \delta\} \leq \frac{1}{\delta^2}\,\mathbb{E}[W_T^\star]^2 \leq \frac{4}{\delta^2}\,\mathbb{E}[W_T]^2 = \frac{4\,T}{\delta^2}; \text{ similarly } \mathbb{P}\{W_{\star T} \leq \delta\} \leq \frac{4\,T}{\delta^2}.$$

Hence for all $\delta > 0$,

$$\mathbb{P}\{W_T^\star - W_{\star T} \geq \delta\} \leq \mathbb{P}\left\{W_T^\star \geq \frac{\delta}{2}\right\} + \mathbb{P}\left\{W_{\star T} \leq \frac{\delta}{2}\right\} \leq \frac{32\,T}{\delta^2}.$$

We now return to the estimates (5.15), (5.16), (5.17) and recall that $\xi_n \leq \eta/2$. Since T satisfies (5.18), the following inequalities (where A denotes some positive constant depending on (x_0, y_0, k_0)) hold $\mathbb{P}$-a.s. on the set F_T:

$$|X_T^n - x_0| \leq \eta/2 + \eta/4 + 2\int_0^T C_t^n dt + AL_T^n + A\int_0^T G^\varepsilon(S_{t-}^n) dM_t^n, \tag{5.19}$$

$$|Y_T^n - y_0| \leq \eta/2 + \eta/4 + AL_T^n + A\int_0^T G^\varepsilon(S_{t-}^n) dM_t^n, \tag{5.20}$$

$$|K_T^n - k_0| \leq \eta/2 + AL_T^n + A\int_0^T G^\varepsilon(S_{t-}^n) dM_t^n, \tag{5.21}$$

where

$$G^{\varepsilon}(s) \;:=\; (1-\alpha)y + \alpha f^{\varepsilon}(s)k \text{ for } s=(x,y,k)\in \bar{\mathcal{S}}\,.$$

Step 3.3. For ω in F_T, we consider the following cases.

Case 1. $\theta^n(\omega) \geq T$. Then, by the definition of $h^n(T\wedge\theta^n)$, we have $h^n(T\wedge\theta^n) \;\geq\; \gamma\; e^{-\beta T}T$.

Case 2. $\theta^n(\omega) < T$. Recall that S^n is càdlagˇ; then, by the definition of the stopping time θ^n, this happens when $S^n_{\theta^n}(w)\notin B(s_0,\eta]$, i.e.,

$$\max\Big[|X^n_{\theta^n(\omega)}(\omega)-x_0|;\quad |Y^n_{\theta^n(\omega)}(\omega)-y_0|;\quad |K^n_{\theta^n(\omega)}(\omega)-k_0|\Big] \;\geq\; \eta.$$

Subcase 2.1. $|X^n_{\theta^n(\omega)}(\omega)-x_0|\geq\eta$. It follows from (5.19) that at least one of the following inequalities holds:

$$\text{(i)}\quad \int_0^{\theta^n(\omega)} C^n_t dt \;\geq\; \eta/16 \quad\text{or}\quad \text{(ii)}\quad L^n_{\theta^n} + \int_0^{\theta^n(\omega)} G^{\varepsilon}(S^n_{t-})dM^n_t \;\geq\; \frac{\eta}{8\,A}.$$

In inequality (i),

$$\frac{\eta}{16} \leq \int_0^{\theta^n(\omega)} C^n_t dt \;\leq\; c_0 T \;+\; \int_0^{\theta^n(\omega)} (C^n_t - c_0)\,dt.$$

Since it is possible to choose T such that $c_0T \;\leq\; \frac{\eta}{32}$, it follows that

$$\frac{\eta}{16} \leq \frac{\eta}{32} \;+\; \int_0^{\theta^n(\omega)} (C^n_t - c_0)^+\,dt;$$

then $\eta/32 \;\leq\; \int_0^{\theta^n(\omega)} (C^n_t - c_0)^+\,dt$, and it follows that

$$h^n(T\wedge\theta^n) \geq \gamma e^{-\beta T}\;\int_0^{\theta^n(\omega)} (C^n_t - c_0)^+\,dt \;\geq\; \gamma e^{-\beta T}\frac{\eta}{32}.$$

In inequality (ii), it immediately follows that $h^n(T\wedge\theta^n) \;\geq\; \gamma e^{-\beta T}\frac{\eta}{8\,A}$.

Subcase 2.2. $|Y^n_{\theta^n(\omega)}-y_0| \;\geq\; \eta$. Then, it follows from inequality (5.20) that

$$\frac{\eta}{4} \leq A\;\left(L^n_{\theta^n(\omega)} + \int_0^{\theta^n} G^{\varepsilon}(S^n_{t-})dM^n_t\right),$$

and hence, $h^n(T\wedge\theta^n(\omega)) \;\geq\; \gamma e^{-\beta T}\frac{\eta}{4\,A}$.

Subcase 2.3. $|K^n_{\theta^n(\omega)}-k_0| \;\geq\; \eta$. By inequality (5.21) we see that in this case,

$$\frac{\eta}{2} \leq A\;\left(L^n_{\theta^n(\omega)} + \int_0^{\theta^n} G^{\varepsilon}(S^n_{t-})dM^n_t\right),$$

and hence, $h^n(T\wedge\theta^n(\omega)) \;\geq\; \gamma e^{-\beta T}\frac{\eta}{2\,A}$.

From the several cases discussed above, it follows that for $\mathbb{P}$-a.e. ω in F_T,

$$h^n(T\wedge\theta^n(\omega)) \geq m_\star \;:=\; \gamma\min\Big[T,\frac{\eta}{32},\frac{\eta}{8A}\Big],$$

and therefore, for T sufficiently small and large n,

$$\mathbb{E}\left[h^n(T\wedge\theta^n)\right] \geq \mathbb{E}\left[\mathbf{1}_{F_T}h^n(T\wedge\theta^n)\right] \;\geq\; m_\star\mathbb{P}(F_T) \;=\; \frac{m_\star}{2}. \qquad \square$$

Remark 3. Let $\mathcal{A}_0(s)$ be the subset of $\mathcal{A}(s)$ consisting of all controls $\nu=(C,L,M)$ with a Lebesgue absolutely continuous component M. Then, it is clear that the above derivation of the DPE is not altered by this additional restriction. Hence, the value problem of this new control problem coincides with V_ε by the comparison result of Theorem 3.1. The same comment holds if the component L is, or both components L and M are, restricted to be Lebesgue absolutely continuous.

6. The convergence result. We first derive a useful estimate.

LEMMA 6.1. *Let s be in $\bar{\mathcal{S}}$. Then for any $\varepsilon\geq 0$, $\mathcal{A}^\varepsilon(s)\subset\mathcal{A}(s)$, and for all $\nu\in\mathcal{A}(s)$ and $t\geq 0$,*

$$0 \;\leq\; Z_t^{0,s,\nu}-Z_t^{\varepsilon,s,\nu} \;\leq\; 4\varepsilon r\, Z_T^{0,s,\nu\,\star}e^{rt}, \quad \textit{where} \quad Z_t^{0,s,\nu\,\star} := \sup_{u\in[0,t]}|Z_u^{0,s,\nu}|.$$

Proof. Clearly the inclusion $\mathcal{A}^\varepsilon(s)\subset\mathcal{A}(s)$ follows from the inequality $Z^{0,s,\nu}\geq Z^{\varepsilon,s,\nu}$.

Step 1. We first prove that $Z^{\varepsilon,s,\nu}\leq Z^{0,\varepsilon,\nu}$ $\mathbb{P}$-a.s. To see this, we consider a sequence of stopping times $(\tau_n)_{n\geq 0}$ exhausting the jumps of the càdlàg process M, with $\tau_0=0$. The dynamics of the processes $K^{\varepsilon,s,\nu}$ and $K^{0,s,\nu}$ are such that

$$d\left(K^{\varepsilon,s,\nu}-K^{0,s,\nu}\right)_t = -\left(K^{\varepsilon,s,\nu}-K^{0,s,\nu}\right)_{t-}dM_t + \left[1-f^\varepsilon\left(S_{t-}^{\varepsilon,s,\nu}\right)\right]K_{t-}^{\varepsilon,s,\nu}dM_t.$$

Then, for all $n\geq 0$, we have $\mathbb{P}$-a.s. for $t\in[\tau_n,\tau_{n+1})$,

(6.1)
$$\begin{aligned} &K_t^{\varepsilon,s,\nu}-K_t^{0,s,\nu} \\ &\quad= e^{-(M_t^c-M_{\tau_n}^c)}\left(K_{\tau_n}^{\varepsilon,s,\nu}-K_{\tau_n}^{0,s,\nu}+\int_{\tau_n}^t e^{M_u^c-M_{\tau_n}^c}\left[1-f^\varepsilon(S_{u-}^{\varepsilon,s,\nu})\right]K_{u-}^{\varepsilon,s,\nu}dM_u\right).\end{aligned}$$

Since $1-f^\varepsilon\geq 0$, this implies that

(6.2)
$$\begin{aligned} K_t^{\varepsilon,s,\nu}-K_t^{0,s,\nu} &\geq e^{-(M_t^c-M_{\tau_n}^c)}(K_{\tau_n}^{\varepsilon,s,\nu}-K_{\tau_n}^{0,s,\nu}) \\ &= e^{-(M_t^c-M_{\tau_n}^c)}((K_{\tau_n-}^{\varepsilon,s,\nu}-K_{\tau_n-}^{0,s,\nu})(1-\Delta M_{\tau_n}) \\ &\qquad +[1-f^\varepsilon(S_{\tau_n-}^{\varepsilon,s,\nu})]K_{\tau_n-}^{\varepsilon,s,\nu}\Delta M_{\tau_n})\geq 0.\end{aligned}$$

Clearly, $Y^{\varepsilon,s,\nu}=Y^{0,s,\nu}$. Then

$$d\left(Z^{\varepsilon,s,\nu}-Z^{0,s,\nu}\right)_t = r\left(Z^{\varepsilon,s,\nu}-Z^{0,s,\nu}\right)_t dt - r(1-\mu)\alpha\left(K^{\varepsilon,s,\nu}-K^{0,s,\nu}\right)dt.$$

Since $Z_0^{\varepsilon,s,\nu}-Z_0^{0,s,\nu}=0$ and $K^{\varepsilon,s,\nu}\geq K^{0,s,\nu}$, this implies that

$$Z_t^{\varepsilon,s,\nu}-Z_t^{0,s,\nu} = -r(1-\mu)\alpha e^{rt}\int_0^t e^{-ru}\left(K_u^{\varepsilon,s,\nu}-K_u^{0,s,\nu}\right)du \;\leq\; 0. \tag{6.3}$$

Step 2. We next prove the second inequality. Observe that $[1-f_\varepsilon(s)]\,k\leq 2\varepsilon z$ for $s=(x,y,k)\in\bar{\mathcal{S}}$, where $z:=x+(1-\mu)\,[(1-\alpha)y+\alpha k]$. Together with (6.2) and (6.2) this shows that, for all $n\geq 0$ and $t\in[\tau_n,\tau_{n+1})$,

$$K_t^{\varepsilon,s,\nu}-K_t^{0,s,\nu}\leq 2\varepsilon\, e^{-(M_t^c-M_{\tau_n}^c)}\left(Z_{\tau_n-}^{\varepsilon,s,nu}+\int_{\tau_n}^t e^{M_u^c-M_{\tau_n}^c}Z_{u-}^{\varepsilon,s,\nu}dM_u\right).$$

Using the increase of M together with the fact that $Z^{\varepsilon,s,\nu} \le Z^{0,s,\nu}$, as shown in the first step of this proof, this provides

$$K_t^{\varepsilon,s,\nu} - K_t^{0,s,\nu} \le 2\varepsilon Z_t^{0,s,\nu\star}\, e^{-(M_t^c - M_{\tau_n}^c)} \left(1 + \int_{\tau_n}^t e^{M_u^c - M_{\tau_n}^c}\, dM_u\right) \le 4\varepsilon Z_t^{0,s,\nu\star}.$$

The required inequality is obtained by plugging this estimate into (6.3). ∎

PROPOSITION 6.2. *The sequence $(V_\varepsilon)_{\varepsilon>0}$ is nonincreasing and $V_\varepsilon \le V$.*

Proof. The inequality $V_\varepsilon \le V$ follows immediately from the fact that $\mathcal{A}^\varepsilon(s) \subset \mathcal{A}(s)$, as stated in Lemma 6.1. To prove that the sequence $(V_\varepsilon)_{\varepsilon>0}$ is nonincreasing, we shall prove that $\mathcal{A}^{\varepsilon_1}(s) \subset \mathcal{A}^{\varepsilon_2}(s)$ whenever $\varepsilon_1 \ge \varepsilon_2$. To do this, it is sufficient to prove that for any control $\nu = (C, L, M) \in \mathcal{A}_\varepsilon(s)$, the associated process $Z^\varepsilon := X^{\varepsilon,s,\nu} + (1-\mu)\left[(1-\alpha)Y^{\varepsilon,s,\nu} + \alpha K^{\varepsilon,s,\nu}\right]$ is nonincreasing with respect to ε. Recall that

$$f^\varepsilon(s) \;=\; h\left(\frac{k}{\varepsilon z}\right), \quad \text{where } z = x + (1-\mu)[(1-\alpha y + \alpha z],$$

and h is a smooth function. From Remark 3, we may restrict the process M to be absolutely continuous with respect to the Lebesgue measure, i.e., $M_t = \int_0^t m_u du$ for some $\mathbb{F}$-adapted process $\{m_t,\ t \ge 0\}$, as the restriction of the control M to this class produces the same value function V_ε.

Then, by classical results on the regularity of flows of stochastic differential equations (see, e.g., [16]), the processes Z^ε, $Y^\varepsilon := Y^{\varepsilon,s,\nu}$ and $K^\varepsilon := K^{\varepsilon,s,\nu}$ are differentiable in ε, and the processes

$$z_t^\varepsilon \;:=\; e^{-rt}\frac{\partial Z_t^\varepsilon}{\partial \varepsilon}, \quad y_t^\varepsilon \;:=\; \frac{\partial Y_t^\varepsilon}{\partial \varepsilon}, \quad k_t^\varepsilon \;:=\; e^{-rt}\frac{\partial K_t^\varepsilon}{\partial \varepsilon}$$

satisfy $y_t^\varepsilon = 0$ for all $t \ge 0$, $z_0^\varepsilon = k_0^\varepsilon = 0$, and solve the system of ODEs

$$\dot{z}_t^\varepsilon \;=\; -r\alpha k_t \quad \text{and} \quad \dot{k}_t^\varepsilon \;=\; a_t + b_t z_t - c_t k_t,$$

where

$$a_t \;:=\; \frac{(K_t^\varepsilon)^2}{\varepsilon Z_t^\varepsilon}\, h'\left(\frac{K_t^\varepsilon}{\varepsilon Z_t^\varepsilon}\right), \qquad b_t \;:=\; \frac{(K_t^\varepsilon)^2}{\varepsilon (Z_t^\varepsilon)^2}\, h'\left(\frac{K_t^\varepsilon}{\varepsilon Z_t^\varepsilon}\right),$$

and

$$e^{-rt} c_t := r + m_t \left[h\left(\frac{K_t^\varepsilon}{\varepsilon Z_t^\varepsilon}\right) + \frac{K_t^\varepsilon}{\varepsilon Z_t^\varepsilon}\, h'\left(\frac{K_t^\varepsilon}{\varepsilon Z_t^\varepsilon}\right)\right].$$

Differentiating once more with respect to the t-variable, we obtain the following second order differential equation for z^ε:

$$-\ddot{z}_t^\varepsilon \;-\; c_t\, \dot{z}_t^\varepsilon \;-\; r\alpha b_t\, z_t^\varepsilon \;-\; r\alpha a_t \;=\; 0 \quad \text{and} \quad \dot{z}_0^\varepsilon = z_0 = 0. \tag{6.4}$$

We now consider the function

$$\hat{z}_t \;:=\; -\frac{r\alpha}{\varepsilon} \int_0^t \int_0^u \frac{(K_t^\varepsilon)^2}{\varepsilon Z_t^\varepsilon}\, h'\left(\frac{K_t^\varepsilon}{\varepsilon Z_t^\varepsilon}\right) du\, dt \quad \text{for} \quad t \ge 0.$$

Since $\hat{z}_t \le 0$, $\dot{\hat{z}}_t \le 0$, $b_t \ge 0$, and $c \ge 0$, it follows that $\hat{z}_t$ is a supersolution of (6.4). By a standard comparison result, we deduce that $z_t^\varepsilon \le \hat{z}_t$, and therefore $z_t^\varepsilon \le 0$ for all $t \ge 0$. This completes the proof. ∎

Our final result states the convergence of V_ε towards V.

PROPOSITION 6.3. *The sequence $(V_\varepsilon)_{\varepsilon>0}$ is nonincreasing and converges towards V, as $\varepsilon \searrow 0$, uniformly on compact subsets of $\bar{\mathcal{S}}$.*

Proof. Let $(\nu^n = (C^n, L^n, M^n))_{n\geq 1}$ be a maximizing sequence of controls for $V(s)$:

$$V(s) - \frac{1}{n} \;\leq\; \mathbb{E}\left[\int_0^\infty e^{-\beta t} U(C_t^n)dt\right] \quad \text{for all} \quad n \geq 1.$$

By the monotone convergence theorem, we verify that

$$\mathbb{E}\left[\int_0^\infty e^{-\beta t} U(C_t^n)dt\right] = \lim_{T\to\infty} \mathbb{E}\left[\int_0^T e^{-\beta t} U(C_t^n)dt\right].$$

Then $V(s) - \frac{1}{2n} \leq \mathbb{E}[\int_0^{T^n} e^{-\beta t} U(C_t^n)dt]$ for some $T^n > 0$. By Lemma 6.1 we have $Z^{0,s,\nu}_{t\wedge T^n} \geq Z^{\varepsilon,s,\nu}_{t\wedge T^n} \geq Z^{0,s,\nu}_{t\wedge T^n} - 4r\varepsilon Z^{0,s,\nu\star}_{T^n}$ $\mathbb{P}$-a.s. for all $t \geq 0$. Then, the stopping times $\tau(\varepsilon, s, n) := \inf\{t \geq 0 : Z_t^{\varepsilon,s,\nu} \leq 0\}$, $\varepsilon \geq 0$, satisfy

$$\tau(0,s,n)\wedge T^n \geq \tau(\varepsilon,s,n)\wedge T^n \text{ and } \lim_{\varepsilon\to 0} \tau(\varepsilon,s,n)\wedge T^n = \tau(0,s,n)\wedge T^n \;\; \mathbb{P}\text{-a.s.}$$

Hence, by the monotone convergence theorem,

$$\lim_{\varepsilon\to 0} \mathbb{E}\left[\int_0^{\tau(\varepsilon,s,n)\wedge T^n} e^{-\beta t} U(C_t^n)dt\right] = \mathbb{E}\left[\int_0^{\tau(0,s,n)\wedge T^n} e^{-\beta u} U(C_t^n)dt\right].$$

Recall from (5.6) and (5.7) that

$$V_\varepsilon(s) \geq \mathbb{E}\left[\int_0^{\tau(\varepsilon,s,n)\wedge T^n} e^{-\beta t} U(C_t^n)dt\right] \quad \text{and}$$
$$\mathbb{E}\left[\int_0^{\tau(0,s,n)\wedge T^n} e^{-\beta t} U(C_t^n)dt\right] = \mathbb{E}\left[\int_0^{T^n} e^{-\beta u} U(C_u^n)du\right].$$

Then

$$\liminf_{\varepsilon\to 0} V_\varepsilon(s) \geq \mathbb{E}\left[\int_0^{T^n} e^{-\beta t} U(C_t^n)dt\right] \;\geq\; V(s) - \frac{1}{2n}.$$

By arbitrariness of $n \geq 1$, this provides $\liminf_{\varepsilon\to 0} V_\varepsilon(s) \geq V(s)$. Together with Proposition 6.2, this shows that $V_\varepsilon(s) \longrightarrow V(s)$ as $\varepsilon \searrow 0$ for every $s \in \bar{\mathcal{S}}$.

We finally recall from Proposition 2.4 that the limit function V is continuous. Since $(V_\varepsilon)_{\varepsilon>0}$ is a monotonic sequence of continuous functions, it follows from the Dini theorem that the convergence holds uniformly on compact subsets of $\bar{\mathcal{S}}$. □

EXACT INTERNAL CONTROLLABILITY FOR THE TWO-DIMENSIONAL MAGNETOHYDRODYNAMIC EQUATIONS*

TEODOR HAVÂRNEANU†, CĂTĂLIN POPA†, AND S. S. SRITHARAN‡

Abstract. In this paper we establish the local exact internal controllability for the two-dimensional magnetohydrodynamic equations. The needed Carleman estimate for the adjoint linearized magnetohydrodynamic equations is also obtained here.

Key words. magnetohydrodynamic equations, controllability, Stokes equations, dynamo equations, observability inequality, Carleman estimates

1. Introduction.

In this paper we study the internal controllability for the magnetohydrodynamic (MHD) equations in two-dimensional bounded domains. We show that the final value (state) of any sufficiently smooth solution (evolution) of the MHD system can be attained by starting from initial states which are "close" enough to the initial state of the target solution and acting in both fluid and magnetic parts of the MHD equations by appropriate locally distributed internal controls. The corresponding three-dimensional result was established by the authors in [7]. The first but less general controllability result for the MHD equations in three-dimensional domains was obtained in [2] (see also [3]). We emphasize here that despite their similarities the two-dimensional and three-dimensional cases are different; they are not particular cases of a more general situation.

As in the three-dimensional case, we shall reduce the local controllability problem for the MHD equations to the global controllability problem for the linearized MHD equations by means of an infinite-dimensional version of the implicit function theorem. This approach is inspired from [9] (see also [5] and [8]), where the related but simpler case of the internal controllability of the Navier–Stokes equations is studied.

To solve the global controllability problem, we approximate it by a family of ad hoc optimal control problems for the same linearized MHD system. The estimates that we need to prove the convergence of the approximation procedure are obtained by using an observability inequality for the adjoint linearized MHD equations. Such an inequality is usually derived from a Carleman inequality for the same equations. For this reason, the main effort here will be directed toward obtaining the required Carleman inequality for the adjoint linearized MHD system. The strategy described here is nothing more than that used in [9] for the case of the Navier–Stokes equations.

Let us mention that two new Carleman inequalities—one for elliptic equations with nonhomogeneous Dirichlet boundary conditions and the other for the Stokes equations, established in [10] and [4], respectively—suggest that our controllability

result for the MHD system can still be improved. More specifically, it is expected to be able to prove that less regular target solutions for the MHD equations can be attained by local internal action if we use the main result in [10] and adapt the approach in [4] to our situation.

2. Functional framework and main result. Let Ω be a bounded multiconnected open set in $\mathbb{R}^2$ whose boundary $\partial\Omega$ is a finite union of mutually disjoint closed curves of class C^2. Such a set can be made simply connected with a finite number of smooth cuts. This means that there exist p mutually disjoint curves $\Gamma_1, \dots, \Gamma_p$ of class C^2 which are not tangent to $\partial\Omega$ such that $\Omega \setminus (\cup_{i=1}^{p} \Gamma_i)$ is simply connected. Let $T > 0$ be fixed. We set $Q = \Omega \times (0,T)$. We also fix an open subset ω of Ω. The controlled MHD equations (with boundary and initial conditions) we consider are the following:

$$
\begin{aligned}
&\frac{\partial y}{\partial t} - \nu\Delta y + (y\cdot\nabla)y + \nabla p + \nabla\left(\frac{1}{2}\ B^2\right) - (B\cdot\nabla)B \\
&\qquad = f + \chi_\omega u && \text{in } Q,\\
&\frac{\partial B}{\partial t} + \eta\,\widetilde{\operatorname{curl}}(\operatorname{curl} B) + (y\cdot\nabla)B - (B\cdot\nabla)y = P(\chi_\omega v) && \text{in } Q,\\
&\operatorname{div} y = 0,\ \operatorname{div} B = 0 && \text{in } Q,\\
&y = 0,\ B\cdot N = 0,\ \operatorname{curl} B = 0 && \text{on } \Sigma = \partial\Omega\times(0,T),\\
&y(\cdot,0) = y_0,\ B(\cdot,0) = B_0 && \text{in } \Omega.
\end{aligned}
\tag{2.1}
$$

Here $y = (y_1, y_2) : \Omega \times [0,T] \longrightarrow \mathbb{R}^2$ is the velocity vector field, $p : \Omega \times [0,T] \longrightarrow \mathbb{R}$ is the pressure, and $B = (B_1, B_2) : \Omega \times [0,T] \longrightarrow \mathbb{R}^2$ is the magnetic field. System (2.1) is controlled through the vector functions $u = (u_1, u_2) : \Omega \times [0,T] \longrightarrow \mathbb{R}^2$ and $v = (v_1, v_2) : \Omega \times [0,T] \longrightarrow \mathbb{R}^2$. The variables of the functions (fields) y, p, B, u, and v are denoted by $x = (x_1, x_2)$ and t (belonging to Ω and $[0,T]$, respectively). The other symbols in (2.1) denote known (given) quantities (or objects). So, ν and η are the kinematic viscosity and magnetic resistivity, which are supposed to be positive. From now on, for the sake of simplicity and without loss of generality, ν and η will be assumed to be 1. Further, $f = (f_1, f_2) : \Omega \times [0,T] \longrightarrow \mathbb{R}^2$ is the density of the external forces, χ_ω is the characteristic function of ω, P is the Leray projector (put there to "kill" the gradient part of $\chi_\omega v$), and $y_0 : \Omega \longrightarrow \mathbb{R}^2$ and $B_0 : \Omega \longrightarrow \mathbb{R}^2$ are the initial velocity and magnetic fields. The operators curl and $\widetilde{\operatorname{curl}}$ are defined as follows:

$$
\begin{aligned}
&\operatorname{curl} B = \frac{\partial B_2}{\partial x_1} - \frac{\partial B_1}{\partial x_2} && \text{for every vector function } B = (B_1, B_2),\\
&\widetilde{\operatorname{curl}}\, w = \left(\frac{\partial w}{\partial x_2}, -\frac{\partial w}{\partial x_1}\right) && \text{for every scalar function } w.
\end{aligned}
$$

It is well known that $\widetilde{\operatorname{curl}}(\operatorname{curl} B) = -\Delta B + \operatorname{grad}(\operatorname{div} B)$. Finally, N is the unit outer normal to $\partial\Omega$.

When Ω is not simply connected (but it remains multiconnected), to assure the well-posedness of problem (2.1), we have to impose the following additional conditions on B on the cuts Γ_i:

$$
\int_{\Gamma_i} B\cdot N\, d\sigma = 0 \ \text{ in } (0,T), \quad i = 1, \dots, p,
\tag{2.2}
$$

where N is the unit outer normal to Γ_i's. (See Appendix I of [11] for an equivalent form of (2.2).) When Ω is simply connected, conditions (2.2) are no longer necessary.

For the statement of our results and the considerations which follow, some function spaces are required. For each positive integer m and $p > 1$, or $p = +\infty$, we denote (as usual) by $W^{m,p}(\Omega)$ the Sobolev space of functions in $L^p(\Omega)$ whose weak derivatives of order less than or equal to m are also in $L^p(\Omega)$. When $p = 2$, we set $H^1(\Omega) = W^{1,2}(\Omega)$. In a similar way, $H^{2,1}(Q)$ is the space of all functions in $L^2(Q)$ whose first and second order weak derivatives with respect to x_1 and x_2, and first order weak derivative with respect to t, are all in $L^2(Q)$, too. The fractional order Sobolev space $H^{1/2}(\Omega)$ will also be required by a certain argument. Since all the functions involved in equations (2.1) (except p) are actually vector functions (fields), we mostly use some product function spaces: $(L^2(Q))^2$, $(H^1(\Omega))^2$, $(W^{1,\infty}(\Omega))^2$, $(W^{2,p}(\Omega))^2$, $(H^{2,1}(Q))^2$, etc., all endowed with the product norms. The time-dependent function space $L^2(0,T;H^1(\Omega))$ contains all (equivalence classes of) measurable functions from $(0,T)$ to $H^1(\Omega)$ having the square of their $H^1(\Omega)$ norm integrable over $(0,T)$. The spaces $L^\infty(0,T;(W^{1,\infty}(\Omega))^2)$ and $L^\infty(0,T;(W^{2,p}(\Omega))^2)$ are defined similarly. Finally, we need the corresponding Sobolev spaces $W^{1,\infty}(0,T;(W^{1,\infty}(\Omega))^2)$ and $W^{1,\infty}(0,T;(W^{2,p}(\Omega))^2)$ containing the functions in $L^\infty(0,T;(W^{1,\infty}(\Omega))^2)$ and $L^\infty(0,T;(W^{2,p}(\Omega))^2)$ whose first order weak derivatives are in $L^\infty(0,T;(W^{1,\infty}(\Omega))^2)$ and $L^\infty(0,T;(W^{2,p}(\Omega))^2)$, respectively. The norms of all the considered spaces are denoted in the same manner: $|\cdot|_{(L^2(Q))^2}$, $|\cdot|_{(H^1(\Omega))^2}$, $|\cdot|_{(H^{2,1}(Q))^2}$, etc.

The natural functional framework for the MHD equations (2.1) is given by the space H of all weakly divergence-free vector functions in $(L^2(\Omega))^2$ which are tangential to the boundary in a weak sense, endowed with the $(L^2(\Omega))^2$ norm. Our considerations here require the following two $(H^1(\Omega))^2$ versions (subspaces) of H:

$$V_1 = \{y \in (H^1(\Omega))^2 : \operatorname{div} y = 0 \ \text{ in } \Omega \ \text{ and } \ y = 0 \ \text{ on } \partial\Omega\}$$

and

$$V_2 = \{B \in (H^1(\Omega))^2 : \operatorname{div} B = 0 \ \text{ in } \Omega \ \text{ and } \ B \cdot N = 0 \ \text{ on } \partial\Omega\}$$

if Ω is simply connected, or

$$V_2 = \{B \in (H^1(\Omega))^2 : \operatorname{div} B = 0 \ \text{ in } \Omega,\ B \cdot N = 0 \ \text{ on } \partial\Omega,$$
$$\text{and } \int_{\Gamma_i} B \cdot N \, d\sigma = 0,\ i = 1, \dots, p\}$$

if Ω is not simply connected (but it is multiconnected).

A specific feature of the MHD system (which distinguishes it from the Navier–Stokes equations) is the fact that the left-hand side of the second equation in (2.1) is in H (as a function of x) if (y, B, p) is a *strong* solution of (2.1), that is, if $y, B \in (H^{2,1}(Q))^2$, $y \in V_1$, $B \in V_2$ (as functions of x), and $\operatorname{curl} B = 0$ on Σ. Indeed, let $\phi \in H^1(\Omega)$, arbitrary. Using a Green-type formula, we have

$$\int_\Omega \widetilde{\operatorname{curl}}(\operatorname{curl} B) \cdot \nabla\phi \, dx$$
$$= \int_\Omega \operatorname{curl} B \operatorname{curl} \nabla\phi \, dx - \int_{\partial\Omega} \operatorname{curl} B (\nabla\phi \cdot \mathtt{T}) d\sigma = 0,$$

because $\operatorname{curl}\nabla\phi = 0$ in Ω and $\operatorname{curl} B = 0$ on $\partial\Omega$. Here $\mathtt{T}$ represents the unit tangent vector $(-N_2, N_1)$ to $\partial\Omega$, where $(N_1, N_2) = N$. Integrating by parts, we also have

$$\begin{aligned}\int_\Omega ((y\cdot\nabla)B - (B\cdot\nabla)y)\cdot\nabla\phi\,dx \\ = -\sum_{i,j=1}^{2}\int_\Omega \frac{\partial y_i}{\partial x_j}\,\frac{\partial B_j}{\partial x_i}\,\phi\,dx - \int_\Omega y\cdot\nabla(\operatorname{div} B)dx + \int_{\partial\Omega}\phi((y\cdot\nabla)B)\cdot N\,d\sigma \\ + \sum_{i,j=1}^{2}\int_\Omega \frac{\partial B_i}{\partial x_j}\,\frac{\partial y_j}{\partial x_i}\,\phi\,dx + \int_\Omega B\cdot\nabla(\operatorname{div} y)dx - \sum_{j=1}^{2}\int_{\partial\Omega}\phi N_j B\cdot\nabla y_j\,d\sigma = 0,\end{aligned}$$

because $y \in V_1$ and $B \in V_2$. (As $y = 0$ on $\partial\Omega$, the vectors $\nabla y_1(x), \nabla y_2(x)$, and $N(x)$ have the same directions for those $x \in \partial\Omega$ at which $\nabla y_1(x)$ and $\nabla y_2(x)$ are different from the vector 0.) Since the left-hand side of (2.1) is in H, the right-hand side must be in H, too. This is the reason of the presence of the Leray projector P before the control parameter $\chi_\omega v$. So, the gradient-type term which is generally associated with an equation like $\operatorname{div} B = 0$ is zero in the second equation in (2.1). For more information about the mathematical setting and analysis of the MHD equations one can consult the bibliography in [2].

Let us fix $\widetilde{y}, \widetilde{p}$, and $\widetilde{B}$ that satisfy both MHD equations and boundary conditions in (2.1):

$$\begin{aligned}&\frac{\partial\widetilde{y}}{\partial t} - \Delta\widetilde{y} + (\widetilde{y}\cdot\nabla)\widetilde{y} + \nabla\widetilde{p} + \nabla\left(\frac{1}{2}\,\widetilde{B}^2\right) - (\widetilde{B}\cdot\nabla)\widetilde{B} = f && \text{in } Q,\\ &\frac{\partial\widetilde{B}}{\partial t} + \widetilde{\operatorname{curl}}(\operatorname{curl}\widetilde{B}) + (\widetilde{y}\cdot\nabla)\widetilde{B} - (\widetilde{B}\cdot\nabla)\widetilde{y} = 0 && \text{in } Q,\\ &\operatorname{div}\widetilde{y} = 0,\ \operatorname{div}\widetilde{B} = 0 && \text{in } Q,\\ &\widetilde{y} = 0,\ \widetilde{B}\cdot N = 0,\ \operatorname{curl}\widetilde{B} = 0 && \text{on } \Sigma.\end{aligned} \tag{2.3}$$

Now we can state the controllability result we have described before.

THEOREM 2.1. *Let Ω be an open, bounded, and multiconnected subset of $\mathbb{R}^2$ whose boundary $\partial\Omega$ is a finite union of mutually disjoint closed curves of class C^2, and let ω be an open subset of Ω. Let $f \in (L^2(Q))^2$ and let $\widetilde{y}, \widetilde{B} \in W^{1,\infty}(0,T;(W^{2,p}(\Omega))^2)$, with $p > 2$, satisfy equations* (2.3). *Then there is $\eta > 0$ such that for any $(y_0, B_0) \in V_1 \times V_2$ which satisfy*

$$|y_0 - \widetilde{y}(\cdot,0)|_{(H^1(\Omega))^2} + |B_0 - \widetilde{B}(\cdot,0)|_{(H^1(\Omega))^2} \le \eta$$

there exist $(u, v) \in (L^2(Q))^4$ and $(y, B, p) \in (H^{2,1}(Q))^4 \times L^2(0,T;H^1(\Omega))$ that satisfy (2.1), (2.2), *and*

$$y(x,T) = \widetilde{y}(x,T),\ B(x,T) = \widetilde{B}(x,T) \quad \textit{a.e. } x \in \Omega.$$

The proof of Theorem 2.1 follows the same lines as the proof of the corresponding three-dimensional result (Theorem 2.1 in [7]). For this reason, we only outline it (see [7] and [2] for details) but emphasize those points where some differences (caused by the different boundary conditions for B and the lower dimension) appear.

3. Carleman inequality for the adjoint linearized MHD equations. Let $\widetilde{y}$ and $\widetilde{B}$ satisfy (2.3). The adjoint linearized (around $\widetilde{y}$ and $\widetilde{B}$) MHD equations are the following:

$$
\begin{aligned}
&\frac{\partial z}{\partial t} + \Delta z + (\widetilde{y}\cdot\nabla)z - z\cdot(\nabla\widetilde{y}) \\
&\qquad - (\widetilde{B}\cdot\nabla)C - C\cdot(\nabla\widetilde{B}) + \nabla q = h && \text{in } Q,\\
&\frac{\partial C}{\partial t} - \widetilde{\operatorname{curl}}(\operatorname{curl} C) + P((\widetilde{y}\cdot\nabla)C + C\cdot(\nabla\widetilde{y}) \\
&\qquad - (\widetilde{B}\cdot\nabla)z + z\cdot(\nabla\widetilde{B})) = H && \text{in } Q,\\
&\operatorname{div} z = 0,\ \operatorname{div} C = 0 && \text{in } Q,\\
&z = 0,\ C\cdot N = 0,\ \operatorname{curl} C = 0 && \text{on } \Sigma.
\end{aligned}
\tag{3.1}
$$

Here $h : \Omega\times[0,T] \longrightarrow \mathbb{R}^2$ and $H : \Omega\times[0,T] \longrightarrow \mathbb{R}^2$ are two given vector functions, and $z\cdot(\nabla\widetilde{y})$ is the vector field of components $z\cdot\partial\widetilde{y}/\partial x_i$, $i = 1, 2$; $C\cdot(\nabla\widetilde{B})$, $C\cdot(\nabla\widetilde{y})$, and $z\cdot(\nabla\widetilde{B})$ are defined in the same way.

The presence of the Leray projector P in (3.1) comes from the fact that the sum $(\widetilde{y}\cdot\nabla)C + C\cdot(\nabla\widetilde{y}) - (\widetilde{B}\cdot\nabla)z + z\cdot(\nabla\widetilde{B})$ is not generally in the space H (defined in the preceding section) but the other terms in the second equation in (3.1) are there (see Theorem 3.1). The Leray projector can be replaced by the gradient of a pseudopressure r in the following way: For any solution (z, q, C) of (3.1) there exists some function $r : \Omega\times[0,T] \longrightarrow \mathbb{R}$ such that

$$
\begin{aligned}
&(\widetilde{y}\cdot\nabla)C + C\cdot(\nabla\widetilde{y}) - (\widetilde{B}\cdot\nabla)z + z\cdot(\nabla\widetilde{B}) \\
&\qquad = P((\widetilde{y}\cdot\nabla)C + C\cdot(\nabla\widetilde{y}) - (\widetilde{B}\cdot\nabla)z + z\cdot(\nabla\widetilde{B})) + \nabla r.
\end{aligned}
\tag{3.2}
$$

To express the Carleman inequality for equations (3.1), some suitable weight functions are needed. Let us fix an open subset ω_0 of ω such that $\omega_0 \subset\subset \omega$. Since Ω is bounded and connected, there exist functions $\psi \in C^2(\overline{\Omega})$ such that

$$
\psi > 0 \ \text{ in } \Omega, \quad \psi = 0 \ \text{ on } \partial\Omega, \quad \text{and} \quad |\nabla\psi| > 0 \ \text{ in } \overline{\Omega}\setminus\omega_0.
$$

Let us fix such a function ψ, too. We set

$$
\varphi(x,t) = \frac{e^{\lambda\psi(x)}}{(t(T-t))^8} \quad \text{and} \quad \alpha(x,t) = \frac{e^{\lambda\psi(x)} - e^{2\lambda|\psi|_{C(\overline{\Omega})}}}{(t(T-t))^8}
$$

for $\lambda > 0$. We denote by $\widehat{\varphi}$ and $\widehat{\alpha}$ the values taken by φ and α on the boundary $\partial\Omega$ (where $\psi = 0$):

$$
\widehat{\varphi}(t) = \frac{1}{(t(T-t))^8} \quad \text{and} \quad \widehat{\alpha}(t) = \frac{1 - e^{2\lambda|\psi|_{C(\overline{\Omega})}}}{(t(T-t))^8}\,\cdot
$$

For establishing the Carleman inequality two variants of φ and α are also needed:

$$
\overline{\varphi}(x,t) = \frac{e^{-\lambda\psi(x)}}{(t(T-t))^8} \quad \text{and} \quad \overline{\alpha}(x,t) = \frac{e^{-\lambda\psi(x)} - e^{2\lambda|\psi|_{C(\overline{\Omega})}}}{(t(T-t))^8}\,\cdot
$$

We set $Q_\omega = \omega \times (0,T)$ and $Q_{\omega_0} = \omega_0 \times (0,T)$. Now we are prepared to present the Carleman inequality for equations (3.1).

THEOREM 3.1. *Let Ω be an open, bounded, and multiconnected subset of $\mathbb{R}^2$ whose boundary $\partial\Omega$ is a finite union of mutually disjoint closed curves of class C^2, and let ω, ω_0, and ω_1 be open subsets of Ω such that $\omega_0 \subset\subset \omega_1 \subset\subset \omega$. We set $Q_{\omega_1} = \omega_1 \times (0,T)$. Let $\widetilde{y}, \widetilde{B} \in L^\infty(0,T;(W^{2,p}(\Omega))^2)$ with $p > 2$. Then there exists $\lambda_0 > 0$ such that for any $\lambda > \lambda_0$ one can find $s_0(\lambda) > 0$ and $c(\lambda) > 0$ that for $s > s_0(\lambda)$ the following inequality holds:*

$$
\begin{aligned}
&\int_Q e^{2s\alpha} \left(\frac{1}{s\varphi} \left(\left| \frac{\partial z}{\partial t} \right|^2 + \left| \frac{\partial C}{\partial t} \right|^2 + \sum_{i,j=1}^{2} \left(\left| \frac{\partial^2 z}{\partial x_i \partial x_j} \right|^2 + \left| \frac{\partial^2 C}{\partial x_i \partial x_j} \right|^2 \right) \right) \right. \\
&\qquad \left. + s\varphi(|\nabla z|^2 + |\nabla C|^2) + s^3\varphi^3(|z|^2 + |C|^2) \right) dx\,dt \\
&\le c(\lambda) \left(\int_{Q_\omega} e^{2s\alpha} s^3 \varphi^3 (|z|^2 + |C|^2) dx\,dt + \int_{Q_{\omega_1}} e^{2s\alpha} s^{\frac{11}{4}} \widehat{\varphi}^{\frac{11}{4}} (q^2 + r^2) dx\,dt \right. \\
&\qquad \left. + \int Q(e^{2s\alpha} + e^{2s\widehat{\alpha}} s^{\frac{3}{4}} \widehat{\varphi}^{\frac{3}{4}})(|h|^2 + |H|^2) dx\,dt \right)
\end{aligned} \tag{3.3}
$$

for all $h, H \in (L^2(Q))^2$ which satisfy $\operatorname{div} h = \operatorname{div} H = 0$ in Q and $H \cdot N = 0$ on Σ, and all corresponding solutions $(z, C, q) \in (H^{2,1}(Q))^4 \times L^2(0,T;H^1(\Omega))$ of system (3.1) and $r \in L^2(0,T;H^1(\Omega))$ which satisfy (3.2).

To make the proof of Theorem 3.1 easier to follow for the reader, we divide it into several intermediate statements, which will be taken under consideration by turns and then put together at the end. First we present two Carleman-type inequalities for the adjoint Stokes equations with the null Dirichlet boundary condition, that is,

$$
\begin{aligned}
&\frac{\partial z}{\partial t} + \Delta z + \nabla q = g && \text{in } Q, \\
&\operatorname{div} z = 0 && \text{in } Q, \\
&z = 0 && \text{on } \Sigma,
\end{aligned} \tag{3.4}
$$

and for the adjoint equations of certain dynamo-type equations with solutions having null curl at the boundary,

$$
\begin{aligned}
&\frac{\partial C}{\partial t} - \widetilde{\operatorname{curl}}(\operatorname{curl} C) = PG && \text{in } Q, \\
&\operatorname{div} C = 0 && \text{in } Q, \\
&C \cdot N = 0,\ \operatorname{curl} C = 0 && \text{on } \Sigma.
\end{aligned} \tag{3.5}
$$

Here $g : \Omega \times [0,T] \longrightarrow \mathbb{R}^2$ and $G : \Omega \times [0,T] \longrightarrow \mathbb{R}^2$ are two given vector functions.

THEOREM 3.2. *Let Ω, ω, ω_0, and ω_1 be open subsets of $\mathbb{R}^2$ as in the statement of Theorem 3.1. Then there exists $\lambda_0 > 0$ such that for any $\lambda > \lambda_0$ one can find*

$s_0(\lambda) > 0$ and $c(\lambda) > 0$ such that for $s > s_0(\lambda)$ we have

$$\int_Q e^{2s\alpha}\left(\frac{1}{s\varphi}\left(\left|\frac{\partial z}{\partial t}\right|^2+\sum_{i,j=1}^{2}\left|\frac{\partial^2 z}{\partial x_i\partial x_j}\right|^2\right)+s\varphi|\nabla z|^2+s^3\varphi^3|z|^2\right)dx\,dt$$

$$\le c(\lambda)\Bigg(\int_{Q_\omega} e^{2s\alpha}s^3\varphi^3|z|^2dx\,dt+\int_{Q_{\omega_1}} e^{2s\alpha}s^{\frac{11}{4}}\widehat{\varphi}^{\frac{11}{4}}q^2dx\,dt \tag{3.6}$$

$$+\int_Q(e^{2s\alpha}+e^{2s\widehat{\alpha}}s^{\frac{3}{4}}\widehat{\varphi}^{\frac{3}{4}})|g|^2dx\,dt+\int_Q e^{2s\alpha}s^{\frac{1}{2}}\widehat{\varphi}^{\frac{1}{2}}|\operatorname{div} g|^2dx\,dt\Bigg)$$

for all $g \in L^2(0,T;(H^1(\Omega))^2)$ and all corresponding solutions $(z,q) \in (H^{2,1}(Q))^2 \times L^2(0,T;H^1(\Omega))$ of system (3.4).

The analogous result for equations (3.5) is as follows.

THEOREM 3.3. *Let Ω, ω, ω_0, and ω_1 be open subsets of $\mathbb{R}^2$ as in the statement of Theorem* 3.1. *Then there exists $\lambda_0 > 0$ such that for any $\lambda > \lambda_0$ one can find $s_0(\lambda) > 0$ and $c(\lambda) > 0$ such that for $s > s_0(\lambda)$ we have*

$$\int_Q e^{2s\alpha}\left(\frac{1}{s\varphi}\left(\left|\frac{\partial C}{\partial t}\right|^2+\sum_{i,j=1}^{2}\left|\frac{\partial^2 C}{\partial x_i\partial x_j}\right|^2\right)+s\varphi|\nabla C|^2+s^3\varphi^3|C|^2\right)dx\,dt$$

$$\le c(\lambda)\Bigg(\int_{Q_\omega} e^{2s\alpha}s^3\varphi^3|C|^2dx\,dt+\int_{Q_{\omega_1}} e^{2s\alpha}s^{\frac{11}{4}}\widehat{\varphi}^{\frac{11}{4}}r^2dx\,dt \tag{3.7}$$

$$+\int_Q(e^{2s\alpha}+e^{2s\widehat{\alpha}}s^{\frac{3}{4}}\widehat{\varphi}^{\frac{3}{4}})|G|^2dx\,dt+\int_Q e^{2s\alpha}s^{\frac{1}{2}}\widehat{\varphi}^{\frac{1}{2}}|\operatorname{div} G|^2dx\,dt\Bigg)$$

for all $G \in L^2(0,T;(H^1(\Omega))^2)$ and all corresponding solutions $C \in (H^{2,1}(Q))^2$ of system (3.5) *and $r \in L^2(0,T;H^1(\Omega))$ which satisfy*

$$G = PG + \nabla r. \tag{3.8}$$

To prove Theorems 3.2 and 3.3, we shall couple two kinds of estimates. First we establish Carleman inequalities for (3.4) and (3.5), viewed as parabolic systems in the unknowns z and C, respectively (so, ∇q and ∇r are passed in the right-hand side near g and G). Since q and r satisfy Poisson equations (obtained by applying the divergence operator to both sides of (3.4) and (3.5)), the needed estimates for ∇q and ∇r are derived by using an adequate Carleman inequality for elliptic equations with nonhomogeneous Dirichlet boundary conditions (obtained by Imanuvilov in [9]). So, let us begin by presenting the Carleman estimates for (3.4) and (3.5), viewed as parabolic systems in z and C.

LEMMA 3.1. *Let Ω be an open, bounded, and connected subset of $\mathbb{R}^2$ having the boundary $\partial\Omega$ of class C^2, and let ω be an open subset of Ω. Then there exists $\lambda_0 > 0$ such that for any $\lambda > \lambda_0$ one can find $s_0(\lambda) > 0$ and $c(\lambda) > 0$ such that for $s > s_0(\lambda)$ we have*

$$\int_Q e^{2s\alpha}\left(\frac{1}{s\varphi}\left(\left|\frac{\partial z}{\partial t}\right|^2+\sum_{i,j=1}^{2}\left|\frac{\partial^2 z}{\partial x_i\partial x_j}\right|^2\right)+s\varphi|\nabla z|^2+s^3\varphi^3|z|^2\right)dx\,dt \tag{3.9}$$

$$\le c(\lambda)\left(\int_{Q_\omega} e^{2s\alpha}s^3\varphi^3|z|^2dx\,dt+\int_Q e^{2s\alpha}|\nabla q|^2dx\,dt+\int_Q e^{2s\alpha}|g|^2dx\,dt\right)$$

for all $g \in (L^2(Q))^2$ *and all corresponding solutions* $(z, q) \in (H^{2,1}(Q))^2 \times L^2(0, T; H^1(\Omega))$ *of system* (3.4).

Estimate (3.9) was essentially obtained by Imanuvilov in [8]. (We refer the reader to Lemma 2.2 in [9] or Lemma 3.1 in [6], too.)

The analogous estimate for equations (3.5) is contained in the following statement.

LEMMA 3.2. *Let* Ω *and* ω *be open subsets of* $\mathbb{R}^2$ *as in the statement of Lemma* 3.1. *Then there exists* $\lambda_0 > 0$ *such that for any* $\lambda > \lambda_0$ *one can find* $s_0(\lambda) > 0$ *and* $c(\lambda) > 0$ *such that for* $s > s_0(\lambda)$ *we have*

$$\begin{aligned} &\int_Q e^{2s\alpha} \left(\frac{1}{s\varphi} \left(\left| \frac{\partial C}{\partial t} \right|^2 + \sum_{i,j=1}^{2} \left| \frac{\partial^2 C}{\partial x_i \partial x_j} \right|^2 \right) + s\varphi |\nabla C|^2 + s^3 \varphi^3 |C|^2 \right) dx\, dt \\ &\qquad \leq c(\lambda) \left(\int_{Q_\omega} e^{2s\alpha} s^3 \varphi^3 |C|^2 dx\, dt + \int_Q e^{2s\alpha} |\nabla r|^2 dx\, dt + \int_Q e^{2s\alpha} |G|^2 dx\, dt \right) \end{aligned} \tag{3.10}$$

for all $G \in (L^2(Q))^2$ *and all corresponding solutions* $C \in (H^{2,1}(Q))^2$ *of system* (3.5) *and* $r \in L^2(0, T; H^1(\Omega))$ *which satisfy* (3.8).

Proof. Inequality (3.10) can be established in almost the same way as its three-dimensional analogue. (See inequality (3.58) in [2] together with its proof.) However, because of the different (though similar) boundary conditions here, and for the reader's convenience, we shall sketch the proof, emphasizing the points where some differences appear.

Let us first describe in a few words the idea behind the proof. The part of the solutions of equations (3.5) outside Q_ω can be removed in the right-hand side of the estimates by varying (increasing) two parameters s and λ introduced into equations by performing a suitable change of unknown function. So, let us set $D = e^{s\alpha} C$. Passing to D in (3.5), we obtain the following system:

$$\begin{aligned} &\frac{\partial D}{\partial t} + \Delta D + s^2 \lambda^2 \varphi^2 |\nabla \psi|^2 D - 2s\lambda\varphi (\nabla\psi \cdot \nabla) D \\ &\qquad - s\lambda^2 \varphi |\nabla\psi|^2 D - s\lambda\varphi \Delta\psi D - s \frac{\partial \alpha}{\partial t} D = e^{s\alpha} PG \quad \text{in } Q, \\ &\operatorname{div} D = s\lambda\varphi (\nabla\psi \cdot D) \quad \text{in } Q, \\ &D \cdot N = 0, \ \operatorname{curl} D = s\lambda\varphi |\nabla\psi| D \cdot \mathtt{T} \quad \text{on } \Sigma, \\ &D(\cdot, 0) = D(\cdot, T) = 0 \quad \text{in } \Omega, \end{aligned} \tag{3.11}$$

where $\mathtt{T}$ is the unit tangent vector $(-N_2, N_1)$ to $\partial\Omega$.

