3.1. Preliminary tools. Let $H : \mathbb{R}^N \times \mathbb{R}^N \to \mathbb{R}$ be the Hamiltonian associated with L through the Fenchel transform, namely,

$$H(x,p) := \max_{q\in\mathbb{R}^N} \{\langle p,q\rangle - L(x,q)\}.$$

The function H is Borel-measurable, and $H(x,\cdot)$ is convex and superlinear for every $x \in \mathbb{R}^N$. For every $a \in \mathbb{R}$, set

$$\sigma_a(x,q) := \max\{\langle q,p\rangle \,:\, H(x,p) \le a\} \qquad \text{for every } q \in \mathbb{R}^N,\ a \in \mathbb{R},$$

where we agree that $\sigma_a(x,q) = -\infty$ whenever $a < -L(x,0) = \min_{\mathbb{R}^N} H(x,\cdot)$.

PROPOSITION 3.3. *For any $a \in \mathbb{R}$, the following properties hold:*

(i) *$\sigma_a(x,\lambda q) = \lambda\,\sigma_a(x,q)$ for every $(x,q) \in \mathbb{R}^N \times \mathbb{R}^N$ and $\lambda > 0$;*

(ii) *$L(x,q) \ge \sigma_a(x,q) - a$ for every $(x,q) \in \mathbb{R}^N \times \mathbb{R}^N$.*

Proof. Assertion (i) is clear by definition. To prove (ii), we recall that L is the Fenchel transform of H (cf. Proposition 2.2), and hence

$$L(x,q) = \max_{p\in\mathbb{R}^N} \{\langle p,q\rangle - H(x,p)\} \ge \max_{H(x,p)\le a} \{\langle p,q\rangle - H(x,p)\} \ge \sigma_a(x,q) - a, \tag{7}$$

as claimed. □

For any $(x,q) \in \mathbb{R}^N \times \mathbb{R}^N$ and $a \in \mathbb{R}$, we set

$$\Lambda_a(x,q) := \{\,\lambda \in [0,+\infty) \,:\, L(x,\lambda q) = \sigma_a(x,\lambda q) - a\} \tag{8}$$

and

$$\underline{\lambda}_a(x,q) := \inf \Lambda_a(x,q), \qquad \overline{\lambda}_a(x,q) := \sup \Lambda_a(x,q).$$

We agree that $\underline{\lambda}_a(x,q) = \overline{\lambda}_a(x,q) = 0$ whenever $\Lambda_a(x,q) = \emptyset$, that is, when $a < -L(x,0)$.

We define the following functions:

$$\alpha_*(u) := \max_{\lambda\in\mathbb{R}} \{u\lambda - \alpha(|\lambda|)\}, \quad \beta_*(u) := \max_{\lambda\in\mathbb{R}} \{u\lambda - \beta(|\lambda|)\} \qquad \text{for every } u \in \mathbb{R},$$

and we remark that they are convex and superlinear as $\alpha(|\cdot|)$ and $\beta(|\cdot|)$ are also. For every $a \in \mathbb{R}$, set

$$R_a := \max\{|u| \,:\, \beta_*(u) \le a\} \tag{9}$$

and

$$\kappa_a := 2\max\{\alpha_*(u) \,:\, |u| \le R_a + 1\}. \tag{10}$$

The following compactness result holds.

LEMMA 3.4. $\Lambda_a(x,q) \subseteq [0,\kappa_a]$ *for every* $(x,q) \in \mathbb{R}^N \times \mathbb{S}^{N-1}$.

Proof. From the definition of α_* and β_*, we obtain

$$\beta_*(|p|) \le H(x,p) \le \alpha_*(|p|) \qquad \text{for all } (x,p) \in \mathbb{R}^N \times \mathbb{R}^N; \tag{11}$$

in particular,

$$\{p \in \mathbb{R}^N \,:\, H(x,p) \le a\} \subseteq \overline{B}_{R_a} \qquad \text{for every } x \in \mathbb{R}^N. \tag{12}$$

Pick up $(x,q)\in\mathbb{R}^N\times\mathbb{S}^{N-1}$. From (7) and Proposition 2.2 we derive that $\lambda\in\Lambda_a(x,q)$ if and only if $\lambda\,q\in\partial_p H(x,p)$ for some $H(x,p)\le a$. In particular,

$$\Lambda_a(x,q)\subseteq\left\{|v|\,:\,v\in\partial_p H(x,p)\quad\text{for some } p\in\overline{B}_{R_a}\right\},$$

and the conclusion follows at once in view of (11) and Proposition 2.1. □

We now fix $(x,q)\in\mathbb{R}^N\times\mathbb{S}^{N-1}$ and examine the properties of the multifunction $a\mapsto\Lambda_a(x,q)$. Proposition 2.2 yields that

$$L(x,\lambda\,q)=\langle p,\lambda\,q\rangle-H(x,p)\qquad\text{for any } p\in\partial_q L(x,\lambda\,q) \tag{13}$$

for any given $\lambda\in\mathbb{R}$. In view of Proposition 3.3(ii), we infer that $\lambda\in\Lambda_a(x,q)$ if and only if $a\in H(x,\partial_q L(x,\lambda\,q))$.

We start by considering the set-valued map $A(\lambda):=H(x,\partial_q L(x,\lambda\,q))$ on $[0,+\infty)$, which is the inverse of $a\mapsto\Lambda_a(x,q)$, in the sense of set-valued analysis (see [32, Chapter 5]). Indeed, note that

$$\Lambda_a(x,q)=\{\,\lambda\in[0,+\infty)\,:\,a\in H(x,\partial_q L(x,\lambda\,q))\}. \tag{14}$$

PROPOSITION 3.5. *Let $A(\cdot)$ as above. The following facts hold:*

(i) *For any $\lambda\in\mathbb{R}$,*

$$A(\lambda)=[\underline{a}(\lambda),\overline{a}(\lambda)]\quad\textit{for some } -L(x,0)\le\underline{a}(\lambda)\le\overline{a}(\lambda)<+\infty.$$

Moreover,

$$A(0)=\{\,-L(x,0)\},\qquad\lim_{\lambda\to+\infty}\underline{a}(\lambda)=+\infty.$$

(ii) *The set-valued map $A(\cdot)$ is upper semicontinuous on $[0,+\infty)$. In particular, $\underline{a}(\cdot)$ is lower semicontinuous and $\overline{a}(\cdot)$ is upper semicontinuous on $[0,+\infty)$.*

(iii) *The set-valued map $\lambda\mapsto A(\lambda)$ is nondecreasing on $[0,+\infty)$.*

(iv) $\bigcup_{\lambda\ge0}A(\lambda)=[-L(x,0),+\infty)$.

Proof. The function $f(\lambda):=L(x,\lambda\,q)$ is convex and superlinear, and hence so is its conjugate f^*. We claim that $A(\lambda)=f^*(\partial f(\lambda))$ for every $\lambda\ge0$. Indeed, by Proposition 2.2 we know that

$$f^*(\partial f(\lambda))=\lambda\,\partial f(\lambda)-f(\lambda)\qquad\text{for any } \lambda\ge0.$$

By classical results of nonsmooth analysis (cf. [16, Theorem 2.3.10]), we also know that $\partial f(\lambda)=\langle\partial_q L(x,\lambda\,q),q\rangle$, and hence the above equality becomes

$$f^*(\partial f(\lambda))=\langle\partial_q L(x,\lambda\,q),\lambda\,q\rangle-L(x,\lambda\,q)\qquad\text{for any } \lambda\ge0,$$

and the right-hand side term coincides with $A(\lambda)$ by (13), as claimed.

Let us now prove the above stated properties of $A(\cdot)$. As f is convex, its subdifferential $\partial f(\lambda)$ is a compact interval of $\mathbb{R}$, so the same is true for $A(\lambda)$. The equality $A(0)=\{-L(x,0)\}$ is an immediate consequence of (13), while the other assertion follows by the superlinearity of f^* and f. That proves (i). The upper semicontinuity of $A(\cdot)$ comes from the fact that the multifunction $\lambda\mapsto\partial f(\lambda)$ is upper semicontinuous and f^* is continuous. The remainder of (ii) follows by definition of $\underline{a}(\cdot)$, $\overline{a}(\cdot)$.

Let us prove (iii). Since f^* and f are convex, the multimappings $u\mapsto\partial f^*(u)$ and $\lambda\mapsto\partial f(\lambda)$ are nondecreasing on $\mathbb{R}$. By superlinearity, we get, in particular,

$$\bigcup_{\lambda\ge0}\partial f(\lambda)=[\underline{u}(0),+\infty)\qquad\text{with } \underline{u}(0)\in\partial f(0).$$

By duality (cf. Proposition 2.2), $0 \in \partial f^*(\underline{u}(0))$, so the monotonicity of $\partial f^*(\cdot)$ yields that f^* is nondecreasing on $[\underline{u}(0), +\infty)$. Item (iv) comes from (ii) and (iii). ∎

Example 3.6. Take a Lagrangian of the form $L(x,q) = F(q) + n(x)$ for every $(x,q) \in \mathbb{R}^N \times \mathbb{R}^N$, with $F(\cdot)$ convex and superlinear, and $n(\cdot)$ Borel-measurable and bounded. We have

$$A(\lambda) = F^*\left(\partial F(\lambda\, q)\right) - n(x) \qquad \text{for every } \lambda \geq 0$$

for any fixed $(x,q) \in \mathbb{R}^N \times \mathbb{S}^{N-1}$. When, for instance, $F(q) = |q|^2/2$, it reduces to

$$A(\lambda) = |\lambda\, q|^2/2 - n(x).$$

We use this information to prove a result that will be crucial in our future analysis.

PROPOSITION 3.7. *Let $(x,q) \in \mathbb{R}^N \times \mathbb{S}^{N-1}$. The following facts hold:*

(i) *For any $a \geq -L(x,0)$, we have*

$$\Lambda_a(x,q) = [\underline{\lambda}_a(x,q), \overline{\lambda}_a(x,q)] \qquad \textit{for some} \quad 0 \leq \underline{\lambda}_a(x,q) \leq \overline{\lambda}_a(x,q) < +\infty.$$

Moreover,

$$\underline{\lambda}_{-L(x,0)}(x,q) = 0, \qquad \lim_{a \to +\infty} \underline{\lambda}_a(x,q) = +\infty.$$

(ii) *The set-valued map $a \mapsto \Lambda_a(x,q)$ is upper semicontinuous and nondecreasing on $[-L(x,0), +\infty)$.*

(iii) *$\underline{\lambda}_a(x,q) = \sup_{b<a} \overline{\lambda}_b(x,q)$ for any $a > -L(x,0)$ and $\overline{\lambda}_a(x,q) = \inf_{b>a} \underline{\lambda}_b(x,q)$ for any $a \geq -L(x,0)$.*

(iv) *$\underline{\lambda}_a(x,q) \geq \frac{a+L(x,0)}{2R_a}$ for any $a > -L(x,0)$, with R_a defined by (9).*

Proof. We recall that $\Lambda_a(x,q) = \{\lambda \geq 0 : a \in A(\lambda)\}$. The monotonicity and coercivity properties of the set-valued map $a \mapsto \Lambda_a(x,q)$ are consequences of Proposition 3.5, while the equality $\underline{\lambda}_{-L(x,0)}(x,q) = 0$ is apparent by definition of (8). In particular, $\Lambda_a(x,q)$ is a bounded interval for any $a \geq -L(x,0)$.

To prove the upper semicontinuity of $a \mapsto \Lambda_a(x,q)$, we need to show that, for each pair of sequences $(a_n)_n$ and $(\lambda_n)_n$ such that $a_n \to a \in \mathbb{R}$, $\lambda_n \to \lambda \in \mathbb{R}$, and $\lambda_n \in \Lambda_{a_n}(x,q)$ for every $n \in \mathbb{N}$, we have $\lambda \in \Lambda_a(x,q)$. This easily follows by the upper semicontinuity of $A(\cdot)$ (in fact, it is equivalent; cf. [32, Theorem 5.7]). In particular, this implies that $\Lambda_a(x,q)$ is closed for any $a \geq -L(x,0)$.

Assertion (iii) immediately follows from the monotone and semicontinuous character of the map $a \mapsto \Lambda_a(x,q)$.

Let us prove (iv). Choose $a > -L(x,0)$ and set $\lambda := \underline{\lambda}_a(x,q)$. By Proposition 3.3(ii) we get

$$\sigma_a(x, \lambda q) = L(x, \lambda q) + a \geq \sigma_{-L(x,0)}(x, \lambda q) + a + L(x,0),$$

and hence by (12),

$$a + L(x,0) \leq \lambda \left(\sigma_a(x,q) - \sigma_{-L(x,0)}(x,q)\right) \leq \lambda \left(R_a + R_{-L(x,0)}\right) |q|,$$

and the statement follows as $R_{-L(x,0)} < R_a$ by definition. ∎

Example 3.8. Let $L(x,q) := |q|^2/2 + n(x)$ for every $(x,q) \in \mathbb{R}^N \times \mathbb{R}^N$, with $n(\cdot)$ Borel-measurable and bounded. For any fixed $(x,q) \in \mathbb{R}^N \times \mathbb{S}^{N-1}$, we have

$$\Lambda_a(x,q) = \left\{ \frac{1}{|q|} \sqrt{2\left(a + n(x)\right)} \right\} \qquad \text{for every } a \geq -n(x).$$

3.2. Optimal reparameterizations. Let us now consider a Lipschitz curve γ defined on a bounded interval $J := [0, \ell]$.

DEFINITION 3.9. *A curve ξ defined on a bounded interval $[0,t]$ is said to be a* reparameterization *of γ if there exists an absolutely continuous map $\varphi : [0,t] \to [0,\ell]$, surjective and nondecreasing, such that*

$$\xi = \gamma \circ \varphi \qquad \text{on } [0,t].$$

We furthermore say that ξ is a (bi)-Lipschitz reparameterization *of γ if φ is a (bi)-Lipschitz homeomorphism.*

Remark 3.10. For reasons that will be clear soon, we want to allow a reparameterization to remain stopped at a point for a specific amount of time. This accounts for the choice of the unusual definition given above.

We introduce the following notation:

$$\begin{aligned}[\gamma]_t &:= \{\xi \in W^{1,1}\big([0,t],\mathbb{R}^N\big) \,:\, \xi \text{ is a reparameterization of } \gamma\}\\ [\gamma]_t^\flat &:= \{\xi \in W^{1,1}\big([0,t],\mathbb{R}^N\big) \,:\, \xi \text{ is a bi-Lipschitz reparameterization of } \gamma\}.\end{aligned}$$

The following lemma comes from classical results of analysis in metric spaces (see, e.g., [24, section VII.2]). We give a proof for the reader's convenience.

LEMMA 3.11. *Let $\xi \in W^{1,1}\big([0,t],\mathbb{R}^N\big)$. Then there exists a Lipschitz curve γ, defined on a bounded interval $[0,\ell]$, such that $\xi \in [\gamma]_t$. We can furthermore assume that γ is parameterized by the arc-length.*

Proof. Let $\varphi(s) := \int_0^s |\dot\xi(\varsigma)|\,\mathrm{d}\varsigma$ for every $s \in [0,t]$, and set $\ell := \varphi(t)$. Clearly, the map $\varphi : [0,t] \to [0,\ell]$ is absolutely continuous, surjective, and nondecreasing. We claim that the statement holds true with $\gamma(s) := \xi(\varphi^{-1}(s))$ for every $s \in [0,\ell]$.

Indeed, it is easy to see that γ is well defined. Now choose a pair of points a, b in $[0,\ell]$ with $a < b$. By the monotone character of φ, we have $\varphi^{-1}(a) = [A_-, A_+]$, $\varphi^{-1}(b) = [B_-, B_+]$ for some $A_- \le A_+ < B_- \le B_+$. Moreover,

$$|\gamma(b) - \gamma(a)| \le \mathcal{H}^1\big(\gamma([a,b])\big) = \mathcal{H}^1\big(\xi([A_-,B_+])\big) = \int_{A_-}^{B_+} |\dot\xi(\varsigma)|\,\mathrm{d}\varsigma = b - a,$$

which yields that γ is 1-Lipschitz continuous. From the fact that $\int_0^\ell |\dot\gamma(\varsigma)|\,\mathrm{d}\varsigma = \mathcal{H}^1\big(\gamma([0,\ell])\big) = \ell$, we finally get that γ is parameterized by the arc-length. ∎

A further step in the analysis is carried out by picking up some special reparameterizations of the curve γ.

DEFINITION 3.12. *Let ξ be a curve defined on a bounded interval $[0,t]$ and $a \in \mathbb{R}$. We say that ξ has an a-*Lagrangian parameterization *if*

$$L(\xi(s),\dot\xi(s)) = \sigma_a(\xi(s),\dot\xi(s)) - a \qquad \text{for a.e. } s \in [0,t].$$

For any $a \in \mathbb{R}$ and $t > 0$, we define

$$\begin{aligned}[\gamma](a,t) &:= \{\xi \in [\gamma]_t \,:\, \xi \text{ has an } a\text{-Lagrangian parameterization}\},\\ [\gamma]^\flat(a,t) &:= \{\xi \in [\gamma]_t^\flat \,:\, \xi \text{ has an } a\text{-Lagrangian parameterization}\}.\end{aligned}$$

Now assume γ is parameterized by the arc-length, and let

$$c_\gamma := \operatorname{ess\,sup}_{s\in J} \; -L\left(\gamma(s),0\right).$$

We define a multifunction $T_\gamma : (c_\gamma, +\infty) \to \mathcal{P}(\mathbb{R}_+)$ by setting

$$T_\gamma(a) := \{t > 0 \,:\, [\gamma]^\flat(a,t) \text{ is nonempty}\}.$$

The properties of the multifunction $T_\gamma(\cdot)$ are stated below.

PROPOSITION 3.13. *Let γ and $T(\cdot) := T_\gamma(\cdot)$ as above. The following facts hold:*

(i) *For any $a > c_\gamma$, $T(a)$ is a compact interval in $(0, +\infty)$, namely,*

$$T(a) := [\underline{T}\,(a), \overline{T}\,(a)] \qquad \text{for some} \quad \overline{T}\,(a) \geq \underline{T}\,(a) > 0.$$

(ii) *The multifunction $\underline{T}(\cdot)$ is nondecreasing and upper semicontinuous on $(c_\gamma, +\infty)$. Moreover, $\inf_{a>c_\gamma} \overline{T}\,(a) = 0$.*

(iii) *Let $\underline{T}(c_\gamma) := \sup_{a>c_\gamma} \overline{T}(a)$. If $\underline{T}(c_\gamma)$ is finite, then $[\gamma](c_\gamma, \underline{T}(c_\gamma)) \neq \emptyset$.*

In particular, for any $0 < t \leq \underline{T}(c_\gamma)$ with $t < +\infty$, there exists $a \geq c_\gamma$ such that γ admits an a-Lagrangian Lipschitz reparameterization on $[0,t]$.

We first prove an auxiliary lemma.

LEMMA 3.14. *Let $\gamma : [0,\ell] \to \mathbb{R}^N$ be a Lipschitz curve parameterized by the arc-length and $a \in \mathbb{R}$. The following facts hold:*

(i) *For every $t > 0$ and $\xi \in [\gamma]_t$, the map $\sigma_a(\xi(\cdot), \dot\xi(\cdot))$ is Lebesgue-measurable on $[0,t]$, and*

$$\int_0^t \sigma_a(\xi(s), \dot\xi(s))\,\mathrm{d}s = \int_0^\ell \sigma_a(\gamma(s), \dot\gamma(s))\,\mathrm{d}s. \tag{15}$$

(ii) *The maps $\underline{\lambda}_a(\gamma(\cdot), \dot\gamma(\cdot))$, $\overline{\lambda}_a(\gamma(\cdot), \dot\gamma(\cdot))$ are Lebesgue-measurable on $[0,\ell]$.*

Proof. Take $t > 0$ and $\xi \in [\gamma]_t$. Since the map $s \mapsto (\xi(s), \dot\xi(s))$ is Lebesgue-measurable, in order to prove (i) it is enough to show that the function σ_a is Borel-measurable on $\mathbb{R}^N \times \mathbb{R}^N$. To this aim, let $(p_n)_n$ and $(\lambda_n)_n$ be dense sequences in $\mathbb{R}^N$ and $(0, +\infty)$, respectively. The Borel-measurable character of σ_a follows at once as we have

$$\sigma_a(x,q) = \inf_k \left(\sup_n \left\{ \langle p_n, q\rangle\, \vartheta_{E_n^k}(x) \right\} \right) \qquad \text{for every } (x,q) \in \mathbb{R}^N \times \mathbb{R}^N,$$

where $E_n^k := \{x \in \mathbb{R}^N \,:\, H(x,p_n) \leq a + 1/k\}$ and $\vartheta_{E_n^k}(\cdot)$ denotes the function identically 1 on E_n^k and $-\infty$ elsewhere. Equality (15) is a consequence of the fact that $\sigma_a(x,\cdot)$ is positively 1-homogeneous.

Let us prove (ii). Since the map $s \mapsto (\gamma(s), \dot\gamma(s))$ takes values in $\mathbb{R}^N \times \mathbb{S}^{N-1}$ for a.e. $s \in [0,\ell]$, it suffices to show that the functions $\underline{\lambda}_a$, $\overline{\lambda}_a$ are Borel-measurable on $\mathbb{R}^N \times \mathbb{S}^{N-1}$. Let us show the statement for $\underline{\lambda}_a$. For each $n \in \mathbb{N}$, set

$$F_n := \{(x,q) \in \mathbb{R}^N \times \mathbb{S}^{N-1} \,:\, H(x, \partial_q L(x, \lambda_n\, q)) \cap (-\infty, a) \neq \emptyset\},$$

which is Borel-measurable for the multifunction $(x,q) \mapsto H(x, \partial_q L(x, \lambda_n\, q))$ that is also. The assertion follows for we have $\underline{\lambda}_a(x,q) = \sup_n \lambda_n\, \chi_{F_n}(x,q)$ on $\mathbb{R}^N \times \mathbb{S}^{N-1}$, in view of (14) and Proposition 3.7. The analogous statement for $\overline{\lambda}_a$ can be proved in a similar way. ∎

Proof of Proposition 3.13. (i) Fix $a > c_\gamma$ and set

$$\underline{\lambda}_a(\varsigma) := \underline{\lambda}_a(\gamma(\varsigma), \dot\gamma(\varsigma)), \quad \overline{\lambda}_a(\varsigma) := \overline{\lambda}_a(\gamma(\varsigma), \dot\gamma(\varsigma)) \qquad \text{for a.e. } \varsigma \in [0,\ell].$$

Let

$$\underline{T}(a) := \int_0^\ell \frac{1}{\overline{\lambda}_a(\varsigma)}\,\mathrm{d}\varsigma, \quad \overline{T}(a) := \int_0^\ell \frac{1}{\underline{\lambda}_a(\varsigma)}\,\mathrm{d}\varsigma.$$

Such quantities are well-defined, positive real values, thanks to Proposition 3.7(iv) and to the measurable character of $\underline{\lambda}_a(\cdot)$, $\overline{\lambda}_a(\cdot)$. To show that they belong to $T(a)$, we will prove the existence of two curves $\underline{\gamma}_a$, $\overline{\gamma}_a$, defined on $\big[0,\underline{T}(a)\big]$ and $\big[0,\overline{T}(a)\big]$, respectively, which are a-Lagrangian bi-Lipschitz reparameterizations of γ. To this aim, let us define

$$\underline{f}_a(s) := \int_0^s \frac{1}{\overline{\lambda}_a(\varsigma)}\,\mathrm{d}\varsigma, \quad \overline{f}_a(s) := \int_0^s \frac{1}{\underline{\lambda}_a(\varsigma)}\,\mathrm{d}\varsigma \qquad \text{for any } s \in [0,\ell]$$

and set

$$\underline{\varphi}_a := (\underline{f}_a)^{-1}, \qquad \overline{\varphi}_a := \big(\overline{f}_a\big)^{-1},$$

defined on $\big[0,\underline{T}(a)\big]$ and $\big[0,\overline{T}(a)\big]$, respectively. As

$$\dot{\underline{\varphi}}_a(\tau) = \overline{\lambda}_a(\underline{\varphi}_a(\tau)), \qquad \dot{\overline{\varphi}}_a(\tau) = \underline{\lambda}_a(\overline{\varphi}_a(\tau)) \qquad \text{for a.e. } \tau,$$

we immediately derive that $\underline{\varphi}_a$ and $\overline{\varphi}_a$ are order-preserving bi-Lipschitz diffeomorphisms. Let us set

$$\underline{\gamma}_a := \gamma \circ \underline{\varphi}_a \quad \text{on } \big[0,\underline{T}(a)\big], \qquad \overline{\gamma}_a := \gamma \circ \overline{\varphi}_a \quad \text{on } \big[0,\overline{T}(a)\big].$$

Since

$$\dot{\underline{\gamma}}_a(\cdot) := \overline{\lambda}_a(\underline{\varphi}_a(\cdot))\,\dot{\gamma}(\underline{\varphi}_a(\cdot)) \qquad \text{a.e. on } \big[0,\underline{T}(a)\big]$$

and

$$\dot{\overline{\gamma}}_a(\cdot) := \underline{\lambda}_a(\overline{\varphi}_a(\cdot))\,\dot{\gamma}(\overline{\varphi}_a(\cdot)) \qquad \text{a.e. on } \big[0,\overline{T}(a)\big],$$

we conclude that the curves $\underline{\gamma}_a$ and $\overline{\gamma}_a$ have an a-Lagrangian parameterization by the very definition of $\overline{\lambda}_a$ and $\underline{\lambda}_a$.

In order to prove that $[\underline{T}(a),\overline{T}(a)] \subseteq T(a)$, we will show that

$$\delta\,\underline{T}(a) + (1-\delta)\,\overline{T}(a) \in T(a) \qquad \text{for any } \delta \in (0,1). \tag{16}$$

Fix $\delta \in (0,1)$ and set

$$\delta(\varsigma) := \frac{\delta\,\overline{\lambda}_a(\varsigma)}{\delta\,\overline{\lambda}_a(\varsigma) + (1-\delta)\,\underline{\lambda}_a(\varsigma)}, \qquad \lambda(\varsigma) := \delta(\varsigma)\,\underline{\lambda}_a(\varsigma) + (1-\delta(\varsigma))\,\overline{\lambda}_a(\varsigma)$$

for almost every $\varsigma \in [0,\ell]$, and

$$f(s) := \int_0^s \frac{1}{\lambda(\varsigma)}\,\mathrm{d}\varsigma \quad \text{for } s \in [0,\ell], \qquad \varphi := f^{-1} \quad \text{on } [0,f(\ell)].$$

Since $\delta(\varsigma) \in [0,1]$ for almost every $\varsigma \in [0,\ell]$, we get that $\lambda_a(\varsigma) \in \Lambda_a(\gamma(\varsigma),\dot{\gamma}(\varsigma))$ for almost every $\varsigma \in [0,\ell]$; in particular, φ is an order-preserving bi-Lipschitz diffeomorphism. Arguing as above, we see that the curve $\gamma_a := \gamma \circ \varphi$ is an a-Lagrangian

bi-Lipschitz reparameterization of γ on $\big[0, f(\ell)\big]$, so $f(\ell) \in T(a)$. Now it is easy to check, by definition of $\delta(\cdot)$, that $f(\ell) = \delta\,\overline{T}\,(a) + (1-\delta)\,\underline{T}\,(a)$. That proves (16) as δ was arbitrarily chosen in $(0,1)$.

Let us now prove that $T(a) \subseteq [\underline{T}\,(a), \overline{T}\,(a)]$. Let $T \in T(a)$ and $\widetilde{\gamma} := \gamma \circ \varphi$ be an a-Lagrangian reparameterization of γ for some order-preserving bi-Lipschitz diffeomorphism $\varphi : [0,T] \to [0,\ell]$. Then

$$\dot{\varphi}(\tau) \in \Lambda_a\left(\gamma(\varphi(\tau)), \dot{\gamma}(\varphi(\tau))\right) \qquad \text{for a.e. } \tau \in [0,T].$$

Let $f := \varphi^{-1}$. We have

$$T = f(\ell) = \int_0^\ell \dot{f}(\varsigma)\,\mathrm{d}\varsigma = \int_0^\ell \frac{1}{\dot{\varphi}(f(\varsigma))}\,\mathrm{d}\varsigma,$$

and since $\dot{\varphi}(f(\varsigma)) \in \Lambda_a(\gamma(\varsigma), \dot{\gamma}(\varsigma)) = [\underline{\lambda}_a(\varsigma), \overline{\lambda}_a(\varsigma)]$ for a.e. $\varsigma \in [0,\ell]$, we clearly get $T \in [\underline{T}\,(a), \overline{T}\,(a)]$.

(ii) Let $b > a > c_\gamma$. Then $\underline{\lambda}_b(\varsigma) \geq \overline{\lambda}_a(\varsigma)$ for almost every $\varsigma \in [0,\ell]$, and hence $\overline{T}(b) \leq \underline{T}(a)$. This proves that $T(\cdot)$ is a nonincreasing multifunction. To prove that $T(\cdot)$ is upper semicontinuous on $(c_\gamma, +\infty)$, it will be enough to show that

$$\underline{T}(a) = \sup_{b>a} \overline{T}(b), \qquad \overline{T}(a) = \inf_{b<a} \underline{T}(b) \qquad \text{for any } a > c_\gamma.$$

This actually follows as a simple application of the monotone convergence theorem and by the monotonicity properties of $\underline{\lambda}_a$, $\overline{\lambda}_a$ (cf. Proposition 3.7(iii)). The last assertion holds by definition of $\underline{T}(a)$ since $\sup_{a>c_\gamma} \overline{\lambda}_a(\varsigma) = +\infty$ for almost every $\varsigma \in [0,\ell]$.

(iii) Let $\underline{T}(c_\gamma)$ be finite. Arguing as in (i), we may find a nonincreasing sequence of Borel-measurable maps $\lambda_n : [0,\ell] \to [0,+\infty)$ such that, for each $n \in \mathbb{N}$,

$$T_n = \int_0^\ell \frac{1}{\lambda_n(\varsigma)}\,\mathrm{d}\varsigma \qquad \text{and} \qquad \lambda_n(\varsigma) \in \Lambda_{c_\gamma+1/n}(\gamma(\varsigma), \dot{\gamma}(\varsigma)) \qquad \text{for a.e. } \varsigma \in [0,\ell],$$

with $\sup_n T_n = \underline{T}(c_\gamma)$. Set

$$\lambda(\varsigma) = \inf_n \lambda_n(\varsigma) \qquad \text{for every } \varsigma \in [0,\ell].$$

Then $\lambda(\cdot)$ is measurable and $\lambda(\varsigma) \in \Lambda_{c_\gamma}(\gamma(\varsigma), \dot{\gamma}(\varsigma))$ for almost every $\varsigma \in [0,\ell]$. Moreover, the monotone convergence theorem yields

$$\underline{T}(c_\gamma) = \sup_{n\in\mathbb{N}}\ T_n = \sup_{n\in\mathbb{N}} \int_0^\ell \frac{1}{\lambda_n(\varsigma)}\,\mathrm{d}\varsigma = \int_0^\ell \frac{1}{\lambda(\varsigma)}\,\mathrm{d}\varsigma;$$

in particular, the map

$$f(s) := \int_0^s \frac{1}{\lambda(\varsigma)}\,\mathrm{d}\varsigma$$

is increasing and absolutely continuous on $[0,\ell]$. A c_γ-Lagrangian Lipschitz reparametrization of γ defined on $[0, \underline{T}(c_\gamma)]$ can now be obtained by setting $\widetilde{\gamma} := \gamma \circ \varphi$ with $\varphi := (f)^{-1}$ on $[0, \underline{T}(c_\gamma)]$. Lastly, the fact that the multifunction is upper semicontinuous, monotone, and convex-set-valued implies that

$$\bigcup_{a>c_\gamma} T(a) = \big(0, \underline{T}(c_\gamma)\big),$$

and this is enough to obtain the remainder of the statement. □

Example 3.15. Let $L(x,q) := |q|^2/2 + n(x)$ for every $(x,q) \in \mathbb{R}^N \times \mathbb{R}^N$, with $n(\cdot)$ Borel-measurable and bounded. Let $\gamma : [0,\ell] \to \mathbb{R}^N$ be a curve parameterized by the arc-length. Then $c_\gamma = \operatorname{ess\,sup}_{s\in[0,\ell]} -n(\gamma(s))$ and (cf. Example 3.8)

$$T_\gamma(a) = \int_0^\ell \frac{1}{\sqrt{2\,(a + n(\gamma(s)))}}\,\mathrm{d}s \qquad \text{for every } a > c_\gamma.$$

We now seek an optimal reparameterization of γ on the interval $[0,t]$ for any given $t \in (0,+\infty)$. For that, it suffices that $\underline{T}_\gamma(c_\gamma) = +\infty$ by Proposition 3.13, but this need not be true in general, not even in the simple case considered in Example 3.15. However, even in the case $\underline{T}_\gamma(c_\gamma) < +\infty$ we are able to derive an estimate on the Lipschitz constants of quasi-optimal reparameterizations. This is a crucial step in our study.

THEOREM 3.16. *Let $\gamma : [0,\ell] \to \mathbb{R}^N$ be a Lipschitz curve parameterized by the arc-length. Then, for every $t \in (0,+\infty)$, there exists $a \geq c_\gamma$ such that*

$$\inf_{\xi\in[\gamma]_t} \int_0^t L(\xi,\dot\xi)\,\mathrm{d}s = \inf_{\xi\in[\gamma]_t} \left\{ \int_0^t L(\xi,\dot\xi)\,\mathrm{d}s \,:\, \|\dot\xi\|_\infty \leq \kappa_a \right\} = \int_0^\ell \sigma_a(\gamma,\dot\gamma)\,\mathrm{d}s - a\,t,$$

with κ_a given by (10). *The above infimum is a minimum whenever $t \leq \underline{T}_\gamma(c_\gamma)$ and is, in particular, attained by some curve belonging to $[\gamma]^\flat(a,t)$ with $a > c_\gamma$ when $t < \underline{T}_\gamma(c_\gamma)$.*

Proof. By Proposition 3.3 and Lemma 3.14, we get

$$\int_0^t L(\xi,\dot\xi)\,\mathrm{d}s \geq \int_0^t \Big(\sigma_a(\xi,\dot\xi) - a\Big)\,\mathrm{d}s = \int_0^\ell \sigma_a(\gamma,\dot\gamma)\,\mathrm{d}s - a\,t \tag{17}$$

for any $a \geq c_\gamma$ and $\xi \in [\gamma]_t$, and (17) is an equality whenever $\xi \in [\gamma](a,t)$. The assertion for $t \leq \underline{T}_\gamma(c_\gamma)$ follows by Proposition 3.13 and Lemma 3.4.

Let us now assume $t > \underline{T}_\gamma(c_\gamma)$ and set $h := t - \underline{T}_\gamma(c_\gamma)$. Let $\xi \in [\gamma](c_\gamma, \underline{T}_\gamma(c_\gamma))$. By definition of c_γ, there exists, for each $n \in \mathbb{N}$, $s_n \in \big(0, \underline{T}_\gamma(c_\gamma)\big)$ such that

$$c_\gamma + L(\xi(s_n),0) < \frac{1}{n}.$$

To ease notation, we will write c_n in place of $-L(\xi(s_n),0)$. We define

$$\xi_n(s) := \begin{cases} \xi(s) & \text{if } s \in (0,s_n], \\ \xi(s_n) & \text{if } s \in [s_n, s_n+h], \\ \xi(s-h) & \text{if } s \in [s_n+h, t). \end{cases}$$

We have

$$\int_0^t L(\xi_n,\dot\xi_n)\,\mathrm{d}s = \int_0^{\underline{T}_\gamma(c_\gamma)} L(\xi,\dot\xi)\,\mathrm{d}s - h\,c_n = \int_0^{\underline{T}_\gamma(c_\gamma)} \sigma_{c_\gamma}(\xi,\dot\xi)\,\mathrm{d}s - \underline{T}_\gamma(c_\gamma)\,c_\gamma$$
$$-h\,c_n = \int_0^\ell \sigma_{c_\gamma}(\gamma,\dot\gamma)\,\mathrm{d}s - c_\gamma\,t + h\,\big(c_\gamma - c_n\big) < \int_0^\ell \sigma_{c_\gamma}(\gamma,\dot\gamma)\,\mathrm{d}s - c_\gamma\,t + \frac{h}{n}.$$

Taking (17) into account, we derive

$$\int_0^\ell \sigma_{c_\gamma}(\gamma,\dot\gamma)\,\mathrm{d}s - c_\gamma\,t \leq \int_0^t L(\xi_n,\dot\xi_n)\,\mathrm{d}s < \int_0^\ell \sigma_{c_\gamma}(\gamma,\dot\gamma)\,\mathrm{d}s - c_\gamma\,t + \frac{h}{n},$$

and we conclude by letting $n \to +\infty$. □

Remark 3.17. If in Theorem 3.16 the Lagrangian is assumed lower semicontinuous in x, we can furthermore say that, for every $t > 0$,

$$\inf_{\xi \in [\gamma]_t} \int_0^t L(\xi, \dot\xi)\,\mathrm{d}s = \min\left\{ \int_0^t L(\xi, \dot\xi)\,\mathrm{d}s \,:\, \xi \in [\gamma](a,t) \right\} \tag{18}$$

for some constant $a \geq c_\gamma$. This can be proved by considering, in place of $T_\gamma(\cdot)$, the set-valued map defined as

$$T^*_\gamma(a) := \{t > 0 \,:\, [\gamma](a,t) \text{ is nonempty}\}$$

for every $a \geq c^*_\gamma := \sup_{s\in J} -L\,(\gamma(s), 0)$. The multifunction $T^*_\gamma(\cdot)$ agrees with $T_\gamma(\cdot)$ on $(c^*_\gamma, +\infty)$. Indeed, the inequality

$$\underline{\lambda}_a(\gamma(s), \dot\gamma(s)) \geq \frac{a - c^*_\gamma}{2R_a} \qquad \text{for a.e. } s \in [0, \ell],$$

which holds by Proposition 3.7, implies that $[\gamma](a,t) = [\gamma]^\flat(a,t)$ for every $a > c^*_\gamma$ and $t > 0$ (cf. the argument that $T(a) \subseteq [\underline{T}\,(a), \overline{T}\,(a)]$ in the proof of Proposition 3.13). On the other hand, we always have

$$T^*_\gamma(c^*_\gamma) = [\underline{T}_\gamma(c^*_\gamma), +\infty) \tag{19}$$

when $T(c^*_\gamma)$ is finite, and that is enough to get the statement in view of (17).

To prove (19), let ξ be a curve belonging to $[\gamma](c^*_\gamma, \underline{T}(c^*_\gamma))$ (which does exist by Proposition 3.13) and take $s_0 \in [0, \underline{T}_\gamma(c^*_\gamma)]$ such that $L(\xi(s_0), 0) = -c^*_\gamma$. Such an s_0 always exists by the upper semicontinuity of $-L(\gamma(\cdot), 0)$ on $[0, \ell]$. For every $h > 0$, define $\xi_h : [0, \underline{T}(c^*_\gamma) + h] \to \mathbb{R}^N$ as

$$\xi_h(s) := \begin{cases} \xi(s) & \text{if } s \in [0, s_0], \\ \xi(s_0) & \text{if } s \in [s_0, s_0 + h], \\ \xi(s - h) & \text{if } s \in [s_0 + h, \underline{T}_\gamma(c^*_\gamma) + h]. \end{cases}$$

It is easily seen that ξ_h is a c^*_γ-Lagrangian reparameterization of γ. This shows that

$$\underline{T}_\gamma(c^*_\gamma) + h \in T^*_\gamma(c^*_\gamma) \qquad \text{for every } h > 0,$$

as claimed.

Remark 3.18. The argument described in Remark 3.17 above actually shows that (18) holds whenever the map $s \mapsto L(\gamma(s), 0)$ attains its infimum on $[0, \ell]$, for instance, when it is lower semicontinuous.

With the aid of the results obtained so far, we can now prove Lemma 3.2.

Proof of Lemma 3.2. Choose $\overline{n} \in \mathbb{N}$ such that $M/\alpha(\overline{n}) < 1/2$ and set

$$A = A(\overline{n}) := \max\{\alpha_*(u) \,:\, |u| \leq 2\,\beta(\overline{n} + 1)\},$$

where $\alpha_*(u) := \max_{\lambda\in\mathbb{R}}\{\lambda u - \alpha(|\lambda|)\}$. We claim that the statement holds with $\kappa := \kappa_A$ defined according to (10). Indeed, pick a curve $\xi \in W^{1,1}\big([0,t], \mathbb{R}^N\big)$ such that

$$\int_0^t L(\xi, \dot\xi)\,\mathrm{d}s < M\,t,$$

and let $\gamma : [0, \ell] \to \mathbb{R}^N$ be a Lipschitz curve, parameterized by the arc-length, such that $\xi \in [\gamma]_t$, according to Lemma 3.11. In view of Theorem 3.16, up to choosing a different ξ in $[\gamma]_t$ without increasing the action, we can always assume that either $\|\dot\xi\|_\infty \le \kappa_{c_\gamma}$ or $\xi \in [\gamma]^\flat(a,t)$ for some $a > c_\gamma$. In the first case, we note that

$$c_\gamma \le \alpha_*(0)$$

for $-L(x,0) \le -\alpha(0) \le \alpha_*(0)$ for every $x \in \mathbb{R}^N$. The claim follows by the definition of κ_A as $\alpha_*(0) \le A$.

Let us instead assume that ξ belongs to $[\gamma]^\flat(a,t)$ for some $a > c_\gamma$. In particular, $|\dot\xi(s)| \neq 0$ a.e. on $[0,t]$. Set $J := \{s \in [0,t] \,:\, 0 < |\dot\xi(s)| < \overline{n}\}$. We have

$$M\,t > \int_0^t L(\xi,\dot\xi)\,\mathrm{d}s \ge \int_0^t \alpha(|\dot\xi|)\,\mathrm{d}s \ge \alpha(\overline{n})\,\big|[0,t]\setminus J\,\big|,$$

and hence $|J| > t/2$. Pick up a differentiability point $\overline{s} \in J$ for ξ. By the fact that ξ has an a-Lagrangian parameterization, we derive that

$$a \in H\left(\xi(\overline{s}), \partial_q L(\xi(\overline{s}), \dot\xi(\overline{s}))\right);$$

in particular, $a \le A$ by Proposition 2.1. As $|\dot\xi(s)| \in \Lambda_a(\xi(s), \dot\xi(s)/|\dot\xi(s)|)$ for a.e. $s \in [0,t]$, the claim follows by Lemma 3.4 since $\kappa_a \le \kappa_A$ by definition (10). □

3.3. Further extensions. Let us now consider a Lagrangian $L : \mathbb{R}^N \times \mathbb{R}^N \to \mathbb{R}_+$ which satisfies in place of (L2), condition (L2)′ for some family $(\beta_n)_{n\in\mathbb{N}}$ of convex, nondecreasing, and superlinear functions from $\mathbb{R}_+$ to $\mathbb{R}_+$; i.e., which is uniformly superlinear in q and locally bounded in $\mathbb{R}^N \times \mathbb{R}^N$. It is easy to generalize Theorem 3.1 as follows.

THEOREM 3.19. *Let $L : \mathbb{R}^N \times \mathbb{R}^N \to \mathbb{R}_+$ be an autonomous Lagrangian satisfying conditions* (L1), (L2)′, (L3). *Then the associated function S defined through* (3) *is locally Lipschitz in $\mathbb{R}^N \times \mathbb{R}^N \times (0,+\infty)$. More precisely, for every $M, r > 0$ there exists a constant $K = K\big(M, r, \alpha, (\beta_n)_n\big)$ such that*

$$S \quad \textit{is } K\textit{-Lipschitz continuous in } \overline{C_M(r)},$$

where $C_M(r) := \{(y,t,x) \in B_r \times B_r \times (0,r) \,:\, |x-y| < M\,t\}$.

Proof. For every $n \in \mathbb{N}$, let us denote by S_n the function associated with the Lagrangian $L_n(x,q) := L(x,q)\,\chi_{B_n}(x) + \beta_n(|q|)\,\chi_{\mathbb{R}^N\setminus B_n}(x)$ through (3). We claim that, for every $M, r > 0$, there exists an index $k = k\big(M, r, \alpha, (\beta_n)_n\big)$ such that

$$S = S_k \quad \text{on } C_M(r). \tag{20}$$

Clearly, that is enough to conclude by Theorem 3.1.

Let us fix $M, r > 0$. We first notice that

$$S(y,x,t) < r\,\beta_m\,(M) \qquad \text{for any } (y,t,x) \in C_M(r), \tag{21}$$

where $m := [r] + 1$. Let γ be a curve in $W^{1,1}\big([0,t], \mathbb{R}^N\big)$ connecting y to x such that γ is quasi optimal for $S(y,x,t)$. By (21), it is not restrictive to assume that

$$\int_0^t L(\gamma,\dot\gamma)\,\mathrm{d}s < r\,\beta_m\,(M)\,,$$

in particular,

$$\int_0^t |\dot\gamma|\,\mathrm{d}s < r\Big(\alpha_1 + \beta_m(M)\Big),$$

with $\alpha_1 > 0$ such that $\alpha(|q|) \geq |q| - \alpha_1$ for any $q \in \mathbb{R}^N$. As γ has end-points lying in B_r, we deduce that γ is entirely contained in the open ball B_k with

$$k := \big[r\big(1 + \alpha_1 + \beta_m(M)\big)\big] + 1.$$

Thus

$$S(y,x,t) = \inf\left\{\int_0^t L(\gamma,\dot\gamma)\,\mathrm{d}s \,:\, \gamma(0) = y,\ \gamma(t) = x,\ \gamma([0,t]) \subset B_k\right\}$$

for every $(y,t,x) \in C_M(r)$, and claim (20) follows at once as L coincides with L_k on $B_k \times \mathbb{R}^N$. □

Remark 3.20. Theorem 3.19 still holds if, in place of condition (L3), L satisfies the following weaker convexity assumption:

(L3)′ For every $t_1 < t_2$ in $\mathbb{R}$ and $\gamma \in W^{1,\infty}\big((t_1,t_2),\mathbb{R}^N\big)$,

$$\lambda \mapsto L(\gamma(s), \lambda\,\dot\gamma(s)) \quad \text{is convex on } \mathbb{R} \qquad \text{for a.e. } s \in (t_1,t_2).$$

The reparameterization techniques and the approach described above can be in fact adapted to this setting. The lack of convexity of L in q gives rise to some technical difficulties. For instance, it is no longer true that L is the Fenchel transform of H. These obstructions can be overcome by computing the Fenchel transform of L along straight lines of any fixed direction, and by accordingly modifying the definition of σ_a. For the details, see [20].

We conclude this section by recording a result proved in [20] that we will need later. Let us denote by $\mathcal{L} = \mathcal{L}\big(\alpha,(\beta_n)_n\big)$ the family of Lagrangians satisfying assumptions (L1), (L2)′, (L3)′, where α and β_n, $n \in \mathbb{N}$, are fixed, convex, nondecreasing, and superlinear functions from $\mathbb{R}_+$ to $\mathbb{R}_+$. Let $\Sigma = \Sigma\big(\alpha,(\beta_n)_n\big)$ be the space of functions S on $\mathbb{R}^N \times \mathbb{R}^N \times (0,+\infty)$ associated via (3) with Lagrangians belonging to $\mathcal{L}$. We endow Σ with the metric induced by the uniform convergence on the compact subset of $\mathbb{R}^N \times \mathbb{R}^N \times (0,+\infty)$. The following result holds (see [20]).

THEOREM 3.21. *The space of functions Σ is compact; i.e., every sequence $(S_k)_k$ in Σ admits a subsequence which converges to some element S of Σ, locally uniformly in $\mathbb{R}^N \times \mathbb{R}^N \times (0,+\infty)$.*

Remark 3.22. The Lagrangian L associated with the limit function S via (3) can be obtained by "differentiation" as follows:

$$L(x,q) = \lim_{h\to 0^+} \frac{S(x,x+hq,h)}{h} \qquad \text{for every } (x,q) \in \mathbb{R}^N \times \mathbb{R}^N. \tag{22}$$

As proved in [20], L is continuous in q for every x and convex for almost every x. However, the convexity of $L(x,\cdot)$ for every $x \in \mathbb{R}^N$ is not ensured, even if the approximating functions S_k are associated with Lagrangians convex in q.

4. Main theorems.

4.1. Lipschitz-regularity of the value function. We now use the information gathered so far to prove some regularity properties of the value function $v : (0,+\infty)\times\mathbb{R}^N \to \mathbb{R}$ defined as

$$v(t,x) := \inf\left\{ u(\gamma(0)) + \int_0^t L(\gamma,\dot\gamma)\,\mathrm{d}s \;:\; \gamma\in W^{1,1}\big([0,t],\mathbb{R}^N\big),\ \gamma(t)=x\right\}, \tag{23}$$

where $u:\mathbb{R}^N\to(-\infty,+\infty]$, $u\not\equiv+\infty$, and L is a Lagrangian satisfying assumptions (L1)–(L3). The above formula can be equivalently restated as

$$v(t,x) = \inf_{y\in\mathbb{R}^N}\Big(u(y)+S_y(t,x)\Big), \tag{24}$$

where $S_y(t,x)$ stands for the function $S(y,x,t)$ associated with L via (3). In what follows, $\operatorname{dom} g$ will denote the effective domain of the function $g:\mathbb{R}^N\to[-\infty,+\infty]$, i.e., the subset of $\mathbb{R}^N$ where g is finite valued; g^+ will denote the positive part of g, namely, $g^+(x) := \max\{g(x),0\}$ for every $x\in\mathbb{R}^N$. We will also use the following notation:

$$\|g\|_{\ell^\infty(E)} := \sup_{x\in E}|g(x)|, \qquad E\subseteq\mathbb{R}^N,$$

or, more simply, $\|g\|_{\ell^\infty}$ when $E=\mathbb{R}^N$.

THEOREM 4.1. *Let v be defined by* (23) *for some $L:\mathbb{R}^N\times\mathbb{R}^N\to\mathbb{R}_+$ satisfying conditions* (L1)–(L3)*. The following facts hold:*

(i) *If $u\not\equiv+\infty$, then*

$$\lim_{t\to0^+}\|\,(v(t,\cdot)-u)^+\,\|_{\ell^\infty(\operatorname{dom}u)}=0, \tag{25}$$

in particular, $\lim_{t\to0^+}v(t,x)\le u(x)$ for every $x\in\mathbb{R}^N$;

(ii) *if u is bounded from below, then $v(t,x)$ is locally Lipschitz in $(0,+\infty)\times\mathbb{R}^N$;*

(iii) *if u is either bounded or in $\mathrm{UC}(\mathbb{R}^N)$, then, for any $t_0>0$, there exists a constant $K_{t_0}=K(t_0,u,\alpha,\beta)$ such that*

$$v(t,x) \qquad \text{is } K_{t_0}\text{-Lipschitz in} \quad [t_0,+\infty)\times\mathbb{R}^N;$$

(iv) *if $u\in\mathrm{Lip}(\mathbb{R}^N)$, then there exists a constant $K=K(u,\alpha,\beta)$ such that*

$$v(t,x) \qquad \text{is } K\text{-Lipschitz in} \quad [0,+\infty)\times\mathbb{R}^N.$$

Proof. Pick a point $x_0\in\operatorname{dom}(u)$ and plug $y=x_0$ into the expression on the right-hand side of (24). We get

$$v(t,x)\le u(x_0)+t\,\beta\left(\frac{|x-x_0|}{t}\right). \tag{26}$$

Inequality (26) with $x_0=x$ immediately gives (25) whenever $x\in\operatorname{dom}(u)$.

Let us now assume that u is bounded from below. By inequality (26), any $y\in\mathbb{R}^N$ which is t-optimal for $v(t,x)$ satisfies

$$u(y)+S_y(t,x)\le u(x_0)+t\left(\beta\left(\frac{|x-x_0|}{t}\right)+1\right),$$

and that yields, for $y \neq x$,

$$\frac{\alpha\left(\frac{|x-y|}{t}\right)}{\frac{|x-y|}{t}} \leq \frac{u(x_0)-u(y)}{|x-y|} + \left(\beta\left(\frac{|x-x_0|}{t}\right)+1\right)\frac{t}{|x-y|}. \tag{27}$$

When (t,x) varies in an open set U compactly contained in $(0,+\infty)\times\mathbb{R}^N$, inequality (27) is certainly false if $(y,t,x) \notin \overline{C_M}$ for a suitably large $M = M(U, \|(-u)^+\|_{\ell^\infty}, \alpha, \beta)$. Hence

$$v(t,x) = \inf_y \left\{ u(y) + S_y(t,x) \,:\, (y,t,x) \in \overline{C_M} \right\} \qquad \text{for every } (t,x) \in U,$$

and assertion (ii) follows, as v is the infimum of a family of equi-Lipschitz functions, by Theorem 3.1.

Items (iii) and (iv) can be proved analogously by replacing x_0 with x in (27) and by choosing as U the sets $(t_0,+\infty)\times\mathbb{R}^N$ and $(0,+\infty)\times\mathbb{R}^N$, respectively. For the case $u \in \mathrm{UC}(\mathbb{R}^N)$, we also use the fact that, for any such u, there exists $\varepsilon > 0$ such that

$$|u(x)-u(y)| < \frac{|x-y|}{\varepsilon} \qquad \text{for every } x,y \in \mathbb{R}^N \text{ with } |x-y| > \varepsilon. \qquad \square$$

Let us now assume that the Lagrangian L satisfies, in place of (L2), condition (L2)′ for some family $(\beta_n)_{n\in\mathbb{N}}$ of convex, nondecreasing, and superlinear functions from $\mathbb{R}_+$ to $\mathbb{R}_+$. We provide the following generalization of Theorem 4.1.

THEOREM 4.2. *Let v be defined by* (23) *for some $L : \mathbb{R}^N \times \mathbb{R}^N \to \mathbb{R}_+$ satisfying conditions* (L1), (L2)′, (L3). *The following facts hold:*

(i) *If $u \not\equiv +\infty$, then*

$$\lim_{t\to 0^+} \| \left(v(t,\cdot)-u\right)^+ \|_{\ell^\infty(B_r \cap \mathrm{dom}\, u)} = 0 \qquad \textit{for every } r > 0,$$

in particular, $\lim_{t\to 0^+} v(t,x) \leq u(x)$ *for every $x \in \mathbb{R}^N$;*

(ii) *if u is either bounded from below or in* $\mathrm{UC}(\mathbb{R}^N)$, *then $v(t,x)$ is locally Lipschitz in $(0,+\infty)\times\mathbb{R}^N$. More precisely, for every open set U compactly contained in $(0,+\infty)\times\mathbb{R}^N$, there exists a constant $K = K\big(U,u,\alpha,(\beta_n)_n\big)$ such that*

$$v(t,x) \qquad \textit{is } K\textit{-Lipschitz in } U.$$

The proof is omitted, for it can be easily recovered by arguing as above and by using Theorem 3.19 in place of Theorem 3.1.

Lastly, we want to point out that all results of this paper can be easily extended to the case when $\mathbb{R}^N$ is replaced by a connected smooth Riemannian manifold $\mathcal{M}$ without boundary. In this case, the Lagrangian L is defined on the tangent bundle $T\mathcal{M}$ of $\mathcal{M}$ and satisfies assumptions (L1), (L2) or (L2)′, (L3), with $T\mathcal{M}$, $\|\cdot\|_x$, and $\mathcal{M}$ in place of $\mathbb{R}^N\times\mathbb{R}^N$, $|\cdot|$ and $\mathbb{R}^N$, respectively.[3] When $\mathcal{M}$ is compact, Theorem 4.1 can be partially improved as follows.

PROPOSITION 4.3. *Let $\mathcal{M}$ be a compact and connected smooth Riemannian manifold without boundary and $L : T\mathcal{M} \to \mathbb{R}_+$ an autonomous Lagrangian satisfying conditions* (L1)–(L3), *with $T\mathcal{M}$, $\|\cdot\|_x$, and $\mathcal{M}$ in place of $\mathbb{R}^N\times\mathbb{R}^N$, $|\cdot|$, and $\mathbb{R}^N$,*

[3] $\|\cdot\|_x$ denotes the Riemannian norm on $T_x\mathcal{M}$ for every $x \in \mathcal{M}$.

respectively. Let v be defined by (23) with $u \not\equiv +\infty$ and bounded from below. Then, for any $t_0 > 0$, there exists a constant $K_{t_0} = K(t_0, \alpha, \beta)$ such that

$$v(t,x) \qquad \text{is } K_{t_0}\text{-Lipschitz in} \quad [t_0, +\infty) \times \mathcal{M}.$$

Remark 4.4. Our point is that the constant K_{t_0} appearing above is independent of the initial cost u, provided v is a well-defined real function on $(0, +\infty) \times \mathcal{M}$. This is actually guaranteed by the conditions $u \not\equiv +\infty$ and $\inf_{\mathcal{M}} u > -\infty$.

Proof. Let us denote by $\delta_{\mathcal{M}}$ the distance on $\mathcal{M}$ induced by its Riemannian metric. For any $M > 0$, set

$$C_M := \{(y, x, t) \in \mathcal{M} \times \mathcal{M} \times (0, +\infty) \,:\, \delta_{\mathcal{M}}(x, y) < M\, t\}.$$

Since $\mathcal{M}$ is compact, for any $t_0 > 0$ there exists M_{t_0}, depending on t_0 and on the diameter of $\mathcal{M}$ only, such that $\mathcal{M} \times \mathcal{M} \times [t_0, +\infty) \subset C_{M_{t_0}}$. Hence

$$v(t,x) = \inf_y \left\{ u(y) + S_y(t,x) \,:\, (y,x,t) \in C_{M_{t_0}} \right\} \quad \text{for any } (t,x) \in [t_0, +\infty) \times \mathcal{M},$$

and the assertion follows, as v is the infimum of a family of equi-Lipschitz functions by Theorem 3.1. ∎

4.2. A compactness result for value functions. Let $\mathcal{L} = \mathcal{L}\big(\alpha, (\beta_n)_n\big)$ be defined as in subsection 3.3, and let $(L_k)_k$ be a sequence of Lagrangians belonging to $\mathcal{L}$ and convex in q. For each $k \in \mathbb{N}$, let

$$v_k(t,x) := \inf \left\{ u_k(\gamma(0)) + \int_0^t L_k(\gamma(s), \dot\gamma(s))\, \mathrm{d}s \;:\; \gamma \in W^{1,1}\big([0,t], \mathbb{R}^N\big),\ \gamma(t) = x \right\}$$

for every $(t,x) \in (0, +\infty) \times \mathbb{R}^N$, where u_k is a function from $\mathbb{R}^N$ to $(-\infty, +\infty]$ with $u_k \not\equiv +\infty$. With the aid of Theorem 3.21, we can prove the following result.

THEOREM 4.5. *Let $(v_k)_k$ be defined as above, and suppose one of the following conditions holds:*

(a) *The functions u_k are equibounded from below on $\mathbb{R}^N$;*

(b) *the functions u_k are equiuniformly continuous on $\mathbb{R}^N$.*

Then, up to subsequences, $(v_k)_k$ locally uniformly converges on $(0, +\infty) \times \mathbb{R}^N$ to the function v defined as

$$v(t,x) := \inf \left\{ u_*(\gamma(0)) + \int_0^t L(\gamma(s), \dot\gamma(s))\, \mathrm{d}s \;:\; \gamma \in W^{1,1}\big([0,t], \mathbb{R}^N\big),\ \gamma(t) = x \right\},$$

where L is a Lagrangian belonging to $\mathcal{L}$ and u_* is the function defined as

$$u_*(x) := \inf \left\{ \liminf_k u_k(x_k) \,:\, x_k \to x \right\} \quad \textit{for every } x \in \mathbb{R}^N.$$

Proof. Let us denote by S_k the function associated with L_k via (3). By Theorem 3.21 we know that, up to subsequences, S_k converge to S, locally uniformly on $\mathbb{R}^N \times \mathbb{R}^N \times (0, +\infty)$. Let L be the element of $\mathcal{L}$ derived from S via (22). For every $M, r > 0$, the functions S_k are equi-Lipschitz continuous. Moreover, for every open set U compactly contained in $(0, +\infty) \times \mathbb{R}^N$ there exists a constant M independent of k such that

$$v_k(t,x) = \inf_y \left\{ u_k(y) + S_k(y,x,t) \,:\, (y,t,x) \in \overline{C_M(r)} \right\} \quad \text{for every } (t,x) \in U,$$

where r is a sufficiently large positive number such that $U \subset (0,r) \times B_r$. To see this, argue as in the proof of Theorem 4.1 and note that M can be estimated in terms of $\sup_k \|(-u_k)^+\|_{\ell^\infty}$ or of the continuity modulus shared by the functions $(u_k)_k$. In particular, the functions v_k are equi-Lipschitz continuous on U. By the Ascoli–Arzelà theorem, the proof then reduces to showing that

$$\lim_k v_k(t,x) = v(t,x) \qquad \text{for every } (t,x) \in U.$$

Let us first prove that

$$v(t,x) \geq \limsup_k v_k(t,x) \qquad \text{for every } (t,x) \in U. \tag{28}$$

Choose $y \in \mathbb{R}^N$ and let $y_k \to y$ such that $u_k(y_k)$ converge to $u_*(y)$. We have

$$u_*(y) + S(y,x,t) = \lim_k u_k(y_k) + S_k(y_k,x,t) \geq \limsup_k v_k(t,x),$$

and (28) follows by taking the infimum of the above inequality for all $y \in \mathbb{R}^N$. Next, let us prove that

$$\liminf_k v_k(t,x) \geq v(t,x) \qquad \text{for every } (t,x) \in U. \tag{29}$$

For each $k \in \mathbb{N}$, take y_k such that $(y_k,t,x) \in \overline{C_M(r)}$ and

$$v_k(t,x) + \frac{1}{k} \geq u_k(y_k) + S_k(y_k,x,t).$$

By possibly considering a subsequence, we can assume that $(y_k)_k$ converges to some point $y \in \mathbb{R}^N$. We infer that

$$\liminf_k v_k(t,x) \geq \liminf_k u_k(y_k) + S(y,x,t) \geq u_*(y) + S(y,x,t),$$

and (29) follows. □

Acknowledgment. The author wishes to thank the anonymous referee who has carefully read the article, pointed out many errors and misprints in previous versions of the paper, and whose critical remarks have been helpful in improving the presentation.

EXISTENCE AND NONEXISTENCE RESULTS OF AN OPTIMAL CONTROL PROBLEM BY USING RELAXED CONTROL*

HONGWEI LOU†

Abstract. Relaxed controls have proved to be very useful in studying the existence of optimal controls in optimal control theory. Many positive results have been obtained in the literature. However, negative results have also made their rare appearances. The optimal control problem considered in this paper looks quite simple. Yet, by treating such a problem, we can get interesting results, substantiating our idea as to whether an optimal control exists or not. In our opinion, the method used in the paper can be applied to more generalized cases.

Key words. optimal control, existence, nonexistence, relaxed control

1. Introduction. Since the introduction by Young [37] and McShane [25] in the late 1930s, generalized curves have been widely used in existence theories for calculus of variations and optimal control theory, especially for problems that lack convex conditions.

In optimal control theory, generalized curves were transformed as relaxed controls by Gamkrelidze [15], McShane [26], and Warga [35]; see also Warga [36]. Thanks to the useful Filippov lemma (see [13] and Corollary 2.26 in Chapter 3 of [18]), it becomes quite convenient to prove that, under some proper conditions, there exists a (classical) control which has the same effect as an optimal relaxed control, leading to the existence of an optimal (classical) control. It is our opinion that relaxed control is the most important tool for studying the existence of optimal controls when a convex condition such as Cesari's condition (see [18], for example) is not assumed.

To the best of our knowledge, the first result on the existence of optimal classical controls without assuming convexity conditions was established by Neustadt [28] for (finite-dimensional) linear systems. Various later results in finite-dimensional spaces were obtained by Artstein [2], Balder [3], [4], [5], [6], Berliocchi and Lasry [8], Cellina and Colombo [9], Cesari [10], Colombo and Goncharov [11], Marcellini [23], Mariconda [24], Olech [29], and Raymond [31], [32], to mention a few. On the other hand, in infinite-dimensional cases, fewer results can be found in the literature. The readers are referred to Flores-Bazán and Perrotta [14] and Suryanarayana [34] for hyperbolic equations and to Lou [19], [20], [22] and Raymond [33] for elliptic and parabolic cases.

For general results concerning the existence of optimal relaxed controls, see [1], [12], and [30] and the references cited therein.

Concerning the nonexistence results, the following is a typical counterexample which has been mentioned in many books; see, for example, [36, Ch. 3, p. 246]. Other similar examples can be found in [10, Ch. 9, p. 321] and [12, Ch. 2, p. 51].

EXAMPLE 1.1. *Let* $U = [-1, 1]$ *(or* $U = \{-1, 1\}$*),*

$$\mathcal{U} = \Big\{ v(\cdot) : [0,1] \to U \;\Big|\; v(\cdot) \text{ measurable} \Big\},$$

$$\frac{dy(t)}{dt} = u(t), \qquad t \in [0,1],$$

and

$$I(u(\cdot)) = \int_0^1 \Big(y^2(t) - u^2(t) \Big)\, dt.$$

Then it is easy to see that

$$I(u(\cdot)) > -1 = \inf_{v(\cdot)\in\mathcal{U}} I(v(\cdot)) \quad \forall\, u(\cdot) \in \mathcal{U}. \tag{1.1}$$

Thus

$$I(\bar{u}(\cdot)) = \inf_{v(\cdot)\in\mathcal{U}} I(v(\cdot))$$

has no solution. That is, optimal control does not exist.

We point out that, in the literature, rare general results were found concerning the nonexistence of optimal controls by using relaxed control.

Now, we would like to state the problems that we are going to study in this paper. To this end, let $\Omega \subset \mathbb{R}^n$ be a bounded domain with a smooth boundary $\partial\Omega$, let $M > 0$ be a given constant, and let[1]

$$\mathcal{U} = \Big\{ v(\cdot) : \Omega \to [0, M] \;\Big|\; v(\cdot) \text{ measurable} \Big\}.$$

For a positive integer m and $p \in [1, +\infty)$, denote by $W^{m,p}(\Omega)$ the usual Sobolev space, i.e.,

$$W^{m,p}(\Omega) = \big\{ f \in L^p(\Omega) \;\big|\; \forall\, |\rho| \le m,\, \partial^\rho f \in L^p(\Omega) \big\}$$

endowed with norm

$$\|f\|_{W^{m,p}(\Omega)} = \sum_{|\rho|\le m} \|\partial^\rho f\|_{L^p(\Omega)},$$

where $\rho = (\rho_1, \rho_2, \ldots, \rho_n)$ is called a multi-index, which is an n-tuple of nonnegative integers ρ_i, $|\rho| = \sum_{i=1}^n \rho_i$, and the derivatives $\partial^\rho f = \partial_{x_1}^{\rho_1} \ldots \partial_{x_n}^{\rho_n} f$ are taken in a weak sense. Denote by $W_0^{m,p}(\Omega)$ the closure of $C_0^\infty(\Omega)$ in $W^{m,p}(\Omega)$. In this paper, we consider the following controlled system:

$$\begin{cases} -\triangle\, y(x) = u(x) & \text{in } \Omega, \\ y|_{\partial\Omega} = 0, \end{cases} \tag{1.2}$$

[1]Naturally, $\mathcal{U}$ is in fact a set of equivalence classes. Two measurable functions $u(\cdot), v(\cdot) : \Omega \to [0, M]$ will appear as the same element of $\mathcal{U}$ if $u(x) = v(x)$ a.e. Ω. The definition of $\mathcal{R}(\Omega, U)$ in section 2 is similar.

where the control $u(\cdot)$ belongs to $\mathcal{U}$ and the corresponding state $y(\cdot)$ is the solution of (1.2). Throughout this paper, by a solution $y(\cdot)$ of (1.2) corresponding to control $u(\cdot)$, we mean $y(\cdot) \in W_0^{1,2}(\Omega)$ and

$$\int_\Omega \nabla y(x) \cdot \nabla \varphi(x)\, dx = \int_\Omega u(x)\varphi(x)\, dx \quad \forall\, \varphi \in C_0^\infty(\Omega).$$

We would like to mention that under the assumptions of this paper, any weak solution $y(\cdot)$ must be in $W^{2,2}(\Omega)$, and therefore, it is necessarily a strong solution.

Next, we introduce the following cost functional:

$$J(u(\cdot)) = \int_\Omega F\big(y(x), u(x)\big)\, dx. \tag{1.3}$$

Then our optimal control problem can be stated as follows.

Problem (C). Find a $\bar{u}(\cdot) \in \mathcal{U}$ such that

$$J(\bar{u}(\cdot)) = \inf_{u(\cdot)\in\mathcal{U}} J(u(\cdot)). \tag{1.4}$$

Any control $\bar{u}(\cdot) \in \mathcal{U}$ satisfying (1.4) is called an optimal (classical) control.

In the rest of this paper, some general existence and nonexistence results for optimal controls will be presented by means of relaxed controls.

2. Relaxation. In this section, we would like to introduce and study the relaxation of our Problem (C). To begin with, let $U = [0, M]$, denote by $\mathcal{M}_+^1(U)$ the set of all probability measures in U, and denote by $\mathcal{R}(\Omega, U)$ the set of all measurable $\mathcal{M}_+^1(U)$-valued functions on Ω. Clearly, $\sigma(\cdot) \in \mathcal{R}(\Omega, U)$ if and only if

$$\sigma(x) \in \mathcal{M}_+^1(U) \quad \text{a.e. } x \in \Omega,$$

and

$$x \mapsto \int_U h(v)\sigma(x)(dv) \text{ is measurable} \quad \forall\, h \in C(U),$$

where $C(U)$ denotes the space of continuous functions on U. Let $C(U)^*$ and $L^1(\Omega; C(U))^*$ be the dual spaces of $C(U)$ and $L^1(\Omega; C(U))$ with the weak star topology, respectively. We regard $\mathcal{M}_+^1(U)$ and $\mathcal{R}(\Omega, U)$ as subspaces of $C(U)^*$ and $L^1(\Omega; C(U))^*$, respectively, by setting

$$\theta(h) \triangleq \int_U h(v)\theta(dv) \quad \forall\, \theta \in \mathcal{M}_+^1(U), \quad h \in C(U) \tag{2.1}$$

and

$$\sigma(g) \triangleq \int_\Omega dx \int_U g(x, v)\sigma(x)(dv) \quad \forall\, \sigma \in \mathcal{R}(\Omega, U), \quad g \in L^1(\Omega; C(U)), \tag{2.2}$$

where (2.2) is well defined by [36, Theorem IV.1.6, p. 266]. Thus,

$$\sigma_k \to \sigma \quad \text{in } \mathcal{R}(\Omega, U)$$

means that

$$\int_\Omega dx \int_U h(x,v)\sigma_k(x)(dv) \to \int_\Omega dx \int_U h(x,v)\sigma(x)(dv)$$
$$\forall\, h \in L^1(\Omega; C(U)).$$

Now, we state our optimal relaxed control problem corresponding to Problem (C) as follows.

Problem (R). Find a $\bar\sigma(\cdot) \in \mathcal{R}(\Omega, U)$ such that

$$J(\bar\sigma(\cdot)) = \inf_{\sigma(\cdot)\in\mathcal{R}(\Omega,U)} J(\sigma(\cdot)), \tag{2.3}$$

where

$$J(\sigma(\cdot)) \stackrel{\triangle}{=} \int_\Omega dx \int_U F\big(y(x), v\big)\sigma(x)(dv), \tag{2.4}$$

and $y(\cdot)$ is the state corresponding to relaxed control $\sigma(\cdot) \in \mathcal{R}(\Omega, U)$; namely, it is the solution of the following:

$$\begin{cases} -\triangle\, y(x) = \displaystyle\int_U v\sigma(x)(dv) \quad \text{in } \Omega, \\ y|_{\partial\Omega} = 0. \end{cases} \tag{2.5}$$

Note that $\mathcal{U}$ can be imbedded into $\mathcal{R}(\Omega, U)$ by identifying each $u(\cdot) \in \mathcal{U}$ with the Dirac measure-valued function $\delta_{u(\cdot)} \in \mathcal{R}(\Omega, U)$. Moreover, $J(\delta_{u(\cdot)})$ defined by (2.4) coincides with $J(u(\cdot))$ defined by (1.3). Thus, notation $J(\sigma(\cdot))$ would not cause any confusion. On the other hand, it is known that $\mathcal{U}$ is dense in $\mathcal{R}(\Omega, U)$; i.e., for any $\sigma(\cdot) \in \mathcal{R}(\Omega, U)$, there exists a sequence $u_k(\cdot)$ in $\mathcal{U}$ such that

$$\delta_{u_k(\cdot)} \to \sigma(\cdot) \quad \text{in } \mathcal{R}(\Omega, U);$$

see, for example, Lemma 2.4 in [21] (where the result is more general); see also [36].

By the density of $\mathcal{U}$ in $\mathcal{R}(\Omega, U)$, one can easily get that, under some weak assumptions (for example, when $F(\cdot,\cdot)$ is continuous),

$$\inf_{\sigma(\cdot)\in\mathcal{R}(\Omega,U)} J(\sigma(\cdot)) = \inf_{u(\cdot)\in\mathcal{U}} J(u(\cdot)). \tag{2.6}$$

Thus, an optimal control of Problem (C) must be an optimal relaxed control of Problem (R). Furthermore, for an optimal relaxed control $\bar\sigma(\cdot)$, if there exists a $\bar u : \Omega \to U$ such that

$$\bar\sigma(x) = \delta_{\bar u(x)} \quad \text{a.e. } x \in \Omega,$$

then $\bar u(\cdot)$ must be measurable, that is, $\bar u(\cdot) \in \mathcal{U}$ (we simply say that $\bar\sigma(\cdot) \in \mathcal{U}$ in this case). Thus, $\bar u(\cdot)$ must be an optimal control of Problem (C). In other words, if Problem (R) has an optimal relaxed control $\bar\sigma(\cdot) \in \mathcal{R}(\Omega, U)$ such that $\operatorname{supp}\bar\sigma(x)$ (the support of $\bar\sigma(x)$) is a singleton of U for almost all $x \in \Omega$, then Problem (C) admits at least one optimal classical control, whereas, if every optimal relaxed control of Problem (R) is not an element of $\mathcal{U}$, then Problem (C) admits no optimal control.

Now, we recall that for (1.2)–(1.3), if $F(\cdot,\cdot)$ is continuous on $\mathbb{R}\times U$, then Cesari's condition is equivalent to $F(y,\cdot)$ being convex. For a general system, the definition

of Cesari's condition is a little bit more complicated, and we refer the readers to [7], [10], and [18]. As an example, we consider a system governed by ordinary differential equations:

$$\frac{dy}{dt} = f(t, y(t), u(t)). \tag{2.7}$$

The cost functional has the form

$$I(u(\cdot)) = \int_{t_0}^{T} f^0(t, y(t), u(t))\, dt,$$

where $y(t) \in \mathbb{R}^m$ and

$$u(\cdot) \in \mathcal{U} = \Big\{ v(\cdot) : [t_0, T] \to U \;\Big|\; v(\cdot) \text{ measurable} \Big\}.$$

Then the definition of Cesari's condition[2] is that for almost all $t \in [t_0, T]$, the set

$$\mathcal{E}(t, y) \triangleq \bigcup_{u \in U} \Big\{ (z, z^0) \in \mathbb{R}^m \times \mathbb{R} \;\Big|\; z = f(t, y, u),\ z^0 \geq f^0(t, y, u) \Big\}$$

has the Cesari property at every $y \in \mathbb{R}^m$:

$$\mathcal{E}(t, y) = \bigcap_{\delta > 0} \overline{\text{co}} \left(\bigcup_{|\tilde{y} - y| < \delta} \mathcal{E}(t, \tilde{y}) \right).$$

For the characterization of the above condition, see Lemma 4.1 of [4], Proposition 2.18 of [5], and Chapter 3 of [18].

One of the most important advantages of relaxed control is that optimal relaxed control exists under relatively weaker conditions. The following lemma is crucial in deriving existence of optimal relaxed controls.

LEMMA 2.1. *Suppose U is a compact metric space. Then $\mathcal{R}(\Omega, U)$ is convex and sequentially compact.*

For a proof of the above lemma, see Warga [36, Theorem IV.2.1, p. 272].

Now we will state the existence and necessary condition for an optimal relaxed control. It is a corollary of Theorems 3.2 and 4.1 in [19].

PROPOSITION 2.2. *Let $M > 0$ and $U = [0, M]$. Suppose that $F \in C^1(\mathbb{R} \times U)$. Then Problem* (R) *admits at least one optimal relaxed control. Let $\bar{\sigma}(\cdot)$ be an optimal relaxed control and $\bar{y}(\cdot)$ be the state corresponding to $\bar{\sigma}(\cdot)$, i.e.,*

$$\begin{cases} -\triangle\, \bar{y}(x) = \displaystyle\int_U v \bar{\sigma}(x)(dv) & \text{in } \Omega, \\ \bar{y}|_{\partial\Omega} = 0. \end{cases} \tag{2.8}$$

Define $\bar{\psi}(\cdot)$ to be the solution of

$$\begin{cases} -\triangle\, \bar{\psi}(x) = -\displaystyle\int_U F_y\big(\bar{y}(x), v\big)\, \bar{\sigma}(x)(dv) & \text{in } \Omega, \\ \bar{\psi}|_{\partial\Omega} = 0 \end{cases} \tag{2.9}$$

[2] Generally, we can define Cesari's condition for a general metric set U.

and

$$H(y,w,\psi) \stackrel{\triangle}{=} w\psi - F(y,w). \tag{2.10}$$

Then

$$\operatorname{supp}\bar{\sigma}(x) \subseteq \Big\{ w \in U \;\Big|\; H\big(\bar{y}(x),w,\bar{\psi}(x)\big) = \max_{v\in U} H\big(\bar{y}(x),v,\bar{\psi}(x)\big) \Big\} \quad a.e.\ x\in\Omega. \tag{2.11}$$

We mention that when $\bar{\sigma}(\cdot)$ is a classical control, i.e., $\bar{\sigma}(\cdot) = \delta_{\bar{u}(\cdot)}$ with $\bar{u}(\cdot)\in\mathcal{U}$, (2.11) becomes

$$H\big(\bar{y}(x),\bar{u}(x),\bar{\psi}(x)\big) = \max_{v\in U} H\big(\bar{y}(x),v,\bar{\psi}(x)\big) \quad \text{a.e. } x\in\Omega. \tag{2.12}$$

This is just the usual maximum condition.

Now we conclude this section by presenting a useful lemma. The set $\{x\in\Omega \mid \varphi(x)\in E\}$ will be denoted by $\{\varphi\in E\}$ for simplicity.

LEMMA 2.3. *Let C be a constant. If $\varphi\in W^{m,1}(\Omega)$, $m\geq 1$, then*

$$\partial^\rho\varphi(x) = 0 \quad a.e.\ on\ \{\varphi = C\} \quad \forall\, 1\leq|\rho|\leq m.$$

For the case $m=1$, the above result can be found in Morrey, Jr. [27, p. 69]. See also Kinderlehrer and Stampacchia [17, Ch. 2]. The remaining cases can be obtained easily by induction.

By Lemma 2.3, if $\varphi(\cdot)\in W^{2,1}(\Omega)$, then we have

$$-\triangle\varphi(x) = 0 \quad \text{a.e. on } \{\varphi = C\} \tag{2.13}$$

for any constant C.

3. Main results. In this section, we will present our main results. The proofs are based on careful analysis of the necessary conditions of the optimal relaxed pairs $(\bar{y}(\cdot),\bar{\sigma}(\cdot))$. We introduce the following standing assumptions.

(P1) The function $F\in C^3(\mathbb{R}\times[0,M])$ such that

$$\begin{array}{l} F_{yy}(y,u)\leq 0, \quad F_{yu}(y,u)\geq 0, \quad F_{uu}(y,u)<0 \\ F_{yyy}(y,u)\geq 0, \quad F_{yyu}(y,u)\geq 0 \end{array} \qquad \forall\, y\in\mathbb{R}, \quad u\in[0,M].$$

(P2)

$$F(0,M) - F(0,0) < 0, \qquad F_y(0,0)\leq 0.$$

It is possible to set other conditions different from (P1)–(P2). We will see that the case we choose is nontrivial and interesting.

We now state our main result.

THEOREM 3.1. *Let $M>0$ and* (P1)–(P2) *hold. Define $(z(\cdot),\zeta(\cdot))$ to be the solution of*

$$\begin{cases} -\triangle z(x) = M \quad in\ \Omega, \\ -\triangle\zeta(x) = -F_y\big(z(x),M\big) \quad in\ \Omega, \\ z|_{\partial\Omega} = \zeta|_{\partial\Omega} = 0, \end{cases} \tag{3.1}$$

and let

$$\ell = \inf_{x\in\Omega}\left[\zeta(x) - \frac{F\big(z(x),M\big) - F\big(z(x),0\big)}{M}\right]. \tag{3.2}$$

Then

(i) *if* $\ell \geq 0$, *Problem* (C) *admits at least one optimal control;*

(ii) *if* $\ell < 0$ *and*

$$F_{yy}(y,u) < 0 \quad \forall\, y \in \mathbb{R}, \quad u \in [0,M], \tag{3.3}$$

Problem (C) *admits no optimal control.*

Proof. Consider Problem (R) corresponding to Problem (C). By Proposition 2.2, there exists a $\bar\sigma(\cdot) \in \mathcal{R}(\Omega,U)$ satisfying (2.3). Moreover, let $\bar y(\cdot)$, $\bar\psi(\cdot)$, and $H(\cdot,\cdot,\cdot)$ be defined by (2.8), (2.9), and (2.10), respectively. Then we have (2.11). Further, it follows from (2.8), the L^p-estimate of the elliptic equation, and

$$\left|\int_U v\bar\sigma(x)(dv)\right| \leq M$$

that

$$\bar y(\cdot) \in W^{2,p}(\Omega) \quad \forall\, p \in [1,+\infty). \tag{3.4}$$

Thus,

$$\bar y(\cdot) \in C^{1,\alpha}(\overline{\Omega}) \quad \forall\, \alpha \in (0,1) \tag{3.5}$$

by the Sobolev imbedding theorem (see [16, Ch. 7], for example). Consequently, by the continuity of F_y, we have

$$\big|F_y(\bar y(x),v)\big| \leq C \quad \forall\, x \in \Omega, \quad v \in U,$$

for some constant $C > 0$. In particular,

$$\left|\int_U F_y(\bar y(x),v)\bar\sigma(x)(dv)\right| \leq C.$$

Therefore, similarly to (3.4)–(3.5), we can get

$$\bar\psi(\cdot) \in W^{2,p}(\Omega) \cap C^{1,\alpha}(\overline{\Omega}) \quad \forall\, p \in [1,+\infty), \quad \alpha \in (0,1). \tag{3.6}$$

Now, let us make an observation on (2.11). By (P1),

$$\frac{\partial^2}{\partial u^2}H(y,u,\psi) = -F_{uu}(y,u) > 0 \quad \forall\,(y,u,\psi) \in \mathbb{R}\times U\times\mathbb{R}. \tag{3.7}$$

Thus, it follows from (2.11) that

$$\begin{aligned}\operatorname{supp}\bar\sigma(x) &\subseteq \begin{cases} \{M\} & \text{if } H(\bar y(x),M,\bar\psi(x)) > H(\bar y(x),0,\bar\psi(x)),\\ \{0\} & \text{if } H(\bar y(x),M,\bar\psi(x)) < H(\bar y(x),0,\bar\psi(x)),\\ \{0,M\} & \text{if } H(\bar y(x),M,\bar\psi(x)) = H(\bar y(x),0,\bar\psi(x)) \end{cases}\\ &= \begin{cases} \{M\} & \text{if } \bar\varphi(x) > h\\ \{0\} & \text{if } \bar\varphi(x) < h\\ \{0,M\} & \text{if } \bar\varphi(x) = h \end{cases} \qquad \text{a.e. } x \in \Omega,\end{aligned} \tag{3.8}$$

where

$$h = \frac{F(0,M) - F(0,0)}{M} \tag{3.9}$$

and

$$\bar{\varphi}(x) = \bar{\psi}(x) - \frac{F\big(\bar{y}(x), M\big) - F\big(\bar{y}(x), 0\big)}{M} + h. \tag{3.10}$$

We have

$$\bar{\varphi}|_{\partial\Omega} = 0, \tag{3.11}$$

and by (P2),

$$h < 0. \tag{3.12}$$

Moreover, by (3.4), (3.6), and (P1), one has

$$\bar{\varphi}(\cdot) \in W^{2,p}(\Omega) \cap C^{1,\alpha}(\overline{\Omega}) \quad \forall\, p \in [1, +\infty), \quad \alpha \in (0,1). \tag{3.13}$$

By (3.11)–(3.12), $\{\bar{\varphi} > h\}$ has a positive measure. Since

$$\int_U v\bar{\sigma}(x)(dv) \geq 0 \quad \text{in } \Omega$$

and (3.8) implies

$$\int_U v\bar{\sigma}(x)(dv) = M > 0 \quad \text{a.e. } x \in \{\bar{\varphi} > h\},$$

we must have

$$\bar{y}(x) > 0 \quad \text{in } \Omega \tag{3.14}$$

by the strong maximum principle for elliptic partial differential equations (see [16, Ch. 3]).

On the other hand, (3.8) implies

$$\operatorname{supp} \bar{\sigma}(x) = \{0\} \quad \text{a.e. } x \in \{\bar{\varphi} < h\}. \tag{3.15}$$

A crucial property of $\bar{\varphi}(\cdot)$ is that $\Omega_1 \equiv \{\bar{\varphi} < h\}$ has a zero measure. Otherwise, suppose that Ω_1 has a positive measure. Then it is an open set since $\bar{\varphi}(\cdot)$ is continuous by (3.13). Then (3.11) and $h < 0$ lead to

$$\bar{\varphi}|_{\partial\Omega_1} = h. \tag{3.16}$$

Consequently, by (2.8)–(2.9), (3.15), and (P1)–(P2), we obtain

$$
\begin{aligned}
(3.17)\quad -\triangle\bar{\varphi}(x) &= -\triangle\bar{\psi}(x) + \triangle\,\frac{F\big(\bar{y}(x),M\big)-F\big(\bar{y}(x),0\big)}{M}\\
&= -\int_U F_y\big(\bar{y}(x),v\big)\,\bar{\sigma}(x)(dv) + \frac{F_y\big(\bar{y}(x),M\big)-F_y\big(\bar{y}(x),0\big)}{M}\triangle\bar{y}(x)\\
&\quad + \frac{F_{yy}\big(\bar{y}(x),M\big)-F_{yy}\big(\bar{y}(x),0\big)}{M}\,|\nabla\bar{y}(x)|^2\\
&= -F_y\big(\bar{y}(x),0\big) + \frac{F_{yy}\big(\bar{y}(x),M\big)-F_{yy}\big(\bar{y}(x),0\big)}{M}\,|\nabla\bar{y}(x)|^2\\
&\ge -F_y\big(\bar{y}(x),0\big)\\
&\ge -F_y(0,0)\ge 0 \quad \text{a.e. } x\in\Omega_1.
\end{aligned}
$$

Combining the above with (3.16) and the weak maximum principle for elliptic partial differential equations, we get that

$$\bar{\varphi}(x)\ge h \quad \text{a.e. } x\in\Omega_1.$$

This is a contradiction. Therefore, Ω_1 must be of zero measure, and

$$\bar{\varphi}(x)\ge h \quad \text{a.e. } x\in\Omega. \tag{3.18}$$

With the above preparation, we are now ready to prove our main results.

(i) Let $\ell\ge 0$. It is enough to prove that there is a classical control $\bar{u}(\cdot)\in\mathcal{U}$ such that

$$J(\bar{u}(\cdot))\le J(\bar{\sigma}(\cdot)). \tag{3.19}$$

In fact, by (3.7) and (3.18), one has

$$H(\bar{y}(x),M,\bar{\psi}(x)) = \max_{v\in U} H(\bar{y}(x),v,\bar{\psi}(x)) \quad \text{a.e. } x\in\Omega.$$

Combining the above with (2.10)–(2.11), we see that for almost all $x\in\Omega$,

$$w\bar{\psi}(x) - F\big(\bar{y}(x),w\big) = M\bar{\psi}(x) - F\big(\bar{y}(x),M\big) \quad \forall\, w\in\operatorname{supp}\bar{\sigma}(x).$$

Thus,

$$
\begin{aligned}
(3.20)\quad J(\bar{\sigma}(\cdot)) &= \frac{1}{2}\int_\Omega dx\int_U 2F\big(\bar{y}(x),v\big)\,\bar{\sigma}(x)(dv)\\
&= \frac{1}{2}\int_\Omega dx\int_U \big[(v-M)\bar{\psi}(x) + F\big(\bar{y}(x),M\big) + F\big(\bar{y}(x),v\big)\big]\,\bar{\sigma}(x)(dv)\\
&= \frac{1}{2}\int_\Omega dx\int_U \big[-\bar{y}(x)F_y\big(\bar{y}(x),v\big) - M\bar{\psi}(x) + F\big(\bar{y}(x),M\big)\\
&\qquad + F\big(\bar{y}(x),v\big)\big]\,\bar{\sigma}(x)(dv);
\end{aligned}
$$

here we have used the equality

$$
\begin{aligned}
&\int_\Omega dx\int_U v\bar{\psi}(x)\,\bar{\sigma}(x)(dv)\\
&\quad = \int_\Omega (-\triangle\bar{y}(x))\bar{\psi}(x)\,dx\\
&\quad = \int_\Omega \bar{y}(x)(-\triangle\bar{\psi}(x))\,dx\\
&\quad = -\int_\Omega dx\int_U \bar{y}(x)F_y\big(\bar{y}(x),v\big)\,\bar{\sigma}(x)(dv).
\end{aligned}
$$

Now, let $V = \{0, M\}$ and $\mathcal{R}(\Omega, V)$ be defined similarly to $\mathcal{R}(\Omega, U)$. Consider the relaxed system

$$\begin{cases} -\triangle\, y(x) = \displaystyle\int_V v\sigma(x)(dv) \quad \text{in } \Omega, \\ -\triangle\, \psi(x) = -\displaystyle\int_V F_y\big(y(x), v\big)\sigma(x)(dv) \quad \text{in } \Omega, \\ y|_{\partial\Omega} = \psi|_{\partial\Omega} = 0 \end{cases} \tag{3.21}$$

and the cost functional

$$\begin{aligned} J^*(\sigma(\cdot)) = \frac{1}{2}\int_\Omega dx \int_V \big[&-y(x)F_y\big(y(x), v\big) \\ &- M\psi(x) + F\big(y(x), M\big) + F\big(y(x), v\big)\big]\,\sigma(x)(dv). \end{aligned} \tag{3.22}$$

Thus $\bar\sigma(\cdot) \in \mathcal{R}(\Omega, V)$ and

$$J^*(\bar\sigma(\cdot)) = J(\bar\sigma(\cdot)). \tag{3.23}$$

Since $\ell \geq 0$, by Lemma 3.3, which will be proved below, we have

$$J^*(\delta_{\bar u(\cdot)}) \leq J^*(\sigma(\cdot)) \quad \forall\, \sigma(\cdot) \in \mathcal{R}(\Omega, V)$$

with

$$\bar u(\cdot) \equiv M.$$

In particular,

$$J(\bar u(\cdot)) = J^*(\delta_{\bar u(\cdot)}) \leq J^*(\bar\sigma(\cdot)) = J(\bar\sigma(\cdot)).$$

The first equality in the above can be verified directly, almost by following the same idea for proving (3.23).

Thus, we have proved that $\bar u(\cdot)$ is an optimal classical control for Problem (C). As a matter of fact, the proof of Lemma 3.3 will show that

$$\bar\sigma(x) = \delta_{\bar u(x)} \quad \text{a.e. } x \in \Omega.$$

(ii) Let $\ell < 0$. We will prove that $\operatorname{supp}\bar\sigma(x)$ is not a singleton in a positive measure set. By (3.8), $\operatorname{supp}\bar\sigma \subseteq \{0, M\}$ for almost all $x \in \Omega$. Thus, we need to show that $\big\{\operatorname{supp}\bar\sigma = \{0, M\}\big\}$ has positive measure, which can be proved if we prove that $E_M \equiv \big\{\operatorname{supp}\bar\sigma \neq \{M\}\big\}$ has positive measure and $E_0 \equiv \big\{\operatorname{supp}\bar\sigma = \{0\}\big\}$ has zero measure.

If E_M has zero measure, by (2.8)–(2.9) and (3.1), we have

$$\bar\psi(x) = \zeta(x) \quad \text{in } \Omega.$$

Thus, it follows from (3.2) and (3.10) that

$$\inf_{x\in\Omega} \bar\varphi(x) = \ell + h < h.$$

This contradicts (3.18). Therefore, E_M has a positive measure.

By (3.8) and (3.18), it holds that

$$\bar{\varphi}(x) = h \quad \text{a.e. } x \in E_0.$$

Thus, by (2.13) and (3.13),

$$-\triangle\, \bar{\varphi}(x) = 0 \quad \text{a.e. } x \in E_0.$$

On the other hand, noting that (3.17) holds on E_0, we get

$$-\triangle\, \bar{\varphi}(x) \geq -F_y\big(\bar{y}(x), 0\big) > -F_y(0,0) \geq 0 \quad \text{a.e. } x \in E_0$$

by (3.3), (3.14), and (P2).

Thus, we see that $0 > 0$ a.e. on E_0. That is, E_0 has a zero measure.

To summarize, we have that $\big\{\operatorname{supp} \bar{\sigma} = \{0, M\}\big\}$ has a positive measure. In other words, an optimal relaxed control of Problem (R) will not be an element of $\mathcal{U}$. Therefore, Problem (C) does not have optimal controls. □

Now we present a lemma used in the proof of the above theorem. Let

$$\mathbf{f}(\cdot) = \begin{pmatrix} f^1(\cdot) \\ f^2(\cdot) \end{pmatrix}, \qquad \mathbf{y}(\cdot) = \begin{pmatrix} y^1(\cdot) \\ y^2(\cdot) \end{pmatrix}. \tag{3.24}$$

Consider the relaxed system

$$\begin{cases} -\triangle\, \mathbf{y} = \displaystyle\int_V \mathbf{f}(\mathbf{y}(x), v)\sigma(x)(dv) \quad \text{in } \Omega, \\ \mathbf{y}|_{\partial\Omega} = 0 \end{cases} \tag{3.25}$$

and the corresponding cost functional

$$\widehat{J}(\sigma(\cdot)) = \int_\Omega dx \int_V f^0(\mathbf{y}(x), v)\sigma(x)(dv). \tag{3.26}$$

We have the following proposition.

PROPOSITION 3.2. *Let $V = \{0, M\}$ and $f^i(\cdot) \in C^1(\mathbb{R}^3)$ $(i = 0, 1, 2)$. Consider* (3.25)–(3.26). *If*

$$\frac{\partial f^1}{\partial y^1}(y^1, y^2, v) \leq 0, \quad \frac{\partial f^1}{\partial y^2}(y^1, y^2, v) = 0, \quad \frac{\partial f^2}{\partial y^2}(y^1, y^2, v) \leq 0, \tag{3.27}$$

then there exists at least one relaxed control $\bar{\sigma}(\cdot)$ minimizing $\widehat{J}(\cdot)$ over $\mathcal{R}(\Omega, V)$. Moreover, let $\bar{\mathbf{y}}(\cdot)$ be the solution of (3.25) *with $\sigma(\cdot)$ replaced by $\bar{\sigma}(\cdot)$, and let $\mathbf{\Psi}(\cdot)$ be the solution of*

$$\begin{cases} -\triangle\, \mathbf{\Psi}(x) = \displaystyle\int_V \big\{\mathbf{f}_{\mathbf{y}}\big(\bar{\mathbf{y}}(x), v\big)\mathbf{\Psi}(x) - f^0_{\mathbf{y}}\big(\bar{\mathbf{y}}(x), v\big)\big\}\bar{\sigma}(x)(dv) \quad \textit{in } \Omega, \\ \mathbf{\Psi}|_{\partial\Omega} = 0, \end{cases} \tag{3.28}$$

where

$$\mathbf{f}_{\mathbf{y}} = \begin{pmatrix} \frac{\partial f^1}{\partial y^1} & \frac{\partial f^2}{\partial y^1} \\ \frac{\partial f^1}{\partial y^2} & \frac{\partial f^2}{\partial y^2} \end{pmatrix}.$$

Then

$$\text{supp}\,\bar{\sigma}(x) \subseteq \Big\{ w \in V \;\Big|\; \widehat{H}(x,w) = \max_{v\in V} \widehat{H}(x,v) \Big\} \quad \textit{a.e. } x \in \Omega, \tag{3.29}$$

where

$$\widehat{H}(x,v) = \langle \mathbf{\Psi}(x), \mathbf{f}(\bar{\mathbf{y}}(x),v)\rangle - f^0(\bar{\mathbf{y}}(x),v).$$

The above proposition still holds if V is replaced by a compact subset of $\mathbb{R}$. It can be proved similarly to Theorems 3.2 and 4.1 in [19]. We omit the proof here. Note that (3.27) is mainly used to guarantee the existence and uniqueness of a solution to (3.25), while Proposition 2.2 can be regarded as a special case of Proposition 3.2.

LEMMA 3.3. *Let $V = \{0, M\}$ and* (P1)–(P2) *hold. Consider the relaxed system* (3.21)–(3.22). *Let ℓ be defined by* (3.1)–(3.2) *and $\ell \geq 0$. Then*

$$J^*(\delta_{\bar{u}(\cdot)}) \leq J^*(\sigma(\cdot)) \quad \forall\, \sigma(\cdot) \in \mathcal{R}(\Omega, V),$$

where

$$\bar{u}(x) \equiv M.$$

Proof. By Proposition 3.2, one can find a relaxed control $\bar{\sigma}(\cdot)$ minimizing $J^*(\cdot)$ over $\mathcal{R}(\Omega, V)$. Moreover,

$$\text{supp}\,\bar{\sigma}(x) \subseteq \Big\{ w \in V \;\Big|\; H^*(x,w) = \max_{v\in V} H^*(x,v) \Big\} \quad \text{a.e. } x \in \Omega, \tag{3.30}$$

where

$$\begin{aligned} H^*(x,u) = \Psi(x)u - \big(z(x) - \bar{y}(x)\big) F_y\big(\bar{y}(x),u\big) - F\big(\bar{y}(x),u\big) \\ + M\bar{\psi}(x) - F\big(\bar{y}(x),M\big) \end{aligned}$$

with $\bar{y}(\cdot)$ solving the following equation:

$$\begin{cases} -\triangle\, \bar{y}(x) = \displaystyle\int_V v\bar{\sigma}(x)(dv) & \text{in } \Omega, \\ -\triangle\, \bar{\psi}(x) = -F_y\big(\bar{y}(x),v\big)\bar{\sigma}(x)(dv) & \text{in } \Omega, \\ \bar{y}|_{\partial\Omega} = \bar{\psi}|_{\partial\Omega} = 0, \end{cases} \tag{3.31}$$

where $z(\cdot)$ is defined by (3.1) and $\Psi(\cdot)$ is the solution of

$$\begin{cases} -\triangle\, \Psi(x) = \displaystyle\int_V F_{yy}\big(\bar{y}(x),v\big)\bar{\sigma}(x)(dv)\,\big(\bar{y}(x) - z(x)\big) \\ \qquad\qquad - F_y\big(\bar{y}(x),M\big) \qquad\qquad \text{in } \Omega, \\ \Psi|_{\partial\Omega} = 0. \end{cases} \tag{3.32}$$

We claim that

$$\text{supp}\,\bar{\sigma}(x) = \{M\} \quad \text{a.e. } x \in \Omega. \tag{3.33}$$

Otherwise, both

$$\widetilde{E} \triangleq \Big\{ x \in \Omega \;\Big|\; \int_V v\bar{\sigma}(x)(dv) < M \Big\}$$

and

$$E \triangleq \Big\{ x \in \Omega \;\Big|\; H^*(x,M) \le H^*(x,0) \Big\} = \Big\{ x \in \Omega \;\Big|\; \Psi(x) \le \Phi(x) \Big\}$$

have positive measures (see (3.30)), where

$$\Phi(x) \triangleq \frac{F_y\big(\bar y(x), M\big) - F_y\big(\bar y(x), 0\big)}{M} \big(z(x) - \bar y(x)\big) + \frac{F\big(\bar y(x), M\big) - F\big(\bar y(x), 0\big)}{M}. \tag{3.34}$$

Since

$$\int_V v \bar\sigma(x)(dv) \le M \quad \text{in } \Omega,$$

while the strict inequality holds on $\widetilde{E}$, by the strong maximum principle for elliptic equations we obtain (see (3.1) and (3.31))

$$\bar y(x) < z(x) \quad \text{a.e. } x \in \Omega. \tag{3.35}$$

Thus, by (P1) it holds that (see (3.1) and (3.32))

(3.36)

$$\begin{aligned}
&-\triangle(\Psi - \zeta) \\
&= \int_V F_{yy}(\bar y, v)\bar\sigma(x)(dv)\,(\bar y - z) - F_y(\bar y, M) + F_y(z, M) \\
&= \left[\int_V F_{yy}(\bar y, v)\bar\sigma(x)(dv) - \int_0^1 F_{yy}(\bar y + t(z-\bar y), M)\,dt\right](\bar y - z) \\
&= \int_V \bar\sigma(x)(dv) \int_0^1 dt \int_0^1 \big[F_{yyy}\big(\bar y + st(z-\bar y), v + s(M-v)\big)(z-\bar y)^2 \\
&\qquad\qquad + F_{yyu}\big(\bar y + st(z-\bar y), v + s(M-v)\big)(M-v)(z-\bar y)\big]\,ds \\
&\ge 0.
\end{aligned}$$

Therefore,

$$\Psi(x) \ge \zeta(x) \quad \text{a.e. } x \in \Omega. \tag{3.37}$$

On the other hand (note (3.34)),

$$\begin{aligned}
&\frac{F\big(z(x), M\big) - F\big(z(x), 0\big)}{M} - \Phi(x) \\
&= \big(z(x) - \bar y(x)\big)^2 \int_0^1 dt \int_0^1 ds \int_0^1 F_{yu}\big(\bar y(x) + \alpha t(z(x) - \bar y(x)), sM\big)\,d\alpha \\
&\ge 0.
\end{aligned}$$

Thus, it follows from (3.2) and $\ell \ge 0$ that

$$\begin{aligned}
\Psi(x) &\ge \zeta(x) \ge \zeta(x) - \ell \\
&\ge \frac{F\big(z(x), M\big) - F\big(z(x), 0\big)}{M} \ge \Phi(x) \quad \text{in } \Omega.
\end{aligned}$$

Consequently,

$$E \subseteq \Big\{ x \in \Omega \;\Big|\; \Psi(x) = \zeta(x) \Big\} \triangleq E_0$$

and

$$E \subseteq \left\{ x \in \Omega \;\middle|\; \zeta(x) = \frac{F\big(z(x), M\big) - F\big(z(x), 0\big)}{M} \right\} \triangleq E_1.$$

Since E has a positive measure, so do E_0 and E_1.

By (3.36) and the strong maximum principle for elliptic equations, E_0 has a positive measure, which means that

$$\Psi(x) \equiv \zeta(x) \quad \text{in } \Omega. \tag{3.38}$$

Thus, by (3.38), we can get from (3.36) and (3.35) that, for almost all $x \in \Omega$,

$$\begin{array}{l} F_{yyy}\big(\bar{y}(x) + st(z(x) - \bar{y}(x)), v + s(M - v)\big) = 0 \\ F_{yyu}\big(\bar{y}(x) + st(z(x) - \bar{y}(x)), v + s(M - v)\big) = 0 \end{array} \quad \forall\, s, t \in [0,1], \quad v \in \operatorname{supp} \bar{\sigma}(x)$$

since in (3.36), both of the two terms before the symbol "$\geq$" are nonnegative.

Noting that

$$\widetilde{E} = \Big\{ x \;\Big|\; \operatorname{supp} \bar{\sigma}(x) \supseteq \{0\} \Big\}$$

and that it has a positive measure, one must have

$$F_{yyy}(y,u) = 0, \quad F_{yyu}(y,u) = 0 \quad \forall\, y \in [0, \max z], \quad u \in [0, M]. \tag{3.39}$$

On the other hand, for any $\sigma(\cdot) \in \mathcal{R}(\Omega, V)$, the corresponding solution $y(\cdot; \sigma(\cdot))$ of (3.21) satisfies

$$0 \leq y(x; \sigma(\cdot)) \leq z(x) \quad \forall\, x \in \Omega.$$

Thus, combining the above with (3.39), we can suppose that

$$F_{yyy}(y,u) = 0, \quad F_{yyu}(y,u) = 0 \quad \forall\, y \in \mathbb{R}, \quad u \in [0, M], \tag{3.40}$$

without loss of generality. Therefore,

$$F(y,u) = Ay^2 + g(u)y + h(u) \quad \forall\, y \in \mathbb{R}, \quad u \in [0, M],$$

where A is a constant and $g(\cdot), h(\cdot) \in C^3[0, M]$. Thus, by (3.1)

$$\begin{aligned} &-\triangle\, \zeta(x) \\ &\quad = -F_y(z(x), M) \\ &\quad = -2Az(x) - g(M) \quad \text{in } \Omega. \end{aligned} \tag{3.41}$$

Further, it follows from Lemma 2.3 that

$$\begin{aligned} &-\triangle\, \zeta(x) \\ &\quad = -\triangle\, \frac{F\big(z(x), M\big) - F\big(z(x), 0\big)}{M} \\ &\quad = -\triangle \left[\frac{g(M) - g(0)}{M} z(x) + \frac{h(M) - h(0)}{M} \right] \\ &\quad = g(M) - g(0) \quad \text{a.e. } x \in E_1. \end{aligned}$$

Therefore,

$$-2Az(x) = 2g(M) - g(0) \quad \text{a.e. } x \in E_1. \tag{3.42}$$

Case 1. $A \neq 0$. We have

$$z(x) = \frac{g(0) - 2g(M)}{2A} \quad \text{a.e. } x \in E_1.$$

Consequently, by (2.13) and $z \in W^{2,2}(\Omega)$, it holds that

$$-\triangle z(x) = 0 \quad \text{a.e. } x \in E_1.$$

Thus, combining the above with (3.1), we get

$$M = 0 \quad \text{a.e. } x \in E_1.$$

This contradicts that E_1 has a positive measure.

Case 2. $A = 0$. In this case, (3.41) and (3.42) imply

$$-\triangle \zeta(x) = -g(M) \quad \text{in } \Omega$$

and

$$g(0) = 2g(M). \tag{3.43}$$

Thus,

$$\zeta(x) = -\frac{g(M)}{M} z(x) \quad \text{in } \Omega.$$

Therefore, by (3.43) and the definition of E_1,

$$\begin{aligned} -\frac{g(M)}{M} z(x) &= \zeta(x) \\ &= \frac{F\big(z(x), M\big) - F\big(z(x), 0\big)}{M} \\ &= \frac{g(M) - g(0)}{M} z(x) + \frac{h(M) - h(0)}{M} \\ &= -\frac{g(M)}{M} z(x) + \frac{h(M) - h(0)}{M} \quad \text{a.e. } x \in E_1. \end{aligned}$$

Consequently,

$$h(M) - h(0) = 0,$$

since E_1 has a positive measure. This contradicts

$$h(M) - h(0) = F(0, M) - F(0, 0) < 0.$$

The above two cases show that no matter what A is, we always end up with a contradiction. Hence, (3.33) must hold, namely,

$$\bar{\sigma}(x) = \delta_M = \delta_{\bar{u}(x)} \quad \text{a.e. } x \in \Omega,$$

proving our lemma. □

Next, for the case that $F_{yy}F_{yu} \geq 0$, we have the following result.

THEOREM 3.4. *Let $M > 0$, $F \in C^3(\mathbb{R} \times [0, M])$, and*

$$F_{uu}(y, u) < 0 \quad \forall\, y \in \mathbb{R}, \quad u \in [0, M].$$

Moreover, suppose that one of the following conditions holds:

(Q1) $F_y(0, 0) \leq 0$ *and* $\forall\, y \geq 0$, $u \in [0, M]$,

$$\begin{aligned} &F_{yy}(y, u) \leq 0, \quad F_{yu}(y, u) \leq 0, \quad F_{yyu}(y, u) \geq 0, \\ &F_{yy}(y, u) + F_{yu}(y, u) < 0. \end{aligned}$$

(Q2) $F_y(0, 0) \geq 0$ *and* $\forall\, y \geq 0$, $u \in [0, M]$,

$$\begin{aligned} &F_{yy}(y, u) \geq 0, \quad F_{yu}(y, u) \geq 0, \quad F_{yyu}(y, u) \leq 0, \\ &F_{yy}(y, u) + F_{yu}(y, u) > 0. \end{aligned}$$

Then Problem (C) *admits at least one optimal control. In fact, any optimal relaxed control of Problem* (R) *is an optimal classical control of Problem* (C).

Proof. Without loss of generality, we suppose that (Q1) holds.

Similar to that in the proof of Theorem 3.1, the relaxed problem (R) admits an optimal relaxed control $\bar{\sigma}(\cdot) \in \mathcal{R}(\Omega, U)$. What we need to prove is that for almost all $x \in \Omega$, $\operatorname{supp} \bar{\sigma}(x)$ is a singleton. To this end, let $\bar{y}(\cdot)$, $\bar{\psi}(\cdot)$, $\bar{\varphi}(\cdot)$, and h be defined as in the proof of Theorem 3.1 (see (2.8)–(2.9) and (3.9)–(3.10)). Then (3.8) holds and thus we need only prove that for almost all $x \in \{\bar{\varphi} = h\}$, $\operatorname{supp} \bar{\sigma}(x)$ is a singleton.

We claim that for almost all $x \in \{\bar{\varphi} = h\}$,

$$\operatorname{supp} \bar{\sigma}(x) = \{0\}. \tag{3.44}$$

If it is not the case, then

$$E \triangleq \big\{x \;\big|\; \operatorname{supp} \bar{\sigma}(x) \neq \{0\}\big\} \cap \{\bar{\varphi} = h\}$$

has a positive measure, and consequently,

$$\bar{y}(x) > 0 \quad \forall\, x \in \Omega.$$

By (2.13), for almost all $x \in E$, it holds that

$$\begin{aligned} 0 = -\triangle \bar{\varphi}(x) &= -\triangle \bar{\psi}(x) + \triangle \frac{F\big(\bar{y}(x), M\big) - F\big(\bar{y}(x), 0\big)}{M} \\ &= -\int_U F_y\big(\bar{y}(x), v\big)\, \bar{\sigma}(x)(dv) + \frac{F_y\big(\bar{y}(x), M\big) - F_y\big(\bar{y}(x), 0\big)}{M} \triangle \bar{y}(x) \\ &\quad + \frac{F_{yy}\big(\bar{y}(x), M\big) - F_{yy}\big(\bar{y}(x), 0\big)}{M} |\nabla \bar{y}(x)|^2. \end{aligned} \tag{3.45}$$

Since (Q1) implies that all three terms in (3.45) are nonnegative, we get that for almost all $x \in E$,

$$\int_U F_y\big(\bar{y}(x), v\big)\, \bar{\sigma}(x)(dv) = 0, \tag{3.46}$$

$$\frac{F_y\big(\bar{y}(x), M\big) - F_y\big(\bar{y}(x), 0\big)}{M} \int_U v\, \bar{\sigma}(x)(dv) = 0. \tag{3.47}$$

Let $x \in E$ be a point satisfying (3.46)–(3.47). Then we have the following cases.

Case 1.

$$\frac{F_y\big(\bar{y}(x), M\big) - F_y\big(\bar{y}(x), 0\big)}{M} \neq 0; \tag{3.48}$$

then

$$\int_U v\,\bar{\sigma}(x)(dv) = 0,$$

and (3.44) follows.

Case 2.

$$\frac{F_y\big(\bar{y}(x), M\big) - F_y\big(\bar{y}(x), 0\big)}{M} = 0. \tag{3.49}$$

By (Q1), we must have

$$F_{yu}\big(\bar{y}(x), u\big) = 0 \quad \forall\, u \in [0, M]$$

and consequently,

$$F_{yy}(\bar{y}(x), 0) < 0.$$

Therefore, by (Q1) and the continuity of F_{yy}, we get

$$\begin{aligned} F_y\big(\bar{y}(x), v\big) &\leq F_y\big(\bar{y}(x), 0\big) \\ &= \int_0^1 F_{yy}\big(t\bar{y}(x), 0\big)\bar{y}(x)\,dt + F_y(0,0) \\ &< 0 \quad \forall\, v \in [0, M]. \end{aligned}$$

Combining the above with (3.46), we get (3.44).

Thus, (3.44) holds for almost all $x \in E$. This is a contradiction. Consequently, (3.44) holds for almost all $\{\bar{\varphi} = h\}$ and we conclude the proof. □

Now, let us look at the case that $(y, u) \mapsto F(y, u)$ is quadratic, i.e.,

$$F(y, u) = ay^2 + byu + cu^2.$$

The following is a summary of what we have obtained in the above for this special case:

(i) If $c \geq 0$, then Cesari's condition holds and Problem (C) admits at least one optimal control.

(ii) If $c < 0$, $a < 0$, $b > 0$, then (P1)–(P2) and (3.3) hold. Thus, we can solve Problem (C) by using Theorem 3.1. More precisely, let

$$\begin{cases} -\triangle\,\xi(x) = 1 & \text{in } \Omega, \\ \xi|_{\partial\Omega} = 0. \end{cases}$$

Then Problem (C) admits at least one optimal control if and only if

$$\max_{x\in\Omega} \xi(x) \leq -\frac{c}{2b}.$$

(iii) If $c < 0$ and $a = b = 0$, then Problem (C) is trivial. It admits an optimal control $\bar{u}(\cdot) \equiv M$.

(iv) If $c < 0$ and $ab \geq 0$, $a + b \neq 0$, then F satisfies the conditions of Theorem 3.4. Thus, any optimal relaxed control $\bar{\sigma}(\cdot)$ is in fact a classical control. Therefore, Problem (C) admits at least one optimal control in this case.

From the above, one can see how our results apply to the quadratic functional case.

Note that in establishing existence results without convexity conditions, most authors assumed that the state and the control are separated in the cost functional, i.e., the functionals take the form $g(x, y(x)) + h(x, u(x))$. On the other hand, Mariconda [24] considered the case when the state variable y and the control variable u are not separated in the integrand of the cost functional, but he assumed that the integrand is concave in the state variable y. As we have seen from our Theorems 3.1 and 3.4, such a concavity is neither sufficient nor necessary for guaranteeing the existence of an optimal control.

Finally, we point out that in some cases, conditions that we presented for guaranteeing the existence of an optimal control are not only sufficient but also necessary. (Consider the cases when $M > 0$, (P1)–(P2), and (3.3) hold. Then, Theorem 3.1 shows that Problem (C) admits at least one optimal control if and only if $\ell \geq 0$.)

Acknowledgment. The author would like to thank the anonymous referees for their helpful comments.

NUMERICAL APPROXIMATIONS FOR NONZERO-SUM STOCHASTIC DIFFERENTIAL GAMES*

HAROLD J. KUSHNER†

Abstract. The Markov chain approximation method is a widely used and efficient family of methods for the numerical solution of many types of stochastic control problems in continuous time for reflected-jump-diffusion–type models. It converges under broad conditions, and it has been extended to zero-sum stochastic differential games. We apply the method to a class of nonzero stochastic differential games with a diffusion system model where the controls for the two players are separated in the dynamics and cost function. There have been successful applications of the algorithms, but convergence proofs have been lacking. It is shown that equilibrium values for the approximating chain converge to equilibrium values for the original process and that any equilibrium value for the original process can be approximated by an ϵ-equilibrium for the chain for arbitrarily small $\epsilon > 0$. The numerical method solves a stochastic game for a finite-state Markov chain.

Key words. stochastic differential games, nonzero-sum games, numerical methods, Markov chain approximations

1. Introduction.

The aim of this paper is to extend the Markov chain approximation method to numerically solve nonzero-sum stochastic differential games. The method is widely used, robust, and relatively easy to implement. It covers the majority of stochastic control problems in continuous time, for controlled reflected-jump-diffusion–type models of recent interest, and converges under broad conditions. The method was extended to zero-sum stochastic differential games in [16, 17, 18], with the last two references concerned with the ergodic cost case, extending partial prior results such as those of [1, 22, 23]. There has been successful numerical work done on nonzero-sum differential games [12, 13], based on this procedure, but there do not seem to exist results concerning convergence. Works such as [5] are concerned with approximations to nonzero-sum games in normal form and do not apply to the system models or to the type of approximations that appear in our numerical approximations.

We will consider a discounted cost problem for a diffusion model in a compact set G with absorption on the boundary. The state space G and the boundary absorption are selected only to simplify the development so that we can concentrate on the issues that are unique to the nonzero-sum case. One can replace the boundary absorption by boundary reflection if the reflection directions satisfy the conditions in [19] or in [16]. We will work with two-player games. Any number of players can be dealt with, but we stick to two for notational simplicity. The nonzero-sum game is difficult because, as opposed to the zero-sum case, its players are not strictly competitive and have their own value functions, and the methods of proof used previously need considerable modification.

The idea of the Markov chain approximation method is to first approximate the controlled diffusion dynamics by a suitable Markov chain on a finite state space with a discretization parameter h, then approximate the cost functions. One solves the game problem for the simpler chain model, and then proves that the value functions associated with equilibrium or ϵ-equilibrium strategies for the chain converge to the value functions associated with equilibrium or ϵ_1-equilibrium strategies for the diffusion model, where $\epsilon_1 \to 0$ as $\epsilon \to 0$. The methods of proof are purely probabilistic; i.e., no PDE techniques are required, so knowledge of whatever PDEs yield the equilibrium values is not needed. The essential condition is a natural "local consistency" condition. Getting approximations that satisfy this condition is usually straightforward. Many methods are discussed in [19] and all of them are applicable to the game problem of interest here. Furthermore, the numerical approximations are represented as processes which are close to the original, which gives the method intuitive meaning. We are not concerned with algorithms for numerically solving the game for the chain model, but rather show only convergence of the solutions to the desired values as the discretization parameter goes to zero.

Let us comment briefly on some of the particular difficulties posed by the nonzero-sum problem. The convergence proof for the single-player case works roughly as follows. One solves for the optimal (cost minimizing) controls for the approximating chain, with optimal value function $V^h(x)$ for approximation parameter h and initial condition x. Then one interpolates the corresponding chain into a continuous-time process and shows that the weak-sense limit is a controlled diffusion. The limit value function $\liminf V^h(x)$ cannot be better than the optimal value $V(x)$ for the diffusion. To show that $\limsup V^h(x)$ cannot be greater than $V(x)$, one uses a particular $0 < \epsilon$-optimal control for the original process that can be applied to the chain for each value of h, and such that the weak-sense limit (process, control) is just the ϵ-optimal (process, control) for the original model. Since the cost values for the chain under this control are no less than $V^h(x)$, the limit is the ϵ-optimal diffusion process. Since ϵ is arbitrary, we have that $\limsup V^h(x) \le V(x)$. Hence $V^h(x) \to V(x)$.

The proof for the two-person zero-sum game in [16] is much harder, but the essential goal is similar. One has the advantages that the controls are determined by a minmax operation and that there is a single cost function, so that one player's gain is another's loss—properties that the nonzero-sum game does not have. One gets an ϵ-optimal *strategy* for player 2 (resp., for player 1), the maximizing (resp., minimizing) player, that is designed such that it can be applied to the approximating chain, no matter what the other players policy is, and such that in the limit, one has this strategy for player 2 (resp., for player 1) and some arbitrary control for player 1 (resp., for player 2). One uses these and the minmax relations to show that the lim inf of the sequence of upper values and lim sup of the sequence of lower values for the chain must be between the lower and upper values for the original problem. Then the uniqueness of the value (proved in [16]) for the original problem yields the desired result.[1]

Such an approach cannot be applied to the nonzero-sum game, where each player has its own value function and one seeks Nash equilibria instead of minmax = maxmin solutions. Furthermore, unique equilibria are not too common, and we are forced to look much more closely at the structure of the chain and (for the purposes of the proof, not for the numerics) try to approximate it so that it has a "diffusion" form with a

[1]The papers [17, 18] concern the ergodic cost function and use quite different methods and relaxed feedback controls.

driving process that does not heavily depend on the control, with minimal change in the values. This requires that we work with strong-sense solutions, rather than with the weak-sense solutions that were used in [19]. Unlike in the single-player problem, one must work with strategies and not simply controls, at least for one player at a time.

In section 2, the model and the cost functions for the players are defined, the boundary conditions are discussed, and a review of some background material is given. We also give a "uniform in the controls" discrete-time approximation that will be used in what follows. The convergence proof heavily depends on the fact that the players' strategies for the original diffusion process can be simplified (uniformly in the controls), with various approximations to the controls and with some players' controls delayed. The necessary results are developed in section 3. A particular representation of an ϵ-equilibrium *strategy*, in terms of a "smooth" conditional probability, depending only on selected samples of the driving Wiener process (and not on the entire Wiener process), is given in section 4. This representation of the strategy will be crucial to the proof. Various facts concerning the Markov chain approximation are collected in subsection 5.1. The reader is referred to [19] for a fuller treatment.

The numerical algorithms use the approximating Markov chain. But the proof of convergence requires that we approximate (uniformly in the controls or strategies) this approximating chain by a process that is driven by a particular martingale difference process which allows us to get analogues of the various approximation results (in section 3); i.e., to show that the probability law of the chain and the costs change little if the control process is approximated in various ways. These results are new and should be of broad use in dealing with numerical approximations. Theorem 6.1 in section 6 shows that an "approximate" equilibrium (value or strategy) for the diffusion is an "approximate" equilibrium (value or strategy) for the chain for a small discretization parameter h. If the ϵ-equilibrium value for the chain is unique for small $\epsilon > 0$, then the convergence proof is complete since an approximate equilibrium value for the chain is also one for the diffusion. If the value is not unique, then the proof of this last fact is more difficult, and we restrict our attention to the case where the diffusion coefficient does not depend on the state. This is done in Theorem 6.2, which is a consequence of Theorem 5.6, which, in turn, applies a strong approximation theorem to show that the discrete-time approximation to the diffusion and that for the interpolated chain are very close, uniformly in the controls.

2. The model. We consider systems of the following form where $x(t) \in \mathbb{R}^v$, Euclidean v-space,

$$x(t) = x(0) + \int_0^t \sum_{i=1}^{2} b^i(x(s), u_i(s))ds + \int_0^t \sigma(x(s))dw(s), \tag{2.1}$$

where player i, $i = 1, 2$, has control $u_i(\cdot)$, and $w(\cdot)$ is a standard vector-valued Wiener process. The control stops at the first time τ that the boundary of a set G is hit (it equals infinity if the boundary is never reached). More will be said about G following Condition A2.1 and in Condition A2.2. Let $\beta > 0$ and let E_x^u denote the expectation given the use of control $u(\cdot) = (u_1(\cdot), u_2(\cdot))$ and initial condition x. Then the cost function for player i is

$$W_i(u) = E_x^u \int_0^\tau e^{-\beta t} k_i(x(s), u_i(s))ds + E_x^u e^{-\beta\tau} g_i(x(\tau)). \tag{2.2}$$

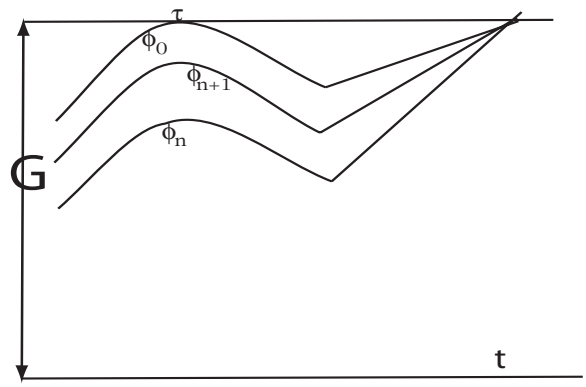

FIG. 1. *Continuity of first exit times.*

Define $b(\cdot) = b^1(\cdot) + b^2(\cdot)$, $k(\cdot) = k_1(\cdot) + k_2(\cdot)$. The following condition is assumed to hold.

CONDITION A2.1. *The functions $b^i(\cdot)$ and $\sigma(\cdot)$ are bounded, continuous, and Lipschitz continuous in x, uniformly in u. The controls $u_i(\cdot)$ for player i take values in U_i, a compact set in some Euclidean space, and the functions $k_i(\cdot)$ and $g_i(\cdot)$ are bounded and continuous.*

A control $u_i(\cdot)$ is said to be in $\mathcal{U}_i$, the set of admissible controls for player i, if it is measurable, nonanticipative with respect to $w(\cdot)$, and U_i-valued. Later we will introduce strategies and admissible relaxed controls. Part of the proof uses a weak convergence analysis as in [19], and to the extent possible we use the results of that reference. For S a topological space, let $D[S;0,\infty)$ denote the S-valued functions on $[0,\infty)$ that are right-continuous and have left-hand limits, and with the Skorkohod topology [7, 19] used. If $S = \mathbb{R}^v$, then we write $D[S;0,\infty) = D^v[0,\infty)$.

The first hitting time τ. Getting numerical solutions requires working in a bounded state space. Often the physics of the problem provide both a bounded state space and the proper boundary conditions. Otherwise, "numerical" boundaries are added. In any case, one needs to provide the necessary boundary conditions. These will be equivalent to either reflection or absorption at the boundary. Both are covered in [19]. Here, we chose boundary absorption, but the details that are unique to the nonzero-sum game problem would be the same in both cases.

The nature of the hitting time τ of the boundary of the set G poses a particular concern from the point of view of the convergence of the numerical algorithm. The proof of convergence generates a sequence of process approximations (continuous-time interpolations of the approximating chain), and the exit or boundary hitting time of this sequence has to converge, in an appropriate probabilistic sense, to the exit time of (2.1). In fact, no matter what the numerical procedure, something analogous must take place. In order to see the problem, refer to Figure 1. In the figure, the sequence of functions $\phi_n(\cdot)$ converges to the limit function $\phi_0(\cdot)$, but the sequence of first contact times (τ_n) of $\phi_n(\cdot)$ converges to a time τ_0, which is not the moment τ of first contact of $\phi_0(\cdot)$ with the boundary line ∂G of G. The problem in this case is that the limit function $\phi_0(\cdot)$ is tangent to ∂G at the time of first contact.

For our control problem, if the approximating costs are to converge to the costs for (2.1), (2.2), then we need to ensure, at least with probability one (w.p.1), that the paths of the limit $x(\cdot)$ are not "tangent" to ∂G at the moment τ of first

hitting the boundary. For $\phi(\cdot)$ in $D^v[0,\infty)$ (with the Skorokhod topology used), define the function $\hat{\tau}(\phi)$ with values in the compactified infinite interval $\overline{\mathbb{R}}^+ = [0,\infty]$ by $\hat{\tau}(\phi) = \infty$ if $\phi(t) \in G^0$, the interior of G, for all $t < \infty$; otherwise use

$$\hat{\tau}(\phi) = \inf\{t : \phi(t) \notin G^0\}.$$

In the example of Figure 1, $\hat{\tau}(\cdot)$ is not continuous at the path $\phi_0(\cdot)$.

If the $\phi_0(\cdot)$ in the figure were a sample path of a Wiener process $w(\cdot)$, then the probability would be zero that it is "tangent" to the boundary of G at the point of first contact. Indeed, w.p.1, the path would cross the line infinitely often in any small time interval after first contact. Hence, w.p.1, the first hitting times of any approximating sequence would converge to the first hitting time of $w(\cdot)$. The situation is similar if the Wiener process were replaced by the solution to a stochastic differential equation with a uniformly positive definite covariance matrix $a(x) = \sigma(x)\sigma'(x)$ if the boundary ∂G of G is "smooth." The following condition will be used. Note that the condition on the stopping time can be assured to hold if the randomized stopping approximation discussed below is used.

CONDITION A2.2. *For a continuous real-valued function $\Phi(\cdot)$ on $\mathbb{R}^v$, define $G = \{x : \Phi(x) \le 0\}$, and suppose that it is the closure of its interior $\{x : \Phi(x) < 0\}$. For each initial condition and control, the function $\hat{\tau}(\cdot)$ is continuous (as a map from $D^v[0,\infty)$ to the compactified interval $[0,\infty]$) w.p.1 relative to the measure induced by the solution to* (2.1).

The tangency problem would be a concern with any numerical method, since they all depend on some sort of approximation. For example, the convergence theorems for the classical finite difference methods for elliptic and parabolic equations generally use a nondegeneracy condition on $a(x)$ in order to (implicitly) guarantee Condition A2.2.

The verification of Condition A2.2 for the case where $a(x)$ is degenerate is more complicated, and one needs to work with the particular structure of the individual case. The boundary can often be divided into several pieces, where we are able to treat each piece separately. For example, there might be a segment where a "directional nondegeneracy" of $a(x)$ guarantees the almost sure continuity of the exit times of the paths which exit on that segment, plus a segment where the direction of the drift gives a similar guarantee, plus a segment on which escape is not possible, and finally a "remaining" segment. Frequently, the last "complementary" set is a finite set of points or a curve of dimension lower than that of the boundary. Special considerations concerning these points can often resolve the issue there. An important class of such a degenerate example is illustrated in [14, pp. 64–66]. In that two-dimensional example, G is the symmetric square box centered about the origin, the system is ($x = (x_1, x_2)$)

$$\begin{aligned} dx_1 &= x_2 dt, \\ dx_2 &= u dt + dw, \end{aligned}$$

and the control $u(\cdot)$ is bounded. The above cited "complementary set" is just the two points which are the intersections of the horizontal axis with the boundary, and these points can be taken care of by a test such as that in Theorem 6.1 of [21].[2]

Randomized stopping. An alternative to Condition A2.2. The boundaries in control problems are often not fixed precisely. For example, they might be introduced simply to bound the state space. The original control problem might be defined in

[2]See also [19, p. 280], where it is shown that the Girsanov transformation can play a useful role in the verification of Condition A2.2.

an unbounded space, but the space is then truncated for numerical reasons. Even if there is a given "target set," it is often not necessary to fix it too precisely. Such considerations give us some freedom to slightly vary the boundary. The "randomized stopping" alternative discussed next exploits these ideas and ensures Condition A2.2. Under randomized stopping, the probability of stopping at time t (if the process has not yet been stopped) goes to unity at that time as $x(t)$ approaches ∂G. This can be formalized as follows [19].

For some small $\epsilon > 0$, let $\bar{\lambda}(\cdot) > 0$ be a continuous function on the set $N_\epsilon(\partial G) \cap G^0$, where $N_\epsilon(\partial G)$ is the ϵ-neighborhood of the boundary and G^0 is the interior of G. Let $\bar{\lambda}(x) \to \infty$ as x converges to ∂G. Then stop $x(\cdot)$ at time t with stopping rate $\bar{\lambda}(x(t))$ and stopping cost $g_i(x(t))$ for player i. Randomized stopping is equivalent to adding an additional (and state-dependent) discount factor which is active near the boundary.

Relaxed controls $r_i(\cdot)$. In control theory, when working with problems concerning convergence of sequences or approximations, it is usual to use the so-called relaxed controls in lieu of ordinary controls. They are used for theoretical purposes only, i.e., to get approximation and convergence proofs. Suppose that for some filtration $\{\mathcal{F}_t, t < \infty\}$, standard vector-valued $\mathcal{F}_t$-Wiener process $w(\cdot)$, and for $i = 1, 2$, $r_i(\cdot)$ is a measure on the Borel sets of $U_i \times [0, \infty)$ such that $r_i(U_i \times [0, t]) = t$ and the process $r_i(A \times [0, \cdot])$ is measurable and nonanticipative for each Borel set $A \subset U_i$. Then $r_i(\cdot)$ is said to be an *admissible relaxed control* for player i with respect to $w(\cdot)$ [8, 19]. Abusing notation slightly, we use $\mathcal{U}_i$ for the set of admissible relaxed controls as well as for the set of admissible ordinary controls $u_i(\cdot)$. If the Wiener process and filtration are obvious or unimportant, we simply say that $r_i(\cdot)$ is an admissible relaxed control or a relaxed control for player i. For Borel sets $A \subset U_i$, we will write $r_i(A \times [t_0, t_1]) = r_i(A, [t_0, t_1])$, and write $r_i(A, t_1)$ if $t_0 = 0$. Define $U = U_1 \times U_2$ and $\mathcal{U} = \mathcal{U}_1 \times \mathcal{U}_2$. Henceforth $\{\mathcal{F}_t\}$ will denote a filtration such that $w(\cdot)$ is an $\mathcal{F}_t$-standard Wiener process and $r(\cdot)$ is admissible for the $r(\cdot)$ of concern.

For almost all (ω, t) and each Borel $A \subset U_i$, one can define the left derivative[3]

$$r_i'(A, t) = \lim_{\delta \to 0} \frac{r_i(A, t) - r_i(A, t - \delta)}{\delta}.$$

Without loss of generality, we can suppose that the limit exists for all (ω, t). Then for all (ω, t), $r_i'(\cdot, t)$ is a probability measure on the Borel sets of U_i, and for any bounded Borel set B in $U_i \times [0, \infty)$,

$$r_i(B) = \int_0^\infty \int_{U_i} I_{\{(\alpha_i, t) \in B\}} r_i'(d\alpha_i, t) dt.$$

An ordinary control $u_i(\cdot)$ can be represented in terms of the relaxed control $r_i(\cdot)$ that is defined by its derivative, which takes the form $r_i'(A, t) = I_A(u_i(t))$, where $I_A(u_i)$ is unity if $u_i \in A$ and is zero otherwise. The weak topology [19] will be used on the space of admissible relaxed controls. Relaxed controls are commonly used in control theory to prove existence and approximation theorems, since any sequence of relaxed controls has a weakly convergent subsequence. The use of relaxed controls does not change the range of values of the cost functions.

Define the "product" relaxed control $r(\cdot)$ by its derivative $r'(\cdot, t) = r_1'(\cdot, t) \times r_2'(\cdot, t)$. Thus $r(\cdot)$ is a product measure, with marginals $r_i(\cdot), i = 1, 2$. We will usually write $r(\cdot) = (r_1(\cdot), r_2(\cdot))$ without ambiguity. The pair $(w(\cdot), r(\cdot))$ is called an *admissible*

[3] "Left" is used because we need the derivative to be nonanticipative.

pair if each $r_i(\cdot)$ is admissible with respect to $w(\cdot)$. In relaxed control terminology, (2.1) and (2.2) are written as

$$\begin{aligned} x(t) &= x(0) + \sum_{i=1}^{2} \int_0^t \int_{U_i} b^i(x(s), \alpha_i) r_i'(d\alpha_i, s) ds + \int_0^t \sigma(x(s)) dw(s) \\ &= x(0) + \int_0^t \int_{U_i} b(x(s), \alpha_i) r'(d\alpha_i, s) ds + \int_0^t \sigma(x(s)) dw(s), \end{aligned} \tag{2.3}$$

$$W_i(x, r) = E_x^r \int_0^\tau e^{-\beta t} \int_{U_i} k_i(x(s), \alpha_i) r_i'(d\alpha_i, s) ds + E_x^r e^{-\beta\tau} g_i(x(\tau)). \tag{2.4}$$

The drift terms can be written as, e.g., $\int_0^t \int_U b(x(s), \alpha) r'(d\alpha, s) ds$.

A discrete-time system. We will also need the discrete-time form

$$\begin{aligned} x^\Delta(n\Delta + \Delta) = x^\Delta(n\Delta) &+ \int_{n\Delta}^{n\Delta+\Delta} \int_U b(x^\Delta(n\Delta), \alpha) r'(d\alpha, s) ds \\ &+ \sigma(x^\Delta(n\Delta))[w(n\Delta + \Delta) - w(\Delta)]. \end{aligned} \tag{2.5}$$

We can define the continuous-time interpolation $x^\Delta(\cdot)$ either by $x^\Delta(t) = x^\Delta(n\Delta)$ for $t \in [n\Delta, n\Delta + \Delta)$, or as (on the same interval)

$$x^\Delta(t) = x^\Delta(n\Delta) + \int_{n\Delta}^t \int_U b(x^\Delta(n\Delta), \alpha) r'(d\alpha, s) ds + \int_{n\Delta}^t \sigma(x^\Delta(n\Delta)) dw(t), \tag{2.6}$$

where it is assumed that $r(t, \cdot)$ is adapted to $\mathcal{F}_{n\Delta-}$ for $t \in [n\Delta, n\Delta + \Delta)$. The associated cost function $W_i^\Delta(x, r)$ is (2.4) with $x^\Delta(\cdot)$ replacing $x(\cdot)$. Let $r^\Delta(\cdot), r(\cdot)$ be admissible relaxed controls with respect to $w(\cdot)$ with $r^\Delta(\cdot) \to r(\cdot)$ w.p.1 (in the weak topology) and $r^\Delta(\cdot)$ adapted as above. Then, as $\Delta \to 0$, the sequence of solutions $\{x^\Delta(\cdot)\}$ also converges w.p.1, uniformly on any bounded time interval, and the limit $(x(\cdot), r(\cdot), w(\cdot))$ solves (2.3). By Condition A2.2, the first hitting times of the boundary also converge w.p.1 to that of the limit. The costs converge as well. The analogous result holds if the randomized stopping alternative is used.

Randomized and relaxed controls. For the discrete-time system (2.5) or (2.6), the relaxed control can be approximated by a randomized ordinary control (which relates the relaxed control to randomized strategies) as follows. Let $r(\cdot)$ be a relaxed control that is admissible with respect to $w(\cdot)$. Let $\tilde{u}_{i,n}^\Delta$ be a random variable with the distribution $r_{i,n}^\Delta(\cdot) = E_{n\Delta}\left[r_i\left(\cdot, [n\Delta, n\Delta + \Delta]\right)\right]/\Delta$, where $E_{n\Delta}$ denotes the conditional expectation given $\mathcal{F}_{n\Delta-}$. Set $\tilde{u}_n^\Delta = (\tilde{u}_{1,n}^\Delta, \tilde{u}_{2,n}^\Delta)$, define its continuous-time interpolation (with intervals Δ) $\tilde{u}^\Delta(\cdot)$, and define $\tilde{x}^\Delta(0) = x^\Delta(0) = x(0)$ and

$$\tilde{x}^\Delta(n\Delta + \Delta) = \tilde{x}^\Delta(n\Delta) + \Delta b(\tilde{x}^\Delta(n\Delta), \tilde{u}_n^\Delta) + \sigma(\tilde{x}^\Delta(n\Delta))[w(n\Delta + \Delta) - w(n\Delta)]. \tag{2.7}$$

Let $\tilde{x}^\Delta(t)$ denote the continuous-time interpolation. Define $r_n^\Delta(\cdot) = r_{1,n}^\Delta(\cdot) r_{2,n}^\Delta(\cdot)$, and let $r^\Delta(\cdot)$ be the relaxed control with derivative $r_n^\Delta(\cdot)$ on $[n\Delta, n\Delta + \Delta)$. Then we have the following result, where $r^\Delta(\cdot)$ is used for $x^\Delta(\cdot)$ in (2.6). The theorem implies that in the continuous limit, randomized controls turn into relaxed controls.

THEOREM 2.1. *Assume Condition* A2.1 *and use* $r_n^\Delta(\cdot)$ *in* (2.5) *and* (2.6). *Then for any* $T < \infty$,

$$\lim_{\Delta \to 0} \sup_{x(0) \in G} \sup_{r \in \mathcal{U}} E \sup_{t \le T} \left| x^\Delta(t) - x(t) \right|^2 = 0, \tag{2.8a}$$

$$\lim_{\Delta \to 0} \sup_{x(0) \in G} \sup_{r \in \mathcal{U}} E \sup_{t \le T} \left| x^\Delta(t) - \tilde{x}^\Delta(t) \right|^2 = 0. \tag{2.8b}$$

Under the additional Condition A2.2*, the costs for* (2.5) *and* (2.7) *converge* (*uniformly in* $x(0), r(\cdot)$) *to those for* (2.3) *as well.*

Comment on the proof. Define $\delta x_n^\Delta = x^\Delta(n\Delta) - \tilde{x}^\Delta(n\Delta)$. Then

$$\begin{aligned}\delta x_{n+1}^\Delta = \delta x_n^\Delta + \Delta \int_U \left[b(x^\Delta(n\Delta),\alpha) - b(\tilde{x}^\Delta(n\Delta),\alpha)\right] r_n^\Delta(d\alpha) \\ + \left[\sigma(x^\Delta(n\Delta)) - \sigma(\tilde{x}^\Delta(n\Delta))\right][w(n\Delta+\Delta) - w(n\Delta)] + N_n^\Delta,\end{aligned}$$

where

$$N_n^\Delta = \Delta\left[\int_U b(\tilde{x}^\Delta(n\Delta),\alpha) r_n^\Delta(d\alpha) - b(\tilde{x}^\Delta(n\Delta),\tilde{u}_n^\Delta)\right]$$

is an $\mathcal{F}_{n\Delta}$- martingale difference by the definition of $\tilde{u}_n^\Delta(\cdot)$ via the conditional distribution given $\mathcal{F}_{n\Delta}$. Also $E_{n\Delta}|N_n^\Delta|^2 = O(\Delta^2)$. The proof of the uniform (in the control and initial condition) convergence to zero of $|x^\Delta(\cdot) - \tilde{x}^\Delta(\cdot)|$ and of the differences between the integrals

$$E\int_0^t e^{-\beta t} k(\tilde{x}^\Delta(s),\tilde{u}^\Delta(s))ds, \quad E\int_0^t\int_U e^{-\beta t} k(x^\Delta(s),\alpha) r^{\Delta,\prime}(d\alpha,s)ds$$

can then be completed by using the Lipschitz condition and this martingale and conditional variance property. This implies (2.8b). An analogous argument can be used to get (2.8a) for each $r(\cdot)$ and $x(0)$. The facts that Condition A2.2 holds for (2.3) and that (2.8) holds imply that the stopping times for $x^\Delta(\cdot), \tilde{x}^\Delta(\cdot)$ converge to those for (2.3) as well, for each $x(0)$ and $r(\cdot)$.

The uniformity in (2.8b) and in the convergence of the costs can be proved by an argument by contradiction that goes roughly as follows. Suppose, for example, that the uniformity in (2.8b) does not hold. Then, for intervals Δ_m and relaxed controls $r^m(\cdot), m = 1, 2, \ldots$, define $r_n^{m,\Delta_m}(\cdot)$ as $r_n^\Delta(\cdot)$ was, but based on $r^m(\cdot)$, and let $r^{m,\Delta_m}(\cdot)$ denote the interpolation of the associated relaxed control. Let $\Delta_m \to 0$. Let $x^m(\cdot)$ solve (2.3) and $x^{m,\Delta_m}(\cdot)$ solve (2.6), both under $r^m(\cdot)$. Let $\tilde{x}^{m,\Delta_m}(\cdot)$ solve (2.7) under $r^{m,\Delta_m}(\cdot)$. Suppose that, for some $T < \infty$, $\limsup_{m\to\infty} E\sup_{t\le T}|x^{m,\Delta_m}(t) - \tilde{x}^{m,\Delta_m}(t)|^2 > 0$.

Take an arbitrary weakly convergent subsequence of $x^m(\cdot), x^{m,\Delta_m}(\cdot)$, $\tilde{x}^{m,\Delta_m}(\cdot)$, $r^m(\cdot)$, $r^{m,\Delta_m}(\cdot)$, $w(\cdot)$, also indexed by m and with the (weak-sense) limit denoted by $x(\cdot), \hat{x}(\cdot), \tilde{x}(\cdot), r(\cdot), \hat{r}(\cdot), \hat{w}(\cdot)$. Then it is easy to show that $x(\cdot) = \hat{x}(\cdot) = \tilde{x}(\cdot)$ and $r(\cdot) = \hat{r}(\cdot)$, that $\hat{w}(\cdot)$ is a standard Wiener process, that $x(\cdot), \hat{x}(\cdot), \tilde{x}(\cdot), \hat{r}(\cdot)$ are nonanticipative with respect to $\hat{w}(\cdot)$, and that the limit set satisfies (2.3). Assume, without loss of generality, that Skorokhod representation is used [7, 19] so that we can suppose that the original and limit processes are all defined on the same probability space and that convergence is w.p.1 in the Skorokhod topology. Then

$$\lim_{m\to\infty} E\sup_{t\le T}\left|\tilde{x}^{m,\Delta_m}(t) - \hat{x}(t)\right|^2 = 0$$

and

$$\lim_{m\to\infty} E\sup_{t\le T}\left|x^{m,\Delta_m}(t) - \hat{x}(t)\right|^2 = 0,$$

a contradiction to the assertion that the uniformity in $x(0)$ and $r(\cdot)$ in (2.8b) does not hold. □

3. Approximating the controls. The convergence proofs will require the use of special approximations to the general ordinary or relaxed controls, and the necessary approximations are developed in this section and in Theorem 4.1.

For each admissible relaxed control $r(\cdot)$ and $\epsilon > 0$, let $r_i^\epsilon(\cdot)$ be admissible relaxed controls with respect to the same filtration and Wiener process $w(\cdot)$, with derivatives $r_i^{\epsilon,\prime}(\cdot)$, and that satisfy

$$\lim_{\epsilon\to 0} \sup_{r_i\in\mathcal{U}_i} E \sup_{t\le T} \left| \int_0^t \int_{U_i} \phi_i(\alpha_i) \left[r_i'(d\alpha_i, s) - r_i^{\epsilon,\prime}(d\alpha_i, s) \right] ds \right| = 0, \quad i = 1, 2, \tag{3.1}$$

for each bounded and continuous real-valued nonrandom function $\phi_i(\cdot)$ and each $T < \infty$. Let $x(\cdot)$ and $x^\epsilon(\cdot)$ denote the solutions to (2.3) corresponding to $r(\cdot)$ and $r^\epsilon(\cdot)$, resp., with the same $w(\cdot)$ used, but perhaps different initial conditions. In particular, define $x^\epsilon(\cdot)$ by

$$x^\epsilon(t) = x^\epsilon(0) + \int_0^t \int_U b(x^\epsilon(s), \alpha) r^{\epsilon,\prime}(d\alpha, s) ds + \int_0^t \sigma(x^\epsilon(s)) dw(s). \tag{3.2}$$

The processes $x(\cdot)$ and $x^\epsilon(\cdot)$ depend on $r(\cdot)$ and $r^\epsilon(\cdot)$, resp., but this dependence is suppressed in the notation. The next theorem shows that the solution $x(\cdot)$ is continuous in the controls in the sense that (3.3) below holds, and that the costs corresponding to $r(\cdot)$ and $r^\epsilon(\cdot)$ are arbitrarily close for small ϵ, uniformly in $r(\cdot)$.

THEOREM 3.1. *Assume Condition* A2.1. *Let* $(r(\cdot), r^\epsilon(\cdot))$ *satisfy* (3.1) *for each bounded and continuous* $\phi_i(\cdot), i = 1, 2$, *and* $T < \infty$. *Define* $\delta x^\epsilon(t) = x^\epsilon(t) - x(t)$. *Then for each* t,

$$\lim_{\epsilon\to 0} \sup_{x(0), x^\epsilon(0): |x^\epsilon(0) - x(0)| \to 0} \sup_{r\in\mathcal{U}} E \sup_{s\le t} |\delta x^\epsilon(s)|^2 = 0. \tag{3.3}$$

Under the additional Condition A2.2,

$$\lim_{\epsilon\to 0} \sup_{x(0), x^\epsilon(0): |x^\epsilon(0) - x(0)| \to 0} \sup_{r\in\mathcal{U}} |W_i(x, r) - W_i(x, r^\epsilon)| = 0, \quad i = 1, 2. \tag{3.4}$$

Comments on the proof. The proof is very similar to that of Theorem 2.1, and we comment only on the use of (3.1). We can write

$$\begin{aligned} \delta x^\epsilon(t) = \delta x^\epsilon(0) &+ \int_0^t \int_U \left[b(x^\epsilon(s), \alpha) - b(x(s), \alpha) \right] r'(d\alpha, s) ds \\ &+ \int_0^t \left[\sigma(x^\epsilon(s)) - \sigma(x(s)) \right] dw(s) \\ &+ \int_0^t \int_U b(x^\epsilon(s), \alpha) \left[r^{\epsilon,\prime}(d\alpha, s) - r'(d\alpha, s) \right] ds. \end{aligned} \tag{3.5}$$

It will be seen that the sup over any finite time interval of the absolute value of the last term of (3.5) goes to zero in mean square, by virtue of (3.1). For small $\lambda > 0$, that term can be rewritten as (modulo $O(\lambda)$)

$$\begin{aligned} &\sum_{l=0}^{[t/\lambda]-1} \int_{l\lambda}^{l\lambda+\lambda} \int_U b(x^\epsilon(l\lambda), \alpha) \left[r^{\epsilon,\prime}(d\alpha, s) - r'(d\alpha, s) \right] ds \\ &+ \sum_{l=0}^{[t/\lambda]-1} \int_{l\lambda}^{l\lambda+\lambda} \left[b(x^\epsilon(s), \alpha) - b(x^\epsilon(l\lambda), \alpha) \right] \left[r^{\epsilon,\prime}(d\alpha, s) - r'(d\alpha, s) \right] ds. \end{aligned} \tag{3.6}$$

Here $[t/\lambda]$ denotes the integer part of t/λ. As $\lambda \to 0$ the expectation of the square of the sup over any finite interval of the last term goes to zero, uniformly in $r(\cdot), r^\epsilon(\cdot), x(0)$, $x^\epsilon(0)$, whether or not (3.1) holds, since

$$\lim_{\lambda\to 0} \sup_r \sup_\epsilon \sup_{l\lambda\le t} E \sup_{s\le\lambda} |x^\epsilon(l\lambda+s) - x^\epsilon(l\lambda)|^2 = 0. \tag{3.7}$$

Assumption (3.1) can be used to show that the same uniform limit in mean square holds for the first term of (3.6) for any λ, as $\epsilon \to 0$. The proof of (3.3) is a consequence of these facts and the Lipschitz condition. The convergence of the costs is a consequence of the convergence of the paths and controls, and an argument concerning the convergence of the stopping times such as used in Theorem 2.1. □

Finite-valued and piecewise-constant approximations $r^\epsilon(\cdot)$ in (3.1). Now some approximations of subsequent interest will be described. It will be seen that we can confine our attention to control processes that are just piecewise-constant and finite-valued ordinary admissible controls. Consider the following discretization of the U_i. Let $U_i \in \mathbb{R}^{c_i}$, Euclidean c_i-space. Given $\mu > 0$, partition $\mathbb{R}^{c_i}$ into disjoint (hyper)cubes $\{R_i^{\mu,l}\}$ with diameters μ. The boundaries can be assigned to the subsets in any way. Define $U_i^{\mu,l} = U_i \cap R_i^{\mu,l}$ for the finite number (p_i^μ) of nonempty intersections. Choose a point $\alpha_i^{\mu,l} \in U_i^{\mu,l}$. Now, given admissible $(r_1(\cdot), r_2(\cdot))$, define the approximating admissible relaxed control $r_i^\mu(\cdot)$ on the control value space $U_i^\mu = \{\alpha_i^{\mu,l}, l \le p_i^\mu\}$ by its derivative as $r_i^{\mu,\prime}(\alpha_i^{\mu,l}, t) = r_i'(U_i^{\mu,l}, t)$. Denote the set of such controls by $\mathcal{U}_i(\mu)$. The following theorem is a consequence of Theorem 3.1. A version can also be found in [16].

THEOREM 3.2. *Assume Conditions* A2.1–A2.2*, and the above approximation of $r_i(\cdot)$ by $r_i^\mu(\cdot) \in \mathcal{U}_i(\mu), i = 1, 2$. Then* (3.1) *and Theorem* 3.1 *hold for μ replacing ϵ, no matter what the $\{U_i^{\mu,l}, \alpha_i^{\mu,l}\}$ are. The same result holds if we approximate only one of the $r_i(\cdot)$.*

Finite-valued, piecewise-constant, and "delayed" approximations. The proofs of convergence depend on showing that the cost changes little if the control actions of any player are discretized in time and are slightly delayed. Let $r_i^\mu(\cdot) \in \mathcal{U}_i(\mu)$, where the control value space for player i is U_i^μ. Let $\Delta > 0$. Define the "backward" differences $\Delta_{i,k}^{\mu,l} = r_i^\mu(\alpha_i^{\mu,l}, k\Delta) - r_i^\mu(\alpha_i^{\mu,l}, k\Delta - \Delta)$, $l \le p_i^\mu$, $k = 1, \ldots$. Define the piecewise-constant ordinary controls $u_i^{\mu,\Delta}(\cdot) \in \mathcal{U}_i(\mu)$ on the interval $[k\Delta, k\Delta + \Delta)$ by

$$u_i^{\mu,\Delta}(t) = \alpha_i^{\mu,l} \text{ for } t \in \left[k\Delta + \sum_{\nu=1}^{l-1} \Delta_{i,k}^{\mu,\nu},\ k\Delta + \sum_{\nu=1}^{l} \Delta_{i,k}^{\mu,\nu}\right). \tag{3.8}$$

Note that on $[k\Delta, k\Delta + \Delta)$, $u_i^{\mu,\Delta}(\cdot)$ takes the value $\alpha_i^{\mu,l}$ on a time interval of length $\Delta_{i,k}^{\mu,l}$. Note also that the $u_i^{\mu,\Delta}(\cdot)$ are "delayed," in that the values of $r_i(\cdot)$ on $[k\Delta - \Delta, k\Delta)$ determine the values of $u_i^{\mu,\Delta}(\cdot)$ on $[k\Delta, k\Delta + \Delta)$. Thus $u_i^{\mu,\Delta}(t), t \in [k\Delta, k\Delta + \Delta)$, is $\mathcal{F}_{k\Delta-}$-measurable. Let $r_i^{\mu,\Delta}(\cdot)$ denote the relaxed control representation of $u_i^{\mu,\Delta}(\cdot)$, with time derivative $r_i^{\mu,\Delta,\prime}(\cdot)$. Let $\mathcal{U}_i(\mu, \delta)$ denote the subset of $\mathcal{U}_i(\mu)$ that are ordinary controls that are constant on the intervals $[l\delta, l\delta + \delta), l = 0, 1, \ldots$.

The intervals $\Delta_{i,k}^{\mu,l}$ in (3.8) are just real numbers. For later use, it is important to have them be some multiple of some small $\delta > 0$, where Δ/δ is an integer. Consider one method of doing this. Divide $[k\Delta, k\Delta + \Delta)$ into Δ/δ subintervals of length δ each. Working in order $l = 1, 2 \ldots$, to each value $\alpha_i^{\mu,l}$ first assign (the integer part) $[\Delta_{i,k}^{\mu,l}/\delta]$

successive subintervals of length δ. The total fraction of time that is unassigned on any bounded time interval will go to zero as $\delta \to 0$, and how control values are assigned to them will have little effect. However, for specificity for future use consider the following method. The unassigned length for value $\alpha_i^{\mu,l}$ is $L_{i,k}^{\mu,\delta,l} = \Delta_{i,k}^{\mu,l} - [\Delta_{i,k}^{\mu,l}/\delta]\delta$, $i \le p_i^\mu$. Define the sum $S_{i,k}^{\mu,\delta} = \sum_l L_{i,k}^{\mu,\delta,l}$, which must be an integral multiple of δ. Then assign each unassigned δ-interval at random with value $\alpha_{i,k}^{\mu,l}$ chosen with probability $L_{i,k}^{\mu,\delta,l}/S_{i,k}^{\mu,\delta}$. By Theorem 2.1, this assignment and randomization approximates the original relaxed control.

Let $\mathcal{U}_i(\mu,\delta,\Delta)$ denote the set of such controls. If $u_i^{\mu,\delta,\Delta}(\cdot)$ is obtained from $r_i(\cdot)$ in this way, then it is a function of $r_i(\cdot)$, but this functional dependence will be omitted in the notation. Let $r_i^{\mu,\Delta,\delta,\prime}(\cdot)$ denote the time derivative of $r_i^{\mu,\Delta,\delta}(\cdot)$. As stated in the next theorem, which is a consequence of Theorem 3.1, for fixed μ and small δ, $u_i^{\mu,\delta,\Delta}(\cdot)$ well approximates the effects of $u_i^{\mu,\Delta}(\cdot)$ and $r_i(\cdot)$, uniformly in $r_i(\cdot)$ and $\{\alpha_i^{\mu,l}\}$. In particular, (3.1) holds in the sense that for each $\mu > 0$, $\Delta > 0$, and bounded and continuous $\phi_i(\cdot)$, for $i = 1, 2$,

$$\lim_{\delta\to 0} \sup_{r_i\in\mathcal{U}_i} E \sup_{t\le T} \left| \int_0^t \int_{U_i} \phi_i(\alpha_i) \left[r_i^{\mu,\delta,\Delta,\prime}(d\alpha_i, s) - r_i^{\mu,\Delta,\prime}(d\alpha_i, s) \right] ds \right| = 0. \tag{3.9}$$

THEOREM 3.3. *Assume Conditions* A2.1–A2.2. *Let $r_i(\cdot) \in \mathcal{U}_i, i = 1, 2$. Given $(\mu,\delta,\Delta) > 0$, approximate as discussed above the theorem to get $r_i^{\mu,\delta,\Delta}(\cdot) \in \mathcal{U}_i(\mu,\delta,\Delta)$. Then* (3.1) *holds for $r_i^{\mu,\delta,\Delta}(\cdot)$ and (μ,δ,Δ) replacing $r_i^\epsilon(\cdot)$ and ϵ, respectively. Also,* (3.9) *holds. In particular, given $\epsilon > 0$, there are $\mu_\epsilon > 0, \delta_\epsilon > 0, \Delta_\epsilon > 0$, and $\kappa_\epsilon > 0$, such that for $\mu \le \mu_\epsilon, \delta \le \delta_\epsilon, \Delta \le \Delta_\epsilon$, and $\delta/\Delta \le \kappa_\epsilon$,*

$$\sup_x \sup_{r_1} \sup_{r_2} \left| W_i(x, r_1, r_2) - W_i(x, r_1, u_2^{\mu,\delta,\Delta}) \right| \le \epsilon. \tag{3.10}$$

The expression (3.10) *holds with the indices* 1 *and* 2 *interchanged or if both controls are approximated.*

Consider the discrete-time system (2.5) *with either the interpolation that is piecewise-constant or* (2.6). *Then the $\mu_\epsilon > 0, \delta_\epsilon > 0, \Delta_\epsilon > 0$, and $\kappa_\epsilon > 0$, can be defined so that*

$$\sup_x \sup_{r_1} \sup_{r_2} \left| W_i(x, r_1, r_2) - W_i^\Delta(x, r_1, u_2^{\mu,\delta,\Delta}) \right| \le \epsilon. \tag{3.11}$$

The expression (3.11) *holds with the indices* 1 *and* 2 *interchanged or if both controls are approximated and/or further delayed by Δ.*

Note on the initial values of the controls. Since the controls are delayed by Δ, we can assign the values on the initial interval $[0, \Delta]$ in any way. Let the values $u_i(l\delta), l\delta \le \Delta$, be in U_i^μ and fixed for $i = 1, 2$.

4. Equilibria and approximations. *Elliott–Kalton strategies.* The classical definition of strategy as used in differential games for models such as (2.1) or (2.3) is that of Elliott and Kalton [6, 9]. A strategy $c_1(\cdot)$ for player 1 is a mapping from $\mathcal{U}_2$ to $\mathcal{U}_1$ with the following property. If admissible controls $r_2(\cdot)$ and $\tilde{r}_2(\cdot)$ satisfy $r_2(s) = \tilde{r}_2(s)$ for $s \le t$, then $c_1(r_2)(s) = c_1(\tilde{r}_2)(s), s \le t$, and with an analogous definition for player 2 strategies. Let $\mathcal{C}_i$ denote the set of such strategies or mappings for player i. An Elliott–Kalton strategy is a generalization of a feedback control. The current control action that it yields for any player is a function only of the past

control actions and does not otherwise depend on the form of the strategy of the other player.

A pair $\bar{c}_i(\cdot) \in \mathcal{C}_i, i = 1, 2$, is said to be an ϵ-equilibrium strategy pair if for all admissible controls $r_i(\cdot), i = 1, 2$,[4]

$$\begin{aligned} W_1(x, \bar{c}_1, \bar{c}_2) &\geq W_1(x, r_1, \bar{c}_2) - \epsilon, \\ W_2(x, \bar{c}_1, \bar{c}_2) &\geq W_2(x, \bar{c}_1, r_2) - \epsilon. \end{aligned} \tag{4.1}$$

The notation $W_1(x, c_1, c_2)$ implies that each player i uses its strategy $c_i(\cdot)$. When writing $W_i(x, c_1, c_2)$, it is assumed that the associated process is well defined. This will be the case here, since Theorem 3.3 implies that it is sufficient to restrict attention to strategies whose control functions are piecewise-constant and finite-valued and can depend only on slightly delayed values of the other players' control realizations. If (4.1) holds with $\epsilon = 0$, then we have an equilibrium strategy pair. The controls can be either ordinary or relaxed. The notation $W_2(x, c_1, r_2)$ implies that player 1 uses its strategy $c_1(\cdot)$ and player 2 uses the relaxed control $r_2(\cdot)$.

The above definition of strategy does not properly allow for randomized controls, where the realized responses given by the strategy of a player to a fixed control process of the other player might differ, depending on the random choices that it makes. So we also allow randomized strategies that have the form of the second line in (4.2) below for either one or both of the players. Theorem 2.1 shows the connection between relaxed and randomized controls.

We will require the following assumption.[5]

ASSUMPTION A4.1. *For each small $\epsilon > 0$ there is an ϵ-equilibrium Elliott–Kalton strategy $(\bar{c}_1^\epsilon(\cdot), \bar{c}_2^\epsilon(\cdot))$ under which the solution to* (2.1) *or* (2.3) *is well defined.*

The following approximation theorem will be a key item in the development.

THEOREM 4.1. *Assume Conditions* A2.1 *and* A2.2. *Given $\epsilon_1 > 0$, there are positive numbers μ, δ, Δ, where Δ/δ is an integer, such that the values for any strategy pair $(c_1(\cdot), c_2(\cdot))$ with $c_i(\cdot) \in \mathcal{C}_i$, and under which the solution to* (2.3) *is well defined,*[6] *can be approximated within ϵ_1 by strategy pairs $c_i^{\mu,\delta,\Delta}(\cdot), i = 1, 2$, of the following form. The realizations of $c_i^{\mu,\delta,\Delta}(\cdot)$ (which depend on the other player's strategy or control) are ordinary controls in $\mathcal{U}_i(\mu, \delta, \Delta)$, and we denote them by $u_i^{\mu,\delta,\Delta}(\cdot)$. For integers n, k, and $k\delta \in [n\Delta, n\Delta + \Delta)$, and α_i taking values in U_i^μ,*

$$\begin{aligned} &P\left\{u_i^{\mu,\delta,\Delta}(k\delta) = \alpha_i \middle| w(s), s \leq k\delta; u_j^{\mu,\delta,\Delta}(l\delta), j = 1, 2, l < k\right\} \\ &= P\left\{u_i^{\mu,\delta,\Delta}(k\delta) = \alpha_i \middle| w(l\Delta), l \leq n; u_j^{\mu,\delta,\Delta}(l\delta), j = 1, 2, l\delta < n\Delta\right\} \\ &= p_{i,k}\left(\alpha_i;\, w(l\Delta), l \leq n; u_j^{\mu,\delta,\Delta}(l\delta), j = 1, 2, l\delta < n\Delta\right), \end{aligned} \tag{4.2}$$

[4]The definition in [6] requires that the controls $r_i(A, \cdot)$ be progressively measurable, and not simply measurable and adapted, for each Borel set A. But due to the approximation results of Theorems 3.1–3.3, this added requirement is unnecessary in our case.

[5]As noted above, one need only restrict attention to strategies that yield control processes that are piecewise-constant, finite-valued, and slightly delayed, or, indeed, to discrete-time systems with such controls. This moderates the assumption considerably. Assumption A4.1 is the weakest possible assumption concerning equilibria. If it does not hold, then there is no numerical problem, since there is no solution. Numerical analysis starts with whatever assumptions are needed to ensure that there is a solution. Criteria for the existence of equilibria are in [2, 4, 11]. See also the seminal work [10] and the review and references for stochastic differential games in general in [20].

[6]One or both of them might be simply fixed relaxed feedback controls.

which defines the functions $p_{i,k}(\cdot)$. For each positive value of μ, δ, Δ, the functions $p_{i,k}(\cdot)$ can be taken to be continuous in the w-arguments for each value of the other arguments.

Suppose that the control process realizations for player i are in $\mathcal{U}_i(\mu, \delta, \Delta)$, but those of the other player are general relaxed controls. Then we interpret (4.2)*, applied to that control, as being based on its discretized approximation, as derived above Theorem* 3.3.

A convenient representation of the values in (4.2). It will be useful for the convergence proofs if the random selections implied by the conditional probabilities in (4.2) are systematized as follows. Let $\{\theta_k\}$ be random variables that are mutually independent and uniformly distributed on $[0,1]$. The $\{\theta_k, k \geq l\}$ will be independent of all system data before time $l\delta$. For each i, n, k, divide $[0,1]$ into (random) subintervals whose lengths are proportional to the conditional probability of the $\alpha_i^{\mu,l}$ as given by (4.2), and select $u_i^{\mu,\delta,\Delta}(k\delta) = \alpha_i^{\mu,l}$ if the random selection of θ_k on $[0,1]$ falls into that subinterval. The same random variables $\{\theta_k\}$ are used for both players, and for all conditional probability rules of the form (4.2). This representation is used only for theoretical purposes.

Proof. By Theorem 3.3, it is sufficient to work with strategies $c_i^{\mu,\delta,\Delta}(\cdot), i = 1, 2$, whose control process realizations are in $\mathcal{U}_i(\mu, \delta, \Delta)$, and that in any interval $[n\Delta, n\Delta + \Delta)$ depend only on the control process values of the other player up to time $n\Delta - \Delta$. So we start with such strategies. However, we need to consider the response of such a strategy if the other player uses controls that are not already discretized. Since, for small μ, δ, Δ, a discretization of the other player's control realizations would have a negligible effect on the costs, uniformly in the control policy realizations of the first player, it is sufficient for the first player to act as though the controls of the other player were already discretized, by computing the discretization.

Continuing, let $u_i^{\mu,\delta,\Delta}(\cdot), i = 1, 2$, denote the policy realizations under the strategies $c_i^{\mu,\delta,\Delta}(\cdot), i = 1, 2$. The probability law of $(u_1^{\mu,\delta,\Delta}(\cdot), u_2^{\mu,\delta,\Delta}(\cdot), w(\cdot))$ determines the law of the corresponding solution to (2.1). The law of evolution of the controls can be written in recursive form, for $i = 1, 2$, and $k\delta \in [n\Delta, n\Delta + \Delta)$,

$$P\left\{u_i^{\mu,\delta,\Delta}(k\delta) = \alpha_i \middle| w(s), s \leq n\Delta; u_j^{\mu,\delta,\Delta}(l\delta), j = 1, 2, l\delta < n\Delta\right\}. \tag{4.3}$$

This yields a "randomized" Elliott–Kalton strategy pair.

Now apply the control rule (4.3) to the piecewise-constant interpolation of the discrete-time system (2.5). The probability law of the solution on $[0, t]$ is determined by the law of $\left(u_1^{\mu,\delta,\Delta}(l\delta), u_2^{\mu,\delta,\Delta}(l\delta), l\delta < t; w(n\Delta), n\Delta \leq t\right)$. Hence, for $k\delta \in [n\Delta, n\Delta + \Delta)$, the probability law of the controls and paths for $x^\Delta(\cdot)$ can be determined from the formula

$$P\left\{u_i^{\mu,\delta,\Delta}(k\delta) = \alpha_i \middle| w(l\Delta), l \leq n; u_j^{\mu,\delta,\Delta}(l\delta), j = 1, 2, l\delta < n\Delta\right\}. \tag{4.4}$$

By Theorem 3.3, for small enough δ, Δ the paths $x^\Delta(\cdot)$ and $x(\cdot)$ and the associated costs are arbitrarily close, uniformly in the controls $u_i^{\mu,\delta,\Delta}(\cdot), i = 1, 2$, where we can suppose (without loss of generality) that the law of evolution of the controls takes the form (4.4). This argument implies that we can restrict the conditioning on $w(\cdot)$ in (4.3) to the samples $w(l\Delta)$.

Now turn to the assertion concerning continuity in the w-arguments. (See also [19, Theorem 10.3.1] on this point.) For $\rho > 0$, consider the smoothed conditional probability defined by

$$p^{\rho}_{i,k}\left(\alpha_i;\, w(l\Delta), l \le n; u^{\mu,\delta,\Delta}_j(l\delta), j = 1,2, l\delta < n\Delta\right)$$
$$= N(\rho)\int e^{-|z-w|^2/2\rho} p_{i,k}\left(\alpha_i; z; u^{\mu,\delta,\Delta}_j(l\delta), j = 1,2, l\delta < n\Delta\right) dz,$$

where $N(\rho)$ is a normalizing constant and $w = \{w(l\Delta), l \le n\}$. The variable z has the same dimension as w. The integral is continuous in the w-variables, uniformly in the others. Also it converges to

$$p_{i,k}\left(\alpha_i;\, w(l\Delta), l \le n; u^{\mu,\delta,\Delta}_j(l\delta), j = 1,2, l\delta < n\Delta\right)$$

for almost all $\{w(l\Delta), l \le n\}$ values as $\rho \to 0$. Hence, by Egoroff's theorem, it converges almost uniformly in any compact set of $\{w(l\Delta), l \le n\}$ values. For almost all $\{w(l\Delta), l \le n\}$ values the smoothed conditional probability will choose the same control values as would the original rule defined by (4.4) with a probability that goes to unity as $\rho \to 0$. Hence, without loss of generality we can suppose that the $p_{i,k}(\cdot)$ are smooth in the w-variables, as asserted. □

5. The Markov chain approximation: Brief review and approximations.

5.1. The Markov chain approximation method. We will start by giving a quick overview of the Markov chain approximation method of [14, 15, 19], starting with some comments for the case where there is only one player. We will then develop some approximation results for the chains that are analogous to those in Theorem 3.3, and which will be crucial for the convergence theorems in section 6. The method consists of two steps. Let $h > 0$ be an approximation parameter. The first step is the determination of a finite-state controlled Markov chain ξ^h_n that has a continuous-time interpolation that is an "approximation" of the process $x(\cdot)$. The second step solves the optimization problem for the chain and a cost function that approximates the one used for $x(\cdot)$. Under a natural "local consistency" condition, the minimal cost function for the chain converges to the minimal cost function for the original problem. In applications, the optimal control for the original problem is also approximated. The approximating chain and local consistency conditions are the same for the game problem. The reference [19] contains a comprehensive discussion of many automatic and simple methods for getting the transition probabilities of the chain. The approximations "stay close" to the physical model and can be adjusted to exploit local features.

The simplest state space for the chain for our model (and the one that we will use for simplicity in the discussion) is based on the regular h-grid S_h in $\mathbb{R}^v$. Define $G_h = S_h \cap G$ and $G^0_h = S_h \cap G^0$. On G^0_h the chain "approximates" the diffusion part of (2.1) or (2.3). Let ∂G_h denote the points in $S_h - G^0_h$ that can be reached in one step from G^0_h under some control. These are the boundary points, and the process stops on first reaching them. It is only the points in $G^0_h \cup \partial G_h$ that are of interest.

Next we define the basic condition of *local consistency.* Let $u^h_n = (u^h_{1,n}, u^h_{2,n})$ denote the controls that are used at step n. Define $\Delta\xi^h_n = \xi^h_{n+1} - \xi^h_n$ and let $E^{h,\alpha}_{x,n}$ denote the expectation given the data to step n (when ξ^h_n has just been computed) with $\xi^h_n = x$ and control value $\alpha = u^h_n$ to be used in the next step. For the game problem, $\alpha = (\alpha_1, \alpha_2)$ with $\alpha_i \in U_i$. Define $a(x) = \sigma(x)\sigma'(x)$. Suppose that there is a

function $\Delta t^h(\cdot)$ (this is obtained automatically when the transition probabilities are calculated; see [19] and the example below) such that (this defines the functions $b^h(\cdot)$ and $a^h(\cdot)$)

$$\begin{aligned} &E^{h,\alpha}_{x,n}\Delta\xi^h_n \equiv b^h(x,\alpha)\Delta t^h(x,\alpha) = b(x,\alpha)\Delta t^h(x,\alpha) + o(\Delta t^h(x,\alpha)),\\ &\operatorname{cov}^{h,\alpha}_{x,n}[\Delta\xi^h_n - E^{h,\alpha}_{x,n}\Delta\xi^h_n] \equiv a^h(x,\alpha)\Delta t^h(x,\alpha) = a(x)\Delta t^h(x,\alpha) + o(\Delta t^h(x,\alpha)),\\ &\lim_{h\to 0}\sup_{x\in G,\alpha\in U}\Delta t^h(x,\alpha) = 0. \end{aligned} \tag{5.1}$$

It can be seen that the chain has the "local properties" (conditional mean change and conditional covariance) of the diffusion process.[7] One can always select the transition probabilities such that the intervals $\Delta t^h(x,\alpha)$ do not depend on the control variable, although the general theory in [19] does not require it. Such a simplification is often done in applications to simplify the coding. Let $p^h(x,y|\alpha)$ denote the probability that the next state is y given that the current state is x and control pair $\alpha = (a_1,\alpha_2)$ is used.

Under our condition that the controls are separated in $b(\cdot)$, in that $b(x,\alpha) = v^1(x,\alpha_1) + b^2(x,\alpha_2)$, if desired one can construct the chain so that the controls are "separated" in which the one-step transition probability has the form

$$p^h(x,y|\alpha) = p^h_1(x,y|\alpha_1) + p^h_2(x,y|\alpha_2). \tag{5.2}$$

A useful representation of the transition probabilities. For the convergence proof, it is useful to have the chains for each h defined on the same probability space, no matter what the controls.[8] This is done as follows. Let $\{\chi_n\}$ be a sequence of mutually independent random variables, uniformly distributed on the interval $[0,1]$ and such that $\{\chi_l, l \geq n\}$ is independent of $\{\xi^h_l, u^h_l, l \leq n\}$. For each value of $x = \xi^h_n, \alpha = u^h_n$, arrange the finite number of possible next states y in some order and divide the interval $[0,1]$ into successive subintervals whose lengths are $p^h(x,y|\alpha)$. Then for $x = \xi^h_n, \alpha = u^h_n$, select the next state according to where the (uniformly distributed) random choice for χ_n falls. The same random variables $\{\chi_n\}$ will be used in all cases, for all controls and values of h. This representation is used only for theoretical purposes.

An example of an approximating chain. The simplest case for illustrative purposes is one-dimensional, and where h is small enough so that $h|b(\alpha,x)| \leq \sigma^2(x)$. Then we can use the transition probabilities and interval, for $x \in G^0_h$ [19, Chapter 5],

$$p^h(x,x\pm h|\alpha) = \frac{\sigma^2(x) \pm hb(x,\alpha)}{2\sigma^2(x)}, \quad \Delta t^h(x,\alpha) = \frac{h^2}{\sigma^2(x)}, \quad \Delta t^h_n = \frac{h^2}{\sigma^2(\xi^h_n)}. \tag{5.3}$$

Admissible controls. Let $\mathcal{F}^h_n$ denote the minimal σ-algebra that measures the control and state data to step n, and let E^h_n denote the expectation conditioned on $\mathcal{F}^h_n$. An admissible control for player i at step n is a U_i-valued random variable that is $\mathcal{F}^h_n$-measurable. Let $\mathcal{U}^h_i$ denote the set of the admissible control processes for player i.

A relaxed control for the chain can be defined as follows. Let $r^h_{i,n}(\cdot)$ be a probability distribution on the Borel sets of U_i such that $r^h_{i,n}(A)$ is $\mathcal{F}^h_n$-measurable for each

[7] Whether the chain is Markovian or not depends on the form of the control that is applied. But the transition probability will always be locally consistent.

[8] This representation of the chain is not needed and was not used for the single player problem or for the zero-sum game. For the nonzero-sum game, it provides a way of dealing with the difficulties in the convergence proof that were described in the introduction.

Borel set $A \in U_i$. Then the $r^h_{i,n}(\cdot)$ are said to be relaxed controls for player i at step n. As for the model (2.3), an ordinary control at step n can be represented by the relaxed control at step n defined by $r^h_{i,n}(A) = I_{\{u^h_{i,n} \in A\}}$ for each Borel set $A \subset U_i$. Define $r^h_n(\cdot)$ by $r^h_n(A_1 \times A_2) = r^h_{1,n}(A_1) r^h_{2,n}(A_2)$, where the A_i are Borel sets in U_i. The associated transition probability is $\int_U p^h(x, y|a) r^h_n(d\alpha)$. If $r^h_{i,n}(A)$ can be written as a measurable function of ξ^h_n for each Borel set A, then the control is said to be relaxed feedback. Under any feedback (or relaxed feedback or randomized feedback) control, the process ξ^h_n is a Markov chain. More general controls, under which there is more "past" dependence and the chain is not Markovian, will be used as well. Let $\mathcal{C}^h_i$ denote the set of control strategies for ξ^h_n.

The cost function. Discretize the costs as follows. The cost functions are the analogs of (2.2) or (2.4). The cost rate for player i is $k_i(x, \alpha_i)\Delta t^h(x, \alpha)$. The stopping costs are $g_i(\cdot)$, and τ^h denotes the first time that the set G^0_h is exited. Let $W^h_i(x, u^h_1, u^h_2)$ denote the expected cost for player i under the control sequences $u^h_i = \{u^h_{i,n}, n \geq 0\}, i = 1, 2$. The numerical problem is to solve the game problem for the approximating chain.

Continuous-time interpolations. The discrete-time chain ξ^h_n is used for the numerical computations. However, for the proofs of convergence, we use a continuous-time interpolation $\xi^h(\cdot)$ of $\{\xi^h_n\}$ that will approximate $x(\cdot)$. This will be a continuous-time process that is constructed as follows. Define $\Delta t^h_n = \Delta t^h(\xi^h_n, u^h_n)$ and $t^h_n = \sum_{i=0}^{n-1} \Delta t^h_i$. Define $\xi^h(t) = \xi^h_n$ on $[t^h_n, t^h_{n+1})$. Define the continuous-time interpolations $u^h_i(\cdot)$ of the control actions for player i by $u^h_i(t) = u^h_{i,n}, t^h_n \leq t < t^h_{n+1}$, and let its (continuous-time) relaxed control representation be denoted by $r^h_i(\cdot)$. Define $r^h(\cdot) = (r^h_1(\cdot), r^h_2(\cdot))$, with time derivative $r^{h,\prime}(\cdot)$. We use $\mathcal{U}^h_i$ for the set of continuous-time interpolations of the control for player i as well.

An alternative interpolation. In [19] an interpolation called $\psi^h(\cdot)$ was used as well, and had some advantages in simplifying the proofs there. We describe it briefly so that the convergence results of [19] can be used where needed. For each h, let $\nu^h_n, n = 0, 1, \ldots,$ be mutually independent and exponentially distributed random variables with unit mean and that are independent of $\{\xi^h_n, u^h_n, n \geq 0\}$. Define $\Delta\tau^h_n = \nu^h_n \Delta t^h_n$, and $\tau^h_n = \sum_{i=0}^{n-1} \Delta\tau^h_i$. Define $\psi^h(t) = \xi^h_n$ and $u^h_\psi(t) = u^h_n$ on $[\tau^h_n, \tau^h_{n+1})$. Now decompose $\psi^h(\cdot)$ in terms of the continuous-time compensator and martingale. Since the intervals between jumps are $\Delta t^h_n \nu^h_n$, where ν^h_n is exponentially distributed and independent of $\mathcal{F}^h_n$, the jump rate of $\psi^h(\cdot)$ when in state x and under control value α is $1/\Delta t^h(x, \alpha)$. Given a jump, the distribution of the next state is given by the $p^h(x, y|\alpha)$, and the conditional mean change is $b^h(x, \alpha)\Delta t^h(x, \alpha)$. So we can write

$$\psi^h(t) = x(0) + \int_0^t b^h(\psi^h(s), u^h_\psi(s))ds + M^h(t), \tag{5.4}$$

where the martingale $M^h(t)$ has quadratic variation process $\int_0^t a^h(\psi^h(s), u^h_\psi(s))ds$. Under any feedback (or randomized feedback) control, the process $\psi^h(\cdot)$ is a continuous-time Markov chain.

It can be shown that [19, sections 5.7.3 and 10.4.1] there is a martingale $\hat{w}^h(\cdot)$ (with respect to the filtration generated by the state and control processes possibly augmented by an "independent" Wiener process) such that

$$M^h(t) = \int_0^t \sigma^h(\psi^h(s), u^h_\psi(s))d\hat{w}^h(s) = \int_0^t \sigma(\psi^h(s))d\hat{w}^h(s) + \epsilon^h(t), \tag{5.5}$$

where $\sigma^h(\cdot)[\sigma^h(\cdot)]' = a^h(\cdot)$ (recall the definition of $a^h(\cdot)$ in (5.1)), and where $\hat{w}^h(\cdot)$ has quadratic variation It and converges weakly to a standard Wiener process. The martingale $\epsilon^h(\cdot)$ is due to the difference between $\sigma(x)$ and $\sigma^h(x)$ (recall the $o(\Delta t^h)$ terms in (5.1)) and

$$\lim_{h\to 0}\sup_{u^h} E\sup_{s\le t}|\epsilon^h(s)|^2 = 0 \tag{5.6}$$

for each t. Thus, where $r^h_\psi(\cdot)$ is the relaxed control representation of $u^h_\psi(\cdot)$,

$$\psi^h(t) = x(0) + \int_0^t\int_U b^h(\psi^h(s),\alpha)r^{h,\prime}_\psi(d\alpha,s)ds + \int_0^t \sigma(\psi^h(s))d\hat{w}^h(s) + \epsilon^h(t). \tag{5.7}$$

The interpolations $\xi^h(\cdot)$ and $\psi^h(\cdot)$ are asymptotically equivalent, as seen in the following theorem, so that any asymptotic results for one are also asymptotic results for the other. We will use $\xi^h(\cdot)$.

THEOREM 5.1. *Assume the local consistency* (5.1). *Then the time scales with intervals Δt^h_n and $\Delta\tau^h_n$ are asymptotically equivalent.*

Proof. Let $f^h(t) = \min\{n : t^h_n \ge t\}$. Write $\Delta\tau^h_n - \Delta t^h_n = (\nu^h_n - 1)\Delta t^h_n$, a martingale difference. By the martingale property we have

$$E\sup_{n<f^h(t)}|t^h_n - \tau^h_n|^2 = E\sup_{n<f^h(t)}\left|\sum_{i=0}^n \Delta t^h_i(v^h_n - 1)\right| \le 4E\sum_{i=0}^{f^h(t)}[\Delta t^h_i]^2 E(v^h_i - 1)^2,$$

which goes to zero as $h\to 0$ by the last line of (5.1). The result is the same if we define $f^h(t) = \min\{n : \tau^h_n \ge t\}$. □

A representation of the approximating chain. By (5.1), we can write

$$\xi^h_{n+1} = \xi^h_n + b^h(\xi^h_n, u^h_n)\Delta t^h_n + \beta^h_n,$$

where β^h_n is a martingale difference with $E^h_n[\beta^h_n][\beta^h_n]' = a^h(\xi^h_n, u^h_n)\Delta t^h_n$. There are martingale differences δw^h_n with conditional (given $\mathcal{F}^h_n$) covariance $\Delta t^h_n I$ such that $\beta^h_n = \sigma^h(\xi^h_n, u^h_n)\delta w^h_n$ [19, section 10.4.1], [14, section 6.6]. Let $w^h(\cdot)$ denote the continuous-time interpolation of $\sum_{i=0}^{n-1}\delta w^h_n$ with intervals Δt^h_n. Then, abusing notation, we can write

$$\begin{aligned}\xi^h(t) &= x(0) + \int_0^t b^h(\xi^h(s), u^h(s))ds + \int_0^t \sigma^h(\xi^h(s))dw^h(s) + \epsilon^h(t),\\ \int_0^t \sigma^h(\xi^h(s), u^h(s))dw^h(s) &= \int_0^t \sigma(\xi^h(s))dw^h(s) + \epsilon^h(t),\end{aligned} \tag{5.8}$$

where $\epsilon^h(\cdot)$ satisfies (5.6) and is due to the $O(\Delta t^h)$ approximation of $a^h(x,\alpha)$ by $\sigma(x)\sigma(x)'$.

Note on convergence. For any subsequence $h\to 0$, there is a further subsequence (also indexed by h for simplicity) such that $(\xi^h(\cdot), r^h_1(\cdot), r^h_2(\cdot),\ w^h(\cdot), \tau^h)$ converges weakly to random processes $(x(\cdot), r_1(\cdot), r_2(\cdot), w(\cdot), \tau)$, where $r_i(\cdot)$ is a relaxed control for player i, $(x(\cdot), r_1(\cdot), r_2(\cdot), w(\cdot), I_{\{\tau^h\le\cdot\}})$ is nonanticipative with respect to the standard vector-valued Wiener process $w(\cdot)$, and, writing $r(\cdot) = (r_1(\cdot), r_2(\cdot))$, the set satisfies

$$x(t) = x(0) + \int_0^t\int_U b(x(s),\alpha)r'(d\alpha,s)ds + \int_0^t \sigma(x(s))dw(s).$$

Also, $W_i^h(x, r_1^h, r_2^h) \to W_i(x, r_1, r_2)$. The proofs of these facts are the same as for the one-player control case in [19, Chapter 10].