If we set

$$P(x,t)D = -\Delta D - s^2\lambda^2\varphi^2 |\nabla\psi|^2 D - s\lambda^2\varphi |\nabla\psi|^2 D + s\lambda\varphi\Delta\psi D + s \frac{\partial\alpha}{\partial t} D,$$

$$R(x,t)D = -2s\lambda\varphi (\nabla\psi \cdot \nabla) D - 2s\lambda^2\varphi |\nabla\psi|^2 D,$$

we may write equations (3.11) as

$$\frac{\partial D}{\partial t} + R(x,t)D - P(x,t)D = e^{s\alpha} PG \ \text{ in } Q. \tag{3.12}$$

Multiplying (3.12) by itself, integrating over Q, and neglecting some nonnegative terms, we obtain the inequality

$$I \leq J + \frac{1}{2} \int_Q e^{2s\alpha} |PG|^2 dx\, dt, \tag{3.13}$$

where

$$I = -\int_Q P(x,t)D \cdot R(x,t)D \, dx \, dt, \quad J = \int_Q \frac{\partial D}{\partial t} \cdot P(x,t)D \, dx \, dt.$$

Multiplication of the five terms of $P(x,t)D$ by the two terms of $R(x,t)D$ in (3.13) produces ten terms (integrals): $I = \sum_{i=1}^{10} I_i$. Eight of them (I_3 through I_{10}) can be estimated identically as the corresponding terms in the three-dimensional case. We refer the reader to [2] (see also [6]) for the expression of those estimates and for other details. So, let us examine the other two terms (which contain ΔD).

Integrating by parts twice and using the fact that $N = (-1/|\nabla\psi|)\nabla\psi$, we obtain

$$\begin{aligned} I_1 &= -2s\lambda \int_Q \varphi(\nabla\psi \cdot \nabla)D \cdot \Delta D \, dx \, dt \\ &\geq -s\lambda^2 \int_Q \varphi |\nabla\psi|^2 |\nabla D|^2 dx \, dt - cs\lambda \int_Q \varphi |\nabla D|^2 dx \, dt \\ &\quad + 2s\lambda \int_\Sigma \varphi |\nabla\psi| \sum_{i=1}^{2} \left(\frac{\partial D_i}{\partial N} \right)^2 d\sigma \, dt - s\lambda \int_\Sigma \varphi |\nabla\psi| \, |\nabla D|^2 d\sigma \, dt, \end{aligned} \tag{3.14}$$

where c (here and throughout this proof) denotes a positive constant depending on ψ only.

Using Green's formula, we have (after some calculation)

$$\begin{aligned} I_2 &= -2s\lambda^2 \int_Q \varphi |\nabla\psi|^2 D \cdot \Delta D \, dx \, dt \\ &\geq \frac{3}{2} \, s\lambda^2 \int_Q \varphi |\nabla\psi|^2 |\nabla D|^2 dx \, dt - cs\lambda^4 \int_Q \varphi |D|^2 dx \, dt \\ &\quad - 2s\lambda^2 \int_\Sigma \varphi |\nabla\psi|^2 \sum_{i,j=1}^{2} D_i \frac{\partial D_i}{\partial x_j} N_j \, d\sigma \, dt \quad \text{for } \lambda \geq 1. \end{aligned} \tag{3.15}$$

(See [2] or [6] for more details.) Let us now estimate the surface integral in (3.15). Using first the second boundary condition in (3.11) and then observing that $D \cdot \nabla(D \cdot \nabla\psi) = 0$ on Σ (thanks to the first boundary condition there), we obtain

$$\begin{aligned} -\sum_{i,j=1}^{2} D_i \frac{\partial D_i}{\partial x_j} N_j &= (\operatorname{curl} D) D \cdot \mathtt{T} - \sum_{i,j=1}^{2} D_i \frac{\partial D_j}{\partial x_i} N_j \\ &= s\lambda\varphi |\nabla\psi| (D \cdot \mathtt{T})^2 - |\nabla\psi|^{-1} \sum_{i,j=1}^{2} D_i D_j \frac{\partial^2 \psi}{\partial x_i \partial x_j} \quad \text{on } \Sigma. \end{aligned} \tag{3.16}$$

Thus, we have

$$\begin{aligned} &-2s\lambda^2 \int_\Sigma \varphi |\nabla\psi|^2 \sum_{i,j=1}^{2} D_i \frac{\partial D_i}{\partial x_j} N_j \, d\sigma \, dt \\ &\geq 2s^2\lambda^3 \int_\Sigma \varphi^2 |\nabla\psi|^3 |D|^2 d\sigma \, dt - cs\lambda^2 \sum_{i=1}^{2} \int_0^T \widehat{\varphi}(t) \left(\int_{\partial\Omega} D_i^2 d\sigma \right) dt. \end{aligned} \tag{3.17}$$

To estimate the integral over $\partial\Omega$ in (3.17), we apply the trace theorem and an interpolation inequality:

$$
\begin{aligned}
s\lambda^2 \int_{\partial\Omega} D_i^2 d\sigma &\le c_1 s\lambda^2 |D_i|^2_{H^{\frac{1}{2}}(\Omega)} \le c_2 s\lambda^2 |D_i|_{L^2(\Omega)} |D_i|_{H^1(\Omega)} \\
&\le c_3 \left(s^{\frac{3}{2}} \lambda^3 |D_i|^2_{L^2(\Omega)} + s^{\frac{1}{2}} \lambda |D_i|^2_{L^2(\Omega)} + s^{\frac{1}{2}} \lambda |\nabla D_i|^2_{L^2(\Omega)} \right).
\end{aligned} \tag{3.18}
$$

Now, inserting first (3.18) into (3.17) and then (3.17) into (3.15), we obtain

$$
\begin{aligned}
I_2 \ge{}& \frac{3}{2}\, s\lambda^2 \int_Q \varphi |\nabla\psi|^2 |\nabla D|^2 dx\, dt \\
&- c \left(s\lambda^4 \int_Q \varphi |D|^2 dx\, dt + s^{\frac{3}{2}} \lambda^3 \int_Q \varphi |D|^2 dx\, dt + s^{\frac{1}{2}} \lambda \int_Q \varphi |\nabla D|^2 dx\, dt \right) \\
&+ 2s^2\lambda^3 \int_\Sigma \varphi^2 |\nabla\psi|^3 |D|^2 d\sigma\, dt \quad \text{for } \lambda \ge 1 \text{ and } s \ge 1.
\end{aligned} \tag{3.19}
$$

We next estimate J. Using successively two Green-type formulas, the initial, final, and boundary conditions in (3.11), and, finally, performing an integration by parts with respect to t, we have

$$
\begin{aligned}
&-\int_Q \Delta D \cdot \frac{\partial D}{\partial t}\, dx\, dt \\
&\quad = \int_Q \widetilde{\operatorname{curl}}(\operatorname{curl} D) \cdot \frac{\partial D}{\partial t}\, dx\, dt - \int_Q \nabla(\operatorname{div} D) \cdot \frac{\partial D}{\partial t}\, dx\, dt \\
&\quad = \frac{1}{2} \int_Q \frac{\partial}{\partial t} (\operatorname{curl} D)^2 dx\, dt - \int_\Sigma \operatorname{curl} D\ \frac{\partial D}{\partial t} \cdot \mathtt{T}\, d\sigma\, dt \\
&\qquad + \frac{1}{2} \int_Q \frac{\partial}{\partial t} (\operatorname{div} D)^2 dx\, dt - \int_\Sigma \operatorname{div} D\ \frac{\partial}{\partial t} (D \cdot N) d\sigma\, dt \\
&\quad = s\lambda \int_\Sigma \varphi |\nabla\psi| (D \cdot \mathtt{T})\ \frac{\partial}{\partial t}\ (D \cdot \mathtt{T}) d\sigma\, dt = -\frac{1}{2}\ s\lambda \int_\Sigma \widehat{\varphi}' |\nabla\psi|\, |D|^2 d\sigma\, dt.
\end{aligned}
$$

Putting this last form of $-\int_Q \Delta D \cdot (\partial D/\partial t) dx\, dt$ into the expression of J, we obtain

$$
J \le -\frac{1}{2}\ s\lambda \int_\Sigma \widehat{\varphi}' |\nabla\psi|\, |D|^2 d\sigma\, dt + c(\lambda) s^2 \int_Q \varphi^{\frac{17}{8}} |D|^2 dx\, dt \quad \text{for } \lambda \ge 1,\ s \ge 1, \tag{3.20}
$$

where $c(\lambda)$ is a positive parameter depending on ψ, T, and λ (see [2] or [6] for more details).

To be able to eliminate the surface integrals in (3.14), (3.19), and (3.20), as well as those in the estimates for $I_3, \dots, I_{10}$, we need to repeat all the previous considerations for $\overline{D} = e^{s\overline{\alpha}} C$. Changing C by $\overline{D}$ in (3.5), we obtain (3.11) where, in all places, λ is replaced by $-\lambda$. So, we have

$$
\frac{\partial \overline{D}}{\partial t} + \overline{R}(x,t)\overline{D} - \overline{P}(x,t)\overline{D} = e^{s\overline{\alpha}} PG \ \text{ in } Q,
$$

where the operators $\overline{P}$ and $\overline{Q}$ are defined as P and Q but with $-\lambda$ instead of λ; consequently, $\overline{\varphi}$ and $\overline{\alpha}$ now replace φ and α there. In the same way as before, we have

$$
\overline{I} \le \overline{J} + \frac{1}{2} \int_Q e^{2s\overline{\alpha}} |PG|^2 dx\, dt, \tag{3.21}
$$

where

$$\overline{I} = -\int_Q \overline{P}(x,t)\overline{D}\cdot\overline{R}(x,t)\overline{D}\,dx\,dt, \qquad \overline{J} = \int_Q \frac{\partial \overline{D}}{\partial t}\cdot\overline{P}(x,t)\overline{D}\,dx\,dt.$$

We write $\overline{I}$ as a sum of ten terms, too: $\overline{I} = \sum_{i=1}^{10} \overline{I}_i$. Each of these terms can be estimated in the same way as its corresponding I_i. For $\overline{I}_1$ and $\overline{I}_2$ we obtain the inequalities

$$\begin{aligned}\overline{I}_1 \geq & -s\lambda^2\int_Q \overline{\varphi}|\nabla\psi|^2|\nabla\overline{D}|^2dx\,dt - cs\lambda\int_Q \overline{\varphi}|\nabla\overline{D}|^2dx\,dt \\ & - 2s\lambda\int_\Sigma \varphi|\nabla\psi|\sum_{i=1}^{2}\left(\frac{\partial\overline{D}_i}{\partial N}\right)^2 d\sigma\,dt - s\lambda\int_\Sigma \varphi|\nabla\psi|\,|\nabla\overline{D}|^2 d\sigma\,dt,\end{aligned} \tag{3.22}$$

$$\begin{aligned}\overline{I}_2 \geq & \frac{3}{2}\,s\lambda^2\int_Q \overline{\varphi}|\nabla\psi|^2|\nabla\overline{D}|^2dx\,dt \\ & - c\left(s\lambda^4\int_Q \overline{\varphi}|\overline{D}|^2dx\,dt + s^{\frac{3}{2}}\lambda^3\int_Q \overline{\varphi}|\overline{D}|^2dx\,dt + s^{\frac{1}{2}}\lambda\int_Q \overline{\varphi}|\nabla\overline{D}|^2dx\,dt\right) \\ & - 2s^2\lambda^3\int_\Sigma \varphi^2|\nabla\psi|^2|D|^2d\sigma\,dt\end{aligned} \tag{3.23}$$

for all $\lambda \geq 1$ and $s \geq 1$. Notice that we have taken into account the fact that $\overline{\varphi} = \varphi$ and $\overline{D} = D$ on Σ (because $\psi = 0$ on $\partial\Omega$). In the same way as the estimate for J was derived, we obtain

$$\overline{J} \leq \frac{1}{2}\,s\lambda\int_\Sigma \widehat{\varphi}'|\nabla\psi|\,|D|^2d\sigma\,dt + c(\lambda)s^2\int_Q \overline{\varphi}^{\frac{17}{8}}|\overline{D}|^2dx\,dt \quad \text{for } \lambda \geq 1,\ s \geq 1. \tag{3.24}$$

Now we add inequalities (3.13) and (3.21). Because of the different signs before the corresponding surface integrals in $I_2, \overline{I}_2, I_3, \overline{I}_3, I_5, \overline{I}_5, I_9$, and $\overline{I}_9$ (see [2] or [6] for the definition of the other quantities), all those surface integrals are canceled. (The different signs come from the odd exponents of the powers of λ.) It remains to see how the four surface integrals in $I_1 + \overline{I}_1$ can be removed. By careful calculations involving both (3.16) and (3.18), we obtain

$$\begin{aligned}& 2s\lambda\int_\Sigma \varphi|\nabla\psi|\sum_{i=1}^{2}\left(\frac{\partial D_i}{\partial N}\right)^2 d\sigma\,dt - s\lambda\int_\Sigma \varphi|\nabla\psi|\,|\nabla D|^2d\sigma\,dt \\ & \quad - 2s\lambda\int_\Sigma \varphi|\nabla\psi|\sum_{i=1}^{2}\left(\frac{\partial\overline{D}_i}{\partial N}\right)^2 d\sigma\,dt + s\lambda\int_\Sigma \varphi|\nabla\psi|\,|\nabla\overline{D}|^2d\sigma\,dt \\ & = -4s^2\lambda^2\int_\Sigma \varphi^2|\nabla\psi|\sum_{i,j=1}^{2}\frac{\partial^2\psi}{\partial x_i\partial x_j}\,D_iD_j\,d\sigma\,dt \\ & \geq -c\left(s^3\lambda^3\int_Q \varphi^3|D|^2dx\,dt + s\lambda\int_Q \varphi|\nabla D|^2dx\,dt\right).\end{aligned} \tag{3.25}$$

(We refer the reader to [2] or [6] for all the details.) So, adding (3.13) and (3.21) and using the estimates (3.14), (3.19), (3.20), and (3.22) through (3.25), as well as

the estimates for $I_3, \dots, I_{10}$ and $\overline{I}_3, \dots, \overline{I}_{10}$ (which can be taken from [2] or [6]), we obtain

$$\begin{aligned} & s\lambda^2 \int_Q \varphi |\nabla \psi|^2 |\nabla D|^2 dx\, dt + s^3\lambda^4 \int_Q \varphi^3 |\nabla \psi|^4 |D|^2 dx\, dt \\ & \quad \le cs\lambda \int_Q \varphi |\nabla D|^2 dx\, dt + cs^3\lambda^3 \int_Q \varphi^3 |D|^2 dx\, dt \\ & \quad + c(\lambda) s^2 \int_Q \varphi^3 |D|^2 dx\, dt + \int_Q e^{2s\alpha} |PG|^2 dx\, dt \\ & \qquad\qquad \text{for } \lambda \ge 1,\ s \ge 1. \end{aligned} \tag{3.26}$$

The key point is now coming. Since, by the third property of ψ, $|\nabla \psi| \ge \rho$ in $\overline{\Omega} \setminus \omega_0$ for some $\rho > 0$, from (3.26), we have

$$\begin{aligned} & \rho^2 s\lambda^2 \int_{Q \setminus Q_{\omega_0}} \varphi |\nabla D|^2 dx\, dt + \rho^4 s^3\lambda^4 \int_{Q \setminus Q_{\omega_0}} |D|^2 dx\, dt \\ & \quad \le cs\lambda \int_Q \varphi |\nabla D|^2 dx\, dt + cs^3\lambda^3 \int_Q \varphi^3 |D|^2 dx\, dt \\ & \quad + c(\lambda) s^2 \int_Q \varphi^3 |D|^2 dx\, dt + \int_Q e^{2s\alpha} |PG|^2 dx\, dt \\ & \qquad\qquad \text{for } \lambda \ge 1,\ s \ge 1. \end{aligned} \tag{3.27}$$

As the powers of s and λ before integrals of $\varphi|\nabla D|^2$ and $\varphi^3|D|^2$ are greater in the left-hand side of (3.27) than in the right-hand side, we can remove the part of $\varphi|\nabla D|^2$ and $\varphi^3|D|^2$ outside Q_{ω_0} in the right-hand side by simply increasing the parameters λ and s. So, taking first $\lambda > \lambda_0 = (c+1)\max(\rho^{-2}, \rho^{-4})$ and then $s > s_0(\lambda) = c(\lambda)\lambda^{-3}(\rho^4\lambda - c - 1)^{-1}$, where c and $c(\lambda)$ are those in (3.27), we obtain

$$\begin{aligned} & s\lambda \int_Q \varphi |\nabla D|^2 dx\, dt + s^3\lambda^3 \int_Q \varphi^3 |D|^2 dx\, dt \\ & \quad \le c(\lambda) \left(s \int_{Q_{\omega_0}} \varphi |\nabla D|^2 dx\, dt + s^3 \int_{Q_{\omega_0}} \varphi^3 |D|^2 dx\, dt + \int_Q e^{2s\alpha} |PG|^2 dx\, dt \right) \\ & \qquad\qquad \text{for } \lambda > \lambda_0,\ s > s_0(\lambda). \end{aligned}$$

Coming back to C ($D = e^{s\alpha} C$), we can rewrite the above inequality as

$$\begin{aligned} & s\lambda \int_Q e^{2s\alpha} \varphi |\nabla C|^2 dx\, dt + s^3\lambda^3 \int_Q e^{2s\alpha} \varphi^3 |C|^2 dx\, dt \\ & \quad \le c(\lambda) \left(s \int_{Q_{\omega_0}} e^{2s\alpha} \varphi |\nabla C|^2 dx\, dt + s^3 \int_{Q_{\omega_0}} e^{2s\alpha} \varphi^3 |C|^2 dx\, dt + \int_Q e^{2s\alpha} |PG|^2 dx\, dt \right) \\ & \qquad\qquad \text{for } \lambda > \lambda_0 \text{ and } s > s_0(\lambda), \end{aligned} \tag{3.28}$$

where λ_0 is possibly greater than that before.

The integral of $e^{2s\alpha}\varphi|\nabla C|^2$ in the right-hand side of (3.28) can be eliminated as

in [2]. So, we have

$$
\begin{aligned}
&s\lambda\int_Q e^{2s\alpha}\varphi|\nabla C|^2dx\,dt + s^3\lambda^3\int_Q e^{2s\alpha}\varphi^3|C|^2dx\,dt\\
&\qquad\le c(\lambda)\left(s^3\int_{Q_{\omega_1}} e^{2s\alpha}\varphi^3|C|^2dx\,dt + \int_Q e^{2s\alpha}|PG|^2dx\,dt\right)\\
&\qquad\qquad\text{for } \lambda>\lambda_0 \text{ and } s>s_0(\lambda),
\end{aligned}
\tag{3.29}
$$

where ω_1 is an open subset of ω such that $\omega_0 \subset\subset \omega_1 \subset\subset \omega$.

It remains to show how estimates such as (3.29) can also be obtained for the first and second order derivatives of C with respect to time and space variables, respectively. To be able to estimate the weighted L^2 norm of $\partial C/\partial t$ in (3.10), we scalarly multiply (3.5) by $e^{2s\alpha}\varphi^{-1}\partial C/\partial t$. Thus, the desired estimate is reduced to that of the integral of $e^{2s\alpha}\varphi^{-1}\partial C/\partial t\cdot\widetilde{\operatorname{curl}}(\operatorname{curl} C)$ over Q. Using a version of Green's formula together with the boundary conditions in (3.5) and then integrating by parts with respect to t, we obtain

$$
\begin{aligned}
&-\int_Q e^{2s\alpha}\varphi^{-1}\ \frac{\partial C}{\partial t}\cdot\widetilde{\operatorname{curl}}(\operatorname{curl} C)dx\,dt\\
&\quad=-\int_Q \operatorname{curl}\left(e^{2s\alpha}\varphi^{-1}\ \frac{\partial C}{\partial t}\right)\operatorname{curl} C\,dx\,dt+\int_\Sigma e^{2s\alpha}\varphi^{-1}\operatorname{curl} C\ \frac{\partial C}{\partial t}\cdot \mathtt{T}\,d\sigma\,dt\\
&\quad=\frac{1}{2}\int_Q e^{2s\alpha}\left(2s\varphi^{-1}\ \frac{\partial\alpha}{\partial t}-\varphi^{-2}\ \frac{\partial\varphi}{\partial t}\right)|\operatorname{curl} C|^2dx\,dt\\
&\qquad+\lambda\int_Q e^{2s\alpha}(2s-\varphi^{-1})\ \operatorname{curl} C\ \widetilde{\operatorname{curl}}\,\psi\cdot\frac{\partial C}{\partial t}\ dx\,dt.
\end{aligned}
$$

Since $|\operatorname{curl} C|^2\le 2|\nabla C|^2$, the last relation leads to the inequality

$$
\int_Q e^{2s\alpha}(s\varphi)^{-1}\left|\frac{\partial C}{\partial t}\right|^2dx\,dt\le c(\lambda)\left(s\int_Q e^{2s\alpha}\varphi|\nabla C|^2dx\,dt+\int_Q e^{2s\alpha}|PG|^2dx\,dt\right)
$$

$$
\text{for } s\ge 1.
$$

This together with (3.29) yields

$$
\begin{aligned}
&\int_Q e^{2s\alpha}(s\varphi)^{-1}\left|\frac{\partial C}{\partial t}\right|^2dx\,dt\\
&\qquad\le c(\lambda)\left(s^3\int_{Q_{\omega_1}} e^{2s\alpha}\varphi^3|C|^2dx\,dt+\int_Q e^{2s\alpha}|PG|^2dx\,dt\right)\\
&\qquad\qquad\text{for } \lambda>\lambda_0 \text{ and } s>s_0(\lambda).
\end{aligned}
\tag{3.30}
$$

Now multiplying (3.5) by $e^{2s\alpha}\varphi^{-1}\Delta C$ and integrating over Q, after some arrangements involving (3.30), we obtain

$$
\begin{aligned}
&\int_Q e^{2s\alpha}(s\varphi)^{-1}|\Delta C|^2dx\,dt\\
&\qquad\le c(\lambda)\left(s^3\int_{Q_{\omega_1}} e^{2s\alpha}\varphi^3|C|^2dx\,dt+\int_Q e^{2s\alpha}|PG|^2dx\,dt\right)\\
&\qquad\qquad\text{for } \lambda>\lambda_0 \text{ and } s>s_0(\lambda).
\end{aligned}
\tag{3.31}
$$

An estimate similar to (3.31) (whose derivation is based on it) can be obtained for $\sum_{i,j=1}^{2} \left|\partial^2 C/\partial x_i \partial x_j\right|^2$, too. (We refer the reader to [2] for more details.) Taking this last estimate together with (3.30) and (3.31), we obtain (3.10), which finishes the proof. □

As we have already mentioned, q in (3.4) and r satisfying (3.8) are solutions to some Poisson equations. Indeed, applying the divergence operator to both sides of (3.4) and (3.5), we see that q and r satisfy

$$\Delta q = \operatorname{div} g \quad \text{and} \quad \Delta r = \operatorname{div} G \quad \text{in } Q. \tag{3.32}$$

So, to estimate the involved weighted L^2 norms of ∇q and ∇r, we may use Imanuvilov's Carleman inequality for second order uniformly elliptic equations with nonhomogeneous Dirichlet boundary conditions (obtained in [9]). Applying this inequality for the first Poisson equation in (3.32) twice and using the energy a priori estimate for the Stokes equations, too, we can establish the following estimate for q.

LEMMA 3.3. *Let Ω, ω, ω_0, and ω_1 be open subsets of $\mathbb{R}^2$ as in the statement of Theorem* 3.1. *Then there exists $\lambda_0 > 0$ such that for any $\lambda > \lambda_0$ one can find $s_0(\lambda) > 0$ and $c(\lambda) > 0$ such that for $s > s_0(\lambda)$ we have*

$$\begin{aligned} &\int_Q e^{2s\alpha} |\nabla q|^2 dx\, dt \\ &\quad \le c(\lambda) \bigg(\int_Q e^{2s\widehat{\alpha}} s^{\frac{11}{4}} \widehat{\varphi}^3 |z|^2 dx\, dt + \int_{Q_{\omega_1}} e^{2s\alpha} s^{\frac{11}{4}} \widehat{\varphi}^{\frac{11}{4}} q^2 dx\, dt \\ &\qquad + \int_Q e^{2s\widehat{\alpha}} s^{\frac{3}{4}} \widehat{\varphi}^{\frac{3}{4}} |g|^2 dx\, dt + \int_Q e^{2s\alpha} s^{\frac{1}{2}} \widehat{\varphi}^{\frac{1}{2}} (\operatorname{div} g)^2 dx\, dt \bigg) \end{aligned} \tag{3.33}$$

for all $g \in L^2(0,T;(H^1(\Omega))^2)$ and all corresponding solutions $(z,q) \in (H^{2,1}(Q))^2 \times L^2(0,T;H^1(\Omega))$ of system (3.4).

The proof of the above lemma is identical to that of its three-dimensional version (see [6] or [7]). In a completely similar way (we may follow the proof of Lemma 3.3 in [6] step by step, because $-\widetilde{\operatorname{curl}}(\operatorname{curl} C) = \Delta C$ when $\operatorname{div} C = 0$) we can obtain the corresponding estimate for ∇r. (See [7] for the three-dimensional variant.)

LEMMA 3.4. *Let Ω, ω, ω_0, and ω_1 be open subsets of $\mathbb{R}^2$ as in the statement of Theorem* 3.1. *Then there exists $\lambda_0 > 0$ such that for any $\lambda > \lambda_0$ one can find $s_0(\lambda) > 0$ and $c(\lambda) > 0$ such that for $s > s_0(\lambda)$ we have*

$$\begin{aligned} &\int_Q e^{2s\alpha} |\nabla r|^2 dx\, dt \\ &\quad \le c(\lambda) \bigg(\int_Q e^{2s\widehat{\alpha}} s^{\frac{11}{4}} \widehat{\varphi}^3 |C|^2 dx\, dt + \int_{Q_{\omega_1}} e^{2s\alpha} s^{\frac{11}{4}} \widehat{\varphi}^{\frac{11}{4}} r^2 dx\, dt \\ &\qquad + \int_Q e^{2s\widehat{\alpha}} s^{\frac{3}{4}} \widehat{\varphi}^{\frac{3}{4}} |G|^2 dx\, dt + \int_Q e^{2s\alpha} s^{\frac{1}{2}} \widehat{\varphi}^{\frac{1}{2}} (\operatorname{div} G)^2 dx\, dt \bigg) \end{aligned} \tag{3.34}$$

for all $G \in L^2(0,T;(H^1(\Omega))^2)$ and all corresponding solutions $C \in (H^{2,1}(Q))^2$ of system (3.5) *and $r \in L^2(0,T;H^1(\Omega))$ which satisfy* (3.8).

The proofs of Theorems 3.2 and 3.3 come to an end by simply coupling (3.9) with (3.33) and (3.10) with (3.34).

Proof of Theorem 3.1. To finish the proof, we have to take inequalities (3.6) and (3.7) together with g and G given by

$$g = -(\widetilde{y}\cdot\nabla)z + z\cdot(\nabla\widetilde{y}) + (\widetilde{B}\cdot\nabla)C + C\cdot(\nabla\widetilde{B}) + h,$$

$$G = -(\widetilde{y}\cdot\nabla)C - C\cdot(\nabla\widetilde{y}) + (\widetilde{B}\cdot\nabla)z - z\cdot(\nabla\widetilde{B}) + H.$$

We have

$$\operatorname{div} g = -\sum_{i,j=1}^{2}\frac{\partial\widetilde{y}_j}{\partial x_i}\,\frac{\partial z_i}{\partial x_j} + \nabla z\cdot\nabla\widetilde{y} + z\cdot\Delta\widetilde{y} + \sum_{i,j=1}^{2}\frac{\partial\widetilde{B}_j}{\partial x_i}\,\frac{\partial C_i}{\partial x_j} + \nabla C\cdot\nabla\widetilde{B} + C\cdot\Delta\widetilde{B},$$

$$\operatorname{div} G = -\sum_{i,j=1}^{2}\frac{\partial\widetilde{y}_j}{\partial x_i}\,\frac{\partial C_i}{\partial x_j} - \nabla C\cdot\nabla\widetilde{y} - C\cdot\Delta\widetilde{y} + \sum_{i,j=1}^{2}\frac{\partial\widetilde{B}_j}{\partial x_i}\,\frac{\partial z_i}{\partial x_j} - \nabla z\cdot\nabla\widetilde{B} - z\cdot\Delta\widetilde{B}.$$

(Here one has taken into account the fact that z, C, h, and H are divergence-free.) As $\widetilde{y}, \widetilde{B} \in L^\infty(0,T;(W^{2,p}(\Omega))^2)$ with $p > 2$, by the Sobolev imbedding theorem we also have $\widetilde{y}, \widetilde{B} \in L^\infty(0,T;(W^{1,\infty}(\Omega))^2)$, so a.e. in Q we can obtain

$$|g| \le c(|\nabla z| + |\nabla C| + |z| + |C|) + |h|, \tag{3.35}$$

$$|G| \le c(|\nabla z| + |\nabla C| + |z| + |C|) + |H|, \tag{3.36}$$

$$|\operatorname{div} g| \le c(|\nabla z| + |\nabla C|) + |\Delta\widetilde{y}|\,|z| + |\Delta\widetilde{B}|\,|C|, \tag{3.37}$$

$$|\operatorname{div} G| \le c(|\nabla z| + |\nabla C|) + |\Delta\widetilde{y}|\,|C| + |\Delta\widetilde{B}|\,|z|. \tag{3.38}$$

By (3.35) and (3.36), we have

$$\begin{aligned}
&\int_Q \left(e^{2s\alpha} + e^{2s\widehat{\alpha}} s^{\frac{3}{4}}\widehat{\varphi}^{\frac{3}{4}}\right)|g|^2 dx\,dt \\
&\quad\le c\int_Q \left(e^{2s\alpha} + e^{2s\widehat{\alpha}} s^{\frac{3}{4}}\widehat{\varphi}^{\frac{3}{4}}\right)(|\nabla z|^2 + |\nabla C|^2 + |z|^2 + |C|^2)dx\,dt \\
&\qquad + \int_Q \left(e^{2s\alpha} + e^{2s\widehat{\alpha}} s^{\frac{3}{4}}\widehat{\varphi}^{\frac{3}{4}}\right)|h|^2 dx\,dt,
\end{aligned} \tag{3.39}$$

$$\begin{aligned}
&\int_Q \left(e^{2s\alpha} + e^{2s\widehat{\alpha}} s^{\frac{3}{4}}\widehat{\varphi}^{\frac{3}{4}}\right)|G|^2 dx\,dt \\
&\quad\le c\int_Q \left(e^{2s\alpha} + e^{2s\widehat{\alpha}} s^{\frac{3}{4}}\widehat{\varphi}^{\frac{3}{4}}\right)(|\nabla z|^2 + |\nabla C|^2 + |z|^2 + |C|^2)dx\,dt \\
&\qquad + \int_Q \left(e^{2s\alpha} + e^{2s\widehat{\alpha}} s^{\frac{3}{4}}\widehat{\varphi}^{\frac{3}{4}}\right)|H|^2 dx\,dt.
\end{aligned} \tag{3.40}$$

By (3.37), we can write

$$\begin{aligned}
\int_Q e^{2s\alpha} s^{\frac{1}{2}}\widehat{\varphi}^{\frac{1}{2}}|\operatorname{div} g|^2 dx\,dt &\le c\int_Q e^{2s\alpha} s^{\frac{1}{2}}\widehat{\varphi}^{\frac{1}{2}}(|\nabla z|^2 + |\nabla C|^2)dx\,dt \\
&\quad + c\int_Q e^{2s\alpha} s^{\frac{1}{2}}\widehat{\varphi}^{\frac{1}{2}}(|\Delta\widetilde{y}|^2|z|^2 + |\Delta\widetilde{B}|^2|C|^2)dx\,dt.
\end{aligned} \tag{3.41}$$

Using Hölder's inequality, the fact that $\widetilde{y}, \widetilde{B} \in L^\infty(0,T;(W^{2,p}(\Omega))^2)$ with $p>2$, and the continuity of the inclusion $(H^1(\Omega))^2 \subset (L^{2p/(p-2)}(\Omega))^2$, we derive

$$\begin{aligned}
&\int_Q e^{2s\alpha}\widehat{\varphi}^{\frac{1}{2}}|\Delta\widetilde{y}|^2|z|^2dx\,dt \\
&\quad\le \int_0^T \widehat{\varphi}^{\frac{1}{2}}|\Delta\widetilde{y}|^2_{(L^p(\Omega))^2}|e^{s\alpha}z|^2_{(L^{\frac{2p}{p-2}}(\Omega))^2}dt \\
&\quad\le c_1\int_0^T \widehat{\varphi}^{\frac{1}{2}}|e^{s\alpha}z|^2_{(H^1(\Omega))^2}dt \\
&\quad\le c_2(\lambda)\int_Q e^{2s\alpha}\widehat{\varphi}^{\frac{1}{2}}(|\nabla z|^2+s^2\varphi^2|z|^2)dx\,dt
\end{aligned} \tag{3.42}$$

and

$$\begin{aligned}
&\int_Q e^{2s\alpha}\widehat{\varphi}^{\frac{1}{2}}|\Delta\widetilde{B}|^2|C|^2dx\,dt \\
&\quad\le c(\lambda)\int_Q e^{2s\alpha}\widehat{\varphi}^{\frac{1}{2}}(|\nabla C|^2+s^2\varphi^2|C|^2)dx\,dt.
\end{aligned} \tag{3.43}$$

Putting inequalities (3.41) through (3.43) together, we obtain

$$\begin{aligned}
&\int_Q e^{2s\alpha}s^{\frac{1}{2}}\widehat{\varphi}^{\frac{1}{2}}|\operatorname{div} g|^2dx\,dt \\
&\quad\le c(\lambda)\int_Q e^{2s\alpha}\left(s^{\frac{1}{2}}\varphi^{\frac{1}{2}}\left(|\nabla z|^2+|\nabla C|^2\right)+s^{\frac{5}{2}}\varphi^{\frac{5}{2}}\left(|z|^2+|C|^2\right)\right)dx\,dt.
\end{aligned} \tag{3.44}$$

In a similar way, using (3.38), we have

$$\begin{aligned}
&\int_Q e^{2s\alpha}s^{\frac{1}{2}}\widehat{\varphi}^{\frac{1}{2}}|\operatorname{div} G|^2dx\,dt \\
&\quad\le c(\lambda)\int_Q e^{2s\alpha}\left(s^{\frac{1}{2}}\varphi^{\frac{1}{2}}\left(|\nabla z|^2+|\nabla C|^2\right)+s^{\frac{5}{2}}\varphi^{\frac{5}{2}}\left(|z|^2+|C|^2\right)\right)dx\,dt.
\end{aligned} \tag{3.45}$$

Now, we add inequalities (3.6) and (3.7), and take estimates (3.39), (3.40), (3.44), and (3.45) into account. Thus, we obtain inequality (3.3) by simply taking s sufficiently large. This finishes the proof of Theorem 3.1. ∎

4. Observability inequalities for the adjoint linearized MHD equations. Using the Carleman inequality (3.3), one can estimate weighted L^2 norms of solutions (z,C) of equations (3.1) taken over the entire Q by weighted L^2 norms of their values taken over Q_ω only. Such estimates are called observability inequalities. We shall express the needed weights by means of the following version of function α (which is no longer $+\infty$ at $t=0$):

$$\beta(x,t)=\frac{e^{\lambda\psi(x)}-e^{2\lambda|\psi|_{C(\overline{\Omega})}}}{(\theta(t)(T-t))^8},$$

where $\lambda>0$ and θ is an increasing C^∞ function such that $\theta(0)>0$ and $\theta(t)=t$ for $t\in[T/2,T]$. The restriction of β on $\partial\Omega$ is denoted by $\widehat{\beta}$:

$$\widehat{\beta}(t)=\frac{1-e^{2\lambda|\psi|_{C(\overline{\Omega})}}}{(\theta(t)(T-t))^8}\,.$$

The first observability inequality we need can be expressed as follows.

THEOREM 4.1. *Let Ω be an open subset of $\mathbb{R}^2$ as in the statement of Theorem 3.1 and let ω be an open subset of Ω. Let $\widetilde{y}, \widetilde{B} \in W^{1,\infty}(0,T;(W^{2,p}(\Omega))^2)$ with $p>2$. Then there exists $\lambda_0>0$ such that for any $\lambda>\lambda_0$ one can find $s_0(\lambda)>0$ and $\delta_0(\lambda)\in(1/2,1)$ such that for $s>s_0(\lambda)$ and $1/2<\delta<\delta_0(\lambda)$ there is some $c(\lambda,s,\delta)>0$ such that the following inequality holds:*

$$\begin{aligned}(4.1)\qquad &\int_Q e^{2s\widehat{\beta}}(T-t)^8\left(|z|^2+|C|^2\right)dx\,dt\\ &\qquad\le c(\lambda,s,\delta)\left(\int_{Q_\omega} e^{2s\delta\widehat{\beta}}\left(|z|^2+|C|^2\right)dx\,dt+\int_Q e^{2s\delta\widehat{\beta}}\left(|h|^2+|H|^2\right)dx\,dt\right)\end{aligned}$$

for all $h, H\in(L^2(Q))^2$ which satisfy $\operatorname{div} h=\operatorname{div} H=0$ in Q and $H\cdot N=0$ on Σ, and all corresponding solutions $(z,C,q)\in(H^{2,1}(Q))^4\times L^2(0,T;H^1(\Omega))$ of system (3.1).

Proof. The complete proof is quite long and can be found in [7]. (See also [6] for a related situation.) We emphasize that there is no significant difference between the two-dimensional and three-dimensional cases. However, for the reader's convenience, we shall provide an outline of the proof, referring the reader to [7] (or [6]) for details.

The main objective of the proof is to remove q and r in (3.3). To be able to do it, we are forced to pass from z, q, h, C, r, and H to their primitives with respect to t. The new functions satisfy parabolic equations similar to (3.1) (which enables us to apply Carleman inequality (3.3) to them, too) but also certain stationary Stokes equations, which taken under consideration will lead us to the elimination of q and r.

So, for $t\in[0,T]$, we consider the auxiliary functions

$$\overline{z}(x,t)=\int_{\frac{T}{2}}^t z(x,\tau)d\tau,\qquad \overline{q}(x,t)=\int_{\frac{T}{2}}^t q(x,\tau)d\tau,\quad \overline{h}(x,t)=\int_{\frac{T}{2}}^t h(x,\tau)d\tau,$$

$$\overline{C}(x,t)=\int_{\frac{T}{2}}^t C(x,\tau)d\tau,\quad \overline{r}(x,t)=\int_{\frac{T}{2}}^t r(x,\tau)d\tau,\quad \overline{H}(x,t)=\int_{\frac{T}{2}}^t H(x,\tau)d\tau.$$

Integrating equations (3.1) from $T/2$ to t and taking (3.2) into account, one easily sees that $\overline{z},\overline{q},\overline{h}$ and $\overline{c},\overline{r},\overline{H}$ satisfy

$$\begin{aligned}&\frac{\partial\overline{z}}{\partial t}+\Delta\overline{z}+(\widetilde{y}\cdot\nabla)\overline{z}-\overline{z}\cdot(\nabla\widetilde{y})-(\widetilde{B}\cdot\nabla)\overline{C}-\overline{C}\cdot(\nabla\widetilde{B})+\nabla\overline{q}\\ &\quad=\overline{h}+\int_{\frac{T}{2}}^t\left(\frac{\partial\widetilde{y}}{\partial\tau}\cdot\nabla\right)\overline{z}\,d\tau-\int_{\frac{T}{2}}^t\overline{z}\cdot\left(\nabla\frac{\partial\widetilde{y}}{\partial\tau}\right)d\tau\\ &\qquad-\int_{\frac{T}{2}}^t\left(\frac{\partial\widetilde{B}}{\partial\tau}\cdot\nabla\right)\overline{C}d\tau-\int_{\frac{T}{2}}^t\overline{C}\cdot\left(\nabla\frac{\partial\widetilde{B}}{\partial\tau}\right)d\tau+z\left(\cdot,\frac{T}{2}\right)\ \text{in } Q,\end{aligned}$$

$$\begin{aligned}(4.2)\qquad &\frac{\partial\overline{C}}{\partial t}-\widetilde{\operatorname{curl}}(\operatorname{curl}\overline{C})+(\widetilde{y}\cdot\nabla)\overline{C}+\overline{C}\cdot(\nabla\widetilde{y})-(\widetilde{B}\cdot\nabla)\overline{z}+\overline{z}\cdot(\nabla\widetilde{B})+\nabla\overline{r}\\ &\quad=\overline{H}+\int_{\frac{T}{2}}^t\left(\frac{\partial\widetilde{y}}{\partial\tau}\cdot\nabla\right)\overline{C}\,d\tau+\int_{\frac{T}{2}}^t\overline{C}\cdot\left(\nabla\frac{\partial\widetilde{y}}{\partial\tau}\right)d\tau\\ &\qquad-\int_{\frac{T}{2}}^t\left(\frac{\partial\widetilde{B}}{\partial\tau}\cdot\nabla\right)\overline{z}\,d\tau+\int_{\frac{T}{2}}^t\overline{z}\cdot\left(\nabla\frac{\partial\widetilde{B}}{\partial\tau}\right)d\tau+C\left(\cdot,\frac{T}{2}\right)\ \text{in } Q,\\ &\operatorname{div}\overline{z}=0,\quad \operatorname{div}\overline{C}=0\qquad\text{in } Q,\\ &\overline{z}=0,\quad \overline{C}\cdot N=0,\quad \operatorname{curl}\overline{C}=0\qquad\text{on }\Sigma.\end{aligned}$$

(We have also used the fact that $z = \partial\overline{z}/\partial t$ and $C = \partial\overline{C}/\partial t$.)

Since equations (4.2) are similar to equations (3.1) (taken together with (3.2)), we can argue as in the proof of Theorem 3.1 to derive a Carleman inequality like (3.3) for the solutions of (4.2). Indeed, it is enough to treat the eight integral terms in (4.2) in the same way in which the corresponding terms in g and G have been treated in the proof of Theorem 3.1 to obtain estimates as (3.39), (3.40), (3.44), and (3.45) for them. Thus we can assert that there exists $\lambda_0 > 0$ such that for any $\lambda > \lambda_0$ one can find $s_0(\lambda) > 0$ and $c(\lambda) > 0$ such that for $s > s_0(\lambda)$ one has

$$\begin{aligned}
&\int_Q e^{2s\alpha}\left(\frac{1}{s\varphi}\left(\left|\frac{\partial\overline{z}}{\partial t}\right|^2+\left|\frac{\partial\overline{C}}{\partial t}\right|^2+\sum_{i,j=1}^{2}\left(\left|\frac{\partial^2\overline{z}}{\partial x_i\partial x_j}\right|^2+\left|\frac{\partial^2\overline{C}}{\partial x_i\partial x_j}\right|^2\right)\right)\right.\\
&\qquad\left.+\ s\varphi(|\nabla\overline{z}|^2+|\nabla\overline{C}|^2)+s^3\varphi^3(|\overline{z}|^2+|\overline{C}|^2)\right)dxdt \qquad (4.3)\\
&\quad\le c(\lambda)\left(\int_{Q_\omega} e^{2s\alpha}s^3\varphi^3(|\overline{z}|^2+|\overline{C}|^2)dxdt+\int_{Q_{\omega_1}} e^{2s\alpha}s^{\frac{11}{4}}\widehat{\varphi}^{\frac{11}{4}}(\overline{q}^2+\overline{r}^2)\,dxdt\right.\\
&\qquad\left.+\int_Q\left(e^{2s\alpha}+e^{2s\widehat{\alpha}}s^{\frac{3}{4}}\widehat{\varphi}^{\frac{3}{4}}\right)\left(|\overline{h}|^2+|\overline{H}|^2+\left|z\left(\cdot,\frac{T}{2}\right)\right|^2+\left|C\left(\cdot,\frac{T}{2}\right)\right|^2\right)dxdt\right).
\end{aligned}$$

The next step is to eliminate the local terms containing $\overline{q}$ and $\overline{r}$ in the right-hand side of (4.3). To do so, we shall try to estimate those terms by local expressions of $\overline{z}, \overline{C}, z, C, \overline{h}$, and $\overline{H}$.

Clearly we may assume that $\overline{q}$ and $\overline{r}$ satisfy

$$\int_{\omega_1}\overline{q}(x,t)dx = 0 \quad\text{and}\quad \int_{\omega_1}\overline{r}(x,t)dx = 0 \quad \text{for all } t\in[0,T]$$

(because, otherwise, we can pass from q and r to $q - (\operatorname{meas}\omega_1)^{-1}\int_{\omega_1} q\,dx$ and $r - (\operatorname{meas}\omega_1)^{-1}\int_{\omega_1} r\,dx$). So we may apply Proposition 1.2 in [11] and obtain

$$\begin{aligned}
&\int_0^T\int_{\omega_1} e^{2s\alpha}s^{\frac{11}{4}}\widehat{\varphi}^{\frac{11}{4}}(\overline{q}^2+\overline{r}^2)dxdt\\
&\qquad\le c_1(\delta)\int_0^T\int_{\omega_1} e^{2s\delta\widehat{\alpha}}(\overline{q}^2+\overline{r}^2)dxdt\\
&\qquad\le c_2(\delta)\int_0^T e^{2s\delta\widehat{\alpha}}\left(|\nabla\overline{q}|^2_{((H_0^1(\omega_1))^2)'}+|\nabla\overline{r}|^2_{((H_0^1(\omega_1))^2)'}\right)dt \qquad (4.4)\\
&\qquad\qquad\qquad\qquad\qquad\qquad \text{for } \frac{1}{2}<\delta<\delta_0(\lambda)<1,
\end{aligned}$$

where

$$\delta_0(\lambda) = \frac{e^{2\lambda|\psi|_{C(\overline{\Omega})}}-e^{\lambda|\psi|_{C(\overline{\Omega})}}}{e^{2\lambda|\psi|_{C(\overline{\Omega})}}-1}\,.$$

(Obviously $\delta_0(\lambda) < 1$ for any $\lambda > 0$, and taking $\lambda > \log 2/|\psi|_{C(\overline{\Omega})}$, we have $\delta_0(\lambda) > 1/2$ as well.)

To estimate the $((H_0^1(\omega_1))^2)'$ norms of $\nabla\overline{q}$ and $\nabla\overline{r}$ in (4.4), we shall use equations (4.2) again, but this time regarded as an elliptic system. In fact we separately consider two elliptic systems, one for $\overline{z},\overline{q},\overline{h}$ and another one for $\overline{C},\overline{r},\overline{H}$, namely,

$$\begin{aligned}
\Delta\overline{z}+\nabla\overline{q} &= \overline{h}-(\widetilde{y}\cdot\nabla)\overline{z}+\overline{z}\cdot(\nabla\widetilde{y})+(\widetilde{B}\cdot\nabla)\overline{C}+\overline{C}\cdot(\nabla\widetilde{B})\\
&\quad+\int_{\frac{T}{2}}^{t}\left(\frac{\partial\widetilde{y}}{\partial\tau}\cdot\nabla\right)\overline{z}\,d\tau-\int_{\frac{T}{2}}^{t}\overline{z}\cdot\left(\nabla\frac{\partial\widetilde{y}}{\partial\tau}\right)d\tau\\
&\quad-\int_{\frac{T}{2}}^{t}\left(\frac{\partial\widetilde{B}}{\partial\tau}\cdot\nabla\right)\overline{C}\,d\tau-\int_{\frac{T}{2}}^{t}\overline{C}\cdot\left(\nabla\frac{\partial\widetilde{B}}{\partial\tau}\right)d\tau\\
&\quad-z+z\left(\cdot,\frac{T}{2}\right) \qquad \text{in } Q,\\
\operatorname{div}\overline{z} &= 0 \qquad \text{in } Q
\end{aligned}\tag{4.5}$$

and

$$\begin{aligned}
\Delta\overline{C}+\nabla\overline{r} &= \overline{H}-(\widetilde{y}\cdot\nabla)\overline{C}-\overline{C}\cdot(\nabla\widetilde{y})+(\widetilde{B}\cdot\nabla)\overline{z}-\overline{z}\cdot(\nabla\widetilde{B})\\
&\quad+\int_{\frac{T}{2}}^{t}\left(\frac{\partial\widetilde{y}}{\partial\tau}\cdot\nabla\right)\overline{C}\,d\tau+\int_{\frac{T}{2}}^{t}\overline{C}\cdot\left(\nabla\frac{\partial\widetilde{y}}{\partial\tau}\right)d\tau\\
&\quad-\int_{\frac{T}{2}}^{t}\left(\frac{\partial\widetilde{B}}{\partial\tau}\cdot\nabla\right)\overline{z}\,d\tau+\int_{\frac{T}{2}}^{t}\overline{z}\cdot\left(\nabla\frac{\partial\widetilde{B}}{\partial\tau}\right)d\tau\\
&\quad-C+C\left(\cdot,\frac{T}{2}\right) \qquad \text{in } Q,\\
\operatorname{div}\overline{C} &= 0 \qquad \text{in } Q.
\end{aligned}\tag{4.6}$$

(We recall that $-\widetilde{\operatorname{curl}}(\operatorname{curl}\overline{C})=\Delta\overline{C}$ when $\operatorname{div}\overline{C}=0$.)

To be able to estimate the $((H_0^1(\omega_1))^2)'$ norm of $\nabla\overline{q}$, we need to split the solutions $(\overline{z},\overline{q})$ of (4.5), considered in ω, into two components. Let $(\overline{z}_1,\overline{q}_1)$ be the solution of the following steady state Stokes equations with homogeneous Dirichlet boundary condition:

$$\begin{aligned}
\Delta\overline{z}_1+\nabla\overline{q}_1 &= \overline{h}-(\widetilde{y}\cdot\nabla)\overline{z}+\overline{z}\cdot(\nabla\widetilde{y})+(\widetilde{B}\cdot\nabla)\overline{C}+\overline{C}\cdot(\nabla\widetilde{B})\\
&\quad+\int_{\frac{T}{2}}^{t}\left(\frac{\partial\widetilde{y}}{\partial\tau}\cdot\nabla\right)\overline{z}\,d\tau-\int_{\frac{T}{2}}^{t}\overline{z}\cdot\left(\nabla\frac{\partial\widetilde{y}}{\partial\tau}\right)d\tau\\
&\quad-\int_{\frac{T}{2}}^{t}\left(\frac{\partial\widetilde{B}}{\partial\tau}\cdot\nabla\right)\overline{C}\,d\tau-\int_{\frac{T}{2}}^{t}\overline{C}\cdot\left(\nabla\frac{\partial\widetilde{B}}{\partial\tau}\right)d\tau\\
&\quad-z+z\left(\cdot,\frac{T}{2}\right) \qquad \text{in } \omega,\\
\operatorname{div}\overline{z}_1 &= 0 \qquad \text{in } \omega,\\
\overline{z}_1 &= 0 \qquad \text{on } \partial\omega.
\end{aligned}\tag{4.7}$$

Subtracting (4.5) and (4.7), one sees that $\overline{z}_2=\overline{z}-\overline{z}_1$ and $\overline{q}_2=\overline{q}-\overline{q}_1$ satisfy the

homogeneous Stokes equations,

$$\begin{aligned} \Delta \overline{z}_2 + \nabla \overline{q}_2 = 0 \qquad & \text{in } \omega, \\ \operatorname{div} \overline{z}_2 = 0 \qquad & \text{in } \omega. \end{aligned} \tag{4.8}$$

From (4.7), using the well-known estimate for the weak solution of the steady state Stokes equations with null boundary conditions as well, it follows that

$$\begin{aligned} &|\nabla \overline{q}_1|_{((H_0^1(\omega_1))^2)'} \\ &\quad \le c\Bigg(|\overline{h}|_{(L^2(\omega))^2} + |z|_{(L^2(\omega))^2} + |-(\widetilde{y}\cdot\nabla)\overline{z} + \overline{z}\cdot(\nabla\widetilde{y}) + (\widetilde{B}\cdot\nabla)\overline{C} + \overline{C}\cdot(\nabla\widetilde{B})|_{((H_0^1(\omega))^2)'} \\ &\qquad + \left| \int_{\frac{T}{2}}^t \left| \left(\frac{\partial \widetilde{y}}{\partial \tau}\cdot\nabla\right)\overline{z} - \overline{z}\cdot\left(\nabla\frac{\partial \widetilde{y}}{\partial \tau}\right) - \left(\frac{\partial \widetilde{B}}{\partial \tau}\cdot\nabla\right)\overline{C} - \overline{C}\cdot\left(\nabla\frac{\partial \widetilde{B}}{\partial \tau}\right) \right|_{((H_0^1(\omega))^2)'} d\tau \right| \\ &\qquad + \left| z\left(\cdot, \frac{T}{2}\right) \right|_{(L^2(\omega))^2} \Bigg). \end{aligned}$$

Estimating the $((H_0^1(\omega))^2)'$ norms of all the products in the right-hand side of the above inequality in the usual way (recalling that $\widetilde{y}, \widetilde{B} \in W^{1,\infty}(0,T;(W^{2,p}(\Omega))^2)$ with $p > 2$), we can write

$$\begin{aligned} &|\nabla \overline{q}_1|_{((H_0^1(\omega_1))^2)'} \\ &\quad \le c\Bigg(|\overline{h}|_{(L^2(\omega))^2} + |\overline{z}|_{(L^2(\omega))^2} + |\overline{C}|_{(L^2(\omega))^2} \\ &\qquad + \left| \int_{\frac{T}{2}}^t \left(|\overline{z}|_{(L^2(\omega))^2} + |\overline{C}|_{(L^2(\omega))^2} \right) d\tau \right| \\ &\qquad + |z|_{(L^2(\omega))^2} + \left| z\left(\cdot, \frac{T}{2}\right) \right|_{(L^2(\omega))^2} \Bigg). \end{aligned} \tag{4.9}$$

To estimate the $((H_0^1(\omega_1))^2)'$ norm of $\nabla \overline{q}_2$, we first remark that $\overline{q}_2$ is harmonic in ω (because, by (4.8), $\Delta \overline{q}_2 = -\Delta \operatorname{div} z_2 = 0$ in ω). So, applying the Laplace operator to (4.8), we obtain

$$\Delta^2 \overline{z}_2 = 0 \text{ in } \omega.$$

A standard interior estimate for the solutions of homogeneous elliptic equations then gives

$$|\overline{z}_2|_{(H^2(\omega_1))^2} \le c|\overline{z}_2|_{(L^2(\omega))^2} \le c\left(|\overline{z}|_{(L^2(\omega))^2} + |\overline{z}_1|_{(L^2(\omega))^2} \right). \tag{4.10}$$

Now using the estimate for the weak solution of (4.7) (interpreted as a stationary Stokes system) once again, in the same way as before, we obtain

$$\begin{aligned} &|\overline{z}_1|_{(L^2(\omega))^2} \\ &\quad \le c\Bigg(|\overline{h}|_{(L^2(\omega))^2} + |\overline{z}|_{(L^2(\omega))^2} + |\overline{C}|_{(L^2(\omega))^2} \\ &\qquad + \left| \int_{\frac{T}{2}}^t \left(|\overline{z}|_{(L^2(\omega))^2} + |\overline{C}|_{(L^2(\omega))^2} \right) d\tau \right| \\ &\qquad + |z|_{(L^2(\omega))^2} + \left| z\left(\cdot, \frac{T}{2}\right) \right|_{(L^2(\omega))^2} \Bigg). \end{aligned} \tag{4.11}$$

From (4.8) it follows that

$$|\nabla \overline{q}_2|_{((H_0^1(\omega_1))^2)'} \le |\overline{z}_2|_{(H^1(\omega_1))^2}.$$

This last inequality taken together with (4.10) and (4.11) yields

$$\begin{aligned} &|\nabla \overline{q}_2|_{((H_0^1(\omega_1))^2)'} \\ &\quad \le c\bigg(|\overline{h}|_{(L^2(\omega))^2} + |\overline{z}|_{(L^2(\omega))^2} + |\overline{C}|_{(L^2(\omega))^2} \\ &\quad\quad + \left| \int_{\frac{T}{2}}^t \left(|\overline{z}|_{(L^2(\omega))^2} + |\overline{C}|_{(L^2(\omega))^2} \right) d\tau \right| \\ &\quad\quad + |z|_{(L^2(\omega))^2} + \left| z\left(\cdot, \frac{T}{2}\right)\right|_{(L^2(\omega))^2} \bigg). \end{aligned} \tag{4.12}$$

Since $\overline{q} = \overline{q}_1 + \overline{q}_2$, inequalities (4.9) and (4.12) give

$$\begin{aligned} &|\nabla \overline{q}|_{((H_0^1(\omega_1))^2)'} \\ &\quad \le c\bigg(|\overline{h}|_{(L^2(\omega))^2} + |\overline{z}|_{(L^2(\omega))^2} + |\overline{C}|_{(L^2(\omega))^2} \\ &\quad\quad + \left| \int_{\frac{T}{2}}^t \left(|\overline{z}|_{(L^2(\omega))^2} + |\overline{C}|_{(L^2(\omega))^2} \right) d\tau \right| \\ &\quad\quad + |z|_{(L^2(\omega))^2} + \left| z\left(\cdot, \frac{T}{2}\right)\right|_{(L^2(\omega))^2} \bigg). \end{aligned} \tag{4.13}$$

Treating equations (4.6) in the same way as equations (4.5) we obtain

$$\begin{aligned} &|\nabla \overline{r}|_{((H_0^1(\omega_1))^2)'} \\ &\quad \le c\bigg(|\overline{H}|_{(L^2(\omega))^2} + |\overline{z}|_{(L^2(\omega))^2} + |\overline{C}|_{(L^2(\omega))^2} \\ &\quad\quad + \left| \int_{\frac{T}{2}}^t \left(|\overline{z}|_{(L^2(\omega))^2} + |\overline{C}|_{(L^2(\omega))^2} \right) d\tau \right| \\ &\quad\quad + |C|_{(L^2(\omega))^2} + \left| C\left(\cdot, \frac{T}{2}\right)\right|_{(L^2(\omega))^2} \bigg). \end{aligned} \tag{4.14}$$

Now we take inequalities (4.4), (4.13), and (4.14) together to obtain

$$\begin{aligned} &\int_{Q_{\omega_1}} e^{2s\alpha} s^{\frac{11}{4}} \widehat{\varphi}^{\frac{11}{4}} (\overline{q}^2 + \overline{r}^2) dxdt \\ &\quad \le c(\lambda, s, \delta) \bigg(\int_{Q_\omega} e^{2s\delta\widehat{\alpha}} (|z|^2 + |C|^2) dxdt + \int_{Q_\omega} e^{2s\delta\widehat{\alpha}} (|h|^2 + |H|^2) dxdt \\ &\quad\quad + \left| z\left(\cdot, \frac{T}{2}\right)\right|^2_{(L^2(\omega))^2} + \left| C\left(\cdot, \frac{T}{2}\right)\right|^2_{(L^2(\omega))^2} \bigg) \qquad \text{for } \frac{1}{2} < \delta < \delta_0(\lambda). \end{aligned} \tag{4.15}$$

Next inserting (4.15) into the Carleman-type inequality (4.3), we obtain

$$\begin{aligned}
&\int_Q e^{2s\alpha}\frac{1}{\varphi}(|z|^2+|C|^2)dxdt \\
&\qquad \le c(\lambda,s,\delta)\bigg(\int_{Q_\omega} e^{2s\delta\widehat{\alpha}}(|z|^2+|C|^2)dxdt+\int_Q e^{2s\delta\widehat{\alpha}}(|h|^2+|H|^2)dxdt \\
&\qquad\quad +\left|z\left(\cdot,\frac{T}{2}\right)\right|^2_{(L^2(\Omega))^2}+\left|C\left(\cdot,\frac{T}{2}\right)\right|^2_{(L^2(\Omega))^2}\bigg) \\
&\qquad\qquad \text{for } \lambda>\lambda_0,\ s>s_0(\lambda),\ \text{and } \frac{1}{2}<\delta<\delta_0(\lambda).
\end{aligned} \tag{4.16}$$

In a standard way (see [9], [6], or [7] for details) we can convert inequality (4.16) into a similar one in which the new weight functions $e^{2s\widehat{\beta}}, (T-t)^8$, and $e^{2s\delta\widehat{\beta}}$ replace $e^{2s\alpha}$, $1/\varphi$, and $e^{2s\delta\widehat{\alpha}}$, respectively, namely,

$$\begin{aligned}
&\int_Q e^{2s\widehat{\beta}}(T-t)^8(|z|^2+|C|^2)dxdt \\
&\qquad \le c(\lambda,s,\delta)\bigg(\int_{Q_\omega} e^{2s\delta\widehat{\beta}}(|z|^2+|C|^2)dxdt+\int_Q e^{2s\delta\widehat{\beta}}(|h|^2+|H|^2)dxdt \\
&\qquad\quad +\left|z\left(\cdot,\frac{T}{2}\right)\right|^2_{(L^2(\Omega))^2}+\left|C\left(\cdot,\frac{T}{2}\right)\right|^2_{(L^2(\Omega))^2}\bigg) \\
&\qquad\qquad \text{for } \lambda>\lambda_0,\ s>s_0(\lambda),\ \text{and } \frac{1}{2}<\delta<\delta_0(\lambda).
\end{aligned} \tag{4.17}$$

Arguing by contradiction one can eliminate the $(L^2(\Omega))^2$ norms of $z(\cdot,T/2)$ and $C(\cdot,T/2)$ in (4.17) and show that (4.1) is true for suitable constants $c(\lambda,s,\delta)$. (We again refer the reader to [9], [6], or [7] for details.) So the proof is complete. □

From the observability inequality (4.1), one can derive the next one, which is in fact an L^2 estimate of z and C taken on Ω at the moment $t=0$ by their values taken on ω but at all the moments $t\in[0,T]$. (We refer the reader to [7] or [6] for the proof.)

THEOREM 4.2. *Under the hypotheses of Theorem* 4.1 *there exists* $\lambda_0>0$ *such that for any* $\lambda>\lambda_0$ *one can find* $s_0(\lambda)>0$ *and* $\delta_0(\lambda)\in(1/2,1)$ *such that for* $s>s_0(\lambda)$ *and* $1/2<\delta<\delta_0(\lambda)$ *there is some* $c(\lambda,s,\delta)>0$ *such that the following inequality holds:*

$$\begin{aligned}
&\int_\Omega \left(|z(x,0)|^2+|C(x,0)|^2\right)dx \\
&\qquad \le c(\lambda,s,\delta)\left(\int_{Q_\omega} e^{2s\delta\widehat{\beta}}\left(|z|^2+|C|^2\right)dx\,dt+\int_Q e^{2s\delta\widehat{\beta}}\left(|h|^2+|H|^2\right)dx\,dt\right)
\end{aligned} \tag{4.18}$$

for all $h,H\in(L^2(Q))^2$ *which satisfy* $\operatorname{div} h=\operatorname{div} H=0$ *in* Q *and* $H\cdot N=0$ *on* Σ, *and all corresponding solutions* $(z,C,q)\in(H^{2,1}(Q))^4\times L^2(0,T;H^1(\Omega))$ *of system* (3.1).

Thus, we have the appropriate tools to approach the controllability problem we are dealing with.

Let us also remark that, as we have already mentioned in the introduction, the results contained in Theorems 4.1 and 4.2 could be substantially improved if we should use the more general Carleman inequality for weak solutions of elliptic equations

with $H^{-1}(\Omega)$ right-hand side in [10] instead of the Carleman inequality for strong solutions of elliptic equations with $L^2(\Omega)$ right-hand side in [9]. Indeed, it seems that applying the new Carleman inequality but keeping the approach here (that is, the use of the primitives with respect to t of the solutions of (3.1)), one could show that the observability inequalities (4.1) and (4.18) (with slightly modified $\widehat{\beta}$) are still valid for $\widetilde{y}$ and $\widetilde{B}$ in $(L^\infty(Q))^2$ with $\partial\widetilde{y}/\partial t$ and $\partial\widetilde{B}/\partial t$ in $L^2(0,T;(L^\infty(\Omega))^2\cap(H^\gamma(\Omega))^2)$, where γ may be any positive exponent. But we can expect even more than this: If we should use the Carleman inequality in [10] but follow the approach in [4], then we could obtain observability inequalities like (4.1) and (4.18) (with modified weight functions) for $\widetilde{y}$ and $\widetilde{B}$ in $(L^\infty(Q))^2$ with $\partial\widetilde{y}/\partial t$ and $\partial\widetilde{B}/\partial t$ in $L^2(0,T;(L^\sigma(\Omega))^2)$ only, where σ is larger than 1. (See [4] for the analogous result for the Navier–Stokes equations.)

5. Global exact null controllability for the linearized MHD equations. The linearization of the controlled MHD equations (2.1) with $\nu=\eta=1$ around $(\widetilde{y},\widetilde{B})$ is the following:

$$
\begin{aligned}
&\frac{\partial y}{\partial t}-\Delta y+(\widetilde{y}\cdot\nabla)y+(y\cdot\nabla)\widetilde{y}-(\widetilde{B}\cdot\nabla)B-(B\cdot\nabla)\widetilde{B}\\
&\qquad+\nabla(\widetilde{B}\cdot B)+\nabla p=f+\chi_\omega u && \text{in } Q,\\
&\frac{\partial B}{\partial t}+\widetilde{\operatorname{curl}}(\operatorname{curl}B)+(\widetilde{y}\cdot\nabla)B+(y\cdot\nabla)\widetilde{B}\\
&\qquad-(\widetilde{B}\cdot\nabla)y-(B\cdot\nabla)\widetilde{y}=F+P(\chi_\omega v) && \text{in } Q,\\
&\operatorname{div}y=0,\ \operatorname{div}B=0 && \text{in } Q,\\
&y=0,\ B\cdot N=0,\ \operatorname{curl}B=0 && \text{on } \Sigma,\\
&y(\cdot,0)=y_0,\ B(\cdot,0)=B_0 && \text{in } \Omega,
\end{aligned}
\tag{5.1}
$$

where $(\widetilde{y},\widetilde{B})$ (together with $\widetilde{p}$) is a solution of (2.3). We also associate condition (2.2) to (5.1).

It is known that if $\widetilde{y},\widetilde{B}\in W^{1,\infty}(0,T;(W^{1,\infty}(\Omega))^2)$, $f,F,u,v\in(L^2(Q))^2$ with $\operatorname{div}F=0$ in Q and $F\cdot N=0$ on Σ, and $(y_0,B_0)\in V_1\times V_2$, then the boundary initial-value problem (5.1) has a unique solution $(y,B,p)\in(H^{2,1}(Q))^4\times L^2(0,T;H^1(\Omega))$ (p is unique up to a constant). In addition, the solution satisfies the following estimate:

$$
\begin{aligned}
&|y|_{(H^{2,1}(Q))^2}+|B|_{(H^{2,1}(Q))^2}+|\nabla p|_{(L^2(Q))^2}\\
&\qquad\le c\left(|y_0|_{(H^1(\Omega))^2}+|B_0|_{(H^1(\Omega))^2}+|f|_{(L^2(Q))^2}+|F|_{(L^2(Q))^2}\right.\\
&\qquad\quad\left.+|u|_{(L^2(Q))^2}+|v|_{(L^2(Q))^2}\right).
\end{aligned}
\tag{5.2}
$$

Two weighted L^2 spaces are needed to formulate the global controllability result for the linear equations (5.1). The space $L^2(Q,(T-t)^{-8}e^{-2s\widehat{\beta}})$ consists of all (equivalence classes of) measurable functions $f:Q\longrightarrow\mathbb{R}$ with $(T-t)^{-4}e^{-s\widehat{\beta}}f\in L^2(Q)$, that is,

$$
\int_Q\frac{1}{(T-t)^8}\ e^{-2s\widehat{\beta}}|f|^2dx\,dt<\infty.
$$

The space $L^2(Q,e^{-2s\delta\widehat{\beta}})$ is defined similarly.

THEOREM 5.1. *Let Ω and ω be as in the statement of Theorem 2.1 and let $\widetilde{y}, \widetilde{B} \in W^{1,\infty}(0,T;(W^{2,p}(\Omega))^2)$ with $p > 2$. Then there are $\lambda > 0$, $s > 0$, and $\delta \in (1/2,1)$ such that for any $f, F \in (L^2(Q,(T-t)^{-8}e^{-2s\widehat{\beta}}))^2$ with $\operatorname{div} F = 0$ in Q and $F \cdot N = 0$ on Σ, $(y_0, B_0) \in V_1 \times V_2$, and $\delta' \in (1/2,\delta)$, there exists $(u,v,y,B,p) \in (L^2(Q))^4 \times (H^{2,1}(Q))^4 \times L^2(0,T;H^1(\Omega))$ which satisfies (5.1), (2.2) and the final conditions*

$$y(x,T) = 0 \quad \text{and} \quad B(x,T) = 0 \quad \text{a.e.} \quad x \in \Omega$$

and which has the following decay at $t = T$:

$$u, v, y, B \in (L^2(Q, e^{-2s\delta\widehat{\beta}}))^2,$$

$$e^{-s\delta'\widehat{\beta}}y, e^{-s\delta'\widehat{\beta}}B \in (H^{2,1}(Q))^2.$$

Proof. We need an approximation of the function $\widehat{\beta}$ which should take a finite value at $t = T$, too. For instance, for $\varepsilon > 0$ we could define $\widehat{\beta}_\varepsilon$ as

$$\widehat{\beta}_\varepsilon(t) = \frac{1 - e^{2\lambda|\psi|_{C(\overline{\Omega})}}}{(\theta(t)(T - t + \varepsilon))^8}\,.$$

Let us now fix $\lambda > 0$, $s > 0$, and $\delta \in (1/2, \delta_0(\lambda))$ such that inequalities (4.1) and (4.2) hold. Then for $\varepsilon > 0$ we consider the corresponding auxiliary optimal control problem:

Minimize

$$(P_\varepsilon) \qquad \begin{aligned} &\frac{1}{2}\int_Q e^{-2s\delta\widehat{\beta}}\left(|u|^2 + |v|^2\right)dx\,dt + \frac{1}{2}\int_Q e^{-2s\delta\widehat{\beta}_\varepsilon}\left(|y|^2 + |B|^2\right)dx\,dt \\ &\quad + \frac{1}{2\varepsilon}\int_\Omega \left(|y(x,T)|^2 + |B(x,T)|^2\right)dx \end{aligned}$$

over all $(u,v) \in (L^2(Q))^4$, where (y,B) satisfies (5.1) and (2.2) (together with some p).

It is known that problem (P_ε) has a unique solution $(u_\varepsilon, v_\varepsilon, y_\varepsilon, B_\varepsilon, p_\varepsilon)$ for any $\varepsilon > 0$.

The idea of the proof is to regard the limit of $(u_\varepsilon, v_\varepsilon, y_\varepsilon, B_\varepsilon, p_\varepsilon)$ when $\varepsilon \longrightarrow 0$ as a possible solution of the controllability problem for system (5.1). To prove the convergence of $(u_\varepsilon, v_\varepsilon, y_\varepsilon, B_\varepsilon, p_\varepsilon)$ we need to obtain L^2 estimates for u_ε and v_ε. To achieve this, we shall combine Pontryagin's maximum principle, applied to problems (P_ε), with the observability inequalities (4.1) and (4.2), applied to the adjoint system.

Let $(u_\varepsilon, v_\varepsilon, y_\varepsilon, B_\varepsilon, p_\varepsilon)$ be the solution of problem (P_ε). Pontryagin's maximum principle asserts that there exists a dual process $(z_\varepsilon, C_\varepsilon, q_\varepsilon)$ which, together with $(u_\varepsilon, v_\varepsilon, y_\varepsilon, B_\varepsilon, p_\varepsilon)$, satisfies the adjoint equations

$$(5.3) \qquad \begin{aligned} &\frac{\partial z_\varepsilon}{\partial t} + \Delta z_\varepsilon + (\widetilde{y}\cdot\nabla)z_\varepsilon - z_\varepsilon\cdot(\nabla\widetilde{y}) \\ &\qquad - (\widetilde{B}\cdot\nabla)C_\varepsilon - C_\varepsilon\cdot(\nabla\widetilde{B}) + \nabla q_\varepsilon = e^{-2s\delta\widehat{\beta}_\varepsilon}y_\varepsilon \quad \text{in } Q, \\ &\frac{\partial C_\varepsilon}{\partial t} - \widetilde{\operatorname{curl}}(\operatorname{curl} C_\varepsilon) + P((\widetilde{y}\cdot\nabla)C_\varepsilon + C_\varepsilon\cdot(\nabla\widetilde{y}) \\ &\qquad - (\widetilde{B}\cdot\nabla)z_\varepsilon + z_\varepsilon\cdot(\nabla\widetilde{B})) = e^{-2s\delta\widehat{\beta}_\varepsilon}B_\varepsilon \quad \text{in } Q, \\ &\operatorname{div} z_\varepsilon = 0,\ \operatorname{div} C_\varepsilon = 0 \quad \text{in } Q, \\ &z_\varepsilon = 0,\ C_\varepsilon\cdot N = 0,\ \operatorname{curl} C_\varepsilon = 0 \quad \text{on } \Sigma, \\ &z_\varepsilon(\cdot,T) = -\frac{1}{\varepsilon}\,y_\varepsilon(\cdot,T),\ C_\varepsilon(\cdot,T) = -\frac{1}{\varepsilon}\,B_\varepsilon(\cdot,T) \quad \text{in } \Omega \end{aligned}$$

and the following maximum conditions:

$$u_\varepsilon = \chi_\omega e^{2s\delta\widehat{\beta}} z_\varepsilon, \quad v_\varepsilon = \chi_\omega e^{2s\delta\widehat{\beta}} C_\varepsilon \quad \text{a.e. in } Q. \tag{5.4}$$

We notice that system (5.3) has the form (3.1) with $h = e^{-2s\delta\widehat{\beta}_\varepsilon} y_\varepsilon$ and $H = e^{-2s\delta\widehat{\beta}_\varepsilon} B_\varepsilon$.

Let us integrate the derivative

$$\frac{d}{dt}\int_\Omega (y_\varepsilon \cdot z_\varepsilon + B_\varepsilon \cdot C_\varepsilon)dx$$

from 0 to T and then use (5.1), (5.3), and (5.4). We obtain

$$\begin{aligned}
&\int_{Q_\omega} e^{2s\delta\widehat{\beta}} \left(|z_\varepsilon|^2 + |C_\varepsilon|^2\right) dx\,dt + \int_Q e^{-2s\delta\widehat{\beta}_\varepsilon} \left(|y_\varepsilon|^2 + |B_\varepsilon|^2\right) dx\,dt \\
&\qquad + \frac{1}{\varepsilon}\int_\Omega \left(|y_\varepsilon(x,T)|^2 + |B_\varepsilon(x,T)|^2\right) dx \\
&\qquad = -\int_Q (f\cdot z_\varepsilon + F\cdot C_\varepsilon)dx\,dt - \int_\Omega (y_0(x)\cdot z_\varepsilon(x,0) + B_0(x)\cdot C_\varepsilon(x,0))dx \\
&\qquad \le \left(\int_Q e^{-2s\widehat{\beta}} \frac{1}{(T-t)^8} \left(|f|^2 + |F|^2\right) dx\,dt\right)^{\frac{1}{2}} \\
&\qquad\quad \times \left(\int_Q e^{2s\widehat{\beta}} (T-t)^8 (|z_\varepsilon|^2 + |C_\varepsilon|^2) dx\,dt\right)^{\frac{1}{2}} \\
&\qquad\quad + \left(|y_0|^2_{(L^2(\Omega))^2} + |B_0|^2_{(L^2(\Omega))^2}\right)^{\frac{1}{2}} \left(\int_\Omega (|z_\varepsilon(x,0)|^2 + |C_\varepsilon(x,0)|^2) dx\right)^{\frac{1}{2}}.
\end{aligned} \tag{5.5}$$

Taking inequality (5.5) together with the observability inequalities (4.1) and (4.18) applied to system (5.3), we have

$$\begin{aligned}
&\int_{Q_\omega} e^{2s\delta\widehat{\beta}} \left(|z_\varepsilon|^2 + |C_\varepsilon|^2\right) dx\,dt + \int_Q e^{-2s\delta\widehat{\beta}_\varepsilon} \left(|y_\varepsilon|^2 + |B_\varepsilon|^2\right) dx\,dt \\
&\qquad \le c\left(|y_0|^2_{(L^2(\Omega))^2} + |B_0|^2_{(L^2(\Omega))^2} + \int_Q e^{-2s\widehat{\beta}} \frac{1}{(T-t)^8} \left(|f|^2 + |F|^2\right) dx\,dt\right),
\end{aligned} \tag{5.6}$$

where c is a positive parameter depending on λ, s, and δ. Passing from z_ε and C_ε to u_ε and v_ε in (5.6) by using (5.4), we obtain

$$\begin{aligned}
&\int_{Q_\omega} e^{-2s\delta\widehat{\beta}} \left(|u_\varepsilon|^2 + |v_\varepsilon|^2\right) dx\,dt + \int_Q e^{-2s\delta\widehat{\beta}_\varepsilon} \left(|y_\varepsilon|^2 + |B_\varepsilon|^2\right) dx\,dt \\
&\qquad \le c\left(|y_0|^2_{(L^2(\Omega))^2} + |B_0|^2_{(L^2(\Omega))^2} + \int_Q e^{-2s\widehat{\beta}} \frac{1}{(T-t)^8} \left(|f|^2 + |F|^2\right) dx\,dt\right),
\end{aligned} \tag{5.7}$$

where the positive constant c is independent of ε. Moreover, now putting (5.5), (4.1), (4.2), and (5.6) together, we have

$$\int_\Omega (|y_\varepsilon(x,T)|^2 + |B_\varepsilon(x,T)|^2) dx \le c\varepsilon \tag{5.8}$$

for some positive constant c independent of ε.

By virtue of (5.7) and (5.2), there exists $(u, v, y, B, p) \in (L^2(Q))^4 \times (H^{2,1}(Q))^4 \times L^2(0,T;H^1(\Omega))$ such that, on a subsequence of $\{\varepsilon\}$, as $\varepsilon \longrightarrow 0$,

$$\begin{aligned} &u_\varepsilon \longrightarrow u, \quad v_\varepsilon \longrightarrow v && \text{weakly in } (L^2(Q))^2,\\ &y_\varepsilon \longrightarrow y, \quad B_\varepsilon \longrightarrow B && \text{weakly in } (H^{2,1}(Q))^2,\\ &p_\varepsilon \longrightarrow p && \text{weakly in } L^2(0,T;H^1(\Omega)). \end{aligned}$$

Thus, letting $\varepsilon \longrightarrow 0$ in (5.1), where u, v, y, B, and p are replaced by u_ε, v_ε, y_ε, B_ε, and p_ε, we see that u, v, y, B, and p satisfy (5.1), too. In addition, by (5.8), we have

$$y(x,T) = 0 \ \text{ and } \ B(x,T) = 0 \ \text{ a.e. } \ x \in \Omega.$$

Finally, the indicated decay of u, v, y, and B at $t = T$ is obtained as in [6]. So, the proof of Theorem 5.1 is complete. □

6. Proof of Theorem 2.1. We shall reduce the controllability of the solution $(\widetilde{y}, \widetilde{B})$ of the MHD equations (2.3) to the controllability of the null solution of a certain version of (2.3) by subtracting (2.1) and (2.3). The differences $y - \widetilde{y}$, $B - \widetilde{B}$, and $p - \widetilde{p}$, also denoted by y, B, and p, satisfy

$$\begin{aligned} &\frac{\partial y}{\partial t} - \Delta y + (y\cdot\nabla)y + (\widetilde{y}\cdot\nabla)y + (y\cdot\nabla)\widetilde{y}\\ &\qquad - (B\cdot\nabla)B - (\widetilde{B}\cdot\nabla)B - (B\cdot\nabla)\widetilde{B}\\ &\qquad + \nabla\left(\frac{1}{2}\ B^2\right) + \nabla(\widetilde{B}\cdot B) + \nabla p = \chi_\omega u && \text{in } Q,\\ &\frac{\partial B}{\partial t} + \widetilde{\operatorname{curl}}(\operatorname{curl} B) + (y\cdot\nabla)B + (\widetilde{y}\cdot\nabla)B + (y\cdot\nabla)\widetilde{B}\\ &\qquad - (B\cdot\nabla)y - (\widetilde{B}\cdot\nabla)y - (B\cdot\nabla)\widetilde{y} = P(\chi_\omega v) && \text{in } Q,\\ &\operatorname{div} y = 0, \ \operatorname{div} B = 0 && \text{in } Q,\\ &y = 0, \ B\cdot N = 0, \ \operatorname{curl} B = 0 && \text{on } \Sigma,\\ &y(\cdot,0) = y_0, \ B(\cdot,0) = B_0 && \text{in } \Omega. \end{aligned} \tag{6.1}$$

The differences $y_0 - \widetilde{y}(\cdot,0)$ and $B_0 - \widetilde{B}(\cdot,0)$ have been denoted here by y_0 and B_0, too. In this way, the original controllability problem can be replaced by that of finding (u, v, y, B, p), which satisfies (6.1) but also $y(\cdot,T) = 0$ and $B(\cdot,T) = 0$ a.e. in Ω.

The null controllability problem for (6.1) can be reformulated as an invertibility property for a certain nonlinear map. Let us define this map in what follows after introducing the needed function spaces.

We take $\lambda > 0$, $s > 0$, and $\delta \in (1/2, 1)$ as in the statement of Theorem 5.1. Let $1/2 < \delta' < \delta$. We denote by $X(Q)$ the space of all $(u, v, y, B, p) \in (L^2(Q))^4 \times (H^{2,1}(Q))^4 \times L^2(0,T;H^1(\Omega))$ which satisfy $(e^{-s\delta'\widehat{\beta}}y, e^{-s\delta'\widehat{\beta}}B) \in (H^{2,1}(Q))^4$, $\partial y/\partial t - \Delta y + (\widetilde{y}\cdot\nabla)y + (y\cdot\nabla)\widetilde{y} - (\widetilde{B}\cdot\nabla)B + (B\cdot\nabla)\widetilde{B} + \nabla(\widetilde{B}\cdot B) + \nabla p - \chi_\omega u \in (L^2(Q,(T-t)^{-8}e^{-2s\widehat{\beta}}))^2$, $\partial B/\partial t + \widetilde{\operatorname{curl}}\,(\operatorname{curl} B) + (\widetilde{y}\cdot\nabla)B + (y\cdot\nabla)\widetilde{B} - (\widetilde{B}\cdot\nabla)y - (B\cdot\nabla)\widetilde{y} - P(\chi_\omega v) \in (L^2(Q,(T-t)^{-8}e^{-2s\widehat{\beta}}))^2$, and

$$\begin{aligned} &\operatorname{div} y = 0, \ \operatorname{div} B = 0 && \text{in } Q,\\ &y = 0, \ B\cdot N = 0, \ \operatorname{curl} B = 0 && \text{on } \Sigma,\\ &y(\cdot,T) = 0, \ B(\cdot,T) = 0 && \text{a.e. in } \Omega. \end{aligned}$$

The space $X(Q)$ becomes a Banach space if we endow it with the norm

$$
\begin{aligned}
|(u,v,y,B,p)|_{X(Q)} = \Bigg(& |u|^2_{(L^2(Q))^2} + |v|^2_{(L^2(Q))^2} \\
& + |e^{-s\delta'\widehat{\beta}} y|^2_{(H^{2,1}(Q))^2} + |e^{-s\delta'\widehat{\beta}} B|^2_{(H^{2,1}(Q))^2} + |p|^2_{L^2(0,T;H^1(\Omega))} \\
& + \int_Q e^{-2s\widehat{\beta}} \frac{1}{(T-t)^8} \Bigg(\left| \frac{\partial y}{\partial t} - \Delta y + (\widetilde{y}\cdot\nabla) y + (y\cdot\nabla)\widetilde{y} \right. \\
& \left. - (\widetilde{B}\cdot\nabla) B - (B\cdot\nabla)\widetilde{B} + \nabla(\widetilde{B}\cdot B) + \nabla p - \chi_\omega u \right|^2 \\
& + \left| \frac{\partial B}{\partial t} + \widetilde{\operatorname{curl}}\,(\operatorname{curl} B) + (\widetilde{y}\cdot\nabla) B + (y\cdot\nabla)\widetilde{B} \right. \\
& \left. - (\widetilde{B}\cdot\nabla) y - (B\cdot\nabla)\widetilde{y} - P(\chi_\omega v) \right|^2 \Bigg) \, dx\, dt \Bigg)^{\frac{1}{2}}.
\end{aligned}
$$

We denote by $Y(Q)$ the space of all $(f,F,y_0,B_0) \in (L^2(Q,(T-t)^{-8}e^{-2s\widehat{\beta}}))^4 \times V_1 \times V_2$ such that $\operatorname{div} F = 0$ in Q and $F\cdot N = 0$ on Σ, which becomes a Banach space, too, if we endow it with the product norm

$$
\begin{aligned}
& |(f,F,y_0,B_0)|_{Y(Q)} \\
& \quad = \left(\int_Q e^{-2s\widehat{\beta}} \frac{1}{(T-t)^8} \left(|f|^2 + |F|^2 \right) dx\, dt + |y_0|^2_{(H^1(\Omega))^2} + |B_0|^2_{(H^1(\Omega))^2} \right)^{1/2}.
\end{aligned}
$$

Now the nonlinear map $\mathcal{A} : X(Q) \longrightarrow Y(Q)$ is defined as follows: for $(u,v,y,B,p) \in X(Q)$,

$$
\begin{aligned}
& \mathcal{A}(u,v,y,B,p) \\
& \quad = \Bigg(\frac{\partial y}{\partial t} - \Delta y + (y\cdot\nabla) y + (\widetilde{y}\cdot\nabla) y + (y\cdot\nabla)\widetilde{y} \\
& \qquad - (B\cdot\nabla) B - (\widetilde{B}\cdot\nabla) B - (B\cdot\nabla)\widetilde{B} \\
& \qquad + \nabla\left(\frac{1}{2} B^2 \right) + \nabla(\widetilde{B}\cdot B) + \nabla p - \chi_\omega u, \\
& \qquad \frac{\partial B}{\partial t} + \widetilde{\operatorname{curl}}\,(\operatorname{curl} B) + (y\cdot\nabla) B + (\widetilde{y}\cdot\nabla) B + (y\cdot\nabla)\widetilde{B} \\
& \qquad - (B\cdot\nabla) y - (\widetilde{B}\cdot\nabla) y - (B\cdot\nabla)\widetilde{y} - P(\chi_\omega v), \\
& \qquad\quad y(\cdot,0), B(\cdot,0) \Bigg).
\end{aligned}
$$

One can show (see [7] or [6]) that if $\delta' > 1/2$, then $\mathcal{A}(u,v,y,B,p) \in Y(Q)$ for $(u,v,y,B,p) \in X(Q)$.

It is easy to calculate the differential of $\mathcal{A}$:

$$\begin{aligned}
&((d\mathcal{A})(\overline{u},\overline{v},\overline{y},\overline{B},\overline{p}))(u,v,y,B,p)\\
&\quad=\Bigg(\frac{\partial y}{\partial t}-\Delta y+(\overline{y}\cdot\nabla)y+(y\cdot\nabla)\overline{y}+(\widetilde{y}\cdot\nabla)y+(y\cdot\nabla)\widetilde{y}\\
&\qquad-(\overline{B}\cdot\nabla)B-(B\cdot\nabla)\overline{B}-(\widetilde{B}\cdot\nabla)B-(B\cdot\nabla)\widetilde{B}\\
&\qquad+\nabla(\overline{B}\cdot B)+\nabla(\widetilde{B}\cdot B)+\nabla p-\chi_\omega u,\\
&\qquad\frac{\partial B}{\partial t}+\widetilde{\operatorname{curl}}\,(\operatorname{curl}B)+(\overline{y}\cdot\nabla)B+(y\cdot\nabla)\overline{B}+(\widetilde{y}\cdot\nabla)B+(y\cdot\nabla)\widetilde{B}\\
&\qquad-(\overline{B}\cdot\nabla)y-(B\cdot\nabla)\overline{y}-(\widetilde{B}\cdot\nabla)y-(B\cdot\nabla)\widetilde{y}-P(\chi_\omega v),\\
&\qquad\quad y(\cdot,0),B(\cdot,0)\Bigg).
\end{aligned}$$

This differential is continuous (see [7]).

Moreover, $\mathcal{A}(0,0,0,0,0)=(0,0,0,0)$. So, we have to show that there exists $\eta>0$ such that for any $(f,F,y_0,B_0)\in Y(Q)$ satisfying

$$|(f,F,y_0,B_0)|_{Y(Q)}<\eta$$

one can find $(u,v,y,B,p)\in X(Q)$ such that

$$\mathcal{A}(u,v,y,B,p)=(f,F,y_0,B_0).$$

(In fact, here it suffices to take $f=F=0$.) According to an infinite-dimensional version of the implicit function theorem (see [1, p. 101]), a sufficient condition assuring such a local invertibility property for $\mathcal{A}$ around $(0,0,0,0,0)$ is that $(d\mathcal{A})(0,0,0,0,0):X(Q)\longrightarrow Y(Q)$ should be an epimorphism. But this expresses nothing else than the global null controllability property for system (5.1) stated by Theorem 5.1. Thus, the proof of Theorem 2.1 is finished.

LQG BALANCING FOR CONTINUOUS-TIME INFINITE-DIMENSIONAL SYSTEMS*

MARK R. OPMEER†

Abstract. In this paper we study the existence of linear quadratic Gaussian (LQG)-balanced realizations for continuous-time infinite-dimensional systems. LQG-balanced realizations are those for which the optimal cost operator for the system and its dual system are equal (and diagonal). The class of systems we consider is that of distributional resolvent linear systems which includes well-posed linear systems as a subclass. We prove the existence of LQG-balanced realizations under a finite cost condition for both the system and its dual system. We also show that an LQG-balanced realization of a well-posed transfer function is well-posed. We further show that approximately controllable and observable LQG-balanced realizations are unique up to a unitary state-space transformation. Finally, we show that the spectrum of the product of the optimal cost operator of a system and its dual system is independent of the particular realization. Our method of proof shows the connections with coprime factorizations, Lyapunov-balanced realizations, and discrete-time systems. The main reason for studying LQG-balanced realizations is that truncated LQG-balanced realizations provide a good approximation of the original system. We show that, under certain conditions, this is also true in the infinite-dimensional case by proving an error bound in the gap-metric.

Key words. balanced realization, infinite-dimensional system, LQG-balanced realization, coprime factorization, Riccati equation

1. Introduction.

Simple models are normally preferred over complex ones in control systems design. Sometimes it is obvious how to construct a simple model for a physical system, but sometimes it is not obvious what the characteristics essential to the controller design of a physical system are. One way of obtaining a simple model in the latter case is to first obtain a sophisticated model that takes every aspect of possible interest into account and then perform model reduction on this sophisticated model. A simple model reduction procedure was introduced by Moore [9] and is now a textbook subject (see, e.g., Zhou and Doyle [24, Chapter 7]). The method proposed by Moore consists of truncating a balanced realization. A balanced realization (also called Lyapunov- or internally balanced) is a realization for which the controllability and observability gramians are equal and diagonal. Lyapunov-balanced realizations are popular because they are relatively easy to compute and there exists an error bound in the H-infinity norm on the basis of which one can show that compensators based on the reduced order model have a certain performance when applied to the full order system. The Lyapunov-balanced realization method is applicable only to stable systems. Alternatively for unstable systems one can use truncations of a linear quadratic Gaussian (LQG)-balanced realization, which for rational transfer functions always exists. An LQG-balanced realization is a realization for which the optimal cost operator for the system and its dual system (with respect to the standard quadratic cost functional) are equal and diagonal. This method was proposed by Verriest [20], [21] and further developed by Jonckheere and Silverman [7].

For an alternative treatment see Mustafa and Glover [10], and for the discrete-time case see Hoffmann, Prätzel-Wolters, and Zerz [6]. The computation of an LQG-balanced realization can also be performed reasonably efficiently, and there exists an error bound in the gap-metric which provides advantages similar to those of the H-infinity error bound for the truncated Lyapunov-balanced realization.

In the case that the system is infinite-dimensional, the model/controller approximation becomes essential. One would like to use the methods of balanced truncation and LQG-balanced truncation in this case, too.

The existence of Lyapunov-balanced and LQG-balanced realizations for irrational transfer functions is nontrivial. A necessary and sufficient condition for the existence of Lyapunov-balanced realizations in discrete time was given by Young [23], [22] (see [19, section 9.5] for the continuous-time case). A necessary and sufficient condition for the existence of LQG-balanced realizations for discrete-time systems was given in [16]. The first of the main results of the present article shows the analogous result for the continuous-time case.

As in the finite-dimensional case it is essential for controller design to have convergence in the H-infinity norm (for Lyapunov-balanced realizations) or the gap-metric (for LQG-balanced realizations); see [2]. Additional assumptions need to be made to ensure this. Under appropriate additional assumptions, a priori error bounds ensuring such convergence were given in [5] for continuous-time Lyapunov-balanced realizations and in [1] for discrete-time Lyapunov-balanced realizations. The second of the main aims of the present article is to provide a priori error bounds in the gap-metric for LQG-balanced realizations in both discrete and continuous time.

The class of continuous-time systems we consider is very general: it includes virtually all causal time-invariant linear systems studied in the literature. Details on this class of systems are given in section 4.

The proofs of our results are based on the discrete-time case [16] supplemented by recent results on coprime factorizations [3] and on the Cayley transform and the linear quadratic regulator (LQR) problem [15], [12].

2. LQG-balanced realizations: The finite-dimensional case. In this section we review some of the results on finite-dimensional LQG-balanced realizations. We consider systems of the form

$$\dot{x}(t) = Ax(t) + Bu(t), \quad x(0) = x_0, \quad y(t) = Cx(t) + Du(t), \tag{1}$$

where A, B, C, D are matrices of compatible dimensions. We consider the linear quadratic regulator (LQR) problem for the cost functional

$$J(x_0, u) := \int_0^\infty \|u(t)\|^2 + \|y(t)\|^2 \, dt,$$

where y is given in terms of x_0 and u by (1). The LQR problem consists of finding for a given x_0 that u for which $J(x_0, u)$ is minimal. As is well known, this problem has a unique solution when the system is minimal: the optimal input u^{opt} is given by the state feedback $u^{\mathrm{opt}}(t) = -(I + D^*D)^{-1}(D^*C + B^*Q)x(t)$, where Q is the unique nonnegative solution of the Riccati equation

$$A^*Q + QA + C^*C = (C^*D + QB)(I + D^*D)^{-1}(D^*C + B^*Q),$$

and the optimal cost is given by $J(x_0, u^{\mathrm{opt}}) = \langle x_0, Qx_0 \rangle$. By duality the "optimal filter cost" is given by $\langle x_0, Px_0 \rangle$, where P is the unique nonnegative solution of the

Riccati equation

$$PA^* - AP + BB^* = (BD^* + PC^*)(I + DD^*)^{-1}(DB^* + CP).$$

The quantity $\langle x_0, Px_0\rangle$ can be interpreted as a measure of the difficulty of reconstructing the initial state x_0 from noisy measurements. The eigenvalues of the product PQ are similarity invariants; their square roots are called the LQG-characteristic values of the system. These invariants can be interpreted as a measure of how important the subspace generated by the eigenvector is for the compensator design. This can be seen from the LQG-balanced realization. An LQG-balanced realization is a realization such that $P = Q = \Lambda$, where Λ is the diagonal matrix containing the LQG-characteristic values. Let λ_i be the square root of an eigenvalue of PQ with eigenvector x_i of length one. Then, in the LQG-balanced realization, the optimal cost with initial condition x_i is λ_i and the difficulty of reconstructing this initial state from noisy measurements is also λ_i. The idea behind LQG-balanced truncation is to restrict the system to the subspace generated by the eigenvectors corresponding to the largest eigenvalues. Since this subspace is most important for compensator design, the system obtained by LQG-balanced truncation seems to be a reasonable approximation. As mentioned in the introduction there is also an error bound which justifies the above heuristics. Let δ_g denote the gap-metric (see Zhou and Doyle [24, Chapter 7]), Σ the original (n-dimensional) system, and Σ_k the k-dimensional LQG-balanced truncation. Then

$$\delta_g(\Sigma, \Sigma_k) \le 2 \sum_{i=k+1}^{n} \frac{\lambda_i}{\sqrt{1+\lambda_i^2}};$$

see Mustafa and Glover [10, section 8.4.5].

3. Discrete-time systems. In this section we review the results in [16] on discrete-time infinite-dimensional LQG-balanced realizations and give some extensions. The discrete-time case is a key ingredient for the proof in continuous time.

Let $\mathcal{U}$, $\mathcal{X}$, $\mathcal{Y}$ be separable Hilbert spaces and

$$\begin{bmatrix} A & B \\ C & D \end{bmatrix} \in \mathcal{L}\left(\begin{bmatrix} \mathcal{X} \\ \mathcal{U} \end{bmatrix}, \begin{bmatrix} \mathcal{X} \\ \mathcal{Y} \end{bmatrix}\right).$$

Such a block operator will be called a *discrete-time system*. We will also denote such a block operator using the notation $[A, B; C, D]$ (we denote a block row of operators by $[X, Y]$ and a block column by $[X; Y]$). We denote the set of nonnegative integers by $\mathbb{Z}^+$. For a given initial state $x_0 \in \mathcal{X}$ and input $u : \mathbb{Z}^+ \to \mathcal{U}$ define the state $x : \mathbb{Z}^+ \to \mathcal{X}$ and output $y : \mathbb{Z}^+ \to \mathcal{Y}$ by

$$x_{n+1} = Ax_n + Bu_n, \quad x_0 = x^0, \quad y_n = Cx_n + Du_n. \tag{2}$$

A sequence $h : \mathbb{Z}^+ \to \mathcal{H}$ is called Z-transformable if the power series

$$\sum_{i=0}^{\infty} h_i z^i$$

has a positive radius of convergence. The Z-transform of a Z-transformable sequence h is defined to be the sum of this series and is denoted by $\hat{h}$. For operators A, B, C, D as above define the *transfer function* $G : \mathbb{D}_r \to \mathcal{L}(\mathcal{U}, \mathcal{Y})$ by

$$G(z) = D + \sum_{i=0}^{\infty} CA^i B z^{i+1},$$

where $\mathbb{D}_r$ is defined to be the largest disc centered at the origin for which the above sum converges (note that it definitely converges on the disc centered at the origin with radius $1/r(A)$, where $r(A)$ is the spectral radius of the operator A). If the input sequence u is Z-transformable, then the output sequence y is also Z-transformable, and if $x^0 = 0$, then the Z-transform of the output is given by

$$\hat{y}(z) = G(z)\hat{u}(z)$$

on some neighborhood of the origin. The function $D + Cz(I - zA)^{-1}B$ is called the *characteristic function* of the discrete-time system. Note that the transfer function and the characteristic function are equal on some neighborhood of the origin but may not be identically equal. A discrete-time system is called a *realization* of the function G if $G(z) = D + Cz(I - zA)^{-1}B$ on some neighborhood of the origin. Any $\mathcal{L}(\mathcal{U}, \mathcal{Y})$-valued function that is holomorphic at the origin can be realized as the transfer function of some discrete-time system. This discrete-time system is far from unique.

3.1. Lyapunov-balanced realizations in discrete time. Although we are studying LQG-balanced realizations, we do this by relating them to Lyapunov-balanced realizations. In this subsection we review some results on Lyapunov-balanced realizations that are needed in what follows. To define what we exactly mean by a Lyapunov-balanced realization we first have to define the input and output maps and the gramians of a discrete-time system.

The input map of a discrete-time system is defined for finitely nonzero $u : \mathbb{Z}^- \to \mathcal{U}$ by (here $\mathbb{Z}^-$ is the set of negative integers)

$$\mathcal{B}u := \sum_{i=0}^{\infty} A^i B u_{-i-1}.$$

A discrete-time system is called *approximately controllable* if the range of $\mathcal{B}$ is dense in $\mathcal{X}$, and it is called *input stable* if $\mathcal{B}$ extends to a bounded operator from $l^2(\mathbb{Z}^-; \mathcal{U})$ to $\mathcal{X}$. For an input stable discrete-time system we define the *controllability gramian* $L_B \in \mathcal{L}(\mathcal{X})$ by $L_B := \mathcal{B}\mathcal{B}^*$.

The output map of a discrete-time system is defined for $x \in \mathcal{X}$ by

$$(\mathcal{C}x)_k := CA^k x, \quad k \in \mathbb{Z}^+.$$

A discrete-time system is called *approximately observable* if $\mathcal{C}$ is one-to-one, and it is called *output stable* if $\mathcal{C}$ is a bounded operator from $\mathcal{X}$ to $l^2(\mathbb{Z}^+; \mathcal{Y})$. For an output stable discrete-time system we define the *observability gramian* $L_C \in \mathcal{L}(\mathcal{X})$ by $L_C := \mathcal{C}^*\mathcal{C}$. A discrete-time system is called *minimal* if it is both approximately controllable and approximately observable.

The Hankel operator $\mathcal{H}$ of a discrete-time system is defined for finitely nonzero $u : \mathbb{Z}^- \to \mathcal{U}$ by

$$(\mathcal{H}u)_k = \sum_{i=0}^{\infty} CA^i B u_{k-i-1}, \quad k \in \mathbb{Z}^+.$$

Note that $\mathcal{H} = \mathcal{C}\mathcal{B}$ and that $\mathcal{H}$ depends only on the transfer function of the system.

DEFINITION 3.1. *A discrete-time system is called* Lyapunov-balanced *if it is input and output stable and $L_B = L_C$, and it is called* compact Lyapunov-balanced *if, in addition, $L_B = L_C$ is compact.*

Young [23], [22] proved that every holomorphic uniformly bounded function on the unit disc (i.e., every element of $\mathbf{H}^\infty(\mathbb{D}, \mathcal{L}(\mathcal{U}, \mathcal{Y}))$) has a minimal Lyapunov-balanced realization. He also noted that if the Hankel operator that has this given function as symbol is compact then there exists a minimal compact Lyapunov-balanced realization. A simplification of the proof of Young can be found in Peller [17, section 11.2] and an alternative proof can be found in Staffans [19, section 9.5]. Young [23], [22] has also shown that minimal Lyapunov-balanced realizations are unique up to a unitary transformation in the state space. Let $[A, B; C, D]$ be a compact Lyapunov-balanced realization and denote by $P : \mathcal{X} \to \mathcal{X}$ the projection onto the subspace spanned by the eigenvectors of $L_B = L_C$ corresponding to the largest n eigenvalues (eigenvalues are counted with multiplicity and it is assumed here that the $n+1$st eigenvalue is different from the nth eigenvalue). Then $[PAP, PB; CP, D]$ is called the n-dimensional *truncated Lyapunov-balanced realization*. Note that the n-dimensional truncated Lyapunov-balanced realization may not be defined for every $n \in \mathbb{Z}^+$ due to repeated eigenvalues. Since eigenvalues of compact operators have finite multiplicity it is defined for infinitely many values of n. When we mention n-dimensional truncated Lyapunov-balanced realizations in what follows we will implictely assume that n is such that this notion is well defined. A truncated Lyapunov-balanced realization is not unique, since the Lyapunov-balanced realization is not. However, since two minimal Lyapunov-balanced realizations of the same transfer function are unitarily equivalent, so are all n-dimensional truncated balanced realizations. Consequently the transfer function of an n-dimensional truncated balanced realization G^n is well defined. The whole idea of Lyapunov-balanced realizations is that G^n is a good approximation of G. That this is indeed the case under certain conditions was proven by Bonnet [1]. The result of Bonnet is the discrete-time version of the continuous-time result in [5]. We summarize the results of Young and Bonnet in the following theorem. We note that the singular values of a compact operator T are the square roots of the eigenvalues of T^*T and that an operator is called *nuclear* if it is compact and its singular values form a summable sequence. The *Hankel singular values* of a system are the singular values of its Hankel operator.