On the construction of $\delta w^h(\cdot)$. A special case. Full details for the general method of constructing $w^h(\cdot)$ are in [19, section 10.4.1], [14, section 6.6]. To illustrate the idea, we will consider a very common case that will be needed in Theorems 5.2, 5.3, 5.4, 5.6, and 6.2. Suppose that $\sigma(\cdot) = \sigma$ is a constant. Suppose that the components of x can be partitioned as $x = (x_1, x_2)$, and σ can be partitioned as $\sigma = \left[\begin{smallmatrix} \sigma_1 & 0 \\ 0 & 0 \end{smallmatrix}\right]$, where the dimension of x_1 is d_1, and σ_1 is a square and invertible matrix of dimension d_1. Partition the $a^h(\cdot)$ in the second line of (5.1) as

$$a^h(x,\alpha) = \begin{bmatrix} a_1^h(x,\alpha) & a_{1,2}^h(x,\alpha) \\ a_{2,1}^h(x,\alpha) & a_2^h(x,\alpha) \end{bmatrix}.$$

As $h \to 0$, $a_1^h(\cdot) \to \sigma_1[\sigma_1]'$ and all other components go to zero, all uniformly in (x, α). Write the analogous partition $w^h(\cdot) = (w_1^h(\cdot), w_2^h(\cdot))$. For any Wiener process $w_2(\cdot)$ that is independent of the other random variables, we can let $w_2^h(\cdot) = w_2(\cdot)$. The only important component of $w^h(\cdot)$ is $w_1^h(\cdot)$, and we can write

$$\begin{aligned} \delta w_{1,n}^h &\equiv w_1^h(t_{n+1}^h) - w_1^h(t_n^h) \\ &= [a_1^h(\xi_n^h, u_n^h)]^{-1/2} \left[\xi_{1,n+1}^h - \xi_{1,n}^h - \int_{t_n^h}^{t_{n+1}^h} \int_U b_1^h(\xi_n^h, \alpha) r^{h,\prime}(s, d\alpha) ds \right] \\ &= [\sigma_1]^{-1} \left[\xi_{1,n+1}^h - \xi_{1,n}^h - \int_{t_n^h}^{t_{n+1}^h} \int_U b_1^h(\xi_n^h, \alpha) r^{h,\prime}(s, d\alpha) ds \right] + \delta\epsilon_n^{1,h}, \end{aligned} \tag{5.9}$$

where $\delta\epsilon_n^{1,h}$ is due to the approximation of $a_1^h(\cdot)$ by $\sigma_1[\sigma_1]'$, and its continuous-time interpolation satisfies (5.6). If an ordinary control is used, then the double integral is just $b_1(\xi_n^h, u_n^h)\Delta t_n^h$.

5.2. First approximations to the chain. Approximation results analogous to those of Theorems 3.1–3.3 can be proved and will be used in the next section. These approximations are of independent interest and should be quite useful for other convergence and approximation analyses for numerical approximations. Theorem 5.2 concerns an approximation to (5.8) that is based on the same $w^h(\cdot)$ process and will be used in Theorem 6.1. The $w^h(\cdot)$ process depends on the control. For the constant σ-case, Theorem 5.3 shows that this control dependence is small and can be factored out, and (uniform in the control) approximations in terms of an independently and identically distributed (i.i.d.) driving sequence are developed. Once this control dependence is factored out, more convenient approximations to the chain can be obtained. This is done in Theorem 5.4, and the results will be used in Theorem 6.2.

Consider the representation (5.8), and for μ, δ, Δ as used in Theorem 3.3 and the $r^h(\cdot) = (r_1^h(\cdot), r_2^h(\cdot))$ in (5.8), define the approximation $u_i^{\mu,\delta,\Delta,h}(\cdot), i = 1, 2$, analogously to what was done above Theorem 3.3. For the process $w^h(\cdot)$ that appears in (5.8) under the original control $r^h(\cdot)$, define the process

$$\xi^{\mu,\delta,\Delta,h}(t) = x(0) + \int_0^t b(\xi^{\mu,\delta,\Delta,h}(s), u^{\mu,\delta,\Delta,h}(s))ds + \int_0^t \sigma(\xi^{\mu,\delta,\Delta,h}(s))dw^h(s). \tag{5.10}$$

Let $r_i^{\mu,\delta,\Delta,h}(\cdot)$ denote the relaxed control representation of $u_i^{\mu,\delta,\Delta,h}(\cdot)$. The process defined by (5.10) is not a Markov chain even if the controls are feedback, since the

$w^h(\cdot)$ is obtained from the process (5.8) under $r^h(\cdot)$ and not under the $r_i^{\mu,\delta,\Delta,h}(\cdot), i = 1,2$. Let $W_i^{\mu,\delta,\Delta,h}(x, r_1^{\mu,\delta,\Delta,h}, r_2^{\mu,\delta,\Delta,h})$ denote the cost for the process (5.10). Define the discrete-time system

(5.11)
$$\tilde{\xi}^{\mu,\delta,\Delta,h}(n\Delta+\Delta) = \tilde{\xi}^{\mu,\delta,\Delta,h}(n\Delta) + \int_{n\Delta}^{n\Delta+\Delta} b(\tilde{\xi}^{\mu,\delta,\Delta,h}(n\Delta), u^{\mu,\delta,\Delta,h}(s))ds + \sigma(\tilde{\xi}^{\mu,\delta,\Delta,h}(n\Delta))[w^h(n\Delta+\Delta) - w^h(n\Delta)],$$

with initial condition $x(0)$ and piecewise-constant continuous-time interpolation denoted by $\tilde{\xi}^{\mu,\delta,\Delta,h}(\cdot)$. Let $\tilde{W}_i^{\mu,\delta,\Delta,h}(x, r_1^{\mu,\delta,\Delta,h}, r_2^{\mu,\delta,\Delta,h})$ denote the associated cost. We have the following analogue of Theorem 3.3.

THEOREM 5.2. *Assume Condition* A2.1. *Given* $(\mu,\delta,\Delta) > 0$, *approximate* $r_i^h(\cdot)$ *as noted above to get* $r_i^{\mu,\delta,\Delta,h}(\cdot)$. *Given* $\epsilon > 0$ *and* $t < \infty$, *there are* $\mu_\epsilon > 0, \delta_\epsilon > 0$, $\Delta_\epsilon > 0$, *and* $\kappa_\epsilon > 0$ *such that, for* $\mu \le \mu_\epsilon, \delta \le \delta_\epsilon, \Delta \le \Delta_\epsilon$ *and* $\delta/\Delta \le \kappa_\epsilon$,

$$\limsup_{h\to 0} \sup_{x, r_1^h, r_2^h} E \sup_{s\le t} \left|\xi^{\mu,\delta,\Delta,h}(s) - \xi^h(s)\right| \le \epsilon, \tag{5.12}$$

and if Condition A2.2 *holds in addition, then*

$$\limsup_{h\to 0} \sup_{x, r_1^h, r_2^h} \left|W_i^{\mu,\delta,\Delta,h}(x, r_1^{\mu,\delta,\Delta,h}, r_2^{\mu,\delta,\Delta,h}) - W_i^h(x, r_1^h, r_2^h)\right| \le \epsilon. \tag{5.13}$$

The expressions (5.12) *and* (5.13) *hold if only one of the controls is approximated and also if* $\xi^{\mu,\delta,\Delta,h}(\cdot)$ *and* $W_i^{\mu,\delta,\Delta,h}(\cdot)$ *are replaced by* $\tilde{\xi}^{\mu,\delta,\Delta,h}(\cdot)$ *and* $\tilde{W}_i^{\mu,\delta,\Delta,h}(\cdot)$, *respectively.*

Comments on the proof. For notational simplicity in the proof, drop the superscripts μ,δ. Define $\delta\xi^{\Delta,h}(t) = \tilde{\xi}^{\Delta,h}(t) - \xi^h(t)$. Then, following the procedure of Theorem 3.1, write

$$\begin{aligned}\delta\xi^{\Delta,h}(t) = &\int_0^t \int_U \left[b(\xi^{\Delta,h}(s),\alpha) - b^h(\xi^h(s),\alpha)\right] r^{h,\prime}(d\alpha, s)ds \\ &+ \int_0^t \left[\sigma(\xi^{\Delta,h}(s)) - \sigma(\xi^h(s))\right] dw^h(s) \\ &+ \int_0^t \int_U b(\xi^{\Delta,h}(s),\alpha)\left[r^{\Delta,h,\prime}(d\alpha, s) - r^{h,\prime}(d\alpha, s)\right] ds + \epsilon_1^h(t).\end{aligned}$$

The $w^h(\cdot), \epsilon_1^h(\cdot)$ are martingales with respect to the filtration induced by the data $(\xi^h(\cdot), r^h(\cdot), w^h(\cdot))$, the martingale $w^h(\cdot)$ has quadratic variation[9] It, and $\epsilon_1^h(\cdot)$ satisfies (5.6). Partition the last integral analogously to what was done in (3.6), with intervals λ. The process $\xi^{\Delta,h}(\cdot)$ satisfies the following version of (3.7):

$$\sup_{\mu,\delta,\Delta} \sup_{r^h} \sup_{l\lambda\le t} E \sup_{s\le\lambda} \left|\xi^{\Delta,h}(l\lambda + s) - \xi^{\Delta,h}(l\lambda)\right|^2 = O(\lambda) + \sup \Delta t^h(x,\alpha).$$

Now, using the martingale property and the Lipschitz condition, one proceeds in the same way that would be used for approximations to (2.3) in Theorem 3.1.

[9] Actually, they are martingales only when evaluated at the time points t_n^h, but the difference is unimportant, since they are constant between such times.

For example, for some constant K (which depends on t), we have the inequality

$$E\sup_{s\le t}\left|\delta\xi^{\Delta,h}(s)\right|^2 \le K\int_0^t E\left|\delta\xi^{\Delta,h}(s)\right|^2 ds + \kappa^{\lambda,h}(t) + O(\lambda)$$
$$+KE\left|\sum_{l=0}^{[t/\lambda]-1}\int_{l\lambda}^{(l+1)\lambda} b(\xi^{\Delta,h}(l\lambda),\alpha)\left[r^{\Delta,h,\prime}(d\alpha,s) - r^{h,\prime}(d\alpha,s)\right]ds\right|^2,$$

where $\kappa^{\lambda,h}(t)$ is due to the $\epsilon_1^h(\cdot)$ and to the use of $\xi^{\Delta,h}(l\lambda)$ in the second line, and $\sup_{s\le t}|\kappa^{\lambda,h}(s)| \to 0$ as $\lambda\to 0, h\to 0$. For each small λ, the last term in the above expression goes to zero uniformly in h as $(\mu,\delta,\Delta)\to 0$, by the method of approximation of the controls. Then (5.12) follows from the resulting inequality and the Bellman–Gronwall lemma. The inequality (5.13) follows from (5.12) and Condition A2.2. □

5.3. Representations and approximations of the chain with control-independent driving noise. The driving noise $w^h(\cdot)$ depends on the path and control. In section 6 it will be useful to have approximations to $\xi^h(\cdot)$ (uniform in the control and initial condition), where the driving noise increments are independent of the path and control. To accomplish this we will need to factor $w^h(\cdot)$ as $w^h(\cdot) = \bar{w}^h(\cdot)+\zeta^h(\cdot)$, where $\bar{w}^h(\cdot)$ does not depend on the control and $\zeta^h(\cdot)$ is "asymptotically negligible." We will work with the model described at the end of subsection 5.1, where $\sigma = \left[\begin{smallmatrix}\sigma_1 & 0\\ 0 & 0\end{smallmatrix}\right]$, the dimension of x_1 is d_1, and σ_1 is a square and invertible matrix of dimension d_1. The approximation and representation results of Theorems 5.3, 5.4, and 5.6 below will hold for such a form. But to simplify the notation and development, we will work with two specific forms, each of which is typical of a large class of models and numerical algorithms. Case 1 below arises when one uses the so-called central-difference approximation to get the transition probabilities. Case 2 arises when one uses a central-difference approximation for the nondegenerate part and a one-sided or "upwind" approximation for the degenerate part [19, Chapter 5]. Both forms are locally consistent. Let $b_i(\cdot)$ denote the ith component of $b(\cdot)$.

Case 1. Suppose that $d_1 = v$, so that σ is invertible. For $a = \sigma\sigma'$, suppose that $a_{i,i} - \sum_{j:j\ne i}|a_{i,j}| \ge 0$. The condition can be weakened if the approximation intervals can depend on the coordinate direction, or if a linear transformation of the state space is used to diagonalize $\sigma\sigma'$ [19, Chapter 5]. Let e_i denote the unit vector in the ith coordinate direction. A central-difference version of the canonical form of the transition probabilities and interpolation interval in [19, equation (3.15), Chapter 5] is[10]

$$p^h(x,x\pm e_ih|\alpha) = \frac{q_{i,i}\pm hb_i(x,\alpha)/2}{Q}, \quad \Delta t^h(x,\alpha) = \Delta t^h = \frac{h^2}{Q},$$
$$p^h(x,x+e_ih+e_jh|\alpha) = p^h(x,x-e_ih-e_jh|\alpha) = \frac{a^+_{i,j}}{2Q},$$
$$p^h(x,x+e_ih-e_jh|\alpha) = p^h(x,x-e_ih+e_jh|\alpha) = \frac{a^-_{i,j}}{2Q}, \tag{5.14}$$
$$Q = \sum_i a_{i,i} - \sum_{i,j:i\ne j}|a_{i,j}|/2, \quad q_{ii} = a_{i,i}/2 - \sum_{j:j\ne i}|a_{i,j}|/2.$$

[10]The form (5.14) and Cases 1 and 2 are selected for specificity in the constructions to follow. Any of the approximations in [19, Chapter 5] could be used, provided that $\sigma(\cdot)$ is constant.

We suppose that $q_{i,i} - h|b_i(x,\alpha)| \geq 0$. A simple computation using (5.14) shows that $b^h(x,\alpha) = b(x,\alpha)$ and $a^h(x,\alpha) = \sigma\sigma' + O(\Delta t^h)$. Also, by (5.14) we can write $\Delta t_n^h = \Delta t^h$. In one dimension, (5.14) reduces to (5.3), where $q_{1,1} = \sigma^2/2$.

Case 2. Suppose that σ can be partitioned as in the last paragraph of subsection 5.1; i.e., $\sigma = \left[\begin{smallmatrix}\sigma_1 & 0\\ 0 & 0\end{smallmatrix}\right]$ where the dimension of x_1 is d_1, and σ_1 is a square and invertible matrix of dimension d_1. The problem concerns the effect of the degenerate part. The following canonical model for such cases is motivated by the general model of [19, Chapter 5]. Define $\bar{b} = \sup_{x,\alpha} \sum_{i=d_1+1}^{v} |b_i(x,\alpha)|$. For this case, redefine $\Delta t^h = \Delta t^h(x,\alpha) = h^2/[Q + h\bar{b}]$. Use the form (5.14) for $i \leq d_1$, with Q replaced by $Q^h = Q + h\bar{b}$. For $i = d_1 + 1, \ldots, v$, use

$$p^h(x, x \pm e_i h|\alpha) = \frac{hb_i^{\pm}(x,\alpha)}{Q^h},$$

and use

$$p^h(x,x|\alpha) = \frac{h\bar{b} - h\sum_{i=d_1+1}^{v} |b_i(x,\alpha)|}{Q^h}.$$

We still have $a^h(x,\alpha) = \sigma\sigma' + O(\Delta t^h)$ and $b^h(x,\alpha) = b(x,\alpha)$. Let E_n^h denote the expectation given all the data up to step n.

THEOREM 5.3. *Use either of the models from Case* 1 *or Case* 2. *Then we can write* $\delta w_n^h = \delta\bar{w}_n^h + \delta\zeta_n^h$, *where the components are martingale differences. The* $\delta\bar{w}_n^h$ *are i.i.d.,* $\{\delta\bar{w}_l^h, l \geq n\}$ *is independent of* $\{\xi_l^h, u_l^h, l \leq n\}$, *and the components have values* $O(h)$. *Also, for either case,* $E_n^h \delta\bar{w}_n^h[\delta\bar{w}_n^h]' = \Delta t^h$, *and* $E_n^h\delta\zeta_n^h[\delta\zeta_n^h]' = O(h\Delta t^h)$, $E_n^h\delta\zeta_n^h[\delta\bar{w}_n^h]' = O(h\Delta t^h)$.

Proof. The proof is a simple construction. The basic approach is to first define δw_n^h as though $b(\cdot) = 0$ and $a^h(x,\alpha) = \sigma\sigma'$. The result will define $\delta\bar{w}_n^h$. Then $\delta\zeta_n^h$ is defined to make up the difference. The facts that the dominant terms in the transition probabilities in (5.14) do not depend on h and that the contributions due to the drift (hence control and state) are proportional to h make this possible. To avoid excessive notation and concentrate on the essential ideas, we start with Case 1 in one dimension. The treatment of the higher-dimensional model follows the same pattern and is illustrated via a two-dimensional case. Then the minor modifications that are required for Case 2 are discussed. The procedure in the general case should be apparent from the three examples.

Case 1, *one dimension.* We can write the double integral term in (5.9) as $b(\xi_n^h, u_n^h)\Delta t^h$, since $b^h(\cdot) = b(\cdot)$. To construct the state transitions, we will use the representation in terms of the random variables χ_n described in the paragraph below (5.2). In one dimension (5.14) is (5.3) and $p^h(x, x \pm h|\alpha) = 0.5 \pm hb(x,\alpha)/[2\sigma^2]$, $\Delta t^h = h^2/\sigma^2$. Now, define $\xi_{n+1}^h - \xi_n^h$ by setting it equal to h if the random sample of χ_n falls in $[0, .5 + hb(\xi_n^h, u_n^h)/2\sigma^2]$, and set it equal to $-h$ otherwise. The "conditional mean" change is $2h[hb(\xi_n^h, u_n^h)/2\sigma^2] = b(\xi_n^h, u_n^h)\Delta t^h$, which is just what is required by the local consistency condition (5.1).

Define the martingale difference term $\delta\bar{w}_n^h$ as follows. Divide $[0,1]$ into the two segments $[0,.5], [.5,1]$. If the random sample of χ_n falls in $[0,.5]$, set $\delta\bar{w}_n^h = h/\sigma$; otherwise set it equal to $-h/\sigma$. It is what δw_n^h would be if $b(\cdot) = 0$ and $a^h(\xi_n^h, u_n^h) = \sigma^2$. Now define $\delta\zeta_n^h$ to make up for the difference. There are two components to $\delta\zeta_n^h$. One component is due to the use of σ in lieu of $[a^h(\xi_n^h, u_n^h)]^{1/2}$ as in the last line of (5.9). Since $a^h(x,\alpha) - \sigma^2 = O(h^2)$, we have $[a^h(x,\alpha)]^{1/2} - \sigma = O(h^2)$, and the corresponding

error in computing the sample values of δw_n^h is $O(h^3)$. The associated interpolated error process clearly satisfies (5.6).

The second component of $\delta\zeta_n^h$ is due to the neglect of the term $b(\cdot)$ in constructing $\delta\bar{w}_n^h$. We handle this as follows. Suppose that $b(\xi_n^h, u_n^h) \geq 0$ (the computation is analogous if $b(\xi_n^h, u_n^h) < 0$). Then, for this second component,[11]

$$\delta\zeta_n^h = (2h - b(\xi_n^h, u_n^h)\Delta t^h)/\sigma \quad \text{if } \chi_n \in [.5, .5 + hb(\xi_n^h, u_n^h)/2\sigma^2],$$

and it equals $-b(\xi_n^h, u_n^h)\Delta t^h/\sigma$ otherwise. The conditional variance of $\delta\zeta_n^h$ is

$$E_n^h \left[2h - b(\xi_n^h, u_n^h)\Delta t^h/\sigma\right]^2 \frac{hb(\xi_n^h, u_n^h)}{2\sigma^2} + E_n^h \left[b(\xi_n^h, u_n^h)\Delta t^h/\sigma\right]^2 \left(1 - \frac{hb(\xi_n^h, u_n^h)}{2\sigma^2}\right) = O(h)\Delta t^h,$$

uniformly in the controls. The $\delta\zeta_n^h$ term depends on the control, but the $\delta\bar{w}_n^h$ term does not. It is simply a Bernoulli sequence, with $\{\delta\bar{w}_l^h, l \geq n\}$ independent of the data up to step n. Also, $E_n^h[\delta\bar{w}_n^h]^2 = \Delta t^h$, $E_n^h \delta\bar{w}_n^h \delta\zeta_n^h = O(h)\Delta t^h$, and $E_n^h[\delta\zeta_n^h]^2 = O(h)\Delta t^h$, uniformly in the controls.

Now, construct the continuous-time martingales $\bar{w}^h(t), \zeta^h(t)$ by interpolating the sums $\sum_{i=0}^{n-1} \delta\bar{w}_i^h$ and $\sum_{i=0}^{n-1} \delta\zeta_i^h$ with intervals Δt^h. Write $w^h(t) = \bar{w}^h(t) + \zeta^h(t)$. The $\bar{w}^h(\cdot)$ does not depend on the control, has quadratic variation It, and $\bar{w}^h(s), s \geq t$, is independent of $\xi^h(s), u^h(s), s \leq t$. The quadratic variation of $\zeta^h(\cdot)$ (and its quadratic covariation with $\bar{w}^h(\cdot)$) is $O(h)$, uniformly in the controls and initial condition.

Comment on the two-dimensional problem for Case 1. The following computation illustrates the procedure in higher dimensions. Now σ is a 2×2 nonsingular matrix. Let $a_{1,2} \geq 0, b_i(\xi_n^h, u_n^h) \geq 0$, for specificity. Divide the unit interval into successive subintervals of lengths $q_{1,1}/Q, q_{1,1}/Q, q_{2,2}/Q, q_{2,2}/Q, a_{1,2}/2Q, a_{1,2}/2Q$. Again, the goal is to reproduce the transition probabilities (5.14). If χ_n falls in $[0, (q_{1,1} + hb_1(\xi_n^h, u_n^h))/Q]$, set $\xi_{1,n+1}^h - \xi_{1,n}^h = h$, and $\xi_{2,n+1}^h - \xi_{2,n}^h = 0$. If χ_n falls in $[(q_{1,1} + hb_1(\xi_n^h, u_n^h))/Q, 2q_{1,1}/Q]$, then set $\xi_{1,n+1}^h - \xi_{1,n}^h = -h$, and $\xi_{2,n+1}^h - \xi_{2,n}^h = 0$. Do the analogous computation for the second component, using the two intervals of length $q_{2,2}/Q$. If χ_n falls in the next to last of the six subintervals, then set $\xi_{n+1}^h - \xi_n^h = (h, h)$, and set it equal to $(-h, -h)$ if χ_n falls in the last of the six subintervals. Define $\delta\bar{w}_n^h$ by repeating the above with $b(x, \alpha) = 0$ and premultiplying by σ^{-1} as follows: For χ_n in the six successive subintervals, define

$$\delta\bar{w}_n^h = \sigma^{-1}\left\{\begin{pmatrix} h \\ 0 \end{pmatrix}, \begin{pmatrix} -h \\ 0 \end{pmatrix}, \begin{pmatrix} 0 \\ h \end{pmatrix}, \begin{pmatrix} 0 \\ -h \end{pmatrix}, \begin{pmatrix} h \\ h \end{pmatrix}, \begin{pmatrix} -h \\ -h \end{pmatrix}\right\}.$$

The procedure is analogous in any dimension.

Comment on Case 2. For ease of presentation, let us work in two dimensions, where only the first component of $x(\cdot)$ has a Wiener process driving term. Then $\bar{b} = \max_{x,\alpha} |b_2(x, \alpha)|$, $Q = 2q_{1,1} = [\sigma_1]^2$, and $Q^h = Q + h\bar{b}$. Slightly modifying the procedure used for Case 1, divide the unit interval into successive subintervals of lengths

$$\frac{q_{1,1}/2}{Q^h}, \frac{q_{1,1}/2}{Q^h}, \frac{h\bar{b}}{Q^h},$$

[11]The $2h$ in the formula is due to the fact that on the interval $\chi_n \in [.5, .5 + hb(\xi_n^h, u_n^h)/2\sigma^2]$, the difference $\xi_{n+1}^h - \xi_n^h$ was implicitly assigned a value $-h$ when $\delta\bar{w}_n^h$ was constructed, when it should have been assigned the value $+h$.

and divide the last subinterval into two further subintervals of lengths

$$h|b_2(x,\alpha)|/Q^h, \quad h[\bar{b} - |b_2(x,\alpha)|]/Q^h,$$

so that there are now four subintervals. First let us construct $\delta\xi_n^h = \xi_{n+1}^h - \xi_n^h$. Analogously to what was done in the one-dimensional example of Case 1, set $\delta\xi_{2,n}^h = 0$ if $\chi_n \in [0, Q/Q^h]$. If $\chi_n \in (Q/Q^h, 1]$, set $\delta\xi_{1,n}^h = 0$ and $\delta\bar{w}_{1,n}^h = 0$. If the random sample of χ_n falls into the fourth subinterval, set $\delta\xi_{2,n}^h = 0$. If it falls into the third subinterval, set $\delta\xi_{2,n}^h = h\ \text{sign}(b_2(\xi_n^h, u_n^h))$. If $\chi_n \in [0, (q_{11} + hb_1(\xi_n^h, u_n^h))/Q^h]$, set $\delta\xi_{1,n}^h = h$, and set it equal to $-h$ if $\chi_n \in [(q_{11} + hb_1(\xi_n^h, u_n^h))/Q^h, 2q_{11}/Q^h]$.

To complete the construction of $\delta\bar{w}_{1,n}^h$, repeat the procedure with $b(\cdot) = 0$ and divide by σ_1. In particular, $\delta\bar{w}_{1,n}^h = h/\sigma_1$ if $\chi_n \in [0, q_{1,1}/Q^h]$. It is $-h/\sigma_1$ if $\chi_n \in (q_{1,1}/Q^h, 2q_{1,1}/Q^h]$, and it is zero otherwise. The variance is h^2/Q^h, which is the current value of Δt^h. The value of the second component $\delta\bar{w}_{2,n}^h$ is unimportant since it is eventually multiplied by zero. So, let us use an independent Bernoulli sequence with values $\pm h/\sqrt{Q^h}$, each taken with probability 1/2.

These constructions yield (5.14) with $\Delta t^h = h^2/Q^h$. The error terms ζ_n^h for this and the previous example are computed using a procedure that is analogous to that in Case 1. □

In the next theorem, $\sigma(\cdot)$ is just the constant σ. The theorem implies that $\xi^h(\cdot)$ can be written in the form

$$\xi^h(t) = x(0) + \int_0^t \int_U b(\xi^h(s),\alpha) r^{h,\prime}(d\alpha, s)ds + \int_0^t \sigma d\bar{w}^h(s) + \epsilon_2^h(t), \tag{5.15}$$

where $\epsilon_2^h(\cdot)$ equals $\epsilon_1^h(\cdot)$ plus a stochastic integral with respect to $\zeta^h(\cdot)$, and satisfies (5.6). Since the martingale $\bar{w}^h(\cdot)$ does not depend on the control and is essentially the sum of i.i.d. zero mean random variables of size $O(h)$, the form (5.15) can be used to obtain approximation theorems of the type in Theorems 3.1–3.3. The controls can be space and time discretized with arbitrarily small change in the costs, just as in the cited theorems. The quadratic variation process of $\bar{w}^h(\cdot)$ is It.

THEOREM 5.4. *Assume Condition* A2.1 *and the models of Theorem* 5.3. *Define*

$$\bar{\xi}^h(t) = x(0) + \int_0^t \int_U b(\bar{\xi}^h(s),\alpha) r^{h,\prime}(d\alpha, s)ds + \int_0^t \sigma d\bar{w}^h(s). \tag{5.16}$$

Then, for each $t > 0$,

$$\lim_{h\to 0} \sup_{x(0), r^h} E \sup_{s\le t} \left|\xi^h(s) - \bar{\xi}^h(s)\right|^2 = 0. \tag{5.17}$$

If Condition A2.2 *is assumed as well, then the costs for the two processes are arbitrarily close, uniformly in the control and initial condition.*

Now, given $(\mu, \delta, \Delta) > 0$, *let* $u_i^{\mu,\delta,\Delta,h}(\cdot)$ *be the delayed and discretized approximation of* $r_i^h(\cdot)$ *that would be defined by the procedure described above Theorem* 3.3, *with the relaxed control representation of the pair* $(i = 1, 2)$ *of approximations being* $r^{\mu,\delta,\Delta,h}(\cdot)$. *Define the system*

$$\begin{aligned}\bar{\xi}^{\mu,\delta,\Delta,h}(t) = x(0) &+ \int_0^t \int_U b(\bar{\xi}^{\mu,\delta,\Delta,h}(s),\alpha) r^{\mu,\delta,\Delta,h,\prime}(d\alpha, s)ds \\ &+ \int_0^t \sigma d\bar{w}^h(s).\end{aligned} \tag{5.18}$$

Then for $t > 0$ and $\gamma > 0$ there are positive numbers $\mu_\gamma, \delta_\gamma, \Delta_\gamma, h_\gamma, \kappa_\gamma$, such that for $\mu \le \mu_\gamma$, $\delta \le \delta_\gamma$, $\Delta \le \Delta_\gamma$, $h \le h_\gamma$, $\delta/\Delta \le \kappa_\gamma$ we have

$$\sup_{r^h, x(0)} E \sup_{s \le t} \left| \bar{\xi}^{\mu,\delta,\Delta,h}(s) - \bar{\xi}^h(s) \right|^2 \le \gamma. \tag{5.19}$$

If Condition A2.2 *is assumed as well, then for small (μ, δ, Δ, h) the costs are arbitrarily close, uniformly in the control and initial condition.*

Comment on the proof. The proof of the various assertions follows the lines of the arguments used in Theorem 5.2, exploiting the martingale properties and the Lipschitz condition. The details are very similar and are omitted.

The terms $[\bar{w}^h(n\Delta + \Delta) - \bar{w}^h(n\Delta)], n = 0, 1, \ldots$, are i.i.d. and have orthogonal components. The covariance is Δ times the identity matrix, and the processes converge to normally distributed random variables as $h \to 0$. It will be useful to quantify this closeness for use in the next section. This will be done in Theorem 5.6, which requires the following strong approximation theorem for i.i.d. random variables.

LEMMA 5.5 (see [3, Theorem 3]). *Let $\{\phi_n\}$ be a sequence of $\mathbb{R}^d$-valued i.i.d. random variables with zero mean and bounded $(2+\delta)$th moment, where $0 < \delta \le 1$. Suppose that the covariance matrix Γ is nonsingular. Then without changing the distribution, one can redefine the sequence on a richer probability space together with a Wiener process $B(\cdot)$ with covariance matrix Γ such that*

$$\left| \sum_{i \le n} \phi_i - B(n) \right| = o(n^{0.5-c}) \tag{5.20}$$

*w.p.*1 *for large n, for some $0 < c < 0.5$.*

The following theorem asserts that if $\sigma(\cdot)$ is constant, then the process defined by (5.18) can be written essentially as the discrete-time system (2.5), which we now write as $x^{\mu,\delta,\Delta,h}(\cdot)$, since the discretized controls are used. Keep in mind that the controls in (5.18) are obtained from the discretization of the relaxed control representation of the interpolation of $\{u_n^h\}$, the original controls for the chain.

THEOREM 5.6. *Assume Conditions* A2.1 *and* A2.2 *and the models used in Theorem* 5.3. *Then we can define the probability space such that $\bar{w}^h(t) = w(t) + \rho^h(t)$, where $w(\cdot)$ is a vector-valued Wiener process whose covariance matrix is the identity. For each $t > 0$, $E \sup_{s \le t} |\rho^h(s)|^2 \to 0$ as $h \to 0$. Let $x^{\mu,\delta,\Delta,h}(\cdot)$ be the solution to* (2.5) *with the same Wiener process $w(\cdot)$ and with the controls that are used in* (5.18). *Then, for any $t > 0$,*

$$\lim_{h \to 0} \sup_{r^h, x(0)} E \sup_{s \le t} \left| x^{\mu,\delta,\Delta,h}(s) - \bar{\xi}^{\mu,\delta,\Delta,h}(s) \right|^2 = 0. \tag{5.21}$$

Proof. Since we have assumed that the same controls are used for both systems (2.5) and (5.18), some explanation is needed. Consider Case 1 and define random variables ϕ_n by $\delta \bar{w}_n^h = \phi_n \sqrt{h^2/Q}$. (For Case 2, the development is the same, but with the normalization factor Q^h replacing the normalization factor Q.) This can be done since the parameter h is only a linear scale factor in the construction of the $\delta \bar{w}_n^h$. Then $\{\phi_n\}$ satisfies the conditions of Lemma 5.5, and we can suppose that the probability space is such that (5.20) holds for some Wiener process $B(\cdot)$, whose covariance matrix will be the identity. In fact, instead of starting with $\{\phi_n\}$, we can start with the pair $\{\phi_n, \chi_n\}$, with the same law as used originally. Let us do this,

but consider only the approximation of the sums of the ϕ_n by $B(\cdot)$ as in Lemma 5.5. Then, on this probability space define $\delta\bar{w}_n^h$ in terms of the ϕ_n, as above. Without loss of generality, we can suppose that ξ_0^h is also defined on this space. The next step is to define u_0^h, which is just a function of ξ_0^h, on this space. For convenience we use the same notation for the controls and states as on the original space. Continuing, define ξ_1^h on the space by constructing it from ξ_0^h, u_0^h, χ_0^h as done in Theorem 5.3. This procedure can be continued so that all of $\{\xi_n^h, u_n^h, \delta\bar{w}_n^h\}$ is defined on the space, and with the same law as used originally. Now, given the control sequence $\{u_n^h\}$, the continuous-time interpolation can be time and space discretized and delayed as in Theorem 5.4.[12]

From Lemma 5.5, we have, w.p.1 for large n,

$$\left|\sum_{i=0}^{n} h\phi_i - hB(n)\right| = h\,o(n^{0.5-c}). \tag{5.22}$$

The process $w(\cdot) = hB(\cdot/\Delta t^h)/\sqrt{Q}$ is a Wiener process whose covariance is the identity. By the above arguments and (5.22), there is a constant $c > 0$ and a $t_h \to 0$ as $h \to 0$ such that

$$\left|\sum_{i=0}^{t/\Delta t^h} \delta\bar{w}_i^h - w(t)\right| = o(t[\Delta t^h]^c) \tag{5.23}$$

w.p.1 for $t \geq t_h$ and small h. By the above arguments concerning the approximation of $\bar{w}^h(\cdot)$ by $w(\cdot)$, we can write $\bar{w}^h(t) = w(t) + \rho^h(t)$, where the process $\rho^h(\cdot)$ has independent increments, and $\lim_{h\to 0} E\sup_{s\leq t}|\rho^h(s)|^2 = 0$. Rewrite (5.18) as

$$\bar{\xi}^{\mu,\delta,\Delta,h}(t) = x(0) + \int_0^t \int_U b(\bar{\xi}^{\mu,\delta,\Delta,h}(s),\alpha) r^{\mu,\delta,\Delta,h,\prime}(d\alpha, s)ds + \sigma dw(t) + \sigma\rho^h(t),$$

and write (2.5) with the controls $r^{\mu,\delta,\Delta,h}(\cdot)$ as (in interpolated form)

$$x^{\mu,\delta,\Delta,h}(t) = x(0) + \int_0^t \int_U b(x^{\mu,\delta,\Delta,h}(s),\alpha) r^{\mu,\delta,\Delta,h,\prime}(d\alpha, s)ds + \sigma dw(t). \tag{5.24}$$

From this point the proof is standard, using the Lipschitz condition and the martingale properties. □

6. An approximate equilibrium for the diffusion process is an approximate equilibrium for the chain and vice versa.

Representations of the transition probability and controls. In the next two theorems, we will use the representations of the transitions of the Markov chain in terms of the i.i.d. random variables $\{\chi_n\}$ discussed in the paragraph after (5.2), and the similar representation for the realizations of the rule (4.2) in terms of the random variables $\{\theta_l\}$ noted in the discussion just below the statement of Theorem 4.1. This ensures that the sample path of the approximating chain depends only on the selected control values and that the selected control value in (4.2) depends only on the past values of the control and Wiener process.

[12] Actually, it is only required that the controls be approximated and delayed such that the control applied on $[n\Delta, n\Delta+\Delta)$ is $\mathcal{F}^h_{n\Delta-}$-measurable. The other aspects of the discretization are not needed.

THEOREM 6.1. *Assume Conditions* A2.1, A2.2, *and* A4.1. *An* ϵ*-equil- ibrium value for* (2.1) *or* (2.3) *is an* ϵ_1*-equilibrium value for the approximating Markov chain, where* $\epsilon_1 \to 0$ *as* $\epsilon \to 0$.

Proof. Let $\epsilon > 0$ be given. By Condition A4.1, there is an ϵ-equilibrium strategy pair for (2.3) under which the solution to (2.3) is well defined. By Theorem 4.1, without loss of generality, and for small enough μ, δ, and Δ, it can be represented as in (4.2), where we assume that Δ/δ is an integer, and the $p_{i,k}(\cdot)$ are continuous in the w-variables. We can suppose without loss of generality that for each n, k, and i, the rule (4.2) is defined for all possible conditioning u-sequences with values in $U_i^\mu, i = 1, 2$. Let $(\bar{c}_1^\Delta(\cdot), \bar{c}_2^\Delta(\cdot))$ denote this strategy pair. The strategies $\bar{c}_i^\Delta(\cdot)$ depend on μ and δ as well as on Δ, but for simplicity we suppress that dependence in the notation.

Recall that when a strategy that is defined by a rule such as (4.2) is applied to an arbitrary relaxed control, the formula (4.2) is actually applied to the space-time discretization of that relaxed control, as defined above Theorem 3.3. These strategies $\bar{c}_i^\Delta(\cdot)$ will need to be adapted for use on the chain. To do this, simply replace the $w(\cdot)$-samples in (4.2) by samples of the $w^h(\cdot)$ process that was used in (5.8) and whose construction was illustrated in (5.9). Keep in mind that these strategies are used only for theoretical purposes to prove a convergence theorem. They are not for practical implementation. For each integer k, the control value $u_i^{\mu,\delta,\Delta,h}(k\delta)$ that is obtained from the rule (4.2) with $w^h(\cdot)$ used will be applied to the chain for all steps m such that $t_m^h \in [k\delta, k\delta + \delta)$. The resulting strategies for the chain will be denoted by $\bar{c}_i^{\Delta,h}(\cdot)$ and are in $\mathcal{C}_i^h$.

We want to show that for small enough (μ, Δ, δ), there are $\epsilon_0 > 0$ and $h_0 > 0$, where $\epsilon_0 \to 0$ as $\epsilon \to 0$ such that for $h \le h_0$ and any sequence $r_i^h(\cdot)$ of admissible relaxed (or ordinary) controls for the chain,

$$
\begin{aligned}
W_1^h(x, \bar{c}_1^{\Delta,h}, \bar{c}_2^{\Delta,h}) &\ge W_1^h(x, r_1^h, \bar{c}_2^{\Delta,h}) - \epsilon_0, \\
W_2^h(x, \bar{c}_1^{\Delta,h}, \bar{c}_2^{\Delta,h}) &\ge W_2^h(x, \bar{c}_1^{\Delta,h}, r_2^h) - \epsilon_0.
\end{aligned} \tag{6.1}
$$

The notation $W_2^h(x, \bar{c}_1^{\Delta,h}, r_2^h)$ implies that player 1 uses strategy $\bar{c}_1^{\Delta,h}(\cdot)$ and player 2 uses relaxed control $r_2^h(\cdot)$ (in continuous-time interpolation notation) or an ordinary control with this relaxed control representation, with the analogous interpretation when the indices are reversed. The notation $W_1^h(x, \bar{c}_1^{\Delta,h}, \bar{c}_2^{\Delta,h})$ implies that player i uses strategy $\bar{c}_i^{\Delta,h}(\cdot), i = 1, 2$.

Suppose that the pair $\bar{c}_i^{\Delta,h}(\cdot), i = 1, 2$, is used for the chain. Let $\bar{r}_i^{\mu,\delta,\Delta,h}(\cdot), i = 1, 2$, denote the (continuous-time interpolation notation) relaxed control representation of the control actions. Let $\xi^h(\cdot)$, $w^h(\cdot)$, and τ^h denote the corresponding continuous-time interpolation of the chain, the "pre-Wiener" process, and the first exit time, respectively. The sequence $(\xi^h(\cdot), \bar{r}_1^{\mu,\delta,\Delta,h}(\cdot), \bar{r}_2^{\mu,\delta,\Delta,h}(\cdot), w^h(\cdot), \tau^h)$ (parametrized by h for fixed μ, δ, Δ) is tight. Select a weakly convergent subsequence ($h \to 0$) with the limit denoted by $(x(\cdot), r_1(\cdot), r_2(\cdot), w(\cdot), \tau)$. The set $(x(\cdot), r_1(\cdot), r_2(\cdot), I_{\{\tau \le \cdot\}})$ is nonanticipative with respect to the standard vector-valued Wiener process $w(\cdot)$, and the set $(x(\cdot), r_1(\cdot), r_2(\cdot), w(\cdot))$ solves (2.3). The limit τ is the first hitting time of the boundary of G by the limit process $x(\cdot)$. The details concerning the tightness, characterization of the limit processes, and boundary hitting times, and that the limit processes solve (2.3), are the same as for the control problem in [19, Chapters 10, 11].

Henceforth, when weak convergent sequences are dealt with, we will assume (without loss of generality) when needed for simplicity in the argument that the Skorokhod

representation is used so that all processes are defined on the same probability space and the weak convergence is equivalent to convergence w.p.1 in the appropriate topology [7, Theorem 1.8, Chapter 3].

Under the Skorokhod representation, the rule (4.2) with the $w^h(\cdot)$-samples used converges w.p.1 to the same rule with the $w(\cdot)$-samples used, due to the convergence $w^h(\cdot) \to w(\cdot)$ and the continuity of the probabilities in (4.2) in the w-variables. Because of this, the limits $r_i(\cdot), i = 1, 2$, are just realizations of the original ϵ-equilibrium strategies $\bar{c}_i^{\Delta}(\cdot), i = 1, 2$. Since the solution to (2.1) or (2.3) is unique for each admissible pair (control, Wiener process), we can conclude that the probability law of any limit set $(x(\cdot), r_1(\cdot), r_2(\cdot), w(\cdot))$ is the same, no matter what the selected convergent subsequence. Hence the original set of processes (before the subsequence was taken) converges weakly to this (unique in the sense of probability law) limit set, where the control is determined by the rules $\bar{c}_i^{\Delta}(\cdot), i = 1, 2$.

By the weak convergence,

$$W_1(x, \bar{c}_1^{\Delta}, \bar{c}_2^{\Delta}) \leftarrow W_1^h(x, \bar{c}_1^{\Delta,h}, \bar{c}_2^{\Delta,h}) \leq \max_{r_1 \in \mathcal{U}_1^h} W_1^h(x, r_1, \bar{c}_2^{\Delta,h}) = W_1^h(x, \hat{r}_1^h, \bar{c}_2^{\Delta,h}), \tag{6.2}$$

$$W_2(x, \bar{c}_1^{\Delta}, \bar{c}_2^{\Delta}) \leftarrow W_2^h(x, \bar{c}_1^{\Delta,h}, \bar{c}_2^{\Delta,h}) \leq \max_{r_2 \in \mathcal{U}_2^h} W_2^h(x, \bar{c}_1^{\Delta,h}, r_2) = W_1^h(x, \bar{c}_1^{\Delta,h}, \hat{r}_2^h). \tag{6.3}$$

It can be shown by a weak convergence argument working with the chain for any fixed $h > 0$ that the maximizing controls $\hat{r}_i^h(\cdot)$ exist. But we need only work with control processes that approximate the maximum values arbitrarily well, and we assume that the $\hat{r}_i^h(\cdot)$ are such controls.

It will be shown that

$$\limsup_{h \to 0} W_1^h(x, \hat{r}_1^h, \bar{c}_2^{\Delta,h}) \leq W_1(x, \bar{c}_1^{\Delta}, \bar{c}_2^{\Delta}) + \epsilon + \rho(\mu, \delta, \Delta), \tag{6.4}$$

where $\rho(\mu, \delta, \Delta) \to 0$ as $(\mu, \delta, \Delta) \to 0$, with the analogous result for indices $1, 2$ interchanged. Inequalities (6.2), (6.3), and (6.4) imply that if player 2 uses $\bar{c}_2^{\Delta,h}(\cdot)$, then player 1 cannot do better (asymptotically as $h \to 0$ and modulo $\rho(\mu, \delta, \Delta) + \epsilon$) than by using $\bar{c}_1^{\Delta,h}(\cdot)$, with the analogous result holding for the other player. This last fact implies the theorem since (μ, δ, Δ) can be made as small as desired.

Now (6.4) will be shown. Let $\{u_1^{\mu,\delta,\Delta,h}(l\delta)\}$ denote the values that are obtained from $\hat{r}_1^h(\cdot)$ by the space and time discretization given above Theorem 3.3, and which are used by the rule $\bar{c}_2^{\Delta,h}(\cdot)$. Let $\{u_2^{\mu,\delta,\Delta,h}(l\delta)\}$ denote the control choices for player 2, based on the rule $\bar{c}_2^{\Delta,h}(\cdot)$ and the control of player 1. Let $r_i^{\mu,\delta,\Delta,h}(\cdot)$ denote the (continuous-time) relaxed control representation of $\{u_i^{\mu,\delta,\Delta,h}(l\delta)\}$. The processes $\xi^h(\cdot)$ and $w^h(\cdot)$ now denote the interpolation of the chain and the pre-Wiener process, resp., under the strategy $\bar{c}_2^{\Delta,h}(\cdot)$ and control $\hat{r}_1^h(\cdot)$. This $w^h(\cdot)$ process will be fixed for each h and used in the rest of the proof.

Define the process $\xi^{\mu,\delta,\Delta,h}(\cdot)$ by (5.10), driven by $\{u_i^{\mu,\delta,\Delta,h}(l\delta)\}, i = 1, 2$, and $w^h(\cdot)$. Note that $\{u_2^{\mu,\delta,\Delta,h}(l\delta)\}$ is the response of $\bar{c}_2^{\Delta,h}(\cdot)$ to any control of player 1 with discretization $\{u_1^{\mu,\delta,\Delta,h}(l\delta)\}$. By Theorem 5.2, we have, for small h,

$$\left| W_i^h(x, \hat{r}_1^h, \bar{c}_2^{\Delta,h}) - W_i^{\mu,\delta,\Delta,h}(x, r_1^{\mu,\delta,\Delta,h}, r_2^{\mu,\delta,\Delta,h}) \right| \leq \rho_1(\mu, \delta, \Delta), \tag{6.5}$$

where $\rho_1(\mu, \delta, \Delta)$ can be made arbitrarily small, uniformly in $\hat{r}^h(\cdot)$, as $(\mu, \delta, \Delta, h) \to 0$ and as $W_i^{\mu,\delta,\Delta,h}(\cdot)$ was defined above (5.11). Also,

$$W_i^{\mu,\delta,\Delta,h}(x, r_1^{\mu,\delta,\Delta,h}, r_2^{\mu,\delta,\Delta,h}) = W_i^{\mu,\delta,\Delta,h}(x, r_1^{\mu,\delta,\Delta,h}, \bar{c}_2^{\Delta,h}). \tag{6.6}$$

Let $\tau^{\mu,\delta,\Delta,h}$ denote the first hitting time of the boundary for $\xi^{\mu,\delta,\Delta,h}(\cdot)$.

The set $(\xi^{\mu,\delta,\Delta,h}(\cdot), \hat{r}_1^h(\cdot), r_1^{\mu,\delta,\Delta,h}(\cdot), r_2^{\mu,\delta,\Delta,h}(\cdot), w^h(\cdot), \tau^{\mu,\delta,\Delta,h})$ is tight. Extract a weakly convergent subsequence, and index it by h also. Denote the limit of the weakly convergent subsequence by $(x(\cdot), \hat{r}_1(\cdot), r_1^{\mu,\delta,\Delta}(\cdot),\ r_2^{\mu,\delta,\Delta}(\cdot),\ w(\cdot), \tau)$. Then, as was the case in an earlier part of the proof, $(x(\cdot), \hat{r}_1(\cdot),\ r_1^{\mu,\delta,\Delta}(\cdot),\ r_2^{\mu,\delta,\Delta}(\cdot),\ w(\cdot), I_{\{\tau\le\cdot\}})$ is nonanticipative with respect to the standard Wiener process $w(\cdot)$, the set $(x(\cdot), r_1^{\mu,\delta,\Delta}(\cdot), r_2^{\mu,\delta,\Delta}(\cdot), w(\cdot))$ satisfies (2.3), and τ is the first hitting time of the boundary. The $r_i^{\mu,\delta,\Delta}(\cdot)$ is just the relaxed control that is defined by the weak-sense limit $\{u_i^{\mu,\delta,\Delta}(l\delta)\}$ of $\{u_i^{\mu,\delta,\Delta,h}(l\delta)\}$.

We need to show that the limits $u_2^{\mu,\delta,\Delta}(l\delta)$ are chosen by the conditional probability law that defines $\bar{c}_2^{\Delta}(\cdot)$; i.e., that (along the selected subsequence)

$$\begin{aligned} &p_{2,k}\left(\alpha_2;\ w^h(l\Delta), l\le n; u_j^{\mu,\delta,\Delta,h}(l\delta), j=1,2, l\delta < n\Delta\right) \\ &\quad\to p_{2,k}\left(\alpha_2;\ w(l\Delta), l\le n; u_j^{\mu,\delta,\Delta}(l\delta), j=1,2, l\delta < n\Delta\right) \end{aligned} \tag{6.7}$$

for $k\delta \in [n\Delta, n\Delta+\Delta)$. In (6.7), the $w^h(\cdot)$ can be replaced by its limit $w(\cdot)$ due to the continuity in w. Since there are only a finite number of values for the control, for any $t<\infty$ the limit $\{u_1^{\mu,\delta,\Delta}(l\delta), u_2^{\mu,\delta,\Delta}(l\delta), l\delta\le t\}$ will be achieved after a finite number of steps through the convergent subsequence, w.p.1. This implies (6.7). (We will comment further on this point at the end of the proof.) Thus the policy $\bar{c}_2^{\Delta}(\cdot)$ acting on any relaxed control with discretization $\{u_1^{\mu,\delta,\Delta}(l\delta)\}$ will yield the sequence $\{u_2^{\mu,\delta,\Delta}(l\delta)\}$. Thus,

$$W_1^{\mu,\delta,\Delta,h}(x, r_1^{\mu,\delta,\Delta,h}(\cdot), \bar{c}_2^{\Delta,h}) \to W_1(x, r_1^{\mu,\delta,\Delta}(\cdot), \bar{c}_2^{\Delta}),$$

and by (6.5) and (6.6), mod $\rho_1(\mu,\delta,\Delta)$,

$$W_1^h(x, \hat{r}_1^h, \bar{c}_2^{\Delta,h}) \to W_1(x, r_1^{\mu,\delta,\Delta}, \bar{c}_2^{\Delta}).$$

We can conclude that

$$\begin{aligned} \lim_{h\to 0} W_1^h(x, \hat{r}_1^h, c_2^{\Delta,h}) &\le W_1(x, r_1^{\mu,\delta,\Delta}(\cdot), \bar{c}_2^{\Delta}) + \rho_1(\mu,\delta,\Delta) \\ &\le W_1(x, \bar{c}_1^{\Delta}, \bar{c}_2^{\Delta}) + \rho_1(\mu,\delta,\Delta) + \epsilon, \end{aligned} \tag{6.8}$$

where the ϵ is due to the fact that $(\bar{c}_1^{\Delta}(\cdot), \bar{c}_2^{\Delta}(\cdot))$ is an ϵ-equilibrium. The arbitrariness of the subsequence implies (6.4). The same argument is used when the indices $1,2$ are reversed.

Finally, let us comment on (6.7). Recall that the discretizations given above Theorem 3.3 use fixed (and asymptotically unimportant) values on the initial interval $[0,\Delta)$, so let us use $u_1^{\mu,\delta,\Delta,h}(l\delta) = u_1(l\delta)$, $u_2^{\mu,\delta,\Delta,h}(l\delta) = u_2(l\delta)$ for fixed $u_i(l\delta)$ and $l\delta<\Delta$. For $k\delta\in[\Delta, 2\Delta)$, we have the rule

$$p_{2,k}\left(\alpha_2; w^h(\Delta); u_1(l\delta), u_2(l\delta), l\delta<\Delta\right), \tag{6.9}$$

and the probability of selecting any $\alpha_2\in U_2^{\mu}$ converges as $w^h(\Delta)\to w(\Delta)$. Then the limit in (6.9) must be the law of $u_2^{\mu,\delta,\Delta}(l\delta)$ for $\Delta\le l\delta<2\Delta$. Using the method of selecting the control values in terms of the θ_i that was recalled above the theorem statement, we can assume that the convergence $u_2^{\mu,\delta,\Delta,h}(l\delta)\to u_2^{\mu,\delta,\Delta}(l\delta), \Delta\le l\delta<2\Delta$,

occurs in a finite number of steps w.p.1, as $h \to 0$ through the convergent subsequence, with the rule (6.9) used. Next, on $[2\Delta, 2\Delta + \Delta)$, we have the rule

$$p_{2,k}\left(\alpha_2; w^h(l\Delta), l \le 2; u_i(l\delta), l\delta < \Delta; u_i^{\mu,\delta,\Delta,h}(l\delta), \Delta \le l\delta < 2\Delta, i = 1, 2\right).$$

The $u_1^{\mu,\delta,\Delta,h}(l\delta), \Delta \le l\delta < 2\Delta$, can be assumed to converge in a finite number of steps as well, w.p.1, and hence, as above, so do the selected values of $u_2^{\mu,\delta,\Delta,h}(l\delta), \Delta \le l\delta < \Delta + 2\Delta$. Continuing in this way yields the form (6.7). □

The converse result. If the ϵ-equilibrium value for the chain is unique for arbitrarily small ϵ, then the converse result is true, namely, that ϵ-equilibrium values for the chain are ϵ_1-equilibrium values for (2.3), where $\epsilon_1 \to 0$ as $\epsilon \to 0$, and we are done, since Theorem 6.1 then implies that the ϵ-equilibrium values for the diffusion are also unique for small ϵ, and that the numerical solutions will converge to the desired value. If the ϵ-equilibrium value for the chain is not unique for arbitrarily small ϵ, then we will show that this "converse" assertion is true for the models used in Theorem 5.3. We are not able to show the converse result when $\sigma(\cdot)$ depends on x, so $\sigma(\cdot)$ is constant in the next theorem and Theorems 5.3–5.6 are applied. Condition A4.1 is not needed.

THEOREM 6.2. *Assume Conditions* A2.1 *and* A2.2 *and the models used in Theorem* 5.3*, where $\sigma(\cdot)$ is constant. Then for any $\epsilon > 0$ there is $\epsilon_1 > 0$, which goes to zero as $\epsilon \to 0$ such that an ϵ-equilibrium value for the chain ξ_n^h for small h is an ϵ_1-equilibrium value for* (2.3).

Proof. Theorem 5.4 says that the paths and cost functions for (5.15) (which is $\xi^h(\cdot)$ under an arbitrary control), (5.16) (where the control is as in (5.15) but the driving process is $\bar{w}^h(\cdot)$), and (5.18) (which is (5.16) with discretized controls) are arbitrarily close, uniformly in the controls, for small (μ, δ, Δ, h). Theorem 5.6 gives the same result for (5.18) and $x^{\mu,\delta,\Delta,h}(\cdot)$ given by (5.24), which is (2.5) with discretized controls. Theorem 3.3 implies the same thing for $x^{\mu,\delta,\Delta,h}(\cdot)$ and (2.3). These uniform closeness results imply that ϵ-equilibrium values for the chain for small h are ϵ_1-equilibrium values for the diffusion. □

ON A MODEL FOR THE EFFICIENT OPERATION OF A BANK OR INSURANCE COMPANY*

JOSEPH G. CONLON† AND HYEKYUNG MIN†

Abstract. In this paper the authors study a model for the optimal operation of a bank or insurance company which was recently introduced by Peura and Keppo. The model generalizes a previous one of Milne and Robertson by allowing the bank to raise capital as well as to pay out dividends. Optimal operation of the bank is determined by solving an optimal control problem. In this paper it is shown that the solution of the optimal control problem proposed by Peura and Keppo exists for all values of the parameters and is unique.

1. Introduction. In this paper we study a model for the optimal operation of a bank or insurance company which was introduced by Peura and Keppo [9]. In this model capital is invested in a risky asset whose evolution is described by Brownian motion with drift. Thus if $X(t)$ is the bank's capital at time t, then

$$dX(t) = \mu dt + \sigma dW(t), \tag{1.1}$$

where $W(t)$ is Brownian motion, $\mu > 0$ is the drift, and $\sigma > 0$ the volatility. For an insurance company model, μ represents the expected premium collection rate minus the expected claims payment rate.

In addition to investing in the asset described by (1.1), the bank also pays dividends to its owners and raises capital from them. Dividend payments can be implemented instantaneously, but capital issuance is associated with a delay of length Δ and a fixed cost K. If capital is ordered at time t, it is actually received at time $t+\Delta$. Since there is a fixed cost K associated with ordering the capital, if an amount s of capital is ordered, then $s-K$ of that goes to increasing the total capital of the bank. Furthermore, in this model the owners decide at time $t+\Delta$ on the actual amount of capital to be raised. Hence, while the decision to *raise* capital is based on information up to time t, the decision on the *amount* to be raised is based on information up to time $t+\Delta$. The fixed cost K is also paid at time $t+\Delta$.

The payment of dividends and the raising of capital is controlled by a policy π. For $t > 0$ let $L^\pi(t)$ be defined by

$$L^\pi(t) = \text{ dividends paid out } - \text{ capital raised up to time } t. \tag{1.2}$$

It is assumed that capital is raised at a set of discrete times $t_1^\pi < t_2^\pi < t_3^\pi < \cdots$, where the number $N^\pi(t)$ of times capital is raised up to time t is given by the formula

$$N^\pi(t) = \sup\{i : t_i^\pi \le t\}. \tag{1.3}$$

†University of Michigan, Department of Mathematics, Ann Arbor, MI 48109-1109 (conlon@umich.edu, hyekyung@umich.edu).

It is also assumed that the time between raising capital is at least Δ and that no dividends are paid out during the period Δ before a capital raising time. Thus, assuming $L^\pi(t)$ is a right continuous process, $L^\pi(t)$ is constant in the interval $\left(t_i^\pi - \Delta,\ t_i^\pi\right)$. At time t_i^π the bank decides the amount of capital it needs to raise. If its portfolio has performed particularly well in the previous time period of length Δ, then it may not raise capital but actually pay out dividends at time t_i^π. In all cases it has to pay the capital raising cost K. Since dividend payments are nonnegative the process $L^\pi(t)$ is increasing for $t \notin \{t_i^\pi : i = 1, 2, \ldots\}$.

Let $X^\pi(t)$ be the amount of capital the bank has at time t. Then from (1.1), (1.2), (1.3) the evolution of $X^\pi(t)$ is governed by the equation

$$dX^\pi(t) = \mu dt + \sigma dW(t) - dL^\pi(t) - K dN^\pi(t). \tag{1.4}$$

As is usual in control theory it is assumed that the policy π depends only on information up to the present time. Hence one assumes that the process $L^\pi(t)$ is right continuous and measurable with respect to the σ field generated by $X^\pi(s)$, $s < t$.

The main concern of [9] is to determine a policy π which maximizes the expected payments to the owners of the bank over its lifetime. They therefore define a value function $V^\pi(x)$, $x \geq 0$, by

$$V^\pi(x) = E\left[\int_0^{\tau_\pi} e^{-\rho t} dL^\pi(t) \Big| X^\pi(0) = x\right], \tag{1.5}$$

where $\tau_\pi = \sup\{t > 0 : X^\pi(s) > 0,\ 0 < s < t\}$ is the lifetime of the bank, and $\rho > 0$ is a predetermined discount factor. Assigning a value to ρ is probably the most problematic part of matching the model to actual data. In [9] they describe ρ as representing the wedge between debt and equity finance due to capital market frictions such as taxation and agency costs of equity. With ρ given, the optimal value function is then given by

$$V(x) = \sup_\pi\ V^\pi(x), \tag{1.6}$$

where the supremum is taken over all allowable strategies. In [9] an expression for the function V of (1.6) is obtained and a corresponding strategy to realize it is given. The function V is characterized by 2 parameters $u_{1,K}(\Delta),\ u_{2,K}(\Delta)$ satisfying $0 \leq u_{1,K}(\Delta) < u_{2,K}(\Delta) < \infty$. If the capital the bank holds is less than $u_{1,K}(\Delta)$, then a capital raising event is initiated. If the capital exceeds $u_{2,K}(\Delta)$, then dividends are paid out. If the capital the bank holds lies between $u_{1,K}(\Delta)$ and $u_{2,K}(\Delta)$, then it is fully invested in the risky asset described by (1.1). A notable feature of the model is that $\tau_\pi < \infty$ with probability 1 for an optimal strategy. Thus maximally efficient operation of the bank gives rise to zero capital in finite time.

The model of Peura and Keppo generalizes an earlier model of Milne and Robertson [8] which allows dividend payments but not the raising of capital (see also [5, 6]). The Milne–Robertson model can be recaptured from that of Peura and Keppo by simply taking the cost K of raising capital to be sufficient large. In that case $u_{1,K}(\Delta) = 0$ and $u_{2,K}(\Delta) = u_0$, where u_0 is the Milne–Robertson threshold for the payment of dividends. The value function V of (1.6) now satisfies the equation

$$(A - \rho)V(x) = 0, \quad 0 < x < u_0,\ V(0) = 0,\ V'(u_0) = 1, \tag{1.7}$$

where A is the infinitesimal generator for the process (1.1),

$$A = \frac{1}{2}\sigma^2 \frac{d^2}{dx^2} + \mu\ \frac{d}{dx}, \tag{1.8}$$

and $u_0 > 0$ is chosen so that the function V, when continued by a linear function for $x > u_0$, is C^2. The complete value function is then this linearly extended function which satisfies (1.7) for $0 \le x \le u_0$.

When K and Δ are small enough then $u_{1,K}(\Delta) > 0$ and it is determined from the solution of a free boundary problem which is a zero latent heat limit for the Stefan problem (see [4] for a Stefan problem occurring in finance). The approach in [9] to obtaining the solution to (1.6) is to study the Bellman inequalities [2, 3] corresponding to the optimal control problem. These are given as follows:

$$\begin{aligned} &\text{(a)} \quad V(0) = 0, \\ &\text{(b)} \quad V(x) \ge MV(x), \\ &\text{(c)} \quad (A-\rho)V(x) \le 0, \\ &\text{(d)} \quad V'(x) \ge 1, \\ &\text{(e)} \quad [V(x) - MV(x)][(A-\rho)V(x)][V'(x) - 1] = 0, \end{aligned} \tag{1.9}$$

where the operator M in (b) is defined by

$$Mf(x) = E\left[e^{-\rho\Delta} \sup_{s\ge 0}\Big[f\Big(X(\Delta)+s\Big) - s - K\Big] I_{\tau>\Delta} | X(0) = x\right],\ x > 0. \tag{1.10}$$

Here $X(t)$ is the diffusion (1.1) and τ is the first hitting time at 0. In (1.10) note that the supremum is *inside* the expectation value. The parameter s denotes the amount of capital raised, whose value can be determined at time of receipt, which is time Δ after the decision to raise capital has been made. In view of (d) in (1.9) the supremum over $s \ge 0$ when $f = V$ is attained as $s \to \infty$. Thus one has

$$MV(x) = \lim_{s\to\infty} E\left[e^{-\rho\Delta}\Big[V\Big(X(\Delta)+s\Big) - s - K\Big] I_{\tau>\Delta} | X(0) = x\right],\ x > 0. \tag{1.11}$$

Evidently a finite limit as $s \to \infty$ in (1.11) exists only if $\lim_{x\to\infty}[V(x) - x] = \beta + K$ exists. In that case the function MV is given by the formula

$$MV(x) = \beta[1 - p(x,\Delta)] + h(x,\Delta), \tag{1.12}$$

where

$$p(x,\Delta) = E[I_{\tau<\Delta}], \quad h(x,\Delta) = E[X(\Delta) I_{\tau>\Delta}]. \tag{1.13}$$

The determination of the parameter β in (1.12) plays a key role in the analysis of the Peura–Keppo model. If the cost K of raising capital is so large that the model reduces to the Milne–Robertson model, with solution V given in (1.7), then β has the value $\beta = V(u_0) - u_0 - K = \mu/\rho - u_0 - K$, which is independent of Δ. As K decreases there should be some critical value of K, $K_{\text{crit}}(\Delta)$ say, at which it begins to become optimal for the bank to raise capital in certain circumstances. In section 2 we define a function $\beta(\Delta)$ which is related to $K_{\text{crit}}(\Delta)$ by the equation $\beta(\Delta) = \mu/\rho - u_0 - K_{\text{crit}}(\Delta)$. One might reasonably expect $K_{\text{crit}}(\Delta)$ to be a decreasing function of Δ, and hence $\beta(\Delta)$ to be increasing. We show in section 2 that this in fact turns out to be the case.

Our main theorem is that the Peura–Keppo solution to (1.6) is the unique solution to the system of inequalities (1.9).

THEOREM 1.1. *For all $K, \Delta > 0$ there is a unique C^1 solution $V(x)$ to the system of inequalities* (1.9). *Further, for $\varepsilon > 0$ there is a control policy $\pi = \pi_\varepsilon$ such that if V_ε is defined by* (1.5), *then* $\lim_{\varepsilon\to 0} V_\varepsilon(x) = V(x)$, $x \ge 0$.

In [9] a formula for the value function $V(x)$ is given once one knows the two threshold values $u_{1,K}(\Delta)$, $u_{2,K}(\Delta)$. For $0 < x < u_{1,K}(\Delta)$, $V(x)$ is determined from equality in (1.9b). For $u_{1,K}(\Delta) < x < u_{2,K}(\Delta)$, $V(x)$ is determined from equality in (1.9c). For $x > u_{2,K}(\Delta)$, $V(x)$ is determined from equality in (1.9d). The threshold values $u_{1,K}(\Delta)$, $u_{2,K}(\Delta)$ are then determined by the requirement that the function V so constructed is C^1 at $u_{1,K}(\Delta)$and C^2 at $u_{2,K}(\Delta)$. Thus $u_{1,K}(\Delta)$, $u_{2,K}(\Delta)$ are solutions of a nonlinear system of two equations, and it is not clear if a solution exists for all positive Δ and nonnegative K. In [9] it is shown that a solution of these equations exists for certain ranges of the parameters Δ, K and that the constructed value function $V(x)$ satisfies most of the conditions of (1.9). There does not, however, seem to be a proof that (1.9c) holds for $0 < x < u_{1,K}(\Delta)$. In section 2 we construct the solution to (1.9) for all positive Δ and nonnegative K. The main mathematical fact needed is that a solution $u(x,t)$, $t > 0$, of the diffusion equation such that the initial data $u(x,0)$ has just one change of sign has at most one sign change for all $t > 0$. This property of the diffusion equation has been used previously [1, 7], and a proof based on probability has been given. In the appendix we give a proof using the maximum principle [10].

In [9] a limiting formula for the value function as $\Delta \to 0$ is given. This formula has the interesting property that condition (a) of (1.9) no longer holds. It corresponds to the fact that for $\Delta \to 0$ one allows the capital of the bank to drop to an arbitrarily low value, and then immediately raises capital to avoid default. The final section of the paper is devoted to establishing this formula and studying the asymptotic behavior of the thresholds $u_{1,K}(\Delta)$, and $u_{2,K}(\Delta)$ as $\Delta \to 0$. We also show that if $u_{1,K}(\Delta) > 0$ the optimal function $V(x)$, which is C^∞ for $x \neq u_{1,K}(\Delta)$, $u_{2,K}(\Delta)$ and C^2 at $x = u_{2,K}(\Delta)$, is not C^2 at $u_{1,K}(\Delta)$.

In section 3 we construct the policies π_ε and give the proof of uniqueness of V. The policy π_ε consists of paying out an immediate dividend of ε when the capital x of the bank reaches the upper threshold $u_{2,K}(\Delta)$. If $0 < x < u_{1,K}(\Delta)$, sufficient capital is raised (after time Δ) to bring the capital to the upper threshold $u_{2,K}(\Delta)$. If $x > u_{2,K}(\Delta)$, sufficient dividend is immediately paid out to bring the capital down to $u_{2,K}(\Delta) - \varepsilon$. For $u_{1,K}(\Delta) < x < u_{2,K}(\Delta)$, the bank's capital is fully invested in the risky asset described by (1.1). In the proof of uniqueness we need to use the fact that solutions to $u(x,t) = 0$ are nondegenerate.

2. Solution to system of Bellman equations. In this section we construct a solution to the system of inequalities (1.9). To do this we first consider solutions $V(x)$ to the equation

$$(A - \rho)V(x) = 0, \ x \in \mathbf{R}. \tag{2.1}$$

For any $u_0 > 0$, there is a unique solution V_0 to (2.1) with the initial conditions,

$$V_0(u_0) = \mu/\rho, \ V_0'(u_0) = 1. \tag{2.2}$$

Evidently (2.1), (2.2) imply that $V_0''(u_0) = 0$. Since solutions to (2.1) have just one point of inflection it follows that the function V_0 is concave for $x < u_0$ and convex for $x > u_0$. Evidently by translation there is a unique u_0 such that $V_0(0) = 0$. This unique u_0 is given in [9] by the formula

$$u_0 = \frac{1}{r_1 + r_2} \ \ln\left[\frac{\rho + \mu r_2}{\rho - \mu r_1}\right], \tag{2.3}$$

where r_1, r_2 are the characteristic roots for (2.1),

$$r_1 = \frac{-\mu + \sqrt{\mu^2 + 2\sigma^2\rho}}{\sigma^2},\ r_2 = \frac{\mu + \sqrt{\mu^2 + 2\sigma^2\rho}}{\sigma^2}.$$

Note that since V_0 is concave for $x < u_0$ and $V_0'(u_0) = 1$ it follows that u_0 of (2.3) satisfies the inequality

$$0 < u_0 < \mu/\rho. \tag{2.4}$$

Next for the diffusion process with generator A, started at $x > 0$, let τ_x be the first hitting time at 0. We define for $x > 0$, $t > 0$ the function $p(x,t)$ by

$$p(x,t) = P(\tau_x < t). \tag{2.5}$$

Then $p(x,t)$ is a solution to the equation

$$\frac{\partial p}{\partial t} = Ap, \quad x > 0,\ t > 0, \tag{2.6}$$

with boundary and initial conditions

$$p(0,t) = 1,\ t > 0; \quad p(x,0) = 0,\ x > 0. \tag{2.7}$$

It is also evident from the representation (2.5) that $p(x,t)$ satisfies the inequalities

$$\frac{\partial p}{\partial t} \geq 0,\ \frac{\partial p}{\partial x} \leq 0,\ x > 0,\ t > 0. \tag{2.8}$$

It follows from (2.6), (2.8) that for any fixed $t > 0$ the function $p(x,t)$ is a convex function of $x, x > 0$.

Let $h(x,t),\ x > 0, t > 0$, be a solution of the equation

$$\frac{\partial h}{\partial t} = Ah,\ x > 0,\ t > 0,$$

with boundary and initial conditions

$$h(0,t) = 0,\ t > 0;\ h(x,0) = x,\ x > 0.$$

It is easy to see that h and p are the same functions as those defined by (1.13), and that they are related by the formula

$$h(x,t) = x + \mu t - \mu \int_0^t p(x,s)ds. \tag{2.9}$$

LEMMA 2.1. *For fixed $t > 0$ the function $h(x,t)$ is a concave function of $x,\ x > 0$. It also satisfies the inequalities*

$$\mu/\rho - u_0 + h(x,t) \leq e^{\rho t}[x - u_0 + \mu/\rho],\ x \geq u_0, \tag{2.10}$$

$$h(x,t) \leq e^{\rho t} V_0(x),\ x \geq 0. \tag{2.11}$$

Proof. The concavity of h follows from (2.9) and the convexity of p. Inequality (2.10) follows from (2.9). Inequality (2.11) follows from the maximum principle for the diffusion equation since $V_0(x) \geq x,\ x > 0$. □

PROPOSITION 2.1. *Suppose u_0 is given by* (2.3) *and the cost K of capital issuance satisfies $K \geq \mu/\rho - u_0$. Define $V(x)$ by*

$$V(x) = V_0(x),\ 0 \leq x \leq u_0;\ V(x) = x - u_0 + \mu/\rho,\ x > u_0. \tag{2.12}$$

Then $V(x)$ is a C^2 function and satisfies the system of inequalities (1.9).

Proof. It is easy to see that the function $V(x)$ of (2.12) satisfies (1.9a)–(1.9e). To prove (b) we note from (2.12) that the parameter β in (1.12) is given by the formula $\beta = \mu/\rho - u_0 - K$, and hence the function $MV(x)$ is given by the expression

$$MV(x) = e^{-\rho\Delta}\left\{\left[\frac{\mu}{\rho} - u_0 - K\right]\{1 - p(x,\Delta)\} + h(x,\Delta)\right\}. \tag{2.13}$$

Now (b) follows from Lemma 2.1 on noting (2.4). □

From (2.11) we have that

$$\frac{\partial h}{\partial x}(0,t) \leq e^{\rho t}V_0'(0),\ t > 0.$$

Observe also that by the Hopf maximum principle [10] one has $\partial p/\partial x(0,t) < 0$, $t > 0$. Hence one may define a smooth function $\beta(t)$, $t > 0$, by the formula

$$\beta(t) = \left[\frac{\partial h}{\partial x}(0,t) - e^{\rho t}V_0'(0)\right] \Big/ \frac{\partial p}{\partial x}(0,t). \tag{2.14}$$

LEMMA 2.2. *The function $\beta(t)$ of* (2.14) *is strictly monotonic increasing and satisfies*

$$\lim_{t\to 0}\beta(t) = 0,\ \lim_{t\to\infty}\beta(t) = \infty.$$

Proof. Observe by the Hopf maximum principle that $\beta(t) > 0,\ t > 0$. To prove monotonicity let $T > 0$ and consider the function $u(x,t)$ defined by

$$u(x,t) = \beta(T)\{1 - p(x,t)\} + h(x,t) - e^{\rho t}V_0(x).$$

Then $u(x,t)$ is a solution of the diffusion equation (2.6) with initial and boundary conditions

$$u(x,0) = \beta(T) + x - V_0(x),\ u(0,t) = 0.$$

Evidently $u(x,0)$ is a monotonically decreasing function satisfying

$$\lim_{x\to 0}u(x,0) = \beta(T), \quad \lim_{x\to\infty}u(x,0) = -\infty.$$

In particular $u(x,0)$ has exactly one sign change. It follows therefore by Theorem A.1 of the appendix that $u(x,t)$ has at most one sign change for any fixed $t > 0$.

Consider now the function $u(x,T)$. Suppose first that $u(x,T) \leq 0,\ x \geq 0$. Then by the Hopf maximum principle $u(x,t) < 0,\ x > 0$, for any $t > T$ and $\partial u/\partial x(0,t) < 0$. Thus $\beta(t) > \beta(T)$. Alternatively there is an interval $(0,\alpha)$ for which $u(x,T) > 0,\ x \in (0,\alpha)$. By the Hopf principle one must then have $\partial u/\partial x(0,T) > 0$, which contradicts the definition of $\beta(T)$. We have shown that $\beta(t)$ is strictly monotonic increasing.

To find the limit of $\beta(t)$ as $t \to 0$ we compute the limits of the numerator and denominator of (2.14). For the numerator we clearly have that

$$\lim_{t\to 0}\left[\frac{\partial h}{\partial x}(0,t) - e^{\rho t}V_0'(0)\right] = 1 - V_0'(0) < 0. \tag{2.15}$$

To find the limit of the denominator we use the Green's functions $G(x,y,t)$ for the equation (2.6). Thus by the reflection principle we have that

$$G(x,y,t) = \frac{1}{\sqrt{2\pi\sigma^2\, t}}\Bigg\{ \exp\left[-\frac{(x-y+\mu t)^2}{2\sigma^2 t}\right] - \exp\left[-\frac{2\mu x}{\sigma^2} - \frac{(x+y-\mu t)^2}{2\sigma^2 t}\right]\Bigg\}, \quad x,y>0,$$

is the Dirichlet Green's function. Hence $p(x,t)$ is given by the formula

$$p(x,t) = 1 - \int_0^\infty G(x,y,t)dy. \tag{2.16}$$

It is easy to see from this that

$$\lim_{t\to 0}\ \sqrt{2\pi\sigma^2 t}\ \frac{\partial p}{\partial x}(0,t) = -2\ , \tag{2.17}$$

whence (2.15) and (2.17) imply $\lim_{t\to 0}\ \beta(t) = 0$. Similarly, one can easily see that $\lim_{t\to\infty}\ \beta(t) = \infty$. □

We may use the function $\beta(t)$ of (2.14) to improve Proposition 2.1.

PROPOSITION 2.2. *Let $\Delta > 0$ and $\beta(\Delta) > 0$ satisfy the inequality $K \geq \mu/\rho - u_0 - \beta(\Delta)$. Then the function $V(x)$ of* (2.12) *satisfies the system of inequalities* (1.9).

Proof. From Lemma 2.2 the function $MV(x)$ of (2.13) satisfies the inequality $MV(x) \leq V_0(x),\ x \geq 0$. To show that (b) of (1.9) holds, we then need to prove

$$MV(x) \leq x - u_0 + \mu/\rho,\ x > u_0.$$

This follows from Lemma 2.1 since $K \geq 0$. □

Next we consider situations for which K does not satisfy the conditions of Proposition 2.2. To help us understand this we define a function $u_2(\beta,t),\ \beta \geq 0,\ t > 0$, as follows:

$$u_2(\beta,t) = u_0 \text{ if } \beta \leq \beta(t).$$

If $\beta > \beta(t)$, then $u_2(\beta,t)$ is the supremum of all $z \in \mathbf{R}$ such that

$$\beta\{1 - p(x,t)\} + h(x,t) \leq e^{\rho t}\ V_0(x - z + u_0),\ x \geq 0.$$

It is evident that $u_2(\beta,t)$ is a monotonic decreasing function of β.

LEMMA 2.3. *The function $g(\beta) = \beta + u_2(\beta,t),\ \beta > 0$, is strictly monotone increasing.*

Proof. Suppose $\beta > \beta(t)$. Since $V_0'(w) \geq 1,\ w \in \mathbf{R}$, we have that for any $\delta > 0$,

$$e^{\rho t}\ V_0(x - u_2(\beta,t) + \delta + u_0) \geq \delta e^{\rho t} + \beta\{1 - p(x,t)\} + h(x,t),\ x \geq 0.$$

Hence,

$$u_2(\beta + \delta e^{\rho t}, t) \geq u_2(\beta, t) - \delta,$$

whence $g(\beta)$ is strictly monotonic. □

LEMMA 2.4. *For any $\beta > \beta(t)$ there exists a unique point $u_1(\beta, t) > 0$ such that*

$$\beta\{1 - p(x,t)\} + h(x,t) < e^{\rho t}\, V_0(x - u_2(\beta,t) + u_0),\ x \geq 0,\ x \neq u_1(\beta,t),$$

$$\beta\{1 - p(x,t)\} + h(x,t) = e^{\rho t}\, V_0(x - u_2(\beta,t) + u_0),\ x = u_1(\beta,t).$$

Proof. Suppose for a given $T > 0$ we have $\beta > \beta(T)$ and define $u(x,t),\ t > 0, x > 0$, by

$$u(x,t) = \beta\{1 - p(x,t)\} + h(x,t) - e^{\rho t}\, V_0(x - u_2(\beta,T) + u_0).$$

Then $u(x,t)$ is a solution of the diffusion equation (2.6) with initial and boundary conditions

$$u(x,0) = \beta + x - V_0(x - u_2(\beta,T) + u_0),\ u(0,t) = -e^{\rho t}\, V_0(u_0 - u_2(\beta,T)).$$

Evidently $u(x,0)$ is a monotonic decreasing function and $\lim_{x\to\infty} u(x,0) = -\infty$. Hence we must have

$$\beta > V_0(u_0 - u_2(\beta,T)),$$

since otherwise $u(x,T) < 0,\ x \geq 0$, which would contradict the definition of $u_2(\beta,T)$.

We show that for small t the set $\{x > 0 : u(x,t) > 0\}$ is an open interval $\big(a(t), b(t)\big)$ with $0 < a(t) < b(t) < \infty$. To see this, first note from (2.9), (2.17) that since $p(x,t)$ is a convex decreasing function there is the inequality

$$1 \leq \frac{\partial h}{\partial x} \leq 1 + 4\mu\sqrt{t}\,/\,\sqrt{2\pi\sigma^2},\ x > 0. \tag{2.18}$$

We can also see from (2.16) that for any $\delta,\ 0 < \delta < 1$, there exist positive constants $C(\delta)$, $K(\delta)$ such that for $0 < t < 1$,

$$p(x,t) < \delta, \quad x > C(\delta)\,\sqrt{t}, \tag{2.19}$$

$$\frac{\partial p}{\partial x}(x,t) < -\frac{K(\delta)}{\sqrt{t}},\ \ 0 < x < C(\delta)\,\sqrt{t}.$$

Choose now $\delta > 0$ such that

$$\beta(1 - 3\delta) > V_0(u_0 - u_2(\beta,T)).$$

Then from (2.18), (2.19) there exists $\varepsilon > 0$ such that for $0 < t < \varepsilon$ the function $u(x,t)$ is increasing for $0 < x < C(\delta)\,\sqrt{t}$ and $u\big(C(\delta)\sqrt{t},\ t\big) > \beta\delta$.

Next we find a region where $u(x,t)$ is decreasing. To see this observe that we may choose $\varepsilon > 0$ sufficiently small so that for $0 < t < \varepsilon$, there is the inequality

$$\frac{\partial p}{\partial x}(x,t) > -\exp\left[-1/t^{1/6}\right],\ x > t^{1/3}.$$

It follows then from (2.9) that $u(x,t)$ is decreasing for $x > t^{1/3}$, provided $0 < t < \varepsilon$. One also has that

$$\inf\left\{u(x,t) - u(C(\delta)\sqrt{t},\ t) : C(\delta)\sqrt{t} < x < t^{1/3}\right\} \geq -C_1\, t^{1/3}$$

for some constant C_1 which depends on δ. If we choose now ε small enough so that $C_1\varepsilon^{1/3} < \beta\delta$, then it follows that $\{x : u(x,t) > 0\}$ consists of an open interval, provided $0 < t < \varepsilon$.

We now invoke Theorem A.2 of the appendix. By the definition of $u_2(\beta, T)$ one has $u(x,T) \leq 0,\ x \geq 0$, and there is a unique $x = u_1(\beta, T)$ for which $u(x,T) = 0$. □

PROPOSITION 2.3. *Let $\Delta > 0$ and $\beta(\Delta) > 0$ satisfy the inequality $K < \mu/\rho - u_0 - \beta(\Delta)$. Then there is a unique solution $\beta > \beta(\Delta)$ to the equation*

$$\beta + u_2(\beta, \Delta) = \mu/\rho - K. \tag{2.20}$$

For this value of β put $u_2 = u_2(\beta,\Delta)$ and $u_1 = u_1(\beta,\Delta)$. Define the function $V(x)$, $x \geq 0$, by

$$\begin{aligned} &V(x) = x - u_2 + \mu/\rho, \quad x > u_2, \\ &V(x) = V_0(x + u_0 - u_2), \quad u_1 < x \leq u_2, \\ &V(x) = e^{-\rho\Delta}\left\{\beta[1 - p(x,\Delta)] + h(x,\Delta)\right\}, \quad 0 \leq x \leq u_1. \end{aligned} \tag{2.21}$$

Then the function $V(x)$ satisfies the system of inequalities (1.9).

Proof. Since $\beta(\Delta) + u_2\big(\beta(\Delta),\Delta\big) = \beta(\Delta) + u_0 < \mu/\rho - K$ it follows from Lemma 2.3 that there is a unique $\beta > \beta(\Delta)$ satisfying (2.20). We can also see that since $K \geq 0$ there is the inequality $u_1 < u_2$. In fact one has

$$\beta[1 - p(x,\Delta)] + h(x,\Delta) < e^{\rho\Delta}V_0(x + u_0 - u_2),\ x \geq u_2. \tag{2.22}$$

This follows from (2.9) since the left-hand side of (2.22) is strictly less than

$$\mu/\rho - K - u_2 + x + \mu\Delta < e^{\rho\Delta}[\mu/\rho + x - u_2] \leq e^{\rho\Delta}V_0(x + u_0 - u_2),\ x \geq u_2,$$

provided $K \geq 0$.

It is clear now that the function V of (2.21) is a C^1 function and C^2 except possibly at the point $x = u_1$. It is also concave with slope 1 for $x \geq u_2$. Hence (a), (d) of (1.9) hold. Next we prove (b). In view of the concavity of V we have that the function MV of (1.10) is given by the expression

$$MV(x) = e^{-\rho\Delta}\left\{\left[\frac{\mu}{\rho} - u_2 - K\right]\left\{1 - p(x,\Delta)\right\} + h(x,\Delta)\right\}. \tag{2.23}$$

Thus $V(x) = MV(x),\ 0 \leq x \leq u_1$, and by the definition of u_1 one has $MV(x) \leq V(x), u_1 \leq x \leq u_2$. For $x \geq u_2$ we also have $MV(x) \leq V(x)$ by the same argument used to show (2.22). We have proved (b) and also (e).

We are left to prove (c). It is easy to see that $(A - \rho)V(x) \leq 0,\ x > u_1$. We consider then the case $0 < x < u_1$. To see this we observe that the function $u_1(\beta',\Delta),\ \beta' > \beta(\Delta)$, is continuous and satisfies $\lim_{\beta' \to \beta(\Delta)} u_1(\beta',\Delta) = 0$. Hence if $0 < x < u_1$, there exists $\beta',\ 0 < \beta' < \beta$ such that $x = u_1(\beta',\Delta)$. Let $w(z)$ be the function

$$w(z) = \beta'\{1 - p(z,\Delta)\} + h(z,\Delta),\ z > 0.$$

By Lemma 2.4 it follows that $(A-\rho)w(z) \le 0$ at $z = u_1(\beta', \Delta) = x$. Since

$$e^{\rho\Delta}\, MV(z) = (\beta - \beta')\{1 - p(z,\Delta)\} + w(z),$$

and $Ap(z,\Delta) = \partial p/\partial t(z,\Delta) \ge 0$, one has therefore that $(A-\rho)V(x) \le 0$. □

3. Uniqueness of the solution. Here we show that the solution to the system of inequalities (1.9) is unique, provided we make some smoothness assumptions on the function $V(x)$. Our first goal is to show that a limiting set of strategies realizes the function $V(x)$ constructed in Propositions 2.1–2.3. In the following we shall use the convention that if $F(t),\ t > 0$, is a right continuous function of time, then at time τ, $F(\tau^+)$ denotes the limit of $F(t)$ as t converges to τ from above.

We first consider the situation in Propositions 2.1 and 2.2. Let ε satisfy $0 < \varepsilon < u_0$. We define a strategy π_ε for the control process (1.4). Suppose the process begins at x with $0 < x < u_0$. For those paths which exit the interval $[0, u_0]$ through u_0 let τ_1 be the exit time. We set $L(t) = 0,\ t \le \tau_1$, and $L(\tau_1^+) = \varepsilon$. Thus $X(\tau_1^+) = u_0 - \varepsilon$. If the process begins at x with $x \ge u_0$, we set $\tau_1 = 0, L(\tau_1^+) = \varepsilon + x - u_0$, whence again $X(\tau_1^+) = u_0 - \varepsilon$. Next we define $\tau_2 > \tau_1$ as the first time the diffusion process with $X(\tau_1^+) = u_0 - \varepsilon$ hits u_0 for paths which exit the interval $[0, u_0]$ through u_0. We put $L(t) - L(\tau_1^+) = 0$, $\tau_1 < t < \tau_2$, $L(\tau_2^+) - L(\tau_1^+) = \varepsilon$. Thus $X(\tau_2^+) = u_0 - \varepsilon$. We proceed in this manner defining a sequence of stopping times $\tau_1, \tau_2, \ldots$ until the diffusion exits $[0, u_0]$ through 0.

LEMMA 3.1. *Let V_ε be the return function* (1.5) *for the strategy $\pi = \pi_\varepsilon$. Then $\lim_{\varepsilon\to 0} V_\varepsilon(x) = V(x)$, where $V(x)$ is given by* (2.12).

Proof. Evidently we have that

$$V_\varepsilon(x) = x - u_0 + \varepsilon + V_\varepsilon(u_0 - \varepsilon), \quad x \ge u_0. \tag{3.1}$$

For the diffusion process started at $x,\ 0 < x < u_0$, let τ_x be the first exit time from the interval $[0, u_0]$. Then we also have that

$$\begin{aligned} V_\varepsilon(x) &= V_\varepsilon(u_0) E\left[\exp(-\rho\tau_x); X(\tau_x) = u_0\right] \\ &= V_\varepsilon(u_0) w(x), \quad 0 < x < u_0, \end{aligned} \tag{3.2}$$

where the function $w(x)$ satisfies

$$(A-\rho)w(x) = 0,\ 0 < x < u_0, \quad w(0) = 0,\ w(u_0) = 1.$$

It follows that $w(x) = \rho\ V_0(x)/\mu$. Letting $x = u_0 - \varepsilon$ in (3.2) and using (3.1), we conclude that $V_\varepsilon(u_0)$ is given by the formula

$$V_\varepsilon(u_0) = \varepsilon \,/\, [1 - w(u_0 - \varepsilon)].$$

Hence $V_\varepsilon(x),\ 0 < x < u_0$, is given by the formula

$$V_\varepsilon(x) = \left[\frac{V_0(u_0) - V_0(u_0 - \varepsilon)}{\varepsilon}\right]^{-1} V_0(x),\ 0 < x < u_0.$$

Since $V_0'(u_0) = 1$ the result follows. □

Next we consider the situation in Proposition 2.3. We define a strategy π_ε for the control process (1.4) whose limiting return function as $\varepsilon \to 0$ yields the function (2.21). If the process begins at x with $x \ge u_2$, we set $\tau_1 = 0,\ L(\tau_1^+) = \varepsilon + x - u_2$, whence

$X(\tau_1^+) = u_2 - \varepsilon$. We require that $0 < \varepsilon < u_2 - u_1$, whence $u_1 < X(\tau_1^+) < u_2$. If the process begins at x with $u_1 < x < u_2$, we set τ_1 to be the first exit time of the diffusion process from the interval $[u_1, u_2]$. If $X(\tau_1) = u_2$, then we put $L(t) = 0,\ t \le \tau_1$, and $L(\tau_1^+) = \varepsilon$, whence $X(\tau_1^+) = u_2 - \varepsilon$. Suppose now $X(\tau_1) = u_1$. We restrict ourselves to all paths of the diffusion process $X(t),\ \tau_1 \le t \le \tau_1 + \Delta$, which satisfy $X(t) > 0$. For these paths we set $L(t) = 0,\ t \le \tau_1 + \Delta$,

$$L((\tau_1 + \Delta)^+) = X(\tau_1 + \Delta) - u_2 - K. \tag{3.3}$$

Note that if Δ is small, the expression in (3.3) is negative. We finally put $X((\tau_1 + \Delta)^+) = u_2$. For $0 < x \le u_1$ we restrict ourselves to all paths of the diffusion process $X(t), t \le \Delta$, which satisfy $X(t) > 0$. For these paths we set $L(t) = 0,\ t \le \Delta$,

$$L(\Delta^+) = X(\Delta) - u_2 - K. \tag{3.4}$$

Finally we put $X(\Delta^+) = u_2$. The process $L(t), t > \tau_1$, is defined similarly.

LEMMA 3.2. *Let V_ε be the return function* (1.5) *for the strategy $\pi = \pi_\varepsilon$. Then* $\lim_{\varepsilon \to 0} V_\varepsilon(x) = V(x)$, *where $V(x)$ is given by* (2.21).

Proof. Arguing as in Lemma 3.1, we have that

$$V_\varepsilon(x) = x - u_2 + \varepsilon + V_\varepsilon(u_2 - \varepsilon),\ x \ge u_2, \tag{3.5}$$

$$V_\varepsilon(x) = V_\varepsilon(u_2) w_2(x) + V_\varepsilon(u_1) w_1(x),\ u_1 < x < u_2, \tag{3.6}$$

where

$$w_2(x) = E\left[\exp(-\rho\tau_x);\ X(\tau_x) = u_2\right],$$

$$w_1(x) = E\left[\exp(-\rho\tau_x);\ X(\tau_x) = u_1\right],$$

and τ_x is the exit time from the interval $[u_1, u_2]$ for the diffusion process started at x. For $0 < x \le u_1$ we have in addition the identity

$$V_\varepsilon(x) = e^{-\rho\Delta} E\left[X(\Delta) - u_2 - K\ ;\ \tau_x > \Delta\right] + e^{-\rho\Delta} V_\varepsilon(u_2) P(\tau_x > \Delta), \tag{3.7}$$

where τ_x is the first time the diffusion started at x hits 0. From (2.21) we can rewrite (3.7) as

$$V_\varepsilon(x) = V(x) + e^{-\rho\Delta}\left\{V_\varepsilon(u_2) - V(u_2)\right\}[1 - p(x, \Delta)]. \tag{3.8}$$

It is clear that for $u_1 < x < u_2$ the function $V(x)$ may be written as

$$V(x) = V(u_2) w_2(x) + V(u_1) w_1(x),\quad u_1 < x < u_2.$$

Hence if we put $g_\varepsilon(x) = V_\varepsilon(x) - V(x)$, we have from (3.6) that

$$g_\varepsilon(x) = g_\varepsilon(u_2) w_2(x) + g_\varepsilon(u_1) w_1(x),\ u_1 < x < u_2. \tag{3.9}$$

Setting $x = u_1$ in (3.8) we also have that

$$g_\varepsilon(u_1) = e^{-\rho\Delta} g_\varepsilon(u_2)[1 - p(u_1, \Delta)]. \tag{3.10}$$

Putting $x = u_2$ in (3.5) yields the identity

$$g_\varepsilon(u_2 - \varepsilon) = g_\varepsilon(u_2) + [V(u_2) - V(u_2 - \varepsilon) - \varepsilon]. \tag{3.11}$$

If we set $x = u_2 - \varepsilon$ in (3.9) and use (3.10), (3.11), we obtain a formula for $g_\varepsilon(u_2)$,

$$g_\varepsilon(u_2) = -[V(u_2) - V(u_2 - \varepsilon) - \varepsilon] \big/ \left\{1 - w_2(u_2 - \varepsilon) - e^{-\rho\Delta}[1 - p(u_1, \Delta)]w_1(u_2 - \varepsilon)\right\}. \tag{3.12}$$

Since V is concave at u_2 the numerator of (3.12) is negative. The denominator is positive since $w_1(x) + w_2(x) < 1$, $u_1 < x < u_2$. Hence $g_\varepsilon(u_2) < 0$. It follows now from (3.5), (3.8), (3.9) that $V_\varepsilon(x) < V(x)$, $x > 0$. Since the numerator of (3.12) is $O(\varepsilon^2)$ and the denominator is from Hopf's maximum principle bounded below by a positive constant times ε, it follows that $\lim_{\varepsilon\to 0} g_\varepsilon(u_2) = 0$. Hence $\lim_{\varepsilon\to 0} V_\varepsilon(x) = V(x)$, $x \geq 0$. □

We have shown that certain limiting strategies yield the return functions given in Propositions 2.1–2.3. Next let $V(x)$ be a C^1 solution of the system of inequalities (1.9). Since $V'(x) \geq 1$, $x > 0$, the limit

$$\beta + K = \lim_{x\to\infty} [V(x) - x] \text{ exists.} \tag{3.13}$$

This limit must be finite. Otherwise the function $MV(x)$ cannot be finite. Hence from (1.10) we have

$$MV(x) = e^{-\rho\Delta}\left\{\beta[1 - p(x, \Delta)] + h(x, \Delta)\right\}. \tag{3.14}$$

LEMMA 3.3. *There exists u_2, ε with $0 < \varepsilon < u_2$ such that $V(x) = \beta + K + x$ for $x \geq u_2$, and for $u_2 - \varepsilon < x \leq u_2$, $V(x)$ is the solution to the initial value problem*

$$(A - \rho)V(x) = 0, \quad V(u_2) = \mu/\rho, \quad V'(u_2) = 1. \tag{3.15}$$

Further, β and u_2 are related by the identity

$$\beta = \mu/\rho - K - u_2. \tag{3.16}$$

Proof. Suppose $u_2 > 0$ is a point which has the property that for some $\delta > 0$ one has $V'(x) = 1$ for $u_2 \leq x < u_2 + \delta$, and $(A - \rho)V(x) = 0$ for $u_2 - \delta < x < u_2$. Since $(A - \rho)V(x) \leq 0$ for $u_2 \leq x < u_2 + \delta$ it follows that $V(u_2) \geq \mu/\rho$. Using the fact that V is C^1 at u_2 and $(A - \rho)V(x) = 0$, $x < u_2$, we can conclude now that $\lim_{x\to u_2-} V''(x) \geq 0$. If $\lim_{x\to u_2-} V''(x) > 0$, then $V'(x) < 1$ for $x < u_2$ with $u_2 - x$ sufficiently small, in contradiction to (1.9). Hence $\lim_{x\to u_2-} V''(x) = 0$, whence $V(u_2) = \mu/\rho$ since $V'(u_2) = 1$. Thus for $u_2 - \delta < x < u_2$ the function V is the solution to (3.15).

From (2.9), (3.13), (3.14) we see that there exists $u_3 > 0$ such that $MV(x) < V(x)$ for $x \geq u_3$. Hence for each $x > u_3$ the function V must satisfy $(A - \rho)V(x) = 0$ or $V'(x) = 1$. Observe now that (3.13) implies that $\{x : (A - \rho)V(x) = 0\}$ does not include a neighborhood of ∞. Hence by the argument of the previous paragraph $\{x : V'(x) = 1\}$ does include a neighborhood of ∞. We define u_2 by

$$u_2 = \inf\{z : V'(x) = 1, \ x \geq z\}.$$

We show that $MV(u_2) < V(u_2)$. To see this, first note that from (3.13) one has $V(x) = \beta + K + x$, $x > u_2$, and we also have that $V(u_2) \geq \mu/\rho$. Now $V'(x) \geq 1$, $0 < x < u_2$, and $V(0) = 0$. Hence $\beta + K \geq 0$. If $\beta \leq 0$, then (2.9), (3.14) yield the inequality

$$MV(u_2) < e^{-\rho\Delta}(u_2 + \mu\Delta).$$

Since there is also the inequality

$$e^{\rho\Delta}V(u_2) \geq \left[e^{\rho\Delta} - 1\right]\mu/\rho + \beta + K + u_2 \geq \mu\Delta + u_2,$$

it follows that $MV(u_2) < V(u_2)$. If on the other hand $\beta \geq 0$, then

$$MV(u_2) < e^{-\rho\Delta}[\beta + u_2 + \mu\Delta],$$

$$e^{\rho\Delta}V(u_2) \geq \mu\Delta + \beta + K + u_2.$$

Hence again we have $MV(u_2) < V(u_2)$.

The result of the lemma now easily follows since by the previous paragraph there exists $\varepsilon > 0$ such that $(A-\rho)V(x) = 0$ for $u_2 - \varepsilon < x < u_2$. From the first paragraph it follows that V is the solution to (3.15). The identity (3.16) follows from the fact that $V(u_2) = \mu/\rho$. □

Next we define $u_1 < u_2$ by

$$u_1 = \inf\{z > 0 : (A-\rho)V(x) = 0,\ z < x < u_2\}.$$

LEMMA 3.4. *If $u_1 > 0$, then $u_2 < u_0$, $\beta > 0$ and $V(x) = MV(x)$ for $0 < x < u_1$.*

Proof. We proceed as in Lemma 2.4 by considering the function $u(x,t)$ given by

$$u(x,t) = \beta\{1 - p(x,t)\} + h(x,t) - e^{\rho t}V_0(x - u_2 + u_0).$$

Then $u(x,t)$ is a solution of the diffusion equation (2.6) with initial and boundary conditions

$$u(x,0) = \beta + x - V_0(x - u_2 + u_0),\ u(0,t) = -e^{\rho t}V_0(u_0 - u_2).$$

Let us suppose first that $u_2 \geq u_0$. In that case $u(0,t) \geq 0$ and $u(x,0)$ is a monotonic decreasing function with $\lim_{x\to\infty} u(x,0) = -\infty$. It is easy to see from this that for small t the function $u(x,t)$ has at most one sign change. Hence by Theorem A.1, u_1 is the unique solution to the equation $u(x,\Delta) = 0$. From Theorem A.3 it follows that $\partial u/\partial x(x,\Delta) < 0$ at $x = u_1$, but this contradicts the C^1 property of the function $V(x)$ at $x = u_1$. We conclude that $u_2 < u_0$.

Assuming $u_2 < u_0$, then $u(0,t) < 0$. Hence $\beta > V_0(u_0 - u_2) > 0$ since otherwise $u(x,t) < 0,\ x \geq 0,\ t > 0$. By Theorem A.2 the set $\{x > 0 : u(x,\Delta) \geq 0\}$ is a closed interval with u_1 as one of its end points. Evidently u_1 must be the rightmost end point. If the interior of the interval is nonempty, then $\partial u/\partial x(x,\Delta) < 0$ at $x = u_1$ by Theorem A.3 of the appendix. Since this again contradicts the C^1 property of V at u_1 we conclude that $\{x > 0 : u(x,\Delta) \geq 0\} = \{u_1\}$. It is clear now that in the notation of section 2 we have $\beta > \beta(\Delta)$, $u_2 = u_2(\beta,\Delta)$, and $u_1 = u_1(\beta,\Delta)$.

Finally we need to show that $V(x) = MV(x),\ 0 < x < u_1$. Let $u_3 = \inf\{z : 0 < z < u_1,\ V(x) = MV(x) \text{ for } z < x < u_1\}$. Evidently $0 \leq u_3 < u_1$. Suppose now $u_3 > 0$. Since $V(x)$ is concave for $x > u_3$ it follows that $V'(u_3) > 1,\ V(u_3) < \mu/\rho$. Let $u_4 = \inf\{z : 0 < z < u_3,\ (A-\rho)V(x) = 0 \text{ for } z < x < u_3\}$. It is easy to see that $V(x)$ is concave for $u_4 < x < u_2$. Let $w(x) = V(x) - MV(x),\ u_4 < x < u_3$. Then we must have that $w(u_4) = w(u_3) = 0$ and $w(x) \geq 0,\ u_4 < x < u_3$. By the argument of Proposition 2.3 we also have that $(A-\rho)w(x) \geq 0,\ u_4 < x < u_3$. Hence by the maximum principle it follows that $w(x) = 0,\ u_4 < x < u_3$. Since this contradicts the definition of u_3 we conclude that $u_3 = 0$. □

PROPOSITION 3.1. *Let $V(x),\ x \geq 0$, be a C^1 solution to the set of inequalities* (1.9). *Then V is the unique solution given by Propositions* 2.1–2.3.

Proof. This follows from Lemmas 3.3 and 3.4. □

We give an alternative proof of Proposition 3.1 which avoids the use of Theorem A.3. Instead, we shall use the technique of "verification theorem" [2, 3].

LEMMA 3.5. *With u_1, u_2 as defined in Lemma* 3.4 *there is the inequality $u_2 \geq u_2(\beta, \Delta)$, where β is the solution to* (2.20).

Proof. Let π_ε be the strategy defined just before Lemma 3.2, where u_1, u_2 are as in Lemma 3.4. If V_ε is the return function (1.5) corresponding to π_ε, then by the argument of Lemma 3.2 we see that $\lim_{\varepsilon \to 0} V_\varepsilon(x) = V(x)$ for $x \geq u_1$, where $V(x)$ is the function discussed in Lemmas 3.3 and 3.4.

Next let $V_{opt}(x)$ be the solution to the control problem constructed in Propositions 2.1–2.3. We shall show that

$$V_{opt}(x) \geq V_\varepsilon(x), \quad x \geq u_1. \tag{3.17}$$

To see this first let $X(t),\ t > 0$, be the diffusion process with generator A. Assume $X(0) > 0$ and τ is the first hitting time at 0. Since $V_{opt}(x)$ is C^1 for $x \geq 0$ and C^2 for all $x \geq 0$ except possibly $x = u_1(\beta, \Delta)$ with β satisfying (2.20), it follows that

$$e^{-\rho t} V_{opt}\left(X(t \wedge \tau)\right) - \int_0^{t \wedge \tau} e^{-\rho s}(A - \rho) V_{opt}\left(X(s)\right) ds \tag{3.18}$$

is a martingale.

Now let $X(0) = u_2 - \varepsilon$ and let τ_1 be the first exit time from the interval $[u_1, u_2]$. Evidently $\tau_1 < \tau$. Since $(A - \rho)V_{opt}(x) \leq 0,\ x \geq 0$, it follows from (3.18) that

$$V_{opt}(u_2 - \varepsilon) \geq E\left[e^{-\rho \tau_1} V_{opt}\left(X(\tau_1)\right)\right]. \tag{3.19}$$

Since $V'_{opt}(x) \geq 1,\ x \geq 0$, it follows that

$$\begin{aligned} &E\left[e^{-\rho \tau_1} V_{opt}\left(X(\tau_1)\right); X(\tau_1) = u_2\right] \\ &\quad \geq E\left[e^{-\rho \tau_1} V_{opt}(u_2 - \varepsilon); X(\tau_1) = u_2\right] + E\left[e^{-\rho \tau_1} \varepsilon; X(\tau_1) = u_2\right]. \end{aligned} \tag{3.20}$$

On using the fact that $MV_{opt}(x) \leq V_{opt}(x),\ x \geq 0$, we also have that

$$\begin{aligned} &E\left[e^{-\rho \tau_1} V_{opt}\left(X(\tau_1)\right); X(\tau_1) = u_1\right] \\ &\quad \geq E\left[e^{-\rho(\tau_1 + \Delta)} V_{opt}(u_2); X(\tau_1) = u_1,\ \tau_1 + \Delta < \tau\right] \\ &\qquad + E\left[e^{-\rho(\tau_1 + \Delta)}\left[X(\tau_1 + \Delta) - u_2 - K\right]; X(\tau_1) = u_1, \tau_1 + \Delta < \tau\right]. \end{aligned}$$

Hence there is the inequality

$$\begin{aligned} &E\left[e^{-\rho \tau_1} V_{opt}\left(X(\tau_1)\right); X(\tau_1) = u_1\right] \\ &\quad \geq E\left[e^{-\rho(\tau_1 + \Delta)} V_{opt}(u_2 - \varepsilon); X(\tau_1) = u_1,\ \tau_1 + \Delta < \tau\right] \\ &\qquad + E\left[e^{-\rho(\tau_1 + \Delta)} \varepsilon; X(\tau_1) = u_1,\ \tau_1 + \Delta < \tau\right] \\ &\qquad + E\left[e^{-\rho(\tau_1 + \Delta)}\left[X(\tau_1 + \Delta) - u_2 - K\right]; X(\tau_1) = u_1, \tau_1 + \Delta < \tau\right]. \end{aligned} \tag{3.21}$$

If we now define τ_1^* as $\tau_1^* = \tau_1$ if $X(\tau_1) = u_2$, $\tau_1^* = \tau_1 + \Delta$ if $X(\tau_1) = u_1$, we have from (3.19), (3.20), (3.21) the inequality

$$V_{opt}(u_2 - \varepsilon) \geq E\left[e^{-\rho\tau_1^*} V_{opt}(u_2 - \varepsilon); \tau_1^* < \tau\right] + E\left[\int_0^{\tau_1^*} e^{-\rho t} dL(t); \tau_1^* < \tau\right], \tag{3.22}$$

where $L(t)$ is the return function associated with the strategy π_ε. Evidently if we iterate the inequality (3.22), we obtain (3.17) for $x = u_2 - \varepsilon$. The inequality for all $x \geq u_1$ follows in a similar way.

If we let $\varepsilon \to 0$ in (3.17), we obtain the inequality $V_{opt}(x) \geq V(x)$, $x \geq u_1$, which implies the result. □

LEMMA 3.6. *With u_1, u_2 as defined in Lemma* 3.4 *there is the inequality $u_2 \leq u_2(\beta, \Delta)$, where β is the solution to* (2.20).

Proof. Let $\pi_{opt,\varepsilon}$ be the strategy of Lemma 3.2 and $V_{opt,\varepsilon}$ the corresponding return function. Then by Lemma 3.2 we have that $\lim_{\varepsilon \to 0} V_{opt,\varepsilon}(x) = V_{opt}(x)$, where V_{opt} is the function given by (2.21). We shall show that for V, the function discussed in Lemmas 3.3 and 3.4, there is the inequality

$$V(x) \geq V_{opt,\varepsilon}(x), \ x \geq u_1(\beta, \Delta), \tag{3.23}$$

where β is the solution to (2.20). In fact the proof of (3.23) is identical to the proof of (3.17) since V satisfies the variational inequalities (1.9). The result follows by letting $\varepsilon \to 0$. □

Proof of Proposition 3.1. We have shown in Lemmas 3.5 and 3.6 that $u_2 = u_2(\beta, \Delta)$ with β satisfying (2.20). Since MV is given by (3.14) and $MV(u_1) = V(u_1)$ we must have $u_1 = u_1(\beta, \Delta)$. The fact that $V(x) = MV(x)$ for $0 < x < u_1$ follows by the argument at the end of Lemma 3.4. □

4. Properties of the thresholds u_1, u_2. In this section we shall study the properties of u_1, u_2 as defined in Proposition 2.3. Evidently u_1, u_2 are functions of $K \geq 0$ and $\Delta > 0$. If $K \geq \mu/\rho - u_0$, then $u_2 = u_0, u_1 = 0$. We shall therefore be interested in the situation where $0 \leq K < \mu/\rho - u_0$.

LEMMA 4.1. *Suppose $0 \leq K < \mu/\rho - u_0$ and for $\Delta > 0$ let $u_{1,K}(\Delta)$, $u_{2,K}(\Delta)$ be the values of u_1, u_2 determined by K, Δ. Then $u_{1,K}, u_{2,K}$ are continuous functions satisfying*

$$\lim_{\Delta \to 0} u_{1,K}(\Delta) = 0, \quad \lim_{\Delta \to 0} u_{2,K}(\Delta) = u_0 - \hat{u}_K, \tag{4.1}$$

where $z = \hat{u}_K$ is the unique solution to the equation

$$V_0(z) = z + \mu/\rho - K - u_0. \tag{4.2}$$

$u_{1,K}(\Delta) = 0$, $u_{2,K}(\Delta) = u_0$, provided $\Delta \geq \Delta_0$, where $\Delta = \Delta_0$ is the unique solution to the equation

$$\beta(\Delta) = \mu/\rho - K - u_0.$$

Proof. It is easy to see that $u_{1,K}(\Delta)$ and $u_{2,K}(\Delta)$, $\Delta > 0$, are continuous functions. Evidently Proposition 2.2 implies that $u_{1,K}(\Delta) = 0$, $u_{2,K}(\Delta) = u_0$ if

$\Delta \geq \Delta_0$. We consider the case $\Delta \to 0$. Then the function $u_2(\beta, \Delta)$ defined just before Lemma 2.3 satisfies

$$\lim_{\Delta \to 0} u_2(\beta, \Delta) = u_0 - z_\beta,$$

where z_β is the unique solution to the equation $V_0(z_\beta) = \beta$. From Proposition 2.3 it follows therefore that $\hat{u}_K = z_\beta$, where β satisfies $\beta + u_0 - z_\beta = \mu/\rho - K$. This equation is evidently the same as (4.2). Note that $0 < \hat{u}_K \leq u_0$ since $V_0(0) = 0$, $V_0(u_0) = \mu/\rho$ and $V_0'(z) > 1$, $z > 0$. □

Next we obtain the first order behavior of $\beta(\Delta), u_{1,K}(\Delta), u_{2,K}(\Delta)$ as $\Delta \to 0$. The first order behavior of $\beta(\Delta)$ can easily be obtained from (2.14), (2.17), (2.18). Thus we have

$$\lim_{\Delta \to 0} \beta(\Delta)/\sqrt{\Delta} = [V_0'(0) - 1]\sqrt{\pi\sigma^2/2} > 0.$$

To obtain the first order behavior of $u_{1,K}(\Delta), u_{2,k}(\Delta)$ as $\Delta \to 0$ we consider the behavior of the functions $u_1(\beta, \Delta), u_2(\beta, \Delta)$ as $\Delta \to 0$, where $\beta > 0$.

LEMMA 4.2. *Let $u_1(\beta, \Delta), u_2(\beta, \Delta)$ be the functions defined in Lemmas* 2.3 *and* 2.4. *Then if $\beta > 0$ there are the limits*

$$\lim_{\Delta \to 0} u_1(\beta, \Delta)/\sigma\sqrt{\Delta}|\ln \Delta|^{1/2} = 1,$$

$$\lim_{\Delta \to 0} \{u_2(\beta, \Delta) - [u_0 - \hat{u}_\beta]\} \Big/ \sigma\sqrt{\Delta}|\ln \Delta|^{1/2} = 1 - 1/V_0'(\hat{u}_\beta),$$

where $\hat{u}_\beta$ is the unique solution $z = \hat{u}_\beta$ to the equation $V_0(z) = \beta$.

Proof. Just as in the proof of Lemma 4.1 we see that $u_1(\beta, \Delta), u_2(\beta, \Delta)$ satisfy

$$\lim_{\Delta \to 0} u_1(\beta, \Delta) = 0, \lim_{\Delta \to 0} u_2(\beta, \Delta) = u_0 - \hat{u}_\beta. \tag{4.3}$$

For $\Delta > 0$ it follows from Lemma 2.4 that $u_1 = u_1(\beta, \Delta)$ and $u_2 = u_2(\beta, \Delta)$ are the unique positive solutions to the system of equations

$$\beta\{1 - p(u_1, \Delta)\} + h(u_1, \Delta) = e^{\rho\Delta} V_0(u_1 - u_2 + u_0), \tag{4.4}$$

$$-\beta \frac{\partial p}{\partial x}(u_1, \Delta) + \frac{\partial h}{\partial x}(u_1, \Delta) = e^{\rho\Delta} V_0'(u_1 - u_2 + u_0). \tag{4.5}$$

We shall look for solutions to (4.4), (4.5) which satisfy (4.3). To do this we first note from (2.16) that $\partial p/\partial x$ is given by the formula

$$-\frac{\partial p}{\partial x}(x, t) = \frac{2}{\sqrt{2\pi\sigma^2 t}} \left\{ \exp\left[-\frac{(x + \mu t)^2}{2\sigma^2 t}\right] + \frac{\mu}{\sigma^2} \exp\left[-\frac{2\mu x}{\sigma^2}\right] \int_0^\infty \exp\left[-\frac{(x + y - \mu t)^2}{2\sigma^2 t}\right] dy \right\}. \tag{4.6}$$

Let $g(z), z > 0$, be the function

$$g(z) = \sqrt{2\pi\sigma^2\Delta} \left\{ -\beta \frac{\partial p}{\partial x}\left(z\sqrt{\Delta}, \Delta\right) + \frac{\partial h}{\partial x}\left(z\sqrt{\Delta}, \Delta\right) - e^{\rho\Delta} V_0'\left(z\sqrt{\Delta} - u_2 + u_0\right) \right\}, \tag{4.7}$$

where u_2 is a fixed parameter restricted to lie in the region

$$\hat{u}_\beta/2 < u_0 - u_2 < (u_0 + \hat{u}_\beta)/2. \tag{4.8}$$

Observe now that in view of (4.8) there are constants $\Delta_0, K_0 > 0$ such that if $0 < \Delta < \Delta_0$ and $a(\Delta), b(\Delta) > 0$ are defined by the identities

$$a(\Delta)^2/2\sigma^2 = -\frac{1}{2}\ln\Delta - K_0, \tag{4.9}$$

$$b(\Delta)^2/2\sigma^2 = -\frac{1}{2}\ln\Delta + K_0,$$

then the function g is strictly monotonic decreasing in the interval $[a(\Delta), b(\Delta)]$ with $g(a(\Delta)) > 0,\ g(b(\Delta)) < 0$. It follows that there is a unique solution $z = z_\Delta(u_2)$ of the equation $g(z) = 0$ in the interval $(a(\Delta), b(\Delta))$. We have shown then that (4.5) gives $u_1 = \sqrt{\Delta}\ z_\Delta(u_2)$ as a unique function of u_2, provided $0 < \Delta < \Delta_0$ and u_2 satisfies (4.8).

Next we wish to estimate the left-hand side of (4.4) when $u_1 = \sqrt{\Delta}\ z$ and $z \in [a(\Delta), b(\Delta)]$. To do this we write

$$p\big(\sqrt{\Delta}\ z, \Delta\big) = -\int_{\sqrt{\Delta}\ z}^{\infty} \frac{\partial p}{\partial x}\ (x, \Delta)dx$$

and use the formula (4.6). Observe now that

$$\begin{aligned}
&\frac{2}{\sqrt{2\pi\sigma^2\Delta}} \int_{\sqrt{\Delta}\ z}^{\infty} \exp\left[-\frac{(x+\mu\Delta)^2}{2\sigma^2\Delta}\right] dx \\
&\quad = \exp\left[-\frac{1}{2\sigma^2}\left(z+\mu\sqrt{\Delta}\right)^2\right] \frac{2}{\sqrt{2\pi\sigma^2}} \int_0^\infty d\xi\ \exp\left[-\frac{\xi(z+\mu\sqrt{\Delta})}{\sigma^2} - \frac{\xi^2}{2\sigma^2}\right] \\
&\quad \le \exp\left[-\frac{1}{2\sigma^2}\left(z+\mu\sqrt{\Delta}\right)^2\right] \frac{2\sigma}{\sqrt{2\pi}(z+\mu\sqrt{\Delta})}.
\end{aligned}$$

We can similarly estimate the contribution to $p(\sqrt{\Delta}\ z, \Delta)$ from the second term in (4.6). Thus we have

$$\begin{aligned}
&\frac{2}{\sqrt{2\pi\sigma^2\Delta}} \int_0^\infty \exp\left[-\frac{(x+y-\mu\Delta)^2}{2\sigma^2\Delta}\right] dy \\
&\qquad \le \frac{2\sigma\sqrt{\Delta}}{\sqrt{2\pi}(x-\mu\Delta)}\ \exp\left[-\frac{1}{2\sigma^2\Delta}(x-\mu\Delta)^2\right], \\
&\int_{\sqrt{\Delta}\ z}^\infty dx\ \frac{2\sigma\sqrt{\Delta}}{\sqrt{2\pi}(x-\mu\Delta)} \frac{\mu}{\sigma^2} \exp\left[-\frac{2\mu x}{\sigma^2}\right] \exp\left[-\frac{1}{2\sigma^2\Delta}(x-\mu\Delta)^2\right] \\
&\qquad \le \frac{2\sigma\sqrt{\Delta}}{\sqrt{2\pi}(z+\mu\sqrt{\Delta})} \exp\left[-\frac{1}{2\sigma^2}(z+\mu\sqrt{\Delta})^2\right],
\end{aligned}$$

provided $z \ge 2\mu\max(1, \sqrt{\Delta_0})$. We conclude then that for Δ_0 sufficiently small there is a constant C such that

$$0 < p\Big(\sqrt{\Delta}\ z, \Delta\Big) \le C\sqrt{\Delta}/|\ln\ \Delta|^{1/2}, \tag{4.10}$$

provided $0 < \Delta \leq \Delta_0,\ z \in [a(\Delta), b(\Delta)]$, and u_2 satisfies (4.8).

Consider now the function $F(u_2)$ defined by

$$F(u_2) = e^{\rho\Delta}\, V_0(u_1 - u_2 + u_0) - h(u_1, \Delta) - \beta\{1 - p(u_1, \Delta)\},\ 0 < \Delta < \Delta_0,$$

for u_2 in the region (4.8) and $u_1 = \sqrt{\Delta}\, z_\Delta(u_2)$ the unique solution of (4.5), $z_\Delta(u_2) \in (a(\Delta), b(\Delta))$. In view of (4.10) it is clear that

$$F(u_0 - \hat{u}_\beta) > 0,\ F\left(u_0 - \hat{u}_\beta + \sqrt{\Delta}\, b(\Delta)\right) < 0,$$

whence there is a solution u_2 to the equation $F(u_2) = 0$ in the region $u_0 - \hat{u}_\beta < u_2 < u_0 - \hat{u}_\beta + \sqrt{\Delta}\ b(\Delta)$. We have therefore shown the existence of a solution (u_1, u_2) to the set of equations (4.4), (4.5), provided $0 < \Delta < \Delta_0$. By Lemma 2.4 the solution is unique. One can now easily derive the asymptotics of $u_1(\beta, \Delta), u_2(\beta, \Delta)$ as $\Delta \to 0$. In fact the asymptotics of $u_1(\beta, \Delta)$ are already a consequence of the fact that $z_\Delta(u_2) \in (a(\Delta), b(\Delta))$. To obtain the asymptotics of $u_2(\beta, \Delta)$ we do a Taylor expansion of $F(u_2)$ about $u_2 = u_0 - \hat{u}_\beta$. Thus we have

$$F(u_2) = e^{\rho\Delta}\left\{V_0(\hat{u}_\beta) + [u_1 - u_2 + u_0 - \hat{u}_\beta]V_0'(\hat{u}_\beta) + O\left([u_1 - u_2 + u_0 - \hat{u}_\beta]^2\right)\right\}$$

$$- u_1 - \beta + O\left(\sqrt{\Delta}/|\ln\ \Delta|^{1/2}\right).$$

Hence the asymptotic form of $u_2 = u_2(\beta, \Delta)$ is obtained from the equation

$$[u_1 - u_2 + u_0 - \hat{u}_\beta]V_0'(\hat{u}_\beta) - u_1 = 0,$$

where $u_1 = u_1(\beta, \Delta)$ has the asymptotic form $u_1(\beta, \Delta) = \sigma\sqrt{\Delta}|\ln\ \Delta|^{1/2}$. □

PROPOSITION 4.1. *Let $u_{1,K}(\Delta), u_{2,K}(\Delta)$ be the functions of Δ defined in Lemma* 4.1. *Then there are the limits*

$$\lim_{\Delta\to 0} u_{1,K}(\Delta)/\sigma\sqrt{\Delta}\ |\ln\ \Delta|^{1/2} = 1, \tag{4.11}$$

$$\lim_{\Delta\to 0} \{u_{2,K}(\Delta) - [u_0 - \hat{u}_K]\}/\sigma\sqrt{\Delta}\ |\ln\ \Delta|^{1/2} = 1, \tag{4.12}$$

where $\hat{u}_K$ is as in Lemma 4.1.

Proof. We use Lemma 4.2 and (2.20). Evidently (4.11) follows directly from Lemma 4.2. To get (4.12) we substitute from Lemma 4.2 the formula for $u_2(\beta, \Delta)$ and solve approximately for $\hat{u}_\beta$. Thus on writing $\hat{u}_\beta = \hat{u}_K + \delta$ we have to highest order

$$V_0(\hat{u}_K + \delta) + u_0 - \hat{u}_K - \delta$$

$$+ [1 - 1/V_0'(\hat{u}_K)]\sigma\sqrt{\Delta}\ |\ln\ \Delta|^{1/2} = \mu/\rho - K.$$

Taylor expanding this last identity about $\delta = 0$ and solving for δ yields

$$\delta = -\sigma\sqrt{\Delta}\ |\ln\ \Delta|^{1/2}/V_0'(\hat{u}_K).$$

Hence we have to highest order

$$\begin{aligned} u_{2,K}(\Delta) &= [u_0 - \hat{u}_\beta] + \sigma\sqrt{\Delta}\ |\ln\ \Delta|^{1/2}\{1 - 1/V_0'(\hat{u}_\beta)\} \\ &= [u_0 - \hat{u}_K - \delta] + \sigma\sqrt{\Delta}\ |\ln\ \Delta|^{1/2}\{1 - 1/V_0'(\hat{u}_K)\} \\ &= u_0 - \hat{u}_K + \sigma\sqrt{\Delta}\ |\ln\ \Delta|^{1/2}. \end{aligned}$$

□

Finally we wish to show that the function $V(x), x \geq 0$, of Proposition 2.3, which is a C^1 function, fails to be twice differentiable at $x = u_1$. To do this let u_2 satisfy $0 < u_2 < u_0$ and $\beta > V_0(u_0 - u_2)$. We consider the function $u(x,t)$ defined by

$$u(x,t) = \beta\{1 - p(x,t)\} + h(x,t) - e^{\rho t} V_0(x - u_2 + u_0). \tag{4.13}$$

Evidently $u(x,0) = \beta + x - V_0(x - u_2 + u_0)$ and $u(0,t) = -e^{\rho t}\ V_0(u_0 - u_2)$, whence $u(0,t) < 0,\ t > 0$.

LEMMA 4.3. *Let $u(x,t)$ be the function* (4.13). *Then there exist $\varepsilon > 0$ and $x(t) > 0$, $0 < t < \varepsilon$, such that $\partial u/\partial x(x,t) > 0$ for $0 \leq x < x(t)$ and $\partial u/\partial x(x,t) < 0$ for $x > x(t)$.*

Proof. We proceed as in Lemma 4.2 observing that the function g of (4.7) is given by

$$g(z) = \sqrt{2\pi\sigma^2\Delta}\ \partial u/\partial x\Big(z\sqrt{\Delta},\ \Delta\Big). \tag{4.14}$$

With $a(\Delta), b(\Delta)$ defined by (4.9) we have seen that, provided $0 < \Delta < \Delta_0$, then $g(z) > 0$ for $0 < z \leq a(\Delta)$, $g(z) < 0$ for $z \geq b(\Delta)$ and g is strictly monotonic decreasing in the interval $[a(\Delta), b(\Delta)]$. □

LEMMA 4.4. *Let $u(x,t)$ be the function* (4.13). *Then there exist $\varepsilon > 0$ and $a(t), b(t) > 0,\ 0 < t < \varepsilon$, such that $\{x > 0 : \partial^2 u/\partial x^2(x,t) > 0\} = (a(t), b(t))$.*

Proof. From (2.9), (4.13) we have that

$$\partial^2 u/\partial x^2(x,t) = -\beta\partial^2 p/\partial x^2(x,t) - \mu \int_0^t \partial^2 p/\partial x^2(x,s)ds - e^{\rho t}\ V_0''(x - u_2 + u_0).$$

Since $p(x,t)$ is a convex function of x it follows that $\partial^2 u/\partial x^2(x,t) < 0$ for $x > u_2$. Since $V_0''(u_0) = 0$, $V_0'''(u_0) = 2\rho/\sigma^2$ we conclude that there exist $\Delta_0 > 0$ and $b(t) > 0,\ 0 < t < \Delta_0$, with the property that $\lim_{t\to 0} b(t) = u_2$, and $\partial^2 u/\partial x^2(x,t) < 0$ if $x > b(t)$ and $\partial^2 u/\partial x^2(x,t) > 0$ if $t^{1/3} < x < b(t)$.

We consider now the interval $0 < x < t^{1/3}$. From (4.14) we may consider the function $g'(z)$ in the region $0 < z < \Delta^{-\,1/6}$ instead of $\partial^2 u/\partial x^2(x,t), 0 < x < t^{1/3}$. We have that

$$g'(z) = \frac{-2\beta(z + \mu\sqrt{\Delta})}{\sigma^2} \exp\left[-\frac{(z + \mu\sqrt{\Delta})^2}{2\sigma^2}\right] \tag{4.15}$$

$$+ G(z,\Delta) - \sqrt{2\pi\sigma^2}\ e^{\rho\Delta}\ \Delta\ V_0''(z\sqrt{\Delta} - u_2 + u_0).$$

We can estimate the function $G(z,\Delta)$ in the same way we obtained the estimate (4.10). In fact differentiating (4.6) and estimating as before, we have the inequality

$$2\left[\frac{x}{\sigma^2 t} + \frac{2\mu}{\sigma^2}\right] \exp\left[-\frac{(x + \mu t)^2}{2\sigma^2 t}\right] \leq \sqrt{2\pi\sigma^2 t}\ \frac{\partial^2 p}{\partial x^2}\ (x,t) \tag{4.16}$$

$$\leq 2\left[\frac{x}{\sigma^2 t} + \frac{4\mu}{\sigma^2}\right] \exp\left[-\frac{(x + \mu t)^2}{2\sigma^2 t}\right],\quad x \geq 2\mu t.$$

From (4.16) we can also estimate $\partial^2 h/\partial x^2$ using the identity

$$-\frac{\partial^2 h}{\partial x^2}\ (x,t) = \mu \int_0^t \frac{\partial^2 p}{\partial x^2}\ (x,s)ds. \tag{4.17}$$

We can estimate the right-hand side of (4.17) by substituting the right-hand side of (4.16) and making the change of variable $w = (x + \mu s)/\sqrt{s}$. Thus we have

$$-\frac{\partial^2 h}{\partial x^2}(x,t) \le \frac{32\mu}{\sigma^2\sqrt{2\pi\sigma^2}} \int_{(x+\mu\sqrt{t})/t}^{\infty} \exp\left[-\frac{w^2}{2\sigma^2}\right] dw \tag{4.18}$$

$$\le \frac{11}{\sqrt{2\pi\sigma^2}} \exp\left[-\frac{(x+\mu t)^2}{2\sigma^2 t}\right],\ x \ge 2\mu t.$$

The function $G(z,\Delta)$ is therefore bounded from the estimates (4.16), (4.18) as

$$0 \le -G(z,\Delta) \le \left(\frac{6\beta\mu}{\sigma^2} + 11\right)\sqrt{\Delta}\ \exp\left[-\frac{(z+\mu\sqrt{\Delta})^2}{2\sigma^2}\right],\ z \ge 2\mu\sqrt{\Delta}. \tag{4.19}$$

From (4.15), (4.19) we see that there exists $\Delta_0 > 0$ such that for $0 < \Delta < \Delta_0$ one has $g'(z) < 0$ for $0 < z < \sigma\sqrt{2|\ln\ \Delta|}$ and $g'(z) > 0$ for $\sigma\sqrt{3|\ln\ \Delta|} < z < \Delta^{-1/6}$. Here there is a solution $z = a(\Delta)/\sqrt{\Delta}$ of the equation $g'(z) = 0$ in the interval $\sigma\sqrt{2\ln\ \Delta} < z < \sigma\sqrt{3\ln\ \Delta}$. Evidently then $\lim_{\Delta\to 0} a(\Delta) = 0$.

We complete the proof by showing that $g''(z) > 0$ for $\sigma\sqrt{2|\ln\ \Delta|} < z < \sigma\sqrt{3|\ln\ \Delta|}$, provided $0 < \Delta < \Delta_0$. This is accomplished by estimating $\partial^3 p/\partial x^3$ in a similar way to how we estimated $\partial^2 p/\partial x^2$. □

LEMMA 4.5. *Let $u(x,t)$ be the function* (4.13), *and define $T > 0$ as $T = \sup\{t > 0 : \sup_{x>0} u(x,t) > u(0,t)\}$. Then for $0 < t < T$ there exists unique $x(t) > 0$ satisfying $\lim_{t\to 0} x(t) = 0$, with the property that $\partial u/\partial x(x,t) > 0$ for $0 \le x < x(t)$ and $\partial u/\partial x(x,t) < 0$ for $x > x(t)$. Furthermore $\partial^2 u/\partial x^2(x(t),t) < 0$.*

Proof. By the definition of T one must have $\partial u/\partial x(x,t) > 0$ for some x when $0 < t < T$. Since $\partial u/\partial x(x,t) < 0$ for x large it follows from Theorem A.1 that a unique $x(t)$ exists for $0 < t < T$. Now we apply the argument in Theorem A.3, using Lemma 4.4 to conclude that $\partial^2 u/\partial x^2(x(t),t) < 0$. □

PROPOSITION 4.2. *The function $V(x)$ defined by* (2.21) *is C^1 but not C^2 at $x = u_1$.*

Proof. Let β be as in (2.21) and let $u(x,t)$ be the function (4.13). Then $u(u_1,\Delta) = \partial u/\partial x(u_1,\Delta) = 0$, $u(0,\Delta) < 0, u(x,\Delta) \to -\infty$ as $x \to \infty$. Then by Lemma 4.5 we have $\partial^2 u/\partial x^2(u_1,\Delta) < 0$, whence V is not C^2. □

Appendix. Some consequences of the maximum principle. Here we prove some general results for the heat equation which are used in earlier sections. Let $a(x,t), b(x,t)$ be uniformly bounded smooth functions in (x,t), $x \in \mathbf{R}$, $t \ge 0$, with the property that a is also uniformly bounded from below by a positive constant. We define the operator L on C^2 functions $u(x,t)$ by

$$Lu(x,t) = a(x,t)\,\frac{\partial^2 u}{\partial x^2} + b(x,t)\frac{\partial u}{\partial x} - \frac{\partial u}{\partial t}.$$

THEOREM A.1. *Suppose $u(x,t)$ is a C^2 function in $\{(x,t) \in \mathbf{R}^2 : x \ge 0,\ t \ge 0\}$ satisfying $Lu \equiv 0$. Suppose further that $u(0,t) = 0$, $t \ge 0$, and the set $\{x > 0 : u(x,0) > 0\}$ is a semi-infinite interval. Then for any $t > 0$ there is at most one point $x(t) > 0$ satisfying $u(x(t),\ t) = 0$.*

Proof. Observe that since the function $u(x,0)$, $x \ge 0$, can be negative only on a bounded set it follows that $u(x,t)$, $x \ge 0$, is uniformly bounded below for all $t \ge 0$. Further, one has $\liminf_{x\to\infty} u(x,t) \ge 0$ for all $t \ge 0$. For some $T > 0$

suppose there is an $x_0 > 0$ with $u(x_0, T) < 0$. Let D be the maximal domain containing (x_0, T) such that $u(x,t) < 0$ for $(x,t) \in D$. Evidently $u(x,t) = 0$ for $(x,t) \in \partial D \cap \mathbf{R} \times (0, \infty)$. Hence by the maximum principle the minimum of u occurs at an interior point unless there exists $(x_1, 0) \in \partial D$ with $u(x_1, 0) < 0$. We conclude that there is a path $\gamma(s),\ 0 \le s \le T$, with $\gamma(T) = x_0$ and $u(\gamma(s), s) < 0,\ 0 \le s \le T$.

Now we define Ω to be the domain $\Omega = \{(x,s) : 0 < x < \gamma(s),\ 0 < s < T\}$. Then $u \le 0$ on $\partial\Omega \cap \mathbf{R} \times [0, T)$ and strictly negative on part of this boundary. The maximum principle therefore implies that u is strictly negative on $\partial\Omega \cap \mathbf{R}^+ \times \{T\}$. Thus u is strictly negative on the interval $(0, x_0]$. We define now $x(t)$ as $x(t) = 0$ if $u(x,t) \ge 0,\ x > 0;\ x(t) = \infty$ if $u(x,t) < 0, x > 0;\ x(t) = \limsup\{x > 0 : u(x,t) < 0\}$ otherwise. If $0 < x(t) < \infty$, then the maximum principle implies that $u(x,t) > 0$ for $x > x(t)$. □

THEOREM A.2. *Suppose $u(x,t)$ is a C^2 function in $\{(x,t) \in \mathbf{R}^2 : x \ge 0,\ t \ge 0\}$ satisfying $Lu \equiv 0$. Suppose further that $u(0,t) < 0,\ t \ge 0$, and that the set $\{x > 0 : u(x,0) > 0\}$ is an open interval. Then for any $t > 0$ the set $\{x > 0 : u(x,t) \ge 0\}$ is either empty, a single point, or a closed interval. If the set is a closed interval, then u is strictly positive on its interior.*

Proof. By Theorem A.1 we may assume that the set $\{x > 0 : u(x,0) > 0\}$ is a finite interval. Hence for all $t \ge 0$, $\limsup_{x\to\infty} u(x,t) \le 0$. Now let $D = \{(x,t) : x > 0,\ t > 0,\ u(x,t) > 0\}$. Since u is uniformly bounded above it follows by the maximum principle that D is connected and that $\{(x,t) : x > 0,\ u(x,0) > 0\} \subset \partial D$. We show that the intersection of D with any line $t =$ constant is either empty or an open interval. To do this let $a(t), b(t)$ be defined by

$$a(t) = \inf\{x > 0 : (x,t) \in D\},$$

$$b(t) = \sup\{x > 0 : (x,t) \in D\}.$$

We define a domain $\Omega = \{(x,t) : t > 0,\ a(t) < x < b(t)\}$, whence $D \subset \Omega$. For $T > 0$ let D_T and Ω_T be defined by $D_T = D \cap [\mathbf{R} \times (0,T)]$, $\Omega_T = \Omega \cap [\mathbf{R} \times (0,T)]$. Suppose for some T one has $D_T \ne \Omega_T$. By the maximum principle if the minimum of u on Ω_T is negative, then it must be at a point (x_0, T) with $a(T) < x_0 < b(T)$. This contradicts Lemma 3 of Chapter 3, section 2 of [10]. Hence $u \ge 0$ on Ω_T and consequently by the maximum principle again $u > 0$ on Ω_T. Applying the maximum principle to the complement of Ω_T in $\mathbf{R} \times (0,T)$ we conclude that the set $\{x \in \mathbf{R} : u(x,t) \ge 0\} = [a(t), b(t)]$.

Finally suppose there is a minimum T such that $\Omega = \Omega_T$. As before the maximum principle implies that u is strictly negative on the complement of $\bar{\Omega}_T$ in $\mathbf{R} \times (0, \infty)$. This completes the proof. □

Next we wish to show that the solution $x(t)$ in Theorem A.1 of the equation $u(x,t) = 0$ is nondegenerate. As a consequence it follows that $x(t)$ is a smooth function of t for $t > 0$.

THEOREM A.3. *Suppose $u(x,t),\ x \ge 0,\ t \ge 0$, satisfies the assumptions of Theorem* A.1. *Let $W_0 = \{x > 0 : \partial u/\partial x(x,0) > 0\}$ and assume that the boundary ∂W_0 of W_0 has no finite limit points. Then there is the inequality $\partial u/\partial x(x(t),t) > 0,\ t > 0$.*

Proof. For $t > 0$ let $W_t = \{x > 0 : \partial u/\partial x(x,t) > 0\}$. Since $\partial u/\partial x(x,t)$ also satisfies a diffusion equation it follows that ∂W_t has no finite limit points. Furthermore, for t small and $x \notin \partial W_t$ the derivative $\partial u/\partial x(x,t)$ is nonzero.

We first show that $\partial u/\partial x(x(t),t) > 0$ for $t > 0$ sufficiently small. We argue by contradiction. Suppose $t_n,\ n = 1, 2, \ldots$, is a positive sequence with $\lim_{n\to\infty} t_n = 0$

such that $x(t_n) \in \partial W_{t_n}$, $n = 1, 2, \ldots$. We may assume without loss of generality that $\lim_{n\to\infty} x(t_n) = x_\infty$. There is then a possibly nontrivial closed interval $[a, b]$ such that $x_\infty \in [a, b]$, $\partial u/\partial x(x, 0) = 0$, $x \in [a, b]$, and $\partial u/\partial x(x, 0) \neq 0$, $x \notin [a, b]$, but sufficiently close to a or b. Suppose now that $\partial u/\partial x(x, 0) > 0$ for x close to a or close to b. Then by the maximum principle it follows that $\partial u/\partial x(x, t) > 0$ for x in a neighborhood of $[a, b]$ when t is sufficiently small. In particular $\partial u/\partial x(x(t_n), t_n) > 0$ for n large, which is a contradiction. Alternatively we can have $\partial u/\partial x(x, 0) > 0$ for x close to a and $\partial u/\partial x(x, 0) < 0$ for x close to b. In that case the maximum principle implies $u(x, t) < 0$ for x in a neighborhood of $[a, b]$ when t is small. This again contradicts the fact that $u(x(t_n), t_n) = 0$ as $n \to \infty$. We conclude therefore that $\partial u/\partial x(x(t), t) > 0$ for $t > 0$ sufficiently small.

Finally we show that $\partial u/\partial x(x(t), t) > 0$ for all t. To see this consider $T > 0$ and suppose that $\partial u/\partial x(x(t), t) > 0$ for all $0 < t < T$, $\lim_{t\to T} x(t) = x_T$. If $x_T = \infty$, then $u(x, T) \leq 0, x \geq 0$. If $x_T = 0$, then $u(x, T) \geq 0, x \geq 0$. Suppose now $0 < x_T < \infty$, whence $u(x, T)$, $x > 0$, takes on both positive and negative values. For $0 < t < T$ there exists $a(t), b(t)$ with $0 \leq a(t) < x(t) < b(t) \leq \infty$ such that $\partial u/\partial x(x, t) > 0$ for $a(t) < x < b(t)$ and $a(t), b(t) \in \partial W_t$ if $a(t) > 0$ and $b(t) < \infty$. Since $u(0, t) = 0$ it follows that $\partial u/\partial x(x, t) < 0$ for $x > 0$ small. Hence $a(t) > 0$.

We show that x_T cannot be the limit as $t \to T$ of any points in $\partial W_t \cap [0, x(t)]$. Suppose first that $\partial W_t \cap [0, x(t)] = \{a(t)\}$. Then $\partial u/\partial x(x, t)$, $0 < x < x(t)$, has just one sign change, whence $\partial u/\partial x(x, T)$, $0 < x < x_T$, has also at most one sign change. Since $u(x_T, T) = u(0, T) = 0$ it follows that $\lim_{t\to T} a(t) < x_T$. Alternatively let $a^*(t) \in \partial W_t \cap [0, x(t)]$ have the property that

$$u(a^*(t), t) = \sup\{u(x, t) : x \in \partial W_t \cap [0, x(t)]\}.$$

Evidently $u(a^*(t), t) < 0$. By the maximum principle it follows that $u(a^*(t), t)$ is a decreasing function of t. Hence x_T cannot be the limit as $t \to T$ of any point in $\partial W_t \cap [0, x(t)]$.

Since we can argue similarly that x_T is not the limit as $t \to T$ of any point in $\partial W_t \cap [x(t), \infty)$ we conclude that $\partial u/\partial x(x(T), T) > 0$. We have shown that the set $\{t > 0 : \partial u/\partial x(x(t), t) > 0\}$ is both open and closed, whence it must be the interval $(0, \infty)$. □

STABILITY OF NONLINEAR FEEDBACK SYSTEMS: A NEW SMALL-GAIN THEOREM*

ANNA L. CHEN†, GUI-QIANG CHEN‡, AND RANDY A. FREEMAN†

Abstract. For the feedback interconnection of general nonlinear systems, the classical small-gain condition is sufficient but not necessary for robust stability. We introduce a weaker notion of gain which yields a small-gain condition that is both necessary and sufficient for robust stability. We also discuss conditions under which the two notions coincide, and we further provide results for dissipation performance measures that are more general than the classical gain measures.

Key words. small-gain theorem, conditional gain, dissipativity, performance analysis, nonlinear systems, feedback connection

1. Introduction.

The classical small-gain theorem [28, 4] provides a sufficient condition for the stability of the feedback interconnection of nonlinear systems, and it has been studied extensively by many researchers. In [28], Zames derived a sufficient condition for the small-gain theorem for general nonlinear systems by using the concepts of loop gain and positivity. Willems [24] systematically studied the passivity theorem, and Anderson proved in [1] the equivalence between the classical small-gain theorem and the passivity theorem for general feedback systems. In [25], Willems established a theorem for dissipative systems in the context of finite-dimensional stationary linear systems with quadratic supply rates, deriving a necessary and sufficient condition in the frequency domain for dissipativity. Hill and Moylan in [10, 17] established conditions for stability and instability for interconnected systems in terms of the properties of dissipative subsystems. In [2], Chen and Desoer derived a necessary and sufficient condition for the robust stability of linear distributed feedback systems. Extensions of these classical results to nonlinear notions of gain appear in [15, 13, 12].

Of course, one may have stability even if the small-gain condition is violated, but it is of interest to know whether the small-gain condition becomes necessary when we treat one of the systems as uncertainty and consider the *robust* stabilization problem. Positive results are available for the case in which the nominal system is linear [5, 3, 20]. More recently, Shamma [19] demonstrated the necessity of the small-gain condition for the robust stability of a class of nonlinear systems with *fading memory*. Shamma and Zhao further developed this approach in [21] and gave a necessary condition for uniform robust invertibility, whereas Gonçalves and Dahleh provided another necessary condition in [7] for nonlinear systems with fading memory.

Unfortunately, the small-gain condition is not necessary for robust stability for

more general classes of nonlinear systems (even time-invariant, first-order systems), as demonstrated by an example in [6]. In this paper, we show how to weaken the standard notion of gain so that we preserve the sufficiency of the small-gain condition while recovering its necessity for the robust stability of general nonlinear systems, even those without fading memory. We call the weakened property *conditional gain*,[1] as it is related to the conditional integral quadratic constraints proposed in [16] (in fact, for the $\mathcal{L}_2$ case, one can develop frequency-domain conditions for conditional gain using such integral quadratic constraints, but we will not pursue this here). Our sufficiency result improves upon the classical small-gain theorem by replacing the gain assumption on one of the subsystems in the loop with the weaker conditional gain assumption. In our necessity result, we show that it suffices to consider only time-invariant, second-order uncertainties, even when the nominal system itself is a distributed and/or time-varying system.

Throughout this paper, we use the behavioral theory of dynamical systems developed in [27, 18], modified to account for the fact that different trajectories may be defined on different time intervals (e.g., for systems admitting finite escape times). We found this behavioral approach to be ideal for our analysis, allowing us to simplify proofs and avoid technicalities associated with other classes of dynamical system models (such as input/output operator-theoretic models or differential-equation state models). Other authors have also found this framework useful in the study of dissipative systems [8, 22].

The organization of this paper is as follows. In section 2, we develop the notions of dissipativity in the context of behavioral dynamical systems. We revisit classical $\mathcal{L}_p$-gain in this context in section 3, where we also present our definition of conditional gain along with the main results of this paper. Moreover, in this section, we present a sufficient condition under which conditional and classical $\mathcal{L}_p$-gains are equivalent notions; this sufficient condition is in the form of a resetting property related to the ones used in [19, 21] to prove the necessity of the small-gain theorem for the robust stability of nonlinear systems with fading memory. This sufficient condition also implies that the conditional and classical notions of $\mathcal{L}_p$-gain are equivalent for linear time-invariant systems. Finally, we extend our results to more general dissipation performance measures in section 4.

2. Dynamical systems, dissipativity, and storage functions. In this section we discuss dissipativity in the context of behavioral dynamical systems [27, 18]. We restrict our attention to continuous-time systems for simplicity. A *trajectory* on a nonempty set $\mathbb{V}$ is a mapping $v : I \to \mathbb{V}$ on a nonempty interval domain $\mathrm{Dom}(v) = I \subset \mathbb{R}$. We use the following notation from [27]: given two trajectories v_1, v_2 on $\mathbb{V}$ and a time $t \in \mathrm{Dom}(v_1) \cap \mathrm{Dom}(v_2)$, we define the *concatenation* of v_1 and v_2 at time t to be the trajectory $v_1 \wedge^t v_2$ on $\mathbb{V}$ given by

$$(v_1 \wedge^t v_2)(\tau) = \begin{cases} v_1(\tau) & \text{when } \tau < t, \\ v_2(\tau) & \text{when } \tau \geqslant t, \end{cases} \tag{2.1}$$

with interval domain $\mathrm{Dom}(v_1 \wedge^t v_2) = \big[(-\infty, t] \cap \mathrm{Dom}(v_1)\big] \cup \big[[t, \infty) \cap \mathrm{Dom}(v_2)\big]$.

A *trajectory space* on $\mathbb{V}$ is a nonempty collection $\mathfrak{T}(\mathbb{V})$ of trajectories on $\mathbb{V}$ which is closed under concatenations: for any $v_1, v_2 \in \mathfrak{T}(\mathbb{V})$ with $t \in \mathrm{Dom}(v_1) \cap \mathrm{Dom}(v_2)$,

[1] The term "conditional gain" was also used in [23] to describe the ultimate virtual-dissipativity performance measure discussed in [9]. In general this system property neither implies nor is implied by our conditional gain property.

we have $v_1 \wedge^t v_2 \in \mathfrak{T}(\mathbb{V})$. A trajectory space $\mathfrak{T}(\mathbb{V})$ together with a subset $\mathcal{B} \subset \mathfrak{T}(\mathbb{V})$ is called a *dynamical system* $H = (\mathfrak{T}(\mathbb{V}), \mathcal{B})$, and the set $\mathcal{B}$ is called the *behavior* of the system H (cf. [27, 18]). When the underlying trajectory space $\mathfrak{T}(\mathbb{V})$ is apparent from context, we will use the terms "system H" and "behavior $\mathcal{B}$" interchangeably. Note that the trajectory space used in [27] is the set of all mappings from a fixed time interval $\mathbb{T}$ into $\mathbb{V}$; here we instead allow different trajectories of a system to be defined on different time intervals. We also allow the behavior $\mathcal{B}$ to be the empty set $\mathcal{B} = \varnothing$ and refer to empty and nonempty systems H accordingly.

Given a trajectory $v \in \mathfrak{T}(\mathbb{V})$ and a time $t \in \mathbb{R}$, we let $\sigma^t v$ denote the time-shifted trajectory $(\sigma^t v)(\cdot) = v(\cdot + t)$ with $\mathrm{Dom}(\sigma^t v) = [\mathrm{Dom}(v) - t]$. We say that a system is *time-invariant* when its behavior $\mathcal{B}$ satisfies $\sigma^t \mathcal{B} = \mathcal{B}$ for all $t \in \mathbb{R}$.

To develop the notion of a state-space system, we introduce a *state space* $\mathbb{X}$ and a mapping $\xi : \mathbb{V} \to \mathbb{X}$ which assigns a state value $\xi q \triangleq \xi(q) \in \mathbb{X}$ to each signal value $q \in \mathbb{V}$. We recall the following from [27].

Definition 2.1. *A system $H = (\mathfrak{T}(\mathbb{V}), \mathcal{B})$ satisfies the* axiom of state *with respect to a mapping $\xi : \mathbb{V} \to \mathbb{X}$ when the following holds: whenever a pair of trajectories $v_1, v_2 \in \mathcal{B}$ and a time $t \in \mathrm{Dom}(v_1) \cap \mathrm{Dom}(v_2)$ are such that $\xi v_1(t) = \xi v_2(t)$, then the concatenation $v_1 \wedge^t v_2$ also belongs to $\mathcal{B}$.*

A system H which satisfies the axiom of state is called a *state-space system*, and we write H as the triple $H = (\mathfrak{T}(\mathbb{V}), \mathcal{B}, \xi)$. Note that the development in [18] requires the axiom of state to hold only at points of continuity in the state trajectory,[2] but we adopt the original definition in [27], which does not require the state space to be endowed with a topology.

Given a trajectory $v \in \mathfrak{T}(\mathbb{V})$ and a state mapping $\xi : \mathbb{V} \to \mathbb{X}$, we let $\mathfrak{G}(v) \subset \mathbb{R} \times \mathbb{X}$ denote the graph of the state trajectory $\xi v(\cdot)$, namely, the set of all pairs $(t, \xi v(t))$ as t varies over $\mathrm{Dom}(v)$. Likewise, given a behavior $\mathcal{B} \subset \mathfrak{T}(\mathbb{V})$, we let $\mathfrak{G}(\mathcal{B})$ denote the union of all graphs $\mathfrak{G}(v)$ as v varies over $\mathcal{B}$. In other words, $(t_0, x_0) \in \mathfrak{G}(\mathcal{B})$ if and only if there is some trajectory $v \in \mathcal{B}$ such that $\xi v(t_0) = x_0$.

One can characterize state-space systems using differential-algebraic equations. For example, let $\mathbb{X} = \mathbb{R}^n$, let $\mathbb{V} = \mathbb{W} \times X$ for some auxiliary signal space $\mathbb{W}$, let ξ be the natural projection of $\mathbb{V}$ onto $\mathbb{X}$, and let $\mathfrak{T}(\mathbb{V})$ be a trajectory space on $\mathbb{V}$ whose members all have domains with nonempty interiors. Given a mapping $F : \mathbb{R} \times \mathbb{V} \times \mathbb{R}^n \to \mathbb{R}^m$, let $\mathcal{B}$ denote the set of trajectories $(w, x) \in \mathfrak{T}(\mathbb{V})$ such that $x(\cdot)$ is absolutely continuous on $\mathrm{Dom}(w, x)$ and

$$F\big(t,\, w(t),\, x(t),\, \dot{x}(t)\big) = 0 \tag{2.2}$$

for almost all $t \in \mathrm{Dom}(w, x)$. Then the system $H = (\mathfrak{T}(\mathbb{V}), \mathcal{B}, \xi)$ is a state-space system. Here the auxiliary signal $w(t)$ can represent a combination of inputs, outputs, or other signals, although at this point there is no need to label them as such. Also, there is no need to assume the existence or uniqueness of solutions to (2.2); whatever solutions do exist belong to the behavior $\mathcal{B}$. This class of systems (2.2) encompasses many of the nonlinear state-space systems studied in standard texts [14].

We next introduce the concepts of abstract energy, storage, and dissipation. Roughly speaking, if a system is dissipative, then it will absorb more energy from the external world than it supplies. To make this idea precise, we will adopt various definitions from [25, 26, 9, 10, 8], modifying them as appropriate to fit our particular behavioral context.

[2] This weaker version of the axiom of state is called the *property of state* in [18].

DEFINITION 2.2. *A* supply rate $\mathbf{S}$ *for a trajectory space* $\mathfrak{T}(\mathbb{V})$ *is a function* $\mathbf{S} : \mathbb{R} \times \mathbb{V} \to \mathbb{R}$ *such that, for every* $v \in \mathfrak{T}(\mathbb{V})$*, the mapping* $t \mapsto \mathbf{S}(t, v(t))$ *is locally integrable on* $\mathrm{Dom}(v)$.

DEFINITION 2.3. *Let* $\mathbf{S}$ *be a supply rate for a trajectory space* $\mathfrak{T}(\mathbb{V})$*, and let* $H = (\mathfrak{T}(\mathbb{V}), \mathcal{B}, \xi)$ *be a state-space system. Given* $(t_0, x_0) \in \mathfrak{G}(\mathcal{B})$*, we define the* available storage $\phi_a(t_0, x_0)$ *for* H *(with respect to* $\mathbf{S}$*) to be the quantity*

$$\phi_a(t_0, x_0) \triangleq - \inf_{\substack{v \in \mathcal{B} \\ t \geqslant t_0}} \int_{t_0}^{t} \mathbf{S}(\tau, v(\tau))\, d\tau, \tag{2.3}$$

where the infimum is taken over all trajectories $v \in \mathcal{B}$ *and all times* $t \geqslant t_0$ *such that* $t_0, t \in \mathrm{Dom}(v)$ *and* $\xi v(t_0) = x_0$*. We say that* H *is* dissipative *with respect to* $\mathbf{S}$ *when* $\phi_a(t_0, x_0) < \infty$ *for every* $(t_0, x_0) \in \mathfrak{G}(\mathcal{B})$.

Note that $\mathfrak{G}(\mathcal{B}) = \varnothing$ if and only if H is empty, in which case H is trivially dissipative. Hence, from this point on we will assume that H is nonempty. Also, because we can take $t = t_0$ to get zero as a possible value of the integral in (2.3), we see that $\phi_a(t_0, x_0) \geqslant 0$ for all $(t_0, x_0) \in \mathfrak{G}(\mathcal{B})$.

DEFINITION 2.4. *Let* $\mathbf{S}$ *be a supply rate for a trajectory space* $\mathfrak{T}(\mathbb{V})$*, and let* $H = (\mathfrak{T}(\mathbb{V}), \mathcal{B}, \xi)$ *be a state-space system. A* virtual storage function *for* H *(with respect to* $\mathbf{S}$*) is a function* $U : \mathfrak{G}(\mathcal{B}) \to \mathbb{R}$ *such that the* dissipation inequality

$$U(t, \xi v(t)) \leqslant U(t_0, \xi v(t_0)) + \int_{t_0}^{t} \mathbf{S}(\tau, v(\tau))\, d\tau \tag{2.4}$$

holds for any $v \in \mathcal{B}$ *and any* $t_0, t \in \mathrm{Dom}(v)$ *with* $t_0 \leqslant t$*. A* storage function *is a virtual storage function which is nonnegative everywhere.*

We now give a behavioral version of the classical result equating dissipativity to the existence of a storage function [25, 26, 9, 8] (e.g., Theorem IV-2 in [26] or Theorem 1 in [8]). Note that the only aspect of the system dynamics needed here is the axiom of state; there is no need to distinguish between inputs and outputs or assume any additional structure of these dynamics.

PROPOSITION 2.5. *A state-space system* $H = (\mathfrak{T}(\mathbb{V}), \mathcal{B}, \xi)$ *is dissipative with respect to a supply rate* $\mathbf{S}$ *if and only if it admits a storage function. Furthermore, if* H *is dissipative, then* ϕ_a *is a storage function and any other storage function* U *satisfies* $U(t_0, x_0) \geqslant \phi_a(t_0, x_0)$ *for all* $(t_0, x_0) \in \mathfrak{G}(\mathcal{B})$.

Proof. First suppose that U is a storage function. Then, since $U \geqslant 0$, we have

$$0 \leqslant U(t_0, x_0) + \int_{t_0}^{t} \mathbf{S}(\tau, v(\tau))\, d\tau \tag{2.5}$$

along all trajectories $v \in \mathcal{B}$ satisfying the initial condition $\xi v(t_0) = x_0$. It follows that $\phi_a(t_0, x_0)$ in (2.3) is bounded from above by the finite value $U(t_0, x_0)$.

Conversely, suppose that H is dissipative and that there exist $v_1 \in \mathcal{B}$ and $t_0, t_1 \in \mathrm{Dom}(v_1)$ with $t_0 \leqslant t_1$ such that

$$\phi_a(t_1, \xi v_1(t_1)) > \phi_a(t_0, \xi v_1(t_0)) + \int_{t_0}^{t_1} \mathbf{S}(\tau, v_1(\tau))\, d\tau. \tag{2.6}$$

Then, from (2.3), there exist $v_2 \in \mathcal{B}$ and $t_2 \geqslant t_1$ such that $t_1, t_2 \in \mathrm{Dom}(v_2)$, $\xi v_2(t_1) = \xi v_1(t_1)$, and

$$-\int_{t_1}^{t_2} \mathbf{S}(\tau, v_2(\tau))\, d\tau > \phi_a(t_0, \xi v_1(t_0)) + \int_{t_0}^{t_1} \mathbf{S}(\tau, v_1(\tau))\, d\tau. \tag{2.7}$$

It follows from the axiom of state that the trajectory $v \triangleq v_1 \wedge^{t_1} v_2$ also belongs to $\mathcal{B}$. Thus, from (2.7), we have

$$-\int_{t_0}^{t_2} \mathbf{S}(\tau, v(\tau))\, d\tau > \phi_a(t_0, \xi v(t_0)), \tag{2.8}$$

which contradicts (2.3). □

Note that if U is a storage function for a system H, then so is $U - \inf U$ where the infimum is taken over $\mathfrak{G}(\mathcal{B})$. Hence, from Proposition 2.5, we have $U - \inf U \geqslant \phi_a$ on $\mathfrak{G}(\mathcal{B})$, which immediately gives us the following.

PROPOSITION 2.6. *If $H = (\mathfrak{T}(\mathbb{V}), \mathcal{B}, \xi)$ is dissipative, then*

$$\inf\big\{\phi_a(t_0, x_0) \;:\; (t_0, x_0) \in \mathfrak{G}(\mathcal{B})\big\} = 0. \tag{2.9}$$

We may interpret Proposition 2.6 as a statement about "bias" in a dissipative system H: for any $\varepsilon > 0$, there exists an initial condition (t_0, x_0) such that $\phi_a(t_0, x_0) \leqslant \varepsilon$, which implies from (2.3) that

$$\int_{t_0}^{t} \mathbf{S}(\tau, v(\tau))\, d\tau \geqslant -\varepsilon \tag{2.10}$$

along every trajectory $v \in \mathcal{B}$ with $\xi v(t_0) = x_0$. In other words, the "bias" ε can be made arbitrarily small by choice of initial condition. If the infimum in (2.9) is actually a minimum, then we can choose $\varepsilon = 0$ and achieve zero bias from some nonempty set of initial conditions.

3. Dissipativity, $\mathcal{L}_p$-gain, and robust stability. Throughout this section, we will consider the $\mathcal{L}_p$ spaces for $1 \leqslant p < \infty$; the case $p = \infty$ is also of interest but requires a somewhat different formulation [11]. We say that a trajectory y on a normed linear space $(\mathbb{Y}, |\cdot|)$ belongs to $\mathcal{L}_p$ when the integral in the norm definition

$$\|y\|_p \triangleq \Big(\int_{\mathrm{Dom}(y)} |y(\tau)|^p\, d\tau\Big)^{1/p} \tag{3.1}$$

exists and is finite. If $t_0, t \in \mathrm{Dom}(y)$ with $t_0 \leqslant t$, then we let $y_{[t_0,t]}$ denote the restriction of the trajectory y to the domain $[t_0, t]$, whereas we let $y_{[t_0]}$ denote the restriction of the trajectory y to the domain $[t_0, \infty) \cap \mathrm{Dom}(y)$. We say that y belongs to the extended space $\mathcal{L}_{pe}$ when $y_{[t_0,t]} \in \mathcal{L}_p$ for every $t_0, t \in \mathrm{Dom}(y)$ with $t_0 \leqslant t$. Likewise, we write $y \in \mathcal{L}_p^+$ when $y_{[t_0]} \in \mathcal{L}_p$ for every $t_0 \in \mathrm{Dom}(y)$. Note that if $y \in \mathcal{L}_{pe}$, then $y \in \mathcal{L}_p^+$ if and only if $y_{[t_0]} \in \mathcal{L}_p$ for *some* $t_0 \in \mathrm{Dom}(y)$.

In this section we assume that the signal space $\mathbb{V}$ is the product $\mathbb{V} = \mathbb{E} \times \mathbb{Y} \times \mathbb{X}$ of a normed linear input space $(\mathbb{E}, |\cdot|)$, a normed linear output space $(\mathbb{Y}, |\cdot|)$, and a state space $\mathbb{X}$. We also assume that the trajectory space $\mathfrak{T}(\mathbb{V})$ is the set of all trajectories (e, y, x) such that $e, y \in \mathcal{L}_{pe}$. Given a nonnegative gain parameter γ, we say that a state-space system $H = (\mathfrak{T}(\mathbb{V}), \mathcal{B}, \xi)$ (with ξ being the natural projection of $\mathbb{V}$ onto $\mathbb{X}$) has $\mathcal{L}_p$-gain $\leqslant \gamma$ when there exists a mapping $\beta : \mathfrak{G}(\mathcal{B}) \to \mathbb{R}$ such that, for all trajectories $(e, y, x) \in \mathcal{B}$ and all $t, t_0 \in \mathrm{Dom}(e, y, x)$ with $t \geqslant t_0$, we have

$$\|y_{[t_0,t]}\|_p^p \leqslant \gamma^p \|e_{[t_0,t]}\|_p^p + \beta\big(t_0, x(t_0)\big). \tag{3.2}$$

Here $\beta(\cdot)$ represents a finite bias which depends only on the initial conditions. Note that we have not defined $\mathcal{L}_p$-gain per se, but only the property of having $\mathcal{L}_p$-gain $\leqslant \gamma$

(this will be sufficient for our purposes). We will also say that H has $\mathcal{L}_p$-gain $< \gamma$ whenever it has $\mathcal{L}_p$-gain $\leqslant \gamma_0$ for some $\gamma_0 < \gamma$.

The classical $\mathcal{L}_p$-gain supply rate for $\mathfrak{T}(\mathbb{V})$ is

$$\mathbf{S}(e, y) = \gamma^p |e|^p - |y|^p, \tag{3.3}$$

and it follows from Definition 2.3 that H is dissipative with respect to this supply rate if and only if, for every initial condition $(t_0, x_0) \in \mathfrak{G}(\mathcal{B})$,

$$\inf_{\substack{e,y,x \\ t \geqslant t_0}} \int_{t_0}^{t} \left(\gamma^p |e(\tau)|^p - |y(\tau)|^p\right) d\tau \triangleq -\phi_a(t_0, x_0) > -\infty, \tag{3.4}$$

where the infimum is taken over all trajectories $(e, y, x) \in B$ and all $t \geqslant t_0$ such that $t, t_0 \in \mathrm{Dom}(e, y, x)$ and $\xi(e, y, x)(t_0) = x(t_0) = x_0$. Thus it is clear that H is dissipative with respect to (3.3) if and only if H has $\mathcal{L}_p$-gain $\leqslant \gamma$. Moreover, we can choose the bias as $\beta \equiv \phi_a$, and it follows from Proposition 2.6 that this bias can always be made arbitrarily small by choosing appropriate initial conditions.

We will consider these classical notions of $\mathcal{L}_p$-gain and dissipation throughout this section. To further motivate our analysis, we first recall the example in [6] which demonstrates that the small-gain condition is not necessary for the robust stability of general nonlinear feedback interconnections.

3.1. A motivating example. This example is a single-input-single-output, time-invariant, first-order nonlinear system H which does *not* have an $\mathcal{L}_2$-gain $\leqslant 1$ but for which nevertheless the system obtained by connecting H in feedback with an uncertain system Δ as shown in Figure 3.1 is stable for any Δ having an $\mathcal{L}_2$-gain < 1.

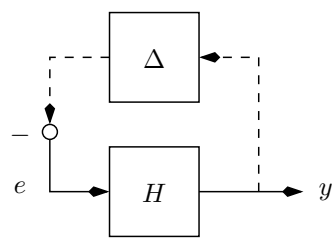

FIG. 3.1. *Performance versus robust stability.*

The system H is described by the following state-space equations:

$$H: \quad \begin{cases} \dot{x} = -\phi'(x) + 2e, & x \in \mathbb{R}, \\ y = \phi'(x) - e, \end{cases} \tag{3.5}$$

where $\phi'(x)$ denotes the derivative of some smooth function $\phi : \mathbb{R} \to \mathbb{R}$. From (3.5), we find that $e^2 - y^2 = \phi'(x)\dot{x}$ and, upon integrating both sides,

$$\phi(x(t)) = \phi(x(t_0)) + \int_{t_0}^{t} \left(e^2(\tau) - y^2(\tau)\right) d\tau, \tag{3.6}$$

which holds along any trajectory of the system H. It follows from Definition 2.4, Proposition 2.5, and the controllability of H that H has $\mathcal{L}_2$-gain $\leqslant 1$ if and only if the function $\phi(\cdot)$ is bounded from below over $\mathbb{R}$, in which case

$$U(x) = \phi(x) - \inf_{x \in \mathbb{R}} \phi(x) \tag{3.7}$$

is a corresponding storage function. Consider now the feedback connection of Figure 3.1, where the (possibly nonlinear, time-varying) uncertain system Δ has an $\mathcal{L}_2$-gain $\leqslant \gamma$ for some $\gamma \in [0,1]$. Let $U_\Delta(t, x_\Delta)$ denote a storage function for Δ which satisfies the corresponding dissipation inequality,

$$U_\Delta(t, x_\Delta(t)) \leqslant U_\Delta(t_0, x_\Delta(t_0)) + \int_{t_0}^{t} \left(\gamma^2 y(\tau)^2 - e(\tau)^2\right) d\tau, \tag{3.8}$$

along trajectories of Δ, where x_Δ denotes the internal state of Δ. We now define a quantity $W(t, x, x_\Delta)$:

$$W(t, x, x_\Delta) = \frac{1}{2}\left(1+\gamma^2\right)\phi(x) + U_\Delta(t, x_\Delta). \tag{3.9}$$

Using (3.6) and (3.8), we see that trajectories of the closed-loop system are such that

$$W(t, x(t), x_\Delta(t)) \leqslant W(t_0, x(t_0), x_\Delta(t_0)) - \frac{1}{2}\left(1-\gamma^2\right) \int_{t_0}^{t} \left(e(\tau)^2 + y(\tau)^2\right) d\tau. \tag{3.10}$$

Because U_Δ is a nonnegative function, it follows from (3.9) and (3.10) that

$$\begin{aligned} \phi(x(t)) &\leqslant \frac{2}{1+\gamma^2}\, W(t_0, x(t_0), x_\Delta(t_0)) - \frac{1-\gamma^2}{1+\gamma^2} \int_{t_0}^{t} \left(e(\tau)^2 + y(\tau)^2\right) d\tau \\ &\leqslant \frac{2}{1+\gamma^2}\, W(t_0, x(t_0), x_\Delta(t_0)) \end{aligned} \tag{3.11}$$

along trajectories of the closed-loop system. In particular, we see from (3.11) that $\phi(x(t))$ is bounded from above in forward time. Now suppose that ϕ satisfies the following:

(i) $\inf \phi = -\infty$ (i.e., ϕ is not bounded from below over $\mathbb{R}$);
(ii) for all $a \in \mathbb{R}$, every connected component of the set $\{\phi \leqslant a\}$ is compact;
(iii) ϕ is positive definite in a neighborhood of zero.

An example of such a function is $\phi(x) = x^2 \cos(x)$. Because the state trajectory $x(t)$ is a continuous function of time, we can conclude from (3.11) and (ii) that $|x(t)|$ and thus also $|\phi(x(t))|$ are bounded in forward time from any initial state of the interconnected system. Furthermore, from (iii), we observe that we have Lyapunov-like stability of the point $x = 0$, namely, for any neighborhood of zero in $\mathbb{R}$, the state $x(t)$ does not leave this neighborhood in forward time provided that the initial state $x(t_0)$ and initial energy $U_\Delta(t_0, x_\Delta(t_0))$ stored in system Δ are sufficiently small. If in addition the gain parameter γ of system Δ is strictly less than one, then we can conclude further from (3.11) that the signals e and y belong to $\mathcal{L}_2^+$. Finally, we know from (i) that the system H does not have an $\mathcal{L}_2$-gain $\leqslant 1$. To summarize, the closed-loop system of Figure 3.1 is robustly stable even though the conditions of the classical small-gain theorem are not satisfied. More precisely, even though H does not have $\mathcal{L}_2$-gain $\leqslant 1$, there does not exist an uncertainty Δ with $\mathcal{L}_2$-gain < 1 which causes the interconnection to exhibit unstable behavior. Even if we allow $\gamma = 1$, we cannot cause the internal state of H to become unbounded or lose the Lyapunov-like stability of its zero equilibrium value. Notice that this does not contradict the known results for linear systems: the Jacobi linearization of H about $x = 0$ indeed has $\mathcal{L}_2$-gain $\leqslant 1$; hence the small-gain condition is satisfied in a neighborhood of the point $x = 0$.

This example demonstrates that for general nonlinear systems the classical small-gain condition is not necessary for robust stability. Our goal is to weaken the definition of gain so that we preserve the sufficiency of the small-gain condition while at the same time recovering its necessity for robust stability.

3.2. Conditional $\mathcal{L}_p$-gain. We have seen that a system has $\mathcal{L}_p$-gain $\leqslant \gamma$ if and only if inequality (3.4) holds for all system trajectories satisfying the initial conditions. To weaken this definition of gain, we require this inequality to hold not for all such system trajectories but only for those that satisfy an auxiliary inequality.

DEFINITION 3.1. *A state-space system $H = (\mathfrak{T}(\mathbb{V}), \mathcal{B}, \xi)$ has* conditional $\mathcal{L}_p$*-gain* $\leqslant \gamma$ *when, for every initial condition $(t_0, x_0) \in \mathfrak{G}(\mathcal{B})$, every $C > 0$, and every $\overline{\gamma} > \gamma$,*

$$\inf_{\substack{e,y,x \\ t \geqslant t_0}} \int_{t_0}^{t} \left(\gamma^p |e(\tau)|^p - |y(\tau)|^p\right) d\tau > -\infty, \tag{3.12}$$

where the infimum is taken over all trajectories $(e, y, x) \in \mathcal{B}$ and all $t \geqslant t_0$ such that $t, t_0 \in \mathrm{Dom}(e, y, x)$, $\xi(e, y, x)(t_0) = x(t_0) = x_0$, and furthermore

$$\sup_{\substack{t \in \mathrm{Dom}(e,y,x) \\ t \geqslant t_0}} \int_{t_0}^{t} \left(\overline{\gamma}^p |e(\tau)|^p - |y(\tau)|^p\right) d\tau < C. \tag{3.13}$$

In other words, a system has conditional $\mathcal{L}_p$-gain when it is not possible to extract arbitrarily large amounts of (abstract) energy from it without pumping arbitrarily large amounts of energy into it in the process. It is clear that any system having $\mathcal{L}_p$-gain $\leqslant \gamma$ also has conditional $\mathcal{L}_p$-gain $\leqslant \gamma$, but the converse need not hold. For example, the system H in (3.5) with $\phi(x) = x^2 \cos(x)$ has conditional $\mathcal{L}_2$-gain $\leqslant 1$ even though the same is not true for the classical, unconditional $\mathcal{L}_2$-gain.

If a system H has $\mathcal{L}_p$-gain $\leqslant \gamma$ for some finite γ, then it follows from (3.2) that H is also $\mathcal{L}_p$-BIBO (bounded-input/bounded-output) stable, namely, that inputs e belonging to $\mathcal{L}_p^+$ generate outputs y which also belong to $\mathcal{L}_p^+$. Systems having only the weaker conditional $\mathcal{L}_p$-gain share the following stability property.

PROPOSITION 3.2. *If a state-space system $H = (\mathfrak{T}(\mathbb{V}), \mathcal{B}, \xi)$ has conditional $\mathcal{L}_p$-gain $\leqslant \gamma$ for some finite γ, then H is $\mathcal{L}_p$-BIBO stable.*

Proof. Fix a trajectory $(e, y, x) \in \mathcal{B}$ such that the input e belongs to $\mathcal{L}_p^+$, choose any $t_0 \in \mathrm{Dom}(e, y, x)$, and choose any $\overline{\gamma} > \gamma$. Then there exists $C > 0$ such that

$$\sup_{\substack{t \in \mathrm{Dom}(e,y,x) \\ t \geqslant t_0}} \int_{t_0}^{t} \overline{\gamma}^p |e(\tau)|^p \, d\tau < C. \tag{3.14}$$

It follows from Definition 3.1 that

$$C - \sup_{\substack{t \in \mathrm{Dom}(e,y,x) \\ t \geqslant t_0}} \int_{t_0}^{t} |y(\tau)|^p \, d\tau > \inf_{\substack{t \in \mathrm{Dom}(e,y,x) \\ t \geqslant t_0}} \int_{t_0}^{t} \left(\gamma^p |e(\tau)|^p - |y(\tau)|^p\right) d\tau > -\infty,$$

from which we conclude that $y_{[t_0]}$ belongs to $\mathcal{L}_p$. ∎

It is of interest to identify classes of systems for which our definitions of $\mathcal{L}_p$-gain and conditional $\mathcal{L}_p$-gain coincide. One such class is characterized by the following result, which employs a resetting property related to the ones used in [19, 21] to prove the necessity of the small-gain theorem for the robust stability of nonlinear systems with fading memory.

THEOREM 3.3. *Let $H = (\mathfrak{T}(\mathbb{V}), \mathcal{B}, \xi)$ be a time-invariant state-space system. Let $Q \subset \mathbb{X}$ be such that H is controllable from Q in the following manner: for every $x_0 \in \mathbb{X}$, there exists $\alpha > 0$ such that, for every $q \in Q$, there exist a trajectory $(e, y, x) \in \mathcal{B}$ and a time interval $[0, t] \subset \mathrm{Dom}(e, y, x)$ such that $x(0) = q$, $x(t) = x_0$,*

and $\|e_{[0,t]}\|_p \leqslant \alpha$. *Suppose also that* H *has the following resetting property with respect to* Q: *there exists* $\beta > 0$ *such that, for all* $x_0 \in \mathbb{X}$, *there exist a trajectory* $(e, y, x) \in \mathcal{B}$ *and a time interval* $[0, t] \subset \mathrm{Dom}(e, y, x)$ *such that* $x(0) = x_0$, $x(t) \in Q$, *and* $\|e_{[0,t]}\|_p \leqslant \beta$. *Then* H *has* $\mathcal{L}_p$*-gain* $\leqslant \gamma$ *if and only if it has conditional* $\mathcal{L}_p$*-gain* $\leqslant \gamma$.

Proof. Suppose that H does not have $\mathcal{L}_p$-gain $\leqslant \gamma$; then there exists $x_0 \in \mathbb{X}$ such that, for any $M > 0$, there exist a trajectory $(e_1, y_1, x_1) \in \mathcal{B}$ and a time interval $[0, t_1] \subset \mathrm{Dom}(e_1, y_1, x_1)$ such that $x_1(0) = x_0$ and

$$\int_0^{t_1} \left(\gamma^p |e_1(\tau)|^p - |y_1(\tau)|^p\right) d\tau \leqslant -M. \tag{3.15}$$

Given this state x_0, we choose α as in the theorem statement and pick $M = \gamma^p \alpha^p + \gamma^p \beta^p + 1$. From the resetting property, there exist a trajectory $(e_2, y_2, x_2) \in \mathcal{B}$ and a time interval $[t_1, t_2] \subset \mathrm{Dom}(e_2, y_2, x_2)$ such that $x_2(t_1) = x_1(t_1)$, $x_2(t_2) \in Q$, and $\|e_{2[t_1,t_2]}\|_p \leqslant \beta$. From the controllability property, there exist a trajectory $(e_3, y_3, x_3) \in \mathcal{B}$ and a time interval $[t_2, t_3] \subset \mathrm{Dom}(e_3, y_3, x_3)$ such that $x_3(t_2) = x_2(t_2)$, $x_3(t_3) = x_0$, and $\|e_{3[t_2,t_3]}\|_p \leqslant \alpha$. We now concatenate these three trajectories using the axiom of state to create a periodic trajectory $(e, y, x) \in \mathcal{B}$ with period t_3 which matches (e_1, y_1, x_1) on the interval $[0, t_1]$, matches (e_2, y_2, x_2) on the interval $[t_1, t_2]$, and matches (e_3, y_3, x_3) on the interval $[t_2, t_3]$. If we now integrate the supply rate over one period, we obtain the bound

$$\int_0^{t_3} \left(\gamma^p |e(\tau)|^p - |y(\tau)|^p\right) d\tau \leqslant -M + \gamma^p \beta^p + \gamma^p \alpha^p = -1. \tag{3.16}$$

If we choose $\overline{\gamma} > \gamma$ such that

$$\left(\overline{\gamma}^p - \gamma^p\right) \int_0^{t_3} |e(\tau)|^p \, d\tau < 1, \tag{3.17}$$

then upon adding inequalities (3.16) and (3.17) we obtain

$$\int_0^{t_3} \left(\overline{\gamma}^p |e(\tau)|^p - |y(\tau)|^p\right) d\tau < 0. \tag{3.18}$$

With C defined as

$$C = 1 + \sup_{0 \leqslant t \leqslant t_3} \int_0^t \left(\overline{\gamma}^p |e(\tau)|^p - |y(\tau)|^p\right) d\tau, \tag{3.19}$$

it follows from (3.18) and (3.19) that

$$\sup_{t \geqslant 0} \int_0^t \left(\overline{\gamma}^p |e(\tau)|^p - |y(\tau)|^p\right) d\tau = \sup_{0 \leqslant t \leqslant t_3} \int_0^t \left(\overline{\gamma}^p |e(\tau)|^p - |y(\tau)|^p\right) d\tau < C, \tag{3.20}$$

but, from (3.16), we have

$$\inf_{t \geqslant 0} \int_0^t \left(\gamma^p |e(\tau)|^p - |y(\tau)|^p\right) d\tau = -\infty. \tag{3.21}$$

We conclude from (3.20), (3.21), and Definition 3.1 that H does not have conditional $\mathcal{L}_p$-gain $\leqslant \gamma$. ∎

We can use Proposition 3.2 and Theorem 3.3 to show that, for linear, time-invariant, finite-dimensional, controllable, and observable state-space systems, the notions of $\mathcal{L}_p$-gain and conditional $\mathcal{L}_p$-gain coincide. Indeed, if such a system H has conditional $\mathcal{L}_p$-gain $\leqslant \gamma$, then we conclude from Proposition 3.2 and the observability of H that all internal modes of H have strictly negative real parts. Hence, with $Q = \{0\}$, the internal stability of H guarantees that the resetting property of Theorem 3.3 holds.

3.3. A conditional small-gain theorem. The behavioral approach allows us to consider feedback interconnections like those of Figure 3.2 without having to impose (or even define) well-posedness. Indeed, let $\mathbb{V}_1 = \mathbb{E} \times \mathbb{Y} \times \mathbb{X}_1$ and $\mathbb{V}_2 = \mathbb{Y} \times \mathbb{E} \times \mathbb{X}_2$, let $\mathfrak{T}(\mathbb{V}_1)$ be the set of all trajectories (e_1, y_1, x_1) such that $e_1, y_1 \in \mathcal{L}_{pe}$, let $\mathfrak{T}(\mathbb{V}_2)$ be the set of all trajectories (e_2, y_2, x_2) such that $e_2, y_2 \in \mathcal{L}_{pe}$, and let ξ_1 and ξ_2 be the natural projections of $\mathbb{V}_1$ and $\mathbb{V}_2$ onto $\mathbb{X}_1$ and $\mathbb{X}_2$, respectively. Now given two state-space systems $H_1 = (\mathfrak{T}(\mathbb{V}_1), \mathcal{B}_1, \xi_1)$ and $H_2 = (\mathfrak{T}(\mathbb{V}_2), \mathcal{B}_2, \xi_2)$, we can define the behavior of their interconnection in Figure 3.2 to be simply the collection of all trajectories $(u_1, u_2, e_1, e_2, y_1, y_2, x_1, x_2)$ satisfying $(e_1, y_1, x_1) \in \mathcal{B}_1$, $(e_2, y_2, x_2) \in \mathcal{B}_2$, and the interconnection constraints $e_1 \equiv u_1 - y_2$ and $e_2 \equiv u_2 + y_1$.

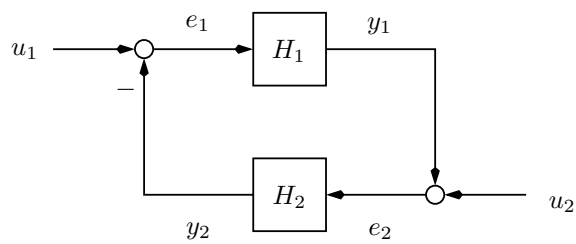

FIG. 3.2. *Canonical feedback interconnection.*

We say that the feedback connection of Figure 3.2 is $\mathcal{L}_p$-stable when, for every initial state condition (t_0, x_{10}, x_{20}) and every input pair $u_1, u_2 \in \mathcal{L}_p^+$, there exists a uniform upper bound on $\|y_{1[t_0]}\|_p$ and $\|y_{2[t_0]}\|_p$ over all trajectories of the interconnection which satisfy the initial conditions $x_1(t_0) = x_{10}$ and $x_2(t_0) = x_{20}$ (in particular, the trajectories e_1, e_2, y_1, and y_2 all belong to $\mathcal{L}_p^+$). Likewise, we say that the feedback connection is $\mathcal{L}_p$-unstable when it is not $\mathcal{L}_p$-stable. In section 4, we will extend our results to more general stability measures.

We will present our new small-gain theorem in two parts, the first one strengthening the classical sufficiency result (see [4], for example) by weakening the assumption on the system H_1, and the second one demonstrating the necessity of conditional gain for robust stability (treating the system H_2 as uncertainty).

THEOREM 3.4 (sufficiency). *If H_1 has conditional $\mathcal{L}_p$-gain $\leqslant \gamma_1$ and H_2 has (unconditional) $\mathcal{L}_p$-gain $\leqslant \gamma_2$, and if $\gamma_1\gamma_2 < 1$, then the feedback connection of Figure* 3.2 *is $\mathcal{L}_p$-stable.*

THEOREM 3.5 (necessity). *If H_1 does not have conditional $\mathcal{L}_p$-gain $\leqslant \gamma_1$, then there exist $\gamma_2 < 1/\gamma_1$ and a time-invariant state-space system H_2 with (unconditional) $\mathcal{L}_p$-gain $\leqslant \gamma_2$ such that the feedback connection of Figure* 3.2 *is $\mathcal{L}_p$-unstable.*

It is significant that the destabilizing system H_2 in Theorem 3.5 can always be chosen as a time-invariant system, even if H_1 is not time-invariant. Moreover, in the proof of this theorem in section 3.5 below, H_2 is constructed as a second-order system, namely, its state space is $\mathbb{X}_2 = \mathbb{R}^2$. Thus, to show that a system H_1 has conditional

gain, it suffices to prove the $\mathcal{L}_p$-stability of the feedback connection of Figure 3.2 for all second-order, time-invariant systems H_2. There is an alternative construction of H_2 which is first-order but time-varying.

3.4. Proof of Theorem 3.4. Fix an initial condition (t_0, x_{10}, x_{20}) and an input pair $u_1, u_2 \in \mathcal{L}_p^+$, and suppose $v = (u_1, u_2, e_1, e_2, y_1, y_2, x_1, x_2)$ is a trajectory of the interconnection. Now H_2 has $\mathcal{L}_p$-gain $\leqslant \gamma_2$, which implies that, for any $t \in \mathrm{Dom}(v)$ with $t \geqslant t_0$, we have

$$\int_{t_0}^{t} |y_2(\tau)|^p \, d\tau \leqslant \gamma_2^p \int_{t_0}^{t} |e_2(\tau)|^p \, d\tau + \beta_2, \tag{3.22}$$

where $\beta_2 = \beta_2(t_0, x_{20})$ is a finite bias. By taking the pth root of both sides of (3.22), we obtain the estimate

$$\|y_{2[t_0,t]}\|_p \leqslant \gamma_2 \|e_{2[t_0,t]}\|_p + \beta_2^{1/p}. \tag{3.23}$$

Because $\gamma_1\gamma_2 < 1$, we can fix $\overline{\gamma}_1 > \gamma_1$ such that $\overline{\gamma}_1\gamma_2 < 1$. We next obtain the following bounds:

$$\begin{aligned} \overline{\gamma}_1^p \|e_{1[t_0,t]}\|_p^p - \|y_{1[t_0,t]}\|_p^p &\leqslant \overline{\gamma}_1^p \big(\|u_{1[t_0,t]}\|_p + \|y_{2[t_0,t]}\|\big)^p - \|(e_2 - u_2)_{[t_0,t]}\|_p^p \\ &\leqslant \overline{\gamma}_1^p (\|u_{1[t_0,t]}\|_p + \gamma_2 \|e_{2[t_0,t]}\|_p + \beta_2^{1/p})^p \\ &\qquad - \|(e_2 - u_2)_{[t_0,t]}\|_p^p. \end{aligned} \tag{3.24}$$

For the case $\|e_{2[t_0,t]}\|_p \leqslant \|u_{2[t_0]}\|_p$, we see from (3.24) that

$$\overline{\gamma}_1^p \|e_{1[t_0,t]}\|_p^p - \|y_{1[t_0,t]}\|_p^p \leqslant \overline{\gamma}_1^p (\|u_{1[t_0]}\|_p + \gamma_2 \|u_{2[t_0]}\|_p + \beta_2^{1/p})^p + 2^p \|u_{2[t_0]}\|_p^p. \tag{3.25}$$

For the case $\|e_{2[t_0,t]}\|_p > \|u_{2[t_0]}\|_p$, it follows from (3.24) that

$$\begin{aligned} \overline{\gamma}_1^p \|e_{1[t_0,t]}\|_p^p - \|y_{1[t_0,t]}\|_p^p &\leqslant \big(\overline{\gamma}_1 \|u_{1[t_0]}\|_p + \overline{\gamma}_1\gamma_2 \|e_{2[t_0,t]}\|_p + \overline{\gamma}_1 \beta_2^{1/p}\big)^p \\ &\qquad - \big(\|e_{2[t_0,t]}\|_p - \|u_{2[t_0]}\|_p\big)^p. \end{aligned} \tag{3.26}$$

Since $\overline{\gamma}_1\gamma_2 < 1$, the right-hand side of (3.26) is bounded from above by a constant which is independent of e_2 or t, but depends only on the fixed quantities t_0, $\|u_{i[t_0]}\|_p$, p, $\overline{\gamma}_1$, γ_2, and x_{20}. The same is true for the right-hand side of (3.25), and we conclude that there exists a constant $C > 0$ depending only on these fixed quantities such that

$$\sup_{\substack{t \in \mathrm{Dom}(v) \\ t \geqslant t_0}} \int_{t_0}^{t} (\overline{\gamma}_1^p |e_1(\tau)|^p - |y_1(\tau)|^p) \, d\tau < C. \tag{3.27}$$

It now follows from Definition 3.1 that there exists a constant $\delta > 0$, depending only on the fixed quantities t_0, $\|u_{i[t_0]}\|_p$, p, $\overline{\gamma}_1$, γ_2, and x_{i0}, such that

$$\|y_{1[t_0,t]}\|_p \leqslant \gamma_1 \|e_{1[t_0,t]}\|_p + \delta^{1/p}. \tag{3.28}$$

Proceeding from (3.23) and (3.28), the rest of the proof is virtually identical to the proof of the classical small-gain theorem as presented in [4, p. 41]. For example, we obtain a bound on $\|y_{1[t_0]}\|_p$ as follows:

$$\begin{aligned} \|y_{1[t_0,t]}\|_p &\leqslant \gamma_1 \|u_{1[t_0,t]}\|_p + \gamma_1 \|y_{2[t_0,t]}\|_p + \delta^{1/p} \\ &\leqslant \gamma_1 \|u_{1[t_0,t]}\|_p + \gamma_1\gamma_2 \|e_{2[t_0,t]}\|_p + \gamma_1 \beta_2^{1/p} + \delta^{1/p} \\ &\leqslant \gamma_1 \|u_{1[t_0]}\|_p + \gamma_1\gamma_2 \|u_{2[t_0]}\|_p + \gamma_1\gamma_2 \|y_{1[t_0,t]}\|_p + \gamma_1 \beta_2^{1/p} + \delta^{1/p}. \end{aligned} \tag{3.29}$$

Upon collecting the $\|y_{1[t_0,t]}\|_p$ terms on the right-hand side, we obtain the bound

$$\|y_{1[t_0,t]}\|_p \leqslant \frac{1}{1-\gamma_1\gamma_2}\Big(\gamma_1\|u_{1[t_0]}\|_p + \gamma_1\gamma_2\|u_{2[t_0]}\|_p + \gamma_1\beta_2^{1/p} + \delta^{1/p}\Big). \tag{3.30}$$

The left-hand side of (3.30) is independent of t, so this provides a bound on $\|y_{1[t_0]}\|_p$ as desired. The calculation for $\|y_{2[t_0]}\|_p$ is analogous.

3.5. Proof of Theorem 3.5. If $H_1 = (\mathfrak{T}(\mathbb{V}_1), \mathcal{B}_1, \xi_1)$ does not have conditional $\mathcal{L}_p$-gain $\leqslant \gamma_1$, then there exist an initial condition $(t_0, x_{10}) \in \mathfrak{G}(\mathcal{B}_1)$, constants $C_1 > 0$ and $\overline{\gamma}_1 > \gamma_1$, a sequence of trajectories $(e_{1n}, y_{1n}, x_{1n}) \in \mathcal{B}_1$ with $t_0 \in \mathrm{Dom}(e_{1n}, y_{1n}, x_{1n})$ and $x_{1n}(t_0) = x_{10}$ for each $n \geqslant 1$, and a sequence of times $t_n \in \mathrm{Dom}(e_{1n}, y_{1n}, x_{1n})$ with $t_n \geqslant t_0$ such that

$$\int_{t_0}^{t_n} \left(\gamma_1^p|e_{1n}(\tau)|^p - |y_{1n}(\tau)|^p\right) d\tau < -n \tag{3.31}$$

and

$$\sup_{\substack{t\in\mathrm{Dom}(e_{1n},y_{1n},x_{1n})\\ t\geqslant t_0}} \int_{t_0}^{t} \left(\overline{\gamma}_1^p|e_{1n}(\tau)|^p - |y_{1n}(\tau)|^p\right) d\tau < C_1 \tag{3.32}$$

for each $n \geqslant 1$. From the axiom of state, the concatenations

$$(e_{11}, y_{11}, x_{11}) \wedge^{t_0} (e_{1n}, y_{1n}, x_{1n})$$

also belong to $\mathcal{B}_1$ and clearly satisfy (3.31)–(3.32), so we may assume without loss of generality that these trajectories are identical before time t_0, namely, that

$$\mathrm{Dom}(e_{1n}, y_{1n}, x_{1n}) \cap (-\infty, t_0) = \mathrm{Dom}(e_{11}, y_{11}, x_{11}) \cap (-\infty, t_0)$$

and

$$(e_{1n}, y_{1n}, x_{1n})(t) = (e_{11}, y_{11}, x_{11})(t)$$

for all $n \geqslant 1$ and all $t \in \mathrm{Dom}(e_{11}, y_{11}, x_{11}) \cap (-\infty, t_0)$. For each $n \geqslant 1$, define

$$e_{2n} = y_{1n}, \qquad y_{2n} = -e_{1n},$$

and

$$x_{2n}(t) = \left(\tanh(t-t_0),\ \frac{1}{n}\tanh(t-t_0)1(t-t_0)\right) \in \mathbb{R}^2 \tag{3.33}$$

for $t \in \mathrm{Dom}(e_{1n}, y_{1n}, x_{1n})$, where $1(s)$ is the unit step function which is 1 when $s \geqslant 0$ and 0 when $s < 0$. By construction, the trajectories (e_{2n}, y_{2n}, x_{2n}) for $n \geqslant 1$ are identical before time t_0, so the concatenation of two of these trajectories at a time before t_0 does not yield a new trajectory. We let $H_2 = (\mathfrak{T}(\mathbb{V}_2), \mathcal{B}_2, \xi_2)$, where $\mathcal{B}_2$ is the collection of all time-shifted versions of these trajectories:

$$\mathcal{B}_2 = \big\{\sigma^t(e_{2n}, y_{2n}, x_{2n}) \ :\ t \in \mathbb{R},\, n \geqslant 1\big\}. \tag{3.34}$$

Clearly, H_2 is time-invariant. To verify the axiom of state, suppose that there exist $t_1, t_2 \in \mathbb{R}$ and $n, m \geqslant 1$ such that $(\sigma^{t_1}x_{2n})(t) = (\sigma^{t_2}x_{2m})(t)$ for some $t \in \mathbb{R}$. By

matching the first state coordinates, we obtain $\tanh(t+t_1-t_0)=\tanh(t+t_2-t_0)$, which implies $t_1=t_2$. By matching the second state coordinates, we then obtain $\frac{1}{n}\tanh(t+t_1-t_0)1(t+t_1-t_0)=\frac{1}{m}\tanh(t+t_1-t_0)1(t+t_1-t_0)$, which implies either $t+t_1\leqslant t_0$ or $n=m$. In either case, it is clear that the concatenation $\sigma^{t_1}(e_{2n},y_{2n},x_{2n})\wedge^t\sigma^{t_1}(e_{2m},y_{2m},x_{2m})$ also belongs to B_2.

We next verify that H_2 has $\mathcal{L}_p$-gain less than or equal to $\gamma_2\triangleq 1/\overline{\gamma}_1$ (which clearly satisfies $\gamma_1\gamma_2<1$). Fix $x_{20}=(a_0,b_0)\in\mathbb{R}^2$ such that $(\sigma^t x_{2n})(0)=x_{20}$ for some $t\in\mathbb{R}$ and some $n\geqslant 1$. Then we have $t=t_0+\tanh^{-1}(a_0)$ and, if $t>t_0$, then also $n=a_0/b_0$. Fix $s\geqslant 0$ and suppose first that $s+t\leqslant t_0$. Because the trajectories (e_{2n},y_{2n},x_{2n}) for $n\geqslant 1$ are identical before time t_0, we have

(3.35)
$$\begin{aligned}\int_0^s\left(\gamma_2^p|e_{2n}(\tau+t)|^p-|y_{2n}(\tau+t)|^p\right)d\tau&=\int_t^{s+t}\left(\gamma_2^p|e_{2n}(\tau)|^p-|y_{2n}(\tau)|^p\right)d\tau\\&\geqslant\min_{t\leqslant r\leqslant t_0}\int_t^r\left(\gamma_2^p|e_{21}(\tau)|^p-|y_{21}(\tau)|^p\right)d\tau,\end{aligned}$$

where the minimum exists because $t,t_0\in\mathrm{Dom}(e_{21},y_{21},x_{21})$, and the input and output trajectories belong to $\mathcal{L}_{pe}$ on their domains. Suppose next that $t\leqslant t_0<s+t$: in this case, we use (3.32) to obtain

(3.36)
$$\begin{aligned}\int_0^s\left(\gamma_2^p|e_{2n}(\tau+t)|^p-|y_{2n}(\tau+t)|^p\right)d\tau&=\int_t^{t_0}\left(\gamma_2^p|e_{2n}(\tau)|^p-|y_{2n}(\tau)|^p\right)d\tau\\&\quad+\int_{t_0}^{s+t}\left(\gamma_2^p|e_{2n}(\tau)|^p-|y_{2n}(\tau)|^p\right)d\tau\\&=\int_t^{t_0}\left(\gamma_2^p|e_{2n}(\tau)|^p-|y_{2n}(\tau)|^p\right)d\tau\\&\quad-\gamma_2^p\int_{t_0}^{s+t}\left(\bar{\gamma}_1^p|e_{1n}(\tau)|^p-|y_{1n}(\tau)|^p\right)d\tau\\&\geqslant\int_t^{t_0}\left(\gamma_2^p|e_{21}(\tau)|^p-|y_{21}(\tau)|^p\right)d\tau-\gamma_2^pC_1.\end{aligned}$$

Finally, if $t>t_0$, then $n=a_0/b_0$ and we obtain again from (3.32) that

(3.37)
$$\begin{aligned}\int_0^s\left(\gamma_2^p|e_{2n}(\tau+t)|^p-|y_{2n}(\tau+t)|^p\right)d\tau&=-\int_{t_0}^{t}\left(\gamma_2^p|e_{2n}(\tau)|^p-|y_{2n}(\tau)|^p\right)d\tau\\&\quad+\int_{t_0}^{s+t}\left(\gamma_2^p|e_{2n}(\tau)|^p-|y_{2n}(\tau)|^p\right)d\tau\\&\geqslant-\int_{t_0}^{t}\left(\gamma_2^p|e_{2n}(\tau)|^p-|y_{2n}(\tau)|^p\right)d\tau-\gamma_2^pC_1.\end{aligned}$$

In all three cases, we obtain finite lower bounds (3.35), (3.36), and (3.37) on the integral of the $\mathcal{L}_p$-gain supply rate which are independent of both n and the upper integration limit s (the lower bound (3.37) appears to depend on n but, in this third case, n is fixed at $n=a_0/b_0$). We conclude that H_2 has $\mathcal{L}_p$-gain $\leqslant\gamma_2$.

Finally, we need to show that the feedback connection of Figure 3.2 is $\mathcal{L}_p$-unstable. Choose inputs $u_1 \equiv 0$ and $u_2 \equiv 0$; then, by construction, for each $n \geqslant 1$, the trajectory $(u_1, u_2, e_{1n}, e_{2n}, y_{1n}, y_{2n}, x_{1n}, x_{2n})$ belongs to the behavior of the interconnection and satisfies the initial condition $(x_{1n}(t_0), x_{2n}(t_0)) = (x_{10}, 0)$. It follows from (3.31) that, for this initial condition, there is no upper bound on the $\mathcal{L}_p$-norms $\|y_{1n[t_0]}\|_p$.

4. Conditional dissipativity. In this section we extend our results to general performance measures characterized by dissipation inequalities, $\mathcal{L}_p$-gain being but one such measure. We will consider the general interconnection G of systems G_1 and G_2 as illustrated in Figure 4.1. Here the interconnection signal w might contain components labeled as inputs and outputs of G_1 and G_2; however, in this behavioral context, there is no need to label them as such. To simplify the sufficiency part of our result, we will assume that the interconnection G is not driven by exogenous signals such as the inputs u_1 and u_2 of Figure 3.2. To simplify the necessity part, we will assume throughout this section that all supply rates are time-invariant, namely, that they do not depend explicitly on the time variable.

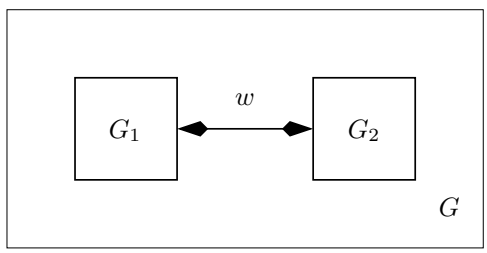

FIG. 4.1. *Behavioral interconnection.*

We first make precise our notion of interconnection in Figure 4.1. Let $\mathbb{W}$ be a nonempty signal set, define $\mathbb{V}_1 \triangleq \mathbb{W} \times \mathbb{X}_1$ and $\mathbb{V}_2 \triangleq \mathbb{W} \times \mathbb{X}_2$ for some nonempty state spaces $\mathbb{X}_1$ and $\mathbb{X}_2$, and let ξ_1 and ξ_2 represent the respective projections of $\mathbb{V}_1$ and $\mathbb{V}_2$ onto $\mathbb{X}_1$ and $\mathbb{X}_2$. Given trajectory spaces $\mathfrak{T}(\mathbb{V}_1)$ and $\mathfrak{T}(\mathbb{V}_2)$, we define $\mathbb{V} = \mathbb{W} \times \mathbb{X}_1 \times \mathbb{X}_2$, we let $\mathfrak{T}(\mathbb{V})$ denote the collection of trajectories (w, x_1, x_2) such that $(w, x_1) \in \mathfrak{T}(\mathbb{V}_1)$ and $(w, x_2) \in \mathfrak{T}(\mathbb{V}_2)$, and we let ξ denote the projection of $\mathbb{V}$ onto $\mathbb{X}_1 \times \mathbb{X}_2$. Finally, we let $\mathfrak{T}(\mathbb{W})$ denote the appropriate projection of $\mathfrak{T}(\mathbb{V})$, namely, $w_1 \in \mathfrak{T}(\mathbb{W})$ whenever there exists $(w, x_1, x_2) \in \mathfrak{T}(\mathbb{V})$ such that $w \equiv w_1$. Note that if $\mathbf{S}$ is a supply rate for $\mathfrak{T}(\mathbb{W})$, then, by simple extension, we may also consider $\mathbf{S}$ to be a supply rate for $\mathfrak{T}(\mathbb{V}_1)$, $\mathfrak{T}(\mathbb{V}_2)$, or $\mathfrak{T}(\mathbb{V})$. Now, given state-space systems $G_1 = (\mathfrak{T}(\mathbb{V}_1), \mathcal{B}_1, \xi_1)$ and $G_2 = (\mathfrak{T}(\mathbb{V}_2), \mathcal{B}_2, \xi_2)$, we define their intersection $G = G_1 \cap G_2$ to be the system $G = (\mathfrak{T}(\mathbb{V}), \mathcal{B}, \xi)$ with behavior

$$\mathcal{B} = \big\{(w, x_1, x_2) \in \mathfrak{T}(\mathbb{V}) \ : \ (w, x_1) \in \mathcal{B}_1 \text{ and } (w, x_2) \in \mathcal{B}_2\big\}. \tag{4.1}$$

It is straightforward to verify that G satisfies the axiom of state. We will describe the desired performance of the interconnection G by means of a supply rate N for $\mathfrak{T}(\mathbb{W})$. For example, if $\mathbb{W}$ is a normed linear space and we are interested in the $\mathcal{L}_p$-stability, we would choose $N(w) = -|w|^p$ (so that G is dissipative with respect to N if and only if $\|w_{[t_0]}\|_p$ is bounded by a constant depending only on t_0 and the initial states).

DEFINITION 4.1. *Given a supply rate N for $\mathfrak{T}(\mathbb{W})$, we say that supply rates $\mathbf{S}_1$ and $\mathbf{S}_2$ for $\mathfrak{T}(\mathbb{W})$ are* N-complementary *when there exist strictly positive constants a,*

b, c, and d such that

$$a\mathbf{S}_1(w) + b\mathbf{S}_2(w) \leqslant N(w) \leqslant c\mathbf{S}_1(w) - d\mathbf{S}_2(w) \tag{4.2}$$

for all $w \in \mathbb{W}$.

For the $\mathcal{L}_p$-gain scenario considered in section 3, we would assume $\mathbb{W} = \mathbb{E} \times \mathbb{Y}$ for normed linear spaces $\mathbb{E}$ and $\mathbb{Y}$, and we would choose the following:

$$N(w) = -|e|^p - |y|^p, \tag{4.3}$$

$$\mathbf{S}_1(w) = \gamma^p|e|^p - |y|^p, \tag{4.4}$$

$$\mathbf{S}_2(w) = -\overline{\gamma}^p|e|^p + |y|^p \tag{4.5}$$

for nonnegative constants γ and $\overline{\gamma}$. In this case, it is straightforward to show that if $\gamma < \overline{\gamma}$, then $\mathbf{S}_1$ and $\mathbf{S}_2$ are N-complementary with $c = d = 1/2$ and

$$a = \frac{\overline{\gamma}^p + 1}{\overline{\gamma}^p - \gamma^p}, \qquad b = \frac{\gamma^p + 1}{\overline{\gamma}^p - \gamma^p}. \tag{4.6}$$

At this point the classical sufficiency of the small-gain condition can be phrased as follows: if G_1 is dissipative with respect to $\mathbf{S}_1$ and G_2 is dissipative with respect to $\mathbf{S}_2$, then if $\gamma < \overline{\gamma}$, the interconnection G is dissipative with respect to N. We will use such phrasing in our general sufficiency result below.

Another common scenario involves *passivity*: for example, suppose $\mathbb{W} = \mathbb{E} \times \mathbb{Y}$ for some real inner product space $\mathbb{E} = \mathbb{Y}$, and consider the following:

$$N(w) = -\langle e, e\rangle - \langle y, y\rangle, \tag{4.7}$$

$$\mathbf{S}_1(w) = \langle e, y\rangle - \varepsilon\langle e, e\rangle, \tag{4.8}$$

$$\mathbf{S}_2(w) = -\langle e, y\rangle - \delta\langle y, y\rangle \tag{4.9}$$

for constants ε and δ. If ε and δ are both strictly positive, then $\mathbf{S}_1$ and $\mathbf{S}_2$ are N-complementary with

$$a = b = \frac{1}{\varepsilon} + \frac{1}{\delta}, \qquad c = d = \frac{1}{1+\varepsilon}. \tag{4.10}$$

Here the classical result states that the feedback connection of two input (or output) strictly passive systems is $\mathcal{L}_2$-stable [14, Lemma 6.8]. In other words, if G_1 is dissipative with respect to $\mathbf{S}_1$ and G_2 is dissipative with respect to $\mathbf{S}_2$, then the interconnection G is dissipative with respect to N.

To strengthen these classical sufficiency results, we introduce the following conditional version of dissipativity.

DEFINITION 4.2. *A state-space system* $G_1 = (\mathfrak{T}(\mathbb{V}_1), \mathcal{B}_1, \xi_1)$ *is* N-conditionally dissipative *with respect to a supply rate* $\mathbf{S}_1$ *when, for every initial* $(t_0, x_{10}) \in \mathfrak{G}(\mathcal{B}_1)$, *every* $C > 0$, *and every supply rate* $\mathbf{S}_2$ *which is* N*-complementary to* $\mathbf{S}_1$,

$$\inf_{\substack{w,x_1 \\ t \geqslant t_0}} \int_{t_0}^{t} \mathbf{S}_1(w(\tau))\, d\tau > -\infty, \tag{4.11}$$

where the infimum is taken over all trajectories $(w, x_1) \in \mathcal{B}_1$ *and all* $t \geqslant t_0$ *such that* $t, t_0 \in \mathrm{Dom}(w, x_1)$, $x_1(t_0) = x_{10}$, *and furthermore*

$$\inf_{\substack{t \in \mathrm{Dom}(w,x_1) \\ t \geqslant t_0}} \int_{t_0}^{t} \mathbf{S}_2(w(\tau))\, d\tau > -C. \tag{4.12}$$

THEOREM 4.3 (sufficiency). *If G_1 is N-conditionally dissipative with respect to $\mathbf{S}_1$, if G_2 is dissipative with respect to $\mathbf{S}_2$, and if $\mathbf{S}_1$ and $\mathbf{S}_2$ are N-complementary, then the intersection $G = G_1 \cap G_2$ is dissipative with respect to N.*

Proof. Fix $(t_0, x_{10}, x_{20}) \in \mathfrak{G}(\mathcal{B})$, and let $(w, x_1, x_2) \in \mathcal{B}$ be such that $x_1(t_0) = x_{10}$ and $x_2(t_0) = x_{20}$. Because G_2 is dissipative with respect to $\mathbf{S}_2$, there exists $C_2 > 0$, depending only on the initial condition (t_0, x_{20}), such that

$$\inf_{\substack{t \in \mathrm{Dom}(w) \\ t \geqslant t_0}} \int_{t_0}^{t} \mathbf{S}_2(w(\tau))\, d\tau > -C_2. \tag{4.13}$$

By the N-conditional dissipativity of G_1, there exists $C_1 > 0$, depending only on the initial condition (t_0, x_{10}, x_{20}), such that

$$\inf_{\substack{t \in \mathrm{Dom}(w) \\ t \geqslant t_0}} \int_{t_0}^{t} \mathbf{S}_1(w(\tau))\, d\tau > -C_1. \tag{4.14}$$

It now follows from (4.2), (4.13), and (4.14) that

$$\inf_{\substack{t \in \mathrm{Dom}(w) \\ t \geqslant t_0}} \int_{t_0}^{t} N(w(\tau))\, d\tau > -aC_1 - bC_2, \tag{4.15}$$

and we conclude that G is dissipative with respect to N. ∎

As before, the use of conditional dissipativity also allows us to recover the corresponding necessity result.

THEOREM 4.4 (necessity). *If G_1 is not N-conditionally dissipative with respect to $\mathbf{S}_1$, then there exists a supply rate $\mathbf{S}_2$ which is N-complementary to $\mathbf{S}_1$ and a time-invariant state-space system G_2 which is dissipative with respect to $\mathbf{S}_2$ such that the intersection $G = G_1 \cap G_2$ is not dissipative with respect to N.*

Proof. Negating Definition 4.2, there exist an initial condition $(t_0, x_{10}) \in \mathfrak{G}(\mathcal{B}_1)$, a constant $C_1 > 0$, a supply rate $\mathbf{S}_2$ which is N-complementary to $\mathbf{S}_1$, a sequence of trajectories $(w_n, x_{1n}) \in \mathcal{B}_1$ with $t_0 \in \mathrm{Dom}(w_n, x_{1n})$ and $x_{1n}(t_0) = x_{10}$ for each $n \geqslant 1$, and a sequence of times $t_n \in \mathrm{Dom}(w_n, x_{1n})$ with $t_n \geqslant t_0$ such that

$$\int_{t_0}^{t_n} \mathbf{S}_1(w_n(\tau))\, d\tau < -n \tag{4.16}$$

and

$$\inf_{\substack{t \in \mathrm{Dom}(w_n, x_{1n}) \\ t \geqslant t_0}} \int_{t_0}^{t} \mathbf{S}_2(w_n(\tau))\, d\tau > -C_1 \tag{4.17}$$

for each $n \geqslant 1$. As argued in section 3.5, we may assume without loss of generality that these trajectories are identical before time t_0. To construct G_2, we define a sequence of state trajectories x_{2n} as in (3.33), and we let the behavior $\mathcal{B}_2$ of G_2 be

$$\mathcal{B}_2 = \big\{\sigma^t(w_n, x_{2n}) \;:\; t \in \mathbb{R},\, n \geqslant 1\big\}. \tag{4.18}$$

Using arguments similar to those in section 3.5, we can show that G_2 is time-invariant, satisfies the axiom of state, and is (unconditionally) dissipative with respect to the supply rate $\mathbf{S}_2$. Furthermore, we conclude from (4.2), (4.16), and (4.17) that

$$\int_{t_0}^{t_n} N(w_n(\tau))\, d\tau \leqslant c \int_{t_0}^{t_n} \mathbf{S}_1(w_n(\tau))\, d\tau - d \int_{t_0}^{t_n} \mathbf{S}_2(w_n(\tau))\, d\tau \leqslant -cn + dC_1 \tag{4.19}$$

for each $n \geqslant 1$. Because the trajectories (w_n, x_{1n}, x_{2n}) belong to the behavior (4.1) of the intersection G, we conclude that G is not dissipative with respect to N. □

An example application of Theorem 4.4 is the following. Suppose we can prove that the feedback connection of a system G_1 with any input and output strictly passive system G_2 is $\mathcal{L}_2$-stable. Then we cannot conclude in general that G_1 is a passive system, but Theorem 4.4 guarantees that G_1 is conditionally passive.

5. Conclusion. It was shown in [6] that the classical definition of $\mathcal{L}_p$-gain is too strong to provide an equivalence between performance and robust stability. We have presented a weaker notion of gain which recovers the necessity while preserving the sufficiency of the small-gain condition. In the necessity proof, the uncertainty can be chosen to be second-order and time-invariant, even when the plant is time-varying and/or infinite-dimensional. We have also shown that these two notions of gain are equivalent for systems having a resetting property (such as fading-memory systems or linear time-invariant systems). Finally, we extended our results to more general dissipation performance measures.

ON WORST-CASE PORTFOLIO OPTIMIZATION*

RALF KORN† AND MOGENS STEFFENSEN‡

Abstract. We formulate a worst-case portfolio optimization problem that technically appears as a game where the investor chooses a portfolio and his opponent, the market, chooses some market crashes. The asymmetry of the opponents' decision processes leads to a new and delicate generalization of the classical Hamilton–Jacobi–Bellman equation in stochastic control. We characterize the optimal controls in general and specify them further in the cases of Hara, logarithmic, and exponential utilities of the investor.

Key words. Hamilton–Jacobi–Bellman equation, stochastic differential games, market crash, utility optimization

1. Introduction. The problem of finding an optimal investment strategy for an investor with a given utility function and a fixed initial endowment—the so-called portfolio optimization problem—is one of the classical problems in financial mathematics and its applications in insurance mathematics. The corresponding modern continuous-time approach was pioneered by Merton [8, 9], who applied classical stochastic control methods to reduce the portfolio problem to a matter of solving a Hamilton–Jacobi–Bellman partial differential equation (HJB equation).

Since Merton's pioneering work, many attempts have been made to solve the portfolio optimization problem in a framework that allows for more realistic models of stock prices, in particular for models that can explain large price movements. Examples where portfolio optimization problems are treated in more general settings are portfolio optimization in jump-diffusion models (see, e.g., Aase [1]) or in a general semimartingale framework (see, e.g., Kramkov and Schachermayer [7]).

A different portfolio problem that includes dramatic negative changes of the stock prices (so-called crashes) has been introduced by Korn and Wilmott [6]. Their main idea consists of two aspects: the separation between normal times where the stock price behaves as a geometric Brownian motion and crash times where it jumps downwards and the introduction of a worst-case functional that resembles the form of a game-theoretic max-min approach. While in Korn and Wilmott [6] the problem is solved only for the choice of the logarithmic utility function, a more general problem of the worst-case form is treated in Korn and Menkens [5]. At first sight, their approach seems to be an approach similar to the HJB-equation approach of stochastic control. However, their arguments are based on equilibrium and indifference considerations, and they derive differential equations for the optimal portfolio processes and not for the value function. Even more, they could prove optimality of their proposed portfolio processes only within the class of (piecewise) deterministic control strategies.

The main purpose of this paper is to put the worst-case portfolio optimization in the HJB-equation framework and thus to connect it with the mainstream of stochastic control theory. This leads us to a type of continuous-time game problem that, to our knowledge, is new in control theory. It is the asymmetry of the opponents' decision processes that makes the game so interesting and challenging from a control theoretical point of view: The investor decides the portfolio process, whereas the opponent, the market, decides when the stock market crashes. One could fear that this very asymmetry prevents solutions to the game problem, but we show that the problem, indeed, has a solution and that the solution can be characterized by a generalized HJB equation.

A related financial game problem is approached by Talay and Zheng [10]. They solve a problem where the opponent of the investor, the market, decides the parameters in a diffusion model. Thus, the idea of seeing the market as an opponent is exactly the same as ours. But since their price processes are continuous, the decisions of both the investor and the market affect only the coefficients of the continuous portfolio process. Therefore, from a financial modeling point of view their problem is completely different from ours.

We do not necessarily believe that the investment decision is a part of a game really played in the sense that the market really tries to hurt the investor. But, on the other hand, even a rational investor could choose to invest as if this were really the case. This is exactly what comes out of basing decision on a worst-case scenario. Thus, when we use the word game throughout, this is mainly because the technical formulation of the worst-case investment problem conforms with the general idea of a stochastic differential game.

Our main result is a verification theorem asserting that a system consisting of an HJB-type inequality, a relation between value functions before and after an action of the market, final conditions, and a complementarity condition determine the value function. This result and its consequences are highlighted by some explicit examples. Note in particular that we do not have to restrict ourselves to (piecewise) deterministic controls. Therefore, the existing work on worst-case portfolio optimization is substantially generalized.

Even more, the explicit form of the optimal portfolio strategy that results from our worst-case approach closely resembles the form of strategies that—in real life applications—are suggested for use in pension savings plans. Thus, our model can also be seen as a theoretical justification of a market practice.

One can imagine other areas where the structure of the problem and its solution can find applications. For example, an insurance company decides on reinsurance against large claims, e.g., triggered by a storm or earthquakes. In its battle against the merciless Mother Earth, the company could adopt a worst-case basis for making certain decisions, e.g., the extent of reinsurance protection. The structure of the HJB equation for such a problem is similar, and the relative explicit characterization of the optimal decision obtained here holds out every promise of success in other areas.

2. The model and the preferences. Take as given a probability space $(\Omega, \mathcal{F}, P)$. Let W be a standard Brownian motion defined on this probability space. Let us consider an agent over a fixed time interval $[0, T]$. At time 0 the agent is endowed with initial wealth x_0, and his problem is to allocate investments over the given time horizon. We assume that the agent's investment opportunities are given by the

following financial market:

$$\begin{aligned} dB(t) &= rB(t)\,dt, \\ B(0) &= 1, \\ dS(t) &= S(t-)\left(\alpha dt + \sigma dW(t) - \beta dN(t)\right), \\ S(0) &= s_0, \end{aligned}$$

where r, α, σ, and β are constants. For $N(t) = 0$, this market is a classical Black–Scholes market. We introduce, however, jumps in the Black–Scholes market and let N be a counting process counting the number of jumps such that

$$N(t) = \#\{0 < s \leq t : S(t) \neq S(t-)\}.$$

Remark 1. (a) Referring to Korn and Wilmott [6] our model above can also be seen as a worst-case approach when downward jumps of arbitrary size from the interval $[0, \beta]$ are possible. Since it is shown there that only the extreme jump size of β enters the following considerations, we have chosen to work only with this jump size above. Note also that we consider relative jump sizes which means that the jump size actually depends on the past performance of our stock. However, we have not yet modeled external market influences on the jump size which would be a possible extension of our model.

(b) We choose to work with constant coefficients here, but generalizations to, e.g., N-dependent coefficients should be straightforward. We do believe that generalizations to markets where the coefficients r, α, σ react on crashes, henceforth called "crashed coefficients," are important and that our results carry over to this situation. Crashed coefficients are considered in Korn [4] and in Korn and Menkens [5], where, however, weaker optimality results than ours below are given. Here we focus on the qualitative form of the new HJB-system characterization. With crashed coefficients the qualitative form of this system will not change, but in the examples and illustrations one would have to distinguish between several different subcases.

In usual jump-diffusion models the counting process is now assumed to follow some probability law on $(\Omega, \mathcal{F}, P)$. One could, e.g., let N be a Poisson process or a Cox process. Here, however, we take the counting process to be chosen by the market, which from the point of view of the agent is considered as an opponent. In other words, the market decides when the stock jumps, and N is to be considered as a decision process held by the market. We speak of jumps in N as interventions.

We assume that the market is able to decide on only a limited number of interventions and denote the maximal number of interventions over $[0, T]$ by n_0. Figure 1 illustrates the process of interventions. The market can, however, also choose not to exercise its intervention options, so at time T the process of interventions can be in any of the states in Figure 1. Further, to avoid technical complications, we assume that the market never intervenes more than once in one time instant (a multiple intervention of the market in one time instant is also not reasonable from an intuitive point of view).

The investment behavior of the agent is modeled by a predictable portfolio strategy π denoting the proportion of wealth invested in S; i.e., π is a decision variable held by the agent. Restricting ourselves to self-financing portfolio strategies, the wealth process follows the differential equation

$$\begin{aligned} X(0) &= x_0, \\ dX(t) &= X(t-)\left(rdt + \pi(t)\left((\alpha - r)\,dt + \sigma dW(t) - \beta dN(t)\right)\right). \end{aligned}$$

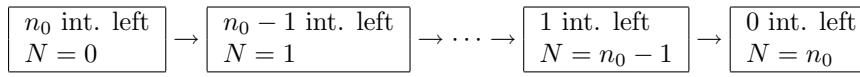

FIG. 1. *Process of interventions.*

The differential equation can be considered as a controlled differential equation with a pair of controls being a pair of portfolio strategies and interventions, i.e., (π, N). The agent is allowed to choose $\pi \in \mathcal{A}$, and the market is allowed to choose an intervention $N \in \mathcal{B}$ such that the pair of controls (π, N) leads to a well-posed optimization problem below. Even more, we consider $\mathcal{A}$ to be the set of all predictable processes (with respect to the σ-algebra generated by the stock price process and the counting process and which in particular carries the information about how many jumps can still at most appear) such that we have

$$E\int_0^T |\pi(t)|^m \, ds < \infty \text{ for } m = 1, 2, \ldots,$$
$$\pi(t)\,\beta < 1 \text{ for all } t \in [0, T].$$

These requirements in particular ensure that the wealth process stays nonnegative and has finite moments of all order. Note that, in a model with jumps, predictability of strategies becomes very important (in contrast to diffusion models, where predictability and adaptedness collapse), since otherwise the investor could choose his position during a crash after the crash has been observed.

Then, given a pair of controls (π, N), the controlled differential equation describing the wealth is given by

$$\begin{aligned} X^{\pi N}(0) &= x_0, \\ dX^{\pi N}(t) &= X^{\pi N}(t-)\left(r\,dt + \pi(t)\left((\alpha - r)\,dt + \sigma\,dW(t) - \beta\,dN(t)\right)\right). \end{aligned} \tag{1}$$

For a fixed time s and given $X^{\pi,N}(s) = x_s$, if τ is the first intervention time after s, we can obviously write

$$\begin{aligned} X^{\pi N}(s) &= x_s, \\ dX^{\pi N}(t) &= X^{\pi N}(t)\left(\left(r + \pi(t)(\alpha - r)\right)dt + \pi(t)\,\sigma\,dW(t)\right), s < t < \tau, \\ X^{\pi N}(\tau) &= X^{\pi N}(\tau-)\left(1 - \pi(\tau)\,\beta\right). \end{aligned}$$

If we only need to consider X until the first intervention time, we can just as well denote the argument N by τ, and we do so below.

We assume that the investor chooses a portfolio process to maximize worst-case expected utility of terminal wealth in the sense of the following optimization problem:

$$\sup_{\pi \in \mathcal{A}} \inf_{N \in \mathcal{B}} E\left[U\left(X^{\pi N}(T)\right)\right].$$

For each function $v \in C^{1,2}$ we define the differential operator $\mathcal{L}^\pi v$ by

$$\mathcal{L}^\pi v(t,x) = v_t(t,x) + v_x(t,x)\left(r + \pi(\alpha - r)\right)x + \frac{1}{2}v_{xx}(t,x)\,\pi^2\sigma^2x^2.$$

3. The Bellman system and the verification theorem. In this section we present and prove the Bellman system connected with the control problem described in the previous section.

We define the value function $\mathcal{J}^n(t,x,\pi)$ by

$$\mathcal{J}^n(t,x,\pi) = E_{t,x,n}\left[U\left(X^{\pi N}(T)\right)\right],$$

where $E_{t,x,n}$ denotes conditional expectation given that $X(t) = x$ and that there are at most n possible jumps left. We define the optimal value function $V^n(t,x)$ by

$$V^n(t,x) = \sup_{\pi\in\mathcal{A}} \inf_{N\in\mathcal{B}} \mathcal{J}^n(t,x,\pi,\tau).$$

We can now present a Bellman system in a verification theorem, the proof of which can be found in the appendix.

THEOREM 2 (verification theorem). 1. Assume that $v^0(t,x)$ is a classical solution of

$$\begin{aligned} 0 &= \sup_{\pi\in\mathcal{A}}\left[\mathcal{L}^\pi v^0(t,x)\right], \\ v^0(T,x) &= U(x), \end{aligned}$$

which is polynomially bounded, and that

$$p^0(t,x) = \arg\sup_{\pi\in\mathcal{A}}\left[\mathcal{L}^\pi v^0(t,x)\right]$$

is an admissible control function. Then we have

$$V^0(t,x) = v^0(t,x),$$

and the optimal control function exists and is given by

$$\pi^{0*}(t,x) = p^0(t,x).$$

2. For $n\in\mathbf{N}$ and every function $v^n\in C^{1,2}$, define the sets $\mathcal{A}'_n(t,x)$ and $\mathcal{A}''_n(t,x)$ by

$$\begin{aligned} \mathcal{A}'_n(t,x) &= \left\{\pi : \pi\in\mathcal{A}, 0\le \mathcal{L}^\pi v^n(t,x)\right\}, \\ \mathcal{A}''_n(t,x) &= \left\{\pi : \pi\in\mathcal{A}, 0\le v^{n-1}(t,x(1-\beta\pi)) - v^n(t,x)\right\}, \end{aligned}$$

respectively. Assume that there exists a polynomially bounded $C^{1,2}$-solution of

$$\begin{aligned} 0 &\le \sup_{\pi\in\mathcal{A}''_n(t,x)}\left[\mathcal{L}^\pi v^n(t,x)\right], \\ 0 &\le \sup_{\pi\in\mathcal{A}'_n(t,x)}\left[v^{n-1}(t,x(1-\beta\pi)) - v^n(t,x)\right], \\ 0 &= \sup_{\pi\in\mathcal{A}''_n(t,x)}\left[\mathcal{L}^\pi v^n(t,x)\right] \sup_{\pi\in\mathcal{A}'_n(t,x)}\left[v^{n-1}(t,x(1-\beta\pi)) - v^n(t,x)\right], \\ v^n(T,x) &= U(x) \end{aligned}$$

and that

$$\begin{aligned} p^n(t,x) &= \arg\sup_{\pi\in\mathcal{A}''_n(t,x)}\left[\mathcal{L}^\pi v^n(t,x)\right], \\ \theta^n(t,x) &= \inf_{s:s\ge t}\left[v^{n-1}\left(s,X^{\pi N}(s)(1-\beta\pi)\right) - v^n\left(s,X^{\pi N}(s)\right)\le 0\right], \end{aligned}$$

where $X^{\pi N}(t) = x$ and s is a stopping time, is a pair of admissible control functions. Then

$$V^n(t,x) = v^n(t,x),$$

and the optimal control functions exist and are given by

$$\pi^{n*}(t,x) = p^n(t,x),$$
$$\tau^{n*}(t,x) = \theta^n(t,x).$$

In the proof of the verification theorem, the following lemma, which is also proved in the appendix, is used.

LEMMA 3. *The value function can be represented in the following ways:*

$$\begin{aligned} V^n(t,x) &= \sup_{\pi}\inf_{N} E_{t,x,n}\left[U\left(X^{\pi N}(T)\right)\right] \\ &= \inf_{N}\sup_{\pi} E_{t,x,n}\left[U\left(X^{\pi N}(T)\right)\right] \\ &= \sup_{\pi}\inf_{\tau} E_{t,x,n}\left[V^{n-1}\left(\tau, X^{\pi\tau}(\tau-)\left(1-\beta\pi(\tau)\right)\right)\right] \\ &= \inf_{\tau}\sup_{\pi} E_{t,x,n}\left[V^{n-1}\left(\tau, X^{\pi\tau}(\tau-)\left(1-\beta\pi(\tau)\right)\right)\right]. \end{aligned}$$

A careful inspection of the proof of Theorem 2 shows that the expectation requirements on the admissible controls and the polynomial growth condition for the value function are indeed only needed for the expectation of the stochastic integrals to vanish just before relations (16) and (21). Of course, these requirements are only sufficient for the proof to go through. The assumption of polynomial growth of the value function is not satisfied for our examples of the logarithmic utility and the exponential utility function below. However, one can directly check that the above proof still goes through for those special choices of the utility functions as it can be verified that the expectations of the two mentioned stochastic integrals vanish.

4. Characterization of the solution. To apply the verification theorem we are now going to construct (in a heuristic way) general candidates for the value functions V^n and the optimal controls along the lines of the theorem. In the following sections it will be shown that for special choices of the utility function U these heuristically derived candidates indeed satisfy all of the requirements of the verification theorem and are thus solutions of the control problem. Let us start by considering the inequality

$$0 \le \sup_{\pi\in\mathcal{A}'_n(t,x)}\left[V^{n-1}\left(t, x\left(1-\beta\pi\right)\right) - V^n(t,x)\right]. \tag{2}$$

Since for $\beta > 0$ and a (strictly) increasing utility function U we have that $V^{n-1}(t, x(1-\beta\pi))$ is a decreasing function of π, the supremum in (2) is obtained for the smallest π with

$$V^n_t(t,x) \ge -V^n_x(t,x)\left(r+\pi\left(\alpha-r\right)\right)x - \frac{1}{2}V^n_{xx}(t,x)\,\pi^2\sigma^2x^2. \tag{3}$$

Under the assumption of a concave V^n we have that the supremum in (2) is attained for the smallest value of π for which (3) holds as an equality. We can now consider

the obvious choice for the separation of the (t,x)-space into the set $\mathcal{M}$, where the right-hand side of the inequality (2) is strictly positive, and its complement, i.e.,

$$\mathcal{M}=\left\{(t,x):\sup_{\pi\in\mathcal{A}_n'(t,x)}\left[V^{n-1}\left(t,x\left(1-\beta\pi\right)\right)-V^n\left(t,x\right)\right]>0\right\}.$$

Outside $\mathcal{M}$, π and V are determined by the set of equations

$$\begin{aligned}V^n\left(t,x\right)&=V^{n-1}\left(t,x\left(1-\beta\pi\right)\right),\\ V_t^n\left(t,x\right)&=-V_x^n\left(t,x\right)\left(r+\pi\left(\alpha-r\right)\right)x-\frac{1}{2}V_{xx}^n\left(t,x\right)\pi^2\sigma^2x^2.\end{aligned}\tag{4}$$

Note that the first equation has to hold by the complementarity condition in the verification theorem. The second equation is argued for above.

We now argue that, even at some points (t,x) inside $\mathcal{M}$, the set of equations (4) determine π and V, which finally leads to an alternative and more relevant separation of the (t,x)-space. Intuitively, this is due to the constraint on π in $\mathcal{A}''$. Inside $\mathcal{M}$ we must have $\sup_{\pi\in\mathcal{A}_n''(s)}\left[\mathcal{L}^\pi v^n\left(s,X^{\pi,\theta}\left(s\right)\right)\right]=0$, again by complementarity. Ignoring the constraint $\pi\in\mathcal{A}_n''\left(t,x\right)$ we can compute the usual candidate for an optimal portfolio process by the first order conditions as:

$$\pi=-\frac{V_x^n\left(t,x\right)}{V_{xx}^n\left(t,x\right)x}\frac{\alpha-r}{\sigma^2}.\tag{5}$$

If, for the strategy (5), we have that

$$V^n\left(t,x\right)\leq V^{n-1}\left(t,x\left(1-\beta\pi\right)\right),$$

then (5) indeed satisfies the constraint $\pi\in\mathcal{A}_n''\left(t,x\right)$ and can be considered as the candidate optimal portfolio. If, however, for π as given in (5), we have that

$$V^n\left(t,x\right)>V^{n-1}\left(t,x\left(1-\beta\pi\right)\right),$$

then again (under suitable assumptions on U and β as mentioned above) we know that $V^{n-1}\left(t,x\left(1-\beta\pi\right)\right)$ decreases as a function of π. We further assume that

$$V^{n-1}\left(t,x\left(1-\beta\pi\right)\right)\to\infty$$

for $x\to\infty$ and $\beta\pi<1$ (this always has to be checked for concrete choices of the utility function U when even more explicit computations are performed in later sections). Since

$$V_x^n\left(t,x\right)\left(r+\pi\left(\alpha-r\right)\right)x+\frac{1}{2}V_{xx}^n\left(t,x\right)\pi^2\sigma^2x^2$$

is increasing for $\pi<-\frac{V_x^n(t,x)}{V_{xx}^n(t,x)x}\frac{\alpha-r}{\sigma^2}$, then $\sup_{\pi\in\mathcal{A}_n''(s)}\left[\mathcal{L}^\pi v^1\left(s,X^{\pi,\theta}\left(s\right)\right)\right]$ is obtained for the π for which

$$V^n\left(t,x\right)=V^{n-1}\left(t,x\left(1-\beta\pi\right)\right)$$

holds, and consequently π and V are determined by the set of equations

$$\begin{aligned}V^n\left(t,x\right)&=V^{n-1}\left(t,x\left(1-\beta\pi\right)\right),\\ V_t^n\left(t,x\right)&=-V_x^n\left(t,x\right)\left(r+\pi\left(\alpha-r\right)\right)x-\frac{1}{2}V_{xx}^n\left(t,x\right)\pi^2\sigma^2x^2.\end{aligned}$$

Since this is the same case as outside $\mathcal{M}$ (see (4)), we realize that $\mathcal{M}$ is not the relevant set that decomposes the state space in an appropriate way. Instead, we consider now a set $\mathcal{N}$ for which it is really (5) that determines the optimal portfolio. Thus, we separate the (t,x)-space into

$$\begin{aligned}(6)\qquad \pi(t,x) &= -\frac{V_x^n(t,x)}{V_{xx}^n(t,x)\,x}\frac{\alpha-r}{\sigma^2},\\ V_t^n(t,x) &= -V_x^n(t,x)\,(r+\pi(\alpha-r))\,x-\frac{1}{2}V_{xx}^n(t,x)\,\pi^2\sigma^2x^2,\end{aligned}$$

and its complement characterized by (4), i.e.,

$$\begin{aligned}(7)\qquad V^n(t,x) &= V^{n-1}(t,x\,(1-\beta\pi)),\\ V_t^n(t,x) &= -V_x^n(t,x)\,(r+\pi(\alpha-r))\,x-\frac{1}{2}V_{xx}^n(t,x)\,\pi^2\sigma^2x^2.\end{aligned}$$

Formally,

$$\begin{aligned}\mathcal{N}=\Bigg\{&(t,x):\pi(t,x)=-\frac{V_x^n(t,x)}{V_{xx}^n(t,x)\,x}\frac{\alpha-r}{\sigma^2},\\ &V_t^n(t,x)=-V_x^n(t,x)\,(r+\pi(\alpha-r))\,x-\frac{1}{2}V_{xx}^n(t,x)\,\pi^2\sigma^2x^2\Bigg\}.\end{aligned}$$

Note in particular that for $n=0$ we have that $\mathcal{N}$ typically equals the whole possible (t,x)-space, while for $n>1$ it might be possible that $\mathcal{N}$ is empty as we show for the specific choices of the utility functions below. But there are also examples where $\mathcal{N}$ will not be empty for $n>1$. In our examples below, this is so for $\beta<1$, where, however, the complement of $\mathcal{N}$ is empty. Examples where neither $\mathcal{N}$ nor its complement are empty for a given n may require a generalized model, such as, e.g., the case of "crashed coefficients" where the diffusion coefficients react on crashes.

5. Power utility. In this section we consider the case of power utility

$$U(x)=\frac{1}{\gamma}x^\gamma,\quad \gamma<1,\quad \gamma\neq 0,$$

and assume $\alpha>r$. Inspired by the solution of the usual portfolio problem we try a solution of the form

$$V^n(t,x)=\frac{1}{\gamma}f^n(t)\left(\frac{x}{f^n(t)}\right)^\gamma$$

leading to

$$\begin{aligned}V_t^n(t,x) &= \frac{1-\gamma}{\gamma}f_t^n(t)\left(\frac{x}{f^n(t)}\right)^\gamma,\\ V_x^n(t,x) &= \left(\frac{x}{f^n(t)}\right)^{\gamma-1},\\ V_{xx}^n(t,x) &= -(1-\gamma)\frac{1}{f^n(t)}\left(\frac{x}{f^n(t)}\right)^{\gamma-2}.\end{aligned}$$

With these relations we obtain the optimal portfolio

$$\pi^{*n}=\begin{cases}\frac{1}{1-\gamma}\frac{\alpha-r}{\sigma^2}, & (t,x,n)\in\mathcal{N},\\ \frac{1}{\beta}\left(1-\left(\frac{f^n(t)}{f^{n-1}(t)}\right)^{\frac{1-\gamma}{\gamma}}\right), & (t,x,n)\notin\mathcal{N}\end{cases}$$

(here we have again implicitly assumed strict concavity of V^n!). The usual solution in the case of $n = 0$ is well-known and given by

$$\pi^{*0}(t,x) = \frac{1}{1-\gamma}\frac{\alpha - r}{\sigma^2},$$
$$f^0(t) = e^{-\left(r+\frac{1}{2}\frac{\alpha-r}{\sigma^2}\frac{1}{1-\gamma}\right)\frac{(T-t)(1-\gamma)}{\gamma}}.$$

As the investor has a strictly increasing utility function, he would like to choose a portfolio process as close as possible to π^{*0} to obtain a high final expected utility. On the other hand, if he chooses $\pi^{*n}(t) = \pi^{*0}$, then the market could do him most possible harm by choosing an immediate crash under the assumption of $\beta > 0$. In the case of $\beta > 0$, we have thus argued for that $\mathcal{N}$ is indeed empty for $n > 0$; i.e., for $n > 0$ we assume that we are always in the situation of

$$\pi^{*n}(t,x) = \frac{1}{\beta}\left(1 - \left(\frac{f^n(t)}{f^{n-1}(t)}\right)^{\frac{1-\gamma}{\gamma}}\right),$$
$$\mathcal{L}^{\pi^{*n}} v^n(t,x) = 0.$$

If we now plug in our guess for $\pi^{*n}(t,x)$ and for $v^n(t,x)$ into the second condition above and use the final condition of

$$v^n(T,x) = v^{n-1}(T,x) = \cdots = v^0(T,x) = \frac{1}{\gamma}x^\gamma$$

implying

$$\pi^{*n}(T,x) = 0,$$

we arrive at the following ordinary differential equation for f (skipping the t-argument in ordinary differential equations below and throughout):

$$f_t^n = f^n\left(-\frac{\gamma}{1-\gamma}\left(r + (\alpha - r)\pi^{*n}\right) + \gamma\frac{1}{2}\left(\pi^{*n}\right)^2\sigma^2\right), f^n(T) = 1,$$

for $n = 1, 2, \ldots$. With the help of this equation and the definition of π^{*n} we can derive an ordinary differential equation for $\pi^{*n}(t)$ which holds for $(t,x,n) \notin \mathcal{N}$:

$$\pi_t^{*n} = \frac{1}{\beta}\left(1 - \pi^{*n}\beta\right)\left((\alpha - r)\left(\pi^{*n} - \pi^{*n-1}\right) - \frac{1}{2}(1-\gamma)\sigma^2\left(\left(\pi^{*n}\right)^2 - \left(\pi^{*n-1}\right)^2\right)\right).$$

Using this differential equation and its final condition $\pi^{*n}(T) = 0$, one can show via induction that its solution satisfies

$$0 \le \pi^{*n}(t) \le \pi^{*n-1}(t) \le \cdots \le \pi^{*0},$$

is unique, and for $n = 1$ can be explicitly given as the solution of a nonlinear equation (see Korn and Wilmott [6] and Korn and Menkens [5]). A consequence of this is in particular that the solution of the differential equation for $f^n(t)$ is always positive, which implies that V^n of the above form is a concave function in x, as desired. Thus, all assumptions of the verification theorem are satisfied, and we have indeed computed the optimal portfolio.

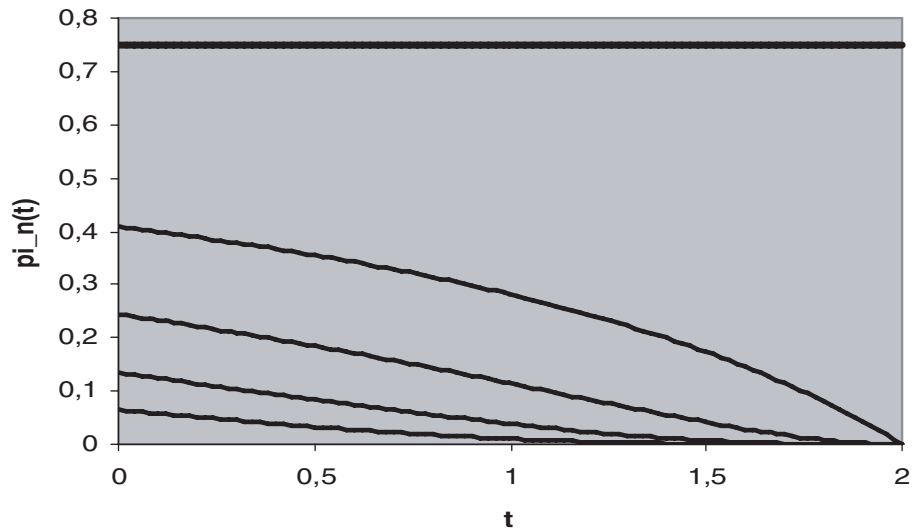

FIG. 2. $\pi^{*n}(t)$ *for* $n = 0, 1, 2, 3, 4$ *(from top to bottom), parameters:* $\beta = 0.05,\ \alpha = 0.11,\ r = 0.05,\ \sigma = 0.4,\ T = 2,\ \gamma = 0.5$.

The form of the optimal portfolio processes is illustrated by Figure 2, where the maximum number n of crashes that can still occur determines which of the five lines is relevant for the optimal portfolio process. If there are still four possible crashes, the investor chooses the portfolio process given by the lowest line in Figure 2. Note that this is a nonconstant process which decreases with time. After a crash (or if, for some other reason, the investor now assumes that there are only three possible crashes left), the investor immediately shifts his portfolio process up to the next line, stays there until the next crash has happened, then jumps up again, etc. Unless the last jump possible has occurred, the investor follows the decreasing line until maturity, and by then he has reduced his fraction of risky investments to zero. This form is very reasonable, because as long as there is a possibility for a crash, the investor is hit by it harder and harder as time goes by since he loses his possibility of compensating by posterior risky investments. It is common advice to pension savers to reduce their risky investments as time to retirement decreases. Thus, our new worst-case approach can be seen as a theoretical framework supporting this market practice.

In the case of $\beta < 0$ it can easily be verified that it is never optimal for the market to intervene if the investor uses the portfolio process $\pi^{*0} = \frac{1}{1-\gamma}\frac{\alpha-r}{\sigma^2}$. Consequently, in this setting we have

$$v^n(t,x) = v^{n-1}(t,x) = \cdots = v^0(t,x),$$

and the optimality criteria of the verification theorem can be satisfied only for the strategy that consists of no intervention before time T at all. This is also intuitively clear, because this portfolio process leads to the highest expected utility in the standard market setting on one hand, and on the other hand a jump of positive size (which is the case for $\beta < 0$) would even make the situation of the investor better. Hence, the infimum over the intervention strategies is attained for the above-mentioned no-jump strategy.

6. Log utility. The situation in the case of the logarithmic utility function is very similar to that of the Hara utility. In fact, it can essentially be solved by using the results of the foregoing section and setting $\gamma = 0$. We therefore shorten its presentation. Consider

$$U(x) = \log x,$$

and assume $\alpha > r$. The main difference to the Hara case is our guess on the form of the value functions (again inspired by the case $n = 0$):

$$\begin{aligned} V^n(t,x) &= \log x + f^n(t), \\ V^n_t(t,x) &= f^n_t(t), \\ V^n_x(t,x) &= \frac{1}{x}, \\ V^n_{xx}(t,x) &= -\frac{1}{x^2}. \end{aligned}$$

Inside $\mathcal{N}$ we obtain the form of π^{*n} as in the case of $n = 0$, while outside $\mathcal{N}$ the (candidate for the) optimal portfolio process is determined by the indifference requirement $V^n(t,x) = V^{n-1}(t, x(1-\beta\pi))$. This leads to

$$\pi^* = \begin{cases} \frac{\alpha - r}{\sigma^2}, & (t,x,n) \in \mathcal{N}, \\ \frac{1 - e^{f^n(t) - f^{n+1}(t)}}{\beta}, & (t,x,n) \notin \mathcal{N}. \end{cases}$$

Again, the case of $n = 0$ is well-known and given by (see, e.g., Korn [3])

$$\begin{aligned} \pi^{*0}(t,x) &= \frac{\alpha - r}{\sigma^2}, \\ f^0(t) &= \left(r + \frac{1}{2} \frac{\alpha - r}{\sigma^2} \right) (T - t). \end{aligned}$$

With the same argument as in the Hara case above, for $\beta > 0$ we conclude that $\mathcal{N}$ is empty for $n > 0$. Then, inserting our resulting guess for the form of the optimal portfolio into (6) leads to a differential equation for f:

$$f^n_t(t) = -\left(r + \pi^{*n}(\alpha - r)\right) + \frac{1}{2}\left(\pi^{*n}\right)^2 \sigma^2, \quad f(T) = 0,$$

which again leads to an ordinary differential equation for π which holds for $(t,x,n) \notin \mathcal{N}$:

$$\begin{aligned} \pi^{*n}_t &= \frac{1}{\beta}(1 - \pi^{*n}\beta)\left(f^{n+1}_t - f^n_t\right) \\ &= \frac{1}{\beta}(1 - \pi^{*n}\beta)\left((\alpha - r)\left(\pi^{*n} - \pi^{*n+1}\right) - \frac{1}{2}\sigma^2\left(\left(\pi^{*n}\right)^2 - \left(\pi^{*n+1}\right)^2\right)\right). \end{aligned}$$

As shown in Korn and Menkens [5] it has a unique solution which is bounded by 0 from below and by $\pi^{*(n-1)}_t$ from above for $n \geq 1$. Also, for numerical examples which are similar to the one given in the Hara utility section, we refer to Korn and Menkens [5].

Further, it is obvious that in the case of $\beta < 0$ the optimal intervention strategy consists of never doing a jump at all.

7. Exponential utility. In this section we consider the case of exponential utility, i.e.,

$$U(x) = -e^{-\theta x},$$

for some $\theta > 0$. Compared to the foregoing examples of the log-utility and the Hara case, the situation for the exponential is fundamentally different with respect to two aspects. First of all, a separation of the t- and the x-variables in the HJB equation is not possible, a property that is essentially due to the fact that the derivative of the exponential function is itself the exponential function. It is well known from standard portfolio optimization (see, e.g., Browne [2]) that it is therefore more suitable to consider the amount of money invested in the risky stock at a time, in our notation $\pi(t) X(t)$, as control variables as opposed to the portfolio process itself. As the second difference, compared to the two utility functions considered above, note that the exponential utility function has a finite slope in $x = 0$, which results in the fact that the (unconstrained) optimal wealth process can attain negative values. Again, this is well known (compare again with Browne [2]). To apply our main verification it would therefore be necessary to refine our definition of an admissible control. This can be done along the lines of Browne [2], but details are left to the reader. Note that in contrast to Korn [4] we do not have to restrict to deterministic strategies. Keeping all of these considerations in mind, we guess the following form of the value function, inspired by the case $n = 0$:

$$V^n(t,x) = -e^{-\theta f(t) x - g^n(t)},$$

leading to

$$\begin{aligned}
V_t^n(t,x) &= -e^{-\theta f(t) x - g^n(t)} \left(-\theta f_t(t) x - g_t^n(t)\right), \\
V_x^n(t,x) &= \theta f(t) e^{-\theta f(t) x - g^n(t)}, \\
V_{xx}^n(t,x) &= -\theta^2 f(t)^2 e^{-\theta f(t) x - g^n(t)}.
\end{aligned}$$

Assuming strict concavity of V^n in x—which is given if f is nonvanishing—(suitable) application of the verification theorem yields the following candidate for the optimal amount of money invested in the stock:

$$\pi^*(t,x) x = \begin{cases} \frac{1}{\theta f(t)} \frac{\alpha - r}{\sigma^2}, & (t,x,n) \in \mathcal{N}, \\ \frac{1}{\theta f(t)} \frac{g^{n+1}(t) - g^n(t)}{\beta}, & (t,x,n) \notin \mathcal{N}. \end{cases}$$

In the case of $n = 0$ it is well known that we have

$$\begin{aligned}
f(t) &= \exp\left(r(T-t)\right), \\
g^0(t) &= \frac{1}{2} \left(\frac{\alpha - r}{\sigma}\right)^2 (T-t), \\
\pi^{*0}(t,x) x &= \frac{1}{\theta} \frac{\alpha - r}{\sigma^2} e^{-r(T-t)}.
\end{aligned}$$

Now since $\mathcal{N}$ is empty for $n > 0$ (the argument for this is similar to the preceding two examples), we use the above derived form of our candidate optimal strategy $\pi^* x$ and insert our guesses in (6) to obtain a differential equation for g^n:

$$g_t^n = -\frac{g^{n+1} - g^n}{\beta} (\alpha - r) + \frac{1}{2} \frac{\left(g^{n+1} - g^n\right)^2}{\beta^2} \sigma^2.$$

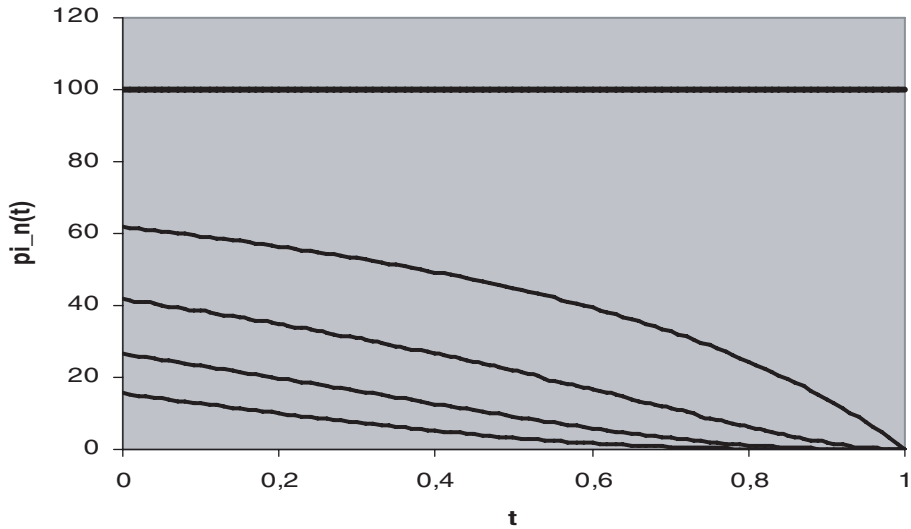

FIG. 3. $\pi^{*n}(t)\,x$ *for* $n = 0, 1, 2, 3, 4$ *(from top to bottom), parameters:* $\beta = 0.05,\ \alpha = 0.16,\ r = 0,\ \sigma = 0.4,\ T = 1,\ \theta = 0.01$.

This results in an ordinary differential equation for $\pi^* x$ for $(t, x, n) \notin \mathcal{M}$:

$$\begin{aligned} \pi_t^{*n} x &= r\pi^{*n} x - \left(\pi^{*n+1} x - \pi^{*n} x\right) \frac{\alpha - r}{\beta} \\ &\quad + \left(\left(\pi^{*n+1} x\right)^2 - \left(\pi^{*n} x\right)^2\right) \frac{\frac{1}{2}\theta f \sigma^2}{\beta}, \\ \pi^{*n}(T)\, x &= 0, \end{aligned}$$

for which we can show with standard arguments that a unique bounded and non-negative solution exists. Before we illustrate the form of the optimal strategy, let us remark that, in the case of $r = 0$, an explicit solution for $n = 1$ exists which has the form (see Korn [4] for a different derivation)

$$\pi^{*1}(t, x)\, x = \frac{\alpha}{\theta\sigma^2} + \frac{2\beta}{\theta\sigma^2[(T-t) - \frac{2\beta}{\alpha}]}.$$

The form of the optimal trading strategies are illustrated in Figure 3. They look very similar to the optimal portfolio processes of Figure 2, and of course the comments for their use depending on the maximum number n of crashes remain valid. However, note that, if we would plot the portfolio processes, we would have very irregular curves as they are inversely proportional to the actual wealth process curve, and for small values of the wealth process the portfolio process can grow above all limits (but the amount of money invested in the stock stays bounded).

8. Conclusion and further aspects. In this paper we have put the worst-case approach to portfolio optimization as developed by Korn and Wilmott [6] into a generalized HJB-equation framework. This has the particular advantage that the restriction to deterministic control processes is no longer required. This framework can be used for a worst-case approach in other areas than finance. The ideas are generally applicable to situations, e.g., in insurance or engineering, where risk is managed by

combining an expectation functional on "normal risks" and a worst-case functional on "extreme risks." But even within the portfolio application, there remain many open problems and generalizations for future research such as

- explicit solution of problems with many stocks (in contrast to the Korn and Wilmott [6] approach, this should be possible in a more explicit way using our new approach),
- explicit solution of problems with nonconstant β (this should again be possible in an easier way in our HJB-equation framework), and
- weakening the regularity assumptions of the verification theorem (maybe via the use of viscosity solution techniques).

Appendix.

Proof of Lemma 3. Let $\varepsilon > 0$. Then, for a given first intervention time τ, we can choose a portfolio strategy π^* which is $\varepsilon/4$-optimal until time τ and a portfolio strategy π^{**} which is arbitrary until time τ and $\varepsilon/4$-optimal after time τ in the sense that the following two inequalities hold (note that we cannot yet assume that V^n is indeed the value function):

$$\begin{aligned}(8)\qquad &\sup_{\pi} E_{t,x,n}\left[V^{n-1}\left(\tau, X^{\pi\tau}\left(\tau-\right)\left(1-\beta\pi\left(\tau\right)\right)\right)\right]\\ &\leq E_{t,x,n}\left[V^{n-1}\left(\tau, X^{\pi^*\tau}\left(\tau-\right)\left(1-\beta\pi^*\left(\tau\right)\right)\right)\right]+\varepsilon/4,\\ (9)\qquad &\sup_{\pi}\inf_{N} E_{\tau,x,n}\left[U\left(X^{\pi N}\left(T\right)\right)\right]\\ &\leq \inf_{N} E_{\tau,X^{\pi^{**}N}(\tau),n-1}\left[U\left(X^{\pi^{**}N}\left(T\right)\right)\right]+\varepsilon/4.\end{aligned}$$

Further, for a given portfolio strategy, introduce an $\varepsilon/4$-optimal strategy for the first intervention τ^* and, given an arbitrary first intervention time τ, an $\varepsilon/4$-optimal intervention strategy N^* after time τ, again in the sense that the following two inequalities are valid:

$$\begin{aligned}(10)\qquad &\inf_{\tau} E_{t,x,n}\left[V^{n-1}\left(\tau, X^{\pi\tau}\left(\tau-\right)\left(1-\beta\pi\left(\tau\right)\right)\right)\right]\\ &\geq E_{t,x,n}\left[V^{n-1}\left(\tau^*\left(\pi\right), X^{\pi\tau^*}\left(\tau^*\left(\pi\right)-\right)\left(1-\beta\pi\right)\right)\right]-\varepsilon/4,\\ (11)\qquad &\inf_{N} E_{\tau,X^{\pi}(\tau),n-1}\left[U\left(X^{\pi N}\left(T\right)\right)\right]\\ &\geq E_{\tau,X^{\pi N^*}(\tau),n-1}\left[U\left(X^{\pi N^*}\left(T\right)\right)\right]-\varepsilon/4.\end{aligned}$$

Then we have the following list of inequalities (explanation follows after):

$$\begin{aligned}(12)\qquad &\sup_{\pi}\inf_{N} E_{t,x,n}\left[U\left(X^{\pi N}\left(T\right)\right)\right]\\ &\geq \inf_{N} E_{t,x,n}\left[E_{\tau,X^{\pi^{**}N}(\tau),n-1}\left[U\left(X^{\pi^{**}N}\left(T\right)\right)\right]\right]\\ &\geq \inf_{\tau} E_{t,x,n}\left[\inf_{N} E_{\tau,X^{\pi^{**}N}(\tau),n-1}\left[U\left(X^{\pi^{**}N}\left(T\right)\right)\right]\right]\\ &\geq \inf_{\tau} E_{t,x,n}\left[\sup_{\pi}\inf_{N} E_{\tau,X^{\pi N}(\tau),n-1}\left[U\left(X^{\pi N}\left(T\right)\right)\right]\right]-\varepsilon/4\\ &\geq \inf_{\tau} E_{t,x,n}\left[V^{n-1}\left(\tau, X^{\pi\tau}\left(\tau-\right)\left(1-\beta\pi\left(\tau\right)\right)\right)\right]-\varepsilon/4\\ &\geq E_{t,x,n}\left[V^{n-1}\left(\tau^*, X^{\pi\tau^*}\left(\tau^*-\right)\left(1-\beta\pi\left(\tau^*\right)\right)\right)\right]-\varepsilon/2.\end{aligned}$$

The first inequality follows from plugging in the portfolio strategy π^{**} and the tower property. The second inequality follows from interchanging the first expectation and the infimum over intervention strategies after the first intervention. The third inequality follows from (9). The fourth inequality follows from the definition of V. The fifth inequality follows from (10). Taking supremum on both sides gives

$$\begin{aligned}(13)\qquad &\sup_{\pi}\inf_{N} E_{t,x,n}\left[U\left(X^{\pi N}(T)\right)\right]\\ &\geq \sup_{\pi} E_{t,x,n}\left[V^{n-1}\left(\tau^*, X^{\pi\tau^*}(\tau^*-)\left(1-\beta\pi(\tau^*)\right)\right)\right]-\varepsilon/2.\end{aligned}$$

We also have the following list of inequalities (explanation follows after):

$$\begin{aligned}&\inf_{N}\sup_{\pi} E_{t,x,n}\left[U\left(X^{\pi N}(T)\right)\right]\\ &\leq \sup_{\pi} E_{t,x,n}\left[E_{\tau,X^{\pi N^*}(\tau),n-1}\left[U\left(X^{\pi N^*}(T)\right)\right]\right]\\ &\leq \sup_{\pi} E_{t,x,n}\left[\inf_{N} E_{\tau,X^{\pi N}(\tau),n-1}\left[U\left(X^{\pi N}(T)\right)\right]\right]+\varepsilon/4\\ &\leq \sup_{\pi} E_{t,x,n}\left[\sup_{\pi}\inf_{N} E_{\tau,X^{\pi N}(\tau),n-1}\left[U\left(X^{\pi N}(T)\right)\right]\right]+\varepsilon/4\\ &\leq \sup_{\pi} E_{t,x,n}\left[V^{n-1}\left(\tau, X^{\pi N}(\tau-)\left(1-\beta\pi(\tau)\right)\right)\right]+\varepsilon/4.\end{aligned}$$

The first inequality follows from plugging in the intervention strategy N^* and the tower property. The second inequality follows from (11). The third inequality is obvious. The fourth inequality follows from the definition of V. Taking infimum on both sides results in

$$\begin{aligned}(14)\qquad &\inf_{N}\sup_{\pi} E_{t,x,n}\left[U\left(X^{\pi N}(T)\right)\right]\\ &\leq \inf_{\tau}\sup_{\pi} E_{t,x,n}\left[V^{n-1}\left(\tau, X^{\pi\tau}(\tau-)\left(1-\beta\pi(\tau)\right)\right)\right]+\varepsilon/4.\end{aligned}$$

Finally we can gather the inequalities (explanation follows after):

$$\begin{aligned}&\sup_{\pi}\inf_{N} E_{t,x,n}\left[U\left(X^{\pi N}(T)\right)\right]\\ &\geq \sup_{\pi} E_{t,x,n}\left[V^{n-1}\left(\tau^*, X^{\pi\tau^*}(\tau^*-)\left(1-\beta\pi(\tau^*)\right)\right)\right]-\varepsilon/2\\ &\geq \inf_{\tau}\sup_{\pi} E_{t,x,n}\left[V^{n-1}\left(\tau, X^{\pi\tau}(\tau-)\left(1-\beta\pi(\tau)\right)\right)\right]-\varepsilon/2\\ &\geq \inf_{\tau} E_{t,x,n}\left[V^{n-1}\left(\tau, X^{\pi^*\tau}(\tau-)\left(1-\beta\pi^*(\tau)\right)\right)\right]-\varepsilon/2\\ &\geq \inf_{\tau}\sup_{\pi} E_{t,x,n}\left[V^{n-1}\left(\tau, X^{\pi\tau}(\tau-)\left(1-\beta\pi(\tau)\right)\right)\right]-3\varepsilon/4\\ &\geq \inf_{N}\sup_{\pi} E_{t,x,n}\left[U\left(X^{\pi N}(T)\right)\right]-\varepsilon\\ &\geq \sup_{\pi}\inf_{N} E_{t,x,n}\left[U\left(X^{\pi N}(T)\right)\right]-\varepsilon.\end{aligned}$$

The first inequality is just (13). The second inequality follows from giving up the specification of the first intervention. The third inequality follows from plugging in the portfolio strategy π^*. The fourth inequality follows from (8). The fifth inequality follows from (14). The sixth inequality is the usual $\sup\inf \leq \inf\sup$ relation.

The reversed line of arguments (left to the reader) gives that

$$\begin{aligned}
&\inf_N \sup_\pi E_{t,x,n}\left[U\left(X^{\pi N}(T)\right)\right] \\
&\leq \sup_\pi \inf_\tau E_{t,x,n}\left[V^{n-1}\left(\tau, X^{\pi N}(\tau-)(1-\beta\pi)\right)\right] + \varepsilon/2 \\
&\leq \sup_\pi \inf_N E_{t,x,n}\left[U\left(X^{\pi N}(T)\right)\right] + \varepsilon \\
&\leq \inf_N \sup_\pi E_{t,x,n}\left[U\left(X^{\pi N}(T)\right)\right] + \varepsilon.
\end{aligned}$$

Since all inequalities above hold for any ε, they must hold as equalities, and consequently the theorem is proved. □

Proof of Theorem 2 (verification theorem). The assertions in the first part of the verification (corresponding to 0 interventions left) are classical and have a proof which can be found in any textbook on dynamic portfolio optimization, e.g., Korn [3].

The second part is proved by induction. First, we prove the verification theorem for $n = 1$. Here the control N and the control τ are equivalent, and we can denote $X^{\pi,N}$ by $X^{\pi,\tau}$.

Choose an arbitrary control (π, τ), and fix a point (t, x). Let X follow the dynamics given in (1) with the time point 0 replaced by the time point t. Inserting $X^{\pi,\tau}$ in v^1 and using Ito's formula we obtain

$$\begin{aligned}
&v^1\left(t, X^{\pi,\tau}(t)\right) = v^1(t,x), \\
&dv^1\left(s, X^{\pi,\tau}(s)\right) = \mathcal{L}^\pi v^1\left(s, X^{\pi,\tau}(s)\right) ds + v_x^1\left(s, X^{\pi,\tau}(s)\right) \sigma X^{\pi,\tau}(s)\, dW(s), t < s < \tau, \\
&dv^1\left(\tau, X^{\pi,\tau}(\tau)\right) = v^1\left(\tau, X^{\pi,\tau}(\tau-)(1-\pi(\tau)\beta)\right) - v^1\left(\tau-, X^{\pi,\tau}(\tau-)\right)
\end{aligned}$$

such that

$$\begin{aligned}
v^1\left(\tau-, X^{\pi,\tau}(\tau-)\right) - v^1(t,x) = &\int_t^\tau \mathcal{L}^\pi v^1\left(s, X^{\pi,\tau}(s)\right) ds \\
&+ \int_t^\tau v_x^1\left(s, X^{\pi,\tau}(s)\right) \sigma X^{\pi,\tau}(s)\, dW(s).
\end{aligned} \tag{15}$$

Now fix the investment strategy $\pi(s) = p(s)$, $t \leq s \leq \tau$, where we use the letter p, sloppily but intuitively clear, for the process $p\left(s, X^{\pi,\tau}(s-)\right)$ coming from applying the function $p(s,x)$ on the process $X^{\pi,\tau}$such that the strategy is predictable as it should be. Then we know from the Bellman system that, for $t \leq s \leq \tau$,

$$0 \leq \mathcal{L}^p v^1\left(s, X^{p,\tau}(s)\right),$$

and, since $p(s) \in \mathcal{A}_1''(s)$, also

$$0 \leq v^0\left(s, X^{p,\tau}(s)(1-\beta p(s))\right) - v^1\left(s, X^{p,\tau}(s)\right).$$

But this means that inserting p in (15) gives the inequality

$$v^1(t,x) \leq v^0\left(\tau, X^{p,\tau}(\tau-)(1-\beta p(\tau))\right) - \int_t^\tau v_x^1\left(s, X^{p,\tau}(s)\right) \sigma X^{p,\tau}(s)\, dW(s).$$

Due to our requirements on the admissible controls and on the value function, the stochastic integral vanishes when taking expectation, leaving us with the inequality

$$v^1(t,x) \leq E_{t,x}\left[v^0\left(\tau, X^{p,\tau}(\tau-)(1-\beta p(\tau))\right)\right]. \tag{16}$$

Then, on the one hand, we can immediately conclude that

$$v^1(t,x) \leq \sup_{\pi} E_{t,x}\left[v^0\left(\tau, X^{\pi,\tau}(\tau-)\left(1-\beta\pi(\tau)\right)\right)\right]$$

such that taking infimum over τ on both sides gives

$$v^1(t,x) \leq \inf_{\tau}\sup_{\pi} E_{t,x}\left[v^0\left(\tau, X^{\pi,\tau}(\tau-)\left(1-\beta\pi(\tau)\right)\right)\right]. \tag{17}$$

On the other hand, taking infimum over τ on both sides of (16) gives

$$v^1(t,x) \leq \inf_{\tau} E_{t,x}\left[v^0\left(\tau, X^{p,\tau}(\tau-)\left(1-\beta p(\tau)\right)\right)\right],$$

and then we can conclude that also

$$v^1(t,x) \leq \sup_{\pi}\inf_{\tau} E_{t,x}\left[v^0\left(\tau, X^{\pi,\tau}(\tau-)\left(1-\beta\pi(\tau)\right)\right)\right]. \tag{18}$$

Consider again (15). Now fix the time $\tau=\theta$. Then we know that

$$v^0\left(s, X^{\pi,\theta}(s-)\left(1-\beta\pi(s)\right)\right) - v^1\left(s-, X^{\pi,\theta}(s-)\right) > 0, t \leq s < \theta, \tag{19}$$

$$v^0\left(\theta, X^{\pi,\theta}(\theta-)\left(1-\beta\pi(\theta)\right)\right) - v^1\left(\theta, X^{\pi,\theta}(\theta-)\right) \leq 0. \tag{20}$$

Now, either $0 > \mathcal{L}^{\pi}v^1(s, X^{\pi,\tau}(s))$ or $0 \leq \mathcal{L}^{\pi}v^1(s, X^{\pi,\tau}(s))$. But if $0 \leq \mathcal{L}^{\pi}v^1(s, X^{\pi,\tau}(s))$, then $\pi \in \mathcal{A}_1'$, and then (19) gives us that

$$\sup_{\pi\in\mathcal{A}_1'(s)}\left[v^0\left(s, X^{\pi,\theta}(s-)\left(1-\beta\pi(s)\right)\right) - v^1\left(s-, X^{\pi,\theta}(s-)\right)\right] > 0.$$

By complementarity, we then know that

$$\sup_{\pi\in\mathcal{A}_1''(s)}\left[\mathcal{L}^{\pi}v^1\left(s, X^{\pi,\theta}(s)\right)\right] = 0.$$

But since $\pi(s) \in \mathcal{A}_1''(s)$ by (19), we then know that

$$\mathcal{L}^{\pi}v^1\left(s, X^{\pi,\theta}(s)\right) \leq 0.$$

So, in any case, $\mathcal{L}^{\pi}v^1\left(s, X^{\pi,\theta}(s)\right) \leq 0$, $s < \theta$. But this means that inserting θ in (15) and using (20) gives the inequality

$$v^1(t,x) \geq -\int_t^{\theta} v_x\left(s, X^{\pi,\theta}(s)\right)\sigma X^{\pi,\theta}(s)\,dW(s) + v^0\left(\theta, X^{\pi,\theta}(\theta-)\left(1-\beta\pi(\theta)\right)\right).$$

Due to our requirements on the admissible controls and on the value function, the stochastic integral vanishes when taking expectation, leaving us with the inequality

$$v^1(t,x) \geq E_{t,x}\left[v^0\left(\theta, X^{\pi,\theta}(\theta-)\left(1-\beta\pi(\theta)\right)\right)\right]. \tag{21}$$

Then, on the one hand, we can conclude that

$$v^1(t,x) \geq \inf_{\tau} E_{t,x}\left[v^0\left(\tau, X^{\pi,\tau}(\tau-)\left(1-\beta\pi(\tau)\right)\right)\right]$$

such that taking supremum over π on both sides gives

$$v^1(t,x) \geq \sup_{\pi}\inf_{\tau} E_{t,x}\left[v^0\left(\tau, X^{\pi,\tau}(\tau-)\left(1-\beta\pi(\tau)\right)\right)\right]. \tag{22}$$

On the other hand, taking supremum over π on both sides of (21) gives

$$v^1(t,x) \geq \sup_\pi E_{t,x}\left[v^0\left(\theta, X^{\pi,\theta}(\theta-)(1-\beta\pi(\theta))\right)\right]$$

such that we can conclude that

$$v^1(t,x) \geq \inf_\tau \sup_\pi E_{t,x}\left[v^0\left(\tau, X^{\pi,\tau}(\tau-)(1-\beta\pi(\tau))\right)\right]. \tag{23}$$

From (17), (18), (22), and (23), we conclude that

$$\begin{aligned} v^1(t,x) &= \inf_\tau \sup_\pi E_{t,x}\left[v^0\left(\tau, X^{\pi}(\tau-)(1-\beta\pi(\tau))\right)\right] \\ &= \sup_\pi \inf_\tau E_{t,x}\left[v^0\left(\tau, X^{\pi}(\tau-)(1-\beta\pi(\tau))\right)\right], \end{aligned}$$

and it only remains to be realized that V is characterized by this equation. □

PRIMAL-DUAL SYMMETRIC INTRINSIC METHODS FOR FINDING ANTIDERIVATIVES OF CYCLICALLY MONOTONE OPERATORS*

HEINZ H. BAUSCHKE†, YVES LUCET‡, AND XIANFU WANG†

Abstract. A fundamental result due to Rockafellar states that every cyclically monotone operator A admits an antiderivative f in the sense that the graph of A is contained in the graph of the subdifferential operator ∂f. Given a method $\mathfrak{m}$ that assigns every finite cyclically monotone operator A some antiderivative $\mathfrak{m}_A$, we say that the method is *primal-dual symmetric* if $\mathfrak{m}$ applied to the inverse of A produces the Fenchel conjugate of $\mathfrak{m}_A$. Rockafellar's antiderivatives do not possess this property. Utilizing Fitzpatrick functions and the proximal average, we present novel primal-dual symmetric intrinsic methods. The antiderivatives produced by these methods provide a solution to a problem posed by Rockafellar in 2005. The results leading to this solution are illustrated by various examples.

Key words. antiderivative, convex function, cyclically monotone operator, Fenchel conjugate, Fitzpatrick function, maximal monotone operator, n-cyclically monotone operator, proximal average, Rockafellar's antiderivative, Rockafellar function, subdifferential operator

1. Introduction.

Suppose that X is a real Banach space with continuous dual X^*, dual pairing $\langle \cdot, \cdot \rangle$, and norm $\|\cdot\|$. We start by recalling some known notions and results concerning (cyclically) monotone operators. These operators play a fundamental role in modern optimization as well as convex and variational analysis; see, e.g., [11, 12, 18, 20, 21, 22, 24] for further information and notation not explicitly defined here. Let A be a *set-valued operator* from X to X^*, i.e., $(\forall x \in X)\ Ax \subseteq X^*$; thus, A is a mapping from X to the power set of X^*. We use the notation $A\colon X \rightrightarrows X^*$ and remark that A can be identified with its *graph* $\operatorname{gra} A := \big\{(x, x^*) \in X \times X^* \mid x^* \in Ax\big\}$. The *domain* of A is $\operatorname{dom} A := \big\{x \in X \mid Ax \neq \varnothing\big\}$ and the *range* of A is $\operatorname{ran} A := A(X) = \bigcup_{x \in X} Ax$. The *inverse* of A is the operator $A^{-1}\colon X^* \rightrightarrows X$, defined by $x \in A^{-1}x^* \Leftrightarrow x^* \in Ax$. Furthermore, let $n \in \{2, 3, \dots\}$. Then A is *n-cyclically monotone* [1, 2, 3, 7, 10, 23] if the implication

$$\left.\begin{array}{c}(a_1, a_1^*) \in \operatorname{gra} A,\\ \vdots\\ (a_n, a_n^*) \in \operatorname{gra} A\\ a_{n+1} := a_1\end{array}\right\} \quad \Rightarrow \quad \sum_{i=1}^{n} \langle a_{i+1} - a_i, a_i^* \rangle \leq 0 \tag{1}$$

holds. Note that 2-monotonicity simplifies to

$$\big(\forall (x,x^*)\in \operatorname{gra} A\big)\big(\forall (y,y^*)\in \operatorname{gra} A\big)\quad \langle x-y, x^*-y^*\rangle \geq 0, \tag{2}$$

i.e., to ordinary *monotonicity*. *Cyclic monotonicity* describes the situation when A is m-cyclically monotone for every $m \in \{2,3,\dots\}$. The operator A is *maximal n-cyclically monotone* if A is n-cyclically monotone and no proper extension (in the sense of inclusion of graphs) of A is n-cyclically monotone. Zorn's lemma guarantees that every n-cyclically monotone operator admits a maximal n-cyclically monotone extension. At one end of the spectrum of maximal n-cyclically monotone operators are the maximal 2-monotone, i.e., the *maximal monotone* operators. At the other end are the *maximal cyclically monotone operators*, which Rockafellar in a groundbreaking paper [19] (see Fact 3.4 below) revealed to be precisely the subdifferential operators of functions that are convex, lower semicontinuous, and proper.

This paper is motivated by the following question posed by Rockafellar in 2005 during open-problem sessions at conferences in Borovets (Bulgaria) and Banff (Canada).

> *Given a cyclically monotone operator A with a finite graph, find a method that produces an antiderivative of A that preserves the natural symmetry induced by convex duality.*

One motivation for the above question that we feel will become particularly relevant for applications as numerical convex analysis matures is the efficient storage and representation of convex functions. This is a surprisingly difficult problem. The perhaps most natural approach of storing grid points (x_i, y_i) causes significant problems because Lagrangian interpolation can fail to recover a convex function [13]. We now describe three other possible approaches. First, one could solve for subgradients x_i^* at each point x_i, or store such data in the first place, and then recover the function via $f(x) = \max_i \big(\langle x - x_i, x_i^*\rangle + y_i\big)$. The resulting function is piecewise linear with a full domain; thus, its conjugate has a bounded domain. Second, one could restrict the model of the function to the convex hull of the points x_i and set the function equal to $+\infty$ outside. Third, one could store the points and subgradients (x_i, x_i^*) along with a scalar y_0 and then recover a function f that satisfies $x_i^* \in \partial f(x_i)$ and $f(x_0) = y_0$. However, the existing representations in the literature [9, 19] are based on piecewise linear functions; so, in the finite graph case, one has to unavoidably privilege either the primal or the dual space in the very model used to recover the function.

In this paper, we provide constructive answers to Rockafellar's question. In fact, we shall exhibit methods for constructing antiderivatives that we call *primal-dual symmetric*. These methods have the property that, when they are applied to A^{-1} instead of A, the Fenchel conjugate of the antiderivative of A is obtained. The mere existence of such methods struck us initially as quite remarkable since antiderivatives are at best unique up to additive constants. These methods also allow for the design of models of convex functions that inherit the symmetry induced by convex duality in the given discrete data. Our constructions are based on Rockafellar's classical construction of an antiderivative as well as on recent work on Fitzpatrick functions and the proximal average operator, which has a close connection to fundamental objects of optimization such as Moreau envelopes and proximal mappings [4, 6]. Another pleasant consequence of primal-dual symmetric methods is their "slope 1" property—we believe that this will aid in efforts to represent convex functions in a numerically stable way (the "slope 1" property guarantees that the derivatives outside the domain of interest have slopes that are neither too small nor too large in magnitude). This is an area of active research that lies beyond the scope of this paper; see [15] for a

one-dimensional framework that is capable to express such antiderivatives and that serves as a starting point for further research.

The remainder of this paper can be summarized as follows. In section 2, we introduce the common ancestor and Fitzpatrick functions [2]. These functions have turned out to be immensely useful in the study of—and they are intimately tied to—n-cyclic monotonicity. We provide a recursion formula for the Fitzpatrick functions (Proposition 2.13) and show that they stabilize when applied to cyclically monotone operators with a finite graph (Theorem 2.16). In section 3, we revisit Rockafellar's classical antiderivative result (Fact 3.4) in the context of Fitzpatrick functions. In fact, his antiderivative satisfies a certain minimality property (Theorem 3.5), it is related to the common ancestor function (Corollary 3.11), and a closed form can be found for some finite-graph operators on $\mathbb{R}$ (Theorem 3.14)—parts of these results, of which we were unaware during the preparation of the originally submitted version of this paper, were previously obtained by Lambert et al. in their interesting work [14] in which they focus on finding upper and lower bounds for antiderivatives using a linear programming formulation. The supremum of all Rockafellar antiderivatives is expressible in terms of a Fitzpatrick function (Theorem 3.15 and Corollary 3.16). Section 4 introduces the notion of a *primal-dual symmetric* method for antiderivatives (Definition 4.6). Such methods provide antiderivatives that depend only on the graph—which makes them *intrinsic*—and that return the Fenchel conjugate of the antiderivative when applied to the inverse operator. Neither Rockafellar's classical antiderivatives nor simple symmetrizations of them have this property (Proposition 4.7). Based on recent work on the proximal average operator, we proceed to present our main result which provides a general construction of primal-dual symmetric methods (Theorem 4.13). Concrete instances are proximal-average-based symmetrizations of the maximum and of the average of Rockafellar's antiderivatives (Examples 4.19 and 4.20). We then present a result (Corollary 4.23) that leads to a resolution of Rockafellar's problem (Corollary 4.26 and Remark 4.27). We conclude the paper with a numerical example (Example 4.28).

Our notation is standard. The subdifferential operator of a convex function f is denoted by ∂f, its Fenchel conjugate by f^*, and its domain by $\operatorname{dom} f$. For a set S, we use $\operatorname{conv} S$, $\overline{\operatorname{conv}}\, S$, $\operatorname{int} S$, and $\overline{S}$ to denote its convex hull, its closed convex hull, its interior, and its closure, respectively. For a nonempty convex subset C of X and a point $x \in C$, the tangent and the normal cone of C at x are denoted by $T_C(x)$ and by $N_C(x)$, respectively. Finally, the set of all functions from X to $]-\infty,+\infty]$ that are convex, lower semicontinuous, and proper is denoted by $\Gamma(X)$ or simply by Γ.

2. The common ancestor and Fitzpatrick functions.

DEFINITION 2.1 (see [2, Definition 2.1]). *Let* $A\colon X \rightrightarrows X^*$, *and let* $(a_1, a_1^*) \in \operatorname{gra} A$. *The* common ancestor functions *are defined by*

$$C_{A,2,(a_1,a_1^*)}\colon X \times X^* \to\,]-\infty,+\infty] : (x,x^*) \mapsto \langle x, a_1^*\rangle + \langle a_1, x^*\rangle - \langle a_1, a_1^*\rangle, \tag{3}$$

and, for every $n \in \{3,4,\dots\}$, *by*

$$\begin{aligned} C_{A,n,(a_1,a_1^*)}\colon X \times X^* &\to\,]-\infty,+\infty] \\ (x,x^*) &\mapsto \sup_{\substack{(a_2,a_2^*)\in\operatorname{gra} A,\\ \vdots \\ (a_{n-1},a_{n-1}^*)\in\operatorname{gra} A}} \left(\sum_{i=1}^{n-2}\langle a_{i+1}-a_i, a_i^*\rangle\right) + \langle x-a_{n-1}, a_{n-1}^*\rangle + \langle a_1, x^*\rangle. \end{aligned} \tag{4}$$

We also set

$$C_{A,\infty,(a_1,a_1^*)} = \sup_{n\in\{2,3,\dots\}} C_{A,n,(a_1,a_1^*)}. \tag{5}$$

It is clear that

$$\big(\forall n \in \{2,3,\dots\}\big) \quad C_{A,n,(a_1,a_1^*)} \text{ is convex and lower semicontinuous,} \tag{6}$$

that the sequence

$$\big(C_{A,n,(a_1,a_1^*)}\big)_{n\in\{2,3,\dots\}} \text{ is increasing and pointwise convergent to } C_{A,\infty,(a_1,a_1^*)}, \tag{7}$$

and that $C_{A,\infty,(a_1,a_1^*)}$ is convex and lower semicontinuous. Moreover,

$$\text{gra } A \text{ finite} \quad \Rightarrow \quad \big(\forall n \in \{2,3,\dots\}\big)\ C_{A,n,(a_1,a_1^*)} \text{ is polyhedral and continuous.} \tag{8}$$

The next result shows that common ancestor functions are closely related to n-cyclic monotonicity. The proof is straightforward and thus omitted.

PROPOSITION 2.2. *Let $A\colon X \rightrightarrows X^*$, and let $n \in \{2,3,\dots\}$. Then A is n-cyclically monotone if and only if*

$$\big(\forall (a,a^*) \in \text{gra } A\big)\big(\forall (b,b^*) \in \text{gra } A\big) \quad C_{A,n,(a,a^*)}(b,b^*) \le \langle b, b^*\rangle. \tag{9}$$

Computationally convenient is the following recursive formula.

PROPOSITION 2.3 (recursion). *Let $A\colon X \rightrightarrows X^*$, let $(a_1,a_1^*) \in \text{gra } A$, let $n \in \{2,3,\dots\}$, and let $(x,x^*) \in X \times X^*$. Then*

$$C_{A,n+1,(a_1,a_1^*)}(x,x^*) = \sup_{(a,a^*)\in \text{gra } A} C_{A,n,(a_1,a_1^*)}(a,x^*) + \langle x-a, a^*\rangle. \tag{10}$$

Proof. By definition, $C_{A,n+1,(a_1,a_1^*)}(x,x^*)$ is the supremum of the terms

$$\begin{aligned}\left(\sum_{i=1}^{n-1}\langle a_{i+1}-a_i, a_i^*\rangle\right) + \langle x-a_n, a_n^*\rangle + \langle a_1, x^*\rangle \\ = \left(\sum_{i=1}^{n-2}\langle a_{i+1}-a_i, a_i^*\rangle\right) + \langle a_n - a_{n-1}, a_{n-1}^*\rangle + \langle a_1, x^*\rangle + \langle x-a_n, a_n^*\rangle,\end{aligned} \tag{11}$$

where $(a_2,a_2^*),\dots,(a_n,a_n^*)$ in gra A. Supremizing first over $(a_2,a_2^*),\dots,(a_{n-1},a_{n-1}^*)$, followed by supremizing over (a_n,a_n^*), we obtain the conclusion. ∎

Due to their implementability, operators with finite graphs are of particular interest. The next result demonstrates that, if a sufficiently high order of cyclic monotonicity is achieved, the common ancestor functions stabilize.

THEOREM 2.4. *Let $A\colon X \rightrightarrows X^*$, let $(a_1,a_1^*) \in \text{gra } A$, and let $n \in \{2,3,\dots\}$. Suppose that A is n-cyclically monotone and that* gra A *has at most n points. Then $C_{A,\infty,(a_1,a_1^*)} = C_{A,n+1,(a_1,a_1^*)}$.*

Proof. Take $(x,x^*) \in X \times X^*$, and take $m \in \{n+2, n+3,\dots\}$. It suffices to show that

$$C_{A,m,(a_1,a_1^*)}(x,x^*) \le C_{A,m-1,(a_1,a_1^*)}(x,x^*), \tag{12}$$

since this and (7) then imply that $C_{A,n+1,(a_1,a_1^*)} = C_{A,n+2,(a_1,a_1^*)} = \cdots = C_{A,\infty,(a_1,a_1^*)}$. Take $(a_2,a_2^*),\dots,(a_{m-1},a_{m-1}^*)$ in gra A. Since gra A contains at most n points and

since $m-1 \geq n+1$, there exist integers k and l such that $1 \leq k < l \leq m-1$ and $a_k = a_l$. Hence

$$\begin{aligned}(13)\quad &\sum_{i=1}^{m-2} \langle a_{i+1} - a_i, a_i^* \rangle + \langle x - a_{m-1}, a_{m-1}^* \rangle + \langle a_1, x^* \rangle \\ &= \sum_{i=1}^{k-1} \langle a_{i+1} - a_i, a_i^* \rangle + \sigma + \sum_{i=l}^{m-2} \langle a_{i+1} - a_i, a_i^* \rangle + \langle x - a_{m-1}, a_{m-1}^* \rangle + \langle a_1, x^* \rangle,\end{aligned}$$

where

$$(14)\qquad \sigma = \sum_{i=k}^{l-1} \langle a_{i+1} - a_i, a_i^* \rangle.$$

We claim that

$$(15)\qquad \sigma \leq 0.$$

Note that σ contains $l-k$ terms. If $l-k \leq n$, then the n-cyclic monotonicity of A implies that $\sigma \leq 0$. Otherwise, $l-k > n$, and we may analogously and recursively split up σ until it is a finite sum of negative terms. This verifies (15). Now (13) implies (12). □

Example 2.5. Suppose that X is a Hilbert space. Let $e \in X$ be such that $\|e\| = 1$, and define A via $\operatorname{gra} A := \{(-e, -e), (e, e)\}$. Then A is (2-cyclically) monotone, and for every $(x, x^*) \in X \times X$ we have

$$(16)\qquad C_{A,2,(-e,-e)}(x, x^*) = -\langle x + x^*, e \rangle - 1,$$

$$(17)\qquad C_{A,2,(e,e)}(x, x^*) = \langle x + x^*, e \rangle - 1,$$

$$(18)\qquad C_{A,3,(-e,-e)}(x, x^*) = \max\big\{ -\langle x + x^*, e \rangle - 1, \langle x - x^*, e \rangle - 3 \big\},$$

$$(19)\qquad C_{A,3,(e,e)}(x, x^*) = \max\big\{ \langle x^* - x, e \rangle - 3, \langle x + x^*, e \rangle - 1 \big\}.$$

THEOREM 2.6. *Let $A\colon X \rightrightarrows X^*$, and let $(a_1, a_1^*) \in \operatorname{gra} A$. Suppose that A is not cyclically monotone. Then $C_{A,\infty,(a_1,a_1^*)} \equiv +\infty$.*

Proof. There exist n points $(a_2, a_2^*), \ldots, (a_{n+1}, a_{n+1}^*)$ in $\operatorname{gra} A$, where $n \in \{2, 3, \ldots\}$, such that

$$(20)\qquad \sigma := \sum_{i=2}^{n+1} \langle a_{i+1} - a_i, a_i^* \rangle > 0, \quad \text{where } a_{n+2} := a_2.$$

Take $(x, x^*) \in X \times X^*$. Take $k \in \{2, 3, \ldots\}$, and define

$$(21)\qquad a_{kn+2} := a_{(k-1)n+2} := \cdots := a_2,$$

$$(22)\qquad a_{kn+1} := a_{(k-1)n+1} := \cdots := a_{n+1},$$

$$(23)\qquad a_{kn} := a_{(k-1)n} := \cdots := a_n,$$

$$(24)\qquad \vdots$$

$$(25)\qquad a_{(k-1)n+3} := a_{(k-2)n+3} := \cdots := a_3,$$

and analogously for $a_{n+2}^*, \ldots, a_{kn+2}^*$. Then

$$C_{A,kn+3,(a_1,a_1^*)}(x,x^*) \geq \sum_{i=1}^{kn+1} \langle a_{i+1}-a_i, a_i^*\rangle + \langle x-a_{kn+2}, a_{kn+2}^*\rangle + \langle a_1, x^*\rangle \tag{26}$$

$$= \langle a_2-a_1, a_1^*\rangle + k\sigma + \langle x-a_2, a_2^*\rangle + \langle a_1, x^*\rangle \tag{27}$$

$$\to +\infty \quad \text{as } k \to +\infty. \tag{28}$$

Therefore, $\lim_{k\to+\infty} C_{A,kn+3,(a_1,a_1^*)}(x,x^*) = +\infty$, and the result now follows from (7). □

Example 2.7. Suppose that X is a Hilbert space. Let $e \in X$ be such that $\|e\| = 1$, and define A via $\operatorname{gra} A := \{(-e,e),(e,-e)\}$. Then A is not monotone, and for every $k \in \{2,3,\ldots\}$ and $(x,x^*) \in X \times X$ we have

$$C_{A,2,(-e,e)}(x,x^*) = \langle x-x^*, e\rangle + 1, \tag{29}$$

$$C_{A,2,(e,-e)}(x,x^*) = \langle x^*-x, e\rangle + 1, \tag{30}$$

$$C_{A,2k-1,(-e,e)}(x,x^*) = 4(k-1) - 2 + \max\big\{\langle x-x^*, e\rangle - 1, -\langle x+x^*, e\rangle + 1\big\}, \tag{31}$$

$$C_{A,2k-1,(e,-e)}(x,x^*) = 4(k-1) - 2 + \max\big\{\langle x+x^*, e\rangle + 1, \langle x^*-x, e\rangle - 1\big\}, \tag{32}$$

$$C_{A,2k,(-e,e)}(x,x^*) = 4(k-1) + \max\big\{\langle x-x^*, e\rangle + 1, -\langle x+x^*, e\rangle - 1\big\}, \tag{33}$$

$$C_{A,2k,(e,-e)}(x,x^*) = 4(k-1) + \max\big\{\langle x+x^*, e\rangle - 1, \langle x^*-x, e\rangle + 1\big\}, \tag{34}$$

$$C_{A,\infty,(-e,e)}(x,x^*) = +\infty, \tag{35}$$

$$C_{A,\infty,(e,-e)}(x,x^*) = +\infty. \tag{36}$$

We now turn to Fitzpatrick functions.

Definition 2.8 (Fitzpatrick functions [2, Definition 2.2]). *Let $A\colon X \rightrightarrows X^*$. For every $n \in \{2,3,\ldots\}$, the* Fitzpatrick function of A of order n *is*

$$F_{A,n} := \sup_{(a,a^*)\in\operatorname{gra} A} C_{A,n,(a,a^*)}. \tag{37}$$

The Fitzpatrick function of A of infinite order *is*

$$F_{A,\infty} := \sup_{n\in\{2,3,\ldots\}} F_{A,n} = \sup_{(a,a^*)\in\operatorname{gra} A} C_{A,\infty,(a,a^*)}. \tag{38}$$

It is clear that each $F_{A,n}$ is convex and lower semicontinuous; moreover, if $\operatorname{gra} A$ is finite, then each $F_{A,n}$ is polyhedral and continuous. The sequence $(F_{A,n})_{n\in\{2,3,\ldots\}}$ is increasing and pointwise convergent to $F_{A,\infty}$, which is convex and lower semicontinuous. An immediate consequence of Definition 2.8 is the following result.

Proposition 2.9 ([2, Proposition 2.3]). *Let $A\colon X \rightrightarrows X^*$, and let $n \in \{2,3,\ldots\}$. Then $F_{A,n}\colon X \times X^* \to [-\infty,+\infty]$ is convex and lower semicontinuous. At $(x,x^*) \in X \times X^*$, the value of $F_{A,n}$ is given by*

$$\sup_{\substack{(a_1,a_1^*)\in\operatorname{gra} A,\\ \vdots \\ (a_{n-1},a_{n-1}^*)\in\operatorname{gra} A}} \left(\sum_{i=1}^{n-2}\langle a_{i+1}-a_i, a_i^*\rangle\right) + \langle x-a_{n-1}, a_{n-1}^*\rangle + \langle a_1, x^*\rangle. \tag{39}$$

Moreover,

$$F_{A,n} \geq \langle\cdot,\cdot\rangle \text{ on } \operatorname{gra} A. \tag{40}$$

PROPOSITION 2.10. *Let $A\colon X \rightrightarrows X^*$, let $n \in \{2,3,\dots\}$, and let $(x,x^*) \in X \times X^*$. Then $F_{A^{-1},n}(x^*,x) = F_{A,n}(x,x^*)$ and $F_{A^{-1},\infty}(x^*,x) = F_{A,\infty}(x,x^*)$.*

Proof. Take $(b_1^*,b_1),\dots,(b_{n-1}^*,b_{n-1})$ in $\operatorname{gra} A^{-1}$ and set

$$\big(\forall i \in \{1,\dots,n-1\}\big) \quad (a_i,a_i^*) := (b_{n-i},b_{n-i}^*) \in \operatorname{gra} A. \tag{41}$$

Then

$$\begin{aligned}\sum_{i=1}^{n-2}\langle b_i, b_{i+1}^* - b_i^*\rangle + \langle b_{n-1}, x^* - b_{n-1}^*\rangle + \langle x, b_1^*\rangle \\ &= \sum_{i=1}^{n-2}\langle b_i, b_{i+1}^*\rangle - \sum_{i=1}^{n-1}\langle b_i, b_i^*\rangle + \langle b_{n-1}, x^*\rangle + \langle x, b_1^*\rangle \\ &= \sum_{i=1}^{n-2}\langle a_{i+1}, a_i^*\rangle - \sum_{i=1}^{n-1}\langle a_i, a_i^*\rangle + \langle a_1, x^*\rangle + \langle x, a_{n-1}^*\rangle \\ &= \sum_{i=1}^{n-2}\langle a_{i+1}-a_i, a_i^*\rangle + \langle x - a_{n-1}, a_{n-1}^*\rangle + \langle a_1, x^*\rangle.\end{aligned} \tag{42}$$

The result follows by supremizing. ∎

FACT 2.11 ([2, Proposition 2.4 and Corollary 2.5]). *Let $A\colon X \rightrightarrows X^*$, and let $n \in \{2,3,\dots\}$. Then*

$$A \text{ is } n\text{-cyclically monotone} \Leftrightarrow F_{A,n} \le \langle\cdot,\cdot\rangle \text{ on } \operatorname{gra} A \Leftrightarrow F_{A,n} = \langle\cdot,\cdot\rangle \text{ on } \operatorname{gra} A, \tag{43}$$

and

$$A \text{ is cyclically monotone} \Leftrightarrow F_{A,\infty} \le \langle\cdot,\cdot\rangle \text{ on } \operatorname{gra} A \Leftrightarrow F_{A,\infty} = \langle\cdot,\cdot\rangle \text{ on } \operatorname{gra} A. \tag{44}$$

COROLLARY 2.12. *Let $A\colon X \rightrightarrows X^*$, and let $n \in \{2,3,\dots\}$. Then A is n-cyclically monotone if and only if A^{-1} is.*

The recursion formula for Fitzpatrick functions that we present next is an immediate consequence of Proposition 2.3. (A special case of it was utilized in [3].)

PROPOSITION 2.13 (recursion). *Let $A\colon X \rightrightarrows X^*$, let $n \in \{2,3,\dots\}$, and let $(x,x^*) \in X \times X^*$. Then*

$$F_{A,n+1}(x,x^*) = \sup_{(a,a^*)\in\operatorname{gra} A} F_{A,n}(a,x^*) + \langle x, a^*\rangle - \langle a, a^*\rangle. \tag{45}$$

Combining Fact 2.11 and Proposition 2.13, we obtain the following result which underlines the importance of the values of the Fitzpatrick function on $\operatorname{dom} A \times \operatorname{ran} A$.

COROLLARY 2.14. *Let $A\colon X \rightrightarrows X^*$, and let $n \in \{3,4,\dots\}$. Then A is n-cyclically monotone if and only if*

$$\big(\forall (a,a^*) \in \operatorname{gra} A\big)\big(\forall (b,b^*) \in \operatorname{gra} A\big) \quad F_{A,n-1}(a,b^*) - \langle a, b^*\rangle \le \langle a-b, a^*-b^*\rangle. \tag{46}$$

Example 2.15. Let $A\colon X \rightrightarrows X^*$ be monotone such that its graph contains two points, and let $n \in \{2,3,\dots\}$. Then $F_{A,n} = \langle\cdot,\cdot\rangle$ on $\operatorname{dom} A \times \operatorname{ran} A$; consequently, A is cyclically monotone.

Proof. The fact that $F_{A,n} = \langle\cdot,\cdot\rangle$ is proved readily by induction. The cyclic monotonicity of A now follows from Corollary 2.14 and from the monotonicity of A. (Alternatively, use Corollary 2.18 below.) ∎

THEOREM 2.16. *Let $A\colon X \rightrightarrows X^*$ be such that* gra A *contains at most n points, where $n \in \{2,3,\ldots\}$. Suppose that A is n-cyclically monotone. Then A is $(n+1)$-cyclically monotone and*

$$F_{A,n+1} = F_{A,n+2} = \cdots = F_{A,\infty}. \tag{47}$$

Proof. Take

$$\big\{(b_1,b_1^*),\ldots,(b_{n+1},b_{n+1}^*)\big\} \subseteq \operatorname{gra} A. \tag{48}$$

We must show that

$$\sigma := \sum_{i=1}^{n+1}\langle b_{i+1}-b_i, b_i^*\rangle \leq 0, \quad \text{where } b_{n+2} := b_1. \tag{49}$$

Since gra A contains no more than n points, there exist integers k and l such that

$$b_k = b_l \quad \text{and} \quad 1 \leq k < l \leq n+1. \tag{50}$$

Then

$$\sigma = \sigma_1 + \sigma_2, \tag{51}$$

where

$$\sigma_1 := \sum_{i=k}^{l-1}\langle b_{i+1}-b_i, b_i^*\rangle \quad \text{and} \quad \sigma_2 := \sum_{i=l}^{n+1}\langle b_{i+1}-b_i, b_i^*\rangle + \sum_{i=1}^{k-1}\langle b_{i+1}-b_i, b_i^*\rangle \tag{52}$$

are two cyclic sums, each of which contains at least one term and hence at most n terms. Since A is n-cyclically monotone, we see that $\sigma_1 \leq 0$ and that $\sigma_2 \leq 0$. Therefore, $\sigma = \sigma_1 + \sigma_2 \leq 0$. The statement concerning the Fitzpatrick functions follows from Theorem 2.4 and Definition 2.8. ∎

Example 2.17. Let $A\colon X \rightrightarrows X^*$ be such that $\operatorname{gra} A = \{(a,a^*)\}$ for some $(a,a^*) \in X \times X^*$. Then A is cyclically monotone, and for every $(x,x^*) \in X \times X^*$ we have

$$F_{A,2}(x,x^*) = F_{A,3}(x,x^*) = \cdots = F_{A,\infty}(x,x^*) = \langle a,x^*\rangle + \langle x,a^*\rangle - \langle a,a^*\rangle. \tag{53}$$

COROLLARY 2.18. *Let $A\colon X \rightrightarrows X^*$ be such that* gra A *contains at most n points, where $n \in \{2,3,\ldots\}$. Suppose that A is n-cyclically monotone. Then A is cyclically monotone.*

Proof. By Theorem 2.16, A is $(n+1)$-cyclically monotone and

$$F_{A,n+1} = F_{A,\infty}. \tag{54}$$

On the other hand, Fact 2.11 yields

$$F_{A,n+1} = \langle\cdot,\cdot\rangle \text{ on } \operatorname{gra} A. \tag{55}$$

The result follows by combining (54), (55), and Fact 2.11. ∎

COROLLARY 2.19. *Let $A\colon X \rightrightarrows X^*$ be such that* gra A *contains at most n points, where $n \in \{2,3,\ldots\}$. Then A is cyclically monotone if and only if*

$$\big(\forall (a,a^*) \in \operatorname{gra} A\big) \quad F_{A,n}(a,a^*) = \langle a,a^*\rangle. \tag{56}$$

Proof. "⇒": On $\operatorname{gra} A$, we always have $\langle \cdot, \cdot \rangle \leq F_{A,n} \leq F_{A,\infty}$. Since A is cyclically monotone, $F_{A,\infty} = \langle \cdot, \cdot \rangle$ on $\operatorname{gra} A$ and hence $F_{A,n} = \langle \cdot, \cdot \rangle$ on $\operatorname{gra} A$. "⇐": By Fact 2.11, A is n-cyclically monotone. The result now follows from Corollary 2.18. ∎

Example 2.20. Suppose that X is a Hilbert space. Let $e \in X$ such that $\|e\| = 1$, and define A via $\operatorname{gra} A = \{(-e, -e), (e, e)\}$. Then A is cyclically monotone but $F_{A,2} \neq F_{A,3}$; in fact, for every $(x, x^*) \in X \times X$, we have

$$F_{A,2}(x, x^*) = \max\big\{ -1 \pm \langle x + x^*, e \rangle \big\} \tag{57}$$

and

$$F_{A,3}(x, x^*) = \cdots = F_{A,\infty}(x, x^*) = \max\big\{ -1 \pm \langle x + x^*, e \rangle, -3 \pm \langle x - x^*, e \rangle \big\}. \tag{58}$$

Proof. The operator A is cyclically monotone since $\operatorname{gra} A \subset \operatorname{gra} \operatorname{Id} = \operatorname{gra} \partial \frac{1}{2} \| \cdot \|^2$. The formulas for $F_{A,2}$ and $F_{A,3}$ follow from Example 2.5. Theorem 2.16 shows that $F_{A,3} = \cdots = F_{A,\infty}$. Finally, we note that $F_{A,2}(2e, -2e) = -1$, whereas $F_{A,3}(2e, -2e) = 1$. ∎

The next example, which is an immediate consequence of Example 2.7 and Definition 2.8, illustrates the nonmonotone case.

Example 2.21. Suppose that X is a Hilbert space. Let $e \in X$ be such that $\|e\| = 1$, and define A via $\operatorname{gra} A := \{(-e, e), (e, -e)\}$. Then A is not monotone, and for every $k \in \{2, 3, \dots\}$ and $(x, x^*) \in X \times X$ we have

$$F_{A,2}(x, x^*) = 1 + \max\big\{ \pm \langle x - x^*, e \rangle \big\}, \tag{59}$$

$$F_{A,2k-1}(x, x^*) = 4(k-1) - 2 + \max\big\{ -1 \pm \langle x - x^*, e \rangle, 1 \pm \langle x + x^*, e \rangle \big\}, \tag{60}$$

$$F_{A,2k}(x, x^*) = 4(k-1) + \max\big\{ 1 \pm \langle x - x^*, e \rangle, -1 \pm \langle x + x^*, e \rangle \big\}, \tag{61}$$

$$F_{A,\infty}(x, x^*) = +\infty. \tag{62}$$

3. Rockafellar functions.

Definition 3.1. *Let $A\colon X \rightrightarrows X^*$, and let $f \in \Gamma$. Then f is an* antiderivative *of A if*

$$\operatorname{gra} A \subseteq \operatorname{gra} \partial f. \tag{63}$$

The following result will turn out to be useful.

Proposition 3.2. *Suppose that X is reflexive. Let $A\colon X \rightrightarrows X^*$, let $f \in \Gamma$, and suppose that f is an antiderivative of A such that $\overline{\operatorname{ran} \partial f} \subseteq \operatorname{conv} \operatorname{ran} A$. Then $\operatorname{dom} f^* = \operatorname{conv} \operatorname{ran} A$.*

Proof. On the one hand, since f is an antiderivative of A, we deduce that $\operatorname{gra} A \subseteq \operatorname{gra} \partial f \Leftrightarrow \operatorname{gra} A^{-1} \subseteq \operatorname{gra}(\partial f)^{-1} = \operatorname{gra} \partial f^* \Rightarrow \operatorname{ran} A = \operatorname{dom} A^{-1} \subseteq \operatorname{dom} \partial f^* \subseteq \operatorname{dom} f^* \Rightarrow \operatorname{conv} \operatorname{ran} A \subseteq \operatorname{conv} \operatorname{dom} f^* = \operatorname{dom} f^*$. Because $\overline{\operatorname{ran} \partial f} \subseteq \operatorname{conv} \operatorname{ran} A$, we see that $\operatorname{dom} f^* \subseteq \overline{\operatorname{dom} f^*} = \overline{\operatorname{dom} \partial f^*} = \overline{\operatorname{dom} (\partial f)^{-1}} = \overline{\operatorname{ran} \partial f} \subseteq \operatorname{conv} \operatorname{ran} A$. Altogether, $\operatorname{dom} f^* = \operatorname{conv} \operatorname{ran} A$. ∎

Definition 3.3 (Rockafellar function). *Let $A\colon X \rightrightarrows X^*$. Then the* Rockafellar functions *are defined by*

$$\big(\forall (a, a^*) \in \operatorname{gra} A\big) \quad R_{A,(a,a^*)}\colon X \to \left]-\infty, +\infty\right] : x \mapsto \sup_{n \in \{2,3,\dots\}} C_{A,n,(a,a^*)}(x, 0). \tag{64}$$

The importance of the Rockafellar functions stems from a fundamental result due to Rockafellar (see [19] or [24, Proposition 2.4.3, Theorem 3.2.8, and Corollary 3.2.11]),

which states that maximal cyclically monotone operators are precisely the subdifferential operators of convex, lower semicontinuous, and proper functions. The following part of Rockafellar's result will be utilized later.

FACT 3.4 (Rockafellar [19] or [24, Proposition 2.4.3 and Corollary 3.2.11]). *Let $A\colon X \rightrightarrows X^*$ be cyclically monotone, and let $(a, a^*) \in \operatorname{gra} A$. Then the following hold:*

(i) *$R_{A,(a,a^*)}$ is convex, lower semicontinuous, and proper, $R_{A,(a,a^*)}(a) = 0$, and $R_{A,(a,a^*)}$ is an antiderivative of A.*

(ii) *If A is maximal cyclically monotone, then any two antiderivatives of A differ only by a constant.*

Among all antiderivatives, Rockafellar functions have a special status due to the following minimality property, which was first observed in [14, Theorem 3.4] for cyclically monotone operators with a finite graph.

THEOREM 3.5. *Let $A\colon X \rightrightarrows X^*$ be cyclically monotone, and let $a \in \operatorname{dom} A$. Then*

(65)
$$(\forall a^* \in Aa)\quad R_{A,(a,a^*)} = \min\big\{f \in \Gamma(X) \mid f \text{ is an antiderivative of } A \text{ with } f(a) \geq 0\big\}$$

(66)
$$= \min\big\{f \in \Gamma(X) \mid f \text{ is an antiderivative of } A \text{ with } f(a) = 0\big\}.$$

Proof. Suppose that $f \in \Gamma$ is an antiderivative of A with $f(a) \geq 0$, and take $a^* \in Aa$ and $x \in X$. Then, for every $x \in X$, $n \in \{1, 2, \dots\}$, and $(a_1, a_1^*), \dots, (a_n, a_n^*)$ belonging to $\operatorname{gra} A$, we have

$$\begin{aligned} f(x) &\geq f(x) - f(a_n) + \left(\sum_{i=1}^{n-1} f(a_{i+1}) - f(a_i)\right) + f(a_1) - f(a) \\ &\geq \langle x - a_n, a_n^*\rangle + \left(\sum_{i=1}^{n-1} \langle a_{i+1} - a_i, a_i^*\rangle\right) + \langle a_1 - a, a^*\rangle. \end{aligned} \tag{67}$$

This implies

$$f \geq R_{A,(a,a^*)}. \tag{68}$$

In view of Fact 3.4(i), the proof is complete. □

COROLLARY 3.6. *Let $A\colon X \rightrightarrows X^*$ be cyclically monotone, let $a \in \operatorname{dom} A$, let $a_1^* \in Aa$, and let $a_2^* \in Aa$. Then $R_{A,(a,a_1^*)} = R_{A,(a,a_2^*)}$.*

Corollary 3.6 and Theorem 2.6 make the following definition well-defined.

DEFINITION 3.7. *Let $A\colon X \rightrightarrows X^*$, and let $a \in \operatorname{dom} A$. Then we set*

$$R_{A,a} := R_{A,(a,a^*)}, \tag{69}$$

where a^* is an arbitrary point in Aa.

COROLLARY 3.8. *Let $A\colon X \rightrightarrows X^*$ be cyclically monotone, and let $a \in \operatorname{dom} A$. Set $B\colon X \rightrightarrows X^*\colon x \mapsto \operatorname{conv}(Ax)$. Then B is cyclically monotone, and $R_{B,a} = R_{A,a}$.*

Proof. It is readily verified that B is cyclically monotone. Hence $R_{B,a}$ is an antiderivative of B and of A such that $R_{B,a}(a) = 0$. By Theorem 3.5, $R_{B,a} \geq R_{A,a}$. On the other hand, $R_{A,a}$ is also an antiderivative of B; thus, again by Theorem 3.5, $R_{A,a} \geq R_{B,a}$. Altogether, $R_{B,a} = R_{A,a}$. □

COROLLARY 3.9. *Suppose that X is reflexive. Let $A\colon X \rightrightarrows X^*$ be cyclically monotone, and let $(a, a^*) \in \operatorname{gra} A$. Then*

$$R_{A,a}^* = \max\big\{g \in \Gamma(X^*) \mid g \text{ is an antiderivative of } A^{-1} \text{ and } g(a^*) = \langle a, a^*\rangle\big\}. \tag{70}$$

Proof. Take $g \in \Gamma(X^*)$ such that g is an antiderivative of A^{-1} and $g(a^*) = \langle a, a^* \rangle$. Then $g^*(a) = 0$, and g^* is an antiderivative of A. By Theorem 3.5, $g^* \geq R_{A,a}$, and therefore $g^{**} = g \leq R^*_{A,a}$. ∎

Corollary 3.9 results in the following interesting counterpart to Theorem 3.5; see also [14, Proposition 4.2].

COROLLARY 3.10. *Suppose that X is reflexive. Let $A\colon X \rightrightarrows X^*$ be cyclically monotone, and let $(a, a^*) \in \operatorname{gra} A$. Then*

(71)
$$R^*_{A^{-1},a^*} - \langle a, a^* \rangle = \max\big\{f \in \Gamma(X) \mid f \text{ is an antiderivative of } A \text{ and } f(a) = 0\big\}.$$

The next result will be used later.

COROLLARY 3.11. *Let $A\colon X \rightrightarrows X^*$, let $(a, a^*) \in \operatorname{gra} A$, and let $n \in \{2, 3, \dots\}$. Suppose that $\operatorname{gra} A$ contains at most n points and that A is n-cyclically monotone. Then A is cyclically monotone, and for every $x \in X$ we have*

$$R_{A,a}(x) = C_{A,n+1,(a,a^*)}(x, 0) \tag{72}$$

$$= \max_{\substack{(a_2,a_2^*)\in\operatorname{gra} A,\\ \vdots \\ (a_n,a_n^*)\in\operatorname{gra} A}} \langle x - a_n, a_n^* \rangle + \langle a_n - a_{n-1}, a_{n-1}^* \rangle + \cdots + \langle a_2 - a, a^* \rangle. \tag{73}$$

Consequently, $R_{A,a}$ is a polyhedral and continuous antiderivative of A with $\operatorname{ran} \partial R_{A,a} \subset \operatorname{conv} \operatorname{ran} A$.

Proof. This follows from Corollary 2.18, Theorem 2.4, (8), Fact 3.4(i), and the Ioffe–Tikhomirov theorem (see, e.g., [24, Theorem 2.4.18]). ∎

Fact 3.4(ii) implies that, if A is maximal cyclically monotone, the Rockafellar functions $\{R_{A,a}\}_{a\in\operatorname{dom} A}$ differ only by constants. For finite-graph operators, this is no longer true as the following consequence of Example 2.5 and Definition 3.3 shows.

Example 3.12. Suppose that X is a Hilbert space. Let $e \in X$ be such that $\|e\| = 1$, and define A via $\operatorname{gra} A := \{(-e, -e), (e, e)\}$. Then for every $x \in X$ we have

$$R_{A,-e}(x) = \max\big\{-\langle x, e\rangle - 1, \langle x, e\rangle - 3\big\} = -2 + |\langle x, e\rangle - 1| \tag{74}$$

and

$$R_{A,e}(x) = \max\big\{\langle x, e\rangle - 1, -\langle x, e\rangle - 3\big\} = -2 + |\langle x, e\rangle + 1|. \tag{75}$$

Consequently, $R_{A,e} \not\geq R_{A,-e}$ and $R_{A,e} \not\leq R_{A,-e}$.

Remark 3.13. Let $A\colon X \rightrightarrows X^*$, and suppose that A is not cyclically monotone. Then Theorem 2.6 and Definition 3.3 imply that the Rockafellar functions $\{R_{A,a}\}_{a\in\operatorname{dom} A}$ are all identically equal to $+\infty$. For a concrete example, see Example 2.7.

Turning momentarily to the case when $X = \mathbb{R}$, we now present not only a considerable generalization of Example 3.12 but also an explicit formula for any Rockafellar function and its subdifferential operator of a cyclically monotone operator with a finite graph. See also [14, section 7].

THEOREM 3.14. *Let $A\colon \mathbb{R} \rightrightarrows \mathbb{R}$ have a finite graph, and suppose that the graph of $B\colon \mathbb{R} \rightrightarrows \mathbb{R}\colon x \mapsto \operatorname{conv}(Ax)$ is*

$$\bigcup_{i=1}^{n} \big(\{a_i\} \times [b_i^-, b_i^+]\big), \tag{76}$$

where $n \in \{1,2,\ldots\}$, $a_1 < a_2 < \cdots < a_n$, *and* $b_1^- \leq b_1^+ \leq b_2^- \leq \cdots \leq b_n^- \leq b_n^+$. *Set* $a_0 := -\infty$ *and* $a_{n+1} := +\infty$. *Suppose that* $k \in \{1,\ldots,n\}$. *Then* R_{A,a_k} *is given by*

$$\mathbb{R} \to \mathbb{R}\colon x \mapsto \begin{cases} (x-a_i)b_i^- + \sum_{j=i+1}^{k} (a_{j-1}-a_j)b_j^- & \text{if } a_{i-1} < x \leq a_i \leq a_k, \\ (x-a_i)b_i^+ + \sum_{j=k}^{i-1} (a_{j+1}-a_j)b_j^+ & \text{if } a_k \leq a_i \leq x < a_{i+1}, \end{cases} \tag{77}$$

and $\partial R_{A,a_k}$ *is given by*

$$\mathbb{R} \rightrightarrows \mathbb{R}\colon x \mapsto \begin{cases} \{b_i^-\} & \text{if } a_{i-1} < x < a_i \leq a_k, \\ [b_i^-, b_{i+1}^-] & \text{if } x = a_i < a_k, \\ [b_k^-, b_k^+], & \text{if } x = a_k, \\ [b_{i-1}^+, b_i^+] & \text{if } a_k < x = a_i, \\ \{b_i^+\} & \text{if } a_k \leq a_i < x < a_{i+1}. \end{cases} \tag{78}$$

Proof. Clearly, A and B are cyclically monotone. Denote the function described in (77) by R, and observe that R is piecewise linear, continuous everywhere, and well-defined at a_k, with

$$R(a_k) = 0. \tag{79}$$

Moreover, (77) implies that ∂R is given by (78), which is clearly monotone. Thus

$$R \in \Gamma(\mathbb{R}). \tag{80}$$

Take $i \in \{1,2,\ldots,n\}$. If $i < k$, then $Aa_i \subseteq Ba_i = [b_i^-, b_i^+] \subseteq [b_i^-, b_{i+1}^-] = \partial R(a_i)$. If $i = k$, then $Aa_i = Aa_k \subseteq Ba_k = [b_k^-, b_k^+] = \partial R(a_k)$. If $k < i$, then $Aa_i \subseteq Ba_i = [b_i^-, b_i^+] \subseteq [b_{i-1}^+, b_i^+] = \partial R(a_i)$. Thus,

$$R \text{ is an antiderivative of } A. \tag{81}$$

Since $\bigcup_{i=1}^n \{(a_i, b_i^-), (a_i, b_i^+)\} \subseteq \operatorname{gra} A$, we deduce from (73) and (77) that

$$R_{A,a_k} \geq R. \tag{82}$$

Hence (79), (80), (81), (82), and Theorem 3.5 imply that $R = R_{A,a_k}$. ∎

The next result links Rockafellar functions to Fitzpatrick functions.

THEOREM 3.15. *Let* $A\colon X \rightrightarrows X^*$. *Then*

$$\big(\forall (x,x^*) \in X \times X^*\big) \quad F_{A,\infty}(x,x^*) = \sup_{a \in \operatorname{dom} A} \langle a, x^* \rangle + R_{A,a}(x). \tag{83}$$

Proof. (See also the proof of [2, Theorem 3.5] for a variant.) Take $(x,x^*) \in X \times X^*$. Using Definitions 2.8, 2.1, 3.3, and 3.7, we see that

$$F_{A,\infty}(x,x^*) = \sup_{n \in \{2,3,\ldots\}} F_{A,n}(x,x^*) = \sup_{n \in \{2,3,\ldots\}} \sup_{(a,a^*) \in \operatorname{gra} A} C_{A,n,(a,a^*)}(x,x^*) \tag{84}$$

$$= \sup_{(a,a^*) \in \operatorname{gra} A} \sup_{n \in \{2,3,\ldots\}} C_{A,n,(a,a^*)}(x,0) + \langle a, x^* \rangle \tag{85}$$

$$= \sup_{(a,a^*) \in \operatorname{gra} A} \langle a, x^* \rangle + R_{A,(a,a^*)}(x) \tag{86}$$

$$= \sup_{a \in \operatorname{dom} A} \langle a, x^* \rangle + R_{A,a}(x), \tag{87}$$

as required. ∎

We deduce that the Fitzpatrick function of infinite order with the second variable set to zero is exactly the supremum of all Rockafellar functions.

COROLLARY 3.16. *Let* $A\colon X \rightrightarrows X^*$. *Then*

$$F_{A,\infty}(\cdot,0) = \sup_{a\in\operatorname{dom} A} R_{A,a}. \tag{88}$$

Remark 3.17. Let $A\colon X \rightrightarrows X^*$ be maximal cyclically monotone. Rockafellar [19] (see Fact 3.4) proved that $A = \partial f$, where $f \in \Gamma$ is uniquely determined up to additive constants. By [2, Theorem 3.5], $F_{A,\infty} = f \oplus f^*$. Thus Corollary 3.16 implies that

$$\sup_{a\in\operatorname{dom} A} R_{A,a} \equiv +\infty \;\Leftrightarrow\; 0 \notin \operatorname{dom} f^* \;\Leftrightarrow\; \inf f(X) = -\infty. \tag{89}$$

COROLLARY 3.18. *Let* $A\colon X \rightrightarrows X^*$ *be cyclically monotone with a finite graph, let* $x^* \in X^*$, *and set* $f := F_{A,\infty}(\,\cdot\,, x^*)$. *Then* f *is polyhedral, continuous, with a full domain,* $\operatorname{gra} A \subset \operatorname{gra} \partial f$, *and* $\overline{\operatorname{ran}\,\partial f} \subseteq \operatorname{conv}\operatorname{ran} A$.

Proof. Since $\operatorname{gra} A$ is finite, Theorem 3.15 yields

$$f = \max_{a\in\operatorname{dom} A} \langle a, x^*\rangle + R_{A,a}. \tag{90}$$

The function f is continuous, polyhedral, with a full domain, as it is the finite maximum of such functions (see Corollary 3.11). Fix $x \in X$, and set $D_x := \big\{a \in \operatorname{dom} A \mid f(x) = \langle a, x^*\rangle + R_{A,a}(x)\big\}$. On the one hand, using the Ioffe–Tikhomirov theorem (see, e.g., [24, Theorem 2.4.18]) and Corollary 3.11, we have

$$\partial f(x) = \overline{\operatorname{conv}}^*\bigcup_{a\in D_x} \partial R_{A,a}(x) \subseteq \overline{\operatorname{conv}}^*\bigcup_{a\in D_x} \operatorname{conv}\operatorname{ran} A = \operatorname{conv}\operatorname{ran} A, \tag{91}$$

where $\overline{\operatorname{conv}}^*$ denotes the weak* closed convex hull operator. Hence $\operatorname{ran}\partial f \subseteq \operatorname{conv}\operatorname{ran} A$, and thus $\overline{\operatorname{ran}\,\partial f} \subseteq \operatorname{conv}\operatorname{ran} A$, since $\operatorname{conv}\operatorname{ran} A$ is compact as a convex hull of finitely many points. On the other hand, Fact 3.4(i) implies that

$$\big(\forall a \in \operatorname{dom} A\big) \quad \operatorname{gra} A \subset \operatorname{gra}\partial R_{A,a}. \tag{92}$$

Combining (91) and (92), we conclude altogether that $\operatorname{gra} A \subset \operatorname{gra}\partial f$. ∎

Example 3.19. Suppose that X is a Hilbert space. Let $e \in X$ such that $\|e\| = 1$, and define A via $\operatorname{gra} A = \{(-e,-e),(e,e)\}$. Then A is cyclically monotone, and for every $x \in X$ we have

$$F_{A,\infty}(x,0) = \max\big\{R_{A,-e}(x), R_{A,e}(x)\big\} = \max\big\{-1 \pm \langle x, e\rangle\big\} = -1 + |\langle x, e\rangle|. \tag{93}$$

Proof. Combine Example 3.12 and Corollary 3.16. ∎

We conclude this section with a result which illustrates how Fitzpatrick functions give rise to the smallest nonnegative antiderivative.

COROLLARY 3.20. *Let* $A : X \rightrightarrows X^*$ *be cyclically monotone with a finite graph. Then*

$$F_{A,\infty}(\cdot,0) = \min\big\{f \in \Gamma(X) \mid f \text{ is an antiderivative of } A \text{ such that } f \geq 0 \text{ on } \operatorname{dom} A\big\}. \tag{94}$$

Proof. Take $f \in \Gamma(X)$ such that f is an antiderivative of A and $f \geq 0$ on $\operatorname{dom} A$. Then Theorem 3.5 implies that $(\forall a \in \operatorname{dom} A)\ f \geq R_{A,a}$; hence, by Corollary 3.16,

$$f \geq \max_{a\in\operatorname{dom} A} R_{A,a} = F_{A,\infty}(\cdot,0). \tag{95}$$

In view of Corollary 3.18 and Fact 3.4(i), $F_{A,\infty}(\cdot,0)$ is an antiderivative of A that is nonnegative on $\operatorname{dom} A$. ∎

4. Intrinsic and primal-dual symmetric methods. From now on,

(96) $\mathcal{A}$ is the set of all cyclically monotone operators on X with finite nonempty graphs.

DEFINITION 4.1. *An* intrinsic method for finding antiderivatives*—or simply an* intrinsic method*—is a mapping* $m\colon \mathcal{A} \to \Gamma\colon A \mapsto m_A$ *such that, for every* $A \in \mathcal{A}$, m_A *is an antiderivative of* A.

Example 4.2. Let $A\colon X \rightrightarrows X^*$ be cyclically monotone, and let $(a, a^*) \in \operatorname{gra} A$. Then the Rockafellar function $R_{A,(a,a^*)} = R_{A,a}$ is an antiderivative (see Fact 3.4) but—due to the dependency on a and the resulting nonuniqueness of Rockafellar functions—there is no corresponding intrinsic method m that produces Rockafellar functions. See Example 3.12 for a concrete example.

Remark 4.3. Given $A \in \mathcal{A}$, an intrinsic method m provides an antiderivatives m_A as a mapping depending only on A or, equivalently, only on the (unordered) graph of A. This key property of intrinsic methods explains why the process of providing Rockafellar functions considered in Example 4.2 is not intrinsic. Similarly, if a method computes antiderivatives by using an enumeration of the graph of A and if a different enumeration may result in a different antiderivative, then such a method cannot be intrinsic.

We now provide two intrinsic methods.

Example 4.4. Let $m\colon \mathcal{A} \to \Gamma\colon A \mapsto F_{A,\infty}(\cdot, 0) = \max_{(a,a^*)\in\operatorname{gra} A} R_{A,(a,a^*)}$. Corollaries 3.16 and 3.18 imply that m is an intrinsic method. Moreover, for every $A \in \mathcal{A}$, the antiderivative m_A has a full domain and $\overline{\operatorname{ran} \partial m_A} \subseteq \operatorname{conv} \operatorname{ran} A$.

Example 4.5. Let $A\colon X \rightrightarrows X^*$ be cyclically monotone such that $\operatorname{gra} A$ contains exactly n points, where $n \in \{1, 2, \dots\}$, and set

$$m_A := \sum_{(a,a^*)\in\operatorname{gra} A} \frac{1}{n} R_{A,(a,a^*)}. \tag{97}$$

Then m_A is an antiderivative of A that is polyhedral and continuous with a full domain and $\overline{\operatorname{ran} \partial m_A} \subseteq \operatorname{conv} \operatorname{ran} A$. Furthermore, the corresponding method $m\colon \mathcal{A} \to \Gamma\colon A \mapsto m_A$ is intrinsic.

Proof. Note that m_A is continuous and polyhedral with a full domain, as a finite sum of such functions. The sum rule (see, e.g., [24, Theorem 2.8.7(iii)]) and Fact 3.4 imply that, for every $(x, x^*) \in \operatorname{gra} A$, we have $x^* \in Ax \subseteq \sum_{(a,a^*)\in\operatorname{gra} A} \frac{1}{n} Ax \subseteq \sum_{(a,a^*)\in\operatorname{gra} A} \frac{1}{n} \partial R_{A,(a,a^*)}(x) = \partial m_A(x)$. Corollary 3.11 shows that, for every $x \in X$, we have $\partial m_A(x) = \sum_{(a,a^*)\in\operatorname{gra} A} \frac{1}{n} \partial R_{A,(a,a^*)}(x) \subseteq \sum_{(a,a^*)\in\operatorname{gra} A} \frac{1}{n} \operatorname{conv} \operatorname{ran} A = \operatorname{conv} \operatorname{ran} A$. Consequently, $\operatorname{ran} \partial m_A \subseteq \operatorname{conv} \operatorname{ran} A$, and hence $\overline{\operatorname{ran} \partial m_A} \subseteq \overline{\operatorname{conv} \operatorname{ran} A} = \operatorname{conv} \operatorname{ran} A$. It is clear that m is intrinsic. ∎

We assume from now on that

$$X \text{ is a Hilbert space.} \tag{98}$$

DEFINITION 4.6. *An intrinsic method* $\mathfrak{m}\colon \mathcal{A} \to \Gamma\colon A \mapsto \mathfrak{m}_A$ *is* primal-dual symmetric *if*

$$\big(\forall A \in \mathcal{A}\big) \quad \mathfrak{m}_{A^{-1}} = \mathfrak{m}_A^*. \tag{99}$$

PROPOSITION 4.7. *While intrinsic, neither*

$$\mathcal{A} \to \Gamma\colon A \mapsto F_{A,\infty}(\cdot, 0) = \max_{(a,a^*)\in\operatorname{gra} A} R_{A,(a,a^*)} \tag{100}$$

nor

(101)
$$\mathcal{A} \to \Gamma\colon A \mapsto \sum_{(a,a^*)\in \operatorname{gra} A} \frac{1}{n_A} R_{A,(a,a^*)}, \quad \text{where } n_A \text{ is the number of points in } \operatorname{gra} A,$$

is primal-dual symmetric.

Proof. On the one hand, both methods produce polyhedral continuous functions with a *full domain*. On the other hand, the Fenchel conjugates of such functions have a *bounded domain*. ∎

Since antiderivatives are only (and at best; see Example 3.12) unique up to a constant, it is perhaps surprising that primal-dual symmetric methods even exist. The remainder of this section is devoted to the derivation of such methods. We shall require several known notions, which we review now.

Let $A\colon X \rightrightarrows X$ be a monotone operator. The *resolvent* of A is (the single-valued, firmly nonexpansive operator) $J_A := (\operatorname{Id}+A)^{-1}$, where Id denotes the identity operator. A classical result due to Minty [16] asserts that J_A has a full domain if and only if A is maximal monotone. The proof of the following result is straightforward and hence omitted.

PROPOSITION 4.8. *Let $A\colon X \rightrightarrows X$ and $B\colon X \rightrightarrows X$ be monotone operators. Then the following are equivalent:*

(i) $\operatorname{gra} A \subseteq \operatorname{gra} B$.
(ii) $\operatorname{gra} A^{-1} \subseteq \operatorname{gra} B^{-1}$.
(iii) *J_B is an extension of J_A; i.e., $J_B = J_A$ on $\operatorname{dom} J_A = \operatorname{ran}(\operatorname{Id}+A)$.*

We further recall that, given $f \in \Gamma$, the *proximal mapping* [17] of f is $\operatorname{Prox}(f) := J_{\partial f}$. It is clear from the definition that, for two points x and x^* in X, one has

$$x^* \in \partial f(x) \quad \Leftrightarrow \quad x = \operatorname{Prox}(f)(x + x^*). \tag{102}$$

PROPOSITION 4.9. *Let $f \in \Gamma$, let $(a, a^*) \in \operatorname{gra} \partial f$, and suppose that $y \in N_{\operatorname{dom} f}(a)$. Then $a = \operatorname{Prox}(f)(2y + a + a^*)$.*

Proof. Since $N_{\operatorname{dom} f}(a)$ is a cone, we have $2y \in N_{\operatorname{dom} f}(a)$. Hence $2y + a + a^* \in a + a^* + \partial\iota_{\operatorname{dom} f}(a) \subseteq a + \partial f(a) + \partial\iota_{\operatorname{dom} f}(a) \subseteq a + \partial(f + \iota_{\operatorname{dom} f})(a) = a + \partial f(a) = (\operatorname{Id}+\partial f)(a)$, and thus $a = \operatorname{Prox}(f)(2y + a + a^*)$. ∎

We need one more notion.

DEFINITION 4.10. *Let $f_0 \in \Gamma$, and let $f_1 \in \Gamma$. The* proximal midpoint average *of f_0 and f_1 is the function*

$$\mathcal{P}(f_0, f_1) := \Big(\tfrac{1}{2}\big(f_0 + \tfrac{1}{2}\|\cdot\|^2\big)^* + \tfrac{1}{2}\big(f_1 + \tfrac{1}{2}\|\cdot\|^2\big)^*\Big)^* - \tfrac{1}{2}\|\cdot\|^2. \tag{103}$$

The proximal average, which is a generalization of the proximal midpoint average with a parameter $\lambda \in [0, 1]$ (the choice $\lambda = \frac{1}{2}$ yields the proximal midpoint average), was introduced in [6] and further studied in [4, 5, 8].

We require the following properties.

FACT 4.11. *Let $f_0 \in \Gamma$, and let $f_1 \in \Gamma$. Then the following hold:*

(i) $\mathcal{P}(f_0, f_1) = \mathcal{P}(f_1, f_0)$.
(ii) $(\mathcal{P}(f_0, f_1))^* = \mathcal{P}(f_0^*, f_1^*)$.
(iii) $\mathcal{P}(f_0, f_1) \in \Gamma$.
(iv) $\operatorname{Prox}(\mathcal{P}(f_0, f_1)) = \frac{1}{2}\operatorname{Prox}(f_0) + \frac{1}{2}\operatorname{Prox}(f_1)$.
(v) *If $f_0 \le f_1$, then $f_0 \le \mathcal{P}(f_0, f_1) \le f_1$.*
(vi) $(\forall \gamma \in \mathbb{R})\ \mathcal{P}(f_0, f_0 + \gamma) = f_0 + \frac{1}{2}\gamma$.

Proof. (i): This is clear from the definition. (ii): See [6, Theorem 6.1]. (iii): This follows from (ii). (iv): See [6, Theorem 6.1]. (v) and (vi) follow readily from the definition. (See also [5, Remark 4.15 and Example 7.1].) ∎

COROLLARY 4.12. *Let $A\colon X \rightrightarrows X$ be cyclically monotone, and let f_0 and f_1 be antiderivatives of A. Then $\mathcal{P}(f_0, f_1)$ is also an antiderivative of A.*

Proof. By assumption, $\operatorname{gra} A \subseteq \operatorname{gra} \partial f_0$ and $\operatorname{gra} A \subseteq \operatorname{gra} \partial f_1$. Using Proposition 4.8, we see that both $\operatorname{Prox}(f_0)$ and $\operatorname{Prox}(f_1)$ extend J_A. Thus, by Fact 4.11(iv), $\operatorname{Prox}(\mathcal{P}(f_0, f_1))$ also extends J_A. Utilizing Proposition 4.8 once more, we deduce that $\mathcal{P}(f_0, f_1)$ is an antiderivative of A. ∎

We are now ready for our main result.

THEOREM 4.13 (symmetrization). *Let $m\colon \mathcal{A} \to \Gamma\colon A \mapsto m_A$ be an intrinsic method. Set*

$$\mathfrak{m}\colon \mathcal{A} \to \Gamma\colon A \mapsto \mathcal{P}\big(m_A, m^*_{A^{-1}}\big). \tag{104}$$

Then $\mathfrak{m}$ is a primal-dual symmetric intrinsic method.

Proof. Fix $A \in \mathcal{A}$. Observe that Corollaries 2.12 and Corollary 4.12 imply that $\mathfrak{m}_A$ is an antiderivative of A; thus, $\mathfrak{m}$ is an intrinsic method. On the one hand, the definitions and Fact 4.11(i) yield

$$\mathfrak{m}_{A^{-1}} = \mathcal{P}\big(m_{A^{-1}}, m^*_{(A^{-1})^{-1}}\big) = \mathcal{P}\big(m_{A^{-1}}, m^*_A\big) = \mathcal{P}\big(m^*_A, m_{A^{-1}}\big). \tag{105}$$

On the other hand, Fact 4.11(ii) implies

$$\mathfrak{m}^*_A = \Big(\mathcal{P}\big(m_A, m^*_{A^{-1}}\big)\Big)^* = \mathcal{P}\big(m^*_A, m^{**}_{A^{-1}}\big) = \mathcal{P}\big(m^*_A, m_{A^{-1}}\big). \tag{106}$$

Altogether, we obtain that $\mathfrak{m}_{A^{-1}} = \mathfrak{m}^*_A$. Therefore, $\mathfrak{m}$ is primal-dual symmetric. ∎

Example 4.14. Let $m\colon \mathcal{A} \to \Gamma\colon A \mapsto m_A$ be intrinsic, and set $\mathfrak{m}\colon \mathcal{A} \to \Gamma\colon A \mapsto \mathcal{P}(m_A, m^*_{A^{-1}})$. Let $A \in \mathcal{A}$ be such that $\operatorname{gra} A \subset \operatorname{gra} \operatorname{Id}$. Then $\mathfrak{m}_A = \frac{1}{2}\|\cdot\|^2$.

Proof. Since $A = A^{-1}$, we have $\mathfrak{m}^*_A = (\mathcal{P}(m_A, m^*_{A^{-1}}))^* = (\mathcal{P}(m_A, m^*_A))^* = \mathcal{P}(m^*_A, m^{**}_A) = \mathcal{P}(m^*_A, m_A) = \mathcal{P}(m_A, m^*_A) = \mathcal{P}(m_A, m^*_{A^{-1}}) = \mathfrak{m}_A$, and the result follows. ∎

Before we present further applications of Theorem 4.13, let us discuss a non-intrinsic variant based on the original Rockafellar function.

THEOREM 4.15. *Let $A\colon X \rightrightarrows X^*$ be cyclically monotone, and let $(a, a^*) \in \operatorname{gra} A$. Set*

$$f_{A,(a,a^*)} := \mathcal{P}\big(R_{A,(a,a^*)}, R^*_{A^{-1},(a^*,a)}\big). \tag{107}$$

Then $f^*_{A,(a,a^*)} = f_{A^{-1},(a^*,a)} := \mathcal{P}\big(R_{A^{-1},(a^*,a)}, R^*_{A,(a,a^*)}\big)$. Moreover,

$$A \text{ is maximal cyclically monotone } \Rightarrow\ f_{A,(a,a^*)} = R_{A,(a,a^*)} + \tfrac{1}{2}\langle a, a^*\rangle. \tag{108}$$

Proof. The proof of $f^*_{A,(a,a^*)} = f_{A^{-1},(a^*,a)}$ is analogous to the one of Theorem 4.13. Now assume that A is maximal cyclically monotone. Since $R_{A,(a,a^*)}$ is an antiderivative of A and $R_{A^{-1},(a^*,a)}$ is an antiderivative of A^{-1}, there exists $\gamma \in \mathbb{R}$ such that

$$R^*_{A^{-1},(a^*,a)} = R_{A,(a,a^*)} + \gamma. \tag{109}$$

Conjugating (109) followed by evaluating at a^* yields $0 = R^*_{A,(a,a^*)}(a^*) - \gamma = \langle a, a^*\rangle - R_{A,(a,a^*)}(a) - \gamma = \langle a, a^*\rangle - \gamma$. Hence

$$R^*_{A^{-1},(a^*,a)} = R_{A,(a,a^*)} + \langle a, a^*\rangle, \tag{110}$$

and this readily implies that $f_{A,(a,a^*)} = \mathcal{P}(R_{A,(a,a^*)}, R_{A,(a,a^*)} + \langle a, a^*\rangle) = R_{A,(a,a^*)} + \frac{1}{2}\langle a, a^*\rangle$. ∎

If the intrinsic method m in Theorem 4.13 produces "nice" antiderivatives, then so does sometimes the symmetrized method $\mathfrak{m}$. Before we state the corresponding result more precisely, we recall the required properties of the proximal midpoint average. Since these properties were stated in finite-dimensional Hilbert spaces, we assume from now on that

$$X \text{ is a finite-dimensional Hilbert space.} \tag{111}$$

Recall that $f \in \Gamma$ is *piecewise linear-quadratic* if $\operatorname{dom} f$ can be written as a finite union of polyhedral sets on which f is of the form $\langle x, Ax\rangle + \langle x, b\rangle + \gamma$, where $A\colon X \to X$ is linear, $b \in X$, and $\gamma \in \mathbb{R}$. The piecewise linear-quadratic functions on X have many nice properties; see [21, sections 10.E and 11.D].

FACT 4.16. *Let $f_0 \in \Gamma$, and let $f_1 \in \Gamma$ be such that f_0 and f_1^* have a full domain. Then the following hold:*

(i) *$\mathcal{P}(f_0, f_1)$ and $\mathcal{P}(f_0^*, f_1^*)$ have a full domain.*
(ii) *If f_0 and f_1 are piecewise linear-quadratic, then so is $\mathcal{P}(f_0, f_1)$.*
(iii) *If f_0 is differentiable and f_1 is strictly convex, then both $\mathcal{P}(f_0, f_1)$ and its conjugate are differentiable and strictly convex.*

Proof. (i): See [5, Theorem 6.2.(i)]. (ii): The functions f_0, f_1, and $\frac{1}{2}\|\cdot\|^2$ are piecewise linear-quadratic. The operations employed to create $\mathcal{P}(f_0, f_1)$ do not lead outside the class of piecewise linear-quadratic functions; consequently, $\mathcal{P}(f_0, f_1)$ is piecewise linear-quadratic as well. (See also [15, Corollary 5.3].) (iii): This follows from (i) and [5, Theorems 6.2.(ii) and 6.2.(iii)]. ∎

COROLLARY 4.17. *Let $m\colon \mathcal{A} \to \Gamma\colon A \mapsto m_A$ be an intrinsic method that produces antiderivatives with a full domain. Set*

$$\mathfrak{m}\colon \mathcal{A} \to \Gamma\colon A \mapsto \mathcal{P}\big(m_A, m_{A^{-1}}^*\big). \tag{112}$$

Then $\mathfrak{m}$ is a primal-dual symmetric intrinsic method, and the following hold:

(i) *$(\forall A \in \mathcal{A})$ $\mathfrak{m}_A$ and $\mathfrak{m}_A^*$ have a full domain.*
(ii) *If $(\forall A \in \mathcal{A})$ m_A is piecewise linear-quadratic, then $(\forall A \in \mathcal{A})$ $\mathfrak{m}_A$ and $\mathfrak{m}_A^*$ are both piecewise linear-quadratic.*

Proof. Theorem 4.13 states that $\mathfrak{m}$ is primal-dual symmetric. Now fix $A \in \mathcal{A}$, set $f_0 := m_A$, and set $f_1 := m_{A^{-1}}^*$. Then $\mathfrak{m}_A = \mathcal{P}(f_0, f_1)$ and, by Fact 4.11(i) and (ii), $\mathfrak{m}_A^* = \mathcal{P}(f_0^*, f_1^*) = \mathcal{P}(f_1^*, f_0^*)$. (i): Since f_0 and f_1^* have a full domain, Fact 4.16(i) (applied to f_0 and f_1 and to f_1^* and f_0^*) implies that $\mathfrak{m}_A$ and $\mathfrak{m}_A^*$ have a full domain. (ii): This is clear from Fact 4.16(ii). ∎

Remark 4.18. Consider Corollary 4.17. In general, antiderivatives are neither differentiable nor strictly convex. However, if for a particularly nice instance $A \in \mathcal{A}$ both m_A and $m_{A^{-1}}$ are differentiable, then we deduce from Fact 4.16(iii) that $\mathfrak{m}_A$ and $\mathfrak{m}_A^*$ are both differentiable and strictly convex. Analogous comments can be made for other symmetrizations of (not necessarily intrinsic) methods based on the proximal midpoint average.

We are now able to provide two examples of primal-dual symmetric intrinsic methods with very nice properties. These are in striking contrast to Proposition 4.7.

Example 4.19. Set $m\colon \mathcal{A} \to \Gamma\colon A \mapsto \max_{(a,a^*)\in \operatorname{gra} A} R_{A,(a,a^*)}$ and $\mathfrak{m}\colon \mathcal{A} \to \Gamma\colon A \mapsto \mathcal{P}(m_A, m_{A^{-1}}^*)$. Then $\mathfrak{m}$ is a primal-dual symmetric intrinsic method, and for every $A \in \mathcal{A}$ both $\mathfrak{m}_A$ and $\mathfrak{m}_A^*$ have a full domain and are piecewise linear-quadratic antiderivatives of A and A^{-1}, respectively.

Proof. For every $A \in \mathcal{A}$, m_A is a convex polyhedral (hence piecewise linear-quadratic) antiderivative of A with full domain (Example 4.4). The conclusion is now a consequence of Corollary 4.17. □

Example 4.20. Set $m\colon \mathcal{A} \to \Gamma\colon A \mapsto \frac{1}{n_A}\sum_{(a,a^*)\in \operatorname{gra} A} R_{A,(a,a^*)}$, where n_A is the number of points in $\operatorname{gra} A$, and $\mathfrak{m}\colon \mathcal{A} \to \Gamma\colon A \mapsto \mathcal{P}(m_A, m^*_{A^{-1}})$. Then $\mathfrak{m}$ is a primal-dual symmetric intrinsic method, and for every $A \in \mathfrak{m}$ both $\mathfrak{m}_A$ and $\mathfrak{m}^*_A$ have a full domain and are piecewise linear-quadratic antiderivatives of A and A^{-1}, respectively.

Proof. For every $A \in \mathcal{A}$, m_A is a convex polyhedral (hence piecewise linear-quadratic) antiderivative of A with a full domain (Example 4.5). The conclusion follows from Corollary 4.17. □

In the remainder of this section, we aim to extract further nice properties enjoyed by these two methods. We require the following results on the proximal midpoint average.

PROPOSITION 4.21. *Let $f_0 \in \Gamma$, let $f_1 \in \Gamma$, and set $f := \mathcal{P}(f_0, f_1)$. Suppose that $a^* \in \partial f_0(a) \cap \partial f_1(a)$. Then*

$$\big(\forall x \in N_{\operatorname{dom} f_0}(a) \cap N_{\operatorname{dom} f_1^*}(a^*)\big) \quad x + a^* \in \partial f(x + a). \tag{113}$$

Proof. Take $x \in N_{\operatorname{dom} f_0}(a) \cap N_{\operatorname{dom} f_1^*}(a^*)$. Proposition 4.9 yields

$$a = \operatorname{Prox}(f_0)(2x + a + a^*). \tag{114}$$

The same result (applied to f_1^*) shows that $a^* = \operatorname{Prox}(f_1^*)(2x + a^* + a)$, which is equivalent to $a^* = (\operatorname{Id} - \operatorname{Prox}(f_1))(2x + a + a^*)$, i.e., to

$$2x + a = \operatorname{Prox}(f_1)(2x + a + a^*). \tag{115}$$

Add (114) and (115), divide the result by 2, and recall Fact 4.11(iv) to deduce that

$$x + a = \operatorname{Prox}(f)\big((x + a) + (x + a^*)\big). \tag{116}$$

The conclusion now follows from (102). □

THEOREM 4.22. *Let $f_0 \in \Gamma$, let $f_1 \in \Gamma$, and set $f := \mathcal{P}(f_0, f_1)$. Suppose that $a^* \in \partial f_0(a) \cap \partial f_1(a)$, and set $N := (N_{\operatorname{dom} f_0}(a) \cap N_{\operatorname{dom} f_1^*}(a^*)) \cup (N_{\operatorname{dom} f_1}(a) \cap N_{\operatorname{dom} f_0^*}(a^*))$. Then the following hold:*

(i) $(\forall y \in a + N)\ y + a^* - a \in \partial f(y)$.

(ii) *f is differentiable at every point $y \in a + \operatorname{int} N$, with $\nabla f(y) = y + a^* - a$.*

Proof. Proposition 4.21 implies (i). On $a + \operatorname{int} N$, we note that $y \mapsto y + a^* - a$ is a continuous selection of ∂f; therefore, $\nabla f(y) = y + a^* - a$ by [18, Proposition 2.8], and (ii) holds. □

COROLLARY 4.23. *Let $m\colon \mathcal{A} \to \Gamma\colon A \mapsto m_A$ be an instrinsic method such that, for every $A \in \mathcal{A}$, $\overline{\operatorname{ran} \partial m_A} \subseteq \operatorname{conv} \operatorname{ran} A$. Set*

$$\mathfrak{m}\colon \mathcal{A} \to \Gamma\colon A \mapsto \mathcal{P}\big(m_A, m^*_{A^{-1}}\big), \tag{117}$$

take $A \in \mathcal{A}$, take $(a, a^*) \in \operatorname{gra} A$, and set $N := N_{\operatorname{conv} \operatorname{dom} A}(a) \cap N_{\operatorname{conv} \operatorname{ran} A}(a^*)$. Then the following hold:

(i) $(\forall y \in a + N)\ y + a^* - a \in \partial \mathfrak{m}_A(y)$.

(ii) $(\forall y \in a + \operatorname{int} N)\ \mathfrak{m}_A$ *is differentiable at* y, *with* $\nabla \mathfrak{m}_A(y) = y + a^* - a$.

Proof. Set $f_0 := m_A$, and set $f_1 := m^*_{A^{-1}}$ so that $\mathfrak{m}_A = \mathcal{P}(f_0, f_1)$. Proposition 3.2 implies that $\operatorname{dom} f_0^* = \operatorname{dom} m_A^* = \operatorname{conv} \operatorname{ran} A$ and that $\operatorname{dom} f_1 = \operatorname{dom} m^*_{A^{-1}} = \operatorname{conv} \operatorname{ran} A^{-1} = \operatorname{conv} \operatorname{dom} A$. The conclusion is therefore a consequence of Theorem 4.22. ∎

Remark 4.24. In view of Examples 4.4 and 4.5, we observe that Corollary 4.23 is applicable when m is either as in Example 4.19 or as in Example 4.20.

Example 4.25. Let m and $\mathfrak{m}$ be as in Corollary 4.23, let $(a, a^*) \in X \times X$, and suppose that $A\colon X \rightrightarrows X$ is given by $\operatorname{gra} A = \{(a, a^*)\}$. Then there exists $\gamma \in \mathbb{R}$ such that $\mathfrak{m}_A = \frac{1}{2}\|\cdot\|^2 + \langle \cdot, a^* - a\rangle + \gamma$.

Proof. Indeed, the set N in Corollary 4.23 is the entire space X, and hence item (ii) of that result implies that $\nabla \mathfrak{m}_A\colon X \to X\colon x \mapsto x + a^* - a$. ∎

We observe next that, on the real line, the subdifferential extending A is actually single-valued—i.e., it corresponds to a gradient—with slope one outside the box $(\operatorname{conv} \operatorname{dom} A) \times (\operatorname{conv} \operatorname{ran} A)$.

COROLLARY 4.26. *Suppose that* $X = \mathbb{R}$, *let* m *and* $\mathfrak{m}$ *be as in Corollary* 4.23, *and let* $A\colon \mathbb{R} \rightrightarrows \mathbb{R}$ *have finite graph* $\{(a_1, a_1^*), \ldots, (a_n, a_n^*)\}$, *where* $a_1 \le a_2 \le \cdots \le a_n$ *and* $a_1^* \le a_2^* \le \cdots \le a_n^*$. *Then*

$$(118)\quad (\forall x < a_1)\quad \mathfrak{m}'_A(x) = x - a_1 + a_1^* \qquad \text{and} \qquad (\forall x > a_n)\quad \mathfrak{m}'_A(x) = x - a_n + a_n^*.$$

Proof. Since $\operatorname{conv} \operatorname{dom} A = [a_1, a_n]$ and $\operatorname{conv} \operatorname{ran} A = [a_1^*, a_n^*]$, the result follows from Corollary 4.23(ii) (applied at (a_1, a_1^*) and at (a_n, a_n^*)). ∎

Remark 4.27. Primal-dual symmetry and the "slope one" property of the extension of the cyclically monotone operator A in Corollary 4.26 were properties deemed desirable by Rockafellar. In view of Remark 4.24, there exist two explicit methods that generate antiderivatives with these desirable properties. Although not the product of an intrinsic method, the function $f_{A,(a,a^*)}$ of Theorem 4.15 has the same properties.

We conclude this paper by numerically illustrating an antiderivative produced by the primal-dual symmetric intrinsic method of Example 4.19.

Example 4.28. Define $A\colon \mathbb{R} \rightrightarrows \mathbb{R}$ via $\operatorname{gra} A := \{(a, \exp(a)) \mid a \in \{0, \pm\frac{1}{2}, \pm 1\}\}$. Because $\operatorname{gra} A \subset \operatorname{gra}(\exp)$, the operator A is cyclically monotone. We interpret A as a 5-point sample of the gradient of the exponential function. Let m and $\mathfrak{m}$ be as in Example 4.19. Figure 1 visualizes the exponential function, the antiderivative m_A, the antiderivative $m^*_{A^{-1}}$, and the antiderivative $\mathfrak{m}_A$ produced by the primal-dual symmetric intrinsic method $\mathfrak{m}$. As predicted by Corollary 3.20, the function m_A is nonnegative on $\operatorname{dom} A$. In Figure 2, we visualized the derivative of the exponential function, its 5-point sample corresponding to A, and the maximal cyclically monotone extension $\partial \mathfrak{m}_A$. Note that by Theorem 3.14 the Rockafellar functions are piecewise linear, and hence their subdifferential operators have a "staircase" graph. On the other hand, $\mathfrak{m}_A$ is piecewise linear-quadratic, and its subdifferential operator displays the "slope one" property guaranteed by Corollary 4.26 outside the rectangle $\operatorname{dom} A \times \operatorname{ran} A$. Both plots were generated in Scilab utilizing software packages discussed in [15]; further details on the numerical implementation will appear elsewhere.

Acknowledgments. The authors thank Jean-Baptiste Hiriart-Urruty for making them aware of [14] and two referees for their pertinent comments.

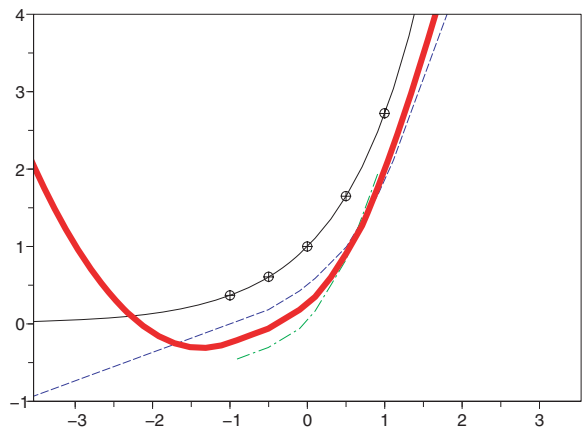

FIG. 1. *The graph of the exponential function (thin black curve) and the* 5 *points (circled) on its graph that led to the operator* A*, the antiderivative* m_A *(dashed blue curve), the antiderivative* $m^*_{A^{-1}}$ *(dashed-dotted green curve), and the proximal-average-based antiderivative* $\mathfrak{m}_A$ *(thick red curve) are shown. Note that* $m_A \geq 0$ *on* $\operatorname{dom} A$*, in accordance with Corollary* 3.20.

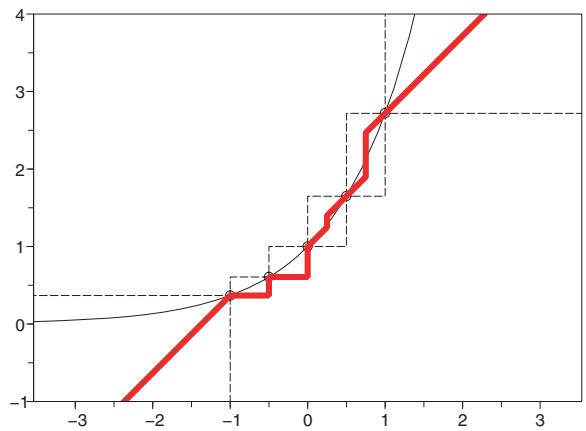

FIG. 2. *The finite graph operator* A *is shown as points (circled) on the graph of the exponential function (thin black curve), which is the same as its derivative. The reconstructed subdifferential operator* $\partial\mathfrak{m}_A$ *(thick red curve) stays inside the rectangles (dashed line) imposed on any monotone extension of* A*. Note the "slope one" property of* $\partial\mathfrak{m}_A$ *outside the rectangle* $\operatorname{conv}\operatorname{dom} A \times \operatorname{conv}\operatorname{ran} A$*, as guaranteed by Corollary* 4.26.

COMPUTING THE L_1-NORM OF CONTINUOUS-TIME LINEAR SYSTEMS*

ARNO LINNEMANN†

Abstract. An algorithm is presented for the computation of the L_1-norm of a linear time-invariant continuous-time system. It is based on the numerical integration of the impulse response and is shown to be quadratically convergent.

Key words. system norm, L_1-norm, computation, impulse response, matrix exponential, sensitivity, integration, trapezoidal rule, nondifferentiable integrand, truncation error, control system

1. Introduction.

System norms are an established tool for measuring performance and robustness of linear systems. Most important are the H_∞-, H_2-, and L_1-norms. Therefore, efficient and reliable algorithms for the computation of these norms are required. The H_2-norm is easiest to compute using appropriate Lyapunov equations. The H_∞-norm can be determined by analyzing the eigenvalues of an associated Hamiltonian matrix, and a careful implementation of corresponding algorithms works fine in most cases. See [2, 4, 6, 7, 9, 10, 14] and the references given therein. In contrast to these results, almost nothing is known regarding the computation of the L_1-norm. For stable single-input single-output continuous-time linear systems

$$\Sigma: \quad \dot{x} = Ax + Bu,\ y = Cx \tag{1}$$

the L_1-norm is given by

$$||\Sigma|| := \int_0^\infty |Ce^{At}B|\, dt. \tag{2}$$

To compute an estimate of the L_1-norm, it is generally advised (see, e.g., [3]) to numerically integrate the function $|Ce^{At}B|$ over a finite interval, where the discrete function values are obtained by simulating the differential equation.

A straightforward implementation of this approach faces two main problems. First, the integrand is nondifferentiable, so that rather slow convergence of standard numerical integration algorithms is expected [12]. Second, it is not clear how the truncation error (obtained by integrating over a finite interval only) behaves.

This paper presents an efficient and reliable algorithm to compute the L_1-norm using the above "simulate and integrate" approach. More specifically, it is shown how the standard trapezoidal rule of numerical integration can be modified to efficiently handle the nondifferentiable integrand. It is shown that the new numerical integration procedure converges quadratically. Moreover, the truncation error is estimated by a computable L_2-norm using the Hölder inequality. Finally, and most importantly for

†Control and Automation, Department of Electrical Engineering and Computer Science, University of Kassel, D-34109 Kassel, Germany (linnemann@uni-kassel.de).

quick convergence in applications, very efficient bounds for the impulse response are derived. These bounds can be employed to integrate without any error in many time intervals, and with relatively small errors in other intervals.

The paper is organized as follows. In section 2, a basic algorithm is described to compute an estimate of the L_1-norm for given discretization points $t_1, t_2, \ldots, t_N$. The details of the algorithm and the underlying theory are developed in sections 3 to 5. Section 6 shows how to adaptively add discretization points to the list $t_1, t_2, \ldots, t_N$ in order to systematically improve the norm estimate. This results in a quadratically convergent algorithm, which computes the L_1-norm to any given accuracy in finitely many steps. Section 7 provides an estimate of the computational cost, and section 8 presents some examples. Sections 2 to 8 are devoted to the single-input single-output case. Extensions to multivariable systems with feedthrough are presented in section 9. The proofs are collected in Appendices A to E. Appendix F contains a closed formula for the L_1-norm of second order systems.

2. The basic algorithm. In this section, an algorithm is described to compute the L_1-norm of a linear system Σ along with a guaranteed error bound. This means that an estimate η for the norm and an error bound ε are computed such that

$$\big|\|\Sigma\| - \eta\,\big| \le \varepsilon. \tag{3}$$

The algorithm is based on the numerical integration of the absolute value of the impulse response

$$g(t) := Ce^{At}B,$$

defined by the matrices $A \in \mathbb{R}^{n\times n}$, $B \in \mathbb{R}^{n\times 1}$, and $C \in \mathbb{R}^{1\times n}$ in (1). It is assumed that the discretization points $t_1 = 0 < t_2 < t_3 < \cdots < t_N$ are given and fixed. The multivariable case and an adaptive version of the algorithm, where the discretization grid is automatically refined and enlarged, are presented later in this paper.

The basic algorithm consists of N parts, namely, to find $\eta_1, \ldots, \eta_{N-1}$ and $\varepsilon_1, \ldots, \varepsilon_{N-1}$ such that

$$\left|\ \int_{t_i}^{t_{i+1}} |g(t)|\,dt - \eta_i\ \right| \le \varepsilon_i,$$

$i = 1, 2, \ldots, N-1$, and to find ε_N such that

$$\int_{t_N}^{\infty} |g(t)|\,dt \le \varepsilon_N.$$

The norm estimate and the associated error in (3) are then given by $\eta = \sum_{i=1}^{N-1} \eta_i$ and $\varepsilon = \sum_{i=1}^{N} \varepsilon_i$, respectively. The numbers $\varepsilon_1, \ldots, \varepsilon_{N-1}$ and the number ε_N are bounds for the so-called approximation and truncation errors, respectively.

The intervals $[t_i, t_{i+1}]$, $i = 1, \ldots, N-1$, can be divided into two categories: The first category consists of those intervals in which it can be guaranteed that $g(t)$ does not change sign. In these intervals, the integral can be exactly computed:

$$\eta_i = \left|CA^{-1}\left(e^{At_{i+1}}B - e^{At_i}B\right)\right|; \quad \varepsilon_i = 0. \tag{4}$$

The second category consists of those intervals which involve a possible sign change in $g(t)$. In these intervals, the estimate η_i can be computed using numerical integration and ε_i is an associated error bound.

To numerically exclude sign changes, lower and upper bounds $\underline{G}_i$ and $\overline{G}_i$ are computed such that

$$\underline{G}_i \le g(t) \le \overline{G}_i, \quad t \in [t_i, t_{i+1}]. \tag{5}$$

The tighter these bounds are, the more intervals exist where the integral is computed using (4) without approximation error. Therefore, the efficiency of the algorithm depends crucially on these bounds. A large part of this paper (section 3 and Appendices A–C) is devoted to deriving new and efficient bounds $\underline{G}_i$ and $\overline{G}_i$.

In the second category, the standard Newton–Cotes formulas of numerical integration cannot be applied, because the associated error bounds assume differentiability of the integrand [12]. Therefore, in section 4 of this paper, the trapezoidal rule and the associated error bounds are modified to be applicable to the possible nondifferentiable integrand $|g(t)|$. They require bounds on $\ddot{g}(t) = CA^2e^{At}B$, which can again be computed using the results of section 3. The resulting bounds $\varepsilon_1, \ldots, \varepsilon_{N-1}$ for the approximation error are new and computable. They are very efficient, since they are either zero or proportional to $(t_{i+1} - t_i)^3$.

The bound ε_N for the truncation error is determined in section 5 by relating the L_1-norm to the L_2-norm using the Hölder inequality and exponential weighting [5].

3. Bounds for the impulse response. The performance of the algorithm presented in section 2 depends crucially on bounds $\underline{G}_i$ and $\overline{G}_i$ such that (5) is satisfied. In this section, these bounds are derived by taking ideas from [11, 13]. These references present various bounds for the sensitivity of the matrix exponential $e^{A+\Delta}$, where Δ is an unstructured perturbation matrix of the same size as A. They show that the tightest bounds are generally provided by the diagonal form, provided the condition number $||S|| \cdot ||S^{-1}||$ of the eigenvector matrix of A is not too large. For an ill-conditioned eigenvector matrix or for multiple eigenvalues, the Schur form provides tighter bounds; see [11, 13]. The advantages of both approaches (diagonal form and Schur form) can be combined by considering a block-diagonal ordered upper-triangular (BDOUT) form, which can be computed using an algorithm suggested in [1]. More specifically, a matrix $A \in \mathbb{C}^{n\times n}$ is said to be in BDOUT form if $A = D + N$, where D is diagonal with eigenvalues ordered according to decreasing real parts and N is strictly upper triangular and block diagonal. More specifically, for stable matrices A,

$$D = \begin{bmatrix} \lambda_1 & 0 & \cdots & 0 \\ 0 & \ddots & \ddots & \vdots \\ \vdots & \ddots & \ddots & 0 \\ 0 & \cdots & 0 & \lambda_n \end{bmatrix}, \quad \lambda_i = \alpha_i + j\omega_i,\ \omega_i \in \mathbb{R},\ \alpha_n \le \alpha_{n-1} \le \cdots \le \alpha_1 < 0,$$

$$N = \begin{bmatrix} N_1 & 0 & \cdots & 0 \\ 0 & \ddots & \ddots & \vdots \\ \vdots & \ddots & \ddots & 0 \\ 0 & \cdots & 0 & N_k \end{bmatrix}, \ N_j = \begin{bmatrix} 0 & a_{j12} & \cdots & a_{j1n_j} \\ \vdots & \ddots & \ddots & \vdots \\ \vdots & & \ddots & a_{j,n_j-1,n_j} \\ 0 & \cdots & \cdots & 0 \end{bmatrix} \in \mathbb{C}^{n_j\times n_j}.$$

Note that the diagonal form, the Jordan form, and the Schur form are special cases of the BDOUT form. Reference [1] describes an algorithm to put a matrix A into BDOUT form by similarity transformations, where the dimensions n_j of the blocks are as small as possible while avoiding ill-conditioned similarity transformations. Note

that similarity transformations SAS^{-1}, SB, CS^{-1} do not affect $g(t)$, so that, without loss of generality, it will be assumed that A is in BDOUT form.

The bounds $\underline{G}_i$ and $\overline{G}_i$ refer to a "perturbation" of the time t in the matrix exponential e^{At}. Compared to the perturbations Δ in [11, 13] this means that Δ has the very special structure $\Delta = A\tau$, where τ is a scalar perturbation. It is clear that much stronger results can be expected under this restricted perturbation class. This is the topic of the present section.

For a (possibly complex) matrix X, let $|X|$ be the real matrix of the same size as X, which is obtained by taking the absolute value componentwise. Moreover, for a (possibly complex) matrix A and a positive scalar T, let

$$\delta(A,T) := \max\{|e^{At} - I|;\ 0 \le t \le T\},$$

where the maximum is taken componentwise. Thus, $\delta(A,T)$ is a matrix of the same size as A.

3.1. Using perturbation results. Taking $T := t_{i+1} - t_i$, the following bounds are obvious:

$$\underline{G}_i := g(t_i) - |C| \cdot \delta(A,T) \cdot |e^{At_i}B|; \quad \overline{G}_i := g(t_i) + |C| \cdot \delta(A,T) \cdot |e^{At_i}B|.$$

"Pulling out" C and $e^{At_i}B$ componentwise using $|\cdot|$, rather than in terms of norms, generally results in tighter bounds, which can be seen from very simple examples like $C = [1\ 1]$, $e^{At_i}B = [1;\ 1]$, $\delta(A,T) = [1\ 1;\ 1\ 0]$. Since $g(t_i)$ and $e^{At_i}B$ are available from the simulation, it remains to derive bounds for $\delta(A,T)$.

If A is diagonal, then $\delta(A,T)$ is also diagonal, with ith entry given by $\delta(\lambda_i,T)$. If λ_i is real, then $\delta(\lambda_i,T)$ can be efficiently bounded by $1 - e^{\lambda_i T}$. The following lemma handles complex λ_i's. Its proof is given in Appendix A.

LEMMA 1. *Let $\lambda = \alpha + j\omega$, $\alpha < 0$, $\omega \neq 0$, and $T > 0$ be given. Let η be an arbitrary number such that $0 \le \eta \le 1$. Then $\delta(\lambda,T) \le \hat{\delta}(\lambda,T,\eta)$, where*

$$\hat{\delta}(\lambda,T,\eta) := \begin{cases} e^{|\lambda|T} - 1 & \text{if} \quad T \le t_1, \\ \max\{\eta,\ (1 + e^{2\alpha t_1} - 2e^{\alpha T}\cos(\omega T))^{\frac{1}{2}}\} & \text{if} \quad t_1 \le T \le t_2, \\ (1 + e^{2\alpha t_1} - 2e^{\alpha t_2}\cos(\omega t_2))^{\frac{1}{2}} & \text{if} \quad T \ge t_2, \end{cases}$$

and

$$t_1 := \frac{\ln(1+\eta)}{|\lambda|}, \quad t_2 := \frac{1}{|\omega|}\left(\pi + \arctan\left(\frac{\alpha}{|\omega|}\right)\right).$$

Given λ, T, and η, the bound $\hat{\delta}(\lambda,T,\eta)$ is quickly computed. The best bound is obtained by minimizing $\hat{\delta}(\lambda,T,\eta)$ over η. This does, however, considerably increase the computational effort, and experiments suggest (see the discussion following the proof in Appendix A) that the extra computational effort is not worth the improvement as compared to $\eta = 0.4$. Thus, in the following, the bound

$$\hat{\delta}(\lambda,T) := \begin{cases} 1 - e^{\lambda T} & \text{if } \lambda \text{ is real,} \\ \hat{\delta}(\lambda,T,0.4) & \text{otherwise} \end{cases}$$

will be employed.

In the general case, when A is in BDOUT form, then $\delta(A,T)$ is also block diagonal and the jth block is given by $\delta(D_j + N_j, T)$, D_j and N_j being the jth blocks on the

diagonal of D and N, respectively. Therefore, without loss of generality, it can be assumed that the BDOUT form has one block only, i.e., $k = 1$.

The following theorem is the main result of this section. The proof is given in Appendix B.

THEOREM 1. *Let $A \in \mathbb{C}^{n\times n}$ and $T > 0$. Assume that $A = D + N$, where*

$$D = \begin{bmatrix} \lambda_1 & 0 & \cdots & 0 \\ 0 & \ddots & & \vdots \\ \vdots & \ddots & \ddots & 0 \\ 0 & \cdots & 0 & \lambda_n \end{bmatrix}, \qquad N = \begin{bmatrix} 0 & a_{12} & \cdots & a_{1n} \\ \vdots & \ddots & \ddots & \vdots \\ \vdots & & \ddots & a_{n-1,n} \\ 0 & \cdots & \cdots & 0 \end{bmatrix},$$

$\lambda_i = \alpha_i + j\omega_i$, $\omega_i \in \mathbb{R}$, and $\alpha_n \le \alpha_{n-1} \le \cdots \le \alpha_1 < 0$. Define

$$\hat{\delta}(D,T) := \begin{bmatrix} \hat{\delta}(\lambda_1,T) & 0 & \cdots & 0 \\ 0 & \ddots & & \vdots \\ \vdots & & \ddots & 0 \\ 0 & \cdots & 0 & \hat{\delta}(\lambda_n,T) \end{bmatrix},$$

$$\varepsilon_k(\lambda_i,T) := \begin{cases} e^{\alpha_i T}T^k & \text{if} \quad T \le \frac{-k}{\alpha_i}, \\ \left(\frac{-k}{\alpha_i\, e}\right)^k & \text{else} \quad (e = 2.781\ldots), \end{cases}$$

$$\varepsilon_k(D,T) := \begin{bmatrix} \varepsilon_k(\lambda_1,T) & 0 & \cdots & 0 \\ 0 & \ddots & \ddots & \vdots \\ \vdots & \ddots & \ddots & 0 \\ 0 & \cdots & 0 & \varepsilon_k(\lambda_n,T) \end{bmatrix},$$

$$\hat{\delta}(A,T) := \hat{\delta}(D,T) + \sum_{k=1}^{n-1} \frac{\varepsilon_k(D,T)\cdot |N|^k}{k!}.$$

Then

$$\delta(A,T) \le \hat{\delta}(A,T).$$

3.2. Using the second derivative. Theorem 1 can also be applied to the second derivative of g, giving the bounds

$$\underline{K}_i := \ddot{g}(t_i) - |CA^2| \cdot \hat{\delta}(A,T) \cdot \left|e^{At_i}B\right|, \tag{6}$$

$$\overline{K}_i := \ddot{g}(t_i) + |CA^2| \cdot \hat{\delta}(A,T) \cdot \left|e^{At_i}B\right|, \tag{7}$$

satisfying

$$\underline{K}_i \le \ddot{g}(t) \le \overline{K}_i, \quad t \in [t_i, t_{i+1}].$$

These bounds can be employed to estimate the approximation error in numerical integration (see the following section). Additionally, they can be used to improve the bounds $\underline{G}_i$ and $\overline{G}_i$ for g, as will be described next.

PROPOSITION 1. *Let g be twice differentiable in a neighborhood of $[a,b]$ and let $\underline{K}$, $\overline{K}$ be such that*

$$\underline{K} \le \ddot{g}(t) \le \overline{K}, \quad t \in [a,b].$$

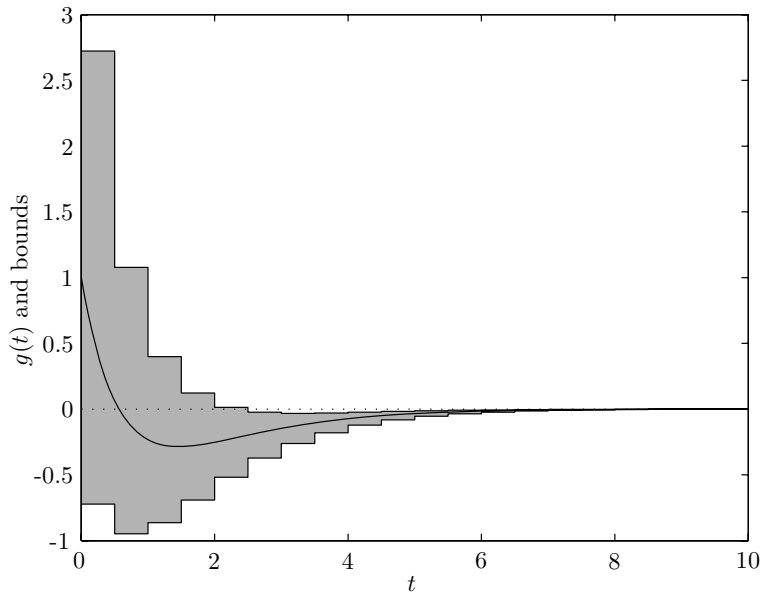

FIG. 1. *Impulse response $g(t)$ of (8) along with upper and lower bounds determined using Theorem 1.*

Then

$$\underline{H} \le g(t) \le \overline{H}, \quad t \in [a, b],$$

where

$$\underline{H} := \begin{cases} \min\{g(a), g(b)\} & \text{if} \quad \overline{K} \le 0 \quad \text{or} \quad \tau(\overline{K}) \notin [a, b], \\ \gamma(\overline{K}) & \text{else}, \end{cases}$$

$$\overline{H} := \begin{cases} \max\{g(a), g(b)\} & \text{if} \quad \underline{K} \ge 0 \quad \text{or} \quad \tau(\underline{K}) \notin [a, b], \\ \gamma(\underline{K}) & \text{else}, \end{cases}$$

$$\tau(K) := \frac{a+b}{2} - \frac{g(b) - g(a)}{K(b-a)},$$

$$\gamma(K) := \frac{g(b) - g(a)}{b-a}\,\tau(K) + \frac{g(a)b - g(b)a}{b-a} + \frac{K}{2}\,(\tau(K) - b)\,(\tau(K) - a).$$

The proof of Proposition 1 is given in Appendix C.