THEOREM 3.2. 1. *Every function in* $\mathbf{H}^\infty(\mathbb{D}, \mathcal{L}(\mathcal{U}, \mathcal{Y}))$ *has a minimal Lyapunov-balanced realization. If the Hankel operator of the function is compact, then it has a minimal compact Lyapunov-balanced realization.*

2. *If, in addition, the Hankel operator of the function is nuclear and the input and output spaces are finite-dimensional, then*

$$\|G - G^n\|_\infty \leq 2 \sum_{i=n+1}^{\infty} \sigma_i,$$

where G^n *is the transfer function of a truncated compact Lyapunov-balanced realization of* G *and the* σ_i *are the Hankel singular values.*

Part 2 of the above theorem was proven in [1], following the continuous-time version in [5], only for the case where the Hankel singular values are distinct. As indicated in [5] the generalization to the case of possibly repeating Hankel singular values is not difficult, except notationally. Details may be found in [14, Chapter 10].

3.2. LQG-balanced realizations in discrete time. In this subsection we summarize the results obtained in [16] on LQG-balanced realizations in discrete time. We also extend these by obtaining an error bound on truncated compact LQG-balanced realizations.

To exactly define the concept of an LQG-balanced discrete-time system we first consider the LQR problem. This problem is as follows: for given $x^0 \in \mathcal{X}$ find an input u that minimizes

$$J(x^0, u) := \sum_{n=0}^{\infty} \|u_n\|^2 + \|y_n\|^2, \tag{3}$$

where y is given in terms of x^0 and u by (2). We introduce the following concept: a discrete-time system satisfies the *finite cost condition* if for every $x^0 \in \mathcal{X}$ there exists a $u \in l^2(\mathbb{Z}^+;\mathcal{U})$ such that the corresponding output $y \in l^2(\mathbb{Z}^+;\mathcal{Y})$. It is well known (see, e.g., [4]) that if the finite cost condition is satisfied, then for every $x^0 \in \mathcal{X}$ there exists a unique $u^{\mathrm{opt}} \in l^2(\mathbb{Z}^+;\mathcal{U})$ that minimizes the cost function (3) and there exists a bounded nonnegative operator Q such that the minimal cost is given by $\langle Qx^0, x^0\rangle$. This operator Q is called the *optimal cost operator*. Similarly, if for the *dual system*

$$\begin{bmatrix} A & B \\ C & D \end{bmatrix}^* = \begin{bmatrix} A^* & C^* \\ B^* & D^* \end{bmatrix}$$

the finite cost condition is satisfied, then there exists an optimal cost operator P for this dual system. This operator P is called the *dual optimal cost operator* of the original system.

Definition 3.3. *A discrete-time system is called* LQG-balanced *if it and its dual both satisfy the finite cost condition and $P = Q$, and it is called* compact LQG-balanced *if, in addition, $P = Q$ is compact.*

Below we state not only the main results obtained in [16], but also some main steps in the proof. These intermediate results are also necessary to obtain the continuous-time analogues.

The optimal cost operator satisfies the following Riccati equation:

$$A^*QA - Q + C^*C = (C^*D + A^*QB)(I + D^*D + B^*QB)^{-1}(B^*QA + D^*C).$$

The optimal input u^{opt} can be given by a state feedback. To explain this we consider the concept of an admissible state feedback pair.

Definition 3.4. *An admissible state feedback pair for a discrete-time system is a pair $[K, F] \in \mathcal{L}([\mathcal{X},\mathcal{U}],\mathcal{U})$ such that $I - F$ is boundedly invertible. The closed-loop system is given by*

$$A^{\mathrm{cl}} := A + B(I - F)^{-1}K, \quad B^{\mathrm{cl}} := B(I - F)^{-1},$$

$$C^{\mathrm{cl}} := \begin{bmatrix} (I - F)^{-1}K \\ C + D(I - F)^{-1}K \end{bmatrix}, \quad D^{\mathrm{cl}} := \begin{bmatrix} (I - F)^{-1} \\ D(I - F)^{-1} \end{bmatrix}.$$

This closed-loop system is obtained by adding the equation $u_n = Kx_n + Fu_n + r_n$ to (2), considering $[u; y]$ as the new output and r as the new input, and solving. The state feedback pair

$$K := -(I + D^*D + B^*QB)^{-1/2}(D^*C + B^*QA), \quad F := I - (I + D^*D + B^*QB)^{-1/2}$$

is admissible and with zero input and initial condition x^0 the output of the closed-loop system is exactly $[u^{\mathrm{opt}}; y^{\mathrm{opt}}]$, the optimal input and output for the system $[A, B; C, D]$. The closed-loop system with this specific admissible state feedback pair will be called the *optimal closed-loop system* corresponding to the system $[A, B; C, D]$.

We give some properties of the optimal closed-loop system that were proven in [16] and some that follow from results in [3]. To formulate these we first recall the concept of a (normalized) right coprime factor.

DEFINITION 3.5. *A function* $[M;N] \in \mathbf{H}^\infty(\mathbb{D}, \mathcal{L}(\mathcal{U}, [\mathcal{U};\mathcal{Y}]))$ *is called a right* factor *of a function* G *if* M *is invertible on some neighborhood of the origin and* $G = NM^{-1}$ *on this region.* M *and* N *as above are called right* coprime *if there exists* $[\tilde{X}, \tilde{Y}] \in \mathbf{H}^\infty(\mathbb{D}, \mathcal{L}([\mathcal{U},\mathcal{Y}],\mathcal{U}))$ *such that* $\tilde{X}M - \tilde{Y}N = I$ *on the unit disc.* $[M;N]$ *as above is called* normalized *if* $M^*M + N^*N = I$ *almost everywhere on the unit circle.*

We note that normalized right coprime factors are unique up to a unitary transformation in $\mathcal{L}(\mathcal{U})$. The following theorem relates factorizations to the optimal closed-loop system.

THEOREM 3.6. *If the system* $[A, B; C, D]$ *satisfies the finite cost condition, then the transfer function of its optimal closed-loop system is a normalized right factor of its transfer function. If, in addition, the dual system also satisfies the finite cost condition, then this factor is right coprime.*

Proof. The first part of the proof follows from Corollary 5.8 of [16]. The second part follows from Lemma 6.7 of [16] and the discrete-time version of [3, Corollary 7.2]. □

Given a realization $[\check{A}, \check{B}; [\check{C}_1; \check{C}_2], [\check{D}_1; \check{D}_2]]$ of a factor $[M;N]$, we can obtain a realization

$$A := \check{A} - \check{B}\check{D}_1^{-1}\check{C}_1, \quad B := \check{B}\check{D}_1^{-1}, \quad C := \check{C}_2 - \check{D}_2\check{D}_1^{-1}\check{C}_1, \quad D := \check{D}_2\check{D}_1^{-1} \tag{4}$$

of NM^{-1}. This follows from [16, Lemma 5.7]. The next result shows how one can obtain an LQG-balanced realization from a Lyapunov-balanced realization of a normalized right coprime factor.

THEOREM 3.7. *Suppose that* G *has a normalized right coprime factor* $[M;N]$. *Let* $[\check{A}, \check{B}; [\check{C}_1; \check{C}_2], [\check{D}_1; \check{D}_2]]$ *be a minimal Lyapunov-balanced realization of this normalized right coprime factor. Define* $[A, B; C, D]$ *by* (4). *Then* $[A, B; C, D]$ *and its dual both satisfy the finite cost condition; its optimal cost operator is* L, *and its dual optimal cost operator is* $L(I - L^2)^{-1}$, *where* L *is the (controllability and observability) gramian of the Lyapunov-balanced realization.*

Proof. That $[M;N]$ has a minimal Lyapunov-balanced realization follows from Theorem 3.2. The rest follows from the first lines of the proof of [16, Theorem 8.2]. □

We note that $I - L$ has a bounded inverse since the Hankel singular values of the optimal closed-loop system are all strictly smaller than one. This last fact follows from the coprimeness of the factorization as in [3, Corollary 7.2].

From the system $[A, B; C, D]$ in Theorem 3.7 we obtain the LQG-balanced realization $[SAS^{-1}, SB; CS^{-1}, D]$, where $S := (I - L^2)^{-1/4}$. The following theorem summarizes some properties of LQG-balanced realizations.

THEOREM 3.8. 1. *Let* $[A_i, B_i; C_i, D_i]$ *with* $i = 1, 2$ *be discrete-time systems that satisfy the finite cost condition and whose duals also satisfy the finite cost condition. If these two systems have the same transfer function, then the nonzero elements of* $\sigma(P_1Q_1)$ *equal the nonzero elements of* $\sigma(P_2Q_2)$.

2. *If* $[A, B; C, D]$ *and its dual both satisfy the finite cost condition, then its transfer function has an LQG-balanced realization.*

3. *If* $[A_i, B_i; C_i, D_i]$ *with* $i = 1, 2$ *are two minimal LQG-balanced realizations of the same transfer function, then there exists a unitary* $U \in \mathcal{L}(\mathcal{X})$ *such that* $[A_1, B_1; C_1, D_1] = [UA_2U^{-1}, UB_2; C_2U^{-1}, D_2]$.

Proof. 1. This is [16, Lemma 7.2] up to an additional assumption that was made there. There it was assumed that the systems were approximately observable. The reason for this was that in [16, Lemma 6.9] this assumption was needed. It was shown in [3, Lemma 4.9] how this assumption can be removed from [16, Lemma 6.9] and this implies that it can also be removed from [16, Lemma 7.2].

2. This is [16, Theorem 8.2].

3. This is [16, Lemma 8.3]. □

The square roots of the nonzero elements of $\sigma(PQ)$ are called the *LQG-characteristic values*. According to part 1 of Theorem 3.8 they do not depend on the realization but only on the transfer function.

We now introduce the metric in which LQG-balanced approximations converge under suitable assumptions. Assume both G_1 and G_2 have normalized right coprime factors $[M_1; N_1]$ and $[M_2; N_2]$, respectively. Define for $i = 1, 2$ the set $Z_i \subset H^2(\mathbb{D}, [U; Y])$ by $Z_i = \{(M_i v; N_i v) : v \in H^2(\mathbb{D}; U)\}$, and let P_i be the orthogonal projection from $H^2(\mathbb{D}, [U; Y])$ onto Z_i. Further define

$$\delta_g(G_1, G_2) = \|P_1 - P_2\|.$$

Note that this does not depend on the particular normalized right coprime factors chosen. The function δ_g is called the *gap-metric*. More information on the gap-metric can be found in [24, Chapter 17] and for nonrational functions in [25]. What is important for us is that

$$\delta_g(G_1, G_2) \leq \left\| \begin{bmatrix} M_1 \\ N_1 \end{bmatrix} - \begin{bmatrix} M_2 \\ N_2 \end{bmatrix} \right\|_\infty. \tag{5}$$

We define truncated LQG-balanced realizations similarly to truncated Lyapunov-balanced realizations. The following new result provides an a priori error bound in the gap-metric for truncated compact LQG-balanced realizations.

THEOREM 3.9. *Suppose a discrete-time system satisfies the following assumptions:*

- *the finite cost condition is satisfied,*
- *the finite cost condition for the dual system is satisfied,*
- *the product PQ of the optimal cost operator and the dual optimal cost operator is nuclear, and*
- *the input and output spaces are finite-dimensional.*

Then the transfer function G has a compact LQG-balanced realization and

$$\delta_g(G, G^n) \leq 2 \sum_{i=n+1}^{\infty} \frac{\mu_i}{\sqrt{1 + \mu_i^2}}, \tag{6}$$

where G^n is the transfer function of an n-dimensional truncated LQG-balanced realization of G.

Proof. From Theorem 3.6 it follows that the transfer function of the given system has a normalized right coprime factor. We show that the Hankel operator of this normalized right coprime factor is nuclear. It follows from [16, Lemmas 5.1 and 6.9] that $L_B L_C = (I + PQ)^{-1} PQ$, where L_B is the controllability gramian of the optimal closed-loop system and L_C is its observability gramian. Since the product PQ is assumed compact, this shows that the product $L_B L_C$ is compact. The eigenvalues are related by

$$\mu_i = \frac{\sigma_i}{\sqrt{1 - \sigma_i^2}}, \quad \sigma_i = \frac{\mu_i}{\sqrt{1 + \mu_i^2}}, \tag{7}$$

where the μ_i are the square roots of the eigenvalues of PQ and the σ_i are the square roots of the eigenvalues of $L_B L_C$. This shows that the square roots of the eigenvalues of $L_B L_C$ are summable. Denote the Hankel operator of the normalized right coprime factor by Γ. As in [16, Lemma 7.2] it follows that the spectrum of $\Gamma^*\Gamma$ equals the spectrum of $L_B L_C$ and the point spectrum of $\Gamma^*\Gamma$ equals the point spectrum of $L_B L_C$ (both with the possible exception of zero). This shows that $\Gamma^*\Gamma$ has only point spectrum (with the possible exception of zero) and that the square roots of the eigenvalues are summable. This shows that the Hankel operator is nuclear.

Denote the normalized eigenvectors of the gramian L of the Lyapunov-balanced realization of the normalized coprime factor by e_n. Since for the optimal control operators of the LQG-balanced realization we have $P^{\mathrm{bal}} = Q^{\mathrm{bal}} = L(I - L^2)^{-1/2}$ from Theorem 3.7 we see that this LQG-balanced realization is actually compact LQG-balanced, and the corresponding orthonormal basis is $\{e_n\}$. We note that the projections associated to Lyapunov-balanced truncation and to LQG-balanced truncation are equal, since the orthonormal bases (including order) are identical. We conclude that the system obtained by applying (4) to the truncated Lyapunov-balanced realization is the truncated LQG-balanced realization. From Theorem 3.2, (5), and (7) we now obtain the estimate (6). □

4. Resolvent linear systems. In this section we recall the concept of a distributional resolvent linear system introduced in [12].

A finite-dimensional linear system is usually described by specifying four matrices A, B, C, D and defining for a given initial state x_0 and an input function $u \in L^2_{\mathrm{loc}}(0,\infty;\mathbb{C}^m)$ the state $x \in C(0,\infty;\mathbb{C}^n)$ and the output $y \in L^2_{\mathrm{loc}}(0,\infty;\mathbb{C}^p)$ as the unique solutions of

$$\dot{x}(t) = Ax(t) + Bu(t), \quad x(0) = x_0, \quad y(t) = Cx(t) + Du(t). \tag{8}$$

As is well known, these unique solutions are given explicitly by

$$\begin{aligned} x(t) &= \mathrm{e}^{At}x_0 + \int_0^t \mathrm{e}^{A(t-s)}Bu(s)\,ds, \\ y(t) &= C\mathrm{e}^{At}x_0 + \int_0^t C\mathrm{e}^{A(t-s)}Bu(s)\,ds + Du(t). \end{aligned} \tag{9}$$

If we Laplace-transform (8) and solve for x and y, we obtain

$$\begin{aligned} \hat{x}(s) &= (sI - A)^{-1}x_0 + (sI - A)^{-1}B\hat{u}(s), \\ \hat{y}(s) &= C(sI - A)^{-1}x_0 + \big(C(sI - A)^{-1}B + D\big)\,\hat{u}(s). \end{aligned} \tag{10}$$

Our approach to infinite-dimensional systems will be to generalize situation (10) rather than situation (8) or (9).

We first study the generalizations of the matrix-valued functions $(sI - A)^{-1}$, $(sI - A)^{-1}B$, $C(sI - A)^{-1}$, and $C(sI - A)^{-1}B + D$.

DEFINITION 4.1. *A* resolvent linear system *on a triple of Hilbert spaces* $(\mathcal{U}, \mathcal{X}, \mathcal{Y})$ *consists of a nonempty connected open subset* Λ *of the complex plane and four operator valued functions* $\mathfrak{a}, \mathfrak{b}, \mathfrak{c}, \mathfrak{d}$ *satisfying*

$\mathfrak{a} : \Lambda \to \mathcal{L}(\mathcal{X})$ *satisfies*

$$\mathfrak{a}(\beta) - \mathfrak{a}(\alpha) = (\alpha - \beta)\mathfrak{a}(\beta)\mathfrak{a}(\alpha) \quad \textit{for all } \alpha, \beta \in \Lambda; \tag{11}$$

$\mathfrak{b} : \Lambda \to \mathcal{L}(\mathcal{U}, \mathcal{X})$ *satisfies*

$$\mathfrak{b}(\beta) - \mathfrak{b}(\alpha) = (\alpha - \beta)\mathfrak{a}(\beta)\mathfrak{b}(\alpha) \quad \textit{for all } \alpha, \beta \in \Lambda; \tag{12}$$

$\mathfrak{c} : \Lambda \to \mathcal{L}(\mathcal{X}, \mathcal{Y})$ *satisfies*

$$\mathfrak{c}(\beta) - \mathfrak{c}(\alpha) = (\alpha - \beta)\mathfrak{c}(\alpha)\mathfrak{a}(\beta) \quad \textit{for all } \alpha, \beta \in \Lambda; \tag{13}$$

$\mathfrak{d} : \Lambda \to \mathcal{L}(\mathcal{U}, \mathcal{Y})$ *satisfies*

$$\mathfrak{d}(\beta) - \mathfrak{d}(\alpha) = (\alpha - \beta)\mathfrak{c}(\beta)\mathfrak{b}(\alpha) \quad \textit{for all } \alpha, \beta \in \Lambda. \tag{14}$$

The function $\mathfrak{a}$ *is called the* pseudoresolvent*,* $\mathfrak{b}$ *is the* incoming wave function*,* $\mathfrak{c}$ *is the* outgoing wave function*, and* $\mathfrak{d}$ *is the* characteristic function *of the resolvent linear system.*

The motivation for introducing this class of systems is the following connection with discrete-time systems.

DEFINITION 4.2. *Let* $\alpha > 0$*. The Cayley transform with parameter* α *of a resolvent linear system with* $\alpha \in \Lambda$ *is the discrete-time system*

$$A_d := -I + 2\alpha\ \mathfrak{a}(\alpha), \quad B_d := \sqrt{2\alpha}\ \mathfrak{b}(\alpha), \tag{15}$$

$$C_d := \sqrt{2\alpha}\ \mathfrak{c}(\alpha), \qquad D_d := \mathfrak{d}(\alpha). \tag{16}$$

Remark 4.3. The Cayley transform with parameter α gives a one-to-one correspondence between the set of resolvent linear systems with $\alpha \in \Lambda$ and the set of discrete-time systems.

The following relation between the characteristic function of a resolvent linear system and that of its Cayley transform is easily proven: $G(s) = G_d(z)$, where $z := (\alpha - s)/(\alpha + s)$.

We define two subclasses of resolvent linear systems for which one can make sense of the dynamical system (10).

DEFINITION 4.4. *A* distributional resolvent linear system *is a resolvent linear system with the additional property that there exist constants* $\alpha, \beta > 0$ *and a polynomial* p *such that*

$$\Lambda_E := \{s \in \mathbb{C} : \operatorname{Re} s \geq \beta, \quad |\operatorname{Im} s| \leq \mathrm{e}^{\alpha \operatorname{Re} s}\} \subset \Lambda \tag{17}$$

and

$$\|\mathfrak{a}(s)\| \leq p(|s|) \quad \textit{for all } s \in \Lambda_E. \tag{18}$$

A region Λ_E as above is called an exponential region (see Figure 1 for a sketch of the boundary of such a region).

It is easily seen using the functional equations from Definition 4.1 that the functions $\mathfrak{b}$, $\mathfrak{c}$, and $\mathfrak{d}$ of a distributional resolvent linear system are also bounded in norm by a polynomial on the exponential region Λ_E.

DEFINITION 4.5. *A distributional resolvent linear system is called* exponentially bounded *if there exist a constant* $\gamma > 0$ *and a polynomial* p *such that*

$$\Lambda_H := \{s \in \mathbb{C} : \operatorname{Re} s \geq \gamma\} \subset \Lambda \tag{19}$$

and

$$\|\mathfrak{a}(s)\| \leq p(|s|) \quad \textit{for all } s \in \Lambda_H. \tag{20}$$

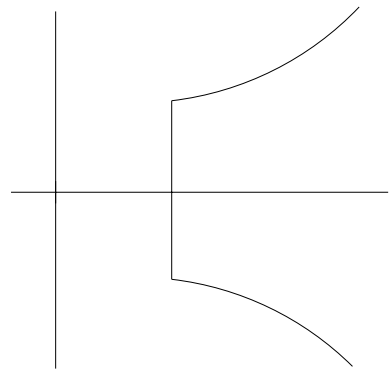

FIG. 1. *A typical example of the boundary of an exponential region.*

Note that the difference between Definitions 4.4 and 4.5 is in the region considered.

Remark 4.6. The term "exponentially bounded" stems from time-domain properties of this subclass. In [12] exponentially bounded distributional resolvent linear systems were called integrated resolvent linear systems. In view of the time-domain results in [13] the term exponentially bounded distributional resolvent linear system, however, seems to be more appropriate.

Remark 4.7. In what follows we will need the following well-known characterization of Laplace transformable Banach space valued distributions by Schwartz. The image of the Schwartz–Laplace transformable Banach space valued distributions is exactly the set of polynomially bounded analytic functions defined on some right half-plane. For details see [18]. A generalization of this Laplace transform was given by Kunstmann. He defined the Laplace transform in such a way that the image of the set of Laplace transformable distributions is exactly the set of functions that are analytic and polynomially bounded on an exponential region (see Kunstmann [8]).

DEFINITION 4.8. *The state x and output y of a distributional resolvent linear system corresponding to the initial state $x_0 \in \mathcal{X}$ and the input u (a $\mathcal{U}$-valued Kunstmann–Laplace transformable distribution) are defined through their Kunstmann–Laplace transforms as*

$$\hat{x}(s) := \mathfrak{a}(s)x_0 + \mathfrak{b}(s)\hat{u}(s), \quad \hat{y}(s) := \mathfrak{c}(s)x_0 + \mathfrak{d}(s)\hat{u}(s). \tag{21}$$

For the case of exponentially bounded distributional resolvent linear systems, if we restrict u to be Schwartz–Laplace transformable, then x and y are Schwartz–Laplace transformable.

For a distributional resolvent linear system we define the set of *stable input-output pairs*

$$\mathcal{V}(x_0) := \left\{ \begin{bmatrix} u \\ y \end{bmatrix} \in \begin{bmatrix} L^2(\mathbb{R}^+;\mathcal{U}) \\ L^2(\mathbb{R}^+;\mathcal{Y}) \end{bmatrix} : y \text{ satisfies (21)} \right\}.$$

DEFINITION 4.9. *We say that a distributional resolvent linear system satisfies the* finite cost condition *if for every $x_0 \in \mathcal{X}$ the set $\mathcal{V}(x_0)$ is nonempty.*

For $\alpha > 0$ the mapping $\mathcal{H}_d : \mathbf{H}^2(\mathbb{C}_0^+;\mathcal{H}) \to \mathbf{H}^2(\mathbb{D};\mathcal{H})$, where $\mathcal{H}$ is a Hilbert space, is unitary. Here $\mathcal{H}_d$ is defined by

$$(\mathcal{H}_d g)(z) = \frac{\sqrt{2\alpha}}{1+z} \; g\left(\alpha \, \frac{1-z}{1+z}\right), \tag{22}$$

with its inverse given by

$$(\mathcal{H}_d^{-1} f)(s) = \frac{\sqrt{2\alpha}}{\alpha + s} \; f\left(\frac{\alpha - s}{\alpha + s}\right). \tag{23}$$

$\mathbb{C}_0^+$ is the right half-plane and $\mathbf{H}^2$ is a Hardy space. The following theorem shows that, for a suitably chosen parameter α, there is a one-to-one relationship between the stable input-output pairs of a distributional resolvent linear system and those of its Cayley transform.

THEOREM 4.10. *Let $(\mathfrak{a}, \mathfrak{b}, \mathfrak{c}, \mathfrak{d})$ be a distributional resolvent linear system with $\alpha \in \Lambda_E$, where $\alpha > 0$. Let $[A_d, B_d; C_d, D_d]$ be its Cayley transform with parameter α. Then $(u; y) \in \mathcal{V}(x_0)$ if and only if $(\mathcal{H}_d u; \mathcal{H}_d y) \in \mathcal{V}_d(x_0)$.*

The following is [12, Lemma 9].

LEMMA 4.11. *For a distributional resolvent linear system on a triple of Hilbert spaces for which the finite cost condition is satisfied there exists a nonnegative operator $Q \in \mathcal{L}(\mathcal{X})$ such that the optimal cost for the cost function*

$$\int_0^\infty \|u(t)\|^2 + \|y(t)\|^2 \, dt \tag{24}$$

is given by $\langle Q x_0, x_0 \rangle$. This Q satisfies the Riccati equation

$$\begin{aligned} &-\mathfrak{a}(\alpha)^* Q - Q\mathfrak{a}(\alpha) + 2\alpha \mathfrak{a}(\alpha)^* Q \mathfrak{a}(\alpha) + \mathfrak{c}(\alpha)^* \mathfrak{c}(\alpha) \\ &= (\mathfrak{c}(\alpha)^* \mathfrak{d}(\alpha) - Q\mathfrak{b}(\alpha) + 2\alpha \mathfrak{a}(\alpha)^* Q \mathfrak{b}(\alpha)) \\ &\quad (I + \mathfrak{d}(\alpha)^* \mathfrak{d}(\alpha) + 2\alpha \mathfrak{b}(\alpha)^* Q \mathfrak{b}(\alpha))^{-1} \\ &\quad (\mathfrak{d}(\alpha)^* \mathfrak{c}(\alpha) - \mathfrak{b}(\alpha)^* Q + 2\alpha \mathfrak{b}(\alpha)^* Q \mathfrak{a}(\alpha)) \end{aligned}$$

for all $\alpha \in \Lambda_E$.

The operator Q mentioned above is called the *optimal cost operator* of the distributional resolvent linear system. We now study admissible state feedbacks.

DEFINITION 4.12. *An* admissible state feedback pair *for a* distributional resolvent linear system *is a pair $[\mathfrak{k}, \mathfrak{f}] : \Lambda_E \to \mathcal{L}(\mathcal{X} \times \mathcal{U}, \mathcal{U})$ that satisfies*

$$\begin{aligned} \mathfrak{k}(\beta) - \mathfrak{k}(\alpha) &= (\alpha - \beta)\mathfrak{k}(\alpha)\mathfrak{a}(\beta), \\ \mathfrak{f}(\beta) - \mathfrak{f}(\alpha) &= (\alpha - \beta)\mathfrak{k}(\beta)\mathfrak{b}(\alpha), \end{aligned}$$

and such that $(I - \mathfrak{f}(s))^{-1}$ exists and is polynomially bounded on some exponential region.

The closed-loop system of a distributional resolvent linear system with an admissible state feedback pair is the distributional resolvent linear system

$$\begin{aligned} \mathfrak{a}^{\mathrm{cl}} &:= \mathfrak{a} + \mathfrak{b}(I - \mathfrak{f})^{-1}\mathfrak{k}, \quad \mathfrak{b}^{\mathrm{cl}} := \mathfrak{b}(I - \mathfrak{f})^{-1}, \\ \mathfrak{c}^{\mathrm{cl}} &:= \begin{bmatrix} (I - \mathfrak{f})^{-1}\mathfrak{k} \\ \mathfrak{c} + \mathfrak{d}(I - \mathfrak{f})^{-1}\mathfrak{k} \end{bmatrix}, \quad \mathfrak{d}^{\mathrm{cl}} := \begin{bmatrix} (I - \mathfrak{f})^{-1} \\ \mathfrak{d}(I - \mathfrak{f})^{-1} \end{bmatrix}. \end{aligned}$$

It can be easily checked that this is indeed a distributional resolvent linear system. The exponential region on which this closed-loop system is defined is the largest exponential region contained in the intersection of the exponential region on which

the original system was defined and the exponential region on which $(I - \mathfrak{f})^{-1}$ exists and is polynomially bounded.

The following is [12, Lemma 8].

LEMMA 4.13. *For a distributional resolvent linear system on a triple of Hilbert spaces for which the finite cost condition is satisfied there exists an admissible state feedback pair such that the optimal control* u^{opt} *for the cost function* (24) *is given by* $\hat{u}^{\mathrm{opt}}(s) = (I - \mathfrak{f}(s))^{-1}\mathfrak{k}(s)x_0$ *for* $s \in \Lambda_E$.

Remark 4.14. A proper proof of Lemma 4.13 is given in [12, Lemma 8]. We do want to mention the main idea of the proof. First, one Cayley-transforms the system with a suitable parameter α. One then defines $\mathfrak{k}(\alpha)$ and $\mathfrak{f}(\alpha)$ in terms of the optimal admissible state feedback pair $[K, F]$ of the Cayley-transformed system. The functions $\mathfrak{k}$ and $\mathfrak{f}$ are then extended to Λ_E using the functional equations from Definition 4.12. In the specific case of the optimal state feedback it is simple to prove that $(I - \mathfrak{f})^{-1}$ exists and is polynomially bounded on an exponential region: its Cayley transform equals the denominator M_d of the normalized right factor mentioned in Theorem 3.6. So the Cayley transform of $(I - \mathfrak{f})^{-1}$ is in H^∞ of the unit disc, from which it follows that $(I - \mathfrak{f})^{-1}$ is in H^∞ of the right half-plane.

DEFINITION 4.15. *An* admissible state feedback pair *for an* exponentially bounded distributional resolvent linear system *is a pair* $[\mathfrak{k}, \mathfrak{f}] : \Lambda_H \to \mathcal{L}(\mathcal{X} \times \mathcal{U}, \mathcal{U})$ *that satisfies*

$$\mathfrak{k}(\beta) - \mathfrak{k}(\alpha) = (\alpha - \beta)\mathfrak{k}(\alpha)\mathfrak{a}(\beta),$$
$$\mathfrak{f}(\beta) - \mathfrak{f}(\alpha) = (\alpha - \beta)\mathfrak{k}(\beta)\mathfrak{b}(\alpha),$$

and such that $(I - \mathfrak{f}(s))^{-1}$ *exists and is polynomially bounded on some right half-plane.*

The closed-loop system of an exponentially bounded distributional resolvent linear system and an admissible state feedback pair in the sense of Definition 4.15 is easily seen to be an exponentially bounded distributional resolvent linear system. Theorem 4.13 holds for exponentially bounded distributional resolvent linear systems with admissible state feedback operator now understood in the stronger sense of Definition 4.15.

DEFINITION 4.16. *The* dual *of a resolvent linear system* $\mathfrak{a}$, $\mathfrak{b}$, $\mathfrak{c}$, $\mathfrak{d}$ *is the resolvent linear system*

$$\mathfrak{a}^d(s) := \mathfrak{a}(\bar{s})^*, \quad \mathfrak{b}^d(s) := \mathfrak{c}(\bar{s})^*, \quad \mathfrak{c}^d(s) := \mathfrak{b}(\bar{s})^*, \quad \mathfrak{d}^d(s) := \mathfrak{d}(\bar{s})^*.$$

Note that the dual of a distributional resolvent linear system is a distributional resolvent linear system and that the dual of an exponentially bounded distributional resolvent linear system is an exponentially bounded distributional resolvent linear system.

The concept of approximate observability has a natural generalization to distributional resolvent linear systems.

DEFINITION 4.17. *A distributional resolvent linear system is said to be* approximately observable *if for zero input the output is zero if and only if the initial state is zero.*

Note that a distributional resolvent linear system is approximately observable if and only if $\mathfrak{c}(s)x_0 = 0$ for all $s \in \Lambda_E$ implies $x_0 = 0$.

DEFINITION 4.18. *A distributional resolvent linear system is said to be* approximately controllable *if its dual system is approximately observable. It is called* minimal *if it is both approximately controllable and approximately observable.*

It is easily seen that a distributional resolvent linear system is approximately controllable (observable) if and only if its Cayley transform with a parameter $\alpha \in \Lambda_E$ is.

We denote by $\mathbf{H}^\infty(\mathbb{C}_0^+, \mathcal{E})$ the Hardy space of uniformly bounded $\mathcal{E}$-valued analytic functions defined on the right half-plane, where $\mathcal{E}$ is a Banach space.

DEFINITION 4.19. *Let Λ_E be an exponential region. A function $G : \Lambda_E \to \mathcal{L}(\mathcal{U}, \mathcal{Y})$, is said to have a* right factorization *if there exist $N \in \mathbf{H}^\infty(\mathbb{C}_0^+, \mathcal{L}(\mathcal{U}, \mathcal{Y}))$ and $M \in \mathbf{H}^\infty(\mathbb{C}_0^+, \mathcal{L}(\mathcal{U}))$ such that $M(s)^{-1}$ exists for all $s \in \Lambda_E$ and $G = NM^{-1}$ on Λ_E.*

This factorization is called normalized *if $[M; N]$ is inner, i.e., if for almost all $\omega \in \mathbb{R}$ we have*

$$M_b(i\omega)^* M_b(i\omega) + N_b(i\omega)^* N_b(i\omega) = I,$$

where M_b and N_b are the boundary functions of M and N, respectively.

This factorization is called right coprime *if there exist $\tilde{X} \in \mathbf{H}^\infty(\mathbb{C}_0^+, \mathcal{L}(\mathcal{U}))$, $\tilde{Y} \in \mathbf{H}^\infty(\mathbb{C}_0^+, \mathcal{L}(\mathcal{Y}, \mathcal{U}))$ such that*

$$\tilde{X}M - \tilde{Y}N = I \quad \text{on } \mathbb{C}_0^+. \tag{25}$$

Using the Cayley transform, we obtain from Theorem 3.6 the following theorem.

THEOREM 4.20. *If a distributional resolvent linear system satisfies the finite cost condition, then its characteristic function has a normalized right factor. If, in addition, the dual finite cost condition is satisfied, then this factor is right coprime.*

The above theorem is a slight generalization of [3, Theorem 8.9]. The proof is almost identical; one simply replaces the reciprocal transform used there by the Cayley transform with a suitable parameter (i.e., positive and in Λ_E). The relation between characteristic functions mentioned in Remark 4.3 is of course essential.

5. Well-posed linear systems. We now show how the well-known class of well-posed linear systems fits into our framework.

DEFINITION 5.1. *A resolvent linear system is called* well-posed *if*

1. *the pseudoresolvent is the resolvent of the generator of a strongly continuous semigroup T;*
2. *for every $x \in \mathcal{X}$ the function $\mathfrak{c}x$ restricts to a function in $\mathbf{H}^2(\mathbb{C}_\omega^+; \mathcal{Y})$, where ω is some real number strictly larger than the growth bound of T;*
3. *for every $x \in \mathcal{X}$ the function $\mathfrak{b}^d x$ restricts to a function in $\mathbf{H}^2(\mathbb{C}_\omega^+; \mathcal{U})$, where ω is some real number strictly larger than the growth bound of T; and*
4. *$\mathfrak{d}$ restricts to a function in $\mathbf{H}^\infty(\mathbb{C}_\omega^+; \mathcal{L}(\mathcal{U}, \mathcal{Y}))$, where ω is some real number strictly larger than the growth bound of T.*

The above definition is equivalent to the usual time-domain definition.

DEFINITION 5.2. *An* admissible state feedback pair *for a* well-posed linear system *is a pair $[\mathfrak{k}, \mathfrak{f}] : \mathbb{C}_\omega^+ \to \mathcal{L}(\mathcal{X} \times \mathcal{U}, \mathcal{U})$ that satisfies*

$$\mathfrak{k}(\beta) - \mathfrak{k}(\alpha) = (\alpha - \beta)\mathfrak{k}(\alpha)\mathfrak{a}(\beta),$$
$$\mathfrak{f}(\beta) - \mathfrak{f}(\alpha) = (\alpha - \beta)\mathfrak{k}(\beta)\mathfrak{b}(\alpha),$$

and such that for every $x \in \mathcal{X}$ the function $\mathfrak{k}x$ restricts to a function in $\mathbf{H}^2(\mathbb{C}_\omega^+; \mathcal{U})$, the function $\mathfrak{f}$ restricts to a function in $\mathbf{H}^\infty(\mathbb{C}_\omega^+; \mathcal{L}(\mathcal{U}))$, and $(I - \mathfrak{f}(s))^{-1}$ exists and is uniformly bounded on some right half-plane.

The above definition is equivalent to the time-domain definition in [19]. In [19] it is shown that the closed-loop system of a well-posed linear system with an admissible state feedback in the sense of Definition 5.2 is a well-posed linear system.

6. LQG-balanced realizations. In this section we prove the continuous-time analogues of the discrete-time results of section 3.2.

DEFINITION 6.1. *For a distributional resolvent linear system that satisfies both the finite cost condition and the dual finite cost condition the nonzero elements of the set* $\sqrt{\sigma(PQ)}$*, where* Q *is the optimal cost operator of the system and* P *is the optimal cost operator of the dual system, are called* LQG-characteristic values.

The following theorem shows that the LQG-characteristic values depend only on the characteristic function.

THEOREM 6.2. *Two distributional resolvent linear systems that both satisfy both the finite cost condition and the dual finite cost condition and whose characteristic functions are equal on an exponential region have the same set of LQG-characteristic values.*

Proof. Cayley-transform both distributional resolvent linear systems with a parameter which is in the exponential region of both. The transfer functions of the Cayley-transformed systems then agree in some neighborhood of zero. It follows from Theorem 3.8 that the LQG-characteristic values of these Cayley-transformed systems are equal. The LQG-characteristic values of a distributional resolvent linear system and its Cayley transform are equal, since the optimal cost operators are equal (which follows from Theorem 4.10). Hence it follows that the LQG-characteristic values of the two distributional resolvent linear systems are equal. □

DEFINITION 6.3. *A distributional resolvent linear system is called* LQG-balanced *if it and its dual both satisfy the finite cost condition and if the optimal cost operators of the system and that of its dual are equal. It is called* compact LQG-balanced *if, in addition, this operator is compact.*

The following theorem gives a necessary and sufficient condition for the existence of LQG-balanced realizations.

THEOREM 6.4. *An* $\mathcal{L}(\mathcal{U},\mathcal{Y})$*-valued holomorphic function, defined and polynomially bounded on an exponential region, has a normalized right coprime factor if and only if it has an LQG-balanced realization.*

Proof. Assume the given function $\mathfrak{d}$ has a normalized right coprime factor $[M;N]$. It follows from [11] or [19, section 9.5] that $[M;N]$ has a minimal well-posed Lyapunov-balanced realization $\mathfrak{a}_L$, $\mathfrak{b}_L$, $[\mathfrak{c}_L^1;\mathfrak{c}_L^2]$, $[M;N]$. Consider the well-posed linear system $\mathfrak{a}_L$, $\mathfrak{b}_L$, $\mathfrak{c}_L^2$, N and the feedback pair $[\mathfrak{k},\mathfrak{f}] := [-\mathfrak{c}_L^1, I-M]$. This feedback pair is admissible for the given system: the algebraic relations easily follow from the fact that the Lyapunov-balanced system is a resolvent linear system (even a well-posed linear system). Since $(I-\mathfrak{f}(s))^{-1} = M^{-1}$ it remains to show that M^{-1} is polynomially bounded on some exponential region. This follows from the equation $M^{-1} = X - Y\mathfrak{d}$ on Λ_E, which follows from the Bezout equation (25). The closed-loop system of the above system with the given feedback pair is $\mathfrak{a}_L - \mathfrak{b}_L M^{-1}\mathfrak{c}_L^1$, $\mathfrak{b}_L M^{-1}$, $[-M^{-1}\mathfrak{c}_L^1; \mathfrak{c}_L^2 - NM^{-1}\mathfrak{c}_L^1]$, $[M^{-1}; NM^{-1}]$. It follows that this is a distributional resolvent linear system. We drop one of the components and obtain the following distributional resolvent linear system:

$$\mathfrak{a}_s := \mathfrak{a}_L - \mathfrak{b}_L M^{-1}\mathfrak{c}_L^1, \quad \mathfrak{b}_s := \mathfrak{b}_L M^{-1}, \quad \mathfrak{c}_s := \mathfrak{c}_L^2 - NM^{-1}\mathfrak{c}_L^1, \quad \mathfrak{d}_s := NM^{-1}. \tag{26}$$

Now choose $\alpha > 0$ in the intersection of the exponential regions of all the systems considered above and Cayley-transform these systems with this parameter. It is obvious from the constructions and Theorem 3.7 that the system (26) has L as its optimal cost operator and $L(I-L^2)^{-1}$ as its dual optimal cost operator, where L is the gramian of the Lyapunov-balanced realization. Define $S := (I-L^2)^{-1/4}$, and define $\mathfrak{a}_l := S\mathfrak{a}_s S^{-1}$, $\mathfrak{b}_l := S\mathfrak{b}$, $\mathfrak{c}_l := \mathfrak{c}S^{-1}$, $\mathfrak{d}_l = \mathfrak{d}_s$. We conclude that $\mathfrak{a}_l$, $\mathfrak{b}_l$, $\mathfrak{c}_l$, $\mathfrak{d}_l$ is

LQG-balanced. Since $\mathfrak{d}_l = NM^{-1} = \mathfrak{d}$ this distributional resolvent linear system is an LQG-balanced realization of $\mathfrak{d}$.

The converse trivially follows from Theorem 4.20. ∎

Theorem 6.4 can be rephrased in terms of realizations as follows. Here Theorem 4.20 is used.

COROLLARY 6.5. *For a distributional resolvent linear system that satisfies both the finite cost condition and the dual finite cost condition there exists an LQG-balanced distributional resolvent linear system such that the characteristic functions of these two systems are equal on some exponential region.*

The following two corollaries show that in the special cases of exponentially bounded distributional resolvent linear systems and well-posed linear systems the LQG-balanced realization belongs to the same class.

COROLLARY 6.6. *For an exponentially bounded distributional resolvent linear system that satisfies both the finite cost condition and the dual finite cost condition there exists an LQG-balanced exponentially bounded distributional resolvent linear system such that the characteristic functions of these two systems are equal on some right half-plane.*

Proof. This follows from the proof of Theorem 6.4 noting that the Bezout equation now shows that the feedback is admissible in the sense of Definition 4.15. ∎

COROLLARY 6.7. *For a well-posed linear system that satisfies both the finite cost condition and the dual finite cost condition there exists an LQG-balanced well-posed linear system such that the characteristic functions of these two systems are equal on some right half-plane.*

Proof. This follows from the proof of Theorem 6.4 noting that the Bezout equation now shows that the feedback is admissible in the sense of Definition 5.2. ∎

Let $\mathfrak{a}$, $\mathfrak{b}$, $\mathfrak{c}$, $\mathfrak{d}$ be an LQG-balanced distributional resolvent linear system, and let $U \in \mathcal{L}(\mathcal{X})$ be unitary. Then obviously $U\mathfrak{a}U^*$, $U\mathfrak{b}$, $\mathfrak{c}U^*$, $\mathfrak{d}$ is also an LQG-balanced distributional resolvent linear system. The next theorem shows that these are all LQG-balanced distributional resolvent linear systems with characteristic function $\mathfrak{d}$ if we assume a minimality assumption on the state space.

THEOREM 6.8. *If two distributional resolvent linear systems whose characteristic functions agree on some exponential region are both LQG-balanced, approximately controllable, and approximately observable, then there exists a unitary state-space transformation between them.*

Proof. Choose a parameter that is in the exponential region of both systems, and Cayley-transform both systems with this parameter. The resulting systems are LQG-balanced, approximately controllable, and approximately observable and have the same transfer function. It follows from part 3 of Theorem 3.8 that these discrete-time systems are unitarily equivalent. From this it follows that the distributional resolvent linear systems are unitarily equivalent. ∎

The gap-metric in continuous time is defined in exactly the same way as was done in discrete time in section 3.2, but with the unit disc $\mathbb{D}$ replaced by the right half-plane $\mathbb{C}_0^+$. It is easily seen that the distance between two systems equals the distance between their Cayley transforms (taken with the same parameter, obviously).

Using the Cayley transform, the following theorem follows immediately from Theorem 3.9.

THEOREM 6.9. *Suppose a distributional resolvent linear system satisfies the following assumptions:*

- *the finite cost condition is satisfied,*

- *the finite cost condition for the dual system is satisfied,*
- *the product PQ of the optimal cost operator and the dual optimal cost operator is nuclear, and*
- *the input and output spaces are finite-dimensional.*

Then there exists a compact LQG-balanced distributional resolvent linear system whose characteristic function equals the characteristic function of the original system on some exponential region and

$$\delta_g(\mathfrak{d}, G^n) \leq 2 \sum_{i=n+1}^{\infty} \frac{\mu_i}{\sqrt{1+\mu_i^2}}, \tag{27}$$

where G^n is the transfer function of an n-dimensional truncated LQG-balanced realization.

7. Conclusions. In this article we have obtained existence and uniqueness results for LQG-balanced realizations for continuous-time infinite-dimensional systems. We also obtained a priori error bounds in the gap-metric for both the continuous-time and the discrete-time cases.

STABILITY OF DISCONTINUOUS DIFFUSION COEFFICIENTS AND INITIAL CONDITIONS IN AN INVERSE PROBLEM FOR THE HEAT EQUATION*

ASSIA BENABDALLAH†, PATRICIA GAITAN‡, AND JÉRÔME LE ROUSSEAU†

Abstract. We consider the heat equation with a discontinuous diffusion coefficient and give uniqueness and stability results for both the diffusion coefficient and the initial condition from a measurement of the solution on an arbitrary part of the boundary and at some arbitrary positive time. The key ingredient is the derivation of a Carleman-type estimate. The diffusion coefficient is assumed to be discontinuous across an interface with a monotonicity condition.

Key words. parabolic equations, Carleman estimates, inverse problem, stability estimate, discontinuous coefficients

DOI. 10.1137/050640047

1. Introduction.

This article is devoted to the question of the identification of a diffusion coefficient, c, for a heat transfer problem in a bounded domain, with the main particularity that c is discontinuous. Such regularity can be encountered in the case of embedded materials.

Let $\Omega \subset \mathbb{R}^n$ be a bounded connected open set. The set $\overline{\Omega}$ is assumed to be a $\mathscr{C}^2$ submanifold with boundary in $\mathbb{R}^n$ (see, e.g., [12, Definition 1.2.1.2]). We set $\Gamma = \partial\Omega$. Let Ω_0 and Ω_1 be two nonempty open subsets of Ω such that

$$\Omega_0 \Subset \Omega \quad \text{and} \quad \Omega_1 = \Omega \setminus \overline{\Omega}_0.$$

We denote by $S = \overline{\Omega}_0 \cap \overline{\Omega}_1$ the interface, which is assumed to be $\mathscr{C}^2$. We shall use the notation $\Omega' = \Omega_0 \cup \Omega_1$. It should be emphasized here that the position of the interface itself is not assumed to be known.

Let $T > 0$. We consider the following transmission problem for the heat equation:

$$\begin{cases} \partial_t y - \nabla \cdot (c \nabla y) = 0 & \text{in } (0,T) \times \Omega', \\ y(t,x) = h(t,x) & \text{on } (0,T) \times \Gamma, \\ \text{transmission conditions (TC1)} & \text{on } (0,T) \times S, \\ y(0,x) = y_0(x), & \text{in } \Omega, \end{cases} \tag{1.1}$$

with

$$y_{|[0,T]\times S_0} = y_{|[0,T]\times S_1}, \quad c_0 \partial_n y_{|[0,T]\times S_0} = c_1 \partial_n y_{|[0,T]\times S_1}, \tag{TC1}$$

where $f_{|S_i}$ is the trace on S of $f_{|\Omega_i}$ and where

$$c = \begin{cases} c_0 & \text{in } \Omega_0, \\ c_1 & \text{in } \Omega_1, \end{cases} \qquad \widetilde{c} = \begin{cases} \widetilde{c}_0 & \text{in } \Omega_0, \\ \widetilde{c}_1 & \text{in } \Omega_1. \end{cases}$$

The boundary condition $h(t,x)$ shall be kept fixed. The diffusion coefficient c shall be kept independent of time, t. If we change the diffusion coefficient c into $\widetilde{c}$, we let $\widetilde{y}$ be the solution of (1.1) associated with $\widetilde{c}$ and $\widetilde{y}_0$ for the initial condition. In the case studied here, the interface remains unchanged when changing coefficients. Its position is, however, not known.

We assume that we can measure both the normal flux $\partial_n \partial_t y$ on $\gamma \subset \partial\Omega$ on the time interval (t_0, T) for some $t_0 \in (0,T)$ and Δy in Ω at time $T' \in (t_0, T)$. In the case of piecewise-*constant* diffusion coefficients, i.e., $c_{|\Omega_i}$, $i = 0, 1$, is constant, our main results are (i) the injectivity of the map

$$L^\infty(\Omega) \times L^2(\Omega) \to L^2((t_0,T)\times\gamma) \times L^2(\Omega),$$
$$(c, y_0) \mapsto (\partial_n \partial_t y, \Delta y(T'))$$

(uniqueness); (ii) the stability for the diffusion coefficient, c (Theorem 3.9): there exists $C > 0$ such that

$$|c - \widetilde{c}|^2_{L^\infty(\Omega)} \le C|\partial_n(\partial_t y - \partial_t \widetilde{y})|^2_{L^2((0,T)\times\gamma)} + C|\Delta y(T',.) - \Delta\widetilde{y}(T',.)|^2_{L^2(\Omega')};$$

and (iii) the stability for the initial condition, y_0 (Theorem 5.5): there exists $C > 0$ such that

$$|y_0 - \widetilde{y}_0|_{L^2(\Omega)} \le C/\left|\ln\left(|(y-\widetilde{y})(T')|_{H^2(\Omega')} + |\partial_n(\partial_t y - \partial_t\widetilde{y})|^2_{L^2((0,T)\times\gamma)}\right)\right|$$

for $|(y-\widetilde{y})(T')|_{H^2(\Omega')} + |\partial_n(\partial_t y - \partial_t\widetilde{y})|^2_{L^2((0,T)\times\gamma)}$ sufficiently small. At the end of section 3 we shall observe that we may require only that the difference of the coefficients, $c - \widetilde{c}$, be piecewise-constant.

The key ingredient to these stability results is a *global* Carleman estimate for the operator $\partial_t - \nabla\cdot(c\nabla(.))$ and the open set Ω.

The use of Carleman estimates to achieve uniqueness and stability results in inverse problems is now well established. Some authors make use of *local* Carleman inequalities and deduce uniqueness and Hölder estimates (see [19], [18], and references cited therein). Others make use of *global* Carleman inequalities and deduce Lipschitz stability results (and hence uniqueness results). We shall follow this second approach. To our knowledge, this method was first used in [16] and then by others, e.g., [2]. We refer the reader to [13, Chapter 8], [14, section 28.2–3] for discussion of local Carleman estimates, and [17] for the parabolic case. For global estimates we refer the reader to [11] and [10].

Stability results for parabolic equations are recent, to our knowledge (see [19], [9]). Apart from [16] there are few results on Lipschitz stability, even for linear cases.

One of the main difficulties in the present problem is to deal with discontinuous diffusion coefficients. Controllability for such parabolic equations has been studied by [8]. A null-controllability property is proved via an observability inequality for the adjoint system, which is deduced in [8] from a *global* Carleman estimate, yet assuming a *monotonicity* on the coefficients c in connection to the observation location: roughly speaking, the observation zone has to be located in the region where the diffusion coefficient is the smallest. Here, to achieve a stability result we have to derive a Carleman estimate for the difference of the two solutions, y, $\widetilde{y}$. This difference is the solution of a nonhomogeneous parabolic equation (with discontinuous coefficient); because of the discontinuity of the diffusion coefficients it does not satisfy the appropriate transmission conditions (TC1), on the interfaces S, defined above. For this reason, under

the same monotonicity assumption as in [8], we derive a peculiar Carleman estimate which includes additional *interface terms* (see Theorem 2.2).

To obtain a stability result, one has to "manage" the dependence of some constants with respect to (w.r.t.) the parameters, s and λ, that appear in the weight functions used in the Carleman estimate (see (2.4) in section 2). The interface terms require some careful treatment. In particular, a stationary-phase argument is used to obtain a sufficiently sharp asymptotic estimate of these terms for s and λ large. Usually, stability estimates are obtained by letting the parameter s become large. Here we also make use of the second parameter λ (see section 4).

As we are concerned with parabolic equations, we have to assume that the observation of the solution occurs at some positive time, $T' > 0$. The suppression of this assumption remains an open problem, and it appears in all articles deriving Lipschitz stability estimates from global Carleman inequalities (see the discussion in the introduction of [16]). However, at the end of section 3 we show that if the position of the interface S is known, we can localize in space the observation at time T'.

The article is organized as follows. In section 2 we derive a Carleman estimate adapted to our problem. In section 3 we prove a stability result for the piecewise-constant diffusion coefficient c when one of the solutions, say $\widetilde{y}$, is in a particular class of solutions. In section 4 we prove that this class is nonempty. As mentioned above we also slightly relax the piecewise-constant condition by imposing solely that the difference of the coefficients be piecewise-constant. In section 5 we prove a stability result for the initial condition under some additional assumptions, particularly on the initial condition itself. The appendix provides some basic regularity properties for the solutions to parabolic equation with nonsmooth coefficients and provides a technical lemma.

We now give some notation and important assumptions. We denote by n the outward unit normal to Ω_1 on S and also the outward unit normal to Ω on Γ. Let S_0 (resp., S_1) be the side of the interface S corresponding to the positive (resp., negative) direction of the normal n.

Note that we do not assume that either Ω_0 or Ω_1 is a connected open set. We shall, however, assume that they are formed with a finite number of connected open sets, say $\Omega_{0,1}, \ldots, \Omega_{0,p_0}$ and $\Omega_{1,1}, \ldots, \Omega_{1,p_1}$, $p_0, p_1 \in \mathbb{N}$. We shall then denote by S_{ij} the interface (possibly empty) between $\Omega_{0,i}$ and $\Omega_{1,j}$.

We make the following assumption.

ASSUMPTION 1.1. *The diffusion coefficient satisfies* $c_i = c_{|\Omega_i} \in \mathscr{C}^1(\overline{\Omega}_i)$, $i = 0, 1$, *and is independent of time* t.

ASSUMPTION 1.2. $c_{0|S} \geq c_{1|S}$ *and* $0 < c_{min} \leq c(x) \leq c_{max}$, $x \in \Omega'$.

Remark 1.3. Assumption 1.1 will be significantly strengthened in section 3 to obtain a stability result. Yet, for some of the results such as the Carleman estimate proved in section 2 and the regularity properties proved in section 4, which can be of some use elsewhere, Assumption 1.1 is sufficient.

We let γ be a subset of the boundary Γ satisfying the following.

ASSUMPTION 1.4. *The interior of* γ *is nonempty w.r.t. the topology on* Γ *induced by the Euclidean topology on* $\mathbb{R}^n$. *Each component of* Ω_1 *contains part of the interior of* γ *in its boundary.*

Examples of situations in which Assumption 1.4 is satisfied are given in Figure 1.

To obtain a Carleman estimate we introduce a geometric assumption, following [8].

ASSUMPTION 1.5. Geometric condition (GC). *We assume that there exist two*

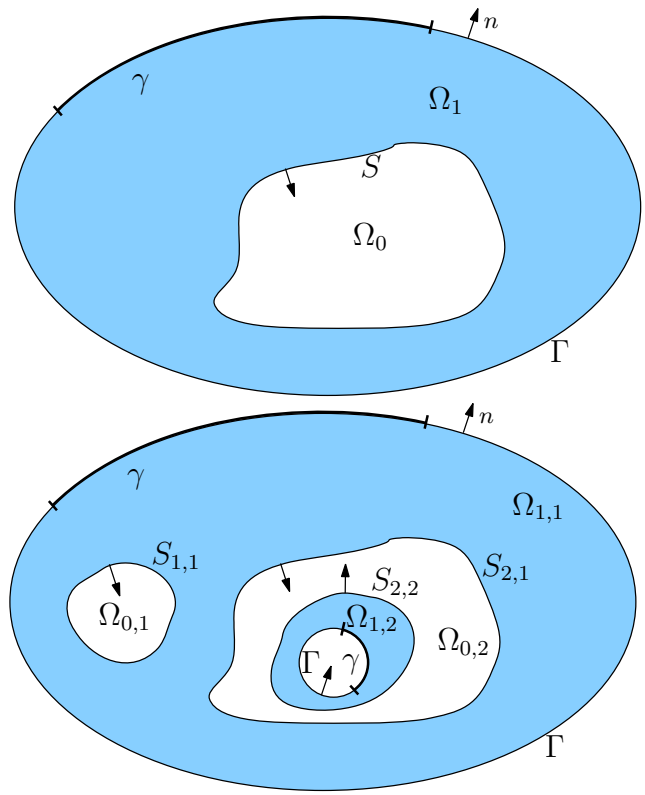

FIG. 1. *Geometric situations in which Assumption* 1.4 *and the geometric condition (GC) are satisfied. Shaded is* Ω_1. *Arrows represent the normal unit vector* n.

disjoint open subsets, $\mathcal{O}^{(1)}$, $\mathcal{O}^{(2)} \Subset \Omega_0$, *and two vector fields,* $\zeta^{(i)} \in \mathscr{C}^1(\overline{\Omega}_0, \mathbb{R}^2)$, $i = 1, 2$, *such that*

$$\zeta^{(i)}(x) \cdot n(x) > 0 \ \ \forall x \in S, \quad i = 1, 2,$$

$$\zeta^{(i)}(x) \cdot n(x) > 0 \ \ \forall x \in \partial\mathcal{O}^{(i)}, \ \ i = 1, 2,$$

$$\zeta^{(i)}(x) \neq 0 \ \ \forall x \in \Omega_0 \setminus \mathcal{O}^{(i)}, \ \ i = 1, 2$$

(n *is the outward unit normal to* Ω_1 *on* S *and the inward unit normal to* $\mathcal{O}^{(i)}$ *on* $\partial\mathcal{O}^{(i)}$, $i = 1, 2$*). Let* $x^{(i)}$ *be the integral curves of* $\zeta^{(i)}$, *i.e.,*

$$\begin{cases} \frac{dx^{(i)}(t)}{dt} = \zeta^{(i)}(x^{(i)}(t)), & t > 0, \\ x^{(i)}(0) = x_0, & x_0 \in S. \end{cases}$$

We also assume that there exists $\mathcal{T} > 0$ *such that for all* $x_0 \in S$ *there exists* $t^{(i)}(x_0) < \mathcal{T}$ *satisfying*

$$x^{(i)}(t) \in \Omega_0 \setminus \mathcal{O}^{(i)} \quad \text{for } 0 < t < t^{(i)}(x_0), \ x_0 \in S, \ i = 1, 2,$$

$$x^{(i)}(t^{(i)}(x_0)) \in \partial\mathcal{O}^{(i)} \quad \textit{for } x_0 \in S,\ i = 1, 2.$$

Note that in Assumption 1.5, there is no restriction to having Ω_0 composed of p_0 components. The examples given in Figure 1 satisfy Assumption 1.5.

We denote by $W^{m,p}(\Omega)$, $m \in \mathbb{N}$, $1 \le p \le \infty$, the usual Sobolev space defined by

$$W^{m,p} = \{u \in L^p(\Omega);\ \partial^\alpha u \in L^p(\Omega) \text{ for } |\alpha| \le m\},$$

where $\alpha = (\alpha_1, \dots, \alpha_n)$ is a multi-index and differentiation is to be understood in the weak sense. As usual we write $H^m(\Omega) = W^{m,2}(\Omega)$. For the definition of $W^{r,p}$ for $r \in \mathbb{R} \setminus \mathbb{N}$ we refer, for instance, to [1].

2. A Carleman estimate. We prove here a Carleman-type estimate with a boundary term on γ in the right-hand side (r.h.s.) of the estimate. For this purpose we shall first introduce a particular type of weight functions, which are constructed using the following lemma.

LEMMA 2.1. *Assume that there exist two disjoint open subsets, $\mathcal{O}^{(1)}$, $\mathcal{O}^{(2)} \Subset \Omega_0$, satisfying Assumption* 1.5. *Let γ be a subset of $\Gamma = \partial\Omega$ satisfying Assumption* 1.4, *and $B^{(i)}$ and $\widetilde{B}^{(i)}$, $i = 1, 2$, be open balls such that $B^{(1)} \Subset \widetilde{B}^{(1)} \Subset \mathcal{O}^{(1)}$ and $B^{(2)} \Subset \widetilde{B}^{(2)} \Subset \mathcal{O}^{(2)}$. Then there exist two functions $\widetilde{\beta}^{(1)}$ and $\widetilde{\beta}^{(2)}$ such that*

$$\widetilde{\beta}^{(1)}(x) = \begin{cases} \widetilde{\beta}_0^{(1)} & \textit{in } \Omega_0, \\ \widetilde{\beta}_1 & \textit{in } \overline{\Omega}_1, \end{cases} \qquad \widetilde{\beta}^{(2)}(x) = \begin{cases} \widetilde{\beta}_0^{(2)} & \textit{in } \Omega_0, \\ \widetilde{\beta}_1 & \textit{in } \overline{\Omega}_1, \end{cases}$$

and the functions $\widetilde{\beta}_0^{(1)}$, $\widetilde{\beta}_0^{(2)}$, and $\widetilde{\beta}_1$ satisfy the following properties: $\widetilde{\beta}_1 \in \mathscr{C}^2(\overline{\Omega}_1)$, $\widetilde{\beta}_1 > 0$ in Ω_1, and

$$\widetilde{\beta}_1 = 0 \quad \textit{on } \Gamma \setminus \gamma, \quad \partial_n \widetilde{\beta}_1 < 0 \quad \textit{on } \Gamma \setminus \gamma,$$

$$\widetilde{\beta}_1 = 2 \quad \textit{on } S, \quad \partial_n \widetilde{\beta}_1 < 0 \quad \textit{on } S,$$

and

$$|\nabla \widetilde{\beta}_1| > 0 \quad \textit{in } \overline{\Omega}_1;$$

for $i = 1, 2$, $\widetilde{\beta}_0^{(i)} \in \mathscr{C}^2(\overline{\Omega}_0)$, $\widetilde{\beta}_0^{(i)} > 0$ in Ω_0,

$$\widetilde{\beta}_0^{(i)} = \widetilde{\beta}_1 = 2 \quad \textit{on } S, \quad i = 1, 2,$$

$$c_0 \partial_n \widetilde{\beta}_0^{(i)} = c_1 \partial_n \widetilde{\beta}_1 \quad \textit{on } S, \quad i = 1, 2,$$

$$\widetilde{\beta}_0^{(1)} \ge 2\widetilde{\beta}_0^{(2)} \quad \textit{in } \widetilde{B}^{(2)}, \tag{2.1}$$

$$\widetilde{\beta}_0^{(2)} \ge 2\widetilde{\beta}_0^{(1)} \quad \textit{in } \widetilde{B}^{(1)}, \tag{2.2}$$

and

$$|\nabla \widetilde{\beta}_0^{(i)}| > 0 \quad \textit{in } \overline{\Omega}_0 \setminus B^{(i)}, \quad i = 1, 2. \tag{2.3}$$

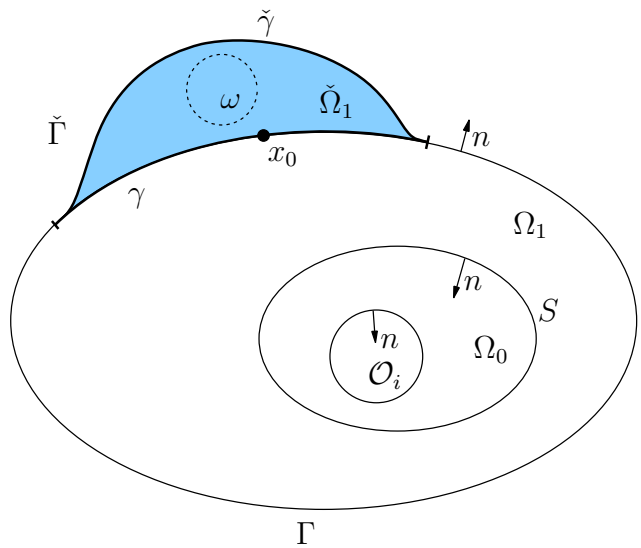

FIG. 2. *Geometrical situation for the proof Lemma* 2.1. *The shaded area represents* $\check{\Omega}_1 \setminus \Omega_1 = \check{\Omega} \setminus \Omega$.

Proof. For the construction of $\widetilde{\beta}_0^{(i)}$, $i = 1, 2$, supported in the connected components of Ω_0, we refer to [8, Lemma 3.2]. We briefly show how the function $\widetilde{\beta}_1$ is constructed. In actuality, the procedure described here has to be performed in each connected component of Ω_1, which is possible since each component contains part of the interior of γ in its boundary by Assumption 1.4.

Let x_0 be in the interior of γ. We can enlarge the open set Ω_1 locally around x_0 while preserving the $\mathscr{C}^2$ regularity of the boundary. Such a procedure is performed in a neighborhood U of x_0 such that $U \cap \Gamma \subset \gamma$. (This can be done by locally straightening out the boundary γ, as $\overline{\Omega}$ is assumed to be a $\mathscr{C}^2$ submanifold with boundary in $\mathbb{R}^n$ [12, Definition 1.2.1.2].) This enlarging procedure affects only γ and leaves $\Gamma \setminus \gamma$ untouched. We call the new boundary $\check{\Gamma}$. We denote by $\check{\Omega}_1$ the extension of Ω_1 and $\check{\Omega}$ that of Ω ($\Omega_1 \subset \check{\Omega}_1$, $\Omega \subset \check{\Omega}$, and $\check{\Gamma} = \partial\check{\Omega}$). Let ω be an open subset such that $\omega \Subset \check{\Omega}_1 \setminus \Omega_1$. The geometry we describe here is illustrated in Figure 2. Following [8, 11], there exists $\mu \in \mathscr{C}^2(\overline{\check{\Omega}})$ that satisfies

$$\mu = 0, \quad \partial_n \mu < 0 \quad \text{on } \check{\Gamma},$$

$$\mu = 2, \quad c_0 \partial_n \widetilde{\beta}_0^{(i)} = c_1 \partial_n \mu < 0 \quad \text{on } S,$$

$$|\nabla \mu| > 0 \quad \text{in } \check{\Omega}_1 \setminus \omega.$$

The function $\widetilde{\beta}_1 := \mu_{|\overline{\Omega}_1}$ satisfies the required properties. ∎

Choosing two functions $\widetilde{\beta}^{(i)}$, $i = 1, 2$, as in the previous lemma, we introduce $\beta^{(i)} = \widetilde{\beta}^{(i)} + K$ with $K = m\|\widetilde{\beta}^{(1)}\|_\infty = m\|\widetilde{\beta}^{(2)}\|_\infty$ and $m > 1$. For $\lambda > 0$ and $t \in (t_0, T)$, we define the following weight functions:

$$\varphi^{(i)}(t,x) = \frac{e^{\lambda\beta^{(i)}(x)}}{(t-t_0)(T-t)}, \qquad \eta^{(i)}(t,x) = \frac{e^{\lambda\overline{\beta}} - e^{\lambda\beta^{(i)}(x)}}{(t-t_0)(T-t)}, \quad i = 1, 2, \tag{2.4}$$

with $\overline{\beta} = 2m\|\widetilde{\beta}^{(i)}\|_\infty$, $i = 1, 2$ (see [8], [10]). We let $t_0 \in (0, T)$, and we set $Q = (t_0, T) \times \Omega$, $Q' = (t_0, T) \times \Omega'$ and recall that $\Omega' = \Omega_0 \cup \Omega_1$.

Let $g \in H^1([t_0, T], H^{\frac{1}{2}}(S))$. We introduce transmission conditions (TC2) on the interval $[t_0, T]$,

$$\text{(TC2)} \qquad \begin{aligned} &q_{|[t_0,T]\times S_0} = q_{|[t_0,T]\times S_1}, \\ &c_0 \partial_n q_{|[t_0,T]\times S_0} = c_1 \partial_n q_{|[t_0,T]\times S_1} + g(t,x), \end{aligned}$$

for a function q which is H^2 in each open set Ω_i, $i = 0, 1$.

We introduce

$$\aleph_g = \Big\{ q \in H^1(t_0, T, H_0^1(\Omega));\ q_{|_{(t_0,T)\times\Omega_i}} \in L^2(t_0, T, H^2(\Omega_i)),\ i = 0, 1, \\ \text{and } q \text{ satisfies (TC2) a.e. w.r.t. } t \Big\}.$$

THEOREM 2.2. *Let γ be a subset of the boundary Γ of an open set Ω of $\mathbb{R}^n$ that satisfies Assumption* 1.5*, and let γ satisfy Assumption* 1.4*. Let c satisfy Assumptions* 1.1 *and* 1.2*. Assume further that $c_{0|_S} - c_{1|_S} \geq \Delta > 0$. Let $g \in H^1(t_0, T, H^{\frac{1}{2}}(S))$. There exists $\lambda_1 = \lambda_1(\Omega, \gamma, \mathcal{O}^{(1)}, \mathcal{O}^{(2)}, c_{min}, c_{max}, \Delta) > 0$, $s_1 = s_1(\lambda_1) > 0$, and a positive constant $C = C(\Omega, \gamma, \mathcal{O}^{(1)}, \mathcal{O}^{(2)}, c_{min}, c_{max}, \Delta)$ so that the following estimate holds:*

$$\begin{aligned} (2.5) \qquad & |M_1^{(1)}(e^{-s\eta^{(1)}} q)|^2_{L^2(Q')} + |M_1^{(2)}(e^{-s\eta^{(2)}} q)|^2_{L^2(Q')} \\ &+ |M_2^{(1)}(e^{-s\eta^{(1)}} q)|^2_{L^2(Q')} + |M_2^{(2)}(e^{-s\eta^{(2)}} q)|^2_{L^2(Q')} \\ &+ s\lambda^2 \iint_Q (e^{-2s\eta^{(1)}} \varphi^{(1)} + e^{-2s\eta^{(2)}} \varphi^{(2)})\ |\nabla q|^2\ dx\ dt \\ &+ s^3\lambda^4 \iint_Q (e^{-2s\eta^{(1)}} {\varphi^{(1)}}^3 + e^{-2s\eta^{(2)}} {\varphi^{(2)}}^3)\ |q|^2\ dx\ dt \\ &\leq C \Bigg[s\lambda \int_{t_0}^T \int_\gamma (e^{-2s\eta^{(1)}} \varphi^{(1)} + e^{-2s\eta^{(2)}} \varphi^{(2)})\ |\partial_n q|^2\ d\sigma\ dt \\ &\quad + \iint_{Q'} (e^{-2s\eta^{(1)}} + e^{-2s\eta^{(2)}})\ |\partial_t q \pm \nabla \cdot (c\nabla q)|^2\ dx\ dt \\ &\quad + s\lambda \int_{t_0}^T \int_S (e^{-2s\eta^{(1)}} \varphi^{(1)} + e^{-2s\eta^{(2)}} \varphi^{(2)})\ |g|^2\ d\sigma\ dt \\ &\quad + \int_{t_0}^T \int_S (e^{-2s\eta^{(1)}} {\varphi^{(1)}}^4 + e^{-2s\eta^{(2)}} {\varphi^{(2)}}^4)\ |g|^2\ d\sigma\ dt \\ &\quad + s^{-2} \int_{t_0}^T \int_S (e^{-2s\eta^{(1)}} + e^{-2s\eta^{(2)}}) |\partial_t g|^2 d\sigma\ dt \Bigg] \end{aligned}$$

for $s \geq s_1$, $\lambda \geq \lambda_1$, and all $q \in \aleph_g$, with M_1 and M_2 to be defined in (2.9)–(2.10).

We recall that $\Omega' = \Omega_0 \cup \Omega_1$ and $Q' = \Omega' \times (t_0, T)$. For a function ρ with a trace on the interface S, from both sides, defined in some sense, we shall denote by ρ_i the trace of $\rho_{|_{\Omega_i}}$ on S, $i = 0, 1$, when there is no ambiguity; in the case $\rho_0 = \rho_1$ we shall simply write ρ. We shall use the notation $[\rho]_S = \rho_0 - \rho_1$ for the jump of ρ across the interface S. We shall adopt Einstein's summation convention for repeated indices.

Proof. We consider $s > 0$ and $q \in \aleph_g$. Let us set $f = \partial_t q + \nabla \cdot (c\nabla q)$ (we treat the case of the operator $\partial_t + \nabla \cdot (c\nabla)$ in the proof; the other case can be treated similarly).

Then $f \in L^2(Q')$ (because of transmission conditions (TC2), observe that q is not in the domain of the operator $\nabla \cdot (c\nabla)$).

In the first part of the proof we shall write η, φ, M_1, etc., in place of $\eta^{(i)}$, $\varphi^{(i)}$, $M_1^{(i)}$, etc., $i = 1, 2$, and treat the two cases at once. We set $\psi = e^{-s\eta}q$. We observe that $\psi(t_0) = \psi(T) = 0$ and since q satisfies transmission conditions (TC2) (and $q(t,.)_{|\Omega_i} \in H^2(\Omega_i)$ a.e. w.r.t. t), we have (a.e. w.r.t. t)

$$c_0 \partial_n \psi_{0|_S}(t,.) = c_1 \partial_n \psi_{1|_S}(t,.) + g_s(t,.) \quad \text{on } S, \tag{2.6}$$

$$\nabla_\tau \psi_{0|_S}(t,.) = \nabla_\tau \psi_{1|_S}(t,.) \quad \text{on } S, \tag{2.7}$$

$$\psi_{0|_S}(t,.) = \psi_{1|_S}(t,.) \quad \text{on } S, \tag{2.8}$$

where $g_s = e^{-s\eta}g$ and ∇_τ denotes the component of the gradient that is tangential to S.

The function ψ satisfies in each Ω_i, $i = 0, 1$,

$$M_1\psi + M_2\psi = f_s$$

with

$$M_1\psi = \nabla \cdot (c\nabla\psi) + s^2\lambda^2\varphi^2|\nabla\beta|^2 c\psi + s(\partial_t\eta)\psi, \tag{2.9}$$

$$M_2\psi = \partial_t\psi - 2s\lambda\varphi c\nabla\beta \cdot \nabla\psi - 2s\lambda^2\varphi c|\nabla\beta|^2\psi, \tag{2.10}$$

$$f_s = e^{-s\eta}f + s\lambda\varphi\nabla \cdot (c\nabla\beta)\psi - s\lambda^2\varphi c|\nabla\beta|^2\psi. \tag{2.11}$$

We have

$$|M_1\psi|^2_{L^2(Q')} + |M_2\psi|^2_{L^2(Q')} + 2(M_1\psi, M_2\psi)_{L^2(Q')} = |f_s|^2_{L^2(Q')}.$$

With the same notation as in [8, Theorem 3.3], we write $(M_1\psi, M_2\psi)_{L^2(Q')}$ as a sum of nine terms I_{ij}, $1 \le i, j \le 3$, where I_{ij} is the inner product of the ith term in the expression of $M_1\psi$ and the jth term in the expression of $M_2\psi$.

As compared to the proof of the Carleman estimate in [8, Theorem 3.3] we only need to adjust the computation of I_{11}, I_{12}, and I_{13} to the present case. In fact the other terms do not involve transmission conditions (2.6) in their computation and thus remain unchanged from the terms obtained in [8].

The term I_{11} follows as

$$I_{11} = \iint_{Q'} \nabla \cdot (c\nabla\psi)\, \partial_t\psi \, dxdt = -\iint_{Q'} c\nabla\psi \cdot \partial_t(\nabla\psi)\, dxdt + \sum_{i=0,1} (-1)^{i+1} \int_{t_0}^{T}\int_S c_i \partial_n\psi_i \, \partial_t\psi \, d\sigma dt,$$

by integration by parts; the surface integral on Γ vanishes since $\partial_t\psi = 0$ there. Noting that $\nabla\psi \cdot \partial_t(\nabla\psi) = \frac{1}{2}\partial_t(|\nabla\psi|^2)$, the first term vanishes since ψ, and thus $\nabla\psi$, vanish at $t = t_0$ and $t = T$ and c is independent of t. For the remaining surface terms we use (2.6), which yields

$$I_{11} = -\int_{t_0}^{T}\int_S g_s \, \partial_t\psi \, d\sigma dt = \int_{t_0}^{T}\int_S \partial_t(g_s)\, \psi \, d\sigma dt,$$

since $g_s \in H^1(t_0, T, H^{\frac{1}{2}}(S))$.

The term I_{12} is given by

$$I_{12} = -2s\lambda \iint_{Q'} \varphi \nabla \cdot (c\nabla\psi) c\nabla\beta \cdot \nabla\psi \, dxdt = 2s\lambda \iint_{Q'} c\nabla\psi \cdot \nabla(\varphi c \nabla\beta \cdot \nabla\psi) \, dxdt$$
$$- 2s\lambda \int_{t_0}^{T}\int_{\Gamma} \varphi c^2 (\nabla\beta\cdot\nabla\psi)(\partial_n\psi) \, d\sigma dt + 2s\lambda \sum_{i=0,1} (-1)^i \int_{t_0}^{T}\int_{S} \varphi c_i^2 (\nabla\beta_i\cdot\nabla\psi_i)(\partial_n\psi_i) \, d\sigma dt.$$

This integration by parts is justified since $\psi(t,.)$ is in H^2 in each Ω_i, $i = 0, 1$. Denoting by I'_{12} the remaining volume integral, we obtain

$$I'_{12} = 2s\lambda^2 \iint_{Q'} \varphi c^2 |\nabla\psi \cdot \nabla\beta|^2 \, dxdt + 2s\lambda \iint_{Q'} \varphi c \, \partial_{x_i}(c\partial_{x_j}\beta)\partial_{x_i}\psi\partial_{x_j}\psi \, dxdt$$
$$+ s\lambda \iint_{Q'} \varphi c^2 \partial_{x_j}\beta\partial_{x_j}|\nabla\psi|^2 \, dxdt.$$

We further compute the last volume integral, denoted by I''_{12}. Observe that $|\nabla\psi|^2_{|\Omega_i}$ is in $W^{1,1}(\Omega_i)$ since $\psi_{|\Omega_i}(t,.) \in H^2(\Omega_i)$, $i = 0, 1$. This allows us to further integrate by parts, since $(c^2\varphi\partial_{x_j}\beta)_{|\Omega_i} \in \mathscr{C}^1(\Omega_i)$, $i = 0, 1$, and yields

$$I''_{12} = -s\lambda \iint_{Q'} \partial_{x_j}(\varphi c^2 \partial_{x_j}\beta)|\nabla\psi|^2 \, dxdt + s\lambda \int_{t_0}^{T}\int_{\Gamma} \varphi c^2 \partial_n\beta |\nabla\psi|^2 \, d\sigma dt$$
$$+ s\lambda \sum_{i=0,1} (-1)^{i+1} \int_{t_0}^{T}\int_{S} \varphi c_i^2 \partial_n\beta_i |\nabla\psi_i|^2 \, d\sigma dt.$$

The remaining volume integral can be further expanded into

$$I'''_{12} = -s\lambda \iint_{Q'} \varphi\partial_{x_j}(c^2\partial_{x_j}\beta)|\nabla\psi|^2 \, dxdt - s\lambda^2 \iint_{Q'} \varphi c^2 |\nabla\beta|^2 |\nabla\psi|^2 \, dxdt.$$

Collecting the surface integrals in a term denoted by J_{12}, we find

$$I_{12} = -s\lambda^2 \iint_{Q'} \varphi c^2 |\nabla\beta|^2 |\nabla\psi|^2 \, dxdt + 2s\lambda^2 \iint_{Q'} c^2\varphi |\nabla\psi \cdot \nabla\beta|^2 \, dxdt + X_1 + J_{12},$$

where

$$X_1 = 2s\lambda \iint_{Q'} \varphi c \, \partial_{x_i}(c\partial_{x_j}\beta)\partial_{x_i}\psi\partial_{x_j}\psi \, dxdt - s\lambda \iint_{Q'} \varphi\partial_{x_j}(c^2\partial_{x_j}\beta)|\nabla\psi|^2 \, dxdt.$$

We now observe that since β is constant on S we have

$$(\nabla\beta \cdot \nabla\psi_i)_{|S} = (\partial_n\beta\partial_n\psi_i)_{|S}, \quad i = 0, 1.$$

Writing $|\nabla\psi|^2 = |\nabla_\tau\psi|^2 + |\partial_n\psi|^2$, we find

$$J_{12} = s\lambda \sum_{i=0,1} (-1)^i \int_{t_0}^{T}\int_{S} \varphi c_i^2 \partial_n\beta_i |\partial_n\psi_i|^2 \, d\sigma dt$$
$$- s\lambda \sum_{i=0,1} (-1)^i \int_{t_0}^{T}\int_{S} \varphi c_i^2 \partial_n\beta_i |\nabla_\tau\psi_i|^2 \, d\sigma dt - s\lambda \int_{t_0}^{T}\int_{\Gamma} \varphi c^2 \partial_n\beta |\partial_n\psi|^2 \, d\sigma dt,$$

where we have used that $\psi_{|\Sigma}$ is constant. Recall that $\nabla_\tau \psi_0 = \nabla_\tau \psi_1$ and that $c_0 \partial_n \beta_0 = c_1 \partial_n \beta_1$ on S. From transmission conditions (TC2) we have

$$|c_0 \partial_n \psi_0|^2 = |c_1 \partial_n \psi_1|^2 + |g_s|^2 + 2(c_1(\partial_n \psi_1) g_s) \quad \text{on } S.$$

We thus obtain

$$\begin{aligned} J_{12} = s\lambda \int_{t_0}^{T}\!\!\int_S \varphi [\partial_n \beta]_S |c_1 \partial_n \psi_1|^2 \, d\sigma dt + s\lambda \int_{t_0}^{T}\!\!\int_S \varphi \partial_n \beta_0 |g_s|^2 \, d\sigma dt \\ - s\lambda \int_{t_0}^{T}\!\!\int_S \varphi [c]_S (c \partial_n \beta) |\nabla_\tau \psi|^2 \, d\sigma dt - s\lambda \int_{t_0}^{T}\!\!\int_\Gamma \varphi c^2 \partial_n \beta |\partial_n \psi|^2 \, d\sigma dt + Y_1, \end{aligned}$$

with

$$Y_1 = 2s\lambda \int_{t_0}^{T}\!\!\int_S \varphi c_1 \partial_n \psi_1 \, \partial_n \beta_0 \, g_s \, d\sigma dt. \tag{2.12}$$

We thus have

$$\begin{aligned} I_{12} = -s\lambda^2 \iint_{Q'} \varphi c^2 |\nabla \beta|^2 |\nabla \psi|^2 \, dxdt + 2s\lambda^2 \iint_{Q'} c^2 \varphi |\nabla \psi \cdot \nabla \beta|^2 \, dxdt \\ + s\lambda \int_{t_0}^{T}\!\!\int_S \varphi [\partial_n \beta]_S |c_1 \partial_n \psi_1|^2 \, d\sigma dt + s\lambda \int_{t_0}^{T}\!\!\int_S \varphi \partial_n \beta_0 |g_s|^2 \, d\sigma dt \\ - s\lambda \int_{t_0}^{T}\!\!\int_S \varphi [c]_S (c \partial_n \beta) |\nabla_\tau \psi|^2 \, d\sigma dt - s\lambda \int_{t_0}^{T}\!\!\int_\Gamma \varphi c^2 \partial_n \beta |\partial_n \psi|^2 \, d\sigma dt \\ + X_1 + Y_1. \end{aligned}$$

The term I_{13} is given by

$$\begin{aligned} I_{13} = -2s\lambda^2 \iint_{Q'} \varphi \nabla \cdot (c \nabla \psi) c |\nabla \beta|^2 \psi \, dxdt = 2s\lambda^2 \iint_{Q'} c \nabla \psi \cdot \nabla (\varphi c |\nabla \beta|^2 \psi) \, dxdt \\ + 2s\lambda^2 \sum_{i=0,1} (-1)^i \int_{t_0}^{T}\!\!\int_S \varphi (c_i \partial_n \psi_i) c_i |\nabla \beta_i|^2 \psi \, d\sigma dt, \end{aligned}$$

where we have used that $\psi_{|\Gamma} = 0$. Expanding the integrand in the volume integral and using (TC2) in the surface term, we obtain

$$I_{13} = 2s\lambda^2 \iint_{Q'} \varphi c^2 |\nabla \beta|^2 |\nabla \psi|^2 \, dxdt + X_2 + Y_2,$$

where

$$\begin{aligned} X_2 = 2s\lambda^2 \iint_{Q'} \varphi c \nabla \psi \cdot \nabla (c |\nabla \beta|^2) \psi \, dxdt + 2s\lambda^3 \iint_{Q'} \varphi c^2 \nabla \psi \cdot \nabla \beta |\nabla \beta|^2 \psi \, dxdt \\ + 2s\lambda^2 \int_{t_0}^{T}\!\!\int_S \varphi (c \partial_n \beta) [\partial_n \beta]_S (c_1 \partial_n \psi_1) \psi \, d\sigma dt, \end{aligned}$$

since $\nabla_\tau \beta_{|S} = 0$ and

$$Y_2 = 2s\lambda^2 \int_{t_0}^{T}\!\!\int_S \varphi c_0 (\partial_n \beta_0)^2 g_s \psi \, d\sigma dt.$$

Following the proof of Theorem 3.3 in [8], we find

$$I_{21} = \frac{1}{2}s^2\lambda^2 \iint_{Q'} \varphi^2 c|\nabla\beta|^2\partial_t|\psi|^2 \, dxdt = -\frac{1}{2}s^2\lambda^2 \iint_{Q'} \partial_t(\varphi^2)c|\nabla\beta|^2|\psi|^2 \, dxdt$$

and

$$\begin{aligned} I_{22} &= -s^3\lambda^3 \iint_{Q'} \varphi^3 c^2|\nabla\beta|^2\nabla\beta\cdot\nabla(|\psi|^2) \, dxdt \\ &= 3s^3\lambda^4 \iint_{Q'} \varphi^3 c^2|\nabla\beta|^4|\psi|^2 \, dxdt + s^3\lambda^3 \int_{t_0}^{T}\int_S \varphi^3|c\partial_n\beta|^2[\partial_n\beta]_S|\psi|^2 \, d\sigma dt + X_3, \end{aligned}$$

with X_3 given by

$$X_3 = s^3\lambda^3 \iint_{Q'} \varphi^3\nabla\cdot(c^2|\nabla\beta|^2\nabla\beta)|\psi|^2 \, dxdt.$$

The terms I_{23}, I_{31} are given by

$$I_{23} = -2s^3\lambda^4 \iint_{Q'} \varphi^3 c^2|\nabla\beta|^4|\psi|^2 \, dxdt,$$

$$I_{31} = \frac{1}{2}s \iint_{Q'} \partial_t\eta\partial_t(|\psi|^2) \, dxdt = -\frac{1}{2}s \iint_{Q'} \partial_t^2\eta|\psi|^2 \, dxdt.$$

The term I_{32} is given by

$$\begin{aligned} I_{32} = -s^2\lambda \iint_{Q'} \varphi(\partial_t\eta)c\nabla\beta\cdot\nabla(|\psi|^2) \, dxdt &= s^2\lambda^2 \iint_{Q'} \varphi(\partial_t\eta)c|\nabla\beta|^2|\psi|^2 \, dxdt \\ &\quad + s^2\lambda \iint_{Q'} \varphi\nabla\cdot((\partial_t\eta)c\nabla\beta)|\psi|^2 \, dxdt, \end{aligned}$$

since $\psi_{|S_0} = \psi_{|S_1}$. Finally, the term I_{33} is given by

$$I_{33} = -2s^2\lambda^2 \iint_{Q'} \varphi c(\partial_t\eta)|\nabla\beta|^2|\psi|^2 \, dxdt.$$

Collecting the terms I_{ij} just computed, we obtain

$$\begin{aligned} &|M_1\psi|^2_{L^2(Q')} + |M_2\psi|^2_{L^2(Q')} + 4s\lambda^2 \iint_{Q'} c^2\varphi|\nabla\psi\cdot\nabla\beta|^2 \, dxdt \\ &\quad + 2s\lambda^2 \iint_{Q'} \varphi c^2|\nabla\beta|^2|\nabla\psi|^2 \, dxdt + 2s^3\lambda^4 \iint_{Q'} \varphi^3 c^2|\nabla\beta|^4|\psi|^2 \, dxdt \\ &\quad + 2s\lambda \int_{t_0}^{T}\int_S \varphi[\partial_n\beta]_S|c_1\partial_n\psi_1|^2 \, d\sigma dt - 2s\lambda \int_{t_0}^{T}\int_\Gamma \varphi c^2\partial_n\beta|\partial_n\psi|^2 \, d\sigma dt \\ &\quad - 2s\lambda \int_{t_0}^{T}\int_S \varphi[c]_S(c\partial_n\beta)|\nabla_\tau\psi|^2 \, d\sigma dt + 2s^3\lambda^3 \int_{t_0}^{T}\int_S \varphi^3|c\partial_n\beta|^2[\partial_n\beta]_S|\psi|^2 \, d\sigma dt \\ &\quad + 2s\lambda \int_{t_0}^{T}\int_S \varphi\partial_n\beta_0|g_s|^2 \, d\sigma dt \\ &\quad = |f_s|^2_{L^2(Q')} - 2(I_{11} + X_1 + Y_1 + X_2 + Y_2 + I_{21} + X_3 + I_{31} + I_{32} + I_{33}). \end{aligned} \tag{2.13}$$

We now consider the surface terms I_{11}, Y_1, Y_2 involving the function g_s and write

$$|I_{11}| = \left| \int_{t_0}^{T}\int_{S} \partial_t(g_s)\, \psi \, d\sigma dt \right| \leq Cs^{-2} \int_{t_0}^{T}\int_{S} |\partial_t g_s|^2 \, d\sigma dt + Cs^2 \int_{t_0}^{T}\int_{S} |\psi|^2 \, d\sigma dt. \tag{2.14}$$

In the proof of Lemma 2.1 we are free to choose β such that $\partial_n\beta_1/c_0 \leq -1$. Since we assume $c_0 - c_1 \geq \Delta$ we obtain

$$[\partial_n\beta]_S = \partial_n\beta_0 - \partial_n\beta_1 = \frac{\partial_n\beta_1}{c_0}(c_1 - c_0) \geq \Delta > 0. \tag{2.15}$$

The second term in (2.14) can thus be absorbed by the term

$$2s^3\lambda^3 \int_{t_0}^{T}\int_{S} \varphi^3 |c\partial_n\beta|^2 [\partial_n\beta]_S |\psi|^2 \, d\sigma dt$$

in (2.13) for s sufficiently large.

The term Y_1 in (2.12) can be estimated by

$$\begin{aligned} |Y_1| &= \left| 2s\lambda \int_{t_0}^{T}\int_{S} \varphi c_1 \partial_n\psi_1 \, \partial_n\beta_0 \, g_s \, d\sigma dt \right| \\ &\leq C_\varepsilon s\lambda \int_{t_0}^{T}\int_{S} \varphi |g_s|^2 \, d\sigma dt + \varepsilon s\lambda \int_{t_0}^{T}\int_{S} \varphi |c_1\partial_n\psi_1|^2 (\partial_n\beta_0)^2 \, d\sigma dt, \quad \varepsilon > 0. \end{aligned} \tag{2.16}$$

For ε sufficiently small, the second surface term in (2.16) can be "absorbed" by the term

$$2s\lambda \int_{t_0}^{T}\int_{S} \varphi [\partial_n\beta]_S |c_1\partial_n\psi_1|^2 \, d\sigma dt$$

in (2.13) by (2.15).

The term Y_2 can be estimated by

$$\begin{aligned} |Y_2| = \left| 2s\lambda^2 \int_{t_0}^{T}\int_{S} \varphi c_0 (\partial_n\beta_0)^2 g_s \psi \, d\sigma dt \right| &\leq Cs\lambda \int_{t_0}^{T}\int_{S} \varphi |g_s|^2 \, d\sigma dt \\ &\quad + Cs\lambda^3 \int_{t_0}^{T}\int_{S} \varphi c_0^2 (\partial_n\beta_0)^4 |\psi|^2 \, d\sigma dt. \end{aligned}$$

Observing that $\varphi \leq CT^4\varphi^3$, the second surface term can be absorbed by the term

$$2s^3\lambda^3 \int_{t_0}^{T}\int_{S} \varphi^3 |c\partial_n\beta|^2 [\partial_n\beta]_S |\psi|^2 \, d\sigma dt$$

in (2.13) for s sufficiently large by (2.15). The two previous "absorption processes" are the points in the proof where the hypothesis $c_0 - c_1 \geq \Delta > 0$ is needed.

Note also that

$$\begin{aligned} s^{-2}|\partial_t g_s|^2 &\leq Cs^{-2}e^{-2s\eta}|\partial_t g|^2 + C(\partial_t\eta)^2 e^{-2s\eta}|g|^2 \\ &\leq Cs^{-2}e^{-2s\eta}|\partial_t g|^2 + CT^2\varphi^4 e^{-2s\eta}|g|^2, \end{aligned}$$

where we have used that $|\partial_t \eta| \leq CT\varphi^2$ [8, equation (90)] (which makes use of the particular choices made above for K and $\overline{\beta}$, which implies that $\overline{\beta} \leq 2\beta$).

Applying the technique presented in the proof of Theorem 3.3 in [8], the previous observations yield the following Carleman estimate (we use the notation $\eta^{(i)}$ instead of η):

(2.17)

$$
\begin{aligned}
&|M_1^{(i)}(e^{-s\eta^{(i)}}q)|^2_{L^2(Q')} + |M_2^{(i)}(e^{-s\eta^{(i)}}q)|^2_{L^2(Q')} + s\lambda^2 \iint_Q e^{-2s\eta^{(i)}}\ \varphi^{(i)}|\nabla q|^2\ dx\ dt \\
&\qquad + s^3\lambda^4 \iint_Q e^{-2s\eta^{(i)}}\ {\varphi^{(i)}}^3|q|^2\ dx\ dt \\
&\leq C\left[s\lambda \int_{t_0}^T\!\!\int_\gamma e^{-2s\eta^{(i)}}\ \varphi^{(i)}|\partial_n q|^2\ d\sigma\ dt + s^3\lambda^4 \int_{t_0}^T\!\!\int_{\widetilde{B}^{(i)}} e^{-2s\eta^{(i)}}{\varphi^{(i)}}^3|q|^2 dx dt\right. \\
&\qquad + \iint_{Q'} e^{-2s\eta^{(i)}}\ |\partial_t q - \nabla\cdot(c\nabla q)|^2\ dx\ dt + s^{-2}\int_{t_0}^T\!\!\int_S e^{-2s\eta^{(i)}}|\partial_t g|^2 d\sigma\ dt \\
&\qquad\qquad \left. + \int_{t_0}^T\!\!\int_S e^{-2s\eta^{(i)}}\ {\varphi^{(i)}}^4|g|^2\ d\sigma\ dt + s\lambda\int_{t_0}^T\!\!\int_S e^{-2s\eta^{(i)}}\ \varphi^{(i)}|g|^2\ d\sigma\ dt\right],
\end{aligned}
$$

for $i = 1, 2$, and for $\lambda \geq \lambda_0(\Omega, \gamma, \mathcal{O}^{(1)}, \mathcal{O}^{(2)}, c_{min}, c_{max}, \Delta)$ and $s \geq s_0(\lambda_0)$ (the sets $\widetilde{B}^{(i)}$ were introduced in Lemma 2.1). Note that the condition $[c]_s \geq 0$ is needed to obtain the previous estimate.

Adding (2.17) for $i = 1, 2$, we deduce (2.5) with the same argumentation as in the proof of Theorem 3.4 in [8]. The terms integrated over $(t_0, T) \times \widetilde{B}^{(i)}$ are absorbed by other terms using properties (2.1)–(2.3) of $\widetilde{\beta}^{(i)}$, $i = 1, 2$. □

Remark 2.3. The Carleman estimate that was just derived is peculiar because of the presence of terms integrated on the interface S. In particular, two terms involve the function g with different powers for the parameters s and λ and for the weight functions $\varphi^{(i)}$, $i = 1, 2$. This Carleman estimate is the key ingredient in the subsequent analysis. The interface terms will require some special treatment. The two parameters s and λ will also have an important role to play in the next section.

Remark 2.4. In the case $g = 0$, the previous Carleman estimate simplifies. By inspection of the proof of Theorem 2.2, observe that in the case $g = 0$, the condition $c_{0|_S} - c_{1|_S} \geq 0$ is sufficient to obtain the Carleman estimate [8]. The case of $c_{0|_S} - c_{1|_S} < 0$ remains open in the case of a dimension greater than or equal to 2. (In the one-dimensional case a Carleman estimate for the heat operator, $\partial_t \pm \partial_x(c\partial_x)$, in arbitrary situations, can be found in [3, 4].)

3. Uniqueness and stability estimate for the diffusion coefficients. In this section we establish a uniqueness result for the discontinuous diffusion coefficient c as well as a stability inequality. This inequality estimates the discrepancy in the coefficients c and $\widetilde{c}$ of two materials (with the same geometry) with an upper bound given by some Sobolev norms of the difference between the solutions y and $\widetilde{y}$ to

$$
\begin{cases}
\partial_t \widetilde{y} - \nabla\cdot(\widetilde{c}\nabla\widetilde{y}) = 0 & \text{in } (0,T)\times\Omega, \\
\widetilde{y}(t,x) = h(t,x) & \text{on } (0,T)\times\Gamma, \\
\text{transmission conditions } (\widetilde{\text{TC1}}) & \text{on } [0,T]\times S, \\
\widetilde{y}(0) = \widetilde{y}_0, &
\end{cases}
\tag{3.1}
$$

with

$$(\widetilde{\text{TC1}}) \qquad \widetilde{y}_{|[0,T]\times S_0} = \widetilde{y}_{|[0,T]\times S_1}, \quad \widetilde{c}_0\partial_n\widetilde{y}_{|[0,T]\times S_0} = \widetilde{c}_1\partial_n\widetilde{y}_{|[0,T]\times S_1},$$

and

$$\begin{cases} \partial_t y - \nabla\cdot(c\nabla y) = 0 & \text{in } (0,T)\times\Omega, \\ y(t,x) = h(t,x) & \text{on } (0,T)\times\Gamma, \\ \text{transmission conditions (TC1)} & \text{on } [0,T]\times S, \\ y(0) = y_0. \end{cases} \tag{3.2}$$

The Carleman estimate proved in the previous section will be the key ingredient in the proof of such a stability estimate.

We introduce

$$\xi = c - \widetilde{c} = \begin{cases} \xi_0 = c_0 - \widetilde{c}_0 & \text{in } \Omega_0, \\ \xi_1 = c_1 - \widetilde{c}_1 & \text{in } \Omega_1. \end{cases}$$

We set $u = y - \widetilde{y}$ and $v = \partial_t u$. Then v is solution to the following problem:

$$\begin{cases} \partial_t v - \nabla\cdot(c\nabla v) = \nabla\cdot(\xi\nabla\partial_t\widetilde{y}) & \text{in } (0,T)\times\Omega', \\ v = 0 & \text{on } (0,T)\times\Gamma, \\ \text{transmission conditions (TC2)} & \text{on } [0,T]\times S, \end{cases} \tag{3.3}$$

with

$$\text{(TC2)} \qquad \begin{cases} v_{|_{[0,T]\times S_0}} = v_{|_{[0,T]\times S_1}}, \\ c_0\partial_n v_{|_{[0,T]\times S_0}} = c_1\partial_n v_{|_{[0,T]\times S_1}} + g(t,x), \end{cases}$$

where

$$g(t,x) = \xi_1\partial_n\partial_t\widetilde{y}_{|_{[0,T]\times S_1}} - \xi_0\partial_n\partial_t\widetilde{y}_{|_{[0,T]\times S_0}} = \alpha\partial_n\partial_t\widetilde{y}_{|_{[0,T]\times S_0}},$$

with $\alpha = \xi_{1|_{S_1}}\frac{\widetilde{c}_{0|_{S_0}}}{\widetilde{c}_{1|_{S_1}}} - \xi_{0|_{S_0}}$.

Let $T' = \frac{1}{2}(T+t_0)$. We make the following assumption.

ASSUMPTION 3.1. *The solutions $\widetilde{y}$ and y belong to $H^2(t_0,T,H^1(\Omega))$ and are such that $y_{|\Omega_i} \in H^1(t_0,T,H^2(\Omega_i))$, $\widetilde{y}_{|\Omega_i} \in H^2(t_0,T,H^2(\Omega_i))$, $i=0,1$. Furthermore, $\widetilde{y}$ satisfies the following:*

1. *Let $r>0$. The solution $\widetilde{y}$ is such that $|\Delta\widetilde{y}(T')| \geq r > 0$ in Ω'.*
2. *$\widetilde{y}_{|\Omega_i}$ is in a bounded domain of $W^{2,\infty}(t_0,T,H^2(\Omega_i))$, $i=0,1$: there exists $M>0$ such that*

$$|\widetilde{y}_{|\Omega_i}(t,.)|^2_{H^2(\Omega_i)} + |\partial_t\widetilde{y}_{|\Omega_i}(t,.)|^2_{H^2(\Omega_i)} + |\partial_t^2\widetilde{y}_{|\Omega_i}(t,.)|^2_{H^2(\Omega_i)} \leq M, \quad i=0,1,$$

   a.e. for $t\in(t_0,T)$.
3. *$\Delta\partial_t\widetilde{y}_{|\Omega_i}$ is in a bounded domain of $L^2(t_0,T,L^\infty(\Omega_i))$, $i=0,1$: there exists $K>0$ such that*

$$\int_{t_0}^T |\Delta\partial_t\widetilde{y}_{|\Omega_i}(t,.)|^2_{L^\infty(\Omega_i)}dt \leq K^2, \qquad i=0,1.$$

In section 4 we shall show that for *any* initial conditions y_0, $\widetilde{y}_0$ in $L^2(\Omega)$ we can achieve the properties listed in Assumption 3.1 by using some particular boundary conditions $h(t,x)$.

From Assumption 3.1, the functions $\widetilde{y}$ and v are such that $\widetilde{y}_{|\Omega_i}, v_{|\Omega_i} \in H^2(\Omega_i)$, $i=0,1$. Then $g \in H^1(t_0,T,H^{\frac{1}{2}}(S))$. The second equality in transmission condition (TC2) thus takes place in the space $H^{\frac{1}{2}}(S)$. Observe that $v=\partial_t(y-\widetilde{y}) \in \aleph_g$ from the above assumption. We can thus apply Carleman estimate (2.5) to v.

We shall use the notation of the proof of Theorem 2.2. We set $\psi^{(i)}=e^{-s\eta^{(i)}}v$, $i=1,2$. With the operator $M_2^{(i)}$ defined in (2.10) we introduce, following [2],

$$I^{(i)}=\int_{t_0}^{T'}\!\!\int_{\Omega'} M_2^{(i)}\psi^{(i)}\ {\varphi^{(i)}}^{\frac{3}{2}}\psi^{(i)}\ dxdt, \quad i=1,2, \quad \text{and} \quad I=\frac{1}{2}(I^{(1)}+I^{(2)}).$$

Note the additional ${\varphi^{(i)}}^{\frac{3}{2}}$ factor as compared to [2]. This will be of importance below.

We have the following estimates.