3.3. Example. Consider the system given by

$$A = \begin{bmatrix} -2 & 0 & 0 \\ 0 & -1 & 1 \\ 0 & 0 & -1 \end{bmatrix}, \quad B = \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}, \quad C = [1 \;\; -1 \;\; 1]. \tag{8}$$

Figures 1 and 2 show the bounds for $g(t)$ and $\ddot{g}(t)$, respectively, obtained using the results of section 3.1 for $T = 0.5$. The bounds in Figure 1 are quite poor, which motivates the extension presented in section 3.2. The bounds on the curvature in Figure 2 are still quite rough, but lead to excellent results when combined with Proposition 1; see Figure 3.

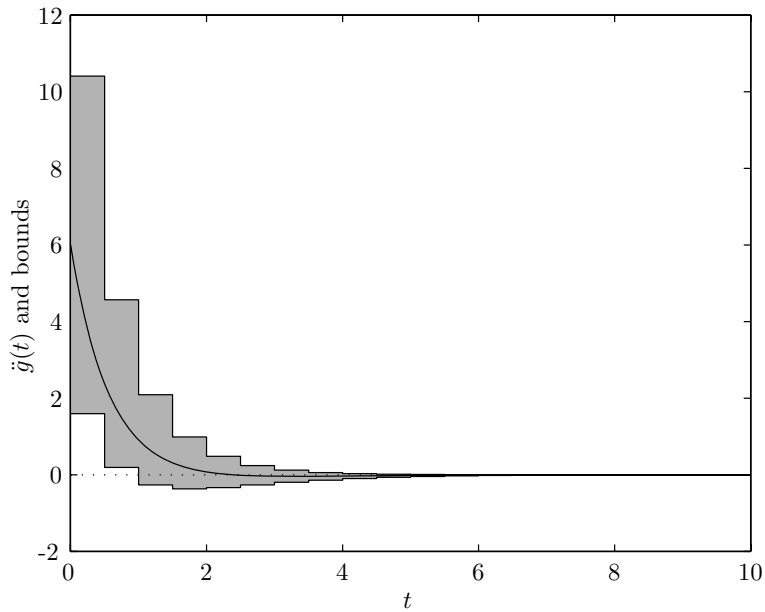

FIG. 2. *Second derivative* $\ddot{g}(t)$ *of the impulse response of* (8) *along with upper and lower bounds determined using Theorem* 1.

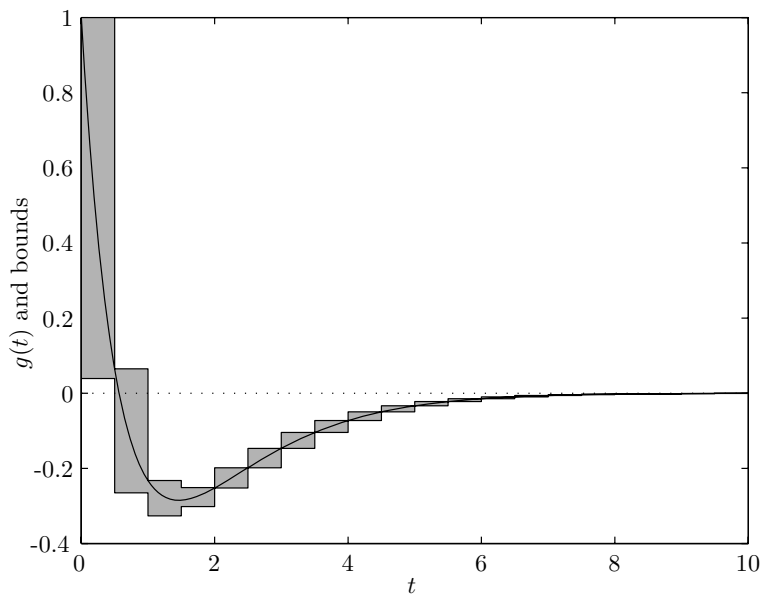

FIG. 3. *Impulse response* $g(t)$ *of* (8) *along with upper and lower bounds determined using Proposition* 1 *and Theorem* 1.

The bounds in Figure 3 fail to be tight only near the local extremum of $g(t)$. This property can be observed in many examples. In our algorithm, the bounds are merely used to detect sign changes in $g(t)$, so that nontight bounds near extrema are generally no problem at all. In the present example, the bounds in Figure 3 restrict

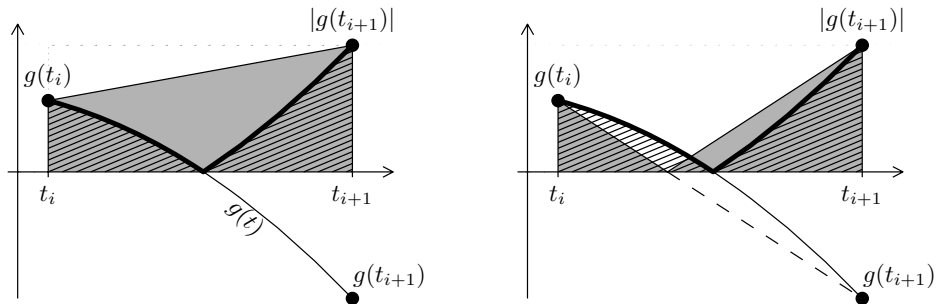

FIG. 4. *Standard trapezoidal rule for the absolute value function (left) and its modification (right). The shaded area corresponds the approximation η_i for the exact integral (striped area).*

sign changes to the interval $0.5 \le t \le 1$, which is the best result that can be expected. It should be noted that explicit bounds like those in Figure 1 are not employed in the algorithm. Figure 1 is included in this paper merely for comparison with Figure 3.

4. A modified trapezoidal rule for $|g(t)|$. This section is devoted to the computation of $\int_{t_i}^{t_{i+1}} |g(t)|\,dt$ with guaranteed error bounds. The traditional estimate

$$\int_{t_i}^{t_{i+1}} |g(t)|\,dt \approx \frac{1}{2}\left(|g(t_i)| + |g(t_{i+1})|\right) \cdot (t_{i+1} - t_i)$$

of the trapezoidal rule has two deficiencies, in case $g(t_i)$ and $g(t_{i+1})$ have different signs: First, the standard error bounds [12] are not applicable, since $|g(t)|$ is not differentiable, in general. Second, it is intuitively clear that a much better estimate η_i is obtained if a straight line interpolating $g(t_i)$ and $g(t_i + 1)$ instead of $|g(t_i)|$ and $|g(t_{i+1})|$ is employed; see Figure 4.

Both deficiencies are removed by the following proposition. It shows that the modified estimate η_i obeys the same error bounds as the trapezoidal rule for differentiable functions. The proof is given in Appendix D.

PROPOSITION 2. *Let g be twice differentiable in a neighborhood of $[a, b]$ and let K be an upper bound for the second derivative, i.e., let K satisfy $|\ddot{g}(t)| \le K$ for all $t \in [a, b]$. Then $|\int_a^b |g(t)|\,dt - \eta| \le \varepsilon$, where*

$$\eta := \begin{cases} |g(a) + g(b)| \cdot \dfrac{b-a}{2} & \text{if} \quad g(a)g(b) \ge 0, \\ \dfrac{g(a)^2 + g(b)^2}{|g(a) - g(b)|} \cdot \dfrac{b-a}{2} & \text{if} \quad g(a)g(b) < 0, \end{cases}$$

$$\varepsilon := \frac{K}{12}(b-a)^3.$$

As an example, consider the impulse response of the system given by (8) in the interval $[a, b]$ with $a = 0.5$, $b = 1$; see Figure 3. The second derivative obeys the bound $K = 4.5694$; see Figure 2. Proposition 2 leads to $\eta = 0.0490$ and $\varepsilon = 0.0476$ (all numbers rounded to 4 digits). The results in section 3 exclude sign changes outside $[a, b]$ (see Figure 3). Thus, outside $[a, b]$, the integral can be exactly computed using (4). Hence we have $|\int_0^{10} |g(t)|\,dt - 0.9425| \le 0.0476$.

Proposition 2 shows that the modified trapezoidal rule gives rise to quadratic convergence. This can be seen as follows. Suppose the interval $[a, b]$ is subdivided into m intervals of length $(b-a)/m$. The corresponding enhanced estimate for the integral obeys the error bound

$$\tilde{\varepsilon} = \sum_{i=1}^{m} \frac{K}{12} \left(\frac{b-a}{m} \right)^3 = \frac{1}{m^2} \varepsilon,$$

which quadratically drops with $1/m$.

Even faster convergence is possible if the bounds $\underline{H}$, $\overline{H}$, and K for $g(t)$ and $\ddot{g}(t)$ are recomputed for each subinterval. First, the new bounds K_i will generally be smaller than K. Second, more efficient bounds $\underline{H}_i$ and $\overline{H}_i$ will in general lead to lots of intervals where the integral can be exactly computed (see the basic algorithm in section 2).

5. The truncation error. As described in section 2, numerical integration will be performed over a finite interval $[0, T_e]$, $T_e = t_N$, only. The resulting truncation error $E := \int_{T_e}^{\infty} |g(t)|\, dt$ tends to zero, as $T_e \to \infty$. The following proposition presents a computable bound for E, based on an exponential weighting idea [5]. Its proof is given in Appendix E.

PROPOSITION 3. *Let $A \in \mathbb{R}^{n \times n}$, $B \in \mathbb{R}^{n \times 1}$, $C \in \mathbb{R}^{1 \times n}$, and $T_e > 0$ be given. Assume that A is stable and denote by $\alpha(A)$ the spectral abscissa of A, i.e.,*

$$\alpha(A) := \max \{ \mathrm{Re}(\lambda_i) : \lambda_i \text{ eigenvalue of } A \}.$$

Choose $\lambda \in \mathbb{R}$ such that $\alpha(A) < -\lambda < 0$ and let $W \in \mathbb{R}^{n \times n}$ be the solution of the Lyapunov equation

$$(A + \lambda I)^T W + W(A + \lambda I) + C^T C = 0.$$

Then

$$E \le \overline{E} := (2\lambda)^{-\frac{1}{2}} \sum_{i=1}^{n} W_{ii}^{\frac{1}{2}} \cdot |\xi_i|,$$

where W_{ii} is the ith entry on the diagonal of W and ξ_i is the ith entry of $e^{AT_e} B$.

In most cases, the "midpoint" $\lambda = -\alpha(A)/2$ gives the best result. Note that W depends on the problem data only and that ξ_i can be obtained from a simulation of the system.

As an example, consider the system given by (8) along with $T_e = 10$ (see Figure 3). Proposition 3 leads to the bound $\overline{E} = 5.45 \cdot 10^{-4}$ for the truncation error.

An alternative bound for the truncation error is obtained using Corollary 5.2 in [8]. In all examples generated so far, Proposition 3 has led to superior results.

6. The adaptive algorithm. The basic algorithm in section 2 assumes the discretization points $t_1, \ldots, t_N$ to be given and leads to a corresponding overall error $\varepsilon = \varepsilon_1 + \cdots + \varepsilon_N$. The finer the discretization, the smaller the discretization errors ε_i. The greater the endpoint $T_e = t_N$, the smaller the truncation error e_N.

In this section, a tolerance $\delta > 0$ is assumed to be given, and it is shown how to adaptively add discretization points such that $\varepsilon < \delta$. The approach is to follow the following steps.

Adaptive algorithm.

Step 1: Based on rough estimates of the settling time of $g(t)$, initial discretization points $t_1, \ldots, t_N$ are determined (see section 6.1 for details).

Step 2: An estimate η for the norm and associated errors $\varepsilon_1, \ldots, \varepsilon_N$ are computed using the basic algorithm sketched in section 2.

Step 3: If $\varepsilon_N > \delta/2$, i.e., the endpoint T_e is too small, then a new endpoint T_e^{new} is determined based on ε_N, δ, and the bounds in section 5 (see section 6.2 for details). The number N is increased and new discretization points are added to the list obtained so far. The estimate η for the norm and the errors ε_i are updated as in Step 2. Step 3 is repeated until $\varepsilon_N \leq \delta/2$.

Step 4: Let $t_1, \ldots, t_N$ be the discretization points and let $\varepsilon_1, \ldots, \varepsilon_N$ be the associated errors which are obtained so far. If $\varepsilon \geq \delta$, then intervals $[t_i, t_{i+1}]$ with large error ε_i are chosen. In these intervals, additional discretization points are inserted such that the new error ε is reduced below δ; see section 6.3 for details.

The adaptive algorithm is guaranteed to terminate after a finite number of steps. It computes an estimate η of the L_1-norm and an associated error in bound ε such that $\varepsilon < \delta$ and (3) is satisfied.

Since $|\xi_i|$ drops exponentially with increasing T_e, Proposition 3 shows that Step 3 of the algorithm converges exponentially. Step 4 converges quadratically by Proposition 2. Thus the overall convergence of the algorithm is quadratic.

If a tolerance δ_{rel} for the relative error is given instead of the tolerance δ on the absolute error, then the H_∞-norm can be used to be translate δ_{rel} to δ, since $||\Sigma||_{H_\infty} \leq ||\Sigma||_{L_1}$.

6.1. The initial grid. The initial discretization points $t_1, \ldots, t_N$ are chosen linearly spaced between $t = 0$ and $t = T_e$. The endpoint T_e is determined from the upper bound $\overline{E}$ of the truncation error in Proposition 3. Using the rough estimate $|\xi_i| \approx e^{\alpha(A)T_e}||B||$ and solving the aim $\overline{E} \approx \delta/2$ for T_e leads to

$$T_e = \max\left\{\frac{1}{\alpha(A)}, \frac{1}{\alpha(A)} \ln\left(\frac{\delta\lambda^{\frac{1}{2}}}{2^{\frac{1}{2}}||B||\Sigma W_{ii}^{\frac{1}{2}}}\right)\right\}.$$

The number N of initial discretization points is fixed to $N = 300$. Of course, more efficient heuristics are possible to choose N depending on δ, T_e, and the curvature of $g(t)$.

6.2. The new discretization endpoint. In Step 3 of the adaptive algorithm, the truncation error ε_N is reduced by increasing the discretization endpoint T_e. An efficient strategy for increasing T_e is obtained by using Proposition 3 as follows. From the simulation in Step 2, the true values $\xi_i = \xi_i^{old}$ and the true upper bound $\varepsilon_N = \overline{E}^{old}$ are obtained for the old endpoint T_e^{old}. If $\overline{E}^{old} > \delta/2$, then the estimate $|\xi_i| \approx e^{\alpha(A)T_e}||B||$ (see section 6.1) was too conservative. A better estimate is given by $|\xi_i| \approx e^{\alpha(A)T_e}\beta_i$, where β_i is obtained from $\left|\xi_i^{old}\right| = e^{\alpha(A)T_e^{old}} \cdot \beta_i$. Using this new approximation in the formula for $\overline{E}$ (see Proposition 3) and solving the aim $\overline{E} \approx \delta/2$ for T_e leads to the following new estimate T_e^{new} for the discretization endpoint:

$$T_e^{new} = T_e^{old} + \frac{1}{\alpha(A)} \ln\left(\frac{\delta}{2\overline{E}^{old}}\right).$$

If $T_e^{new} - T_e^{old}$ is smaller than a threshold κ, then $T_e^{new} = T_e^{old} + \kappa$ is chosen, in order to guarantee convergence of the algorithm.

6.3. Refinement of the discretization. In this section, the details of the refinement in Step 4 of the adaptive algorithm are elaborated. Without loss of generality it is assumed that the intervals $[t_i, t_{i+1}]$ are sorted such that $\varepsilon_1 \geq \varepsilon_2 \geq \cdots \geq \varepsilon_{N-1}$. The idea is to choose k and m and to divide each of the intervals $[t_i, t_{i+1}]$, $1 \leq i \leq k$, into m subintervals of length $(t_{i+1} - t_i)/m$. This leads to new estimates $\tilde{\eta}_i$ and to improved error bounds $\tilde{\varepsilon}_i$, $1 \leq i \leq k$.

The discussion following Proposition 2 shows that $\tilde{\varepsilon}_i = \varepsilon_i / m^2$. The overall integration error is then given by

$$\tilde{\varepsilon} := \frac{1}{m^2} \left(\sum_{i=1}^{k} \varepsilon_i \right) + \left(\sum_{i=k+1}^{N} \varepsilon_i \right).$$

Solving the requirement $\tilde{\varepsilon} \leq \delta$ for m leads to a lower bound for m depending on k. An optimal k minimizing $k \cdot m$ is easily obtained by direct search.

7. Numerical issues. To estimate the computational time, let M be the total number of intervals to be analyzed by the algorithm and note that the computational effort is dominated by those operations which are to be performed in each of the M intervals. For the sake of a simplified presentation it is assumed that the discretization points t_i are equally spaced, i.e., $t_{i+1} - t_i = T$.

The computations in the interval $[t_i, t_{i+1}]$ involve the determination of

$$x_{i+1} = e^{At_{i+1}} B = e^{AT} x_i, \quad x_1 = B, \tag{9}$$

$g(t_i) = Cx_i$, $\ddot{g}(t_i) = CA^2 x_i$, and $\underline{K}_i$, $\overline{K}_i$ (according to (6), (7)). This requires $n^2 + 3n$ multiplications. The computation of $\underline{H}_i$ and $\overline{H}_i$ according to Proposition 1 takes 3 to 13 multiplications, depending on which case applies. The estimate η_i (including ε_i) according to Proposition 2 requires 1 to 4 multiplications, whereas the computation of the exact value according to (4) takes n multiplications.

In summary, the total number of multiplications per discretization point t_i is given by $n^2 + 5n$, where it is assumed that the mean number of multiplications according to Propositions 1 and 2 are both smaller than n. Considering the fact that the computation of the impulse response requires $n^2 + n$ multiplications per discretization point, it can be concluded that the cost for the computation of the L_1-norm and for an accurate simulation of the impulse response are in the same order of magnitude.

In addition to the above estimates, the computational time is roughly proportional to the number M of intervals to be analyzed. In the adaptive algorithm, this number crucially depends on the shape of the impulse response: Smooth impulse responses with few zeros generally lead to small M. The following section contains examples with considerable oscillations in the impulse response, which is the "worst case" for the adaptive algorithm.

When implemented in finite arithmetic, rounding errors are inevitable. A complete rounding error analysis is beyond the scope of this paper. However, mostly standard components of numerical linear algebra and integration are employed, whose numerical properties are well understood: The rounding error analysis in [11] can be applied to the computation of x_i, $g(t_i)$, $\ddot{g}(t_i)$, $\underline{K}_i$, $\overline{K}_i$, and η_i according to (4). Moreover, the estimate η in Proposition 2 and the bound $\hat{\delta}$ in Theorem 1 can be reliably computed, basically because no cancellation of leading digits is involved [12]. Finally, the numerical properties of the Lyapunov equation in Proposition 3 are well known [11]. A complete error analysis of the algorithm, including the bounds $\underline{H}_i$ and $\overline{H}_i$ according to Proposition 1, is still to be done.

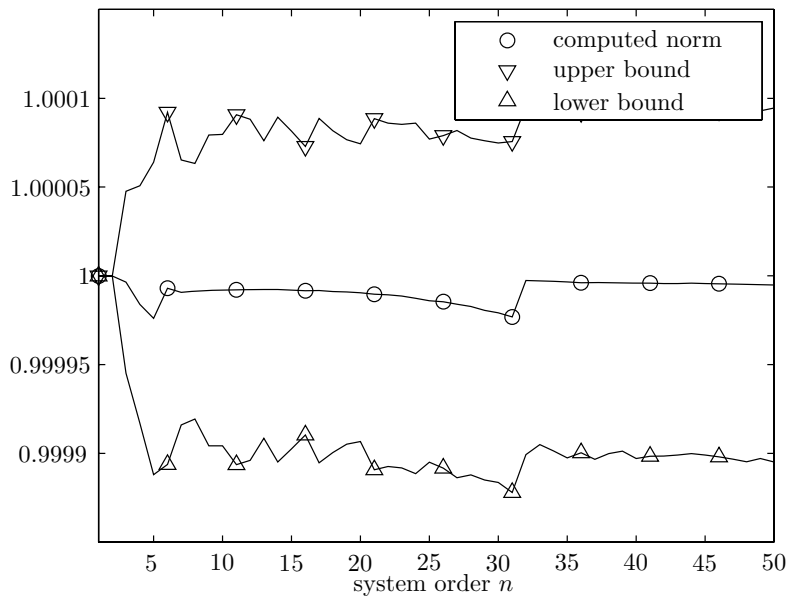

FIG. 5. *Computed L_1-norm for Example* 1.

8. Examples. In this section, the adaptive algorithm of section 6 is applied to examples. The timing results refer to a MATLAB implementation on a 1.8 GHz PC.

Example 1. Consider a system given by the transfer function

$$G(s) = \prod_{i=1}^{n} \frac{1}{T_i s + 1}, \quad T_i = i^2.$$

Figure 5 shows the computed L_1-norm along with the computed (guaranteed) upper and lower bounds for $n = 1, 2, \ldots, 50$ and tolerance $\delta = 10^{-4}$. Figure 6 shows the corresponding computing time. It increases quadratically with n, as expected from section 7. In summary, the algorithm works well for this medium-sized problem.

Example 2. Consider the system given by the transfer function

$$G(s) = \frac{(s-1)^n}{(s+1)^{n+2}}$$

for $n = 1, 2, \ldots$. This is a challenging example, because its BDOUT form (see section 3) consists of one block only and its impulse response oscillates heavily (see Figure 7). For $n = 25$, the L_1-norm $||\Sigma|| = 3.2469$ is computed within a relative tolerance of $\delta_{rel} = 10^{-4}$ in 0.3 seconds. For $n = 50$, the computation of the L_1-norm $||\Sigma|| = 4.3960$ takes 14 seconds.

Example 3. Consider the second order system given by the transfer function

$$F(s) = \frac{1}{s^2 + 2ds + 1}, \quad d = 0.1.$$

Its L_1-norm can be efficiently computed using the closed formulas in Appendix F. Ignoring rounding errors, the computed norm is exact. This allows us to check the result of the adaptive algorithm in section 6 for consistency. Figure 8 shows the relative error bound computed by the adaptive algorithm for various values of the relative

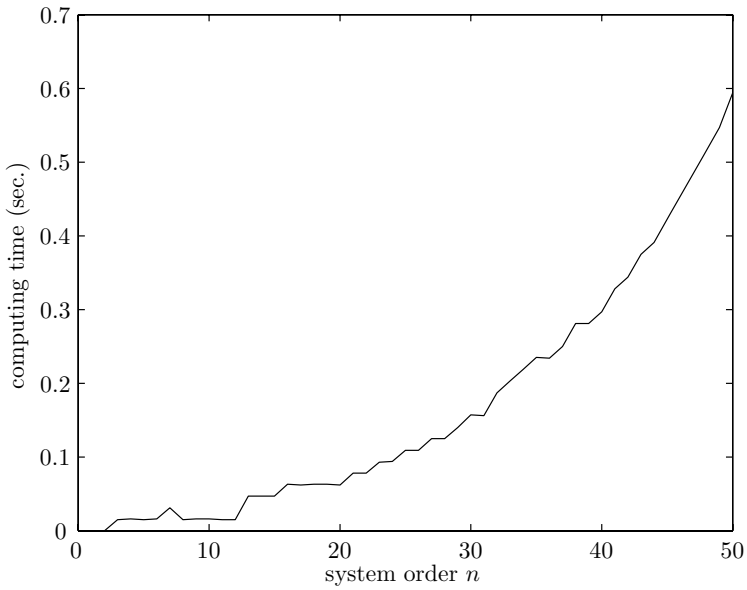

FIG. 6. *Computing time for Example* 1.

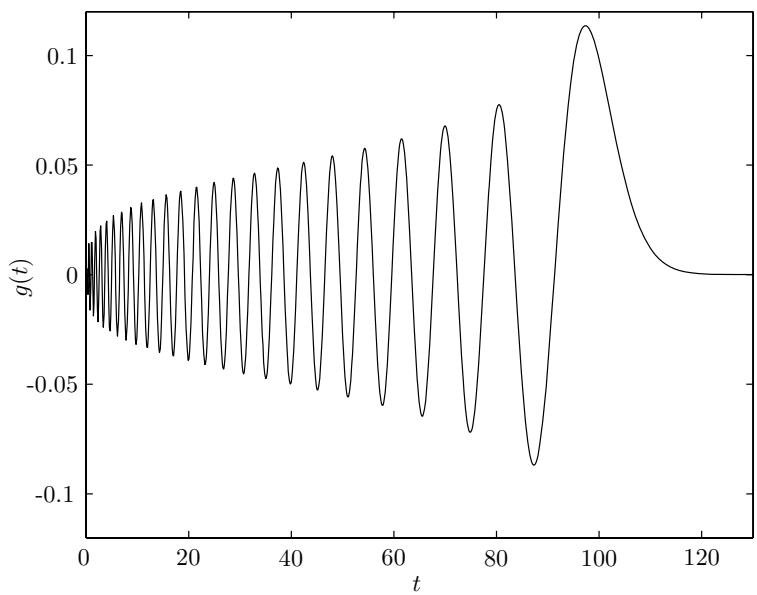

FIG. 7. *Impulse response of the system in Example* 2 *for* $n = 50$.

tolerance δ_{rel}. The true relative error (computed using Appendix F) shows that the algorithm works well even for small δ_{rel}. Figure 9 shows how the computing time behaves towards the tolerance. Thus, for moderate values of δ_{rel} ($\delta_{rel} \geq 10^{-6}$, say), the computing time stays essentially constant. For smaller values of δ_{rel}, the computing time increases. As expected from the quadratic convergence of the algorithm, a decrease of two decades in δ_{rel} results in a increase of one decade in computing time.

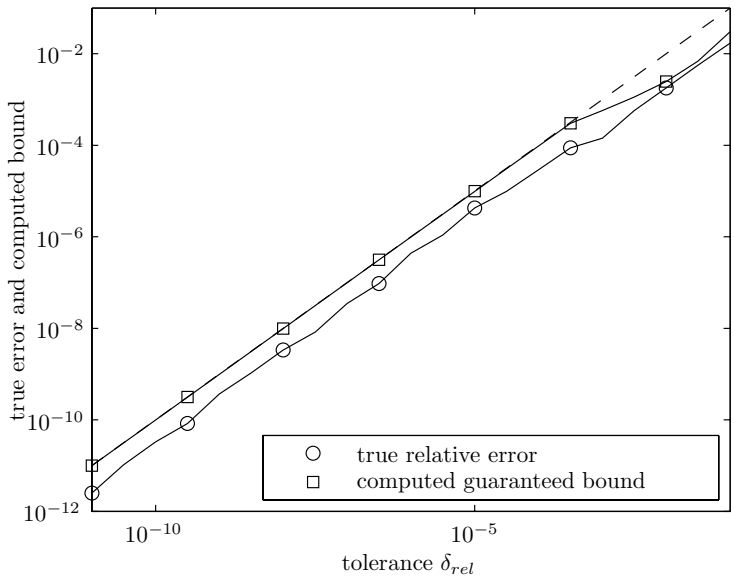

FIG. 8. *Relative error in Example* 3.

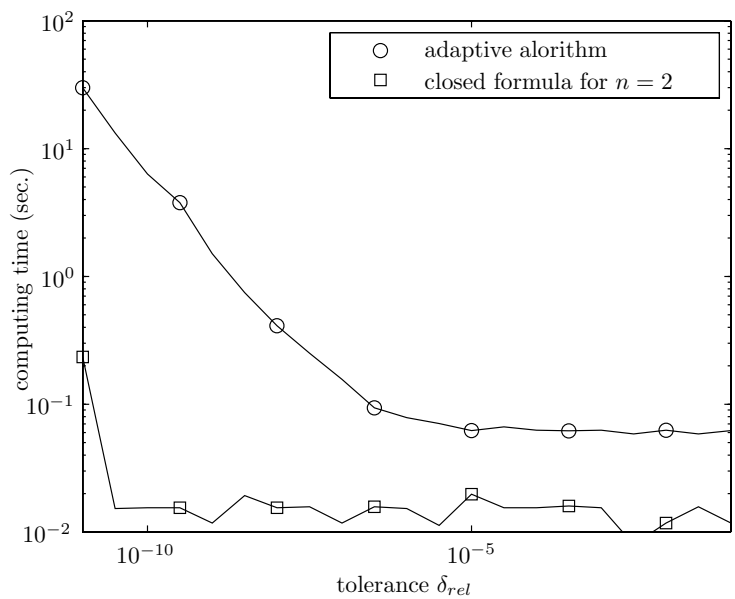

FIG. 9. *Computing time in Example* 3.

9. Multivariable systems. In this section, extensions to multivariable systems with feedthrough are discussed. Accordingly, let the system be given by matrices $A \in \mathbb{R}^{n\times n}$, $B \in \mathbb{R}^{n\times m}$, $C \in \mathbb{R}^{p\times n}$, and $D \in \mathbb{R}^{p\times m}$. Denoting the columns of B by B_k, the rows of C by C_ℓ, and the entries of D by $D_{\ell k}$, the L_1-norm is given by

$$||\Sigma|| := \max_{\ell=1,\dots,p} \sum_{k=1}^{m} \left(\int_0^\infty |C_\ell e^{At} B_k| \, dt + |D_{\ell k}| \right); \tag{10}$$

see [3]. Thus the computation of the multivariable L_1-norm amounts to $m \cdot p$ computations for single-input single-output systems. By exploiting the structure of (10), the computational cost can, however, be reduced. For the sake of illustration, two possible savings are sketched in the following.

The first one is due to the fact that the computational effort is dominated by the cost of determining x_{i+1} via (9), which does not depend on outputs. Assuming that identical discretization points t_i are employed for all outputs in Steps 1 and 2 of the adaptive algorithm and following the reasoning in section 7, the computational cost per discretization point and input can be reduced from $p(n^2 + 5n)$ to $n^2 + 5pn$.

Another saving concerns Step 4 of the adaptive algorithm in the multivariable case. This is due to the fact that the overall L_1-norm is given by the maximum over the L_1-norms for the outputs; see (10). Suppose that, in some iteration of an adaptive algorithm, estimates for the p single-output multiple-input norms and associated rough error bounds are available. Suppose further that the upper bound for the ℓth output is smaller than the lower bound for the qth output. Under these assumptions, the ℓth output can be discarded from further consideration. This reasoning generally leads, especially in applications which widely spread single-output norms, to a considerable reduction of outputs to be handled.

10. Conclusions. The L_2- and H_∞-norms can be efficiently computed by exploiting their characterizations in terms of Lyapunov equations and Hamiltonian matrices, respectively. Similar characterizations are not available for the L_1-norm. Therefore, the numerical computation of the L_1-norm is more involved. The algorithm of the present paper is based on the numerical integration of the absolute value of the impulse response. It is shown to be quadratically convergent and appears to be the first serious algorithm for the computation of the L_1-norm.

Although the paper does not include a complete rounding error analysis, it is expected that the algorithm is numerically reliable, because it is based on standard components from numerical linear algebra and numerical integration. The examples with state dimension up to 50 suggest that the algorithm works well for medium-sized problems.

It is important to note that the algorithm also determines an associated guaranteed error bound for the computed norm. This is an extra feature as compared to Hamiltonian algorithms for the computation of the H_∞-norm.

As far as computational speed is concerned, the L_1-algorithm of this paper cannot, however, compete with algorithms for the computation of L_2- and H_∞-norms.

Appendix A. Proof of Lemma 1. The first inequality of the lemma follows from

$$|e^{\lambda t} - 1| \le |\lambda| t + \frac{1}{2} |\lambda|^2 t^2 + \cdots \le e^{|\lambda|\tau} - 1, \quad t \le \tau. \tag{11}$$

As for the second inequality, note that $t_1 < t_2$ and consider the function

$$f(t) := |e^{\lambda t} - 1|^2 = e^{2\alpha t} + 1 - 2e^{\alpha t} \cos(\omega t).$$

Using (11), it follows that $f(t) \le (e^{|\lambda| t_1} - 1)^2 = \eta^2$, $t \le t_1$. Moreover, for $t_1 \le t \le t_2$, we have

$$f(t) \le f_2(t) := e^{2\alpha t_1} + 1 - 2e^{\alpha t} \cos(\omega t).$$

This proves the second inequality, since f_2 is monotonically increasing for $0 \le t \le t_2$. The third inequality follows from $f_2(t) \le f_2(t_2)$, $t \ge t_2$. ∎

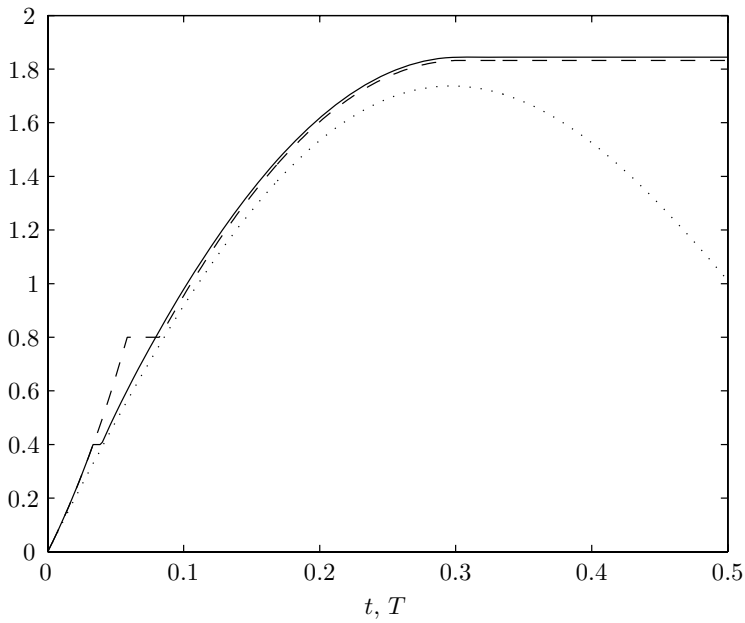

FIG. 10. *Function* $|e^{\lambda t} - 1|$ *(dotted) and bounds* $\hat{\delta}(\lambda, T, \eta)$ *for* $\eta = 0.4$ *(solid) and* $\eta = 0.8$ *(dashed).*

The idea behind Lemma 1 can be illustrated using the function $f(t)$, which is monotonically increasing between 0 and its first local maximum t_2'. Since t_2' is also the global maximum, the best bound is given by

$$\delta_{best}(\lambda, T) := \begin{cases} |e^{\lambda T} - 1|, & T \le t_2', \\ |e^{\lambda t_2'} - 1|, & T \ge t_2'. \end{cases}$$

Unfortunately, there is no analytical expression available for t_2'. In the proof of Lemma 1, $f(t)$ is replaced by $f_2(t)$ using some fixed t_1 and $\eta = e^{|\lambda| t_1} - 1$. Decreasing t_1 improves the bound for values of T which are slightly above t_1 but deteriorates the bound for larger values of T. Figure 10 shows the function $|e^{\lambda t} - 1|$ for $\lambda = -1 + 10j$ along with the bounds for $\eta = 0.4$ and $\eta = 0.8$. It shows that the compromise $\eta = 0.4$ leads to acceptable values for all T.

Appendix B. Proof of Theorem 1. Following along the same lines as those in [13], it can be shown that $|e^{At} - I| \le \delta(D, T) + \sum_{k=1}^{n-1} (|e^{Dt}|t^k)|N|^k/k!$. Hence the proof follows from Lemma 1 and

$$\max_{0 \le t \le T} e^{\alpha t} t^k = \begin{cases} e^{\alpha T} T^k & \text{if } T \le \dfrac{k}{-\alpha}, \\ \left(\dfrac{k}{-\alpha e} \right)^k & \text{else,} \end{cases}$$

which is valid for $\alpha < 0$, $T > 0$, and $k \le 1$. ∎

Appendix C. Proof of Proposition 1. The linear function

$$p(t) = \frac{g(b) - g(a)}{b - a}\, t + \frac{g(a)b - g(b)a}{b - a} \tag{12}$$

interpolates $g(t)$ at $t = a$ and $t = b$. Therefore, using the standard representation of the error in polynomial interpolation [12],

$$g(t) = p(t) + \frac{1}{2}\,(t-a)\,(t-b)\,\ddot{g}(\xi), \tag{13}$$

where $t, \xi \in [a,b]$. Thus $h(t) := p(t) + \frac{1}{2}(t-a)(t-b)\overline{K}$ satisfies $g(t) \geq h(t)$, $t \in [a,b]$. Let $t \in [a,b]$. If $\overline{K} \leq 0$, then $h(t) \geq p(t)$ and hence $g(t) \geq p(t) \geq \min\{g(a), g(b)\}$. If $\overline{K} \geq 0$, then $h(t)$ has an unique minimum at $t = \tau(\overline{K})$. If this minimum is outside the interval $[a,b]$, then again $g(t) \geq \min\{g(a), g(b)\}$, $t \in [a,b]$. If $\tau(\overline{K}) \in [a,b]$, then $g(t) \geq h(t) \geq h(\tau(\overline{K}))$, $t \in [a,b]$, which proves the lower bound $\underline{H}$. The upper bound $\overline{H}$ can be derived along the same lines. □

Appendix D. Proof of Proposition 2. Consider the function $p(t)$ defined in (12). Straightforward computations show that $\int_a^b |p(t)|\,dt = \eta$. By (13) the integration error can be estimated as follows:

$$\left| \int_a^b |g(t)|\,dt - \eta \right| \leq \int_a^b |g(t) - p(t)|\,dt \leq -\frac{K}{2} \int_a^b (t-a)(t-b)\,dt.$$

The proof now follows from the standard Newton–Cotes formula for the trapezoidal rule [12]. □

Appendix E. Proof of Proposition 3. The triangle inequality implies

$$E \leq \sum_{i=1}^{n} \left(\int_0^\infty \left| Ce^{At} e_i \right| dt \right) |\xi_i|.$$

The identity $e^{At} = e^{(A+\lambda I)t} \cdot e^{-\lambda t}$ and the Hölder inequality lead to $\int_0^\infty \left| Ce^{At} e_i \right| dt \leq N_1 \cdot N_2$, where $N_1^2 = \int_0^\infty \left| Ce^{(A+\lambda I)t} e_i \right|^2 dt$ and $N_2^2 = \int_0^\infty (e^{-\lambda t})^2\,dt = 1/(2\lambda)$. Thus the proof follows by expressing the L_2-norm N_1 in terms of the Lyapunov equation; see, e.g., [14]. □

Appendix F. Second order systems. In this section, closed formulas for the L_1-norm of second order systems are derived. It is shown how to efficiently compute the L_1-norm while avoiding any simulations. The formulas depend on parameters $\alpha_1, \alpha_2, \lambda_1, \lambda_2, \alpha, \beta, \lambda, \omega$ of the impulse response (see below). It should be noted that these parameters can be easily computed from a state-space model of the system. The general case is separated into three cases as follows.

F.1. Real disjoint eigenvalues. In this case, the impulse response reads $g(t) = \alpha_1 e^{\lambda_1 t} + \alpha_2 e^{\lambda_2 t}$, $t \geq 0$, where $\alpha_1 \in \mathbb{R}$, $\alpha_2 \in \mathbb{R}$, $\lambda_1 < 0$, $\lambda_2 < 0$, $\lambda_1 \neq \lambda_2$. Straightforward computations show that $g(t)$ changes its sign if and only if $\alpha_1 \neq 0$, $\alpha_2 \neq 0$, $\alpha_1 \alpha_2 < 0$, $t_0 > 0$, where $t_0 := \ln(\frac{-\alpha_2}{\alpha_1})/(\lambda_1 - \lambda_2)$. If these conditions are satisfied, t_0 is the unique zero of $g(t)$ and the L_1-norm is given by

$$||g||_{L_1} = \left| \int_0^{t_0} g(t)\,dt \right| + \left| \int_{t_0}^\infty g(t)\,dt \right| = \left| a - \frac{\alpha_1}{\lambda_1} - \frac{\alpha_2}{\lambda_2} \right| + |a|,$$

where $a := \frac{\alpha_1}{\lambda_1} e^{\lambda_1 t_0} + \frac{\alpha_2}{\lambda_2} e^{\lambda_2 t_0}$. If $g(t)$ does not change sign, then, obviously,

$$||g||_{L_1} = \left| \int_0^\infty g(t)\,dt \right| = \left| \frac{\alpha_1}{\lambda_1} + \frac{\alpha_2}{\lambda_2} \right|.$$

F.2. Repeated eigenvalues. In this case, the impulse response reads $g(t) = \alpha e^{\lambda t} + \beta t e^{\lambda t}$. Identifying the possible zero of this function as in section F.1, leads to the result

$$||g||_{L_1} = \begin{cases} |a| + \left| a - \dfrac{\alpha}{\lambda} + \dfrac{\beta}{\lambda^2} \right| & \text{if } \beta \neq 0,\ \dfrac{-\alpha}{\beta} > 0, \\ \left| \dfrac{\alpha}{\lambda} - \dfrac{\beta}{\lambda^2} \right| & \text{else,} \end{cases}$$

where $a := \frac{1}{\lambda} e^{\lambda t_0} \left(\alpha + \beta t_0 - \frac{\beta}{\lambda} \right)$.

F.3. Complex eigenvalues. In this case, the impulse response reads $g(t) = e^{\lambda t}(\alpha \sin(\omega t) + \beta \cos(\omega t))$, where $\alpha \in \mathbb{R}$, $\beta \in \mathbb{R}$, $\lambda < 0$, $\omega > 0$. Without loss of generality it is assumed that $(\alpha, \beta) \neq 0$. The function $g(t)$ has infinitely many zeros $t_0, t_1, t_2, \ldots$ in $[0, \infty]$ of the form $t_k = s_0 + k\pi/\omega$, where

$$s_0 = \begin{cases} \dfrac{\pi}{2\omega} & \text{if } \alpha = 0, \\ \dfrac{1}{\omega} \arctan\left(\dfrac{-\beta}{\alpha} \right) & \text{if } \alpha \neq 0,\ \dfrac{-\beta}{\alpha} \geq 0, \\ \dfrac{1}{\omega} \left(\arctan\left(\dfrac{-\beta}{\alpha} \right) + \pi \right) & \text{if } \alpha \neq 0,\ \dfrac{-\beta}{\alpha} < 0. \end{cases}$$

Thus

$$||g||_{L_1} = |N_0| + \sum_{k=1}^{\infty} |N_k|,$$

where

$$N_0 = \int_0^{s_0} g(t)\, dt; \quad N_k = \int_{t_{k-1}}^{t_k} g(t)\, dt, \quad k = 1, 2, 3, \ldots.$$

Elementary computations show that $N_0 = d - \frac{\beta\lambda - \alpha\omega}{\lambda^2 + \omega^2}$ and $|N_k| = |d|(1+q)q^{k-1}$, $k \geq 1$, where

$$d = \frac{(\alpha\lambda + \beta\omega)\sin(\omega s_0) + (\beta\lambda - \alpha\omega)\cos(\omega s_0)}{\lambda^2 + \omega^2} e^{\lambda s_0}, \quad q = e^{\lambda\pi/\omega},$$

which implies

$$||g||_{L_1} = \left| d - \frac{\beta\lambda - \alpha\omega}{\lambda^2 + \omega^2} \right| + |d| \frac{1+q}{1-q}. \qquad \square$$

EXACT CONTROLLABILITY FOR THE TIME DEPENDENT TRANSPORT EQUATION*

MICHAEL V. KLIBANOV† AND MASAHIRO YAMAMOTO‡

Abstract. The exact controllability theorem for the time dependent transport equation is proved.

Key words. exact controllability, transport equation, Carleman estimate

AMS subject classifications. 93B05, 82C70, 82B40

DOI. 10.1137/060652804

1. Introduction.

Let $\Omega \subset R^N$ be a strictly convex bounded domain with the boundary $\partial\Omega \in C^1$. The assumption of strict convexity of Ω makes the arguments simpler in many places, and in order to concentrate on the main issue, the exact controllability, we make this assumption here. Let $S^{N-1} \subset \mathbb{R}^N$ be the unit sphere and ν be the unit vector. Denote

$$W = \Omega \times S^{N-1} \times (0,T), \quad \Gamma = \Gamma(T) = \partial\Omega \times S^{N-1} \times (0,T),$$

$$\Gamma_+ = \Gamma_+(T) = \{(x,t,\nu) \in \Gamma : (n(x),\nu) > 0\},$$

$$\Gamma_- = \Gamma_-(T) = \{(x,t,\nu) \in \Gamma : (n(x),\nu) \le 0\},$$

where $(,)$ is the scalar product and $n(x)$ is the unit outward normal vector to $\partial\Omega$ at x.

In this paper, we consider the homogeneous transport equation:

$$Mu := u_t + (\nu, \nabla u) + a(x,t,\nu)u - \int_{S^N-1} g(x,t,\nu,\mu)u(x,t,\mu)d\sigma_\mu = 0 \text{ in } W \tag{1.1}$$

(e.g., [3], [5]). Here $\nu \in S^{N-1}$ is the unit vector of particle velocity, $u(x,t,\nu)$ is the density of particle flow, a is an absorption coefficient, and g is a scattering indicatrix.

In this publication, the exact controllability theorem for the time dependent transport equation (1.1) is proved for the first time. The transport equation governs diffusion processes, as long as they are linear ones, e.g., propagation of neutrons (see the classic book of Case and Zweifel [3]). A particularly interesting example is propagation of the near infrared light (originated by lasers) in a diffuse background, such as human tissues. The latter has applications in medical optical imaging; see, e.g., the review papers by Das, Liu, and Alfano [4] and Wang, Li, and Jiang [37]. Therefore

the transport equation plays an important role in the diffusion theory. We refer the reader to such classical books of physics as the books of Case and Zweifel [3], Dautray and Lions [5], Ishimaru [16], and Landau and Lifshitz [23]. See Larsen and Keller [24] as well as [5] concerning the diffusion approximation. We also refer the reader to the review paper of Ukai [36] and to his book [35]. It is stated in section 1.3 of [3] that the transport equation is actually the equation of the balance and that it is a linearized Boltzmann equation; see, e.g., [36] for the Boltzman equation. Moreover, one can relate the transport equation to the equations of fluid dynamics such as the Euler and the Navier–Stokes equations through an asymptotic expansion of a solution of the Boltzmann equation; e.g., see pp. 42–44 in [36]. As for related physical backgrounds, see [23], especially, p. 89, and [24]. Thus the exact controllability for the transport equation is as important as it is for the equation of parabolic type.

There are many publications on the exact controllability, and the authors are unable to review all of them here. The following is an incomplete list of publications, and the reader can consult the references therein. The papers of Russell [32] and Seidman [33] are early works. Lions has introduced the duality method in [27], [28], [29] (also, see Komornik [22]). We can further list early works: for hyperbolic equations, see, e.g., Bardos, Lebeau, and Rauch [2], Lasiecka and Triggiani [25], Triggiani [34], and, e.g., Zuazua [38] for a plate equation. Exact controllability results are obtained for a variety of partial differential equations; see e.g., Eller and Masters [8] for Maxwell's equations, and Fursikov [9], Fursikov and Imanuvilov [10], Imanuvilov [14], and Imanuvilov and Yamamoto [15] for parabolic equations.

Our proof of the exact controllability consists of two conventional stages. On the first stage the so-called continuous observability estimate is established, i.e., the Lipschitz stability estimate for the time dependent transport equation with the lateral boundary data on the lateral side of the time cylinder (Theorem 1.2). This estimate is an important ingredient of the duality method, which is applied on the second stage. The continuous observability estimate is proved using the method of Carleman estimates. Note that, unlike other techniques, this method enables us to prove the Lipschitz stability for a "transport inequality" (Theorem 1.3). This is because Carleman estimates enable one to "suppress" low order terms which depend on t (i.e., the third and fourth terms in Mu given by (1.1)) by the principal part of the operator. Although our proof is based on the two conventional stages, the execution of each stage needs independent considerations.

First step. By integration by parts and the method of characteristics, one can prove the continuous observability estimate in the case where $a(x,t,\nu)$ and $g(x,t,\nu,\mu)$ in (1.1) are independent of t and the proof is not difficult. Our Carleman estimate can treat also the t-dependent case equally. In many cases, such as nuclear fission, since the physical properties are changed in t, it is natural to assume that the coefficients in (1.1) should depend on t. See [35], [36] for the related physical backgrounds. Moreover, our method by a Carleman estimate can yield the continuous observability estimate for the transport inequality, to which other methods in [2], [28], [29], etc., are not applicable. The continuous observability estimate for the transport inequality should be discussed, for example, if the nonhomogeneous term cannot be determined precisely, but we have to estimate the energy.

Second step. Naturally we have to consider the weak solution to the nonhomogeneous boundary value problem of (1.1). However, there are very few papers in English treating this subject. Note that in Douglis [6] and Ukai [36], the homogeneous boundary value problem of (1.1) is mainly discussed. Bardos [1, pp. 205–208] treats a nonhomogeneous boundary value problem, and the result in [1] may be able

to shorten our argument at this step after some modification in the cylindrical domain $\Omega \times (0,T)$ in (x,t). However, here we define the weak solution in a way that is different and more compatible with the duality argument, which is essential for the exact controllability.

The Lipschitz stability estimate for the transport equation was recently established by Klibanov and Pamyatnykh [20]. However, it is necessary to modify the proof of [20] here for the following three reasons. The first and the most important is linked with the weighted scalar product (1.9) in Theorem 1.2 with the weight function $|\cos(n,\nu)|$. Weight functions were not considered in [20]. The delicacy here is due to the fact that this weight function is vanishing at a set $S \subset \Gamma_-$. It is well known, however, that the presence of zeros of weight functions in Hilbert spaces usually causes complications in the analysis. Because of this, we need to carefully evaluate the boundary terms in the pointwise Carleman estimate for the principal part of the differential operator of the transport equation, which was not done in [20]. The second reason is that the result of [20] was established for solutions $u \in C^1$, whereas we need to work with weak solutions $u \in L^2$ of the transport equation. The latter causes significant additional complications; see Remark 2.1. Third, the Lipschitz stability estimate was proved in [20] in the entire time cylinder, and this estimate is similar to estimate (1.10) in our case. However, in addition to (1.10), we need to obtain an estimate at the top $\{t = T\}$ of the time cylinder; see (1.11).

The method of Carleman estimates was applied for the proof of the continuous observability estimate by Klibanov and Malinsky [18]. They have done this for the case of hyperbolic equations with the constant principal part and low order terms, $w_{tt} = \Delta w + lot$, where "*lot*" stands for lower order terms. In Kazemi and Klibanov [17], the idea of [18] was applied to a more general case of hyperbolic inequalities, $|w_{tt} - \Delta w| \leq A(|\nabla w| + |w_t| + |w| + |f(x,t)|), A = const. > 0$, and the case when one boundary condition is given only at a part of the boundary was considered. One of the auxiliary results of the book of Klibanov and Timonov [19] is an extension of the method of [17] and [18] to the case of a more general hyperbolic inequality, $|a(x)w_{tt} - \Delta w| \leq A(|\nabla w| + |w_t| + |w| + |f(x,t)|)$, with some restrictions imposed on the positive function $a(x)$. The method of [17] and [18] enabled one to establish the exact controllability for the hyperbolic equations with lower order terms; see, e.g., the review paper of Gulliver et al. [11]. The previously applied method of multipliers was working (at least at the time of [17] and [18]) only under the assumption $lot = 0$; see Ho [12] for the first publication of the method of multipliers. Currently Carleman estimates are widely used in control theory for proofs of continuous observability results; see, e.g., [9], [10], [11], [14], and [15]. In this paper we modify the idea of [17], [18], [19] for the case of the transport equation.

In order to take into account the nonzero boundary condition, we derive a pointwise Carleman estimate, as was originated in the book of Lavrent'ev, Romanov, and Shishatskiĭ [26]. Another popular method of deriving of Carleman estimates is that of Hörmander [13]. This method is well suited for the so-called unique continuation theorems, which establishes that certain zero boundary conditions correspond only to the zero solution. However, it cannot be applied in our case. The reason is that one of the requirements of the method of [13] is the zero boundary condition, while our goal is to estimate the solution via a nonzero boundary condition.

All functions considered in this paper are real valued. Thus, Hilbert spaces here contain only real valued functions. Let $z_1, z_2 \in \overline{\Omega}$ be two points such that

$$|z_1 - z_2| = \max_{x,y \in \overline{\Omega}} |x - y| .$$

Without loss of generality we assume that $0 = (z_1 + z_2)/2$. Clearly, $0 \in \Omega$. Denote

$$R = \max_{x \in \overline{\Omega}} |x| .$$

For a function $g(x)$ with $x \in \mathbb{R}^N$, denote $g_i = \partial g / \partial x_i$ whenever the differentiation is appropriate.

In (1.1), we assume that

$$a \in C^1(\overline{W}), \quad g \in C^1(\overline{W} \times S^{N-1}). \tag{1.2}$$

It seems that the weaker assumptions $a \in C(\overline{W}), g \in C(\overline{W} \times S^{N-1})$ may be sufficient. Still, we prefer to use (for brevity) a little bit stronger assumption (1.2) to introduce the definition of the weak solution, which in turn relies on Theorem 2.1. In this paper we consider the following problem.

Exact controllability problem. Consider the zero initial condition

$$u \mid_{t=0} = 0 \tag{1.3}$$

and the boundary condition

$$u \mid_{\Gamma_-} = p(x, t, \nu), \tag{1.4}$$

where $p \in L^2_{\cos}(\Gamma_-)$ (see below for the definition of the Hilbert space $L^2_{\cos}(\Gamma_-)$). We assume that the weak solution $u \in C([0, T]; L^2(\Omega \times S^{N-1}))$ of the problem (1.1)–(1.4) can be defined (Theorem 2.2). Let $u_T(x, \nu) \in L^2(\Omega \times S^{N-1})$ be an arbitrary function. Find a boundary condition (i.e., boundary control) $p = p(u_T) \in L^2_{\cos}(\Gamma_-)$ such that the resulting function $u(x, t, \nu)$ is such that

$$u(x, T, \nu) = u_T(x, \nu). \tag{1.5}$$

Here we can interpret T as the "steering time." Our main result is the following theorem.

THEOREM 1.1. *Let Ω be a strictly convex bounded domain with $\partial\Omega \in C^1$ and $T > 2R$. Then for any function $u_T(x, \nu) \in L^2(\Omega \times S^{N-1})$ there exists a control function $p = p(u_T) \in L^2_{\cos}(\Gamma_-)$ such that if the function u is the weak solution of the initial boundary value problem* (1.1)–(1.4), *then* (1.5) *holds.*

In this paper, without loss of generality, we can assume that the initial value of the controlled system (1.1) is zero. In fact, let Theorem 1.1 be proved and let $u = u(x, t, \nu)$ be the weak solution to (1.1), (1.4) and $u|_{t=0} = u_0$ for a $u_0 \in L^2(\Omega \times S^{n-1})$. For given u_0 and u_T, we have to find a control function $p \in L^2_{\cos}(\Gamma_-)$ such that the function u satisfies (1.5). Let v be the weak solution to $Mv = 0$ in W, $v|_{t=0} = u_0$, and $v|_{\Gamma_-} = 0$. Setting $w = u - v$, we have $Mw = 0$ in W, $w|_{t=0} = 0$ and $w|_{\Gamma_-} = p$. Therefore by Theorem 1.1 in the case of the zero initial condition, which is assumed to be solved, for w we can find $p \in L^2_{\cos}(\Gamma_-)$ such that $w(x, T, \nu) = u_T(x, \nu) - v(x, T, \nu)$. This control p steers u from u_0 at $t = 0$ to u_T at $t = T$.

Consider the weak solution of the adjoint transport equation

$$M^* v := v_t + (\nu, \nabla v) - a(x, t, \nu) v + \int_{S^{N-1}} g(x, t, \mu, \nu) v(x, t, \mu) d\sigma_\mu = 0 \quad \text{in } W, \tag{1.6}$$

$$v(x, T, \nu) = v_0(x, \nu) \in L^2(\Omega \times S^{N-1}), \tag{1.7}$$

$$v \mid_{\Gamma_+} = 0. \tag{1.8}$$

We introduce the weighted scalar product as

$$\langle p, q\rangle = \int_{\Gamma_-} p(x,t,\nu)q(x,t,\nu)\cdot|\cos(n,\nu)|dS_x dt d\sigma_\nu. \tag{1.9}$$

By Lemma 2.1 (below), (1.9) is a scalar product which generates a Hilbert space, which we denote by $L^2_{\cos}(\Gamma_-)$. Note that

$$L^2(\Gamma_-)\subset L^2_{\cos}(\Gamma_-) \text{ and } \|p\|_{L^2_{\cos}(\Gamma_-)}\le \|p\|_{L^2(\Gamma_-)} \quad \forall p\in L^2(\Gamma_-);$$

that is, the $L^2_{\cos}(\Gamma_-)-$ norm is weaker than the $L^2(\Gamma_-)$-norm. The necessity of the introduction of the weighted space $L^2_{\cos}(\Gamma_-)$ can be seen from (3.13) (section 3). In order to prove Theorem 1.1, we combine the duality argument with the following continuous observability result.

THEOREM 1.2. *Assume that Ω is a strictly convex bounded domain with $\partial\Omega\in C^1$ and $T>2R$. Let the function v be the weak solution of the adjoint problem* (1.6)–(1.8) *in the sense of Definition* 2.1. *Let $v\mid_{\Gamma_-}:=(Kv_0)(x,t,\nu)\in L^2_{\cos}(\Gamma_-)$ be the generalized trace of the function v on Γ_- (Definition* 3.1*). Then the following Lipschitz stability estimates are valid:*

$$\|v\|_{L^2(W)}\le C\|Kv_0\|_{L^2_{\cos}(\Gamma_-)}, \tag{1.10}$$

$$\|v_0\|_{L^2(\Omega\times S^{n-1})}\le C\|Kv_0\|_{L^2_{\cos}(\Gamma_-)}, \tag{1.11}$$

where the positive constant $C=C(\Omega,T,\|a\|_{C(\overline{W})},\|g\|_{C(\overline{W}\times S^{N-1})})$ depends only on numbers R, T and norms $\|a\|_{C(\overline{W})}$ and $\|g\|_{C(\overline{W}\times S^{N-1})}$.

Theorem 1.2 is derived from the following theorem, which asserts a continuous observability estimate for the corresponding transport inequality.

THEOREM 1.3. *Assume that Ω is a strictly convex bounded domain with $\partial\Omega\in C^1$ and $T>2R$. Suppose that the function $v\in C^1_{tv grad}(\overline{W})$ satisfies the "transport inequality"*

$$|v_t+(\nu,\nabla v)|\le M\left[|v|+\int_{S^{N-1}}|v(x,t,\mu)|d\sigma_\mu+|f(x,t,\nu)|\right] \text{ in } W, \tag{1.12}$$

where M is a positive constant and the function $f\in L^2(W)$. Then

$$\|v\|_{L^2(W)}\le M_1[\|v\mid_\Gamma\|_{L^2_{\cos}(\Gamma)},+\|f\|_{L_2(W)}], \tag{1.13}$$

$$\|v(x,t_0,\nu)\|_{L^2(\Omega\times S^{N-1})}\le M_1[\|v\mid_\Gamma\|_{L^2_{\cos}(\Gamma)},+\|f\|_{L_2(W)}] \quad \forall t_0\in[0,T], \tag{1.14}$$

where the positive constant $M_1=M_1(\Omega,T,M)$ depends only on numbers Ω,T, and M.

The space $C^1_{tv grad}(\overline{W})$ is defined in subsection 2.2, and we note that $C^1_{tv grad}(\overline{W})\not\subset C^1(\overline{W})$. For $v\in C^1(\overline{W})$, the proof of the Carleman estimate can also be done in a traditional way with the commutator, but in our case we need some device (see (4.6)). Although the smoothness condition $v\in C^1_{tv grad}(\overline{W})$ of this theorem can be relaxed, to save space we are not doing this here, because Theorem 1.2 is more important for our goal. In this paper $C=C(\Omega,T,\|a\|_{C(\overline{W})},\|g\|_{C(\overline{W}\times S^{N-1})})$ and $M_1=M_1(\Omega,T,M)$ denote different positive constants depending on parameters listed. The conditions of Theorem 1.1 are assumed to be satisfied below. In section 2 we introduce the weak solutions of the problems (1.1)–(1.4) and (1.6)–(1.8). In section 3 we prove Theorem 1.1, assuming that Theorem 1.2 is valid. In section 4 we prove Theorems 1.2 and 1.3.

2. Strong and weak solutions.

2.1. The space $L^2_{\cos}(\Gamma_-)$ of controls. In this subsection we prove the following lemma.

LEMMA 2.1. *$L^2_{\cos}(\Gamma_-)$ is a Hilbert space.*

Proof. First, we have to prove that $\langle p, p\rangle = 0 \Leftrightarrow p = 0$. We set $\Phi := \{(x,\nu) \in \partial\Omega \times S^{N-1} : \cos(n,\nu) = 0\}$. It is sufficient to prove that

$$meas\,(\Phi) = 0.$$

Since the boundary $\partial\Omega \in C^1$ class, we can locally represent $\partial\Omega$ by $\{x_1 = 0\}$ via choosing suitable coordinates. Therefore, without loss of generality, we can assume that $\partial\Omega = \cup_{j=1}^J \partial_j\Omega$ and in each Γ_j, we set $n(x) = (1,0,\dots,0)^T$ by changing variables. Here the superscript "T" means the transpose. Then $\cos(n(x),\nu) = 0$ is equivalent to $\nu = (0,\nu_2,\dots,\nu_N)^T$ with $\sum_{j=2}^N \nu_j^2 = 1$. Hence $\Phi \cap (\partial_j\Omega \times S^{N-1}) \subset \partial_j\Omega \times S^{N-2}$; that is, $\Phi\cap(\partial_j\Omega\times S^{N-1})$ is a $(2N-3)$-dimensional hypersurface in the $(2N-2)$-dimensional space. Hence $meas(\Phi\cap(\partial_j\Omega\times S^{N-1})) = 0$. Therefore $meas(\Phi\cap(\cup_{j=1}^J\partial_j\Omega\times S^{N-1})) = meas(\Phi) = 0$. Thus we see that (1.9) defines a scalar product.

Second, we prove the completeness of $L^2_{\cos}(\Gamma_-)$. Let $\{p_k\}_{k=1}^\infty \subset L^2_{\cos}(\Gamma_-)$ be a Cauchy sequence in the norm of $L^2_{\cos}(\Gamma_-)$; that is, $\lim_{k,\ell\to\infty} \|p_k - p_\ell\|_{L^2_{\cos}(\Gamma_-)} = 0$. Then $\{p_k|\cos(n,\nu)|^{\frac12}\}_{k=1}^\infty$ is a Cauchy sequence in $L^2(\Gamma_-)$. Hence, there exists a function $\widetilde{p} \in L^2(\Gamma_-)$ such that

$$\lim_{k\to\infty}\int_{\Gamma_-} |\widetilde{p} - p_k|\cos(n,\nu)|^{\frac12}|^2 dS_x dt d\sigma_\nu = 0.$$

Denote

$$q = \frac{\widetilde{p}}{|\cos(n,\nu)|^{\frac12}}.$$

Hence, $q \in L^2_{\cos}(\Gamma_-)$. Therefore,

$$\lim_{k\to\infty}\int_{\Gamma_-}\left|\frac{\widetilde{p}}{|\cos(n,\nu)|^{\frac12}} - p_k\right|^2 |\cos(n,\nu)| dS_x dt d\nu = \lim_{k\to\infty}\|q - p_k\|^2_{L^2_{\cos}(\Gamma_-)} = 0,$$

which proves the completeness of $L^2_{\cos}(\Gamma_-)$. ∎

2.2. Strong solution. Consider the case when (1.3) is replaced with

$$u\,|_{t=0} = f(x,\nu). \tag{2.1}$$

For the exact controllability, we need a weak solution. However, there are few publications where weak solutions with nonzero boundary values in $L^2_{\cos}(\Gamma_-)$ are introduced. For complete accounts, see Chapter 2 in Ukai [35], which is a monograph in Japanese, and Bardos [1], whose argument can be modified in our case. As for the weak solution with the homogenous boundary data, there are rich references, for example, Bardos [1], Douglis [6], and Ukai [36]. In principle, the L^2-solution of the transport equation with nonhomogeneous boundary value in $L^2_{\cos}(\Gamma_-)$ can be defined by the transposition method (see Chapter 3 in Lions and Magenes [30] or pp. 46–50 in Lions [29]). However, it is convenient for our goal—the exact controllability to define the weak solution via density arguments—and we give self-contained descriptions for

completeness. For this, we use a result of Prilepko and Ivankov [31] about strong solutions.

We first assume that

$$f \in C^\infty(\overline{\Omega} \times S^{N-1}) \text{ and } f(x,\nu) \in C_0^\infty(\Omega) \quad \forall \nu \in S^{N-1}, \tag{2.2}$$

(2.3)

$$p \in C^\infty(\overline{\Gamma}_-), \quad p(x,t,\nu) := p_{x,\nu}(t) \in C_0^\infty(0,T) \quad \text{for every appropriate pair } (x,\nu).$$

Following [31], we introduce the functional space

$$C^1_{t\nu grad}(\overline{W}) = \left\{ u(x,t,\nu) : u, u_t, \frac{d}{ds}u(x+s\nu,t,\nu) \mid_{s=0} \in C(\overline{W})\ \forall \nu \in S^{N-1} \right\},$$

$$\|u\|_{C^1_{t\nu grad}(\overline{W})} = \|u\|_{C(\overline{W})} + \|u_t\|_{C(\overline{W})} + \left\| \frac{d}{ds}u(x+s\nu,t,\nu) \mid_{s=0} \right\|_{C(\overline{W})}.$$

Rewrite (1.1) in a different form:

$$u_t + \frac{d}{ds}u(x+s\nu,t,\nu) \mid_{s=0} + a(x,t,\nu)u - \int_{S^{N-1}} g(x,t,\nu,\mu)u(x,t,\mu)d\sigma_\mu = 0 \quad \text{in } W. \tag{2.4}$$

Equations (1.1) and (2.4) are not equivalent. If, for example, the derivatives $u_t, u_i \in C(\overline{W})$ and the function u satisfies (2.4), then this function also satisfies (1.1). However, if a function $u \in C^1_{t\nu grad}(\overline{W})$ satisfies (2.4), but not all of its derivatives u_i exist, then this function might not be a solution of (1.1). Therefore (2.4) is more general than (1.1). Theorem 2.1 is a simplified version of Theorem 1.1 of [31].

THEOREM 2.1. *Let $\Omega \subset \mathbb{R}^N$ be a strictly convex bounded domain with $\partial\Omega \in C^1$. Assume that conditions* (1.2), (2.2), *and* (2.3) *hold. Then there exists unique solution $u \in C^1_{t\nu grad}(\overline{W})$ of the problem* (1.4), (2.1), (2.4).

Remark 2.1. In the view of our goal, a significant complication linked with Theorem 2.1 is an insufficient smoothness guaranteed by this theorem. In other words, we cannot work directly with the "individual" derivatives u_i, because their existence is not guaranteed. Rather, we need to work with the directional derivatives $du(x+s\nu,t,\nu)/ds \mid_{s=0}$. Furthermore, we cannot even claim that such a directional derivative equals $(\nu, \nabla u)$. The key idea, which helps to overcome these complications, is the introduction of an orthogonal matrix A_{ν_0} in (2.6).

In this section we will relax smoothness conditions (2.2), (2.3). We need these minimal conditions in order to introduce the weak solution. On the other hand, we need the weak solution for the duality argument.

2.3. Weak solution.

LEMMA 2.2 (energy conservation). *Suppose that conditions* (1.2), (2.2), *and* (2.3) *are fulfilled. Let the function $u \in C^1_{t\nu grad}(\overline{W})$ be a solution of the problem* (1.4), (2.1), (2.4). *Denote*

$$E(u,t) = \int_\Omega \int_{S^{N-1}} |u(x,t,\nu)|^2 d\sigma_\nu dx.$$

Then there exists a positive constant $C = C(\Omega, T, \|a\|_{C(\overline{W})}, \|g\|_{C(\overline{W}\times S^{N-1})})$ such that for any two numbers $t_1, t_2 \in [0,T]$

$$E(u,t_2) \le C[E(u,t_1) + \|p\|^2_{L^2_{\cos}(\Gamma_-)}]. \tag{2.5}$$

Proof. Fix an arbitrary vector $\nu_0 \in S^{N-1}$. Let $A_{\nu_0} = (a^{ij}_{\nu_0})_{i,j=1}^N$ be an orthogonal matrix such that

$$A_{\nu_0}\nu_0 = \widetilde{\nu}_0 := (1, 0, 0, \dots, 0)^T. \tag{2.6}$$

Let

$$y = A_{\nu_0}x. \tag{2.7}$$

Denote $A_{\nu_0}\Omega = \{y = Ax : x \in \Omega\}$. Also, for any point $y = A_{\nu_0}x \in \partial(A_{\nu_0}\Omega)$ (hence, $x \in \partial\Omega$) let $\widetilde{n}(y) = A_{\nu_0}n(x)$ be the unit outward normal vector at the point y. Denote

$$\widetilde{u}(y,t,\eta) = u\left(A^{-1}_{\nu_0}y, t, A^{-1}_{\nu_0}\eta\right) \quad \forall \eta \in S^{N-1}, \tag{2.8}$$

$$\widetilde{a}(y,t,\widetilde{\nu}_0) = a\left(A^{-1}_{\nu_0}y, t, A^{-1}_{\nu_0}\widetilde{\nu}_0\right), \tag{2.9}$$

$$\widetilde{g}(y,t,\widetilde{\nu}_0,\eta) = g\left(A^{-1}_{\nu_0}y, t, A^{-1}_{\nu_0}\widetilde{\nu}_0, A^{-1}_{\nu_0}\eta\right) \quad \forall \eta \in S^{N-1}. \tag{2.10}$$

In the new coordinates, noting that $\widetilde{u}(y,t,\widetilde{\nu}_0) = u(x,t,\nu_0)$ and

$$u(x + s\nu_0, t, \nu_0) = u(A^{-1}_{\nu_0}(y + s\widetilde{\nu}_0), t, \nu_0) = \widetilde{u}(y + s\widetilde{\nu}_0, t, \widetilde{\nu}_0)$$
$$= \widetilde{u}(y_1 + s, y_2, \dots, y_n, t, \widetilde{\nu}_0),$$

we have

$$\frac{d}{ds}u(x + s\nu_0, t, \nu_0) \mid_{s=0} = \widetilde{u}_{y_1}(y,t,\widetilde{\nu}_0). \tag{2.11}$$

Hence, setting $\nu = \nu_0$ in (1.1), we obtain

$$(\widetilde{u}_t + \widetilde{u}_{y_1} + \widetilde{a}\widetilde{u})(y,t,\widetilde{\nu}_0) - \int_{S^{N-1}} \widetilde{g}(y,t,\widetilde{\nu}_0,\eta)\widetilde{u}(y,t,\eta)d\sigma_\eta = 0. \tag{2.12}$$

Since $u \in C^1_{t\nu grad}(\overline{W})$, we have by (2.11)

$$\widetilde{u}(y,t,\widetilde{\nu}_0), \widetilde{u}_t(y,t,\widetilde{\nu}_0), \widetilde{u}_{y_1}(y,t,\widetilde{\nu}_0) \in C(\overline{A_{\nu_0}\Omega} \times [0,T]). \tag{2.13}$$

Actually, the goal of the transformation (2.7)–(2.10) was to obtain (2.12) with $\widetilde{u}_{y_1}(y,t,\widetilde{\nu}_0) \in C(A_{\nu_0}\overline{\Omega} \times [0,T])$.

Multiply both sides of (2.12) by the function $\widetilde{u}(y,t,\widetilde{\nu}_0)$. We obtain for this vector $\widetilde{\nu}_0$

$$[(\widetilde{u}^2)_t + (\widetilde{u}^2)_{y_1}](y,\tau,\nu_0) = -2\widetilde{a}\widetilde{u}^2(y,\tau,\nu_0) + 2\widetilde{u}(y,\tau,\nu_0) \cdot \int_{S^{N-1}} \widetilde{g}(y,\tau,\widetilde{\nu}_0,\eta)\widetilde{u}(y,\tau,\eta)d\sigma_\eta,$$

where $\tau \in (0,T)$. Integrating this equality with respect to $(y,\tau) \in A_{\nu_0}\Omega \times (t_1,t)$, $t \in (t_1,T)$, we obtain

$$\int_{A_{\nu_0}\Omega} \widetilde{u}^2(y,t,\widetilde{\nu}_0)dy + \int_{t_1}^t \int_{\partial(A_{\nu_0}\Omega)} \cos(\widetilde{n},y_1)\widetilde{u}^2(y,\tau,\widetilde{\nu}_0)dS_y d\tau$$
$$= \int_{A_{\nu_0}\Omega} \widetilde{u}^2(y,t_1,\widetilde{\nu}_0)dy - 2\int_{t_1}^t \int_{A_{\nu_0}\Omega} \widetilde{a}\widetilde{u}^2(y,\tau,\widetilde{\nu}_0)dyd\tau$$
$$+ 2\int_{t_1}^t \int_{A_{\nu_0}\Omega} \widetilde{u}(y,\tau,\widetilde{\nu}_0)\left[\int_{S^{N-1}} \widetilde{g}(y,\tau,\widetilde{\nu}_0,\eta)\widetilde{u}(y,\tau,\eta)d\sigma_\eta\right]dyd\tau.$$

Changing variables "backwards," $x = A_{\nu_0}^{-1} y$, and noting that by (2.6) $\cos(\widetilde{n}(y), y_1) = \cos(n(x), \nu_0)$, we obtain

$$\begin{aligned}(2.14)\qquad &\int_\Omega u^2(x,t,\nu_0)dx + \int_{t_1}^t \int_{\partial\Omega} \cos(n,\nu_0) u^2(x,\tau,\nu_0) dS_x d\tau \\ &= \int_\Omega u^2(x,t_1,\nu_0)dx - 2\int_{t_1}^t \int_\Omega (au^2)(x,\tau,\nu_0)dxd\tau \\ &\quad + 2\int_{t_1}^t \int_\Omega u(x,\tau,\nu_0)\left[\int_{S^{N-1}} g(x,\tau,\nu_0,\eta)u(x,\tau,\eta)d\sigma_\eta\right]dxd\tau.\end{aligned}$$

Let

$$\Gamma(t_1,t) = \Gamma \cap \{(x,t,\nu) : t \in (t_1,t)\},$$

$$\Gamma_-(t_1,t) = \Gamma_- \cap \Gamma(t_1,t) \quad \text{and} \quad \Gamma_+(t_1,t) = \Gamma_+ \cap \Gamma(t_1,t).$$

Recalling that $\nu_0 \in S^{N-1}$ is an arbitrary vector, we can now integrate (2.14) with respect to $\nu_0 \in S^{N-1}$. We obtain

$$\begin{aligned}(2.15)\qquad &\int_{S^{N-1}}\int_\Omega u^2(x,t,\nu)dxd\sigma_\nu + \int_{\Gamma(t_1,t)} \cos(n(x),\nu)u^2(x,\tau,\nu)dS_x d\sigma_\nu d\tau \\ &= \int_{S^{N-1}}\int_\Omega u^2(x,t_1,\nu)dxd\sigma_\nu - 2\int_{t_1}^t\int_{S^{N-1}}\int_\Omega (au^2)(x,\tau,\nu)\,dxd\sigma_\nu d\tau \\ &\quad + 2\int_{t_1}^t\int_{S^{N-1}}\int_\Omega u(x,\tau,\nu)\left[\int_{S^{N-1}} g(x,\tau,\nu,\eta)u(x,\tau,\eta)d\sigma_\eta\right]dxd\sigma_\nu d\tau.\end{aligned}$$

Since $\Gamma(t_1,t) = \Gamma_-(t_1,t) \cup \Gamma_+(t_1,t)$, $\Gamma_-(t_1,t) \subset \Gamma_-(T)$, and $\cos(n(x),\nu) > 0$ on $\Gamma_+(t_1,t)$, we have

$$\begin{aligned}&\int_{\Gamma(t_1,t)} \cos(n,\nu)u^2(x,\tau,\nu)dS_x d\sigma_\nu d\tau \geq \int_{\Gamma_-(t_1,t)} \cos(n,\nu)u^2(x,\tau,\nu)dS_x d\sigma_\nu d\tau \\ &\geq \int_{\Gamma_-(T)} \cos(n,\nu)u^2(x,\tau,\nu)dS_x d\sigma_\nu d\tau = -\int_{\Gamma_-(T)} |\cos(n,\nu)|u^2(x,\tau,\nu)dS_x d\sigma_\nu d\tau \\ &= -\|u\|^2_{L^2_{\cos}(\Gamma_-)} = -\|p\|^2_{L^2_{\cos}(\Gamma_-)}.\end{aligned}$$

Also,

$$\begin{aligned}&\left|\int_{t_1}^t\int_{S^{N-1}}\int_\Omega u(x,\tau,\nu)\left[\int_{S^{N-1}} g(x,\tau,\nu,\eta)u(x,t,\eta)d\sigma_\eta\right]dxd\sigma_\nu d\tau\right| \\ &\leq C\left|\int_{t_1}^t\int_{S^{N-1}}\int_\Omega |u(x,\tau,\nu)|\left(\int_{S^{N-1}}|u(x,t,\eta)|d\sigma_\eta\right)dxd\sigma_\nu d\tau\right| \\ &= C\int_{t_1}^t\int_\Omega\left(\int_{S^{N-1}}|u(x,\tau,\nu)|d\sigma_\nu \cdot \int_{S^{N-1}}|u(x,\tau,\mu)|d\sigma_\mu\right)dxd\tau \\ &\leq C\int_{t_1}^t\int_\Omega\int_{S^{N-1}} u^2(x,\tau,\nu)d\sigma_\nu dxd\tau.\end{aligned}$$

At the last inequality, we used the Cauchy–Schwarz inequality. Hence we obtain from (2.15)

$$E(u,t) \le E(u,t_1) + \|p\|^2_{L^2_{\cos}(\Gamma_-)} + C\int_{t_1}^{t} E(u,\tau)d\tau.$$

Hence the Gronwall inequality leads to (2.5). □

THEOREM 2.2. *Let $\Omega \subset \mathbb{R}^N$ be a strictly convex bounded domain with $\partial\Omega \in C^1$ and let conditions* (1.2) *hold. Let $f \in L^2(\Omega \times S^{N-1})$ and $p \in L^2_{\cos}(\Gamma_-)$ be two arbitrary functions. Consider two functional sequences $\{f_k\}_{k=1}^{\infty}$, $\{p_k\}_{k=1}^{\infty}$ satisfying conditions* (2.2) *and* (2.3) *and such that*

$$\lim_{k\to\infty} \|f_k - f\|_{L^2(\Omega\times S^{N-1})} = \lim_{k\to\infty} \left\| p_k - p\sqrt{|\cos(n,\nu)|} \right\|_{L^2(\Gamma_-)} = 0.$$

Let $u_k \in C^1_{tv grad}\left(\overline{W}\right)$ be the solution of the boundary value problem (1.4), (2.1), (2.4) *with the initial condition f_k and the boundary condition p_k. Then there exists a function $u \in C([0,T]; L^2(\Omega \times S^{N-1}))$ such that $\lim_{k\to\infty} \|u_k - u\|_{C([0,T];L^2(\Omega\times S^{N-1}))} = 0$. Inequality* (2.5) *holds for this function u, and*

$$\|u\|_{C([0,T];L^2(\Omega\times S^{N-1}))} \le C\left(\|f\|_{L^2(\Omega\times S^{N-1})} + \|p\|_{L^2_{\cos}(\Gamma_-)}\right). \tag{2.16}$$

For any pair of functions $f \in L^2\left(\Omega \times S^{n-1}\right)$ and $p \in L^2_{\cos}\left(\Gamma_-\right)$ the resulting function u is independent of functional sequences $\{f_k\}_{k=1}^{\infty}$ and $\{p_k\}_{k=1}^{\infty}$.

Proof. The existence of a sequence $\{p_k\}_{k=1}^{\infty}$ satisfying conditions (2.3) and such that $\lim_{k\to\infty}\|p_k - p\sqrt{\cos(n,\nu)}\|_{L^2(\Gamma_-)} = 0$ follows from the fact that the function $p\sqrt{|\cos(n,\nu)|} \in L^2(\Gamma_-)$ and the set of functions satisfying (2.3) is dense in $L^2(\Gamma_-)$. Also, since the $L^2_{\cos}(\Gamma_-)$-norm is weaker than the $L^2(\Gamma_-)$-norm and $\{p_k\}_{k=1}^{\infty}$ is a Cauchy sequence in $L^2(\Gamma_-)$, it follows that the sequence $\{p_k\}_{k=1}^{\infty} \subset L^2_{\cos}(\Gamma_-)$ and it is a Cauchy sequence in $L^2_{\cos}(\Gamma_-)$. Since functions $u_k \in C^1_{tv grad}\left(\overline{W}\right)$, it follows that $u_k \in C([0,T]; L^2(\Omega \times S^{N-1}))$. Thus, setting $t_1 = 0$, $u = u_k - u_\ell$, $f = f_k - f_\ell$, and $p = p_k - p_\ell$ in (2.5) and taking the maximum in t, we see that $\{u_k(x,t,\nu)\}_{k=1}^{\infty}$ is a Cauchy sequence in the space $C([0,T]; L^2(\Omega \times S^{N-1}))$. Hence we define the function $u(x,t,\nu)$ as $u := \lim_k \to \infty u_k$ in $C([0,T]; L^2(\Omega \times S^{N-1}))$. Since (2.5) holds for functions u_k, it also holds for the function u, which implies (2.16). The independence of the function u on specific sequences $\{f_k\}_{k=1}^{\infty}$ *and* $\{p_k\}_{k=1}^{\infty}$ follows from (2.5). □

DEFINITION 2.1. *Let $\Omega \subset \mathbb{R}^N$ be a strictly convex bounded domain with $\partial\Omega \in C^1$ and let functions a and g satisfy conditions* (1.2). *Let the function $u \in C([0,T]; L^2(\Omega \times S^{N-1}))$ be the one obtained as the limit described in Theorem* 2.2. *Then we call this function u the* weak solution *of the initial boundary value problem* (1.1), (1.4), (2.1) *with the initial condition $f \in L^2\left(\Omega \times S^{N-1}\right)$ and the boundary condition $p \in L^2_{\cos}\left(\Gamma_-\right)$.*

By (2.16) the limit u is independent of choices of sequences f_k, p_k. Thus the following theorem follows from Theorem 2.2 and Definition 2.1.

THEOREM 2.3. *Let $\Omega \subset \mathbb{R}^N$ be a strictly convex bounded domain with $\partial\Omega \in C^1$ and let conditions* (1.2) *hold. Then for each pair of functions $f \in L^2\left(\Omega \times S^{n-1}\right)$ and $p \in L^2_{\cos}\left(\Gamma_-\right)$ the weak solution $u \in C([0,T]; L^2(\Omega \times S^{N-1}))$ of the problem* (1.1), (1.4), (2.1) *exists and is unique, and* (2.16) *holds.*

Consider now the adjoint problem (1.6)–(1.8). Similarly to (2.4) and following the same considerations, we rewrite (1.6) as

(2.17)
$$v_t + \frac{d}{ds} v\left(x + s\nu, t, \nu\right)|_{s=0} - a(x,t,\nu)v + \int_{S^{N-1}} g(x,t,\mu,\nu)v(x,t,\mu)d\sigma_\mu = 0 \quad \text{in } W.$$

The following result follows immediately from Lemma 2.2 and Theorems 2.1–2.3 via the change of variables $t \Leftrightarrow \tau = T - t$.

THEOREM 2.4. *Let $\Omega \subset \mathbb{R}^N$ be a strictly convex bounded domain with $\partial\Omega \in C^1$ and let conditions* (1.2) *hold. Suppose that in* (1.7) *the function $v_0 \in C^\infty\left(\overline{\Omega} \times S^{N-1}\right)$ and $v_0(x,\nu) \in C_0^\infty(\Omega)$ for all $\nu \in S^{N-1}$. Let the function $v \in C^1_{tv grad}\left(\overline{W}\right)$ be a solution of the problem* (1.7), (1.8), (2.17) *(Theorem* 2.1*). Denote*

$$E(v,t) = \int_\Omega \int_{S^{N-1}} |v(x,t,\nu|^2 \, d\nu dx.$$

Then there exists a positive constant $C = C\left(\Omega, T, \|a\|_{C\left(\overline{W}\right)}, \|g\|_{C\left(\overline{W} \times S^{N-1}\right)}\right)$ such that for any two numbers $t_1, t_2 \in [0,T]$

$$E(v,t_2) \leq CE(v,t_1). \tag{2.18}$$

Thus, the solution $v \in C^1_{tv grad}\left(\overline{W}\right)$ of the problem (1.7), (1.8), (2.17) *both exists and is unique. Next, assume that $v_0 \in L^2\left(\Omega \times S^{N-1}\right)$ is an arbitrary function. Let $\{v_{0k}\}_{k=1}^\infty \subset C^\infty\left(\overline{\Omega} \times S^{N-1}\right)$ be a sequence such that $v_{0k}(x,\nu) \in C_0^\infty(\Omega)$ for all $\nu \in S^{N-1}$ and $\lim_{k\to\infty} \|v_{0k} - v_0\|_{L_2(\Omega \times S^{N-1})} = 0$. Let $\{v_k\}_{k=1}^\infty \in C^1_{tv grad}\left(\overline{W}\right)$ be the sequence of solutions of the initial boundary value problem* (1.7), (1.8), (2.17) *with initial conditions $v_k|_{t=0} = v_{0k}$. Then there exists a function $v = v(x,t,\nu) \in C([0,T]; L^2(\Omega \times S^{N-1}))$ such that $\lim_k \to \infty \|v_k - v\|_{C([0,T];L^2(\Omega \times S^{N-1}))} = 0$. For any given function $v_0 \in L^2\left(\Omega \times S^{N-1}\right)$ the function v is independent of the functional sequence $\{v_{0k}\}_{k=1}^\infty$. Furthermore,*

$$\|v\|_{C([0,T];L^2(\Omega \times S^{N-1}))} \leq C\|v_0\|_{L^2(\Omega \times S^{N-1})}. \tag{2.19}$$

DEFINITION 2.2. *We call the function $v \in C([0,T]; L^2(\Omega \times S^{N-1}))$ constructed in Theorem* 2.4 *the "weak solution" of the adjoint problem* (1.6)–(1.8).

Therefore, the following corollary follows from Theorem 2.4.

COROLLARY 2.1. *For any function $v_0 \in L_2\left(\Omega \times S^{N-1}\right)$ there exists a unique weak solution $v \in C([0,T]; L^2\left(\Omega \times S^{N-1}\right))$ to* (1.6)–(1.8). *Estimate* (2.19) *holds for this function v.*

3. Proof of Theorem 1.1. In this section we prove Theorem 1.1, assuming that Theorem 1.2 holds. By Theorem 2.3, for any function $p \in L^2_{\cos}(\Gamma_-)$ there exists a unique weak solution u of the problem (1.1), (1.3), and (1.4). Also, by Corollary 2.1 for any function $v_0 \in L^2(\Omega \times S^{N-1})$ there exists a unique weak solution v of the problem (1.6)–(1.8).

3.1. Generalized trace of the weak solution of the adjoint problem (1.6)–(1.8). For the weak solution v of the problem (1.6)–(1.8), we define in this subsection a generalized trace of the function $v|_{\Gamma_-} \in L^2_{\cos}(\Gamma_-)$. Consider the case when the function p in (1.4) satisfies conditions (2.3). In addition, assume for a while that the function v_0 in (1.7) satisfies the following two conditions:

$$v_0 \in C^\infty\left(\overline{\Omega} \times S^{N-1}\right) \tag{3.1}$$

and

$$v_0(x,\nu) \in C_0^\infty(\Omega) \quad \forall \nu \in S^{N-1}. \tag{3.2}$$

Therefore, Theorems 2.1 and 2.3 guarantee that unique solutions $u, v \in C^1_{tvgrad}\left(\overline{W}\right)$ exist for the following two initial boundary value problems:

$$u_t + \frac{d}{ds} u\left(x + s\nu, t, \nu\right) |_{s=0} + a(x,t,\nu)u - \int_{S^{N-1}} g(x,t,\nu,\mu)u(x,t,\mu)d\sigma_\mu = 0 \quad \text{in } W, \tag{3.3}$$

$$u\,|_{t=0} = 0, \tag{3.4}$$

$$u\,|_{\Gamma_-} = p(x,t,\nu) \tag{3.5}$$

and the adjoint problem

$$v_t + \frac{d}{ds} v\left(x + s\nu, t, \nu\right) |_{s=0} - a(x,t,\nu)v + \int_{S^{N-1}} g(x,t,\mu,\nu)v(x,t,\mu)d\sigma_\mu = 0 \quad \text{in } W, \tag{3.6}$$

$$v(x,T,\nu) = v_0\left(x,\nu\right), \quad (x,\nu) \in \Omega \times S^{N-1}, \tag{3.7}$$

$$v\,|_{\Gamma_+} = 0. \tag{3.8}$$

By (3.4), we have

$$\int_0^T u_t v dt = (uv)\left(x,T,\nu\right) - \int_0^T u v_t dt. \tag{3.9}$$

Fix an arbitrary vector $\nu_0 \in S^{N-1}$. Let A_{ν_0} be an orthogonal matrix satisfying (2.6). Introduce again notations (2.7)–(2.10). In addition, let $\widetilde{v}(y,t,\widetilde{\nu}_0) = v(A^{-1}_{\nu_0}y, t, A^{-1}_{\nu_0}\nu_0)$. Since in the new coordinates

$$\frac{d}{ds} u\left(x + s\nu_0, t, \nu_0\right) |_{s=0} = \widetilde{u}_{y_1}\left(y,t,\widetilde{\nu}_0\right)$$

and

$$\frac{d}{ds} v\left(x + s\nu_0, t, \nu_0\right) |_{s=0} = \widetilde{v}_{y_1}\left(y,t,\widetilde{\nu}_0\right),$$

(3.3), (3.6), and (3.9) imply that

$$\int_{A_{\nu_0}\Omega} \int_0^T \left\{ \left(-\widetilde{u}_{y_1} - \widetilde{a}\widetilde{u}\right)(y,t,\widetilde{\nu}_0) + \int_{S^{N-1}} \widetilde{g}(y,t,\widetilde{\nu}_0,\eta)\widetilde{u}(y,t,\eta)d\sigma_\eta \right\} \widetilde{v}(y,t,\widetilde{\nu}_0)dtdy$$

$$= \int_{A_{\nu_0}\Omega} \int_0^T \left\{ \left(= \widetilde{v}_{y_1} - \widetilde{a}\widetilde{v}\right)(y,t,\widetilde{\nu}_0) + \int_{S^{N-1}} \widetilde{g}(y,t,\eta,\widetilde{\nu}_0)\widetilde{v}(y,t,\eta)d\sigma_\eta \right\} \widetilde{u}(y,t,\widetilde{\nu}_0)dtdy \tag{3.10}$$

$$+ \int_{A_{\nu_0}\Omega} \left(\widetilde{u}\widetilde{v}\right)(y,T,\widetilde{\nu}_0)dy.$$

For an arbitrary vector $\nu \in S^{N-1}$ denote

$$\partial\Omega_-(\nu) = \{x \in \partial\Omega : (n(x), \nu) \le 0\}, \quad \partial\Omega_+(\nu) = \{x \in \partial\Omega : (n(x), \nu) > 0\}.$$

Hence, by (3.5) and (3.8)

$$u(x,t,\nu) = p(x,t,\nu) \text{ for } x \in \partial\Omega_-(\nu), \qquad v(x,t,\nu) = 0 \text{ for } x \in \partial\Omega_+(\nu). \tag{3.11}$$

Let $\widetilde{p}(y,t,\widetilde{\nu}_0) = p\left(A_{\nu_0}^{-1}y, t, A_{\nu_0}^{-1}\widetilde{\nu}_0\right)$. Integrating by parts, we obtain for the two terms in (3.10)

$$\int_{A_{\nu_0}\Omega} (-\widetilde{u}_{y_1} \cdot \widetilde{v})(y,t,\widetilde{\nu}_0)dy - \int_{A_{\nu_0}\Omega} (\widetilde{u} \cdot \widetilde{v}_{y_1})(y,t,\widetilde{\nu}_0)dy$$

$$= -\int_{\partial\left(A_{\nu_0}\Omega\right)} (\widetilde{u} \cdot \widetilde{v})(y,t,\widetilde{\nu}_0)\cos(\widetilde{n}, y_1)\, dS_y.$$

Change variables "backwards" ($y \Leftrightarrow x = A_{\nu_0}^{-1}y$, $\nu_0 = A_{\nu_0}^{-1}\widetilde{\nu}_0$) in the last integral and note again that by (2.6) $\cos(\widetilde{n}(y), y_1) = \cos(n(x), \nu_0)$. Hence, using (3.11), we obtain

$$-\int_{\partial\left(A_{\nu_0}\Omega\right)} (\widetilde{p} \cdot \widetilde{v})(y,t,\widetilde{\nu}_0)\cos(\widetilde{n}, y_1)\, dS_y = -\int_{\partial\Omega} (u \cdot v)(x,t,\nu_0)\cos(n,\nu_0)\, dS_x$$

$$= -\int_{\partial\Omega_-(\nu_0)} (p \cdot v)(x,t,\nu_0)\cos(n,\nu_0)\, dS_x.$$

Hence, integrating with respect to $t \in (0,T)$, we obtain

$$\int_0^T \int_\Omega (-\widetilde{u}_{y_1} \cdot \widetilde{v})(y,t,\widetilde{\nu}_0)dydt - \int_0^T \int_\Omega (\widetilde{u} \cdot \widetilde{v}_{y_1})(y,t,\widetilde{\nu}_0)dydt$$

$$= -\int_0^T \int_{\partial\Omega_-(\nu_0)} p(x,t,\nu_0)v(x,t,\nu_0)\cos(n,\nu_0)\, dS_x dt. \tag{3.12}$$

Changing variables "backwards" in the rest of the integrals of (3.10), substituting (3.12), integrating with respect to $\nu_0 \in S^{N-1}$, and noting that

$$\int_{S^{N-1}} \int_0^T \int_{\partial\Omega_-(\nu)} (\dots) dS_x dt d\sigma_\nu = \int_{\Gamma_-} (\dots) dS_x dt d\sigma_\nu,$$

we obtain

$$-\int_{\Gamma_-} p(x,t,\nu)v(x,t,\nu)\cos(n,\nu)\, dS_x dt d\sigma_\nu = \int_{S^{N-1}} \int_\Omega u(x,T,\nu)v(x,T,\nu)dxd\sigma_\nu. \tag{3.13}$$

Since

$$-\cos(n,\nu) = |\cos(n,\nu)| \quad \text{on } \Gamma_-,$$

(1.9) implies that (3.13) can be rewritten as

$$\langle p, v\rangle = \int_{S^{N-1}} \int_\Omega u(x,T,\nu)v(x,T,\nu)dxd\sigma_\nu. \tag{3.14}$$

For all functions $p \in L^2_{\cos}(\Gamma_-)$, we define the linear operator L by

$$Lp = u(x,T,\nu) \quad \text{for } (x,\nu) \in \Omega \times S^{N-1}, \tag{3.15}$$

where $u \in C([0,T]; L^2(\Omega \times S^{N-1}))$ is the weak solution of the problem (3.3)–(3.5) (Theorem 2.3). Also, for all functions v_0 satisfying conditions (3.2), we define the linear operator K by

$$Kv_0 = v(x,t,\nu) \quad \text{for } (x,t,\nu) \in \Gamma_-,$$

where the function $v \in C^1_{tv grad}\left(\overline{W}\right)$ is the strong solution of the boundary value problem (3.6)–(3.8) (Theorem 2.1).

It follows from (3.15) and (2.16) that

$$\|u(x,T,\nu)\|_{L^2(\Omega\times S^{N-1})} = \|Lp\|_{L^2(\Omega\times S^{N-1})} \le C\,\|p\|_{L^2_{\cos}(\Gamma_-)} \quad \forall p \in L^2_{\cos}(\Gamma_-).$$

Hence, the linear operator $L : L^2_{\cos}(\Gamma_-) \to L^2\left(\Omega \times S^{N-1}\right)$ is bounded:

$$\|Lp\|_{L^2(\Omega\times S^{N-1})} \le \|L\|\,\|p\|_{L^2\cos(\Gamma_-)} \quad \forall p \in L^2_{\cos}(\Gamma_-). \tag{3.16}$$

Let $[,]$ be the scalar product in the Hilbert space $L^2\left(\Omega \times S^{N-1}\right)$. Hence, it follows from (3.7), (3.13), (3.14), and (1.9) that for all functions $p \in L^2_{\cos}(\Gamma_-)$ and all functions v_0 satisfying conditions (3.2) the following equality holds:

$$\langle p, Kv_0\rangle = [Lp, v_0]. \tag{3.17}$$

Let $v_0(x,\nu)$ be an arbitrarily given function satisfying conditions (3.1) and (3.2). Denote $\widetilde{p} = Kv_0$. Then by (3.17)

$$\|Kv_0\|^2_{L^2_{\cos}(\Gamma_-)} = \langle Kv_0, Kv_0\rangle = \langle \widetilde{p}, Kv_0\rangle = [L\widetilde{p}, v_0]. \tag{3.18}$$

Using (3.16), (3.18), and the Cauchy–Schwarz inequality, we obtain

$$\begin{aligned}\|Kv_0\|^2_{L^2_{\cos}(\Gamma_-)} &= \langle Kv_0, Kv_0\rangle = [L\widetilde{p}, v_0]\\ &\le \|L\| \cdot \|\widetilde{p}\|_{L^2_{\cos}(\Gamma_-)} \cdot \|v_0\|_{L^2(\Omega\times S^{N-1})}\\ &= \|L\| \cdot \|Kv_0\|_{L^2_{\cos}(\Gamma_-)} \cdot \|v_0\|_{L^2(\Omega\times S^{N-1})}.\end{aligned}$$

Hence

$$\|Kv_0\|_{L^2_{\cos}(\Gamma_-)} \le \|L\|\,\|v_0\|_{L^2(\Omega\times S^{N-1})}. \tag{3.19}$$

Since the set of functions v_0 satisfying conditions (3.1) and (3.2) is dense in $L^2(\Omega \times S^{N-1})$, we can uniquely extend the bounded operator K, which was originally defined on the set of functions satisfying (3.1) and (3.2), to the bounded operator defined on the whole space $L^2(\Omega \times S^{N-1})$. We denote this extension by the same notation: $Kv_0 = v|_{\Gamma_-}$, where v is the weak solution of the initial boundary value problem (3.6)–(3.8). Hence, it follows from (3.19) that $K : L^2(\Omega \times S^{N-1}) \to L^2_{\cos}(\Gamma_-)$ is a bounded linear operator.

DEFINITION 3.1. *Let $v_0 \in L^2(\Omega \times S^{N-1})$ be an arbitrary function and let v be the weak solution of the adjoint problem* (3.6)–(3.8) *(Definition* 2.2*). We call the function $Kv_0 \in L^2_{\cos}(\Gamma_-)$ the generalized trace of the function v on Γ_-.*

3.2. Application of the theory of closed range operators. It follows from the above that inequality (3.19) holds for any function $v_0 \in L^2(\Omega \times S^{N-1})$. This means that (3.17) holds for all functions $p \in L^2_{\cos}(\Gamma_-)$ and all functions $v_0 \in L^2\left(\Omega \times S^{N-1}\right)$. Therefore, (3.17) implies that

$$L^* = K. \tag{3.20}$$

We now apply estimate (1.11) of Theorem 1.2. By (1.11), we have $\|v_0\|_{L^2(\Omega \times S^{N-1})} \leq C\|Kv_0\|_{L^2_{\cos}(\Gamma_-)}$. Hence, combining this estimate with (3.20), we obtain

$$\|v_0\|_{L^2(\Omega \times S^{N-1})} \leq C\,\|L^* v_0\|_{L^2_{\cos}(\Gamma_-)} \quad \forall v_0 \in L^2(\Omega \times S^{N-1}). \tag{3.21}$$

The estimate (3.21) implies that the operator $L^* = K$ is one-to-one and its range $R(L^*) = L^*(L^2(\Omega \times S^{N-1})) \subset L^2_{\cos}(\Gamma_-)$ is closed. It now follows immediately from Lemma 3, p. 488, of the classic book of Dunford and Schwartz [7] that the operator $L : L^2_{\cos}(\Gamma_-) \to L^2\left(\Omega \times S^{N-1}\right)$ is surjective; i.e., its range is $R(L) = L^2(\Omega \times S^{N-1})$.

In other words, we have proved that for any function $u_T(x,\nu) \in L^2\left(\Omega \times S^{N-1}\right)$ one can find a control function $p \in L^2_{\cos}(\Gamma_-)$ such that $Lp = u(x,T,\nu) = u_T(x,\nu)$, where $u(x,t,\nu) \in C([0,T]; L^2(\Omega \times S^{N-1}))$, is the weak solution of the initial boundary value problem (3.3)–(3.5). Thus, the proof of Theorem 1.1 is complete. □

4. Proofs of Theorems 1.2 and 1.3. Recall that by the definition of the number R (see introduction)

$$|x| \leq R \quad \forall x \in \overline{\Omega}. \tag{4.1}$$

4.1. Carleman estimate. Consider the function

$$\psi(x,t) = |x|^2 - \alpha\left(t - \frac{T}{2}\right)^2, \qquad \alpha = const. \in (0,1). \tag{4.2}$$

The Carleman weight function is defined as

$$\varphi(x,t) = \exp[\lambda\psi(x,t)],$$

where $\lambda > 1$ is a parameter. Let $c = const. \in (0,R)$. Denote

$$G_c = \{(x,t) \in \Omega \times \mathbb{R} : \psi(x,t) > c^2\}. \tag{4.3}$$

Clearly,

$$G_{c_1} \subset G_{c_2} \text{ if } c_1 > c_2. \tag{4.4}$$

The boundary ∂G_c of the domain G_c consists of two parts, $\partial G_c = \partial_1 G_c \cup \partial_2 G_c$, where

$$\partial_1 G_c = \{(x,t) \in \overline{\Omega} \times \mathbb{R} : x \in \partial\Omega\ \} \quad \text{and} \quad \partial_2 G_c = \overline{G}_c \cap \left\{\psi(x,t) = c^2\right\}. \tag{4.5}$$

Hence, $\partial_1 G_c$ is a part of the boundary $\partial\Omega \times \mathbb{R}$ of the time cylinder $\Omega \times \mathbb{R}$, and $\partial_2 G_c$ is a part of the level surface (hyperboloid) of the function $\psi(x,t)$.

LEMMA 4.1. *Let $T > 2R$. Denote $\alpha(R,T) := (2R/T)^2$. Then for all $\alpha \in [\alpha(R,T),1)$ and for all $c \in (0,R)$ the domain $G_c \neq \varnothing$ and $G_c \subset \Omega \times (0,T)$.*

Proof. The following implication follows from (4.5):

$$\partial_1 G_c \subset \{\partial\Omega \times (0,T)\} \Rightarrow G_c \subset \Omega \times (0,T).$$

On the other hand, by (4.2), (4.3), and (4.5)

$$\partial_1 G_c \subset \{\partial\Omega \times (0,T)\} \Leftrightarrow \max_{\partial\Omega}[\psi(x,T)] < c^{2\cdot}.$$

By (4.1) and (4.2)

$$R^2 - \alpha\frac{T^2}{4} < c^2 \Rightarrow \max_{\partial\Omega}[\psi(x,T)] = \max_{\partial\Omega}[\psi(x,0)] < c^{2\cdot}.$$

Since $T > 2R$, the number $\alpha(R,T) = (2R/T)^2 \in (0,1)$. On the other hand, for all $\alpha \in [\alpha(R,T),1)$

$$R^2 - \alpha\frac{T^2}{4} \le R^2 - \alpha(R,T)\frac{T^2}{4} = R^2 - \left(\frac{2R}{T}\right)^2\frac{T^2}{4} = 0 < c^2.$$

Also, since all points of the segment of the straight line connecting points z_1 and z_2 belong to the domain Ω, it follows that for all $c \in (0,R)$

$$[G_c \cap \{t = T/2\}] \cap \Omega = \{x \in \Omega : |x| > c\} \neq \varnothing. \qquad \square$$

In any Carleman estimate for a differential operator, only the principal part of this operator is considered. In other words, a Carleman estimate for a differential operator is independent of its lower order terms including the integral term in (1.1), which is the advantage of our method. As for the lower order terms, they are incorporated at a later stage when either a uniqueness or stability result is proved for a corresponding Cauchy problem. Hence, we denote

$$L_0 u = u_t + \frac{d}{ds}u(x + s\nu, t, \nu)\,|_{s=0} \quad \forall \nu \in S^{N-1}. \tag{4.6}$$

Because of the insufficient smoothness guaranteed by Theorem 2.1 (Remark 2.1), it is convenient to formulate the Carleman estimate for the operator L_0 in terms of the above vector $\widetilde{\nu}_0 = (1,0,0,\dots,0)^T = A_{\nu_0}\nu_0$ in (2.6), where $\nu_0 \in S^{N-1}$ is an arbitrarily chosen unit vector.

LEMMA 4.2 (pointwise Carleman estimate). *Let $T > 2R$ and in* (4.2) *let the constant $\alpha \in [\alpha(R,T),1)$ (Lemma* 4.1*). Then for all values of the parameter $\lambda > 1$ and for all functions $u \in C^1_{tv grad}(\overline{W})$, the following pointwise Carleman estimate holds:*

$$(L_0 u)^2\varphi^2 \ge 2\lambda(1-\alpha)u^2\varphi^2 + \nabla\cdot U + V_t \quad \forall (x,t) \in G_c, \quad \forall \nu \in S^{N-1}, \tag{4.7}$$

where the vector function (U,V) can be estimated as

$$|(U,V)| \le C\lambda u^2\varphi^2 \tag{4.8}$$

and the vector function U is such that

$$\left|\int_{\partial_1 G_c}(U,n)\,dS_x dt\right| \le C\lambda\int_{\partial_1 G_c}|\cos(n,\nu)|\,u^2\varphi^2 dS_x dt \quad \forall \nu \in S^{N-1}. \tag{4.9}$$

Proof. By Lemma 4.1, $G_c \subset \Omega \times (0,T)$. Fix an arbitrary vector $\nu_0 \in S^{N-1}$. Let $A_{\nu_0} = \left(a^{ij}_{\nu_0}\right)_{ij=1}^n$ be an orthogonal matrix such that (2.6) is fulfilled. Introduce again notations (2.7) and (2.8). Then (4.2) and (4.6) imply that

$$L_0\widetilde{u} = \widetilde{u}_t + \widetilde{u}_{y_1}, \quad \psi(y,t) = |y|^2 - \alpha\left(t - \frac{T}{2}\right)^2, \quad \varphi(y,t) = \exp[\lambda\psi(y,t)].$$

Hence, the resulting domain $\widetilde{G}_c$ has the same form as the original domain G_c. Denote $v = \widetilde{u} \cdot \exp\left[\lambda\psi(y,t)\right] = \widetilde{u} \cdot \varphi$. Then

$$\widetilde{u} = v \exp\left\{\lambda\left[\alpha\left(t - \frac{T}{2}\right)^2 - |y|^2\right]\right\},$$

$$\widetilde{u}_{y_1} = \left(v_{y_1} - 2\lambda y_1 v\right) \exp\left[-\lambda\psi(y,t)\right],$$

$$\widetilde{u}_t = \left[v_t + 2\lambda\alpha\left(t - \frac{T}{2}\right) v\right] \exp\left[-\lambda\psi(y,t)\right].$$

Hence, for this vector ν_0

$$\begin{aligned}
(L_0 u)^2 \varphi^2 &= \left\{\left(v_t + v_{y_1}\right) - 2\lambda\left[y_1 - \alpha\left(t - \frac{T}{2}\right)\right] v\right\}^2 \\
&\geq -4\lambda\left[y_1 - \alpha\left(t - \frac{T}{2}\right)\right] v \left(v_t + v_{y_1}\right) \\
&= \left\{-2\lambda\left[y_1 - \alpha\left(t - \frac{T}{2}\right)\right] v^2\right\}_t - 2\lambda\alpha v^2 \\
&\quad + \left\{-2\lambda\left[y_1 - \alpha\left(t - \frac{T}{2}\right)\right] v^2\right\}_{y_1} + 2\lambda v^2 \\
&= 2\lambda\left(1 - \alpha\right)\widetilde{u}^2\varphi^2 + \nabla_y \cdot \widetilde{U} + V_t.
\end{aligned}$$

Thus,

$$(L_0\widetilde{u})^2\varphi^2 \geq 2\lambda\left(1 - \alpha\right)\widetilde{u}^2\varphi^2 + \nabla_y \cdot \widetilde{U} + \widetilde{V}_t, \tag{4.10}$$

where

$$\nabla_y \cdot \widetilde{U} = \left\{-2\lambda\left[y_1 - \alpha\left(t - \frac{T}{2}\right)\right]\widetilde{u}^2\varphi^2\right\}_{y_1} \tag{4.11}$$

and

$$\widetilde{V}_t = \left\{-2\lambda\left[y_1 - \alpha\left(t - \frac{T}{2}\right)\right]\widetilde{u}^2\varphi^2\right\}_t. \tag{4.12}$$

The backwards change of variables $y \to x$ will replace $\nabla_y \cdot \widetilde{U}$ with $\nabla_x \cdot U$ and $\widetilde{V}_t$ with V_t. Hence, (4.10) is equivalent to (4.6). It is clear from (4.11) and (4.12) that estimate (4.8) holds for the vector function (U, V).

Thus, in order to finish the proof, we now need to prove (4.9). Consider the integral

$$\int_{\widetilde{G}_c} \nabla_y \cdot \widetilde{U} dy dt.$$

Obviously,

$$\int_{\widetilde{G}_c} \nabla_y \cdot \widetilde{U} dy dt = \int_{G_c} \nabla_x \cdot U dx dt.$$

By the Gauss theorem, we have

$$\int_{\widetilde{G}_c} \nabla_y \cdot \widetilde{U} dy dt = \int_{\partial_1 \widetilde{G}_c} \left(\widetilde{U}, \widetilde{n}\right) dS_{y,t} + \int_{\partial_2 \widetilde{G}_c} \left(\widetilde{U}, \widetilde{n}\right) dS_{y,t}. \tag{4.13}$$

In order to prove (4.9), we estimate from the above the first integral on the right-hand side of (4.13). Using (4.11) and recalling again that by (2.6) $\cos(\widetilde{n}(y), y_1) = \cos(n(x), \nu_0)$, where $x = A_{\nu_0}^{-1} y$, we obtain

$$\left| \int_{\partial_1 \widetilde{G}_c} \left(\widetilde{U}, \widetilde{n}\right) dS_y dt \right| = \left| 2\lambda \int_{\partial_1 \widetilde{G}_c} \cos(\widetilde{n}, y_1) \left[y_1 - \alpha \left(t - \frac{T}{2} \right) \right] \widetilde{u}^2 \varphi^2 dS_y dt \right|$$

$$\leq C\lambda \int_{\partial_1 \widetilde{G}_c} |\cos(\widetilde{n}, y_1)| \, \widetilde{u}^2 \varphi^2 dS_y dt = C\lambda \int_{\partial_1 G_c} |\cos(n, \nu_0)| \, u^2 \varphi^2 dS_y dt.$$

On the other hand,

$$\int_{\partial_1 \widetilde{G}_c} \left(\widetilde{U}, \widetilde{n}\right) dS_y dt = \int_{\partial_1 G_c} (U, n) \, dS_x dt.$$

Hence,

$$\left| \int_{\partial_1 G_c} (U, n) \, dS_x dt \right| \leq C\lambda \int_{\partial_1 G_c} |\cos(n, \nu_0)| \, u^2 \varphi^2 dS_y dt,$$

which proves (4.9) for $\nu = \nu_0$. Since $\nu_0 \in S^{N-1}$ is an arbitrary vector and (4.10) holds, the proof is complete. □

4.2. Proof of Theorem 1.3. Since $T > 2R$, $\sqrt{5R^2 + T^2} > 3R$. Hence, we choose a number $\varepsilon = \varepsilon(\Omega)$ so small that

$$0 < \varepsilon \leq \min\left(\frac{R}{3}, \frac{\sqrt{5R^2 + T^2} - 3R}{4} \right) \tag{4.14}$$

and

$$\{|x| < 3\varepsilon\} \subset \Omega. \tag{4.15}$$

From now on we set $\alpha = [1 + \alpha(R, T)]/2$ in the function ψ in (4.2), for the sake of the definiteness, where the number $\alpha(R, T) = (2R/T)^2 \in (0, 1)$ was chosen in Lemma 4.1. Choose the number $\delta = \delta(\varepsilon) = \varepsilon/20$. Since $\varepsilon/2 + 3\delta \in (0, R)$, by Lemma 4.1 and (4.4)

$$G_{\varepsilon/2+3\delta} \neq \varnothing \text{ and } G_{\varepsilon/2+3\delta} \subset G_{\varepsilon/2+2\delta} \subset G_{\varepsilon/2+\delta} \subset G_{\varepsilon/2} \subset \Omega \times (0, T). \tag{4.16}$$

Introduce the "cut-off" function $\chi(x, t) \in C^1(\overline{\Omega} \times [0, T])$ such that $0 \leq \chi \leq 1$ and

$$\chi(x, t) = \begin{cases} 1 & \text{in } G_{\varepsilon/2+2\delta}, \\ 0 & \text{in } \{\Omega \times (0, T)\} \backslash G_{\varepsilon/2+\delta}. \end{cases} \tag{4.17}$$

Let the function $v \in C^1_{t\nu grad}\left(\overline{W}\right)$ be a solution of the adjoint transport equation (1.6). For $(x, t, \nu) \in \Gamma(T)$ let the function $q(x, t, \nu)$ be its boundary value, $v|_{x \in \partial\Omega} := q(x, t, \nu)$. Denote

$$w(x, t, \nu) = v(x, t, \nu) \chi(x, t). \tag{4.18}$$

Then

$$L_0 w = w_t + \frac{d}{ds} w\left(x+\nu s, t, \nu\right)\mid_{s=0}$$

$$= \chi\left(v_t + \frac{d}{ds} v\left(x+\nu s, t, \nu\right)\mid_{s=0}\right) + v\left(\chi_t + \sum_{i=1}^{n} \nu_i \chi_i\right).$$

Therefore, using (1.12), we obtain

$$\left| w_t + \frac{d}{ds} w\left(x+\nu s, t, \nu\right)\mid_{s=0}\right| \le M_1\left[|w| + \int_{S^{N-1}} |w(x,t,\mu)|\, d\sigma_\mu + |f|\right]$$

$$+ M_1\left(1-\chi\right)\left[|v| + \int_{S^{N-1}} |v(x,t,\mu)|\, d\sigma_\mu\right].$$

Here and below $M_1 = M_1\left(M, \Omega, T\right)$ denotes different positive constants depending only on M, Ω, and T. Square both sides of the latter equality, multiply by the function $\varphi(x,t)$, integrate over $G_{\varepsilon/2}$, and apply the Carleman estimate of Lemma 4.2 to the resulting left-hand side. Note that derivatives $\chi_t, \chi_i, i = 1, \dots, n$, are bounded and differ from zero only in the domain $G_{\varepsilon/2+\delta} \backslash G_{\varepsilon/2+2\delta}$. Hence, (4.8) implies that the corresponding vector function $(U, V) = 0$ on $\partial_2 G_{\varepsilon/2}$. Also, $V\cos(n,t) = 0$ on $\partial_1 G_{\varepsilon/2}$. Hence, the Gauss theorem and (4.9) imply that

$$\left|\int_{G_{\varepsilon/2}} \left(\nabla\cdot U + V_t\right) dxdt\right| = \left|\int_{\partial_1 G_{\varepsilon/2}} \left(U, n\right) dS_x dt\right| \le C\lambda \int_{\partial_1 G_{\varepsilon/2}} \left|\cos\left(n,\nu\right)\right| v^2 \varphi^2 dS_x dt$$

$$= C\lambda \int_{\partial_1 G_{\varepsilon/2}} \left|\cos\left(n,\nu\right)\right| q^2 \varphi^2 dS_x dt.$$

Thus, we obtain for all $\nu \in S^{N-1}$

$$2\lambda(1-\alpha)\int_{G_{\varepsilon/2}} w^2\varphi^2 dxdt \tag{4.19}$$

$$\le M_1\left[\int_{G_{\varepsilon/2}} \left(|w|^2 + \int_{S^{N-1}} w^2 d\sigma_\mu + f^2\right)\varphi^2 dxdt\right]$$

$$+ M_1 \int_{G_{\varepsilon/2}} \left(1-\chi\right) v^2\varphi^2 dxdt + M_1 \int_{G_{\varepsilon/2}} \left(1-\chi\right) \int_{S^{N-1}} v^2\left(x,t,\mu\right) d\sigma_\mu$$

$$+ C\lambda \int_{\partial_1 G_{\varepsilon/2}} \left|\cos\left(n,\nu\right)\right| q^2\varphi^2 dS_x dt.$$

For each $c \in (0, R)$ denote $H_c = G_c \times S^{N-1}$, $M_c = \partial_1 G_c \times S^{N-1}$, and $dh = dxdtd\sigma_\nu$. Integrate (4.19) with respect to $\nu \in S^{N-1}$. Noticing that

$$\int_{H_{\varepsilon/2}} \left(\int_{S^{N-1}} w^2\left(x,t,\mu\right) d\sigma_\mu\right)\varphi^2 dh = A_N \cdot \int_{H_{\varepsilon/2}} w^2\varphi^2 dh,$$

where A_N is the area of the unit sphere S^{N-1}, we obtain

(4.20)
$$2\lambda(1-\alpha)\int_{H_{\varepsilon/2}} w^2\varphi^2 dh \le M_1\left(\int_{H_{\varepsilon/2}}\left(w^2+f^2\right)\varphi^2 dh + \int_{H_{\varepsilon/2}}(1-\chi)v^2\varphi^2 dh\right) + M_1\lambda\int_{M_{\varepsilon/2}}|\cos(n,\nu)|\, q^2\varphi^2 dS_x dt d\sigma_\nu.$$

Choose $\lambda_0 = \lambda_0(C) > 1$ such that $C/(\lambda_0(1-\alpha)) < 1$. Then

$$M_1\int_{H_{\varepsilon/2}} w^2\varphi^2 dh \le \lambda(1-\alpha)\int_{H_{\varepsilon/2}} w^2\varphi^2 dh \quad \forall\lambda > \lambda_0.$$

Hence, (4.20) leads to

(4.21)
$$\lambda\int_{H_{\varepsilon/2}} w^2\varphi^2 dh \le M_1\int_{H_{\varepsilon/2}}(1-\chi)v^2\varphi^2 dh + M_1\lambda\int_{M_{\varepsilon/2}}|\cos(n,\nu)|\, q^2\varphi^2 dS_x dt d\sigma_\nu + M_1\int_{H_{\varepsilon/2}} f^2\varphi^2 dh \quad \forall\lambda > \lambda_0.$$

Estimate from the below the left-hand side of inequality (4.21). By (4.17) and (4.18) $w = v$ in $H_{\varepsilon/2+2\delta}$. Also, by (4.16) $H_{\varepsilon/2+3\delta} \subset H_{\varepsilon/2+2\delta} \subset H_{\varepsilon/2+\delta} \subset H_{\varepsilon/2}$ and by (4.3) $\varphi^2(x,t) \ge \exp\left[2\lambda\left(\varepsilon/2+3\delta\right)^2\right]$ in $H_{\varepsilon/2+3\delta}$. Hence,

(4.22)
$$\lambda\int_{H_{\varepsilon/2}} w^2\varphi^2 dh \ge \lambda\int_{H_{\varepsilon/2+3\delta}} w^2\varphi^2 dh = \lambda\int_{H_{\varepsilon/2+3\delta}} v^2\varphi^2 dh \ge \lambda\exp\left[2\lambda\left(\varepsilon/2+3\delta\right)^2\right]\int_{H_{\varepsilon/2+3\delta}} v^2 dh.$$

Estimate now the right-hand side of inequality (4.21) from the above. Since by (4.17) $1-\chi(x,t) = 0$ in $G_{\varepsilon/2+2\delta}$, we have

$$\sup_{H_{\varepsilon/2}}\left[(1-\chi)\varphi^2\right] \le \exp\left[2\lambda\left(\varepsilon/2+2\delta\right)^2\right].$$

Hence,

(4.23)
$$\int_{H_{\varepsilon/2}}\int(1-\chi)v^2\varphi^2 dh \le \exp\left[2\lambda\left(\varepsilon/2+2\delta\right)^2\right]\int_{H_{\varepsilon/2}} v^2 dh.$$

Therefore (4.21)–(4.23) imply that

(4.24)
$$\lambda\exp\left[2\lambda\left(\varepsilon/2+3\delta\right)^2\right]\int_{H_{\varepsilon/2+3\delta}} v^2 dh \le M_1\exp\left[2\lambda\left(\varepsilon/2+2\delta\right)^2\right]\cdot\int_W v^2 dh + M_1\lambda\int_\Gamma|\cos(n,\nu)|q^2\varphi^2 dS_x dt s\sigma_\nu + M_1\int_{H_{\varepsilon/2}} f^2\varphi^2 dh.$$

Let $m = \sup_{G_{\varepsilon/2}} [\psi(x,t)]$. Then (4.24) leads to

$$\lambda \exp\left[2\lambda\left(\varepsilon/2+3\delta\right)^2\right] ||v||^2_{L^2(H_{\varepsilon/2+3\delta})} \leq M_1 \exp\left[2\lambda\left(\varepsilon/2+2\delta\right)^2\right] ||v||^2_{L^2(W)} + M_1\lambda e^{2\lambda m}||q||^2_{L^2_{\cos}(\Gamma)} + M_1 e^{2\lambda m}\left\|f\right\|^2_{L^2(W)},$$

where the Hilbert space $L^2_{\cos}(\Gamma)$ is defined similarly with $L^2_{\cos}(\Gamma_-)$. Dividing this inequality by $\lambda \exp\left[2\lambda(\varepsilon/2+3\delta)^2\right]$, we obtain

(4.25)

$$||v||^2_{L^2(H_{\varepsilon/2+3\delta})} \leq M_1 \exp\left[-2\lambda\delta\left(\varepsilon+5\delta\right)\right] ||v||^2_{L^2(W)} + M_1 e^{2\lambda m}\left[||q||^2_{L^2_{\cos}(\Gamma)} + \left\|f\right\|^2_{L^2(W)}\right].$$

An inconvenience of the domain $H_{\varepsilon/2+3\delta}$ for our goal is that

$$H_{\varepsilon/2+3\delta} \cap \{t = T/2\} \subset \left(\Omega \times S^{N-1}\right), \quad \text{but} \quad \left(\Omega \times S^{N-1}\right) \diagdown H_{\varepsilon/2+3\delta} \cap \{t = T/2\} \neq \varnothing.$$

Thus, we now "shift" this domain. Choose an x_0 such that $|x_0| = 3\varepsilon/2$. By (4.15) $x_0 \in \Omega$. Consider the domain

$$G_{\varepsilon/2}(x_0) = \left\{(x,t) \in \Omega \times \mathbb{R} : |x-x_0|^2 - \alpha\left(t - \frac{T}{2}\right)^2 > \left(\frac{\varepsilon}{2}\right)^2\right\} \tag{4.26}$$

$$= \left\{(x,t) \in \Omega \times \mathbb{R} : \psi\left(x - x_0, t\right) > \left(\frac{\varepsilon}{2}\right)^2\right\},$$

which is obtained by a shift of the domain $G_{\varepsilon/2}$. We now prove that

$$G_{\varepsilon/2}(x_0) \subset \Omega \times (0,T). \tag{4.27}$$

Indeed, since by (4.1)

$$\max_{x \in \overline{\Omega}} |x - x_0| \leq |x| + |x_0| \leq R + \frac{3}{2}\varepsilon,$$

using (4.2), we obtain

$$\max_{x \in \partial\Omega} \left[\psi(x - x_0, T)\right] \leq \left(R + \frac{3}{2}\varepsilon\right)^2 - \frac{R^2}{2} - \frac{T^2}{8}.$$

It follows from (4.14) that

$$\left(R + \frac{3}{2}\varepsilon\right)^2 - \frac{R^2}{2} - \frac{T^2}{8} < \left(\frac{\varepsilon}{2}\right)^2.$$

Hence,

$$\max_{x \in \partial\Omega} \left[\psi(x - x_0, T)\right] < \left(\frac{\varepsilon}{2}\right)^2,$$

which proves (4.27). Also since $\delta = \delta(\varepsilon) = \varepsilon/20$, it follows from (4.26) that $(0, T/2) \in G_{\varepsilon/2+3\delta}(x_0) \cap \{t = T/2\}$, which proves that

$$G_{\varepsilon/2+3\delta}(x_0) \cap [\Omega \times (0,T)] \neq \varnothing.$$

Hence, the Carleman estimate of Lemma 4.2 is valid for the domain $G_{\varepsilon/2}(x_0)$. Thus, similarly to (4.25), we obtain

$$||v||^2_{L^2\left(H_{\varepsilon/2+3\delta}(x_0)\right)} \leq M_1 \exp\left[-2\lambda\delta\left(\varepsilon+5\delta\right)\right]||v||^2_{L^2(W)} + M_1 e^{2\lambda m}\left[||q||^2_{L^2_{\cos}(\Gamma)} + \|f\|^2_{L^2(W)}\right], \tag{4.28}$$

where $H_{\varepsilon/2+3\delta}\left(x_0\right) = G_{\varepsilon/2+3\delta}(x_0) \times S^{N-1}$.

It follows from (4.2)–(4.4) and (4.26) that

$$G_{\varepsilon/2+3\delta} \cap \{t = T/2\} = \left\{|x| > \frac{\varepsilon}{2} + 3\delta\right\} \cap \Omega \tag{4.29}$$

and

$$G_{\varepsilon/2+3\delta}\left(x_0\right) \cap \{t = T/2\} = \left\{|x - x_0| > \frac{\varepsilon}{2} + 3\delta\right\} \cap \Omega. \tag{4.30}$$

Consider the ball $B\left(0, \varepsilon/2 + 4\delta\right)$,

$$B\left(0, \frac{\varepsilon}{2} + 4\delta\right) = \left\{x : |x| < \frac{\varepsilon}{2} + 4\delta\right\} = \left\{x : |x| < \frac{7}{10}\varepsilon\right\} = B\left(0, \frac{7}{10}\varepsilon\right).$$

By (4.15) $B\left(0, \varepsilon/2 + 4\delta\right) \subset \Omega$. We now prove that $B\left(0, \varepsilon/2 + 4\delta\right) \subset G_{\varepsilon/2+3\delta}\left(x_0\right) \cap \{t = T/2\}$. Let $x \in B\left(0, \varepsilon/2 + 4\delta\right)$ be an arbitrary point of the ball B. Then

$$|x - x_0| \geq |x_0| - |x| = \frac{3}{2}\varepsilon - |x| > \frac{3}{2}\varepsilon - \frac{\varepsilon}{2} - 4\delta = \varepsilon - 4\delta.$$

Since $\delta = \varepsilon/20$, we have $\varepsilon - 4\delta > \varepsilon/2 + 3\delta$. Hence,

$$|x - x_0| > \varepsilon - 4\delta > \frac{\varepsilon}{2} + 3\delta \quad \forall x \in B\left(0, \frac{\varepsilon}{2} + 4\delta\right).$$

Hence, by (4.30) $B\left(0, \varepsilon/2 + 4\delta\right) \subset \left\{G_{\varepsilon/2+3\delta}(x_0) \cap \{t = T/2\}\right\}$. Hence,

$$\left\{|x| \leq \frac{\varepsilon}{2} + 3\delta\right\} \subset B\left(0, \frac{\varepsilon}{2} + 4\delta\right) \subset \left\{G_{\varepsilon/2+3\delta}(x_0) \cap \{t = T/2\}\right\}. \tag{4.31}$$

Recall that by (4.16) and (4.26)

$$\left\{G_{\varepsilon/2+3\delta} \cap \{t = T/2\}\right\} \subset \Omega, \left\{G_{\varepsilon/2+3\delta}(x_0) \cap \{t = T/2\}\right\} \subset \Omega. \tag{4.32}$$

Therefore, (4.29)–(4.32) lead to

$$\Omega = \left(G_{\varepsilon/2+3\delta} \cup G_{\varepsilon/2+3\delta}\left(x_0\right)\right) \cap \{t = T/2\}.$$

Hence, there exists a number $\eta \in (0, T/2)$ such that the layer

$$E_\eta = \left\{(x,t) : x \in \Omega, \left|t - \frac{T}{2}\right| < \eta\right\} \subset \left(G_{\varepsilon/2+3\delta} \cup G_{\varepsilon/2+3\delta}\left(x_0\right)\right).$$

Hence, estimates (4.25) and (4.28) imply that

$$||v||^2_{L^2(E_\eta \times S^{N-1})} \leq M_1 \exp\left[-2\lambda\delta\left(\varepsilon+5\delta\right)\right]||v||^2_{L^2(W)} + M_1 e^{2\lambda m}\left[||q||^2_{L^2_{\cos}(\Gamma)} + \|f\|^2_{L^2(W)}\right].$$

Hence, by the mean value theorem there exists a number $t_1 \in (T/2-\eta, T/2+\eta)$ such that

$$||v(x,t_1,\nu)||^2_{L^2(\Omega\times S^{N-1})} \leq \frac{M_1}{2\eta}\exp\left[-2\lambda\delta(\varepsilon+5\delta)\right]||v||^2_{L^2(W)} + \frac{M_1}{2\eta}e^{2\lambda m}\left[||q||^2_{L^2_{\cos}(\Gamma)} + \|f\|^2_{L^2(W)}\right].$$

That is, with a new constant M_1

$$||v(x,t_1,\nu)||^2_{L^2(\Omega\times S^{N-1})} \leq M_1\exp\left[-2\lambda\delta(\varepsilon+5\delta)\right]||v||^2_{L^2(W)} + M_1 e^{2\lambda m}\left[||q||^2_{L^2_{\cos}(\Gamma)} + \|f\|^2_{L^2(W)}\right]. \tag{4.33}$$

This inequality and the energy estimate (2.16) lead to (with a new constant M_1)

$$||v||^2_{L^2(W)} \leq M_1\exp\left[-2\lambda(\varepsilon+5\delta)\right]||v||^2_{L^2(W)} + M_1 e^{2\lambda m}\left[||q||^2_{L^2_{\cos}(\Gamma)} + \|f\|^2_{L^2(W)}\right]. \tag{4.34}$$

Choose $\lambda \geq \lambda_0$ such that $C\exp\left[-2\lambda\delta(\varepsilon+5\delta)\right] < 1/2$. Then (4.34) implies that for this λ

$$\|v\|_{L^2(W)} \leq M_1\left[||q||_{L^2_{\cos}(\Gamma)} + \|f\|_{L^2(W)}\right]. \tag{4.35}$$

Using (4.33) and (4.35), we obtain that

$$\|v(x,t_1,\nu)\|_{L^2(\Omega\times S^{N-1})} \leq M_1\left[||q||_{L^2_{\cos}(\Gamma)} + \|f\|_{L^2(W)}\right].$$

Hence, using (2.16), we obtain that

$$\|v(x,t_0,\nu)\|_{L^2(\Omega\times S^{N-1})} \leq M_1\left[||q||_{L^2_{\cos}(\Gamma)} + \|f\|_{L^2(W)}\right] \quad \forall t_0 \in [0,T]. \tag{4.36}$$

□

4.3. Proof of Theorem 1.2. Estimates (4.35) and (4.36) are valid for any strong solution $v \in C^1_{tv grad}\left(\overline{W}\right)$ of the adjoint transport equation (1.6) with the boundary condition $v\,|_{x\in\partial\Omega} = q(x,t,\nu)$. Clearly, these estimates are also valid for any strong solution $u \in C^1_{tv grad}\left(\overline{W}\right)$ of the original equation (1.1) with the boundary condition $u\,|_{x\in\partial\Omega} = q(x,t,\nu)$. Recall now that Theorem 1.2 is concerned with the weak solution of the problem (1.6)–(1.8). Hence, by (1.8) we need to assume that $v\,|_{\Gamma_+} = 0$ and $f = 0$. Recalling that $v\,|_{\Gamma_-} := (Kv_0)(x,t,\nu)$, we see that (4.35) and (4.36) lead to (1.10) and (1.11), respectively. Thus, Theorem 1.2 is valid for strong solutions $v \in C^1_{tv grad}(\overline{W})$ of (1.6) with the boundary condition (1.8).

Consider now an arbitrary function $v_0 \in L^2\left(\Omega\times S^{N-1}\right)$, and let the function $v \in L^2(W)$ be the weak solution of the problem (1.6)–(1.8). Let $\{v_{0k}\}_{k=1}^{\infty}$ be a sequence of functions satisfying conditions (3.1), (3.2) and such that

$$\lim_{k\to\infty}\|v_0 - v_{0k}\|_{L^2(\Omega\times S^{N-1})} = 0. \tag{4.37}$$

Let $\{v_k\}_{k=1}^{\infty} \subset C^1_{tv grad}\left(\overline{W}\right)$ be the corresponding sequence of solutions of the problem (1.6)–(1.8) with the initial condition $v_k\,|_{t=T} = v_{0k}$. Then by Theorem 2.4

$$\lim_{k\to\infty}\|v - v_k\|_{L^2(W)} = 0.$$

In addition, functions $p_k := v_k|_{\Gamma_-} := Kv_{0k} \in L^2_{\cos}(\Gamma_-)$, and by Definition 3.1 of the generalized trace of the weak solution, we see that

$$\lim_{k\to\infty} \|p - p_k\|_{L^2\cos(\Gamma_-)} = 0. \tag{4.38}$$

Replacing v_0 with v_{0k} in estimates (1.10) and (1.11), we see that

$$\|v_k\|_{L^2(W)} \le C \|Kv_{0k}\|_{L^2_{\cos}(\Gamma_-)} \tag{4.39}$$

and

$$\|v_{0k}\|_{L^2(\Omega\times S^{N-1})} \le C \|Kv_{0k}\|_{L^2_{\cos}(\Gamma_-)}. \tag{4.40}$$

Since $K : L^2(\Omega \times S^{N-1}) \to L^2_{\cos}(\Gamma_-)$ is a bounded linear operator (see section 3 after (3.19)), the passage to limits in (4.37)–(4.40) yields (1.10) and (1.11) for the weak solution v. □

THE MULTI-AGENT RENDEZVOUS PROBLEM. PART 1: THE SYNCHRONOUS CASE*

J. LIN†, A. S. MORSE‡, AND B. D. O. ANDERSON§

Abstract. This paper is concerned with the collective behavior of a group of $n > 1$ mobile autonomous agents, labelled 1 through n, which can all move in the plane. Each agent is able to continuously track the positions of all other agents currently within its "sensing region," where by an agent's *sensing region* we mean a closed disk of positive radius r centered at the agent's current position. The *multi-agent rendezvous problem* is to devise "local" control strategies, one for each agent, which without any active communication between agents cause all members of the group to eventually rendezvous at a single unspecified location. This paper describes a solution to this problem consisting of individual agent strategies which are mutually synchronized in the sense that all depend on a common clock.

Key words. cooperative control, distributed control, multi-agent systems

1. Introduction.

Current interest in cooperative control has led to the development of a number of distributed control algorithms capable of causing large groups of mobile autonomous agents to perform useful tasks [11, 12, 13, 14, 15, 16, 17, 18, 19, 20]. Of particular interest here are provably correct algorithms which solve what we shall refer to as the "multi-agent rendezvous problem." This problem, which was considered previously in [19, 1], is concerned with the collective behavior of a group of $n > 1$ mobile autonomous agents, labelled 1 through n, which can all move in the plane. Each agent is able to continuously track the positions of all other agents currently within its "sensing region," where by an agent's *sensing region* we mean a closed disk of positive radius r centered at the agent's current position. The *multi-agent rendezvous problem* is to devise "local" control strategies, one for each agent, which without any active communication between agents cause all members of the group to eventually rendezvous at a single unspecified location.

In this paper, as in [1], we consider distributed strategies which guide each agent toward rendezvous by performing a sequence of "stop-and-go" maneuvers. A *stop-and-go maneuver* takes place within a time interval consisting of two consecutive subintervals. The first, called a *sensing period*, is an interval of fixed length during which the agent is stationary. The second, called a *maneuvering period*, is an interval of variable length during which the agent moves from its current position to its next

"way-point" and again comes to rest. Successive way-points for each agent are chosen to be within r_M units of each other, where r_M is a prespecified positive distance no larger than r. It is assumed that there has been chosen for each agent i a positive number τ_{M_i}, called a *maneuver time*, which is large enough so that the required maneuver for agent i from any one way-point to the next can be accomplished in at most τ_{M_i} seconds. Since our interest here is exclusively with devising *high level* strategies which dictate when and where agents are to move, we will use point models for agents and shall not deal with how maneuvers are actually carried out or with how vehicle collisions are to be avoided.

In this paper we describe a family of stop-and-go strategies which solves the problem. The family includes the specific strategies proposed in [1] and consists of agent strategies which are mutually synchronized in the sense that all depend on a common clock. In a sequel to this paper [12] we propose and analyze families of strategies which also solve the problem, but without the need for synchronization.

In the synchronous case treated here, the kth maneuvering periods of all n agents begin at the same time $\bar{t}_k$. The kth way-point of each agent is a function of the positions of its "registered neighbors" at time $\bar{t}_k$. Agent i's registered neighbors at time $\bar{t}_k$ are all those other agents positioned within its sensing region at time $\bar{t}_k$. This notion of a neighbor induces a *symmetric* relation on the agent group since agent j is a registered neighbor of agent i at time $\bar{t}_k$ just in case agent i is a registered neighbor of agent j at the same time. Because of this it is possible to characterize neighbor relationships at time $\bar{t}_k$ with a simple graph whose vertices represent agents and whose edges represent existing neighbor relationships (see section 2.2). Although the neighbor relation is symmetric, it is clearly not transitive. On the other hand, if agent i is at the same position as neighbor j at time $\bar{t}_k$, then any registered neighbor of agent j at time $\bar{t}_k$ must certainly be a registered neighbor of agent i at the same time. It is precisely because of this *weak transitivity* property that one can infer a *global* condition of the entire agent group from a *local* condition of one agent and its neighbors. In particular, if the graph characterizing neighbor relationships at time $\bar{t}_k$ is connected, and any one agent is at the same position as all of its neighbors, then the weak transitivity property guarantees at once that all n agents have rendezvoused at time $\bar{t}_k$.

One way to ensure that a neighbor graph is connected at time $\bar{t}_k$, assuming it is connected when the rendezvousing process begins, is to constrain each agent's way-points to be positioned in such a way so that no agent can lose any of its registered neighbors when it moves from one way-point to the next. This can be accomplished using a clever idea taken from [1]. An immediate consequence is that each agent's set of registered neighbors is nondecreasing and, because of this, ultimately converges to a fixed neighbor set for $\bar{t}_k$ sufficiently large.

A second local constraint is to require the way-point of each agent i at the beginning of its kth maneuvering period to lie in the "local" convex hull $\mathcal{H}_i(k)$ of agent i's own position at time $\bar{t}_k$ and the sensed positions of its registered neighbors at the same time. It is quite easy to prove that doing this causes the global convex hull $\mathcal{H}(k+1)$ of all n agent positions at time $\bar{t}_{k+1}$ to be contained in the corresponding global convex hull $\mathcal{H}(k)$ at time $\bar{t}_k$.

A third constraint is to stipulate that for each i, the only condition under which agent i's kth way-point can be positioned at a corner of $\mathcal{H}_i(k)$ is when $\mathcal{H}_i(k)$ is a single point. The global implication of doing this is that the diameter of $\mathcal{H}(k+1)$ must either be strictly smaller than the diameter of $\mathcal{H}(k)$ or every agent must be at

the same position as all of its registered neighbors at time $\bar{t}_k$—and this is true whether or not the graph characterizing neighbor relationships at time $\bar{t}_k$ is connected.

In section 4, a more or less standard Lyapunov-based argument is used to prove that if the preceding constraints are adopted by all agents and if the graph characterizing initial neighbor positions is connected, then all n agents will eventually rendezvous at a single point. Not surprisingly, the Lyapunov function used for this purpose is the diameter of the global convex hull. However, although connectivity of the graph characterizing initial neighbor positions is sufficient for rendezvousing, it is not necessary. An example illustrating this is given in section 3.2. The example deals with the situation when the initial neighbor graph consists of two connected components, with one "encircling" the other in a suitably defined sense.

2. The synchronous agent system. In the synchronous case treated in this paper, the maneuvering times for all agents are all the same positive value τ_M. Along any trajectory of the system to be considered, the real time axis can be partitioned into a sequence of consecutive time intervals $[0, t_1), [t_1, t_2), \ldots [t_{k-1}, t_k), \ldots$, each of length at least τ_M. Each interval consists of a sensing period followed by a maneuvering period of fixed length τ_M. All agents function in synchronization in the sense that all are at rest during sensing periods and all can maneuver only during maneuvering periods. In particular, all agents actions are synchronized to the time sequence $\bar{t}_1, \bar{t}_2, \ldots \bar{t}_k \ldots$, where $\bar{t}_k$ denotes the real time $t_k - \tau_M$ at which the kth maneuvering period begins. Agent i's *registered neighbors* at the beginning of its kth maneuvering period, $[\bar{t}_k, t_k)$, are those agents, except for agent i, which are within agent i's sensing region at time $\bar{t}_k$. Note that this definition is a symmetric relation on the set of all agents; i.e., if agent i is a registered neighbor of agent j at the beginning of maneuvering period k, then agent j is a registered neighbor of agent i at the beginning of the same maneuvering period.

2.1. Pairwise motion constraint. A pair of agents which are registered neighbors at the beginning of maneuvering period k are said to satisfy the *pairwise motion constraint* during the period if the positions to which they move at time t_k are both within a closed disk of diameter r centered at the mean of their registered positions at time $\bar{t}_k$. The definition implies that any two agents which are registered neighbors at the beginning of maneuvering period k will be registered neighbors at the beginning of maneuvering period $k+1$ if they satisfy the pairwise motion constraint during the kth maneuvering period. We are interested in strategies possessing this property and accordingly make the following assumption.

Cooperation assumption. During each maneuvering period k, each pair of agents which are registered neighbors at the beginning of the period restrict their motions to satisfy the pairwise motion constraint.

Agent i's *kth way-point* is the point to which agent i is to move at time t_k. Thus if $x_i(t)$ denotes the position of agent i at time t represented in a world coordinate system, then $x_i(t_k)$ and agent i's kth way-point are one and the same. The rule which determines each such way-point is a function depending only on the number and relative positions of agent i's registered neighbors. In particular, if agent i has m_i registered neighbors at time $\bar{t}_k$, positioned relative to agent i at points

$$z_j \stackrel{\Delta}{=} x_{i_j}(\bar{t}_k) - x_i(\bar{t}_k), \quad j \in \{1, 2, \ldots, m_i\}, \tag{1}$$

then agent i's kth way-point is

$$x_i(t_{k-1}) + u_{m_i}(z_1, z_2, \ldots, z_{m_i}), \tag{2}$$

where $u_0 = 0$, $u_m : \mathbb{D}^m \to \mathbb{D}_M$, $m \in \{1, \dots, n-1\}$, and $\mathbb{D}$ and $\mathbb{D}_M$ are the closed disks of radii r and r_M, respectively, centered at the origin in $\mathbb{R}^2$. In other words, if agent i has no registered neighbors at time $\bar{t}_k$ (i.e., $m_i = 0$), it does not move during the kth maneuvering period. On the other hand, if agent i has $m_i > 0$ neighbors at time $\bar{t}_k$ with relative positions $z_1, z_2, \dots, z_{m_i}$, then agent i moves to the position $x_i(t_{k-1}) + u_{m_i}(z_1, z_2, \dots, z_{m_i})$ at time t_k. Thus

$$x_i(t_k) = x_i(t_{k-1}) + u_{m_i(\bar{t}_k)}(x_{i_1}(\bar{t}_k) - x_i(\bar{t}_k),\ x_{i_2}(\bar{t}_k) - x_i(\bar{t}_k), \dots,\ x_{i_{m_i(\bar{t}_k)}}(\bar{t}_k) - x_i(\bar{t}_k)). \tag{3}$$

In what follows we will explain how the u_m are defined. At the very least we will require each to be a continuous function.

2.2. Definition of u_m. We have already defined $u_0 = 0$. To define u_m for $m > 0$ it is necessary to take into account the pairwise motion constraint. Toward this end, for each $z \in \mathbb{D}$, let $\mathcal{C}(z)$ denote the closed disk of diameter r centered at the point $\frac{1}{2}z$. More generally, for each $\{z_1, z_2, \dots, z_m\} \in \mathbb{D}^m$, let

$$\mathcal{C}(z_1, z_2, \dots, z_m) = \bigcap_{j=1}^{m} \mathcal{C}(z_j). \tag{4}$$

Note that 0 is in each $\mathcal{C}(z_i)$ and, moreover, that each such $\mathcal{C}(z_i)$ is closed and strictly convex. Consequently $\mathcal{C}(z_1, z_2, \dots, z_m)$ is either the singleton $\{0\}$ or a strictly convex, closed set containing 0. We can now define u_m to be any continuous function on $\mathbb{D}^m$ satisfying

$$u_m(z_1, z_2, \dots, z_m) \in \mathbb{D}_M \cap \mathcal{C}(z_1, z_2, \dots, z_m) \cap \langle 0, z_1, z_2, \dots, z_m \rangle \ \forall \{z_1, z_2, \dots, z_m\} \in \mathbb{D}^m, \tag{5}$$

where $\langle 0, z_1, z_2, \dots, z_m \rangle$ is the convex hull of the points $0, z_1, z_2, \dots, z_m$. The u_m are further required to have the property that

$$u_m(z_1, z_2, \dots, z_m) \neq \text{a corner}^1 \text{ of } \langle 0, z_1, z_2, \dots, z_m \rangle \tag{6}$$

unless $z_1 = z_2 = \cdots = z_m = 0$. In other words, u_m is required to be (i) a continuous function on $\mathbb{D}^m$ which maps each $\{z_1, z_2, \dots, z_m\} \in \mathbb{D}^m$ into $\mathbb{D}_M \cap \mathcal{C}(z_1, z_2, \dots, z_m) \cap \langle 0, z_1, z_2, \dots, z_m \rangle$ and (ii) a function with the property that $u_m(z_1, z_2, \dots, z_m)$ is not a corner of $\langle 0, z_1, z_2, \dots, z_m \rangle$ unless $z_1 = z_2 = \cdots = z_m = 0$. Examples of functions satisfying these conditions will be given in what follows.

2.3. Target points. One way to go about defining specific u_m which are continuous and which satisfy (5) and (6) is by first defining what we shall refer to as a "target point." By a *target point* we mean a continuous function $\tau : \mathbb{D}^m \to \langle 0, z_1, z_2, \dots, z_m \rangle$ defined in such a way that for each $\{z_1, z_2, \dots, z_m\} \in \mathbb{D}^m$ for which 0 is a corner of $\langle 0, z_1, z_2, \dots, z_m \rangle$, the segment of the line from 0 to $\tau(z_1, z_2, \dots, z_m)$ which lies within $\mathcal{C}(z_1, z_2, \dots, z_m)$ has positive length. For should it be possible to define such a τ, one could satisfy (5) and (6) as well as the continuity requirement with a control of the form

$$u_m = g(z_1, z_2, \dots, z_m)\tau(z_1, z_2, \dots, z_m),$$

[1]Recall that a point x in a polytope $\mathbb{P}$ in $\mathbb{R}^m$ is a *corner* if the only points y and z in $\mathbb{P}$ for which x is a convex combination are $y = z = x$.

where $g : \mathbb{D}^m \to \mathbb{R}$ is any continuous, positive definite function satisfying

$$g < \max_{(0,1]} \left\{ \mu : \mu\tau \in \mathbb{D}_M \bigcap \mathcal{C}(z_1, z_2, \ldots, z_m) \right\}.$$

Note that $g\tau \in \langle 0, z_1, z_2, \ldots, z_m \rangle$ for all $g \in [0,1]$ because $0 \in \langle 0, z_1, z_2, \ldots, z_m \rangle$. The role of g is therefore to scale down the magnitude of τ enough to ensure that $g\tau$ is in the constraint set $\mathbb{D}_M \bigcap \mathcal{C}(z_1, z_2, \ldots, z_m)$.

It might be thought that one could choose for τ the centroid of $\langle 0, z_1, z_2, \ldots, z_m \rangle$ or perhaps the average of the z_i and 0, namely

$$\tau \triangleq \frac{1}{m+1} \sum_{i=1}^{m} z_i.$$

Both candidate definitions satisfy the requirement that $\tau(z_1, z_2, \ldots, z_m)$ must be a point in $\langle 0, z_1, z_2, \ldots, z_m \rangle$. Unfortunately, simple examples show that the centroid definition does not necessarily yield a function which satisfies the continuity requirement, while the averaging definition may lead to a function which fails to satisfy the requirement that when 0 is a corner of $\langle 0, z_1, z_2, \ldots, z_m \rangle$, the segment of the line from 0 to $\tau(z_1, z_2, \ldots, z_m)$ which lies within $\mathcal{C}(z_1, z_2, \ldots, z_m)$ has positive length. For example, the centroid of the convex hull of the points $(0,0)$, $z_1 = (0,1)$, and $z_2 = (p,1)$ is at $(\frac{p}{3}, \frac{2}{3})$ for $p > 0$ and at $(0, \frac{1}{2})$ for $p = 0$ so the centroid is discontinuous at $p = 0$. As a counterexample to the use of coordinate averaging to define a target point, note that the average of the four points located at $(0,0)$, $z_1 = (-r, 0)$, $z_2 = (\frac{2r}{3}, \frac{r}{2})$, and $z_3 = (\frac{r}{3}, \frac{r}{2})$ is at $(0, \frac{r}{4})$, while the constraint set $\mathcal{C}(z_1, z_2, z_3)$ determined by these points must be contained in the constraint disk $\mathcal{C}(z_1)$. Since the line $\mathcal{L}$ from $(0,0)$ to $(0, \frac{r}{4})$ is tangent to this disk at the origin, the intersection of $\mathcal{L}$ with $\mathcal{C}(z_1, z_2, z_3)$ is just the point $(0,0)$ and consequently not a line segment of positive length.

In what follows we shall approach the problem of defining τ in a slightly different way. We begin by stating the following proposition which provides a simple condition on $\tau(\cdot)$, which, if satisfied, automatically implies satisfaction of the requirement that when 0 is a corner of $\langle 0, z_1, z_2, \ldots, z_m \rangle$, the segment of the line from 0 to $\tau(z_1, z_2, \ldots, z_m)$ which lies within $\mathcal{C}(z_1, z_2, \ldots, z_m)$ has positive length.

PROPOSITION 1. *Let $z_1, z_2, \ldots, z_m$ be a set of $m > 0$ points in $\mathbb{D}$ which are not all 0. If 0 is a corner of $\langle 0, z_1, z_2, \ldots, z_m \rangle$ and z is any nonzero point in $\mathbb{D}$ within r units of each point in $\{z_1, z_2, \ldots, z_m\}$, then the segment of the line from 0 to z which lies in $\mathcal{C}(z_1, z_2, \ldots, z_m)$ has positive length.*

The proofs of this and subsequent propositions and lemmas are in section 6.

Proposition 1 suggests the following approach for defining a target point. First, for each $z \in \mathbb{D}$, let $\mathcal{D}(z)$ denote a closed disk of radius r centered at z. More generally, for any set of $m > 0$ points $z_1, z_2, \ldots, z_m$ in $\mathbb{D}$, write

$$\mathcal{D}(z_1, z_2, \ldots, z_m) = \bigcap_{i=1}^{m} \mathcal{D}(z_i).$$

By construction, each point in $\mathcal{D}(z_1, z_2, \ldots, z_m)$ is within r units of each point in $\{z_1, z_2, \ldots, z_m\}$ and conversely. Thus $0 \in \mathcal{D}(z_1, z_2, \ldots, z_m)$ because $z_i \in \mathbb{D}$, $i \in \{1, 2, \ldots, m\}$.

Second, note that if $z_1, z_2, \ldots, z_m$ is any set of $m > 0$ points in $\mathbb{D}$ which are not all zero and for which 0 is a corner of $\langle 0, z_1, z_2, \ldots, z_m \rangle$, then by Proposition 1 the segment of the line from 0 to any nonzero point $\mathbb{D} \cap \mathcal{D}(z_1, z_2, \ldots, z_m)$ which lies in

$\mathcal{C}(z_1, z_2, \ldots, z_m)$ must have positive length. It follows that any continuous function $\tau : \mathbb{D}^m \to \langle 0, z_1, z_2, \ldots, z_m \rangle$ which satisfies

$$\tau(z_1, z_2, \ldots, z_m) \in \mathbb{D} \bigcap \mathcal{D}(z_1, z_2, \ldots, z_m) \bigcap \langle 0, z_1, z_2, \ldots, z_m \rangle$$

and which is nonzero whenever 0 is a corner of $\langle 0, z_1, z_2, \ldots, z_m \rangle$ and $z_1, z_2, \ldots, z_m$ are not all zero fulfills all the conditions required to be a target point. In what follows we will show that there are at least two different ways to so define τ.

2.3.1. The centroid of $\mathbb{D} \cap \mathcal{D}(z_1, z_2, \ldots, z_m)$. In order for the centroid of $\mathbb{D} \cap \mathcal{D}(z_1, z_2, \ldots, z_m)$ to be a target point, it must depend continuously on the z_i and, in addition, must have the property that it is nonzero for any set of m points in $\mathbb{D}$ which are not all zero and for which 0 is a corner of $\langle 0, z_1, z_2, \ldots, z_m \rangle$. These properties are guaranteed by the following two propositions.

PROPOSITION 2. *Let $z_1, z_2, \ldots, z_m$ be a set of $m > 0$ points in $\mathbb{D}$ which are not all 0. Then the centroid of $\mathbb{D} \cap \mathcal{D}(z_1, z_2, \ldots, z_m)$ is in $\langle 0, z_1, z_2, \ldots, z_m \rangle$. If, in addition, 0 is a corner of $\langle 0, z_1, z_2, \ldots, z_m \rangle$, then $\mathbb{D} \cap \mathcal{D}(z_1, z_2, \ldots, z_m)$ has a nonempty interior, and the centroid of $\mathbb{D} \cap \mathcal{D}(z_1, z_2, \ldots, z_m)$ cannot be at 0.*

PROPOSITION 3. *The function which assigns to each set of $m > 0$ points $z_1, z_2, \ldots, z_m$ in $\mathbb{D}$ the centroid of $\mathbb{D} \cap \mathcal{D}(z_1, z_2, \ldots, z_m)$ is continuous.*

Examination of the proof of Proposition 3 given in section 6 reveals that the continuity of the centroid of $\mathbb{D} \cap \mathcal{D}(z_1, z_2, \ldots, z_m)$ depends crucially on the fact that the centroid is at 0 whenever the area of $\mathbb{D} \cap \mathcal{D}(z_1, z_2, \ldots, z_m)$ is zero. This property is not shared by the centroid of $\langle 0, z_1, z_2, \ldots, z_m \rangle$, and it is for this reason that the centroid of $\langle 0, z_1, z_2, \ldots, z_m \rangle$ is not a continuous function of the z_i.

It turns out that Propositions 2 and 3 both hold if the set $\mathbb{D} \cap \mathcal{D}(z_1, z_2, \ldots, z_m)$ is replaced throughout by the constraint set $\mathbb{D} \cap \mathcal{C}(z_1, z_2, \ldots, z_m)$. This can be shown using essentially the same proofs of the propositions as those given in the appendix. What this means then is that the centroid of $\mathbb{D} \cap \mathcal{C}(z_1, z_2, \ldots, z_m)$ is also a valid target point.

2.3.2. The center of the smallest circle containing $\langle 0, z_1, z_2, \ldots, z_m \rangle$. It is also possible to define τ to be the center of the smallest circle containing $\langle 0, z_1, z_2, \ldots, z_m \rangle$. To understand why this is so, let us note first that for any set of points $z_i \in \mathbb{D}$, $i \in \{1, 2, \ldots, m\}$, the set of points $\mathcal{Q} \triangleq \{0, z_1, \ldots, z_m\}$ is contained in a circle of radius r centered at 0. It follows that the center of this circle is at most r units from every point in $\mathcal{Q}$. This suggests that one might choose for $\tau(z_1, z_2, \ldots, z_m)$ the center $\tau_C(z_1, z_2, \ldots z_m)$ of the smallest circle containing $\mathcal{Q}$ or, equivalently, $\langle 0, z_1, z_2, \ldots, z_m \rangle$, since $\tau_C(z_1, z_2, \ldots, z_m)$ would have to be within r units of every point in $\mathcal{Q}$. It is known that there is such a smallest circle [17] and that if the z_i are not all zero, $\tau_C(z_1, z_2, \ldots z_m)$ is either the midpoint between two of the points in $\mathcal{Q}$ or a point within the interior of a triangle formed from at least one set of three points in $\mathcal{Q}$ [1]. In either case it is clear that $\tau_C(z_1, z_2, \ldots z_m) \in \langle 0, z_1, z_2, \ldots, z_m \rangle$ and, if the z_i are not all zero and 0 is a corner of $\langle 0, z_1, z_2, \ldots, z_m \rangle$, that $\tau_C(z_1, z_2, \ldots z_m)$ is nonzero as well. Furthermore it can be shown that $\tau_C(z_1, z_2, \ldots z_m)$ depends continuously on the z_i [18]. In other words, $\tau_C(z_1, z_2, \ldots z_m)$ satisfies all the conditions required to be a target point. This elegant choice for τ is the one proposed in [1].

3. Main results. Define $t_0 = 0$. Note that because agents do not move during sensing periods, for $k \geq 1$ the position of each agent at time t_{k-1} is the same as its

position at time $\bar{t}_k$. Thus (3) can be rewritten as

$$
\begin{aligned}
x_i(t_k) = x_i(t_{k-1}) & \\
& + u_{m_i(t_{k-1})}(x_{i_1}(t_{k-1}) - x_i(t_{k-1}),\ x_{i_2}(t_{k-1}) \\
& - x_i(t_{k-1}), \ldots,\ x_{i_{m_i(t_{k-1})}}(t_{k-1}) - x_i(t_{k-1})),
\end{aligned} \tag{7}
$$

where $m_i(t_{k-1}) \triangleq m_i(\bar{t}_k)$. Because of this, the system just defined admits the model of a nonlinear discrete-time system with state $x(t_k) = \text{column } \{x_1(t_k), x_2(t_k), \ldots x_n(t_k)\}$ evolving on the time set $t_0, t_1, \ldots t_k, \ldots$. Analysis of this system depends on the relationships between neighbors and how they evolve with time. These relationships can be conveniently described by a simple, undirected graph with vertex set $\{1, 2, \ldots, n\}$ which is defined so that (i, j) is one of the graph's edges just in case agents i and j are registered neighbors at the beginning of maneuvering period k. Since these relationships can change from one maneuvering period to the next, so can the graph which describes them. In what follows we use the symbol $\mathcal{P}$ to denote a suitably defined set, indexing the class of all simple graphs $\mathbb{G}_p$ on n vertices. Let us partially order the set $\{\mathbb{G}_p : p \in \mathcal{P}\}$ by agreeing to say that $\mathbb{G}_p$ is contained in $\mathbb{G}_q$ if the edge set of $\mathbb{G}_p$ is a subset on the edge set of $\mathbb{G}_q$. It is natural then to define the *union* of a collection of such graphs, $\{\mathbb{G}_{p_1}, \mathbb{G}_{p_2}, \ldots, \mathbb{G}_{p_m}\}$, to be the simple graph $\mathbb{G}$ with vertex set $\{1, 2, \ldots, n\}$ and edge set equaling the union of the edge sets of all of the graphs in the collection.

Let $\sigma(k)$ denote the index of the graph in $\{\mathbb{G}_p : p \in \mathcal{P}\}$ which describes the relationship between registered neighbors at the beginning of maneuvering period k. Because of the cooperation assumption, we know that each agent keeps all of its registered neighbors as the system evolves. What this means is the sequence of graphs $\mathbb{G}_{\sigma(1)}, \mathbb{G}_{\sigma(2)}, \ldots, \mathbb{G}_{\sigma(k)}, \ldots$ forms the ascending chain

$$
\mathbb{G}_{\sigma(1)} \subset \mathbb{G}_{\sigma(2)} \subset \cdots \subset \mathbb{G}_{\sigma(k)} \subset \cdots. \tag{8}
$$

Because $\{G_p : p \in \mathcal{P}\}$ is a finite set, the chain must converge to the graph

$$
\mathbb{G} \triangleq \bigcup_{k=1}^{\infty} \mathbb{G}_{\sigma(k)} \tag{9}
$$

in a finite number of steps. Since the sequence of graphs stops changing in a finite number of steps, rendezvousing at a single point can only occur if $\mathbb{G}$ is a complete graph. There is, however, no a priori guarantee that, along a particular trajectory, $\mathbb{G}$ will turn out to be complete. On the other hand, it is clear that $\mathbb{G}$ will always be at least connected if the initial graph $\mathbb{G}_{\sigma(1)}$ in the ascending chain is. It turns out that connectivity of $\mathbb{G}_{\sigma(1)}$ implies not only that $\mathbb{G}$ is connected but also that the types of distributed control strategies just described actually cause all agents to rendezvous at a single point.

3.1. Rendezvousing.

THEOREM 1. *Let $u_0 = 0 \in \mathbb{D}_M$ and for each $m \in \{1, 2, \ldots, n-1\}$, let $u_m : \mathbb{D}^m \to \mathbb{D}_M$ be any continuous function satisfying* (5) *and* (6). *For each set of initial agent positions $x_1(0), x_2(0), \ldots, x_n(0)$, each agent's position $x_i(t)$ converges to a unique point $p_i \in \mathbb{R}^2$ such that for each $i, j \in \{1, 2, \ldots, n\}$, either $p_i = p_j$ or $||p_i - p_j|| > r$. Moreover, if agents i and j are registered neighbors at any time t, then $p_i = p_j$.*

The proof of this theorem is given in section 4.

Theorem 1 states that the strategies under consideration cause all agents' positions to converge to points in the plane with the property that each two such points are either equal to each other or separated by a distance greater than r units. The theorem further states that if two agents are ever registered neighbors of each other, then their positions converge to the same point. We are led to the following corollary.

COROLLARY 1. *If the graph characterizing registered neighbors at the beginning of period* 1 *is connected, then the positions of all* n *agents converge to a common point in the plane.*

It is quite straightforward to extend these results to the leader-follower case when the rendezvous point is specified at the outset. This can be accomplished by simply fixing one additional agent (i.e., a virtual agent) at the desired rendezvous point and letting the remaining n agents maneuver just as before. With initial graph connectivity of all $n+1$ agent positions, convergence to the position of the virtual agent is then assured.

A more interesting case occurs when two virtual agents are fixed at distinct points in the plane. In this case it can be shown that with initial connectivity of the $(n+2)$-agent graph, all n agents will eventually move to positions on the line connecting the two virtual agents and will distribute themselves in a predictable manner depending on only the number of agents, r, and the distance between the two fixed, virtual agents. This behavior will be explored in greater depth in another paper dealing with forming formations using distributed control.

3.2. Trapping. While the graph connectivity hypothesis of Corollary 1 is sufficient for rendezvousing, it is not necessary. For example, suppose that the $\mathbb{G}_{\sigma(1)}$ has a connected component $\mathbb{G}_C$ which contains a simple closed cycle whose vertices are $i_1, i_2, \ldots, i_m$. Then in the plane, the geometric form obtained by connecting by a straight line the initial position of each agent $i_j \in \{i_1, i_2, \ldots, i_m\}$ with its registered neighbors with labels in $\{i_1, i_2, \ldots, i_m\}$ will be a simple, closed, polygon $\mathbb{P}$. It turns out that if the initial positions of all agents whose labels are not in the vertex set of $\mathbb{G}_C$ are within $\mathbb{P}$, then rendezvous will necessarily occur. While this conclusion might appear to be an obvious consequence of the established property that agents $i_j \in \{i_1, i_2, \ldots, i_m\}$ eventually rendezvous at a point, actually proving that this is true is not so straightforward. There are two reasons for this. First, there is no guarantee that the polygon $\mathbb{P}(k)$ formed by the positions at time t_k of agents $i_j \in \{i_1, i_2, \ldots, i_m\}$ will remain simple as the system evolves, even if it is initially; thus just what it means for an agent to be "inside" of $\mathbb{P}(k)$ requires a more sophisticated notion of interior than the obvious one for a simple closed curve in the plane, and this in turn complicates the analysis. Second, it is quite possible that an agent initially positioned inside of $\mathbb{P}(0)$ will be outside of $\mathbb{P}(k)$ for some $k > 0$. In what follows we explain how to overcome both of these difficulties and in so doing we establish a rendezvousing result along the lines just described.

We begin by reviewing the concept of a "winding number" and what it means for a point to be inside of a closed curve in $\mathbb{R}^2$. Let $\kappa : [0,1] \to \mathbb{R}^2$ be any continuous closed curve and let y be any point in $\mathbb{R}^2$ which does not lie on κ. The *winding number* of y with respect to κ, written $\mathrm{wn}(\kappa, y)$, is the number of times a point p traversing κ encircles y in a counterclockwise direction as p makes a full circuit of κ. Points not on κ with nonzero winding numbers are inside of κ, while those with a winding number of zero are outside of κ. There is a well-known formula for $\mathrm{wn}(\kappa, y)$, involving the integral around a closed contour $\tilde{\kappa} : [0,1] \to \mathbb{C}$ in the complex plane [15]. $\tilde{\kappa}$ is a

representation of κ resulting from the assignment to each vector $x = [\,a \quad b\,]'$ in $\mathbb{R}^2$ the associated complex number $\tilde{x} \triangleq a + jb$. In this setting, $\mathrm{wn}(\kappa, y)$ is given by the contour integral

$$\mathrm{wn}(\kappa, y) = \frac{1}{2\pi j} \oint_{\tilde{\kappa}} \frac{dz}{z - \tilde{y}}.$$

We will use this formula in what follows to prove Lemma 8.

The closed curves of interest here are of a specific type determined by finite point sets in $\mathbb{R}^2$. In particular, let us note that any ordered set of $m > 0$ points $\{y_1, y_2, \ldots, y_m\}$ in $\mathbb{R}^2$ uniquely determines a continuous, piecewise linear, closed curve $c : [0, m] \to \mathbb{R}^2$ defined so that

$$c(t) = (t + 1 - i)y_{i+1} + (i - t)y_i, \qquad i - 1 \le t \le i, \qquad i \in \{1, 2, \ldots, m\},$$

where $y_{m+1} = y_1$. An ordered set $\{y_1, y_2, \ldots, y_m\}$ of three or more such points is called a *cycle* if $||y_{i+1} - y_i|| \le r,\ i \in \{1, 2, \ldots, m\}$; in what follows we denote such a cycle by $\lceil y_1, y_2, \ldots, y_m \rceil$. A point $z \in \mathbb{R}^2$ is called an *interior point* of $\lceil y_1, y_2, \ldots, y_m \rceil$ if it is an interior point of the closed, piecewise linear curve c determined by $\{y_1, y_2, \ldots, y_m\}$.

A point $z \in \mathbb{R}^2$ is said to be *linked* to a nonempty set of vectors $\{y_1, y_2, \ldots, y_m\}$ in $\mathbb{R}^2$ if for some $i \in \{1, 2, \ldots, m\}$, $||z - y_i|| \le r$. More generally, z is *connected* to $\{y_1, y_2, \ldots, y_m\}$ through a set of vectors $\{x_1, x_2, \ldots, x_n\}$ in $\mathbb{R}^2$ if there exists a subset $\{x_{i_1}, x_{i_2}, \ldots, x_{i_k}\}$ with $x_{i_k} \in \{y_1, y_2, \ldots, y_m\}$ such that $||z - x_{i_1}|| \le r$ and $||x_{i_{s-1}} - x_{i_s}|| \le r,\ i \in \{2, 3, \ldots k\}$. The following corollary to Theorem 1 will be proved later in this section.

COROLLARY 2. *Suppose that the set of initial positions* $\{x_1(0), x_2(0), \ldots, x_n(0)\}$ *of the n agents contains a cycle* $\lceil x_{i_1}(0), x_{i_2}(0), \ldots, x_{i_m}(0) \rceil$. *Then all agents initially positioned inside the cycle eventually rendezvous at one point with all agents with positions initially connected to the cycle through* $\{x_1(0),\ x_2(0), \ldots,\ x_n(0)\}$.

In what follows we use the abbreviated notation $\mathbf{C}(k) \triangleq \lceil x_{i_1}(t_k), x_{i_2}(t_k), \ldots, x_{i_m}(t_k) \rceil, k \ge 0$, and say that a vector x is connected to $\mathbf{C}(k)$ whenever x is connected to $\mathbf{C}(k)$ through $\{x_1(t_k),\ x_2(t_k), \ldots,\ x_n(t_k)\}$. Note that Corollary 2 does not require agents initially positioned inside of $\mathbf{C}(0)$ to be connected to $\mathbf{C}(0)$. It is natural to say that such "disconnected" agents are ultimately *trapped* by those agents whose initial positions comprise $\mathbf{C}(0)$. This particular group behavior is accordingly referred to as "trapping."

Consider the situation hypothesized in Corollary 2. We already know from Theorem 1 that all agents with positions initially connected to $\mathbf{C}(0)$ eventually rendezvous at a single point. So what remains to be shown is that all agents at initial positions interior to $\mathbf{C}(0)$ but not connected to it also rendezvous at the same point. To do this it is enough to show that each such initially disconnected internal agent eventually moves at some finite time t_K to a position which is connected to $\mathbf{C}(K)$—for once this happens, Theorem 1 can be applied with a start time of t_K, thereby enabling one to conclude that the agent under consideration will eventually rendezvous at the same point as the agents with positions initially connected to $\mathbf{C}(0)$. Carrying out this program relies on three key propositions which follow and which are proved in section 6.

PROPOSITION 4. *The interior of any cycle* $\lceil y_1, y_2, \ldots, y_m \rceil$ *in* $\mathbb{R}^2$ *is contained in its convex hull* $\langle y_1, y_2, \ldots, y_m \rangle$.

This proposition is used as follows. Note that because all agents initially positioned at points comprising $\mathbf{C}(0)$ eventually rendezvous at a single point, the diameter

of the convex hull $\langle x_{i_1}(t_k), x_{i_2}(t_k), \ldots, x_{i_m}(t_k)\rangle$ must eventually become smaller than r and remain so for all future time. What this and Proposition 4 therefore imply is that any agent whose position remains inside of $\mathbf{C}(k)$ for all time must at some finite time $t_{\bar{k}}$ reach a position connected to $\mathbf{C}(\bar{k})$. Unfortunately not every agent initially positioned at a point inside of and disconnected from $\mathbf{C}(0)$ can be counted on to be so accommodating. We will deal with this situation by proving that when such an agent first leaves $\mathbf{C}(k)$—say at time $t_{\bar{k}}$—it automatically moves to a position connected to $\mathbf{C}(\bar{k})$. Let A be the label of such an agent and let $x_A(t_{\bar{k}})$ denote its position at time $t_{\bar{k}}$. Below we shall argue using the following proposition that all of agent A's registered neighbors at the beginning of maneuvering period $\bar{k}-1$ are inside of $\mathbf{C}(\bar{k}-1)$ at time $t_{\bar{k}-1}$.

PROPOSITION 5. *Let $\lceil y_1, y_2, \ldots, y_m\rceil$ be a cycle in $\mathbb{R}^2$ which contains a point z which is not linked to $\lceil y_1, y_2, \ldots, y_m\rceil$. Then any point within r units of z is either inside of $\lceil y_1, y_2, \ldots, y_m\rceil$ or is linked to $\lceil y_1, y_2, \ldots, y_m\rceil$.*

We've assumed that $x_A(t_{\bar{k}})$ is not inside of $\mathbf{C}(\bar{k})$, and that $x_A(t_{\bar{k}-1})$ is inside of $\mathbf{C}(\bar{k}-1)$ and not connected to $\mathbf{C}(\bar{k}-1)$. Clearly $x_A(t_{\bar{k}-1})$ is not linked to $\mathbf{C}(\bar{k}-1)$. From Proposition 5 it follows that all of agent A'*s* registered neighbors at the beginning of maneuvering period $k-1$ are at positions at time $\bar{t}_{\bar{k}-1}$ {and consequently time $t_{\bar{k}-1}$} which are either inside of $\mathbf{C}(\bar{k}-1)$ or linked to $\mathbf{C}(\bar{k}-1)$. If any registered neighbor's position were connected to $\mathbf{C}(\bar{k}-1)$, then $x_A(t_{\bar{k}-1})$ would be connected to $\mathbf{C}(\bar{k}-1)$, which we have explicitly assumed is not the case. Therefore none of A'*s* registered neighbors is connected (or therefore linked) to $\mathbf{C}(\bar{k}-1)$ at time $t_{\bar{k}-1}$; moreover, all must be inside of $\mathbf{C}(\bar{k}-1)$ because of Proposition 5.

To show that under these conditions, $x_A(t_{\bar{k}})$ is necessarily connected to $\mathbf{C}(\bar{k})$, we will make use of the following concept. Let us agree to call a cycle $\lceil \bar{y}_1, \bar{y}_2, \ldots, \bar{y}_m\rceil$ a *successor* of a given cycle $\lceil y_1, y_2, \ldots, y_m\rceil$ if, in addition to the cycle requirement that $||\bar{y}_{i+1} - \bar{y}_i|| \le r,\ \ i \in \{1, 2, \ldots, n\}$, the inequalities $||\bar{y}_i - y_i|| \le r,\ ||\bar{y}_{i+1} - y_i|| \le r$, and $||\bar{y}_i - y_{i+1}|| \le r$ all hold for $i \in \{1, 2, \ldots, m\}$. Observe that each cycle in the sequence $\lceil y_1, y_2, \ldots, y_m\rceil, \lceil \bar{y}_1, y_2, \ldots, y_m\rceil, \lceil \bar{y}_1, \bar{y}_2, \ldots, y_m\rceil, \ldots, \lceil \bar{y}_1, \bar{y}_2, \ldots, \bar{y}_m\rceil$ is a successor of the cycle which precedes it. It is easy to verify that for each $k \ge 0$, $\mathbf{C}(k+1)$ is a successor of $\mathbf{C}(k)$.

PROPOSITION 6. *Let $\lceil \bar{y}_1, \bar{y}_2, \ldots, \bar{y}_m\rceil$ be a successor of a given cycle $\lceil y_1, y_2, \ldots, y_m\rceil$ in $\mathbb{R}^2$. Suppose that $z_1, z_2, \ldots, z_k$ are $k > 0$ interior points of $\lceil y_1, y_2, \ldots, y_m\rceil$ which are not linked to $\lceil y_1, y_2, \ldots, y_m\rceil$ and which satisfy $||z_1 - z_i|| \le r$, $i \in \{2, 3, \ldots, k\}$. Then each point in the convex hull $\langle z_1, z_2, \ldots, z_k\rangle$ is either an interior point of $\lceil \bar{y}_1, \bar{y}_2, \ldots, \bar{y}_m\rceil$ or is linked to $\lceil \bar{y}_1, \bar{y}_2, \ldots, \bar{y}_m\rceil$.*

Recall that the strategy under consideration puts $x_A(t_{\bar{k}})$ at a point in the convex hull of the set consisting of $x_A(t_{\bar{k}-1})$ and the positions at time $t_{\bar{k}-1}$ of agent A's registered neighbors. Proposition 6 therefore implies that $x_A(t_{\bar{k}})$ must be either inside of $\mathbf{C}(\bar{k})$ or linked to it. Since we have ruled out the former by assumption, $x_A(t_{\bar{k}})$ is linked and therefore connected to $\mathbf{C}(\bar{k})$ as claimed. This completes the proof of Corollary 2. □

4. Analysis. The aim of this section is to establish the correctness of Theorem 1. Towards this end, let $\{\{x_1(t_k), x_2(t_k), \ldots, x_n(t_k)\} : k \ge 1\}$ be a system trajectory determined by (7) and any initial set of agent positions. Let k^* denote the value of k for which the ascending chain shown in (8) converges to the limit graph $\mathbb{G}$ in (9). Thus for $t_k \ge t_{k^*}$, the neighbors of each agent do not change. For each $i \in \{1, 2, \ldots, n\}$, let $\{i_1, i_2, \ldots, i_{m_i}\}$ denote the set of indices labelling the neighbors of agent i. For simplicity, we will deal only with the case when each agent has at least one neighbor.

This means that all m_i are positive integers. These assumptions imply that for $k \geq k^*$, the system under consideration will have a state $\{x_1(t_k), x_2(t_k), \ldots, x_n(t_k)\}$ taking values in the space

$$(10)\, \mathcal{X} = \{\{x_1, x_2, \ldots x_n\} : ||x_j - x_i|| \leq r,\ \ j \in \{i_1, i_2, \ldots, i_{m_i}\}, i \in \{1, 2, \ldots, n\}\}.$$

4.1. Error system. To analyze system behavior it is convenient to introduce a suitably defined "error system." For $\{x_1, x_2, \ldots, x_n\} \in \mathcal{X}$, define

$$e_i = x_i - x_n, \quad i \in \{1, 2, \ldots, n\}, \tag{11}$$

and note that $e_n = 0$. Let $e \stackrel{\Delta}{=} \{e_1, e_2, \ldots, e_{n-1}\}$. In view of (10) and the fact that $e_j - e_i = x_j - x_i$ for all $i, j \in \{1, 2, \ldots, n\}$, we see that e takes values in the closed space

$$\mathcal{E} = \{\{e_1, e_2, \ldots e_{n-1}\} : e_n = 0, ||e_j - e_i|| \leq r, \quad j \in \{i_1, i_2, \ldots, i_{m_i}\},\ i \in \{1, 2, \ldots, n\}\}. \tag{12}$$

Note that

$$x_{i_j}(t_{k-1}) - x_i(t_{k-1}) = e_{i_j}(t_{k-1}) - e_i(t_{k-1}), \quad j \in \{1, 2, \ldots, m_i\}, \quad i \in \{1, 2, \ldots, n\}.$$

It follows that the update equation (7) for x_i can be written as

$$x_i(t_k) = x_i(t_{k-1}) + f_i(e(k-1)), \quad k \geq k^*, \tag{13}$$

where $f_i : \mathcal{E} \to \mathbb{D}$ is the continuous function

$$\{e_1, e_2, \ldots, e_{n-1}\} \longmapsto u_{m_i}(e_{i_1} - e_i,\ e_{i_2} - e_i, \ldots,\ e_{i_{m_i}} - e_i)|_{e_n = 0}.$$

In view of (13) and the definition of the e_i,

$$(14)\, e_i(t_k) = e_i(t_{k-1}) + f_i(e(t_{k-1})) - f_n(e(t_{k-1})), \quad k > k^*,\ i \in \{1, 2, \ldots, n-1\}.$$

This enables us to define the *error system*

$$e(t_k) = e(t_{k-1}) + f(e(t_{k-1})), \quad k > k^*, \tag{15}$$

where $f(e) = \{f_1(e) - f_n(e),\ f_2(e) - f_n(e), \ldots,\ f_{n-1}(e) - f_n(e)\}$.

4.2. Proving convergence in the style of Lyapunov. In what follows, we will prove that under certain conditions $e(t_k) \to 0$ as $k \to \infty$. We will do this using the positive definite function $V : \mathcal{E} \to \mathbb{R}$ defined by

$$V(e) = \text{dia}\{e_1, e_2, \ldots, e_{n-1}, 0\}, \tag{16}$$

where for any set of vectors $y_1, y_2, \ldots, y_m$ in $\mathbb{R}^2$, dia$\{y_1, y_2, \ldots, y_m\}$ denotes the diameter[2] of $\langle y_1, y_2, \ldots, y_m \rangle$. The following proposition is central to the proof of Theorem 1.

PROPOSITION 7. *The difference function $\Delta : \mathcal{E} \to \mathbb{R}$ defined by*

$$\Delta(e) = V(e + f(e)) - V(e) \tag{17}$$

is negative semidefinite. Moreover, if $\mathbb{G}$ is connected, then Δ is negative definite.

[2]Recall that the *diameter* of a closed set $\mathcal{S} \subset \mathbb{R}^2$ is the maximum of $||s_1 - s_2||$ over all $s_1, s_2 \in \mathcal{S}$.

Proof of Theorem 1. In general the graph $\mathbb{G}$ to which the ascending chain (8) converges for some finite $k = k^*$ consists of a finite set of connected components. Suppose that $\mathbb{G}_c$ is any one of these. To prove Theorem 1 it is enough to show that the positions of those agents whose indices are the vertices of $\mathbb{G}_c$ converge to a common point. For simplicity we will do this only for the case when $\mathbb{G}_c = \mathbb{G}$, since, except for notation, the proof is essentially the same even if $\mathbb{G}_c \neq \mathbb{G}$.

By hypothesis $n > 1$. Note that if $e(t_k) = 0$ for some $k = \bar{k}$, then all agents are in the same position at time $t_{\bar{k}}$; moreover, any such position will remain fixed for all $t \geq t_{\bar{k}}$ because $f(0) = 0$. Therefore to complete the proof it is enough to show that $e(t_k)$ tends to 0 as $k \to \infty$.

Let $V : \mathcal{E} \to \mathbb{R}$ be defined as in (16). Note that

$$V(e(t_k)) = \operatorname{dia}\{x_1(t_k), x_2(t_k), \ldots, x_n(t_k)\} \tag{18}$$

because the diameter of a convex set in $\mathbb{R}^2$ is invariant under translation of the set. From this and Proposition 7, it follows that the difference function

$$\Delta(e(t_k)) = V(e(t_k) + f(e(t_k))) - V(e(t_k))$$

is nonpositive for $k \geq k^*$. Thus $V(e(t_k))$ is a monotone nonincreasing function of k for $k \geq k^*$. Since for $k \geq k^*$, $V(e(t_k))$ is bounded above by $V(e(t_{k^*}))$ and below by 0, there must exist a finite limit

$$V^* \triangleq \lim_{k \to \infty} V(e(t_k)).$$

We claim that $V^* = 0$. To prove this claim, suppose that it is false. Then $V^* > 0$. Let $\mathcal{B}$ denote the set of all points $e \in \mathcal{E}$ such that $V^* \leq V(e) \leq V(e(t_{k^*}))$. Note that $\mathcal{B}$ is closed and bounded because $V(\cdot)$ is continuous and $\mathcal{E}$ is closed. Moreover, $0 \notin \mathcal{B}$ because $V(\cdot)$ is positive definite and bounded away from zero on $\mathcal{B}$. By Proposition 7, $\Delta(\cdot)$ is negative definite. Therefore for all $e \in \mathcal{B}$, $\Delta(e) < 0$. From this, the compactness of $\mathcal{B}$, and the continuity of $\Delta(\cdot)$, it follows that

$$\mu \triangleq \max_{e \in \mathcal{B}} \Delta(e)$$

is a finite negative number. Since $e(t_k) \in \mathcal{B}$ for $k \geq k^*$, it must therefore be true that

$$V(e(t_{k+1})) - V(e(t_k)) = \Delta(e(t_k)) \leq \mu, \quad k \geq k^*.$$

Thus by summing,

$$V(e(t_k)) \leq V(e(t_{k^*})) + (k - k^*)\mu, \quad k \geq k^*.$$

Therefore, for k sufficiently large, $V(e(t_k))$ must be negative because $\mu < 0$. But this is impossible because $V(\cdot)$ is positive definite. Hence V^* cannot be positive. □

The proof just given is basically a standard Lyapunov argument[3] applied to the system (17). It is worth pointing out here that the continuity of $\Delta(\cdot)$ is crucial to the proof as is the fact that $\mathcal{E}$ is closed. If $\mathcal{E}$ were not a closed set, the preceding proof would break down because one could not conclude that $\mathcal{B}$ is closed. The closure of $\mathcal{E}$ is

[3]It is worth noting that a similar proof could also be crafted using recent results by Moreau which appeared in [16] after this paper was submitted in December, 2004.

a direct consequence of the fact that sensing regions are defined to be closed sets. The continuity of $\Delta(\cdot)$ is a consequence of the requirement that the $u_m(\cdot)$ be continuous functions. In summary, for the present analysis to go through, it is essential that sensing regions be closed sets and that the $u_m(\cdot)$ be continuous functions. Whether or not these requirements can be relaxed by approaching convergence differently remains to be seen.

5. Concluding remarks. In this paper we have reconsidered the multi-agent rendezvous problem originally posed in [1] and have described several alternate synchronous solutions. We have provided an example which shows that rendezvousing can in some cases be guaranteed to occur even if the graph characterizing initial relations is not initially connected. In a sequel to this paper [12] we will explain how rendezvousing can be achieved asynchronously, without assuming that the agents share a common clock.

Since this paper and its sequel [12] were written, a number of papers on rendezvous have appeared. We refer the reader to [3] for additional references and for interesting new results on the rendezvous problem posed in higher dimensional spaces and with more general assumptions about sensing and communications.

6. Appendix. The proof of Proposition 1 depends on the following lemma.

LEMMA 1. *Let $z_1, z_2, \ldots, z_m$ be a set of $m > 0$ points in $\mathbb{D}$ which are not all 0. If 0 is a corner of $\langle 0, z_1, z_2, \ldots, z_m\rangle$, then the constraint set $\mathcal{C}(z_1, z_2, \ldots, z_m)$ has a nonempty interior.*

Proof of Lemma 1. Suppose that $\mathcal{C}(z_1, z_2, \ldots, z_m)$ has an empty interior in which case $\mathcal{C}(z_1, z_2, \ldots, z_m)$ is the singleton $\{0\}$. It will be enough to prove that 0 is not a corner of $\langle 0, z_1, z_2, \ldots, z_m\rangle$. In what follows we shall assume, without loss of generality, that 0 is on the boundary of each disk in the intersection; for if there were any disks in the intersection which contained the origin in their interiors, all such disks could be removed from the intersection without changing what the intersection equals.

To proceed, let us note first that $m > 1$ because each $\mathcal{C}(z_i)$ has a nonempty interior and, by hypothesis, the intersection $\mathcal{C}(z_1, z_2, \ldots, z_m)$ does not. Next observe that since $m > 1$ and $\mathcal{C}(z_1)$ has a nonempty interior, there must be a least integer $j \in \{2, 3, \ldots, m\}$ such that $\mathcal{I} \triangleq \bigcap_{i=1}^{j-1} \mathcal{C}(z_j)$ has a nonempty interior and $\mathcal{I} \cap \mathcal{C}(z_j)$ contains just the origin. The intersection of any positive number of disks from $\{\mathcal{C}(z_1), \mathcal{C}(z_2), \ldots, \mathcal{C}(z_m)\}$ is either the origin or a convex set with a nonempty interior; moreover, the latter will always be a strictly convex set whose edges are arcs from circles bounding disks in the intersection and whose corners are intersections of such arcs. It follows that $\mathcal{C}(z_j)$ must either be tangent at the origin to an arc which is from a circle bounding some disk $\mathcal{C}(z_k) \in \{\mathcal{C}(z_1), \mathcal{C}(z_2), \ldots, \mathcal{C}(z_{j-1})\}$ or $\mathcal{C}(z_j)$'s boundary must pass through a corner of $\mathcal{I}$ at the origin. If the former is true, then z_k must equal $-z_j$. Since $z_j \neq 0$, this means that the origin is halfway between z_k and z_j on the line connecting these two points. Hence the origin cannot be a corner of the polytope $\langle 0, z_1, z_2, \ldots, z_m\rangle$.