LEMMA 3.2. *Let $\lambda \geq \lambda_1$ and $s \geq s_1$; then*

$$\begin{aligned}|I| \leq Cs^{-3/2}\lambda^{-2}\Bigg[& s\lambda\int_{t_0}^{T}\!\!\int_{\gamma}(e^{-2s\eta^{(1)}}\varphi^{(1)}+e^{-2s\eta^{(2)}}\varphi^{(2)})\ |\partial_n v|^2\ d\sigma\ dt \\ & + \iint_{Q'}(e^{-2s\eta^{(1)}}+e^{-2s\eta^{(2)}})\ |\partial_t v-\nabla\cdot(c\nabla v)|^2\ dx\ dt \\ & + s\lambda\int_{t_0}^{T}\!\!\int_{S}(e^{-2s\eta^{(1)}}\varphi^{(1)}+e^{-2s\eta^{(2)}}\varphi^{(2)})\ |g|^2\ d\sigma\ dt \\ & + \int_{t_0}^{T}\!\!\int_{S}(e^{-2s\eta^{(1)}}{\varphi^{(1)}}^4+e^{-2s\eta^{(2)}}{\varphi^{(2)}}^4)\ |g|^2\ d\sigma\ dt \\ & + s^{-2}\int_{t_0}^{T}\!\!\int_{S}(e^{-2s\eta^{(1)}}+e^{-2s\eta^{(2)}})|\partial_t g|^2 d\sigma\ dt\Bigg].\end{aligned}$$

Proof. Observe that

$$|I^{(i)}| \leq \frac{1}{2}s^{-3/2}\lambda^{-2}\left(|M_2^{(i)}\psi^{(i)}|^2_{L^2(Q')}+s^3\lambda^4\iint_Q {\varphi^{(i)}}^3 e^{-2s\eta^{(i)}}|v|^2dxdt\right), \qquad i=1,2.$$

(We recall that $Q'=(t_0,T)\times\Omega'$.) Thus

$$\begin{aligned}|I| \leq \frac{1}{2}s^{-3/2}\lambda^{-2}\Bigg(&|M_2^{(1)}\psi^{(1)}|^2_{L^2(Q')}+|M_2^{(2)}\psi^{(2)}|^2_{L^2(Q')} \\ &+s^3\lambda^4\iint_Q(e^{-2s\eta^{(1)}}{\varphi^{(1)}}^3+e^{-2s\eta^{(2)}}{\varphi^{(2)}}^3)\ |v|^2\ dx\ dt\Bigg),\end{aligned}$$

which yields the result from Carleman estimate (2.5). ∎

LEMMA 3.3. *Let $\lambda \geq \lambda_1$ and $s \geq s_1$; then*

$$\begin{aligned}
&\int_{\Omega'} \left(e^{-2s\eta^{(1)}} {\varphi^{(1)}}^{\frac{3}{2}} + e^{-2s\eta^{(2)}} {\varphi^{(2)}}^{\frac{3}{2}} \right) (T',x)\ |v(T',.)|^2\ dx \\
&\quad \leq Cs^{-3/2}\lambda^{-2} \left[s\lambda \int_{t_0}^{T}\!\!\int_{\gamma} (e^{-2s\eta^{(1)}} \varphi^{(1)} + e^{-2s\eta^{(2)}} \varphi^{(2)})\ |\partial_n v|^2\ d\sigma\ dt \right. \\
&\qquad + \iint_{Q'} (e^{-2s\eta^{(1)}} + e^{-2s\eta^{(2)}})\ |\nabla \cdot (\xi \nabla \partial_t \widetilde{y})|^2\ dx\ dt \\
&\qquad + s\lambda \int_{t_0}^{T}\!\!\int_{S} (e^{-2s\eta^{(1)}} \varphi^{(1)} + e^{-2s\eta^{(2)}} \varphi^{(2)})\ |g|^2\ d\sigma\ dt \\
&\qquad + \int_{t_0}^{T}\!\!\int_{S} (e^{-2s\eta^{(1)}} {\varphi^{(1)}}^4 + e^{-2s\eta^{(2)}} {\varphi^{(2)}}^4)\ |g|^2\ d\sigma\ dt \\
&\qquad \left. + s^{-2} \int_{t_0}^{T}\!\!\int_{S} (e^{-2s\eta^{(1)}} + e^{-2s\eta^{(2)}}) |\partial_t g|^2 d\sigma\ dt \right].
\end{aligned}$$

Proof. We evaluate integral $I^{(i)}$, $i = 1, 2$, using (2.10),

$$\begin{aligned}
I^{(i)} &= \int_{t_0}^{T'}\!\!\int_{\Omega'} \left(\partial_t \psi^{(i)} - 2s\lambda \varphi^{(i)} c \nabla \beta^{(i)} \cdot \nabla \psi^{(i)} - 2s\lambda^2 \varphi^{(i)} c |\nabla \beta^{(i)}|^2 \psi^{(i)} \right) {\varphi^{(i)}}^{\frac{3}{2}} \psi^{(i)}\, dxdt \\
&= \frac{1}{2} \int_{t_0}^{T'}\!\!\int_{\Omega'} {\varphi^{(i)}}^{\frac{3}{2}} \partial_t |\psi^{(i)}|^2\ dxdt - s\lambda \int_{t_0}^{T'}\!\!\int_{\Omega'} {\varphi^{(i)}}^{\frac{5}{2}} c \nabla \beta^{(i)} \cdot \nabla |\psi^{(i)}|^2\ dxdt \\
&\qquad - 2s\lambda^2 \int_{t_0}^{T'}\!\!\int_{\Omega'} {\varphi^{(i)}}^{\frac{5}{2}} c |\nabla \beta^{(i)}|^2 |\psi^{(i)}|^2 dxdt \\
&= \frac{1}{2} \int_{t_0}^{T'}\!\!\int_{\Omega'} {\varphi^{(i)}}^{\frac{3}{2}} \partial_t |\psi^{(i)}|^2\ dxdt + s\lambda \int_{t_0}^{T'}\!\!\int_{\Omega'} \nabla \cdot ({\varphi^{(i)}}^{\frac{5}{2}} c \nabla \beta^{(i)}) |\psi^{(i)}|^2\ dxdt \\
&\qquad - 2s\lambda^2 \int_{t_0}^{T'}\!\!\int_{\Omega'} {\varphi^{(i)}}^{\frac{5}{2}} c |\nabla \beta^{(i)}|^2 |\psi^{(i)}|^2 dxdt,
\end{aligned}$$

by integration by parts, without any remaining integral over $(t_0, T') \times S$ by condition transmission (2.8). With an integration by parts w.r.t. t in the first integral, we then obtain

$$\begin{aligned}
&\frac{1}{2} \int_{\Omega'} {\varphi^{(i)}}^{\frac{3}{2}} |\psi^{(i)}(T',.)|^2\ dx = I^{(i)} + \frac{1}{2} s\lambda^2 \int_{t_0}^{T'}\!\!\int_{\Omega'} {\varphi^{(i)}}^{\frac{5}{2}} c |\nabla \beta^{(i)}|^2 |\psi^{(i)}|^2 dxdt \\
&\quad - s\lambda \int_{t_0}^{T'}\!\!\int_{\Omega'} {\varphi^{(i)}}^{\frac{5}{2}} \nabla \cdot (c \nabla \beta^{(i)}) |\psi^{(i)}|^2\ dxdt + \frac{3}{4} \int_{t_0}^{T'}\!\!\int_{\Omega'} (\partial_t \varphi^{(i)}) {\varphi^{(i)}}^{\frac{1}{2}} |\psi^{(i)}|^2\ dxdt, \\
&\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad i = 1, 2,
\end{aligned} \tag{3.4}$$

since ${\varphi^{(i)}}^{\frac{3}{2}} \psi^{(i)}(t_0, .) = 0$. Adding (3.4) for $i = 1, 2$, we obtain

$$\begin{aligned}
&\int_{\Omega'} \left(e^{-2s\eta^{(1)}} {\varphi^{(1)}}^{\frac{3}{2}} + e^{-2s\eta^{(2)}} {\varphi^{(2)}}^{\frac{3}{2}} \right) (T',x)\ |v(T',.)|^2\ dx \\
&\leq 4|I| + C(s\lambda^2 + s\lambda + 1) \int_{t_0}^{T'}\!\!\int_{\Omega'} \left(e^{-2s\eta^{(1)}(t,x)} {\varphi^{(1)}}^{\frac{5}{2}} + e^{-2s\eta^{(2)}(t,x)} {\varphi^{(2)}}^{\frac{5}{2}} \right) |v|^2 dxdt,
\end{aligned} \tag{3.5}$$

observing that $|\partial_t \varphi^{(i)}| \le CT{\varphi^{(i)}}^2$, $i = 1, 2$. We use Carleman estimate (2.5) to obtain an upper bound for the last term in (3.5), which yields the result by Lemma 3.2. ∎

We shall now assume the following.

ASSUMPTION 3.4. *The diffusion coefficients c and $\widetilde{c}$ are piecewise-constant, in the sense that $c_{|\Omega_i}$ (resp., $\widetilde{c}_{|\Omega_i}$) are constant in each connected component of Ω_i, $i = 0, 1$. We define*

$$c_{0,j} = c_{|\Omega_{0,j}},\ j = 1, \dots, p_0, \quad c_{1,j} = c_{|\Omega_{1,j}},\ j = 1, \dots, p_1,$$

with similar notation for $\widetilde{c}$ and ξ.

In this case observe that, in Ω',

$$\begin{aligned} v(T', x) = c\Delta u(T', x) + \xi\Delta\widetilde{y}(T', x) &= \sum_{j=1}^{p_0} c_{0,j}\Delta u(T', x)\chi_{\Omega_{0,j}} + \sum_{j=1}^{p_1} c_{1,j}\Delta u(T', x)\chi_{\Omega_{1,j}} \\ &\quad + \sum_{j=1}^{p_0} \xi_{0,j}\Delta\widetilde{y}(T', x)\chi_{\Omega_{0,j}} + \sum_{j=1}^{p_1} \xi_{1,j}\Delta\widetilde{y}(T', x)\chi_{\Omega_{1,j}}, \end{aligned}$$

from the equation satisfied by u expressed at time T' and the definition of v above.

From Lemma 3.3, we obtain

$$\begin{aligned} &\int_{\Omega'} \left(e^{-2s\eta^{(1)}} {\varphi^{(1)}}^{\frac{3}{2}} + e^{-2s\eta^{(2)}} {\varphi^{(2)}}^{\frac{3}{2}} \right) (T', x) |\xi\Delta\widetilde{y}(T', x)|^2 dx \\ &\quad \le C \int_{\Omega'} \left(e^{-2s\eta^{(1)}} {\varphi^{(1)}}^{\frac{3}{2}} + e^{-2s\eta^{(2)}} {\varphi^{(2)}}^{\frac{3}{2}} \right) (T', x) |c\Delta u(T', x)|^2 dx \\ &\qquad + Cs^{-3/2}\lambda^{-2} \Bigg[s\lambda \int_{t_0}^{T}\int_{\gamma} (e^{-2s\eta^{(1)}}\varphi^{(1)} + e^{-2s\eta^{(2)}}\varphi^{(2)})\ |\partial_n v|^2\ d\sigma\ dt \\ &\qquad\qquad + \iint_{Q'} (e^{-2s\eta^{(1)}} + e^{-2s\eta^{(2)}})\ |\nabla\cdot(\xi\nabla\partial_t\widetilde{y})|^2\ dx\ dt \\ &\qquad\qquad + s\lambda \int_{t_0}^{T}\int_{S} (e^{-2s\eta^{(1)}}\varphi^{(1)} + e^{-2s\eta^{(2)}}\varphi^{(2)})\ |g|^2\ d\sigma\ dt \\ &\qquad\qquad + \int_{t_0}^{T}\int_{S} (e^{-2s\eta^{(1)}}{\varphi^{(1)}}^4 + e^{-2s\eta^{(2)}}{\varphi^{(2)}}^4)\ |g|^2\ d\sigma\ dt \\ &\qquad\qquad + s^{-2} \int_{t_0}^{T}\int_{S} (e^{-2s\eta^{(1)}} + e^{-2s\eta^{(2)}}) |\partial_t g|^2 d\sigma\ dt \Bigg]. \end{aligned} \tag{3.6}$$

From Assumption 3.1 we find that

$$|\Delta\partial_t\widetilde{y}(t, x)|^2 \le k^2(t)|\Delta\widetilde{y}(T', x)|^2 \quad \text{in each } (t_0, T)\times\Omega_i,\ i = 0, 1,$$

for

$$k(t) = \frac{1}{r}\sup_{i=0,1} |\Delta\partial_t\widetilde{y}_{|\Omega_i}(t, .)|_{L^\infty(\Omega_i)}.$$

From Assumption 3.1, $k \in L^2(t_0, T)$ and $|k|_{L^2(t_0,T)} \le K' = \frac{1}{r}K$. These observations yield the following estimation of the third term in the r.h.s. of (3.6):

$$\begin{aligned} &\int_{t_0}^{T}\int_{\Omega_i} (e^{-2s\eta^{(1)}} + e^{-2s\eta^{(2)}})\ |\xi\Delta\partial_t\widetilde{y}|^2\ dx\ dt \\ &\quad \le K'^2 \sum_{i=0,1}\sum_{j=1}^{p_i} |\xi_{i,j}|^2 \int_{\Omega_{i,j}} \left(e^{-2s\eta^{(1)}(T',x)} + e^{-2s\eta^{(2)}(T',x)} \right) |\Delta\widetilde{y}(T', x)|^2 dx, \end{aligned} \tag{3.7}$$

where we have used that

$$e^{-2s\eta^{(i)}(t,x)} \leq e^{-2s\eta^{(i)}(T',x)}, \quad x \in \Omega,\ t \in (t_0,T),\ i=1,2.$$

Observing that $0 < C \leq \varphi^{(i)}$, $i=1,2$, since $\beta^{(i)} \geq 0$ and $\frac{1}{(T-t)(t-t_0)} \geq C > 0$, we obtain

$$\int_{t_0}^{T}\int_{\Omega_i} (e^{-2s\eta^{(1)}} + e^{-2s\eta^{(2)}})\ |\xi\Delta\partial_t\widetilde{y}|^2\ dx\ dt$$
$$\leq K'^2 \sum_{i=0,1}\sum_{j=1}^{p_i} |\xi_{i,j}|^2 \int_{\Omega_{i,j}} \left(e^{-2s\eta^{(1)}}\varphi^{(1)\,\frac{3}{2}} + e^{-2s\eta^{(2)}(T',x)}\varphi^{(2)\,\frac{3}{2}}\right)(T',x)|\Delta\widetilde{y}(T',x)|^2 dx.$$

We now treat the interface terms that appear in the r.h.s. of the Carleman estimate. Recall that

$$g(t,x) = \alpha\partial_n\partial_t\widetilde{y}_{|[0,T]\times S_0}, \quad \alpha = \xi_1\frac{\widetilde{c}_0}{\widetilde{c}_1} - \xi_0.$$

Note that $\eta(t,.)$ is constant on S. We denote this constant by $\eta(t,S)$. More generally we shall denote by $\rho(S)$ the value on S of a function ρ which is constant on S. We obtain

$$\int_{t_0}^{T}\int_S (e^{-2s\eta^{(1)}} + e^{-2s\eta^{(2)}})|\partial_t g|^2 d\sigma\ dt \leq \int_{t_0}^{T} (e^{-2s\eta^{(1)}(t,S)} + e^{-2s\eta^{(2)}(t,S)}) \int_S |\partial_t g|^2 d\sigma\ dt$$
$$\leq M'|\xi|^2 \int_{t_0}^{T} (e^{-2s\eta^{(1)}(t,S)} + e^{-2s\eta^{(2)}(t,S)})dt,$$

from trace inequalities and from Assumption 3.1, for $M' = C_{Tr}(1+\frac{c_{max}}{c_{min}})^2 M$, where $|\xi| = \sqrt{\xi_0^2+\xi_1^2}$, since $|\alpha| \leq (1+\frac{c_{max}}{c_{min}})|\xi|$ from Assumption 1.2. The constant C_{Tr} is the constant found in the trace estimates

$$\int_S |\partial_n\widetilde{\rho}|^2 \leq C_{Tr}|\rho|^2_{H^2(\Omega_i)}, \quad i=0,1,$$

if $\rho_{|\Omega_i} \in H^2(\Omega_i)$, $i=0,1$. Similarly, since $\varphi^{(i)}$, $i=1,2$, are constant on S, we have

$$\int_{t_0}^{T}\int_S (e^{-2s\eta^{(1)}}\varphi^{(1)^j} + e^{-2s\eta^{(2)}}\varphi^{(2)^j})\ |g|^2\ d\sigma\ dt$$
$$\leq M'|\xi|^2 \int_{t_0}^{T} (e^{-2s\eta^{(1)}}\varphi^{(1)^j} + e^{-2s\eta^{(2)}}\varphi^{(2)^j})(t,S)\ dt, \quad j \in \mathbb{N}.$$

With

$$w_k(s,\lambda) := \int_{t_0}^{T} (e^{-2s\eta^{(1)}}\varphi^{(1)^k} + e^{-2s\eta^{(2)}}\varphi^{(2)^k})(t,S)\ dt, \quad k \in \mathbb{N},$$

and

$$W_{i,j}(s,\lambda) := \int_{\Omega_{i,j}} (e^{-2s\eta^{(1)}}\varphi^{(1)\,\frac{3}{2}} + e^{-2s\eta^{(2)}}\varphi^{(2)\,\frac{3}{2}})(T',x)|\Delta\widetilde{y}(T',x)|^2 dx,$$

$i = 0, 1$, $j = 1, \dots, p_i$, we thus obtain, for $\lambda \geq \lambda_1$ and $s \geq s_1$,

$$\begin{aligned}
&\sum_{i=0,1}\sum_{j=1}^{p_i} |\xi_{i,j}|^2 \Big\{ (1 - CK'^2 s^{-\frac{3}{2}}\lambda^{-2}) W_{i,j}(s,\lambda) \\
&\qquad\qquad - CM'[s^{-\frac{1}{2}}\lambda^{-1} w_1(s,\lambda) + s^{-\frac{3}{2}}\lambda^{-2} w_4(s,\lambda) + s^{-\frac{7}{2}}\lambda^{-2} w_0(s,\lambda)] \Big\} \\
&\quad \leq C \int_{\Omega'} \left(e^{-2s\eta^{(1)}} {\varphi^{(1)}}^{\frac{3}{2}} + e^{-2s\eta^{(2)}} {\varphi^{(2)}}^{\frac{3}{2}} \right) (T', x) |c\Delta u(T', .)|^2 dx \\
&\quad + C s^{-\frac{1}{2}} \lambda^{-1} \int_{t_0}^{T}\!\!\int_{\gamma} (e^{-2s\eta^{(1)}} \varphi^{(1)} + e^{-2s\eta^{(2)}} \varphi^{(2)}) \, |\partial_n v|^2 \, d\sigma \, dt. \qquad (3.8)
\end{aligned}$$

To obtain a stability result we need to prove that the coefficients for $|\xi_{i,j}|^2$, $i = 0, 1$, $j = 1, \dots, p_i$, can be made positive. To do so we need to understand the behavior of the integrals $w_k(s,\lambda)$ and $W_{i,j}(s,\lambda)$ as s and λ become large.

We first establish the asymptotic behavior of $w_k(s,\lambda)$. We set

$$w_k^{(i)}(s,\lambda) := \int_{t_0}^{T} e^{-2s\eta^{(i)}(t,S)} {\varphi^{(i)}}^k(t,S) \, dt, \quad k \in \mathbb{N}.$$

LEMMA 3.5. *The following estimates holds:*

$$\begin{aligned}
w_k^{(i)}(s,\lambda) = e^{-2s\eta^{(i)}(T',S)} \, {\varphi^{(i)}}^k(T',S) \Bigg\{ &\frac{\sqrt{\pi} s^{-\frac{1}{2}}}{\sqrt{\phi''(T')}\sqrt{e^{\lambda\overline{\beta}} - e^{\lambda\beta^{(i)}(S)}}} \\
&+ \mathcal{O}\left(\frac{s^{-\frac{3}{2}}}{(e^{\lambda\overline{\beta}} - e^{\lambda\beta^{(i)}(S)})^{\frac{3}{2}}} \right) \Bigg\}, \qquad (3.9)
\end{aligned}$$

with $\phi(t) = \frac{1}{(T-t)(t-t_0)}$, *for* $s > s_2 > 0$ *and* $\lambda > \lambda_2 > 0$.

Proof. Let $T^{(2)}$ and $T^{(3)}$ be such that $t_0 < T^{(2)} < T' < T^{(3)} < T$. We choose $\chi_1 \in \mathscr{C}_c^\infty([t_0, T^{(2)}))$, $\chi_2 \in \mathscr{C}_c^\infty((t_0, T))$, and $\chi_3 \in \mathscr{C}_c^\infty((T^{(3)}, T])$, all three nonnegative, such that $\chi_1 + \chi_2 + \chi_3 = 1$ and $\chi_1 = 1$ in a neighborhood of t_0, $\chi_2 = 1$ in a neighborhood of T', and $\chi_3 = 1$ in a neighborhood of T. With this partition of unity we break $w_k^{(i)}$ into three pieces: $w_k^{(i)} = w_k^{(i,1)} + w_k^{(i,2)} + w_k^{(i,3)}$ with

$$w_k^{(i,j)}(s,\lambda) := \int_{t_0}^{T} e^{-2s\eta^{(i)}(t,S)} {\varphi^{(i)}}^k(t,S) \, \chi_j(t) \, dt, \quad j = 1, 2, 3.$$

The first and the third term are treated similarly. Let $s_2 > 0$ and $\lambda_2 > 0$. We set $\tau(s,\lambda,S) = s(e^{\lambda\overline{\beta}} - e^{\lambda\beta^{(i)}(S)})$. We observe

$$\begin{aligned}
w_k^{(i,1)}(s,\lambda) &= e^{k\lambda\beta^{(i)}(S)} \int_{t_0}^{T} e^{-2s\eta^{(i)}(t,S)} \phi^k(t) \, \chi_1(t) \, dt \\
&\leq e^{k\lambda\beta^{(i)}(S)} e^{-2(s-s_2)\eta^{(i)}(T^{(2)},S)} \int_{t_0}^{T} e^{-2s_2\eta^{(i)}(t,S)} \phi^k(t) \, \chi_1(t) \, dt \\
&\leq C(s_2,\lambda_2) e^{k\lambda\beta^{(i)}(S)} e^{-2(s-s_2)\eta^{(i)}(T^{(2)},S)} \\
&\leq C e^{k\lambda\beta^{(i)}(S)} e^{-2s\eta^{(i)}(T',S)} e^{-2s(\eta^{(i)}(T^{(2)},S) - \eta^{(i)}(T',S))} \\
&= e^{k\lambda\beta^{(i)}(S)} e^{-2s\eta^{(i)}(T',S)} \mathcal{O}(\tau(s,\lambda,S)^{-l}),
\end{aligned}$$

for all $l \in \mathbb{N}$, if $s > s_2$ and $\lambda > \lambda_2$, since

$$s(\eta^{(i)}(T^{(2)}, S) - \eta^{(i)}(T', S)) = \tau(s, \lambda, S)(\phi(T^{(2)}) - \phi(T')),$$

and $\phi(T^{(2)}) - \phi(T') > 0$.

For the second term $w_k^{(i,2)}$ we write

$$\begin{aligned} w_k^{(i,2)}(s,\lambda) &:= e^{k\lambda\beta^{(i)}(S)} \int_{t_0}^{T} e^{-2\tau(s,\lambda,S)\phi(t)} \phi^k(t)\ \chi_2(t)\ dt \\ &= e^{k\lambda\beta^{(i)}(S)} e^{-2\tau(s,\lambda,S)\phi(T')} \int_{t_0}^{T} e^{-2\tau(s,\lambda,S)(\phi(t)-\phi(T'))} \phi^k(t)\ \chi_2(t)\ dt. \end{aligned}$$

We then apply the following stationary phase formula [15, Theorem 7.7.5] in one dimension:

$$\begin{aligned} &\left| \int u(y) e^{i\omega f(y)} dy - e^{i\omega f(y_0)} \left(\frac{\omega f''(y_0)}{2\pi i} \right)^{-\frac{1}{2}} \sum_{l<l_1} \omega^{-l} L_l u \right| \\ &\qquad \le C\omega^{-l_1-\frac{1}{2}} \sum_{|\alpha|\le 2l_1} \sup |\partial^\alpha u|, \qquad \omega > 0,\ u \in \mathscr{C}_c^\infty, \end{aligned}$$

where L_l is a differential operator of order $2l$ evaluated at T', $L_0 u = u(T')$. (To obtain the additional factor $-\frac{1}{2}$ in the r.h.s. as compared to the formula given in [15, Theorem 7.7.5], simply write the formula to the order $l_1 + 1$.) This formula is valid if $\mathrm{Im}(f) \ge 0$, $\mathrm{Im}(f(y_0)) = 0$, $f'(y_0) = 0$, $f''(y_0) \ne 0$, and $f'(y) \ne 0$ in $\mathrm{supp}(u) \setminus \{y_0\}$. Here the phase function $f(t) = i(\phi(t) - \phi(T'))$ is imaginary (note that $\phi''(T') > 0$), $\omega = 2\tau(s, \lambda, S)$, and $u = \phi^k \chi_2$. The stationary point is $t = T'$. With $l_1 = 1$, we obtain

$$\begin{aligned} &\left| \int_{t_0}^{T} e^{-2\tau(s,S)(\phi(t)-\phi(T'))} \phi^k(t)\ \chi_2(t)\ dt - \phi^k(T') \sqrt{\frac{\pi}{\phi''(T')}} \tau(s,\lambda,S)^{-\frac{1}{2}} \right| \\ &\qquad \le C\tau(s,\lambda,S)^{-3/2}. \end{aligned}$$

This yields (3.9). ∎

To achieve our goal we also need an estimation from below for the terms $W_{i,j}(s,\lambda)$. We set

$$W_{k,j}^{(i)}(s,\lambda) := \int_{\Omega_{k,j}} e^{-2s\eta^{(i)}(T',x)} \varphi^{(i)\,\frac{3}{2}}(T', x)\ |\Delta\widetilde{y}(T', x)|^2 dx,$$

$k = 0, 1$, $j = 1, \ldots, p_k$, $i = 1, 2$. For the terms $W_{0,j}^{(i)}(s,\lambda)$, we have the following.

LEMMA 3.6. *Let $\varepsilon > 0$. We have*

$$W_{0,j}^{(i)}(s,\lambda) \ge C_{s_2,i,j} \frac{r^2 |S_j|}{s\lambda} e^{-2s\eta^{(i)}(T',S)} (\varphi^{(i)}(T', S))^{\frac{1}{2}} e^{-\lambda\varepsilon}, \quad i = 1, 2,\ j = 1, \ldots, p_0,$$

for $s \ge s_2 > 0$, $\lambda > 0$, and where $S_j = \bigcup_{k=1,\ldots,p_1} S_{jk}$.

Proof. In the proof, we shall write β in place of $\beta^{(i)}$, etc. Taking δ sufficiently small, we start by choosing a small neighborhood W of S_j in $\overline{\Omega}_0$ *globally* parametrized by $(\sigma, y) \in [0, \delta] \times S_j$ (see the proof of Lemma A.6 in the appendix). In fact, we

can choose the coordinates and the small neighborhood of S_j such that $\sigma = cst$ corresponds to level sets for the function β (use $\nabla\beta$ for the vector field v in the proof of Lemma A.6). Note that in the neighborhood W the function β decreases with σ.

Estimating from below the Jacobian[1] originating from the change of variables and observing that the integrand is constant w.r.t. y, we obtain

$$\begin{aligned} W_{0,j}(s,\lambda) &\geq Cr^2|S_j| \int_0^\delta e^{-2s\eta(T',\sigma)}\varphi^{\frac{3}{2}}(T',\sigma)d\sigma \\ &= Cr^2|S_j|e^{-2s\eta(T',S)} \int_0^\delta e^{-2s(\eta(T',\sigma)-\eta(T',S))}\varphi^{\frac{3}{2}}(T',\sigma)d\sigma. \end{aligned}$$

We now use the change of variables $\sigma' = \eta(T',\sigma) - \eta(T',S) \geq 0$, which yields

$$W_{0,j}(s,\lambda) \geq Cr^2|S_j|\lambda^{-1}e^{-2s\eta(T',S)} \int_0^{\delta'} e^{-2s\sigma'}\varphi^{\frac{1}{2}}(T',\sigma)|\partial_\sigma\beta|^{-1}d\sigma',$$

where $\delta' = \eta(T',\delta) - \eta(T',S)$. We can find in W a positive lower bound for $(\partial_\sigma\beta)^{-1}$ independent of δ, i.e., the size of W. We thus obtain

$$\begin{aligned} W_{0,j}(s,\lambda) &\geq Cr^2|S_j|\lambda^{-1}e^{-2s\eta(T',S)}\varphi^{\frac{1}{2}}(T',\delta) \int_0^{\delta'} e^{-2s\sigma'}d\sigma' \\ &\geq Cr^2|S_j|s^{-1}\lambda^{-1}e^{-2s\eta(T',S)}\varphi^{\frac{1}{2}}(T',\delta) \int_0^{s\delta'} e^{-2\sigma'}d\sigma' \\ &\geq C'(s)r^2|S_j|s^{-1}\lambda^{-1}e^{-2s\eta(T',S)}\varphi^{\frac{1}{2}}(T',\delta), \end{aligned}$$

with $C'(s)$ increasing with s. Observe now that

$$\begin{aligned} \varphi(T',\delta) &= \frac{e^{\lambda\beta(\delta)}}{(T-T')(T'-t_0)} = \frac{e^{\lambda\beta(S)}}{(T-T')(T'-t_0)}e^{\lambda(\beta(\delta)-\beta(S))} \\ &= \varphi(T',S)e^{\lambda(\beta(\delta)-\beta(S))}. \end{aligned}$$

Choosing δ sufficiently small such that $\frac{1}{2}(\beta(S)-\beta(\delta)) \leq \varepsilon$ thus yields the desired result. □

With the previous lemmas we can now prove that the coefficient of $|\xi_{0,j}|^2$, $j = 1,\ldots,p_0$, in (3.8) can be made positive. This requires taking *both* λ and s sufficiently large.

PROPOSITION 3.7. *Let $1 \leq j \leq p_0$. There exists $\lambda_{2,j} \geq \lambda_1$ such that if $\lambda \geq \lambda_{2,j}$, then for s sufficiently large*

$$\begin{aligned} A_{0,j} &= (1 - CK'^2 s^{-\frac{3}{2}}\lambda^{-2})W_{0,j}(s,\lambda) \\ &\quad - CM'[s^{-\frac{1}{2}}\lambda^{-1}w_1(s,\lambda) + s^{-\frac{3}{2}}\lambda^{-2}w_4(s,\lambda) + s^{-\frac{7}{2}}\lambda^{-2}w_0(s,\lambda)] \geq C(s,\lambda) > 0, \end{aligned}$$

with $C(s,\lambda) = C(s,\lambda,r,K,M,c_{max},c_{min},j)$.

Proof. It suffices to prove the result for $w_k^{(i)}(s,\lambda)$ and $W_{0,j}^{(i)}(s,\lambda)$. We shall write β in place of $\beta^{(i)}$, etc. We take s sufficiently large such that $(1-CK'^2 s^{-\frac{3}{2}}\lambda^{-2}) \geq c_0 > 0$.

[1]Note that the estimation from below of the Jacobian is independent from the size of the neighborhood W.

From Lemmas 3.9 and 3.6, for $\varepsilon > 0$ we obtain, for s sufficiently large,

$$A_{0,j} \geq -s^{-2}\nu(\lambda)C_1 e^{-2s\eta(T',S)} + \frac{1}{s\lambda}e^{-2s\eta(T',S)}\left[\frac{C_0}{2}C_\varepsilon r^2|S_j|(\varphi(T',S))^{\frac{1}{2}}e^{-\lambda\varepsilon} - CM'\frac{\sqrt{\pi}\varphi(T',S)}{\sqrt{\phi''(T')}\sqrt{e^{\lambda\overline{\beta}}-e^{\lambda\beta(S)}}}\right], \tag{3.10}$$

where ν is a bounded function. We first treat the second term in the previous expression. Note that this term originates from the estimate from below for $W_{0,j}^{(i)}$ and the estimate of $s^{-\frac{1}{2}}\lambda^{-1}w_1^{(i)}$ by Lemma 3.5. The other terms in $A_{0,j}$ and the remaining part of the estimation of $s^{-\frac{1}{2}}\lambda^{-1}w_1^{(i)}$ are lumped into the first term of (3.10).

Now choose $\varepsilon < \frac{1}{2}(\overline{\beta} - \beta(S))$ (recall that $\overline{\beta} > \beta(S)$ because $m > 1$). Then since $\overline{\beta} > \beta(S)$ we have

$$\frac{\varphi(T',S)}{\sqrt{e^{\lambda\overline{\beta}}-e^{\lambda\beta(S)}}} = o((\varphi(T',S))^{\frac{1}{2}}e^{-\lambda\varepsilon})$$

for λ large. Thus the second term can be made positive for λ, say $\lambda = \lambda_{2,j}$, sufficiently large.

Once λ is fixed larger than $\lambda_{2,j}$, the first term in (3.10) can be made positive by taking s sufficiently large. □

We now prove that the coefficient of $|\xi_{1,j}|^2$, $j = 1, \ldots, p_1$, in (3.8) can be made positive. Here, the parameter λ is not of use.

PROPOSITION 3.8. *Let $1 \leq j \leq p_1$. Let $\lambda \geq \lambda_1$. Then for s sufficiently large*

$$\begin{aligned} A_{1,j} &= (1 - CK'^2 s^{-\frac{3}{2}}\lambda^{-2})W_{1,j}(s,\lambda) \\ &\quad - CM'[s^{-\frac{1}{2}}\lambda^{-1}w_1(s,\lambda) + s^{-\frac{3}{2}}\lambda^{-2}w_4(s,\lambda) + s^{-\frac{7}{2}}\lambda^{-2}w_0(s,\lambda)] \geq C(s,\lambda) > 0, \end{aligned}$$

with $C(s,\lambda) = C(s,\lambda,r,K,M,c_{max},c_{min})$.

Proof. It suffices to prove the result for $w_k^{(i)}(s,\lambda)$ and $W_{1,j}^{(i)}(s,\lambda)$. We shall write β in place of $\beta^{(i)}$, etc. We take s sufficiently large such that $(1 - CK'^2 s^{-\frac{3}{2}}\lambda^{-2}) \geq C_0 > 0$.

We first write

$$e^{-2s\eta(t,S)} = e^{-2s\eta(T',S)}e^{-2s(\eta(t,S)-\eta(T',S))}$$

and observe that for $s \geq s_0 > 0$

$$\int_{t_0}^{T} e^{-2s(\eta(t,S)-\eta(T',S))}\varphi^k(t,S)dt \leq L(s_0,\lambda,k),$$

for some positive $L(s_0,\lambda,k)$. From Lemma 2.1, there exists $V \Subset \Omega_{1,j}$ such that $\inf_{x\in V}\beta > \beta(S)$. Then with

$$\eta_{max}^{T',V} = \sup_{x\in V}\frac{e^{2\lambda K^{(i)}} - e^{\lambda\beta^{(i)}(x)}}{(T'-t_0)(T-T')}$$

we have $-\eta(T',x) \geq -\eta_{max}^{T',V} > -\eta(T',S)$, for $x \in V$ and $s > 0$. These observations yield

$$W_{1,j}(s) \geq r^2\int_V e^{-2s\eta(T',x)}\varphi^{\frac{3}{2}}(T',x)dx \geq C(\lambda)r^2|V|e^{-2s\eta_{max}^{T',V}}$$

and

$$w_k(s) \leq L(s_0, \lambda, k) e^{-2s\eta(T',S)},$$

which implies the result. □

With (3.8) and Propositions 3.7 and 3.8, recalling that $v = u_t = \partial_t(y - \widetilde{y})$, we have thus obtained the following stability result.

THEOREM 3.9. *Let γ be a subset of the boundary Γ of an open set Ω of $\mathbb{R}^n$ that satisfies Assumption* 1.5*, and let γ satisfy Assumption* 1.4*. We assume that the diffusion coefficients c and $\widetilde{c}$ satisfy Assumptions* 1.2 *and* 3.4 *and $c_0 - c_1 \geq \Delta > 0$. Let y_0, $\widetilde{y}_0$ in $L^2(\Omega)$ and let y, $\widetilde{y}$ be solutions to* (3.1)–(3.2) *satisfying Assumption* 3.1*. Then there exists a constant C,*

$$C = C(\Omega, T, t_0, \gamma, S, \mathcal{O}^{(1)}, \mathcal{O}^{(2)}, M, K, r, c_{min}, c_{max}, \Delta),$$

such that

(3.11)
$$\sum_{i=0,1} \sum_{j=1}^{p_i} |c_{ij} - \widetilde{c}_{ij}|^2 \leq C|\partial_n(\partial_t y - \partial_t \widetilde{y})|^2_{L^2((0,T)\times\gamma)} + C|\Delta y(T',.) - \Delta\widetilde{y}(T',.)|^2_{L^2(\Omega')}.$$

We shall see in Proposition 4.5 below that we can achieve the regularity properties and estimates of Assumption 3.1.

Remark 3.10. Observe than in the statement of Theorem 3.9 the initial condition y_0 and $\widetilde{y}_0$ need not be equal (see systems (3.1)–(3.2)).

Remark 3.11. If the position of the interface S is known, we can improve the result of Theorem 3.9 by locally observing the solutions y and $\widetilde{y}$ at time T'. Let $\omega = \omega_0 \cup \omega_1$, with ω_1 a neighborhood of γ in $\overline{\Omega}_1$ and ω_0 a neighborhood of S in $\overline{\Omega}_0$. We can, in fact, relax Assumption 3.1 with the following: Let $r > 0$; then the solution $\widetilde{y}$ is such that $|\Delta\widetilde{y}(T')| \geq r > 0$ in ω. Then, we obtain a stability estimate by solely observing y and $\widetilde{y}$ at time T' on ω in place of Ω:

(3.12)
$$\sum_{i=0,1} \sum_{j=1}^{p_i} |c_{ij} - \widetilde{c}_{ij}|^2 \leq C|\partial_n(\partial_t y - \partial_t \widetilde{y})|^2_{L^2((0,T)\times\gamma)} + C|\Delta y(T',.) - \Delta\widetilde{y}(T',.)|^2_{L^2(\omega)}.$$

We briefly sketch the proof, as it closely follows the exposition of the proof of estimate (3.11) in this section. It relies on the following lemma.

LEMMA 3.12. *Let $s_3 > 0$ and $\lambda_3 > 0$. There exists $C > 0$ such that for all $s \geq s_3$ and $\lambda \geq \lambda_3$ we have*

$$\int_{\Omega_i} \left(e^{-2s\eta^{(1)}} {\varphi^{(1)}}^{\frac{3}{2}} + e^{-2s\eta^{(2)}(T',x)} {\varphi^{(2)}}^{\frac{3}{2}} \right)(T',x)dx$$
$$\leq C \int_{\omega_i} \left(e^{-2s\eta^{(1)}} {\varphi^{(1)}}^{\frac{3}{2}} + e^{-2s\eta^{(2)}(T',x)} {\varphi^{(2)}}^{\frac{3}{2}} \right)(T',x)dx, \qquad i = 0, 1.$$

Proof. Note that β reaches its maximum in $\overline{\Omega}_1$ on γ. Set $A = \sup_{\Omega_1 \setminus \omega_1} \beta$, let $\varepsilon > 0$ be sufficiently small such that $B = A + \varepsilon < \sup_{\Omega_1} \beta$, and define $\widetilde{\omega}_1 = \{x \in \Omega_1;\ A + \varepsilon < \beta(x)\}$. Then $\widetilde{\omega}_1 \subset \omega_1$, with nonempty interior, and we set $K = \frac{|\Omega_1 \setminus \widetilde{\omega}_1|}{|\widetilde{\omega}_1|}$.

We define $\eta_B^{(i)}$ and $\varphi_B^{(i)}$ to be equal to $\eta^{(i)}$ and $\varphi^{(i)}$ at time T' and $\beta(x)$ replaced by B. Then for all $s \geq s_3$ and $\lambda \geq \lambda_3$ we have

$$\int_{\Omega_1 \setminus \widetilde{\omega}_1} e^{-2s\eta_B^{(i)}} {\varphi_B^{(i)}}^{\frac{3}{2}} dx \leq K \int_{\widetilde{\omega}_1} e^{-2s\eta_B^{(i)}} {\varphi_B^{(i)}}^{\frac{3}{2}} dx, \quad i = 1, 2.$$

We conclude by observing that, for $i = 1, 2$,

$$\begin{aligned} e^{-2s\eta_B^{(i)}} &\leq e^{-2s\eta^{(i)}(T',x)}, \quad \varphi_B^{(i)} \leq \varphi^{(i)}(T', x), \quad x \in \widetilde{\omega}_1, \\ e^{-2s\eta^{(i)}(T',x)} &\leq e^{-2s\eta_B^{(i)}}, \quad \varphi^{(i)}(T', x) \leq \varphi_B^{(i)}, \quad x \in \Omega_1 \setminus \widetilde{\omega}_1. \end{aligned}$$

The same method can be applied for the second set of integrals on Ω_0 and ω_0. ∎

Continuation of Remark 3.11. In the statement of Lemma 3.3 we can replace the integration domain, Ω', in the l.h.s. of the estimate by ω.

To reach an equation of the form of (3.8) with the volume integrals computed[2] over ω in place of Ω we write the following counterpart to (3.7):

$$\begin{aligned} &\sum_{i=0,1} \int_{t_0}^{T} \int_{\Omega_i} (e^{-2s\eta^{(1)}} + e^{-2s\eta^{(2)}}) \, |\xi \Delta \partial_t \widetilde{y}|^2 \, dx \, dt \\ &\qquad \leq K'^2 \sum_{i=0,1} \sum_{j=1}^{p_i} |\xi_{i,j}|^2 \int_{\Omega_{i,j} \cap \omega} \left(e^{-2s\eta^{(1)}(T',x)} + e^{-2s\eta^{(2)}(T',x)} \right) |\Delta \widetilde{y}(T', x)|^2 dx \end{aligned}$$

by Lemma 3.12. The result of Lemma 3.6 remain unchanged as ω_0 is a neighborhood of S in $\overline{\Omega}_0$. In the proof of Proposition 3.8 we can choose the open set V to be in ω_1.

Remark 3.13. Note that if we assume that $y(T', .) = \widetilde{y}(T', .)$, then the stability estimate becomes

$$\sum_{i=0,1} \sum_{j=1}^{p_i} |c_{ij} - \widetilde{c}_{ij}|^2 \leq C |\partial_n (\partial_t y - \partial_t \widetilde{y})|^2_{L^2((0,T)\times\gamma)}.$$

Such an additional assumption is sometimes made, e.g., in [16].

With Theorem 3.9 we have the following uniqueness result.

COROLLARY 3.14. *Under the same assumptions as in Theorem* 3.9 *and if*

$$\begin{aligned} &\partial_n (\partial_t (y - \widetilde{y}))(t, x) = 0 \quad \text{in } (t_0, T) \times \gamma, \\ &\Delta y(T', x) - \Delta \widetilde{y}(T', x) = 0 \quad \text{in } \Omega', \end{aligned}$$

then $c = \widetilde{c}$. *Furthermore,* $y_0 = \widetilde{y}_0$.

Proof. The second assertion remains to be proved. If $c = \widetilde{c}$, then $u = y - \widetilde{y} \in \mathscr{D}_A$, with $A = \nabla \cdot (c \nabla(.))$ (see the appendix), is the solution to

$$\begin{cases} \partial_t u - \nabla \cdot (c \nabla u) = 0 & \text{in } (0, T) \times \Omega, \\ u = 0 & \text{on } (0, T) \times \Gamma, \\ u(0, x) = u_0(x) & \text{in } \Omega, \end{cases}$$

with $u_0 = y_0 - \widetilde{y}_0$. Thus $u = S(t)u_0$. We have $\Delta(u)(T') = 0$ in Ω'. Thus $\nabla \cdot (c \nabla u)_{|_{\Omega'}}(T') = 0$. Since $u(T') \in \mathscr{D}_A$ we have $u(T') = 0$. Since the semigroup $S(t)$

[2]Including the definition of $W_{i,j}$, $i = 0, 1$, $j = 1, \ldots, p_i$.

generated by $-\nabla\cdot(c\nabla(.))$ is analytic by Proposition 5, we obtain that $S(t)u_0 = 0$ for all $t > 0$. The continuity in $t = 0^+$ yields $u_0 = 0$. □

If we make further assumptions on the initial conditions y_0 and $\widetilde{y}_0$, we can in fact obtain a stability result for these initial conditions as well. This is the subject of section 5.

Remark 3.15. In the stability result obtained here, we have made the choice to make some of the measurements on part of the boundary $(0,T)\times\Gamma$. Derivation of a Carleman estimate, as in [8], with an r.h.s. with an "observation" in an inner volume $(0,T)\times\omega$ of $(0,T)\times\Omega_1$ would yield a stability estimate like (3.11) with $|\partial_t y - \partial_t\widetilde{y}|_{L^2((t_0,T)\times\omega)}$ in the r.h.s.

Remark 3.16. Observe that in place of Assumption 3.4 we could have assumed solely that the difference $\xi = c - \widetilde{c}$ is piecewise-constant. Then, we would replace $c\Delta u$ by $\nabla\cdot(c\nabla u)$ in the r.h.s. of (3.8). This would yield a stability estimate of the form

$$\sum_{i=0,1}\sum_{j=1}^{p_i}|c_{ij}-\widetilde{c}_{ij}|^2 \le C|\partial_n(\partial_t y-\partial_t\widetilde{y})|^2_{L^2((0,T)\times\gamma)} + C|\nabla y(T',.)-\nabla\widetilde{y}(T',.)|^2_{(L^2(\Omega'))^n} + C|\Delta y(T',.)-\Delta\widetilde{y}(T',.)|^2_{L^2(\Omega')}. \tag{3.13}$$

In Remark 4.7, we show that Assumption 3.1 can be fulfilled, in the case where ξ is piecewise-constant, if $|\nabla\widetilde{c}|$ is sufficiently small and $\widetilde{c}$ sufficiently regular.

Remark 3.17. Here we have set the r.h.s. of the parabolic equations in (3.1) and (3.2) to zero. With a nonvanishing r.h.s., say $f(t,x)$, the same stability result holds once the hypotheses of Assumption 3.1 are fulfilled, since (3.3) is preserved. Assuming that the function $f(t,x)$ is bounded and sufficiently regular, say of class $\mathscr{C}^k$, with k sufficiently large, we can obtain the same results as in Proposition 4.5 of section 4, by a slight modification of the argumentation. In this case also, the class of solutions y and $\widetilde{y}$ satisfying Assumption 3.1 is nonempty.

Remark 3.18. The stability result obtained here can be extended to a more complicated geometry, for instance in the case of three or more embedded materials. We can consider some open sets $V_0,\dots,V_m$ such that

$$V_0 \Subset V_1 \Subset \cdots \Subset V_m = \Omega$$

and then set $\Omega_i := V_i\setminus\overline{V}_{i-1}$, $i = 1,\dots,m$, and $\Omega_0 = V_0$. We then assume the diffusion coefficient to be piecewise-constant, constant on each connected component of Ω_i, and assume a monotony condition across interfaces as in Assumption 1.2. With geometric conditions on the open sets Ω_i, $i = 0,\dots,m$, similar to those made on Ω_0 and Ω_1 here we can then prove a Carleman estimate of the form (2.5). The method exposed in this section then yields a stability result as in Theorem 3.9. For more details see our complete preprint [5]. The results of section 5 can be extended similarly.

4. Existence of solutions y, $\widetilde{y}$ satisfying Assumption 3.1. We propose a possible choice of boundary condition h and of initial condition $\widetilde{y}_0$ to achieve the particular properties for the solutions y and $\widetilde{y}$ listed in Assumption 3.1 needed in the proof of Theorem 3.9.

We shall denote by $S(t)$ (resp., $\widetilde{S}(t)$) the analytic semigroup generated by unbounded operator A (resp., $\widetilde{A}$) formally defined by $-\nabla\cdot(c\nabla(.))$ (resp., $-\nabla\cdot(\widetilde{c}\nabla(.))$) on $L^2(\Omega)$ with domain (see the appendix)

$$\mathscr{D}_A = \{u\in H_0^1(\Omega);\ \nabla\cdot(c\nabla u)\in L^2(\Omega)\}$$
$$(\text{resp., } \mathscr{D}_{\widetilde{A}} = \{u\in H_0^1(\Omega);\ \nabla\cdot(\widetilde{c}\nabla u)\in L^2(\Omega)\}).$$

The convention we use here is $S(t) = e^{-tA}$.

LEMMA 4.1. *Let $r > 0$ and let $\widetilde{c} \in L^\infty(\Omega)$. There exist $\widetilde{y}_0 \in \mathscr{D}_{\widetilde{A}}$ and $\chi : [0,T] \to \mathbb{R}$ such that the solution to*

$$\begin{cases} \partial_t \widetilde{y} - \nabla \cdot (\widetilde{c} \nabla \widetilde{y}) = 0 & \text{in } (0,T) \times \Omega, \\ \widetilde{y}(t,x) = \chi(t) & \text{on } (0,T) \times \Gamma, \\ \widetilde{y}(t,.) - \chi(t) \in \mathscr{D}_{\widetilde{A}}, & 0 < t \leq T, \\ \widetilde{y}(0) = \widetilde{y}_0 \end{cases} \tag{4.1}$$

satisfies $|\nabla \cdot (\widetilde{c} \nabla \widetilde{y})(T')| \geq r > 0$ a.e. The function χ can be chosen such that χ' is a positive constant.

Proof. Observe that $p(t,x) = \widetilde{y}(t,x) - \chi(t)$ is the solution to

$$\begin{cases} \partial_t p - \nabla \cdot (\widetilde{c} \nabla p) = -\chi'(t) & \text{in } (0,T) \times \Omega, \\ p(t,x) = 0 & \text{on } (0,T) \times \Gamma, \\ p(t,.) \in \mathscr{D}_{\widetilde{A}}, & 0 < t \leq T, \\ p(0,x) = \widetilde{y}_0(x) - \chi(0) = p_0 \in L^2(\Omega) \end{cases} \tag{4.2}$$

and is thus given by Duhamel's formula [21]

$$p(t) = \widetilde{S}(t) p_0 - \int_0^t \widetilde{S}(t-s) \chi'(s) ds. \tag{4.3}$$

In fact, we choose χ of the form $\chi(t) = -\rho t$, where ρ is a negative constant. We also choose $\widetilde{y}_0$ such that $p_0 = \widetilde{y}_0 \in \mathscr{D}_{\widetilde{A}}$ and $\nabla \cdot (\widetilde{c} \nabla \widetilde{y}_0) \geq r_0 > r$ a.e. in Ω (choose $f \in L^2(\Omega)$ such that $f > r_0$, and solve the elliptic problem $\nabla \cdot (\widetilde{c} \nabla \widetilde{y}_0) = f$ for $\widetilde{y}_0$ in $H_0^1(\Omega)$). We choose ρ such that $-r_0 < \rho \leq -r < 0$.

The solution p to (4.2) is unique in $\mathscr{C}^1([0,T], L^2(\Omega)) \cap \mathscr{C}^0([0,T], \mathscr{D}_{\widetilde{A}})$ and given by (4.3) [7, Theorem 3 and following Remark 2, section XVII B.1]. Denoting by $\mathbf{1}$ the function identically equal to 1 on Ω, we find

$$p(t) = \widetilde{S}(t) p_0 + \rho \int_0^t \widetilde{S}(s) \mathbf{1} ds,$$

which yields $q := -\widetilde{A} p + \rho \mathbf{1} := \widetilde{S}(t)(\nabla \cdot (\widetilde{c} \nabla p_0) + \rho \mathbf{1})$ [21, Theorem 1.2.4]. Hence q is the solution to

$$\begin{cases} \partial_t q - \nabla \cdot (\widetilde{c} \nabla q) = 0 & \text{in } (0,T) \times \Omega, \\ q(t,x) = 0 & \text{on } (0,T) \times \Gamma, \\ q(t,.) \in \mathscr{D}_{\widetilde{A}}, & 0 < t \leq T, \\ q(0,x) = q_0(x) := \nabla \cdot (\widetilde{c} \nabla p_0) + \rho \mathbf{1}. \end{cases}$$

We now apply the maximum principle (which is valid for L^∞ diffusion coefficients) [6, proof of Theorem IX.3], which reads for the time interval $[0, T']$

$$\operatorname*{ess\,inf}_{\overline{Q}_{T'}} \mathrm{q} \geq \min(0, \operatorname*{ess\,inf}_{\Omega} \mathrm{q}_0) = 0, \qquad \mathrm{Q}_{\mathrm{T}'} = (0, \mathrm{T}') \times \Omega.$$

This yields $\nabla \cdot (\widetilde{c} \nabla p)(T', x) \geq -\rho \geq r > 0$ a.e. ∎

LEMMA 4.2. *Let $l > n/2$ and $l \geq 2$. Let $\widetilde{c} \in L^\infty(\Omega)$ be such that $\widetilde{c}_{|\Omega_i}$ is $\mathscr{C}^{l-1}(\overline{\Omega}_i)$, $i = 0, 1$. Let Ω be such that S and $\partial\Omega$ are of class $\mathscr{C}^l$. Let $\widetilde{y}_0 \in \mathscr{D}_{\widetilde{A}}$ and the function*

$\chi : [0.T] \to \mathbb{R}$, *such that* χ' *is constant, both be chosen according to Lemma* 4.1. *Then* $\nabla\cdot(\widetilde{c}\nabla\widetilde{y})_{|\Omega_i} \in \mathscr{C}^k((0,T], L^\infty(\Omega_i))$, $i = 0, 1$, *for all* $k \in \mathbb{N}$. *Let* $\varepsilon > 0$; *then* $\nabla\cdot(\widetilde{c}\nabla\widetilde{y})_{|\Omega_i}$, $i = 0, 1$, *remain in a bounded domain of* $\mathscr{C}^k([\varepsilon, T], L^\infty(\Omega_i))$ *for all* $k \in \mathbb{N}$, *uniformly w.r.t.* $\widetilde{c}$ *and* $\widetilde{y}_0$, *for* $0 < c_{min} \le \widetilde{c} \le c_{max}$ *and* $\nabla \cdot (\widetilde{c}\nabla\widetilde{y}_0)$ *in a bounded domain of* $L^2(\Omega)$.