Now suppose that the boundary of $\mathcal{C}(z_j)$ passes through a corner of $\mathcal{I}$ at the origin. Let $\mathcal{C}(z_k)$ and $\mathcal{C}(z_l)$ denote two disks in $\{\mathcal{C}(z_1), \mathcal{C}(z_2), \ldots, \mathcal{C}(z_{j-1})\}$ whose intersection at the origin determines this corner. Under these conditions, $z_k + z_l \neq 0$—for if $z_k + z_l = 0$, then $\mathcal{C}(z_k)$ and $\mathcal{C}(z_l)$ would be tangent, and $\mathcal{I}$ would consequently contain just the origin. Moreover, the intersection $\mathcal{C}(z_j) \cap \mathcal{C}(z_k) \cap \mathcal{C}(z_l)$ must consist of just the origin—for if this were not so, then $\mathcal{I} \cap \mathcal{C}(z_j)$ would have a nonempty interior since $\mathcal{I}$ coincides locally, in an open neighborhood of 0, with $\mathcal{C}(z_k) \cap \mathcal{C}(z_l)$.

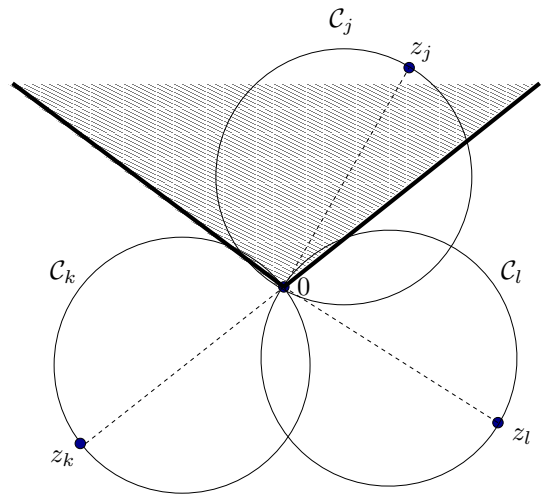

FIG. 1. *Three constraint disks whose intersection is the origin.*

As illustrated in Figure 1, the requirement that $\mathcal{C}(z_j) \cap \mathcal{C}(z_k) \cap \mathcal{C}(z_l)$ consist of just the origin implies that $\mathcal{C}(z_j)$ must be positioned in such a way so that it intersects only at the origin with a cone of points determined by tangents to $\mathcal{C}(z_k)$ and $\mathcal{C}(z_l)$ at the origin. This means that z_j must lie within the opposing cone shown in grey in Figure 1. Hence the origin is within the interior of the convex hull of z_j, z_k, and z_l. Therefore the origin cannot be a corner of $\langle 0, z_1, z_2, \ldots, z_m \rangle$. □

Proof of Proposition 1. Lemma 1 and the hypothesis that 0 is a corner of $\langle 0, z_1, z_2, \ldots, z_m \rangle$ imply that $\mathcal{C}(z_1, z_2, \ldots, z_m)$ has a nonempty interior. From this and the hypothesis that $z \neq 0$, it follows that if 0 is an interior point of $\mathcal{C}(z_1, z_2, \ldots, z_m)$, then a line segment with the required property must exist.

Suppose next that 0 is on the boundary of $\mathcal{C}(z_1, z_2, \ldots, z_m)$. To complete the proof it is clearly enough to show that the line from 0 to z passes through the interior of each disk $\mathcal{C}(z_j)$ for which 0 is a boundary point. Let $\mathcal{C}(z_j)$ be such a disk in which case $||z_j|| = r$. Suppose that the line from 0 to z does not pass through the interior $\mathcal{C}(z_j)$. This means that $z_j' z \leq 0$ and thus that $||z||^2 - 2z_j' z + ||z_j||^2 \geq ||z||^2 + ||z_j||^2$. Since $||z - z_j||^2 = ||z||^2 - 2z_j' z + ||z_j||^2$ and $||z_j|| = r$, it follows that

$$||z - z_j||^2 \geq ||z||^2 + r^2.$$

But $||z||^2 > 0$ because $z \neq 0$, so

$$||z - z_j|| > r.$$

This contradicts the hypothesis that z is within r units of each point in $\{z_1, z_2, \ldots, z_m\}$. Therefore the line from 0 to z must pass through the interior $\mathcal{C}(z_j)$. □

The proof of Proposition 2 depends on the following two lemmas.

LEMMA 2. *Let $z_1, z_2, \ldots, z_m$ be a set of $m > 0$ points in $\mathbb{D}$ which are not all zero. Let $\mathcal{E}(x, y)$ be an edge of $\langle 0, z_1, z_2, \ldots, z_m \rangle$ with distinct corners x and y. Write $\mathcal{L}(x, y)$ for the line passing through x and y, and let $\mathcal{S}(x, y)$ denote the closed half-plane bounded by this line whose intersection with $\langle 0, z_1, z_2, \ldots, z_m \rangle$ is $\mathcal{E}(x, y)$. If z is any point in $\mathcal{S}(x, y)$ which is also in $\mathbb{D} \cap \mathcal{D}(z_1, z_2, \ldots, z_m)$, then the reflection of z about $\mathcal{L}(x, y)$ is also in $\mathbb{D} \cap \mathcal{D}(z_1, z_2, \ldots, z_m)$.*

Proof of Lemma 2. Note that $\langle 0, z_1, z_2, \ldots, z_m\rangle$ is contained in the half-plane obtained by reflecting $\mathcal{S}(x, y)$ about $\mathcal{L}(x, y)$. Because of this, for each $w \in \mathcal{S}$

$$||\bar{w} - q|| \leq ||w - q|| \quad \forall q \in \langle 0, z_1, z_2, \ldots, z_m\rangle,$$

where $\bar{w}$ is the reflection of w about $\mathcal{L}(x, y)$. In particular, this implies that

$$||\bar{z} - z_i| \leq ||z - z_i||, \quad i \in \{0, 1, 2, \ldots, m\}, \tag{19}$$

where $z_0 = 0$ and $\bar{z}$ is the reflection of z about $\mathcal{L}(x, y)$. But

$$||z - z_i|| \leq r, \quad i \in \{0, 1, 2, \ldots, m\}, \tag{20}$$

because $z \in \mathbb{D} \cap \mathcal{D}(z_1, z_2, \ldots, z_m)$. From (19) and (20) it follows that $\bar{z} \in \mathbb{D} \cap \mathcal{D}(z_1, z_2, \ldots, z_m)$. □

LEMMA 3. *Let $\mathcal{L}$ be a line in $\mathbb{R}^2$ which divides a given closed set $\mathcal{D}$ into closed subsets $\mathcal{P}$ and $\mathcal{Q}$ with $\mathcal{Q}$ convex. If the reflection of $\mathcal{P}$ about $\mathcal{L}$ is a subset of $\mathcal{Q}$, then the centroid of $\mathcal{D}$ is in $\mathcal{Q}$.*

Proof. Let $\bar{\mathcal{P}}$ denote the reflection of $\mathcal{P}$ about $\mathcal{L}$. By hypothesis, $\bar{\mathcal{P}} \subset \mathcal{Q}$. Then write $\mathcal{Q} - \bar{\mathcal{P}}$ for the complement of $\bar{\mathcal{P}}$ in $\mathcal{Q}$. By symmetry, the centroid of $\mathcal{P} \cup \bar{\mathcal{P}}$ is in $\mathcal{L} \subset \mathcal{Q}$. Meanwhile, the centroid of $\mathcal{Q} - \bar{\mathcal{P}}$ must also be in $\mathcal{Q}$ because $\mathcal{Q}$ is convex and $\mathcal{Q} - \bar{\mathcal{P}} \subset \mathcal{Q}$. Thus the centroid of $\mathcal{D}$ must be in $\mathcal{Q}$ because it is the average of the centroids of $\mathcal{P} \cup \bar{\mathcal{P}}$ and $\mathcal{Q} - \bar{\mathcal{P}}$ weighted by the areas of $\mathcal{P} \cup \bar{\mathcal{P}}$ and $\mathcal{Q} - \bar{\mathcal{P}}$, respectively. □

Proof of Proposition 2. Write $\mathcal{D}$ for $\mathbb{D} \cap \mathcal{D}(z_1, z_2, \ldots, z_m)$ and let $\{\mathcal{E}_1, \mathcal{E}_2, \ldots, \mathcal{E}_k\}$ denote the set of edges of $\langle 0, z_1, z_2, \ldots, z_m\rangle$. For each such edge $\mathcal{E}_i$, let $\mathcal{L}_i$ denote the line in $\mathbb{R}^2$ containing $\mathcal{E}_i$ and write $\mathcal{S}_i$ for the closed half-plane bounded by this line whose intersection with $\langle 0, z_1, z_2, \ldots, z_m\rangle$ is $\mathcal{E}_i$. Let $\bar{\mathcal{S}}_i$ denote the reflection of $\mathcal{S}_i$ about $\mathcal{L}_i$. In view of Lemma 2,

$$\overline{\mathcal{S}_i \cap \mathcal{D}} \subset \mathcal{D}, \quad i \in \{1, 2, \ldots, k\},$$

where $\overline{\mathcal{S}_i \cap \mathcal{D}}$ is the reflection of $\mathcal{S}_i \cap \mathcal{D}$ about $\mathcal{L}_i$. Since $\overline{\mathcal{S}_i \cap \mathcal{D}}$ is also a subset of $\bar{\mathcal{S}}_i$,

$$\overline{\mathcal{S}_i \cap \mathcal{D}} \subset \bar{S}_i \cap \mathcal{D}, \quad i \in \{1, 2, \ldots, k\}. \tag{21}$$

Moreover, by de Morgan's rule

$$\{\mathcal{S}_i \cap \mathcal{D}\} \cup \{\bar{S}_i \cap \mathcal{D}\} = \mathcal{D}, \quad i \in \{1, 2, \ldots, k\},$$

because $\mathcal{S}_i \cup \bar{\mathcal{S}}_i = \mathbb{R}^2$, $i \in \{1, 2, \ldots, k\}$. Thus for each $i \in \{1, 2, \ldots\}$, $\mathcal{L}_i$ divides $\mathcal{D}$ into two closed convex regions, namely $\mathcal{S}_i \cap \mathcal{D}$ and $\bar{S}_i \cap \mathcal{D}$. From this, (21), and Lemma 3 it follows that

$$\text{centroid}\{\mathcal{D}\} \in \bar{\mathcal{S}}_i \cap \mathcal{D}, \quad i \in \{1, 2, \ldots, k\}.$$

Therefore

$$\text{centroid}\{\mathcal{D}\} \in \bigcap_{i=1}^{k} \{\bar{\mathcal{S}}_i \cap \mathcal{D}\}. \tag{22}$$

But

$$\bigcap_{i=1}^{k} \{\bar{\mathcal{S}}_i \cap \mathcal{D}\} = \langle 0, z_1, z_2, \ldots, z_m\rangle \bigcap \mathcal{D} \tag{23}$$

because

$$\langle 0, z_1, z_2, \ldots, z_m \rangle = \bigcap_{i=1}^{k} \bar{\mathcal{S}}_i.$$

From (22) and (23) it follows that centroid$\{\mathcal{D}\} \in \langle 0, z_1, z_2, \ldots, z_m \rangle$.

Now suppose that 0 is a corner of $\langle 0, z_1, z_2, \ldots, z_m \rangle$. Then in view of Lemma 1, $\mathbb{D} \cap \mathcal{C}(z_1, z_2, \ldots, z_m)$ has a nonempty interior. To prove that $\mathbb{D} \cap \mathcal{D}(z_1, z_2, \ldots, z_m)$ also has a nonempty interior, it is therefore enough to show that

$$\mathcal{C}(z_1, z_2, \ldots, z_m) \subset \mathcal{D}(z_1, z_2, \ldots, z_m). \tag{24}$$

Recall that for $z \in \mathbb{D}$, $\mathcal{D}(z) = \{x : ||z - x|| \leq r\}$ and $\mathcal{C}(z) = \{x : ||\frac{1}{2}z - x|| \leq \frac{r}{2}\}$. Thus for $x \in \mathcal{C}(z)$

$$||z - x|| = \left\| \frac{1}{2}z - x + \frac{1}{2}z \right\| \leq \left\| \frac{1}{2}z - x \right\| + \left\| \frac{1}{2}z \right\| \leq \frac{r}{2} + \frac{1}{2}||z|| \leq r;$$

thus $x \in \mathcal{D}(z)$. Hence $\mathcal{C}(z) \subset \mathcal{D}(z)$, $z \in \mathbb{D}$, from which (24) follows.

To prove that the centroid of $\mathcal{D}$ is not at 0, it is enough to show that it is not at 0 whenever it lies on an edge of $\langle 0, z_1, z_2, \ldots, z_m \rangle$ which contains 0. Accordingly, let $\mathcal{E}_j$ be an edge of $\langle 0, z_1, z_2, \ldots, z_m \rangle$ which contains both 0 and the centroid of $\mathcal{D}$. Since the centroid of $\mathcal{D}$ lies in $\mathcal{L}_j$, and both $\mathcal{S}_j \cap \mathcal{D}$ and $\bar{\mathcal{S}}_j \cap \mathcal{D}$ have nonempty interiors, it must be true that

$$\text{area}\{\mathcal{S}_j \cap \mathcal{D}\}d = \text{area}\{\bar{\mathcal{S}}_j \cap \mathcal{D}\}\bar{d},$$

where d is the distance from the centroid of $\mathcal{S}_j \cap \mathcal{D}$ to the point closest on $\mathcal{L}_j$ and $\bar{d}$ is correspondingly the distance from the centroid of $\bar{\mathcal{S}}_j \cap \mathcal{D}$ to the point closest on $\mathcal{L}_j$. But area$\{\overline{\mathcal{S}_j \cap \mathcal{D}}\}$ = area$\{\mathcal{S}_j \cap \mathcal{D}\}$, so

$$\text{area}\{\overline{\mathcal{S}_j \cap \mathcal{D}}\}d = \text{area}\{\bar{\mathcal{S}}_j \cap \mathcal{D}\}\bar{d}. \tag{25}$$

We claim that

$$\overline{\mathcal{S}_j \cap \mathcal{D}} = \bar{\mathcal{S}}_j \cap \mathcal{D}. \tag{26}$$

To establish this claim, we first note that $\overline{\mathcal{S}_j \cap \mathcal{D}} \subset \bar{\mathcal{S}}_j \cap \mathcal{D}$ because (21) holds for all $i \in \{1, 2, \ldots, k\}$. Thus to prove (26) it is enough to show that the complement of $\overline{\mathcal{S}_j \cap \mathcal{D}}$ in $\bar{\mathcal{S}}_j \cap \mathcal{D}$, denoted by $\mathcal{W}$, is empty. Towards this end, suppose that $\mathcal{W}$ is nonempty and has a nonempty interior. Since $\bar{\mathcal{S}}_j \cap \mathcal{D} = \{\overline{\mathcal{S}_j \cap \mathcal{D}}\} \cup \mathcal{W}$ and $\{\overline{\mathcal{S}_j \cap \mathcal{D}}\} \cap \mathcal{W}$ is empty, it must be true that

$$\text{area } \{\bar{\mathcal{S}}_j \cap \mathcal{D}\}\bar{d} = \text{area } \{\overline{\mathcal{S}_j \cap \mathcal{D}}\}d_1 + \text{area } \{\mathcal{W}\}d_2,$$

where d_1 is the distance from the centroid of $\{\overline{\mathcal{S}_j \cap \mathcal{D}}\}$ to the point closest on $\mathcal{L}_j$ and d_2 is correspondingly the distance from the centroid of $\mathcal{W}$ to the point closest on $\mathcal{L}_j$. But $\overline{\mathcal{S}_j \cap \mathcal{D}}$ is the reflection of $\mathcal{S}_j \cap \mathcal{D}$ about $\mathcal{L}_j$, and thus $d_1 = d$. Therefore

$$\text{area } \{\bar{\mathcal{S}}_j \cap \mathcal{D}\}\bar{d} = \text{area } \{\overline{\mathcal{S}_j \cap \mathcal{D}}\}d + \text{area } \{\mathcal{W}\}d_2.$$

This and (25) imply that area $\{\mathcal{W}\}d_2 = 0$. But $d_2 \neq 0$ because we have assumed that $\mathcal{W}$ has a nonempty interior. This implies that area $\{\mathcal{W}\} = 0$, which contradicts the hypothesis that $\mathcal{W}$ has a nonempty interior. Therefore $\mathcal{W}$ has an empty interior.

To show that $\mathcal{W}$ is actually empty or, equivalently, that (26) holds, it is enough to prove that the interior of $\bar{\mathcal{S}}_j \cap \mathcal{D}$ is contained in $\overline{\mathcal{S}_j \cap \mathcal{D}}$. For if this is true, then (26) holds, because both sets are closed and convex with nonempty interiors and $\overline{\mathcal{S}_j \cap \mathcal{D}} \subset \bar{\mathcal{S}}_j \cap \mathcal{D}$.

Suppose that the interior of $\bar{\mathcal{S}}_j \cap \mathcal{D}$ is not contained in $\overline{\mathcal{S}_j \cap \mathcal{D}}$. Then there must be a point p in the interior of $\bar{\mathcal{S}}_j \cap \mathcal{D}$ which is not in $\overline{\mathcal{S}_j \cap \mathcal{D}}$. Since $\{p\}$ and $\overline{\mathcal{S}_j \cap \mathcal{D}}$ are disjoint and each is a closed, convex set, there must be a line $\bar{\mathcal{L}}$ which separates the two and intersects neither. From this it is clear that there is an open set $\mathcal{N}_p \subset \bar{\mathcal{S}}_j \cap \mathcal{D}$ which contains p and which does not intersect $\bar{\mathcal{L}}$. It follows that $\mathcal{N}_p$ and $\overline{\mathcal{S}_j \cap \mathcal{D}}$ are disjoint and thus that $\mathcal{N}_p \subset \mathcal{W}$. But this is impossible because $\mathcal{W}$ has no interior. Therefore $\mathcal{W}$ is empty. We have therefore proved that $\mathcal{D}$ is *symmetric* about $\mathcal{L}_j$ in the sense that (26) holds.

Since $\mathcal{D}$ has a nonempty interior, its boundary consists of circular arcs resulting from the intersection of $m+1$ disks of radius r. Let $\mathcal{A}$ denote a circular arc of positive length which lies in $\mathcal{S}_j$ and which comprises part of the boundary of $\mathcal{D}$. In view of $\mathcal{D}$'s symmetry about $\mathcal{L}_j$ as defined by (26), the reflection of $\mathcal{A}$ about $\mathcal{L}_j$, namely $\bar{\mathcal{A}}$, must be a circular arc of positive length which lies in $\bar{\mathcal{S}}_j$ and which comprises part of the boundary of $\mathcal{D}$. Let x and y be points in $\{0, z_1, z_2, \ldots, z_m\}$ which define disks $\mathcal{D}(x)$ and $\mathcal{D}(y)$ whose boundaries contain $\mathcal{A}$ and $\bar{\mathcal{A}}$, respectively. Clearly the reflection of $\mathcal{D}(x)$ about $\mathcal{L}_j$ must equal $\mathcal{D}(y)$, which implies that $\bar{x} = y$. Thus $\bar{x} \in \langle 0, z_1, z_2, \ldots, z_m \rangle$. Since either $\bar{x}$ or x must be in $\mathcal{S}_j$, at least one of these two points must be in $\mathcal{S}_j \cap \langle 0, z_1, z_2, \ldots, z_m \rangle$, which is equal to $\mathcal{E}_j$. This can only occur if $\bar{x} = x$. In summary we have shown that if $\mathcal{A}$ is any circular arc of positive length comprising part of the boundary of $\mathcal{D}$, and if x is any point in $\{0, z_1, z_2, \ldots, z_m\}$ which defines a disk $\mathcal{D}(x)$ whose boundary contains $\mathcal{A}$, then x must be in $\mathcal{E}_j$.

Now let y be the nonzero endpoint of the edge $\mathcal{E}_j$, let $\mathcal{A}$ be any circular arc of positive length comprising part of the boundary of $\mathcal{D}$, and let $x_{\mathcal{A}}$ be any point in $\{0, z_1, z_2, \ldots, z_m\}$ which defines a disk $\mathcal{D}(x_{\mathcal{A}})$ whose boundary contains $\mathcal{A}$. As we have just shown, $x_{\mathcal{A}} \in \mathcal{E}_j$. This means there must be a number $\lambda \in [0,1]$ such that $x_{\mathcal{A}} = \lambda y$. Let z be any point in $\mathbb{D} \cap \mathcal{D}(y)$. Then by definition $||z|| \le r$ and $||y - z|| \le r$. Therefore

$$\begin{aligned} ||x_{\mathcal{A}} - z|| &= ||\lambda y - z|| = ||\lambda(y-z) - (1-\lambda)z|| \\ &\le ||\lambda(y-z)|| + ||(1-\lambda)z|| \le \lambda||y-z|| + (1-\lambda)||z|| \le r, \end{aligned}$$

so $z \in \mathcal{D}(x_{\mathcal{A}})$. Since z was chosen arbitrarily,

$$\mathbb{D} \cap \mathcal{D}(y) \subset \mathcal{D}(x_{\mathcal{A}}).$$

This containment holds for each disk $\mathcal{D}(x_{\mathcal{A}})$ whose boundary contains a circular arc $\mathcal{A}$ of positive length comprising part of the boundary of $\mathcal{D}$. Since the intersection of the $\mathcal{D}(x_{\mathcal{A}})$ over all such $\mathcal{A}$ is $\mathcal{D}$, it must therefore be true that

$$\mathbb{D} \cap \mathcal{D}(y) \subset \mathcal{D}. \tag{27}$$

On the other hand, $\mathcal{D} \subset \mathcal{D}(y)$ since $y \in \langle 0, z_1, z_2, \ldots, z_m \rangle$. Thus $\mathcal{D} \subset \mathbb{D} \cap \mathcal{D}(y)$. This and (27) thus imply that

$$\mathbb{D} \cap \mathcal{D}(y) = \mathcal{D}.$$

It follows that the centroid of $\mathcal{D}$ must be the centroid of $\mathbb{D} \cap \mathcal{D}(y)$. But the centroid of two intersection disks with the same radius must be at the midpoint between their centers. Therefore the centroid of $\mathcal{D}$ is at $\frac{1}{2}y$ which is not 0. □

Proof of Proposition 3. In what follows we write z for the n-tuple $\{z_1, z_2, \ldots, z_m\} \in \mathbb{D}^m$, and $\mathcal{S}(z)$ for the intersection $\mathbb{D} \cap \mathcal{D}(z_1, z_2, \ldots, z_m)$. Thus for $x, y \in \mathbb{D}^m$, $\mathcal{S}(x) \cap \mathcal{S}(y) = \mathbb{D} \cap \mathcal{D}(x_1, x_2, \ldots, x_m) \cap \mathcal{D}(y_1, y_2, \ldots, y_m)$. For $x \in \mathbb{D}^m$, let $\alpha(\mathcal{S}(x))$ and $\sigma(\mathcal{S}(x))$ denote, respectively, the area and centroid of $\mathcal{S}(x)$. Note that $\sigma(\mathcal{S}(x)) = 0$ whenever $\alpha(\mathcal{S}(x)) = 0$. This crucial property (which is not true for polygons) is a consequence of the fact that $\mathcal{S}(x)$ is either strictly convex with nonempty interior or the singleton 0.

It will first be shown that $z \longmapsto \sigma(\mathcal{S}(z))$ is continuous at each point $x \in \mathbb{D}^m$ at which $\alpha(\mathcal{S}(x)) = 0$. Let x be any such point. Clearly $\sigma(\mathcal{S}(x)) = 0$. Let $\epsilon > 0$ be fixed. Since $z \longmapsto \text{diameter}(\mathcal{S}(z))$ is continuous on $\mathbb{D}^m$, there must be a number $\delta > 0$ such that $\text{diameter}(\mathcal{S}(z)) \leq \epsilon$ whenever $||z - x|| \leq \delta$. But both 0 and $\sigma(\mathcal{S}(z))$ are points in $\mathcal{S}(z)$ for all $z \in \mathbb{D}^m$. Hence $||\sigma(\mathcal{S}(z))|| \leq \text{diameter}(\mathcal{S}(z)),\ z \in \mathbb{D}^m$; thus $|\sigma(\mathcal{S}(z))| \leq \epsilon$ whenever $||z - x|| \leq \delta$. Therefore $z \longmapsto \sigma(\mathcal{S}(z))$ is continuous at each point $x \in \mathbb{D}^m$ at which $\alpha(\mathcal{S}(x)) = 0$.

It will now be shown that $z \longmapsto \sigma(\mathcal{S}(z))$ is continuous at each point $x \in \mathbb{D}^m$ at which $\alpha(\mathcal{S}(x)) > 0$. Let x be such a point. Pick $\epsilon > 0$ and define

$$\bar{\epsilon} = \frac{\epsilon}{\epsilon + 4r} \alpha(\mathcal{S}(x)). \tag{28}$$

Since $z \longmapsto \alpha(\mathcal{S}(z))$ and $z \longmapsto \alpha(\mathcal{S}(x) \cap \mathcal{S}(z))$ are continuous on $\mathbb{D}^m$ and $\alpha(\mathcal{S}(x) \cap \mathcal{S}(x)) = \alpha(\mathcal{S}(x))$, there must be a number $\delta > 0$ such that

$$|\alpha(\mathcal{S}(x)) - \alpha(\mathcal{S}(z))| \leq \bar{\epsilon} \quad \text{and} \quad |\alpha(\mathcal{S}(x)) - \alpha(\mathcal{S}(x) \cap \mathcal{S}(z))| \leq \bar{\epsilon} \tag{29}$$

whenever $||z - x|| \leq \delta$. Fix z at any such value. To complete the proof it is enough to show that

$$||\sigma(\mathcal{S}(x)) - \sigma(\mathcal{S}(z))|| \leq \epsilon. \tag{30}$$

From the first inequality in (29), $\alpha(\mathcal{S}(z)) \geq \alpha(\mathcal{S}(x)) - \bar{\epsilon}$. But from (28), $\alpha(\mathcal{S}(x)) - \bar{\epsilon} = \frac{4r\bar{\epsilon}}{\epsilon}$ and thus

$$\alpha(\mathcal{S}(z)) \geq \frac{4r\bar{\epsilon}}{\epsilon}. \tag{31}$$

In general

$$\mathcal{S}(x) = (\mathcal{S}(x) \cap \mathcal{S}(z)) \cup \mathcal{X} \quad \text{and} \quad \mathcal{S}(z) = (\mathcal{S}(x) \cap \mathcal{S}(z)) \cup \mathcal{Z}, \tag{32}$$

where $\mathcal{X}$ and $\mathcal{Z}$ are the complements of $\mathcal{S}(x) \cap \mathcal{S}(z)$ in $\mathcal{S}(x)$ and $\mathcal{S}(z)$, respectively. If $\mathcal{S}(x) \cap \mathcal{S}(z)$ is a strictly proper subset of $\mathcal{S}(x)$ (respectively, $\mathcal{S}(z)$), then $\mathcal{X}$ (respectively, $\mathcal{Z}$) is a subset with nonempty interior; in this case $\alpha(\mathcal{X})$ and $\sigma(\mathcal{X})$ (respectively, $\alpha(\mathcal{Z})$ and $\sigma(\mathcal{Z})$) are well defined. If, on the other hand, $\mathcal{S}(x) \cap \mathcal{S}(z)$ equals $\mathcal{S}(x)$ (respectively, $\mathcal{S}(z)$), then $\mathcal{X}$ (respectively, $\mathcal{Z}$) is the empty set; in this case $\alpha(\mathcal{X})$ (respectively, $\alpha(\mathcal{Z})$) is zero, and $\sigma(\mathcal{X})$ (respectively, $\sigma(\mathcal{Z})$) is taken to be the 0 vector in $\mathbb{R}^2$.

In view of (32)

$$\alpha(\mathcal{S}(x)) = \alpha(\mathcal{S}(x) \cap \mathcal{S}(z)) + \alpha(\mathcal{X}), \tag{33}$$

$$\alpha(\mathcal{S}(z)) = \alpha(\mathcal{S}(x) \cap \mathcal{S}(z)) + \alpha(\mathcal{Z}), \tag{34}$$

$$\alpha(\mathcal{S}(x))\sigma(\mathcal{S}(x)) = \alpha(\mathcal{S}(x) \cap \mathcal{S}(z))\sigma(\mathcal{S}(x) \cap \mathcal{S}(z)) + \alpha(\mathcal{X})\sigma(\mathcal{X}), \tag{35}$$

$$\alpha(\mathcal{S}(z))\sigma(\mathcal{S}(z)) = \alpha(\mathcal{S}(x) \cap \mathcal{S}(z))\sigma(\mathcal{S}(x) \cap \mathcal{S}(z)) + \alpha(\mathcal{Z})\sigma(\mathcal{Z}). \tag{36}$$

Subtracting (33) from (34) and (35) from (36), one obtains

$$\alpha(\mathcal{S}(z)) - \alpha(\mathcal{S}(x)) = \alpha(\mathcal{Z}) - \alpha(\mathcal{X}) \tag{37}$$

and

$$\alpha(\mathcal{S}(z))\sigma(\mathcal{S}(z)) - \alpha(\mathcal{S}(x))\sigma(\mathcal{S}(x)) = \alpha(\mathcal{Z})\sigma(\mathcal{Z}) - \alpha(\mathcal{X})\sigma(\mathcal{X}), \tag{38}$$

respectively. Using (37) to eliminate $\alpha(\mathcal{Z})$ from (38), there results

$$\alpha(\mathcal{S}(z))\sigma(\mathcal{S}(z)) - \alpha(\mathcal{S}(x))\sigma(\mathcal{S}(x)) = \alpha(\mathcal{X})\{\sigma(\mathcal{Z}) - \sigma(\mathcal{X})\} + \{\alpha(\mathcal{S}(z)) - \alpha(\mathcal{S}(x))\}\sigma(\mathcal{Z}),$$

which can be rewritten as

$$\sigma(\mathcal{S}(z)) - \sigma(\mathcal{S}(x)) = \frac{1}{\alpha(\mathcal{S}(z))} \times \{\alpha(\mathcal{X})\{\sigma(\mathcal{Z}) - \sigma(\mathcal{X})\} + \{\alpha(\mathcal{S}(z)) - \alpha(\mathcal{S}(x))\}\{\sigma(\mathcal{Z}) - \sigma(\mathcal{S}(x))\}\}. \tag{39}$$

Since the centroids of $\mathcal{Z}, \mathcal{X}, \mathcal{S}(z)$, and $\mathcal{S}(x)$ are all in $\mathbb{D}$, it must be true that the norm of each is bounded above by r. This and (40) imply that

$$||\sigma(\mathcal{S}(z)) - \sigma(\mathcal{S}(x))|| \leq \left\| \frac{1}{\alpha(\mathcal{S}(z))} \right\| \{2r||\alpha(\mathcal{X})|| + 2r||\alpha(\mathcal{S}(z)) - \alpha(\mathcal{S}(x))||\}. \tag{40}$$

But $\|\frac{1}{\alpha(\mathcal{S}(z))}\| \leq \frac{\epsilon}{4r\bar{\epsilon}}$ because of (31); moreover, $||\alpha(\mathcal{X})|| \leq \bar{\epsilon}$ because of (33) and the second inequality in (29). From these inequalities, the first inequality in (29), and (40), it follows that (30) is true. □

Proof of Proposition 4. Note first that each point on the piecewise linear curve c determined by the points $y_1, y_2, \ldots, y_m$ is on a line connecting two of these points. It follows that each point on c is contained in $\langle y_1, y_2, \ldots, y_m \rangle$. Let y be an interior point of $\lceil y_1, y_2, \ldots, y_m \rceil$; in other words, $\mathrm{wn}(y, c) \neq 0$. Because of this, c must encircle y at least once. Since y is an interior point, any line of sufficient length which passes through y must intersect c at a minimum of two distinct points. Since points on c are in $\langle y_1, y_2, \ldots, y_m \rangle$, y must therefore be in $\langle y_1, y_2, \ldots, y_m \rangle$ as well. □

The proof of Proposition 5 depends on the following fact.

LEMMA 4. *Let a, b, c, d be four points in the plane positioned so that the line from a to b intersects the line from c to d, and so that $||a - b|| \leq r$ and $||c - d|| \leq r$. Then*

$$\min\{||a - d||,\ ||b - c||\} \leq r \quad \text{and} \quad \min\{||a - c||,\ ||b - d||\} \leq r. \tag{41}$$

Proof of Lemma 4. Let e denote any point at which the line from a to b intersects the line from c to d. Since $a-d = (a-e)+(e-d)$ and $c-b = (c-e)+(e-b)$, we can use the triangle inequality to get $||a-d|| \leq ||a-e||+||e-d||$ and $||c-b|| = ||c-e||+||e-d||$, respectively. Adding these inequalities yields

$$||a - d|| + ||c - b|| \leq ||a - e|| + ||e - d|| + ||c - e|| + ||e - b||.$$

But because a, b, and e are colinear and c, d, and e are colinear, $||a - e|| + ||e - b|| = ||a - b||$ and $||c - e|| + ||e - d|| = ||c - d||$, respectively. Therefore

$$||a - d|| + ||c - b|| \leq ||a - b|| + ||c - d|| \leq 2r.$$

It follows that either $||a-d|| \leq r$ or $||c-b|| \leq r$. By the same reasoning, either $||a-c|| \leq r$ or $||d-b|| \leq r$. Therefore (41) is true. □

Proof of Proposition 5. Suppose w is within r units of z and is not interior to $\lceil y_1, y_2, \ldots, y_m \rceil$. Then the line connecting z and w must intersect the line from y_j to y_{j+1} for some $j \in \{1, 2, \ldots, m\}$. Since $||y_j - y_{j+1}|| \leq r$, Lemma 4 can be applied with $a = z$, $b = w$, $c = y_j$, and $d = y_{j+1}$. It follows from (41) that either z or w is linked to $\lceil y_1, y_2, \ldots, y_m \rceil$. Therefore w is so linked. □

The proof of Proposition 6 depends on the following lemmas.

LEMMA 5. *Let a, b, and c be three points in the plane such that $||a-b|| \leq r$ and $||a-c|| \leq r$. Any point in the convex hull of a, b, and c is within at most r units of both a and either b or c.*

Proof of Lemma 5. Let $d = \frac{1}{2}(b+c)$. Since $d - a = \frac{1}{2}\{(a-b)+(a-c)\}$, it must be true that $||d-a|| \leq \frac{1}{2}\{||a-b|| + ||a-c||\}$. From this and the hypotheses $||a-b|| \leq r$ and $||a-c|| \leq r$, it follows that $||d-a|| \leq r$. Moreover, from the triangle inequality, $||b-c|| \leq ||b-a|| + ||a-c||$. Therefore $||b-c|| \leq 2r$. Since d is the midpoint between b and c, $||b-d|| \leq r$ and $||c-d|| \leq r$. Thus the sets $\langle a, b, d\rangle$ and $\langle a, c, d\rangle$ each have diameter no greater than r. Since $\langle a, b, c\rangle = \langle a, b, d\rangle \cup \langle a, c, d\rangle$, it follows that any point in $\langle a, b, c\rangle$ must be in $\langle a, b, d\rangle$ or $\langle a, c, d\rangle$ and consequently within r units of a and either b or c. □

LEMMA 6. *Suppose that $z_1, z_2, \ldots, z_k$ are $k > 0$ interior points of a given cycle $\lceil y_1, y_2, \ldots, y_m \rceil$ which are not linked to $\lceil y_1, y_2, \ldots, y_m \rceil$ and which satisfy $||z_1 - z_i|| \leq r$, $i \in \{2, 3, \ldots, k\}$. Then each point in the convex hull $\langle z_1, z_2, \ldots, z_k\rangle$ is an interior point of $\lceil y_1, y_2, \ldots, y_m \rceil$.*

Proof of Lemma 6. Note first that if there is any point $z \in \langle z_1, z_2, \ldots, z_k\rangle$ which is not an interior point of $[y_1, y_2, \ldots, y_m]$, then z would have to be either on or outside of the piecewise linear curve c determined by $y_1, y_2, \ldots, y_m$; in either case this would mean that the line connecting z to any point in $\{z_1, z_2, \ldots, z_k\}$ would have to intersect c since, by assumption, $z_1, z_2, \ldots, z_k$ are interior points of c. Since any such line is contained in $\langle z_1, z_2, \ldots, z_k\rangle$, the convex hull itself would have to intersect c. Thus to prove the lemma it is enough to show that $\langle z_1, z_2, \ldots, z_k\rangle$ does not intersect c. To do this it is sufficient to show that for each pair of points $z_i, z_j \in \{z_1, z_2, \ldots, z_k\}$, the line ℓ_{ij} from z_i to z_j does not intersect c. To do this we suppose the contrary, namely that there is a pair of points $z_i, z_j \in \{z_1, z_2, \ldots, z_k\}$ such that ℓ_{ij} intersects c. Suppose this intersection occurs on the line ℓ between y_q and y_{q+1}.

First consider the case when either z_i or z_j equals z_1 in which case $||z_i - z_j|| \leq r$. To prove that ℓ_{ij} does not intersect ℓ, it is sufficient to prove that for any $s \in \{2, 3, \ldots, k\}$, ℓ_{1s} and ℓ do not intersect. Suppose that for some such s such an intersection exists. Since $||y_q - y_{q+1}|| \leq r$ and $||z_1 - z_s|| \leq r$, Lemma 4 applies with $a = z_1$, $b = z_s$, $c = y_q$, and $d = y_{q+1}$. It follows from (41) that either z_1 or z_s is within r units of either y_q or y_{q+1}. This means that either z_1 or z_s is linked to $\lceil y_1, y_2, \ldots, y_m \rceil$, which is a contradiction. Therefore for any $s \in \{2, 3, \ldots, k\}$, ℓ_{1s} and ℓ do not intersect. In particular, ℓ_{ij} does not intersect ℓ if either z_i or z_j equals z_1.

Now suppose that neither z_i nor z_j equals z_1. From what has just been shown we can conclude that ℓ does not intersect either ℓ_{1i} or ℓ_{1j}. Since ℓ is assumed to intersect ℓ_{ij}, either y_q or y_{q+1} must be in the convex hull $\langle z_1, z_i, z_j\rangle$. But $||z_1 - z_i|| \leq r$ and $||z_1 - z_j|| \leq r$; thus from Lemma 5 we can conclude that either y_q or y_{q+1} must be within r units of z_1. But this is a contradiction of the hypothesis that z_1 is not linked to $\lceil y_1, y_2, \ldots, y_m \rceil$. Hence ℓ_{ij} and ℓ do not intersect. □

LEMMA 7. *For any four points a, b, c, d in $\mathbb{R}^2$, the set $\langle a, b, d\rangle \cup \langle a, c, d\rangle \cup \langle b, c, d\rangle$ is convex.*

Proof of Lemma 7. For the case when $d \in \langle a,b,c\rangle$, the union $\langle a,b,d\rangle \cup \langle a,c,d\rangle \cup \langle b,c,d\rangle$ equals $\langle a,b,c\rangle$ which is convex. Suppose therefore that $d \notin \langle a,b,c\rangle$. Then the line through at least one of the bounding edges of $\langle a,b,c\rangle$—say the edge from b to c—must separate d and $\langle a,b,c\rangle$. We claim that the four- (or less) corner polygon $\mathbb{P} = \langle a,b,d\rangle \cup \langle a,c,d\rangle$ is convex. This certainly must be true if either $c \in \langle a,b,d\rangle$ or $b \in \langle a,c,d\rangle$, since in either case $\mathbb{P}$ would be a polygon with at most three corners. On the other hand, if neither of these cases holds, then the line segment from b to c must lie totally within $\mathbb{P}$. Thus in this case the line segment between any pair of corners of $\mathbb{P}$ must lie completely within $\mathbb{P}$. Since any four- (or less) corner polygon in the plane with this property is necessarily convex, $\mathbb{P}$ is convex. Finally we note that $\langle b,c,d\rangle \subset \mathbb{P}$ because b, c, and d are in $\mathbb{P}$. Thus $\langle a,b,d\rangle \cup \langle a,c,d\rangle \cup \langle b,c,d\rangle = \mathbb{P}$ so $\langle a,b,d\rangle \cup \langle a,c,d\rangle \cup \langle b,c,d\rangle$ is convex as claimed. ∎

LEMMA 8. *Let $\kappa : [0,1] \to \mathbb{R}^2$ be any continuous closed curve, and let a and b be any two distinct points on κ. Let κ_1 be the closed curve consisting of the segment of κ from a to b together with the straight line segment from b to a. Let κ_2 be the closed curve consisting of the segment of κ from b to a together with the straight line segment from a to b. Then for any point $y \in \mathbb{R}^2$ which is not on κ or on the line from a to b,*

$$\mathrm{wn}(y,\kappa) = \mathrm{wn}(y,\kappa_1) + \mathrm{wn}(y,\kappa_2). \tag{42}$$

Proof. Write ϕ_1 and ϕ_2 for the segments of κ from a to b and b to a, respectively, and let ℓ_1 and ℓ_2 denote the line segments from a to b and b to a, respectively. Then

$$\begin{aligned}\mathrm{wn}(y,\kappa_1) + \mathrm{wn}(y,\kappa_2) &= \frac{1}{2\pi j}\left\{\oint_{\tilde{\kappa_1}} \frac{dz}{z-\tilde{y}} + \oint_{\tilde{\kappa_2}} \frac{dz}{z-\tilde{y}}\right\} \\ &= \frac{1}{2\pi j}\left\{\int_{\tilde{\phi_1}} \frac{dz}{z-\tilde{y}} + \int_{\tilde{\ell_1}} \frac{dz}{z-\tilde{y}} + \int_{\tilde{\phi_2}} \frac{dz}{z-\tilde{y}} + \int_{\tilde{\ell_2}} \frac{dz}{z-\tilde{y}} + \right\}.\end{aligned}$$

But

$$\int_{\tilde{\ell_1}} \frac{dz}{z-\tilde{y}} + \int_{\tilde{\ell_2}} \frac{dz}{z-\tilde{y}} = 0,$$

so

$$\mathrm{wn}(y,\kappa_1) + \mathrm{wn}(y,\kappa_2) = \frac{1}{2\pi j}\left\{\int_{\tilde{\phi_1}} \frac{dz}{z-\tilde{y}} + \int_{\tilde{\phi_2}} \frac{dz}{z-\tilde{y}}\right\} = \frac{1}{2\pi j}\oint_{\tilde{\kappa}} \frac{dz}{z-\tilde{y}}$$

from which (42) follows. ∎

LEMMA 9. *Let $\lceil y_1, y_2, \ldots, y_m\rceil$ and $\lceil \bar{y}_1, y_2, \ldots, y_m\rceil$ be cycles such that $||y_1 - \bar{y}_1|| \leq r$. If z is an interior point of $\lceil y_1, y_2, \ldots, y_m\rceil$, then either $||z - \bar{y}_1|| \leq r$ or z is an interior point of $\lceil \bar{y}_1, y_2, \ldots, y_m\rceil$ or both.*

Proof of Lemma 9. Suppose z is not an interior point of $\lceil \bar{y}_1, y_2, \ldots, y_m\rceil$. It is enough to prove that $||z - \bar{y}_1|| \leq r$. Towards this end let c, $\bar{c}$, c_1, c_2, and $\bar{c}_2$ denote the piecewise linear closed curves determined by the ordered point sets $\{y_1, y_2, \ldots, y_m\}$, $\{\bar{y}_1, y_2, \ldots, y_m\}$, $\{y_2, y_3, \ldots, y_m\}$, $\{y_1, y_2, y_m\}$, and $\{\bar{y}_1, y_2, y_m\}$, respectively.

Suppose first that z is inside or on c_2; that is, $z \in \langle y_1, y_2, y_m\rangle$. By Lemma 7, $\langle y_1, y_2, \bar{y}_1\rangle \cup \langle y_1, y_m, \bar{y}_1\rangle \cup \langle y_2, y_m, \bar{y}_1\rangle$ is a convex set. Thus $\langle y_1, y_2, y_m\rangle \subset \langle y_1, y_2, \bar{y}_1\rangle \cup \langle y_1, y_m, \bar{y}_1\rangle \cup \langle y_2, y_m, \bar{y}_1\rangle$ because y_1, y_2, and y_m are all in the union. Therefore $z \in \langle y_1, y_2, \bar{y}_1\rangle \cup \langle y_1, y_m, \bar{y}_1\rangle \cup \langle y_2, y_m, \bar{y}_1\rangle$. We have assumed $||y_1 - \bar{y}_1|| \leq r$. Moreover, $||\bar{y}_1 - y_2|| \leq r$ and $||\bar{y}_1 - y_m|| \leq r$ because $\lceil \bar{y}_1, y_2, \ldots, y_m\rceil$ is assumed to be a cycle.

Thus no matter whether z is in $\langle y_1, y_2, \bar{y}_1\rangle$, $\langle y_1, y_m, \bar{y}_1\rangle$, or $\langle y_2, y_m, \bar{y}_1\rangle$, Lemma 5 applies, and it can be concluded that $||z - \bar{y}_1|| \leq r$ as claimed.

Consider next the case when z is outside of c_2; in other words, $\text{wn}(z, c_2) = 0$. Since z is not on c_2, it is clearly not on the line segment from y_2 to y_m. Therefore Lemma 8 can be applied to c, c_1, and c_2 providing that $\text{wn}(z, c) = \text{wn}(z, c_1) + \text{wn}(z, c_2)$. But by assumption z is an interior point of $\lceil y_1, y_2, \ldots, y_m\rceil$, so $\text{wn}(z, c) \neq 0$. Therefore

$$\text{wn}(z, c_1) \neq 0. \tag{43}$$

By assumption, z is not an interior point of $\lceil \bar{y}_1, y_2, \ldots, y_m\rceil$. Thus z must be either on $\bar{c}$ or outside of $\bar{c}$. If z is on $\bar{c}$, then it is linked to $\{\bar{y}_1, y_2, \ldots, y_m\}$. On the other hand, if z is outside of $\bar{c}$, then $\text{wn}(z, \bar{c}) = 0$. Moreover, in this case $\text{wn}(z, \bar{c}) = \text{wn}(z, c_1) + \text{wn}(z, \bar{c}_2)$ because of Lemma 8. From this and (43), it follows that $\text{wn}(z, \bar{c}_2) \neq 0$. Thus z is inside of $\bar{c}_2$. But $\lceil \bar{y}_1, y_2, \ldots, y_m\rceil$ is a cycle, so $||\bar{y}_1 - y_2|| \leq r$ and $||y_m - \bar{y}_1|| \leq r$. From this and Lemma 5, it follows that $||z - \bar{y}_1|| \leq r$ as claimed. □

Proof of Proposition 6. Consider the sequence of cycles $\lceil y_1, y_2, \ldots, y_m\rceil$, $\lceil \bar{y}_1, y_2, \ldots, y_m\rceil$, $\lceil \bar{y}_1, \bar{y}_2, \ldots, y_m\rceil, \ldots, \lceil \bar{y}_1, \bar{y}_2, \ldots, \bar{y}_m\rceil$, each being a successor of the one before it. Let z be any point in $\langle z_1, z_2, \ldots, z_k\rangle$. By Lemma 6, z is an interior point of $\lceil y_1, y_2, \ldots, y_m\rceil$. Therefore by Lemma 9, either $||z - \bar{y}_1|| \leq r$ or z is an interior point of $\lceil \bar{y}_1, y_2, \ldots, y_m\rceil$. If the former is true, then z is clearly linked to $\lceil \bar{y}_1, \bar{y}_2, \ldots, \bar{y}_m\rceil$. On the other hand, if the latter is true, Lemma 9 can again be used, this time to reach the conclusion that either $||z - \bar{y}_2|| \leq r$ or z is an interior point of $\lceil \bar{y}_1, \bar{y}_2, \ldots, y_m\rceil$ which is not linked to $\lceil \bar{y}_1, \bar{y}_2, \ldots, y_m\rceil$. Continuing this process a finite number of times completes the proof. □

The proof of Proposition 7 is a simple consequence of the following lemmas.

LEMMA 10. *Let $\mathcal{S}$ be a closed, bounded convex set in $\mathbb{R}^m$. If x and y are vectors in $\mathcal{S}$ for which*

$$||x - y|| = \text{diameter}(\mathcal{S}), \tag{44}$$

then x and y are corners of $\mathcal{S}$.

Proof of Lemma 10. Suppose (44) holds. It is enough to show that y is a corner of $\mathcal{S}$. Suppose that it is not. Then there must be *distinct* vectors x_1 and x_2 in $\mathcal{S}$ and a number $\alpha \in (0, 1)$ for which $y = \alpha x_1 + (1 - \alpha)x_2$. In view of (44) and the definition of $\text{dia}(\mathcal{S})$, the function $f(\lambda) \triangleq ||x - \lambda x_1 - (1 - \lambda)x_2||^2$ must attain its maximum on $[0, 1]$ at the interior point $\lambda = \alpha$. But this is impossible because $f(\lambda)$ is a nonconstant, convex function of λ. Therefore, by contradiction y must be a corner of $\mathcal{S}$. □

LEMMA 11. *Let $\{x_1, x_2, \ldots, x_n\} \in \mathcal{X}$ be fixed. Then*

$$\text{dia}\{\bar{x}_1, \bar{x}_2, \ldots, \bar{x}_n\} \leq \text{dia}\{x_1, x_2, \ldots, x_n\}, \tag{45}$$

where for $i \in \{1, 2, \ldots, n\}$,

$$\bar{x}_i = x_i + u_{m_i}(x_{i_1} - x_i,\ x_{i_2} - x_i, \ldots,\ x_{i_{m_i}} - x_i). \tag{46}$$

Moreover, if $\mathbb{G}$ is connected, then either the inequality in (45) *is strict or $x_1 = x_2 = \cdots = x_n$.*

Proof of Lemma 11. By definition, for $m > 0$, $u_m(\cdot)$ maps the vectors $z_i \in \mathbb{D}$, $i \in \{1, 2, \ldots, m\}$, into a point $\bar{z}$ in the convex hull $\langle 0, z_1, z_2, \ldots z_m\rangle$; moreover, $\bar{z}$ is not a corner of $\langle 0, z_1, z_2, \ldots, z_m\rangle$ unless $z_1 = z_2 = \cdots = z_m = 0$. In the present context this means that for $i \in \{1, 2, \ldots, n\}$, $x_i + u_{m_i}(\cdot)$ maps the vectors $x_{i_j} - x_i \in \mathbb{D}, j \in$

$\{1, 2, \ldots, m_i\}$, into the point $\bar{x}_i$ in the convex hull $\langle x_i, x_{i_1}, x_{i_2}, \ldots, x_{i_{m_i}}\rangle$; moreover, $\bar{x}_i$ is not a corner of $\langle x_i, x_{i_1}, x_{i_2}, \ldots, x_{i_{m_i}}\rangle$ unless $x_i = x_{i_1} = x_{i_2} = \cdots = x_{i_{m_i}}$. Since each $\langle x_i, x_{i_1}, x_{i_2}, \ldots, x_{i_{m_i}}\rangle$ is a subset of $\langle x_1, x_2, \ldots, x_n\rangle$, it must be true that

$$\langle \bar{x}_1, \bar{x}_2, \ldots \bar{x}_n\rangle \subset \langle x_1, x_2, \ldots x_n\rangle. \tag{47}$$

Moreover, $\bar{x}_i$ is not a corner of $\langle x_1, x_2, \ldots, x_n\rangle$ unless $x_i = x_{i_1} = x_{i_2} = \cdots = x_{i_{m_i}}$. Inequality (45) is a direct consequence of (47).

Now suppose that $\mathbb{G}$ is connected and that the x_i are not all equal. Then for each $i \in \{1, 2, \ldots, n\}$, there is at least one $i_j \in \{i_1, i_2, \ldots, i_{m_i}\}$ for which $x_{i_j} \neq x_i$. This means that it cannot be true that $x_i = x_{i_1} = x_{i_2} = \cdots = x_{i_{m_i}}$ for any value of $i \in \{1, 2, \ldots, n\}$. Therefore $\bar{x}_i,\ i \in \{1, 2, \ldots, n\}$, is not a corner of $\langle x_1, x_2, \ldots, x_n\rangle$. From this and Lemma 10 it follows that the inequality in (45) is strict. □

It is worth noting that (47) establishes that the sequence of convex hulls of agent positions generated on successive steps must form a descending chain of convex sets. As a consequence, one can conclude at once that the sequence has a limit set $\mathcal{H}$ into which all agents must eventually move and remain. While this fact does not depend upon the $u_m(\cdot)$ being continuous, the fact that $\mathcal{H}$ is actually a single point does.

Proof of Proposition 7. Note that (11) implies that

$$\operatorname{dia}\{x_1, x_2, \ldots, x_n\} = \operatorname{dia}\{e_1, e_2, \ldots, e_{n-1}, 0\}$$

because the diameter of a convex set is invariant under translation. Therefore

$$V(e) = \operatorname{dia}\{x_1, x_2, \ldots, x_n\}. \tag{48}$$

Next observe that Lemma 11 says that

$$\operatorname{dia}\{x_1 + f_1(e), x_2 + f_2(e), \ldots, x_n + f_n(e)\} \leq \operatorname{dia}\{x_1, x_2, \ldots, x_n\} \tag{49}$$

with the inequality being strict if $\mathbb{G}$ is connected. But

$$\begin{aligned}
&\operatorname{dia}\{x_1 + f_1(e), x_2 + f_2(e), \ldots, x_n + f_n(e)\} \\
&\quad = \operatorname{dia}\{e_1 + f_1(e) - f_n(e), e_2 + f_2(e) - f_n(e), \ldots, x_{n-1} + f_{n-1}(e) - f_n(e), 0\} \\
&\quad = V(e + f(e)).
\end{aligned}$$

From this, (49), and (48) it is clear that

$$V(e + f(e)) - V(e)$$

is a negative semidefinite function and actually a negative definite function if $\mathbb{G}$ is connected. □

THE MULTI-AGENT RENDEZVOUS PROBLEM. PART 2: THE ASYNCHRONOUS CASE*

J. LIN†, A. S. MORSE‡, AND B. D. O. ANDERSON§

Abstract. This paper is concerned with the collective behavior of a group of $n > 1$ mobile autonomous agents, labelled 1 through n, which can all move in the plane. Each agent is able to continuously track the positions of all other agents currently within its "sensing region," where by an agent's *sensing region* we mean a closed disk of positive radius r centered at the agent's current position. The *multi-agent rendezvous problem* is to devise "local" control strategies, one for each agent, which without any active communication between agents cause all members of the group to eventually rendezvous at a single unspecified location. This paper describes a family of unsynchronized strategies for solving the problem. Correctness is established appealing to the concept of "analytic synchronization."

Key words. cooperative control, distributed control, multi-agent systems, asynchronous systems

1. Introduction.

This paper is concerned with the collective behavior of a group of $n > 1$ mobile autonomous agents, labelled 1 through n, which can all move in the plane. Each agent is able to continuously track the positions of all other agents currently within its "sensing region," where by an agent's *sensing region* we mean a closed disk of positive radius r centered at the agent's current position. The *multi-agent rendezvous problem* is to devise "local" control strategies, one for each agent, which without any active communication between agents cause all members of the group to eventually rendezvous at a single unspecified location.

The rendezvous problem, which is also sometimes called a "gathering problem," has been studied before assuming that all agents possess either unlimited visibility (e.g., $r = \infty$) [4] or a common sense of direction [9, 5] or both; see [5] for additional references. The problem has also been addressed before without making either of these assumptions [1, 8]. This paper also treats the case in which individual agents have limited visibility and distinct frames of reference. What distinguishes this work from that in [1, 8] is that individual agents clocks are taken to be unsynchronized. These three features, namely limited sensing, no common frame of reference or sense of direction, and no common clock, are of obvious practical importance but have apparently not been dealt with before at the same time as components of one multi-

agent rendezvous problem.

As in [1, 8], we consider distributed strategies which guide each agent toward rendezvous by performing a sequence of "stop-and-go" maneuvers. A *stop-and-go maneuver* takes place within a time interval consisting of two consecutive subintervals. The first, called a *sensing period*, is an interval of fixed length during which the agent is stationary. The second, called a *maneuvering period*, is an interval of variable length during which the agent moves from its current position to its next "way-point" and again comes to rest. Successive way-points for each agent are chosen to be within r_M units of each other, where r_M is a prespecified positive distance no larger than r. It is assumed that there has been chosen for each agent i a positive number τ_{M_i}, called a *maneuver time*, which is large enough so that the required maneuver for agent i from any one way-point to the next can be accomplished in at most τ_{M_i} seconds. Since our interest here is exclusively with devising *high level* strategies which dictate when and where agents are to move, we will use point models for agents and shall not deal with how maneuvers are actually carried out or with how vehicle collisions are to be avoided.

In the synchronous case treated in [1, 8], the kth maneuvering period of each agent is synchronized to begin at the same time $\bar{t}_k$ as the kth maneuvering period of every other agent. Agent i's registered neighbors at the beginning of its kth maneuvering period are taken to be all those other agents positioned within agent i's sensing region at the beginning of the period. Because of synchronization, this notion of a registered neighbor induces a *symmetric* relation on the agent group in that agent j is a registered neighbor of agent i at the beginning of maneuvering period k just in case agent i is a registered neighbor of agent j at the same time. As a result, it is possible to characterize neighbor relationships at time $\bar{t}_k$ with a simple graph whose vertices represent agents and whose edges represent existing neighbor relationships [8]. Although the neighbor relation is symmetric, it is clearly not transitive. On the other hand, if agent i is at the same position as neighbor j at time $\bar{t}_k$, then any registered neighbor of agent j at time $\bar{t}_k$ certainly must be a registered neighbor of agent i at the same time. It is precisely because of this *weak transitivity* property that one can infer a *global* condition of the entire synchronized agent group from a *local* condition of one agent and its neighbors. In particular, if the graph characterizing neighbor relationships at time $\bar{t}_k$ is connected, and any one agent is at the same position as all of its neighbors, then the weak transitivity property guarantees at once that all n agents have rendezvoused at time $\bar{t}_k$.

Our aim in this paper is to relax the synchronization requirement. In particular we will not require synchronization of the start times of the maneuvering periods of different agents. To accomplish this it is necessary to modify somewhat what is meant by a registered neighbor of agent i at time $\bar{t}_{ik}$ where for the asynchronous case under consideration, $\bar{t}_{ik}$ denotes the time at which agent i's kth maneuvering period begins. Our definition is guided by considerations discussed above for the synchronous case. For example, the new definition is crafted to retain versions of the symmetry and weak transitivity properties of the registered neighbor relation inherent in the synchronous case. Doing this is challenging, because unlike the synchronous case, the times each agent registers its neighbors and its neighbors' positions are not synchronized with the times its neighbors do the same thing.

Exactly the same way-point update rules considered in the synchronous case [8] are adopted for the asynchronous case. Thus the only functional differences between the two cases are the definitions of registered neighbors and registered neighbor po-

sitions. Of course in the asynchronous case, way-point updates are computed asynchronously, whereas in the synchronous case they are not.

Not surprisingly, the analysis of the asynchronous version of the problem is considerably more challenging than that of the synchronous version. For example, while it is more or less obvious in the synchronous case that the proposed way-point update rules causes all agents to retain their neighbors as the system evolves [8], proving that this is also true in the asynchronous case involves a number of steps.

Just as in the synchronous case, it is possible to characterize neighbor relationships with a graph. This is done in section 3 by first merging together into a single ordered time set the distinct "event times" $\bar{t}_{ik}$, $i \in \{1, 2, \ldots, n\}$, $k \geq 1$, generated by all n agents. The elements of this set are then relabelled as $t_1, t_2, \ldots$ in such a way so that $t_j < t_{j+1}$, $j \in \{1, 2, \ldots\}$. With this notation, agent i's registered neighbors at its kth event time $\bar{t}_{ik}$ are its registered neighbors at time $t_{P_i(k)}$, where $P_i(k)$ denotes that value of p for which $t_p = \bar{t}_{ik}$. For each $i \in \{1, 2, \ldots, n\}$, the domain of definition of agent i's registered neighbors is then extended from the set $\{t_{P_i(k)} : k \geq 1\}$ to the set $\{t_p : p \geq P_i(1)\}$ by stipulating that for values of t_p which are between two successive event times of agent i, say between $\bar{t}_{ik}$ and $\bar{t}_{i(k+1)}$, agent i's registered neighbors are the same as its registered neighbors at time $\bar{t}_{ik}$. This means that registered neighbors of each agent are defined at each time $t_p \geq t_{\bar{p}}$, where $\bar{p} \triangleq \max\{P_1(1), P_2(1), \ldots P_n(1)\}$. Because of this, it is possible to describe neighbor relationships with a directed graph with vertex set $\{1, 2, \ldots, n\}$ and directed edge set defined so that (i, j) is a directed edge from vertex i to vertex j just in case agent j is a registered neighbor of agent i at event time t_s. The main result of this paper (Corollary 1) is that if this graph is ever strongly connected, then rendezvous of all n agents will eventually occur.

Establishing the correctness of Corollary 1 requires the analysis of the asymptotic behavior of the *asynchronous* process which describes the n-agent system. Despite the apparent complexity of this process, it is possible to capture its salient features using a suitably defined *synchronous* discrete-time, hybrid dynamical system $\mathbb{S}$. We call the sequence of steps involved in defining $\mathbb{S}$ *analytic synchronization*. Analytic synchronization is applicable to any finite family of continuous or discrete-time dynamical processes $\{\mathbb{P}_1, \mathbb{P}_2, \ldots, \mathbb{P}_n\}$ under the following conditions. First, each process $\mathbb{P}_i$ must be a dynamical system whose inputs consist of functions of the states of the other processes as well as signals which are exogenous to the entire family. Second, each process $\mathbb{P}_i$ must have associated with it an ordered sequence of event times $\{t_{i1}, t_{i2}, \ldots\}$ defined in such a way so that the state of $\mathbb{P}_i$ at event time $t_{i(k_i+1)}$ is uniquely determined by values of the exogenous signals and states of the $\mathbb{P}_j$, $j \in \{1, 2, \ldots, n\}$, at event times t_{jk_j} which occur prior to $t_{i(k_i+1)}$ but in the finite past. Event time sequences for different processes need not be synchronized. Analytic synchronization is a procedure for creating a single synchronous process for purposes of analysis which captures the salient features of the original n asynchronously functioning processes. As a first step, all n event time sequences are merged into a single ordered sequence of even times $\mathcal{T}$. This clever idea has been used before in [2] to study the convergence of totally asynchronous iterative algorithms. Second, the "synchronized" state of $\mathbb{P}_i$ is then defined to be the original of $\mathbb{P}_i$ at $\mathbb{P}_i$'s event times $\{t_{i1}, t_{i2}, \ldots\}$ plus possibly some additional state variables; at values of $t \in \mathcal{T}$ between event times t_{ik_i} and $t_{i(k_i+1)}$, the synchronized state of $\mathbb{P}_i$ is taken to be the same as the value of its original state at time t_{ik}. Although it is not always possible to carry out all of these steps, in this case it is. What ultimately results is a synchronous dynamical system evolving on $\mathcal{T}$ with a state composed of the synchronized states of the n individual processes under con-

sideration. The definition of $\mathbb{S}$ in section 4.1 illustrates the analytic synchronization procedure.

2. The asynchronous agent system. The strategy analyzed in [1, 8] cannot be regarded as truly distributed because each agent's decisions must be synchronized to a common clock shared by all other agents in the group. In what follows we redefine the strategies so that a common clock is not required. To do this it will be necessary to modify somewhat what is meant by a registered neighbor and by a registered neighbor's position.

For each agent i, the real time axis can be partitioned into a sequence of time intervals $[0, t_{i1}), [t_{i1}, t_{i2}), \ldots, [t_{i(k-1)}, t_{ik}), \ldots$, each of length at most $\tau_D + \tau_{M_i}$, where τ_D is a number greater than τ_{M_i} called a *dwell time*. Each interval $[t_{i(k-1)}, t_{ik})$ consists of a *sensing period* $[t_{i(k-1)}, \bar{t}_{ik})$ of fixed length τ_D during which agent i is stationary, followed by a maneuvering period $[\bar{t}_{ik}, t_{ik})$ of length at most τ_{M_i} during which agent i moves from its current position to its next way-point. Although all agents use the same dwell time, they operate asynchronously in the sense that the time sequences $t_{i1}, t_{i2}, \ldots$, $i \in \{1, 2, \ldots, n\}$, are uncorrelated. Thus each agent's strategy can be implemented independent of the rest, without the need for a common clock.

2.1. Registered neighbors. Because of the asynchronous nature of the control strategies under consideration, care must be exercised in defining what is meant by a registered neighbor if one is to end up with something similar to the symmetry property of the neighbor relationship defined in the synchronous case. For the asynchronous case, agent i's *registered neighbors* at time $\bar{t}_{ik}$ (i.e., at the beginning of its kth maneuvering period $[\bar{t}_{ik}, t_{ik})$) are taken to be those agents which are fixed at one position within agent i's sensing region for at least $\tau_S > 0$ seconds during agent i's kth sensing period $\mathcal{S}_i(k) \triangleq [t_{i(k-1)}, \bar{t}_{ik})$. Here τ_S is a positive number called a *sensing time*. For reasons to be made clear below, we shall require τ_S to satisfy

$$\tau_S \leq \frac{1}{2}(\tau_D - \tau_{M_i}) \qquad \forall i \in \{1, 2, \ldots, n\}. \tag{1}$$

Note that this implies that $\tau_D > \tau_{M_i}$, $i \in \{1, 2, \ldots, n\}$, which means that the n agents spend more time between successive way-points sensing their neighbors' positions than they do maneuvering between successive way-points. For any agent j, there may be more than one distinct interval of length at least τ_S within $\mathcal{S}_i(k)$ during which agent j is stationary. Let t^* denote the end time of the last of these. For purposes of calculation, agent i takes the *registered position* of agent j at the beginning of its kth maneuvering period to be the actual position of agent j at *registration time* t^*. To attain a symmetry-like property for the asynchronous case, it is necessary to make sure that the *registration interval* $[t^* - \tau_S,\ t^*)$ lies within one of agent j's sensing periods. One way to guarantee this is to require each agent to keep moving during each of its maneuvering periods except possibly for brief periods which are each shorter than τ_S. Another way is to equip each agent with a signaling device (such as a light in the case of visual sensing) which is on just in case the agent is in one of its sensing periods. In what follows we will assume that registration of each agent j during one of agent i's sensing periods always occurs at the end of a registration interval $[t^* - \tau_S,\ t^*)$ which also lies within one of agent j's sensing periods. Note that this and the requirement that agent j be stationary during its sensing periods together imply that agent j's registered position $x_j(t^*)$ is equal to $x_j(\bar{t}_{jk^*})$, where k^* is the sensing/maneuvering interval of agent j during which registration takes place.

2.1.1. Neighbor characterization. Prompted by the preceding, let us agree to say that for each $i, j \in \{1, 2, \dots, n\}$, agent j's *pth* sensing period $\mathcal{S}_j(p)$ *strongly overlaps* agent i's kth sensing period $\mathcal{S}_i(k)$ if the overlap $\mathcal{S}_j(p) \cap \mathcal{S}_i(k)$ is a nonempty interval of length at least τ_S seconds. In what follows we write $\mathcal{S}_j(p) \cap \mathcal{S}_i(k) \succ \tau_S$ whenever $\mathcal{S}_i(k)$ and $\mathcal{S}_j(p)$ strongly overlap. Let us note that because all sensing periods of all agents are τ_D seconds long, the largest number of sensing periods of any one agent which a given sensing period of agent i can overlap is two. On the other hand, each sensing period of agent i must strongly overlap at least one sensing period of every other agent. To understand why this is so, note first that the maximal possible amount of time between two successive sensing periods of agent j is τ_{M_j}, but τ_{M_j} is bounded above by $\tau_D - 2\tau_S$ because of (1). Thus the maximal possible amount of time between two successive sensing periods of agent j is no greater than $\tau_D - 2\tau_S$. Given this and the fact that all sensing periods are τ_D seconds long, it follows that each sensing period of agent i must strongly overlap at least one sensing period of each agent j.

It is possible to be more explicit about which sensing periods of agent j overlap $\mathcal{S}_i(k)$. For each $i, j \in \{1, 2, \dots, n\}$ and each $k \geq 1$, let $\lceil \bar{t}_{ik} \rceil_j$ denote the smallest integer q such that $\bar{t}_{jq} \geq \bar{t}_{ik}$. In other words, $\lceil \bar{t}_{ik} \rceil_j$ is the unique integer for which $\bar{t}_{ik} \in (\bar{t}_{j(q-1)}, \bar{t}_{jq}]$. Set $q = \lceil \bar{t}_{ik} \rceil_j$. In view of the definition of $\lceil \cdot \rceil_j$ and the preceding discussion it is clear that the only sensing periods of agent j which $\mathcal{S}_i(k)$ can overlap are $\mathcal{S}_j(q-1)$ and $\mathcal{S}_j(q)$; moreover, $\mathcal{S}_i(k)$ must strongly overlap one of these. There are three possible situations which might occur. In the first, shown in Figure 1(a), the only sensing period of agent j which overlaps $\mathcal{S}_i(k)$ is $\mathcal{S}_j(q-1)$; in this case the length of the overlap is $\tau_D - (\bar{t}_{ik} - \bar{t}_{j(q-1)})$, and this length will always be greater than or equal to τ_S. Therefore in this situation, $\mathcal{S}_i(k)$ and $\mathcal{S}_j(q-1)$ strongly overlap. For the second situation, shown in Figure 1(b), the only sensing period of agent j which overlaps $\mathcal{S}_i(k)$ is $\mathcal{S}_j(q)$; in this case the length of the overlap is $\tau_D - (\bar{t}_{jq} - \bar{t}_{ik})$, and this length will also always be greater than or equal to τ_S. Therefore in this situation $\mathcal{S}_i(k)$ and $\mathcal{S}_j(q)$ strongly overlap. The only other possible situation that can occur, which is shown in Figure 1(c), is when $\mathcal{S}_i(k)$ is overlapped by both $\mathcal{S}_j(q-1)$ and $\mathcal{S}_j(q)$. In this case the lengths of the first and second overlapping intervals are $\tau_D - (\bar{t}_{j(q-1)} - \bar{t}_{ik})$ and $\tau_D - (\bar{t}_{ik} - \bar{t}_{jq})$, respectively, and at least one of these lengths will always be greater than or equal to τ_S. Thus in this situation, $\mathcal{S}_i(k)$ strongly overlaps $\mathcal{S}_j(q-1)$ or $\mathcal{S}_j(q)$ or both. We summarize.

LEMMA 1 (overlaps). *Let i and j be distinct integers in $\{1, 2, \dots, n\}$. Let $\bar{t}_{ik}$ be fixed and define $q = \lceil \bar{t}_{ik} \rceil_j$. The only possible sensing periods of agent j which $\mathcal{S}_i(k)$ can overlap are $\mathcal{S}_j(q-1)$ and $\mathcal{S}_j(q)$; moreover, $\mathcal{S}_i(k)$ must strongly overlap at least one of these. In addition,*

1. *$\mathcal{S}_i(k) \cap \mathcal{S}_j(q) \succ \tau_S$ if and only if $\bar{t}_{jq} - \bar{t}_{ik} \leq \tau_D - \tau_S$;*
2. *$\mathcal{S}_i(k) \cap \mathcal{S}_j(q-1) \succ \tau_S$ if and only if $\bar{t}_{ik} - \bar{t}_{j(q-1)} \leq \tau_D - \tau_S$.*

Note that for agent j to be a registered neighbor of agent i at the beginning of agent i's kth maneuvering period, it is necessary and sufficient that agent j be "within range of agent i" (i.e., within agent i's sensing region) during a sensing period of agent j which strongly overlaps $\mathcal{S}_i(k)$. Consider again Figure 1 where $q = \lceil \bar{t}_{ik} \rceil_j$. In the situation depicted in Figure 1(a), agent j will be a registered neighbor of agent i just in case $||x_i(\bar{t}_{ik}) - x_j(\bar{t}_{j(q-1)})|| \leq r$; moreover, if this condition holds, $x_j(\bar{t}_{j(q-1)})$ will be the registered position of agent j. Similarly in the situation shown in Figure 1(b), agent j will be a registered neighbor of agent i just in case $||x_j(\bar{t}_{jq}) - x_i(\bar{t}_{ik})|| \leq r$; moreover, if this condition holds, $x_j(\bar{t}_{jq})$ will be the registered position of agent j.

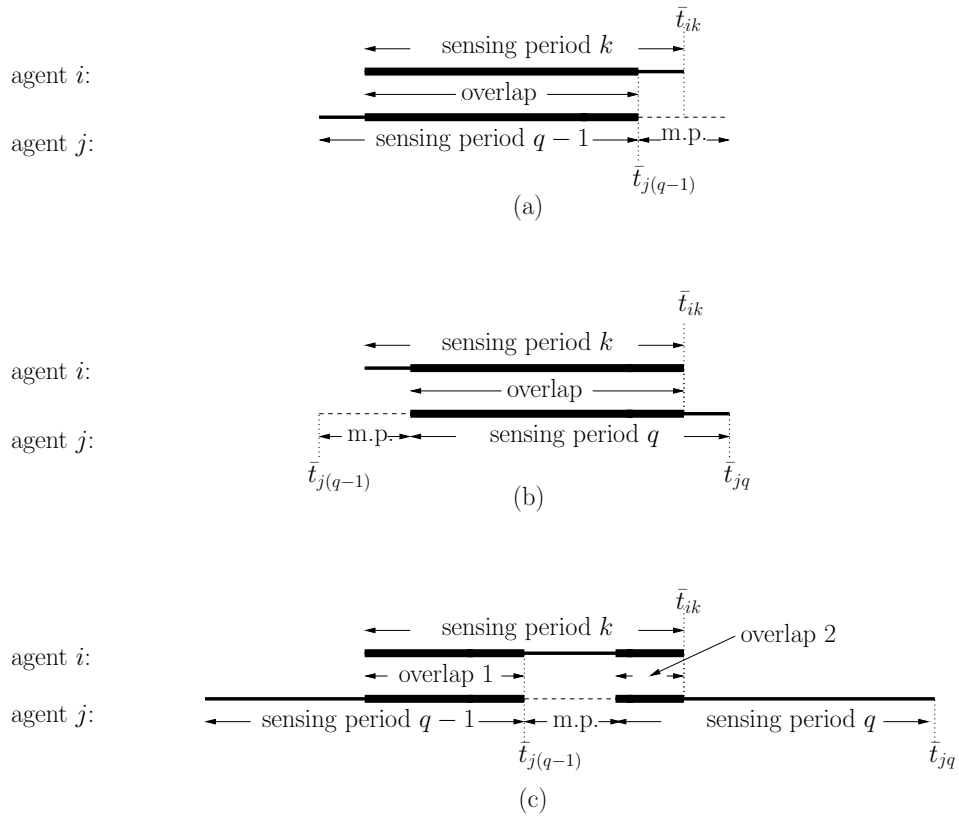

FIG. 1. *Sensing period overlaps.*

The remaining situation shown in Figure 1(c) is slightly more complicated. If, on the one hand, the length of the second overlap is greater than or equal to τ_S and $||x_j(\bar{t}_{jq}) - x_i(\bar{t}_{ik})|| \leq r$, then agent j will be a registered neighbor of agent i with registered position $x_j(\bar{t}_{jq})$. If either of these two conditions fails to hold, if the length of the first overlap is greater than or equal to τ_S, and if $||x_i(\bar{t}_{ik}) - x_j(\bar{t}_{j(q-1)})|| \leq r$, then agent j will be a registered neighbor of agent i, and $x_j(\bar{t}_{j(q-1)})$ will be its registered position. The following proposition summarizes these observations.

PROPOSITION 1 (neighbor characterization). *Let $i, j \in \{1, 2, \ldots, n\}$ and $\bar{t}_{ik}$ be fixed and let $q = \lceil \bar{t}_{ik} \rceil_j$. Then agent j is a registered neighbor of agent i at the beginning of agent i's kth maneuvering period if and only if at least one of the following is true.*

(A) $\mathcal{S}_i(k) \cap \mathcal{S}_j(q) \succ \tau_S$ *and* $||x_j(\bar{t}_{jq}) - x_i(\bar{t}_{ik})|| \leq r$.

(B) $\mathcal{S}_i(k) \cap \mathcal{S}_j(q-1) \succ \tau_S$ *and* $||x_i(\bar{t}_{ik}) - x_j(\bar{t}_{j(q-1)})|| \leq r$.

Moreover, if (A) *is true, then $x_j(\bar{t}_{jq})$ is the registered position of agent j at the beginning of agent i's kth maneuvering period, and if* (A) *is not true while* (B) *is, then $x_j(\bar{t}_{j(q-1)})$ is the registered position of agent j at the beginning of agent i's kth maneuvering period.*

2.1.2. Neighbor relationship symmetry. The definition of a registered neighbor determines a relationship between agents similar to the symmetric relationship determined by the definition of a registered neighbor in the synchronous case [8]. Suppose that agent j is a registered neighbor of agent i at the beginning of agent i's kth maneuvering period. In view of Proposition 1, either condition (A) or condition

(B) must hold. Suppose first that condition (A) is true. Then $\mathcal{S}_i(k)$ strongly overlaps $\mathcal{S}_j(q)$, and agent i is in range of agent j during the overlap. There are two cases to consider. First, it is possible that $\mathcal{S}_i(k+1)$ also strongly overlaps $\mathcal{S}_j(q)$ for at least τ_S time units and agent i is in range of agent j during this overlap; in this case agent i would be a registered neighbor of agent j at time $\bar{t}_{jq}$, and $x_i(\bar{t}_{i(k+1)})$ would be its registered position. Second, it is possible either that $\mathcal{S}_i(k+1)$ does not strongly overlap $\mathcal{S}_j(q)$ or that agent i is not in range of agent j during this overlap; in this case agent i would be a registered neighbor of agent j at time $\bar{t}_{jq}$, and $x_i(\bar{t}_{ik})$ would be its registered position. Thus in summary, if condition A is true, then agent i will be a registered neighbor of agent j at time $\bar{t}_{jq}$ with registered position which could be either $x_i(\bar{t}_{ik})$ or $x_i(\bar{t}_{i(k+1)})$.

Suppose next that condition (A) does not hold. In view of Proposition 1, condition (B) must hold. In other words, $\mathcal{S}_i(k)$ must strongly overlap $\mathcal{S}_j(q-1)$, and agent i must be in range of agent j during this overlap. In view of Lemma 1, this must be the last sensing period of agent i with these properties because we have assumed that condition (A) does not hold. Therefore agent i must be a registered neighbor of agent j at time $\bar{t}_{j(q-1)}$, and $x_i(\bar{t}_{ik})$ must be its registered position. We summarize.

PROPOSITION 2 (neighbor relationship symmetry). *Suppose that agent j is a registered neighbor of agent i at the beginning of agent i's kth maneuvering period. Let $q = \lceil \bar{t}_{ik} \rceil_j$. If condition* (A) *of Proposition* 1 *holds, then agent i is a registered neighbor of agent j at the beginning of agent j's qth maneuvering period with either $x_i(\bar{t}_{ik})$ or $x_i(\bar{t}_{i(k+1)})$ as its registered position. If condition* (A) *of Proposition* 1 *does not hold, then condition* (B) *must hold and agent i is a registered neighbor of agent j at the beginning of agent j's $(q-1)$st maneuvering period with registered position $x_i(\bar{t}_{ik})$.*

2.1.3. Motion constraint. In the synchronous case treated in [1], each agent's way-points are constrained to positions defined in such a way so that no agent can lose any of its neighbors as it moves from one way-point to the next. This is accomplished by adopting a clever idea proposed in [1] which we call the *pairwise motion constraint.* Neighbor retention can also be achieved in the asynchronous case by enforcing the following constraint. Agent i is said to satisfy the *motion constraints induced by its neighbors* if for each $j \in \{1, 2, \ldots, n\}$ for which $j \neq i$ and each $k \in \{1, 2, \ldots\}$ for which agent j is a registered neighbor of agent i at the beginning of maneuvering period k, the position to which agent i moves at the end of the period is within a closed disk of diameter r centered at the mean of agent i's position at the beginning of the period (i.e., at time $\bar{t}_{ik}$) and the registered position of agent j at the beginning of the period. As mentioned, in the synchronous case, satisfaction of the pairwise motion constraint by agent i and neighbor j causes each to retain the other as a neighbor. The following proposition implies that essentially the same thing is true in the asynchronous case when the induced motion constraints are satisfied by agents i and j.

PROPOSITION 3 (neighbor retention). *Suppose that agents i and j satisfy the motion constraints induced by their registered neighbors. If agent j is a registered neighbor of agent i at the beginning of agent i's kth maneuvering period, then agent j is also a registered neighbor of agent i at the beginning of agent i's $(k+1)$st maneuvering period.*

In proving Proposition 3 and several subsequent claims we will make use of the inequalities

$$\bar{t}_{j(q+p)} - \bar{t}_{jq} \geq p\tau_D, \quad p \in \{0, 1, 2, \ldots\}, \quad q \in \{1, 2, \ldots\}, \quad j \in \{1, 2, \ldots, n\}, \tag{2}$$

and

$$\bar{t}_{i(k+1)} - \bar{t}_{ik} \leq 2(\tau_D - \tau_S), \quad k \in \{1, 2, \ldots\}, \quad i \in \{1, 2, \ldots, n\}, \tag{3}$$

which are both direct consequences of the definitions of the sensing and maneuver periods and (1). To justify (2), let us first recall that for each integer $s \geq 1$, $\bar{t}_{js}$ is at the end of agent j's sth sensing period. In addition, agent j's sensing periods do not intersect and are each of length τ_D. It follows that $\bar{t}_{j(s+1)} - \bar{t}_{js} \geq \tau_D$, $s \geq 1$, and thus that (2) is true. To justify (3), note that $\bar{t}_{i(k+1)}$ can be written as $\bar{t}_{i(k+1)} = \bar{t}_{ik} + \tau_D + \tau$, where τ is the length of agent i's kth maneuvering period. Since τ is constrained to satisfy $\tau \leq \tau_{M_i}$, we can write $\bar{t}_{i(k+1)} \leq \bar{t}_{ik} + \tau_D + \tau_{M_i}$. From this and (1) it follows that $\bar{t}_{i(k+1)} \leq \bar{t}_{ik} + \tau_D + (\tau_D - 2\tau_S)$ and thus that (3) is true.

To prove Proposition 3, we will make use of the two conditions characterizing a registered neighbor in Proposition 1. Each of these conditions in turn involves both an overlap requirement and a range requirement. The next lemma provides the needed facts about the way in which two agents' sensing periods overlap. This is followed by Lemma 3 which provides the range information needed to prove Proposition 3 and subsequent claims.

LEMMA 2. *Let i and j be distinct integers in $\{1, 2, \ldots, n\}$. Let $\bar{t}_{ik}$ be fixed and define $q = \lceil \bar{t}_{ik} \rceil_j$. Then*

$$\lceil \bar{t}_{i(k+1)} \rceil_j \in \{q, q+1, q+2\}. \tag{4}$$

1. *If $\lceil \bar{t}_{i(k+1)} \rceil_j = q$, then $\mathcal{S}_i(k+1) \cap \mathcal{S}_j(q) \succ \tau_S$.*
2. *If $\lceil \bar{t}_{i(k+1)} \rceil_j = q+1$, then $\mathcal{S}_i(k+1) \cap \mathcal{S}_j(q) \succ \tau_S$ or $\mathcal{S}_i(k+1) \cap \mathcal{S}_j(q+1) \succ \tau_S$.*
3. *If $\lceil \bar{t}_{i(k+1)} \rceil_j = q+2$, then $\mathcal{S}_i(k) \cap \mathcal{S}_j(q) \succ \tau_S$ and $\mathcal{S}_i(k+1) \cap \mathcal{S}_j(q+1) \succ \tau_S$.*

Moreover, if $\lceil \bar{t}_{i(k+1)} \rceil_j \in \{q+1, q+2\}$, then $\mathcal{S}_i(k)$ and $\mathcal{S}_i(k+1)$ are the only sensing periods of agent i which can strongly overlap $\mathcal{S}_j(q)$.

Proof of Lemma 2. It will be shown first that (4) is true. Since $\bar{t}_{ik} \in (\bar{t}_{j(q-1)} - \bar{t}_{jq}]$ and $\bar{t}_{i(k+1)} > \bar{t}_{ik}$, it must be true that $\bar{t}_{i(k+1)} > \bar{t}_{j(q-1)}$. Thus $\lceil \bar{t}_{i(k+1)} \rceil \geq q$. To prove that $\lceil \bar{t}_{i(k+1)} \rceil_j \leq q+2$, we use (3) and the fact that $\bar{t}_{ik} \leq \bar{t}_{jq}$ to write $\bar{t}_{i(k+1)} \leq 2(\tau_D - \tau_S) + \bar{t}_{jq}$. In view of (2) (with $p = 1$), $2(\tau_D - \tau_S) + \bar{t}_{jq} \leq \tau_D + \bar{t}_{j(q+1)} \leq \bar{t}_{j(q+2)}$. Therefore $\bar{t}_{i(k+1)} \leq \bar{t}_{j(q+2)}$. This means that $\lceil \bar{t}_{i(k+1)} \rceil_j \leq q+2$. Thus (4) is true.

To prove assertion 1, we use (2) with i substituted for j and $p = 1$ to write $\bar{t}_{i(k+1)} \geq \bar{t}_{ik} + \tau_D$. In view of the definition of q, $\bar{t}_{ik} > \bar{t}_{j(q-1)}$. Therefore $\bar{t}_{i(k+1)} - \bar{t}_{j(q-1)} > \tau_D > \tau_D - \tau_S$. The hypothesis $\lceil \bar{t}_{i(k+1)} \rceil = q$ implies that Lemma 1 holds with $k+1$ substituted for k. Thus $\mathcal{S}_i(k+1)$ and $\mathcal{S}_j(q-1)$ cannot overlap because of the lemma's last claim. Since the lemma also states that $\mathcal{S}_i(k+1)$ must strongly overlap either $\mathcal{S}_j(q-1)$ or $\mathcal{S}_j(q)$, it must be true that $\mathcal{S}_i(k+1)$ strongly overlaps $\mathcal{S}_j(q)$. Therefore assertion 1 is true.

Assertion 2 assumes that $\lceil \bar{t}_{i(k+1)} \rceil_j = q+1$. Lemma 1 thus applies with $k+1$ and $q+1$ replacing k and q, respectively. From this it follows that the only sensing periods of agent j which can overlap $\mathcal{S}_1(k+1)$ are $\mathcal{S}_j(q)$ and $\mathcal{S}_j(q+1)$; moreover, $\mathcal{S}_1(k+1)$ must strongly overlap at least one of these. Thus assertion 2 is true.

Assertion 3 assumes that $\lceil \bar{t}_{i(k+1)} \rceil_j = q+2$. Thus $\bar{t}_{j(q+1)} < \bar{t}_{i(k+1)}$. But $\bar{t}_{jq} + \tau_D \leq \bar{t}_{j(q+1)}$ because of (2) (with $p = 1$), and $\bar{t}_{i(k+1)} \leq \bar{t}_{ik} + 2(\tau_D - \tau_S)$ because of (3). Therefore $\bar{t}_{jq} \leq \bar{t}_{ik} + \tau_D - 2\tau_S$. It follows that $\bar{t}_{jq} - \bar{t}_{ik} + \tau_D - \tau_S$. Therefore by the first assertion of Lemma 1, $\mathcal{S}_i(k)$ and $\mathcal{S}_j(q)$ must strongly overlap. It remains to be shown that $\mathcal{S}_i(k+1) \cap \mathcal{S}_j(q+1) \succ \tau_S$ if $\lceil \bar{t}_{i(k+1)} \rceil_j = q+2$. Since $\lceil \bar{t}_{i(k+1)} \rceil_j = q+2$, Lemma 1 applies with $k+1$ and $q+2$ replacing k and q, respectively. Thus, to prove that $\mathcal{S}_i(k+1)$ and $\mathcal{S}_j(q+1)$ also strongly overlap, it is enough to show that $\bar{t}_{i(k+1)} - \bar{t}_{j(q+1)} \leq \tau_D - \tau_S$.

To do this, we first use (3) and the fact that $\bar{t}_{ik} \le \bar{t}_{jq}$ to write $\bar{t}_{i(k+1)} \le \bar{t}_{jq}+2(\tau_D-\tau_S)$. From this and (2) with $p=1$ there follows $\bar{t}_{i(k+1)} \le \bar{t}_{j(q+1)} + \tau_D - 2\tau_S$. Therefore $\bar{t}_{i(k+1)} \le \bar{t}_{j(q+1)} + \tau_D - \tau_S$. Thus $\mathcal{S}_i(k+1) \cap \mathcal{S}_j(q+1) \succ \tau_S$, so assertion 3 is true.

Now suppose that $\lceil \bar{t}_{i(k+1)} \rceil_j \in \{q+1, q+2\}$. Then in either case $\bar{t}_{jq} \le \bar{t}_{i(k+1)}$. Therefore $\bar{t}_{ik} \le \bar{t}_{jq} \le \bar{t}_{i(k+1)}$. If $\bar{t}_{ik} \ne \bar{t}_{jq}$, then $\bar{t}_{ik} < \bar{t}_{jq} \le \bar{t}_{i(k+1)}$, which means that $\lceil \bar{t}_{jq} \rceil = \bar{t}_{i(k+1)}$; thus Lemma 1 applies with k and q replaced by q and $k+1$, respectively. Therefore in this case $\mathcal{S}_i(k)$ and $\mathcal{S}_i(k+1)$ are the only sensing periods of agent i which can strongly overlap $\mathcal{S}_j(q)$. Now suppose that $\bar{t}_{ik} = \bar{t}_{jq}$. This means that $\lceil \bar{t}_{jq} \rceil = \bar{t}_{ik}$; thus Lemma 1 applies with k and q interchanged. Therefore in this case $\mathcal{S}_i(k-1)$ and $\mathcal{S}_i(k)$ are the only sensing periods of agent i which can strongly overlap $\mathcal{S}_j(q)$. To complete the proof, it is enough to show that $\mathcal{S}_i(k-1)$ cannot strongly overlap $\mathcal{S}_j(q)$. Towards this end, first note that $\bar{t}_{ik} \ge \bar{t}_{i(k-1)} + \tau_D$ because of (2). Thus $\bar{t}_{jq} \ge \bar{t}_{i(k-1)} + \tau_D$, so $\bar{t}_{jq} - \bar{t}_{i(k-1)} > +\tau_D - \tau_S$. Therefore $\mathcal{S}_i(k-1)$ cannot strongly overlap $\mathcal{S}_j(q)$ because of Lemma 1. □

LEMMA 3. *Let $q = \lceil \bar{t}_{ik} \rceil_j$. Suppose that agents i and j satisfy the motion constraints induced by their registered neighbors. If agent j is a registered neighbor of agent i at the beginning of agent i's kth maneuvering period, then*

$$||x_i(\bar{t}_{i(k+1)}) - x_j(\bar{t}_{jq^*})|| \le r, \tag{5}$$

$$||x_i(\bar{t}_{i(k+1)}) - x_j(\bar{t}_{j(q^*+1)})|| \le r, \tag{6}$$

where $q^* = q$ if condition (A) *of Proposition* 1 *is true and $q^* = q-1$ if it is not. Moreover, in either case*

$$||x_i(\bar{t}_{ik}) - x_j(\bar{t}_{jq})|| \le r. \tag{7}$$

Proof of Lemma 3. First suppose that agent j is a registered neighbor of agent i at the beginning of maneuvering period k. Thus by Proposition 1, x_{jq^*} is agent j's registered position, and

$$||x_i(\bar{t}_{ik}) - x_j(\bar{t}_{jq^*})|| \le r, \tag{8}$$

where $q^* = q$ if condition A holds and $q^* = q-1$ if it does not. The positions of agent i at the beginning and end of its kth maneuvering period are $x_i(\bar{t}_{ik})$ and $x_i(t_{ik})$, respectively. Therefore since agent i satisfies the motion constraint induced by agent j during this period, $||x_i(t_{ik}) - \frac{1}{2}\{x_i(\bar{t}_{ik}) + x_j(\bar{t}_{jq^*})\}|| \le \frac{r}{2}$. But $x_i(\bar{t}_{i(k+1)}) = x_i(t_{ik})$ because agent i does not move during sensing period $[t_{ik},\ \bar{t}_{i(k+1)})$. This enables us to rewrite the preceding inequality as

$$\left\| x_i(\bar{t}_{i(k+1)}) - \frac{1}{2}\{x_i(\bar{t}_{ik}) + x_j(\bar{t}_{jq^*})\} \right\| \le \frac{r}{2}. \tag{9}$$

Observe that

$$x_i(\bar{t}_{i(k+1)}) - x_j(\bar{t}_{jq^*}) = x_i(\bar{t}_{i(k+1)}) - \frac{1}{2}\{x_i(\bar{t}_{ik}) + x_j(\bar{t}_{jq^*})\} - \frac{1}{2}\left(x_j(\bar{t}_{jq^*}) - x_i(\bar{t}_{ik})\right).$$

Hence

$$\begin{aligned} ||x_i(\bar{t}_{i(k+1)}) - x_j(\bar{t}_{jq^*})|| \le & \left\| x_i(\bar{t}_{i(k+1)}) - \frac{1}{2}\{x_i(\bar{t}_{ik}) + x_j(\bar{t}_{jq^*})\} \right\| \\ & + \left\| \frac{1}{2}\left(x_j(\bar{t}_{jk^*}) - x_i(\bar{t}_{ik})\right) \right\|. \end{aligned}$$

From this, (8), and (9) there follows $||x_i(\bar{t}_{i(k+1)}) - x_j(\bar{t}_{jq^*})|| \leq \frac{r}{2} + \frac{r}{2} = r$. Therefore (5) is true.

It will now be shown that (6) is also true. By Proposition 2, agent i is a registered neighbor of agent j at the beginning of agent j's q^*th maneuvering period, where $q^* = q$ if condition (A) of Proposition 1 holds and $q^* = q - 1$ if it does not. Thus by Proposition 1

$$||x_j(\bar{t}_{jq^*}) - \bar{x}_i|| \leq r, \tag{10}$$

where $\bar{x}_i$ denotes the registered position of agent i at $\bar{t}_{jq^*}$. The positions of agent j at the beginning and end of its q^*th maneuvering period are $x_j(\bar{t}_{jq^*})$ and $x_j(t_{jq^*})$, respectively. Therefore since agent j satisfies the motion constraint induced by agent i during this period, $||x_j(t_{jq^*}) - \frac{1}{2}\{x_j(\bar{t}_{jq^*}) + \bar{x}_i\}|| \leq \frac{r}{2}$. But $x_j(\bar{t}_{j(q^*+1)}) = x_j(t_{jq^*})$ because agent j does not move during sensing period $q^* + 1$. Therefore

$$\left\| x_j(\bar{t}_{j(q^*+1)}) - \frac{1}{2}\{x_j(\bar{t}_{jq^*}) + \bar{x}_i\} \right\| \leq \frac{r}{2}. \tag{11}$$

In view of Proposition 2, $\bar{x}_i$ could be either $x_i(\bar{t}_{ik})$ or $x_i(\bar{t}_{i(k+1)})$ if condition A of Proposition 1 holds, while $\bar{x}_i = x_i(\bar{t}_{ik})$ if it does not. Consider first the case when $\bar{x}_i = x_i(\bar{t}_{ik})$. It is then possible to rewrite (11) as

$$\left\| x_j(\bar{t}_{j(q^*+1)}) - \frac{1}{2}\{x_j(\bar{t}_{jq^*}) + x_i(\bar{t}_{ik})\} \right\| \leq \frac{r}{2}. \tag{12}$$

But

$$\begin{aligned} ||x_i(\bar{t}_{i(k+1)}) - x_j(\bar{t}_{j(q^*+1)})|| &= \left\| x_i(\bar{t}_{i(k+1)}) - \frac{1}{2}\{x_i(\bar{t}_{ik}) + x_j(\bar{t}_{jq^*})\} \right. \\ &\quad \left. -(x_j(\bar{t}_{j(q^*+1)}) - \frac{1}{2}\{x_j(\bar{t}_{jq^*}) + x_i(\bar{t}_{ik})\}) \right\| \\ &\leq \left\| x_i(\bar{t}_{i(k+1)}) - \frac{1}{2}\{x_i(\bar{t}_{ik}) + x_j(\bar{t}_{jq^*})\} \right\| \\ &\quad + \left\| x_j(\bar{t}_{j(q^*+1)}) - \frac{1}{2}\{x_j(\bar{t}_{jq^*}) + x_i(\bar{t}_{ik})\} \right\|. \end{aligned}$$

From this, (9), and (12) it follows that $||x_i(\bar{t}_{i(k+1)}) - x_j(\bar{t}_{j(q^*+1)})|| \leq r$ and thus that (6) holds.

It will now be shown that (6) also holds for the case when $\bar{x}_i = x_i(\bar{t}_{i(k+1)})$ which only occurs when $q^* = q$. Assuming this possibility, (11) can be written as

$$\left\| x_j(\bar{t}_{j(q^*+1)}) - \frac{1}{2}\{x_j(\bar{t}_{jq^*}) + x_i(\bar{t}_{i(k+1)})\} \right\| \leq \frac{r}{2}. \tag{13}$$

Observe that it is possible to write

$$\begin{aligned} x_j(\bar{t}_{j(q^*+1)}) - x_i(\bar{t}_{i(k+1)}) &= x_j(\bar{t}_{j(q^*+1)}) - \frac{1}{2}\{x_j(\bar{t}_{jq^*}) + x_i(\bar{t}_{i(k+1)})\} \\ &\quad - \frac{1}{2}\left(x_i(\bar{t}_{i(k+1)}) - \frac{1}{2}\{x_j(\bar{t}_{jq^*}) + x_i(\bar{t}_{ik})\} \right) \\ &\quad + \frac{1}{4}\left(x_j(\bar{t}_{jq^*}) - x_i(\bar{t}_{ik}) \right). \end{aligned}$$

Clearly

$$||x_j(\bar{t}_{j(q^*+1)}) - x_i(\bar{t}_{i(k+1)})|| \leq \left\| x_j(\bar{t}_{j(q^*+1)}) - \frac{1}{2}\{x_j(\bar{t}_{jq^*}) + x_i(\bar{t}_{i(k+1)})\} \right\| + \frac{1}{2}\left\| x_i(\bar{t}_{i(k+1)}) - \frac{1}{2}\{x_j(\bar{t}_{jq^*}) + x_i(\bar{t}_{ik})\} \right\| + \frac{1}{4}\left\| x_j(\bar{t}_{jq^*}) - x_i(\bar{t}_{ik}) \right\|.$$

Using (8), (9), and (13) we thus obtain $||x_j(\bar{t}_{j(q^*+1)}) - x_i(\bar{t}_{i(k+1)})|| \leq \frac{r}{2} + \frac{r}{4} + \frac{r}{4} = r$. Thus (6) holds in this case too.

In view of (8), (7) is true if $q^* = q$. To prove that (7) also holds if $q^* = q - 1$, we first write

$$x_j(\bar{t}_{j(q^*+1)}) - x_i(\bar{t}_{ik}) = x_j(\bar{t}_{j(q^*+1)}) - \frac{1}{2}\{x_j(\bar{t}_{jq^*}) + x_i(\bar{t}_{ik})\} - \frac{1}{2}\left(x_i(\bar{t}_{ik}) - x_j(\bar{t}_{jq^*})\right).$$

Therefore

$$||x_j(\bar{t}_{j(q^*+1)}) - x_i(\bar{t}_{ik})|| \leq \left\| x_j(\bar{t}_{j(q^*+1)}) - \frac{1}{2}\{x_j(\bar{t}_{jq^*}) + x_i(\bar{t}_{ik})\} \right\| + \left\| \frac{1}{2}\left(x_i(\bar{t}_{ik}) - x_j(\bar{t}_{jq^*})\right) \right\|. \tag{14}$$

But if $q^* = q - 1$, both (8) and (12) hold. From these inequalities and (14) it follows that $||x_j(\bar{t}_{j(q^*+1)}) - x_i(\bar{t}_{ik})|| \leq \frac{1}{r} + \frac{1}{r} = r$ and therefore that (7) is true. □

Proof of Proposition 3. Consider first the case when $\lceil \bar{t}_{i(k+1)} \rceil = q$. If condition (A) of Proposition 1 holds, then $q^* = q$ and

$$||x_i(\bar{t}_{i(k+1)}) - x_j(\bar{t}_{jq})|| \leq r \tag{15}$$

because of (5). On the other hand, if condition (A) of Proposition 1 does not hold, then $q = q^* - 1$ and (15) still holds, in this case because of (6). Since $\lceil \bar{t}_{i(k+1)} \rceil = q$, it must be true that $\mathcal{S}_i(k+1) \cap \mathcal{S}_j(q) \succ \tau_S$ because of Lemma 2. This and (15) mean that condition (A) of Proposition 1 is satisfied with $k+1$ substituted for k. Therefore agent j is a registered neighbor of agent i at $\bar{t}_{i(k+1)}$.

Now suppose that $\lceil \bar{t}_{i(k+1)} \rceil \in \{q+1, q+2\}$. Consider first the case when condition (A) of Proposition 1 holds. Then Lemma 3 applies with $q^* = q$, so

$$||x_i(\bar{t}_{i(k+1)}) - x_j(\bar{t}_{j(q+1)})|| \leq r \tag{16}$$

and

$$||x_i(\bar{t}_{i(k+1)}) - x_j(\bar{t}_{jq})|| \leq r. \tag{17}$$

If $\lceil \bar{t}_{i(k+1)} \rceil = q + 1$, then $\mathcal{S}_i(k+1)$ must strongly overlap either $\mathcal{S}_j(q)$ or $\mathcal{S}_j(q+1)$ because of Lemma 2. In view of (16) and (17), condition (A) of Proposition 1 is satisfied in either situation with $k+1$ substituted for k and $q+1$ substituted for q. Therefore agent j is a registered neighbor of agent i at $\bar{t}_{i(k+1)}$. If $\lceil \bar{t}_{i(k+1)} \rceil = q + 2$, then $\mathcal{S}_i(k+1)$ and $\mathcal{S}_j(q+1)$ still must strongly overlap because of Lemma 2. Thus in

this case condition (B) of Proposition 1 is satisfied with $k+1$ substituted for k and $q+2$ substituted for q. Therefore agent j is a registered neighbor of agent i at $\bar{t}_{i(k+1)}$.

Consider finally the case when condition (A) of Proposition 1 does not hold. Since (7) holds, $\mathcal{S}_i(k)$ and $\mathcal{S}_j(q)$ cannot overlap. Therefore $\lceil t_{ik} \rceil \neq q+2$ because of statement 3 in Lemma 2. Thus $\lceil t_{ik} \rceil = q+1$. In addition, Lemma 2 states that the only sensing periods of agent i which can strongly overlap $\mathcal{S}_j(q)$ are $\mathcal{S}_i(k)$ and $\mathcal{S}_i(k+1)$. Since $\mathcal{S}_j(q)$ must strongly overlap at least one sensing period of agent i, it must be true that

$$\mathcal{S}_j(q) \cap \mathcal{S}_i(k+1) \succ \tau_S. \tag{18}$$

Since condition (A) of Proposition 1 does not hold, condition (B) must hold, because agent j is a neighbor of agent i at $\bar{t}_{ik}$. Thus Lemma 3 applies with $q^* = q-1$, so by (6),

$$||x_i(\bar{t}_{i(k+1)}) - x_j(\bar{t}_{jq})|| \leq r. \tag{19}$$

Since $\lceil \bar{t}_{i(k+1)} \rceil = q+1$, (19) and (18) show that condition (B) of Proposition 1 is satisfied with $k+1$ and $q+1$ substituted for k and q, respectively. □

2.2. Unsynchronized agent strategies. We are interested in strategies which cause agents to retain their registered neighbors. We therefore make the following assumption.

Cooperation assumption. Each agent i satisfies the motion constraints induced by each of its registered neighbors.

Suppose that the cooperation assumption is satisfied. Proposition 3 states that if agent j is a registered neighbor of agent i during maneuvering interval k, then it will also be a registered neighbor of agent i during maneuvering interval $k+1$. In other words, if the cooperation assumption is satisfied, each agent retains all of its prior registered neighbors as the system evolves. Thus if $\mathcal{N}_i(k)$ denotes the set of labels of agent i's neighbors at the beginning of its kth maneuvering period, then $\mathcal{N}_i(k) \subset \mathcal{N}_i(k+1),\ k \geq 1$.

Agent i's *kth way-point* $\bar{x}_i(k)$ is the point to which agent i moves at the end of its kth maneuvering period. Thus if $x_i(t)$ denotes the position of agent i at time t represented in a world coordinate system, then $x_i(t_{ik})$ and agent i's kth way-point are one and the same. The rule which determines $\bar{x}_i(k)$ is essentially the same as that considered previously for the synchronous case in [1, 8], except that now $\bar{x}_i(k)$ depends on agent i's own position at the beginning of its kth maneuvering period and the registered (relative) positions of agent i's registered neighbors at the beginning of the period. In particular, if agent i has m_{ik} registered neighbors at time $\bar{t}_{ik}$ with registered positions $z_1, z_2, \ldots, z_{m_{ik}}$ relative to agent i's, then agent i moves to the position $\bar{x}_i(k) = x_i(t_{i(k-1)}) + u_{m_{ik}}(z_1, \ldots, z_{m_{ik}})$ at the end of the period where

$$z_j = x_{ii_j}(\bar{t}_{ik}) - x_i(t_{i(k-1)}), \quad j \in \{1, 2, \ldots, m_{ik}\}, \tag{20}$$

and $x_{ii_j}(\bar{t}_{ik})$ is the registered position of neighbor i_j at time $\bar{t}_{ik}$. As in [8], $u_0 = 0$, and for $m \in \{1, \ldots, n-1\}$, u_m is a continuous control law mapping $\mathbb{D}^m$ into $\mathbb{D}_M$, where $\mathbb{D}$ and $\mathbb{D}_M$ are the closed disks of radii r and r_M, respectively, centered at the origin in $\mathbb{R}^2$. For $m > 0$, u_m is defined so that the aforementioned neighbor motion constraint is satisfied and, in addition, so that for each $\{z_1, z_2, \ldots, z_m\} \in \mathbb{D}^m$, $u_m(z_1, z_2, \ldots, z_n)$ is in the convex hull of $\{0, z_1, z_2, \ldots, z_m\}$, but not at a corner unless

$z_1 = z_2 = \cdots = z_m = 0$. Examples of $u_m(\cdot)$ satisfying these *control law requirements* can be found in [1, 8].

Since each agent is assumed to move to its kth way-point at the end of its kth maneuvering period, agent i's position at time t_{ik} is given by

$$x_i(t_{ik}) = x_i(t_{i(k-1)}) + u_{m_{ik}}(x_{ii_1}(\bar{t}_{ik}) - x_i(t_{i(k-1)}), \ldots, x_{ii_{m_{ik}}}(\bar{t}_{ik}) - x_i(t_{i(k-1)})). \tag{21}$$

In view of Proposition 1 and (7), the formulas for the $x_{ij}(\bar{t}_{ik})$ can be written as

$$x_{ij}(\bar{t}_{ik}) = \left\{ \begin{array}{ll} x_j(\bar{t}_{jq}) & \text{if } \mathcal{S}_i(k) \cap \mathcal{S}_j(q) \succ \tau_S \\ x_j(\bar{t}_{j(q-1)}) & \text{otherwise} \end{array} \right\}, \quad j \in \mathcal{N}_i(k), \tag{22}$$

where $q = \lceil \bar{t}_{ik} \rceil_j$ and

$$\mathcal{N}_i(k) = \{j : ||x_i(\bar{t}_{ik}) - x_j(\bar{t}_{iq})|| \leq r \text{ and } \mathcal{S}_i(k) \cap \mathcal{S}_j(q) \succ \tau_S\} \bigcup \{j : ||x_i(\bar{t}_{ik}) - x_j(\bar{t}_{i(q-1)})|| \leq r \text{ and } \mathcal{S}_i(k) \cap \mathcal{S}_j(q-1) \succ \tau_S\}. \tag{23}$$

The expressions for the $x_{ij}(\bar{t}_{ik})$ in (22) are a direct consequence of the characterization of registered positions in Proposition 1, the fact that (7) holds whenever $j \in \mathcal{N}_i(k)$, and the implication of Lemma 1 that $\mathcal{S}_i(k) \cap \mathcal{S}_j(q-1) \succ \tau_S$ whenever $\mathcal{S}_i(k) \cap \mathcal{S}_j(q) \not\succ \tau_S$. Of course the neighbor set $\mathcal{N}_i(k)$ and the registration positions x_{ij}, $j \in \mathcal{N}_i(k)$, all depend on i and k.

3. Main results. Note that because agents do not move during sensing periods, for each $i \in \{1, 2, \ldots, n\}$ the positions of agent i at times $t_{i(k-1)}$ and t_{ik} are the same as at times $\bar{t}_{ik}$ and $\bar{t}_{i(k+1)}$, respectively. Thus (21) can also be written as

$$x_i(\bar{t}_{i(k+1)}) = x_i(\bar{t}_{ik}) + u_{m_{ik}}(x_{ii_1}(\bar{t}_{ik}) - x_i(\bar{t}_{ik}), \ldots, x_{ii_{m_{ik}}}(\bar{t}_{ik}) - x_i(\bar{t}_{ik})). \tag{24}$$

The n equations given by (24) for $i \in \{1, 2, \ldots, n\}$ together with (22) and (23) completely describe the evolution of the positions of the n agents under consideration as each maneuvers from way-point to way-point. Just as in the synchronous case, the analysis of these equations depends on the relationships between registered neighbors and how these relationships evolve with time. To characterize these relationships, we first extend the domain of definition of each agent's registered neighbors from its set of maneuvering period start times to a suitably defined set of "event times" common to all n agents. By an *event time* is meant any time $\bar{t}_{ik}$ at which any maneuvering period $[\bar{t}_{ik}, t_{ik})$ of any agent begins. Let $\{\bar{t}_{ik} : i \in \{1, 2, \ldots, n\}, k \geq 1\}$ denote the set of all distinct event times. Label this set's elements as $t_1, t_2, \ldots, t_p, \ldots$ in such a way that $t_p < t_{p+1}$, $j \in \{1, 2, \ldots\}$. For $i \in \{1, 2, \ldots, n\}$, let P_i denote that strictly monotone function from the set of positive integers $\mathcal{I}$ to $\mathcal{I}$ which assigns to $k \in \mathcal{I}$ that value of $p \in \mathcal{I}$ for which $t_p = \bar{t}_{ik}$. Thus with this notation, $t_{P_i(k)} = \bar{t}_{ik}$, so agent i's registered neighbors at its kth event time $t_{P_i(k)}$ are its registered neighbors at time $\bar{t}_{ik}$. For each $i \in \{1, 2, \ldots, n\}$ we extend the domain of definition of agent i's registered neighbors from the set $\{t_{P_i(k)} : k \geq 1\}$ to the set $\{t_p : p \geq P_i(1)\}$ by stipulating that for values of t_p which are between two successive event times of agent i, say between t_{ik} and $t_{i(k+1)}$, agent i's registered neighbors are the same as its registered neighbors at time t_{ik}.

Let $\mathcal{T} \triangleq \{t_{\bar{p}}, t_{\bar{p}+1}, t_{\bar{p}+2}, \ldots\}$ denote the set of all event times greater than or equal to $t_{\bar{p}}$, where $\bar{p} \triangleq \max\{P_1(1), P_2(1), \ldots P_n(1)\}$. Note that the registered neighbors of each agent are defined at each time t_p in $\mathcal{T}$. For each $p \geq \bar{p}$, it is therefore possible to describe neighbor relationships using a directed[1] graph $\mathbb{G}_p$ with vertex set $\{1, 2, \ldots, n\}$ and directed edge set defined so that (i, j) is a directed edge from vertex i to vertex j just in case agent j is a registered neighbor of agent i at event time t_p.

Let us partially order the set of all directed graphs with vertex set $\{1, 2, \ldots, n\}$ by agreeing to say that $\mathbb{G}$ is contained in $\bar{\mathbb{G}}$ if the edge set of $\mathbb{G}$ is a subset on the edge set of $\bar{\mathbb{G}}$. It is natural then to define the *union* of a collection of such graphs to be the directed graph with vertex set $\{1, 2, \ldots, n\}$ and edge set equaling the union of the edge sets of all of the graphs in the collection. Because of the cooperation assumption and Proposition 3, we know that each agent keeps all of its registered neighbors as the system evolves. What this means is the sequence of graphs $\mathbb{G}_{\bar{p}}, \mathbb{G}_{\bar{p}+1}, \ldots, \mathbb{G}_p, \ldots$ forms the ascending chain

$$\mathbb{G}_{\bar{p}} \subset \mathbb{G}_{\bar{p}+1} \subset \cdots \mathbb{G}_p \cdots. \tag{25}$$

Because the set of directed graphs on vertices $\{1, 2, \ldots, n\}$ is a finite set, the chain must converge to the graph

$$\mathbb{G} \triangleq \bigcup_{p=\bar{p}}^{\infty} \mathbb{G}_p \tag{26}$$

in a finite number of steps. More is true. Suppose that agent i has agent j as a registered neighbor at the beginning of one of agent i's maneuvering periods. Then because of Proposition 2, agent i must be a registered neighbor of agent j at the beginning of one of agent j's maneuvering periods. These observations together with the cooperation assumption imply that agents i and j must both eventually become and remain registered neighbors of each other. As a consequence, there must be directed arcs in $\mathbb{G}$ from vertex i to vertex j as well as from vertex j to vertex i. Clearly $\mathbb{G}$ must be a directed graph with the property that for each distinct pair of vertices—say i and j—either there is no directed arc connecting one to the other or there are two directed arcs, one from vertex i to vertex j and the other from vertex j to vertex i. Directed graphs with this property are usually regarded as simple graphs whose edges represent such pairs of directed arcs [6]. In what follows we shall adopt this viewpoint and refer to $\mathbb{G}$ as a simple graph. Our main result is as follows.

THEOREM 1. *Let $u_0 = 0 \in \mathbb{D}_M$ and for each $m \in \{1, 2, \ldots, n-1\}$, let $u_m : \mathbb{D}^m \to \mathbb{D}_M$ be any continuous function satisfying the aforementioned control law requirements. For each set of initial agent positions $x_1(0), x_2(0), \ldots, x_n(0)$, each agent's position $x_i(t)$ converges to a unique point $\pi_i \in \mathbb{R}^2$ such that for each $i, j \in \{1, 2, \ldots, n\}$, either $\pi_i = \pi_j$ or $||\pi_i - \pi_j|| > r$. Moreover, if agent j is a registered neighbor of agent i at the beginning of one of agent i's maneuvering periods, then $\pi_i = \pi_j$.*

This theorem will be proved in section 4.

Theorem 1 states that the strategies under consideration cause all agents' positions to converge to points in the plane with the property that each pair of such points are either equal to each other or separated by a distance greater than r units.

[1]It will soon be clear that the aforementioned symmetry of the neighbor relationship will ultimately enable us to characterize neighbor relationships with a simple, undirected graph as in the synchronous case.

The theorem further states that if one agent is ever a registered neighbor of another, then both converge to the same point. Thus all n agents' positions will converge to a single point if any one directed graph in the ascending chain is strongly connected. We are led to the following corollary.

COROLLARY 1. *If at any event time $t_p \geq t_{\bar{p}}$, the directed graph $\mathbb{G}_p$ characterizing registered neighbors is strongly connected, then positions of all n agents converge to a common point in the plane.*

4. Analysis. The aim of this section is to establish the correctness of Theorem 1. This requires the analysis of the asymptotic behavior of the *asynchronous* process described by (22) and (24) for $i \in \{1, 2, \ldots, n\}$. Despite the apparent complexity of this process, it is possible to capture its salient features for t_s sufficiently large using a suitably defined *synchronous* discrete-time, hybrid dynamical system $\mathbb{S}$. The process of constructing a synchronous process to model the behavior of an asynchronous process is called *analytic synchronization* and has been outlined in the introduction to this paper. In what follows we demonstrate the utility of this idea by applying it to the problem at hand.

4.1. A synchronous model of the asynchronous agent system. It is sufficient to analyze the behavior of the n-agent system for times beyond the time at which each agent's neighbor set stops changing. Analytic synchronization would thus have us define $\mathbb{S}$ to be a synchronous system evolving on the event time set $\{t_p : p \in \mathcal{P}\}$ where $\mathcal{P} = \{p; p \geq p^*\}$ and p^* is the smallest value of $p \geq \bar{p}$ for which the ascending chain shown in (25) has converged to the limit graph $\mathbb{G}$ in (26). To reduce clutter we will instead define $\mathbb{S}$ to be a synchronous discrete-time dynamical system evolving on the index set $\mathcal{P}$. Thus for $p \in \mathcal{P}$, the registered neighbors of each agent do not change. For simplicity, we will only deal with the case when each agent has at least one neighbor for $t_p \geq t_{p^*}$. The position update equation (24) for agent i can thus be written as

$$x_i(\bar{t}_{i(k+1)}) = x_i(\bar{t}_{ik}) + u_{m_i}(x_{ii_1}(\bar{t}_{ik}) - x_i(\bar{t}_{ik}), \ldots, x_{ii_{m_i}}(\bar{t}_{ik}) - x_i(\bar{t}_{ik})), \tag{27}$$

where m_i is a positive number and $\mathcal{N}_i \triangleq \{i_1, i_2, \ldots, i_{m_i}\}$ is the set of indices labelling agent i's registered neighbors. Just as before,

$$x_{ij}(\bar{t}_{ik}) = \begin{cases} x_j(\bar{t}_{jq}) & \text{if } \mathcal{S}_i(k) \cap \mathcal{S}_j(q) \succ \tau_S, \\ x_j(\bar{t}_{j(q-1)}) & \text{otherwise,} \end{cases} \tag{28}$$

and

$$\mathcal{N}_i = \{j : ||x_i(\bar{t}_{ik}) - x_j(\bar{t}_{iq})|| \leq r \text{ and } \mathcal{S}_i(k) \cap \mathcal{S}_j(q) \succ \tau_S\}$$

$$\bigcup \{j : ||x_i(\bar{t}_{ik}) - x_j(\bar{t}_{i(q-1)})|| \leq r \text{ and } \mathcal{S}_i(k) \cap \mathcal{S}_j(q-1) \succ \tau_S\}, \tag{29}$$

where $q = \lceil \bar{t}_{ik} \rceil_j$. Note that it must be true that

$$||x_j(\bar{t}_{jq}) - x_i(\bar{t}_{ik})|| \leq r \tag{30}$$

because of (7). In view of (29) it also must be true that

$$||x_j(\bar{t}_{j(q-1)}) - x_i(\bar{t}_{ik})|| \leq r \text{ if } \mathcal{S}_i(k) \cap \mathcal{S}_j(q) \not\succ \tau_S. \tag{31}$$

Inequalities (30) and (31) are consequences of the assumption that $j \in \mathcal{N}_i$. These inequalities will translate into constraints on the state of $\mathbb{S}$.

4.1.1. Definition of $\mathbb{S}$. We will take as the state space of $\mathbb{S}$ the space $\mathcal{X}$ of all lists $\{y_1, y_2, \ldots, y_n, w_1, w_2, \ldots, w_n\}$ satisfying

$$\left.\begin{array}{l} y_i, w_i \in \mathbb{R}^2, \\ ||y_i - y_j|| \le r \end{array}\right\}, \qquad j \in \mathcal{N}_i, \quad i \in \{1, 2, \ldots, n\}. \tag{32}$$

In what follows we often write y for $\{y_1, y_2, \ldots, y_n\}$ and w for $\{w_1, w_2, \ldots, w_n\}$. We sometimes refer to $\{y_i, w_i\}$ as the state of "node" i. For $i \in \{1, 2, \ldots, n\}$ let P_i^{-1} be a left inverse of P_i and let $\mathcal{P}_i = \mathcal{P} \cap \text{image } P_i$. We now define $\mathbb{S}$ to be a time-varying system with state $\{y, w\}$; for each $i \in \{1, 2, \ldots, n\}$, the state of node i evolves on $\mathcal{P}$ according to update equations defined for $p \in \mathcal{P}_i$ by

$$y_i(p+1) = y_i(p) + u_{m_i}(v_{ii_1}(p) - y_i(p), \ldots, \ v_{ii_{m_i}}(p) - y_i(p)), \tag{33}$$

$$w_i(p+1) = y_i(p), \tag{34}$$

where

$$v_{ij}(p) = \left\{\begin{array}{ll} y_j(p) & \text{if } \mathcal{S}_i(P_i^{-1}(p)) \cap \mathcal{S}_j(\lceil t_p \rceil_j) \succ \tau_S, \\ w_j(p) & \text{otherwise} \end{array}\right\}, \qquad j \in \mathcal{N}_i, \tag{35}$$

and by

$$y_i(p+1) = y_i(p), \tag{36}$$

$$w_i(p+1) = w_i(p) \tag{37}$$

for $p \notin \mathcal{P}_i$. We require that y_i satisfies the *neighbor constraints*

$$||y_i(p) - w_j(p)|| \le r \ \text{ if } \quad \mathcal{S}_i(P_i^{-1}(p)) \cap \mathcal{S}_j(\lceil t_p \rceil_j) \not\succ \tau_S, \ \ p \in \mathcal{P}_i, \quad j \in \mathcal{N}_i. \tag{38}$$

Note that these constraint requirements together with the definition of $\mathcal{X}$ and v_{ij} ensure that $||v_{ij} - y_i(p)|| \le r$ whenever $p \in \mathcal{P}_i$. This in turn is necessary for (33) to make sense because the domain of u_{m_i} is $\mathbb{D}^{m_i}$.

The preceding defines $\mathbb{S}$ to be a synchronous discrete-time dynamical system with state constraints given by (38). The definition depends on the $\mathcal{N}_i$ as well as the n event time sequences $\{\bar{t}_{ik}; k \ge 1\}$. We have assumed that the $\mathcal{N}_i$ are nonempty; in addition, $\mathcal{N}_i \subset \{1, 2, \ldots, i-1, i+1, \ldots, n\}$. As a consequence of Proposition 2 and the assumption that neighbors stop changing, the $\mathcal{N}_i$ all have the following *symmetry property:* If $j \in \mathcal{N}_i$, then $i \in \mathcal{N}_j$. Because of the symmetry property we can associate with the $\mathcal{N}_i$ a simple graph $\mathbb{G}$ with vertex set $\{1, 2, \ldots, n\}$ and edge set defined in such a way that (i, j) is in the edge set just in case $i \in \mathcal{N}_j$ and $j \in \mathcal{N}_i$. Note that this is precisely the same as the simple graph mentioned just before Theorem 1. As for event times, recall that each event time sequence is strictly monotone increasing and that together they all satisfy Lemma 1, (2), and (3). In defining $\mathbb{S}$, these are the only properties of the $\mathcal{N}_i$ and the event times which are assumed.

4.1.2. Validation of $\mathbb{S}$. We claim that $\mathbb{S}$ provides a synchronous model of the asynchronous agent system describe by (27)–(31). The first step in justifying this claim is to define

$$\left.\begin{array}{l} y_i(p) = x_i(\bar{t}_{ik}), \\ w_i(p) = x_i(\bar{t}_{i(k-1)}) \end{array}\right\}, \quad P_i(k-1) < p \le P_i(k), \ \ k \in P_i^{-1}(\mathcal{P}), \tag{39}$$

for $i \in \{1, 2, \ldots, n\}$. Note that y_i has been defined so that it is constant between agent i's event times and agrees with x_i whenever p is such that t_p is within one of agent i's sensing periods.

To justify the claim that $\mathbb{S}$ models (27)–(31), we need to prove that with the $y_i(p)$ and $w_i(p)$ defined by (39), $\{y(p), w(p)\} \in \mathcal{X},\ p \in \mathcal{P}$, and (33)–(38) are satisfied. In view of (30) and the definition of the $y_i(p)$ in (2), it is clear that for $i \in \{1, 2, \ldots, n\}$, $||y_i(p) - y_j(p)|| \leq r, j \in \mathcal{N}_i,\ p \in \mathcal{P}$. Therefore $\{y(p), w(p)\} \in \mathcal{X},\ p \in \mathcal{P}$. It remains to be shown that (33)–(38) are satisfied. To accomplish this, fix $p \in \mathcal{P}$ and suppose that k is that value for which $P_i(k) \leq p < P_i(k+1)$. Set $p_1 = P_i(k)$ and $p_2 = P_i(k+1)$. By definition,

$$y_i(p_1) = x_i(\bar{t}_{ik}), \tag{40}$$

$$w_i(p_1) = x_i(\bar{t}_{i(k-1)}), \tag{41}$$

$$y_i(p_2) = x_i(\bar{t}_{i(k+1)}), \tag{42}$$

$$w_i(p_2) = x_i(\bar{t}_{ik}), \tag{43}$$

$$y_i(s) = y_i(p_2),\ \ p_1 < s \leq p_2, \tag{44}$$

$$w_i(s) = w_i(p_2),\ \ p_1 < s \leq p_2. \tag{45}$$

Suppose first that $p \notin \mathcal{P}_i$ or, equivalently, that $p_1 < p < p_2$. Then $p_1 < p + 1 \leq p_2$, so $y_i(p+1) = y_i(p_2)$ and $w_i(p+1) = w_i(p_2)$ because of (44) and (45), respectively. But $y_i(p) = y_i(p_2)$ and $w_i(p) = w_i(p_2)$ also because of (44) and (45), respectively. It follows that (36) and (37) are true.

Now suppose that $p \in \mathcal{P}_i$ or, equivalently, that $p = p_1$. Then $p_1 < p + 1 \leq p_2$, so $y_i(p+1) = y_i(p_2)$ and $w_i(p+1) = w_i(p_2)$ because of (44) and (45), respectively. It follows from (42) and (43) that

$$y_i(p+1) = x_i(\bar{t}_{i(k+1)}) \tag{46}$$

and

$$w_i(p+1) = x_i(\bar{t}_{ik}). \tag{47}$$

But

$$x_i(\bar{t}_{ik}) = y_i(p) \tag{48}$$

because of (40); thus (34) is true.

Fix $j \in \mathcal{N}_i$ and set $q = \lceil t_p \rceil_j$. To justify (38) and (33) we will need to express $x_j(\bar{t}_{iq})$, $x_j(\bar{t}_{i(q-1)})$, and k in terms of y_j, w_j, and p, respectively. Note first that $t_p = \bar{t}_{ik}$ because $p = p_1$. Thus

$$q = \lceil \bar{t}_{ik} \rceil_j, \tag{49}$$

so $\bar{t}_{j(q-1)} < \bar{t}_{ik} \leq \bar{t}_{jq}$. This means that $P_j(q-1) < P_i(k) \leq P_j(q)$ and thus that $P_j(q-1) < p \leq P_j(q)$. But by definition $y_j(s) = x_j(\bar{t}_{jq})$ and $w_j(s) = x_j(\bar{t}_{j(q-1)})$ for $P_j(q-1) < s \leq P_j(q)$. Therefore

$$x_j(\bar{t}_{jq}) = y_j(p), \tag{50}$$

$$x_j(\bar{t}_{j(q-1)}) = w_j(p). \tag{51}$$

Finally note that

$$k = P_i^{-1}(p) \tag{52}$$

because $P_i(k) = p_1 = p$. It is now clear from (40), (51), and (52) that the inequality in (31) translates into neighbor constraint (38).

In addition, examination of (48)–(52) together with the definitions of $x_{ij}(\bar{t}_{ik})$ and $v_{ij}(p)$ in (28) and (35), respectively, reveals that

$$x_{ij}(\bar{t}_{ik}) = v_{ij}(p). \tag{53}$$

From this and (48) it follows that the expression for $x_i(\bar{t}_{i(k+1)})$ in (27) can be written as

$$x_i(\bar{t}_{i(k+1)}) = y_i(p) + u_{m_i}(v_{ii_1}(p) - y_i(p), \ldots, \ v_{ii_{m_i}}(p) - y_i(p)).$$

This and (46) thus finally justify (33).

By a *trajectory* of $\mathbb{S}$ is meant a sequence of states $\{\{y(p), w(p)\} : p \in \mathcal{P}\}$ which satisfy (33)–(37) as well as the neighbor constraints (38). The preceding proves that the family of such trajectories is nonempty and contains the trajectory which represents the actual agent system under consideration. It turns out that the trajectory representing the actual agent system has an additional property which we will exploit later.

LEMMA 4. *For $i \in \{1, 2, \ldots, n\}$, let $y_i(p)$ and $w_i(p)$ be defined by* (39). *Let $i \in \{1, 2, \ldots, n\}$ and $s \in \mathcal{S}_i$ be fixed. Suppose that for some $j \in \{1, 2, \ldots, n\}$ and $p \in \mathcal{P}_i$,*

$$||y_i(p+1) - y_j(p)|| \leq r, \tag{54}$$

$$||w_i(p+1) - y_j(p)|| \leq r. \tag{55}$$

Then $j \in \mathcal{N}_i$.

Proof of Lemma 4. Since $p \in \mathcal{P}_i$ and P_i is strictly monotone, there is a unique integer k for which $p = P_i(k)$. Let $q = \lceil \bar{t}_{ik} \rceil$. As noted previously in the development leading to (46)–(50), $y_i(p+1) = x_i(\bar{t}_{i(k+1)})$, $w_i(p) = x_i(\bar{t}_{ik})$, and $y_j(p) = x_j(\bar{t}_{jq})$. Thus (54) and (55) translate into $||x_i(\bar{t}_{i(k+1)}) - x_j(\bar{t}_{jq})|| \leq r$ and $||x_i(\bar{t}_{ik}) - x_j(\bar{t}_{jq})|| \leq r$, respectively. Moreover, Lemma 1 states that $\mathcal{S}_i(k)$ must strongly overlap either $\mathcal{S}_j(q)$ or $\mathcal{S}_j(q-1)$. If the former is true, then condition (A) of Proposition 1 is satisfied and thus $j \in \mathcal{N}_i$. Suppose next that $\mathcal{S}_i(k)$ does not strongly overlap $\mathcal{S}_j(q)$. Then $\bar{t}_{i(k+1)} \in \{q, q+1\}$ because of (4) and condition 3 in Lemma 2. If $\bar{t}_{i(k+1)} = q$, then $\mathcal{S}_i(k+1) \cap \mathcal{S}_j(q) \geq \tau_S$ because of condition 1 in Lemma 2. Thus condition (A) of Proposition 1 is satisfied when $k+1$ is substituted for k; thus in this case $j \in \mathcal{N}_i$. Suppose $\bar{t}_{i(k+1)} = q+1$. In view of Lemma 2, $\mathcal{S}_i(k)$ and $\mathcal{S}_i(k+1)$ are the only sensing periods of agent i which can strongly overlap $\mathcal{S}_j(q)$. Since $\mathcal{S}_j(q)$ must be strongly overlapped by at least one of agent i's sensing periods, it must be true that $\mathcal{S}_i(k+1) \cap \mathcal{S}_j(q) \geq \tau_S$. Thus condition (B) of Proposition 1 is satisfied with $k+1$ and $q+1$ substituted for k and q, respectively. Therefore $j \in \mathcal{N}_i$. □

Conditions (54) and (55) do not necessarily imply that $j \in \mathcal{N}_i$ for every trajectory of $\mathbb{S}$. The claim of Lemma 4 is that the implication does indeed hold if the trajectory in question is the one which models the actual agent system.

4.2. Properties of $\mathbb{S}$. In section 4.1 we defined $\mathbb{S}$ and proved that it faithfully models the actual agent system. In this section we derive several important properties of $\mathbb{S}$.

4.2.1. Local convex hulls. In what follows we denote the convex hull of a given set of points $x_1, x_2, \ldots, x_q$ in $\mathbb{R}^2$ by $\langle x_1, x_2, \ldots, x_q \rangle$. We write $\mathcal{H}_i(p)$ for the *ith local convex hull*

$$\mathcal{H}_i(p) = \langle y_i(p), y_{i_1}(p), \ldots, y_{i_{m_i}}(p), w_i(p), w_{i_1}(p), \ldots, w_{i_{m_i}}(p) \rangle,$$

where $\{i_1, i_2, \ldots, i_{m_i}\} = \mathcal{N}_i$. We also write $\mathcal{H}(p)$ for the (global) convex hull

$$\mathcal{H}(p) = \langle y_1(p), y_2(p), \ldots, y_n(p), w_1(p), w_2(p), \ldots, w_n(p) \rangle,$$

and $\mathcal{K}(p)$ for the set of corners of $\mathcal{H}(p)$. Clearly

$$\mathcal{H}_i(p) \subset \mathcal{H}(p), \qquad i \in \{1, 2, \ldots, n\}, \quad p \in \mathcal{P}. \tag{56}$$

This fact plays a role in the proof of the following lemma which establishes a fundamental property of $\mathbb{S}$.

LEMMA 5.

$$\mathcal{H}(p+1) \subset \mathcal{H}(p), \quad p \in \mathcal{P}. \tag{57}$$

Proof of Lemma 5. Fix $i \in \{1, 2, \ldots, n\}$ and note that (33) and the control law requirement that $u_m(z_1, z_2, \ldots, z_m) \in \langle 0, z_1, \ldots, z_m \rangle$, $z_i \in \mathbb{D}$, imply that $y_i(p+1) \in \mathcal{H}_i(p)$, $p \in \mathcal{P}_i$; thus $y_i(p+1) \in \mathcal{H}(p)$, $p \in \mathcal{P}_i$, because of (56). Moreover, $y_i(p+1)$ is also in $\mathcal{H}(p)$ for $p \notin \mathcal{P}_i$ because of (36). Therefore $y_i(p+1) \in \mathcal{H}(p)$ for all $p \in \mathcal{P}$. Similarly, $w_i(p+1) \in \mathcal{H}(p)$, $p \in \mathcal{P}$, because of (34) and (37). Thus $\{y_i(p+1), w_i(p+1)\} \subset \mathcal{H}(p)$, $p \in \mathcal{P}$. Since this holds for all $i \in \{1, 2, \ldots, n\}$, (57) is true. □

4.2.2. Stationary nodes. Let us agree to say that node i is *stationary* at time $p \in \mathcal{P}_i$ if

$$y_i(p) = v_{ii_1}(p) = \cdots = v_{ii_{m_i}}(p).$$

The terminology is prompted by the fact that if node i is stationary at p, then $y_i(p+1) = y_i(p)$; this can be seen from (33) and the control law requirements imposed on u_{m_i}. In addition, the requirement that $u_m(z_1, z_2, \ldots, z_m)$ not be a corner of $\langle 0, z_1, \ldots, z_m \rangle$ unless $z_1 = z_2 = \cdots = z_m = 0$ implies that if $y_i(p+1)$ is a corner of $\langle y_i(p), v_{ii_1}(p), \ldots, v_{ii_{m_i}}(p) \rangle$, then node i must be stationary at p. The following lemma implies that this is also true if $y_i(p+1)$ is a corner of $\mathcal{H}(p)$.

LEMMA 6. *Fix $i \in \{1, 2, \ldots, n\}$ and $\bar{p} \in \mathcal{P}_i$. If $y_i(\bar{p}+1) \in \mathcal{K}(\widehat{p})$ for some $\widehat{p} \le \bar{p}$, then node i must be stationary at each $p \in \mathcal{P}_i \cap \{p : \widehat{p} \le p \le \bar{p}\}$ and*

$$y_i(p) = y_i(\bar{p}+1) \tag{58}$$

for all such p.

Proof of Lemma 6. Let $p_1, p_2, \ldots, p_m$ denote the elements of the set $\mathcal{P}_i \cap \{p : \widehat{p} \le p \le \bar{p}\}$, ordered so that $p_1 < p_2 < \cdots < p_m = \bar{p}$. To prove the lemma it is sufficient to show that the following statements hold for $k \in \{1, 2, \ldots, m\}$:

(i) Node i is stationary at $p_k, p_{k+1}, \ldots, p_m$.

(ii) $y_i(p_k) = y_i(p_{k+1}) = \cdots = y_i(p_m) = y_i(\bar{p}+1)$.

Let $\bar{\mathcal{H}}(p_s) = \langle y_i(p_s), v_{ii_1}(p_s), \ldots, v_{ii_{m_i}}(p_s) \rangle$, $s \in \{1, 2, \ldots, m\}$. Note that u_m must satisfy the control law requirement $u_m(z_1, z_2, \ldots, z_m) \in \langle 0, z_1, \ldots, z_m \rangle$. In view of (33), it must therefore be true that

$$y_i(p_s + 1) \in \bar{\mathcal{H}}(p_s), \quad s \in \{1, 2, \ldots, m\}. \tag{59}$$

Note next that the definition of v_{ij} in (35) implies that $v_{ij}(p_s) \in \{y_j(p_s), w_j(p_s)\}$, $s \in \{1, 2, \dots, m\}$. Therefore $\bar{\mathcal{H}}(p_s) \subset \mathcal{H}_i(p_s)$. But $\mathcal{H}_i(p_s) \subset \mathcal{H}(p_s)$; moreover, $\mathcal{H}(p_s) \subset \mathcal{H}(\widehat{p})$ because of Lemma 5. Thus $\bar{\mathcal{H}}(p_s) \subset \mathcal{H}(\widehat{p})$. This implies that

$$\bar{\mathcal{H}}(p_s) \cap \mathcal{K}(\widehat{p}) \subset \bar{\mathcal{K}}(p_s), \quad s \in \{1, 2, \dots, m\}, \tag{60}$$

where $\bar{\mathcal{K}}(p_s)$ is the corner set of $\bar{\mathcal{H}}(p_s)$.

Recall that $p_m = \bar{p}$. By assumption, $y_i(\bar{p}+1) \in \mathcal{K}(\widehat{p})$. These facts and (59) imply that $y_i(p_m+1) \in \bar{\mathcal{H}}(p_m) \cap \mathcal{K}(\widehat{p})$. Thus $y_i(p_m+1) \in \bar{\mathcal{K}}(p_m)$ because of (60). Therefore node i is stationary at p_m, and because of this, $y_i(p_m+1) = y_i(p_m)$. Thus statements (i) and (ii) above are true for $k = m$. If $m = 1$, the proof is complete.

Suppose next that $m > 1$ and that statements (i) and (ii) hold for all $k \in \{q+1, \dots, m\}$ where q is some integer satisfying $1 < q+1 \le m$. In view of (36), $y_i(p) = y_i(p_{q+1})$ for $p_q < p \le p_{q+1}$. Therefore

$$y_i(p_q + 1) = y_i(p_{q+1}). \tag{61}$$

By hypothesis, (ii) holds for $k = q+1$; thus $y_i(p_q+1) = y_i(\bar{p}+1)$. Therefore $y_i(p_q+1) \in \mathcal{K}(\widehat{p})$. But $y_i(p_q+1) \in \bar{\mathcal{H}}(p_q)$ because of (59). Therefore $y_i(p_q+1) \in \bar{\mathcal{H}}(p_q) \cap \mathcal{K}(\widehat{p})$. From this and (60) it follows that $y_i(p_q+1) \in \bar{\mathcal{K}}(p_q)$. Therefore node i is stationary at p_q, and because of this $y_i(p_q+1) = y_i(p_q)$. Hence $y_i(p_q) = y_i(p_{q+1})$ because of (61). Thus statements (i) and (ii) above are true for $k = \{q, q+1, \dots, m\}$. By induction, statements (i) and (ii) must hold for all $k \in \{1, 2, \dots, m\}$. ∎

4.2.3. Equilibrium states. By an *equilibrium state* of $\mathbb{S}$ we mean a state which does not change under the action of (33)–(37) under any conditions for every value of $p \in \mathcal{P}$. It is easy to see that equilibrium states are precisely those states $\{y, w\} \in \mathcal{X}$ for which

$$y_i = y_{ii_1} = \cdots = y_{ii_{m_i}} = w_i = w_{ii_1} \cdots = w_{ii_{m_i}} \quad \forall i \in \{1, 2, \dots, n\}.$$

Note that each equilibrium state is invariant under the action of (33)–(37) under any and all possible conditions. It is clear that if $\mathbb{S}$ is in an equilibrium state at p, then each node of $\mathbb{S}$ is stationary at p. It is also not difficult to see that if each node of $\mathbb{S}$ is stationary at p, then $\mathbb{S}$ is at an equilibrium state at time $p+1$.

4.2.4. Locally rendezvoused nodes. In what follows we will say node $i \in \{1, 2, \dots, n\}$ has *locally rendezvoused* at time p if $\mathcal{H}_i(p)$ is a single point, i.e., if $y_i(p) = y_{i_1}(p) = \cdots = y_{i_{m_i}}(p) = w_i(p) = w_{i_1}(p) = \cdots = w_{i_{m_i}}(p)$. Note that if a node has locally rendezvoused at p, it must be stationary at p. The following proposition provides a criterion for a node of $\mathbb{S}$ to be locally rendezvoused.

PROPOSITION 4. *Let $p_1 < p_2 < p_3 < p_4$ be four consecutive values of p in $\mathcal{P}_i$. If $y_i(p_4+1) \in \mathcal{K}(p_1)$, then node i is locally rendezvoused at $p = p_3$.*

The proof of Proposition 4 depends on the following lemmas.

LEMMA 7. *Let p_1 and p_2 be two consecutive values of p in $\mathcal{P}_i$. Suppose for some $i \in \{1, 2, \dots, n\}$ that $y_i(p_2+1) \in \mathcal{K}(p_1)$. Then*

$$y_i(p_1) = y_j(p_1), \quad j \in \mathcal{N}_i. \tag{62}$$

Proof of Lemma 7. By hypothesis, $y_i(p_2+1) \in \mathcal{K}(p_1)$. Therefore by Lemma 6, $y_i(p_1) = y_i(p_2)$ and node i is stationary at both p_1 and p_2. Because node i is stationary at p_2, $y_i(p_2) = v_{ij}(p_2)$, $j \in \mathcal{N}_i$. Therefore

$$y_i(p_1) = v_{ij}(p_2), \ j \in \mathcal{N}_i. \tag{63}$$

To justify (62) it is therefore enough to show that

$$v_{ij}(p_2) = y_j(p_1),\ j \in \mathcal{N}_i. \tag{64}$$

For this fix $j \in \mathcal{N}_i$ and define $k = P_i^{-1}(p_1)$ and $q = \lceil \bar{t}_{ik} \rceil_j$. Since $p_1 = P_i(k)$ and $\bar{t}_{j(q-1)} < \bar{t}_{ik} \leq \bar{t}_{jq}$,

$$P_j(q-1) < p_1 \leq P_j(q). \tag{65}$$

Let $\bar{q} = \lceil \bar{t}_{i(k+1)} \rceil_j$. Since $p_2 = P_i(k+1)$ and $\bar{t}_{j(\bar{q}-1)} < \bar{t}_{i(k+1)} \leq \bar{t}_{j\bar{q}}$,

$$P_j(\bar{q}-1) < p_2 \leq P_j(\bar{q}). \tag{66}$$

By Lemma 2, $\bar{q} \in \{q, q+1, q+2\}$. We claim that no matter which value $\bar{q}$ takes,

$$v_{ij}(p_2) \in \{y_j(P_j(q)),\ y_j(P_j(q+1)),\ y_j(P_j(q+2))\}. \tag{67}$$

To justify this claim, consider first the case when $\bar{q} = q$. Then $\mathcal{S}_i(k+1) \cap \mathcal{S}_j(q) \succ \tau_S$ because of Lemma 2. In general $\bar{q} = \lceil t_{p_2} \rceil_j$ because $t_{p_2} = \bar{t}_{i(k+1)}$. Thus in this case $q = \lceil t_{p_2} \rceil_j$. In addition $k+1 = P_i^{-1}(p_2)$. Therefore $\mathcal{S}_i(P_i^{-1}(p_2)) \cap \mathcal{S}_j(\lceil t_{p_2} \rceil_j) \succ \tau_S$. From this and (35) it follows that $v_{ij}(p_2) = y_j(p_2)$. In view of (36), $y_j(p) = y_j(P_j(q))$ for all values of p in the range $P_j(q-1) < p \leq P_j(q)$. But $P_j(q-1) < p_2 \leq P_j(q)$ because of (66). Therefore $y_j(p_2) = y_j(P_j(q))$. Thus $v_{ij}(p_2) = y_j(P_j(q))$ which proves that (67) holds in this case.

Now suppose that $\bar{q} = \{q+1, q+2\}$. In this case $v_{ij}(p_2)$ equals either $y_j(p_2)$ or $w_j(p_2)$ because of (35). In view of (36), $y_j(p) = y_j(P_j(\bar{q}))$ for $P_j(\bar{q}-1) < p \leq P_j(\bar{q})$. From this and (66) it follows that $y_j(p_2) = y_j(P_j(\bar{q}))$. Thus if $v_{ij}(p_2) = y_j(p_2)$, then $v_{ij}(p_2) = y_j(P_j(\bar{q}))$. Since $\bar{q} \in \{q+1, q+2\}$, (67) must hold in this situation. To prove that (67) also holds in the alternative situation, when $v_{ij}(p_2) = w_j(p_2)$, we exploit the relation $w_j(P_j(\bar{q}-1)+1) = y_j(P_j(\bar{q}-1))$ which is valid because of (34). In view of (37), $w_j(p)$ is constant for p in the range $P_j(\bar{q}-1) < p \leq P_j(\bar{q})$. But p_2 is in this range because of (66); clearly $P_j(\bar{q}-1)+1$ is as well. Therefore $w_j(p_2) = w_j(P_j(\bar{q}-1)+1)$. It follows that $w_j(p_2) = y_j(P_j(\bar{q}-1))$. Thus if $v_{ij}(p_2) = w_j(p_2)$, then $v_{ij}(p_2) = y_j(P_j(\bar{q}-1))$. Since $\bar{q} \in \{q+1, q+2\}$, (67) must hold in this situation too. Thus (67) holds under all conditions.

It will now be shown that

$$v_{ij}(p_2) = y_j(P_j(q)). \tag{68}$$

Consider first the situation when $v_{ij}(p_2) = y_j(P_j(s))$, where s is fixed at either value in $\{q+1, q+2\}$. Since node i is stationary at p_2, $v_{ij}(p_2) = y_i(p_2+1)$. Thus $y_j(P_j(s)) = y_i(p_2+1)$. By hypothesis, $y_i(p_2+1) \in \mathcal{K}(p_1)$. Thus $y_j(P_j(s)) \in \mathcal{K}(p_1)$. Moreover, $p_1 \leq P_j(q)$ because of (65). Thus by Lemma 6, $y_j(P_j(s)) = y_j(P_j(q))$. Therefore (68) holds when $v_{ij}(p_2) = y_j(P_j(s))$ for $s \in \{q+1, q+2\}$. In view of (67), the only other possibility is $v_{ij}(p_2) = y_j(P_j(q))$. Therefore (68) is true under all conditions.

It remains to be shown that (64) holds. In view of (36), $y_j(p) = y_j(P_j(q))$ for p in the range $P_j(q-1) < p \leq P_j(q)$. But (65) shows that p_1 is in this range so $y_j(p_1) = y_j(P_j(q))$. From this and (68) it follows that (64) holds. □

LEMMA 8. *For any integers $i \in \{1, 2, \ldots, n\}$ and $k \geq 1$,*

$$P_i(k+1) - P_i(k) \leq 2(n-1). \tag{69}$$

Moreover, for any integer $j \in \{1,2,\dots,n\}$ which is not equal to i, there are at most two successive positive integers $s, s+1$ such that

$$P_i(k) \le P_j(s) < P_j(s+1) \le P_i(k+1). \tag{70}$$

Proof of Lemma 8. Fix $i,j \in \{1,2,\dots,n\}$ and $k>0$. Let s and p be positive integers such that $\bar{t}_{ik} \le \bar{t}_{js} < \bar{t}_{j(s+p)} \le \bar{t}_{i(k+1)}$. These inequalities imply that $\bar{t}_{j(s+p)} - \bar{t}_{js} < \bar{t}_{i(k+1)} - \bar{t}_{ik}$. But $p\tau_D \le \bar{t}_{j(s+p)} - \bar{t}_{js}$ because of (2) and $\bar{t}_{i(k+1)} - \bar{t}_{ik} < 2\tau_D$ because of (3). Therefore $p\tau_D < 2\tau_D$, so $p=1$. Thus there are at most two successive event times $\bar{t}_{js}$ and $\bar{t}_{j(s+1)}$ for which $\bar{t}_{ik} \le \bar{t}_{js} < \bar{t}_{j(s+1)} \le \bar{t}_{i(k+1)}$. Moreover, since $\{j : j \in \{1,2,\dots,n\},\ j \ne i\}$ contains $n-1$ integers, it therefore follows that the number of distinct event times in the set $\{\bar{t}_{js} : j \in \{1,2,\dots,n\},\ j \ne i,\ s \ge 1\}$ which satisfy $\bar{t}_{ik} \le \bar{t}_{js} \le \bar{t}_{i(k+1)}$ does not exceed $2(n-1)$. But $P_i(\cdot)$ and $P_j(\cdot)$ are strictly monotone increasing, and $\bar{t}_{iq} = t_{P_i(q)}$, $\bar{t}_{jq} = t_{P_j(q)}$ for all $q \ge 1$. Therefore (69) is true, and there are at most two successive integers $s, s+1$ for which (70) holds. □

Proof of Proposition 4. By hypothesis, $y_i(p_4+1) \in \mathcal{K}(p_1)$, and $p_1 < p_2 < p_3 < p_4$. Therefore by Lemma 6,

$$y_i(p_2) = y_i(p_3) = y_i(p_4) = y_i(p_4+1), \tag{71}$$

and node i is stationary at p_3 and p_4. In view of (34), $w_i(p_2+1) = y_i(p_2)$. But $w_i(p) = w_i(p_3)$ for $p_2 < p \le p_3$ because of (37), so $w_i(p_2+1) = w_i(p_3)$. Therefore $y_i(p_2) = w_i(p_3)$. From this and (71) it follows that

$$y_i(p_3) = w_i(p_3). \tag{72}$$

By hypothesis $y_i(p_4+1) \in \mathcal{K}(p_1)$. In addition, $y_i(p_4+1) \in \mathcal{H}(p_3)$ because of (71). Thus $y_i(p_4+1) \in \mathcal{K}(p_1) \cap \mathcal{H}(p_3)$. In view of Lemma 5, $\mathcal{H}(p_3) \subset \mathcal{H}(p_1)$. Thus $\mathcal{K}(p_1) \cap \mathcal{H}(p_3) \subset \mathcal{K}(p_3)$. Therefore $y_i(p_4+1) \in \mathcal{K}(p_3)$. Hence by Lemma 7,

$$y_i(p_3) = y_j(p_3), \quad j \in \mathcal{N}_i. \tag{73}$$

In view of (72) and (73), node i will be rendezvoused at p_3 provided that

$$y_j(p_3) = w_j(p_3), \ \ j \in \mathcal{N}_i. \tag{74}$$

It will now be shown that this is true.

Fix $j \in \mathcal{N}_i$ and let $q = \lceil \bar{t}_{ik} \rceil_j$, where $k = P_i^{-1}(p_3)$. Equivalently, q is the unique integer for which $P_j(q-1) < p_3 \le P_j(q)$. In view of (36) and (37), $y_j(p)$ and $w_j(p)$ are constant for p in the range $P_j(q-1) < p \le P_j(q)$. Since both p_3 and $P_j(q-1)+1$ are in this range,

$$y_j(p_3) = y_j(P_j(q-1)+1) \quad \text{and} \quad w_j(p_3) = w_j(P_j(q-1)+1). \tag{75}$$

Note next that $y_i(p_4+1) = y_i(p_4)$ because node i is stationary at p_4. From this and (71) and (73) it follows that $y_i(p_4+1) = y_j(p_3)$. Thus $y_i(p_4+1) = y_j(P_j(q-1)+1)$. Since $y_i(p_4+1) \in \mathcal{K}(p_1)$ it must be true that

$$y_j(P_j(q-1)+1) \in \mathcal{K}(p_1). \tag{76}$$

In view of Lemma 8, there can be at most two consecutive integers in $\mathcal{P}_j$ which are in the set $\{p : P_j(q-1) \le p \le P_j(q)\}$. Since p_3 is one such integer, it must be true that p_1 is not in the set. Therefore $p_1 < P_j(q-1)$. From this, (76), and Lemma 6 it follows that $y_j(P_j(q-1)+1) = y_j(P_j(q-1))$. But $w_j(P_j(q-1)+1) = y_j(P_j(q-1))$ because of (34), so $w_j(P_j(q-1)+1) = y_j(P_j(q-1)+1)$. From this and (75) it follows that $w_j(p_3) = y_j(p_3)$. Therefore (74) is true. □

4.3. Error system. To analyze system behavior it is helpful to use a suitably defined error system $\bar{\mathbb{S}}$ derived from $\mathbb{S}$. Towards this end, for each $p \in \mathcal{P}$ let

$$\left.\begin{array}{l} \bar{y}_i(p) \ = y_i(p) - w_n(p), \\ \bar{w}_i(p) = w_i(p) - w_n(p) \end{array}\right\}, \qquad i \in \{1, 2, \ldots, n\}. \tag{77}$$

Note that

$$\bar{w}_n(p) = 0, \quad p \in \mathcal{P}. \tag{78}$$

Using (33)–(37) we obtain the update equations for $\{\bar{y}_i, \bar{w}_i\}$ defined for $p \in \mathcal{P}_i$ by

$$\bar{y}_i(p+1) = \bar{y}_i(p) + u_{m_i}(\bar{v}_{ii_1}(p) - \bar{y}_i(p), \ldots, \ \bar{v}_{ii_{m_i}}(p) - \bar{y}_i(p)) - \omega(p)\bar{y}_n(p), \tag{79}$$

$$\bar{w}_i(p+1) = \bar{y}_i(p) - \omega(p)\bar{y}_n(p), \tag{80}$$

where

$$\bar{v}_{ij}(p) = \left\{\begin{array}{ll} \bar{y}_j(p) & \text{if } \mathcal{S}_i(P_i^{-1}(p)) \cap \mathcal{S}_j(\lceil t_p \rceil_j) \succ \tau_S, \\ \bar{w}_j(p) & \text{otherwise} \end{array}\right\}, \qquad j \in \mathcal{N}_i, \tag{81}$$

and by

$$\bar{y}_i(p+1) = \bar{y}_i(p) - \omega(p)\bar{y}_n(p), \tag{82}$$

$$\bar{w}_i(p+1) = \bar{w}_i(p) - \omega(p)\bar{y}_n(p) \tag{83}$$

for $p \notin \mathcal{P}_i$. Here $\omega(p) = 1$ if $p \in \mathcal{P}_n$ and $\omega(p) = 0$ otherwise. In terms of error variables, the neighbor constraints given by (38) can be written as

$$||\bar{y}_i(p) - \bar{w}_j(p)|| \leq r \ \text{ if } \ \mathcal{S}_i(P_i^{-1}(p)) \cap \mathcal{S}_j(\lceil t_p \rceil_j) \not\succ \tau_S, \ \ p \in \mathcal{P}_i \quad j \in \mathcal{N}_i. \tag{84}$$

In what follows $\bar{\mathbb{S}}$ denotes the error system defined by (79)–(84). Note that the state of $\bar{\mathbb{S}}$, namely $\{\bar{y}_1(p), \ldots, \bar{y}_n(p), \bar{w}_1(p), \ldots, \bar{w}_{n-1}(p)\}$, takes values in the closed space $\bar{\mathcal{X}}$ of all lists $\{\bar{y}_1, \ldots, \bar{y}_n, \bar{w}_1, \ldots, \bar{w}_{n-1}\}$ satisfying

$$\left.\begin{array}{l} \bar{y}_i, \bar{w}_i \in \mathbb{R}^2, \\ ||\bar{y}_i - \bar{y}_j|| \leq r \end{array}\right\}, \qquad j \in \mathcal{N}_i, \quad i \in \{1, 2, \ldots, n\}. \tag{85}$$

It is possible to describe the preceding state update equations concisely as

$$\bar{x}(p+1) = f(p, \bar{x}(p)), \quad p \in \mathcal{P},$$

where $\bar{x}$ is the state $\{\bar{y}_1, \ldots, \bar{y}_n, \bar{w}_1, \ldots, \bar{w}_{n-1}\}$, $f(p, \cdot) : \bar{\mathcal{X}}(p) \to \bar{\mathcal{X}}$ is the next state map defined by (79)–(83), and $\bar{\mathcal{X}}(p)$ is the set of states in $\bar{\mathcal{X}}$ for which the neighbor constraints (84) hold at time p. It is important to recognize that even though there are infinitely many possible values of p, there are only finitely many distinct $\bar{\mathcal{X}}(p)$ and finitely many distinct $f(p, \cdot)$. Moreover, each $\bar{\mathcal{X}}(p)$ is closed because of (84), and each $f(p, \cdot)$ is continuous on its domain because each $u_m(\cdot)$ is. The following lemma summarizes these observations.

LEMMA 9. *There exist a finite index set $\mathcal{Q}$ and a finite set of continuous functions $F_q : \mathcal{X}_q \to \bar{\mathcal{X}}$ with closed domains such that the following statement is true. For any $p \in \mathcal{P}$ there is a $q \in \mathcal{Q}$ such that $\bar{\mathcal{X}}(p) = \mathcal{X}_q$ and $F_q(\cdot) = f(p, \cdot)$.*

The implication of Lemma 9 is that if $\{\bar{x}(p) : p \in \mathcal{P}\}$ is a trajectory of $\bar{\mathbb{S}}$, then there are indices $q(p) \in \mathcal{Q}$, $p \in \mathcal{P}$ such that

$$\bar{x}(p) = F_{q(p)}F_{q(p-1)} \cdots F_{q(\tau+1)}(\bar{x}(\tau)), \quad p > \tau, \quad p, \tau \in \mathcal{P}. \tag{86}$$

Here $F_{q(p)}F_{q(p-1)} \cdots F_{q(\tau+1)}$ is a "composed function," where by the composition of functions F_s and F_q we mean the function $F_qF_s : \mathcal{X}_{qs} \to \bar{\mathcal{X}}$, whose domain $\mathcal{X}_{qs}$ is the inverse image of $\mathcal{X}_q$ under F_s, and whose action on $\bar{x}$ is $\bar{x} \longmapsto F_q(F_s(\bar{x}))$. Composition is an associative operation, and because of this, the operation extends unambiguously to finite families of F_q. Note that any such composed function $F = F_{q_1}F_{q_2} \cdots F_{q_k}$ has a closed domain on which it is continuous.

Suppose that $\bar{p} > 0$ is fixed. If follows from the preceding that there are $q(p) \in \mathcal{Q}$ such that

$$\bar{x}(p + \bar{p}) = F_{q(p+\bar{p})}F_{q(p+\bar{p}-1)} \cdots F_{q(p+1)}(\bar{x}(p)), \quad p \in \mathcal{P}. \tag{87}$$

It is important to recognize that even though the composed function $F_{q(p+\bar{p})}F_{q(p+\bar{p}-1)} \cdots F_{q(p+1)}(\bar{x}(p))$ depends on p, there can be only a finite number of such composed functions. This is because the family of maps $\{F_q : q \in \mathcal{Q}\}$ is a finite set and because the composed functions in question are all compositions of exactly $\bar{p}$ maps in the family. The following proposition summarizes these observations.

PROPOSITION 5. *Let $\bar{p} > 0$ be fixed. There exist a finite index set $\bar{\mathcal{Q}}$, a finite set of closed subsets $\bar{\mathcal{X}}_q \subset \bar{\mathcal{X}}$, and a finite set of continuous maps $D_q : \bar{\mathcal{X}}_q \to \bar{\mathcal{X}}$, $q \in \bar{\mathcal{Q}}$, with the following property. For each trajectory $\{\bar{x}(p) : p \in \mathcal{P}\}$ of $\bar{\mathbb{S}}$, and each $p \in \mathcal{P}$, there is a $q \in \bar{\mathcal{Q}}$ such that*

$$\bar{x}(\bar{p} + p) = D_q(\bar{x}(p)). \tag{88}$$

4.4. Global rendezvous. It is natural to say that the n nodes of $\mathbb{S}$ have (globally) *rendezvoused* at time p if $\mathcal{H}(p)$ is a single point, i.e., if $y_1(p) = y_2(p) = \cdots = y_n(p) = w_1(p) = w_2(p) = \cdots = w_n(p)$. In view of the definitions of t_p and the y_i and w_i in (39), it is clear that the rendezvousing of all n nodes at time p implies the rendezvousing of all n agents at time t_p. It is also clear that the rendezvousing of all n nodes at time p implies that each node has locally rendezvoused at p. Under certain conditions the converse is also true.

LEMMA 10. *Suppose $\mathbb{G}$ is a connected graph. Suppose in addition that $\{\{y(p), w(p)\} : p \in \mathcal{P}\}$ is the trajectory of $\mathbb{S}$ defined by (39). If for some $i \in \{1, 2, \ldots, n\}$ and $p \in \mathcal{P}_i$, node i is locally rendezvoused, then the n nodes of $\mathbb{S}$ have globally rendezvoused.*

Proof of Lemma 10. Suppose node i is locally rendezvoused at $p \in \mathcal{P}_i$. Then $y_i(p) = y_j(p)$ and $w_i(p) = y_j(p), j \in \mathcal{N}_i$. Moreover, since node i is locally rendezvoused at p, it must be stationary at p. Therefore $y_i(p+1) = y_i(p)$; in addition, $w_i(p+1)) = y_i(p)$ because of (34). Thus $y_i(p+1) = y_j(p)$ and $w_i(p+1) = y_j(p)$, $j \in \mathcal{N}_i$. Fix $j \in \mathcal{N}_i$ and $k \in \mathcal{N}_j$. Then $||y_j(p) - y_k(p)|| \leq r$ because of the definition of $\mathcal{X}$. Therefore $||y_i(p+1) - y_k(p)|| \leq r$ and $||w_i(p+1) - y_k(p)|| \leq r$. It follows from Lemma 4 that $k \in \mathcal{N}_i$. Since this holds for every $k \in \mathcal{N}_j$, it must be true that $\mathcal{N}_j \subset \mathcal{N}_i$. Since j is arbitrary, this must be true for all $j \in \mathcal{N}_i$. Since $\mathbb{G}$ is connected, this can happen only if $\mathbb{G}$ is complete. Thus $\mathcal{N}_i = \{1, 2, \ldots, n\}$ which means that $\mathcal{H}_i(p) = \mathcal{H}(p)$. By hypothesis $\mathcal{H}_i(p)$ is a single point. Therefore $\mathcal{H}_i(p)$ is also a single point, so the n nodes of $\mathbb{S}$ have globally rendezvoused. □

Establishing the preceding result requires one to be able to conclude that if for some $i, j \in \{1, 2, \ldots, n\}$ and some $p \in \mathcal{P}_i$, nodes i and j are in the same "position" in

the sense that $y_i(p) = y_j(p) = w_i(p)$, then $\mathcal{N}_j \subset \mathcal{N}_i$. In words, what this is roughly saying is that if node j is in the same position as node i, then node j's "neighbors" must also be neighbors of node i. This *transitivity property* is not true in general, but it is true if $y(p)$ and $w(p)$ are defined by (39). This is a consequence of Lemma 4.

The following proposition shows that if $\mathcal{H}$ does not change for a sufficiently long period of time, then the n nodes have rendezvoused.

PROPOSITION 6. *Suppose that $\mathbb{G}$ is a connected graph. Suppose in addition that $\{y(p), w(p) : p \in \mathcal{P}\}$ is the trajectory of $\mathbb{S}$ defined by* (39). *Suppose that p_a and p_b are values in $\mathcal{P}$ for which $p_b - p_a \geq 8n$ and*

$$\operatorname{dia}\{\mathcal{H}(p_a)\} = \operatorname{dia}\{\mathcal{H}(p_b)\}. \tag{89}$$

Then the n nodes of $\mathbb{S}$ have rendezvoused at $p = p_b$.

Proof of Proposition 6. Choose $i \in \{1, 2, \ldots, n\}$ so that for some $z \in \mathcal{H}(p_b)$, $||y_i(p_b) - z|| = \operatorname{dia}\{\mathcal{H}(p_b)\}$. Then $y_i(p_b) \in \mathcal{K}(p_b)$. In view of Lemma 5, $\mathcal{H}(p_b) \subset \mathcal{H}(p_a)$. Therefore $y_i(p_b), z \in \mathcal{H}(p_a)$. Moreover, $||y_i(p_b) - z|| = \operatorname{dia}\{\mathcal{H}(p_a)\}$ because of (89); thus

$$y_i(p_b) \in \mathcal{K}(p_a). \tag{90}$$

Let p_4 be the largest value of $p \in \mathcal{P}_i$ such that $p_4 < p_b$. Define $k = P_i^{-1}(p_4) - 3$ so that $P_i(k+3) = p_4$. Then $p_4 < p_b \leq P_i(k+4)$. By (69),

$$p_b - p_4 \leq 2(n-1). \tag{91}$$

In view of (36), $y_i(p)$ is constant for p in the range $p_4 < p \leq P_i(k+4)$. Since both $p_4 + 1$ and p_b are in this range, $y_i(p_4 + 1) = y_i(p_b)$. Thus

$$y_i(p_4 + 1) \in \mathcal{K}(p_a). \tag{92}$$

Define $p_1 = P_i(k)$, $p_2 = P_i(k+1)$, and $p_3 = P_i(k+2)$. Clearly $p_1 < p_2 < p_3 < p_4$. Moreover, $p_{j+1} - p_j \leq 2(n-1)$, $j \in \{1, 2, 3\}$, because of (69). From these inequalities and (91) it follows that $p_b - p_1 \leq 8(n-1)$. By hypothesis, $p_b - p_b \geq 8n$. Therefore $p_a < p_1$. In view of Lemma 5, $\mathcal{H}(p_4) \subset \mathcal{H}(p_1)$ and $\mathcal{H}(p_1) \subset \mathcal{H}(p_a)$. Therefore $\mathcal{H}(p_1) \cap \mathcal{K}(p_a) \subset \mathcal{K}(p_1)$. But $\mathcal{H}(p_4 + 1) \subset \mathcal{H}(p_1)$ because of Lemma 5; thus $y_i(p_4 + 1) \in \mathcal{H}(p_1)$. This and (92) imply that $y_i(p_4 + 1) \in \mathcal{H}(p_1) \cap \mathcal{K}(p_a)$. Therefore $y_i(p_4 + 1) \in \mathcal{K}(p_1)$. From this and Proposition 4 it follows that node i has locally rendezvoused at p_3. Therefore by Lemma 10, the n nodes of $\mathbb{S}$ are rendezvoused at p_3. □

The following theorem is our main convergence result concerning $\mathbb{S}$. The main result of this paper, Theorem 1, is an immediate consequence.

THEOREM 2. *Let $\{\{y(s), w(s)\} : p \in \mathcal{P}\}$ be the trajectory of $\mathbb{S}$ defined by* (39). *If $\mathbb{G}$ is a connected graph, then*

$$\lim_{s \to \infty} \operatorname{dia}\langle y_1(s), y_2(s), \ldots, y_n(s), w_1(s), w_2(s), \ldots, w_n(s)\rangle = 0. \tag{93}$$

Proof of Theorem 2. In what follows we write $x(p)$ for $\{y_1(p), \ldots, y_n(p), w_1(p), \ldots, w_n(p)\}$ and $\bar{x}(p)$ for the error vector $\{\bar{y}_1(p), \ldots, \bar{y}_n(p), \bar{w}_1(p), \ldots, \bar{w}_{n-1}(p)\}$ defined by (77). Let $V : \mathcal{X} \to \mathbb{R}$ denote the diameter function $x \longmapsto \operatorname{dia}\langle y_1, y_2, \ldots, y_n, w_1, w_2, \ldots, w_n\rangle$. Similarly, let $\bar{V} : \bar{\mathcal{X}} \to \mathbb{R}$ denote the diameter function $\bar{x} \longmapsto \operatorname{dia}\langle \bar{y}_1, \bar{y}_2, \ldots, \bar{y}_n, \bar{w}_1, \bar{w}_2, \ldots, w_{n-1}, 0\rangle$. Note that

$$V(x(p)) = \bar{V}(\bar{x}(p)). \tag{94}$$

Note in addition that because $0 \in \langle \bar{y}_1, \bar{y}_2, \ldots, \bar{y}_n, \bar{w}_1, \bar{w}_2, \ldots, w_{n-1}, 0\rangle$, $\bar{V}$ is radially unbounded, whereas V is not.

As a consequence of Lemma 5, $V(x(p))$ is a monotone nonincreasing function of p. Clearly $V(x(p))$ is bounded below by 0. Moreover, $V(x(p))$ is bounded above by $V(x(0))$ because $V(\cdot)$ is continuous. Therefore there must exist a finite limit

$$V^* = \lim_{p\to\infty} V(x(p)).$$

We claim that $V^* = 0$. To prove this claim, suppose it is false. Then $V^* > 0$. This means that the trajectory $\{x(p) : p \in \mathcal{P}\}$ cannot contain any points in the set $\mathcal{E} = \{x : V(x) = 0\}$. To proceed, fix $\bar{s} > 8n$ and let $\Delta(x(p))$ denote the difference

$$\Delta(x(p)) = V(x(\bar{p} + p)) - V(x(p)). \tag{95}$$

Since $V(x(p))$ is monotone nonincreasing, $\Delta(x(p)) \leq 0, p \in \mathcal{P}$. In the light of Proposition 6 and the fact that $\mathcal{E}$ has no points in common with $\{x(p) : p \in \mathcal{P}\}$, one can conclude that $\Delta(x(p)) \neq 0, p \in \mathcal{P}$. Therefore

$$\Delta(x(p)) < 0, \quad p \in \mathcal{P}. \tag{96}$$

Define $\bar{\Delta}(\bar{x}(p))$ as

$$\bar{\Delta}(\bar{x}(p)) = \bar{V}(\bar{x}(\bar{p} + p)) - \bar{V}(\bar{x}(p)). \tag{97}$$

In view of (94)

$$\Delta(x(p)) = \bar{\Delta}(\bar{x}(p)). \tag{98}$$

Therefore

$$\bar{\Delta}(\bar{x}(p)) < 0, \quad p \in \mathcal{P}. \tag{99}$$

According to Proposition 5, for each $p \in \mathcal{P}$ there is a continuous function D_q such that $\bar{x}(p + \bar{p}) = D_q(x(p))$. Let $\mathcal{W}_q$ denote the set of state pairs $(\bar{x}(p + \bar{p}), \bar{x}(p))$ along the given trajectory of $\bar{\mathbb{S}}$ for which this formula holds. It follows that

$$\{(x(s + \bar{s}), x(s)) : s \in \mathcal{S}\} = \bigcup_{q\in\mathcal{Q}} \mathcal{W}_q$$

and that each $\mathcal{W}_q$ is a closed set. We claim that each $\mathcal{W}_q$ is bounded as well. This is in fact so because of (94), because $\bar{V}$ is radially unbounded, and because $0 \leq V(x(p)) \leq V(x(0)) < \infty$.

For $(\widehat{x}, \bar{x}) \in \mathcal{W}_q$ define $\Delta_q : \mathcal{W}_q \to \mathbb{R}$ so that $(\widehat{x}, \bar{x}) \longmapsto \bar{V}(D_q(\widehat{x})) - V(\bar{x})$. Note that Δ_q is a continuous function on $\mathcal{W}_q$ whose value at each point $(\widehat{x}, \bar{x}) \in \mathcal{W}_q$ agrees with $\bar{\Delta}(\bar{x}(p))$ for some p. It follows from (99) that

$$\Delta_q(\widehat{x}, \bar{x}) < 0, \quad (\widehat{x}, \bar{x}) \in \mathcal{W}_q.$$

Define

$$\mu_q = \sup_{(\widehat{x},\bar{x})\in\mathcal{W}_q} \Delta_q(\widehat{x}, \bar{x}).$$

Since $\mathcal{W}_q$ is compact and Δ_q is negative and continuous on $\mathcal{W}_q$, it must be true that $\mu_q < 0$. Let

$$\mu = \max_{q \in \mathcal{Q}} \mu_i.$$

Since $\mathcal{Q}$ is finite, $\mu < 0$. Clearly

$$\Delta_q(\widehat{x}, \bar{x}) \leq \mu, \quad (\widehat{x}, \bar{x}) \in \mathcal{W}_q, \quad q \in \mathcal{Q}. \tag{100}$$

Note that by construction, for each $p \in \mathcal{S}$ there must be a $q \in \mathcal{Q}$ such that $\bar{\Delta}(\bar{x}(p)) = \Delta_q(\bar{x}(p + \bar{p}), \bar{x}(p))$. From this and (100) it follows that

$$\bar{\Delta}(\bar{x}(p)) \leq \mu, \quad p \in \mathcal{P}.$$

Therefore

$$\Delta(x(p)) \leq \mu, \quad p \in \mathcal{P},$$

because of (98). Note that

$$V(x(p + \bar{p})) - V(x(p)) = \Delta(x(p)) \leq \mu, \quad p \in \mathcal{P}.$$

Thus by summing,

$$V(x(p + k\bar{p})) \leq V(x(p)) + k\mu, \quad k \geq 1.$$

Therefore, for k sufficiently large $V(x(p + k\bar{p}))$ must be negative because $\mu < 0$. But this is impossible because $V(\cdot)$ is positive semidefinite. Hence V^* cannot be positive. This concludes the proof. □

5. Concluding remarks. The analysis used in this paper exploits ideas which appear to have much in common with the embedding process discussed in Chapter 7 of [2] for analyzing "partially asynchronous iterative algorithms." This suggests that the tools developed in [2] may be helpful in further understanding the asynchronous system considered in this paper.

The asynchronous multi-agent rendezvous problem we have considered serves as an example of the type of problem to which the idea of analytic synchronization can be applied. The asynchronous version of the flocking problem considered in [3] provides another. Despite these examples, there are several unsettled issues concerning the analytic synchronization idea. First, it is not clear what the general process is for choosing a state vector. Second, it is also not clear what the exact conditions are on an asynchronously interacting set of dynamical systems for analytic synchronization to be possible. The examples provided by this paper and by [3] may help to more precisely formulate these issues and to lead to their resolution.

THE ANALYSIS OF EXACT CONTROLLABILITY OF NEUTRAL-TYPE SYSTEMS BY THE MOMENT PROBLEM APPROACH*

RABAH RABAH† AND GRIGORY M. SKLYAR‡

Abstract. The problem of exact null-controllability is considered for a wide class of linear neutral-type systems with distributed delay. The main tool of the analysis is the application of the moment problem approach and the theory of the basis property of exponential families. A complete characterization of this problem is given. The minimal time of controllability is specified. The results are based on the analysis of the Riesz basis property of eigenspaces of the neutral-type systems in Hilbert space.

Key words. neutral-type systems, exact controllability, moment problem, Riesz basis, distributed delays

1. Introduction.

Many applied problems from physics, mechanics, biology, and other fields can be described by partial differential equations or delay differential equations. This leads to the construction and study of the infinite-dimensional system theory concerning also the systems with control. In this context the problem of controllability for distributed parameter systems leads to the study of the abstract controllability problem in infinite-dimensional spaces, which may be formulated in Hilbert spaces as follows. Consider the abstract system

$$\dot{x} = \mathcal{A}x + \mathcal{B}u, \tag{1.1}$$

where $x(t) \in X, u(t) \in U$, X and U being Hilbert spaces, $\mathcal{A}$ is the generator of a C_0-semigroup $\mathrm{e}^{\mathcal{A}t}$, and $\mathcal{B} \in \mathcal{L}(U, X)$ is a bounded operator. The problem of controllability is to find all the states x_T that can be reached from a fixed initial state (say 0) at a finite time T by the choice of the controls $u(\cdot) \in L_2(0, T; U)$. The mild solution of the system (1.1) is given by

$$x(t) = \mathrm{e}^{\mathcal{A}t}x(0) + \int_0^t \mathrm{e}^{\mathcal{A}(t-\tau)}\mathcal{B}u(\tau)\mathrm{d}\tau.$$

The reachability set from 0 at time T is defined by

$$\mathcal{R}_T = \left\{ x : x = \int_0^T \mathrm{e}^{\mathcal{A}t}\mathcal{B}u(t)\mathrm{d}t, \quad u(\cdot) \in L_2(0, T; U) \right\}.$$

For finite-dimensional systems the natural concept of controllability is when $\mathcal{R}_T = X$ (Kalman). For infinite-dimensional systems, as has been pointed out by several authors (Fattorini, Triggiani, Russel, Balakrishnan, and others), this concept is not realistic. It is easy to show that $\mathcal{R}_{T_1} \subset \mathcal{R}_{T_2}$ as $T_1 < T_2$. In general, there is no universal time T_0 such that $\mathcal{R}_{T_0} = \mathcal{R}_T$ for all $T > T_0$. However, for several classes of systems important for application this property holds (hyperbolic-type and neutral-type systems). In these cases, a natural way to formulate the controllability problem is the following setting:

(i) to find the maximal possible set $\mathcal{R}_T$ (depending on T),

(ii) to find the minimal T for which the set $\mathcal{R}_T$ becomes the maximal possible.

In order to obtain more profound and precise results by using this approach, it is important to consider a concrete class of systems and to use the specificity of this class. In this paper, we consider the problem of controllability for a general class of neutral systems with distributed delays given by the equation

$$\begin{cases} \dfrac{\mathrm{d}}{\mathrm{d}t}[z(t) - Kz_t] = Lz_t + Bu(t), \quad t \geq 0, \\ z_0 = f, \end{cases} \tag{1.2}$$

where $z_t : [-1, 0] \to \mathbb{C}^n$ is the history of z defined by $z_t(s) = z(t + s)$. The difference and delay operators K and L, respectively, are defined by

$$Kf = A_{-1}f(-1) \quad \text{and} \quad Lf = \int_{-1}^{0} A_2(\theta)\frac{\mathrm{d}}{\mathrm{d}\theta}f(\theta)\,\mathrm{d}\theta + \int_{-1}^{0} A_3(\theta)f(\theta)\,\mathrm{d}\theta$$

for $f \in H^1([-1, 0], \mathbb{C}^n)$, where A_{-1} is a constant $n \times n$ matrix, A_2, A_3 are $n \times n$ matrices whose elements belong to $L_2(-1, 0)$, and B is a constant $n \times r$ matrix.

We consider the operator model of the neutral-type system (1.2) introduced by Burns, Herdman, and Stech [3] in product spaces (see also [5]). The state space is $M_2(-1, 0; \mathbb{C}^n) = \mathbb{C}^n \times L_2(-1, 0; \mathbb{C}^n)$, shortly M_2, and (1.2) can be reformulated as

$$\dot{x}(t) = \mathcal{A}x(t) + \mathcal{B}u(t), \quad x(0) = \begin{pmatrix} y \\ f \end{pmatrix}, \quad \mathcal{B} = \begin{pmatrix} B \\ 0 \end{pmatrix}, \quad \mathcal{A} = \begin{pmatrix} 0 & L \\ 0 & \frac{\mathrm{d}}{\mathrm{d}\theta} \end{pmatrix}, \tag{1.3}$$

with $\mathcal{D}(\mathcal{A}) = \{(y, z(\cdot)) \in M_2 : z \in H^1([-1, 0]; \mathbb{C}^n), y = z(0) - A_{-1}z(-1)\}$.

In the particular case when $A_2(\theta) = A_3(\theta) = 0$, which corresponds to $L = 0$, we will use the notation $\widetilde{\mathcal{A}}$ for $\mathcal{A}$.

Suppose that the initial condition for the system (1.2) is $z(t) = z_0(t), t \in [-1, 0]$, and let us put $z_t(\theta) = z(t + \theta), \theta \in [-1, 0]$, and $y = z(0) - A_{-1}z(-1)$. The semigroup generated by $\mathcal{A}$ is given by

$$\mathrm{e}^{\mathcal{A}t}\begin{pmatrix} y \\ z_0(\cdot) \end{pmatrix} = \begin{pmatrix} z_t(0) - A_{-1}z_t(-1) \\ z_t(\cdot) \end{pmatrix} = \begin{pmatrix} z(t) - A_{-1}z(t-1) \\ z(t + \cdot) \end{pmatrix}.$$

It can be shown that the reachability set $\mathcal{R}_T$ is such that $\mathcal{R}_T \subset \mathcal{D}(\mathcal{A})$ for all $T > 0$. This is a consequence of the fact that for all $u(\cdot) \in L_2$ the corresponding solution of (1.2) is in H^1 and then the solution of (1.3) is in $\mathcal{D}(\mathcal{A})$ (see [5, Proposition 2.2] for the existence of the solution and [5, Corollary 2.7] for the property of the reachability subset). This naturally leads to the following definition of exact controllability.

Definition 1.1. *The system* (1.3) *is exactly null-controllable by controls from* L_2 *at the time* T *if* $\mathcal{R}_T = \mathcal{D}(\mathcal{A})$. *This means that the set of solutions of the system* (1.2), $\{z(t), t \in [T - 1, T]\}$, *coincides with* $H^1([T - 1, T]; \mathbb{C}^n)$.

This problem was the focus of attention of several authors in the 1970s and 1980s. The main results were devoted to systems with one or several discrete delays. This may be explained by the fact that the explicit, in this case, form of solutions is known and, as a result, the semigroup describing the solutions of (1.2) is known explicitly.

The main result for the system

$$\dot{z}(t) - A_{-1}\dot{z}(t-h) = A_0 z(t) + A_1 z(t-h) + Bu$$

is that the exact controllability holds if and only if (see [9, 12])

(i) $\operatorname{rank}(\,\Delta(\lambda) \quad B\,) = n$,

(ii) $\operatorname{rank}(\,B \quad A_{-1}B \quad \cdots \quad A_{-1}^{n-1}B\,) = n$,

where $\Delta(\lambda) = \lambda I - \lambda A_{-1}\mathrm{e}^{-\lambda h} - A_0 - A_1\mathrm{e}^{-\lambda h}$. For the particular case of scalar control (B is $n \times 1$ matrix) the time of exact controllability is given in [6]: $T > nh$, where h is the delay. For the general case, it is shown in [2] that the reachability set cannot increase for $T > nh$.

The case of noncommensurate delays with a distributed term was precisely studied in the paper by Yamamoto [16]. General conditions were given using the input-output technique. Conditions of approximate controllability (in [16], quasi reachability) in the time domain were explicitly given for a system without distributed delay (see also [8]).

In contrast to the above-mentioned works, we consider the model with distributed delays (1.2). In this case, we know only that the solution of (1.2) exists but the corresponding semigroup is not explicitly known. Then the technique using the explicit form of the solution, via an expression of the semigroup, cannot be used. So one needs another tool to analyze the controllability. In the similar situation of the controllability problems for hyperbolic systems, the powerful technique of the moment problem has been proved to be useful. It is caused by the fact that the operators corresponding to hyperbolic systems are as a rule skew-adjoint or close to skew-adjoint and then they possess a basis of eigenvectors. The expansion of the steering conditions in this basis allows the controllability problem for these systems to be reduced to a trigonometric problem with respect to some families of exponentials. Thus, the further analysis concerns the solvability of the non-Fourier trigonometric moment problem and is based on the profound theory of the Riesz bases of exponentials. This theory, originated by the famous Paley–Wiener theorem, has essentially been developed in the last decades (see monographs by Avdonin and Ivanov [1] and by Young [17] and the references therein).

The main idea of our work is to apply the moment problem method to the analysis of controllability of neutral-type systems. Note in this context that the case of neutral-type systems differs essentially from those mentioned above since the operator $\mathcal{A}$ of the system is not skew-adjoint and, moreover, may not have a basis of eigenvectors or even generalized eigenvectors. The first element of our consideration is the spectral analysis of the operator model (1.3) given in our previous works, together with Rezounenko [10, 11]. In these papers, it is shown that, under the condition that the matrix A_{-1} is not singular, the operator $\mathcal{A}$ (even if it does not verify the Riesz basis property) possesses a Riesz basis of finite-dimensional invariant subspaces. This allows the construction of a special Riesz basis in the space M_2 in which the steering conditions

$$\begin{pmatrix} y_T \\ z_T(\cdot) \end{pmatrix} = \int_0^T \mathrm{e}^{\mathcal{A}(T-\tau)}\mathcal{B}u(\tau)\mathrm{d}\tau \tag{1.4}$$

take the form of a moment problem quadratically close to some special non-Fourier moment problems with respect to a family of quasi polynomials. These questions are

considered in sections 2 and 3. Let us notice that the detailed attention accorded to the construction of the needed Riesz basis is essentially motivated by the fact that, in the general case, the operator $\mathcal{A}$ may not possess a spectral Riesz basis. Otherwise, for example, if the eigenvalues of the matrix A_{-1} are simple, our construction would be much simpler. The main tool of the analysis of solvability of the obtained moment problem is based on the theory of families of exponentials [1, 17]. The basic elements of this approach used in our paper are given in section 4. Below we give a complete analysis of the controllability problem for neutral-type systems. In the course of the main part of the work, we consider the case when $\det A_{-1} \neq 0$. In this case, the controllability of system (1.2) is equivalent to the solvability of the moment problem obtained in section 3. We consider first the single input case in section 5 and give not only the conditions of exact null-controllability but also determine the time of controllability. These results are an extension of the result obtained in [6]. In section 6, we consider the solvability of the moment problem for the multivariable case ($\dim B = n \times r, r > 1$). We introduce some special indices m_1 and $\overline{m}$ which enable the moment problem to be characterized. We show that the exact null-controllability holds for time $T > \overline{m}$ and does not hold for $T < m_1$. Finally, we complete the results on controllability by getting rid of the assumption $\det A_{-1} \neq 0$ in section 7. We then obtain the precise time of controllability using the first controllability index of the pair (A_{-1}, B), say n_1 (cf., for example, [15, Chapter 5]). Our main result is the following.

THEOREM 1.2. *The system* (1.3) *is exactly null-controllable if and only if the following conditions are verified.*

(i) *There is no* $\lambda \in \mathbb{C}$ *and* $y \in \mathbb{C}^n, y \neq 0$, *such that* $\Delta^*_{\mathcal{A}}(\lambda)y = 0$ *and* $B^*y = 0$, *where*

$$\Delta^*_{\mathcal{A}}(\lambda) = \lambda I - \lambda \mathrm{e}^{-\lambda} A^*_{-1} - \lambda \int_{-1}^{0} \mathrm{e}^{\lambda s} A^*_2(s)\mathrm{d}s - \int_{-1}^{0} \mathrm{e}^{\lambda s} A^*_3(s)\mathrm{d}s,$$

or equivalently $\operatorname{rank}(\,\Delta_{\mathcal{A}}(\lambda) \quad B\,) = n$ *for all* $\lambda \in \mathbb{C}$.

(ii) *There is no* $\mu \in \sigma(A_{-1})$ *and* $y \in \mathbb{C}^n, y \neq 0$, *such that* $A^*_{-1}y = \bar{\mu}y$ *and* $B^*y = 0$, *or equivalently* $\operatorname{rank}(\,B \quad A_{-1}B \quad \cdots \quad A^{n-1}_{-1}B\,) = n$.

If conditions (i) *and* (ii) *hold, then the system is controllable at the time* $T > n_1$ *and not controllable at the time* $T \leq n_1$, *where* n_1 *is the controllability index of the pair* (A_{-1}, B).

If the delay is h instead of 1, the time of exact controllability is $T = n_1 h$.

2. The choice of the basis. In this section, we assume that the matrix A_{-1} is not singular, $\det A_{-1} \neq 0$.

Let us recall [10] that the spectrum of $\widetilde{\mathcal{A}}$ (the state operator corresponding to the case $A_2 = A_3 = 0$) consists of only the eigenvalues that are the roots of the equation $\det \Delta_{\widetilde{\mathcal{A}}}(\lambda) = \det(\lambda I - \lambda \mathrm{e}^{-\lambda} A_{-1}) = 0$, i.e.,

$$\sigma(\widetilde{\mathcal{A}}) = \{\lambda^{(k)}_m = \ln|\mu_m| + \mathrm{i}(\arg \mu_m + 2k\pi)\} \cup \{0\},$$

where $\{\mu_m, m = 1, \ldots, \ell\} = \sigma(A_{-1})$.

The operator $\widetilde{\mathcal{A}}$ possesses a Riesz basis of generalized eigenvectors which may be characterized as follows (see [10, 11]).

Let ν_m be the number of Jordan blocks corresponding to $\mu_m \in \sigma(A_{-1})$ and let $p_{m,j},\ j = 1, \ldots, \nu_m$, be the dimension of the corresponding blocks; then

1. to any $\lambda_m^{(k)} \neq 0$ and to any $j = 1, \dots, \nu_m$ there corresponds a Jordan chain of generalized eigenvectors of $\widetilde{\mathcal{A}}$, noted $\{\widetilde{\varphi}_{m,k}^{j,1}, \widetilde{\varphi}_{m,k}^{j,2}, \dots, \widetilde{\varphi}_{m,k}^{j,p_{m,j}}\}$ such that

$$\widetilde{\mathcal{A}}\widetilde{\varphi}_{m,k}^{j,1} = \lambda_m^{(k)}\widetilde{\varphi}_{m,k}^{j,1}, \quad (\widetilde{\mathcal{A}} - \lambda_m^{(k)} I)\widetilde{\varphi}_{m,k}^{j,s} = \widetilde{\varphi}_{m,k}^{j,s-1}, \qquad s = 2, \dots, p_{m,j};$$

2. the root space of $\widetilde{\mathcal{A}}$ corresponding to $0 \in \sigma(\widetilde{\mathcal{A}})$ is of dimension

$$n + \dim \operatorname{Ker}(A_{-1} - I)^n.$$

If $1 = \mu_g \in \sigma(A_{-1}),\ g \in \{1, \dots, \ell\}$, then for any $j \in \{1, \dots, \nu_g\}$ there exists a Jordan chain $\{\widetilde{\varphi}_0^{j,1}, \widetilde{\varphi}_0^{j,2}, \dots, \widetilde{\varphi}_0^{j,p_{g,j}+1}\}$ such that

$$\widetilde{\mathcal{A}}\widetilde{\varphi}_0^{j,1} = 0, \quad \widetilde{\mathcal{A}}\widetilde{\varphi}_0^{j,s} = \widetilde{\mathcal{A}}\widetilde{\varphi}_0^{j,s-1}, \qquad s = 2, \dots, p_{m,j} + 1,$$

and, besides, there exist $n - \nu_g$ linearly independent eigenvectors $\widetilde{\varphi}_0^j,\ j = \nu_g + 1, \dots, n$, such that $\widetilde{\mathcal{A}}\widetilde{\varphi}_0^j = 0$;

3. any collection $\{\widetilde{\varphi}_{m,k}^{j,s},\ s = 1, \dots, p_{m,j},\ j = 1, \dots, \nu_m\}$ forms a basis in the space $\operatorname{Ker}(\widetilde{\mathcal{A}} - \lambda_m^{(k)} I)^n,\ \lambda_m^{(k)} \neq 0$. The collection

$$\{\widetilde{\varphi}_0^{j,s},\ s = 1, \dots, p_{m,j} + 1,\ j = 1, \dots, \nu_m\} \bigcup \{\widetilde{\varphi}_0^j,\ j = \nu_g + 1, n\}$$

forms a basis in $\operatorname{Ker}\widetilde{\mathcal{A}}^n$.

In the following, we refer to this basis as $\{\widetilde{\varphi}\}$ omitting the indices when they are not necessary. The concrete form of interest to us is that which corresponds to the nonzero eigenvalues and then takes the form

$$\widetilde{\varphi}_{m,k}^{j,s} = \begin{pmatrix} 0 \\ \mathrm{e}^{\lambda_m^{(k)} t} P_m^{j,s}(\theta) \end{pmatrix} \tag{2.1}$$

with

$$P_m^{j,s}(\theta) = \sum_{r=1}^{s} D_{m,j}^r \sum_{i=0}^{s-r} \beta_r^{i,s} \frac{\theta^i}{i!}. \tag{2.2}$$

The constant vectors $D_{m,j}^i$ form a basis in $\mathbb{C}^n$ designed from the Jordan chains of the matrices A_{-1}. These vectors and the constants $\beta_q^{i,s}$ in the polynomials $P(\theta)$ do not depend on k.

This gives that, in particular,

$$\inf\{\|\widetilde{\varphi}_{m,k}^{j,s}\|, k \in \mathbb{Z}\} = \rho > 0, \qquad \sup\{\|\widetilde{\varphi}_{m,k}^{j,s}\|, k \in \mathbb{Z}\} = R < \infty. \tag{2.3}$$

The corresponding biorthogonal basis to $\{\widetilde{\varphi}\}$ will be denoted by $\{\widetilde{\psi}\}$.

PROPOSITION 2.1. *For any m, k the vectors of the biorthogonal basis $\{\widetilde{\psi}\}$ form the following Jordan chain with respect to the adjoint operator $\widetilde{\mathcal{A}}^*$:*

$$(\widetilde{\mathcal{A}}^* - \bar{\lambda}_m^{(k)} I)\widetilde{\psi}_{m,k}^{j,p_{m,j}} = 0, \qquad (\widetilde{\mathcal{A}}^* - \bar{\lambda}_m^{(k)} I)\widetilde{\psi}_{m,k}^{j,s} = \widetilde{\psi}_{m,k}^{j,s+1}, \qquad s = 0, \dots, p_{m,j} - 1,$$

where $\bar{\lambda}$ is the complex conjugate of λ.

Proof. To prove the statement we need to observe that

$$\left\langle (\widetilde{\mathcal{A}} - \lambda_m^{(k)} I)\widetilde{\varphi}, \widetilde{\psi}_{m,k}^{j,p_{m,j}} \right\rangle = 0 \quad \forall \widetilde{\varphi} \in \{\widetilde{\varphi}\}.$$

Hence $\widetilde{\psi}_{m,k}^{j,p_{m,j}} \in \mathcal{D}(\widetilde{\mathcal{A}}^*)$ and $(\widetilde{\mathcal{A}}^* - \bar{\lambda}_m^{(k)} I)\widetilde{\psi}_{m,k}^{j,p_{m,j}} = 0$. Next, for $s = 0, \dots, p_{m,j} - 1$ we have

$$\left\langle (\widetilde{\mathcal{A}} - \widetilde{\lambda}_m^{(k)} I)\widetilde{\varphi}, \widetilde{\psi}_{m,k}^{j,s} \right\rangle = 0 \quad \forall \widetilde{\varphi} \in \{\widetilde{\varphi}\} \backslash \{\widetilde{\varphi}_{m,k}^{j,s+1}\}$$

and

$$\left\langle (\widetilde{\mathcal{A}} - \lambda_m^{(k)} I)\widetilde{\varphi}_{m,k}^{j,s+1}, \widetilde{\psi}_{m,k}^{j,s} \right\rangle = 1.$$

This means that $\widetilde{\psi}_{m,k}^{j,s} \in \mathcal{D}(\widetilde{\mathcal{A}}^*)$ and $(\widetilde{\mathcal{A}}^* - \bar{\lambda}_m^{(k)} I)\widetilde{\psi}_{m,k}^{j,s} = \widetilde{\psi}_{m,k}^{j,s+1}$. □

Let us give the concrete form of elements $\widetilde{\psi}_{m,k}^{j,s}$ corresponding to the nonzero eigenvalues.

PROPOSITION 2.2. *Let $\{C_{m,j}^1, \dots, C_{m,j}^{p_{m,j}}\}$ be the jth Jordan chain of A_{-1}^* corresponding to $\bar{\mu}_m$:*

$$A_{-1}^* C_{m,j}^1 = \bar{\mu}_m C_{m,j}^1, \quad (A_{-1}^* - \bar{\mu}_m I) C_{m,j}^s = C_{m,j}^{s-1}, \qquad s = 2, \dots, p_{m,j}.$$

Then the vectors $\widetilde{\psi}_{m,k}^{j,p_{m,j}-r}$ are of the form

$$\widetilde{\psi}_{m,k}^{j,p_{m,j}-i} = \begin{pmatrix} \frac{1}{\bar{\lambda}_m^{(k)}} \sum_{s=0}^{i} q_{m,j}^{i,1+s} C_{m,j}^{1+s} \\ \mathrm{e}^{-\bar{\lambda}_m^{(k)}\theta} \sum_{s=0}^{i} \widetilde{q}_{m,j}^{i,1+s}(\theta) C_{m,j}^{1+s} \end{pmatrix}, \tag{2.4}$$

where $i = 0, \dots, p_{m,j} - 1$ and the coefficients q and $\widetilde{q}(\theta)$ do not depend on k.

In particular, the eigenvectors are given by

$$\widetilde{\psi}_{m,k}^{j,p_{m,j}} = \beta_{m,k}^j \begin{pmatrix} \frac{1}{\bar{\lambda}_m^{(k)}} C_{m,j}^1 \\ \mathrm{e}^{\bar{\lambda}_m^{(k)}\theta} C_{m,j}^1 \end{pmatrix}, \qquad \beta_{m,k}^j \in \mathbb{C}. \tag{2.5}$$

Proof. The proof may be obtained by a simple calculation. □

Let us now recall [10] that the space M_2 possesses a Riesz basis of $\mathcal{A}$-invariant finite-dimensional subspaces $\{V\} = \{V_m^{(k)},\ |k| > N,\ m = 1, \dots, \ell\} \cup \{\widehat{V}_N\}$, where

$$V_m^{(k)} = P_m^{(k)} M_2, \qquad P_m^{(k)} = \frac{1}{2\pi \mathrm{i}} \int_{L_m^{(k)}} R(\lambda, \mathcal{A}) \mathrm{d}\lambda,$$

where $L_m^{(k)}$ are circles of fixed radius $r < r_0 = \frac{1}{3} \min\{|\lambda_m^k - \lambda_i^j|,\ (m,k) \neq (i,j)\}$, centered at λ_m^k, and $\widehat{V}_N$ is the subspace spanned on all the generalized eigenvectors of $\mathcal{A}$ whose eigenvalues are located outside the circles $L_m^{(k)}$, $|k| > N$, $m = 1, \dots, \ell$, with $\dim \widehat{V}_N = 2(N+1)n$. Let us remark that this Riesz basis property is valid for all sufficiently large $N \geq N_0$. Moreover, it is shown in [10] that

$$\sum_{k \in \mathbb{Z}} \sum_{m=1}^{\ell} \left\| P_m^{(k)} - \widetilde{P}_m^{(k)} \right\|^2 < \infty, \tag{2.6}$$

where

$$\widetilde{P}_m^{(k)} = \frac{1}{2\pi \mathrm{i}} \int_{L_m^{(k)}} R(\lambda, \widetilde{\mathcal{A}}) \mathrm{d}\lambda, \qquad \mathrm{Im} \widetilde{P}_m^{(k)} = \mathrm{Ker}(\widetilde{\mathcal{A}} - \lambda_m^{(k)} I)^n.$$

So, in this sense, the basis $\{V\}$ is asymptotically quadratic close to the spectral basis of $\widetilde{\mathcal{A}}$. Consider now the biorthogonal to $\{V\}$ basis of subspaces

$$\{W\} = \{W_m^{(k)},\ |k| > N,\ m = 1, \dots, \ell\} \cup \{\widehat{W}_N\},$$

i.e., the basis that may be defined by

$$W_m^{(k)} = \left(\sum_{\substack{(i,j)\neq(m,k)\\ |i|>N, j=1,\dots,\ell}} V_j^{(i)} + \widehat{V}_N \right)^{\perp}, \quad m = 1, \dots, \ell,\ |k| > N,$$

and

$$\widehat{W}_N = \left(\sum_{\substack{|i|>N\\ j=1,\dots,\ell}} V_j^{(i)} \right)^{\perp}.$$

One can easily check that the basis $\{W\}$ consists of $\mathcal{A}^*$-invariant subspaces and, besides,

$$W_m^{(k)} = P_m^{(k)*} M_2, \qquad P_m^{(k)*} = \frac{1}{2\pi \mathrm{i}} \int_{\bar{L}_m^{(k)}} R(\lambda, \mathcal{A}^*) \mathrm{d}\lambda, \qquad |k| > N,\ m = 1, \dots, \ell,$$

where $\bar{L}_m^{(k)}$ are the complex conjugate circles to $L_m^{(k)}$.

The finite-dimensional operator $\mathcal{A}^*_{\big|\widehat{W}_N}$ has the spectrum $\sigma(\mathcal{A}^*_{\big|\widehat{W}_N})$ which is the complex conjugate of the spectrum $\sigma(\mathcal{A}_{\big|\widehat{V}_N})$. Let us consider this relation in more detail. Let $\widehat{\lambda}_m,\ m = 1, \dots, \ell_N$, be the eigenvalues of $\mathcal{A}_{\big|\widehat{V}_N}$, and $\widehat{\nu}_m$ the number of Jordan blocks corresponding to $\widehat{\lambda}_m \in \sigma(\mathcal{A}_{\big|\widehat{V}_N})$ with the dimension of blocks $\widehat{p}_{m,j},\ j = 1, \dots, \widehat{\nu}_m$. Let $\widehat{\varphi}_m^{j,s},\ j = 1, \dots, \widehat{\nu}_m;\ s = 1, \dots, \widehat{p}_{m,j}$, be a Jordan basis of generalized vectors of $\mathcal{A}_{\big|\widehat{V}_N}$, i.e.,

$$\mathcal{A}\widehat{\varphi}_m^{j,1} = \widehat{\lambda}_m \widehat{\varphi}_m^{j,1}, \qquad (\mathcal{A} - \widehat{\lambda}_m I)\widehat{\varphi}_m^{j,s} = \widehat{\varphi}_m^{j,s-1}, \qquad s = 2, \dots, \widehat{p}_{m,j}, \tag{2.7}$$

for the subspace $\widehat{V}_N$.

We can now formulate the following statement.

Proposition 2.3. *The family*

$$\{\widehat{\psi}_m^{j,s},\ m = 1, \dots, \ell_N;\ j = 1, \dots, \widehat{\nu}_m;\ s = 1, \dots, \widehat{p}_{m,j}\} \subset \widehat{W}_N$$

biorthogonal to $\{\widehat{\varphi}_m^{j,s}\}$, *i.e.,* $\langle \widehat{\varphi}_m^{j,s}, \widehat{\psi}_r^{i,k} \rangle = \delta_{\{(m,j,s),(r,i,k)\}}$, *forms a Jordan basis of generalized eigenvectors of* $\mathcal{A}^*_{\big|\widehat{V}_N}$:

$$\mathcal{A}^* \widehat{\psi}_m^{j,\widehat{p}_{m,j}} = \bar{\widehat{\lambda}}_m \widehat{\psi}_m^{j,\widehat{p}_{m,j}}, \qquad (\mathcal{A}^* - \bar{\widehat{\lambda}}_m I)\widehat{\psi}_m^{j,s} = \widehat{\psi}_m^{j,s+1}, \qquad s = 0, \dots, \widehat{p}_{m,j} - 1,$$

for the subspace $\widehat{W}_N$.

Proof. The proof is analogous to the proof of Proposition 2.1. □

Now we have all the elements to define the Riesz basis that we will use for the analysis of the steering condition (1.4).

We consider the spectral, with respect to the operator $\widetilde{\mathcal{A}}$, basis $\{\widetilde{\varphi}\}$ described above and the corresponding biorthogonal basis $\{\widetilde{\psi}\}$. For a given $N > N_0$ we put

$$\psi^{j,s}_{m,k} = P^{(k)*}_m \widetilde{\psi}^{j,s}_{m,k},\ |k| > N,\ m = 1.\ldots,\ell;\quad j = 1,\ldots,\nu_m;\ s = 1,\ldots,p_{m,j}. \tag{2.8}$$

Then we complete the collection (2.8) by the set

$$\{\widehat{\psi}^{j,s}_m;\ m = 1,\ldots,\ell_N;\ j = 1,\ldots,\widehat{\nu}_m; s = 1,\ldots,\widehat{p}_{m,j}\},$$

which contains $2(N+1)n$ vectors forming a Jordan basis in $\widehat{W}_N$ (Proposition 2.3).

THEOREM 2.4. *Let the condition* (2.3) *be satisfied and let* N *be sufficiently large. Then the collection*

$$\{\psi\} = \{\psi^{j,s}_{m,k}\} \cup \{\widehat{\psi}^{j,s}_m\},$$

where $\psi^{j,s}_{m,k}$ *are given by* (2.8) *and* $\psi^{j,s}_m$ *are defined in Proposition* 2.3*, constitutes a Riesz basis of* M_2*.*

Proof. We start with the fact that under condition (2.3) the collection $\{\widetilde{\psi}\}$ forms a Riesz basis in M_2. In particular, this implies that the collection $\{\widetilde{\psi}^{j,s}_{m,k},\ |k| > N\}$ forms a Riesz basis in the closure of its linear span

$$\operatorname{Cl}\operatorname{Lin}\{\widetilde{\psi}^{j,s}_{m,k},\ |k| > N\} = \operatorname{Cl}\sum_{|k|>N}\sum_{m=1}^{\ell}\operatorname{Ker}\left(\widetilde{\mathcal{A}}^* - \bar{\lambda}^{(k)}_m I\right)^{\max_j p_{m,j}}.$$

On the other hand, from (2.6) and (2.8) we have

$$\sum_{|k|>N}\sum_{m,j,s}\left\|\psi^{j,s}_{m,k} - \widetilde{\psi}^{j,s}_{m,k}\right\|^2 = \sum_{|k|>N}\sum_{m,j,s}\left\|P^{(k)*}_m - \widetilde{P}^{(k)*}_m\right\|^2\left\|\widetilde{\psi}^{j,s}_{m,k}\right\|^2.$$

This implies that for any $\varepsilon > 0$ there exists a large N_1 such that if $N > N_1$, then

$$\sum_{|k|>N}\sum_{m,j,s}\left\|\psi^{j,s}_{m,k} - \widetilde{\psi}^{j,s}_{m,k}\right\|^2 < \varepsilon. \tag{2.9}$$

Hence for this N, the family $\{\psi^{j,s}_{m,k}\}_{|k|>N}$ is quadratically close to $\{\widetilde{\psi}^{j,s}_{m,k}\}_{|k|>N}$ and, therefore, forms a Riesz basis in the closure of its linear span

$$\operatorname{Cl}\operatorname{Lin}\{\psi^{j,s}_{m,k},\ |k| > N\} = \operatorname{Cl}\sum_{|k|>N}\sum_{m=1}^{\ell} W^{(k)}_m.$$

Since, due to Proposition 2.3, the set $\{\widehat{\psi}^{j,s}_m\}$ is a basis in $\widehat{W}_N$ and

$$\operatorname{Cl}\sum_{|k|>N}\sum_{m}^{\ell} W^{(k)}_m + \widehat{W}_N = M_2,$$

the union

$$\{\psi^{j,s}_{m,k},\ |k| > N\} \cup \{\widehat{\psi}^{j,s}_m\}$$

is a Riesz basis in M_2. This ends the proof. □

By $\{\varphi\}$ we denote the Riesz basis biorthogonal to the basis $\{\psi\}$ in Theorem 2.4.

Remark 2.5. The elements of the basis $\{\varphi\}$ which correspond to the part $\{\widehat{\psi}_m^{j,s}\}$ are the generalized eigenvectors $\{\widehat{\varphi}_m^{j,s}\}$ of the operator $\mathcal{A}$ (see (2.7)). So,

$$\{\varphi\} = \{\varphi_{m,k}^{j,s},\ |k| > N\} \cup \{\widehat{\varphi}_m^{j,s}\}.$$

Moreover, it is easy to show that there exists N_1 such that for any given $N > N_1$ and $m = 1, \dots, \ell$ *the collection* $\{\varphi_{m,k}^{j,s},\ j = 1, \dots, \nu_m; s = 1, \dots, p_{m,j}\}$ *is a basis of* $V_m^{(k)}$. The chosen basis $\{\varphi\}$ will be used in our further analysis of the steering conditions by the moment problem method. In this context, we notice that the construction of a proper basis becomes rather complicated only in the case when the spectrum of the matrix A_{-1} is not simple and, as a consequence, the operator $\mathcal{A}$ may not possess a spectral Riesz basis. If all eigenvalues of A_{-1} are simple, the basis $\{\varphi\}$ constructed in this section coincides with a spectral basis of $\mathcal{A}$.

3. Expansion of the steering condition in the Riesz basis. In order to use the results of section 2, we assume that the matrix A_{-1} is not singular.

Let us expand the steering condition (1.4) with respect to the basis $\{\varphi\}$ and to the biorthogonal basis $\{\psi\}$. Consider a state $x = \binom{y}{z(\cdot)} \in M_2$; this state is reachable at time T if and only if

$$\sum_{\varphi\in\{\varphi\}} \langle x, \psi\rangle\, \varphi = \sum_{\varphi\in\{\varphi\}} \int_0^T \left\langle \mathrm{e}^{\mathcal{A}t}\mathcal{B}u(t), \psi\right\rangle \mathrm{d}t\varphi, \quad u(\cdot) \in L_2(-1, 0; \mathbb{C}^r).$$

Then the steering condition (1.4) can be substituted by the following system of equalities:

$$\langle x, \psi\rangle = \int_0^T \left\langle \mathrm{e}^{\mathcal{A}t}\mathcal{B}u(t), \psi\right\rangle \mathrm{d}t, \quad \psi \in \{\psi\},\ u(\cdot) \in L_2(-1, 0; \mathbb{C}^r). \tag{3.1}$$

Let $\{b_1, \dots, b_r\}$ be an arbitrary basis in $\mathrm{Im}B$, the image of the matrix B and $\mathbf{b}_i = \binom{b_i}{0} \in M_2,\ i = 1, \dots, r$ (more precision on the choice of this basis will be given in section 6). Then the right-hand side of (3.1) takes the form

$$\int_0^T \left\langle \mathrm{e}^{\mathcal{A}t}\mathcal{B}u(t), \psi\right\rangle \mathrm{d}t = \sum_{i=1}^r \int_0^T \left\langle \mathrm{e}^{\mathcal{A}t}\mathbf{b}_i, \psi\right\rangle u_i(t)\mathrm{d}t. \tag{3.2}$$

Let us omit the index i for $\mathbf{b}_i$ and for any $\mathbf{b} \in \{\mathbf{b}_1, \dots, \mathbf{b}_r\}$ transform the term $\left\langle \mathrm{e}^{\mathcal{A}t}\mathbf{b}u(t), \psi\right\rangle,\ \psi \in \{\psi_{m,k}^{j,s},\ |k| > N\}$ as follows:

$$\begin{aligned} \left\langle \mathrm{e}^{\mathcal{A}t}\mathbf{b}, \psi_{m,k}^{j,s}\right\rangle &= \left\langle \mathrm{e}^{\mathcal{A}t}\mathbf{b}, P_m^{(k)*}\widetilde{\psi}_{m,k}^{j,s}\right\rangle \\ &= \left\langle P_m^{(k)}\mathrm{e}^{\mathcal{A}t}\mathbf{b}, \widetilde{\psi}_{m,k}^{j,s}\right\rangle \\ &= \left\langle \widetilde{P}_m^{(k)}\mathrm{e}^{\widetilde{\mathcal{A}}t}\mathbf{b}, \widetilde{\psi}_{m,k}^{j,s}\right\rangle + \left\langle (P_m^{(k)}\mathrm{e}^{\mathcal{A}t} - \widetilde{P}_m^{(k)}\mathrm{e}^{\widetilde{\mathcal{A}}t})\mathbf{b}, \widetilde{\psi}_{m,k}^{j,s}\right\rangle. \end{aligned} \tag{3.3}$$

LEMMA 3.1. *There exists a sequence* $\{\alpha_k\}, \sum_{|k|>N}\alpha_k^2 < \infty$, *such that for all* $m = 1, \dots, \ell;\ j = 1, \dots, \nu_m$, *and* $s = 1, \dots, p_{m,j}$ *the following estimates hold:*

$$\left|\left\langle (P_m^{(k)}\mathrm{e}^{\mathcal{A}t} - \widetilde{P}_m^{(k)}\mathrm{e}^{\widetilde{\mathcal{A}}t})\mathbf{b}, \widetilde{\psi}_{m,k}^{j,s}\right\rangle\right| \le \frac{\alpha_k}{|k|}, \quad |k| > N, \quad t \in [0, T]. \tag{3.4}$$

Proof. Let us denote by $R(\lambda,\mathcal{A})$ and $R(\lambda,\widetilde{\mathcal{A}})$ the resolvents of the operators $\mathcal{A}$ and $\widetilde{\mathcal{A}}$. Taking into account the relation (2.3) we can write

$$\begin{aligned}
&\left|\left\langle (P_m^{(k)}\mathrm{e}^{\mathcal{A}t}-\widetilde{P}_m^{(k)}\mathrm{e}^{\widetilde{\mathcal{A}}t})\mathbf{b},\widetilde{\psi}_{m,k}^{j,s}\right\rangle\right| \\
&\quad=\left|\left\langle \tfrac{1}{2\pi\mathrm{i}}\int_{L_m^k}\mathrm{e}^{\lambda t}\left(R(\lambda,\mathcal{A})-R(\lambda,\widetilde{\mathcal{A}})\right)\mathrm{d}\lambda\cdot\mathbf{b},\widetilde{\psi}_{m,k}^{j,s}\right\rangle\right| \\
&\quad=\tfrac{1}{2\pi}\left|\int_{L_m^k}\mathrm{e}^{\lambda t}\left\langle\left(R(\lambda,\mathcal{A})-R(\lambda,\widetilde{\mathcal{A}})\right)\mathbf{b},\widetilde{\psi}_{m,k}^{j,s}\right\rangle\mathrm{d}\lambda\right| \\
&\quad\le\tfrac{1}{2\pi}\int_{L_m^k}\left|\mathrm{e}^{\lambda t}\right|\left\|\left(R(\lambda,\mathcal{A})-R(\lambda,\widetilde{\mathcal{A}})\right)\mathbf{b}\right\|\left\|\widetilde{\psi}_{m,k}^{j,s}\right\||\mathrm{d}\lambda| \\
&\quad\le C\int_{L_m^k}\left|\mathrm{e}^{\lambda t}\right|\left\|\left(R(\lambda,\mathcal{A})-R(\lambda,\widetilde{\mathcal{A}})\right)\mathbf{b}\right\||\mathrm{d}\lambda|
\end{aligned}\tag{3.5}$$

with $C>0$. Now we need to estimate $\|(R(\lambda,\mathcal{A})-R(\lambda,\widetilde{\mathcal{A}}))\mathbf{b}\|$. In order to do that, we need to use an explicit expression for the resolvents of the operators $\mathcal{A}$ and $\widetilde{\mathcal{A}}$ given in [10, Proposition 2.2] (for the proof see [11] and also [5]). We obtain

$$\left(R(\lambda,\mathcal{A})-R(\lambda,\widetilde{\mathcal{A}})\right)\mathbf{b}=\begin{pmatrix}(I-A_{-1}\mathrm{e}^{-\lambda})\left(\Delta_{\mathcal{A}}^{-1}(\lambda)-\Delta_{\widetilde{\mathcal{A}}}^{-1}(\lambda)\right)b\\ \mathrm{e}^{\lambda\theta}\left(\Delta_{\mathcal{A}}^{-1}(\lambda)-\Delta_{\widetilde{\mathcal{A}}}^{-1}(\lambda)\right)b\end{pmatrix},$$

where

$$\Delta_{\mathcal{A}}(\lambda)=\lambda I-\lambda\mathrm{e}^{-\lambda}A_{-1}+\lambda\int_{-1}^{0}\mathrm{e}^{\lambda s}A_2(s)\mathrm{d}s-\int_{-1}^{0}\mathrm{e}^{\lambda s}A_3(s)\mathrm{d}s,$$

and, from that, $\Delta_{\widetilde{\mathcal{A}}}(\lambda)=\lambda I-\lambda\mathrm{e}^{-\lambda}A_{-1}$. From the relation

$$\Delta_{\widetilde{\mathcal{A}}}^{-1}(\lambda)-\Delta_{\mathcal{A}}^{-1}(\lambda)=\Delta_{\mathcal{A}}^{-1}(\lambda)\left(\lambda\int_{-1}^{0}\mathrm{e}^{\lambda s}A_2(s)\mathrm{d}s+\int_{-1}^{0}\mathrm{e}^{\lambda s}A_3(s)\mathrm{d}s\right)\Delta_{\widetilde{\mathcal{A}}}^{-1}(\lambda),$$

and using the estimates [11, formulas (25), (26)],

$$\left\|\Delta^{-1}_{\mathcal{A}\text{ or }\widetilde{\mathcal{A}}}(\lambda)\right\|\le C_1|\lambda|^{-1},\quad C_1>0,\quad \lambda\in L_m^{(k)},\quad |k|>N,\ m=1,\dots,\ell,$$

we get the inequality

$$\left\|\left(R(\lambda,\mathcal{A})-R(\widetilde{\lambda,\mathcal{A}})\right)\mathbf{b}\right\|\le\frac{C_2}{|\lambda|^2}\left(|\lambda|\left\|\int_{-1}^{0}\mathrm{e}^{\lambda s}A_2(s)\mathrm{d}s\right\|+\left\|\int_{-1}^{0}\mathrm{e}^{\lambda s}A_3(s)\mathrm{d}s\right\|\right).\tag{3.6}$$

For $\lambda\in L_m^{(k)}$ we can put $\lambda=\widetilde{\lambda}+2k\pi\mathrm{i}$, where $\widetilde{\lambda}\in L_m^{(0)}=\{\xi:|\xi-\ln|\mu_m|+\mathrm{i}\arg\mu_m|=r\}$. This yields

$$\begin{aligned}
\left\|\int_{-1}^{0}\mathrm{e}^{\lambda s}A_2(s)\mathrm{d}s\right\| &= \left\|\int_{-1}^{0}\mathrm{e}^{\widetilde{\lambda}s}A_2(s)\mathrm{e}^{2\pi\mathrm{i}ks}\mathrm{d}s\right\| = C_2^{(k)}(\widetilde{\lambda}),\\
\left\|\int_{-1}^{0}\mathrm{e}^{\lambda s}A_3(s)\mathrm{d}s\right\| &= \left\|\int_{-1}^{0}\mathrm{e}^{\widetilde{\lambda}s}A_3(s)\mathrm{e}^{2\pi\mathrm{i}ks}\mathrm{d}s\right\| = C_3^{(k)}(\widetilde{\lambda}),
\end{aligned}\tag{3.7}$$

where

$$\sum_{|k|>N}\left[C_j^{(k)}(\widetilde{\lambda})\right]^2 \le \int_{-1}^{0}|\mathrm{e}^{\widetilde{\lambda}s}|^2\|A_j(s)\|^2\mathrm{d}s,\quad j=2,3.$$

Since for all values of the parameter

$$\widetilde{\lambda}\in\bigcup_{m=1}^{\ell}L_m^{(0)}$$

the L_2-norm of the matrix functions $\mathrm{e}^{\widetilde{\lambda}s}A_j(s)$, $j=2,3$, on the interval $[-1,0]$ are uniformly bounded, then there exists $\delta>0$ such that

$$\sum_{|k|>N}\left(C_j^{(k)}(\widetilde{\lambda})\right)^2\le\delta<\infty,\quad j=2,3,\quad \widetilde{\lambda}\in\bigcup_{m=1}^{\ell}L_m^{(0)}. \tag{3.8}$$

Finally, from (3.6) and (3.7), for $\widetilde{\lambda}\in L_m^{(k)}$ we obtain

$$\left\|\left(R(\lambda,\mathcal{A})-R(\lambda,\widetilde{\mathcal{A}})\right)\mathbf{b}\right\|\le\frac{C_2}{|\widetilde{\lambda}+2k\pi\mathrm{i}|}\left(|\widetilde{\lambda}+2k\pi\mathrm{i}|C_2^{(k)}(\widetilde{\lambda})+C_3^{(k)}(\widetilde{\lambda})\right),\quad \widetilde{\lambda}\in L_m^{(0)}. \tag{3.9}$$

Then the inequalities (3.5), (3.6), and (3.9) give the validity of (3.4). The proof is complete. □

Let us consider the first term on the right-hand side of (3.3). Since $\widetilde{\psi}_{m,k}^{j,s}\in W_m^{(k)}$ and due to Proposition 2.1, we have

$$\begin{aligned}\left\langle\widetilde{P}_m^{(k)}\mathrm{e}^{\widetilde{\mathcal{A}}t}\mathbf{b},\widetilde{\psi}_{m,k}^{j,s}\right\rangle &= \left\langle\mathbf{b},\mathrm{e}^{\widetilde{\mathcal{A}}^*t}\widetilde{P}_m^{(k)*}\widetilde{\psi}_{m,k}^{j,s}\right\rangle\\ &= \left\langle\mathbf{b},\mathrm{e}^{\widetilde{\mathcal{A}}^*t}\widetilde{\psi}_{m,k}^{j,s}\right\rangle\\ &= \left(\langle\mathbf{b},\widetilde{\psi}_{m,k}^{j,p_{m,j}}\rangle\tfrac{t^{p_{m,j}-s}}{(p_{m,j}-s)!}+\cdots+\langle\mathbf{b},\widetilde{\psi}_{m,k}^{j,s}\rangle\right)\mathrm{e}^{\lambda_m^{(k)}t}.\end{aligned} \tag{3.10}$$

Lemma 3.2. *There exists a constant δ_1 such that*

$$\left|\left\langle\mathbf{b},\widetilde{\psi}_{m,k}^{j,s}\right\rangle\right|\le\frac{\delta_1}{|k|} \tag{3.11}$$

for all $|k|>N$, $m=1,\dots,\ell, j=1,\dots,\nu_m, s=1,\dots,p_{m.j}$. Moreover, we have

$$\left\langle\mathbf{b},\widetilde{\psi}_{m,k}^{j,p_{m.j}}\right\rangle=\frac{1}{\bar{\lambda}_m^{(k)}}\left\langle b,C_{m,j}^1\right\rangle,$$

where $C_{m,j}^1$ are the eigenvectors of A_{-1} corresponding to $\bar{\mu}_m$ and $\widetilde{\psi}_{m,k}^{j,p_{m.j}}$ are as in the formula (2.5) *in Proposition* 2.2 *with $\beta_{m,k}^j=1$.*

Proof. Taking into account (2.3), we get

$$\begin{aligned}\left|\langle\mathbf{b},\widetilde{\psi}_{m,k}^{j,s}\rangle\right| &= \left|\langle\mathbf{b},\widetilde{P}_m^{(k)*}\widetilde{\psi}_{m,k}^{j,s}\rangle\right|\\ &= \left|\langle\widetilde{P}_m^{(k)}\mathbf{b},\widetilde{\psi}_{m,k}^{j,s}\rangle\right|\\ &= \tfrac{1}{2\pi}\left|\int_{L_m^{(k)}}\langle R(\lambda,\widetilde{\mathcal{A}})\mathbf{b},\widetilde{\psi}_{m,k}^{j,s}\rangle\mathrm{d}\lambda\right|\\ &\le C\int_{L_m^{(k)}}\left\|R(\lambda,\widetilde{\mathcal{A}})\mathbf{b}\right\|\mathrm{d}\lambda,\qquad C>0,\end{aligned} \tag{3.12}$$

where C is a constant. The explicit expression of the resolvent $R(\lambda, \widetilde{\mathcal{A}})$ is given by (see [10, 11])

$$R(\lambda, \widetilde{\mathcal{A}})\mathbf{b} = \begin{pmatrix} (I - A_{-1}\mathrm{e}^{-\lambda})\Delta_{\widetilde{\mathcal{A}}}^{-1}(\lambda)b \\ \mathrm{e}^{\lambda\theta}\Delta_{\widetilde{\mathcal{A}}}^{-1}(\lambda)b \end{pmatrix}.$$

Since $\|\Delta_{\widetilde{\mathcal{A}}}^{-1}\| \leq C_1|\lambda|^{-1}$ with $C_1 > 0$ and for $\lambda \in L_m^{(k)},\ |k| > N,\ m = 1, \ldots, \ell$, we obtain the estimate

$$\left\| R(\lambda, \widetilde{\mathcal{A}})\mathbf{b} \right\| \leq \frac{C_2}{|k|}, \qquad C_2 > 0, \quad \lambda \in L_m^{(k)}.$$

This, together with (3.12), leads to (3.11).

The second statement follows directly:

$$\left\langle \mathbf{b}, \widetilde{\psi}_{m,k}^{j,p_{m.j}} \right\rangle = \left\langle \begin{pmatrix} b \\ 0 \end{pmatrix}, \widetilde{\psi}_{m,k}^{j,p_{m.j}} \right\rangle = \frac{1}{\bar{\lambda}_m^{(k)}} \left\langle b, C_{m,j}^1 \right\rangle.$$

This completes the proof. □

LEMMA 3.3. *Assume that* $\left\langle b, C_{m,j}^s \right\rangle = 0,\ s = 1, \ldots, r,\ r < p_{m,j}$; *then*

$$\left\langle \mathbf{b}, \widetilde{\psi}_{m,k}^{j,p_{m,j}-r} \right\rangle = \frac{q_{m,j}^r}{\bar{\lambda}_m^{(k)}} \left\langle b, C_{m,j}^{r+1} \right\rangle, \tag{3.13}$$

where the coefficients $q_{m,j}^r$ *do not depend on* k.

Proof. This is a direct consequence of the relation (2.4). □

Let us denote by $q_{m,k}^{j,s,d}(t)$ the polynomials

$$q_{m,k}^{j,s,d}(t) = k \left(\frac{\left\langle \mathbf{b}_d, \widetilde{\psi}_{m,k}^{j,p_{m,j}} \right\rangle}{(p_{m,j} - s)!} t^{p_{m,j}-s} + \frac{\left\langle \mathbf{b}_d, \widetilde{\psi}_{m,k}^{j,p_{m,j}-1} \right\rangle}{(p_{m,j} - s - 1)!} t^{p_{m,j}-s-1} + \cdots + \left\langle \mathbf{b}_d, \widetilde{\psi}_{m,k}^{j,s} \right\rangle \right) \tag{3.14}$$

and by $f_{m,k}^{j,s,d}(t)$ the functions

$$f_{m,k}^{j,s,d}(t) = k \left\langle \left(P_m^{(k)} \mathrm{e}^{\mathcal{A}t} - \widetilde{P}_m^{(k)} \mathrm{e}^{\widetilde{\mathcal{A}}t} \right) \mathbf{b}_d, \widetilde{\psi}_{m,k}^{j,s} \right\rangle. \tag{3.15}$$

With these notations (and also due to (3.2), (3.3), and (3.10)), the infinite part of the system (3.1) corresponding to $\psi \in \{\psi_{m,k}^{j,s}\},\ |k| > N$, reads as

$$k \left\langle \begin{pmatrix} y_T \\ z_T(\cdot) \end{pmatrix}, \psi_{m,k}^{j,s} \right\rangle = \sum_{d=1}^{r} \int_0^T \left(\mathrm{e}^{\lambda_m^{(k)} t} q_{m,k}^{j,s,d}(t) + f_{m,k}^{j,s,d}(t) \right) u_d(t) \mathrm{d}t. \tag{3.16}$$

Moreover, due to Lemmas 3.1, 3.2, and 3.3, the functions (3.14) and (3.15) verify the following properties:

(P1) the coefficients of the polynomials $\{q(t)\}$ are uniformly bounded as $|k| > N$;

(P2) the set of leading coefficients of the nontrivial polynomials $\{q(t)\}$ does not have a limit point at 0;

(P3) $\sum_{|k|>N} |f_{m,k}^{j,s,d}(t)|^2 < \alpha < \infty,\ t \in [0, T],\ \alpha > 0.$

Next we observe that if $\psi = \widehat{\psi}_m^{j,s},\ m = 1, \dots, \ell_N,\ j = 1, \dots, \widehat{\mu}_m,\ s = 1, \dots, \widehat{p}_{m,j}$, then

$$\begin{aligned}\left\langle \mathrm{e}^{\mathcal{A}t}\mathbf{b}_d, \psi \right\rangle, &= \left\langle \mathbf{b}_d, \mathrm{e}^{\mathcal{A}^* t}\psi \right\rangle \\ &= \widehat{q}_m^{j,s,d}(t)\mathrm{e}^{\widehat{\lambda}_m t},\end{aligned}$$

where

$$\widehat{q}_m^{j,s,d}(t) = \left(\frac{\left\langle \mathbf{b}_d, \widehat{\psi}_{m,k}^{j,p_{m,j}} \right\rangle}{(\widehat{p}_{m,j} - s)!} t^{\widehat{p}_{m,j}-s} + \frac{\left\langle \mathbf{b}_d, \widehat{\psi}_{m,k}^{j,\widehat{p}_{m,j}-1} \right\rangle}{(\widehat{p}_{m,j} - s - 1)!} t^{\widehat{p}_{m,j}-s-1} + \dots + \left\langle \mathbf{b}_d, \widehat{\psi}_{m,k}^{j,s} \right\rangle \right).$$

Therefore, the finite part of the system (3.1) corresponding to $\psi \in \{\widehat{\psi}_m^{j,s}\}$ reads as

$$\left\langle \begin{pmatrix} y_T \\ z_T(\cdot) \end{pmatrix}, \widehat{\psi}_m^{j,s} \right\rangle = \sum_{d=1}^{r} \int_0^T \mathrm{e}^{\widehat{\lambda}_m t} \widehat{q}_{m,k}^{j,s,d}(t) u_d(t) \mathrm{d}t. \tag{3.17}$$

Thus, we observe that the state $\binom{y_T}{z_T(\cdot)} \in M_2$ is reachable from 0 at the time $T > 0$ if and only if the equalities (3.16) and (3.17) hold for some controls $u_d(\cdot) \in L_2(0, T),\ d = 1, \dots, r$. These equalities pose a kind of moment problem, which is the main object of our further analysis.

4. The problem of moments and the Riesz basis property. In this section, we recall the general properties of the problem of moments that will be applied to the analysis of the problem (3.16)–(3.17) given in section 3.

Consider a collection of functions $\{g_k(t),\ t \in [0, \infty[\}_{k\in\mathbb{N}}$ assuming that for any $k \in \mathbb{N},\ T > 0,\ g_k(\cdot) \in L_2(0, T)$, and consider the following problem of moments:

$$s_k = \int_0^T g_k(t) u(t) \mathrm{d}t, \qquad k \in \mathbb{N}. \tag{4.1}$$

We start with the following well-known fact, which is a consequence of Bari theorem [4, Chapter 6] and [17, Chapter 4] (see also [14] for a direct proof and the references therein).

PROPOSITION 4.1. *The following statements are equivalent:*

(i) *For the scalars $s_k,\ k \in \mathbb{N}$, the problem (4.1) has a solution $u(\cdot) \in L_2(0, T)$ if and only if $\{s_k\} \in \ell_2$, i.e., $\sum_{k\in\mathbb{N}} s_k^2 < \infty$;*

(ii) *the family $\{g_k(t)\}_{k\in\mathbb{N}},\ t \in [0, T]$, forms a Riesz basis in the closure of its linear span*

$$\mathrm{Cl}\,\mathrm{Lin}\{g_k(t),\ k \in \mathbb{N}\}.$$

Using this proposition, we can prove the following result.

PROPOSITION 4.2. *Let us denote by $\mathcal{L}(0, T)$ the closed subspace*

$$\mathrm{Cl}\,\mathrm{Lin}\{g_k(t),\ k \in \mathbb{N}\} \subset L_2(T_0, T).$$

Let us suppose that for some $T_1 > 0$ the functions $\{g_k(t)\}_{k\in\mathbb{N}},\ t \in [0, T_1]$, form a Riesz basis in $\mathcal{L}(0, T_1) \subset L_2(0, T_1)$ and $\mathrm{codim}\mathcal{L}(0, T_1) < \infty$. Then for any $0 < T < T_1$, there exists an infinite-dimensional subspace $\ell^T \subset \ell_2$ such that the problem of moments (4.1) is unsolvable for $\{s_k\} \in \ell^T$ if $\{s_k\} \neq \{0\}$.

Proof. We introduce for all $T > 0$ the operator $Q_T : L_2(0,T) \to \ell_2$ given by

$$Q_T u(\cdot) = \left\{ \int_0^T g_k(t) u(t) \mathrm{d}t \right\}_{k \in \mathbb{N}}. \tag{4.2}$$

This gives $Q_{T_1}(L_2(0,T_1)) = \ell_2$ by Proposition 4.1. The operator Q_{T_1} is bounded due to the closed graph theorem. It is easy to see that the adjoint operator $Q^*_{T_1}$ acts as

$$Q^*_{T_1}\{s_k\}_{k\in\mathbb{N}} = \sum_{k\in\mathbb{N}} s_k g_k(t) \in \mathcal{L}(0,T_1).$$

Let us denote now by $Q_1 : \mathcal{L}(0,T_1) \to \ell_2$ the one-to-one operator defined as follows:

$$Q_1 u(\cdot) = \{c_k\} \qquad \text{for} \qquad u(\cdot) = \sum_{k\in\mathbb{N}} c_k g_k(\cdot),\ \{c_k\}, \in \ell_2.$$

Now consider the decomposition $L_2(0,T_1) = X_1 \oplus X_2$, where

$$X_1 = \{u(\cdot) : u(t) \equiv 0,\ t \in [0,T]\}, \qquad X_2 = \{u(\cdot) : u(t) \equiv 0,\ t \in [T,T_1]\},$$

and observe that since $\operatorname{codim} \mathcal{L}(0,T_1) < \infty$, then the intersection $X = X_1 \cup \mathcal{L}(0,T_1)$ is an infinite-dimensional subspace in $L_2(0,T_1)$. Finally, let us denote $\ell^T = Q_1(X)$. The above considerations prove that this subspace is infinite dimensional. Taking $u(\cdot) \in X_2$ and $\{s_k\} \in \ell^T$, we obtain

$$\langle Q_{T_1} u(\cdot), \{s_k\}\rangle = \langle u(\cdot), Q^*_T\{s_k\}\rangle = \int_0^T u(t) \sum_{k\in\mathbb{N}} s_k g_k(t) \mathrm{d}t = 0,$$

because $\sum_{k\in\mathbb{N}} s_k g_k(t) \in X_1$. Thus $Q_{T_1}(X_2) \perp \ell^T$ and, therefore, (4.1) is unsolvable for $\{s_k\} \in \ell^T$ if $\{s_k\} \neq \{0\}$. □

PROPOSITION 4.3. *Let us consider the moment problem*

$$s_k = \sum_{d=1}^{r} \int_0^T g^d_k(t) u_d(t) \mathrm{d}t, \qquad k \in \mathbb{N}, \tag{4.3}$$

with the assumption

$$\sum_{k\in\mathbb{N}} \int_0^T |g^d_k(t)|^2 \mathrm{d}t < \infty, \qquad d = 1, \dots, r. \tag{4.4}$$

Then the set $S_{0,T}$ of sequences $\{s_k\}$ for which problem (4.3) *is solvable is a nontrivial submanifold of ℓ_2, i.e., $S_{0,T} \neq \ell_2$.*

Proof. Let us introduce the operator $Q^r_T : L^r_2(0,T) \to \ell^2$ defined by

$$Q^r_T u(\cdot) = \{s_k\}_{k\in\mathbb{N}} = \left\{ \sum_{d=1}^{r} \int_0^T g^d_k(t) u_d(t) \mathrm{d}t \right\}_{k\in\mathbb{N}}, \qquad u(\cdot) = (u_1(\cdot), \dots, u_r(\cdot)).$$

Then, if $\|u(\cdot)\| \le 1$, we obtain

$$\sum_{k=N}^{\infty} |s_k|^2 = \sum_{d=1}^{r} \sum_{k=N}^{\infty} \left| \int_0^T g_k^d(t) u_d(t) \right|^2 \mathrm{d}t \le \sum_{d=1}^{r} \sum_{k=N}^{\infty} \int_0^T |g_k^d(t)|^2 \mathrm{d}t,$$

and then $\sum_{k=N}^{\infty} |s_k|^2 \to 0$ as $N \to \infty$. This means that the set $\{Q_T^r u(\cdot),\ \|u(\cdot)| \le 1\}$ satisfies the criterion of compactness in ℓ^2 (see, for example, [7, Chapter 5]). Hence Q_T^r is a compact operator and therefore $\mathrm{Im} Q_T^r \ne \ell_2$. □

In the following, our analysis will be based on the theory of families of exponential developed by Avdonin and Ivanov in [1]. We are particularly interested in the basis properties of such families.

Let $\delta_1, \dots, \delta_\ell$ be different, modulus $2\pi\mathrm{i}$, complex numbers, and let $m_1, \dots, m_\ell$ and N be natural integers. Let us denote by $\widetilde{\mathcal{E}}_N$ the family

$$\widetilde{\mathcal{E}}_N = \left\{ \mathrm{e}^{(\delta_s + 2\pi\mathrm{i}k)t}, t\mathrm{e}^{(\delta_s+2\pi\mathrm{i}k)t}, \dots, t^{m_s-1}\mathrm{e}^{(\delta_s+2\pi\mathrm{i}k)t} \right\}_{\substack{|k|>N \\ s=1,\dots,\ell}}.$$

Next, let $\varepsilon_1, \dots, \varepsilon_r$ be another collection of different complex numbers such that $\varepsilon_j \ne \delta_s + 2\pi\mathrm{i}k,\ j = 1, \dots, r;\ s = 1, \dots, \ell;\ |k| > N$, and let $m_1', \dots, m_r'$ be positive integers. Let us denote by $\mathcal{E}_0$ the collection

$$\mathcal{E}_0 = \left\{ \mathrm{e}^{\varepsilon_j t}, t\mathrm{e}^{\varepsilon_j t}, \dots, t^{m_s'-1}\mathrm{e}^{\varepsilon_j t} \right\}_{j=1,\dots,r}.$$

The following theorem is the main tool of our further analysis.

THEOREM 4.4. (i) *If* $\sum_{j=1}^{r} m_j' = (2N+1)\sum_{s=1}^{\ell} m_s$, *then the family* $\mathcal{E} = \widetilde{\mathcal{E}}_N \cup \mathcal{E}_0$ *constitutes a Riesz basis in* $L_2(0, \sum_{s=1}^{\ell} m_s)$.

(ii) *If* $T > \sum_{s=1}^{\ell} m_s$, *then independently of the number of elements in* $\mathcal{E}_0$, *the family* $\mathcal{E}$ *forms a Riesz basis of the closure of its linear span in the space* $L_2(0,T)$.

Proof. (i) We make use of [1, Theorem II.4.23]. According to this theorem, let us consider the complex function

$$f(z) = \mathrm{e}^{\frac{\mathrm{i}z}{2}\sum_{s=1}^{\ell} m_s} \prod_{s=1}^{\ell} \left(\sin\left(\frac{z}{2} - \frac{\delta_s}{2} \right) \right)^{m_s} R(z),$$

where

$$R(z) = \prod_{j=1}^{r} (z - \varepsilon_j)^{m_j'} \left(\prod_{\substack{s=1,\dots,\ell \\ |k|\le N}} (z - \delta_s - 2\pi\mathrm{i}k)^{m_s} \right)^{-1} \to 1 \quad \text{as} \quad z \to \infty.$$

One can easily verify that $f(z)$ extended to the points $\delta_s + 2\pi\mathrm{i}k,\ s = 1, \dots, \ell,\ |k| \le N$, by continuity, is an entire function of the sine type (see [1, Definition II.1.27] and also [17, section 4.5]). Representing

$$\prod_{s=1}^{\ell} \left(\sin\left(\frac{z}{2} - \frac{\delta_s}{2} \right) \right)^{m_s} = \prod_{s=1}^{\ell} \left(\frac{\mathrm{e}^{\frac{\mathrm{i}z}{2}} \mathrm{e}^{\frac{-\mathrm{i}\delta_s}{2}} - \mathrm{e}^{\frac{-\mathrm{i}z}{2}} \mathrm{e}^{\frac{\mathrm{i}\delta_s}{2}}}{2\mathrm{i}} \right)^{m_s},$$

we get

$$\prod_{s=1}^{\ell}\left(\sin\left(\frac{z}{2}-\frac{\delta_s}{2}\right)\right)^{m_s}=C_0\mathrm{e}^{\frac{\mathrm{i}z}{2}\sum_{s=1}^{\ell}m_s}+C_1\mathrm{e}^{\frac{-\mathrm{i}z}{2}\sum_{s=1}^{\ell}m_s}+\sum_{j=2}^{N_0}C_j\mathrm{e}^{\mathrm{i}zq_j},$$

where C_j are constants and $q_j\in\{-\frac{1}{2}\sum_{s=1}^{\ell}m_s,\frac{1}{2}\sum_{s=1}^{\ell}m_s\}$, $j=2,\dots,N_0$. And then the growth indicator of the function f (see [1, Paragraph II.1.4.2]) is of the form

$$\begin{aligned}h_f(\phi)&=\limsup_{\rho\to\infty}\frac{1}{\rho}\ln|f(\rho\mathrm{e}^{\mathrm{i}\phi})|\\&=\limsup_{\rho\to\infty}\frac{1}{\rho}\ln\left|C_0\mathrm{e}^{\mathrm{i}z\sum_{s=1}^{\ell}m_s}+C_1+\sum_{j=2}^{N_0}C_j\mathrm{e}^{\mathrm{i}z(q_j+\frac{1}{2}\sum_{s=1}^{\ell}m_s)}\right|\\&=\begin{cases}0, & \phi\in[0,\pi],\\ -\sum_{s=1}^{\ell}m_s\sin\phi, & \phi\in[-\pi,0].\end{cases}\end{aligned}$$

Therefore, the indicator diagram is $G_f=\big[-\mathrm{i}\sum_{s=1}^{\ell}m_s,0\big]$. Finally, observe that the set of zeros of f is exactly

$$\{\delta_s+2\pi\mathrm{i}k\}_{\substack{s=1,\dots,\ell\\|k|>N}}\bigcup\{\varepsilon_j\}_{j=1,\dots,r},$$

the roots $\delta_s+2\pi\mathrm{i}k$ are of multiplicity m_s, and the roots ε_j are of multiplicity m_j'. To summarize, we conclude that $f(z)$ is a generating function (see [1, Definition II.4.21]) of the family $\mathcal{E}$ on the interval $[0,\sum_{s=1}^{\ell}m_s]$ and, therefore, this family is a Riesz basis of $L_2(0,\sum_{s=1}^{\ell}m_s)$. The statement is proved.

(ii) Let us denote $\gamma=T-\sum_{s=1}^{\ell}m_s>0$ and choose a complex number μ such that

$$\mu+\frac{2\pi\mathrm{i}m}{\gamma}\neq\delta_s+2\pi\mathrm{i}k\quad\text{and}\quad\mu+\frac{2\pi\mathrm{i}m}{\gamma}\neq\varepsilon_j$$

for all $m,k\in\mathbb{Z}$, $s=1,\dots,\ell$, $j=1,\dots,r$. Let us put $m'=\sum_{j=1}^{r}m_j'$ and

$$\begin{aligned}\mathcal{E}_1^{(m')}&=\left\{\mathrm{e}^{(\mu+\frac{2\pi\mathrm{i}m}{\gamma})t}\right\}_{m\in\mathbb{Z}\setminus\{1,\dots,m'\}},\\\widetilde{\mathcal{E}}_N&=\left\{\mathrm{e}^{(\delta_s+2\pi\mathrm{i}k)t},t\mathrm{e}^{(\delta_s+2\pi\mathrm{i}k)t},\dots,t^{m_s-1}\mathrm{e}^{(\delta_s+2\pi\mathrm{i}k)t}\right\}_{\substack{|k|>N\\s=1,\dots,\ell}}\end{aligned}$$

and consider the family

$$\widetilde{\mathcal{E}}_N\cup\mathcal{E}_0\cup\mathcal{E}_1^{(m')}.$$

Now let us introduce a complex function of the sine type given by

$$f_1(z)=\mathrm{e}^{\mathrm{i}(\frac{z}{2}\sum_{s=1}^{\ell}m_s+\gamma)}\prod_{s=1}^{\ell}\left(\sin\left(\frac{z}{2}-\frac{\delta_s}{2}\right)\right)^{m_s}R_1(z)\sin\gamma\left(\frac{z}{2}-\frac{\mu}{2}\right),$$

where

$$R_1(z)=\prod_{j=1}^{r}(z-\varepsilon_j)^{m_j'}\left(\prod_{m=1}^{m_j'}\left(z-\mu-\frac{2\pi\mathrm{i}m}{\gamma}\right)\right)^{-1}\to1\quad\text{as}\quad z\to\infty.$$

Then, by arguments analogous to those given in the proof of part (i), it follows that $f_1(z)$ is a generating function of $\widetilde{\mathcal{E}}_N \cup \mathcal{E}_0 \cup \mathcal{E}_1^{(m')}$ on the interval $[0,T]$. Therefore, this family forms a Riesz basis of $L_2(0,T)$. Now, since $\mathcal{E} \subset \widetilde{\mathcal{E}}_N \cup \mathcal{E}_0 \cup \mathcal{E}_1^{(m')}$, this means that $\mathcal{E}$ forms a Riesz basis in $\operatorname{Cl}\operatorname{Lin}\mathcal{E} \subset L_2(0,T)$. The proof of the theorem is complete. □

Now we apply Theorem 4.4 to the collection of functions appearing in (3.16). Let us fix $d \in \{1,\dots,r\}$ and choose an arbitrary subset $L \subset \{1,\dots,\ell\}$. Next, for any $m \in L$ we choose $j(m) \in \{1,\dots,\nu_m\}$ and denote $J(L) = \{j(m)\}_{m\in L}$. Finally, for any couple $(m, j(m))$, $m \in L$, we put $\pi_{m,j(m)} = \deg q_{m,k}^{j(m),1,d}(t) + 1$. Let us recall that from (3.14) and Lemmas 3.2 and 3.3 it follows that this degree does not depend on k.

THEOREM 4.5. *For any choice of $d, L, J(L)$, for any $p'_{m,j(m)}$, such that $1 \le p'_{m,j(m)} \le \pi_{m,j(m)}$, and for any $T \ge n' = \sum_{m\in L} p'_{m,j(m)}$ the collection of functions*

$$\Phi_1 = \left\{ \mathrm{e}^{\lambda_m^{(k)} t} q_{m,k}^{j(m),s,d}(t),\ |k| > N;\ m \in L;\ s = \pi_{m,j(m)} - p'_{m,j(m)} + 1, \dots, \pi_{m,j(m)} \right\}$$

constitutes a Riesz basis of $\operatorname{Cl}\operatorname{Lin}\Phi_1$ *in* $L_2(0,T)$.

If in addition N is large enough, then the family

$$\Phi_2 = \left\{ \mathrm{e}^{\lambda_m^{(k)} t} q_{m,k}^{j(m),s,d}(t) + f_{m,k}^{j(m),s,d}(t) \right\}_{|k|>N;\ m\in L;\ s=\pi_{m,j(m)}-p'_{m,j(m)}+1,\dots,\pi_{m,j(m)}}$$

also forms a Riesz basis of $\operatorname{Cl}\operatorname{Lin}\Phi_2$ *in* $L_2(0,T)$.

If $T = n'$, the subspaces $\operatorname{Cl}\operatorname{Lin}\Phi_1$ *and* $\operatorname{Cl}\operatorname{Lin}\Phi_2$ *are of finite codimension* $(2N+1)n'$ *in* $L_2(0,n')$.

Proof. Consider the linear operator $\mathcal{T} : \operatorname{Lin}\Phi_1 \to \operatorname{Lin}\Phi_1$ defined on the elements of Φ_1 by the equalities

$$\mathcal{T}(\mathrm{e}^{\lambda_m^{(k)} t} q_{m,k}^{j(m),s,d}(t)) = \mathrm{e}^{\lambda_m^{(k)} t} t^{p'_{m,j(m)}-s}$$

for $|k| > N$; $m \in L$; $s = \pi_{m,j(m)} - p'_{m,j(m)} + 1, \dots, \pi_{m,j(m)}$. It follows from the properties (P1) and (P2) (see section 3) and Theorem 4.4 that the operator $\mathcal{T}$ is bounded in the sense of $L_2(0,T)$ and its extension to $L = \operatorname{Cl}\operatorname{Lin}\Phi_1$ is a bounded one-to-one operator from L to L. Hence, since the images of the elements of Φ_1 form a Riesz basis of L (Theorem 4.4), then Φ_1 is also a Riesz basis of this subspace of $L_2(0,T)$.

Next, let us introduce in $L_2(0,T)$ an equivalent norm $\|\cdot\|_1$ in which the system Φ_1 becomes orthonormal. Let Φ_1^c be an orthonormal complement of the basis Φ_1 to a basis of $L_2(0,T)$. Now using the property (P3), we choose the scalar N large enough so that

$$\sum_{\substack{|k|>N\\ m\in L\\ s\in I_m}} \|f_{m,k}^{j(m),s,d}\|_1^2 \le C \sum_{\substack{|k|>N\\ m\in L\\ s\in I_m}} \|f_{m,k}^{j(m),s,d}\|_{L_2}^2 < 1,$$

where $I_m = \pi_{m,j(m)} - p'_{m,j(m)} + 1, \dots, \pi_{m,j(m)}$. Then $\Phi_2 \cup \Phi_1^c$ is quadratically close in $\|\cdot\|_1$ to the orthonormal system $\Phi_1 \cup \Phi_1^c$ with a quadratic distance less than 1. This means that $\Phi_2 \cup \Phi_1^c$ forms also a Riesz basis in $L_2(0,T)$ (see Gohberg and Krein [4]). As a consequence, Φ_2 is a Riesz basis in $\operatorname{Cl}\operatorname{Lin}\Phi_2$.

Finally, let us observe that in the case $T = n'$ the space L, which is also presented as

$$L = \operatorname{Cl}\operatorname{Lin}\left\{ \mathrm{e}^{\lambda_m^{(k)} t} t^{p'_{m,j(m)}-s}, |k| > N; m \in L, s = \pi_{m,j(m)} - p'_{m,j(m)} + 1, \dots, \pi_{m,j(m)} \right\},$$

is of codimension $(2N+1)n'$ in $L_2(0,T)$ (see Theorem 4.4). Then Φ_1^c consists of exactly $(2N+1)n'$ elements. The proof is complete. □

5. Analysis of the controllability for a single control. Let us study the solvability of the systems of equalities (3.16) and (3.17). We assume again that the matrix A_{-1} is not singular, $\det A_{-1} \neq 0$.

Consider the sequence of functions

$$\left\{\int_0^T \mathrm{e}^{\lambda_m^{(k)} t} q_{m,k}^{j(m),s,d}(t) + f_{m,k}^{j(m),s,d}(t)\mathrm{d}t\right\} = \left\{\int_0^T \mathrm{e}^{\lambda_m^{(k)} t} q_{m,k}^{j(m),s,d}(t)\mathrm{d}t + \int_0^T f_{m,k}^{j(m),s,d}(t)\mathrm{d}t\right\} \tag{5.1}$$

for $|k| > N,\ s = 1, \dots, p_{m,j(m)}$, and any fixed d, m, j and $u(\cdot) \in L_2(0,T)$. It follows from Theorem 4.5 that all nonzero functions of the collection

$$\left\{\mathrm{e}^{\lambda_m^{(k)} t} q_{m,k}^{j(m),s,d}(t),\ |k| > N;\ s = 1, \dots, p_{m,j}\right\}$$

form a Riesz basis of their linear span in $L_2(0,T')$ if T' is large enough. Therefore, by Proposition 4.1, the first term of (5.1) belongs to the class ℓ_2. On the other hand, the second term also belongs to ℓ_2 due to Proposition 4.3. This gives the following proposition.

PROPOSITION 5.1. *If the state* $\binom{y_T}{z_T(\cdot)}$ *is reachable from* 0 *by the system* (1.3), *then it satisfies the following equivalent conditions:*

(C1) $\sum_{\substack{|k|>N \\ m,j,s}} k^2 |\langle \binom{y_T}{z_T(\cdot)}, \psi_{m,k}^{j,s}\rangle|^2 < \infty$,

(C2) $\sum_{\substack{|k|>N \\ m=1,\dots,\ell}} k^2 \|P_m^{(k)} \binom{y_T}{z_T(\cdot)}\|^2 < \infty$,

(C3) $\binom{y_T}{z_T(\cdot)} \in \mathcal{D}(\mathcal{A})$.

Proof. The condition (C1) follows from the previous consideration. Note that actually the validity of (C1) does not depend on the choice of the basis $\{\psi\}$. In fact, we can observe that

$$P_m^{(k)} \begin{pmatrix} y_T \\ z_T(\cdot) \end{pmatrix} = \sum_{\substack{j=1,\dots,\nu_m \\ s=1,\dots,p_{m,j}}} \left\langle \begin{pmatrix} y_T \\ z_T(\cdot) \end{pmatrix}, \psi_{m,k}^{j,s} \right\rangle \phi_{m,k}^{j,s}.$$

From here and since $\{\psi\}$ is a Riesz basis [14], we deduce that there exist two constants c and C (independently of m and k) such that

$$c^2 \sum_{j,s} \left| \left\langle \begin{pmatrix} y_T \\ z_T(\cdot) \end{pmatrix}, \psi_{m,k}^{j,s} \right\rangle \right|^2 \le \|P_m^{(k)} \begin{pmatrix} y_T \\ z_T(\cdot) \end{pmatrix}\|^2 \le C^2 \left| \left\langle \begin{pmatrix} y_T \\ z_T(\cdot) \end{pmatrix}, \psi_{m,k}^{j,s} \right\rangle \right|^2 \tag{5.2}$$

and this gives the equivalence between (C1) and (C2). Let us show now that (C1) and (C2) are equivalent to (C3).

First of all, we notice that from the explicit form of the resolvent $R(\lambda, \mathcal{A})$ given in [11, Proposition 1] and by arguments and estimates given in the proof of [11, Theorem 2.9], it follows that there exists a constant C such that

$$\|R(\lambda, \mathcal{A})| \le C, \qquad \lambda \in L_m^{(k)}, \quad |k| > N,\ m = 1, \dots, \ell. \tag{5.3}$$

Let $\mathcal{A}_m^{(k)} : V_m^{(k)} \to V_m^{(k)}$ be the restriction of the operator $\mathcal{A}$ to its invariant subspace $V_m^{(k)}$. Then due to (5.3) we have

$$\begin{aligned} \|\mathcal{A}_m^{(k)} v\| &\le \int_{L_m^{(k)}} |\lambda| \|R(\lambda,\mathcal{A})\| \|v\| |\mathrm{d}\lambda| \le C_1 |k| \|v\|, \\ \left\| \left(\mathcal{A}_m^{(k)}\right)^{-1} v \right\| &\le \int_{L_m^{(k)}} \frac{1}{|\lambda|} \|R(\lambda,\mathcal{A})\| \|v\| |\mathrm{d}\lambda| \le \frac{C_1'}{|k|} \|v\|, \end{aligned}$$

where $v \in V_m^{(k)}$ and the constants C_1, C_1' do not depend on m, k. From this, one can obtain for $v \in V_m^{(k)}$ the inequality

$$\frac{1}{C_1'} \|v\| \le \frac{1}{k} \|\mathcal{A}_m^{(k)} v\| \le C_1 \|v|. \tag{5.4}$$

With our notations, the condition (C3) is obviously equivalent to

$$\sum_{\substack{|k|>N \\ m=1,\dots,\ell}} \left\| \mathcal{A}_m^{(k)} P_m^{(k)} \begin{pmatrix} y_T \\ z_T(\cdot) \end{pmatrix} \right\|^2 < \infty.$$

But, on the other hand, due to (5.4) this condition is equivalent to (C2). This completes the proof. □

From Proposition 5.1 it follows once more, as was pointed out in the introduction (see also [5]), that the set $\mathcal{R}_T$ of the states reachable from 0 by virtue of the system (1.3) and controls from $L_2(0,T)$ is always a subset of $\mathcal{D}(\mathcal{A})$. This justifies also Definition 1.1 given in the introduction: *the system* (1.3) *is said to be null-controllable at the time* T *if* $\mathcal{R}_T = \mathcal{D}(\mathcal{A})$. Next, we give the necessary conditions of null-controllability.

THEOREM 5.2. *Assume that the system* (1.3) *is null-controllable by controls from* $L_2(0,T)$ *for some* $T > 0$. *Then the following two conditions hold.*

(i) *There is no* $\lambda \in \mathbb{C}$ *and* $y \in \mathbb{C}^n, y \ne 0$, *such that* $\Delta_{\mathcal{A}}^*(\lambda) y = 0$ *and* $B^* y = 0$, *where*

$$\Delta_{\mathcal{A}}^*(\lambda) = \lambda I - \lambda \mathrm{e}^{-\lambda} A_{-1}^* - \lambda \int_{-1}^{0} \mathrm{e}^{\lambda s} A_2^*(s) \mathrm{d}s - \int_{-1}^{0} \mathrm{e}^{\lambda s} A_3^*(s) \mathrm{d}s,$$

or equivalently $\operatorname{rank} \begin{pmatrix} \Delta_{\mathcal{A}}(\lambda) & B \end{pmatrix} = n$ *for all* $\lambda \in \mathbb{C}$.

(ii) *There is no* $\mu \in \sigma(A_{-1})$ *and* $y \in \mathbb{C}^n, y \ne 0$, *such that* $A_{-1}^* y = \bar{\mu} y$ *and* $B^* y = 0$, *or equivalently* $\operatorname{rank} \begin{pmatrix} B & A_{-1}B & \cdots & A_{-1}^{n-1}B \end{pmatrix} = n$.

First we prove the following lemma.

LEMMA 5.3. *Condition* (i) *of Theorem* 5.2 *is equivalent to the following condition:*

(i′) *There is no eigenvector* g *of the adjoint operator* $\mathcal{A}^*$ *belonging to* $\operatorname{Ker} \mathcal{B}^*$.

Proof of Lemma 5.3. We make use of the following explicit form of $\mathcal{A}^*$:

$$\mathcal{A}^* \begin{pmatrix} y \\ z(\cdot) \end{pmatrix} = \begin{pmatrix} A_2^*(0) y + z(0) \\ -\frac{\mathrm{d}}{\mathrm{d}\theta} \left(z(\theta) + A_2^*(\theta) y \right), + A_3^*(\theta) y \end{pmatrix}$$

with the domain

$$\begin{aligned} \mathcal{D}(\mathcal{A}^*) = \big\{ \big(y, z(\cdot) \big) \in M_2 : z(\theta) + A_2^*(\theta) y \in H^1([-1,0], \mathbb{C}^n), \\ (A_{-1}^* A_2^*(0) - A_2^*(-1)) y = z(-1) - A_{-1}^* z(0) \big\}. \end{aligned}$$

From this expression of the adjoint operator, one can show that $\mathcal{A}^*g = \lambda g$ if and only if

$$g = \begin{pmatrix} y \\ \left(\lambda \mathrm{e}^{-\lambda\theta} I - A_2^*(\theta) + \lambda \mathrm{e}^{-\lambda\theta} \int_0^\theta \mathrm{e}^{\lambda s} A_2^*(s)\mathrm{d}s + \mathrm{e}^{-\lambda\theta} \int_0^\theta \mathrm{e}^{\lambda s} A_3^*(s)\mathrm{d}s\right) y \end{pmatrix},$$

where $y \in \operatorname{Ker} \Delta^*(\lambda)$. Since $\mathcal{B}^*g = B^*y$, the proof of the lemma is complete. □

Proof of Theorem 5.2. Let (i) be false. Then by Lemma 5.3 there exists a vector $g \neq 0$ such that $\mathcal{A}^*g = \lambda g$ and $g \in \operatorname{Ker} \mathcal{B}^*$. Consider an arbitrary state $\binom{y_T}{z_T(\cdot)} \in \mathcal{R}_T$, i.e., which is of the form (1.4). This gives

$$\left\langle \begin{pmatrix} y_T \\ z_T(\cdot) \end{pmatrix}, g \right\rangle = \int_0^T \left\langle u(t), \mathcal{B}^* \mathrm{e}^{\mathcal{A}^* t} g \right\rangle \mathrm{d}t = 0.$$

This means that $\mathcal{R}_T$ is not dense in M_2 and so cannot be equal to $\mathcal{D}(\mathcal{A})$ which is dense in M_2 because $\mathcal{A}$ is an infinitesimal generator. Hence null-controllability is impossible.

Now let condition (ii) not hold, i.e., there exists a nonzero vector $y \in \mathbb{C}^n$ such that

$$A_{-1}^* y = \bar{\mu}_m y \qquad \text{and} \qquad B^* y = 0. \tag{5.5}$$

With our notations, we can represent y as

$$y = \sum_{j=1}^{\nu_m} \alpha_j C_{m,j}^1,$$

where $C_{m,j}^1$ is a basis of the eigenspace of A_{-1}^* corresponding to the eigenvalue $\bar{\mu}_m$. Among the moment equalities (3.16) we can extract those corresponding to $s = p_{m,j}$ (for fixed m and $j = 1, \dots, \nu_m$), i.e.,

$$s_k^j = k \left\langle \begin{pmatrix} y_T \\ z_T(\cdot) \end{pmatrix}, \psi_{m,k}^{j,p_{m,j}} \right\rangle = \sum_{d=1}^{r} \int_0^T \left(\mathrm{e}^{\lambda_m^{(k)} t} q_{m,k}^{j,p_{m,j},d}(t) + f_{m,k}^{j,p_{m,j},d}(t) \right) u_d(t) \mathrm{d}t \tag{5.6}$$

for $|k| > N,\ j = 1, \dots, \nu_m$. From (3.14) and Lemma 3.2 we have

$$q_{m,k}^{j,p_{m,j},d}(t) = k \left\langle \mathbf{b}_d, \bar{\psi}_{m,k}^{j,p_{m,j}} \right\rangle = \frac{k}{\bar{\lambda}_m^{(k)}} \left\langle b_d, C_{m,j}^1 \right\rangle. \tag{5.7}$$

Let us show that the moment problem (5.6) cannot be solved for all $\{s_k^j\} \in \ell_2$.

Assume the opposite; then the problem

$$\widetilde{s}_k^j = \sum_{j=1}^{\nu_m} \bar{\alpha}_j s_k^j = \sum_{d=1}^{r} \int_0^T \sum_{j=1}^{\nu_m} \bar{\alpha}_j \left(\mathrm{e}^{\lambda_m^{(k)} t} q_{m,k}^{j,p_{m,j},d}(t) + f_{m,k}^{j,p_{m,j},d}(t) \right) u_d(t) \mathrm{d}t$$

is also solvable for all $\{\widetilde{s}_k^j\} \in \ell_2$. On the other hand, (5.5) and (5.7) imply

$$\sum_{j=1}^{\nu_m} \bar{\alpha}_j \mathrm{e}^{\lambda_m^{(k)} t} q_{m,k}^{j,p_{m,j},d}(t) = \mathrm{e}^{\lambda_m^{(k)} t} \frac{k}{\bar{\lambda}_m^{(k)}} \left\langle b_d, \sum_{j=1}^{\nu_m} \alpha_j C_{m,j}^1 \right\rangle = 0.$$

Hence the latter moment problem reads as

$$\widetilde{s}_k^j = \sum_{d=1}^{r} \int_0^T g_k^d(t) u_d(t) \mathrm{d}t, \tag{5.8}$$

where $g_k^d(t) = \sum_{j=1}^{\nu_m} \bar{\alpha}_j f_{m,k}^{j,p_{m,j},d}(t)$, $|k| > N$, and, due to the property (P3), these functions satisfy

$$\sum_{|k|>N} \int_0^T |g_k^d(t)|^2 \mathrm{d}t < \infty.$$

However, by Proposition 4.3 it follows that the set of solvability of (5.8) is a linear submanifold $\ell' \subset \ell_2$, $\ell' \neq \ell_2$. From the obtained contradiction, we conclude that there exist sequences $\{s_k^j\}_{\substack{|k|>N \\ j=1,\dots,\nu_m}}$ for which (5.6) is not solvable. This means that there exist states $\binom{y_T}{z_T(\cdot)}$ that satisfy (C1) but are not reachable from 0 by the system (1.3). Thus $\mathcal{R}_T \neq \mathcal{D}(\mathcal{A})$. □

The following results will be used to prove the main results on controllability. They are also of independent interest.

LEMMA 5.4. *Assume that for an abstract system* (1.1) *the following conditions hold:*

(a) $\mathcal{R}_T \subset \mathcal{D}(\mathcal{A})$ *for all* $T > 0$,

(b) *for some* $T_0 > 0$ *the set* $\mathcal{R}_{T_0}$ *is a closed subspace of finite codimension in the space* $X_{\mathcal{A}} = \mathcal{D}(\mathcal{A})$, *with the standard graph norm* $\|x\|_{\mathcal{A}} = \sqrt{\|x\|^2 + \|\mathcal{A}x\|^2}$.

Then for all $T \geq T_0$ *we have* $\mathcal{R}_T = L$, *where* L *is a subspace of* $\mathcal{D}(\mathcal{A})$ *invariant by the semigroup* e^{At} *and* $0 < \operatorname{codim} L \leq \operatorname{codim} \mathcal{R}_{T_0} < \infty$.

Proof. Taking into account the inclusion $\mathcal{R}_{T_1} \subset \mathcal{R}_{T_2}$ as $T_1 \subset T_2$ we infer from assumptions (a) and (b) that there exists $\varepsilon > 0$ such that

$$\mathcal{R}_T = L, \quad T \in]T_0, T_0 + \varepsilon], \tag{5.9}$$

where L is a subspace such that $0 \leq \operatorname{codim} L \leq \operatorname{codim} \mathcal{R}_{T_0}$. Let us show that the relation (5.9) holds also for all $T > T_0$. To do that it is enough to prove that

$$\mathcal{R}_{T_0 + \frac{3}{2}\varepsilon} = L. \tag{5.10}$$

Let us put

$$\mathcal{R}_{T_2}^{T_1} = \left\{ x : x = \int_{T_1}^{T_2} \mathrm{e}^{\mathcal{A}t} B u(t) \mathrm{d}t, u \in L_(T_1, T_2; U) \right\}$$

and $\mathcal{R}_T^0 = \mathcal{R}_T$. Let us prove first that

$$\mathcal{R}_{T_0 + \frac{3}{2}\varepsilon}^{T_0 + \varepsilon} \subset L. \tag{5.11}$$

In fact, it is easy to see that $\mathcal{R}_{T_0 + \frac{3}{2}\varepsilon}^{T_0 + \varepsilon} = \mathrm{e}^{\mathcal{A}\frac{\varepsilon}{2}} \mathcal{R}_{T_0 + \varepsilon}^{T_0 + \frac{\varepsilon}{2}}$. On the other hand, it follows from (5.9) that $L = \mathcal{R}_{T_0 + \varepsilon} = \mathcal{R}_{T_0 + \frac{\varepsilon}{2}}$ and hence $\mathcal{R}_{T_0 + \varepsilon}^{T_0 + \frac{\varepsilon}{2}} \subset \mathcal{R}_{T_0 + \varepsilon} = L$. Therefore

$$\mathrm{e}^{\mathcal{A}\frac{\varepsilon}{2}} \mathcal{R}_{T_0 + \varepsilon}^{T_0 + \frac{\varepsilon}{2}} \subset \mathrm{e}^{\mathcal{A}\frac{\varepsilon}{2}} L = \mathrm{e}^{\mathcal{A}\frac{\varepsilon}{2}} \mathcal{R}_{T_0 + \frac{\varepsilon}{2}} = \mathcal{R}_{T_0 + \varepsilon}^{\frac{\varepsilon}{2}} \subset \mathcal{R}_{T_0 + \varepsilon} = L.$$

Now from (5.11) and from the obvious relation

$$\mathcal{R}_{T_0+\frac{3}{2}\varepsilon} = \mathcal{R}_{T_0+\varepsilon} + \mathcal{R}^{T_0+\varepsilon}_{T_0+\frac{3}{2}\varepsilon},$$

we infer that

$$L \subset \mathcal{R}_{T_0+\frac{3}{2}\varepsilon} = \mathcal{R}_{T_0+\varepsilon} + \mathcal{R}^{T_0+\varepsilon}_{T_0+\frac{3}{2}\varepsilon} \subset L + L = L,$$

which proves (5.10).

Thus (5.9) is valid for all $T > T_0$. Then $L = \cup_{T>0}\mathcal{R}_T$, and, therefore, it is an invariant subspace for the semigroup $\{e^{\mathcal{A}t}\}_{t\geq 0}$. The lemma is proved. □

In the following, we denote by $X_{\mathcal{A}}$ the space $\mathcal{D}(\mathcal{A}) \subset M_2$ with the graph norm.

THEOREM 5.5. *For the system* (1.3) *let there exist a natural* N *and* $T_0 > 0$ *such that the moment problem* (3.16) *for* $T = T_0$ *and* $|k| > N$ *is solvable for all the vectors*

$$\left\{ k \left\langle \begin{pmatrix} y_T \\ z_T(\cdot) \end{pmatrix}, \psi^{j,s}_{m,k} \right\rangle \right\}_{|k|>N}$$

satisfying the condition (C1). *Then, from the condition* (i′) *of Lemma* 5.3, *it follows that* $\mathcal{R}_T = \mathcal{D}(\mathcal{A})$ *as* $T > T_0$.

Proof. Let us denote by $L_N \subset \mathcal{D}(\mathcal{A})$ the subspace

$$L_N = \mathrm{Cl}_{X_{\mathcal{A}}} \sum_{\substack{|k|>N \\ m=1,\dots,\ell}} V^{(k)}_m$$

and by P_N a projector onto L_N in $X_{\mathcal{A}}$. From the assumption on solvability of the problem (3.16), it follows that $P_N\mathcal{R}_{T_0} = L_N$. This, in particular, means that $\mathcal{R}_{T_0}$ is a subspace of finite codimension: $\operatorname{codim} L_N = (2N+1)n$ in $\mathcal{D}(\mathcal{A})$. Then by Lemma 5.4 we conclude that $\mathcal{R}_T = L$ as $T > T_0$, where $L \subset \mathcal{D}(\mathcal{A})$ is invariant with respect to $\{e^{\mathcal{A}t}\}_{t\geq 0}$ and $\operatorname{codim} L \leq (2N+1)n$. Let us prove that under the condition (i′) we have in fact $L = \mathcal{D}(\mathcal{A})$.

Assume the contrary. Then let us consider the dual space $X^*_{\mathcal{A}}$ and denote by $L^\perp \subset X^*_{\mathcal{A}}$ the subspace of functionals on $X_{\mathcal{A}}$ which are 0 on L. Obviously $L^\perp$ is finite dimensional. Denote by $\mathcal{A}^*_1$ the infinitesimal extension of $\mathcal{A}^*$ to the space $X^*_{\mathcal{A}}$ generating the semigroup $e^{\mathcal{A}^*_1 t}$. Since, due to Lemma 5.4, L is invariant with respect to $\{e^{\mathcal{A}t}\}_{t\geq 0}$, and then $L^\perp$ is invariant with respect to $\{e^{\mathcal{A}^*_1 t}\}_{t\geq 0}$. Taking into account the finite dimensionality of $L^\perp$, we conclude that $L^\perp \subset \mathcal{D}(\mathcal{A}^*_1)$ and there exists an eigenvector g of the operator $\mathcal{A}^*_1$ that lies in $L^\perp$. Let us notice now that the collection of subspaces $\{V^{(k)}_m, m = 1,\dots,\ell; |k| > N\}$ is a Riesz basis also for the space $X_{\mathcal{A}}$ and all these subspaces are invariant for the operator $\mathcal{A}_1 = \mathcal{A}_{|_{\mathcal{D}(\mathcal{A})}}$. This implies that the collection $\{W^{(k)}_m, m = 1,\dots,\ell; |k| > N; \widehat{W}_N\}$ is a Riesz basis of invariant subspaces for $\mathcal{A}^*_1$ in the space $X^*_{\mathcal{A}}$. From this, we infer that all the eigenvectors of $\mathcal{A}^*_1$ lie in

$$\bigcup_{m,k} W^{(k)}_m \bigcup \widehat{W}_N \subset \mathcal{D}(\mathcal{A}^*)$$

and, therefore, g is also an eigenvector for $\mathcal{A}^*$. Since $g \in L^\perp$, then

$$\left\langle \int_0^T e^{\mathcal{A}t}\mathcal{B}u(t)\mathrm{d}t, g \right\rangle = 0, \quad u(\cdot) \in L_2(0,T;U).$$

If we put $u(t) \equiv u \in U,\ t \in [0,T]$, the latter relation brings

$$0 = \int_0^T \left\langle u, \mathcal{B}^* \mathrm{e}^{\mathcal{A}^* t} g \mathrm{d}t \right\rangle = \int_0^T \langle u, \mathcal{B}^* g \rangle \, \mathrm{e}^{\mu t} \mathrm{d}t = \langle u, \mathcal{B}^* g \rangle \int_0^T \mathrm{e}^{\mu t} \mathrm{d}t$$

for all $u \in U$, where $\mathcal{A}^* g = \bar{\mu} g$. This implies $g \in \operatorname{Ker} \mathcal{B}^*$, which contradicts (C1). That completes the proof. □

Now we are ready to prove the first important result of our work.

THEOREM 5.6. *Let conditions* (i) *and* (ii) *of Theorem* 5.2 *hold. Then*

(i) *the system* (1.3) *is null-controllable at the time T as $T > n$;*

(ii) *if the system* (1.3) *is of single control ($r = 1$), then the estimation of the time of controllability in* (i) *is exact, i.e., the system is not controllable at time $T = n$.*

If the delay is h instead of 1, the time of exact controllability is $T = nh$.

Proof. Here we prove (i) for the case of a single control. In the case of multivariable control we obtain a more precise estimate for the time of controllability in section 6.

First of all, let us observe that conditions (i) and (ii) of Theorem 5.2 imply, in the case of single control, that all the eigenspaces of $\mathcal{A}^*$ and $\widetilde{\mathcal{A}}^*$ are one dimensional. In fact, otherwise we will have that there exists an eigenvector g of $\mathcal{A}^*$ or $\widetilde{\mathcal{A}}^*$ such that $\langle \mathbf{b}, g \rangle = 0$. But we know that g has the form

$$g = \begin{pmatrix} y \\ z(\theta) \end{pmatrix},$$

where y is a nonzero eigenvector for the pencil $\Delta^*(\lambda)$ (that is, $\Delta^*(\lambda_0) y = 0$ for some λ_0) or of the matrix A_{-1}^*, respectively. Since $\langle \mathbf{b}, g \rangle = 0$ gives $\langle b, y \rangle = 0$ we arrive at a contradiction with the conditions of Theorem 5.2.

Thus, equalities (3.16) and (3.17) take, in our case, the form

$$k \left\langle \begin{pmatrix} y_T \\ z_T(\cdot) \end{pmatrix}, \psi_{m,k}^{1,s} \right\rangle = \int_0^T \left(\mathrm{e}^{\lambda_m^{(k)} t} q_{m,k}^{1,s}(t) + f_{m,k}^{1,s}(t) \right) u(t) \mathrm{d}t, \tag{5.12}$$

where $|k| > N,\ m = 1, \dots, \ell,\ s = 1, \dots, p_{m,1}$, and

$$\left\langle \begin{pmatrix} y_T \\ z_T(\cdot) \end{pmatrix}, \widehat{\psi}_m^{1,s} \right\rangle = \int_0^T \mathrm{e}^{\widehat{\lambda}_m t} \widehat{q}_m^{1,s}(t) u(t) \mathrm{d}t, \tag{5.13}$$

where $m = 1, \dots, \ell_N,\ s = 1, \dots, \widehat{p}_{m,1}$. From Lemmas 3.2 and 5.3, it follows that all polynomials $\{q(t)\},\ \{\widehat{q}(t)\}$ are nontrivial and $\deg q_{m,k}^{1,s}(t) = p_{m,1} - s,\ \deg \widehat{q}_m^{1,s}(t) = \widehat{p}_{m,1} - s$. This gives

$$\sum_{m=1}^{\ell} p'_{m,1} = \sum_{m=1}^{\ell} \left(\deg q_{m,k}^{1,1} + 1 \right) = \sum_{m=1}^{\ell} p_{m,1} = n.$$

Applying Theorem 4.5, we find that for a large enough N, the collection

$$\Phi = \left\{ \mathrm{e}^{\lambda_m^{(k)} t} q_{m,k}^{1,s}(t) + f_{m,k}^{1,s}(t) \right\}_{\substack{|k|>N \\ m=1,\dots,\ell \\ s=1,\dots,p_{m,1}}} \bigcup \left\{ \mathrm{e}^{\widehat{\lambda}_m t} \widehat{q}_m^{1,s}(t) \right\}_{\substack{m=1,\dots,\ell_N \\ s=1,\dots,\widehat{p}_{m,1}}}$$

forms a Riesz basis in $\operatorname{Cl} \operatorname{Lin} \Phi \subset L_2(0,T)$. Then by Proposition 4.1 the moment problem (5.12) is solvable if and only if (C1) holds. Due to Theorem 5.5, this yields $\mathcal{R}_T = \mathcal{D}(\mathcal{A})$ for $T > n$.

To prove (ii) we first recall that the total number of elements of the family

$$\widehat{\Phi} = \left\{ \mathrm{e}^{\widehat{\lambda}_m t} \widehat{q}_m^{1,s}(t),\ m = 1, \dots, \ell_N;\ s = 1, \dots, \widehat{p}_{m,1} \right\}$$

equals $\sum_{m=1}^{\ell} \widehat{p}_{m,1} = (2N+2)n$. Since $\sum_{m=1}^{\ell} p_{m,1} = n$, we have

$$\sum_{m=1}^{\ell} \widehat{p}_{m,1} = (2N+1) \sum_{m=1}^{\ell} p_{m,1} + n.$$

On the other hand, it follows from Theorem 4.5 that in $L_2(0,n)$ we have

$$\operatorname{codim} \operatorname{Cl} \operatorname{Lin} \Phi_1 = (2N+1)n = (2N+1) \sum_{m}^{\ell} p_{m,1},$$

where

$$\Phi_1 = \left\{ \mathrm{e}^{\lambda_m^{(k)} t} q_{m,k}^{1,s}(t) + f_{m,k}^{1,s}(t),\ |k| > N,\ m = 1, \dots, \ell,\ s = 1, \dots, p_{m,1} \right\}.$$

This means that the family $\Phi = \Phi_1 \cup \widehat{\Phi}$ contains at least n functions, which are presented as linear combinations of the others. As a consequence, the set of reachability $\mathcal{R}_T$ for $T = n$ cannot be equal to $\mathcal{D}(\mathcal{A})$. More precisely, the codimension of $\mathcal{R}_T$ in $\mathcal{D}(\mathcal{A})$ satisfies the estimation $n \le \operatorname{codim} \mathcal{R}_T < \infty$. The theorem is proved. □

Remark 5.7. It is clear that the system (1.3) is also uncontrollable at time $T < n$. Moreover, it follows from Proposition 4.2 that, in this case, the set $\operatorname{Cl} \mathcal{R}_T$ is of infinite codimension in $X_{\mathcal{A}}$.

6. Controllability in the multivariable case. Let us now consider the multivariable case: $\dim B = r$ with also the assumption that the matrix A_{-1} is not singular, $\det A_{-1} \neq 0$.

Let $\{b_1, \dots, b_r\}$ be an arbitrary basis noted β. Let us introduce a set of integers. We denote $B_i = (\, b_{i+1}, \dots, b_r \,)$, $i = 0, 1, \dots, r-1$, which gives in particular $B_0 = B$ and $B_{r-1} = (\, b_r \,)$ and we put formally $B_r = 0$. We need in the following the integers

$$m_i^{\beta} = \operatorname{rank} (\, B_{i-1} \quad A_{-1}B_{i-1} \quad \cdots \quad A_{-1}^{n-1}B_{i-1} \,) - \operatorname{rank} (\, B_i \quad A_{-1}B_i \quad \cdots \quad A_{-1}^{n-1}B_i \,) \tag{6.1}$$

corresponding to the basis β. Let us denote

$$m_1 = \max_{\beta} m_1^{\beta}, \qquad \overline{m} = \min_{\beta} \max_{i} m_i^{\beta}, \tag{6.2}$$

for all possible choices of a basis β. It is easy to show that for all β, there exists i such that $m_i^{\beta} \ge m_1$ and then $\overline{m} \ge m_1$. Indeed, assume that m_1 is realized on the basis $\beta = \{b_1, \dots, b_r\}$, and consider an arbitrary basis $\beta_0 = \{b_1^0, \dots, b_r^0\}$. Then there exists i such that $\operatorname{Lin} \{b_i^0, \dots, b_r^0\} \not\subset \operatorname{Lin} \{b_2, \dots, b_r\}$ but $\operatorname{Lin} \{b_{i+1}^0, \dots, b_r^0\} \subset \operatorname{Lin} \{b_2, \dots, b_r\}$. For this integer i we have $m_i^{\beta_0} \ge m_1$.

Now we can formulate the main result of this section.

THEOREM 6.1. *Let conditions* (i) *and* (ii) *of Theorem* 5.2 *hold. Then*

(i) *the system* (1.3) *is null-controllable at the time* $T > \overline{m}$*;*

(ii) *the system* (1.3) *is not controllable at the time* $T < m_1$.

If the delay is h instead of 1, then in (i) and (ii) $\overline{m}$ and m_1 must be replaced by $\overline{m}h$ and $m_1 h$, respectively.

Proof. We show first that the system is not controllable at the time $T < m_1$.

Assume that the system is controllable. Let the basis where m_1 is realized be $\{b_1, \dots, b_r\}$. Consider now the relation (3.16) together with (3.14) and (3.15) given by the controllability problem. The basis $\{\widetilde{\psi}\}$ arising in (3.14) and (3.15) is given by (2.4) and expressed via the rootvectors $C^s_{m,j}$ of the matrix A^*_{-1}.

Let us choose the vectors $C^s_{m,j}$. Consider the subspace

$$\operatorname{Im}\left(\begin{array}{cccc} B_1 & A_{-1}B_1 & \cdots & A_{-1}^{n-1}B_1 \end{array}\right),$$

where $B_1 = \left(\begin{array}{ccc} b_2 & b_3 & \cdots \quad b_r \end{array}\right)$. Then the subspace

$$\mathcal{N}_1 = \{\operatorname{Im}\left(\begin{array}{cccc} B_1 & A_{-1}B_1 & \cdots & A_{-1}^{n-1}B_1 \end{array}\right)\}^{\perp} = \bigcap_{i=0}^{n-1} \operatorname{Ker} B_1^* {A^*_{-1}}^i$$

is invariant by A^*_{-1}. The condition of controllability gives that $A^*_{-1|_{\mathcal{N}_1}}$ has, for each eigenvalue $\overline{\mu}$, only one Jordan chain. Indeed, on the contrary, if there are two chains in $\mathcal{N}_1$, then there are two independent eigenvectors corresponding to the same eigenvalue in $\mathcal{N}_1 \subset \operatorname{Ker} B_1^*$, i.e., both these vectors are orthogonal to $b_2, \dots, b_r$. Then there exists a linear combination of these eigenvectors, which is orthogonal also to b_1 and, as a consequence, belongs to $\operatorname{Ker} B^*$. This contradicts the controllability condition.

Note also that $\dim \mathcal{N}_1 = n - \dim \operatorname{Im}\left(\begin{array}{cccc} B_1 & A_{-1}B_1 & \cdots & A_{-1}^{n-1}B_1 \end{array}\right) = m_1$. We take the corresponding vectors $C^s_{m,j}$ in $\mathcal{N}_1$. This implies

$$\left\langle C^s_{m,j}, b_i \right\rangle = 0, \quad i = 2, \dots, r.$$

This means that m is chosen such that $\overline{\mu}_m$ is an eigenvalue of $A^*_{-1|_{\mathcal{N}_1}}$, j is the number of the unique Jordan chain in $\mathcal{N}_1$, and s is the index of the vectors in the Jordan chain.

Let $\Omega_{\mathcal{N}_1}$ be the set of indices of the eigenvalues $\overline{\mu}_m \in \sigma(A^*_{-1|_{\mathcal{N}_1}})$. For each $m \in \Omega_{\mathcal{N}_1}$ we have a Jordan chain, say with the number $j(m)$ in $\mathcal{N}_1$. The indices of the corresponding generalized eigenvectors are

$$s \in \left\{p_{m,j(m)}, p_{m,j(m)} - 1, \dots, p_{m,j(m)} - p'_{m,j(m)} + 1\right\} = I_m,$$

the length of the Jordan chain is $p'_{m,j(m)}$, and $C^{p_{m,j(m)}}_{m,j(m)}$ is an eigenvector. For $m \in \Omega_{\mathcal{N}_1}$, $j(m)$ and $s \in I_m$ we consider the relation (3.16) which is the expression of the controllability condition. As $C^s_{m,j(m)} \in \mathcal{N}_1$, we get

$$k \left\langle \begin{pmatrix} y_T \\ z_T(\cdot) \end{pmatrix}, \psi^{j(m),s}_{m,k} \right\rangle = \int_0^T \mathrm{e}^{\lambda^{(k)}_m t} q^{j(m),s,1}_{m,k}(t) u_1(t) \mathrm{d}t + \sum_{d=1}^{r} \int_0^T f^{j,s,d}_{m,k}(t) u_d(t) \mathrm{d}t \tag{6.3}$$

for $|k| > N$. From the hypothesis of controllability at the time T, it follows that the left-hand side gives an arbitrary element of ℓ_2, and then the relation (6.3) may be represented by the expression

$$x = [Q_1 + F]\, u(\cdot), \quad x \in \ell_2, \tag{6.4}$$

where the operators Q_1 and F are linear bounded operators from $L_2(0,T)$ to ℓ_2 defined by

$$Q_1 u(\cdot) = \left\{ \int_0^T \mathrm{e}^{\lambda_m^{(k)} t} q_{m,k}^{j(m),s,1}(t) u_1(t) \mathrm{d}t;\ m \in \Omega_{\mathcal{N}_1},\ |k| > N,\ s \in I_m \right\},$$

$$Fu(\cdot) = \left\{ \sum_{d=1}^{r} \int_0^T f_{m,k}^{j(m),s,d}(t) u_d(t) \mathrm{d}t;\ m \in \Omega_{\mathcal{N}_1},\ |k| > N, s \in I_m \right\}.$$

We now need the following lemmas.

LEMMA 6.2. *The operator F is compact.*

Proof. By (P3) the operator F is compact in the same way as Q_T^r is compact in Proposition 4.3. □

LEMMA 6.3. *The image of the operator Q_1 is of infinite codimension.*

Proof. Let us recall that $m_1 = \dim \mathcal{N}_1$. Then for each k, the sum of the length of Jordan chains of the operator $\widetilde{\mathcal{A}}$ corresponding to the Jordan chains in $\mathcal{N}_1$ is m_1:

$$\sum_{m \in \Omega_{N_1}} p'_{m,j(m)} = m_1.$$

Let us first show that the family

$$\left\{ \mathrm{e}^{\lambda_m^{(k)} t} q_{m,k}^{j(m),s,1}(t),\ m \in \Omega_{\mathcal{N}_1},\ |k| > N,\ s \in I_m \right\} \tag{6.5}$$

forms a Riesz basis of the closure of its linear span in the space $L_2(0, m_1)$. In order to do that, we have to consider the family

$$\left\{ \mathrm{e}^{\lambda_m^{(k)} t}, \mathrm{e}^{\lambda_m^{(k)} t} t, \dots, \mathrm{e}^{\lambda_m^{(k)} t} t^{p_{m,j(m)}-1};\ m \in \Omega_{\mathcal{N}_1},\ |k| > N, \right\}. \tag{6.6}$$

This family forms a Riesz basis of the closure of its linear span in $L_2(0, m_1)$ by Theorem 4.4. Moreover, the closure of its linear span is of finite codimension $(2N+1)m_1$ since it may be completed by a family of $(2N+1)m_1$ functions to get a Riesz basis of $L_2(0, m_1)$. The relation between the families (6.5) and (6.6) may be written as

$$\mathcal{T}(\mathrm{e}^{\lambda_m^{(k)} t} q_{m,k}^{j(m),s,1}(t)) = \mathrm{e}^{\lambda_m^{(k)} t} t^{p_{m,j(m)}-s},$$

where $\mathcal{T}$ is a linear bounded invertible operator in the closure of the linear span of the family (6.5). This implies that this family forms a Riesz basis in the closure of its linear span, which is of finite codimension. Then, from Proposition 4.2, the problem of moments

$$s_{m,k}^{j(m),s} = \int_0^T \mathrm{e}^{\lambda_m^{(k)} t} q_{m,k}^{j(m),s,1}(t) u_1(t) \mathrm{d}t$$

is not solvable in a subspace of infinite codimension and this implies that $\operatorname{Im} Q_1$ is of infinite codimension. Lemma 6.3 is proved. □

Let us now show that, from the fact that $\operatorname{Im} Q_1$ is of infinite codimension and F is a compact operator, we have $\operatorname{Im}[Q_1 + F] \neq \ell_2$.

The necessary and sufficient condition of the equality $\operatorname{Im}[Q_1 + F] = \ell_2$ is (cf., for example, [13, Theorem 4.13])

$$\exists \gamma > 0 \quad \forall x \in \ell_2, \quad \|[Q_1 + F]^* x\| \geq \gamma \|x\|.$$

We know that $\operatorname{Ker} Q_1^* = (\operatorname{Im} Q_1)^\perp$ is an infinite-dimensional closed subspace. This implies that

$$\forall x \in \operatorname{Ker} Q_1^*, \quad \|F^* x\| \geq \gamma \|x\|$$

for the same scalar γ, and this is impossible because F is a compact operator. Hence $\operatorname{Im}[Q_1 + F] \neq \ell_2$ and this implies that (6.4) is not possible for all $x \in \ell_2$.

Then the relation (6.3) is not possible for all $(y_T, z_T(\cdot)) \in \mathcal{D}(\mathcal{A})$ if $T < m_1$. Part (ii) of the theorem is proved.

Let us now prove part (i) of the theorem.

First we choose a basis for the relation (3.16). Let $\beta = \{b_1, \dots, b_r\}$ be an arbitrary basis of $\operatorname{Im} B$ and $T > \max\{m_i^\beta, i = 1, \dots, r\}$. Consider now the subspaces

$$\mathcal{N}_i = \bigcap_{j=0}^{n-1} \operatorname{Ker} B_i^* {A_{-1}^*}^j,$$

where $B_i = (\, b_{i+1} \quad \cdots \quad b_r \,)$, $i = 1, \dots, r-1$, $B_0 = B$, and $B_r = 0$. We have $\mathcal{N}_0 = 0$, $\mathcal{N}_r = \mathbb{C}^n$, and $\mathcal{N}_i \subset \mathcal{N}_{i+1}$ for $i = 0, \dots, r-1$. The subspaces $\mathcal{N}_i$ are invariant by A_{-1}^*. In order to construct the basis $\{\psi\}$ corresponding to $|k| > N$, we first choose a basis of generalized eigenvectors of A_{-1}^* in the following way. Let us take a basis in $\mathcal{N}_1$ as in the first part of the proof. Then we complete this basis up to a basis of $\mathcal{N}_2$ by extending some Jordan chains from $\mathcal{N}_1$ and by adding Jordan chains corresponding to some other eigenvalues. In the same way, we extend our basis up to the basis of $\mathcal{N}_3, \dots, \mathcal{N}_r = \mathbb{C}^n$.

Remark 6.4. The part of the obtained basis of $\mathcal{N}_i$ not belonging to $\mathcal{N}_{i-1}$, $i = 1, \dots, r$, does not contain two chains corresponding to the same eigenvalue. We have already proved that in $\mathcal{N}_1$ there do not exist two chains with the same eigenvalue. Suppose now that $\mathcal{N}_2$ contains the end of the first chain and the beginning of the second chain corresponding to the same eigenvalue. Let $y_1^{\mathrm{o}} \in \mathcal{N}_2, y_1^{\mathrm{o}} \notin \mathcal{N}_1$ be the continuation of the first chain from $\mathcal{N}_1$. If the maximal order of the rootvectors in $\mathcal{N}_1$ is p, then the order of y_1^{o} is $p+1$. Let y_2^{n} be a new eigenvector in the second chain of $\mathcal{N}_2$ corresponding to the same eigenvalue. Let us consider the vector $y = \alpha y_1^{\mathrm{o}} + \beta y_2^{\mathrm{n}}$. We know that y_1^{o} is not orthogonal to b_2, because if $y_1^{\mathrm{o}} \perp b_2$, then $y_1^{\mathrm{o}} \in \mathcal{N}_1$. Then one can choose α, β such that $y \perp b_2$. Then, for this choice of α and β, $y \in \mathcal{N}_1$ and it is a rootvector of higher order than p in $\mathcal{N}_1$, which contradicts the construction of $\mathcal{N}_1$ (the maximal order in $\mathcal{N}_1$ is $p-1$). This proves the remark for $i = 2$. For $i > 2$, the proof is the same.

We have then a basis in $\mathbb{C}^n$ of Jordan chains of A_{-1}^* formed by successive bases of

$$\mathcal{N}_1 \subset \mathcal{N}_2 \subset \cdots \subset \mathcal{N}_r = \mathbb{C}^n.$$

Let us denote by $\Omega_{\mathcal{N}_i/\mathcal{N}_{i-1}}$, $i = 1, \dots, r$ ($\Omega_{\mathcal{N}_1/\mathcal{N}_0} = \Omega_{\mathcal{N}_1}$), the set of the indices m of the eigenvalues of the matrix A_{-1}^* for which there exists chains in $\mathcal{N}_i$ not belonging to N_{i-1}. Since for any $m \in \Omega_{\mathcal{N}_i/\mathcal{N}_{i-1}}$ such a chain is unique we can denote its number by $j(m)$.

Using the constructed basis, we obtain a basis $\{\psi\}$ by the relation (2.4). In this basis, the relations (3.16) may be written as follows, and noted as $(\mathbf{R}_i, i = 1, \dots, r)$.

The first family $(\mathbf{R}_1)$ is

$$(\mathbf{R}_1)\qquad k\left\langle \begin{pmatrix} y_T \\ z_T(\cdot) \end{pmatrix}, \psi_{m,k}^{j(m),s} \right\rangle = \int_0^T \mathrm{e}^{\lambda_m^{(k)} t} q_{m,k}^{j(m),s,1}(t) u_1(t)\mathrm{d}t + \sum_{d=1}^{r} \int_0^T f_{m,k}^{j(m),s,d}(t) u_d(t)\mathrm{d}t \tag{6.7}$$

for $m \in \Omega_{\mathcal{N}_1},\ s = p_{m,j(m)} - p_{m,j(m)}^{1\prime} + 1, \dots, \pi_{m,j(m)}^1, p_{m,j(m)} - 1,\ |k| > N,\ \pi_{m,j(m)}^1 = p_{m,j(m)}$.

The second family $(\mathbf{R}_2)$ is

$$(\mathbf{R}_2)\qquad \begin{aligned} k\left\langle \begin{pmatrix} y_T \\ z_T(\cdot) \end{pmatrix}, \psi_{m,k}^{j(m),s} \right\rangle &= \int_0^T \mathrm{e}^{\lambda_m^{(k)} t} q_{m,k}^{j(m),s,1}(t) u_1(t)\mathrm{d}t \\ &\quad + \int_0^T \mathrm{e}^{\lambda_m^{(k)} t} q_{m,k}^{j(m),s,2}(t) u_2(t)\mathrm{d}t \\ &\quad + \sum_{d=1}^{r} \int_0^T f_{m,k}^{j(m),s,d}(t) u_d(t)\mathrm{d}t \end{aligned} \tag{6.8}$$

for $m \in \Omega_{\mathcal{N}_2/\mathcal{N}_1},\ s = \pi_{m,j(m)}^2 - p_{m,j(m)}^{2\prime} + 1, \dots, \pi_{m,j(m)}^2,\ |k| > N$, where $\pi_{m,j(m)}^2$ and $p_{m,j(m)}^{2\prime}$ are some integer.

The last one $(\mathbf{R}_r)$ being

$$(\mathbf{R}_r)\qquad k\left\langle \begin{pmatrix} y_T \\ z_T(\cdot) \end{pmatrix}, \psi_{m,k}^{j(m),s} \right\rangle = \sum_{d=1}^{r} \int_0^T \mathrm{e}^{\lambda_m^{(k)} t} q_{m,k}^{j(m),s,d}(t) u_d(t)\mathrm{d}t + \sum_{d=1}^{r} \int_0^T f_{m,k}^{j,s,d}(t) u_d(t)\mathrm{d}t \tag{6.9}$$

for $m \in \Omega_{\mathcal{N}_r/\mathcal{N}_{r-1}},\ j = j(m),\ s = \pi_{m,j(m)}^r - p_{m,j(m)}^{r\prime} + 1, \dots, \pi_{m,j(m)}^r,\ |k| > N$, with some integer $\pi_{m,j(m)}^r$ and $p_{m,j(m)}^{r\prime}$.

For each $|k| > N$ the number of equalities $(\mathbf{R}_i, i = 1, \dots, r)$ is exactly m_i^β (see the definition of this number in (6.1)).

Remark 6.5. Let us specify that in the collections $(\mathbf{R}_i, i = 1, \dots, r)$, for each k there exists only one group of quasi polynomials corresponding to the given exponent. Moreover, for each $i, \dots, r$, the quasi polynomials corresponding to $d = i$ have degrees $0, 1, \dots, p^{i\prime}$, as follows from (2.4), (3.14), and Lemma 3.3.

Before solving the problems $(\mathbf{R}_i, i = 1, \dots, r)$ we solve first the same problems with $f_{m,k}^{j,s,d} = 0$, noted $(\mathbf{R}_i^0, i = 1, \dots, r)$.

LEMMA 6.6. *The problems* $(\mathbf{R}_i^0, i = 1, \dots, r)$ *obtained from* $(\mathbf{R}_i, i = 1, \dots, r)$ *by the assumption that* $f_{m,k}^{j,s,d} = 0$ *with* $T > \max\{m_i^\beta, i = 1, \dots, r\}$ *are solvable if and only if the left-hand side is an element of* ℓ_2.

Proof. Consider the problem $(\mathbf{R}_1^0)$ obtained from (6.7) with the assumption $f_{m,k}^{j,s,d} = 0$. This problem is solvable if and only if the left-hand side is ℓ_2 by Theorem 4.5. *If this problem is not solvable, then the problems* $(\mathbf{R}_i^0)$ *are not solvable.* If $(\mathbf{R}_1^0)$ is solvable, then we can find a solution $u_1(t)$. Then, in the problem $(\mathbf{R}_2^0)$ the term

$$\int_0^T \mathrm{e}^{\lambda_m^{(k)} t} q_{m,k}^{j(m),s,1}(t) u_1(t)\mathrm{d}t$$

on the right-hand side is determined and may be moved to the left-hand side. Hence $(\mathbf{R}_2^0)$ is a new moment problem with unknown function $u_2(t)$. It is solvable if and only if the left-hand side is in ℓ_2.

Repeating this argumentation up to $(\mathbf{R}_r^0)$, we obtain that the global problem $(\mathbf{R}_i^0, i = 1, \dots, r)$ is solvable if and only if the right-hand side in (6.7)–(6.9) is in ℓ_2. The proof of Lemma 6.6 is complete. □

Let us now return to the general problem $(\mathbf{R}_i, i = 1, \dots, r)$ given in (6.7)–(6.9). One can represent the equalities $(\mathbf{R}_i, i = 1, \dots, r)$ in the following operator form:

$$x = Q_N u(\cdot) + F_N u(\cdot), \quad x \in \ell_2, \quad u(\cdot) \in L_2(0, T; \mathbb{C}^r),$$

with N the integer for which the problem is considered ($|k| > N$). We shall prove that there exists N sufficiently large such that

$$\operatorname{Im} Q_N = \ell_2 \Longrightarrow \operatorname{Im} [Q_N + F_N] = \ell_2,$$

and the last equality means that $(\mathbf{R}_i, i = 1, \dots, r)$ is solvable if $(\mathbf{R}_i^0, i = 1, \dots, r)$ is solvable, i.e., if the left-hand sides in (6.7)–(6.9) are in ℓ_2.

Suppose that $\operatorname{Im} Q_N = \ell_2$; then there exists a constant $\gamma_N > 0$ such that $\|Q_N^* x\| \geq \gamma_N \|x\|$ for all $x \in \ell_2$ (see, for example, [13, Theorem 4.13]). Let $N > N_0$ and let us denote by ℓ_2^N the Hilbert space $\ell_2(N) = \{s_k, |k| > N : \sum_{|k|N} |s_k|^2 < \infty\}$; then $Q_N = P Q_{N_0}$ where $P : \ell_2^{N_0} \to \ell_2^N$ is the projector defined by

$$P(\{s_k, |k| > N_0\}) = \{s_k, |k| > N\}.$$

Then $Q_N^* = Q_{N_0}^* P^*$ and $\|P^* x\| = \|x\|$. This gives

$$\|Q_N^* x\| = \|Q_{N_0}^* P^* x\| \geq \gamma_{N_0} \|x\|.$$

This means that for all $N > N_0$, $\|Q_N^* x\| \geq \gamma \|x\|$ for all $x \in \ell_2$, where $\gamma = \gamma_0$.

Consider now the operator F_N. By the property (P3) (section 3) we have $\|F_N\| \to 0$ when $N \to \infty$. Hence the norm $\|Q_N - Q_N - F_N\| = \|F_N\|$ can be made arbitrarily small, say $\|F_N\| \leq \frac{\gamma}{2}$. This gives that the operator $Q_N + F_N$ is also surjective because

$$\|[Q_N^* + F_N^*]x\| \geq \|Q_N^* x\| - \|F_N^* x\| \geq \gamma \|x\| - \frac{\gamma}{2} \|x\| = \frac{\gamma}{2} \|x\|.$$

Then from Lemma 6.6 it follows that if $T > \max\{m_i^\beta, i = 1, \dots, r\}$, the moment problem $(\mathbf{R}_i, i = 1, \dots, r), |k| > N$, is solvable for all left-hand sides in ℓ_2.

Applying now Theorem 5.5, we conclude that $\mathcal{R}_T = \mathcal{D}(\mathcal{A})$. The proof of the theorem is complete. □

7. Controllability in the general case. In the previous section, we use the assumption that the system (1.2) is a pure neutral-type system ($\det A_{-1} \neq 0$). However, this condition is in fact a technical assumption that allows the use of the Riesz basis of eigenspaces of the operator $\mathcal{A}$ in M_2 and the moment problem approach.

In this section, we show that conditions (i) and (ii) of Theorem 5.2 are necessary and sufficient for exact controllability for the general neutral systems (A_{-1} may be a singular matrix). We obtain also the precise time of controllability. From Theorem 6.1 it is not clear what happens if the time T is such that $m_1 \leq T \leq \overline{m}$ even if the conditions of controllability are satisfied. In this section, the exact time of controllability is given. In order to do that, we need the classical concept of the controllability indices.

Recall that the first index n_1 may be defined as the minimal integer ν such that (see, for example, [15, Chapter 5])

$$\operatorname{rank}\left(B, A_{-1}B, \ldots, {A_{-1}}^{\nu-1}B\right) = n.$$

LEMMA 7.1. *Assume that the pair $(\mathcal{A}_{-1}, B)$ is controllable. Let n_1 be the index of controllability of the couple (A_{-1}, B) and let $\overline{m}, m_1$ be defined by* (6.2). *Then $m_1 \le n_1 \le \overline{m}$.*

Proof. Let $\beta = \{b_1, \ldots, b_r\}$ be an arbitrary basis of $\operatorname{Im} B$. Then

$$A^{n_1}b_1 \in \operatorname{Im}\left(B \quad AB \quad \cdots \quad A^{n_1-1}B\right) = \operatorname{Im}\left(B \quad AB \quad \cdots \quad A^{n-1}B\right).$$

This may be written as

$$A^{n_1}b_1 \in \operatorname{Lin}\{b_1, Ab_1, \ldots, A^{n_1-1}b_1\} + \operatorname{Im}\left(B_1 \quad AB_1 \quad \cdots \quad A^{n_1-1}B_1\right).$$

This gives that $m_1^\beta \le n_1$ for all β. Hence $m_1 \le n_1$.

Let us now consider the indices $m_1^\beta, \cdots, m_r^\beta$. By the definition of the integers m_i^β we get that

$$\left\{b_1, \ldots, A^{m_1{}^\beta-1}b_1, b_2, \ldots, A^{m_2{}^\beta-1}b_2, \ldots, b_r, \ldots, A^{m_r{}^\beta-1}b_r\right\}$$

is a basis in $\mathbb{C}^n$. This may be verified remarking first that, by definition, the vectors $b_r, \ldots, A^{m_r^\beta-1}b_r$ are linearly independent and

$$\operatorname{Lin}\{b_r, \ldots, A^{m_r^\beta-1}b_r\} = \operatorname{Lin}\{b_r, \ldots, A^{n-1}b_r\}.$$

Then we have to consider the previous step, i.e., m_{r-1}^β, and state that

$$\left\{b_{r-1}, \ldots, A^{m_{r-1}^\beta}b_{r-1}, b_r, \ldots, A^{m_r-1}b_r\right\}$$

are also linearly independent and

$$\operatorname{Lin}\left\{b_{r-1}, \ldots, A^{m_{r-1}^\beta-1}b_{r-1}, b_r, \ldots, A^{m_r{}^\beta-1}b_r\right\} = \operatorname{Lin}\left\{b_{r-1}, \ldots, A^{n-1}b_{r-1}, b_r, \ldots, A^{n-1}b_r\right\}$$

and so on.

We have then $m_1^\beta + \cdots + m_r^\beta = n$ and then $\operatorname{rank}\left(B \quad AB \quad \cdots \quad A^{\overline{m}^\beta-1}B\right) = n$, where $\max\{m_i^\beta, i = 1, \ldots, r\}$. This gives $n_1 \le \overline{m}^\beta$ for all β and hence $n_1 \le \overline{m}$. This completes the proof of the lemma. □

It is well known that in contrast to indices $m_1, \overline{m}$, the controllability index n_1 is invariant under feedback. This means that n_1 is the same for all couples $(A_{-1} + BP, B)$, where P is an $r \times n$ matrix. Then one can choose a feedback matrix P and a basis in $\mathbb{C}^n$ such that $A_{-1} + BP$ take the following form (see [15, Theorem 5.10 and Corollary 5.3]):

$$F = \operatorname{diag}\{F_1, \ldots, F_r\},$$

where

$$F_i = \begin{pmatrix} 0 & 1 & 0 & \cdots & 0 \\ 0 & 0 & 1 & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & \cdots & 1 \\ a_1^i & a_2^i & a_3^i & \cdots & a_{n_i}^i \end{pmatrix}$$

and B becomes

$$G = \operatorname{diag}\{g_1, \dots, g_r\},$$

where $g_i = (\,0 \quad 0 \quad \cdots \quad 1\,)^{\mathrm{T}}$, the dimension being $n_i \times 1$. It is easy to check that $\overline{m}(F,G) = m_1(F,G) = n_1$. Moreover, the spectrum of F may be chosen arbitrarily by means of an appropriate choice of P.

Let us now return to the controllability problem for the system (1.2) (or equivalently (1.3)). We first give a preliminary result.

LEMMA 7.2. *The system* (1.2) *is exactly null-controllable at the time T if and only if the perturbed system*

(7.1)
$$\dot z(t) = (A_{-1} + BP)\dot z(t-1) + \int_{-1}^{0} A_2(\theta)\dot z(t+\theta)\mathrm{d}\theta + \int_{-1}^{0} A_3(\theta) z(t+\theta)\mathrm{d}\theta + Bu$$

is exactly null-controllable at the same time T.

Proof. Obviously it is enough to prove one implication only. Assume that the system (1.2) is controllable at the time T. It means that for any function $f(t) \in H^1(T-1, T; \mathbb{C}^n)$ there exists a control $u(t) \in L_2(0, T; \mathbb{C}^n)$ such that the solution of the equation

$$\dot z(t) = A_{-1}\dot z(t-1) + \int_{-1}^{0} A_2(\theta)\dot z(t+\theta)\mathrm{d}\theta + \int_{-1}^{0} A_3(\theta) z(t+\theta)\mathrm{d}\theta + Bu(t), \tag{7.2}$$

with the initial condition $z(t) = 0, t \in [-1, 0]$, verifies $z(t) = f(t), t \in [T-1, T]$. Let us rewrite (7.2) in the form

$$\dot z(t) = (A_{-1} + BP)\dot z(t-1) + \int_{-1}^{0} A_2(\theta)\dot z(t+\theta)\mathrm{d}\theta + \int_{-1}^{0} A_3(\theta) z(t+\theta)\mathrm{d}\theta + Bv(t),$$

where $v(t) = u(t) - P\dot z(t-1), t \in [0, T]$. Since $z(t-1) \in H^1([0, T]; \mathbb{C}^n)$, then $v(t) \in L_2(0, T; \mathbb{C}^n)$. Thus, the control $v(t)$ transfers the state $z(t) = 0, t \in [-1, 0]$, to the state $z(t) = f(t), t \in [T-1, T]$, by virtue of the perturbed system. This means that it is also controllable at the time T. ∎

We have the following result, which concludes our considerations.

THEOREM 7.3. *Let the neutral-type system* (1.2) *be in the general form, i.e., without the assumption* $\det A_1 \neq 0$. *Conditions* (i) *and* (ii) *of Theorem* 5.2 *are necessary and sufficient for the exact controllability of the system. Under these conditions, the precise time of controllability is $T = n_1$. This means that the system is not controllable for $T \leq n_1$ and is controllable for $T > n_1$.*

If the delay is h instead of 1, then the exact time of controllability is $n_1 h$.

Proof. According to Theorem 5.2, the proof of necessity is needed for the case when $\det A_1 = 0$. Let us first show that condition (ii) holds. Assume that (ii) is not verified. Then there exist vectors $z_0 \neq 0$ such that $A_{-1}^* z_0 = \lambda_0 z_0$ and $B^* z_0 = 0$. If for all such vectors $\lambda_0 \neq 0$, then one can find P_0 such that $A_{-1} + BP_0$ is not singular. Then, according to Lemma 7.2, the perturbed system (7.1) with $P = P_0$ is exactly null-controllable. This gives that the pair $(A_{-1} + BP_0, B)$ is controllable, which contradicts the existence of such vectors z_0.

Suppose that for some vector $z_0 \neq 0$, we have $A_{-1}^* z_0 = 0$ and $B^* z_0 = 0$. Then, multiplying (1.2) by z_0 we get

$$\langle \dot{z}(t), z_0 \rangle = \left\langle A_{-1}\dot{z}(t-1) + \int_{-1}^{0} A_2(\theta)\dot{z}(t+\theta)\mathrm{d}\theta + \int_{-1}^{0} A_3(\theta) z(t+\theta)\mathrm{d}\theta + Bu(t), z_0 \right\rangle$$

and the exact null-controllability definition means that this relation holds for an arbitrary function $\langle \dot{z}(t), z_0 \rangle \in L_2(T-1, T)$. As $\langle A_{-1}\dot{z}(t-1), z_0\rangle = 0$ and $\langle Bu(t), z_0\rangle = 0$, this gives, after a change of variables,

$$\begin{aligned}
\langle \dot{z}(t), z_0 \rangle &= \left\langle \int_{-1}^{0} A_2(\theta)\dot{z}(t+\theta)\mathrm{d}\theta + \int_{-1}^{0} A_3(\theta) z(t+\theta)\mathrm{d}\theta, z_0 \right\rangle \\
&= \left\langle \int_{t-1}^{t} A_2(s-t)\dot{z}(s)\mathrm{d}s + \int_{t-1}^{t} A_3(s-t) z(s)\mathrm{d}s, z_0 \right\rangle \\
&= \begin{pmatrix} K_2(z_0) & K_3(z_0) \end{pmatrix} \begin{pmatrix} \dot{z}(\cdot) \\ z(\cdot) \end{pmatrix},
\end{aligned}$$

where $K_j : L_2((T-2, T); \mathbb{C}^n) \longrightarrow L_2(T-1, T), j = 2, 3$, are linear operators defined by

$$\left(K_j(z_0)w\right)(t) = \int_{t-1}^{t} A_j(s-t)w(s)\mathrm{d}s = \int_{T-1}^{T} \widehat{A}_j(s-t)w(s)\mathrm{d}s,$$

and

$$\widehat{A}_j(s) = \begin{cases} A_j(s), & s \in [-1, 0], \\ 0, & s \notin [-1, 0]. \end{cases}$$

The operators $K_j, j = 2, 3$, are clearly compact operators because

$$\int_{T-1}^{T} \left(\int_{T-2}^{T} \|\widehat{A}_j(s-t)\|^2 \mathrm{d}s \right) \mathrm{d}t = \int_{T-1}^{T} \left(\int_{-1}^{0} \|A_j(\theta)\|^2 \mathrm{d}\theta \right) \mathrm{d}t < \infty;$$

see, for example, [7, Chapter 6]. Then the image of the operator $\begin{pmatrix} K_2(z_0) & K_3(z_0) \end{pmatrix}$ cannot coincide with $L_2(T-1, T)$. Thus, such a vector z_0 does not exist. This gives that condition (ii) is necessary.

Let us now prove the necessity of condition (i). If A_{-1} is nonsingular, it is proved in Theorem 5.2. Assume now that A_{-1} is singular. Then (since we have proved (ii)) we can choose a matrix P such that $A_{-1} + BP$ is not singular. According to Lemma 7.2, the perturbed system (7.1) is still exactly null-controllable. Using Theorem 5.2, we have the following statement: there do not exist $\lambda \in \mathbb{C}$ and $y \in \mathbb{C}^n$ such that

$$\left[\lambda I - \lambda \mathrm{e}^{-\lambda} \left(A_{-1}^* + P^* B^* \right) - \lambda \int_{-1}^{0} \mathrm{e}^{\lambda s} A_2^*(s)\mathrm{d}s - \int_{-1}^{0} \mathrm{e}^{\lambda s} A_3^*(s)\mathrm{d}s \right] y = 0$$

and $B^* y = 0$. This gives condition (i).

Now we prove the sufficiency. Assume that conditions (i) and (ii) are verified. Then they are also verified for the perturbed system. From condition (ii) we can choose a matrix P such that $A_{-1} + BP$ is nonsingular and $\overline{m}(A_{-1} + BP, B) = m_1(A_{-1} + BP, B) = n_1$. And this gives that the perturbed system is exactly null-controllable at the time $T > n_1$ and is not controllable at the time $T < n_1$. By Lemma 7.2 we infer that our system (1.2) satisfies the same condition.

Moreover, it is easy to prove, arguing as in the proof of Theorem 5.6, that the system (1.2) is also not controllable at the time $T = n_1$. More precisely, the codimension of $\mathcal{R}_{n_1}$ in X_A is finite and not less than n_1. For $T < n_1$, the codimension of $\mathcal{R}_T$ is infinite. □

8. Conclusion and perspectives. The main goal of this paper is to demonstrate how the moment problem approach can be used in the controllability problem for delay systems of neutral type. To this end, we chose a quite general model (1.2) with distributed delays in the function and its derivative, a pointwise neutral term determined by a matrix A_{-1}, and the control term by a matrix B. Using our approach, we have given a complete analysis of the exact null-controllability for this model. Namely,

(i) we showed that the maximal possible set of the states reachable from 0 by the system at some time $T > 0$ is the space H^1;
(ii) we found the conditions of the parameters of the system under which this set of reachability can be maximally possible (the conditions of exact controllability);
(iii) we proved that, under the above conditions, the system is exactly controllable at the time T if and only if $T > n_1$, where n_1 is the first controllability index of the couple (A_{-1}, B) (the time of exact controllability).

As a perspective, we consider the extension of our approach to systems with several pointwise neutral terms and to the general case of distributed neutral-type delay,

$$Kf = \int_{-1}^{0} \mathrm{d}\mu(\theta) f(\theta), \quad f \in C([-1, 0], \mathbb{C}^n),$$

where μ is a matrix-valued function of bounded variation and continuous at zero. One can prove that, for this class of systems, the generalized Riesz basis property of the model operator $\mathcal{A}$ is preserved. However, the immediate spectral analysis of this operator is more complex. In the case when the delays in the neutral terms are commensurable, the results on exact controllability are expected to be similar to those obtained in the present paper. In the general case, the formulation and the proofs may be much more complicated. This problem is to be considered in our forthcoming works.

ON THE GENERICITY OF THE DIFFERENTIAL OBSERVABILITY OF CONTROLLED DISCRETE-TIME SYSTEMS*

SABEUR AMMAR†, MOHAMED MABROUK‡, AND JEAN-CLAUDE VIVALDA§

Abstract. In this paper, we prove the genericity of the differential observability for discrete-time systems with more outputs than inputs.

Key words. observability, nonlinear systems, discrete-time systems, transversality theory

AMS subject classifications. 93B07, 93B29, 93C55

DOI. 10.1137/060677938

1. Introduction.

In this paper, we study the genericity of the differential observability for discrete-time controlled nonlinear systems such that

$$\begin{cases} x_{k+1} = f(x_k, u_k), \\ y_k = h(x_k, u_k), \\ x_k \in X,\ u_k \in U,\ y_k \in \mathbb{R}^p, \end{cases} \tag{1}$$

where

(i) X and U are C^∞ compact connected second-countable manifold with dimensions n and m, respectively;

(ii) $f : X \times U \to X$ is a parametrized diffeomorphism: that is to say, for every $u \in U$, the mapping $f(\cdot, u)$ is a C^∞ diffeomorphism; we denote by $\mathrm{Diff}_{\mathrm{U}}(X)$ the set of all parametrized diffeomorphisms;

(iii) $h : X \times U \to \mathbb{R}^p$ is a C^∞ mapping.

To be more specific, we shall introduce some notations. Given $f \in \mathrm{Diff}_{\mathrm{U}}(X)$ and $h \in C^\infty(X \times U, \mathbb{R}^p)$, we denote by $\underline{u_N}$ the finite sequence $(u_0, \dots, u_{N-1})$ of elements of U, and we define recursively $f^k(x, \underline{u_k})$ by

$$f^1(x, \underline{u_1}) = f(x, u_0),$$

$$f^{k+1}(x, \underline{u_{k+1}}) = f(f^k(x, \underline{u_k}), u_k) \qquad \text{for } k \geq 1.$$

Let us recall the notion of observability investigated in this paper.

DEFINITION 1. *Two initial conditions x_0 and $\bar{x}_0$ and an input u (i.e., a sequence $(u_k)_{k\geq 0}$ of elements of U) being given, x_k and $\bar{x}_k$ denote the points $x_k = f^k(x_0, \underline{u_k})$ and $\bar{x}_k = f^k(\bar{x}_0, \underline{u_k})$.*

System (1) *is said to be observable for input u if for any initial conditions $x_0 \neq \bar{x}_0$, there exists an index k (possibly depending on the initial conditions) such that $x_k \neq \bar{x}_k$.*

System (1) *is said to be observable if it is observable for each input.*

Below, we are introducing a stronger notion of observability. We consider the mapping $\Theta_{2n+1}^{f,h}$ from $X \times U^{2n+1}$ to $\mathbb{R}^{(2n+1)p} \times U^{2n+1}$ defined by

$$\Theta_{2n+1}^{f,h}(x, \underline{u_{2n+1}}) = (h(x,u_0), h(f^1(x,\underline{u_1}),u_1), \ldots, h(f^{2n}(x,\underline{u_{2n}}),u_{2n}), \underline{u_{2n+1}}).$$

Notice that this mapping is the discrete-time analogous of the mapping $S\Phi_k^\Sigma$ defined in [4].

DEFINITION 2. *We shall say that system* (1) *is* strongly observable *if the related mapping* $\Theta_{2n+1}^{f,h}$ *defined above is one-to-one.*

In [3], we proved that system (1) is generically strongly observable as long as $p > \dim U$; more precisely, we proved that the set of pairs (f,h) which make the mapping $\Theta_{2n+1}^{f,h}$ one-to-one is a residual.

In this article, we deal with a stronger notion of observability.

DEFINITION 3. *We shall say that system* (1) *is* strongly differentially observable *if, for every fixed sequence* $\underline{u_{2n+1}}$, *the mapping* $\bar{\Theta}_{2n+1}^{f,h}$ *from* X *to* $\mathbb{R}^{(2n+1)p}$ *defined by*

$$\bar{\Theta}_{2n+1}^{f,h}(x) = (h(x,u_0), h(f^1(x,\underline{u_1}),u_1), \ldots, h(f^{2n}(x,\underline{u_{2n}}),u_{2n}))$$

is an embedding.

In the continuation of [3], the goal of this paper is to prove that system (1) is strongly differentially observable as long as $p > \dim U$.

On this subject, one has to mention first the important work from Gauthier and Kupka. In a first paper, also with Hammouri (see [5]), the authors investigated the genericity of observability for uncontrolled continuous-time systems. This work was generalized by Gauthier and Kupka in [6, 4], where the authors proved the genericity of differential observability for systems with more outputs than inputs. To be more precise, in their paper, the authors consider the set, denoted by $\mathscr{O}$, of systems Σ such that the mapping $S\Phi_\Sigma^N$ (analogous, for continuous time systems, to mapping $\Theta_{2n+1}^{f,h}$) is an embedding; they show that, provided that a bound on the derivative of the control is given, this set is $\mathscr{O}$ open and dense. When this condition is not assumed, the authors prove that this set is residual (and therefore dense) but the openness property remains an open problem. In our case, we assume that the controls belong to a compact manifold, so this difficulty disappears. Also, we do not have to consider the case of nonsmooth controls. Nevertheless, there are some other difficulties; for example, we have to pay special attention to periodic points of f_u. As far as we are concerned by discrete-time systems, we have to cite several papers on the subject of the genericity of the observability: first, a paper written by Aeyels [2] in which the author considers uncontrolled continuous-time systems and the discrete-time systems obtained by discretizing the continuous ones. In [2], the author introduced the notion of P-observability. The system

$$\begin{cases} \dot{x} &= f(x), \\ y &= h(x) \end{cases} \tag{2}$$

is said to be P-observable if, given a time $T > 0$ and a finite subset P of $[0,T]$, for every pair (x,y) of distinct elements in X^2, there exists a $t_i \in P$ such that $h \circ \Phi_{t_i}(x) \neq h \circ \Phi_{t_i}(y)$, where Φ denotes the flow of f. One of the results in this paper is the proof of the existence of an open and dense set of vector fields such that (a vector field f in this set being fixed) the subset of functions h belonging to $C^r(X,\mathbb{R})$

such that the system (f,h) is P-observable is open and dense in $C^r(X,\mathbb{R})$. This is true for almost any finite subset P of $(2\dim X+1)$ points in $[0,T]$.

To an uncontrolled discrete-time system such that

$$\begin{cases} x_{k+1} &= f(x_k), \\ y_k &= h(x_k), \\ x_k \in M, \text{ compact manifold, } y_k \in \mathbb{R}\,, \end{cases} \tag{3}$$

is attached a map analogous to the map $\Theta^{f,h}_{2n+1}$ defined above: consider

$$\begin{aligned} \Phi: \quad M &\longrightarrow \mathbb{R}^{2n+1} \\ x &\longmapsto (h(x), h\circ f(x), \ldots, h\circ f^{2n}(x)), \end{aligned}$$

where n is the dimension of manifold M. In [10], the proof that, generically, Φ is an embedding is sketched, while in [8] and [11] the same result is proved in greater detail (see also the concluding remarks of [2]). In the case of controlled discrete-time systems, in [9], the authors investigate controlled discrete-time systems and obtained some results which are similar (but not identical) to the one presented here; namely, they present a result of genericity of the observability, but it is not a result about observability for every input. As in the present paper, the tools used in the work of these authors belong to the transversality theory.

Before going straight to the point, we want to add some words about the fact that the observation function h depends on u. This situation is not common in automatic control theory, but the opposite assumption leads to clumsy statements. Nevertheless, as explained in the conclusion of [3], the result of genericity can also be proved for systems where h does not depend on u. The paper is organized as follows: in the next section, some facts from transversality theory are recalled; in section 3, the main result is stated together with some definitions and lemmas; in section 4, our result is proved through the demonstration of five lemmas.

2. Some facts from transversality theory. In this section we recall some theorems from differential topology which will be intensively used in the proof of the main result of this paper. For details on the C^∞ Whitney topology, the reader is referred to the book "Stable Mappings and their Singularities" [7].

If X and Y are two smooth manifolds, then $J^k(X,Y)$ will denote, as usual, the set of k-jets from X to Y, $\alpha: J^k(X,Y)\to X$ is the source map, and $\beta: J^k(X,Y)\to Y$ is the target map; moreover, we denote by $C^r(X,Y)$ $(1\le r\le+\infty)$ the set of C^r maps from X to Y. If f is in $C^\infty(X,Y)$, then j^kf denotes the k-jet of f. Recall that the set $C^\infty(X,Y)$ endowed with the Whitney topology is a Baire space and so every residual set of $C^\infty(X,Y)$ (i.e., every countable intersection of open dense subsets) is dense.

The notion of transversality is of paramount importance for our purpose, and we recall its definition below.

Definition 4. *Let f be a smooth mapping between two smooth manifolds X and Y, W a submanifold of Y, and x a point in X. We shall say that f intersects W* transversely *at x if either*

(i) $f(x)\notin W$ *or*

(ii) $f(x)\in W$ *and* $T_{f(x)}Y = T_{f(x)}W + df_x(T_xX)$,

with T_xX denoting the tangent space to X at x and df_x the Jacobian of f at x. We shall say that f intersects W transversely if it intersects W transversely at x for all x in W. We shall use the symbol $\pitchfork$ to denote the transversality.

The following theorem states a result of genericity [7].

THEOREM 1 (Thom transversality theorem). *Let X and Y be smooth manifold, W a submanifold of $J^k(X,Y)$, and let*

$$T_W = \{f \in C^\infty(X,Y) \mid j^k f \pitchfork W\}.$$

Then T_W is a residual subset of $C^\infty(X,Y)$ in the C^∞ topology. Moreover, if W is closed, then T_W is open.

The following result generalizes the above theorem to multijet spaces. We first define the set $X^{(s)} = \{\,(x_1,\dots,x_s) \in X^s \mid x_i \neq x_j \text{ for } 1 \leq i < j \leq s\,\}$ and the mapping

$$\begin{aligned} \alpha^s : \big(J^k(X,Y)\big)^s &\longrightarrow X^s \\ (\sigma_1,\dots,\sigma_s) &\longmapsto \big(\alpha(\sigma_1),\dots,\alpha(\sigma_s)\big), \end{aligned}$$

and we let $J^k_s(X,Y) = (\alpha^s)^{-1}(X^{(s)})$, notice that $J^k_s(X,Y)$ is a submanifold of $(J^k(X,Y))^s$.

For $f \in C^\infty(X,Y)$, we can define

$$\begin{aligned} j^k_s f : \quad X^{(s)} &\longrightarrow J^k_s(X,Y) \\ (x_1,\dots,x_s) &\longmapsto \big(j^k f(x_1),\dots,j^k f(x_s)\big). \end{aligned}$$

THEOREM 2 (multijet transversality theorem). *Let W be a submanifold of $J^k_s(X,Y)$, and let*

$$T_W = \{f \in C^\infty(X,Y) \mid j^k_s f \pitchfork W\}.$$

Then T_W is a residual subset of $C^\infty(X,Y)$ in the C^∞ topology. Moreover, if W is compact, then T_W is open.

We shall use also a transversality theorem due to Abraham (see [1]). Let $\mathcal{A}, X$, and Y be C^r manifolds and ρ a map from $\mathcal{A}$ to $C^r(X,Y)$.

For $a \in \mathcal{A}$, we write ρ_a, the C^r map

$$\begin{aligned} \rho_a : X &\longrightarrow Y \\ x &\longmapsto \rho_a(x) = \rho(a)(x), \end{aligned}$$

and we say that ρ is a C^r representation if the evaluation map

$$\begin{aligned} \mathrm{ev}_\rho : \mathcal{A} \times X &\longrightarrow Y \\ (a,x) &\longmapsto \rho_a(x) = \rho(a)(x) \end{aligned}$$

is a C^r map from $\mathcal{A} \times X$ to Y.

THEOREM 3 (Abraham transversal density theorem). *Let $\mathcal{A}, X, Y$ be C^r manifolds, $\rho : \mathcal{A} \to C^r(X,Y)$ a C^r representation, $W \subset Y$ a submanifold (not necessarily closed), and $\mathrm{ev}_\rho : \mathcal{A} \times X \to Y$ the evaluation map. Define $\mathcal{A}_W \subset \mathcal{A}$ by*

$$\mathcal{A}_W = \{a \in \mathcal{A} \mid \rho_a \pitchfork W\}.$$

Assume that

1. *X has a finite dimension n and W has a finite codimension q in Y;*
2. *$\mathcal{A}$ and X are second countable;*

3. $r > \max(0, n-q)$;
4. $\mathrm{ev}_\rho \pitchfork W$.

Then $\mathcal{A}_W$ is residual in $\mathcal{A}$.

Notice that manifold $\mathcal{A}$ is not necessarily finite dimensional; it may be a Banach space or an open subset of a Banach space.

Finally, we shall need the following theorem that can also be found in [1].

THEOREM 4 (openness of transversal intersection). *Let $\mathcal{A}$, X, and Y be C^r manifolds with X finite dimensional, $W \subset Y$ a closed C^r submanifold, K a compact subset of X, and $\rho : \mathcal{A} \to C^r(X, Y)$ a C^r representation. Then the subset $\mathcal{A}_{KW} \subset \mathcal{A}$ defined by*

$$\mathcal{A}_{KW} = \{a \in \mathcal{A} \mid \rho_a \pitchfork_x W \text{ for } x \in K\}$$

is open.

3. Main result. We state here our main result and some lemmas used in the proof of our theorem. Our framework is the set $\mathrm{Diff}_{\mathrm{U}}(X) \times C^\infty(X \times U, \mathbb{R}^p)$ equipped with the Whitney topology; obviously, $\mathrm{Diff}_{\mathrm{U}}(X)$ is open in $C^\infty(X \times U, X)$ for this topology. In the theorem below, we assume that $\dim U < p$.

THEOREM 5. *The set of mappings $(f, h) \in \mathrm{Diff}_{\mathrm{U}}(X) \times C^\infty(X \times U, \mathbb{R}^p)$ such that the mapping $\bar{\Theta}^{f,h}_{2n+1}$ is an embedding is open and dense in $\mathrm{Diff}_{\mathrm{U}}(X) \times C^\infty(X \times U, \mathbb{R}^p)$ equipped with the Whitney topology.*

We begin by proving the easiest part of this result: the openness of the set of mappings (f, h) such that $\Theta^{f,h}_{2n+1}$ is an embedding.

Proof. Consider the mapping

$$\begin{aligned} \Phi : \quad X \times U^{2n+1} &\longrightarrow C^\infty(X \times U^{2n+1}, (\mathbb{R}^p)^{2n+1} \times U^{2n+1}) \\ (f, \underline{u_{2n+1}}) &\longmapsto (\Theta^{f,h}_{2n+1}, \underline{u_{2n+1}}), \end{aligned}$$

which is obviously continuous for the Whitney topology. Clearly, $\Phi(f, \underline{u_{2n+1}})$ is an embedding iff the mapping $\Theta^{f,h}_{2n+1}(\cdot, \underline{u_{2n+1}})$ is an embedding for every finite sequence $\underline{u_{2n+1}} \in U^{2n+1}$. Now, since X and U are compact manifolds, the set of embeddings from $X \times U^{2n+1}$ to $(\mathbb{R}^p)^{2n+1} \times U^{2n+1}$ is open for the Whitney topology, so, due to the continuity of Φ, the set of mappings $\Theta^{f,h}_{2n+1}(\cdot, \underline{u_{2n+1}})$, which are embeddings for every $\underline{u_{2n+1}}$, is open. ∎

We shall now prove the density part of the theorem. Notice that in the continuous-time case, the set of pairs (f, h) (with f a parametrized vector field) is a Banach space for the C^r topology ($r < +\infty$), but this is not the case for the set of pairs (f, h), where f is a parametrized diffeomorphism. So, it is not possible to copy directly the reasoning of [6]. The proof of this theorem will be somewhat awkward and will be based on several technical lemmas. Before stating these lemmas, we describe below our global strategy.

Suppose that $\mathscr{P}_1(f, h)$ and $\mathscr{P}_2(f, h)$ are two properties depending on $(f, h) \in \mathrm{Diff}_{\mathrm{U}}(X) \times C^\infty(X \times U, \mathbb{R}^p)$ whose conjunction is equivalent to the fact that $\bar{\Theta}^{f,h}_{2n+1}$ is an immersion. In Proposition 1, we shall prove that, for a given $f \in \mathrm{Diff}_{\mathrm{U}}(X)$, a given integer $r \geq 1$, and for every integer l there exists a subset $U^r_l(f)$ of $C^\infty(X \times U, \mathbb{R}^p)$, open and dense for the C^r topology, such that if h belongs to the intersection $\bigcap_{l \geq 0} U^r_l(f)$, then the pair (f, h) satisfies property $\mathscr{P}_1$. Moreover, we shall prove that, for every integer l, the set

$$\mathscr{U}^r_l = \bigcup_{f \in \mathcal{D}_U} \{f\} \times U^r_l(f)$$

($\mathcal{D}_U$ open dense set of $\mathrm{Diff}_{\mathrm{U}}$) is open dense in $\mathrm{Diff}_{\mathrm{U}}(X) \times C^\infty(X \times U, \mathbb{R}^p)$ equipped with the C^r topology. In Proposition 2, we shall prove that the set

$$E = \{\, (f,h) \in \mathrm{Diff}_{\mathrm{U}}(X) \times C^\infty(X \times U, \mathbb{R}^p) \mid \mathscr{P}_2(f,h) \text{ is true} \,\}$$

contains a residual set of $\mathrm{Diff}_{\mathrm{U}}(X) \times C^\infty(X \times U, \mathbb{R}^p)$. Hence, clearly, the set $E \cap (\bigcap_{k \geq 0 r \geq 1} \mathscr{U}_k^r)$ contains a residual set for the C^∞ topology and a pair (f,h) belonging to this set satisfies both properties $\mathscr{P}_1$ and $\mathscr{P}_2$.

We shall give the definition of periodic points before stating our propositions.

Definition 5. *Let $f \in \mathrm{Diff}_{\mathrm{U}}(X)$. We shall say that the point $(x, \underline{u_{2n+1}}) \in X \times U^{2n+1}$ is periodic for f if there exist two different integers $s' < s$ in $\{0, \ldots, 2n\}$ such that $f^{s'}(x, \underline{u_{s'}}) = f^s(x, \underline{u_s})$. If $(x, \underline{u_{2n+1}})$ is a periodic point, then its period is the smallest integer s such that the above equality is satisfied.*

Notations. We denote by $\mathscr{P}_f$ the set of all periodic points of f; obviously, $\mathscr{P}_f$ is a closed subset of $X \times U^{2n+1}$. We denote also by $\mathscr{P}_f^c$ the set complement of $\mathscr{P}_f$: $\mathscr{P}_f^c = X \times U^{2n+1} \setminus \mathscr{P}_f$.

First, we want to state a lemma about a property of continuity of the sets of periodic points; before that, we recall the definition of the Hausdorff distance between sets.

Definition 6. *Let (E,d) be a metric space, if A and B are subsets of E, then the Hausdorff distance between A and B is defined by*

$$\delta(A,B) = \sup_{x \in A} d(x,B) + \sup_{y \in B} d(y,A).$$

We suppose that X and U are equipped with distances which are compatible with their topologies, so we can speak of the Hausdorff distance on $X \times U^{2n+1}$, and we state the following lemma.

Lemma 1. *There exists an open and dense set in $\mathrm{Diff}_{\mathrm{U}}(X)$, denoted by $\mathcal{D}_{\mathrm{U}}$, such that for each $f \in \mathcal{D}_{\mathrm{U}}$,*

(i) *if $\mathscr{P}_f = \varnothing$, then $\mathscr{P}_g = \varnothing$ for every g in some neighborhood of f;*

(ii) *if $\mathscr{P}_f \neq \varnothing$, then $\delta(\mathscr{P}_f, \mathscr{P}_g)$ tends to 0 as g tends to f for the C^∞ topology.*

Property $\mathscr{P}_1(f,h)$ is related to the periodic points of f and is the object of the following proposition.

Proposition 1. *Let $f \in \mathcal{D}_{\mathrm{U}}$ be given. For each $r > 0$ there exists a sequence $(U_l^r(f))_{l \geq 1}$ of open and dense sets for the C^r topology included in $C^\infty(X \times U, \mathbb{R}^p)$ such that for every mapping h in $\cap_{l \geq 1} U_l^r(f)$, the mapping $\bar{\Theta}_{2n+1}^{f,h}$ is an immersion at each point of $\mathscr{P}_f^c$.*

Moreover, for every nonzero integer l, the set

$$\mathscr{U}_l^r = \bigcup_{f \in \mathcal{D}_{\mathrm{U}}} \{f\} \times U_l^r(f)$$

is open and dense in $\mathrm{Diff}_{\mathrm{U}}(X) \times C^\infty(X \times U, \mathbb{R}^p)$ for the C^r topology.

The second proposition is concerned with property $\mathscr{P}_2(f,h)$; before stating it, we introduce some sets of covectors. We denote by π the canonical projection from T^*X, the cotangent bundle of X to X, and, given an integer $k > n$, we define the set $(T^*X)^{\otimes k}$ by

$$(T^*X)^{\otimes k} = \{\, (p_1, \ldots, p_k) \in (T^*X)^k \mid \pi(p_1) = \cdots = \pi(p_k) \,\}$$

and the set $V(k, T^*X)$ by

$$V(k, T^*X) = \{\, (p_1, \ldots, p_k) \in (T^*X)^{\otimes k} \mid \operatorname{rank}(p_1, \ldots, p_k) < n \,\}.$$

Clearly, $(T^*X)^{\otimes k}$ is a submanifold of $(T^*X)^k$ and $V(k, T^*X)$ is a finite union of submanifolds of $(T^*X)^{\otimes k}$ whose codimension (the codimension of the highest dimensional submanifold of the union) is equal to $k - n + 1$ (see [5]).

We state now our second proposition.

PROPOSITION 2. *The set of pairs* $(f, h) \in \mathrm{Diff}_{\mathrm{U}}(X) \times C^\infty(X \times U, \mathbb{R}^p)$ *such that the mapping* $\bar{\Theta}^{f,h}_{2n+1}$ *is an immersion at each point of* $\mathscr{P}_f$ *is residual.*

Notation. If p is a point of a manifold M, then, hereafter, we shall denote by T_pM the tangent space to M at p.

4. Proof of the main result.

4.1. Proof of Lemma 1. For the proof of this result, we need the following lemma.

LEMMA 2. *There exists a residual subset, denoted by* $\mathcal{R}$, *of* $\mathrm{Diff}_{\mathrm{U}}(X)$ *such that if* f *is in this subset, then* $\mathscr{P}_f$ *is either the empty set or a finite union of submanifolds of* $X \times U^{2n+1}$ *of codimension greater than or equal to* n.

Proof. Let f be in $\mathrm{Diff}_{\mathrm{U}}(X)$ and s be a positive integer less than or equal to $2n$. Consider the following mapping:

$$\begin{aligned} j^0_s f : \quad (X \times U)^{(s)} \quad &\longrightarrow \quad J^0_s(X \times U, X) \\ ((x_0, u_0), \ldots, (x_{s-1}, u_{s-1})) \quad &\longmapsto \quad \big((x_0, u_0, f^1(x_0, \underline{u_1})), \ldots, \\ &\qquad\qquad (x_{s-1}, u_{s-1}, f^1(x_0, \underline{u_s}))\big). \end{aligned}$$

Let s' be a nonnegative integer less than s, and, in $(X \times U \times X)^s$, consider the submanifold $W_{s',s}$ defined as

$$W_{s',s} = \{\, ((x_0, u_0, z_0), \ldots, (x_{s-1}, u_{s-1}, z_{s-1})) \mid x_i = z_{i-1} \text{ for } i = 1, \ldots, s-1 \text{ and } z_{s-1} = z_{s'-1} \,\}.$$

Notice that the codimension of $W_{s',s}$ is equal to sn. By applying the multijet transversality theorem, we can assert that the set of diffeomorphisms f in $\mathrm{Diff}_{\mathrm{U}}(X)$ transverse to $W_{s',s}$ is a residual, so, generically, $V_{s',s} = (j^0_s f)^{-1}(W_{s',s})$ is either empty or a submanifold of $(X \times U)^{(s)}$ (and also of $(X \times U)^s$) of codimension $s\,n$. Denoting by π the projection from $(X \times U)^s$ to $X \times U^s$, it follows that $\pi(V_{s',s})$ is either empty or a submanifold of codimension greater or equal to $s\,n - (s-1)n = n$ from which we deduce that generically the set of periodic points of f with period equal to s is either empty or a finite union of submanifold of $X \times U^{2n+1}$ of codimensions greater than or equal to n. □

We have now proved that, generically, $\mathscr{P}_f$ is not equal to the whole space $X \times U^{2n+1}$. We are now ready to prove Lemma 1; hereafter, we shall denote by f_u the diffeomorphism $x \mapsto f(x, u)$, the control u being fixed.

For the existence of $\mathcal{D}_U$, we shall prove that, in fact, the set $\mathscr{R}$ of the above lemma is open. Take f in $\mathcal{R}$ and suppose that $\mathscr{P}_f$ is empty. Let d be a distance on X which is compatible with the topology of X. For every pair (s', s) of integers such that $0 \le s' < s \le 2n$, we define $\beta_{s',s}$ as

$$\beta_{s',s} = \inf\{\, d(f^{s'}(x, \underline{u_{s'}}), f^s(x, \underline{u_s})) \mid (x, \underline{u_{2n+1}}) \in X \times U^{2n+1} \,\}.$$

Due to the compactness of $X \times U^{2n+1}$, the real numbers $\beta_{s',s}$ are all positive; otherwise there would exist $(x, \underline{u_{2n+1}})$ such that $f^{s'}(x, \underline{u_{s'}}) = f^s(x, \underline{u_s})$, which contradicts the emptiness of $\mathscr{P}_f$. Take now $\varepsilon > 0$ and consider a neighborhood $\mathscr{V}$ of f such that if g is in this neighborhood, then $d(f^k(x, \underline{u_k}), g^k(x, \underline{u_k})) < \varepsilon$ for all $(x, \underline{u_{2n+1}}) \in X \times U^{2n+1}$ and all $k = 1, \ldots, 2n$. If g is in $\mathscr{V}$, then we have

$$\begin{aligned} d(f^{s'}(x, \underline{u_{s'}}), f^s(x, \underline{u_s})) &\leq d(f^{s'}(x, \underline{u_{s'}}), g^{s'}(x, \underline{u_{s'}})) + d(g^{s'}(x, \underline{u_{s'}}), g^s(x, \underline{u_s})) \\ &\quad + d(g^s(x, \underline{u_s}), f^s(x, \underline{u_s}) \\ &\leq 2\varepsilon + d(g^{s'}(x, \underline{u_{s'}}), g^s(x, \underline{u_s})). \end{aligned}$$

This inequality implies that

$$\beta_{s',s} \leq 2\varepsilon + d(g^{s'}(x, \underline{u_{s'}}), g^s(x, \underline{u_s})) \tag{4}$$

for all $(x, \underline{u_{2n+1}})$ in $X \times U^{2n+1}$ and all pair (s', s). So if $(x, \underline{u_{2n+1}})$ is a periodic point for g, there exists a pair (s', s) such that $d(g^{s'}(x, \underline{u_{s'}}), g^s(x, \underline{u_s})) = 0$, and from (4), we then have

$$\beta_{s',s} \leq 2\varepsilon.$$

If ε is chosen small enough, then this last inequality is not possible and so a diffeomorphism g belonging to $\mathscr{V}$ cannot have periodic points.

Suppose now that f is such that $\mathscr{P}_f$ is nonempty. Then we shall prove the existence of a neighborhood $\mathscr{V}$ of f such that if g is in $\mathscr{V}$, then $j^0_s g$ is transverse to the submanifolds W'_s, s defined in the proof of Lemma 2. We reason by contradiction; for every positive integer k, take the neighborhood $\mathscr{V}_k$ of f constituted by the mappings g such that $d(f(x,u), g(x,u)) < 1/k$ and $d'(j^1 f(x,u), j^1 g(x,u)) < 1/k$ (d' denotes a distance on $J^1(X \times U, X)$). Suppose the existence of a sequence of diffeomorphisms $g_k \in \mathscr{V}_k$ and elements $v_k \in X \times U^{2n+1}$ such that $v_k = (x_k, \underline{u^k_{2n+1}})$ is a periodic point (with period s_k) of g_k at which the mapping $j^0_{s_k} g_k$ is not transverse to the submanifold $W_{s'_k, s_k}$ defined in the proof of the above lemma. As $X \times U^{2n+1}$ is compact, we can assume that the sequence $(v_k)_{k \geq 1}$ is convergent with limit v and can also assume that s'_k and s_k do not depend on k. First, we shall see that $v = (x, \underline{u_{2n+1}})$ is a periodic point for f; we have

$$\begin{aligned} d(f^{s'}(x, \underline{u_{s'}}), f^s(x, \underline{u_s})) &\leq d(f^{s'}(x, \underline{u_{s'}}), f^{s'}(x_k, \underline{u^k_{s'}})) + d(f^{s'}(x_k, \underline{u^k_{s'}}), g^{s'}_k(x_k, \underline{u^k_{s'}})) \\ &\quad + d(g^{s'}_k(x_k, \underline{u^k_{s'}}), g^s_k(x_k, \underline{u^k_s})) + d(g^s_k(x_k, \underline{u^k_s}), f^s(x_k, \underline{u^k_s})) \\ &\quad + d(f^s(x_k, \underline{u^k_s}), f^s(x, \underline{u_s})) \\ &\leq 2/k + d(f^{s'}(x, \underline{u_{s'}}), f^{s'}(x_k, \underline{u^k_{s'}})) + d(f^s(x_k, \underline{u^k_s}), f^s(x, \underline{u_s})). \end{aligned}$$

So, due to the continuity of f, for every $\varepsilon > 0$, we have

$$d(f^{s'}(x, \underline{u_{s'}}), f^s(x, \underline{u_s})) \leq 2/k + \varepsilon,$$

provided that k is chosen large enough. This proves that $f^{s'}(x\underline{u_{s'}}) = f^s(x, \underline{u_s})$. Now at point v, $j^0 f$ is transverse to $W_{s'_n s}$ and, if k is large enough, this is still true for g_k

at point v_k: a contradiction. We proved the existence of an open and dense set $\mathcal{D}_U$ such that if f belongs to this set, $\mathscr{P}_f$ is either empty or a finite union of submanifolds of codimensions at least n.

Now take f in $\mathcal{D}_U$ and assume that $\mathscr{P}_f$ is nonempty; for every $\varepsilon > 0$, due to the compactness of set $\mathscr{P}_f$, we can cover it with a finite union of open balls: $\mathscr{P}_f \subset \cup_{i=1}^{N} B(v_i, \varepsilon)$, the v_i being elements of $\mathscr{P}_f$. Let K be the complement in $X \times U^{2n+1}$ of this union of open balls, as $\mathscr{P}_f$ is a finite union of n-dimensional submanifolds, and K is nonempty if ε is small enough; in this case, we define the numbers $\beta_{s',s}$ as follows:

$$\beta_{s',s} = \inf\{\, d(f^{s'}(x, \underline{u_{s'}}), f^{s}(x, \underline{u_s})) \mid (x, \underline{u_{2n+1}}) \in K \,\}.$$

Obviously, due to the compactness of K, all the $\beta_{s',s}$'s are positive, and, if g belongs to a sufficiently small neighborhood of f, by reasoning as above, we can obtain the inequality (4) for all $(x, \underline{u_{2n+1}}) \in K$. Consequently, if g belongs to a sufficiently small neighborhood of f, then the periodic points of g cannot belong to K and are all located in the union $\cup B(v_i, \varepsilon)$, which implies that the distance $d(v, \mathscr{P}_f)$ is less than ε for every v in $\mathscr{P}_g$.

The proof that, for every $w \in \mathscr{P}_f$, the distance $d(w, \mathscr{P}_g)$ can be made arbitrarily small for g in a sufficiently small neighborhood of f is a little harder. Take f in $\mathcal{D}_U$ and let $(x_0, \underline{u^0_{2n+1}})$ be a periodic point of f such that $f^s(x_0, \underline{u^0_s}) = f^{s'}(x_0, \underline{u^0_{s'}})$; then we can regard $f^{s'}(x_0, \underline{u^0_{s'}})$ as a fixed point of the map $f_{u^0_{s-1}} \circ \cdots \circ f_{u^0_{s'}}$ and, for $i = s', \ldots, s-1$, we shall prove the existence of functions $x \mapsto u_i(x)$, defined in a neighborhood of $f^{s'}(x_0, \underline{u^0_{s'}})$, such that the function $f^{s',s}(x)$ defined as

$$f^{s',s}(x) = f(f \ldots (f(x, u_{s'}(x)), u_{s'+1}(x)), \ldots, u_{s-1}(x))$$

has a fixed point at $f^{s'}(x_0, \underline{u^0_{s'}})$ and is transverse to $\Delta X \triangleq \{\, (x, x) \mid x \in X \,\}$ at this fixed point. To this end, we exploit the fact that the mapping $j^0_s f$ is transverse to $W_{s',s}$ at $w = ((x_0, u^0_0), \ldots, (x^0_{s-1}, u^0_{s-1}))$ (where $x^0_i = f(x^0_{i-1}, u^0_{i-1}) = f^i(x_0, \underline{u_i})$ for $i = 1, \ldots, s-1$). Given a tangent vector of $(X \times U \times X)^s$ at $j^0_s f(w)$ represented by the finite sequence $(l_0, m_0, l'_0), \ldots, (l_{s-1}, m_{s-1}, l'_{s-1})$, where $l_i \in \mathrm{T}_{x_i} X$, $m_i \in \mathrm{T}_{u^0_i} U$, and $l'_i \in \mathrm{T}_{x_{i+1}} X$, consider the two following sequences:

(i) $(t_0, \mu_0), \ldots, (t_{s-1}, \mu_{s-1})$ with $t_i \in \mathrm{T}_{x_i} X$ $\mu_i \in \mathrm{T}_{u_i} U$, which represents a tangent vector of $(X \times U)^{(s)}$ at w;

(ii) and $(\bar{t}_0, \bar{\mu}_0, \bar{t}_1), (\bar{t}_1, \bar{\mu}_1, \bar{t}_2) \ldots, (\bar{t}_{s-1}, \bar{\mu}_{s-1}, \bar{t}_s)$ with $\bar{t}_i \in \mathrm{T}_{x_i} X$, $\bar{\mu}_i \in \mathrm{T}_{u_i} U$, and $\bar{t}_s = \bar{t}_{s'}$, which represents a tangent vector of $W_{s',s}$ at $j^0_s f(w)$. The union of these two sequences gives a solution of the following system:

$$\left\{\begin{array}{rl} t_0 + \bar{t}_0 = l_0, \\ \mu_0 + \bar{\mu}_0 = m_0, \\ A_0 t_0 + B_0 \mu_0 + \bar{t}_1 = l'_0, \\ \vdots \qquad\qquad \vdots \\ t_{s-1} + \bar{t}_{s-1} = l_{s-1}, \\ \mu_{s-1} + \bar{\mu}_{s-1} = m_{s-1}, \\ A_{s-1} t_{s-1} + B_{s-1} \mu_{s-1} + \bar{t}_s = l'_{s-1}, \end{array}\right. \tag{5}$$

where $\bar{t}_s = \bar{t}_{s'}$, and A_i denotes the partial derivative with respect to x of f at point

(x_i^0, u_i^0) and B_i the partial derivative with respect to u of f at the same point. Manipulating the equalities of system (5), we get the formula

$$A_{s-1}A_{s-2}\cdots A_{s'}\cdot t_{s'} + \sum_{i=1}^{s-s'}\Big(\prod_{j=1}^{i-1} A_{s-j}\Big)B_{s-i}\cdot\mu_{s-i}$$

$$= l'_{s-1} + \sum_{i=2}^{s-s'}\Big(\prod_{j=1}^{i-1} A_{s-j}\Big)\cdot l'_{s-i} - \sum_{i=1}^{s-s'-1}\Big(\prod_{j=1}^{i} A_{s-j}\Big)\cdot l_{s-i} - \bar{t}_s.$$

Taking into account that $\bar{t}_s = \bar{t}_{s'} = l_{s'} - t_{s'}$, we get

$$A_{s-1}A_{s-2}\cdots A_{s'}\cdot t_{s'} - t_{s'} + \sum_{i=1}^{s-s'}\Big(\prod_{j=1}^{i-1} A_{s-j}\Big)B_{s-i}\cdot\mu_{s-i}$$

$$= l'_{s-1} + \sum_{i=2}^{s-s'}\Big(\prod_{j=1}^{i-1} A_{s-j}\Big)\cdot l'_{s-i} - \sum_{i=1}^{s-s'-1}\Big(\prod_{j=1}^{i} A_{s-j}\Big)\cdot l_{s-i} - l_{s'}. \tag{6}$$

Consider now the mapping $f^{s',s}(x)$ with the smooth mappings $x \mapsto u_i(x)$ chosen in such a way that $u_i(x_{s'}^0) = u_i^0$, the derivative of this mapping at $x_{s'}^0$, is given by the formula

$$df^{s',s}(x_{s'}^0) = A_{s-1}A_{s-2}\cdots A_{s'} + \sum_{i=1}^{s-s'}\Big(\prod_{j=1}^{s-s'-i} A_{s-j}\Big)B_{s'+i-1}K_{s'+i-1},$$

where the K_j's denote the derivatives of the mappings $u_j(x)$ at point $x_{s'}^0$. Now, as is well known [7], the mapping $f^{s',s}$ is transverse to ΔX at point $x_{s'}^0$ iff the following equation of unknown t

$$df^{s',s}(x_{s'}^0).t - t = l \tag{7}$$

has a solution for all vectors l belonging to the tangent space to X at $x_{s'}^0$. If the linear mapping $A_{s-1}\cdots A_{s'}$ does not admit 1 as an eigenvalue, it suffices to choose the u_i's such that their derivatives vanish at $x_{s'}^0$ and, in this case, (7) will have a solution for every t.

In the case where $A_{s-1}\cdots A_{s'}$ does not have this property, we can suppose that $t_{s'}$ is nonzero. As a matter of fact take $\tau_{s'} \neq 0$ such that $A_{s-1}\cdots A_{s'}\cdot\tau_{s'} = \tau_{s'}$ and define recursively the τ_i's by $\tau_{i+1} = A_i\tau_i$ for $i = s', \ldots, s-1$ and $\tau_i = A_i^{-1}\tau_{i+1}$ for $i = 0, \ldots, s'-1$; obviously, we have $\bar{t}_s - \tau_s = \bar{t}_{s'} - \tau_{s'}$ and, if we replace t_i by $t_i + \tau_i$ $(i = 0, \ldots, s-1)$ and $\bar{t}_i$ by $\bar{t}_i - \tau_i$ $(i = 0, \ldots, s)$, then equalities (5) remain satisfied and, obviously, we have $t_{s'} \neq 0$ or $t_{s'} + \tau_{s'} \neq 0$. Since $t_{s'}$ can be assumed to be nonzero, it is possible to design the mappings $x \mapsto u_i(x)$ in such a way that $K_j\cdot t_{s'} = \mu_j$, as the right-hand member of (6) can be chosen arbitrarily; we can see that (7) admits always a solution. We can reformulate this property of transversality of $f^{s',s}$ by saying that the submanifold V_f, constituted by the points $(x, f^{s',s}(x))$ and locally defined around the point $x_{s'}^0$, intersects ΔX at $(x_{s'}^0, x_{s'}^0)$ and is transverse to ΔX at this point. Now, if we take a mapping g close to f, then $g^{s',s}$ will be close to $f^{s',s}$ and the submanifold V_g constituted by the points $(x, g^{s',s}(x))$ will be close from V_f, and since V_f, V_g, and ΔX are n-dimensional submanifolds of the manifold $X \times X$

of dimension $2n$ since the intersection between V_f and ΔX is nonempty, the same is true for the intersection $V_g \cap \Delta X$ provided that V_g is close enough to V_f; moreover, the intersection points in $V_g \cap \Delta X$ will be close to $x^0_{s'}$. Now let $\bar{x}^0_{s'}$ be a point in the intersection $V_g \cap \Delta X$, a fixed point of $g^{s',s}$, and be regarded as the image of a point $(\bar{x}_0, \underline{\bar{u}_{s'}})$ by the mapping $g^{s'}$. Now this last point is closed to $(x_0, \underline{u_{s'}})$ if g is close to f and is a periodic point of g.

4.2. Proof of Proposition 1. We denote by h_u the mapping $x \mapsto h(x,u)$ and by $df_u(x)$ (resp., $dh_u(x)$) the derivative of f_u (resp., h_u) at x; subsequently, we shall regard the p components of $dh_u(x)$ as covectors of $T^*_x X$.

Consider the representation ρ from $C^\infty(X \times U, \mathbb{R}^p)$ to $C^\infty(\mathscr{P}^c_f, (T^*X)^{\otimes(2n+1)p})$ defined through the following evaluation map ev_ρ:

$$\begin{aligned} \mathrm{ev}_\rho : \quad C^\infty(X \times U, \mathbb{R}^p) \times \mathscr{P}^c_f \quad &\longrightarrow \quad (T^*X)^{\otimes(2n+1)p} \\ (h, x, \underline{u_{2n+1}}) \qquad &\longmapsto \quad \big(dh_{u_0}(x), d(h_{u_1} \circ f_{u_0})(x), \dots, \\ &\qquad\qquad d(h_{u_{2n}} \circ f_{u_{2n}} \circ \dots \circ f_{u_0})(x)\big). \end{aligned}$$

We shall prove the existence of a residual set in $C^\infty(X \times U, \mathbb{R}^p)$ such that if h belongs to this set, then ρ_h is transverse to $V((2n+1)p, T^*X)$; we shall do this thanks to the Abraham transversal density theorem with $\mathcal{A} = C^\infty(X \times U, \mathbb{R}^p)$, endowed with the C^r topology ($\mathcal{A}$ is a Banach space), $X = \mathscr{P}^c_f$, $Y = (T^*X)^{\otimes(2n+1)p}$, and $W = V((2n+1)p, T^*X)$ (notice that W is closed).

Clearly, the first three hypotheses of this theorem are satisfied for every r large enough and to prove that $\mathrm{ev}_\rho \pitchfork W$, it is sufficient to prove that the evaluation map is a submersion. The point $(x_0, \underline{u_{2n+1}})$ being given, the mapping $\mathrm{ev}_\rho(\cdot, x_0, \underline{u_{2n+1}})$ from $C^\infty(X \times U, \mathbb{R}^p)$ to $(T^*M)^{\otimes(2n+1)p}$ is linear and so is equal to its derivative; hence, in order to prove that ev_ρ is a submersion it is sufficient to prove that for every $(p_0, \dots, p_{2n}) \in (T^*M)^{\otimes(2n+1)p}$ there exists $h \in C^\infty(X \times U, \mathbb{R}^p)$ such that

$$\text{(8)} \qquad \begin{cases} p_0 = dh_{u_0}(x_0), \\ p_i = d(h_{u_i} \circ f_{u_{i-1}} \circ \dots \circ f_{u_0})(x_0) \qquad \text{for } i = 1, \dots, 2n. \end{cases}$$

But, letting $x_i = f^i(x_0, \underline{u_i})$, $d(h_{u_i} \circ f_{u_{i-1}} \circ \dots \circ f_{u_0})(x_0) = dh_{u_i}(x_i) \circ d(f_{u_{i-1}} \circ \dots \circ f_{u_0})(x_0)$, the pairs (x_i, u_i) being mutually different, it is always possible to find $h \in C^\infty(X \times U, \mathbb{R}^p)$ such that the relations (8) are satisfied.

So we can apply the Abraham transversal density theorem: the set of mappings h in $C^\infty(X \times U, \mathbb{R}^p)$ such that the mapping ρ_h is transverse to $V((2n+1)p, T^*X)$ is a residual set denoted by $\mathscr{R}_r(f)$; now the intersection of the $\mathscr{R}_r(f)$'s gives a set $\mathscr{R}(f)$ which is residual for the C^∞ topology. Now notice that the codimension of $V((2n+1)p, T^*X)$ is greater than or equal to $(2n+1)p - n + 1$, which is greater than $n + (2n+1)m$, the dimension of $\mathscr{P}^c_f$, so saying that ρ_h is transverse to $V((2n+1)p, T^*X)$ is equivalent to saying that the range of ρ_h does not intersect $V((2n+1)p, T^*X)$, which is equivalent to saying that $\bar{\Theta}^{f,h}_{2n+1}$ is an immersion at each point of $\mathscr{P}^c_f$. At this stage, we have proven the existence of a residual set $\mathscr{R}(f)$ included in $C^\infty(X \times U, \mathbb{R}^p)$ such that for every h in $\mathscr{R}(f)$ the mapping $\bar{\Theta}^{f,h}_{2n+1}$ is an immersion at each point of $\mathscr{P}_f$.

For the sake of readability, we shall denote by the same letter, d, distances defined on X or on $X \times U$ which are compatible with the topologies of these spaces.

Given $f \in \mathcal{D}_U$, for every positive integer l consider the compact $K_l(f)$ defined by

$$K_l(f) = \begin{cases} X \times U^{2n+1} & \text{if } \mathscr{P}_f \text{ is empty,} \\ \{\, v \in X \times U^{2n+1} \mid d(v, \mathscr{P}_f) \geq 1/l \,\} & \text{if } \mathscr{P}_f \neq \varnothing. \end{cases}$$

Endow $C^\infty(X \times U, X)$ with the C^r topology and consider the sets $U_k^r(f)$ defined as

$$U_l^r(f) = \{\, h \in C^\infty(X \times U, \mathbb{R}^p) \mid \rho_h \pitchfork_x W \text{ for } x \in K_l(f) \,\}.$$

Using Theorem 4, we can see that $U_l^r(f)$ is open for the C^r topology, and, since $\mathscr{R}_r(f)$ is obviously included in $U_l^r(f)$, it is also dense. Proving that the set

$$\mathscr{U}_l^r = \bigcup_{f \in \mathcal{D}_U} \{f\} \times U_l^r(f)$$

is open is quite a delicate task.

We first prove that, given $\varepsilon > 0$ and $f_0 \in \mathcal{D}_U$, there exists a neighborhood $\mathscr{V}_{f_0}$ of f_0 such that if f belongs to this neighborhood, then for all v in $K_l(f)$, we have $d(v, K_l(f_0)) < \varepsilon$. To prove this point, we will reason by contradiction. We take neighborhoods (in the C^0 topology) of f_0 under the form

$$\mathscr{V}_n = \{\, f \in \mathcal{D}_U \mid d(f_0(x,u), f(x,u)) < 1/n \text{ for all } (x,u) \in X \times U \,\}.$$

Assume the existence of a positive real number ε_0 such that, for every positive integer n, there exist $f_n \in \mathscr{V}_n$ and $v_n \in K_l(f_n)$ such that $d(v_n, K_l(f_0)) > \varepsilon_0$. For each v_n let $\bar{v}_n \in \mathscr{P}_{f_0}$ such that $d(v_n, \bar{v}_n) = d(v_n, \mathscr{P}_{f_0})$. Due to the compactness of $X \times U$, we can suppose that all of these sequences are convergent, and consequently, the sequence $d_n \triangleq d(v_n, \mathscr{P}_{f_0})$ is convergent. Assume that $\lim_{n\to\infty} d_n < 1/l$; then there exists an $\alpha > 0$ such that $d_n < 1/l - \alpha$ for every positive n. In this case, there exist w_n in $\mathscr{P}_{f_n}$ such that $d(\bar{v}_n, w_n)$ tends to 0 as n tends to infinity and we have

$$\begin{aligned} d(v_n, w_n) &\leq d(v_n, \bar{v}_n) + d(\bar{v}_n, w_n) \\ &< 1/l - \alpha + d(\bar{v}_n, w_n) \\ &< 1/l - \alpha/2 \text{ for all n large enough.} \end{aligned}$$

This last inequality is in contradiction with the appurtenance of v_n to $K_l(f_n)$.

In the case where $\lim_{n\to\infty} d_n = 1/l$, let v be the limit of v_n. We then have $d(v, \mathscr{P}_{f_0}) = 1/l$ and so v is in $K_l(f_0)$; therefore, $d(v_n, K_l(f_0)) \leq d(v_n, v)$ and this last quantity becomes less than ε_0 if n is large enough: a contradiction.

Now, let (f_0, h_0) be in $\mathscr{U}_l^r$. Then take a neighborhood $\mathscr{V}_{f_0}$ of f_0 for the C^r topology such that if f belongs to this neighborhood, then the distance $d(v, K_l(f_0))$ is less than ε for every v in $K_l(f)$. If ε is chosen small enough, then there exists a neighborhood $\mathscr{W}_{h_0}$ of h_0 such that if the pair (f,h) belongs to $\mathscr{V}_{f_0} \times \mathscr{W}_{h_0}$, then the representation ρ_h^f related to the pair (f,h) is such that its evaluation map is a submersion at every point of $K_l(f)$.

4.3. Proof of Proposition 2. In order to prove this result, we need three lemmas. Let x_0 be a periodic point of order $s \leq 2n$, that is to say there exists $s' < s$ such that $f^{s'}(x_0, \underline{u_{s'}}) = f^s(x_0, \underline{u_s})$ and $f^i(x_0, \underline{u_i}) \neq f^j(x_0, \underline{u_j})$ if $i, j < s$; we denote

by x_i the iterated of x_0 by f, to be more precise, $x_i = f^i(x_0, \underline{u_i})$, and we also put $z_i, = f(x_i, u_i)$ and $y_i = h(x_i, u_i)$. We consider the list L,

$$(x_0, u_0, z_0, y_0), \ldots, (x_{2n}, u_{2n}, z_{2n}, y_{2n}),$$

and we say that two elements (x_i, u_i, z_i, y_i) and (x_j, u_j, z_j, y_j) are equivalent if $(x_i, u_i) = (x_j, u_j)$. In each equivalence class, we retain the term of the least index and obtain the following list L' extracted from L:

$$(x_{i_0}, u_{i_0}, z_{i_0}, y_{i_0}), \ldots, (x_{i_r}, u_{i_r}, z_{i_r}, y_{i_r})$$

with $i_0 < i_1 < \cdots < i_r$ (necessarily $i_0 = 0$). We then claim the following lemma.

LEMMA 3. *In the list L' above, we can find $r + 1$ equalities between the terms x_i and z_i.*

Proof. Let j be an index less than r. We consider two cases:

1. If $i_{j+1} = i_j + 1$, then we have $z_{i_j} = x_{i_j+1} = x_{i_{j+1}}$;
2. if $i_{j+1} > i_j + 1$, then the term of index $i_j + 1$ was removed from list L because there exists an index $k < i_j + 1$ such that $(x_k, u_k) = (x_{i_j+1}, u_{i_j+1})$; hence in the list L', there exists an index $i_l \leq i_j$ such that $x_{i_l} = x_{i_j+1} = z_{i_j}$.

To sum up, for each index $i_0, \ldots, i_r$, we can write $z_{i_j} = x_{i_l}$ with $i_l = i_j + 1$ or $i_l \leq i_j$. Thus, we can write r equalities between the x_i's and the z_i's.

Now, to show the existence of a $(r + 1)$th equality, we consider two cases:

1. The term (x_s, u_s, z_s, u_s) belongs to the list L' and in this case we have the additional equality $x_s = x_{s'}$ (notice that the term $(x_{s'}, u_{s'}, z_{s'}, y_{s'})$ cannot be removed from list L because there does not exist an index $i < s$ such that $x_{s'} = x_i$).

2. The term (x_s, u_s, z_s, u_s) does not belong to the list L' and in this case we have $(x_s, u_s) = (x_{s'}, u_{s'})$ because there exists an index $i < s$ such that $(x_s, u_s) = (x_i, u_i)$ and this index i is necessarily equal to s'.

If $i_r < s$, then $i_r + 1 \leq 2n$ and there exists an index $k \leq r$ such that $x_{i_r+1} = x_{i_k}$ but $x_{i_r+1} = z_{i_r}$.

If $s < i_r$, then let k_0 be the least index such that $s < i_{k_0}$. We also have

$$\begin{aligned} x_{i_{k_0}} &= z_{i_{k_0}-1} \\ &= f(x_{i_{k_0}-1}, u_{i_{k_0}-1}), \end{aligned}$$

but the term of index $i_{k_0} - 1$ does not belong to list L' and so there exists i_j such that $i_j < i_{k_0} - 1$ and $(x_{i_{k_0}-1}, u_{i_{k_0}-1}) = (x_{i_j}, u_{i_j})$, so $x_{i_{k_0}} = z_{i_j}$. This last equality has not been taken into account above because $i_{k_0} \geq s + 1$ and $s \geq i_j + 1$ and so $i_{k_0} \geq i_j + 2$. We then have $i_{k_0} > i_j$ and cannot have $i_{k_0} = i_j + 1$. □

The next two lemmas are concerned with the derivatives of the components of $\Theta^{f,h}_{2n+1}$.

LEMMA 4. *Let r be a given nonnegative integer and $(i_0, \ldots, i_{n-1})$ be a given sequence of indices in $\{0, \ldots, r\}$. Given $r + 1$ matrices $(A_0, \ldots, A_r)$ in $\mathrm{GL}(n, \mathbb{R})$, we consider the related sequence of matrices $(\tilde{A}_0, \ldots, \tilde{A}_{n-1})$, where*

(i) $\tilde{A}_0 = A_0$;
(ii) *for $j \geq 1$, $\tilde{A}_j = A_{i_j} \tilde{A}_{j-1}$.*

Let $1 \leq k \leq n - 1$ and consider the subset W_k of $\mathrm{GL}(n, \mathbb{R})^{r+1} \times \mathbb{P}^{n-1}$ ($\mathbb{P}^{n-1}$ is the projective space of dimension $n - 1$) constituted by the elements $(A_0, \ldots, A_r, l)$ such that, with $(\tilde{A}_0, \ldots, \tilde{A}_{n-1})$ being the sequence related to $(A_0, \ldots, A_r)$,

(i) *the family $(l, \tilde{A}_0 l, \ldots, \tilde{A}_{k-2} l)$ is linearly independent (this family reduces to (l) if $k = 1$);*

(ii) *the family* $(l, \tilde{A}_0 l, \dots, \tilde{A}_{k-1} l)$ *is linearly dependent.*

The set W_k *is a submanifold of* $\mathrm{GL}(n,\mathbb{R})^{r+1} \times \mathscr{P}_f^{n-1}$ *with codimension equal to* $n-k$.

Proof. Denote by V_k the set of sequences $(v_0, \dots, v_{n-1})$ of n elements of $\mathbb{R}^n$ such that

(i) the family $(v_0, \dots, v_{k-1})$ is linearly independent;

(ii) the family $(v_0, \dots, v_k)$ is linearly dependent;

then V_k is a submanifold of $\mathbb{R}^{n^2}$ of codimension $n-k$. This claim is a particular case of a more general proposition concerned with codimension of sets of linear homomorphisms; its proof can be found in [7, Prop. 5.3 p. 60].

We consider the domains of charts U_i, $i = 1, \dots, n$ of $\mathbb{P}^{n-1}$, where U_i is the set of lines of $\mathbb{R}^n$ generated by $(x_1, \dots, x_n)$ with $x_i \neq 0$; we shall define mappings φ_i $(i = 1, \dots, n)$ from U_i to $\mathbb{R}^{n^2}$. In what follows, the computations will be made only with φ_1, the reasoning being the same for the other mappings φ_i with $i \geq 2$.

We define φ_1 by

$$\begin{array}{rccc} \varphi_1 : & \mathrm{GL}(n,\mathbb{R})^{r+1} \times \mathbb{P}^{n-1} & \longrightarrow & \mathbb{R}^{n^2} \\ & (A_0, \dots, A_r, l) & \longmapsto & (\bar{l}, \tilde{A}_0 \bar{l}, \dots, \tilde{A}_{n-1} \bar{l}), \end{array}$$

where $\bar{l}$ is the element of $\mathbb{R}^n$ which represents l and whose first component is equal to 1. Clearly $W_k \cap U_1 = \varphi_1^{-1}(V_k)$ and we shall show that φ_1 is transverse to V_k which will prove that the codimension of W_k is the same as the one of V_k: $n-k$.