Proof. We use the notation of the proof of Lemma 4.1. We set $p(t,x) = \widetilde{y}(t,x) - \chi(t)$ and observe that $q := -\widetilde{A}p + \rho\mathbf{1}$ is the solution to

$$\begin{cases} \partial_t q - \nabla \cdot (\widetilde{c}\nabla q) = 0 & \text{in } (0,T)\times\Omega, \\ q(t,x) = 0 & \text{on } (0,T)\times\Gamma, \\ q(t,.) \in \mathscr{D}_{\widetilde{A}}, & 0 < t \le T, \\ q(0,x) = q_0(x) := \nabla \cdot (\widetilde{c}\nabla p_0) + \rho\mathbf{1}. \end{cases}$$

From Corollary 5 we have that $q_{|(0,T]\times\Omega_i} \in \mathscr{C}^k((0,T]; H^l(\Omega_i))$, $i = 0, 1$, for all $k \in \mathbb{N}$. Since $l > n/2$, the space $H^l(\Omega_i)$ is continuously embedded in $L^\infty(\Omega_i)$, which yields the result. The last statement follows from Remark 5. ∎

Remark 4.3. In the case of $n = 2, 3$, which concerns most of the applications, we choose $m = 2$. The condition on S, $\partial\Omega$ and the coefficients $\widetilde{c}_{|\Omega_i}$ in the previous lemma are then the default ones assumed in the introduction.

Let the function χ, such that $\rho = -\chi'$ is constant, be chosen according to Lemma 4.1. We then have the following regularity property.

LEMMA 4.4. *Let* $c, \widetilde{c} \in L^\infty(\Omega)$ *be such that* $c_{|\Omega_i}, \widetilde{c}_{|\Omega_i}$ *are* $\mathscr{C}^1(\overline{\Omega}_i)$, $i = 0, 1$; $0 < c_{min} \le c, \widetilde{c} \le c_{max}$; *and* y_0, $\widetilde{y}_0 \in L^2(\Omega)$ *remain in a bounded domain of* $L^2(\Omega)$. *The solutions* $\widetilde{y}$ *and* y *to*

$$\begin{cases} \partial_t \widetilde{y} - \nabla \cdot (\widetilde{c}\nabla\widetilde{y}) = 0 & \textit{in } (0,T)\times\Omega, \\ \widetilde{y}(t,x) = \chi(t) & \textit{on } (0,T)\times\Gamma, \\ \textit{transmission conditions (TC1)}, \\ \widetilde{y}(0) = \widetilde{y}_0, \end{cases}$$

$$\begin{cases} \partial_t y - \nabla \cdot (c\nabla y) = 0 & \textit{in } (0,T)\times\Omega, \\ y(t,x) = \chi(t) & \textit{on } (0,T)\times\Gamma, \\ \textit{transmission conditions (TC1)}, \\ y(0) = y_0 \end{cases}$$

belong to $\mathscr{C}^k((0,T], H^1(\Omega))$ *and are such that* $\widetilde{y}_{|\Omega_i}, y_{|\Omega_i} \in \mathscr{C}^k((0,T], H^2(\Omega_i))$, $i = 0, 1$, *for all* $k \in \mathbb{N}$. *Let* $\varepsilon > 0$; *then for all* $k \in \mathbb{N}$, $\widetilde{y}_{|\Omega_i}, y_{|\Omega_i}$ *remain in a bounded domain of* $\mathscr{C}^k((\varepsilon, T], H^2(\Omega_i))$, $i = 0, 1$, *uniformly w.r.t.* $\widetilde{c}$, y_0, *and* $\widetilde{y}_0$.

Proof. We work out the proof for y. We define $p(t,x) = y(t,x) - \chi(t)$. The function p is the solution to

$$\begin{cases} \partial_t p - \nabla \cdot (c\nabla p) = \rho & \text{in } (0,T)\times\Omega, \\ p(t,x) = 0 & \text{on } (0,T)\times\Gamma, \\ p(t,.) \in \mathscr{D}_A, & 0 < t \le T, \\ p(0) = p_0 = y_0 - \chi(0) \in L^2(\Omega). \end{cases} \tag{4.4}$$

It suffices to prove the result for p. Since ρ is constant, the (mild) solution to (4.4) is a classical solution [21, Theorem 4.3.2]. We prove below that $p \in \mathscr{C}^k((0,T], \mathscr{D}_A)$,

$k > 0$. Thus $p \in \mathscr{C}^k((0,T], L^2(\Omega))$. Since $D_A \subset H_0^1$ with continuous injection, then $p \in \mathscr{C}^k((0,T], H_0^1(\Omega))$. By Proposition 5 the maps $p \mapsto p_{|\Omega_i}$, $i = 0, 1$, are continuous from $\mathscr{D}_A$ into $H^2(\Omega_i)$. Thus $p_{|\Omega_i} \in \mathscr{C}^k((0,T], H^2(\Omega_i))$.

The solution p is given by

$$p(t) = S(t)p_0 + \rho \int_0^t S(s)\mathbf{1}ds,$$

where $\mathbf{1}$ is the function identically equal to 1 on Ω. The first term $p_1 = S(t)p_0$ in $\mathscr{C}^k((0,T], \mathscr{D}_{A^l})$ for all $k, l > 0$ by Proposition 5. For the second term $p_2 = \rho \int_0^t S(s)\mathbf{1}ds$ we have (see [21, Theorem 1.2.4]) $-Ap_2 = \rho(S(t)\mathbf{1} - \mathbf{1})$. Thus $Ap_2 \in \mathscr{C}^k((0,T], L^2(\Omega))$, i.e., $p_2 \in \mathscr{C}^k((0,T], \mathscr{D}_A)$, for all $k > 0$. The boundedness statement follows from Remark 5. □

With the proposed initial condition $\widetilde{y}_0$ and boundary condition $h(t,x) = \chi(t)$, we have thus obtained the following regularity and boundedness properties.

PROPOSITION 4.5. *Let $r > 0$. Let $y_0 \in L^2(\Omega)$. Let Ω be such that S and $\Gamma = \partial\Omega$ are of class $\mathscr{C}^l$, and let $\widetilde{c} \in L^\infty(\Omega)$ be such that $\widetilde{c}_{|\Omega_i}$ is $\mathscr{C}^{l-1}(\overline{\Omega}_i)$, $i = 0, 1$, with $> n/2$, $l \geq 2$. There exists $h(t,x) \in \mathscr{C}([0,T] \times \Gamma)$ and an initial condition $\widetilde{y}_0 \in \mathscr{D}_{\widetilde{A}}$ such that the solutions y, $\widetilde{y}$ to systems (3.1)–(3.2) satisfy the following:*

1. $\nabla \cdot (\widetilde{c}\nabla\widetilde{y})(T') \geq r > 0$;
2. $\nabla \cdot (\widetilde{c}\nabla\widetilde{y})_{|\Omega_i} \in \mathscr{C}^k([t_0,T], L^\infty(\Omega_i))$, $i = 0, 1$, *for all* $k \in \mathbb{N}$;
3. y, $\widetilde{y} \in \mathscr{C}^k([t_0,T], L^2(\Omega)) \cap \mathscr{C}^k((t_0,T], H^1(\Omega))$ *for all* $k \in \mathbb{N}$;
4. $y_{|\Omega_i}, \widetilde{y}_{|\Omega_i} \in \mathscr{C}^k([t_0,T], H^2(\Omega_i))$, $i = 0, 1$, *for all* $k \in \mathbb{N}$.

The restrictions $\widetilde{y}_{|\Omega_i}$ remain in a bounded domain of $\mathscr{C}^k([t_0,T], H^2(\Omega_i))$ and $\nabla \cdot (\widetilde{c}\nabla\widetilde{y})_{|\Omega_i}$ in a bounded domain of $\mathscr{C}^k([t_0,T], L^\infty(\Omega_i))$, uniformly w.r.t. $\widetilde{c}$ and $\widetilde{y}_0$ if $0 < c_{min} \leq \widetilde{c} \leq c_{max}$ and $\nabla \cdot (\widetilde{c}\nabla\widetilde{y}_0)$ remain in a bounded domain of $L^2(\Omega)$.

With Proposition 4.5 we observe that Assumption 3.1 can be fulfilled in the framework of Assumption 3.4 when $c_{min} \leq \widetilde{c} \leq c_{max}$ and $\widetilde{y}_0 \in \mathscr{D}_{\widetilde{A}}$ such that $\nabla \cdot (\widetilde{c}\nabla\widetilde{y}_0)$ remain in a bounded domain of $L^2(\Omega)$ for properly chosen boundary conditions $h(t,x)$.

Remark 4.6. Observe that we could simply assume that $\widetilde{y}_0 \in L^2(\Omega)$ and design the boundary condition $h(t,x)$ to reach a proper state in $\mathscr{D}_{\widetilde{A}}$ in a finite time $t_1 < t_0$. This can be achieved as the parabolic equation we study here is null-controllable, i.e., exactly controllable to the trajectories [8].

Remark 4.7. In the case where we assume only that ξ is piecewise-constant, then from Proposition 4.5.1, we can obtain Assumption 3.1.1, in the case where $|\nabla\widetilde{c}|$ is sufficiently small, since, from the proof of Lemma 4.2, we also find that $\nabla\widetilde{y}_{|\Omega_i}$, $i = 0, 1$, remain in bounded domains of $\mathscr{C}^k([\varepsilon,T], (L^\infty(\Omega_i))^n)$. Note that we need to assume a sufficiently large regularity on the coefficient $\widetilde{c}$ in the proof of Lemma 4.2.

5. Uniqueness and stability estimate for the initial conditions. In this section we closely follow the method of [22]. We shall assume the following.

ASSUMPTION 5.1. *Let $r_0 > 0$. The initial conditions y_0 and $\widetilde{y}_0$ satisfy*

1. *y_0 is in a bounded domain of $\mathscr{D}_A$;*
2. *$\widetilde{y}_0$ is in a bounded domain of $\mathscr{D}_{\widetilde{A}}$;*
3. *$\nabla \cdot (\widetilde{c}\nabla\widetilde{y}_0) \geq r_0$;*
4. *y, $\widetilde{y}$ are in a bounded domain of $\mathscr{C}^1([0,T], L^2(\Omega))$, where y and $\widetilde{y}$ are the solutions to (3.1)–(3.2).*

Observe that Assumption 5.1.4 implies that $\widetilde{y}_{|\Omega_i}, y_{|\Omega_i}$ are in a bounded domain of $\mathscr{C}([0,T], H^2(\Omega_i))$, $i = 0, 1$, by Proposition A.3.

We define $\widetilde{z} = \partial_t \widetilde{y} \in \mathscr{C}([0,T], L^2(\Omega))$, and thus $\widetilde{z}(0)$ is well defined in $L^2(\Omega)$. We introduce w the solution to

$$\begin{cases} \partial_t w - \nabla \cdot (c \nabla w) = 0 & \text{in } (0,T) \times \Omega, \\ w(t,x) = \partial_t h(t,x) & \text{on } (0,T) \times \Gamma, \\ \text{transmission conditions (TC1)} & \text{on } (0,T) \times S, \\ w(0) = \widetilde{z}(0), \end{cases} \tag{5.1}$$

and we further assume the following.

ASSUMPTION 5.2. *The functions $\widetilde{z}$, w are in a bounded domain of $L^2(0,T,H^1(\Omega))$.*

We also assume that the diffusion coefficients c and $\widetilde{c}$ are piecewise-constant (Assumption 3.4).

Observe that if we choose the boundary condition $h(t,x) = -\rho t$ for $0 < t \leq T$ according to the proof of Lemma 4.1 (with $0 < r < r_0$), then the above assumption are fulfilled. In fact, the results of section 4 show that Assumption 3.1 is then satisfied. In addition, Assumptions 5.1.4 and 5.2 are fulfilled by the following lemma.

LEMMA 5.3. *If $h(t,x) = -\rho t$, then the solutions y, $\widetilde{y}$ to* (3.1)–(3.2) *and w to* (5.1) *satisfy Assumptions* 5.1.4 *and* 5.2.

Proof. We prove $w \in L^2(0,T,H^1(\Omega))$. The proof is the same for $\widetilde{z}$. Let $p(t,x) = w(t,x) - \partial_t h(t,x) = w(t,x) + \rho$. Then p satisfies

$$\begin{cases} \partial_t p - \nabla \cdot (c \nabla p) = 0 & \text{in } (0,T) \times \Omega, \\ p(t,x) = 0 & \text{on } (0,T) \times \Gamma, \\ \text{transmission conditions (TC1)} & \text{on } (0,T) \times S, \\ p(0) = \widetilde{z}(0) + \rho \in L^2(\Omega). \end{cases}$$

We thus have the usual energy estimate

$$\frac{1}{2}|p(t)|^2_{L^2(\Omega)} + \int_0^t \int_\Omega c |\nabla p|^2 dt dx = \frac{1}{2}|p(0)|^2_{L^2(\Omega)},$$

and p, and thus w, is in $L^2(0,T,H^1(\Omega))$ and remains in a bounded domain of this space if $c_{min} \leq c \leq c_{max}$ and $\widetilde{y}_0$ remains in a bounded domain of $\mathscr{D}_{\widetilde{A}}$.

To prove that y is in a bounded domain of $\mathscr{C}^1([0,T], L^2(\Omega))$ (the proof is the same for $\widetilde{y}$), we set $p(t,x) = y(t,x) + \rho t$ and observe that $q := -Ap + \rho \mathbf{1}$ is $\mathscr{C}([0,T], L^2(\Omega))$ and thus $p \in \mathscr{C}([0,T], \mathscr{D}_A)$. Then $p \in \mathscr{C}^1([0,T], L^2(\Omega))$. ∎

Define v_1 and v_2 that satisfy

$$\begin{cases} \partial_t v_1 - \nabla \cdot (c \nabla v_1) = \nabla \cdot ((c - \widetilde{c}) \nabla \partial_t \widetilde{y}) & \text{in } (0,T) \times \Omega', \\ v_1 = 0 & \text{on } (0,T) \times \Gamma, \\ \text{transmission conditions (TC2)} & \text{on } (0,T) \times S, \\ v_1(0) = 0, \end{cases}$$

$$\begin{cases} \partial_t v_2 - \nabla \cdot (c \nabla v_2) = 0 & \text{in } (0,T) \times \Omega', \\ v_2 = 0 & \text{on } (0,T) \times \Gamma, \\ \text{transmission conditions (TC1)} & \text{on } (0,T) \times S, \\ v_2(0) = \partial_t (y - \widetilde{y})(0). \end{cases}$$

Observe that $\partial_t (y - \widetilde{y})(0)$ is well defined and in a bounded domain of $L^2(\Omega)$ by Assumption 5.1.

With an argument of logarithmic convexity we have

$$|v_2(t)|_{L^2(\Omega)} \leq K^{1-t/T'} \, |v_2(T')|^{t/T'}_{L^2(\Omega)}, \quad 0 \leq t \leq T'. \tag{5.2}$$

Such an estimate makes use of the convexity of $F(t) = \ln(|v_2(t)|^2_{L^2(\Omega)})$ and $|v_2(0)|_{L^2(\Omega)} \leq K$ (see [20, section 2.3] for further details).

We now prove the following lemma.

LEMMA 5.4. *There exists $C > 0$ such that*

$$|v_1(t)|_{L^2(\Omega)} \leq C|c - \widetilde{c}|^{\frac{1}{2}}_{L^\infty(\Omega)}, \quad 0 \leq t \leq T.$$

Note that v_1 satisfies transmission condition (TC2) and thus does not belong to $\mathscr{D}_A$. We thus cannot use some argument of regularity w.r.t. the source term from parabolic theory for v_1.

Proof. First observe that $v_1 = w - \widetilde{z}$. From Assumption 5.2, w and $\widetilde{z}$ remain in a bounded domain of $L^2(0,T,H^1(\Omega))$. Now $\partial_t(w - \widetilde{z}) - \nabla \cdot (c\nabla w - \widetilde{c}\nabla\widetilde{z}) = 0$, which after multiplication by $w - \widetilde{z}$, integration over Ω, and an integration by parts, yields

$$\begin{aligned} 0 &= \frac{1}{2}\partial_t \int_\Omega |w - \widetilde{z}|^2 \, dx + \int_\Omega (c\nabla w - \widetilde{c}\nabla\widetilde{z}) \cdot (\nabla w - \nabla\widetilde{z}) \, dx \\ &= \frac{1}{2}\partial_t \int_\Omega |w - \widetilde{z}|^2 \, dx + \int_\Omega (c - \widetilde{c})\nabla w \cdot (\nabla w - \nabla\widetilde{z}) \, dx + \int_\Omega \widetilde{c}|\nabla w - \nabla\widetilde{z}|^2 \, dx \end{aligned}$$

since $\nabla \cdot (c\nabla w - \widetilde{c}\nabla\widetilde{z}) \in L^2(\Omega)$ by the definitions of $\mathscr{D}_A$ and $\mathscr{D}_{\widetilde{A}}$ (see the appendix). We thus obtain

$$\begin{aligned} \frac{1}{2}\partial_t \int_\Omega |w - \widetilde{z}|^2 \, dx &\leq \left| \int_\Omega (c - \widetilde{c})\nabla w \cdot (\nabla w - \nabla\widetilde{z}) \, dx \right| \\ &\leq |c - \widetilde{c}|_{L^\infty(\Omega)} \, |\nabla w|_{L^2(\Omega)} \, |\nabla w - \nabla\widetilde{z}|_{L^2(\Omega)}. \end{aligned}$$

Integrating over $(0,t)$ yields the result. ∎

As in section 3, we define $v = \partial_t(y - \widetilde{y})$ and observe that $v = v_1 + v_2$. We thus have

$$|v(t)|_{L^2(\Omega)} \leq |v_1(t)|_{L^2(\Omega)} + |v_2(t)|_{L^2(\Omega)} \leq C(|c - \widetilde{c}|^{\frac{1}{2}}_{L^\infty(\Omega)} + |v_2(T')|^{t/T'}_{L^2(\Omega)}), \quad 0 \leq t \leq T',$$

and

$$\begin{aligned} |v_2(T')|_{L^2(\Omega)} &\leq |v(T')|_{L^2(\Omega)} + |v_1(T')|_{L^2(\Omega)} \\ &\leq C(|(\Delta y - \Delta\widetilde{y})(T')|_{L^2(\Omega)} + |c - \widetilde{c}|_{L^\infty(\Omega)} + |c - \widetilde{c}|^{\frac{1}{2}}_{L^\infty(\Omega)}), \end{aligned}$$

making use of

$$v = \nabla \cdot (c\nabla u) + \nabla((c - \widetilde{c}) \cdot \nabla\widetilde{y}) = c(\Delta y - \Delta\widetilde{y}) + (c - \widetilde{c})\Delta\widetilde{y} \quad \text{in } \Omega',$$

where Assumption 3.4 was applied. This yields

$$|v(t)|_{L^2(\Omega)} \leq C\left(|c - \widetilde{c}|^{\frac{1}{2}}_{L^\infty(\Omega)} + \nu^{t/T'}\right), \quad 0 \leq t \leq T',$$

with $\nu = |(y-\widetilde{y})(T')|_{H^2(\Omega')} + |c-\widetilde{c}|_{L^\infty(\Omega)} + |c-\widetilde{c}|^{\frac{1}{2}}_{L^\infty(\Omega)}$. Because of the regularity of v w.r.t. time t we now have

$$|y_0-\widetilde{y}_0|_{L^2(\Omega)} = |u_0|_{L^2(\Omega)} = \left|\int_0^{T'} v(t)dt - u(T')\right|_{L^2(\Omega)}$$
$$\leq \int_0^{T'} |v(t)|_{L^2(\Omega)}dt + |y(T')-\widetilde{y}(T')|_{L^2(\Omega)},$$

which gives

$$|y_0-\widetilde{y}_0|_{L^2(\Omega)} \leq C\left(T'\frac{\nu-1}{\ln(\nu)} + T'|c-\widetilde{c}|^{\frac{1}{2}}_{L^\infty(\Omega)}\right) + |y(T')-\widetilde{y}(T')|_{L^2(\Omega)}.$$

We thus have

$$|y_0-\widetilde{y}_0|_{L^2(\Omega)} \leq C\left(\frac{\nu-1}{\ln(\nu)} + C'\nu\right).$$

Observing that $x < \frac{x-1}{\ln(x)}$ for $x \in (0,1)$, we obtain

$$|y_0-\widetilde{y}_0|_{L^2(\Omega)} \leq C\frac{\nu-1}{\ln(\nu)} \quad \text{if } \nu < 1.$$

With Theorem 3.9 we obtain

$$|c-\widetilde{c}|^2_{L^\infty(\Omega)} \leq C|\partial_n(\partial_t y - \partial_t\widetilde{y})|^2_{L^2((0,T)\times\gamma)} + C|\Delta y(T',.) - \Delta\widetilde{y}(T',.)|^2_{L^2(\Omega')}. \tag{5.3}$$

When the r.h.s. of (5.3) is sufficiently small, we obtain

$$0 < \nu \leq C\left(|\partial_n(\partial_t y - \partial_t\widetilde{y})|^2_{L^2((0,T)\times\gamma)} + |\Delta y(T',.) - \Delta\widetilde{y}(T',.)|^2_{L^2(\Omega')}\right)^{\frac{1}{4}} < 1.$$

In that case

$$\ln(\nu) \leq C'\ln(C|(y-\widetilde{y})(T')|^2_{H^2(\Omega')} + C|\partial_n(\partial_t y - \partial_t\widetilde{y})|^2_{L^2((0,T)\times\gamma)}) < 0,$$

and thus

$$\frac{\nu-1}{\ln(\nu)} \leq C'(\nu-1)/\ln(C|(y-\widetilde{y})(T')|^2_{H^2(\Omega')} + C|\partial_n(\partial_t y - \partial_t\widetilde{y})|^2_{L^2((0,T)\times\gamma)}).$$

We thus obtain the following stability theorem for the initial conditions.

THEOREM 5.5. *Under the hypothesis of Theorem* 3.9*, in addition to Assumptions* 5.1 *and* 5.2 *there exist some constants* $C, C' > 0$*,*

$$C = C(\Omega, T, t_0, \gamma, S, \mathcal{O}^{(1)}, \mathcal{O}^{(2)}, M, K, r, c_{min}, c_{max}, \Delta),$$
$$C' = C'(\Omega, T, t_0, \gamma, S, \mathcal{O}^{(1)}, \mathcal{O}^{(2)}, M, K, r, c_{min}, c_{max}, \Delta),$$

such that

$$|y_0-\widetilde{y}_0|_{L^2(\Omega)} \leq C'/\left|\ln\left(C|(y-\widetilde{y})(T')|_{H^2(\Omega')} + C|\partial_n(\partial_t y - \partial_t\widetilde{y})|_{L^2((0,T)\times\gamma)}\right)\right|$$

for $|(y-\widetilde{y})(T')|_{H^2(\Omega')} + |\partial_n(\partial_t y - \partial_t\widetilde{y})|_{L^2((0,T)\times\gamma)}$ *sufficiently small.*

Appendix. Basic regularity properties. Let $\mathcal{A}$ be formally defined by $-\nabla \cdot (c\nabla(.))$ on $L^2(\Omega)$. The diffusion coefficient c is first assumed to be in $L^\infty(\Omega)$ and such that $c(x) \geq \alpha > 0$ for all $x \in \Omega$. We denote by A the unbounded operator with domain

$$\mathscr{D}_A = \{u \in H_0^1(\Omega);\ \nabla \cdot (c\nabla u) \in L^2(\Omega)\},$$

defined by $A(u) = -\nabla \cdot (c\nabla(u))$ for $u \in \mathscr{D}_A$.

PROPOSITION A.1. *Let $u_0 \in L^2(\Omega)$. There exists a unique u such that*

$$u \in \mathscr{C}([0,T]; L^2(\Omega)) \cap \mathscr{C}^1(]0,T]; L^2(\Omega)) \cap \mathscr{C}(]0,T]; \mathscr{D}_A)$$

and

$$\begin{cases} \partial_t u - \nabla \cdot (c\nabla(u)) = 0, \quad t \in]0,T], \\ u(0) = u_0, \end{cases} \tag{A.1}$$

for $T > 0$ (T can be chosen to be ∞). Furthermore, $u \in L^2(0,T; H_0^1(\Omega))$ and $u \in \mathscr{C}^k(]0,T]; \mathscr{D}_{A^l})$ for all $k, l \in \mathbb{N}$.

If $u_0 \in \mathscr{D}_A$, then

$$u \in \mathscr{C}^1([0,T]; L^2(\Omega)) \cap \mathscr{C}([0,T]; \mathscr{D}_A).$$

PROPOSITION A.2. *The semigroup $S(t)$ generated by the unbounded operator A on $L^2(\Omega)$ is analytic.*

We now give further regularity properties when placed in the geometrical situation studied in this article, that is, if the diffusion coefficient c is piecewise $\mathscr{C}^1$ and discontinuous across some $\mathscr{C}^2$ interface S. We use the notation set in the main text of the article.

PROPOSITION A.3. *Let the diffusion coefficient, c, be such that $c_{|\Omega_i} \in \mathscr{C}^1(\overline{\Omega}_i)$, $i = 0, 1$. If $p \in \mathscr{D}_A$, then $p_{|\Omega_i} \in H^2(\Omega_i)$, $i = 0, 1$. Furthermore $|p_{|\Omega_i}|_{H^2(\Omega_i)} \leq C|\nabla \cdot (c\nabla p)|_{L^2(\Omega)}$.*

COROLLARY A.4. *Let $m \in \mathbb{N}$, and let $c_{|\Omega_i} \in \mathscr{C}^{m+1}(\Omega_i)$, $i = 0, 1$, and S and $\partial\Omega$ be of class $\mathscr{C}^{m+2}$. Then if $u_0 \in L^2(\Omega)$, the solution u to* (A.1) *is such that $u_{|\Omega_i} \in \mathscr{C}^k((0,T], H^{m+2}(\Omega_i))$, $i = 0, 1$, for all $k \in \mathbb{N}$.*

Remark A.5. Let $\varepsilon > 0$. With the notation of the above corollary, observe that the map

$$\begin{aligned} L_{\varepsilon,i} : L^2(\Omega) &\to \mathscr{C}^k([\varepsilon, T], H^{m+2}(\Omega_i)), \\ u_0 &\mapsto (t \mapsto u_{|\Omega_i}(t)), \end{aligned}$$

is continuous for $i = 0, 1$, since [6, Theorem VII.7]

$$\begin{aligned} |u(t)|_{L^2(\Omega)} &\leq |u_0|_{L^2(\Omega)}, \\ |\partial_t u(t)|_{L^2(\Omega)} = |\nabla \cdot (c\nabla u(t))|_{L^2(\Omega)} &\leq \left|\frac{1}{t}\right| u_0|_{L^2(\Omega)}. \end{aligned}$$

We finish with the following lemma, which is needed in section 3.

LEMMA A.6. *There exists a neighborhood W of S globally parametrized with $(\sigma, y) \in]-\epsilon, \epsilon[\times S$.*

Proof. In a small neighborhood of S we can extend the unit normal vector n to S into a $\mathscr{C}^2$ vector field v. In an even smaller neighborhood U of S we can assume that v is such that $|v| \geq a > 0$. If we integrate this vector field, we find that there is $\epsilon > 0$ such that the flow χ_σ of this $\mathscr{C}^2$ vector field over the interval $]-\epsilon, \epsilon[$ is confined in U, since S is compact. For $y \in S$, the orientation of the unit normal (see above) is such that $\chi_\sigma(y) \in \Omega_1$ for $\sigma \in]-\epsilon, 0[$, and $\chi_0(y) = y$ and $\chi_\sigma(y) \in \Omega_0$ for $\sigma \in]0, \epsilon[$.

Now set

$$W = \{\chi_\sigma(y);\ y \in S \text{ and } \sigma \in\ ]-\epsilon, \epsilon[\,\},$$

which is an open neighborhood of S. Note that if x is in W, then there exist a unique $y \in S$ and a unique $\sigma \in\ ]-\epsilon, \epsilon[$ such that $x = \chi_\sigma(y)$. □

NONLINEAR AIMD CONGESTION CONTROL AND CONTRACTION MAPPINGS*

URIEL G. ROTHBLUM† AND ROBERT SHORTEN‡

Abstract. This papers analyzes a class of nonlinear *additive-increase multiplicative-decrease* (AIMD) protocols that are widely deployed in communication networks. It is demonstrated that the use of these protocols guarantees that the system has a unique stable outcome to which it converges geometrically under all starting points. The development is based on a contraction argument and the derivation of explicit bounds on the contraction coefficient of corresponding operators in terms of the network parameters. In particular, bounds on the corresponding rate of convergence are obtained, improving upon known bounds for standard (linear) AIMD networks.

Key words. AIMD congestion control, high-speed networking, contraction mappings

DOI. 10.1137/050646226

1. Introduction.

Traffic generated by the *transmission control protocol* (TCP) accounts for 85%–95% of all traffic on today's Internet [8]. TCP, in congestion avoidance mode, is based primarily on Chiu and Jain's [6] *additive-increase multiplicative-decrease* (AIMD) paradigm for decentralized allocation of a shared resource (e.g., bandwidth) among competing users. The AIMD paradigm is based upon a network of users competing for the available resource by using two basic strategies; they probe for their share of the available resource by utilizing more and more of the resource (the additive-increase (AI) stage) and then instantaneously downscale their utilization-rates in a multiplicative fashion when notified (simultaneously) that capacity was reached (the multiplicative-decrease stage). With some minor modifications, the AIMD algorithm has served the networking community well over the past two decades and it continues to provide the basic building block upon which today's Internet communication is built.

From a mathematical perspective, the dynamics of networks in which the AIMD algorithm is deployed have been studied extensively in the networking, computer science, and mathematics literature; for example, see [5, 10, 19, 24, 25, 26, 27, 29] and references therein. In these papers, some fundamental properties have been established for systems that are controlled by the AIMD algorithm, both in a deterministic and in a stochastic setting; see, for example, [1, 2, 3]. In particular, it has been shown that (with a fixed number of users) such networks possess unique stable equilibria to which the system converges geometrically under all starting points. However, recently in the context of designing high-speed communication networks, several authors have suggested basic modifications to the AIMD algorithm; for example, see [7, 9, 11, 13, 14, 20, 28]. One idea underlying these modifications is to allow the employment of more aggressive probing for available bandwidth by replacing the

linear-in-time increase of probing that is a feature of TCP with nonlinear growth. We refer to the resulting algorithms as nonlinear AIMD (NAIMD) algorithms. While the modifications appear minor from an algorithmic viewpoint, they result in networks with dynamic properties different than those employing the basic (linear) AIMD; see [4]. Remarkably, despite increasing deployment of these algorithms (e.g., a high-speed TCP algorithm is implemented as part of the Linux operating system), many basic questions pertaining to the behavior of such networks have not yet been addressed (with the notable exception of [20, 21]). Our contribution here is to use contraction arguments to prove convergence of a large class of congestion control protocols that are currently being explored for deployment on the Internet. These include HTCP, High-speed TCP, and many others [7, 13, 14]. In doing this, we model the network of TCP flows not by using a fluid approximation, or by placing assumptions of the distribution of times between congestion notifications, but rather as a system of interacting agents that are coupled together via a capacity constraint. This approach is in contrast to much of the prior work on the topic [15, 16, 17, 18], a large amount of which makes use of either a fluid assumption or assumptions on the stochastic nature of the drop process. A key advantage of modeling the interactions between the AIMD flows in this manner is that we capture not only the network asymptotics, but also the dynamic properties of the network, such as network convergence rate, using only standard linear algebraic arguments.

The objective of the current paper is to examine and study a class of NAIMD algorithms. Under the assumption of user-synchronization, we show that the corresponding networks always possess a unique equilibrium to which the system converges geometrically. Specifically, we observe resource-utilizations at instances when the system becomes saturated (congested) and demonstrate that the transition between consecutive saturation instances is governed by a *contraction* transformation. The aforementioned properties of equilibria then follow from standard results about contractions (see section 3). Our development is based on the derivation of explicit bounds on the contraction coefficient in terms of the network parameters, yielding bounds on the corresponding rate of convergence; in particular, we improve previously obtained bounds for standard AIMD algorithms.

Our results are important for a number of reasons. Network congestion control represents one of the most important problems in decentralized control, both from a practical and a theoretical perspective. Networks in which AIMD-like algorithms are deployed form the backbone of today's Internet; yet surprisingly, many properties of such networks remain unexplored. In particular, the manner in which the NAIMD parameters of each of the users affect the existence and uniqueness of the network equilibria, the nature of the network equilibria, and the rate of convergence to the equilibrium state, as well as the sensitivity of the equilibrium state to changes in network parameters (the ability to control the network fairness), is a very important issues that has yet to be adequately addressed by the research community in a general setting. An equally important consideration in the design of networks is whether new protocols can co-exist with standard AIMD networks without completely starving standard AIMD sources of the available resource. Our results in this paper present a partial solution to many of these questions and represent a first step in addressing these basic system-theoretic issues.

The outline of the paper is as follows. We describe standard and nonlinear variants of AIMD in section 2. In section 3 we introduce preliminaries, in particular about contractions. We use operators to formulate the evolution of the resource-utilization

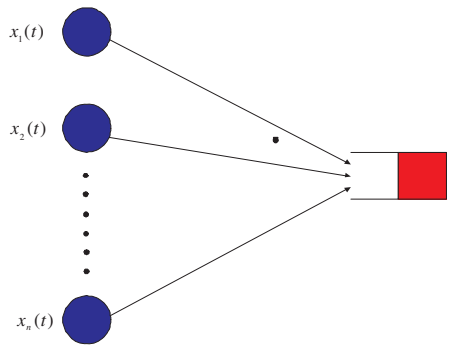

FIG. 1. *n-player system.*

in section 4 and prove our main results in section 5. Section 6 is devoted to final conclusions.

2. Preamble: AIMD congestion control. In their original paper [6], Chiu and Jain consider a system in which n-users compete for a resource having limited availability per unit time, e.g., bandwidth in communication networks. The users' actions consist of (continuously) probing the availability of the resource by submitting requests for its use—these requests are satisfied whenever global capacity is not exceeded. The situation is depicted in Figure 1, with $x_i(t)$ representing the number of units of the resource that user $i = 1, \ldots, n$ is using at time $t \geq 0$. A key assumption in the model formulated by Chiu and Jain is the assertion that the users do not communicate directly with each other. Further, users are provided information about the availability of the resource only when the collective utilization of the resource exceeds some capacity constraint. At such time-instances, referred to as *congestion events*, all users are instantly and simultaneously informed through a binary feedback. The users are assumed to respond instantly to these notifications of congestion by decentralized downscaling of their individual utilization-rates. Given this basic setting, the problem is then to develop an algorithm that produces probing strategies for the users so that each user will infer his or her "fair" share of the shared resource in a decentralized manner.

Comment. In the current paper we focus on the *synchronized* problem, referring to simultaneous notification of congestion to all users to which they all respond. In *unsynchronized systems*, the signal about system-saturation is not transmitted simultaneously to all users. While synchronization is not valid in many real communication networks, the study of such systems is important for two reasons. First, it represents an important first step towards the understanding of more general systems. Second, synchronization appears to be a common feature of high-speed communication networks [28], and consequently the understanding of the behavior of such networks may be of merit in some practical situations.

Linear AIMD congestion control. The AIMD algorithm of Chiu and Jain describes probing strategies that evolve in cycles, each cycle having two phases. The first phase of the cycles is instantaneous. It occurs when capacity is reached, users are notified, and each user responds by downscaling his or her utilization-rate (abruptly) by a multiplicative factor. This phase is called the *multiplicative-decrease* (MD) phase. During the second phase of a cycle, each user increases the utilization-rate linearly until congestion is reached again, at which point the first phase of the next cycle is

entered. The second phase is called the *additive-increase* (AI) phase. The utilization-rate at the end of the AI phase is then the initial transmission-rate for the next cycle. (The expression AIMD, rather than MDAI, is used because of historic reasons.)

Denote the share of the collective resource allocated to player i at time t by $x_i(t)$ and let $x(t) = [x_1(t), \ldots, x_n(t)]^T$. The capacity constraint requires that $\sum_{i=1}^{n} x_i(t) < C$, with C as the total capacity of the resource available to the entire system. Without loss of generality, we may and will assume that units of the resource are normalized so that $C = 1$.

The kth cycle begins at a time t^k at which the global utilization of the resource reaches capacity. The instantaneous decrease of the utilization-rate of player i during the MD phase of the kth cycle is expressed by

$$x_i(t_+^k) = \beta_i x_i(t^k), \tag{1}$$

where t_+^k is an instance after t^k and β_i is a constant in the open interval $(0, 1)$. During the AI phase of the kth cycle, the utilization-rate of user i evolves according to

$$x_i(t) = x_i(t_+^k) + \alpha_i(t - t^k), \tag{2}$$

where t_+^k is as before and α_i is a positive constant. The $(k+1)$st cycle begins at time t^{k+1}, which equals the time t at which the right-hand side of (2) reaches capacity.

A typical trajectory of the utilization-rates in a system with two users that apply AIMD with $\beta_1 = 0.25, \beta_2 = 0.5$, and $\alpha_1 = \alpha_2 = 1$ is depicted in Figure 2. In this figure, points on the line $\{x \in \mathbb{R}^2 : x_1, x_2 \geq 0\,, x_1 + x_2 = 1\}$ represent the utilization-rates at congestion events.

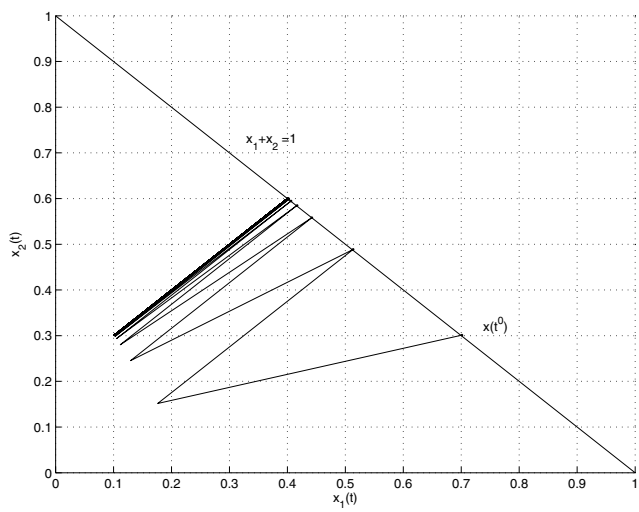

FIG. 2. *Utilization-rates under AIMD.*

Motivated by trajectories of the form illustrated in Figure 2, we find that a convenient framework in which to study the implication of the AIMD algorithm is to consider the utilization-rates at congestion events that occur at times $t^1, t^2, \ldots$. Combining (1) and (2), we see that the evolution of the utilization-rate of user i between the kth and $(k+1)$st congestion points is given by

$$x_i(t^{k+1}) = \beta_i x_i(t^k) + \alpha_i(t^{k+1} - t^k). \tag{3}$$

This avenue of investigation is explored in [5, 26], where it is shown that the transformation of the utilization-rates between consecutive congestion points is linear. Specifically, as $\sum_{i=1}^{n} x_i(t^k) = \sum_{i=1}^{n} x_i(t^{k+1}) = 1$, we have that

$$1 = \sum_{i=1}^{n} x_i(t^{k+1}) = \sum_{i=1}^{n} \beta_i x_i(t^k) + \left(\sum_{i=1}^{n} \alpha_i \right) (t^{k+1} - t^k)$$

and

$$t^{k+1} - t^k = \frac{1 - \sum_{i=1}^{n} \beta_i x_i(t^k)}{\sum_{i=1}^{n} \alpha_i} = \frac{\sum_{i=1}^{n} (1 - \beta_i) x_i(t^k)}{\sum_{i=1}^{n} \alpha_i};$$

substituting this expression into (3), we have that

$$x(t^{k+1}) = A x(t^k), \tag{4}$$

where

$$A = \begin{bmatrix} \beta_1 & 0 & \cdots & 0 \\ 0 & \beta_2 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & \beta_n \end{bmatrix} + \frac{1}{\sum_{j=1}^{n} \alpha_i} \begin{bmatrix} \alpha_1 \\ \vdots \\ \alpha_n \end{bmatrix} \begin{bmatrix} 1 - \beta_1, & \ldots & , 1 - \beta_n \end{bmatrix}. \tag{5}$$

The following facts are deducible from the above explicit form of A (see [5]):

(a) (Synchronized) AIMD systems have a unique fixed point.

(b) The vector $x(t^k)$ asymptotically approaches the ray generated by the vector $[\frac{\alpha_1}{1-\beta_1}, \ldots, \frac{\alpha_n}{1-\beta_n}]^T$; convergence is geometric at a rate that equals the second largest modulus of an eigenvalue of the matrix A.

(c) By renumbering the users in decreasing order of their multiplicative factor β_i, that is, having $0 < \beta_n \leq \cdots \leq \beta_2 \leq \beta_1 < 1$, the second largest eigenvalue of A is bounded below by β_2 and above by β_1.

Nonlinear AIMD congestion control. We next describe a nonlinear variant of the basic AIMD algorithm, which we call the NAIMD. Specifically, NAIMD coincides with the standard (linear) AIMD, except that in the AI phase the increase in the utilization-rate of each user i is dictated by a nonlinear function of time that we denote by $a_i(.)$. So, (2) has to be modified by replacing the (multiplying constant) α_i by (the function) a_i, while (1) remains unchanged. The evolution of the utilization-rate of user i between the kth and $(k+1)$st congestion points is then given by

$$x_i(t^{k+1}) = \beta_i x_i(t^k) + a_i(t^{k+1} - t^k), \tag{6}$$

which replaces (3).

It has been recently shown by several authors that some choices of the $a_i(\cdot)$ lead to poor dynamic properties, including the lack of stable utilization-rates; see [4, 11]). The analysis presented here, together with the analysis and modeling framework in [12], constitutes an important first step in modeling high-speed networks that employ AIMD-like protocols. In [12] the authors use a "product of matrices" approach to establish conditions that guarantee the stability of the network where the growth functions are functions of the current state. Here we use contraction mapping arguments to establish the important result of unconditional stability of the network when the growth functions are functions of time since the last notification of congestion.

In particular, in the current paper we restrict our attention to the application of NAIMD with functions $a_i(.)$ that are nondecreasing. A number of authors have already shown that corresponding strategies offer an attractive framework for designing congestion control that is suitable for deployment in high-speed networks [13]. As in the linear case, one may consider the NAIMD only at the congestion points over which it defines an operator that maps the utilization-rates between consecutive points. Our principal contribution is the introduction of a contraction mapping approach to show that this class of operators is well behaved and has properties that are parallel to those of standard (linear) AIMD.

The next example illustrates the evolution of the utilization-rates in a 2-user system in which NAIMD is applied and to which our forthcoming results apply.

Example 1. Consider a system with two users that apply NAIMD with $\beta_1 = 0.25, \beta_2 = 0.5, a_1(t) = t$, and $a_2(t) = t^2$ for all $t \geq 0$. The trajectory of the utilization-rates in this system is depicted in Figure 3.

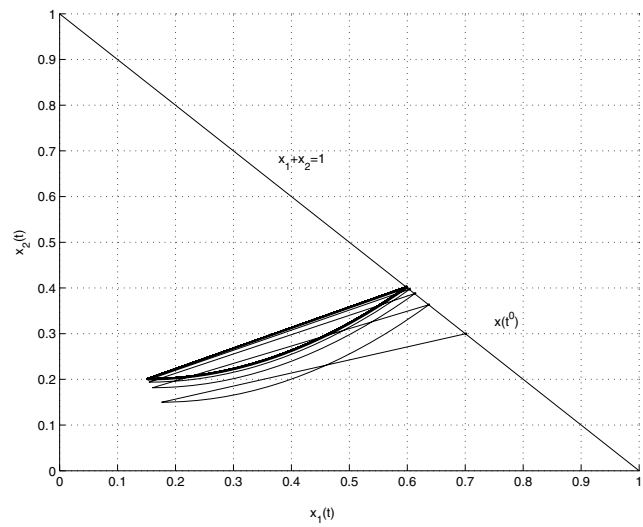

FIG. 3. *Utilization-rates under NAIMD.*

3. Notation and preliminaries. Throughout, we use notation $\mathbb{R}$ for the set of real numbers, $\mathbb{R}^n$ for the n-dimensional real Euclidean space, and $\mathbb{R}^{n\times n}$ for the space of $n \times n$ matrices with real entries. As usual, subscripts are used to denote coordinates of vectors and matrices, the notation $\leq$ and $<$ is used, respectively, for the coordinatewise weak and strict order over vectors and matrices, and $||\,.\,||_1$ denotes the ℓ_1 norm on $\mathbb{R}^n$. Given a vector β in $\mathbb{R}^n$, we use the notation D_β for the diagonal $n \times n$ matrix, whose diagonal elements are $\beta_1, \ldots, \beta_n$. Given two vectors u and v in $\mathbb{R}^n$, their *Hadamard product* $(u_1v_1, \ldots, u_nv_n)^T = D_u v \in \mathbb{R}^n$ will be denoted $u \circ v$. Given a convex set $C \subseteq \mathbb{R}^n$, its *tangential hull* $\{\alpha(x - y) : x, y \in C \text{ and } \alpha \in \mathbb{R}\}$ will be denoted $\text{tng}(C)$ (it is the smallest hyperplane containing C, translated to the origin).

With n as a given positive integer, we let e^i denote the ith unit vector and we let e denote the vector $(1, \ldots, 1)^T \in \mathbb{R}^n$. Also, we let S denote the *unit simplex* $\{x \in \mathbb{R}^n : x \geq 0\,, \sum_{i=1}^n x_i = 1\}$; in particular, $\text{tng}\,(S) = \{z \in \mathbb{R}^n : e^T z = 0\}$.

Given an operator $\mathcal{A}$ on a compact subset C of $\mathbb{R}^n$, we denote the ℓ_1 *operator*

norm of $\mathcal{A}$ on C by $||\mathcal{A}||_1^C$, that is,

$$||\mathcal{A}||_1^C = \max_{x,y\in C, x\neq y} \frac{||\mathcal{A}(x)-\mathcal{A}(y)||_1}{||x-y||_1}. \tag{7}$$

When C is convex and $\mathcal{A}$ is a linear operator represented by a matrix A (that is, $\mathcal{A}(x) = Ax$ for each $x \in C$), we have that

$$||\mathcal{A}||_1^C = \max_{z\in \mathrm{tng}(C), z\neq 0} \frac{||Az||_1}{||z||_1} = \max_{z\in \mathrm{tng}(C), ||z||_1=1} ||Az||_1. \tag{8}$$

We say that $\mathcal{A}$ is a *contraction on C with respect to the ℓ_1* norm if $||\mathcal{A}||_1^C < 1$. In this case, the Banach fixed point theorem assures us that $\mathcal{A}$ has a unique fixed point, say, x^*, and that the iterates of $\mathcal{A}$ on any arbitrarily selected point $x \in C$ converge geometrically to x^* at a rate that is bounded by $\gamma \equiv ||\mathcal{A}||_1^C$; specifically, we have that

$$||\mathcal{A}^n(x) - x^*||_1 \leq \frac{\gamma^n}{1-\gamma}||x - Ax||_1 \quad \text{for } n = 0, 1, \ldots. \tag{9}$$

To verify (9) with $n = 0$ observe that $||x - x^*||_1 \leq ||x - Ax||_1 + ||Ax - Ax^*||_1 \leq ||x-Ax||_1+\gamma||x-x^*||_1$, implying that $||x-x^*||_1 \leq (1-\gamma)^{-1}||x-Ax||_1$. For arbitrary $n \geq 0$, we then have that $||\mathcal{A}^n(x) - x^*||_1 = ||\mathcal{A}^n(x) - \mathcal{A}^n(x^*)||_1 \leq \gamma^n||x - x^*||_1 \leq \frac{\gamma^n}{1-\gamma}||x - Ax||_1$. The significance of (9) is in the fact that it allows one to bound the proximity to the unique fixed point of iterates of $\mathcal{A}$ on an arbitrary point in terms of the computable quantity $(1 - \gamma)^{-1}||x - Ax||_1$ and the geometrically decreasing term γ^n.

4. Operator-formulation. As stated in the preamble, we assume throughout that the capacity of the resource is normalized to 1. Our first undertaking is to formally model the evolution of the utilization-rates in an n-user system that is governed by the nonstandard (that is, not necessarily linear) variant of AIMD with transition over each cycle expressed by (6). The data we have at hand is then a vector $\beta \in \mathbb{R}^n$ and functions $a_i(\cdot) : [0, \infty) \to [0, \infty)$ for $i = 1, \ldots, n$ that are assumed to have the following properties:

(i) $0 < \beta < e$.
(ii) For $i = 1, \ldots, n$, $a_i(\cdot)$ is nondecreasing and continuous and has $a_i(0) = 0$.
(iii) $\sum_i a_i(\cdot)$ is strictly increasing and its range includes $[0, 1]$.

For each $t \in [0, \infty)$, let $a(t) = [a_1(t), \ldots, a_n(t)]^T$. Also, let $g(\cdot) : [0, \infty) \to [0, \infty)$ be the function that maps each $0 \leq t < \infty$ into $g(t) = e^T a(t)$. The assumptions about the $a_i(\cdot)$'s assure us that the function $g(\cdot)$ is strictly increasing and continuous and that its range includes $[0, 1]$. These properties of $g(\cdot)$ assure us that it has a continuous, strictly increasing inverse on $[0, 1]$, which we denote $g^{-1}(\cdot)$.

Consider a cycle k in which the initial utilization-rates of the users are $x_1, \ldots, x_n$, respectively, and let $x = (x_1, \ldots, x_n)^T$. As the total resource capacity is normalized to 1, we have that $x \in S$. Let t_x be the duration of a phase in which the initial utilization-rates are given by x. It then follows that, with

$$x_i = x_i(t^k) \text{ and } t_x = t^{k+1} - t^k,$$

by (6) the transition of the utilization-rate over a cycle which starts with utilization-rates represented by $x \in S$ is expressed by

$$\mathcal{A}(x) = (\beta \circ x) + a(t_x). \tag{10}$$

Notification of congestion is transmitted when the cumulative transmission-rate reaches the unit capacity, implying that

$$1 = \sum_{i=1}^{n} \mathcal{A}(x)_i = e^T(\beta \circ x) + e^T a(t_x).$$

So,

$$t_x = g^{-1}[1 - e^T(\beta \circ x)] \tag{11}$$

(the expression $g^{-1}[1-e^T(\beta\circ x)]$ is well defined because $0 < e^T(\beta\circ x) = \sum_{i=1}^{n} \beta_i x_i < 1$). Substituting (11) into (10), we conclude that

$$\mathcal{A}(x) = (\beta \circ x) + a\Big(g^{-1}[1 - e^T(\beta \circ x)]\Big). \tag{12}$$

Observing that for $x \in S$, $\mathcal{A}(x) \geq (\beta \circ x) \geq 0$ and

$$\begin{aligned} e^T\mathcal{A}(x) &= e^T(\beta \circ x) + e^T a\Big(g^{-1}[1 - e^T(\beta \circ x)]\Big) \\ &= e^T(\beta \circ x) + [1 - e^T(\beta \circ x)] = 1, \end{aligned}$$

we have that $\mathcal{A}$ maps S into S; that is, $\mathcal{A}$ is an operator on S.

The operator $\mathcal{A}$ expresses the transitions of the utilization-rates over the phases AIMD. Specifically, denote the vector of utilization-rates at the beginning of phase $k = 1, 2, \ldots$ by x^k. We then have from (6) and the above derivation that

$$x^{k+1} = \mathcal{A}(x^k). \tag{13}$$

We next study the operator $\mathcal{A}$ with the goal of understanding the evolution of the utilization-rate when NAIMD is followed. In particular, we will establish that $\mathcal{A}$ is a contraction with respect to the ℓ_1 norm on S, ensuring that $\mathcal{A}$ has a stable unique fixed point and that iterates of $\mathcal{A}$ applied to an arbitrary initial point converge to that fixed point.

5. Main results.

5.1. Existence and uniqueness of fixed points.

Our first result shows that the operator $\mathcal{A}$ has a unique fixed point.