To this end we begin by the characterization of the tangent space of V_k; let $(v_0, \dots, v_{n-1})$ be an element of V_k, and from the matrix M whose columns are the vectors v_i $(i = 0, \dots, n-1)$ we can extract a squared $k \times k$ nonsingular submatrix, without loss of generality. We can assume that this submatrix is constituted by the k first lines and columns of M, and we write the $n \times (k+1)$ matrix whose columns are the vectors $(v_0, \dots, v_k)$ as follows:

$$\begin{pmatrix} A & B \\ C & D \end{pmatrix}$$

with A a squared matrix of order k, C a $(n-k) \times k$ matrix, and the column $(BD)^{\mathrm{T}}$ the vector $\tilde{A}_{k-1} \bar{l}$. The sequence $(v_0, \dots, v_{n-1})$ belongs to V_k iff $D - CA^{-1}B = 0$ [7, p. 60], so a vector $(t_0, \dots, t_{n-1})$ is tangent to V_k at $(v_0, \dots, v_{n-1})$ iff

$$L' - H'A^{-1}B + CA^{-1}HA^{-1}B - CA^{-1}L = 0, \tag{9}$$

where H is a square matrix of order k, H' is a $(n-k) \times k$ matrix, L is a column matrix with k lines, and L' is a column matrix with $n-k$ lines such that the columns of the matrix

$$\begin{pmatrix} H & L \\ H' & L' \end{pmatrix}$$

are constituted by the vectors $(t_0, \dots, t_k)$; notice that this equality can be written as

$$\begin{pmatrix} -CA^{-1} & I_{n-k} \end{pmatrix} \left\{ \begin{pmatrix} L \\ L' \end{pmatrix} - \begin{pmatrix} H \\ H' \end{pmatrix} A^{-1}B \right\} = 0. \tag{10}$$

Let $e = (A_0, \dots, A_r, l)$ be an element of $\mathrm{GL}(n,\mathbb{R})^{r+1} \times \mathbb{P}^{n-1}$ such that $\varphi_1(e) \in V_k$. We shall consider only the derivative with respect to $A_{i_{k-1}}$. We then have

$$\begin{aligned} &\mathrm{d}\varphi_1(e).(0, \dots, 0, M, 0, \dots, 0) \\ &\quad = (0, \psi_0(M, \bar{l}_0), \dots, \psi_{k-2}(M, \bar{l}_0), M\tilde{A}_{k-2}\bar{l}_0 + A_{i_{k-1}}\psi_{k-2}(M, \bar{l}_0), \dots), \end{aligned}$$

where $\psi_i(M, \bar{l}_0)$ is the expression obtained by replacing successively each occurrence of $A_{i_{k-1}}$ in $\tilde{A}_i$ by M; obviously, if $\tilde{A}_i$ does not contain $A_{i_{k-1}}$, then $\psi_i(M, \bar{l}_0)$ is zero. Denote by $w_0, \dots, w_{k-2}$ the vectors $\bar{l}_0, \tilde{A}_0\bar{l}_0, \dots, \tilde{A}_{k-3}\bar{l}_0$. The expression $\psi_i(M, \bar{l}_0)$ is either zero or a sum of terms of the form $B_j M w_j$ with $0 \le j \le k-2$, the vectors $w_0, \dots, w_{k-2}$ being linearly indépendent, and we can find a matrix M such that $Mw_j = 0$ for $j = 0, \dots, k-2$; moreover, the term $M\tilde{A}_{k-2}\bar{l}_0$ can be made equal to an arbitrary vector. By replacing in the right-hand member of (10), $(H, H')^{\mathrm{T}}$ and $(L, L')^{\mathrm{T}}$ by the corresponding components of $\mathrm{d}\varphi_1(e)$, we find the expression

$$\begin{pmatrix} -CA^{-1} & I_{n-k} \end{pmatrix} M\tilde{A}_{k-2}\bar{l}_0,$$

which can be made nonzero. In conclusion, we can find $n-k$ (the codimension of V_k) independent matrices M such that $\mathrm{d}\varphi_1(e)(0, \dots, M, \dots, 0)$ does not belong to the tangent space of V_k. □

We first introduce a definition.

DEFINITION 7. *Consider $r+1$ matrices $A_0, \dots, A_r$ in $\mathrm{GL}(n, \mathbb{R})$ and $r+1$ matrices $C_0, \dots, C_r$ in $\mathscr{M}_{p,n}(\mathbb{R})$. We say that the finite sequence of n matrices $D_0, \dots, D_{n-1}$ is differentially related to the family $(A_0, C_0, A_1, C_1, \dots, A_r, C_r)$ if*

(i) *$D_0 = C_0$ and for $j \ge 1$, each D_j is equal to $C_{i_j}\tilde{A}_{j-1}$, where $i_j \in \{0, \dots, r\}$, and $\tilde{A}_{j-1}$ is a product of j matrices taken in the set $\{A_0, \dots, A_r\}$;*

(ii) *if $D_j = C_{i_j}\tilde{A}_{j-1}$, then D_{j+1} has the form $D_{j+1} = C_{i_{j+1}}A_{i_j}\tilde{A}_{j-1}$;*

(iii) *each matrix $C_0, \dots, C_r$ is involved at least one time in the D_i's; to be more precise, there exist indices $0 \le i_0 < \cdots < i_{r-1}$ such that $C_{i_j} = C_j$.*

For the sake of readability, hereafter, we shall denote by $\mathscr{M}$ the set $\mathrm{GL}(n, \mathbb{R}) \times \mathscr{M}_{p,n}(\mathbb{R})$.

LEMMA 5. *Take $r+1$ matrices $A_0, \dots, A_r$ in $\mathrm{GL}(n, \mathbb{R})$ and $r+1$ matrices $C_0, \dots, C_r$ in $\mathscr{M}_{p,n}(\mathbb{R})$ and $D_0, \dots, D_{r-1}$ a sequence differentially related to the family $(A_0, C_0, \dots, A_r, C_r)$. Consider the set*

$$W = \{ (A_0, C_0, A_1, C_1, \dots, A_r, C_r) \in \mathscr{M}^{r+1} \mid \exists x \in \mathbb{R}^n, D_0x = D_1x = \cdots = D_{\bar{r}}x = 0 \},$$

where $\bar{r} = \max(r, n-1)$. We claim that W is a submanifold of $\mathscr{M}^{r+1}$ with codimension greater than $(r+1)m$.

Proof. We denote by $\mathbb{P}^{n-1}$ the $n-1$-dimensional real projective space, and for $k = 0, \dots, n-1$ we consider the sets M_k of elements

$$(A_0, C_0, \dots, A_r, C_r, \ell) \in \mathscr{M}^{r+1} \times \mathbb{P}^{n-1}$$

such that the family $(\ell, \tilde{A}_0\ell, \dots, \tilde{A}_{k-1}\ell)$ is linearly independent (if $k = 0$, this family reduces to (ℓ)). Obviously, the sets M_k are open in $\mathscr{M}^{r+1} \times \mathbb{P}^{n-1}$; remark also that if E is the subset of matrices of $\{C_0, \dots, C_r\}$ involved in the terms $D_0, \dots, D_k$ and if $\operatorname{card} E < r+1$, then there exist r' matrices $D_{j_1}, \dots, D_{j_{r'}}$ whose indices $j_1, \dots, j_{r'}$ are greater than k and such that $\{C_{i_{j_1}}, \dots, C_{i_{j_{r'}}}\}$ is the set complement of E in $\{C_0, \dots, C_r\}$.

We also define the sets N_k as the subsets of elements $(A_0, C_0, \dots, A_r, C_r, \ell)$ of M_k such that

(i) if $k < n-1$, then the family $(\ell, \tilde{A}_0\ell, \dots, \tilde{A}_{k-1}\ell, \tilde{A}_k\ell)$ is linearly dependent;

(ii) $D_0\ell = D_1\ell = \cdots = D_k\ell = D_{j_1}\ell = \cdots = D_{j_{r'}}\ell = 0$.

If we denote by π the projection from $\mathscr{M}^{r+1} \times \mathbb{P}^{n-1}$ to $\mathscr{M}^{r+1}$, then obviously $W \subset \cup_{k=0}^{n-1}\pi(N_k)$. Clearly, the codimension of N_k is equal to $n-(k+1)+(k+1+r')p$

and so the codimension of $\pi(N_k)$ is greater than or equal to $n-(k+1)+(k+1+r')$ $p-(n-1)=(k+1+r')p-k$. As W is included in the union of the projections of the N_k's, its codimension is greater than or equal to $\min_{0\le k\le n-1}\operatorname{codim}(N_k)$ but

$$\begin{aligned}(k+1+r')p-k &\ge (k+1+r')(m+1)-k \qquad \text{since } p>m\\ &= (k+1+r')m+r'+1\\ &\ge (r+1)m+r'+1\\ &> (r+1)m. \qquad \square\end{aligned}$$

The proof will result from an application of the multijet transversality theorem. To fix $s\le 2n$, we shall prove that the set of pairs (f,h) such that the mapping $\Theta^{f,h}_{2n+1}$ is an immersion at each periodic point x of f is residual as a finite intersection of residual sets.

If x_0 is a s-periodic point for $f\in \mathrm{Diff}_{\mathrm{U}}(X)$, as shown in the proof of Lemma 3, then we can find a list of $r+1$ equalities between the x_i's and the z_i's.

We consider the mapping

$$\begin{array}{rccl} j^1_{r+1}(f,h): & (X\times U)^{(r+1)} & \longrightarrow & J^1_{r+1}(X\times U, X\times\mathbb{R}^p)\\ & (\xi_0,\upsilon_0,\dots,\xi_r,\upsilon_r) & \longmapsto & (j^1(f,h)(\xi_0,\upsilon_0),\dots,j^1(f,h)(\xi_r,\upsilon_r)),\end{array}$$

and we shall define a submanifold W of $J^1_{r+1}(X\times U, X\times\mathbb{R}^p)$. Let $(\mathscr{O}_i\times\mathscr{U}_i,(\varphi_i,\psi_i))$ be a chart of $X\times U$ at (x_i,u_i), and the local expression of the above mapping is given by

$$\begin{array}{rccl} \bar{j}: & \varphi_0(\mathscr{O}_0)\times\psi_0(\mathscr{U}_0)\times\cdots\times\varphi_r(\mathscr{O}_r)\times\psi_r(\mathscr{U}_r) & \longrightarrow & E_0\times\cdots\times E_r\\ & (\bar{\xi}_0,\bar{\upsilon}_0\dots,\bar{\xi}_r,\bar{\upsilon}_r) & \longmapsto & (\beta_0,\dots,\beta_r)\end{array}$$

with

$$\begin{aligned} Ei &= \varphi_i(\mathscr{O}_i)\times\psi_i(\mathscr{U}_i)\times \mathrm{GL}(n,\mathbb{R})\times\mathscr{M}_{p,n}(\mathbb{R}),\\ \beta_i &= (\bar{\xi}_i,\bar{\upsilon}_i,\bar{f}(\bar{\xi}_i,\bar{\upsilon}_i),\bar{h}(\bar{\xi}_i,\bar{\upsilon}_i),d\bar{f}(\bar{\xi}_i,\bar{\upsilon}_i),d\bar{h}(\bar{\xi}_i,\bar{\upsilon}_i)),\end{aligned}$$

and $\bar{\xi}_i$, $\bar{\upsilon}_i$, $\bar{f}$, and $\bar{h}$ the local expressions of ξ_i, υ_i, f, and h, respectively. We put $A_i=d\bar{f}(\bar{\xi}_i,\bar{\upsilon}_i)$ and $C_i=d\bar{h}(\bar{\xi}_i,\bar{\upsilon}_i)$. We define locally the submanifold W defined by one of the sets of the $r+1$ equalities shown in the proof of Lemma 3 and by the relations between matrices A_i and C_i as shown in Lemma 5. We shall give an estimate of $\operatorname{codim}(W)$.

To this end, we denote by W_1 the submanifold containing W which is defined only by the equalities bearing on matrices A_i and C_i and by π the projection from the Cartesian product $E\triangleq E_0\times\cdots\times E_r$ to $(\mathrm{GL}(n,\mathbb{R})\times\mathscr{M}_{p,n}(\mathbb{R}))^{r+1}$; the codimension of W in E is equal to the codimension of W as a submanifold of W_1 plus the codimension of W_1 in E. The codimension of W as a submanifold of W_1 is equal to $(r+1)\,n$ and the codimension of W_1 in E is greater than or equal to the codimension of its projection $W_2\triangleq\pi(W_1)$. Applying Lemma 5, we can say that the codimension of a set of matrices as W_2 is greater than $(r+1)m$, so the codimension of W is greater than $(r+1)(n+m)$, which is the dimension of $(X\times U)^{(r+1)}$. Thus $\bar{j}$ is transverse to W iff $\bar{j}(\bar{\xi}_0,\bar{\upsilon}_0,\dots,\bar{\xi}_r,\bar{\upsilon}_r)\notin W$ for all $(\bar{\xi}_0,\bar{\upsilon}_0,\dots,\bar{\xi}_r,\bar{\upsilon}_r)$.

For each r from 0 to $2n$, we consider a countable family $\mathscr{F}$ of charts covering $(X \times U)^{r+1}$ and consider the application of the Thom transversality theorem to each chart of $\mathscr{F}$ as explained previously. If $(f,h) \in \mathrm{Diff_U}(X) \times C^\infty(X, \mathbb{R}^p)$ and $(x_0, \underline{u_{2n+1}})$ is a periodic point of f with period no greater than $2n$, then starting from x_0 we consider the list L' as in Lemma 3; the element $(x_0, u_0, \ldots, x_{i_r}, u_{i_r})$ constituting L' belongs to one of the charts of the family $\mathscr{F}$, and together with the z_i's satisfy $r+1$ equalities as explained in Lemma 3. Moreover, the above reasoning shows that the set of pairs (f,h), such that $\Theta^{f,h}_{2n+1}$ is an immersion at each periodic point of f lying in one of the charts of family $\mathscr{F}$, is residual by considering the (countable) intersection of all the residual sets related to the charts of $\mathscr{F}$; Proposition 2 is then proven.

5. Conclusion. Let us denote by $\mathscr{O}_1$ the set of pairs $(f,h) \in \mathrm{Diff_U}(X) \times C^\infty(X \times U, \mathbb{R}^p)$ such that the mapping $\Theta^{f,h}_{2n+1}$ is an immersion; the conjunction of Propositions 1 and 2 proves that $\mathscr{O}_1$ is residual. Let us denote by $\mathscr{O}_2$ the set of pairs $(f,h) \in \mathrm{Diff_U}(X) \times C^\infty(X \times U, \mathbb{R}^p)$ such that the mapping $\Theta^{f,h}_{2n+1}$ is one-to-one; in [3], under the assumption that X and U are compact, we proved that $\mathscr{O}_2$ is also residual. Let us denote by $\mathscr{O}_3$ the set of pairs $(f,h) \in \mathrm{Diff_U}(X) \times C^\infty(X \times U, \mathbb{R}^p)$ such that the mapping $\Theta^{f,h}_{2n+1}$ is an embedding; we can conclude that $\mathscr{O}_3$ is residual as the intersection of $\mathscr{O}_1$ and $\mathscr{O}_2$. Moreover, we also proved the openness of $\mathscr{O}_3$; therefore we can assert that $\mathscr{O}_3$ is open and dense.

Acknowledgment. The authors thank the second reviewer for his fruitful remarks and suggestions.

AN INTRODUCTION TO QUANTUM FILTERING*

LUC BOUTEN†, RAMON VAN HANDEL†, AND MATTHEW R. JAMES‡

Abstract. This paper provides an introduction to quantum filtering theory. An introduction to quantum probability theory is given, focusing on the spectral theorem and the conditional expectation as a least squares estimate, and culminating in the construction of Wiener and Poisson processes on the Fock space. We describe the quantum Itô calculus and its use in the modeling of physical systems. We use both reference probability and innovations methods to obtain quantum filtering equations for system-probe models from quantum optics.

Key words. quantum filtering, quantum probability, quantum stochastic processes

1. Introduction.

Since even before the industrial revolution, feedback control has played a major role in the development of technology. Nowadays, many machines and devices that make up our everyday lives use feedback to provide efficient and reliable performance despite ever increasing complexity and miniaturization, and a rich control theory has been developed to aid in the design of feedback controllers based on device models from classical physics. As microtechnology is making way for nanotechnology, however, we are now rapidly approaching the boundary of the classical world past which the effects of quantum mechanics cannot be neglected.

The laws of quantum mechanics tell us that any description of the phenomena at small scales is inherently nondeterministic in nature. This opens new areas of application for stochastic control theory, which could play a role in a future generation of technology. In particular, as observations of quantum systems are inherently noisy, the theory of filtering—the extraction of information from a noisy signal—forms an integral part of quantum feedback control theory.

Quantum filtering was already implicit in early work on quantum measurement theory by Davies in the 1960s [24, 25]. In its modern form, the study of quantum filtering and control was pioneered by Belavkin in a series of articles dating back to the early 1980s [9, 10, 11, 12, 13]. The theory developed by Belavkin provides an essential foundation for statistical inference in, e.g., quantum optical systems, and much of what we will discuss in the second half of this article is based on his work. The theory gained popularity in the physics community after it was independently developed on a more heuristic level by Carmichael in the early 1990s [22] under the name "quantum trajectory theory" and has since been widely applied in the description of quantum optical experiments and as a computational tool.

Based on the foundations of quantum filtering theory, methods from classical nonlinear and stochastic control can be developed and applied to design feedback control laws for quantum systems. These methods may be optimal in some sense or otherwise designed with relevant considerations in mind (e.g., stability). The resulting controllers are intended to be implemented with some classical technology (e.g., digital or analog electronics). Recent experiments implementing quantum feedback controls [3, 35, 58, 21] have led to renewed interest in the field, which is now rapidly expanding [10, 64, 28, 27, 17, 43, 15, 61, 16, 44, 37, 30, 60, 62, 18]. We believe that a fruitful interaction between stochastic control and theoretical and experimental physics will be essential in paving the way towards the engineering of quantum technologies.

This paper provides an introduction to quantum filtering theory. There are three key ingredients that are required for the development of the theory. First, we need to capture both classical probability and quantum mechanics within the framework of a generalized probability theory, called noncommutative or quantum probability theory. The central object in this theory, the spectral theorem, provides a link between quantum systems and the associated probabilistic measurement outcomes. Second, we need a noncommutative generalization of the concept of conditional expectations. As in classical probability, we will find that a suitably restricted definition of the quantum conditional expectation is none other than a least squares estimator, which elucidates its role in quantum filtering theory. Finally, we need a noncommutative analog of stochastic calculus and quantum stochastic differential equations (QSDEs). This provides a broad class of models for which we can obtain filtering equations.

A typical physical scenario, to which the theory that we will develop can be applied, is illustrated schematically in Figure 5.1. A cloud of (usually cold, trapped) atoms interacts with the electromagnetic field in free space; this can be coherent light from a laser, or even the vacuum. Depending on their internal state the atoms can, for example, emit radiation into the field. If we detect this radiation using an optical detection setup, we can try to infer some information on the internal state of the atoms—this is precisely the goal of quantum filtering theory. If we wanted to control the state of the atoms, we could then feed back some function of the state estimates through a suitable actuator. Recent laboratory experiments (e.g., [58]) implement precisely such a setup and provide a motivating example for the theory.

We begin in section 2 by providing some background for quantum filtering. This includes a discussion of the quantum mechanics and quantum probability in the simplest, finite-dimensional context. In section 3 quantum probability is developed in detail. Then in section 4 we show how Wiener and Poisson processes emerge in a particular quantum probabilistic model based on the Fock space, and how these can be used to develop a noncommutative stochastic calculus. In section 5 we introduce a class of system-observation models that describe typical experiments in quantum optics. Section 6 deals with the derivation of quantum filtering equations using the reference probability approach, while section 7 gives an alternative derivation using the innovations or martingale method.

Scope. It has been our aim to make quantum probability and filtering theory accessible, modulo a set of technicalities, to readers with a minimal number of prerequisites. We (only) presume some familiarity with probability theory and elementary functional analysis. We have put an emphasis on introducing the mathematical structures of quantum probability theory and on demonstrating their significance and their use. As a consequence we do not everywhere achieve the highest level of rigor; we are particularly lax in the use of unbounded operators and their domains. It is

our hope that skimming over these technicalities has enabled us to paint a clearer picture of the pillars of the theory and of the essential techniques involved. That being said, we should point out that many of the tools described in this paper are applied regularly and successfully by physicists without paying any attention to the technical issues involved; the reader should not hesitate to get his feet wet!

It is an ambitious project to introduce an unfamiliar probability theory, a new stochastic calculus, and to even solve a nontrivial problem (filtering) within the confines of about 40 pages. Though we have tried to give a pedagogical treatment, the explanations are sometimes necessarily terse; we hope that the reader will be sufficiently compelled to work his way through the paper. Needless to say there are many omissions; one that particularly deserves mention is the linear case: indeed, the quantum Kalman filter, and the corresponding theory of quantum LQG control, can be developed along similar lines to the filters we will discuss. We have chosen to omit this topic in order to avoid the technicalities of QSDEs with unbounded coefficients, but refer instead to [30] and the references therein.

Notation. The sets of natural, real, and complex numbers are denoted $\mathbf{N}$, $\mathbf{R}$, and $\mathbf{C}$, respectively. In general, script symbols (e.g., $\mathscr{Y}$) are used for von Neumann algebras, while calligraphic symbols (e.g., $\mathcal{Y}$) stand for σ-algebras. $\mathcal{B}$ is the Borel σ-algebra on $\mathbf{R}$. Classical probability spaces are denoted as $(\Omega, \mathcal{F}, \mathbf{P})$, and $E_{\mathbf{P}}$ denotes the expectation with respect to the measure $\mathbf{P}$. Blackboard symbols (e.g., $\mathbb{P}$) denote states on von Neumann algebras. Sans serif symbols (e.g., H) are used for Hilbert spaces. Hilbert space adjoints, as well as the scalar complex conjugate, are indicated by *, and the Hilbert space inner product is denoted by $\langle \cdot, \cdot \rangle$. The commutator of two bounded operators is denoted by $[X, Y] = XY - YX$. I is the identity operator.

2. Background and motivation. In this article we adopt a modern quantum probability formulation of quantum mechanics. *Quantum probability* is the noncommutative counterpart of Kolmogorov's axiomatic characterization of classical probability theory. In addition to the natural interpretation and mathematical tools provided by Kolmogorov's formalism, one of its major successes is that conditioning is a derived concept rather than an additional axiom. The situation is much the same in quantum probability; in particular, the conditioning axiom or "projection postulate," as it is traditionally posed in quantum mechanics, can emerge as a consequence of conditional expectation and the physical idea that in a single experiment one only has direct access to information contained in a commutative subalgebra of observables.

Considering the success of the classical (Kolmogorov) theory, it should come as no surprise that the mathematical abstraction provided by the framework of quantum probability pays off significantly (as we will see throughout the article). Introductory physics textbooks on quantum mechanics rarely use such a description, however. In this section we introduce the basic concepts of quantum probability in their simplest form and attempt to provide contact with ideas about quantum mechanics that readers may be familiar with. This is intended to provide a reference point for interpreting the quantum probabilistic framework used in this paper.

2.1. Some textbook quantum mechanics. According to the textbook by Merzbacher [51, p. 1], "Quantum mechanics is the theoretical framework within which it has been found possible to describe, correlate, and predict the behavior of a vast range of physical systems, from particles through nuclei, atoms, and radiation to molecules and condensed matter." Central to quantum mechanics are the notions of *observables*, which are mathematical representations of physical quantities that can (in principle) be measured, and *states*, which summarize the status of physical systems

and permit the calculation of statistical quantities (such as probabilities, expectations, correlations) of observables.

Indeed, the reader may be familiar with the *Schrödinger wavefunction* $\psi(q,t)$ for a particle of mass m moving in a force field $V(q)$ (dependent on position q, in one dimension for simplicity). If Q is the observable representing position (defined in Example 3.9), the expected position of the particle when in a state described by $\psi(q,t)$ at time t is defined to be

$$\langle Q\rangle = \int q|\psi(q,t)|^2 dq. \tag{2.1}$$

The wavefunctions are normalized to one $\int |\psi(q,t)|^2 dq = 1$, so that $|\psi(q,t)|^2$ could be interpreted as the probability density of the position of the particle. The dynamics of the particle are described by the famous *Schrödinger wave equation*

$$i\hbar\frac{\partial\psi(q,t)}{\partial t} = -\frac{\hbar^2}{2m}\frac{\partial^2\psi(q,t)}{\partial q^2} + V(q)\psi(q,t), \tag{2.2}$$

where $\hbar = h/2\pi$, h is *Planck's constant*, and $i^2 = -1$.

The key distinction between classical (i.e., nonquantum) and quantum mechanics is that quantum mechanics is *noncommutative*, meaning that there exist observables that do not commute, a fact which has deep implications. The momentum observable P (defined in Example 3.9) does not commute with the position observable Q; in fact $[Q,P] = QP - PQ = i\hbar I$. The most famous implication of this failure of commutativity is *Heisenberg's uncertainty relation*, which asserts that

$$\Delta Q\Delta P \geq \frac{1}{2}|\langle i[Q,P]\rangle| = \frac{\hbar}{2}, \tag{2.3}$$

where the variances are defined by $\Delta Q = (\langle Q^2\rangle - \langle Q\rangle^2)^{1/2}$, $\Delta P = (\langle P^2\rangle - \langle P\rangle^2)^{1/2}$. Naive interpretation of the Heisenberg uncertainty relation can be misleading; we will discuss its precise meaning in the following section. Nonetheless, it evidently implies that there is a fundamental irreducible randomness in quantum mechanics. This is in contrast to classical randomness, which in principle can be eliminated with enough effort and information. Experimental evidence has repeatedly confirmed the irreducible randomness of quantum mechanical observations.

Let us make this somewhat vague discussion a little more precise. For simplicity, we will work in this section only in a finite-dimensional setting (in which observations can only take a finite number of values; i.e., they are finite-state random variables). First, recall that if $A = A^*$ is a self-adjoint operator on a finite-dimensional Hilbert space $\mathsf{H} = \mathbf{C}^n$, it has at most n (distinct) real eigenvalues. The set $\mathrm{spec}(A) = \{a_j\}$ of eigenvalues of A is called the spectrum of A, and A can be written as

$$A = \sum_{a\in\mathrm{spec}(A)} a\,P_a, \tag{2.4}$$

where P_a is the projection operator onto the subspace of H spanned by vectors with eigenvalue a. The projections resolve the identity $\sum_{a\in\mathrm{spec}(A)} P_a = I$.

In this finite-dimensional setting, the following operational characterization of quantum mechanical models (often referred to as the "postulates" of quantum mechanics) can be found in most introductory textbooks.

Observables. Physical quantities like position, momentum, spin, etc. are represented by self-adjoint operators on the Hilbert space H and are called *observables*. These are the noncommutative counterparts of random variables.

States. A state is meant to provide a summary of the status of a physical system that enables the calculation of statistical quantities associated with observables. A generic state is specified by a *density matrix* ρ, which is a self-adjoint operator on H that is positive $\rho \geq 0$ and normalized $\mathrm{Tr}[\rho] = 1$. This is the noncommutative counterpart of a probability density.

Measurement. A *measurement* is a physical procedure or experiment that produces numerical results related to observables. In any given measurement, the allowable results take values in the spectrum $\mathrm{spec}(A)$ of a chosen observable A. Given the state ρ, the value $a \in \mathrm{spec}(A)$ is observed with probability $\mathrm{Tr}[\rho P_a]$. Consequently, the expectation of an observable A is given by $\langle A \rangle = \mathrm{Tr}[\rho A]$.

Conditioning. Suppose that a measurement of A gives rise to the observation $a \in \mathrm{spec}(A)$. Then we must condition the state in order to predict the outcomes of subsequent measurements by updating the density matrix ρ using

$$\rho \mapsto \rho'[a] = \frac{P_a \rho P_a}{\mathrm{Tr}[\rho P_a]}. \tag{2.5}$$

This is known as the "projection postulate."

Evolution. A *closed* (i.e., isolated) quantum system evolves in a *unitary* fashion: a physical quantity that is described at time $t = 0$ by an observable A is described at time $t > 0$ by $A(t) = U(t)^* A U(t)$, where $U(t)$ is a unitary operator for each time t. The unitary is generated by the *Schrödinger equation*

$$i\hbar \frac{d}{dt} U(t) = H(t) U(t), \tag{2.6}$$

where the (time-dependent) Hamiltonian $H(t)$ is a self-adjoint operator for each t.

Before continuing, we make the following remarks.

Remark 2.1. *Pure states.* The set of density matrices ρ is convex; we can thus wonder what are the extremal points in this set, i.e., those that correspond to the most informative states. It is not difficult to show that the set of extremal density matrices is the set of projections onto one-dimensional subspaces. Thus we can specify any extremal state uniquely (up to a phase factor $e^{i\varphi}$) by a single unit vector $\psi \in \mathsf{H}$ in the corresponding subspace, and $\mathrm{Tr}[\rho X] = \langle \psi, X\psi \rangle$ for any operator X. In classical probability theory, the set of probability measures is also convex and the extremal measures are deterministic (Dirac) measures. In the quantum mechanical setting, on the other hand, the Heisenberg uncertainty relation implies that even extremal states do not give deterministic measurement outcomes for all observables.

Historically, and in most textbooks, quantum mechanics is first formulated in terms of the extremal states (called *pure states*) and the description is later generalized to density matrices (*mixed states*). The Schrödinger wavefunction $\psi(q, t)$ is an example of a pure state vector in an infinite-dimensional Hilbert space setting. □

Remark 2.2. *Heisenberg vs. Schrödinger picture.* In the above description of time evolution we work with a fixed state while the observables change in time. This conforms to the usual treatment in classical probability theory, where the underlying probability measure is fixed at the outset and the random variables are time dependent (stochastic processes). In quantum mechanics this is known as the *Heisenberg picture*; equally (or perhaps more) popular is the *Schrödinger picture*, in which the observables

are considered fixed and the density matrix evolves as $\rho(t) = U(t)\rho U(t)^*$. The two pictures are essentially equivalent as $\mathrm{Tr}[\rho A(t)] = \mathrm{Tr}[\rho(t)A]$ for any observable A.

Note that if we start in a pure state, then unitary evolution preserves this property; in terms of the state vector, $\psi(t) = U(t)\psi$. Intuitively, this enforces the physical idea that no information is lost from an isolated system. Together with (2.6) we obtain the traditional Schrödinger equation for $\psi(t)$, of which (2.2) is a special case (for a specific choice of H, in infinite dimensions). *We will always work in the Heisenberg picture*, however, as we will be dealing with (quantum) stochastic processes. □

As a basic illustration we discuss the following simple example.

Example 2.3. One of the classic experimental demonstrations of the necessity of quantum mechanics was performed in 1922 by Stern and Gerlach. A silver atom is subjected to an inhomogeneous magnetic field. The atom possesses an intrinsic magnetic moment and hence experiences a force that is proportional to the component of its magnetic moment in the direction of the field gradient. As Stern and Gerlach did not prepare the atom in a particular orientation, they expected it to be deflected randomly in a continuous range of directions corresponding to a random orientation of the magnetic moment. Repeated runs of the experiment showed, however, that the atom is randomly deflected into two discrete directions only—the reason being that in quantum mechanics the intrinsic magnetic moment (or spin) observable is discrete, rather than continuous. Atoms deflected in the upper direction are said to have "spin up," while those in the lower direction have "spin down."

A simple model of a spin is as follows. Let $\mathsf{H} = \mathbf{C}^2$, and consider the observable

$$\sigma_z = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} \tag{2.7}$$

representing spin in the z direction. We have $\mathrm{spec}(\sigma_z) = \{-1, 1\}$, which correspond to spin down and spin up, respectively. In terms of the eigenprojections

$$P_{z,1} = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}, \qquad P_{z,-1} = \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix},$$

we can write $\sigma_z = P_{z,1} - P_{z,-1}$. The next step is to introduce a state. Consider a pure state, given by the vector $\psi = (c_1 \; c_{-1})^T$ with $|c_1|^2 + |c_{-1}|^2 = 1$. If we observe σ_z, we obtain the outcome 1 (spin up) with probability $\langle \psi, P_{z,1}\psi\rangle = |c_1|^2$, or the outcome -1 with probability $\langle \psi, P_{z,-1}\psi\rangle = |c_{-1}|^2$. □

2.2. A first look at quantum probability. The description of quantum mechanics in the previous section contains the rudiments of a viable probability theory. We will now formalize these ideas, once again restricting ourselves to the finite-dimensional case for simplicity (the general theory, which will be discussed in section 3, is conceptually very similar). Two key ideas, which we elaborate on below, form the essence of the formalism: the first is that a set of measurements made in a single realization[1] of a quantum experiment corresponds to a particular choice of a commutative algebra of observables; and the second is that any such commutative algebra is entirely equivalent to a classical (Kolmogorov) probability model.

A classical probability model is described by a probability space $(\Omega, \mathcal{F}, \mathbf{P})$. Here Ω, the sample space, is not of essential importance; the basic ingredients of the theory

[1]By a *realization* or an *experiment* we mean that random variables are assigned a definite value, as is the case if we perform measurements on a single physical system. In classical probability this corresponds to the choice of a sample point $\omega \in \Omega$; the quantum case is a little more subtle.

are the events that can occur, contained in the σ-algebra $\mathcal{F}$, and their probabilities, which are determined by the measure $\mathbf{P}$. Equivalently, we could describe an event $F \in \mathcal{F}$ by a random variable χ_F which takes the value 1 if F occurs and 0 otherwise (the indicator function on F), and the probability of the event is simply the expectation of χ_F. We have already encountered such objects in the previous section: events are precisely those observables that are projection operators ($P = P^* = P^2$), and the probability of an event P is given by $\mathbb{P}(P) = \mathrm{Tr}[\rho P]$. Thus the set of projections, together with the linear map $\mathbb{P}$, play much the same role as the classical pair $\mathcal{F}, \mathbf{P}$.

We run into trouble in the quantum case when we try to ascribe joint probabilities to certain events. This is always possible in classical probability theory: the joint probability of the events A and B is $\mathbf{P}(A \cap B) = E_{\mathbf{P}}(\chi_A \chi_B)$. But given two projection operators P, Q, the operator PQ is not guaranteed to be a projection or even an observable ($(PQ)^* = QP$), *unless* P and Q commute. This simple observation is no coincidence; it has the following physical interpretation: in a single realization of a quantum probability model, we can only verify the truth of a set of commuting events. This is in contrast with classical probability where in every realization any event is either true or false, whether we choose to observe it or not. In quantum probability we can a priori choose to verify the truth of an arbitrary event, but subsequently some of the other events (those that do not commute with the observed event, said to be *incompatible*) become meaningless within the same realization.

The incompatibility of events is a significant conceptual departure from classical probability and requires a little getting used to. In many ways, however, this is the only essential departure from classical probability theory. We now begin to construct the mathematical formalism of quantum probability, and we will show that it is indeed very close to Kolmogorov's theory.

Consider the following idea. Suppose we decide to measure an observable A and obtain a particular outcome $a \in \mathrm{spec}(A)$. Then we do not need to perform another measurement to know that any function $f(A)$ would give the outcome $f(a)$; in essence, this is merely a relabeling of the measurement outcomes of A. Indeed,

$$A = \sum_{a \in \mathrm{spec}(A)} a\, P_a \quad \Longrightarrow \quad f(A) = \sum_{a \in \mathrm{spec}(A)} f(a)\, P_a, \tag{2.8}$$

and all such operators commute with each other. Thus measuring A "automatically" measures all functions $f(A)$. The set of operators $\mathscr{A} = \{X : X = f(A),\ f : \mathbf{R} \to \mathbf{C}\}$ forms a *commutative $*$-algebra*, i.e., arbitrary (complex) linear combinations, products, and adjoints of operators in $\mathscr{A}$ are still in $\mathscr{A}$, $I \in \mathscr{A}$, and all elements of $\mathscr{A}$ commute. We will call $\mathscr{A}$ the $*$-algebra *generated*[2] *by* A. A linear map $\mathbb{P} : \mathscr{A} \to \mathbf{C}$ that is positive ($\mathbb{P}(A) \geq 0$ if $A \geq 0$) and normalized ($\mathbb{P}(I) = 1$) is called a *state* on $\mathscr{A}$ (clearly we can always write such a state as $A \mapsto \mathrm{Tr}[\rho A]$ for some density matrix ρ). Note that the projections $P \in \mathscr{A}$ are precisely those events that we can distinguish by measuring A, and $\mathbb{P}(P)$ gives their probabilities. We can similarly generate the commutative $*$-algebra of functions of an arbitrary set of commuting observables.

The algebraic structure we have introduced is of fundamental importance as it provides us with a direct connection to the classical theory, as follows.

THEOREM 2.4 (spectral theorem, finite-dimensional case). *Let $\mathscr{A}$ be a commutative $*$-algebra of operators on a finite-dimensional Hilbert space, and let $\mathbb{P}$ be a state*

[2]In fact, it is the smallest $*$-algebra of operators that contains A.

on $\mathscr{A}$. Then there are a probability space $(\Omega, \mathcal{F}, \mathbf{P})$ and a map ι from $\mathscr{A}$ onto the set of measurable functions on Ω that is a $*$-isomorphism, i.e., a linear bijection with $\iota(AB) = \iota(A)\iota(B)$ (pointwise) and $\iota(A^*) = \iota(A)^*$, and moreover $\mathbb{P}(A) = E_{\mathbf{P}}(\iota(A))$.

Proof. The proof is an elementary exercise in linear algebra. As the Hilbert space H has dimension $n < \infty$, we can, without loss of generality, suppose that $\mathsf{H} = \mathbf{C}^n$ and that $\mathscr{A}$ is a commutative $*$-algebra of complex $n \times n$ matrices. As all the elements of $\mathscr{A}$ commute, we can find a unitary matrix U such that U^*AU is a diagonal matrix for every $A \in \mathscr{A}$. Let $\Omega = \{1, \ldots, n\}$. Define $\iota(A) : \Omega \to \mathbf{C}$ by $\iota(A)(i) = (U^*AU)_{ii}$ for every $A \in \mathscr{A}$. Next, define $\mathcal{F} = \sigma\{\iota(A) : A \in \mathscr{A}\}$. Finally, define $\mathbf{P}(S) = \mathbb{P}(\iota^{-1}(\chi_S))$ for every $S \in \mathcal{F}$. We have now explicitly constructed $(\Omega, \mathcal{F}, \mathbf{P})$ and ι. □

Evidently the commutative $*$-algebra structure is completely equivalent to classical probability theory; by simultaneously diagonalizing all the operators in the algebra, we obtain an explicit representation of measurable random variables as the functions on the diagonals. We also note the following. Suppose we are given some (large) commutative $*$-algebra $\mathscr{A}$, and consider a subalgebra $\mathscr{B} \subset \mathscr{A}$ generated by a single element $B \in \mathscr{A}$. If we apply the map ι to $\mathscr{B}$, we obtain precisely the subset of functions on Ω that are measurable with respect to $\sigma\{\iota(B)\}$. Thus subalgebras play the same role in quantum probability as sub-σ-algebras in classical probability; they allow us to keep track of particular subsets of information.

We do not a priori have a basis for specifying a particular commutative $*$-algebra; given a quantum system, we could decide to measure any of a large set of incompatible observables. The discussion up to this point motivates the following definition.

Definition 2.5 (quantum probability space, finite-dimensional case). *A pair $(\mathscr{N}, \mathbb{P})$, where $\mathscr{N}$ is a (not necessarily commutative) $*$-algebra of operators on a finite-dimensional Hilbert space and $\mathbb{P}$ is a state on $\mathscr{N}$, is called a (finite-dimensional) quantum probability space.*

Usually we will choose $\mathscr{N}$ to be the set of all (bounded) operators $\mathscr{B}(\mathsf{H})$ on some underlying Hilbert space H. The principles of quantum probability now amount to the following. In each realization, we must make a choice of commutative $*$-subalgebra $\mathscr{A} \subset \mathscr{N}$ which fixes the observations. Every statistic that pertains to these observations (e.g., the statistics compiled by repeating the experiment many times with the same choice of $\mathscr{A}$) is now described by the classical probability model obtained through the spectral theorem. The reader should convince himself that the operational description given in the previous section fits neatly within this model (with the exception of conditioning, which we discuss in section 2.4).

Notice that in contrast to a classical probability space $(\Omega, \mathcal{F}, \mathbf{P})$, there are no sample points $\omega \in \Omega$ in a quantum probability space. The sample points emerge through the spectral theorem after the choice of a commutative $*$-subalgebra.

Example 2.6. Let us reformulate Example 2.3. Set $\mathsf{H} = \mathbf{C}^2$ and choose $\mathscr{N} = \mathscr{B}(\mathsf{H}) = M_2$, the $*$-algebra of 2×2 complex matrices. The pure state is defined by $\mathbb{P}(A) = \langle \psi, A\psi \rangle = \psi^* A \psi$ (recall that $\psi = (c_1 \ c_{-1})^T$ with $|c_1|^2 + |c_{-1}|^2 = 1$).

The observable σ_z, used to represent spin measurement in the z direction, generates a commutative $*$-subalgebra $\mathscr{A}_z \subset \mathscr{N}$. It is not difficult to see that $\mathscr{A}_z$ is simply the linear span of the events $P_{z,1}$ and $P_{z,-1}$. Let us now apply the spectral theorem; we obtain the probability space $(\Omega, \mathcal{F}, \mathbf{P})$ where $\Omega = \{1, 2\}$, $\mathcal{F} = \{\varnothing, \{1\}, \{2\}, \Omega\}$, $\mathbf{P}(\{1\}) = |c_1|^2$, etc., and $\iota(P_{z,1}) = \chi_{\{1\}}$, $\iota(P_{z,-1}) = \chi_{\{2\}}$. In particular, the random variable $\iota(\sigma_z) : (1, 2) \mapsto (1, -1)$ has precisely the right properties.

Now suppose we do not wish to measure the intrinsic angular momentum (spin)

in the z direction, but in the x direction. This corresponds to the observable

$$\sigma_x = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \tag{2.9}$$

which has the spectral decomposition $\sigma_x = P_{x,1} - P_{x,-1}$ with

$$P_{x,1} = \frac{1}{2}\begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix}, \qquad P_{x,-1} = \frac{1}{2}\begin{pmatrix} 1 & -1 \\ -1 & 1 \end{pmatrix}.$$

The observable σ_x also generates a commutative $*$-subalgebra $\mathscr{A}_x = \mathrm{span}\{P_{x,1}, P_{x,-1}\}$ to which we can apply the spectral theorem. However, as σ_x and σ_z do not commute, they cannot be jointly represented on a classical probability space through the spectral theorem. In other words, σ_x and σ_z are incompatible and their joint statistics are undefined; hence they cannot both be observed in the same realization. □

To conclude this section, let us say a few words about the interpretation of the Heisenberg uncertainty relation. The relation says that the product of the variances of two noncommuting observables is bounded from below by a positive constant. It is important to realize, however, that the two observables cannot be measured in the same realization as they are incompatible—in particular, the *co*variance of the observables is undefined. Rather, the uncertainty relation is a statement about the properties of quantum states: for any state, the statistics of the two observables, compiled in the course of separate realizations in each of which only one of the observables is measured, must obey the Heisenberg inequality.[3]

2.3. Composite systems. We will often wish to form a composite probability model from two separate probability spaces. In classical probability theory, two probability spaces $(\Omega_1, \mathcal{F}_1, \mathbf{P}_1)$ and $(\Omega_2, \mathcal{F}_2, \mathbf{P}_2)$ can be merged into a single probability space $(\Omega_1 \times \Omega_2, \mathcal{F}_1 \times \mathcal{F}_2, \mathbf{P}_1 \times \mathbf{P}_2)$ where $\mathbf{P}_1 \times \mathbf{P}_2$ is the product measure. We now briefly describe the noncommutative counterpart.

Consider a composite system constructed from two quantum probability spaces $(\mathscr{N}_1, \mathbb{P}_1)$, $(\mathscr{N}_2, \mathbb{P}_2)$ of operators on the Hilbert spaces H_1 and H_2, respectively. The composite quantum probability space consists of operators on the tensor product Hilbert space $\mathsf{H}_1 \otimes \mathsf{H}_2$; for vectors $\psi_1, \phi_1 \in \mathsf{H}_1$ and $\psi_2, \phi_2 \in \mathsf{H}_2$, the inner product on $\mathsf{H}_1 \otimes \mathsf{H}_2$ is given by

$$\langle \psi_1 \otimes \psi_2, \phi_1 \otimes \phi_2 \rangle = \langle \psi_1, \phi_1 \rangle \langle \psi_2, \phi_2 \rangle,$$

which is extended by linearity to any vector in the tensor product space. The algebra $\mathscr{N}_1 \otimes \mathscr{N}_2$ is generated by elements of the form

$$(A_1 \otimes A_2)(\psi_1 \otimes \psi_2) = A_1\psi_1 \otimes A_2\psi_2,$$

where $A_1 \in \mathscr{N}_1$ and $A_2 \in \mathscr{N}_2$. Finally, the product state is defined by

$$(\mathbb{P}_1 \otimes \mathbb{P}_2)(A_1 \otimes A_2) = \mathbb{P}_1(A_1)\mathbb{P}_2(A_2)$$

[3]In the physics literature one often find statements to the effect that the Heisenberg uncertainty relation limits the precision with which we can "imperfectly" observe two noncommuting observables simultaneously, i.e., within the same realization. This is a misconception. Though the idea of an imperfect measurement can be implemented rigorously (see, e.g., [38]), this gives rise to an uncertainty relation which is different from Heisenberg's uncertainty relation [4].

and is extended by linearity. The quantum probability space $(\mathscr{N}_1 \otimes \mathscr{N}_2, \mathbb{P}_1 \otimes \mathbb{P}_2)$ of operators on the Hilbert space $\mathsf{H}_1 \otimes \mathsf{H}_2$ describes the composite system. The reader should verify that if $\mathscr{N}_1$ and $\mathscr{N}_2$ are commutative, then applying the spectral theorem to the composite system is equivalent to applying the spectral theorem to the individual subsystems, then forming the composite classical probability space.

2.4. Conditional expectations. Let us recall for a moment the Stern–Gerlach experiment of Examples 2.3 and 2.6. We have introduced the observables σ_z and σ_x, corresponding to spin in the z and x directions. These observables are incompatible, so we cannot measure them in the same realization. Recall that in order to measure σ_z, Stern and Gerlach apply a field gradient in the z direction; the atom then acquires momentum in that direction proportional to σ_z, and we can determine the value of σ_z in that realization by observing whether the atom is deflected up (1) or down (-1). Similarly, σ_x is measured by orienting the field gradient along the x axis.

We would not be measuring both σ_z and σ_x by applying both field gradients simultaneously, but rather as magnetic fields add vectorially, this would measure the spin in some other direction in the x-z plane whose observable commutes with neither σ_z nor σ_x. On the other hand, we could first apply the field gradient in the z direction until we can resolve σ_z, then turn this field off and switch on a field in the x direction to resolve σ_x. It is a characteristic feature of quantum mechanics that the measurement outcomes in such a procedure can differ drastically depending on what order we apply the fields. It is thus of crucial importance to specify precisely how such measurements are performed by including in the quantum probability space a model of the measurement apparatus (or *probe*).

We defer the discussion of the Stern–Gerlach measurement with magnetic fields until we have developed the necessary machinery in section 3. For the sake of example, we develop in this section a simpler probe model which shows the main features of the procedure. We will see that this probe model, together with the concept of conditional expectations, reproduces precisely the traditional projection postulate of section 2.1.

Let us begin by discussing *conditional expectations* in the noncommutative context. The key observation we need is the following. The conditional probability of an event B given an event A is the probability that B is true given that A is true in the same realization. Hence the concept of conditioning inherently makes sense only in the context of quantities that can be observed in the same realization of an experiment. This means that we can only define conditional expectations in commutative subalgebras of a quantum probability space; but as long as we are restricted to the commutative case, the spectral theorem allows us to define any probabilistic operation directly in terms of the associated classical probability space (see [18]).

To be more precise, let $(\mathscr{N}, \mathbb{P})$ be a quantum probability space, $\mathscr{A} \subset \mathscr{N}$ be a commutative subalgebra, and $B \in \mathscr{N}$ be a self-adjoint element that commutes with every $A \in \mathscr{A}$. Then B and $\mathscr{A}$ generate a larger commutative subalgebra $\mathscr{C} \subset \mathscr{N}$, to which we can apply the spectral theorem to obtain a $*$-isomorphism ι. The conditional expectation is now simply inherited from the classical space as $\mathbb{P}(B|\mathscr{A}) = \iota^{-1}(E_{\mathbf{P}}(\iota(B)|\sigma\{\iota(\mathscr{A})\}))$. Note, however, that if B, C are two self-adjoint operators that commute with every $A \in \mathscr{A}$, this does not necessarily imply that B and C commute. The set $\mathscr{A}' = \{B \in \mathscr{N} : AB = BA \ \forall A \in \mathscr{A}\}$, the *commutant* of $\mathscr{A}$ (in $\mathscr{N}$), is the largest $*$-subalgebra of operators that can be conditioned on $\mathscr{A}$. The conditional expectation is defined as above for its self-adjoint elements, and extends to all of $\mathscr{A}'$ by linearity.

From this discussion and the definition of the classical conditional expectation, we extract the following definition directly in terms of the quantum probability space.

DEFINITION 2.7 (conditional expectation, finite-dimensional case). *Let $(\mathscr{N}, \mathbb{P})$ be a finite-dimensional quantum probability space and let $\mathscr{A} \subset \mathscr{N}$ be a commutative $*$-subalgebra. Then $\mathbb{P}(\cdot|\mathscr{A}) : \mathscr{A}' \to \mathscr{A}$ is called (a version of) the conditional expectation from $\mathscr{A}'$ onto $\mathscr{A}$ if $\mathbb{P}(\mathbb{P}(B|\mathscr{A})A) = \mathbb{P}(BA)$ for all $A \in \mathscr{A}$, $B \in \mathscr{A}'$.*

As we will see in section 3, the discussion above generalizes directly to the infinite-dimensional case. In finite dimensions it is convenient to give an explicit expression for the conditional expectation. Note that a finite-dimensional $*$-algebra is a finite-dimensional linear space. Then $\langle A, B\rangle_{\mathbb{P}} = \mathbb{P}(A^*B)$ turns the algebra into a pre-Hilbert space; i.e., it is a Hilbert space except that $A \mapsto \langle A, A\rangle_{\mathbb{P}} = \|A\|_{\mathbb{P}}^2$ may have a nontrivial null space. In particular, the fundamental property $\mathbb{P}(\mathbb{P}(B|\mathscr{A})A) = \mathbb{P}(BA)$ for all $A \in \mathscr{A}$ is precisely that of orthogonal projection from $\mathscr{A}'$ onto the linear subspace $\mathscr{A}$, which in a pre-Hilbert space is uniquely determined up to an event of zero probability. Note that the classical characterization of $\mathbb{P}(B|\mathscr{A})$ as the least mean square estimate of B in $\mathscr{A}$ follows immediately. We will elaborate on this point in section 3.

An explicit expression for $\mathbb{P}(B|\mathscr{A})$ is easily obtained if we find an orthogonal basis for $\mathscr{A}$. Any commutative $*$-algebra in finite dimensions is spanned by a set of projections that resolve the identity. This is easily seen: in n dimensions any self-adjoint operator is a linear combination of at most n projections that resolve the identity, and as all the operators in the $*$-algebra commute they must be expressible as linear combinations of the same projections. Let $\mathscr{A} = \operatorname{span}\{P_a\}$ for some set of orthogonal projections P_a resolving the identity. Then a version of the conditional expectation is given by

$$\mathbb{P}(B|\mathscr{A}) = \sum_{P \in \{P_a\} : \mathbb{P}(P) \neq 0} \frac{P}{\|P\|_{\mathbb{P}}} \left\langle \frac{P}{\|P\|_{\mathbb{P}}}, B \right\rangle_{\mathbb{P}} = \sum_{P \in \{P_a\} : \mathbb{P}(P) \neq 0} \frac{\mathbb{P}(PB)}{\mathbb{P}(P)} P. \tag{2.10}$$

Note what could happen if we naively fill in some $B \notin \mathscr{A}'$. Then $\langle P, B\rangle_{\mathbb{P}} \neq \langle B, P\rangle_{\mathbb{P}}$ for some $P \in \{P_a\}$, which implies that we obtain complex coefficients in the sum even if B is an observable. Hence the expression does not make sense unless $B \in \mathscr{A}'$.

Example 2.8. This example serves to illustrate conditional expectations; it is not meant to represent a particular physical scenario. Consider $\mathsf{H} = \mathbf{C}^3$, $\mathscr{N} = M_3$, and $\mathbb{P}(X) = \langle \psi, X\psi\rangle$ with $\psi = (1\ 1\ 1)^T/\sqrt{3}$. Define $A, B \in \mathscr{N}$ by

$$A = \begin{pmatrix} 4 & 0 & 0 \\ 0 & 4 & 0 \\ 0 & 0 & 5 \end{pmatrix} = 4 \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{pmatrix} + 5 \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix}, \qquad B = \begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 2 \end{pmatrix}.$$

Let $\mathscr{A}$ be the $*$-algebra generated by A. Then

$$\mathscr{A}' = \left\{ \begin{pmatrix} a & b & 0 \\ c & d & 0 \\ 0 & 0 & x \end{pmatrix} \ : \ a, b, c, d, x \in \mathbf{C} \right\}.$$

Note that $\mathscr{A}'$ is not a commutative algebra, despite that every element of $\mathscr{A}'$ commutes with every element of $\mathscr{A}$. As $B \in \mathscr{A}'$, we can use (2.10) to calculate

$$\mathbb{P}(B|\mathscr{A}) = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 2 \end{pmatrix} = 1 \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{pmatrix} + 2 \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix} \in \mathscr{A}.$$

The observable $\mathbb{P}(B|\mathscr{A})$ is the orthogonal projection of B onto $\mathscr{A}$ with respect to the inner product $\langle A, B\rangle_{\mathbb{P}} = \mathbb{P}(A^*B)$. By the projection theorem, $\mathbb{P}(B|\mathscr{A})$ is an element of $\mathscr{A}$ that minimizes the mean square error $\|B - \mathbb{P}(B|\mathscr{A})\|_{\mathbb{P}}$. □

We now proceed to develop a simple probe model that reproduces the projection postulate. Recall that the conditional *probability* of an event P given a commuting event Q is simply given by $\mathbb{P}(PQ)/\mathbb{P}(Q)$. This is equivalent to $\mathbf{P}(A \cap B)/\mathbf{P}(B)$ by the spectral theorem, where A and B are the sets corresponding to P and Q.

Example 2.9. *Simple probe model.* We will work in a generic n-dimensional setting, $n < \infty$. Let $\mathsf{H} = \mathbf{C}^n$, $\mathscr{N} = M_n$ (the set of $n \times n$ complex matrices), and let $\mathbb{P}(X) = \mathrm{Tr}[\rho X]$ be some state on $\mathscr{N}$. Let A, B be two observables in $\mathscr{N}$ that do not commute. Hence we cannot measure A and B directly in the same realization. However, we can have the system interact with an external probe system, in such a way that the observable A is copied to some probe observable A' after the interaction. If A' commutes with B, we interpret this procedure (like in the Stern–Gerlach example) as an (indirect) measurement of A followed by a (direct) measurement of B.

The strategy is simple. First, we describe the probe system by a separate probe quantum probability space $(\mathscr{N}_p, \mathbb{P}_p)$ and form the composite space $(\mathscr{N} \otimes \mathscr{N}_p, \mathbb{P} \otimes \mathbb{P}_p)$. Next, we introduce an interaction. Recall from section 2.1 that the evolution of an isolated system is described by a unitary transformation. Hence, we will choose a probe observable $I \otimes A'$ and construct a suitable unitary operator U so that the probe observable $U^*(I \otimes A')U$ after the interaction gives the same outcome as $A \otimes I$ would have before the interaction. Note that, by construction, the system observable $B \otimes I$ commutes with $I \otimes A'$ after the interaction, $[U^*(I \otimes A')U, U^*(B \otimes I)U] = 0$. Hence we can measure them within the same realization.

We now fill out the details of this model. Let $A = \sum_{a \in \mathrm{spec}(A)} a\, P_a$, and we denote by m the number of elements in $\mathrm{spec}(A)$ (the number of possible measurement outcomes). For the probe algebra, we choose $\mathsf{H}_p = \mathbf{C}^m$, $\mathscr{N}_p = M_m$. Now fix an observable $A' \in \mathscr{N}_p$ that has the same spectrum as A. $A' = \sum_{a \in \mathrm{spec}(A)} a\, P'_a$ and that P'_a are projections onto one-dimensional subspaces of H_p; hence we can fix an orthonormal basis of vectors $\psi_a \in \mathsf{H}_p$ such that $P'_a = \psi_a \psi_a^*$. Now define the operator $X'_{ab} = \psi_b \psi_a^* + \psi_a \psi_b^* + \sum_{c \neq a,b} \psi_c \psi_c^* \in \mathscr{N}_p$ for $a \neq b$, and $X'_{aa} = I$; these operators switch the events P'_a and P'_b in the sense $X'_{ab} P'_a X'_{ab} = P'_b$, $X'_{ab} P'_b X'_{ab} = P'_a$, and $X'_{ab} P'_c X'_{ab} = P'_c$ for $c \neq a, b$. Finally, set $\mathbb{P}_p(X) = \mathrm{Tr}[X P'_p]$ where we have fixed some $p \in \mathrm{spec}(A)$ at the outset.

Now consider the operator $U \in \mathscr{N} \otimes \mathscr{N}_p$ defined by $U = \sum_{a \in \mathrm{spec}(A)} P_a \otimes X'_{ap}$. As $(X'_{ap})^2 = I$ it follows that $U^*U = UU^* = U^2 = I$; i.e., U is unitary. Note that $U^*(I \otimes P'_c)U = P_c \otimes P'_p + (1 - P_c) \otimes P'_c$ if $c \neq p$, $U^*(I \otimes P'_p)U = \sum_a P_a \otimes P'_a$. We calculate $(\mathbb{P} \otimes \mathbb{P}_p)(U^*(I \otimes P'_c)U(P_c \otimes I))/(\mathbb{P} \otimes \mathbb{P}_p)(P_c \otimes I) = 1$ for every c; i.e., the conditional probability that $U^*(I \otimes A')U$ gives the outcome c, given that we have observed $A \otimes I$ with outcome c, is one. Thus the unitary interaction U precisely copies the system observable A onto the probe observable A'.

We can now measure the system observable B after interaction with the probe. In particular, let us calculate the expectation of B conditioned on the probe measurement. Define $\mathscr{A}$ as the commutative $*$-algebra generated by $U^*(I \otimes A')U$, and note that $U^*(B \otimes I)U \in \mathscr{A}'$. Thus we can use (2.10) to calculate

$$(\mathbb{P} \otimes \mathbb{P}_p)(U^*(B \otimes I)U|\mathscr{A}) = \sum_c \frac{(\mathbb{P} \otimes \mathbb{P}_p)(U^*(B \otimes P'_c)U)}{(\mathbb{P} \otimes \mathbb{P}_p)(U^*(I \otimes P'_c)U)}\, U^*(I \otimes P'_c)U$$

$$= \sum_c \frac{\mathbb{P}(P_c B P_c)}{\mathbb{P}(P_c)}\, U^*(I \otimes P_c')U = \sum_c \mathrm{Tr}[\rho_c B]\, U^*(I \otimes P_c')U,$$

where $\rho_c = P_c \rho P_c / \mathrm{Tr}[\rho P_c]$. This is precisely the projection postulate of section 2.1.

This example may be somewhat bewildering, and we encourage the reader to work through the procedure for a particular model (e.g., that of Example 2.8), paying particular attention to which operators do and do not commute. The reader should convince himself that different answers are obtained if one first measures B then A.

Finally, we note that though we have here measured A through a probe and B directly, there is no reason to stop here. If, in addition to A and B, we want to measure an observable C that does not commute with B, we would introduce a second probe to measure B as well. Now suppose that $C = A$. If we first measure A through the probe, then measure A again, we would (obviously) obtain the same outcome. However, if we first probe A, then probe B, and then measure A, we obtain a different outcome from that of the first measurement of A! The reader is encouraged to work out also this case. The reason for this phenomenon is that the interaction with the probe that is used for the observation of B disturbs the system in such a way that its value of A is changed. This effect is known as "measurement back action." □

The previous example, in particular the construction of the probe and the corresponding interaction, may seem rather ad hoc, and indeed we have only chosen this rather artificial example to reproduce the projection postulate. This is not a shortcoming of the theory we have outlined, however, but rather highlights the importance of including a reasonable model of the probe in the quantum probability space. Indeed, most realistic measurement setups are not of this type and the projection postulate of section 2.1 cannot be used to describe such systems. For example, we will see in section 3 that the Stern–Gerlach measurement is only approximately described by the projection postulate. Later we will describe even more complicated optical measurements in which we wish to condition system observables based on the observation of stochastic processes in continuous time (the signal from a photodetector). It is the latter, most practically useful case where we need quantum filtering theory.

Remark 2.10. It is important to realize that statements like the projection postulate do not really implement the notion of conditioning; they consist of a pure conditioning component and of a particular physical probe model which has no statistical significance. One also finds in the literature generalizations of the projection postulate, called instruments, which implement different types of probes [25, 40]. In the quantum probability context of this paper it is most natural to separate the two parts; we will take existing probe models from physics and concentrate on the calculation of the associated conditional expectations (filtering). □

3. Noncommutative probability theory. In the finite-dimensional case, we have seen in section 2 that quantum mechanics can be modeled as a noncommutative probability theory. In this section we present a general formulation for quantum probability that has wide applicability. We give a general definition of quantum probability space, prove the existence and uniqueness of conditional expectations, and prove a quantum version of Bayes' rule that is very helpful for quantum filtering.

Almost all of the features of the full theory can already be seen in the finite-dimensional case discussed in section 2; the main difficulties in the general case are the technicalities involved in the theory of infinite-dimensional Hilbert spaces. This parallels the difficulties in classical probability theory—though finite-state random

variables can be treated by almost trivial (counting, combinatoric) methods, the description of continuous random variables requires us to upgrade our machinery using methods of real analysis. Similarly, the elementary linear algebra that underlies finite-dimensional quantum probability must be upgraded to functional analysis if we wish to treat the infinite-dimensional case. Conceptually, however, the two cases are very similar, and the reader is encouraged to develop an intuitive understanding of the finite-dimensional case before tackling the full formalism. For a thorough introduction to functional analysis we refer the reader to the excellent textbook [56].

3.1. Quantum probability spaces. Let H be a complex Hilbert space, and denote by $\mathscr{B}(\mathsf{H})$ the set of all bounded (linear) operators on H. We restrict ourselves (for the time being) to bounded operators as we wish to construct $*$-algebras of such operators: attempting to do this with unbounded operators would get us into no end of trouble, as we would surely run into domain problems. Recall that for $A \in \mathscr{B}(\mathsf{H})$, the usual Hilbert space adjoint $A^* \in \mathscr{B}(\mathsf{H})$ is defined by $\langle \psi, A\phi\rangle = \langle A^*\psi, \phi\rangle \; \forall \psi, \phi \in \mathsf{H}$. With this involution $\mathscr{B}(\mathsf{H})$ is a $*$-algebra in the sense of section 2.

We wish to introduce a structure that plays the same role as a $*$-algebra in the finite-dimensional case. It turns out, however, that the $*$-algebra structure in itself is not sufficient in the infinite-dimensional case; we need to impose an additional technical condition in order to be able to prove an infinite-dimensional version of the spectral theorem (Theorem 2.4). The additional condition has a natural interpretation which we will discuss below; however, the reader should not be too worried about this technicality, particularly if he is not familiar with nets or locally convex topologies. In practice we will rarely need to verify this property directly.

DEFINITION 3.1. *A positive linear functional $\mu : \mathscr{B}(\mathsf{H}) \to \mathbf{C}$ is said to be* normal *if $\mu(\sup_\alpha A_\alpha) = \sup_\alpha \mu(A_\alpha)$ for any upper bounded increasing net $\{A_\alpha\}$ of positive elements in $\mathscr{B}(\mathsf{H})$. The locally convex topology on $\mathscr{B}(\mathsf{H})$ defined by the family of seminorms $\{A \mapsto |\mu(A)| : \mu \text{ normal}\}$ is called the* normal topology.

For a detailed discussion of nets, locally convex topologies, etc., see [56].

DEFINITION 3.2 (von Neumann algebra). *A von Neumann algebra $\mathscr{N}$ is a $*$-subalgebra of $\mathscr{B}(\mathsf{H})$ that is closed in the normal topology. A state $\mathbb{P}$ on $\mathscr{N}$ is normal if it is the restriction to $\mathscr{N}$ of a normal state on $\mathscr{B}(\mathsf{H})$.*

We can now extend the spectral theorem to the infinite-dimensional case, essentially showing that commutative von Neumann algebras with normal states are equivalent to classical probability spaces. See, e.g., [57, Proposition 1.18.1] for a proof. Conceptually, we are guided by the finite-dimensional case; Theorem 3.3 extends the idea of simultaneous diagonalization to infinite-dimensional operators. Though technically much more involved, the flavor of the procedure remains the same.[4]

THEOREM 3.3 (spectral theorem). *Let $\mathscr{C}$ be a commutative von Neumann algebra. Then there is a measure space $(\Omega, \mathcal{F}, \mu)$ and a $*$-isomorphism ι from $\mathscr{C}$ to $L^\infty(\Omega, \mathcal{F}, \mu)$, the algebra of bounded measurable complex functions on Ω up to μ-a.s. equivalence. Moreover, a normal state $\mathbb{P}$ on $\mathscr{C}$ defines a probability measure $\mathbf{P}$, which is absolutely continuous with respect to μ such that $\mathbb{P}(C) = E_{\mathbf{P}}(\iota(C))$ for all $C \in \mathscr{C}$.*

Before we continue, let us demonstrate the significance of the additional technical conditions on a von Neumann algebra. First, we give an example of a $*$-subalgebra

[4]The additional measure μ that shows up in the theorem has no direct physical significance; its job is to identify "enough" null sets in $L^\infty(\Omega)$ so we can construct the $*$-isomorphism ι. We can generally not use $\mathbf{P}$ for this purpose as there may be projections $P \in \mathscr{C}$ with $\mathbb{P}(P) = 0$; if ι were to map to $L^\infty(\Omega, \mathcal{F}, \mathbf{P})$, then necessarily $\iota(P) = 0$ and hence ι would not be invertible. The precise details of the construction are never an issue, as we will never use μ and only prove results $\mathbf{P}$-a.s.

of $\mathscr{B}(\mathsf{H})$ that is not a von Neumann algebra.

Example 3.4. Let $\mathsf{H} = L^2([0,1])$ and $\mathscr{A} = C([0,1])$, the commutative algebra of continuous functions on the unit interval. We can consider $A \in \mathscr{A}$ as an operator on H under pointwise multiplication; i.e., $(A\psi)(x) = A(x)\psi(x)$ for every $\psi \in \mathsf{H}$. Then $\mathscr{A}$ satisfies all the requirements of a von Neumann algebra except that it is not closed in the normal topology. Indeed, one can construct, for example, an increasing sequence of continuous functions that converges to $\chi_{[0,1/2]}$, which is discontinuous.

The problem is that the only indicator functions in $\mathscr{A}$ are $\chi_\varnothing$ and $\chi_{[0,1]}$: all other indicator functions on $[0,1]$ are discontinuous. Hence from a probabilistic point of view $\mathscr{A}$ defines a trivial theory, as the only events in $\mathscr{A}$ are the trivial ones. Nonetheless $\mathscr{A}$ is much larger than the algebra $\mathbf{C}$ that is generated by $\chi_\varnothing$ and $\chi_{[0,1]}$. Hence $\mathscr{A}$ cannot be $*$-isomorphic to the set of measurable functions on some measure space. The role of normal closure is to avoid this complication. Indeed, this property guarantees that any von Neumann algebra is generated by its projections [45]. □

Like normal closure, normality of the state is also required in order for the spectral theorem to hold. Note that for normal states the expectation of an increasing set of observables converges to the expectation of their least upper bound; i.e., the monotone convergence property holds. This corresponds to the more basic property of countable additivity. In the following example we construct a state which is not normal.

Example 3.5. Let $\mathsf{H} = \ell^2(\mathbf{N})$ and $\mathscr{A} = \ell^\infty(\mathbf{N})$, acting on H by pointwise multiplication. $\mathscr{A}$ is closed in the normal topology; i.e., it is a commutative von Neumann algebra. Now introduce a state on $\mathscr{A}$ which is given by the expression[5]

$$\mathbb{P}(A) = \lim_{N\to\infty} \frac{1}{N} \sum_{n=1}^{N} A(n), \qquad A \in \mathscr{D} \subset \mathscr{A}, \tag{3.1}$$

on a suitably chosen linear subspace $\mathscr{D}$. $\mathbb{P}$ is not a normal state; to see this, let us introduce the events $P_n \in \mathscr{A}$ defined by $(P_n\psi)(k) = \psi(k)$ if $k \le n$, and zero otherwise. $\{P_n\}$ is an increasing sequence of projections in $\mathscr{A}$ whose least upper bound is the identity $P_\infty = I$. However, straightforward calculation shows that $\mathbb{P}(P_n) = 0$ for any finite n, whereas $\mathbb{P}(I) = 1$. We conclude that the state $\mathbb{P}$ is not normal.

Note that what we have constructed is precisely the classical model of a uniform distribution over the natural numbers $\mathbf{N}$. This does not give rise to a well-defined probability model in the sense of Kolmogorov, however, as the uniform distribution on $\mathbf{N}$ does not obey the property that the probability of a countable union of disjoint events is the sum of the probabilities of these events (which is exactly what went wrong above). Requiring that the state be normal is equivalent to requiring that it gives rise to a countably additive measure [46], which rules out our example. □

Remark 3.6. Definition 3.2 is one of many equivalent definitions of a von Neumann algebra. We have emphasized normality as it is close to the probabilistic notion of monotone convergence. Normal closure turns out to be equivalent to closure in several other topologies, notably the weak and strong operator topologies on $\mathscr{B}(\mathsf{H})$. We will not concern ourselves with topological issues in this article; see, e.g., [20, section 2.4].

The following definition should come as no surprise.

Definition 3.7 (quantum probability space). *A quantum probability space is a pair $(\mathscr{N}, \mathbb{P})$, where $\mathscr{N}$ is a von Neumann algebra and $\mathbb{P}$ is a normal state.*

[5] Equation (3.1) does not by itself define a state, as there are many $A \in \mathscr{A}$ for which the limit does not exist. However, note that (3.1) is well defined on a linear subspace, e.g., $\mathscr{D} = \{A \in \mathscr{A} : \exists c \in \mathbf{C} \text{ s.t. } \lim_{n\to\infty} A(n) = c\}$. Now $\mathbb{P}$ can be extended from $\mathscr{D}$ to $\mathscr{A}$ using the Hahn–Banach theorem.

The structure has precisely the same interpretation as in section 2, of which we briefly remind the reader. In each realization we must choose a commutative von Neumann subalgebra $\mathscr{A} \subset \mathscr{N}$ which fixes the observations. Every statistic that pertains to these observations is then described by the classical probability model obtained by applying the spectral theorem to $(\mathscr{A}, \mathbb{P})$. The equivalence between commutative quantum probability spaces and classical probability spaces is the foundation of the theory; a commutative quantum probability model *is* a classical probabilistic model, and we will often implicitly identify these two pictures.

In this article we will only use three types of von Neumann algebras. We list these below; they will be used throughout without comment.

(i) $\mathscr{A} = \mathscr{B}(\mathsf{H})$ is a von Neumann algebra. Moreover, any *vector state* on $\mathscr{A}$ ($\mathbb{P}(A) = \langle \psi, A\psi \rangle$ for fixed $\psi \in \mathsf{H}$), or any convex combination of vector states, is a normal state. Many models from quantum mechanics are described by such a model.

(ii) $\mathscr{A} = L^\infty(\Omega, \mathcal{F}, \mathbf{P})$, acting on $\mathsf{H} = L^2(\Omega, \mathcal{F}, \mathbf{P})$ by pointwise multiplication, is a commutative von Neumann algebra. Moreover, any state of the form $\mathbb{P}(X) = E_{\mathbf{P}}(X)$ is a normal state. This is a *classical probability model*.

(iii) Given $\mathscr{S} \subset \mathscr{B}(\mathsf{H})$, recall that $\mathscr{S}' = \{X \in \mathscr{B}(\mathsf{H}) : XS = SX \ \forall S \in \mathscr{S}\}$ is called the *commutant* of $\mathscr{S}$ in $\mathscr{B}(\mathsf{H})$. The following theorem (see [45, Theorem 5.3.1] for a proof) allows us to construct von Neumann subalgebras of $\mathscr{B}(\mathsf{H})$.

THEOREM 3.8 (double commutant theorem). *Let $\mathscr{S} \subset \mathscr{B}(\mathsf{H})$ be any self-adjoint set, i.e., $S \in \mathscr{S} \Rightarrow S^* \in \mathscr{S}$. Then $\mathscr{A} = \mathscr{S}''$ is the smallest von Neumann subalgebra of $\mathscr{B}(\mathsf{H})$ that contains $\mathscr{S}$. In particular, $\mathscr{S}$ is a von Neumann algebra iff $\mathscr{S} = \mathscr{S}''$.*

Given any $\mathscr{S} \subset \mathscr{B}(\mathsf{H})$, we call $\mathrm{vN}(\mathscr{S}) = (\mathscr{S} \cup \mathscr{S}^*)''$ the von Neumann algebra generated by $\mathscr{S}$. We will repeatedly use this construction in the following. For example, suppose that we decide to measure in one realization some commuting set of observables $A_1, \ldots, A_n$. Then $\mathscr{A} = \mathrm{vN}(A_1, \ldots, A_n)$ is a commutative von Neumann algebra which, through the spectral theorem, describes the associated classical probability model. $\mathscr{A}$ is the quantum probability equivalent of the σ-algebra generated by a set of random variables.

3.2. Random variables. Now that we have a general definition of a quantum probability space, we can develop some tools to deal with random variables. Recall from section 2 that any self-adjoint element of a quantum probability space can be decomposed into events using (2.4), which gives its interpretation as an observable (random variable). Let us show how to do this in the infinite-dimensional case.

Let $(\mathscr{N}, \mathbb{P})$ be a quantum probability space and consider an element $A \in \mathscr{N}$ which is self-adjoint $A = A^*$. Then $\mathscr{A} = \mathrm{vN}(A) \subset \mathscr{N}$ is a commutative von Neumann algebra. By the spectral theorem, there is a probability space $(\Omega, \mathcal{F}, \mathbf{P})$ and a $*$-isomorphism ι that maps A to some (measurable) random variable $a : \Omega \to \mathbf{R}$. We can now apply classical probability theory; in particular, for any Borel set $B \in \mathcal{B}$ we have the event $[a \in B] = \{\omega \in \Omega : a(\omega) \in B\} = a^{-1}(B) \in \mathcal{F}$. To map this event back to $\mathscr{A}$ we simply invert ι; the projection corresponding to $[a \in B]$ is denoted by $P_A(B) = \iota^{-1}(\chi_{[a \in B]})$, and we call the map P_A from $\mathcal{B}$ to the projections in $\mathscr{N}$ the *spectral measure* of A. But this object is a familiar one from functional analysis [56]; in fact, it is well known that we can express A in terms of its spectral measure by

$$A = \int_{\mathbf{R}} \lambda \, P_A(d\lambda), \tag{3.2}$$

where the integral is defined in a suitable sense [56, sections 7.3 and 8.3]. Equation (3.2) is precisely the infinite-dimensional counterpart of (2.4). We emphasize the

physical interpretation of $P_A(B)$: it is the event [A takes a value in B], which occurs with probability $\mathbb{P}(P_A(B))$.

This would be all there is to it, were it not for the fact that our algebras contain only bounded operators (recall that unbounded operators cannot be defined on the entire Hilbert space, and hence cannot be added or multiplied at will). Evidently we did not lose much by this choice, as the probabilistic model is already contained in an algebra of bounded operators by the spectral theorem. An unfortunate side effect, however, is that self-adjoint operators in the algebra can only represent *bounded* random variables, whereas many observations of interest are quite naturally unbounded (think of a Gaussian random variable). This means that we need to deal with unbounded observables separately. We briefly discuss one way of doing this.

Consider a von Neumann algebra $\mathscr{N} \subset \mathscr{B}(\mathsf{H})$. In general, an observable is defined by a (not necessarily bounded) self-adjoint operator A on some dense domain in H. We need to relate the unbounded operator A to $\mathscr{N}$. The trick we use is remarkably simple: we compute a bounded function of A. Define $T_A = (A+iI)^{-1}$. By elementary spectral theory [56], any self-adjoint A has a real spectrum, and hence $A+iI$ is invertible with bounded inverse. We say that A is *affiliated* to $\mathscr{N}$ if $T_A \in \mathscr{N}$. This is the equivalent of the classical notion of a random variable that is measurable with respect to some σ-algebra $\mathcal{G}$. Note that every self-adjoint A is affiliated to $\mathscr{B}(\mathsf{H})$, and if A is also bounded, then A is affiliated to $\mathscr{N}$ iff $A \in \mathscr{N}$.

We wish to represent A as a classical (unbounded) random variable. To this end, define the von Neumann algebra generated by A as $\mathrm{vN}(A) = \mathrm{vN}(T_A)$. Now note that T_A commutes with its adjoint, and hence $\mathrm{vN}(A)$ is a commutative von Neumann algebra to which we can apply the spectral theorem. All we need to do is to "package" A into T_A, apply ι, and "unpack" it on the other end; in other words, we define $\iota(A) = \iota(T_A)^{-1} - i$. Once we have done this, we can define a spectral measure P_A for A in the usual way, and indeed (3.2) still holds even for unbounded A [56]. We remark that A being affiliated to $\mathscr{N}$ corresponds to the fact that $P_A(B) \in \mathscr{N}$ for every $B \in \mathcal{B}$; this is precisely the classical notion of measurability.

Unbounded operators are a nuisance, but unfortunately they are a fact of life in mathematical physics. In this article, particularly in the later sections, we will occasionally add and multiply unbounded operators without justification; a detailed analysis of the operator domains is beyond our scope. Though this does not often cause trouble, the reader should keep in mind that a fully rigorous treatment must verify that any addition or multiplication of unbounded operators is indeed well defined. We quote one useful result: operators affiliated to a *commutative* von Neumann algebra can be added and multiplied at will (see [45, Theorem 5.6.15] and [54]).

Example 3.9. We take $\mathsf{H} = L^2(\mathbf{R})$ and $\mathscr{N} = \mathscr{B}(\mathsf{H})$. The vector

$$\psi \in \mathsf{H}, \qquad \psi(x) = (2\pi)^{-1/4}\sigma^{-1/2}\exp\left(-\frac{(x-\mu)^2}{4\sigma^2}\right)$$

defines the (pure) state $\mathbb{P}(X) = \langle \psi, X\psi \rangle$. Now consider the self-adjoint operators

$$(Q\psi)(x) = x\psi(x), \qquad (P\psi)(x) = -i\hbar\frac{d}{dx}\psi(x),$$

which are prototypical observables for the position Q and momentum P of a quantum particle. Both are unbounded observables, but their domains include at least the set of smooth functions with compact support which is dense in $L^2(\mathbf{R})$.

What random variables do these represent? We can read off from the definition that Q is a Gaussian random variable with mean μ and variance σ^2—as Q is already in "diagonal" form (Q is affiliated to $L^\infty(\mathbf{R}) \subset \mathscr{N}$), its spectral measure is given by

$$(P_Q(B)\psi)(x) = \chi_B(x)\psi(x)$$

and it is evident that $\mathbb{P}(P_Q(B))$ is a Gaussian measure with mean μ and variance σ^2. Alternatively, consider the characteristic function $q(k) = \mathbb{P}(e^{ikQ})$ of Q. Unlike Q, e^{ikQ} is a bounded operator, and we can directly compute

$$q(k) = \langle \psi, e^{ikQ}\psi\rangle = (2\pi)^{-1/2}\sigma^{-1}\int_{-\infty}^{\infty} e^{ikx}\, e^{-(x-\mu)^2/2\sigma^2}\, dx = e^{ik\mu - k^2\sigma^2/2}$$

which is the characteristic function of a Gaussian random variable with mean μ and variance σ^2. Similarly, e^{ikP} is a bounded operator, and we compute

$$p(k) = \mathbb{P}(e^{ikP}) = \langle \psi, e^{ikP}\psi\rangle = \int_{-\infty}^{\infty} \psi(x)\,\psi(x+\hbar k)\, dx = e^{-\hbar^2 k^2/8\sigma^2}$$

which is the characteristic function of a Gaussian random variable with mean zero and variance $\hbar^2/4\sigma^2$. Thus both Q and P are Gaussian random variables, but their joint distribution is undefined as they do not commute. Note that we cannot choose σ so that both Q and P have arbitrarily small variance: this is a manifestation of the Heisenberg uncertainty relation (compare (2.3)). □

The following example plays a central role in the physics of harmonic oscillators; we will encounter a very similar construction later for continuous-time quantum stochastic processes. We will need the following classic result (see, e.g., [45] for a proof).

THEOREM 3.10 (Stone's theorem). *Let $\mathscr{N}$ be a von Neumann algebra and let $\{U_t\}_{t\in\mathbf{R}} \subset \mathscr{N}$ be a group of unitary operators that is strongly continuous. Then there is a unique self-adjoint A affiliated to $\mathscr{N}$, the* Stone generator*, such that $U_t = e^{itA}$.*

Example 3.11. Let $\mathsf{H} = \ell^2(\mathbf{N})$ and $\mathscr{N} = \mathscr{B}(\mathsf{H})$. Define the complete orthonormal basis $\{\psi_n,\ n = 0, 1, \ldots\} \subset \mathsf{H}$, where $\psi_n(k) = 1$ if $k = n$ and $\psi_n(k) = 0$ otherwise. Moreover, we define for every $\alpha \in \mathbf{C}$ the *exponential vector* $e(\alpha) \in \mathsf{H}$ by $e(\alpha)(k) = \alpha^k/\sqrt{k!}$, and we remark that the linear span D of all exponential vectors is dense in H. The normalized exponential vectors $e(\alpha)e^{-|\alpha|^2/2}$ are called coherent vectors and can be used to define the coherent states $\mathbb{P}_\alpha(X) = \langle e(\alpha), Xe(\alpha)\rangle\, e^{-|\alpha|^2}$.

The simplest random variable we can investigate is defined by $(\lambda\psi)(k) = k\psi(k)$—i.e., this is the natural diagonal operator affiliated to $\ell^\infty(\mathbf{N}) \subset \mathcal{N}$. The spectral measure of λ is given by $(P_\lambda(B)\psi)(k) = \chi_B(k)\psi(k)$, from which we obtain directly

$$\mathbb{P}_\alpha(P_\lambda(B)) = \langle e(\alpha), P_\lambda(B)e(\alpha)\rangle\, e^{-|\alpha|^2} = \sum_{k\in B} \frac{e^{-|\alpha|^2}(|\alpha|^2)^k}{k!}.$$

Thus, evidently, λ is a Poisson-distributed random variable with intensity $|\alpha|^2$.

Can we find other interesting observables affiliated to $\mathscr{N}$? In many cases, physically relevant observables are found to be the Stone generators of particular unitary symmetry groups; see, e.g., [38] for a lucid discussion. Let us try to implement this procedure with the two-dimensional translation group. As a first attempt, let us define a translation operator by $D_\gamma e(\alpha) = e(\alpha+\gamma)\, e^{|\alpha|^2/2 - |\alpha+\gamma|^2/2}$ for $\gamma \in \mathbf{C}$; the constant

factor ensures that $\|D_\gamma e(\alpha)\| = \|e(\alpha)\|$, as must be the case for any unitary operator. Unfortunately, D_γ is not in fact unitary; a straightforward calculation shows

$$\langle e(\beta), D_\gamma^* D_\gamma e(\alpha)\rangle = \langle D_\gamma e(\beta), D_\gamma e(\alpha)\rangle = e^{\beta^*\alpha} e^{i\,\mathrm{Im}(\beta^*\gamma) - i\,\mathrm{Im}(\alpha^*\gamma)}$$

which contradicts unitarity $D_\gamma^* D_\gamma = I$, i.e., $\langle e(\beta), D_\gamma^* D_\gamma e(\alpha)\rangle = \langle e(\beta), e(\alpha)\rangle = e^{\beta^*\alpha}$. To fix this, define the *Weyl operator*

$$W_\gamma e(\alpha) = e(\alpha+\gamma)\, e^{|\alpha|^2/2 - |\alpha+\gamma|^2/2} e^{i\,\mathrm{Im}(\alpha^*\gamma)} = e(\alpha+\gamma)\, e^{-\gamma^*\alpha - |\gamma|^2/2}.$$

The Weyl operator is unitary and provides a projective unitary representation [38] in the sense that $W_\alpha W_\beta = W_{\alpha+\beta} e^{i\,\mathrm{Im}(\beta^*\alpha)}$. Note that it is sufficient to define the action of W_α only on exponential vectors; we can then extend to D by linearity, and as D is dense and W_α is bounded the Weyl operators are uniquely extended to all of H.

Now fix $\beta \in \mathbf{C}$ and consider the unitary group $\{W_{t\beta}\}_{t\in\mathbf{R}}$. This group is continuous ($W_{t\beta} e(\gamma) \to e(\gamma)$ as $t \to 0$) and hence by Stone's theorem, there exists a self-adjoint operator B_β such that $W_{t\beta} = e^{itB_\beta}$. Finding the distribution of the observable B_β is straightforward, as the characteristic function of B_β is given by

$$b_\beta(k) = \mathbb{P}_\alpha(W_{k\beta}) = \langle e(\alpha), e(\alpha+k\beta)\rangle\, e^{-k\beta^*\alpha - k^2|\beta|^2/2 - |\alpha|^2} = e^{2ik\,\mathrm{Im}(\alpha^*\beta) - k^2|\beta|^2/2}.$$

Hence B_β is a Gaussian random variable with mean $2\,\mathrm{Im}(\alpha^*\beta)$ and variance $|\beta|^2$.

Our next task is to obtain an explicit representation of B_β. We proceed as follows:

$$B_\beta e(\alpha) = \frac{1}{i}\frac{d}{dt} W_{t\beta} e(\alpha)\bigg|_{t=0} = i\beta^*\alpha\, e(\alpha) - i\,\frac{d}{dt} e(\alpha + t\beta)\bigg|_{t=0}.$$

One can verify explicitly that this expression makes sense, i.e., $B_\beta e(\alpha) \in \mathsf{H}$. Note that we cannot extend B_β to all of H, as B_β is unbounded. However, we see that the domain of B_β contains at least the exponential domain D.

Let us introduce the following notation. Define $q = B_i$, $p = B_{-1}$, and $a = (q+ip)/2$. Note that q and p are self-adjoint by Stone's theorem, whereas a has the adjoint $a^* = (q-ip)/2$. Moreover, we find that $a\, e(\alpha) = \alpha\, e(\alpha)$. But then

$$(a\, e(\alpha))(k) = \alpha\,\frac{\alpha^k}{\sqrt{k!}} = \sqrt{k+1}\,\frac{\alpha^{k+1}}{\sqrt{(k+1)!}} = \sqrt{k+1}\, e(\alpha)(k+1).$$

This implies that we can extend the domain of a to include also the $\{\psi_n\}$ by defining $a\,\psi_{k+1} = \sqrt{k+1}\,\psi_k$ (where $a\,\psi_0 = 0$). Furthermore, from

$$\langle \psi_m, a^*\psi_k\rangle = \langle a\psi_m, \psi_k\rangle = \sqrt{m}\,\delta_{(m-1)k} = \sqrt{k+1}\,\delta_{m(k+1)}$$

we can read off $a^*\psi_k = \sqrt{k+1}\,\psi_{k+1}$. a^* is known as the creation (or raising) operator and a as the annihilation (or lowering) operator.

Finally, note that $\lambda = a^*a$. From a classical probability point of view this is very remarkable indeed. Not only do both Poisson and Gaussian random variables emerge from the same state $\mathbb{P}_\alpha$, but there is even a *continuous* map $q, p \mapsto (q-ip)(q+ip)/4 = \lambda$ that transforms two Gaussian random variables into a Poisson random variable. One could never continuously transform a continuous classical random variable into a discrete classical random variable; however, we get away with it here because p, q, and λ do not commute with one another. Thus in each realization we can choose to measure either a discrete or a continuous random variable, but not both. □

Remark 3.12. Though presented rather differently, the last two examples are in fact $*$-isomorphic in the case that $\sigma^2 = \frac{1}{2}$ in the first example. For example, if $\alpha \in \mathbf{R}$, we can map $p \mapsto 2^{1/2}\hbar^{-1}P$, $q \mapsto 2^{1/2}Q$, and $\mathbb{P}_\alpha \mapsto \mathbb{P}_{\mu=2^{1/2}\alpha,\sigma=2^{-1/2}}$. From the expression for $b_\beta(k)$ we see that in a coherent state both p and q must have the same variance. In the first example we allowed for the variance of Q to shrink, though this necessarily increases the variance of P. This results in a "squeezed state" which can also be introduced in the context of the second example. We will not construct such states here; in the following, we will only use coherent states. □

3.3. Conditional expectation. We now consider conditional expectations, following the treatment of [18]. The following definition is identical to the one in section 2.

Definition 3.13 (conditional expectation). *Let $(\mathscr{N}, \mathbb{P})$ be a quantum probability space and let $\mathscr{A} \subset \mathscr{N}$ be a commutative von Neumann subalgebra. Then the map $\mathbb{P}(\cdot|\mathscr{A}) : \mathscr{A}' \to \mathscr{A}$ is called (a version of) the conditional expectation from $\mathscr{A}'$ onto $\mathscr{A}$ if $\mathbb{P}(\mathbb{P}(B|\mathscr{A})A) = \mathbb{P}(BA)$ for all $A \in \mathscr{A}$, $B \in \mathscr{A}'$.*

We briefly recall the significance of $\mathscr{A}'$. $\mathscr{A}$ is the algebra generated by our observations: it must be commutative, as we cannot observe incompatible events in a single experiment. We now wish to find the conditional statistics of an observable B that is not affiliated to $\mathscr{A}$. However, as we have already observed $\mathscr{A}$, this is only sensible if B commutes with every element in $\mathscr{A}$—there would be no physical way to test our predictions if we could not subsequently measure B in the same realization.

Remark 3.14. Recall that if $B = B^*$, we can use the spectral theorem to obtain explicitly $\mathbb{P}(B|\mathscr{A}) = \iota^{-1}(E_{\mathbf{P}}(\iota(B)|\sigma\{\iota(\mathscr{A})\}))$. This representation extends even to the case that B is an unbounded self-adjoint operator that is affiliated to $\mathscr{A}'$. For simplicity we will discuss below the properties of $\mathbb{P}(B|\mathscr{A})$ assuming that B is bounded, but with suitable care the treatment extends also to the unbounded case. □

Remark 3.15. A more general definition (see, e.g., [59]), of which Definition 3.13 is a special case, is often used in quantum probability. Unlike our definition, which is motivated by statistical inference and filtering, the more general "conditional expectation" allows for conditioning on noncommutative algebras and does not have a direct statistical interpretation. The more general definition is used, e.g., in the theory of noncommutative Markov processes [47]. We will not dwell on this further. □

Theorem 3.16. *The conditional expectation of Definition* 3.13 *exists and is unique with probability one* (*any two versions P and Q of $\mathbb{P}(B|\mathscr{A})$ satisfy $\|P-Q\|_{\mathbb{P}} = 0$, where $\|X\|_{\mathbb{P}}^2 = \mathbb{P}(X^*X)$*). *Moreover, $\mathbb{P}(B|\mathscr{A})$ is the least mean square estimate of B given $\mathscr{A}$ in the sense that $\|B - \mathbb{P}(B|\mathscr{A})\|_{\mathbb{P}} \le \|B - A\|_{\mathbb{P}}$ for all $A \in \mathscr{A}$.*

Proof. (i) *Existence.* We have already established that for self-adjoint $B \in \mathscr{A}'$, we can explicitly define a $\mathbb{P}(B|\mathscr{A})$ that satisfies the conditions of Definition 3.13 using the spectral theorem. The classical conditional expectation exists, and moreover the conditional expectation of a bounded random variable is bounded. Hence $\mathbb{P}(B|\mathscr{A})$ exists in $\mathscr{A}$ for self-adjoint $B \in \mathscr{A}'$. But any $B \in \mathscr{A}'$ can be written as $B = B_1 + iB_2$ with self-adjoint $B_1 = (B + B^*)/2$ and $B_2 = i(B^* - B)/2$. As $\mathbb{P}(B_1|\mathscr{A})$ and $\mathbb{P}(B_2|\mathscr{A})$ exist and $\mathbb{P}(B|\mathscr{A}) = \mathbb{P}(B_1|\mathscr{A}) + i\mathbb{P}(B_2|\mathscr{A})$ satisfies the conditions of Definition 3.13, existence is proved.

(ii) *Uniqueness with probability one.* Define the pre-inner product $\langle X, Y\rangle = \mathbb{P}(X^*Y)$ on $\mathscr{A}'$ (it might have nontrivial kernel). Then $\langle A, B - \mathbb{P}(B|\mathscr{A})\rangle = \mathbb{P}(A^*B) - \mathbb{P}(A^*\mathbb{P}(B|\mathscr{A})) = 0$ for all $A \in \mathscr{A}$ and $B \in \mathscr{A}'$, i.e., $B - \mathbb{P}(B|\mathscr{A})$ is orthogonal to $\mathscr{A}$. Now let P and Q be two versions of $\mathbb{P}(B|\mathscr{A})$. It follows that $\langle A, P - Q\rangle = 0$ for all $A \in \mathscr{A}$. But $P - Q \in \mathscr{A}$, so $\langle P - Q, P - Q\rangle = \|P - Q\|_{\mathbb{P}}^2 = 0$.

(iii) *Least squares.* Let P be a version of $\mathbb{P}(B|\mathscr{A})$. Then for all $K \in \mathscr{A}$

$$\|B-K\|_{\mathbb{P}}^2 = \|B-P+P-K\|_{\mathbb{P}}^2 = \|B-P\|_{\mathbb{P}}^2 + \|P-K\|_{\mathbb{P}}^2 \geq \|B-P\|_{\mathbb{P}}^2,$$

where, in the second step, we used that $(B-\mathbb{P}(B|\mathscr{A})) \perp (\mathbb{P}(B|\mathscr{A})-K) \in \mathscr{A}$. □

Remark 3.17. The usual elementary properties of classical conditional expectations and their proofs [63] carry over directly. In particular, we have linearity, positivity, invariance of the state $\mathbb{P}(\mathbb{P}(B|\mathscr{A})) = \mathbb{P}(B)$, invariance of $\mathscr{A}$ ($\mathbb{P}(B|\mathscr{A}) = B$ if $B \in \mathscr{A}$), the tower property $\mathbb{P}(\mathbb{P}(B|\mathscr{A})|\mathscr{C}) = \mathbb{P}(B|\mathscr{C})$ if $\mathscr{C} \subset \mathscr{A}$, the module property $\mathbb{P}(AB|\mathscr{C}) = B\,\mathbb{P}(A|\mathscr{C})$ for $B \in \mathscr{C}$, etc. As an example, let us prove linearity. It suffices to show that $Z = \alpha\,\mathbb{P}(A|\mathscr{C}) + \beta\,\mathbb{P}(B|\mathscr{C})$ satisfies $\mathbb{P}(ZC) = \mathbb{P}((\alpha A+\beta B)C)$ for all $C \in \mathscr{C}$. But this is immediate from the linearity of $\mathbb{P}$ and Definition 3.13. □

3.4. The Bayes formula. In section 2 we were able to calculate conditional expectations explicitly as all algebras were finite-dimensional. In most physical situations, however, at least the probe (and often the system as well) admits continuous observables and therefore we must deal with infinite-dimensional algebras. In this case it is usually not so simple to calculate the conditional expectations directly; however, the following Bayes-type formula will be of considerable assistance.

LEMMA 3.18 (Bayes formula [18]). *Let $\mathscr{C}$ be a commutative von Neumann subalgebra and let $\mathscr{C}'$ be equipped with a normal state $\mathbb{P}$. Choose $V \in \mathscr{C}'$ such that $V^*V > 0$ and $\mathbb{P}(V^*V) = 1$. Then we can define a new state on $\mathscr{C}'$ by $\mathbb{Q}(A) = \mathbb{P}(V^*AV)$ and*

$$\mathbb{Q}(X|\mathscr{C}) = \frac{\mathbb{P}(V^*XV|\mathscr{C})}{\mathbb{P}(V^*V|\mathscr{C})}, \qquad X \in \mathscr{C}'.$$

Proof. Let K be an element of $\mathscr{C}$. For all $X \in \mathscr{C}'$, we can write

$$\begin{aligned}\mathbb{P}(\mathbb{P}(V^*XV|\mathscr{C})K) &= \mathbb{P}(V^*XKV) = \mathbb{Q}(XK) = \mathbb{Q}(\mathbb{Q}(X|\mathscr{C})K)\\ &= \mathbb{P}(V^*V\mathbb{Q}(X|\mathscr{C})K) = \mathbb{P}(\mathbb{P}(V^*V\mathbb{Q}(X|\mathscr{C})K|\mathscr{C})) = \mathbb{P}(\mathbb{P}(V^*V|\mathscr{C})\mathbb{Q}(X|\mathscr{C})K).\end{aligned}$$

As this holds for all $K \in \mathscr{C}$, and as by construction the conditional expectations are elements of $\mathscr{C}$, we conclude that $\|\mathbb{P}(V^*XV|\mathscr{C}) - \mathbb{P}(V^*V|\mathscr{C})\mathbb{Q}(X|\mathscr{C})\|_{\mathbb{P}} = 0$, or equivalently, $\mathbb{P}(V^*XV|\mathscr{C}) = \mathbb{P}(V^*V|\mathscr{C})\mathbb{Q}(X|\mathscr{C})$ $\mathbb{P}$-a.s. □

We now have sufficient tools to deal with the Stern–Gerlach experiment described in section 2. Though the following example is not of much practical importance, it demonstrates the use of the Bayes theorem in a concrete setting. We will use a very similar "reference probability method" to obtain filtering equations later on.

Example 3.19. *Stern–Gerlach experiment.* Consider an atom with two degrees of freedom: a spin degree of freedom $\mathscr{N}_\mu = \mathscr{B}(\mathbf{C}^2)$ carrying the observables σ_x, σ_z etc., and a single spatial degree of freedom $\mathscr{N}_x = \mathscr{B}(\ell^2(\mathbf{N}))$ with the affiliated position q and momentum p observables defined[6] in Example 3.11 (we use the notations of that example). The total algebra describing the atom is then $\mathscr{N} = \mathscr{N}_\mu \otimes \mathscr{N}_x$. Initially the spin and position/momentum of the atom are uncorrelated; hence we work with the state $\mathbb{P} = \mathbb{P}_\mu \otimes \mathbb{P}_0$, where $\mathbb{P}_\mu$ is an arbitrary spin state and $\mathbb{P}_0(X) = \langle\psi_0, X\psi_0\rangle = \langle e(0), Xe(0)\rangle$. The latter implies that initially $I\otimes q$ and $I\otimes p$ (which we will interpret as position and momentum in the z direction) have zero mean and unit variance.

[6] We saw in Remark 3.12 that this description is $*$-isomorphic to the usual definition of position and momentum up to some numerical constants. These are not of essence, however, as they just correspond to a change of units in which we measure position and momentum. A little more care must be taken if we wish to make quantitative predictions on the outcomes of actual experiments; we will not worry about this, however, and work in arbitrary units.

To measure the spin, we apply a magnetic field gradient that is linear in q for some fixed period of time. The resulting force on the particle will cause its momentum to change; an observation of the momentum of the particle after the interaction should thus provide a measurement of its spin σ_z. In other words, the atomic spatial degree of freedom acts as a probe for the atomic spin degree of freedom. The action of the magnetic field is described by the unitary[7]

$$U = \exp(i\kappa\,\sigma_z \otimes q) = P_{z,1} \otimes e^{i\kappa q} + P_{z,-1} \otimes e^{-i\kappa q} = P_{z,1} \otimes W_{i\kappa} + P_{z,-1} \otimes W_{-i\kappa},$$

where $\kappa \in \mathbf{R}$ is the field gradient. Let us thus begin by calculating the characteristic function of $U^*(I \otimes p)U$, the momentum of the atom after the interaction:

$$\begin{aligned}\mathbb{P}(e^{ik\,U^*(I\otimes p)U}) &= \mathbb{P}(U^*(I \otimes W_{-k})U) = \mathbb{P}_\mu(P_{z,1})\,\mathbb{P}_0(W_{-i\kappa}W_{-k}W_{i\kappa}) \\ &\quad + \mathbb{P}_\mu(P_{z,-1})\,\mathbb{P}_0(W_{i\kappa}W_{-k}W_{-i\kappa}) = \mathbb{P}_\mu(P_{z,1})\,e^{2i\kappa k - k^2/2} + \mathbb{P}_\mu(P_{z,-1})\,e^{-2i\kappa k - k^2/2}.\end{aligned}$$

Hence the momentum of the atom after the interaction is distributed as a sum of two Gaussians of unit variance and means 2κ and -2κ, which are weighted, respectively, by $\mathbb{P}_\mu(P_{z,1})$ and $\mathbb{P}_\mu(P_{z,-1})$. Note that we cannot perfectly resolve the spin-up and down states using a Stern–Gerlach measurement; as the tails of the two Gaussians overlap, there is always a nonzero probability that we assign the wrong spin to the atom by looking, e.g., at the sign of the observed momentum. However, the error probability becomes very small when the gradient κ is large.

After the interaction, we may want to measure a spin observable $\sigma \in \mathscr{N}_\mu$ that does not necessarily commute with σ_z (e.g., σ_x). To describe this, let us calculate $\mathbb{P}(U^*(\sigma \otimes I)U|\mathrm{vN}(U^*(I \otimes p)U))$, the conditional expectation of the spin observable σ after the interaction given our observation of the momentum of the atom.

We begin by using the following elementary property: if U is a unitary operator and we define the state $\mathbb{Q}(X) = \mathbb{P}(U^*XU)$, then $\mathbb{P}(U^*XU|U^*\mathscr{C}U) = U^*\mathbb{Q}(X|\mathscr{C})U$ (this can be verified directly using Definition 3.13). Thus we obtain

$$\mathbb{P}(U^*(\sigma \otimes I)U|\mathrm{vN}(U^*(I \otimes p)U)) = U^*\mathbb{Q}(\sigma \otimes I|\mathrm{vN}(I \otimes p))U.$$

We would like to apply the Bayes rule to $\mathbb{Q}(\sigma \otimes I|\mathrm{vN}(I \otimes p))$. As U does not commute with $I \otimes p$, however, the Bayes rule does not apply in this form.

Fortunately, we can circumvent this problem using the following trick. Using the Baker–Campbell–Hausdorff formula, we can rewrite $e^{i\kappa q}$ as

$$e^{i\kappa q} = e^{i\kappa(a+a^*)} = e^{-\kappa^2/2}e^{i\kappa a^*}e^{i\kappa a}.$$

Beware that the Baker–Campbell–Hausdorff formula technically only holds for exponentials of bounded operators; thus here and below there will be domain issues, but these can be resolved with suitable care. As $a\,\psi_0 = 0$, we can write

$$e^{i\kappa q}\psi_0 = e^{-\kappa^2/2}e^{i\kappa a^*}e^{i\kappa a}\psi_0 = e^{-\kappa^2/2}e^{i\kappa a^*}\psi_0 = e^{-\kappa^2/2}e^{i\kappa a^*}e^{-i\kappa a}\psi_0 = e^{-\kappa^2}e^{\kappa p}\psi_0.$$

We obtain

$$\mathbb{P}_0(e^{-i\kappa q}Xe^{i\kappa q}) = \langle e^{i\kappa q}\psi_0, Xe^{i\kappa q}\psi_0\rangle = e^{-2\kappa^2}\langle e^{\kappa p}\psi_0, Xe^{\kappa p}\psi_0\rangle = e^{-2\kappa^2}\mathbb{P}_0(e^{\kappa p}Xe^{\kappa p}).$$

[7]This is the solution of (2.6) at some fixed time t for a suitable interaction Hamiltonian H.

It follows that we can equivalently replace U by V:

$$\mathbb{Q}(X) = \mathbb{P}(U^*XU) = \mathbb{P}(V^*XV), \quad V = e^{-\kappa^2} e^{\kappa\,\sigma_z \otimes p} = e^{-\kappa^2}(P_{z,1} \otimes e^{\kappa p} + P_{z,-1} \otimes e^{-\kappa p}).$$

V is not unitary, but it does commute with $I \otimes p$. Hence the Bayes rule gives

$$\mathbb{P}(U^*(\sigma \otimes I)U | \mathrm{vN}(U^*(I \otimes p)U)) = \frac{U^*\mathbb{P}(V^*(\sigma \otimes I)V | \mathrm{vN}(I \otimes p))U}{U^*\mathbb{P}(V^*V | \mathrm{vN}(I \otimes p))U}.$$

We can now use the module property and independence of $\sigma \otimes I$ and $I \otimes p$ under $\mathbb{P}$ to calculate explicitly the numerator and denominator; elementary manipulations give

$$\begin{aligned}
&\mathbb{P}[U^*(\sigma \otimes I)U | \mathrm{vN}(U^*(I \otimes p)U)] \\
&= \frac{\mathbb{P}_\mu(P_{z,1}\sigma P_{z,1}) e^{2\kappa\, U^*(I\otimes p)U} + \mathbb{P}_\mu(P_{z,-1}\sigma P_{z,-1}) e^{-2\kappa\, U^*(I\otimes p)U} + 2\,\mathrm{Re}\,\mathbb{P}_\mu(P_{z,-1}\sigma P_{z,1})}{\mathbb{P}_\mu(P_{z,1}) e^{2\kappa\, U^*(I\otimes p)U} + \mathbb{P}_\mu(P_{z,-1}) e^{-2\kappa\, U^*(I\otimes p)U}}.
\end{aligned}$$

By definition, $\mathbb{P}(U^*(\sigma \otimes I)U | \mathrm{vN}(U^*(I \otimes p)U))$ is affiliated to $\mathrm{vN}(U^*(I \otimes p)U)$, and indeed the expression above is simply a function of $U^*(I \otimes p)U$. If we observe $U^*(I \otimes p)U$ and obtain the value $\tilde{p}$, then the spectral theorem tells us that the conditional expectation takes the value given by the expression above if we simply substitute $\tilde{p}$ for $U^*(I \otimes p)U$. Note that the formula is not equivalent to the one given by the projection postulate for a measurement of σ_z. For large κ, however, we obtain approximately the projection postulate expression, and this becomes exact as $\kappa \to \infty$. □

4. Stochastic processes and quantum Itô calculus. After a general introduction to quantum probability, we now turn to one particular quantum probability space which we will use throughout the remainder of the article. In section 5 we shall argue that this model appropriately describes the quantum electromagnetic field and its interaction with matter. In the laboratory, the electromagnetic field can be measured by devices like photodetectors which can produce an electric current or even a discrete photocount. The statistics of data records from such experiments are well approximated by the model considered here. The model is rich and we will discover that it contains many interesting classical stochastic processes, i.e., a whole family of Poisson and Wiener processes. However, these processes do not commute with each other. An extension of the Itô calculus, due to Hudson and Parthasarathy [42], unites all these processes in one noncommutative stochastic calculus.

4.1. Poisson processes on Fock space. The theory we are about to discuss can be approached from many sides; here we have chosen to get started by finding a quantum probability space that naturally admits a Poisson process, and build the theory from there. As we have a particular classical process in mind, the general theory gives a hint as to how we could proceed. First, we define the process on a classical space $(\Omega, \mathcal{F}, \mathbf{P})$; equivalently, we can form the algebra $\mathscr{A} = L^\infty(\Omega, \mathcal{F}, \mathbf{P})$ acting on $\mathsf{H} = L^2(\Omega, \mathcal{F}, \mathbf{P})$ by pointwise multiplication, with a suitable state $\mathbb{P}$, and represent the process as a family of observables affiliated to $\mathscr{A}$. To create a noncommutative model, we could now broaden our horizon and consider $\mathscr{N} = (\mathscr{B}(\mathsf{H}), \mathbb{P})$ rather than just $\mathscr{A}$. Obviously such a construction does not necessarily carry a physical interpretation; this must be considered separately; see section 5. For the time being, however, we will use this convenient construction to provide us with a rich quantum stochastic model. The following discussion is heavily inspired by the work of Maassen [50].

Consider a classical Poisson process on a finite time interval $[0, T]$. We wish to describe the space of paths Ω. This is not difficult; a Poisson process on a finite time

interval has (a.s.) finitely many jumps n. Hence we can specify every relevant path by specifying its jump times. Let us thus introduce

$$\Omega = \bigcup_{n=0}^{\infty} \Omega_n, \qquad \Omega_0 = \{\varnothing\}, \quad \Omega_n = \{\{t_1, \ldots, t_n\} : t_1 < t_2 < \cdots < t_n \in [0,T]\}. \tag{4.1}$$

In other words, Ω is the set of ordered sequences in $[0,T]$ with a finite number of elements. We still need to introduce a σ-algebra $\mathcal{F}$ and a measure $\mathbf{P}$. To this end, consider Ω_n as a subset of the cube $([0,T]^n, e^{-T}\mu_n)$ where μ_n is the Lebesgue measure, so that Ω_n inherits a σ-algebra $\mathcal{F}_n$ and a measure $\mathbf{P}_n$ from the cube. Under $\mathbf{P}_n$ the jump times $t_1, \ldots, t_n$ are uniformly distributed (as must be the case for a Poisson process with fixed rate) and $\mathbf{P}_n(\Omega_n) = T^n e^{-T}/n!$. The measure $\mathbf{P}$ induced on Ω is precisely the probability measure of a Poisson process with unit rate.

We now introduce the Hilbert space $\mathsf{F} = L^2(\Omega, \mathcal{F}, \mathbf{P})$. It is called the *symmetric* or *Boson Fock space* and plays a central role in the following. We will also need the spaces $\mathsf{F}_{t]}$, $\mathsf{F}_{[t}$, and $\mathsf{F}_{[s,t]}$, defined identically to F except that the interval $[0,T]$ is replaced by $[0,t]$, $[t,T]$, and $[s,t]$, respectively. It is not difficult to see that for any $0 < s < t < T$ we have[8] $\Omega = \Omega_{s]} \times \Omega_{[s,t]} \times \Omega_{[t}$, and as the Poisson process has independent increments the measure splits up similarly. It follows that

$$\mathsf{F} = \mathsf{F}_{s]} \otimes \mathsf{F}_{[s,t]} \otimes \mathsf{F}_{[t} \qquad \forall\, 0 < s < t < T. \tag{4.2}$$

This important property is known as a continuous tensor product structure; it will play a key role in the definition of quantum stochastic integrals, as it gives a natural notion of adaptedness. Indeed, the algebra $\mathscr{W} = \mathscr{B}(\mathsf{F})$ splits up accordingly,

$$\mathscr{W} = \mathscr{W}_{s]} \otimes \mathscr{W}_{[s,t]} \otimes \mathscr{W}_{[t} = \mathscr{B}(\mathsf{F}_{s]}) \otimes \mathscr{B}(\mathsf{F}_{[s,t]}) \otimes \mathscr{B}(\mathsf{F}_{[t}). \tag{4.3}$$

A process of operators $\{X_t\}$ affiliated to $\mathscr{W}$ is said to be *adapted* if X_t is affiliated to $\mathscr{W}_{t]}$ for every t; equivalently, X_t is of the form $X_{t]} \otimes I$ as an operator on $\mathsf{F}_{t]} \otimes \mathsf{F}_{[t}$.

Next, let us introduce a set of interesting vectors. The reader should keep in mind Example 3.11 which is conceptually quite similar. Let $f \in L^\infty([0,T])$ be a complex Lebesgue measurable function. Then we can define the *exponential vector*

$$e(f)(\varnothing) = 1, \quad e(f)(\tau) = \prod_{t \in \tau} f(t), \qquad f \in L^\infty([0,T]),\ \tau \in \Omega. \tag{4.4}$$

It is not difficult to verify that $e(f) \in \mathsf{F}$, as

$$\langle e(g), e(f)\rangle = \sum_{n=0}^{\infty} \frac{e^{-T}}{n!} \left(\int_0^T g^*(t) f(t)\, dt \right)^n = \exp\left[\int_0^T (g^*(t) f(t) - 1)\, dt \right],$$

hence $\langle e(f), e(f)\rangle = e^{\|f\|_2^2 - T} < \infty$ for any $f \in L^\infty([0,T])$. We define D, the exponential domain, as the linear span of all $e(f)$, $f \in L^\infty([0,T])$, and we note that D is dense in F. The exponential vectors have the important property that they factorize over the continuous tensor product structure (4.2): indeed, it is evident from (4.4) that $e(f) = e(f_{s]}) \otimes e(f_{[s,t]}) \otimes e(f_{[t})$ where $f_{t]}$ is the restriction of f to $[0,t]$, etc.

[8] A more precise statement would be something like $\Omega = \Omega_{s]} \times \Omega_{(s,t]} \times \Omega_{(t}$; however, the only paths for which this makes a difference are those that have jumps exactly at times s or t, which is a set of $\mathbf{P}$-measure zero. For notational simplicity, we are free to always use closed time intervals $[s,t]$.

We are now ready to define a Poisson process. Let us first define it as a random variable on Ω; we simply write $N_t(\tau) = |\tau \cap [0,t]|$, where $|\tau|$ denotes the number of elements in the set $\tau \in \Omega$. The random variable N_t counts the number of jumps up to time t, and hence $\{N_t\}$ is by construction a Poisson process with unit rate under the measure $\mathbf{P}$. We now turn this into an operator process by pointwise multiplication:

$$(\Lambda_t\psi)(\tau) = N_t(\tau)\,\psi(\tau) = |\tau \cap [0,t]|\,\psi(\tau), \qquad \psi \in \mathsf{F},\ \tau \in \Omega,\ t \in [0,T]. \tag{4.5}$$

$\{\Lambda_t\}$ is called the *gauge process*; it is not difficult to see that though Λ_t is an unbounded operator,[9] it is affiliated to $\mathscr{W}_{t]}$ and hence the gauge process is adapted; in fact, the increments $\Lambda_t - \Lambda_s$ are even affiliated to $\mathscr{W}_{[s,t]}$. Furthermore, Λ_s and Λ_t commute for all $s,t \in [0,T]$, and indeed $\mathrm{vN}(\Lambda_t,\ t \in [0,T]) = L^\infty(\Omega,\mathcal{F},\mathbf{P}) \subset \mathscr{W}$ is commutative. Hence we could use the spectral theorem to map Λ_t back to a classical stochastic process. It is somewhat futile to diagonalize the operators using the spectral theorem, however, as we have already constructed them in diagonal form.

We have yet to introduce a state; a particularly interesting class of states are the *coherent states* $\mathbb{P}_f(X) = \langle e(f), X\,e(f)\rangle\, e^{T-\|f\|_2^2}$. Because of the continuous tensor product property, the coherent states split up as follows:

$$X = X_{s]} \otimes X_{[s,t]} \otimes X_{[t}, \qquad \mathbb{P}_f(X) = \mathbb{P}_{f_{s]}}(X_{s]})\ \mathbb{P}_{f_{[s,t]}}(X_{[s,t]})\ \mathbb{P}_{f_{[t}}(X_{[t}). \tag{4.6}$$

But as $\Lambda_t - \Lambda_s$ is affiliated to $\mathscr{W}_{[s,t]}$, it follows that under the state $\mathbb{P}_f$ the gauge process has independent increments. Furthermore, if we denote by $P_{\Lambda_t-\Lambda_s}(B)$ the spectral measure of $\Lambda_t - \Lambda_s$, then we have

$$\mathbb{P}_f(P_{\Lambda_t-\Lambda_s}(B)) = \mathbb{P}_{f_{[s,t]}}(\chi_B(|\tau \cap [s,t]|)) = \sum_{n\in B} \frac{e^{-\int_s^t |f(r)|^2\,dr}}{n!} \left(\int_s^t |f(r)|^2\,dr\right)^n.$$

Evidently, Λ_t is an inhomogeneous Poisson process with rate $|f(t)|^2$ under the state $\mathbb{P}_f$. Note in particular that as $e(1)(\tau) = 1$, we have for any $X \in L^\infty(\Omega,\mathcal{F},\mathbf{P})$ the relation $\mathbb{P}_1(X) = \langle 1, X\,1\rangle = E_{\mathbf{P}}(X)$; hence the fact that under $\mathbb{P}_1$ the gauge process is a Poisson process with unit rate is exactly what we expect from the definition of $\mathbf{P}$. Under $\mathbb{P}_0$, on the other hand, the gauge process does not register any counts; $\mathbb{P}_0 = \phi$ is called the *vacuum state*, and $e(0) = \Phi$ is called the *vacuum vector*.

4.2. Weyl operators and Wiener processes. We have now exhausted the diagonal observables affiliated to the space $(L^\infty(\Omega,\mathcal{F},\mathbf{P}),\mathbb{P}_f)$: every such observable is some functional of the Poisson process Λ_t with rate $|f|^2$. Let us thus explore whether we can find interesting observables affiliated to $\mathscr{W}$ that do not commute with Λ_t. To this end, we follow again essentially Example 3.11. Given $f,g \in L^\infty([0,T])$ we look for a unitary operator $W(f)$ that implements the translation group $W(f)e(g) \propto e(f+g)$. A calculation identical to the one in Example 3.11 shows that we should define

$$W(f)e(g) = e^{-\int_0^T \left(f^*(t)g(t) + \frac{1}{2}f^*(t)f(t)\right)dt} e(f+g) = e^{-\langle f,g\rangle_2 - \|f\|_2^2/2}\,e(f+g). \tag{4.7}$$

The unitary operator $W(f)$ is called a *Weyl operator* and provides a projective unitary representation in the sense that $W(f)W(g) = W(f+g)\,e^{i\,\mathrm{Im}\langle g,f\rangle_2}$. Note that it is

[9] As can be verified by explicit computation, the domain of Λ_t contains at least D, the exponential domain. The reader may ask himself why we have only defined exponential vectors $e(f)$ for $f \in L^\infty([0,T])$ rather than $f \in L^2([0,T])$: this is because the latter may not be in the domain of Λ_t. Our domain D is sometimes called the *restricted* exponential domain in the literature.

sufficient to define the action of $W(f)$ only on exponential vectors; we can extend to D by linearity, and as D is dense and $W(f)$ is bounded the Weyl operators are uniquely extended to all of F. An important property, which follows immediately from the definition of $W(f)$ and the continuous tensor product property, is that

$$W(f)e(g) = W(f_{s]})e(g_{s]}) \otimes W(f_{[s,t]})e(g_{[s,t]}) \otimes W(f_{[t})e(g_{[t}). \tag{4.8}$$

In particular, we see that $W(f\chi_{[0,t]})$ is an adapted operator process.

Now fix $f \in L^\infty([0,T])$ and consider the unitary group $\{W(kf)\}_{k\in\mathbf{R}}$; this group is in fact continuous [55], and hence by Stone's theorem (Theorem 3.10) there exists a self-adjoint $B(f)$ such that $W(kf) = e^{ikB(f)}$. The operators $B(f)$, $f \in L^\infty([0,T])$, are called *field operators*. Finding the distribution of the observable $B(f)$ is straightforward, as the characteristic function of $B(f)$ (under the coherent state $\mathbb{P}_g$) is given by

$$b_f(k) = \mathbb{P}_g(W(kf)) = \langle e(g), e(g+kf)\rangle e^{T-\|g\|_2^2 - k\langle f,g\rangle_2 - k^2\|f\|_2^2/2} = e^{2ik\,\mathrm{Im}\langle g,f\rangle_2 - k^2\|f\|_2^2/2}.$$

Hence $B(f)$ is a Gaussian random variable with mean $2\,\mathrm{Im}\langle g,f\rangle_2$ and variance $\|f\|_2^2$. In the vacuum, i.e., $g=0$, the mean vanishes; for simplicity, we will restrict ourselves to the vacuum case in the following.

Consider the operator process $\{B_t^\varphi = B(e^{i\varphi}\chi_{[0,t]}) : t \in [0,T]\}$ for some fixed, real function $\varphi \in L^\infty([0,T])$. B_t^φ is adapted, as we have already established that $W(f\chi_{[0,t]})$ is adapted for any f; moreover, $B(e^{i\varphi}\chi_{[s,t]}) = B_t^\varphi - B_s^\varphi$ is affiliated to $\mathscr{W}_{[s,t]}$ due to (4.8). This immediately tells us two important things. First, B_t^φ and B_s^φ commute for all $s,t \in [0,T]$; indeed, $B_t^\varphi - B_s^\varphi$ must commute with $B_s^\varphi - B_0^\varphi$, and commutativity follows from $B_0^\varphi = 0$. This means that $\mathrm{vN}(B_t^\varphi,\ t \in [0,T])$ is a commutative algebra and hence we can represent B_t^φ for every t as a classical random variable on the same probability space $(\Omega^\varphi, \mathcal{F}^\varphi, \mathbf{P}^\varphi)$; in particular, $\iota(B_t^\varphi)$ is a classical stochastic process. Second, (4.6) implies that the process B_t^φ has independent increments. But we have established $B_t^\varphi - B_s^\varphi$ is (in the vacuum) a mean zero Gaussian random variable with variance $t-s$, and as B_t^φ has independent increments we have established that $\iota(B_t^\varphi)$ is precisely a Wiener process on $(\Omega^\varphi, \mathcal{F}^\varphi, \mathbf{P}^\varphi)$.

Let us introduce the following notation. Define $Q_t = B(i\chi_{[0,t]})$, $P_t = B(-\chi_{[0,t]})$, and $A_t = (Q_t + iP_t)/2$. Note that Q_t and P_t are self-adjoint by Stone's theorem, whereas A_t has the adjoint $A_t^* = (Q_t - iP_t)/2$. We now compute

$$B(f)e(g) = \frac{1}{i}\frac{d}{dk}W(kf)e(g)\bigg|_{k=0} = i\langle f,g\rangle_2\, e(g) - i\,\frac{d}{dk}e(g+kf)\bigg|_{k=0}.$$

Evidently $A_t e(g) = \langle \chi_{[0,t]}, g\rangle_2\, e(g) = \int_0^t g(s)ds\, e(g)$. But then we can write

$$(A_t e(g))(\tau) = \int_0^t g(s)\,ds \prod_{r\in\tau} g(r) = \int_0^t g(s) \prod_{r\in\tau} g(r)\,ds = \int_0^t e(g)(\tau\cup\{s\})\,ds.$$

In particular, this formula extends to any $\psi \in \mathsf{F}$ for which the integral on the right-hand side (with $e(g)$ replaced by ψ) defines a normalizable vector. A_t is called the Fock space *annihilation operator*, as it generalizes the corresponding notion introduced in Example 3.11. The reader should verify that its adjoint can be expressed as

$$(A_t^*\psi)(\tau) = \sum_{s\in\tau\cap[0,t]} \psi(\tau\backslash\{s\})$$

on a sufficiently large domain. Not surprisingly, A_t^* is called the *creation operator*. It is conventional in quantum stochastic calculus to use A_t and its adjoint rather than Q_t and P_t; we shall conform to this standard.

In summary, we have constructed a quantum probability space $(\mathscr{W}, \phi)$ that admits an entire family (indexed by φ) of Wiener processes. Note, however, that these processes do not necessarily commute for different φ; in fact, it is not difficult to establish that $[B(f), B(g)]\psi = 2i\,\mathrm{Im}\langle f, g\rangle_2\,\psi$ on a suitably large domain (e.g., $\psi \in \mathsf{D}$). Therefore, even though every B_t^φ defines a Wiener process, these cannot be represented on the same classical probability space for different $\varphi_{1,2}$ unless $\mathrm{Im}(e^{i(\varphi_1-\varphi_2)}) = 0$.

We have also defined a Poisson process Λ_t, but unfortunately it vanishes in the vacuum. Consider, however, the process $\Lambda_t(f) = W(f)^*\Lambda_t W(f)$; for any Borel function b we can write $\phi(b(\Lambda_{t_1}(f), \ldots, \Lambda_{t_n}(f))) = \mathbb{P}_f(b(\Lambda_{t_1}, \ldots, \Lambda_{t_n}))$. Evidently $\Lambda_t(f)$ has the same statistics in the vacuum as does Λ_t under the coherent state $\mathbb{P}_f$. This shows that we can define even a whole family of Poisson processes in the vacuum. We do not lose much by restricting ourselves to the vacuum as an underlying state (as we will do in the remainder of the article), as we can always transform to a coherent state by "sandwiching" with Weyl operators. Note that like the family B_t^φ, the processes $\Lambda_t(f)$ do not commute amongst each other. We see that the quantum probability space $(\mathscr{W}, \phi)$ gives rise to a rich family of incompatible stochastic processes.

4.3. Quantum stochastic calculus. Now that we have obtained Wiener and Poisson processes, we can try to develop stochastic integrals with respect to these processes and an associated stochastic calculus. Note that if we were only interested in, e.g., integrating with respect to Q_t an adapted process which commutes with Q_t, then we could simply use the classical Itô integral definition through the spectral theorem. This will not suffice for our purposes, however, as we will want to consider stochastic differential equations that are driven simultaneously by the noncommuting noises Q_t and P_t (and even Λ_t). Moreover, we would like to have an Itô rule that tells us how to multiply stochastic integrals with respect to Q_t and P_t.

Our motivation for developing generalized quantum stochastic calculus is that this allows us to rigorously define and manipulate Schrödinger equations, as in (2.6), with a white-noise Hamiltonian formally defined by $H(t) = H_0 + H_1\,\dot{Q}_t + H_2\,\dot{P}_t$. In section 5 we will see that such models emerge naturally in applications. In this section we sketch the development of quantum stochastic calculus as it was introduced in a seminal paper by Hudson and Parthasarathy [42]. For a full development of this calculus we refer the reader to [42, 41, 55]. The Hudson–Parthasarathy approach has some technical issues, not surprisingly involving the unboundedness of operators, the full extent of which is still being explored. Though we cannot go into detail here, we will attempt to sketch some of the issues and give references to recent literature.

We work in the following setting. We wish to integrate processes against the three noises A_t, A_i^*, and Λ_t (the *fundamental noises*); i.e., we want to define $\int_0^t L_s\,dM_s$ where M_t is one of the fundamental noises. The noises are defined on the quantum probability space $(\mathscr{W}, \phi)$, but we will want to couple these noises to an external quantum system, the *initial system*,[10] with which they interact. To this end, let us introduce the initial Hilbert space h, $\mathscr{B} = \mathscr{B}(\mathsf{h})$, and the associated initial quantum

[10]This name has the following origin. Recall from section 2 that observables X evolve in time as $X_t = U_t^* X U_t$ (we will define a unitary evolution U_t in section 5). We would like to think of $X \otimes I \in \mathscr{B} \otimes \mathscr{W}$ as describing the external system; however, $U_t^*(X \otimes I)U_t$ will not be of the form $Y \otimes I$ except at $t = 0$. Hence the initial system observable $X \otimes I$ describes the external system at the initial time $t = 0$.

probability space $(\mathscr{B},\rho)$. We will choose our integrands L_t to be adapted processes on $(\mathscr{B}\otimes\mathscr{W},\rho\otimes\phi)$; i.e., each L_t is affiliated to $\mathscr{B}\otimes\mathscr{W}_{t]}$ and acts as I on $\mathscr{W}_{[t}$.

As usual, we begin with simple processes. Given $s<t$, recall that for the fundamental processes M_t-M_s is affiliated to $\mathscr{W}_{[s,t]}$, whereas for adapted processes L_s is affiliated to $\mathscr{B}\otimes\mathscr{W}_{s]}$; hence we can naturally write $L_s(M_t-M_s)=L_s\otimes(M_t-M_s)$. In particular, the increment M_t-M_s commutes with L_s, and we have no problems with operator multiplication of these unbounded operators. Let $\{t_i : i=0,\ldots,n,\ t_i<t_{i+1}\}$ be a sequence of times with $t_0=0$ and $t_n=T$. By definition, we set

$$L_t=\sum_{i=0}^{n-1}L_{t_i}\chi_{[t_i,t_{i+1})}(t)\quad\Longrightarrow\quad\int_0^t L_s\,dM_s=\sum_{i=0}^{n-1}L_{t_i}\otimes(M_{t_{i+1}\wedge t}-M_{t_i\wedge t}).$$

This definition makes sense as long as the operators L_t and M_t have a sufficiently large common dense domain that the sum is well defined. To enforce this, we will require that the domain of every L_t contains at least the exponential domain D.

Now comes the hard part in any integration theory: given a quadruple of suitably restricted adapted processes (E,F,G,H), such that these admit simple approximations (E^n,F^n,G^n,H^n), we wish to define the integral

$$I_t=\int_0^t(E_t\,d\Lambda_t+F_t\,dA_t+G_t\,dA_t^*+H_t\,dt)\tag{4.9}$$

as a limit, in some sense, of the corresponding integrals I_t^n over the simple processes. Recall that in the classical theory, the Itô isometry allows us to define the stochastic integral as a mean square limit of simple processes, and a little more work shows that every square-integrable process admits a mean square approximation by simple processes. Things are not quite so "simple" in the noncommutative case, however.

To see what goes wrong, consider for simplicity the case $\mathsf{h}=\mathbf{C}$ so that we can forget about the initial state ρ. We already encountered the noncommutative L^2 (semi)norm $\|X\|_\phi^2=\phi(X^*X)$ when we discussed conditional expectations. We are thus looking for a suitable unbounded operator I_t such that we have mean square convergence, $\|I_t-I_t^n\|_\phi^2=\langle(I_t-I_t^n)\Phi,(I_t-I_t^n)\Phi\rangle\to0$ as $n\to\infty$. But this is a very ill-defined problem, as it only depends on the action of I_t on the vacuum vector Φ; in particular, what do we choose as the domain of I_t, and how do we define I_t on vectors orthogonal to Φ? There could be a large number of inequivalent ways of doing this, giving rise to limiting operators with very different properties.[11]

The solution of Hudson and Parthasarathy works as follows. First of all, we fix the domain of I_t at the outset: every stochastic integral will have $\mathsf{h}\otimes\mathsf{D}$ as its domain (one could choose a dense domain in h as well; we will not worry about this). To specify I_t as a limit of simple integrals I_t^n, we choose I_t as the unique operator on $\mathsf{h}\otimes\mathsf{D}$ such that $\langle(I_t-I_t^n)\,v\otimes\psi,(I_t-I_t^n)\,v\otimes\psi\rangle\to0$ for every $\psi\in\mathsf{D}$, $v\in\mathsf{h}$ (it is sufficient to verify this for $\psi=e(f)$, $f\in L^\infty([0,T]))$. In essence this is like a mean square limit, but simultaneously for every coherent state. A suitable estimate replaces the Itô isometry [42, Corollary 1] and shows that this limit exists as long as $\int_0^T\|(E_s-E_s^n)\,v\otimes\psi\|^2ds\to0$ as $n\to\infty$ for every $\psi\in\mathsf{D}$, $v\in\mathsf{h}$ (and similarly for F,G,H), independent of the approximation. Finally, [42, Proposition 3.2] shows

[11] This was not a problem for the definition of conditional expectations; as all versions of the conditional expectation are affiliated to a single commutative algebra, they are a.s. equivalent by the spectral theorem. On the other hand, various "versions" of I_t that satisfy $\|I_t-I_t^n\|_\phi\to0$ need not even commute, and such operators are fundamentally inequivalent.

that every square-integrable process, i.e., $\int_0^T \|E_s\, v \otimes \psi\|^2 ds < \infty$ for all $\psi \in \mathsf{D}$, $v \in \mathsf{h}$, admits a suitable approximation by simple processes. We thus arrive at the following.

DEFINITION 4.1 (quantum Itô integral). *An operator process $\{X_t\}$ is stochastically integrable if it is adapted and square integrable. Given a quadruple (E, F, G, H) of such processes, the stochastic integral* (4.9) *is uniquely defined as the limit of simple approximations on the domain $\mathsf{h} \otimes \mathsf{D}$.*

Remark 4.2. It is often convenient to denote an expression of the form

$$X_t = X + \int_0^t (E_s\, d\Lambda_s + F_s\, dA_s + G_s\, dA_s^* + H_s\, ds),$$

symbolically as

$$dX_t = E_t\, d\Lambda_t + F_t\, dA_t + G_t\, dA_t^* + H_t\, dt, \qquad X_0 = X.$$

Both notations are used interchangeably in the literature.

A property that we will exploit in future is $\Lambda_t\Phi = A_t\Phi = 0$. It is immediate from the definition that stochastic integrals with respect to A_t and Λ_t acting on Φ vanish. Hence the vacuum expectations of stochastic integrals with respect to A_t and Λ_t vanish as well. Furthermore, as $\langle \Phi, A_t^*\Phi\rangle = \langle A_t\Phi, \Phi\rangle = 0$, we see that at least for simple processes (and indeed this holds for any integrand) the vacuum expectation of stochastic integrals with respect to A_t^* vanish. Note, however, that $A_t^*\Phi \neq 0$.

Our next task is to develop a stochastic calculus; the integrals defined above are not of much use, unless we have an Itô product rule with which they can be manipulated. Once again we run into unpleasant problems. If I_t and J_t are integrals of the form (4.9), there is no reason to expect that their product I_tJ_t is a well-defined operator on the domain $\mathsf{h} \otimes \mathsf{D}$. The idea of Hudson and Parthasarathy is inspired by the identity $\langle \psi', X^*Y\psi\rangle = \langle X\psi', Y\psi\rangle$ for bounded operators; rather than finding an expression for I_tJ_t, they calculate $\langle I_t\, v' \otimes \psi', J_t\, v \otimes \psi\rangle$ for every $v, v' \in \mathsf{h}$, $\psi, \psi' \in \mathsf{D}$, which is always well defined. One finds explicitly a lengthy expression [42, Theorems 4.3 and 4.4], which is essentially the quantum Itô rule expressed in terms of $\mathsf{h} \otimes \mathsf{D}$-matrix elements.

In practice, however, we are mostly interested in calculating actual operator products I_tJ_t. We will need the concept of an *adjoint pair*; two operators X and $X^\dagger$ are said to be an adjoint pair if $\langle v' \otimes \psi', X\, v \otimes \psi\rangle = \langle X^\dagger\, v' \otimes \psi', v \otimes \psi\rangle$ for every $v, v' \in \mathsf{h}$, $\psi, \psi' \in \mathsf{D}$. It is not difficult to verify that if (E, F, G, H) and $(E^\dagger, F^\dagger, G^\dagger, H^\dagger)$ are adjoint pairs, then I_t and $I_t^\dagger$ form an adjoint pair, where

$$I_t^\dagger = \int_0^t (E_t^\dagger\, d\Lambda_t + F_t^\dagger\, dA_t^* + G_t^\dagger\, dA_t + H_t^\dagger\, dt). \tag{4.10}$$

In essence, the adjoint $\dagger$ replaces the Hilbert space adjoint $*$ on the domain $\mathsf{h} \otimes \mathsf{D}$. Now suppose that we can verify explicitly that the product I_tJ_t is well defined; then we can read off an expression for I_tJ_t from the matrix elements $\langle I_t^\dagger\, v' \otimes \psi', J_t\, v \otimes \psi\rangle$. This gives the following explicit form of the quantum Itô rule.

THEOREM 4.3 (quantum Itô rule [55, Proposition 25.26]). *Let (F, G, H, I), (B, C, D, E), and $(B^\dagger, C^\dagger, D^\dagger, E^\dagger)$ be quadruples of stochastically integrable processes such that the latter two quadruples are adjoint pairs. Define the stochastic integrals*

$$dX_t = B_t\, d\Lambda_t + C_t\, dA_t + D_t\, dA_t^* + E_t\, dt,$$
$$dY_t = F_t\, d\Lambda_t + G_t\, dA_t + H_t\, dA_t^* + I_t\, dt,$$

and suppose that we have verified that the product X_tY_t is well defined and that $X_tF_t, \dots, X_tI_t$, $B_tY_t, \dots, E_tY_t$, and $B_tF_t, B_tG_t, \dots, E_tI_t$ are well defined and stochastically integrable. Then the process X_tY_t satisfies the relation

$$d(X_tY_t) = X_t\,dY_t + (dX_t)\,Y_t + dX_t\,dY_t,$$

where $X_t\,dY_t = X_tF_t\,d\Lambda_t + X_tG_t\,dA_t + X_tH_t\,dA_t^* + X_tI_t\,dt$, $(dX_t)\,Y_t = B_tY_t\,d\Lambda_t + C_tY_t\,dA_t + D_tY_t\,dA_t^* + E_tY_t\,dt$, and $dX_t\,dY_t = B_tF_t\,d\Lambda_t + C_tF_t\,dA_t + B_tH_t\,dA_t^* + C_tH_t\,dt$ are evaluated according to the following quantum Itô table.

$dX \setminus dY$	dA_t	$d\Lambda_t$	dA_t^*	dt
dA_t	0	dA_t	dt	0
$d\Lambda_t$	0	$d\Lambda_t$	dA_t^*	0
dA_t^*	0	0	0	0
dt	0	0	0	0

In particular, the theorem holds if B_t, C_t, D_t, E_t, and X_t are bounded processes [42]*, in which case the adjoints $B^\dagger$, $C^\dagger$, etc. are simply taken to be the Hilbert space adjoints B^*, C^*, etc., and X_t extends uniquely to a bounded operator in $\mathscr{W}_{t]}$.*

Remark 4.4. The choice to restrict attention to a fixed domain $\mathsf{h} \otimes \mathsf{D}$ allowed Hudson and Parthasarathy [42] to develop a viable quantum stochastic calculus. This choice, however, has quite a few drawbacks; we highlight one of the problems. Suppose X is self-adjoint; implicit in this statement is that the domains of X and X^* coincide. It can happen that if we restrict the domain of X, then the restricted operator admits many inequivalent self-adjoint extensions; see [56, pages 257–259] for an example. Hence the restriction to a fixed domain can become a real, physical problem, that prevents us from uniquely interpreting unbounded operators on $\mathsf{h} \otimes \mathsf{D}$ as observables.

Such problems have prompted the development of alternative approaches to quantum stochastic integration, and the topic is still under active investigation. In a significant recent achievement Attal and Lindsay [5], building on several earlier approaches (see, e.g., [52, 14] and the references therein), develop a theory in which the integrals achieve their maximal domains. Unfortunately, the theory is very technical and a little daunting for everyday use. A different approach that even precedes Hudson and Parthasarathy is that of Barnett, Streater, and Wilde [8]. Their theory is attractive as it is completely algebraic in nature (the Hilbert space and its domains do not play a fundamental role), but lacks a satisfactory Itô rule.

Despite these issues, the Hudson–Parthasarathy approach works quite well. In practice one usually works with a "noisy Schrödinger equation" (5.2), the solution of which is unitary and thus bounded. As long as the integrals and integrands are bounded, they are uniquely defined by their specification on a dense domain. In this article, in keeping with our attitude towards unbounded operators, we will not worry about such issues and assume that we can apply the quantum Itô rules. □

Example 4.5. In section 5 we will encounter quantum stochastic differential equations (QSDEs), the treatment of which proceeds along the same lines as the classical theory. We claim that the Weyl operator $W(f_{t]})$ is the solution of the QSDE

$$dW(f_{t]}) = \Big\{ f(t)\,dA_t^* - f(t)^*\,dA_t - \frac{1}{2}|f(t)|^2\,dt \Big\} W(f_{t]}). \tag{4.11}$$

In particular, one can verify the Weyl relation $W(f)W(g) = W(f+g)\,e^{i\,\mathrm{Im}\langle g,f\rangle_2}$

directly using the quantum Itô rule. From (4.11) and $W(kf) = e^{ikB(f)}$ we obtain

$$B(f) = \int_0^T (if(t)^*\, dA_t - if(t)\, dA_t^*).$$

Hence $dB_t^\varphi = ie^{-i\varphi(t)}\, dA_t - ie^{i\varphi(t)}\, dA_t^*$, and the quantum Itô rules reduce to the classical Itô rule $(dB_t^\varphi)^2 = dt$. Finally, recall that we defined Poisson processes $\Lambda_t(f) = W(f)^*\Lambda_t W(f) = W(f_{t]})^*\Lambda_t W(f_{t]})$ (the latter equality is due to $W(f) = W(f_{t]}) \otimes W(f_{[t})$ and the fact that $W(f_{[t}) \in \mathscr{W}_{[t}$ is unitary and commutes with the adapted process Λ_t). Using the quantum Itô rule we obtain the explicit representation

$$d\Lambda_t(f) = d\Lambda_t + f(t)^*\, dA_t + f(t)\, dA_t^* + |f(t)|^2\, dt, \tag{4.12}$$

for which the quantum Itô rules reduce to the classical product rule $(d\Lambda_t(f))^2 = d\Lambda_t(f)$ for a Poisson process. □

5. The filtering problem in quantum optics. Many realistic physical scenarios are very well described by quantum stochastic differential equations driven by the processes A_t, A_t^*, and Λ_t discussed in the previous section. Of course, as in the classical theory, white-noise systems are only an idealization of physical interactions; a Markov limit of wide-band noise in the spirit of Wong and Zakai (see [36] for details) gives stochastic models in the Itô form. For a large class of quantum systems, particularly those arising in the field of quantum optics, such approximations are extremely good and describe laboratory experiments essentially to experimental precision. Though a detailed discussion of the physics involved in the modelling of such systems is beyond the scope of this article, we here very briefly describe the physical origin of the equations that are widely used in the physics community [34], describe the measurements that are made, and set up the quantum filtering problem to be solved.

5.1. The quantum optics model. The basic model of quantum optics consists of some fixed physical system, e.g., a collection of atoms, in interaction with the electromagnetic field. The atomic observables are self-adjoint operators on a Hilbert space h. The description of the electromagnetic field and its interaction with the atoms follows from basic physical arguments (see the excellent monograph [23] for a thorough treatment of this theory, known as *quantum electrodynamics*). It turns out that the free electromagnetic field, i.e., an optical field in empty space, is described by a stationary Gaussian (noncommutative) wide-band noise $\tilde{a}(t, \mathbf{r})$ that propagates through space at the speed of light c; i.e., if we restrict ourselves to a single spatial dimension, $\tilde{a}(t + \tau, z) = \tilde{a}(t, z - c\tau)$. If we now place the atoms at the origin $z = 0$, then the quantum dynamics is given by a Schrödinger equation of the form

$$\frac{d}{dt}\tilde{U}(t) = [-iH + L\,\tilde{a}^*(t,0) - L^*\,\tilde{a}(t,0)]\,\tilde{U}(t), \qquad \tilde{U}(0) = I, \tag{5.1}$$

where $L \in \mathscr{B}$ is an atomic (dipole) operator and $H \in \mathscr{B}$ is an atomic Hamiltonian, H being self-adjoint. This equation, which follows directly from the physical model, has wide-band right-hand side. Note that we have set $\hbar = 1$ for convenience, a convention ubiquitous in physics (the only consequence is a change of units).

We now want to approximate the wide-band noise by white noise. This can be done in a rigorous way [1, 2, 36], but we will not detail the procedure here (a brief sketch can be found in [62]). Suffice it to say that one arrives at the following QSDE:

$$dU_t = \Big\{L\, dA_t^* - L^*\, dA_t - \frac{1}{2}L^*L\, dt - iH\, dt\Big\}U_t, \qquad U_0 = I, \tag{5.2}$$

which is driven by the noncommuting white-noise processes A_t and A_t^*. Note that this is almost precisely of the same form as (5.1), except that we have added the Itô correction term $-\frac{1}{2}L^*LU_t\,dt$. A Picard iteration argument [42, 55] ensures existence and uniqueness of the solution. The adjoint U_t^* satisfies

$$dU_t^* = U_t^*\Big\{L^*\,dA_t - L\,dA_t^* - \frac{1}{2}L^*L\,dt + iH\,dt\Big\}, \qquad U_0^* = I.$$

Using the quantum Itô rule we can calculate $d(U_t^*U_t) = d(U_tU_t^*) = 0$; i.e., the solution U_t is unitary for all t (as the solution of a Schrödinger equation should be).

Henceforth we will take (5.2) as our physical model. U_t defines the time evolution or *flow* $j_t : X \mapsto U_t^*(X \otimes I)U_t$ of every atomic observable $X \in \mathscr{B}$ (recall the time evolution in section 2.1); i.e., an observation of $X \in \mathscr{B}$ at time t is described by the observable $X_t = j_t(X)$. Using the Itô rules, we find an explicit dynamical equation

$$dj_t(X) = j_t(\mathcal{L}_{L,H}(X))\,dt + j_t([L^*, X])\,dA_t + j_t([X, L])\,dA_t^*, \quad X \in \mathscr{B}, \tag{5.3}$$

where the so-called Lindblad generator [48] is given by

$$\mathcal{L}_{L,H}(X) = i[H, X] + L^*XL - \frac{1}{2}(L^*LX + XL^*L), \qquad X \in \mathscr{B}.$$

In quantum probability, this object plays the same role as the infinitesimal generator of a Markov diffusion in classical probability theory.

Remark 5.1. Though it is unusual, one could use a very similar notation in classical stochastic models. Suppose some system is described by an underlying configuration x_t that obeys $dx_t = b(x_t)\,dt + \sigma(x_t)\,dW_t$. Then the "observables" in the theory, i.e., things we could try to measure, are functions f of the configuration of the system. The observable f at time t is described by the random variable $j_t(f) = f(x_t)$. Using the classical Itô rules, we get $dj_t(f) = j_t(\mathcal{L}f)\,dt + j_t(\Sigma f)\,dW_t$ where $\mathcal{L}f(x) = \sum_i b^i(x)\partial_i f(x) + \frac{1}{2}\sum_{ij}\sigma^i(x)\sigma^j(x)\partial_i\partial_j f(x)$ is the generator of the Markov diffusion x_t, and $\Sigma f(x) = \sum_i \sigma^i(x)\partial_i f(x)$. This expression is the classical analog of (5.3); the sample paths x_t do not have a quantum counterpart, however. □

5.2. Measurements. Having described the system and its interaction with the field, let us now turn to the observations that we can perform. Unlike in classical models, where one observes the system directly (with the addition of some corrupting noise), in quantum models an observation is generally performed in the field. From the system's perspective, the interaction with the field looks like an (albeit noncommutative) noisy driving force. Similarly, however, the field is perturbed by its interaction with the atoms and carries off information as it propagates away after the interaction. By performing a measurement in the field, then, we can attempt to perform statistical inference of the atomic observables. The entire setup is depicted in Figure 5.1.

To calculate the perturbation of the field by the atoms we once again calculate $U_t^*YU_t$, where now, however, Y is a field observable. The field observable of interest depends on the type of measurement we choose to perform. Without entering into the details, we mention two types of measurement that are extremely common in quantum optics: direct photodetection (photon counting), for which the observation at time t is given by $Y_t^\Lambda = U_t^*\Lambda_tU_t$, and homodyne detection, for which $Y_t^W = U_t^*(A_t + A_t^*)U_t$ (more generally $Y_t^W = U_t^*(e^{-i\varphi}A_t + e^{i\varphi}A_t^*)U_t$). We refer the reader to [6, 7] for a detailed treatment of quantum optical measurements. Using the Itô rules we obtain

$$dY_t^\Lambda = d\Lambda_t + j_t(L)\,dA_t^* + j_t(L^*)\,dA_t + j_t(L^*L)\,dt, \tag{5.4}$$

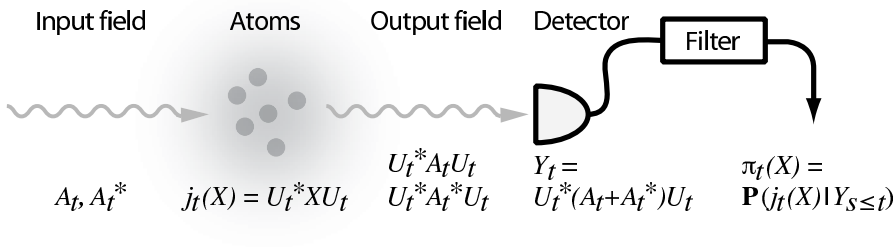

FIG. 5.1. *Diagram of the quantum filtering setup in quantum optics. An optical field, described by the field operators A_t, A_t^*, interacts with a system, e.g., a cloud of atoms. After the atom-field interaction the field operators, as well as system operator, X, are rotated by the unitary U_t. The field is detected, giving rise to the observation Y_t. Finally, the quantum filter (implemented on a classical signal processor) estimates atomic observables based on the field observations.*

$$dY_t^W = j_t(L + L^*)\,dt + dA_t + dA_t^*. \tag{5.5}$$

Intuitively, it would appear that Y_t^Λ is like a Poisson process whose intensity is controlled by $j_t(L^*L)$ (recall Example 4.5), whereas Y_t^W looks like a noisy observation of $j_t(L + L^*)$. One should be careful with this conclusion, however, as $j_t(L)$ need not commute with A_t or A_t^*, nor with itself at different times.

It is essential, however, that the observation process commutes with itself at different times and is hence equivalent to a classical stochastic process through the spectral theorem. An observation process that does not obey this property cannot be observed in a single realization of an experiment and is physically meaningless. Let us show that the observations processes we have defined above do obey this property, which is called the *self-nondemolition* property. Let Z be any operator of the form $I \otimes Z_{s]} \otimes I$ on $\mathsf{h} \otimes \mathsf{F}_{s]} \otimes \mathsf{F}_{[s}$ and let $t \ge s$. Then the Itô rules give directly

$$U_t^* Z U_t = U_s^* Z U_s + \int_s^t U_\tau^* \mathcal{L}_{L,H}(Z) U_\tau \, d\tau + \int_s^t U_\tau^* [L^*, Z] U_\tau \, dA_\tau + \int_s^t U_\tau^* [Z, L] U_\tau \, dA_\tau^*.$$

Now let $Z = A_s + A_s^*$ or $Z = \Lambda_s$. In both cases $\mathcal{L}_{L,H}(Z) = [Z, L] = 0$ as L and H are system observables and Z is a field observable. Hence $Y_s^W = U_t^*(A_s + A_s^*)U_t$ and $Y_s^\Lambda = U_t^* \Lambda_s U_t$ for all $t \ge s$. It is now easily verified, using the unitarity of U_t and the fact that $A_s + A_s^*$ and Λ_s are commutative processes, that $[Y_t^W, Y_s^W] = [Y_t^\Lambda, Y_s^\Lambda] = 0$ for all t, s. We denote by $\mathscr{Y}_t^W$ and $\mathscr{Y}_t^\Lambda$ the commutative von Neumann algebras generated by the observation processes Y_s^W and Y_s^Λ, $s \le t$, respectively. Do note, however, that Y_t^W and Y_t^Λ do not commute with each other; in any experiment, we can choose to perform only one of these measurements. Once we have made this choice, however, we can use the spectral theorem to represent the observations Y_t as a classical stochastic process $\iota(Y_t)$ on a probability space.

5.3. Statement of the filtering problem. Moving on to the next step in our program, we now wish to use the information gained from the measurement process to infer something about the system. To find a least mean square estimate of a system observable $X \in \mathscr{B}$ at time t, given the observations Y_t up to this time, we must calculate the conditional expectation

$$\pi_t(X) = \mathbb{P}(j_t(X) | \mathscr{Y}_t), \tag{5.6}$$

where $\mathscr{Y}_t = \mathrm{vN}(Y_s : 0 \le s \le t)$. The remainder of this article is devoted to finding a recursive equation for $\pi_t(X)$ (the *filtering equation*). Recall, however, that the conditional expectation is only defined if $j_t(X)$ is in the commutant of $\mathscr{Y}_t$, the interpretation being that statistical inference of an observable is only physically meaningful if the conditional statistics could possibly be tested through a compatible experiment. Through an entirely identical procedure to the one used to show the self-nondemolition property, we can show that $j_t(X)$ is in the commutant of $\mathscr{Y}_t$ for any $X \in \mathscr{B}$. This is known as the *nondemolition property*, which can be written as

$$[j_t(X), Y_s] = 0 \quad \forall s \le t,\ X \in \mathscr{B}. \tag{5.7}$$

We note that we have now obtained a system-theoretic model of our system and observations, defined on the quantum probability space $(\mathscr{B} \otimes \mathscr{W}, \mathbb{P} = \rho \otimes \phi)$ by

$$dj_t(X) = j_t(\mathcal{L}_{L,H}(X))\,dt + j_t([L^*, X])\,dA_t + j_t([X, L])\,dA_t^*, \tag{5.8}$$

$$dY_t = j_t(L + L^*)\,dt + dA_t + dA_t^* \tag{5.9}$$

in the case of homodyne detection, or by (5.8), and

$$dY_t = d\Lambda_t + j_t(L)\,dA_t^* + j_t(L^*)\,dA_t + j_t(L^*L)\,dt \tag{5.10}$$

in the case of counting observations. These equations define a system-observation model in direct analogy to such models used throughout classical nonlinear filtering and stochastic control theory.

Remark 5.2. Unlike in a classical filtering scenario, we have not added any independent corrupting noise to the observations. Nonetheless, the filtering problem does not reduce to a problem with complete observations because the system is driven by noise that does not commute with the observations. Hence the problem of partial observations is intrinsic to quantum measurement theory. The quantum filtering problem considered here is the simplest possible one; one could add additional corrupting noise as in the classical case, have the system interact with multiple fields (some of which are observed, others unobserved), etc. These are not essential complications, however, and filters for such models are obtained much in the same way. □

6. The reference probability method. The goal of this section is to derive the quantum filtering equation, a recursive equation for $\pi_t(X)$, using a method that is close to the classical reference probability method of Duncan [29], Mortensen [53], and Zakai [66]. We consider first the homodyne detection case, then the photon counting case. In section 7 we will rederive the filtering equation for the homodyne detection case using martingale methods; the chief advantage of the reference probability method is that it is somewhat simpler to apply. The following approach is based on [18].

6.1. Homodyne detection. Let us briefly recall the classical reference probability procedure; for an introduction see, e.g., [32]. In order to simplify the filtering problem, one starts by introducing a new probability measure, using a Girsanov transformation [49, section 6.3], under which the measurement record is a Wiener process. Then various (elementary) properties of the conditional expectation allow the filtering problem to be expressed, and solved, with respect to the new measure. We now apply this logic to the quantum filtering problem. Note that we have already applied the method in Example 3.19; the following is essentially a continuous time version of that example.

We consider the homodyne detection setup given by (5.8) and (5.9). We could try to find a new state under which Y_t is a Wiener process; however, it will be more convenient to work not in terms of Y_t but in terms of $Z_t = A_t + A_t^*$, as it is very easy to manipulate Z_t using the methods of section 4. Thus before we really start filtering, let us transform the problem in terms of Z_t. Introduce the state $\mathbb{Q}^t$ defined by

$$\mathbb{Q}^t(X) = \mathbb{P}(U_t^* X U_t), \tag{6.1}$$

with U_t as in section 5, and we fix from now on $\mathbb{P} = \rho \otimes \phi$. Now recall from Example 3.19 that $\mathbb{Q}(X) = \mathbb{P}(U^*XU)$ implies $\mathbb{P}(U^*XU|U^*\mathscr{C}U) = U^*\mathbb{Q}(X|\mathscr{C})U$ (this is easily checked using the definition of the conditional expectation). Thus we have

$$\mathbb{P}(j_t(X)|\mathscr{Y}_t) = U_t^* \mathbb{Q}^t(X|\mathscr{C}_t) U_t, \qquad X \in \mathscr{B}, \tag{6.2}$$

where $\mathscr{C}_t = \mathrm{vN}(Z_s : 0 \le s \le t)$. Note that $\mathscr{Y}_t = U_t^* \mathscr{C}_t U_t$ follows from the fact that $U_s^* Z_s U_s = U_t^* Z_s U_t$ for $t \ge s$, the property we used in section 5.2 to prove self-nondemolition of Y_t. The ease with which we will now be able to manipulate $\mathbb{Q}^t(X|\mathscr{C}_t)$ highlights the usefulness of the transformation (6.2).

Our strategy will be as follows. We wish to calculate $\mathbb{Q}^t(X|\mathscr{C}_t)$; however, the state $\mathbb{P}$ has the nice property that $Z_{s\le t}$, which generates $\mathscr{C}_t$, is a $\mathbb{P}$-Wiener process. We want to use the Bayes formula, Lemma 3.18, in order to express $\mathbb{Q}^t(X|\mathscr{C}_t)$ in terms of $\mathbb{P}$-conditional expectations. We run into a problem, however, as the "change of measure" operator U_t that relates $\mathbb{P}$ with $\mathbb{Q}^t$ does not satisfy the requirement of Lemma 3.18 that[12] $U_t \in \mathscr{C}_t'$. To solve this problem, we will replace U_t by a different operator V_t which is affiliated to $\mathscr{C}_t'$, but which still defines the same state in the sense that $\mathbb{P}(U_t^* X U_t) = \mathbb{P}(V_t^* X V_t)$ for every X. The following technique, to our knowledge, first appeared in [39]; it replaces Girsanov's theorem in the quantum context.

LEMMA 6.1. *Let V_t be the solution of the QSDE*

$$dV_t = \Big\{ L\,(dA_t^* + dA_t) - \frac{1}{2} L^* L\,dt - iH\,dt \Big\} V_t. \tag{6.3}$$

Then V_t is affiliated to $\mathscr{C}_t'$ and $\mathbb{Q}^t(X) = \mathbb{P}(V_t^* X V_t)$ for all $X \in \mathscr{B} \otimes \mathscr{W}$.

Proof. Let us assume for simplicity that the state ρ on $\mathscr{B}$ is pure; we can always obtain a mixed state later by taking convex combinations. Then $\mathbb{P}(X) = \langle \psi \otimes \Phi, X\, \psi \otimes \Phi \rangle$ for some vector $\psi \in \mathsf{h}$ (and $\Phi \in \mathsf{F}$ is the vacuum vector). To show that $\mathbb{P}(U_t^* X U_t) = \mathbb{P}(V_t^* X V_t)$, it is thus sufficient to show that

$$U_t\, \psi \otimes \Phi = V_t\, \psi \otimes \Phi. \tag{6.4}$$

Note that $\big\langle (U_t - V_t)\psi \otimes \Phi,\, (U_t - V_t)\psi \otimes \Phi \big\rangle = \big\langle \psi \otimes \Phi,\, (U_t - V_t)^*(U_t - V_t)\psi \otimes \Phi \big\rangle$. A simple application of the quantum Itô rule and the fact that vacuum expectations of stochastic integrals vanish show that $\big\langle \psi \otimes \Phi,\, (U_t - V_t)^*(U_t - V_t)\psi \otimes \Phi \big\rangle = 0$ and (6.4) holds. ∎

Note that the only difference between the equation for U_t, (5.2), and the equation for V_t, (6.3), is that we have modified the coefficient in front of dA_t. In principle, we could change the integrand of the A_t-integral arbitrarily without affecting how the QSDE acts on the vacuum; essentially this is due to the fact that any integral with respect to A_t vanishes when acting on the vacuum, as remarked after Remark 4.2.

[12] If this were the case, then we could calculate $Y_t = U_t^* Z_t U_t = Z_t U_t^* U_t = Z_t$; i.e., the observations would carry no information about the system and the filtering problem would be trivial.

In Lemma 6.1 we exploit this fact to modify U_t precisely so that it is in the commutant of $\mathscr{C}_t$; indeed, (6.3) is driven only by the noise $Z_t = A_t + A_t^*$ and its coefficients are in $\mathscr{B} \subset \mathscr{C}_t'$. We are now ready to apply the Bayes formula, Lemma 3.18. Together with Lemma 6.1 and (6.2), we immediately obtain the following result.

THEOREM 6.2 (noncommutative Kallianpur–Striebel). *Define for any system operator $X \in \mathscr{B}$ the unnormalized conditional expectation*

$$\sigma_t(X) = U_t^* \, \mathbb{P}(V_t^* X V_t | \mathscr{C}_t) \, U_t \in \mathscr{Y}_t. \tag{6.5}$$

Then the conditional expectation (5.6) *is given by*

$$\pi_t(X) = \frac{\sigma_t(X)}{\sigma_t(I)} \qquad \forall \, X \in \mathscr{B}. \tag{6.6}$$

We now obtain an explicit expression for $\sigma_t(X)$.

THEOREM 6.3 (unnormalized quantum filtering equation). *The unnormalized conditional expectation $\sigma_t(X)$ satisfies the following linear QSDE:*

$$d\sigma_t(X) = \sigma_t(\mathcal{L}_{L,H}(X)) \, dt + \sigma_t(L^* X + X L) \, dY_t. \tag{6.7}$$

To obtain (6.7) we will need to take conditional expectations of quantum Itô integrals. Let us briefly show how to do this. First, we claim that if K_t is an adapted process with K_s affiliated to $\mathscr{C}_s'$, then $\mathbb{P}(K_s|\mathscr{C}_t) = \mathbb{P}(K_s|\mathscr{C}_s)$ for $s \le t$. This follows from the fact that $\mathscr{C}_t = \mathscr{C}_s \otimes \mathscr{C}_{[s,t]}$ and that K_s is independent from $\mathscr{C}_{[s,t]}$ by adaptedness. Second, conditional expectations and integrals can be exchanged as follows:

$$\mathbb{P}\left(\int_0^t K_s \, ds \middle| \mathscr{C}_t \right) = \int_0^t \mathbb{P}(K_s|\mathscr{C}_s) \, ds, \qquad \mathbb{P}\left(\int_0^t K_s \, dZ_s \middle| \mathscr{C}_t \right) = \int_0^t \mathbb{P}(K_s|\mathscr{C}_s) \, dZ_s.$$

These properties are immediate if K_t is a simple process, and a proof of the general case is not difficult.

Proof. Using the quantum Itô rules we have

$$V_t^* X V_t = X + \int_0^t V_s^* \mathcal{L}_{L,H}(X) V_s \, ds + \int_0^t V_s^* (L^* X + X L) V_s \, d(A_s + A_s^*).$$

We next take conditional expectations of the terms in this expression; we obtain

$$\begin{aligned} \mathbb{P}(V_t^* X V_t | \mathscr{C}_t) = \mathbb{P}(X) &+ \int_0^t \mathbb{P}(V_s^* \mathcal{L}_{L,H}(X) V_s | \mathscr{C}_s) \, ds \\ &+ \int_0^t \mathbb{P}(V_s^* (L^* X + X L) V_s | \mathscr{C}_s) \, d(A_s + A_s^*). \end{aligned}$$

Another application of the quantum Itô rules now yields (6.7). ∎

By applying the Itô rules to the noncommutative Kallianpur–Striebel formula (6.6), we obtain an expression for the normalized conditional state

$$d\pi_t(X) = \pi_t(\mathcal{L}_{L,H}(X)) dt + \Big(\pi_t(L^* X + X L) - \pi_t(L^* + L) \, \pi_t(X) \Big) \Big(dY_t - \pi_t(L^* + L) \, dt \Big). \tag{6.8}$$

This (normalized) *quantum filtering equation* is a quantum analog of the classical Kushner–Stratonovich equation of nonlinear filtering. Note that this is a classical

stochastic differential equation by the spectral theorem: it is a recursive equation that is only driven by the (commutative) observations Y_t. Hence it can be implemented on a classical (digital) signal processor, as depicted in Figure 5.1.

Remark 6.4. Equation (6.8) is expressed in terms of the conditional state $\pi_t(X)$, where $X \in \mathscr{B}$. Now recall from section 2 that any state on a finite-dimensional Hilbert space can be expressed as $\mathrm{Tr}[\rho X]$ for some density matrix ρ. Similarly, if h (and hence $\mathscr{B}$) is finite dimensional, then we can always write $\pi_t(X) = \mathrm{Tr}[\rho_t X]$ where ρ_t, the conditional density matrix, is a (random) density matrix that is a function of the observations up to time t. From (6.8) we obtain explicitly

$$d\rho_t = -i[H,\rho_t]\,dt + (L\rho_t L^* - \tfrac{1}{2}L^*L\rho_t - \tfrac{1}{2}\rho_t L^*L)\,dt + (L\rho_t + \rho_t L^* - \mathrm{Tr}[(L+L^*)\rho_t]\rho_t)\,dW_t,$$

where $dW_t = dY_t - \mathrm{Tr}[(L+L^*)\rho_t]\,dt$. In section 7 we will see that W_t is a Wiener process. It is this representation that is usually found in the physics literature. □

6.2. Photon counting measurements. We now consider the photon counting setup given by (5.8) and (5.10). We would like to follow the same procedure as for homodyne detection. The following lemma, which replaces Lemma 6.1, suggests how to proceed. The proof is identical to that of Lemma 6.1.

LEMMA 6.5. *Let U'_t be the solution of the QSDE*

$$dU'_t = \Big\{L'\,dA_t^* - L'^*\,dA_t - \frac{1}{2}L'^*L'\,dt - iH'\,dt\Big\}U'_t$$

and let V'_t be the solution of

$$dV'_t = \Big\{L'(d\Lambda_t + dA_t^* + dA_t + dt) - \frac{1}{2}L'^*L'\,dt - L'\,dt - iH'\,dt\Big\}V'_t.$$

Then V'_t is affiliated to $\mathrm{vN}(\Lambda_s + A_s^* + A_s + s : s \le t)'$ *and* $\mathbb{P}(U_t'^* X U'_t) = \mathbb{P}(V_t'^* X V'_t)$.

Define $Z_t = \Lambda_t + A_t^* + A_t + t$ and $\mathscr{C}_t = \mathrm{vN}(Z_s : 0 \le s \le t)$. Lemma 6.5 directly provides us with a nondemolition change of measure, provided that we rotate our problem so that $\mathscr{Y}_t = U_t'^*\mathscr{C}_t U'_t$ using a suitable unitary operator U'_t. Then, defining $\sigma_t(X) = U_t'^*\,\mathbb{P}(V_t'^* X V'_t|\mathscr{C}_t)\,U'_t$, the Kallianpur–Striebel formula holds for $\sigma_t(X)$.

Define R_t as the solution of the QSDE

$$dR_t = (dA_t - dA_t^* - \tfrac{1}{2}dt)\,R_t.$$

Recall Example 4.5; evidently R_t is a Weyl operator, and in particular $\Lambda_t = R_t^* Z_t R_t$. But recall that $Y_t = U_t^*\Lambda_t U_t = U_t^* R_t^* Z_t R_t U_t$; thus $U'_t = R_t U_t$ is our rotation of choice. Using the quantum Itô rules we obtain

$$dU'_t = \Big\{(L-I)\,dA_t^* - (L^*-I)\,dA_t - \frac{1}{2}(L^*L + I - 2L + 2iH)\,dt\Big\}U'_t,$$

which corresponds to the nondemolition change of measure

$$dV'_t = \Big\{(L-I)\,dZ_t - \frac{1}{2}(L^*L - I + 2iH)\,dt\Big\}V'_t.$$

For $X \in \mathscr{B}$, using the quantum Itô rules we obtain

$$dV_t'^* X V'_t = V_t'^*\big(\mathcal{L}_{L,H}(X)\big)V'_t\,dt + V_t'^*(L^*XL - X)V'_t\,(dZ_t - dt).$$

Finally, using the definition of σ_t and the quantum Itô rules we obtain

$$d\sigma_t(X) = \sigma_t(\mathcal{L}_{L,H}(X))\,dt + \big(\sigma_t(L^*XL) - \sigma_t(X)\big)\big(dY_t - dt\big),$$

which is the unnormalized quantum filtering equation for counting observations.

Using the Kallianpur–Striebel formula $\pi_t(X) = \sigma_t(X)\,/\,\sigma_t(I)$ we can now obtain an expression for the normalized conditional state

$$d\pi_t(X) = \pi_t(\mathcal{L}_{L,H}(X))\,dt + \left(\frac{\pi_t(L^*XL)}{\pi_t(L^*L)} - \pi_t(X)\right)\big(dY_t - \pi_t(L^*L)\,dt\big),$$

which is the normalized quantum filtering equation for photon counting.

7. The innovations method. In this section we rederive the filtering equation for homodyne detection, (6.8), using martingale methods that are analogous to the classical case [13, 17]. We follow the classical treatment as in [33], [31, Chapter 18], and [65, Chapter 7]. Martingale methods have enjoyed wide and successful application in classical stochastic theory. The procedure is less straightforward than the reference probability method, however, and some familiarity with classical filtering theory would be helpful (see, e.g., [26] for an excellent introduction).

Let $\xi_t, \beta_t, \lambda_t, \mu_t$ be adapted processes affiliated to $\mathscr{Y}_t'$, where

$$\xi_t = \xi_0 + \int_0^t \beta_s\,ds + m_t = \xi_0 + \int_0^t \beta_s\,ds + \int_0^t (\lambda_s\,dA_s + \mu_s\,dA_s^*). \tag{7.1}$$

The measurement process Y_t is given by (5.9), and in what follows we write $h_t = j_t(L + L^*)$ and $Z_t = A_t + A_t^*$. Note that the conditional expectation $\hat{\xi}_t = \mathbb{P}(\xi_t|\mathscr{Y}_t)$ is well defined, and similarly for the coefficients β_t, λ_t, and μ_t.

The main filtering result for a process of the form (7.1) is the following.

THEOREM 7.1 (noncommutative Fujisaki–Kallianpur–Kunita). *Under the above assumptions, the filtered process $\hat{\xi}_t$ satisfies the QSDE*

$$d\hat{\xi}_t = \hat{\beta}_t\,dt + (\hat{\lambda}_t + \widehat{\xi_t h_t} - \hat{\xi}_t\hat{h}_t)\,dW_t, \tag{7.2}$$

where $\hat{r}_t \equiv \mathbb{P}(r_t|\mathscr{Y}_t)$ for any r_t affiliated to $\mathscr{Y}_t'$, and $dW_t = dY_t - \hat{h}_t\,dt$ defines the $\mathscr{Y}_t$-Wiener process (with respect to $\mathbb{P}$) W_t, called the innovations process.

The filtering expression (7.2) is formally identical to the classical case [31, Theorem 18.11] and [65, Proposition 3.2]. Before we prove Theorem 7.1, we will show how to obtain the quantum filtering equation (6.8) using this result.

COROLLARY 7.2. *The conditional state $\pi_t(X)$ is given by* (6.8).

Proof. We set $\lambda_t = -j_t([X, L^*])$, $\mu_t = j_t([X, L])$, $\beta_t = j_t(\mathcal{L}_{L,H}(X))$, and $\xi_t = j_t(X)$. Then $\widehat{\xi_t h_t} = \pi_t(X(L + L^*))$, $\hat{\xi}_t\hat{h}_t = \pi_t(X)\pi_t(L + L^*)$, $\hat{\lambda}_t = -\pi_t([X, L^*])$, and $\hat{\beta}_t = \pi_t(\mathcal{L}_{L,H}(X))$. Hence using (7.2), (6.8) follows. ∎

Proof of Theorem 7.1. *Step* 1. We first show that the process

$$M_t = \hat{\xi}_t - \hat{\xi}_0 - \int_0^t \hat{\beta}_s\,ds$$

is a $\mathscr{Y}_t$-martingale, i.e., $\mathbb{P}(M_t|\mathscr{Y}_s) = M_s$ for all $s \le t$. This property is equivalent to $\mathbb{P}((M_t - M_s)K) = 0$ for all $K \in \mathscr{Y}_s$, or equivalently

$$\mathbb{P}\left[\left(\hat{\xi}_t - \hat{\xi}_s - \int_s^t \hat{\beta}_r\,dr\right)K\right] = \mathbb{P}\left[\left(\xi_t - \xi_s - \int_s^t \beta_r\,dr\right)K\right] = \mathbb{P}[(m_t - m_s)K] = 0$$

for all $K \in \mathscr{Y}_s$, where we have used Definition 3.13 in the first step. But as $K \in \mathscr{Y}_s \subset \mathscr{B} \otimes \mathscr{W}_{s]}$,

$$\mathbb{P}[(m_t - m_s)K] = \mathbb{P}\left[K \int_s^t (\lambda_r \, dA_r + \mu_r \, dA_r^*)\right] = \mathbb{P}\left[\int_s^t (K\lambda_r \, dA_r + K\mu_r \, dA_r^*)\right] = 0,$$

where we have used that the vacuum expectation of quantum Itô integrals vanishes. Thus we have demonstrated that M_t is a $\mathscr{Y}_t$-martingale.

Step 2. We now show that W_t is a Wiener process under $\mathbb{P}$. We begin by verifying that the innovations process

$$W_t = Y_t - \int_0^t \hat{h}_s \, ds \tag{7.3}$$

is a $\mathscr{Y}_t$-martingale. We need to show that $\mathbb{P}[(W_t - W_s)K] = 0$ for any $s \le t$ and $K \in \mathscr{Y}_s$. This is equivalent to

$$\mathbb{P}\left[\left(Y_t - Y_s - \int_s^t \hat{h}_r \, dr\right) K\right] = \mathbb{P}\left[\left(Y_t - Y_s - \int_s^t h_r \, dr\right) K\right] = 0$$

for all $K \in \mathscr{Y}_s$, where the second expression follows from the definition of the conditional expectation. But from (5.9) we obtain

$$\mathbb{P}\left[\left(Y_t - Y_s - \int_s^t h_r \, dr\right) K\right] = \mathbb{P}[(Z_t - Z_s)K] = 0$$

as $K \in \mathscr{Y}_s \subset \mathscr{B} \otimes \mathscr{W}_{s]}$, $(Z_t - Z_s) \in \mathscr{W}_{[s,t]}$, and hence $\mathbb{P}[(Z_t - Z_s)K] = \mathbb{P}(K)\,\mathbb{P}(Z_t - Z_s) = 0$. Thus W_t is a $\mathscr{Y}_t$-martingale.

From (7.3) we read off the Itô rule $dW_t^2 = dt$; classically, a process that obeys this property and is a martingale must be a Wiener process by Lévy's theorem (e.g., [31, Lemma 18.7]). But we can simply apply the classical result, as W_t is a commutative process (note that $\hat{h}_t \in \mathscr{Y}_t$ for $s \le t$ by construction) and is hence equivalent to the corresponding classical process obtained through the spectral theorem.

Now that we have shown that W_t is a Wiener process, we can try to represent the martingale M_t as a stochastic integral with respect to W_t. As usual in filtering theory the ordinary martingale representation theorem does not suffice for this purpose, but the representation theorem of Fujisaki–Kallianpur–Kunita (e.g., [49, Theorem 5.20]) allows us to conclude nonetheless that

$$M_t = \int_0^t \gamma_s \, dW_s \quad \Longrightarrow \quad \hat{\xi}_t = \hat{\xi}_0 + \int_0^t \hat{\beta}_s \, ds + \int_0^t \gamma_s \, dW_s \tag{7.4}$$

for some adapted process $\gamma_t \in \mathscr{Y}_t$.

Step 3. We next obtain a first expression for $\widehat{\xi_t Y_t}$:

$$\widehat{\xi_t Y_t} = \int_0^t [\widehat{\beta_s Y_s} + \widehat{\xi_s h_s} + \hat{\lambda}_s] ds + M_1(t), \tag{7.5}$$

where $M_1(t)$ is a $\mathscr{Y}_t$-martingale. As before, it suffices to show that

$$\mathbb{P}((M_1(t) - M_1(s))K) = \mathbb{P}\left[\left(\xi_t Y_t - \xi_s Y_s - \int_s^t [\beta_s Y_s + \xi_s h_s + \lambda_s] ds\right) K\right] = 0$$

for all $K \in \mathscr{Y}_s$, where we have used the definition of the conditional expectation. But

$$\begin{aligned} d(\xi_t Y_t) &= (d\xi_t)Y_t + \xi_t dY_t + d\xi_t dY_t \\ &= (\beta_t dt + dm_t)Y_t + \xi_t(hdt + dZ_t) + dm_t dZ_t \\ &= (\beta_t Y_t + \xi_t h_t + \lambda_t)dt + (Y_t\lambda_t + \xi_t)dA_t + (Y_t\mu_t + \xi_t)dA_t^*. \end{aligned}$$

Hence exactly as before, it follows that $M_1(t)$ is a $\mathscr{Y}_t$-martingale.

Step 4. Next, we derive a second expression for $\widehat{\xi_t Y_t}$:

$$\widehat{\xi_t Y_t} = \int_0^t [\hat{\beta}_s Y_s + \hat{\xi}_s \hat{h}_s + \gamma_s]ds + M_2(t), \tag{7.6}$$

where $M_2(t)$ is a $\mathscr{Y}_t$-martingale. To show this, note that $\widehat{\xi_t Y_t} = \hat{\xi}_t Y_t$. By Itô's rules,

$$\begin{aligned} d(\hat{\xi}_t Y_t) &= (d\hat{\xi}_t)Y_t + \hat{\xi}_t dY_t + d\hat{\xi}_t dY_t \\ &= (\hat{\beta}_t dt + \gamma_t dW_t)Y_t + \hat{\xi}_t(\hat{h}_t dt + dW_t) + \gamma_t dW_t dW_t \\ &= (\hat{\beta}_t Y_t + \hat{\xi}_t \hat{h}_t + \gamma_t)dt + (\gamma_t Y_t + \hat{\xi}_t)dW_t \end{aligned}$$

which establishes (7.6).

Step 5. We can now identify γ_t. From (7.5) and (7.6) we have two representations for $\widehat{\xi_t Y_t}$. By uniqueness, it follows that the finite variation terms are equal, namely,

$$\widehat{\beta_s Y_s} + \widehat{\xi_s h_s} + \hat{\lambda}_s = \hat{\beta}_s Y_s + \hat{\xi}_s \hat{h}_s + \gamma_s.$$

Therefore $\gamma_s = \widehat{\xi_s h_s} + \hat{\lambda}_s - \hat{\xi}_s \hat{h}_s$ as required. □

8. Conclusion. In this article we have provided an introduction to quantum filtering. Our goal has been to emphasize the mathematical structures of quantum probability and to show their use in system-probe models from quantum optics. We have seen that the techniques employed in quantum filtering theory closely mirror their analogs in the classical theory of nonlinear filtering. As in the classical theory, an important role is played by the conditional expectation as the mean least square estimate of the system given the observations thus far.

The spectral theorem provides a one-to-one correspondence between commutative von Neumann algebras equipped with normal states and classical (Kolmogorov) probability spaces. This enabled us to represent commuting observables (self-adjoint operators acting on a Hilbert space) as random variables on a single classical probability space. For an observable X that commutes with all members of a commutative family of observables $\mathscr{Y}$, we can define the conditional expectation of X onto $\mathscr{Y}$ by pulling back the classical conditional expectation of X onto $\mathscr{Y}$, both represented on a classical probability space via the spectral theorem. For this procedure to work, it is crucial that the family $\mathscr{Y}$ is commutative, the *self-nondemolition* property, and that X commutes with $\mathscr{Y}$, the *nondemolition* property.

As a model for the quantum electromagnetic field we introduced the algebra $\mathscr{W}$ of bounded operators on the Boson Fock space equipped with the vacuum state ϕ. We studied families of commuting operators affiliated to $\mathscr{W}$, and by representing these commuting operators on a classical probability space, we found that $(\mathscr{W}, \phi)$ contains families of Wiener and Poisson processes, all of which can be written as linear combinations of the so-called fundamental noises Λ_t (gauge process), A_t^* (creation process), and A_t (annihilation process). These families of operators do not necessarily

commute with each other, and therefore the different Wiener and Poisson processes in $(\mathscr{W}, \phi)$ cannot be represented on the same classical probability space. Physically, these processes can all be observed with a suitable measurement setup (e.g., homodyne detection or photon counting); however, these observations cannot be made in a single realization of the experiment, as the different families do not commute.

Although the noncommuting processes affiliated to $(\mathscr{W}, \phi)$ cannot be represented on the same probability space, it is still possible to capture them within a single stochastic calculus. Stochastic integrals with respect to the fundamental noises can be defined as operators affiliated with $\mathscr{W}$, and a quantum Itô rule (integration by parts rule) based on a quantum Itô table for the fundamental noises can be shown to hold [42]. The interaction of some fixed system, e.g., a cloud of atoms, with the electromagnetic field in a Markov limit [1, 36] is given by a unitary U_t that satisfies a quantum stochastic differential equation, i.e., a stochastic differential equation given in terms of quantum stochastic integrals with respect to the fundamental noises. Note that the equation for U_t can therefore be driven by different noises that do not necessarily commute with each other.

Given the unitary U_t, the Heisenberg evolution of the observables of the system (e.g., a cloud of atoms) is given by $j_t(X) = U_t^* X U_t$. Instead of directly observing the system at time t, we only had access to field observables up to time t, e.g., $Y_s = U_s^*(A_s + A_s^*)U_s,\ 0 \le s \le t$ (homodyne detection) or $Y_s = U_s^* \Lambda_s U_s,\ 0 \le s \le t$ (photon counting). We showed that these system-observation pairs satisfy the nondemolition requirements that are necessary for the existence of the conditional expectation $\mathbb{P}(j_t(X)|\mathscr{Y}_t)$ of a system observable $j_t(X)$ at time t onto the observations thus far. The quantum filtering equation recursively propagates the conditional expectation, our best estimate of system observables, in time. In close analogy with the classical case, we derived the quantum filtering equation in two ways, once using a change of measure technique and once using martingales and martingale representation.

There are many points we did not touch upon in this introduction to quantum filtering. Some noteworthy omissions are the linear theory [30] and models in discrete time with discrete observables [19]. Another notable omission is how the filtering equations can be used when controlling a quantum system [10, 11, 28, 18]. As in the classical case, a separation theorem can be shown to hold [18]. This means that the optimal controller will depend on the observation history only through the filter. This separates the control problem into an estimation step (filtering) and a control step based on the estimates only.

SINGLE OUTPUT-DEPENDENT OBSERVABILITY NORMAL FORM*

GANG ZHENG†, DRISS BOUTAT‡, AND JEAN-PIERRE BARBOT§

Abstract. This paper gives the sufficient and necessary conditions which guarantee the existence of a diffeomorphism in order to transform a nonlinear system without inputs into a canonical normal form that is output dependent. Moreover, we extend our results to a class of systems with inputs.

Key words. observability, normal forms

1. Introduction. Since Luenberger's work [9], the design of an observer for observable linear systems with linear outputs has been a well-known concept. In order to use the same observer for nonlinear systems, the so-called observability linearization problem for nonlinear systems was born. The sufficient and necessary conditions which guarantee the existence of a diffeomorphism and of an output injection to transform a single output nonlinear system without inputs into a linear one with an output injection were firstly addressed in [12]. Then, for a multi-output nonlinear system without inputs, the linearization problem was partially solved in [13]. The complete solution to the linearization problem was given in [16]. Another approach was introduced for the analytical systems in [11] by assuming that the spectrum of the linear part must lie in the Poincaré domain, and it was generalized in [14] by assuming that the spectrum of the linear part must lie in the Siegel domain. These assumptions are not generically fulfilled. Other approaches using quadratic normal forms were given in [1] and [3]. All these approaches enable us to design an observer for a larger class of nonlinear systems.

Meanwhile, other researchers worked directly on designing nonlinear observers, such as high-gain observers [6], [4], [7]. Nevertheless, even if the conditions which guarantee the linearization method to design an observer were not generically fulfilled, this method would still remain important for the nonlinear observer design because (1) it works well for nonanalytic systems, and (2) because it could be used not only in adaptive theory but also for the observation of systems with unknown inputs. All these reasons explain why researchers continue to investigate this matter.

In [10], the author gave the sufficient and necessary geometrical conditions to transform a nonlinear system into a so-called output-dependent time scaling linear canonical form, while the author of [5] gave the dual geometrical conditions of [10].

In this paper, as an extension of [17], we will propose a method to deduce the geometrical conditions which are sufficient and necessary to guarantee the existence

of a local diffeomorphism $z = \phi(x)$ which transforms the locally observable dynamical system

$$\left\{ \begin{array}{l} \dot{x} = f(x), \\ y = h(x), \end{array} \right. \tag{1.1}$$

where $x \in U \subset \mathbb{R}^n$, $f : U \subset \mathbb{R}^n \to \mathbb{R}^n$ and $h : U \subset \mathbb{R}^n \to \mathbb{R}$ are sufficiently smooth, into the form

$$\left\{ \begin{array}{l} \dot{z} = A(y)z + \beta(y), \\ y = z_n = Cz, \end{array} \right. \tag{1.2}$$

where

$$A(y) = \begin{pmatrix} 0 & \cdots & 0 & 0 & 0 \\ \alpha_1(y) & \cdots & 0 & 0 & 0 \\ \vdots & \ddots & \ddots & \cdots & \vdots \\ 0 & \cdots & \alpha_{n-2}(y) & 0 & 0 \\ 0 & \cdots & 0 & \alpha_{n-1}(y) & 0 \end{pmatrix}, \ \beta(y) = \begin{pmatrix} \beta_1(y) \\ \beta_2(y) \\ \vdots \\ \beta_{n-1}(y) \\ \beta_n(y) \end{pmatrix},$$

and where $\alpha_i(y) \neq 0$ for $y \in]-a, a[$ and $a > 0$. This kind of linearization is called the single output-dependent observability (SODO) normal form.

For dynamical systems in the form of (1.2) we may, for example, apply the following high-gain observer [2]:

$$\left\{ \begin{array}{l} \dot{\hat{z}} = A(y)\hat{z} + \beta(y) - \Gamma^{-1}(y) R_\rho^{-1} C^T (C\hat{z} - y), \\ 0 = -\rho R_\rho - \bar{A}^T R_\rho - R_\rho \bar{A} + C^T C, \end{array} \right. \tag{1.3}$$

where $\Gamma(y)$ is the $n \times n$ diagonal matrix

$$\Gamma(y) = \operatorname{diag}\left[\prod_{i=1}^{n-1} \alpha_i(y), \prod_{i=2}^{n-1} \alpha_i(y), \ldots, \alpha_{n-1}(y), 1 \right],$$

and $\bar{A}$ is the $n \times n$ matrix defined as

$$\bar{A} = \begin{pmatrix} 0 & \cdots & 0 & 0 \\ 1 & \cdots & 0 & 0 \\ \vdots & \ddots & \vdots & \vdots \\ 0 & \cdots & 1 & 0 \end{pmatrix}.$$

Indeed, here the output of system (1.2) is considered as an input of (1.3). Setting $e = z - \hat{z}$, we see that the observation error can be obtained as follows:

$$\dot{e} = \left(A(y) - \Gamma^{-1}(y) R_\rho^{-1} C^T C \right) e.$$

The convergence of such an observer is proved in [2], and thus in section 4 we simply highlight the design of such an observer for systems in the form (1.2).

Moreover, we generalize our result to a class of systems with inputs. Then we discuss some useful corollaries in order to deal with affine systems and the so-called left invertibility problem.

This paper is organized as follows. The next section addresses notations and technical results which are key to proving our main result. In section 3, we present

our method to deduce the geometrical conditions for a nonlinear system without inputs in order to transform it into a SODO normal form. Section 4 is devoted to the generalization of our results to a class of systems with inputs. Also in section 4, some practical cases are studied, including the state affine systems and the left invertibility problem. Throughout this paper, examples are shown in order to highlight our theoretical results.

2. Notations and technical results. Throughout this article, we denote by $L_f^{i-1}h$ for $1 \leq i \leq n$ the $(i-1)$th Lie derivative of output h in the direction of f, and we set $\theta_i = dL_f^{i-1}h$ as its differential. Assume that system (1.1) is locally observable, and thus that $\theta = (\theta_1, \ldots, \theta_n)^T$ is a basis of the cotangent bundle T^*U of U. Then we also consider the vector field τ_1 defined in [12] as

$$\begin{cases} \theta_i(\tau_1) = 0 \text{ for } 1 \leq i \leq n-1, \\ \theta_n(\tau_1) = 1, \end{cases} \tag{2.1}$$

and by induction we define

$$\tau_k = (-1)^{k-1} ad_f^{k-1}(\tau_1) \text{ for } 2 \leq k \leq n. \tag{2.2}$$

It is clear that $\{\tau_1, \ldots, \tau_n\}$ is a basis of the tangent bundle TU of U.

Let us recall a famous result from [12].

THEOREM 2.1. *The following conditions are equivalent:*

(i) *There exist a diffeomorphism and an output injection which transform system* (1.1) *into normal form* (1.2) *with* $\alpha_k(y) = 1$ *for* $1 \leq k \leq n-1$.

(ii) $[\tau_i, \tau_j] = 0$ *for* $1 \leq i, j \leq n$.

If for some $1 \leq k \leq n-1$ the functions $\alpha_k(y)$ in the form (1.2) are not constant, then (ii) of Theorem 2.1 is not fulfilled. Consequently, the rest of this section is devoted to using $[\tau_i, \tau_n]$ in order to determine all the functions $\alpha_i(y)$ for $1 \leq i \leq n-1$.

LEMMA 2.2. *For a system in the form* (1.2) *we have for* $1 \leq k \leq n-1$,

$$\begin{aligned} \tau_k = {} & \frac{1}{\pi_k}\frac{\partial}{\partial z_k} + \left(A_{k-1}^k(z_n)\, z_{n-1} + \eta_{k-1}^k(z_n)\right)\frac{\partial}{\partial z_{k-1}} \\ & + \sum_{i=1}^{k-2}\left(A_i^k(z_n)\, z_{n-k+i} + \sum_{j=n-k+i+1}^{n-1}\sum_{l=j}^{n-1} T_{j,l}^k(z_n)\, z_j z_l\right)\frac{\partial}{\partial z_i} \\ & + \sum_{i=1}^{k-2}\left(\sum_{j=n-k+i+1}^{n}\eta_i^k(z_n)\, z_j + O_{z_n}^{[3]}(z_{n-k+i+1}, \ldots, z_{n-1})\right)\frac{\partial}{\partial z_i}, \end{aligned} \tag{2.3}$$

where $\pi_n = 1$ *and* $\pi_{k-1} = \pi_k \alpha_{k-1}$ *for* $2 \leq k \leq n$; $\eta_i^k(z_n)$ *and* $T_{j,l}^k(z_n)$ *are some smooth functions of* z_n; $O_{z_n}^{[3]}(z_{n-k+2}, \ldots, z_{n-1})$ *represents the residue higher than order* 2 *with a coefficient which is a function of* z_n; *and*

$$\begin{aligned} A_i^k(z_n) = {} & (-1)^{k-i+1} \\ & \times \left(S_{k-i,1}^k \frac{\pi_i'}{\pi_i^2} + \sum_{m=k-i+1}^{k-1} S_{k-i,m-k+i+1}^k \frac{\pi_{k-m}'}{\pi_{k-m}^2}\left(\prod_{j=k-i+1}^{m}\alpha_{k-j}\right)\right)\pi_{n-k+i}, \end{aligned} \tag{2.4}$$

where $S^k_{k-i,1}$ *and* $S^k_{k-i,m-k+i+1}$ *are defined as*

(2.5) $S^k_{j,1} = 1, S^k_{j,l} = S^{k-1}_{j-1,l} + S^{k-1}_{j,l-1}$ *for* $2 \le k \le n,\ 1 \le j \le k-1,$ *and* $1 \le l \le k-j,$

and $S^k_{0,l} = S^k_{i,0} = 0.$

Proof. For a system in the (1.2) form, (2.1) gives $\tau_1 = \frac{1}{\pi_1}\frac{\partial}{\partial z_1}$. Then we use (2.2) to obtain

$$\tau_2 = \frac{1}{\pi_2}\frac{\partial}{\partial z_2} + \left(\frac{\pi_1'}{\pi_1^2}\pi_{n-1}z_{n-1} + \frac{\pi_1'}{\pi_1^2}\beta_n\right)\frac{\partial}{\partial z_1},$$

and

$$\begin{aligned}\tau_3 = {} & \frac{1}{\pi_3}\frac{\partial}{\partial z_3} + \left(\left(\frac{\pi_1'}{\pi_1^2}\alpha_1 + \frac{\pi_2'}{\pi_2^2}\right)\pi_{n-1}z_{n-1} + \left(\frac{\pi_1'}{\pi_1^2}\alpha_1 + \frac{\pi_2'}{\pi_2^2}\right)\beta_n\right)\frac{\partial}{\partial z_2} \\ & - \left(\frac{\pi_1'}{\pi_1^2}\pi_{n-2}z_{n-2} + \left(\frac{\pi_1'}{\pi_1^2}\pi_{n-1}\right)'\pi_{n-1}z_{n-1}^2\right)\frac{\partial}{\partial z_1} \\ & - \left(\left(\left(\frac{\pi_1'}{\pi_1^2}\pi_{n-1}\right)'\beta_n + \pi_{n-1}\beta_n'\right)z_{n-1} + \frac{\pi_1'}{\pi_1^2}\pi_{n-1}\beta_{n-1} + \beta_n\beta_n'\right)\frac{\partial}{\partial z_1}.\end{aligned}$$

Then by an induction, for $3 < k \le n$, we get

$$\begin{aligned}\tau_k = {} & \frac{1}{\pi_k}\frac{\partial}{\partial z_k} + \left(A^k_{k-1}(z_n)\, z_{n-1} + \eta^k_{k-1}(z_n)\right)\frac{\partial}{\partial z_{k-1}} \\ & + \sum_{i=1}^{k-2}\left(A^k_i(z_n)\, z_{n-k+i} + \sum_{j=n-k+i+1}^{n-1}\sum_{l=j}^{n-1} T^k_{j,l}(z_n)\, z_j z_l\right)\frac{\partial}{\partial z_i} \\ & + \sum_{i=1}^{k-2}\left(\sum_{j=n-k+i+1}^{n}\eta^k_i(z_n)\, z_j + O^{[3]}_{z_n}(z_{n-k+i+1},\ldots,z_{n-1})\right)\frac{\partial}{\partial z_i},\end{aligned}$$

where

$$\begin{aligned}A^k_i(z_n) = {} & (-1)^{k-i+1} \\ & \times \left(S^k_{k-i,1}\frac{\pi_i'}{\pi_i^2} + \sum_{m=k-i+1}^{k-1} S^k_{k-i,m-k+i+1}\frac{\pi_{k-m}'}{\pi_{k-m}^2}\left(\prod_{j=k-i+1}^{m}\alpha_{k-j}\right)\right)\pi_{n-k+i},\end{aligned}$$

with the coefficients S^k_i given by the rule (2.5). ∎

In order to determine the $\alpha_i(y)$ for $1 \le i \le n-1$, we impose that

$$\frac{\partial}{\partial z_i}h \circ \phi^{-1} = \begin{cases} 0 \text{ for } 1 \le i \le n-1, \\ 1 \text{ when } i = n. \end{cases}$$

Now we are ready to state a set of differential equations which enables us to compute functions α_i for $1 \le i \le n-1$.

PROPOSITION 2.3. *If there exists a diffeomorphism which transforms system* (1.1) *into form* (1.2)*, then*

$$[\tau_k, \tau_n] = \lambda_k(y)\tau_k + G^{[1]}_n + R \text{ for } 1 \le i \le n-1,$$

where

$$G_n^{[1]} = \sum_{i=1}^{k-2} \left(\frac{1}{\pi_k} T_{k,n-k+i}^k z_{n-k+i} \right) \frac{\partial}{\partial z_i} + \frac{1}{\pi_k} T_{k,k}^k z_k \frac{\partial}{\partial z_{2k-n}},$$

and

$$R = \sum_{i=1}^{k-2} \left(\sum_{j=n-k+i+1}^{n} \bar{\eta}_i^k (z_n) + O_{z_n}^{[2]} (z_{n-k+i+1}, \ldots, z_{n-1}) \right) \frac{\partial}{\partial z_i}$$

and

$$\lambda_k(y) = \operatorname{diag}\{\delta_1^k(y), \ldots, \delta_i^k(y), \ldots, \delta_k^k(y), 0, \ldots, 0\} \text{ for } 1 \le i \le k-1, \tag{2.6}$$

where $\delta_k^k = A_k^n + \frac{\pi_k'}{\pi_k}$ *and* $\delta_i^k = A_i^n - A_{n-k+i}^n - \frac{(A_i^k)'}{A_i^k}$ *for* $1 \le i \le k-1$, *and* A_i^k *is given as in* (2.4).

Proof. According to (2.3), for $1 \le k \le n-1$ we have

$$\begin{aligned}
[\tau_k, \tau_n] = & \left(A_k^n + \frac{\pi_k'}{\pi_k} \right) \frac{1}{\pi_k} \frac{\partial}{\partial z_k} \\
& + \sum_{i=1}^{k-2} \left(\left(A_i^n - A_{n-k+i}^n - \frac{(A_i^k)'}{A_i^k} \right) A_i^k z_{n-k+i} + \frac{1}{\pi_k} T_{k,n-k+i}^k z_{n-k+i} \right) \frac{\partial}{\partial z_i} \\
& \quad + \frac{1}{\pi_k} T_{k,k}^k z_k \frac{\partial}{\partial z_{2k-n}} \\
& + \sum_{i=1}^{k-2} \left(\sum_{j=n-k+i+1}^{n} \bar{\eta}_i^k (z_n) + O_{z_n}^{[2]} (z_{n-k+i+1}, \ldots, z_{n-1}) \right) \frac{\partial}{\partial z_i}.
\end{aligned}$$

Set $\lambda_k(y) = \operatorname{diag}\{\delta_1^k(y), \ldots, \delta_i^k(y), \ldots, \delta_k^k(y), 0, \ldots, 0\}$, where $\delta_k^k = A_k^n + \frac{\pi_k'}{\pi_k}$ and $\delta_i^k = A_i^n - A_{n-k+i}^n - \frac{(A_i^k)'}{A_i^k}$ for $1 \le i \le k-1$. Then

$$[\tau_k, \tau_n] = \lambda_k(y) \tau_k + G_n^{[1]} + R. \qquad \square \tag{2.7}$$

Remark 1. In (2.7), $\lambda_k(y)$ could be uniquely determined since $G_n^{[1]}$ might be separated according to the coefficients of second-order terms in τ_n.

Finally, the following result enables us to determine all the functions $\alpha_i(y)$ for all $1 \le i \le n-1$.

PROPOSITION 2.4. *If there exists a diffeomorphism which transforms system* (1.1) *into form* (1.2), *then* $\alpha_i = \frac{\pi_i}{\pi_{i+1}}$ *for* $1 \le i \le n-2$, *and* $\alpha_{n-1} = \pi_{n-1}$, *where*

$$\begin{cases}
\pi_i = c_i \exp \left[\int \left(\exp \int \left(\delta_i^i - \delta_i^{n-1} - \delta_{i+1}^{i+1} \right) dy - \bar{B}_i^{n-1} \right) dy \right] \text{ for } 1 \le i \le n-2, \\
\pi_{n-1} = c_{n-1} \exp \left(\int \left(\dfrac{\delta_{n-1}^{n-1} - \bar{A}_{n-1}^n}{2} \right) dy \right),
\end{cases}$$

with $\bar{B}_1^k = 0$, *and for* $1 \le i, k \le n-1$, *and* $1 \le i \le n-1$,

$$\bar{B}_i^k = \sum_{m=k-i+1}^{k-1} S_{k-i,m-k+i+1}^k \frac{\pi'_{k-m}}{\pi_{k-m}}. \tag{2.8}$$

Proof. Define

$$B_i^k = \frac{\pi'_i}{\pi_i} + \bar{B}_i^k. \tag{2.9}$$

According to (2.4), for $1 \le i, k \le n-1$,

$$\frac{\left(A_i^k\right)'}{A_i^k} = \frac{\left(B_i^k\right)'}{B_i^k} - \frac{\pi'_i}{\pi_i} + \frac{\pi'_{n-k+i}}{\pi_{n-k+i}}.$$

As $\delta_k^k = A_k^n + \frac{\pi'_k}{\pi_k}$, hence we have

$$\delta_i^{n-1} = A_i^n - A_{1+i}^n - \frac{\left(B_i^{n-1}\right)'}{B_i^{n-1}} + \frac{\pi'_i}{\pi_i} - \frac{\pi'_{1+i}}{\pi_{1+i}} = \delta_i^i - \delta_{1+i}^{1+i} - \left(\frac{\pi'_i}{\pi_i} + \bar{B}_i^{n-1}\right)' \Big/ \left(\frac{\pi'_i}{\pi_i} + \bar{B}_i^{n-1}\right),$$

which yields

$$\pi_i = c_i \exp\left[\int \left(\exp \int \left(\delta_i^i - \delta_i^{n-1} - \delta_{1+i}^{1+i}\right) dy - \bar{B}_i^{n-1}\right) dy\right] \text{ for } 1 \le i \le n-2,$$

where $\bar{B}_i^{n-1}$ is defined as in (2.8) and $c_i \in R$, $c_i \neq 0$.

As $\delta_{n-1}^{n-1} = 2\frac{\pi'_{n-1}}{\pi_{n-1}} + \bar{A}_{n-1}^n$, where

$$\bar{A}_{n-1}^n = \sum_{m=2}^{n-1} S_{1,m}^n \frac{\pi'_{n-m}}{\pi_{n-m}},$$

then

$$\pi_{n-1} = c_{n-1} \exp\left(\int \left(\frac{\delta_{n-1}^{n-1} - \bar{A}_{n-1}^n}{2}\right) dy\right). \qquad \square$$

Remark 2. For system (1.2), if we set $\alpha_i = s(y)$ for $1 \le i \le n-1$, then

$$\delta_{n-1}^{n-1} = A_{n-1}^n + \frac{\pi'_{n-1}}{\pi_{n-1}} = 2\frac{\pi'_{n-1}}{\pi_{n-1}} + \sum_{i=2}^{n-1} \frac{\pi'_{n-i}}{\pi_{n-i}}.$$

By the definition of π_i for $1 \le i \le n-1$, we have $\pi_k = s^{n-k}$ for $1 \le k \le n-1$, and therefore

$$\delta_{n-1}^{n-1} = 2\frac{s'}{s} + \sum_{i=2}^{n-1} i\frac{s'}{s} = l_n \frac{s'}{s},$$

where $l_n = \frac{n(n-1)}{2} + 1$. In such a way, we obtain the same result as the one stated in [10].

3. Main result. If there exists a diffeomorphism which transforms system (1.1) into form (1.2), then (2.8) of Proposition 2.4 gives all α_i for $1 \leq i \leq n-1$. Therefore, let us consider a new family of vector fields defined as follows:

$$\widetilde{\tau}_1 = \pi_1 \tau_1 \text{ and } \widetilde{\tau}_{i+1} = \frac{1}{\alpha_i}[\widetilde{\tau}_i, f] \text{ for } 1 \leq i \leq n-1. \tag{3.1}$$

Set

$$\theta(\widetilde{\tau}_1, \cdots, \widetilde{\tau}_n) = \begin{pmatrix} 0 & 0 & \cdots & 0 & 1 \\ 0 & \vdots & \cdots & \pi_{n-1} & \widetilde{l}_{2,n} \\ \vdots & \ldots & \ddots & \ldots & \vdots \\ \vdots & \pi_2 & \cdots & \cdots & \vdots \\ \pi_1 & \widetilde{l}_{n,2} & \cdots & \cdots & \widetilde{l}_{n,n} \end{pmatrix} := \widetilde{\Lambda},$$

where

$$\widetilde{l}_{k,j} = \theta_k(\widetilde{\tau}_j) \text{ for } 2 \leq k \leq n \text{ and } n-k+2 \leq j \leq n.$$

Consider the R^n-valued form ω,

$$\omega = \widetilde{\Lambda}^{-1}\theta := (\omega_1, \omega_2, \ldots, \omega_n)^T, \tag{3.2}$$

where, for $1 \leq s \leq n$, we have

$$\omega_s = \sum_{m=1}^{n} r_{s,m}\theta_m. \tag{3.3}$$

Then the following algorithm gives all the components of ω.

ALGORITHM 1.

For $1 \leq j \leq n$,

$$r_{n,j} = \cdots = r_{n-j+2,j} = 0 \text{ and } r_{n-j+1,j} = 1.$$

For $2 \leq k \leq n-1$ *and* $1 \leq j \leq n$,

$$r_{n-k,j} = -\sum_{i=2}^{k} \widetilde{l}_{k,n-k+i-(j-1)} r_{n-k+i-(j-1),j}.$$

Then (3.3) *becomes*

$$\omega_s = \sum_{m=1}^{n-s+1} r_{s,m}\theta_m.$$

THEOREM 3.1. *The following conditions are equivalent:*

(1) *There exists a diffeomorphism which transforms system* (1.1) *into a SODO normal form* (1.2).

(2) *There exists a family of functions* $\alpha_i(y)$ *for* $1 \leq i \leq n-1$ *such that the family of vector fields* $\widetilde{\tau}_i$ *for* $1 \leq i \leq n$ *defined in* (3.1) *satisfies the following commutativity conditions:*

$$[\widetilde{\tau}_i, \widetilde{\tau}_j] = 0 \text{ for } 1 \leq i, j \leq n. \tag{3.4}$$

(3) *There exists a family of functions* $\alpha_i(y)$ *for* $1 \leq i \leq n-1$ *such that the* R^n*-valued form* ω *defined in* (3.2) *satisfies the following condition:*

$$d\omega = 0. \tag{3.5}$$

Proof. Assume that there exists a diffeomorphism which transforms system (1.1) into form (1.2). Then we compute $\alpha_i(y)$ for $1 \leq i \leq n-1$ from (2.8) in Proposition 2.4. Thus, it is easy to show that $\tau_1 = \frac{1}{\pi_1}\frac{\partial}{\partial z_1}$, which yields that $\widetilde{\tau}_1 = \frac{\partial}{\partial z_1}$, and then by construction we obtain $\widetilde{\tau}_i = \frac{\partial}{\partial z_i}$ for $2 \leq i \leq n$. Consequently, we have $[\widetilde{\tau}_i, \widetilde{\tau}_j] = 0$ for $1 \leq i, j \leq n$.

Reciprocally, assume that there exists $\alpha_i > 0$ for $1 \leq i \leq n-1$ such that $[\widetilde{\tau}_i, \widetilde{\tau}_j] = 0$ for $1 \leq i, j \leq n$. Then we know (see [8], [15]) that we can find a local diffeomorphism $\phi = z$ such that

$$\phi_*(\widetilde{\tau}_i) = \frac{\partial}{\partial z_i}.$$

As $\phi_*(\widetilde{\tau}_i) = \frac{\partial}{\partial z_i}$ is constant, hence we have

$$\frac{\partial}{\partial z_i}\phi_*(f) = \phi_*\left([\widetilde{\tau}_i, f]\right) = \alpha_i \phi_*(\widetilde{\tau}_{i+1}) = \alpha_i \frac{\partial}{\partial z_{i+1}},$$

and thus $\frac{\partial}{\partial z_i}\phi_*(f) = \alpha_i \frac{\partial}{\partial z_{i+1}}$ for $1 \leq i \leq n-1$. Consequently, by integration we obtain $\phi_*(f) = A(y)z + \beta(y)$.

Moreover, as $dh \circ \widetilde{\tau}_i = 0$ for $1 \leq i \leq n-1$ and $dh \circ \widetilde{\tau}_n = 1$, we obtain $h \circ \phi^{-1} = z_n$.

Finally, in order to prove that in Theorem 3.1 condition (2) is equivalent to condition (3), it is sufficient to prove that (3.4) is equivalent to (3.5).

Recall that for any two vector fields X, Y, we have

$$d\omega(X, Y) = L_X\left(\omega(Y)\right) - L_Y\left(\omega(X)\right) - \omega([X, Y]).$$

Setting $X = \widetilde{\tau}_i$ and $Y = \widetilde{\tau}_j$, we obtain

$$d\omega(\widetilde{\tau}_i, \widetilde{\tau}_j) = L_{\widetilde{\tau}_i}\omega(\widetilde{\tau}_j) - L_{\widetilde{\tau}_j}\omega(\widetilde{\tau}_i) - \omega([\widetilde{\tau}_i, \widetilde{\tau}_j]).$$

As $\omega(\widetilde{\tau}_j)$ and $\omega(\widetilde{\tau}_i)$ are constant, then we have

$$d\omega(\widetilde{\tau}_i, \widetilde{\tau}_j) = -\omega([\widetilde{\tau}_i, \widetilde{\tau}_j]).$$

Because ω is an isomorphism and $(\widetilde{\tau}_i)_{1 \leq i \leq n}$ is a basis of TU, then (3.4) is equivalent to (3.5). ∎

Remark 3. (i) The R^n-valued form ω can be viewed as an isomorphism $TU^n \to U \times \mathbb{R}^n$ which brings each $\widetilde{\tau}_i$ to the canonical vector basis $\frac{\partial}{\partial z_I}$. Moreover, $d\omega = 0$ means that there is a local diffeomorphism $\phi : U \to U$ such that ω is the tangent map of ϕ.

(ii) The diffeomorphism $\phi(x) = z$ is determined by $\omega = \phi_*(x)$, which can be given locally as

$$z_i = \phi_i(x) = \int_\gamma \omega_i + \phi_i(0) \text{ for } 1 \leq i \leq n,$$

where γ is a smooth path from 0 to x lying in a neighborhood $V_0 \subseteq U$ of 0.

The following simple example is studied in order to illustrate Theorem 3.1.

Example 1. Let us consider the following system

$$\left\{\begin{array}{l} \dot{x}_1 = \dfrac{\gamma(y)}{1+x_4}x_1x_3, \\ \dot{x}_2 = \dfrac{\beta(y)}{1+x_4}x_1, \\ \dot{x}_3 = \mu(y)x_2, \\ \dot{x}_4 = \gamma(y)x_3, \\ y = x_4, \end{array}\right. \tag{3.6}$$

which gives

$$\left\{\begin{array}{l} \theta_1 = dx_4, \\ \theta_2 = \gamma dx_3 + \gamma' x_3 dx_4, \\ \theta_3 = \gamma\mu dx_2 + 2\gamma'\gamma x_3 dx_3 + \left((\gamma\mu)' x_2 + (\gamma'\gamma)' x_3^2\right) dx_4, \\ \theta_4 = \gamma\mu\dfrac{\beta}{1+x_4}dx_1 + \left(2\gamma'\mu + (\gamma\mu)'\right)\gamma x_3 dx_2 \\ \qquad + \left(2\gamma'\gamma\mu x_2 + \gamma\,(\gamma\mu)' x_2 + 3\gamma\,(\gamma'\gamma)' x_3^2\right) dx_3 + O^{[2]}\,(x_1,\ x_2,\ x_3)\,\theta_1. \end{array}\right.$$

Then we have $\tau_1 = \frac{1+x_4}{\gamma\mu\beta}\frac{\partial}{\partial x_1}$. Consequently, we obtain

$$\left\{\begin{array}{l} \tau_2 = \frac{1}{\gamma\mu}\frac{\partial}{\partial x_2} + (1+x_4)\,\gamma\frac{(\gamma\mu\beta)'}{(\gamma\mu\beta)^2}x_3\frac{\partial}{\partial x_1}, \\ \tau_3 = \frac{1}{\gamma}\frac{\partial}{\partial x_3} - \gamma\mu\,(1+x_4)\,\frac{(\gamma\mu\beta)'}{(\gamma\mu\beta)^2}x_3\frac{\partial}{\partial x_2} + \left(\frac{(\gamma\mu)'}{(\gamma\mu)^2} + \beta\frac{(\gamma\mu\beta)'}{(\gamma\mu\beta)^2}\right)\gamma x_2\frac{\partial}{\partial x_1} + R_{1,3}\tau_1, \\ \tau_4 = \frac{\partial}{\partial x_4} + \left(\frac{\gamma'}{\gamma} + \frac{(\gamma\mu)'}{(\gamma\mu)} + \frac{(\gamma\mu\beta)'}{(\gamma\mu\beta)}\right)x_3\frac{\partial}{\partial x_3} - \left(\frac{(\gamma\mu)'}{(\gamma\mu)} + 2\frac{(\gamma\mu\beta)'}{(\gamma\mu\beta)}\right)x_2\frac{\partial}{\partial x_2} \\ \qquad + \left(\frac{1}{1+x_4} + \frac{(\gamma\mu\beta)'}{\gamma\mu\beta}\right)x_1\frac{\partial}{\partial x_1} + R_{1,4}\,(z_3,z_2)\,\tau_1 + R_{2,3}(z_3^2)\tau_2. \end{array}\right.$$

A straightforward computation gives

$$\begin{aligned} &\delta_1^1 = 2\frac{(\gamma\mu\beta)'}{\gamma\mu\beta},\ \delta_2^2 = -2\frac{(\gamma\mu\beta)'}{\gamma\mu\beta},\ \delta_3^3 = 2\frac{\gamma'}{\gamma} + \frac{(\gamma\mu)'}{\gamma\mu} + \frac{(\gamma\mu\beta)'}{\gamma\mu\beta}, \\ &\delta_1^3 = 4\frac{(\gamma\mu\beta)'}{(\gamma\mu\beta)} - \left[\frac{(\gamma\mu\beta)'}{(\gamma\mu\beta)}\right]' \Big/ \left[\frac{(\gamma\mu\beta)'}{(\gamma\mu\beta)}\right], \\ &\delta_2^3 = -\left(2\frac{\gamma'}{\gamma} + \frac{(\gamma\mu)'}{\gamma\mu} + 3\frac{(\gamma\mu\beta)'}{\gamma\mu\beta}\right) - \left(\frac{(\gamma\mu)'}{\gamma\mu} + \frac{(\gamma\mu\beta)'}{\gamma\mu\beta}\right)' \Big/ \left(\frac{(\gamma\mu)'}{\gamma\mu} + \frac{(\gamma\mu\beta)'}{\gamma\mu\beta}\right). \end{aligned}$$

According to (2.8) in Proposition 2.4, we obtain

$$\left\{\begin{array}{l} \pi_1 = c_1\exp\left[\int\left(\exp\int\left(\delta_1^1 - \delta_1^3 - \delta_2^2\right)dy\right)dy\right] = c_1\gamma\mu\beta, \\ \pi_2 = c_2\exp\left[\int\left(\exp\int\left(\delta_2^2 - \delta_2^3 - \delta_3^3\right)dy - \dfrac{\pi_1'}{\pi_1}\right)dy\right] = c_2\gamma\mu, \\ \pi_3 = c_3\exp\left(\int\left(\dfrac{1}{2}\left(\delta_3^3 - \dfrac{\pi_1'}{\pi_1} - \dfrac{\pi_2'}{\pi_2}\right)\right)dy\right) = c_3\gamma. \end{array}\right.$$

Thus $\alpha_1 = \frac{\pi_1}{\pi_2} = \frac{c_1}{c_2}\beta$, $\alpha_2 = \frac{\pi_2}{\pi_3} = \frac{c_2}{c_3}\mu$, and $\alpha_3 = \frac{\pi_3}{\pi_4} = c_3\gamma$, so the new vector fields are

$$\widetilde{\tau}_1 = c_1\,(1+x_4)\,\frac{\partial}{\partial x_1},\ \widetilde{\tau}_2 = c_2\frac{\partial}{\partial x_2},\ \widetilde{\tau}_3 = c_3\frac{\partial}{\partial x_3},\ \widetilde{\tau}_4 = \frac{\partial}{\partial x_4} + \frac{x_1}{1+x_4}\frac{\partial}{\partial x_1}.$$

It is clear that $[\widetilde{\tau}_i, \widetilde{\tau}_j] = 0$ for all $1 \leq i, j \leq 4$. Therefore, according to Theorem 3.1, system (3.6) can be transformed into SODO normal form (1.2).

Moreover, as

$$\widetilde{\Lambda} = \begin{pmatrix} 0 & 0 & 0 & 1 \\ 0 & 0 & \gamma & \gamma' x_3 \\ 0 & \gamma\mu & 2\gamma'\gamma x_3 & (\gamma\mu)' x_2 + 2(\gamma'\gamma)' x_3^2 \\ \gamma\mu\beta & (2\gamma'\mu + (\gamma\mu')) \gamma x_3 & 2\gamma'\gamma\mu x_2 + \gamma(\gamma\mu)' x_2 + 6\gamma(\gamma'\gamma)' x_3^2 & \gamma \frac{x_1}{(1+x_4)^2} \mu\beta + R \end{pmatrix},$$

where $R = O^{[2]}_{x_4}(x_1,\ x_2,\ x_3)$, a straightforward computation gives

$$\omega = \widetilde{\Lambda}^{-1}\theta = \begin{pmatrix} d\dfrac{x_1}{c_1(1+x_4)}, & d\left(\dfrac{x_2}{c_2}\right), & d\left(\dfrac{x_3}{c_3}\right), & dx_4 \end{pmatrix}^T.$$

As $\omega = d\phi$, thus the diffeomorphism which transforms system (3.6) into SODO normal form (1.2) is

$$\phi(x) = z = \left(\frac{x_1}{c_1(1+x_4)}, \frac{x_2}{c_2}, \frac{x_3}{c_3}, x_4\right)^T,$$

with which system (3.6) could be transformed into

$$\begin{cases} \dot{z}_1 = 0, \\ \dot{z}_2 = \dfrac{c_1}{c_2}\beta(y) z_1, \\ \dot{z}_3 = \dfrac{c_2}{c_3}\mu(y) z_2, \\ \dot{z}_4 = c_3\gamma(y) z_3. \end{cases}$$

So far in this paper, we have considered only systems without inputs. The next section is devoted to systems that are also driven by an input term.

4. Extension to systems with inputs. Consider a system with inputs in the form

$$\begin{cases} \dot{x} = f(x) + g(x,u), \\ y = h(x), \end{cases} \tag{4.1}$$

where $x \in U \subset \mathbb{R}^n$, $f : U \subset \mathbb{R}^n \to \mathbb{R}^n$, $g : U \times \mathbb{R}^m \to \mathbb{R}^n$, and $h : U \subset \mathbb{R}^n \to \mathbb{R}$ are analytic functions and where $g(x,0) = 0$ for $x \in U$.

For system (4.1), the SODO normal form along its output trajectory $y(t)$ is

$$\begin{cases} \dot{z} = A(y)z + \beta(y) + \eta(y,u), \\ y = z_n = Cz, \end{cases} \tag{4.2}$$

where $A(y)$ and $\beta(y)$ are given as in (1.2), and $\eta(y,u) = [\ \eta_1(y,u),\ \eta_2(y,u), \ldots, \eta_n(y,u)\ ]^T$.

THEOREM 4.1. *System* (4.1) *can be transformed into SODO normal form* (4.2) *by a diffeomorphism if and only if*

(i) *one of the conditions in Theorem* 3.1 *is fulfilled.*

(ii) $[g, \widetilde{\tau}_i] = 0$ *for* $1 \leq i \leq n-1$.

Proof. From Theorem 3.1, we can state that there exists a diffeomorphism ϕ such that

$$\phi_*(f) = A(y)z + \beta(y).$$

For $1 \le i \le n-1$, because $\phi_*(\widetilde{\tau}_i) = \frac{\partial}{\partial z_i}$ is constant, hence we have

$$\frac{\partial}{\partial z_i}\phi_*(g) = \phi_*([g, \widetilde{\tau}_i]) = 0.$$

Therefore $\phi_*(g) = \eta(y,u)$. Thus, we obtain the form (4.2). □

Remark 4. If $g(x,u) = g_1(x)u_1 + \cdots + g_m(x)u_m$, and both conditions (i) and (ii) of Theorem 4.1 are fulfilled, then

$$\eta(y,u) = B_1(y)u_1 + \cdots + B_m(y)u_m.$$

Let us now study some special cases of the term $\eta(y,u)$.

COROLLARY 4.2. *Assume that conditions* (i) *and* (ii) *of Theorem* 4.1 *are fulfilled.*
(a) *If* $[g, \widetilde{\tau}_n] = 0$, *then*

$$\eta(y,u) = \eta(u).$$

(b) *If* $g(x,u) = g_1(x)u_1 + \cdots + g_m(x)u_m$ *and*

$$[g_k, \widetilde{\tau}_i] = 0 \text{ for } 1 \le i \le n \text{ and } 1 \le k \le m,$$

then

$$\eta(y,u) = B_1u_1 + \cdots + B_mu_m,$$

where B_i *are constant vector fields.*

Example 2. Let us consider the system

$$\begin{cases} \dot{x}_1 = \dfrac{\gamma(y)}{1+x_3}x_1x_2 + \dfrac{x_1}{1+x_3}u, \\ \dot{x}_2 = \dfrac{\mu(y)}{1+x_3}x_1, \\ \dot{x}_3 = \gamma(y)x_2 + u, \\ y = x_3. \end{cases} \tag{4.3}$$

A straightforward computation gives

$$\tau_1 = \frac{1+x_3}{\gamma\mu}\frac{\partial}{\partial x_1},\ \tau_2 = \frac{1}{\gamma}\frac{\partial}{\partial x_2} + \left((1+x_3)\frac{(\gamma\mu)'}{\gamma\mu^2}\right)x_2\frac{\partial}{\partial x_1},$$
$$\tau_3 = \frac{\partial}{\partial x_3} + \left(\frac{(\mu\gamma)'}{(\mu\gamma)} + \frac{\gamma'}{\gamma}\right)x_2\frac{\partial}{\partial x_2} + \left(\frac{1}{1+x_3} - \frac{(\gamma\mu)'}{\gamma\mu}\right)x_1\frac{\partial}{\partial x_1}.$$

Then we obtain

$$\delta_1^1 = 0,\ \delta_2^2 = 2\frac{\gamma'}{\gamma} + \frac{(\mu\gamma)'}{(\mu\gamma)},\ \delta_1^2 = -\frac{(\mu\gamma)'}{(\mu\gamma)} - 2\frac{\gamma'}{\gamma} - \left(\frac{(\mu\gamma)'}{(\mu\gamma)}\right)' \Big/ \left(\frac{(\mu\gamma)'}{(\mu\gamma)}\right).$$

Then according to (2.8), we have

$$\begin{cases} \pi_1 = c_1 \exp\left[\int \left(\exp \int \left(\delta_1^1 - \delta_1^2 - \delta_2^2\right) dy\right) dy\right] = c_1\gamma\mu, \\ \pi_2 = c_2 \exp\left(\int \left(\frac{1}{2}\left(\delta_2^2 - \frac{\pi_1'}{\pi_1}\right)\right) dy\right) = c_2\gamma, \end{cases}$$

which yields $\alpha_1(y) = \frac{c_1}{c_2}\mu(y)$ and $\alpha_2(y) = c_2\gamma(y)$. Therefore, we obtain $\widetilde{\tau}_1 = c_1(1+x_3)\frac{\partial}{\partial x_1}$, $\widetilde{\tau}_2 = c_2\frac{\partial}{\partial x_2}$, and $\widetilde{\tau}_3 = \frac{\partial}{\partial x_3} + \frac{x_1}{1+x_3}\frac{\partial}{\partial x_1}$.

As $g = \frac{x_1}{1+x_3}\frac{\partial}{\partial x_1} + \frac{\partial}{\partial x_3} = \widetilde{\tau}_3$, then $[g, \widetilde{\tau}_1] = [g, \widetilde{\tau}_2] = 0$, and system (4.3) is transformed into

$$\begin{cases} \dot{z}_1 = 0, \\ \dot{z}_2 = \dfrac{c_1}{c_2}\mu(y)\, z_1, \\ \dot{z}_3 = c_2\gamma(y)\, z_2 + u, \\ y = z_3 \end{cases} \tag{4.4}$$

by the diffeomorphism

$$\phi(x) = z = \left(\frac{x_1}{c_1(1+x_3)}, \frac{x_2}{c_2}, x_3\right)^T.$$

Following the proposed high-gain observer in the form (1.3), the corresponding observer for system (4.4) can be designed as follows:

$$\begin{cases} \dot{\hat{z}}_1 = -\dfrac{\rho^3}{\gamma\mu}(\hat{z}_3 - z_3), \\ \dot{\hat{z}}_2 = \dfrac{c_1}{c_2}\mu(y)\,\hat{z}_1 - 3\dfrac{\rho^2}{\gamma}(\hat{z}_3 - z_3), \\ \dot{\hat{z}}_3 = c_2\gamma(y)\,\hat{z}_2 - 3\rho(\hat{z}_3 - z_3) + u, \end{cases}$$

where ρ is the tunable gain. For a more specific, yet simple, simulation, choose $c_1 = c_2 = 1$, $u(t) = 1$, $\mu(y) = 1+y^2$, and $\gamma(y) = 2+\cos(y)$. Its simulation results are presented in Figures 4.1, 4.2, and 4.3 which, respectively, present the convergences of the system's states and their estimations.

In addition, in order to solve the left invertibility problem, the observability matching condition (OMC) for system (4.1) with $m = 1$ is

$$\begin{cases} L_g L_f^{i-1} h = 0 \ \forall x \in U,\ 1 \le i \le n-1, \\ L_g L_f^{n-1} h \neq 0. \end{cases}$$

COROLLARY 4.3. *Assume conditions* (i) *and* (ii) *of Theorem* 4.1 *are fulfilled and that the OMC is verified. Then*

$$\eta(y,u) = [\eta_1(y,u),\, 0,\, \ldots,\, 0]^T.$$

Remark 5. The OMC for system (4.1) with $m = 1$ is equivalent to $g \in span\{\widetilde{\tau}_1\}$.

We give another example in order to highlight Corollary 4.3.

Example 3. Consider the system

$$\begin{cases} \dot{x}_1 = u, \\ \dot{x}_2 = \mu(y)x_1 + \mu(y)x_1^2 + \dfrac{x_2}{1+x_1}u, \\ \dot{x}_3 = \gamma(y)\dfrac{x_2}{1+x_1}, \\ y = x_3. \end{cases} \tag{4.5}$$

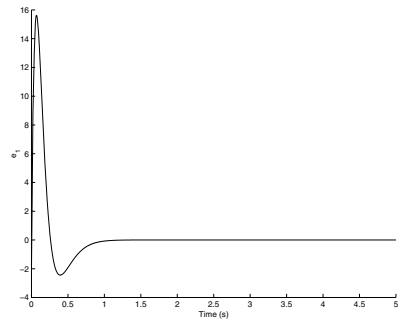

FIG. 4.1. *Observation error between* z_1 *and* $\hat{z}_1$.

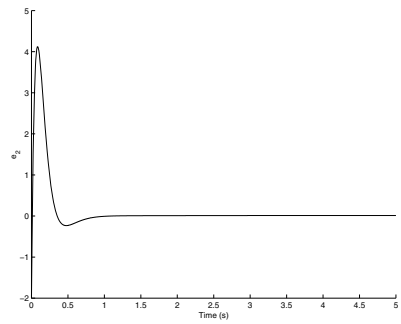

FIG. 4.2. *Observation error between* z_2 *and* $\hat{z}_2$.

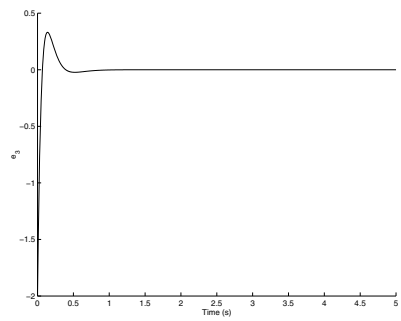

FIG. 4.3. *Observation error between* z_3 *and* $\hat{z}_3$.

A straightforward computation gives $\tau_1 = \frac{1}{\gamma\mu}\frac{\partial}{\partial x_1} + \frac{1}{\gamma\mu}\frac{x_2}{1+x_1}\frac{\partial}{\partial x_2}$. From (2.8) in Proposition 2.4, we can determine $\alpha_1(y) = \frac{c_1}{c_2}\mu(y)$ and $\alpha_2(y) = c_2\gamma(y)$. Thus, we have $\widetilde{\tau}_1 = c_1\frac{\partial}{\partial x_1} + c_1\frac{x_2}{1+x_1}\frac{\partial}{\partial x_2}$, $\widetilde{\tau}_2 = c_2(1+x_1)\frac{\partial}{\partial x_2}$, and $\widetilde{\tau}_3 = \frac{\partial}{\partial x_3}$.

As $g \in span\{\widetilde{\tau}_1\}$, then the OMC condition is fulfilled, therefore system (4.5) could be transformed by the diffeomorphism

$$\phi(x) = z = \left(\frac{x_1}{c_1}, \frac{x_2}{c_2(1+x_1)}, x_3\right)^T$$

into

$$\begin{cases} \dot{z}_1 = \dfrac{u}{c_1}, \\ \dot{z}_2 = \dfrac{c_1}{c_2}\mu(y)\, z_1, \\ \dot{z}_3 = c_2\gamma(y)\, z_2, \\ y = z_3. \end{cases}$$

5. Conclusion. In this paper, we have put forward the geometrical conditions which allow us to determine whether a nonlinear system can be transformed locally into the SODO normal form by means of a diffeomorphism and of an output injection. In our main result we state two equivalent ways to check these conditions. In the first one, we used Lie brackets commutativity, and the second one was based on the one forms. Moreover, an extension of our results is stated for a class of nonlinear systems with inputs.

Acknowledgments. We are deeply grateful to the anonymous reviewers for valuable comments and helpful suggestions that enabled us to improve the presentation of this paper. We are also deeply grateful to Professor Vincent Maki for many corrections.

CONTROLLABILITY OF A CLASS OF NEWTONIAN FILTRATION EQUATIONS WITH CONTROL AND STATE CONSTRAINTS*

XU LIU† AND HANG GAO‡

Abstract. This paper addresses a study of the controllability of a class of Newtonian filtration equations, with nonnegative constraints on the control and state variables. When the control enters the system through the whole domain where the equation evolves, we characterize the set of nonnegative targets which are approximately controllable at any time $T > 0$. The proof combines the Fenchel–Rockafellar duality theory and a fixed point argument. When the control is restricted to be active in a proper open subset of the whole domain, we prove a negative controllability result by means of a localization technique which reflects the underlying obstruction phenomenon in the system.

Key words. Newtonian filtration equation, approximate controllability, Fenchel–Rockafellar duality theory, obstruction phenomenon

1. Introduction and main results.

Consider the following controlled system governed by a Newtonian filtration equation:

$$\begin{cases} y_t(x,t) - (y^m)_{xx}(x,t) = \chi_\omega u(x,t), & (x,t) \in Q, \\ y(-1,t) = y(1,t) = 0, & t \in (0,T), \\ y(x,0) = y_0(x), & x \in (-1,1), \end{cases} \tag{1.1}$$

where $Q = (-1,1) \times (0,T)$, $1 < m < 3$, χ_ω denotes the characteristic function of a domain $\omega \subseteq (-1,1)$, u is a nonnegative control function, and y_0 is a given initial value.

Newtonian filtration equations, as an important class of quasilinear degenerate parabolic equations, come from a variety of diffusion phenomena as a net action of matters. They are suggested as mathematical models of physical problems in many fields such as filtration, phase transition, biochemistry, and dynamics of biological groups. For example, for a homogeneous, isotropic, and rigid porous medium filled with a fluid, the flow is governed by the continuity equation

$$\theta_t + \operatorname{div} \overrightarrow{V} = 0$$

and Darcy's law

$$\overrightarrow{V} = -K(\theta)\nabla\varphi,$$

where θ denotes the volumetric moisture content, $\overrightarrow{V}$ the macroscopic velocity of the fluid, $K(\theta)$ the hydraulic conductivity, and φ the total potential. If absorption and

chemical, osmotic, and thermal effects are ignored, then, after a necessary change of variables, for horizontal flow, we have

$$\theta_t = \triangle \theta^m.$$

We shall focus our attention on the simple case—the one-dimensional case. Note that system (1.1) is degenerate whenever $m > 1$. Compared to linear equations and quasilinear equations without degeneracy, such equations, to a certain extent, reflect more exactly the physical reality. Indeed, when $m = 1$, (1.1) becomes the heat equation. In this case the solution possesses the property of infinite speed of propagation of disturbances; i.e., any nontrivial nonnegative initial data implies the positivity of the solution after the initial time. If $m > 1$, (1.1) is degenerate. In this case, the solution possesses the property of finite speed of propagation of disturbances. On the other hand, the appearance of degeneracy makes the problem more difficult. Therefore, in the last four decades the study in this direction has attracted a large number of researchers, and great progress has been made (see [1], [4], [9], [21], and the references cited therein).

The goal of this paper is to study the controllability and noncontrollability of system (1.1). Many papers have been devoted to the controllability of semilinear nondegenerate parabolic systems without control/state constraints. We mention here an incomplete list of related works: [2], [10], [11], [13], [17], [19], [20], and the rich references cited therein. However, as far as we know, only a few papers have been published on the controllability of degenerate parabolic equations. In [5] and [6], the authors study the null controllability of linear degenerate parabolic equations. In [14] and [15], the authors discuss the approximate controllability of quasilinear degenerate p-Laplacian equations. In [8] the authors prove an obstruction phenomenon, which implies that system (1.1) with $0 < m < 1$ is not approximately controllable under a local control at any time. We notice that in the above mentioned papers, the authors do not put any constraint on the control or state variables. Meanwhile, very little is known about the controllability of parabolic equations with control/state constraints. In [18], the constrained controllability problem for the abstract evolution equation is studied. In [23], the author establishes a criterion for approximate controllability of a heat equation under a nonnegative step boundary control function. In [7], the authors prove that the semilinear parabolic equation is approximately controllable with a nonnegative constraint on the control, provided that the nonlinearity is a nondecreasing continuous function. The authors prove this result by means of a cancellation technique, which consists in modifying the control associated to the linear case by means of a perturbation which cancels the nonlinearity appearing in the equation and guarantees the nonnegativity of control function.

In this paper we shall discuss the controllability and noncontrollability with nonnegative constraints on the control and state variables for system (1.1) with $1 < m < 3$, which is a degenerate quasilinear parabolic equation. To the best of our knowledge, no reference has addressed this controllability problem before. In contrast to the case of unconstrained controllability problems, constraint on the control introduces essential difficulties, even if the control acts in the whole domain. Indeed, it is well known that in the case without constraint, for most linear systems, the approximate controllability and null controllability may hold simultaneously. However, in [18] the authors point out that this is not true for the constrained case, even for linear evolution systems.

In [7], by virtue of the monotonicity of the nonlinearity, the key point in deriving the desired controllability is to show the existence of a nonnegative control for

the linearized system. However, it seems that this technique does not work for our quasilinear problem. In fact, since the nonlinearity $(y^m)_{xx}$ of system (1.1) has no monotonicity, we could not construct a nonnegative control function directly as in [7]. Instead, we shall make use of the Fenchel–Rockafellar duality theory to represent the nonnegative control with minimal energy for the linearized system and further solve our quasilinear controllability problem by means of a fixed point argument. Also, since the principal part of system (1.1) is nonlinear, we cannot use the method developed in [11] and [7] to prove the uniform boundedness of control functions, which is critical when employing the fixed point method (see Remark 3.1). Rather, following [12], we shall use two functionals and suitable key estimates for the solution of the linearized system to establish the desired uniform boundedness. On the other hand, in order to show a negative controllability result for system (1.1), we shall prove an obstruction phenomenon for this system by means of a localization technique.

In order to state our main results, we need to introduce some definitions. First, due to the degeneracy of system (1.1), we are interested only in the generalized solution of system (1.1) in the following sense.

DEFINITION 1.1. *A function y is called a nonnegative generalized solution of system* (1.1) *if*

(1) $y \geq 0$ *a.e. in* Q, $y \in C([0,T]; L^2(-1,1))$, *and* $y^m \in L^1(Q)$, *and*

(2) *for any* $\varphi \in C^2(\overline{Q})$ *with* $\varphi(-1,t) = \varphi(1,t) = \varphi(x,T) = 0$, *the following equality holds:*

$$\iint_Q [y(x,t)\varphi_t(x,t) + y^m(x,t)\varphi_{xx}(x,t)]dxdt + \iint_Q \chi_\omega u(x,t)\varphi(x,t)dxdt = -\int_{-1}^{1} y_0(x)\varphi(x,0)dx.$$

It is well known that, for each $y_0 \in L^2(-1,1)$ with $y_0 \geq 0$ a.e. in $(-1,1)$ and $u \in L^2(Q)$ with $u \geq 0$ a.e. in Q, system (1.1) admits one and only one nonnegative generalized solution in the sense of Definition 1.1 (see [1], [4], and [9]). Moreover, the unique generalized solution y satisfies

$$\|y\|_{C([0,T];L^2(-1,1))} \leq \|y_0\|_{L^2(-1,1)} + \int_0^T \|u(\cdot,t)\|_{L^2(-1,1)}dt.$$

Next, set

$$L^2_+(-1,1) = \{\xi \in L^2(-1,1);\ \xi \geq 0 \text{ a.e. in } (-1,1)\},$$
$$L^2_+(Q) = \{\xi \in L^2(Q);\ \xi \geq 0 \text{ a.e. in } Q\},$$
$$L^2_+(-1,1) + Y_d = \{y + Y_d;\ y \in L^2_+(-1,1)\},$$

where $Y_d \in L^2(-1,1)$ is the value at time T of the solution of system (1.1) with $u = 0$. We need the following notions.

DEFINITION 1.2. *Target $y_1 \in L^2_+(-1,1)$ is said to be approximately controllable with a nonnegative constraint on the control if for each $\varepsilon > 0$ and $y_0 \in L^\infty(-1,1)$ with $y_0 \geq 0$ a.e. in $(-1,1)$, there exists a nonnegative control function $u \in L^2_+(Q)$ such that the corresponding solution y of system* (1.1) *satisfies*

$$\|y(\cdot,T;u) - y_1\|_{L^2(-1,1)} < \varepsilon.$$

DEFINITION 1.3. *System* (1.1) *is said to be approximately controllable with a nonnegative constraint on the control if any target* $y_1 \in L^2_+(-1,1) + Y_d$ *is approximately controllable.*

Remark 1.4. Since the solution of system (1.1) reaches Y_d at time T without any control input, by the comparison principle, if we add a nonnegative control to this system, then the value at time T of the solution of system (1.1) belongs to $L^2_+(-1,1) + Y_d$. This is the reason to choose this space as the target set.

Now, the main results in this paper are stated as follows.

THEOREM 1.5. *If* $\omega = (-1,1)$*, then system* (1.1) *is approximately controllable with a nonnegative constraint on the control at any time* $T > 0$*.*

Remark 1.6. If system (1.1) is replaced by

$$\begin{cases} y_t(x,t) - (|y|^{m-1}y)_{xx}(x,t) = u(x,t), & (x,t) \in Q, \\ y(-1,t) = y(1,t) = 0, & t \in (0,T), \\ y(x,0) = y_0(x), & x \in (-1,1), \end{cases} \tag{1.2}$$

we do not need to study the nonnegative solution. The unconstrained approximate controllability of system (1.2) is obvious. Indeed, by the well-known results, for each $\varepsilon > 0$, y_0 sufficiently smooth and $y_1 \in L^2(-1,1)$, there exist two regular functions y and v satisfying

$$\begin{cases} y_t(x,t) - y_{xx}(x,t) = v(x,t), & (x,t) \in Q, \\ y(-1,t) = y(1,t) = 0, & t \in (0,T), \\ y(x,0) = y_0(x), & x \in (-1,1), \end{cases}$$

such that

$$\|y(\cdot,T) - y_1\|_{L^2(-1,1)} < \varepsilon. \tag{1.3}$$

If choosing $u = v + y_{xx} - (|y|^{m-1}y)_{xx} \in L^\infty(Q)$, then y and u satisfy system (1.2) and (1.3). By density, for any $y_0 \in L^2(-1,1)$, system (1.2) is approximately controllable.

Combining Theorem 1.5 and energy estimates for system (1.1), it is easy to show that any nonnegative target $y_1 \in L^2_+(-1,1)$ is approximately controllable with a nonnegative constraint on the control for a long time, i.e.,

COROLLARY 1.7. *Suppose* $\omega = (-1,1)$*. Then for each* $\varepsilon > 0$*,* $y_0 \in L^\infty(-1,1)$ *with* $y_0 \geq 0$ *a.e. in* $(-1,1)$ *and target* $y_1 \in L^2_+(-1,1)$*, there exist a time* $T > 0$ *and a nonnegative control function* $u \in L^2_+(Q)$ *such that the corresponding solution* y *of system* (1.1) *satisfies*

$$\|y(\cdot,T;u) - y_1\|_{L^2(-1,1)} < \varepsilon.$$

Theorem 1.5 tells us that when the control is active in the whole domain ($\omega = (-1,1)$), any target $y_1 \in L^2_+(-1,1) + Y_d$ is approximately controllable at any time. But when the control is restricted to act in a proper subdomain ω of $(-1,1)$, one could not expect the same result. Indeed, we have the following negative result.

THEOREM 1.8. *If* $\omega \subseteq (-1,1)$ *and* $\omega \neq (-1,1)$*, then there exists a time* $T^* > 0$ *such that for any* $0 < T < T^*$*, one can find a target in* $L^2_+(-1,1) + Y_d$ *which is not approximately controllable at time* T*.*

The rest of this paper is organized as follows. In section 2 we study the constrained approximate controllability of linearized system. Section 3 is devoted to the proof of the approximate controllability of system (1.1). In section 4 we discuss the noncontrollability for this system when the control is locally acted.

2. Constrained controllability of the linearized system. In this section, we study the approximate controllability of the linearized system with nonnegative constraints on the control and state.

First, for each $z \in K := \{\xi \in L^2(Q);\ \|\xi\|_{L^\infty(0,T;L^2(-1,1))} \le C_1^*,\ 0 \le \xi \le C_2^*$ a.e. in $Q\}$ (C_1^* and C_2^* are two constants to be determined in section 3), we consider the system

$$\begin{cases} y_t - \left[(\frac{1}{k} + mz^{m-1})y_x\right]_x = u, & (x,t) \in Q, \\ y(-1,t) = y(1,t) = 0, & t \in (0,T), \\ y(x,0) = y_0(x), & x \in (-1,1), \end{cases} \tag{2.1}$$

where k is an arbitrary fixed positive integer and $y_0 \in L^\infty(-1,1)$ with $y_0 \ge 0$ a.e. in $(-1,1)$. Set

$$E = \{y(\cdot,T;u);\ u \in L^2_+(Q)\}.$$

Then we have the following known result (see [7]).

LEMMA 2.1. *E is dense in $L^2_+(-1,1) + y(\cdot,T;0)$, where $y(\cdot,T;0)$ denotes the value at time T of the solution of system (2.1) with $u = 0$.*

Next, we are ready to find a nonnegative control with minimal norm. The method is based on the following Fenchel–Rockafellar duality theory (see [3]).

LEMMA 2.2. *Let X and Y be real Banach spaces. Let $F : X \to (-\infty, +\infty]$ and $G : Y \to (-\infty, +\infty]$ be two proper, convex, and lower semicontinuous functionals. Let $L : X \to Y$ be a linear continuous operator. We suppose that there exists a $u_0 \in X$ such that $F(u_0) < +\infty$ and G is continuous at Lu_0. Set*

$$J(u) = F(u) + G(Lu)$$

and

$$\hat{J}(\varphi_T) = F^*(L^*\varphi_T) + G^*(-\varphi_T).$$

Then we have

$$\inf_{u\in X}\{J(u)\} = -\inf_{\varphi_T \in Y^*}\{\hat{J}(\varphi_T)\}, \tag{2.2}$$

where L^* denotes the adjoint operator of L, $F^*(\varphi) := \sup_{u\in X}\{(\varphi,u)_{X^*,X} - F(u)\}$ $\forall \varphi \in X^*$, and similarly for G^* defined in Y^*. Moreover, if $u^* \in X$ and $\varphi_T^* \in Y^*$ are the minimizers of the functionals J and $\hat{J}$, respectively, then

$$0 \in \partial F(u^*) - L^*\varphi_T^*, \tag{2.3}$$

where ∂F denotes the subdifferential of F.

For each $\varepsilon > 0$ and $y_d \in L^2_+(-1,1)$, consider the following functional defined on $L^2(Q)$:

$$J(u) = \frac{1}{2}\iint_Q u^2(x,t)dxdt + \begin{cases} 0 & \text{if } \|y(\cdot,T;u) - y_1\|_{L^2(-1,1)} \le \varepsilon \text{ and } u \ge 0 \text{ in } Q, \\ +\infty & \text{otherwise,} \end{cases}$$

where $y(\cdot,\cdot;u)$ denotes the solution of system (2.1) associated to u and $y_1 = y_d + y(\cdot,T;0)$.

By Lemma 2.1, $J(u) \not\equiv +\infty$. At the same time, by classical control theory, there exists a unique $u^* \in L^2(Q)$ such that

$$J(u^*) = \inf\{J(u);\, u \in L^2(Q)\}.$$

We rewrite the functional J as

$$J(u) = \frac{1}{2}\iint_Q u^2(x,t)dxdt + \begin{cases} 0 & \text{if } u \geq 0 \text{ in } Q, \\ +\infty & \text{otherwise} \end{cases}$$
$$+ \begin{cases} 0 & \text{if } \|y(\cdot,T;u) - y_1\|_{L^2(-1,1)} \leq \varepsilon, \\ +\infty & \text{otherwise} \end{cases}$$

and apply Lemma 2.2 with $X = L^2(Q)$ and $Y = L^2(-1,1)$.

Taking

$$F(u) = \frac{1}{2}\iint_Q u^2(x,t)dxdt + \begin{cases} 0 & \text{if } u \geq 0 \text{ in } Q, \\ +\infty & \text{otherwise,} \end{cases}$$

$$G(\xi) = \begin{cases} 0 & \text{if } \|\xi - y_d\|_{L^2(-1,1)} \leq \varepsilon, \\ +\infty & \text{otherwise,} \end{cases}$$

and

$$L(u) = \tilde{y}(\cdot,T;u),$$

where $\tilde{y}$ denotes the solution of system (2.1) with $y_0 = 0$, we can easily prove that the conditions of Lemma 2.2 are satisfied.

We consider the system

$$\begin{cases} \varphi_t + \left[(\frac{1}{k} + mz^{m-1})\varphi_x\right]_x = 0, & (x,t) \in Q, \\ \varphi(-1,t) = \varphi(1,t) = 0, & t \in (0,T), \\ \varphi(x,T) = \varphi_T(x), & x \in (-1,1), \end{cases} \tag{2.4}$$

where $\varphi_T \in L^2(-1,1)$.

For any $\varphi_T \in L^2(-1,1)$ and $u \in L^2(Q)$, multiplying the first equation of system (2.4) by $\tilde{y}(\cdot,\cdot;u)$ and integrating on Q, we get

$$\int_{-1}^{1} \varphi_T(x)\tilde{y}(x,T)dx = \iint_Q \varphi(x,t)u(x,t)dxdt,$$

which implies

$$L^*(\varphi_T) = \varphi \quad \forall \varphi_T \in L^2(-1,1),$$

where φ is the corresponding solution of system (2.4). Moreover,

$$G^*(-\varphi_T) = \sup\left\{-\int_{-1}^{1} \varphi_T(x)\xi(x)dx;\, \xi \in L^2(-1,1),\, \|\xi - y_d\|_{L^2(-1,1)} \leq \varepsilon\right\}$$
$$= \varepsilon\|\varphi_T\|_{L^2(-1,1)} - \int_{-1}^{1} \varphi_T(x)y_d(x)dx$$

and

$$\begin{aligned} F^*(L^*\varphi_T) &= \sup\left\{\iint_Q \varphi(x,t)u(x,t)dxdt - \frac{1}{2}\iint_Q u^2(x,t)dxdt;\ u \in L^2_+(Q)\right\} \\ &= \sup\left\{\frac{1}{2}\iint_Q \varphi^2(x,t)dxdt - \frac{1}{2}\iint_Q [u(x,t)-\varphi(x,t)]^2dxdt;\ u \in L^2_+(Q)\right\} \\ &= \frac{1}{2}\iint_Q \varphi_+^2(x,t)dxdt, \end{aligned}$$

where $w_+ := \max\{w, 0\}$. Thus by (2.2), we have

$$\inf_{u\in L^2(Q)} J(u) = -\inf_{\varphi_T\in L^2(-1,1)} \hat{J}(\varphi_T),$$

where

$$\hat{J}(\varphi_T) = \frac{1}{2}\iint_Q \varphi_+^2(x,t)dxdt + \varepsilon\|\varphi_T\|_{L^2(-1,1)} - \int_{-1}^{1}\varphi_T(x)y_d(x)dx.$$

By classical control theory, there exists a unique $\varphi_T^* \in L^2(-1,1)$ such that

$$\hat{J}(\varphi_T^*) = \inf\{\hat{J}(\varphi_T);\ \varphi_T \in L^2(-1,1)\}.$$

At the same time, by (2.3), we get

$$\iint_Q \left(\varphi^* - \frac{u+u^*}{2}\right)(u^*-u)dxdt \geq 0 \quad \forall u \in L^2_+(Q),$$

where φ^* is the solution of system (2.4) with $\varphi_T = \varphi_T^*$. The above inequality implies

$$u^* = \varphi_+^* \quad \text{in } Q. \tag{2.5}$$

Thus the linearized system (2.1) is approximately controllable with nonnegative constraints on the control and state, and the control with minimal norm satisfies (2.5).

3. Constrained controllability of system (1.1). First, we consider the constrained approximate controllability of the quasilinear system

$$\begin{cases} y_t - \left[(\frac{1}{k} + my^{m-1})y_x\right]_x = u, & (x,t) \in Q, \\ y(-1,t) = y(1,t) = 0, & t \in (0,T), \\ y(x,0) = y_0(x), & x \in (-1,1), \end{cases} \tag{3.1}$$

where k is an arbitrary fixed positive integer and $y_0 \in L^\infty(-1,1)$ with $y_0 \geq 0$ a.e. in $(-1,1)$.

For each $z \in K = \{\xi \in L^2(Q);\ \|\xi\|_{L^\infty(0,T;L^2(-1,1))} \leq C_1^*,\ 0 \leq \xi \leq C_2^* \text{ a.e. in } Q\}$ (C_1^* and C_2^* will be specified later) and $\varphi_T \in L^2(-1,1)$, we denote by φ the corresponding solution of system (2.4). For any fixed $y_d \in L^2_+(-1,1)$, denote by φ_T^* the minimizer of the functional defined on $L^2(-1,1)$,

$$\hat{J}(\varphi_T) = \frac{1}{2}\iint_Q \varphi_+^2(x,t)dxdt + \varepsilon\|\varphi_T\|_{L^2(-1,1)} - \int_{-1}^{1}\varphi_T(x)y_d(x)dx,$$

and denote by φ^* the solution of system (2.4) with $\varphi_T = \varphi_T^*$.

Noting that φ_T^* and φ^* depend on $z \in K$, we define the operator

$$L: \ K \to L^2(Q),$$
$$z \mapsto y,$$

where $y = L(z)$ denotes the solution of system (2.1) with $u^* = \varphi_+^*$. From the discussion of section 2, the definition of L is reasonable, and for each $z \in K$, we have

$$\|y(\cdot, T; u^*) - y_d - Y_d^z\|_{L^2(-1,1)} \le \varepsilon,$$

where Y_d^z denotes the value at time T of the solution of system (2.1) with $u = 0$.

In the following, we shall prove that L has a fixed point by Schauder's fixed point theorem, which yields the approximate controllability of system (3.1).

Step 1. We prove that $L(K) \subseteq K$. First, we shall establish the uniform boundedness of $\{\varphi_+^*\}$ for $z \in K$. For any $z \in K$ and $\varphi_T \in L^2(-1,1)$, we denote by φ the corresponding solution of system (2.4). Consider the following two functionals defined on $L^2(-1,1)$:

$$\hat{J}(\varphi_T) = \frac{1}{2}\iint_Q \varphi_+^2(x,t)dxdt + \varepsilon\|\varphi_T\|_{L^2(-1,1)} - \int_{-1}^1 \varphi_T(x)y_d(x)dx,$$

$$\bar{J}(\varphi_T) = \frac{1}{2}\iint_Q \varphi_+^2(x,t)dxdt - \int_{-1}^1 \varphi(x, T-\delta)y_d(x)dx,$$

where $\delta > 0$ is a constant to be determined later. Denote by φ_T^* the minimizer of the functional $\hat{J}$. We shall show that there exists a suitable $\delta > 0$ such that, for any $z \in K$ and $\varphi_T \in L^2(-1,1)$,

$$\varepsilon\|\varphi_T\|_{L^2(-1,1)} - \int_{-1}^1 [\varphi_T(x) - \varphi(x, T-\delta)]\, y_d(x)dx \ge 0. \tag{3.2}$$

This leads to

$$\bar{J}(\varphi_T^*) \le \hat{J}(\varphi_T^*) \le 0.$$

Thus

$$\iint_Q \varphi_+^{*2}(x,t)dxdt \le 2\int_{-1}^1 \varphi^*(x, T-\delta)y_d(x)dx \le 2\int_{-1}^1 \varphi_+^*(x, T-\delta)y_d(x)dx. \tag{3.3}$$

Here we use the fact that $y_d \ge 0$ a.e. in $(-1,1)$. Since φ^* solves

$$\begin{cases} \varphi_t^* + \left[(\frac{1}{k} + mz^{m-1})\varphi_x^*\right]_x = 0, & (x,t) \in Q, \\ \varphi^*(-1,t) = \varphi^*(1,t) = 0, & t \in (0,T), \\ \varphi^*(x,T) = \varphi_T^*(x), & x \in (-1,1), \end{cases} \tag{3.4}$$

multiplying the first equation of system (3.4) by φ_+^* and integrating on $(-1,1) \times (T-\delta, t)$, where $t \in (T-\delta, T)$, we get

$$\int_{-1}^1 \varphi_+^{*2}(x, T-\delta)dx \le \int_{-1}^1 \varphi_+^{*2}(x,t)dx.$$

Integrating the above inequality with respect to t on $(T-\delta, T)$, it follows that

$$\int_{-1}^{1} \varphi_+^{*2}(x, T-\delta)dx \le \frac{1}{\delta} \iint_Q \varphi_+^{*2}(x,t)dxdt. \tag{3.5}$$

Taking into account (3.3) and (3.5), we have

$$\|\varphi_+^*\|_{L^2(Q)} \le \frac{2}{\delta^{1/2}} \|y_d\|_{L^2(-1,1)}, \tag{3.6}$$

which means that $\{\varphi_+^*\}$ is uniformly bounded in $L^2(Q)$ if inequality (3.2) is valid.

Next, we shall specify constants C_1^* and C_2^* in the definition of set K. For any $z \in K$, multiplying by y the first equation of system (2.1) with $u = \varphi_+^*$ and integrating with respect to x on $(-1,1)$, we get

$$\frac{1}{2}\frac{d}{dt}\int_{-1}^{1} y^2(x,t)dx \le \int_{-1}^{1} \varphi_+^*(x,t)y(x,t)dx.$$

By Gronwall's inequality and (3.6), we have

$$\begin{aligned} \|y\|_{L^\infty(0,T;L^2(-1,1))} &\le e^{T/2}(\|y_0\|_{L^2(-1,1)} + \|\varphi_+^*\|_{L^2(Q)}) \\ &\le e^{T/2}(\|y_0\|_{L^2(-1,1)} + \frac{2}{\delta^{1/2}}\|y_d\|_{L^2(-1,1)}) \\ &:= C_1^*. \end{aligned} \tag{3.7}$$

At the same time, using the weak maximum principle (see [16]) for system (2.1) with $u = \varphi_+^*$, by (3.6), we get that there exists a constant $C = C(k) > 0$ independent of z such that

$$\begin{aligned} \|y\|_{L^\infty(Q)} &\le \|y_0\|_{L^\infty(-1,1)} + C\|\varphi_+^*\|_{L^2(Q)} \\ &\le \|y_0\|_{L^\infty(-1,1)} + \frac{2C}{\delta^{1/2}}\|y_d\|_{L^2(-1,1)} \\ &:= C_2^*. \end{aligned}$$

With the choice of C_1^* and C_2^*, we get that $L(K) \subseteq K$.

Now, we show that inequality (3.2) holds for some $\delta > 0$. Without loss of generality, we suppose $y_d \in C_0^1(-1,1)$. Multiplying the first equation of system (2.4) by y_d and integrating on $(-1,1) \times (T-\delta, T)$, we get

$$\int_{-1}^{1} [\varphi_T(x) - \varphi(x, T-\delta)]y_d(x)dx - \int_{T-\delta}^{T}\int_{-1}^{1} \left(\frac{1}{k} + mz^{m-1}\right)\varphi_x(x,t)y_{dx}(x)dxdt = 0.$$

It suffices to show that there exists a $\delta > 0$ such that, for any $z \in K$ and $\varphi_T \in L^2(-1,1)$,

$$\int_{T-\delta}^{T}\int_{-1}^{1} \left(\frac{1}{k} + mz^{m-1}\right)|\varphi_x(x,t)y_{dx}(x)|dxdt \le \varepsilon\|\varphi_T\|_{L^2(-1,1)}. \tag{3.8}$$

By Hölder's inequality and inequality (3.7), we estimate the term on the left-hand

side of inequality (3.8):

$$\begin{aligned}
&\int_{T-\delta}^{T}\int_{-1}^{1}(\tfrac{1}{k}+mz^{m-1})|\varphi_x(x,t)y_{dx}(x)|dxdt\\
&\quad\le \|y_{dx}\|_{L^\infty(-1,1)}\|(\tfrac{1}{k}+mz^{m-1})^{1/2}\varphi_x\|_{L^2(Q)}\|(\tfrac{1}{k}+mz^{m-1})^{1/2}\|_{L^2((-1,1)\times(T-\delta,T))}\\
&\quad\le \|y_{dx}\|_{L^\infty(-1,1)}\|\varphi_T\|_{L^2(-1,1)}\|(1+mz^{m-1})^{1/2}\|_{L^2((-1,1)\times(T-\delta,T))}\\
&\quad\le \|y_{dx}\|_{L^\infty(-1,1)}\|\varphi_T\|_{L^2(-1,1)}\left\{2\delta+2^{(3-m)/2}m\delta\|z\|^{m-1}_{L^\infty(0,T;L^2(-1,1))}\right\}^{1/2}\\
&\quad\le \|y_{dx}\|_{L^\infty(-1,1)}\|\varphi_T\|_{L^2(-1,1)}\cdot\\
&\left\{2\delta+2^{(3-m)/2}m\delta\left[e^{T/2}\left(\|y_0\|_{L^2(-1,1)}+\frac{2}{\delta^{1/2}}\|y_d\|_{L^2(-1,1)}\right)\right]^{m-1}\right\}^{1/2}. \qquad (3.9)
\end{aligned}$$

Since $1<m<3$, we can choose a sufficiently small constant $\delta>0$, such that inequality (3.8) is valid and δ depends only on y_0, y_d, and ε.

Thus inequality (3.2) is valid. At the same time, we also conclude that $\{\|\varphi_+^*\|_{L^2(Q)}\}$ is uniformly bounded and $L(K)\subseteq K$.

Remark 3.1. From the above discussion, a critical point to the proof of Step 1 is the uniform boundedness of $\{\varphi_+^*\}$, i.e., estimate (3.6). Taking into account that the principal part of system (3.1) is nonlinear, we cannot use the same method as that in [11, Proposition 2.3] and in [7, Proposition 15] to prove it. Indeed, for any $z\in K$, we fail to get the uniform boundedness of the minimizer $\{\varphi_T^*\}$ of $\hat{J}(\varphi_T)$. The uniform boundedness of $\{\varphi_T^*\}$ implies that of $\{\varphi_+^*\}$. The latter is enough for our discussion. Here we make use of two functionals $\hat{J}(\varphi_T)$ and $\bar{J}(\varphi_T)$ introduced in [12] and suitable estimates for the linearized system to prove (3.6).

Step 2. We prove the continuity of L. Let $\{z_n\}$ be any convergent sequence in K, say,

$$z_n\to z_0 \quad \text{strongly in } L^2(Q).$$

Denote by $\hat{J}_n$ and $\hat{J}_0$ the functional $\hat{J}$ with $z=z_n$ and $z=z_0$ in (2.4), respectively. Let φ_n be the solution of system (2.4) with $z=z_n$ and $\varphi_T=\varphi_{Tn}$, where φ_{Tn} is the minimizer of $\hat{J}_n$. Let y_n be the solution of system (2.1) with $z=z_n$ and $u=\varphi_{n+}$. Then we have the following result.

LEMMA 3.2. *There exists a constant $C>0$ independent of z_n such that*

$$\|\varphi_{Tn}\|_{L^2(-1,1)}\le C.$$

Proof. Suppose that there exists a subsequence of $\{z_n\}$ (still denoted by $\{z_n\}$) such that $\|\varphi_{Tn}\|_{L^2(-1,1)}\to+\infty$, $n\to+\infty$. Let

$$\hat{\varphi}_n=\frac{\varphi_n}{\|\varphi_{Tn}\|_{L^2(-1,1)}},\quad \hat{\varphi}_{Tn}=\frac{\varphi_{Tn}}{\|\varphi_{Tn}\|_{L^2(-1,1)}}.$$

Then

$$\frac{\hat{J}(\varphi_{Tn})}{\|\varphi_{Tn}\|_{L^2(-1,1)}}=\frac{1}{2}\iint_Q\hat{\varphi}_{n+}^2(x,t)dxdt\|\varphi_{Tn}\|_{L^2(-1,1)}+\varepsilon-\int_{-1}^{1}\hat{\varphi}_{Tn}(x)y_d(x)dx.$$

If $\liminf_{n\to+\infty}\frac{1}{2}\iint_Q\hat{\varphi}_{n+}^2(x,t)dxdt>0$, then

$$\liminf_{n\to+\infty}\frac{\hat{J}(\varphi_{Tn})}{\|\varphi_{Tn}\|_{L^2(-1,1)}}\ge\varepsilon. \qquad (3.10)$$

On the other hand, suppose that

$$\liminf_{n\to+\infty} \frac{1}{2} \iint_Q \hat{\varphi}_{n+}^2(x,t)dxdt = 0. \tag{3.11}$$

Since $\|\hat{\varphi}_{Tn}\|_{L^2(-1,1)} = 1$, we can extract a subsequence (still denoted by $\{\hat{\varphi}_{Tn}\}$) which weakly converges to some element $\hat{\varphi}_T$ in $L^2(-1,1)$. Since $z_n \to z_0$ strongly in $L^2(Q)$ and $0 \le z_n \le C_2^*$ a.e. in Q, we can extract a subsequence (still denoted by $\{z_n\}$) which converges to z_0 in $L^p(Q)$ for any $0 < p < +\infty$. Thus $\hat{\varphi}_n$ converges to some element $\hat{\varphi}$ strongly in $L^2(Q)$ and weakly in $L^2(0,T;H_0^1(-1,1))$. We can easily verify that $\hat{\varphi}$ is the solution of system (2.4) with $z = z_0$ and $\varphi_T = \hat{\varphi}_T$. By (3.11), we get

$$\hat{\varphi}_+ = 0 \quad \text{a.e. in } Q.$$

Thus

$$\hat{\varphi}_T(x) \le 0 \quad \text{a.e. in } (-1,1).$$

Moreover, noticing that $y_d \ge 0$ a.e. in $(-1,1)$, we have

$$\liminf_{n\to+\infty} \frac{\hat{J}(\varphi_{Tn})}{\|\varphi_{Tn}\|_{L^2(-1,1)}} \ge \varepsilon - \int_{-1}^{1} \hat{\varphi}_T(x) y_d(x) dx \ge \varepsilon. \tag{3.12}$$

But $\hat{J}(\varphi_{Tn}) \le \hat{J}(0) = 0$, which is a contradiction to (3.10) and (3.12). This completes the proof. □

By (3.9), there exist a subsequence of $\{\varphi_{Tn}\}$ (still denoted by itself) and $\hat{\varphi}_T \in L^2(-1,1)$ such that

$$\varphi_{Tn} \to \hat{\varphi}_T \text{ weakly in } L^2(-1,1). \tag{3.13}$$

Thus $\{\varphi_n\}$ and $\{y_n\}$ have subsequences (still denoted by themselves) which satisfy, respectively,

$$\begin{aligned} &\varphi_n \to \hat{\varphi} \quad \text{strongly} \quad \text{in } L^2(Q), \\ &y_n \to y \quad \text{weakly} \quad \text{in } L^2(0,T;H_0^1(-1,1)), \\ &y_n \to y \quad \text{strongly} \quad \text{in } L^2(Q), \end{aligned} \tag{3.14}$$

where $\hat{\varphi}$ is the solution of system (2.4) with $z = z_0$ and $\varphi_T = \hat{\varphi}_T$ and y is the solution of system (2.1) with $z = z_0$ and $u = \hat{\varphi}_+$. Since

$$\hat{J}_n(\varphi_{Tn}) \le \hat{J}_n(\varphi_T) \quad \forall \varphi_T \in L^2(-1,1),$$

by (3.13) and (3.14), we have

$$\lim_{n\to+\infty} \hat{J}_n(\varphi_T) = \hat{J}_0(\varphi_T), \quad \hat{J}_0(\hat{\varphi}_T) \le \liminf_{n\to+\infty} \hat{J}_n(\varphi_{Tn}).$$

This implies

$$\hat{J}_0(\hat{\varphi}_T) \le \hat{J}_0(\varphi_T) \quad \forall \varphi_T \in L^2(-1,1);$$

that is, $\hat{\varphi}_T$ is the minimizer of $\hat{J}_0$. Thus L is a continuous operator.

Step 3. We prove the compactness of L. Taking into account the uniform boundedness of $\{\varphi_+^*\}$ in $L^2(Q)$ for $z \in K$, if we denote by y the solution of system (2.1) with $u = \varphi_+^*$, then

$$\|y\|_{L^2(0,T;H_0^1(-1,1))} + \|y_t\|_{L^2(0,T;H^{-1}(-1,1))} \le C$$

with C independent of z. By Aubin's compact theorem, $L(K)$ is a compact subset of $L^2(Q)$. Thus L is a compact operator.

By Schauder's fixed point theorem, the above discussion implies that L has a fixed point. Thus system (3.1) is approximately controllable with nonnegative constraints on the control and state; that is, for each $\varepsilon > 0$ and $y_d \in L_+^2(-1,1)$, there exists a nonnegative control function $u_k \in L_+^2(Q)$ such that the corresponding nonnegative solution y_k of system (3.1) satisfies

$$\|y_k(\cdot,T;u_k) - y_d - y_k(\cdot,T;0)\|_{L^2(-1,1)} < \frac{\varepsilon}{2}, \tag{3.15}$$

where $y_k(\cdot,\cdot;0)$ denotes the solution of system (3.1) with $u = 0$.

Next, we discuss the constrained approximate controllability of system (1.1).

Proof of Theorem 1.5. By (3.6), $\{u_k\}$ can be chosen such that

$$\|u_k\|_{L^2(Q)} \le C,$$

with C independent of k. Thus there exist a subsequence of $\{u_k\}$ (still denoted by $\{u_k\}$) and a nonnegative function $u^* \in L_+^2(Q)$ such that

$$u_k \to u^* \text{ weakly in } L^2(Q).$$

Using Moser's iteration and a similar method used in the proof of Lemma 5 in [1], we have that there exists a constant $C > 0$ independent of k such that

$$\|y_k\|_{L^\infty(Q)\cap C([0,T];L^2(-1,1))} \le C, \quad \|y_k^{(m-1)/2} y_{kx}\|_{L^2(Q)} \le C,$$

$$\|y_k^m(x+h,t) - y_k^m(x,t)\|_{L^2(Q_h)} \le C|h|, \quad \|y_k^m(x,t+h) - y_k^m(x,t)\|_{L^2(Q_h)}^2 \le C|h|^{1/2},$$

where h is a real parameter and $Q_h := \{(x,t) \in Q;\ (x+h,t) \in Q,\ (x,t+h) \in Q\}$.

Thus there exist a subsequence of $\{y_k\}$ (still denoted by itself) and $w \in L^\infty(Q)$ such that for any $p > 1$

$$y_k^m \to w \text{ strongly in } L^p(Q).$$

Define $y := w^{1/m}$. Then there exists a subsequence of $\{y_k\}$ such that

$$y_k \to y \quad \text{a.e. in Q.}$$

By the Lebesgue dominated convergence theorem, this yields that for any $p > 1$

$$y_k \to y \text{ strongly in } L^p(Q).$$

By (3.1), for any test function $\varphi \in C^2(\overline{Q})$ satisfying the conditions of Definition 1.1, y_k satisfies the following integral equality:

$$\iint_Q \left[y_k(x,t)\varphi_t(x,t) + \frac{1}{k} y_k(x,t)\varphi_{xx}(x,t) + y_k^m(x,t)\varphi_{xx}(x,t) \right] dxdt$$
$$= -\iint_Q u_k(x,t)\varphi(x,t)dxdt - \int_{-1}^{1} y_0(x)\varphi(x,0)dx.$$

Letting $k \to +\infty$, we get

$$\begin{aligned}&\iint_Q [y(x,t)\varphi_t(x,t) + y^m(x,t)\varphi_{xx}(x,t)]dxdt\\ &= -\iint_Q u^*(x,t)\varphi(x,t)dxdt - \int_{-1}^{1} y_0(x)\varphi(x,0)dx.\end{aligned}$$

Thus y is the nonnegative generalized solution of system (1.1) with $u = u^*$.

At the same time,

$$y_k(\cdot, T; u_k) \to y(\cdot, T; u^*) \text{ weakly in } L^2(-1,1). \tag{3.16}$$

Similarly, there exists a subsequence of $\{y_k(\cdot,\cdot;0)\}$ (still denoted by itself) such that for any $p > 1$

$$\begin{aligned} y_k(\cdot,\cdot;0) &\to y(\cdot,\cdot;0) \quad \text{strongly} \quad \text{in } L^p(Q),\\ y_k(\cdot,T;0) &\to y(\cdot,T;0) \quad \text{weakly} \quad \text{in } L^2(-1,1),\end{aligned} \tag{3.17}$$

where $y(\cdot,\cdot;0)$ is the generalized solution of system (1.1) with $u = 0$.

By (3.16) and (3.17), for each $\varepsilon > 0$, there exists a $K > 0$ such that

$$\|y(\cdot,T;u^*) - y_d - y(\cdot,T;0)\|_{L^2(-1,1)} \le \|y_K(\cdot,T;u_K) - y_d - y_K(\cdot,T;0)\|_{L^2(-1,1)} + \frac{\varepsilon}{2}.$$

Taking into account (3.15), we have

$$\|y(\cdot,T;u^*) - y_d - y(\cdot,T;0)\|_{L^2(-1,1)} \le \varepsilon,$$

which means that system (1.1) is approximately controllable with nonnegative constraints on the control and state. We complete the proof of Theorem 1.5.

Combining Theorem 1.5 and energy estimates for system (1.1), we also get that any nonnegative target is approximately controllable for a long time.

Proof of Corollary 1.7. Taking into account the proof of Theorem 1.5, we can easily get that for each $\varepsilon > 0$ and $y_1 \in L^2_+(-1,1)$, there exists a constant $\gamma > 0$ such that if $y_0 \in L^\infty(-1,1)$ satisfies $\|y_0\|_{L^2(-1,1)} < \gamma$, then we can find a nonnegative control function $u \in L^2_+(Q)$ satisfying

$$\|y(\cdot,T;u) - y_1\|_{L^2(-1,1)} < \varepsilon,$$

where y denotes the corresponding solution of system (1.1).

For any $y_0 \in L^\infty(-1,1)$ with $y_0 \ge 0$ a.e. in $(-1,1)$, denote by $\bar{y}$ the solution of system (1.1) with $u = 0$. Multiplying the first equation of system (1.1) with $u = 0$ by $\bar{y}^m$ and integrating with respect to x on $(-1,1)$, we have

$$\frac{1}{m+1}\frac{d}{dt}\int_{-1}^{1} \bar{y}^{m+1}(x,t)dx + \int_{-1}^{1} (\bar{y}^m)_x^2(x,t)dx = 0. \tag{3.18}$$

By Poincáre's inequality, there exists a constant $C > 0$ such that

$$\int_{-1}^{1} \bar{y}^{2m}(x,t)dx \le C\int_{-1}^{1} (\bar{y}^m)_x^2(x,t)dx.$$

Set

$$C_1 = \frac{m+1}{C} 2^{\frac{1-m}{1+m}}.$$

By Hölder's inequality and (3.18), we get

$$\begin{aligned}
&\frac{d}{dt}\int_{-1}^{1} \bar{y}^{m+1}(x,t)dx + C_1 \left[\int_{-1}^{1} \bar{y}^{m+1}(x,t)dx\right]^{\frac{2m}{m+1}} \\
&\le \frac{d}{dt}\int_{-1}^{1} \bar{y}^{m+1}(x,t)dx + C_1 2^{\frac{m-1}{m+1}} \int_{-1}^{1} \bar{y}^{2m}(x,t)dx \\
&\le \frac{d}{dt}\int_{-1}^{1} \bar{y}^{m+1}(x,t)dx + (m+1)\int_{-1}^{1} (\bar{y}^m)_x^2(x,t)dx = 0.
\end{aligned}$$

Hence $\int_{-1}^{1} \bar{y}^{m+1}(x,t)dx$ is less than or equal to the solution of the following problem:

$$H'(t) + C_1 H^{2m/(m+1)}(t) = 0,$$

$$H(0) = \int_{-1}^{1} y_0^{m+1}(x)dx.$$

This implies

$$\int_{-1}^{1} \bar{y}^{m+1}(x,t)dx \le H(t) = \left[C_1 \frac{m-1}{m+1} t + \left(\int_{-1}^{1} y_0^{m+1}(x)dx\right)^{\frac{1-m}{1+m}}\right]^{\frac{1+m}{1-m}}.$$

On the other hand,

$$\|\bar{y}(\cdot,t)\|_{L^2(-1,1)} \le 2^{\frac{m-1}{2m+2}} \|\bar{y}(\cdot,t)\|_{L^{m+1}(-1,1)}.$$

Thus

$$\|\bar{y}(\cdot,t)\|_{L^2(-1,1)} \le 2^{\frac{m-1}{2m+2}} \left[C_1 \frac{m-1}{m+1} t + \left(\int_{-1}^{1} y_0^{m+1}(x)dx\right)^{\frac{1-m}{1+m}}\right]^{\frac{1}{1-m}}. \tag{3.19}$$

Taking into account (3.19) and $m > 1$, we can find a sufficiently large $T_1 > 0$ such that

$$\|\bar{y}(\cdot,T_1)\|_{L^2(-1,1)} < \gamma.$$

Therefore, for any $T > T_1$, we can find a nonnegative control function u defined on $(-1,1) \times (T_1,T)$ such that y_1 is approximately controllable at time T.

We choose

$$\tilde{u}(x,t) = \begin{cases} 0, & (-1,1) \times (0,T_1), \\ u(x,t), & (-1,1) \times (T_1,T), \end{cases}$$

and denote by y the solution of system (1.1) with $u = \tilde{u}$; then

$$\|y(\cdot,T;\tilde{u}) - y_1\|_{L^2(-1,1)} < \varepsilon.$$

This implies that for any nonnegative target $y_1 \in L^2_+(-1,1)$, we can find a time $T > 0$ and a nonnegative control function $\tilde{u} \in L^2_+(Q)$ such that y_1 is approximately controllable. We complete the proof of Corollary 1.7.

4. Noncontrollability of system (1.1) under a local control. In this section, we consider the control system

$$\begin{cases} y_t(x,t) - (y^m)_{xx}(x,t) = \chi_\omega u(x,t), & (x,t) \in Q, \\ y(-1,t) = y(1,t) = 0, & t \in (0,T), \\ y(x,0) = y_0(x), & x \in (-1,1), \end{cases} \tag{4.1}$$

where ω is a nonempty strict open subset of $(-1,1)$. First, using a technique of local estimates, we shall prove an L^∞-obstruction phenomenon to the solution of system (4.1). We need the following iteration lemma.

LEMMA 4.1 (see [21]). *Let $\{y_n\}$ $(n = 0,1,2,\cdots)$ be a sequence of positive numbers satisfying*

$$y_{n+1} \le C b^n y_n^{1+\alpha},$$

where $C > 0$, $b > 1$ and $\alpha > 0$ are constants. If

$$y_0 \le C^{-1/\alpha} b^{-1/\alpha^2},$$

then

$$\lim_{n\to+\infty} y_n = 0.$$

In what follows, for a fixed $x_0 \in (-1,1)\backslash\overline{\omega}$ and a positive constant $R > 0$ satisfying $B_{2R}(x_0) = (x_0 - 2R,\, x_0 + 2R) \subseteq (-1,1)\backslash\overline{\omega}$, define

$$\phi(t,\rho) = \sup_{\tau\in(0,t)} \tau^{1/(m+1)} \sup_{\rho\le r\le 2R} \frac{\|y(\cdot,\tau)\|_{L^\infty(B_r(x_0))}}{r^{2/(m-1)}},$$

$$K(t,\rho) = t^{-1} + t^{(1-m)/(1+m)} \phi^{m-1}(t,\rho),$$

$$\psi(t,\rho) = \sup_{\tau\in(0,t)} \sup_{\rho\le r\le 2R} r^{(1+m)/(1-m)} \int_{B_r(x_0)} y(x,\tau)dx,$$

where $0 < t \le T$ and $0 < \rho < R$.

We now prove the following lemma.

LEMMA 4.2. *There exists a constant $C > 0$ such that for any $0 < t \le T$, $0 < \rho < R$, and any control function $u \in L^2_+(\omega \times (0,T))$, the solution of system (4.1) satisfies*

$$\|y(\cdot,t)\|_{L^\infty(B_\rho(x_0))} \le C\,[K(t,\rho)]^{3/(3m+1)} \left(\int_{\frac{t}{4}}^t \int_{B_{2\rho}(x_0)} y^{m+1} dx d\tau \right)^{2/(3m+1)}. \tag{4.2}$$

Proof. For $n = 0,1,2,\ldots$, denote

$$\begin{aligned} &t_n = \frac{t}{2} - \frac{t}{2^{n+2}},\ \rho_n = \rho + \frac{\rho}{2^n},\ \bar{\rho_n} = \frac{1}{2}(\rho_n + \rho_{n+1}), \\ &B_n = B_{\rho_n}(x_0),\ B_n' = B_{\bar{\rho_n}}(x_0), \\ &Q_n = B_n \times (t_n, t),\ Q_n' = B_n' \times (t_{n+1}, t), \\ &k_n = k - \frac{k}{2^n}, \end{aligned}$$

where $k > 0$ will be specified later. Obviously

$$Q'_{n+1} \subseteq Q_{n+1} \subseteq Q'_n \subseteq Q_n.$$

Let ξ_n be a smooth function defined on Q_n, satisfying

$$0 \le \xi_n \le 1 \text{ in } Q_n, \quad \xi_n = 1 \text{ in } Q'_n,$$

$$\xi_n = 0 \text{ on } \{x_0 \pm \rho_n\} \times (t_n, t) \cup B_n \times \{t_n\},$$

$$|\xi_{nx}| \le \frac{2^{n+2}}{\rho}, \quad 0 \le \xi_{nt} \le \frac{2^{n+3}}{t}.$$

Multiplying the first equation of (4.1) by $(y-k_n)_+^m \xi_n^2$ and integrating on Q_n, by Höder's inequality, we get

(4.3)
$$\begin{aligned}
&\frac{1}{m+1}\int_{B_n}(y-k_n)_+^{m+1}(x,t)\xi_n^2(x,t)dx + m^2\iint_{Q_n}(y-k_n)_+^{m-1}y^{m-1}y_x^2\xi_n^2 dxd\tau \\
&\quad = \frac{2}{m+1}\iint_{Q_n}(y-k_n)_+^{m+1}\xi_n\xi_{n\tau}dxd\tau - 2m\iint_{Q_n}(y-k_n)_+^{m}y^{m-1}y_x\xi_n\xi_{nx}dxd\tau \\
&\quad \le \frac{C2^n}{t}\iint_{Q_n}(y-k_n)_+^{m+1}dxd\tau + \frac{1}{2}m^2\iint_{Q_n}(y-k_n)_+^{m-1}y^{m-1}y_x^2\xi_n^2 dxd\tau \\
&\qquad + C\iint_{Q_n}(y-k_n)_+^{m+1}y^{m-1}\xi_{nx}^2 dxd\tau \\
&\quad \le \frac{C2^n}{t}\iint_{Q_n}(y-k_n)_+^{m+1}dxd\tau + \frac{1}{2}m^2\iint_{Q_n}(y-k_n)_+^{m-1}y^{m-1}y_x^2\xi_n^2 dxd\tau \\
&\qquad + \frac{C4^n}{\rho^2}\sup_{t_n\le\tau\le t}\|y(\cdot,\tau)\|_{L^\infty(B_n)}^{m-1}\iint_{Q_n}(y-k_n)_+^{m+1}dxd\tau;
\end{aligned}$$

here and hereafter C denotes a different constant. Moreover,

(4.4)
$$\begin{aligned}
\iint_{Q_n}(y-k_n)_+^{m-1}y^{m-1}y_x^2\xi_n^2 dxd\tau &\ge \iint_{Q_n}(y-k_n)_+^{2m-2}y_x^2\xi_n^2 dxd\tau \\
&= \frac{1}{m^2}\iint_{Q_n}\left[(y-k_n)_+^m\right]_x^2\xi_n^2 dxd\tau.
\end{aligned}$$

Hence if we denote

$$w_n = (y-k_n)_+^m,$$

then by (4.3) and (4.4) we have

$$\sup_{t_{n+1}\le\tau\le t}\int_{B'_n} w_n^{\frac{m+1}{m}}(x,\tau)dx + \iint_{Q'_n} w_{nx}^2 dxd\tau \le C4^n K(t,\rho)\iint_{Q_n} w_n^{\frac{m+1}{m}}dxd\tau. \tag{4.5}$$

Let $\bar{\xi_n}$ be another smooth function defined on B'_n, satisfying

$$0 \le \bar{\xi_n} \le 1, \quad \bar{\xi_n} = 1 \text{ in } B_{n+1}, \quad |\bar{\xi}_{nx}| \le \frac{2^{n+2}}{\rho}.$$

By the Gagliardo–Nirenberg embedding inequality, we get

$$\begin{aligned}\iint_{Q_{n+1}} w_{n+1}^{(4m+2)/m}dxd\tau &\le \iint_{Q'_n} (w_{n+1}\bar{\xi_n})^{(4m+2)/m}dxd\tau\\ &\le \iint_{Q'_n} (w_n\bar{\xi_n})^{(4m+2)/m}dxd\tau\\ &\le C\iint_{Q'_n} (w_{nx}^2 + w_n^2\bar{\xi_{nx}}^2)dxd\tau\\ &\quad\cdot\left[\sup_{t_{n+1}\le\tau\le t}\int_{B'_n} w_n^{(m+1)/m}(x,\tau)dx\right]^2.\end{aligned} \tag{4.6}$$

We notice that the definition of w_n and $\phi(t,\rho)$ implies

$$\begin{aligned}\iint_{Q'_n} w_n^2\bar{\xi_{nx}}^2dxd\tau &\le \frac{C4^n}{\rho^2}\iint_{Q'_n}(y-k_n)_+^{2m}dxd\tau\\ &\le \frac{C4^n}{\rho^2}\sup_{t_{n+1}\le\tau\le t}\|(y-k_n)_+\|_{L^\infty(B'_n)}^{m-1}\iint_{Q'_n}(y-k_n)_+^{m+1}dxd\tau\\ &\le C4^nK(t,\rho)\iint_{Q'_n}(y-k_n)_+^{m+1}dxd\tau.\end{aligned} \tag{4.7}$$

Substituting (4.5) and (4.7) into (4.6) and estimating its right-hand side, we obtain

$$\iint_{Q_{n+1}} w_{n+1}^{(4m+2)/m}dxd\tau \le C4^{3n}K^3(t,\rho)\left[\iint_{Q_n}(y-k_n)_+^{m+1}dxd\tau\right]^3. \tag{4.8}$$

Set

$$A_n = \{(x,\tau)\in Q_n;\, y(x,\tau) > k_n\},\quad |A_n| = \operatorname{meas} A_n.$$

By Hölder's inequality and (4.8), we get

$$\begin{aligned}\iint_{Q_{n+1}}(y-k_{n+1})_+^{m+1}dxd\tau &\le \left[\iint_{Q_{n+1}}(y-k_{n+1})_+^{4m+2}dxd\tau\right]^{\frac{m+1}{4m+2}}|A_{n+1}|^{\frac{3m+1}{4m+2}}\\ &\le 4^{\frac{3m+3}{4m+2}n}[K(t,\rho)]^{\frac{3m+3}{4m+2}}|A_{n+1}|^{\frac{3m+1}{4m+2}}\\ &\quad\cdot\left[\iint_{Q_n}(y-k_n)_+^{m+1}dxd\tau\right]^{\frac{3m+3}{4m+2}}.\end{aligned} \tag{4.9}$$

On the other hand, we notice that

$$\begin{aligned}\iint_{Q_n}(y-k_n)_+^{m+1}dxd\tau &\ge \iint_{Q_{n+1}}(k_{n+1}-k_n)^{m+1}dxd\tau\\ &= \frac{k^{m+1}}{2^{(n+1)(m+1)}}|A_{n+1}|.\end{aligned} \tag{4.10}$$

Thus we derive from (4.9) and (4.10) that

$$\iint_{Q_{n+1}}(y-k_{n+1})_+^{m+1}dxd\tau \le C4^{n\beta_1}2^{n\beta_2}k^{\beta_3}K^{\beta_4}(t,\rho)\left[\iint_{Q_n}(y-k_n)_+^{m+1}dxd\tau\right]^{\frac{3m+2}{2m+1}},$$

where $\beta_1 = (3m+3)/(4m+2)$, $\beta_2 = (m+1)(3m+1)/(4m+2)$, $\beta_3 = -(m+1)(3m+1)/(4m+2)$, and $\beta_4 = (3m+3)/(4m+2)$. Applying Lemma 4.1, we conclude that if

$$\iint_{Q_0} y^{m+1} dx d\tau \le C k^{(3m+1)/2} K^{-3/2}(t,\rho),$$

then

$$\int_{\frac{t}{2}}^{t} \int_{B_\rho(x_0)} (y-k)_+^{m+1} dx d\tau = 0.$$

Therefore, if we take

$$k = C[K(t,\rho)]^{3/(3m+1)} \left(\iint_{Q_0} y^{m+1} dx d\tau \right)^{2/(3m+1)},$$

then

$$\|y(\cdot,t)\|_{L^\infty(B_\rho(x_0))} \le k;$$

that is,

$$\|y(\cdot,t)\|_{L^\infty(B_\rho(x_0))} \le C[K(t,\rho)]^{3/(3m+1)} \left(\int_{\frac{t}{4}}^{t} \int_{B_{2\rho}(x_0)} y^{m+1} dx d\tau \right)^{2/(3m+1)}.$$

We get the conclusion of Lemma 4.2. □

LEMMA 4.3. *There exist two positive constants C_1 and C_2 such that for any $t > 0$,*

$$\phi(t,\rho) \le C_1 \int_0^t \tau^{(1-m)/(1+m)} \phi^m(\tau,\rho) d\tau + C_2 [\psi(t,\rho)]^{2/(m+1)}. \tag{4.11}$$

Proof. Denote

$$\Phi(t,\rho) = t^{1/(m+1)} \frac{\|y(\cdot,t)\|_{L^\infty(B_\rho(x_0))}}{\rho^{2/(m-1)}}.$$

Multiplying (4.2) by $t^{1/(m+1)} \rho^{2/(1-m)}$, we get

(4.12)

$$\begin{aligned}
\phi(t,\rho) &\le C t^{1/(m+1)} \rho^{2/(1-m)} [K(t,\rho)]^{3/(3m+1)} \left(\int_{\frac{t}{4}}^{t} \int_{B_{2\rho}(x_0)} y^{m+1} dx d\tau \right)^{2/(3m+1)} \\
&\le C t^{1/(m+1)} \rho^{2/(1-m)} \left[t^{-1} + t^{(1-m)/(1+m)} \phi^{m-1}(t,\rho) \right]^{3/(3m+1)} \\
&\quad \cdot \left(\int_{\frac{t}{4}}^{t} \int_{B_{2\rho}(x_0)} y^{m+1} dx d\tau \right)^{2/(3m+1)} \\
&\le C t^{-2/[(m+1)(3m+1)]} \rho^{2/(1-m)} \left(\int_{\frac{t}{4}}^{t} \int_{B_{2\rho}(x_0)} y^{m+1} dx d\tau \right)^{2/(3m+1)} \\
&\quad + C t^{4/[(m+1)(3m+1)]} \rho^{2/(1-m)} [\phi(t,\rho)]^{(3m-3)/(3m+1)} \\
&\quad \cdot \left(\int_{\frac{t}{4}}^{t} \int_{B_{2\rho}(x_0)} y^{m+1} dx d\tau \right)^{2/(3m+1)}.
\end{aligned}$$

Denote

$$H^1 = t^{-2/[(m+1)(3m+1)]}\rho^{2/(1-m)}\left(\int_{\frac{t}{4}}^{t}\int_{B_{2\rho}(x_0)} y^{m+1}dxd\tau\right)^{2/(3m+1)},$$

$$H^2 = t^{4/[(m+1)(3m+1)]}\rho^{2/(1-m)}[\phi(t,\rho)]^{(3m-3)/(3m+1)}\left(\int_{\frac{t}{4}}^{t}\int_{B_{2\rho}(x_0)} y^{m+1}dxd\tau\right)^{2/(3m+1)}.$$

By the definition of $\phi(t,\rho)$ and $\psi(t,\rho)$, we have

$$\begin{aligned} H^1 &= \left[\int_{\frac{t}{4}}^{t} t^{-1/(m+1)}\int_{B_{2\rho(x_0)}} \rho^{(3m+1)/(1-m)}y^{m+1}dxd\tau\right]^{2/(3m+1)} \\ &\le C\left[t^{-1}\int_{\frac{t}{4}}^{t}\tau^{\frac{m}{m+1}}\frac{\|y(\cdot,\tau)\|^m_{L^\infty(B_{2\rho}(x_0))}}{\rho^{2m/(m-1)}}\rho^{\frac{1+m}{1-m}}\int_{B_{2\rho}(x_0)} ydxd\tau\right]^{2/(3m+1)} \\ &\le C[\phi(t,\rho)]^{2m/(3m+1)}[\psi(t,\rho)]^{2/(3m+1)} \\ &\le \frac{1}{4}\phi(t,\rho) + C[\psi(t,\rho)]^{2/(m+1)} \end{aligned} \tag{4.13}$$

and

$$\begin{aligned} H^2 &= [\phi(t,\rho)]^{(3m-3)/(3m+1)}\left(\int_{\frac{t}{4}}^{t}\int_{B_{2\rho}(x_0)} t^{\frac{2}{m+1}}\rho^{\frac{3m+1}{1-m}}y^{m+1}dxd\tau\right)^{2/(3m+1)} \\ &\le C[\phi(t,\rho)]^{(3m-3)/(3m+1)}\left[\int_{\frac{t}{4}}^{t}\tau^{(1-m)/(1+m)}\frac{1}{\rho}\right. \\ &\quad \left.\cdot\int_{B_{2\rho(x_0)}}\tau\frac{\|y(\cdot,\tau)\|^{m+1}_{L^\infty(B_{2\rho}(x_0))}}{\rho^{2(m+1)/(m-1)}}dxd\tau\right]^{2/(3m+1)} \\ &\le C[\phi(t,\rho)]^{(3m-3)/(3m+1)}\left[\int_{\frac{t}{4}}^{t}\tau^{(1-m)/(1+m)}\Phi^{m+1}(\tau,2\rho)d\tau\right]^{2/(3m+1)} \\ &\le C[\phi(t,\rho)]^{(3m-1)/(3m+1)}\left[\int_{\frac{t}{4}}^{t}\tau^{(1-m)/(1+m)}\phi^m(\tau,\rho)d\tau\right]^{2/(3m+1)} \\ &\le \frac{1}{4}\phi(t,\rho) + C\int_0^t\tau^{(1-m)/(1+m)}\phi^m(\tau,\rho)d\tau. \end{aligned} \tag{4.14}$$

Now the conclusion of Lemma 4.3 follows from (4.12), (4.13), and (4.14). □

LEMMA 4.4. *$\psi(t,\rho)$ and $\phi(t,\rho)$ satisfy*

$$\begin{aligned} \psi(t,\rho) \le C\Bigg\{&\int_0^t\tau^{-m/(1+m)}[\phi(\tau,\rho)]^{(m-1)/2}\psi(\tau,\rho)d\tau \\ &+\int_0^t\tau^{(2-m)/(1+m)}[\phi(\tau,\rho)]^{(3m-3)/2}\psi(\tau,\rho)d\tau\Bigg\} \\ &+|||y_0|||_\rho, \end{aligned} \tag{4.15}$$

where $|||y_0|||_\rho = \sup_{\rho\le r\le 2R} r^{(1+m)/(1-m)}\int_{B_r(x_0)} y_0(x)dx$.

Proof. We choose a smooth function ξ defined on $B_{2\rho}(x_0)$ such that

$$0 \le \xi \le 1, \quad \xi = 1 \text{ in } B_\rho(x_0), \quad |\xi_x| \le \frac{1}{\rho}.$$

Multiplying the first equation of (4.1) by $\tau^{1/2} y^{(m-1)/2}\xi^2$ and integrating on $B_{2\rho}(x_0)\times(0,t)$, we get

$$\begin{aligned}
&\frac{2}{m+1}\int_{B_{2\rho}(x_0)} t^{1/2}[y(x,t)]^{(m+1)/2}\xi^2(x)dx \\
&\quad + \frac{m(m-1)}{2}\int_0^t\int_{B_{2\rho}(x_0)} \tau^{1/2} y^{(3m-5)/2} y_x^2\xi^2 dxd\tau \\
&= \frac{1}{m+1}\int_0^t\int_{B_{2\rho}(x_0)} \tau^{-1/2} y^{(m+1)/2}\xi^2 dxd\tau - 2m\int_0^t\int_{B_{2\rho}(x_0)} \tau^{1/2} y^{(3m-3)/2} y_x\xi\xi_x dxd\tau \\
&\le \frac{1}{m+1}\int_0^t\int_{B_{2\rho}(x_0)} \tau^{-1/2} y^{(m+1)/2}\xi^2 dxd\tau + C\int_0^t\int_{B_{2\rho}(x_0)} \tau^{1/2} y^{(3m-1)/2}\xi_x^2 dxd\tau \\
&\quad + \frac{m(m-1)}{4}\int_0^t\int_{B_{2\rho}(x_0)} \tau^{1/2} y^{(3m-5)/2} y_x^2\xi^2 dxd\tau.
\end{aligned}$$

Thus we have

$$\begin{aligned}
\int_0^t\int_{B_{2\rho}(x_0)} \tau^{1/2} y^{(3m-5)/2} y_x^2\xi^2 dxd\tau &\le C\int_0^t\int_{B_{2\rho}(x_0)} \tau^{-1/2} y^{(m+1)/2} dxd\tau \\
&\quad + \frac{C}{\rho^2}\int_0^t\int_{B_{2\rho}(x_0)} \tau^{1/2} y^{(3m-1)/2} dxd\tau.
\end{aligned} \tag{4.16}$$

Denote

$$L(t) = \frac{1}{\rho^2}\int_0^t\int_{B_{2\rho}(x_0)} \tau^{1/2} y^{(3m-1)/2} dxd\tau,$$

$$J_2(t) = \int_0^t\int_{B_{2\rho}(x_0)} \tau^{-1/2} y^{(m+1)/2} dxd\tau.$$

Then we can derive

$$\begin{aligned}
J_2(t) &\le \int_0^t \tau^{-1/2}\rho^{\frac{1+m}{m-1}} \|y(\cdot,\tau)\|^{(m-1)/2}_{L^\infty(B_{2\rho}(x_0))}\rho^{\frac{1+m}{1-m}}\int_{B_{2\rho}(x_0)} y(x,\tau)dxd\tau \\
&\le C\int_0^t \tau^{\frac{-m}{m+1}}\rho^{\frac{2m}{m-1}}\left[\tau^{1/(m+1)}\frac{\|y(\cdot,\tau)\|_{L^\infty(B_{2\rho}(x_0))}}{\rho^{2/(m-1)}}\right]^{\frac{m-1}{2}}\psi(\tau,\rho)d\tau \\
&\le C\rho^{2m/(m-1)}\int_0^t \tau^{-m/(m+1)}[\phi(\tau,\rho)]^{(m-1)/2}\psi(\tau,\rho)d\tau
\end{aligned} \tag{4.17}$$

and

$$\begin{aligned}
L(t) &\le \frac{1}{\rho^2}\int_0^t \tau^{1/2}\rho^{\frac{1+m}{m-1}}\|y(\cdot,\tau)\|^{\frac{3m-3}{2}}_{L^\infty(B_{2\rho}(x_0))}\int_{B_{2\rho}(x_0)}\rho^{\frac{1+m}{1-m}} y(x,\tau)dxd\tau \\
&\le \int_0^t \rho^{\frac{2m}{m-1}}\tau^{\frac{2-m}{m+1}}\left[\tau^{1/(m+1)}\frac{\|y(\cdot,\tau)\|_{L^\infty(B_{2\rho}(x_0))}}{\rho^{2/(m-1)}}\right]^{(3m-3)/2}\psi(\tau,\rho)d\tau \\
&\le C\rho^{2m/(m-1)}\int_0^t \tau^{(2-m)/(m+1)}[\phi(\tau,\rho)]^{(3m-3)/2}\psi(\tau,\rho)d\tau.
\end{aligned} \tag{4.18}$$

Substituting (4.17) and (4.18) into (4.16), we get

$$\begin{aligned}&\int_0^t\int_{B_{2\rho}(x_0)}\tau^{1/2}y^{(3m-5)/2}y_x^2\xi^2dxd\tau\\ &\le C\rho^{2m/(m-1)}\int_0^t\tau^{-m/(m+1)}[\phi(\tau,\rho)]^{(m-1)/2}\psi(\tau,\rho)d\tau\\ &\quad+C\rho^{2m/(m-1)}\int_0^t\tau^{(2-m)/(m+1)}[\phi(\tau,\rho)]^{(3m-3)/2}\psi(\tau,\rho)d\tau.\end{aligned}\tag{4.19}$$

Multiplying the first equation of (4.1) by ξ^2 and integrating on $B_{2\rho}(x_0)\times(0,t)$, we have

$$\begin{aligned}\int_{B_\rho(x_0)}y(x,t)dx&\le\int_{B_{2\rho}(x_0)}y_0(x)dx+2m\int_0^t\int_{B_{2\rho}(x_0)}y^{m-1}y_x\xi\xi_xdxd\tau\\ &\le\int_{B_{2\rho}(x_0)}y_0(x)dx\\ &\quad+\frac{C}{\rho}\left(\int_0^t\int_{B_{2\rho}(x_0)}\tau^{1/2}y^{\frac{3m-5}{2}}y_x^2\xi^2dxd\tau\right)^{1/2}\\ &\quad\cdot\left(\int_0^t\int_{B_{2\rho}(x_0)}\tau^{-1/2}y^{\frac{m+1}{2}}dxd\tau\right)^{1/2}.\end{aligned}\tag{4.20}$$

Taking into account (4.17) and (4.19), in (4.20), we get

$$\begin{aligned}\int_{B_\rho(x_0)}y(x,t)dx&\le\int_{B_{2\rho}(x_0)}y_0(x)dx\\ &\quad+C\rho^{(1+m)/(m-1)}\int_0^t\tau^{-m/(m+1)}[\phi(\tau,\rho)]^{(m-1)/2}\psi(\tau,\rho)d\tau\\ &\quad+C\rho^{(1+m)/(m-1)}\int_0^t\tau^{(2-m)/(m+1)}[\phi(\tau,\rho)]^{(3m-3)/2}\psi(\tau,\rho)d\tau.\end{aligned}$$

Multiplying both sides of the above inequality by $\rho^{(1+m)/(1-m)}$, we get (4.15). ∎

LEMMA 4.5. *There exist constants γ_1, γ_2, γ_3, and $t^*>0$ such that*

$$\phi(t,\rho)\le\gamma_1|||y_0|||_\rho^{2/(m+1)},\quad \psi(t,\rho)\le\gamma_2|||y_0|||_\rho,\tag{4.21}$$

where $t<\min\{t^*,T,\gamma_3|||y_0|||_\rho^{1-m}\}$.

Proof. Since $\psi(\cdot,\rho)$ is increasing, by (4.11), it follows that for any fixed $t^*>0$,

$$\phi(t,\rho)\le C_1\int_0^t\tau^{(1-m)/(1+m)}\phi^m(\tau,\rho)d\tau+C_2[\psi(t^*,\rho)]^{2/(m+1)},\ t<t^*.$$

Hence $\phi(t,\rho)$ is less than or equal to the solution of the following problem:

$$H'(t)=C_1t^{(1-m)/(1+m)}H^m(t),$$

$$H(0)=C_2[\psi(t^*,\rho)]^{2/(m+1)}.$$

This implies

$$\phi(t,\rho) \le H(t) = C_2[\psi(t^*,\rho)]^{\frac{2}{m+1}} \left[1 - \frac{C_1(1+m)(m-1)}{2C_2^{1-m}}(t\psi^{m-1}(t^*,\rho))^{\frac{2}{1+m}}\right]^{1/(1-m)},$$

provided that the value in the bracket is positive.

If we take t^* such that

$$1 - \frac{C_1(1+m)(m-1)}{2C_2^{1-m}}(t^*\psi^{m-1}(t^*,\rho))^{2/(1+m)} > 0,$$

then

$$\phi(t,\rho) \le C_2[\psi(t,\rho)]^{\frac{2}{m+1}} \left[1 - \frac{C_1(1+m)(m-1)}{2C_2^{1-m}}(t\psi^{m-1}(t,\rho))^{\frac{2}{1+m}}\right]^{1/(1-m)}$$

for $t < t^*$.

Thus there exist positive constants δ_1 and δ_2 such that

$$(t\psi^{m-1}(t,\rho))^{2/(1+m)} \le \delta_1, \tag{4.22}$$

$$\phi(t,\rho) \le \delta_2[\psi(t,\rho)]^{2/(1+m)} \tag{4.23}$$

for $t < t^*$.

Substituting (4.22) and (4.23) into (4.15), we obtain

$$\begin{aligned}
\psi(t,\rho) &\le C\int_0^t \tau^{-m/(1+m)}[\psi(\tau,\rho)]^{2m/(1+m)}d\tau \\
&\quad + C\int_0^t \tau^{(2-m)/(1+m)}[\psi(\tau,\rho)]^{(4m-2)/(1+m)}d\tau + |||y_0|||_\rho \\
&\le C\int_0^t \tau^{-m/(1+m)}[\psi(\tau,\rho)]^{2m/(1+m)}\left(1 + \tau^{\frac{2}{1+m}}[\psi(\tau,\rho)]^{2(m-1)/(1+m)}\right)d\tau \\
&\quad + |||y_0|||_\rho \\
&\le C\int_0^t \tau^{-m/(1+m)}[\psi(\tau,\rho)]^{2m/(1+m)}d\tau + |||y_0|||_\rho
\end{aligned}$$

for $t < t^*$.

Hence $\psi(t,\rho)$ is less than or equal to the solution of the following problem:

$$M'(t) = Ct^{-m/(1+m)}[M(t)]^{2m/(1+m)},$$

$$M(0) = |||y_0|||_\rho.$$

This implies

$$\psi(t,\rho) \le M(t) = |||y_0|||_\rho \left[1 - \frac{C(m-1)t^{1/(1+m)}}{|||y_0|||_\rho^{(1-m)/(1+m)}}\right]^{(1+m)/(1-m)},$$

provided that

$$1 - \frac{C(m-1)t^{1/(1+m)}}{|||y_0|||_\rho^{(1-m)/(1+m)}} > 0.$$

Thus there exist two constants γ_2 and γ_3 such that if $t < \min\left\{t^*, \gamma_3|||y_0|||_\rho^{1-m}\right\}$, then

$$\psi(t,\rho) \le \gamma_2|||y_0|||_\rho.$$

Furthermore, by (4.23), there exists a constant $\gamma_1 > 0$ such that

$$\phi(t,\rho) \le \gamma_1|||y_0|||_\rho^{2/(1+m)}.$$

Thus we get the conclusion of Lemma 4.5. □

The above inequality implies that

$$\|y(\cdot,t)\|_{L^\infty(B_\rho(x_0))} \le \gamma_1 t^{-1/(1+m)}\rho^{2/(m-1)}|||y_0|||_\rho^{2/(1+m)} \tag{4.24}$$

for $t < \min\left\{t^*, T, \gamma_3|||y_0|||_\rho^{1-m}\right\} := T^*$.

By (4.24), for any time $T < T^*$ and initial value $y_0 \in L^\infty(-1,1)$ with $y_0 \ge 0$ a.e. in $(-1,1)$, we can always find a target $y_1 \in L^2_+(-1,1) + Y_d$ satisfying $\|y_1\|_{L^\infty(B_\rho(x_0))} > \gamma_1 T^{-1/(1+m)}\rho^{2/(m-1)}|||y_0|||_\rho^{2/(1+m)} + 1$ such that for any $u \in L^2_+(\omega \times (0,T))$, the corresponding solution y of system (4.1) satisfies

$$\|y(\cdot,T;u) - y_1\|_{L^2(-1,1)} > \frac{1}{2},$$

which shows that y_1 is not approximately controllable at time T. The above result implies the conclusion of Theorem 1.8.

Remark 4.6. Using the same method as that in [22], we can prove that the solution of system (4.1) has the property of finite speed of propagation for each nonnegative control. However, by this result, we cannot explain why system (1.1) is not approximately controllable at small time, unlike the case of a hyperbolic system. Indeed, the method used in [22] determines that the speed of propagation of solution depends on the control function closely. Here we use a technique of local estimates to prove an obstruction phenomenon, which leads to a negative controllability result. In fact, inequality (4.24) implies the finite speed of propagation of solution for system (4.1).

Acknowledgment. The authors thank all reviewers for their constructive comments.

ROBUST CONTROL APPROACH TO OPTION PRICING: A REPRESENTATION THEOREM AND FAST ALGORITHM*

PIERRE BERNHARD†, NAÏMA EL FAROUQ‡, AND STÉPHANE THIERY†

Abstract. The so-called interval model for security prices, together with a robust control approach, allows one to construct a consistent theory of option pricing, including discrete time trading and arbitrary transaction costs. In this context, a new representation theorem for the viscosity solution of the relevant Isaacs (differential) quasi-variational inequality leads to simple formulas and fast numerical algorithms to compute a hedging portfolio. We argue that in spite of a less satisfactory market model, the overall theory is not much less realistic than the classical Black and Scholes theory but rather only that it shifts from the portfolio model to the market model the place where the model is violated when sudden large price changes occur on the market. As such, and subject to a more detailed validation, the new theory might be the basis of a possible alternative as a normative theory whenever transaction costs or discrete time trading are the main concerns.

Key words. option pricing, hedging, transaction costs, robust control, impulse control

1. Introduction.

1.1. The robust control approach to option pricing. In [7, 8, 11], we introduced a robust control approach to option pricing, and more specifically to the design of a hedging portfolio and management strategy, using the so-called interval model for the market and a robust control approach to hedging.

The main claims of that new approach are, on the one hand, the possibility of constructing a consistent theory of hedging portfolios with either continuous or discrete time trading paradigms, the former being the limit of the latter for vanishing time steps, with one and the same (continuous time) market model, and, on the other hand, to accommodate transaction costs and closing costs in a natural way, with a nontrivial hedging portfolio.

We postpone until the last section the discussion of the drawbacks of the "interval model" as compared to the classical Samuelson geometric diffusion. But we dispel at once one criticism, that it does not make use of probabilistic knowledge on the price trajectories. Indeed, it is now known that Black and Scholes formula can be recovered via a purely deterministic scheme. Cox, Ross, and Rubinstein [13] and Kolokol'tsov [16] derive it in passing to the limit as the step size vanishes in a discrete time model. In their model, though, the underlying market model changes with the step size, in a way so as to generate a random walk in the limit. In [7] we obtain that same formula directly with a continuous time model of price evolution and continuous trading but still without endowing the set of possible price histories with a probability law.

Here, after summarizing some previous results, we show a new representation of the solution of the problem at hand—and thus of the pricing function—in terms of

the solution of a pair of simple coupled first order linear PDEs in two variables. This yields a fast algorithm to compute both the seller's price and the hedging strategy, thus alleviating the computational complexity that could heretofore be considered a drawback of that approach. Also, we provide a more detailed comparison of the new pricing paradigm with the classical Black and Scholes formula than in the previous papers on that topic and some numerical evaluations of the robustness of the new theory to violations of its market model.

At this point, we wish to stress two things: on the one hand, we do not claim a kind of overall superiority of the new theory over that of Black and Scholes. We claim only that this is a possible approach that may, concerning certain problems, be interesting to use in comparison with the more classical ones.

On the other hand, if we can convince the reader of this fact, he will accept that, concerning a new theory, it is not as yet as well documented as the long-standing Black and Scholes theory, nor as well understood in all its implications.

Among other shortcomings at this time, we do not yet have detailed and comparative validation data. And, in contrast with [16, 21, 22] and most of the literature on superreplication, we have investigated only the *seller's price* of our model, i.e., the price that the seller must charge to make sure to always hedge his costs, that is, as long as the market does not violate the hypotheses of the model.

1.2. Related contributions. Among previous uses of this type of model, let us quote the following.

McEneaney [18] may have been the first to replace the stochastic framework with a robust control approach. He derives the so-called stop loss strategy for bounded variation trajectories. He also recovers the Black and Scholes theory, but this is done at the price of artificially modifying the portfolio model with no other justification than recovering the Itô calculus and the Black and Scholes PDE.

As already noted, Cox, Ross, and Rubinstein [13] introduced a nonstochastic approach to the theory of option pricing in a discrete time setting. Their market model is related to ours in that where we allow for an interval of possible future stock prices, they allow only the end points of such an interval. This model clearly involves no claim of being realistic for any finite time step. Its only objective is to converge, as the time step vanishes, to a continuous random walk, to recover either the Black and Scholes theory or another one with possible price jumps, depending on how the market model behaves in that limiting process.

Kolokol'tsov [16, 17] generalizes the approach of Cox, Ross, and Rubinstein by allowing the same "interval model" as we use here. He notices, as we do in [6], the coincidence with Cox, Ross, and Rubinstein's theory when the final payment is convex. He expands that theory to "rainbow" options, based on several common stocks, and performs a limiting operation similar to that of Cox, Ross, and Rubinstein to derive an equivalent of the Black and Scholes formula for these options. In the case of the interval model, the author points out that the strategy proposed leads to superreplication, so that the trader might have a positive result. This leads him to define a range of "reasonable" or "fair" prices and a mean price. (In this setting, we consider here only his upper bound, i.e., a seller's price.)

In [7], we recover both the stop-loss strategy and the complete Black and Scholes theory without any probability in the model, without having to artificially modify the portfolio model, simply by choosing carefully the set of admissible underlying stock price trajectories and using a weak version of a lemma of Föllmer [15]. The model used there is *not* an interval model. To the contrary, it uses a set of trajectories

in which the trajectories of Samuelson's model almost surely lie. This explains why we recover the Black and Scholes theory while in the present setting we arrive at a different set of formulas.

A special quotation must be made for the amazing book by Shafer and Vovk [24]. They start from the same analysis of hedging as we do in terms of a game against "nature." But where we conclude that we can do without probability theory, they claim that this *is* probability theory. Or rather they claim that this can be an alternative to Kolmogorov's measure-theoretical foundation of probability theory, and they proceed to recover many results, such as asymptotic and ergodic theorems, from this new viewpoint. Our seller's price is their "upper expectation" (of which they claim that it is the price likely to be found on the market). Yet, they are more interested in recovering classical probabilities and elaborating on the classical Black and Scholes theory than in providing alternative models and tackling the problems of transaction costs and discrete trading that we consider. We did not find hints to something like the interval model in this fascinating book, but the relationship of that theory with our model deserves further thinking.

Pujal [20] and Aubin, Pujal, and Saint-Pierre [2] have also adopted the robust control approach (they call it "tychastic" approach), with a market model which is a more general version of our model, since it applies a priori to rainbow options as well. Yet, they do not allow jumps in the content of the portfolio, limiting its rate of change. Saint-Pierre [23] has done efficient implementations of that theory with exactly the interval market model that we use below. He has a fast algorithm which bears a strong resemblance to ours, although precisely asserting their relationship is made difficult by the fact that since their portfolio model is more restrictive than ours, the value function cannot coincide. And our fast algorithm is based upon a representation theorem for our value function.

Similar thoughts are developed by Olsder [19], although this is only a preliminary analysis as stated by the author. And very similar ideas have been developed by Dupire [14] in the context of what he calls "dominance" theory. Barles and Soner [3] developed a different approach to option pricing that let them deal with transaction costs, but then, the price they arrive at depends on the rest of the trader's portfolio.

We took the phrase "interval model" from Roorda, Engwerda, and Schumacher [21, 22], where the authors adopt a viewpoint close to that of robust control. In particular their definition of a market model is the same as ours: a set of possible price trajectories. Their analysis is somewhat different from ours, as they do endow the set of possible trajectories with a probability law. Yet, because they have an interval model, they also run into a superreplication problem and, in a fashion similar to Kolokol'tsov, define a range of "fair" prices.

1.3. Paper outline. In the next section, we present the interval model, both in the continuous trading formalism and in its discretized form, and the portfolio model we adopt, which includes transaction costs and closing costs at will. The consideration of closing costs obliges us to distinguish the cases where the closing is "in kind" or "in cash," because the closing costs born by the trader are not the same.

Section 3 is devoted to the continuous trading problem. We recall the main results we have obtained so far, stressing the case of simple call and put. Next we show a new representation theorem of the solution of the pricing problem. The complete proof of this theorem, and its main use, relies on results of the next section. We also investigate the optimal trading strategies, which have a simple form.

In section 4, we investigate the discrete trading theory. We provide a discrete

time version of the representation theorem and derive from it a new fast algorithm to compute the seller's price. And as we have a convergence theorem of the discrete trading seller's price toward the continuous trading one as the time step vanishes [11], this is also a discretization algorithm for the continuous problem.

Finally, having displayed what can be achieved with this new model, we discuss in the final section its relative strengths and weaknesses compared with the classical Black and Scholes theory. As the main weakness of the new theory is in the unrealistic assumption of the market model, this discussion is mostly based upon an investigation of the robustness of our hedging strategies to violations of that hypothesis. In that discussion, we take a normative view of our theory, i.e., as a decision aid, rather than the positive view of a predictive theory which is more common in economical thinking.

2. Interval model.

2.1. Riskless interest rate. We assume a fixed, known, riskless interest rate ρ characteristic of that economy. In a classical fashion, all monetary values will be assumed to be expressed in end-time value computed at that fixed riskless rate, so that, without loss of generality, the riskless rate can be taken as (seemingly) zero. (It reappears in the theory of American options, but we have not covered it here for lack of space.)

2.2. Market. We share with Roorda, Engwerda, and Schumacher [21, 22] the view that a market model is a set Ω of possible price trajectories. Our model is defined by two real numbers $\tau^- < 0$ and $\tau^+ > 0$, and Ω is the set of all absolutely continuous functions $u(\cdot)$ such that for any two time instants t_1 and t_2,

$$\mathrm{e}^{\tau^-(t_2-t_1)} \le \frac{u(t_2)}{u(t_1)} \le \mathrm{e}^{\tau^+(t_2-t_1)}\,. \tag{1}$$

The notation τ^ε will be used to handle both τ^+ and τ^- at a time. Hence, in that notation, it is understood that $\varepsilon \in \{-,+\}$, sometimes identified to $\{-1,+1\}$.

In the continuous trading theory, we shall use the equivalent characterization

$$\dot{u} = \tau u\,, \quad \tau \in [\tau^-, \tau^+]\,. \tag{2}$$

In that formulation, $\tau(\cdot)$ is a measurable function, which plays the role of the "control" of the market. We shall let Ψ denote the set of measurable functions from $[0,T]$ into $[\tau^-,\tau^+]$. It is equivalent to specify a $u(\cdot)\in\Omega$ or a $(u(0),\tau(\cdot))\in\mathbb{R}^+\times\Psi$. This is an a priori unknown time function. The concept of nonanticipative strategies embodies that fact.

In the discrete trading theory, we shall call h our time step with $T = \mathcal{K}h$, $\mathcal{K}$ being an integer. The hypothesis (1) translates into[1]

$$u(t+h) \in [\mathrm{e}^{\tau^- h}u(t), \mathrm{e}^{\tau^+ h}u(t)]\,.$$

For convenience, we let

$$u(t+h) = (1+\tau(t))u(t)\,, \quad \tau(t) \in [\tau_h^-, \tau_h^+] \tag{3}$$

with

$$\tau_h^\varepsilon = \mathrm{e}^{\tau^\varepsilon h} - 1\,, \quad \varepsilon = \pm\,. \tag{4}$$

[1]It does *not* translate into $u(t+h) \in \{\mathrm{e}^{\tau^- h}u(t), \mathrm{e}^{\tau^+ h}u(t)\}$ as in the Cox–Ross–Rubinstein theory.

Alternatively, we shall write, for any integer k, $u(kh) = u_k$, so that (3) also reads

$$u_{k+1} = (1 + \tau_k)u_k\,, \quad \tau_k \in [\tau_h^-, \tau_h^+], \tag{5}$$

and we let Ψ denote the set of such sequences $\{\tau_k\}$.

The case where h goes to zero will be of interest also. But, contrary to the classical limit process in the Cox–Ross–Rubinstein theory, we keep the underlying continuous time model, hence here τ^+ and τ^-, fixed. Then τ_h^ε behaves as $h\tau^\varepsilon$.

2.3. Portfolio. A (hedging) portfolio will be composed of an amount v (in end-time value) of underlying stock, and an amount y of riskless *bonds*, for a total worth of $w = v + y$. In the normalized (or end-value) representation, the bonds are seemingly with zero interest.

2.3.1. Buying and selling. We let $\xi(t)$ be the buying rate (a sale if $\xi(t) < 0$), which is the trader's control. Therefore we have, in continuous time,

$$\dot v = \tau v + \xi\,. \tag{6}$$

However, there is no reason to restrict the buying/selling rate, so that there is no bound on ξ. To avoid mathematical ill-posedness, we explicitly admit "infinite" buying/selling rate in the form of instantaneous block buy or sale of a finite amount of stock at time instants chosen by the trader together with the amount. Thus the control of the trader also involves the choice of finitely many time instants t_k and trading amounts ξ_k, and the model must be augmented with

$$v(t_k^+) = v(t_k) + \xi_k\,, \tag{7}$$

meaning that $v(\cdot)$ has a jump discontinuity of size ξ_k at time t_k. Equivalently, we may keep formula (6) but allow for impulses $\xi_k\delta(t - t_k)$ in $\xi(\cdot)$.

We shall therefore let $\xi(\cdot) \in \Xi$, the set of real time functions (or rather distributions) defined over $[0, T]$ which are the sum of a measurable function $\xi_c(\cdot)$ and a finite number of weighted translated Dirac impulses $\xi_k\delta(t - t_k)$.

2.3.2. Transaction costs. We assume that there are transaction costs. In this paper, we assume that they are proportional to the transaction amount. But we allow for different proportionality coefficients for a buy or a sale of underlying stock. Hence let C^+ be the cost coefficient for a buy, and $-C^-$ for a sale, so that the cost of a transaction of amount ξ is $C^\varepsilon\xi$ with $\varepsilon = \operatorname{sign}(\xi)$. We have chosen C^- negative, so that, as it should, that formula always gives a positive cost.

We shall use the convention that when we write $C^\varepsilon(\textit{expression})$, and except if otherwise specified, the symbol ε in C^ε stands for the sign of the *expression*.

Our portfolio will always be assumed *self-financed*; i.e., the sale of one of the commodities, underlying stock or riskless bonds, must exactly pay for the buy of the other one *and* the transaction costs. It is a simple matter to see that the worth w of the portfolio then obeys

$$\dot w = \tau v - C^\varepsilon\xi\,, \tag{8}$$

and at jump instants,

$$w(t_k^+) = w(t_k^-) - C^{\varepsilon_k}\xi_k. \tag{9}$$

This is equivalent to

$$w(t) = w(0) + \int_0^t (\tau(s)v(s) - C^\varepsilon\xi(s))\,\mathrm{d}s - \sum_{k|t_k<t} C^{\varepsilon_k}\xi_k\,. \tag{10}$$

2.3.3. Discrete trading. The discrete trading case can be seen as a sequence of jumps at prescribed time instants $t_k = kh$, $k \in \mathbb{K} = \{0, 1, \dots \mathcal{K}\text{–}1\} \subset \mathbb{N}$, and $h \in \mathbb{R}^+$ a prescribed time step, such that $\mathcal{K}h = T$. Writing u_k, v_k, w_k for $u(kh), v(kh), w(kh)$, it leads to

$$v_{k+1} = (1 + \tau_k)(v_k + \xi_k)\,, \tag{11}$$

$$w_{k+1} = w_k + \tau_k(v_k + \xi_k) - C^{\varepsilon_k}\xi_k\,. \tag{12}$$

We shall use the explicit form

$$w_n = w_0 + \sum_{k=0}^{n-1}(\tau_k(v_k + \xi_k) - C^{\varepsilon_k}\xi_k)\,. \tag{13}$$

A *dynamic portfolio* will be a pair of time functions $(v(\cdot), w(\cdot))$, whether time is continuous or discrete, also denoted $(\{v_k\}, \{w_k\})_{k\in\mathbb{K}}$ in the latter case.

2.4. Hedging.

2.4.1. Strategies. The initial portfolio is to be created at step 0. As a consequence the seller's price is obtained taking $v(0) = 0$. Then, formally, admissible hedging strategies will be functions $\varphi : \Omega \to \Xi$ which enjoy the property of being nonanticipative:

$$\forall (u_1(\cdot), u_2(\cdot)) \in \Omega \times \Omega, \quad [u_1|_{(0,t)} = u_2|_{(0,t)}] \Rightarrow [\varphi(u_1(\cdot))|_{[0,t]} = \varphi(u_2(\cdot))|_{[0,t]}].$$

(It is understood here that the restriction of $\delta(t-t_k)$ to a closed interval not containing t_k is 0, and its restriction to a closed interval containing t_k is an impulse.)

In practice, we shall find optimal hedging strategies made of a jump at initial time, followed by a state feedback law $\xi(t) = \phi(t, u(t), v(t))$.

In discrete time, the situation is much simpler. We need only a nonanticipative strategy $\varphi : \Omega \to \mathbb{R}^T$ giving $\xi_k = \varphi_k(u_0, u_1, \dots, u_k)$. Again, we shall find it in the form of a state feedback $\xi_k = \phi_k(u_k, v_k)$.

Yet, these are only nonanticipative laws, the equivalent of stochastic adapted strategies. We have shown in [11] how to handle *strictly* nonanticipative strategies, the equivalent of the stochastic predictable strategies.

We shall call Φ the set of admissible trading strategies.

2.4.2. Closing costs. The idea of a hedging portfolio is that at exercise time, the writer is going to close off its position after abiding by its contract, buying or selling some of the underlying stock according to the necessity. We assume that it sustains proportional costs on this final transaction. We allow for the case where these costs would be different from the running transaction costs because compensation effects might lower them and also allow for the case without closing costs just by making their rate 0. Therefore let $c^+ \le C^+$ and $-c^- \le -C^-$ be these rates.

It is a simple matter to see that, in order to cover both cases where the buyer does or does not exercise its option, the portfolio worth at final time should be $N(u, v)$, given for a call and a closure in kind by

$$N(u, v) = \max\{c^\varepsilon(-v)\,,\ u - K + c^\varepsilon(u - v)\}\,,$$

where the notation convention for $c^\varepsilon(expression)$ holds. We expect that on a typical optimum hedging portfolio for a call, $0 \le v(T) \le u(T)$. Hence

$$N(u, v) = \max\{-c^- v\,,\ u - K + c^+(u - v)\}\ . \tag{14}$$

In the case of a put, where $-u(T) \le v(T) \le 0$, we need to replace the above expression by

$$N(u,v) = \max\{-c^+ v\,,\ K - u - c^-(u+v)\}. \tag{15}$$

The case of a closure in cash is similar but leads to less appealing mathematical formulas in later developments. The details can be found in [10].

2.4.3. Hedging portfolio. An initial portfolio $(v(0), w(0))$ and an admissible trading strategy φ, together with a price history $u(\cdot)$, generate a dynamic portfolio. We set the following.

DEFINITION 2.1. *An initial portfolio* $(v(0) = 0, w(0) = w_0)$ *and a trading strategy* φ *constitute a* hedge *at* u_0 *if for any* $u(\cdot) \in \Omega$ *such that* $u(0) = u_0$ *(equivalently, for any admissible* $\tau(\cdot)$*), the dynamic portfolio thus generated satisfies*

$$w(T) \ge N(u(T), v(T))\,. \tag{16}$$

Now, we may use (10) at time T to rewrite this:

$$\forall \tau(\cdot) \in \Psi\,, \quad N(u(T), v(T)) + \int_0^T \Big(-\tau(t)v(t) + C^\varepsilon \xi(t)\Big)\,\mathrm{d}t + \sum_k C^{\varepsilon_k}\xi_k - w_0 \le 0\,.$$

This in turn is clearly equivalent to

$$w_0 \ge \sup_{\tau(\cdot)\in\Psi} \left[N(u(T), v(T)) + \int_0^T \Big(-\tau(t)v(t) + C^\varepsilon \xi(t)\Big)\,\mathrm{d}t + \sum_k C^{\varepsilon_k}\xi_k \right].$$

We further set the following.

DEFINITION 2.2. *The* seller's price *of the option at* u_0 *is the worth of the cheapest hedging portfolio at* u_0*.*

The seller's price at u_0 is therefore

$$P(u_0) = \inf_{\varphi\in\Phi} \sup_{\tau(\cdot)\in\Psi} \left[N(u(T), v(T)) + \int_0^T \Big(-\tau(t)v(t) + C^\varepsilon \xi(t)\Big)\,\mathrm{d}t + \sum_k C^{\varepsilon_k}\xi_k \right], \tag{17}$$

where it is understood that $v(0) = 0$ and that $\xi(\cdot) = \varphi(u_0, \tau(\cdot))$.

In the case of discrete trading, we get similarly as the seller's price at u_0

$$P(u_0) = \min_{\varphi\in\Phi} \sup_{\{\tau_k\}\in\Psi} \left[N(u_K, v_K) + \sum_{k=0}^{K-1} \Big(-\tau_k(v_k + \xi_k) + C^{\varepsilon_k}\xi_k\Big) \right]. \tag{18}$$

3. Continuous trading.

3.1. The differential game. We are therefore led to the investigation of the impulse control differential game whose dynamics are given by (2), (6), and (7) and the criterion by (17). In a classical fashion we introduce its Isaacs value function:

$$W(t,u,v) = \inf_{\varphi\in\Phi} \sup_{\tau(\cdot)\in\Psi} \left[N(u(T), v(T)) + \int_t^T \Big(-\tau(s)v(s) + C^\varepsilon \xi(s)\Big)\,\mathrm{d}s + \sum_{k|t_k\ge t} C^{\varepsilon_k}\xi_k \right], \tag{19}$$

where the dynamics are integrated from $u(t) = u$, $v(t) = v$. Hence the seller's price is $P(u_0) = W(0, u_0, 0)$.

There are new features in that game, in that, on the one hand, impulse controls are allowed, and hence an Isaacs quasi-variational inequality (or QVI; see Bensoussan and Lions [4]) should be at work, but, on the other hand, impulse costs have a zero infimum. As a consequence, that QVI is degenerate, and no general result is available. In Bernhard, El Farouq, and Thiery [11], we introduce the so-called Joshua transformation that lets us show the following fact.

THEOREM 3.1. *The function W defined by* (19) *is a continuous viscosity solution of the following "differential QVI":*

$$
\begin{aligned}
0 = \min\Bigg\{ & \frac{\partial W}{\partial t} + \max_{\tau\in[\tau^-,\tau^+]} \tau \left[\frac{\partial W}{\partial u} u + \left(\frac{\partial W}{\partial v} - 1 \right) v \right], \\
& \frac{\partial W}{\partial v} + C^+, \quad -\left(\frac{\partial W}{\partial v} + C^- \right) \Bigg\}, \\
W(T, u, v) = {} & N(u, v)\,.
\end{aligned}
\tag{20}
$$

This PDE in turn lends itself to an analysis, either along the lines of the Isaacs–Breakwell theory through the construction of a field of characteristics for a transformed game (see [11]) or using the theory of viscosity solutions and the representation theorem as outlined hereafter. The solution we seek is further characterized by its behavior at infinity. Yet its uniqueness does not derive from the classical results on viscosity solutions. We have to take this into account in our proof of Theorem 3.2 below.

3.2. Simple call or put.

3.2.1. Representation formula. We give here a new theory of (20). We introduce two functions $\check{v}(t, u)$, a representation of the singular manifold, and $\check{w}(t, u)$, the restriction of W to that manifold, handled jointly as

$$
\mathcal{V}(t, u) = \begin{pmatrix} \check{v}(t, u) \\ \check{w}(t, u) \end{pmatrix}.
$$

That pair of functions is entirely defined by a linear PDE that involves the following two matrices (q^- and q^+ are defined hereafter in (22)):

$$
\mathcal{S} = \begin{pmatrix} 1 & 0 \\ 1 & 0 \end{pmatrix} \quad \text{and} \quad \mathcal{T} = \frac{1}{q^+ - q^-} \begin{pmatrix} \tau^+ q^+ - \tau^- q^- & \tau^+ - \tau^- \\ -(\tau^+ - \tau^-) q^+ q^- & \tau^- q^+ - \tau^+ q^- \end{pmatrix},
$$

and it seems to play a very important role in the overall theory. Namely,

$$
\mathcal{V}_t + \mathcal{T}(\mathcal{V}_u u - \mathcal{S}\mathcal{V}) = 0\,. \tag{21}
$$

The definitions of q^+ and q^-, as well as the terminal conditions at T for (21), depend on the type of option considered. For a simple call or put, and a closure in kind, we have

$$
\begin{aligned}
q^-(t) &= \max\{(1 + c^-) \exp[\tau^-(T - t)] - 1\,,\ C^-\}\,, \\
q^+(t) &= \min\{(1 + c^+) \exp[\tau^+(T - t)] - 1\,,\ C^+\}\,.
\end{aligned}
\tag{22}
$$

Notice that $q^\varepsilon = C^\varepsilon$ for $t \le t_\varepsilon$, with

$$T - t_\varepsilon = \frac{1}{\tau^\varepsilon} \ln \frac{1 + C^\varepsilon}{1 + c^\varepsilon} \ . \tag{23}$$

The terminal conditions are given, for a call, by

$$\mathcal{V}^t(T,u) = \begin{cases} (\,0 \quad 0\,) & \text{if } u < \dfrac{K}{1+c^+}\,, \\ \dfrac{(1+c^+)u - K}{c^+ - c^-}(\,1 \quad -c^-\,) & \text{if } \dfrac{K}{1+c^+} \le u < \dfrac{K}{1+c^-}\,, \\ (\,u \quad u - K\,) & \text{if } u \ge \dfrac{K}{1+c^-} \end{cases} \tag{24}$$

and symmetric formulas for a put. (All combinations call/put, closure in kind/in cash, are detailed in [10]).

We claim the following fact.

THEOREM 3.2. *The function W defined by* (19) *is given by*

$$W(t,u,v) = \check{w}(t,u) + q^\varepsilon(\check{v}(t,u) - v)\,, \quad \varepsilon = \operatorname{sign}(\check{v} - v)\,, \tag{25}$$

where q^ε is given by formula (22) *(for a simple call or put), and $(\check{v}\ \check{w}) = \mathcal{V}^t$ is given by* (21) *and the terminal conditions* (24) *for a call (and symmetrical formulas for a put).*

Proof. The proof is done by checking first that the function (25) is indeed a viscosity solution of (20). That complete check is rather lengthy, as it involves checking the viscosity condition on many manifolds where ∇W may be discontinuous. It is given in the appendix.

Then we notice that the function W thus constructed has (in the Joshua transformed form of [11]) the regularity required[2] by the classical verification theorem in its detailed form of [5] (replacing "lower value" by "upper value"). The viscosity conditions imply the satisfaction of the old corner conditions, as developed in that paper. Thus the verification theorem applies, and that function is indeed the value function of the original differential game. (Let us add that numerical integration supports that claim with great accuracy.) □

It can also be shown that the solution of (21) is nontrivial only in the region where the option may end either in the money or out of the money, i.e., the region

$$\frac{K}{1+c^+} \mathrm{e}^{-\tau^+(T-t)} \le u \le \frac{K}{1+c^-} \mathrm{e}^{-\tau^-(T-t)}\,. \tag{26}$$

Outside of this region, it keeps the form of the terminal condition.

COROLLARY 3.3. *The seller's price of a call is $\check{w}(0,u_0) + q^+(0)\check{v}(0,u_0)$, with $\check{v}$ and $\check{w}$ initialized as in* (24) *(and symmetrically for a put).*

3.2.2. Optimal trading strategy. A hedging strategy is $\xi = 0$ (does no trading) as long as $w \ge W(t,u,v)$. When $w = W(t,u,v)$, it is defined in terms of $\varepsilon = \operatorname{sign}(\check{v}(t,u) - v)$ and is $\xi = 0$ if $t \ge t_\varepsilon$, a positive jump towards $\check{v}$ if $\varepsilon = +1$ and $t < t_+$, and a negative jump towards $\check{v}$ if $\varepsilon = -1$ and $t < t_-$. On the manifold $v = \check{v}$,

[2] It is continuous, which is more than required by the theorem, piecewise C^2 in domains defined by C^2 manifolds on which it has simple gradient discontinuities.

we have shown that there is a control, depending on τ, that keeps $w(t)$ on or "above" the graph of W.

The dependence of the control $\xi(t)$ on the instantaneous rate $\tau(t)$ is undesirable. It is not implementable as such and is not an admissible causal strategy. (Accepting such strategies would create arbitrage opportunities.) However, the convergence theorem of [11], recalled in the next section, provides a practical solution: use the discrete time theory with whatever time step is feasible. It gives an exact (within our model) admissible hedging strategy for a portfolio value close to the optimum one.

4. Discrete trading.

4.1. The multistage game. In the case of discrete trading, we have to investigate the game whose dynamics are given by (5) and (11), and the criterion by (18). This is a completely classical dynamic game. Let $W^h(kh,u,v) = W^h_k(u,v)$ be its Isaacs value function. We immediately obtain its Isaacs equation and the following theorem.

THEOREM 4.1. *The value function W^h is given by the recursion*

$$
\begin{aligned}
&\forall k < \mathcal{K}, \forall (u,v)\,, \quad W^h_k(u,v)\\
&= \min_{\xi} \max_{\tau\in[\tau_h^-,\tau_h^+]} [W^h_{k+1}((1+\tau)u,(1+\tau)(v+\xi)) - \tau(v+\xi) + C^\varepsilon \xi],\\
&\forall (u,v)\,, \quad W^h_{\mathcal{K}}(u,v) = N(u,v)\,.
\end{aligned}
\tag{27}
$$

Finally, the main theorem of [11], and a central result in that theory, is the following convergence theorem. Let $W^h(t,u,v)$ be the function obtained by linear interpolation in time between $W^h_k(u,v)$ and $W^h_{k+1}(u,v)$ with $t \in [kh,(k+1)h]$.

THEOREM 4.2. *The functions W^h converge uniformly on every compact towards the function W (of the continuous trading theory) when the step h goes to zero (in a dyadic fashion: $h = T/(2^n)$, $n \to \infty$).*

Optimal hedging strategy. An important consequence of this theorem is that, even if we are almost in a "continuous trading" situation, the optimal portfolio and trading strategy can be approached by a discrete trading strategy. However, the optimal discrete trading strategy does *not* make use of τ_k to compute ξ_k. Thus it alleviates the problem of the dependence of the optimal strategy on τ in the continuous time theory.

As a matter of fact, one computes a sequence of $\check{v}^h_k(u)$ (see the next paragraph), and let $\varepsilon = \operatorname{sign}(\check{v}^h_k(u_k) - v_k)$. The optimal discrete time hedging strategy is just to do nothing if $t_k \geq t_\varepsilon$ (see (23))—but for most realistic value of the parameters, this is immaterial because $T - t_\varepsilon < h$—and for all other discrete time instants to jump to $v = \check{v}^h_k(u_k)$, which therefore plays the role of an optimum portfolio composition.

4.2. A fast algorithm. We propose here a new fast algorithm to compute the solution of (27), which, in view of Theorem 4.2, also yields a fast algorithm to approximate a solution of the continuous trading problem. It can be viewed as a particular difference scheme for (21).

Define the following recursion:

$$
\begin{aligned}
q^\varepsilon_K &= c^\varepsilon\,,\\
q^\varepsilon_{k+\frac{1}{2}} &= (1+\tau^\varepsilon_h) q^\varepsilon_{k+1} + \tau^\varepsilon_h\,,\\
q^\varepsilon_{k+1} &= \varepsilon \min\{\varepsilon q^\varepsilon_{k+\frac{1}{2}}\,,\, \varepsilon C^\varepsilon\}\,,
\end{aligned}
\tag{28}
$$

and let, for every integer ℓ,

$$Q_\ell^\varepsilon = \begin{pmatrix} q_\ell^\varepsilon & 1 \end{pmatrix} \quad \text{and} \quad \mathcal{V}_\ell^h(u) = \begin{pmatrix} \check{v}_\ell^h(u) \\ \check{w}_\ell^h(u) \end{pmatrix}. \tag{29}$$

Take $\check{v}_{\mathcal{K}}^h(u) = \check{v}(T,u)$, $\check{w}_{\mathcal{K}}^h(u) = \check{w}(T,u)$ as given by (24) for a call (symmetrically for a put) and

$$\mathcal{V}_k^h(u) = \frac{1}{q_{k+\frac{1}{2}}^+ - q_{k+\frac{1}{2}}^-} \begin{pmatrix} 1 & -1 \\ -q_{k+\frac{1}{2}}^- & q_{k+\frac{1}{2}}^+ \end{pmatrix} \begin{pmatrix} Q_{k+1}^+ \mathcal{V}_{k+1}^h((1+\tau^+)u) \\ Q_{k+1}^- \mathcal{V}_{k+1}^h((1+\tau^-)u) \end{pmatrix}. \tag{30}$$

We leave to the reader the tedious, but straightforward, task to check that this is indeed a consistent finite difference scheme for (21).

We claim the following.

THEOREM 4.3. *The solution of* (27) *is given by* (28), (29), (30), *and* (24) *for a call, as*

$$W_k^h(u,v) = \check{w}_k^h(u) + q_k^\varepsilon(\check{v}_k^h(u) - v) = Q_k^\varepsilon \mathcal{V}_k^h(u) - q_k^\varepsilon v, \quad \varepsilon = \operatorname{sign}(\check{v}_k^h(u) - v).$$

The proof is given in appendix, together with that of the equivalent "continuous" theorem, Theorem 3.2.

COROLLARY 4.4. *The seller's price of a call is* $Q_0^+ \mathcal{V}_0^h(u_0)$ *with* $\mathcal{V}_{\mathcal{K}}^h$ *initialized as in* (24) *(a symmetric form holds for a put.)*

The important fact, of course, is that we now have two sequences of functions of one variable to compute, $\{\check{v}_k^h(\cdot)\}$ and $\{\check{w}_k^h(\cdot)\}$, instead of one sequence of functions of two variables $\{W_k^h(\cdot,\cdot)\}$. This is a major saving in computer time and memory. We have typically discretized u and v with 300 to 3000 points each. Therefore the saving is in a ratio of 1:100 to 1:1000. This algorithm has been programmed.[3] The results were indeed identical to those obtained with the straightforward discretization of the Isaacs equation but much faster and with the above reduction in memory space.

5. Discussion. We wish to discuss here the strengths and weaknesses of this new theory as compared to the classical Black and Scholes theory [12] and related work. While we have no pretense to a global superiority of the new theory over the classical one, we wish to show that it might for some purposes be a possible alternative, given more experience and validation work.

Let us first notice that for a put or call option, and for small transaction costs, the general appearance of our seller's price as a function of $u(0)$ is very similar to that of the classical Black and Scholes theory. (Some curves are published in [7].) This can be understood as a consequence of the convergence theorem, Theorem 4.2, and of the fact that for such a convex terminal payoff, our discrete transaction price with zero transaction costs coincides with that of Cox, Ross, and Rubinstein, which itself is close to a Black and Scholes price curve for small time steps. The difference between the two theories is likely to show up more for digital options, which we are currently investigating. Indeed, our PDE is first order, and as a consequence the discontinuity in the boundary value—the terminal payment—propagates backward in time, while the second order Black and Scholes PDE would yield a smooth solution for any time less than exercise time. (But in the absence of transaction costs and in continuous

[3]This was done by Laurent Fischer and Loïc Maitrehut, students at ESSI whose contribution we acknowledge.

time, the optimal hedging portfolio is bound to go to infinity in the neighborhood of the discontinuity. Our theory avoids that difficulty.)

To go further in a comparison, one must distinguish what the mathematics strictly say, and what is practically possible beyond the mathematically grounded facts, thanks to some robustness in the theory.

5.1. Strict mathematical properties. Clearly, a major weakness of our model is that it rules out from the start very fast price variations in the market. If we try to take τ^- and τ^+ so large that the model is (essentially) always satisfied, then we will end up with too large a price. This is a classical fact that because our market model is incomplete we have to resort to superreplication, potentially ending up with an unrealistically large price. Hence we shall get a reasonable premium only by tolerating some violations of the market model.

Now, the Black and Scholes theory has its own theoretical shortcomings. On the one hand, it fundamentally assumes that trading is continuous and with no delay. It is impossible, within Samuelson's model, to achieve hedging if the trading is not done continuously, except with the trivial—and too expensive—portfolio $v = u$. On the other hand, within Samuelson's model, *there is no nontrivial hedging portfolio for option pricing with transaction costs* [25]. The first problem arises from the fact that Samuelson's model may display arbitrarily large variations in any finite time, the second one from the closely related fact that it has almost surely trajectories of unbounded total variation. (This in itself could be considered as not very realistic.)

Let us concentrate on the continuous versus discrete trading issue. Real trading has to be discrete, forcing a discrepancy between real trading and the Black and Scholes theory. This is of little consequence as long as the price of the underlying stock does not change too quickly. But when it does, that discrepancy becomes potentially fatal.

Hence both theories fail under the same circumstances: when there are unusually fast variations of the price of the underlying stock on the market. In our theory the market model is violated; in that of Black and Scholes, it is the portfolio model which fails.

Mathematically, it is impossible to reconcile a model that allows for arbitrarily large stock price variations within one time step with discrete time hedging. Hence a mathematical theory has to give up one of the two features. The Black and Scholes theory gives up the (theoretical) ability to do discrete trading. We wanted to develop a theory of discrete trading, the discrete time market model being consistent with (i.e., the time sampling of) a continuous time underlying market model, kept fixed as the time step is decreased. Thus we had to give up a model that would allow for arbitrarily large price variations in one step of time. Yet we wanted a model less idealized than that of Cox, Ross, and Rubinstein—and not dependent on the time step. Thus we were forced to invent the interval model, at the price of giving up market completeness. And it is no surprise that other authors came up with the same model.

Turning now to the transaction costs issue, they are a natural ingredient of our theory. Indeed we were forced to introduce them to avoid the naive "stop loss" strategy, which is the only solution of the hedging problem in the absence of transaction costs. While we view our ability to deal with transaction costs, even large ones, as a strength of the new theory, the fact that in their absence the only solution is the naive one may be viewed as a limitation of any model with bounded variation trajectories. In contrast, it takes the difficult theory of diffusion limits to deal approximately with

small transaction costs in the Black and Scholes theory.

Finally, once transaction costs are introduced, it is only natural to assume that there are closing costs as well. The introduction of those costs creates a difference between closure in kind or closure in cash. Yet, if this difference is deemed annoying, closing costs may be removed, just by setting c^- and c^+ to zero, this time with no detrimental effect on the theory.

5.2. Robustness. Now, it is well known that in practice, the Black and Scholes theory, and the derived hedging strategy, can be used with discrete transactions, provided that they are frequent enough. Also, small transaction costs can be tolerated, and furthermore, an approximation of perfect hedging can be developed with the concept of diffusion limits (see [1]), although this does not contradict the claim of [25]. These are features of robustness of that theory to small violations of the hypotheses used to derive it.

The new theory also seems to exhibit a fair degree of robustness, as displayed by the following numerical experiments. In all these experiments, the exercise price K is taken as the unit of monetary value.

5.2.1. Theoretical average payments. In a first series of experiments, we assumed that the ratio $\tau = (u_{k+1} - u_k)/u_k$ obeys a probability law with compact support $[\sigma^-, \sigma^+]$ but that this compact is strictly larger than the range $[\tau^-, \tau^+]$ used to compute the hedging strategy of our theory. And we computed the expected overall cost to a trader using that hedging strategy under this hypothesis. This was done with the help of the discrete Kolmogorov equation which gives us an "exact" (up to the precision of the numerical computation) expected value, in contrast with a Monte Carlo simulation.[4]

For the law of τ, we used either a uniform law over $[\sigma^-, \sigma^+]$, a rather pessimistic case, or a "hat" law, with a piecewise affine density, null at the end points and maximal at $\tau = 0$. And we used $\sigma^\varepsilon = (1 + \Delta)\tau^\varepsilon$, with $\Delta > 0$. In all the simulations, we used the formulas for a closure in cash (deemed more realistic) and the following set of parameters:

τ^-	τ^+	C^-	C^+	c^-	c^+	$\mathcal{K}$
-5%	3%	$-.7\%$	$.7\%$	$-.35\%$	$.35\%$	44

In Figures 1 and 2, we have plotted the premium $P(u_0)$ computed with the hypothesis $\tau \in [\tau^-, \tau^+]$ and, on the same graphics, the total expected expense $Q_\Delta(u_0)$ computed with the same data as P, except that τ is distributed over $[\sigma^-, \sigma^+]$, for various values of Δ. Figure 1 corresponds to a uniformly distributed τ and Figure 2 to a "hat" law. The curve $Q_\Delta(\cdot)$ with $\Delta = .85$ in the first case ($\Delta = 162$ in the second) can hardly be distinguished from the curve $P(\cdot)$.

In Figure 3, we plot the difference $P(K) - Q_\Delta$ as a function of Δ for the two probability laws of σ: uniform or "hat." The conclusion is that for a "spillover" up to 85% in the case of the uniform law, and 162% in the case of the "hat" law, the expected result is still positive for the trader.

5.2.2. Simulations with price series. In a second set of experiments, we started from stock price time series. We computed sets of intervals $[\tau^-, \tau^+]$ aimed to contain a variable fraction, say p, of the realizations of τ on this sample and to be centered, i.e., chosen such that the number of occurrences of τ less than τ^- is the

[4]These computations were done by M'hamed Oumouhou during an internship.

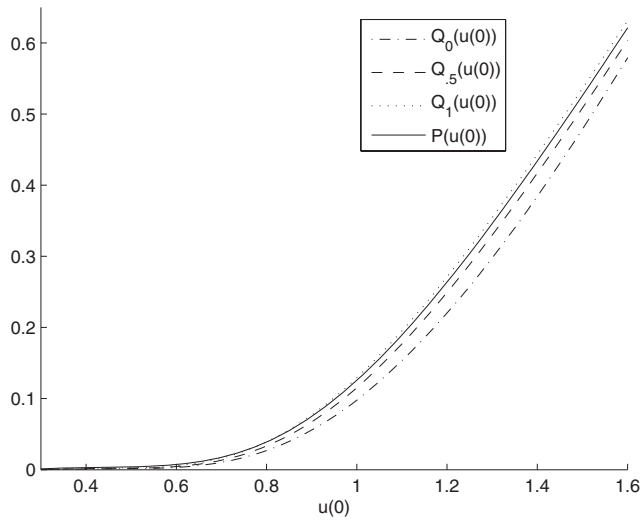

FIG. 1. *Total expense compared with computed premium as a function of u_0 for various values of the spillover ratio Δ. Case τ uniformly distributed.*

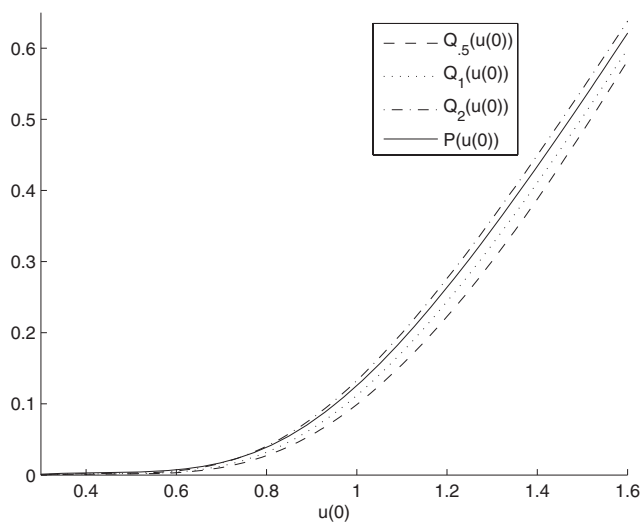

FIG. 2. *Total expense compared with computed premium as a function of u_0 for various values of the spillover ratio Δ. Case of the "hat" law.*

same as the number of occurrences above τ^+. With each of these intervals $[\tau^-, \tau^+]$, we computed the premium and the hedging strategy advocated by our theory. Then we simulated the effect of that hedging strategy if it had been used by the trader to hedge an option and computed the total cost to the trader. When this cost ends up higher than the premium, it means that the trader using this interval $[\tau^-, \tau^+]$ and acting according to our theory would have lost money.

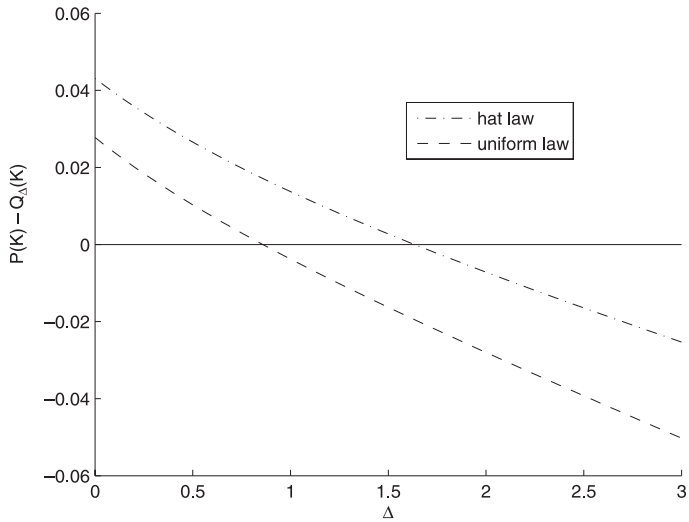

FIG. 3. *The difference* $P(K) - Q_\Delta(K)$ *as a function of* Δ.

As a complement to that test, we compute an empirical (a posteriori) historical volatility of the underlying price, compute the Black and Scholes theoretical premium for that volatility, and see for which $[\tau^-, \tau^+]$, if any, our theory gives approximately the same premium. Remember, though, that our theory always assumes non zero transaction costs, contrary to that of Black and Scholes. Therefore to make a more significant comparison, in the incurred cost of the simulations, we separated the transaction costs from those due to price variations.

We ran that experiment both with real stock price series and for simulated "log-normal" price series, a situation ideally favorable to the Black and Scholes theory since it is the hypothesis it is based upon.

Figures 4–7 show the result of four of these experiments, typical of the many we performed. We plot our premium and the cost incurred by the trader excluding transaction costs against the fraction p of points lying outside of the interval $[\tau^-, \tau^+]$ used. We also show on the same graph the Black and Scholes premium for $K = u_0$. The conclusion is that, for transaction costs less than 1%, for many simulations, taking an interval $[\tau^-, \tau^+]$ that excludes up to 30% of the observed τ_k's yields a premium larger than or equal to the total cost, but excluding transaction costs, the coincidence happens at a higher exclusion ratio and close to the Black and Scholes premium. Some simulations, mainly at low volatilities, show a Black and Scholes premium significantly less than ours. More investigations are needed to completely understand these cases.

5.3. Conclusion. A careful analysis shows that it is rather natural to resort to such "interval models," and this explains why several authors developed that idea independently. To this remark, we add that for the strict problem of hedging a contingent claim, the robust control approach, also used by several of these authors, whether explicitly or implicitly, allows us to proceed without endowing the set of admissible stock price trajectories with a probability law. This is so since what is sought is a hedge for *every* possible trajectory. (And this remark carries over to the Black and Scholes theory if one carefully picks the set of admissible trajectories, as

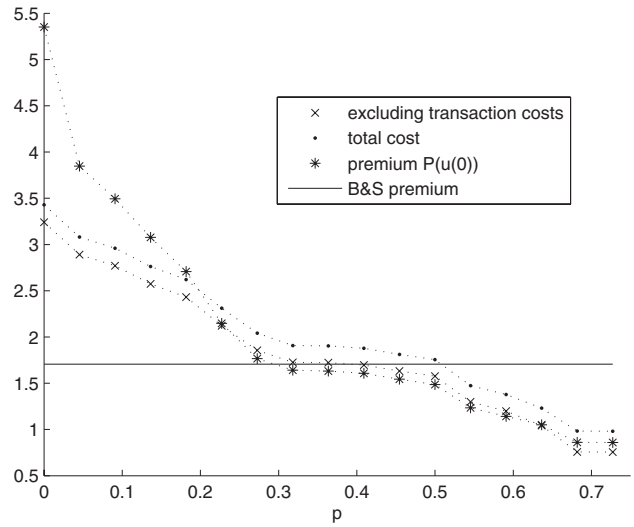

FIG. 4. *Premium and costs incurred as a function of the fraction p; AirFrance series, August* 18, 1998 *to October,* 20, 1998 *(volatility* $\simeq .03$*).*

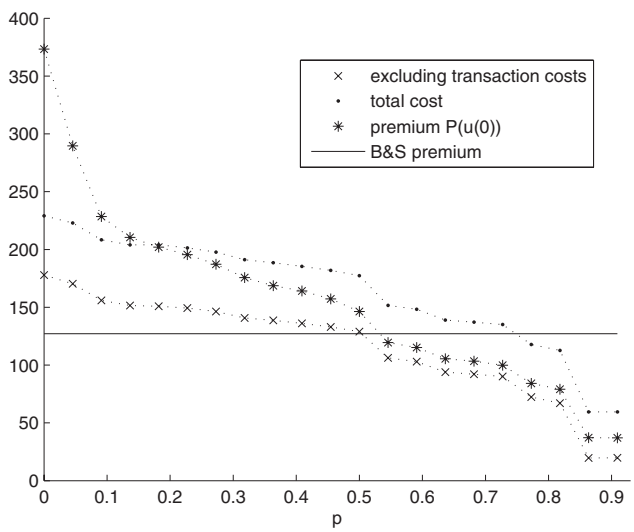

FIG. 5. *Premium and total cost as a function of p; CAC*40 *series, March* 6, 1998 *to May* 8, 1998 (volatility $\simeq .01$).

shown in [7].)

The resulting theory exhibits a strong mathematical structure, that can be exploited to get semiexplicit formulas via a fast algorithm transaction costs, whether in discrete trading or continuous trading. The latter is the limit of the former with vanishing step size; this, we stress, keeps *the same* continuous time model for the underlying price trajectories. Thus the discrete trading strategy, which is very simple

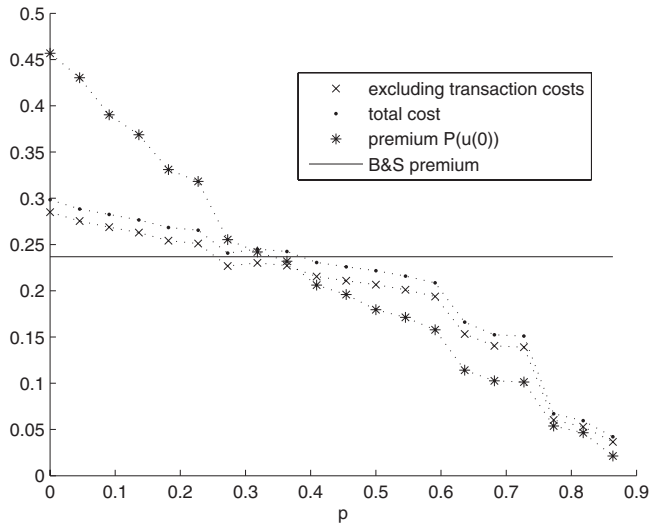

FIG. 6. *Premium and total cost as a function of p; log-normal series,* $\sigma = .1$.

to implement, is a good approximation of the theoretical continuous strategy.

The seller's prices computed qualitatively and quantitatively resemble the Black and Scholes prices, although the presence of transaction costs makes them larger.

The hedging strategies derived from the theory exhibit a fair degree of robustness to violations of the market model. Our simulations show that picking an interval containing 70% of the actual relative price variations often leads to a premium comparable to the Black and Scholes premium and an effective hedging. Yet, these simulations were ran using a posteriori "statistical" information on the price series. If an approach based upon the interval model is to be routinely used, one must also develop new statistical tools to inform it.

This robustness analysis is carried out in a *normative* perspective, to show that this theory can be used on the actual market as a *decision aid*. We have at this point no claim to a *positive* theory that would *explain* premiums actually used by the operators, less so that the current market is overwhelmingly dominated by the Black and Scholes theory, which is, in that respect, self-enforcing.

We feel that the results provided so far point to the conclusion that this theory might be useful in some situations, for instance, when transaction costs are too high to be neglected or when time discretization is critical.

In any extent, this is by all means a young theory. There remains a large work of sensitivity analysis, simulations, and validation to perform. We hope to have proved that it is worthwhile pursuing.

Appendix A. Proof of Theorems 3.2 and 4.3.

A.1. Theorem 4.3. We make the proof in the case of a call. The argument for a put is completely similar.

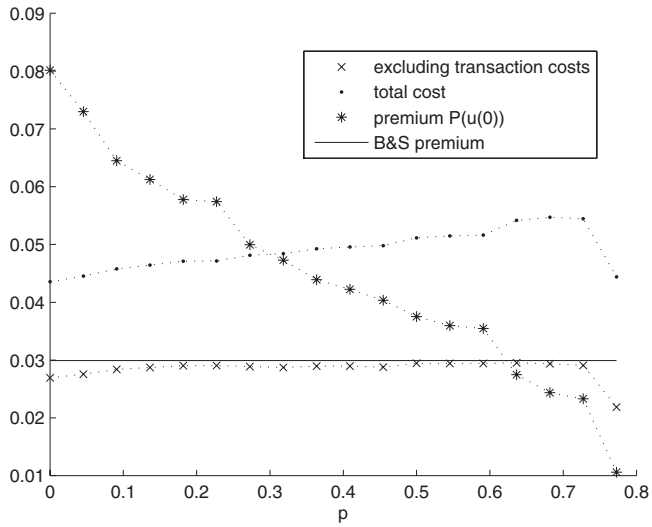

FIG. 7. *Premium and total cost as a function of p; log-normal series, $\sigma = .01$.*

It is useful to notice an alternate, "two-stage" form of the recursion (27):

$$W^h_{k+\frac{1}{2}}(u,v) = \max_{\tau\in[\tau_h^-,\tau_h^+]} [W^h_{k+1}((1+\tau)u,(1+\tau)v) - \tau v]\,, \tag{31}$$

$$W^h_k(u,v) = \min_{\xi} [W^h_{k+\frac{1}{2}}(u,v+\xi) + C^\varepsilon \xi]\,. \tag{32}$$

This form shows that the convexity of N is preserved, and the W^h_k are convex.[5]

Note that the formula of the theorem is correct at final time, $k = K$. Assume it is correct at time $k+1$. Consider the step (31). Because W^h_{k+1} is convex, the maximum is reached either at τ_h^- or at τ_h^+. For each u, the function to be maximized in τ is piecewise affine in v, and its graph as a function of v can be represented as two wedges with one branch sloping downwards (see Figure 8), one for each τ^ε. These can be written as

$$W^+_{k+\frac{1}{2}} := \check{w}^+_{k+\frac{1}{2}} + q^\varepsilon(\check{v}^+_{k+\frac{1}{2}} - v)\,,$$
$$W^-_{k+\frac{1}{2}} := \check{w}^-_{k+\frac{1}{2}} + q^\varepsilon(\check{v}^-_{k+\frac{1}{2}} - v)\,,$$

where $\check{v}^+_{k+\frac{1}{2}}$, $\check{v}^-_{k+\frac{1}{2}}$, $\check{w}^+_{k+\frac{1}{2}}$, and $\check{w}^-_{k+\frac{1}{2}}$ are easily written in terms of $\check{v}^h_{k+1}$ and $\check{w}^h_{k+1}$ evaluated at $(1+\tau^+)u$ and $(1+\tau^-)u$.

As a result, $\check{v}_k$ is obtained as the abscissa of the intersection of the two wedges in this graph. (In the figure, $\check{v}^\varepsilon$ stands for $\check{v}^\varepsilon_{k+\frac{1}{2}} = \check{v}_{k+1}((1+\tau^\varepsilon)u)/(1+\tau^\varepsilon)$, $\varepsilon = \pm$.)

Now, we claim the following fact.

PROPOSITION A.1. *We have for all (k,u)*

$$\frac{1}{1+\tau_h^-}\check{v}^h_{k+1}((1+\tau_h^-)u) \le \check{v}^h_k(u) \le \frac{1}{1+\tau_h^+}\check{v}^h_{k+1}((1+\tau_h^+)u)\,.$$

[5]Hence, from the convergence theorem, so is $W(t,\cdot,\cdot)$.

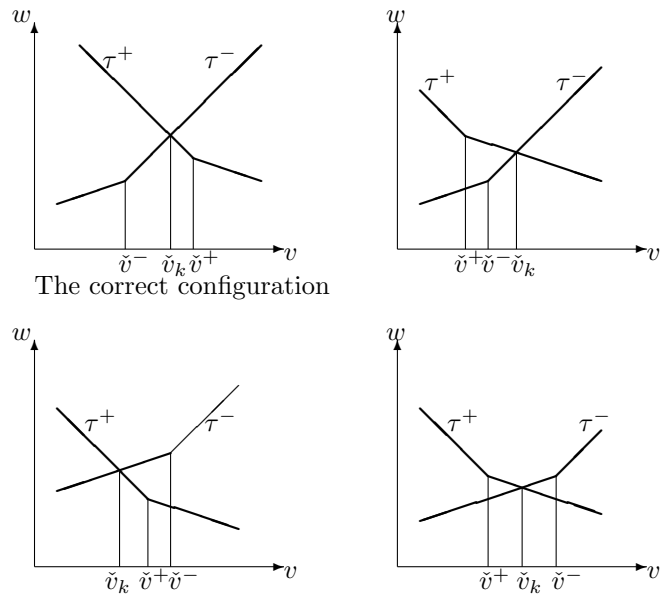

FIG. 8. *Four possible configurations.*

Proof. Assume that the left-hand inequality does not hold. Then a *decrease* of the price of the underlying stock (by a factor $1+\tau^-$) would result in the cheapest hedging portfolio having a *larger* content (in number of shares) in this stock than the previous one, a contradiction for a call (and for any option with an increasing payment function). □

Only the first possibility in the figure is consistent with the proposition, and it results in the max being again a simple wedge. Its minimum is achieved at the intersection of the right branch of the graph with τ^- and the left branch of the graph with τ^+. This gives the formulas (30). (One needs to notice that the q^ε_k as given by (28) coincide with $q^\varepsilon(kh)$ as defined by (22).)

Their remains to carry out (32). It is an inf convolution with a wedge function acting on the v variable only. It leaves unchanged branches with a slope between $-C^+$ and $-C^-$ (and the min is then reached at $\xi = 0$) and replaces steeper slopes by these two limit ones, hence the min or max operations in (22).

A.2. Theorem 3.2. We have to show that formula (25), where $\varepsilon = \operatorname{sign}(\check{v} - v)$, q^ε is given by (22), and $\mathcal{V}(t,u)$ is the solution of the PDE (21), is the (regular) viscosity solution of (20). Let

$$
\begin{aligned}
&H(t,u,v,\mathrm{D}W,\tau) := W_t + \tau[W_u u + (W_v - 1)v]\,,\\
&\bar{H}(t,u,v,\mathrm{D}W) := \max\nolimits_{\tau\in[\tau^-,\tau^+]} H(t,u,v,\mathrm{D}W,\tau)\,.
\end{aligned}
\tag{33}
$$

Then (20) reads

$$
\min\{\bar{H}(t,u,v,\mathrm{D}W)\,, W_v + C^+\,, -W_v - C^-\} = 0\,. \tag{34}
$$

Define $Q^\varepsilon = (q^\varepsilon \;\; 1)$ and $\mathbb{1} = \left(\begin{smallmatrix}1\\1\end{smallmatrix}\right)$.

A.2.1. Preliminary propositions. The proof of the theorem is by checking that formula (25) indeed provides a (sufficiently regular) viscosity solution of (34). We

therefore review the manifolds where our formula allows for a gradient discontinuity of $\mathcal{V}$.

We first stress a simple fact, as a consequence of the definition (22).

PROPOSITION A.2. *For $\varepsilon = 1$ and $\varepsilon = -1$,*

- *if $t \le t_\varepsilon$, $q^\varepsilon = C^\varepsilon$;*
- *if $t > t_\varepsilon$, $q^\varepsilon \in [c^\varepsilon, C^\varepsilon]$ and*

$$\dot{q^\varepsilon} = -\tau^\varepsilon (q^\varepsilon + 1). \tag{35}$$

We also claim the following important fact.

PROPOSITION A.3. *For all $(t,u,v) \in [0,T] \times \mathbb{R}^+ \times \mathbb{R}$,*

$$Q^\varepsilon \mathcal{V}_t \le 0\,, \quad \textit{or equivalently} \quad \operatorname{sign}[Q^\varepsilon(\mathcal{V}_u u - \mathbb{1}\check{v})] = \varepsilon. \tag{36}$$

Proof. The equivalence of the two forms of the claim comes from the fundamental PDE (21) and the the fact that

$$Q^\varepsilon \mathcal{T} = \tau^\varepsilon Q^\varepsilon\,. \tag{37}$$

Simple geometry shows that Proposition A.1 implies

$$\check{w}^+_{k+\frac{1}{2}} + q^-_{k+\frac{1}{2}}(\check{v}^+_{k+\frac{1}{2}} - \check{v}^-_{k+\frac{1}{2}}) \le \check{w}^-_{k+\frac{1}{2}} \le \check{w}^+_{k+\frac{1}{2}} + q^+_{k+\frac{1}{2}}(\check{v}^+_{k+\frac{1}{2}} - \check{v}^-_{k+\frac{1}{2}})\,. \tag{38}$$

In the limit as $h \to 0$, $W^h \to W$, but also $\mathcal{V}^h \to \mathcal{V}$ that satisfies the PDE (21). And since the defining recursion (30) is a consistent discretization scheme for (21), the differentials converge, and, as a tedious but simple calculation shows, (38) converges to (36). □

For a given (t,u,v), let $\varepsilon = \operatorname{sign}(\check{v}(t,u) - v)$. As a consequence of (36), and keeping in mind that $q^\varepsilon + 1 > 0$,

$$\operatorname{sign}[(\check{w}_u + q^\varepsilon \check{v}_u)u - (q^\varepsilon + 1)v] = \varepsilon\,, \tag{39}$$

so that the max in $\bar{H}$ is reached at $\tau = \tau^\varepsilon$.

A.2.2. Differentiable case. We first investigate regions of (t,u,v) space where our formula (25) gives a differentiable function. The partials of (25) are given by

$$W_t = Q^\varepsilon \mathcal{V}_t + \dot{q^\varepsilon}(\check{v} - v)\,, \quad W_u = Q^\varepsilon \mathcal{V}_u\,, \quad W_v = -q^\varepsilon\,,$$

where $Q^\varepsilon \mathcal{V}_t = -\tau^\varepsilon Q^\varepsilon V_u u + \tau^\varepsilon(1+q^\varepsilon)\check{v}$ using (21) with (37). Replacing these partials in (33) with property (39), it follows that

$$\bar{H}(t,u,v,\mathrm{D}W) = \left(\dot{q^\varepsilon} + \tau^\varepsilon(1+q^\varepsilon)\right)(\check{v} - v)\,.$$

If $t > t_\varepsilon$, Proposition A.2 leads to $\bar{H} = 0$, while the other two terms in (34) are positive because of Proposition A.2.

If $t < t_\varepsilon$, $\bar{H}(t,u,\check{v},\mathrm{D}W) = 0$ and

$$\bar{H}(t,u,v,\mathrm{D}W) = \tau^\varepsilon(1+C^\varepsilon)(\check{v}(t,u) - v) \ge 0$$

since $\tau^+ > 0$ and $\tau^- < 0$, so that $\varepsilon = \operatorname{sign}(\check{v} - v)$ is also the sign of τ^ε and $1 + C^\varepsilon > 0$ by hypothesis. Moreover, according to Proposition A.2, one of the other two terms in (34) is zero and the other one positive.

A.2.3. The singular manifold $v = \check{v}$. On the manifold $v = \check{v}(t,u)$, formula (25) for W is nondifferentiable. It has a nonvoid subdifferential, obtained by replacing q^ε by $q = \lambda q^+ + (1-\lambda)q^-$ in the formulas for the partial derivatives in either of the regions $\varepsilon = -1$ or $\varepsilon = 1$. This is so because these partials are affine in q^ε.

Now, for each ϵ, the maximum in τ in $\bar{H}$, reached at τ^ε, is 0. Therefore, for $\tau^{-\varepsilon}$, $H \leq 0$. Hence, as an affine function of q (for fixed τ) which ranges from 0 to a negative number, H is nonpositive for all possible q's. Hence so is its max in τ, $\bar{H}$. The other two terms in (34) are trivially nonpositive for all λ. Therefore the minimum of the three terms is nonpositive, and this is the viscosity condition.

A.2.4. Boundaries of the nontrivial region. We adapt and complete here a result of [11] (Proposition 8.1).

PROPOSITION A.4. *Along the manifolds $u = K\exp(-\tau^\varepsilon(T-t))$, the gradients of $\mathcal{V}$ may be discontinuous, with discontinuities $\delta\mathcal{V}_t$ and $\delta\mathcal{V}_u$ satisfying $\delta\mathcal{V}_t = -\tau^\varepsilon\delta\mathcal{V}_u$ and $(q^{-\varepsilon}\ 1)\delta\mathcal{V}_u = 0$.*

Proof. Let $(\hat{t},\hat{u})$ be a tangent to a manifold bearing a gradient discontinuity of a continuous solution of (21). Let $(\delta\mathcal{V}_t, \delta\mathcal{V}_u)$ be that discontinuity. Continuity of $\mathcal{V}$ imposes that

$$\hat{t}\delta\mathcal{V}_t + \hat{u}\delta\mathcal{V}_u = 0\,.$$

Now, because $\mathcal{V}$ satisfies (21) in both open half spaces on each side of the manifold, it follows that

$$\delta\mathcal{V}_t + \mathcal{T}\delta\mathcal{V}_u u = 0\,.$$

Hence, combining the two equations, we get

$$\left(\frac{1}{u}\frac{\hat{u}}{\hat{t}}I - \mathcal{T}\right)\delta\mathcal{V}_u = 0\,,$$

which is possible with a nonzero $\delta\mathcal{V}_u$ if and only if $\hat{u}/u\hat{t}$ is an eigenvalue of $\mathcal{T}$, hence either τ^- or τ^+. Therefore, the gradient discontinuity has to be born by a curve of the form $u = u_T\exp(-\tau^\varepsilon(T-t))$, and in this formula, we have to choose $u_T = K$ to embed the gradient discontinuity of $N(u,v)$ in that curve.

Then $\delta\mathcal{V}_u$ has to be the eigenvector of $\mathcal{T}$ associated with the corresponding eigenvalue, i.e., $(1\ -q^{-\varepsilon})$, as is easily checked ∎

Assume we are hedging a call, thus with $0 \leq v \leq u$. On the left boundary $u = K\exp(-\tau^+(T-t))$, we have $\varepsilon = -1$, and the discontinuities of the gradient of our function W are given by $(\delta W_t, \delta W_u, \delta W_v) = (Q^-\delta\mathcal{V}_t, Q^-\delta\mathcal{V}_u, 0) = 0$. Therefore the function (25) is smooth. A similar argument applies along the boundary $u = K\exp(-\tau^-(T-t))$. And symmetric arguments hold for a put.

A.2.5. Boundaries of the jump regions. Finally, one has to check the two manifolds $t = t_\varepsilon$, where $\mathcal{V}_t$ is discontinuous, because q_t^ε is. It can be seen that the superdifferential of W is nonempty there, and is made of all the vectors $(Q^\varepsilon\mathcal{V}_t + \delta, W_u, -C^\varepsilon)$ with $\delta \in [-\tau^\varepsilon(1+C^\varepsilon)(\check{v}-v), 0]$, and notice that $-\tau^\varepsilon(1+C^\varepsilon)(\check{v}-v) < 0$ (which shows that it is the superdifferential which is nonempty). As a consequence, the viscosity condition reads

$$\forall\delta \in [-\tau^\varepsilon(1+C^\varepsilon)(\check{v}-v), 0]\,, \quad Q^\varepsilon\mathcal{V}_t + \delta + \tau^\varepsilon[Q^\varepsilon\mathcal{V}_u u - (C^\varepsilon+1)v] \geq 0\,.$$

However, we have already seen that this quantity is zero for δ at the lower end of the interval. And thus the inequality does hold, ending the proof.

Remark A.1.

1. It can be noted that this direct check confirms only the fact that the field of extremal trajectories constructed in [11] satisfies the relevant corner conditions as developed in the Isaacs–Breakwell theory. Yet, here we have an explicit formula that guarantees that there are no other singular surfaces in the state space. This is difficult to ascertain with the previous theory.
2. We have shown in [9] further relationships between (20) on the one hand and (21) and (25) on the other hand.

Acknowledgments. We wish to acknowledge the help of many intern students from École Polytech'Nice-Sophia and from the department of mathematics, both at the University of Nice-Sophia Antipolis, and notably M'hamed Oumouhou, whose many numerical computations helped build confidence in the theory. We also wish to thank three anonymous reviewers for providing much help in improving this paper and one of them for pointing out the book by Shafer and Vovk.