THEOREM 5.1. *There exists a unique $t^* > 0$ satisfying $e^T(I - D_\beta)^{-1}a(t^*) = 1$; further, for this t^*,*

$$x^* \equiv (I - D_\beta)^{-1}a(t^*) \tag{14}$$

is a unique fixed point of the operator $\mathcal{A}$.

Proof. Evidently, a vector $\bar{x} \in S$ is a fixed point of the operator $\mathcal{A}$ defined by (10) if and only if

$$(I - D_\beta)\bar{x} = \bar{x} - (\beta \circ \bar{x}) = a(t_{\bar{x}}) \tag{15}$$

(with $t_{\bar{x}}$ defined by (11)). As $0 < \beta < e$, $I - D_\beta$ is invertible and its inverse is the diagonal matrix whose diagonal elements are $(1-\beta_1)^{-1}, \ldots, (1-\beta_n)^{-1}$; in particular, $(I - D_\beta)^{-1} = \sum_{k=0}^{\infty} D_\beta^k \geq I$ and (15) is equivalent to

$$\bar{x} = (I - D_\beta)^{-1}a(t_{\bar{x}}). \tag{16}$$

As $e^T x = 1$ for each $x \in S$, we conclude that if $\bar{x}$ is a fixed point of $\mathcal{A}$, then $\bar{x}$ must satisfy (16) and

$$e^T (I - D_\beta)^{-1} a(t_{\bar{x}}) = 1. \tag{17}$$

We next construct a point $x^* \in S$ that uniquely satisfies (16); it will then follow from the above paragraph that x^* is a unique fixed point of $\mathcal{A}$. Our construction is motivated by (17).

Let $h(\cdot) : [0, \infty) \to [0, \infty)$ be the real-valued function mapping each $t \geq 0$ into $h(t) = e^T (I - D_\beta)^{-1} a(t)$. The properties of $a(\cdot)$ assure us that $h(\cdot)$ is continuous, $h(0) = 0$, and for all $t > t' > 0$, $h(t) = e^T (I - D_\beta)^{-1} a(t) \geq e^T a(t) = g(t) > 0$ and $h(t) - h(t') = e^T (I - D_\beta)^{-1} [a(t) - a(t')] \geq e^T [a(t) - a(t')] > 0$. So, $h(\cdot)$ is continuous and strictly increasing and its domain includes $[0, 1]$ (recall that the domain of $g(\cdot)$ includes $[0, 1]$). These properties of $h(\cdot)$ assure us that there is a unique $t^* > 0$ satisfying $h(t^*) = 1$. With x^* given by (14), we then have that $x^* = (I - D_\beta)^{-1} a(t^*) \geq a(t^*) \geq 0$ and $e^T x^* = e^T (I - D_\beta)^{-1} a(t^*) = 1$, so $x^* \in S$. Further,

$$g(t^*) = e^T a(t^*) = e^T (I - D_\beta) x^* = e^T x^* - e^T D_\beta x^* = 1 - e^T (\beta \circ x^*),$$

implying that $t^* = g^{-1}[1 - e^T (\beta \circ x^*)] = t_{x^*}$. Substituting $t^* = t_{x^*}$ into (14) implies that $x^* = (I - D_\beta)^{-1} a(t_{x^*})$, verifying that $x^* \in S$ satisfies (16)—the characterizing condition for fixed points of $\mathcal{A}$. We conclude that x^* is a fixed point of $\mathcal{A}$. Further, (17) shows that any fixed point $\bar{x}$ of $\mathcal{A}$ must satisfy $h(t_{\bar{x}}) = 1 = h(t^*)$; as $h(\cdot)$ is strictly increasing, we then have that $t_{\bar{x}} = t^*$ and (16) implies that $\bar{x} = (I - D_\beta)^{-1} a(t_{\bar{x}}) = (I - D_\beta)^{-1} a(t^*) = x^*$. □

Theorem 5.1 and its proof do not show that the operator $\mathcal{A}$ is a contraction; consequently, they do not imply that the unique fixed point of $\mathcal{A}$ has the useful properties of fixed points of contractions, i.e., successive approximation and stability. However, (14) provides an explicit representation of the unique fixed point of $\mathcal{A}$ in terms of a (unique) solution of the equation $e^T (I - D_\beta)^{-1} a(t) = 1$, generally not available from contraction arguments. Further, we observe that as the function mapping each nonnegative t into $e^T (I - D_\beta)^{-1} a(t)$ is strictly increasing, a solution to $e^T (I - D_\beta)^{-1} a(t) = 1$ can be approximated by bisection, yielding an efficient computational method to approximate x^*.

We next illustrate the unique fixed point of the system described in Example 1.

Example 1 (continued). For the data of Example 1, $e^T (I - D_\beta)^{-1} a(t) = \frac{4}{3} t + 2t^2$ for each $t \geq 0$, $t^* = .45$, and $x(t^*)^T = (\frac{4}{3} t^*, 2(t^*)^2) = (.6, .4)$; the latter is consistent with Figure 3.

5.2. Contractions.

A. The linear case. In the linear case we have a vector $a \in \mathbb{R}^n \setminus \{0\}$ satisfying $a \geq 0$ such that $a(t) = at$ for all $t \geq 0$. In this case, $g(t) = e^T at$ for each $t \geq 0$ and $g^{-1}(y) = y / e^T a$ for each $0 \leq y \leq 1$, so (12) yields the following representation for the operation of $\mathcal{A}$ on $x \in S$:

$$\begin{aligned} \mathcal{A}(x) &= \beta \circ x + a \frac{1 - e^T (\beta \circ x)}{e^T a} = D_\beta x + a \frac{e^T x - e^T D_\beta x}{e^T a} \\ &= \left[D_\beta + \frac{a e^T (I - D_\beta)}{e^T a} \right] x \end{aligned} \tag{18}$$

(in addition to (12), the above uses the facts that $\beta \circ x = D_\beta x$ and $e^T x = 1$ for each

$x \in S$). Equation (18) shows that $\mathcal{A}$ is linear on S, represented by the matrix $[D_\beta + \frac{ae^T(I-D_\beta)}{e^T a}] \in \mathbb{R}^{n\times n}$. In particular, we see that $\mathcal{A}$ is invariant under the multiplication of a by a positive scalar. Thus, without loss of generality, we can and will assume that $e^T a = 1$, in which case (18) simplifies to

$$\mathcal{A}(x) = [D_\beta + ae^T(I - D_\beta)]x. \tag{19}$$

Let

$$A = [D_\beta + ae^T(I - D_\beta)]. \tag{20}$$

As $e^T a = 1$,

$$e^T A = e^T[D_\beta + ae^T(I - D_\beta)] = e^T D_\beta + e^T ae^T - e^T ae^T D_\beta = e^T,$$

and as $0 < \beta < e$, A is nonnegative. So, A is column-stochastic. In particular, its Perron–Frobenius eigenvalue is 1 with e^T as a corresponding left-eigenvector.

Our next goal is to show that $\mathcal{A}$ is a contraction on S with respect to the ℓ_1 norm; in fact, we derive an explicit bound on the ℓ_1 operator norm of $\mathcal{A}$. It will be convenient to enumerate the indices so that

$$1 > \beta_1 \geq \beta_2 \geq \cdots \geq \beta_n > 0. \tag{21}$$

THEOREM 5.2. *Let $a \in S$ and $\beta \in \mathbb{R}^n$ satisfy* (21). *Then*

$$||\mathcal{A}||_1^S = \beta_1(1 - a_1) + \beta_2 a_1 \leq \beta_1 < 1. \tag{22}$$

Proof. As $\mathcal{A}$ is linear with representing $n \times n$ matrix $[D_\beta + ae^T(I - D_\beta)]$ (see (19)), we have from (8) that

$$||\mathcal{A}||_1^S = \max_{z\in \mathrm{tng}(S), ||z||_1=1} ||[D_\beta + ae^T(I - D_\beta)]z||_1. \tag{23}$$

The right-hand side of (23) is the maximum of a convex function of z over the polytope $\{z \in \mathbb{R}^n : e^T z = 0, ||z||_1 = 1\}$ and is attained at one of the vertices of that polytope; these vertices have the representation $\frac{1}{2}(e^i - e^j)$, where $i, j = 1, \ldots, n$ and $i \neq j$. Thus,

$$||\mathcal{A}||_1^S = \max_{1\leq j<i\leq n} \frac{1}{2}||[D_\beta + ae^T(I - D_\beta)](e^i - e^j)||_1. \tag{24}$$

We observe that for $s, u = 1, \ldots, n$,

$$\left\{[D_\beta + ae^T(I - D_\beta)]e^s\right\}_u = \begin{cases} \beta_s + a_s(1 - \beta_s) & \text{if } u = s, \\ a_u(1 - \beta_s) & \text{if } u \neq s\ . \end{cases}$$

Recalling (21) and the normalization condition $e^T a = 1$, we conclude that for

$i, j = 1, \ldots, n$ and $i > j$ we have that $\beta_j \geq \beta_i$ and

$$\begin{aligned}
&\left\| [D_\beta + ae^T(I - D_\beta)] \Big(\frac{e^i - e^j}{2} \Big) \right\|_1 \\
&\quad = \frac{1}{2} \Big(|\beta_i + a_i(1 - \beta_i) - a_i(1 - \beta_j)| + |\beta_j + a_j(1 - \beta_j) - a_j(1 - \beta_i)| \\
&\qquad + \sum_{u \neq i,j} |a_u(1 - \beta_i) - a_u(1 - \beta_j)| \Big) \\
&\quad = \frac{1}{2} \Big(|\beta_i + a_i(\beta_j - \beta_i)| + |\beta_j(1 - a_j) + a_j\beta_i| + \sum_{u \neq i,j} |a_u(\beta_j - \beta_i)| \Big). \\
&\quad = \frac{1}{2} \Big([\beta_i + a_i(\beta_j - \beta_i)] + [\beta_j(1 - a_j) + a_j\beta_i] + \sum_{u \neq i,j} a_u(\beta_j - \beta_i) \Big) \\
&\quad = \frac{1}{2} \Big(\beta_i + (1 - a_j)(\beta_j - \beta_i) + [\beta_j(1 - a_j) + a_j\beta_i] \Big) \\
&\quad = \beta_j(1 - a_j) + \beta_i a_j. \qquad (25)
\end{aligned}$$

In particular, the right-hand side of (25) lies between β_j and β_i. It now follows from (21) that the maximum on the right-hand side of (24) equals $\beta_1(1 - a_1) + \beta_2 a_1$, attained when $j = 1$ and $i = 2$. Finally, the inequalities on the right-hand side of (22) are immediate from (21). □

The following immediate corollary of Theorem 5.2 demonstrates that (synchronized) AIMD results in a unique stable point to which the system converges geometrically from all potential starting points.

COROLLARY 5.3. *In the linear case, $\mathcal{A}$ has a unique fixed point x^* to which the iterates of $\mathcal{A}$ on any arbitrarily selected point in S converge geometrically; in particular,* (9) *is satisfied for every $x \in S$.*

Proof. The conclusions follow from Theorem 5.2 and the standard properties of contractions. □

Let $\tau(A)$ denote the second largest modulus of A's eigenvalues. Theorem 5.2 yields the following bound on $\tau(A)$.

COROLLARY 5.4.

$$\tau(A) \leq ||\mathcal{A}||_1^S = \beta_1(1 - a_1) + \beta_2 a_1 \leq \beta_1 < 1. \qquad (26)$$

Proof. As the matrix A defined by (20) is column-stochastic, the main result of [23] implies that for every norm $|| \cdot ||$, the matrix norm of A over the intersection of the $|| \cdot ||$-unit ball and the hyperplane $\{z \in R^n : e^T z = 0\}$ is an upper bound on $\tau(A)$. As $\text{tng}(S) = \{z \in R^n : e^T z = 0\}$, we have that the right-hand side of (23) is a specification of this bound when $|| \cdot ||$ is the ℓ_1 norm, yielding the first inequality of (26). The remaining parts of (26) follow from Theorem 5.2. □

The dynamics of network-transmission under the (synchronized) linear version of AIMD was studied in [5]. The principal contribution of that paper was showing that the matrix $A' \equiv [D_\beta + \frac{ae^T(I - D_\beta)}{e^T a}]$ is diagonally similar to the sum of a real symmetric matrix and a real rank-1 perturbation. The following facts are then easily deduced:

(a) A' is diagonally similar to a (real) positive diagonal matrix.
(b) Except for the Perron eigenvalue, all of the eigenvalues of A' lie in the interval $[\beta_n, \beta_1]$.
(c) If all the β_i's are distinct and $\lambda_1, \ldots, \lambda_n$ are the eigenvalues of A', then $0 < \beta_n < \lambda_{n-1} < \beta_{n-2} < \cdots < \lambda_2 < \beta_1 < \lambda_1 = 1$.

(d) $\beta_2 \le \tau(A) \le \beta_1$ (and in the inequalities are strict when the β_i's are distinct).

Corollary 5.4 established that $\tau(A) \le \beta_1(1-a_1) + \beta_2 a_1$; when $\beta_1 \ne \beta_2$, this is a tighter upper bound on $\tau(A)$ than is available from (d). The following example demonstrates the fact that we derive an improved bound.

Example 2. Consider a system with three users that are governed by standard (linear) AIMD with $\beta_1 = 0.8, \beta_2 = 0.7, \beta_3 = 0.2$, and $\alpha_1 = \alpha_2 = \alpha_2 = 1$. From (5), the matrix A is then given by

$$A = \begin{bmatrix} 0.8 & 0 & 0 \\ 0 & 0.7 & 0 \\ 0 & 0 & 0.5 \end{bmatrix} + \frac{1}{3}\begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix} [0.2 \;\; 0.3 \;\; 0.8].$$

From the results in [5] stated in (d) we have that the eigenvalue of A with the second largest modulus, say λ_2, satisfies $0.7 \le \lambda_2 \le 0.8$. From Corollary 5.4 we have the sharper upper bound:

$$\lambda_2 \le \beta_1(1-a_1) + \beta_2 a_1 = 0.7667.$$

The eigenvalues of A are $1.0000, 0.7549$, and 0.5785, respectively, demonstrating the virtue of the bound on λ_2 derived in Theorem 5.2 over the bound from (d).

We conclude the discussion of the linear version of AIMD with a specification of Theorem 5.2 to the case where the vector a is a unit vector—a case that will prove useful in analyzing networks under the nonlinear variant of AIMD.

COROLLARY 5.5. *If $a = e^i$ for some $i = 1, \ldots, n$ and $\beta \in \mathbb{R}^n$ satisfies* (21)*, then $||\mathcal{A}||_1^S = \beta_1$ when $i = 1$ and $||\mathcal{A}||_1^S = \beta_1$ when $i \ne 1$.*

B. The general (nonlinear) case. We next consider the general AIMD case in which $a(\cdot)$ is not necessarily linear, and we use our earlier results for the linear case to demonstrate that, in the more general case as well, the operator $\mathcal{A}$ is a contraction on S.

Given a vector $a \in \mathbb{R}^n$, we will use the notation $\mathcal{A}^a$ for the linear operator corresponding to the case where $a(t) = at$ for each $t \ge 0$.

THEOREM 5.6. *The operator $\mathcal{A}$ satisfies*

$$||\mathcal{A}||_1^S \le \max_{i=1,\ldots,n} ||\mathcal{A}^{e^i}||_1^S = \beta_1 < 1. \tag{27}$$

Proof. Consider any two points $x, y \in S$. Without loss of generality, assume that $e^T(\beta \circ x) \le e^T(\beta \circ y)$. As g^{-1} is (strictly) increasing, it follows that

$$t_x = g^{-1}[1 - e^T(\beta \circ x)] \ge g^{-1}[1 - e^T(\beta \circ y)] = t_y. \tag{28}$$

As $a(\cdot)$ is nondecreasing, we conclude that $a(t_x) \ge a(t_y)$, and therefore

$$||a(t_x) - a(t_y)||_1 = e^T[a(t_x) - a(t_y)] = g(t_x) - g(t_y) = e^T(\beta \circ y) - e^T(\beta \circ x). \tag{29}$$

We next observe (from (10)) that

$$\mathcal{A}(x) - \mathcal{A}(y) = \beta \circ (x - y) + a(t_x) - a(t_y). \tag{30}$$

From (30) and (29) we conclude that

$$\begin{aligned} ||\mathcal{A}(x) - \mathcal{A}(y)||_1 &\le ||\beta \circ (x-y)||_1 + ||a(t_x) - a(t_y)||_1 \\ &= ||\beta \circ (x-y)||_1 + e^T(\beta \circ y) - e^T(\beta \circ x). \end{aligned} \tag{31}$$

As $\sum_i x_i = \sum_i y_i = 1$, there exists an index i^* with $x_{i^*} \geq y_{i^*}$. We next consider the linear case determined by the vector $a = e^{i^*}$ and the vector β unchanged. Specifically, we let $\mathcal{A}^{e^{i^*}}$ be the linear operator that corresponds to the matrix $[D_\beta + e^{i^*}e^T(I - D_\beta)]$. Let t_x^* and t_y^* be defined by (11) with respect to this (linear) case. As $e^T e^{i^*} = 1$, we have that $t_x^* = 1 - e^T(\beta \circ x)$, $t_y^* = 1 - e^T(\beta \circ y)$, and

$$t_x^* - t_y^* = e^T(\beta \circ y) - e^T(\beta \circ x) \geq 0. \tag{32}$$

Similar to the derivation of (30), we get that

$$\mathcal{A}^*(x) - \mathcal{A}^*(y) = \beta \circ (x - y) + e^{i^*}(t_x^* - t_y^*). \tag{33}$$

As $x_{i^*} \geq y_{i^*}$ and $t_x^* \geq t_y^*$, we conclude from (33), (32), and (31) that

$$\begin{aligned} ||\mathcal{A}^*(x) - \mathcal{A}^*(y)||_1 &= [\beta_{i^*}(x_{i^*} - y_{i^*}) + (t_x^* - t_y^*)] + \sum_{u \neq i^*} |\beta_u(x_u - y_u)| \\ &= \sum_u |\beta_u(x_u - y_u)| + (t_x^* - t_y^*) \\ &= ||\beta \circ (x - y)||_1 + e^T(\beta \circ y) - e^T(\beta \circ x) \\ &\geq ||\mathcal{A}(x) - \mathcal{A}(y)||_1, \end{aligned} \tag{34}$$

implying that

$$||\mathcal{A}(x) - \mathcal{A}(y)||_1^S \leq \max_i ||\mathcal{A}^{e^i}||_1^S = \beta_1 \tag{35}$$

(the last equality following from Corollary 5.5). ∎

Equation (27) demonstrates that β_1 is a bound on the contraction coefficient of $\mathcal{A}$—it is remarkable that this bound is independent of the $a_i(\cdot)$'s.

As for the linear case, we get the following immediate corollary of Theorem 5.6—it demonstrates that (synchronized) NAIMD results is a unique stable point to which the system converges geometrically from every potential starting point.

COROLLARY 5.7. *In the general (nonlinear) case, $\mathcal{A}$ has a unique fixed point x^* to which the iterates of $\mathcal{A}$ on any potential starting point converge geometrically; in particular,* (9) *is satisfied for every $x \in S$.*

Proof. The conclusions follow from Theorem 5.6 and the standard properties of contractions. ∎

6. Conclusions. In this paper we have presented, for the first time, a proof of stability for a class of NAIMD algorithms. Bounds on the rate of convergence are given for these algorithms and simulation results are given to illustrate the efficacy of our results. Future work will report on the behavior of unsynchronized networks. In this context the recent results presented in [30, 31] are likely to prove useful.

BOLZA PROBLEMS WITH DISCONTINUOUS LAGRANGIANS AND LIPSCHITZ-CONTINUITY OF THE VALUE FUNCTION*

ANDREA DAVINI†

Abstract. We study the local Lipschitz-continuity of the value function v associated with a Bolza problem in the presence of a Lagrangian $L(x,q)$, convex and uniformly superlinear in q, but only Borel-measurable in x. Under these assumptions, the associated integral functional is not lower semicontinuous with respect to the suitable topology which ensures the existence of minimizers, so all results known in the literature fail to apply. Yet, the Lipschitz regularity of v does not depend on the existence of minimizers. In fact, it is enough to control the derivatives of quasi-minimal curves, but the problem is nontrivial due to the general growth conditions assumed here on $L(x,\cdot)$. We propose a new approach, based on suitable reparameterization arguments, to obtain suitable a priori estimates on the Lipschitz constants of quasi minimizers. As a consequence of our analysis, we derive the Lipschitz-continuity of v and a compactness result for value functions associated with sequences of locally equibounded discontinuous Lagrangians.

1. Introduction.

1.1. Description of the problem and main results.

A typical issue in partial differential equations is that of proving the local Lipschitz-continuity in $(0,+\infty)\times\mathbb{R}^N$ of the *value function*

$$v(t,x) := \inf\left\{ u(\gamma(0)) + \int_0^t L(s,\gamma(s),\dot\gamma(s))\,\mathrm{d}s \ :\ \gamma\in W^{1,1}\big([0,t],\mathbb{R}^N\big),\ \gamma(t)=x \right\}$$

associated with a Lagrangian $L:[0,+\infty)\times\mathbb{R}^N\times\mathbb{R}^N\to(-\infty,+\infty]$ and to a possibly discontinuous *initial cost* $u:\mathbb{R}^N\to(-\infty,+\infty]$. This is an important step when one is interested in showing that v is a solution, in a suitable generalized sense, of the equation

$$\partial_t u + H(x,Du) = 0 \qquad \text{in } (0,+\infty)\times\mathbb{R}^N, \tag{1}$$

where H is the Hamiltonian associated with L through the Fenchel transform. When L is continuous, it is well known that v is a solution of (1) in the *viscosity sense* (see, e.g., [3, 4, 26]). For discontinuous (and autonomous) Lagrangians, a PDE interpretation of the value function has been provided by Dal Maso and Frankowska in [18, 19]. By making use of the so-called contingent derivatives, these authors prove that v satisfies the Hamilton–Jacobi equation, in a suitable generalized sense, and characterize it as the unique solution of the associated Cauchy problem with initial datum u when the latter is lower semicontinuous.

The study of discontinuous Hamilton–Jacobi equations is a field which is gaining attention from the viewpoints of both theory and applications; see [6, 8, 10, 11, 12,

13, 28, 30, 33, 34]. It is related to the study of geodesic distances, some discontinuous control problems, combustion phenomena in nonhomogeneous media, and geometric optic propagation in the presence of layers; see [5, 23, 27]. The analysis we will develop here supplies the tools for proving representation formulas for generalized solutions of time-dependent measurable Hamilton–Jacobi equations in the spirit of [12]. This issue will be discussed in the forthcoming paper [9].

The Lipschitz-continuity of v is strictly related to the regularity of solutions to the *Bolza problem*,

$$\min\left\{u(\gamma(0)) + \int_0^t L(s,\gamma(s),\dot\gamma(s))\,\mathrm{d}s \;:\; \gamma \in W^{1,1}\big([0,t],\mathbb{R}^N\big),\ \gamma(t)=x\right\}, \tag{2}$$

and to the possibility of finding some a priori estimates on the Lipschitz constants of minimizers. Clearly, any solution of (2) is also a Lagrangian minimizer with respect to its boundary conditions.

The study of regularity properties of Lagrangian minimizers is a classical topic in the calculus of variations; see, for instance, [7, 15]. The first results were obtained by Tonelli in 1915 [35] and the early 1920s [36] for real-valued smooth Lagrangians $L(s,x,q)$, coercive and strictly convex in q. More recently, Tonelli's results have been generalized by Clarke and Vinter [17] to the case of measurable, locally bounded integrands $L(s,x,q)$ which are locally Lipschitz in x, convex, and uniformly superlinear in q. By using the tools of nonsmooth analysis, the classical Euler–Lagrange necessary condition is expressed in terms of a differential inclusion.

The autonomous case has been widely studied. The results of [17] have been extended by Ambrosio, Ascenzi, and Buttazzo in [2] to the case of a locally bounded Lagrangian $L(x,q)$, convex and uniformly superlinear in q. In [18], Dal Maso and Frankowska succeeded in proving the same results without assuming any convexity in q. They also obtained some uniform estimates on the Lipschitz constant of the minimizers, which are used to prove that the associated value function v is locally Lipschitz in $(0,+\infty)\times\mathbb{R}^N$, provided problem (2) admits solutions for every $(t,x)\in(0,+\infty)\times\mathbb{R}^N$.

Here we will be concerned with the case of a Borel-measurable Lagrangian $L:\mathbb{R}^N\times\mathbb{R}^N\to\mathbb{R}$, locally bounded with respect to (x,q), convex, and uniformly superlinear in q. The growth conditions assumed on L can be restated in the following equivalent form:

$$\alpha(|q|)\le L(x,q)\le\beta(x,|q|)\qquad\text{for every } (x,q)\in\mathbb{R}^N\times\mathbb{R}^N,$$

where $\alpha(\cdot)$ and $\beta(x,\cdot)$ are superlinear functions from $[0,+\infty)$ to $\mathbb{R}$, with β locally bounded on $\mathbb{R}^N\times[0,+\infty)$ (cf. Lemma 2.3). The model example of Lagrangians included in this class are of the form

$$L(x,q)=F(q)+n(x),$$

with $F(\cdot)$ convex and superlinear, and $n(\cdot)$ Borel-measurable and bounded.

The main result we prove is the local Lipschitz-continuity of the value function v in $(0,+\infty)\times\mathbb{R}^N$. Several Lipschitz-regularity results for the value function associated with a discontinuous Lagrangian, depending on the continuity properties enjoyed by the initial cost, are given in section 4. Moreover, a compactness result holding for sequences of value functions is derived in subsection 4.2 as a consequence of what was proved in [20] (cf. Theorem 3.21). This kind of result essentially relies on the fact that

all the Lipschitz estimates we provide do not depend explicitly on the Lagrangian but only on the way $L(x,q)$ grows when $|q| \to +\infty$, i.e., on the functions α, β.

We remark that all results of the paper hold, with the obvious changes of notation, if $\mathbb{R}^N$ is replaced by a connected, smooth Riemannian manifold $\mathcal{M}$ without boundary. Proofs can be rephrased by using local coordinates. When $\mathcal{M}$ is compact, some additional information on the Lipschitz continuity of the value function is deduced.

With respect to the literature quoted above, the key new point in this paper consists of dealing with a case when the minimizers of the Bolza problem do not exist in general. This gives rise to serious technical difficulties, since all arguments known in the literature exploit the existence of minimizers to derive information on their Lipschitz constants, and this in turn gives the desired regularity of v via a rather standard argument. The same reasoning, however, works as soon as we provide suitable integral estimates on the derivatives of quasi-optimal curves for $v(t,x)$ (i.e., curves that realize the value $v(t,x)$ in (2), up to an addition of a suitably small positive constant) depending with some uniformity on $(t,x) \in (0,+\infty) \times \mathbb{R}^N$. The problem is, however, nontrivial due to the general growth conditions assumed here on $L(x,\cdot)$, in particular to the fact that functions $\alpha(\cdot), \beta(x,\cdot)$ may have different growths for $|q| \to +\infty$.

The novelty of our approach relies on an unusual way of employing the DuBois–Raymond condition, which motivates the introduction of a distinct family of Lipschitz curves parameterized in a special way (cf. Definition 3.12). The core of our arguments consists of proving that, in the formula defining $v(t,x)$, it is not restrictive to consider only curves belonging to this family (see section 3). Once this is established, it is rather easy to obtain the a priori estimates on the Lipschitz constants of quasi-optimal curves for $v(t,x)$ that are needed to derive the desired regularity of the value function.

The analysis outlined above is carried out through suitable reparameterization techniques which use, in an essential way, the fact that L is autonomous and convex in q. The argument on which they are based was originally introduced in [22] and subsequently developed in [21] in the case of a continuous Lagrangian, but its use for the kind of problems studied herein seems new. A substantial effort is furthermore made to extend the techniques to the measurable setting and to gather the necessary information needed in the case at hand.

We end this discussion by mentioning that a possible alternative way to attack the problem would be to find a relaxed formulation of (2) in order to apply the results of [18]. The difficulty here is proving that the relaxation of the functional $\gamma \mapsto \int_0^t L(\gamma, \dot\gamma)\,\mathrm{d}s$ admits an integral representation on $W^{1,1}\big([0,t],\mathbb{R}^N\big)$. The results proved in [1] ensure that this approach actually works if the Lagrangian enjoys the following growth conditions in q:

$$|q|^p \le L(x,q) \le \Lambda\,(1+|q|^p) \qquad \text{for every } (x,q) \in \mathbb{R}^N \times \mathbb{R}^N$$

for some $p > 1$ and $\Lambda > 0$. If we were to extend such results to the more general cases considered here, we would encounter difficulties similar to the ones previously described. As a matter of fact, a technical adaptation of the arguments here employed allows us to generalize the results of [1] to a wider class of abstract and integral functionals of autonomous type that includes, in particular, the ones considered in this paper. This issue is specifically studied in [20].

1.2. Strategy of the proof. To study the problem, we find it convenient to introduce the function

$$S(y,x,t) := \inf\left\{\int_0^t L(\gamma,\dot\gamma)\,\mathrm{d}s \,:\, \gamma\in W^{1,1}\big([0,t],\mathbb{R}^N\big),\ \gamma(0)=y,\ \gamma(t)=x\right\} \tag{3}$$

defined for every $(y,x,t)\in\mathbb{R}^N\times\mathbb{R}^N\times(0,+\infty)$, and to express v in the following equivalent form:

$$v(t,x)=\inf_{y\in\mathbb{R}^N}\Big(u(y)+S(y,x,t)\Big)\qquad\text{for every } (t,x)\in(0,+\infty)\times\mathbb{R}^N,$$

where u is a function from $\mathbb{R}^N$ to $(-\infty,+\infty]$ which is either uniformly continuous or bounded from below. To get the required regularity of v, it is enough to prove that S is locally Lipschitz in $\mathbb{R}^N\times\mathbb{R}^N\times(0,+\infty)$. This would immediately follow from [18] if we were able to prove that minimizing curves for $S(y,x,t)$ exist for every $(y,x,t)\in\mathbb{R}^N\times\mathbb{R}^N\times(0,+\infty)$. Unfortunately, this need not be true in our case. In fact, the superlinearity of $L(x,\cdot)$ and the Dunford–Pettis theorem (see [7, Chapter 2]) actually imply that every minimizing sequence for $S(y,x,t)$ admits a subsequence uniformly converging to some limit curve, but the lack of continuity of L does not guarantee that the associated integral functional is lower semicontinuous for the convergence at hand (classical results by Olech [29] and Ioffe [25] ensure that this is true if the Lagrangian is lower semicontinuous in x and convex in q), so the standard *direct method of the calculus of variations* fails to apply (see [7]).

Yet, existence of minimizers is not necessary to derive the desired regularity for S. Indeed, a fairly standard argument (see, for instance, [18, Proof of Theorem 4.4]) shows that S is locally Lipschitz as soon as we provide some a priori estimates on the Lipschitz constants of quasi minimizers for $S(y,x,t)$, with some uniformity with respect to $(y,x,t)\in\mathbb{R}^N\times\mathbb{R}^N\times(0,+\infty)$.[1] When the existence of a minimizer γ is postulated, as in [18], or ensured by the assumptions made on L, as in [17, 19], these can be derived from the fact that γ satisfies the DuBois–Raymond necessary condition, namely, that there exists a constant $a\in\mathbb{R}$ such that

$$L(\gamma(s),\dot\gamma(s))=\langle\dot\gamma(s),p\rangle-a\qquad\text{for every } p\in\partial_q L(\gamma(s),\dot\gamma(s)) \tag{4}$$

for almost every $s\in[0,t]$. Using the superlinearity of $L(x,\cdot)$, it is then easy to show that a is locally bounded with respect to (y,x,t), and this provides the desired control on the Lipschitz constant of γ.

Even if this reasoning cannot be applied in our case, we nevertheless notice that condition (4), which is crucial for obtaining the desired estimates, only provides information on the parameterization of the curve: When γ is action-minimizing, its parameterization must obey an optimality condition.

The idea we develop here is to separate the issue of parameterization from that of minimizing the action. This is achieved by first considering a minimization problem

[1] An *ε-minimizer* for $S(y,x,t)$ is a curve $\gamma\in W^{1,1}\big([0,t],\mathbb{R}^N\big)$ with $\gamma(0)=y$, $\gamma(t)=x$ such that

$$\int_0^t L(\gamma(s),\dot\gamma(s))\,\mathrm{d}s < S(y,x,t)+\varepsilon.$$

We say that γ is a *quasi minimizer* or it is *quasi optimal* for $S(y,x,t)$ if it is an ε-minimizer with $\varepsilon>0$ suitably small.

with fixed support as follows: We fix a Lipschitz curve $\gamma : [0, \ell] \to \mathbb{R}^N$ parameterized by the arc-length, the *support*, and we try to solve the problem

$$\min \left\{ \int_0^t L(\xi, \dot{\xi})\, \mathrm{d}s \,:\, \xi \in [\gamma]_t \right\} \tag{5}$$

for every $t > 0$, where $[\gamma]_t$ denotes the family of absolutely continuous curves $\xi : [0, t] \to \mathbb{R}^N$ obtained through a reparameterization of γ.[2] Here, the crucial remark is the following: Any solution of (5) satisfies (4) for some $a \in \mathbb{R}$; conversely, any $\xi \in [\gamma]_t$ satisfying (4) for some $a \in \mathbb{R}$ is a solution to (5) (cf. the proof of Theorem 3.16).

However, the existence of minimizers of (5) is not clear. The idea exploited here is to introduce the notion of *a-Lagrangian parameterization* for a curve ξ (cf. Definition 3.12), which amounts to requiring that ξ satisfy (4). Then we consider the multifunction $T_\gamma(\cdot)$ defined on $\mathbb{R}$ by

$$T_\gamma(a) := \{t > 0 \,:\, [\gamma]^\flat(a, t) \text{ is nonempty}\} \qquad \text{for every } a \in \mathbb{R},$$

where $[\gamma]^\flat(a, t)$ denotes the subset of $[\gamma]_t$ consisting of a-Lagrangian bi-Lipschitz reparameterizations of γ, and we remark that, by what we previously observed, the relation $t \in T_\gamma(a)$ implies that problem (5) admits a solution in $[\gamma]^\flat(a, t)$. Our attention is then addressed to establishing the relevant properties of the multifunction $T_\gamma(\cdot)$, with particular interest in its range $\bigcup_{a\in\mathbb{R}} T_\gamma(a)$ (see Proposition 3.13). When this coincides with $(0, +\infty)$, we conclude that problem (5) is solvable for every $t > 0$. In particular, (5) has a minimizer belonging to $[\gamma]^\flat(a, t)$ for some $a \in \mathbb{R}$, and its Lipschitz constant can be estimated by some $\kappa_a \in \mathbb{R}$ only depending on a and on the kind of growth conditions assumed on L. However, our analysis reveals that the range of $T_\gamma(\cdot)$ may actually be a bounded interval of the form $(0, T)$. In this instance, a solution to (5) exists if $t \le T$. For $t > T$, the minimum in (5) is only an infimum, in general; nevertheless, we are able to prove that this value can be obtained by minimizing the action over the family of κ_{c_γ}-Lipschitzian reparameterizations of γ, where κ_{c_γ} is a positive constant that can be estimated in terms of the growth conditions assumed on L (see Theorem 3.16).

This information is used to obtain the needed priori estimates on the Lipschitz constants of quasi minimizers (see Lemma 3.2): Since any absolutely continuous curve from $[0, t]$ to $\mathbb{R}^N$ belongs to $[\gamma]_t$ for a suitable choice of the Lipschitz curve $\gamma : [0, \ell] \to \mathbb{R}^N$ (cf. Lemma 3.11), we can always assume that a quasi minimizer for $S(y, x, t)$ is κ_a-Lipschitz continuous for some $a \in \mathbb{R}$. By using the superlinearity of $L(x, \cdot)$, we see that the constant a is last estimated with some uniformity with respect to (y, x, t).

1.3. Plan of the article. Section 2 contains the main notation and assumptions, together with some well-known propositions that will be needed in the rest of the paper.

The properties of the function S are studied in section 3. In subsection 3.1 some preliminary results are collected. The definition of a-Lagrangian reparameterization and the reparameterization arguments are presented in subsection 3.2. Here, the main properties of the multifunction $T_\gamma(\cdot)$ are established and used to study an action-minimization problem with fixed support. The information gathered is then exploited to derive the required priori estimates on the Lipschitz constants of quasi minimizers

[2] That is, $\xi = \gamma \circ \varphi$ on $[0, t]$ for some absolutely continuous map $\varphi : [0, t] \to [0, \ell]$ surjective and nondecreasing (cf. Definition 3.9).

(cf. Lemma 3.2), which is all we need to prove Theorem 3.1. To simplify the exposition, the Lagrangian L is initially assumed locally bounded in q, uniformly with respect to x. The consequent extension to the case of Lagrangians locally bounded in (x, q) is easily derived in subsection 3.3 via a localization argument (see Theorem 3.19). Here a sequential compactness result for locally equibounded discontinuous Lagrangians, established in [20], is recalled for later use.

The main results of the paper are derived in section 4 as a simple application of the preceding analysis. Subsection 4.1 contains several Lipschitz-regularity results for the value function associated with a discontinuous Lagrangian, depending on the continuity properties assumed on the initial cost. An extension to the case when $\mathbb{R}^N$ is replaced by a compact and connected smooth Riemannian manifold $\mathcal{M}$ without boundary is also provided. Lastly, subsection 4.2 contains a compactness result for the value functions associated with sequences of locally equibounded discontinuous Lagrangians.

2. Notation and standing assumptions. We list below the symbols used throughout this paper:

N	an integer number
$B_r(x)$	the open ball in $\mathbb{R}^N$ of radius r centered at x
B_r	the open ball in $\mathbb{R}^N$ of radius r centered at 0
$\mathbb{S}^{N-1}$	the $(N-1)$-dimensional unitary sphere of $\mathbb{R}^N$
$\mathcal{H}^k$	the k-dimensional Hausdorff measure
$\langle \cdot, \cdot \rangle$	the scalar product in $\mathbb{R}^N$
$[u]$	the integer part of $u \in \mathbb{R}$
$\mathbb{R}_+$	the set of nonnegative real numbers
$\mathcal{P}(\mathbb{R}_+)$	the family of subsets of $\mathbb{R}_+$
$\mathrm{UC}(\mathbb{R}^N)$	the space of uniformly continuous real functions on $\mathbb{R}^N$
$\mathrm{Lip}(\mathbb{R}^N)$	the space of Lipschitz-continuous real functions on $\mathbb{R}^N$

Given a subset U of $\mathbb{R}^k$, we denote by $\overline{U}$ its closure. We furthermore say that U is *compactly contained* in a subset V of $\mathbb{R}^k$ if $\overline{U}$ is compact and contained in V. If E is a Lebesgue measurable subset of $\mathbb{R}^k$, we denote by $|E|$ its k-dimensional Lebesgue measure, and we say that E is *negligible* whenever $|E| = 0$. The characteristic function of E is denoted by χ_E. We say that a property holds *almost everywhere* (*a.e.*) on $\mathbb{R}^k$ if it holds up to a negligible subset of $\mathbb{R}^k$. The Euclidean norm of $u \in \mathbb{R}^k$ is denoted by $|u|$. Given a measurable vector-valued function $f : E \to \mathbb{R}^m$, we write $\|f\|_\infty$ to mean $(\sum_{i=1}^k \|f_i\|^2_{L^\infty(E)})^{1/2}$, where f_i and $\|f_i\|_{L^\infty(E)}$ denote the ith component of f and the L^∞-norm of f_i, respectively. Given $X \subseteq \mathbb{R}^k$, we will denote by $\mathcal{B}(X)$ the family of all Borel subsets of X. A multifunction Γ from X to compact subsets of $\mathbb{R}$ is said to be *Borel-measurable* (cf. [14]) if

$$\{x \in X : \Gamma(x) \cap U \neq \emptyset\} \in \mathcal{B} \qquad \text{for every open set } U \subseteq \mathbb{R}.$$

We say that Γ is *upper semicontinuous* at x if, for any $\varepsilon > 0$, there exists $\delta > 0$ such that

$$\Gamma(z) \subseteq \Gamma(x) + (-\varepsilon, \varepsilon) \qquad \text{for all } z \in B_\delta(x) \cap X.$$

When $k = 1$, we say that Γ is *nondecreasing on* X if

$$\sup \Gamma(x) \leq \inf \Gamma(y) \qquad \text{for every } x, y \in X \text{ with } x < y.$$

We say that Γ is *nonincreasing on* X if the multifunction $-\Gamma(\cdot)$ is nondecreasing on X. A function $g : \mathbb{R}^k \to (-\infty, +\infty]$ will be called *superlinear* if

$$\lim_{|x|\to+\infty} \frac{g(x)}{|x|} = +\infty.$$

For a convex function f from $\mathbb{R}^k$ to $\mathbb{R}$, we will denote by $\partial f(x)$ the *subdifferential* of f at x, defined as

$$\partial f(x) := \{p \in \mathbb{R}^k \,:\, f(y) \geq f(x) + \langle p, y - x\rangle \quad \text{for every } y \in \mathbb{R}^k\}.$$

The set $\partial f(x)$ is closed and convex, and the multifunction $x \mapsto \partial f(x)$ is upper semicontinuous on $\mathbb{R}^k$. We furthermore have the following (see [31]).

PROPOSITION 2.1. *Let $f : \mathbb{R}^k \to \mathbb{R}$ be convex. Then f is locally Lipschitz in $\mathbb{R}^k$. More precisely, for every $x_0 \in \mathbb{R}^k$ and $r, \delta > 0$, we have*

$$|f(x) - f(y)| \leq |x - y|\, \frac{2}{\delta} \sup_{B_{r+\delta}(x_0)} |f| \qquad \textit{for every } x, y \in B_r(x_0).$$

In particular, $\partial f(x) \subset (2 \sup_{B_{r+1}} |f|)\, \overline{B}_1$ for every $x \in B_r$.

Given a function $f : \mathbb{R}^k \to \mathbb{R}$, we define its conjugate $f^* : \mathbb{R}^k \to (-\infty, +\infty]$ as follows:

$$f^*(x) := \sup_{y\in\mathbb{R}^k} \{\langle x, y\rangle - f(y)\} \qquad \text{for every } x \in \mathbb{R}^k.$$

We record for later use the following well-known facts (cf. [31, Theorem 23.5]).

PROPOSITION 2.2. *Let $f : \mathbb{R}^k \to \mathbb{R}$ be superlinear and convex. Then f^* is locally bounded and convex on $\mathbb{R}^k$. Moreover,*

$$f(x) = f^{**}(x) := \sup_{y\in\mathbb{R}^k} \{\langle x, y\rangle - f^*(y)\} \qquad \textit{for every } x \in \mathbb{R}^k.$$

The following conditions on $x, x^* \in \mathbb{R}^k$ are equivalent to each other:

(i) $f(x) + f^*(x^*) \leq \langle x, x^*\rangle$;
(ii) $f(x) + f^*(x^*) = \langle x, x^*\rangle$;
(iii) $x^* \in \partial f(x)$;
(iv) $x \in \partial f^*(x^*)$.

By a modulus we mean a nondecreasing function from $\mathbb{R}_+$ to $\mathbb{R}_+$, vanishing and continuous at 0. We denote by $W^{1,1}\big([0,t], \mathbb{R}^N\big)$ the space of absolutely continuous curves from the interval $[0,t]$ to $\mathbb{R}^N$. We recall that a curve $\gamma : [a,b] \to \mathbb{R}^N$ is said to be *parameterized by the arc-length* if $|\dot\gamma(s)| = 1$ for almost every $s \in (a,b)$. Throughout the paper, α, β always denote two functions from $\mathbb{R}_+$ to $\mathbb{R}_+$ that are convex, nondecreasing, and superlinear.

We will denote by L a function from $\mathbb{R}^N \times \mathbb{R}^N$ to $\mathbb{R}$ so as to satisfy the following assumptions:

(L1) L is Borel-measurable on $\mathbb{R}^N \times \mathbb{R}^N$;
(L2) $\alpha(|q|) \leq L(x,q) \leq \beta(|q|)$ for all $(x,q) \in \mathbb{R}^N \times \mathbb{R}^N$;
(L3) $L(x,\cdot)$ is convex for every $x \in \mathbb{R}^N$.

By (L2), it is not restrictive to assume, up to adding a constant to it, that L is positive. This will be systematically done in what follows. We also point out that the second inequality in (L2) is equivalent to requiring that

$$\sup\{L(x,q) \,:\, (x,q) \in \mathbb{R}^N \times B_R\} < +\infty \qquad \text{for any } R > 0.$$

In fact, the following holds.

LEMMA 2.3. *Let U be an open subset of $\mathbb{R}^k$ and $L : U \times \mathbb{R}^k \to \mathbb{R}_+$ such that*

$$\sup\{L(x,q) \,:\, x \in U,\, |q| \le n\} < +\infty \qquad \textit{for every } n \in \mathbb{N}.$$

Then there exists a function $\beta : \mathbb{R}_+ \to \mathbb{R}_+$, convex and nondecreasing, such that

$$L(x,q) \le \beta(|q|) \qquad \textit{for every } (x,q) \in U \times \mathbb{R}^k.$$

Proof. Set

$$a_n := \sup\{L(x,q) \,:\, x \in U,\, |q| \le n\} \qquad \text{for each } n \in \mathbb{N},$$

and

$$f(h) := \sum_{n=1}^{\infty} a_n\, \chi_{[n-1,n)}(h) \qquad \text{for every } h \ge 0.$$

As $L(x,q) \le f(|q|)$ for every $(x,q) \in U \times \mathbb{R}^k$, it will be enough to prove the statement for f. For each $n \in \mathbb{N}$, choose $m_n := \max\{2a_n/(n-1),\, a_n - a_{n-1}\}$ and set

$$\beta(h) := \sup_{n\in\mathbb{N}}\{\, a_{n+1} + m_{n+1}(h-n)\} \qquad \text{for every } h \ge 0.$$

By definition, each map $h \mapsto a_{n+1} + m_{n+1}(h-n)$ is greater than or equal to f on $[n-1,n)$ and less than 0 on $[0,n/2)$, and hence

$$f(h) \le \beta(h) < +\infty \qquad \text{for every } h \ge 0.$$

The remainder of the assertion follows, as β is the supremum of a family of convex and increasing functions. ∎

To any L satisfying assumptions (L1)–(L3) we associate the function $S(y,x,t)$, defined in (3), for every $(y,x,t) \in \mathbb{R}^N \times \mathbb{R}^N \times (0,+\infty)$. It is easy to check that the function S enjoys the following inequalities:

$$t\,\alpha\left(\frac{|y-x|}{t}\right) \le S(y,x,t) \le t\,\beta\left(\frac{|y-x|}{t}\right) \qquad \text{on } \mathbb{R}^N \times \mathbb{R}^N \times (0,+\infty). \tag{6}$$

Later on in the paper, condition (L2) will be relaxed to cover the case of a Lagrangian L locally bounded with respect to (x,q), i.e., such that

$$\sup\{L(x,q) \,:\, (x,q) \in B_R \times B_R\} < +\infty \qquad \text{for any } R > 0.$$

By Lemma 2.3, this amounts to replacing condition (L2) with the following:

(L2)′ $\alpha(|q|) \le L(x,q) \le \beta_n(|q|)$ for all $(x,q) \in B_n \times \mathbb{R}^N$ and $n \in \mathbb{N}$, where $(\beta_n)_{n\in\mathbb{N}}$ is a family of convex, nondecreasing, and superlinear functions from $\mathbb{R}_+$ to $\mathbb{R}_+$.

3. The key results. The goal of our analysis is to prove the local Lipschitz continuity of the function S associated via (3) with a Lagrangian satisfying assumptions (L1), (L2), (L3). As previously noticed, condition (L2) amounts to requiring that the function $L(x,\cdot)$ be superlinear and locally bounded on $\mathbb{R}^N$, uniformly with respect to x. The precise statement of the result that we will establish is the following.

THEOREM 3.1. *Let $L : \mathbb{R}^N \times \mathbb{R}^N \to \mathbb{R}_+$ be an autonomous Lagrangian satisfying conditions* (L1)–(L3). *Then the associated function S defined in* (3) *is locally Lipschitz in $\mathbb{R}^N \times \mathbb{R}^N \times (0, +\infty)$. More precisely, for every $M > 0$ there exists $K = K(M, \alpha, \beta)$ such that*

$$S \quad \text{is } K\text{-Lipschitz continuous in } \overline{C_M},$$

where $C_M := \{(y, x, t) \in \mathbb{R}^N \times \mathbb{R}^N \times (0, +\infty) \,:\, |x - y| < M\, t\}$.

The consequent extension to the case of Lagrangians locally bounded with respect to (x, q) will be easily derived via a localization argument at the end of this section; see Theorem 3.19.

Theorem 3.1 can be proved via a rather standard argument as soon as we derive some a priori estimates on the Lipschitz constant of quasi-optimal curves parameterized in $[0, t]$ and connecting y to x for every $(y, x, t) \in C_M$. This information can be derived from the following lemma.

LEMMA 3.2. *Let $x, y \in \mathbb{R}^N$ and $t > 0$ such that $S(y, x, t) < M\, t$. Then there exists a constant $\kappa = \kappa(M, \alpha, \beta)$ such that*

$$S(y, x, t) = \inf \left\{ \int_0^t L(\xi, \dot\xi)\, \mathrm{d}s \,:\, \xi(0) = y,\ \xi(t) = x,\ \|\dot\xi\|_\infty \le \kappa \right\}.$$

The proof of Lemma 3.2 is quite delicate and relies on a careful analysis of the role played by reparameterizations. It will be carried out in the next two subsections. Before that, let us show how Lemma 3.2 can be used to prove Theorem 3.1.

Proof of Theorem 3.1. For a fixed $M > 0$, choose (y_1, t_1, x_1) and (y_2, t_2, x_2) in C_M, and set

$$h := |t_1 - t_2| + |x_1 - x_2| + |y_1 - y_2|, \qquad s_0 := \frac{t_1 - t_2}{2} + h.$$

Since C_M is convex, it suffices to prove the statement locally, namely for small values of h. Choose $h < t_2/2$ so that $s_0 < t_1/2$. Fix $\varepsilon > 0$ and let $\gamma_1 \in W^{1,1}\big([0, t_1], \mathbb{R}^N\big)$ be an ε-minimizer connecting y_1 to x_1. As $S(y_1, x_1, t_1) < t_1\, \beta(M)$, by Lemma 3.2 we can assume $\|\dot\gamma\|_\infty \le \kappa$ for some constant $\kappa = \kappa(M, \alpha, \beta)$. Choose $u_1, v_1 \in \mathbb{R}^N$ so that

$$\gamma_1(s_0) = y_2 + h u_1, \qquad \gamma_1(t_1 - s_0) = x_2 + h v_1,$$

and note that $|u_1|, |v_1| < 1 + 2\kappa$. Define a curve $\gamma_2 : [0, t_2] \to \mathbb{R}^N$ connecting y_2 to x_2 by setting

$$\gamma_2(s) := \begin{cases} y_2 + s u_1 & \text{if } s \in [0, h], \\ \gamma_1(s_0 + s - h) & \text{if } s \in [h, t_2 - h], \\ x_2 + (t_2 - s) v_1 & \text{if } s \in [t_2 - h, t_2]. \end{cases}$$

Recalling that L is positive, we get

$$\begin{aligned} S(y_2, x_2, t_2) - S(y_1, x_1, t_1) &\le \int_0^{t_2} L(\gamma_2, \dot\gamma_2)\, \mathrm{d}s - \int_0^{t_1} L(\gamma_1, \dot\gamma_1)\, \mathrm{d}s \ + \varepsilon \\ &\le \int_0^{h} L(\gamma_2, u_1)\, \mathrm{d}s + \int_{t_2 - h}^{t_2} L(\gamma_2, u_2)\, \mathrm{d}s \ + \varepsilon \le 2\, \beta(1 + 2\kappa)\, h \ + \varepsilon, \end{aligned}$$

so, setting $\widetilde K := 2\, \beta(1 + 2\kappa)$, we obtain

$$S(y_2, x_2, t_2) - S(y_1, x_1, t_1) \le \widetilde K\, (|t_1 - t_2| + |x_1 - x_2| + |y_1 - y_2|) + \varepsilon.$$

As ε is arbitrary, the conclusion follows at once by interchanging the roles of (y_1, t_1, x_1) and (y_2, t_2, x_2) and by setting $K := \sqrt{2N + 1}\, \widetilde K$. ∎
